oxygen is Ni–O(1) 2.089(1) Å, and the distances of Ni–N(1) and Ni–O(2) are 2.192(2), 2.114(2) Å, respectively. Because the acylate oxygen atoms coordinate with the nickel atom, the bond length of C(7)–N(4) 1.306(3) Å is shorter than the other bond length C(3)–N(10) 1.329(4) Å existing in non-coordinating pendant groups. This decrease in bond length is due to the unpaired electrons of nitrogen atoms at amide residues transferring to the C–N single bond. And this delocalization of electronic density made the C=O double bonds lengthen [from C(10)–O(2) 1.234(3) to C(7)–O(1) 1.255(3) Å]. The ligand serves as a N_4O_2 donor for the nickel atom. Two non-coordinating pendant amide groups may adopt a clockwise or anticlockwise fashion for a given arrangement. O(1), Ni and N(2) atoms are nearly in one line with an angle of 161.00(8)°.

The blue crystal of complex **3** consists of the dication $[Cu(L)]^{2+}$, two non-coordinated nitrates and a water molecule of crystallization. Fig. 3 shows the cation together with the atom-labeling scheme. The geometry about the copper atom is tetragonal pyramid. For the smaller ion radii of the copper atom, only one acylate oxygen together with four amine nitrogen atoms coordinate to the central metal atom. The bond length of the coordinated acylate oxygen to the copper, Cu–O(1) 2.137(3) Å, is significantly longer than the Cu–N(amine) bonds, average 2.0465(3) Å. This is different from the nickel complex, the bond length of Ni–O(1) is shorter than the Ni–N(amine) bonds, average 2.153(2) Å. Four amine nitrogen atoms are copla-

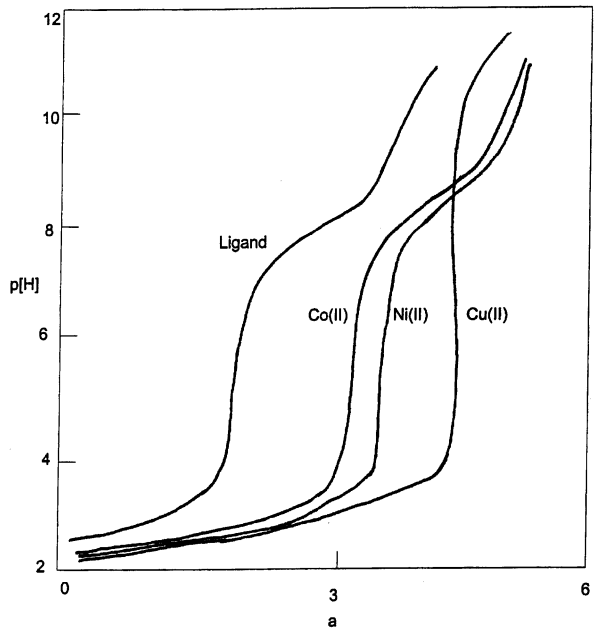

Fig. 4. Potentiometric equilibrium curves for ligand and metal complexes.

nar with a mean deviation of 0.0477 Å. Co and Ni atoms are prone to coordinate to the oxygen atom, and the Cu atom is more likely to form a coordination bond with the nitrogen atom. This similar bond relationship can be observed in the analogous complexes with the ligand 1,4,7,10-tetrakis(2-cycanoethyl)-1,4,7,10-tetraazacyclododecane [22]. The copper atom and O(1) are at the same side of this plane with distances of 0.496 and 2.579 Å, respectively. The angles between the oxygen, central copper atom and nitrogen atoms are in the range 92.6 ~ 113.0°, which forms a slightly distorted tetragonal pyramid coordination environment.

2.3. Potentiometric titrations

The potentiometric equilibrium curve of this ligand as shown in Fig. 4, is found to have two inflections at $a = 2$ and $a = 3$ (where $a =$ moles of base per mole of ligand). From $a = 0$ to $a = 2$, and $a = 3$ to $a = 4$, there are two buffer regions. In the first buffer region, two substituted ammonium ions were neutralized. Between the first and second inflection, the third substituted ammonium ion was neutralized. Fig. 5 gives the species distribution plot of ligand, at pH < 2, $[H_3L]^{3+}$ reaches the highest concentration (79.7%). The distribution of $[H_2L]^{2+}$ arrives at maximum value of 99.9% at pH 5.7. In more basic conditions, pH 11.4, the ligand exits in free base type. The probable processes of stepwise deprotonation constants are listed in Table 5. Compared with the famous ligand, Cyclen, the first deprotonated constant is lower than 0.29 logarithm units, which resulted from the electron-withdrawing pendant groups existing at nitrogen atoms of this ligand [24]. Using the direct titration method, the stability constants of three complexes were determined. Co and Ni complexes have a similar titration curve: both of them have two inflections of $a = 3$ and $a = 4$. [ML](M = Co, Ni) form and are stable at pH 2 ~ 6.5, and $\log K_{[ML]}$(M = Co, Ni) = 17.11 and 16.83, respectively. The hydroxo species $[Co(OH)L]^{+}$ form from pH 7, then the $[Co(OH)_2L]$ dominated. However, the stability constants of the Cu complex are lower than these by about two logarithm units ($\log K_{[CuL]} = 15.00$) and the Cu complex had one inflection at $a = 4$; [CuL] reaches maximum concentration at pH 3.9. This species is stable in the range 3 ~ 11.5, and then a hydroxy species $[Cu(OH)L]^{+}$ forms. Fig. 6 gives the species distribution plot of a Co complex as an example.

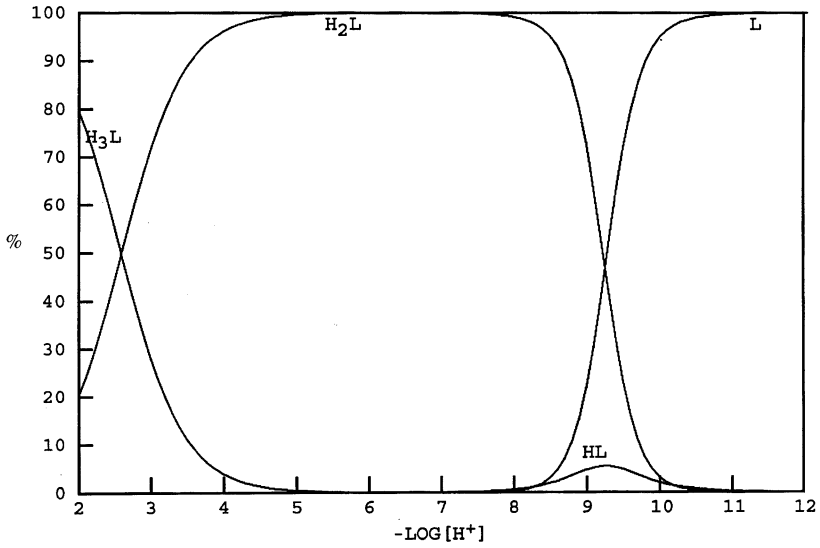

Fig. 5. Species distribution diagram for the ligand.

2.4. Cleavage of pBR 322 DNA analyses

For the cobalt complex, DNA cleavage was analyzed by monitoring the conversion of supercoiled DNA (Form I) to the nicked circular molecules (Form II) and linear DNA (Form III). The tests were performed under aerobic conditions with H_2O_2 as a reducing agent. No cleavage occurs in the absence of H_2O_2 or with uncomplexed Co atoms (not shown). As shown in Figs. 7 and 8, complex **1** can effectively cleave duplex DNA. Incubation of the pBR 322 DNA at 37°C for 2 h with 6.25 μM of complex **1** causes the complete conversion of Form I to Form II. It is clear that the degradation of pBR 322 DNA is highly dependent on the concentration of complex **1** used. As complex **1** concentration increases the probability of double strand scissions is enhanced once the DNA has undergone a single strand break. This is manifested in the gel by the appearance of linear DNA molecules (Form III) from 6.25 μM. The percentage of linear DNA molecules observed with Co complex increases with the increase of the concentration as shown in Fig. 7. The percentage of Form III demonstrates a linear correlation with

concentration. The analytical results are listed in Table 6. At the same time, when the concentration of complex **1** increased from 6.25 to 200 μM, the supercoiled DNA could be completely cleaved to form linear DNA as shown in Fig. 8. The cleavage percentages and respective concentrations are listed in Table 7. From the above results, we therefore conclude that the activation of the cobalt complex leads mainly to single strand cleavage of duplex DNA in lower concentration (< 6.25 μM). When the concentration of cobalt complex increases, the linear DNA appears, which exhibits the double strand cleaving ability of this complex. This phenomenon is first reported in comparison with famous DNA cleaving agents, such as Cu–phen or Co–salen complexes, which only showed single strand cleaving ability. In conclusion, complex **1** has the promising possibility to be developed into a chemical nuclease if the detailed mechanism can be clearly elucidated in further experiments.

The possible mechanism of this cleavage may be due to the Fenton type chemistry, which involves the release of diffusible hydroxyl radical or molecular oxygen or other active intermediates. This conclusion will be supported by further experiments in which the degradation products should be detected. When Bhattacharya and Mandal [25] treated plasmid pTZ 19R with Co–salen complex, they thought that in the presence of co-reductant, DTT, Co(II) complex could form an air-stable adduct: Co(II)–complex–O_2, which can induce efficient DNA damage under physiological conditions. They also concluded that the co-oxidant induced product [Co^{III}–complex] lacked the O_2 binding ability and failed to induce DNA nicking. This is consistent with Bailly's results [26]. Bailly et al. showed that the Co-2,9-bis(2-hydroxyphenyl)-1,10-phenanthroline complex, in the presence of MPA as reductant, can cleave pUC12 DNA to form nicked or linear DNA at different concentrations. In this case, we performed electron paramagnetic resonance (EPR) measurements to detect the production of hydroxyl radicals or oxygen molecules by means of the spin-trapping technique (using DMPO as trapping agent, DMPO = 5,5′-dimethylpyrroline *N*-oxide). The spin-trapping experiment showed that the cleavage occurred possibly via an OH radical mechanism. From Fig. 9, the EPR spectrum of the Co complex exhibited four hyperfine patterns with the parameter $g = 2.005$ in DMSO solution with a concentration of 5 mM, which is consistent with results observed in Co–BLM [27]. Because of the existence of water molecules, both in Co complex and H_2O_2 solution, the DMPO–OH spin adduct showed the typical four-line spectrum. Water appears to exert a leveling effect in the sense that only hydroxyl radicals could be detected in the aqueous solutions.

The other three complexes did not show similar cleaving ability under similar conditions.

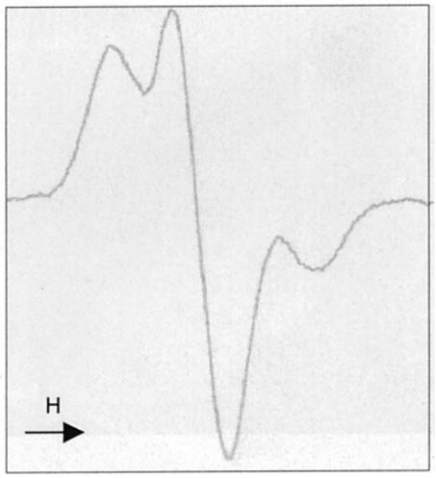

Fig. 9. EPR spectrum.

3. Experimental

The macrocyclic amine, Cyclen, was synthesized according to the method described by Richman and Atkins [28]. The ligand was prepared as reported [12]. All other chemicals were obtained from commercial sources and used as received.

3.1. Preparation of ligand

Cyclen (3 mmol, 500 mg) and acrylamide (14 mmol, 1.0 g) were dissolved in CH_3OH (5 ml), the mixture reacted under nitrogen at 60°C for 48 h. To the obtained solution ether was added until the separation of oily substances. After standing for one more hour, white crystals were deposited. The crystals were filtered and washed with CH_3Cl (20 ml) and dried over P_2O_5 in vacuum.

Yield: 1.1 g, 80.4%. m.p. 175°C. (Found: C, 50.65; H, 8.65; N. 23.76; *Anal*. Calc. for $C_{20}H_{40}N_8O_4$: C, 50.61; H, 8.92; N, 23.61%). ^{1}H NMR (300 Hz, D_2O): δ 2.4–2.6, t, 8H (N–CH_2); δ 2.6–2.8, m, 16H (CH_2 of macrocycle); δ 2.8–3.0, q, 8H (–CH_2–C=O). IR (KBr pellet): 3379s, 3155s, 2426w, 1672s, 1442s, 1358s, 1086m, 725s, 557m, 461m.

3.2. Preparation of complexes

3.2.1. $Co(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}2H_2O$ (1)

To $Co(NO_3)_2{\cdot}6H_2O$ (0.5 mmol, 145 mg) in EtOH (15 ml) was added L (0.5 mmol, 228 mg), the reaction mixture was stirred at room temperature overnight. Red precipitate formed quickly. After filtration, the solids were washed with ether and dried with P_2O_5 in vacuum.

Yield: 136 mg, 40.3%. m.p. 186°C.(dec.) (Found: C, 35.38; H, 6.61; N, 20.67; *Anal*. Calc. for $Co(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}2H_2O$: C, 35.56; H, 6.56; N, 20.73%). IR (KBr pellet): 3411s, 3180m, 2426w, 1676s, 1620s, 1385s, 1074m, 567m.

3.2.2. $Ni(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}2H_2O$ (2)

To $Ni(NO_3)_2{\cdot}6H_2O$(0.5 mmol, 146 mg) in MeOH (20 ml) was added L (0.5 mmol, 228 mg), the reaction mixture was stirred at room temperature overnight. The solution turned green and clear, the solvent was evaporated under vacuum. The green solids collected were washed with ether repeatedly and dried with P_2O_5 in vacuum. The crystal suitable for X-ray diffraction was obtained from the slow diffusion of ether into the DMF solution of complex.

Yield: 312 mg, 95.5%. m.p. 205°C (dec.) (Found: C, 36.61; H, 6.37; N, 21.31; *Anal*. Calc. for $Ni(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}2H_2O$: C, 36.54; H, 6.44; N, 20.31%). IR (KBr pellet): 3408s, 3180m, 2426w, 1676s, 1620s, 1385s, 1078m, 579m. FAB-MS: m/z 577 [$M^+ - NO_3$], 515 [$M^+ - 2NO_3$], 443, 227.

3.2.3. $Cu(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}H_2O$ (3)

To $Cu(NO_3)_2{\cdot}3H_2O$ (0.5 mmol, 121 mg) in H_2O (20 ml) was added L (0.5 mmol, 228 mg), the reaction mixture was stirred at room temperature overnight. The solution was blue and clear, the solvent was evaporated under vacuum. The blue solids were collected, washed with ether repeatedly and dried with P_2O_5 in vacuum. The crystal suitable for X-ray diffraction was obtained from the slow diffusion of ether into the DMF solution of complex.

Yield: 225 mg, 68%. m.p. 225°C (dec.) (Found: C, 36.37; H, 6.36; N, 21.15; *Anal*. Calc. for $Cu(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}H_2O$: C, 36.28; H, 6.39; N, 20.15%). IR (KBr pellet): 3377s, 3199s, 2426w, 1666s, 1385s, 1072s, 557m.

3.2.4. $Zn(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}H_2O$ (4)

To $Zn(NO_3)_2{\cdot}6H_2O$ (0.5 mmol, 148 mg) in EtOH (20 ml) was added L (0.5 mmol, 228 mg), white precipitate formed quickly. The reaction mixture was stirred at room temperature overnight. After filtration, the solids were washed with ether and dried with P_2O_5 in vacuum.

Yield: 234 mg, 71.5%. m.p. 234°C (dec.) (Found: C, 36.64; H, 6.34; N, 21.28; *Anal*. Calc. for $Zn(NO_3)_2C_{20}H_{40}N_8O_4{\cdot}H_2O$: C, 36.68; H, 6.31; N, 20.38%). IR (KBr pellet): 3348s, 3160s, 2426w, 1670s, 1620s, 1385s, 1082m, 579m, 463m. EI MS: m/z 503, 429, 369, 357, 295.

3.3. Crystallographic

Red–green–blue prismatic crystals of $C_{20}H_{44}N_{10}O_{12}Co$ (**1**) $C_{20}H_{44}N_{10}O_{12}Ni$ (**2**) and $C_{20}H_{42}N_{10}O_{11}Cu$ (**3**) having approximate dimensions of $0.20 \times 0.20 \times 0.30$ mm were mounted on a glass filter. All measurements were made on a Rigaku AFC 7R automated four-circle diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) and a 12 kW rotating anode generator. The cell parameters were determined by 25 reflections in the 2θ range $18.77° < 2\theta < 21.55°$ for **1**, $16.12 < 2\theta < 25.78°$ for **2**, $13.56 < 2\theta < 21.48°$ for **3**. For the intensity data collection, the φ–2θ scan mode was used to a maximum 2θ value of 50.0° for **1**, 55.0° for **2** and 50.0° for **3** at a scan rate of 16° min^{-1}. The weak reflections ($I < 13\sigma(I)$) were rescanned (maximum of four scans) and the counts were accumulated to ensure good counting statistics. Stationary background counts were recorded on each side of the reflection. The ratio of peak counting time to background counting time was 2:1. The diameter of the incident beam collimator was 1.0 mm, the crystal to detector distance was 235 mm, and the computer-controlled detector aperture was set to 9.0×13.0 mm (horizontal × vertical). The intensities of three respective reflections were measured after every 200 reflections. Over the course of data collection, the standards decreased or increased by

−0.9% for **1**, 0.1% for **2** and 0.0% for **3**. A linear correction factor was applied to the data to account for this phenomenon. The linear absorption coefficient, μ, for Mo Kα radiation was 6.60 cm^{-1} for **1**, 7.4 cm^{-1} for **2** and 8.4 cm^{-1} for **3**. An empirical absorption correction based on azimuthal scans of several reflections was applied which resulted in transmission factors ranging from 0.93 to 1.00 for **1** and **2**, using the program DIFABS, which resulted in transmission factors ranging from 0.88 to 1.15 for **3**. The data were corrected for Lorentz and polarization effects. Pertinent crystallographic parameters for **1**, **2** and **3** are given in Table 1.

The structure was solved by heavy atom Patterson and expanded using Fourier techniques [29–31]. The non-hydrogen atoms were refined anisotropically [32]. Hydrogen atoms were included but not refined [33]. Refinements were carried out by the full-matrix least-squares method, where the function minimized is $\Sigma w(|F_o| - |F_c|)^2$ with $w = 1/\sigma(F_o)$.

Neutral atom scattering factors were taken from Cromer and Waber. Anomalous dispersion effects were included in F_{calc}; the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley. The values for the mass attenuation coefficients are those of Creagh and Hubbel. All calculations were performed using the TEXAN crystallographic software of the Molecular Structure Corporation.

3.4. Potentiometric equilibrium measurements and computation

Stock solutions of Co(II), Ni(II) and Cu(II) nitrate were used for potentiometric experiments, and the concentrations of metal ions were close to 0.02 M in all cases. A carbonate-free KOH solution was prepared from a Dilute-it ampoule and standardized with potassium acid phalate. Reagent grade potassium chloride was used as supporting electrolyte for all the experiments. The potentiometric equilibrium measurements in the absence of and in the presence of metal ions were carried out with a Corning 250 digital pH meter. The ionic strength of the medium was maintained at 0.100 M by the titration of a KCl solution. The potentiometric cell was fitted with glass and calomel electrodes in a water-jacketed reaction vessel maintained at 25.0 ± 0.1°C, and was calibrated with standard aqueous HCl and KOH solution to read −log[H] directly. The measurements were carried out under an atmosphere of Argon gas. The equilibrium constants were determined with the program BEST, the species distribution diagrams were obtained with the programs SPE and SPEPLOT [34].

3.5. Cleavage of pBR 322 DNA

DNA(supercoiled pBR 322) was purchased from Huamei Chemicals. In a typical run, each reaction mixture contained 0.15 μg of supercoiled pBR322 DNA, 5 μl of the tested complexes at the desired concentration in 1% DMSO as solvent, and 5 μl hydrogen peroxide (40 mmol l^{-1}) was added as a co-oxidant reagent. After incubation at 37°C for 2 h, 1 μl of loading buffer (0.25% bromophenol blue, 0.25% xylene cyanol, 30% glycerol in H_2O) was added to each tube and the mixed solution was loaded on 1% agarose gel. The electrophoresis was carried out for 2 h at 50 V in TBE buffer (89 mM Tris–borate, pH 8.3, 1 mmol l^{-1} EDTA). Gels were stained with ethidium bromide (1 μg ml^{-1}) for 30 min prior to being photographed under UV light. Figs. 8 and 9 give the DNA cleavage results of the electrophoresis on agarose gel.

3.6. EPR measurement

The X-band EPR spectra of the metal complex (5 mM in DMSO) were recorded at 77 K using a Bruker ESP-300 spectrometer operating with a 100 kHz magnetic field modulation. For spin-trapping experiments, 3 mM DMPO was added to the metal complex solution at 5 mM.

4. Supplementary material

Atomic coordinates, bond angles, bond distances and thermal parameters assisted to these three complexes have been deposited at the Cambridge Crystallographic Data Center. Data are available on request from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) with CIF deposition codes: 137312, 137554 and 137555.

Acknowledgements

We thank Jie Sun of the Shanghai Institute of Organic Chemistry for helping in the structure determination, and Hauy Keng Loke and Gang Xing for EPR experimental assistance and Dr Paul Lindahl for helpful discussion.

Received 1 December 1999; accepted 21 March 2000

Abstract

Organotin(IV) compounds of the potentially ambidentate *O*-cholesteryl-*O*-phenyl phosphorothioate ligand formulated as $Me_3SnOSPR'R''$ (**1**), $Ph_3SnOSPR'R''$ (**2**), $O(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$ (**3**), $S(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$ (**4**), ($R' = O$-Ph; $R'' = O$-cholesteryl) were obtained and characterized by elemental analyses, IR, MS and multinuclear NMR (^1H, ^{13}C, ^{31}P and ^{119}Sn) spectroscopy. The spectroscopic data are consistent with bonding of the phosphorothioate ligand through both sulfur and oxygen atoms to the Sn(IV) center. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Phosphorothiates; Organotin(IV); Bioactive groups; Cholesteryl

1. Introduction

The coordination chemistry of Tin(IV) derivatives towards phosphorus-based acids continues to receive attention mainly due to the reactivity, interesting structural features and anticancer activity of some organotin(IV) compounds [1,2]. The structural chemistry of such compounds presents a great diversity and is influenced by factors such as the number and nature of organic groups bonded to the tin and phosphorus atoms, as well as the type of donor atom (O, S, Se) [3]. Recently, we have reported the preparation of a new ambidentate phosphorothioate ligand, containing a bioactive group, Na[OSPR′R″], [R = *O*-Ph, R″ = *O*-cholesteryl] [4]. In order to investigate the coordinating ability of this new ligand towards different organotin(IV) entities, the ligand was reacted with the following monochlorotin(IV) compounds: Me_3SnCl, Ph_3SnCl, $O(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$ and $S(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$. The resulting phosphorothioatotin(IV) derivatives (**1**–**4**) were characterized by elemental analyses, as well as IR, MS and multinuclear NMR (^1H, ^{13}C, ^{31}P, ^{119}Sn) spectroscopy.

2. Results and discussion

The organotin(IV)-*O*-cholesteryl-*O*-phenyl phosphorothioate compounds reported here were synthesized by the following reaction route, using stoichiometric ratios in refluxing chloroform. Compounds **1**–**4**, are soluble in common organic solvents and were characterized by elemental analyses (C, H, P) as well as IR, mass and multinuclear NMR (^1H, ^{13}C, ^{31}P, ^{119}Sn) spectroscopy.

$$R_nSnCl + Na[OSPR'R''] \rightarrow R_nSnOSPR'R'' + NaCl$$

[R′ = *O*-Ph, R″ = *O*-cholesteryl]

[$R_n = Me_3$ (**1**), Ph_3 (**2**), $O(CH_2CH_2S)_2(n\text{-Bu})$ (**3**), $S(CH_2CH_2S)_2(n\text{-Bu})$ (**4**)].

2.1. Infrared spectra

Infrared spectra were interpreted by comparison with reported spectra of known *O*- and *S*-alkyl esters of monothiophosphinic acids, their sodium salts and other analogous derivatives (Table 1). The new compounds showed strong bands in the regions 1030–1170, 950–970, and 510–570 cm^{-1}, assigned to ν(P)–O–C, νP–O–(C) and ν(P–S), respectively [5]. The absence of bands in the regions 1200–1180 cm^{-1} due to ν(P=O) as well as in 630–580 cm^{-1} for ν(P=S) suggests that the ligand is coordinated to Sn(IV) in **1–4** through the sulfur and oxygen donor atoms. When the phosphorothioate ligand is bonded through both donor atoms it is possible that it displays either a chelating binding mode (type (a)) or a bridge binding mode (type (b)), (Fig. 1). In the present cases of compounds **1–4**, it is not possible to know from IR data if the interaction is of the type (a) or (b).

2.2. Mass spectra

The mass spectra of the four organotin(IV) derivatives (**1–4**) were recorded with FAB positive source. The spectra do not show the molecular ion, but the data are easily related to the proposed structures, with the normal loss of *n*-Bu, the presence of polymeric species, due to the FAB method and fragments arising from the R_nSn entity and the ligand.

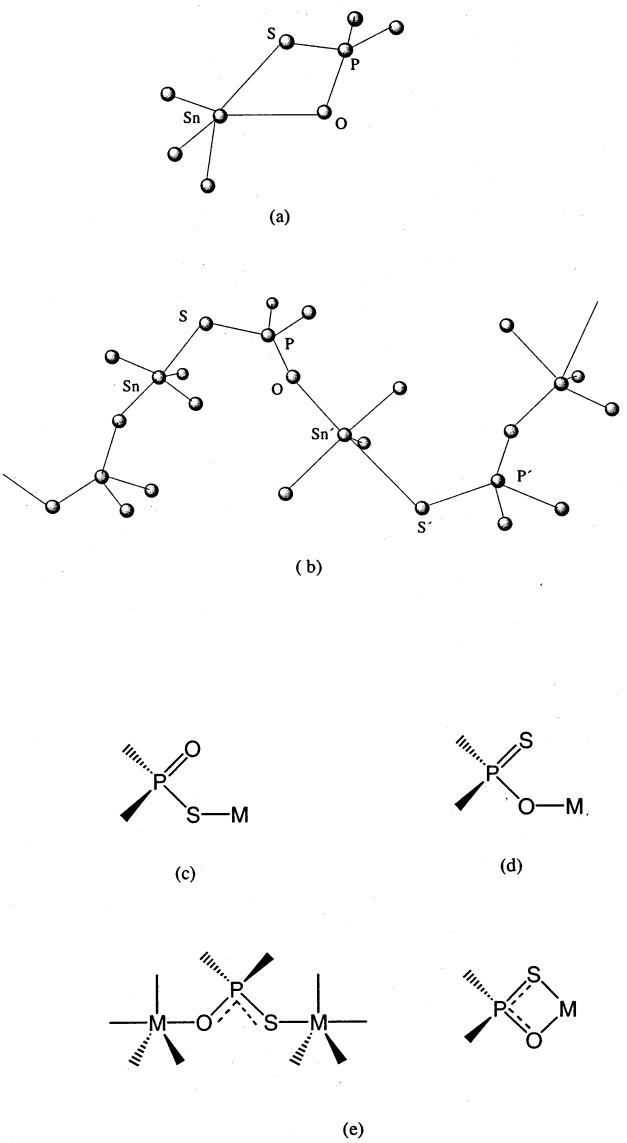

Fig. 1. Binding modes of tin(IV) phosphorothioates.

2.3. NMR spectra

The ^{1}H and ^{13}C NMR spectra of compounds **1**–**4**, confirmed the identity of the compounds, showing the expected integration and multiplicities. (Table 2(a)). Compounds **1** and **2** presented the corresponding signal sets for the groups attached to Sn, indicating the equivalence of such groups (Table 2(b)), while the stannocanes **3** and **4** showed the complex signals characteristic of these rings [9]. As expected, the ^{13}C NMR signal of the C*i* of *O*-Ph and the C_{base} of *O*-cholesteryl appeared as doublets, due to phosphorus coupling.

The ^{31}P NMR spectra for **1**–**4** correspond to a singlet (Table 3). In a ^{31}P NMR spectroscopy study of a series of di-isopropylthiophosphate derivatives, Glidewell [10] suggested that when the derivative is *S*-bonded (binding mode type (c)) the value of δ ^{31}P is $< +30$ ppm, while for *O*-bonding (binding mode type

Table 3
^{31}P and ^{119}Sn NMR data of Na[OSPR′R″], $Me_3SnOSPR'R''$, $Ph_3SnOSPR'R''$, $O(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$, $S(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$ [R′ = *O*-Ph, R″ = *O*-cholesteryl]

Derivative	δ (^{31}P) (ppm)	δ (^{119}Sn) (ppm)
Na[OSPR′R″]	50.16	
$Me_3SnOSPR'R''$	49.45	−146.76
$\varnothing_3SnOSPR'R''$	34.29	−80.87
$O(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$	51.21	−45.18
$S(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$	51.91	−50.75

(d)) δ ^{31}P is $> +58$ ppm and if it is both *O*- and *S*-bonded (binding mode type (e)) the value corresponds to $+58 > \delta$ $^{31}P > +30$ (Fig. 1).

Compounds **1**–**4** fall in the range from 34.74 to 51.91 ppm and the bonding through both oxygen and sulfur is suggested for each one of this new organotin compounds. It is interesting to note, that ^{31}P chemical shift of these compounds showed differences compared with complexes of related metal centers; for example some organogermanium [6], organoantimony(V) [11] and organotin(IV) [12] compounds, primary bonded through oxygen, present values for ^{31}P from 40.0 to 80.0 ppm. The ^{119}Sn chemical shifts is influenced by the variation in the coordination number and bond angles at tin, by any dπ–pπ bonding effect and by the presence of electronegative substituents [13–15]. When the tin coordination number increases from four to five or six to seven, the ^{119}Sn signal gradually moves to lower field. Thus, for five-coordinate compounds, δ ^{119}Sn has a value from 0 to -200, six-coordinated δ ^{119}Sn from -125 to -365 and seven-coordinated δ ^{119}Sn from -400 to -700 ppm. The δ ^{119}Sn of compounds **1**–**4**, fall in the range from 0 to -200 ppm (Table 3) and it is suggested that both the sulfur and the oxygen atom participate in the bonding to Sn. It is interesting to note that anisobidentate behavior is present in related organotin(IV) derivatives such as dialkyltin(IV) bis(dialkyldithiophosphates) [13] or diorganotin(IV) diphenylphosphinothioates [8] and these compounds have a ^{119}Sn NMR chemical shift close to those of ours. The NMR data suggest that **1**–**4** are penta-coordinated; however, the situation is more complex in the stannocane derivatives **3** and **4**, where the Sn–O or Sn–S intramolecular interaction is able to increase the coordination number to six. However, such interaction is of the secondary type and possibly is not very strong in solution.

In conclusion, data from both the ν(P–O), ν(P–S) infrared bands and the ^{31}P chemical shifts, indicate that the ligand in these new compounds is most probably bonded in an ambidentate fashion through oxygen and sulfur atoms and the ^{119}Sn NMR data point to the presence of five-coordinated tin species in solution.

3. Materials and methods

All reagents and solvents were of commercial grade and the starting material. $O(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$ [9], $S(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$ [9] and Na[OSPR′R″][4], were prepared by literature methods. Elemental analyses (C, H, P) were performed by Galbraith Laboratories, Inc. (Knoxville, TN). IR spectra (4000–200 cm^{-1}) were recorded on KBr discs using a Perkin–Elmer 282B Spectrophotometer; FAB(+) mass spectra using a JEOL SX-102A instrument. ^1H, ^{13}C, ^{31}P and ^{119}Sn NMR spectra were obtained at room temperature in $CDCl_3$ solution using a Varian VXR-300S spectrometer operating at 300, 75.4, 121.4 and 111.85 MHz, respectively. TMS, H_3PO_4 85% and Me_4Sn 33% were used as external standards.

*3.1. Preparation of $Me_3SnOSPR'R''$ (**1**), $Ph_3SnOSPR'R''$ (**2**), $O(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$ (**3**) and $S(CH_2CH_2S)_2Sn(n\text{-Bu})OSPR'R''$ (**4**)*

To a chloroform solution of sodium *O*-cholesteryl-*O*-phenyl-phosphorothioate Na[OSPR′R″] (0.25 g, 0.43 mM), was added a stoichiometric solution of the corresponding Me_3SnCl, Ph_3SnCl, $O(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$ or $S(CH_2CH_2S)_2Sn(n\text{-Bu})Cl$ also in chloroform (10 ml). The mixture was stirred under reflux for 4 h. The precipitated sodium chloride was filtered off and the filtrate after drying over anhydrous Na_2SO_4 was con-

Received 16 November 1999; accepted 10 April 2000

Abstract

The title compound $[MoS_4Cu_3(dppm)_3][BF_4]]\cdot 2H_2O$ (dppm = $Ph_2PCH_2PPh_2$) was synthesized for nonlinear optical studies by the reaction of $(Et_4N)_2MoS_4$ and $[Cu_2(dppm)_2(MeCN)_4][BF_4]_2$ in CH_3CN solution. Single-crystal X-ray analysis revealed that three copper atoms and the MoS_4^{2-} form a distorted 'flywheel' array with W–Cu separations of 2.7754(14), 2.792(2) and 2.820 (2) Å. The third-order nonlinear optical properties were investigated by a Z-scan technique with 7 ns laser pulses at 532 nm. It was observed that the nonlinear absorption is very small, but it has considerable third-order large nonlinear refractive index.

Keywords: Tetrathiometalate; Nonlinear optical properties; Synthesis; Copper compounds; Crystal structures; Dppm

The tetrathiometallates MS_4^{2-} (M = Mo, W) have been shown to be able to act as multidentate ligands with a variety of transition metal ions [1]. They have been used extensively as starting materials in synthesizing Mo(W) containing inorganic clusters [2,3] and in catalytic studies [4,5]. Studies on these clusters have been expanded to include their third-order nonlinear optical (NLO) properties in our laboratory. Traditionally, NLO research has been largely focused on conjugated polymers, semiconductors and discrete organic molecules [6,7]. In our search for better NLO materials we have undertaken a series of studies on the structure and NLO properties of Mo(W)–Cu(Ag, Au, Pd)–S clusters [8–14]. In this article, we report the synthesis, X-ray crystal structure and nonlinear optical properties of a novel cluster compound containing μ_4-S: $[MoS_4Cu_3(dppm)_3][BF_4]\cdot 2H_2O$. We also compare its third-order NLO absorptive and refractive properties with those of other reported cluster compounds.

1. Experimental

1.1. Reagents

The reaction was performed under anaerobic conditions using standard Schlenk techniques; solvents were purified, distilled and degassed prior to use. The reagents $[Et_4N]_2[MoS_4]$ and $[Cu_2(dppm)_2(MeCN)_4][BF_4]_2$ were prepared according to the literature [15,16].

1.2. Physical measurements

Infrared spectra were recorded on a Fourier Nicolet FT-170SX spectrophotometer with pressed KBr pellets and the electronic spectrum of the title cluster was measured with a Hitachi U-3410 spectrophotometer. Carbon and hydrogen analyses were performed on a PE 240C Elemental Analyser.

1.3. Nonlinear optical (NLO) measurements

The dimethylforminade (DMF) solution of the title cluster was contained in a 1-mm thick quartz cuvette with concentration of 3.6×10^{-4} M. The sample was irradiated by a Q-switched frequency-doubled Nd:YAG laser, which produced linearly polarized 7 ns (FWHM) optical pulses at 532 nm. The laser was operated at a pulse repetition rate of 10 Hz. The spatial profiles of the optical pulses were nearly Gaussian after passing through a spatial filter. The laser beam was then divided by a beam splitter into two parts: one was used as a reference for the incident energy and the other was focused onto the sample by a focusing mirror of 25 cm focal length. The minimum beam radius of the focused laser beam was determined to be 30 ± 5 μm. Both incident and transmitted pulse energies were measured simultaneously by two energy detectors (Rjp-735 energy probes, Laser Precision), which were linked to a computer by an IEEE interface. The NLO properties of the sample were determined by performing the Z-scan measurements [17]. The sample was mounted on a translation stage that was controlled by a computer to move along the Z-axis with respect to the focal point. To determine both the sign and magnitude of the nonlinear refraction, a 1.0 mm diameter aperture was placed in front of the transmission detector and the transmittance was recorded as a function of the sample position on the Z-axis (closed-aperture Z-scan). For measuring the nonlinear absorption, the Z-dependent sample transmittance was taken without the aperture (open-aperture Z-scan).

1.4. Syntheses

1.4.1. $[MoS_4Cu_3(dppm)_3][BF_4]\cdot 2H_2O$

A mixture of $[Cu_2(dppm)_2(MeCN)_4][BF_4]_2$ (237.3 mg, 0.1923 mmol) and $(Et_4N)_2MoS_4$ (93 mg, 0.1923 mmol) in acetonitrile (25 ml) was stirred at room temperature for 2 h. The volume of the solution was reduced to 5 ml and an orange precipitate was obtained upon the addition of diethyl ether. Vapor diffusion of diethyl ether into a CH_2Cl_2 solution gave a product isolated as an air-stable orange crystalline solid. *Anal.* Calc. for $C_{75}H_{70}BCu_3F_4MoO_2P_6S_4$: C, 53.28; H, 4.17; Found: C, 53.60; H, 4.20%. IR spectra (KBr pellet): Mo–S, 480.0 and 454.8 cm^{-1}.

1.5. X-ray structure determination

An orange crystal with dimension of $0.45 \times 0.25 \times 0.10$ mm was stuck to the end of a glass fiber by using neutral jelly, which was mounted on a Siemens SMART CCD area-detecting diffractometer. The structure was solved by using a direct method and expanded with subsequent Fourier syntheses. The quality of the solution was comprised somewhat by disorder in the BF_4^- ion and solvent water molecules. Rotational disorder about the B–F_1 bond of the BF_4^- ion was modeled with another three F atoms each occupying two half-weighted sites. All B–F distances were restrained to be similar with a standard deviation of 0.03 Å using SADI instruction (SHELXTL Version 5) [18], as were all F···F distances within each idealized tetrahedron. The four solvent water oxygen atoms contained a site-occupancy factor of 0.5. All non-hydrogen atoms in the cation portion were refined anisotropically. Hydrogen atoms riding on carbon atoms (C–H = 0.95 Å) were introduced in ideal positions and refined with an isotropic temperature factor 20% greater than that of the parent atoms. No attempts were made to generate hydrogen atoms for solvent water molecules. Refinement of the structure was carried out by full-matrix least-squares methods, and the final cycle of full-matrix least-squares refinement converged to give $R = 0.0678$ and $wR = 0.1661$. The crystallographic data and details concerning the intensity are summarized in Table 1.

2. Results and discussion

2.1. Structure of the title compound

The ORTEP diagram of the cation $[MoS_4Cu_3(dppm)_3]^+$ of the title compound is depicted in Fig. 1. The selected bond lengths and angles are given in Tables 2 and 3. The Mo atom has retained its initial tetrahedral coordination, with S–Mo–S angles in the range of 107.06(11)–112.79(12)°. The three Cu

atoms and the MoS_4^{2-} form a distorted 'flywheel' array. There are two different coordination modes of the bridging S atom. The atoms S_1, S_2 and S_3 are bonded to Mo and only one Cu atom, but S_4 adopts a μ_4-bridging mode, being bonded to Mo and the three Cu atoms. Each of the three Cu atoms is in a distorted tetrahedron. Compounds with a μ_4-S moiety asymmetrically bonded to two kinds of metal ion are not unprecedented in the literature. Examples include $(n\text{-}Bu_4N)_2[MoOS_3Cu_3(NCS)_3]$, $[MoCu_2OS_3(PPh_3)_3]$ and $[NEt_4]_3[WOS_3(CuBr)_3(\mu\text{-}Br)]\cdot 2H_2O$ [19–21]. The Mo–Cu bond lengths [2.7754(14), 2.792(2) and 2.820(2) Å] are longer than those observed in $[Et_4N]_4[Mo_2O_2S_6Cu_6I_6]$ (av. 2.661 Å) [22], but comparable with those of $(n\text{-}Bu_4N)_2[MoOS_3Cu_3(NCS)_3]$. Each of the three copper atoms is in a distorted tetrahedron. The six-membered ring comprising Cu, S, Cu, P, C and P has a boat conformation, whereas the other related rings have a chair conformation. This is probably due to the rigidity of the $[MoS_4]^{2-}$ group and the steric crowding of the phenyl groups of dppm.

2.2. The third-order NLO properties of the title compound

The electronic spectrum of the title compound in DMF is depicted in Fig. 2. It was noted that the compound has relatively low linear absorption in the visible and near-IR region. The lowest absorption peak is located at 560 nm. The Z-scan results for the compound are shown in Fig. 3, where the filled circles were the Z-scan data measured without the aperture and the open circles were the results obtained from the division of the closed aperture Z-scan data by the open aperture Z-scan data. To obtain the NLO parameters we employed a Z-scan theory [17], which considers nonlinearities of third-order nature. The total absorption coefficient can be written as $\alpha = \alpha_0 + \alpha_2 I$, where α_0 and

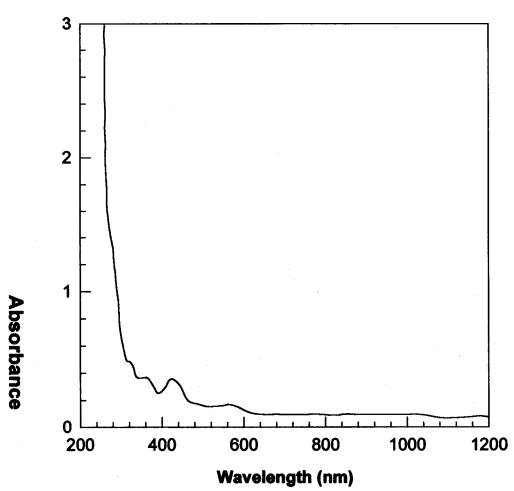

Fig. 2. Electronic spectrum of $[MoS_4Cu_3(dppm)_3][BF_4]\cdot 2H_2O$ (3.6×10^{-4} M) (_) DMF. The optical path is 1 mm.

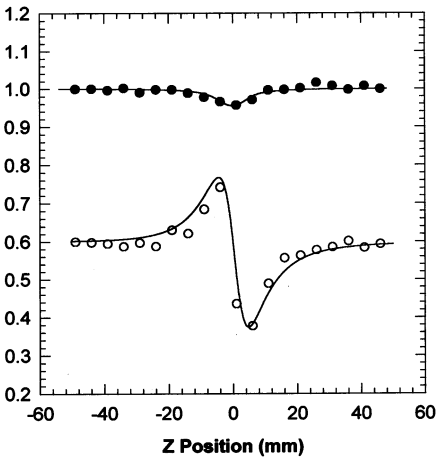

Fig. 3. The normalised Z-scan data $[MoS_4Cu_3(dppm)_3][BF_4]\cdot 2H_2O$ (3.6×10^{-4} M) in DMF solution with 532 nm, 7 ns laser pulses. The optical path is 1 mm. The peak incident irradiance of the pulses at focus is 420 MW cm^{-2}. The experimental data were measured without (●) an aperture. The open circles (○) were obtained by dividing the Z-scan data collected with the aperture by those collected without the aperture, they have been vertically displaced by -0.4 for clarity. The solid curves are the theoretical fits based on the Z-scan theory.

α_2 are the linear and nonlinear absorption coefficients, respectively, and I is the irradiance of the laser beam within the sample. The total refractive coefficient can be expressed as $n = n_0 + n_2 I$, where n_0 and n_2 are the linear and nonlinear refractive indices. The good fits between the theory and our experimental data suggest that the observed NLO phenomena can be expressed effectively by third-order susceptibilities. In Fig. 3, it was observed that the compound shows a negative sign for n_2. This indicates that the laser beam propagating in it undergoes a self-defocusing process. Table 4 lists the measured nonlinear absorption coefficient, α_2, and nonlinear refractive index, n_2, for the title compound. In accordance with the observed α_2 and n_2 values, the modulus of the third-order molecular susceptibility γ can be calculated using Eq. (1)

$$|\gamma| = \frac{1}{NF^4}\sqrt{\left(\left|\frac{9\times 10^8 \varepsilon_0 n_0^2 c^2 \alpha_2}{4\pi\omega}\right|^2 + \left|\frac{c n_0^2 n_2}{80\pi^2}\right|^2\right)} \quad (1)$$

where ε_0 and c are the permittivity and the speed of light in a vacuum, respectively, ω is the angular frequency of the light, N the concentration of the cluster (in cm^3) and $F^4 = 3$ is the local Lorentz field factor. We calculated that $|\gamma| = 2.4 \times 10^{-29}$ esu for the title compound. This calculated value is several orders of magnitude greater than the well known NLO materials (for example 1×10^{-32}–1×10^{-31} esu for metallophthalocyanines at 1064 nm [23] and 7.5×10^{-34} esu for C_{60} at 1910 nm [24]). It should be noted that the Z-scan measurements reported here could not reveal the origin of the measured α_2 and n_2 values for the title compound. Excited-state effects, two-photon absorption, third-order bound-electronic effect and nonlinear scattering are the possible mechanism behind the observed nonlinearities [25–27]. The observed self-defocusing property possessed by the compound shows that it can be a promising material for applications such as protection of optical sensors. It is also interesting to compare this compound with other different structural clusters such as twin-nested, nested and butterfly-shaped clusters [9,19,20,22]. Table 4 shows that the title compound is comparable with most of the other clusters in terms of the effective n_2 value.

3. Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK on request, quoting the deposition number 135206.

Abstract

Two new uranyl phosphate compounds have been prepared and their structures determined. $[UO_2(H_2PO_4)_2(H_2O)]_2\cdot$(18-crown-6)$\cdot 5H_2O$ (**1**) and $UO_2(H_2PO_4)_2(H_2O)\cdot$(18-crown-6)$\cdot 3H_2O$ (**2**) contain neutral one-dimensional $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains that are nearly identical to those of a previously reported binary phosphate, $UO_2(H_2PO_4)_2(H_2O)\cdot 2H_2O$ (**3**). The new compounds, however, crystallized with either one-half or one 18-crown-6 molecule per uranium atom for **1** and **2**, respectively. The seven-coordinate uranium(VI) assumes a pentagonal bipyramidal configuration, which is common for uranyl compounds. Empty 18-crown-6 molecules are hydrogen bonded to the uranyl phosphate chains as well as to lattice water molecules and function as 'packing-directing' agents. © 2000 Elsevier Science Ltd. 1. Introduction

Phosphate coordination plays a significant role in several areas of uranium chemistry. Various forms of phosphate are used in the processing of uranium both before and after its use as a nuclear fuel [1,2]. Phosphate matrices have been proposed as potential hosts for uranium and the light actinides to reduce solubility or as secondary barriers to enhance adsorption of mobile species [3–5]. In addition, the phosphate anion is prevalent in natural systems [6–8] and must be considered when evaluating the environmental complexation possibilities for uranium(IV, VI) ions. In order to predict and understand the formation and behavior of actinide phosphate complexes in solution and phosphate-mediated actinide migration in waste streams, it is important to examine the structure, bonding, stability, and spectroscopic properties of these species. Surprisingly, the few uranium phosphates characterized to date show a remarkable array of structural and chemical diversity [9–11]. For example, uranium can exist in multiple oxidation states (most commonly $+4$ and $+6$ in aqueous systems) and assume coordination numbers that can vary from six to nine inclusive. In addition, frameworks can be charged or neutral and of variable dimensionality (zero-, one-, two- or three-). Finally, the phosphate-binding mode can be bridging or terminal, unidentate or bidentate. Combinations of the aforementioned features quickly result in a vast number of new structural possibilities. What conditions dictate the occurrence of each of these features remain unclear and are the subject of ongoing research.

One approach to devising novel uranium phosphate structure types is to exert influence over structural features through the introduction of co-crystallites or templating agents. Crown ethers have historically been used as ion sequestering, separation and crystallizing agents, but they occasionally act as neutral addition species. In the present study, their usefulness as crystal-

PII: S0277-5387(00)00408-3

lizing agents was employed to encourage single-crystal growth of new phases. Their effectiveness in this area has been proven through the many uranium-crown complexes previously reported [12–18]. Uranium and the uranyl cation (UO_2^{2+}) can interact with crown ether molecules in a number of ways. For example, in UO_2(18-crown-6)$(CF_3SO_3)_2$, the uranyl ion resides within the crown ether cavity [18]. In [(dicyclohexano-18-crown-6)$(H_3O)]_2[UCl_6]$, the hydronium cation resides within the crown ether molecule and functions as a countercation to the UCl_6^{2-} anion [14]. In neutral coordination compounds, empty crown ether molecules have been known to hydrogen bond to the uranyl moieties, as shown by crystalline $UO_2(NO_3)_2(H_2O)_2{\cdot}2H_2O{\cdot}$(18-crown-6) [12] and $UO_2(SO_4)(H_2O)_3{\cdot}0.5$(18-crown-6) [15].

Herein we report the synthesis and structural characterization of $[UO_2(H_2PO_4)_2(H_2O)]_2{\cdot}$(18-crown-6)$\cdot 5H_2O$ (**1**) and $UO_2(H_2PO_4)_2(H_2O){\cdot}$(18-crown-6)$\cdot 3H_2O$ (**2**). Compounds **1** and **2** contain neutral one-dimensional uranyl phosphate chains that crystallized with either one-half or one 18-crown-6 molecule per uranium atom, respectively. Despite the variability in 18-crown-6 content, the two compounds both contain $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains that are nearly identical to each other and to those of a previously reported binary phosphate, $UO_2(H_2PO_4)_2(H_2O){\cdot}2H_2O$ (**3**) [19].

2. Experimental

2.1. General procedures

Chemicals of reagent grade quality were obtained commercially (uranyl nitrate hexahydrate, Fluka; 85% H_3PO_4, Fisher; 1,4,7,10,13,16-hexaoxacyclooctadacane (18-crown-6), Aldrich) and used without further purification. Uranium tetrachloride was prepared by methods previously described [20]. Water was purified in a Millipore Milli-Q Ultra-pure water purification system. Elemental analyses were performed in our laboratories on a Perkin–Elmer series II 2400 CHN analyzer.

2.2. Synthesis

2.2.1. Preparation of $[UO_2(H_2PO_4)_2(H_2O)]_2{\cdot}$(18-crown-6)$\cdot 5H_2O$ (1)

UCl_4 (11.0 mg, 0.003 mmol), 85% H_3PO_4 (38.8 mg, 0.03 mmol PO_4) and 18-crown-6 (75.6 mg, 0.03 mmol) were added to 2.6817 g of H_2O in a glass vial and briefly stirred. The resulting solution was allowed to evaporate slowly. After approximately 60 days, gold crystals precipitated from the solution (crystalline yield, 5 mg, 25%). A crystal of suitable size for single-crystal X-ray diffraction was isolated, briefly dried in air, and then transferred to a mineral oil matrix for analysis.

Compound **1** was also prepared by an alternate synthesis. $UO_2(NO_3)_2{\cdot}6H_2O$ (15.1 mg, 0.003 mmol), 85% H_3PO_4 (38.8 mg, 0.03 mmol PO_4) and 18-crown-6 (75.6 mg, 0.03 mmol) were added to 2.6817 g of H_2O in a glass vial and briefly stirred. After approximately 21 days, gold crystals precipitated from the solution (crystalline yield, 20 mg, 83%). Crystals of **1** appear to be moderately stable in air at room temperature (r.t.). *Anal.* Calc. for $C_{12}H_{46}O_{33}P_4U_2$: C, 10.93; H, 3.52. Found: C, 11.82; H, 3.71%. A crystal of suitable size for single-crystal X-ray diffraction was isolated, briefly dried in air, and then transferred to a mineral oil matrix for analysis.

2.2.2. Preparation of $UO_2(H_2PO_4)_2(H_2O){\cdot}$(18-crown-6)$\cdot 3H_2O$ (2)

A procedure identical to that described for the preparation of **1** from UCl_4 was followed. After approximately 30 days, gold crystals separated from the solution (crystalline yield 5 mg, 21%). A crystal of suitable size for single-crystal X-ray diffraction was isolated, briefly dried in air, and then transferred to a mineral oil matrix for analysis. *Anal.* Calc. for $C_{12}H_{36}O_{20}P_2U$: C, 18.00; H, 4.54. See **1** above for analysis results on crystal mixtures. The crystals decompose within hours of isolation at r.t. and within 2 weeks when left in the reaction solution.

2.3. Crystallography

The crystallographic data for both compounds **1** and **2** were collected using a sealed, graphite monochromatized Mo Kα X-ray source ($\lambda = 0.71073$ Å) on a Bruker P4/CCD/PC diffractometer. The crystals were mounted from a matrix of mineral oil and cooled to 203 K using a Bruker LT-2 temperature device. A hemisphere of data was collected using a combination of φ and ω scans, with 30 s frame exposures and 0.3° frame widths. Data collection and initial indexing and cell refinement was handled using SMART [21] software. Frame integration and final cell parameter calculation were carried out using SAINT [22] software. The data were corrected for absorption using the SADABS [23] program. Decay of reflection intensity was not observed. The structures were refined by full-matrix least-squares technique on F^2. Structure solutions and refinements were performed using SHELXTL PC [24] and SHELX-93 [25], respectively.

2.3.1. $[UO_2(H_2PO_4)_2(H_2O)]_2{\cdot}$(18-crown-6)$\cdot 5H_2O$ (1)

A small pale gold plate was attached to a glass fiber with silicone grease. The data were collected and processed as described above. The selection of the space group $P\bar{1}$ was confirmed by the subsequent successful solution and refinement of the structure by direct methods and difference Fourier techniques. The initial solution revealed the uranium, phosphorus, and the

majority of all non-hydrogen atom positions. The remaining atomic positions were determined from subsequent Fourier synthesis. Hydrogen atom positions were fixed (C–H = 0.97 Å). The hydrogen atoms were refined using the riding model, with isotropic temperature factors fixed to 1.2 times the equivalent isotropic U of the carbon atom to which they were bound. Water and phosphate hydrogen atoms were not included in the final model. The final refinement included anisotropic temperature factors on all non-hydrogen atoms. Additional details of data collection and structure refinement are listed in Table 1.

2.3.2. $UO_2(H_2PO_4)_2(H_2O)\cdot$(18-crown-6)$\cdot 3H_2O$ (2)

A large gold crystal was attached to a glass fiber with silicone grease. The data were collected and processed as described above. The space group $P2_12_12_1$ was uniquely determined by its systematic absences. The structure was solved by direct methods and difference Fourier techniques. The initial solution revealed the uranium, phosphorus, and the majority of all non-hydrogen atom positions. The remaining atomic positions were determined from subsequent Fourier synthesis and refinement was performed as described above. Water and phosphate hydrogen atoms were not included in the final model. A racemic twin was refined using the TWIN command, and the scale factor refined to 0.5811(8). The final refinement included anisotropic temperature factors on all non-hydrogen atoms. Additional details of data collection and structure refinement are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

Aqueous phosphoric acid solutions react with UCl_4 or $UO_2(NO_3)_2\cdot6H_2O$ in the presence of 18-crown-6 to form transparent gold-colored crystals of **1** and **2**. Single crystals were isolated from these solutions that were prepared at different times, but in an identical fashion. Single-crystal X-ray diffraction analyses revealed that both **1** and **2** form under these conditions. Repeated elemental analyses carried out on single crystals prepared from uranyl nitrate consistently gave C and H results intermediate for the two compounds, but were always closer to the calculated percentages for **1**. These data suggest that both species are present simultaneously and that **1** may form preferentially to **2**. We have been unable to prepare the two compounds in a pure form.

It is interesting to note that the formulas of **3**, **1** and **2** are suggestive of a solid solution having the formula $[UO_2(H_2PO_4)_2(H_2O)]\cdot x$(18-crown-6), where $0\le x\le1$. However, X-ray analysis shows that the compounds are non-isomorphic and each represents a unique line in the $[UO_2(H_2PO_4)_2(H_2O)]\cdot$(18-crown-6) phase diagram.

3.2. Structural studies

3.2.1. $[UO_2(H_2PO_4)_2(H_2O)]_2\cdot$(18-crown-6)$\cdot 5H_2O$ (1)

Compound **1** crystallizes in the triclinic space group $P\bar{1}$ and consists of one-dimensional $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains (Fig. 1) that hydrogen bond to empty crown ether molecules and water solvate molecules in the lattice (Fig. 2). A summary of the crystallographic data is given in Table 1 and a list of selected bond distances and angles is given in Table 2. The asymmetric unit contains one 18-crown-6 molecule, five solvate water molecules, and two crystallographically distinct $UO_2(H_2PO_4)_2(H_2O)$ subunits. Each uranium is coordinated by two uranyl oxygen atoms at the average bonding distance of 1.76(1) Å to form linear

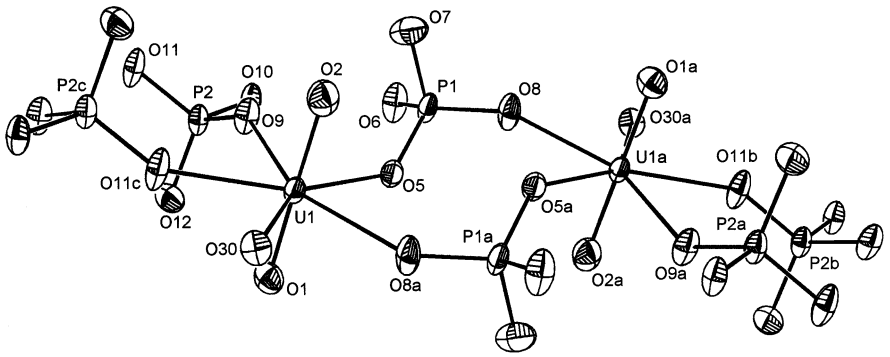

Fig. 1. ORTEP view of a portion of a $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chain of **1**.

UO_2^{2+} ions (O1–U1–O2, O3–U2–O4 angles, 178.9(3) and 177.7(3)°, respectively). The uranyl oxygen atoms form the apices of a pentagonal bipyramid, while the equatorial positions are occupied by the oxygens of a water molecule and four $(H_2PO_4)^-$ groups that bind in an μ-η^1 fashion. The mean U–O distance for all equatorial bonds is 2.38(1) Å. The equatorial and uranyl bond distances and angles are typical of the U(VI) uranyl species and comparable with those of $UO_2(H_2PO_4)_2(H_2O)\cdot 2H_2O$ (**3**) [26].

There are four crystallographically independent phosphate tetrahedra (P1, P2, P3, P4). In each tetrahedron there are two long P–O bonds and two short P–O bond distances. For P1 these distances are, respectively, 1.569(8), 1.569(7), 1.487(1) and 1.510(7) Å. For P2 the long P–O bond distances are 1.583(6) and 1.551(8) Å and the short distances are 1.492(7) and 1.515(7) Å. A similar pattern is exhibited for P3 and P4. The P–O bond distances longer than 1.55 Å are indicative of protonated phosphate oxygens, as described in related complexes [26,27]. The structural data suggest that the phosphate tetrahedra are all doubly protonated (as in **3**), and establish the necessary charge balance.

The bond distances and angles of the 18-crown-6 moiety are virtually identical to other crystallographically characterized examples [12]. As shown in Fig. 2, the crown and lattice water molecules participate in an extensive system of hydrogen bonding that cohesively binds the structure. A list of hydrogen bonding distances is given in Table 4. Two of the lattice water molecules (Ow1 and Ow2) are hydrogen bonded to the crown ether, the protonated phosphate oxygen atoms and the coordinated water molecule, O31. Three additional lattice water molecules (Ow3, Ow4 and Ow5) connect adjacent chains along a line that diagonally bisects the *bc* plane. These water solvates form hydrogen bonds to the protonated phosphate oxygen atoms O7, O12, O16, and O20 (bond distances span a range 2.590(4)–3.032(2) Å), but do not interact with the crown molecules.

The uranyl phosphate portion of **1** is quite similar to that in $UO_2(H_2PO_4)_2(H_2O)\cdot 2H_2O$ (**3**). The metric parameters of **3** [19] (uranyl bond distances of 1.774(1) and 1.773(1) Å, the O1–U1–O2 bond angle of 177.6(5)°, average equatorial bond distance of 2.38(1) Å) compare closely to those of **1** (see Table 2). The uranyl phosphate chains of **3** are spatially related to one another in

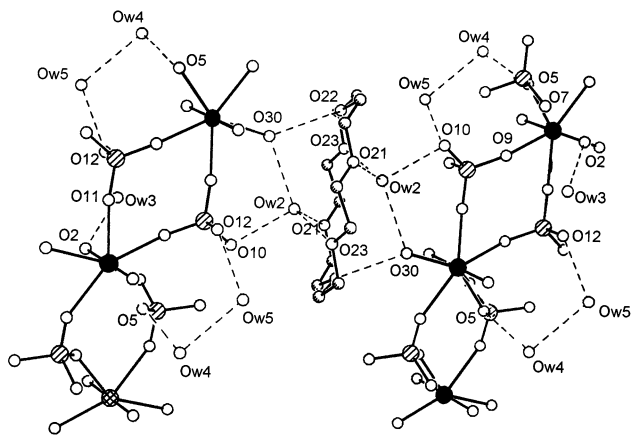

Fig. 2. Ball and stick view of a portion of **1** showing hydrogen bonding interactions (indicated by dashed bonds) between the lattice water molecules, crown ether molecules and phosphate chains. The filled balls represent uranium, the striped ones phosphorous and the empty ones oxygen.

a manner reminiscent of **1**. The lattice arrangement is discussed below.

3.2.2. $UO_2(H_2PO_4)_2(H_2O)\cdot$(18-crown-6)$\cdot 3H_2O$ (2)

Compound **2** crystallizes in the orthorhombic space group $P2_12_12_1$. As in **1**, the structure of **2** consists of one-dimensional $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains that run along the crystallographic *a* axis and hydrogen bond to empty crown ether molecules and water solvate molecules in the lattice. The asymmetric unit contains one 18-crown-6 molecule, three solvate water molecules, and a pentagonal bipyramidal $UO_2(H_2PO_4)_2(H_2O)$ subunit. U1 is coordinated by two axial uranyl oxygen atoms (1.766(5), 1.772(4) Å; O1–U1–O2 bond angle, 177.6(2)°) and five equatorial oxygen atoms, which include the oxygens of a water molecule and four $(H_2PO_4)^-$ groups that bind in an μ-η^1 fashion. The mean U–O distance for all equatorial bonds is 2.386(9) Å. There are two crystallographically independent phosphate tetrahedra, P1 and P2, with protonation schemes identical to that of compound **1**. In **2**, P–O bond distances range from 1.485(5) to 1.587(4) Å in P1 and 1.490(5) to 1.574(5) Å in P2. As in **1**, the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains are virtually identical to those in the binary phosphate **3** [19].

The bond distances and angles of the 18-crown-6 molecules are typical and the structure is rendered cohesive by a network of hydrogen bonds (Table 3). The lattice waters Ow1 and Ow2 are positioned above and below the plane of the crown ether rings. Ow1 is hydrogen bonded to the protonated phosphate oxygen, O6, the crown ether oxygen atoms, O12, O13 and O14 and Ow3 (see Table 4). Ow2 is hydrogen bonded to the protonated phosphate oxygen, O5, the crown ether oxygen atoms, O15, O16 and O17 and the uranium bound water, O11. Ow3 is hydrogen bonded to the protonated phosphate oxygen, O9, and the uranium bound water, O11.

The differences between **1**, **2**, and **3** are best illustrated by analyzing the general packing around the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains. Views down the chain axis of the three compounds are given in Fig. 3. The structures can be viewed as parallel chains of $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ that pack with one dimensional 'chains' of 18-crown-6 molecules. In all three compounds, each $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chain has six nearest neighbor chains that form pseudo-hexagonal arrays. In **2**, each $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ unit is surrounded by six 18-crown-6 chains, which separate them from the other uranyl phosphate chains (Fig. 3(b)). In contrast, the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains of **3** are hydrogen bonded to six identical $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains through lattice water molecules to form a cohesive, three-dimensional network (Fig. 3(c)). The hydrogen bonds to the lattice water molecules are apparently optimized when the interchain uranyl units are roughly parallel (in the direction normal to the chains). In compound **1**, each $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chain is surrounded by four 18-crown-6 chains and two $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains. As in **3**, the hydrogen bonding between adjacent $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains is mediated through lattice water molecules and, therefore, the relative orientations of the interchain uranyl units in the two compounds are quite similar. Since the direct $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ interchain interactions are absent in **2**, the lattice packing reflects the optimization of the interactions between the 18-crown-6 molecules and the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains. As a result, the uranyl phosphate chains in **2** have a different packing motif relative to **1** or **3** and the 18-crown-6 molecules can be viewed as 'packing directing' agents.

4. Conclusions

The crystal chemistry of the $[UO_2(H_2PO_4)_2(H_2O)]\cdot$18-crown$\cdot 6H_2O$ system is governed by the manner in which the lattice water and crown ether molecules interact with the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains. Compound **1** has one-half of a crown ether molecule and 2.5 molecules of lattice water per uranium, while **2** has one crown ether and three lattice water molecules per uranium. Compound **3** has two lattice waters per uranium and represents the optimized packing of the inorganic binary phosphate.

Because the 18-crown-6 molecules interrupt the direct interactions between the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains, they also lower the dimensionality of the crystal lattice. Compound **3** has coordinate linkages along the chain axes and can be viewed as a three-dimensional structure in view of the strong interchain hydrogen bonding contacts. In contrast, the direct interchain hydrogen bonding interactions in compound **1** only extend in two

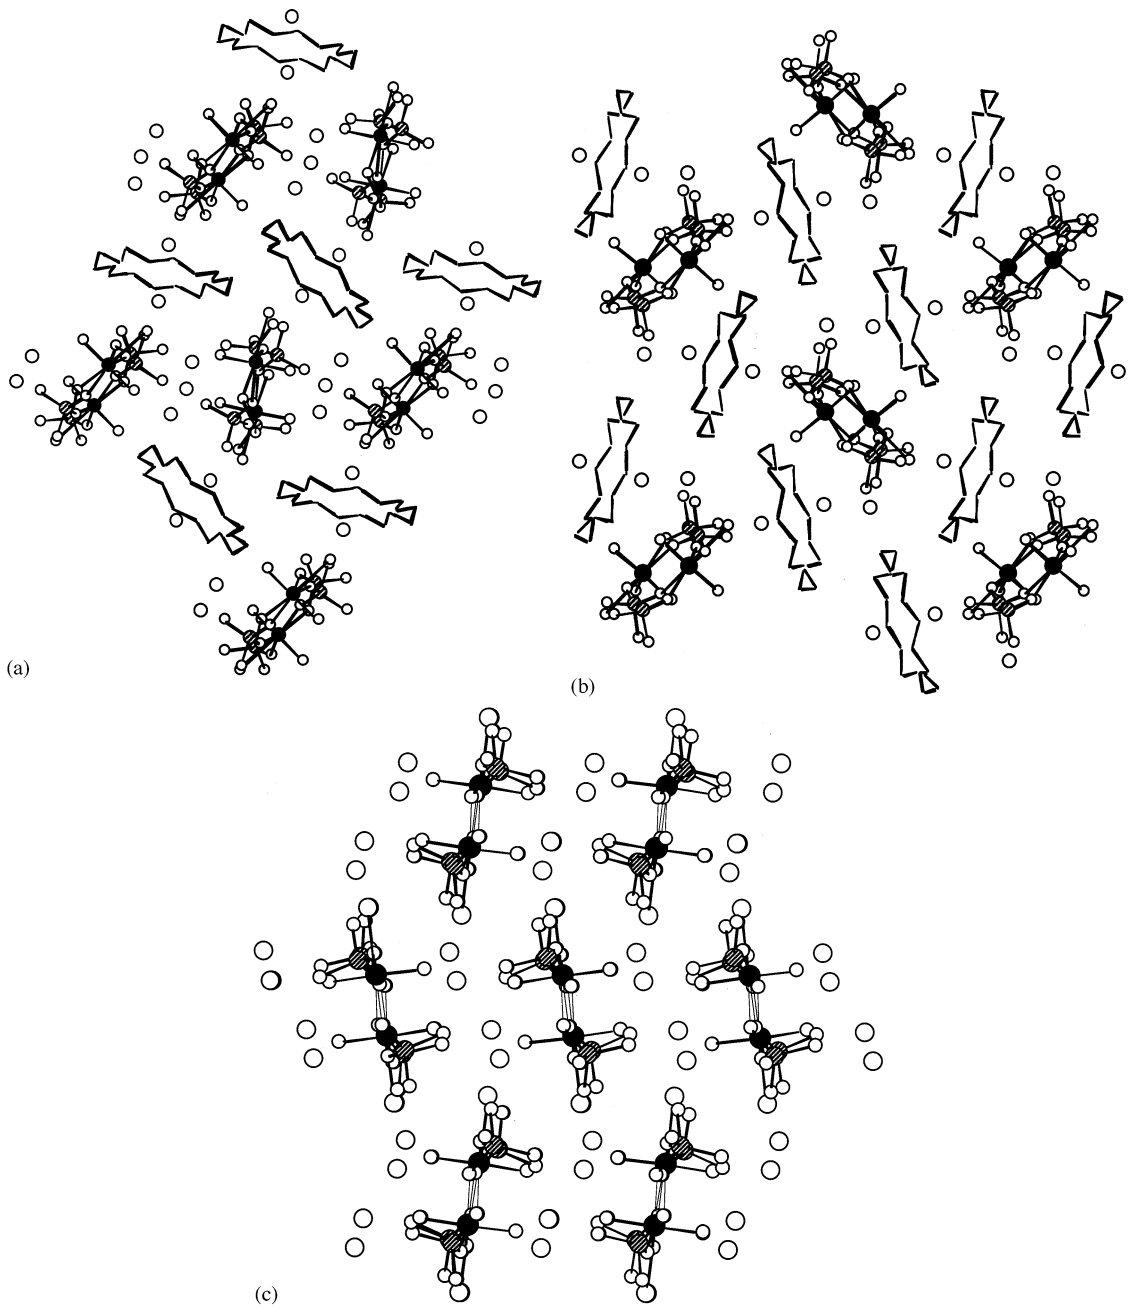

Fig. 3. Ball and stick views of the structures of **1** (3a), **2** (3b) and **3** (3c) viewed down the phosphate chains. The crown ether molecules are shown as stick drawings for clarity. The filled balls represent uranium, the striped ones phosphorous and the empty ones oxygen.

directions and, as such, the structure can be viewed as alternating layers of organic (18-crown-6) and inorganic lamellae. Finally, the $[UO_2(H_2PO_4)_2(H_2O)]_\infty$ chains in **2** are isolated and can be viewed as one-dimensional. The 18-crown-6 acts as a 'packing-directing agent' and controls the dimensionality of the structure. This effect may be reproducible with other neutral molecules that have a tendency to form hydrogen bonds.

5. Supplementary material

Crystallographic data have been deposited with the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK, and are available on request quoting the deposition numbers 136233 for $[UO_2(H_2PO_4)_2(H_2O)]_2 \cdot$(18-crown-6)$\cdot 5H_2O$ and 136232 for $UO_2(H_2PO_4)_2(H_2O) \cdot$(18-crown-6)$\cdot 3H_2O$.

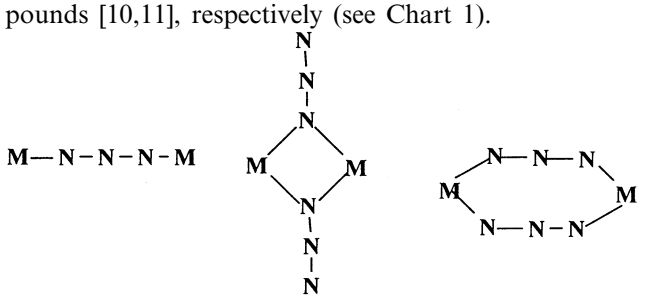
Abstract



Two new binuclear complexes bridged by end-to-end azido, $[Ni_2(TLA)_2(N_3)_3]\cdot(ClO_4)$ (**1**) and $[Mn_2(TLA)_2(N_3)_3]\cdot(ClO_4)$ (**2**), where TLA is tris(6-methyl-2-pyridylmethyl)amine, have been synthesized and characterized. The structures of the two complexes have been studied by X-ray diffraction analysis. The complex **1** cation is a dimeric structure consisting of two $[(TLA)Ni(N_3)]^+$ units linked by an end-to-end (μ-1,3-N_3^-) bridging azide anion. There is an inversion center at the center N(2) of the bridged azido group. Each of the Ni^{II} atoms is in a distorted octahedral configuration. The crystal structure of **2** is very similar to that of **1**, in which the Mn^{II} atoms by bridging the azide group are also in the distorted octahedral environment. The variable temperature magnetic susceptibilities of the title complexes have been studied. For **1**, the exchange integral is $J = -20.45\ cm^{-1}$, $g = 2.23$; for **2**, $J = -2.99\ cm^{-1}$, $g = 2.04$, indicating the existence of an intramolecular antiferromagnetic interaction between the two metal ions in both complexes. The spectral properties of the two complexes have been studied further by UV–Vis techniques, and the results have been discussed in detail. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Binuclear nickel(II) complex; Binuclear manganese(II) complex; Crystal structures; Magnetic properties; Tris(6-methyl-2-pyridylmethyl)amine

1. Introduction

Studies on the coordination properties of bi- and polynuclear nickel(II) and manganese(II) complexes have attracted a lot of attention in recent years [1–4]. The investigation of the magnetic properties of such compounds has been an active field of research, since the study on the correlation between magnetism and structure for nickel(II) and manganese(II) complexes can help not only in further understanding the interaction between magnetic coupling centers in metalloproteins and enzymes, but also to develop the field of molecular magnetism.

With regard to the factors that affect magnetic exchange pathways between paramagnetic centers, the choice of bridging ligands is of great importance because the magnetic-exchanging interaction in these compounds might be propagated or affected by the bridging ligand through various pathways and exhibit different magnetic strengths of the molecules. The pseudohalide ion, azide anion N_3^-, shows a great tendency to act as a bridging ligand between metallic centers [5–7]. As is well-known, the azido ligand stabilizes either end-on or end-to-end coordination modes when it links two metal centers, giving ferromagnetic [8,9] or antiferromagnetic compounds [10,11], respectively (see Chart 1).

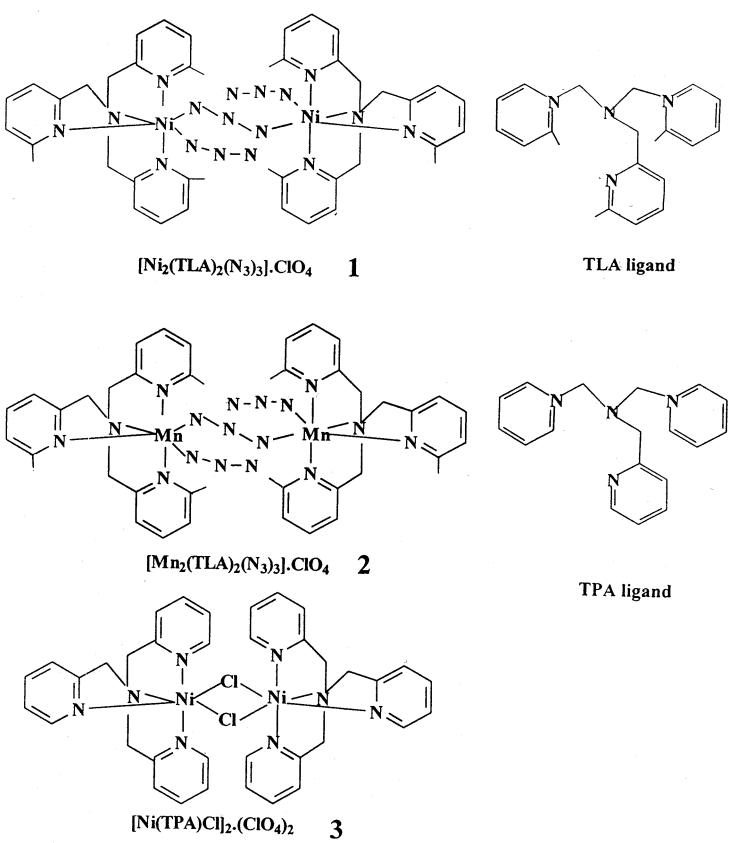
The binuclear complexes of tris(2-pyridylmethyl)-amine (TPA) and its derivatives, bridged by various groups as the model compounds for understanding the oxygen-transporting process in metal protein, have made significant contributions [12–14]. The crystal structure and magnetism of several mononuclear and binuclear metal complexes of TPA have been reported by this group [15]. In order to further explore the relationship between the bridging ligand and substituted groups on the ligand with the properties of TPAs complexes, we report herein the synthesis, crystal structures, magnetism, and spectral characters of the new binuclear nickel(II) and binuclear manganese(II) complexes of TLA and azido mixing ligands (Scheme 1).

2. Experimental



2.1. Materials and general methods

All the starting materials and organic solvents for synthesis were of analytical grade as purchased commercially and purified by standard methods prior to use. The TLA ligand was prepared by using the published procedure [16]. IR spectra were recorded on a Nicolet 170 SX FTIR spectrophotometer. Electronic spectra were measured in acetonitrile solution on a Shimadzu UV-365 for complex **1** and UV-240 spectrophotometer for complex **2**. Variable temperature magnetic susceptibility was measured on a MPMS 7 Quantum Design SQUID magnetometer in the temperature range 4–300 K, and diamagnetic corrections were made by using Pascal's constants [17]. Elemental analysis was carried out on a Perkin–Elmer model 240 analyzer. X-band ESR spectra were performed at room temperature (r.t.) on a JES-FEIXG spectrometer.

2.2. Syntheses

2.2.1. $[Ni_2(TLA)_2(N_3)_3]\cdot ClO_4$ (1)

A solution of TLA (33.2 mg, 0.1 mmol) in MeOH (10 cm^3) was added dropwise into a solution of $Ni(ClO_4)_2\cdot 6H_2O$ (36.6 mg, 0.1 mmol) in absolute methanol (10 cm^3) under stirring, and a solution of NaN_3 (26.0 mg, 0.4 mmol) in MeOH (5 cm^3) was added to the solution mentioned above. The resulting green solution was further stirred for ca. 30 min, and then it was filtered. The filtration was left to stand for over 2 weeks under ambient conditions, and green needle crystals of **1** were obtained (85 mg, 85%). IR (KBr pellets): 3445 (H_2O), 2952, 2924, 2120, 2042 (N_{3asym}^-), 1606, 1577 (py-ring), 1452, 1353, 1298 (N_{3sym}), 1095, 1005, 790,

2.2.2. $[Mn_2(TLA)_2(N_3)_3]\cdot(ClO_4)$ (2)

For the synthesis of complex **2**, similar procedures to that of complex **1** were followed, and the colorless needle crystals of **2** suitable for X-ray structure determination were obtained (80 mg, 80%). IR (KBr pellets): 3473, 3417, 3369, 3073, 2963, 2853, 2121, 2045 (N_{3asym}), 1604, 1577 (py-ring), 1453, 1387, 1353, 1296 (N_{3asym}^{-}), 1094, 1007, 790, 624, 557, 453 cm^{-1}. *Anal.* Calc. for $C_{42}H_{48}Mn_2N_{17}ClO_4$: C, 50.4; H, 4.80; N, 23.8. Found: C, 49.7; H, 4.50; N, 23.8%.

CAUTION: Perchlorate salts and azide compounds are potentially explosive. Treat the compounds with great care.

2.3. Crystallographic studies

The crystals of complexes **1** and **2** were mounted on a Siemens P4 diffractometer equipped with a graphite crystal monochromator for data collection. The determination of unit cell parameters and the data collection were performed with Mo Kα radiation ($\lambda=0.71073$ Å). Unit cell dimensions were obtained by least-square refinements of setting angles of 25 reflections. The structure was solved by direct methods and the metal atoms were located from E-maps. The other non-H atoms were determined with successive Fourier difference synthesis. Final refinement by full-matrix least-squares methods was carried out with anisotropic thermal parameters for non-H atoms. The H atoms were treated as riding on their attached atoms, refined isotropically and placed at calculated positions. All the calculations were performed on a computer using the SHELXL-93 and SHELXL-86 program packages [18]. The crystal data of complex **1** are not good since the quality of the crystal we obtained was not good, although many attempts were made under different conditions. The crystal data and data collection details are summarized in Table 1.

3. Results and discussions

3.1. Synthesis of the metal complexes

There are two types of azido group-linked metal center as the bridged ligand by end-to-end or end-on fashions. According to the above, the dimeric molecule could be obtained. However, when all the azido groups incorporate the metal centers as a terminal ligand, the monomer complex with mixing ligands is obtained. Thus, the ratio of ligand to azido salt and the reaction conditions are the important factors for the synthesis of polynuclear metal complexes.

The monomeric complex of general formula $(M\cdot L)\cdot ClO_4$ (L = TLA) can be considered as precursors in the synthesis of polynuclear metal systems with the azido anion. The synthetic strategy is based on the following equations:

$$M(ClO_4)_2 + TLA \rightarrow [M(TLA)]ClO_4 \quad (1)$$

$$[M(TLA)]ClO_4 + N_3^- \rightarrow [M(TLA)\cdot(N_3)]\cdot ClO_4 \quad (2)$$

$$2[M(TLA)\cdot N_3]\ ClO_4 + N_3^- \rightarrow [M_2(TLA)_2(N_3)_3]\cdot ClO_4 \quad (3)$$

(M = Ni^{II} and Mn^{II})

3.2. Crystal structure of $[Ni_2(TLA)_2(N_3)_3]\cdot ClO_4$ (1)

Fig. 1 shows an ORTEP view of complex **1**, and the selected bond distances and angles are given in Table 2. From Fig. 1, it can be seen that there are two unique units $[(TLA)Ni(N_3)]^+$ linked by single μ-end-to-end azide bridging groups with an inversion center at the N(2) center of the bridged azide group. Another two azide groups act as terminal ligands. Each nickel atom is in a distorted octahedral environment consisting of four nitrogen atoms from TLA and two nitrogen atoms from a bridging azide and coordinated terminal azide groups, respectively.

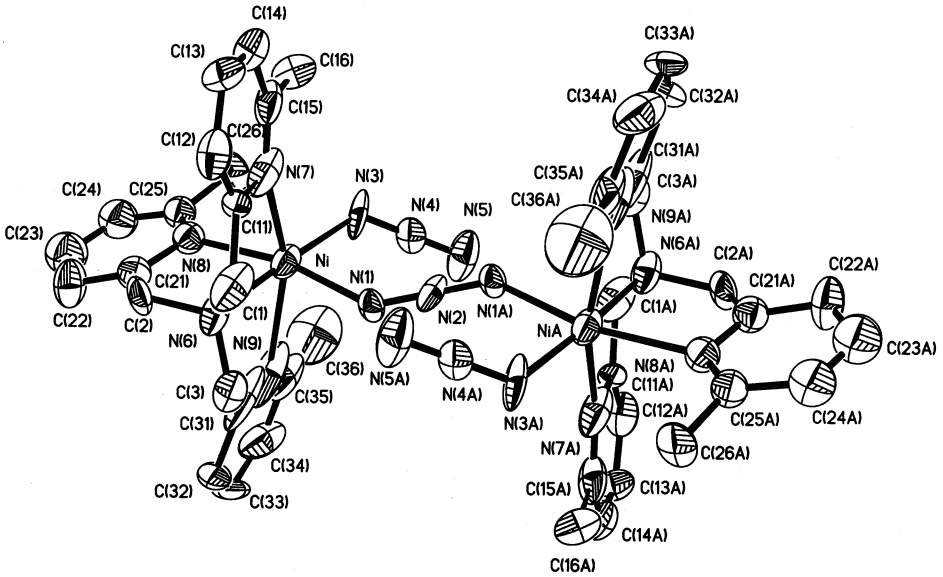

Fig. 1. ORTEP view and labelling scheme of complex **1**.

The intramolecular distance of Ni^{II}–Ni^{II} in complex **1** is 6.188 Å, being longer than the Ni^{II}–Ni^{II} distances found for bis(μ-1,3-azido) nickel(II) complexes (5.220 Å) [19], and also much longer than that of $[Ni(TPA)Cl]_2$ $(ClO_4)_2$ (**3**) [15a] bridged by bis(μ-Cl) (3.523 Å). The geometry of **1** is similar to **3** except for the bridging ligand and the substituted methyl groups on TPA.

In complex **1**, the average Ni–N_{py} bond length is 2.23 Å, which is ~0.15 Å longer than that of Ni–N_{py} in **3**. It might arise from the presence of the 6-methyl groups on the pyridine rings, whose steric interactions prevent the pyridine nitrogen from coordinating to the nickel(II) center at the optimum bond length. However, the Ni–N_{amine} distance is 0.067 Å shorter than that of Ni–N_{amine} in **3**. The Ni-μ-N_{azido} bond length is 2.117 Å, which is longer than that found for bis(μ-azido) nickel(II) complexes (2.069 Å) [19]. The Ni–N(terminal azido) bonds have lengths of 2.047 Å, which is shorter than that of Ni–N(bridged azido) bonds [2.117(7) Å] in **1**, it might be due to the repulsion of the two unique units in **1** as well as the stronger *trans* influence of the 6-methylpyridine than that of the tertiary amine group of TLA ligand [20].

The bridging angles of the binuclear complexes are directly related to the magnetic coupling. Most end-to-end (EE) bridging modes of azido lead to antiferromagnetic coupling except the nickel(II) complex reported recently by Hong and Do [21]. The bridging angle of Ni–N(1)–N(2) in **1** is 139.1 (5)°, which is smaller than that found for other singly bridged nickel(II) complexes, for instance $[Ni_2(macro)_2(N_3)_3]^+$ (142°) [22], and is bigger than that found for the bis(μ-azido)nickel(II) complex (135°) [19]. The N(7)–Ni–N(9) angle of 156.6(3)° in **1** is smaller than the corresponding angle of **3** (the N21–Ni–N31 angle is 161.8(7)° in **3**), indicating stronger repulsion of the 6-methyl groups on the pyridine rings of TLA and the flexibility of the singly bridged azide group in comparison to the doubly bridged chlorine atoms.

3.3. Crystal structure of $[Mn_2(TLA)_2(N_3)_3]\cdot(ClO_4)$ (2)

The ORTEP structure of complex **2** is shown in Fig. 2, and the selected bond distances and angles are listed in Table 3.

The structure of **2** is quite similar to that of **1**, and the local geometry around each Mn^{II} center is also in a distorted octahedron environment with one of the bridging azide nitrogens [N(2)] and the pyridine nitrogen [N(9)] occupying the axial positions. The equatorial positions are occupied by the other terminal azide nitrogen [N(3)], two pyridine nitrogens [N(8) and N(7)]

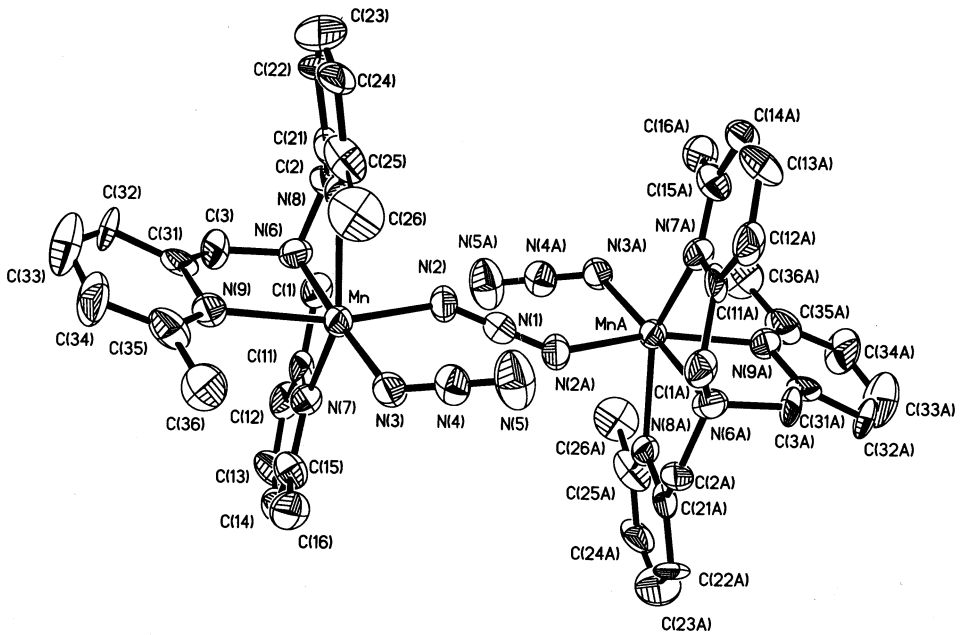

Fig. 2. ORTEP view and labelling scheme of complex **2**.

and the amine nitrogen [N(6)] of TLA. The two Mn^{II} centers are linked by a bridging azido (end-to-end, μ-1,3-N_3 coordination mode). The intramolecular Mn^{II}–Mn^{II} distance in **2** is 6.367 Å, being slightly longer than that of Ni^{II}–Ni^{II} in **1**. The average Mn–N_{py} bond length of **2** is 2.37 Å, being longer than those of Mn–N_{bipy} [2.255 (4) Å] [23], while the distance of Mn–N(8) [2.420(13) Å] is longer than other the two Mn–N_{py} distances [Mn–N(7) = 2.295(13) and Mn–N(9) = 2.375(13) Å] due to the steric hindrance of the coordinated terminal azido groups. The bond length of Mn–N(bridging azido) [2.210(13) Å] is much longer than that of Mn–N(terminal azido) [2.073(14) Å] being the result of repulsion of the two units $[(TLA)Mn(N_3)]^+$ in **2**. The bridged angle N(1)–N(2)–Mn [141.2(10)°] is larger than that in **1** [N(2)–N(1)–Ni] (139.1°), and this might be one of the factors leading to the difference in magnetic properties of **1** and **2**.

3.4. Magnetic properties

The magnetic behavior of complex **1** and **2** was measured throughout the temperature range 4–300 K. The temperature dependence of the magnetic susceptibility and the magnetic moments for the title complexes are shown in Figs. 3 and 4, respectively.

From Fig. 3, it can be seen that the effective magnetic moment (μ_{eff}) of complex **1** decreases slowly in the 300–50 K temperature range, but sharply decreases below 50 K. This behavior is characteristic of antiferromagnetic spin-exchange interactions between paramagnetic ions. The observed magnetic behavior clearly demonstrates the existence of intramolecular antiferromagnetic spin-exchange interactions through the N–N–N bridging ligand in this complex. The downturn in the effective magnetic moment plots may be attributed to zero-field splitting of the triplet Ni^{II} in complex **1**.

In order to quantitatively understand the magnitude of the spin-exchange interaction between the intramolecular Ni^{II}–Ni^{II} ions, the magnetic data of complex **1** were fit to the susceptibility Eq. (4), which is

Table 3

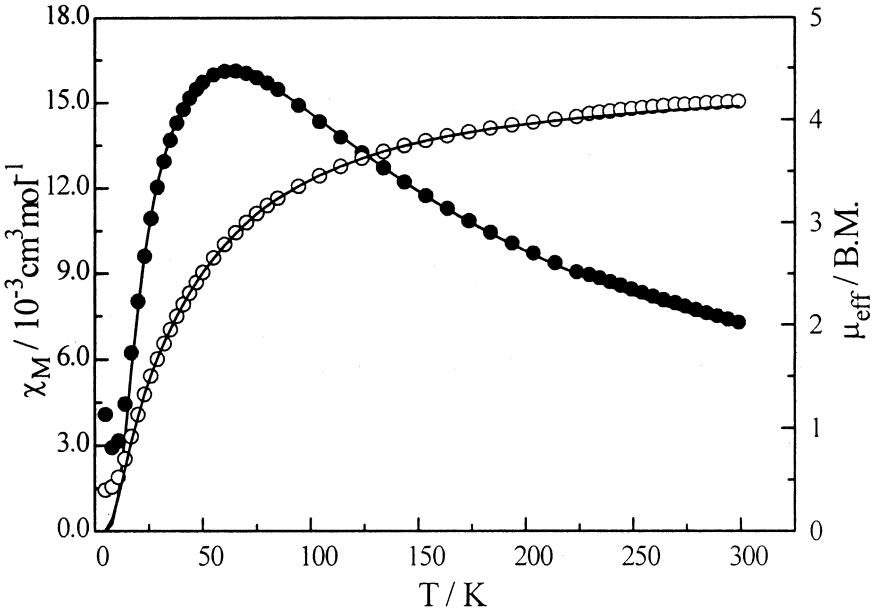

Fig. 3. The temperature variation of magnetic susceptibility (●) and magnetic moment (○) for complex **1**.

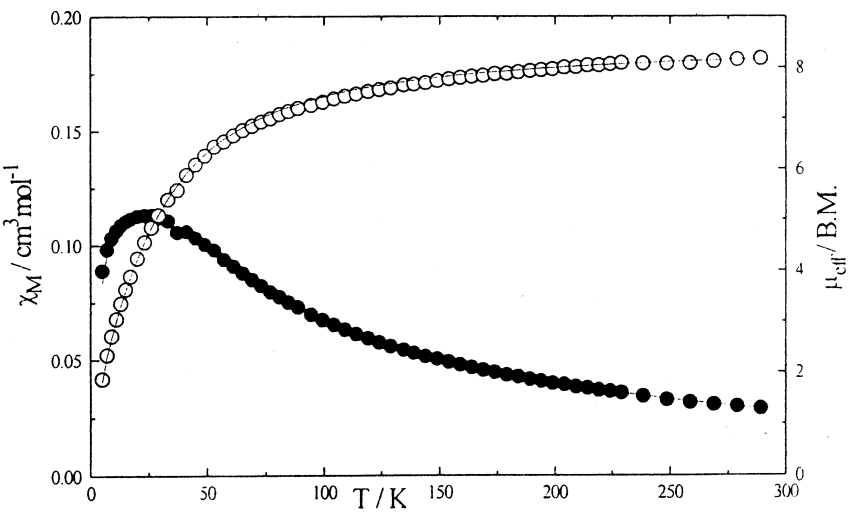

Fig. 4. The temperature variation of magnetic susceptibility (●) and magnetic moment (○) for complex **2**.

based on the Heisenberg spin-exchange operator: $\hat{H} = -2J\hat{S}_1\hat{S}_2$.

$$\chi_M = \{2Ng^2\beta^2 \times [5 + \exp(-4J/kT)]\} / \{kT \times [5 + 3\exp(-4J/kT) + \exp(6J/kT)]\} \quad (4)$$

where χ_M denotes the susceptibility per binuclear complex molecule, and other symbols have their usual meanings. As shown in Fig. 3, a good least-squares fit to the experimental data was attained from Eq. (4). The magnetic parameters thus obtained are $J = -20.5$ cm^{-1}, $g = 2.2$ and the agreement factor defined by $F = \Sigma(\chi i_{obs} - \chi i_{cald})^2(\chi i_{obs})^{-1}$ is equal to 5.3×10^{-5}. The results further indicate that there exists an intramolecular antiferromagnetic spin-exchange interaction between two Ni^{II} ions in complex **1**. The magnetic behavior is in good agreement with this fact, where the super-exchange interaction in the M–N–N–N–M mode is antiferromagnetic coupling. It is also in good agreement with those of metal binuclear complexes with μ-1,3-azide-bridged [19,24]. In complex **3**, there is a ferromagnetic spin-exchange interaction. However, complex **1** shows an antiferromagnetic spin-exchange interaction between Ni^{II} ions. From the magnetic behavior of complexes **1** and **3**, it is obvious that the magnetic properties of the binuclear complexes of the same system ligands can be adjusted by altering the bridging ligands.

For complex **2**, the magnetic behavior is similar to that of complex **1**. It adopted a susceptibility equation based on the Hamiltonian: $\hat{H} = -2J\hat{S}_1\hat{S}_2$. The molar magnetic susceptibility is given by Eq. (5):

$$\chi_M = [(2Ng^2\beta^2)/kT]\cdot \{[(55 + 30\exp(-10J/kT) + 14\exp(-18J/kT) + 5\exp(-24J/kT) + \exp(-28J/kT))]/ [11 + 9\exp(-10J/kT) + 7\exp(-18J/kT) + 5\exp(-24J/kT) + 3\exp(-28J/kT) + \exp(-30J/kT)]\} \quad (5)$$

The temperature dependence of the magnetic susceptibility for **2** is shown in Fig. 4. The μ_{eff} value is 8.30 BM at r.t., which is slightly lower than the spin-only value of 8.36 BM excepted for two uncoupled high-spin Mn^{II} ions. Upon cooling, the magnetic moment value decreases slowly from 8.30 BM (300 K) to 6.45 BM (50 K), indicating the presence of a weak antiferromagnitic exchange interaction. The magnetic susceptibility of **2** was obtained by using Eq. (5), and the least-squares fitting with an assumed g value of 2.04 ($g_{exp} = 2.018$ by EPR) gives the parameters: $J = -2.99\ cm^{-1}$ and $F = 2.87 \times 10^{-5}$, $R = 3.58 \times 10^{-4}$ $[R = (\chi_{calc} - \chi_{obs})^2]/\Sigma(\chi_{obs})^2]$. The J value is much smaller than that of complex **1**.

The weaker antiferromagnetic interaction can be further illustrated by the fact that in complex **1** the unpaired electrons are in molecular orbitals that are probably dominantly nickel $3_{dx^2-y^2}$ and 3_{dz^2} in character. The four orbits, two on each nickel center, will interact with the azido orbit of the correct symmetry and thereby provide a potential 'pathway' for antiferromagnetic exchange between the two nickel centers [25].

For complex **2**, the $|J|$ value is much smaller than that of **1**. This situation may be illustrated as follows: in the Ni^{II} complex there are two magnetic orbits on each nickel atom, but there are five magnetic orbits on each atom in the case of Mn^{II}. However, the interaction between only a part of the magnetic orbits can be considered for the contribution of magnetic behavior. The other unpaired electrons that do not participate on manganese atom 'dilute' the magnetic coupling action [26].

3.5. Electronic spectra

The electronic spectra of the title complexes in methanol solution have been studied, these have been assigned and summarized in Table 4. The spectral data of complex **3** and listed for comparison. For complex **1**, three absorption bands have been observed. The two bands in the visible and infrared range are assigned to d–d spin-allowed transition of the Ni^{II} ion in an octahedral crystal field and the stronger absorption band in the UV range is assigned to the charge-transfer band [27]. According to Lever's transition energy ratio [28], some coordination field parameters of the complexes have been obtained by using two observed bands v_1 and v_2, and the calculated results are summarized in Table 4. From the data of Table 4, it has been observed that the Dq value of **1** is lower than that of **3**, indicating the stronger coordination field strength of TPA in comparison to that of TLA. The values of $\beta < 1$ show strongly covalent bonding of Ni^{II} in complex **1** [29], and the covalent property of metal–nitrogen bonds in **1** is greater than that in **3** from the β value [β value of **1** (0.785) is lower than that of **3** (0.838)]. It might be illustrated that although the substituted methyl groups on the pyridines of TLA as the electron-donating groups increase the electronic density on the ligand, they meanwhile increase the space hindrance. Both electronic and hindrance effects result in **1** being less

Table 4
Electronic spectral data and some coordination field parameters of **1**, **2** and **3** in MeOH solution

Complex	λ (nm)	$\varepsilon \times 10^{-3}$ ($M^{-1}\ cm^{-1}$)	Assignment	Dq (cm^{-1})	B	β
1	312	1.840	L → M (CT) $^3A_{2g} \rightarrow {}^3T_{1g}(P)$; v_3			
	655	0.035	d → d $^3A_{2g} \rightarrow {}^3T_{1g}(F)$; v_2	940	817	0.785
	1064	0.056	d → d $^3A_{2g} \rightarrow {}^3T_{2g}(F)$; v_1			
2	264	18.44	π → π*			
	206	16.97	n → π*			
3 [15a]	323	1.108 (v_3)	L → M (CT) $^3A_{2g} \rightarrow {}^3T_{1g}(P)$; v_3			
	595	0.043 (v_2)	d → d $^3A_{2g} \rightarrow {}^3T_{1g}(F)$; v_2	1046	872	0.838
	955	0.042 (v_1)	d → d $^3A_{2g} \rightarrow {}^3T_{2g}(F)$; v_1			

stable than **3**, implying the space effect as the main factor.

For complex **2**, two bands around 264 and 206 nm with high intensity in UV-range have been observed, which can be assigned to the transitions in the ligands themselves. The d–d transition band of **2** is not observed in the dilute solution.

4. Supplementary material

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition numbers CCDC 132443 and 132442 for **1** and **2**, respectively.

POLYHEDRON

Complexes of praseodymium(III) with D-gluconic acid

Sébastien Giroux, Patrice Rubini *, Bernard Henry, Sabrina Aury

Laboratoire de Chimie Physique Organique et Colloïdale, Université Henri Poincaré-Nancy I, Unité Mixte CNRS-UHP (SRSMC, UMR no. 7565), BP 239, 54506 Vandoeuvre-Les-Nancy Cedex, France

Received 25 February 2000; accepted 8 May 2000

Abstract

The complexation of the praseodymium(III) ion with D-gluconic acid was studied by potentiometry, UV–Vis spectrophotometry, circular dichroism (CD) experiments and ^{1}H and ^{13}C NMR. In order to determine the coordination sites, the study of the complexation with D-galactonic and D-gulonic acids was also achieved. It was found that six different complexes are formed in solution from pH 2 to 11.5. The formation constants were determined. For four species among the six, D-gluconic acid binds the cation with deprotonated hydroxylic group(s) in addition to the carboxylate group. On the basis of the spectroscopic results, the structures of the complexes are discussed. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: D-Gluconic acid; D-Galactonic acid; D-Gulonic acid; Praseodymium(III); Complexation

1. Introduction

Gluconic acid is used more and more in the industrial domain for its complexing properties. Gluconate is non-toxic and fully biodegradable. It is prepared from maize or wheat starch [1] and available potentially in great quantity.

If the complexing ability of gluconic acid for metallic cations is largely accepted [2–6], detailed studies on the nature of the complexes formed in solution and their structures are not so numerous. It was shown that gluconic acid binds to cations in basic solutions by the carboxylate group and deprotonated hydroxyl functions, but the exact coordination sites are difficult to determine in solution, although some NMR [7–9] and circular dichroism [10] studies on a few systems have been performed in order to solve this problem.

Among the cations studied, the lanthanides ions have not been studied much [2,10,11], particularly the lanthanide(III) ions. Nevertheless, as they are hard acids, the complexation with D-gluconic acid, which binds to cations by oxygen atoms, must be strong. This work is devoted to the study of the complexation of D-gluconic acid with the cation Pr(III) in aqueous solutions from pH 2 to 11.5. The stoichiometry and the formation constants of the complexes were determined by pH-potentiometry. The system was ascertained by spectroscopic studies such as UV–Vis spectrophotometry and NMR and by CD experiments. For the CD study, a comparison with D-gulconic and D-galactonic acids, which are epimers of D-gluconic acid, was made in order to know which oxygens of the ionized hydroxyl groups are bound to the cation.

This work is the first step in the study of the complexation of D-gulonic acid (and other polyhydroxylated carboxylic acids) with the series of the lanthanide(III) ions. Besides the thermodynamical and the structural aspects, we are interested also in the search for ligands which present selectivity along the lanthanide series.

2. Experimental

2.1. Materials

Potassium D-gluconate (Fluka 99%), D-galactonic acid γ-lactone (Fluka 99%), D-gulonic acid γ-lactone

(Fluka 97%) and praseodymium(III) nitrate (Strem Chem 99.9%) were used without further purification. The concentration of Pr(III) was determined by a standard procedure using EDTA (Merck). pH-metric titrations were performed with NaOH (Merck or SDS) standard solutions.

2.2. pH-metric measurements

pH-metric titrations were performed in aqueous solutions for the investigation of the protonation and coordination equilibria at $T = 298.0 \pm 0.1$ K and at an ionic strength $I = 0.1$ mol l^{-1} ($NaClO_4$) under an argon atmosphere. An automatic titration set, including a Dosimat 665 (Metrohm) autoburette, an Orion-525 A precision digital pH-meter and a Mettler Toledo Inlab 422 type combined glass electrode, was used for the titrations. The species formed in the systems were characterized by the following general equilibrium process:

$$pM + qL + rH \rightleftharpoons M_pL_qH_r \quad (\beta_{pqr})$$

$$\beta_{pqr} = \frac{[M_pL_qH_r]}{[M]^p[L]^q[H]^r}$$

where M denotes the lanthanide(III) ion and L denotes the non-protonated ligand molecules (L^-). Charges are omitted for simplicity, but can be easily calculated taking into account that the fully protonated ligand is LH. The detailed description of the experimental procedure and data evaluation, using the PSEQUAD computer program [12] were described earlier [13,14]. The protonation and the complex formation constants were determined from four and eight independent titrations (~ 100 data points per titration), respectively. The metal-to-ligand ratio was varied between 1:1 and 1:6, using praseodymium(III) concentration ranging from 1.3×10^{-3} to 5.6×10^{-3} mol l^{-1}. The pH-metric data between pH 2 and 11.3 were used for the evaluation.

For the analysis of the titration curves, the formation of the hydroxo complex MOH^{2+} (MH_{-1}) was taken into consideration with a formation constant value ($\log \beta_{10-1}$) equal to -8.82 [14].

It must be noted that the accurate determination of the acidity constant of D-gluconic, D-galactonic and D-gulonic acids is not so easily calculated because of the lactonization of these molecules in acidic solutions. The gluconate solution must be acidified just before the beginning of the titration and the speed of the titration before the equivalence point must be adjusted to avoid lactone formation at the maximum on one hand, and to allow a good stabilization of the measurements on the other hand. The value obtained in this work ($pK_a = 3.472 \pm 0.007$) is in agreement with those reported in the literature for identical experimental conditions ($t = 25°C$, $I = 0.1$ mol l^{-1}) [16–18].

2.3. UV–Vis spectrophotometry

The visible absorption spectra were recorded on a Varian Cary 3E UV–Vis spectrophotometer. The Pr(III) concentration was 3×10^{-2} mol l^{-1} initially and the ligand (D-gluconic acid) to metal ratios 1.1:1 and 2.1:1. pH was varied by the addition of soda or perchloric acid. The different spectra were normalized by considering the band of the nitrate anions, the intensity of which depends only on the concentration of these ions (and not on pH).

As the concentrations of the seven possible species present in solution (Pr^{3+}, PrL^{2+}, $PrLH^{+}_{-1}$, $PrLH_{-2}$, $PrLH_2^{+}$, PrL_2H_{-1} and $PrL_2H^{2-}_{-3}$) are known from the potentiometric results and by using the Beer–Lambert equation, the ε values of each complex as a function of the wavelength could be computed, taking into account the spectra recorded at different pH values and L:M ratios:

$$D_i(\lambda) = \sum_J \varepsilon_j(\lambda) \cdot C_{ji} \cdot 1$$

where j denotes one of the seven species ($j = 1$–7) and $i = 1$–7, seven different spectra. Therefore the determination of the seven ε values consists in the matricial resolution of seven equations with seven unknown quantities.

2.4. Circular dichroism experiments

CD spectra were recorded on a Jobin-Yvon DGG circular dichroism spectrophotometer on solutions of Pr(III) with a concentration equal to 5×10^{-2} mol l^{-1}, for ligand to metal ratios equal to 1:1 and 5:1 and for different pH values. Only the domain 430–500 nm was observed.

2.5. NMR spectroscopy

^1H and ^{13}C NMR spectra were recorded on a Bruker DRX 400 apparatus at 400 and 100.6 MHz, respectively. ^1H chemical shifts were measured relatively to DSS, the chemical shift of which is the same as that of TMS; the concentration of the ligand was 0.1 mol l^{-1} and the solvent D_2O. ^{13}C NMR chemical shifts were measured with respect to dioxane and converted to the TMS scale using the value $\delta_{dioxane} = 67.4$ ppm. The concentration of the ligand was fixed to 0.3 mol l^{-1} and the solvent was a mixture of H_2O and D_2O (80/20 v/v)

In D_2O solutions, the pD value was obtained by adding 0.40 to the value read on the pH-meter [19].

3. Results

3.1. pH-metric measurements

From potentiometric experiments, a set of six complexes formed between Pr(III) and D-gluconic acid can be determined: ML^{2+}, MLH^{+}_{-1}, MLH_{-2}, ML_2^{+}, ML_2H_{-1} and $ML_2H^{2-}_{-3}$ (the ligand, under its acidic form, is noted LH). The corresponding formation constants are: $\log \beta_{110} = 2.78 \pm 0.03$, $\log \beta_{11-1} = -3.34 \pm 0.02$, $\log \beta_{11-2} = -10.09 \pm 0.01$, $\log \beta_{120} = 5.57 \pm 0.03$, $\log \beta_{12-1} = -0.67 \pm 0.05$ and $\log \beta_{12-3} = -19.13 \pm 0.08$. From these values, some characteristic protonation constants can be calculated:

$$ML^{2+} \rightarrow MLH^{+}_{-1} + H^{+} \qquad pK = 6.12$$

$$MLH^{+}_{-1} \rightarrow MLH_{-2} + H^{+} \qquad pK = 6.75$$

$$ML_2^{+} \rightarrow ML_2H_{-1} + H^{+} \qquad pK = 6.24$$

Some representative distribution diagrams of these complexes in function of pH are represented in Fig. 1. The complexation starts at pH 2 with the formation of the complex ML. The formation constant of this species is of the same order of magnitude as those for comparable polyhydroxylated carboxylic acids [20,21]. ML and ML_2 complexes are present together in solution up to pH 7–8 but ML_2 predominates over ML for ligand to metal ratios higher than 2:1 from pH ~ 3–4. At neutral pH values, MLH_{-1} or ML_2H_{-1} are the major species (ML_2H_{-1} for high ligand to metal L:M ratios). From pH ~ 8, MLH_{-2} becomes the predominant species up to pH ~ 11. Beyond this value, ML_2H_{-3} predominates. It must be noted that, for low L:M ratios, a precipitate is observed at pH ~ 8–9.

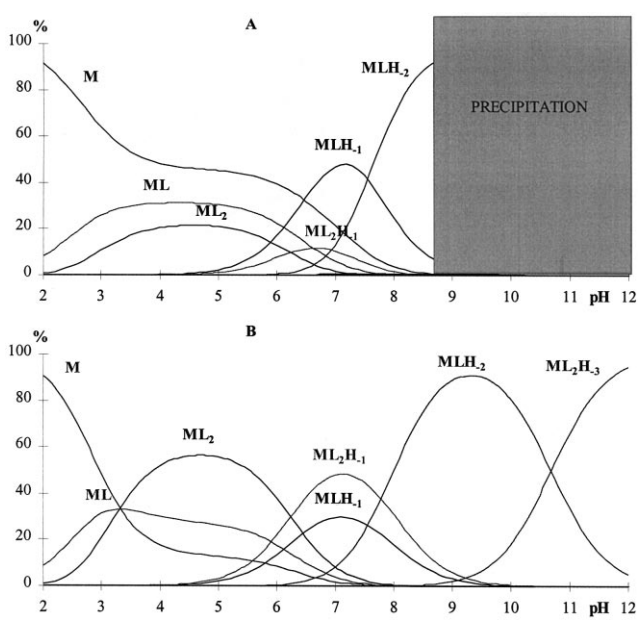

Fig. 1. Distribution diagrams for the Pr(III):D-gluconic acid system. $[Pr(III)] = 5 \times 10^{-3}$ mol l^{-1}. Ligand to metal ratio L:M = 1:1 (A) and L:M = 5:1 (B).

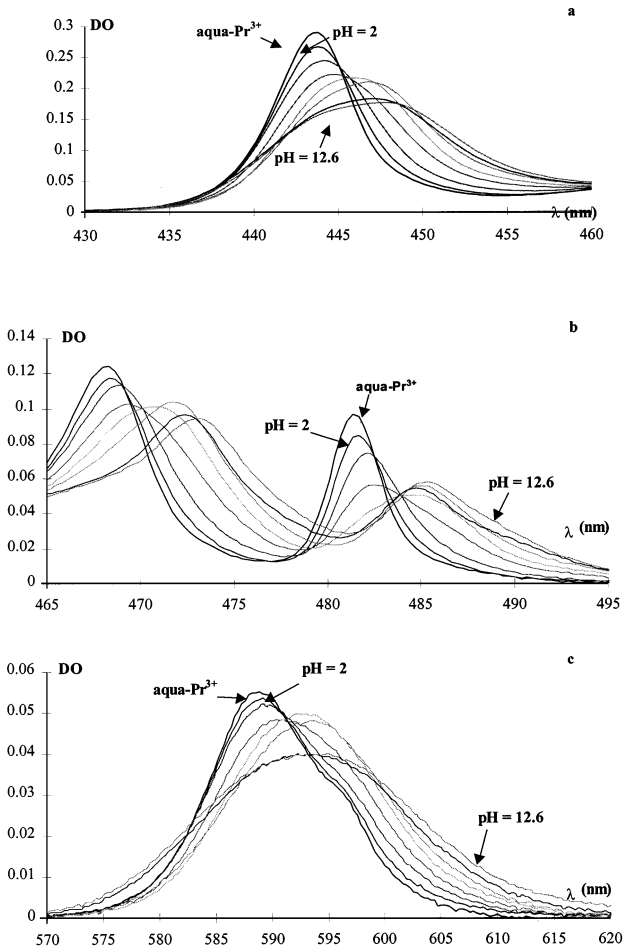

Fig. 2. Visible spectrophotometic spectra of the system Pr(III):D-gluconic acid in a 2.1:1 ratio ($Pr(III) = 0.03$ mol l^{-1}) corresponding to the $^3P_2$ (a), $^3P_1$ and $^3P_0$ (b) and $^1D_2$ (c) transitions. Evolution of the spectra from pH 2 to 12.6.

3.2. UV–Vis spectroscopy

UV–Vis spectra of Pr(III)/D-gluconic acid solutions present band absorptions in the visible region (solutions are pale green) corresponding to $^3P_2$, $^3P_1$, $^3P_0$ (around 450–490 nm) and $^1D_2$ (around 590 nm) transitions. This spectroscopy can be used to study the complexation at different pH values, but it is well known that the shifts due to complexation are weak for lanthanides ions [22]. Nevertheless spectra show clearly an evolution when pH is varied (Fig. 2). At pH 4.2 where the species ML_2 is predominant, it can be seen on the spectra for L:M = 2.1:1 that the peak corresponding to M^{3+} without ligand is slightly (but surely) shifted and its intensity decreases. At pH 7, where ML_2H_{-1} is the major complex, the shift of the bands is more pronounced (~ 4 cm^{-1} towards the high wavelengths) and distinct peaks from those of the free metal are clearly

observed. Around pH ~ 8 where MLH_{-2} arises, a decrease in the intensity of the peaks and a broadening are observed. Finally, for high pH values (11–12), spectra do not much differ from those recorded at pH ~ 8. It is clearly shown, by varying pH, that four major species are formed in solutions, exactly as the potentiometric results proved (the four complexes: ML_2, ML_2H_{-1}, MLH_{-2} and ML_2H_{-3} are found to be dominant for L:M = 2.1:1, successively from pH 2 to 12). From the spectra recorded for different pH values and two different L:M ratios and from the knowledge of the proportions of the different complexes from the pH-metric results, the ε values of the seven species (six complexes plus the M^{3+} aquo-cation) can be calculated. The results are presented in Fig. 3. It is clear that, if the system found from the potentiometric experiments was wrong, it would not be possible to fit all these results and to obtain reasonable ε values and a correct peak shape for all the species.

3.3. Complexation of Pr(III) by D-galactonic and D-gulonic acids

D-Gluconic acid has four asymmetric carbons and the interaction of this ligand with Pr(III) which presents

absorption bands in the UV–vis domain may generate effects in the circular dichroism (CD) spectra providing that the asymmetry centers are not too far from the complexation sites. CD studies may be very useful to determine these sites and to obtain information about the coordination mode of D-gluconic acid with the lanthanide(III) ions. In order to have elements of comparison and a better information on the coordination sites, it was decided to study the complexation of Pr(III) with two epimers of D-gluconic acid:D-galactonic acid which differs from D-gluconic acid only by the configuration of the C_4 carbon (carbon in γ position relative to the carboxylic function) and D-gulonic acid which differs from D-galactonic acid by the configuration of the C_3 atom.

It is necessary, before recording CD spectra with these ligands, to know which complexes are formed with Pr(III) and if they are different from those found for D-gluconic acid. A potentiometric study was made and the nature of the complexes and their formation constants are summarized in Table 1. The complexes ML, MLH_{-1}, MLH_{-2} and ML_2 are shared by the three ligands. ML_2H_{-1} does not exist for the system Pr(III)/D-gulonic acid. The bigger differences are observed in basic media. For D-galactonic acid, no complex at basic pH was determined since a precipitate is systematically observed from pH ~ 9.5. For D-gulonic acid, the dimeric species $M_2L_2H_{-3}$ and $M_2L_2H_{-5}$ replace the complex ML_2H_{-3} for D-gluconic acid. The respective distribution diagrams for D-galactonic and D-gluconic acids are not so different from each other, as can be seen in Fig. 4 (drawn for L:M = 5:1): ML_2 predominates at pH 2–6 and ML_2H_{-1} at pH ~ 6 – 8. The distribution diagram for D-gulonic acid is a little different from the two others, particularly in the pH domain ~ 6–8.

3.4. CD experiments

Katzin performed circular dichroic studies [10] of hydroxy acids complexes with the praseodymium ion but he did not know exactly the repartition of the different species according to pH. He worked on acidic, neutral and basic complexes. Furthermore, our detailed work on the formation of complexes as a function of pH, resumed this CD study. Spectra were recorded for

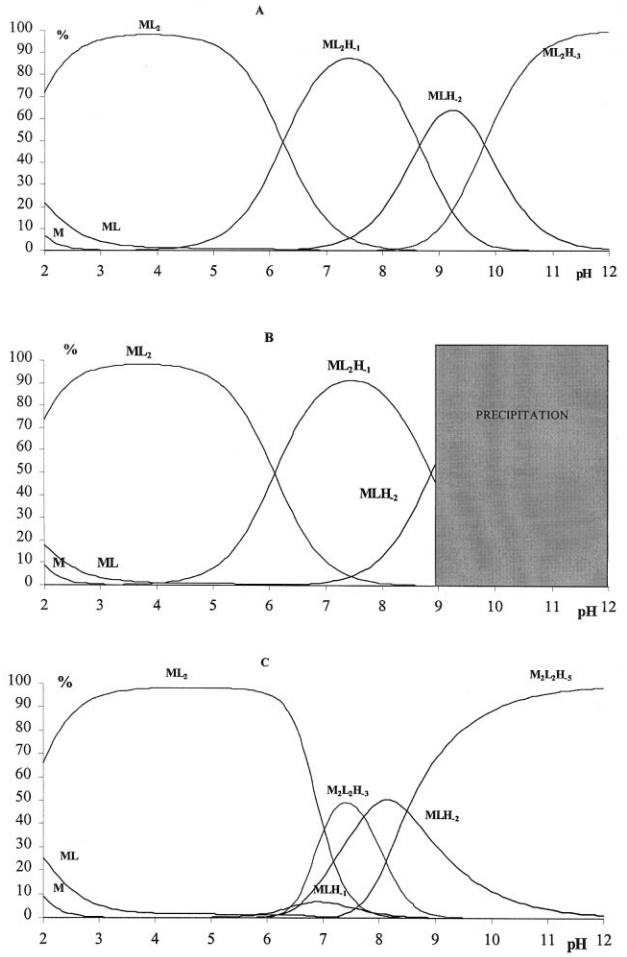

Fig. 4. Distribution diagrams for the systems Pr^{3+}:D-gluconic acid (A), Pr^{3+}:D-galactonic acid (B) and Pr^{3+}:D-gulonic acid (C) for L:M = 5:1 and [M] = 0.05 mol l^{-1}.

L:M = 5:1 (Pr(III) = 0.05 mol l^{-1}) as well for D-gluconic acid as for D-gulonic and D-galactonic acids (Fig. 5). At pH 4, the complex ML_2 is predominant and there is practically no dichroic effects. At pH ~ 6–7, strong CD effects are seen. This pH domain corresponds to the existence of the complex ML_2H_{-1} for D-gluconic and D-galactonic acid. It can be noted that the spectra are inverted as already reported by Katzin [10]. This probably denotes the participation to the complexation of a hydroxyl or a deprotonated hydroxyl group. It must also kept in mind that D-gluconic acid and D-galactonic acid only differ from the configuration of the C_4 carbon. It can be concluded that the hydroxyl group or the hydroxylate in γ position relative to the carboxylate is probably involved in the coordination. For D-gulonic acid, the complexes present at pH 6.5–7.5 are $M_2L_2H_{-3}$ and MLH_{-2}; the CD spectrum is quite different from those observed for the other molecules but strong CD effects are also observed. It must be noted that, for D-gluconic and D-galactonic acids, there is at the most one deprotonated OH function in the complex ML_2H_{-1} whereas, for $M_2L_2H_{-3}$ and MLH_{-2} complexes with D-gulonic acid, the ligand is potentially under the form LH_{-2} with two ionized OH functions.

The spectrum obtained at pH 11.0 with D-gluconic acid is quite different from those obtained at pH 6–7. It corresponds to the domain of existence of the complex ML_2H_{-3}, the structure of which is discussed below. The corresponding UV–Vis spectrum shows broader absorption bands than those observed at lower pH values.

3.5. ^1H and ^{13}C NMR

Solutions of D-gluconic acid and praseodymium(III) ion for various L:M ratios and pH values were examined by ^1H and ^{13}C NMR. Pr(III) cation is paramagnetic and leads to broadenings of the peaks in the NMR spectra, particularly for the nuclei which are close to the binding sites. The assignment of the peaks for free D-gluconic in ^{13}C NMR spectra has been made already [7,23].

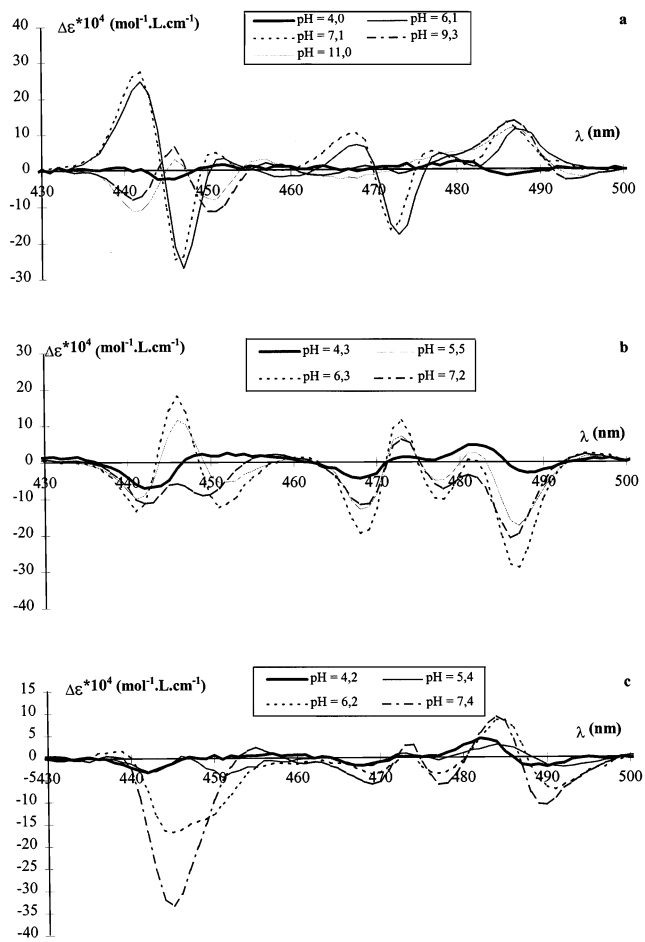

Fig. 5. CD spectra of Pr(III):D-gluconic acid (A), Pr(III):D-galactonic acid (B) and Pr(III):D-gulonic acid (C) solutions for different pH values (L:M = 5:1 and [M] = 0.05 mol l^{-1}).

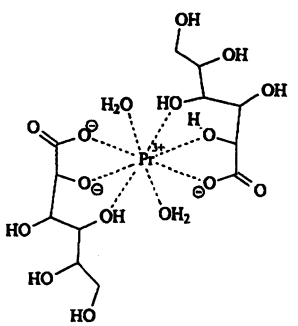
[a] [L] = 0.1 mol l^{-1}; pH 4.0.

At pH 4, where ML_2 is present at 100% for these experimental conditions, ^{13}C NMR spectra as well as ^{1}H NMR spectra show clearly that the peak, the most affected by the presence of Pr(III), corresponds to the carbon of the carboxylate group and the hydrogen on the carbon C_2, in ^{13}C and ^{1}H NMR, respectively. The effect plays as well on the line-width as on the shift of the signals. The further from the carboxylate the carbon or proton nuclei are, the less their shifts and line-width are affected (Table 2). This indicates clearly a coordination by the carboxylate group for the complex ML_2.

At pH 7.5 (complex ML_2H_{-1} after the potentiometric results), the peaks are much broadened, even for large L:M ratios, but very little shifted. Probably the exchange between free and bound ligand molecules is slow relative to the NMR time scale. The signal due to bound molecules is very broad and probably much shifted and cannot be detected. The signals of the free ligand are broadened because the exchange with bound molecules (the signal of which are very broad) occurs at a rate allowing the observation of separate free signals but generating, nevertheless, a broadening of the peaks. The most disturbed signals are, in order: C_1, C_2, C_3 and C_4.



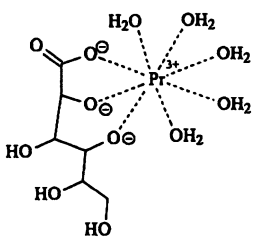
In the domain of existence of the species ML_2H_{-3}, at pH 11.4, the ^{1}H and ^{13}C NMR spectra correspond to that of the free ligand: signals are narrow and not shifted. It was verified that the complex is paramagnetic by measuring the magnetic susceptibility. The signals observed are those of the free ligand only, as proved by the measurements of the integrals of the peaks compared to those of an external reference (contained in a capillary tube). The signals of the bound molecules do not appear in the spectrum: they are probably very broad and shifted. The exchange rate between bound and free ligands is slow relative to the NMR time scale, slower than that observed in the case of the complex ML_2H_{-1}.

4. Discussion

The calculations from potentiometric experiments allowed us to show that six different complexes are formed in aqueous solutions containing the praseodymium(III) cation and D-gluconic acid. In acidic domains, the species ML^{2+} and ML_2^{+} are present. ML_2^{+} is predominant where L:M is higher than 2:1, except for low cation concentrations at low pH values. The site of coordination in these complexes is the carboxylate group as revealed mainly by ^{1}H and ^{13}C NMR (Table 2). It can be noted that the peak of the carbon C_2 is also broadened and shifted, indicating that, the corresponding hydroxyl group gives probably rise to an interaction with the cation. This interaction is weak since no CD effect is observed. The formation constant of the complex PrL^{2+} ($\log \beta_{110} = 2.78$) is higher than that found for the complex AlL^{2+} ($\log \beta_{110} = 1.98$) [16]. This observation could confirm the participation of the hydroxyl group of the carbon C_2 to the coordination in the case of Pr(III) since, if it is considered that the interaction between the carboxylate group and the trivalent cation is essentially electrostatic, the formation constant of the species AlL^{2+} should be higher than that of PrL^{2+}.

Around pH ~ 6–8 appear the complexes MLH_{-1} and ML_2H_{-1}. For high L:M ratios, ML_2H_{-1} is pre-

dominant. The ionization constants of ML and ML_2 are very close together (6.12 and 6.24, respectively) indicating that the same process of deprotonation occurs in both cases. The loss of a proton can be due to the deprotonation of a OH group of the ligand or to the ionization of a coordinated water molecule. The pK for the latter process is 8.82 [15] for the aqua-complex $Pr(H_2O)_n^{3+}$ and is probably higher in ML or ML_2 as the result of the weakening of the Pr–OH_2 bond due to the coordination of the negatively charged carboxylate group [14]. It can be said that, in the complexes MLH_{-1} and ML_2H_{-1}, a OH group of D-gluconic acid is deprotonated and bound to the cation. These species give rise to absorption bands in the visible spectrum clearly shifted with respect to those relative to ML or ML_2 complexes. The coordination of an hydroxylate is also proved by the CD experiments. A clear CD effect occurs at pH 6–7; this indicates that the cation is bound to an atom close to a chiral center. ^1H and ^{13}C NMR spectra show that the exchange between free and bound molecules is slow relatively to the NMR time scale and much slower than in the case of the ML and ML_2 complexes, due to a stronger complexation. NMR seems to indicate that the coordination sites of D-gluconic acid are the carboxylate and the hydroxylate on carbon 2, forming a five-membered ring chelate for LH_{-1}. Nevertheless our dichroic studies on D-gluconic and D-galactonic acids show that the CD spectra for these two ligands are inverted at pH 6. Since D-galactonic and D-gluconic acids differ only by the configuration of the C_4 carbon, it seems that the OH group of the carbon C_4 plays a role in the coordination of these molecules with Pr(III). The following structure for ML_2H_{-1} can be proposed:



It must be noted that the coordination by the C_2–O^- group has been proposed already for the complexes of D-gluconic acid with Co(II), W(VI) and Mo(VI) by Escandar et al. [9] and by Ramos et al. [6].

For ligand to metal ratios L:M lower than 2:1, a precipitate appears systematically at pH 8. For L:M > 2:1, it is possible to go through the pH domain 8–11 without observing precipitation, but, if the pH is adjusted in this domain, a green precipitate appeared after a few minutes. We could not obtain crystals from this solid and a characterization by X-ray analysis was not possible. The ^1H NMR spectrum of an acidic aqueous solution in which the precipitate is dissolved, is identical to the NMR spectrum of a 1:1 cation/ligand solution at the same pH. The ^1H NMR analysis of the supernatant solution, which results from the precipitation of a 1:1 ligand to cation mixture at pH 8–10, indicates that there is no ligand in this phase. These two results and the microanalysis of the precipitate allow confirmation of the 1:1 stoichiometry of the solid complex which can be written MLH_{-2} as proved by the potentiometric study. The neutral character of the species explains its non-solubility in water. The acidity constant of MLH_{-1} corresponding to the reaction:

$$MLH^+_{-1} \rightarrow MLH_{-2} + H^+$$

has a value equal to 6.75. It is higher than the pK_a of ML^{2+} and smaller than the hydrolysis constant of the aqua-complex $Pr(H_2O)_n^{3+}$. This is consistent with the deprotonation of a second OH group of the ligand. As the CD experiments seem to prove that the OH group of the carbon C_4 plays a role in the coordination of D-gluconic acid in the species MLH_{-1} (see above), it can be concluded that it is probably this group which is deprotonated. The following structure for MLH_{-2} can be proposed:

For high pH values, the potentiometric results indicate the formation of the complex $(ML_2H_{-3})^{2-}$. The NMR spectra showed that the exchange between free and bound ligand molecules is slow relative to the NMR time scale as for the complexes MLH_{-1} or ML_2H_{-1}. For ML_2H_{-3}, the simultaneous presence of LH_{-1} and LH_{-2} (D-gluconate with one or two deprotonated alcoholic functions, respectively) can be envisaged. A coordination sphere including two LH_{-1} ligands and a hydroxyl ion OH^- can be also taken into consideration. It is not possible to conclude the structure of this complex from our spectroscopic studies but the latter assumption seems to be the most plausible. Indeed, as a result of the studies on the complexation of other trivalent lanthanide ions by D-gluconic acid (results to be published), it was found that, for some cations, a gel is formed at basic pH. An explanation could be the formation of a polymeric structure of entities ML_2H_{-2} linked together by OH^- bridges.

5. Conclusions

From a combination of pH-potentiometry and various spectroscopic methods we have shown that D-gluconic acid forms with Pr(III) six different complexes in aqueous solutions. At low pH, D-gluconic acid binds with the carboxylate group in the species ML and ML_2. At higher pH values, deprotonated OH groups participate to the coordination, that in α to the carboxylate group and, probably, for MLH_{-2} that in γ-position to the carboxylate group too. At $pH > 11$, the species ML_2H_{-3} is predominant and there is a strong presumption that a polymeric structure is formed where entities ML_2H_{-2} would be bound together by ions OH^-.

The existence of the complex MLH_{-2} at neutral pH values makes possible the extraction of this species in an organic phase (since this species is neutral), but the ligand must be more hydrophobic. In this field, we reported the preparation of hydrophobic derivatives of tartaric acid [21]: HOOC–CHOH–CHOH–CONHR where R is a long alkyl chain, to be used in the liquid–liquid extraction of lanthanide(III) ions (these compounds have the same complexing sites as D-gluconic acid).

The study of the complexation of other lanthanide(III) ions with D-gluconic acid is in progress in order to know if selectivity is observed along the series.

Acknowledgements

NMR spectra and a part of the CD spectra were recorded on the apparatus of 'Service Commun de RMN' and 'Service Commun de Biophysicochimie des Interactions Moléculaires' of University Henri Poincaré-Nancy I, respectively. Some of the CD experiments were also performed at the Jozsef Attila University, Department of Inorganic and Analytical Chemistry, Szeged, Hungary. The authors are grateful to Bela Gyurcsik and to Attila Jancso for their assistance and competence. The authors would like to thank Dr D. Champmartin for her help in NMR experiments.

Received 1 February 2000; accepted 3 May 2000

Abstract

A new azido-nickel(II) one-dimensional (1D) compound of $[Ni(phen)(N_3)_2]_n$ (phen = 1,10-phenanthroline) was prepared and characterized by X-ray crystallography and magnetic measurement. Its structure consists of nickel chains in which the nickel(II) ions are alternatively bridged by double end-on and double end-to-end azido bridges. The nickel(II) ions have a distorted octahedral environment, completed by the two nitrogen atoms of the phen ligand. The variable temperature magnetic susceptibility of the title compound has been investigated in the temperature range 4–300 K and revealed alternating antiferromagnetic ($J_{AF} = -4.77$ cm^{-1}) and ferromagnetic ($J_F = +28.08$ cm^{-1}) interactions. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Azido-bridged nickel(II) compounds; Crystal structures; Magnetic properties

1. Introduction

One-dimensional (1D) magnetic chain compounds have been a very active area of magnetic materials and have been widely investigated from both experimental and theoretical viewpoints [1]. The azido group is a versatile bridging ligand which can generate complexes from binuclear [2], tetranuclear [3], cubane [4], 1D [5–7], 2D [8,9] to 3D compounds [10], and specifically for nickel(II) a large number of 1D compounds have been reported [7]. The coordination modes generally observed for the bridging azido groups are end-on with ferromagnetic interaction and end-to-end with antiferromagnetic interaction. The end-to-end nickel–azide system has been extensively studied from synthetic and magnetic points of view and suitable models were proposed to explain and predict the magnitude of the antiferromagnetic coupling as a function of the bond parameters in the bridge region [2,11]. Non-azido chain complexes with alternating ferromagnetic and antiferromagnetic couplings have been reported [12]. To the best of our knowledge, 1D nickel–azide systems with alternating ferromagnetic (through end-on bridges) and antiferromagnetic (through end-to-end bridges) interactions are very scarce. In the present paper, we describe the preparation of single crystal of the 1D compound $[Ni(phen)(N_3)_2]_n$ (phen = 1,10-phenanthroline) and we investigated its magnetic properties as a function of the temperature. The exchange interactions between nickel(II) ions through the double end-on and double end-to-end azido bridges are also analyzed.

2. Experimental

2.1. Materials

1,10-Phenanthroline and nickel(II) nitrate hexahydrate and sodium azide were purchased from commercial sources and used as received.

2.2. Preparation of a single crystal of $[Ni(phen)(N_3)_2]_n$

A single crystal of $[Ni(phen)(N_3)_2]_n$ was grown in aqueous solution by a slow-diffusion method using a

H-double-tube glass vessel. The starting solution was an aqueous solution of $Ni(phen)(NO_3)_2$ (0.01 M) in one arm and an aqueous solution of NaN_3 (0.02 M) in the other one. After 1 month, green crystals separated out of solution. *Anal.* Calc. for $C_{12}H_8N_8Ni$: C, 44.63; H, 2.50; N, 34.70; Ni, 18.71. Found: C, 44.75; H, 2.69; N, 34.96; Ni, 18.84%. The occurrence in the IR spectrum of two strong peaks at 2050 and 2075 cm^{-1}, corresponding to $\nu_{as}(N_3)$ stretching vibrations, suggests the presence of different types of azide ligand.

2.3. Measurements

Elemental analysis for carbon, hydrogen and nitrogen were carried out on a Perkin–Elmer model 240 elemental analyzer. Metal contents were determined by EDTA titration. The IR spectra were recorded on a Shimadzu model 408 IR spectrophotometer using KBr pellets. Variable temperature magnetic susceptibilities were measured on an MPMS-7 SQUID magnetometer.

Diamagnetic corrections were made with Pascal's constants for all constituent atoms, and the magnetic moments were calculated using the equation $\mu_{eff} = 2.828(\chi_M T)^{1/2}$.

2.4. Crystal structure determination and refinement

A single green crystal of the title compound having the approximate dimensions $0.30 \times 0.25 \times 0.20$ mm was put on Bruker Smart 1000 diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å). Data were collected at room temperature to $2\theta_{max}$ of 25.02° index ranges $-8 \le h \le 7$, $-10 \le k \le 11$ and $-12 \le l \le 6$ with a total of 2547 reflections collected including 2132 independent reflections ($R_{int} =$ 0.0153). A summary of the crystallographic data is given in Table 1. The structure was solved with direct methods using the SHELXS-97. Full-matrix least-squares refinement on F^2 was carried out using SHELXL-97. The final agreement factor values are $R_1 = 0.0293$ and $wR_2 = 0.0803$ $(I > 2\sigma)$ where $R_1 = \Sigma(||F_o| - |F_c||)/\Sigma|F_o|$, $wR_2 = (\Sigma w(|F_o|^2 - |F_c|^2)^2/\Sigma w|F_o|^2)^2$, and $w = 1/[\sigma^2(F_o^2) + (0.0602P)^2 + 0.0102P]$ where $P = (F_o^2 + 2F_c^2)/3$. Selected bond distances and angles are given in Table 2.

3. Result and discussion

3.1. Description of the crystal structure

A labeled diagram of $[Ni(phen)(N_3)_2]_n$ is shown in Fig. 1. The crystal structure is made of chains of Ni(II)

ions alternatively linked by double end-on and double end-to-end azido bridges. The 1D nickel(II) chains are interconnected by weak hydrogen bonding contacts involving the azide nitrogens in end-on mode and the C–H groups of the phen molecules. A sketch of the unit cell is shown in Fig. 2.

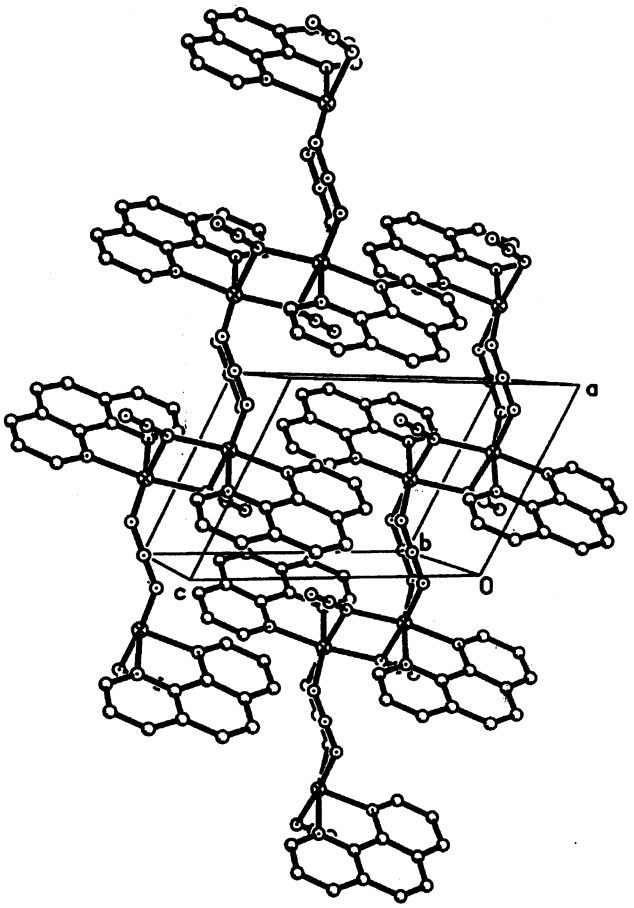

Fig. 2. A sketch of the unit cell of $[Ni(phen)(N_3)_2]_n$.

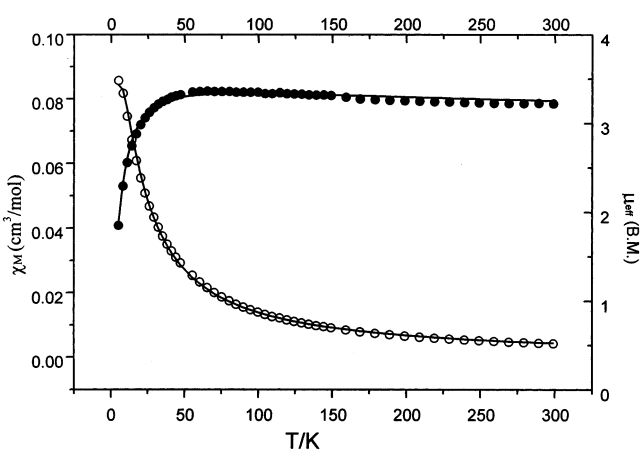

Fig. 3. Molar susceptibility (○) and effective magnetic moment (●) values per Ni(II) atom for $[Ni(phen)(N_3)_2]_n$ as a function of temperature. Solid lines represent the best theoretical fits.

Two nitrogen atoms of the phen ligand complete a distorted NiN_6 octahedral environment. Four nitrogen atoms N(1), N(2), N(3), N(6B), two from azide groups and the other two from phen, form a basal plane and the nickel(II) ion is in this least-squares plane. The values of the two axial Ni–N(azide) bonds are 2.139(2) and 2.163(2) Å for Ni(1)–N(6) and Ni(1)–N(5A), respectively, which are longer than the equatorial ones. The phen ligand is planar and the Ni–N(phen) average bond length is 2.086 Å. The end-on and end-to-end azido bridges are propagated within the chain with a mutual perpendicular arrangement. The end-on bridging azides are quasi-linear (N(6)–N(7)–N(8), 179.0(3)°) and the Ni(1)–N(6)–Ni(1B) angle in end-on mode is 100.53(8)°, which is in good agreement with the results usually obtained for these kind of bridges [13]. The end-to-end azido bridges adopt a chair conformation for the Ni–$(N_3)_2$–Ni unit. The Ni(1)–N(3)–N(4) and Ni(1A)–N(5)–N(4) angles are 116.95(17)° and 128.33(17)°, respectively. The torsion angle (τ) formed by Ni–N–N–N–Ni is 65.8° and the dihedral angle (δ) is 39.0° (as defined as the dihedral angle between the plane defined the six *N*-azido atoms of end-to-end bridges and the N(3)–Ni(1)–N(5A) plane). The intrachain Ni···Ni separations are 3.2541(6) and 5.0933(8) Å in the end-on and end-to-end azido bridges, respectively. The shortest interchain Ni···Ni distance is 7.108(5) Å.

3.2. Magnetic properties

Magnetic susceptibility data of the title compound in the range 4–300 K were collected. The molar susceptibility data is plotted in Fig. 3. In this figure, the μ_{eff} values and the results of the fitting procedure are also included. The effective magnetic moment (μ_{eff}) was found to be 3.22 BM at room temperature which is greater than the value expected for an uncoupled Ni(II) ion. This value slightly increased when the temperature was lowered and attained a shoulder in the temperature range 75–20 K. It reached a maximum of 3.36 BM at 65.20 K, then it decreased with decreasing temperature.

This compound should exhibit alternating ferromagnetic and antiferromagnetic interactions, since end-on azido bridges with a bridging angle (100.53(8)°) as observed here are able to mediate a ferromagnetic interaction between the Ni(II) magnetic centers, and the end-to-end azido bridges with an Ni–N–N bond angle 116.95(17)/128.33(17)° lead to antiferromagnetic coupling [2]. Consequently, the magnetic behavior of the title compound must be explained by assuming a positive J_F for end-on bridges and a negative J_{AF} for end-to-end bridges. The magnetic data were analyzed through the alternating ferromagnetic and antiferromagnetic Heisenberg chain model using the Hamiltonian

$$\hat{H} = -\sum_{i=1}^{N-1} (J_{AF}\hat{S}_{2i}\hat{S}_{2i+1} - J_F\hat{S}_{2i}\hat{S}_{2i-1})$$

where N is the number of spin pairs. J_{AF} and J_F are the nearest neighbor antiferro- and ferromagnetic exchange interactions. Escuer et al. [13] developed an expression for the $N =$ infinite extrapolation with $S = 1$ spins. We used this expression to fit the experimental data. However, at temperatures below ca. 10 K, the calculated molar susceptibility values are less than the experimental values. Taking into account interchain interaction, we modified the molar magnetic susceptibility by employing the equation

$$\chi_M = \chi_{chain}/[1 - \chi_{chain}(2zJ'/Ng^2\beta^2)]$$

where J' is the interchain coupling constant and $z = 2$, the number of nearest Ni(II) neighbors. Other symbols have the usual meanings. The fitting result is perfect. The best-fitting parameters are: $J_{AF} = -4.77$ cm^{-1}, $J_F = +28.08$ cm^{-1}, $\alpha = 5.88$, $g = 2.12$, $zJ' = -0.21$ cm^{-1} and $R = 2.03 \times 10^{-5}$ (R is an agreement factor defined as $R = \Sigma[(\chi_M)_{obs} - (\chi_M)_{calc}]^2/\Sigma[(\chi_M)_{obs}]^2$ and the alternating parameter α defined as $J_F/|J_{AF}|$). The best fitting J_F is almost consistent with the J_F value obtained in a similar compound [14], which was not determined accurately due to poor fitting results below 50 K. The fitting result is also agreement with the calculations performed by Ruiz et al. [15] by means of density functional methods, which predict a maximum ferromagnetic coupling around the bond angle Ni–N–Ni = 104° (end-on bridges) and a narrow range of this bond parameter, in which a minor J_F value is expected. The antiferromagnetic superexchange J_{AF} through double end-to-end azido bridges has been modeled as a function of the dihedral angle δ and J_{AF} should decrease with increasing dihedral δ [7]. In the current case, δ is 39.0° and J_{AF} value is -4.77 cm^{-1}, which is almost in agreement with the regulation.

4. Supplementary data

POLYHEDRON

Synthesis, crystal structure and reactivity of the dihydroborate $[Li(Et_2O)][B(C_6F_5)_2(H)_2]$

Richard E. Douthwaite *

Inorganic Chemistry Laboratory, South Parks Road, Oxford, OXI 3QR, UK

Received 21 February 2000; accepted 10 May 2000

Abstract

The new dihydroborate $[Li(Et_2O)][B(C_6F_5)_2(H)_2]$ (**1**) has been prepared and characterised by single-crystal X-ray diffraction. In the solid state **1** exhibits a one-dimensional chain structure that is a result of intermolecular Li–F interactions. Reaction between **1** and one equivalent of Cp_2TiCl or 0.5 equivalents of Cp_2TiCl_2 gives the violet compound $Cp_2Ti\{(\mu\text{-}H)_2B(C_6F_5)_2\}$ (**2**), which has also been characterised by single-crystal X-ray diffraction. Addition of two equivalents of PMe_3 to **2** does not result in elimination of a borane:phosphine adduct, but yields the ionic compound $[Cp_2Ti(PMe_3)_2][H_2B(C_6F_5)_2]$ (**3**). © 2000 Elsevier Science Ltd. Keywords: Hydroborates; Lithium; Titanium(IV); Bonding; Crystal structures

1. Introduction

Tetrahydroborate $[BH_4]^-$ and its derivatives are used extensively as reducing agents in organic chemistry [1]. In addition d- and f-block metal complexes of BH_4^- have a rich chemistry and have been investigated as pre-catalysts for olefin polymerisation, hydrogenation and as precursors for transition metal hydrides and borides [2]. Reported herein is the synthesis, characterisation and some reactivity of the dihydroborate $[BH_2(C_6F_5)_2]^-$, a compound related to the C_6F_5 substituted boranes $B(C_6F_5)_3$ and $B(C_6F_5)_2H$, which have been investigated as co-catalysts for Zeigler–Natta polymerisation [3].

2. Results and discussion

Reaction at 25°C between $B(C_6F_5)_2Cl$ and excess LH in Et_2O gave $[(Et_2O)Li][(\mu\text{-}H)_2B(C_6F_5)_2]$ (**1**) in 90% yield. Compound **1** decomposes slowly in air and is very soluble in ethers and has good solubility in aromatic solvents such as benzene. The $^{11}B\{^1H\}$ NMR spectrum of **1** shows a single resonance at $\delta = -29.9$, indicative of borate species and the ^1H coupled spectrum a triplet ($J = 81$ Hz) ascribed to two protons directly bonded to a boron atom. In addition, elemental analysis and integration of the ^1H NMR spectrum of several independently prepared samples of **1** showed a constant ratio of 1:1 between Et_2O and $[(H)_2B(C_6F_5)_2]^-$. IR spectroscopy of **1** shows two absorptions at 2318 and 2380 cm^{-1} attributed to B–H vibrations. This was determined from comparison with the IR spectrum (H/D 1.37) of the deuterated isotopomer $[(Et_2O)Li][(\mu\text{-}D)_2B(C_6F_5)_2]$ (D_2-**1**) prepared from $B(C_6F_5)_2Cl$ and excess LiD. Attempts to synthesize the mixed isotopomer $[(Et_2O)Li][(\mu\text{-}D)(\mu\text{-}H)B(C_6F_5)_2]$ from $BH(C_6F_5)_2$ and LiD and also reaction between $B(C_6F_5)_2D$ and LiH gave mixtures of $[(Et_2O)Li][(\mu\text{-}D)_{2-x}(\mu\text{-}H)_xB(C_6F_5)_2]$ (where $x = 0$–2), a result of H/D exchange similar to that reported between BH_4^- and BD_4^- [4].

Determination of the single-crystal X-ray structure of **1** confirmed the proposed formulation (Fig. 1). The asymmetric unit of **1** contains half of the molecule and the remainder of the molecular structure is generated by mirror symmetry. The geometry about each lithium atom is a pseudo-trigonal bipyramid with a B–H hydro-

gen atom and Et_2O oxygen atom occupying apical positions. The equatorial sites are comprised of the remaining B–H hydrogen and two *ortho* fluorine atoms from an adjacent $[(H)_2B(C_6F_5)_2]^-$ moiety (Li1–F1 1.972(7) Å). This intermolecular bonding interaction gives rise to a very unusual one-dimensional chain structure shown in the packing diagram (Fig. 2). A few examples of solid state Li–F interactions have been structurally characterised, including fluorobenzenes coordinated to lithium hexamethyldisilazide dimers, one of which incorporating *para*-difluorobenzene, crystallises in a one-dimensional polymer structure (Li–F 1.999(8) Å) [5].

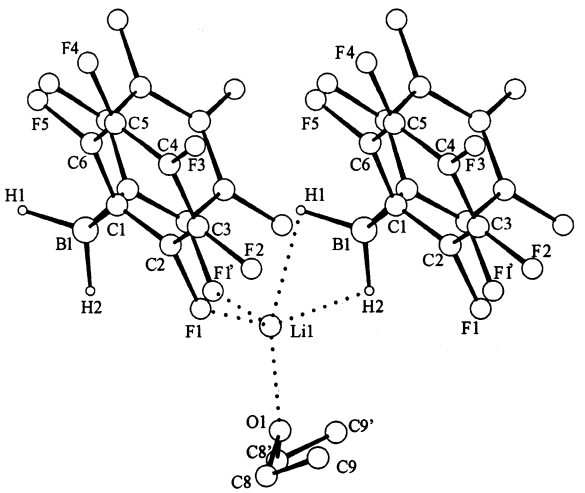

Fig. 1. Structure of **1**. Et_2O hydrogen atoms have been removed for clarity. Selected bond lengths (Å) and angles (°): Li(1)–H(1) 2.139(9), Li(1)–H(2) 1.884(6), Li(1)–F(1) 1.972(7), H(1)–B(1)–H(2) 111.6(5), Li(1)–O(1) 1.879(7), H(1)–Li(1)–H(2) 55.2(5), H(1)–Li(1)–O(1) 159.9(6), F(1)–Li(1)–O(1) 106.3(5), H(1)–Li(1)–F(1) 85.9(4).

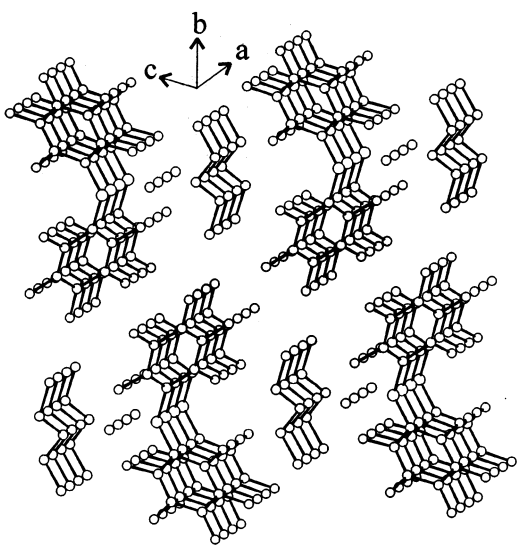

Fig. 2. Packing diagram of **1** illustrating 1-D chain structure along *a* axis. All hydrogen atoms have been removed for clarity.

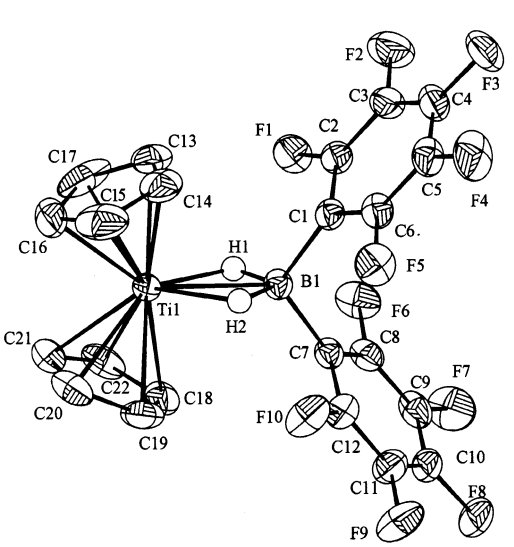

Fig. 3. Molecular structure of **2**. All hydrogen atoms were calculated. Cp hydrogen atoms have been removed for clarity. Selected bond lengths (Å) and angles (°): Ti(1)–B(1) 2.440(3), Ti(1)–H(1) 1.91(1), B(1)–H(1) 1.21(1), Cp_{cent}–Ti(1) 2.03 H(1)–B(1)–H(2) 100.8(7), H(1)–Ti(1)–H(2) 58.1(2), Cp_{cent}–Ti(1)–Cp_{cent} 138.0.

Initial exploration of the chemistry of **1** shows it to be effective as a reagent for the preparation of transition metal complexes of $[(H)_2B(C_6F_5)_2]^-$. An example has been previously described from reaction between Cp_2ZrH_2 and two equivalents of the borane $BH(C_6F_5)_2$ to give $Cp_2Zr\{(\mu\text{-}H)_2B(C_6F_5)_2\}_2$ [6]. However, **1** is a reagent of more general utility for the preparation of this class of compound. For example, reaction between Cp_2TiCl and **1** in C_6H_6 yields the violet Ti(III) complex $Cp_2Ti\{(\mu\text{-}H)_2B(C_6F_5)_2\}$ (**2**). Compound **2** is stable as a solid in air for hours and has good solubility in aromatic and ether solvents. No signals in the ^1H or ^{11}B spectrum of **2** could be observed; however, ^{19}F NMR spectroscopy did yield relatively sharp resonances at δ −158.9 and −166.2, facilitating assessment of product purity. The IR spectrum of **2** displays bands attributable to B–H vibrations at 2073, 2008 and 1367 cm^{-1} assigned from comparison with the deuterium isotopomer $Cp_2Ti\{(\mu\text{-}D)_2B(C_6F_5)_2\}$ ([D_2]-**2**) prepared from [D_2]-**1** and Cp_2TiCl. The IR spectrum of **2** is indicative of bidentate coordination of the dihydroborate [2] and the molecular structure obtained from a single-crystal X-ray diffraction study corroborates this (Fig. 3). The μ-H atoms were calculated; however, it is clear from the disposition of the $B(C_6F_5)_2$ fragment relative to Cp_2Ti that the hydrogen atoms occupy sites in a plane containing Ti(1) and B(1).

Comparison between the IR and structural data of **2** and the known tetrahydroborate $Cp_2Ti\{(\mu\text{-}H)_2BH_2\}$ (Ti–B 2.440(3) Å, IR $\nu = 1936$ cm^{-1}) [7] indicate greater ionic character in the bonding between Cp_2Ti and $[(H)_2B(C_6F_5)_2]$ [8]. Perhaps the clearest evidence of this is reaction between **2** and strong σ-donor ligands

such as PMe_3. Under ambient conditions it has been reported that no reaction occurs between $Cp_2Ti\{(\mu\text{-}H)_2BH_2\}$ and PMe_3 [7]. In contrast, on addition of two equivalents of PMe_3 to a toluene solution of **2**, a blue viscous oil immediately precipitates that can be crystallised from THF/pentane to give a blue microcrystalline solid (**3**). Compound **3** is extremely sensitive to air and is insoluble in non-polar organic solvents, sparingly soluble in diethyl ether and very soluble in THF. Spectroscopic data and elemental analysis are consistent with the formulation $[Cp_2Ti(PMe_3)_2][H_2B(C_6F_5)_2]$. No ^1H NMR resonance was observed for **3** that could be ascribed to the $[Cp_2Ti(PMe_3)_2]^+$ fragment and the ^{31}P NMR spectrum was featureless. The ^1H NMR did however contain a 1:1:1:1 signal at δ 2.40 ($^1J(B, H) = 86.0$ Hz) and the ^{11}B NMR a triplet at δ −26.0. In addition, IR spectroscopy showed B–H stretches (confirmed by reaction between $[D_2]$-**2** and two equivalents of PMe_3) at 2314 and 2361 cm^{-1}. On steric grounds and the similarity between the IR data of compounds **1** and **3** in comparison to **2**, and the observation of NMR signals attributable to $[H_2B(C_6F_5)_2]^-$, an ionic formulation for **3** seems likely. This is a surprising result as reaction between transition metal tetrahydroborates and σ-donors (L) invariably result in formation of borane adducts $L{:}BH_3$. This reaction type has however been observed in an alternative preparation of **2** that gives the adduct $Et_2O{:}B(C_6F_6)H$ as a by-product. Addition of two equivalents of **1** to Cp_2TiCl_2 in benzene gave **2** and $Et_2O{:}B(C_6F_5)_2H$ with concomitant elimination of H_2 (Eq. (1)), illustrating that in this system **1** acts as a reducing agent in a similar manner to $LiBH_4$.

$$2\ (\mathbf{1}) + Cp_2TiCl_2 \rightarrow (\mathbf{2}) + Et_2O{:}B(C_6F_5)_2H + 0.5H_2 + 2LiCl \quad (1)$$

In conclusion, the high yield synthesis of **2** shows that the new dihydroborate **1** is an effective reagent for the simple preparation of transition metal derivatives of $[H_2B(C_6F_5)_2]^-$. It was further observed that unusual reactivity is exhibited by compound **2** in comparison to the $[BH_4]^-$ analogue, presumably a consequence of the electron withdrawing effect of the C_6F_5 groups. The presence of two bulky electron withdrawing C_6F_5 groups will also attenuate the propensity of $[H_2B(C_6F_5)_2]^-$ to act as a reducing agent. Compound **1** and transition metal derivatives of $[H_2B(C_6F_5)_2]^-$ may therefore find use in the selective reduction of organic substrates [1].

3. Experimental

All manipulations were performed under nitrogen in a dry box or using standard Schlenk techniques. All solvents were dried over the appropriate drying agent and distilled under nitrogen. LiH, LiD, PMe_3, and Cp_2TiCl_2 were purchased from Aldrich and used as received. Cp_2TiCl [9] and $(C_6F_5)BCl$ [3] were prepared according to a literature method. ^1H, ^{13}C, ^{11}B and ^{19}F NMR spectra were recorded at 500, 125.7, 160.6 and 470.4 MHz, respectively, at probe temperature on a Varian Unity 500 spectrometer. Proton and carbon spectra were referenced internally to the residual solvent proton and ^{13}C resonance, respectively, relative to tetramethylsilane. Boron spectra were referenced externally to $Et_2O{:}BF_3$ and fluorine externally to $CClF_3$. Infrared spectra were recorded on a Mattson–Polaris FT interferometer. Microanalyses were obtained at the Inorganic Chemistry Laboratory, Oxford.

3.1. $[(Et_2O)Li][(\mu\text{-}H)_2B(C_6F_5)_2]$ (1)

To a solid mixture of $(C_6F_5)_2BCl$ (20 g, 52.6 mmol) and LiH (2 g, 251.8 mmol) was added Et_2O (100 ml) and the white mixture stirred at room temperature (r.t.) for 12 h. The volatiles were removed under reduced pressure and the resulting white solid extracted with Et_2O (2 × 50 ml) to give a colourless solution. Removal of the volatiles and washing with pentane (2 × 20 ml) gave **1** as a white powder (90% yield). Crystals were obtained by crystallisation from benzene. *Anal.* Found: C, 45.00; H, 2.87; B, 2.50; Li, 1.64. Calc. C, 44.90; H, 2.83; B, 2.53; Li, 1.62.%. ^1H NMR (500 MHz, benzene-d_6): $\delta = 2.89$ (q, $^3J(H, H) = 7$ Hz, 4H, OCH_2CH_3), 2.00 (1:1:1:1, $^1J(B, H) = 81.0$ Hz, 2H, BH_2), 0.71 (t, $^1J(H, H) = 7$ Hz, 6H, OCH_2CH_3); ^{11}B NMR (160.6 MHz, benzene-d_6): $\delta = -29.9$ (t, $^1J(B, H) = 81.0$ Hz); ^{19}F NMR (470.4 MHz, benzene-d_6): $\delta = -135.5$ (m, 2F), −160.6 (m, 1F), −164.3 (m, 2F); $^{13}C\{^1H\}$ NMR (125.8 MHz, benzene-d_6): $\delta = 148.48$ (d, $^1J(C, F) = 231.0$ Hz), 139.06 (d, $^1J(C, F) = 246.7$ Hz), 137.5 (d, $^1J(C, F) = 250.5$ Hz), 120.6 (br. s), 66.1, 13.9; IR (KBr pellet): $\nu(BH_2) = 2380$ cm^{-1} (br m), 2314 (br m).

3.2. $Cp_2Ti\{(\mu\text{-}H)_2B(C_6F_5)_2]$ (2): method 1

To solid mixture of $[(Et_2O)Li][(\mu\text{-}H)_2B(C_6F_5)_2]$ (500 mg, 1.17 mmol) and Cp_2TiCl (290 mg, 1.17 mmol) was added benzene (30 ml) and the green mixture stirred at r.t. for 90 min to give a white solid and violet supernatant. The volatiles were removed under reduced pressure and the resulting violet solid was extracted with benzene (2 × 30 ml) or until the washings were colourless. Removal of the volatiles and washing with ice cold Et_2O (2 × 5 ml) gave **2** as a violet microcrystalline solid (82% yield). Crystals were obtained by crystallisation from hot toluene. *Anal.* Found: C, 50.37; H, 2.28; B, 2.04; Ti, 9.03. Calc.: C, 50.33; H, 2.30; B, 2.06; Ti, 9.12%. ^{19}F NMR (470.4 MHz, benzene-d_6): $\delta = -158.9$ (br s, 1F), −166.2 (br s, 2F) (only two resonances could be found); IR (KBr pellet): $\nu(BH_2) = 2075$ cm^{-1} (br m), 2008 (br m), 1373 (s).

3.3. Method 2

At r.t. benzene was added (30 ml) to a solid mixture of $[(Et_2O)Li][(\mu\text{-}H)_2B(C_6F_5)_2]$ (500 mg, 1.17 mmol) and Cp_2TiCl_2 (136 mg, 0.55 mmol). On stirring, the red reaction mixture immediately became green with evolution of a gas. Over a further period of 1 h, gas evolution ceased and a violet supernatant developed with precipitation of a white solid. The volatiles were removed under reduced pressure and the solid washed with pentane (2×10 ml). Final work-up was as described in method 1 (80% yield).

3.4. $[Cp_2Ti(PMe_3)_2][H_2B(C_6F_5)_2]$ (3)

To a violet benzene (20 ml) solution of $Cp_2Ti\{(\mu\text{-}H)_2B(C_6F_5)_2\}$ (200 mg, 0.30 mmol) was added a benzene (10 ml) solution of PMe_3 (46 mg, 0.70 mmol). Immediately the reaction developed a dark blue colour and after 5 min gave an oily blue solid precipitate and colourless supernatant. The volatiles were removed under reduced pressure and the blue powder was washed with pentane (2×10 ml) and crystallised from 3:1 THF–pentane (3 ml) at -80°C to give **3** as a blue crystalline solid (95% yield). *Anal.* Found: C, 50.85; H, 3.30; B 1.55; P, 8.97; Ti, 6.93. Calc.: C, 50.32; H, 3.15, B, 1.62; P, 9.28; Ti, 7.17%. ^{1}H NMR (500 MHz, THF-d_8): $\delta = 2.40$ (1:1:1:1, ^1J(B, H) = 86.0 Hz, BH_2); ^{11}B NMR (160.6 MHz, THF-d_6): $\delta = 26.0$ (t, ^3J(B, H) = 86.0 Hz); IR (KBr pellet): $\nu(BH_2) = 2361$ cm^{-1} (br m), 2314 (br m).

4. Structural studies

Crystals of $[(Et_2O)Li][(\mu\text{-}H)_2B(C_6F_5)_2]$ (**1**) and $Cp_2Ti\{(\mu\text{-}H)_2B(C_6F_5)_2\}$ (**2**) were isolated under dinitrogen. Crystals of **1** were flame sealed in glass capillaries and crystals of **2** were covered with a polyfluoroether and mounted on glass fibres. Data were collected on an Enraf–Nonius DIP2000 image plate diffractometer with graphite monochromated Mo Kα radiation ($\lambda =$ 0.71069 Å). The images were processed with the DENZO and SCALEPACK programs [10]. All solution, refinement and graphical calculations were performed using the CRYSTALS and CAMERON software packages [11,12]. Crystal structures were solved by direct methods using the SIR92 program [13] and were refined by full-matrix least-squares on *F*. All non-hydrogen atoms were refined with anisotropic displacement parameters unless otherwise stated below.

4.1. Crystal data for 1

$C_{16}H_{12}B_1F_{10}Li_1O_1$, $M = 418$, monoclinic, $a =$ 5.0060(4), $b = 19.068(3)$, $c = 9.6780(13)$ Å, $\beta =$ 99.151(8)°, $V = 912.1(2)$ Å^3, $T = 294$ K, space group $P2_1/m$, $Z = 4$, μ(Mo Kα) = 0.16 mm^{-1}, 3512 measured reflections, 1688 independent ($R_{int} = 0.046$), 958 reflections with $I > 3\sigma(I)$, $R(F) = 0.055$, $wR(F) = 0.076$, disorder is present in the ethyl groups of Et_2O. The best results were obtained by refining over two sites the occupancies of each carbon atom adjacent to oxygen. Hydroborate hydrogens were located and refined isotropically. The remaining Et_2O hydrogens were placed in calculated positions and allowed to ride on their corresponding carbon atoms with fixed thermal parameters.

4.2. Crystal data for 2

$C_{22}H_{12}B_1F_{10}Ti_1$, $M = 525.03$, triclinic, $a = 11.6410(9)$, $b = 12.7490(12)$, $c = 15.7680(13)$ Å, $\alpha = 90.754(9)$, $\beta =$ 109.448(11), $\gamma = 110.35(1)$°, $V = 2046.8(8)$ Å^3, $T = 220$ K, space group $P\bar{1}$, $Z = 2$, μ(Mo Kα) = 0.51 mm^{-1}, 10197 measured reflections, 7713 independent ($R_{int} =$ 0.045), 5972 reflections with $I > 3\sigma(I)$, 626 parameters, $R(F) = 0.058$, $wR(F) = 0.062$. Hydroborate hydrogen atoms were placed in calculated positions with fixed thermal parameters and then refined with anisotropic displacement parameters. The remaining Cp hydrogens were placed in calculated positions and allowed to ride on their corresponding carbon atoms with fixed thermal parameters.

5. Supplementary material

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK, on request, quoting the deposition numbers CCDC 137188 (**1**) and 137187 (**2**).

POLYHEDRON

Synthesis and spectral properties of some new cobalt/tungsten chain triphos {$PhP(CH_2CH_2PPh_2)_2$} bridged multimetallic complexes

Paul K. Baker *, Margaret M. Meehan

Department of Chemistry, University of Wales, Bangor, Gwynedd, LL57 2UW, UK

Received 27 March 2000; accepted 15 May 2000

Abstract

Reaction of $[Co_2(CO)_8]$ with two equivalents of L, L′ or L″ {L, L′ or L″ = $[WI_2(CO)\{PhP(CH_2CH_2PPh_2)_2$-*P*,*P*′$\}(\eta^2$-$RC_2R')]$; L, R = R′ = Me; L′, R = R′ = Ph; L″, R = Me, R′ = Ph} in CH_2Cl_2 at room temperature gives the new chain triphos bridged salts, *trans*-$[Co(CO)_3$(L, L′ or L″)$_2][Co(CO)_4]$ (**1**–**3**) in high yield. Refluxing complexes **1**–**3** in toluene for 2 h gives the neutral metal–metal bonded complexes $[Co_2(CO)_6$(L, L′ or L″)$_2]$ (**4**–**6**). All the new multimetallic complexes have been characterised by elemental analysis (C, H and N), IR, ^1H and $^{31}P\{^1H\}$ NMR spectroscopy. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Multimetallic; Cobalt carbonyl complexes; Tungsten(II); Alkyne complexes; Chain triphos-bridged

1. Introduction

Multimetallic organotransition-metal complexes containing bridging phosphine ligands have received considerable attention over the years [1–10]. Although examples throughout the range of transition-metal chemistry have been described, very few examples involving phosphine-bridges between cobalt and tungsten have been reported. A cobalt dppe-bridged example is $[\{Co(CO)_2(\eta^3$-$C_3H_4R)\}_2(\mu$-dppe)] {dppe = bis(diphenylphosphino)ethane}, which has been prepared by reacting $[Co(CO)_3(\eta^3$-$C_3H_4R)]$ (R = H, Me) with dppe [11]. Hitherto, until our work described herein, no examples containing chain triphos {$PhP(CH_2CH_2PPh_2)_2$} bridging cobalt and tungsten centres have been reported.

In 1996 [12], we described the preparation and crystallographic characterisation (R = R′ = Me; R = Me, R′ = Ph), of the bidentately attached chain triphos complexes, $[WI_2(CO)\{PhP(CH_2CH_2PPh_2)_2$-*P*,*P*′$\}(\eta^2$-$RC_2R')]$ which have the potential to act as monodentate phosphine ligands to a further metal centre. In this paper we describe the reactions of $[WI_2(CO)$-$\{PhP(CH_2CH_2PPh_2)_2$-*P*,*P*′$\}(\eta^2$-$RC_2R')]$ as monodentate phosphines with $[Co_2(CO)_8]$ to give a range of new multimetallic complexes.

2. Experimental

All reactions described in this paper were carried out using standard vacuum/Schlenk line techniques. The starting materials, $[WI_2(CO)\{PhP(CH_2CH_2PPh_2)_2$-*P*,*P*′$\}(\eta^2$-$RC_2R')]$ (R = R′ = Me or Ph; R = Me, R′ = Ph) were prepared by the literature method [12]. All chemicals used were purchased from commercial sources, and CH_2Cl_2 was dried over calcium hydride and distilled before use.

Elemental analyses (C, H and N) were recorded on a Carlo Erba Elemental analyser MOD 1108 (helium used as a carrier gas). IR spectra were recorded on a Perkin–Elmer 1600 FT-IR spectrophotometer. ^1H and $^{31}P\{^1H\}$ NMR spectra were recorded on a Bruker AC 250 MHz NMR spectrometer. Molecular weights of selected complexes were determined using Rast's method [13], using camphor as the standard. Physical and analytical data are given in Table 1.

2.1. Preparation of *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$] (1)

To a stirred solution of [Co$_2$(CO)$_8$] (0.04 g, 0.12 mmol) dissolved in CH_2Cl_2 (30 cm^3) in a Schlenk tube at room temperature, [WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-MeC$_2$Me)] (L) (0.24 g, 0.23 mmol) was added, and the reaction mixture was stirred for 24 h. The resulting green solution was filtered through celite, and the solvent was removed in vacuo giving a green crystalline powder of *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$] (**1**). Complex **1** was recrystallised from CH_2Cl_2–Et_2O. Yield of pure product = 0.27 g, 97%.

Similar reactions of [Co$_2$(CO)$_8$] with two equivalents of [WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-RC$_2$R′)] {L′ = R and R′ = Ph; L″ = R = Me, R′ = Ph} gives the complexes *trans*-[Co(CO)$_3$(L′ or L″)$_2$][Co(CO)$_4$] (**2**) and (**3**).

2.2. Refluxing *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$] (1) in toluene to give [Co$_2$(CO)$_6$L$_2$] (4)

A toluene solution of *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$] (**1**) (0.17 g, 0.07 mmol) was refluxed for 90 min under an N_2 atmosphere to give, after cooling and filtering, the green complex [Co$_2$(CO)$_6$L$_2$] (**4**). Complex **4** was recrystallised from CH_2Cl_2–Et_2O, to give a yield of pure product = 0.12 g, 74%.

Similar reflux reactions of *trans*-[Co(CO)$_3$(L′ or L″)$_2$][Co(CO)$_4$] in toluene for 2 and 7 h, respectively gave the neutral complexes [Co$_2$(CO)$_6$(L′)$_2$] (**5**) and [Co$_2$(CO)$_6$(L″)$_2$] (**6**).

3. Results and discussion

The tungsten phosphine complex, [WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-RC$_2$R′)] [12], are prepared by treating the bis(alkyne) complexes [WI$_2$(CO)(NCMe)(η^2-RC$_2$R′)$_2$] (R = R′ = Me, Ph; R = Me, R′ = Ph) [14] with one equivalent of chain triphos {PhP(CH$_2$CH$_2$PPh$_2$)$_2$}. Previous studies [15–21], have shown that reaction of [Co$_2$(CO)$_8$] with monodentate phosphines (L) generally gives *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$], which can be converted to the Co–Co bonded complexes [Co$_2$(CO)$_6$L$_2$] by refluxing in benzene [22–25]. Equimolar quantities of [Co$_2$(CO)$_8$] and L [L = WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-MeC$_2$Me)] react in CH_2Cl_2 for 2 h to give, as identified by IR spectroscopy, a mixture of products, namely *trans*-[Co(CO)$_3$L$_2$][Co(CO)$_4$], [Co$_2$(CO)$_7$L] and a third product, possibly [Co$_2$(CO)$_6$L$_2$] {ν(CO) = 1958(br) and 1974(br) cm^{-1}}. Similar IR spectra were obtained from the reactions of equimolar quantities of [Co$_2$(CO)$_8$] and L′ or L″ [L′ = WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-PhC$_2$Ph); L″ = WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-MeC$_2$Ph)]. In view of these observations, we decided to investigate the reactions of [Co$_2$(CO)$_8$] with two equivalents of L, L′ and L″.

Reactions of [Co$_2$(CO)$_8$] with two equivalents of L, L′ or L″ in CH_2Cl_2 at room temperature gave the new salts, *trans*-[Co(CO)$_3$(L, L′ or L″)$_2$][Co(CO)$_4$] (**1**–**3**) in very good yield. Complexes **1**–**3** have been characterised fully by elemental analysis (C, H and N), ^{1}H and ^{31}P{^{1}H} NMR spectroscopy. Molecular weight studies by Rast's method [13] confirm the trimetallic ionic nature of these complexes. Complexes **1**–**3** are soluble in polar solvents such as $CHCl_3$ and CH_2Cl_2, but as they are salts they are insoluble in Et_2O and hydrocarbon solvents. They are very air-sensitive in solution, but can be kept in the solid state if stored under nitrogen in the dark.

The infrared spectrum of complex **1** (L, R = R′ = Me), in $CHCl_3$ shows bands at 1888 cm^{-1} (vs) due to the tetrahedral anion, [Co(CO)$_4$]$^-$, a very strong band at 1958 cm^{-1} due to L {L = [WI$_2$(CO){PhP(CH$_2$CH$_2$PPh$_2$)$_2$-*P*,*P*′}(η^2-MeC$_2$Me)] has ν(CO)($CHCl_3$) = 1957 cm^{-1}}, and a strong band at 1999 cm^{-1} due to the cation, *trans*-[Co(CO)$_3$L$_2$]$^+$ {cf. *trans*-[Co(CO)$_3$(P^{i}Pr$_3$)$_2$]$^+$ has ν(CO)($CHCl_3$) = 1990 cm^{-1}} [26]. The ^{31}P{^{1}H} NMR spectra of **1**–**3** generally show six resonances. For example, the but-2-yne complex **1**, has resonances at δ = 22.7 and 20.2 ppm due to the central phosphorus atom, and two sets at δ = 31.4 due to the two different diastereoisomers for the *trans*-phosphines at-

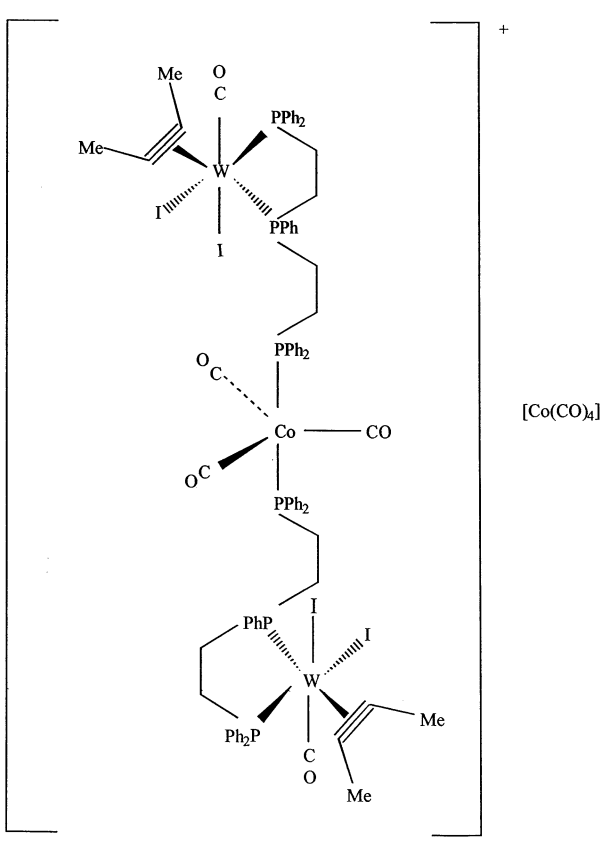

Fig. 1. Proposed structure for the complex *trans*-[Co(CO)$_3$L$_2$]-[Co(CO)$_4$] (**1**).

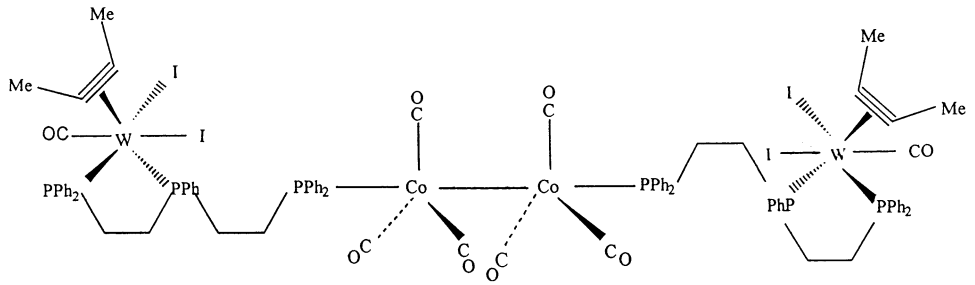

Fig. 2. Proposed structure for the complex $[Co_2(CO)_6L_2]$ (**4**).

tached to the cobalt, and two resonances at $\delta = 3.8$ and -2.2 ppm due to the two diastereoisomers of the end phosphorus atoms on the chain triphos attached to the tungsten. It should be noted that the X-ray crystal structure of the but-2-yne complex $[WI_2(CO)\{PhP(CH_2CH_2PPh_2)_2\text{-}P,P'\}(\eta^2\text{-}MeC_2Me)]$ (L) has two diastereoisomers in the asymmetric unit [12]. One possible isomer of **1** is shown in Fig. 1. We have made a number of unsuccessful attempts to grow suitable single crystals for X-ray analysis of complexes **1**–**3**, by using a wide range of different solvent and temperature conditions.

Refluxing complexes **1**–**3** in toluene, gave the dinuclear Co–Co bonded complexes $[Co_2(CO)_6(L, L' \text{ or } L'')_2]$ (**4**–**6**) in good yield. Complexes **4**–**6** were more soluble than **1**–**3** in chlorinated solvents and slightly soluble in diethyl ether. They are air-sensitive in solution and the solid state, but less sensitive than the salts **1**–**3**. The carbonyl band at ≈ 1888 cm^{-1}, due to the tetrahedral anion $[Co(CO)_4]^-$, has as expected disappeared, and the bands at 1974 and 1958 cm^{-1} in **4** due to the complex $[Co_2(CO)_6L_2]$ are related to the bands for the bis(triphenylphosphine) complex, $[Co_2(CO)_6(PPh_3)_2]$ $\{\nu(CO)(CHCl_3) = 1977, 1957 \text{ cm}^{-1}\}$ [25]. The very strong band at 1958 cm^{-1} also masks the single carbonyl band in L $\{\nu(CO) = 1957 \text{ cm}^{-1}$ [12]$\}$. Manning [25] has carried out a detailed IR analysis of $[Co_2(CO)_6L_2]$ type complexes and shows the 2000 cm^{-1} region of the spectrum is compatible with local D_{3h} or D_{3d} symmetry of the $[Co_2(CO)_6]$ unit [27]. As with complexes **1**–**3**, the $^{31}P\{H\}$ NMR spectra are complex and show that there are several isomers of these complexes in solution. One possible isomer of **4**–**6** is shown in Fig. 2. As for complexes **1**–**3**, no suitable single crystals of **4**–**6** were grown for X-ray analysis despite numerous attempts. This may be due to the high molecular weights of these complexes.

In conclusion, we have described the synthesis and characterisation of the new multimetallic chain triphos-bridged complexes, *trans*-$[Co(CO)_3(L, L' \text{ or } L'')_2][Co(CO)_4]$ and $[Co_2(CO)_6(L, L' \text{ or } L'')_2]$. In the future we will explore the nature of these complexes as potentially mixed hydroformylation (Co centres)/metathesis (W centres) homogeneous catalysts.

Received 22 March 2000; accepted 26 April 2000

Abstract

Reactions of $[RuCl_2(Me_2SO)_4]$ with silver carboxylates, $[Ag(O_2CR)]$ (R = Me, CF_3) in cold dichloromethane afford the title compounds, $[Ru(O_2CR)_2(H_2O)(Me_2SO)_3]$ in good yield as pale cream crystals. X-ray crystal structure determinations have been performed on both complexes. In each case the geometry about the ruthenium centre is essentially octahedral with three S-bonded Me_2SO ligands arranged in a fac configuration, two monodentate carboxylate anions and a coordinated H_2O molecule. The carboxylate ligands are H-bonded to the H_2O ligand via their non-coordinated oxygen atoms. The structures are compared with those previously reported for the alcohol dehydrogenation catalyst $[Ru(O_2CCF_3)_2(MeOH)(CO)(PPh_3)_2]$ and a closely related ruthenium carboxylate complex $[Ru(O_2CCF_3)_2(H_2O)(PMe_3)_3]$. © 2000 Elsevier Science Ltd. 1. Introduction

Dialkyl sulfoxides, notably dimethyl sulfoxide (dmso), are important in coordination chemistry as excellent solvents and versatile ambidentate S-, O- or S,O-donor ligands [1,2]. The chemistry of ruthenium sulfoxide complexes is particularly well developed, largely because of their potential in the fields of homogeneous catalysis [3–5] and antitumour activity [6–8], and their utility as intermediates in the synthesis of a wide range of ruthenium coordination compounds [9–11]. However to the best of our knowledge no ruthenium complexes containing sulfoxide and simple carboxylate ligands in the same coordination sphere have been characterised. We became interested in such complexes because of our earlier work on the development of ruthenium carboxylate based alcohol dehydrogenation catalysts $[Ru(O_2CR)_2(H_2O)(CO)(PPh_3)_2]$ [12]. In this paper we report the synthesis and characterisation of two new ruthenium–dmso–carboxylate complexes $[Ru(O_2CR)_2(H_2O)(Me_2SO)_3]$ closely related to our previously reported alcohol dehydrogenation catalysts.

2. Experimental

Ruthenium trichloride trihydrate was obtained from Johnson Matthey, dimethylsulfoxide, silver acetate and silver trifluoroacetate were purchased from Avocado. Dichlorotetrakis(dimethylsulfoxide)ruthenium was prepared using a literature procedure [11].

2.1. Bis(acetato)aquatris(dimethylsulfoxide)ruthenium(II)

Dichlorotetrakis(dimethylsulfoxide)ruthenium (2.00 g, 4.2 mmol) was dissolved in dichloromethane (100 cm^3) contained in a 250 cm^3 conical flask covered with aluminium foil to exclude light. Silver acetate (1.6 g, 9.6 mmol) was added and the mixture stirred for 24 h. Filtration to remove silver salts left an almost colourless solution, which was evaporated to dryness under reduced pressure. Crystallisation of the residue from dichloromethane–light petroleum (b.p. 60–80°C) afforded cream needle crystals (Yield 1.69 g, 87%) *Anal.* Found: C, 25.50; H, 5.35. Calc. for $C_{10}H_{26}O_8RuS_3$: C, 25.45; H 5.55%.

PII: S0277-5387(00)00432-0

2.2. Bis(trifluoroacetato)aquatris(dimethylsulfoxide)-ruthenium(II)

Bis(trifluoroacetato)aquatris(dimethylsulfoxide)ruthenium was similarly prepared using silver trifluoroacetate, with a shorter reaction time (3 h), and obtained as cream micro crystals from dichloromethane–light petroleum (b.p. 60–80°C). Yield 76%: *Anal*. Found: C, 20.85; H, 3.35. Calc. for $C_{10}H_{20}F_6O_8RuS_3$: C, 20.7; H, 3.5%.

2.3. Crystallography

X–ray crystal structures have been determined for $[Ru(O_2CMe)_2(H_2O)(Me_2SO)_3]$ (**1**) and $[Ru(O_2CCF_3)_2(H_2O)(Me_2SO)_3]$ (**2**). In both cases crystals suitable for X-ray diffraction study were grown from dichloromethane–light petroleum solutions. Pale cream needles of (**1**) and pale cream crystals of (**2**) were mounted on thin glass fibres using a fast setting epoxy resin. A total of 180 oscillation frames of 90 s exposure time with 1° in θ were recorded using a Nonius Kappa CCD diffractometer, with a detector to crystal distance of 35 mm. The crystals were indexed for the first ten frames using a DENZO package [13] and positional data were refined along with diffractometer constants to give the final unit cell parameters. Integration and scaling of the whole data sets resulted in a total of 6412 data (3281 unique) for **1** and 17 565 data (3733 unique) for **2** which were corrected for Lorentz and polarisation effects. The structures were solved using the direct methods option of SHELXS-86 [14] and developed via alternating least squares cycles and difference Fourier synthesis [SHELXL-97] [15] with the aid of the program RES2INS [16]. All non-hydrogen atoms were modelled anisotopically, while hydrogen atoms were assigned an isotopic parameter 1.2 times (1.5 times for CH_3 groups) that of the parent atom and allowed to ride. Crystal data and structural refinement details for **1** and **2** are given in Table 1.

3. Results and discussion

The new ruthenium(II) carboxylate complexes $[Ru(O_2CR)_2(H_2O)(Me_2SO)_3]$ were prepared by the reaction of $[RuCl_2(Me_2SO)_4]$ with the appropriate silver carboxylate in dichloromethane at room temperature and in the absence of light. Crystallisation from dichloromethane–light petroleum afforded the complexes in good yield as very pale cream coloured, air stable crystals. The complexes are soluble in a range of organic solvents, notably chloroform and dichloromethane, but the solutions show some tendency to darken on standing. The ambient temperature ^{1}H NMR spectrum of the acetate complex **1** displayed a sharp singlet at δ 2.05 attributable to the acetate protons, and three singlets-one at δ 3.30 and a partially resolved pair at ca. δ 3.25-attributable to the protons of the dmso ligands. The 1:3 integration ratio corresponds with the proposed stoichiometry. On cooling the sample to 214 K the signals arising from the dmso ligands separated out into three rather broad but well resolved singlets of equal intensity δ 3.39, 3.35 and 3.30. These are consistent with fac arrangement of three S-bonded dmso ligands. One singlet can be attributed to the methyl protons of the unique dmso ligand *trans* to H_2O, the remaining two singlets arise from the stereochemically non-equivalent methyl groups attached to each of the remaining two chemically and magnetically equivalent dmso ligands. The ambient temperature ^{1}H NMR spectrum of the trifluoroacetate complex (**2**) likewise displayed three partially resolved singlets at ca. δ 3.32, 3.30 and 3.29. The corresponding ^{19}F NMR spectrum consisted of a strong, rather broad singlet at

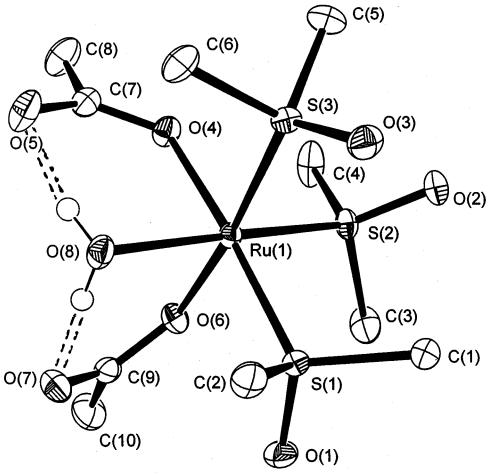

Fig. 1. Molecular structure and atom numbering scheme for $[Ru(O_2CMe)_2(H_2O)(Me_2SO)_3]$ (**1**) (methyl hydrogen atoms omitted for clarity).

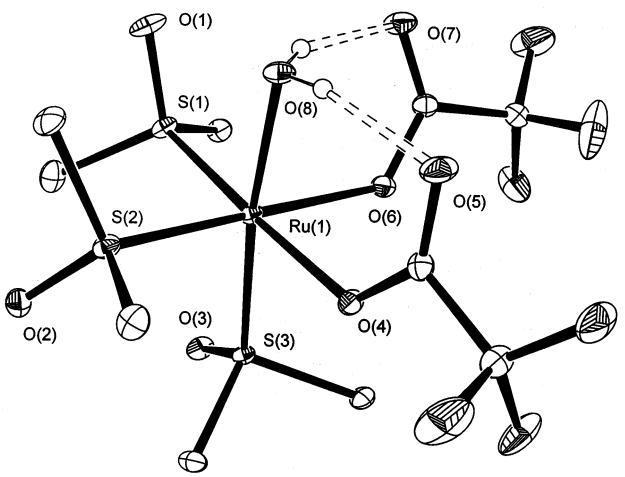

Fig. 2. Molecular structure and atom numbering scheme for $[Ru(O_2CCF_3)_2(H_2O)(Me_2SO)_3]$ (**2**) (methyl hydrogen atoms omitted for clarity).

δ −73.6, and a sharp but much weaker singlet at δ −76.4. We attribute the former to the coordinated trifluoroacetate, and the latter to traces of free trifluoroacetic acid. No signals attributable to the protons of the water ligand were observed, presumably they were shifted by H-bonding effects and broadened by exchange reactions.

Evidence concerning the nature of the complexes was also provided by infrared spectroscopy. The acetato complex (**1**) has values of 1570 and 1338 cm^{-1} for $\upsilon(OCO)_{asym}$ and $\upsilon(OCO)_{sym}$, respectively giving a value of 232 cm^{-1} for $\Delta\upsilon$, consistent with monodentate acetate [17]. Corresponding data for the trifluoroacetato complex (**2**) are 1693, 1450 and 243 cm^{-1}, respectively, again indicating monodentate coordination. The infrared spectra also show absorptions at ca. 1160–1050 cm^{-1} attributable to υ(S=O) for S-bonded dmso. Similar assignments for the parent compound, $[RuCl_2(S\text{–}Me_2SO)_3(O\text{–}Me_2SO)]$ were 1120 and 1090 cm^{-1} [11].

In order to facilitate an investigation of H-bonding interactions between coordinated water and carboxylate ligands, and to make comparisons with related ruthenium carboxylate complexes, notably the dehydrogenation catalysts $[Ru(O_2CCF_3)_2(ROH)(CO)(PPh_3)_2]$ (R = H, alkyl), X-ray crystal structures determinations were performed on **1** and **2**. Molecular structures and atomic labelling schemes for **1** and **2** are shown in Figs. 1 and 2, respectively, selected bond length and bond angle data are presented in Tables 2 and 3. The two complexes display similar overall geometry, in each case

the octahedral ruthenium(II) centre is coordinated to a fac set of three S-bonded dmso ligands, similar to that found in the parent complex $[RuCl_2(S–Me_2SO)_3(O–Me_2SO)]$ [18]. Two monodentate carboxylate ligands and a water molecule complete the coordination sphere. Angles subtended at ruthenium by adjacent pairs of donor atoms range from 83.51 (8)° to 95.61 (2)° for **1** and from 84.52 (10)° to 96.11 (3)° for **2**. Ruthenium–sulfur bond lengths which range from 2.2462 (6) to 2.2735 (7) Å for **1** and from 2.2481 (9) to 2.2607 (9) Å for **2**, are very typical for dmso S-bonded to ruthenium(II) [18]. However, in each case one Ru–S bond, *trans* to carboxylate, differs significantly in length from the other two, *trans* to carboxylate and aqua ligands. If these differences were attributable to *trans* effects, the Ru–S bond *trans* to the aqua ligand would be expected to have the anomalous value. Since this is clearly not the case in either complex it seems likely that intramolecular steric interactions between adjacent ligands, rather than *trans* effects, are responsible for the differing Ru–S bond lengths. In the acetate complex (**1**) where the anomalous Ru–S(3) bond (2.2735 (7) Å) is ca. 0.027 Å longer than the other two, the difference is tentatively attributed to steric interactions involving ligands in the O(4)–O(6)–S(1)–S(3) plane. For the trifluoroacetate complex (**2**) where the anomalous Ru–S(2) bond (2.2481(9) Å) is ca 0.012 Å shorter than the other two the dominant steric interactions appear to involve ligands in the O(4)–O(8)–S(1)–S(3) plane.

The ruthenium oxygen bond lengths for **1** and **2** are significantly shorter than those reported for the closely related complex fac-$[Ru(O_2CCF_3)_2(H_2O)(PMe_3)_3]$. The differences, ca. 0.05 Å for Ru–O_2CR and ca. 0.09 Å for Ru–OH_2, no doubt reflect the greater *trans* effect of PMe_3 relative to S-bound Me_2SO. In each complex the aqua ligand is oriented to permit H-bonding to the non-coordinated oxygen atoms of the two adjacent carboxylate ligands. The O (carboxylate)···O (aqua) distances are 2.579 (3) and 2.631 (3) Å for **1** and 2.654 (4) and 2.690 (4) Å for **2**. Corresponding O (carboxylate)···H (aqua) distances are 1.78 (4) and 1.89 (4) Å for **1** and 1.91 (7) and 2.04 (6) Å for **2**. These values are similar to those previously reported for fac-$[Ru(O_2CCF_3)_2(H_2O)(PMe_3)_3]$ [19] which displays an analogous pattern of H-bonding interactions.

The ability of water to complete successfully with the non-coordinated oxygen atoms of the carboxylate ligands for coordination sites in these complexes is no doubt largely due to the strong RCO_2^-–H_2O H-bonding interactions. A similar stereochemical arrangement of H-bonded carboxylate and aqua or alcohol ligands also prevails in the alcohol dehydrogenation catalysts $[Ru(O_2CCF_3)_2(ROH)(CO)(PPh_3)_2]$ (R = H, alkyl), and is thought to play a key role in the initial step of the catalytic cycle, namely transfer of oxygen bound hydrogen from the alcohol to a carboxylate ligand [12].

4. Supplementary data

Supplementary data for the structural analyses has been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 141469 and 141468 for compounds **1** and **2.** Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

Dimeric and polymeric square-pyramidal copper(II) complexes containing equatorial–apical chloride or acetate bridges

Nimma Rajaiah Sangeetha, Samudranil Pal *

School of Chemistry, University of Hyderabad, Hyderabad 500 046, India

Abstract

Syntheses, crystal structures and physical properties of four new copper(II) complexes of deprotonated aroylhydrazones of 2-pyridine-carboxaldehyde are reported. Two of the complexes contain chloride as a coligand and the other two contain acetate as a coligand. In each complex, the planar tridentate monoanionic ligand binds the metal ion via the pyridine-N, the imine-N and the amide-O atoms. The fourth site is satisfied by the chloride or the acetate-O to form a square-plane. In the solid state, both complexes containing the acetate as the coligand exist as centrosymmetric dimeric species with the metal ion in a distorted square-pyramidal coordination sphere and the acetate group acting as a monoatomic equatorial–apical bridge. One of the complexes containing chloride is a similar centrosymmetric dichloro-bridged dinuclear species. However, the other one exists as a polymeric chain species via equatorial–apical chloride bridges. The electronic spectra of the complexes in methanol solutions display a ligand-field band in the visible region (687–713 nm). The complexes are redox active and, in each case, two reduction responses are observed in the potential range -0.06 to -0.29 and -0.60 to -0.70 V (vs. Ag/AgCl) in methanol solutions. Cryomagnetic studies revealed that no significant spin–spin interaction is operative between the metal ions in any of these four complexes. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Copper(II) complexes; Dinuclear and polynuclear; Crystal structures; Equatorial–apical bridge; Paramagnetic

1. Introduction

Dinuclear copper complexes are of interest mainly due to their structural, magnetic, catalytic and electron transfer properties [1–4]. Such complexes are also important as models for copper proteins containing dimetallic active sites [5–9]. Tridentate Schiff-bases are very efficient as binucleating ligands for metal ions which prefer square-planar based geometry. Aroylhydrazones of 2-pyridine-carboxaldehyde (HL **I**, H represents the dissociable amide proton) can coordinate a given metal ion via the pyridine-N, the imine-N and the amide-O centres. In addition, the deprotonated monobasic hydrazones can also form amide-O bridged dinuclear copper complexes. We have been interested in such monomeric and dimeric species with a specific aim of studying the effect of amide protonation state on the coordination geometry, redox and interaction between the two metal ions [10–14]. During our recent attempts to prepare such species, we have isolated four new copper(II) complexes. Two of them have chloride and the other two have acetate as the coligand. In solid state, one of the chloride containing complexes exists as a chain-like polymer formed via equatorial–apical single chloride bridges. On the other hand, rest of the complexes are dimers formed through equatorial–apical chloro- or rare monoatomic acetato-bridges. Herein, we report the syntheses, X-ray structures, spectroscopic, electrochemical and magnetic properties of these complexes.

Hpabh (R = H)
Hpamh (R = OMe)

2. Experimental

The hydrazones, Hpabh and Hpamh were prepared in ~90% yields by condensing equimolar quantities of 2-pyridine-carboxaldehyde and the corresponding aroylhydrazine in methanol. All other solvents and chemicals used were of analytical grade available commercially.

2.1. Preparation of $[Cu_2(\mu\text{-}Cl)_2(pabh)_2]$ (1)

A methanol solution (5 cm^3) of $CuCl_2 \cdot 2H_2O$ (170 mg, 1.0 mmol) was added to a solution (15 cm^3) of Hpabh (225 mg, 1.0 mmol) and KOH (56 mg, 1.0 mmol) in methanol. The mixture was stirred at room temperature in air for 30 min. The green solid which separated was collected by filtration, washed with water and dried in vacuum over anhydrous $CaCl_2$. Yield 220 mg (68%). *Anal.* Found: C, 48.0; H, 3.0; N, 12.8. Calc. for $C_{13}H_{10}N_3OCuCl$: C, 48.31; H, 3.12; N, 12.99%. Selected IR bands (cm^{-1}): 1601s, 1561w,1487s, 1462s, 1425m, 1375s, 1294m, 1215w, 1148s, 1082s, 920m, 775m, 714s, 417w.

2.2. Preparation of $[Cu(pamh)Cl]_n$ (2)

This was synthesised by the procedure described for **1** from Hpamh, KOH and $CuCl_2 \cdot 2H_2O$ in 70% yield. *Anal.* Found: C, 47.4; H, 3.3; N, 11.8. Calc. for $C_{14}H_{12}N_3O_2CuCl$: C, 47.60; H, 3.42; N, 11.89%. Selected IR bands (cm^{-1}): 1605s, 1557w, 1532w, 1508m, 1483m, 1447m, 1370s, 1252s, 1167s, 1076m, 1020m, 912w, 847m, 762m, 675w, 623m, 505w.

2.3. Preparation of $[Cu_2(\mu\text{-}O_2CCH_3)_2(pabh)_2]$ (3)

Hpabh (225 mg, 1.0 mmol) was added to a methanol solution (15 cm^3) of $Cu(O_2CCH_3)_2 \cdot H_2O$ (200 mg, 1.0 mmol) and the mixture was boiled under reflux for 1 h. The reaction mixture was then cooled to room temperature. The complex, which separated as a dark green crystalline solid, was collected by filtration, washed with ice-cold methanol and dried under vacuum.. Yield 230 mg (66%). *Anal.* Found: C, 51.8; H, 3.8; N, 12.0. Calc. for $C_{15}H_{13}N_3O_3Cu$: C, 51.94; H, 3.78; N, 12.11%. Selected IR bands (cm^{-1}): 1626s, 1606s, 1557w, 1489s, 1464s, 1425m, 1366s, 1213w, 1145s, 1082s, 920s, 800w, 768s, 716s, 681s, 575w, 521m, 463m, 415m.

2.4. Preparation of $[Cu_2(\mu\text{-}O_2CCH_3)_2(pamh)_2]$ (4)

This complex was prepared by the procedure described for **3** from Hpamh and $Cu(O_2CCH_3)_2 \cdot H_2O$ in 65% yield. *Anal.* Found: C, 50.8; H, 4.0; N, 11.1. Calc. for $C_{16}H_{15}N_3O_4Cu$: C, 50.99; H, 4.01; N, 11.15%. Selected IR bands (cm^{-1}): 1625s, 1604s, 1556w, 1512m, 1483m, 1451s, 1362s, 1254s, 1167s, 1080s, 920s, 843m, 764s, 679s, 621m, 509m, 417m.

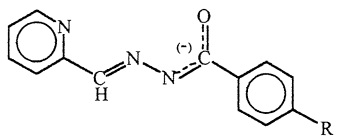
2.5. Physical measurements

A Perkin–Elmer model 240C elemental analyser was used to obtain microanalytical (C, H, N) data. Infrared spectra were collected on a JASCO-5300 FT IR spectrophotometer using KBr pellets. Electronic spectra were recorded on a JASCO-7800 UV–Vis spectrophotometer. A JEOL FE-3X spectrometer was used to obtain the ESR spectra. The spectra were calibrated with the help of DPPH. A Cypress model CS-1090/CS-1087 electroanalytical system was used for cyclic voltammetric experiments with methanol solutions of the complexes containing tetrabutylammonium perchlorate as supporting electrolyte. The three electrode measurements were carried out at 298 K under a dinitrogen atmosphere with platinum disk working electrode, a platinum wire auxiliary electrode and a Ag/AgCl reference electrode. The potentials reported in this work are uncorrected for junction contributions. The variable temperature (17–300 K) magnetic susceptibility measurements were performed using the Faraday technique with a set-up comprising a George Associates Lewis coil force magnetometer, a CAHN microbalance and an Air Products cryostat. $Hg[Co(NCS)_4]$ was used as the standard. Diamagnetic corrections, calculated from Pascal's constants [15], were used to obtain the molar paramagnetic susceptibilities.

2.6. Crystallographic studies

Single crystals were obtained by slow evaporation of methanol solutions of the complexes. Complex **1** crystallises as a tetrahydrate. In each case, the data were collected on an Enraf–Nonius Mach-3 single crystal diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by ω-scan method at 293 K. Unit cell parameters were determined by the least-squares fit of 25 reflections having 2θ values in the range 18–30°. Stability of the crystal was monitored by measuring the intensities of three check reflections after every 1.5 h during the data collection. None of the crystals displays any decay during data collection. The data were corrected for Lorentz-polarisation effects. No absorption correction was applied. The structures were solved by direct methods and refined by full-matrix least-squares on F^2 and Fourier techniques. Due to insufficient data, only Cu, N and O atoms were refined anisotropically for **3**. For the other three complexes, all the non-hydrogen atoms were refined anisotropically. Hydrogen atoms were added at calculated positions by using riding model for structure factor calculation, but not refined. Calculations were done using the programs of XTAL software [16] for data reduction and SHELX-97

programs [17] for structure solution and refinement. ORTEX6a package [18] was used for molecular graphics. Significant crystal data for all the complexes are listed in Table 1.



3. Results and discussion

3.1. Synthesis

The complexes **1** and **2**, of empirical formula CuLCl (L = pabh$^-$ for **1**; L = pamh$^-$ for **2**), were synthesised in good yields by reacting one equivalent each of HL, $CuCl_2{\cdot}2H_2O$ and KOH in methanol. Other two complexes, **3** and **4**, containing acetate as the coligand were obtained as $CuL(O_2CCH_3)$ (L = pabh$^-$ for **3**; L = pamh$^-$ for **4**) in comparable yields from reaction of equimolar quantities of $Cu(O_2CCH_3)_2{\cdot}H_2O$ and HL in methanol. While for the chloro-complexes (**1** and **2**) KOH was required to deprotonate the amide functionality, in the latter cases (**3** and **4**), the acetate of the metal salt appears to be sufficient for the deprotonation of the amide functionality. Elemental analysis data for the complexes are consistent with the empirical formulae mentioned above.

3.2. Spectroscopic properties

Infrared spectrum of each of the two complexes containing chloride as coligand displays a strong peak with a shoulder near 1603 cm^{-1}. The origin of a peak in this region might involve the stretching due to the HC=N–N---C(---O)– moiety of the deprotonated ligands (**II**) [19–21]. In addition to the same peak at $\sim$1605 cm^{-1}, the spectra of the complexes containing acetate show a peak near 1625 cm^{-1} possibly due to the ν_{as} stretch of the unidentate acetate group [22]. All the complexes display a strong peak in the range 1362–1375 cm^{-1}. However, this peak is significantly stronger for acetate coordinated complexes compared to the peak observed for chloride containing complexes. This difference is most likely due to the ν_s stretch of the acetate in this region [22].

II

The electronic spectra of the complexes display a weak absorption in the range 687–713 nm (Table 2). Absorptions in this region observed for other square-planar or square-pyramidal copper(II) complexes of Schiff bases and similar ligands have been assigned to d–d transition [12,13,23,24]. In addition to this weak band, the complexes of pabh$^-$ display two strong absorptions and the complexes of pamh$^-$ exhibit three intense bands in the range 385–252 nm. These higher energy absorptions are most probably due to the ligand-to-metal charge transfer and intraligand transitions [24].

The room temperature powder ESR spectral profiles of the complexes investigated in this study are very similar. For all the complexes $g_{\|} > g_{\perp}$ (Table 2) which is typical of square-planar or square-pyramidal copper(II) complexes [25,26]. Thus the unpaired electron resides in the $d_{x^2-y^2}$ orbital.

3.3. Redox potentials

In methanol solutions cyclic voltammograms of the complexes display two reduction responses (Table 2). The first response is observed in the potential range −0.06 to −0.29 V and the second one appears in the range −0.60 to −0.70 V (vs. Ag/AgCl). In each case, assuming a monomeric species in solution, the current height of the first reduction is comparable with that of the known one-electron redox processes under identical conditions [27]. However, the current height of the second reduction is two to three times larger than that of the first reduction. The potential of the first response for chloride containing complexes is higher than that observed for the complexes containing acetate. There is no such trend in the potentials for the second reduction (Table 2). It has been observed earlier that with the increase of the basicity of the coordinating atom, the metal–ligand σ-bond strength increases and as a result the metal centred reduction potential decreases [28]. The basicity of the acetate-O is much higher than that of chloride. Thus the first reduction response most probably involves the metal centre and the second reduction is associated with the coordinated ligand.

3.4. Description of structures

The molecular structures of **1**, **2**, **3** and **4** are illustrated in Figs. 1–4, respectively. The corresponding selected bond parameters for the complexes are listed in Tables 3–6. The asymmetric unit of complex **1** includes one Cu(pabh)Cl fragment and two water molecules. The water molecules are hydrogen bonded to the oxygen (O1) and the nitrogen (N3) centres (Fig. 1) of the deprotonated amide functionality. The O1–O(water) and N3–O(water) distances are 3.069(3) and 2.939(3) Å, respectively. The asymmetric units of the other three complexes contain the CuLX ($X = Cl^-$ or $CH_3CO_2^-$) moiety. In each of the four complexes the planar ligand coordinates the metal ion via the pyridine-N, the imine-N and the amide-O atoms forming two five-membered chelate rings. In **1** and **2** the fourth site of the square-plane around the metal ion is occupied by a chloride ion. An acetate-O completes the square-plane in **3** and **4**. The chelate bite angles in the five-membered rings formed by the amide-O and the imine-N, and the pyridine-N and the imine-N are in the range 78.61(14)–79.2(2) and 80.04(15)–80.55(19)°, respectively. The N–N, C–N and C–O distances in the =N–N---C(---O)– fragment of the coordinated ligands are in the range 1.353(5)–1.380(7), 1.321(7)–1.331(6) and 1.278(8)–1.289(6) Å, respectively. These distances are consistent with the deprotonated form of the amide functionality [10–14,29,30]. The Cu–N(pyridine) distance is significantly longer than the Cu–N(imine) distance. The former is in the range 2.028(2)–2.045(4) Å, whereas the latter is within 1.915(4)–1.933(3) Å. This difference is possibly due to the rigidity of the tridentate ligand [31] and the better π-backbonding in the Cu–N(imine) bond than that in the Cu–N(pyridine) bond [29,30,32]. The Cu–O(amide) distance (1.971(3)–1.989(5) Å) is shorter than that observed in copper(II) complexes where the

metal ion is coordinated to the oxygen of a protonated amide functionality [13,33–35].

In solid state, **2** forms a one-dimensional chain of copper(II) ions via equatorial–apical chloride bridges (Fig. 2b). This type of single chloride bridged polymeric species is unique for copper(II) containing a tridentate coligand. The Cu···Cl(apical) and inter-monomer metal···metal distances are 2.7821(13) and 4.2866(7) Å, respectively. The Cu–Cl–Cu bridge angle is 117.60(5)°. The four coordinating atoms O1, N2, N1 and Cl are nearly coplanar (Fig. 2a). The largest deviation from the mean plane is 0.012 Å. The metal centre is at 0.126 Å from the mean plane towards the apical chloride bridge.

[a] Symmetry transformation used to generate equivalent atoms: $1-x, -y, 1-z$.

The other three complexes crystallise as centrosymmetric dinuclear species in which each copper(II) is in a distorted square-pyramidal coordination sphere. In **1**, the chloride ions act as equatorial–apical bridges (Fig. 1). The acetate ions perform the role of monoatomic bridges in the same fashion in **3** and **4** (Figs. 3 and 4). The metal···metal distance in the diacetato-bridged complexes, **3** (3.273(2) Å) and **4** (3.273(1) Å) are identical. However the same (3.3918(9) Å) in **1** is significantly longer. The O1, N2, N1 and Cl atoms form the base (largest deviation from the mean plane, 0.11 Å) of the square-pyramid in **1**. The metal centre is displaced from this base towards the apical bridging Cl′ by 0.23 Å. In **3** and **4**, the planar N,N,O-coordinating ligand and the acetate-O comprise the square-base of the pyramid. The largest deviations from the NNOO mean planes are 0.06 Å (**3**) and 0.04 Å (**4**). In **3**, the displacement of the metal ion towards the apical bridging acetate-O is 0.11 Å and that in **4** is 0.10 Å. Such displacement is very common in square-pyramidal copper(II) complexes [12,13,36,37]. A few structurally characterised dicopper(II) complexes of planar tridentate ligands containing equatorial–apical bridging chloride [38–50] or acetate [51–60] groups are known. In **1**, Cu–Cl and Cu–Cl′ distances are 2.2440(9) and 2.6682(10) Å. The Cu–Cl–Cu′ bridge angle is 86.89(3)°. In similar dichloro-bridged dicopper(II) complexes, the Cu–Cl(equatorial) and Cu–Cl(apical) distances are in the range 2.218–2.329 and 2.526–3.129 Å, respectively. In these complexes the Cu–Cl–Cu bridge angle varies from 83.291–91.989° [38–50]. In **3** and **4**, the bond parameters of the Cu_2O_2 unit are very similar. The Cu–O and Cu–O′ distances observed are 1.935(5) and 2.286(6) Å and 1.922(3) and 2.282(2) Å for **3** and **4**, respectively. The Cu–O–Cu′ bridge angles are 101.4(2)° (**3**) and 101.94(15)° (**4**). The values of Cu–O(equatorial) and Cu–O(apical) distances and the Cu–O–Cu bridge angles reported for similar diacetato-bridged complexes are in the range 1.951–1.987, 2.427–2.572 and 95.338–106.681°, respectively [51–60].

An interesting observation in the structures of the two diacetato-bridged complexes is the distances between the uncoordinated acetate oxygen atoms and the azomethine (–HC=N–) carbon atoms of the adjacent dimers (3.162(10) Å for **3** and 3.199(6) Å for **4**). Thus a one dimensional assembly of the dimer is formed by involvement of the molecule in two pairs of reciprocal C–H···O interactions with its two neighbours on both sides.

3.5. Magnetic properties

Magnetic susceptibility measurements for powdered samples of the four complexes were carried out in the temperature range 17–300 K at a constant magnetic field of 5 kG. The room temperature effective magnetic moments (μ_{eff}/monomer) are in the range 1.84–1.92 μ_B (Table 2). On cooling there is no significant change in the magnetic moments. At 17 K the magnetic moments are within 2.07–2.19 μ_B. That each complex behaves essentially as a Curie paramagnet is readily apparent from the linear plots of inverse magnetic susceptibility values (per monomer) against temperature. The data were fit using the expression for Curie–Weiss law. The Curie (C) and the Weiss constants (θ in K) are 0.45 and -3.57, 0.42 and 1.98, 0.45 and -1.41, and 0.46 and -1.04 for **1**, **2**, **3**, and **4**, respectively.

Magnetostructural studies on equatorial–apical dichloro-bridged copper(II) dimers have been reported [41,61]. The exchange coupling constant (J) in such complexes cover a wide range ($+6$ to -41.3 cm^{-1}) [41–43,46,61]. An empirical relationship has been observed between the extent of the Cu···Cu interaction and the ratio ϕ/R, where ϕ is the Cu–Cl–Cu bridge angle and R is the longer Cu–Cl distance [41,61]. With the increase of the ratio ϕ/R the value of $-2J$ decreases and reaches a minimum and then again in-

creases. The magnitude of J is very small for most of the complexes in which $\phi/R \approx 33$. In **1** this ratio is 32.6. The paramagnetic nature of **1** is consistent with this ratio.

Magnetic properties of very few single chloride bridged polymeric copper(II) complexes analogous to **2** are reported [62]. In all of them the intrachain magnetic interaction is very weak ($J = -6.1$–1.58 cm^{-1}). However a trend in the Cu–Cl–Cu bridge angle (ϕ) and the value of J has been observed [62]. The coupling constant (J) decreases with the increase of ϕ. For large ϕ (144.6°), the J is negative (-6.1 cm^{-1}). Weak ferromagnetic interaction is observed for species with smaller Cu–Cl–Cu angle ($\phi = 113.58(5)°$, $J = 1.58$ cm^{-1}; $\phi = 128.1°$, $J = 0.48$ cm^{-1}). Although the small positive Weiss constant (1.98 K) observed for **2** indicates the near paramagnetic nature, it is interesting that ϕ (117.60(5)°) in **2** is intermediate of the above two values.

Compared to the dichloro-bridged complexes magnetic data for diacetato-bridged dimeric species similar to **3** and **4** are scarce. The coupling constants J reported for the previously studied complexes are very small and within the range -1.54 to $+0.63$ cm^{-1} [51,53,54,56]. The small values of θ observed for **3** and **4** suggest a similar situation where no significant spin–spin interaction exists between the metal ions.

4. Conclusions

One polymeric and three dimeric copper(II) complexes with N,N,O-donor ligands have been synthesised and structurally characterised by X-ray crystallography. Metal ions are in distorted square-pyramidal N_2OCl_2 or N_2O_3 coordination sphere in these complexes. The polymeric chain complex is formed via single chloride bridges. In the dimers, chloride or acetate ions act as the monoatomic bridging units. In all the complexes the bridging units are in equatorial–apical fashion. The spectral properties (UV–Vis and ESR) are similar to those of other complexes containing square-planar or square-pyramidal copper(II). The complexes are redox active in methanol solutions. Variable temperature magnetic susceptibility measurements revealed the paramagnetic nature of the complexes.

5. Supplementary material

Crystallographic data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition Nos. CCDC 141222–141225.

Acknowledgements

Financial assistance for this work was provided by the Council of Scientific and Industrial Research, New Delhi (Grant no. 01(1422)/96/EMR-II). N.R.S thanks the University Grants Commission, New Delhi for a research fellowship. We are grateful to Professor A.R. Chakravarty for providing the variable temperature magnetic susceptibility data and to Professor P.S. Zacharias for allowing the use of the electroanalytical system. The X-ray crystallographic studies were performed at the National Single Crystal Diffractometer Facility, School of Chemistry, University of Hyderabad. We thank the Department of Science and Technology, New Delhi, for setting up this facility.

Abstract

Palladium(II) complexes of the general type $[Pd(L\cap L)Cl_2]$ (**4**–**6**) and their corresponding dicationic complexes $[Pd(L\cap L)(NCCH_3)_2](BF_4)_2$ (**7**–**9**) (L∩L = [(1-(thiomethyl)-2-(diphenylarsino)ethane] (S∩As, **1**) (**4**, **7**) [1-(thiomethyl)-2-(diphenylphosphino)ethane] (S∩P, **2**) (**5**, **8**) and [1,2-bis(diphenylphosphino)ethane] (P∩P, **3**) (**6**, **9**) have been synthesized and utilized as catalysts for the polymerization reaction of bicyclo[2.2.1]hept-2-ene (norbornene). The dichloride complexes can be activated with methylaluminoxane (MAO), while the corresponding dicationic compounds were used as single component catalysts for the polymerization reactions. Catalytic performance of the new type of catalyst can be altered by modifying the donor atoms in the bidentate ligand. The activity of the Pd(II) complexes towards the polymerization reaction increases with increasing the *trans*-influence of the donor atoms (P∩P > S∩P > S∩As). The influence of donor atoms on the length of the Pd–Cl bonds was elucidated by X-ray structure analysis carried out on the palladium(II) complex $[Pd(S\cap As)Cl_2]$ (**4**). © 2000 Elsevier Science Ltd. Keywords: Palladium(II) complexes; Mixed donor ligands; *Trans*-influence; X-ray crystallography; Methylaluminoxane (MAO); Norbornene; Polymerization

1. Introduction

Different methods for polymerization of bicyclo[2.2.1]hept-2-ene (norbornene) are known: ring-opening metathesis polymerization (ROMP) [1], cationic polymerization, radical polymerization [2] and the vinyl-type olefin addition (1,2-insertion), where the polymerization involves exclusively the π bond and leaves the bicyclic monomer unit intact [3]. Polymerization of norbornene to poly(2,3-bicyclo[2.2.1]heptene) was first reported in the early 1960s [4]. In addition to Ti(IV)- and Zr(IV)-based catalysts [5], Pd(II) compounds have also been applied successfully for the polymerization of norbornene to amorphous, transparent polymer products, which consist of 2,3-linked bicyclic units (Fig. 1) [3]. The first generation of the palladium catalysts consisted of neutral palladium(II) halides [6]. These compounds required long polymerization time and elevated temperatures and resulted in low yields and lower molecular weights materials. Cationic palladium(II) complexes in which the Pd(II) center is surrounded by four weakly coordinated nitrile ligands [3] (e.g. $[Pd(NCCH_3)_4](BF_4)_2$) represent the current catalyst generation of highly increased activity. However, by using these chelate-free solvated complexes, no control on the polymer microstructure is feasible. Furthermore, this type of catalyst is not soluble in chlorinated solvents such as CH_2Cl_2 and chlorobenzene. A catalyst system consisting of palladium(II) based catalyst precursor and methylaluminoxane as activator was also reported to catalyze efficiently the polymerization reaction [7].

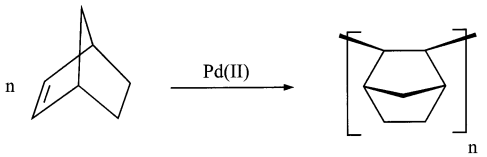

Fig. 1. Structure of poly(2,3-bicyclo[2.2.1]heptene).

In a previous report we presented new palladium(II) complexes with ethylene-bridged bisindolinyl nitrogen ligands together with weakly coordinated acetonitrile moieties as active, single component catalysts for the polymerization of norbornene. Using this catalyst system a monomer conversion up to 70% could be reached [8]. As an extension of our studies upon both the coordination chemistry of heteroatom-containing ligands and the polymerization of cyclic olefines [8–10] we report here on the application of palladium(II) complexes stabilized with ethylene-bridged bidentate ligands that contain different donor atoms (S∩As, **1** and S∩P, **2**) as a new type of catalyst for the polymerization reaction of norbornene. Their catalytic behavior was compared with that for the symmetrical P∩P based Pd(II) complexes. In addition, the influence of the donor atoms P, As, and S on the catalytic conduct of the complexes has been rationalized.

2. Experimental

2.1. Materials

All reactions were carried out under dry Argon using standard Schlenk techniques. The ligands (S∩As) (**1**), (S∩P) (**2**) [11], and the palladium(II) complexes $[Pd(S\cap As)Cl_2]$ (**4**) [9b], $[Pd(S\cap P)Cl_2]$ (**5**) [9b] and $[Pd(P\cap P)Cl_2]$ (**6**) [12] were prepared according to literature procedures. MAO was purchased from WITCO. Toluene was purified by distillation over $LiAlH_4$. CH_2Cl_2 and CH_3CN were purified by distillation over CaH_2 and P_2O_5, respectively. Reagent grade chemicals were used as received unless otherwise stated

2.2. Physical measurements

Elemental analyses was performed by the Microanalytical Laboratories of Ulm University, Germany. ^1H NMR spectra were recorded on a Bruker AC 200 spectrometer. Infrared spectra (KBr film) were measured on a Bruker model IFS113V spectrometer. Molecular weights and molecular weight distributions were determined by a Waters 150-C GPC chromatograph relative to polystyrene standards. Thermogravimetric analysis (TGA) data were collected by a Perkin–Elmer DSC-7 with a 20 K min^{-1} heating rate.

2.3. Synthesis of the complexes

The complexes $[Pd(S\cap As)(NCCH_3)_2](BF_4)_2$ (**7**), $[Pd(S\cap P)(NCCH_3)_2](BF_4)_2$ (**8**) and $[(P\cap P)Pd(NCCH_3)_2](BF_4)_2$ [13] (**9**) were prepared following a previously published procedure [14]. The corresponding dichloride complex **4**, **5**, or **6** (0.89 mmol) was mixed with $AgBF_4$ (0.35 g, 1.79 mmol) in CH_3CN (50 ml). After the mixture had been stirred for 12 h at room temperature (r.t.), the resulting agile precipitate was removed by filtration and the filtrate was evaporated under reduced pressure. The residue was dissolved in CH_2Cl_2 (40 ml), filtered and the filtrate was evaporated to dryness under reduced pressure and dried under vacuum.

IR (CsI, cm^{-1}): 2299 (w), 2325 (w) (C≡N), 1062 (s, br) (BF_4).

2.4. X-ray crystal structure determination for 4

Crystal data for compound **4** was collected on a Rigaku AFC7S single-crystal diffractometer at 193(2) K using graphite monochromatized Mo Kα radiation (0.71073 Å). The intensities were corrected for Lorentz and polarization effects. An experimental absorption correction (ψ-scan) was performed. The structures were solved by direct methods (SHELXTL/PC program). All non-hydrogen atoms were refined anisotropically and hydrogen atoms isotropically on calculated positions. Final calculations were performed with SHELXTL/PC and SHELXL-93 program systems. The final cell parameters and specific data collection parameters are summarized in Table 1.

2.5. Polymerization experiments

To a solution of the palladium(II) complex (**4**–**6**) (50 mg) in CH_2Cl_2 (50 ml), 1,2-dichlorobenzene (5.0 ml) and nitrobenzene (2 ml), norbornene was added (Table 2, entries 4–6). When MAO-activation was utilized

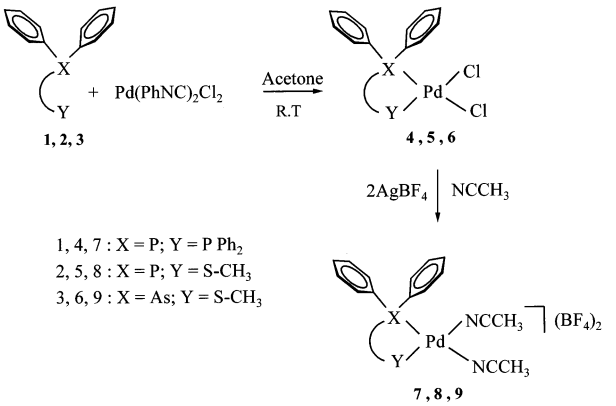

Fig. 2. Structure of the palladium(II) complexes **4**–**9**.

3. Results and discussion

The air- and moisture-stable palladium(II) complexes $[Pd(S \cap As)Cl_2]$ (**4**), $[Pd(S \cap P)Cl_2]$ (**5**) and $[Pd(P \cap P)Cl_2]$ (**6**) were prepared by stirring the ligands **1**–**3**, respectively, with $Pd(NCPh)Cl_2$ in acetone following literature procedures [9b]. Chloride abstraction from compounds **4**–**6** with $AgBF_4$ afforded the solvated diacetonitrile complexes **7**–**9**, respectively (Fig. 2). The complexes were characterized by elemental analysis, ^1H NMR and IR spectroscopy.

3.1. Crystal structure of complex *4*

Suitable crystals of $[Pd(S \cap As)Cl_2]$ (**4**) (Fig. 3) were obtained by crystallization from acetone. Selected bond lengths and angles are given in Table 3. The Pd atom is at the center of approximately square-planar arrangement. The complex form monoclinic crystals with space group $P2_1/n$ which also similar to that for the complexes $[Pd(S \cap P)Cl_2]$ (**5**) [15] and $[Pd(P \cap P)Cl_2]$ (**6**) [12].

A comparison among the X-ray structural data of complexes **4**–**6** showed that the Pd–Cl bond is obviously sensitive to the nature of the *trans* donor atom. The Pd–Cl_1 and Pd–Cl_2 bond lengths in the compound **4** are 2.3143(8) and 2.3575(9) Å, respectively, the first is *trans* to S and the second is *trans* to As. The distances

Table 2
Polymerization results [a]

Entry	Ligand	Catalyst	Al/Pd (mol ratio)	$\bar{M}_w$ (g mol^{-1}) [b]	$\bar{M}_w/\bar{M}_n$ [b]	Yield (g)	Conversion (%)
1	S∩As	**4**	200	1.50×10^4	1.65	0.77	15.8
2	S∩P	**5**	200	2.86×10^5	1.81	2.29	42.6
3	P∩P	**6**	200	2.82×10^5	1.34	2.56	62.6
4	S∩As	**7**		7.67×10^5	1.92	3.04	86.1
5	S∩P	**8**		5.71×10^5	1.87	3.51	92.9
6	P∩P	**9**		4.73×10^5	1.91	3.43	98.4

[a] Polymerization conditions: solvent, toluene (entries 1–3), CH_2Cl_2 (50 ml), 1,2-dichlorobenzene (5.0 ml), nitrobenzene (1.0 ml); norbornrne/Pd(II) mol ratio, 500; T, r.t; time, 2 h.
[b] Measured by GPC (relative to polystyrene).

in compound **5** are 2.3719(13) Å (Pd–Cl_1) and 2.3116(12) Å (Pd–Cl_2), which are *trans* to P and S, respectively [12]. These bonds are shorter than those in [Pd(P∩P)Cl_2] (**6**) (2.415(3) Å (Pd–Cl_1) and 2.394(3) Å (Pd–Cl_2)) [13] which suggest that with increasing the *trans*-influence of the donor atom the length of Pd–Cl bond *trans* to it increases. The variation of Pd–Cl distances shown above are in agreement with the *trans*-influence orderings (P > As > S) [9]. In summary, we could say that the ligands exert a stronger influence in the order (P∩P) > (S∩P) > (S∩As).

The higher weakening effect caused on the Pd–Cl bond when phosphorus is the *trans* donor atom is in harmony with previous NMR investigations carried out on the corresponding dialkyl complexes (the methyl signals are shifted up field with increasing *trans*-influence) [9b]. This was explained in terms of weakening effect caused by the donor atom on the Pd–CH_3 bond *trans* to it.

3.2. Polymerization behavior

Polymerization reactions of norbornene were carried out using the MAO activated palladium(II) chloride complexes (**4**–**6**) in toluene or by utilizing the self-activated dicationic species (**7**–**9**) in a reaction medium consisting of a mixture of dichloromethane, 1,2-dichlorobenzene and nitrobenzene (Table 2). The amorphous, transparent polymer products consist of 2,3-linked norbornene units. Monomer conversion up to 98% can be reached by the right choice of the ligand and the catalyst system.

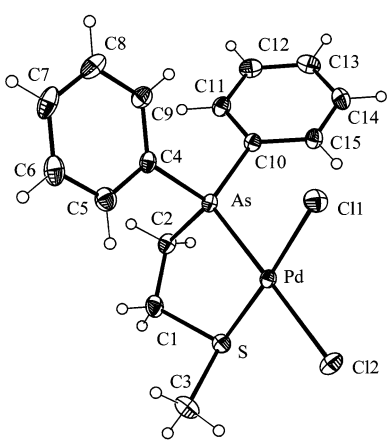

Fig. 3. ORTEP plot of the molecular structure of compound **4**. Displacement ellipsoids are drawn at the 50% probability level.

Table 3
Selected bond lengths (Å) and angles (°) for complex **4**

Pd–S	2.2785(8)	As–C(4)	1.929(3)
Pd–Cl(1)	2.3143(8)	As–C(2)	1.961(3)
Pd–As	2.3190(6)	S–C(3)	1.809(3)
Pd–Cl(2)	2.3575(9)	S–C(1)	1.840(3)
S–Pd–Cl(1)	175.86(3)	Cl(1)–Pd–Cl(2)	93.86(4)
S–Pd–As	87.55(3)	As–Pd–Cl(2)	177.60(2)
Cl(1)–Pd–As	88.31(3)	C(1)–S–Pd	106.84(11)
S–Pd–Cl(2)	90.28(4)	C(2)–As–Pd	105.47(10)

Higher polymer yields were obtained by using the single-component Pd(II) catalysts **7**–**9** (Table 2, entries 4–6) compared to the Pd(II)/MAO catalyst systems **4**–**6** (Table 2, entries 1–3). The complexes with phosphine ligands [Pd(S∩P)$(NCCH_3)_2$]$(BF_4)_2$ (**8**) and [Pd(P∩P)$(NCCH_3)_2$]$(BF_4)_2$ (**9**) showed a considerably higher activity for norbornene polymerization than the corresponding complex [Pd(S∩As)$(NCCH_3)_2$]$(BF_4)_2$ (**7**) under similar reaction conditions (Table 2). The same behavior was also observed when utilizing the Pd(II)/MAO catalyst systems **4**–**6**. However, a decrease in the yield of polymer was observed using these catalysts for polymerization in toluene that can be attributed to precipitation of the polymer in toluene before all the monomer had been consumed.

The higher rate of monomer conversion using complex **9** might be due to the stronger *trans*-influence of the ligand (P∩P, **3**) compared to that for the mixed ligands (S∩P, **2**) and (S∩As, **1**), which leads to the weakening of the in situ formed Pd–alkyl bond, allowing therefore faster monomer insertion. Previous investigations on the corresponding alkyl palladium(II) and platinum(II) complexes showed also that the weakening effect on the metal–alkyl bond *trans* to the donor atom increases in the order P > As > N > S [9a,b].

No change in the color of the polymerization media due to the decomposition of the palladium catalysts was observed in either system, which indicates a rare ligand dissociation under the applied polymerization conditions. The IR spectra of the polymers are similar to those of the previously described vinyl-type poly(norbornene)s, prepared by Pd(II) catalysis [3e,8]. No absorption bands due to double bonds resulting from ring opening (ROMP) were observed. According to thermogravimetric analysis (TGA) under nitrogen, the poly(norbornene)s prepared utilizing the complexes that carry phosphorus donor atom (**5**, **6**, **8** and **9**) show higher stability; the polymer products start to decompose at temperatures above 425°C. This is about 100°C higher compared to the polymers produced by **4** and **7** or [Pd$(NCCH_3)_4$]$(BF_4)_2$, where decomposition commences at 335°C [3a].

4. Conclusion

Palladium(II) complexes bearing bidentate ligands with different donor atoms were used successfully as

catalysts for the polymerization reaction of norbornene. These compounds are a new type of Pd(II)-based catalyst for the polymerization of cyclic monomers. Higher catalytic activity was observed for the dicationic Pd(II) single-component catalysts (**7**–**9**) compared to the Pd(II)/MAO catalyst system (**4**–**6**). By maintaining the structural features of the complexes (**4** and **5** or **7** and **8**) we have been able to look into the influence of the donor atoms on their catalytic conduct. With increasing the *trans*-influence of the donor atom, the in situ formed Pd–alkyl bond *trans* to it is weakened and thus catalytic activity of the compound is increased.

5. Supplementary material

Crystallographic data for the structure reported in this paper have been deposited at the Cambridge Crystallographic Data Center as supplementary publication number CCDC-134953. Copies of the data can be obtained on application to: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

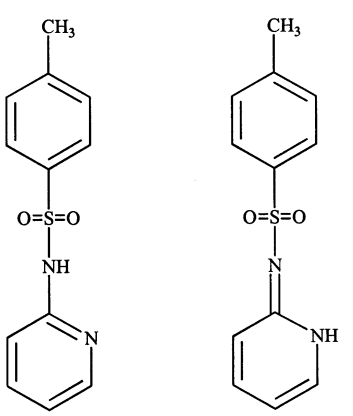
Abstract



Several complexes with tosylamides were synthesised by the electrochemical oxidation of cobalt in an acetonitrile solution of [(4-methylphenyl)sulfonyl]-imino-1*H*-pyridine (HL) and the appropriate neutral coligand: L′ (pyridine, 2,2′-bipyridine, 1,10-phenanthroline or *N*,*N*-dimethylformamide). The structures of bis-(*N*,*N*-dimethylformamide)bis{[(4-methylphenyl)sulfonyl]-2-pyridyl-amide}cobalt(II), bis-(pyridine)bis{[(4-methylphenyl)sulfonyl]-2-pyridyl-amide}cobalt(II), 2,2′-bipyridine bis{[(4-methylphenyl)sulfonyl]-2-pyridyl-amide}cobalt(II) and 1,10-phenanthroline bis{[(4-methylphenyl)sulfonyl]-2-pyridyl-amide}cobalt(II) were determined by X-ray diffraction methods. In these monomeric complexes, the cobalt atom is in a distorted octahedral environment. The vibrational and electronic spectra of the complexes are discussed and are shown to agree with the structures.

1. Introduction

The coordination chemistry of amides is scarce due to the difficulty of the substitution of a metal ion for an amide proton. However, if a sulfonamide group substitutes the amide group, the electron withdrawal of the sulfonyl group causes important changes and the formation of the complexes is facilitated [1].

This is one of the reasons why the coordination chemistry of sulfonamide ligands has been investigated in recent years [2,3]. Electron withdrawal of the sulfonyl group causes important changes in both the neutral ligand and in the complexes. Free molecules, such as tosylsulfonylimino-1*H*-pyridine, are expected to exist in

(I) (II)

the form **I**. However, crystallographic and spectroscopic data show that the most stable is **II** [3]. This electron withdrawal of the sulfonyl group increases the acidity of the hydrogen on the pyridine group and complexes are easily obtained by the deprotonation of

PII: S0277-5387(00)00437-X

the ligand. This deprotonation may be carried out with an electrochemical procedure.

Electrochemical methods have been widely used for the synthesis of metallic complexes, especially those of weakly acid organic ligands [4–8]. Of particular relevance to the present work are metal complexes with heterocyclic ligands, such as pyridine derivatives containing, apart from the nitrogen atom, sulfur [9,10], oxygen and sulfur [11] or selenium [12] atoms as additional donor atoms.

In this paper, we now report the electrochemical synthesis and characterisation of several cobalt(II) complexes with the mentioned ligand, where an *N*-tosylamido group substitutes a pyridine ring, and the additional atom is another nitrogen atom.

2. Experimental

Acetonitrile, dichloromethane, 2-aminopyridine, tosyl chloride, pyridine, 2,2′-bipyridine, 1,10-phenanthroline, *N*,*N*-dimethylformamide and all other reagents were commercial products and were used as supplied. Cobalt (Aldrich Chemie) was used as 2 × 2 cm plates.

The proligand, HL, was prepared by reaction of the amine and the tosyl chloride following the method previously described [3]. Before its use, the product was recrystallized from $CH_3CN/(CH_3)_2CO$.

2.1. Preparation of complexes. General procedure

The complexes were obtained following an electrochemical procedure [8]. A solution of the proligand and the appropriated coligand (either pyridine, DMF, 2,2′-bipyridine or 1,10-phenanthroline) in a mixture of acetonitrile–dichloromethane containing about 20 mg of tetraethylammonium perchlorate as a current carrier was electrolysed using a platinum wire as the cathode and a cobalt plate as the sacrificial anode. In all cases, hydrogen was evolved at the cathode.

2.1.1. *[CoL_2py_2] (**1**)*

Electrolysis of an acetonitrile–dichloromethane (25 + 25 ml) solution containing the proligand HL (201.4 mg, 0.81 mmol), pyridine (ca. 1 ml) and tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 14 V for 2 h dissolved 21.1 mg of cobalt (E_f = 0.48). At the end of the experiment the pale pink solid product was filtered, washed with hot acetonitrile and ether and dried in vacuo. The compound was characterised as [CoL_2py_2]: *Anal.* Found: H, 4.7; C, 57.2; N, 11.8; S, 8.7. Calc. for [$C_{34}H_{32}CoN_6O_4S_2$]: C, 57.4; H, 4.5; N, 11.8; S, 9.0%. IR (KBr, cm^{-1}): 3071(m), 3069(m), 2973(sh), 1593(s), 1463(s), 1315(b), 1135(b), 1038(s), 981(vb), 702(s), 662(s), 579(s), 559(b), 531(s), 430(m). Crystals suitable for X-ray diffraction studies were obtained by crystallisation from $(CH_3)_2CO$–CH_3CN.

2.1.2. *[$CoL_2(DMF)_2$] (**2**)*

Electrolysis of an acetonitrile–*N*,*N*-dimethylformamide (50 + 10 ml) solution containing HL (327.8 mg, 1.3 mmol) and tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 14 V for 2.2 h dissolved 22.2 mg of cobalt (E_f = 0.46). At the end of the experiment the pale pink solid product was filtered, washed with hot acetonitrile and ether and dried in vacuo. The compound was characterised as [CoL_2DMF_2]: *Anal.* Found: H, 4.93; C, 51.6; N, 12.09; S, 9.52. Calc. for [$C_{30}H_{36}CoN_6O_6S_2$]: C, 51.50; H, 5.19; N, 12.01; S, 9.17%. IR (KBr, cm^{-1}): 3082(w), 3064(vw), 2923(m), 2851 (w), 1650(s), 1596(m), 1466(s), 1450(m), 1392(m), 1321(s), 1265(m), 1137(m), 1090(m), 784(m), 661(m), 577(m), 554(m). Crystals were obtained by recrystallisation from $(CH_3)_2CO$–CH_3CN.

2.1.3. *[CoL_2bipy] (**3**)*

Electrolysis of an acetonitrile–dichloromethane (25 + 25 ml) solution containing HL (201.0 mg, 0.81 mmol), 2,2′-bipyridine (67.2 mg, 0.43 mmol) and tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 10 V for 2.16 h dissolved 22.1 mg of cobalt (E_f = 0.47). At the end of the experiment the pale pink solid was filtered, washed with hot acetonitrile and ether and dried in vacuo. The compound was characterised as [CoL_2bipy]. *Anal.* Found: C, 57.5; H, 4.5; N, 11.8; S, 8.9. Calc. for [$C_{34}H_{30}CoN_6O_4S_2$]: C, 57.5; H, 4.3; N, 11.8; S, 9.0%. IR (KBr, cm^{-1}): 3107(w), 3064(vw), 2919(m), 1595(s), 1465(s), 1319(s), 1138(s), 1138(s), 1088(m), 1011(m), 976 (m), 764(m), 736(s), 667(s). Crystals were obtained by crystallisation from $(CH_3)_2CO$–CH_3CN.

2.1.4. *[CoL_2phen] (**4**)*

Electrolysis of an acetonitrile–dichloromethane (25 + 25 ml) solution containing HL (202.1, 0.81 mmol), 1,10-phenanthroline (83.3 mg, 0.46 mmol) and tetraethylammonium perchlorate (ca. 20 mg) at 10 mA and 13.5 V for 2.12 h dissolved 21.7 mg of cobalt (E_f = 0.46). At the end of the experiment the pale pink solid was filtered, washed with hot acetonitrile and ether and dried in vacuo. The compound was characterised as [CoL_2phen]: *Anal.* Found: C, 58.74; H, 4.23; N, 11.52, S, 8.41. Calc. for [$C_{36}H_{30}CoN_6O_4S_2$]: C, 58.93; H, 4.12; N, 11.45; S, 8.74%. IR (KBr, cm^{-1}): 3062(w), 3023(w), 2921(sh), 1588(s), 1559(s), 1515(m), 1495(m), 1315(m), 1178(m), 1134(m), 1038 (m), 981(m), 847(m), 727(s), 702(s), 662(m). Crystals by crystallisation from $(CH_3)_2CO$–CH_3CN.

2.2. Physical measurements

The C, N, H and S contents of the compounds were determined on a Carlo–Erba EA 1108 microanalyser. IR spectra were recorded as KBr mulls on a Bruker Vector-22 spectrophotometer. The ^{1}H NMR spectrum of the ligand was recorded on a Bruker ARX-400 MHz spectrometer using Cl_3CD as solvent. Solid-state electronic spectra were recorded on a Shimadzu UV 3101 PC. Magnetic measurements were made using a DMS VSM 1160 instrument.

2.3. Crystal structure determination

The data collection, in all the cases at room temperature, was taken on a MACH3 Enraf–Nonius using Mo Kα radiation for $[CoL_2py_2]$ and for $[CoL_2bipy]$. Data were corrected for polarization and Lorentz effects. Ψ-scan absorption corrections were applied [13]. The data collection for $[CoL_2DMF_2]$ and $[CoL_2phen]$ was taken on a Siemens Smart CCD area-detector diffractometer with graphite-monochromated Mo Kα radiation. Absorption corrections were carried out using SADABS [14].

All the structures were solved by direct methods and refined by a full-matrix least-squares based on F^2 [15]. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in idealised positions and refined with isotropic displacement parameters. Correct absolute structures of $[CoL_2phen]$ were determined by using the Flack parameter [16]. Atomic scattering factors and anomalous dispersion corrections for all atoms were taken from the International Tables for X-ray Crystallography [17]. Details of crystal data and structural refinement are given in Table 1.

3. Results and discussion

Anodic oxidation of cobalt metal in a non-aqueous solution containing (4-methylphenyl)sulfonyl]imino-1*H*-pyridine and one coligand as pyridine (py), *N*,*N*-dimethylformamide (DMF), 2,2′-bipyridine (bipy) or 1,10-phenanthroline (phen) yields crystalline products of formulae $[CoL_2py_2]$, $[CoL_2DMF_2]$, $[CoL_2bipy]$ and $[CoL_2phen]$, respectively. The values of the electrochemical efficiency, defined as the amount of metal dissolved per number of Faradays, were close to 0.5 mol F^{-1} in all cases. This value is compatible with the mechanism

Cathode: $2HL + 2e^- \rightarrow 2L^- + H_2$

Anode: $Co \rightarrow Co^{2+} + 2e^-$

The overall reactions can be described as

$Co + 2HL + nL' \rightarrow [CoL_2L'_n] + H_2$

$n = 1$; L′ = bipy or phen.

$n = 2$; L′ = py or DMF.

3.1. Description of the structures of $[CoL_2py_2]$ (1), $[CoL_2DMF_2]$ (2), $[CoL_2bipy]$ (3), and $[CoL_2phen]$ (4)

The molecular structures are shown in Figs. 1–4. Selected bond lengths and angles are given in Tables

2–5 for each compound. In the four complexes the cobalt atom is in a highly distorted octahedral environment but they are different to each other. In the case of **1**, **3** and **4**, the environment is $[CoN_6]$, and in **2** is $[CoO_2N_4]$. Compounds **1** and **2** contain two N–N anionic ligands and two monodentate ligands, but **3** and **4** have three bidentate N–N ligands, two anionic and one neutral.

3.1.1. Molecular structure of $[CoL_2py_2]$ (1)

The cobalt atom in $[CoL_2py_2]$ is in an octahedral environment $[CoN_6]$. The nitrogen atoms of the two neutral pyridine molecules are in *trans* positions, and the nitrogen atoms of the two anionic tosylato ligands are in the equatorial plane. As the cobalt atom is in a symmetry center, the equivalent nitrogen atoms of the tosylato ligands are in *trans* positions.

The Co–N bond lengths of the apical positions are slightly longer, 2.164(3) Å, than the Co–N bonds lengths on the equatorial plane, 2.125(3) and 2.138(3) Å. This is probably because the apical ligands are neutral, but the ligands in the equatorial plane are anionic. Similar behaviour has been found in the pyridine complex containing other anionic ligands, such as in diaqua-dipyridyl-bis(*N*-(4-methyl-2-sulfamoyl-Δ^2-1,3,4-thiadiazolin-5-ylidene)acetamide)cobalt(II) [18], with a Co(II)–N_{py} distance of 2.198(2) Å and other

[a] Symmetry transformations used to generate equivalent atoms: $-x+1, -y+1, -z+1$.

Co–N distance of 2.108(2) Å. Nevertheless, there are some examples where the Co–N_{py} bond lengths are longer than the other Co–N bond lengths and all the ligands are neutral. That is the case for (1,3,5-tris-(pyridine-2-carboxaldimino)-cyclohexane-N^1,N^2,N^3,N^4,N^5,N^6)cobalt(II) diperchlorate [19], with average bond distances Co–N_{py} of 2.231 Å and Co–N_{imino} of 2.131 Å, or (1,1,1-tris(pyridine-2-aldiminomethyl)ethane)-cobalt(II) diperchlorate [20] with average bond distances Co–N_{py} of 2.150 Å and Co–N_{imino} of 2.097 Å.

A tetrahedral coordination around the cobalt atom has been found for bis{[(4-methylphenyl)sulfonyl][2-(2-pyridyl)phenyl]amine}cobalt(II) [2]. In this case, the Co–N distances are shorter, average Co–N_{amide} = 1.963(2) and Co–N_{py} = 2.042(2) Å, as expected for a complex with a lower coordination number.

The ligand bond distances and angles are normal and do not deserve special discussion. The neutral pyridine is almost perpendicular to the pyridine ring belonging to the anionic ligand, with a dihedral angle of 86.93(12)°. The pyridine ring of the anionic ligand is almost coplanar with the small chelate ring Co–N(12)–C(15)–N(11), with a dihedral angle of 3.92(14)°.

The most important deviation of the octahedron from regularity is the small bite of the ligand, 62.93(11)°. This value is in the range for a four-member chelate ring found for complexes of cobalt(II): 55.3° in hexakis[(μ^2-methoxo)-(μ^2-σ^3-1,5-di-*p*-tolyl-1,4-pentaazadienido)cobalt(II)] mesitylene solvate [21] and 65.8° in diaqua-bis[(*N*,*N*′-methylene-bis(L-prolinato)]-cobalt(II) sesquihydrate [22] or 65.5° in diaqua-[*N*,*N*′-methylene-bis(4-hydroxy-L-prolinato)]cobalt(II) [23].

3.1.2. Molecular structure of $[CoL_2DMF_2]$ (2)

In this compound, the metal environment is $[CoN_4O_2]$. The cobalt atom is in a centre of symmetry coordinated by two *N*,*N*-bidentate anionic ligands and by two molecules of DMF through the oxygen atom. The coordination polyhedron can be described as an octahedron with the neutral DMF ligands in the axial positions and the anionic ligands in the equatorial plane. As happens in $[CoL_2py_2]$, the ligands in the apical positions are slightly farther than the ligands in the equatorial plane. All the other features are very

similar to those in [CoL_2py_2]. The Co–O bond length (2.1635(14) Å) and the angles C–O–Co (127.91(14)°) are in the range for Co(II) complexes with DMF as the ligand, like, for example, *trans*-bis(benzo(1,3)-thiazole)-bis(*N*,*N* - dimethylformamide) - bis(isothiocyanato)cobalt(II) [24], with values of 2.118 Å and 126.14°, respectively.

3.1.3. Molecular structure of [CoL_2 bipy] (3)

The cobalt atom in **3** is in a distorted octahedral environment [CoN_6], with the two anionic tosyl ligands and the neutral bipyridine molecule as *N*,*N*-bidentate ligands. The small bite angles of the ligands, especially in the case of the anionic ligand, are the main reason for the distortion. So, the angles N_{amide}–Co–$N_{pyridine}$ are 61.3(2) and 61.4(2)° in each anionic ligand, with a chelate ring of four members (see above) and 76.6(2)° in the bipyridine, with a chelate ring of five members. The pyridine fragments of the anionic ligands are in *trans* positions, and consequently if these are considered as the apical positions, the equatorial plane is formed by the amide nitrogen atoms of the tosylamide ligands and the nitrogen atoms of the bipyridine molecule. The cobalt atom is 0.024(3) Å out of this equatorial plane. The pyridine rings in *trans* positions are also almost perpendicular between them, dihedral angle of 80.5(2)°, and form dihedral angles with the equatorial plane of 76.5(2) and 79.3(2)°. It is worth noting that while the Co–N bond distances in the case of one of the tosyl ligands are quite similar, 2.121(6) and 2.185(6) Å, for the other one, one of the distances is significantly shorter than the other, 2.259(6) and 2.066(6) Å. Such disposition of the ligands around the metal corresponds approximately to non-crystallographic two-fold point symmetry.

The distances Co–N_{bipy}, 2.106(6) and 2.119(6) Å, are slightly shorter that those found in tris(2,2′-bipyridine)cobalt(II) dichloride [25], average 2.130 Å, or in *cis*-dichloro-bis(2,2′-bipyridyl-*N*,*N*′)cobalt(II) [26], average 2.154 Å.

The distances and angles of the anionic ligands are normal, with dihedral angles between the rings of 83.5(2) and 78.2(2)°, this last one in the case of the anisodentate ligand. The free ligand shows dihedral angles of 83.7(1) and 87.6(1)° [3].

3.1.4. Molecular structure of [CoL_2 phen] (4)

Compound **4** contains a cobalt atom in a distorted octahedral geometry coordinated by two nitrogen atoms of an neutral ligand (phen), and by four nitrogen atoms of two anionic ligands. This is similar to **3**, but there is an important difference between these compounds in the disposition of the ligands around the metal. In the case of **4**, the amide nitrogen atoms of the anionic ligands occupy the axial positions, and the equatorial plane is formed by the pyridine nitrogen atoms of the anionic ligands and the nitrogen atoms of the phenanthroline molecule. This structure corresponds to that of the Λ isomer. This geometry has also been found in the corresponding Ni(II) complexes with this ligands and either bipyridine or phenanthroline [3].

The Co–N distances to one of the anionic ligands are very similar, 2.140(5) and 2.143(5) Å, but the other anionic ligand again shows an anisobidentate behaviour, Co–N distances 2.120(6) and 2.215(6) Å. The dihedral angle between the pyridine ring and the phenyl ring is 85.12(18) and 81.98(23)° in each ligand, respectively. The disposition of the pyridine rings of the ligands are almost perpendicular, with a dihedral angle between the pyridine rings of 89.95(22)°.

The distances Co–N_{phen} (2.113(5) and 2.122(5) Å) are quite similar to those found in 1,10-phenanthroline bis{2-[(2-pyrrole)methylimino]phenolato}cobalt(II) [27], 2.22 and 2.16 Å, and in tris(1,10-phenanthroline)-cobalt(II) diperchlorate monohydrate [28] (average 2.128 Å, max. 2.141 Å, min. 2.109 Å).

3.2. Spectroscopic and magnetic studies

The IR spectra of the complexes do not show the band attributable to ν(N–H), which in the free ligand appears at 3230 cm^{-1}, confirming that the hydrogen atom of the amide group is lost during the electrolysis. The IR spectra of the mixed complexes show IR absorptions typical of coordinated pyridine (662 and 430

cm^{-1}), *N*,*N*-dimethylformamide (2923, 2850, 1650 and 1392 cm^{-1}), 2,2′-bipyridine (764 and 736 cm^{-1}) and 1,10-phenanthroline (1515, 847 and 727 cm^{-1}).

The magnetic moments of $[CoL_2py_2]$, 4.49 BM $[CoL_2DMF_2]$, 4.39 BM $[CoL_2bipy]$, 4.41 BM and $[CoL_2phen]$ 4.66 BM, are in the low limit for high-spin Co(II) complexes (4.7–5.2 BM). The solid reflectance spectra of $[CoL_2py_2]$, $[CoL_2DMF_2]$, $[CoL_2bipy]$ and $[CoL_2phen]$ show three bands at 28 170, 21 500, 9700, 28 450, 20 325, 8740, 25 757, 20 800, 8830 and 25 850, 20 600, 8925 cm^{-1}, respectively. They can be assigned to the $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$, $^4A_{2g} \leftarrow {}^4T_{1g}$ and $^4T_{2g} \leftarrow {}^4T_{1g}$ transitions, and are in accordance with an octahedral geometry for the complex. These conclusions are in keeping with the X-ray diffraction results.

4. Supplementary material

The atomic positions, full list of bond lengths and angles and other crystallographic data are available on request from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), quoting the deposition numbers CCDC 139406–139409.

Abstract

Treatment of copper(I) bromide with one equivalent of 1,2-bis(diphenylphosphino)ethane (dppe), followed by the addition of one equivalent of heterocyclic thione L {L = pyridine-2-thione (py2SH), pyrimidine-2-thione (pymtH), imidazole-2-thione (imtH), benz-1,3-imidazoline-2-thione ($bzimtH_2$), benz-1,3-thiazoline-2-thione (bztztH), 2-mercapto-1-methylimidazole (meimtH), 4,6-dimethylpyrimidine-2-thione (dmpymtH), and 6-ethoxybenz-1,3-thiazoline-2-thione (etObztztH) in dry acetone affords the dinuclear complexes $[CuBr(dppe)(L)]_2$ in ca. 60–80% yield. These compounds have been characterized by their IR, far-IR, UV–Vis and ^1H NMR spectroscopic data. The crystal structure of $[CuBr(dppe)(py2SH)]_2$ has been determined by single-crystal X-ray diffraction methods. In the dinuclear complex in which the two monomers are related by inversion, each Cu(I) centre exhibits a tetrahedral coordination sphere involving, besides the bromine, the exocyclic sulfur of one thione molecule and two phosphor atoms from two different diphosphine units. Vibrational, electronic and ^1H NMR spectral data of the complexes are discussed in relation to the structure. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Owing to their relevance in biological systems, heterocyclic thiones have attracted considerable attention as ligands in metal complexes [1]. Because of their application in catalytic functions, transition metal complexes with phosphine ligands have also been studied extensively [2]. In recent years, we have explored the group IB metal complexes blending both heterocyclic thione and tertiary arylphosphine ligands. In the course of our investigations, whose major target was the study of the factors that govern the coordination geometry of the metal atom, a large set of compounds with an interesting and in some cases unpredictable structural variety has been observed [3]. Although the interplay of several parameters like the geometrical flexibility of the coinage metals and electronic properties or bulkiness on the part of the ligands make structural prediction of these complexes virtually impossible, steric demands of the phosphine ligands seems to be of major importance causing significant changes on the coordination geometry of the metal atom [4]. To obtain further insight into this very interesting field of research we, therefore, decided to initiate a comparative investigation on substituting the unidentate triarylphosphines with acyclic multidentate phosphine ligands.

Recent interest in copper(I) bis(diphosphine) complexes, which are mostly polynuclear species containing bridging diphosphines, stems from their potential biological significance [5]. In this work, we report on the reaction of copper(I) bromide with 1,2-bis(diphenylphosphino)ethane (dppe) and several heterocyclic thione ligands, as well as the structure of $[CuBr(dppe)(py2SH)]_2$.

2. Experimental

2.1. Materials and instruments

Copper(I) bromide, 1,2-bis(diphenylphosphino)-ethane and all solvents are commercially available and were used as obtained, while the thiones (E. Merck or Aldrich) were recrystallized from hot ethanol prior to their use. IR, UV, Vis and NMR spectra, conductivities, melting points and elemental analyses of carbon, nitrogen and hydrogen were performed as described previously [6].

2.2. Preparation of the complexes

The complexes of the formula $[CuBr(dppe)(L)]_2$ were prepared according to the following general procedure. A solution of 1,2-bis(diphenylphosphino)ethane (99.6 mg, 0.25 mmol) in dry acetone (20 ml) was added to a stirred suspension of CuBr (35.3 g, 0.25 mmol) in 15 ml of the same solvent and the mixture was stirred and moderately heated. After the formation of a complete clear solution, 0.25 mmol of the appropriate thione, dissolved in dry acetone (30 ml), was added slowly and the stirring was continued for 2 h. The resulting solution was filtered off and allowed to cool. Slow evaporation of the solvent at room temperature (r.t.) gave the microcrystalline solid, which was filtered off and dried in vacuo.

2.2.1. $[CuBr(dppe)(py2SH)]_2$

Yellow crystals. Yield: 80%, m.p. 220°C. *Anal.* Calc. for $C_{62}H_{58}Br_2Cu_2N_2P_4S_2$: C, 57.0; H, 4.5; N, 2.1. Found: C, 56.3; H, 4.5; N, 2.1%. UV–Vis (λ, log ε): 295 (4.46); 244 (4.52). IR (cm^{-1}): 3048 m, 2960 m, 2897 s, 1610 s, 1577 vs, 1500 s, 1433 vs, 1366 s, 1132 vs, 1097 s, 882 m, 745 vs, 695 vs, 518 s, 479 s, 448 s, 336 m. ^1H NMR: δ 14.25 (s, >NH), 7.60–7.10 (m, aromatic), 2.17 (s, P–CH_2CH_2–P).

2.2.2. $[CuBr(dppe)(pymtH)]_2$

Orange–red crystals. Yield: 80%, m.p. 148°C. *Anal.* Calc. for $C_{60}H_{56}Br_2Cu_2N_4P_4S_2$: C, 55.1; H, 4.3; N, 4.2. Found: C, 55.9; H, 4.4; N, 4.2%. UV–Vis (λ, log ε): 290 (4.69); 247 (4.66). IR (cm^{-1}): 3066 m, 2923 w, 1606 m, 1564 vs, 1480 s, 1432 vs, 1324 s, 1175 vs, 1091 s, 1025 m, 744 vs, 697 vs, 511 s, 481 m, 448. ^1H NMR: δ 14.80 (s, >NH), 7.50–7.20 (m, aromatic), 2.17 (s, P–CH_2CH_2–P).

2.2.3. $[CuBr(dppe)(bzimtH_2)]_2$

Pale-yellow crystals. Yield: 60%, m.p. 146°C. *Anal.* Calc. for $C_{66}H_{60}Br_2Cu_2N_4P_4S_2$: C, 57.3; H, 4.4; N, 4.1. Found: C, 57.8; H, 4.2; N, 4.1%. UV–Vis (λ, log ε): 309 (4.95); 248 (5.09). IR (cm^{-1}): 3049 s, 2925 m, 1618 m, 1500 vs, 1463 s, 1434 vs, 1359 s, 1172 s, 1099 s, 1026 m, 740 vs, 694 vs, 512 s, 478 m, 418 m. ^1H NMR: δ 12.43 (s, >NH), 7.65–7.15 (m, aromatic), 2.17–2.50 (m, P–CH_2CH_2–P).

2.2.4. $[CuBr(dppe)(bztzH)]_2$

Yellow crystals. Yield: 66%, m.p. 177°C. *Anal.* Calc. for $C_{66}H_{58}Br_2Cu_2N_2P_4S_4$: C, 55.9; H, 4.5; N, 2.0. Found: C, 54.8; H, 4.1; N, 2.1%. UV–Vis (λ, log ε): 328 (4.38); 244 (4.58). IR (cm^{-1}): 3057 m, 2953 m, 1597 m, 1490 vs, 1458 s, 1428 vs, 1321 vs, 1170 s, 1099 s, 1076 m, 1031 vs, 1013 s, 745 vs, 693 s, 512 s, 423 m. ^1H NMR: δ 12.90 (s, >NH), 7.70–7.26 (m, aromatic), 2.03–2.59 (m, P–CH_2CH_2–P).

2.2.5. $[CuBr(dppe)(meimtH)]_2$

Pale-yellow crystals. Yield: 75%, m.p. 225°C. *Anal.* Calc. for $C_{60}H_{60}Br_2Cu_2P_4N_4S_2$: C, 54.9; H, 4.6; N, 4.3. Found: C, 55.3; H, 4.9; N, 4.1%. UV–Vis (λ, log ε): 266 (4.31); 245 (4.25). IR (cm^{-1}): 3131 m, 3046 m, 2940 w, 1572 vs, 1478 vs, 1433 vs, 1281 vs, 1254 m, 1153 s, 1095 s, 1025 m, 998 m, 883 m, 756 vs, 670 vs, 514 vs, 487 s, 416 m, 341 m. ^1H NMR: δ 12.50 (s, >NH), 7.80–7.26 (m, aromatic), 6.80–6.75 (m, –CH=CH–), 3.67 (s, >N–CH_3), 2.03–2.17 (m, P–CH_2CH_2–P).

2.2.6. $[CuBr(dppe)(imtH)]_2$

Red–brown crystals. Yield: 65%, m.p. 171°C. *Anal.* Calc. for $C_{58}H_{60}Br_2Cu_2N_4P_4S_2$: C, 54.1; H, 4.7; N, 4.3. Found: C, 53.7; H, 4.4; N, 4.9%. UV–Vis (λ, log ε): 290 (4.54); 243 (4.42). IR (cm^{-1}): 3138 m, 3055 m, 2950 w, 1582 vs, 1480 s, 1438 vs, 1306 m, 1169 vs, 1115 vs, 989 m, 738 vs, 730 vs, 697 vs, 618 s, 535 vs, 511 vs, 406 m, 340 m. ^1H NMR: δ 13.10 (s, >NH), 7.76–7.26 (m, aromatic), 2.52 (s, N–CH_2CH_2–N), 2.09–2.17 (m, P–CH_2CH_2–P).

2.2.7. $[CuBr(dppe)(dmpymtH)]_2$

Yellow crystals. Yield: 76%, m.p. 246°C. *Anal.* Calc. for $C_{64}H_{64}Br_2Cu_2N_4P_4S_2$: C, 56.3; H, 4.7; N, 4.1. Found: C, 55.8; H, 4.5; N, 4.0%. UV–Vis (λ, log ε): 294 (4.80); 247 (4.74). IR (cm^{-1}): 3148 m, 2910 w, 1614 vs, 1560 vs, 1483 s, 1433 vs, 1320 m, 1227 vs, 1189 s, 1098 s, 1027 m, 982 m, 885 m, 741 vs, 694 vs, 512 vs, 484 s, 416 m, 341 m. ^1H NMR: δ 13.95 (s, >NH), 7.66–7.08 (m, aromatic), 2.30 (s, C–CH_3), 2.17 (s, P–CH_2CH_2–P).

2.2.8. $[CuBr(dppe)(etObztztH)]_2$

Pale-yellow crystals. Yield: 70%, m.p. 177°C. *Anal.* Calc. for $C_{70}H_{66}Br_2Cu_2N_2O_2P_4S_4$: C, 55.8; H, 4.4; N, 1.8. Found: C, 55.3; H, 4.6; N, 2.0%. UV–Vis (λ, log ε): 331 (4.37); 247 (4.30). IR (cm^{-1}): 3033 m, 2925 w, 1601 vs, 1483 vs, 1427 vs, 1398 s, 1332 s, 1260 s, 1224 vs, 1099 s, 1044 vs, 1026 vs, 943 m, 877 m, 740 vs, 692 vs, 668 s, 584 s, 512 vs, 489 s, 421 m. ^1H NMR: δ 13.84 (s, >NH), 7.86–7.05 (m, aromatic), 4.07 (q, O–CH_2–C), 2.16 (s, P–CH_2CH_2–P), 1.45 (t, CH_3–C).

2.3. Collection and reduction of X-ray data

The unit cell and intensity data were collected on a Delft Instruments FAST diffractometer using the routines ENDEX, REFINE and MADONL in the MADNES software [7] and processed using ABSMAD [8]; detailed procedures are described by Darr et al. [9]. Absence of crystal decay in the X-ray beam was confirmed by checking equivalent reflections at the beginning and end of data collection, which lasted about 8 h. The structure was solved with SIR-92 [10] and refined with SHELX93 [11]. Details of crystal data and structure refinement and bond lengths (Å) and angles (°) are given in Tables 1 and 2, respectively. The copper, bromine, sulfur, phosphorus, nitrogen and carbon atoms were refined with anisotropic temperature factors. The hydrogen atoms were allowed to ride on their attached atoms with common isotropic temperature factors for methyl and non-methyl hydrogens. An absorption correction was made with DIFABS [12].

3. Results and discussion

The complexes were prepared by reacting equimolar quantities of copper(I) bromide and 1,2-bis-(diphenylphosphino)ethane (dppe), followed by the addition of one equivalent of the appropriate thione (L) in

dry acetone solution. This procedure, frequently used for the preparation of copper(I) halide complexes containing both heterocyclic thiones and triphenyl- or tritolylphosphine ligands, gave monomeric complexes of the formula $[CuX(PPh_3)_2L]$ [3] or dimers $[CuX(PPh_3)L]_2$ with the two copper centres being bridged either by the halogen [13] or by the thione-S atom [14]. In this work we expected that replacement of the monodentate phosphine by the bidentate dppe would lead to the formation of chelated products; however, this was not the case.

All the complexes are coloured solids soluble in chloroform, methanol, ethanol, acetone and acetonitrile. They are stable in air and moisture and can be, after the isolation, manipulated in air without appreciable decomposition. Their solutions are non-conducting in acetone and chloroform. Room temperature magnetic measurements confirm the diamagnetic nature of the compounds.

3.1. Spectroscopy

The electronic absorption spectra of the complexes in chloroform solutions are dominated by broad bands in the regions 240–250 and 280–330 nm attributable to intraligand transitions of the dppe, since the uncoordinated dppe also absorbs strongly in this region.

The infrared spectra of the compounds, recorded in the range 4000–250 cm^{-1}, show, apart from the existence of strong phosphine bands, all of the bands required by the presence of the heterocyclic thione ligands. In detail they exhibit the usual four 'thioamide bands' in the regions $\sim$1510, 1320, 1000 and 750 cm^{-1}, although in some cases partly masked by strong phosphine absorptions, as well as the characteristic NH stretching vibrations observed in the 3050–3160 cm^{-1} region. The shifts observed for these bands due to coordination (upward shifts of 15–35 cm^{-1} for thioamide I, downward shifts of 10–30 cm^{-1} for thioamide II and III) in combination with the lack of ν(SH) bands at ca. 2500–2600 cm^{-1} [15] signify the exclusive S-coordination mode of the thione ligands.

The prevailance of the thione tautomer in the complexes is further confirmed by the ^1H NMR spectra of the compounds, which display, apart from the signals expected for the phosphine and thione ligands, a single resonance at $\delta \sim 12$–14 ppm attributed to the NH proton.

3.2. Description of the structure

The ability of 1,2-bis(diphenylphosphino)ethane (dppe) to chelate Cu(I) is well known and a few double-chelated cationic $Cu(dppe)_2^+$ species have been observed [16,17]. Most of the structurally characterized binuclear copper(I) complexes involving dppe ligands are, however, of the type $[Cu_2(dppe)_3L_2]$ [18–23], in which the diphosphine units act at the same time both as chelating ligands for each of the copper atoms and as a bridge between them. The double bridging coordination mode realized in the case of the complex under investigation is quite common for univalent Group 1B metal complexes of bis(diphenylphosphino)methane (dppm) [24–27].

Bond lengths and angles are given in Table 2. The atomic arrangement in the complex is shown in Fig. 1. The basic structural unit of $[Cu(dppe)(py2SH)Br]_2$ is a dimer in which the two monomers are related by inversion. The two copper atoms are doubly bridged by two dppe ligands to form a ten-membered $Cu_2P_4C_4$ ring. The slightly distorted tetrahedral coordination around copper is completed by one sulphur atom from the thione ligand and one bromine atom.

The Cu–S and Cu–Br bond lengths lie in the range normally observed for tetrahedrally coordinated copper(I) complexes with terminal bromine and thione-sulphur donors [28]. The two individual Cu–P distances of 2.2564(13) and 2.2778(12) Å are somewhat shorter than those found for bridging dppe in other dimeric copper(I) complexes, e.g. $[Cu_2Cl_2(dppe)_3]$ (2.284(6) Å) [20] and $[Cu_2(3\text{-}Me_3Sipyt)_2(dppe)_3]$ (2.294(3) Å) [23].

The irregularities in the tetrahedral coordination geometry about the copper(I) centre are best reflected in the values of the bond angles, since only three of them are close to the ideal tetrahedral value. As expected, the largest angle [P–Cu–P = 123.14(4)°] arises between the two most bulky ligands, whereas the presence of intramolecular hydrogen bonds between the bromine and the N(1)H, C(4)H(4) and C(19)H(19A) hydrogen [N(1)···Br = 3.226(3) Å, N(1)–H = 0.880(4) Å, H···Br = 2.367(3) Å, N(1)–H–Br = 165.1(3)°; C(4)···Br = 3.585(5) Å, C(4)–H(4) = 0.951(7) Å, H(4)···Br = 2.902(5) Å, C(4)–H(4)–Br = 129.6(5)°; C(19)···Br = 3.582(4) Å, C(19)–H(19) = 0.990(5) Å, H(19)···Br = 2.703(4) Å, C(19)–H(19)–Br = 148.1(4)°] could be responsible for the moderate narrowing of the P(1)–Cu–Br angle [101.25(3)°]. It is interesting to note that all these angles are in qualitative agreement with the corresponding values already observed for a series of monomeric copper(I) halide complexes that contain one heterocyclic thione and two monodentate triphenylphosphine ligands, exhibiting the same $CuSP_2X$ core [28]. Given that steric constrains between the ligands are of significance in achieving minimum energy arrangements around the metal centre, this fact indicates that the steric requirements of the bridging dppe units within the dimer $[Cu(dppe)(py2SH)Br]_2$ are approximately of the same magnitude as those of the triphenylphosphine ligands in the monomeric complexes $[Cu(PPh_3)_2(S)X]$ [29]. It seems plausible, therefore, to invoke steric reasons in order to explain the feature of the complex under investigation, the most energetically favourable

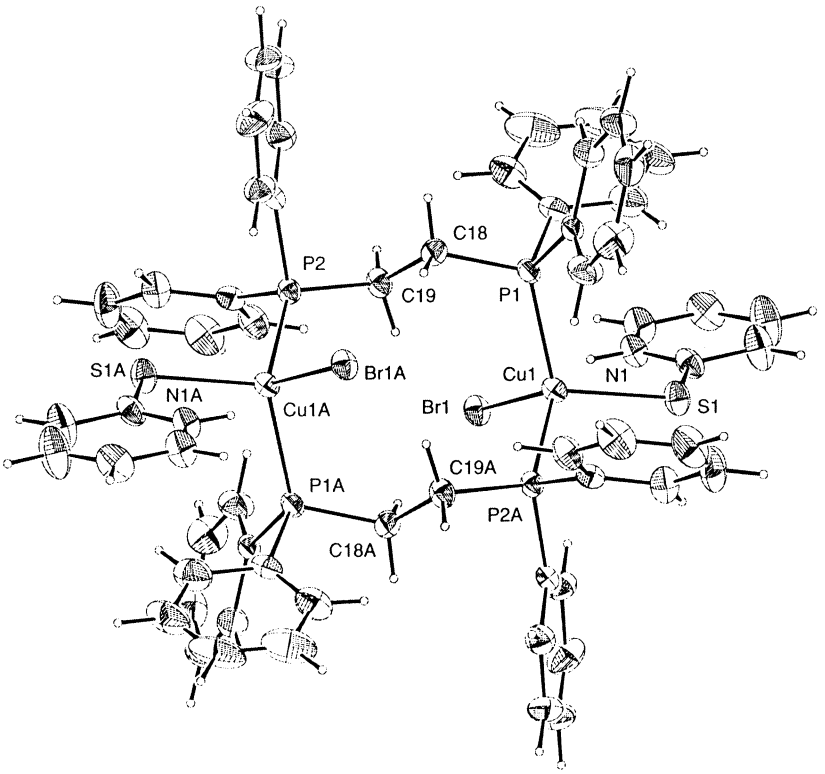

Fig. 1. A view of the complex with atom labels. Displacement ellipsoids are shown at the 50% probability level.

situation being manifested by the appearance of doubly bridged dppe ligands but not by the formation of five-membered chelate rings.

4. Supplementary material

Supplementary data are available free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk) quoting the deposition number CCDC-114060.

Received 17 February 2000; accepted 25 April 2000

Abstract

The mononuclear tungsten pentacarbonyl complexes with 1,2-bis(4-pyridyl)ethane and 4,4′-bipyridine were synthesised by the irradiation, with a UV source, of solutions of tungsten hexacarbonyl and the relevant N-containing ligand. Both complexes were characterised by single-crystal X-ray diffraction and in both structures, the coordination geometry of the tungsten atom is slightly distorted from octahedral. © 2000 Elsevier Science Ltd. Keywords: Mononuclear; Tungsten pentacarbonyl complexes; 1,4-Bipyridine; 1,2-Bis(4-pyridyl)ethane

1. Introduction

Organometallic complexes between transition metal carbonyls and N-containing heterocycles have been the subject of considerable interest in recent years. Their photochemical and electronic properties and potential for industrial applications have led to many studies for use as photosensitisers, catalysts and conducting coordinating polymers [1–6]. It is known that the photochemical properties of these transition metal complexes are dominated by low-lying charge-transfer (MLCT), excited states, which have been extensively investigated [7–18]. Attention has also been given to the electronic interactions across ligands that bridge the binuclear complexes [19–27]; on photoexcitation they provide a relatively simple route for the study and understanding of intramolecular electron transfer processes [6,28–31], magnetic coupling interactions from one metal to another and inner-sphere electron-transfer mechanisms [32–40]. Binuclear systems are particularly interesting in that electron transfer can be studied between one metal centre and another across a conjugated system. These interactions can be varied using different ligands, which will change the metal–metal distance, the extent of conjugation between metal sites, complex planarity and π-acceptor–donor ligand interactions.

Most of the studies of such complexes involve metals with different oxidation states. However, at the moment, there is substantial interest in the photochemical and optical properties of binuclear zero valent Group 6 metal carbonyl complexes [5]. Bridged complexes of the type $(OC)_5M–L–M'(CO)_5$ and $(OC)_4M–L–M'(CO)_4$ have been synthesised containing two $(OC)_5M–$ and two $(OC)_4M–$ moieties, respectively, where M, M′ = Cr, Mo or W. It is interesting to attempt to understand the photophysical and photochemical changes that occur when forming these binuclear compounds and the effect of changing the shape and degree of conjugation of the binucleating ligand between the metal centres.

Creutz and Taube first reported the synthesis of the complex Ru(II)–L–Ru(III) where the ligand [19] acts as a bridge between the two metal centres in which elec-

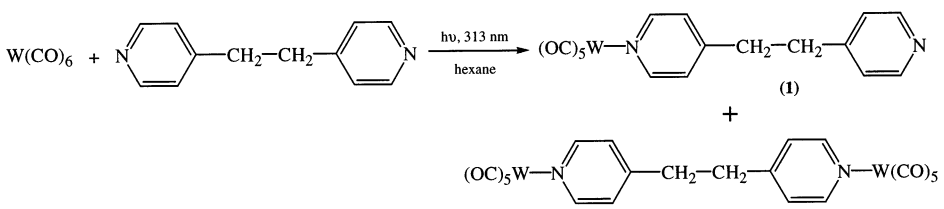
tron transfer can take place via an inner sphere mechanism. Such metallorganic dimers have been synthesised by a variety of routes in attempts to further elucidate the mechanism of electron transfer. Work on these ligand-bridged systems using tungsten in heteronuclear complexes has been reported [5]. These complexes were found to be stable in solid form, but in solution are air and/or light sensitive. The instability of these complexes is thought to be due to cleavage of the M–L–M bond as shown in the bridged dimer $(OC)_5Mo(pyz)Mo(CO)_5$. There is interest in pyrazine-type-bridged dimers where the two nitrogen donors are *trans*- to each other which focuses on the electronic, photochemical and photophysical properties of these complexes. Binuclear 4,4′-bipyridine systems have also been synthesised, and show similar light and air sensitivity but as yet, have not been the subject of investigation. Similarly to pyrazine, the nitrogen donors in 4,4′-bipyridine are *trans*- to each other where the metal–metal separation is increased from 6.9 Å for pyrazine to 11.2 Å for 4,4′-bipyridine, and so far no X-ray crystal structure has been reported for these complexes.

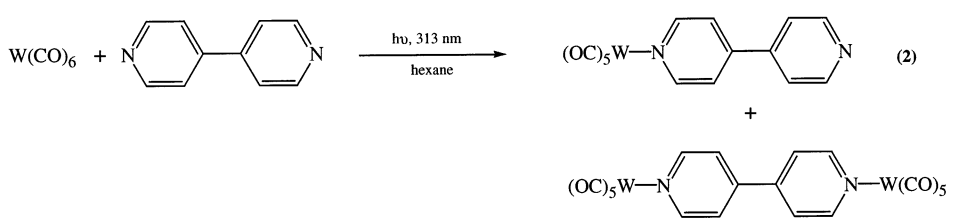
Our work has been concerned with the synthesis of complexes between various substituted pyridine derivatives and tungsten hexacarbonyl (see Scheme 1). In this paper, we report the crystal and molecular structures of pentacarbonyl-1,2-bis(4-pyridyl)ethanetungsten (**1**) and pentacarbonyl-4,4′-bipyridinetungsten (**2**). The synthesis and characterisation of such 1:1 adducts is a step towards a route to synthesise binuclear hetreonuclear complexes which may have interesting electronic properties.

2. Experimental



2.1. Pentacarbonyl-1,2-bis(4-pyridyl)ethanetungsten (*1*)

A solution of 1,2-bis(4-pyridyl)ethane (0.368 g, 2 mmol) and finely ground tungsten hexacarbonyl (1.407 g, 4 mmol) in dry N_2 purged hexane (150 ml) was irradiated at $\lambda = 313$ nm using a 200 W medium pressure tungsten lamp. After 2 h reaction time a green solution and a yellow precipitate were obtained. The yellow precipitate was isolated and the solution taken to dryness. The residual solid contained a mixture of the mononuclear and binuclear materials, which were separated by column chromatography (alumina, 50:50 hexane–benzene) the monomer crystallised from this as fine yellow needles. m/z 508 [M^+], 480 [$M^+ - CO$] and 452 [$M^+ - 2 \times CO$]. Found: C, 37.4; H, 1.6; N 6.0; Calc.: C, 37.5; H, 1.7; N, 5.9%.



2.2. Pentacarbonyl-4,4′-bipyridinetungsten (*2*)

The reaction of 4,4′-bipyridine (0.312 g, 2 mmol) with finely ground tungsten hexacarbonyl (1.41 g, 4 mmol) in dry N_2 purged hexane (150 ml) was carried out with UV irradiation at $\lambda = 313$ nm, 200 W medium pressure tungsten lamp, and after 1.5 h afforded a yellow coloured suspension containing the mononuclear and binuclear complexes. The reaction was monitored by FTIR spectroscopy. During this reaction the binuclear complex precipitated from solution as an orange crystalline solid and the mononuclear complex remained in solution and was isolated by column chromatography

(alumina, 50:50 hexane–benzene), to yield a product which crystallised as needles from a 50:50 hexane–benzene mixture. m/z 480 [M^+], 452 [$M^+ - CO$] and 424 [$M^+ - 2\times CO$]. Found: C, 40.1; H, 2.3; N, 5.7; Calc.: C, 40.2; H, 2.4, N, 5.5%.

2.3. X-ray crystallography

The structure of the subject compounds were determined by single X-ray methods. Measurements were made on samples mounted on a glass capillary. The intensity data were collected with a CAD4 diffractometer in a $\omega/2\theta$ scan mode with graphite-monochromated Mo Kα, and corrected for absorption by the empirical method (ψ-scan) [41]. The unit cell parameters were determined by a least squares refinement on diffractometer angles for automatically centred reflections. The structure was solved by the heavy atom method using the SHELX-97 program package [42] and then refined anisotropically (non-hydrogen atoms) by a full-matrix least-square on F^2. All hydrogen atoms were calculated geometrically (riding model) using the AFIX command on the SHELX-97 program. The program PLATON for Windows [43] was used for drawing molecular structures. Crystal data and details of the intensity measurements are given in Table 1. Atomic coordinates, thermal parameters and bond lengths and angles have been deposited at the Cambridge Crystallographic Data Centre.

3. Results and discussion

A two-stage reaction is often used in the synthesis of these binuclear complexes where usually the initial photolysis of tungsten hexacarbonyl in 0.1 M THF in hexane yields a mononuclear THF adduct. This on further thermochemical reaction with the same or a different pyridine ligand derivative gives a binuclear metal complex plus some of the mononuclear component [6,28–31]. In this instance the synthesis of the THF adduct was bypassed and direct photolysis of 2 mol of the pyridine derivative with 1 mol of tungsten hexacarbonyl in dry hexane was used as a synthetic route to the mononuclear complex.

The structure of complex **1** was determined by single-crystal X-ray diffraction methods. The unit cell and molecular structures are shown in Figs. 1 and 2, respectively. Selected bond distances and angles are given in Table 2. The structure is based on mononuclear units with four molecules of the complex in the unit cell. The tungsten atoms lie on the faces of the cell. The structure shows coordination at one nitrogen atom of 1,2-bis(4-pyridyl)ethane to the tungsten atom $(WCO)_5$ leaving the other nitrogen uncoordinated. The non-coordinated pyridyl ring lies almost perpendicular to the complexed ring and probably maximises packing. The molecule

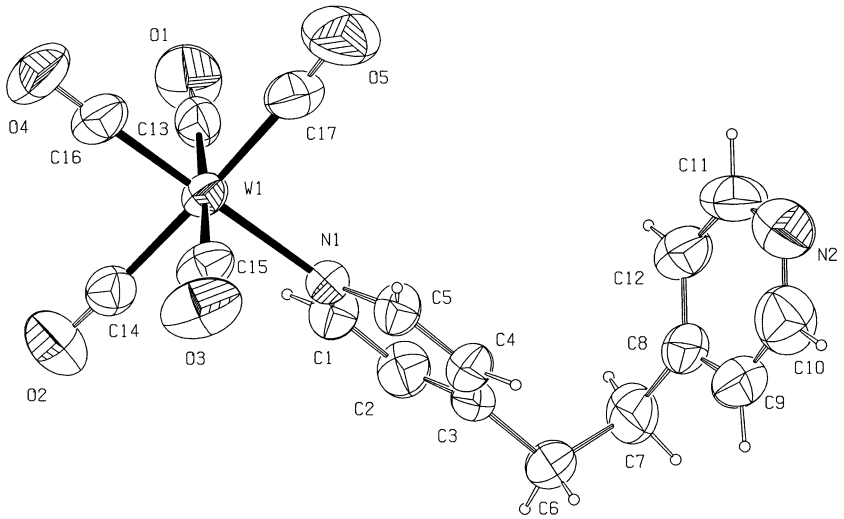

Fig. 2. The molecular structure of pentacarbonyl-1,2-bis(4-pyridyl)ethanetungsten.

has C_1 symmetry. The tungsten is hexacoordinated through the ring nitrogen atom, an axial carbon monoxide group and four equatorial carbon monoxide groups, the metal can be defined as distorted octahedral. The W1–N1 bond distance is 2.271(4) Å whilst the corresponding axial W1–C16 carbon monoxide bond length is 1.955(6) Å which is somewhat shorter. The four axial carbon monoxide bond lengths W1–C13, W1–C15, W1–C14 and W1–C17 are 2.029(6), 2.025(6), 2.025(7) and 2.037(7) Å, respectively, which are all comparable. It is interesting to note that the bond angles C13–W1–C15 177.2(2)° and C14–W1–C17 177.8(2)° both deviate away from linearity. Van der Waals repulsions between the H atoms on the complexed ring and the equatorial carbon monoxide groups attached to the tungsten atom may cause distortion away from octahedral.

The structure of complex **2** (Fig. 3) was also determined by single-crystal X-ray diffraction methods. Selected bond lengths and bond angles are given in Table 3. The complex has a C_2 axis through the central atoms C3–W1–N1–N2. Tungsten is hexacoordinated with a single ring nitrogen atom, a corresponding axial carbon monoxide group and four equatorial carbon monoxide groups. The W1–N1 bond length is 2.273(5) Å, which is identical to that found in the pentacarbonyl-1,2-bis(4-pyridyl)ethane tungsten analogue, complex **1**. The tungsten-axial carbon monoxide bond length is 1.954(8) Å, which is similar to the related bond length in complex **1** (1.955(6) Å). The four axial carbon monoxide bond lengths, W1–C1, W1–C1a, W1–C2 and W1–C2a are 2.025(6), 2.025(6), 2.031(6) and 2.031(6) Å, respectively, and are almost identical in length. The *trans*-equatorial bond lengths C1–W1–C1a 176.2(3)° and C2–W1–C2a 176.7(3)° again both deviate away from linearity of 180° and very slightly more than in complex **1.** Similarly this exhibits an distorted octahedral environment for the tungsten atom whereby this distortion is again thought to be due to van der Waals repulsion between the H atoms of the complexed ring and the equatorial carbon monoxide groups coordinated to the tungsten atom.

4. Conclusions

The single-crystal X-ray structures of complexes **1** and **2** have been successfully carried out and analysed. Further photochemical studies will be carried out on these complexes. Complex **2** has a linear conjugated system but complex **1** is non-linear where the two methylene groups break the π-conjugation within this complex. The tungsten–nitrogen bond lengths in complex **1** and complex **2** are almost identical 2.271(4) and 2.273(5) Å, which compares well with that observed in the bidentate metallacycle $Me_2Sn(CHSiMe_3C_5H_3N)_2$-$W(CO)_4$ [44] of 2.215(7) and 2.228(7) Å.

Other similar complexes containing the π-system, tetracarbonyl-2,2-bipyridinetungsten and pentacarbonyl-1,2-bis(4-pyridyl)ethenetungsten have been synthesised and we are awaiting the X-ray crystallographic analysis. This will permit further studies of mononuclear substitution and π-conjugation within these complexes.

5. Supplementary material

Complete bond lengths and angles, and co-ordinates and displacement parameters have been deposited at the Cambridge Crystallographic Centre. Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 140616 and 146017. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Heterodinuclear complexes of the types [(dppe)M(μ-$SR)_2$Pd(η^3-allyl)][ClO_4] (M = Pd or Pt) and [(dppe)Pt(μ-SC_2H_4S)Pd(η^3-allyl)][ClO_4] [dppe = 1,2-bis(diphenylphosphino)ethane; allyl = C_3H_5 or C_4H_7] have been obtained by reaction of the corresponding *cis*-dithiolato complexes, [M($SR)_2$ (dppe)] or [Pt(SC_2H_4S)(dppe)], and [Pd(η^3-allyl)($PhCN)_2$][ClO_4]. The identity of these complexes has been established by NMR (^{1}H and ^{31}P) spectroscopy. The crystal structure of [(dppe)Pd(μ-SC_6H_4Me-*p*)$_2$Pd(η^3-C_3H_5)][ClO_4] has been determined by single-crystal X-ray methods. The *p*-tolyl groups on the sulfur atoms adopt a *syn* conformation with respect to the central Pd–S_2–Pd core. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Palladium; Platinum; Thiolate complexes; Allyl complexes

1. Introduction

The relevance of transition-metal complexes with S-donor ligands as models of biologically redox-active metalloproteins [1] has stimulated interest in the chemistry of metal thiolates [2,3]. Platinum and palladium μ-thiolate complexes are also of recent interest due to their possible use in homogeneous catalysis [4–6]. For example, systems of the type [Pt_2(μ-SR)(μ-$Cl)Cl_2(PR'_3)_2$]/$SnCl_2 \cdot H_2O$ have a high catalytic activity in the hydrogenation of styrene [7].

We have recently described the synthesis of di- and tri-nuclear nickel(II), palladium(II) or platinum(II) complexes with bridging thiolato groups of the types [NBu_4]$_2$[$M_2(C_6F_5)_4$(μ-$SR)_2$], [NBu_4]$_2$[$M_3(C_6F_5)_4$(μ-$SR)_4$] (M = Ni, Pd or Pt) [8,9] and [{Pd($CH_2C_9H_6N$)}$_2$(μ-SR)(μ-O_2CR'')] ($CH_2C_9H_6N$ = 8-quinolylmethyl) [10]. Dinuclear thiolato-bridged allylpalladium complexes have been reported recently [11]. On the other hand, the synthesis and study of heterobinuclear complexes have been the subject of active research over the past years, as they can serve as models for active intermediates in heterobimetallic catalysis [12].

In this paper we report the preparation of a variety of heterodinuclear MM′ (M = Pd, Pt; M′ = Pd) complexes with bridging thiolato ligands by using *cis*-dithiolato complexes [M($SR)_2$ (dppe)] [M = Pd or Pt; dppe = 1,2-bis(diphenylphosphino)ethane] and [Pd(η^3-allyl)($PhCN)_2$]$^+$, which contain the readily removable PhCN ligands, as building blocks.

2. Experimental

The C, H, N, S analyses were performed with a Carlo Erba model EA 1108 microanalyzer. Decomposition temperatures were determined with a Mettler TG-50 thermobalance at a heating rate of 5°C min^{-1} and the solid sample under nitrogen flow (100 ml min^{-1}). Molar conductivities were measured in acetone solution (c Å 5×10^{-4} mol dm^{-3}) with a Crison 525 conducti-

meter. The NMR spectra were recorded on a Bruker AC 200E or Varian Unity 300 spectrometer, using $SiMe_4$ and H_3PO_4 as standards, respectively. Infrared spectra were recorded on a Perkin–Elmer 1430 spectrophotometer using Nujol mulls between polyethylene sheets. Solvents were dried by the usual methods. The starting complexes $[M(SR)_2](dppe)$ (M = Pd or Pt), $[Pt(SC_2H_4S)(dppe)]$ [13] and $[Pd(\eta^3\text{-allyl})(PhCN)_2][ClO_4]$ (allyl = C_3H_5 or C_4H_7) [14] were prepared by procedures described elsewhere.

Safety note. **Caution!** Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of these materials should be prepared, and they should be handled with great caution.

2.1. Preparation of complexes *1–11*

To a solution of the corresponding benzonitrile complex $[Pd(\eta^3\text{-allyl})(PhCN)_2][ClO_4]$ (0.3 mmol) in methanol (20 cm^3) was added the corresponding *cis*-dithiolato complex $[M(SR)_2$ (dppe)] or $[Pt(SC_2H_4S)(dppe)]$ (0.3 mmol) with constant stirring at room temperature (r.t.) (2 h for the palladium compounds or 4 h for the platinum complexes) to afford a suspension from which the solvent was partially evaporated under reduced pressure and, after addition of water, filtered-off. The desired yellow complex was air-dried.

2.2. Determination of the X-ray crystal structure of complex **2**

A single crystal of complex **2** (approximate dimensions 0.55 × 0.37 × 0.24 mm) was mounted on an Enraf–Nonius CAD4 diffractometer equipped with a graphite monochromator for Mo Kα radiation. The crystallographic data are shown in Table 1 (Fig. 1). Accurate cell parameters were determined by least-squares fitting of 25 high-angle reflections. The scan method was ω–2Θ and the empirical Psi scan mode absorption correction was applied. The structure was solved by heavy atom methods SHELXS-86 [15] and refined anisotropically on F^2 [16]. Hydrogen atoms were introduced in calculated positions. The residual peaks in the final Fourier difference synthesis were located close to the metal atoms.

3. Results and discussion

The mononuclear palladium and platinum complexes [M(SR)$_2$ (dppe)] (M = Pd or Pt) or [Pt(SC$_2$H$_4$S)(dppe)] [dppe = 1,2-bis(diphenylphosphino)ethane] react with [Pd(η^3-allyl)(PhCN)$_2$][ClO$_4$] (allyl = C$_3$H$_5$ or C$_4$H$_7$) in a 1:1 molar ratio to give heterodinuclear complexes of the types [(dppe)M(μ-SR)$_2$Pd(η^3-allyl)][ClO$_4$] (M = Pd or Pt) (**1**–**9**) and [(dppe)Pt(μ-SC$_2$H$_4$S)Pd(η^3-allyl)][ClO$_4$] (**10** and **11**) with the concomitant release of PhCN (Scheme 1).

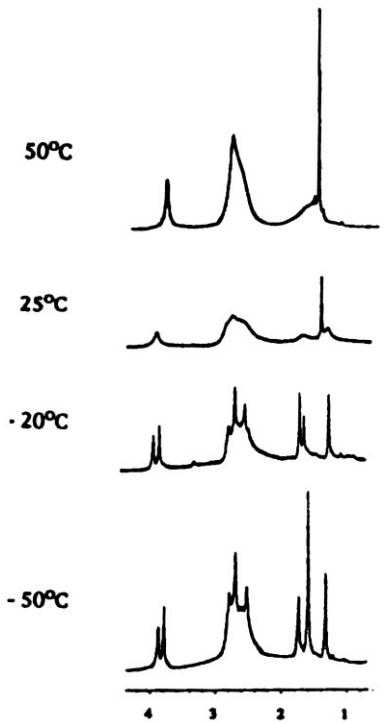

Fig. 2. Variable-temperature ^{1}H NMR spectrum of **11**.

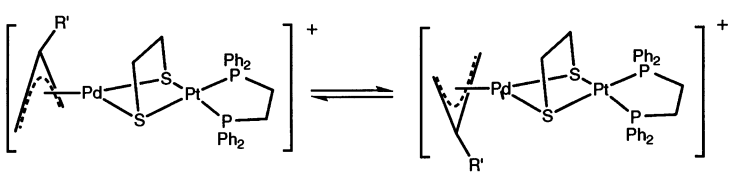
The new complexes **1**–**11** have been characterized on the basis of partial elemental analyses and spectroscopic data and they behave in acetone as 1:1 electrolytes [17], in accordance with the formulas given.

The ^{31}P NMR spectra show a single resonance and those of the platinum complexes are flanked by the satellites due to coupling to ^{195}Pt, the coupling constant being in the range 2700–3100 Hz.

The ^{1}H NMR spectra of complexes **1**–**9** show a single set of resonances, indicating that both thiolate ligands are equivalent and the free rotation of the thiolate aryl or alkyl group around the C–S bond. The ^{1}H NMR spectra of complexes **1**–**3** and **5**–**7** show also three resonances with the expected intensity ratio (1:2:2) and peak multiplicities in the allylic group region (multiplet for CC*H*C, doublet for *syn* protons, and doublet for *anti* protons) whereas the spectra of complexes **4** and **8**–**9** show three singlet resonances for the methylallyl group with the expected intensity ratio of 2:2:3.



However, the ^{1}H NMR spectra of complexes **10** and **11** show broad bands at room temperature, which suggests a fluxional behavior in the ^{1}H NMR scale of time. Rotation of the η^{3}-allyl group has been suggested as a possible dynamic process [18]. The ^{1}H NMR spectrum of complex **11** at -50°C (Fig. 2) shows two different singlets at δ 3.91 and 3.83 assigned to *syn* protons and two additional singlets at δ 1.86 and 1.80 due to the Me protons of the allyl groups of the two conformational isomers tentatively shown in Scheme 2 (signals due to the *anti* protons are obscured by resonances of dppe and SC_2H_4S ligands).

Table 2
Selected distances (Å) and bond angles (°) for complex **2**

		C(39)–Pd(2)–S(1)	105.58(14)
		C(41)–Pd(2)–S(1)	171.3(2)
		C(40)–Pd(2)–S(2)	137.1(2)
		C(39)–Pd(2)–S(2)	172.24(14)
		C(41)–Pd(2)–S(2)	105.1(2)
		C(41)–C(40)–C(39)	142.4(8)

Suitable crystals of complex **2** were grown from acetone–ethanol. The structure of **2** is shown in Fig. 1 and selected lengths and angles in Table 2. Both metal atoms, Pd(1) and Pd(2), are coordinated in a slightly distorted square-planar geometry and the phenyl groups on the sulfur atoms adopt a *syn* arrangement with respect to the central Pd–S_2–Pd core. The same conformation has been recently found in $[(C_6F_5)_2Ni(\mu\text{-}SPh)_2Pd(dppe)]$ [19], $[\eta^5\text{-}C_5H_4SiMe_3)_2Ti(\mu\text{-}SPh)_2Pd(C_6F_5)_2]$ [20] and $[\eta^5\text{-}C_5H_5)Ti(\mu\text{-}SMe)_2PtMe_2]$ [21].

The Pd(1)–S distances are 2.3742(3) and 2.3783(8) Å, significantly longer than Pd(2)–S distances, 2.3465(8) and 2.3524(9) Å. This is due to the strong *trans* influence of the phosphine ligand [19]. The Pd···Pd distance is 3.2428(4) Å, showing no significant metal–metal interaction. The PdSPdS ring adopts a hinged square-planar geometry with a dihedral angle of 129.9° along

Scheme 2.

the S···S line. As expected, the PdP_2C_2 chelate ring is non-planar. The Pd-η^3-allyl distances are in the range expected for a Pd(II)-allyl.

4. Supplementary material

Supplementary data for complex **2** are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition number CCDC 139771. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Cadmium(II) complexes of fully condensed Schiff-base ligands derived from two different symmetrical and asymmetrical tripodal tetraamines and 2-acetylpyridine; the novel observations for heptadentate mono-capped trigonal antiprismatic Schiff-base complexes

Received 20 March 2000; accepted 26 April 2000

Abstract

In the presence of cadmium(II), 2-acetylpyridine condenses with tris(3-aminopropyl)amine, tpt, and bis(3-aminopropyl)(2-aminoethyl)amine, ppe, in absolute methanol to produce two fully condensed potentially heptadentate Schiff-base complexes, $[Cd(py_3tpt)](ClO_4)_2$ and $[Cd(py_3ppe)](ClO_4)_2$. X-ray structure analysis of the former complex shows mono-capped distorted trigonal antiprism geometry wherein the Cd–unique nitrogen distance is 2.486 Å. In comparison with the weighted mean of other Cd–N distances, 2.425 Å, this indicates a 'bonding' interaction. The mean of the bond angles about the bridging amine atom (C–N1–C), 107.43°, is quite close to sp^3 hybridization as expected for an unconstrained tertiary amine nitrogen atom. The ^1H NMR, COSY and HMQC spectra shows six inequivalent protons, two for each methylene group caused by the rigidity of resulting six-membered chelate rings. © 2000 Elsevier Science Ltd. Keywords: Cadmium(II) complexes; Schiff-base ligands; Symmetrical complexes; Asymmetrical complexes; Heptadentate ligands

1. Introduction

Schiff-base complexes are considered to be among the most important stereochemical models in main group and transition metal coordination chemistry due to their preparative accessibility and structural variety [1,2]. We have prepared some symmetrical and asymmetrical tripodal tetraamines and their macrocyclic and acyclic Schiff-base complexes of Ni(II) and Cu(II) [3–5]. Other workers and we have reported the synthesis of fully condensed potentially heptadentate Schiff-base complexes [6–8]. N.J. Rose suggested a monocapped trigonal antiprismatic coordination polyhedron for latter complexes [9] and X-ray analysis have shown that these complexes are considerably distorted from trigonal antiprism (TAP), toward trigonal prism (TP). The metal–unique nitrogen distance is much longer than other metal nitrogen distances and there is the intriguing question about the nature of this bond. Some of the important features of these complexes are now described in text books and reviews where particular attention is given to the relationship between the M–N bond distances and the electronic configuration of the metal ion [7,10,11]. We now report usage of one symmetrical and one asymmetrical tetraamine, tris(3-aminopropyl)amine, tpt, and bis(3-aminopropyl)(2-aminoethyl)amine, ppe, to prepare two acyclic potentially heptadentate Schiff-base complexes of Cd(II). We also make a comparison with previous data, in order to study the influence of the nature of the ligand as well as the metal ion on the metal–ligand distances and geometry of this type of complex.

2. Experimental

2-Acetylpyridine was obtained from Aldrich and was used without further purification. The tripodal tetraamine ligands, tpt and ppe, were synthesized according to methods that we have earlier reported [3,5]. IR and NMR spectra were measured on Schimadzu IR-435, Bruker DPX 300 and 400 NMR spectrometer, respectively.

2.1. [Cd(py$_3$tpt)](ClO$_4$)$_2$·H$_2$O (1)

2-Acetylpyridine (0.182 g, 1.5 mmol) was added to a solution of tpt·4HCl (0.177 g, 0.5 mmol) and $Cd(NO_3)_2 \cdot 4H_2O$ (0.111 g, 0.5 mmol) and NaOMe (0.216 g, 4 mmol) in absolute MeOH (150 cm^3). The resulting colorless solution was boiled under reflux and stirred for 36 h, during which time it changed to pink. $NaClO_4$ (0.4 g) was added, the solution was filtered and the filtrate reduced to ca. 10 cm^3. Crystalline compound was obtained by slow diffusion of Et_2O vapor into this solution, yielding 0.2 g (60%) of the complex, $[Cd(py_3tpt)](ClO_4)_2 \cdot H_2O$ (**1**). *Anal.* Found: C, 43.5; H, 4.6; N, 11.3. Calc. for $C_{30}H_{41}N_7Cl_2O_9Cd$: C, 43.56; H, 4.96; N, 11.8%. FAB MS (positive FAB in nitrobenzyl alcohol): m/z 710 [M − ClO_4^+], isotopic pattern corresponds to the proposed formulation. 2.2. [Cd(py$_3$ppe)](ClO$_4$)$_2$ (2)

This compound was prepared analogously using ppe·4HCl. After the concentration and cooling stages, a yellowish powder was obtained and recrystallized by slow diffusion of Et_2O vapor into a solution in methanol producing white powder. yielding 0.11 g (32%) of the complex, $[Cd(py_3ppe)](ClO_4)_2$. *Anal.* Found: C, 43.5; H, 4.5; N, 12.1. Calc. for $C_{29}H_{37}N_7Cl_2O_8Cd$: C, 43.8; H, 4.7; N, 12.4%. FAB MS (positive FAB in nitrobenzyl alcohol): m/z 696 [M − ClO_4^+], isotopic pattern corresponds to the proposed formulation. IR (Nujol mull, cm^{-1}): 1640, 1589,1566, 1100 vs.

2.3. X-ray crystal structure determination

Suitable crystals of **1** were obtained by slow diffusion of diethyl ether vapor into a methanol solution. Three-dimensional X-ray data were collected at room temperature in the $4.32 < 2\theta < 50.08°$ range on a Rigaku AFC65 diffractometer by the ω–2θ method, using Mo Kα radiation ($\lambda = 0.71073$ Å). The structures was solved by Patterson and Fourier techniques and refined by full-matrix least-squares regression (SHELX97) [12]. Complex scattering factors were taken from [13] and from SHELX97. The parameters of the crystal, data collection, solution and refinement are given in Table 1.

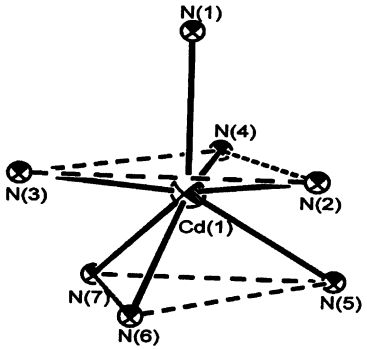

Fig. 2. The nitrogen atoms arrangement around the metal ion in compound **1**.

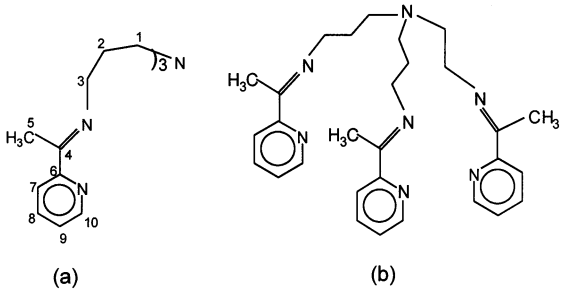

Fig. 3. Two potentially heptadentate ligands; py_3tpt (a) and py_3ppe (b).

3. Results and discussion

The synthesis of both complexes is confirmed by elemental analysis IR and FAB mass spectroscopy. Condensation of all primary amine groups is confirmed by the lack of N–H stretching bands in the IR region 3150–3450 cm^{-1} and the presence of strong C=N (Schiff-base) stretching bands at 1630 and 1640 cm^{-1} for compounds **1** and **2**, respectively. The presence of lattice water for compound **1** was shown by bands at 3500 and 3590 cm^{-1}. Broad intense bands at ca. 1100 cm^{-1} due to ClO_4^- shows no splitting, indicating the absence of coordination of ClO_4^- for both complexes. The structure of compound **1** is also determined by NMR techniques and X-ray crystal structure analysis.

3.1. X-ray crystal structure analysis

X-ray crystal structure analysis of complex **1** shows that the three imine, three pyridine and unique tertiary nitrogen donor atoms arranged at apices of a distorted capped trigonal antiprism (Figs. 1 and 2). Selected bond lengths and bond angles of this complex together with some TAP structural model parameters [7] are given in Table 2. The Cd–N bond lengths are in the

normal range, and the Cd(II)–unique nitrogen distance, 2.486 A°, is about the weighted mean of the other Cd–N distances, 2.425 Å, and is even shorter than one of the Cd–N distances (Cd–N7). In other similar complexes of py_3tren with Cd(II) and other metal ions, $[M(py_3tren)]^{2+}$ the metal–unique nitrogen distance is long for an actual bond. In both $[Cd(py_3tpt)]^{2+}$ and $[Cd(py_3tren)]^{2+}$ the Cd–imine bond lengths are shorter than Cd–pyridine bond lengths. As can be seen in Fig. 2 the Cd(II) ion is displaced toward the imine nitrogen triangle and the mean of Cd–imine distances, 2.350 Å, is shorter than that of Cd–py distances, 2.497 Å. The cadmium ion is so near to imine nitrogen plane that the mean of three imine–Cd–imine angles, 117.6°, and three N1–Cd–imine angles, 80.96°, are near to 120 and 90°, respectively. In the cases of py_3tren complexes, the mean of the metal–imine distances is shorter than that of the metal–pyridine distances but there is not such a noticeable displacement toward the imine nitrogen triangle. The mean of the bond angles about the bridging amine atom (C–N1–C), 107.43°, is close to sp^3 hybridization as expected for an unconstrained tertiary amine nitrogen atom, but for $[M(py_3tren)]^{2+}$ complexes this angle varies from 112° in the Mn(II) and Cd(II) complexes up to a maximum value of 120° in the Fe(II) complex.

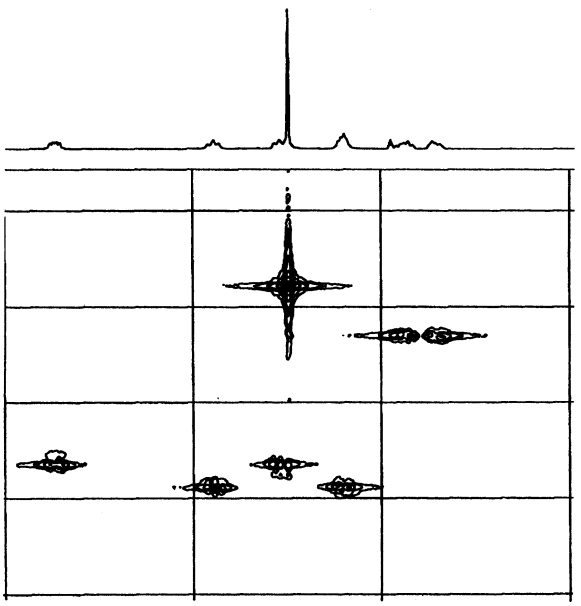

Fig. 4. The HMQC spectrum of compound **1** at the aliphatic region.

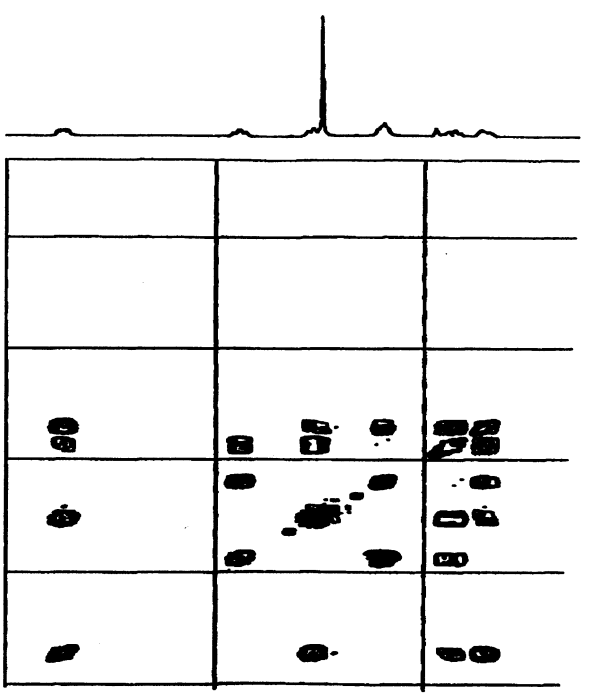

Fig. 5. The COSY spectrum of compound **1** at the aliphatic region.

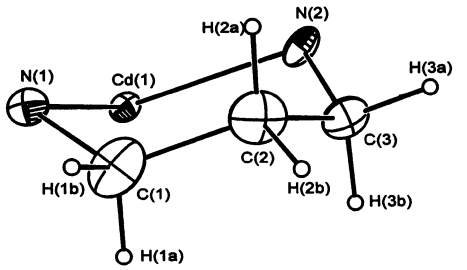

Fig. 6. One of the rigid six-membered chelate rings in compound **1**.

3.2. NMR spectra

Compound **1** was studied with ^1H NMR, ^{13}C NMR, DEPT, COSY and HMQC spectroscopy. While the ^{13}C NMR spectrum shows that there are, as we expect, three distinct methylene carbons but its ^1H NMR, COSY and HMQC spectra shows six kinds of protons two for each methylene groups (Figs. 4 and 5). The COSY spectrum confirms the geminal coupling of two protons of each methylene group. Such geminal coupling of protons will occur in the rigid six-membered rings and we observed this even up to 60° (maximum limit of temperature in actonitrile solution). It seems from COSY spectrum that both protons of C3 (Fig. 3a) have a coupling to protons of C2 but between protons of C1 and C2 the protons with higher chemical shifts couple with each other and there is also similar coupling between protons with smaller chemical shifts. One of these six-membered rings of compound **1** is shown in Fig. 6. The protons H1a, H2a and H3b are axial and protons H1b, H2b and H3a are equatorial. The N1 is a unique tertiary nitrogen atom and N2 is one of the three imine nitrogen atoms. There is no plane of symmetry through any of the carbon atoms, so that the methylene protons are in principle all non-equivalent. This is of course true for all other tren and tpt derivatives but the effects are not seen in their NMR spectra.

The additional factor in the present case is the rigidity of the chelate rings, which is forced by the strong co-ordinating of N(1) and the anchoring effect of the pyridine units.

4. Conclusion

The existence of a 'bonding' interaction between the capping unique nitrogen atom and the cadmium ion in **1** was confirmed by X-ray analysis and NMR investigations. The stronger co-ordination of the unique nitrogen atom to the metal ion in this complex than in the previously prepared $[M(py_3tren)]^{2+}$ complexes is probably due to the great intrinsic flexibility of the tri-methylene chains in $[Cd(py_3tpt)]^{2+}$ complex. The NMR spectrum of this complex shows the three resulting six-membered chelate rings are so rigid that two axial and equatorial protons of each methylene group are non-equivalent.

5. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 141926. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 18 February 2000; accepted 19 May 2000

Abstract

Several homoleptic silyl complexes of arsenic(III) and antimony(III), namely $As(SiR_2R')_3$ (R = Me, R′ = cyclohexyl (Cy); R = Me, R′ = Ph; R = R′ = Ph) and $Sb(SiPh_3)_3$, have been prepared via salt elimination reactions of $R_2R'SiCl$ and Na_3E (E = As or Sb). The structures of two complexes, $As(SiMe_2Cy)_3$ and $Sb(SiPh_3)_3$, have been determined by X-ray crystallography. Both structures possess a three-coordinate Group 15 element centre with a pyramidal geometry of the ESi_3 core. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Homoleptic silyl complexes; Arsenic; Antimony

1. Introduction

There has been a significant amount of interest in the chemistry of silyl complexes of arsenic(III) and antimony(III) over the last few decades. These compounds, in combination with Group 13 species (e.g. halides and alkyls), are excellent starting materials for preparing molecules containing Group 13 element-arsenic or -antimony bonds [1]. Such compounds have attracted a great deal of attention due to their potential applications as single-source precursors for the deposition of thin films of the corresponding semiconductor material by organometallic chemical vapour deposition (OMCVD) [1,2]. Silylarsines have also been used for the preparation of inter-Group 15 element phases [3].

Tris(silyl)arsenic and antimony complexes were first synthesised about 30 years ago [4–10], with further developments occurring some years later [11–15]. Although there have been studies into the synthesis and reactivity of silyl Group 15 complexes [4], structural characterisation of these compounds have emerged only very slowly. Until recently, single crystal X-ray diffraction studies of silyl complexes of As and Sb were limited to $E_2(SiMe_3)_4$ (E = As or Sb) [16,17] and the lithium–arsenide and antimonide salts, $[Li(L)_n][E(SiMe_3)_2]$ (where $n = 1$, E = As or Sb, L = DME; $n = 2$, E = As, L = thf) and $[Li(thf)_2][As(SiPr^i_3)(SiFAr_2)]$ (Ar = 2,4,6-triisopropylphenyl) [18–20]. The only examples of structures of tris(silyl)arsenic and antimony complexes include $As(SiMe_2Bu^t)_3$ (**1**) [21], $As(SiMe_3)_2(SiPh_3)$ (**2**) [21], and $Sb(SiMe_2Ph)_3$ (**3**) [22].

In this contribution, we present the synthesis and characterisation of a series of tris(silyl) complexes of arsenic(III) and antimony(III). Our motivation was to explore further the structural characteristics of these complexes and to isolate a range of stable silyl complexes.

2. Results and discussion

The reaction between Na_3As (generated in situ from arsenic powder and sodium metal in thf) and chlorodimethylcyclohexylsilane in thf at reflux temperature afforded, after work-up, colourless crystals of the complex $As(SiMe_2Cy)_3$ (**4**) (Cy = cyclohexyl), according to Eq. (1):

$$Na_3E + 3R_2R'SiCl \rightarrow E(SiR_2R')_3 + 3NaCl \quad (1)$$

4; E = As, R = Me, R′ = Cy
5; E = As, R = Me, R′ = Ph

7; E = Sb, R = Ph, R′ = Ph

Similar methods for the preparation of other tris(silyl)arsenic complexes have been described previously [14,15]. Spectroscopic and analytical data were consistent with the anticipated formula of **4** and the structure was confirmed by X-ray crystallography, the results of which are shown in Fig. 1. Selected bond lengths and angles are given in Table 1. The solid state structure of **4** consists of individual molecules with no unusually short intermolecular contacts between the monomeric units. Although not required crystallographically, individual molecules of **4** possess approximate C_3 symmetry. The geometry about the arsenic centre is pyramidal [av. Si–As–Si 101.6(3)°] with the average As–Si bond length of 2.361(7) Å being similar to those observed in **1** and **2** [21]. The relative orientation of the three dimethylcyclohexylsilyl groups at the arsenic centre is all-staggered with each cyclohexyl group placed between two methyl groups of a neighbouring silyl group. As such, the structure is similar to that observed for **1** [21] and the related antimony complex $Sb(SiMe_2Ph)_3$ (**3**) [22].

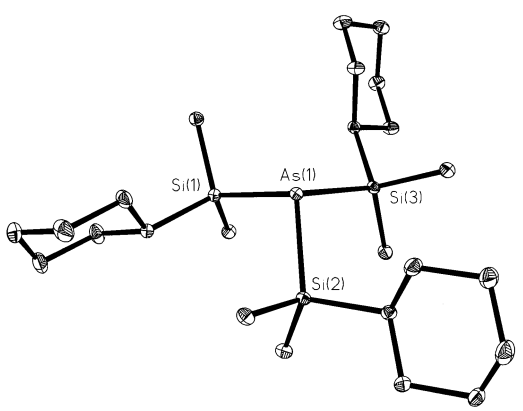

Fig. 1. Molecular structure of compound **4** showing the atom numbering scheme. Atoms are drawn as 30% probability ellipsoids. Hydrogen atoms are omitted for clarity.

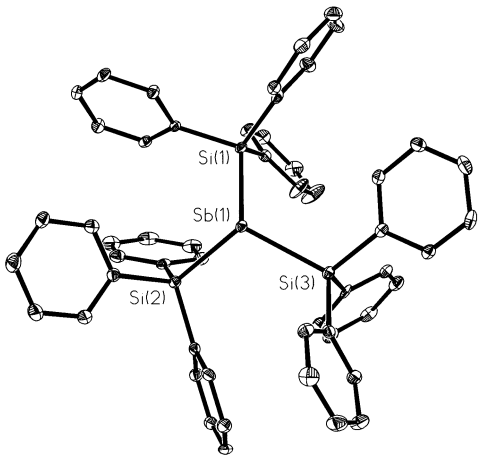

Fig. 2. Molecular structure of compound **7** showing the atom numbering scheme. Atoms are drawn as 30% probability ellipsoids. Hydrogen atoms are omitted for clarity.

A similar reaction between Na_3As and chlorodimethylphenylsilane in thf at reflux temperature afforded, after work-up, colourless crystals of the complex $As(SiMe_2Ph)_3$ (**5**) (Eq. (1)). Spectroscopic and analytical data for **5** were consistent with the expected formula. Unfortunately, an attempted crystal structure determination was only partially successful due to disorder problems. However, the structure of **5** is apparently similar to that of compound **1** [21], **4** and the related antimony derivative **3** [22].

The analogous reaction between Na_3As and chlorotriphenylsilane in thf at reflux temperature (Eq. (1)) resulted in a cream crystalline solid, spectroscopic and analytical data for which were consistent with the formula $As(SiPh_3)_3$ **6**. Unfortunately X-ray quality crystals of **6** could not be isolated. Interestingly, previous attempts to prepare **6** and the antimony analogue, $Sb(SiPh_3)_3$ (**7**), via the reaction between 3 equivalents of triphenylsilyllithium and the appropriate element(III) chloride were reported to be unsuccessful [23]. However, compound **7** has reportedly been prepared from the reaction of $SbEt_3$ and 3 equivalents of triphenylsilane, although **7** was poorly characterised [9]. A related reaction between $Sb(SiEt_3)_3$ and 3 equivalents of triphenylsilane was also reported to result in the formation of **7**; no characterisation of this material was published [7]. However, compound **7** can be prepared in a similar manner to the arsine complexes **4**–**6** as described in Section 3. Spectroscopic and analytical data for **7** were consistent with the expected formula and the structure was confirmed by X-ray crystallography, the results of which are shown in Fig. 2. Selected bond distances and angles are given in Table 1. The solid state structure of **7** consists of individual molecules with no unusually short intermolecular contacts between the monomeric units. Although not required crystallographically, individual molecules of **7** possess approxi-

mate C_3 symmetry. The geometry about the antimony centre is pyramidal [av. Si–Sb–Si 106.60(4)°] with the average Sb–Si bond length of 2.600(12) Å being slightly longer than that observed in **3** [av. Sb–Si 2.559 Å] [22]. The greater deviation from ideal tetrahedral coordination geometry and the longer Sb–Si bond lengths observed in **7** are probably a result of the increased steric requirements of the Ph_3Si ligand. A similar effect was noted on comparison of the As–Si bond distances and Si–As–Si angles in compounds **1** and **2** [21].

In conclusion, several homoleptic silyl arsenic(III) and antimony(III) compounds have been synthesised and characterised. Two of the compounds, $As(SiMe_2Cy)_3$ and $Sb(SiPh_3)_3$ were structurally characterised. Complexes **4**–**7** are possible precursors for the preparation of arsenides and antimonides and the reactivity of these complexes is currently being investigated.

3. Experimental

3.1. General procedures

All manipulations were performed under a dry, oxygen-free dinitrogen atmosphere using standard Schlenk techniques or in a MBraun Unilab glove box. All solvents were distilled from appropriate drying agents prior to use (sodium–toluene and hexanes; potassium–THF; CaH_2 for CH_2Cl_2). All other reagents were procured commercially from Aldrich and used without further purification. Microanalytical data were obtained at University College London.

3.2. Physical measurements

NMR spectra were recorded on Brüker AMX300 or DRX500 spectrometers at UCL. The NMR spectra are referenced to CD_2Cl_2 or $CDCl_3$, which were degassed and dried over molecular sieves prior to use; ^1H and ^{13}C chemical shifts are reported relative to $SiMe_4$ (0.00 ppm). Mass spectra (CI) were run on a micromass ZABSE instrument, and IR spectra on a Nicolet 205 instrument. Melting points were obtained in sealed glass capillaries under argon and are uncorrected.

3.3. Preparations

All of the compounds were synthesised by the same general procedures, hence only one example is described in detail below.

3.3.1. Synthesis of compound *4*

A mirror of sodium metal is generated on the inner surface of a Schlenk flask by heating and stirring sodium (1.00 g, 43.5 mmol). After cooling to room temperature (r.t.) arsenic powder (1.09 g, 14.5 mmol) and a few crystals of naphthalene were added. THF (40 ml) was added and the resulting black slurry was heated at reflux for 24 h. After cooling to r.t. chlorodimethylcyclohexylsilane (8 ml, 43.2 mmol) was added dropwise with stirring and the reaction mixture was refluxed for a further 12 h. The resulting black slurry was cooled to r.t. and pumped to dryness in vacuo. Toluene (40 ml) was added to the remaining black–grey solid and the mixture was filtered through Celite. The volume of the filtrate was reduced to ca. 15 ml and cooling of this solution to −20°C afforded a 67% yield of colourless crystalline **4**. M.p. 80–82°C. ^1H NMR ($CDCl_3$): δ 0.29 (s, 18H, $SiMe_2$), 0.72–1.83 (m, 33H, SiCy). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 0.01 ($SiMe_2$), 26.8, 27.7, 28.1, 28.4 (SiCy). CIMS: m/z 499 [M^+], 359 [$M^+ - SiMe_2Cy$]. *Anal.* Calc. for $C_{24}H_{51}AsSi_3$: C, 57.79; H, 10.30. Found: C, 57.48; H, 10.44%.

3.3.2. Compound *5*

Yield: 52% of colourless crystalline **5**. M.p. 122–124°C. ^1H NMR (CD_2Cl_2): δ 0.35 (s, 18H, $SiMe_2$), 7.25–7.55 (m, 15H, SiPh). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 1.7 ($SiMe_2$), 127.5 (*m*-C of SiPh), 128.8 (*p*-C of SiPh), 133.7 (*o*-C of $SiPh_3$), *ipso* carbon not detected. CIMS: m/z 481 [M^+]. *Anal.* Calc. for $C_{24}H_{33}AsSi_3 \cdot 0.5CH_2Cl_2$: C, 56.25; H, 6.55. Found: C, 56.25; H, 6.54%.

3.3.3. Compound *6*

Yield: 65% of pale yellow crystalline **6**. M.p. 180°C (dec.). ^1H NMR ($CDCl_3$): δ 6.98–7.30 (m, 45H, $SiPh_3$). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 127.2 (*m*-C of $SiPh_3$), 128.8 (*p*-C of $SiPh_3$), 136.2 (*o*-C of $SiPh_3$), *ipso* carbon not detected. CIMS: m/z 853 [M^+], 595 [$M^+ - SiPh_3$]. *Anal.* Calc. for $C_{54}H_{45}AsSi_3$: C, 76.03; H, 5.32. Found: C, 75.98; H, 5.45%.

3.3.4. Compound *7*

Yield: 58% of colourless crystalline **7**. M.p. 127°C (dec.). ^1H NMR (CD_2Cl_2): δ 6.87–7.54 (m, 45H, $SiPh_3$). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 126.2 (*m*-C of $SiPh_3$), 128.2 (*p*-C of $SiPh_3$), 135.5 (*o*-C of $SiPh_3$), *ipso* carbon not detected. CIMS: m/z 901 [M^+]. *Anal.* Calc. for $C_{54}H_{45}SbSi_3$: C, 72.07; H, 5.04. Found: C, 72.61; H, 5.08%.

3.4. Structure determinations

Crystals of **4** and **7** were mounted on a glass fibre using silicones grease and cooled on the diffractometer. Crystallographic measurements were carried out with a Nonius Kappa CCD diffractometer equipped with graphite-monochromated Mo Kα radiation using a combination of ϕ and ω scans with 2° frames and a detector-to-crystal distance of 30 mm. Integration was carried out by the program DENZO-SMN [24]. Data sets were corrected for Lorentz and polarisation effects and for the effects of absorption using the program SCALEPACK [24]. The structure was solved using the

direct methods option of SHELXS-97 [25] and developed using conventional alternating cycles of least-squares refinement and difference Fourier synthesis (SHELXL-97) [25] with the aid of XSeed [26]. All non-hydrogen atoms were refined anisotropically, while hydrogen atoms were fixed in idealised positions and allowed to ride. Hydrogen atom thermal parameters were tied to those of the atom to which they were attached. All calculations were carried out on a Silicon Graphics Indy workstation or an IBM-PC compatible personal computer. Crystal data and details of the data collections and refinements are given in Table 2.

4. Supplementary material

Crystallographic data have been deposited with the CCDC and are available on request from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) by quoting the deposition numbers 140720 and 140721.

Abstract

Two new five-coordinate Lewis-base adducts of cobalt(II) N_2O_2 Schiff-base complexes, [Co(Salpad)$_2$(*t*-MeStpy)] and [Co(H$_2$(fsa)$_2$phn)(*t*-MeStpy)]·0.5H$_2$O (where H(Salpad) = 2-[*N*-(4-phenylaminophenyl)formimidoyl]phenol, H$_4$(fsa)$_2$phn = *N*,*N*′-*o*-phenylenebis(3-carboxysalicylaldimine), and *t*-MeStpy = *trans*-1-(4-methylphenyl)-2-(4-pyridyl)ethene), have been synthesized in order to investigate the influence of the in-plane donor atom topology on the spin-state of the cobalt(II) ion. The compounds have been characterized by analytical and spectroscopic methods. The spin-state behavior of cobalt(II) was investigated by variable-temperature magnetic susceptibility measurements over the temperature range 10–380 K. For [Co(Salpad)$_2$(*t*-MeStpy)] the magnetic data indicate a spin-quartet ground state which can be described using an axial spin Hamiltonian ($D = 16.57$ cm^{-1}, $g = 2.39$ for CoN_2O_2N') with additional temperature-independent paramagnetism ($N\alpha = 360 \times 10^{-6}$ cm^3 mol^{-1}). The compound [Co(H$_2$(fsa)$_2$phn)(*t*-MeStpy)]·0.5H$_2$O undergoes a thermally-induced $S = 1/2 \leftrightarrow S = 3/2$ spin equilibrium at high temperatures. The magnetic properties of the four-coordinate [Co(Salpad)$_2$] precursor are also reported here. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Schiff bases; Cobalt complexes; Spin crossover; Photosensitive ligands; LD-LISC effect

1. Introduction

There is much current interest in five- and six-coordinate transition-metal Schiff-base complexes because these species can display a variety of structural and magnetic properties [1]. Depending on the chemical environment, the metal ion can exist in different spin states. When the high-spin (HS) and low-spin (LS) states of a d^4–d^7 transition metal ion are in close energy proximity, it may also undergo a HS↔LS conversion under the effect of an external perturbation (temperature, pressure). Then the magnetic behavior depends on small inductive, geometrical and sterical effects. In comparison to the vast number of papers dealing with iron(II) [2–6] and iron(III) [7,8] spin-crossover complexes, there are relatively few studies dealing with cobalt(II) complexes [9–12]. In these compounds, the cobalt(II) ion can display a $S = 3/2 \leftrightarrow S = 1/2$ spin crossover. In a few cases it lies in an oxygen–nitrogen closest environment, as in five- or six-coordinated Lewis-base adducts of cobalt(II) chelates derived from the phenolic anions of the *N*,*N*′-bridged Schiff-bases of salicylaldehyde [10,11] (see **I**) or 3-formylsalicylic acid [9] (see **II**). The family of compounds Co(H$_2$(fsa)$_2$R)L$_x$ ($x = 1$ or 2, L = H$_2$O or pyridines; see **II**) is particularly attractive because it displays not only various structural and magnetic properties, but it also exhibits the most abrupt thermally-induced spin transitions ever observed for cobalt(II) derivatives [13–16].

Ia: R_1 = H; R = $(CH_2)_2$
Ib: R_1 = H; R = C_6H_4
IIa: R_1 = COOH; R = $(CH_2)_2$
IIb: R_1 = COOH; R = C_6H_4

For most spin-crossover metal complexes, the transition was triggered by varying temperature or pressure. It is now possible to observe the switching of spin states of some transition metal complexes with an optical excitation according to the so-called ligand-driven light-induced spin change (LD-LISC) effect [4]. It consists in the *trans*/*cis* photoisomerization of the ligands and the subsequent change of the ligand-field strength and the spin state of the metal center. A spin conversion triggered by the ligand isomerization has been evidenced for the first time in iron(II) complexes [4–6] and recently in an iron(III) complex [7]. From the basic concept of LD-LISC, it is expected that the spin change can also be observed in d^7 transition-metal complexes, which contains one or two photosensitive ligands in the molecule. For this purpose, we have prepared Co(II) complexes containing a 4-styrylpyridine derivative as a photoisomerizable ligand in an axial position and polydentate Schiff-base ligands.

In this paper, we report the synthesis and magnetic properties of a new five-coordinate species from the family of compounds $[Co(H_2(fsa)_2phn)L_x]$ (see **IIb**), namely $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (**3**), where $H_2(fsa)_2phn^{2-}$ denotes the phenolic dianion of the Schiff-base *N*,*N*′-*o*-phenylenebis(3-carboxysalicylaldimine) and *t*-MeStpy is *trans*-1-(4-methyl-phenyl)-2-(4-pyridyl)ethene. In this compound, the cobalt(II) ion undergoes a gradual high-spin (HS)↔low-spin (LS) interconversion, in the range of high temperatures, that can be described in terms of spin equilibrium.

We also focus on another five-coordinate cobalt(II) complex, $[Co(Salpad)_2(t\text{-MeStpy})]$ (**2**), which is derived from the bidentate Schiff-base 2-[*N*-(4-phenylaminophenyl)formimidoyl]phenol, H(Salpad). We report here the magnetic and spectral properties of the five-coordinate adduct, as well as those of the four-coordinate cobalt(II) parent complex, $[Co(Salpad)_2]$ (**1**).

2. Experimental

2.1. Solvents and reagents

All the reagents and solvents were purchased from commercial sources (Aldrich) and used as received. The photosensitive ligand, *trans*-1-(4-methylphenyl)-2-(4-pyridyl)ethene (or *t*-MeStpy) was prepared as reported in Ref. [5]. The Schiff-base, 2-[*N*-(4-phenylaminophenyl)formimidoyl]phenol, H(Salpad), and its metal chelate, $[Co(Salpad)_2]$ (**1**), were obtained according to the procedures described previously [17]. The Schiff base, *N*,*N*′-*o*-phenylenebis(3-carboxysalicylaldimine), $H_4(fsa)_2phn$, was prepared according to the literature [15]. Part of the experiments were carried out under an atmosphere of dried argon and in the dark in order to prevent both metal ion oxidation and ligand photoisomerization.

2.2. Preparation of $[Co(Salpad)_2(t\text{-MeStpy})]$ (2)

To a suspension of **1** (0.5 mmol, 316 mg) in 15 ml of toluene was added with stirring an methanolic solution (10 ml) containing 3 mmol of *t*-MeStpy (585 mg). The mixture was then heated at 60°C for 5 h. The resulting brown precipitate was collected, washed with ether, and dried under vacuum. Yield 273 mg ($\sim$66%). *Anal.* Calc. for $C_{52}H_{43}CoN_5O_2$ ($F_w = 828.88$): C, 75.35; H, 5.23; Co, 7.11; N, 8.45. Found: C, 76.58; H, 5.28; Co, 7.42; N, 8.27%.

2.3. Preparation of $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (3)

The synthesis of **3** implies, as a first step, the preparation of $[Co(H_2(fsa)_2phn)(H_2O)_2]$ according to the procedure described previously by Zarembowitch et al. [16]. Both water molecules of $[Co(H_2(fsa)_2phn)(H_2O)_2]$ are removed by heating the solid phase at $\sim$65°C for 3 h, and a square-planar compound, $[Co(H_2(fsa)_2phn)]$, is formed, as shown by thermogravimetric analysis. The mixture of 0.5 mmol (240 mg) of $[Co(H_2(fsa)_2phn)]$ and 2.5 mmol (488 mg) of *t*-MeStpy in 10 ml of anhydrous ethanol was heated in the dark (to prevent ligand photoisomerization) at 40°C for 5 h. A brown precipitate was formed. The excess of *t*-MeStpy was removed by washing with ethanol. The precipitate of $[Co(H_2(fsa)_2phn)(trans\text{-MeStpy})]\cdot 0.5H_2O$ was isolated by filtration and dried under an argon stream. *Anal.* Calc. for $C_{36}H_{28}CoN_3O_{6.5}$ ($F_w = 665.57$): C, 64.96; H, 4.24; Co, 8.85; N, 6.31; O, 15.62. Found: C, 64.46; H, 4.19; Co, 8.93; N, 6.08; O, 15.32%.

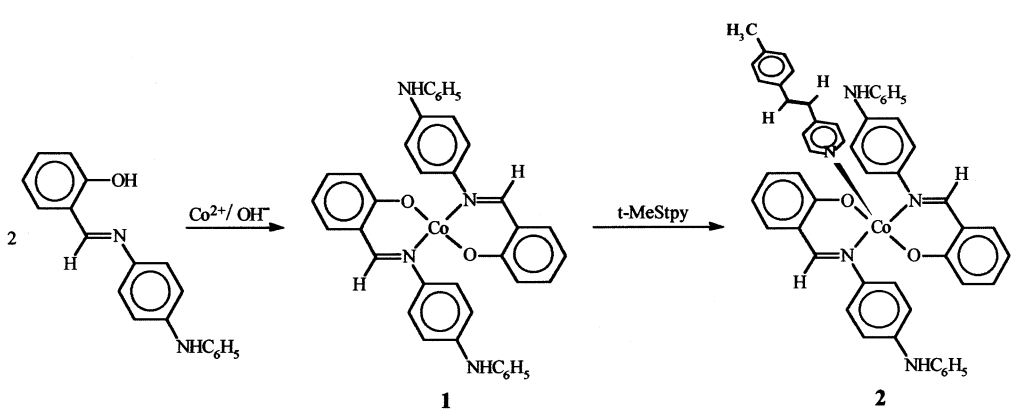
2.4. Physical measurements

IR spectra (KBr pellets) were recorded on a BIO RAD FTS-135 spectrophotometer. Diffuse reflectance UV–Vis spectra were obtained with a VSU-2P (Carl Zeiss) spectrophotometer. UV electronic spectra, in non-aqueous solutions, were recorded with a UV4 Unicam spectrophotometer. Magnetic measurements were performed on polycrystalline samples, using a Quantum Design MPMS-5S SQUID magnetometer. The independence of susceptibility, with regard to the strength of the applied magnetic field, was checked for each compound at room temperature (r.t.). Diamagnetic correction was estimated at -357×10^{-6}, -478×10^{-6} and -340×10^{-6} $cm^3\ mol^{-1}$ for $[Co(Salpad)_2]$ (**1**), $[Co(Salpad)_2(t\text{-MeStpy})]$ (**2**) and $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (**3**), respectively. Elemental analyses were performed on a Carlo Erba model 1108 CHNS-O elemental analyzer. The electric

conductivities were determined in DMF (10^{-3} M) on an OK 102/l Radelkis conductometer.

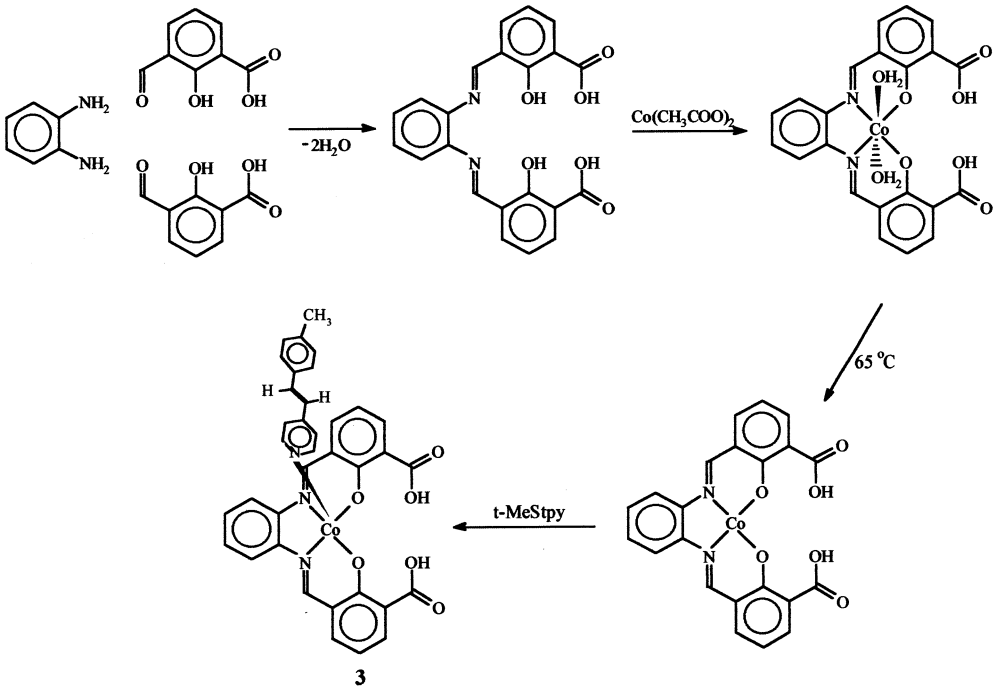
3. Results and discussion

In previous papers [17] we have showed that bidentate Schiff-base 2-[*N*-(4-phenyl-aminophenyl)formimidoyl]phenol, H(Salpad), is a very suitable ligand to form neutral 3d metal complexes corresponding to a stoichiometry of M(II):Salpad (1:2) type. In these complexes, the Schiff-base acts as a chelate monoanionic ligand with coordination involving phenolato oxygen and imino nitrogen atoms. The reaction of 1 equiv. of cobalt(II) acetate with 2 equiv. of H(Salpad), in a slightly basic solution, yields the complex [Co(Salpad)$_2$] (**1**), as shown in Scheme 1. By treating 1 equiv. of **1** with 1 equiv. of *t*-MeStpy (where *t*-MeStpy = *trans*-1-(4-methylphenyl)-2-(4-pyridyl)ethene), a five-coordinate adduct, [Co(Salpad)$_2$(*t*-MeStpy)] (**2**), is obtained (see Scheme 1 and Section 2).



[Co(H$_2$(fsa)$_2$phn)(*t*-MeStpy)]·0.5H$_2$O (**3**) was prepared according to Section 2 and the reactions shown in Scheme 2. All the experiments have been carried out under an argon atmosphere in order to avoid the oxidation to the cobalt(III) species.

We were not able to obtain single crystals suitable for X-ray crystallographic studies; however, useful information regarding the structures of compounds **1**–**3** was derived from spectroscopic and magnetic measurements (vide infra). The non-electrolytic nature of these compounds was established from conductance measurements carried out in DMF solutions (10^{-3} M). The three compounds show very small molar electric conductivity values ($\Lambda_M = 6$–14 ohm^{-1} cm^2 mol^{-1}).



3.1. Infrared and electronic spectra

The IR spectra of compounds **1**–**3** show absorptions characteristic of coordinated ligands. Our discussion is confined to the most important vibrations of the 4000–400 cm^{-1} region in relation to structure. The mode ν(C=N), present as a strong band at 1620 cm^{-1} in the free ligand spectrum of H(Salpad), lies at 1600 and 1602 cm^{-1}, respectively, in the spectra of compounds **1** and **2**, suggesting an imino–nitrogen coordination [18]. The free ligand exhibits a medium band around 3030 cm^{-1} is due to the intra-molecularly hydrogen bonded OH group. The absence of this band in the spectra of compounds **1** and **2**, as well as the shift to higher energy by 20–30 cm^{-1} of the phenolic ν(C–O) bands, can be interpreted as proving the involvement of the phenolato oxygen atom in coordination [19]. In the case of compound **3**, the band due to the ν(C=N) mode lies at 1607 cm^{-1}. This band is shifted considerablly to lower frequencies when compared with that (1630 cm^{-1}) of the ligand H$_4$(fsa)$_2$phn [15], suggesting that the cobalt atom is bounded in the N_2O_2 coordination site provided by this ligand. This conclusion is supported further by an intense band located at 1705 cm^{-1} in the IR spectrum of compound **3**, which is due to the ν_{asym}(C=O) mode associated with the two uncoordinated –COOH groups of the Schiff-base ligand. A similar band was previously observed [13,18] with the IR spectra of several mononuclear 3d metal complexes from the family [M(H$_2$(fsa)$_2$R)L$_x$] (see **II**), where H$_2$(fsa)$_2$R^{2-} is the dianion of the Schiff base resulting from 2:1 condensation of 3-formylsalicylic acid with various diamine and L is a pyridine derivative. Another solid argument for the formation of five-coordinate adducts **2** and **3** consists in the appearance in their IR spectra of the very characteristic bands of *t*-MeStpy (near 810, 970 and 1600 cm^{-1}) [20]. In the case of **3**, the presence of water results in a strong IR absorption at 3433 cm^{-1}.

Further evidence for the formation of the two *t*-MeStpy adducts is provided by UV–Vis spectrometry. The electronic spectrum of compound **2**, recorded in acetonitrile solution at r.t., clearly indicates the presence of a broad intense band with maximum around 313 nm ($\sim$31 950 cm^{-1}), which corresponds to the

Scheme 1. Synthesis of [Co(Salpad)$_2$] (**1**) and [Co(Salpad)$_2$(*t*-MeStpy)] (**2**).

Scheme 2. Stepwise synthesis of $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (**3**).

t-MeStpy $\pi \rightarrow \pi^*$ absorbtion, according to the previous assignments [4,5]. A band of the same nature was also observed in the r.t. spectrum of compound **3** (in dimethylformamide solution) around 315 nm ($\sim$ 31 750 cm^{-1}).

The electronic spectrum of compound **1**, recorded by diffuse reflectance technique, clearly indicates the presence of a *pseudo*-tetrahedral Co(II) chromophore, while those of compounds **2** and **3** show the characteristic features of five-coordinated cobalt(II) ions, with a distorted square-pyramidal stereochemistry. The tetrahedral compound is distinguished by its relative intense ligand field band, the maximum at 10 900 cm^{-1} (Fig. 1) corresponding to a splitted component of the second spin-allowed transition ($^4T_1$ (F) $\leftarrow {}^4A_2$) of the ideal tetrahedron, while the third band, due to the spin-allowed $^4T_1$ (P) $\leftarrow {}^4A_2$ transition, should be located on the side of high energies, in overlapping with the charge transfer bands.

The square pyramidal stereochemistry of compound **2** may be also established from UV–Vis spectral data, by comparison with similar literature spectra [21]. The two bands centered at 8110 and 11 050 cm^{-1} in the UV–Vis spectrum of **2** are assigned to the spin-allowed transitions $^4B_1 \leftarrow {}^4A_2$ and $^4B_2 \leftarrow {}^4A_2$, respectively. Though the available spectral data are not enough detailed to indicate the *cis* or *trans* disposal of $[N_2O_2]$ set of the equatorial plane, we assumed that a *trans* arrangement is adopted, where the steric effects should be reduced [22]. In addition, this arrangement can be governed by packing effects because of the more symmetrical molecular unity and a subsequent gain in the lattice energy. The diffuse reflectance spectrum of compound **3** also shows two bands of moderate intensity in the visible region, at 7610 and 12 300 cm^{-1}. It can be inferred that the coordination polyhedron around the cobalt(II) ion is an axially elongated square-pyramid, with the donor atom *cis*-$[N_2O_2]$ set provided by the Schiff base $H_4(fsa)_2phn$ occupying the basal plane and with *t*-MeStpy as an axial ligand. This result is in accordance with the X-ray crystal structure of the similar complex [Co(salen)(py)] [11].

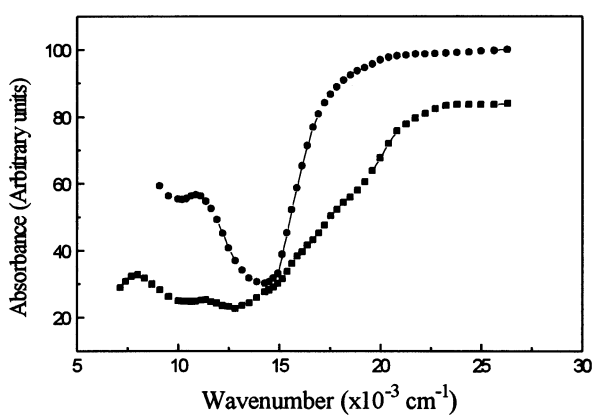


Fig. 1. Diffuse reflectance spectra of (●) $[Co(Salpad)_2]$ (**1**) and (■) $[Co(Salpad)_2(t\text{-MeStpy})]$ (**2**).

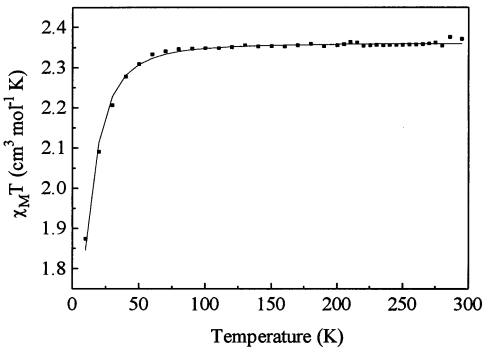

Fig. 2. Plot of $\chi_M T$ vs. T for [Co(Salpad)$_2$] (**1**).

3.2. Magnetic properties

Variable-temperature magnetic susceptibility measurements were carried out for complexes **1** and **2** in the temperature range 10–300 K. The $\chi_M T$ versus T plots (χ_M denoting the molar magnetic susceptibility) are given in Figs. 2 and 3, respectively. The $\chi_M T$ product of [Co(Salpad)$_2$] (**1**) is quasi-independent of temperature in the range of high temperatures, passing from 2.37 cm^3 mol^{-1} K at 295 K to 2.33 cm^3 mol^{-1} K at 60 K (Fig. 2).

Below 60 K it decreases more rapidly, reaching 1.87 cm^3 mol^{-1} K at 10 K. The high-temperature values corresponding to the plateau are in the range expected for a *pseudo*-tetrahedral Co(II) complex with an orbitally non-degenerate $^4A_2$ ground state. For [Co(Salpad)$_2$(*t*-MeStpy)] (**2**), the $\chi_M T$ values slightly vary from 2.79 cm^3 mol^{-1} K at 295 K to 2.68 cm^3 mol^{-1} K at 70 K and then drop more rapidly reaching 2.09 cm^3 mol^{-1} K at 10 K (Fig. 3). The higher magnetic moments suggest a supplementary contribution, aside from the pure spin one. A second-order orbital contribution is possible, as it is qualitatively argued in the following. For the actual C_{2v} symmetry the set of lowest quartet states, A_2, B_1, B_2 formed by the splitting of the T_1 parent allows a nonvanishing expectation value for the orbital momentum operator, which spans the same set of representations, a_2, b_1, b_2. In each nondiagonal matrix element is contained a contribution behaving like the triple product, $A_2 \otimes B_1 \otimes B_2 \equiv A_1$, as indicative of a nonvanishing quantity. For a *trans*-[Co(II)N$_2$O$_2$N′] chromophore, the lowest first and second spin quartet states are quite close forming a quasidegenerate ground state. This results in a second order contribution from these elements to the ground state orbital moment.

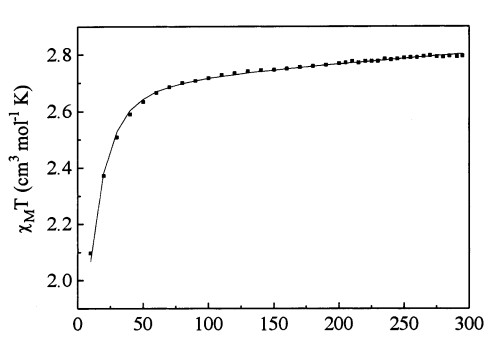

Fig. 3. Plot of $\chi_M T$ vs. T for [Co(Salpad)$_2$(*t*-MeStpy)] (**2**).

We interpret the magnetic behaviors of **1** and **2** in terms of a large zero field splitting (ZFS) of a $^4A_2$ ground-state with no contribution from a doublet state even at low temperature. The ZFS Hamiltonian can be taken in the simplified axial form: $H = g\beta HS + D[S_z^2 - 1/3S(S+1)]$, and for $S = 3/2$ the susceptibility data are described by Eq. (1):

$$\chi_M T = \frac{g^2}{8}\left[\frac{9}{4} + \frac{3}{x}\frac{1-e^{-x}}{1+e^{-x}}\right] + N\alpha T \quad (1)$$

where, $x = 2D/kT$ and $N\alpha$ is the temperature independent paramagnetism (TIP).

By a least-squares fitting, the following parameters were found: $g = 2.24$ and $D = 14.91$ cm^{-1} ($N\alpha$ being assumed to be zero) for **1**, and $g = 2.39$, $D = 16.57$ cm^{-1} and $N\alpha = 360 \times 10^{-6}$ emu, for **2**. The values are in line with similar systems [10,14] and the reliability factors defined as $R(\chi_M T) = \{\Sigma[(\chi_M T)_{obs} - (\chi_M T)_{calc}]^2 / \Sigma[(\chi_M T)_{obs}]^2\}^{1/2}$ are below 10^{-4}.

It is worth noting that the perturbational term of orbital magnetism is not important for a five-coordinate cobalt(II) compound with a *cis*-[N$_2$O$_2$] configuration of the equatorial plane, because the orbitally non-degenerate ground state of the metal ion is quite spaced from the following ones. This affirmation is corroborated with the magnetic behavior of the square-pyramidal compound [Co(H$_2$(fsa)$_2$phn)(*t*-MeStpy)]·0.5H$_2$O (**3**) (where H$_2$(fsa)$_2$phn^{2-} denotes the phenolic dianion of the Schiff-base *N*,*N*′-*o*-phenylenebis(3-carboxysalicylaldimine); see Scheme 2), as well as with those of the well known [Co(Saloph)(2-MeImd)] [10] (Saloph^{2-} being the phenolic dianion of the Schiff-base *N*,*N*′-*o*-phenylenebis(salicylaldimine)), where the high-temperature magnetic moments are very close to the spin-only value. The molar magnetic susceptibilities (χ_M) of **3** were measured over the temperature range 10–380 K. The cobalt(II) ion exhibits a rather smooth thermally-induced spin crossover without any detectable hysteresis.

As shown in Fig. 4, the temperature dependence of the $\chi_M T$ product is more pronounced in the interval 380–200 K decreasing from 1.61 cm^3 mol^{-1} K at 380 K to 0.93 cm^3 mol^{-1} K at 200 K. The curve then has a plateau between 160 and 40 K, at $\sim$0.82 cm^3 mol^{-1} K, and $\chi_M T$ values drop again at lower temperatures, reaching 0.66 cm^3 mol^{-1} K at 10 K. The latter decrease may be due to a weak intermolecular exchange coupling between neighboring cobalt atoms. It is worth pointing out that this behavior is very different from

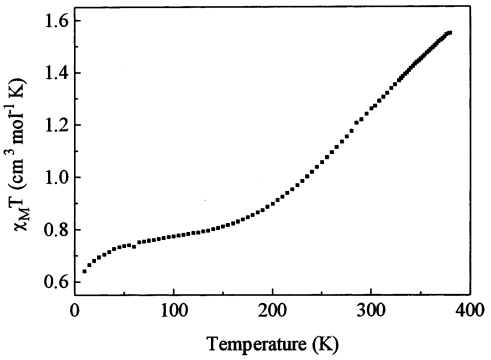

Fig. 4. Plot of $\chi_M T$ vs. T for $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (**3**).

that of the compound **2**, which is also square-pyramidal, but with a *trans* arrangement for the equatorial plane.

4. Conclusion

By combining the results described here with previously published work it is possible to rationalize new synthetic routes leading to cobalt(II) spin-crossover compounds. The compound $[Co(H_2(fsa)_2phn)(t\text{-MeStpy})]\cdot 0.5H_2O$ (**3**) is particularly attractive since, to the best of our knowledge, this is the first five-coordinate species containing a photosensitive ligand in the molecule which displays a thermally-induced spin conversion. In addition, its transition temperature range ($T_{1/2} \sim 270$ K) is significantly shifted towards higher values, as compared with the critical temperatures of 101 K ($T\downarrow$) and 105 K ($T\uparrow$) reported [16] for the precursor compound $[Co(H_2(fsa)_2phn)(H_2O)_2]$. There is a possibility that this complex, like other square-pyramidal Co(II) complexes, presents noticeable distortion of the coordination core by moving the metal out of the equatorial plane. The dependence of the spin states on this distortion precludes the comparison of the properties of the complexes containing *trans* and *cis* ligand isomers.

Received 7 February 2000; received in revised form 2 June 2000; accepted 7 June 2000

Abstract

Primary alanes $[RAlH_2]_2$ can be stabilized kinetically by employment of very bulky alkyl or aryl substituents. They are easily prepared by reacting the appropriate lithium trihydroalanate precursor with organic halides, anhydrous hydrogen halides or halogens. Reactions of these aluminum hydrides with a wide variety of substrates ranging from protic reagents such as water, alcohols, amines, phosphines or thiols over ketones, nitriles or isonitriles to silylated species such as siloxanes or silyl halides are presented. Primary alanes were shown to be unique starting materials for a number of interesting compounds that were otherwise not accessible, or only available in low yields. In addition, postulated intermediates of aluminum hydride reductions of organic substrates such as ketones or nitriles can be isolated when using bulky primary alanes. © 2000 Elsevier Science Ltd. 1. Introduction

Hydrides of the Group 13 metals are considerably less well investigated than their lighter boron counterparts. Nonetheless, recent years have seen a much-increased level of interest in the area. Various aspects of their chemistry and applications have been the subject of a number of reviews [1–8]. The metal hydrides are of course of inherent interest since they are compounds of a fundamental type. In this regard it is interesting to note that although AlH_3 has been known for almost 60 years [9], GaH_3 has only been well characterized within the last decade [4]. However, in this review we focus on a specific class of Group 13 metal hydrides which up until recently had received little attention. These are the monosubstituted (or primary) alanes of the general formula $RAlH_2$ and the related alanate ions $[RAlH_3]^-$ (R = organo or related group). Traditionally, such compounds have been regarded as unstable owing to their tendency to undergo redistribution reactions (vide infra, Eq. (1)). However, the employment of large R substituents has enabled several examples to be stabilized. These have proven to not only have interesting structures, but also a rich chemistry which allows access to several other classes of aluminum compounds that were either unavailable or difficult to synthesize by other routes.

The field of aluminum hydride chemistry could be said to have been inaugurated when AlH_3 was first synthesized as an impure solid by Stecher and Wiberg [9] in 1942. It was obtained by thermolysis of crystalline $H_3Al{\cdot}NMe_3$, which itself was obtained by fractional crystallization of NMe_3 solutions of the residue from glow-discharge reactions of mixtures of $(Me_3Al)_2$ and H_2 [9]. The subsequent synthesis of $LiAlH_4$ from the reaction of LiH with $AlCl_3$ by Schlesinger and co-workers in 1946 [10] introduced aluminum hydrides as new, powerful and easy to handle reducing and/or hydride-

PII: S0277-5387(00)00455-1

transfer reagents for organic and inorganic chemistry [11,12]. It was subsequently recognized that the reducing power and selectivity could be modified by substitution of some of the hydrides by other groups such as amides, alkoxides, alkyls, aryls, etc. [13–15]. Typical examples include the ubiquitous diisobutylaluminum hydride (DIBALH), diethylaluminum hydride, lithium aluminum tri-*tert*-butoxyhydride and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al), all of which are commercially available. While the synthesis, structure and reactivity of these and related compounds are well documented and understood [12,16], until recently there was only scant information available for primary alanes $(RAlH_2)_n$ and their related alkali metal hydride adducts (or alanates) $[M][RAlH_3]$ (M = alkali metal), which also feature one organic substituent on aluminum. This was due to the difficulty in obtaining pure compounds owing to the ease of ligand distribution reactions (Eq. (1)).

$$2RAlH_2 \rightleftharpoons R_2AlH + AlH_3 \quad (1)$$

Although the synthesis, structure and reactivity of unsolvated primary alanes $(RAlH_2)_n$ and their related alanates $[RAlH_3]^-$ (R = alkyl or aryl) form the main theme of this review, data on related solvated species and primary aluminum hydride compounds with other substituents will be provided when they are relevant to the discussion.

2. Synthesis and structures

Early investigations of aluminum hydrides utilized electrical glow discharges in mixtures of Me_3Al and H_2 as a synthetic approach [9]. Addition of NMe_3 to the resulting mixtures afforded several fractions which were identified as the base stabilized adducts $Me_nAlH_{3-n}\cdot NMe_3$ ($n = 0–3$). Only $H_3Al\cdot NMe_3$ was obtained as a crystalline solid. Some 20 years later Peters and Bartocha [17,18] reported the synthesis of what were described as pure $MeAlH_2\cdot NMe_3$ and $EtAlH_2\cdot NMe_3$ by three different methods:

Alkylation of $H_3Al\cdot NMe_3$ with mercury dialkyl R_2Hg (R = Me, Et).

$$R_2Hg + 2H_3Al\cdot NMe_3 \rightarrow 2RAlH_2\cdot NMe_3 + Hg + H_2 \quad (2)$$

'Syn-proportionation' of $H_3Al\cdot NMe_3$ with $R_3Al\cdot NMe_3$.

$$2H_3Al\cdot NMe_3 + R_3Al\cdot NMe_3 \rightarrow 3RAlH_2\cdot NMe_3 \quad (3)$$

Reduction of R_2AlCl with $LiAlH_4$ in the presence of NMe_3.

$$R_2AlCl + LiAlH_4 \xrightarrow{NMe_3} 2RAlH_2\cdot NMe_3 + LiCl \quad (4)$$

However, later investigations suggested that Peters' and Bartocha's '$MeAlH_2\cdot NMe_3$' consisted of an equilibrium mixture of 4.3% $Me_3Al\cdot NMe_3$, 21.8% $Me_2AlH\cdot NMe_3$, 38.5% $MeAlH_2\cdot NMe_3$ and 35.4% $AlH_3\cdot NMe_3$ [19]. In agreement with this finding, freshly prepared $PhAlH_2\cdot NMe_3$ was shown to rearrange easily at room temperature (r.t.) into mixtures containing Ph_2AlH and $Ph_3Al_2H_3\cdot NMe_3$ [20]. In light of these results the reported $PhAlH_2$ [21] is also likely to be a mixture of species. So far the only structurally authenticated primary organoalanes $[RAlH_2]_n$ with simple organic groups such as methyl are those which are stabilized by complexation with BH_3 or Cp_2TiH as in $MeAl(BH_4)_2$ [22] or $MeAl(Cp_2TiH_2)_2$ [23]. Both compounds feature five-coordinate aluminum with a terminal Me group and two bridging $Ti/B(\mu\text{-}H)_2Al$ units.

Another method for the stabilization of primary alanes employs the chelate effect, i.e. intramolecular base stabilization. Typical ligands include mono- and bis-*o*-(aminomethyl)phenyl and 3-aminopropyl. These ligands have permitted the isolation of five-coordinate monomeric and dimeric aluminum hydrides 2,6-$(R_2NCH_2)_2C_6H_3AlH_2$ (R = Me [24], Et [25]), [2-$(Me_2NCH_2)C_6H_4AlH_2]_2$ [26] and $[Me_2NCH_2CH_2\text{-}CH_2AlH_2]_2$ [27]. The latter two species dimerize via $Al\text{-}(\mu\text{-}H)_2\text{-}Al$ bridges. The synthesis was effected by reacting the dihalide precursors with $LiAlH_4$ or MH (M = Li, Na).

$$RAlCl_2 \xrightarrow{LiAlH_4 \text{ or } MH} RAlH_2 \quad (5)$$

Heterosubstituted, unsolvated primary alanes such as $[H_2AlNMe_2]_3$ [28–30], $[H_2Al(\mu\text{-}N(CH_2CH_2)_2S)]_2$ [31] $[H_2AlO\textit{t}\text{-}Bu]_2$ [32], $[(\textit{t}\text{-}Bu_2MeCO)AlH_2]_2$, $[(\textit{t}\text{-}BuMe\text{-}CHO)AlH_2]_4$ [33], $[H_2AlOCH\textit{t}\text{-}Bu_2]_4$ [34], or $[H_2AlP(SiMe_3)_2]_3$ [35] have been synthesized by aminolysis, alcoholysis, ketone reduction or dehydrosilylation reactions involving amine or ether solvated AlH_3 and the appropriate substrate. These compounds are associated through bridging of the aluminums through the heteroatoms.

Finally, employment of bulky substituents like Mes* and 2,6-$Ar_2C_6H_3$– (Ar = Mes, Trip = 2,4,6-*i*-$Pr_3C_6H_2$–, Mes* = 2,4,6-*t*-$Bu_3C_6H_2$–) allowed access to the first stable, base-free primary organoalanes $[Mes^*AlH_2]_2$ and $[2,6\text{-}Ar_2C_6H_3AlH_2]_2$. In contrast to the heterosubstituted primary alanes these compounds are associated through hydride bridges (vide infra). They can be conveniently synthesized by a simple two-step reaction sequence as shown in Eqs. (6) and (7). Reaction of the bulky aryllithium starting material RLi with $AlH_3\cdot NMe_3$ affords the dimeric lithium trihydroalanates $[RAl(H)(\mu\text{-}H)_2LiL_2]_2$ (L = Et_2O, THF) [36]. Removal of LiH from the alanates by reaction with organic or silyl halides such as MeI and *n*-BuBr or Me_3SiCl gave the primary alanes [37,38].

$$2RLi + 2AlH_3\cdot NMe_3 \xrightarrow{L} [RAl(H)(\mu\text{-}H)_2LiL_2]_2 + 2NMe_3 \quad (6)$$

$$[RAl(H)(\mu\text{-}H)_2LiL_2]_2 + 2R'X \rightarrow [RAlH_2]_2 + 2R'H + 2LiX \quad (7)$$

Trihydroalanates $[M][RAlH_3]$ were first described in the 1960s by Zakharkin and Gavrilenko [39], but it was not until 1994 that the first crystal structures were reported [36,40]. Their common feature is a puckered eight-membered ring $[Li(\mu\text{-}H)Al(\mu\text{-}H)]_2$ skeleton which arises from the association of two $RAlH_3^-$ anions through two ether solvated Li^+ cations, which affords $Al(\mu\text{-}H)Li(\mu\text{-}H)Al$ linkages (Fig. 1).

The ^1H NMR data for crystals of $[Mes^*AlH_3Li(THF)_2]_2$, which were recrystallized in the presence of excess THF, suggest the formation of a putative monomeric species $Mes^*AlH_3Li(THF)_3$ [41]. If the bidentate ligand tetramethylethane-1,2-diamine (TMEN) was used instead of THF, crystals of $[(Me_3Si)_3CAlH_3]^-$ $[Li(TMEN)_2]^+$ with discrete anions and cations were obtained (Fig. 2) [42]. The recently published trihydroalanate $BmtAlH_3Li(DME)_2$ (Bmt = 4-*t*-butyl-2,6-bis[(2,2′,6,6′-tetramethyl-*m*-terphenyl-2′-yl)-methyl]phenyl, DME = 1,2-dimethoxyethane) features only one Li–H–Al bridge between the ions [43]. Table 1 lists the crystallographically characterized trihydroalanates. The coordination environment at the aluminum atoms is generally distorted tetrahedral with the $Al–H_{term}$ distances being only slightly shorter than the $Al–H_{bridg}$ distances. In general, it appears that the aggregation state of the lithium trihydroalanates — dimeric, monomeric, monomeric ion pairs — does not significantly affect the metric parameters at the aluminum centers.

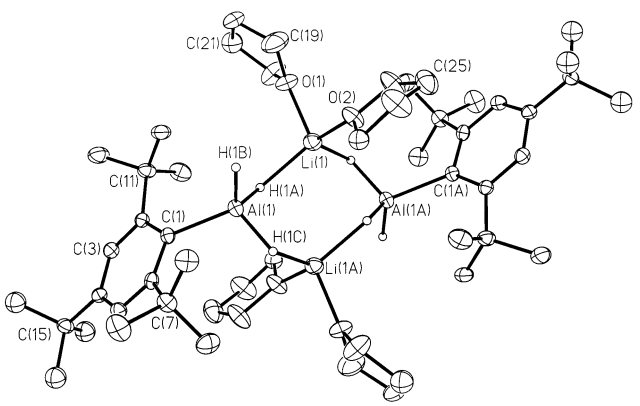

Fig. 1. Thermal ellipsoid plot (35%) of $[Mes^*AlH_3Li(THF)_2]_2$. H-atoms except of those bound to aluminum are not shown for clarity [36].

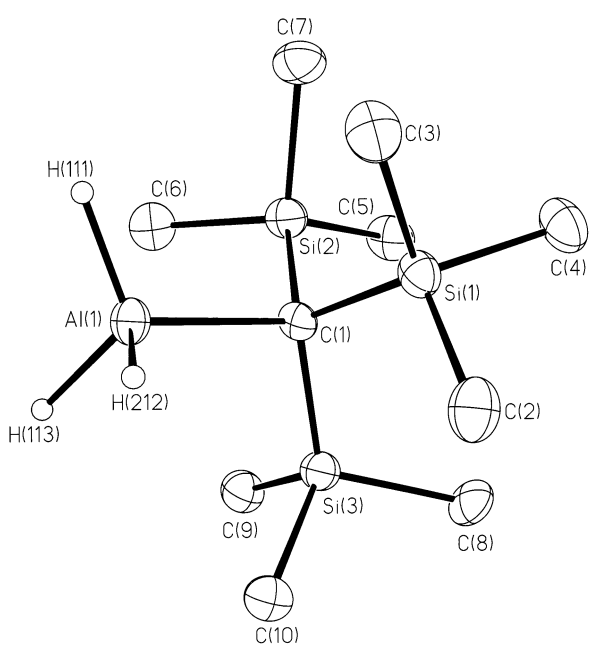

Fig. 2. Thermal ellipsoid plot (35%) of the anion $[(Me_3Si)_3CAlH_3]^-$ in $[(Me_3Si)_3CAlH_3]^-[Li(TMEN)_2]^+$. H-atoms except of those bound to aluminum are not shown for clarity [42].

At present, the $(Me_3Si)_3C$ group is the smallest alkyl substituent that has been shown to stabilize the organotrihydroalanate structure $RAlH_3^-$ against rearrangement to $R_2AlH_2^-$ and AlH_4^- (Eq. (8)).

$$2RAlH_3^- \rightarrow R_2AlH_2^- + AlH_4^- \quad (8)$$

Attempted isolation of $t\text{-}BuAlH_3^-$ only afforded the rearranged species $t\text{-}Bu_2AlH_2Li(THF)_2$ [40]. The least bulky aryl substituent capable of effecting the stabilization of compounds of this class appears to be the Trip-substituent in the species $[TripAlH_3Li(OEt_2)]_n$ [38].

The aryltrihydroalanates $[ArAl(H)(\mu\text{-}H)_2LiL_2]_2$ (Ar = Mes*, 2,6-$Mes_2C_6H_3$–, 2,6-$Trip_2C_6H_3$–, L = Et_2O, THF) have proven to be excellent starting materials for the syntheses of the primary alanes $[ArAlH_2]_2$ (see Eq. (7) and Table 2). These compounds are the only base free primary organoalanes that have been completely characterized. The reaction of $[(Me_3Si)_3CAlH_3Li(THF)_2]_2$ with 1 equiv. of Me_3SiCl afforded $[(Me_3Si)_3C]_2Al_2H_5Li(THF)_2$ whose cyclic structure is similar to the corresponding indium compound [44]. The addition of a further equivalent of Me_3SiCl gave the base stabilized alane $[(Me_3Si)_3CAlH_2{\cdot}THF]$ [45]. However, treatment of $[TripAlH_3Li(OEt_2)]_n$ with Me_3SiCl afforded only the known secondary alane $[Trip_2AlH]_2$ [38]. Ligand migration in these systems appears to be facile and it can only be suppressed by the use of the very bulky trisilylmethyl, Mes* or terphenyl substituents.

The structures of the three crystallographically characterized primary organoalanes are very similar: all are dimeric via hydrogen bridges and the aryl substituents are *trans* to each other. The $Al–H_{term}$ distances are in the range 1.46–1.50 Å, whereas the $Al–H_{bridg}$ distances are significantly longer at 1.65–1.74 Å. The internal angles $H_{bridg}–Al–H_{bridg}$ are narrow at 77–81°, while the widest angles are $H_{term}–Al–C_{ipso}$ at 127–135.5°, proba-

bly indicative of some steric strain as shown in the structure of $[Mes^*AlH_2]_2$ (Fig. 3).

The terphenyl substituted primary alanes form stable adducts with Et_2O and NMe_3 (Table 2) although the Et_2O may be removed by gentle warming under reduced pressure. On the other hand, $[Mes^*AlH_2]_2$ does not form stable adducts with Et_2O, THF, NMe_3 or NEt_3, although its NMR spectrum in C_6D_6 solutions displays a drastically changed chemical shift in the presence of 1 or 2 equiv. of THF. This, together with a large increase of its solubility, may be interpreted as a result of a weak adduct formation. So far, only the very strong donor HMPA has afforded a monomeric adduct ($MesAlH_2^*OP(NMe_2)_3$) as a stable solid (vide infra) [46]. The feeble reactivity of $[Mes^*AlH_2]_2$ towards Lewis bases may be explained by the presence of the bulky *o*-*t*-Bu groups that display short C–H···Al contacts (ca. 2.25–2.40 Å) and thus hinder access to the metal center [37].

It is interesting to note that these primary alanes are considerably more thermally stable than the 'simple' aluminum hydrides $H_3Al{\cdot}NMe_3$ or $LiAlH_4$. Decomposition occurs at or above the melting points at 173–177°C (Mes*–) [37], 219–221°C (2,6-$Mes_2C_6H_3$–) and 310–320°C (2,6-$Trip_2C_6H_3$–) [38], cf. ca. 105°C for $H_3Al{\cdot}NMe_3$ [9] or 125°C for $LiAlH_4$ [10].

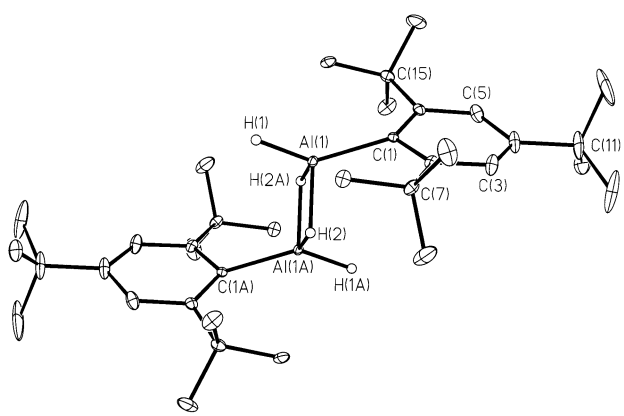

Fig. 3. Thermal ellipsoid plot (35%) of $[Mes^*AlH_2]_2$. H-atoms except of those bound to aluminum are not shown for clarity [37].

3. Reactivity

The availability of stable, well-defined primary alanes and their lithium hydride adducts has allowed for the first time the systematic study of their chemistry. As will be discussed in more detail later, these aluminum hydrides have proven to be important starting materials for a wide variety of compounds, some of which are difficult to synthesize by other routes.

4. Organoaluminum dihalides and pseudohalides

Sterically crowded primary alanes offer a potentially facile route to bulky organoaluminum dihalides $RAlX_2$, which are often difficult to synthesize by more obvious traditional routes. For example, the less sterically crowded organoaluminum dihalides are generally obtained by ligand exchange reactions between R_3Al and AlX_3 [47,48] as shown in Eq. (9).

$$R_3Al + 2AlX_3 \rightarrow 3RAlX_2 \quad (9)$$

In contrast, large, bulky substituents have a low tendency to migrate and in many cases it is not possible to synthesize the required R_3Al or R_2AlX starting materials. For example, $Trip_2AlBr$ does not react with $AlBr_3$ at r.t., but the reaction which proceeded at ca. 150°C was complicated by side reactions such as C–H activation [49]. The alternative 'direct' reaction of organolithium or -magnesium compounds with AlX_3 (Eq. (10)) affords the desired product only in a few cases and often in low yield.

$$RLi + AlX_3 \rightarrow RAlCl_2 + LiCl \quad (10)$$

Among the problems encountered in this reaction are ether or THF cleavage reactions (as seen in the reaction of $(Me_3Si)_3CLi(THF)_2$ and AlX_3 [50]), low yields and difficulty in purification ($< 30\%$ for $Mes^*Li(THF)_2 + AlBr_3$ [51]), formation of lithium halide adducts (e.g. $(2,6\text{-}Mes_2C_6H_3AlBr_3Li)_2$ [52]) and lack of organo group transfer, e.g. $Mes^*MgBr(THF) + AlCl_3$ yields two-coordinate Mes^*_2Mg instead of Mes^*AlCl_2 [53].

In contrast, the lithium trihydroalanates $RAlH_3Li(L)_n$ have proven efficient starting materials for the synthetically very useful organoaluminum dihalides $RAlX_2$ via reaction with alkyl or silyl halides as described in Eq. (11).

$$RAlH_3Li(L)_n + 3R'X \rightarrow 2RAlX_2 + 3R'H + LiX \quad (11)$$

$R' = \text{alkyl or } SiMe_3,\ X = \text{halide}$

In a related reaction Roesky and co-workers have recently found that $(Me_3Si)_3CAlMe_2(THF)$ was also a source for $(Me_3Si)_3CAlX_2(THF)$ [54]. Here the halide was introduced by reaction with Me_3SnX (X = F, Cl) or X_2 (X = Br, I). Interestingly, the halide transfer reagent reacted preferentially with the Al–Me bond.

Reaction of HX (X = Cl, Br) with the lithium trihydroalanate $[(Me_3Si)_3CAlH_3Li(THF)_2]_2$ leads cleanly to the appropriate organoaluminum dihalides $(Me_3Si)_3CAlX_2(THF)$ at r.t. with concomitant H_2 evolution [42]. Hydrogen fluoride also reacted smoothly, but gave the tetrameric LiF adduct $[(Me_3Si)_3CAlF_3Li(THF)]_4$, which features a cube-like $Al_4Li_4F_8$ core with bridging fluorides [55]. Treatment of $[(Me_3Si)_3CAlH_3Li(THF)_2]_2$ with Br_2 or I_2 also affords the dibromide or diiodide compounds, but in lower yields [42]. Similarly, a low yield of Mes^*AlI_2 may be isolated from the reaction of $[Mes^*AlH_3Li(THF)_2]_2$ with I_2 [41].

$$[RAlH_3Li(THF)_2]_2 + 6HX \rightarrow 2RAlX_2(THF) + 6H_2 + 2LiX + 2THF \quad (12)$$

$$[RAlH_3Li(THF)_2]_2 + 3X_2 \rightarrow 2RAlX_2(THF) + 3H_2 + 2LiX + 2THF \quad (13)$$

In these reactions the more reactive Al–H bond is cleaved preferentially. In the case of the Mes* substituted aluminum hydrides the steric strain caused by the bulky substituent apparently decreases the reactivity difference so that other methods of Al–X bond formation were investigated.

The elimination of Me_3SiH from the reaction of $ArAlH_3Li(L)_2$ or $[ArAlH_2]_2$ with Me_3SiCl (Eqs. (14) and (15)) is currently the most effective and clean method for the synthesis of $ArAlCl_2$ (Ar = Mes*, 2,6-$Mes_2C_6H_3$, 2,6-$Trip_2C_6H_3$) compounds [38,53].

$$[ArAlH_3Li(L)_2]_2 + 6Me_3SiCl \rightarrow 2ArAlCl_2(L) + 6Me_3SiH + 2LiCl + 2L \quad (14)$$

$$[ArAlH_2]_2 + 4Me_3SiCl \xrightarrow{L} 2ArAlX_2(L) + 4Me_3SiH \quad (15)$$

This reaction proceeds smoothly at r.t. over a period of several hours. The presence of 1 or 2 equiv. of Et_2O or THF seems to be required, especially if $[ArAlH_2]_2$ is reacted with the chlorosilane (Eq. (15)). The aryl aluminum dichlorides are isolated in the form of their THF (Ar = Mes* [53]) or Et_2O adducts (Ar = 2,6-$Mes_2C_6H_3$, 2,6-$Trip_2C_6H_3$ [38]), $ArAlCl_2{\cdot}L$. The coordinated donor molecule can be removed under mild conditions to give the base free monomeric (Ar = Mes*) or dimeric (Ar = 2,6-$Mes_2C_6H_3$, 2,6-$Trip_2C_6H_3$) aryl aluminum dichlorides. By using only 2 equiv. of Me_3SiCl the potentially useful mixed aryl aluminum hydride halide $Mes^*Al(H)Cl{\cdot}THF$ can be isolated in good yield [53].

$$[Mes^*AlH_3Li(THF)_2]_2 + 4Me_3SiCl \rightarrow 2Mes^*Al(H)Cl{\cdot}THF + 4Me_3SiH + 2LiCl + 2THF \quad (16)$$

The major advantage of these reactions is that the Al–C bond remains unaffected, i.e. there is high selectivity

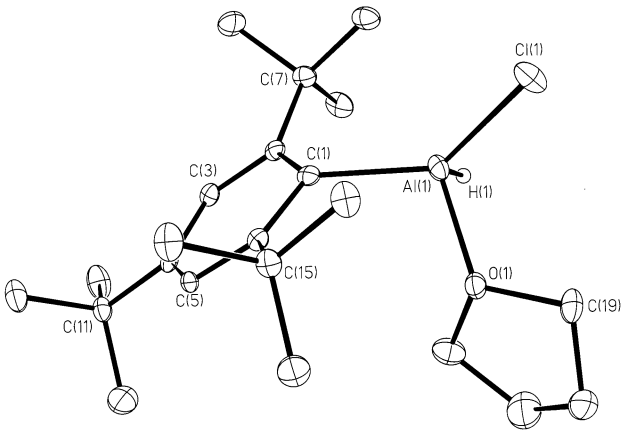

Fig. 4. Thermal ellipsoid plot (35%) of Mes*Al(H)Cl·THF. H-atoms except those bound to aluminum are not shown for clarity [53].

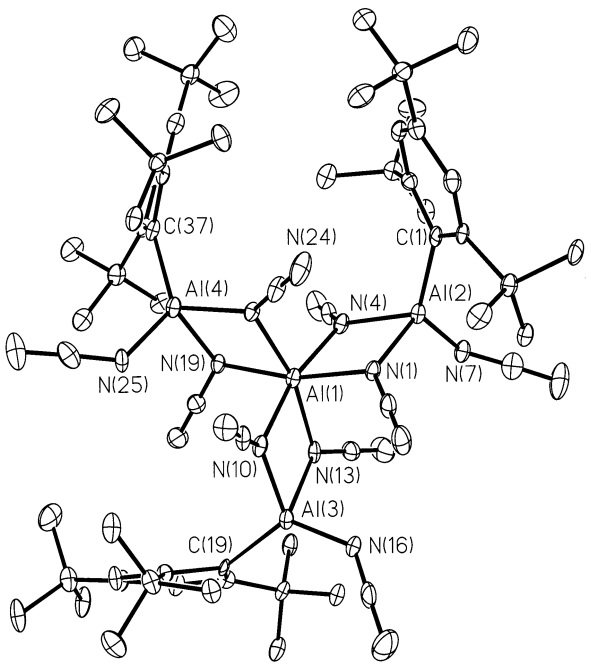

Fig. 5. Thermal ellipsoid plot (35%) of $[Mes*Al(N_3)]_3Al$. H-atoms are not shown for clarity [41].

even in the presence of high steric congestion. The steric crowding is illustrated in Fig. 4, which shows the distorted Mes* substituent in Mes*Al(H)Cl·THF. An additional practical advantage of the use of Me_3SiCl is that it can be used as a neat liquid, whereas the use of HX usually requires the setup of calibrated stock solutions.

Dehydrosilylation (Me_3SiH elimination) reactions have also led to novel organoaluminum azide and cyanide derivatives. Aluminum azides are currently of interest as possible precursors for AlN, an important ceramic material [56,57]. Aluminum cyanides may be of interest in the area of crystal engineering (cf. $Ga(CN)_3$ [58]).

The reaction of $[Mes*AlH_3Li(THF)_2]_2$ with Me_3SiN_3 afforded $[Mes*Al(N_3)_3Li(THF)_m]_n$ on the basis of NMR spectroscopic data, but no pure material could be isolated. However, the use of $[Mes*AlH_2]_2$ as starting material in the presence of at least 1 equiv. of THF resulted in the isolation of colorless, crystalline $Mes*Al(N_3)_2·THF$. The THF can easily be removed at 60–80°C under reduced pressure to give $[Mes*Al(N_3)_2]_n$ with a so far unknown structure. Repeated attempts at crystallization resulted in the isolation of a few colorless crystals of the unexpected azide $[Mes*Al(N_3)_3]_3Al$ (Fig. 5). However, the synthesis of this compound is difficult to reproduce [41].

Investigations on the NMR scale showed that $[Mes*AlH_2]_2$ reacted rapidly with Me_3SiCN at r.t., even in the absence of THF to give $[Mes*Al(CN)_2]_n$ and the concomitant Me_3SiH [41].

5. Aluminum chalcogen compounds

5.1. Aluminum alcoholates and thiolates

Aluminum alcoholates (i.e. alkoxides and aryloxides) are an industrially important class of compounds which may be illustrated by their use in, e.g. the Meerwein–Ponndorf–Verley reduction, i.e. the reduction of aldehydes to alcohols (Eq. (17)) [59], or as Lewis-acid catalysts in organic transformations such as Aldol reactions, Diels–Alder reactions [60] and polymerizations [61].

$$R{-}\overset{\overset{O}{\|}}{C}{-}R' + CH_3{-}\overset{\overset{OH}{|}}{CH}{-}CH_3 \xrightleftharpoons{Al(OCHMe_2)_3} R{-}\overset{\overset{OH}{|}}{CH}{-}R' + CH_3{-}\overset{\overset{O}{\|}}{C}{-}CH_3 \quad (17)$$

Their structure is generally not well defined and often consists of a mixture of oligomers connected by Al–O–Al linkages [62,63]. The coordination number at aluminum is four or higher, whereas that of oxygen is three. Large substituents and, sometimes, careful control of the reaction conditions can limit the amount of oligomerization and crystalline species may be isolated.

Common synthetic approaches to alcoholates have included the alcoholysis of Al–C and Al–H bonds, oxidation of organoaluminum compounds and reduction of carbonyl compounds. Until recently, low coordinate aluminum alcoholates were limited to bulky alkoxides or aryl oxides [64,65].

It was expected that the bulky primary alanes and alanates would be convenient starting materials for low coordinate and well-defined aluminum alcoholates $RAl(OR)_2$, which could be of interest as Lewis-acid catalysts in organic transformations [60].

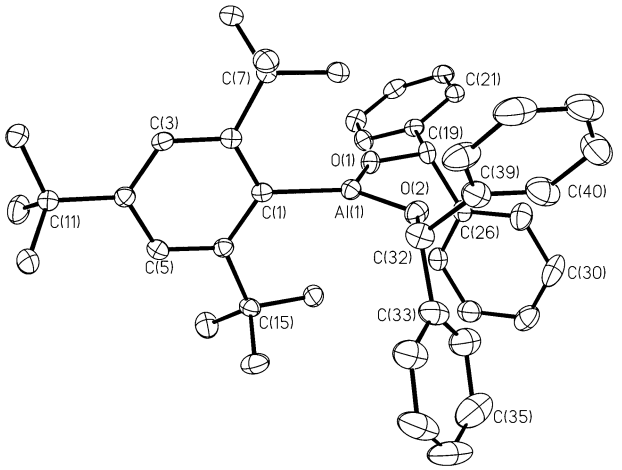

Fig. 6. Thermal ellipsoid plot (35%) of Mes*Al(OCH_2Ph)$_2$. H-atoms are not shown for clarity [41].

The compound [(Me_3Si)$_3$$CAlH_3Li(THF)_2$]$_2$ reacted with alcohols to give the organotrisalkoxy (or aryloxy) alanates (Me_3Si)$_3$$CAl(OR)_3Li(THF)_n$ ($n = 1$, R = Me, *i*-Pr, *t*-Bu, CH_2-*t*-Bu, CH_2Ph, $CHPh_2$; $n = 2$, R = Et, Ph; $n = 4$, R = Me) [66].

$$[(Me_3Si)_3CAlH_3Li(THF)_2]_2 + 6ROH \rightarrow 2(Me_3Si)_3CAl(OR)_3Li(THF)_n + 6H_2 \quad (18)$$

Reaction of [Mes*AlH_2]$_2$ with the geminal diol $Ph_2Si(OH)_2$ afforded only low yields of [Mes*Al-(μ-O)$_2$$SiPh_2$]$_n$. The main product was identified as the Al–C bond cleavage product Mes*H. A similar result was also observed in the reaction of [Mes*AlH_2]$_2$ with *i*-PrOH [67]. Again, the Al–C bond in [(Me_3Si)$_3$$CAlH_3$-$Li(THF)_2$]$_2$ remains intact, whereas significant bond cleavage was observed for [Mes*AlH_2]$_2$.

The reaction of aldehydes and ketones with aluminum hydrides provides an alternative and aprotic route to aluminum alcoholates [68].

$$>Al–H + O{=}CRR' \rightarrow >Al–OC(H)RR' \quad (19)$$

The lithium alanate [(Me_3Si)$_3$$CAlH_3Li(THF)_2$]$_2$ reacts smoothly with acetaldehyde, acetone, trimethylacetaldehyde, benzaldehyde and benzophenone to give the appropriate lithium trisalkoxy alanates [66]. As already seen, a LiOR elimination is not observed. Similarly, $BmtAlH_3Li(DME)_2$ was shown to reduce Ph_2CO and $PhCO_2Ph$ quantitatively to $PhCH_2OH$. The intermediate $BmtAl(OCH_2Ph_2)_3Li$ was characterized by ^1H and ^{27}Al NMR spectroscopy [43].

The lithium free alane [Mes*AlH_2]$_2$ afforded Mes*Al($OCHPh_2$)$_2$ upon treatment with benzaldehyde (Fig. 6). However, use of acetone at r.t. led to considerable Al–C bond cleavage, which was explained by formation of the corresponding enol, $CH_2{=}C(OH)CH_3$, a protic reagent. The ester ethyl acetate was cleanly reduced to [Mes*Al(OEt)$_2$]$_n$ and styrene oxide was regioselectively opened to [Mes*Al(H)OCH_2CH_2Ph]$_n$ [41].

Thiols and disulfides react with [(Me_3Si)$_3$$CAlH_3Li$-$(THF)_2$]$_2$ to afford the lithium tristhiolato aluminum compounds (Me_3Si)$_3$$CAl(SR)_3Li(THF)_2$, which have a structure similar to the related alkoxide derivatives [69]. The compound [Mes*AlH_2]$_2$ smoothly cleaved the Se–Se bond in diphenyl diselenide to give colorless crystals of [Mes*Al(H)$SePh$]$_n$, which can react with additional diphenyl diselenide to afford Mes*Al($SePh$)$_2$ [41].

5.2. Alumoxanes

The development of so-called 'single-site' olefin polymerization catalysts has increased the demand for alumoxanes (RAlO)$_n$ [70]. Despite of the huge quantities of alumoxanes, especially methyl alumoxane (MAO), being produced and consumed each year, their structure is only partially understood [71]. It is now clear that MAO probably consists of a mixture of oligomers with four-coordinate aluminum centers and three-coordinate oxygen donors [72]. In addition, there is also a significant portion that consists of complexed and free $AlMe_3$ present in commercial MAO solutions [73,74].

Controlled hydrolysis of *t*-Bu_3Al has afforded discrete and stable alumoxane molecules [*t*-BuAlO]$_n$ (n = 6–12), most of which were characterized by X-ray crystallography [75,76]. This work also established that even four-coordinate aluminum in these alumoxanes is sufficiently Lewis-acidic for use as a co-catalyst in the polymerization systems, and the term 'latent Lewis-acidity' was coined [77]. It was therefore of interest to learn if an alumoxane with three-coordinate aluminum centers (as was originally proposed for MAO) could be synthesized and what properties it would have. The Mes* substituent was thought to be bulky enough to stabilize a three-coordinate aluminum center in [Mes*AlO]$_n$. Initial attempts using [Mes*AlH_2]$_2$ and water or [2,6-$Mes_2C_6H_3AlH_2$]$_2$ and dry air only led to intractable mixtures [46]. Using HMPA as the oxygen source in Mes*AlH_2·$OP(NMe_2)_3$ required temperatures of ca. 135°C for a reaction to occur and resulted in the formation of the metallated alumoxane [2,4-*t*-Bu_2-(6-CMe_2CH_2)$C_6H_2Al(OP(NMe_2)_3)]_2O$ (Fig. 7). The sulfoxides DMSO and Ph_2SO reacted rapidly with [Mes*AlH_2]$_2$ to afford the desired alumoxane, [Mes*AlO]$_4$ (Fig. 8), in low to moderate yields. A high yield (ca. 80%) route was found by using the silane elimination method. The cyclic siloxane (Me_2SiO)$_3$ cleanly formed the alumoxane in refluxing benzene within a period of 12 h (Eq. (20))[78].

$$6[Mes^*AlH_2]_2 + 4(Me_2SiO)_3 \rightarrow 3[Mes^*AlO]_4 + 12Me_2SiH_2 \quad (20)$$

The more sterically encumbered siloxane (Me_3Si)$_2$O did not show any reactivity toward [Mes*AlH_2]$_2$. Interest-

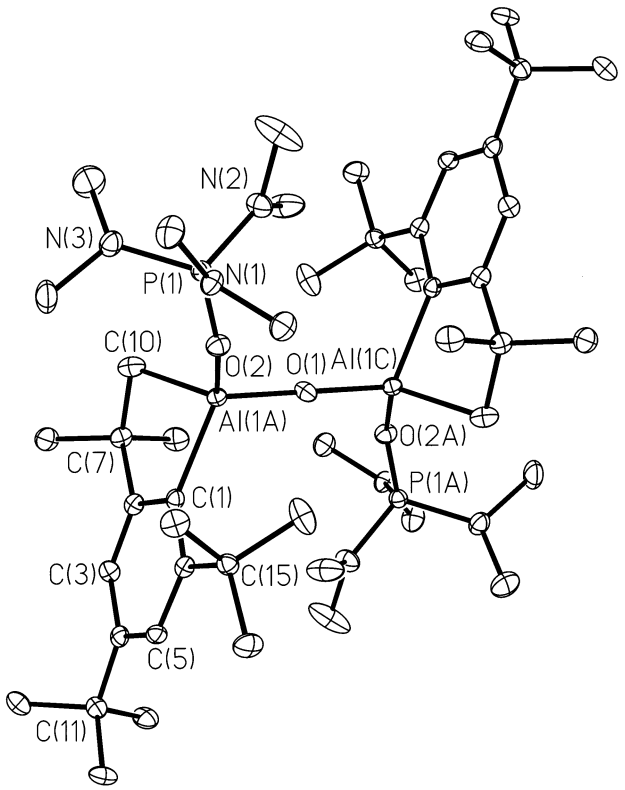

Fig. 7. Thermal ellipsoid plot (35%) of [2,4-*t*-Bu_2-(6-CMe_2CH_2)C_6H_2-$Al(OP(NMe_2)_3)]_2O$. H-atoms are not shown for clarity [46].

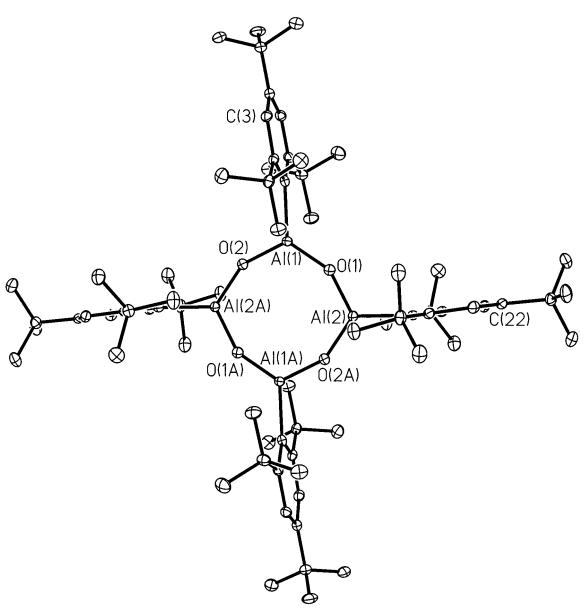

Fig. 8. Thermal ellipsoid plot (35%) of $[Mes*AlO]_4$. H-atoms are not shown for clarity [78].

ingly, the reaction of the terphenyl substituted primary alane $[2,6\text{-}Mes_2C_6H_3AlH_2]_2$ with $(Me_2SiO)_3$ required temperatures of 110–130°C and resulted in mixtures from which only $[2,6\text{-}Mes_2C_6H_3Al(Me)(\mu\text{-}H]_2$ could be isolated in crystalline form. In this case, a methyl group was transferred from silicon to aluminum by an, as yet, unknown pathway [41].

The structure of $[Mes*AlO]_4$ features a unique, almost planar, eight-membered Al_4O_4 ring with three-coordinate aluminum and two-coordinate oxygen (Fig. 8). Despite the low coordination number, no catalytic activity was observed in ethene polymerization experiments with Cp_2ZrMe_2. There was also no complex formation between $[Mes*AlO]_4$ and Cp_2ZrMe_2 or Cp_2ZrCl_2. However, the Lewis acidic $AlMe_3$ and $AlEt_3$ react with $[Mes*AlO]_4$ to give 'mixed' alumoxanes. One of the products of the $AlEt_3$ reaction was characterized by X-ray diffraction as $[Mes*(Et)AlOAlEt_2(Mes*AlO)]_2$ (Fig. 9), which is the only structurally characterized product formed by the reaction of an alumoxane with a trialkylalane [78]. A possible pathway may be initial complexation of AlR_3 by the oxygen donors of $[Mes*AlO]_4$ (cf. crown ethers and $AlMe_3$ [79]) followed by alkyl group migration and rearrangement.

The sulfur analogue, the dimeric $[Mes*AlS]_2$, whose structure is shown in Fig. 10, can also be obtained in

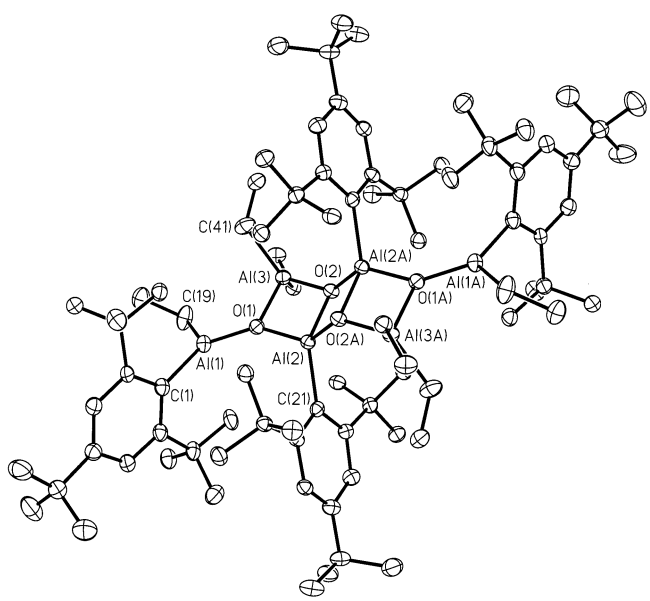

Fig. 9. Thermal ellipsoid plot (35%) of $[Mes*(Et)AlOAlEt_2$-$(Mes*AlO)]_2$. H-atoms are not shown for clarity [78].

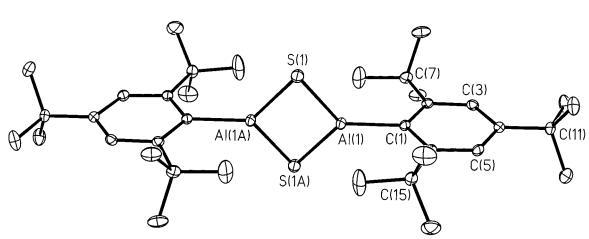

Fig. 10. Thermal ellipsoid plot (35%) of $[Mes*AlS]_2$. H-atoms are not shown for clarity [80].

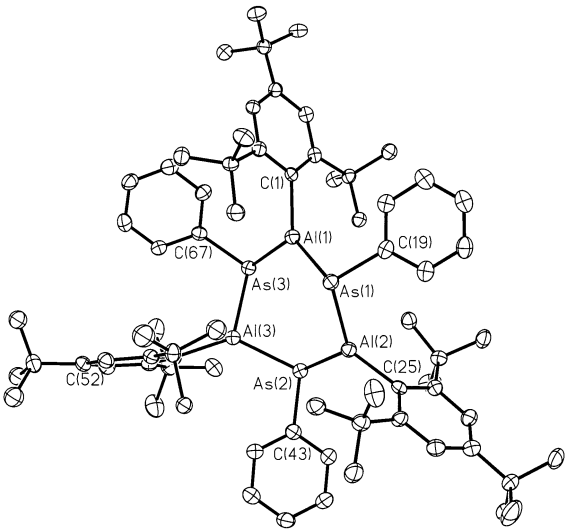

Fig. 11. Thermal ellipsoid plot (35%) of $[Mes^*AlAsPh]_3$. H-atoms are not shown for clarity [85].

high yields by the dehydrosilylation method. Here, $(Me_3Si)_2S$ is sufficiently reactive to afford the product in almost quantitative yields [80].

6. Aluminum pnictogen compounds

The synthesis of the 'alumazene' $[MeAlNDipp]_3$ ($Dipp = C_6H_3\text{-}2,6\text{-}i\text{-}Pr_2$) in 1988 [81] sparked interest in the synthesis of low-coordinate aluminum pnictogen compounds to study the possibility of multiple bonding between these elements [65]. In addition, some work has concentrated on finding (molecular) precursors for the synthesis of AlE insulators (E = N) [82,83] and semiconductors (E = P, As, Sb) [35,84]. Primary alanes with bulky substituents were therefore expected to be ideal starting materials for the synthesis of low-coordinate aluminum pnictogen compounds $[RAlER']_n$ or $RAl(EHR')_2$ (Eqs. (21) and (22)).

$$RAlH_2 + H_2ER \xrightarrow{-H_2} RAl(H)E(H)R' \xrightarrow{-H_2} 1/n[RAlER']_n \quad (21)$$

$$RAlH_2 + 2H_2ER \xrightarrow{-2H_2} RAl(EHR')_2 \quad (22)$$

Accordingly, $[Mes^*AlH_2]_2$ was found to react cleanly at elevated temperatures with H_2NPh and H_2NSiPh_3 to give the dimeric imides $[Mes^*AlNPh]_2$ [85] and $[Mes^*AlNSiPh_3]_2$ [86], which have planar Al_2N_2 cores. The trimeric aluminum phosphide and arsenide compounds $[Mes^*AlEPh]_3$ (E = P, As) were produced similarly [85]. The latter two compounds are formally heavier element Group 13–15 analogs of benzene. The crystal structures, however, showed a significant degree of pyramidalization at the phosphorus or arsenic atoms (Fig. 11), so that extensive aromatic delocalization can be largely ruled out.

The intermediate, a mixed hydride pnictide RAl(H)E(H)R′, could not be isolated. In fact, ^1H NMR studies on the $[Mes^*AlH_2]_2$–H_2NPh system showed an equilibrium involving $[Mes^*AlH_2]_2$, $[Mes^*Al(H)N(H)NPh]_n$ and $Mes^*Al(N(H)Ph)_2$. The latter compound could be crystallized and characterized by X-ray diffraction. The reaction of the bulkier amine $DippNH_2$ with $[Mes^*AlH_2]_2$ afforded the bisamide $Mes^*Al(N(H)Dipp)_2$ as the only isolable product [85]. Interestingly, the benzylamine H_2NCH_2Mes does not form the expected imide either. C–H activation is observed instead [86].

The terphenyl substituted primary alane $[2,6\text{-}Mes_2C_6H_3AlH_2]_2$ reacts smoothly with H_2NPh and H_2AsPh at r.t. For the reaction with H_2PPh a temperature of ca. 160°C was required. Here, the products are the dimeric mixed hydride pnictide compounds $[2,6\text{-}Mes_2C_6H_3Al(H)E(H)Ph]_2$ (Fig. 12). Elimination of the 2nd equiv. of H_2 was accompanied by decomposition. However, in the presence of excess H_2AsPh at 150–160°C $[2,6\text{-}Mes_2C_6H_3AlH_2]_2$ reacted to form an interesting Al–As cage compound $[(2,6\text{-}Mes_2C_6H_3Al)_2\{\mu\text{-}As(H)Ph\}_2(\mu\text{-}PhAsAsPh)]$ with an As–As bond [87].

In order to probe the feasibility of dehydrosilylation for the synthesis of Al–N compounds (with the goal of making AlN) the mixed aluminum hydride amide $Mes^*Al(H)N(SiMe_3)_2$ was synthesized (Eq. (23)). An alternative method, the reaction of $LiN(SiMe_3)_2$ with $[Mes^*AlH_2]_2$ also gave $Mes^*Al(H)N(SiMe_3)_2$, but in yields of less than 40% due to competing Mes*Li elimination.

$$[Mes^*AlH_2]_2 + 2HN(SiMe_3)_2 \rightarrow 2Mes^*Al(H)N(SiMe_3)_2 + H_2 \quad (23)$$

The crystal structure revealed a planar C(*ipso*)Al(H)N core with the hydride and one of the Me_3Si substituents in a *cis* configuration, an orientation which should

support Me_3SiH elimination. However, at the temperatures required for a reaction to occur, competing reactions such as C–H activation and ligand migration also take place. The formal dehydrosilylation product was formed in only 7% yield [88]. An unusually high rotational barrier around the Al–N bond of 18.5(2) kcal mol^{-1} was measured for $Mes^*Al(H)N(SiMe_3)_2$. Crystal structure data indicate that this is more likely due to steric constraints than Al–N π-bonding.

The lithium alanate $[(Me_3Si)_3CAlH_3Li(THF)_2]_2$ reacts with aniline to give the lithium alkylbis(amido)-hydroalanate $(Me_3Si)_3CAlH(\mu\text{-}N(H)Ph)_2Li(THF)_2$ or the alkyltris(amido)alanate $(Me_3Si)_3CAl\{N(H)Ph\}_3Li(THF)_4$, depending on the amount of aniline added [42].

Aluminum nitrogen bonds may also be formed by the reaction of aluminum hydrides with nitriles or isonitriles. The former reaction, i.e. the reduction of nitriles, is a general procedure in organic chemistry (Eq. (24)) [89].

$$>Al\text{–}H \xrightarrow{N\equiv CR} \text{–}Al(H)N{=}C(H)R \rightarrow \text{‘–}Al{=}NCH_2R\text{’} \quad (24)$$

Reaction of $[Mes^*AlH_2]_2$ with nitriles RCN (R = Me, *t*-Bu, Mes) gives the *ortho*-metalated dimers, *cis* and *trans* $[AlC_6H_2\text{-}2,4\text{-}t\text{-}Bu_2\text{-}6\text{-}CMe_2CH_2\{\mu^2\text{-}N(H)CH_2R\}]_2$. In the case of R = *t*-Bu the intermediate $[Mes^*Al(H)N{=}C(H)R]_2$ can be isolated. The formation of an aluminum imide $[Mes^*AlNCH_2R]_n$ was not observed [86]. Similarly, the lithium alanate $BmtAlH_3Li(DME)_2$ was reported to reduce PhCN in a stepwise fashion to PhCH=NH and then $PhCH_2NH_2$ [43]. The isonitrile *t*-BuNC is cleanly reduced to $[Mes^*AlN(t\text{-}Bu)CH_2]_2$, a C- and N-metalated methylbutylamine. No intermediate was isolated. The dimeric compound, which features a six-membered $(AlNC)_2$ ring can be described as a heavier analog of a substituted 1,4-cyclohexadiene (Fig. 13). Refluxing in benzene for 1 h also led to C–H activation of the *o*-*t*-Bu groups of the Mes* substituent [86].

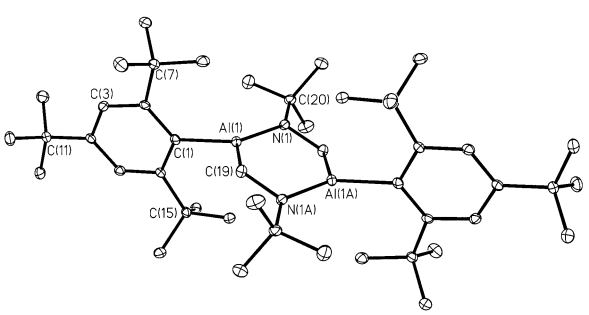

Fig. 13. Thermal ellipsoid plot (35%) of to $[Mes^*AlN(t\text{-}Bu)CH_2]_2$. H-atoms are not shown for clarity [86].

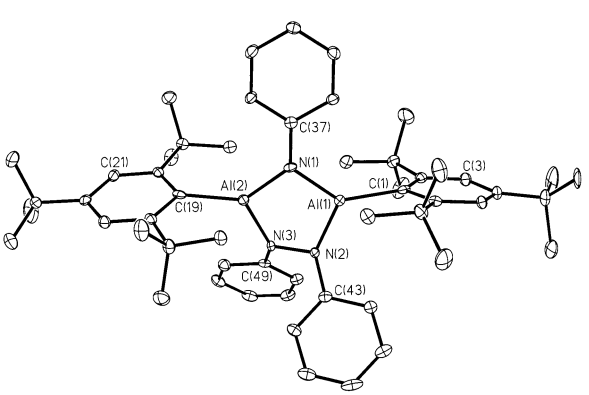

Fig. 14. Thermal ellipsoid plot (35%) of $Mes^*AlN(Ph)Al(Mes^*)N(Ph)NPh$. H-atoms are not shown for clarity [90].

The alane $[Mes^*AlH_2]_2$ also reacts with azobenzene (Eq. (25)) or 1,2-diphenyl hydrazine (Eq. (26)) to give the unique five-membered ring compound $Mes^*\overline{AlN(Ph)Al(Mes^*)N(Ph)N}Ph$, which is a formal aluminum–nitrogen analog of the cyclopentadienide anion, and $[Mes^*AlNPh]_2$ [90].

$$3/2[Mes^*AlH_2]_2 + 2PhNNPh \rightarrow Mes^*\overline{AlN(Ph)Al(Mes^*)N(Ph)N}Ph + 1/2[Mes^*AlNPh]_2 + 3H_2 \quad (25)$$

$$3/2[Mes^*AlH_2]_2 + 2Ph(H)NN(H)Ph \rightarrow Mes^*\overline{AlN(Ph)Al(Mes^*)N(Ph)N}Ph + 1/2[Mes^*AlNPh]_2 + 5H_2 \quad (26)$$

The five-membered ring compound can be viewed as an intermediate in the reduction of diazenes and hydrazines to amines. Fig. 14 shows that the product has a nonplanar Al_2N_3 core indicating little if any π-electron delocalization. This result is in agreement with recent theoretical calculations on the parent compound $H\overline{AlN(H)AlN(H)N}H$ [91].

An NMR experiment to investigate the donor properties of pyridine towards $[Mes^*AlH_2]_2$ showed a rapid 1,2 and 1,4 addition of the Al–H group to give Mes*Al(1,2-dihydropyridyl)- and Mes*Al(1,4-dihydropyridyl)-containing compounds. Isomerization to primarily the 1,4 addition products occurs over a period of 14 days [92]. A similar reaction has also been observed for $LiAlH_4$ and pyridine [93,94]. This reaction was found to be reversible, so that lithium tetrakis-(*N*-dihydropyridyl)-alanate could be used as a mild hydride donor for the reduction of ketones.

7. Miscellaneous reactions

A synthetically very useful reaction is the hydroalumination of alkenes and alkynes, i.e. the formal addition of Al–H across a double or triple bond [95,96].

$$>Al\text{–}H + R_2C{=}CR_2 \rightarrow >Al\text{–}CR_2\text{–}C(H)R_2 \quad (27)$$

The most common reagent employed is the secondary alane $(i\text{-}Bu_2AlH)_3$ and the reaction may be promoted

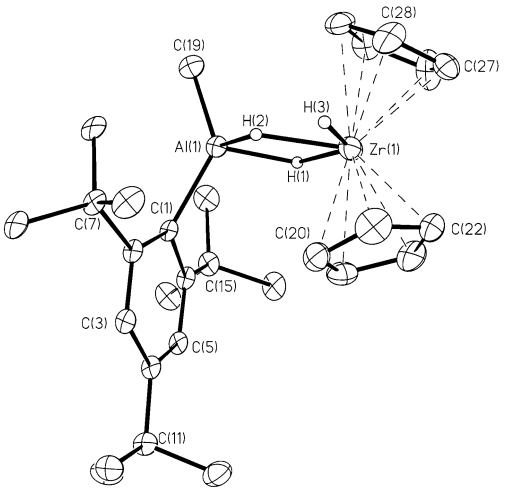

Fig. 15. Thermal ellipsoid plot (35%) of Mes*Al(Me)(μ-H)$_2$Zr(H)Cp$_2$. H-atoms except of those bound to aluminum or zirconium are not shown for clarity [97].

by transition-metal catalysts. Interestingly, [Mes*AlH$_2$]$_2$ does not react with internal alkynes RC≡CR (R = Me, Ph, Me$_3$Si) at temperatures below its melting/decomposition point. A complicated product mixture was obtained when [Mes*AlH$_2$]$_2$ and Me$_3$SiC≡CSiMe$_3$ were reacted at 170°C. The addition of donors like THF did not influence the outcome of these reactions [92].

Similary, there was also no reaction between the weak organic acid CpH and [Mes*AlH$_2$]$_2$, even in refluxing benzene with or without THF added [67].

Addition of Cp$_2$ZrMe$_2$ to [Mes*AlH$_2$]$_2$ in hexane or benzene resulted in methyl and hydride exchange to give a mixture of Cp$_2$ZrH$_2$, Mes*AlMe$_2$ and Mes*Al(Me)(μ-H)$_2$Zr(H)Cp$_2$. The latter compound was characterized by X-ray crystallography (Fig. 15) [97]. It can be viewed as an intermediate in the methyl and hydride exchange reaction. A related methyl free mixed hydride species, Mes*Al(H)(μ-H)$_2$Zr(H)Cp$_2$, can be obtained by the reaction of Cp$_2$Zr(H)Cl with [Mes*AlH$_3$Li(THF)$_2$]$_2$. Its structure is probably similar to the methyl-containing compound according to IR and NMR spectroscopic results. Preliminary experiments concerning the reaction of Mes*Al(H)(μ-H)$_2$-Zr(H)Cp$_2$ with PhC≡CPh or its use as a catalyst in the reaction of [Mes*AlH$_2$]$_2$ with PhC≡CPh afforded only complicated intractable mixtures.

Reactions of [Mes*AlH$_2$]$_2$ with other transition-metal complexes like Cp$_2$MoH$_2$ or (Cy$_3$P)$_2$Ni with the goal of synthesizing compounds with metal–aluminum bonds led to decomposition of the alane [92].

8. Summary

Aluminum hydrides have been widely used in many areas of chemistry since their first isolation in the 1940s. The employment of large sterically protecting substituents has only recently allowed the synthesis and systematic study of the reactivity and structures of primary alanes RAlH$_2$ and the related trihydroalanates RAlH$_3$Li. These new compounds are crystalline and thermally stable. The steric bulk of the substituents makes it possible to isolate intermediates in a variety of 'organic' reductions. In addition, the compound [Mes*AlH$_2$]$_2$ has been shown to be a uniquely suitable starting material for low coordinate aluminum compounds, which could not be synthesized by alternative routes. These species with Al–N, Al–P, Al–As, Al–O and Al–S bonds have contributed significantly to the current knowledge of the ability of aluminum to engage in multiple bonding [65]. Finally, the dehydrosilylation reaction has proven to be a convenient method for the formation of aluminum heteroelement bonds. This is also transferable to 'simple' systems such as the reaction of H$_3$Al·NMe$_3$ with (Me$_3$Si)$_2$S to afford the cluster (Me$_3$NAl)$_4$S$_6$, essentially a solvated form of the inorganic salt Al$_2$S$_3$ [98].

Abstract

Reaction of three phenolate ligands, viz. salicylaldehyde (HL^1), 2-hydroxyacetophenone (HL^2) and 2-hydroxynaphthylaldehyde (HL^3), (abbreviated in general as HL, where H stands for the phenolic proton) with $[Ru(PPh_3)_3Cl_2]$ in 1:1 mole ratio gives complexes of the type $[Ru(PPh_3)_2(L)Cl_2]$. The structure of the $[Ru(PPh_3)_2(L^2)Cl_2]$ complex has been solved by X-ray crystallography. The coordination sphere around ruthenium is $O_2P_2Cl_2$ with a *cis–trans–cis* geometry, respectively. The $[Ru(PPh_3)_2(L)Cl_2]$ complexes are one-electron paramagnetic (low-spin d^5, $S = 1/2$) and show rhombic ESR spectra in 1:1 dichloromethane–toluene solution at 77 K. In dichloromethane solution the $[Ru(PPh_3)_2(L)Cl_2]$ complexes show several intense LMCT transitions in the visible region. Reaction between the phenolic ligands and $[Ru(PPh_3)_3Cl_2]$ in 2:1 mole ratio in the presence of a base affords the $[Ru(PPh_3)_2(L)_2]$ complexes in two isomeric forms. ^1H NMR spectra of one isomer shows that it does not have any C_2 symmetry and has the *cis–cis–cis* disposition of the three sets of donor atoms. ^1H NMR spectra of the other isomer shows that it has C_2 symmetry. The structure of the isomer of the $[Ru(PPh_3)_2(L^1)_2]$ complex has been solved by X-ray crystallography. The coordination sphere around ruthenium is O_4P_2 with a *cis–trans–cis* disposition of the carbonylic oxygens, phenolate oxygens and phosphorus atoms, respectively. The $[Ru(PPh_3)_2(L)_2]$ complexes are diamagnetic (low-spin d^6, $S = O$) and show intense MLCT transitions in the visible region. Cyclic voltammetry on the $[Ru(PPh_3)_2(L)Cl_2]$ complexes shows a ruthenium(III)–ruthenium(II) reduction near -0.3 V versus SCE and a ruthenium(III)–ruthenium(IV) oxidation in the range 1.08–1.24 V versus SCE. Cyclic voltammetry on both isomers of the $[Ru(PPh_3)_2(L)_2]$ complexes shows a ruthenium(II)–ruthenium(III) oxidation within 0.09–0.41 V versus SCE, followed by a ruthenium(III)-ruthenium(IV) oxidation within 1.31–1.52 V versus SCE. © 2000 Elsevier Science Ltd. Keywords: Ruthenium; Phenolic ligands; Synthesis; Structure; Redox properties

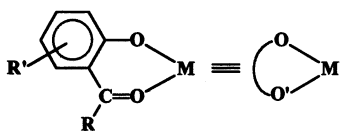
1. Introduction



The chemistry of ruthenium has currently been receiving a lot of attention [1–10] primarily because of the fascinating electron-transfer and energy-transfer properties displayed by the complexes of this metal. Ruthenium offers a wide range of oxidation states and the reactivities of the ruthenium complexes depend on the stability and interconvertibility of these oxidation states, which in turn depend on the nature of ligands bound to the metal. Complexation of ruthenium by ligands of different types has thus been of particular interest. In the present study, which has originated from our interest in the chemistry of ruthenium in different coordination environments [11–18], we have chosen phenolic ligands of type **1** as the principal ligand, which are abbreviated in general as HL where H stands for the dissociable phenolic proton. The deprotonated ligands are known to coordinate metal ions as bidentate O,O-donor forming six-membered chelate rings (**2**) [19,20]. Three different phenolic ligands have been used in this study, which are shown in **1** along with their specific abbreviations.

2

While phenolate oxygen is a recognized hard donor, and coordination by it is known to stabilize the higher oxidation states of ruthenium [21–23], coordination of metals by carbonylic oxygen has also recently been of considerable interest in bioinorganic chemistry [24–28]. It may be mentioned here that ruthenium chemistry of these ligands has not been explored much [19]. Stability of different oxidation states of ruthenium is expected to depend on the number of phenolate and carbonylic oxygen in the coordination sphere and in the case of mixed-ligand complexes, on the nature of coligands also. Herein we have restricted our studies to some mono- and bis-phenolate complexes of ruthenium, which have been synthesized by reacting the phenolic ligands with $[Ru(PPh_3)_3Cl_2]$ under different experimental conditions. The chemistry of complexes of the type $[Ru(PPh_3)_2(L)Cl_2]$ and $[Ru(PPh_3)_2(L)_2]$ has been described in this paper with special reference to synthesis, stereoisomerism and electron-transfer properties.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride was purchased from Arora Matthey, Calcutta, India, and was converted into $RuCl_3 \cdot 3H_2O$ by repeated evaporation with concentrated hydrochloric acid. Triphenylphosphine (PPh_3), triethylamine (NEt_3) and salicylaldehyde (HL^1) were obtained from SD, India. 2-Hydroxyacetophenone (HL^2) and 2-hydroxynaphthaldehyde (HL^3) were purchased, respectively, from Spectrochem, India and Aldrich. All other chemicals and solvents were reagent grade commercial materials and were used as received. $[Ru(PPh_3)_3Cl_2]$ was prepared following a reported procedure [29]. Purification of acetonitrile and preparation of tetraethylammonium perchlorate (TEAP) for electrochemical work were performed as before [30,31].

2.2. Preparation of complexes

2.2.1. $[Ru(PPh_3)_2(L^1)Cl_2]$

HL^1 (15 mg, 0.12 mmol) was added to a suspension of $[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) in ethanol (40 cm^3) and the mixture was stirred for 5 h to produce a green solution. On partial evaporation of the solvent, $[Ru(PPh_3)_2(L^1)Cl_2]$ separated out as a green crystalline solid, which was collected by filtration, washed with ethanol and dried in air. The yield was 55 mg (64%).

2.2.2. $[Ru(PPh_3)_2(L^2)Cl_2]$

This was synthesized by following the same procedure above using HL^2 instead of HL^1. The yield was 60 mg (69%).

2.2.3. $[Ru(PPh_3)_2(L^3)Cl_2]$

Dichloromethane (40 cm^3) was added to a solid mixture of $[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) and HL^3 (20 mg, 0.12 mmol) and the solution was stirred for 3 h to afford a green solution. On evaporation of the solvent, a green solid was obtained, which was washed with ethanol and dried in air. Purification of this product was achieved by chromatography through a silica gel column. Using toluene as the eluent a green band resulted, which was collected. Evaporation of the eluate gave $[Ru(PPh_3)_2(L^3)Cl_2]$ as a green microcrystalline solid. The yield was 55 mg (61%).

2.2.4. ctc and ccc isomers of $[Ru(PPh_3)_2(L^1)_2]$

2.2.4.1. Method A. $[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) was added to a hot solution of HL^1 (30 mg, 0.24 mmol) in ethanol (40 cm^3), followed by NEt_3 (30 mg, 0.30 mmol). The mixture was refluxed for 2 h to produce a red solution. On partial evaporation of solvent, a microcrystalline red solid precipitated, which was collected by filtration, washed thoroughly with water and dried in vacuo over P_4O_{10}. Purification was achieved by chromatography through silica gel column. Using toluene and 1:4 acetonitrile–toluene as the eluents, two different red bands resulted, which were collected separately and evaporation of the eluates, respectively, gave the ctc and ccc isomers of $[Ru(PPh_3)_2(L^1)_2]$. The yield was 30 mg (33%) for the ctc isomer and 32 mg (35%) for the ccc isomer.

2.2.4.2. Method B. $[Ru(PPh_3)_2(L^1)Cl_2]$ (50 mg, 0.06 mmol) was dissolved in a minimum volume of dichloromethane and to it a solution of HL^1 (10 mg, 0.08 mmol) in ethanol (30 cm^3) was added, followed by NEt_3 (10 mg, 0.10 mmol). The solution was refluxed for 4 h. Upon evaporation of the solution, a red crystalline solid was obtained, which was washed with water and dried in vacuo over P_4O_{10}. The solid was then purified as in Method A. The ctc and ccc isomers of $[Ru(PPh_3)_2(L^1)_2]$ were obtained in 36 and 32% yields, respectively.

2.2.5. ctc and ccc isomers of $[Ru(PPh_3)_2(L^2)_2]$

These isomers have been prepared by following the above procedures. In method A, HL^2 was used instead of HL^1. The ctc and ccc isomers of $[Ru(PPh_3)_2(L^2)_2]$ were obtained in 30 and 34% yields. In method B $[Ru(PPh_3)_2(L^2)Cl_2]$ and HL^2 were used instead of $[Ru(PPh_3)_2(L^1)Cl_2]$ and HL^1, respectively. Yields of the ctc and ccc isomers were 35 and 33%, respectively.

2.2.6. ctc and ccc isomers of $[Ru(PPh_3)_2(L^3)_2]$

These isomers have been prepared by following the above procedures (Section 2.2.4). In method A, HL^3 was used instead of HL^1. The ctc and ccc isomers of $[Ru(PPh_3)_2(L^3)_2]$ were obtained in 32 and 36% yields. In method B, $[Ru(PPh_3)_2(L^3)Cl_2]$ and HL^1 were used instead of $[Ru(PPh_3)_2(L^1)Cl_2]$ and HL^1, respectively. Yields of the ctc and ccc isomers were 32 and 34%, respectively.

2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were obtained on a Perkin–Elmer 783 spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on Shimadzu UV 240 spectrophotometer. Magnetic susceptibilities were measured using a PAR 155 Vibrating sample magnetometer fitted with a Walker scientific L75FBAL magnet. ^1H NMR spectra were recorded on a Bruker AC-200 spectrometer using TMS as the internal standard. ESR spectra were recorded on a Varian Model 109C E-line X-band spectrometer fitted with a quartz Dewar for measurements at 77 K (liquid dinitrogen). All spectra were calibrated with the help of DPPH ($g = 2.0037$). Electrochemical measurements were made using a PAR model 273 potentiostat. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in a three electrode configuration. Dinitrogen gas was purified by successively bubbling it through alkaline dithionite and concentrated sulfuric acid. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials. An RE 0089 X-Y recorder was used to trace the voltammograms.

[a] $R_1 = \Sigma\|F_o|-|F_c\|/\Sigma|F_o|$.
[b] $wR_2 = [\Sigma[w(F_o^2-F_c^2)^2]/\Sigma[w(F_o^2)^2]]^{1/2}$.
[c] GOF $= [\Sigma[w(F_o^2-F_c^2)^2]/(M-N)^{1/2}$, where M is the number of reflections and N is the number of parameters refined.
[d] $R_f = \Sigma\|F_o|-|F_c\|/\Sigma|F_o|$.
[e] $R_w = [\Sigma w(|F_o|-|F_c|)^2/\Sigma w(F_o)^2]^{1/2}$.
[f] GOF $= [\Sigma w(|F_o|-|F_c|)^2/(M-N)]^{1/2}$, where M is the number of reflections and N is the number of parameters refined.

2.4. Crystallography

Single crystals of $[Ru(PPh_3)_2(L^2)Cl_2]$ were grown by slow diffusion of hexane into a dichloromethane solution of the complex. Selected crystal data and data collection parameters are given in Table 1. Data were collected on a Siemens Smart CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by ω scans within the angular range $1.57 < \theta < 25.00°$. X-ray data reduction, structure solution and refinement were done using SHELXTL-PLUS package. The structure was solved by direct methods.

Single crystals of ctc-$[Ru(PPh_3)_2(L^1)_2]$ were grown by slow diffusion of benzene into an acetonitrile solution of the complex. Selected crystal data and data collection parameters are given in Table 1. The unit cell dimensions were determined by a least-squares fit of 25 centered reflections ($10.80 \le \theta \le 20.94°$). Data were collected on an Enraf–Nonius CAD-4 diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by $\theta - 2\theta$ scans within the angular range $3.0 < 2\theta < 45.0°$. Three standard reflections, used to check the crystal stability towards X-ray exposure, showed no significant intensity variation over the course of data collection. X-ray data reduction, and structure solution and refinement were carried out using the SHELXS-97 package. The structure was solved by the direct methods.

3. Results and discussion

3.1. Preparation and characterization

afford complexes of the type $[Ru(PPh_3)_2(L)Cl_2]$. It is interesting to note here that ruthenium has undergone a one-electron oxidation during the course of this synthetic reaction. In view of the ruthenium(III)–ruthenium(II) reduction potentials in these complexes (vide infra), oxygen in air appears to have served as the oxidant. Compositions of the complexes have been confirmed by their microanalytical data (Table 2). As all the three phenolate ligands used in the present study are asymmetric bidentate in nature, the $[Ru(PPh_3)_2(L)Cl_2]$ complexes may exist in three geometric isomeric forms (**3**–**5**).

3 **4** **5**

To distinguish between the possible three isomers, molecular structure of a representative complex, viz. $[Ru(PPh_3)_2(L^2)Cl_2]$, has been determined by X-ray crystallography. The structure is shown in Fig. 1 and selected bond distances and angles are presented in Table 3. The $O_2P_2Cl_2$ coordination sphere around ruthenium is distorted octahedral in nature, which is

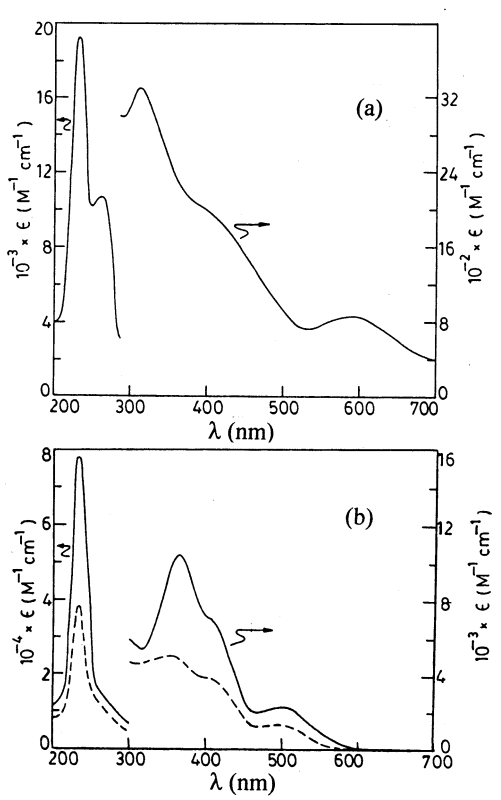

Fig. 2. Electronic spectra of (a) $[Ru(PPh_3)_2(L^3)Cl_2]$ and (b) ctc-$[Ru(PPh_3)_2(L^1)_2]$ (—) and ccc-$[Ru(PPh_3)_2(L^1)_2]$ (------) in dichloromethane solution.

reflected in the bond parameters. The two bulky PPh_3 ligands are in *trans* positions, as is usually observed in complexes of ruthenium(III) having the $Ru(PPh_3)_2$ moiety [32–34], while the two chloride ligands have occupied *cis* positions. The observed bond distances are all quite normal as observed in structurally characterized complexes of ruthenium containing similar ligands [19,32–34]. This structure determination thus shows that $[Ru(PPh_3)_2(L^2)Cl_2]$ has structure **3**. As all the three $[Ru(PPh_3)_2(L)Cl_2]$ complexes display similar properties (vide infra), the other two $[Ru(PPh_3)_2(L)Cl_2]$ complexes are assumed to have a similar structure as $[Ru(PPh_3)_2(L^2)Cl_2]$.

Infrared spectra of the $[Ru(PPh_3)_2(L)Cl_2]$ complexes show many sharp and strong vibrations in the 1600–300 cm^{-1} region, of which the vibrations near 520, 700 and 745 cm^{-1} are also observed in $[Ru(PPh_3)_3Cl_2]$ and hence these are attributable to the $Ru(PPh_3)_2$ fragment of the $[Ru(PPh_3)_2(L)Cl_2]$ complexes. One new band, observed near 1580 cm^{-1} in all these complexes, is assigned to the ν(C=O) vibration of the coordinated phenolate ligand. The ν(Ru–Cl) stretching vibration appears as a strong band in all the complexes near 330 cm^{-1}. The infrared spectral data thus correspond to the composition of the complexes. The $[Ru(PPh_3)_2(L)Cl_2]$ complexes are soluble in common polar organic solvents, like dichloromethane, chloroform, acetonitrile, etc., producing green solutions. Electronic spectra of these complexes have been recorded in dichloromethane solution. A selected spectrum is shown in Fig. 2 and spectral data are listed in Table 2. Each complex shows few intense absorptions in the visible region together with some very intense absorptions in the ultraviolet region. The absorptions in the ultraviolet region may be assigned to transitions occurring within the ligand orbitals. To have an insight into the nature of transitions appearing in the visible region, qualitative EHMO calculations have been performed [35,36] on a model of the $[Ru(PPh_3)_2(L)Cl_2]$ complexes, which was computer generated from $[Ru(PPh_3)_2(L^1)Cl_2]$ by replacing the phenyl groups of the PPh_3 ligands with hydrogen. A partial MO diagram is shown in Fig. 3. The highest occupied (singly occupied) molecular orbital (MO-1) and the next two filled orbitals (MO-2 and MO-3) of this model are predominantly ($\geq 80\%$) ruthenium t_2 in character. There are two filled molecular orbitals (MO-4 and MO-5) below these metal t_2 orbitals, which are localized almost entirely ($\geq 96\%$) on the phenolate ligand. The intense absorptions observed in the visible region may therefore be assigned to the allowed ligand-to-metal charge-transfer transitions occurring from the filled orbitals of the phenolate ligand (MO-4 and MO-5) to the half-filled ruthenium t_2 orbital (MO-1).

Magnetic susceptibility show that all the three $[Ru(PPh_3)_2(L)Cl_2]$ complexes are one-electron paramagnetic, which is in accordance with the +3 oxidation state of ruthenium (low-spin d^5, $S = 1/2$) in these complexes. Electron spin resonance spectra of the $[Ru(PPh_3)_2(L)Cl_2]$ complexes, recorded in 1:1 dichloromethane–toluene solution at 77 K, show rhombic spectra with three distinct signals (g_1, g_2 and g_3 in the order of decreasing magnitude). A representative spectrum is shown in Fig. 4 and the spectral data are

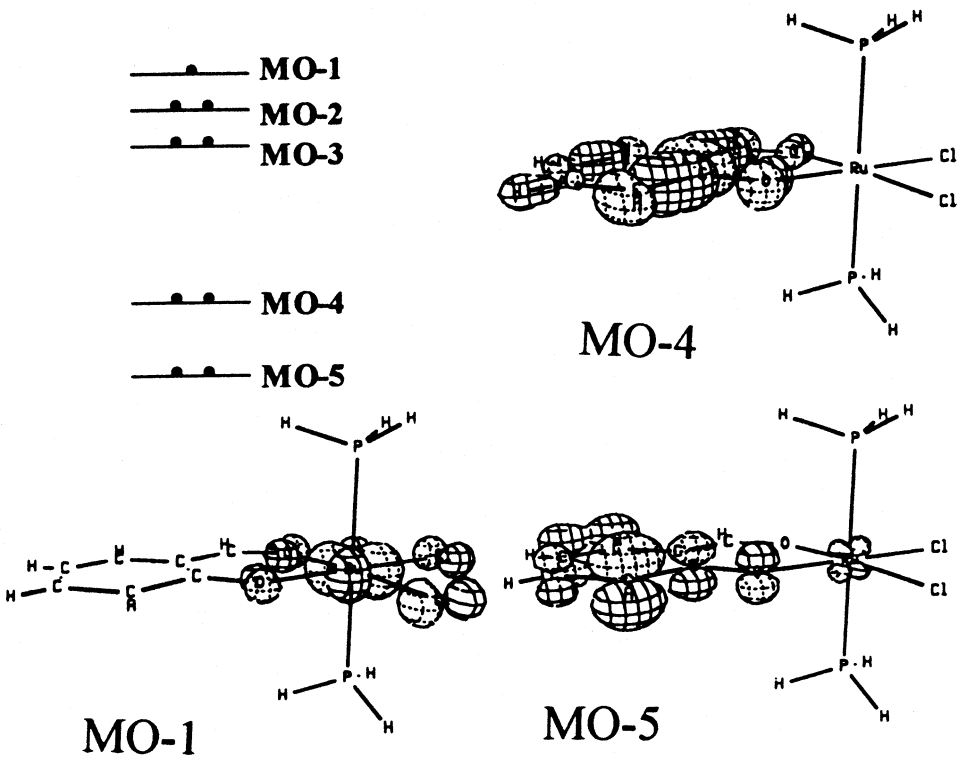

Fig. 3. Qualitative molecular orbital diagram of $[Ru(PPh_3)_2(L)Cl_2]$.

presented in Table 4. The observed rhombicity of the ESR spectra is understandable in terms of the gross molecular symmetry of these complexes containing the three non-equivalent P–Ru–P, O(phenolic)–Ru–Cl and O(carbonylic)–Ru–Cl axes. The rhombic distortion can be thought of a combination of axial distortion (Δ, which splits t_2 into **a** and **e**) and rhombic distortion (V, which splits **e**). The splitting pattern is illustrated in Fig. 4. Spin-orbit coupling causes further changes in the energy gaps. Thus two electronic transitions (transition energies ΔE_1 and ΔE_2; $\Delta E_1 < \Delta E_2$) are possible within these three levels. All these energy parameters have been computed (Table 4) using the observed g values, the g tensor theory of low-spin d^5 complexes and a reported method [37–39]. The axial distortion is observed to be much stronger than the rhombic one. The ΔE_1 transition falls in the infrared region (3200–3700 cm^{-1}) and could not be detected. The ΔE_2 transition, which is expected to occur near 6000 cm^{-1} ($\sim$1667 nm), could not be verified either because of the non-transparency of the solvent in this region. However, the ESR data analysis shows that the $[Ru(PPh_3)_2(L)Cl_2]$ complexes are significantly distorted from ideal octahedral geometry, which was also observed in the structural analysis of $[Ru(PPh_3)_2(L_2)Cl_2]$.

3.1.2. $[Ru(PPh_3)_2(L)_2]$ complexes

These complexes have been prepared in two different ways (Scheme 1). Direct reaction of the phenolic ligands (HL) with $[Ru(PPh_3)_3Cl_2]$ in 2:1 mole ratio proceeds smoothly in refluxing ethanol in the presence of a base to afford the bis complexes of type $[Ru(PPh_3)_2(L)_2]$. These complexes can also be prepared from $[Ru(PPh_3)_2(L)Cl_2]$ by reacting them with one equivalent of the respective phenolic ligand (HL) in the presence of a base. Thin layer chromatographic experiments indicated the presence of two isomers (isomer-I and isomer-II) in all $[Ru(PPh_3)_2(L)_2]$ complexes, which have

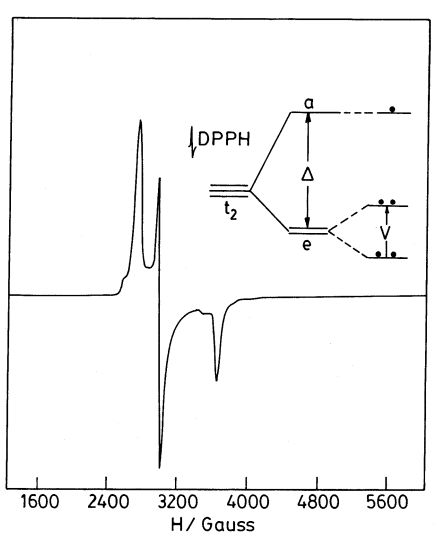

Fig. 4. ESR spectrum of $[Ru(PPh_3)_2(L^2)Cl_2]$ in 1:1 dichloromethane–toluene solution at 77 K.

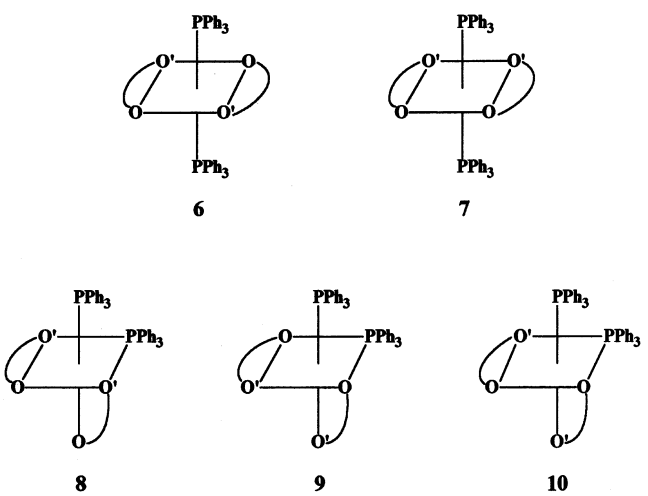

Table 4
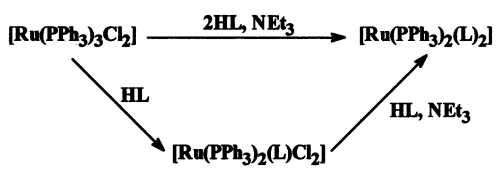
Magnetic moment and ESR g values [a] and derived parameters [b] of the $[Ru(PPh_3)_2(L)Cl_2]$ complexes

Compound	μ_{eff} (BM)	g_1	g_2	g_3	Δ/λ	V/λ	$\Delta E_1/\lambda$	$\Delta E_2/\lambda$
$[Ru(PPh_3)_2(L^1)Cl_2]$	1.85	2.497	2.212	1.791	4.313	−2.450	3.236	5.801
$[Ru(PPh_3)_2(L^2)Cl_2]$	1.93	2.428	2.233	1.828	4.574	−1.976	3.691	5.830
$[Ru(PPh_3)_2(L^3)Cl_2]$	1.97	2.407	2.258	1.795	4.065	−1.264	3.515	5.029



[a] In 1:1 dichloromethane–toluene solution at 77 K.
[b] Spin-orbit coupling constant (λ) for complexed ruthenium(III) is $\sim$1000 cm^{-1}.

been separated by column chromatography. Microanalytical data of these complexes are in good agreement with their compositions (Table 2). Both isomers of these complexes are diamagnetic, which corresponds to the bivalent state of ruthenium (low-spin d^6, $S = O$) in these complexes.

As all three phenolate ligands used in the present study are asymmetric, the $[Ru(PPh_3)_2(L)_2]$ complexes may exist in five geometrical isomeric forms (**6**–**10**). Isomers **6**–**9** have a C_2 axis, while isomer **10** does not have any C_2 symmetry. ^1H NMR spectra have been recorded on both isomers of all three $[Ru(PPh_3)_2(L)_2]$ complexes in $CDCl_3$ solution. Isomer-I of all three complexes clearly shows the presence of a C_2 axis, while isomer-II indicates the absence of C_2 symmetry. For example, isomer-I of $[Ru(PPh_3)_2(L^1)_2]$ shows only one aldehydic proton signal at 8.68 ppm, while isomer-II of $[Ru(PPh_3)_2(L^1)_2]$ shows two aldehydic proton signals (1H each) at 8.36 and 8.53 ppm. This shows that isomer-II has structure **10**, where the three sets of donor atoms are in *cis* positions and henceforth this isomer will be labeled as the *cis*–*cis*–*cis* or ccc isomer.

It has not been possible to assign specific stereochemistry of isomer-I on the basis of ^1H NMR spectral results alone. However, as complexes of ruthenium with the $Ru(PPh_3)_2$ are known to Prefer *cis*-disposition of PPh_3 ligands [33,34,40], these $[Ru(PPh_3)_2(L)_2]$ complexes may be assumed to have either structure **8** or **9**. To sort out this problem of stereochemistry of isomer-I, the molecular structure of isomer-I of $[Ru(PPh_3)_2(L^1)_2]$ has been determined by X-ray crystallography. The structure is shown in Fig. 5 and selected bond distances and angles are presented in Table 5. Ruthenium has a distorted octahedral O_4P_2 coordination sphere with the two PPh_3 ligands in *cis* positions, the two phenolate oxygens in *trans* positions and the two carbonylic oxygens in *cis* positions. Therefore isomer-I of $[Ru(PPh_3)_2(L^1)_2]$ has structure **9** (henceforth referred to as the ctc isomer to indicate the *cis*–*trans*–*cis* dispositions of the carbonylic oxygens, phenolate oxygens and phosphines, respectively). The observed bond parameters are all quite normal. In view of the similarity in synthetic procedure and properties, isomer-I of the other two $[Ru(PPh_3)_2(L)_2]$ complexes are assumed to have similar ctc structure.

Infrared spectra of ctc and ccc isomers of the $[Ru(PPh_3)_2(L)_2]$ complexes are very similar. Each shows characteristic vibrations near 500, 700, 750 cm^{-1}, indicating the presence of the $Ru(PPh_3)_2$ moiety. The ν(C=O) vibration is observed as a strong band near 1580 cm^{-1} in all these complexes. The $[Ru(PPh_3)_2(L)_2]$ complexes are soluble in common organic solvents like dichloromethane, chloroform, acetone, acetonitrile, etc., forming intense red solutions. Electronic spectra of these complexes, recorded in dichloromethane solution, show several intense absorptions in the visible region and few absorptions of very high intensity in the ultraviolet region (Fig. 2, Table 2). The latter absorptions are assigned to transitions within the ligand orbitals. The former absorptions in the visible region are probably due to allowed metal-to-ligand charge-transfer transitions. Multiple charge-transfer transitions are common in such mixed ligand complexes, primarily because of the lower symmetry splitting of the metal orbitals and presence of different accepting orbitals. For proper assignment of the absorptions in the visible region, qualitative EHMO calculations have been performed as before on models of the ctc and ccc isomersa of $[Ru(PPh_3)_2(L^1)_2]$, where phenyl groups of the PPh_3 ligands have been replaced by hydrogen. The results of these calculations are qualitatively very similar for both the isomers. A partial MO diagram for one isomer is shown in Fig. 6. The highest occupied molecular orbital (HOMO) and the next two filled orbitals (HOMO-1 and HOMO-2) are basically ($>75\%$) ruthenium t_2 orbitals. There are two relatively close vacant molecular orbitals above these filled orbitals, the lowest unoccupied molecular orbital (LUMO) and the next unoccupied orbital (LUMO + 1), which are primarily ($>95\%$) π-orbitals of the phenolate ligands. The intense absorptions observed in the visible region may therefore be assigned to the charge-transfer transitions occurring from the filled ruthenium t_2 orbitals to the vacant π-orbitals of the phenolate ligands.

3.2. Electron-transfer properties

Electron-transfer properties of the $[Ru(PPh_3)_2(L)Cl_2]$ and $[Ru(PPh_3)_2(L)_2]$ have been studied in acetonitrile solution by cyclic voltammetry. Representative voltammograms are shown in Fig. 7 and voltammetric data are presented in Table 2.

Each $[Ru(PPh_3)_2(L)Cl_2]$ complex shows a reductive response on the negative side of SCE and an oxidative response on the positive side. Both responses are quasi-reversible in nature. The reduction, observed near -0.3 V (all potentials are referenced to SCE), is tentatively assigned to ruthenium(III)-ruthenium(II) reduction and the oxidation, which occurs within 1.08–

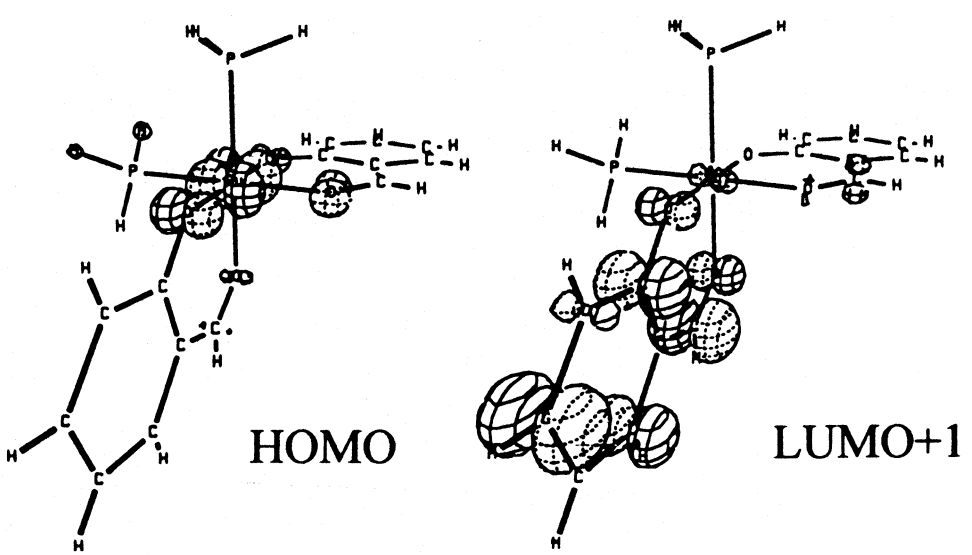

Fig. 6. Qualitative molecular orbital diagram of $[Ru(PPh_3)_2(L)_2]$.

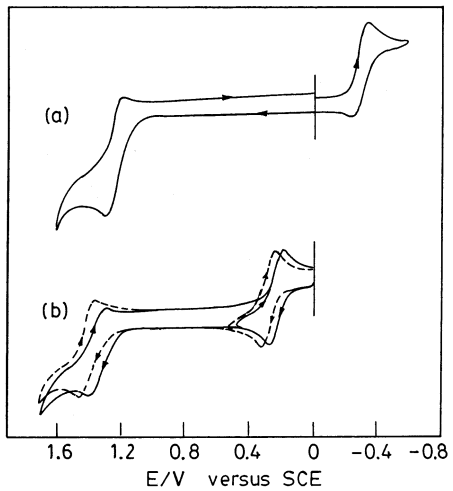

Fig. 7. Cyclic voltammograms of (a) $[Ru(PPh_3)_2(L^3)Cl_2]$ and (b) ctc-$[Ru(PPh_3)_2(L^1)_2]$ (—) and ccc-$[Ru(PPh_3)_2(L^1)_2]$ (-------) in acetonitrile solution (0.1 M TEAP) at a scan rate of 50 mV s^{-1}.

1.24 V, is tentatively assigned to ruthenium(III)–ruthenium(IV) oxidation. Both potentials have shifted to a little more negative values in $[Ru(PPh_3)_2(L^2)Cl_2]$ relative to $[Ru(PPh_3)_2(L^1)Cl_2]$, which may be attributed to the electron donating character of the methyl group in L^2.

Both isomers of $[Ru(PPh_3)_2(L)_2]$ complexes show two oxidative responses on the positive side of SCE. The first oxidation, which is observed within 0.09–0.41 V, is reversible in nature and is assigned to ruthenium(II)–ruthenium(III) oxidation. The second quasi-reversible oxidation appears within 1.31–1.52 V and is tentatively assigned to the ruthenium(III)–ruthenium(IV) oxidation. Potentials of both oxidations have been observed to shift to lower values in the ctc isomer than the ccc isomer, which indicates that the lower oxidation states are more comfortable in the ccc isomer than in the ctc isomer. This is in accordance with the higher probability of dπ-pπ backbonding in the ccc isomer [41–43]. The oxidation potentials are observed to be a little lower in $[Ru(PPh_3)_2(L^2)_2]$ than in $[Ru(PPh_3)_2(L^1)_2]$, as before. The cyclic voltammetric studies indicate that the +3 state of ruthenium is stable in the $O_2P_2Cl_2$ coordination sphere in the $[Ru(PPh_3)_2(L)Cl_2]$ complexes and so is the +2 state of ruthenium in the O_4P_2 coordination sphere in the $[Ru(PPh_3)_2(L)_2]$ complexes.

4. Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge, CB2 1EZ, UK, on request, quoting the deposition numbers CCDC 138541 and 138542.

Abstract

Reaction of three phenolate ligands, viz. 2,4,6-tribromophenol (HL^1, where H stands for the phenolic proton), 2-nitrophenol (HL^2) and 2,4,6-trinitrophenol (HL^3O), with $[Ru(PPh_3)_3Cl_2]$ in a 2:1 molar ratio in the presence of a base gives complexes of type $[Ru(PPh_3)_2(L)_2]$ ($L = L^1$, L^2 and L^3). The 2,4,6-tribromophenolate ligand (L^1) binds to ruthenium as a bidentate O,Br-donor, while the 2-nitrophenolate ligand (L^2) acts as a bidentate O,O-donor. 2,4,6-Trinitrophenol (HL^3O) undergoes oxygen loss from one nitro group at the *ortho* position and coordinates to ruthenium in the 2-nitroso-4,6-dinitrophenolate (L^3) form through the nitroso nitrogen and phenolate oxygen. The structures of the $[Ru(PPh_3)_2(L^1)_2]$ and $[Ru(PPh_3)_2(L^3)_2]$ complexes have been solved by X-ray crystallography. In $[Ru(PPh_3)_2(L^1)_2]$ the coordination sphere around ruthenium is $O_2P_2Br_2$ with a *trans–cis–cis* disposition of the three sets of donor atoms, respectively. In $[Ru(PPh_3)_2(L^3)_2]$ ruthenium has a $N_2O_2P_2$ coordination sphere with a *cis–cis–trans* arrangement of the three sets of donor atoms, respectively. The $[Ru(PPh_3)_2(L)_2]$ complexes are diamagnetic (low-spin d^6, $S = 0$) and in acetonitrile solution show intense MLCT transitions in the visible region. Cyclic voltammetry on the $[Ru(PPh_3)_2(L)_2]$ complexes shows a reversible ruthenium(II)–ruthenium(III) oxidation within 0.63–0.71 V versus SCE followed by an irreversible ruthenium(III)–ruthenium(IV) oxidation near 1.5 V versus SCE. © 2000 Elsevier Science Ltd. Keywords: Ruthenium; Phenolic ligands; Synthesis; Structure; Redox properties

1. Introduction

There is much current interest in the chemistry of ruthenium [1–10], most of which is due to the fascinating electron-transfer and energy-transfer properties displayed by the complexes of this metal. The coordination environment around the metal primarily dictates properties of the ruthenium complexes. Complexation of ruthenium by ligands of different types has thus been of particular interest. In the present work, which has emerged from our continued interest in the chemistry of ruthenium in different coordination environments [11–25], our objective has been to explore the chemistry of ruthenium bound to phenolate oxygens. Phenolate oxygen is a recognized hard donor and hence coordination of ruthenium by phenolate oxygen is of particular importance with regard to stabilization of the higher oxidation states of this metal [26–29]. The initial goal of the present study was to investigate the coordinating ability of simple phenols with no additional donor atoms. As a source of ruthenium, $[Ru(PPh_3)_3Cl_2]$ has been used, which is well known for its efficiency in binding to ligands of different types via dissociation of PPh_3 and chloride ligands [29–33]. However, we have observed that until a second donor site is incorporated at the *ortho* position of the phenyl ring, no tractable phenolate complex is formed.

When phenols of type **1** (abbreviated in general as HL, where H stands for the dissociable phenolic proton) are used, where D is the second donor atom linked to the *ortho* carbon directly or via one intervening atom, stable complexes of general formula $[Ru^{II}(PPh_3)_2(L)_2]$ are formed. The chemistry of these complexes is described in this paper with special reference to synthesis, structure and redox properties.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride was purchased from Arora Matthey, Calcutta, India and was converted to $RuCl_3{\cdot}3H_2O$ by repeated evaporation with concentrated hydrochloric acid. Triphenylphosphine, triethylamine, 2,4,6-tribromophenol (HL^1), 2-nitrophenol (HL^2) and 2,4,6-trinitrophenol (HL^3O) were obtained from SD Fine Chemicals, Mumbai, India. $[Ru(PPh_3)_3Cl_2]$ was prepared following a reported procedure [34]. Purification of acetonitrile and preparation of tetraethylammonium perchlorate (TEAP) for electrochemical work were performed as reported in the literature [35,36]. All other chemicals and solvents were reagent grade commercial materials and were used as received.

2.2. Preparation of complexes

2.2.1. $[Ru(PPh_3)_2(L^1)_2]$

$[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) and 2,4,6-tribromophenol (85 mg, 0.26 mmol) were taken up in 30 cm^3 methanol and triethylamine (42 mg, 0.42 mmol) was added. The resulting mixture was stirred for 2 h. A dark-red microcrystalline solid separated out, which was collected by filtration, washed with methanol and dried in vacuo. Recrystallization from 1:4 dichloromethane–hexane solution afforded shiny red crystals of $[Ru(PPh_3)_2(L^1)_2]$. The yield was 94 mg (70%).

2.2.2. $[Ru(PPh_3)_2(L^2)_2]$

This compound was prepared by following the same above procedure using 2-nitrophenol instead of 2,4,6-tribromophenol. The yield was 70 mg (75%).

2.2.3. $[Ru(PPh_3)_2(L^3)_2]$

To a solution of 2,4,6-trinitrophenol (50 mg, 0.22 mmol) in ethanol (30 cm^3) was added $[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) and triethylamine (42 mg, 0.42 mmol). The resulting mixture was heated at reflux for 2.5 h to produce a red solution. Upon cooling the solution to room temperature, a dark red crystalline solid separated out, which was collected by filtration, washed with ethanol and dried in air. Recrystallization from dichloromethane–benzene afforded shiny red crystals of $[Ru(PPh_3)_2(L^3)_2]$. The yield was 34 mg (30%).

2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were obtained on a Perkin–Elmer 783 spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on a Shimadzu UV 240 spectrophotometer. Magnetic susceptibilities were measured using a PAR 155 vibrating sample magnetometer fitted with a Walker scientific L75FBAL magnet. Electrochemical measurements were made using a PAR model 273 potentiostat. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in a three-electrode configuration. A RE 0089 X-Y recorder was used to trace the voltammograms. Dinitrogen gas was purified by successively bubbling it through alkaline dithionite and concentrated sulfuric acid. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials.

2.4. Crystallography

Single crystals of $[Ru(PPh_3)_2(L^1)_2]$ were grown by slow diffusion of hexane into a dichloromethane solution of the complex. Selected crystal data and data collection parameters are given in Table 1. The unit cell dimensions were determined by a least-squares fit of 25 centered reflections ($11.4 \leq \theta \leq 25.5°$). Data were collected on an Enraf–Nonius CAD-4 diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by ω scans within the angular range $2.15 < \theta < 27.49°$. Three standard reflections were used to check the crystal stability towards X-ray exposure and they showed no significant intensity variation over the course of data collection. X-ray data reduction, structure solution and refinement were done using the SHELXS-97 and SHELXL-97 packages. The structure was solved by the direct method.

Single crystals of $[Ru(PPh_3)_2(L^3)_2]$ were grown by slow diffusion of benzene into a dichloromethane solution of the complex. Selected crystal data and data collection parameters are given in Table 1. The unit cell dimensions were determined by a least-squares fit of 25 centered reflections ($10.84 < \theta < 19.80°$). Data were collected on an Enraf–Nonius CAD-4 diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by θ–2θ scans within 2θ max 50.0°. Three standard reflections, used to check the crystal stability towards X-ray exposure, showed no significant

intensity variation over the course of data collection. X-ray data reduction, and structure solution and refinement were done using the NRCVAX package. The structure was solved by the direct method.

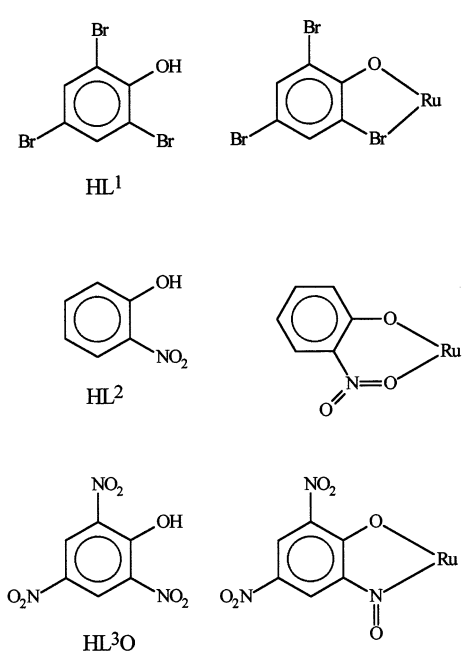

Fig. 1. The phenolic ligands and their coordination modes.

3. Results and discussion

Three phenolic ligands have been used in the present study which are shown, along with their individual abbreviation and coordination mode, in Fig. 1. The phenolic ligands react smoothly with $[Ru(PPh_3)_3Cl_2]$ in the presence of a base to afford complexes of type $[Ru(PPh_3)_2(L)_2]$. It may be noted here that unlike in the reactions of the first two phenolic ligands, heating of the reaction mixture at reflux was necessary in the reaction of 2,4,6-trinitrophenol with $[Ru(PPh_3)_3Cl_2]$ for obtaining the phenolate complex. It is also interesting to note that 2,4,6-trinitrophenol undergoes oxygen loss from one nitro group during the course of the synthetic reaction and coordinates in the nitrosophenolate fashion. Hence 2,4,6-trinitrophenol is abbreviated as HL^3O (see Fig. 1) to underline this oxo-transfer reaction. Mechanism of this oxygen loss reaction is not yet clear. However, oxygen from the nitro group is probably transferred to the PPh_3, dissociated from $[Ru(PPh_3)_3Cl_2]$. Indirect evidence of this oxo-transfer comes from detection of $OPPh_3$ in the residue of the synthetic reaction (after isolation of $[Ru(PPh_3)_2(L^3)_2]$), identified by its characteristic infrared spectrum (ν_{P-O} observed at 1185 cm^{-1}). Triphenylphosphine is well known to act as an oxygen-scavenger in many oxo-transfer reactions [37–40]. The role of $[Ru(PPh_3)_3Cl_2]$ in this oxo-transfer reaction is not yet clear, but that it does not act as a mere supplier of PPh_3 is clear from the fact that a mixture of PPh_3 and 2,4,6-trinitrophenol is unable to bring about any oxo-transfer reaction. Prior coordination of the 2,4,6-trinitrophenolate ligands to ruthenium in the nitrophenolate fashion followed by oxo-transfer from the metal-bound ligands appears to be probable. It may also be noted here that the yield of

$$2[Ru(PPh_3)_3Cl_2] + 2HL^3O \rightarrow [Ru(PPh_3)_2(L^3)_2] + 2HCl + 2OPPh_3 + [Ru(PPh_3)_2Cl_2] \quad (1)$$

$[Ru(PPh_3)_2(L^3)_2]$ is rather low, which might be attributed to the fact that $[Ru(PPh_3)_3Cl_2]$ dissociates in solution yielding free PPh_3 and an unstable $[Ru(PPh_3)_2Cl_2]$ species [41,42]. Hence 2 mol of $[Ru(PPh_3)_3Cl_2]$ (which supply 2 mol of PPh_3) are required for the reduction of 2 mol of 2,4,6-trinitrophenol. The 2 mol of reduced ligand (L^3) utilize only 1 mol of $[Ru(PPh_3)_2Cl_2]$ for complex formation (Eq. (1)). The other mole of $[Ru(PPh_3)_2Cl_2]$ probably undergoes decomposition [41,42]. Some characterization data of the complexes are given in Table 2. Elemental (C, H, N) analytical data agree well with the compositions of the $[Ru(PPh_3)_2(L)_2]$ complexes. All three complexes are diamagnetic, which corresponds to the bivalent state of ruthenium (low-spin d^6, $S = 0$) in these complexes.

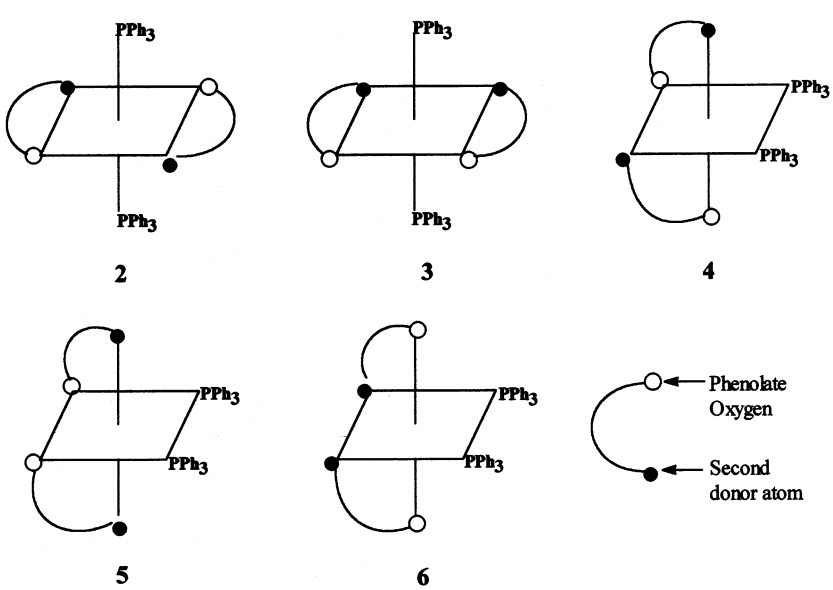

Table 2
Microanalytical, electronic spectral and cyclic voltammetric data

Compound	Microanalytical data [a]			Electronic spectral data [b] λ_{max} (nm), ε (M^{-1} cm^{-1})	Cyclic voltammetric data [c] $E_{1/2}$ (V), ΔE_p (mV)
	%C	%H	%N		
$[Ru(PPh_3)_2(L^1)_2]$	44.82 (44.83)	2.68 (2.65)		495(1200), 310(6200), 250(27 900), 220(43 300)	0.63(60), 1.48 [d]

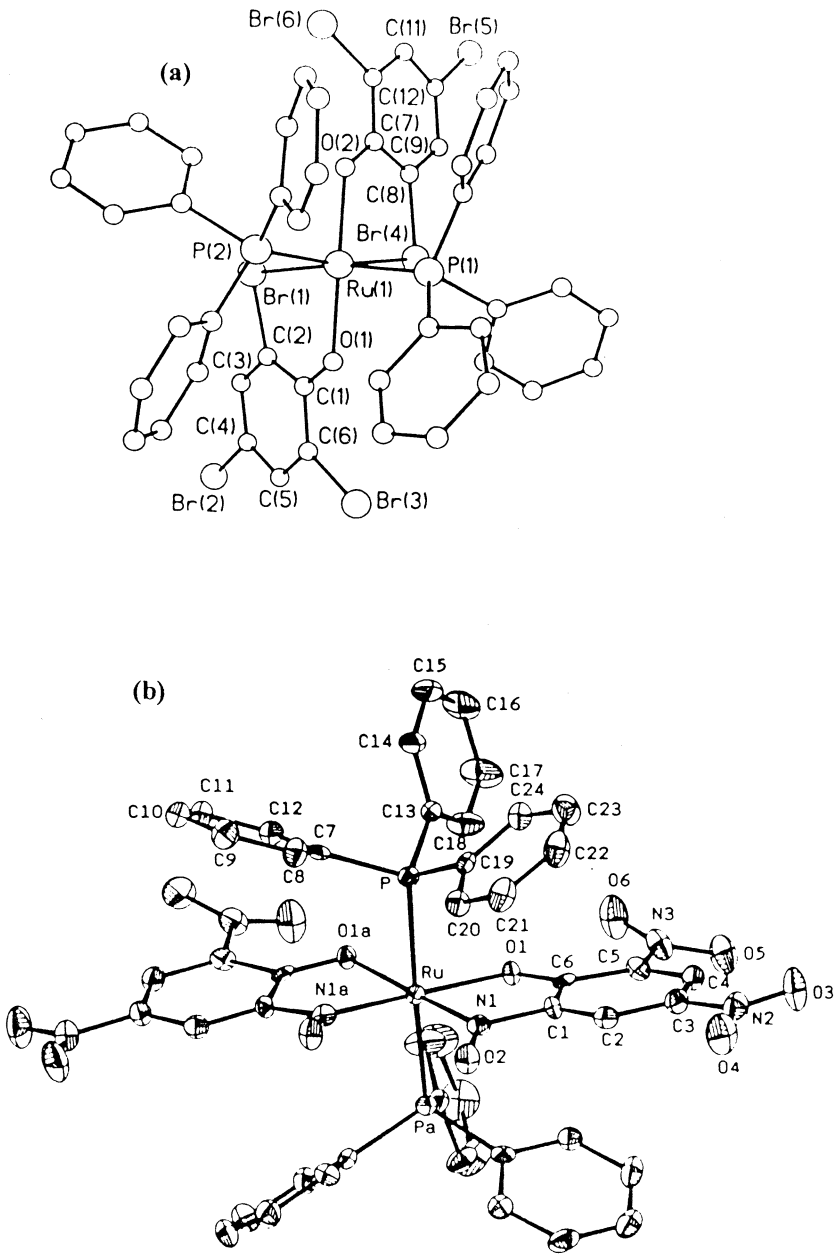
[a] Calculated values are in parentheses.
[b] Dichloromethane solution.
[c] Solvent, acetonitrile; Supporting electrolyte, TEAP; reference electrode, SCE; $E_{1/2} = 0.5(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are anodic and cathodic peak potentials, respectively; $\Delta E_p = E_{pa} - E_{pc}$; scan rate, 50 mV s^{-1}.
[d] E_{pa} value.

From the composition of the complexes and also from the fact that ruthenium(II) prefers to be hexacoordinated, the phenolic ligands appear to have served as bidentate ligands. Five geometrical isomers (**2**–**6**) are then possible for the $[Ru(PPh_3)_2(L)_2]$ complexes.

To sort out the problem of stereochemistry and also to authenticate coordination mode of the phenolic ligands, molecular structures of $[Ru(PPh_3)_2(L^1)_2]$ and $[Ru(PPh_3)_2(L^3)_2]$ have been solved by X-ray crystallography [43]. The structures are shown in Fig. 2 and selected bond parameters are given in Table 3. In $[Ru(PPh_3)_2(L^1)_2]$, 2,4,6-tribromophenol is coordinated to ruthenium via loss of the phenolic proton, as a bidentate O,Br-donor ligand forming a five-membered chelate ring with a bite angle of 80.55°. While the phenolate oxygens are mutually *trans*, the PPh_3 ligands are mutually *cis* and the two bromines are also mutually *cis*. Hence the $O_2P_2Br_2$ coordination sphere around ruthenium has a *trans–cis–cis* geometry (**6**) with regard to mutual dispositions of the three pairs of donor atoms. The coordination sphere around ruthenium is distorted octahedral in nature, which is reflected in the bond parameters around ruthenium. While the Ru–O and Ru–P distances are quite normal [18,21,44,45], the Ru–Br lengths are a bit longer than is usually observed [46–48]. The C–Br lengths corresponding to the coordinated bromines are slightly longer than the other two C–Br distances in the same ligand and this may be attributed to coordination of the bromine to ruthenium(II). The phenolate C–O lengths are also quite usual [44,45]. The $[Ru(PPh_3)_2(L^2)_2]$ complex could not be characterized crystallographically [43]. However, the 2-nitrophenolate ligand is known to coordinate as bidentate O,O-donor forming a six-membered chelate ring [49] as shown in Fig. 1. The same coordination mode of the 2-nitrophenolate ligand is assumed in $[Ru(PPh_3)_2(L^2)_2]$.

Structure determination of $[Ru(PPh_3)_2(L^3)_2]$ shows that 2,4,6-trinitrophenol is coordinated, via loss of the phenolic proton and reduction of one nitro group at the *ortho* position, as a 2-nitroso-4,6-dinitrophenolate anion. Chelation takes place from the nitroso nitrogen and phenolate oxygen forming a five-membered chelate ring with a bite angle of 80.85°. The coordinated nitrogens are mutually *cis*, the phenolate oxygens are also mutually *cis* and the two coordinated PPh_3 ligands are mutually *trans*. The coordination sphere around ruthenium is slightly distorted octahedral $N_2O_2P_2$ with a *cis–cis–trans* geometry, respectively (**3**). While the Ru–P distances are normal [50,51], the bond distances within the N–O chelates are rather unusual. The Ru–N bonds are significantly shorter than usually observed [15,16,18]. Such a short Ru–N distance is known to result only from very strong π-interaction [52]. The Ru–O bonds are longer than usually observed [21,45]. The observed C–O lengths are shorter than usual phenolate C–O distances [44,45]. The unusual nature of observed bond distances in $[Ru(PPh_3)_2(L^3)_2]$ appears to result from the combined effect of the possible resonance in the nitrosophenolate ligand (**7**) and the π-bonding interaction [52–54] between ruthenium(II) and the imine-oxo moiety of the nitrosophenolate ligand.



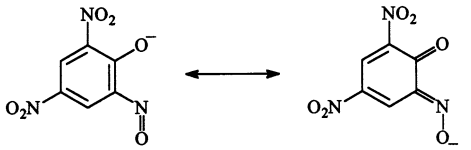


Fig. 2. View of the (a) $[Ru(PPh_3)_2(L^1)_2]$ and (b) $[Ru(PPh_3)_2(L^3)_2]$ molecules.

7

This strong π-interaction is also reflected in the *cis* disposition of this imine nitrogens [53,54]. In complexes containing the $Ru^{II}(PPh_3)_2$ moiety, the two triphenylphosphines usually take up *cis* positions [15,18,45,55,56], which has also been observed in $[Ru(PPh_3)_2(L^1)_2]$ (vide supra). In $[Ru(PPh_3)_2(L^3)_2]$ the imine-oxo group appears to be a stronger π-acceptor than PPh_3 and thus forces the bulky PPh_3 ligands to take up *trans* positions for less steric hindrance.

The IR spectra of these complexes show many sharp bands of different intensities in the 1700–400 cm^{-1} region due to vibrations arising from the coordinated PPh_3 and phenolic ligands and are therefore complex in nature. No attempt has been made to assign individual bands. However, the strong vibrations near 520, 700, and 740 cm^{-1} displayed by all the complexes indicate the presence of the $Ru(PPh_3)_2$ fragment [15,18,44,45]. The $[Ru(PPh_3)_2(L)_2]$ complexes are soluble in polar solvents like acetonitrile, dichloromethane, chloroform, etc, producing intense red solutions. Electronic spectra of the complexes have been recorded in dichloromethane solution. All these complexes show several intense absorptions in the visible and ultraviolet region. Spectral data are presented in Table 2. The intense absorptions in the ultraviolet region are attributable to transitions within the ligand orbitals and those in the visible region are probably due to allowed metal-to-ligand charge-transfer transitions. Multiple charge-transfer transitions in such mixed-ligand complexes are known to result from lower symmetry splitting of the metal level, the presence of different acceptor orbitals and from the mixing of singlet and triplet configurations in the excited state through spin-orbit coupling [57–60].

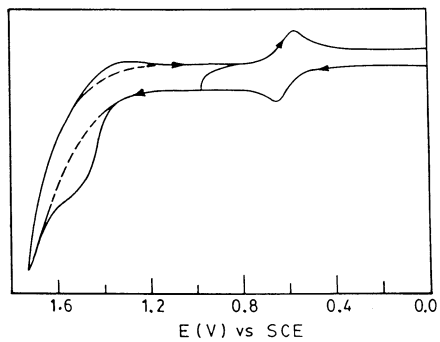

Fig. 3. Cyclic voltammogram of $[Ru(PPh_3)_2(L^1)_2]$ in acetonitrile solution (0.1 M TEAP) at a scan rate of 50 mV s^{-1}.

Electrochemical properties of all the complexes have been studied in acetonitrile solution (0.1 M TEAP) by cyclic voltammetry. A selected voltammogram is shown in Fig. 3 and the voltammetric data are presented in Table 2. Each complex shows two oxidative responses on the positive side of SCE. The first oxidative response is observed within 0.63–0.71 V versus SCE and is assigned to the ruthenium(II)–ruthenium(III) oxidation (Eq. (2)) This oxidation is reversible in nature with a peak-to-peak separation (ΔE_p) of 60–70 mV, which does not change when the scan rate is changed.

$$[Ru^{II}(PPh_3)_2(L)_2] \rightleftharpoons [Ru^{III}(PPh_3)_2(L)_2]^+ + e^- \quad (2)$$

$$[Ru^{III}(PPh_3)_2(L)_2]^+ \rightarrow [Ru^{IV}(PPh_3)_2(L)_2]^{2+} + e^- \quad (3)$$

The anodic peak current (i_{pa}) is also equal to the cathodic peak current (i_{pc}) as expected for a reversible electron-transfer process. The one-electron nature of this oxidation has been verified by comparing its current heights with those of the standard ferrocene–ferrocenium couple under identical experimental conditions. The second oxidative response, which appears near 1.5 V versus SCE, is irreversible and is tentatively assigned to ruthenium(III)–ruthenium(IV) oxidation (Eq. (3)). One-electron stoichiometry of the oxidation is verified by comparing its current height (i_{pa}, calculated after deduction of solvent contribution from the observed current at E_{pa}) with that of the ruthenium (II)–ruthenium(III) oxidation.

4. Conclusions

The present study shows that coordination of phenols to ruthenium as simple monodentate oxygen donor ligands is probably not possible, but phenols having a second donor site linked to the *ortho* position can bind to ruthenium as a bidentate ligand affording stable complexes.

5. Supplementary data

Copies of supplementary data can be obtained free of charge from The Director, Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), quoting the deposition numbers CCDC 141332 and CCDC 141333.

POLYHEDRON

Competitive lithium-7 NMR study of the complexation of some alkaline earth and transition metal ions with 18-crown-6 in acetonitrile and its 50:50 mixtures with nitrobenzene and nitroethane

Mojtaba Shamsipur *, Tayyebeh Madrakian

Department of Chemistry, Razi University, Kermanshah, Iran

Received 21 January 2000; accepted 27 April 2000

Abstract

Lithium-7 NMR spectroscopy was used to investigate the stoichiometry and stability of a Li^+ complex with 18-crown-6 (18C6) in pure acetonitrile and its 50:50 (w/w) mixtures with nitrobenzene and nitromethane. A competitive ^7Li NMR method was also employed to probe the complexation of Mg^{2+}, Ca^{2+}, Ba^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+} and Cd^{2+} ions with 18C6 in the same solvent systems. In all solvents, the stability of the resulting 1:1 complexes was found to vary in the order $Ba^{2+} > Ca^{2+} > Cd^{2+} > Mg^{2+} \approx Cu^{2+} > Ni^{2+} > Co^{2+} > Zn^{2+}$. © 2000 Elsevier Science Ltd. Keywords: Macrocyclic polyether 18-crown-6; Acetonitrile; Alkaline earth metal ions; Transition metal ions

Because of the vital importance of recognition and binding of ionic substrates to organic hosts, such as enzymes, antibodies and membrane carriers, model studies on the recognition of cations using synthetic host compounds, such as macrocyclic polyethers and their aza- and thia-substituted derivatives, are of special interest [1–3]. There is an extensive amount of literature reported on the study of macrocyclic ligands and their interaction with a wide variety of cations, anions and neutral guests [4–7]. Structural, spectral, electrochemical, thermodynamic and kinetic properties of macrocyclic complexation have been investigated [4], and detailed thermodynamic and kinetic data for different macrocyclic complexes evaluated by different physico–chemical methods in various solvent media are reported [5–7]. During their formation, the selectivity and stability of metal ion complexes with macrocyclic ligands is of special importance in their use as suitable neutral carriers for the selective transport across liquid membranes [8–10] and for constructing membrane-selective sensors for different metal ions [11–13].

In recent years, we have introduced some competitive spectrophotometric [14–17], polarographic [18] and potentiometric [19] methods to investigate the thermodynamics and kinetics of complexation of a variety macrocycle–metal ion systems which possess no spectrophotometric or electrochemical properties under the experimental conditions used. In this paper, we used ^7Li NMR as a very sensitive probe to study the complexation of Mg^{2+}, Ca^{2+}, Ba^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+} and Cd^{2+} ions with 18-crown-6 (18C6) in acetonitrile (AN) and its 50:50 (w/w) mixtures with nitrobenzene (NB) and nitromethane (NM) by a competitive technique. It should be noted that the alkaline earth and transition metal ions used have unsuitable NMR properties such as low receptivity, high quadrupole moment, insensitive chemical shifts, etc.

1. Experimental

The macrocyclic polyether 18-crown-6 (18C6, Merck) was precipitated as its acetonitrile complex [20]. The resulting crystals were isolated and kept under vacuum at room temperature for several days to remove the

PII: S0277-5387(00)00417-4

acetonitrile. Lithium perchlorate (Merck) was purified and dried as reported elsewhere [21]. The nitrate salts of all other cations used were of the highest purity available from Fluka and used without any further purification except for vacuum drying over P_2O_5. Spectroscopic grade acetonitrile, nitrobenzene and nitromethane (Merck) were used as received.

All NMR measurements were made on a Jeol FX90Q FT-NMR spectrometer with a field strength of 21.13 kG. At this field, lithium-7 resonates at 33.74 MHz. An aqueous 4.0 M LiCl solution was used as the external reference and the reported lithium-7 chemical shifts are referenced to this solution. The paramagnetic (downfield) shift from the reference is designated as being positive. The concentration of all cations used was 0.005 M. All chemical shift measurements were carried out at a temperature of 27.0 ± 0.1°C.

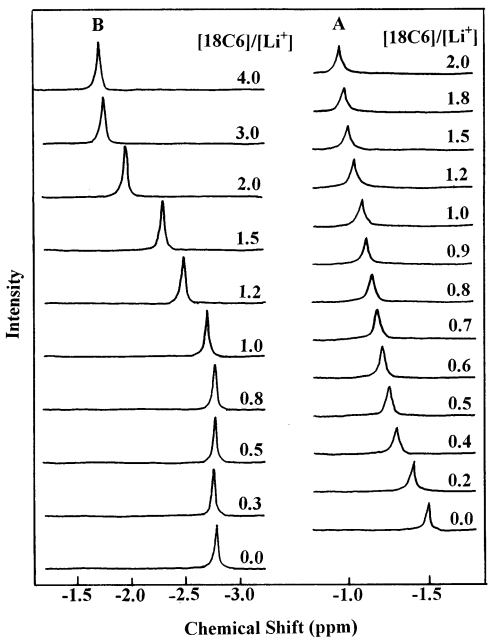

Fig. 1. Lithium-7 NMR spectra for Li^+–18C6–acetonitrile (A) and Li^+–18C6–Ba^{2+}–acetonitrile–nitrobenzene (B) systems.

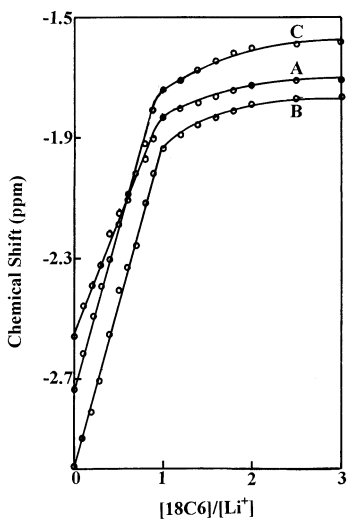

Fig. 2. Lithium-7 chemical shifts as a function of the 18C6/Li^+ mole ratio in acetonitrile (A), acetonitrile–nitrobenzene (B) and acetonitrile–nitromethane (C) solutions.

2. Results and discussion

Lithium-7 chemical shifts were measured as a function of the mole ratio of complexant 18C6 to lithium ion in acetonitrile, acetonitrile–nitrobenzene and acetonitrile–nitromethane solutions. In all cases, only one population-averaged resonance was observed, indicating that the exchange rate of the cation between the bulk solution and the complexed site is fast on the NMR time scale (Fig. 1). The resulting mole data are shown in Fig. 2. As can be seen, in all three cases, addition of 18C6 to the Li^+ ion solution causes an almost linear paramagnetic shift that begins to level off at mole ratios greater than unity. The slope of the corresponding mole ratio plots changes significantly at the point where the ligand-to-cation mole ratio is equal to one, showing the formation of a relatively stable complex.

The formation constants of 1:1 complexes were calculated from the variation of the ^7Li chemical shift crown/Li^+ mole ratio. It was been shown previously [22] that the observed chemical shift is given by

$$\delta_{obs} = \{[(K_{Li}C_{Li}C_{18C6} - 1) + (K_{Li}^2C_{18C6}^2 + K_{Li}^2C_{Li}^2 - 2K_{Li}^2C_{18C6}C_{Li} + 2K_{Li}C_{18C6} + 2K_{Li}C_{Li} + 1)^{1/2}](\delta_{Li} - \delta_{Li-18C6})/2K_{Li}C_{Li}\} + \delta_{Li-18C6} \quad (1)$$

where K_{Li} is the formation constant for the 1:1 complex, C_{18C6} and C_{Li} are the analytical concentrations of the crown ether and Li^+ ion, respectively, and δ_{Li} and $\delta_{Li-18C6}$ are the respective chemical shifts of the free and complexed lithium ion. The non-linear least-squares curve-fitting program KINFIT [23] was used to evaluate K_{Li} and $\delta_{Li-18C6}$ values for the 1:1 complexes by fitting the δ_{obs} versus C_{18C6} data (at constant $C_{Li} =$ 0.005 M) to Eq. (1).

A sample computer fit of the ^7Li chemical shift–mole ratio data is shown in Fig. 3(A), and the calculated $\log K_f$ values are given in Table 1. A fair agreement between the observed and calculated chemical shifts shown in Fig. 3(A) further supports the formation of a complex with 1:1 stoichiometry between Li^+ and 18C6.

In contrast to ^7Li and other NMR active alkali metals, most alkaline earth and transition metal nuclei cannot be accurately used in an NMR study of their macrocyclic complexes. This is mainly because of their high quadrupole moments and low receptivities [24].

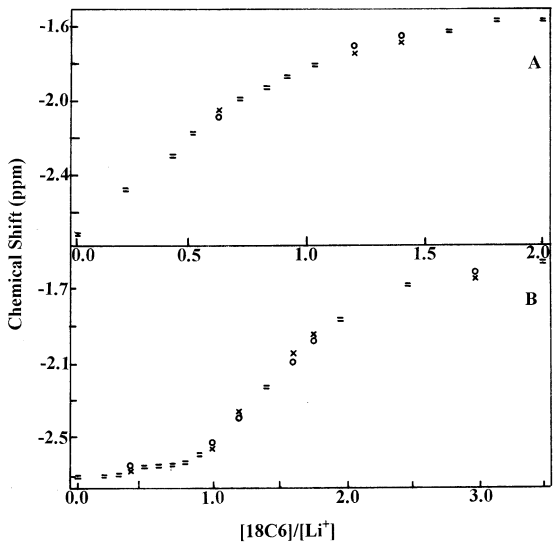

Fig. 3. Computer fit of lithium-7 chemical shift vs. 18C6/Li^+ mole ratio for Li^+–18C6 (A) and Li^+–18C6–Ca^{2+} (B) systems in acetonitrile–nitrobenzene solution. (×) Experimental point; (○) calculated point; (=) experimental and calculated points are the same within the resolution of the plot.

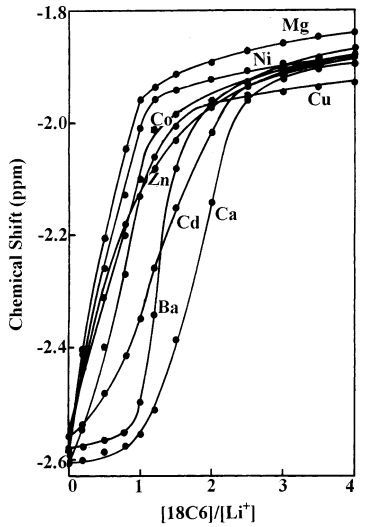

Fig. 4. Lithium-7 chemical shifts as function of 18C6/Li^+ mole ratio in acetonitrile solution in the presence of different M^{2+} ions.

Thus, in this work, we decided to employ ^7Li NMR as a very sensitive probe [21,22,25–27] to investigate the complex formation of Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+}, Mg^{2+}, Ca^{2+} and Ba^{2+} ions with 18C6 in the solvent media used. The variation of lithium-7 chemical shift in the presence of an equimolar concentration of different alkaline earth and transition metal ions (0.005 M) as a function of 18C6/Li^+ mole ratio in different solvent systems was measured. Typical spectra are shown in Fig. 1(B) and the resulting chemical shift–mole ratio plots are illustrated in Figs. 4–6.

As is obvious from Figs. 4–6, unlike the cases involved in the formation of 1:1 Li^+–18C6 complex (Fig. 2) in which the change in chemical shift with the 18C6/Li^+ mole ratio is quite linear at mole ratios < 1, the ^7Li chemical shift shows a curved relationship for 18C6/Li^+ mole ratios between 0 and 2. However, in all cases, a plateau in the chemical shift is reached at mole ratios > 2. This is obviously indicative of the quantitative formation of 1:1 complexes of 18C6 with both Li^+ and M^{2+} ions. It is worthwhile noting that in the cases of Cd^{2+}, Ca^{2+} and Ba^{2+} ions, the corresponding mole ratio plots (Figs. 4–6) also show a distinct infection point at a 18C6/Li^+ mole ratio of ca. 1, most probably due to significant differences in the stability of the 18C6 complexes of these cations with that of Li^+–18C6 in solution [5,6].

The competitive complexation equilibria for the case of 1:1 complexation between 18C6 and Li^+ and M^{2+} ions can be written as:

$$Li^+ + 18C6 = Li^+–18C6$$

$$K_{Li} = [Li^+–18C6]/[Li^+][18C6] \quad (2)$$

Table 1
Formation constants of different metal ion complexes with 18C6 in various solvents [a]

Metal ion [b]	Log K_f		
	Acetonitrile	Acetonitrile–nitrobenzene	Acetonitrile–nitromethane
Co^{2+} (0.75)	2.15 ± 0.03	2.38 ± 0.07	2.59 ± 0.04
Ni^{2+} (0.69)	2.34 ± 0.06	2.59 ± 0.04	2.77 ± 0.04
Cu^{2+} (0.77)	2.48 ± 0.02	2.67 ± 0.08	2.94 ± 0.04
Zn^{2+} (0.74)	2.07 ± 0.05	2.33 ± 0.02	2.48 ± 0.06
Cd^{2+} (0.95)	3.07 ± 0.04	3.16 ± 0.05	3.91 ± 0.20
Mg^{2+} (0.72)	2.31 ± 0.02	2.62 ± 0.04	3.05 ± 0.04
Ca^{2+} (1.00)	4.14 ± 0.16	4.21 ± 0.06	4.34 ± 0.08
Ba^{2+} (1.35)	4.24 ± 0.30	4.58 ± 0.16	5.39 ± 0.30
Li^+ (0.76)	2.52 ± 0.07	2.80 ± 0.10	2.98 ± 0.06

[a] The errors associated with log K_f values are ± S.D.
[b] The values in parentheses are the ionic radii in angstroms [31].

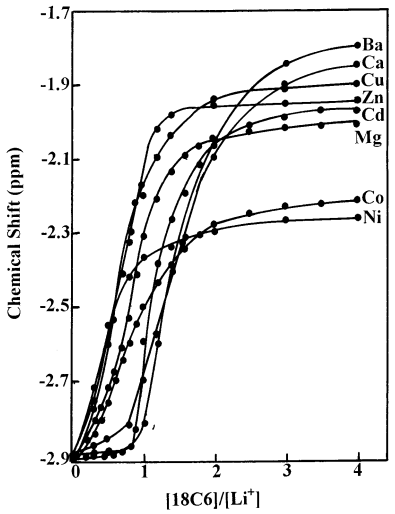

Fig. 5. Lithium-7 chemical shifts as a function of 18C6/Li^+ mole ratio in acetonitrile–nitrobenzene solution in the presence of different M^{2+} ions.

$$M^{2+} + 18C6 = M^{2+}\text{–}18C6$$

$$K_M = [M^{2+}\text{–}18C6]/[M^{2+}]/[18C6] \quad (3)$$

The free 18C6 concentration, [18C6], is then obtained from Eq. (4) [14]:

$$K_{Li}K_M[18C6]^3 - \{K_{Li}K_M(C_{18C6} - C_{Li} - C_M) - K_{Li} - K_M\}[18C6]^2 - \{K_{Li}(C_{18C6} - C_{Li}) + K_M(C_{18C6} - C_{Li}) - 1\}[18C6] - C_{18C6} = 0 \quad (4)$$

where C_{18C6}, C_{Li} and C_M are the analytical concentrations of 18C6, Li^+ ion and M^{2+} ion, respectively. In this case, the observed ^7Li chemical shift is obtained from Eq. (5) [22]:

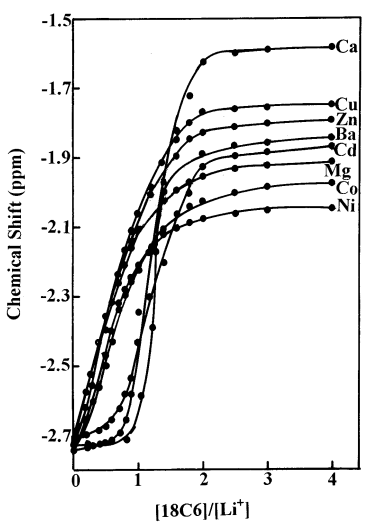

Fig. 6. Lithium-7 chemical shifts as a function of 18C6/Li^+ mole ratio in acetonitrile–nitromethane solution in the presence of different M^{2+} ions.

$$\delta_{obs} = P_{Li}\delta_{Li} + P_{Li\text{–}18C6}\delta_{Li\text{–}18C6} \quad (5)$$

where P_{Li} and $P_{Li\text{–}18C6}$ are the mole fractions of the free and complexed Li^+ ion, respectively. By substitution from Eq. (2) and the mass balance equation $C_{Li} = [Li^+] + [Li^+\text{–}18C6]$, Eq. (5) can be written as:

$$\delta_{obs} = \{\delta_{Li} + \delta_{Li\text{–}18C6}[18C6]K_{Li}\}/\{1 + K_{Li}[18C6]\} \quad (6)$$

The K_M values were evaluated by obtaining the free [18C6] from Eq. (4) and fitting the chemical shift–mole ratio data to Eq. (6) using the KINFIT program.

A sample computer fit of the mole ratio data for a remary Li^+–18C6–M^{2+} system is shown in Fig. 3(B) and the resulting log K_f values for all M^{2+}–18C6 complexes are also included in Table 1. Our assumption that the 1:1 stoichiometry of both Li^+–18C6 and M^{2+}–18C6 complexes seems reasonable in the light of a fair agreement between the observed and calculated chemical shifts [5,6]. It should be noted that the curve-fitting method used in this study is not able to evaluate the K_f values accurately at values $> 10^6$.

The data given in Table 1 clearly indicate the influence of solvent properties on the stability of the resulting 18C6 and Li^+ complexes, and all M^{2+} ions used. Amongst the different factors affecting the stability of macrocyclic crown ethers in solution [5,6], the ability of solvent to solvate ionic species and, thus, compete with the ligands for the cation is of vital importance [14,19,21,22,25–27]. Of course, the interaction of some solvents with macrocyclic ligands [7,20,28] is of equal importance, although much less appreciated. Thus, the thermodynamic stability of metal ion–macrocycle complexes is not just a measure of the absolute strength of ion–dipole interactions between the cation and the donating oxygen atoms of crown ethers, but it is also a measure of the relative strength as compared with ionic solvation.

From Table 1, it is obvious that the stability of all 18C6 complexes increases in the order acetonitrile < acetonitrile–nitrobenzene < acetonitrile–nitromethane. It is well known that the Gutmann donor number of solvents [29] is an important measure in complexation reactions [5,6,14–19,21,22,25–27]. It should be noted that acetonitrile, nitrobenzene and nitromethane possess similar dielectric constants (i.e. $\varepsilon_{AN} = 37.5$, $\varepsilon_{NM} = 34.8$ and $\varepsilon_{NM} = 35.6$), but have quite different donor numbers (i.e. $DN_{AN} = 14.1$, $DN_{NB} = 4.4$ and $DN_{NM} = 2.7$) [29]. Acetonitrile, as a solvent of intermediate solvating ability, can thus compete with the crown ether for metal ions more readily than nitrobenzene and, especially, nitromethane as low donicity solvents. In addition, it has been shown that acetonitrile can solvate the macrocyclic ligand to a large extent [20,28], while nitrobenzene and nitromethane have no significant interaction with the ligand [7]. Thus, it is not unexpected to observe a rather large increase in the stability of the

metal ion–18C6 complexes with addition of nitrobenzene and, especially, nitromethane to acetonitrile solutions.

The data given in Table 1 revealed that the stability of M^{2+}–18C6 complexes vary in the order $Ba^{2+} > Ca^{2+} > Cd^{2+} > Mg^{2+} \approx Cu^{2+} > Ni^{2+} > Co^{2+} > Zn^{2+}$. As is obvious, with the exception of the Cd^{2+} ion, transition metal complexes form weaker complexes with 18C6 than the alkaline earth metal ions used. This is not only due to the soft character of the transition metal ions, which result in weaker interactions with the donating oxygens of the macrocyclic ring as hard bases [30], but also because of the small ionic radii (i.e. 0.69–0.77 Å) [31] for the cavity of 18C6 (with an anionic radius of 1.3–1.6 Å) [32]. However, the Cd^{2+} ion ($r = 0.95$ Å) [31], despite its weaker soft–hard interaction with the macrocycle, forms a more stable complex than the hard Mg^{2+} ion, most probably due to its more suitable size for the 18C6 cavity than the magnesium ion ($r = 0.72$ Å) [31]. On the other hand, as expected [5,6], the hard Ba^{2+} ion with the most suitable ionic size for the cavity of 18C6 ($r = 1.35$ Å) [31] forms the most stable complex in the series. Finally, the Ca^{2+} ion ($r = 1.00$ Å) [31] with a similar ionic size to Cd^{2+}, but possessing a hard character [30], forms the second most stable 18C6 complex among the cations used.

It is worth noting that, in the case of 18C6 complexes with the metal ions of the first transition series, the stability of the resulting complexes decrease in the order $Cu^{2+} > Ni^{2+} > Co^{2+} > Zn^{2+}$. This sequence follows the Irving–Williams order [33] which generally holds for equilibrium constants of different complexes of the metal ions of first transition series [14,34].

Transition metal complexes of benzil-α-monoxime (BMO); X-ray structure determination of $Co(BMO)_3$

P. Sambasiva Reddy, K. Hussain Reddy *

Department of Chemistry, Sri Krishnadevaraya University, Anantapur 515 003, India

Received 28 January 2000; accepted 8 May 2000

Abstract

Cobalt(III), nickel(II) and copper(II) complexes of benzil-α-monoxime (BMO) have been synthesized and characterized by elemental analyses, conductivity, magnetic susceptibility measurements, IR and electronic spectral data. The molar conductivity data show them to be non-electrolytes. The monoanionic bidentate behavior of BMO is inferred from IR spectral studies. The electronic spectral data suggest planar geometry for nickel(II) and copper(II) complexes. The nickel complex assumes an octahedral structure in a coordinating solvent (*N*,*N*-dimethylformamide (DMF)). The $[Co(BMO)_3]$ complex has been isolated as a single crystal and its structure was determined by X-ray diffraction. X-ray data confirms the presence of a *fac*-octahedral configuration for this complex. Electrochemical studies suggest that the cobalt complex undergoes two single one-electron reduction steps corresponding to $Co(III) \rightarrow Co(II)$ and $Co(II) \rightarrow Co(I)$. © 2000 Elsevier Science Ltd. 1. Introduction

Oximes are widely recognized ligands [1,2]. In general, monoxime is known to coordinate in three different ways (structures **I**, **II** and **III**). In structure **III** monoxime acts as a bridging ligand. Among carbonyl oximes diacetylmonoxime is the most studied ligand. Ni(II), Cu(II) and Co(III) complexes of diacetyl monoxime have been reported [3–5]. There is considerable confusion in the literature [6] about the nickel complexes of benzil-α-monoxime (BMO). Because of this, no report is available on Co(III), Ni(II) and Cu(II) complexes of BMO. In continuation of our ongoing research [7–11] on the metal complexes of benzil-based derivatives, we report herein the synthesis and characterization of metal complexes with BMO. The structure of $Co(BMO)_3$ is determined by X-ray single-crystal diffraction. Variety in structural features of BMO metal complexes is presented in this paper.

2. Experimental

2.1. Materials and methods

Benzil and hydroxylamine hydrochloride were of reagent grade. Solvents used for the synthesis of ligands and their metal complexes were redistilled. All other chemicals were of AR grade and used as supplied.

2.2. Preparation of ligand

BMO was prepared according to the procedure described previously [12].

2.3. Preparation of complexes

Attempts to prepare a cobalt(II) complex of BMO were not successful. Cobalt(III), nickel(II) and copper(II) complexes were prepared by mixing a hot methanolic solution of metal chlorides (1 mol) and ligand (2 mol). To the boiling solution of the ligand (0.01776 mol) in methanol (100 cm^3) was added metal chloride dissolved in a minimum quantity of methanol and refluxed for 30 min. NaOAc (2 g) was added to the

Table 1
Analytical data of ligand and their metal complexes

Ligand/complex	Color (m.p. ° C)	Percentage [a] of		
		Carbon	Hydrogen	Nitrogen
BMO	light pink (140–141)	74.00 (74.66)	4.57 (4.80)	6.50 (6.20)
$[Co(BMO)_3]$	orange red (195–197)	68.20 (68.94)	4.15 (4.10)	5.70 (5.74)
$[Ni(BMO)_2]$	light green (215–218)	65.95 (66.40)	3.72 (3.75)	5.48 (5.53)
$[Cu(BMO)]_n$	dark green (175–177)	65.67 (65.75)	3.85 (3.91)	5.49 (5.47)

[a] Calculated values are in parentheses.

reaction mixture (in the case of the copper complex CH_3ONa is added) and refluxed for another 30 min. Crystalline complexes which separated from the solution were collected by filtration, washed with hot water and a small quantity of methanol and dried under vacuum over $CaCl_2$. The analytical data of the ligand and their complexes are presented in Table 1.

2.4. Physical measurements

The elemental microanalyses were carried out at the RSIC, CDRI, Lucknow, India. The molar conductance of the complexes in *N*,*N*-dimethylformamide (DMF) (1×10^{-3} M) solution were measured at 28°C with a Systronic model 303 direct reading conductivity bridge. Magnetic measurements were carried out in the polycrystalline state on a PAR model 155 vibrating sample magnetometer operating at a field strength between 2 and 8 KG. High purity Ni metal (saturation moment 55 emu g^{-1}) was used as a standard. The electronic spectra were recorded in DMF and $CHCl_3$ with a Shimadzu UV-160 A spectrophotometer. The FT-IR spectra were recorded in the range 4600–50 cm^{-1} with a JASCO FT/IR-5300 in KBr and polyethylene medium. ^1H NMR spectra were obtained using a JEOL-GSX-400 NMR instrument at r.t. The voltammetric measurements were performed on Bio-analytical Systems (BAS) CV-27 assembly in conjunction with an X-Y recorder. These measurements were made on the degassed (N_2 bubbling for 5 min) solution in dimethylformamide (1×10^{-3} M) containing 0.1 M tetraethylammonium perchlorate as the supporting electrolyte. The system consisted, working (glass carbon), an auxiliary (Pt wire) and reference (Ag/AgCl) electrodes.

2.5. X-ray crystallography and structure solution

A diffraction quality crystal of cobalt(III) complex was grown at room temperature (r.t.) by slow evaporation of the complex in dimethylformamide solvent. Intensity data for a dark orange crystal with approximate dimensions $0.3 \times 0.2 \times 0.2$ mm were measured at r.t. 273(2) K on an Enraf–Nonius CAD4 diffractometer using monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) with a scan mode of ω–2θ. No decomposition of the crystal occurred during the data collections. The Co atom was located from an E-map . The other non-hydrogen atoms were determined with successive difference Fourier syntheses. Final refinement by full-matrix least-squares methods was carried out with anisotropic thermal parameters for non-hydrogen atoms. The hydrogen atoms, included in the refinement were located in succeeding difference Fourier synthesis after the non-hydrogen atoms were refined anisotropically.

3. Results and discussion

The analytical data of the ligand (Table 1) is consistent with its proposed molecular formula. All the complexes are insoluble in water and methanol, but readily soluble (except copper complex) in $CHCl_3$, DMF and DMSO. The copper complex is sparingly soluble in DMF and DMSO. The physico-chemical and analytical data for all the complexes are given in Table 1. The analytical data (Table 1) are consistent with the proposed molecular formula. The molar conductivity data reveal the nonelectrolytic nature of all the complexes. Cobalt(III) and nickel(II) complexes are diamagnetic and the magnetic moment of the copper(II) complex is found to be 1.24 BM indicating the presence of one unpaired electron. The value is subnormal because it is quite less than the experimental magnetic moment (1.9–2.1 BM) values. It may suggest the existence of polymeric species.

3.1. Electronic spectra

The electronic spectra (Table 2) of the cobalt complex are recorded in $CHCl_3$ and DMF. The most intense band in the highest energy region has been assigned to π–π* transition of ligand. The next lowest energy band found at 27 397 cm^{-1} (in $CHCl_3$), 27 777 cm^{-1} (in DMF) has been assigned to charge transfer transitions [13].

In the electronic spectrum of the nickel complex in DMF, three bands are observed at 10 152 cm − 1 (ν_1); 17 094 (ν_2); 22 772 cm^{-1} (ν_3) assigned to $^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)$; $^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g}(F) \rightarrow {}^3T_{1g}(P)$ transitions [14], respectively. The ratio of ν_1:ν_2 lies at 1.68 as required for an octahedral Ni(II) complex. The ligand field parameters, field splitting energy (10 Dq), Racah interelectronic repulsion parameter β, covalent factor and ligand field stabilization energy (LFSE) have been calculated and presented in Table 3. The electronic data (in DMF) suggest an octahedral geometry for the nickel

complex. DMF is a known coordinating solvent and presumably coordinates nickel in both axial positions to complete the octahedral structure.

The electronic spectrum of the nickel complex is also recorded in chloroform. The spectral behavior in chloroform is in agreement with the square-planar coordination of nickel. The electronic spectrum of the copper complex is recorded in DMF covering a 50 000–125 000 cm^{-1} range. The absorption band is observed at 33 330 cm^{-1} is due to π–π^*/charge transfer transition. However, the low intensity band is observed at 16 863 cm^{-1}. This band is assigned to the $^2B_{1g} \rightarrow {}^2A_{1g}$ transition [14,15] suggesting the presence of square-planar geometry.

3.2. IR spectra

Important IR spectral bands of BMO and its complexes are given in Table 4. A broad band of medium intensity is observed at 3389 cm^{-1} in the spectrum of the free ligand. This band is absent in the spectra of all complexes suggesting the deprotonation of oxime proton in complex formation. The downward shift of ν(C=N) and ν(C=O) bands in the spectra of all complexes suggests the coordination of the metal ion through the azomethine nitrogen and the oxygen atom of the C=O group. The non ligand bands in the 456–490 and 422–445 cm^{-1} regions are tentatively assigned to ν(M–O) and ν(M–N) stretching vibrations [16], respectively.

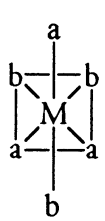
3.3. ^1H NMR spectra

Cobalt(III) and nickel(II) complexes are characterized by high resolution (400 MHz) ^1H NMR spectra in $CDCl_3$ solvent. In the case of the ligand a singlet is observed in the low field region of the spectra at δ 8.227 ppm, but it is absent in the cobalt and nickel complexes, which indicates the absence of an oxime proton in these complexes.

Table 5
Cyclic voltammetric data of cobalt, nickel and copper complexes (10^{-3} M) in DMF containing 0.1 M $TEAClO_4$ at 1.0 V/S^{-1} at glassy carbon electrode (Temp. 26°C)

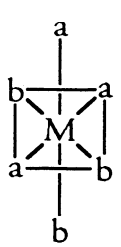
Complex	Scan rate	Redox couple	E_{pc} (V)	E_{pa} (V)	DE (mV)	$E_{1/2}$ (V)	$-i_c/i_a$
$[Co(BMO)_3]$	100	III/II	−0.52	−0.18	340	0.35	
		II/I	−0.128				
$[Ni(BMO)_2]$	100	II/I	−1.20				
$[Cu(BMO)]_n$	100	III/II	+0.28	+0.55	270	0.415	0.651

3.4. Cyclic voltammetric studies



The cyclic voltammograms for cobalt, nickel and copper complexes are recorded in dimethylformamide. The cyclic voltammetric data for all the complexes are given in Table 5.

The cyclic voltammogram of the present cobalt complex has a single reversible electron [Co(III) → Co(II)] couple with $E_{1/2} = -0.35$ V. This complex also has an irreversible cathodic peak at $E_{pc} = -1.28$ V, corresponding to Co(II) → Co(I).



The cyclic voltammogram data for the copper complex show a single reduction wave at $E_{1/2} = +0.415$ V and have a quasi reversible behavior [17] as indicated by the non-equivalent current intensity of cathodic and anodic peaks ($-i_c/i_a = 0.615$ at 100 mV s^{-1}). The reversible couple is assigned to Cu(III) → Cu(II), which is similar to values reported earlier [18–21].

Electronic spectral data together with magnetic moment data suggest an octahedral structure of the $[Co(BMO)_3]$ complex. Thus, it is a tris(benzil-α-monoximato)cobalt(III) complex.

No isomers are possible for tris-chelated complexes with symmetrical ligands. However, cobalt complexes with unsymmetrical ligands give facial and meridonial isomers.

facial

meridonial

The present ligand, BMO is unsymmetrical ligand. Now the question is whether the $Co(BMO)_3$ has facial configuration or meridonial configuration. The ^1H NMR spectrum of $Co(BMO)_3$ gave no information about the configuration of the complex. Hence it is considered worthwhile to study the complex using the X-ray diffraction technique. The results obtained in the X-ray structure determination of the complex are presented herein.

3.5. X-ray crystal and molecular structure of the cobalt(III) complex of BMO

The crystallographic data and data collection details for$[Co(BMO)_3]$ are summarized in Table 6. The molecular structure of $[Co(BMO)_3]$ is shown in Fig. 1 and the important bond lengths and bond angles are listed in Table 7.

From Fig. 1, it can be seen that cobalt is six-coordinate with three nitrogen atoms [N(1), N(2), N(3)] and three oxygen atoms [O(2), O(4), O(6)], thus giving an octahedral configuration from three unsymmetrically bonding bidentate ligands.

As expected, the three imino nitrogen atoms give stronger coordination bonds. This is evident by shorter Co–N bond lengths (1.868–1.901 Å). The Co–O bond

Isomerization of 2-methyl-3-butyn-2-ol into prenal: mechanistic observations on tricomponent catalyst systems of the type $Ti(OR)_4$–CuCl–$R'CO_2H$. Crystal structure of $[CuCl(Me_2C(OH)C{\equiv}CH)]_4$

Received 28 February 2000; accepted 22 May 2000

Abstract

The mechanism of the title catalytic system was investigated, in particular by synthesizing several compounds that model the postulated metal–oxo–propargyloxo intermediates, such as $[Ti(\mu\text{-}O)(O\text{–}Bu^t)(O_2CTol)]_2$ (Tol = *p*-MeC_6H_4), $Ti(OCMe_2C{\equiv}CH)_4$ and $[CuCl(Me_2C(OH)C{\equiv}CH)]_4$. The molecular structure of $[CuCl(Me_2C(OH)C{\equiv}CH)]_4$ was determined by X-ray crystallography and heterobimetallic Ti–Cu complexes comprising the 2-methyl-3-butyn-2-oxo fragment are reported. © 2000 Elsevier Science Ltd. Keywords: α-Acetylenic alcohols; Isomerization; Rearrangement; Heterobimetallic titanium–copper systems

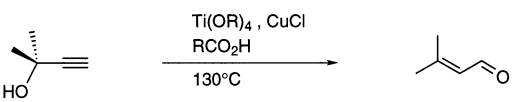
1. Introduction



α,β-Ethylenic carbonyl compounds such as prenal (3-methyl-2-butenal) are important intermediates in the manufacture of fragrances, carotenoids or vitamins [1], and their synthesis via isomerization of α-acetylenic alcohols has been known for many years [2,3]. This type of reaction was initially catalysed in protic media, as first shown by Meyer and Schuster [2], before oxo complexes of early transition metals such as vanadium, rhenium and molybdenum were found to be efficient catalysts [4–6]. The oxo ligands were supposed to play a key mechanistic role as receptors of migrating propargyl groups, in the [3,3] sigmatropic rearrangement of metal–oxo–propargyloxo entities (Scheme 1).

More recently however, Chabardès has shown [7] that efficient and selective isomerization of α-acetylenic alcohols such as 2-methyl-3-butyn-2-ol (1,1-dimethylpropargyl alcohol) can be achieved homogeneously in the presence of mixtures of titanium alkoxides, copper (I) chloride and carboxylic acids. Despite the absence of an oxo ligand, these tricomponent catalyst systems are even more efficient than the previous oxo catalysts (Scheme 2).

The mechanism suggested for the operation of these new systems is summarized in Scheme 3 [7]. By analogy

Scheme 3.

with the metal–oxo catalysts, it involves initial formation of a titanium propargyloxo complex **a** via reaction of the carboxylic acid and titanium precursor. Copper chloride, which is necessary for activity, activates the propargyloxide ligand by interaction with the carbon–carbon triple bond **b**. Such an interaction would favour the [3,3] sigmatropic rearrangement leading to **c**. Decoordination of CuCl from the allenyloxo ligand of **c** would then give **d**, and displacement of the rearranged ligand by a further molecule of propargyl alcohol, followed by its spontaneous isomerization, yields the α,β-ethylenic carbonyl product and regenerates **a**.

In this paper, we wish to discuss the initial steps of this mechanism on the basis of reactivity and model studies.

2. Experimental

All manipulations were carried out under an atmosphere of argon using standard dry box, vacuum line, or Schlenk tube techniques. Solvents were distilled under nitrogen in the presence of a suitable drying agent. Copper(I) chloride (Strem) was purified via a known method [14]. Titanium tetraisopropoxide and titanium tetratertiobutoxide (Aldrich) were purified by fractional distillation. Carboxylic acids were dried under vacuum over P_2O_5. 2-Methyl-3-butyn-2-ol (Aldrich) was refluxed over CaH_2, fractionally distilled, and stored over molecular sieves (4 Å) in a dry box. Elemental analyses were performed by the CNRS Microanalytical Laboratory at Strasbourg or Lyon, France. Infrared (IR) spectra were recorded as nujol mulls on a Perkin–Elmer 597 or a Perkin–Elmer 1650 (FTIR) spectrometer; absorption bands are listed in reciprocal cm as weak (w), medium (m), or strong (s). 200 MHz ^{1}H NMR and 50 MHz ^{13}C{^{1}H} NMR spectra were recorded on a Bruker SY200 instrument; chemical shifts (δ) are given in parts per million relative to TMS.

2.1. Experimental procedure for catalytic isomerisation of 2-methyl-3-butyn-2-ol

In a typical experiment, 2-methyl-3-butyn-2-ol (8.41 g, 100 mmol), *n*-nonane (3.41 g) (internal standard for GC analysis), crotonic acid (1.47 g, 17 mmol), copper(I) chloride (150 mg, 1.5 mmol), Ti(O–Pr^i)$_4$ (42 ml, 1.4 mmol) and *o*-dichlorobenzene (13 ml) were introduced into a round-bottom flask fitted with a reflux condenser, under an atmosphere of argon. The mixture was heated to 100°C, after 1 h reaction, GC analysis of the reaction mixture indicated 98% conversion of 2-methyl-3-butyn-2-ol into prenal.

2.2. Preparation and characterization of [Ti(μ-O)(O–Bu^t)(O$_2$CTol)]$_2$ (1)

Under an atmosphere of argon, a solution of Ti(^{t}O–Bu)$_4$ (2.50 g, 7.35 mmol) and TolCO$_2$H (1.00 g, 36.72 mmol) (Tol = *p*-MeC$_6$H$_4$) in 20 ml of dry C$_6$H$_6$ was refluxed for 9 h. After removal of the volatiles under vacuum and extraction of the residue in pentane (10 ml), the solution was kept at −20°C overnight. The resulting white precipitate was filtered and redissolved in 10 ml of pentane, and the solution was maintained at −20°C for a few hours. The solution was then filtered, and the white solid was dried in vacuo to give 1.20 g of **1** (yield 60%). *Anal.* Calc. for $C_{24}H_{32}O_8Ti_2$ (**1**): C, 52.96; H, 5.93. Found: C, 54.50; H, 5.62%. IR (nujol mull, cm^{-1}) 1607 s ($\nu_{C=C}$); 1526 s ($\nu_{as\ COO}$); 1412 s ($\nu_{s\ COO}$); 1237 s, 1130 s, 1000 s (ν_{C-O}); 869 s; 764 s (ν_{Ti-O}); 628 m; 592 m; 464 m. ^{1}H NMR (200 MHz, C$_6$D$_6$; δ (ppm)) 8.18 (d, $^3J_{Ha-Hb}$ = 8 Hz, 2H, H$_{a\ Tol}$); 6.76 (d, $^3J_{Ha-Hb}$ = 8 Hz, 2H, H$_{b\ Tol}$); 1.86 (s, 3H, Me$_{Tol}$); 1.49 (s, 9H, ^{t}Bu). ^{13}C{^{1}H} NMR (50 MHz, CDCl$_3$; δ (ppm)) 155.5 (CO$_2$H); 144.5, 130.0, 129.0, 127.1 (C$_{aromatic}$); 31.0 (*C*Me$_3$); 31.1 (C*Me*$_3$); 21.9 (Me$_{Tol}$).

2.3. Preparation and characterization of Ti(OCMe$_2$C≡CH)$_4$ (2)

To a solution of TiCl$_4$ (556 mg, 2.93 mmol) in pentane (20 ml) was added dropwise at −30°C a solution of 2-methyl-3-butyn-2-ol (1.11 g, 13.2 mmol) and triethylamine (1.30 g, 13.2 mmol) in pentane (20 ml), under an atmosphere of argon. The mixture was stirred overnight (−20°C) and then filtered to give a colorless solution. The volatiles were removed under vacuum to yield the product as pale yellow oil (880 mg, 79%). Further purification was achieved by vacuum

distillation. *Anal*. Calc. for $C_{20}H_{28}O_4Ti$ (**2**): C, 63.16; H, 7.42. Found: C, 63.17; H, 7.44%. IR (nujol mull, cm^{-1}) 3290 s ($\nu_{\equiv C-H}$); 2090 w ($\nu_{C\equiv C}$); 1210 s, 1130 s, 1000 s (ν_{C-O}). ^1H NMR (200 MHz, C_6D_6; δ (ppm)) 2.10 (s, 1H, ≡C–H); 1.67 (s, 6H, Me). $^{13}C\{^1H\}$ NMR (50 MHz, C_6D_6; δ (ppm)) 89.2 (*C*≡CH); 76.3 (C–O); 70.0 (≡CH); 33.2 (Me).

2.4. Preparation and characterization of $[CuCl(Me_2C(OH)C\equiv CH)]_4$ (3)

Under an atmosphere of argon, 500 mg of freshly purified CuCl was stirred at about 50°C with 2 ml of 2-methyl-3-butyn-2-ol until a clear solution was obtained. After hot filtration over celite, the colorless filtrate was allowed to cool slowly to room temperature to give, after a few days, colorless crystals of **3**, which were suitable for X-ray analysis. Crystals were washed with pentane (3 × 2 ml) and dried under vacuum (yield 45%). *Anal*. Calc. for $C_{20}H_{32}O_4Cl_4Cu_4$ (**3**): C, 32.80; H, 4.40. Found: C, 32.82; H, 4.32%. IR (nujol mull, cm^{-1}) 3500–3200 m (ν_{OH}); 3180 s ($\nu_{\equiv C-H}$); 1940 m ($\nu_{C\equiv C}$); 1205 s, 1160 s (ν_{C-O}); 240 w ($\nu_{Cu-Cl-Cu}$). ^1H NMR (200 MHz, C_6D_6; δ (ppm)) 2.22 (s, 1H, ≡C–H); 1.57 (s, 1H, OH); 1.31 (s, 6H, Me). $^{13}C\{^1H\}$ NMR (50 MHz, C_6D_6; δ (ppm)) 89.54 (*C*≡CH); 70.07 (≡CH); 64.70 (C–O); 31.35 (Me).

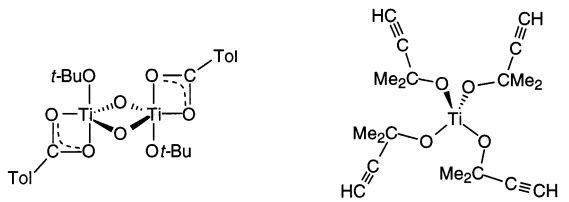
2.5. Crystal structure determination

Crystal data were obtained at −100°C using a Philips PW1100/16 diffractometer with Cu Kα graphite-monochromated radiation ($\lambda = 1.5418$ Å). The scan width (°) in the $\theta/2\theta$ mode used was $\Delta\theta = 0.80 + 0.14 \tan\theta$. A total of 953 *hkl* reflections were recorded within $3 < \theta < 52°$, and 823 reflections having $I > 3\sigma(I)$ were used for determining and refining the structure. The structure was determined using direct methods and refined using full-matrix least-squares to $R(F) = 0.039$ and $R_w(F) = 0.056$, GOF = 1.478, maximum electronic density = 0.765 $eÅ^{-3}$, 145 variables. The Nonius Open-Molen/Alpha package [15] was used for all calculations. Selected crystal data for **3**: $C_{10}H_{16}O_2Cl_2Cu_2$, $M_r = 366.22$, orthorhombic, space group *Pba*2, $a = 9.170(2)$, $b = 18.544(5)$, $c = 8.188(2)$ Å, $V = 1392(1)$ $Å^3$, $Z = 4$, $D_{calc} = 1.75$ g cm^{-3}, $\mu = 7.231$ mm^{-1}.

2.6. Reaction between $TiCl_4$ and 3

In an NMR tube containing 15 mg of **3** (0.014 mmol) in 0.45 ml $CDCl_3$ were added 10 ml of $TiCl_4$ (0.055 mmol). The solution became pink after a few minutes at 20°C. ^1H NMR (200 MHz, $CDCl_3$): δ 2.80 (s, 1H, ≡CH); 1.87 (s, 6H, Me). When the solution was kept at room temperature for 24 h, it turned blue. GC analysis and ^1H NMR spectroscopy showed complete conversion into prenal: ^1H NMR (200 MHz, $CDCl_3$): δ 9.95 (d, $^3J_{H-H} = 8$ Hz, 1H, CHO); 5.89 (m, 1H, =CH); 2.17 (d, $^4J_{H_a-H} = 1$ Hz, 3H, Me_a); 1.98 (d, $^4J_{H_b-H}$ 1 Hz, 3H, Me_b).

2.7. Reaction between CuCl and 2



CuCl (104 mg, 1.06 mmol) was added to a solution of **2** (400 mg, 1.06 mmol) in 15 ml CH_2Cl_2. The mixture was stirred at 20°C for 1 h and then filtered to eliminate unreacted CuCl. Removal of volatiles under vacuum yielded orange oil (450 mg). ^1H NMR (200 MHz, CD_2Cl_2) δ 2.69 (s, 1H, ≡CH); 1.65 (s, 6H, Me) and peaks from residual **2**. IR (nujol mull, cm^{-1}) 3190 s ($\nu_{\equiv CH}$); 1940 m ($\nu_{C\equiv C}$) and bands from residual **2**. The reaction was also followed in situ by ^1H NMR in $CDCl_3$.

3. Results and discussion

3.1. Formation of titanium–oxo functions

To investigate the initiation step of the mechanism, we first measured the influence of the nature of the carboxylic acid on the catalytic efficiency of a given pair of titanium and copper compounds. Using a mixture of $Ti(O–Pr^i)_4$ and CuCl (1:1), isomerization of 2-methyl-3-butyn-2-ol (50 equivalents) at 100°C, in the presence of five equivalents of various carboxylic acids, reaches the following conversion percentages after 30 min: 3,3-dimethylacrylic acid ($pK_a = 5.12$), 98%; crotonic acid ($pK_a = 4.69$), 97%; *p*-methoxybenzoic acid ($pK_a = 4.49$), 88%; *p*-*t*-butylbenzoic acid ($pK_a = 4.39$), 82%; *p*-toluic acid ($pK_a = 4.37$), 72%; acetic acid ($pK_a = 4.75$), 48%; benzoic acid ($pK_a = 4.19$), 42%; *p*-chlorobenzoic acid ($pK_a = 3.97$), 10%; *p*-nitrobenzoic acid ($pK_a = 3.41$), 3%. The reaction rates therefore decrease with decreasing pK_a values. This implies that, if carboxylic acids are necessary for the formation of titanium oxo species, too strong an acid will be less favourable; the lower activity obtained with acetic acid demonstrates that other factors contribute.

On the other hand, we have found that the reaction of $Ti(O–Bu^t)_4$ with *p*-toluic acid (benzene, 80°C) yields significant amounts of a bridged oxo species which could be separated and formulated as $\{Ti(\mu\text{-}O)(O–Bu^t)(O_2CTol)\}_2$ (**1**), and whose structure is proposed in Scheme 4 on the basis of spectroscopic data. This confirms that titanium alkoxides can be effectively convert into oxo species in the presence of carboxylic acids [8,9]. Complex **1** is analogous to earlier compounds such as $\{Ti(\mu\text{-}O)(\mu\text{-}O_2CR)_2\}_2$ [8b–c, 9e] and catalyses the rearrangement of 2-methyl-3-butyn-2-ol into prenal as efficiently as its titanium tetraalkoxide precursor. However, analogous substrates or reactants

1 2

Scheme 4.

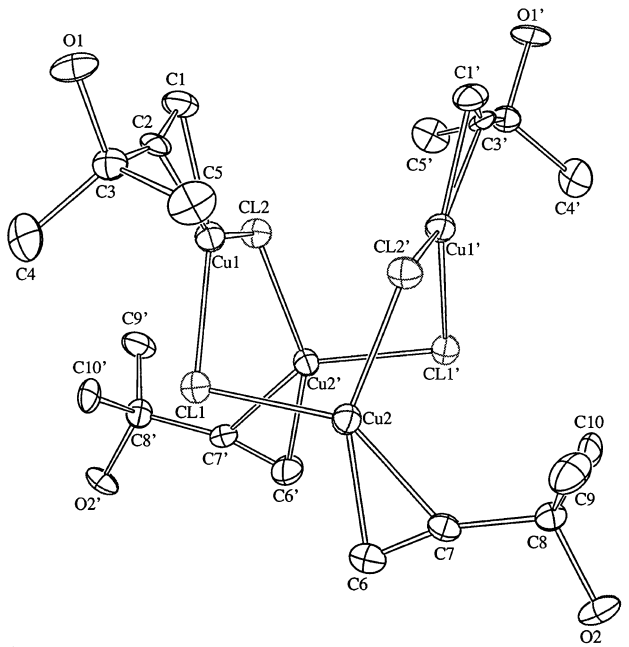
lead to less clear-cut results. For example, addition of crotonic acid to $Ti(O–Pr^i)_4$ only affords mixtures of carboxylato and *i*-propyloxo complexes, in which the presence of an oxo function could not be firmly established.

3.2. Formation of titanium–propargyl oxide complexes

In species **a**, a 1,1-dimethyl-propargyloxo ligand bound to titanium is also involved. This would arise from alkoxide exchange between OR ligands initially present in $Ti(OR)_4$ and 2-methyl-3-butyn-2-ol. Such an exchange process has literature precedent [10] and, with R = *i*-Pr, we obtained a mixture of products of general formula $Ti(O–Pr^i)_{4-n}(OCMe_2C{\equiv}CH)_n$ ($n = 0–4$). A well-defined propargyl oxide complex was synthesized by reacting four equivalents of 2-methyl-3-butyn-2-ol with $TiCl_4$ in the presence of triethylamine, leading to $Ti(OCMe_2C{\equiv}CH)_4$ (**2**) in good yield. The bulkiness of the dimethylpropargyloxo ligands probably prevents association by means of oxygen bridges, allowing a monomeric geometry similar to that of $Ti(O–Bu^t)_4$ [10] to be proposed for this compound (Scheme 4). Reaction of 1,1-dimethylpropargyl alcohol to form the tetraalkoxide **2** is revealed by a chemical shift variation of $^1H_{Me}$ from 1.32 to 1.67 ppm, and of $^1H_{C{\equiv}CH}$ from 2.02 to 2.10 ppm (in C_6D_6), the infrared $\nu_{C{\equiv}C}$ being only slightly modified. It is worth noting that complex **2** is as active as other $Ti(OR)_4$ catalysts, and that, in the absence of 1,1-dimethylpropargyl alcohol, its ligands isomerize as expected into prenal (100°C, Ti:Cu:acid = 1:1:5).

Further comparison of the ability of various titanium complexes to catalyse the rearrangement of 2-methyl-3-butyn-2-ol has led to following qualitative sequence (CuCl:crotonic acid:2-methyl-3-butyn-2-ol = 1:5:50, 100°C, 30 min reaction):

$Ti(O–Bu^t)_4 \approx Ti(O–Pr^i)_4 > TiCl(O–Pr^i)_3 \approx TiO(acac)_2 > TiCl_2(O–Pr^i)_2 > Cp_2TiCl_2 > TiCl_3(O–Pr^i)$. Such a result is consistent with rapid alkoxide exchange on titanium, and completes earlier results [7] by showing, in particular, the negative effect of chloro ligands.



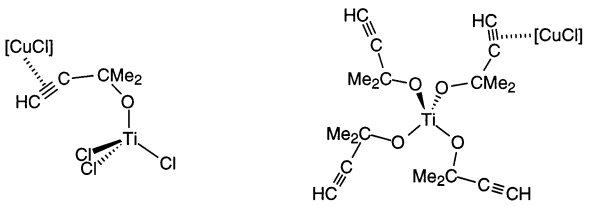


Fig. 1. ORTEP diagram of compound **3**. Hydrogen atoms are omitted. Selected bond distances (Å): Cu(1)–Cl(1) = 2.263(3), Cu(1)–Cl(2) = 2.286(2), Cu(2)–Cl(1) = 2.258(2), Cu(2)–Cl(2') = 2.266(3), Cu(1)–C(1) = 2.01(1), Cu(1)–C(2) = 2.037(8), Cu(2)–C(6) = 1.97(1), Cu(2)–C(7) = 2.021(9), C(1)–C(2) = 1.19(1), C(6)–C(7) = 1.18(1). Selected bond angles (°): Cl(1)–Cu(1)–Cl(2) = 105.9(1), C(1)–Cu(1)–C(2) = 34.2(3), C(6)–Cu(2)–C(7) = 34.3(4), C(1)–C(2)–C(3) = 161.1(9), C(6)–C(7)–C(8) = 164(1).

3.3. Formation of copper(I)–chloride complexes of 2-methyl-3-butyn-2-ol

The role of the copper chloride component of the catalyst system would be to interact with, and hence activate, the carbon–carbon triple bond of α-acetylenic alcohols, as in species **b** (Scheme 3). The affinity of copper (I) complexes for alkynes, resulting in the formation of π-adducts, is well-established [11], and we have verified that various propargylic alcohols effectively coordinate through their triple bond to copper (I). Complexes such as $[CuCl(2\text{-butyn-1-ol})]_4$, $[Cu(CF_3CO_2)(2\text{-methyl-3-butyn-2-ol})]_2$, and $[Cu(bipy)(2\text{-methyl-3-butyn-2-ol})]PF_6$ were appropriately synthesized [5b]. In particular, dissolution of CuCl into 2-methyl-3-butyn-2-ol, followed by filtration and slow crystallization, yielded colorless, air-sensitive crystals of $\{CuCl(Me_2C(OH)C{\equiv}CH)\}_4$ (**3**). The ^1H NMR spectrum of **3** in C_6D_6 showed the terminal acetylenic proton of the 2-methyl-3-butyn-2-ol shifted downfield on coordination, from 2.02 to 2.22 ppm (and from 2.42 to 2.60 ppm in $CDCl_3$), whereas the methyl signal is hardly shifted. This feature characterizes bonding of the carbon–carbon triple bond to copper, which is further defined by the shift of the infrared C≡C stretching band from 2110 cm^{-1} for the free ligand to 1940 cm^{-1} for **3**.

Scheme 5.

The crystal structure of **3** has been determined by single-crystal X-ray diffraction. An ORTEP drawing is shown in Fig. 1, along with selected interatomic distances and angles. The molecular structure consists of two $Cu_2Cl_2(C_5H_8O)_2$ units crystallographically related by a twofold symmetry axis, yielding an overall tetrameric arrrangement of four copper atoms lying at the vertices of a slightly distorted tetrahedron. The two metal centers of the dimeric units are linked through a nearly symmetrical chloride bridge, with Cu(1)–Cl(1) = 2.263(3) and Cu(2)–Cl(1) = 2.258(2) Å. The two dimeric units are associated similarly one to each other, with Cu(1)–Cl(2) = 2.286(2) and Cu(2)–Cl(2′) = 2.266(3) Å, leading to an eight-membered ring possessing a boat configuration. Each copper atom is further bound to the carbon–carbon triple bond of a 2-methyl-3-butyn-2-ol molecule, thus adopting an approximate trigonal planar geometry, as already observed in other copper(I)–alkyne compounds [12]. The copper–alkyne interaction is weak, as revealed by the short carbon–carbon bonds of 1.19(1) and 1.18(1) Å, but strong enough to deviate the propargyl skeleton from linearity by 18.9(9) and 16(1)°.

This shows how coordination of CuCl to the carbon–carbon triple bond of a catalytic intermediate such as **b** may facilitate subsequent rearrangement step (Scheme 3) by favoring nucleophilic attack of the titanium–oxo function on the terminal acetylenic carbon: besides making the triple bond more reactive, it also brings the terminal acetylenic carbon closer to the oxo ligand [13].

3.4. Formation of heterobimetallic Ti–Cu–propargyl oxide complexes

In order to model more precisely species **b**, we attempted to synthesize titanium–propargyl oxide complexes such as **2** in which the carbon–carbon triple bond of the propargyl oxide ligand would be bound to copper (I) chloride as in **3**. Thus, addition of four equivalents of $TiCl_4$ to tetrameric **3** was followed by ^1H NMR in $CDCl_3$. Rapid reaction occurs, as revealed by the significant shift of the methyl and acetylenic proton signals from respectively 1.54 and 2.60 ppm to 1.87 and 2.80 ppm, and by the disappearance of the hydroxyl proton. Such downfield displacements are similar to those observed on conversion of 1,1-dimethylpropargyl alcohol into **2**, suggesting that the four hydroxy functions of the copper tetramer have reacted, each with one molecule of $TiCl_4$, to yield the bimetallic complex $[CuCl(Me_2C(OTiCl_3)C{\equiv}CH)]_4$ (**4**). However, the degree of association in **3** may be modified during the course of reaction, especially if chlorides bridge titanium centers. A simple representation of a monomeric unit of **4** is given in Scheme 5.

On the other hand, addition of one equivalent of CuCl to **2** in $CDCl_3$ results in the emergence of a new 1,1-dimethylpropargyl oxide spectrum in which the acetylenic proton signal is shifted downfield to 2.69 ppm, although features of **2** are still observed. This suggests that a fraction of the carbon–carbon triple bonds of **2** coordinates to CuCl, as depicted in **5** for instance (Scheme 5). The spectrum of the uncomplexed propargyl oxide ligands of **5** would be identical to that of **2**, itself certainly still present. The infrared spectrum of the orange oil obtained after removal of all volatiles under vacuum, showing two $\nu_{C\equiv C}$ bands at 2100 and 1940 cm^{-1}, confirms this conclusion.

Unfortunately, neither **4** nor **5** was stable enough to be isolated. Interestingly, **4** decomposed at room temperature within 24 h with liberation of prenal, mimicking not only the structure of intermediate **b**, but also its reactivity.

In conclusion, our results are consistent with the mechanistic proposal of Scheme 3. The respective role of titanium, copper and carboxylic acid in the catalytic system has been confirmed, and the observation of heterobimetallic Ti–Cu complexes of 2-methyl-3-butyn-2-ol, in particular, is unprecedented to our knowledge.

4. Supplementary data

Further details of the structure investigation have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 141001. Abstract

Tetra(tetraphenylimidophosphinato)thorium, $Th(tpip)_4$ (**1**), was obtained from $Th(NO_3)_4{\cdot}4H_2O$ and Ktpip in aqueous medium. The analogous uranium compound, $U(tpip)_4$ (**2**), has been prepared by reacting UCl_4 with Ktpip in a 1:4 stoichiometric ratio, either in THF or in aqueous solution. X-ray diffraction analysis showed that compounds **1** and **2** were isostructural. The metal center is eight-coordinate by way of four bidentate tetraphenylimidophosphinate ligands in a square antiprismatic configuration. $UCl(tpip)_3$ (**3**) has been isolated from the reaction of uranium tetrachloride with 3 equiv. of Ktpip in aqueous solution. When this reaction was run in THF both compounds, $U(tpip)_4$ and $UCl(tpip)_3$, were obtained. The molecular structure of **3** has been determined by X-ray crystallography. The uranium atom is seven-coordinate in a pentagonal bipyramidal configuration. These compounds were also characterized by infrared and ^1H and ^{31}P NMR spectroscopies. © 2000 Elsevier Science Ltd. 1. Introduction

Bidentate oxygen ligands, such as carboxylates, tropolonates, β-ketoenolates, and oxalates have been used extensively in actinide chemistry [1]. They usually chelate to a single metal center, but they can also bridge dimetal units. Due to the large ionic radii of the actinide metals the coordination number of the metal atom is increased frequently by the presence of additional small molecules.

The synthesis of tris(tetraphenylimidodiphosphonato)lanthanide complexes ($Ln(tpip)_3$) has been reported before [2a]. The X-ray crystal structure of the praseodymium compound free from any external ligand has been determined, but the compound readily forms adducts with water, carboxylic acids, and carboxylates [2b]. It was reported that $Pr(tpip)_3$ induces important shifts in the ^1H NMR spectra of carboxylic acids and carboxylates, as a result of the formation of labile adducts, which makes this compound a useful NMR-shift reagent [2b–d]. Recently, long-lived highly luminescent terbium and europium complexes with these ligands were reported [3]. Although there is no evidence of water coordination in the structure, addition of water in the acetonitrile solution of $Tb(tpip)_3$ and $Eu(tpip)_3$ leads to shortening of the emission lifetime, which indicates some involvement of the water molecules in the coordination sphere of the lanthanide.

Due to the great flexibility of the chelating rings observed for these ligands which show wide variations in the ring angles (P–N–P, M–O–P, O–P–N), and also to its larger bite compared with other bidentate oxygen ligands, we decided to study the complexes of the early actinides, thorium and uranium, with the tetraphenylimidophosphinate ligand to determine how the different sizes of the metal ions would influence the

molecular structure of the complexes and if additional ligands would be needed to stabilize them. Herein we wish to report the synthesis of the first actinide tetraphenylimidophosphinate complexes.

2. Experimental

2.1. General procedures and techniques

The preparation and manipulation of the uranium compounds were carried out using standard Schlenk-line and dry-box techniques in an atmosphere of dinitrogen. UCl_4 was prepared as described previously [4]. $Th(NO_3)_4{\cdot}4H_2O$ was purchased from BDH Ltd. and used as received. $HN[P(O)(C_6H_5)_2]_2$ was prepared as reported previously [5]. THF and TDF were distilled from Na–benzophenone ketyl under nitrogen. NMR spectra were recorded at 27°C on a Varian 300 spectrometer in TDF. All ^1H NMR chemical shifts are reported in ppm relative to the ^1H impurity in TDF at δ 3.70 and the ^{31}P chemical shift to an external reference of H_3PO_4. Infrared spectra were recorded on a Perkin–Elmer 577 spectrophotometer as Nujol mulls between CsI plates. Elemental analyses were performed on a CE Instruments EA 1110 CHN analyzer.

2.2. Preparation of the compounds

2.2.1. Ktpip

To a suspension of $HN[P(O)(C_6H_5)_2]_2$ in methanol was slowly added a solution of KOH (10%) in water. After addition of the stoichiometric amount of KOH the suspension gives a clear solution, which was used in this form for the preparation of the compounds isolated in aqueous solution. For the reactions run in THF, the solution of Ktpip was evaporated to dryness to yield a white solid which was further recrystallized from ethanol.

2.2.2. $Th(tpip)_4$ (**1**)

Addition of an aqueous solution of the potassium salt of the ligand tpip (205 mg, 0.45 mmol) to an aqueous solution of $Th(NO_3)_4{\cdot}4H_2O$ (62 mg, 0.11 mmol) results in immediate formation of a white precipitate. This was collected over a filter, washed with water several times and dried under vacuum. Yield: 77% (160 mg, 0.084 mmol). The compound could be recrystallized from a THF–hexane solution yielding transparent crystals of **1**. IR spectrum (Nujol, cm^{-1}): $\nu(P_2N)$ 1210, 800; ν(PC) 745, 720, 695. ^1H NMR (THF-d_8, 27°C, δ ppm): 7.64 (2H, dd, 7.8, 4.6 Hz), 7.08 (1H, m), and 6.86 (2H, m). $^{31}P\{^1H\}$ NMR (THF-d_8, 27°C, δ ppm): 20.37. *Anal.* Calc. for $C_{96}H_{80}N_4O_8P_8Th$ (1897.55): C, 60.77; H, 4.25; N, 2.95. Found: C, 59.77; H, 4.33; N, 2.67%.

2.2.3. $U(tpip)_4$ (**2**)

Compound **2** was prepared by two methods.

2.2.3.1. Method a. An aqueous solution of Ktpip (437 mg, 0.96 mmol) was slowly added to 90 mg (0.24 mmol) of UCl_4, under nitrogen. There was an immediate formation of a light-green precipitate. The mixture was stirred for 10 min and evaporated to dryness. The compound was extracted with THF. Removal of the solvent under vacuum yielded a green solid in ca. 70% yield (319 mg, 0.17 mmol). *Anal.* Calc. for $C_{96}H_{80}N_4O_8P_8U$ (1903.54): C, 60.57; H, 4.24; N, 2.94. Found: C, 58.39; H, 3.96; N, 2.68%.

2.2.3.2. Method b. A stoichiometric amount of Ktpip (214 mg, 0.47 mmol) was added to a THF solution of UCl_4 (47 mg, 0.12 mmol) in a glove box. After separation of the KCl precipitate, removal of the solvent under vacuum yielded a light-green compound, which was washed with *n*-hexane and dried under vacuum. Yield: 76% (90 mg, 0.047 mmol). Crystals suitable for X-ray diffraction analysis were obtained by recrystallization from a concentrated THF solution, layered with *n*-hexane. IR spectrum (Nujol, cm^{-1}): $\nu(P_2N)$ 1208, 795; ν(PC) 745, 725, 690. ^1H NMR (THF-d_8, 27°C, δ ppm): 7.35 (1H, m), 6.97 (2H, m), 6.43 (2H, br). $^{31}P\{^1H\}$ NMR (THF-d_8, 27°C, δ ppm): −11.79. *Anal.* Calc. for $C_{96}H_{80}N_4O_8P_8U$: C, 60.57; H, 4.24; N, 2.94. Found: C, 58.42; H, 3.92; N, 2.68%.

2.2.4. $UCl(tpip)_3$ (**3**)

Addition of an aqueous solution of Ktpip (246 mg, 0.54 mmol) to UCl_4 (70.4 mg, 0.18 mmol), under a nitrogen atmosphere, resulted in immediate formation of a light-green precipitate. After stirring for a few minutes, the mixture was dried under vacuum, and the compound was extracted with THF. Removal of the solvent under vacuum yielded the green compound with a yield of 50% (137 mg, 0.09 mmol). Green crystals of **3** suitable for X-ray diffraction analysis were obtained from a THF–hexane solution. IR spectrum (Nujol, cm^{-1}): $\nu(P_2N)$ 1235, 1205 and 815; ν(PC) 750, 725, 690. ^1H NMR (THF-d_8, 27°C, δ ppm): 8.15 (2H, dd, 7.4, 4.6 Hz), 7.30 (1H, m), 7.05 (2H, m). $^{31}P\{^1H\}$ NMR (THF-d_8, 27°C, δ ppm): −14.12. *Anal.* Calc. for $C_{72}H_{60}ClN_3O_6P_6U$ (1522.61): C, 56.80; H, 3.97; N, 2.76. Found: C, 56.29; H, 3.61; N, 2.63%.

2.3. X-ray crystallographic analysis of $Th(tpip)_4$ (**1**), $U(tpip)_4$ (**2**) and $UCl(tpip)_3$ (**3**)

Crystals were mounted in thin-walled glass capillaries in a nitrogen-filled glove box. Data were collected at room temperature on an Enraf–Nonius CAD-4 diffractometer with graphite-monochromatized Mo Kα radiation. A summary of the crystallographic data is given in

Table 1. Data were corrected for Lorentz-polarization effects, for decay (no decay was observed for **3**) and for absorption by empirical corrections based on ψ scans [6].

The structures were solved by Patterson methods [7] and subsequent difference Fourier techniques and refined by full-matrix least-squares procedures on F^2 using SHELXL-93 [8]. Compounds **1** and **2** are isomorphous. In their lattice there is one molecule of THF of crystallization per asymmetric unit. Aditionally, the three strongest peaks in the difference Fourier map, severely disordered across a center of symmetry, were indicative of another solvent present, possibly hexane, the disorder of which could not be modelled, and so they were taken into account as full-occupancy carbon atoms (they were excluded from the formula, from the molecular weight and from the calculation of the density in Table 1). All but the solvent atoms were refined anisotropically and the contributions of the hydrogen atoms were included in calculated positions (except those of the solvent). Atomic scattering factors and anomalous dispersion terms were taken as in Ref. [8].

3. Results and discussion

3.1. Synthesis

$Th(tpip)_4$ (**1**) was obtained as a white precipitate by reacting an aqueous solution of $Th(NO_3)_4{\cdot}4H_2O$ with 4 equiv. of an aqueous solution of Ktpip. Compound **1** is insoluble in common aromatic and aliphatic hydrocarbons and in halogenated solvents, but dissolves in THF from where transparent crystals suitable for X-ray diffraction analysis could be obtained.

Addition of 4 equiv. of an aqueous solution of potassium tetraphenylimidophosphinate to UCl_4, under a nitrogen atmosphere, resulted in immediate formation of a light green precipitate. After drying under vacuum, the solid was extracted with THF giving a green compound, $U(tpip)_4$ (**2**), in good yield. **2** could also be obtained by reacting anhydrous potassium tetraphenylimidophosphinate with UCl_4, in THF solution, in the appropriate amounts. $UCl(tpip)_3$ (**3**) was obtained as a light-green precipitate when 3 equiv. of Ktpip in aqueous solution were added to UCl_4. When this reaction was run in THF solution there is concomitant formation of $UCl(tpip)_3$ and $U(tpip)_4$, as shown by its ^1H and ^{31}P NMR spectra. Recrystallization from THF did not allow the separation of the compounds.

Attempts to obtain the analogous $ThCl(tpip)_3$ failed. When $ThCl_4$ reacts with 3 equiv. of Ktpip, either in aqueous or THF solution, a mixture of compounds is obtained. One compound could be identified as $Th(tpip)_4$ by its ^1H and ^{31}P NMR spectra. The other species is probably $ThCl(tpip)_3$, by comparison with the result obtained in the uranium case. To support this hypothesis the typical Th–Cl vibration could be identified in the

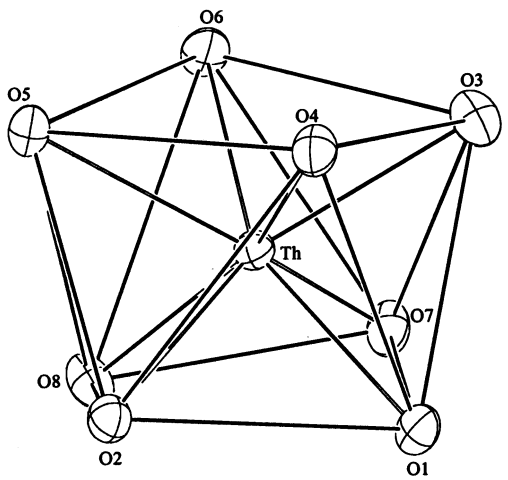

Fig. 2. View of the coordination geometry around the Th atom in [Th(tpip)$_4$].

IR spectrum of the mixture. Attempts to recrystallize the compound yielded always crystals of **1**.

3.1.1. IR spectroscopy

The solid state IR spectra of the complexes show absorptions characteristic of P–N bonds [9,10]. The absorptions due to the phosphazenic stretching vibration (PNP) appear as a doublet centered at 1210 cm^{-1} in complex **1**, whereas this band is centered at 1208 cm^{-1} in complex **2**. The spectrum of **3** is more complex in this region, with bands centered at 1230, 1200 and 1190 cm^{-1}. Bands in the region 775–690 cm^{-1} are assigned to the P–C(phenyl) vibrations [10]. In addition the spectrum of **3** shows the U–Cl stretching vibration at 270 cm^{-1}.

3.1.2. NMR spectroscopy

The room temperature ^{1}H NMR spectra of all the complexes are deceptively simple exhibiting only one set of complex multiplets associated with the aromatic protons of the ligands and one single resonance in the ^{31}P{^{1}H} NMR spectra. The magnetic equivalence of the chelating ligands indicates a fluxional process which is fast in the NMR time scale. By lowering the temperature the resonances broaden and shift but a limit static spectrum is not obtained. The assignment of the resonances could be done on the basis of their relative intensity and multiplicity. In the ^{1}H NMR spectrum of **1** the resonances due to the *o*-, *p*-, and *m*-protons of the aromatic rings appear as complex multiplets centered at 7.64, 7.08 and 6.86 ppm, respectively, and the ^{31}P NMR spectrum showed one single resonance at 20.37 ppm. In the spectrum of **2** the *p*- and the *m*-protons appear as complex triplets centered at 7.35 and 6.97 ppm, respectively, and the *o*-protons as a broad resonance at 6.43 ppm. The ^{31}P NMR spectrum displays one resonance at -11.79 ppm. The resonances due to the *o*-, *p*-, and *m*-protons of **3** are multiplets centered at 8.15, 7.30 and 7.05 ppm, respectively, and the resonance due to the phosphorus atoms is located at -14.12 ppm.

A stoichiometric amount of pyridine was added to the less crowded compound **3** in TDF in a NMR tube. The NMR spectrum of the mixture displays the resonances due to compound **3** and free pyridine only, in contrast with the tris(tetraphenylimidodiphosphonato)lanthanide complexes (Ln(tpip)$_3$) [2], which form adducts with neutral small ligands.

To confirm the identity of **1**, **2**, and **3** and to establish their coordination geometry the solid state structures of the compounds were determined by single crystal X-ray diffraction.

3.2. Crystallographic studies

3.2.1. Complexes *1* and *2*

Compounds **1** and **2** are isostructural and crystallized from THF as monomeric molecules. The metal center is eight-coordinate by way of four bidentate tetraphenylimidophosphinate groups and displays distorted square antiprismatic (SAP) geometry. Fig. 1 shows a perspective view of the molecule **1** (**2** is isomorphous and is not illustrated, but equal atomic numbering schemes are used for **1** and **2**). Each two tpip ligands are chelated along the edges of the square faces of the SAP polyhedron (Fig. 2). Both 'square' faces, O(1)–O(2)–O(8)–O(7) and O(3)–O(4)–O(5)–O(6), are quite bent (dihedral angles of its diagonals are 16.8, 12.6°, and 15.7, 13.1° for **1** and **2**, respectively), which together with the ϕ values (20.8, 18.9° and 21.4, 19.2° for **1** and **2**, respectively) leads to distortion of the SAP along the pathway towards dodecahedron (DD), as shown in Table 2, where the values of the shape

Table 2
Values [a] of the δ and ϕ shape parameters (°) for $[Th(tpip)_4]\cdot OC_4H_8$ and $[U(tpip)_4]\cdot OC_4H_8$

[a] Values referred to the normalized polyhedron. δ_s, dihedral angles referred to the diagonals of the square faces of the polyhedron; δ_l, dihedral angles referred to the lateral edges of the polyhedron; ϕ, values for the planarity of the two orthogonal trapezoids.

parameters [11] for the normalized polyhedra are shown.

Selected bond lengths and angles are given in Table 3. Only one tpip ligand (containing the O(7) and O(8) atoms) is symmetrically bonded to the metal center, whilst the others are asymmetrically bonded. The An–O bond lengths average 2.41(3) Å for **1**, (range: 2.376(7)–2.459(6) Å) and 2.37(3) Å for **2** (range: 2.324(7)–2.425(7) Å), which is consistent with the difference of the ionic radii of Th(IV) and U(IV).

The O–An–O bond angles are similar and average 71.8(2)° for **1** and 72.3(2)° for **2**. The Th–O bond lengths and the O–Th–O bond angles are comparable to the values 2.40(2) Å and 70.5(4)° of the eight-coordinate tetrakis(thenoyltrifluoroacetonato)thorium(IV), $Th(TTA)_4$ [12], which presents a dodecahedral geometry. The U–O bond length and the O–U–O bond angles in **2** compare with the values of 2.32(3) Å and 71(1)° in the eight-coordinate SAP [β-$U(acac)_4$] [13] and with the values of 2.34(1) Å and 70.8(2)° in [U(PhCOCHCOPh)$_4$] [14].

The more relevant parameters for the tpip ligands are the P–O and P–N bond distances, which are equivalent in both compounds (average P–O and P–N: 1.518(11) and 1.583(6) Å in **1**, 1.517(7) and 1.584(11) Å in **2**). These distances are shorter than the corresponding single bonds, suggesting electron delocalization over the chelate rings, as already observed by other authors for analogous complexes with the tetraphenyldithioimidophosphinate ligand [15]. The maximum variations observed in the ring angles P–N–P, O–P–N and An–O–P within the four chelate rings in compounds **1** and **2** are similar, as expected, as they are isomorphous (compound **1**: 2.4, 2.0, 4.6°; compound **2**: 2.1, 2.1, 4.4°). In **1** and **2** the O_2P_2N chelate rings show significant deviations from planarity (atomic deviations in the range −0.142 to 0.188 Å). All the six-membered AnO_2P_2N rings are non-planar with the rings containing the O3/O4 and O7/O8 atoms being almost planar within AnO_2P_2 with some folding about the P···P axis (fold angles: 16.9 and 25.7° for **1**, 18.1 and 27.0° for **2**). The different deformations observed for each chelate ring reflects the flexible nature of these ligands.

3.2.2. Complex **3**

The uranium atom is in a pentagonal bipyramidal configuration (PB) in complex **3**, with two chelating rings (O(3)/O(4) and O(5)/O(6)) and the O(1) atom of the third chelating ring occupying the equatorial plane, while the chlorine and the O(2) atoms are in the axial positions (Cl–U–O(2) angle of 176.1(2)°). An ORTEP drawing of **3** is shown in Fig. 3, selected bond lengths and angles are listed in Table 4.

The U–O bond lengths and the O–U–O bond angles range from 2.268(6) to 2.355(5) Å (average 2.31(3) Å) and from 72.0(2) to 79.0(2)° (average 74.6(2)°), respectively. The ligand containing oxygens in equatorial and axial positions presents the largest O–U–O bond angle

O(1)–U–O(4)	73.0(2)	O(2)–U–Cl	176.1(2)
O(1)–U–O(5)	74.8(2)	O(3)–U–Cl	93.9(2)
O(3)–U–O(6)	68.6(2)	O(4)–U–Cl	89.7(2)
O(2)–U–O(3)	90.1(2)	O(5)–U–Cl	86.4(2)
O(2)–U–O(4)	91.4(2)	O(6)–U–Cl	96.3(2)

(O(1)–U–O(2) angle of 79.0(2)°). The U–O bond lengths in **3** are shorter than in complex **2**, as it would be expected for a complex with a lower coordination number and compares with the value of 2.32(2) Å in the seven-coordinate (PB) $UCl_2(acac)_2(OPPh_3)$ [16]. The U–Cl bond length in **3** (2.624(3) Å) is comparable with the value of 2.617(8) Å found in $UCl_2(acac)_2(OPPh_3)$ [16].

As in compounds **1** and **2**, the P–O and P–N bond distances are similar (average P–O and P–N: 1.516(11), 1.581(12) Å) but shorter than the corresponding single bonds. **3** shows higher values for the maximum variations in the ring angles P–N–P, O–P–N and U–O–P within the three chelate ring (6.8, 3.8. and 5.3°) reflecting again the large flexibility of the ligand. This flexibility is also manifested by the folding of some rings along the P···P axis, as already mentioned for **1** and **2**, as well as by the folding of some rings along the O···O axis. One of the O_2P_2N chelate rings (the one containing the O3/O4 atoms) shows significant deviations from planarity, while the other two are almost planar. The UO_2P_2N rings containing the O1/O2 and the O5/O6 atoms, show folding angles of 11.1 and 12.1° about the O···O and P···P axes, respectively.

4. Conclusions

So far, the structures reported here are the first structurally characterized actinide complexes with tpip ligands. The complexes isolated demonstrate the influence of the ionic radii of the actinide ions in the structure of the resulting complexes nicely. For the smaller uranium ion both compounds $U(tpip)_4$ and $UCl(tpip)_3$ could be synthesized while for the thorium ion only the more coordinative saturated $Th(tpip)_4$ could be isolated.

Received 29 March 2000; accepted 23 May 2000

Abstract

Europium(II) hydrotris(pyrazol-1-yl)borate complexes, $Eu(HBpz_3)_2L_2$ (L = diphenylsulfoxide (**1**) and bis(pentamethylene)urea (**2**)), have been synthesized. Characterization of **1** and **2** by infrared absorption spectroscopy points to coordination of the neutral ligands through the sulfoxide and carbonyl oxygens, respectively. This was corroborated by X-ray diffraction analysis. In both compounds the metal centre is eight-coordinate by way of the six nitrogens of the two tridentate pyrazolyl ligands and the oxygen atoms of the diphenylsulfoxide or bis(pentamethylene) urea ligands, in a square antiprismatic configuration. Both complexes are luminescent at 77 K and display emission bands with maxima at 610 and 632 nm for **1** and **2**, respectively. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

The chemistry of the lanthanides in low-oxidation states is being widely studied because of their potential in organic synthesis [1] and the luminescent properties of complexes containing Eu^{2+} ions [2].

Most of the chemistry of the lanthanide ions in low oxidation states has been mainly based on the cyclopentadienyl type ligands, but recently an increasing interest has been directed towards other ligand frameworks [3]. One of the ligand systems that has been explored is based on polypyrazolylborate ligands, which have been considered similar to the cyclopentadienyls. Some years ago we and others initiated an extensive investigation into the synthesis of hydrotris(pyrazolyl)borate ($Tp^{R,R'}$) anchored lanthanide(II) complexes. $Ln(Tp^{Me,Me})_2$ (Ln = Sm, Yb, Eu) [4], $Ln(HBpz_3)_2 \cdot 2THF$ and $Ln(Bpz_4)_2 \cdot 2THF$ (Ln = Sm, Yb, Eu) [5], $Ln(Tp^{Ph,Me})_2$ and $Ln(Tp^{thyenyl,Me})_2$ (Ln = Sm, Yb) [6], $Ln(Tp^{tBu,Me})_2$ (Ln = Sm, Yb) [7] are among the compounds which have been isolated upon reaction of the appropriate di-iodides with the wide variety of accessible hydrotrispyrazolylborate ligands. The luminescent behaviour of $Eu(HBpz_3)_2 \cdot 2THF$ and $Eu(Bpz_4)_2 \cdot 2THF$ have also been reported [5]. $Eu(HBpz_3)_2 \cdot 2THF$ proved to be a very good emitter and, therefore, a potentially good phosphor.

This paper describes the synthesis, characterization, spectroscopic studies and structural determination of europium bishydrotris(pyrazol-1-yl)borate complexes with the neutral ligands diphenylsulfoxide (DPSO) and bis(pentamethylene)urea (BPMU).

2. Experimental

2.1. Materials and instrumentation

All synthetic procedures were carried out under nitrogen using glove box and Schlenk-line techniques. Solvents used were purified by distillation from sodium benzophenone ketyl and degassed immediately before use. $KHBpz_3$ [8] and $Eu(HBpz_3)_2{\cdot}2THF$ [5] were prepared as previously described. Europium(II) iodide solutions were prepared according to literature procedures [9]. Diphenylsulfoxide and bis(pentamethylene)urea were purified by sublimation under vacuum. Infrared absorption spectra were recorded on a Perkin–Elmer 577 spectrophotometer using Nujol mulls between CsI plates. Emission spectra were recorded on a Hitachi Perkin–Elmer MPF-4 spectrofluorimeter with modifications for solid samples positioning and thermostating at low temperatures [10]. As all the samples were oxygen and water sensitive they were sealed in quartz tubes under vacuum. Although no quantum emission efficiencies could be obtained in our laboratories, the experimental conditions followed allowed a comparison of relative emission efficiencies.

2.2. Preparation of the complexes

2.2.1. $Eu(HBpz_3)_2{\cdot}2DPSO$ (1)

To a solution of $Eu(HBpz_3)_2{\cdot}2THF$ (200 mg, 0.277 mmol) in THF was added diphenylsulfoxide (112 mg, 0.554 mmol). After the addition the solution turns immediately from yellow to orange. Stirring was continued for 16 h. Removal of the solvent under reduced pressure yielded a yellow solid, which was further crystallized from toluene. Yield: 60% (163 mg, 0.166 mmol). IR (Nujol, cm^{-1}): ν(BH) 2395, 2435. *Anal.* Calc. for $C_{42}H_{40}B_2N_{12}O_2S_2Eu$: C, 51.34; H, 4.10; N, 17.11. Found: C, 49.70; H, 3.94; N, 16.57%.

2.2.2. $Eu(HBpz_3)_2{\cdot}2BPMU$ (2)

The compound was prepared as described for **1**, by reacting $Eu(HBpz_3)_2{\cdot}2THF$ (255 mg, 0.353 mmol) in THF with bis(pentamethylene)urea (139 mg, 0.706 mmol). Yield: 60% (205 mg, 0.211 mmol). IR (Nujol, cm^{-1}): ν(BH) 2390, 2430. *Anal.* Calc. for $C_{40}H_{60}N_{16}B_2O_2Eu$: C, 49.50; H, 6.23; N, 23.09. Found: C, 49.27; H, 6.82; N, 23.11%.

2.3. X-ray crystallographic analysis of $Eu(HBpz_3)_2{\cdot}2DPSO$ and $Eu(HBpz_3)_2{\cdot}2BPMU$

Orange crystals of **1** and **2**, of approximate dimensions $0.54 \times 0.18 \times 0.14$ mm and $0.43 \times 0.22 \times 0.14$ mm, respectively, were mounted in thin-walled glass capillaries in a nitrogen-filled glove-box. Data were collected at room temperature (r.t.) on an Enraf–Nonius CAD-4 diffractometer with graphite-monochromated Mo Kα radiation, using a ω–2θ scan mode. Unit cell parameters were obtained by least-square refinement of the setting angles of 25 reflections with $16.6 < 2\theta < 25.1°$ for **1** and $15.9 < 2\theta < 25.8°$ for **2**. A summary of the crystallographic data is given in Table 1.

Observed [$I > 2\sigma(I)$]	5465	8169
Number of parameters	431	550
R_1 [a]	0.0751	0.0575
wR_2 [b]	0.1394	0.0904

[a] $R_1 = \Sigma||F_o|-|F_o||/\Sigma|F_o|$.

[b] $wR_2 = [\Sigma(w(F_o^2-F_c^2)^2)/\Sigma(w(F_o^2)]^{1/2}$; $w = 1/[\sigma^2(F_o^2)+(aP)^2+bP]$, where $P = (F_o^2+2F_c^2)/3$. The values were calculated for data with $I > 2\sigma(I)$.

Data were corrected [11] for Lorentz and polarization effects, for linear decay and for absorption by empirical corrections based on ψ scans. The heavy atom positions were located by Patterson methods using SHELXS-86 [12]. The remaining atoms were located by successive difference Fourier maps and refined by least-squares refinements on F^2 using SHELXS-93 [13]. All the non-hydrogen atoms (except the phenyl carbon atoms, which showed large U_{iso} values) were refined with anisotropic thermal motion parameters, and the contribution of the hydrogen atoms was included in calculated positions. The relatively weak diffraction of crystal **1** limited the accuracy of the structural analysis. The final difference Fourier syntheses revealed electron densities between 0.80 and -0.57 e Å^3 for **1** and 1.06 and -0.49 e Å^3 for **2**, near the heavy atoms. Atomic scattering factors and anomalous dispersion terms were taken as in [13]. Drawings were made with ORTEPII [14] and all the calculations were performed on a Dec α 3000 computer.

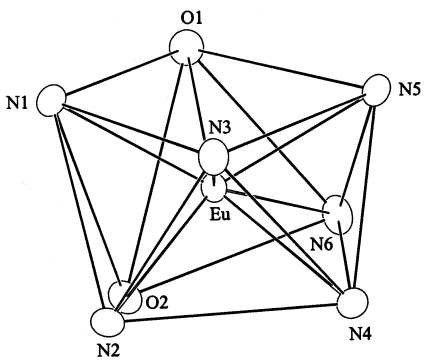

Fig. 2. Coordination polyhedron of $Eu(HBpz_3)_2{\cdot}2BPMU$ (**2**).

3. Results and discussion

3.1. Synthesis and characterization of complexes $Eu(HBpz_3)_2{\cdot}2L$ ($L = DPSO$, $BPMU$)

Replacement of the two molecules of THF in $Eu(HBpz_3)_2{\cdot}2THF$ by DPSO or BPMU was readily achieved by adding 2 equiv. of the appropriate reagent to one equivalent of $Eu(HBpz_3)_2{\cdot}2THF$ in THF solution. After addition, the yellow solution of $Eu(HBpz_3)_2{\cdot}2THF$ turned immediately to orange. Recrystallization from toluene afforded the expected $Eu(HBpz_3)_2{\cdot}2DPSO$ (**1**) and $Eu(HBpz_3)_2{\cdot}2BPMU$ (**2**), as orange crystalline materials in reasonable yield.

The compounds are soluble in common aromatic and ether type solvents. The infrared spectra exhibit the ν(B–H) stretching vibration between 2390 and 2435 cm^{-1} consistent with tridentate ($HBpz_3$) ligands. In the spectrum of **1** ν(SO) appears at 967 cm^{-1}, whereas in neat DPSO it appears at 1000 cm^{-1}. This is within the range of observed ν(SO) shifts towards lower energies that occur in other DPSO complexes [15,16] and it is indicative of coordination through the oxygen of the sulfoxide group. Infrared spectra of **2** show ν(CO) at 1620 cm^{-1}. The CO stretching in neat BPMU appears at 1648 cm^{-1}. This shift to lower energy has also been observed in other complexes containing ligands with the carbonyl group [17] and is indicative of coordination through the carbonyl oxygen.

Due to the poor elemental analysis and to the Eu(II) ion paramagnetism, which hampered characterization of the complexes by NMR spectroscopy, unambiguous characterizations of the complexes were not possible. In order to confirm the identity of **1** and **2** and establish the coordination geometry at the metal single crystal X-ray studies of the compounds were undertaken.

3.2. Crystal structures of *1* and *2*

In both compounds the crystal structures consist of discrete molecular units. In the structure of **1** there are two crystallographically independent molecules in the asymmetric unit in which both molecules have imposed C_2 symmetry with the europium atoms lying on a two-fold rotation axis. The europium atoms are eight-coordinate, by six nitrogen atoms of the two tridentate ligands and two oxygen atoms of the DPSO/BPMU groups. The coordination geometries are best described as distorted square antiprismatic (SAP), as shown in Figs. 1 and 2.

Each tridentate ligand occupies two triangular faces of the SAP polyhedra while the oxygen atoms are in adjacent sites along a lateral edge. Polytopal analysis [18] of these structures reveals a substantial distortion of the SAP geometry towards dodecahedral (DD), as shown in Table 2, where the values of the shape parameters, δ and ϕ, are listed for both compounds along with the values for the idealized polyhedra.

The 'square' faces of the polyhedra are quite bent (**1**, 9.6° for molecule 1 and 8.4° for molecule 2; **2**, 5.8 and 25.6°), which together with the average ϕ values (**1**, 22.6° for molecules 1 and 2; **2**, 26.3°) takes the coordination polyhedra along the geometric pathway towards DD. In the structure of **2** the δ values of 5.8 and 25.6° show that one 'square' face is quite bent when compared with the other. As can be seen in Table 2 the coordination polyhedra for the two independent molecules of **1** are very similar. Also, the structures of **1** and **2** are similar in terms of both the disposition of the ligands and the coordination geometry. However, a more irregular polyhedron is observed in **2** to allow the same set of the two tripodal ligands to accomodate the more sterically demanding BPMU group relatively to DPSO. The SAP geometry observed for these complexes is in contrast to that observed in the related eight-coordinate $Eu(Bpz_4)_2{\cdot}2THF$ complex in which a bicapped trigonal prismatic (BCTP) geometry was found [5].

Tables 3 and 4 show selected bond lengths and bond angles for **1** and **2**. Within three standard deviations the two independent molecules of **1** have similar molecular dimensions.

The molecular structure of one of the molecules of **1** is shown in Fig. 3 along with the numbering scheme for the atoms around the Eu(1) atom. Fig. 4 shows the molecular structure of **2**.

Table 2
Normalized shape parameters (°) for Eu[HB(pz)$_3$]$_2$·2DPSO (**1**) and Eu[HB(pz)$_3$]$_2$·2BPMU (**2**) [a]

	Atoms	1		2		SAP	BCTP	DOD
		Molecule 1 [b]	Molecule 2 [b]	Atoms

ϕ	5–7–6–3	25.9	24.8	N(3) N(1) O(2) N(6)	36.9	24.5	14.1	0.0

[a] All data refer to normalized polyhedra.
[b] The numbering of atoms is as shown in Fig. 1.
[c] δ_S = dihedral angles referred to the diagonals of the square faces of the polyhedron.
[d] δ_1 = dihedral angles referred to the lateral edges of the polyhedron.
[e] ϕ = values for the planarity of the two orthogonal trapezoids.

The average Eu–N bond distances (2.69 for **1** and 2.72 Å for **2**) compare with the value of 2.70 Å observed for Eu(Bpz$_4$)$_2$·2THF [5].

The average Eu–O bond distances (2.58(1) for **1** and 2.604(4) for **2**) are comparable with the values of 2.649(5) observed for Eu(Bpz$_4$)$_2$·2THF [5] and with the value of 2.64(2) Å in the eight-coordinate complex $Cp^*_2Sm(THF)_2$ [19]. The O–Eu–O bond angle in **1** is 84.8(5) and 80.6(5)° (av. 82.7(5)°) which is smaller than the value of 88.1(1)° found in **2**, reflecting the more sterically demanding nature of the BPMU ligand imposed by the nonplanarity of their rings.

3.3. Luminescence studies

Luminescence spectra were studied for complexes synthesized in this work as well as for the previously reported complex Eu(Tp^{Me,Me})$_2$ [4]. The results obtained were compared with the spectra already studied for Eu(Bpz$_4$)$_2$·2THF and Eu(HBpz$_3$)$_2$·2THF [5], in order to evaluate their spectral characteristics and relative emission efficiencies.

Eu(HBpz$_3$)$_2$·2DPSO is not luminescent at r.t., however a weak emission is observed at 77 K. It is a broad band with a maximum at 610 nm, very similar to the one observed for Eu(HBpz$_3$)$_2$·2THF. Eu(HBpz$_3$)$_2$·2BPMU is also not luminescent at r.t., but at 77 K is strongly luminescent presenting a broad band with maximum at 632 nm. Eu(Tp^{Me,Me})$_2$ is a very strong emitter, either at r.t. or at 77 K. It shows a broad band with maximum emission at 587 nm at 298 K, which shifts to 600 nm at 77 K maintaining its line shape. This wavelength shift with temperature was also observed in Eu(HBpz$_3$)$_2$·2THF [5] which is also a very strong emitter, presenting at r.t. a broad band with maximum at 586 nm. This maximum shifts to 607 nm at 77 K. In the same study, Eu(Bpz$_4$)$_2$·2THF was found to be a weaker emitter, showing a relatively narrow band with maximum at 460 nm [5].

Excitation spectra were also recorded. The spectrum of Eu(HBpz$_3$)$_2$·2DPSO is very similar to the spectrum obtained for the complex with coordinated THF, showing a large band between 320 and 400 nm with a shoulder at 330 nm. The spectrum of Eu(HBpz$_3$)$_2$·2BPMU shows a broad peak from 310 to 560 nm, with shoulders at 380 and 520 nm. For Eu(Tp^{Me,Me})$_2$ this peak appears between 390–490 nm, with a shoulder at 320 nm. Previous work [5] showed that the excitation band for the complexes Eu(HBpz$_3$)$_2$·2THF is very broad, extending from 285 to ca. 500 nm.

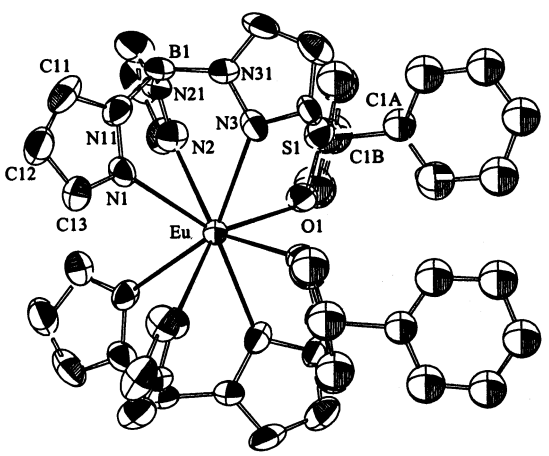

Fig. 3. ORTEP diagram of molecule 1 of $Eu(HBpz_3)_2 \cdot 2DPSO$ (**1**), using 30% probability ellipsoids.

The results obtained indicate the antenna effect of the coordinated polypyrazolyl ligands. Whereas the solvent free europium complex with the 3,5-dimethylpolypyrazolyl ligand, $Eu(Tp^{Me,Me})_2$, and the complex with the less bulky pyrazolyl borate ligand, $Eu(HBpz_3)_2 \cdot THF$, show strong luminescence, the complex with the tetrapolypyrazolyl ligand $Eu(Bpz_4)_2 \cdot 2THF$, as reported before is a very weak emitter [5]. This complex has one of the pyrazolyl rings of the ligand not coordinated to the metal, and the weak luminescence was explained by the vibrations or even rotations (in the solid state) which can provide very efficient internal conversion channels.

When, in $Eu(HBpz_3)_2 \cdot 2THF$, the tetrahydrofuran molecules are replaced by diphenylphosphine oxide or bispentamethyleneurea no luminescence is observed at r.t.

An explanation for this phenomenon is possibly the fact that donor ligands, more strongly bound than THF, present less isolation between the excited ion and ligand moieties, making energy transfer to the latter easier. At r.t. quenching of the emitting level is facilitated via thermal excitation back to a lower energy state of the ligand. At low temperature this effect is diminished and emission is observed for both complexes, being the complex with BMPU the stronger emitter. Recent studies on dissociation in the gas phase of several $Eu(HBpz_3)_2 \cdot 2L$ (L = neutral ligand) positive ions, made by Fourier transform ion cyclotron resonance spectrometry, showed that BMPU is weakly bonded [20]. Moreover, if the structures of both compounds are compared it can be seen that the BMPU adduct is more stereochemically congested, so non-radiative quenching due to vibration should be more difficult.

It has been observed in Eu(II) complexes that increasing the distance between absorbing groups and the Eu(II) ion causes an strengthening in emission intensity [2]. Considering the energy of the excited state of Eu(II), the neutral ligand absorption is in the vicinity of a $\pi \rightarrow \pi^*$ transition.

On the other hand, one can not discard the possibility of mixing of electronic states of Eu(II) and ligand vibrational states. This mixing can open an internal conversion channel for energy relaxation, which can account for the quantum efficiency lowering. It has been observed in Eu(III) complexes with β-diketonates that the substitution of methyl for phenyl groups in the diketonate ligands lowers both emission lifetimes and emission quantum yields [21]. These lifetimes are further lowered by introduction of substituents in the phenyl groups.

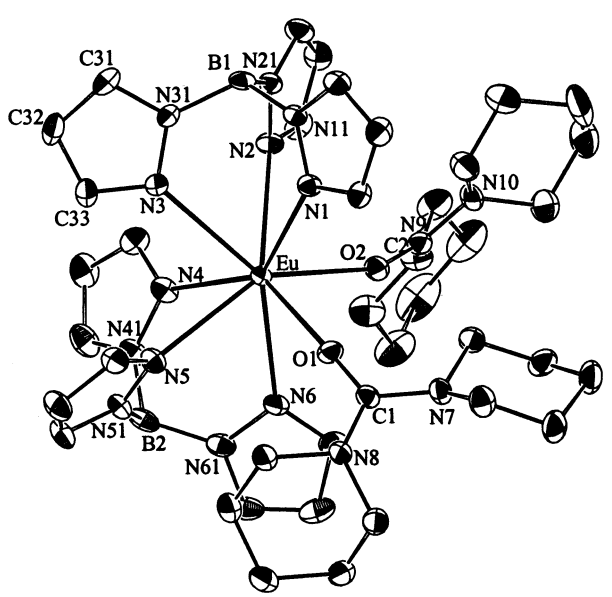

Fig. 4. ORTEP diagram of $Eu(HBpz_3)_2 \cdot 2BPMU$ (**2**), using 30% probability ellipsoids.

Concluding polypyrazolylborate ligands seemed to provide an interesting antenna effect for the luminescence of the europium complexes studied. The choice of the polypyrazolylborate ligand type and the choice of the neutral ligand, when needed to stabilise the complex should determine the emission quantum efficiencies of this type of europium compound.

4. Supplementary data

Atomic co-ordinates, bond lengths and angles and thermal parameters have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 140084 and 140085. Received 10 January 2000; accepted 7 June 2000

Abstract

Nickel(II) piperidinedithiocarbamate complexes of the composition [Ni(pipdtc)(P-P)]X and $[Ni_2(pipdtc)_2(NCS)_2(dpph)]$ (X = NCS, ClO_4, I; P-P = 1,2-bis(diphenylphosphino)ethane (dppe), 1,4-bis(diphenylphosphino)butane (dppb), 1,6-bis(diphenylphosphino)hexane (dpph), 1,4-bis(diphenylphosphino)ferrocene (dppf); pip = C_5H_{10}; dtc = S_2CN^-) have been synthesized. The compounds have been characterized by elemental analyses, IR, electron and ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectroscopies, thermal analysis, magneto-chemical and conductivity measurements. A single-crystal X-ray analysis of the $[Ni(pipdtc)(dppf)]ClO_4$ complex proved four-coordinated nickel in a deformed square-planar arrangement with a S_2P_2 donor set. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Nickel(II) piperidinedithiocarbamate complexes; Synthesis; X-ray structure

1. Introduction

To date, no nickel(II) piperidinedithiocarbamate complexes with bidentate P-P donor ligands in the coordination sphere have been prepared. Only diamagnetic complexes with triphenylphosphine (PPh_3) as a monodentate phosphorus donor ligand of composition $[Ni(pipdtc)(PPh_3)_2]ClO_4$ [1] and $[NiX(pipdtc)(PPh_3)]$ (X = Cl, Br, I, NCS) [1–3] have been synthesized. In both above complexes it was found that the central nickel atom is four-coordinated in a distorted square-planar arrangement of donor atoms with a NiS_2P_2, and NiS_2PX chromophore, respectively. This fact was proved by single-crystal X-ray analysis of the $[Ni(pipdtc)(PPh_3)_2]ClO_4 \cdot PPh_3 \cdot H_2O$ complex [4] in the case of the NiS_2P_2 chromophore.

In the framework of systematic study of dithiocarbamates at our department we focused attention to preparation and study of nickel(II) piperidinedithiocarbamates with bidentate phosphorus donor ligands in the coordination sphere. The aim of the present work was to study the influence of ligands used on structure and physico-chemical properties of the synthesized complexes.

2. Experimental

2.1. Materials

Nitromethane, acetone, 1,2-bis(diphenylphosphino)-ethane (dppe), 1,4-bis(diphenylphosphino)butane (dppb), 1,6-bis(diphenylphosphino)hexane (dpph) and 1,4-bis(diphenylphosphino)ferrocene (dppf) were supplied by Fluka Co. All other reagents were obtained from Lachema Co. and were of p.a. purity.

2.2. Syntheses

Caution! Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only a small amount of the material should be prepared and it should be handled with care.

2.2.1. Preparation of [Ni(pipdtc)(P-P)]X (P-P = dppe, dppb, dpph, dppf; X = ClO_4, NCS, I)

Fine pulverized $NiX_2 \cdot nH_2O$ (1 mmol, i.e. 0.21 g $Ni(NCS)_2 \cdot 2H_2O$, 0.37 g $Ni(ClO_4)_2 \cdot 6H_2O$, 0.42 g $NiI_2 \cdot 6H_2O$) and P-P ligand (1 mmol, i.e. 0.40 g dppe, 0.43 g dppb, 0.46 g dpph, 0.56 g dppf) was added to a suspension of fine pulverized [Ni(pipdtc)$_2$] [5] (1 mmol, 0.39 g) in 50 cm^3 of absolute EtOH. The mixture was intensively stirred under reflux for 5–6 h till the reaction components were dissolved and then filtered. The solid formed after standing for 3 days at room temperature (r.t.) in all cases (except of **1**). It was filtered off, washed with Et_2O and dried under an IR lamp at 40°C. A volume of the reaction solution of complex **1** was reduced to 1/5 and then an excess of water was added to it. The solid substance was obtained by freezing out of the above mixture to −25°C. It was separated by filtration, washed with water and dried under an IR lamp at 40°C. (Yields: 0.52 g (75%) for **1**, 0.57 g (80%) for **2**, 0.56 g (78%) for **3**, 0.61 g (82%) for **4**, 0.64 g (79%) for **5**, 0.63 g (76%) for **7**, 0.71 g (81%) for **8**, 0.70 g (78%) for **9**).

NMR data for **9**.* ^{1}H NMR: δ aromatic region: 8.79(s), 7.80(s), 7.62(s), 7.53(s), 7.28(s), 7.00(s), 6.85(s), 6.64(s), methylene region: 4.91(s), 4.60(s), 4.43(s), 3.73(s), 3.52(s), 3.34(s), 3.27(s), 2.53(s), 2.19(s), 2.08(s), 1.67(s); $^{13}C\{^1H\}$ NMR: δ aromatic region: 134.4(t), 133.7(s), 133.6(s), 132.8(unres.), 132.0(s), 130.2(s), 130.0(s), 129.6(s), 129.0(t), 127.9(s), 127.8(s), methine region: 76.00(s), 74.5(s), methylene region: 48.3(s), 47.5(s), 25.5(s), 25.3(s), 25.2(s), 24.1(s), 23.8(s); $^{31}P\{^1H\}$ NMR: δ 32.6(s).

*2.2.2. Preparation of [Ni_2(pipdtc)$_2$(NCS)$_2$(dpph)]·2H_2O (**6**)*

Fine pulverized $Ni(NCS)_2 \cdot 2H_2O$ (1 mmol, 0.21 g) and dpph (1 mmol, 0.46 g) was added to a suspension of fine pulverized [Ni(pipdtc)$_2$] (1 mmol, 0.39 g) in 50 cm^3 of absolute EtOH. The solid formed during intensive stirring of the reaction mixture under reflux (6 h). The substance was dissolved in CH_2Cl_2 and then filtered. Red microcrystals formed after standing of solution for 3 days at r.t. They were filtered off, washed with Et_2O and dried under an IR lamp at 40°C. (Yield: 0.75 g (72%)).

NMR data for **6**: ^{1}H NMR: δ aromatic region: 7.53 (s), 7.42 (m), methylene region: 3.57 (s), 2.78 (s), 2.40 (s), 2.00 (s), 1.66 (s), 1.53 (s), 1.16 (t); $^{13}C\{^1H\}$ NMR: δ 198.4 (s), aromatic region: 132.7 (s), 131.0 (s), 130.5 (s), 130.4 (s), 129.6 (s), 128.8 (s), 128.4 (unres.), 128.2 (s), methylene region: 57.7 (s), 47.7 (s), 25.7 (unres.), 25.15 (s), 24.3 (s), 23.5 (s), 18.2 (s); $^{31}P\{^1H\}$ NMR: δ 25.4 (s).

2.3. Physical measurements

The content of nickel was determined by the chelatometric titration on murexid as an indicator. Chlorine and bromine were determined by the Schöniger method [6]. The elemental analyses (C, H, N, S) were performed on an EA 1108 instrument (FISONS). The r.t. magnetic susceptibilities of all complexes were measured by the Faraday method. $Co[Hg(NCS)_4]$ was used as a calibrant. Diamagnetic corrections were made with Pascal's constants [7]. Conductivities were measured with an OK 102/1 conductivity meter (Radelkis, Budapest) at 25°C. Diffuse-reflectance electronic absorption spectra (45 000–11 000 cm^{-1}) were carried out on a Specord M40 (Carl Zeiss, Jena). IR spectra (4000–400 cm^{-1}) were recorded on a Specord M80 (Carl Zeiss, Jena) using Nujol mulls. ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectra of the complexes were recorded in $CDCl_3$ on a Bruker AVANCE DRX 300 or 500 instruments. Chemical shifts of ^1H and ^{13}C spectra were given upfield with respect to $SiMe_4$, chemical shifts of ^{31}P spectra were given upfield with respect to 85% aqueous solution of H_3PO_4.

2.4. Crystal structure determination of **8**

Single crystals of **8** were obtained direct from reaction mixture. A crystal of size $0.80 \times 0.20 \times 0.20$ mm was used for data collection. All geometric and intensity data were collected on a κ-axis four-circle diffractometer KUMA KM-4CCD equipped with a OXFORD Cryostream cooler at temperature 150 K. A total of 23 686 reflections (of which 6 482 [$R_{int} = 0.0831$] were unique) in the range $7.28 < 2\theta < 50.00°$ were collected at 150(2) K with monochromatic Mo Kα radiation ($\lambda = 0.71073$ Å, $V = 55$ kV, $I = 30$ mA) and 0.7 mm collimator. A distance of 50 mm between the crystal and CCD detector was chosen. All rotations were performed around omega axis perpendicular to the direction of the X-ray beam. Six different orientations of diffractometer axis (ϕ, κ and θ) were chosen in sequence for covering of practically full 2–50° 2θ hemisphere. A total of 1800 frames were recorded. The exposure time was 20 s for each 0.33° rotation step. The cell parameters were retrieved from all frames using KM4 software and refined on all strong reflections. Data reduction was processed by 3D profile analysing software KM4RED, which corrects intensities for Lorentz and polarization effects too.

Crystal data and structure refinement: $C_{40}H_{38}ClFeNNiO_4P_2S_2$: monoclinic, $P2_1/n$, $a = 10.056(2)$, $b = 15.813(2)$, $c = 24.000(3)$ Å, $\beta = 101.70(2)°$, $V = 3737.1(10)Å^3$, $Z = 4$, $D_{X\text{-ray}} = 1.551$ g cm^{-3}, $\mu = 1.205$ mm^{-1}, $F(000) = 1800$, GOF = 1.018, extinction coefficient = 0.00083(13), 632 parameters, $R_1(obs.) = 0.0617$, $wR_2(obs.) = 0.1220$, $R_1(all) = 0.0761$, $wR_2(all) = 0.1341$, $\Delta F_{max} = 0.612$ e $Å^{-3}$, $\Delta F_{min} = -0.788$ e $Å^{-3}$.

The structure was solved by the direct methods using the program SHELXS-97 [8]. The structure was refined anisotropically by the full-matrix least-squares procedure on F^2 with weight: $w = 1/[\sigma^2(F_o^2) + (0.0250P)^2 + 27.0000P]$, where $P = (F_o^2 + 2F_c^2)/3$, using the SHELXL-97 program [9]. All H-atoms were found from differential Fourier maps and all their parameters were left free for refinement. The O(1), O(2) and O(3) atoms of perchlorate anion are disordered and their positions and U_{eq}-factors were refined using a combination of FVAR and EADP instructions. Additional calculations were made using PARST95 [10].

3. Results and discussion

Composition and analytical data for the complexes are listed in Table 1. The results of physico-chemical studies are summarized in Table 2. All the [Ni(p-ipdtc)(P-P)]X complexes are diamagnetic and behave as electrolytes of the 1:1 type [11]. An ionic binding of the ClO_4 and NCS anions is also supported by IR spec-

troscopy. Strong maxima at 1085 cm^{-1} [$\nu_3(ClO_4)$], 620 cm^{-1} [$\nu_4(ClO_4)$] were found in the IR spectra of the [Ni(pipdtc)(P-P)]ClO_4 complexes (**2**, **4**, **5**, **8**) which can characterize an ionic nature of the perchlorate anion [12]. Maximum at 2050 cm^{-1} may be connected with the ν(C≡N) vibration of the ionic binding NCS group [13].

The binuclear complex $[Ni_2(pipdtc)_2(NCS)_2(dpph)]\cdot 2H_2O$ (**6**) is also diamagnetic. Maxima observed in the IR spectrum of this complex at 2092 and 842 cm^{-1} can be attributable to the ν(C≡N) and ν(C–S) vibrations. The presence of these maxima indicates that the NCS group is coordinated to nickel through the N atom [13].

An assumption of square-planar geometry around the central atom in both types of the above complexes (**1**–**9**) may be also supported by electronic absorption spectra. Medium strong maxima found in the 18 800–21 600 cm^{-1} region in the electronic spectra of all complexes can be attributed to the $^1A_{1g} \rightarrow {}^1B_{1g}$ electron transition [14]. The maxima above 30 000 cm^{-1} are assignable to intraligand transitions in the S_2CN group [15,16]. In the IR spectra of all the complexes characteristic maxima at 1536–1510 cm^{-1} [ν(C–N)] and 998–988 cm^{-1} [ν(C–S)] were observed for dithiocarbamate ligands [13,15].

The thermal decompositions of the hydrated complexes (**1**, **3**, **6**) begin at 60°C. The dehydratation is accompanied by *endo*-effects on DTA-curves (see Table 2). Further thermal decompositions of **1**, **3** and **6** proceed without formation of thermally stable intermediates. Thermal decays of **7** and **9** begin at 190 and 180°C, respectively. The next process of decomposition also proceeds without formation of thermally stable intermediates. The decomposition of the complexes containing the perchlorate anion (**5**) were not performed owing to their possible explosivity.

The structure of [Ni(pipdtc)(dppf)]ClO_4 (**8**) was determined by a single-crystal X-ray analysis. Selected bond lengths and angles are listed in Table 3. The complex [Ni(pipdtc)(dppf)]$^+$ cation is shown in Fig. 1. As excepted, X-ray structure analysis proved that the nickel(II) atom is four-coordinated by two sulfur atoms from pipdtc and by two phosphorus atoms from dppf in distorted square-planar arrangement. The NiS_2P_2 chromophore is nearly planar even if the group of atoms deviates significantly from planarity [$\Sigma((d/s)^2 = 2758.04$, $\chi^2 = 5.99$ at 95% probability level for 3 degrees of freedom]. A degree of the distortion is also apparent from displacements of the Ni(1), S(1), S(2), P(1) and P(2) atoms from a least-squares plane fitted through the above atoms [10]. The deviations are as follows: Ni(1) −0.0153(5), S(1) 0.030(12), S(2) 0.0345(12), P(1) 0.0352(12) and P(2) 0.096(2) Å. An increase of π-electron density over the S_2CN^- moiety was also proved. This delocalization of electron density is obvious from shortening of the C–S [1.733(5) and 1.727(4) Å] and

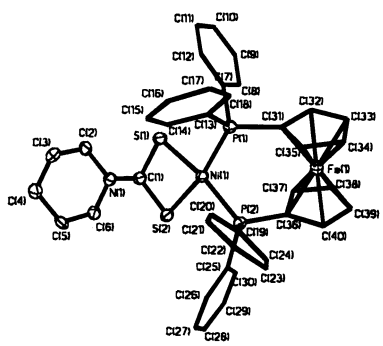

Fig. 1. Molecular structure of the $[Ni(pipdtc)(dppf)]^+$ cation. The hydrogen atoms and ClO_4^- anion are omitted for clarity.

C(1)–N(1) [1.307(6) Å] bond lengths considering the typical C–N (1.47 Å) and C–S (1.81 Å) single bonds [17]. An ionic binding of perchlorate anion is also supported by X-ray structure determination. A direct distance between Ni(1) and Cl(1) atoms is equal to 8.3363(19) Å.

The ligand coordination in [Ni(pipdtc)(P-P)]X complexes is identical to that in the [Ni(plddtc)(dppb)]I·H_2O complex (plpddtc = pyrrolidinedithiocarbamate anion) which structure was elucidated by single-crystal X-ray analysis [18]. In the case of $[Ni_2(pipdtc)_2(NCS)_2(dppf)]\cdot 2H_2O$ we assume that dppf forms a bridge between neighbouring nickel(II) ions to which is coordinated through phosphorus atoms. Unfortunately, any attempts to prepare single crystals of this complex have not been successful yet.

As expected, the $^{31}P\{^1H\}$ NMR spectra measured for selected complexes exhibit one signal at 63.0 ppm (**1**), 62.8 ppm (**2**), 20.7 (**3**), 30.0 ppm (**4**), 25.0 ppm (**5**), 25.4 ppm (**6**), 29.4 ppm (**7**), 32.7 ppm (**8**), and 32.6 ppm (**9**), respectively, corresponding to one kind of phosphorus atoms in the molecule.

Abstract

Reactions of HgX_2 (X = Cl, Br, I) with the very bulky tertiary phosphine, tris(2,6-dimethoxyphenyl)phosphine (DMPP), in either a 1:1 or a 1:2 ratio, result in only the isolation of the 1:1 adducts. The structures adopted in the solid state are markedly influenced by the steric requirement of the phosphine. In contrast to the 1:1 triphenylphosphine adducts reported earlier, which are dimeric, the DMPP mercury(II) chloride and bromide complexes are weakly linked dimers while the iodide is the first example of a mercury iodide–phosphine complex with a monomeric distorted trigonal-planar arrangement around mercury. All three complexes contain secondary interactions with the *o*-methoxy groups. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Mercury(II) halides; Phosphine complexes; Crystal structures

1. Introduction

Following Mann's seminal work in 1940 [1], mercury(II) halides are now known to form a wide range of stoichiometries with tertiary phosphine ligands. By far the most common are the 1:1 and 2:1 complexes, $(R_3P)_nHgX_2$ ($n = 1,2$; X = Cl, Br, I). The 2:1 complexes have a monomeric pseudo-tetrahedral structure with the degree of distortion depending on the σ-donor ability and steric requirement of the phosphine [2–6]. In contrast the 1:1 complexes exhibit a remarkable variety of structures in the solid state, ranging from weakly linked polymeric units with strong σ-donors such as Me_3P and Et_3P, to discrete dimeric structures for weak donors such as Ph_3P [6–13]. The nature of the halide also has an effect on the adopted structure, exemplified by the series Pr_3PHgX_2 (X = Cl, Br, I) in which the chloride and bromide are halogen-bridged dimers with increasing asymmetry in the HgX_2Hg bridge, whereas the β-iodide has a polymeric loosely linked trigonal-planar arrangement [13] (the α-iodide is unique in having both phosphines coordinated to the same mercury atom in a dimeric arrangement [11]). These variations stem from the increased donor capacity from chloride to iodide towards mercury, resulting in a weakening association from chloride to iodide.

Both tris(2,4,6-trimethoxyphenyl)phosphine (TMPP) and tris(2,6-dimethoxyphenyl)phosphine (DMPP) are sterically demanding ligands (cone angle 184° [14]) and have very high basicities ($pK_a = 11.02$ and 9.33, respectively [15]) and are therefore likely to result in the formation of complexes with low coordination numbers [14,16]. Transition-metal chemistry of TMPP has been studied extensively by Dunbar and co-workers and the phosphine has been shown to behave as a mono-, di- and tri-dentate ligand [17]. Tertiary phosphines con-

taining 2,6-dimethoxyphenyl groups, including DMPP, have also been the subject of study, forming transition-metal complexes with a variety of modes of coordination of the ligand [18]. However, interest in these types of extremely bulky ligands with non-transition metals has been very limited. Bowmaker and co-workers [19] have formed only complexes of unusual stoichiometry (e.g. of empirical formula $TMPPHg_2X_4$ and $(TMPP)_2Hg_3X_6$) with TMPP and suspensions of HgX_2 in acetonitrile and our studies with this ligand and the Group 12 metal halides will be reported elsewhere. Herein we report the formation and structures of a series of 1:1 complexes of HgX_2 (X = Cl, Br, I) with DMPP.

2. Experimental

DMPP was prepared using the Aldrich as supplied reagents, 1,3-dimethoxybenzene, butyllithium and triphenylphosphite, by the previously described method [14]. Melting points were obtained using an electrothermal melting point apparatus and are uncorrected. ^{31}P-$\{^1H\}$ NMR spectra were recorded as solutions in acetone and acetonitrile using a Bruker AC250 spectrometer with 85% H_3PO_4 as external reference. Far IR spectra were recorded with background subtraction using a Magna-IR750 Nicolet spectrometer from 600–50 cm^{-1}, to a resolution of 2 cm^{-1} on samples dispersed in a paraffin wax disk. Raman spectra were obtained from a Renishaw Ramascope 1000 Raman Microscope using a 780 nm near IR laser. All spectra were recorded using a 200 exposure 'extended' scan between 3400 and 300 cm^{-1} and a 0.5 s static scan down to 50 cm^{-1}. Elemental analyses were carried out by the Sheffield University Centre for Chemical Instrumental Analytical Services.

2.1. Preparations

2.1.1. Tris(2,6-dimethoxyphenylphosphine)-dichloromercury(II) (1)

To a solution of mercury(II) chloride (0.270 g, 1.0 mmol), dissolved in warm ethanol (30 cm^3), was added DMPP (0.442 g, 1.0 mmol) also dissolved in warm ethanol (25 cm^3) with stirring. The white precipitate which formed immediately was filtered off under suction and dried in vacuo, yielding a white powder; m.p. 273–275°C (Found: C, 40.21; H, 3.80. $C_{24}H_{27}O_6PHgCl_2$ requires C, 40.37; H, 3.81%) ^{31}P-$\{^1H\}$ NMR (MeCN solution) δ −31.19 (s).

2.1.2. Tris(2,6-dimethoxyphenylphosphine)-dibromomercury(II) (2)

DMPP (0.442 g, 1.0 mmol), dissolved in warm ethanol (25 cm^3), was added to a warm ethanolic solution (30 cm^3) of mercury(II) bromide (0.360 g, 1.0 mmol). The immediate white precipitate was filtered off under suction and dried in vacuo, yielding a white powder; m.p. 265–268°C (Found: C, 35.15; H, 3.35. $C_{24}H_{27}O_6PHgBr_2$ requires C, 35.89; H, 3.36%) ^{31}P-$\{^1H\}$ NMR (MeCN solution) δ −27.88(s).

2.1.3. Tris(2,6-dimethoxyphenylphosphine)-diiodomercury(II) (3)

A warm ethanolic solution (25 cm^3) of DMPP (0.442 g, 1.0 mmol) was added to a similar solution (30 cm^3) of mercury(II) iodide. A slight cream precipitate was formed, which increased as the solution was steadily evaporated down to 30 cm^3. Filtration under suction yielded very pale cream crystals which were dried in vacuo; m.p. 194–197°C (Found: C, 32.15; H, 3.03. $C_{24}H_{27}O_6PHgI_2$ requires C, 32.13; H, 3.01%) ^{31}P-$\{^1H\}$ NMR (MeCN solution) δ −26.31(s).

2.2. X-ray crystallography

Crystals suitable for X-ray analysis were grown by slow evaporation of ethanolic solutions of the complexes, mounted on glass fibres and intensity data was collected. A summary of crystal data, data collection strategy and model refinement parameters are given in Table 1.

The structures were solved via direct methods and then subjected to full-matrix least-squares refinement on F_o^2 using the SHELXL-97 [20] suite of programs. For all structures non-hydrogen atoms were made anisotropic, with hydrogens in calculated positions (C–H = 0.96 Å, with U_{iso} tied to U_{eq} of the parent atoms). Absorption corrections were applied using the RefDelf approach of DIFABS [21] for $DMPPHgCl_2$ and the semi-empirical comparison of multiple and symmetry equivalent reflections employed in SORTAV [22] for $DMPPHgBr_2$ and $DMPPHgI_2$. Large residual electron density is observed as satellite peaks around mercury in all three structures. These are commonly attributed to the inability to correctly account for the large absorption effects of heavy metal centres.

3. Results and discussion

Reaction of mercury(II) halides in ethanol solution with DMPP, also dissolved in ethanol, in a 1:1 mole ratio resulted in the formation of solid deposits of complexes having 1:1 stoichiometry. The addition of a solution of 1 mol of the mercury(II) halides to 2 mol of the phosphine also resulted in the formation of the 1:1 complexes: clearly the bulk of the phosphine precludes the formation of the 2:1 complexes, which are readily formed with triphenylphosphine [1] ($pK_a = 2.73$ [23]) and several other tertiary phosphines [2–6].

Colourless crystals of all three complexes, suitable for X-ray analysis, were grown by slow evaporation from ethanolic solutions. In the only other complete series of 1:1 tertiary phosphine–mercury(II) halides structurally characterised, the tripropylphosphine series [13], the structures vary from a slightly asymmetrically bridged dimer for the chloride, through a much more asymmetric bromide, to a weakly linked polymeric arrangement for the iodide reflecting the stronger donor ability $I^- > Br^- > Cl^-$ to mercury. In marked contrast the structures of the DMPP complexes are overwhelmingly dominated by the steric bulk of the phosphine ligand with the Hg–P bond length increasing along the series chloride to iodide (Table 2), all being longer than in the corresponding Pr_3P [13] and Ph_3P [7,12] complexes due to the buttressing effect of the *ortho* methoxy groups. The chloride (Fig. 1) is a very weakly linked centrosymmetric dimer with a much greater degree of asymmetry in the bridging region (Hg–Cl_{br}; 2.475(3), 2.902(4) Å cf. Hg–Cl_{term}, 2.514(4) Å) than in the corresponding Ph_3P [7] (2.623(8), 2.658(8) Å) or Pr_3P [13] complexes (2.638(4), 2.780(4) Å) and with the angles P–Hg–Cl_{term} (113.11(12)°) and P–Hg–Cl_{br} (105.78(11)°) to the longer bridging bond being much smaller than the angle between phosphorus and the shorter bridging chloride (138.95(14)°). The bromide (Fig. 2) shows an even closer similarity in the Hg–Br_{term} (2.6129(6) Å) and the shorter of the two bridging distances (2.6272(6) Å) (c.f. the longer bridging Hg–Br distance of 2.9195(6) Å) and with similar angles to the chloride, indicating that this is an even weaker linked dimeric structure.

The trend is complete with the iodide which shows a completely monomeric structure (Fig. 3), with both Hg–I distances agreeing to within ca. 0.04 Å, the $PHgI_2$ unit being planar and there being no intermolecular Hg···I distances less than 4 Å. This represents the first structurally characterised tertiary phosphine–mercury(II) iodide complex which has a monomeric essentially trigonal-planar arrangement, with angles around mercury varying from 107.95(3) to 132.86(4)°. However, the two PHgI angles are quite different (119.12(4) and 132.86(4)°), which is due to some particularly strong interactions between the central mercury atom and oxygens [O(2), O(4) and O(6)] of the methoxy groups (3.089, 3.268 and 2.672 Å, respectively). These contacts are within the sum of the van der Waals radii for the interacting atoms and may be considered to be bonding, resulting in six-coordinate mercury. The geometry about Hg(1), when considering the interactions with methoxy group oxygens, is very distorted from idealised octahedral geometry (see Table 2).

The dimeric Cl and Br complexes also exhibit weak secondary interaction with the *ortho* methoxy groups at around the sum of the van der Waal's radii [24], as seen

in Table 2. A comparison of the phosphine moiety, with the previously determined structure [25] shows some distortions, due to the interaction of the methoxy groups with the mercury centre.

3.1. Solution ^{31}P NMR spectra

The spectra of all three complexes were recorded as solutions in acetone and acetonitrile solutions, though the solubility was low in both solvents. The spectra all contained a single line due to species which contain the non-magnetic isotope of mercury. The expected satellites due to $^1J(^{199}Hg^{31}P)$ coupling (^{199}Hg 16.84% natural abundance, nuclear spin $I = 1/2$) were not observed in acetone solution due to the weak intensity of the spectra because of the very low solubility of the complexes. The chemical shifts in acetonitrile were slightly larger (Table 3) and also the slightly greater solubility allowed observation of mercury–phosphorus coupling. The $\delta(^{31}P)$ and $^1J(^{199}Hg^{31}P)$ coupling constants are listed in Table 3, together with the results reported by Bowmaker et al. for 1:1 mixtures of HgX_2 and TMPP in MeCN solution for comparison [19]. The signals are clearly halogen-dependent with chemical shifts and coupling constants increasing from iodide to chloride, in accordance with observations elsewhere [26]. These results, together with the non-electrolytic behaviour of the complexes in MeCN solution, clearly show the presence of only one phosphorus-containing species in solution. This is in marked contrast to Bowmaker's work [19] on the very similar TMPP–HgX_2 system in which NMR studies (Table 3) of equimolar mixtures in MeCN solution showed the presence of halogen-dependent parameters assigned to $[TMPPHgX]^+$ and a non-halogen-dependent parameter due to $[(TMPP)_2Hg]^{2+}$, both associated with $[Hg_2X_6]^{2-}$ anions. For the chloride these two species were present in approximately equal amounts, decreasing to $\sim 13\%$ of the latter for the iodide.

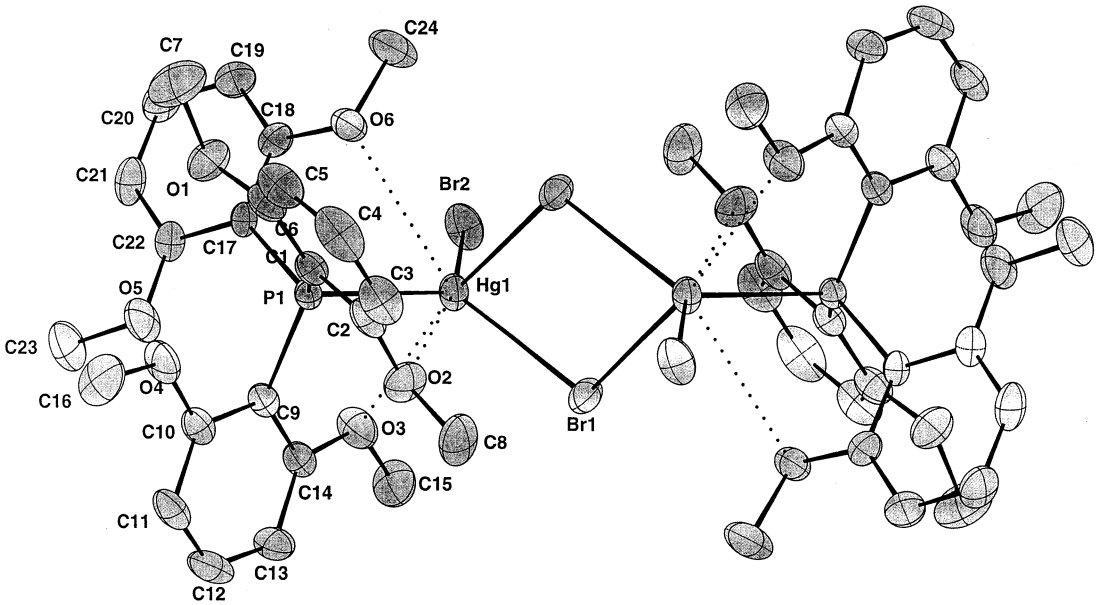

Fig. 2. The molecular structure of $DMPPHgBr_2$ with ellipsoids at 30% probability.

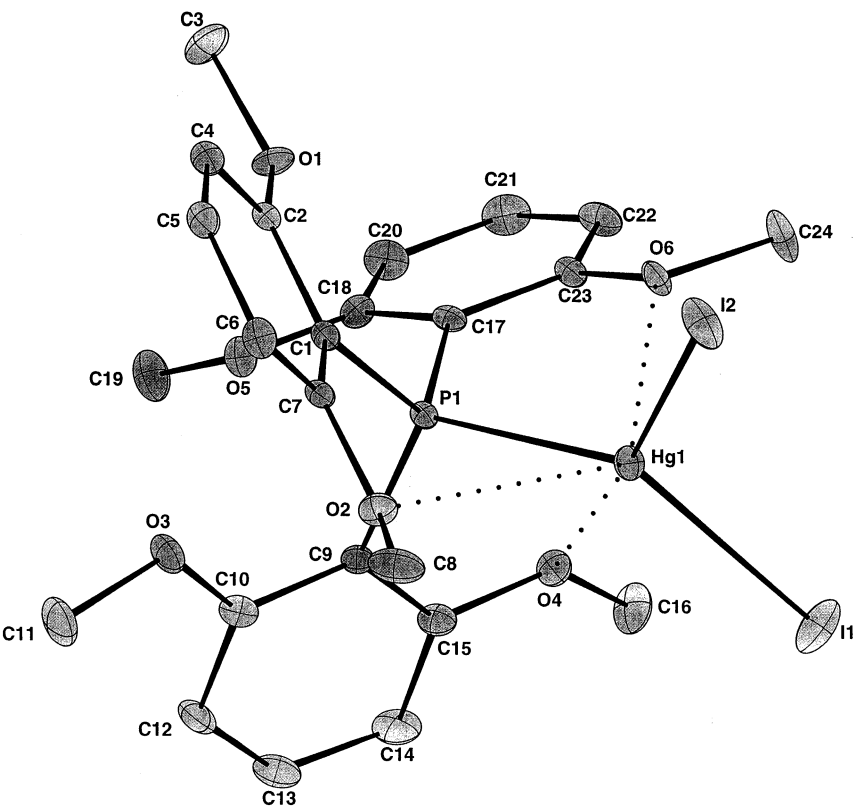

Fig. 3. The molecular structure of $DMPPHgI_2$ with ellipsoids at 30% probability.

3.2. Vibrational spectra

The assignment of vibrational spectral features of a range of R_3PHgX_2 complexes has previously been correlated with their full crystal and molecular structures [26]. The structural variety found for these complexes gives rise to differences in vibration spectra. For example terminal and bridging Hg–Cl stretching frequencies [26] in symmetrical (or near symmetrical) halogen bridged dimers are usually separated by $\sim 120\ cm^{-1}$. The absorptions below $600\ cm^{-1}$ found in the IR and Raman spectra of $DMPPHgX_2$ are listed in Table 4 and

Table 3

[a] Data for $[TMPPHgX]^+$ and $[(TMPP)_2Hg]^{2+}$ shown for comparison [19].

the Raman spectra are shown in Fig. 4. There are several bands common to all three spectra which must be due to skeletal vibrations of the phosphine ligand, but the halogen-dependent bands can readily be identified. In the spectra of the chloride the closeness of the two νHg–Cl vibrations at 250(vs) and its shoulder at 230 cm^{-1} (Raman) may be ascribed to the weak nature of chloride bridging in the complex.

For the bromide a similar picture emerges with peaks which are clearly associated with νHg–Br vibrations occurring at 161(vs) cm^{-1} and a strong shoulder at 142 cm^{-1}, again illustrating the weak association of the dimer as confirmed by the crystallographic data. The monomeric nature of the iodide results in two much sharper, very strong absorption bands at 148 and 118 cm^{-1}, which may be ascribed to the νHg–I symmetric and asymmetric stretching vibrations, respectively. Terminal Hg–I vibrations have been assigned [27] at ~ 150/135 cm^{-1} in $[Hg_2I_6]^{2-}$ and 160/154 cm^{-1} in $[HgI_3]^-$.

4. Conclusions

The bulky nature of DMPP precludes the formation of the well known 2:1 tertiary phosphine–mercury(II) halide complexes and only 1:1 complexes have been isolated. This is in marked contrast to the structurally similar TMPP system where only ionic complexes of somewhat unusual stoichiometry ($L_2Hg_2X_8$ and $L_2Hg_3X_6$) have been isolated [19]. X-ray structures of $DMPPHgX_2$ (X = Cl, Br, I) display a trend from weakly linked dimers for the chloride and bromide, while the iodide is unique in being the first example of a monomeric tertiary phosphine–mercury(II) iodide complex, having a distorted trigonal-planar arrangement around mercury. ^{31}P NMR and conductance studies show the presence of only one non-ionic species in solution and vibrational spectral data are consistent with the structural results.

5. Supplementary material

Full details of atomic coordinates, bond lengths and angles and thermal parameters have been deposited as supplementary material; CCDC reference numbers, CCDC 133199–133201. Supplementary data are available on request from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The stability constants and coordination modes of the mixed-ligand complexes formed by Cu(II), Ni(II), Zn(II), ethylenediamine (en), 2,2′-bipyridine (bpy), glycinate (Gly), disodium salt of 4,5-dihydroxybenzene 1,3-disulfonate (Tiron), diethylenetriamine (dien) or 2,2′:6,2″-terpyridine (terpy) (= ligand B) and acetohydroxamate (Aha), *N*-methylacetohydroxamate (MeAha) or *N*-phenylacetohydroxamate (PhAha) (= ligand A) were determined in water (25°C, $I = 0.2$ M KCl) by pH-metric, spectrophotometric, EPR and calorimetric methods. Mixed-ligand complexes with typical hydroxamate type chelation mode involving the NHO^- moiety are formed in all systems. However, further copper(II) induced deprotonation of the NHO^- moiety of Aha in the presence of en or bpy results in the formation of mixed-ligand complexes with hydroximato chelates at high pH. The results show the favoured coordination of a hydroxamate to metal(II)–en and especially to a metal(II)–bpy moiety. If ligand B is Gly, the increase of stability of the mixed-ligand complexes is as expected on statistical basis, whereas the formation of complexes involving O,O-coordinated hydroxamate and O,O-coordinated Tiron is unfavoured. The tridentate coordination of dien or terpy results in five-coordinated mixed-ligand copper(II) complexes in which, most probably, the hydroxamate moiety adopts an equatorial–axial coordination mode. This quite unstable hydroxamate chelate can not hinder the hydrolysis of the complex above pH 8. Under very basic conditions acetohydroximato moieties ($-CONO^{2-}$) displace the rigid terpy ligand from the coordination sphere and complexes, $[Cu(AhaH_{-1})_2]^{2-}$ involving hydroximato chelates are formed. © 2000 Elsevier Science Ltd. Keywords: Mixed-ligand complexes; Solution equilibrium; Hydroxamic acid; Copper(II), nickel(II) and zinc(II) complexes

1. Introduction

Hydroxamate molecules, one of the major classes of naturally occurring metal complexing agents, have been thoroughly studied as ligands. Numerous papers showed that monohydroxamic acids adopt a typical binding mode. As disclosed first by an X-ray diffraction study of the benzohydroxamate complex of iron(III), the chelation involves the oxygens belonging to carbonyl and NHOH groups [1]. Complexes of simple hydroxamic acids have been studied both in solution and in solid state [2–9]. First of all Fe(III) but also some other metal ions, e.g. Co(II), Co(III), Ni(II), Zn(II), Cu(II) and V(IV) were involved in studies. The relevancy of the results to siderophore-mediated iron uptake by microorganisms was discussed in reviews [10,11].

Scheme 1.

Investigations on the complex formation with simple primary hydroxamic ligands in aqueous solution demonstrated clearly that, depending on pH, two (O,O) bonding modes of the ligands are accessible to metal ions like Cu(II) and VO(IV) [8,9]. The hydroxamato(1 −) type mode arises from the first deprotonation step and involves the coordination of the NHO^- moi-

ety (**I**, see Scheme 1). The hydroximato(2 −) form of the ligand is produced by further metal-induced deprotonation of NHO^- (**II**).

The coordination of the nitrogen atom of hydroxamic moiety was never found in metal complexes formed by simple hydroxamic acids even if this nitrogen atom can be converted into very effective binding site in aminohydroxamates, as demonstrated by studies on aminohydroxamates both in solution and in the solid state [12].

In contrast with binary systems of hydroxamic acids or aminohydroxamic acids, their ternary systems have been studied only in a few cases [12–15]. Nevertheless, mixed ligand complexes are better models for understanding the reactivity of hydroxamic acids in biological systems (e.g. inhibition of metalloenzymes). We have performed a systematic study in solution aimed at establishing the coordination modes of hydroxamic acids and the stability of the resulting chelates in the presence of additional ligands. The ternary systems examined involve metal(II), hydroxamate (ligand A) and an additional ligand (ligand B) like ethylenediamine (en), 2,2′-bipyridine (bpy), glycinate (Gly), the disodium salt of 4,5-dihydroxybenzene 1,3-disulfonate (Tiron), diethylenetriamine (dien), or 2,2′:6,2″-terpyridine (terpy).

2. Experimental

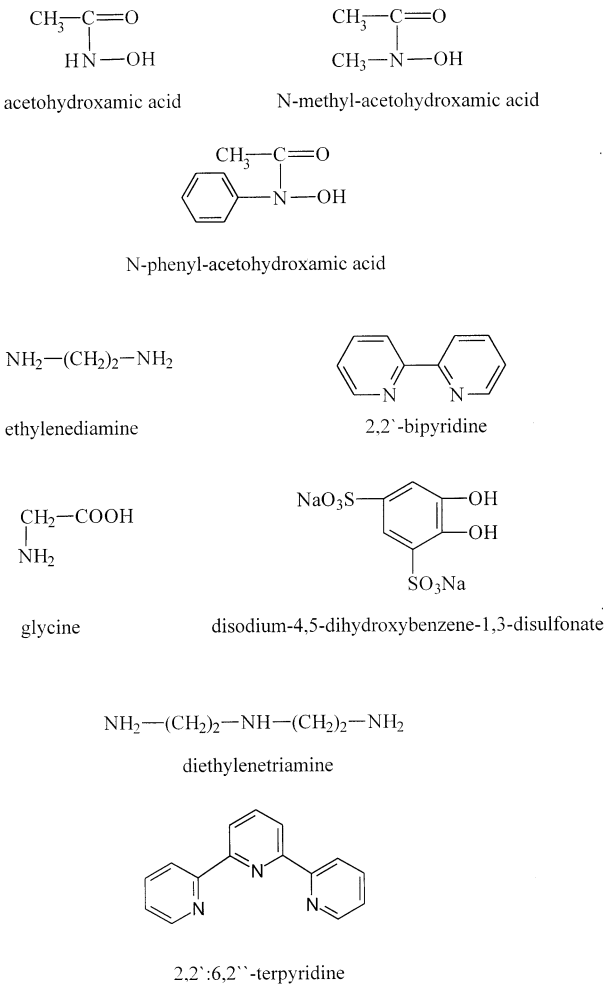
2.1. Chemicals

Acetohydroxamic acid (Aha), en, bpy, Gly, Tiron, dien, and terpy were pure commercially available chemicals (Sigma, Reanal, Aldrich and Fluka). *N*-Methylacetohydroxamic (MeAha) and *N*-phenylacetohydroxamic (PhAha) acids were prepared by standard procedures from the corresponding carboxylic esters and hydroxylamine [16]. Freshly distilled en and dien were dissolved in known amounts of HCl solutions. The purity of the ligands and the concentration of the ligand stock solutions were determined by Gran's method [17]. The metal ion stock solutions were prepared from $CuCl_2{\cdot}2H_2O$, $NiCl_2{\cdot}5H_2O$ (Reanal). ZnO (Reanal) was dissolved in a known amount of HCl solution. The concentrations of the copper(II), nickel(II) and zinc(II) stock solutions were determined gravimetrically via the precipitation of quinolin-8-olates.

2.2. Potentiometric, spectrophotometric, calorimetric and EPR studies

All the measurements were carried out at 0.2 M ionic strength (KCl) and 25°C. Carbonate-free KOH solution of known concentration (ca. 0.2 M) was used as titrant. The binary systems were studied previously [8,18–22], however most of the constants were redetermined in the present work. The pH-metric titrations were performed over the pH range 2.0–10.5, or below precipitation, on 10.00 cm^3 samples. The ligand concentration varied in the range 2×10^{-3}–8×10^{-3} M. In the binary systems, the metal–ligand ratios were, generally, in the range 1:1–1:8, and samples at four or five different ratios were measured. The metal:ligand A:ligand B ratios were 1:1:1, 1:2:1, 1:1:2 and 1:2:2. The pH-metric titrations were made with a Radiometer pHM84 instrument equipped with a Metrohm 6.0234.100 combined electrode. The titrant was added from a Metrohm 715 Dosimat autoburette. The electrode system was calibrated by the method of Irving et al. [23] so that the pH-meter readings could be converted into hydrogen ion concentration. A pK_w value of 13.756 was determined in the present work. The pH-metric results were used to establish the stoichiometry of the species and to calculate the stability constants. Calculations were performed with the program PSEQUAD [24]. In the pH regions where the experimental findings indicated hydrolysis (a continuous decrease in the pH or the formation of a precipitate) calculations were not performed. The volume of the titrant was fitted and the accepted fittings were below 1×10^{-2} cm^3.

UV–Visible measurements were carried out on systems containing copper(II) and nickel(II). The metal ion to ligand ratios were 1:1, 1:2 and 1:5 for the binary systems and the metal:ligand A:ligand B ratios were 1:1:1 and 1:2:1 for the ternary systems. Titrations were made on samples containing the metal(II) ion at $3–5 \times 10^{-3}$ M. A HP 8453 spectrophotometer was used to record the spectra in the region of 300–800 nm.



Calorimetric measurements were performed to determine the enthalpy changes of the reaction of the [CuB] complex (B = bpy, dien or terpy) with Aha and KOH using an LKB 8700 solution calorimeter. Samples of the [CuB] species (25 cm^3, $c = 3.0 \times 10^{-3}$ M, pH 10) were reacted with ampoules containing a known amount of Aha or KOH.

EPR spectra were recorded on a Varian E9 spectrometer at the X-band frequency (9.15 GHz) at 120 K. Ethylene glycol was added to aqueous samples to ensure glass formation.

3. Results and discussion

3.1. Solution equilibria

Among the hydroxamic acids (ligand A), the primary derivative Aha was studied with copper(II), nickel(II) and zinc(II), whereas the secondary ones, MeAha and PhAha were studied only with copper(II). The type of donor atom (nitrogen donors, oxygen donors or mixed,

Scheme 2.

in alyphatic or in aromatic compounds) and number of donor atoms (two or three) were varied in ligands B. The formulae of the neutral ligands are shown in Scheme 2.

3.1.1. Binary systems

The copper(II), nickel(II) and zinc(II) complexes of the hydroxamic ligands were already studied in previous works of ours and most of the systems containing copper(II) were characterised by EPR, too [8,18]. Stability constants for the metal ion–ligand B complexes were determined in former works [19–22], but those for the copper(II)–dien, copper(II)–terpy, nickel(II)–Tiron and zinc(II)–Tiron complexes were redetermined in the present work. Owing to oxidation reactions involving the ligand, the copper(II)–Tiron system could not be investigated. On the other hand, as the formation of $[Cu(terpy)]^{2+}$ occurs below the measurable pH range, overall stability constant was not obtained for this species. Instead, the equilibrium process

$$[Cu(terpy)]^{2+} + H_2O \rightleftharpoons [Cu(terpy)(OH)]^{+} + H^{+} \quad (1)$$

what takes place in a measurable pH range (ca. 7–10) was characterised. The equilibrium models and corresponding stability constants ($\log \beta$) are summarised in Table 1. EPR and electron absorption parameters for copper(II) simple complexes are shown in Table 2 (Cu(II)–Aha hydroximate species which formed beyond the capability of glass electrode potentiometry were detected only by EPR).

The main conclusions drawn for the coordination modes of hydroxamic ligands in the binary systems are as follows: exclusively hydroxamate-type (O,O) coordination (the ligand chelates the metal ion via the monoanionic form R–CO–NR′–O$^-$) exists in all the nickel(II)– and zinc(II)–hydroxamate complexes as well as in copper(II)–MeAha (R′ = Me) and –PhAha (R′ = Ph) complexes [18]. Hydroximate-type chelated complexes arising from a further deprotonation process of the hydroxamic moiety (the dianionic form R–CO–N–O^{2-} is involved) exist only in the copper(II)–Aha (R′ = H) system at high pH [8]. The hydroximate chelation is significantly more stable than the hydroxamate one and is clearly indicated by EPR spectra. The decrease of $g_{\|}$ and increase of $A_{\|}$ parameters of EPR spectra, in comparison to the hydroxamate species (see Table 2), substantiate a significant strengthening of the in plane bonds in the copper(II) coordination sphere.

3.1.2. Ternary systems

The stability constants for mixed-ligand complexes giving the best fit of the pH-metric titration curves are listed in Table 3.

Table 3 lists the logarithmic overall constants expressed by the equation

$$pM + qA + rB + sH \rightleftharpoons M_pA_qB_rH_s \quad (2)$$

except for mixed-ligand complexes containing terpy, for which data related to the equilibrium

$$MB + A \rightleftharpoons MAB \quad (3)$$

have been determined. As Table 3 shows, mixed-ligand complexes with stoichiometry [MAB] are formed in all systems. In addition, $[MABH_{-1}]$ species exist in metal(II)–Aha–bpy/en systems, and also $[MA_2B]$ and/or $[MAB_2]$ complexes exist in some nickel(II) and zinc(II) containing systems.

The relative stability of the mixed-ligand complexes, as compared with the corresponding binary species, could be evaluated in different ways. In most cases the relative stability of [MAB] is expressed in terms of $\Delta\log K_{MAB}$, the logarithmic stability constant for the equilibrium

$$MA + MB \rightleftharpoons MAB + M \quad (4)$$

The equilibrium constant for Eq. (4) can be calculated from the experimentally measured stability constants according to equation:

[a] Standard deviations are shown in parenthesis for the complexes determined in the present work.
[b] Log K values related to the following process: MB + A $\rightleftharpoons$ MAB.

$$\Delta\log K_{MAB} = \log \beta_{MAB} - (\log \beta_{MA} + \log \beta_{MB}) \quad (5)$$

The differences between $\Delta\log K_{MAB}$ data calculated by Eq. (5) and its statistical values are evaluated. If bidentate ligands are coordinated to the metal ion, depending on the geometry of the complex, the following statistical values can be calculated for $\Delta\log K_{MAB}$: -0.4 for complexes with nearly octahedral geometry, e.g. nickel(II) and zinc(II) complexes, and -0.9 for distorted copper(II) complexes [25]. $\Delta\log K_{MAB}$ values calculated by Eq. (5) are listed in Table 4.

The results in Table 4 substantiate that the formation of mixed-ligand complexes with N-donor bidentate ligands B is favoured ($\Delta\log K_{MAB}$ values are higher than statistical). It is true especially with the aromatic bpy. Formation of mixed-ligand complexes involving hydroxamate and an other O-donor ligand B like Tiron is unfavoured ($\Delta\log K_{MAB}$ values are significantly lower than statistical).

The relative stability of the mixed-ligand complexes with compositions [MA$_2$B] and [MAB$_2$], could be also evaluated in different ways, e.g. it is possible to calculate the stability constants expected on a statistical basis [26] through the equations:

$$\log \beta^{stat}_{MA_2B} = 2/3\log \beta_{MA_3} + 1/3\log \beta_{MB_3} + \log 3 \quad (6)$$

$$\log \beta^{stat}_{MAB_2} = 2/3\log \beta_{MB_3} + 1/3\log \beta_{MA_3} + \log 3 \quad (7)$$

The values of $\log \beta^{stat}_{MA_2B}$ (15.28 for [Ni(Aha)$_2$(en)] and 16.07 for [Ni(Aha)$_2$(bpy)]) and $\log \beta^{stat}_{MAB_2}$ (16.77 for [Ni(Aha)(en)$_2$]$^+$ and 14.10 for [Ni(Aha)(Gly)$_2$]$^-$) are calculated by use of the corresponding constants listed in Table 1. From a comparison of these data with the experimentally measured constants ($\log \beta^{meas}$) in Table 3 we conclude that the formation of [Ni(Aha)(Gly)$_2$]$^-$ is as expected on the statistical basis, but the formation of en and bpy containing mixed-ligand species is much more favoured. Similar calculations for the zinc(II) containing species lead to the same conclusion. Concentration distribution curves for zinc(II)–Aha–bpy (a) and zinc(II)–Aha–Tiron (b) are shown in Fig. 1.

Fig. 1 clearly indicates that mixed-ligand species dominate in zinc(II)–Aha–bpy above pH 7, whereas no significant mixed-ligand complex formation occurs in the zinc(II)–Aha–Tiron system. These results are in agreement with the general finding that the formation

$[Cu(Gly)]^{+} + MeAha$	6.29		

of mixed-ligand complexes is favoured with ligands having different types of donor atom [27].

The situation is somewhat different when the coordinating ligand B is tridentate, terpy or dien. $\Delta\log K_{MAB}$ values were not calculated in these cases (equilibrium constant for Cu + terpy $[Cu(terpy)]^{2+}$ is not available which prevents the calculation of $\Delta\log K_{MAB}$ for the copper(II)–hydroxamate–terpy complexes); however, a comparison of the stepwise stability constants of the mixed-ligand species (see Table 5) shows much lower constants for the complexes involving dien or terpy than for the species containing en, bpy or Gly. There are significant differences in the calorimetric results, too. Namely, the ΔH value is -19.4 kJ mol^{-1} for the process $[Cu(bpy)]^{2+}$ + Aha and those of $[Cu(terpy)]^{2+}$ + Aha and $[Cu(dien)]^{2+}$ + Aha are $+2.8$ and -0.2 kJ mol^{-1}, respectively. The corresponding ΔS values, in turn, are 87, 90 and 68 J mol^{-1} K^{-1}.

In order to interpret the above results one must take into account that tridentate terpy and dien ligands occupy three equatorial positions of copper(II) in their [CuB] complexes. It means that only one position remains available for the coordination of a second ligand in the plane. Possible modes of coordination of a hydroxamate ligand in the mixed-ligand complexes are: (i) monodentate coordination at the fourth equatorial position; (ii) formation of a (O,O) chelate in the plane by the replacement of one of the three N atoms of dien/terpy; (iii) formation of a (O,O) chelate through equatorial–axial binding mode. Thermodynamic results do not allow us to differentiate the above three possibilities. It is known, however, that the axial coordination in copper(II) complexes results in a red shift of the electron absorption maximum λ_{max} [28]. The pH dependence of λ_{max} in the visible spectra collected on all copper(II)–terpy/dien–hydroxamate systems indicates a significant red shift in the pH region corresponding to the formation of species CuAB. This is clearly demonstrated in Fig. 2 which shows the pH–λ_{max} plot together with the species distribution curves for the copper(II)–Aha–dien. The value of λ_{max} increases from 615 (at pH ca. 7) to 685 nm (at pH 8.8), but starts to decrease above pH 9. Consequently, the red shift which parallels the formation of $[Cu(Aha)(dien)]^{+}$ supports a significant axial interaction in copper(II)–terpy/dien–hydroxamate mixed-ligand complexes.

$[MABH_{-1}]$ is detected only with the Aha ligand in which hydrogen is the R_N substituent, but it is not formed in measurable concentration with MeAha and PhAha secondary derivatives. As an illustration of the different behaviour of the complexes formed by primary and secondary hydroxamates, Fig. 3 shows the electron absorption spectra obtained as a function of pH for copper(II)–Aha–en (a) and copper(II)–MeAha–en (b) systems.

In nickel(II)– and zinc(II)–Aha systems, the species $[MABH_{-1}]$ is formed just before the precipitation so that it can be considered a mixed hydroxo species, denotated better as [MAB(OH)]. Instead, the complex remains in solution and is a dominant species in copper(II)–Aha–en/bpy systems. Parallel with its formation, a significant blue shift in the λ_{max} values is observed (see Fig. 3(a)) which supports the strengthening of the equatorial bonds in the chelated species. A comparison of the above findings with the results for the corresponding binary systems supports that the coordinated hydroxamate moiety of Aha looses a proton in the $[CuAB]^{+} \rightleftharpoons [CuABH_{-1}] + H^{+}$ process resulting in the formation of very stable copper(II)–hydroximato–en/bpy complexes.

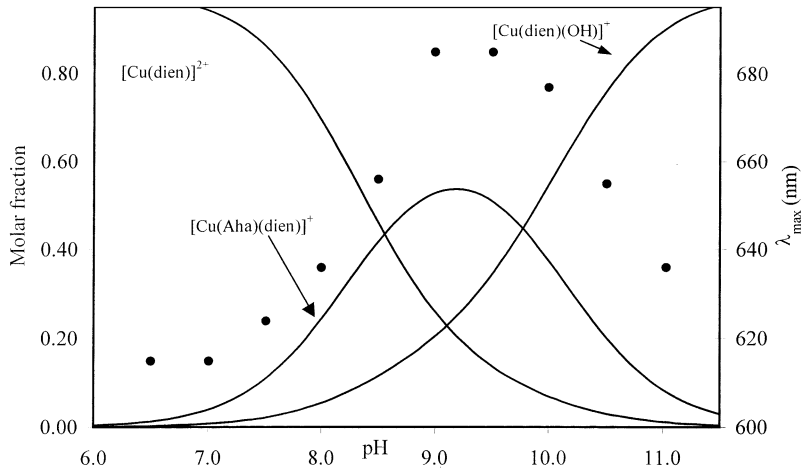

Fig. 2. Concentration distribution curves for copper(II)–Aha–dien mixed-ligand complexes are plotted together with the λ_{max} values in dependence of pH (●) ($c_{Cu(II)} = c_{terpy} = 3 \times 10^{-3}$ M, $c_{Aha} = 6 \times 10^{-3}$ M).

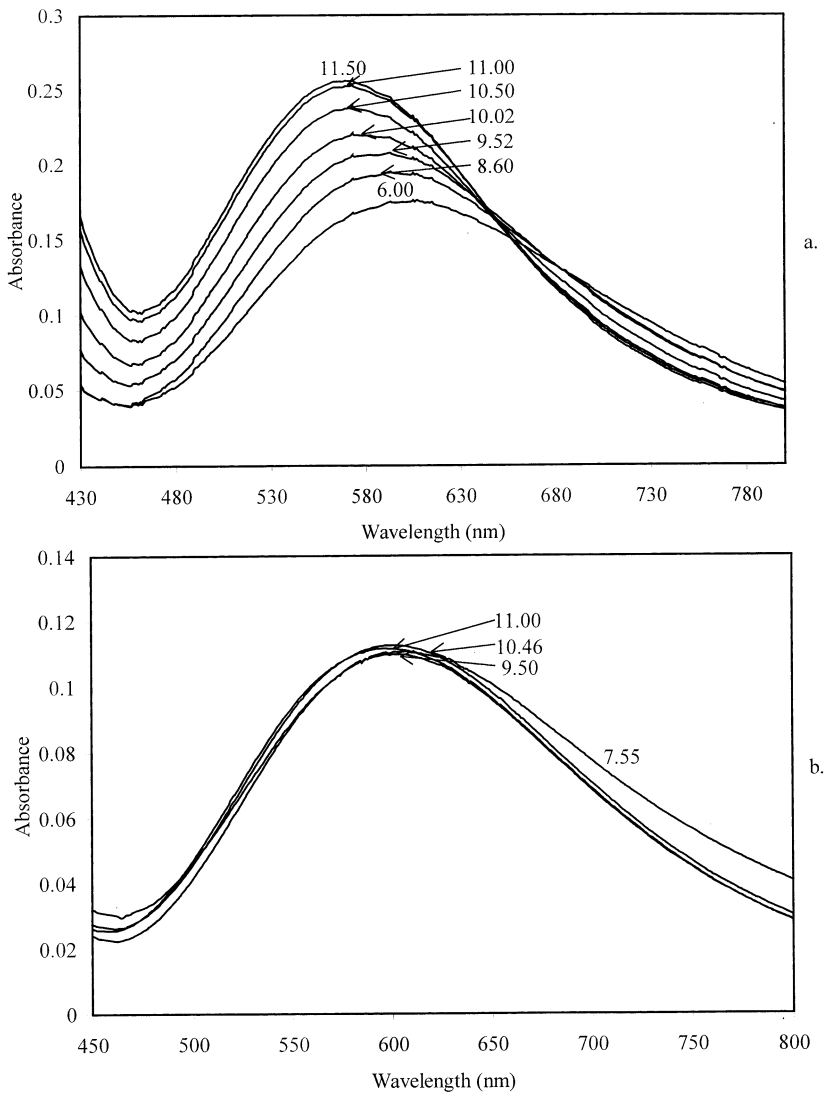

Fig. 3. UV–Vis spectra for copper(II)–Aha–en (a) and copper(II)–MeAha–en (b) at different pH values in the range 430–800 nm ($c_{Cu(II)} = 5 \times 10^{-3}$ M, $c_{Aha} = c_{en} = c_{MAha} = 5 \times 10^{-3}$ M).

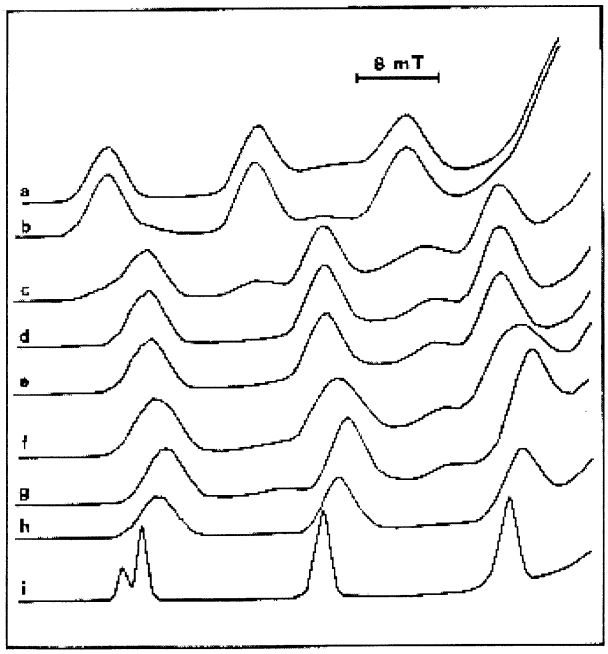

Fig. 4. Parallel region of frozen-solution EPR spectra recorded on copper(II)–Aha–bpy system at the 1:2:1 molar ratio ($c_{Cu(II)} = 5 \times 10^{-3}$ M) at different pH values: (a) 2.55, (b) 3.60, (c) 4.60, (d) 6.50, (e) 9.50, (f) 10.45, (g) 11.25 and (h) 12.48. Spectrum (i) belongs to $[Cu(OH)_4)]^{2-}$. Main species: (a,b) $[CuB]^{2+}$, (c–f) $[CuAB]^{+}$, (g) $[CuABH_{-1}]$ and (h) $[CuBH_{-2}]$.

3.2. EPR results

In order to get more complete information about the bonding modes in mixed ligand complexes formed in the copper(II)–Aha/MeAha–bpy/terpy/dien systems, EPR measurements were also performed and spectra were recorded at different pH values. Selected spectra for the Cu(II)–Aha–bpy system at the 1:2:1 molar ratio are shown in Fig. 4.

The measured $g_{\|}$ and $A_{\|}$ parameters and the proposed bonding modes in the various complexes are listed in Table 6.

The conclusions that can be drawn from the EPR results are substantially in agreement with those derived from equilibrium studies, but interesting new information has been got also in some cases. Details for the individual systems are described below.

3.2.1. Copper(II)–Aha/MeAha–bpy systems

Following the formation of the monochelated copper(II)–bpy complex, a new species starts to form at pH ca. 4.5 in copper(II)–Aha–bpy (see Fig. 4) and at pH lower than 3 in copper(II)–MeAha–bpy. This species, $[CuAB]^{+}$, predominates until pH 10.5 in the latter system and only the hydrolysis of this species can be found at higher pH. The donor atoms in the equatorial plane are the same in the $[Cu(Aha)(bpy)]^{+}$ and $[Cu(MeAha)(bpy)]^{+}$ species, as indicated by their similar spectral values. A further complex $[CuABH_{-1}]$ is formed in the copper(II)–Aha–bpy system at pH ca. 10. For this species, $g_{\|}$ is lower and $A_{\|}$ higher (see Table 5), supporting the presence of a stronger in-plane field than in the preceding complex $[CuAB]^{+}$. Therefore, the spectral changes could be assumed as the distinctive features for the second proton dissociation from the hydroxamic group of Aha and the formation of a hydroximato-type chelate in the species $[CuABH_{-1}]$. All the above findings are in complete agreement with equilibrium studies.

In both ternary systems involving MeAha and Aha EPR spectra show the signals due to a dimeric species present as a minor component in solution over the pH range 6–11. The species is distinguished, in the region of the spectrum corresponding to $\Delta M = 1$ resonances, by two peaks centred at 0.295 and 0.338 T attributable to the perpendicular features. A g factor of 2.07 is measured at the middle point between these two resonances and a value of 0.042 cm^{-1} is calculated for the 'zero-field splitting' value, D. A $\Delta M = 2$ transition, without resolved hyperfine structure, is observed in the range 0.150–0.170 T. Similar spectral features were not observed in the binary systems; therefore, it is likely

Table 6
EPR parameters for the Cu(II)–ligand A–ligand B mixed complexes [a]

Ligand A	Ligand B	Species	$g_{\|}$	$A_{\|}$ ($\times 10^{-4}$ cm^{-1})	Donor atoms
Aha	bpy	[MAB]	2.239	192	ha (O,O), 2 (N)
		$[MABH_{-1}]$	2.219	199	hi (O,O), 2 (N)
		$[M_2AB]$			
		$[M_2A_2B_2]$			
MeAha	bpy	[MAB]	2.235	193	ha (O,O), 2 (N)
Aha	dien	[MAB]	2.240	181	ha (O,O), 3 (N)
MeAha	dien	[MAB]	2.241	182	ha (O,O), 3 (N)
Aha	terpy	[MAB]	2.267	158	ha (O,O), 3 (N)
MeAha	terpy	[MAB]	2.266	160	ha (O,O), 3 (N)

[a] ha, hydroxamato; hi, hydroximato.

that the dimer is a mixed-ligand species. As judged from the signal intensity, the concentration of the dimer is quite low and this could be the reason why the species was not detected by solution equilibrium studies and their structure not fully characterised.

The most likely hypothesis is that the dimer is formed by bridging of $[Cu(bpy)]^{2+}$ and $[Cu(Aha)]^{+}$ by two OH^{-} ions. In the copper(II)–bpy binary system the hydrolysis starts at pH 6 with the formation of a dimeric complex $[Cu_2(bpy)_2(OH)_2]^{2+}$. In the presence of hydroxamate it is probable that one of the bpy molecules is replaced by a hydroxamate ligand. Since the species is observed both with Aha and MeAha, the hydroxamate form of the ligands seems involved.

An examination of molecular models shows that the interatomic distance in a $[(bpy)Cu(\mu\text{-}OH)_2Cu(Aha)]^{+}$ complex is of ca. 3 Å. If we assume that the structure is nearly planar, we can apply the Steven's equation [29] (a value of 90° for ϑ, the angle formed by Cu–Cu axis and the direction of the magnetic field is used) to correlate the D parameter to the Cu–Cu distance R in the dimer.

$$R^3 = \frac{0.325 g_{\perp}^2}{D} |1 - 3\cos^2 \vartheta|$$

By use of this equation we calculate a Cu–Cu distance of 3.2 Å.

For the sake of comparison, it must be observed that in $[Cu_2(\mu\text{-}OH)_2(bpy)_2]SO_4 \cdot 5H_2O$, the copper separation is ca. 2.9 Å in the solid state [30–32], while it changes to ca. 3.4 Å in solution [33].

3.2.2. Copper(II)–Aha/MeAha–dien/terpy systems

The dien and terpy ligands chelate the metal ion in the $[CuB]^{2+}$ species by use of three nitrogen atoms. The basicity of their nitrogens is, however, significantly different from each other (see Table 1). As a result, their mixed-ligand complexes are formed in significantly different pH ranges. Namely, the EPR parameters that can be calculated from the spectra recorded in copper(II)–Aha/MeAha–terpy at 1:3:1 molar ratio below pH 7 are consistent with the presence of the $[Cu(terpy)]^{2+}$ complex (see Table 2) and signals characteristic of complexes $[CuAB]^{+}$ are observed above pH 7. Instead, the monochelated $[Cu(hydroxamato)]^{+}$ species predominates in the pH range 4–4.5 if dien is ligand B, and is replaced by $[Cu(dien)]^{2+}$ and, to a smaller extent, by the bis chelated hydroxamato complex $[CuA_2]$ as the pH is raised. Mixed-ligand complexes $[CuAB]^{+}$ are formed above pH 8. The EPR spectra for these complexes are of the tetragonal type and substantiate a five-coordinated metal ion with approximate square pyramidal geometry. As EPR results show (Table 6), the geometry is more distorted with the more sterically rigid terpy ligand. However, to establish which groups are bound in the plane and which are in an axial position is a rather difficult task.

If the pH is increased further, the replacement of hydroxamates by OH^{-} is documented by both pH-metric and spectrophotometric results (see Fig. 2). The EPR results indicate again the significant differences existing at very high pH (above 11) between the behaviour of Aha and MeAha and also between dien and terpy. The formation of the hydroximato bis-chelated complex $[CuA_2H_{-2}]^{2-}$ takes place in the copper(II)–Aha–terpy system, as it is supported by its characteristic EPR parameters ($g_{\|} = 2.217$ and $A_{\|} = 203 \times 10^{-4}$ cm^{-1}) and the hydrolysed species of terpy $[CuBH_{-1}]^{+}$ appears only as a minor species. At pH values higher than 12, the formation of the hydrolysed species of Aha, $[CuAH_{-1}(OH)_2]^{2-}$, is observed. However, in the copper(II)–Aha–dien system the hydrolysed complex of dien is the predominant species. With MeAha $[CuBH_{-1}]$ is formed in both the copper(II)–MeAha–dien and copper(II)–MeAha–terpy systems at high pH.

Abstract

The title compound has been isolated upon the reaction of copper(II) chloride and triaminoguanidine hydrochloride in concentrated HCl. An X-ray study has shown that the crystal structure of this complex is composed of $[Cu(TAGH_2)Cl_3]^+$ cations, Cl^- anions and water molecules. The complex cation involved the coordinated triaminoguanidinium(2 +) cation bonded to the Cu(II) ion via N atoms of the amino group and the C=N moiety as a chelate bidentate ligand. The square-planar environment of the Cu atom is formed by two Cl atoms (2.2769(9) and 2.3002(9) Å) and two N atoms (Cu–N 1.987(2) and 2.043(2) Å). The long Cu–Cl bonds (2.728(1) and 2.941(1) Å) which complement the environment to a distorted square bipyramid allow us to separate the staggered cation chains. μ_{ef} values are 1.83 and 1.86 μB at 78 and 300 K, respectively. © 2000 Elsevier Science Ltd. Keywords: Cu(II) complex; Structure; Triaminoguanidinium(2 +) ion

1. Introduction

The research on the reaction products of guanidine and its amino derivatives (aminoguanidine $NH_2NHC(NH)NH_2$ (AG), diaminoguanidine $NH_2NHC(NH)NHNH_2$ (DAG), and triaminoguanidine $NH_2NHC(NNH_2)NHNH_2$ (TAG) and copper(II) salts is of considerable interest. Information on these is useful, in particular, for the inhibiting properties of guanidines and their amino derivatives for the formation of the nitrogen oxide in the human body [1,2].

The structure and acid–base properties of AG, DAG and TAG motivate their potential participation in complexation as protonated, deprotonated and neutral forms depending on pH. All these potential compounds have been realized for AG, e.g. the prepared complex $Cu(AG)_2(NO_3)_2$ containing the AG molecules [3]. This compound was taken as a copper precursor [4]. The complex $[Co(AGH)_2Cl_4]$ involves the coordinated aminoguanidinium(1 +) cations [5]. The compounds $(AGH_2)_2[CuCl_6]$ and $(AGH_2)_2[CuBr_6]$ have been synthesized containing the isolated $[CuCl_6]^{4-}$ or $[CuBr_6]^{4-}$ anions and counterions — the aminoguanidinium(2 +) cations [6–8]. The first compound possesses reversible low-temperature thermochromism. Finally, the chelate nickel(II) compound with the deprotonated AG form has been prepared [9].

Little data on the DAG and TAG forms which participate in the coordination exist. The complexes $Cu(DAG)(NO_3)_2$, $Cu(DAG)_2(NO_3)_2$, and $Cu(DAG)_2(NO_3)_2 \cdot HNO_3$ have been prepared previously [10]. In the first two compounds, the DAG molecules are coordinated; for the latter complex it has been proposed that both the DAG molecule and the diaminoguanidinium(1 +) cation may be coordinated. This assumption has received further support: the coordinated cation mentioned has been revealed in the crystal structure of $[Cu(DAGH)Cl_3]$[11]. The reaction between the copper(II) nitrate and TAG in aqueous solution at ca. pH 1 resulted in the compound $Cu(TAG)(NO_3)_2$ containing the TAG molecule [10]. Ref. [9] reports on the preparation of unstable chelate nick-

el(II) compounds with the deprotonated DAG and TAG forms. Data on complex compounds containing the protonated coordinated TAG form are not available. This article reports on the synthesis and properties of the compound prepared upon the reaction of the copper(II) chloride and TAG in concentrated HCl. In the structure of this compound the form mentioned has been revealed.

2. Experimental

We used 'p' grade $CuCl_2 \cdot 2H_2O$, triaminoguanidine hydrochloride (TAG·HCl) synthesized by the reaction of AG·HCl and hydrazine hydrate similarly to the preparation procedure for $TAG \cdot HNO_3$ [12]. The Cu content was found by complexonometric titration with Trilon B solution; the C, H, N analysis was performed at the Analytical Laboratory of the Novosibirsk Institute of Organic Chemistry.

The thermal curves were obtained in air on a MOM derivatigraph (heating rate 2.5°C min^{-1}, for a 50 mg sample). IR spectra were recorded on SPECORD 75IR and BOMEN MB-102 spectrophotometers from samples as suspensions in vaseline and fluorinated oils and pellets with polyethylene, respectively. Magnetic susceptibility was measured by the Faraday method over the range 78–300 K.

2.1. Preparation of $[Cu(TAGH_2)Cl_3]Cl \cdot H_2O$

To a solution of 0.35 g (0.0025 mol) of TAG·HCl in 5 ml of water was added 10 ml of concentrated HCl and then a solution of 0.43 g (0.0025 mol) of $CuCl_2 \cdot 2H_2O$ in 10 ml of concentrated HCl. The solution were mixed, and the light-green precipitate was filtered off with suction, washed with a cool mixture of 5 ml of H_2O and 20 ml of concentrated HCl, dried and held in an desiccator over $Mg(ClO_4)_2$. Yield 0.7 g (90%). Found: C, 3.6; H, 3.6; Cu, 19.1; N 25.5. Calc. for $CH_{12}Cl_4CuN_6O$: C, 3.7; H, 3.6; Cu, 19.3; N, 25.5%. IR spectrum (ν, cm^{-1}): 3490, 3240, 3160, ~3000(br), 1660, 1645, 1600, 1570, 1500, 1420, 1230, 1180, 1150, 1120, 1100, 1070, 880, 675, 645, 570, 460, 313, 307(sh), 288, 210.

2.2. Crystal structure determination

X-ray quality crystals were selected from sets of materials obtained from solutions containing smaller concentrations of initial reagents by slow crystallization. The identity of solid phases obtained by different methods was checked by X-ray phase analysis. The orthorhombic unit cell parameters are $a = 10.070(2)$, $b = 11.603(2)$, $c = 18.390(4)$ Å, $V = 2148.7(7)$ $Å^3$, space group $Pbca$, $Z = 8$, $D_{calc} = 2.037$ g cm^{-3}, $\mu = 3.001$ mm^{-1}. The set of reflections from a single crystal ($0.04 \times 0.07 \times 0.52$ mm, color light-green) was obtained on a CAD-4 automatic diffractometer (λ Mo Kα, graphite monochromator, the 1–25° θ range, 2177 collected I_{hkl}, absorption was accounted for by transmission curves) using the standard technique. The structure was solved by direct methods and refined by the full-matrix least-squares method in an anisotropic approximation for all non-hydrogen atoms and isotropically for H atoms with positions located on a difference electron density map. The final R indices are $R_1 = 0.0310$, $wR_2 = 0.0589$ for 1322 non-zero unique I_{hkl} (167 parameters) with $I > 2\sigma(I)$; GOOF = 0.422. The bond lengths and bond angles and hydrogen bond parameters are reported in Tables 1 and 2, respectively. All calculations were performed by using the SHELX-97 program package.

3. Results and discussion

The reaction of the triaminoguanidine hydrochloride and the Cu(II) chloride in dilute solutions of HCl is complicated by the intense redox reaction (gassing). The compound $[Cu(TAGH_2)Cl_3]Cl \cdot H_2O$ was isolated by using highly concentrated HCl ($C \approx 10$ mol l^{-1}). This substance is stable in dry air and decomposes in water. According to the TG curve, on heating at ca. 40°C, the mass of the complex gradually begins to decrease, perhaps, due to the elimination process of water (estimated content 5.1%). After a partial elimination (mass loss ca. 2%) at 110°C, the mass loss is observed to be sharply defined owing to the decomposition of the substance. An extreme rate of mass loss is observed at 150°C from the DTG data.

The structure is composed of $[Cu(TAGH_2)Cl_3]^+$ cations, Cl^- anions and H_2O molecules. Triaminoguanidine enters into the composition of the complex cation as the $TAGH_2^{2+}$ cation (protonated at

two amino groups). The latter is connected to the copper(II) ion by N atoms of the amino group and the C=N moiety (Fig. 1) as a chelate bidentate ligand. The protonated amino groups are distant from the Cu atom. Its square-planar environment is formed by two Cl atoms (2.2769(9) and 2.3002(9) Å) and two N atoms of the triaminoguanidinium(2 +) cation forming a five-membered chelate cycle CuN_3C (Cu–N 1.987(2) and 2.043(2) Å, N–Cu–N 79.16(8)°). The Cl atoms (2.728(1) and 2.941(1) Å) alter the square geometry to a distorted square bipyramid. Taking into account these bonds, one can separate the staggered cation chains along [100] with the outerspheric Cl^- ions and water molecules located in between (Fig. 2). All structure moieties are connected by strong hydrogen bonds (Table 2).

In the only known compound with the coordinated aminoguanidium(1 +) cation, $[Co(AGH)_2Cl_4]$, no chelate cycle is formed and the cation is bonded to the cobalt(II) ion by the N atom of the hydrazine amino group as a monodentate ligand [5]. In $[Cu(DAGH)Cl_3]$ investigated by us [11], the $DAGH^+$ cation, along with $TAGH_2^{2+}$, and the Cu(II) ion form the same five-membered chelate cycle but the molecule contains only the coordinated Cl^- ions [11]. An increase in the charge of the intraspheric cations ($TAGH_2^{2+}$ rather than $DAGH^+$) necessitates an extra anion. As is shown in the present study, it is located just in the outer sphere. Besides, in $[Cu(DAGH)Cl_3]$, the distance to the chlorine atom which formally complements CN of Cu (4 + 1) to 6 is significantly larger (3.178(2) Å), suggesting the molecules of the complex are isolated. Note that the chelate bond lengths are close in $[Cu(DAGH)Cl_3]$ and $[Cu(TAGH_2)Cl_3]Cl{\cdot}H_2O$ but in the latter the character of the multiple C=N bond in the cation CN 3 mode is more clearly defined, i.e. C=N is 1.288(3) and C–N are 1.354(3) and 1.363(3) Å while the corresponding bond lengths in $[Cu(DAGH)Cl_3]$ are 1.309, 1.337 and 1.342 Å and 1.311, 1.333 and 1.336 Å in $[Co(AGH)_2Cl_4]$, respectively.

The IR spectrum of TAG·HCl shows two peaks at 3340 and 3220 cm^{-1} over the ν(NH) range while the absorptions at 1690 and 1620 cm^{-1} are due to ν(CN) and $\delta(NH_2)$ vibrations. The protonated of TAG by one proton proceeds the N atom of C=N moiety [13]. Spectroscopic characteristics of $[Cu(TAGH_2)Cl_3]Cl{\cdot}H_2O$ are in good agreement with XRD analysis data. The appearance of a broad band at ca. 3000 cm^{-1}, typical of the $\nu(NH_3^+)$ group, confirms data on the protonation of two TAG amino groups. The novel bands (compared to TAG·HCl) at 1570 and 1500 cm^{-1} are assigned to $\delta(NH_3^+)$ [14]. The 3240 and 3160 cm^{-1} bands belong to the coordinated amino group; vibrations of the water of crystallization manifest themselves in the intense absorption band at 3490 cm^{-1}. Changes in spectrum (as compared to TAG·HCl) over the ν(CN) and $\delta(NH_2)$ range — a low-energy frequency shift — are associated with the coordination of the amino group and the N atom of the C=N moiety of the protonated amidrazone group. Over this interval (1600–1660 cm^{-1}), a picture is complicated by the superposition of the $\delta(H_2O)$ absorption bands. The 313, 307(sh), 288 cm^{-1} bands are assigned to ν(Cu–Cl) vibrations and 460 cm^{-1} to the Cu–N bond vibrations [15]. A comparison of data on the crystal structures and IR spectra for TAG·HCl and $[Cu(TAGH_2)Cl_3]Cl{\cdot}H_2O$ shows that chelation influences the protonation mode of the amidrazone –C=N–NH_2 group. If the nitrogen atom of the C=N moiety is protonated in TAG·HCl, the protonation of TAG proceeds at two amino groups in the complex because this atom is coordinated to the Cu(II) ion. The compound $[Cu(TAGH_2)Cl_3]Cl{\cdot}H_2O$ is paramagnetic, μ_{ef} values are 1.83 and 1.86 μB at 78 and 300 K, respectively, and correspond to the d^9 configura-

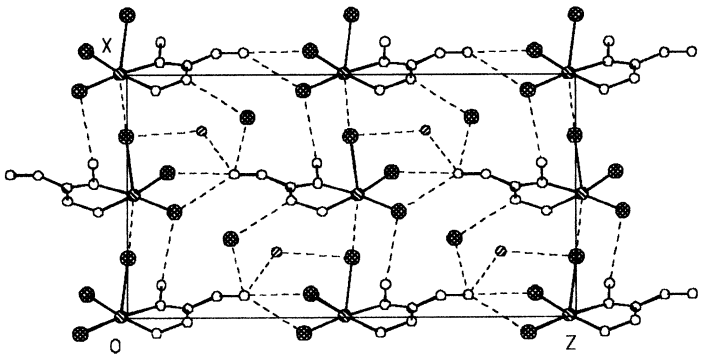

Fig. 2. Projection of crystal structure onto (010) plane.

tion. These data show the lack of exchange interaction between the unpaired electrons of the Cu(II) ions. The compound possesses low-temperature thermochromism: its color changes from light-green to blue upon cooling to liquid nitrogen temperature.

A decrease in temperature does not change the color of the blue complex $[Cu(DAGH)Cl_3]$. A difference in the properties of the complexes containing the coordinated diaminoguanidinium(1 +) and triaminoguanidinium(2 +) cations may be associated with differences in the coordination environment of the copper atom. It is likely that in the $TAGH_2^{2+}$ complex a temperature decrease causes the shortening of the longest Cu–Cl bond in the cation chains while this is not the case in the $DAGH^+$ complex because its molecules are isolated.

4. Conclusions

The compound synthesized is the first complex cation containing the coordinated triaminoguanidinium(2 +) cation. The chelate bidentate coordination of the diaminoguanidinium(1 +) and triaminoguanidinium(2 +) cations to the Cu(II) ion give grounds for the preparation of similar compounds with other metal ions.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC 131489. Abstract

The reactions of triphenylcarbonium hexafluorophosphate, $(CPh_3)(PF_6)$, with the terminal nitrido ligands of $[ReN(Et_2dtc)_2(Me_2PhP)]$ ($Et_2dtc^- = N,N$-diethyldithiocarbamate) and $(Bu_4N)[ReNCl_4]$ are described. The resulting imido complexes $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)](PF_6)$ and $(Bu_4N)[Re(NCPh_3)Cl_4(OReO_3)]$ have been studied by X-ray crystallography showing short rhenium–nitrogen multiple bond lengths of 1.706(6) and 1.686(6) Å, respectively. Nevertheless, the structural trans influence due to the imido ligand is significantly smaller than that of 'N^{3-}' which leads to a decreasing of the trans Re–S bond length by 0.24 Å in $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)](PF_6)$. Despite the addition of the bulky $^{+}CPh_3$ to the nitrido ligand, the $N{\equiv}Re{-}L_{(equatorial)}$ angles are only slightly increased in $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)]^+$, whereas those in $[Re(NCPh_3)Cl_4(OReO_3)]^-$ are smaller compared with the values in the starting complex which may also be attributed to the occupation of the sixth coordination position by perrhenate. The rhenium(VI) compounds ($5d^1$) $[Re(NCPh_3)X_4Y]^-$ (X = F, Cl, Br, NCS; Y = X or $OReO_3$) were studied by EPR spectroscopy indicating a noticeable loss of electron density in the central '$ReNX_4$' moiety upon addition of $^{+}CPh_3$ to the nitrido site of the $[ReNX_{4(5)}]^{-,(2-)}$ starting complexes. The EPR parameters of mixed-ligand intermediates of the general composition $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ (Y = Cl, Br or $OReO_3$) which are formed during ligand exchange reactions are clearly correlated to the composition of the coordination sphere and can be used to characterize the mixed-ligand species unambiguously. © 2000 Elsevier Science Ltd. Keywords: Rhenium; Nitrido complexes; Imido complexes; EPR spectroscopy; X-ray structures

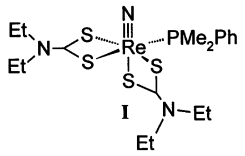
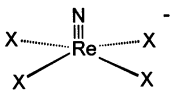
1. Introduction



Rhenium complexes with terminal nitrido ligands readily undergo reactions with electrophilic reagents [1–3]. Following this approach numerous compounds containing nitrido bridges between the transition metal and boron [4], gallium [5], gold [6], tin [7], zinc [8], molybdenum [9] or rhenium [10] have been prepared and characterized. Similar reactions with disulfur dichloride, phosphines or F_2 (or XeF_2) lead to thionitrosyls [11], phosphorane iminates [12] or *N*-halogenoimido complexes [13].

The conversion of the nitrido ligand to an imido function succeeds upon reactions with carbonium ions. Recently, we demonstrated that nitrido ligands can trap carbonium cations which arise from the condensation of two acetone molecules in the presence of an acid [14] as has been suggested by Bishop et al. [15]. Alkylation of nitrido ligands with $^{+}CPh_3$ salts has been proved for molybdenum, tungsten and osmium complexes [16]. The formation of complexes with the $Re(NCPh_3)$ moiety has been reported in [15], but no crystallographical data are available up to now.



In the present paper we describe the reactions of $(CPh_3)(PF_6)$ with bis(diethyldithiocarbamato)(dimethylphenylphosphine)nitridorhenium(V), $[ReN(Et_2dtc)_2(Me_2PhP)]$ (**I**), and (pseudo)halogenonitridorhenates(VI), $[ReNX_{4(5)}]^{-,(2-)}$ (X = F, Cl, Br, NCS) (**II**), which lead to triphenylmethylimido complexes of Re(V) and Re(VI), respectively, as well as the crystal structures of the products $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)]^+$ and $[Re(NCPh_3)Cl_4(OReO_3)]^-$.

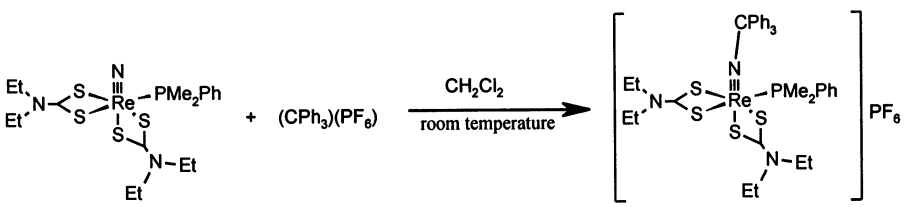
I

II



X = F, Cl, Br, NCS

We show that the nitridorhenate(VI) compounds **II** are suitable starting materials for the formation of new rhenium(VI) imido complexes containing the $Re(NCPh_3)$ moiety. EPR spectroscopy appears to be a valuable method to study these reactions. The hyperfine structure and ligand hyperfine structure data are used to characterize the bonding properties in the molecular orbital of the unpaired electron and are compared with the results of the starting complexes **II**.

2. Results and discussion

Treatment of $[ReN(Et_2dtc)_2(Me_2PhP)]$ or $(Bu_4N)[ReNCl_4]$ with $(CPh_3)(PF_6)$ in dichloromethane results in the formation of triphenylmethylimido complexes. The formal oxidation states of the metal, '+5' and '+6' remain unchanged. Thus, the $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)]^+$ cation is formed and the occupation of the sixth position of the rhenium(VI) compound by a perrhenate ligand yields $[Re(NCPh_3)Cl_4(OReO_3]^-$. The products have been isolated as PF_6^- and Bu_4N^+ salts, respectively. The crystalline solids are stable in air. Solutions of $(Bu_4N)[Re(NCPh_3)Cl_4(OReO_3)]$, however, slowly decompose even at room temperature. Thus, the crystallization procedure has been performed at low temperatures for this compound. Infrared bands between 1150 and 1200 cm^{-1} have been assigned to the imido vibrations which is in accord with previous findings [1].

The formation of $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)](PF_6)$ from complex **I** and $(CPh_3)(PF_6)$ in dichloromethane (Eq. (1)) is almost quantitative. The blue crystals obtained are readily soluble in organic solvents like CH_2Cl_2, $CHCl_3$ or acetone.

(1)

No decomposition of the complex has been observed as solid or in solution. The compound has been identified by common spectroscopic methods and the formation of the imido ligand '$NCPh_3^{2-}$' was confirmed by both IR and NMR spectroscopy and by X-ray crystallography.

The preferred electrophilic attack at the nitrido ligands does not necessarily mean that this is the most nucleophilic site of the molecule with respect to a study at an nitridoosmium thiolato complex where alkylation was achieved at the nitrido site or the thiolato site in dependence on the steric requirements of the attacking electrophile [16]. Similar results have been derived from the reactions of compound **I** with boranes where nitrido bridges are formed with bulky alkyl or aryl boranes [17,18] or boron halides [5b], whereas a preferred attack at the sulfur donors is observed when BH_3 is applied [4].

Single crystals of $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)](PF_6)$ have been obtained by slow diffusion of *n*-hexane into a solution of the complex in CH_2Cl_2. They contain one molecule of the solvent per complex molecule. The structure consists of well-separated complex cations and PF_6^- anions. Two crystallographically independent ion pairs are contained in the asymmetric unit of the triclinic unit cell. Since there are no significant differences between them, only one arbitrarily chosen $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)]^+$ cation is shown in Fig. 1 [19]. Table 1 contains selected bond lengths and angles. The rhenium atom has a distorted octahedral coordination environment. Main distortions are due to the restricting bite angle of the dithiocarbamato ligands which form four-membered chelate rings. The rhenium–nitrogen multiple bond is only slightly lengthened by the conversion of a nitrido site into an imido one, but the structural trans influence due to the multiply bonded ligand decreases significantly. The Re–S(32) bond length (averaged value from both molecules) in $[Re(NCPh_3)(Et_2dtc)_2(Me_2PhP)]^+$ is shorter by 0.24 Å compared with the value in the nitrido compound **I** [20]. The Re=N–C angles of 172.5° (averaged from both molecules) is in the range of values which have been found for the other structurally characterized transition metal complexes with $NCPh_3^{2-}$ units (163.3–179° [14–16]). The same holds true for the N(10)–C(10) bond length.

In a recently published short communication [21] we reported on the existence of tetrahalogeno(triphenylmethylimido)rhenium(VI) species which we have detected spectroscopically using EPR in reaction mixtures containing $[ReNX_4]^-$ complexes (X = Cl, Br) and $^+CPh_3$. Solutions of the complexes were sufficiently stable for detailed EPR spectroscopic studies. A slow decomposition that accompanied a decrease of the in-

tensity of the EPR signals, however, was observed over a period of hours and we were not able to isolate pure, crystalline samples which allowed crystallographic studies and an unambiguous assignment of the structures of the new compounds. Considerable amounts of perrhenate has been detected spectroscopically in the decomposition products which suggested a disproportionation of the rhenium(VI) complexes to diamagnetic rhenium(V) compounds and perrhenate. The rate of decomposition

can be decreased at low temperature. Thus, we were able to isolate yellow–brown single crystals of $(Bu_4N)[Re(NCPh_3)Cl_4(OReO_3)]$ by overlayering a CH_2Cl_2 solution of the complex with *n*-hexane at low temperatures.

The structure of $(Bu_4N)[Re(NCPh_3)Cl_4(OReO_3)]$ is built up of well separated $[Re(NCPh_3)Cl_4(OReO_3)]^-$ anions and tetrabutylammonium cations. An ellipsoid representation [19] of the complex anion is given in Fig. 2. Selected distances and angles are listed in Table 2. The rhenium atom is six-coordinate with a short Re=N bond of 1.686(6) Å. The occupation of the sixth position by perrhenate leads to smaller N–Re–Cl angles (mean value 96.4°) compared with the situation in $[ReNCl_4]^-$ (102.8° [22]). Thus, the rhenium atom is situated 0.260(1) Å above a least-square plane which is formed by the four Cl atoms. The Re(1)–O(1) distance of 2.091(5) Å is shorter than the values found for the bonds to coordinated water molecules in [Re{NB-

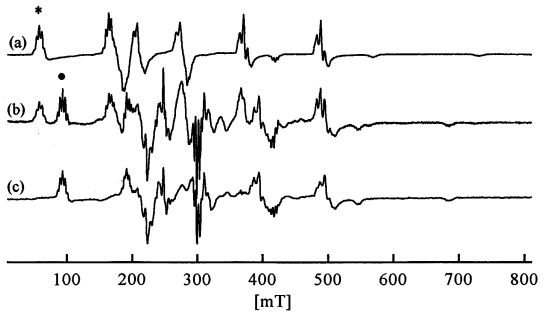

Fig. 3. Experimental X-band EPR spectra of a $[ReNF_4]^-/^+CPh_3$ mixture in CH_2Cl_2 at $T = 130$ K. (a) Immediatly after treatment of $[ReNF_4]^-$ with an excess of $(CPh_3)(PF_6)$. (b) After standing for 3 min at r.t. (c) After standing for 8 min at r.t. (*) $[ReNF_4]^-$. (●) $[Re(NCPh_3)F_4Y]^-$; Y = F or $OReO_3$.

$(C_6F_5)_3\}Cl_4(OH_2)]^-$ (2.282(4) Å [23]) or $[(H_2O)Br_4Re{\equiv}N{-}ReBr_4{-}N{\equiv}ReBr_4(OH_2)]^{2-}$ (2.41(2) Å [24]) and can be compared with the coordinated perrhenate ions in $[Re(NO)Cl_2(PPh_3)(OPPh_3)(OReO_3)]$ (2.058(8) Å [25]) or $[Re(NO)Cl_2(OPPh_3)_2(OReO_3)]$ (2.068(1) Å [25]). This indicates a significantly lower *trans* influence of the imido ligand compared with the situation in complexes with terminal nitrido ligands (Re–O bond in *mer*,*cis*-$[ReN(Cl)(Me_2PhP)_3(OSO_2CF_3)]$: 2.403(5) Å [26]) and explains the formation of a six-coordinate complex despite the addition of the bulky CPh_3 unit to the nitrido ligands. Similar results have been found for nitrogen bridges between rhenium and boron [4,18].

During the formation of $[Re(NCPh_3)X_4Y]^-$ complexes (X = F, Cl, Br, NCS; Y = X or $OReO_3$) by reactions of nitridorhenate(VI) compounds **II** with an excess of triphenylmethylcarbonium salt $(CPh_3)(PF_6)$ in dichloromethane solutions the formal oxidation state of the Re, '+6', remains unchanged. Thus, the triphenylmethylimido complexes as well as the nitridorhenate(VI) starting complexes $[ReNX_{4(5)}]^{-,\,(2-)}$ (X = F, Cl, Br, NCS) are favored for EPR spectroscopy because of their $5d^1$ ($S = 1/2$) configuration. The EPR spectra of the $\{Re^{VI}N\}$ starting compounds **II** are well characterized [22,27–29]. As found for the recently published tetrahalogeno(triphenylmethylimido)rhenium(VI) species (halide = Cl, Br) [21] the complexes $[Re(NCPh_3)X_4Y]^-$ (X = F, NCS; Y = X or $OReO_3$) give well resolved frozen solution X-band EPR spectra. For the characterization of chemical reactions of the nitridorhenate(VI) species **II** with $^+CPh_3$ the experimental EPR spectra of frozen solutions ($T = 130$ K) of a $[ReNF_4]^-/^+CPh_3$ mixture are given in Fig. 3(a–c). Fig. 3(a) shows the EPR spectrum of the starting complex $[ReNF_4]^-$ [28]. In the spectrum of $[ReNF_4]^-$ with an excess of $^+CPh_3$ (recorded 3 min after mixing of the reactants) in addition to the signals of the $[ReNF_4]^-$ species there are new signals which indicate the formation of $[Re(NCPh_3)F_4Y]^-$ (Y = F or $OReO_3$) (Fig. 3(b)). After standing for 8 min at room temperature only the signals of the triphenylmethylimido complex were observed (Fig. 3(c)). The EPR spectra of the $[Re(NCPh_3)X_4Y]^-$ imido complexes (X = F, Cl, Br, NCS; Y = X or $OReO_3$) show a typical axially symmetric pattern with six ^{185,187}Re hyperfine structure (hfs) lines (nuclear spin ^{185,187}Re: $I^{Re} = 5/2$, natural abundance ^{185}Re 37.4% and ^{187}Re 62.6%) in the parallel and the perpendicular part. Due to the large ^{185,187}Re hfs coupling constants and the nuclear quadrupole moments of the rhenium isotopes the equidistant hfs lines are disturbed.

The rhenium(VI) compounds of the general formulae $[Re(NCPh_3)X_4Y]^-$ (X = F, Cl, Br, NCS; Y = X or $OReO_3$) can be described by the spin Hamiltonian (2):

$$\mathbf{H}_{sp} = \mathbf{g}\cdot\mu_B\cdot\mathbf{S}\cdot\mathbf{B}_0 + \mathbf{S}\cdot\mathbf{A}^{Re}\cdot\mathbf{I}^{Re} + \mathbf{I}^{Re}\cdot\mathbf{Q}^{Re}\cdot\mathbf{I}^{Re} + \sum_{i=1}^{4}\mathbf{S}\cdot\mathbf{A}_i^X\cdot\mathbf{I}_i^X \quad (2)$$

with X = F, Br; all other symbols have their usual meaning. The last term stands for the ligand hfs interaction with the ^{19}F nuclei (^{19}F: $I^F = 1/2$) and the ^{79,81}Br nuclei (^{79,81}Br: $I^{Br} = 3/2$, natural abundance ^{79}Br 50.7% and ^{81}Br 49.3%), respectively. ^{19}F ligand hfs couplings are well-resolved in the parallel part (quintets with 1:4:6:4:1 intensity ratio) as well as in the perpendicular part (distorted 1:2:1 multiplets) of the above mentioned EPR spectra (see Fig. 3). The notation of the ligand hfs tensor components is the commonly used one for d^1 systems [21,28,29]. All spectral parameters determined for the triphenylmethylimido complexes $[Re(NCPh_3)X_4Y]^-$ (X = F, Cl, Br, NCS; Y = X or $OReO_3$) are summarized in Table 3 and are compared with those of the $\{Re^{VI}N\}$ starting compounds **II**. The comparison of the EPR parameters yields the following results:

1. For the $\{Re^{VI}N\}$ species **II** as well as for the triphenylmethylimido complexes typical axially symmetric spectra were detected. This indicates a electrophilic attack of the $^+CPh_3$ to the nitrido ligand of **II**.
2. On going from the $\{Re^{VI}N\}$ to the $\{Re^{VI}(NCPh_3)\}$ complexes an increase of the $g_\parallel$ values and an decrease of the $g_\perp$ values is observed.
3. The magnitudes of the Re hfs coupling constants $A_\parallel^{Re}$ and $A_\perp^{Re}$ of the imido compounds are about 10–20% smaller than those of the starting complexes **II**.
4. After the addition of $^+CPh_3$ to the nitrido site of the starting compounds **II** the magnitudes of the ligand hfs coupling parameters A_i^X (X = F, Br) are slightly increased.

The differences outlined in the statements (1)–(4) suggest a noticeable loss of spin-density of the central '$ReNX_4$' moiety (X = F, Cl, Br, NCS) upon formation of the $\{Re(NCPh_3)\}$ complexes. In order to account for the changes of the bonding situation in the compounds under study we calculated the molecular orbital (MO) coefficients α and α' of the MO of the unpaired electron for the $[ReNX_{4(5)}]^{-,\,(2-)}$ [27–29] and the $[Re(NCPh_3)$-

Table 3
EPR parameter [a] for $[Re(NCPh_3)X_4Y]^-$ and $[ReNX_{4(5)}]^{-,\,(2-)}$ with X = F, Cl, Br, NCS and Y = X, $OReO_3$ (hyperfine coupling constants are given in 10^{-4} cm^{-1})

[a] Experimental error: $g_i \pm 0.003$; $A_i^{Re} \pm 3$; $A_i^X \pm 1.0$ (X = F, Br).
[b] $g_{av} = (g_\parallel + 2g_\perp)/3$; $A_{av}^{Re} = (A_\parallel^{Re} + 2A_\perp^{Re})/3$; $A_{av}^X = (A_\sigma^X + A_\pi^X + A_z^X)/3$.
[c] Estimated from linewidth considerations.
[d] Not resolved.

for the $[ReNX_{4(5)}]^{-,\,(2-)}$ [27–29] and the $[Re(NCPh_3)X_4Y]^-$ complexes (X = F, Cl, Br, NCS; Y = X or $OReO_3$) [21] from the experimental hfs parameters. The molecular orbital of the unpaired electron (C_{4v} symmetry assumed) is of 'in-plane π-type' as given in Eq. (3):

$$\psi_{MO}(b_2) = \alpha|5d_{xy}\rangle - \alpha'|\phi_L\rangle \quad (3)$$

where ϕ_L represents a linear combination of mainly p orbitals of the donor atoms of the (pseudo)halide ligands (L). The squared coefficients α^2 and $(\alpha')^2$ are a measure of covalency of the Re–ligand$_{(equatorial)}$ bonds in this MO. Applying the generally accepted formalism of Morton and Preston [30], the s, p and d spin-densities $(c_s^X)^2$, $(c_p^X)^2$ and $(c_d^X)^2$ are calculated by means of Eqs. (4a) and (4b):

$$(c_s^X)^2 = (a_{iso,exp}^X / a_{iso,th}^X) \quad (4a)$$

$$(c_{p,d}^X)^2 = (b_{dip,exp}^X / b_{dip,th}^X) \quad (4b)$$

In these equations, $a_{iso,th}^X$ and $b_{dip,th}^X$ are the isotropic and dipolar parts of the (ligand) hyperfine tensor and have been calculated by Morton and Preston [30] for the case when the unpaired electron is completely localized in the corresponding s, p and d function of the nucleus X under discussion. $a_{iso,exp}^X$ and $b_{dip,exp}^X$are the experimentally obtained values. The spin-densities calculated are listed in Table 4.

From the values given in Table 4 the following conclusions can be drawn:

1. They indicate a predominant Re $5d_{xy}$ character in the highest occupied molecular orbital (HOMO). For the α^2 values of the fluoro and chloro species we estimated values larger than 100%. The discrepancies in the α^2 values may be due to inaccuracies in the atomic orbitals of the heavy Re atom. Also, relativistic effects as discussed for Au^{II} compounds [31,32] may have an influence.
2. The α^2 values decrease, as expected, with an increase of the 'heaviness' of the equatorial donor atoms. The isothiocyanato complexes shows a noticeably small α^2 value which is attributed to the π-acceptor behavior of the NCS^- ligands.
3. For the triphenylmethylimido complexes a remarkable decrease of the α^2 values was observed.

Table 4
Experimentally obtained spin-density distribution [a] for $[Re(NCPh_3)X_4Y]^-$ and $[ReNX_{4(5)}]^{-,\,(2-)}$ complexes (X = F, Cl, Br, NCS, Y = X, $OReO_3$)

[a] Contributions of a sixth ligand coordinated in a trans position to the 'N^{3-}' or '$NCPh_3^{2-}$' are small and therefore neglected.

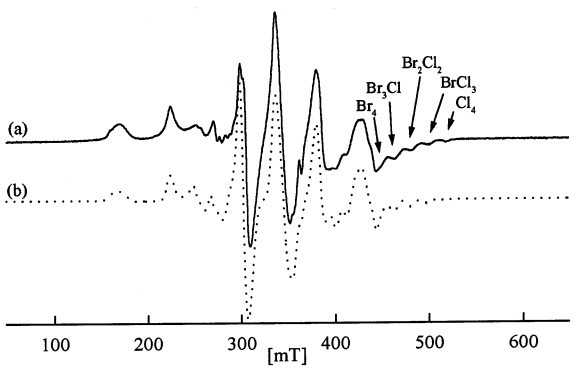

Fig. 4. (a) Experimental X-band EPR spectrum of $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ complexes ($n = 0$–4; Y = Cl, Br or $OReO_3$) in CH_2Cl_2 at $T = 130$ K. In the high-field region of the parallel part all three mixed-ligand species and the parent compounds are detected. (b) Simulated spectrum.

Table 5
Experimentally obtained [a] and calculated [b] EPR parameters $g_\parallel$ and $A_\parallel^{Re}$ for $[Re(NCPh_3)$–$Br_{4-n}Cl_nY]^-$ mixed-ligand complexes ($n = 1$–3; Y = Cl, Br or $OReO_3$) (hyperfine coupling constants are given in 10^{-4} cm^{-1})

	$g_\parallel$		$A_\parallel^{Re}$	
	Found	Calculated	Found	Calculated
$[Re(NCPh_3)Br_4Y]^-$	2.145	2.145	542	542
$[Re(NCPh_3)$-$Br_3ClY]^-$	2.104	2.101	569	573
$[Re(NCPh_3)$ $\times Br_2Cl_2Y]^-$	2.057	2.057	601	603
$[Re(NCPh_3)$-$BrCl_3Y]^-$	2.013	2.013	633	633
$[Re(NCPh_3)Cl_4Y]^-$	1.969	1.969	664	664

[a] Experimental error: $g_\parallel \pm 0.003$; $A_\parallel^{Re} \pm 5$.
[b] $p = ([Re(NCPh_3)Br_{4-n}Cl_nY]^-) = \{(4-n)p([Re(NCPh_3)$-$Br_4Y]^-) + np([Re(NCPh_3)Cl_4Y]^-)\}$ with $p = g_\parallel$ and $A_\parallel^{Re}$; Y = Cl, Br or $OReO_3$.

4. On going from the nitrido to the imido complexes a slightly increase of the $(\alpha')^2$ values was found.
5. On going from nitrido to imido nitrogen (i.e. changing the formal charge from '−3' to '−2') spin-density will be transferred from Re to the added CPh_3 unit.

In the frozen solution EPR spectra of $[ReNCl_4]^-$/$[ReNBr_4]^-$ mixtures containing an excess of $(CPh_3)(PF_6)$, in addition to the signals of the parent imido complexes $[Re(NCPh_3)X_4Y]^-$ (X = Cl, Br; Y = X or $OReO_3$), new signals are to be seen in the high-field region ($m_I^{Re} = -5/2$) of the parallel part. These are attributed to rhenium(VI) imido mixed-ligand complexes of the general formulae $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ ($n = 1$–3; Y = Cl, Br or $OReO_3$). A typical experimental EPR spectrum and its simulation is reproduced in Fig. 4. The perpendicular part of the spectrum is very complex due to many lines overlapping. Therefore, no attempts were made to derive the EPR parameters $g_\perp$ and $A_\perp^{Re}$. The tensor components $g_\parallel$ and $A_\parallel^{Re}$ of the parallel part of the spectra are summarized in Table 5. Due to the large linewidths ($\Delta B_{pp} \geq 7$ mT) $^{35,37}Cl$, $^{79,81}Br$ and ^{14}N hfs interactions were not resolved.

The investigation of ligand-exchange reactions by means of EPR requires knowledge about the dependence of the EPR parameters on the type (composition, symmetry) of the coordination sphere. Extensive investigations have been made e. g. on the nitridorhenate(VI) complexes of the general formulae $[ReNX_4]^-$ (X = F, Cl, Br) [22,33]. According to this a nearly linear dependence of the EPR spectral quantities $g_\parallel$ and $A_\parallel^{Re}$ on the 'heaviness' of the first coordination sphere is expected. This can be defined for the $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ complexes ($n = 0$–4; Y = Cl, Br or $OReO_3$) under study as given in Eq. (5):

$$g_\parallel,\ A_\parallel^{Re} \sim \lambda_L/\lambda_{Re} = (1/4)[n\lambda_{Cl} + (4-n)\lambda_{Br}]/\lambda_{Re} \quad (5)$$

where λ_{Cl}, λ_{Br} and λ_{Re} are the spin-orbit coupling constants of chlorine, bromine and rhenium, respectively.

The proportionality (Eq. (5)) holds true if there are no significant differences concerning the structure and bonding properties of the complexes considered. Thus, if the $g_\parallel$ values and the hfs coupling parameters $A_\parallel^{Re}$ of the parent complexes are known, the $g_\parallel$ and $A_\parallel^{Re}$ values of the mixed-ligand complexes can be estimated simply using the 'additivity rule' given in Eq. (6):

$$\begin{aligned} p &= ([Re(NCPh_3)Br_{4-n}Cl_nY]^-) \\ &= \{(4-n)p([Re(NCPh_3)Br_4Y]^-) \\ &\quad + np([Re(NCPh_3)Cl_4Y]^-)\} \end{aligned} \quad (6)$$

with $p = g_\parallel$ and $A_\parallel^{Re}$. In Table 5 the $g_\parallel$ and $A_\parallel^{Re}$ values estimated for $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ mixed-ligand complexes ($n = 1$–3; Y = Cl, Br or $OReO_3$) according to Eq. (6) are compared with the experimentally derived ones. It can be seen that the experimental values are well reproduced by Eq. (6). Fig. 5 illustrates the nearly linear dependence of the observed EPR quantities of the $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ complexes ($p = 0$–4; Y = Cl, Br or $OReO_3$) on the composition of the first coordination sphere.

3. Experimental

$(NBu_4)[ReNCl_4]$ [22] and $[ReN(Et_2dtc)_2)(Me_2PhP)]$ [20] have been prepared by literature procedures. $(CPh_3)(PF_6)$ has been purchased from ALDRICH and used without further purification. IR spectra have been recorded on a Perkin–Elmer Spectrum 1000. NMR spectra have been measured on a Bruker DRX-250

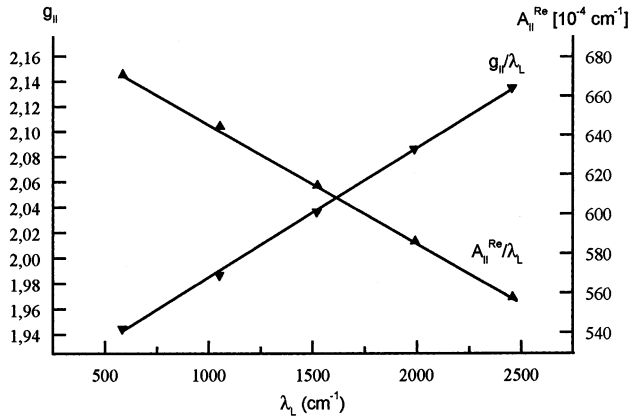

Fig. 5. Dependence of $g_{\|}$ and $A_{\|}^{Re}$ of $[Re(NCPh_3)Br_{4-n}Cl_nY]^-$ complexes ($n = 0$–4; Y = Cl, Br or $OReO_3$) on the effective spin-orbit coupling $\lambda_L = 1/4[(4-n)\lambda_{Br} + \lambda_{Cl}]$. $\lambda_{Cl} = 586$ cm^{-1} and $\lambda_{Br} = 2460$ cm^{-1}.

instrument with TMS and H_3PO_4 as standards. FAB mass spectra have been obtained using a TSQ 70 (Finnigan MAT) with nitrobenzylalcohol as matrix (8 keV, xenon). EPR spectra have been recorded for CH_2Cl_2 solutions at $T = 130$ K in the X-band ($\nu \approx 9.5$ GHz) with a Bruker ESP 300E spectrometer under standard conditions (typically modulation frequency 100 kHz, modulation amplitude 5 G, microwave power 4 mW).

3.1. *[Re(NCPh$_3$)(Et$_2$dtc)$_2$(Me$_2$PhP)](PF$_6$)*

[ReN(Et_2dtc)$_2$(Me_2PhP)] (63 mg, 0.1 mmol) was dissolved in ca. 5 ml CH_2Cl_2 and (CPh_3)(PF_6) (44 mg, 0.11 mmol) was added. The color of the solution immediately changed to blue. The volume was reduced to about 2 ml after stirring at room temperature (r.t.) for 1 h and overlayered with *n*-hexane. Blue needles deposited upon diffusion of *n*-hexane into the dichloromethane solution. Yield: 94 mg (85%). *Anal.* Found: C, 42.0; H, 3.9; N, 3.8; S, 11.2. Calc. for $C_{38}H_{48}Cl_2F_6N_3P_2ReS_4$: C, 41.2; H, 4.3; N, 3.8; S, 11.5%. IR (ν_{max}/cm^{-1}): 1192 s (Re=N). ^{1}H NMR (acetone-d_6/ppm): 1.12–186 (18H, CH_3); 3.32–3.85 (8H, CH_2); 7.01–7.26 (20H, phenyl). ^{13}C NMR (acetone-d_6/ppm): 12.1, 12.5 (CH_3, phosphine); 14.1, 14.3, 14.4, 14.6 (CH_3, Et_2dtc^-); 45.0, 45.3, 45.9, 47.0 (CH_2); 94.5 (CPh_3); 128.4, 12.6, 128.9, 129.3, 129.4, 131.0, 131.4, 140.7 (phenyl).

3.2. *(Bu$_4$N)[Re(NCPh$_3$)Cl$_4$(OReO$_3$)]*

(Bu_4N)[$ReNCl_4$] (59 mg, 0.1 mmol) was dissolved in 3 ml CH_2Cl_2 and solid (CPh_3)(PF_6) (39 mg, 0.1 mmol) was added at −20°C. The mixture was carefully overlayered with *n*-hexane and kept for crystallization at −20°C. Yellow–brown crystals deposited during a period of several days which were removed by filtration and dried in vacuum. Yield: 48 mg (45%). *Anal.* Found: C, 39.2; H, 4.9; Cl, 11.2; N, 2.9. Calc. for $C_{35}H_{51}Cl_4N_2O_4Re_2$: C, 39.0; H, 4.7; Cl, 13.0; N, 2.6%. IR (ν_{max}/cm^{-1}): 1163 s (Re=N).

3.3. *X-ray structural determinations*

The intensities for the X-ray structural determinations were collected on an automated single crystal diffractometer (Enraf–Nonius, Delft, The Netherlands) with Mo Kα radiation ($\lambda = 0.71073$ Å) at −65°C. HELENA [34] was used for data reduction. The structures were solved by direct methods using SHELXS-97 [35]. Subsequent Fourier-difference map analyses yielded the positions of the non-hydrogen atoms. Refinement was performed using SHELXL-97 [36]. Hydrogen atoms have been included at calculated positions and refined using the 'riding model' option of SHELXL-97. Crystal data and more details of the data collections and refinements are contained in Table 6.

Abstract

The ability of calix[4]arene bis(crown-6) in the 1,3-alternate conformation (BC6) to co-extract caesium and pertechnetate ions from acidic or basic aqueous to organic solutions, which is of interest for nuclear waste reprocessing, has previously been demonstrated. We report the crystal structures of the complexes formed by this ligand with sodium and caesium ions with perrhenate (isoelectronic to pertechnetate) counter-ions, in an acidic medium. The sodium complex $[(Na^+\cdot H_2O)_2BC6](ReO_4^-)_2$ (**1**) differs from the previously reported sodium nitrate complex mainly by the dissociation of the anion–cation pair. Three forms of the caesium complex are described, $[(Cs^+)_2(ReO_4^-)BC6](ReO_4^-)\cdot H_2O$ (**2**), $[(Cs^+)_2(ReO_4^-)(H_2O)BC6](ReO_4^-)(H_2O)_{0.5}$ (**3**) and $[(Cs^+)_{1.5}(ReO_4^-)BC6](ReO_4^-)_{0.5}$ (**4**), which differ one from the other by the coordination mode of the perrhenate ions (monodentate, bidentate, bridging) and the position of the caesium ion in the crown. © 2000 Elsevier Science Ltd. Keywords: Calixcrowns; Caesium ion; Sodium ion; Perrhenate ion; Pertechnetate ion; Nuclear reprocessing

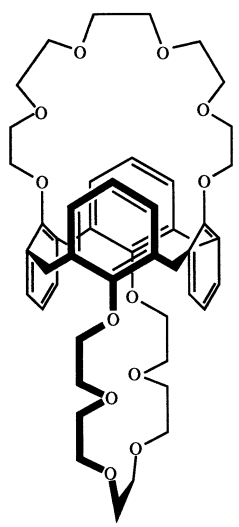
1. Introduction

Nuclear fission provides an almost infinite source of energy but presents the important drawback of generating nuclear wastes, which are presently the subject of much concern. The wastes produced during reprocessing are divided into two classes: (i) low- and medium-level liquid wastes (LLLW and MLLW) and (ii) high-level liquid wastes (HLLW). Recovery of technetium (high-yield fission product ^{99}Tc, present as TcO_4^- ions in aqueous acid solution) from HLLW is one of the important new challenges, not only because of its environmental impact due to its long half-life of 2.13×10^5 years and its relative mobility in disposals [1], but also because it is the most important of the radionuclides in nuclear medicine [2]. A lot of work has been devoted to the development of extractants selective for this anion. The close relationship between TcO_4^- and the isoelectronic perrhenate ion ReO_4^- makes the latter a convenient and widely used model for the former [2].



With the advent of macrocyclic ligands such as crown ethers, cryptands and calixarenes, supramolecular chemistry has developed rapidly in a wide range of application fields. Although development of anionic complexation has been slower than that of cations, recent studies have shown that this field of research could have already found applications for industrial purposes [3]. In the particular area of concern, the extraction of the tetrahedral pertechnetate anion TcO_4^- from aqueous solutions by several crown ether compounds has been reported. For example, dicyclohexyl-18-crown-6 has been shown to extract TcO_4^- from water acidified with nitric acid into trichlorobenzene [4], as well as dibenzo-crown-6 from an acid medium into 1,2-dichloroethane or dibenzo-crown-6 and a series of related crown ethers and cryptands from alkaline media into various organic solvents [5]. In all those cases, the

PII: S0277-5387(00)00464-2

extracted species is $[M^+/H^+$: crown ether$]TcO_4^-$ ($M^+ = Na^+$, K^+). Di-*tert*-butylcyclohexyl-18-crown-6 co-extracts Sr^{2+} and TcO_4^- from a nitric acid solution into octanol [6]. Benzo-15-crown-5 (B15C5) and dibenzo-18-crown-6 (DB18C6) extract ReO_4^- into 1,2-dichloroethane by forming the compounds $[M^+(B15C5)_n]ReO_4^-$ and $[M^+DB18C6]ReO_4^-$ ($M^+ = Na^+$, K^+, NH_4^+; $n = 1, 2$), respectively [7]. The existence of such crown ether complexes was confirmed by the determination of some crystalline structures in the case of $Na^+ReO_4^-$, in which the perrhenate ion is bound to the sodium ions included in the crown ether [8,9a,b], or not bound in the case of the large wrapping tetrabenzo-24-crown-8 [9c]. Recently, the ability of a tripodal tris(amido benzo-15-crown-5) to co-extract sodium and pertechnetate ions has been demonstrated [10]. Macrocycles other than crown ethers have also been investigated for perrhenate or pertechnetate extraction. A calix[4]arene functionalized with amido groups at the 1,3-positions of the upper rim was reported to act as a poor complexant for ReO_4^- [11]. Recently, the presence of Na^+ ions in the aqueous phase has been shown to be necessary for the extraction of perrhenate ions by 25,26,27,28-tetrakis[(ethoxycarbonyl)methoxy]-*p*-*tert*-butylcalix[4]arene (L) into 1,2-dichloroethane and the corresponding extracted complex $[Na^+L]ReO_4^- \cdot H_2O$ has been prepared and characterized [12]. However, the presence of an alkali metal counter-ion may not be a requisite: the positively charged, bowl-shaped, π-metalated calix[*n*]arenes ($n = 4, 5$) and cyclotriveratrylene (CTV) have been shown to be versatile anion complexants, the latter being selective for large tetrahedral species such as ReO_4^- and TcO_4^- [13].

The simultaneous removal of technetium and caesium ions from nuclear wastes by using calix[4]arene bis(crown-6) (BC6, represented on Scheme 1) in the 1,3-alternate conformation has recently been reported by Moyer et al. in the case of alkaline solutions [14] and by some of us in the case of acidic ones [15]. The extraction experiments performed in an acidic (HNO_3) medium demonstrate that trace amounts of technetium could be recovered with different calix[4]arenes mono or bis(crown-6). All the calixcrowns investigated give distribution coefficients close to 8 except for calix[4]arene bis(naphtho-crown-6) which coextracts pertechnetate ions to a lesser extent [16]. This result is related to the ability of BC6 to selectively complex caesium ions [17]. Crystal structure determinations and molecular modeling have shown that caesium ions are held in the crown ether loops by six Cs–O bonds and are also bound to a counter-ion (generally a bidentate nitrate ion, but also iodide, which is close to TcO_4^- in terms of size and charge density [10]) [18]. It was anticipated that the interactions between caesium and pertechnetate ions were the result of the replacement of nitrate by pertechnetate counter-ions. We report in this paper the crystal structures of sodium and caesium ion (both present in nuclear wastes) complexes of BC6 obtained in an acidic medium with perrhenate counter-ions, as a model for pertechnetate ones.

2. Experimental

2.1. Synthesis

The 1,3-alternate calix[4]arene bis(crown-6) (BC6) ligand has been synthesized as already reported [17].

2.1.1. $[(Na^+ \cdot H_2O)_2BC6](ReO_4^-)_2$ (1)

A mixture of BC6 (0.13 mmol) and a large excess of $NaNO_3$ (4 mmol) and perrhenic acid (1 ml; water solution, 65–70% in weight) in 30 ml of 1:1 methanol–chloroform was refluxed for 5 h. The unreacted residue was then filtered off and the solution allowed to slowly evaporate, leading to colorless single crystals of complex **1**.

2.1.2. $[(Cs^+)_2(ReO_4^-)BC6](ReO_4^-) \cdot H_2O$ (2), $[(Cs^+)_2(ReO_4^-)(H_2O)BC6](ReO_4^-)(H_2O)_{0.5}$ (3) and $[(Cs^+)_{1.5}(ReO_4^-)BC6](ReO_4^-)_{0.5}$ (4)

A mixture of BC6 (0.12 mmol), a large excess of $CsNO_3$ (1 mmol) and perrhenic acid (100 μl; water solution, 65–70% in weight) in 20 ml of 1:1 chloroform–acetonitrile was refluxed for 2 h. The unreacted residue was then filtered off and the solution allowed to slowly evaporate. Three types of single crystal were collected in the same batch, corresponding to complexes **2**–**4**.

All the single crystals investigated in the present study were of rather low quality (particularly those of **2**), which resulted in crystal structure determinations of moderate quality (even for data collected at 100 K).

2.2. Crystallography

The data were collected on a Nonius Kappa-CCD area detector diffractometer [19] using graphite monochromated Mo Kα radiation (0.71073 Å). The crystals were introduced in Lindemann glass capillaries with a protecting 'Paratone' oil (Exxon Chemical Ltd.) coating. The data were processed with the HKL package [20]. The structures were solved by direct methods with SHELXS-97 [21], expanded by subsequent Fourier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [22]. Absorption effects were corrected empirically with the program MULABS from PLATON [23]. The geometrically constrained hydrogen atoms were introduced at calculated positions (unless those of water molecules) as riding atoms, with a displacement parameter equal to 1.2 times that of the parent atom. All non-hydrogen atoms were refined anisotropically in complexes **1**, **2** and **4**, and Re, Cs and O atoms only in **3**, in order to keep a number of parameters compatible with the number of reflections. Some soft restraints on bond distances had to be applied in all four structures, particularly in the ether chains. The correct enantiomorph in **3** has been determined from the value of the Flack parameter [0.069(15)] [24]. Crystal data and structure refinement parameters are given in Table 1. The molecular drawings were done with SHELXTL [25]. All calculations were performed on a Silicon Graphics R5000 workstation.

3. Results and discussion

The asymmetric unit in **1** comprises half a molecule with a binary symmetry axis including two diametrically opposed methylene bridge carbon atoms. Such an overall geometry has already been observed, in several caesium ion and acetonitrile complexes of BC6 [18]. In the binuclear sodium nitrate complex of BC6 previously reported (**6**) [26], the complexed species is $Na^+(NO_3^-)\cdot H_2O$, the sodium atom being bound to three ether oxygen atoms, to a bidentate nitrate ion and to the water molecule. The water molecule is itself hydrogen bonded to the two ether oxygen atoms nearer to the calixarene core (hydrogen bonds inferred from the O···O distances). The main difference observed in complex **1** is that the perrhenate counter-ion is not bound to the cation. As illustrated in Fig. 1, each of the two sodium cations is loosely bound to three ether oxygen atoms with a non-optimal mean Na–O distance of 2.8(2) Å (Table 2), larger than that in **6** [distances in the range 2.44(2)–2.86(2), mean value 2.6(1) Å], in spite of the lower temperature used for the data recording in the present case. This mean value corresponds to the largest Na–O distances in crown ether complexes [9,27]. The Na–O_{water} distance is also larger in **1** [2.39(1) Å, compared to 2.18(2) and 2.24(2) Å in **6**] and corresponds to the largest of previously published values [27,28]. Conversely, the O···O hydrogen bond distances in **1** [mean value 2.69(8) Å] are lower than in **6** [mean value 2.86(3) Å]. The resulting four-coordination is rare in sodium complexes; however, one example has been given in the domain of calixarene chemistry, which is

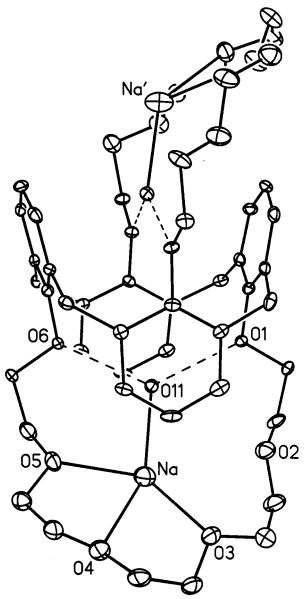

Fig. 1. Complex of BC6 with $(Na^+\cdot H_2O)ReO_4^-$ (**1**). Hydrogen bonds in dashed lines. Hydrogen atoms and perrhenate ions omitted for clarity. Primed atoms are related to unprimed ones by the binary axis.

the sodium complex of tetrakis[(ethoxycarbonyl)methoxy]calix[4]arene in the 1,3-alternate conformation [29]: in this case, the Na–O bond lengths [2.288–2.434 (mean value 2.36(6)) Å] are shorter than in **1**, probably as a result of a less rigid ligand geometry. In both cases, the existence of π-interactions involving the aromatic rings is unlikely. The sodium cation and the three bound ether oxygen atoms in **1** define a plane within ±0.290(6) Å, which makes a dihedral angle of 129.3(3)° with the mean plane defined (within ± 0.143(6) Å) by the sodium cation, the water oxygen atom and the two ether oxygen atoms hydrogen bonded to it. The concave region of the space defined by these two planes, which was occupied by the nitrate ion in **6**, is free in **1**. However, neighboring molecules are arranged so that their $Na[O_{ether}]_3$ planes are roughly parallel, with a Na···Na distance of 4.09(2) Å, comparable to those in a recently reported different sodium–calixarene complex [3.182 and 4.203 Å] [28]. The structures of **1** and **6** present some analogies with those of 18-crown-6 complexes of $(Na^+\cdot H_2O)$ recently published [30], in which intramolecular hydrogen bonds influence the sodium ion position and contribute to the stability of the complex, with the difference that the water molecule is located close to the mean plane of the crown in **1** and **6**, whereas it is positioned out of the crown in the other cases. The two perrhenate ions, which occupy voids in the lattice, are unremarkable, with a mean Re–O distance of 1.68(4) Å and a mean O–Re–O angle of 109(7)°. The conformation of the ether chain can be characterized by the sequence of torsion angles it defines, and particularly the *gauche* O–C–C–O angles sequence [31], which, in the present case, is $g^-g^+g^+g^-g^+$ (Table 3). This conformation (or its equivalent $g^+g^-g^+g^+g^-$), with *gauche* angles that may be rather far from their ideal value of 60° [departure up to 21° in **1**] and in some cases one of the *anti* C–O–C–C angles far from its ideal value [100(1)° in **1**], is the second most frequent conformation in BC6 complexes and is also observed in one of the two crowns of complex **6** [32]. On the whole, in spite of the absence of any bound counter-ion in **1**, there are only slight differences between the location of the $(Na^+\cdot H_2O)$ moiety and the ether chain conformation in **1** and **6**. We had previously assumed that, due to the lack of complemen-

tarity between Na^+ and BC6, the electrostatic interactions between the cation and its counter-ion were playing a major role [26]. Besides, molecular dynamics simulations have been reported which show evidence of a 'pulling' effect of the picrate counter-ion in the case of the sodium complex of BC6 in chloroform [33]. Even if the formation of other species in solution cannot be ruled out, the present structure can be considered as a counter-example, the nature of the complex being only slightly perturbed by the absence of a coordinated counter-ion, and, in particular, the relative positioning of Na^+ and H_2O being retained. However, this solid state structure does not give any clue concerning the complexation mechanism, in which the counter-ion might be present as an active species.

The asymmetric unit in **2** comprises one complete BC6 molecule (Fig. 2). One caesium ion is located at the center of each crown, with a mean Cs–O distance of 3.3(2) Å, comparable to those previously obtained in complexes with nitrate, thiocyanate or iodide counter-ions [18]. One of the perrhenate ions is bridging the caesium ions of neighboring molecules, which gives rise to infinite chains made of parallel molecules related one to the other by the (1/2, 1/2, 0) translation (i.e. the chains are parallel to the [110] direction). Such a formation of polymeric species has already been encountered in the caesium nitrate complex of calix[4]arene bis[-bis(1,2-phenylene)-crown-6] [34]. The coordinated anion is monodentate towards each ion, giving a resulting coordination number of 7 for the caesium cation, with $Cs–O_{perrhenate}$ distances of 3.39(2) and 3.28(2) Å. To the best of our knowledge, no crystal structure comprising a caesium–perrhenate bond has been reported up to now [35]. The two caesium ions are displaced by 0.783(8) and 0.654(8) Å from the mean planes defined by the six bonding oxygen atoms (with deviations of 0.26 and 0.15 Å, respectively), which are usual values [18]. The dihedral angles between each of the four aromatic rings and the mean plane defined by the four methylene carbon atoms are 76.7(5), 78.1(6), 79.5(4) and 77.4(5)° [mean value 78(1)°]. As in the previous structures of caesium complexes with 1,3-alternate calixarenes, the short $Cs\cdots C_{aromatic}$ distances are indicative of possible cation···π interactions, the π-cloud acting as a donor towards the soft caesium cation; among those distances, the shortest ones [3.21(3) and 3.17(3) Å for Cs(1) and Cs(2), respectively] involve the aromatic carbon atoms diametrically opposite to those bearing the oxygen atoms. The O–C–C–O torsion angles define a $g^-g^+g^+g^-g^+$ sequence in both crowns, with a low value for the first g^+ angle. Some C–O–C–C angles are rather far from the ideal value of 180°, the lowest value being 121(3)°. Such a conformation is close to that observed in **1**, and also in the caesium complexes of BC6 with other monodentate counter-ions such as NCS^- and I^- [36,37]. The second, non-bonding, per-

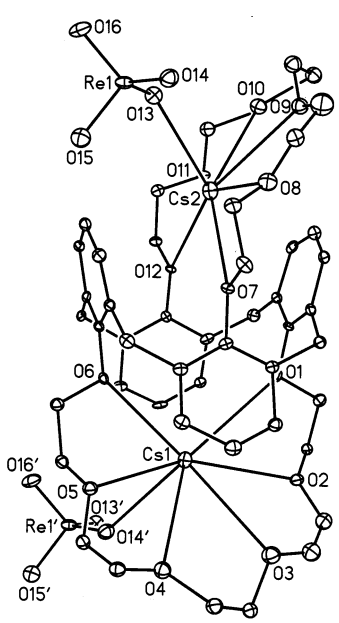

Fig. 2. View of the polymeric caesium complex **2**. Hydrogen atoms and non-coordinated perrhenate ions omitted for clarity. Symmetry code: ′ = $x - 0.5$, $0.5 + y$, z.

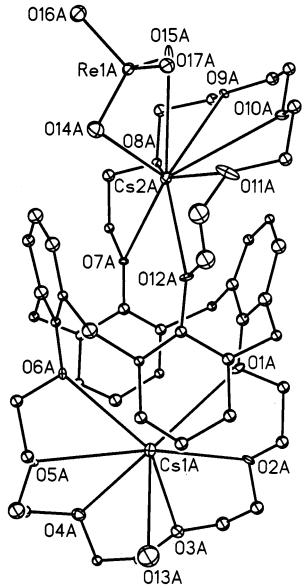

Fig. 3. View of the caesium complex **3**. Hydrogen atoms and non-coordinated perrhenate ion and water molecule omitted for clarity.

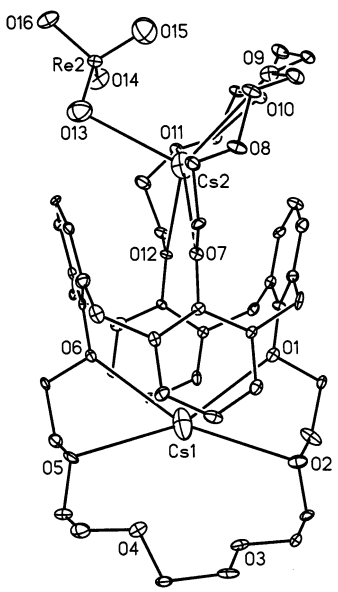

Fig. 4. View of the caesium complex **4**. Hydrogen atoms and non-coordinated perrhenate ion omitted for clarity.

rhenate ion is located on two sites with crystallographically imposed 0.5 occupation. One of them, on a symmetry center, has been interpreted as transformed from the tetrahedral ReO_4^- to an octahedral $ReO_4(H_2O)_2^-$ species, with two short Re–O distances [1.64(5) Å] and four longer ones [2.02(5) and 2.07(6) Å], two of which are likely associated with water molecules. This bis(aquo) complex of ReO_4^- can be compared with the bis(aquo) complexes of Re_2O_7, in which the $Re–O_{water}$ distances are somewhat larger (2.16–2.22 Å) [38].

The asymmetric unit in the second form obtained for the caesium perrhenate complex, **3**, comprises two independent molecules with nearly similar geometries (noted A and B). One of them is represented in Fig. 3. The coordination environment of the two caesium cations is different from the one in **2**. In both molecules A and B, the two caesium ions are located at the center of the crowns, with identical mean $Cs–O_{ether}$ distances of 3.2(1) Å for Cs(1) and 3.3(2) Å for Cs(2). One of the caesium ions [Cs(2)] is bound to a bidentate perrhenate ion with a mean Cs–O distance of 3.4(2) Å (the bonding mode is more symmetrical in molecule A than in molecule B), which results in a coordination number of 8. The other cation [Cs(1)] is bound to a water molecule (7-coordination), with Cs–O distances of 3.21(5) and 3.28(3) Å in molecules A and B, respectively (few crystal structures displaying $Cs–O_{water}$ bonds have been reported, the corresponding distances being in the range 3.013–3.660 Å [39]). This is the first occurrence of a water molecule coordinated to caesium ions in the present family of compounds. By contrast with the case of sodium ions, this water molecule occupies the usual location of the counter-ion and is not included within the calixcrown cavity, which is filled by the cation. The Cs(2) ions are located at 0.84(1) and 0.77(1) Å from the mean planes defined by the six ether oxygen atoms (deviations of 0.31 and 0.58 Å), in molecules A and B, respectively. The corresponding values for the Cs(1) ions are 0.605(7) and 0.320(8) Å (deviations of 0.35 and 0.22 Å). The dihedral angles between the aromatic rings and the mean planes defined by the methylene bridges are 74.9(7), 73.3(6), 78.1(7) and 82.5(6)° [mean value 77(4)°] in molecule A and 77.7(7), 76.4(7), 76.3(7) and 77.3(7)° [mean value 76.9(7)°] in molecule B. The crowns define the O–C–C–O torsion angles sequences $g^+g^-g^+g^+g^-$ and $g^+g^-g^+g^-g^-$ in molecule A and $g^-g^-g^+g^+g^-$ and $g^+g^-g^-g^+g^-$ in molecule B. The sequence $g^+g^-g^+g^-g^-$, with one C–O–C–C value far from 180°, is also observed in the sodium ion complex of BC6. Finally, the sequence $g^-g^-g^+g^+g^-$, with two C–O–C–C values far from 180°, has already been encountered in caesium complexes with monodentate nitrate [40] and thiocyanate [36] as counter-ions. The two non-bonding perrhenate counter-ions associated with molecules A and B are hydrogen bonded to a water molecule, which is also hydrogen bonded to one of the oxygen atoms of the complexed anion.

The case of complex **4** is even more unusual (Fig. 4). The asymmetric unit comprises one complete molecule. Two caesium ions, one of them with a 0.5 occupation factor (which corresponds to the location of the corresponding perrhenate ion on a binary axis), are complexed with different environments. Cs(2) is bound as usual to the six ether oxygen atoms [mean Cs–O distance 3.3(2) Å] and to a monodentate perrhenate ion [Cs–O distance 3.50(2) Å]. Its distance with respect to

the mean plane defined by the six oxygen atoms (deviation 0.38 Å) is 0.777(4) Å. The second cation [Cs(1)] is only bound to four ether oxygen atoms [mean Cs–O distance 3.1(1) Å, the other two distances can be considered too large for a coordinative bond] and displaced towards the calixarene aromatic cavity. The displacement of Cs(1) with respect to the usual location evidences the pulling effect of coordinated counter-ions or solvent molecules, whereas this effect was hindered in the sodium complex **1** by the co-complexation of a water molecule in the inner part of the calixcrown coordination site. This is the first occurrence of such a coordination mode in this family of compounds. The resulting coordination number is 4, which is unusual and presumably only possible in this case due to the Cs···π interactions involving the aromatic rings: the shortest $Cs(1)\cdots C_{aromatic}$ distances, involving the three carbon atoms of each ring opposite to the phenolic oxygen atom are in the range 3.14(2)–3.66(2) [mean value 3.4(2)] Å, which is the usual range. The complexation of caesium ions by polyhapto interactions in calix[4]arene systems in cone conformations has been described, with shortest Cs···C distances of 3.545(3) [41] and 3.53(1) Å [39a]. Cs(1) is located at 0.604(5) Å from the mean plane defined by the four bonding oxygen atoms (rms deviation 0.06). The calixarene core is no more distorted than in **2** and **3**, with dihedral angles between the aromatic rings and the plane defined by the four methylene bridges of 80.1(3), 76.2(3), 74.7(3) and 80.1(3)° [mean value 78(3)°], i.e. two rings more tilted than the others. The ether chains conformations correspond to O–C–C–O torsion angles sequences $g^-g^+g^-g^-g^+$ and $g^-g^+g^-g^+g^+$, for the crowns associated with Cs(1) and Cs(2), respectively, with in each case only one C–O–C–C angle value far from 180°. The peculiar coordination mode of Cs(1) is not associated with a particularly distorted crown conformation. The non-coordinated perrhenate ion is unremarkable. As a final remark, one can notice that the unit cells of **3** and **4** appear related one to the other, the expression of the cell parameters of **4** in terms of those of **3** being *c*, *b*, 2*a*, which reflects rather similar crystal packing, in spite of the chemical differences between the two compounds.

4. Conclusion

Some general conclusions can be drawn from this work, which are of interest in the scope of the perrhenate (or pertechnetate) extraction. In all the alkali-metal ion complexes reported herein, the perrhenate ion, present in excess in solution, has completely replaced the nitrate ion. ReO_4^- presents the same variety of coordination modes than NO_3^-, with a more current tendency to be non-coordinating (at least one cation is not bound in each of the caesium complexes structures **2**–**4**, whereas it has been observed only once among numerous caesium nitrate complexes [18]). An unusual phenomenon is the observation of all those coordination modes in different crystals from the same batch, which indicates that various forms are present in solution. The dissociation of the anion/cation pair observed in the case of the sodium cation is to be compared to the crystal structures reported in the cases of the tetrabenzo-24-crown-8 [9c] and 25,26,27,28-tetrakis[(ethoxycarbonyl)methoxy]-*p*-*tert*-butylcalix[4]arene [12] complexes, in which the perrhenate ion is not bound to sodium. However, in the last two cases, the origin of the dissociation is likely to be found in the high coordination number provided by the ligand (8 in both complexes) and in steric effects (the geometry of the ligand does not permit a close approach of the anion), whereas, in complex **1**, the very low coordination number and the geometry would make the anion bonding likely. These results give some clues to explain the extraction experiments. When one or two benzenic units are included in the crowns of calix[4]arene mono or bis(crown-6), a strong decrease in sodium nitrate or nitric acid extraction occurs, which is linked to the lipophilic character of the aromatic units, thus enhancing the selectivity for caesium ions [34]. On the other hand, as indicated above, the pertechnetate (or perrhenate) ions are less extracted by calix[4]arene bis(naphthocrown-6) than by the other members of the series, which all give similar extraction results. The explanation which can be proposed is that those anions, which can be more distant from the calixarene than nitrate ions, are likely to be less sensitive to the presence of aromatic units on the crown, except for the bulky and very lipophilic naphtho units.

5. Supplementary data

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Center, deposition numbers CCDC 141077 (**1**), 141078 (**2**), 141079 (**3**) and 141080 (**4**). Abstract

With doubly protonated piperazine or ethylenediamine as cations, eight Th(IV) malonato or substituted malonato complexes have been prepared and characterised by elemental analysis, thermal analysis, IR and ^{13}C CPMAS NMR spectroscopy. One polymeric U(IV) malonato complex has also been prepared and characterised by elemental analysis, thermal analysis and IR spectroscopy. $(C_4H_{12}N_2)_2[Th(C_3H_2O_4)_4]\cdot H_2O$ (**2**), $(C_2H_{10}N_2)_2[Th(C_3H_2O_4)_4(H_2O)]$ (**3**), $(C_4H_{12}N_2)_2[Th(C_4H_4O_4)_4]\cdot 2H_2O$ (**4**), $(C_2H_{10}N_2)_2[Th(C_5H_6O_4)_4]\cdot 5H_2O$ (**6**) and $[U(C_3H_2O_4)_2(H_2O)_3]_n$ (**9**) have been further characterised by single-crystal X-ray diffraction. Two types of monomeric anion structure are identified in the Th compounds: four 1,5-bidentate ligands in a distorted square antiprismatic geometry, giving coordination number (CN) 8; and four 1,5-bidentate ligands and a coordinated H_2O molecule in a capped square antiprismatic geometry, giving CN 9. The U compound has a 3D polymeric structure, with U in an approximately capped square antiprismatic geometry, achieving CN 9 from two 1,5-bidentate ligands, each of which also bridges through a carbonyl oxygen to an adjacent U centre, and three H_2O molecules. In the crystallographically-characterised Th compounds, the Th–O and C–O distances are correlated with the carbonyl resonance positions in the ^{13}C CPMAS NMR spectra, allowing prediction of structural types in the non-crystalline compounds. © 2000 Elsevier Science Ltd. 1. Introduction

Uranyl carboxylato complexes have been extensively studied for many years and a wide variety of structural types, including monomers, dimers, 1D infinite chains, 2D sheets and 3D polymers have been identified. It has been suggested that the structures of uranyl carboxylate compounds may be rationalised in relation to ligand size, additional functionality and stoichiometry [1]. To test this hypothesis, a systematic study of the coordination chemistry of uranyl with malonate and substituted malonates has recently been undertaken [2,3]. Structural diversity in the solid state can be achieved by varying counter-cations and by slight modification of the ligand substituent groups [2,3]. The two axial oxygen atoms of the uranyl ion confine coordination of the ligands to the equatorial plane and thus exert a considerable influence on the coordination chemistry, giving overall coordination numbers (CNs) of 6, 7 or 8. By contrast, there is no such stereochemical restriction of the coordination sphere for tetravalent actinide ions [An(IV)] [4], so a comparative study of the coordination chemistry of An(VI) and An(IV) with malonate-type ligands may aid the identification of the general principles governing of complexation of actinides by hard, O-donor chelating ligands. Unfortunately there is little relevant information in the literature and, indeed, there are no reports of structurally characterised Th(IV) or U(IV) malonato complexes. By contrast, several ox-

alato complexes of U(IV) and Th(IV) are well-characterised [5–7], although synthetic and structural differences from the malonato analogues might now be expected. In this paper we report the synthesis of eight Th(IV) and one U(IV) malonato or substituted malonato compounds, the further characterisation of these compounds by spectroscopic techniques and, in five cases, by X-ray crystallography.

2. Experimental

2.1. Synthesis

All chemicals were reagent grade, purchased from Strem Chemicals, Aldrich or Lancaster and used without further purification unless otherwise specified. Reactions were carried out in hydroxylic media (H_2O and MeOH) with an initial metal to ligand ratio of 1:2 for **1** and 1:4 for the other preparations. All manipulations of U(IV) were carried out in a dinitrogen atmosphere.

2.2. Preparation of bis(malonato)thorium(IV) trihydrate

$Th(C_3H_2O_4)_2{\cdot}3H_2O$ (**1**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of malonic acid (0.21 g, 2 mmol) in H_2O (30 cm^3). A white solid product formed after a few hours, was collected by filtration and dried in air, yield 95%. *Anal.* Found: C, 15.00, H, 2.00, Th, 47.55. Calc. for $C_6H_{10}O_{11}Th$: C, 14.70, H, 2.08, Th, 47.34%. IR (KBr disc, cm^{-1}): 3374 m, 3248 w, 3026 w, 1673 m, 1613 vs (br), 1413 w, 1381 m, 1316 w, 1289 w, 1203 w, 1086 w, 953 m, 934 m, 866 w, 702 s, 583 m). TG/DTA: 107°C (-4.3%, endo, $-H_2O = 4.2\%$), 214°C (endo), 309 and 399°C (-62.5%, both exo), residue 33.2%, $ThO_2 = 31.0\%$).

2.4. Preparation of bis(ethylenediammonium) tetrakis(malonato)aquathorate(IV)

$(C_2H_{10}N_2)_2[Th(C_3H_2O_4)_4(H_2O)]$ (**3**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of malonic acid and ethylenediamine (0.42 g, 4 mmol and 0.28 cm^3, 4 mmol, respectively) in H_2O (30 cm^3). The solution was left to stand for a week. A white crystalline product, formed by dropwise addition of MeOH (ca. 20 cm^3), was collected by filtration and dried in air, yield 85%. *Anal.* Found: C, 24.63, H, 4.00, N, 7.27, Th, 29.52. Calc. for $C_{16}H_{30}N_4O_{17}Th$: C, 24.56, H, 3.86, N, 7.16, Th, 29.65%. IR (KBr disc, cm^{-1}): 3457 vs (br), 1593 vs (br), 1426 m, 1350 w, 1274 w, 1197 w, 963 w, 936 w, 713 w). TG/DTA: 172°C (-2.5%, endo, $-H_2O = 2.2\%$), 204°C (endo), 342 and 419°C (-61.2%, both exo), residue 36.3%, $ThO_2 = 33.7\%$).

2.5. Preparation of bis(piperazinium) tetrakis(methylmalonato)thorate(IV) dihydrate

$(C_4H_{12}N_2)_2[Th(C_4H_4O_4)_4]{\cdot}2H_2O$ (**4**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of methylmalonic acid and piperazine (0.48 g, 4 mmol and 0.76 g, 4 mmol, respectively) in H_2O (30 cm^3). A white solid product formed after few days, was collected by filtration and dried in air, yield 85%. *Anal.* Found: C, 32.00, H, 5.00, N, 6.26, Th, 25.69. Calc. for $C_{24}H_{44}N_4O_{18}Th$: C, 31.72, H, 4.88, N, 6.16, Th, 25.54%. IR (KBr disc, cm^{-1}): 3478 m (br), 3248 w, 3004 w, 1625 s, 1597 s, 1414 s, 1350 m, 1281 m, 1011 m, 931 m, 869 w, 768 w, 684 m, 585 w). TG/DTA: 140°C (-3.7%, endo, $-2H_2O = 3.9\%$), 226°C (endo), 320°C (exo, -64.4%), residue 31.7%, $ThO_2 = 29.1\%$).

2.6. Preparation of bis(piperazinium)tetrakis(dimethylmalonato)thorate(IV)

$(C_4H_{12}N_2)_2[Th(C_5H_6O_4)_4]$ (**5**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of dimethylmalonic acid and piperazine (0.52 g, 4 mmol and 0.76 g, 4 mmol, respectively) in H_2O (30 cm^3). A white solid product formed overnight, was collected by filtration and dried in air, yield 80%. *Anal.* Found: C, 35.93, H, 5.14, N, 5.98, Th, 24.61. Calc. for $C_{28}H_{48}N_4O_{16}Th$: C, 36.21, H, 5.21, N, 6.03, Th, 24.98%. IR (KBr disc, cm^{-1}): 3458 m (br), 3000 w, 2454 w, 1636 vs, 1596 w, 1562 m, 1466 m, 1406 s, 1353 s, 1299 m, 1206 s, 1089 w, 897 s, 803 w, 768 w, 689 m, 586 w, 504 w). TG/DTA: 259°C [-42.9%, endo, $-2(\text{cation} + \text{ligand}) = 42.7\%$], 383°C (exo, -27.0%), residue 30.1%, $ThO_2 = 28.4\%$).

2.7. Preparation of bis(ethylenediammonium) tetrakis(dimethylmalonato)thorate(IV) pentahydrate

$(C_2H_{10}N_2)_2[Th(C_5H_6O_4)_4]\cdot 5H_2O$ (**6**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of dimethylmalonic acid and ethylenediamine (0.52 g, 4 mmol and 0.28 cm^3, 4 mmol, respectively) in H_2O (30 cm^3). A white crystalline product formed after a week, was collected by filtration and dried in air, yield 65%. *Anal.* Found: C, 30.30, H, 5.65, N, 6.00, Th, 24.01. Calc. for $C_{24}H_{54}N_4O_{21}Th$: C, 29.82, H, 5.63, N, 5.79, Th, 24.00%. IR (KBr disc, cm^{-1}): 3451 vs (br), 1632 vs, 1561 w, 1460 w, 1402 s, 1385 w, 1352 m, 1200 m, 892 m, 795 w, 720 w, 688 w, 582 w). TG/DTA: 55°C (-2.1%, endo, $-H_2O = 2.0$%), 228°C (endo), 362°C (exo, -66.8%), residue 31.2%, $ThO_2 = 29.5$%).

2.8. Preparation of bis(piperazinium) tetrakis(diethylmalonato)thorate(IV) hexahydrate

$(C_4H_{12}N_2)_2[Th(C_7H_{10}O_4)_4]\cdot 6H_2O$ (**7**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of diethylmalonic acid and piperazine (0.64 g, 4 mmol and 0.76 g, 4 mmol, respectively) in H_2O (30 cm^3). After a few hours, a white solid product formed, which was collected by filtration and dried in air, yield 70%. *Anal.* Found: C, 37.35, H, 6.35, N, 4.74, Th, 19.94. Calc. for $C_{36}H_{76}N_4O_{22}Th$: C, 37.63, H, 6.67, N, 4.88, Th, 20.19%. IR (KBr disc, cm^{-1}): 3468 vs (br), 3247 m, 2975 w, 1636 m, 1613 s, 1461 w, 1441 w, 1381 s, 1316 m, 1271 w, 1176 w, 1087 w, 1061 w, 950 m, 814 m, 742 w, 704 w, 570 w). TG/DTA: 64°C (-9.5%, endo, $-6\ H_2O = 9.4$%), 235°C (-39.3%, endo, -2(cation + ligand) = 40.0%], 390°C (exo, -24.4%), residue 25.8%, $ThO_2 = 23.0$%).

2.9. Preparation of bis(ethylenediammonium) tetrakis(diethylmalonato)thorate(IV) monohydrate

$(C_2H_{10}N_2)_2[Th(C_7H_{10}O_4)_4]\cdot H_2O$ (**8**). A solution of thorium nitrate tetrahydrate (0.55 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of diethylmalonic acid and ethylenediamine (0.64 g, 4 mmol and 0.28 cm^3, 4 mmol, respectively) in H_2O (30 cm^3). A white crystalline product formed after a few days, and was collected by filtration and dried in air, yield 75%. *Anal.* Found: C, 37.98, H, 5.86, N, 5.33, Th, 23.23%. Calc. for $C_{32}H_{62}N_4O_{17}Th$: C, 38.32, H, 5.83, N, 5.59, Th, 23.14%. IR (KBr disc, cm^{-1}): 3475 vs (br), 1638 s, 1619 s, 1384 s, 1318 w, 1274 w, 946 m, 818 m, 704 w, 581 w). TG/DTA: 61°C (-2.3%, endo, $-H_2O = 2.2$%), 239°C [-37.7%, endo, -2(cation + ligand) = 38.5%], 400°C (exo, -32.5%), residue 27.5%, $ThO_2 = 26.3$%).

2.10. Preparation of triaquabis(malonato)uranium(IV)

$[U(C_3H_2O_4)_2\cdot(H_2O)_3]_n$ (**9**). Uranium(IV) chloride (UCl_4) was prepared following a published method by reaction of UO_3 with excess hexachloropropene [8]. A solution of uranium(IV) chloride (0.38 g, 1 mmol in 5 cm^3 H_2O) was added to a solution of malonic acid and ethylenediamine (0.42 g, 4 mmol and 0.28 cm^3, 4 mmol, respectively) in H_2O (35 cm^3) under a dinitrogen atmosphere. A grey precipitate formed immediately and was redissolved by adding malonic acid (0.21 g, 2 mmol in 5 cm^3 H_2O). A dark green crystalline product formed after few weeks and was collected by filtration and vacuum dried in a desiccator, yield 50%. *Anal.* Found: C, 14.72, H, 2.00, U, 47.71. Calc. for $C_6H_{10}O_{11}U$: C, 14.53, H, 2.02, U, 47.98%. IR (cm^{-1}): 3317 s (br), 1589 s, 1563 s, 1449 m, 1361 m, 1264 w, 1168 w, 953 m, 808 w, 768 w, 649 w). TG/DTA: 61°C (-2.3%, endo, $-H_2O = 2.2$%), 239°C (-37.7%, endo, -2(cation + ligand) = 38.5%), 400°C (exo, -32.5%), residue 27.5%, $UO_2 = 26.3$%).

2.11. Crystallography, thermoanalysis and ^{13}C CPMAS NMR spectroscopy

Crystallographic data for compounds **2**–**4**, **6** and **9** were collected and analysed as summarised in Table 1. Thermogravimetric and differential thermal analysis was carried out on a Seiko (TG/DTA 220) Thermal Analyser over a temperature range from ambient to approximately 600°C, at a heating rate of 10 C min^{-1} and an air flow rate of 100 cm^3 min^{-1}. High resolution ^{13}C NMR spectra were recorded at 75.4 MHz using the cross polarisation-magic angle spinning (CPMAS) technique on a Varian Unity-300 spectrometer with a spinning speed of ca. 4.0 kHz. The acquisition time was 0.050 s, spectral width was 30 007.5 Hz, contact time was 1.5 ms and recycle time was 3.000 s. The chemical shift scale was referenced by setting the CH_3 peak in a sample of solid hexamethylbenzene, run using the same conditions, to 16.5 ppm.

3. Results

3.1. Synthesis

The effects of initial metal:ligand (M:L) ratio and of the presence of N-base can be illustrated using malonic acid as proligand and piperazine as an N-base. In the case of Th, if the proligand is not neutralised to produce a countercation, the neutral product **1** with M:L = 1:2 forms, regardless of the initial M:L ratio. If the malonic acid is neutralised by piperazine, the products vary according to the initial M:L ratio. The 1:2 neutral product forms from a starting stoichiometry of

1:2, while the 1:4 anionic product forms with an initial stoichiometry of 1:4 or higher. In all cases, there is no evidence of NO_3^- being retained as a ligand in the resultant solid products. By contrast, the U compound **9**, with M:L = 1:2, forms under conditions which, in the case of Th, led to the 1:4 compound **3**.

3.2. Crystallography

Selected bond lengths and angles for **2**–**4**, **6** and **9** are listed in Tables 2–6. The asymmetric unit of **2** contains half of the molecule and the other half can be generated by a twofold symmetry operation. The cation is unexceptional. The anion structure is shown in Fig. 1. The thorium atom is eight-coordinate with four terminal 1,5-bidentate ligands, giving a monomeric structure. It has a distorted square antiprismatic geometry with significantly different Th–O distances, 2.337(2) Å for O(1), an average of 2.395(2) Å for the O(5) and O(7) atoms from the same ligand and 2.450(2) Å for O(3). The ligands have boat conformations flattened at the Th end.

The asymmetric unit of **3** contains a whole molecule with one cation unexceptional and the other disordered. The anion structure is shown in Fig. 2. The thorium atom is coordinated by four 1,5-bidentate malonate ligands and one H_2O molecule, giving the thorium atom a CN of 9. It has approximately a mono-capped

square antiprismatic geometry (Fig. 3), with the capped square face of the antiprism being more planar than the uncapped one. The average Th–O distances are 2.416(5) Å for O(2), O(1), O(6) (which comprise the capped face) and O(5), 2.448(5) Å for O(9) and O(14), 2.469(5) Å for O(10) and 2.564(5) Å for O(17), the H_2O molecule. One ligand has a boat conformation while the other three are puckered.

The asymmetric unit of **4** contains a quarter of the molecule and the other three quarters can be generated by three twofold symmetry operations. The cation is unexceptional. The anion structure is shown in Fig. 4. The thorium atom is coordinated by four 1,5-bidentate methylmalonate ligands, giving a monomeric structure with the thorium atom in eight-coordination and Th–O distances of 2.393(2) Å for O(1) and 2.406(2) Å for O(2). It has a distorted square antiprismatic geometry and the ligand is puckered, so no typical conformation can be assigned to it.

The asymmetric unit of **6** contains a whole molecule with two slightly different cations. The anion structure is shown in Fig. 5. The thorium atom is coordinated by four 1,5-bidentate ligands giving the thorium atom a CN of 8. It has a distorted square antiprismatic geometry with Th–O distances ranging from 2.372(5) Å for O(5) to 2.448(5) Å for O(2). One ligand has a boat conformation flatted at the Th end, but the other three ligands are puckered and no typical conformations can be assigned to them.

Selected bond lengths and angles for **9** are listed in Table 5. The asymmetric unit consists of a uranium atom located on a twofold axis along the U–O(6) direction, a 1,5-bidentate ligand and two-coordinated H_2O molecules. The full structure is generated by the twofold symmetry and the coordination polyhedron of uranium is shown in Fig. 6. The uranium atom has, approximately, a mono-capped square antiprismatic geometry (Fig. 7), with the two remaining coordination positions filled by carbonyl oxygen atoms, O(4) and O(4A), one of which, O(4), is the capping atom. The CN of 9 [2 O(1), 2 O(2), 2 O(3), 2 O(4) and 1 O(6)] is achieved through two tridentate ligands (1,5-bidentate to one uranium atom and μ_1 bridging to another uranium atom through a third O atom of one carboxylate group) and three H_2O molecules, forming a 3D polymeric structure. The U–O distances for the chelate malonate ligand are 2.315(4) Å for O(3) and 2.434(4) Å for O(2). For the bridging O atom, O(4), the U–O distance is 2.420(4) Å. There are two kinds of coordinated H_2O molecules, one O(6) with a U–O distance of 2.414(5) Å and two symmetry equivalent O(1)'s with a longer U–O distance (2.483(4) Å). The chelate malonate ligand has a boat conformation flattened at the U end.

4. Discussion

4.1. Structural comparison

Several tetrakis(oxalato)thorate(IV) and uranate(IV) compounds have been previously characterised by X-

ray crystallography [5–7]. Structural data for $K_4[Th(C_2O_4)_4]\cdot 4H_2O$ (**10**), $K_4[U(C_2O_4)_4]\cdot 4H_2O$ (**11**) and $Ba_2[U(C_2O_4)_4(H_2O)]\cdot 7H_2O$ (**12**) together with those of the thorium(IV) malonato and substituted malonato compounds characterised in this study are summarised in Table 7. Compounds **10** and **11** are isostructural, with the metal centres coordinated by three 1,4-bidentate oxalate ligands and two tetradentate bridging ligands, forming an infinite chain structure with thorium or uranium in ten-coordination, approximately in a bicapped square antiprismatic geometry. With this relatively high CN, the coordination sphere is crowded, giving long average M–O distances (2.49(2) Å for Th–O and 2.467(8) Å for U–O). For the barium compound (**12**), monomeric $[U(C_2O_4)_4(H_2O)]^{4-}$ anions with four 1,4-bidentate oxalate ligands and a coordinated H_2O molecule were identified [7], suggesting that the size and coordination polyhedron of the cations are an important control on structural type. In the Th malonates, the size of the protonated N-base cations may thus lead to the eight- and nine-coordinate monomeric structures observed.

There is a strong correlation between CN and mean Th–O distance (Fig. 8), with an increase of 1 in CN

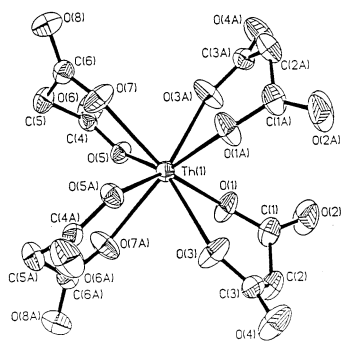

Fig. 1. An ORTEP drawing of the anion structure in **2** (50% probability ellipsoids).

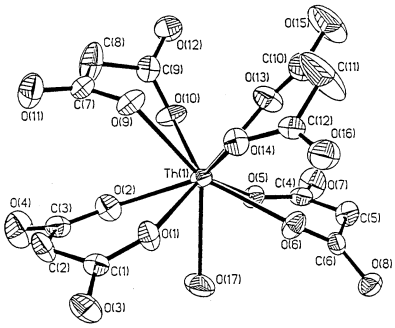

Fig. 2. An ORTEP drawing of the anion structure in **3** (50% probability ellipsoids).

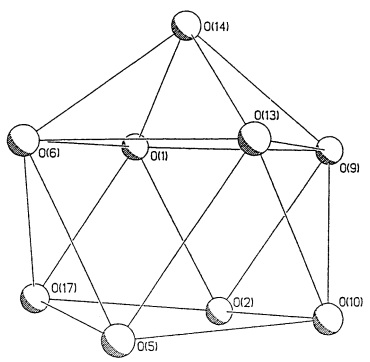

Fig. 3. Coordination polyhedron of Th in **3**.

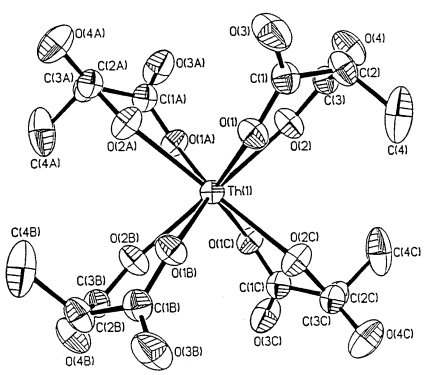

Fig. 4. An ORTEP drawing of the anion structure in **4** (50% probability ellipsoids).

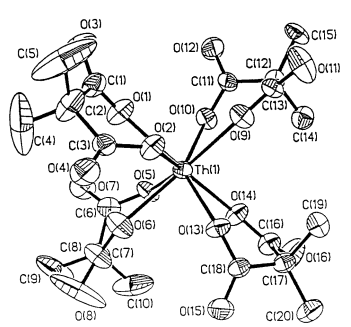

Fig. 5. An ORTEP drawing of the anion structure in **6** (50% probability ellipsoids).

leading to an increase of around 0.04 Å in mean interatomic distance. There is also apparently a similar relationship for the U compounds although, for a given CN, the U–O distance is around 0.04 Å shorter than the Th–O distance, consistent with the smaller radius of the U^{4+} cation. This relationship also suggests that the mean U–O distance in an eight-coordinate U^{4+} oxalate or malonate complex would be around 2.36 Å, which is perhaps a little short to permit easy adoption of such a CN.

Recent EXAFS studies of the coordination of tetravalent actinide ions with water and carbonate ligands have given first shell coordination numbers and distances of 10.8 at 2.45 for Th with H_2O [9], 10.8 at 2.42 for U with H_2O [9], 11.2 at 2.40 for Np with H_2O [10] and 10 at 2.42 for $[Pu(CO_3)_5]^{6-}$ [11]. There is no obvious reflection of the actinide contraction in these CNs although this may be a result of the uncertainties in the EXAFS analysis, which is typically ± 1. However, in the aquo complexes there is perhaps evidence of a decrease in interatomic distance from Th to Np. These ligands are clearly much more compact than malonate and in the malonate complexes described here, the larger size of the ligands would be expected to lead to longer interatomic distances for relatively lower CNs.

4.2. Thermogravimetric and differential thermoanalysis

The compounds decompose in two main steps, the first being dehydration and the second decomposition of organic components to leave a final residue of the dioxide [12,13]. In principle, this gives a method of distinguishing between ligating and lattice water molecules and hence can give an indication of CN.

Compounds **2**, **4** and **6** have monomeric anion structures with CN 8 and lose their lattice H_2O molecules at 107, 140 and 55°C, respectively. The higher dehydration temperature for **4** (140 C) is probably due to the lattice H_2O molecules being trapped in the crystal packing (see above). Compound **3** also has a monomeric anion structure but includes a coordinated H_2O molecule to give a CN of 9. This is only lost at 172°C. The DTA curve of **9** is complex, with several overlapping features, although the first change is endothermic and starts at 185°C. This relatively high temperature is consistent with the presence of coordinated H_2O molecules, as identified by X-ray crystallography.

Compound **1** loses three H_2O molecules at 186°C, suggesting that in **1** the three H_2O molecules are coordinated to the thorium centre and that it may be structurally similar to **9**. By contrast, **6**, **7** and **8** lose their H_2O molecules at low temperature (about 60°C), suggesting that they do not contain coordinated H_2O molecules and therefore have a CN of 8. The final residual mass from all the Th compounds is generally

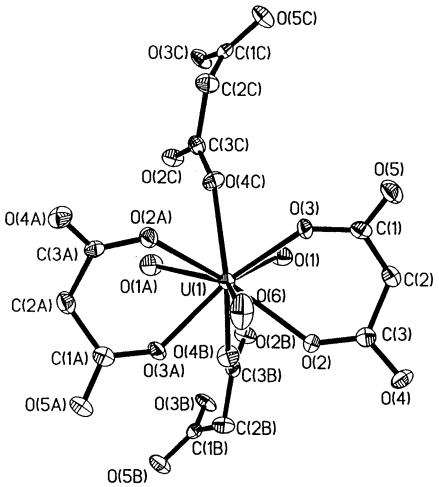

Fig. 6. An ORTEP drawing of the structure of **9** (50% probability ellipsoids).

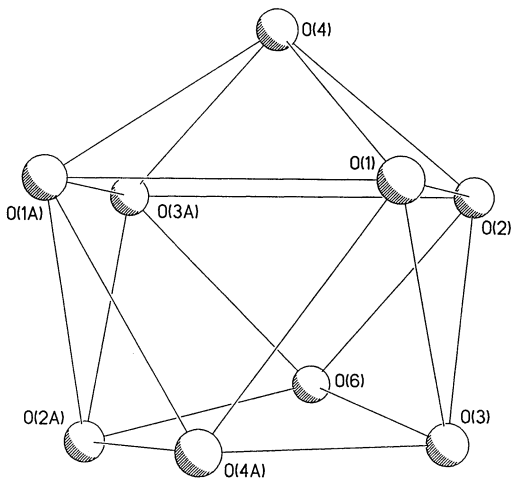

Fig. 7. Coordination polyhedron of U in **9**.

2–3% higher than expected for a pure ThO_2 product, suggesting that the final residue could be a mixture, for example, of thorium oxide and carbonate. Elemental analysis of the TGA/DTA residues confirms that there is a trace of carbon in the final products. Compound **9** decomposes to UO_2, again containing a trace of carbon.

4.3. ^{13}C CPMAS NMR spectroscopy

Expansions of the carbonyl region of the ^{13}C CPMAS NMR spectra of **1**–**8** are shown in Fig. 9 and the chemical shifts are listed in Table 8. Generally, the chemical shift, $\delta_{C=O}$, increases with the bulk of the substituent groups on the ligand. The stoichiometry, TG/DTA data and ^{13}C CPMAS NMR for **7** and **8** are similar to those of **2**, suggesting they have similar monomeric anion structures. Compounds **4** and **5** have very similar ^{13}C CPMAS NMR spectra although the former has H_2O molecules in the lattice. Compound **1** has a different stoichiometry to the rest. Compound **9** is paramagnetic and it was not possible to obtain a ^{13}C CPMAS NMR spectrum.

The ^{13}C CPMAS NMR results can be related to the known crystal structures using the crystallographic data and carbonyl (^{13}C CPMAS) patterns summarised in Table 9. The anionic structure of **2** has a twofold symmetry axis, so that four carbonyl peaks might be expected in its ^{13}C CPMAS NMR spectrum. Experimentally three carbonyl peaks are observed, and these correlate with three distinct groups of Th–O and/or C–O distances. The anion in **4** has three twofold symmetry axes, so two carbonyl peaks may be expected in its ^{13}C CPMAS NMR spectrum. One carbonyl peak is actually observed, reflecting the similarity of the Th–O and/or C–O distances. The anionic structures of **3** and **6** have no crystallographically imposed symmetry so, in principle, eight carbonyl peaks might be expected. In practice, four distinct groups of Th–O and C–O distances can be identified in the crystal structure and these correspond to the four carbonyl peaks observed in the ^{13}C CPMAS NMR spectra. The groupings of Th–O and C–O distances are not directly correlated, so consideration of either or both could account for the structure of the ^{13}C NMR spectra. There is no obvious relationship between C=O distances and the patterns in the carbonyl region of the ^{13}C NMR spectra.

Table 7
Structural comparisons of dicarboxylato compounds of U(IV) and Th(IV)

Compound	structural type	CN	M–O distances (Å)	Average (Å)	Ref.

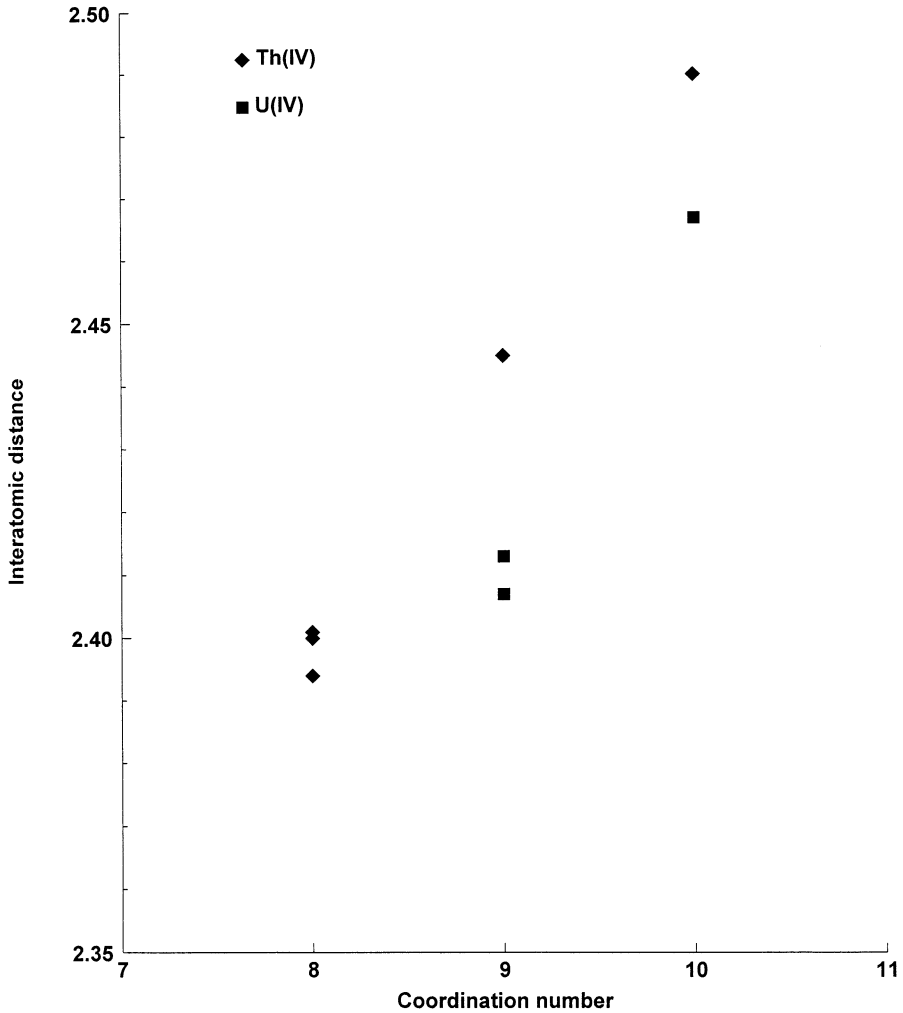

Fig. 8. Relationship between CN and mean interatomic distance in U(IV) and Th(IV) dicarboxylate complexes.

4.4. Infrared spectroscopy

Infrared spectroscopy has been widely used as a fingerprint method for metal carboxylates, with the difference in wavenumber between the antisymmetric and symmetric carboxylate mode, $\Delta\nu$ ($=\nu_{as}-\nu_{s}$), often being used to estimate bonding types [14–19]. Several attempts have been made to rationalise and distinguish structures of carboxylate groups by values [18–20]. Since the symmetric and antisymmetric stretching frequencies are highly sensitive to the structures and environments of the carboxylate groups, the nature of the accompanying ligands and the identity of the central metal ion, the bonding type predicted with IR spectroscopic data is often at variance with the real bonding, as determined from the crystal structures [21,22]. IR spectra of some Th(IV) acetato and halogenoacetato complexes have been reported [23], but no attempt has been made to predict bonding modes. Because of the generally low symmetry, the antisymmetric and symmetric stretching frequencies are normally split. The carboxylate stretching frequencies for the compounds studied here are summarised in Table 10. The values range from 140 to 260 cm^{-1} and perhaps fall into two groups, 160–211 and 230–260 cm^{-1}. However, the crystallographically characterised compounds, all of which contain 1,5-bidentate ligands, cover a wide range of values from 167 to 260 cm^{-1}, which suggests that any grouping of the values is fortuitous. Only compounds **1** and **9** have values as low as 140 cm^{-1}, which may be a characteristic of the slightly different bonding type in **9**, where bridging carbonyl groups are present. The similarity in values for **1** and **9** (Table 10), which have the same stoichiometry, supports the suggestion, from thermal analysis, that **1** could have a similar 3D polymeric structure to **9**.

5. Conclusions

Dicarboxylate complexes of the early actinides are readily formed in aqueous media, with oxalate and malonate being good examples. In the case of UO_2^{2+}, CN 4, 5 or 6 in the equatorial plane has been observed and a range of structural types has been identified in the solid state. Variable CN (8, 9 or 10) is also possible for Th^{4+}, while CN 9 and 10 have been identified for U^{4+}, but without the stereochemical control exerted by the axial O groups in UO_2^{2+}. Under reaction conditions in which bridging occurs in UO_2^{2+} complexes, CN of 8 or 9 are observed for Th^{4+} without any tendency to form bridges. By contrast, there appears to be a single favoured, bridging structure for U^{4+} in these conditions. Metal–ligand bond distances in Th^{4+} and U^{4+} malonate and oxalate complexes, determined from X-ray crystallography, are strongly correlated

Abstract

New unsymmetrical binuclear copper(II) complexes of the general formula $[Cu_2L(X)]ClO_4$, (X = OH, OAc) have been prepared by in situ complexation of the compound 3-[*N*-methyl-*N*-(2-hydroxy-3,5-dichlorobenzyl)aminomethyl]-5-bromosalicylaldehyde (**mhdab**) with various primary amines, copper(II) perchlorate and appropriate sodium salt. Positive ion FAB mass spectral studies of the complexes show the presence of a dicopper core in the complexes. Electronic spectra of the complexes show a broad band for the d–d transition in the region around 635–685 nm. A cyclic voltammetric study of the complexes shows two quasi-reversible reduction waves in the range $E^1_{pc} = -0.52$ to -0.86 V and $E^2_{pc} = -1.02$ to -1.16 V, and the reduction potentials are sensitive towards the chemical environment around the copper atoms. Cryomagnetic investigation of the complexes shows a moderately strong antiferromagnetic spin exchange interaction between the two copper(II) ions ($-2J$ 60–170 cm^{-1}). ESR spectra of the complexes show a broad band at room temperature. The electrochemical and magnetic properties of the complexes are compared on the basis of the rigidity and conjugation of the ligands H_2L^1, H_2L^2 and H_2L^3. © 2000 Elsevier Science Ltd. Keywords: Binuclear Cu(II) complexes; Magnetic properties; Electrochemistry; ESR

Interest in the synthesis of new binuclear copper(II) complexes is mainly due to their applications in bioinorganic chemistry, magnetochemistry and homogeneous catalysis. Copper is an essential trace element for life processes and several copper-containing proteins have been identified. In particular, a dicopper active center is found in many copper proteins like hemocyanin, tyrosinase and also in multinuclear proteins like laccase, ceruloplasmin, catechol oxidases and ascorbate oxidase [1–4]. Although all these proteins contain binuclear copper active sites, their functions, nature of the amino acid coordination and stereochemistry of the active site vary. Understanding the functional and structural properties of these binuclear active site by developing small dicopper complexes as models for these metalloproteins is the main objective of bioinorganic chemistry, which links the chemistry of coordination complexes and life processes. In magnetochemistry, the study of magnetic properties of these dicopper complexes offered considerable information about the basic factors governing the superexchange phenomenon, which is very much important in understanding the physics of magnetic materials, superconductivity and in the construction of molecular ferromagnets [5]. From Robson's pioneering work on binuclear copper(II) complexes, most of the work is concerned with the studies of symmetrical dicopper complexes and the study of unsymmetrical dicopper complexes is sparse [4,6]. Synthesis of unsymmetrical binucleating ligands and their copper(II) complexes has gained attention in recent years with the establishment of the unsymmetrical nature of the active site of hemocyanin [7] and tyrosinase [8]. The present work deals with the synthesis, spectral, electrochemical and magnetic properties of a few unsymmetrical binuclear copper(II) complexes.

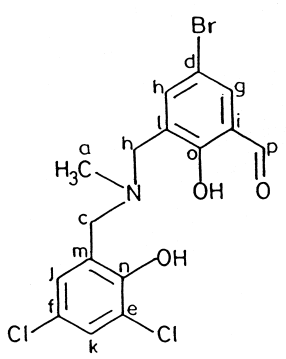
1. Experimental

1.1. Materials and methods



All the chemicals were obtained from commercial sources and used without any further purifications. 2-Aminophenylbenzimidazole [9] and 2-methylaminoethyl-4,6- dichlorophenol [10] were prepared by following the literature procedures. Commercial grade methanol was distilled from quick lime and used. HPLC grade dimethylformamide was purchased from Qualigens's fine chemicals. Elemental analyses were carried out using a Carlo Erba elemental Analyser Model 1106. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ using a JOEL GSX 400 NMR spectrometer. Mass (EI) spectra were recorded on a JMS-DX303 HF Mass spectrometer. Positive ion fast atom bombardment (FAB) mass spectra were recorded on a SX 102/DA-6000 mass spectrometer in which the matrix solvent used was 3-nitrobenzyl alcohol. IR spectra were recorded on a Hitachi 270-50 spectrophotometer in the spectral range 400–4000 cm^{-1} using KBr discs. Electronic spectra of the complexes were recorded using a Hewlett–Packerd 8452A spectrophotometer. Molar conductivity was measured by using an Elico model SX80 conductivity bridge using freshly prepared solution of the complex in DMF. Cyclic voltammograms were obtained on an apparatus comprising a PAR model 173 potentiostat/galvanostat, model 175 universal programmer, model 176 current/voltage convertor, 179 coulometer and a Perkin–Elmer Hitachi 057 X-Y recorder. The measurements were carried out under oxygen free condition using a three electrode cell in which the working and auxiliary electrodes were small platinum foils (1 × 1 cm) and the reference electrode was saturated Ag/AgCl. Tetra(*n*-butyl)ammonium perchlorate was used as supporting electrolyte. The magnetic susceptibility of the complexes was measured in the temperature range 77–300 K using a PAR model 155 vibrating sample magnetometer, and the instrument was calibrated with the use of metallic nickel. Room temperature magnetic moment of the complexes was measured using Guoy balance, in which $Hg[Co(SCN)_4]$ was used as the calibrant. X-band ESR spectra of the complexes were recorded on Varian EPR-E 112 spectrophotometer using DPPH as the reference.

1.2. Preparation of the precursor ligands

1.2.1. 3-[N-Methyl-N-(2-hydroxy-3,5-dichlorobenzyl)-aminomethyl]-5-bromosalicylaldehyde (**mhdab**)

2-Methylaminomethyl-4,6-dichlorophenol (2.05 g, 0.01 mol) and paraformaldehyde (0.33 g, 0.011 mol) were stirred in 75 cm^3 glacial acetic acid for 24 h. To this mixture 5-bromosalicylaldehyde (2.0 g, 0.02 mol) was added and stirred for 48 h. The mixture was heated on a water bath for 7 h and neutralized with solid Na_2CO_3. The residue was extracted with CH_2Cl_2. The solvent was evaporated. Column chromatographic separation on silica gel (4:1 CH_2Cl_2–MeOH) afforded the product. M.p. 97°C, Yield 1 g, (25%), IR KBr disc 1680 cm^{-1} for CHO, Mass (EI) $m/z = 416$ [M − 2]. *Anal.* Calc. for $C_{16}H_{14}BrCl_2NO_3$: C, 45.83; H, 3.34; N, 3.34. 1.3. Preparation of the complexes

The μ-phenoxo-μ-(X)-dicopper(II) complexes $[Cu_2L^{1-3}(X)]ClO_4$ (**1**–**6**) were prepared by following the general procedure [11]. To the precursor compound **mhdab** (0.42 g, 1 mmol), dissolved in 75 cm^3 of methanol, primary amine (1 mmol) (2-aminomethylpyridine for H_2L^1 or 2-aminophenylbenzimidazole for H_2L^2 or *N*,*N*-dimethylpropanediamine for H_2L^3) was added and refluxed for 2 h. The resulting solution was added to a solution of copper(II) perchlorate hexahydrate (0.75 g, 2 mmol) dissolved in 50 ml of methanol and refluxed for a further hour. The mixture was then reacted with one equivalent of NaX (X = OH, OAc), dissolved in 5 cm^3 of 1:4 water–methanol and refluxed for a further hour. The solid complex that deposited on slow evaporation of the solvent was filtered, washed with diethyl ether and dried.

1.3.1. $[Cu_2L^1(OH)]ClO_4 \cdot H_2O \cdot MeOH$ (1)

Dark green plates were deposited, which were filtered and dried, whereupon the crystals turned to green powder. *Anal.* Calc. for $C_{23}H_{25}BrCl_3Cu_2N_3O_9$: C, 34.45; H, 3.12; N, 5.24. 2. Results and discussion

2.1. Syntheses

Reaction of 5-bromosalicylaldehyde, 2-methylaminomethyl-4,6-dichlorophenol and paraformaldehyde in acetic acid medium afforded the desired precursor compound **mhdab**. The IR spectra of the compound showed the characteristic peak at 1680 cm^{-1} for the aldehyde group.

Condensation of the aldehyde **mhdab** with 2-aminomethylpyridine, 2-aminophenyl-benzimidazole and *N*,*N*-dimethylpropanediamine gave the ligands H_2L^1, H_2L^2 and H_2L^3, respectively (Fig. 1), which were complexed in situ with copper(II) perchlorate hexahydrate and appropriate sodium salt in methanol medium. In all the complexes the characteristic IR peak for the CHO group at 1680 cm^{-1} is absent and the characteristic peak for the C=N around 1610–1630 cm^{-1} is

observed, which indicates the effective condensation of the aldehyde group with the primary amines.

2.2. Spectroscopy

The positive ion FAB mass spectral study was carried out for selected complexes **1**, **4** and **6** to confirm the binuclearity of the complexes. All three complexes show the molecular ion peak assignable to the $[Cu_2L(X)]^+$ fragment. The molecular ion peak for complex **1** is observed at $m/z = 668$ for the $[Cu_2L^1(OH)H_2O]^+$ fragment, the molecular ion peak for complex **4** is observed at $m/z = 792$ for the fragment $[Cu_2L^2(OAc)]^+$ and complex **6** shows the molecular ion peak for the fragment $[Cu_2L^3(OAc)MeOH]^+$ at $m/z = 719$. The FAB mass spectrum of complex **4** is given in Fig. 2.

IR spectra of the complexes show the characteristic peak for the C=N group around 1610–1630 cm^{-1}, along with a broad band centered around 3400 cm^{-1}, indicating the presence of coordinated or lattice water and a strong symmetrical peak around 1100 cm^{-1}, indicating the presence of an uncoordinated ClO_4 ion in the complexes. A characteristic peak for the acetate of the complexes **2**, **4** and **6** was observed in the region 1540 cm^{-1}. The electronic spectra of the complexes were recorded in DMF, which show a weak band in the region around 635–685 nm for the d–d transition along with shoulders around 375–430 nm, which are most probably due to the charge transfer transitions originated from the phenolate to copper [12] or benzimidazole to copper [13]. The intense peak observed below 300 nm is assigned to the ligand–ligand charge transfer transition. Appearance of a single d–d band in the region around 650 nm indicates that the coordination geometry around the copper atoms is basically four-coordinated planar with weak axial interactions and the red shift in the λ_{max} value for complexes **1**, **2** and **5**, **6** with respect to the complexes **3**, **4**, indicates that the complexes of the ligands H_2L^1 and H_2L^3 have relatively more distorted geometry than the complexes of the ligand H_2L^2 [14].

2.3. Electrochemical studies

All the complexes show a molar conductance value in the range 45–60 Λ_m/S cm^2 mol^{-1} in DMF, which indicates that the complexes are 1:1 electrolyte in nature [15]. The cyclic voltammograms of the complexes show two redox waves in the cathodic potential region and the data are given in Table 2. Constant potential electrolysis of complexes **2** and **5** at 100 mV more negative to their first reduction potential consumed one electron per molecule and consumed two electrons per molecule at the potential −1.25 V, which indicates the involvement of two single electron transfers in the reduction processes. Based on the coulometric results,

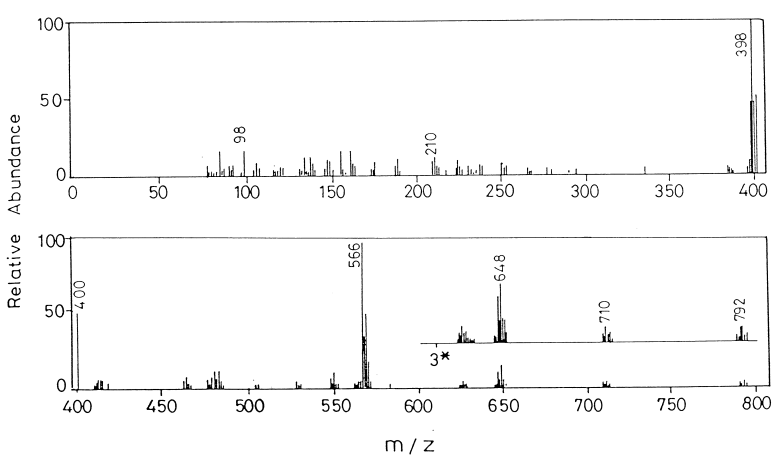

Fig. 2. FAB mass spectra for complex **4**.

Table 2
Electrochemical data for the complexes

Complex	E^1_{pc} (V)	E^1_{pa} (V)	$E^1_{1/2}$ (V)	ΔE (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E^2_{1/2}$ (V)	ΔE (mV)
1	−0.64	−0.50	−0.57	140	−1.15	−1.00	−1.07	150
2	−0.58	−0.46	−0.52	120	−1.05	−0.79	−0.92	260
3	−0.86	−0.62	−0.74	240	−1.11	−1.02	−1.06	90
4	−0.81	−0.55	−0.68	270	−1.10	−1.00	−1.05	100
5	−0.62	−0.34	−0.48	280	−1.12	−0.96	−1.02	280
6	−0.52	−0.32	−0.40	200	−1.02	−0.68	−0.85	340

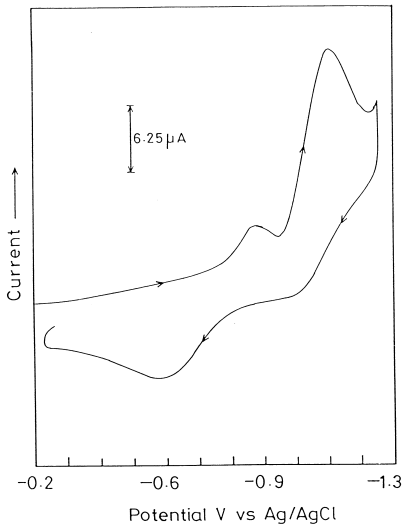

Fig. 3. Cyclic voltammogram for complex **3**.

the two reduction peaks observed in the cyclic voltammograms are attributed to the two stepwise one electron transfers as given below

$$[Cu(II)Cu(II)] \leftrightharpoons [Cu(II)Cu(I)] \leftrightharpoons [Cu(I)Cu(I)]$$

The cyclic voltammetric response of the complexes follow the typical characteristics of a quasi-reversible redox process. The cyclic voltammogram for complex **3** was given in Fig. 3.

A closer observation of the electrochemical data of the complexes of the ligands H_2L^1, H_2L^2 and H_2L^3 will be interesting to identify which end of the present unsymmetrical complexes is reduced first in one electron reductive processes. Although all the complexes undergo reduction at negative potentials, it is interesting to note that for all the complexes, irrespective of their exogenous bridging donor, there is a notable shift in the first reduction potential and there is only a minor shift in the second reduction potential. Since nitrogen is a soft donor when compared with the phenoxide oxy-gen [16], it is reasonable to say that the first reduction is associated with the copper atom in the ONN compartment in these ligands. The pronounced shift in the reduction potential is most probably due to the chemically different environments of this compartment. The second reduction peak observed at almost same potential seems to be associated with the copper atom in the ONO compartment, where the chemical environment is identical for all the three ligands.

From the table it is observed that the order of first reduction potential for the complexes of the ligand is $H_2L^3 < H_2L^1 < H_2L^2$. The NNO compartment comprises a *N*,*N*-dimethylpropanediamine side arm in the ligand H_2L^3, 2-methylpyridine in ligand H_2L^1 and 2′-phenylbenzimidazole in the ligand H_2L^2. The reduction observed at high negative potential for the complexes of the ligand H_2L^2 (**3**–**4**) may be the result of the greater planarity of the complexes induced by the rigidity [17] due to direct attachment of the benzimidazole group [18] to the phenyl ring and conjugation [19] of the phenylbenzimidazole side arm. Further, the complexes of the ligand H_2L^3 undergo reduction at less negative potential when compared with the complexes of the H_2L^1 ligand. The easy reduction of the complexes of the ligand H_2L^3 may be due to the more flexible [20] nature of the *N*,*N*-dimethylpropanediamine side arm when compared with the 2-methylpyridine side arm.

A comparison of the reduction potentials of the complexes of a particular ligand indicates that the reduction potential is exogenous, bridging donor dependent and the acetato bridged complexes undergo reduction at less negative potential when compared with the hydroxo bridged complexes. This behaviour seems to be associated with the increased number of atoms (–O–C–O–) involved in the acetate bridge, which may provide more flexibility for the acetato bridged complexes as against the hydroxo bridged complexes.

2.4. Magnetic properties

The magnetic moments of the complexes are subnormal at room temperature, suggesting the presence of an antiferromagnetic interaction within the complex. A variable temperature magnetic moment measurement was carried out for complexes **1**–**3**, **5** and **6** in the temperature range 77–300 K to evaluate the temperature dependence of magnetic properties of the complexes. Analyses were carried out by fitting the experimental

Table 3
Temperature dependence magnetic parameters and ESR spectrum data for the complexes

Complex	μ_{eff} (BM per molecule)		$-2J$ (cm^{-1})	P (%)	ESR data (g)	
	298 K	77 K			$g_{\|\|}$	$g_{\perp}$
1	2.19	1.17	82	0.25	2.19	2.06
2	2.35	1.06	59	0.18	2.18	2.02
3	1.86	1.10	167	0.51	2.05	
4	1.92				2.20	
5	2.15	1.08	97	0.19	2.08	2.02
6	2.64	1.56	56	0.45	2.20	2.01

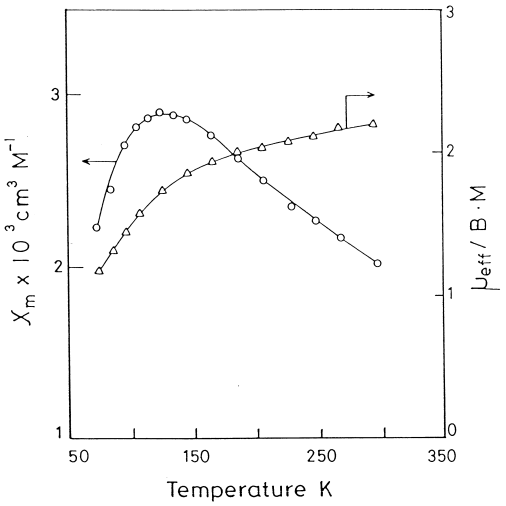

Fig. 4. Temperature dependence of magnetic properties for **1**.

susceptibility values to the modified Bleaney–Bowers equation.

$$\chi_m = (Ng^2\beta^2/3kT)\,[3 + \exp(-2J/kT)]^{-1}\,(1 - P) + (0.45P/T) + N\alpha$$

where χ_m is the molar magnetic susceptibility of the complex, P is the percentage of monomeric impurities and other symbols have their usual meanings. $N\alpha$ and g have been fixed as 120×10^{-6} cm^3 mol^{-1} and 2.20, respectively for all magnetic simulations. The best fit parameters are tabulated in Table 3. Temperature dependence of the magnetic properties for complexes **1** is given in Fig. 4.

The exchange integral values ($-2J$) observed for the complexes is in the range 60–170 cm^{-1}, which indicates the presence of antiferromagnetic coupling between the copper atoms. A comparison of the observed $-2J$ value of the complexes **1**, **3** and **5** shows that for the phenylbenzimidazole substituted complex **3**, the $-2J$ value is 167 cm^{-1}, indicating the strong antiferromagnetic coupling between the copper atoms when compared with complexes **1** and **5** ($-2J = 82$ and 97 cm^{-1}, respectively). In the complexes of all the three ligands reported in the present work, the geometry around the phenolic side arm (ONO) would be the same, but the geometry around the other copper atom (ONN) will be different due to the variations in chemical environments. As observed in the electrochemical properties of the complexes, the most probable reason for the strong exchange interaction may be the planarity of the phenylbenzimidazole compartment due to rigidity and conjugation of the phenylbenzimidazole side arm, which seems to reduce the dihedral angle between the two copper planes, thereby causing effective antiferromagnetic coupling in the complex. Relatively less exchange interaction observed in complexes **1** and **5** may be due to the flexibility of the *N*,*N*′-dimethylpropanediamine side arm of the ligand H_2L^3 and five membered ring formation in complex **1** of the ligand H_2L^1, which may increase the dihedral angle between the copper planes, resulting in a weak exchange interaction in these complexes. The variation in the $-2J$ values of complexes **1**, **2** or **5**, **6** is due to the effect of the exogenous bridging donor. The higher $-2J$ value observed for the acetato-bridged complexes when compared with their corresponding hydroxo bridged complexes is possibly due to the counter-complementary nature of the overlap of the magnetic orbitals involving the monoatomic and three atom bridging ligands [21–23].

2.5. EPR spectroscopy

Room temperature ESR spectra of the complexes were studied. The ESR spectra of complexes **1**, **3** and **5**

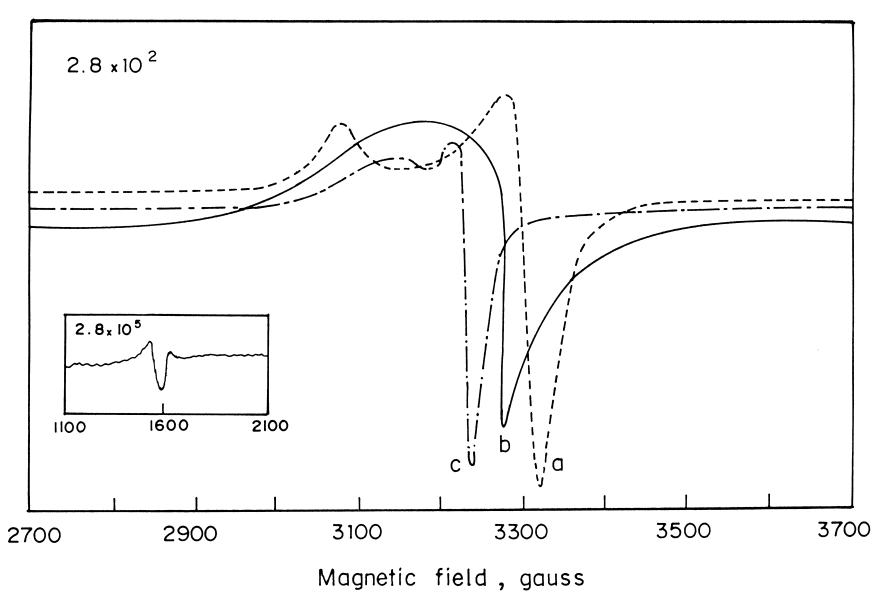

Fig. 5. ESR spectra for complex (a) **1**; (b) **3** and (c) **5**. The half-field signal for complex **3** is inserted.

are given in Fig. 5. The g value of the complexes was evaluated using the relationship $h\upsilon = g\beta H$ and given in Table 3. The ESR spectra of the complexes of the ligands H_2L^1 and H_2L^3 show asymmetric signal with poorly resolved hyperfine splitting signals; however' the complexes of the ligand H_2L^2 show only a broad signal. In addition, all the complexes show a signal for $\Delta Ms = 2$ transition at the low field region around 1600 G, with $g \approx 4$.

$g_{\|} > g_{\perp}$ values observed for the complexes suggest a planar-based geometry with $d_{x^2-y^2}$ ground state [24]. Appearance of a hyperfine splitting component for the complexes of the ligands H_2L^1 and H_2L^3 indicates that the antiferromagnetic coupling in the complexes is weak when compared with the complexes of the ligand H_2L^2.

Abstract

Treatment of *nido*-7,8-$C_2B_9H_{12}^-$ with *N*-halosuccinimide (halo = chloro, bromo or iodo) formed the corresponding *nido*-9,11-(halo)$_2$-7,8-$C_2B_9H_{10}^-$ ion in good yield. The *nido*-9,11-Br_2-7,8-$C_2B_9H_{10}^-$ ion was deprotonated with *n*-butyllithium and then reacted with cobalt(II) chloride to form the *commo*-3,3′-Co(4,7-Br_2-3,1,2-$CoC_2B_9H_9)_2^-$ ion. A single-crystal X-ray structure determination of this cobalt complex is reported. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Halogenated carborane anions; Cobalt bis(dicarbollide); Boron; Carborane; Halogenation

1. Introduction

A few halogenated derivatives of the *nido*-[7,8-$C_2B_9H_{12}]^-$ ion are known [1–3,5,8,12]. Reaction of [$(CH_3)_3$NH][*nido*-7,8-$C_2B_9H_{12}$] with I_2 in refluxing MeOH formed [$(CH_3)_3$NH)][*nido*-9,11-I_2-7,8-$C_2B_9H_{10}$] in good yield [2]. The positions of iodination were determined by a single-crystal X-ray diffraction study [2].

There have been several studies of direct halogenation of *commo*-3,3′-Co(3,1,2-$CoC_2B_9H_{11})_2$ anion [also referred to as the cobalt bis(dicarbollide) anion] and these are outlined in a recent review [10]. Halogenation of 1,2-$C_2B_{10}H_{12}$ followed by conversion of this icosahedral molecule to its *nido*-[7,8-$C_2B_9H_{12}$] anion derivatives and then deprotonation and complexation with $CoCl_2$ has formed the *commo*-3,3′-Co(9-X-3,1,2-$CoC_2B_9H_{10})_2^-$ ion, X = Cl or Br as well as other halogenated derivatives [9].

Reaction of Me_3NH[*commo*-3,3′-Co(3,1,2-$CoC_2B_9H_{11})_2$] (**1**) with *N*-chlorosuccinimide or *N*-bromosuccinimide in THF formed the dihalogenated derivatives Me_3NH[*commo*-3,3′-Co(8-X-3,1,2-$CoC_2B_9H_{10})_2$], X = Cl or Br, respectively [4]. A single-crystal X-ray study of the dichloro derivative has been reported [4]. Treatment of **1** in refluxing glacial acetic acid solution with excess bromine formed [*commo*-3,3′-Co(8,9,12-Br_3-3,1,2-$CoC_2B_9H_8)_2]^-$ [7]. A single-crystal X-ray determination of this hexabromo derivative has been reported [11]. This hexabromo-derivative has been studied as a weakly coordinating anion [13]. Reaction of **1** with six equivalents of iodine monochloride in refluxing methylene chloride gave [*commo*-3,3′-Co(8,9,12-I_3-3,1,2-$CoC_2B_9H_8)_2]^-$ [6].

In this report, we describe the syntheses of the *nido*-9,11-X_2-7,8-$C_2B_9H_{10}^-$ anions (X = Cl, Br and I) employing *N*-halosuccinimide as the halogenation reagent. We also report the synthesis, characterization and single-crystal X-ray structure determination of a new brominated cobalt dicarbollide anion obtained by complexation of two *nido*-9,11-Br_2-7,8-$C_2B_9H_9^{2-}$ dianions with cobalt(II) chloride.

2. Experimental

2.1. Physical measurements

Boron (^{11}B) NMR spectra were recorded at 128.4 MHz using a Varian Unity INOVA 400 spectrometer or at 80.21 MHz using a Bruker AF 250SY spectrometer. ^{11}B chemical shift values were reported relative to BF_3(diethylether). Proton (^{1}H) NMR were obtained on the same instruments and referenced to the protio solvent impurities. Proton chemical shift values were reported relative to tetramethylsilane. Elemental analysis for [$(CH_3)_3NH$][*nido*-9,11-Br_2-7,8-$C_2B_9H_{10}$] was performed at Los Alamos National Laboratories.

2.1.1. Synthesis of [$(CH_3)_4N$][*nido*-9,11-Cl_2-7,8-$C_2B_9H_{10}$]

In a 150-ml beaker, [$(CH_3)_3NH$][7,8-$C_2B_9H_{12}$] (0.50 g, 2.6 mmol) was dissolved in 25 ml CH_3CN. A solution of *N*-chlorosuccinimide (1.04 g, 7.8 mmol, three equivalents) in 25 ml of CH_3CN was added to the reaction beaker and the mixture was stirred at 25°C for 2 h. Evaporation of the CH_3CN gave a white crystalline solid that was dissolved in 120 ml of H_2O. Precipitation at 25°C with $(CH_3)_4NCl$ (0.86 g, 7.8 mmol, three equivalents) yielded 0.59 g (81%) of product. HRMS (positive ion FAB with glycerol matrix) (m/z) observed 350.2969, calculated 350.2973 [$(Me_4N)_2(C_2B_9H_{10}Cl_2)^+$] ($\Delta = 0.4$ mmu, 1.2 ppm).

2.1.2. Synthesis of [$(CH_3)_3NH$][*nido*-9,11-Br_2-7,8-$C_2B_9H_{10}$]

A THF solution of trimethylammonium dicarbollide [$(CH_3)_3NH$][7,8-$C_2B_9H_{12}$] was refluxed with 2.2 equivalents of *N*-bromosuccinimide for 15 min. After evaporation of the solution to dryness, the resulting white solid was dissolved in water giving a clear, colorless solution. The addition of two equivalents of $(CH_3)_3NHCl$ produced a flocculent white solid which was recovered by filtration. The compound identified as [$(CH_3)_3NH$][9,11-Br_2-7,8-$C_2B_9H_{10}$] was formed in 82% yield. Elemental analysis: Found: C, 17.19; H, 5.72; N, 4.15. *Anal*. Calc. For $C_5H_{20}B_9Br_2N$: C, 17.09; H, 5.74; N, 3.99%. HRMS (positive ion FAB with glycerol matrix) (m/z) observed 412.1621, calculated 412.1631 [$(Me_3NH)_2(C_2B_9H_{10}Br_2)^+$] ($\Delta = 1.0$ mmu, 1.2 ppm). ^{1}H NMR: acetone-d_6 solvent, 2.2 ppm, carborane CH.

2.1.3. Synthesis of [$(CH_3)_3NH$][*nido*-9,11-I_2-7,8-$C_2B_9H_{10}$]

A magnetic stir bar was placed in a 150-ml beaker to which [$(CH_3)_3NH$][7,8-$C_2B_9H_{12}$] (1.98 g, 10 mmol) and 12.5 ml THF were then added. A solution of *N*-iodosuccinimide (4.66 g, 21 mmol, 2.1 equivalents) in 12.5 ml of THF was added to the reaction beaker and the mixture was stirred at 25°C for 20 min. Evaporation of the THF gave a white crystalline solid that was dissolved in 200 ml H_2O. Precipitation at 25°C with $(CH_3)_3NHCl$ (2.4 g, 25 mmol, 2.5 equivalents) yielded 3.6 g (78%) of product.

2.1.4. Preparation of [Et_4N^+][*commo*-3,3′-Co(4,7-Br_2-3,1,2-$CoC_2B_9H_9)_2$]

To a two-neck, round-bottom flask equipped with a magnetic stir bar and nitrogen inlet, 0.1052 g (0.2994 mmol) of [Me_3NH] [9,11-Br_2-7,8-$C_2B_9H_{10}$] and 2.4 ml of dry THF were added. The vessel was flushed with nitrogen and cooled to -78°C using a dry ice–acetone bath; then 1.8 ml of 2.5 M (4.5 mmol) *n*-butyllithium were added and the vessel was warmed to room temperature. Upon warming, 0.0712 g (0.549 mmol) of dry cobalt(II) chloride was added, which resulted in a black liquid. The THF was removed by rotary evaporation and the remaining residue was washed with methylene chloride. After suction filtration to remove any cobalt or cobalt chloride, the methylene chloride solution was slowly evaporated and gave an orange crystalline solid. The yield was not established. The compound appeared to slowly decompose upon prolonged exposure to moist air at room temperature. ^{11}B and ^{1}H NMR data are summarized in Tables 2 and 3, respectively.

2.1.5. X-ray structure determination for [Et_4N^+][(*commo*-3,3′-Co(4,7-Br_2-3,1,2-$CoC_2B_9H_9)_2$]

A thin orange crystal of dimensions $0.03 \times 0.22 \times 0.40$ mm was affixed to the end of a glass fiber using

silicon grease and transferred to the goniostat where it was cooled to −170°C. A systematic search of a limited hemisphere of reciprocal space was used to determine that the crystal possessed no symmetry or systematic absences, indicating a triclinic space group. Subsequent solution and refinement confirmed the centrosymmetric choice, $P\bar{1}$ (see Table 4).

The diffractometer utilized for data collection was designed and constructed locally. A Picker four-circle goniostat equipped with a Furnas monochromator (HOG crystal) was modified by addition of stepping motors (Slo-Syn) on each of the four axes, and a fifth motor drives a 20-position filter/attenuator wheel. The latter allows top/bottom-left/right alignment of reflections. All motors are driven by a locally designed ISA board in an IBM PC compatible computer. The computer also has a timer/scalar board that is used to accumulate the counts from the scintillation counter used with the goniostat. The control software, PCPS is the Picker software written by Streib of the IUMSC. The software for the structure solution and refinement include SHELXTL-PC, and other versions of SHELX, as well as the XTEL program library.

Data were collected using a standard moving crystal–moving detector technique with fixed backgrounds at each extreme of the scan. Data were corrected for Lorentz and polarization effects and equivalent reflections were then averaged after application of an analytical absorption correction. The structure was readily solved using direct methods (SHELXTL-PC) and Fourier techniques. The cobalt and four bromine atoms were clearly visible, and the remaining atoms appeared in subsequent difference Fourier maps. The hydrogen atoms associated with the anion were located in difference Fouriers and included as fixed atom contributors in the final cycles of refinement. A final difference Fourier was featureless, the largest peak being 0.7 e $Å^{-3}$.

3. Results and discussion

The reaction of [$(CH_3)_3NH$][7,8-$C_2B_9H_{12}$] with 2.5–3.0 equivalents of *N*-halosuccinimide provided a convenient route to the series of compounds [$(CH_3)_3NH$]-[9,11-X-7,8-$C_2B_9H_{10}$] where X = Cl, Br or I. The compound [$(CH_3)_3NH$][9,11-Cl_2-7,8-$C_2B_9H_{10}$] was obtained in 81% yield when the reaction was carried out using three equivalents of *N*-chlorosuccinimide in acetonitrile solvent. Other solvents (benzene, CH_2Cl_2,

DMF and DMSO) gave a mixture of monochloro- and dichloro-dicarbollide anions and decomposition products.

The compound $[(CH_3)_3NH][9,11\text{-}I_2\text{-}7,8\text{-}C_2B_9H_{10}]$ had been prepared previously from $[(CH_3)_3NH][7,8\text{-}C_2B_9H_{12}]$ and I_2 in refluxing methanol [2]. The ^{11}B NMR spectra of our diiodo product (in acetone-d_6) (see Table 1) and that of Ref. [2] (in ethanol) are in good agreement. The positions of iodination were determined by a single-crystal X-ray diffraction study of $[(CH_3)_3NH][9,11\text{-}I_2\text{-}7,8\text{-}C_2B_9H_{10}]$ [2].

The high-resolution mass spectra (FAB^+) are in agreement with the dihalo (halo = Cl or Br) *nido*-carborane cage formulae.

A comparison of the ^{11}B NMR chemical shift data is presented in Table 1. The assignments for the parent $7,8\text{-}C_2B_9H_{12}^-$ ion [2] and the $9,11\text{-}Br_2\text{-}7,8\text{-}C_2B_9H_{10}^-$ ion (study done here) are based on ^{11}B–^{11}B COSY NMR experiments. Previously, other face-substituted $7,8\text{-}C_2B_9H_{12}^-$ ions were analyzed by this 2D method [2]. The ^{11}B NMR assignments for the dichloro- and diido-$7,8\text{-}C_2B_9H_{10}^-$ ions were made based on the similarity to the other existing NMR studies. The chemical shift for the 9,11-halogen substituted boron nuclei shows the only significant variation. This change is similar to that found for other halogen-substituted cage-boron series.

3.1. $[Et_4N^+][Co(4,7\text{-}Br_2\text{-}1,2\text{-}C_2B_9H_9)_2^-]$

Deprotonation of $[(CH_3)_3NH^+][4,7\text{-}Br_2\text{-}1,2\text{-}C_2B_9H_{10}]$ with excess *n*-butyllithium in dry THF at −78.5°C, followed by warming to room temperature and the addition of cobalt(II) chloride, yielded the first 4,7-bromine substituted cobalt dicarbollide anion; (see numbering scheme for this anion in Fig. 1).

The structure of $[Et_4N^+][$*commo*-3,3′-Co(4,7-Br_2-3,1,2-$CoC_2B_9H_9)_2]$ was determined by a single-crystal X-ray study and is illustrated in Fig. 2. The cobalt atom is complexed in an η^5 fashion to each of the two ligands. The Co–B and Co–C bond distances of this new brominated cobalt *nido*-$C_2B_9H_9Br_2$ dicarbollide anion were found to be in the range 2.099(14)–2.168(13) and 2.044(11)–2.058(9) Å, respectively (see Table 5). These values are similar to the reported Co–B

$Br–B–B_{5,5',11,11'}$	111.3(3)	112.4(6)	108.7(5)	109.3(5)
$Br–B–B_{9,9',12,12'}$	117.8(6)	117.3(7)	113.7(7)	115.5(5)

and Co–C distances of $[(CH_3)_4N^+][commo\text{-}3,3'\text{-}Co(8,9,12\text{-}Br_3\text{-}3,1,2\text{-}CoC_2B_9H_8)_2]$, which are in the range 2.05(2)–2.17(3) and 1.98(2)–2.09(2) Å, respectively [11].

Two enantiomers of this species exist by definition of the determined space group, $P\bar{1}$. These two mirror images are a result of the steric interference of the 4,7-position bromine atoms, which inhibits free rotation of the two dicarbollide ligands about the axis running through B(10), the cobalt atom and B(10′). The ^{11}B NMR spectrum (see Table 2) exhibits two unique environments for the 4,7-positioned boron atoms (two singlets) as well as for the 5,11-positioned boron atoms (two doublets). The ^{1}H NMR spectrum also exhibits two unique environments for the cage carbons (see Table 3). The structural effect of the steric interference of the bromine atoms is observed in the large bond angles of $Br–B_7–B_8$ and $Br–B_{7'}–B_{8'}$ (Table 6). Attempts to unlock the cage have so far proven unsuccessful. Observance of the ^{11}B NMR spectrum at 100°C showed no convergence of the two 4,7-peaks.

The $commo\text{-}3,3'\text{-}Co(4,7\text{-}Cl_2\text{-}3,1,2\text{-}CoC_2B_9H_9)_2^-$ ion was prepared by a similar reaction. It was not fully characterized; however, the ^{11}B NMR spectrum contained resonances at (multiplicity, intensity); 9.0 (s, 2B), 6.0 (d, 2B), 4.2 (s, 2B), −0.4 (d, 4B), −3.0 (d, 2B), −5.5 (d, 2B), −14.5 (d, 2B), −21 ppm (d, 2B). This spectrum is consistent with the expected structure of the complex and similar to the spectrum obtained for the tetrabromo derivative.

Abstract

From the non-covalent binding modes used in supramolecular chemistry, metal ion complexation and hydrogen bonding are combined in order to synthesise new inorganic polymers as precursors for thin layer deposition. With the same coordinating ligands, DME and water, but in varying stoichiometries, two different dimensional compounds are obtained. The synthesis and crystal structures of the one- and three-dimensional polymers are described together with a third example for better control of the supramolecular products formed. © 2000 Elsevier Science Ltd. Keywords: Calcium; H-bonding; Inorganic Polymers; Alkaline Earth; X-ray structure

1. Introduction

The bonding modes used in supramolecular chemistry provide elegant tools to design and synthesise architectures of nanoscopic dimensions with novel structural and functional properties [1]. Non-covalent interactions, such as hydrogen bonding, metal ion coordination, electrostatic and hydrophobic forces, permit precise positioning of molecular components in a well-defined supramolecular architecture [2]. The final product is built up following a series of spontaneous recognition, growth, and termination steps of suitable components and specified interaction schemes.

Whereas the underlying principles of non-covalent interactions are generally well understood, the next challenge in the implementation of supramolecular devices in molecular based materials lies in the generation of spatially confined and macroscopically ordered compounds. In our aim to develop new precursors for thin metal oxide films, especially high-temperature superconductors, we study the formation of inorganic polymers of alkaline earth metal halide derivatives based on metal ion complexation and covalent or hydrogen bonding in organic donor solvents [3]. For both cases, it is in general very difficult to control and predict the coordination sphere of the metal, the bridging mode of the anions and the resulting overall dimensionality of the compound [4–8]. The latter is influenced by the donor ligand, that is its size, strength, polarizability and concentration, its capacity to build non-covalent bonds in order to obtain a network, as well as thermodynamic conditions during the reaction and crystallisation. In the case of mixed ligand systems, the product that is formed also depends on the orientation and arrangement of the donors around the metal ion. In this work, two calcium compounds will be presented, $[Ca(DME)_3(H_2O)_3]I_2 \cdot DME$ (**1**) and $[Ca(DME)_2(H_2O)_4]I_2$ (**2**), which feature the same type of ligands in their coordination sphere but in different stoichiometries and spatial arrangements, thus leading

to H-bridged polymers of different dimensionality. They might be regarded as early intermediate species on the formation of sol–gels via solvation by water and following hydrolysis starting from $[Ca(DME)_3I_2]$, and leading to $[Ca(OH)_2(H_2O)_y]$. The third compound $[Ca\{CH_3(OCH_2)_2OCH_3\}(H_2O)_4]I_2$ (**3**) is an example derived from **2** which shows how an isosteric ligand to the two DME molecules of **2** can maintain the same overall structure.

2. Experimental

All reactions were carried out under an atmosphere of dried nitrogen using standard inert atmosphere and Schlenk techniques, unless otherwise stated. DME (1,2-dimethoxy ethane) was distilled from sodium benzophenone under N_2, *n*-hexane was distilled from $LiAlH_4$ under N_2, and distilled water was degassed with N_2. Triethylene glycol dimethyl ether (triglyme) was obtained p.a. from Fluka and distilled from sodium benzophenone under vacuum. $CaI_2{\cdot}5H_2O$ obtained from Aldrich Chemicals Co. was dried under vacuum at 200°C. IR spectra were taken on CsI plates in Nujol on a Perkin–Elmer Spectrum-One.

2.1. $[Ca(DME)_3(H_2O)_3]I_2{\cdot}DME$ (1)

Dried CaI_2 (0.4 g, 1.36 mmol) was dissolved in 50 ml of a 100:1 mixture of DME and water. The slightly yellow solution was filtered and evaporated to 35 ml under vacuum, layered with *n*-hexane and left at 243 K overnight. Colourless crystals of **1** in a yield of 84% referring to CaI_2 were collected. More product could be isolated from the mother liquid by concentrating the solution. The crystals are stable at room temperature. However, they lose solvent after several hours of exposure to air. IR of **1**: 3802(vw), 3415(vs, sh), 3210(s), 2926 (Nujol), 2114(w, sh), 1641(m), 1609(s), 1454 (Nujol), 1367 (Nujol), 1303(vw), 1281(m), 1246(m), 1116(vs), 1060(s), 1025(s), 982(m), 940(m), 864(s), 840(sh), 722 (Nujol) 553(s, sh), 376(m), 301(m). Elemental analysis of **1**. Found: C, 24.92; H, 5.92; Ca, 6.23. *Anal.* Calc.:C, 25.35; H, 6.23; Ca, 6.04%.

2.2. $[Ca(DME)_2(H_2O)_4]I_2$ (2)

Dried CaI_2 (0.32 g, 1.09 mmol) was dissolved in 30 ml of a 100:5 mixture of DME and water. The pale yellow solution was filtered, stored at room temperature, and after 3 days colourless single crystals of **2** were obtained in a yield of 72% referring to CaI_2. The compound is stable at air and room temperature. IR of **2**: 3383(m, sh), 3020(w), 2926 (Nujol), 1607(vs), 1460 (Nujol), 1376 (Nujol), 1247(w), 1192(m), 1114(s), 1061(m), 1025(m), 979(w), 864(m), 790(w), 722 (Nujol), 551(m), 315(m, sh). Elemental analysis of **2**. Found: C, 17.31; H, 4.80; Ca, 7.55. *Anal.* Calc.: C, 17.60; H, 5.17; Ca, 7.34%.

2.3. $[Ca\{CH_3(OCH_2)_3OCH_3\}(H_2O)_4]I_2$ (3)

$CaI_2(H_2O)_5$ (0.46 g, 1.23 mmol) were dissolved in 50 ml triglyme. The light yellow solution was layered with *n*-hexane and left to diffuse at room temperature. Colourless single crystals of **3** were obtained after 3 days in a yield of 23% referring to Ca. The same product **3** is obtained when recrystallising **2** from triglyme in 88% yield. The compound is very stable at air and room temperature. IR of **3**: 3381(m), 3182(m), 2929 (Nujol), 1958(w), 1603(s), 1456 (Nujol), 1350 (Nujol), 1285(m), 1247(s), 1199(vs), 1110(vs), 1028(sh), 982(m), 943(s), 848(vs, sh), 723 (Nujol), 540(s, sh), 389(w), 347(m), 238 (m). Elemental analysis. Found: C, 17.52; H, 4.68; Ca, 7.48. *Anal.* Calc.: C, 17.66; H, 4.82; Ca, 7.37%.

2.4. X-ray crystallographic structural solution of $[Ca(DME)_3(H_2O)_3]I_2{\cdot}DME$ (1), $[Ca(DME)_2(H_2O)_4]I_2$ (2) and $[Ca\{CH_3(OCH_2)_3OCH_3\}(H_2O)_4]I_2$ (3)

A colourless cube-like crystal of **1** having the dimensions $0.46 \times 0.38 \times 0.38$ mm was mounted on a glass fibre. For **2**, a colourless crystal with a rhombic habitus of dimensions $0.37 \times 0.32 \times 0.12$ mm was chosen. The needle-like crystal chosen from **3** had the dimensions $0.07 \times 0.07 \times 0.58$ mm. All measurements were carried out on a STOE STADI 4 four circle diffractometer with graphite monochromated Mo Kα radiation and at 200 K. Pertinent data collection and reduction information as well as selected bond distances and angles are given in Tables 1 and 2. Cell constants and an orientation matrix for data collection, obtained from a least-squares refinement using the setting angles of 25 carefully centred reflections corresponded to a triclinic cell for **1** and **2**, the space group being $P\bar{1}$. For **3**, the monoclinic space group $C2/c$ was found. The intensities of two standard reflections measured every 2 h showed no significant change throughout the measurements. The structures were solved with direct methods and refined using the programme SHELX [9]. The hydrogen positions in the water molecules could in all three cases be determined by difference Fourier maps.

3. Results

Dry CaI_2 dissolves quite well in etheral solvents like THF, DME (monoglyme, $CH_3OC_2H_4OCH_3$) and higher glymes (diglyme, triglyme, tetraglyme) but even better in the presence of traces of water. Excess water leads to the formation of sol–gels of composition of $[Ca(OH)_2(H_2O)_y]$.

Dissolving CaI_2 in a 100:1 mixture of DME and water yields a slightly yellow solution from which colourless crystals of $[Ca(DME)_3(H_2O)_3]I_2 \cdot DME$ (**1**) were obtained at −30°C after layering with *n*-hexane. **1** crystallises in the triclinic space group $P\bar{1}$ with one molecule per unit cell. The calcium atoms in **1** feature a coordination number of seven (CN = 7) with two molecules of DME and three water ligands (Fig. 1). With respect to the oxygen atoms of the donor molecules, the coordination geometry can be described as a distorted pentagonal bipyramid with two of the water molecules in axial positions (O7 and O9), the oxygen atoms of the third water and the two DME ligands occupying approximately the five positions around the almost planar equator. The Ca–O(H_2O) bond lengths are with 2.348(3)–2.351(3) Å by 0.7–1.0 Å shorter than the Ca–O(DME) distances, the difference as expected between mono- and bidentate ligands.

[a] Bond distances (Å) and angles (°).

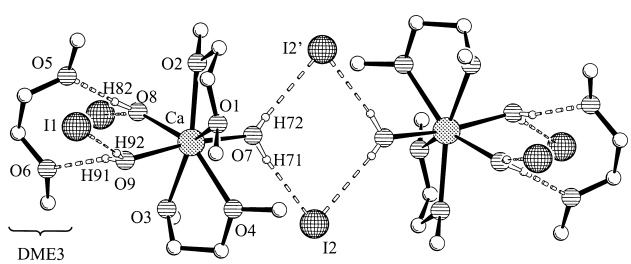

Fig. 1. Excerpt from the band structure of **1** showing two cationic units linked together to dimers via hydrogen bonding by I2.

With these five ligands, the closer coordination sphere of seven oxygen atoms around the calcium atom is fully described. However, a second, outer coordination sphere must be taken into account. In fact, a third solvent molecule, DME3, is bound to the cationic complex. Whereas the Ca–O(DME3) distances are 4.198(3) and 4.369(3) Å, much too long for direct interactions, the ligand is actually bound via hydrogen bonding between two of the water molecules involving O8–H82 and O9–H91 and the oxygen atoms of the third DME3, O5 and O6, respectively. The two water molecules O8 and O9 are both classified as class 1′, and type J concerning their hydrogen bonding [10,11]. The corresponding bond lengths are O8(H82)–O5, 2.756(4)

Å (1.90(4) Å) and O9(H91)–O6, 2.820(4) Å (1.99(6) Å). This complex, containing an inner and outer coordination sphere around the alkaline earth metal, describes the cationic fraction of the unit cell, and is part of the polymer structure.

Two such cationic units form dimers via hydrogen bonding involving both hydrogen atoms H71 and H72 of the water molecule O7 and the anion I2 as well as their symmetry equivalents O7' and I2'. The iodide acts as μ_2-bridge between two calcium complexes, featuring a H71–I2–H72′ angle of 87.21(8)°. The hydrogen bonds are O7(H71)–I2 3.611(3) Å (2.70(6) Å) and O7(H72)–I2′ 3.502(3) Å (2.78(5) Å) long. The water molecule O7 is of class 1, type D in the classification of hydrogen bonded water molecules with respect to its lone pair coordination [10,11]. A crystallographic inversion center is found in the geometric middle of the rhombus formed by O7–I2–O7′–I2′. Opposite to the axial water O7, in the *trans* position on the pentagonal bipyramid,

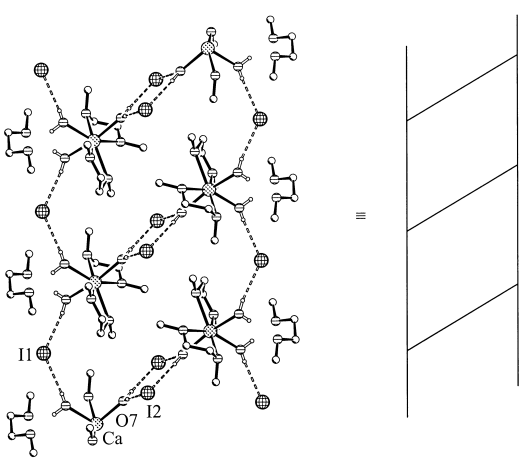

Fig. 2. View onto the band structure of **1**, compared to a railway or ladder arrangement.

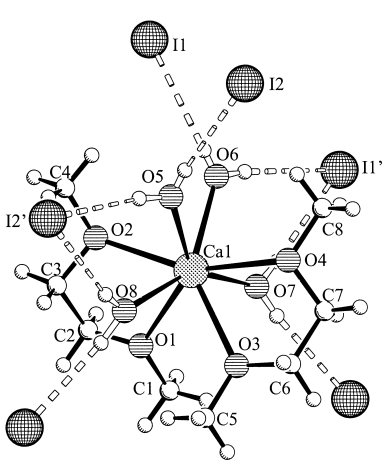

Fig. 3. Square antiprismatic coordination sphere of **2** and corresponding H-bonding.

the water molecule O9 is partially blocked by H-bonds of H92 to the third DME molecule. It thus cannot form the same type of hydrogen bonding as O7, hindering the structure from the formation of strands along this axis and restraining it to dimers.

These cationic dimers are linked to each other to form a ladder structure by hydrogen bonding of the water molecules O8(H81) and O9(H92) via one hydrogen atom to I1 which acts as μ_2-bridging ligand between the dimers with I1–O(H) distances of 3.492(4) (2.75(5)) Å and 3.514(4) (2.74(5)) Å, respectively (Fig. 2). The O8(H81)–I1–O9(H92) angle is with 134.07(9)° (130.57(9)°) about 40° wider than the O7–I2–O7′ angle. Thus, **1** builds up a one-dimensional polymer, the dimers forming a ribbon-like structure. In the crystal, these bands are stacked onto each other alternating in an ABAB fashion. The cavities of approximate average diameter of 6 Å thus formed are filled with one free DME molecule per asymmetric unit.

Higher concentrations of water yield a different adduct. From a solution of dry CaI_2 in a mixture 100:5 DME–water, compound $[Ca(DME)_2(H_2O)_4]I_2$ (**2**) is obtained at room temperature. Colourless blocks crystallise in the triclinic space group $P\bar{1}$ with two cationic units and four iodide per unit cell. Again, two DME molecules are directly coordinated to the alkaline earth cation, and the angles between the DME molecules are very similar to the ones in **1**, leaving the rest of the coordination sphere to four water molecules instead of three. The calcium thus reaches a coordination number of eight (CN = 8) with a distorted square antiprismatic geometry, two water molecules and one DME in each square plane (Fig. 3). The Ca–O distances in **2** reach from 2.417(2) to 2.436(2) Å for water and from 2.503(2) to 2.514(3) Å for the DME ligands. All water molecules are involved in hydrogen bonding, each of them being linked to two iodide. Two of them, O6 and O7, of one square face of the antiprism and I1 thus build up a ribbon-like structure in one direction. A second strand is formed by the other two water molecules O5 and O8 of the second square face and their hydrogen bonding to I2, featuring a direction vector of the ribbon almost perpendicular to the first (Fig. 4(a)). The corresponding O(H)–I distances are between 3.510(3) and 3.586(3) Å long. The water molecules O5 and O6 are of class 1, type D, whereas the water ligands O7 and O8 are of class 1′, type J concerning their hydrogen bonding modes [10,11]. In total, a three-dimensional network results with channels along the *c*-axes with a diameter of approximately 5 Å (Fig. 4(b)).

Each of the anions I1 and I2 is μ_4-bridging between three cationic units $[Ca(DME)_2(H_2O)_4]^{2+}$, having contacts with two water molecules of one cationic unit and one water of a second and a third unit. Crystallo-

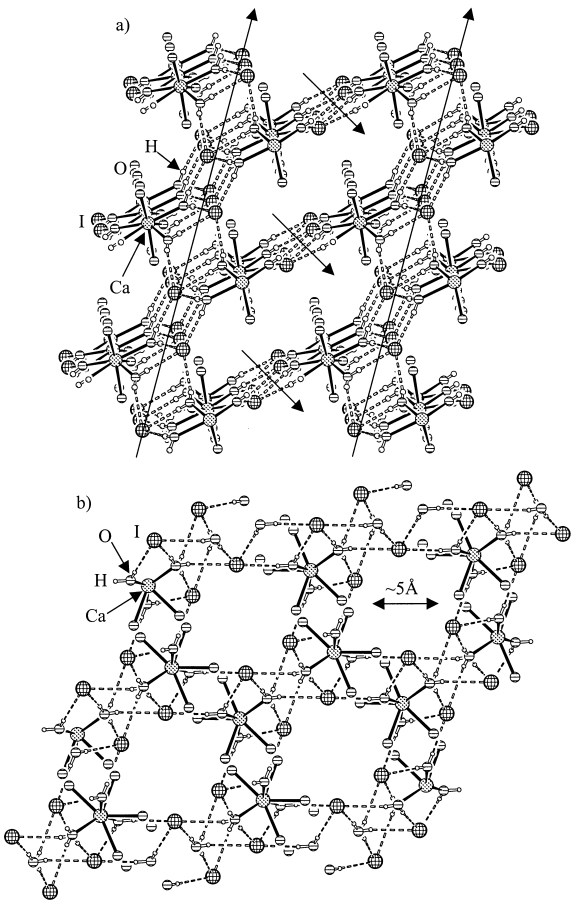

Fig. 4. (a) View of **2** along *b*, onto the *ac*-plane showing the orientation of the bands formed by hydrogen bonding; (b) View of **2** along *c*, onto *ab*-plane.

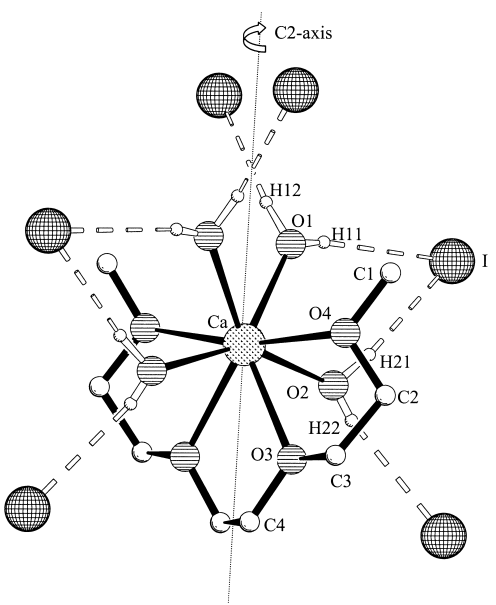

Fig. 5. Square antiprismatic coordination sphere of **3** and corresponding H-bonding, the H-atoms of the triglyme ligand are omitted for clarity.

graphic inversion centres are found in the geometric middle of each O*n*–I*m*–O*n*′–I*m*′ rhombus (*m* = 1; *n* = 6, 7 and *m* = 2; *n* = 5, 8).

In order to preorganise the positioning of the two DME molecules to each other in **2**, they were formally replaced by a triglyme ligand. The compound $[Ca\{CH_3(OCH_2)_3OCH_3\}(H_2O)_4]I_2$ (**3**) was obtained in form of colourless blocks and crystallises in the monoclinic space group *C*2/*c* (no. 15). In the cationic part of the structure, the calcium lies on a crystallographic two-fold axis which also passes through the geometrical middle of the triglyme ligand (0, *y*, 1.4 (e)) (Fig. 5).

The metal ion has a coordination number of eight, and presents the coordination geometry of a distorted square antiprism like **2** with two water molecules and two oxygen atoms of the triglyme in one square plane, the other two oxygen atoms and the two water molecules are situated in the other plane of the prism. As a result, the hydrogen bonds that are built up between the water ligands and the iodides are very similar to the ones in **2** and again lead to a three-dimensional network (Fig. 6). The hydrogen bonds maintained by O1 and O1′ correspond to the ones built by O5 and O6 in **2** and are also of type D, class 1, whereas O2 and O2′ are of type J, class 1′ similar to O7 and O8 in **2** [10,11].

4. Discussion

Comparing **1** and **2** reveals a surprisingly similar close coordination of the alkaline earth cation by the two DME molecules both in angles and in orientation. Formally, the third H-bound DME in **1** has been taken off, and one of the water molecules in the axial positions of the distorted pentagonal bipyramid of **1** has been replaced by two water molecules in **2**. However, the Ca–O bond lengths in **1** are almost 0.1 Å shorter than in **2** (Table 2). A similar trend is observed for the Ca–O distances concerning the water ligands. This is due to the difference in the coordination number varying from seven in **1** to eight in **2** and explains the elongation of bond lengths for the latter. As the iodide anions in **2** are shared between four water molecules, the O(H)–I hydrogen bonds are by up to 0.08 Å longer than in **1** where the anion acts as μ_2-bridging ligand.

The presence of a further DME molecule in **1** sterically hinders the approach of the strands to each other, and the formation of a sheet-like or three-dimensional structure via μ_4-bridging iodide is excluded. In **2**, the absence of the H-bound DME3 allows the mutual approach of two parallel ribbons. The space left by the elimination of DME3 is filled by the iodide of the neighbour strand, leading to new H-bonding and allowing the iodide to act as an μ_4-bridging ligand. By the additional water molecule in **2**, networking is improved

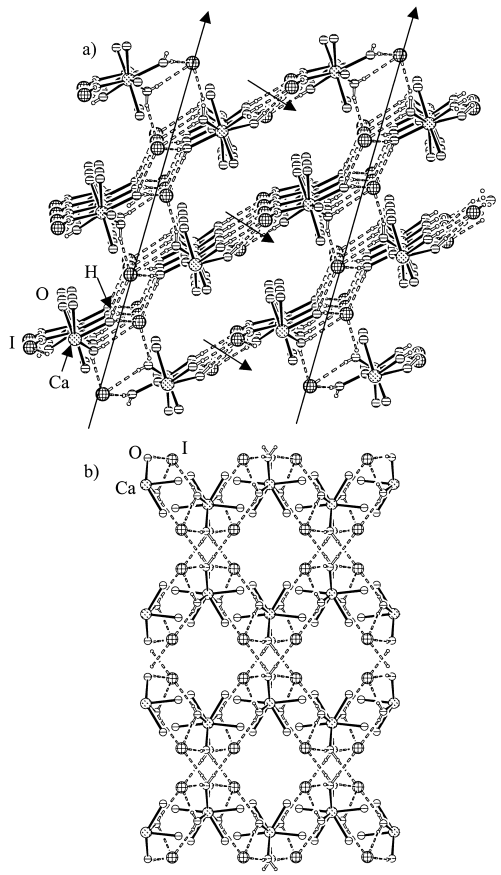
in the opposite direction as well, which finally leads to the three-dimensional structure in contrast to **1**.

Both compounds can be regarded as early intermediates on the way to sol–gels starting from $[Ca(DME)_3I_2]$ [12,13] towards $[Ca(OH)_2(H_2O)_y]$. A following reaction mechanism can be proposed.

On addition of water ligands to $[Ca(DME)_3I_2]$, the iodides which are directly linked to the alkaline earth cation will be formally replaced by H_2O molecules, the halide being displaced into the outer coordination sphere, linked by hydrogen bonding (Scheme 1). As the coordination sphere around the equatorial positions is dense, one DME molecule is formally substituted by a third H_2O ligand which can be placed more easily at the metal center and allow the type of hydrogen bonding to a third DME in an outer ligand sphere as is shown in the crystal structure of **1**. Higher concentrations of H_2O will displace DME from the second coordination sphere and lead to compound **2**. On further addition of water to compound **2**, hydrolysis occurs, and the formation of a white sol–gel of composition $[Ca(OH)_2(OH_2)_y]$ can be observed. More investigations are on the way in order to identify other intermediates of this hydrolysis reaction.

As **2** and **3** have very similar structural features, the only difference being the formal replacement of two DME molecules in **2** by a triglyme ligand in **3**, one should expect similar bond lengths in both compounds. However, the average Ca–O distances in **3** are up to 0.02 Å shorter than in **2**. The bite angles of the triglyme ligand and the $O(H_2O)$–Ca–$O(H_2O)$ angles of **3** between neighbouring water molecules are on average smaller than in **2**. Concerning the hydrogen bonding part of the two structures, the parameters such as H–I–H and I–O–I angles as well as O(H)–I distances are in the same order of magnitude. The difference between **2** and **3** is thus found in the metal ion complexation and can be expressed in the valence bond sum [14,15] for calcium which can be calculated to be 2.15 for **2** and 2.24 for **3**, meaning a stronger, more efficient complexation for **3** by the triglyme ligand than for **2** by the two DME ligands. The same valence bond sum as for **3** is calculated for **1** which has a lower coordination number for calcium than **3**, meaning that the DME and water ligands are more strongly bound than in **2** due to the lower coordination number for calcium.

Other polymer structures built from alkali or alkaline earth metal ion complexation and hydrogen bonding have been described in the literature, without however rationalising the influences of the ligands and their concentrations on the final dimensionality of the structures. Thus, the complex $[Na\{N(CH_2CH_2OH)_3\}I]$ features a coordination number of seven for the sodium cation which is coordinated by four heteroatoms of one ligand, two oxygen atoms of neighbouring ligands and the iodide, and builds one-dimensional chains via additional hydrogen bonding between the ligands [16]. A parallel sheet structure is obtained when replacing the iodide by a perchlorate anion which offers a wider, yet directed range of hydrogen bonding possibilities due to its tetrahedral arrangement of oxygen atoms [17]. Infinite chains of dimers, cross-linked via ClO_4^- into sheets by van der Waals contacts, are observed in the barium compound $[Ba\{N(CH_2CH_2OH)_3\}_2(ClO_4)_2]$ [17]. Hydro-



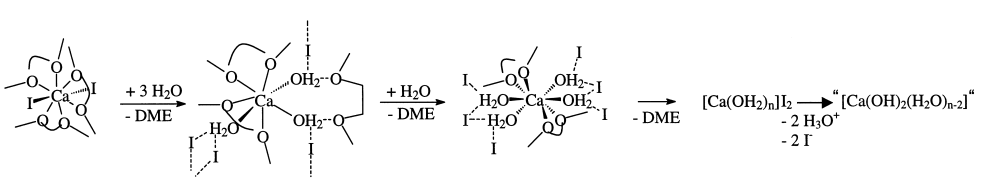


Fig. 6. Three-dimensional network formed by **3**.

Scheme 1.

gen bonding due to water ligands is described in $[(py)_4Mg(OH_2)_2]I_2$2py, yielding dimeric units, and $[Ba(ClO_4)_2(OH_2)(py)]$ which forms two-dimensional sheets (py = pyridine) [6]. Three-dimensional networks are observed by hydrogen bonding between water molecules and halide anions in the compounds $[(dien)_2Ca(OH_2)Cl]Cl$, $[(dien)_2Ca(OH_2)_2]Br_2$ and $[(en)_4Ba(OH_2)]Br_2$ [8]. In all cases described, the final structure and dimensionality were unpredictable. A study of two calcium complexes $[Ca(OH_2)_2(L)_4]I_2$ with a very similar octahedral coordination geometry with L = THF (tetrahydrofurane) for one and CH_3-$COOC_2H_5$ (ethyl acetate) for the other compound shows that even slight differences in the coordination sphere lead to a two-dimensional sheet structure in the first case and a one-dimensional polymer in the second case [3]. The determination of the strength of hydrogen bonds from IR spectra and X-ray data was attempted for intramolecular O–X bond lengths for which X = H or D [18]. For O–H···Y with Y = F, Cl, Br or I however, more reliable data are still needed before it will be possible to rationalise the strength of hydrogen bonding in compounds such as **1**, **2** and **3**.

5. Conclusions

It can be seen from **1**, **2**, **3** and the examples known from the literature that the ligands, their size and number as well as the type of counter ion play an important role in the building of hydrogen bonds. Two new structures, **1** and **2**, are presented that clearly show the dependence of stoichiometry for a pair of given ligands on the network formation. Reorganisation of the cationic building block can be achieved by the utilisation of a polyether ligand that is very similar in coordination and size to the diethers used in **1** and **2**. This allows one to predict with high probability the same hydrogen bonding structure for **3** that was obtained in **2**. It is still however a long way away from an efficient rationalisation of the pathway behind the formation of inorganic polymers based on complexation and hydrogen bonding, especially of the type O(H)···X, where X = halide.

6. Supplementary material

Crystallographic data have been deposited with the CCDC deposition numbers CCDC 141463 for **1**, CCDC 141464 for **2** and CCDC 141688 for **3**. Abstract

The partial hydrolysis of a mixture of molybdenum and tantalum methoxides (Mo:Ta = 1:2) with stoichiometric amounts of water yields a new bimetallic complex $Mo_2Ta_4O_8(OMe)_{16}$ (**I**) on crystallization from toluene. The molecules of **I** appear to be a combination of two $MoO_2(O^iPr)_2$ units with the earlier described $Ta_4O_4(O^iPr)_{12}$ core. The thermal reduction of a mixture of $MoO(O^iPr)_4$ and $Ta_2(O^iPr)_{10}$ (in a 1:1 Mo:Ta ratio) followed by oxidation of the products by dry oxygen, provides access to $Mo_4Ta_4O_{16}(O^iPr)_{12}$ (**II**). The same procedure, using $LiMo_2O_4(O^iPr)_4(OC_2H_4OMe)$ instead of $MoO(O^iPr)_4$, yielded trimetallic $LiMo_4Ta_3O_{14}(O^iPr)_9(OC_2H_4OMe)_3$ (**III**) in minor yields. The molecular structure of **II** can be described as a distorted cube, the corners of which are occupied in turn by $[(^iPrO)_3Ta(\mu\text{-}O)_3]$ octahedra and $[MoO(\mu\text{-}O)_3]$ tetrahedra sharing common vertexes. The molecular structure of **III** can be derived from that of **II** by replacing one $[(^iPrO)_3Ta(\mu\text{-}O)_3]$ octahedron with an $[Li(\mu,\eta^2\text{-}OC_2H_4OMe)_3]$ trigonal prism (the coordination number of the three Mo atoms is then increased to six). © 2000 Elsevier Science Ltd. 1. Introduction

Heterometallic alkoxides of heavy transition elements appear to be potent precursors of fine powders of the mixed-metal oxides and corresponding metal alloys having a broad range of applications [1,2]. We have reported earlier the isolation and characterization of the mixed-metal molybdenum(VI) and Group 4, e.g. $Zr_3Mo_8O_{24}(O^iPr)_{12}(^iPrOH)_4$ [3], and Group 7, e.g. $ReMoO_2(OMe)_7$ [4], derivatives. It appeared challenging to extend this study to the Group 5 derivatives and we report here the isolation and structural characterization of the bimetallic alkoxides of molybdenum(VI) and tantalum and of the related trimetallic complex of these elements and lithium. A preliminary communication reporting the isolation and a short description of the molecular structure of $Mo_2Ta_4O_8(OMe)_{16}$ has been published [5].

2. Experimental

All manipulations were carried out in a dry nitrogen atmosphere using the Schlenk technique or a dry box. The alcohols were purified by distillation over $Al(O^iPr)_3$ or $Mg(OMe)_2$ under argon. IR spectra of Nujol mulls were registered with a Bruker IFS-55 spectrometer. The ^1H NMR spectra were obtained with a Varian 400 MHz spectrometer, using dry deaerated toluene as solvent (using TMS as internal and 20 vol% solution of $CDCl_3$ as external standards). The metal ratio in the samples was determined, exploiting the facilities of Arrhenius Laboratory, Stockholm University, Sweden, on a JEOL-820 scanning electron microscope (SEM), supplied with a Link AN-10000 energy dispersive spectrometer (EDS). The total contents of the incombustible residues for the samples was determined using Perkin–Elmer TGA-7 device (in air, 10°C min^{-1}, final temperature 800°C).

The starting reagents used in this work ($MoO(OMe)_4$ and $LiMo_2O_4(O^iPr)_4(OC_2H_4OMe)$ [6] $Ta(OMe)_5$, and

0277-5387/00/$ - see front matter © 2000 Elsevier Science Ltd. All rights reserved.
PII: S0277-5387(00)00443-5

$Ta(O^iPr)_5$ [7]) were prepared by anodic oxidation of metals in alcohols and purified according to conventional techniques. An alcohol interchange reaction with isopropanol was used to obtain $MoO(O^iPr)_4$ and was performed by repeated (three times) dissolution of a measured quantity of methoxide in an excess of ^{i}PrOH with subsequent evaporation to dryness.

2.1. Preparation of $Mo_2Ta_4O_8(OMe)_{16}$ (I)

$MoO(OMe)_4$ (0.584 g, 2.47 mmol) and $Ta(OMe)_5$ (1.734 g, 5.16 mmol) were dissolved in 20 ml MeOH and then a solution of H_2O (0.13 ml, 7.2 mmol) in 20 ml MeOH was added dropwise to the bright yellow solution over a period of 1 h. The transparent colorless solution formed was then evaporated to dryness in vacuo and the glassy residue was redissolved in 5 ml of toluene and left to crystallize at −30°C for 2 days. The colorless crystals obtained were separated by decantation, washed with 1 ml toluene and dried in vacuo. Yield: 1.353 g (71%). IR (cm^{-1}): 1160 s, 1155 s, 1146 s, 1133 s, 1059 s br, 1035 sh, 1028 s, 935 s, 912 s, 837 sh, 826 s br, 732 w, 616 s br, 578 m, 547 s, 540 s, 527 s br, 502 s, 494 s, 449 m br. The ^{1}H NMR spectrum of **I** is shown in Fig. 1.

2.2. Preparation of $Mo_4Ta_4O_{16}(O^iPr)_{12}$ (II)

$MoO(O^iPr)_4$ (0.472 g, 1.36 mmol) and $Ta(O^iPr)_5$ (0.674 g, 1.41 mmol) were dissolved in 5 ml of toluene and the bright yellow solution obtained was refluxed for 30 min. The brownish–orange viscous liquid thus formed was left at room temperature (r.t.) for 2 weeks in a flask covered by a serum cup and it changed color slowly to light brown. The solvent was evaporated in vacuo and the light-brown glassy residue redissolved in 3 ml of hexane and left overnight to crystallize. The colorless transparent crystals formed were separated by filtration and dried in vacuo. Yield: 0.127 g (18%). IR (cm^{-1}): 1381 m, 1367 m, 1337 w, 1262 w, 1179 s, 1168 m, 1120 s br, 1007 s br, 966 w, 904 sh, 877 s, 840 s, 810 s br, 684 sh, 583 s br, 565 sh, 455 m br. ^{1}H NMR (ppm): 5.28 septet (1H, C*H*), 1.56 doublet (6H, CH_3).

2.3. Preparation of $LiMo_4Ta_3O_{14}(O^iPr)_9(OC_2H_4OMe)_3$ (III)

The procedure used was analogous to that for the preparation of **II** except that $LiMo_2O_4(O^iPr)_4$-(OC_2H_4OMe) was used instead of $MoO(O^iPr)_4$. The crystals of **III** were obtained in minor yields after prolonged storage in toluene solution in contact with dry air (about 2 months) of the products of thermal reduction.

2.4. Crystallography

2.4.1. Crystal data for $C_{16}H_{48}O_{24}Mo_2Ta_4$ (I)

$M = 1450.22$, monoclinic, space group $P2_1/n$, $a = 9.3422(18)$, $b = 9.455(2)$, $c = 22.621(6)$ Å, $b = 99.94(3)°$, $V = 1968.3(8)$ Å^3, $D_{calc} = 2.599$ g cm^{-3} for $Z = 2$, λ(Mo Kα) = 0.71073 Å, 4414 [$R_{int} = 0.1053$] independent reflections with $I > 2\sigma(I)$ were collected at 22°C up to $2\theta_{max} = 56.58°$ with a Bruker SMART CCD 1K diffractometer. The structure was solved by standard direct methods; the coordinates of tantalum and molybdenum

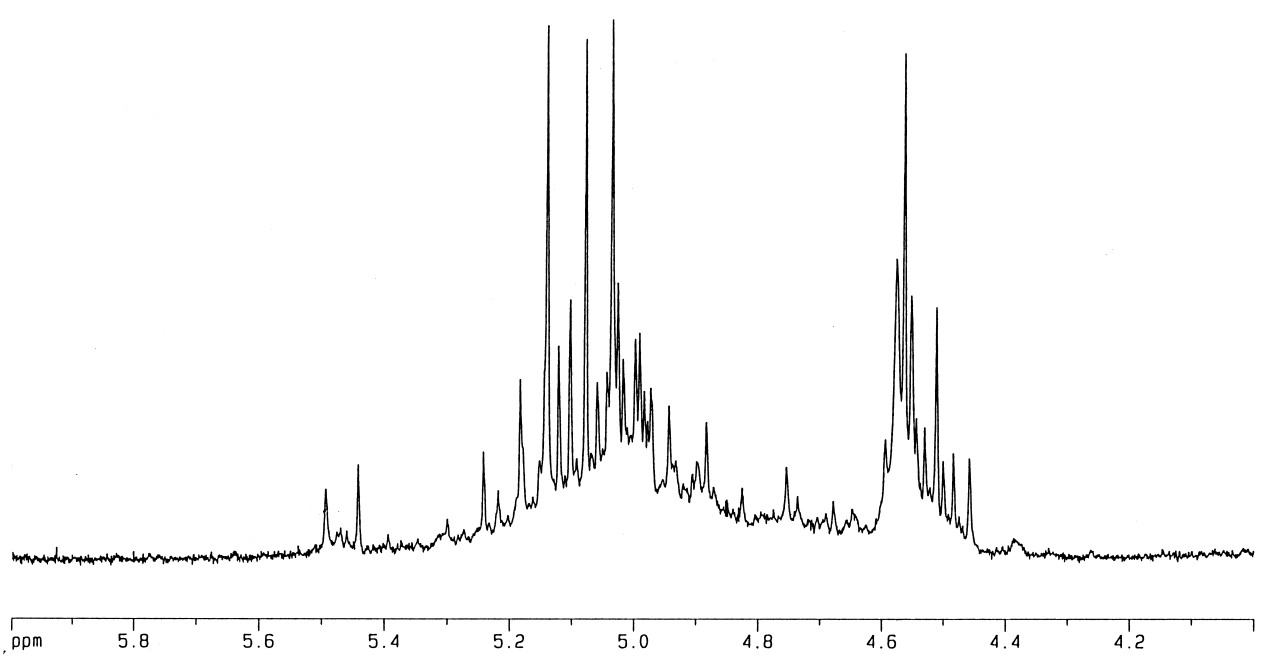

Fig. 1. The ^{1}H NMR spectrum of $Mo_2Ta_4O_8(OMe)_{16}$ (**I**) (toluene, 300 K).

atoms were taken from the initial solution and the other non-hydrogen atoms were located in subsequent Fourier syntheses. The structure was refined by full-matrix least-squares in an isotropic and then anisotropic approximation. Final discrepancy factors are $R = 0.0501$ and $wR_2 = 0.0711$.

*2.4.2. Crystal data for $C_{36}H_{84}O_{28}Mo_4Ta_4$ (**II**)*

$M = 2072.59$, tetragonal, space group $I\bar{4}$, $a = b = 14.998(6)$, $c = 14.974(8)$ Å, $V = 3368(3)$ Å^3, $D_{calc} = 2.044$ g cm^{-3} for $Z = 2$, λ(Mo Kα) = 0.71073 Å, 785 [$R_{int} = 0.0000$] independent reflections with $I > 2\sigma(I)$ were collected at 22°C up to $2\theta_{max} = 41.58°$ with a Bruker SMART CCD 1K diffractometer. The structure was solved by direct methods, applying HKLF 5 option for the experimental data file because of the presence of two twinning domains (creating a pseudo 3-fold axis and a pseudo-symmetry plane, the crystal thus having six individual components with an ideal crystallographic symmetry). The coordinates of tantalum and molybdenum atoms were taken from the initial solution and refined anisotropically. The other non-hydrogen atoms were located in subsequent Fourier syntheses and refined isotropically, the geometrical restraints being applied to conserve the idealized geometry for the ^{i}Pr-radicals (subjected to rotational disorder at r.t.). Final discrepancy factors are $R_1 = 0.0766$ and $wR_2 = 0.1933$.

*2.4.3. Crystal data for $C_{36}H_{84}O_{29}Mo_4Ta_3Li$ (**III**)*

$M = 1914.58$, triclinic, space group $P\bar{1}$, $a = 14.628(4)$, $b = 14.721(4)$, $c = 17.238(6)$ Å, $\alpha = 90.620(17)$, $\beta = 95.908(18)$, $\gamma = 118.354(9)°$, $V = 3241.6(17)$ Å^3, $D_{calc} = 1.962$ g cm^{-3} for $Z = 2$, λ(Mo Kα) = 0.71073 Å, 8399 [$R_{int} = 0.0534$] independent reflections with $I > 2\sigma(I)$ were collected at 22°C up to $2\theta_{max} = 45.00°$ with a Bruker SMART CCD 1K diffractometer. The coordinates of tantalum and molybdenum atoms were taken from the initial solution and refined anisotropically. The coordinates of all other non-hydrogen atoms were located in subsequent Fourier synthese and refined in anisotropic approximation for the oxygen atoms and isotropically for the carbon atoms. Final discrepancy factors are $R_1 = 0.0636$ and $wR_2 = 0.1516$.

The positions of the hydrogen atoms in the structures **I**–**III** were calculated geometrically and included in the final cycles of the refinement in isotropic approximation. All calculations were performed with an IBM PC using SHELXTL-NT programs [8].

3. Results and discussion

Taking into account the absence of complex formation between the monooxoalkoxides of molybdenum(VI), $MoO(OR)_4$, and tantalum alkoxides, $Ta(OR)_5$, [9] we decided to apply the microhydrolysis as the latter leads to oxoalkoxide species [10,11] that might have unsaturated coordination and thus be prone to aggregation with the formation of heterometallic products. The Mo:Ta = 1:2 ratio was chosen initially taking into account the existence of a bimetallic oxoalkoxotantalate of $I_2Zn_2Ta_4O_4(O^iPr)_{14}$ [12] composition, in which molecular structure the ZnI(μ-OR)$_2$(μ_3-O) tetrahedra appeared to be as sterically demanding as should be necessary for the $MoO_2(OR)(\mu\text{-}OR)_2(\mu_3\text{-}O)$ octahedra. When the hydrolysis of a mixture of methoxides with stoichiometric amounts of water was carried out in MeOH and the transparent solution obtained was left overnight to crystallize, the amorphous solid product collected did not contain tantalum (according to EDS analysis) and displayed an IR spectrum identical with that described for $MoO_2(OMe)_2$ [13]. To enhance the formation of heterometallic species, which could occur only via the Lewis acid–base interaction mechanism, a non-donor solvent was used (thus removing the concurrent Lewis base, MeOH). Evaporation of the reaction mixture produced by the hydrolytic treatment, to dryness and redissolution of the residue in toluene produced a clear solution from which the expected heterometallic complex, $Mo_2Ta_4O_8(OMe)_{16}$ (**I**), was obtained by crystallization at low temperatures.

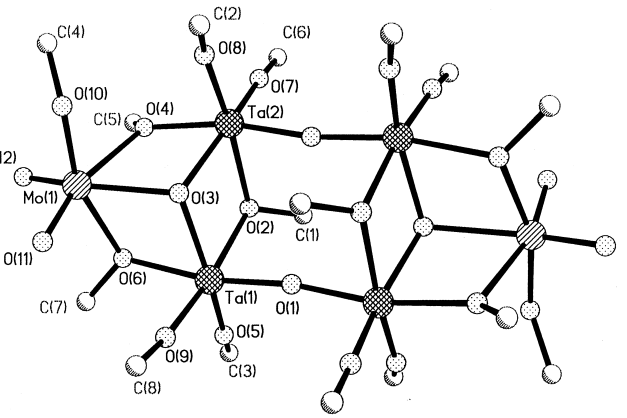

Fig. 2. The molecular structure of $Mo_2Ta_4O_8(OMe)_{16}$ (**I**).

The molecular structure of **I**, determined by an X-ray single crystal study (see Fig. 2 and Tables 1 and 2), was analogous to that of the chosen structural prototype, $I_2Zn_2Ta_4O_4(O^iPr)_{14}$ [12]. It is composed of centrosymmetric hexanuclear molecules, with the Ta–O distances (see Table 2) divided into two large groups, the first of which includes the bonds with the bridging alkoxoligands (Ta(1)–O(2) 2.125(7), Ta(2)–O(2) 2.128(7), Ta(1)–O(6) 2.125(7), Ta(2)–O(4) 2.043(7) Å) and the triply-bridging oxoatom (Ta(1)–O(3) 2.044(7), Ta(2)–O(3) 2.026(7) Å), and the second includes the bonds to the terminal alkoxide ligands (Ta(1)–O(5) 1.859(8), Ta(1)–O(9) 1.859(8), Ta(2)–O(7) 1.852(8),

Ta(2)–O(8) 1.865(8) Å) and the doubly-bridging oxoatom (Ta(1)–O(1) 1.890(7) and Ta(2)–O(1)# 1.931(7) Å). The Ta(1)–Ta(2) distance of 3.155(9) Å is quite short (compared with 3.31 Å in the Zn–Ta complex). The coordination of the doubly-bridging oxogroups is also almost linear, Ta(1)–O(1)–Ta(2)# 172.0(4)°. The coordination of the Mo atom is rather distorted in comparison with that usually observed [14]. The Mo–O distances themselves fall into the common ranges: 1.686–1.700(9) for the double bonds, 1.883(8) for the terminal alkoxide one and 2.134–2.279(8) for the alkoxide and oxo-bridging groups. However, the sum of the bond lengths in the *trans*-position differ noticeably (3.873(15), 3.979(17) and 4.017(16) Å) and the bond angles deviate strongly from 180° (O(10)–Mo(1)–O(6) 161.3(3), O(11)–Mo(1)–O(4) 164.1(4) and O(12)–Mo(1)–O(3) 151.7(4)°).

The IR spectrum of **I** is in good agreement with its molecular structure: there is a strong doublet present at 935 and 912 cm^{-1}, corresponding to vibrations in the *cis*-MoO_2 fragment [14], a very strong and broad band at 837 cm^{-1}, that can be attributed to vibrations with participation of oxobridging ligands, and a number of strong and well-defined bands in the area corresponding to the M–OR vibrations (616 s br, 578 m, 547 s, 540 s, 527 s, 502 s, 494 s, 449 m br). It should be mentioned that **I** supposedly does not exist in solution: it is almost insoluble in toluene at r.t. and when dissolved under reflux does not crystallize on cooling for several weeks. The ^1H NMR spectra of **I** (see Fig. 1) are strikingly complex: at least 20 sharp and well defined signals are observed between 4.40 and 5.20 ppm indicating presumably the destruction of the molecules on dissolution and the coexistence in solution of different molecular aggregates. The dissolution in MeOH in contrast occurs easily at r.t. and a very high solubility can in fact be observed on dissolution, but after several hours precipitation of an insoluble sediment characterized as $MoO_2(OMe)_2$ takes place (see above). Compound **I** is almost insoluble in hexane even on heating.

Analogous experiments to those used in the preparation of **I** were carried out with the isopropoxides of the title elements but did not lead to isolation of any crystalline product. At the same time it was found that oxidation of the bimetallic alkoxides of molybdenum(V) and tantalum, such as $Mo_4Ta_2O_8(O^iPr)_{14}$ or $Mo_3Ta_2O_8(O^iPr)_{10}$, with dry air led to the formation of a colorless crystalline product containing Mo and Ta in

[a] Symmetry transformations used to generate equivalent atoms: # 1 $-x$, $-y+1$, $-z$.

1:1 composition (according to EDS analysis) in minor yields [9]. The solution containing $MoO(O^iPr)_4$ and $Ta(O^iPr)_5$ in a 1:1 molar ratio in toluene was then prepared and subjected to thermal tretament in an analogous manner to that used for the complete reduction of Mo(VI) to Mo(V). It was then left at r.t. in a flask covered by a serup cup that provides good protection against moisture but not against oxygen in air. Complete oxidation, accompanied by the appropriate color change, occurred in 2 weeks and the bimetallic complex $Mo_4Ta_4O_{16}(O^iPr)_{12}$ (**II**) was obtained on crystallization from hexane in rather low yields. One of the major difficulties in the isolation of **II** appears to be its very high solubility in hydrocarbon solvents (achieving at least 50 wt% in both toluene and hexane).

The molecular structure of **II** (see Figs. 3 and 4 and Tables 1 and 3) is composed of non-centrosymmetric octanuclear molecules, the arrangement of the metal atoms in which can be described best as a distorted cube. The vertexes of this cube contain the molybdenum and tantalum atoms in turn. The former are tetracoordinated, building tetraoxomolybdate anions,

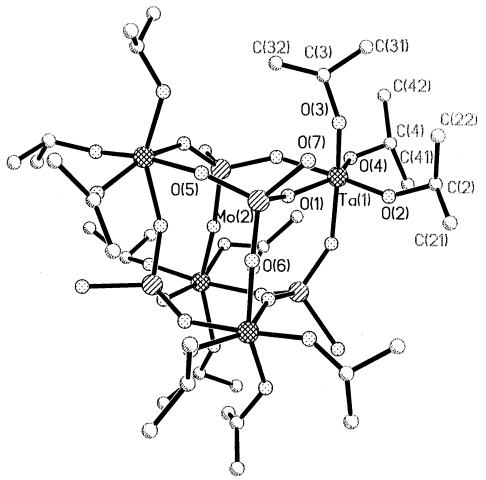

Fig. 3. The molecular structure of $Mo_4Ta_4O_{16}(O^iPr)_{12}$ (**II**).

Mo(2)O(7){μ-O(1)}{μ-O(5)}{μ-O(6)}, the latter hexacoordinated, forming Ta(1){μ-O(1)}{μ-O(5)}{μ-O(6)}O(2)O(3)O(4) octahedral units. The bonding parameters (Table 3) inside the tetraoxomolybdate unit are quite close to those usually observed for such fragments in polyoxometallate structures [15] (Mo–O 1.76(3)–1.77(3) for Mo–O–Ta bridging fragments and Mo(2)–O(7) 2.04(6) for the terminal Mo=O bond, the O–Mo–O angles being quite close to the tetrahedral ones, i.e. 110(4)–116(3)°). The bond lengths and angles inside the $Ta(\mu\text{-}O)_3(OR)_3$ octahedron (see Table 3) are within the ranges usually observed for tantalum oxoalkoxides [7]. The metal–oxygen core in structure **II** can be considered as the first representative of an unusual oxometallate core composed by four tetrahedra

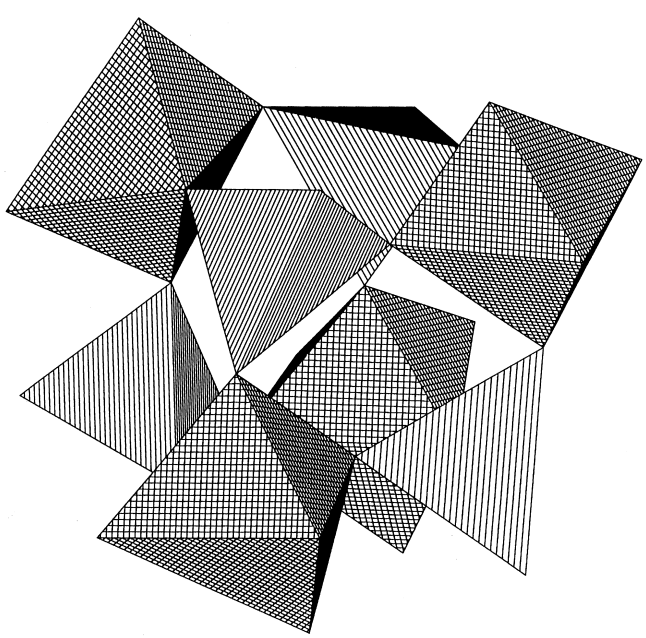

Fig. 4. A polyhedral presentation of the metal–oxygen core in the structure of **II**.

[a] Symmetry transformations used to generate equivalent atoms: # 1 $-x+2$, $-y+1$, z; # 2 $-y+3/2$, $x-1/2$, $-z+3/2$; # 3 $y+1/2$, $-x+3/2$, $-z+3/2$.

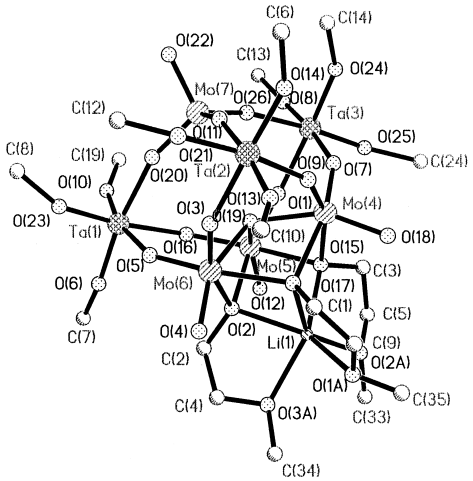

Fig. 5. The molecular structure of $LiMo_4Ta_3O_{14}(O^iPr)_9(OC_2H_4OMe)_3$ (**III**): the β-carbon atoms of the isopropoxide groups are omitted for clarity.

and four octahedra, sharing vertexes with each other (see Fig. 4).

The IR spectrum of **II** appears to be in good agreement with its molecular structure described above: it displays three broad and intensive lines that correspond to the vibration of the tetraoxomolybdate core at 877, 840 and 840 cm^{-1} and two strong lines at 583 and 455 cm^{-1} typical of Ta–OR bond vibration. Structure of **II** is preserved in hydrocarbon solution because the NMR spectra obtained in toluene display only one kind of well-defined signal for both methyne and methyl protons (all the isopropoxide groups in the solid state structure of **II** are terminal and have analogous bonding parameters), while the dissociation in solution would supposedly lead to the appearance of several different signals.

An attempt to prepare a trimetallic alkoxide complex using $LiMo_2O_4(O^iPr)_4(OC_2H_4OMe)$ instead of $MoO(O^iPr)_4$ yielded trimetallic $LiMo_4Ta_3O_{14}(O^iPr)_9(OC_2H_4OMe)_3$ (**III**) in minor yields (only a small crop of single crystals could be isolated from the viscous liquid media on complete removal of the solvent). Compound **III**, in analogy with **II**, possesses very high solubility in hydrocarbon solvents. The molecular structure of **III** (see Figs. 5 and 6 and Tables 1 and 4) is closely related to that of **II** and can be obtained from the latter by replacement of one of the $[(^iPrO)_3Ta(\mu\text{-}O)_3]$ octahedra with a $[Li(\mu,\eta^2\text{-}OC_2H_4OMe)_3]$ trigonal prism and demonstrates a distorted trigonal symmetry. The three $[MoO(\mu\text{-}O)_3]$ tetrahedra that were in contact with the $[(^iPrO)_3Ta(\mu\text{-}O)_3]$ octahedron that is removed get their μ-O groups, which became 'free', fused to one μ_3-O ligand. The molybdenum atoms complete their coordination number to six by coordinating two additional μ-OR 2-methoxyethoxide groups each. The coordination of the tantalum atoms is very close to that observed in **II** (the distances to the oxygen atoms of the terminal O^iPr-groups are essentially the same 1.832(14)–1.865(11) Å, while the lengths of the oxo-bridges vary a little more 1.988(10)–2.114(10) Å, with no obvious difference observed between the bridges to the tetrahedrally coordinated Mo(7) and 'pseudooctahedrally'-'4 + 2' coordinated Mo(4), Mo(5) and Mo(6) atoms). The bonding parameters for Mo(7) indicate a rather regular tetrahedral coordination (Mo(7)–O 1.697(13)–1.772(13) Å, the O–Mo(7)–O angles usual for a tetrahedron 105.8(6)–113.6(6)°). The bonding

parameters for Mo(4), Mo(5) and Mo(6) are very similar and indicate the same kind of distortion for the octahedra: the shortest bonds are those to the terminal oxygen atoms (1.690(11)–1.739(10) Å), the oxobridges to the tantalum atoms are also rather short (1.771(11)–1.840(10) Å), the triply bridging oxoatom has a longer Mo–O(19) distance, essentially same for all the three Mo atoms (2.045(10)–2.075(10) Å) and the longest distances are those to the alkoxobridges (2.155(12)–2.168(11) Å). It is very interesting to note that the lithium atoms definitely do not have an octahedral coordination but, indeed, have a trigonal prismatic coordination analogous to that observed for one of the symmetrically independent Li atoms in the structure of $[\{LiWO_2(OC_2H_4OCH_3)_3\}_2{\cdot}2Li(HOC_2H_4OCH_3)_2]^{2+}$ cations [6]. In both cases, this coordination appears to be forced by the parallel arrangement of the three 2-methoxyethoxide groups providing a pair of donor atoms each.

The molecule of **III** also represents a new type of a polyoxometallate core with a combination of octahedral and tetrahedral elements via sharing the common vertexes.

4. Supplementary material

Supplementary data are available from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers CCDC-139287 (**I**), CCDC-142959 (**II**), and CCDC-142960 (**III**).

Acknowledgements

The authors express their sincerest gratitude to Dr Regine Herbst-Irmer, who succeeded in resolving the twinning in the structure of **II** and provided a lot of help with its refinement. The authors are grateful to Dr C. Sandström for the assistance with the NMR experiments, to Dr G. Westin for providing access to EDS-analysis and to the Swedish Council for Natural Science Research for financial support of this work.

Abstract

The product isolated as colourless crystals from the reaction system $TeCl_4$–$SbCl_5$–18-crown-6–MeCN has been identified (X-ray diffraction studies) as the ionic salt $[(18\text{-crown-6})Te(Cl)(\mu\text{-}O)_2Te(Cl)(18\text{-crown-6})][SbCl_6]_2$. The μ-oxo-bridged cations have a centre of inversion and feature a distorted eight-coordinate metal environment involving two bridging oxygen atoms (Te–O 1.960(4) Å), one terminal chlorine atom (Te–Cl 2.361(2) Å) and five of the six oxygen atoms of the crown ligand (Te–O 2.549(4)–2.886(5) Å). The question of stereochemical involvement of the lone pair of electrons associated with each Te(IV) centre is considered. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: μ-oxo-Bridged cations; Crown ether complexation; Crystal structures; Bridging oxygen atoms

1. Introduction

In the solid state $TeCl_4$ has a cubane-like tetrameric structure wherein each metal centre is six-coordinate (distorted O_h) and the lone pair electrons associated with Te(IV) are visualised as pointing to the centre of the cube [1]. In solution, lattice breakdown can provide neutral mononuclear species and solvated $TeCl_3^+$ and Cl^- ions. Although a number of $TeCl_4(L)_n$ adducts have been noted, very few have been studied by X-ray crystallography, e.g. $TeCl_4[(Me_2N)_2C{=}S]_2$ [2], $TeCl_4[Ph_3P{=}O]_2$ and $TeCl_4[Ph_2P(S)\cdot CH_2\cdot P(S)Ph_2]\cdot MeCN$ [3]. Salts of the pyramidal cation $TeCl_3^+$ have been reported, e.g. $[TeCl_3][AlCl_4]$ α-form (A) [4], $[TeCl_3][AlCl_4]$ β-form (B) [5], $[TeCl_3][SbF_6]$ (C) [5] and $[TeCl_3][AsF_6]$ (D) [5]. In all of these examples the tetrahedral $TeCl_3E$ (E = lone pair) primary bond geometry becomes expanded as a result of significant secondary bonding interactions (Te···Y) involving halogen atom(s) (Y) of the complex anion, e.g. $TeCl_3Y_3E$ (distorted monocapped octahedron), (A) and (B); $TeCl_3Y_4E$ (C); $TeCl_3Y_5E$ (D). Our interest in macrocyclic complexation of p-block metallo-species has featured crown ether, crown thioether and aza ligands with Ga(III), In(III), Ge(IV), Sn(IV), As(III), Sb(III) and Bi(III) [6]. In this study of the $TeCl_4$–18-crown-6–$SbCl_5$–MeCN system we probe the binding of Te(IV) with a typical crown ether ligand; rather than the expected entrapment of the $TeCl_3^+$ cation, as formed by direct halide transfer $TeCl_4 \rightarrow SbCl_5$, a novel μ-oxo-Te(IV)–18-crown-6 complex was isolated. Specifically for Te(IV)–crown ether complexes there are three examples in the literature, viz. $[TeCl_3(15\text{-crown-5})][TeCl_5]$ [7], $[TeCl_3(15\text{-crown-5})]_2[TeCl_6]$ [7] and $[TeCl_3(15\text{-crown-5})][SbCl_6]$ [8]. Structural characterisation of the latter reveals the tellurium atom positioned over the ring cavity and linked symmetrically to the five oxygen atoms of the crown ligand.

2. Materials and methods

Manipulations were carried out using a Schlenk high-vacuum system in conjunction with a standard di-nitrogen-filled glove-box. Acetonitrile was pre-dried over molecular sieves and then freshly distilled from CaH_2 under a di-nitrogen atmosphere prior to use. $TeCl_4$, 18-crown-6 and $SbCl_5$ were used as supplied (Aldrich).

☆ 18-crown-6 = 1,4,7,10,13,16-hexaoxacyclooctadecane.

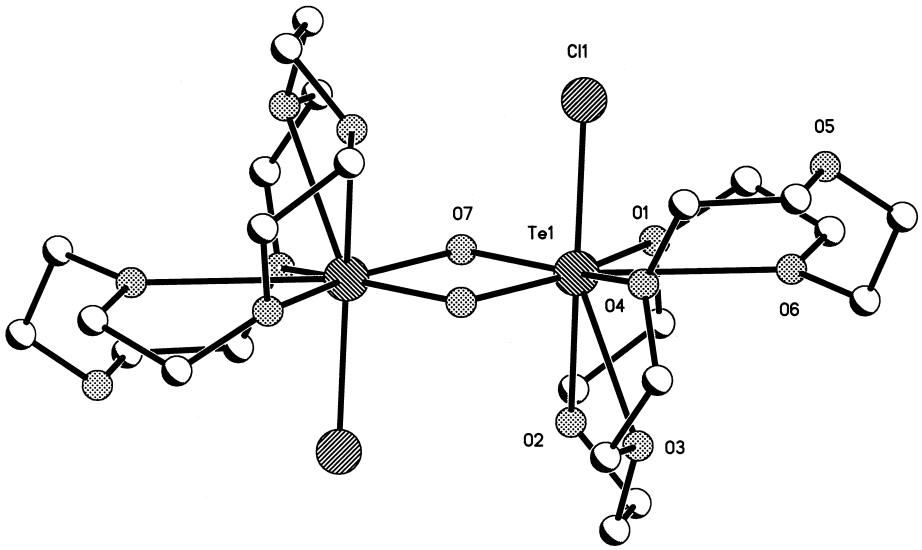

Fig. 1. The structure of the cation $[(18\text{-crown-6})Te(Cl)(\mu\text{-}O)_2Te(Cl)(18\text{-crown-6})]^{2+}$ showing atom notation used.

IR spectra were recorded using a Perkin–Elmer 580B spectrometer with samples as Nujol mulls placed between CsI discs. Elemental analyses were carried out using a CE440 elemental (C, H, N) analyser.

2.1. [(18-crown-6)Te(Cl)(μ-O)$_2$Te(Cl)(18-crown-6)][SbCl$_6$]$_2$

A solution of $SbCl_5$ (0.80 g, 2.68 mmol) in acetonitrile (20 cm^3) was added dropwise to a stirred solution of $TeCl_4$ (0.72 g, 2.67 mmol) in acetonitrile (20 cm^3) maintained at 0 °C. Directly afterwards a solution of 18-crown-6 (0.71 g, 2.69 mmol) in acetonitrile (20 cm^3) was further added and the resulting solution was stirred for 12 h at room temperature. Gradual removal of solvent in vacuo (ca. 50% by volume) provided a crop of colourless needle crystals. Yield 0.22 g, 5.3%. Found: C, 18.26; H, 3.02. Calc. for $C_{24}H_{48}O_{14}Cl_{14}Sb_2Te_2$: C, 18.53; H, 3.11%.

IR: $\bar{\nu}_{max}$ (cm^{-1}) (Nujol): 1287 (m), 1250 (m), 1141 (m), 1094 (s), 1077 (s), 970 (s), 946 (m), 839 (w), 723 (w), 340 (vs, $SbCl_6$).

2.2. X-ray crystallography

Data were collected using a Siemens SMART CCD area-detector diffractometer. Absorption corrections were applied using SADABS [9]. The structure was solved by direct methods and refined by full-matrix least-squares on F^2 for all data using SHELXL-97 [10].

2.2.1. Crystal data

$TeClC_{12}H_{24}O_7SbCl_6$, $M = 777.81$, monoclinic, $a = 8.4328(12)$, $b = 12.3141(15)$, $c = 23.764(2)$ Å, $\beta = 96.169(3)°$, $U = 2453.5(5)$ Å^3, $T = 180(2)$ K, space group $P2(1)/n$, $Z = 4$, μ(Mo Kα) = 3.082 mm^{-1}, wavelength = 0.71073 Å, 12 475 reflections measured, 4285 unique ($R_{int} = 0.044$). The final values of R_1 [$I > 2\sigma(I)$] and wR_2 are 0.0408 and 0.0984, respectively.

3. Results and discussion

Reaction of $TeCl_4$ and $SbCl_5$ in acetonitrile in the presence of 18-crown-6 provided colourless crystals of $[(18\text{-crown-6})Te(Cl)(\mu\text{-}O)_2Te(Cl)(18\text{-crown-6})][SbCl_6]_2$, which are highly sensitive to the merest trace of air/moisture. Partial hydrolysis of the 'direct' halide abstraction cation $[TeCl_3(18\text{-crown-6})]^+$ is seen as the root cause for the formation of the oxo-species. The ionic structure of the title compound has been established by X-ray diffraction; the cation is depicted in Fig. 1 (with atom notation) and selected bond dimensions are listed in Table 1. The dinuclear μ-oxo-bridged cations possess a two-fold axis of symmetry and feature a distorted eight-coordinate metal environment com-

[(2,4,6-Ph$_3$C$_6$H$_2$)Te(Br)(μ$_2$-O)]$_2$	2.084(5)	102.4(2)	77.6(2)	[12]
	1.898(4)			
[(2,4,6-Ph$_3$C$_6$H$_2$)Te(I)(μ$_2$-O)]$_2$	2.086(2)	102.3(1)	77.8(1)	[12]
	1.914(2)			

prising the two bridging oxygen atoms, a terminal chlorine atom Te–Cl 2.361(2) Å (for comparison [TeCl$_3$][AlCl$_4$] Te–Cl 2.279, 2.281, 2.277 Å [5], [TeCl$_4$]$_4$ Te–Cl 2.31 Å [1]) and five of the oxygen atoms of the oxacrown ligand. Although the [Te(μ-O)$_2$Te] subunit is rare, with only three structures listed, viz. [(cyclenH$_3$)Te(μ$_2$-O)]$_2$Cl$_2$·2MeOH·4CHCl$_3$ [11] and [(2,4,6-Ph$_3$C$_6$H$_2$)Te(X)(μ$_2$-O)]$_2$ where X = Br, I [12], the bond dimensions show a high degree of uniformity with the Te–O$_{bridge}$ distances in the region 1.9–2.0 Å (see Table 2).

Of the six donor oxygen atoms of the ring, five are within binding distance of the metal with Te–O$_{crown}$ distances 2.549(5)–2.886(5) Å (van der Waal radii, Te 2.06 and O 1.52 Å [13]); for direct comparison the Te–O$_{crown}$ bond distances in [TeCl$_3$(15-crown-5)][SbCl$_6$] are found in the range 2.66(3)–2.79(3) Å. The remaining oxygen atom lies well outside this region and is clearly not involved in coordination to the metal Te···O(5) 4.144(5) Å. The resulting distorted crown conformation is seen as a direct consequence of stereochemical activity of the lone pair associated with Te(IV) pointing towards the O(5) region. Thus, the metal coordination geometry can be described as a distorted ψ-capped square antiprism with the lone pair occupying a capped (rectangular) face to the exclusion of O(5), (see Fig. 2).

The SbCl$_6^-$ anions are unexceptional with regular octahedral coordination about Sb atoms, Sb–Cl (mean) 2.364(2) Å, Cl–Sb–Cl (mean) 89.94(7) and 179.21(7)°.

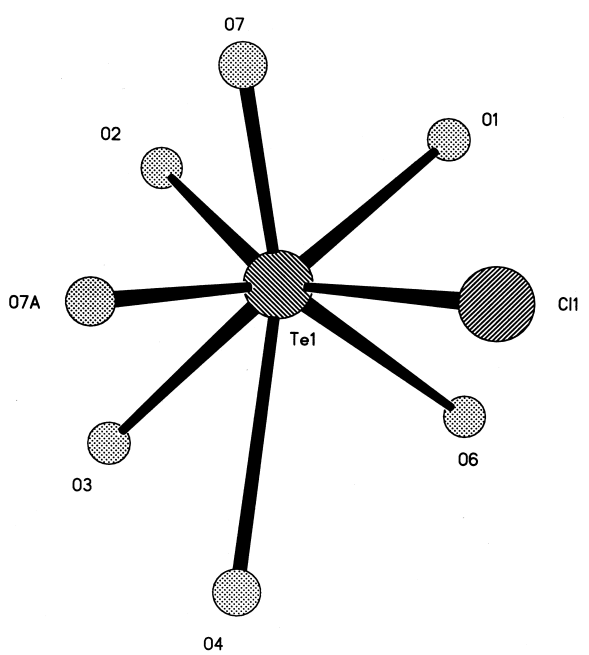

Fig. 2. The coordination geometry of the Te(IV) centres in the cation [(18-crown-6)Te(Cl)(μ-O)$_2$Te(Cl)(18-crown-6)]$^{2+}$.

4. Supplementary material

Additional material containing non-hydrogen and hydrogen atomic coordinates, thermal parameters, and the remaining bond lengths and angles are available from The Director, Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the Deposition Number 141855.

Abstract

The isomeric complexes *trans*-$[NiL_2(NCS)_2]$ (violet) (**1**) and *cis*-$[NiL_2(NCS)_2]$ (blue) (**2**) [L = 1-(2-aminoethyl)pyrrolidine] have been synthesized, varying solvents and temperature, and their X-ray crystal structures have been determined. Both the isomers possess the same space group, $P2_1/c$, having distorted octahedral geometry. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Nickel(II)thiocyanate; 1-(2-Aminoethyl)pyrrolidine; Crystal structures; *cis*/*trans* Isomers

1. Introduction

The chemistry of amine with nickel(II)thiocyanate is well documented, but the examples for the formation of both *cis* and *trans* isomers with the same amine are rare. The mutual interaction between the amine ligands is found to be responsible for the stability of the *cis* or *trans* isomer as in the case of 1,2-bis(2-imidazolinyl)benzene which yields the *cis* species whereas 1,2-bis(2-imidazolinyl)ethane generates the *trans* species [1]. The amine, phenylethylamine, is reported to yield *cis* as well as *trans* species but the latter is stabilized only as clathrates with *sec*-butylbenzene or *o*-xylene [2]; thus, they are not isomers. Ethane-1,2-diamine and its derivatives which form five-membered chelate rings with nickel(II)thiocyanate always produce the *trans* species [3–5], but propane-1,3-diamine [6] and *N*-methylpropane-1,3-diamine [7] which form six-membered chelate rings result the *cis*-diisothiocyanato species. Recently, there has been a report of the reaction of ethane-1,2-diamine and nickel(II)selenocyanate where a pure *trans* species has been synthesized, although on variation of preparative method a new species has been derived whose unit cell contains two moieties of *cis* species along with one moiety of tris-(ethane-1,2-diamine)nickel(II) selenocyanate [8]. The foregoing facts lead us to pursue the reaction of nickel(II)thiocyanate with the ethane-1,2-diamine analogue to synthesize *trans* as well as *cis* isomers in pure form altering the preparative procedure. We were able to synthesize both the *cis*- and *trans*-diisothiocyanato species with 1-(2-aminoethyl)pyrrolidine as ligand on variation of temperature as well as reaction medium. The present paper reports the synthesis, characterization and single-crystal X-ray diffraction studies of *cis* and *trans* isomers of diisothiocyanato bis[1-(2-aminoethyl)-pyrrolidine]nickel(II).

2. Experimental

2.1. Materials

High-purity (98%) 1-(2-aminoethyl)pyrrolidine (L) was purchased from Lancaster Chemical Company and used as received and all the non-aqueous solvents were dried before use.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer and nickel(II) content was estimated gravimetrically [9]. IR-spectra (4000–400 cm^{-1}) were taken at 27°C using a Perkin–Elmer IR 783 where KBr was used as medium. Electronic spectra (1400–200 nm) were obtained at 27°C using a Hitachi UV–Vis–NIR model U-3410 where Nujol was used as a medium as well as a reference. The magnetic susceptibility was measured at 27°C using an EG and G PAR 155 vibrating sample magnetometer, where $[HgCo(SCN)_4]$ was used as a reference material and diamagnetic corrections were made using Pascal's constants. Molar conductivity values were measured using a Systronics 304 conductivity meter, where the cell constant was calibrated with 0.02 M KCl.

2.3. Synthesis of the complexes

trans-$[NiL_2(NCS)_2]$ (**1**) (violet) was synthesized by adding diamine (2 mmol) (L) in methanol (5 cm^3) to the nickel(II)thiocyanate (1 mmol) dissolved in methanol (10 cm^3) at a temperature lower than 10°C. The resulting solution was stirred for a few minutes. A violet complex was separated out, filtered, washed with isopropanol and dried in a $CaCl_2$-desiccator (yield, 81%). Found for **1**: C, 41.6; H, 6.7; N, 20.8; Ni, 14.5. Calc. for $NiC_{14}H_{28}N_6S_2$: C, 41.7; H, 6.9; N, 20.8; Ni, 14.6%. $\mu_{eff} = 2.97$ μB. λ_{max} (Nujol): 936, 566 and 362 nm. Single crystals suitable for X-ray analysis were obtained by slow evaporation of the methanolic solution of **1** by maintaining the temperature < 10°C.

cis-$[NiL_2(SCN)_2]$ (**2**) (blue), was synthesized using the same method as above but keeping the temperature above 30°C. The blue complex formed was kept in a $CaCl_2$-desiccator (yield, 76%). Found for **2**: C, 41.5; H, 6.9; N, 20.7; Ni 14.6. Calc. for $NiC_{14}H_{28}N_6S_2$: C, 41.7; H, 6.9; N, 20.8; Ni, 14.6%. $\mu_{eff} = 2.98$ μB. λ_{max} (Nujol): 979, 580 and 370 nm. Single crystals suitable for X-ray analysis were obtained by slow evaporation of the methanolic solution of **1** by maintaining the temperature > 30°C.

2.4. X-ray data collection and structure determination

The data for complex **1** were collected on a Nonius CAD4 diffractometer using the $\omega - 2\theta$ scan technique while the diffraction data for complex **2** were collected similarly on a Nonius MACH3 diffractometer. Both sets of data were corrected for Lorentz and polarization factors and empirical absorption corrections were carried out using ψ-scan data of some selected reflections using the NRCVAX suite of programs [10]. The structures were solved by direct methods and partial difference Fourier techniques using the SHELXS-86 [11] program and refined using SHELXL-93 [12].

3. Results and discussion

Both the temperature and solvents have very important role in the syntheses of the isomers (Table 1). Treatment of nickel(II)thiocyanate with diamine in 1:2 ratio in alcohol (MeOH/EtOH/2-PrOH)–water mixture (99:1) above 30°C yields the pure *cis* isomer whereas if the temperature is maintained below 10°C the *trans* species is the only product. The mixture of *cis* and *trans* isomers results in the temperature range, 10–30°C; with an increasing percentage of the *cis* isomer with increasing temperature. When the above reaction is carried out in alcohol (dried before use by distillation with Mg) the pure *trans* isomer is obtained till the temperature is raised up to 50°C, a mixture of the *cis* and *trans* isomer results in the temperature range 50–55°C, and above 55°C the *cis* complex is the only product. The reaction was also carried out in dry non-alcoholic solvent, e.g. CH_3CN, CH_2Cl_2 and $CHCl_3$ (where the nickel(II)-thiocyanate is taken in suspension due to its insolubility in these solvents) and the results were found to be the same as in dry alcohol. When the same reaction is performed in water medium the *cis* isomer is the only

Table 1

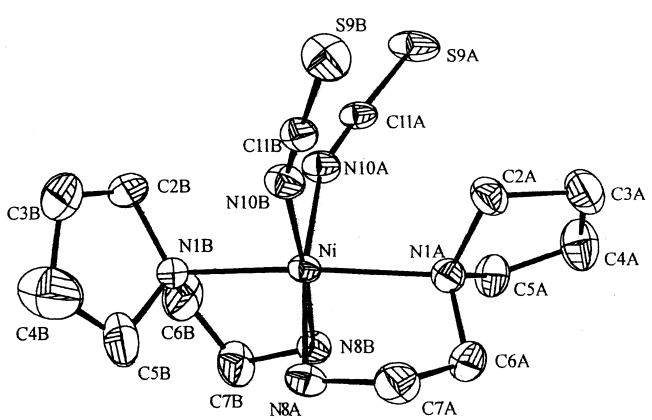

Fig. 2. ORTEP diagram of *cis*-[$NiL_2(SCN)_2$]. Ellipsoids are drawn at 50% probability.

product, irrespective of temperature. From the foregoing facts it is apparent that water, with the highest dielectric constant among the solvents used in the synthesis, stabilizes the more polar *cis* isomer, and the *trans* isomer is obtained from the less polar solvents. Temperature plays a very important role in the synthesis of the complexes. Molar conductivity data (Table 2) show that both the *cis* and *trans* isomers are almost nonconducting at low temperatures (~0°C) but their conductivity increases with temperature indicating appreciable solvation at higher temperature:

$$NiL_2(NCS)_2 + \text{solvent} \rightleftharpoons [NiL_2(\text{solvent})(NCS)]^+ + NCS^-$$

The synthesis of *cis* or *trans* complexes at different temperature seems to be related to the solvation of the complex; the greater the level of solvation, the higher the yield of the *cis* complex. As for example in ethanol, where solvation is much less compared to water, the *trans* isomer is obtained only at high temperatures (>50°C).

The composition of the complexes $NiL_2(NCS)_2$ (violet) (**1**) and $NiL_2(NCS)_2$ (blue) (**2**) has been confirmed by elemental analyses. The complexes exhibit IR bands comparable to those of the diamine systems whose chelate character has been established by X-ray single-crystal structure analyses [13,14]. The magnetic and electronic spectral data of the complexes are in good agreement with octahedral nickel(II). The IR bands for complex **1** (ν_{C-N} at 2077 cm^{-1}) and for complex **2** (ν_{C-N} at 2081 and 2096cm^{-1}) suggest that the violet species is *trans* and the blue is *cis* [15].

Figs. 1 and 2 show ORTEP [16] views of the complexes with the atom numbering schemes. Crystal data are summarized in Table 3. Selected bond distances and angles involving the Ni ions are shown in Table 4. In both the complexes the Ni coordination is distorted-octahedral with the four N-atoms of two bidentate 1-(2-aminoethyl)pyrrolidine and two N-atoms of two isothiocyanate groups. In **1** the isothiocyanato groups are *cis* and in **2** they are *trans* to each other. The pyrrolidine groups of the two diamines remains *trans* in both the isomers. There are still other possible isomers with this ligand set that would be obtained by flipping the orientation of one of the chelating ligands in each of the products with pyrrolidine *cis* to pyrrolidine configuration. However, they could not be synthesized because there would be severe steric interaction between the pyrrolidine groups. It is seen that the two ligands coordinate to the metal ion in the *trans* configuration in **1** and in the *cis* configuration in **2**. The shorter Ni–N coordination distances involving the thiocyanate nitrogens can be explained by the fact that these nitrogen atoms are sp^2 hybridized. Also, the relatively longer Ni–N bonds involving the ring nitrogen atoms (N1) can be attributed to strong steric hindrance caused by the bulky pyrrolidine ring. The Ni–N distances are consistent with the corresponding nickel(II)-amine complexes [14,17].

The coordinating ligands (L) in both the complexes are disordered. The C6 atom of the ethylamine moiety in **1** has alternative positions, with partial occupancies

of 0.76 and 0.24. In complex **2**, three atoms (C3B, C4B, C5B) of ligand B are disordered with partial occupancies of 0.51 and 0.49 in two alternative sets of coordinates.

In **1**, the corresponding crystallographically independent five-membered ring is disordered and flips between the twist [$q_2 = 0.385(6)$ Å, $\phi_2 = -130.4(5)°$] and envelope [$q_2 = 0.302(10)$ Å, $\phi_2 = -1.3(12)°$] conformations. The pyrrolidine ring in the crystallographic asymmetric unit of **1** is in the envelope conformation [$q_2 = 0.389(3)$ Å, $\phi_2 = -178.9(5)°$]. The pyrrolidine ring in ligand A of **2** is in the envelope conformation [$q_2 = 0.331(4)$ Å, $\phi_2 = -0.8(9)°$] while in ligand B it flips between the twist [$q_2 = 0.205(16)$ Å, $\phi_2 = -127.4(44)°$] and the envelope [$q_2 = 0.242(9)$ Å, $\phi_2 = 6.9(33)°$] conformations. In complex **2**, the five-membered ring (N1–C6–C7–N8–Ni), formed by the coordination of the pyrrolidine and ethylamine nitrogen atoms to the Ni ion, is in the twist conformation [$q_2 = 0.441(4)$ Å, $\phi_2 = 60.1(4)°$] for ligand A and in the envelope conformation [$q_2 = 0.458(5)$ Å, $\phi_2 = -145.2(5)°$] for ligand B [18]. Although no hydrogen bonds are present in the crystal structure of **1**, the crystal structure of **2** is stabilized by two intermolecular N–H···S hydrogen bonds between screw related molecules (N8B···S9B($-x+1, y-\frac{1}{2}, -z+\frac{1}{2}$), 3.537(3); H8B1···S9B, 2.67; N8B···S9A($-x+1, y-\frac{1}{2}, -z+\frac{1}{2}$), 3.618(3); H8B2···S9A, 2.76 Å; ∠N8B–H8B1···S9B 162.8(3)°; ∠N8B–H8B2···S9A 160.6(3)°).

4. Conclusion

The present report reveals that by using the ligand 1-(2-aminoethyl)pyrrolidine, both the *cis*-diisothiocyanato species (which is a rather uncommon geometrical isomer among the bis-complexes of ethane-1,2-diamine derivatives with Ni(II)), and the usual *trans* isomer, can be both synthesized in pure form; one has to simply choose the proper solvent and vary the reaction temperature to get the desired isomer.

5. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, deposition numbers 132798/132799. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

We thank the Regional Sophisticated Instrumentation Centre, Bose Institute, Calcutta-700 009, for the single-crystal X-ray diffractometer facility. Financial support by the Council of Scientific and Industrial Research, New Delhi, as a grant to N.R.C. is also gratefully acknowledged.

POLYHEDRON

Synthesis and structures of two-dimensional coordination polymers constructed by metal salts and 4,4′-bipyridine

Ming-Liang Tong, Shao-Liang Zheng, Xiao-Ming Chen *

School of Chemistry and Chemical Engineering, Zhongshan University, Guangzhou 510275, PR China

Received 23 February 2000; accepted 5 June 2000

Abstract

Two nitrate compounds, $[Cu(4,4'\text{-bpy})_2(NO_3)_2]\cdot(paba)_3$ (**1**) and $[Cd(4,4'\text{-bpy})_2(H_2O)_2](NO_3)_2\cdot 4H_2O$ (**2**) (4,4′-bpy = 4,4′-bipyridine; paba = 4-aminobenzic acid), were obtained from the reactions of different metal salts and 4,4′-bpy. Compounds **1** and **2** are made up of two-dimensional square $[M_4(4,4'\text{-bpy})_4]$ grids in which the cavity has dimensions of 11.01×11.02 and 11.69×11.81 Å for **1** and **2**, respectively. In **1**, the guest paba molecules are enclathrated in the hydrophobic host cavities or situated between the coordination layers and interlinked into one-dimensional hydrogen-bonding chains through hydrogen bonding and C–H···π interactions, which further interpenetrate and contact the square grids through their functional moieties (pyridyl rings, amine groups and carboxylic groups), resulting in a new three-dimensional molecular network. In **2**, the lattice water molecules and nitrate ions are situated between the coordination layers, and extensive hydrogen bonds between the host grid and guest molecules extend the two-dimensional coordination layer into a three-dimensional molecular network. © 2000 Elsevier Science Ltd. Keywords: 4,4′-Bipyridine; Coordination polymers; Copper(II) complexes; Cadmium(II) complexes

1. Introduction

The synthesis of coordination polymers with large channels or cavities has been rapidly expanding due to their intriguing structural diversity and potential functions as microporous solids for molecular adsorption, ion exchange, and heterogeneous catalysis [1–3]. The construction of such cavities, mainly surrounded by aromatic edges, is very attractive since their shape, size and function may be controlled by the different oxidation states, the coordination preference of the metal ions, the types of ligands and solvents and the molar ratio of the metal ions and the ligands. On the other hand, the design of supramolecular architectures is also of interest in the field of host–guest chemistry. A number of the infinite frameworks well meet these requirements, because the hosts employed are relatively rigid, contain large cavities and the van der Waals surfaces and electrostatic potential surfaces of the host and guest may be complementary [4]. Although a wide range of infinite one-, two- and three-dimensional coordination frameworks have already been generated with simple, linear spacers such as 4,4′-bipyridine (4,4′-bpy) and pyrazine [5], it is somewhat surprising that very few frameworks have been reported to enclathrate larger organic guest molecules [6,7].

We have recently reported a series of non-interpenetrating open-frameworks with variable cavities or channels, in which the rod-like rigid spacers such as 4,4′-bpy, pyrazine and the related species are chosen as the building blocks [7,8]. We report herein the preparation and crystal structures of two layer-type coordination networks constructed by metal(II) salts with 4,4′-bpy, namely $[Cu(4,4'\text{-bpy})_2(NO_3)_2]\cdot(paba)_3$ (**1**) and $[Cd(4,4'\text{-bpy})_2(H_2O)_2](NO_3)_2\cdot 4H_2O$ (**2**) (paba = 4-aminobenzic acid).

2. Experimental

2.1. Materials and physical measures

All reagents were commercially available and used as received. The C, H, N microanalyses were carried out with a Perkin–Elmer 240 elemental analyzer. The FTIR spectra were recorded from KBr pellets in range 4000–400 cm^{-1} on a Nicolet 5DX spectrometer.

2.2. Synthesis of metal complexes

2.2.1. $[Cu(4,4'\text{-bpy})_2(NO_3)_2]\cdot(paba)_3$ (1)

To a solution of $Cu(NO_3)_2\cdot 3H_2O$ (0.242 g, 1.0 mmol) in 4:1 (v/v) MeOH–H_2O (10 cm^3), a solution of 4,4′-bpy (0.156 g, 1.0 mmol) in MeOH (5 cm^3) was slowly added with stirring for 15 min at 60°C, and the solution was adjusted to pH 4.5 by addition of dilute HNO_3 solution, then a solution of paba (2.0 mmol, 0.274 g) in MeOH (5 cm^3) was slowly added. Dark blue block-like crystals were deposited within five days in 78% yield based on 4,4′-bpy (*Anal.* Calc. for $C_{41}H_{37}CuN_9O_{12}$: C, 54.04; H, 4.09; N, 13.83. Found: C, 53.89; H, 4.02; N, 13.72%). Infrared data (ν cm^{-1}): 3461m, 3363m, 3336m, 3232m, 3100m, 3061m, 2957m, 2918m, 2850m, 1673s, 1601vs, 1568m, 1517m, 1494w, 1409s, 1385vs, 1343s, 1313vs, 1285s, 1222s, 1168s, 1120m, 1071m, 1042w, 1017w, 932w, 855w, 818m, 776m, 726w, 696w, 644m, 609m, 547m, 498m.

2.2.2. $[Cd(4,4'\text{-bpy})_2(H_2O)_2](NO_3)_2\cdot 4H_2O$ (2)

A methanolic solution (10 cm^3) of 4,4′-bpy (0.156 g, 1.0 mmol) was added dropwise to a stirring aqueous solution (5 cm^3) of $Cd(NO_3)_2\cdot 4H_2O$ (0.308 g, 1.0 mmol) at 50°C for 15 min. An ethanolic solution (10 cm^3) of 4,4′-bpy (0.156 g, 1.0 mmol) was then added. The resulting colorless solution was allowed to stand in air at r.t. for 3 weeks, yielding colorless block-like crystals (64% yield based on 4,4′-bpy). *Anal.* Calc. for $C_{20}H_{28}CdN_6O_{12}$: C, 36.57; H, 4.30; N, 12.79. Found: C, 36.45; H, 4.21; N, 12.65%. Infrared data (ν cm^{-1}): 3409m, 3107w, 3057w, 1609s, 1539w, 1489s, 1384vs, 1278s, 1222m, 1075m, 1039m, 1011w, 983w, 807m, 723w, 674w, 632m, 568w, 491w.

2.3. X-ray crystallography

A summary of selected crystallographic data for **1** and **2** is given in Table 1. The data collections for the two complexes were carried out on a Siemens R3m diffractometer using graphite-monochromatized Mo Kα (λ 0.71073 Å) radiation at 298(2) K. Lorentz-polarization and absorption corrections were applied [9]. The structures were solved with direct methods and refined with full-matrix least-squares technique using the SHELXS-97 and SHELXL-97 programs, respectively [10,11]. Non-hydrogen atoms were refined anisotropically. The organic hydrogen atoms were generated geometrically (C–H = 0.96 Å); the aqua hydrogen atoms were located from difference maps and refined with isotropic temperature factors. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated [12]. The non-hydrogen atomic coordinates and selected bond lengths (Å) and angles (°) for complexes **1** and **2** are given in Table 2. Drawings were produced with SHELXTL [13].

3. Results and discussion

3.1. Preparation

Generally, with a 1:1 molar ratio of metal–4,4′-bpy, one-dimensional polymeric products or two- and three-dimensional interpenetrating networks should be expected in absence of suitable guest molecules [7a, 14]. However, only the two-dimensional coordination net-

work of **1** was isolated in high yield when the reactions were conducted with equivalents of the copper salt, 4,4′-bpy and paba, in an MeOH–H_2O mixture. Therefore, the presence of guest paba molecules in the reaction system may be very important in the formation of the two-dimensional polymeric structures, which is similar to other recently observed phenomena [7b, 8]. On performing the above reactions with a 1:2:3 molar ratio of Cu–4,4′-bpy–paba, crystals of **1** were also isolated in high yield, suggesting that the guest paba molecules present here may serve as templates to exclude self-inclusion or interpenetration [14].

Four metal-4,4′-bpy compounds having the similar formula to **2**, $M(4,4'\text{-bipy})_2(H_2O)_mX_2\cdot nH_2O$ (M = Cu(II), Zn(II) or Mn(II); X = ClO_4^-, NO_3^-, BF_4^-, or SCN^-), have been recently synthesized and structurally characterized [7a, 15]. However, their coordination structures are greatly different from that of **2**. In the former case one-dimensional coordination chains are generated first, and are further extended into higher dimensional networks by hydrogen bonding interactions. The difference may result from the different reaction conditions. The formers were synthesized by one-pot methods, whereas **2** was obtained by addition of the 4,4′-bpy ligand in two steps.

3.2. Crystal structures

3.2.1. $[Cu(4,4'\text{-bpy})_2(NO_3)_2]\cdot(paba)_3$ (*1*)

Compound **1** is made up of neutral two-dimensional square grids and guest paba molecules. Each layer is constructed of a common planar square with a Cu(II) atom and a 4,4′-bpy at each corner and side, respectively. The square cavity has dimensions of 11.01 × 11.02 Å, which are very similar to that of a recently reported Cu(II)–4,4′-bpy compound [7b]. The Cu(II) atom in Jahn–Teller tetragonally elongated distorted octahedral geometry, similar to those in two reported Cu-4,4′-bpy coordination networks [7b, 8g], is ligated by four pyridyl groups in the equatorial positions [Cu–N = 1.996(3)–2.014(3) Å] and weakly by two monodentate NO_3^- groups in the apical positions [Cu–O = 2.461(3) and 2.762(3) Å, respectively].

The most interesting structural features are the host–guest interactions between the host square $[Cu_4(4,4'\text{-bpy})_4(NO_3)_8]_n$ grids and the guest paba molecules, as shown in Fig. 1. The guest paba molecules are enclosed in the hydrophobic host cavities or situated between the coordination layers, and also make contact with the host grids through hydrogen bonding and C–H···π interactions [16]. Each cavity accommodates a pair of centrosymmetrically-orientated paba molecules, which are parallel to each other with a face-to-face distance of ca. 3.68 Å, indicating significant π–π interactions. Each guest paba molecule in the cavity forms three types of hydrogen bonds. The carboxylic group forms a pair of intermolecular hydrogen bonds (O···O = 2.614(6) and 2.657(6) Å) with a carboxylic group of another guest paba molecule occupying the cavity of an adjacent upper or lower coordination layer, as well as an acceptor hydrogen bond (N···O = 3.083 Å) between one of its carboxylic oxygen atom and the amine group of paba situated between the coordination layers. The paba amine group forms a donor hydrogen bond with the carboxylic group of an adjacent paba molecule situated between the coordination layers (N···O = 3.032 Å). Furthermore, there is close edge-to-face C–H···π interaction with carbon-to-carbon contacts at ca. 3.75–3.89 Å, between the aromatic rings of each guest paba molecule in the cavity and a pair of opposite edges of the host

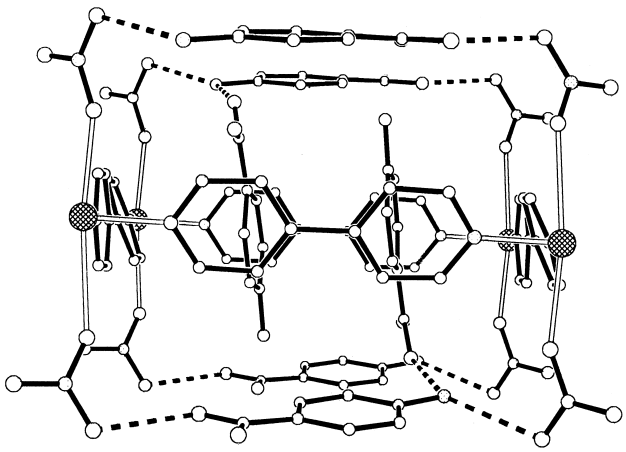

Fig. 1. Side view showing the host–guest interactions in **1**. Hydrogen bonds are represented by broken lines.

square grid, and the pyridyl rings of a pair of edges are therefore ideally coplanar. On the other hand, the guest paba molecules situated between the coordination layers similarly form extensive hydrogen bonds among the amine groups, carboxylic groups and the uncoordinated nitrate oxygen atoms (O···O = 2.673, N···O = 3.078–3.083 Å). These hydrogen bonding and C–H···π interactions rationally influence the crystalline architecture. The guest molecules are interlinked into one-dimensional hydrogen-bonding chains with two types of hourglass shaped holes, which interpenetrate and contact with the square grids through their functional moieties such as pyridyl rings, amine groups and carboxylic groups, resulting in a three-dimensional molecular networks (Fig. 2).

3.2.2. *[Cd(4,4′-bpy)$_2$(H$_2$O)$_2$](NO$_3$)$_2$·4H$_2$O* (**2**)

Compound **2** is made up of cationic two-dimensional square grids, lattice water molecules and nitrate anions. Each layer features a perfectly planar, though slightly distorted, square with a Cd(II) atom and a 4,4′-bpy at each corner and side, respectively (*cis* N–Cd–N = 88.60(5), 91.40(5)°) (see Fig. 3(a)). The Cd(II) atom, being located on a two-fold crystallographic axis, has slightly distorted octahedral geometry, being ligated by four pyridyl groups [Cd–N = 2.326(3)–2.371(3) Å] and two aqua ligands [Cd–O = 2.305(3) Å]. The square cavity has dimensions of 11.69 × 11.81 Å, which are comparable to those of closely related compounds such as [Cd(4,4′-bpy)$_2$(H$_2$O)$_2$](PF$_6$)$_2$·2(4,4′-bpy)·4H$_2$O [6a],

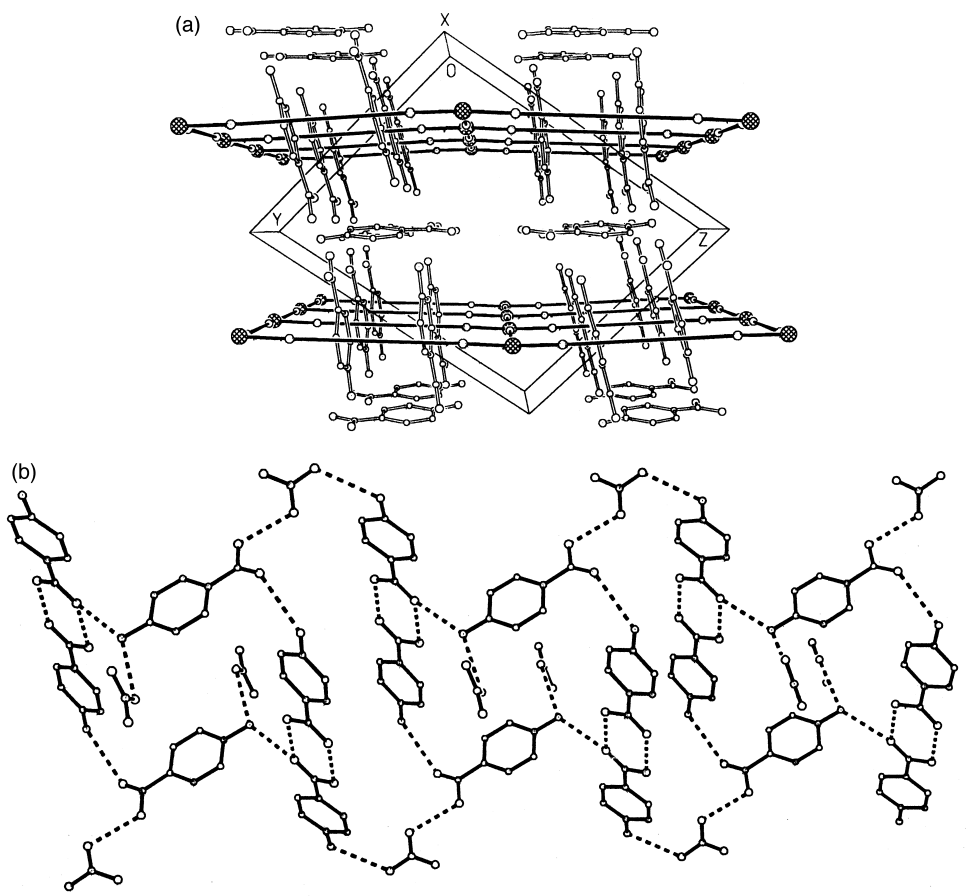

Fig. 2. (a) The 3-D network of **1** viewed from *a*-axis direction (hydrogen bonds are omitted for clarity); (b) 1-D hydrogen-bonded chains in **1**. Carbon and hydrogen atoms are omitted for clarity, the 4,4′-bpy molecular rods are shown as single bold lines. Hydrogen bonds are represented by broken lines.

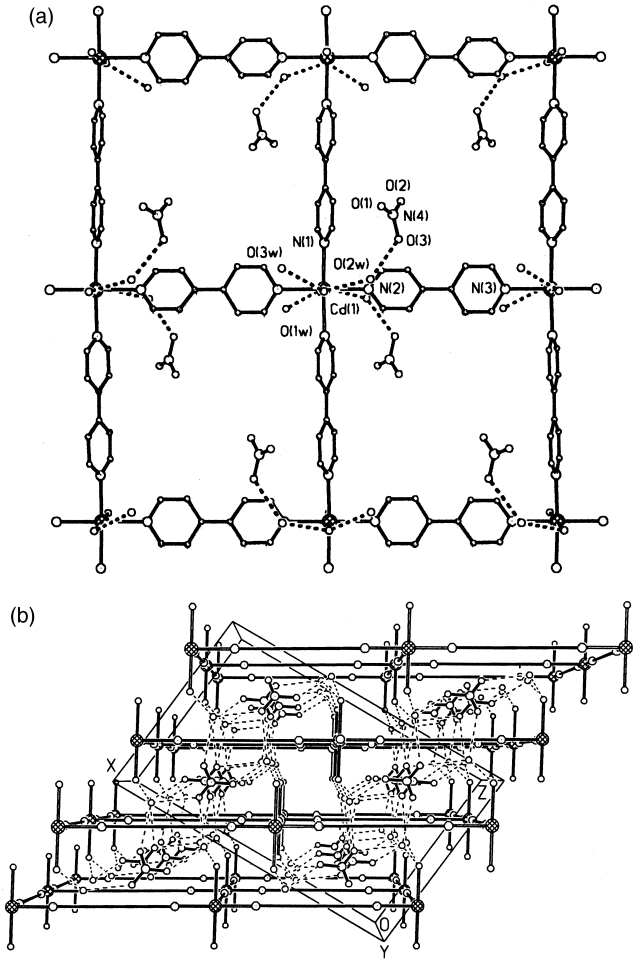

Fig. 3. (a) Top view of the square grids of **2**; (b) side view of the molecular packing of **2**. Carbon and hydrogen atoms are omitted for clarity, the 4,4′-bpy molecular rods are shown as single bold lines. Hydrogen bonds are represented by broken lines.

$[Cd(4,4'\text{-bpy})_2(NO_3)_2]\cdot 2(o\text{-}C_6H_4Br_2)$ [6b], $[Cd(4,4'\text{-bpy})_2(H_2O)_2](ClO_4)_2\cdot 1.5(4,4'\text{-bpy})\cdot(C_6H_4NO_3Cl)\cdot H_2O$ [6c] and $[Cd(4,4'\text{-bpy})_2(H_2O)_2](ClO_4)_2\cdot 2(2,4'\text{-bpy})\cdot H_2O$ [7b]. It is noteworthy that the pyridyl rings of a pair of opposite edges are ideally parallel though no larger guest molecule is enclathrated in each hydrophobic host cavity. This may be attributed to C–H···O hydrogen bonding interaction between the nitrate ions and the related 4,4′-bpy ligands (the shortest C···O distance = 3.214(3) Å), which has recently been documented elsewhere [17]. The offset superposition [8a] of each pair of adjacent layers by half of the noncoplanar edges divides the square voids into rectangular channels. The nitrate ions and lattice water molecules are situated between the coordination layers and form extensive hydrogen bonds among the aqua ligands, nitrate ions and the lattice water molecules (O···O = 2.663(4)–2.855(6) Å), which extend the two-dimensional coordination layers into a three-dimensional molecular network (Fig. 3(b)).

4. Conclusions

Two two-dimensional coordination polymers assembled by metal(II) salts and 4,4′-bpy have been prepared and characterised. Compound **1** is made up of neutral two-dimensional square $[Cu_4(4,4'\text{-bpy})_4]$ grids, in which the cavity has dimensions of 11.01×11.02 Å and are occupied by large guest paba molecules. The guest molecules are interlinked into one-dimensional hydrogen-bonding chains, which interpenetrate and contact with the square grids, resulting in a three-dimensional molecular network. Compound **2** is made up of cationic two-dimensional square $[Cd_4(4,4'\text{-bpy})_4]$ grids in which the square cavity has dimensions of 11.69×11.81 Å. The lattice water molecules and nitrate ions are situated between the coordination layers and hydrogen-bonded to the host grids.

5. Supplementary data

Supplementary data have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 139161 and 139162. Abstract

The first two members of a new family of nitrogen-donor ligands, the bis(pyrazolyl)silanes $Me_2Si(3,5\text{-}R_2pz)_2$ (R = H, Me), have been readily synthesized in almost quantitative yield from Me_2SiCl_2 and the alkali metal pyrazolates M(3,5-R_2pz) (M = Li or Na). Both bidentate ligands, abbreviated Bps and Bps^{Me_2}, respectively, have been used to prepare the zinc derivatives $LZnX_2$ (L = Bps, Bps^{Me_2}; X = Cl, Br, I), all of which have been characterized by a combination of analytical and spectroscopic techniques and, in the case of $(Bps^{Me_2})ZnI_2$, also by single-crystal X-ray diffraction. © 2000 Elsevier Science Ltd. 1. Introduction

Trofimenko's poly(pyrazolyl)borates or scorpionates (Fig. 1) are among the most conspicuous ligands in modern coordination chemistry [1]. Their popularity stems from the distinctive steric and electronic effects that can be obtained by changing the nature, number, and position of the substituents in the pyrazole rings, thus allowing the reactivity at the metal centers they support to be fine-tuned. Not surprisingly, these ligands have been used to prepare complexes with metals all across the periodic table, some of which have found interesting applications in catalysis and bioinorganic chemistry [2,3]. In contrast, the synthesis and reactivity of their neutral and isosteric carbon-centered analogues, the poly(pyrazolyl)methanes $H_nC(3,5\text{-}R_2pz)_{4-n}$ ($n = 1, 2$), is considerably less developed [4,5], perhaps due to the relatively small number of such ligands currently available. However, recent developments in bis(pyrazolyl)methane chemistry, including the synthesis of potential platinum anticancer agents [6] and the preparation of asymmetric allylic alkylation [7], olefin hydrogenation [8], and alkyne hydroamination catalysts [9], prompted us to seek a high-yield, straightforward route to alternative neutral analogues of the bis(pyrazolyl)borates. We envisioned that the closely related but hitherto unknown bis(pyrazolyl)silanes $Me_2Si(3,5\text{-}R_2pz)_2$ (Fig. 2) would be excellent candidates to meet this demand and could be readily prepared in excellent yields given the enhanced reactivity of the Si–Cl versus C–Cl bonds towards nucleophiles (see below). Based on

nomenclature introduced a few years ago for the tris(pyrazolyl)borates [1], we will abbreviate the new ligands $Bps^{RR'}$, where R and R′ are the alkyl or aryl substituents in the 3- and 5-positions of the pyrazolyl rings, respectively and two methyl groups are assumed to be attached to the silicon center.

In this paper we present the synthesis and characterization of the first two representatives of this new family of bidentate ligands, namely the bis(pyrazolyl)dimethylsilane $Me_2Si(pz)_2$ (Bps) and the bis(3,5-dimethylpyrazolyl)dimethylsilane $Me_2Si(3,5\text{-}Me_2pz)_2$ (Bps^{Me_2}). Given the role that nitrogen-donor groups such as pyrazolyl or imidazolyl play in model compounds of the active sites in a number of zinc enzymes (e.g. carbonic anhydrase, carboxypeptidase A) [10,11], an initial investigation of the binding properties of the new ligands was centered on simple derivatives of this metal, as described below.

2. Results and discussion

2.1. Ligand synthesis

The bis(pyrazolyl)silanes Bps and Bps^{Me_2} were readily prepared from the reactions of dichlorodimethylsilane and two molar equivalents of the corresponding alkali metal pyrazolates M(3,5-R_2pz) (M = Li or Na), as illustrated in Eq. (1):

$$Me_2SiCl_2 + 2M(3,5\text{-}R_2pz) \xrightarrow[\substack{M=Li,\ Na\\ R=H,\ Me}]{\text{pentane}} Bps^{RR} + 2MCl \quad (1)$$

Both compounds were isolated in excellent yield (90–95%) as white powders after separating the alkali chloride by-products by filtration. They are stable in dry air for at least 6 months and they are soluble in aliphatic and aromatic hydrocarbons, acetonitrile, ethers and dichloromethane. However, they slowly decompose in acetone or in the presence of solvents with acidic protons such as water and alcohols, an important difference with respect to the analogous $H_2C(3,5\text{-}R_2pz)_2$ ligands. It is also important to note that we have recently used a similar approach to prepare the tridentate ligands $MeSi(3,5\text{-}Me_2pz)_3$ (Tps^{Me_2}) [12] and $MeSi(3\text{-}^tBupz)_3$ ($Tps^{^tBu}$) [13] from the reactions of $MeSiCl_3$ and three molar equivalents of the corresponding lithium pyrazolates, an observation that illustrates the general applicability of our methodology.

2.2. Preparation of zinc complexes

The zinc(II) derivatives $LZnX_2$ (L = Bps, Bps^{Me_2}; X = Cl, Br, I) were prepared by mixing equimolar amounts of the zinc halides and the ligands dissolved in diethyl ether or tetrahydrofuran (THF), as represented in Eq. (2), and isolated as white or off-white

$$ZnX_2 + Bps^{RR} \xrightarrow[\substack{X=Cl,\ Br,\ I\\ R=H,\ Me}]{Et_2O \text{ or } THF} (Bps^{RR})ZnX_2 \quad (2)$$

diamagnetic solids in 65–85% yield. While the $(Bps)ZnX_2$ complexes are insoluble in all common organic solvents of low to medium polarity, the $(Bps^{Me_2})ZnX_2$ derivatives are slightly soluble in THF or dichloromethane, solvents in which their solubilities increase in the order Cl < Br < I. Dissolution of both series of complexes in more polar or coordinating solvents such as acetone, acetonitrile, or dimethylsulfoxide (DMSO) results in significant decomposition or the immediate displacement of the ligands, as established by ^{1}H NMR spectroscopy.

The new $LZnX_2$ complexes were characterized by a combination of analytical and spectroscopic techniques, with elemental analyses (CHN) being consistent with the formation of simple 1:1 adducts. All the complexes were characterized by solid-state infrared (IR) spectroscopy and, in the case of the Bps^{Me_2} derivatives, by both ^{1}H NMR and $^{13}C\{^1H\}$ NMR spectroscopy in solution. In general, both IR and NMR data for the new compounds are similar to those reported for a number of related zinc bis(pyrazolyl)alkane complexes [14–20]. For example, in the ^{1}H NMR spectra of the series $(Bps^{Me_2})ZnX_2$, all the signals are downfield shifted between 0.14 and 0.54 ppm relative to the corresponding values obtained for the free ligand in the same solvent. The deshielding effect (Δ) observed upon complexation is more pronounced for the pyrazolyl methyl groups ($\Delta \approx 0.47$ ppm) than for either the 4-H ($\Delta \approx 0.27$ ppm) or the methylsilyl protons ($\Delta \approx 0.15$ ppm). Similarly, downfield shifts of between 2 and 7 ppm relative to the free ligand are found for all the resonances in the ^{13}C NMR spectra of the Bps^{Me_2} complexes, an observation that is unlike the data published for the bis(pyrazolyl)alkane analogues, which typically show both positive and negative Δ values.

2.3. Structure of $(Bps^{Me_2})ZnI_2$

Single crystals suitable for an X-ray diffraction study of $(Bps^{Me_2})ZnI_2$ were obtained by slow evaporation at room temperature of a concentrated THF solution of the title compound (Fig. 3). A selection of bond lengths and angles is given in Table 1. The four-coordinate complex exhibits a slightly distorted tetrahedral geometry in the solid state that resembles those of the related bis(pyrazolyl)alkane complexes $\{H_2C(3,4,5\text{-}Me_3pz)_2\}ZnBr_2$ [20] and $\{Me_2C(pz)_2\}ZnX_2$ (X = Cl, Br, I, O_2CCF_3) [16,18,21]. However, the angles subtended at zinc in $(Bps^{Me_2})ZnI_2$, in the approximate range 99–115°, deviate less from the ideal tetrahedral values than those found in the bis(pyrazolyl)alkane complexes. Specifically, the N–Zn–N angle in $(Bps^{Me_2})ZnI_2$ (ca. 99.2°) is significantly larger than the corresponding values

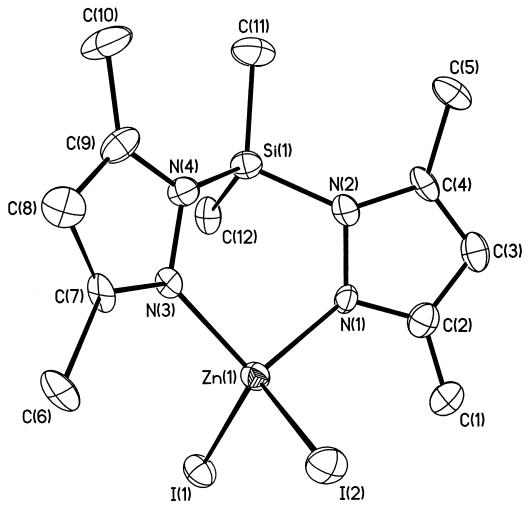

Fig. 3. ORTEP showing one of the two independent molecules of $(Bps^{Me_2})ZnI_2$, with hydrogen atoms omitted for clarity and thermal ellipsoids at the 30% probability level.

Table 1
Selected bond lengths (Å) and angles (°) for $(Bps^{Me_2})ZnI_2$

Zn(1)–I(1)	2.5484(9)	Zn(1)–N(1)	2.044(6)
Zn(1)–I(2)	2.5981(10)	Zn(1)–N(3)	2.047(6)
I(1)–Zn(1)–I(2)	113.48(3)	N(1)–Zn(1)–N(3)	99.3(2)
N(1)–Zn(1)–I(1)	112.38(16)	N(1)–Zn(1)–I(2)	106.85(15)
N(3)–Zn(1)–I(1)	115.56(16)	N(3)–Zn(1)–I(2)	108.05(16)

found in bis(pyrazolyl)alkane derivatives, typically between 84 and 89° [16,18,20,21]. It is likely that this observation is a consequence of the larger size of the silicon atom in the bis(pyrazolyl)silane derivatives relative to that of the carbon centers in the alkane analogues, a phenomenon that may have implications in the reactivity of the complexes that these ligands support.

The average Zn–I and Zn–N bond distances in $(Bps^{Me_2})ZnI_2$, 2.571 and 2.042 Å, respectively, are within the range of the corresponding values observed in $\{Me_2C(pz)_2\}ZnI_2$ [18], in the bis(pyrazole) complex $\{3,5\text{-}(^tBuph)_2pzH\}_2ZnI_2$ [22], and in various other nitrogen-donor adducts of ZnI_2 [23–31]. All the remaining interatomic distances (i.e. Si–N, Si–C, C–N and C–C bond lengths) are also normal.

3. Conclusions

In summary, the bis(pyrazolyl)silanes Bps and Bps^{Me_2}, two new bidentate nitrogen-donor ligands representing alternative neutral analogues of the corresponding anionic bis(pyrazolyl)borates, have been readily synthesized and their first transition metal derivatives have been prepared. While continuing to investigate the coordination chemistry of Bps and Bps^{Me_2}, we have also extended our methodology to the syntheses of more sterically demanding ligands, in particular those having no bis(pyrazolyl)methane analogues. In this regard, we have already prepared the 3-*tert*-butyl- and 3,5-diphenyl-substituted bis(pyrazolyl)silanes $Bps^{^tBu}$ and Bps^{Ph_2}, the synthesis and reactivity of which will be reported in due course.

4. Experimental

4.1. General considerations

All reactions were performed under dry oxygen-free nitrogen in an Innovative Technology System One-M-DC glovebox or under argon using a combination of high-vacuum and Schlenk techniques [32–34]. Solvents were purified and degassed by standard procedures and all commercially available reagents were used as received. The lithium pyrazolates Li(3,5-R_2pz) (R = H, Me) were prepared by deprotonation of the corresponding pyrazoles with *n*-butyllithium in pentane and isolated as white solids in ca. 90% yield [12]. ^1H and ^{13}C NMR spectra were obtained on General Electric QE 300 or Varian Gemini (300 MHz) FT spectrometers. Chemical shifts (δ) are reported in parts per million relative to $SiMe_4$ ($\delta = 0$ ppm) and were referenced internally with respect to the solvent resonances (δ 5.32 for $CDHCl_2$, 7.15 for C_6D_5H, 53.8 for CD_2Cl_2, 128.0 for C_6D_6,); coupling constants are given in hertz (Hz). IR spectra were recorded as KBr pellets on a Midac Collegian FT spectrophotometer and data are reported in cm^{-1}; relative intensities of the absorptions are indicated in parentheses (vs = very strong, s = strong, m = medium, w = weak, sh = shoulder). Elemental analyses were determined by Atlantic Microlab, Inc. (Norcross, GA) or Desert Analytics (Tucson, AZ).

4.2. Synthesis of Bps

Me_2SiCl_2 (0.41 ml, 3.38 mmol) was slowly added via syringe to a stirred suspension of Na(pz) (0.61 g, 6.77 mmol) in pentane (75 ml). After stirring for 1 h, the suspension was filtered using a fritted funnel and the collected solid (NaCl) washed with pentane (2 × 20 ml). The solvent was removed under reduced pressure from the combined filtrate and washings to give an analytically and spectroscopically pure white solid, which was dried in vacuo for 1 h (0.59 g, 91%). M.p. = 48–49°C. NMR data (in C_6D_6): ^1H δ 0.62 (s, 6 H, CH_3Si), 6.09 (dd, $^3J_{H-H} = 1.4$ and 2.4, 2 H, 4-*H* in pz), 7.28 (d, $^3J_{H-H} = 2.4$, 2 H, 3-*H* or 5-*H* in pz), 7.77 (d, $^3J_{H-H} = 1.4$, 2 H, 3-*H* or 5-*H* in pz); ^{13}C δ −2.6 (q, $^1J_{C-H} = 122$, 2 C, CH_3Si), 107.4 (d, $^1J_{C-H} = 177$, 2 C, 4-*C* in pz), 134.9 (d, $^1J_{C-H} = 185$, 2 C, 3-*C* or 5-*C* in pz), 144.4 (d,

$^1J_{C-H} = 184$, 2 C, 3-*C* or 5-*C* in pz). IR data (cm^{-1}): 3092 (w), 2964 (w), 1767 (w), 1512 (m), 1403 (m), 1382 (m), 1375 (m), 1277 (s), 1269 (s), 1173 (s), 1165 (s), 1075 (s), 1037 (s), 951 (m), 916 (m), 900 (m), 842 (sh), 816 (vs), 785 (s), 768 (vs), 691 (s), 668 (w), 618 (s), 498 (vs), 421 (vs). *Anal*. Calc. for $C_8H_{12}N_4Si$: C, 50.0; H, 6.3; N, 29.1. Found: C, 49.8; H, 6.5; N, 28.9%.

4.3. Synthesis of (Bps)$ZnCl_2$

A solution of Bps (0.164 g, 0.853 mmol) in tetrahydrofuran (5 ml) was added to a stirred, filtered solution of $ZnCl_2$ (0.116 g, 0.851 mmol) in the same solvent (10 ml), resulting in the immediate formation of an off-white precipitate. The suspension was stirred for 45 min, concentrated under reduced pressure to ca. 5 ml, and treated with pentane (10 ml). The product was isolated by filtration, washed with pentane (3×5 ml), and dried in vacuo for 1 h (0.186 g, 67%). M.p. = 238°C (dec.). IR data (cm^{-1}): 3144 (m), 3121 (m), 3102 (m), 3013 (w), 2963 (m), 2899 (w), 1784 (w), 1652 (w), 1513 (m), 1422 (s), 1408 (m), 1389 (vs), 1378 (m), 1283 (vs), 1272 (s), 1182 (vs), 1169 (s), 1122 (w), 1089 (vs), 1065 (vs), 979 (m), 920 (w), 913 (w), 847 (vs), 826 (vs), 785 (vs), 691 (s), 611 (s), 488 (s), 429 (s). *Anal*. Calc. for $C_8H_{12}Cl_2N_4SiZn$: C, 29.2; H, 3.7; N, 17.1. Found: C, 28.8; H, 3.9; N, 16.9%.

4.4. Synthesis of (Bps)$ZnBr_2$

A solution of Bps (0.095 g, 0.494 mmol) in tetrahydrofuran (3 ml) was added to a stirred solution of $ZnBr_2$ (0.111 g, 0.493 mmol) in the same solvent (5 ml), resulting in the immediate formation of an off-white precipitate. The suspension was stirred for 20 min and the product separated by decantation, washed with tetrahydrofuran (5 ml), and dried in vacuo for 1 h (0.148 g, 72%). M.p. = 268°C (dec.). IR data (cm^{-1}): 3153 (m), 3140 (m), 3118 (m), 3102 (m), 2962 (m), 2895 (w), 1524 (m), 1511 (m), 1475 (s), 1421 (s), 1406 (s), 1388 (s), 1350 (s), 1289 (sh), 1282 (s), 1266 (s), 1181 (s), 1169 (m), 1121 (vs), 1088 (s), 1063 (vs), 1046 (s), 979 (m), 912 (m), 845 (s), 823 (vs), 782 (vs), 690 (s), 611 (s), 588 (m), 487 (m), 429 (m). *Anal*. Calc. for $C_8H_{12}Br_2N_4SiZn$: C, 23.0; H, 2.9; N, 13.4. Found: C, 23.1; H, 2.9; N, 13.4%.

4.5. Synthesis of (Bps)ZnI_2

A solution of Bps (0.144 g, 0.749 mmol) in diethylether (3 ml) was added to a stirred solution of ZnI_2 (0.240 g, 0.752 mmol) in the same solvent (5 ml), resulting in the immediate formation of an off-white precipitate. The suspension was stirred for 20 min and the product separated by decantation, washed with diethylether (2×5 ml), and dried in vacuo for 30 min (0.275 g, 72%). M.p. = 282°C (dec.). IR data (cm^{-1}): 3144 (w), 3116 (w), 2964 (w), 1522 (w), 1510 (w), 1474 (m), 1420 (w), 1405 (m), 1389 (m), 1356 (m), 1282 (m), 1264 (s), 1181 (w), 1121 (s), 1089 (s), 1064 (vs), 1046 (vs), 978 (w), 948 (w), 910 (w), 843 (w), 831 (m), 816 (s), 793 (s), 779 (m), 770 (s), 703 (w), 674 (m), 609 (m). *Anal*. Calc. for $C_8H_{12}I_2N_4SiZn$: C, 18.8; H, 2.4; N, 11.0. Found: C, 18.5; H, 2.3; N, 11.0%.

4.6. Synthesis of Bps^{Me_2}

Me_2SiCl_2 (2.40 ml, 19.8 mmol) was slowly added via syringe to a stirred suspension of Li(3,5-Me_2pz) (4.03 g, 39.5 mmol) in pentane (150 ml). After being stirred for 2 h, the suspension was filtered using a fritted funnel and the collected solid (LiCl) was washed with pentane (2×20 ml). The solvent was removed under reduced pressure from the combined filtrate and washings to give an analytically and spectroscopically pure white solid, which was dried in vacuo for 1 h (4.62 g, 94%). M.p. = 44–45°C. ^{1}H NMR data (in C_6D_6): δ 0.85 (s, 6 H, CH_3Si), 1.80 [s, 6 H, (CH_3)$_2$pz], 2.24 [s, 6 H, (CH_3)$_2$pz], 5.72 (s, 2 H, 4-*H* in 3,5-Me_2pz); ^{1}H NMR data (in CD_2Cl_2): δ 0.87 (s, 6 H, CH_3Si), 1.91 [s, 6 H, (CH_3)$_2$pz], 2.19 [s, 6 H, (CH_3)$_2$pz], 5.87 (s, 2 H, 4-*H* in 3,5-Me_2pz); ^{13}C NMR data (in C_6D_6): δ −0.2 (q, $^1J_{C-H} = 121$, 2 C, *C*H$_3$Si), 11.6 [q, $^1J_{C-H} = 126$, 2 C, (*C*H$_3$)$_2$pz], 13.9 [q, $^1J_{C-H} = 128$, 2 C, (*C*H$_3$)$_2$pz], 108.7 (d, $^1J_{C-H} = 172$, 2 C, 4-*C* in 3,5-Me_2pz), 146.9 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me_2pz), 152.4 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me_2pz); ^{13}C NMR data (in CD_2Cl_2): δ −0.1 (q, $^1J_{C-H} = 122$, 2 C, *C*H$_3$Si), 11.7 [q, $^1J_{C-H} = 128$, 2 C, (*C*H$_3$)$_2$pz], 13.7 [q, $^1J_{C-H} = 127$, 2 C, (*C*H$_3$)$_2$pz], 108.8 (d, $^1J_{C-H} = 172$, 2 C, 4-*C* in 3,5-Me_2pz), 147.5 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me_2pz), 152.8 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me_2pz). IR data (cm^{-1}): 3201 (m), 3131 (m), 3109 (m), 3038 (m), 2960 (m), 2878 (m), 2791 (w), 2729 (w), 2610 (w), 1595 (m), 1555 (m), 1484 (m), 1465 (m), 1420 (m), 1370 (w), 1327 (m), 1308 (s), 1261 (s), 1149 (m), 1091 (m), 1029 (vs), 966 (w), 810 (vs), 781 (s), 738 (m), 692 (m), 662 (m), 587 (m). *Anal*. Calc. for $C_{12}H_{20}N_4Si$: C, 58.0; H, 8.1; N, 22.6. Found: C, 57.7; H, 8.2; N, 22.4%.

4.7. Synthesis of (Bps^{Me_2})$ZnCl_2$

A solution of Bps^{Me_2} (0.365 g, 1.469 mmol) in THF (10 ml) was added to a stirred, slightly cloudy solution of $ZnCl_2$ (0.200 g, 1.468 mmol) in the same solvent (20 ml), resulting in the formation of a white precipitate. After being stirred for 30 min, the solution was concentrated under reduced pressure to ca. 10 ml and pentane (20 ml) added. The white product was isolated by filtration, washed with pentane (30 ml), and dried in vacuo for 18 h (0.403 g, 71%). M.p. = 242°C (dec.). NMR data (in CD_2Cl_2): ^{1}H δ 1.04 (s, 6 H, CH_3Si), 2.43

[s, 6 H, (CH_3)$_2$pz], 2.55 [s, 6 H, (CH_3)$_2$pz], 6.14 (s, 2 H, 4-*H* in 3,5-Me$_2$pz); ^{13}C{^{1}H} δ 1.9 (s, 2 C, *C*H$_3$Si), 14.3 [s, 2 C, (*C*H$_3$)$_2$pz], 14.5 [s, 2 C, (*C*H$_3$)$_2$pz], 111.1 (s, 2 C, 4-*C* in 3,5-Me$_2$pz), 151.0 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz), 159.2 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz). IR data (cm^{-1}): 3341 (m), 3317 (m), 3125 (w), 3004 (w), 2971 (w), 2922 (w), 1570 (m), 1555 (s), 1485 (w), 1440 (m), 1416 (m), 1381 (w), 1328 (m), 1305 (m), 1266 (m), 1146 (s), 1139 (s), 1048 (s), 1032 (w), 983 (w), 850 (s), 825 (vs), 804 (s), 762 (m), 694 (m), 668 (w), 591 (w), 505 (m), 478 (w), 440 (m), 414 (w). *Anal.* Calc. for $C_{12}H_{20}Cl_2N_4SiZn$: C, 37.5; H, 5.2; N, 14.6. Found: C, 37.1; H, 5.3; N, 14.9%.

4.8. Synthesis of (Bps^{Me_2})ZnBr$_2$

A solution of Bps^{Me_2} (0.221 g, 0.890 mmol) in THF (10 ml) was added to a stirred solution of $ZnBr_2$ (0.200 g, 0.888 mmol) in the same solvent (20 ml), resulting in the formation of a white precipitate. After being stirred for 15 min, the solution was concentrated under reduced pressure to ca. 5 ml and pentane (25 ml) added. The white product was isolated by filtration, washed with pentane (20 ml), and dried in vacuo for 1 h (0.370 g, 88%). M.p. = 192°C (dec.). NMR data (in CD_2Cl_2): ^{1}H δ 1.01 (s, 6 H, CH_3Si), 2.43 [s, 6 H, (CH_3)$_2$pz], 2.59 [s, 6 H, (CH_3)$_2$pz], 6.14 (s, 2 H, 4-*H* in 3,5-Me$_2$pz); ^{13}C{^{1}H} δ 2.0 (s, 2 C, *C*H$_3$Si), 14.3 [s, 2 C, (*C*H$_3$)$_2$pz], 15.0 [s, 2 C, (*C*H$_3$)$_2$pz], 111.5 (s, 2 C, 4-*C* in 3,5-Me$_2$pz), 151.5 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz), 159.6 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz). IR data (cm^{-1}): 3358 (m), 3344 (m), 3340 (sh), 2967 (w), 1574 (m), 1572 (m), 1555 (s), 1474 (w), 1438 (m), 1420 (m), 1327 (m), 1301 (m), 1266 (m), 1184 (w), 1145 (m), 1136 (m), 1047 (vs), 984 (w), 849 (m), 826 (vs), 803 (m), 762 (m), 693 (m), 668 (m), 657 (m), 564 (w), 503 (m), 478 (m), 439 (m). *Anal.* Calc. for $C_{12}H_{20}Br_2N_4SiZn$: C, 30.4; H, 4.3; N, 11.8. Found: C, 30.1; H, 4.3; N, 11.9%.

Table 2
Crystallographic data for (Bps^{Me_2})ZnI$_2$

Formula	$C_{12}H_{20}I_2N_4SiZn$
Formula weight	567.58
Crystal system	triclinic
Space group	$P\bar{1}$ (no. 2)
Temperature (K)	244(2)
a (Å)	8.8701(16)
b (Å)	15.305(3)
c (Å)	15.6865(19)
α (°)	66.948(10)
β (°)	85.581(14)
γ (°)	76.924(11)
V (Å^3)	1908.6(5)
Z	4
D_{calc} (g cm^{-3})	1.975
μ(Mo Kα) (mm^{-1})	4.581
θ_{max} (°)	25
Number of data	6202
Number of parameters	361
R_1 ($I>2\sigma(I)$) [a]	0.0420
wR_2 ($I>2\sigma(I)$) [a]	0.1032

[a] $R_1 = \Sigma(|F_o|-|F_c|)/\Sigma|F_o|$; $\{\Sigma[w(F_o^2-F_c^2)^2]/\Sigma[w(F_o^2)^2\}^{1/2}$.

4.9. Synthesis of (Bps^{Me_2})ZnI$_2$

A solution of Bps^{Me_2} (0.200 g, 0.805 mmol) in diethyl ether (10 ml) was added to a stirred solution of ZnI_2 (0.257 g, 0.805 mmol) in the same solvent (20 ml), resulting in the formation of a white precipitate. After being stirred for 1 h, the solution was concentrated under reduced pressure to ca. 10 ml and pentane (10 ml) added. The white product was isolated by filtration, washed with pentane (20 ml), and dried in vacuo for 1 h (0.390 g, 85%). M.p. = 210°C (dec.). NMR data (in CD_2Cl_2): ^{1}H δ 1.01 (s, 6 H, CH_3Si), 2.45 [s, 6 H, (CH_3)$_2$pz], 2.64 [s, 6 H, (CH_3)$_2$pz], 6.15 (s, 2 H, 4-*H* in 3,5-Me$_2$pz); ^{13}C{^{1}H} δ 2.2 (s, 2 C, *C*H$_3$Si), 14.3 [s, 2 C, (*C*H$_3$)$_2$pz], 15.7 [s, 2 C, (*C*H$_3$)$_2$pz], 111.8 (s, 2 C, 4-*C* in 3,5-Me$_2$pz), 151.3 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz), 159.8 (s, 2 C, 3-*C* or 5-*C* in 3,5-Me$_2$pz). IR data (cm^{-1}): 3337 (s), 3134 (w), 2965 (w), 1570 (s), 1555 (s), 1547 (s), 1476 (m), 1474 (m), 1439 (m), 1420 (m), 1381 (w), 1326 (m), 1301 (m), 1267 (m), 1182 (w), 1142 (s), 1133 (s), 1046 (vs), 1029 (w), 983 (w), 846 (s), 824 (vs), 800 (s), 761 (m), 692 (w), 655 (m), 589 (w), 562 (m), 499 (m), 477 (w), 439 (m). *Anal.* Calc. for $C_{12}H_{20}I_2N_4SiZn$: C, 25.4; H, 3.6; N, 9.9. Found: C, 25.4; H, 3.4; N, 10.0%.

4.10. X-ray structure determination

A summary of crystal data collection and refinement parameters is given in Table 2. A crystal suitable for data collection was selected and mounted with epoxy glue on the tip of a fine glass fiber. Data were collected on a Siemens P4 diffractometer equipped with a SMART/CCD detector using Mo Kα radiation (λ = 0.71073 Å). No evidence of symmetry higher than triclinic was observed in either the axial views or diffraction data. *E*-statistics suggested the centrosymmetric space group option $P\bar{1}$, which yielded chemically reasonable and computationally stable results of refinement. The structure was solved by direct methods, completed by subsequent difference Fourier syntheses, and refined by full-matrix, least-squares procedures. An empirical absorption correction was applied to the data using DIFABS [35]. There are two crystallographically independent but chemically equivalent molecules in the asymmetric unit. All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were treated as idealized contributions. All software and sources of the scattering factors are contained in the SHELXTL (version 5.10) program library [36].

5. Supplementary data

Crystallographic data (excluding structure factors) for $(Bps^{Me_2})ZnI_2$ have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 142657. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The syntheses and characterisation of chromium(III) complexes with tris(2-benzimidazolylmethyl)amine (ntb), 2-guanidinobenzimidazole (2gb), 2,6-bis(2-benzimidazolyl)pyridine (bbimpy) and 2-(2-pyridyl)benzimidazole (2pb), of composition $[Cr(ntb)Cl_2]Cl\cdot 4.5H_2O$ (**1**), $[Cr(2gb)_3]Cl[ZnCl_4]\cdot CH_3OH$ (**2**), $[Cr(2gb)_3]Cl_3\cdot 4H_2O$ (**3**), $[Cr_2(2gb)_4(\mu\text{-}OH)_2](ClO_4)_4\cdot 5H_2O$ (**4**), $[Cr(bbimpy)Cl_3]$ (**5**) and $[Cr(2pb)_2Cl_2]Cl\cdot C_2H_5OH\cdot 0.5H_2O$ (**6**) are presented. The compounds are obtained from Cr(III) in alcoholic solution, or a Cr(II) aqueous acidic solution. The latter were carried out under air-free conditions. The reaction of 2gb with Cr(II) in aqueous solution yielded a dinuclear compound. The X-ray crystal structures of **1** and **4** are discussed. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Chromium(III) complexes; Tris(2-benzimidazolylmethyl)amine; 2-Guanidinobenzimidazole; 2,6-Bis(2-benzimidazolyl)pyridine; 2-(2-Pyridyl)benzimidazole; Crystal structures

1. Introduction

Imidazole is a typical heterocyclic ligand with nitrogen as the donor atom. It is also a component of biologically important molecules [1]. Because of this, the coordination chemistry of related ligands has been the subject of numerous investigations [1]. Amongst them, the coordinating behaviour of chelating benzimidazolic ligands has been studied by several research groups, some of them with an interest in mimicking biological activities [2–6]. Benzimidazoles exhibit a wide variety of pharmacological activities like fungicides or anti-helminthics amongst others [7]. Studies about the coordination chemistry of benzimidazolic ligands have been carried out mainly on labile metal ions [1,8–10]. It is worth mentioning that there are only a limited number of reports on chromium(III) complexes containing imidazoles [11–14] or benzimidazoles [14,15]. The synthesis, reactivity and magnetic properties of dinuclear chromium(III) species containing OH^- bridges have been studied for the last two decades [16,17]. However, none of them contained imidazolic or benzimidazolic ligands.

We have been interested in the coordinating ability of benzimidazolic ligands towards transition metal ions [8,18,19]. Here we describe the synthesis and characterisation of substitution inert chromium(III) coordination compounds with four benzimidazolic ligands. The X-ray crystal structures of $[Cr(ntb)Cl_2]Cl\cdot 2H_2O\cdot C_2H_5OH$ and $[Cr_2(2gb)_4(\mu\text{-}OH)_2](ClO_4)_4\cdot 4.67H_2O$ are discussed.

2. Experimental

2.1. Materials

Metallic chromium, zinc and mercury, anhydrous $CrCl_3$, $CrCl_2$, $CrCl_3{\cdot}nH_2O$, 2-guanidinobenzimidazole (2gb), 2,6-bis(2-benzimidazolyl)pyridine (bbimpy), 2-(2-pyridyl)benzimidazole (2pb) and tris(2-benzimidazolylmethyl)amine (ntb), methanol, ethanol and $HClO_4$ were used as analytical reagents and obtained from Aldrich. They were used without further purification.

2.2. Syntheses

2.2.1. $[Cr(ntb)Cl_2]Cl{\cdot}4.5H_2O$ (1)

Anhydrous $CrCl_3$ (0.158 g, 1.00 mmol) was placed in the filter thimble of a Soxhlet extractor together with Zn–Hg amalgam (1 cm^3), and a solution of ntb (0.407 g, 1.00 mmol) in anhydrous methanol (50 cm^3) was added to the reservoir flask. N_2 was bubbled through the ntb solution for 10 min before heating and chromium chloride was then extracted as a green solution that reacted with ntb. A green precipitate formed and was isolated by vacuum filtration (0.270 g, 42.3%). (Found: C, 44.65; H, 4.20; N, 14.90. $C_{24}H_{20}N_7CrCl_3{\cdot}4.5H_2O$ requires C, 44.56; H, 4.67; N, 15.16%). Green crystals of **1** (minimum formula $C_{26}H_{31}O_3N_7CrCl_3$) were obtained simply by mixing the solutions of $CrCl_3{\cdot}nH_2O$ and ntb in ethanol and leaving the solution to stand for few days.

2.2.2. $[Cr(2gb)_3]Cl[ZnCl_4]{\cdot}CH_3OH$ (2), $[Cr(2gb)_3]Cl_3{\cdot}4H_2O$ (3)

Anhydrous $CrCl_3$ (1.0 g, 6.3 mmol) and Zn powder (10 mg) were stirred together in anhydrous methanol (50 cm^3). A solution of 2gb (3.31 g, 18.9 mmol) in hot anhydrous methanol was added with stirring. The mixture was heated (40°C) with stirring for 3 h. A pink solid precipitated immediately **2**, which was filtered off. The red solution deposited small red crystals of **3** by slow evaporation. Compound **2**: (0.128 g, 2.4%). (Found: C, 35.20; H, 4.47; N, 25.38. $C_{25}H_{31}ON_{15}CrZnCl_5$ requires C, 35.23; H, 3.68; N, 24.65%). Compound **3**: (4.50 g, 95.2%). (Found: C, 38.13; H, 4.15; N, 27.16. $C_{24}H_{35}O_4N_{15}CrCl_3$ requires C, 38.13; H, 4.67; N, 27.79%).

2.2.3. $[Cr_2(2gb)_4(\mu\text{-}OH)_2](ClO_4)_4{\cdot}5H_2O$ (4)

A solution of 2gb (0.525 g, 3.00 mmol) in methanol (30 cm^3) was deoxygenated with N_2 in a vacuum line. Chromium metal (0.32 g, 6.00 mmol), or $CrCl_2$ (0.737 g, 6.00 mmol), was dissolved in 6 cm^3 of deoxygenated 2.0 M $HClO_4$. 1.0 cm^3 of this chromium(II) solution was injected into the 2gb solution. Air was allowed into the flask, and 2.0 g of $NaClO_4$ was added. X-ray quality purple crystals deposited from the solution, which were filtered off (0.635 g, 48.1%). (Found: C, 28.74; H, 3.41; N, 20.85. $C_{32}H_{48}O_{23}N_{20}Cr_2Cl_4$ requires C, 28.97; H, 3.65; N, 21.12%).

2.2.4. $[Cr(bbimpy)Cl_3]$ (5)

Anhydrous $CrCl_3$ (0.158 g, 1.00 mmol) was placed in the filter thimble of a Soxhlet extractor together with Zn–Hg amalgam (1 cm^3). A solution of bbimpy (0.622 g, 2.00 mmol) in anhydrous ethanol (60 cm^3) was placed into the reservoir flask. N_2 was bubbled through the ligand solution for 10 min before heating and chromium chloride was then extracted as a green solution that reacted with the bbimpy ligand. A green solid precipitated and was isolated by vacuum filtration (0.435 g, 92.6%). (Found: C, 48.77; H, 2.95; N, 14.82. $C_{19}H_{13}N_5CrCl_3$ requires C, 48.59; H, 2.80; N, 14.90%).

2.2.5. $[Cr(2pb)_2Cl_2]Cl{\cdot}C_2H_5OH{\cdot}0.5H_2O$ (6)

Anhydrous $CrCl_3$ (0.158 g, 1.0 mmol) was placed in the filter thimble of a Soxhlet extractor together with Zn–Hg amalgam (1 cm^3) and a solution of 2pb (0.585 g, 3.0 mmol) in anhydrous ethanol (60 cm^3) was added to the reservoir flask. N_2 was bubbled through the ligand solution for 10 min before heating and the chromium chloride was then extracted as a green solution that reacted with the 2pb ligand. A green precipitate formed and was isolated by vacuum filtration (0.294 g, 49.5%). (Found: C, 51.65; H, 4.02; N, 13.99. $C_{24}H_{18}N_6CrCl_3{\cdot}C_2H_5OH{\cdot}0.5H_2O$ requires C, 51.71; H, 4.17; N, 13.92%).

2.3. Physical measurements

An FT-IR spectrometer (Perkin–Elmer 1600) was used for obtaining IR spectra of solid samples in KBr pellets (4000–400 cm^{-1}). The UV–Vis spectra (diffuse reflectance) were recorded on a Cary-5E (Varian) spectrometer (250–2500 nm). Elemental analyses were carried out with a Fisons EA 1180 analyser. Magnetic susceptibility measurements of powdered samples were recorded on a Johnson–Matthey DG8 5HJ balance using the Gouy method. Magnetic susceptibilities were measured on powdered samples of **4** in the temperature range 17–280 K using a Vibrating Sample Magnetometer Model 4500 from EG & G PARC.

2.4. Crystallography

Pertinent crystal data for **1** and **4** are given in Table 1. The diffraction data for **4** were collected at 298 K on a Siemens P4 diffractometer in the 2θ range 3–50° ($\lambda = 0.71073$ Å) at variable scan speed in ω (4–60° min^{-1}). Data were corrected for absorption using 12 ψ-scans with χ close to 90° (min = 0.712, max = 0.758). Data for **1** were collected at 183 K with the crystal mounted on a glass fibre coated with perfluorpolyether

oil. 1200 frames were measured on a Siemens P4 diffractometer equipped with an area detector in the hemisphere scan mode ($\phi=0$–360°, 10 s exposure per frame), which corresponds to the 2θ range 3–58° ($\lambda=$ 0.71073 Å). Absorption correction was applied using SADABS [20] (min = 0.804, max = 0.883). Both structures were solved and refined using SHELXTL 5.03 [21] and SHELX-97-2 [22], without constraints or restraints for non-H atoms. Most of the H atoms were placed on idealised positions and refined using a riding model with a fixed isotropic U factor. H atoms for the OH groups in **4** and for the water molecules in **1** were found on difference maps and refined as remaining H. In the case of **4**, H atoms were omitted for the water molecules.

[a] There is also contribution from $\delta(NH_2)$ and ν(C=N) from the guanidine group.
[b] Calculated for the dinuclear compound.

3. Results and discussion

3.1. Synthesis and characterisation of the coordination compounds

Six coordination compounds with the benzimidazolic ligands: ntb, 2gb, bbimpy and 2pb Fig. 1, were synthesised and characterised by spectroscopic and analytical methods.

Two different synthetic routes were used for preparing the coordination compounds. In the first technique, chromium(III) is extracted, in anhydrous methanol or ethanol, from $CrCl_3$ by means of a Soxhlet and then reacted with the ligand, as previously reported for chelating ligands [23]. For the second method, a chromium(II) acidic aqueous solution is reacted with the ligand under oxygen-free conditions, followed by air oxidation [24]. The solution of chromium(II) is made from $CrCl_2$ or chromium metal in $HClO_4$ under a nitrogen atmosphere.

Compounds **1**, **5** and **6** can be prepared by either of these techniques, i.e. from Cr(II) or $CrCl_3$; however, yields are better when using the Soxhlet method.

The reactions with the 2gb ligand yielded two different types of chromium(III) compound, i.e. two mononuclear compounds **2** and **3**, and a dinuclear species **4**. The dinuclear compound is bridged by two hydroxo moieties and was obtained when a chromium(II) acid aqueous solution was reacted with a methanolic solution of 2gb. The coordination sphere of each chromium(III) contains two chelating 2gb molecules. It is known that the synthesis of the chromium(III) dinuclear species containing hydroxo bridges requires the addition of a base; however, in some instances this is not necessary, depending on the basicity of the ligand and the molar ratio of ligand to metal ion [16,17]. We here suggest that the basicity of 2gb is responsible for the formation of the hydroxo bridges. The same method of synthesis gave mononuclear species when ntb, bbimpy or 2pb were reacted with an acidic aqueous Cr(II) solution, indicating that they are less basic than 2gb.

Table 2 shows some of the main IR vibrational frequencies, UV–Vis absorption bands and magnetic moments.

3.2. Spectroscopy

The main vibrational frequencies observed for the benzimidazolic ring are those due to the ν(N–H), ν(C=C)+ν(C=N) vibrations, δ(N–H) and δ(C–H) benzimidazolic ring out of plane [8,10,25,26]. All the IR spectra of the coordination compounds show these vibrations, however in all cases the bands are shifted towards higher energy as compared with the position in the free ligand, Table 2. These results are indicative of ligand coordination through the imidazolic nitrogen. For the 2gb complexes the band due to ν(NH···N) from the guanidine group in the ligand [8] is shifted from 3444 to 3300 cm^{-1} for **2** and **3**, and to 3341 cm^{-1} for **4**.

The strong band at 1317 (bbimpy) and 1314 cm^{-1} (2pb) in the spectra of the ligands is shifted towards higher energy and splitted upon chelation, indicating coordination through the pyridinic nitrogen [27,28]. The split band appears at 1321 and 1310 cm^{-1} for **5** and at 1323 and 1302 cm^{-1} for **6**. In the low-frequency infrared spectra of **1**, **5** and **6** the vibrational bands at 360, 343 and 361 cm^{-1}, respectively, were assigned as ν(Cr–Cl) [29], corroborating the presence of coordinated chlorides.

For Cr(III) hexacoordinated complexes there are three spin-allowed transitions in the electronic spectrum, ν_1 $^4T_{2g} \leftarrow {}^4A_{2g}$, ν_2 $^4T_{1g}(F) \leftarrow {}^4A_{2g}$ and ν_3 $^4T_{1g}(P) \leftarrow {}^4A_{2g}$

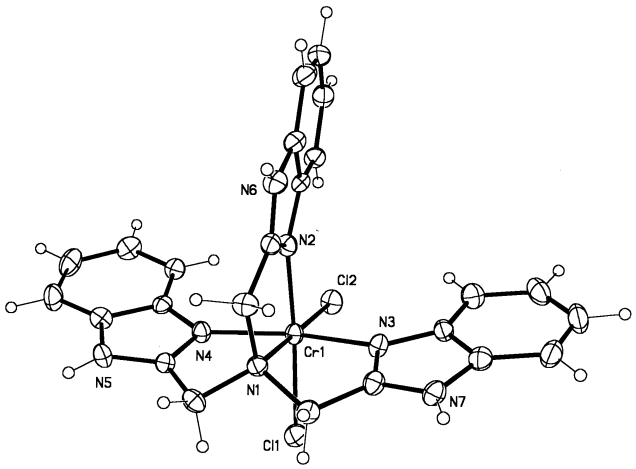

Fig. 2. Geometry for the cation $[CrCl_2ntb]^+$ in complex **1**. Thermal ellipsoids are at 50% probability level.

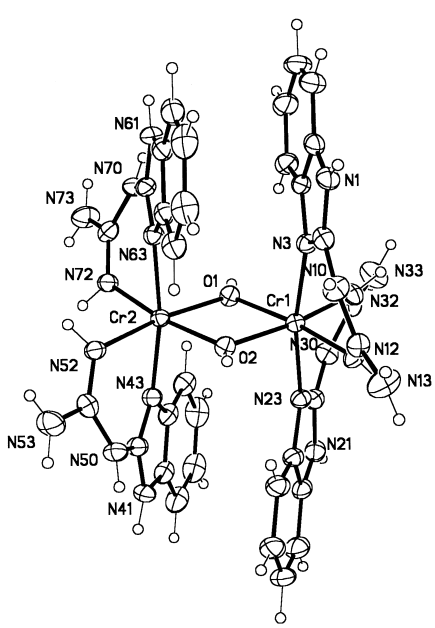

Fig. 3. Geometry for the cation $[Cr_2(2gb)_4(\mu\text{-}OH)_2]^{4+}$ in complex **4**. Thermal ellipsoids are at 30% probability level.

[30]. The diffuse reflectance spectra of compounds **1**–**6**, show three absorption bands, the first one in the region from 16 600 to 20 050 cm^{-1}, the second band from 20 000 to 25 400 cm^{-1} and the third from 25 000 to 36 100 cm^{-1}, where ν_1 correspond to 10 Dq for each complex (Table 2). The third band for compounds **1**, **3**, **4**, **5** and **6** appears as a shoulder obscured by CT bands. The electronic spectra of the compounds reported here are in reasonable agreement with those in the literature [30,31].

The magnetic moments at room temperature for compounds **1**, **2**, **3**, **5** and **6** correspond to the expected values for mononuclear chromium(III) compounds. Compound **4** has a magnetic moment at room temperature of 4.96 MB, smaller than the expected value (5.43 MB spin only) for a Cr(III) dinuclear species [32]. Studies of the variable temperature magnetic susceptibility of **4** were made at 3500 Oe and in the temperature range 17–280.15 K. Least-squares analysis was used to fit the data to a susceptibility expression based on the isotropic spin Hamiltonian [33]:

$$H = -2J(S_1 \cdot S_2)$$

The best fit of the susceptibility data reveals that the dinuclear compound has weak antiferromagnetic coupling ($J = -2.05$ cm^{-1}). This value is within the range of those for other dinuclear di-μ-hydroxo-chromium(III) complexes [17].

3.3. Description of the structures

3.3.1. Complex *1*

The cation $[CrCl_2ntb]^+$ is depicted in Fig. 2. Ntb acts as a tetradentate ligand coordinating through the amine N atom and the three benzimidazole N atoms to the metal ion, as reported for a number of ntb complexes [2]. Two Cl atoms in a *cis* configuration complete the coordination sphere, yielding an hexacoordinated arrangement for the metal. It should be mentioned that only two related ntb-containing complexes with an hexacoordinated metal environment have been reported up to now, with Fe(II) [34] and Ni(II) [9]. On the other hand, **1** is the first reported X-ray characterised Cr(III)–ntb complex.

As expected, the tertiary N atom presents a bond length about 0.10 Å longer than those for the benzimidazole N atoms (see Table 3). The tripodal ntb ligand is forced to adopt a planar geometry in order to retain the octahedral geometry on the metal–dihedral angle between the aromatic moieties containing the rings [N3, N7] and [N4, N5] is 10.1°, while angles of these planes with the third moiety [N2, N6] are 89.6 and 79.6°. This uncommon spatial arrangement for ntb reflects the great versatility of this tripodal ligand in order to take in the preferred geometry of the metal ion. On the other

hand, the Cr ion lies in the plane formed by N1, N3, N4 and Cl2 (calculated maximal deviation: 0.025 Å). As a result of these features, the deviations from an ideal octahedral geometry around the Cr ion are the following: *trans* angles range from 157.18(14) to 177.98(10)° and *cis* angles from 78.30(13) to 99.52(10)°.

Ethanol and water molecules included in the cell form a complex tri-dimensional network of hydrogen bonds using benzimidazolic N atoms and chlorine atoms as acceptors (H···A separations in the range 1.854–2.468 Å), which probably greatly stabilises the crystal.

3.3.2. Complex *4*

Complex **4** is the first X-ray characterised Cr(III) complex including 2gb as ligand. The dinuclear cation $[Cr_2(2gb)_4(\mu\text{-}OH)_2]^{4+}$ is depicted in Fig. 3. It should be mentioned that the charge of the cation is in line with the four ClO_4^- anions present in the asymmetric unit and with the fact that the H atoms of the OH groups were found on difference Fourier maps. The $(\mu\text{-}OH)_2$ bridge is symmetric, with Cr–O bond lengths in the range 1.953(3)–1.961(3) Å. The metal–metal separation, 3.085 Å, is similar to that reported for other complexes containing the $Cr_2(\mu\text{-}OH)_2$ fragment, as well as the Cr–O–Cr angles, 104.02° [35–38] (Table 4). Each Cr(III) ion coordinates two 2gb ligands with Cr–N bond lengths in the short range 2.019(3)–2.060(3) Å, as expected. For each ligand, the N atom bonded to the benzimidazolic moiety lies in the plane of the imidazole: deviations for N10, N30, N50 and N70 from the mean planes formed by the benzimidazolic groups are in the range 0.040–0.048 Å. This point confirms that the coordinated 2gb ligand in **4** is the same as the free ligand depicted in Fig. 1. However, deviations from an ideal octahedral geometry are smaller than in the case of **1**, because 2gb acts as a bidentate ligand while ntb is tetradentate: *cis* and *trans* angles for Cr1 are from 75.83(11) to 95.54(13)° and from 168.30(14) to 169.29(14)°, respectively, and ranges are similar for Cr2. This distortion is reflected in the dihedral angles between the benzimidazolic rings for two 2gb coordinated on the same metal centre: 29.0° between planes [N1, N3] and [N21, N23] and 29.6° between planes [N41, N43] and [N61, N63]. In spite of the parallel arrangement of the benzimidazolic rings in the complex, no intramolecular interactions are observed: the shortest calculated separation between the centroids of the benzene rings is 4.13 Å.

As in the previous case, numerous hydrogen bonds which involve five water molecules, μ-OH groups, NH of imidazole, NH and NH_2 of 2gb stabilise, the crystals (H···A separations from 1.971 to 2.624 Å).

4. Supplementary data

Supplementary data are available from the CCDC on request, quoting the deposition numbers CCDC 140724 (**1**) and 140725 (**4**). The information can be obtained free of charge from The Director, Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The interaction of benzene, *p*-xylene, and naphthalene with a strong two-ended Lewis acid, $Rh_2(O_2CCF_3)_4$, led to one-dimensional linear polymers of 1:1 composition, $[Rh_2(O_2CCF_3)_4 \cdot L]_\infty$, where $L = C_6H_6$ (**1**), p-$(CH_3)_2C_6H_4$ (**2**), and $C_{10}H_8$ (**3**). Compounds **1**–**3** have been characterized by elemental analysis and IR spectroscopy and their structures have been determined by X-ray diffraction. In the crystal structures of the compounds the alternating arrangement of the dirhodium(II) tetrakis(trifluoroacetate) units with the aromatic ligands coordinated to their axial positions forms infinite chains extended along one direction of the unit cell. The rare bridging off-centered, η^2:η^2 coordination of arene groups by the Rh(II) centers was found to be preferred in all three cases with the two closest Rh–C_{arene} distances averaged to 2.662(6) Å in the benzene complex (**1**), to 2.684(7) Å in the *p*-xylene analogue (**2**), and to 2.588(9) Å in the naphthalene product (**3**). © 2000 Elsevier Science Ltd. 1. Introduction

Dirhodium(II) tetrakis(trifluoroacetate) exhibits an extensive axial coordination chemistry with a variety of strong N, O, P-containing bases [1]. Our research interest has been recently focused on studies of weak axial interactions by the powerful two-ended Lewis acid, $Rh_2(O_2CCF_3)_4$ [2]. We introduced a solid state deposition technique ('solventless' synthesis) [2] as an efficient way to study these interactions and to avoid competitive coordination of solvents in solutions. Our recent results have included the first structurally characterized π-complex with an aromatic ligand (hexamethylbenzene), $[Rh_2(O_2CCF_3)_4 \cdot (C_6Me_6)]_\infty$ [2a] and a compound $[Rh_2(O_2CCF_3)_4 \cdot (C_2Ph_2)]_\infty$ [2e] with both a triple carbon–carbon bond and an arene system from the bifunctional diphenylacetylene ligand involved in coordination (Scheme 1). A rare off-centered orientation of the aromatic ligands at the Rh(II) centers has been found in both dirhodium trifluoroacetate chain compounds, with the C_6Me_6 and the Ph_2C_2 ligands. We believe systematic research is needed in order to get more insight into complexation of arenes by the electron-deficient dirhodium(II) carboxylate molecules, as these interactions have an important role in some catalytic and aromatic substitution reactions [3]. Therefore, we have extended the number of arene ligands to benzene, *p*-xylene and naphthalene and report here on their interactions with $Rh_2(O_2CCF_3)_4$. The first two ligands are commonly used as non-coordinating solvents for studying weak interactions in the Lewis acid–Lewis base systems. Naphthalene is the first conjugated arene molecule used for such reactions with the dirhodium moiety. With all three ligands the products are analogous one-dimensional linear polymers of 1:1 composition, namely $[Rh_2(O_2CCF_3)_4 \cdot C_6H_6]_\infty$ (**1**), $[Rh_2(O_2CCF_3)_4 \cdot (p\text{-}(CH_3)_2C_6H_4)]_\infty$ (**2**) and $[Rh_2(O_2CCF_3)_4 \cdot C_{10}H_8]_\infty$ (**3**). They have been crystallographically characterized and their structures have been compared.

2. Experimental

2.1. General

All manipulations were carried out under an atmosphere of dry, oxygen-free dinitrogen by employing Schlenk techniques. Solvents were dried and deoxygenated by refluxing over appropriate agents before use. The anhydrous form of $Rh_2(O_2CCF_3)_4$ was prepared using a literature procedure [4]. Naphthalene ($C_{10}H_8$) was purchased from Aldrich and sublimed before use. The IR spectra were recorded on a Perkin–Elmer 16PC FTIR spectrophotometer using KBr pellets. Elemental analysis was done by Canadian Microanalytical Services, Ltd.

2.2. Synthesis of $Rh_2(O_2CCF_3)_4 \cdot C_6H_6$ (1)

A few drops of distilled benzene were added to the solid unligated $Rh_2(O_2CCF_3)_4$ (0.10 g, 0.15 mmol) in a Pyrex tube. The excess of benzene was removed under vacuum. The tube was then sealed and left in a furnace at 90°C for 24 h. Green crystals of **1** were deposited on the walls after slow cooling of the tube over 48 h to r.t. Yield: 0.030 g, 27%.

2.3. Synthesis of $Rh_2(O_2CCF_3)_4 \cdot (p\text{-}(CH_3)_2C_6H_4)$ (2)

2.3.1. $Rh_2(O_2CCF_3)_4$ in benzene containing p-xylene

The solution containing $Rh_2(O_2CCF_3)_4$ (0.10 g, 0.15 mmol) in 5 ml of benzene containing *p*-xylene (the ratio of $p\text{-}(CH_3)_2C_6H_4$ to C_6H_6 was found by NMR to be about 1:100) was layered with 10 ml of hexanes at r.t. This resulted in deposition of a few crystals of **2** in a week.

2.3.2. $Rh_2(O_2CCF_3)_4$ in p-xylene

The vial containing solution of $Rh_2(O_2CCF_3)_4$ (0.10 g, 0.15 mmol) in 5 ml of *p*-xylene was placed in the Ar glovebox. After keeping the solution for one week at 0°C light-green plates of **2** had appeared. Yield: 0.089 g, 77%.

2.3.3. p-Xylene added to unligated $Rh_2(O_2CCF_3)_4$

A few drops of anhydrous *p*-xylene were added to the solid unligated $Rh_2(O_2CCF_3)_4$ (0.10 g, 0.15 mmol) in a Pyrex tube. The excess of solvent was removed under vacuum. The tube was then sealed and left in a furnace at 95°C for 2 days. Green crystals of **2** were deposited on the walls after slow cooling of the tube over 24 h to r.t. Yield: 0.046 g, 40%.

Anal. Calc. for $C_{16}H_{10}F_{12}O_8Rh_2$: C, 25.25; H, 1.32. Found: C, 24.98; H, 1.32%. IR (KBr, cm^{-1}): 1665.6 (s), 1191.4 (s), 868.4 (s), 840.9 (m), 794.9 (m), 739.4 (s), 540.8 (s).

2.4. Synthesis of $Rh_2(O_2CCF_3)_4 \cdot C_{10}H_8$ (3)

Unligated $Rh_2(O_2CCF_3)_4$ (0.066 g, 0.10 mmol) was mixed with freshly sublimed naphthalene (0.012 g, 0.10 mmol) under an inert atmosphere. The mixture was sealed in an evacuated Pyrex tube and the tube was placed in a furnace at 90°C. Green block-shaped crystals of **3** were deposited over two days in the 'cold' zone of the tube, where the temperature was about 5°C lower. Yield: 0.027 g, 35%. *Anal.* Calcd. for $C_{18}H_8F_{12}O_8Rh_2$: C, 27.50; H, 1.03. Found: C, 27.47; H, 1.03%. IR (KBr, cm^{-1}): 1683.9 (m), 1669.6 (s), 1653.0 (m), 1558.3 (s), 1540.0 (m), 1506.4 (m), 1456.7 (m), 1192.2 (s), 1167.5 (s), 861.0 (m), 784.8 (m), 739.8 (s), 525.9 (m), 457.8 (m), 418.0 (m).

2.5. X-ray structure determinations

Single crystals of compounds **1**–**3** were obtained as described above. X-ray diffraction experiments were carried out on a Nonius FAST diffractometer with an area detector using Mo Kα radiation. Details concern-

ing data collection have been fully described elsewhere [4]. Each crystal was mounted on the tip of a quartz fibre with silicone grease, and the set-up was quickly placed in the cold N_2 stream (-60°C) of a low-temperature controller. Fifty reflections were used in the cell indexing and about 200 reflections in the cell refinement.

All calculations were done on a DEC Alpha running VMS. The coordinates of rhodium and oxygen atoms for the structures were found in direct method *E* maps using the structure solution program SHELXTL [5]. The positions of the remaining atoms were located after an alternating series of least-squares cycles and difference Fourier maps using the SHELXL-93 package [6]. The fluorine atoms of all CF_3 groups were found to be disordered over two or three different rotational orientations. Anisotropic displacement parameters were assigned to all non-hydrogen atoms, except the disordered fluorine atoms. Hydrogen atoms of aromatic ligands were included in the structure factor calculations at idealized positions. Relevant crystallographic data for compounds **1**–**3** are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

Our experimental procedure included both the solid state deposition approach (**1**–**3**) and solution synthesis (**2**). Preparations of **1** and **2** are good examples of using a solid deposition technique for studying interactions of $Rh_2(O_2CCF_3)_4$ with liquid ligands, benzene and *p*-xylene in this case. The key factor in this synthesis is the use of extremely small amounts of suitable solvent, almost close to the equimolar ratio of the arene to the dirhodium molecules. This solid state approach was recently shown to be an effective route for obtaining unusual structures and compositions unattainable in solutions for the systems containing solvents, for example, $Rh_2(O_2CCF_3)_4$–THF [2b] and $Rh_2(O_2CCF_3)_4$–DMSO [2d]. The fact that dirhodium trifluoroacetate was forming an adduct with benzene became obvious a few years ago [4], but at that time suitable crystals had not been obtained from solution. The solid state approach (Section 2.2) applied here for benzene produced crystals of $Rh_2(O_2CCF_3)_4{\cdot}C_6H_6$ (**1**) in moderate yield and of quality suitable for X-ray diffraction study.

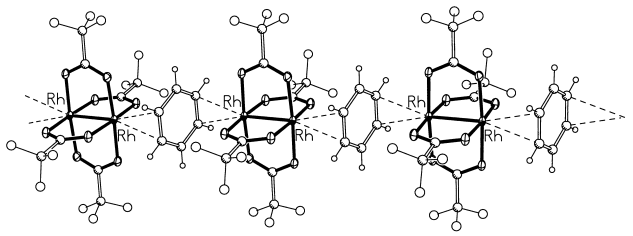

Fig. 1. Fragment showing the alternating arrangement of $Rh_2(O_2CCF_3)_4$ and C_6H_6 in the chain structure of **1**. Rhodium and oxygen atoms are represented by thermal ellipsoids at the 40% probability level. Carbon, fluorine and hydrogen atoms are shown as spheres of arbitrary radii. Axial contacts to Rh atoms are drawn by dashed lines. Only rhodium atoms are labeled for clarity.

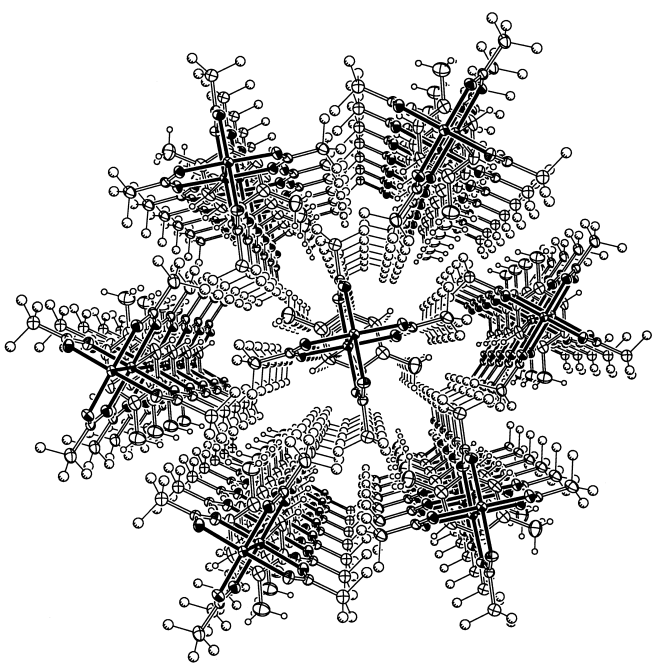

Fig. 2. Crystal packing of 1D chains of **2** viewed along the [100] direction of the unit cell.

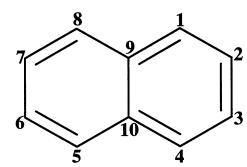
The formation of complex **2**, $Rh_2(O_2CCF_3)_4\cdot(p\text{-}(CH_3)_2C_6H_4)$, was first observed accidentally in the benzene–hexane solution system (Section 2.3.1). The presence of *p*-xylene was explained by the fact that it is added to both benzene and hexanes stills at the stage of the preparation the Na–K amalgam. Later the yield of **2** was increased by using neat *p*-xylene as a solvent (Section 2.3.2); in addition, product **2** was also obtained by the solid state approach (Section 2.3.3). The first synthesis of **2** (Section 2.3.1) is an interesting example of a competition in solution of weak π-donor ligands for coordination by the strong Lewis acid, $Rh_2(O_2CCF_3)_4$. The *p*-xylene, being a stronger donor than benzene (even though present in solutions as a minor component), binds preferentially to axial positions of dirhodium trifluoroacetate units to form **2**. This fact should be taken into account when studying weak interactions in so-called 'noncoordinating' solvents such as benzene, toluene or xylenes, which can be considered as weak Lewis bases themselves, as we clearly observed for the systems containing $Rh_2(O_2CCF_3)_4$. Similar observations were made when studying weakly coordinating anions, which have about the same nucleophilicity toward various cations as toluene [7]. Interestingly, in the case of *p*-xylene ligand, both solution and solid state techniques yielded the same product, the chain polymer of 1:1 composition in which the aromatic ring is acting as a bidentate ligand, while for THF and DMSO [2b,d], solution reactions always resulted only in the formation of the discrete bis-adduct molecules with monodentate coordination of ligands.

The solid state deposition approach ('solventless' technique, indeed, in this case) has been used (Section 2.4) for studying complexation of $Rh_2(O_2CCF_3)_4$ with the solid sublimable ligand, naphthalene, to give crystals of $Rh_2(O_2CCF_3)_4\cdot C_{10}H_8$ (**3**). In contrast to the single ring aromatic ligands, benzene and *p*-xylene, naphthalene, the simplest compound having fused arene rings, was used for coordination with $Rh_2(O_2CCF_3)_4$. From previous reports on transition-metal–naphthalene complexes, (η^6-naphthalene) sandwiches containing a metal in the zero-valent state (Cr, Mo, etc) have been traditionally prepared by metal vapor synthesis technique [8]. Recently, the naphthalene radical anion reductions of a variety of transition metal precursors have been introduced as a convenient method for the synthesis of anionic bis or tris(naphthalene) metal complexes [9], with examples such as $[(\eta^6\text{-}C_{10}H_8)_2Ti]^{2-}$ [9b], or structurally characterized $[(\eta^4\text{-}C_{10}H_8)_3Zr]^{2-}$ [9c]. Some mixed ligand naphthalene complexes have been also obtained using this technique, as for example $[Ru(\eta^6\text{-}C_{10}H_8)(1,5\text{-cyclooctadiene})]$ [10] and $[Fe(\eta^6\text{-}C_{10}H_8)(Cy_2PC_2H_4PCy_2)]$ [11].

3.2. Crystal structures



Three new complexes **1**–**3** have been obtained as green crystals, which were extremely unstable for **1** (loss of benzene), relatively stable for **3**, with **2** being an intermediate case; any exposure to solvent media led to the solvolytic cleavage of **1**–**3**. All products have been examined by X-ray crystallography and the 1:1 composition was confirmed by elemental analysis. All three structures consisted of the dirhodium(II) tetrakis(trifluoroacetate) molecules alternating with aromatic ligands, C_6H_6 (**1**), $p\text{-}(CH_3)_2C_6H_4$ (**2**), and $C_{10}H_8$ (**3**), which are bound at axial positions of the Rh_2 units thus forming linear one-dimensional chains (Fig. 1). These chains lying parallel in the crystal are extended in the structure along the [100] direction ([001] in the case of **3**) of the unit cell (Fig. 2). Selected distances and angles for **1**–**3** are given in Table 2. The coordination of arene

ligands in **1**–**3** was found to be off-center (Fig. 3) as in the cases of the C_6Me_6 and the Ph_2C_2 dirhodium complexes reported earlier [2a,e]. For benzene and *p*-xylene ligands (**1** and **2**) two opposite edges of the arene ring approach the axial sites of the neighboring dirhodium dimers in the $\eta^2(1,2):\eta^2(4,5)$ bridging fashion. For the single-ring aromatic ligands, in addition to the common η^6-binding mode, there are only a few examples with benzene and *p*-xylene ligands bonding two metal centers in the off-centered way, for example, $[(^tBu_3SiO)_3Ta]_2[\mu\text{-}\eta^2(1,2):\eta^2(4,5)\text{-}C_6H_6]$ [12] and $[(Cy_2PC_2H_4PCy_2)Co]_2[\mu\text{-}\eta^3:\eta^3\text{-}C_6H_4(CH_3)_2]$ [13]. There was also a systematic study of the Ag(I)-aromatic interactions, including benzene, xylenes and naphthalene ligands [14], which were all examples of an η^2 off-centered donation of π-electrons to Ag^+, including one unusual η^1-benzene compound [15].

In complex **3** both arene rings of the naphthalene molecule are engaged in coordination to the different Rh(II) centers in the $\eta^2(1,2):\eta^2(5,6)$ mode (see numbering in Scheme 2, Fig. 4). This is a rare unsymmetrical mode for the μ^2-naphthalene in transition metal complexes [16–18]. The two coordination modes of naphthalene mentioned above, the most common for the discrete transition metal complexes obtained so far, were η^4 and η^6. Several different bridging, μ^2 modes of naphthalene have been found [16–18] in a number of the multidecker compounds with different d- and f-block transition metals: $CpV(\mu^2\text{-}\eta^6:\eta^6\text{-}C_{10}H_8)VCp$ [16a], $[CpV(\mu^2\text{-}\eta^6:\eta^2\text{-}C_{10}H_8)Yb(THF)Cp]_n$ ($Cp = \eta^5\text{-}C_5H_5$) [16b], $(C_6H_6)Ru(\mu^2\text{-}\eta^4:\eta^6\text{-}C_{10}H_8)Cr(CO)_3$ [17].

Scheme 2.

The two closest Rh–C_{arene} distances average to 2.662(6) in (**1**), 2.684(7) in (**2**) and to 2.588(9) Å in (**3**) indicating the tightest metal–arene interaction in the naphthalene compound. At first glance, this contrasts to the general assumption that naphthalene binds less strongly to a metal than benzene [19], and to the data on bond-dissociation energies via calorimetric methods revealing that the naphthalene–Cr bond in the $Cr(CO)_3$ complex is 6 kcal mol^{-1} weaker than the benzene–Cr bond [8c]. However, it is worth emphasizing that those data were valid for the discrete η^6-compounds, while in the chain polymers **1** and **2** each arene ring coordinates two metal centers, and in **3** different rings of naphthalene are involved in coordination. This means that axial

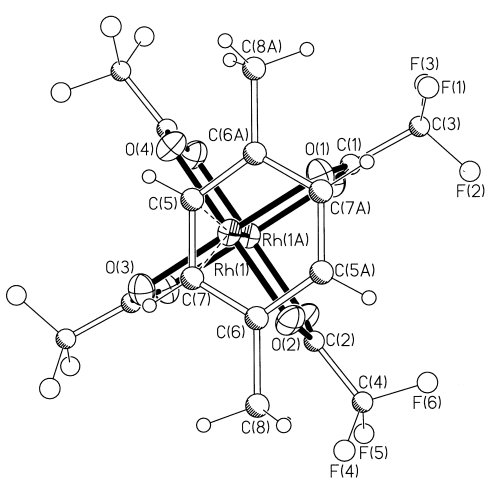

Fig. 3. The view almost down the Rh–Rh axis of the $Rh_2(O_2CCF_3)_4 \cdot (p\text{-}(CH_3)_2C_6H_4)$ unit in the chain structure of **2**. Rhodium and oxygen atoms are represented by thermal ellipsoids at the 40% probability level. Carbon, fluorine and hydrogen atoms are shown as spheres of arbitrary radii. Two closest axial contacts to Rh atoms are drawn by dashed lines.

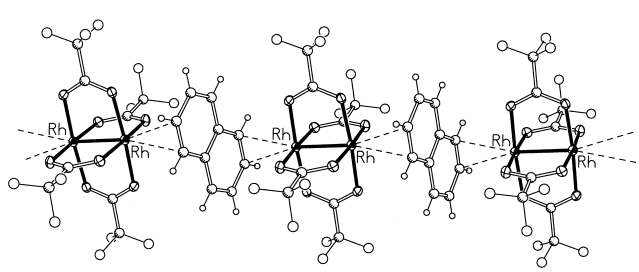

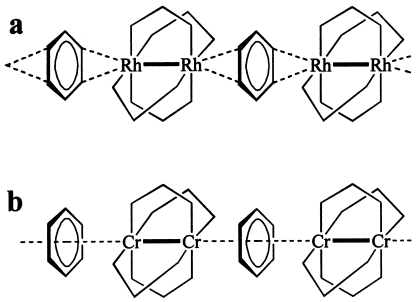

Fig. 4. Fragment showing the alternating arrangement of $Rh_2(O_2CCF_3)_4$ and $C_{10}H_8$ in the chain structure of **3**. Rhodium and oxygen atoms are represented by thermal ellipsoids at the 40% probability level. Carbon, fluorine and hydrogen atoms are shown as spheres of arbitrary radii. The shortest Rh–C_{arene} contacts are drawn by dashed lines. Only rhodium atoms are labeled for clarity.

Scheme 3.

contacts to arene are expected to be shorter in **3** than in **1** and **2**. Actually the Rh–arene center distances are very close, being in the range of 2.97–2.99 Å, for all dirhodium polymers mentioned in Table 2, except in the diphenylacetylene compound where the distance is 3.06 Å. All of the arene complexes, **1**–**3**, demonstrate asymmetry in the two nearest metal–carbon distances. The difference in these two Rh–C_{arene} contacts is the most significant (0.172 Å) in complex **2** with *p*-xylene compared to the benzene (0.032 Å) and to the naphthalene (0.042 Å) polymers. It was 0.017 Å in the $[Rh_2(O_2CCF_3)_4{\cdot}C_6Me_6]_\infty$ compound [2a].

The unsymmetrical $\eta^2{:}\eta^2$ complexation of arene groups (Scheme 3a) seems to be preferred for the dirhodium(II) trifluoroacetate one-dimensional polymers based on the several examples obtained so far. This contrasts to the dichromium carboxylates with coordinated aromatic ligands of the 1:1 composition, including benzene and p-xylene analogues, in which arene rings were lying centrically on the line between two dimetal units and thus having a η^6 (Scheme 3b) symmetrical coordination [20]. In $[Bi_2(O_2CCF_3)_4{\cdot}C_6Me_6]_\infty$, the only arene adduct of a main group element tetracarboxylate, the C_6Me_6 molecules are also acting in an η^6 coordination mode [21].

The unsymmetrical complexation of aromatics in **1**–**3** causes no detectable distortion of the arene rings. The mean C–C distances are the same, averaged to 1.39(1) in **1**–**3**.

There was an attempt to compare the inductive effect of different substituents of arene ligands on the Cr–Cr and the Cr–ring center distances [20]. One might expect that the stronger the nucleophile substituent is, the stronger is the interaction of an axial ligand with the dimetal moiety (which, in turn, would result in the elongation of the metal–metal distance). However, there was no simple relationship found for a number of relative compounds between the ionization potentials of arenes and the Cr–Cr distances [20]. The latter was shown to be influenced by other variables, packing forces being the most important one. This is also the case for a number of dirhodium tetrakis(trifluoroacetate) chain polymers with coordinated arenes studied here. The present results show that the electronic properties of aromatic ligands in donor–acceptor complexes with $Rh_2(O_2CCF_3)_4$ are not simply correlated with their coordination strength. For example, the relatively strong donor, hexamethylbenzene, has the longest Rh–C_{arene} contacts (averaged to 2.779(6) Å [2a]) among the arenes studied (Table 2). The difference, 0.19 Å, in these two shortest Rh–C_{arene} contacts in $[Rh_2(O_2CCF_3)_4{\cdot}(C_6Me_6)]_\infty$ compared to the naphthalene analogue (2.588(9) Å) is significant, while the Rh–Rh distances are exactly the same for two compounds. Obviously, packing forces and other stereochemical factors are very important in these arene–metal interactions, capable of overriding electronic factors.

In **3** the naphthalene molecule approaches the rhodium atoms via the 1,2 and 5,6 C–C bonds. This could well be an electronic effect since it is these bonds that have the highest π-bond order, 0.73, compared to 0.61 for the 2,3 and 6,7 bonds (Scheme 2), according to Hückel calculations [22].

3.3. Conclusions

In summary, complexation of π-arene ligands, benzene, *p*-xylene and naphthalene, with the dirhodium unit has been examined by preparing a number of 1:1 coordination polymers with $Rh_2(O_2CCF_3)_4$. It is found that dirhodium tetrakis (trifluoroacetate) exhibits a selective coordination toward weak donor bases, such as benzene and *p*-xylene, in solutions. The crystalline complexes **1**–**3** have a one-dimensional framework constructed by the dirhodium units and arene ligands bound to its axial positions through two carbon atoms at each end. The geometry of coordinated arene bridges is unsymmetrical, an $\eta^2{:}\eta^2$ type, in all cases. Complex **3**, $[Rh_2(O_2CCF_3)_4{\cdot}(C_{10}H_8)]_\infty$ constitutes the first example of such products with a dicyclic arene system. We think that related and novel compounds with polycyclic aromatic ligands having an extended delocalized π-system will generally be accessible by the technique introduced, and studies on arene ligands with multicoordination-site possibilities are under way.

4. Supplementary Material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre CCDC Nos. 140762, 140763 and 140764 for compounds **1**, **2** and **3**, respectively. Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

Gold(I) complexes containing the cationic ylide ligand bis(methyldiphenylphosphonio)methylide

Inocencio Romeo, Manuel Bardají, M. Concepción Gimeno, Mariano Laguna *

Departamento de Química Inorgánica, Instituto de Ciencia de Materiales de Aragón, Universidad de Zaragoza-CSIC, 50009 Zaragoza, Spain

Received 9 March 2000; accepted 15 June 2000

Abstract

The ylide $Ph_2PCH{=}PPh_2Me$ can be selectively P-alkylated by MeI or MeO_3SCF_3 to form the bis(methyldiphenylphosphonio)methylide salts $[MePPh_2CHPPh_2Me]A$ (A=I (**1**), CF_3SO_3 (**2**)). The ylidic carbon shows a weak nucleophilicity and does not give typical reactions with common organic electrophiles, including Wittig type reactions, but it is able to displace tetrahydrothiophene in [AuX(tht)] to give the corresponding C-coordinated gold(I) compounds $[Au\{CH(PPh_2Me)_2\}X]CF_3SO_3$ (X=Cl (**3**), C_6F_5 (**4**)). The crystal structure of (**4**) displays a linear coordination for the gold atom, single P–C bond lengths and a PCP angle of 119.1(3)° for the ligand. © 2000 Elsevier Science Ltd. Keywords: Gold(I) complexes; Cationic ylide ligand; Bis(methyldiphenylphosphonio)methylide salts; P-alkylation

1. Introduction

Carbodiphosphorane chemistry has attracted much attention not only because of the synthesis and geometry of the P=C=P fragment [1] but also for the synthesis of metallic complexes. Therefore several mononuclear copper, gold, silver [2,3], iridium [4], platinum [5,6], rhenium [7,8], tungsten [6,8,9], manganese, chromium, iron and nickel [8] or dinuclear gold [10] and iron [11] derivatives have been prepared.

On the contrary the mesomeric phosphonium ylides $R_3PCHPR_3^+$ have often been overlooked because of their intermediate position on the carbodiphosphoranes and not C_{ylidic}-bonded metallic complexes have been described so far. Some complexes containing the unit $-CH_2PR_2CHPR_2CH_2-$ have been reported with the ligand acting as quelate through the CH_2 groups [10,12,13].

In this paper, the synthesis of the phosphoranium salts $[MePPh_2CHPPh_2Me]A$ (A=I, CF_3SO_3) and their first metallic complexes $[Au[CH(PPh_2Me)_2)X]CF_3SO_3$ (X=Cl, C_6F_5) are reported, which in spite of the weak nucleophilic character of the ylidic carbon are stable. X-ray diffraction studies of the pentafluorophenyl derivative were carried out to fully characterize their geometry.

2. Experimental

All the reactions were carried out under a dry nitrogen atmosphere at room temperature (r.t.). IR spectra were recorded on a Perkin–Elmer 883 spectrophotometer, over the range 4000–200 cm^{-1}, by using Nujol mulls between polyethylene sheets. ^1H, ^{19}F and $^{31}P\{^1H\}$ NMR spectra were recorded on a Varian UNITY 300 or Bruker ARX-300 apparatus in $CDCl_3$ solutions; chemical shifts are quoted relative to $SiMe_4$ (external, ^1H), $CFCl_3$ (external, ^{19}F) and 85% H_3PO_4 (external, ^{31}P). C, H, N and S analyses were performed with a Perkin–Elmer 2400 microanalyzer. Mass spectra were recorded on a VG Autospec using LSIMS technique (with cesium gun) and 3-nitrobenzyl alcohol as matrix.

2.1. Preparation of the ligands

2.1.1. $[MePh_2PCHPPh_2Me]I$ (**1**)

To a diethyl ether suspension (10 ml) of $[Ph_2PCH_2PPh_2Me]I$ [14] (0.54 g, 1 mmol) was added an

[b] $wR \quad (F^2) = [\Sigma\{w(F_o^2 - F_c^2)2\}/\Sigma\{w(F_o^2)^2\}]^{0.5}$; $\quad w^{-1} = \sigma^2(F_o^2) + (aP)^2 + bP$, where $P = [F_o^2 + 2F_c^2]/3$ and a and b are constants adjusted by the program.

[c] $S = [\Sigma\{w(F_o^2 - F_c^2)^2\}/(n-p)]^{0.5}$, where n is the number of data and p the number of parameters.

Scheme 1.

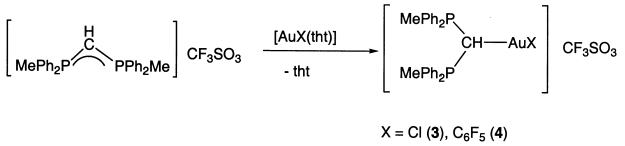
2.1.2. [$MePh_2PCHPPh_2Me$]CF_3SO_3 (2)

As stated for (**1**) but adding drop by drop MeO_3SCF_3 instead of MeI till all the white solid has precipitated. Yield of 2: 65%. ^{1}H NMR: 8 7.8–7.2 (m, 20H, Ph), 2.04 (d, 6H, $^2J_{HP} = 12.3$, Me–P), 1.30 (t, 1H, $^2J_{HP} = 5.6$ Hz, P–CH–P); ^{31}P{^{1}H} NMR: δ 16.5. Anal. Calc. $C_{28}H_{27}F_3O_3P_2S$: C, 59.8; H, 4.85;S, 5.7. Found: C, 60.0; H, 4.65; S, 5.55.

2.2. Preparation of the gold(I) complexes

2.2.1. [$Au\{CH(PPh_2Me)_2\}X$]CF_3SO_3; X=Cl (3), C_6F_5 (4)

To a dichloromethane solution (20 ml) of 2 (0.11 g, 0.2 mmol) was added 0.2 mmol of [AuX(tht)] (X=Cl 0.064 g, C6F5 0.09 9) [15,16]. The mixture was stirred for 90 min, then concentrated to ca. 5 ml and the addition of diethyl ether (15 ml) afforded complexes **3**–**4** as white solids, which were washed with diethyl ether (3×5 ml). Yield of (**3**): 88%. ^{1}H NMR: 6 7.8–7.2 (m, 20H, Ph), 4.66 (t, 1H, $^2J_{HP} = 16.8$, P–CH–P), 2.14 (d, 6H, $^2J_{HP} = 12.4$ Hz, Me–P); ^{31}P{^{1}H} NMR: δ 22.1. Anal. Calc. $C_{28}H_{27}ClF_3O_3P_2SAu$: C, 42.3; H, 3.4; S, 4.05. Found: C, 42.35; H, 3.75; S, 4.0. Yield of (**4**): 87%. ^{1}H NMR: δ 7.8–7.2 (m, 20H, Ph), 4.28 (t, 1H, $^2J_{HP} = 16.7$, P–CH–P), 2.22 (d, 6H, $^2J_{HP} = 11.9$ Hz, Me–P); ^{19}F NMR: δ −78.0 (s, 3F, CF_3), −117.0 (m, $2F_o$), −161.3 (t, $1F_p$), −164.8 (m, $2F_m$); ^{31}P{^{1}H} NMR: δ 22.7. Anal. Calc. $C_{34}H_{27}F_8O_3P_2SAu$: C, 44.1; H, 2.95; S, 3.45. Found: C, 44.35; H, 3.0; S, 3.3.



2.3. X-ray crystallography

The crystal was mounted in inert oil on a glass fibre and transferred to the cold gas stream of a Siemens P4 diffractometer equipped with an Oxford low temperature attachment. Data were collected using monochromated Mo Kα radiation ($\lambda = 0.71073$). Scan type theta-2theta. Absorption correction was applied based on Ψ-scans. The structure was solved by the heavy-atom method, and refined on F^2 using the program SHELXL-93 [17]. Non hydrogen atoms were refined anisotropically. Hydrogen atoms were included using a riding model. Further details are given in Table 1.

3. Results and discussion

3.1. Ligand synthesis

The phosphoranium salts were prepared following the Scheme 1. First it was carried out the reaction of bis(diphenylphosphino)methane (dppm) with MeI to give the monomethylated product. This compound was deprotonated in the presence of an excess of sodium hydride to afford a yellow solution of the mono-ylide

Scheme 2.

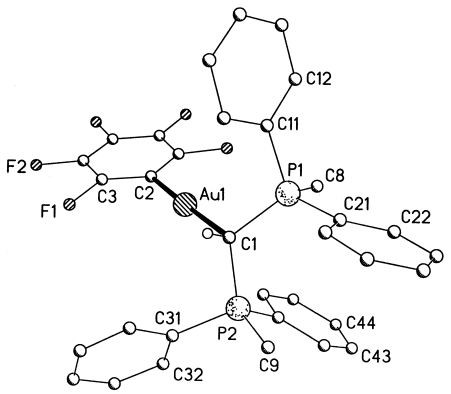


Fig. 1. Structure of the cation of complex **4** in the crystal with the numbering scheme. Radii are arbitrary; hydrogen atoms except at C1 are omitted for clarity.

$Ph_2PCH{=}PPh_2Me$, air and moisture sensitive, which had been already prepared by a transylidation reaction [14]. Ylides can be easily alkylated although a mixture of the C-alkylated and the P-alkylated derivatives are usually obtained [18,19]. The alkylation of our ylide affords purely the P-alkylated derivative, by using MeI or methyl triflate as reagents, which is probably due to the stability of the bisphosphonium fragment. Even by adding 100% excess of MeI the P-alkylated derivative was the only compound obtained. However the addition of methyltriflate to the ylide in a 2:1 molar ratio leads mainly to a mixture of the P-alkylated derivative (**2**) and the phosphonium salt $PPh_2Me_2^+$ coming from the cleavage of (**2**).

These derivatives are air- and moisture-stable white solids at room temperature. The IR spectrum of (**2**) shows absorptions at 1266, 1222 and 638 cm^{-1} from the triflate anion [20]. The ^1H NMR spectra of (**1**) and (**2**) are very similar showing a doublet around 2 ppm for the methyl group and a higher field triplet (about 1.35 ppm) for the methylide bridge. In the $^{31}P\{^1H\}$ NMR spectra it can be observed, in both cases, a singlet at 16.5 ppm as expected for two equivalent phosphorus atoms.

These phosphoranium salts are very stable, which has been explained by the very weak nucleophilicity of the ylidic carbon which prevents nucleophilic substitution or addition reactions. In fact, typical Wittig reactions for these ylides are only known if hydrogen is replaced by fluor in the carbanion, that has been explained because fluor destabilizes negative charges in an alfa position [21,22]. That is why to our knowledge there is no metallic complexes containing the ligand $R_3P{=}CH{-}PR_3^+$. On the contrary and as stated before for the corresponding carbodiphosphorane ligands $R_3P{=}C{=}PR_3$, of which the ylidic carbon is a stronger nucleophile, coordination compounds are well known, although most of them are only mononuclear C-coordinated complexes. Reactions of ylides with electrophiles such as benzaldehyde, acetyl chloride, benzoyl chloride, benzyl chloride and carbon disulfide gave no reaction.

3.2. Gold(I) complexes synthesis

We have previously reported several gold(I) complexes with C-coordination to ylides coming from the dppm [23]. For instance we have prepared the corresponding C-bonded gold complexes by coordination to $[Au(C_6F_5)SPPh_2CH(PPh_2Me)]$ [24] or to $[Au(C_6F_5)$-$PPh_2CH(PPh_2Me)]$ [25] which are very close to ligands **1**–**2** (equals by substituting the P- or S-coordinated gold(I) fragment for methyl) and they also are very stable ylides. Therefore we carried out the same reactions between the phosphoranium salts **1**–**2** and gold(I) complexes (see Scheme 2). The reactions evolve with displacement of tetrahydrothiophene (tht) to afford complexes **3**–**4** as white solids air and moisture stable.

Their IR spectra show absorptions at 335 cm^{-1} (**3**) due to ν(Au–Cl) [26], 955 and 797 cm^{-1} from the pentafluorophenyl groups (**4**) [27], and 1265, 1222, 638 (**3**), 1250,1224 and 638 cm^{-1} (**4**) from triflate anions. The ^1H NMR spectra show an almost unchanged doublet around 2.1 ppm for the methyl group and a triplet at 4.66 ppm for (**3**) and 4.28 ppm for (**4**) due to the methylide bridge, clearly low-field shifted from (**2**) ($\Delta\delta$ is 3.36 ppm for (**3**) and 2.98 ppm for (**4**)). The $^{31}P\{^1H\}$ NMR spectra show a singlet around 22 ppm and again about 6 ppm low-field shifted after gold coordination. The ^{19}F NMR spectrum of (**4**) shows the pattern of a pentafluorophenyl group besides of the triflate counterion. The LSIMS mass spectra show the base peak at $m/z = 413$ due to the bis(phosphonium)methylide ligand and at 645 (20%, for (**3**)) and at 777 (65%, for (**4**)) corresponding to $[M{-}CF_3SO_3]^+$.

3.3. Crystal structure of $[Au\{CH(PPh_2Me)_2\}(C_6F_5)]CF_3SO_3$

The structure of the cation is shown in Fig. 1, with selected bond lengths and angles in Table 2. It consists of a gold(I) center bonded to two kinds of carbon atoms, one coming from a pentafluorophenyl group and the other from an ylidic ligand. Both distances Au–C are very different; $Au^I{-}C_6F_5$ is 2.029(6), which is of the same order as that found in related complexes such as $[Au(C_6F_5)_2\{(PPh_2)_2CH\}Au(C_6F_5)]$ (2.048(8) Å)

Table 2
Selected bond lengths (Å) and angles (°) for complex **4**

Au(1)–C(2)	2.029(6)	P(1)–C(21)	1.795(6)

C(8)–P(1)–C(1)	111.4(3)	C(12)–C(11)–P(1)	119.9(7)
C(8)–P(1)–C(21)	108.5(3)	C(22)–C(21)–P(1)	123.2(5)
C(1)–P(1)–C(21)	112.6(3)	C(26)–C(21)–P(1)	118.1(5)
C(8)–P(1)–C(11)	108.9(4)	C(36)–C(31)–P(2)	119.7(5)
C(1)–P(1)–C(11)	108.4(3)	C(32)–C(31)–P(2)	121.3(6)
C(21)–P(1)–C(11)	107.0(3)	C(42)–C(41)–P(2)	120.7(5)
C(1)–P(2)–C(9)	112.3(3)	C(46)–C(41)–P(2)	119.9(5)
C(1)–P(2)–C(41)	111.8(3)	C(3)–C(2)–Au(1)	125.9(5)
C(9)–P(2)–C(41)	109.0(4)	C(7)–C(2)–Au(1)	120.3(5)

[28] or $[(F_5C_6)AuCH(PPh_2AuPPh_2)_2CHAu(C_6F_5)]$ (2.012(13) Å) [29] or to the one for the Au–C_6F_5 group *trans* to the ylidic carbon in $[(F_5C_6)AuPPh_2CH(PPh_2Me)Au(C_6F_5)]$ (2.011(11) Å) [25]. In the latter the Au–C_6F_5 distance *trans* to the phosphorus ligand is longer, 2.053(15) Å, as corresponds to the higher *trans* influence of the phosphine ligand. The Au–C_{ylidic} bond length is 2.112(6) Å and the value agrees well with those in the complexes mentioned. The gold atom displays an almost linear coordination (175.9(2)°). There are not short gold–gold interactions presumably because steric effects of the bulky ligand prevent the intimate approach required for metal–metal contacts, as have been observed for other complexes with crowded ligands [30].

The P–C_{ylidic} bond lengths are 1.781(6) and 1.792(6) Å, far from those found in $MePPh_2P{=}C{=}PPh_2Me$ (1.645 Å) [31,32] or in $[Au(C_6F_5)PPh_2CH(PPh_2Me)]$ [25] (1.692 Å), as expected because of the absence of double bond character in complex **4**. In fact the distances compare well with the other P–C single bond lengths found in the ligand (from 1.788(7) to 1.799(7) Å), although they are shorter than those reported in $[PPh_3CH_2PPh_3][FeCl_4]$ (1.822(4) and 1.816(4) Å) [33].

The P–C–P angle is 119.1(3)°, slightly smaller than that found in $MePPh_2P{=}C{=}PPh_2Me$ (121.8°) or $[Au(C_6F_5)PPh_2CH(PPh_2Me)]$ (126.0(4)°) due to hybridization state, also smaller than that found in $[PPh_3CH_2PPh_3][FeC1_4]$ (123.4(2)°), probably because of electrostatic repulsion in the latter [33] but bigger than that in $[(F_5C_6)AuPPh_2CH(PPh_2Me)AuC_6F_5]$ 114.9(6)° presumably because the major steric repulsion of an Au–C_6F_5 unit compared to a methyl group. The P–C–Au angles, 109.1(3) and 105.7(3)°, are close to a tetrahedral disposition.

4. Supplementary material

Crystallographic data for complex **4** (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 141436. Copies can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1123-336033; e-mail: deposit @ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The complexation processes between Cu(II) and the antihypotension drug Effortil (HEff) at different reaction conditions lead to the formation of two types of complex — a mononuclear violet one, $CuEff_2{\cdot}2CH_3OH$, and the binuclear green $Cu_2Eff_2Cl_2$. Monocrystals of the mononuclear $CuEff_2{\cdot}2CH_3OH$ complex were isolated and their structure determined by X-ray diffraction. Copper is coordinated through O^- and N of OH and NH groups from the ligands in a perfectly flat tetragon. The crystal structure also includes two solvent CH_3OH molecules per $CuEff_2$ unit. The $CuEff_2$ fragments are linked by hydrogen bonds. The binuclear $Cu_2Eff_2Cl_2$ complex was characterized using electronic and IR spectra, EPR, magnetochemical, calorimetric, thermogravimetric methods and elemental analysis. The complex contains bidentately bound monoanionic ligands and chloride ions. Each Cu atom is coordinated with NH, and bridged by the deprotonated OH group of Effortil with the second Cu center. The chloride ions are coordinated with copper as terminal ligands. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Recently it was assumed and found that arterial blood pressure is a process regulated by the biometals copper and zinc [1–4]. On the other hand, the drugs for treatment of arterial hypertension are effective ligands and it could be presumed that their action is at least partially related to complexation with the two metals, causing a shift in their homeostasis. From this point of view, we have already studied the complex formation between Cu(II) and different anti-hypertensives such as ACE-inhibitors [5], vasodilators [6] and diuretics [7,8]. Special attention was paid to the β-blockers [8–13], the drugs most widely used for this purpose, which represent aminoalcohols of type **I**, and differ by the substituent R in the phenyl ring.

(I) **(II)**

It seems worth noting however, that one of the most efficient drugs used against arterial hypotension, Effortil, **II** also represents an aminoalcohol of the same type. It was interesting therefore, to study whether its behavior towards copper is analogous and why its effect on the blood pressure is just the opposite.

Hence, the aim of the present study was investigation of the complexation processes between copper(II) and Effortil.

2. Experimental

2.1. Apparatus and analysis

The IR spectra in the 4000–100 cm^{-1} range were recorded on a Perkin–Elmer 893 spectrometer both in Nujol and CsI, the X-band EPR spectra on a Bruker ER 420 spectrometer and the electronic spectra were obtained on a Specord UV–Vis (Carl–Zeiss, Jena). The calorimetric and gravimetric studies were performed on DSC-2C and TGS-2 Perkin–Elmer equipment in argon. The magnetic measurements were carried out in argon atmosphere by the Faraday balance. The elemental analysis was performed according to the standard methods: C and H were determined as CO_2 and H_2O, N through the Duma's method, chlorine by titration with $Hg(NO_3)_2$ after wet digestion of the sample. Copper(II) was determined after ignition of a sample, dissolution of the residue in diluted HNO_3 and titration with standard solution of EDTA using indicator Murexide at pH 8 (ammonia buffer). The potentiometric measurements were provided with aqueous solutions of $(Cu(ClO_4)_2 \cdot 6H_2O)$ containing 5×10^{-4} Cu(II) and 1×10^{-3} mol dm^{-3} of Effortil base (HEff). Aliquots of these solutions with Cu–HEff molar ratio 1:2 were titrated with 9.95×10^{-3} mol dm^{-3} $HClO_4$ to obtain the stability constants. The ionic strength was adjusted to 0.1 mol dm^{-3} with $NaClO_4 \cdot H_2O$. Argon was bubbled through the samples to remove O_2 and CO_2 and for stirring the solution. Measurements were performed on a Radiometer PHM84 pH-meter with accuracy of ± 0.001 pH units, equipped with a GK240C combined electrode and an ABU80 automatic burette for potentiometric titration. The stability constants were calculated by means of a general computation program (PSEQUAD) [14]. X-ray diffraction was studied on a monocrystal using an Enraf–Nonius CAD-4 diffractometer. A transparent violet crystal of $CuEff_2 \cdot 2CH_3OH$ was selected and mounted on an Enraf–Nonius CAD-4 diffractometer. A hemisphere of 1743 independent reflections, of which 1620 with $I > 2\sigma(I)$, was collected at r.t. using graphite monochromated Mo Kα radiation ($\lambda = 1.71073$ Å). The structure was solved by direct methods (SHELXTL) [15] and refined by least squares on F^2 (SHELX-96) [16]. First the Cu, N and O atoms were located according to the difference Fourier map and their positions refined isotropically. Next the C atoms were found and all the atoms refined anisotropically. Finally the H atoms were refined using a riding model. The main crystal and refinement data are listed in Table 1.

Table 1
Crystal data and structure refinement for the mononuclear complex $CuEff_2 \cdot 2CH_3OH$

Empirical formula	$Cu(C_{10}NO_2H_{14})_2 \cdot 2CH_3OH$

2.2. Synthesis

The ligand was obtained from Sopharma, Bulgaria, $CuCl_2 \cdot 2H_2O$ and CH_3OH (both of analytical grade) were supplied by Riedel E. de Haën AG.

2.2.1. The mononuclear complex

HEff·HCl (0.0541 g) was dissolved in 10 ml methanol. The addition of 1 ml methanolic Cu(II) solution containing 0.0043 g $CuCl_2 \cdot 2H_2O$ and NaOH (0.0200 g in 20 ml methanol) at molar ratio Cu–HEff·HCl–NaOH = 1:10:20 leads to the formation of a violet solution from which a crystalline violet mononuclear complex was obtained after four months. It was filtered, washed with methanol and dried over P_2O_5. *Anal.* Found: C, 54.21; H, 6.97; N, 5.63; Cu, 12.01. Calc. for $CuEff_2 \cdot 2CH_3OH$: C, 54.36; H, 7.05; N, 5.76; Cu, 12.07%. The mononuclear complex was also obtained in aqueous solution, at excess of the ligand, Cu–HEff·HCl = 1:2–1:10 and pH 10.5.

The synthesis of the binuclear complex was realized using 0.0541 g HEff·HCl in 10 ml methanol, Cu(II) salt (0.0213 g $CuCl_2 \cdot 2H_2O$ in 5 ml methanol) and NaOH (0.0100 g in 10 ml methanol). The molar ratio was Cu–HEff·HCl–NaOH = 1:2:2. After three days a green precipitate was formed and it was filtered, washed with methanol and dried over P_2O_5. *Anal.* Found: C, 42.94; H, 5.00; N, 5.04; Cu, 22.61. Calc. for $Cu_2Eff_2Cl_2$: C, 43.02; H, 5.05; N, 5.02; Cu, 22.76%.

3. Results and discussion

3.1. Mononuclear $CuEff_2{\cdot}2CH_3OH$ complex

3.1.1. X-ray data and crystal structure

The structure is shown in Fig. 1, and selected bond lengths and angles in Table 2.

In the structure the Cu atoms occupy one crystallographically independent special position. Each Cu atom is coordinated by two OH groups and two N atoms from two ligand molecules in a perfectly flat tetragon. The Cu–O and Cu–N distances (1.905 and 2.042 Å) and O–Cu–N angles (85.60 and 94.40°) are typical for a four-fold square coordination and compare well with the distances reported for similar copper complexes [17]. The $CuEff_2$ and the solvent methanol molecules are arranged in layers parallel to the b-axis. A complex network of hydrogen bonds links these layers in a 3D structure (Fig. 2). The closest Cu–Cu separation corresponds to the a-axis (7.737 Å) which clearly indicates that there is no direct magnetic interaction between the Cu centers in the structure. The C–C, C–N and C–O distances in the Effortil and methanol molecules range from 1.375 to 1.528 Å and the C–H distances are of the order 0.8–1.1 Å.

3.1.2. Electronic spectra

In methanolic solution the mononuclear complex shows an absorbence at 519 nm ($\varepsilon = 92$ l mol^{-1} cm^{-1}) and 626 nm ($\varepsilon = 75$ l mol^{-1} cm^{-1}). These data are in accordance with the assumption for the formation of Cu–N and Cu–O bonds. As a rule the first ones are

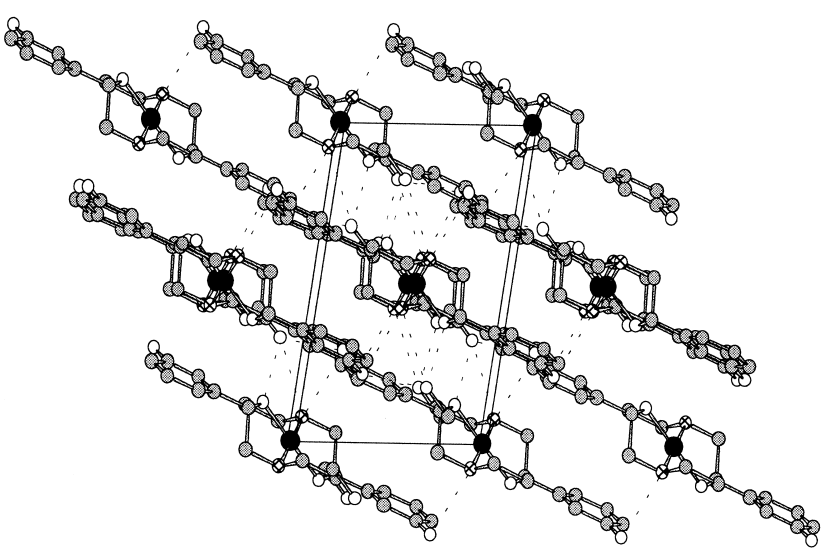

Fig. 2. The 3D structure of $CuEff_2{\cdot}2CH_3OH$, view along the b-axis. Copper, nitrogen, carbon and oxygen atoms are depicted as black, hatched, filled and open circles, respectively, hydrogen atoms are omitted for clarity. The hydrogen bonds are shown as dotted lines.

connected with absorbencies at wavelengths below 600 nm and the second type in the range 600–750 nm, but quite often these regions are not so strictly localized and separated. The position and the intensity of the bands observed are characteristic for Cu(II) complexes with a tetragonal geometry [18,19].

3.1.3. Magnetic measurements

The temperature dependence of the magnetic susceptibility is typical for a normal mononuclear paramagnetic complex (Fig. 3(a)), without any measurable exchange interaction between the Cu(II) centers. The Curie–Weiss law is not obeyed in the temperature range studied and in such conditions the magnetic moment was calculated using the equation $\mu_{eff} = 2.828(\kappa_M T - \theta)^{1/2}$; $\theta = -80$. At low temperatures, the magnetic moment μ is temperature dependent and corresponds to a tetrahedral coordination of copper(II) (Fig. 4) but at higher temperatures (>253 K), the μ-value differs from the theoretical one. Most probably the deviation observed is due to a deformation of the tetrahedral structure to a nearly square-planar one, a fact supported by the obtained EPR data, is also observed in other similar complexes [10,11] and is directly confirmed in the present work by X-ray diffraction data.

3.1.4. EPR spectra

The methanolic solution of the complex at room temperature shows an isotropic spectrum with a resolved hyperfine structure from ^{63,65}Cu and parameters $g_{iso} = 2.103$, $A_{iso} = 86$ at $H_{iso} = 3300$ G. The spectrum of the same solution at 77 K exhibits an anisotropic signal with an additional resolved SHFS from ^{14}N in the perpendicular region of the magnetic field due to the formation of Cu–N bonds. The EPR parameters ($g_{//} = 2.23$, $g_{\perp} = 2.07$, $A_{//} = 204$, $A_{\perp} = 24$, $A_N = 14$ G) are typical for Cu(II) complexes with a nearly square-planar symmetry. The EPR data for the solid state complex at ambient temperature are analogous to those for frozen solutions at 77 K as in other similar cases [10,11,13].

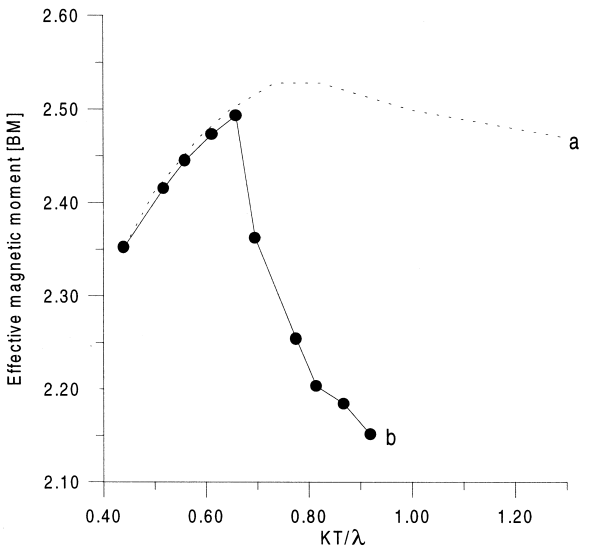

Fig. 4. Graphs μ_{eff} vs. T for the monouclear complex (a) theoretical dependence for a tetrahedral Cu(II) complex; (b) experimental data ($\theta = -80$).

3.1.5. IR spectra

The Effortil base shows absorption bands at 3450 and 3200 cm^{-1} corresponding to ν(OH) and ν(NH), a broad band in the 2600–2800 cm^{-1} range, that can be attributed to $\nu(NH_2^+)$ and a band at 1600 cm^{-1} assigned to δ(NH). In the complex the band at 3450 cm^{-1} is observed with a low intensity, as a result of OH group deprotonation in the aminoalcohol fragment and the presence of CH_3OH. The coordination of NH follows from the shift of the bands of the complex to 3180 and 1650 cm^{-1}. The absorbence in the 2600–2800 cm^{-1} range practically disappears in the complex, which is also an indication for coordination of NH. In the far IR spectrum of the complex, new bands at 475 and 370 cm^{-1} are observed, corresponding to ν(Cu–N) and ν(Cu–O) respectively [20].

3.1.6. Calorimetric and thermogravimetric data

The thermogravimetric study of the complex shows a reduction of the sample weight with about 13.20% in the temperature range 350–430 K. This fact correlates well with the expected value of 13.17% that corresponds to the elimination of two methanol molecules. It is also supported by the DSC data obtained (Fig. 5) showing an endothermic effect at about 400 K, with an enthalpy change of 13.3 cal g^{-1}. The value is higher than the expected one, probably due to another endothermic process at the same temperature interval, indications for which are observed in the DSC curve in Fig. 5.

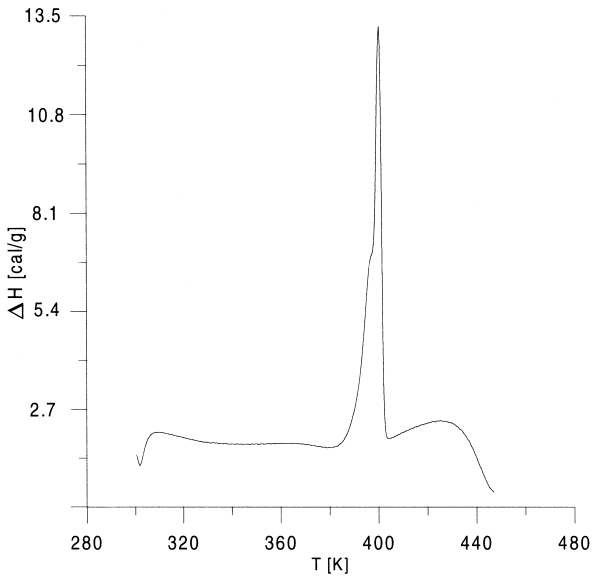

Fig. 5. DSC data for the mononuclear complex $CuEff_2{\cdot}2CH_3OH$.

3.1.7. Dissociation and stability constant

The dissociation (acidity) constant of Effortil using a free base was determined as $pK_a = 8.83 \pm 0.09$. For a molar ratio Cu–HEff = 1:2, two stability constants were calculated: $lg\beta_1[Cu(Eff)]^+ = 5.52 \pm 0.05$; $lg\beta_2[Cu(Eff)_2] = 10.55 \pm 0.04$.

Two Effortil molecules are coordinated to Cu(II), consequently forming the complexes $[Cu(Eff)]^+$ and $[Cu(Eff)_2]$.

3.2. Binuclear complex — $Cu_2Eff_2Cl_2$

3.2.1. Electronic spectra

The methanolic solution of the green complex shows absorbance at 700 nm ($\varepsilon = 96$ l mol^{-1} cm^{-1}) and 385 nm ($\varepsilon = 106$ l mol^{-1} cm^{-1}). The first band is associated with d–d transitions in Cu(II), engaged in Cu–O bonds. The second band at 385 nm is attributed to a ligand-to-metal charge-transfer when a polynuclear copper(II) complex with oxygen-bridge ligand is formed [10,11,13]. It is interesting to notice that in such binuclear complexes, with both Cu–N and Cu–O bonds there is usually no separate bond at $\lambda < 600$ nm, typical for Cu–N bond, but only one broad complex band at 600–700 nm [9–13,22].

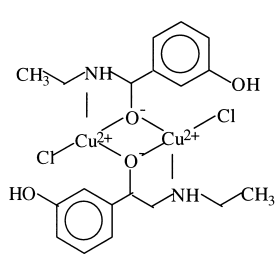
3.2.2. Magnetic data

The temperature dependence of the magnetic susceptibility (Fig. 3(b)) is typical for cases of antiferromagnetic exchange interaction between copper(II) centers (see for example [21]). In complexes of that type, the intramolecular antiferromagnetism leads first to an increase of the magnetic susceptibility to a maximum (at the Neel's temperature) and then it decreases as a result of disturbance of the exchange interaction. At high temperatures the complex exhibits a normal paramagnetic character.

These results are in accordance with the other spectral and EPR data indicating the formation of binuclear species in this case, namely the EPR signals at lower and higher fields (1350 and 5470 G, respectively) and the absorbence at 385 nm in the electronic spectra as well.

3.2.3. EPR spectra

In methanolic solution at room temperature, the complex is EPR silent. The spectrum of the same solution at 77 K shows a weak signal at 3300 G and two signals at 1350 and 5470 G. The last two signals are connected with an antiferomagnetic coupling between Cu(II) centers in bi- and polynuclear structures [22]. The spectrum of the solid phase complex shows the same signals as the frozen solution. Similar EPR spectra for Cu(II) complexes with a nearly square-planar geometry were already reported [10,13].



3.2.4. IR spectra

The absorption bands at 3450 and 3200 cm^{-1} (ν(OH) and ν(NH)) of the Effortil base are transformed into one broad band at 3400–3250 cm^{-1} in the spectrum of the complex. The band at 1600 cm^{-1} (δ(NH)) shifts to 1620 cm^{-1} in the complex and the absorbance in the 2600–2800 cm^{-1} range ($\nu(NH_2^+)$) practically disappears. The far IR spectrum of the complex shows three new bands at 538, 420 and 251 cm^{-1} assigned to ν(Cu–N), ν(Cu–O) and ν(Cu–Cl), respectively [20].

3.2.5. Calorimetric and thermogravimetric data

The calorimetric and thermogravimetric studies were provided in the 300–500 K range. The results obtained have shown that no solvent molecules are present in the structure of the solid binuclear green complex.

All data obtained for the $Cu_2Eff_2Cl_2$ complex indicate that they are similar to those for the analogous binuclear Cu(II) complexes of pindolol and oxprenolol, studied by X-ray diffraction [12,13,23]. On the grounds of all these considerations, structure **III** was suggested for the $Cu_2Eff_2Cl_2$ binuclear complex **III**.

(III)

4. Discussion

Effortil forms two types of complex, depending on the solvent and the metal-to-ligand molar ratio. At excess of the ligand, the mononuclear soluble violet complex $Cu(Eff)_2 \cdot 2CH_3OH$ was formed in alkaline methanolic solution, from which the neutral complex very slowly spontaneously precipitated.

The violet complex, however, was obtained in aqueous alkaline solution in a soluble form only, a fact indicating that most probably in such conditions it includes hydroxyl ions instead of solvent molecules and the charged complex thus formed remains in solution. The negative charge of this complex was confirmed by its sorption on anionite (Amberlite IRA-400, Merck). That was the reason for isolating the mononuclear complex in a solid phase only from methanol.

On the other hand the binuclear complex is formed at compatible amounts of the metal and the ligand (1:1–1:2) and only in alkaline methanolic media. In this case, the deprotonated oxygens of the two coordinated ligands act as bridges between the two copper atoms in the framework of the binuclear complex. Each Cu atom is bound also with NH from one ligand, thus forming a chelate ring with one Cl^- present as a terminal ligand. This configuration of the binuclear complex was already proved by us with different methods, including X-ray diffraction for Cu(II) complexes of some β-blockers with similar chemical composition and structure [23]. Unfortunately, in the present case we were unable to obtain crystals of proper size for X-ray study.

The mononuclear violet complex precipitated from methanolic solution can be transformed slowly in excess of the ligand into the green binuclear one after addition of proper amount of Cu(II) in the solution. The reciprocal process, however, is much slower and occurs only partially when excess of Heff is added to the solvent containing the green precipitate. These experiments show that the two complexes can be transformed into each other by changing the reaction conditions in an appropriate way.

5. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Centre, CCDC No. 140618. Copies of this information may be obtained free of charge from The Director, CCDC 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Stoichiometry, stability constants and structure of the complexes formed in the reaction of copper(II), nickel(II), zinc(II), cobalt(II) and cadmium(II) with $(GlyCys)_2$ containing disulfide bond were determined by potentiometric, UV–Vis, NMR and EPR spectroscopic methods. The complex $[Ni(GlyCys)_2 \cdot H_2O]$ was prepared in the solid state and its structure determined by single crystal X-ray diffraction method. Disulfide sulfur atoms of $(GlyCys)_2$ were not metal-binding sites in any of the systems studied in solution or in the solid state. It was found that copper(II) is able to induce deprotonation and coordination of the peptide amide nitrogen donor atoms. This resulted in the formation of [CuL], $[Cu_2H_{-2}L]$ and $[CuH_{-1}L]^-$ as the major species in solution. In the case of nickel(II), cobalt(II), zinc(II) and cadmium(II) the complex [ML] predominates, and the outstanding stability of this species was explained by the formation of a macrochelate between the (NH_2, CO)-coordinated five-membered chelates in solution. Crystal structure of $[Ni(GlyCys)_2 \cdot H_2O]$ revealed the octahedral geometry of nickel(II) in a polymeric structure. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Disulfide; Peptides; Transition metal ions

1. Introduction

Disulfide bonds (S–S) have an outstanding significance in the stabilisation of protein structures. As a consequence, both complex formation and redox reactions of this moiety are of much biological importance. In general the disulfide bond easily undergoes reductive cleavage giving rise to sulfur radicals, thiols, thioethers or thiolate anions. The metal ion promoted disproportionation of disulfides has already been well clarified [1], while the insertion of a metal-bond nitrogen atom into a disulfide bond has been described recently [2]. The various redox reactions of disulfide bridges are often involved in the catalytic activity of various metalloenzymes including nickel containing methyl-coenzyme M reductase [3].

There are many examples in the literature of the interactions of metal ions and organic ligands containing disulfide bonds and the most important aspects of the coordination chemistry of organodisulfide ligands have already been reviewed [4]. It is also obvious from these studies that apart from the soft metal ions the stable coordination of disulfide sulfur atoms generally takes place in aprotic solvents or in the absence of other strongly coordinating donor groups. Consequently, in the case of the simplest and biologically important disulfide ligands (cystine, oxidized glutathione and D-penicillamine disulfide) the amino, carboxylate and amide functions are the major metal binding sites for the 3d divalent metal ions, while the disulfide sulfur atoms are uncoordinated or take part in a weak interaction. The structure of the dimeric species obtained in the reaction of copper(II) and D-penicillamine disulfide has been described via the equatorial coordination of the amino acid binding sites with a

PII: S0277-5387(00)00469-1

weak axial interaction of sulfur atoms [5]. In the case of oxidised glutathione a 2:1 = Cu(II):GSSG complex was prepared with (ON_3) equatorial binding sites and weak axial interaction of both sulfur atoms [6]. Copper(II) complexes of pyridine- or imidazole-containing disulfide ligands were also characterised by the formation of Cu–S(disulfide) bonds in solution on the basis of charge transfer transition around 310–330 nm [7]. The existence of a relatively short Cu(II)–S bond length was reported in the complexes of dithiodipropanoate [8] and synthetic macrocyclic bis(disulfide) tetramine ligands, while other examples of copper(II) complexes of disulfides have been reviewed by Fox et al. [9]. As concerns the other 3d transition metal ions a strong interaction of nickel(II) and sulfur atom was reported in the nickel(II) complex of a ligand containing both pyridine and disulfide donor functions [10].

In a previous study we reported the results of potentiometric and spectroscopic studies in solution on the cobalt(II), nickel(II), copper(II) and zinc(II) complexes of three disulfide ligands: D-penicillamine disulfide, oxidised glutathione and L-cysteinylglycine disulfide [11]. The amino, carboxylate and the amide functions were detected as the exclusive metal binding sites and no indication on the formation of M–S bonds was obtained. In the case of the copper(II)-oxidised glutathione system many other studies have been performed in solution, but the Cu(II)–S interaction was excluded in all cases [12–15]. The peptide hormones oxytocin and vasopressin are other examples of simple peptides containing disulfide bonds. The twenty-membered ring linked by the disulfide bridges (between Cys^1 and Cys^6 residues) provides a unique conformation of these molecules. This resulted in the increased stability of metal complexes [16–18]. The enhancement of thermodynamic stability was, however, not attributed to a significant Cu(II)–S interaction, which was only detected in the 2N complexes of oxytocin [16]. The development of a more intense charge transfer band around 380 nm in the 2N complex of the copper(II)–glipressin (GlyGlyGly-Lys^8–vasopressin) system also was explained by the formation of Cu(II)–S(disulfide) bond [18]. In contrast with the above-mentioned 3d transition metal ions the soft palladium(II) and platinum(II) interact easily with disulfides and the existence of strong Pd–S and Pt–S bonds were reported in the complexes of cystine or oxidized glutathione [19–21].

The survey of the literature data obtained for the complexes of disulfide derivatives of peptides with 3d transition element reveals that the formation of M–S bonds are generally negligible in solution. On the other hand, the results obtained for the copper(II) complexes of glipressin suggest that the formation of this bond requires a specific arrangement of donor groups in the peptide chain [18]. The role of specific amino acid sequences in the enhanced metal binding ability of peptide molecules is well known and it is probably best represented by the C-terminal His peptides, e.g. GlyHis and GlyGlyHis [22,23]. Similar increased stability of the copper(II) or nickel(II) complexes of peptides were reported with several other peptide sequences including GlyGlyCys [24], X–X–Asp [25] and to a smaller extent with the tripeptides of methionine [26]. The oxidised form of the dipeptide glycyl-L-cysteine, $(GlyCys)_2$, contains the disulfide sulfur atoms in a chelating position with the amide nitrogen. Therefore this molecule can be a promising candidate for the metal ion promoted formation of disulfide complexes. In this paper we report the results of combined potentiometric and spectroscopic studies on the copper(II), nickel(II), cobalt(II), zinc(II) and cadmium(II) complexes of $(GlyCys)_2$ in solution. The crystal structure of the nickel complex of $(GlyCys)_2$ also has been determined by single crystal X-ray diffraction method.

2. Experimental

2.1. Materials

The peptides glycyl-L-cysteine disulfide, $(GlyCys)_2$, and glycineamide were purchased from Bachem and their purity checked via potentiometric titrations. Stock solutions of the metal ions ($CoCl_2$, $NiCl_2$, $CuCl_2$, $ZnCl_2$ and $Cd(NO_3)_2$) were prepared from analytical grade reagents and their concentrations were checked gravimetrically via precipitation of oxinates.

2.2. Potentiometric studies

The pH-potentiometric titrations were performed in 5 cm^3 samples in the metal ion concentration range 2–4×10^{-3} mol dm^{-3} and with metal ion to ligand ratios between 2:1 and 1:2. The measurements were made with a Radiometer pHM64 pH-meter equipped with a Russel CWR/320/757 combined electrode and an ABU-13 automatic burette containing a carbonate free stock solution of potassium hydroxide. 40–60 titration points were recorded for all different ratios. During the titration argon was bubbled through the samples to ensure the absence of oxygen and carbon dioxide, and stirring of the solutions. All pH-potentiometric measurements were carried out at a constant ionic strength of 0.2 mol dm^{-3} KCl (KNO_3 for cadmium(II)) and at constant temperature (298 K). The pH-readings were converted to hydrogen ion concentration and the overall stability constants ($\log \beta_{pqr}$) were calculated by means of a general computational program (PSEQUAD) [27].

$$pM + qH + rL \rightleftharpoons M_pH_qL_r$$

$$\beta_{pqr} = \frac{[M_pH_qL_r]}{[M]^p[H]^q[L]^r}$$

2.3. Spectroscopic studies

UV–Vis absorption spectra of copper(II) and nickel(II) complexes were recorded on an HP 8453 diode array spectrophotometer in the concentration range of 4×10^{-3} mol dm^{-3} for copper(II) and 10^{-2} mol dm^{-3} for nickel(II). Anisotropic X-band EPR spectra of copper(II) complexes were recorded at 120 K using a Varian E-9 spectrometer in frozen solution after addition of ethylene glycol to ensure good glass formation. Proton NMR spectra of the free ligand and zinc(II) complexes ($c_L = c_{Zn} = 10^{-2}$ mol dm^{-3}) were measured in D_2O as a function of pD. The spectra were recorded on a Bruker MA 360 MHz instrument using TSP (sodium 3-trimethylsilylpropionate) as internal standard.

2.4. Crystallisation of [Ni(GlyCys)$_2$·H$_2$O] ($C_{10}H_{18}N_4NiO_7S_2$)

One equivalent of $(GlyCys)_2$ was added to a solution of $NiCl_2$ in water ($c = 0.1$ mol dm^{-3}) and the pH was adjusted to 8.50. The solution was transferred into a glass tube and methanol was layered on it. Green crystals were formed at the interface which were filtered off, washed with a mixture of cold water and methanol and dried in air.

2.5. Structure analysis and refinement

Green prism crystals ($0.3 \times 0.25 \times 0.2$ mm) of $C_{10}H_{18}N_4NiO_7S_2$, $M = 429.11$, trigonal, $a = 12.988(4)$, $b = 12.988(6)$, $c = 20.665(7)$ Å, $V = 3019$ Å^3, $Z = 6$, space group: $P3_121$, $\rho_{calc} = 1.416$ g cm^{-3}. Data were collected at 293(1) K, Enraf Nonius MACH3 diffractometer, Mo Kα radiation $\lambda = 0.71073$ Å, ω-2θ motion, $\theta_{max} = 25.5°$, 2017 measured, 2017 unique reflections of which 1519 were with $I > 2\sigma(I)$, decay: 1%. The structure was solved using the SIR-92 software [28] and refined on F^2 using SHELX-97 [29] program, publication material was prepared with the WINGX-97 suite [30]. $R(F) = 0{,}0853$ and $wR(F^2) = 0.246$ for 2017 reflections, 220 parameters. The maximum and minimum residual electron densities are 1.057 and -0.607 e Å^{-3}, respectively.

3. Results and discussion

Stability constants of the proton and metal ion complexes of $(GlyCys)_2$ were determined by pH-potentiometric titrations of the samples containing the metal ion and ligands at different ratios. The stability constants of the complexes and the corresponding pK values are included in Table 1.

The lowest pK values (around 2–3) correspond to the deprotonation of the carboxylic groups, while the other two deprotonation processes in the pH range 7–9 results from the ammonium groups. The potentiometric titration curves provide an unambiguous proof that extra deprotonation processes occur only in the copper(II) containing systems. In the copper(II)–$(GlyCys)_2$ = 2:1 system two equivalents of base are titrated in addition to the carboxylic and ammonium groups suggesting that copper(II) is able to induce deprotonation and coordination of amide nitrogen donor atoms. In the case of cobalt(II), nickel(II), zinc(II) and cadmium(II) the parent mono and bis complexes can form and the coordination of the amide groups can be ruled out below pH 10. On the other hand, stable pH values cannot be determined in more alkaline solutions, because all metal ions are able to induce disproportionation of disulfide bonds in alkaline solutions as was reported for oxidised glutathione [1]. As a consequence, only the experimental points below pH 10 were used for calculation of stability constants of metal complexes.

Table 1
pK values and stability constants ($\log \beta_{pqr}$) of the metal complexes of $(GlyCys)_2$[a]

		Cu(II)	Ni(II)	Co(II)	Zn(II)	Cd(II)
pK_1	2.06(4)					
pK_2	3.21(2)					
pK_3	7.75(2)					
pK_4	8.77(2)					
$[MHL]^+$		14.55(4)	12.85(3)	12.01(5)	12.55(9)	11.70(20)
[ML]		10.35(3)	7.41(2)	5.51(1)	6.69(2)	5.40(3)

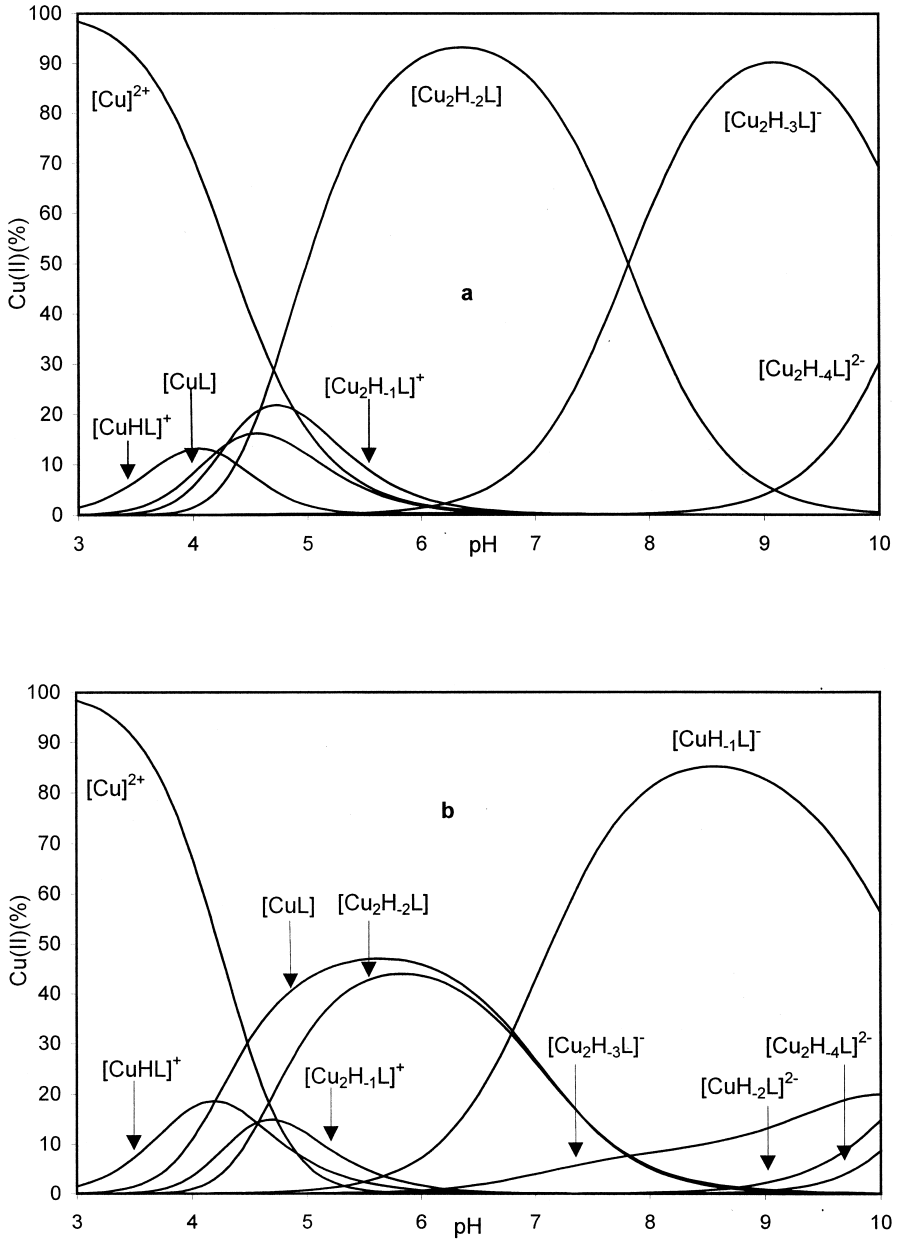

Fig. 1. Concentration distribution of the complexes formed in the copper(II)–$(GlyCys)_2$ system. (a) $c_{Cu} = 8 \times 10^{-3}$ mol dm^{-3}, $c_L = 4 \times 10^{-3}$ mol dm^{-3}; and (b) $c_{Cu} = c_L = 4 \times 10^{-3}$ mol dm^{-3}.

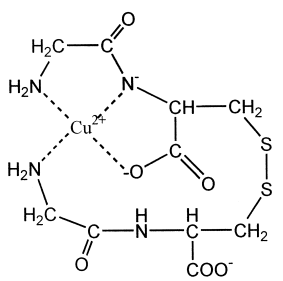
In agreement with the conclusions drawn from the titration curves, Table 1 shows a significant difference in the complex formation processes of copper(II) and the other metal ions. Namely, in the case of copper both mono- and dinuclear species can form, while the other systems are characterised by the formation of [ML] as the major species. Concentration distributions of the various complexes formed in the copper(II)–$(GlyCys)_2$ system at 1:1 and 2:1 ratios are shown in Fig. 1.

It can be seen from Fig. 1 that in the copper(II)–$(GlyCys)_2$ system the complex formation starts above pH 3 and the stoichiometry of the first species is $[CuHL]^+$, which can correspond to the coordination of the terminal amino and neighbouring carbonyl oxygen donor atoms in a five-membered chelate, while the amino group at the other side of the disulfide bridge remains uncoordinated and protonated. EPR spectra of equimolar solutions support this conclusion (see Table 2), because the parallel region of EPR spectra provides the parameters reminescent to those of (NH_2, CO) species of GlyGly [31].



The species [CuL] is present in the pH range 4.5–6.5 and its spectral parameters show a close similarity to those of $[CuH_{-1}L]$ of GlyGly or other common dipeptides. It supports that one dipeptide unit of the

molecule is coordinated as the common dipeptides, (NH_2, N^-, COO^-), while the other side is still free with protonated amino group. The visible spectra of equimolar solutions do support this conclusion, because $\lambda_{max} = 635$ and 640 nm and $\varepsilon = 74$ and 84 $dm^3\ mol^{-1}\ cm^{-1}$ can be obtained for the [CuL] of $(GlyCys)_2$ and $[CuH_{-1}L]$ of GlyGly, respectively [31]. Further increase of pH results in a blue shift of absorption spectra ($\lambda_{max} = 612$ nm and $\varepsilon = 80$ $dm^3\ mol^{-1}\ cm^{-1}$) and it is accompanied with a characteristic change of EPR parameters. The most reasonable explanation for the binding sites of the species $[CuH_{-1}L]^-$ that one more nitrogen donor from the other dipeptide unit of the molecule coordinates to copper(II) as it is represented by Scheme 1.

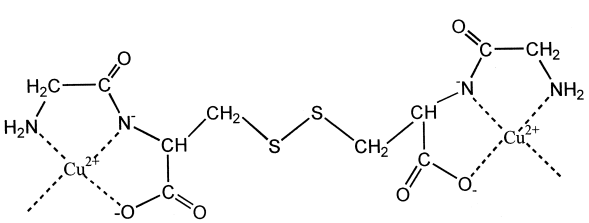


Table 2
Parameters of the parallel region of EPR spectra of the complexes formed in copper(II)–$(GlyCys)_2$ and copper(II)–GlyGly systems[a]

Species	Coordination	$g_{\|}$	$10^{-4}A_{\|}/cm^{-1}$
Cu(II)–$(GlyCys)_2$			
$[CuHL]^+$	(NH_2, CO)	2.330	153
[CuL]	(NH_2, N^-, COO^-)	2.236	193
$[CuH_{-1}L]^-$	(NH_2, N^-, COO^-) + (NH_2, CO)	2.215	171
Cu(II)–GlyGly [b]			
$[CuL]^+$	(NH_2, CO)	2.332	161
$[CuH_{-1}L]$	(NH_2, N^-, COO^-)	2.248	185
$[CuH_{-1}L_2]^-$	(NH_2, N^-, COO^-) + (NH_2, CO)	2.232	168

[a] For the $[CuH_{-1}LB]^-$ complex of GlyGly and *N*-acetyllysine $g_{\|} = 2.226$ and $A_{\|} = 168 \times 10^{-4}$ cm^{-1} were measured.
[b] Data are taken from Ref. [31]

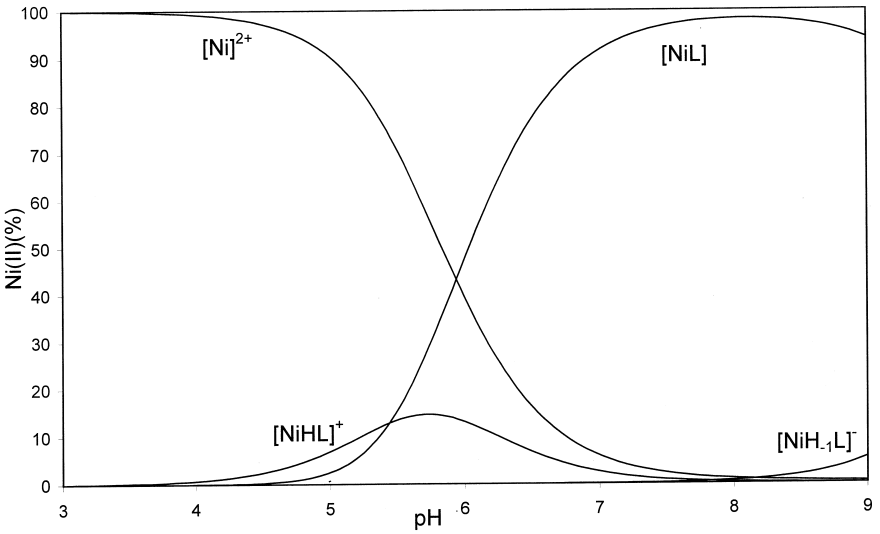
Scheme 1.

Scheme 2.

The binding mode in Scheme 1 is similar to that of GlyGly in $[CuH_{-1}L_2]^-$, but in the case of GlyGly the second ligand coordinates via the amino-N and carbonyl-O donor atoms in an equatorial-axial equilibrium. The mixed complex $[CuH_{-1}LB]^-$ provides a good model for the structure of $[CuH_{-1}L]^-$ of $(GlyCys)_2$. In the ternary species B represents *N*-acetyllysine, which is a monodentate amino donor via the ε-amino group and the spectral parameters $A_{\|} = 168 \times 10^{-4}$ cm^{-1}, $g_{\|} = 2.226$ and $\lambda_{max} = 612$ nm, $\varepsilon = 96$ $dm^3\ mol^{-1}\ cm^{-1}$ were reported for the mixed ligand complex [32]. The spectral data for the species $[CuH_{-1}L]^-$ of $(GlyCys)_2$ are slightly different from those of the complexes described above. However, the spectral trend observed on passing from (NH_2, N^-, COO^-) to (NH_2, N^-, COO^-) + (NH_2, CO) coordination, namely the simultaneous decrease of both $A_{\|}$ and $g_{\|}$, is the same in all the three systems. This trend is unusual for a regular geometry and indicates the achievement of a distorted structure even if further data are needed for a complete understanding of the details of structural changes. In any case, it means that in the species $[CuH_{-1}L]^-$ the two dipeptide residues linked by the disulfide bridge are not identical, being tridentately coordinated from one end and monodentately from the other one. This binding mode, of course, should result in some enhancement of the thermodynamic stability of the complexes and suppresses the hydroxo complex formation. It is reflected in the increase of p*K* for the formation of the hydroxo complexes $[CuH_{-2}L]^{2-}$, because the values 9.37 and 10.58 can be obtained for GlyGly and $(GlyCys)_2$, respectively.

The potentiometric titration curves indicate that in the copper(II)–$(GlyCys)_2$ system two additional equivalents of base can be titrated in the presence of excess of metal ion. In principle, the extra base consumption can correspond to both deprotonation of the second amide nitrogen or only hydrolytic processes. The spectral changes during titration definitely support the amide coordination above pH 5 and it results in dinuclear complex formation as it is shown by Fig. 1. A comparison of Fig. 1(a, b) reveals that the dimeric species are also present in equimolar solution but their concentration will predominate only in the presence of metal ion excess. The absorption maximum of the complex $[Cu_2H_{-2}L]$ appears at $\lambda_{max} = 639$ nm, which corresponds to the assumption that both copper(II) is coordinated in the (NH_2, N^-, COO^-) environment as it is depicted by Scheme 2. The dimeric complex $[Cu_2H_{-2}L]$ has two free coordination sites, which are occupied by water molecules or hydroxide ions in slightly basic media (see Fig. 1).

EPR spectra of the samples containing metal ion excess are poorly resolved, but the signals of free copper(II) ions disappear by pH 6 and the significant line



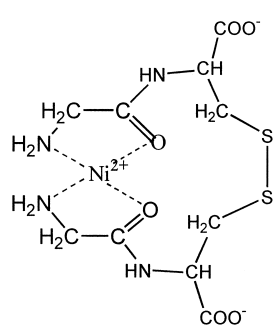


Fig. 2. Concentration distribution of the complexes formed in the nickel(II)–$(GlyCys)_2$ system. $c_{Ni} = c_L = 4 \times 10^{-3}$ mol dm^{-3}.

broadening can be explained by the dipolar coupling between the copper(II) units of the species $[Cu_2H_{-2}L]$.

Another question which arises in connection with the structural characterisation of the copper(II) complexes of $(GlyCys)_2$ is whether the disulfide moiety took part in any interaction with the metal ion. The absence of any characteristic charge transfer band below 400 nm and the clear evidence for the existence of the (NH_2, N^-, COO^-) binding site seem to rule out the involvement of sulfur atom in metal binding in solution. In part this is in contradiction with our expectations, but can be explained by the more effective coordination of the charged carboxylate residue. On the other hand, it should be emphasized that this result was obtained in solution and a weak metal ion interaction with the disulfide bond is still a possibility in the solid state as it was found for the copper(II) complex of D-penicillamine disulfide [5,11].

The pH-potentiometric titration curves of nickel(II)–$(GlyCys)_2$ system at different metal ion to ligand ratios show that there is no any extra base consuming process below pH 9. This is clear evidence that the amide nitrogen is not a metal binding site and the 1:1 complex should have an outstanding thermodynamic stability as compared to that of the bis complex. Equilibrium data in Table 1 reveal that the formation of only three species $[NiHL]^+$, [NiL] and $[NiH_{-1}L]^-$ can be detected in this system. The corresponding species distribution curves are shown by Fig. 2 and it can be seen that $[NiHL]^+$ and $[NiH_{-1}L]^-$ are only minor species and the interaction of nickel(II) and $(GlyCys)_2$ can be described almost exclusively by the formation of the species [NiL]. A reasonable explanation for the outstanding thermodynamic stability of the species [NiL] and for the lack of bis(ligand) complex formation can be given by the assumption of the binding mode shown by Scheme 3. The enhanced thermodynamic stability of the complex [NiL] probably stems from the formation of 16-membered loop around the central metal ion. This loop is a consequence of the presence of the disulfide bond in the molecule supporting that this residue affects the thermodynamic stability of the complexes via the change of the conformation of the molecules without the formation of a direct Ni–S bond. The increased nickel binding ability of $(GlyCys)_2$ as compared to that amino acid amides is reflected in the corresponding stability constants, too. Namely, $\log \beta_1 = 7.41$ was obtained for [NiL] of $(GlyCys)_2$, while $\log \beta_2 = 4.93$ was reported for $[NiL_2]^{2+}$ of valineamide [33]. The formation of a similar loop or macrochelate and extra stabilization of the complex was reported in the copper(II)-oxidised glutathione system [11].

According to Scheme 3 the species [NiL] has the same binding sites as that of $[NiL_2]^{2+}$ of glycineamide [33,34]. The absorption spectra of the complexes show the presence of octahedral central metal ions in both species and in the visible range the spectral parameters $\lambda_1 = 373$ and 373 nm and $\lambda_2 = 620$ and 621 nm were measured for [NiL] of $(GlyCys)_2$ and $[NiL_2]^{2+}$ of

Scheme 3.

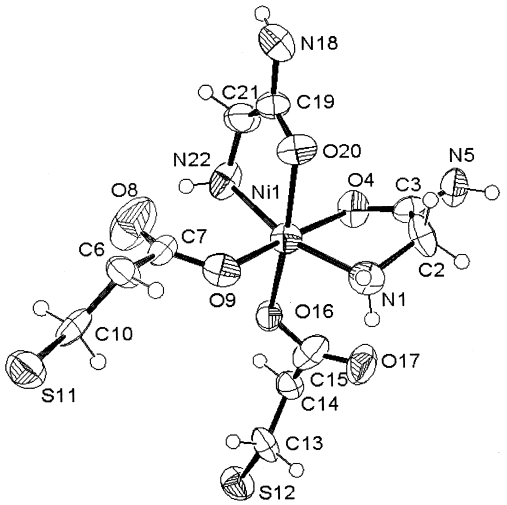

Fig. 3. ORTEP view and numbering scheme of $[Ni(GlyCys)_2 \cdot H_2O]$ (50% probability displacement ellipsoids).

glycineamide, respectively. These parameters show a very close similarity in the binding sites, but on the other hand there is a big difference in the complex formation processes of $(GlyCys)_2$ and glycineamide. Namely, in the nickel(II)–glycineamide system the species $[NiL_2]^{2+}$ is present only in a narrow pH range (around pH 8) and by pH 9 it is followed by the complete formation of the square planar and diamagnetic $[NiH_{-2}L_{-2}]$ complex with the cooperative deprotonation of two amide nitrogens. This reaction and the formation of square planar complexes, however, can not be detected at any pH or metal ion to ligand ratios in the nickel(II)–$(GlyCys)_2$ system. It supports that the binding mode presented by Scheme 3 prevents deprotonation and coordination of the amide groups and also prevents the interaction with the disulfide bond.

The exclusive formation of the species [NiL] in the pH range of 6–9 and its structural peculiarity stimulated us to prepare the complex in the solid state. The compound was obtained with the stoichiometric composition of $C_{10}H_{18}N_4NiO_7S_2$ ($[Ni(GlyCys)_2 \cdot H_2O]$) and X-ray quality crystals were grown from a mixture of methanol and water. The crystal structure of the complex $[Ni(GlyCys)_2 \cdot H_2O]$ shows octahedral nickel(II) ions (Fig. 3), but in contrast with Scheme 3 in a coordinatively saturated environment. Four coordination sites of the octahedron are occupied by two amino-N and two carbonyl-O donor atoms, while the remaining two co-ordination sites are occupied by the carboxylate residues. Thus all coordination sites of the metal ions and all possible donor functions of the ligands take part in binding in the solid state. The other difference between the structures obtained in solution and in the solid state is that the $(NH_2, CO)_2$ coordination environment exists in a polymeric network in the solid state and that the two five-membered chelate rings come from two different ligands. Selected examples of bond lengths and angles are collected in Table 3.

It can be seen from Fig. 3 and also from Table 3 that coordination geometry of the central Ni(II) ion corresponds to a slightly distorted octahedron. The bond lengths of the three different types of metal–ligand bond (Ni–N(amino), Ni–O(carbonyl) and Ni–O-(carboxylate)) are quite close to each other being in the range 2.070–2.111 Å. There are more significant differences in the bond angles. The smallest values are obtained for the chelating sites N(22)–Ni(1)–O(20) and N(1)–Ni(1)–O(4) are 78.2 and 80.7°, respectively. The monodentate carboxylate donor functions are more separated, but they are in *cis* arrangement, while the two nitrogen donors occupy *trans* positions. The Ni(II)–S distance ranges from 5.864 to 6.603 Å, supporting that the disulfide donors are not involved in metal binding in the solid state either. The complex crystallizes in space group of $P3_121$ with significant solvent accessible void volumes. However, only one solvent water molecule with high isotropic atomic displacement parameter for oxygen (O1w) could be located on the electron density map. The void space can be explained by the polymeric nature of the structure. N1, N5, N18, N22, O18 and O1w donors participate in

an infinite H-bond network while N1 and N22 form intramolecular H-bonds, too. For the numbering scheme see Fig. 3. There are 14 and 26 membered macrocycles in the structure formed by the sigma bond network of ligands coordinated to Ni(II). Fig. 4 is another view of the complex showing that one ligand is coordinated to four independent metal ions providing a polymeric network, in which all coordination sites of the metal ions and all donor groups of the ligands (except disulfide sulfur atoms) are involved in coordinative bonds.

The results obtained for the structure of [NiL] in the solid state seem to be in contradiction with those suggested in solution. However, it should be considered that the structure presented in Scheme 3 was suggested for rather diluted solutions, where the existence of coordinatively unsaturated metal ions is quite common. Steric requirements rule out the binding of free carboxylate residues to the same metal ion in the monomeric complex, but they can act as additional binding sites for another [NiL] unit in more concentrated solutions. As a consequence, the coordinatively unsaturated loop structure will be destroyed during crystallisation, but the major metal binding sites (NH_2, $CO)_2$ will remain the same.

The complex formation processes of cobalt(II), zinc(II) and cadmium(II) with $(GlyCys)_2$ are rather similar to those of nickel(II). Namely, the species [ML] predominates in all cases and it should have the same binding sites as reported for the nickel(II) complexes. The corresponding stability constants are, however, smaller than those of nickel(II). This results in two major differences between nickel(II) and the other metal ions. On the one hand, the lower thermodynamic stability of the complexes is not able to prevent metal ion hydrolysis and results in precipitation in slightly basic media. On the other hand, there is an increased tendency for the formation of bis(ligand) complexes. This is especially true for cobalt(II) and cadmium(II), but the ratio of stepwise stability constants is rather high even with these metal ions ($\log(K_1/K_2) = 2.15$ and 2.40 for cobalt(II) and cadmium(II), respectively) supporting the fact that [ML] is the major species with all metal ions. Proton NMR spectra of the ligand and zinc(II) containing systems provided further evidence for the existence of [ZnL] as major species in zinc(II)–$(GlyCys)_2$ system. Protons of CH_2(Gly) moieties are detected as a singlet both in the free ligand and in the zinc(II) complex, but the chemical shift of their protons is a function of pD and the extent of complexation. The NMR peaks were obtained as follows: 3.892 and 3.893 ppm (pD 3.90), 3.871 and 3.674 ppm (pD 6.50), 3.783 and 3.659 ppm (pD 7.40), 3.639 and 3.643 ppm (pD 8.05) for the free ligand and Zn(II): $(GlyCys)_2 = 1{:}1$ solutions, respectively. These data clearly indicate that there is no complex formation below pH ~ 4 while the very small changes of CH_2 peaks in the zinc(II) containing systems between pD 6.50 and 8.05 suggest the existence of one major species in agreement with the complexation with nickel(II) shown by Fig. 2. None of the above mentioned results provided evidence for the existence of M–S bond in complexes. In some sense it contradicts with our previous expectations based upon the location of disulfide bond in the amino acid sequence of the peptide. After the coordination of the first two nitrogen donors (amino and amide) both carboxylate-O and disulfide-S atoms are in favourable position for metal ion coordination. The preference of (NH_2, N^-, COO^-)-binding to that of (NH_2, N^-, S) probably comes from the charge neutralization and from the higher flexibility of the small carboxylate function. On the other hand, these results indicate that sulfur atoms of disulfide bonds are even weaker donors towards 3d transition metal ions than the thioether sulfur atoms [26].

To summarize the results obtained for the metal complexes of the disulfide bridged peptide molecule $(GlyCys)_2$ it can be concluded that in the case of 3d transition elements including copper(II), nickel(II), cobalt(II) and zinc(II) the stable coordination of nitrogen and oxygen donors in chelates rules out the formation of M–S bonds both in solution and, at least in the case of nickel(II), in the solid state. The complex formation processes of $(GlyCys)_2$ are, however, significantly different from those of simple di- or tetrapeptides (e.g. from diglycine or tetraglycine), which is caused by the presence of the disulfide bonds. In the case of copper(II) it results in the enhanced stability of the species with (N_3O) donor sites, $[CuH_{-1}L]^-$, in equimolar solution and in the formation of dinuclear complexes in the presence of excess of copper(II). As concerns the other 3d transition metal ions the stable coordination of the amino and carbonyl functions prevent amide and disulfide coordination and this results in the formation of a sixteen-membered loop around the central metal ion (see Scheme 3 for nickel(II)). The complexes of cadmium(II) are very similar to those of

zinc(II) or especially cobalt(II) and the sulfur coordination was ruled out with this metal ion, too. Cadmium(II) generally prefers the coordination of sulfur donor atoms [35], but in this case the binding in a stable chelate should be accompanied by the formation of Cd(II)–N(amide) bond, which has not yet been reported in peptides.

4. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 143861. Copies of this may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

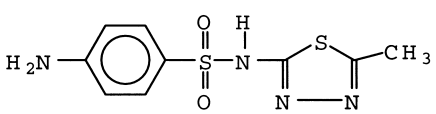
Abstract



The synthesis and characterisation of copper, cobalt, nickel and zinc compounds with sulfamethizole (4-amino-*N*-(5-methyl-1,3,4-thiadiazole-2-yl)sulfanilamide) (Hsmtz) are described. The first crystal structures of ternary sulfamethizole complexes are reported. The crystal structures of $Cu(smtz)_2(py)_2(OH_2)\cdot H_2O$ (**1**), $M(smtz)_2(py)_2(OH_2)_2$ [M = Co (**2**), Ni (**3**)] and $\{Cu(smtz)_2(dmf)_2\}_\infty$ (**5**) were determined by X-ray diffraction. The Cu(II) ion exhibits a square pyramidal geometry in complex **1**, while in the other compounds the metal ion presents a distorted octahedral environment. In compounds **1**, **2** and **3** the deprotonated sulfamethizole acts as monodentate ligand coordinating through the thiadiazole N atom and in compound **5** it behaves as a bridge linking two metal cations via the thiadiazole and the amino nitrogen atoms. The IR, electronic, EPR and thermal data are consistent with the crystal structures. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Sulfamethizole; Metal complexes; Crystal structures; Spectroscopic properties

1. Introduction

Among the N-substituted sulfanilamides, sulfamethizole (4-amino-*N*-(5-methyl-1,3,4-thiadiazole-2-yl)sulfanilamide) (Hsmtz) (Scheme 1) is one of the most used antibacterial drugs. It is expended as 'thiosulfil'. Sulfamethizole is extensively used in the treatment of the urinary tract infections [1]. The mechanism of action is based on the competitive antagonism of PABA (*p*-aminobenzoic acid) and the sulfanilamide derivative. Recently, sulfamethizole has been used as capsules containing contrast medium for assessment of gastric emptying in functional dyspepsia patients [2].

The Hsmtz has several groups with donor atoms that are able to interact with metal ions. Metal complexes of Hsmtz have been reported [3], but until now no crystal structure of binary or ternary sulfamethizole metal complexes had been determined. Previously, we have undertaken an investigation on the coordination properties of the sulfathiazole [4-amino-*N*-2-thiazolylbenzenosulfonamide, Hstz], a sulfonamide closely related

Scheme 1. 4-amino-*N*-(5-methyl-1,3,4-thiadiazole-2-yl)sulfanilamide (sulfamethizole).

to sulfamethizole. We have found that it presents different coordination behaviour as a ligand, acting as: (i) monodentate through the amino group [4,5]; (ii) monodentate via the thiazole N atom [6]; (iii) bidentate bridging two metal ions through the N_{amino} and the $N_{thiazole}$ [7]; (iv) bidentate through the $N_{thiazole}$ and the $N_{sulfonamido}$ [8]; (v) bidentate to one Cu(II) through the $N_{thiazole}$ and the $N_{sulfonamido}$ and bridging to an adjacent Cu(II) through the N_{amino} [9].

The different coordination abilities of the sulfathiazole have led us to study the chelating properties of the sulfamethizole in order to compare the behaviour of both sulfanilamides. In this work we synthesise and characterise Cu, Co, Ni and Zn complexes of sulfamethizole and report the first crystal structures of sulfamethizolate complexes.

2. Experimental

2.1. Physical measurements

All reagents were of the highest grade commercially available and used without further purification. Elemental analyses (C, H, N) were done at the microanalytical laboratory of the University of Salamanca. IR spectra were recorded on a Mattson Satellite FTIR spectrometer. Samples were prepared using the KBr technique. Electronic spectra were registered on a Shidmazu UV 2101PC spectrophotometer using the diffuse reflectance technique. EPR spectra were carried out with a Brucker ER 200 D spectrometer. Magnetic susceptibility measurements at r.t. were taken with a fully automatized AZTEC DSM8 pendulum-type susceptometer. Mercury tetrakis(thyocianato)cobaltate(II) was used as a susceptibility standard. Data were corrected for diamagnetic contribution, which were estimated from Pascal's constants. Thermogravimetric analyses were made in air atmosphere using a Shimadzu TGA-50H.

2.2. Synthesis of the complexes

2.2.1. $Cu(smtz)_2(py)_2(OH_2)\cdot H_2O$ (1)

A 50 ml sample of a 1:1 aqueous pyridine solution containing 5 mmol of Hsmtz was added to an equal volume of an aqueous solution of $CuSO_4\cdot 5H_2O$ (10 mmol) containing 25% per volume of pyridine, slowly and with continuous stirring. Immediately, the mixture took on an intense blue colour. After 3 days prismatic blue crystals were obtained. They were filtered, washed and dried at vacuum. *Anal.* Calc. for $C_{28}H_{30}N_{10}O_5S_4$: C, 43.2; H, 3.8; N, 18.0; Cu, 8.2. Found: C, 42.4; H, 4.0; N, 17.7; Cu, 8.1%.

2.2.2. $M(smtz)_2(py)_2(OH_2)_2$ [M = Co (2), Ni (3), Zn (4)]

The compounds were obtained by a procedure similar to that described for the copper complex but using $CoCl_2\cdot 6H_2O$, $NiCl_2\cdot 6H_2O$ and $ZnCl_2\cdot 2H_2O$ instead of $CuSO_4\cdot 5H_2O$. The resulting solutions were orange, blue and white, respectively. They were left to stand at r.t. and after few days single crystals suitable for X-ray diffraction were obtained for the Co and Ni complexes, while a white solid was obtained for the Zn complex. *Anal.* Calc. for $C_{28}H_{32}CoN_{10}O_6S_4$: C, 42.5; H, 4.0; N, 17.7. Found: C, 42.8; H, 4.0; N, 17.6%. *Anal.* Calc. for $C_{28}H_{32}N_{10}O_6S_4$: C, 43.2; H, 3.8; N, 18.0. Found: C, 42.4; H, 4.0; N, 17.7%. *Anal.* Calc. for $C_{28}H_{32}ZnN_{10}O_6S_4$ C, 42.1; H, 4.0; N, 17.5. Found: C 42.6; H 3.9; N 17.8%.

2.2.3. $\{Cu(smtz)_2(dmf)_2\}_\infty$ (5)

Sulfamethizole (3 mmol) was added to 1 mmol of copper acetate in 30 ml of dimethylformamide. The resulting solution was left to stand at r.t. and after few days prismatic green crystals were obtained. *Anal.* Calc. for $C_{24}H_{32}CuN_{10}O_6S_4$: C, 38.5; H, 4.3; N, 18.7. Found: C, 38.9; H, 4.1; N, 18.9%.

2.3. Crystallographic data and structure determination

2.3.1. $Cu(smtz)_2(py)_2(OH_2)\cdot H_2O$ (1) and $Ni(smtz)_2(py)_2(OH_2)_2$ (3)

Diffraction measurements of the selected blue (Cu) and pale green (Ni) prismatic crystals, with approximate sizes $0.10 \times 0.20 \times 0.25$ mm (Cu) and $0.15 \times 0.25 \times 0.25$ mm (Ni), were carried out at 290 K using an Enraf–Nonius CAD-4 single-crystal diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.7107$ Å). The unit cell dimensions were determined from the angular settings of 25 reflections with $9 < \theta < 13°$ (Cu) and $8 < \theta < 14°$ (Ni). The intensity data of 6965 (Cu) and 3281 (Ni) reflections were measured in the limits $1 < \theta < 25°$ using ω–2θ scan technique, variable speed, width $(0.80 + 0.35\tan\theta)°$ in ω and maximum scan time of 60 s per reflection in the *hkl* ranges 0–18, 0–13, −23–23 (Cu) and 0–9, −12–12, −12–12 (Ni). Three reflections were measured every hour as intensity controls without significant decay. Some double measured reflections were averaged, $R_{int} = 0.025$ (Cu) and 0.007 (Ni), resulting in 6079 (Cu) and 2957 (Ni) independent reflections of which 3673 (Cu) and 2441 (Ni) were considered, observed with the $[I > 2\sigma(I)]$ criterion. Absorption correction was not applied. The structure was solved by direct methods using the program SIR92 [10]. All non-hydrogen atoms were anisotropically refined by least-squares on F_{obs} using the X-RAY76 System [11]. The hydrogen atoms, kept fixed in the refinement with a common isotropic thermal parameter, were located by difference synthesis. In the

final stages an empirical weighting scheme was chosen as to give no trends in $\langle w\Delta^2F\rangle$ versus $\langle F_o\rangle$ and versus $\langle \text{sen}\,\theta/\lambda\rangle$ using the program PESOS [12]. Geometrical calculations were made with PARST [13]. Atomic scattering factors and anomalous dispersion corrections were taken from reference [14]. All calculations were performed on a VAX6410. Graphical manipulations were produced by the ORTEP-3 for Windows program [15]. Other relevant parameters of the crystal structure determination are listed in Table 1.

2.3.2. *Co(smtz)$_2$(py)$_2$(OH$_2$)$_2$ (**2**)*

A rose-coloured prismatic crystal of $Co(smtz)_2(py)_2(H_2O)_2$ was mounted on a glass fibre and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the range of $11.00 < \theta < 18.12°$ in an Enraf–Nonius MACH3 automatic diffractometer [16]. Data were collected at 293 K using Mo Kα radiation ($\lambda = 0.71073$ Å) and the ω-scan technique, and corrected for Lorentz and polarisation effects [17]. A semi-empirical absorption correction (ψ-scans) was made [18]. The structure was solved by direct methods [19] and subsequent difference Fourier maps, and refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [20]. All hydrogen atoms were located from difference Fourier maps and were refined isotropically. Atomic scattering factors from International Tables for X-ray Crystallography [14]. Molecular graphics from PLATON-98 [21]. A summary of the crystal data, experimental details and refinement results are listed in Table 1.

2.3.3. *{Cu(smtz)$_2$(dmf)$_2$}$_\infty$ (**5**)*

A green crystal, size 0.2 × 0.2 × 0.2 mm was mounted on an Enraf–Nonius CAD-4 single-crystal diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.7173$ Å). The unit cell dimensions were determined from the angular settings of 25 reflections with $3.57 < \theta < 25.98°$. The space group was determined to be $P2_1/c$ from systematic absences. The intensity data of 3025 reflections, in the hkl range (0, 0, −14) to (11, 18, 13) and limits ($0 < \theta < 25°$) were measured using the ω–2θ scan technique and variable scan rate with a maximum scan time of 60 s per reflection. The intensity of the primary beam was checked throughout the data collection by monitoring three standard reflections every 60 min. On all reflections profile analysis was performed [22]. Lorentz-polarization corrections were applied and then the data were reduced to F_o^2 values. The structure was solved by Patterson methods using DIRDIF [23]. Isotropic least squares refinement on F^2 was made using SHELX-93[24]. During the final stages of the refinement on F^2 the positional parameters and the anisotropic thermal parameters of the non-H atoms were refined. All non-hydrogen atoms were anisotropically refined. All hydrogen atoms were geometrically placed and isotropically refined. The final conventional agreement factors were $R = 0.044$ and $wR_2 = 0.147$ for 3016 observed reflections and 236 variables. The function minimised was $\Sigma w(F_o^2 - F_c^2)/\Sigma wF_o^2]^{1/2}$, $w = 1/[\sigma 2(F_o^2 + 0.0828P)^2]$ with σF_o^2 from counting statistic and $P = (\max(F_o^2) + 2F_c^2)/3$. The final difference Fourier map showed a peak of 0.54 Å^3 very close to the C11′, the others peak no deeper than −0.39 Å^3. Atomic scattering factors were taken from International Tables for X-ray Crystallography [14]. Geometrical calculations were made with PARST [13]. Graphical manipulations were performed with EUCLID [25]. All calculations were made at the University of Valencia on the S.C.S.I.E. X-ray section VAX-computers. Other relevant parameters are collected in Table 1.

3. Results and discussion

3.1. *Crystal structures of Cu(smtz)$_2$(py)$_2$(OH$_2$)·H$_2$O (**1**), Co(smtz)$_2$(py)$_2$(OH$_2$)$_2$·(**2**) and Ni(smtz)$_2$(py)$_2$(OH$_2$)$_2$ (**3**)*

Selected bond distances and angles of the three crystal structures are shown in Table 2. Figs. 1–3 show ORTEP drawings of compounds **1**, **2** and **3**, respectively.

In compound **1** the copper atom is five co-ordinated with a geometry near to a regular square pyramidal.

Table 2

N(12)–Cu–N(112)	90.4(2)				

The equatorial plane is defined by two thiadiazole N atoms from two sulfamethizolate ligands in *trans* position and by two pyridine N atoms. The axial site is occupied by a water O atom at longer distance, 2.183(4) Å. The $Cu–N_{thiadiazole}$ bond length 2.002(4) Å, is significantly shorter than the $Cu–N_{thiadiazole}$ of the related $[Cu(Hacm)_2(tn)_2]$ compound (H_2acm = acetazolamide, tn = propylenediamine) [26]. The $Cu–N_{py}$, 2.045(5) Å ones are comparable to those found in other pyridine compounds [6]. The *cis* angles in the equatorial plane ranging from 90.6(2) to 88.4(2)° do not deviate significantly from 90°. The τ value of 0.07 [$\tau = (\alpha - \beta/60)$] indicates a small distortion from a regular square pyramidal geometry [27].

The Co(II) ion in compound **2** and the Ni(II) ion in compound **3** are six co-ordinated by two pyridine N atoms and two thiadiazole N pertaining to two sulfamethizolate ligands in the equatorial sites and two water O atoms are in the apical positions. In both complexes the $M–N_{thiadiazole}$ and the $M–N_{py}$ are markedly longer than the $M–O_w$ distance. So, the geometry of the complexes can be described as compressed distorted octahedral. As expected from the ionic radii of the divalent metal ions the $Co–N_{thiadiazole}$, 2.2110(18) Å and the $Co–N_{py}$, 2.157(2) Å are longer than the $Ni–N_{thiadiazole}$, 2.163(2) Å and the $Ni–N_{py}$, 2.100(3) Å. However, the corresponding $M–O_w$ are practically the same [$Co–O_w$, 2.0457(18) Å and $Ni–O_w$, 2.040(2) Å]. The $Ni–N_{thiadiazole}$ bond is slightly longer than the same distance in the $[Ni(Hacm)_2(NH_3)_4]$ complex [28]. The $M–N_{py}$ are similar to those of the $M(macm)_2(py)_2(OH_2)_2$ (M = Co, Ni; macm = methazolamidate) [29]. Angles around the metal do not differ significantly from those of a regular octahedron.

Several interesting aspects can be deduced from a comparison of bond distances of the **2** and **3** complexes with those of the compound **1**. The equatorial Cu–N lengths are significantly shorter than the Co–N and the Ni–N ones. In particular, the $M–N_{thiadiazole}$ is the short-

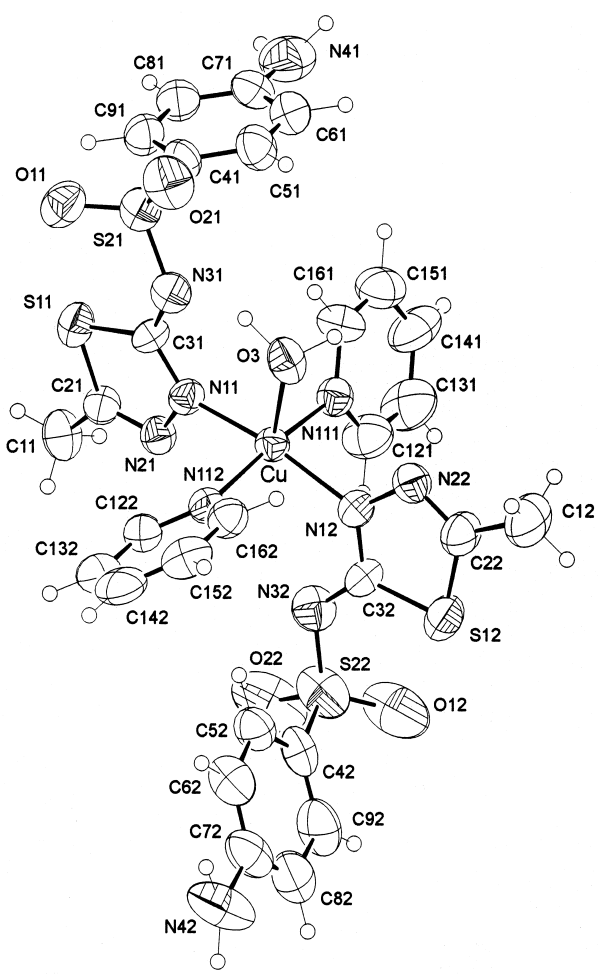

Fig. 1. ORTEP drawing of $Cu(smtz)_2(py)_2(OH_2)\cdot H_2O$ (**1**).

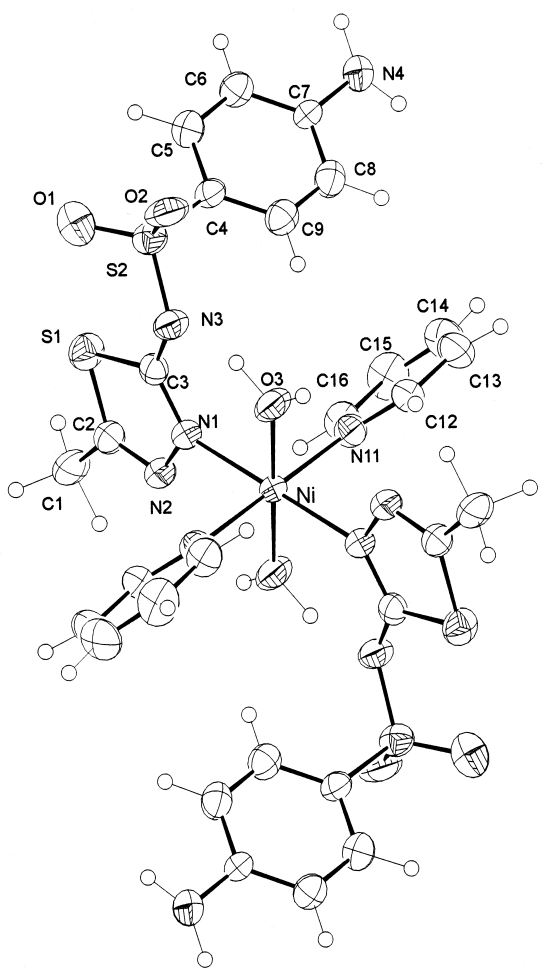

Fig. 3. ORTEP drawing of $Ni(smtz)_2(py)_2(OH_2)_2$ (**3**).

est bond distance in the copper complex, whereas it is the longest one in the nickel and cobalt compounds.

It must be noted that the sulfamethizole ligand acts as monodentate coordinating through the thiadiazole N atom closest to the deprotonated sulfonamido group although it presents several donor atoms and therefore it offers different coordination possibilities. The same coordination behaviour has been exhibited by the related acetazolamide in the octahedral $[Cu(Hacm)_2(tn)_2]$ and $[Ni(Hacm)_2(NH_3)_4]$ complexes [26,28] and by the sulfathiazole in the $[Cu(stz)(py)_3Cl]$ and $[Cu(stz)_2(mim)_2]\cdot H_2O$ compounds [6,9].

3.2. Crystal structure of $\{Cu(smtz)_2(dmf)_2\}_\infty$ (5)

A drawing of the complex is presented in Fig. 4. Selected bond and angles of the coordination polyhedron are listed in Table 3.

The structure is a coordination polymer in which each Cu(II) ion presents an octahedral geometry. The equatorial plane is defined by two $N_{thiadiazole}$ atoms *trans* one another and two N_{amino} atoms from four sulfamethizolate ligands. Two O atoms of two disordered dimethylformamide molecules are placed in the apical positions at the distance of 2.391(4) Å. Each cupric ion is connected with the other Cu ions by four sulfamethizolate anions acting as bridges via the $N_{thiadiazole}$ and N_{amino} atoms.

The four in-plane Cu–N bond distances [Cu–$N_{thiadiazole}$, 2.083(4); Cu–N_{amino}, 2.056(4) Å] are similar. The Cu–$N_{thiadiazole}$ is longer than this distance in compound **1**. Regarding to the Cu–N_{amino} length it is in the range found for the corresponding distances in Cu complexes of the sulfathiazole ligand [from 2.020 to 2.071 Å] [4]. The Cu–O_{dmf} bond lengths can be regarded as normal [30].

The largest deviation from a regular octahedral geometry is found in the axial angles involving the amino N atoms [94.8(2) and 85.2(2)°].

The sulfamethizolate anion behaves as a bridging ligand through the $N_{thiadiazole}$ and N_{amino} atoms. This coordination behaviour is different to that exhibit by the ligand in the complexes described above, although is similar to that observed for the sulfathiazole in the $[Zn(stz)_2]\cdot H_2O$ complex [7].

A comparison of the four crystal structures described in this paper shows that no remarks can be noted as far as the sulfamethizole bond distances are concerned. From a different coordination behaviour of the sulfamethizole in compound **5** with respect to complexes **1**, **2** and **3**, only a slight difference can be observed in the N(4)–C(7) bond lengths [1.424(6) compound **5**, 1.382(9) compound **1**, 1.398(3) complex **2** and 1.402(5) Å complex **3**]. Moreover, the different strength binding of the $N_{thiadiazole}$ does not modify significantly the N–N distance [1.390(5) compound **5**, 1.376(9) compound **1**, 1.387(3) complex **2** and 1.386(3) Å complex **3**]. This fact could be related to the charge delocalization through the thiadiazole ring as a consequence of the deprotonation of the sulfonamide group.

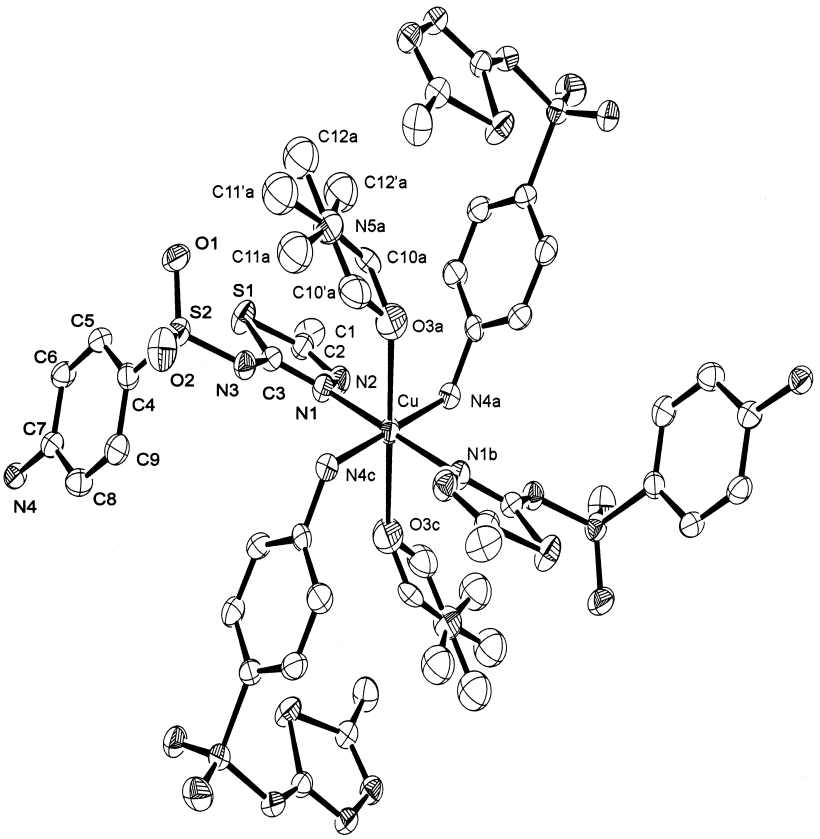

Fig. 4. ORTEP drawing of $\{Cu(smtz)_2(dmf)_2\}_\infty$ (**5**).

3.3. IR spectra

A comparative study of the IR spectra of the complexes with that of the free ligand and those of the complexes of related ligands gives some positive information regarding the binding sites of the sulfamethizole. All the complexes show very similar spectral pattern. The strong bands at 3440, 3360 and 3250 cm^{-1} in the IR of the ligand attributed to $\nu_{as}(NH_2)$, $\nu_s(NH_2)$ and $\nu(NH)$ of the amino group appear at the same range in the IR spectra of complexes **1**, **2**, **3** and **4**. However, these bands are modified in the IR spectrum of the compound **5** as a consequence of the interaction of the amino group with the copper(II) ion.

With respect to the 1,3,4-thiadiazole ring modes, because of the rigidity of the penta-atomic ring, the vibrational spectra can not be interpreted in terms of localised vibrations, being many atoms involved in several vibration modes. The strong band at 1550 cm^{-1} in the ligand is shifted to 1450–1440 cm^{-1} in the complexes. On the one hand this is due to deprotonation of the sulfonamido group that gives rise to a delocalization of the negative charge between the $N_{sulfonamidate}$ and the thiadiazole ring and on the other hand, to the interaction of the $N_{thiadiazole}$ with the metal ions.

The SO_2 group modes of the ligand appear as strong bands at 1325 (ν_{as}) and 1128 cm^{-1} (ν_s). In the complexes, the asymmetric mode is shifted to 1290–1260 cm^{-1} and the symmetric vibration gives rise a band practically unchanged with respect to that of the ligand.

Table 3
Selected bond distances (Å) and angles (°) for $\{Cu(smtz)_2(dmf)_2\}_\infty$ (**5**) [a]

Cu–O(3) # 1	2.391(4)
Cu(1)–O(3) # 2	2.391(4)
Cu–N(1)	2.083(4)
Cu(1)–N(1) # 3	2.083(4)
Cu–N(4) # 1	2.056(4)
Cu(1)–N(4) # 2	2.056(4)
O(3) # 1–Cu–O(3) # 2	180.0
N(4) # 1–Cu–N(1)	88.4(2)

N(4) # 1–Cu–N(4) # 2	180.0
N(4) # 1–Cu–O(3) # 1	94.8(2)
N(4) # 2–Cu–O(3) # 1	85.2(2)
N(1)–Cu–O(3) # 1	89.2(2)
N(1) # 1–Cu–O(3) # 1	90.8(2)
N(1)–Cu–N(1) # 3	180.0

[a] Symmetry transformations used to generate equivalent atoms # 1: $-x+2$, $y-1/2$, $-z+5/2$; # 2: x, $-y+1/2$, $z-1/2$; # 3 $-x+2$, $-y$, $-z+2$; # 4: $-x+2$, $y+1/2$, $-z+5/2$.

In spite of the coordination of one of the $N_{thiadiazole}$ to metal ions, the complexes present the same N–N bond distances so, the band located at 990 cm^{-1} assigned to a ν(N–N) mode does not change in the IR spectra of the complexes.

A shift of the ν(S–N) band is observed in the IR spectra of the complexes (940–930 cm^{-1}) with respect to that of the ligand (920 cm^{-1}). This could be attributed to deprotonation of the sulfonamido group and consequently the shortening of the S–N bond distance.

A band at 3470 cm^{-1} in the IR spectra of the compounds **1** and **4** is attributed to ν(O–H) vibration. The IR spectrum of the complex **5** shows a strong band at 1650 cm^{-1} assigned to a ν(C=O) vibration of the dmf molecules. The pyridine ring breathing band in compounds **1**, **2**, **3** and **4** is found at 1040 cm^{-1}, according to the fact that the pyridine molecules are coordinated [31].

3.4. Magnetic properties, electronic and EPR spectra

At room temperature the Cu(II) complexes have magnetic moment (2.01 BM for **1** and 1.94 BM for **5**) somewhat higher than the spin-only value. Such divergence is not uncommon in mononuclear Cu(II) complexes due to mixing-in of some angular momentum from the closely lying excited states via spin–orbit coupling [32]. The cobalt complex presents a magnetic moment (4.11 BM) slightly lower than the common values of octahedral complexes. This fact could be attributed to the distortion of the coordination polyhedra that leads to a minor orbital contribution to the magnetic moment. The magnetic moment value for the Ni(II) compound (2.90 BM), indicative of a slight orbital contribution, is in the range found for octahedral complexes.

The diffuse reflectance (DR) spectra of the $Cu(smtz)_2(py)_2(OH_2)\cdot H_2O$ (**1**) and the $\{Cu(smtz)_2(dmf)_2\}_\infty$ (**5**) with a well-defined d–d maximum at 595 (compound **1**) and 660 nm (compound **5**) agree well with the square pyramidal geometry and the octahedral geometry deduced from their crystal structures. The DR spectra of compounds **2** and **3** (with maxima at 490 and 600 nm, respectively) fit for an octahedral environment according to their crystal structures.

Intense absorption in the ultraviolet region (ca. 300 nm) is a feature common to all the complexes and it is attributed to an intra-ligand transition.

The polycrystalline powder EPR spectrum at room temperature of the compound **1** is axial in nature with a poorly resolved parallel component. The EPR spectrum of the zinc copper-doped compound is also axial anisotropy with a four-line hyperfine structure due to the interaction of the unpaired electron with the nuclear spin of the copper nucleus. The ground state parameters extracted from the experimental spectrum by simulation [33], $g_\parallel = 2.26$, $g_\perp = 2.07$ and $A_\parallel = 140 \times 10^4$ cm^{-1} are in good agreement with a square pyramidal geometry. The compound **5** shows a rhombic polycrystalline powder EPR spectrum with $g_3 = 2.20$; $g_2 = 2.13$ and $g_1 = 2.08$ values, according to the copper coordination polyhedron.

3.5. Thermal analyses of compounds *1–4*

The thermal study of the compound **1** has a first step at 120°C corresponding to the loss of two water molecules (% experimental weight 4.78; calculated weight 4.52). The second step, that take place at 180°C, corresponds to a loss of the two pyridine molecules (% experimental weight 17.94; calculated weight 19.86). There is a third step at 350°C where the two aniline groups of the sulfonamidate are lost (% experimental weight 25.62, calculated 23.38) and a fourth step where the pyrolytic decomposition takes place leaving a percentage residual weight of 12.85% that can be attributed to a mixture of CuO and $CuSO_4$.

The compound **2** is stable to 110–120°C. At this temperature range the first step of the thermal decomposition starts. This step corresponds to the loss of the two pyridine ligands (% experimental weight 19.06, calculated weight for two pyridines 19.98). Between 200–250°C a second step occurs where the weight loss corresponds to a water molecules and aniline groups of the sulfonamidate ligand (% experimental weight 34.25, calculated weight 31.62). In a third step the pyrolytic decomposition of the rest takes place, yielding a residue that it is a mixture of cobalt sulphate and cobalt oxide.

The TG curve of the compound **3** presents a first step (150°C) where the loss of the pyridine and water molecules takes place at the same time (% experimental weight 23.07. calculated weight 24.54). The second (250–500°C) and third (500–600°C) steps agree with the pyrolytic decomposition of the compound. As in the other processes the residue is a mixture of nickel sulphate and nickel oxide.

The TG curve of the compound **4** shows two separate thermal events. Until 150°C the compound does not present any loss of weight. Between 150–400°C a first step takes place with a weight loss of 52.68% that can be attributed to a loss of two pyridine, two water molecules and two aniline groups. The second step corresponds to the pyrolytic decomposition of the compound. The residue is composed of a mixture of zinc sulphate and zinc oxide.

From a comparison of the first step of the thermal process we can observe a different stability of the water molecules between the compound **1** and the rest of the complexes. The lower temperature of water loss in the compound **1** can be related with the larger Cu–OH_2 bond length observed in this compound with respect to

the other M–OH_2 bond distances (M = Co and Ni) in the compounds **2** and **3**.

4. Supplementary data

Supplementary crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 140608, 140609, 140610 and 140611. Abstract

Compounds L^1 and L^2 were obtained by reaction of 2-(bromomethyl)naphthalene with 1,4,10-trioxa-7,13-diazacyclopentadecane and 1,4,7-trioxa-10-azacyclododecane, respectively. These receptors contain aza–oxa crowns attached covalently to fluorescent groups. The protonation and coordination behaviour of L^1 and L^2 against metal ions has been studied in dioxane:water (70:30 v/v, 25°C, 0.1 M potassium nitrate) using potentiometric methods. All metal ions studied form complexes with L^1 and L^2 with the logarithm of the formation constants $L + M^{2+} = [M(L)]^{2+}$ in the sequence $Cd^{2+} \cong Pb^{2+}$, $Zn^{2+} < Hg^{2+}$ for L^1 and $Zn^{2+} < Ni^{2+} < Pb^{2+} < Cd^{2+} < Cu^{2+}$ for L^2. The fluorescent behaviour of L^1 and L^2 was studied in dioxane:water (70:30, v/v) and in acetonitrile in the presence of Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+}, Hg^{2+}, Pb^{2+} cations and chloride, bromide, sulfate and phosphate anions. The most significant feature is the quenching of the fluorescence produced by Cu^{2+} in acetonitrile. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Macrocyclic ligands; Naphthylmethyl fluorescent groups; Aza–oxa crowns

1. Introduction

The development of new chemical sensors based on the application of supramolecular concepts is an area of current interest. The fundamentals involve the functionalisation of suitable coordination sites with appropriate groups that are able to switch their state upon guest binding [1–9]. When the switching process is followed by a change in an easily observable macroscopic parameter (such as redox potential, absorption or emission sprectrum, etc.), then monitoring results in information on the presence or absence of a certain guest [10–16]. The recognition process in these molecules operates as follows: in the first step there is a guest–receptor interaction usually governed by well-known binding rules. In the second step there is a non-covalent, generally supramolecular in nature, interaction between the guest attached to the binding sites of the receptor and the signalling subunit. The latter interaction produces a macroscopically observable change in an easily to measure physical property. The nature of the signalling subunit not only determines the type of macroscopic signal but it also has a control on the selectivity. In fact, some factors can be controlled easily to obtain selectivity against a target guest: (i) the nature of the binding sites; (ii) the nature of the signalling unit, and (iii) the solvent in which the receptor–guest interaction takes place. We recently described [17] that the functionalisation of aza–oxa macrocycles with either ferrocenyl or anthracenyl subunits leads to molecules that can sense mercury selectively in an aqueous environment. With the aim of continuing those studies, we functionalised the cyclic aza crown ethers 1,4,10-trioxa-7,13-diazacyclopentadecane and 1,4,7-trioxa-10-azacyclododecane with naphthylmethyl groups and studied the fluorescent emission of the pendant signalling subunits in the presence of metal ions and anions in dioxane:water (70:30, v/v) and acetonitrile.

2. Experimental

2.1. Physical measurements

Potentiometric titrations were carried out in dioxane:water (70:30 v/v, 0.1 M potassium nitrate, 25°C) for L^1 and L^2, using a reaction vessel with a water thermostat at 25.0 ± 0.1°C under nitrogen. The titrant was added using a Crison 2031 microburete. Potentiometric measurements were carried out using a Crison 2002 pH meter and a combined glass electrode. A PC was used to control the titration system automatically. The electrode was calibrated using a known hydrogen concentration by titrating known amounts of HCl with CO_2-free KOH solution and determining the equivalent point by the Gran's method [18] which gives the standard potential $E'°$ and the ionic product of the solvent ($K'_w = [H^+][OH^-]$, $\log K = -16.20$ for dioxane:water 70:30 v/v, 0.1 M potassium nitrate, 25°C). The computer program SUPERQUAD [19] was used to calculate the protonation and stability constants. The titration curves for each system (ca. 250 experimental points corresponding to at least three titration curves; pH range investigated 2.5–10; concentration of the ligand and cations was ca. 1.2×10^{-3} M) were treated either as a single set or separate entities without significant variations in the values of the stability constants. Fluorescence measurements were made on an Edinburgh analytical instrument using L^1 and L^2 at a concentration of ca. 3.00×10^{-5} M in dioxane:water (70:30, v/v) or acetonitrile.

2.2. Synthesis of L^1 and L^2

The corresponding aza–oxa macrocycle (0.91 mmol) and 2-(bromomethyl)naphthalene (1.81 mmol for L^1 and 1.14 mmol for L^2) were refluxed in dichloromethane for 72 h in the presence of K_2CO_3. The solvent was removed, the residue dissolved in dichloromethane and then purified by column chromatography on alumina using CH_2Cl_2:CH_3OH (98:2) as eluent. A pale yellow oil was obtained.

L^1: Yield 385 mg, 85%. *Anal.* Found: C, 71.55; H, 7.84; N, 5.51. Calc. for $C_{32}H_{38}N_2O_3 \cdot 2H_2O$: C, 71.91; H, 7.86; N, 5.24%. ^{1}H NMR ($CDCl_3$): δ 2.76 (s, CH_2N, 4H), 2.80 (s, CH_2, 4H), 3.50–3.70 (m, CH_2O, 12H), 4.6 (s, CH_2–$C_{10}H_7$, 2H), 7.33 (m, $C_{10}H_7$, 4H), 7.41 (d, $C_{10}H_7$, 2H), 7.70 (d, $C_{10}H_7$, 2H). FABMS (R_{int}, %): 521 $[M + Na]^+$ (25), 499 (100), 46 (5).

L^2: Yield 269 mg, 75%. *Anal.* Found: C, 68.49; H, 7.82; N, 4.19. Calc. for $C_{19}H_{25}NO_3 \cdot H_2O$: C, 68.46; H, 8.10; N, 4.20%. ^{1}H NMR ($CDCl_3$): δ 2.75 (t, CH_2N, 4H), 2.83 (t, CH_2N, 4H), 3.5–3.7 (m, CH_2O, 12H), 4.60 (s, CH_2–$C_{10}H_7$, 2H), 7.50 (m, $C_{10}H_7$, 4H), 8.01 (d, $C_{10}H_7$, 2H), 8.60 (d, $C_{10}H_7$, 2H). FABMS (R_{int}, %): 338 $[M + Na]^+$ (90), 316 (100), 154 (10), 141 (80).

3. Results and discussion

L^1 and L^2 where synthesised by reaction of 2-(bromomethyl)naphthalene with 1,4,10-trioxa-7,13-diazacyclopentadecane and 1,4,7-trioxa-10-azacyclododecane, respectively. ^{1}H and ^{13}C NMR, mass spectra and elemental analysis are in agreement with the proposed formulation. L^1 and L^2 are aza–oxa macrocycles containing pendant fluorescent naphthylmethyl groups [20–22]. We studied the fluorescent behaviour of receptors L^3 and L^4 in dioxane:water mixtures recently. It was found that L^3 sense the presence of Hg^{2+} at basic pH selectively [23]. We also studied the electrochemical sensing behaviour of similar ligands to L^1 and L^2 but functionalised with ferrocenylmethyl groups and found that both could sense the presence of Hg^{2+} selectively and electrochemically [23]. Bearing this in mind, we synthesised and studied the coordination and emission behaviour of the L^1 and L^2 ligands which are analogous to those functionalised previously with anthracenyl or ferrocenyl but having the naphthyl group as fluorescent groups.

3.1. Coordination behaviour

The protonation and coordination behaviour of L^1 and L^2 against metal ions was studied in dioxane:water (70:30 v/v, 25°C, 0.1 M potassium nitrate) using potentiometric methods. Table 1 shows the protonation constants of L^1 and L^2. As expected, these display two and one protonation processes, respectively. Protonation constants are similar to those obtained for the analogous anthracenyl-functionalised ligands L^3 and L^4 (Scheme 1). For instance, the logarithms of the first protonation process $L + H^+ \rightleftharpoons HL^+$ for L^1 and L^2 are $\log K = 8.17$ and 7.64, whereas the logarithms for L^3 and L^4 for the same process are 8.30 and 7.80, respectively.

Table 2 shows the stability constants for the formation of the Zn^{2+}, Cd^{2+}, Pb^{2+} and Hg^{2+} complexes of L^1 in dioxane:water (70:30, v/v). All metal ions form complexes with L^1 with the logarithm of the formation

Scheme 1.

constants $L^1 + M^{2+} \rightleftharpoons [M(L^1)]^{2+}$ in the sequence $Zn^{2+} \cong Cd^{2+}$, $Pb^{2+} < Hg^{2+}$. For instance, the logarithm of the formation constant of the complex $[M(L^1)]^{2+}$ with $M = Zn^{2+}$, Cd^{2+}, Pb^{2+} is $\log K = 7.10$, 6.93, 6.91, respectively, whereas the value for the formation of the $[Hg(L^1)]^{2+}$ complex is $\log K = 12.25$. Therefore, the stability constant for the formation of the $[M(L^1)]^{2+}$ complex ($M^{2+} + L^1 \rightleftharpoons [M(L^1)]^{2+}$) is ca. 10^5 times larger for Hg^{2+} than those for Zn^{2+}, Cd^{2+} and Pb^{2+}. The presence of naphthylmethyl groups attached to the coordination sites does not modify the coordination behaviour of the aza–oxa macrocyclic cavity substantially. For instance, the logarithms of the stability constants for the formation of $[M(L)]^{2+}$ complexes (with L = 1,4,10-trioxa-7,13-diazacyclopentadecane and $M = Zn^{2+}$, Cd^{2+} and Pb^{2+} in water) have been reported to be $\log K = 5.19$, 6.46 and 5.85, respectively [24,25].

The stability constants of L^3 in dioxane:water (70:30, v/v) mixtures with several metal ions have also been determined recently. L^3 forms complexes with transition metal ions with stability constants for the formation of the $[M(L^3)]^{2+}$ species in the sequence $Zn^{2+} \cong Cd^{2+}$, $Pb^{2+} < Hg^{2+}$. The stability constant for the formation of the $[Hg(L)]^{2+}$ complex is very similar for both L^1 and L^3 receptors ($\log K = 12.25$ and 12.70, respectively). In contrast, the stability constants for the formation of the $[M(L)]^{2+}$ complexes ($M = Zn^{2+}$, Cd^{2+} and Pb^{2+}) are approximately ten times larger for the L^1 ligand than the L^3 ligand.

We also studied the solution behaviour of the ligand L^2 in dioxane:water (70:30, v/v) in the presence of the metal ions Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+}. Table 1 gives the stability constants of the complexes with L^2. L^2 forms stronger complexes with Cu^{2+} than with other metal ions studied. Fig. 1 shows the distribution diagram of the L^2–H^+–Cu^{2+} system. The constants for the formation of the $[M(L^2)]^{2+}$ complexes are in the sequence $Zn^{2+} < Ni^{2+} < Pb^{2+} < Cd^{2+} < Cu^{2+}$. The coordination behaviour of the non-functionalised receptor 1,4,7-trioxa-10-azacyclododecane was reported in methanol:water against the metal ions Zn^{2+}, Cd^{2+} and Hg^{2+} with values of the logarithms of the formation constants of the $[M(L)]^{2+}$ complexes of 3.7, < 4.5 and > 11 for Zn^{2+}, Cd^{2+} and Hg^{2+}, respectively [26]. The stability constants for the formation of the Zn^{2+} and

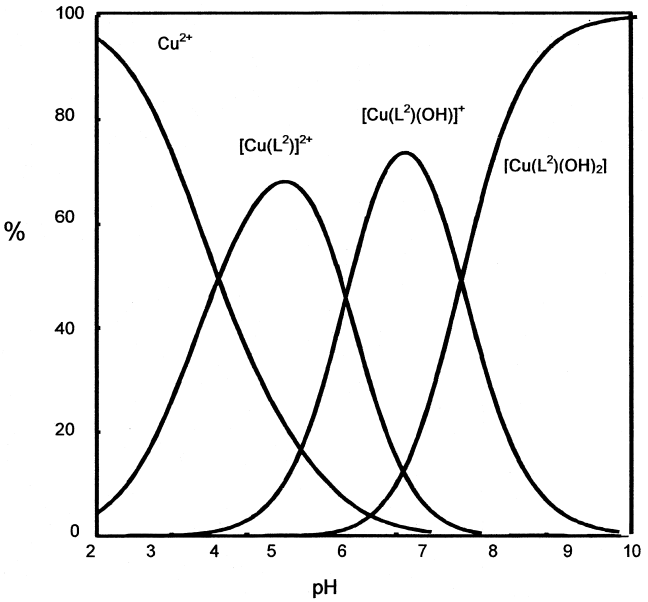

Fig. 1. Distribution diagram of the L^2–H^+–Cu^{2+} system.

Cd^{2+} complexes with the ligand 1,4,7-trioxa-10-azacyclododecane are analogous to those obtained here with L^2 (log $K = 3.96$ and 5.38, respectively, for the formation of $[Zn(L^2)]^{2+}$ and $[Cd(L^2)]^{2+}$ complexes, see Table 3). The coordination behaviour of L^4 in dioxane:water (70:30, v/v) mixtures using potentiometric methods with the Cd^{2+} and Pb^{2+} metal ions was also reported recently. Logarithms of the stability constants for the formation of the $[Cd(L^4)]^{2+}$ and $[Pb(L^4)]^{2+}$ complexes are 3.63 and 4.02, respectively.

3.2. Fluorescent behaviour

The fluorescent behaviour of L^1 and L^2 was studied in dioxane:water mixtures as a function of the pH and in the presence of the cations Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+}, Hg^{2+} or Pb^{2+}. The fluorescent response of both L^1 and L^2 is pH dependent. Disappointingly, the emission intensity as a function of the pH is not modified in the presence of any of the metal ions studied and therefore neither L^1 nor L^2 display sensing properties in this medium. This contrasts strongly with the selective sensing properties of L^3 under similar experimental conditions [17].

As was stated above, selectivity could be investigated by modifying the coordination core, using a different signalling subunit or carrying out the experiment in a different solvent. Aza crown ethers are known to coordinate transition metal ions and the naphthyl group has been used satisfactorily as a fluorescent signalling subunit [20–22]. Therefore, both L^1 and L^2 appear to be good candidates for metal signalling and, although dioxane:water mixtures did not give any conclusion of interest, a change in the solvent would probably lead to positive results. Therefore, the fluorescent behaviour of L^1 and L^2 was also studied in acetonitrile in the presence of acid and transition metal ions. Addition of one equivalent of acid to L^1 produces an enhancement of the fluorescence with $I_{acid}/I_{L^1} = 1.286$. Addition of a second equivalent gave an I_{acid}/I_{L^1} ratio of 1.693. Further addition of acid does not change the fluorescence band intensity significantly. For L^2, addition of one equivalent of acid gave only a slight enhancement of the fluorescence intensity with an I_{acid}/I_{L^2} ratio of 1.103. No further modification was observed by addition of more acid.

In the presence of transition metals both L^1 and L^2 display a similar behaviour. All metal ions produced a partial quenching of the intensity fluorescent band of L^1 at 360 nm in the order $Pb^{2+} < Cd^{2+} < Hg^{2+} < Zn^{2+} < Ni^{2+} \ll Cu^{2+}$ with $I_{complex}/I_{L^1}$ ratios of 0.793, 0.600, 0.520, 0.362, 0.187 and ca. 0, respectively. The intensity of the band at 335 nm of L^2 is reduced in the order $Hg^{2+} < Zn^{2+} < Pb^{2+} < Ni^{2+} < Cd^{2+} \ll Cu^{2+}$ with $I_{complex}/I_{L^2}$ ratios of 1.124, 1.124, 1.052, 1.052, 0.575 and ca. 0, respectively. Fig. 2 shows the fluorescent spectrum of L^2 in the presence of various metal ions. The most significant feature is the total quenching that produces the presence of Cu^{2+} selectively.

In order to compare the effect of using a different signalling subunit, the fluorescent behaviour of L^3 and L^4 was also studied in acetonitrile in the presence of acid and metal ions.

Addition of one equivalent of trifluoroacetic acid to L^3 modified the fluorescence spectrum of the free recep-

Table 3
Stability constants (log K) for the formation of Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+} complexes of L^2 in dioxane:water (70:30, v/v) at 25°C in 0.1 M KNO_3 [a]

Reaction	Cu^{2+}	Zn^{2+}	Cd^{2+}	Pb^{2+}	Ni^{2+}
$M^{2+} + L^2 \rightleftharpoons [M(L^2)]^{2+}$	5.72(2)	3.96(5)	5.38(3)	4.86(1)	4.79(3)
$M^{2+} + L^2 + H_2O \rightleftharpoons [M(L^2)(OH)]^{+} + H^{+}$	0.41(1)	−3.42(1)	−2.51(3)	−2.18(1)	−2.43(2)
$M^{2+} + L^2 + 2H_2O \rightleftharpoons [M(L^2)(OH)]_2^{+} + 2H^{+}$	−6.46(2)	−10.42(2)	−11.03(3)	−10.17(1)	−11.05(3)

[a] Values in parentheses are standard deviations on the last significant digit.

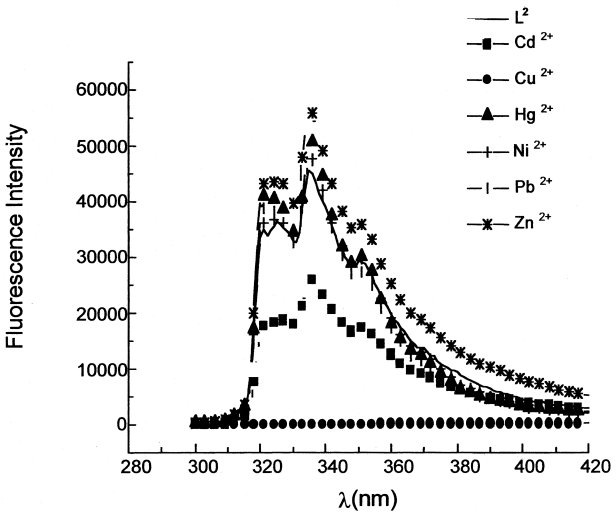

Fig. 2. Fluorescent spectra of L^2 in the presence of the metal cations Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+}, Hg^{2+} and Pb^{2+}.

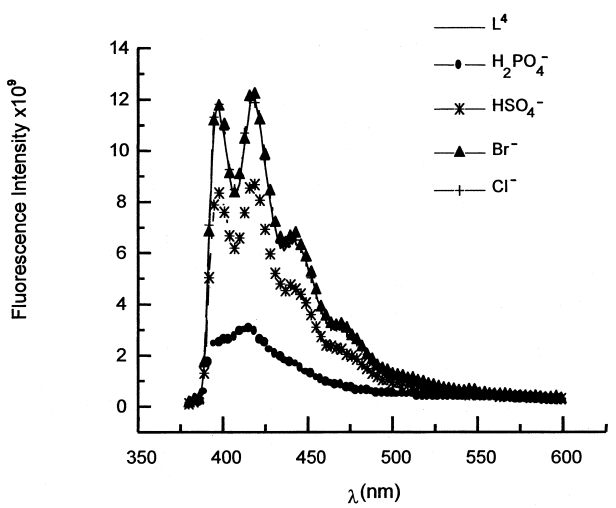

Fig. 3. Fluorescent spectra of L^4 in the presence of the anions $H_2PO_4^-$, HSO_4^-, Br^- and Cl^-.

tor significantly, with the presence of a new band centred at ca. 475 nm due probably to the formation of an exciplex. Whereas Ni^{2+} and Cu^{2+} enhances the emission intensity of the anthracenyl groups ($I_{complex}/I_{L^3} = 2.216$ and 1.859 for Ni^{2+} and Cu^{2+}, respectively), the presence of Zn^{2+}, Cd^{2+}, Hg^{2+} and Pb^{2+} gave a similar spectrum to that obtained in the presence of trifluoroacetic acid.

In the presence of one equivalent of trifluoroacetic acid, L^4 gave an enhancement of the fluorescence with an I_{acid}/I_{L^4} ratio of 3.163. In the presence of metal ions (one equivalent) the fluorescence band is very close to that found in the presence of one equivalent of acid.

The fluorescent behaviour of L^1, L^2, L^3 and L^4 was also studied in dioxane:water mixtures as a function of the pH in the presence of chloride, bromide, sulfate, phosphate and adenosine triphosphate anions. However, the emission fluorescent intensity versus pH curve is not modified in the presence of any of the anions studied. In order to complete the study, the emission properties of the ligands L^1, L^2, L^3 and L^4 were also monitored in acetonitrile in the presence of anions. The most interesting feature is that shown by the receptor L^4 whose fluorescent behaviour was studied in the presence of the tetrabutylammonium salts of Cl^-, Br^-, HSO_4^- and $H_2PO_4^-$ (see Fig. 3). Whereas the emission intensity of the fluorescent band is not modified in the presence of chloride or bromide, addition of HSO_4^- produces a slight decrease in the fluorescence intensity with $I_{complex}/I_{L^4} = 0.723$. The quenching induced by the addition of $H_2PO_4^-$ with $I_{complex}/I_{L^4} = 0.252$ is most noticeable.

Abstract

Reduction of 2-cyanopyridine by sodium in dry methanol in the presence of thiosemicarbazide produces 2-pyridineformamide thiosemicarbazone, HAm4DH. Complexes of HAm4DH with cadmium(II) chloride, bromide and iodide have been prepared and spectroscopically characterized, and crystal structures of $[Cd(HAm4DH)Cl_2]\cdot DMSO$, $[Cd(HAm4DH)Br_2]\cdot H_2O$ and $[Cd(HAm4DH)I_2]$ have been determined by X-ray diffractometry. In each of these complexes neutral HAm4DH coordinates via its pyridyl and imine nitrogens and sulfur, and the cadmium atom is pentacoordinated to the thiosemicarbazone and the two halo ligands. The coordination polyhedra of the three complexes are best described as square pyramidal, with $[Cd(HAm4DH)Br_2]$ having the greatest distortion toward a trigonal bipyramid. The hydrogens attached to nitrogens in coordinated HAm4DH form hydrogen bonds with oxygen atoms in solvent molecules and with halo ligands on adjacent molecules. © 2000 Elsevier Science Ltd. 1. Introduction

Although N(4)-substituted 2-formyl-, 2-acetyl- and 2-benzoylpyridine thiosemicarbazones [1–3] possess substantial in vitro activity against various human tumor lines [4], they are poorly soluble in water. Therefore, these thiosemicarbazones and their metal complexes are less promising when tested in vivo. In an attempt to enhance the water solubility of thiosemicarbazones and their complexes, a new series in which the thiosemicarbazone moiety is attached to an amide carbon rather than an aldehyde or ketone carbon has been prepared. Following our studies of complexes of 2-pyridineformamide *N*(4)-methylthiosemicarbazone, HAm4M [5,6], and of Group 12 metal complexes of various 2-acetylpyridine thiosemicarbazones [7–9], we recently communicated the structures of 2-pyridineformamide thiosemicarbazone (HAm4DH) (Fig. 1) and of its complexes with zinc chloride, bromide and iodide [10]. Here we present the structures of complexes of HAm4DH with cadmium chloride, bromide and iodide, and compare them to their zinc analogues and to previously studied cadmium complexes of heterocyclic thiosemicarbazones [11].

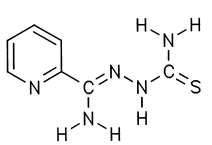

Fig. 1. 2-Pyridineformamide thiosemicarbazone, HAm4DH.

2. Experimental

Infrared spectra in KBr pellets (4000–400 cm^{-1}) and Nujol mulls (500–100 cm^{-1}) were recorded in a Bruker IFS 66V spectrometer. ^1H and ^{13}C NMR spectra were recorded in DMSO-d_6 solutions in a Bruker WM-300 spectrometer using TMS as internal reference. Elemental analysis was performed with a Carlo Erba 1108 elemental analyzer. The melting point was determined with a Büchi apparatus.

$[Cd(HAm4DH)Br_2]$	yellow	240	18.13 (17.99)	1.89 (1.94)	14.86 (14.98)	6.76 (6.86)
$[Cd(HAm4DH)I_2]$	yellow	210	15.12 (14.97)	1.57 (1.62)	12.47 (12.47)	5.48 (5.71)

The details of the preparation of HAm4DH were communicated in our earlier report on its zinc complexes [10]. The cadmium complexes were prepared as follows. A solution of $CdCl_2$, $CdBr_2$ or CdI_2 (0.002 mol) in EtOH (30 mL) was mixed with a solution of HAm4DH (0.002 mol) in the same solvent (30 mL) and the mixture was stirred under reflux for 2 h. The resulting solids were filtered out, washed with anhydrous ether to apparent dryness, and placed on a warm plate at 35°C. Yields were 97.4, 94.3 and 83.5% for $[Cd(HAm4DH)Cl_2]\cdot 0.25H_2O$, $[Cd(HAm4DH)Br_2]$ and $[Cd(HAm4DH)I_2]$, respectively. Their partial elemental analyses are listed in Table 1 with their melting points.

Crystals of $[Cd(HAm4DH)Cl_2]\cdot$DMSO were grown from a 1:1 v/v DMSO–EtOH mixture, and crystals of $[Cd(HAm4DH)Br_2]\cdot H_2O$ and $[Cd(HAm4DH)I_2]$ from 96% ethanol. The crystals were mounted on glass fibers and used for data collection in an automatic diffractometer (Enraf–Nonius MACH3 for $[Cd(HAm4DH)Cl_2]\cdot$DMSO and $[Cd(HAm4DH)I_2]$; CAD4 for $[Cd(HAm4DH)Br_2]\cdot H_2O$). Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the ranges 9.422–20.833° for $[Cd(HAm4DH)Cl_2]\cdot$DMSO, 7.921–45.065° for $[Cd(HAm4DH)Br_2]\cdot H_2O$ and 9.327–21.137° for $[Cd(HAm4DH)I_2]$. Data for $[Cd(HAm4DH)Br_2]\cdot H_2O$ were collected at 293(2) K using Cu Kα radiation ($\lambda =$ 1.54184 Å), and data for $[Cd(HAm4DH)Cl_2]\cdot$DMSO and $[Cd(HAm4DH)I_2]$ using Mo Kα radiation ($\lambda = 0.71073$ Å). The ω-scan technique were employed for the three crystals and the data were corrected for Lorentz and polarization effects [12]. A semi-empirical absorption correction was made for the three crystals [13]. The structures were solved by direct methods [14], which showed the positions of all non-hydrogen atoms, and refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [15]. The positions of most hydrogens were calculated (C–H 0.93–0.97 Å) and refined using a riding model; the exceptions were the H_2O hydrogens in the bromo complex, which were located from difference Fourier maps and refined isotropically. In $[Cd(HAm4DH)Cl_2]\cdot$DMSO a weak peak found near Cd(11) in the Fourier difference synthesis at 1.052 Å was included in the final model as a Cd(12) atom; the occupancy factors refined to 0.93(1) for Cd(11) and 0.07(1) for Cd12. Atom scattering factors were taken from the International Tables for X-ray Crystallography [16]. Molecular graphics were generated with PLATON-98 [17] for $[Cd(HAm4DH)Cl_2]\cdot$DMSO and $[Cd(HAm4DH)I_2]$, and with ZORTEP [18] for $[Cd(HAm4DH)Br_2]\cdot H_2O$.

3. Results and discussion

Crystal and structure refinement data for the three cadmium complexes are summarized in Table 2. Selected bond lengths and angles are listed in Tables 3 and 4. Perspective views of $[Cd(HAm4DH)Cl_2]\cdot$DMSO, $[Cd(HAm4DH)Br_2]\cdot H_2O$ and $[Cd(HAm4DH)I_2]$ are shown in Figs. 2–4, respectively. Hydrogen bonding parameters are compiled in Table 5, and the root-mean-square plane data in Table 6.

3.1. Structures of the $[Cd(Am4DH)X_2]$ complexes

In all three complexes HAm4DH coordinates via its pyridyl and imine nitrogens and its sulfur, and the two halo ligands bring the coordination number to five. As found previously with metal complexes of heterocyclic thiosemicarbazones [1–3], in $[Cd(HAm4DH)Cl_2]$ and $[Cd(HAm4DH)Br_2]$ the Cd–N(2) bond is shorter than the Cd–N(1) bond, by ca. 0.08 and 0.06 Å, respectively. The two Cd–X bond distances also differ, by ca. 0.06 Å in the chloro complexes and ca. 0.07 Å in the bromo compound. However, in $[Cd(HAm4DH)I_2]$ neither the two Cd–N bond lengths nor the two Cd–I distances differ significantly. Cd–N(1) is significantly shorter in the iodo complex than in the others (as also in the $[Zn(HAm4DH)X_2]$ series [10]), but the Cd–N(2) and Cd–S bond lengths are similar in all three. The average Cd–X distance increases in the expected order Cd–Cl < Cd–Br < Cd–I. Comparison of $[Cd(HAm4DH)Cl_2]$ with $[Cd(HFo4DH)Cl_2]$, where HFo4DH is 2-formylpyridine thiosemicarbazone, shows that Cd–N(2) is much shorter in the former, 2.307(6) compared to 2.350(3) Å [11], but the lengths of the other bonds are similar in the two compounds. The difference in Cd–N(2) is presumably due to the N(2) amino group of

HAm4DH having a larger inductive effect than the hydrogen in HFo4DH.

In the analogous series of zinc complexes only bond angles involving halogen atoms differed significantly [10]. The same is essentially true for the cadmium series, the greatest bond angle differences concerning X(1)–Cd–N(2) and X(2)–Cd–N(2), which respectively increase and decrease with increasing halogen size. The N(1)–Cd–S(1) angles, which reflect the two bite angles of the bichelate bonding system, average 142.6(3)°, as against 148.6(2)° for the analogous zinc complexes. These ligands may not be able to maintain N,N,S-coordination with larger metal ions: in $[Hg(HAm4DH)_2Br_2]$ only the sulfurs are coordinated [19].

In all three complexes the thiosemicarbazone bond lengths (Table 3) differ slightly from their values in HAm4DH [10]. As in the zinc series [10], the S(1)–C(7) bonds shorten with increasing halogen size, and other bonds involving C(7) are consequently altered. By contrast, C(6)–N(2) is longest in $[Cd(HAm4H)I_2]$, which suggests that coordination via the thione sulfur is weakest, and bonding via the imine nitrogen strongest, in this sterically more crowded complex. Of the six known Group 12 metal complexes of HAm4DH, $[Cd(HAm4DH)I_2]$ differs most from HAm4DH in its thiosemicarbazone bond distances: for example, the S(1)–C(7) distance is 1.671(15) Å in the complex and 1.698(2) Å in the ligand, and the C(6)–N(2) distance 1.322(16) Å in $[Cd(HAm4DH)I_2]$ and 1.293(2) Å in HAm4DH. The fact that the C–S bond is shorter in $[Cd(HAm4DH)I_2]$ than HAm4DH indicates the importance of intermolecular hydrogen bonding in the latter. Coordination also alters bond angles in the vicinity of the coordinating imine nitrogen, N(2), and the thione sulfur, S(1).

In $[Cd(HAm4DH)I_2]$, which crystallized without an accompanying solvent molecule, N(3)–H(3), N(4)–H(4A) and N(5)–H(5B) all form hydrogen bonds with I(1) of one neighboring molecule while N(4)–H(4B) hydrogen bonds to I(2) of a second neighboring molecule (Table 5). In $[Cd(HAm4DH)Cl_2]\cdot DMSO$, N(3)–H(3) and N(5)–H(5A) form hydrogen bonds with the oxygen of the DMSO molecule and N(4)–H(4A), N(4)–H(4B) and N(5)–H(5B) with Cl atoms on three different neighboring molecules. The hydrogen bonding in $[Cd(HAm4DH)Br_2]\cdot H_2O$ is similar to that of $[Cd(HAm4DH)Cl_2]\cdot DMSO$, with the water molecule supplying the oxygen instead of DMSO; additionally, the hydrogens of the water molecule interact with the bromo ligands. The crystals of these cadmium complexes thus feature dense hydrogen bond networks, which contributes to their stability and helps to promote crystal growth.

The planarity in HAm4DH of the pyridine ring and the thiosemicarbazone moiety is generally retained in the cadmium complexes; the greatest change in the thiosemicarbazone moiety occurs in $[Cd(HAm4DH)I_2]$ (Table 6). As in the zinc series [10], the angle between the best planes of the pyridine ring and the thiosemicarbazone moiety increases in the order $[Cd(HAm4DH)Cl_2] < [Cd(HAm4DH)Br_2] < [Cd(HAm4DH)I_2]$. In the chloro and iodo complexes this angle is smaller for Cd than for Zn, while the reverse holds for the bromo complexes: $[Cd(HAm4DH)Cl_2]$, 2.04(24)°; $[Zn(HAm4DH)Cl_2]$, 5.46(11)°; $[Zn(HAm4DH)Br_2]$, 6.92(16)°; $[Cd(HAm4DH)Br_2]$, 8.22(36)°; $[Cd(HAm4DH)I_2]$, 9.25(61)° and $[Zn(HAm4DH)I_2]$, 11.44(58)°.

The values of the geometrical parameter $\tau = (\beta - \alpha)/60$ [20], where $\alpha = Cl(2)–Cd–N(2)$ and $\beta = N(1)–Cd–S(1)$, show that, like the Zn complexes, all three Cd complexes are closer to ideal square pyramid with X(1) apical than to a trigonal bipyramid (Table 7). However, $[Cd(HAm4DH)Br_2]$ ($\tau = 0.39$) is closer to a trigonal bipyramid than any of the Group 12 complexes prepared with HAm4DH or any of the other Group 12 complexes listed in Table 7, which includes $[Cd(HAc4DH)Cl_2]$ [11] and six cadmium complexes of N(4)-substituted 2-acetylpyridine thiosemicarbazones [7–9].

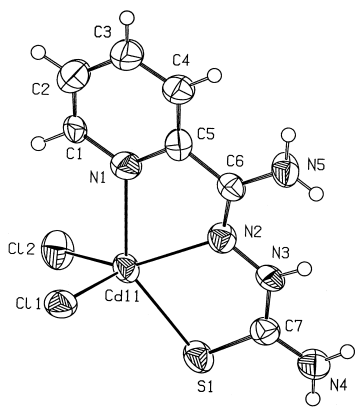

Fig. 2. Perspective view of dichloro(2-pyridineformamide thiosemicarbazone) cadmium(II), $[Cd(Am4DH)Cl_2]$, showing 50% probability ellipsoids for the nonhydrogen atoms and the numbering scheme of the atoms in the molecule.

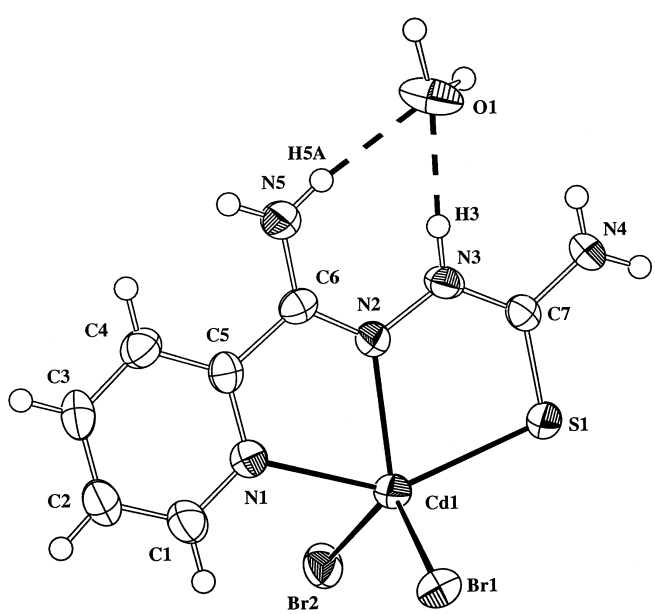

Fig. 3. Perspective view of dibromo(2-pyridineformamide thiosemicarbazone) cadmium(II) monohydrate, $[Cd(Am4DH)Br_2]\cdot H_2O$, drawn with 50% probability ellipsoids. Some of the hydrogen bonds are shown by dashed lines.

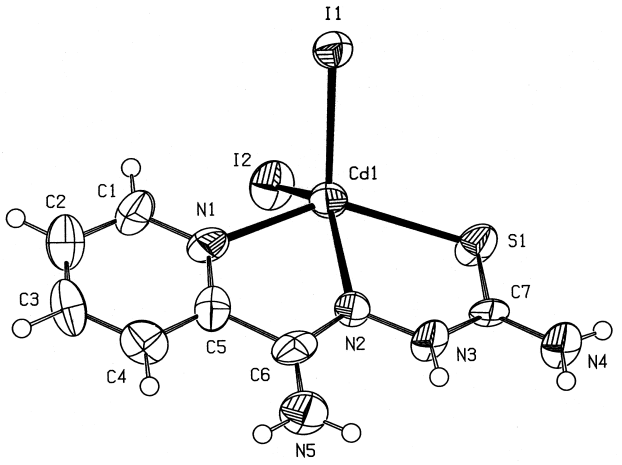

Fig. 4. Perspective view of diiodo(2-pyridineformamide thiosemicarbazone) cadmium(II), [Cd(Am4DH)I_2] with thermal ellipsoids at 50% probability. The hydrogen atoms (○) are drawn with an arbitrary radius of 0.1 Å.

3.2. Infrared spectra

The IR bands that are most useful for determining the coordination mode of the thiosemicarbazone are given in Table 8. As many as four bands can be assigned to ν(NH). The highest energy band in the spectrum of HAm4DH at 3421 cm^{-1}, is attributable to $\nu_a(N14H_2)$ on the basis of previous studies of thiosemicarbazones [11]. In the complexes there are substantial shifts to lower energy of the other three bands, which in view of the distances listed in Table 5 is probably due to the stronger hydrogen bonding interactions of coordinated HAm4DH. The fact that the ν(C=N) band at 1590 cm^{-1} in the spectrum of HAm4DH shifts to smaller wavenumbers in the spectra of the cadmium complexes indicates coordination of the imine nitrogen, as does the band in the 344–400 cm^{-1} range assigned to ν(CdN(2)) [21]. This range for ν(CdN(2)) is lower than is found for cobalt(II), nickel(II) and copper(II) complexes of related thiosemicarbazones [5,6], which is consistent with the larger size and longer bonds of cadmium. Coordination of the sulfur is indicated by a similar decrease in energy of the thioamide IV band, which derives considerable intensity from ν(CS), and by the appearance of a band in the 247–316 cm^{-1} range assignable to ν(CdS) [22,23]. Coordination of the pyridyl nitrogen shifts the out-of-plane ring deformation ρ(py) some 18–21 cm^{-1} to higher frequencies. In the 100–500 cm^{-1} region, assignation to ν(Cd–X) of two strong bands whith energies increasing in the order [Cd(HAm4DH)I_2] < [Cd(HAm4DH)Br_2] < [Cd(HAm4DH)-Cl_2] affords ν(Cd–Br)/ν(Cd–Cl) and ν(Cd–I)/ν(Cd–Cl) ratios of ca. 0.63 and 0.60, respectively (Table 8).

3.3. NMR spectra

Also included in Table 8 are ^{1}H, ^{13}C and ^{113}Cd NMR spectral assignments for HAm4DH and its cadmium complexes. As in other studies of heterocyclic thiosemicarbazones [1–3], N(13)H interacts with the solvent

and is assigned to the signal furthest downfield, and the $N(14)H_2$ protons are assigned to the two resonances in the region around 7.85 ppm, which disappear on addition of D_2O to the sample. The $N(15)H_2$ protons are assigned to the resonance at 6.91 ppm, which is similar to the chemical shift found for HAm4M, 6.86 ppm [6]. None of these signals shifts significantly upon coordination to cadmium. Of the ^{13}C NMR signals of the free ligand, the signal for the thione carbon, C(7), does not shift significantly on complexation, but the signal of the imine carbon, C(6), shifts from 142.0 to 144.6–144.8 ppm in the complexes, as has also been observed for other thiosemicarbazone complexes with Group 12 dihalides [7–9].

The ^{113}Cd NMR spectra show a single signal between 387 ppm, for $[Cd(HAm4DH)Cl_2]$, and 291 ppm, for $[Cd(HAm4DH)I_2]$. The metal atom is in each case less deshielded than in the corresponding dihalide (CdX_2) in DMSO [24]. These findings are consistent with those obtained for other complexes of cadmium(II) halides with thiosemicarbazones [6–9] and are compatible with pentacoordination of the metal [25].

4. Conclusion

These three cadmium complexes are similar in their structural and spectral properties. The results presented here form a basis for future comparison with complexes of the same ligand with other metals, and with cadmium complexes of N(4)-substituted 2-pyridineformamide thiosemicarbazones. The strong intermolecular hydrogen bonds of HAm4DH become even stronger in the cadmium complexes, particularly when a solvate molecule is present in the crystal.

5. Supplementary material

Crystallographic data for $C_{10}H_{15}CdCl_2N_5OS_2$ {$[Cd(HAm4DH)Cl_2]\cdot$DMSO, CCDC-139834}, $C_7H_{11}Br_2CdN_5OS$ {$[Cd(HAm4DH)Br_2]\cdot H_2O$, CCDC-139835} and $C_7H_9CdI_2N_5SCd$ {$[Cd(HAm4DH)I_2]$, CCDC-139836} have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC-1003/m. Received 28 February 2000; accepted 26 June 2000

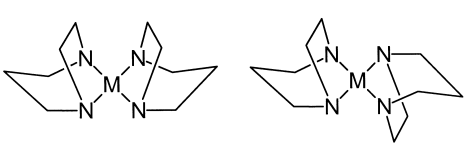
Abstract



A new complex of formula $[Cu(dach)_2(CCl_3CO_2)]CCl_3CO_2$ (dach = 1,4-diazacycloheptane) has been synthesised and its crystal structure determined by single-crystal X-ray diffraction. The crystal structure contains two independent copper(II)-centred cations (one disordered) and two trichloroacetate ions. Both copper(II) atoms are pentacoordinate. The chelated 1,4-diazacycloheptane moieties are in a double boat conformation and represent the first structurally characterised example of a *trans* configuration for two such ligands at a metal centre. The compound was also characterised by IR, electronic and EPR spectra, cyclic voltammetry, and magnetic susceptibility studies. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Copper(II); 1,4-Diazacycloheptane; Trichloroacetate; Crystal structures

1. Introduction

Acyclic diamines having a $N(CH_2)_nN$ grouping in their molecular framework have long been accepted as excellent chelating agents for transition metal ions and many results on these diamine complexes in solution and also in the solid state have been reported [1,2]. Reports on complexed cyclic diamines are, however, still scarce [1,3]. The seven-membered ring diamine 1,4-diazacycloheptane (dach) was examined as a chelating agent for nickel(II) and copper(II). Nickel(II) complexes of dach were planar, but the geometry of both tetra- and pentacoordinate complexes of copper(II) was dependent on the solvent and the anions present [4]. Comparing the formation constants of acyclic diamine complexes of Ni(II) and Cu(II), it is seen that complexes of ethylenediamine and its N- and C-substituted derivatives [5a–c] are more stable than those of 1,3-diaminopropane and higher homologues [5d]. Although *N*-alkylation of ethylenediamines might increase the complex stability due to increased basicity, it was actually found that the resulting steric effects caused a decrease in stability [5]. *C*-Alkylation of ethylenediamine gave increased complex stability, although the basicity of the amine was not significantly changed [5c]. This effect was attributed to a shielding of the metal–nitrogen bonds from polar solvents by the C-substituents, thus enhancing interactions between the metal ion and nitrogen dipoles [5e]. A combination of effects leading to enhanced stability might be expected if, in the chelated structure, the metal ion forms part of a bicyclic system rather than a single ring upon coordination with a secondary amine [5].

The dach ligand can assume a boat-chair conformation to minimise all non-bonded interactions [6]. In this conformation, the axial positions of the metal ion are markedly shielded and additional coordination is restricted.

In bis-dach complexes the two dach ligands can coordinate to the central metal ion in two different ways. The two carbon chains can be on the same side of the plane formed by the four nitrogen atoms to give a *cis* configuration, or on opposite sides of the plane, resulting in a *trans* configuration (Scheme 1).

The crystal structural analysis of the pyramidal complex $[Cu(dach)_2(NO_3)_2]\cdot 0.5H_2O$ shows the *cis* configuration to exist with each ring in a double boat form [7]. In the presence of non-coordinating solvents and anions, the four planar nitrogen atoms exert a major influence on the metal atoms with the carbon chains playing a passive role. The *cis* form can easily accommodate a fifth ligand on the metal, giving a pyramidal structure. On the other hand, the *trans* form can coordinate with two additional ligands, forming a tetragonally distorted octahedral structure. Hence, under certain conditions there may be an equilibrium between the *cis* and *trans* forms of the diamine complexes and in certain complexes the *trans* form may predominate. However, no evidence of a *trans* form has yet been obtained.

We report here the X-ray crystal structure of a copper trichloroacetate complex of 1,4-diazacycloheptane together with its IR, electronic and ESR spectra, magnetic susceptibility and electrochemical data. This shows the so far elusive *trans* configuration, but with only one additional ligand to give a five-coordinate structure.

2. Experimental

2.1. Synthesis

Copper trichloroacetate was synthesised as reported earlier [8]. 1,4-Diazacycloheptane was purchased from Fluka Chemie, Switzerland, and used as received.

Copper trichloroacetate (0.85 g, 2 mmol) was dissolved in methanol (15 ml). The solution was added to a solution of the dach ligand (0.44 g, 4 mmol) in methanol (20 ml) over a period of 10 min at 0°C with constant stirring. The reaction mixture was then stirred for about 2 h at 0°C and the solvent was allowed to evaporate slowly at room temperature (r.t.). Dark blue prismatic crystals of the title compound suitable for X-ray analysis were obtained after 3–4 days. They were collected and dried under vacuum. Found: C, 28.4; H, 3.9; N, 9.3; Cu, 10.8. $C_{14}H_{24}Cl_6CuN_4O_4$ requires C, 28.6; H, 4.1; N, 9.5; Cu, 10.8%.

2.2. Measurements

Infrared spectra were obtained from KBr discs on a Perkin–Elmer 883 spectrophotometer; electronic spectra were recorded from methanol solutions with a Hitachi U-3400 (UV–Vis, NIR) spectrophotometer. Cyclic voltammograms were obtained with an EG and G Princeton Applied Research Potentiostat/Galvanostat and a BAS X-Y recorder by using a three-electrode configuration, including a platinum-coil working electrode, a platinum-coil auxiliary electrode, and a saturated calomel electrode as a reference electrode; dichloromethane was used as the solvent and tetrabutylammonium perchlorate as a supporting electrolyte. X-band ESR spectra were measured on a JEOL JES-RE1X ESR spectrometer (X-band microwave unit, 100 kHz field modulation); the band frequency was calibrated with 1,1-diphenyl-2-picrylhydrazyl (DPPH, $g = 2.0036$).

2.3. X-ray crystallography

Crystal data: $C_{14}H_{24}Cl_6CuN_4O_4$, $M = 588.6$, orthorhombic, space group $P2_12_12_1$, $a = 11.0134(10)$, $b = 14.7433(13)$, $c = 27.292(3)$ Å, $V = 4431.5(7)$ Å^3, $Z = 8$, $D_{calc} = 1.764$ g cm^{-3}, λ(Mo Kα) = 0.71073 Å, $\mu = 1.74$ mm^{-1}, $T = 160$ K, crystal size $0.30 \times 0.13 \times 0.11$ mm. Measurements were made on a Bruker AXS SMART CCD area-detector diffractometer. Measured intensity data covered more than a hemisphere of reciprocal space. Semi-empirical absorption corrections were based on symmetry-equivalent and repeated reflections (transmission 0.663–0.862). 27 787 reflections were measured ($\theta_{max} = 28.37°$), giving 10 112 unique data with $R_{int} = 0.0476$.

The structure was solved by direct methods and refined on F^2 values, with anisotropic displacement parameters and riding hydrogen atoms. Twofold disorder was resolved for the coordinated trifluoroacetate in one of the two independent cations; no restraints were required. At convergence $R_w = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2} = 0.0734$ for all data, conventional $R = 0.0460$ on F values of 8238 reflections having $F_o^2 > 2\sigma(F_o^2)$, goodness-of-fit = 1.102 for all F^2 values and 571 refined parameters. A final difference synthesis contained no features outside ± 0.47 e Å^{-3}. The crystal was probably racemically twinned, with an enantiopole parameter of 0.599(11) [9].

Programs were standard Bruker AXS control and integration software, and SHELXTL [10].

3. Results and discussion

3.1. IR spectra

The ν(C=O) band at 1683 cm^{-1} is assigned to the free trichloroacetate ion [11]. The ν_{asym}(C=O) band at 1688 cm^{-1} and ν_{sym}(C=O) band at 1310 cm^{-1} give $\Delta\nu = 378$ cm^{-1}, indicating the presence of trichloroacetate as a monodentate ligand [12]. Both coordinated and uncoordinated trichloroacetate are confirmed by the crystal structure analysis.

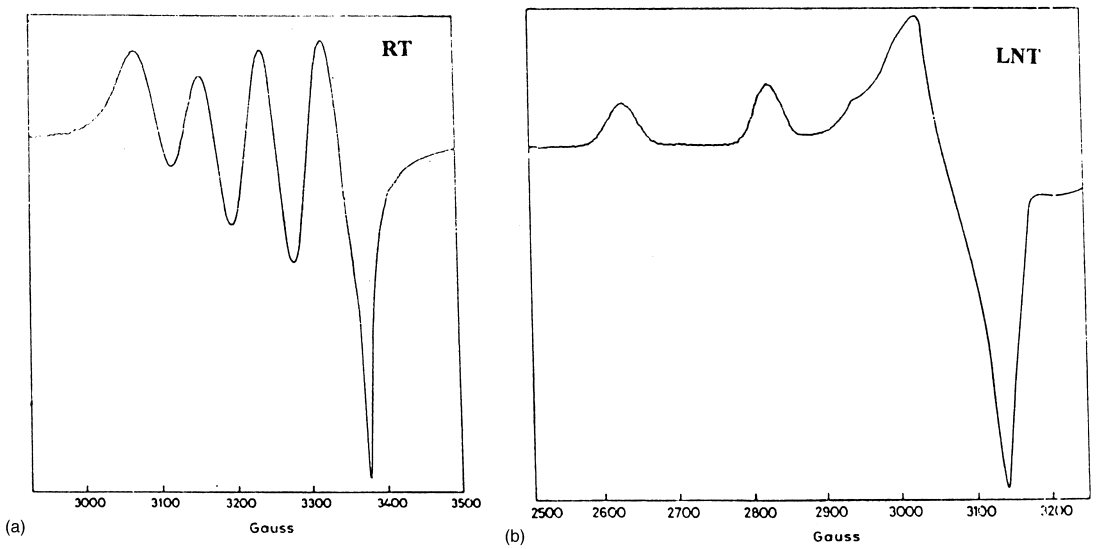

Fig. 1. ESR spectra in methanol solution: (a) at room temperature; (b) at liquid nitrogen temperature.

The bands resulting from the NH stretching vibrations in the complex are at 3289 and 3217 cm^{-1}. It is reasonable to assign the two bands at 431 and 502 cm^{-1} as ν(Cu–N) stretching modes [13]. The characteristic IR bands of the dach ligand are at 2978, 2891, 1494, 1475, 1462, 1446, 1349, 1286, 1127, 1107, 980, 969, 825, and 730 cm^{-1} [13].

3.2. Electronic spectra

The title compound in methanol solution exhibits a sharp absorption band at 28 490 cm^{-1}, along with a broad absorption band having a maximum at 16 273 cm^{-1}. Due to the Jahn–Teller distortion, the majority of copper(II) complexes are tetragonally distorted with four short and two long metal–ligand bonds and are usually expected to absorb near 16 000 cm^{-1} [14,15]. From the observed values it is evident that the absorption is due to the $^2B_{1g} \rightarrow {}^2A_{1g}$ transition in a tetragonally distorted octahedral geometry having CuN_4O_2 chromophores. The other high energy transition at 28 490 cm^{-1} is attributed to ligand-to-metal charge transfer (LMCT) transitions.

From the electronic spectra, it seems that copper(II) is in octahedral coordination in this complex in methanol solution. This is probably due to weak coordination of a second anion as an extra ligand in solution.

3.3. ESR spectra

The ESR spectra of the complex were recorded from powder samples and from methanol solution at r.t. and at liquid nitrogen temperature.

When measured on powder samples at r.t., the spectrum showed an axially symmetric pattern with $g_{\parallel} = 2.20$ and $g_{\perp} = 2.02$. No hyperfine structure was resolved for either $g_{\parallel}$ or $g_{\perp}$, even at liquid nitrogen temperature. The ESR spectrum of the copper(II) complex in solution is shown in Fig. 1. It exhibits a set of four well resolved peaks in the high field region. The g tensor values of copper(II) complexes can be used to derive the ground state [16]. In axially elongated octahedral and square-planar complexes, the unpaired electron occupies the $d(x^2 - y^2)$ orbital with a $^2B_{1g}$ ground state resulting in $g_{\parallel} > g_{\perp}$. However, in a compressed octahedron the unpaired electron occupies the $d(z^2)$ orbital with a $^2A_{1g}$ ground state having $g_{\parallel} > g_{\perp}$. The observed g values suggest that the unpaired electron lies predominantly in the $d(x^2 - y^2)$ orbital. The higher g values are due to a greater elongation in the z axis of the complex with the $^2B_{1g}$ ground state.

3.4. Magnetic measurements

The r.t. magnetic moment of the complex (1.99 BM) is a little larger, which should be associated with some orbital contribution and should be dependent on temperature [17]. Variable temperature magnetic susceptibility measurements are more helpful in this respect. The magnetic behaviour of the complex was studied over the temperature range 300–10 K. Correction for the diamagnetism of the complex was estimated from Pascal's constants to be 271.57 $cm^3\ mol^{-1}$. The magnetic susceptibility data for the complex may be interpreted in terms of the Curie–Weiss law

$$\chi_M^{corr} = Ng^2\beta^2/4K(T - \theta) + N_\alpha$$

where χ_M^{corr} is the molar susceptibility corrected for diamagnetism, $N_\alpha = 60 \times 10^{-6}$ cgs unit is the corrected value of temperature-independent paramagnetism, and the remaining symbols have their usual meanings. It

was found that the complex follows the Curie–Weiss law; the $1/\chi_M$ versus T plot is linear. The values are in the range expected for copper(II) complexes in a magnetically dilute environment [17].

3.5. Electrochemical data

The cyclic voltammogram of the complex exhibits one reduction wave at -1.07 V versus SCE, which appears to correspond to the Cu(II)/Cu(I) couple. The reduction is quasi-reversible. The ratio of the anodic to cathodic peak currents (I_{pa}/I_{pc}) is nearly 1 [18].

3.6. Crystal structure

The title compound contains two copper-centred complex ions of very similar stereochemistry, which are nonetheless crystallographically distinct. Perspective drawings of each molecule **A** and **B** are shown in Fig. 2. Selected bond lengths and angles are listed in Table 1.

In each cation the two dach ligands apparently enforce a distorted square-based pyramidal geometry, which can be assessed using the structural index parameter $\tau = (\beta - \alpha)/60$, where β and α are the two largest coordination angles; $\tau = 0$ for perfect square pyramidal and 1 for trigonal bipyramidal geometry [19]. The value of τ is 0.12 for **A** and 0.08 for **B**, indicating the geometry to be square pyramidal. The complex cation comprises copper(II) coordinated by a pair of dach ligands and a trichloroacetate anion in the primary coordination sphere. In each molecule four nitrogen atoms of two dach ligands form the approximate square-planar arrangement, with a trichloroacetate anion occupying the apex of a distorted square pyramid. The copper atoms lie out of the two N_4 basal planes by 0.317 and 0.308 Å in the direction of the axially bonded ligand.

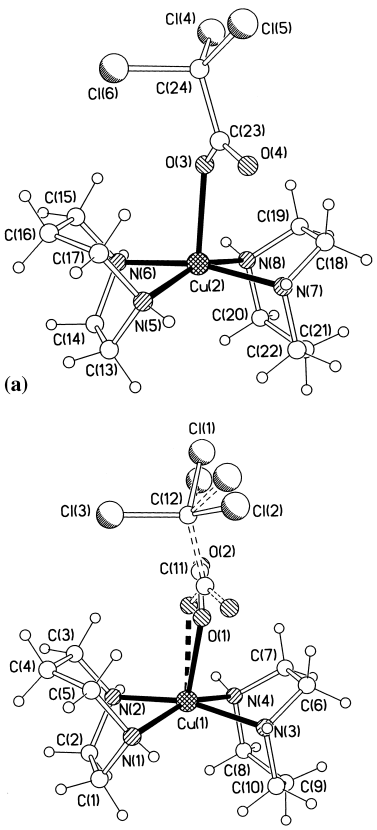

Fig. 2. Perspective view of cations **A** and **B**.

Table 1
Selected bond lengths (Å) and angles (°)

Cu(2)–O(3)	2.220(2)		
N(6)–Cu(2)–N(7)	166.14(14)	N(6)–Cu(2)–N(5)	78.01(13)
N(7)–Cu(2)–N(5)	99.83(12)	N(6)–Cu(2)–N(8)	99.31(12)
N(7)–Cu(2)–N(8)	77.68(14)	N(5)–Cu(2)–N(8)	158.82(13)
N(6)–Cu(2)–O(3)	96.93(12)	N(7)–Cu(2)–O(3)	96.80(12)
N(5)–Cu(2)–O(3)	106.63(12)	N(8)–Cu(2)–O(3)	94.54(12)
Molecule B			
Cu(1)–N(2)	2.008(3)	Cu(1)–N(3)	2.006(3)
Cu(1)–N(4)	2.022(3)	Cu(1)–N(1)	2.025(3)
Cu(1)–O(1)	2.233(7)	Cu(1)–O(2X)	2.266(11)
N(2)–Cu(1)–N(3)	164.13(14)	N(2)–Cu(1)–N(4)	98.44(12)
N(3)–Cu(1)–N(4)	77.33(14)	N(2)–Cu(1)–N(1)	77.81(14)
N(3)–Cu(1)–N(1)	100.74(13)	N(4)–Cu(1)–N(1)	159.61(14)
N(2)–Cu(1)–O(1)	108.44(18)	N(3)–Cu(1)–O(1)	87.43(18)
N(4)–Cu(1)–O(1)	105.12(17)	N(1)–Cu(1)–O(1)	95.00(17)
N(2)–Cu(1)–O(2X)	90.5(2)	N(3)–Cu(1)–O(2X)	104.7(2)
N(4)–Cu(1)–O(2X)	89.9(3)	N(1)–Cu(1)–O(2X)	110.1(3)

The four Cu–N bond lengths fall within the range usually observed for heterocyclic ligands [20]. The fifth position is occupied at a longer distance by an oxygen atom of a trifluoroacetate ligand; this is disordered over two orientations in the case of complex **B**. Similar disorder has also been observed in other ions [21].

The overall single positive charge on the complex cation is balanced by a second, uncoordinated, trifluoroacetate anion, which appears to be coordinated in methanol solution (see above). Even though the copper ion is only pentacoordinate in the solid state, the two dach ligands are arranged in a *trans* configuration, which in principle renders the two axial positions equally accessible for ligand attachment.

Dimetallic thiolate-bridged complexes: synthesis and rich electrochemistry of dinickel(II) and dizinc(II) monothiolate complexes

Sally Brooker *, Paul D. Croucher, Tony C. Davidson, Paul D. Smith

Department of Chemistry, University of Otago, PO Box 56, Dunedin, New Zealand

Received 29 February 2000; accepted 5 May 2000

Abstract

The synthesis of the two-armed amine precursor 2,6-di[*N*-(3′-aminopropyl)aminomethyl]-4-methylphenol (**1**) is detailed. Zinc(II) and nickel(II) templated Schiff base condensation reactions of **1** and 2,6-diformyl-4-methylthiophenolate (obtained by base hydrolysis of *S*-(2,6-diformyl-4-methylphenyl)dimethylthiocarbamate (**2**)), in IPA, yield the macrocyclic complexes $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**) and $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**), respectively. Addition of two equivalents of NaNCS to **4**, in DMF, gives the complex $[Ni_2L1(NCS)_2(DMF)]$ (**5**). An acyclic complex, $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**), is formed by reaction of two equivalents of nickel(II) ions with 2,6-diformyl-4-methylthiophenolate, pyrazole and two equivalents of 2-(2-aminoethyl)pyridine. Single crystal X-ray diffraction studies of **4** and **5** revealed differing environments for the nickel(II) ions within the macrocycle: in the case of **4** one nickel ion is square planar whilst the other is octahedral, whereas in **5** both nickel ions are high spin but one is square pyramidal whilst the other is octahedral. In contrast, the structure determination carried out on **6** shows that both of the nickel ions are square planar. ^1H and ^{13}C NMR studies show that the diamagnetic compounds $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**) and $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**) remain intact in $MeNO_2$-d_3 solution. In MeCN-d_3 solution the dizinc complex **3** again retains its integrity. In contrast, the dinickel complex **6** has some tendency to coordinate MeCN in the otherwise vacant axial sites leading to traces of paramagnetic species in solution and to very broad signals in the ^1H NMR spectrum. Electrochemical studies, in MeCN, on the soluble dinickel(II) complexes **4** and **6**, revealed a series of one electron processes (-1.23^{QR}, $+0.65^{I}$ and $+1.00^{R}$ V versus 0.01 M $AgNO_3$–Ag for **4**; -1.46^{I}, -0.96^{R}, $+1.03^{I}$ and $+1.50^{I}$ V versus 0.01 M $AgNO_3$–Ag for **6**; where R, reversible; I, irreversible; QR, quasireversible), in contrast to the dizinc(II) complex **3** which is redox inactive over this range. © 2000 Elsevier Science Ltd. 1. Introduction

In order to provide distinctive coordination environments for transition metal ions we have developed routes to ligands which contain unusual mixtures of donors [1–6]. A key strategy has been the tailoring of new classes of unsymmetrical macrocycles, which incorporate two different head units. In contrast to the usual one-pot syntheses of symmetrical macrocycles from two relatively simple difunctionalised starting materials [7] most of the unsymmetrical polynucleating macrocycles prepared to date have been built up in a stepwise, controlled, manner [8]. The use of mono-N-protected diaminoalkanes to facilitate the stepwise formation of two-armed amine precursors was reported by Martell and coworkers [9] and we have subsequently extended the use of this approach with some success [1–4,10]. Here we detail the synthesis of **1** which incorporates a phenol head unit and provides access to an unsymmetrical macrocyclic ligand, $(L1)^{2-}$, which possesses an unprecedented combination of phenolate and thiophenolate head units, along with imine and amine nitrogen groups (Fig. 1). In contrast to all of the other macrocyclic complexes derived from **2** [11–18] the complexes of $(L1)^{2-}$ described here, $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**), $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**) and $[Ni_2L1(NCS)_2(DMF)]$

(**5**), incorporate a single bridging thiolate donor atom and the impact of this change is significant (vide infra) [2,3]. Prior to these macrocyclic studies [2,3,11–18], Robson and co-workers had investigated the coordination chemistry of acyclic ligands prepared from **2** [19–26], including the palladium(II) complex $[Pd_2L2Cl_2]Cl$ [22]. Here we describe the nickel(II) complex $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**) of the acyclic ligand $(L2)^-$. This was prepared because, like $(L1)^{2-}$, it provides only a single thiolate bridge, and because it is closely related to the dinickel(II) complexes of the Schiff-base macrocyclic ligand $(L3)^{2-}$ (Fig. 1) which have exhibited rich, reversible redox chemistry. The electrochemistry of these complexes is presented and discussed.

2. Experimental

CAUTION: *perchlorate salts are potentially explosive and should therefore be handled with appropriate care.*

Measurements were carried out, and solvents purified, as previously described [12,13], with the exception of the NMR spectra of **6**, which were obtained on a Varian 500 MHz spectrometer. *S*-(2,6-Diformyl-4-methylphenyl)dimethylthiocarbamate (**2**) [12] and *N*-acetyldiaminopropane [4] were prepared as previously described. Ethanol was distilled from magnesium ethoxide before use (5 g magnesium and 0.5 g iodine per litre of ethanol). Reactions to produce complexes **3**–**6** were carried out under nitrogen using Schlenk techniques.

2.1. 2,6-Di[*N*-(3′-aminopropyl)aminomethyl]-4-methylphenol hydrochloride (1·4HCl)

Step 1. A solution of *N*-acetyldiaminopropane (7.06 g, 58.1 mmol) in EtOH (50 ml) was added to a suspension of 2,6-diformyl-4-methylphenol (4.77 g, 29.0 mmol) in EtOH (50 ml) and the resulting dark brown solution was refluxed (4 h). The reaction mixture was then cooled (273 K) and an excess of sodium borohydride (4.83 g, 128 mmol) added in three approximately equal portions over 1 h. The pale mixture was stirred and allowed to warm up to room temperature over 4 h, followed by refluxing for a further 4 h. Water (50 ml) was then added to the cloudy yellow mixture. The mixture became thick and waxy in appearance. After cooling the solution was concentrated (50 ml) and then extracted with CH_2Cl_2 (150 ml) in a continuous extractor (18 h). The CH_2Cl_2 fraction was removed, concentrated (50 ml), washed with H_2O (3 × 50 ml), dried with anhydrous $MgSO_4$ and then taken to dryness under vacuum to yield the *N*-protected precursor as a yellow oil. ^1H NMR (300 MHz, solvent $CDCl_3$, reference TMS) 6.80 (s, 2H), 6.7 (s, 1H), 3.83 (s, 4H), 3.30 (dd, 4H), 2.69 (t, 4H), 2.22 (s, 3H), 1.94 (s, 6H), 1.69 (quintet, 4H); ^{13}C NMR (75 MHz, $CDCl_3$ reference TMS) 170.4, 154.1, 127.6, 124.1, 128.8, 50.9, 46.6, 38.0, 29.0, 23.2, 20.4.

Step 2. Isolation of **1**, as the HCl salt, was via hydrolysis of the *N*-acetyl groups in the above oil by refluxing with 20% HCl (200 ml) for 12 h. The excess HCl was removed under vacuum, the resulting tacky

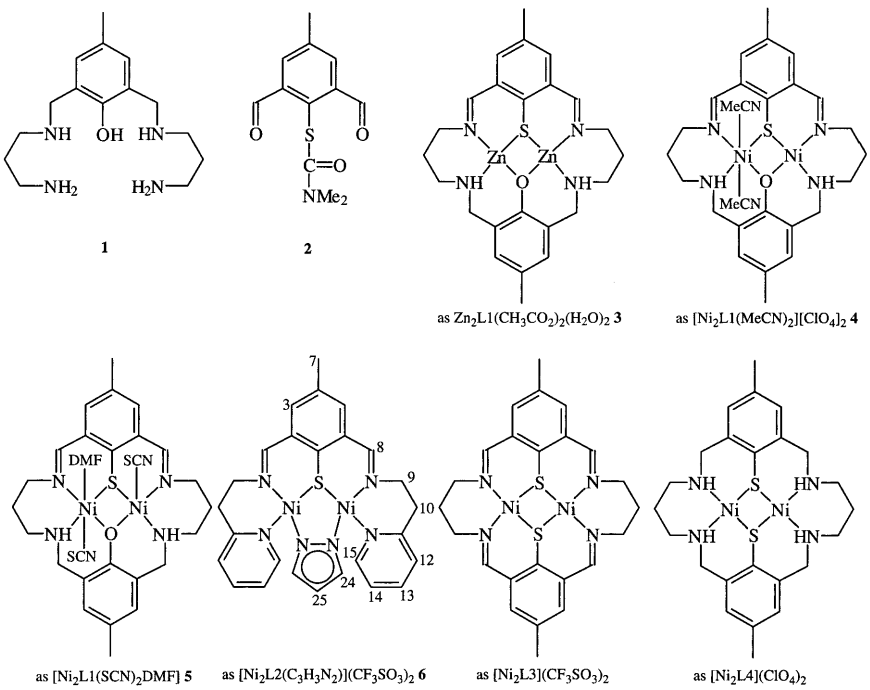

Fig. 1. The two-armed amine precursor **1**, the masked-thiolate head unit **2** and complexes $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**), $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**), $[Ni_2L1(NCS)_2(DMF)]$ (**5**), $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**), $[Ni_2L3](CF_3SO_3)_2$ and $[Ni_2L4](ClO_4)_2$.

brown solid extracted into MeOH (100 ml), filtered and the clear solution evaporated to dryness under vacuum to give a white powder. Yield 8.00 g, 64%. Found: C, 42.3; H, 7.7; N, 12.8. $C_{15}H_{32}N_4OCl_4$ requires C, 42.3; H, 7.6; N, 13.1%. ν_{max} (cm^{-1}) (KBr disk, inter alia) 3359, 3000, 2338, 2005, 1604, 1487 cm^{-1}; ^1H NMR (300 MHz, solvent D_2O, reference DSS) 7.26 (s, 2H), 4.26 (s, 4H), 3.18 (dd, 4H), 3.06 (dd, 4H), 2.24 (s, 3H), 2.09 (q, 4H); ^{13}C NMR (75 MHz, solvent D_2O, reference DSS) 153.8, 134.9, 122.8, 136.6, 49.4, 46.8, 39.3, 26.3, 22.1.

2.2. 2,6-Di[N-(3′-aminopropyl)aminomethyl]-4-methylphenol (**1**)

This was prepared prior to use by reacting the above HCl salt (0.43 g, 1 mmol) with KOH (0.04 g, 4 mmol) in EtOH (40 ml). The mixture was stirred at 298 K (1 h), evaporated to dryness under vacuum and the resulting residue was taken up in $CHCl_3$ (20 ml), dried over anhydrous $MgSO_4$ then filtered to remove both the desiccant and the KCl by product. Finally the $CHCl_3$ was removed under vacuum to yield **1** as a pale yellow oil which was used promptly, without further purification.

2.3. $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**)

NaOH (0.04 g, 1 mmol) and **2** (0.25 g, 1 mmol) were dissolved in IPA (50 ml) and refluxed for 5 h under a nitrogen atmosphere. To this was added a solution of zinc(II) acetate dihydrate (0.444 g, 2 mmol) in IPA. Compound **1** (0.28 g, 1 mmol) in IPA (10 ml) was then added dropwise to produce a bright yellow solution which was refluxed for 1 h under nitrogen. The reaction mixture was cooled to room temperature, filtered and evaporated to dryness under vacuum to give a yellow residue. This solid was extracted into CH_2Cl_2 (50 ml), filtered and concentrated (10 ml). A yellow powder was obtained from a CH_2Cl_2 solution via slow vapour diffusion of pentane. The solid was collected and dried under vacuum. Yield 0.30 g, 45%. Found: C, 47.2; H, 5.8; N, 7.9; S, 4.1. $C_{28}H_{40}N_4SO_7Zn_2$ requires C, 47.5; H, 5.7; N, 7.9; S, 4.5%. ν_{max} (cm^{-1}) (KBr disk, inter alia) 3236, 1631. ^1H NMR (300 MHz, solvent $CDCl_3$, reference TMS) 8.18 (s, 2H), 7.09 (s, 2H), 6.79 (s, 2H), 4.68 (t, 4H), 4.47 (t, 4H), 3.59 (d, 2H), 3.22 (m, 4H), 2.97 (m, 4H), 2.59 (s, 3H), 2.29 (s, 3H), 2.15 (s, 6H), 1.78 (m, 4H); ^{13}C NMR (75 MHz, $CDCl_3$ reference TMS) 179.4, 166.0, 158.7, 136.8, 134.9, 133.1, 132.3, 127.9, 126.4, 62.2, 54.3, 50.9, 36.2, 30.3, 25.4, 20.3; Λ_m (MeCN), 35 mol^{-1} cm^2 Ω^{-1} (cf. 220–300 mol^{-1} cm^2 $^{-1}$ for a 2:1 electrolyte in MeCN) [31]; FAB mass spectrum m/z 612 $[Zn_2L1(CH_3CO_2)]^+$, 553 $[Zn_2L1]^+$.

2.4. $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**)

NaOH (0.04 g, 1 mmol) and **2** (0.25 g, 1 mmol) were dissolved in IPA (50 ml) and refluxed for 5 h under a nitrogen atmosphere. To this was added a solution of nickel(II) perchlorate hexahydrate (0.73 g, 2 mmol) in IPA (10 ml), which produced a brown solution. Compound **1** (0.28 g, 1 mmol) in IPA (10 ml) was then added dropwise and the resulting mixture was refluxed under nitrogen for 3 h. The solution was filtered, concentrated to 10 ml and cooled (253 K, 18 h), yielding a red–brown powder which was collected, washed with IPA (10 ml) and dried under vacuum. Yield 0.17 g, 20%. Found: C, 40.6; H, 4.5; N, 10.2; S, 3.9. $C_{28}H_{36}N_6SO_9Cl_2Ni_2$ requires C, 41.0; H, 4.4; N, 10.2; S, 3.9%. ν_{max} (cm^{-1}) (KBr disk, inter alia) 3238, 1631, 1093, 624. Λ_m (MeCN), 280 mol^{-1} cm^2 Ω^{-1} (cf. 220–300 mol^{-1} cm^2 Ω^{-1} for a 2:1 conductor in MeCN) [31]; λ_{max} (MeCN) nm (ε dm^{-3} mol^{-1} cm^{-1}) 800 (19); FAB mass spectrum m/z 540, $[Ni_2L1]^+$; $\mu = 3.0$ BM per complex.

2.5. $[Ni_2L1(NCS)_2(DMF)]\cdot 2H_2O$ (**5**$\cdot 2H_2O$)

Sodium thiocyanate (0.05 g, 0.51 mmol) was added to a solution of **4** (0.21 g, 0.25 mmol) in DMF (5 ml). Addition of IPA (60 ml) precipitated a green–brown powder that was collected, washed with IPA (10 ml) and dried under vacuum. Yield 0.09 g, 52%. A small number of brown plate-like crystals of $[Ni_2L1(NCS)_2$-(DMF)], suitable for X-ray diffraction, were obtained from DMF via slow vapour diffusion of Et_2O. Found: C, 45.7; H, 5.2; N, 13.1. $C_{29}H_{41}N_7S_3O_4Ni_2$ requires C, 45.5; H, 5.4; N, 12.8% ν_{max} (cm^{-1}) (KBr disk, inter alia) 3244, 2083, 1630. Λ_m (DMF), 76 mol^{-1} cm^2 Ω^{-1} (cf. 50–90 mol^{-1} cm^2 Ω^{-1} for a 1:1 conductor in DMF) [31]; λ_{max} (DMF) nm (ε dm^{-3} mol^{-1} cm^{-1}) 850 (15), 650 (46); FAB mass spectrum m/z 598 $[Ni_2L1(NCS)]^+$, 540 $[Ni_2L1]^+$; $\mu = 4.5$ BM per complex.

2.6. $[Ni_2L2(C_3H_3H_2)](CF_3SO_3)_2$ (**6**)

NaOH (0.02 g, 0.5 mmol) and **2** (0.13 g, 0.5 mmol) were dissolved in IPA (60 ml) and refluxed for 5 h under a nitrogen atmosphere. To this was added a solution of pyrazole (0.04 g, 0.5 mmol) and NaOH (0.02 g, 0.5 mmol) in IPA (30 ml) followed by a solution of nickel(II) trifluoromethanesulfonate hexahydrate (0.39 g, 1 mmol) in IPA (10 ml), which produced a red–brown solution. 2-(2-Aminoethyl)pyridine (0.11 g, 1 mmol) in IPA (50 ml) was added dropwise. No colour change was observed. The solution was refluxed for a further 2 h under nitrogen, filtered hot to remove a trace of powder, and on cooling the filtrate a brown powder precipitated. Red–brown crystals were obtained from MeCN via slow vapour diffusion of Et_2O. Yield 0.87 g, 42%. Found: C, 39.1; H, 3.3; N, 9.5; S,

10.7. $C_{28}H_{26}N_6S_3O_6F_6Ni_2$ requires C, 38.7; H, 3.0; N, 9.6; S, 11.0% ν_{max} (cm^{-1}) (KBr disk, inter alia) 1630, 1611, 1268, 1028, 632. λ_m (MeCN), 280 mol^{-1} cm^2 Ω^{-1} (cf. 220–300 mol^{-1} cm^2 Ω^{-1} for a 2:1 conductor in MeCN) [31]; λ_{max} (MeCN) nm (ε dm^{-3} mol^{-1} cm^{-1}) 365 (1900), 463 (620) shoulder, 540 (390) shoulder; ^1H NMR (500 MHz, solvent $MeNO_2$-d_3, referenced to solvent) 8.52 (d, 2H), 8.12 (t, 2H), 7.90 (s, 2H), 7.70 (d, 2H), 7.60 (s, 2H), 7.45 (t, 2H), 6.24 (d, 2H), 5.88 (t, 1H), 5.36 (t, 2H), 4.20 (d, 2H), 3.70 (d, 2H), 3.40 (t, 2H), 2.4 (s, 3H); ^{13}C NMR (125 MHz, solvent $MeNO_2$-d_3, referenced to solvent) 172.9, 160.6, 153.0, 145.0, 142.9, 141.2, 140.7, 135.5, 126.0, 125.5, 125.1, 109.3, 54.2, 37.4, 20.5; FAB mass spectrum m/z 570 $[Ni_2L2(C_3H_3H_2)]^+$, 503 $[Ni_2L2]^+$; $\mu = 0.0$ BM. Crystal data: $C_{28}H_{26}N_6Ni_2O_6S_3F_6$, red block, $0.70 \times 0.40 \times 0.22$ mm^3, monoclinic, space group $P2_1/c$; $a = 15.7537(3)$; $b = 14.0559(3)$; $c = 16.8208(3)$ Å, $\beta = 115.6990(10)°$; $V = 3356.24(16)$ $Å^3$; $Z = 4$. A total of 23 171 reflections were collected on a Bruker SMART diffractometer at 142 K in the range $2 < 2 < 61°$, and the 7698 independent reflections were used in the structural analysis after a semi-empirical absorption correction had been applied ($T_{min} = 0.75$, $T_{max} = 1.00$). The structure was solved by direct methods (SHELXS-97) [32,33] and refined against all F^2 data (SHELXL-97) [34] to $R_1 = 0.0439$ (for 7449 $F > 4\sigma(F)$; $wR_2 = 0.0905$ and goodness-of-fit = 1.320 for all 7698 F^2; 461 parameters, all non-hydrogen atoms anisotropic; $+0.47/-0.65$ e $Å^{-3}$).

3. Results and discussion

3.1. Synthesis

The Schiff base condensation of two equivalents of *N*-acetyldiaminopropane with one equivalent of 2,6-diformyl-4-methylphenol was followed by reduction of the imine bonds by sodium borohydride and hydrolysis of the protecting groups with aqueous acid to yield **1** as the tetrahydrochloride salt.

The deprotection of the masked-thiolate head unit **2** (Fig. 1), to produce the unmasked thiophenolate head unit, was carried out in situ using NaOH in IPA [12], and then the appropriate metal salt and **1** were added to form the complexes $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**) (45% yield) and $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**) (20% yield). The infrared spectra of **3** and **4** were consistent with macrocycle formation: an imine stretch was present at 1631 cm^{-1} for both **3** and **4**, and no peaks corresponding to unreacted primary amine or carbonyl were present. The addition of 2.2 equivalents of sodium thiocyanate to an acetonitrile solution of complex **4** causes the precipitation of a solid which on recrystallisation from DMF by vapour diffusion of diethylether yields $[Ni_2(L1)(NCS)_2(DMF)]$ (**5**).

Complex $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**) (Fig. 1) was prepared from the reaction of two equivalents of nickel(II) ions with hydrolysed **2**, pyrazole and two equivalents of 2-(2-aminoethyl)pyridine, in 42% yield. An imine stretch was present at 1630 cm^{-1} in the infrared spectrum and no carbonyl or amine peaks were observed. The ease of synthesis and stability of **6** contrast with the instability of one of the two imine bonds in the dipalladium(II) complex $[Pd_2L2Cl_2]Cl$ [22].

Complex **3** is a non-conductor in freshly prepared MeCN solution, indicating that the acetate ions are coordinated in solution. As expected, complex **4** is a 2:1 conductor in MeCN. Complex **5** takes some time to dissolve in DMF and is a 1:1 conductor in this solvent, indicating that on dissolution of this neutral complex a thiocyanate ion dissociates. Complex **6** is a 2:1 conductor in MeCN, indicating that the pyrazolate anion remains coordinated in solution.

3.2. Crystal structures

The X-ray crystal structures of the dinickel(II) complexes **4** [2] and **5** [3] have been presented in preliminary communications and in both cases differing environments for the nickel(II) ions within the $L1^{2-}$ macrocycle were revealed (Fig. 1). In the case of complex **4** one nickel ion is square planar whilst the other is octahedral, whereas in complex **5** both nickel ions are high spin but one is square pyramidal whilst the other is octahedral.

Dark red single crystals of $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**) were obtained by diethylether vapour diffusion into an MeCN solution of **6** and the structure determined (Fig. 2). There is one complete molecule, containing two square planar nickel(II) ions, in the asymmetric unit. Each nickel atom is bound to a bridging thiolate sulfur, an imine nitrogen, a pyridine nitrogen and a pyrazolate nitrogen, giving a N_3S coordination sphere. In order to accommodate the geometries of the nickel ions the two square planes are at an angle of 46.32(4)° to each other and the complex adopts a bowed shape with the thiophenolate head unit almost perpendicular to the two pyridine rings (85.4 and 84.7°). Examination of the dihedral angles between the respective $Ni(N_{L2-})_2$ and $NiSN_{pyrazolate}$ planes reveals a similar degree of tetrahedral distortion away from square planar (12.9–16.2°) to that found in the butylene chain analogue of $[Ni_2L3]^{2+}$ (15.4–18.9°) [13]. Due to the two atom pyrazolate bridge and the flexible nature of the acyclic ligand the Ni···Ni separation is greater, by 0.08–0.36 Å, than that observed in related macrocyclic complexes (Fig. 1) [2,3,11–13]. There are π–π stacking interactions between adjacent complexes with the thiophenolate ring of one complex lying over that of another (3.46–3.89 Å apart).

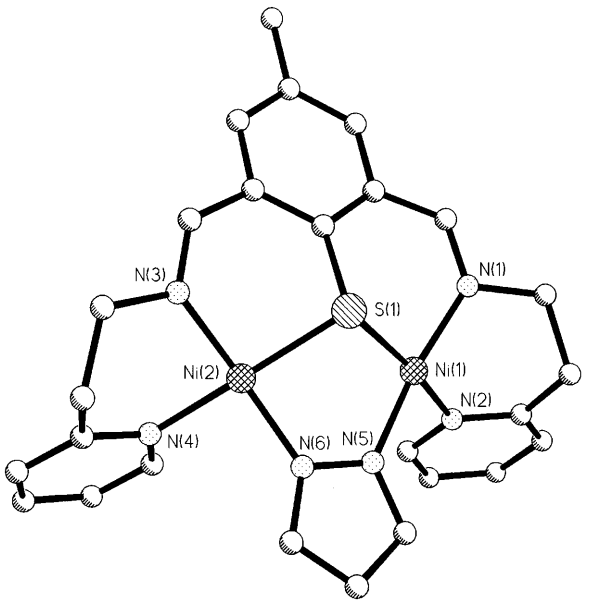

Fig. 2. Perspective view of the cation of **6**, $[Ni_2L2(C_3H_3N_2)]^{2+}$ (hydrogen atoms and triflate ions omitted for clarity). Selected bond lengths (Å) and angles (°): Ni(1)–N(5) 1.870(2), Ni(1)–N(1) 1.894(2), Ni(1)–N(2) 1.917(2), Ni(1)–S(1) 2.1872(6), Ni(2)–N(6) 1.875(2), Ni(2)–N(3) 1.898(2), Ni(2)–N(4) 1.930(2), Ni(2)-S(1) 2.1944(6), S(1)–C(1) 1.766(2), Ni(1)···Ni(2) 3.376(1), N(5)–Ni(1)–N(1) 170.50(9), N(5)–Ni(1)–N(2) 90.83(9), N(1)–Ni(1)–N(2) 89.56(8), N(5)–Ni(1)–S(1) 87.75(7), N(1)–Ni(1)–S(1) 93.26(6), N(2)–Ni(1)–S(1) 171.28(7), N(6)–Ni(2)–N(3) 168.54(9), N(6)–Ni(2)–N(4) 91.56(9), N(3)–Ni(2)–N(4) 90.17(9), N(6)–Ni(2)–S(1) 87.48(6), N(3)–Ni(2)–S(1) 93.03(6), N(4)–Ni(2)–S(1) 168.59(7), C(1)–S(1)–Ni(1) 103.68(8), C(1)–S(1)–Ni(2) 103.02(8), Ni(1)–S(1)–Ni(2) 100.79(2).

Comparison of the structure of **6** with that of the two complexes in the asymmetric unit of $[Pd_2L2Cl_2]Cl$ [22] reveals significant differences between them. In the case of **6** the two-atom pyrazolate bridge helps to pin the structure together, something which has been seen before in complexes of related two-armed thiophenolate ligands [23–25]. This bridge also requires the two arms to be held such that the two pyridine rings are almost parallel to each other. In contrast, in $[Pd_2L2Cl_2]Cl$ the two non-bridging chloride ions twist away from one another and hence force the two arms to twist in opposite directions with respect to the plane of the bridging thiophenolate moiety (the pyridine and phenyl ring planes intersect at 21.9 and 93.9° in the Pd(1)–Pd(2) complex and 14.9 and 87.2° in the Pd(3)/Pd(4) complex) [22]. The two square planes of donor atoms within each dipalladium complex are at much greater angles to each other (75.3° Pd(1)/Pd(2); 77.0° Pd(3)/Pd(4)) than is the case in **6**. Another consequence of the non-bridging chloride ions is that the metal ions are separated by a greater distance in the case of the palladium(II) complex (3.798 and 3.893 Å) [22] than in **6**.

3.3. NMR studies

Inspection of the ^1H and ^{13}C NMR data obtained for **3** and **6** establishes that both complexes have two-fold symmetry in solution (Fig. 1). For the macrocyclic dizinc complex **3** similar spectra were obtained in both MeCN-d_3 and $MeNO_2$-d_3. In the non-coordinating solvent $MeNO_2$-d_3 the acyclic dinickel complex **6** gave easily assigned diamagnetic ^1H and ^{13}C NMR spectra (Fig. 3). In coordinating solvents such as MeCN-d_3 **6** has some tendency to coordinate solvent molecules in the otherwise vacant axial sites leading to traces of paramagnetic species in solution. The ^1H NMR spectrum obtained for **6** in MeCN-d_3 is too broad to be assigned.

3.4. Electrochemical studies

Electrochemical studies were performed in MeCN, versus a 0.01 M $AgNO_3$–Ag reference electrode, on all complexes except the dinickel(II) complex **5** which was not soluble enough. The macrocyclic dizinc(II) complex **3** shows no electrochemical response within the solvent limits of MeCN (-2.4 to $+1.6$ V, Fig. 4). In contrast, the dinickel(II) complexes **4** and **6** both exhibit a series

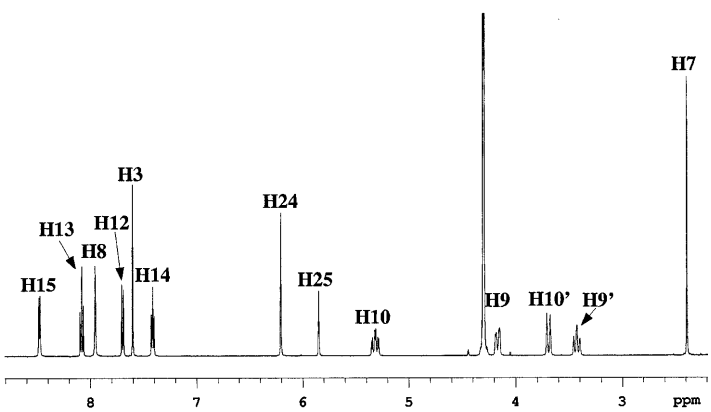

Fig. 3. ^1H NMR spectrum of $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**) in $MeNO_2$-d_3 (numbering scheme as in Fig. 1).

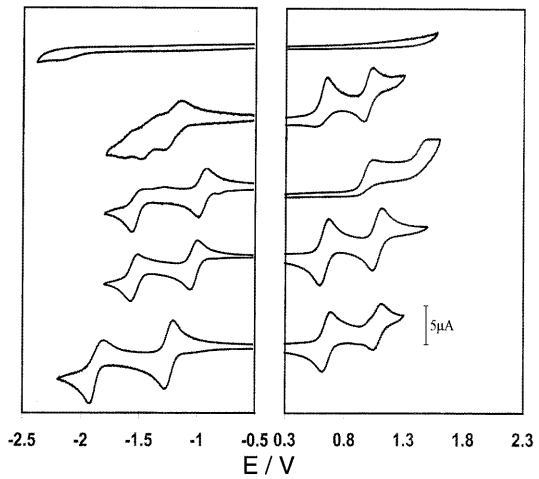

Fig. 4. Cyclic voltammograms of complexes (listed from top to bottom): $Zn_2L1(CH_3CO_2)_2(H_2O)_2$ (**3**), $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**), $[Ni_2L2(C_3H_3N_2)](CF_3SO_3)_2$ (**6**), $[Ni_2L3](CF_3SO_3)_2$ and $[Ni_2L4](ClO_4)_2$ as 1 mmol l^{-1} solutions in MeCN (200 mV s^{-1}, 0.1 M NEt_4ClO_4, platinum electrode, versus 0.01 M $AgNO_3$–Ag).

of redox processes. The macrocyclic complex **4** has three redox processes between -1.3 and $+1.3$ V and the acyclic complex **6** has four redox processes between -1.8 and $+1.7$ V (Fig. 4). All of these approximately one-electron processes are believed to be largely metal-centred (Table 1) [11–13]. Two further reduction processes occur for the macrocyclic complex **4**, at -1.50 and -1.61 V (Fig. 4).

The two oxidation processes of the macrocyclic complex $[Ni_2L1(MeCN)_2](ClO_4)_2$ (**4**) occur at remarkably similar potentials to those of the two macrocyclic complexes $[Ni_2L3](CF_3SO_3)_2$ and $[Ni_2L4](ClO_4)_2$ (Fig. 1) [11–13], which are also 2:1 conductors in MeCN solution [26]. This is despite considerable differences in the macrocyclic donors, the most significant of which is changing one of the two thiophenolate bridges to a phenolate bridge. This is consistent with the electron being removed from the axial nickel(II) orbital, which is more sensitive to the ability of the MeCN solvent to coordinate axially (as nickel(III) is expected to have a coordination number greater than four) than to changes in the macrocyclic donors in the equatorial plane. Curiously, the first oxidation process for **4** is irreversible, independent of scan speed and of whether or not the second oxidation process is included in the scan.

The two oxidation processes of the acyclic complex **6** occur at significantly higher potentials than those of the macrocyclic complexes **4**, $[Ni_2L3](CF_3SO_3)_2$ and $[Ni_2L4](ClO_4)_2$, and both processes are irreversible. This indicates that the combination of losing the macrocyclic cavity and of replacing one thiophenolate or phenolate bridge by a pyrazolate bridge has significantly reduced the ability of the ligand to stabilise nickel(III). We have previously shown that replacement of both thiophenolate bridges by phenolate bridges also significantly increases the potential of these processes [13]. Interestingly the first process in the diphenolate macrocyclic complex occurs at a similar potential to that observed here for the acyclic complex **6**. The irreversibility of both of these processes for complex **6** may be due to a structural rearrangement occurring on removal of an electron from the nickel(II) ions, which are no longer constrained in a macrocyclic ring, leading to the pyrazolate dissociating from at least one nickel ion [20].

As expected, the reduction processes are more dependent on the nature of the donors in the equatorial plane (Fig. 4) [13]. In general, changing from a thiophenolate to a phenolate donor makes it harder to reduce the nickel(II) ion [13,20]. Likewise, changing from an imine to an amine donor also destabilises the nickel(I) oxidation state due to a reduction in the π-acceptor ability of the ligand [11,27,28].

As anticipated, replacing a thiophenolate diimine unit in $[Ni_2L3](CF_3SO_3)_2$ by a phenolate diamine unit in **4** has, as is seen from the potential of the first reduction process, significantly reduced the ability of the ligand to stabilise nickel(I). It is interesting to note that the potential of the first reduction process observed for complex **4** is very similar to that observed for the tetra-amine macrocyclic complex $[Ni_2L4](CF_3SO_3)_2$.

The two reduction processes observed for the acyclic complex **6**, are well separated and occur at very similar potentials to those observed for the tetra-imine complex

Table 1
Potentials ($E_{1/2}$, V) for the dinickel complexes [a]

	$Ni(I)_2 \Leftrightarrow Ni(I)Ni(II)$	$Ni(I)Ni(II) \Leftrightarrow Ni(II)_2$	$Ni(II)_2 \Leftrightarrow Ni(II)Ni(III)$	$Ni(II)Ni(III) \Leftrightarrow Ni(III)_2$
$[Ni_2L1(MeCN)_2](ClO_4)_2$	-1.50^{I}	-1.23^{QR}	$+0.65^{I}$	$+1.00^{R}$
$[Ni_2L2(C_3H_3H_2)](CF_3SO_3)_2$	-1.46^{I}	-0.96^{R}	$+1.03^{I}$	$+1.50^{I}$
$[Ni_2L3](CF_3SO_3)_2$	-1.46^{R}	-1.01^{R}	$+0.63^{R}$	$+1.07^{R}$
$[Ni_2L4](ClO_4)_2$	-1.86^{QR}	-1.18^{R}	$+0.69^{R}$	$+1.10^{QR}$

[a] R, reversible; QR, quasireversible; I, irreversible (hence in this case $E_{pa/pc}$ is quoted not $E_{1/2}$); these assignments were made on the basis of peak separation ΔE (cf. ferrocene), analysis of the ratio of peak currents and scan rate dependence of $E_{1/2}$ [35]. Controlled potential electrolysis of **4** at -1.30 V and of **6** at -1.10 V transferred ca. one electron equivalent of charge (0.90 and 0.93, respectively) and, by comparisons of the peak height currents, the remaining processes are therefore also assigned to be one-electron processes.

$[Ni_2L3](CF_3SO_3)_2$. This indicates that the replacement of N_{imine} by $N_{pyridine}$, both π-acceptors, and of S by $N_{pyrazolate}$ has had minimal overall effect on the reduction processes. The biggest difference is that the second process is less reversible for the acyclic complex **6** than for the macrocyclic complex $[Ni_2L3](CF_3SO_3)_2$. It is quite common for macrocyclic complexes to exhibit more reversible redox behaviour than acyclic analogues [13].

4. Conclusions

A series of dinuclear complexes incorporating a single bridging-thiolate donor have been prepared and characterised. Interestingly the redox potentials observed for the soluble dinickel(II) complexes **4** and **6**, do not simply fall in between those observed for the dinickel(II) complexes containing either none or two such bridging-thiolate donors. Complexes **4** and **5** are interesting first generation structural models for the [Ni–Fe] hydrogenases as they incorporate bridging thiolate sulfur and oxygen donors between two transition metal ions as is thought to be the case in the oxidised inactive forms of this enzyme. More importantly, they are uncommon examples of complexes in which the nickel ions have adopted two different geometries (and indeed spin states in the case of 4) despite the fact that the ligand provided potentially equivalent binding sites. Finally, complex **5** is a rare example of a high-spin square-pyramidal thiolate-coordinated nickel(II) ion [29]. These results illustrate the ability of macrocyclic ligands to provide unusual donor environments to the incorporated metal ions, resulting in complexes with intriguing structures and/or properties [30].

5. Supplementary material

Atomic coordinates, thermal parameters, and bond lengths and angles have been deposited at the Cambridge Crystallographic Data Centre, CCDC No. 137369. See Instructions for Authors, Polyhedron, 2000, Issue 1. Any request to the CCDC for this material should quote the full literature citation and the deposition number. Abstract

In this paper we report the synthesis of three new complexes of Zn(II) and Co(III) with two ligands, methyl pyruvate thiosemicarbazone (Hmpt) and α-ketoglutaric acid thiosemicarbazone (H_3ct). The three compounds [Zn(H_2pt)(Hpt)Cl] (**A**), [Zn(H_2ct)$_2$]·H_2O (**B**), [Co(H_2ct)(Hct)]·H_2O (**C**), are characterized by IR spectroscopic techniques and the structures determined by single-crystal X-ray diffraction analysis. In **A** an interesting feature is the different behavior of the two ligand molecules, one terdentate and the other monodentate. The coordination geometry about zinc is better described as intermediate between an ideal square pyramid and trigonal bipyramid, while in **B** and **C** the metals are six-coordinated in a distorted octahedral geometry. All compounds are monomeric. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Zinc complexes; Cobalt complex; α-Ketoglutaric acid; Thiosemicarbazones; Crystal structures; Spectroscopic properties

1. Introduction

Recently we described the synthesis, the spectroscopic characterization and X-ray structural analysis of some zinc and cobalt complexes with mono- and bisthiosemicarbazones [1,2], with the aim to understand the correlation between structural features and the biological properties of these classes of compounds [3], under different experimental conditions. Continuing this program of research we have synthesized a new complex [Zn(H_2pt)(Hpt)Cl] (**A**) starting from $ZnCl_2$ and the ligand Hmpt (Hmpt = methylpyruvate thiosemicarbazone) [4]. Upon preparative conditions, in alcoholic medium, Hmpt is converted to its hydrolyzed form (H_2pt). An interesting result of the present study is the different behavior of the two ligand molecules, the first terdentate, the second unusually monodentate through the sulfur atom. In the course of our investigation this latter coordinating behavior has only been found in two copper(I) complexes [5,6]. The aliphatic nature of the Hmpt ligand gives unsatisfactory biological results due to poor solubility in biological solvents and therefore a different aliphatic thiosemicarbazone, the α-ketoglutaric acid (H_3ct) derivative has also been synthesized. This ligand presents more potential donor atoms and a variety of potential conformations; its complexes with zinc [Zn(H_2ct)$_2$]·H_2O (**B**) and cobalt [Co(H_2ct)(Hct)]·H_2O (**C**) have been synthesized and characterized with the aim to elucidate the correlation between the structure and the induced differentiation by these compounds in Friend erythroleukemia cells (FLC).

2. Experimental

2.1. Synthesis of ligands and complexes

The preparation of the ligand Hmpt·0.5H_2O was the same as previously described [4].

The ligand H_3ct (α-ketoglutaric acid thiosemicarbazone) was prepared according to a procedure previously reported [7] and achieved as transparent crystals (m.p. = 184.8°C). Found: C, 33.01; H, 4.17; N, 18.86; S, 14.90. $C_6H_9N_3O_4S$ requires: C, 32.87; H, 4.14; N, 19.17; S, 14.63%.

2.1.1. [Zn(H$_2$pt)(Hpt)Cl] (A)

A batch of 0.25 g (1.83 mmol) of anhydrous $ZnCl_2$ was added with stirring to an absolute ethanol solution (30 ml) of 0.34 g (1.83 mmol) of Hmpt·0.5H_2O. After 60 min of stirring at room temperature (r.t.) the clear solution (ca. pH 5) was allowed to stand. Pale yellow crystals of the product **A** were grown by slow evaporation of the solvent. Analytical data and complete structural determinations showed that the ligand (in its hydrolyzed form) to metal ratio in the product was 2:1. Found: C, 22.64; H, 3.76; N, 19.96, S, 15.22. $C_8H_{13}ClN_6O_4S_2Zn$ requires: C, 22.76; H, 3.10; N, 19.91; S, 15.19%.

We have observed that the nature of the product obtained by this procedure depends on the amount of water involved in the synthesis. Molecules of water were present in the medium because we employed an undryed appreciably hygroscopic organic solvent (EtOH abs.), a deliquescent inorganic salt and a hemihydrate ligand. Upon these conditions the reaction proceeds through different new ligand forms as a function of temperature and these new ligands are converted into products of different nature. The driving force of the reaction is the formation of the most stable product. At 'high' temperature Hept (ethyl pyruvate thiosemicarbazone) is formed by transesterification of the ligand precursor Hmpt·0.5H_2O, at r.t. the ligand Hmpt is hydrolyzed into H_2pt (pyruvic acid thiosemicarbazone). So this reaction, sensitive to a change in temperature and in the amount of water present, can be used to generate zinc complexes containing different ligands. Alternatively compound **A** was obtained by reaction of $ZnCl_2$ with Hmpt·0.5H_2O in a 1:1 molar ratio, in MeOH at reflux for 2 h (pH of resulting solution 5–6), as confirmed by analytical and spectroscopic data.

2.1.2. Preparations of [Zn(H$_2$ct)$_2$]·H$_2$O (B) and [Co(H$_2$ct)(Hct)]·H$_2$O (C)

A solution of $ZnCl_2$ (0.1 g) in 20 ml of water was added to a warm aqueous solution (20 ml) of H_3ct (ratio metal:H_3ct = 2:1) and then stirred for 5 min. The resulting clear solution (ca. pH 1) was allowed to stand at r.t. and after evaporation gave pale yellow crystals of **B** (m.p. = 247.6°C). Found: C, 28.01; H, 4.02; N, 16.20; S, 12.39. $C_{12}H_{18}N_6O_9S_2Zn$ requires: C, 27.73; H, 3.49; N, 16.17; S. 12.33%.

The complex [Co(H_2ct)(Hct)]·H_2O (**C**) was similarly obtained as deep brown crystals by aerobic oxidation of the starting material, $CoCl_2·6H_2O$ in refluxing aqueous solution for 1 h (pH 2) (m.p. = 260.4°C). Found: C, 28.42; H, 3.54; N, 16.14; S, 12.65. $C_{12}H_{17}N_6O_9S_2Co$ requires: C, 28.13; H, 3.34; N, 16.40; S, 12.52%.

Compound **B** was also obtained as a crystalline product by evaporation of (i) an aqueous solution (pH 3) and (ii) an EtOH (abs.) solution (pH 1) containing the reactant in an equimolar amount previously refluxed for 30 min. Despite the ratio employed upon the experimental conditions described above, these reactions gave only monometallic compounds containing two independent ligand molecules.

2.2. Physical measurements

The FT IR spectra were recorded on a Nicolet 5PC spectrophotometer in the frequency range 4000–400 cm^{-1} using KBr discs. Microanalyses (C, H, N and S) were made on Carlo Erba instruments CHNS-O EA 1108 automatic equipment.

2.3. X-ray structure determination

The crystal and instrumental parameters used in the unit-cell determination and data collection are summarized in Table 1. All intensity data were collected on a CAD4 diffractometer for **A**, on a Siemens AED for **B** and on a Philips for **C** by the θ–2θ technique. The structures were solved by the heavy-atom technique starting from a three-dimensional Patterson analysis for compounds **A** and **C**, and by direct methods for **B** using the SHELX-86 [8] programs. For all compounds successive Fourier syntheses gave coordinates of non-hydrogen atoms which were refined by full-matrix least-squares with anisotropic thermal parameters for compounds **B** and **C**. In compound **A** however, the carbon atoms were isotropically refined. Hydrogen atoms were located from a ΔF map and introduced in the last refinement cycles for **B** and **C**, while for **A** were partly located and partly (methyl groups) calculated at their geometrical positions and maintained as fixed contributors in the last calculation. The hydrogen atoms of the carboxylic groups O(4)–C(7)–O(3) in **A** and O(6)–C(6)–O(5) in **C** have not been located, but the interaction O(3)···N(6) = 2.58(3) Å and the distances C(7)–O(3) = 1.30(4) Å in **A** and C(6)–O(5) = 1.311(4) Å in **C** indicate O(3) and O(5), respectively, as hydroxylic moieties. The absorption correction was neglected in **A** and **C** in view of small crystal dimensions. In **A** a correction for secondary extinction [9] was applied owing to an unsuccessful absorption correction. In compound **B** the absorption correction was applied following the method of Walker and Stuart [10]. The final atomic coordinates are given as supplementary material (see Section 4). Atomic scattering factors were taken from Ref. [11]. All calculations were performed on a Gould 6440 Powernode computer of the Centro di

3. Results and discussion

3.1. Description of the structure

The structure of **A** is shown in Fig. 1 and consists of discrete molecular units. Although the metal can be formally described as having a square-pyramidal coordination, the distortion around the zinc center gives it a structure intermediate between the five-coordinated extremes of an ideal square pyramid and a trigonal bipyramid [15]. An interesting result of the present study is the different behavior of the two ligand molecules, the first terdentate via the S,N (iminic) and O (carboxylic) donor atoms as earlier found in [Zn(Hpt)$_2$], [Zn(Hept)Cl$_2$] (Hept = ethyl pyruvate thiosemicarbazone) [1] and in other Mn(II), Zn(II), Co(III) and Cu(II) complexes [1,2,4,16], the second unusually monodentate through the sulfur atom. This latter coordinating behavior has been found in the course of our investigations only in two copper(I) complexes with Hmpt and H_2mpipt (methyl pyruvate-hydrazinopyruvoylthiosemicarbazone) [5,6]. The terdentate ligand shows a Z configuration about the C(1)–N(2) bond and the carboxylate oxygen *cis* to N(3), while the monodentate molecule shows an E configuration about C(5)–N(5) bond as the free ligand and the carboxylic oxygen O(3) *cis* to N(6).

In the copper(I) compounds however, the ligand shows different configurations [5,6]. The versatility of this ligand, involving the change of its configuration, suggests that different factors, such as electronic effects, play essential roles in determining the formation of the metal complexes and their related biological properties. Experiments concerning the biological activity (as erythroid differentiation, cell proliferation, potential antiviral action) have been undertaken, but the poor solubility of the complexes with Hmpt causes some difficulties in the reproducibility of the experimental data.

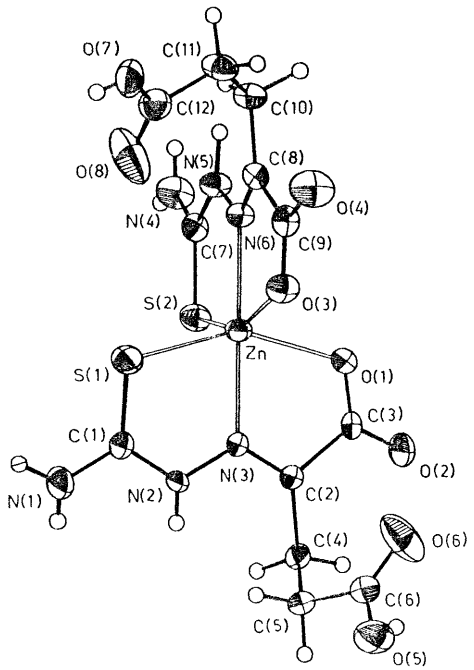

Fig. 2. ORTEP drawing of **B** with thermal ellipsoids at 50% probability level.

In solution and in the presence of metal ions the ligand may exist in equilibrium with the two thione and thiol tautomeric forms. In the solid state the terdentate exists in the thione form, while the monodentate one is in the thiol form (see Table 2).

The thione ligand is singly deprotonated but the thiol molecule is neutral and its iminic nitrogen forms an intramolecular hydrogen bond with the O(1) oxygen coordinated to zinc (Fig. 1). The thiol ligand is bound more tightly to the zinc ion than the thione chelate (Zn–S(2) = 2.368(7), Zn–S(1) = 2.476(8) Å).

The terdentate molecule is nearly planar, the largest deviation from the best plane being for the terminal O(2), probably due to the hydrogen bond with N(1) (N(1)–H(11)···O(2) = 2.71(3) Å). The monodentate ligand deviates considerably from planarity. In fact the thiosemicarbazide moiety and the pyruvic group are planar, but the dihedral angle between them is 11.4(7)°.

The zinc **B** and cobalt **C** complexes with H_3ct are monomeric and the metal coordination in both cases is distorted octahedral with two terdentate ligands (Figs. 2 and 3).

In the zinc complex both ligands are monodeprotonated, while in the cobalt complex one of the ligands is mono and the second is bideprotonated, in accordance with the oxidation state III for cobalt. In both compounds the two ligands are in the meridional configuration (S and O atom *cis* to each other and the N atoms *trans*) as found in other octahedral cobalt and zinc complexes [1,2,17].

A crystallization water molecule is present in both compounds and even if the environment of the metal is

very similar they are not isostructural. The charge and radium of the cations and the ligands different charge delocalization probably change the electronic and steric situation and therefore the packing.

In the Zn complex, **B**, the two ligands, both monodeprotonated, are in the thione form (S(1)–C(1) = 1.690(3), S(2)–C(7) = 1.683(3) Å, Table 3) and not planar even though the thiourea moiety and the carboxylic group are planar as previously found in other similar compounds [3]. The dihedral angles between them are 11.6(1) and 6.8(1)°, respectively, for S(1)– and S(2)-molecules.

The oxidation state three of cobalt is shown by its coordination bond lengths Co–S, Co–N and Co–O (Table 4) which are in the expected ranges of 2.201–2.230, 1.891–1.901 and 1.945–1.968 Å, respectively, as already noted for several Co(III) complexes [2,17]. The loss of the proton originally bound to N(5) produces a negative charge which is delocalized in the N6–N5–C7 system as indicated by the bond distances and in particular S(2)–C(7) = 1.744(3) Å and C(7)–N(5) = 1.326(4) Å. The other ligand not deprotonated on N(2), is in the thione form [S(1)–C(1) = 1.711(3), C(1)–N(2) = 1.357(4) Å]. The dihedral angles between the thiourea moiety and the carboxylic group are 1.6(1) (thione) and 9.6(1)° (thiol), respectively.

The $–CH_2–CH_2–COOH$ groups adopt different conformation (C(6) and C(12) are synclinal in **B**, and antiperiplanar in **C** with regard to C(2) and C(8), respectively) as shown by the torsion angles (C(2)–C(4)–C(5)–C(6) = −63.6(3), −169.7(3); C(8)–C(10)–C(11)–C(12) = −46.3(4), −165.1(3)°). These conformations are probably adopted in order to form intermolecular hydrogen bonds.

The large steric constraints in the two five-membered chelate rings distort the coordination to metal in complex **B** much more than that in complex **C**, probably as a consequence of the large size of the Zn(II) cation with respect to Co(III). In fact N(3)–Zn–N(6) = 167.6(1)°; N(3)–Co–N(6) = 177.9(1)°, S(1)–Zn–O(1) = 150.1(1)°; S(1)–Co–O(1) = 170.5(1)°; S(2)–Zn–O(3) = 152.7(1)°, S(2)–Co–O(3) = 170.2(1)°. The dihedral angle between Zn–S(1)–N(3)–O(1) and Zn–S(2)–N(6)–O(3) planes is 82.8(1)°, while the corresponding angle in the Co complex is 90°. This easy deformation of the geometry of the ligands in the coordination sphere to the Zn atom seems to be connected with a structural or a catalytic role of the metal.

In **A** the packing interactions are very important. Chains of molecules determined by hydrogen bonds N(1)–H(11)···O(2) $(x-1/2,\ 1/2-y,\ 1/2+z)$ = 2.71(3) Å are joined together with N–H···Cl bonds (N(1)–H(21)···Cl $(1/2-x,\ 1/2+y,\ 1/2-z)$, N(2)–H(2)···Cl $((1/2-x,\ 1/2+y,\ 1/2-z))$ to form ribbons parallel to (2 0 2) planes. These ribbons are linked by N(4)–H(42)···O(4) $(x-1/2,\ -y-1/2,\ 1/2+z)$ bonds.

In **B** and **C** the packing is determined essentially by hydrogen bonds between nitrogens of amine groups, the carboxylate oxygen atoms and the water molecules which have different neighbors in the two compounds.

A comparison of the structures of the complexes with both ligands, Hmpt and H_3ct, and those of similar zinc and cobalt compounds, suggests the following considerations: (a) a greater variation in the bonding geometry of the zinc complexes is observed; (b) both ligands have aliphatic properties, but the complexes with H_3ct are more soluble in biological solvents; (c) both ligands yield complexes with different stoichiometry depending on the inorganic ion or on the ligand whether it is in a neutral or monoanionic form.

The correlation between structural analysis and biological activity (induced differentiation in FLC, assay carried out as previously reported in Refs. [18,19]) shows that the studied complexes with H_3ct do not have biological activity, probably due to the complete octahedral coordination sphere and the presence of polar acid groups which could prevent transfer through the cellular membrane.

However the action mechanism of these molecules will have to be clarified.

3.2. IR spectra

As reported in the experimental, the ligand molecule Hmpt·0.5H_2O upon preparative conditions hydrolyzed in its derivative H_2pt (pyruvic acid thiosemicarbazone) still containing SNO potential coordinating sites. The ligands H_2pt and H_3ct differ from each other only by the groups (–CH_3 or –$(CH_2)_2$–COOH, respectively) bonded to the imminic carbon atom of the thiosemicarbazone moiety. Consequently the IR spectra of their metal complexes namely **A**, **B** and **C**, exhibit some similarities and distinct differences. In particular significant spectra differences are observed for the octahedral neutral metal chelates of H_3ct, despite their structural analogies and similar molecular formula [Zn(H_2ct)$_2$]·H_2O and [Co(H_2ct)(Hct)]·H_2O. On the contrary, **A** and **B**, the zinc complexes of H_2pt and H_3ct, respectively, which have different coordination numbers, produce similar features in their spectra. This can be explained in terms of electronic and steric effects. The zinc compounds that contain a d^{10} metal center, do not feel the ligand field stabilization effects so their spectral features are a result of steric forces between parts of the molecules. On the contrary, in the Co(III) complex with a geometric structure imposed by ligand field requirements, are most important the electronic effects.

On the basis of the above observations we assigned the selected bands present in the infrared spectra of compounds (reported in Table 5) in agreement with the X-ray structural data.

Strong broad structured bands spanning from 3700–2600 cm^{-1} which appear in the spectra of all compounds are due to νOH, νNH and νCH stretching vibrations. The three medium–strong intensity bands at around 3366, 3280 and 3169 cm^{-1} in the spectra of H_3ct, **B** and **C** are assigned to $\nu_{as}NH_2$, ν_sNH_2 and νNH, respectively. These bands are overlapped with the broad lattice water bands (compounds **B** and **C**) and are superimposed upon the broader more intense O–H stretching absorption typical of the carboxylic acid functions. For complex [Zn(H_2pt)(Hpt)Cl] (**A**), the $\nu_{as}NH_2$ modes give rise to a band with maximum intensity at 3400 cm^{-1}. Its position is shifted by 34 cm^{-1} toward higher frequencies with respect to those previously observed at ca. 3366 cm^{-1} for H_3ct **B** and **C**. Such a shift can be interpreted as being due to the presence of a coordinated chloride anion. Moreover the new νNH band observed at 3131 cm^{-1} may be due to the effect of simultaneous interactions of the NH group of the monodentate ligand with the neighboring $–COO^-$ and C=S coordinated groups. A comparison of the bands present in the 1720–1630 cm^{-1} region of the

spectrum of [Zn(H_2pt)(Hpt)Cl] with those observed for [Zn(Hpt)$_2$] [1] and {[Cu(Hpt)Cl]·2H_2O}$_n$ [4] can provide information about the different situation (free or coordinated) of the carboxylic groups. The C=O bands of compound **A** at 1651 (s) and 1636 (vs) cm^{-1} are attributed to the stretching modes of the coordinate carboxylate groups as the *anti*monodentate terminal, while the other two, that show the same features, at 1708 (s) and 1667 (vs) cm^{-1} are indicative of an uncoordinated carboxylic group. On the basis of this observation attempts can be made to related values of carbon–oxygen stretching frequencies to the nature of the complexes **B** and **C** as reported in Table 5. In the zinc complexes and also in compound **B** the shifts of the C=O bands are most likely caused by the vibrational coupling of the C=O in the solid state H-bonded structure. This phenomenon is, at least in part, eliminated in the Co(III) complexes by the field effect of the charge delocalization due to the loss of the azomethyne hydrogen. The IR spectrum obtained by crystals of ligand H_3ct which present the same X-ray crystallographic data published in Ref. [20], indicates that H_3ct forms both intra- and intermolecular hydrogen bond networks. These are responsible for the positions of the bands corresponding to the modes which involve νNH_2 and νNH vibrations (found at lower frequencies with respect to those in the spectra of **B** and **C**) and probably cause the multiply-split bands due to the C=O stretching vibrations. The significant IR bands of $\nu_s(COO^-)$ and of those arising from interaction between C–O stretching and O–H bending of the carboxylic acid function appear in the range 1496–1241 cm^{-1}. Absorptions in the region 1616–1552 cm^{-1} are associated with carbon–nitrogen double bond stretching vibration. For the other compounds, the spectrum of complex **A** presents a strong doublet located between 1601 and 1552 cm^{-1} in agreement with the structural data. On coordination of complex **C** deprotonation of the imino-hydrogen of the ligand H_3ct occurs such that the strong bands associated with the ν(C=N) are observed at higher frequencies with respect to those of the free ligand and complex **B**. Strong bands corresponding to normal modes in which the stretching vibration of the C=S groups are involved, appeared in the range 1201–1172 cm^{-1} for all the compounds studied. Finally, other bands which contains ν(CS) character, indicative of the involvement of the sulfur atom in binding the metal coordination center, are found at lower frequencies.

4. Supplementary material

Supplementary data have been deposited with the Cambridge Crystallographic Data Center, deposition numbers CCDC 137145, 137146 and 137147 for compounds **A**, **B** and **C**, respectively. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

$[NiL(SeCN)_2(H_2O)]$ [L = bis(3-aminopropyl)amine (dpt), (**1**), (2-aminoethyl)(3-aminopropyl)amine (aepn), (**2**) and bis(2-aminoethyl)methylamine) (medien), (**3**)] have been synthesized and characterized in the solid state by X-ray single crystal analysis (**1** and **2**), IR, electronic spectra and magnetic measurement. Structure analyses of (**1**) and (**2**) reveal that the nickel(II) center is coordinated in a distorted octahedral fashion and the two SeCN groups are attached in *trans* position. Upon heating they undergo deaquation followed by color change, yielding dinuclear species bridging through selenocyanate. The deaquated dinuclear complexes have been characterized by IR, electronic spectra and magnetic susceptibility measurement. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Nickel(II)selenocyanate; Bis(3-aminopropyl)amine; (2-Aminoethyl)(3-aminopropyl)amine; Bis(2-aminoethyl)methylamine; Thermochromism

1. Introduction

Exploitation of thiocyanate anion as bridging ligand between nickel(II) centers has attracted much attention from chemists in recent years. A large number of dinuclear and polynuclear nickel(II) amine complexes with thiocyanate anion have been structurally and magnetically characterized [1–5]. Recently this laboratory also reported [6,7] a number of interesting thiocyanato bridged dinuclear and polynuclear complexes of nickel(II) with linear chain triamine ligand. In contrast, the number of selenocyanate bridged complexes of Ni(II) is negligible in the literature [8,9] as (i) destabilization of selenocynate anion separating selenium and (ii) the weak affinity of selenium towards nickel(II), though Vicente et al. [9] reported first structurally and magnetically characterized bis(μ-selenocyanate) nickel(II) dinuclear compound, $(\mu\text{-}SeCN)_2[Ni(medpt)(SeCN)_2]_2$ where medpt = *N*,*N*-bis(3-aminopropyl)methylamine. This led us to pursue the chemistry of nickel(II) selenocyanate with other linear chain triamines in search of complexes having bridging selenocyanate. Here we report the synthesis and characterization of $[NiL(SeCN)_2(H_2O)]$ and, $(\mu\text{-}SeCN)_2[NiL(SeCN)_2]_2$ (where L = bis(3-aminopropyl)amine (dpt), (2-aminoethyl)(3-aminopropyl)-amine (aepn), and bis(2-aminoethyl)methylamine) (medien), and X-ray single crystal structures of $[Ni(dpt)(SeCN)_2(H_2O)]$ and $[Ni(aepn)(SeCN)_2(H_2O)]$.

2. Experimental

2.1. Materials

High purity bis(3-aminopropyl)amine (dpt), (2-aminoethyl)(3-aminopropyl)amine (aepn), bis(2-aminoethyl)methylamine (medien) and potassium selenocyanate were purchased from Aldrich Chemical Company Inc. and used as received. All other chemicals were AR grade.

2.2. Physical measurement

Elemental analyses (carbon, hydrogen, nitrogen) were performed using Perkin–Elmer 240C elemental analyzer and Ni(II) content was estimated gravimetrically [10]. IR spectra (4000–400 cm^{-1}) were taken at 27°C using Nicolet Magna-IR 750 spectrometer series -II, electronic spectra (1600–200 nm) at 27°C using a Hitachi UV–VIS–NIR model U-3410 spectrometer where Nujol was used as medium as well as reference. The magnetic susceptibility was measured at 27°C using an EG and G PAR155 vibrating sample magnetometer, where $Hg[Co(SCN)_4]$ was used as a reference material and diamagnetic correction was made by using Pascal's constants. Molar conductance was measured using a systronics 304 conductivity meter where the cell constant was calibrated with 0.02 M KCl solution and dry methanol was used as solvent. The thermal analysis (TG-DTA) was carried out on a Shimadzu DT-30 thermal analyzer in dynamic atmosphere of dinitrogen (flow rate, 30 cm^3 min^{-1}). The sample particle size was within 150–200 mesh.

2.3. Preparation of the complexes

2.3.1. *[Ni(dpt)(SeCN)$_2$(H$_2$O)] (blue) (**1**), [Ni(aepn)(SeCN)$_2$(H$_2$O)] (violet) (**2**) and [Ni(medien)(SeCN)$_2$(H$_2$O)] (sky blue) (**3**)*

An aqueous solution (5 cm^3) of triamine (1 mmol) was added dropwise with constant stirring to an aqueous solution (10 cm^3) of $Ni(ClO_4)_2{\cdot}6H_2O$ (0.365 g, 1 mmol). KSeCN (0.288 g, 2 mmol) dissolved in water (5 cm^3) was added slowly to it with stirring. The resulting mixture after filtration was kept in a $CaCl_2$ desiccator. After a few days desired complexes were separated, washed with chilled water and dried in a $CaCl_2$ desiccator. Yield: 80%. (Found (**1**): C, 22.9; H, 4.3; N, 16.8; Ni, 14.1%, $\mu_{eff} = 3.16$ BM; λ_{max} (nm) (Nujol) 480, 820, 1520; IR spectrum (cm^{-1}) in KBr: 3348 br (νO–H, νNH_2); 2088 (νCN); 733 ($\rho_r H_2O$), 626 ($\rho_w H_2O$). 2.4. X-ray diffraction structural study

Single crystals suitable for X-ray analysis were obtained by recrystallization of **1** and **2** from water. A single crystal of complex **1** was mounted on a Rigaku/AFC 7 diffractometer, while the crystal of complex **2** was mounted on a Siemens P4 diffractometer. Lattice constants and orientation matrices were determined by least-squares refinement of the angular settings of 25 well-centred reflections. Crystal data collection and structure solution parameters for both the complexes are summarized in Table 1. Intensity data were collected using Mo Kα radiation ($\lambda = 0.7107$ Å) with ω–2θ scan mode for both the complexes. For both (**1**) and (**2**), the stability of crystals was measured during X-ray exposures by monitoring three standard reflections at a regular interval. The intensity data were corrected for Lorentz and Polarisation effects [11]. Both structures were solved by Patterson techniques followed by Fourier synthesis and refined through full matrix least-square calculations. Both the structures were analogous but the unsymmetrical molecule of complex **2** showed disorder about the twofold axis. As N3 atom of complex **2** occupied general position and the twofold axis passed through near N3 atom, both N3 and C4 showed symmetry imposed disorder. So their occupancy factors were taken as 0.5. Anisotropic refine-

ments were carried out for the non-hydrogen atoms. Hydrogen atoms on water oxygen were located from difference map for complex **1**, but were unsuccessful for complex **2**. The hydrogen atoms were introduced in the final structure-factor calculations at idealized position with fixed isotropic thermal parameters. Complex neutral atom scattering factors [12] were used throughout. All calculations were carried out using TEXSAN [13], PLATON-99 [14], and ZORTEP [15] programs for complex **1** and SHELXS-86 [16], SHELXL-93 [17], PLATON-99 [14] and ZORTEP [15] programs for complex **2**. Selected bond distances and bond angles are listed in Table 2.

3. Results and discussion

We obtained the complexes by having one molecule of water in case of other triamines, i.e. dpt, aepn and medien following the method of synthesis for (μ-SeCN)$_2$[Ni(medpt)(SeCN)$_2$]$_2$ (medpt = *N*,*N*-bis(3-aminopropyl)methylamine) adopted by Vicente et al. [9]. The IR-spectrum of the aquated species (**1**, **2** and **3**) shows broad band in the region 3200–3400 cm^{-1} (νOH, νNH$_2$) which is assumed to be due to the overlapping of νOH with νNH$_2$ band (Fig. 1). The presence of IR band ρ_r(H$_2$O) at ~800 cm^{-1} and ρ_w(H$_2$O) at ~645 cm^{-1} [18] suggests that the water molecule is coordinated to nickel(II). The complexes also exhibit IR bands (νCH$_2$, δNH$_2$, δCH$_2$) comparable to analogous system whose chelate character has been authenticated by X-ray single crystal structure analysis [6]. The single band for νCN at ~2100 cm^{-1} (Fig. 1) suggests that two SeCN groups are linked to Ni(II) in *trans* position [18]. The conductance datum shows that the complexes are nonelectrolyte. Above facts suggest that all aquated species are mononuclear and the nickel(II) is surrounded by one tridentate amine, two isoselenocyanate groups and one molecule of water having N$_5$O chromophore. The magnetic susceptibility and electronic spectral data are in good agreement with the octahedral geometry around nickel(II). It is to note that the slight difference in color amongst the aquated species reflected in electronic spectral band position has arisen due to the difference in the ligand field strength of the respective triamine.

*3.1. Molecular structures of [Ni(dpt)(SeCN)$_2$(H$_2$O)] (**1**) and [Ni(aepn)(SeCN)$_2$(H$_2$O)] (**2**)*

The structural analyses of **1** and **2** reveal that both the crystal structures consist of discrete mononuclear molecules. Crystal lattices are having same space group and almost same parameters. The only difference between them is the chain length of the triamine ligand. Molecular structure of the two complexes are similar and the ZORTEP diagrams are shown in Figs. 3 and 4. The selected bond distances and angles are tabulated in Table 2.

In both the complexes the coordination polyhedra around the metal centres are best described as distorted octahedron with N_5O chromophore. The distortion from ideal octahedral geometry is due to assymetric nature of the binding ligand and the deviations of the refine angles formed at the metal centres (Table 2) from 90°. Four nitrogen atoms (N1, N1*, N2, N2*) define as equatorial plane and the remaining one nitrogen atom (N3) and one oxygen atom (O) are in axial positions. The two SeCN ligands are *trans* to each other. Ni–N distances are in the range [2.065(5)–2.127(10) Å] which are consistent with corresponding values of analogous octahedrally coordinated nickel (II) complexes [6,7]. The bond angles between terminal nitrogen atoms (N2–Ni–N2*) are 172.3(3) and 174.69(17)° for complexes **1** and **2**, respectively. The angles between secondary nitrogen atom and aqua O-atom are 180.0(8)° for (**1**) and 168.4 (2)° for (**2**). The corresponding angles N1–Ni–N1* are 179.84(14)° for (**1**) and 179.0(3)° for (**2**). The mean plane of the four equatorial atoms passes through the Ni atom. The maximum deviations of Ni atom from the mean planes passed through four equatorial N atoms are 0.069 Å for (**1**) and 0.038 Å for (**2**). Thus the structural analyses corroborate the geometry proposed based on physicochemical studies.

The aquated species (**1**, **2** and **3**) upon careful (to inhibit selenium separation) heating undergo deaquation in the temperature range ~100–150°C (Fig. 2) and transform to respective deaquated species (**1a**, **2a** and **3a**) with visual color change. The deaquation temperature ranges also corroborate the presence of coordinated water molecule (vide infra). The deaquated species are stable in humid atmosphere (90% RH) but they revert on crystallization from boiling water. IR spectra show (i) the absence of bands responsible for water moiety; (ii) well resolved νNH_2 band; and (iii) the splitting of νCN band into two sharp peaks (Fig. 1). It is interesting to note that the IR spectral profile has unique resemblance to (μ-SeCN)$_2$[Ni(medpt)(SeCN)$_2$]$_2$ [9] (Fig. 1). The electronic spectral band position shifts also slightly corroborating the respective color of the deaquated species. We have calculated ratio ν_2/ν_1 (where ν_1 is assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$ and the second main peak ν_2 to $^3A_{2g} \rightarrow {}^3T_{1g}$) bands which are found to

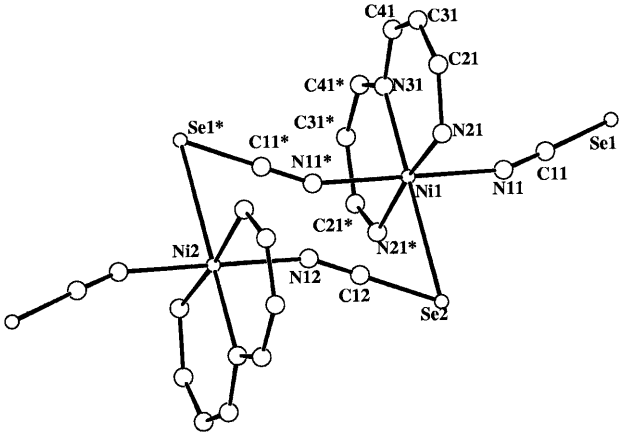

Fig. 5. Proposed ball and stick diagram of $(\mu\text{-SeCN})_2$-$[Ni(dpt)(SeCN)_2]_2$ (**1a**) (model structure is achieved after translating one of the two closest monomers in the unit cell of $[Ni(dpt)(SeCN)_2(H_2O)]$ (**1**) by -0.43, -0.59 and -0.33 (fractional) and keeping other monomer fixed).

be 1.77 (**1a**), 1.76 (**2a**) and 1.73 (**3a**) suggesting octahedral geometry [19] in them rather than penta coordinated species, if at all generated after deaquation. The magnetic susceptibility values also corroborate it. In order to satisfy the proposed geometry one of the SeCN groups must bridge the two nickel(II) centers resulting dinuclear species in them. We tried to prepare their single crystals but ultimately failed as they are not soluble in suitable solvents. As a result we propose the structure suggested by Vicente et al. [9] for the corresponding medpt complex. This tell us that the triamine, medpt in reaction with nickel(II) selenocyanate creates an unique environment which activates Se coordination which is rare in the literature. Whereas in the case of the other three triamines, Se coordination does not take place in aquated species but after withdrawal of the water moiety from the coordination sphere the environment suits Se coordination to nickel(II). The proposed model structure of dinuclear compound formed after deaquation is shown in Fig. 5.

4. Supplementary data

Supplementary data have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 141092 and 141093. Abstract

Copper complexes based on the $[Cu_2(bpbp)]^{3+}$ core (bpbp$^-$ = 2,6-bis((*N*,*N*′-bis-(2-picolyl)amino)methyl)-4-tertbutylphenolate) containing methoxide or water ancillary ligands, $[Cu_2(bpbp)(OCH_3)](ClO_4)_2$ (**1**), $[Cu_2(bpbp)(OH_2)_2](ClO_4)_3$ (**2**) and $Cu_2(bpbpH)(OH_2)_4(ClO_4)_4$ (**3**), were isolated from methanol–water solutions above pH 3, between pH 2–3, and below pH 2, respectively. ESR and magnetochemistry reveal that the copper ions are antiferromagnetically ($J = -156$ cm^{-1}) and weakly ferromagnetically ($J = +5.3$ cm^{-1}) coupled in the doubly-bridged **1** and its singly-bridged pseudo acid congener **2**, respectively. They are uncoupled in **3**, consistent with each copper atom being bound only by an amine and two pyridine donors of bpbpH and oxygen donors of water and/or perchlorate. Thus the phenol residue of the dinucleating ligand is protonated and uncoordinated. Further, the ESR spectra show that complexes **1**, **2** and **3** retain their integrity in solution. ESI mass spectra demonstrate that, as expected, the cations are labile in solution. However, the patterns that emerge support the formulations; numerous ions containing the $[Cu_2(bpbp)]^{3+}$ core plus water, hydroxide and methoxide ligands are observed. The intensities of the more protonated species increase in the spectra going from complex **1** to **3**. The only complex to give a molecular ion for the intact cation was **1**, and only from methanol solutions. However, the dominant ion observed in the mass spectra of **1** is $[Cu_2(bpbp)(OH)]^{2+}$ from all solvents tried. Thus in solution, the methoxide complex, **1**, is in equilibrium with the isoelectronic hydroxide complex, $[Cu_2(bpbp)(OH)](ClO_4)_2$, with the latter favored. Complex **1** was used to provide a labile preformed core for bridge replacement reactions, and the acetate and pyrazolate complexes, $[Cu_2(bpbp)(CH_3CO_2)](ClO_4)_2$ (**4**) and $[Cu_2(bpbp)(C_3H_3N_2)](ClO_4)_2$ (**5**), were prepared in this manner. © 2000 Elsevier Science Ltd. Keywords: Dicopper complexes; Solvent-derived ancillary ligands; Acid–base congeners

1. Introduction

Metal-solvent species are often proposed as labile intermediates in the reaction cycles of enzymes and catalysts, since solvent (usually water)-derived ligands can be replaced easily by incoming substrates. Water-derived species can also be reactants: coordinated hydroxide ligands are often proposed to be the nucleophilic hydroxides in hydrolytic enzymatic processes, e.g. in carbonic hydratase. The solid state characterisation of simple coordination compounds incorporating these motifs, i.e. weak solvent or hydroxide ligands, can be difficult due to (i) their lability; (ii) a necessity for extensive lattice water of crystallisation or (iii) their propensity for polymerisation reactions or carbonate formation. Dimetallic activation of substrates is a particular fascinating area and mechanisms for the dinuclear catalysis of hydrolysis reactions have been proposed for both enzymes and coordination complexes. For example, dipalladium systems are capable of high turnover catalysis in nitrile hydration reactions [1]. The crucial intermediate containing the

PII: S0277-5387(00)00482-4

hydroxide nucleophile was proposed to contain the M–(HOH···OH)–M motif; however, this intermediate could not be isolated. This structural motif has now been crystallographically characterised in several dinuclear complexes [2], two of which promote hydrolysis reactions [2a,b]. Species containing this motif and related dimetallic/solvent motifs are likely to be relevant to dinuclear hydrolysis enzymes like phosphatases and urease in which two metal ions are within 4 Å of each other [3].

A study of the copper complexes of the acyclic phenolate-hinged dinucleating ligand 2,6-bis[(bis-(2-pyridylmethyl)amino)methyl]-4-tertbutylphenolato-(1−) (bpbp$^-$) [4] is described here, for which compounds with solvent ligands bound at the exogenous, potentially dimetallic, site have been isolated. Dicopper complexes of related dinucleating alkoxo- and phenoxo-hinged ligands containing exogenous oxo-acid bridging groups supporting the dimetallic structures are well-known. Complexes with solvent species are much rarer.

2. Experimental

IR spectra were measured as KBr discs using a Hitachi 270-30 IR spectrometer.

Electrospray ionization mass spectra (ESIMS) were obtained using a Finnigan TSQ 700 triple quadrupole instrument equipped with a Finnigan API source in the nanoelectrospray mode. Electron spin resonance (ESR) measurements at X-band frequency were obtained using a Bruker ESP-380E FT-EPR spectrometer. Elemental analyses were carried out at the microanalytical laboratory of the H.C. Ørsted Institute, Copenhagen. 2,6-Bis[(bis-(2-pyridylmethyl)amino)methyl]-4-tertbutylphenol (bpbpH) was prepared as described previously [4].

CAUTION! Although no problems were encountered in the preparation of the perchlorate salt, suitable care should be taken when handling such potentially hazardous compounds.

2.1. $[Cu_2(bpbp)(OCH_3)](ClO_4)_2$ (1)

$Cu(ClO_4)_2{\cdot}6H_2O$ (0.3639 g, 0.98 mmol) dissolved in methanol (5 ml) was added to bpbpH (0.2813 g, 0.49 mmol) dissolved in methanol (10 ml) to give a green–brown solution (pH 2). A suspension of $(NH_4)_2CO_3$ (0.102 g, 1.1 mmol) in methanol (15 ml) was added dropwise to give clear dark green solution (pH ~ 7). The mixture was filtered and dark green crystals of the title compound deposited. Yield 0.368 g (81%). Found: C, 46.71; H, 4.69; N, 8.71. *Anal.* Calc. for $C_{37}H_{42}N_6O_{10}Cl_2Cu_2{\cdot}0.72H_2O$: C, 46.94; H, 4.68; N, 8.88%.

2.2. $[Cu_2(bpbp)(H_2O)_2](ClO_4)_3{\cdot}H_2O$ (2)

$[Cu_2(bpbp)(OMe)](ClO_4)_2$ (31.7 mg, 0.0334 mmol) was dissolved in a warm water–acetone mixture (1:1, 5 ml). One drop of concentrated perchloric acid (0.02 g, 0.2 mmol) was added to give a brown solution (pH ≈ 2). On standing in an open vessel, long thin brown needles of the product were deposited. Yield 67%. Found: C, 41.23; H, 4.30; N, 7.79; Cl, 10.38. *Anal.* Calc. for $C_{36}H_{45}Cl_3Cu_2N_6O_{16}$: C, 41.13; H, 4.31; N, 7,99; Cl, 10.12%.

2.3. $Cu_2(bpbpH)(OH_2)_4(ClO_4)_4$ (3)

$[Cu_2(bpbp)(OMe)](ClO_4)_2$ (21.1 mg, 0.0223 mmol) was dissolved in 4 ml of warm acetone. Two drops of concentrated perchloric acid (0.04 g, 0.4 mmol) were added to give a blue solution (pH ≈ 1). On standing in an open vessel, blue crystals of the product were deposited. Yield 43%. Found: C, 36.80; H, 4.35; N, 7.19; Cl, 14.03. *Anal.* Calc. for $C_{36}H_{49}Cl_4Cu_2N_6O_{21}$: C, 36.93; H, 4.22; N, 7.18; Cl, 12.11%.

2.4. $[Cu_2(bpbp)(CH_3CO_2)](ClO_4)_2$ (4)

A solution of sodium acetate (87.7 mg, 1.07 mmol) and a single drop of concentrated perchloric acid in 10 ml of methanol was added to a solution of $[Cu_2(bpbp)(OMe)](ClO_4)_2$ (26.7 mg, 0.0282 mmol) dissolved in 5 ml of warm methanol to give a green solution (pH ~ 6). On standing in an open vessel, olive green crystals of the product were deposited. These were collected and washed with water. Yield 73%. Found: C, 47.40; H, 4.53; N, 8.68; Cl, 7.48. *Anal.* Calc. for $C_{38}H_{42}Cl_2Cu_2N_6O_{11}$: C, 47.70; H, 4.42; N, 8.77; Cl, 7.41%.

2.5. $[Cu_2(bpbp)(C_3H_3N_2)](ClO_4)_2$ (5)

Pyrazole (0.901 g, 13.43 mmol) was added to a suspension of $[Cu_2(bpbp)(OMe)](ClO_4)_2$ (68.7 mg, 0.0726 mmol) in methanol (20 ml). The solution became clear dark green on heating. On standing in an open vessel, olive green crystals of the product were deposited. These were collected and washed with methanol. Yield 48%. Found: C, 48.47; H, 4.41; N, 11.64; Cl, 7.48. *Anal.* Calc. for $C_{39}H_{42}Cl_2Cu_2N_8O_9$: C, 48.55; H, 4.39; N, 11.61; Cl, 7.35%.

2.6. X-ray crystal structure determination

The structure of **1** was determined with data measured at 120 K using an area detector [5], data were processed using SAINT [5] and XPREP [5]. Absorption corrections were made by integration using XPREP [5]. The structure was determined using SIR97 [6] and

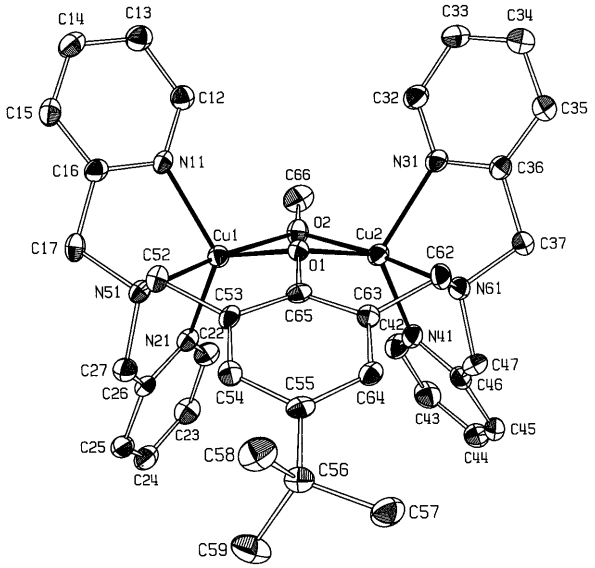
refined using the local modification of ORFLS [7] in the KRYSTAL [8] package. Non-hydrogen atoms were refined with anisotropic displacement parameters, hydrogen atoms of the ligands were kept fixed in calculated positions (C–H = 0.95 Å) and given isotropic displacement parameters 20% larger than those of the atoms to which they were attached. There were two waters of crystallization, one of the sites being only partially occupied, the hydrogen atoms for these were not included in the calculations. Atomic scattering factors were taken from Ref. [9]. Crystal data and details of the structure determinations are given in Table 1.

2.7. Magnetochemistry

A Quantum design MPMS5 Squid magnetometer was used to obtain magnetic susceptibility in a field of 1 T. Samples of mass ca. 20 mg were contained in a calibrated gelatine capsule, which was held in the centre of a plastic drinking straw fixed to the sample oval. The instrument was calibrated by use of a standard palladium sample supplied by Quantum Design Inc.



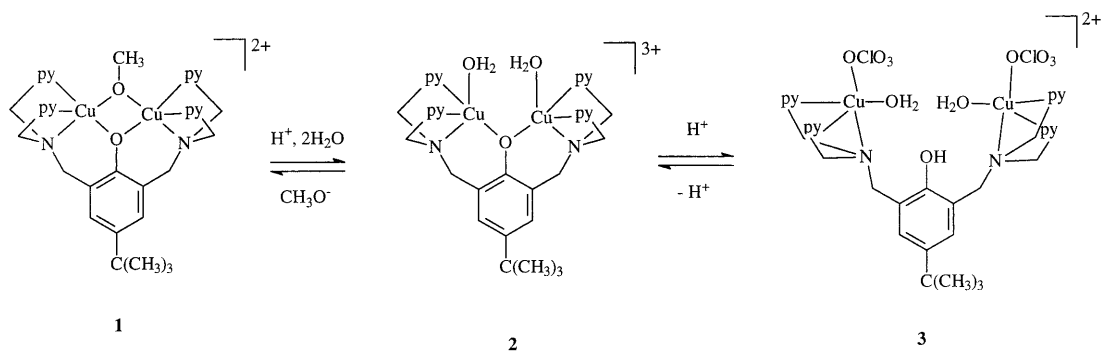


Fig. 1. Drawing of $[Cu_2(bpbp)(CH_3O)]^{2+}$ (**1**) showing the atom numbering scheme, thermal ellipsoids are drawn at the 50% probability level.

3. Results and discussion

The reaction of bpbpH with two equivalents of copper perchlorate in a methanol–water solvent system was investigated over a range of acid strengths, and three different crystalline dicopper complexes were recovered (Scheme 1). The green crystalline compound isolated above pH 3 is the methoxide complex, $[Cu_2(bpbp)(OCH_3)](ClO_4)_2$ (**1**), which is structurally analogous to $[Cu_2(bmbp)(OCH_3)](ClO_4)_2$ (bmbp$^-$ = 2,6-bis[(bis-(2-pyridylmethyl)amino)methyl]-4-methylphenolato(1−) [10]. The X-ray crystal structure of **1** is shown in Fig. 1. Selected distances and angles are shown in Table 2. The geometry about the copper atoms is trigonal bipyramidal, with the methoxide O atom and amine N atoms and each Cu atom defining the threefold axes; O2–Cu1–N51 = 172.2° and O2–Cu2–N61 = 172.9°. Cu–N distances are in the range 2.020(3)–2.089(3) Å, with the bonds to the amine N

Scheme 1.

atoms being the shorter than those to the pyridine N atoms, whereas they would normally be expected to be longer. Similarly the axial Cu–O(2) distances are about 0.1 Å shorter than the equatorial Cu–O(1) bonds. Attempts were made to obtain the hydroxide complex, $[Cu_2(bpbp)(OH)](ClO_4)_2$, which is isoelectronic with **1**, as a solid product. No solid compound could be isolated from aqueous solutions above pH 3 in the absence of methanol. At pH values between 2 and 3 a brown crystalline compound was isolated and formulated as the diaqua complex $[Cu_2(bpbp)(OH_2)_2](ClO_4)_3$ (**2**). This compound is the pseudo acid congener (protonation of the bridging methoxide and replacement by two terminal water ligands) of **1** (Scheme 1). Below pH 2 solutions are blue and a blue compound, formulated as $Cu_2(bpbpH)(OH_2)_4(ClO_4)_4$ (**3**), was obtained. It is proposed that the phenoxide hinge of the ligand is protonated and no longer coordinated to the copper atoms. The structure for the cation in **3** is depicted in Scheme 1 with a perchlorate and a water ligand on each copper ion. We believe this to be the most likely arrangement for the stoichiometry; however, this cannot be confirmed without a crystal structure analysis. Two terminal waters on each copper and uncoordinated perchlorate is a feasible alternative arrangement. However, the splitting of the perchlorate stretch in the IR spectrum of **3** compared with **1** and **2**, is consistent with the structural proposal in Scheme 1. Otherwise the IR spectra are of **1**, **2** and **3** are essentially indistinguishable. Also, ions in the ESI mass spectra provide circumstantial evidence for the presence of coordinated perchorates in **3**, since ions bearing two pechlorates were prevalent in the spectra of **3** and not in the spectra of **1** and **2**.

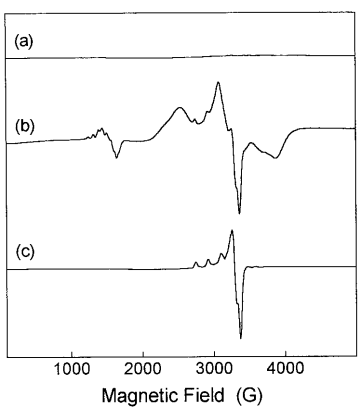

Fig. 2. The ESR spectra of (a) complex **1**; (b) complex **2**; (c) complex **3**, in a 9:1 methanol–water solution at 102 K.

Complex **1** was used to prepare 'bridge-substituted' products: the reaction of **1** with the acid forms of the potential 3-atom and 2-atom bridging groups, acetate and pyrazolate gave the compounds $[Cu_2(bpbp)(CH_3CO_2)](ClO_4)_2$ (**4**) and $[Cu_2(bpbp)(C_3H_3N_2)](ClO_4)_2$ (**5**). The methoxide/hydroxide leaving group is capable of deprotonating the incoming bridged ligands. This type of chemistry is well documented.

3.1. ESR and magnetic properties

ESR spectra and magnetic susceptibility measurements are consistent with the X-ray structure of **1** and the proposed structures of **2** and **3**. Fig. 2 shows the solution ESR spectrum of **1**, **2** and **3**, respectively, recorded in 9:1 methanol–water at 102 K. The ESR spectra obtained for neat powdered samples are slightly broader. No signal was observed for **1** (Fig. 2(a)) due to the strong intramolecular antiferromagnetic coupling. The ESR spectrum of **2** in Fig. 2(b) gave the first indication of a ferromagnetic coupling between the copper atoms of this complex. Signals at 'half field' (1500 G) are due to $\Delta M_s = 2$ transitions in the coupled $S = 1$ state, the frozen solution spectrum shows Cu hyperfine splitting [11]. The lines at 2700 and 3800 G are due to the $\Delta M_s = \pm 1$ transitions and the strong line at 3300 G is probably due to monomer impurity. The ESR spectrum of **3** in Fig. 2(c) shows an unperturbed axial signal consistent with non-interacting square-pyramidal copper atoms.

Magnetic susceptibility measurements on powdered samples show an interesting variation in the sign and size of exchange coupling in compounds **1**–**3**. Complex **1** is antiferromagnetically coupled (Fig. 3) with best fit parameter values obtained using a $-2J\bar{S}_1 \cdot \bar{S}_2$ Hamiltonian of $g = 2.03$, $J = -156\ cm^{-1}$, $N_\alpha = 60 \times 10^{-6}\ cm^3\ mol^{-1}$ and % monomer = 1%. In the figure it can be seen that a contaminating spin-coupled species, possibly the μ-OH bridged analogue (see also Ref. [10]) is present and gives rise to the humps in μ_{eff} between 30 and 120 K. The rapid increase in χ below 25 K (not

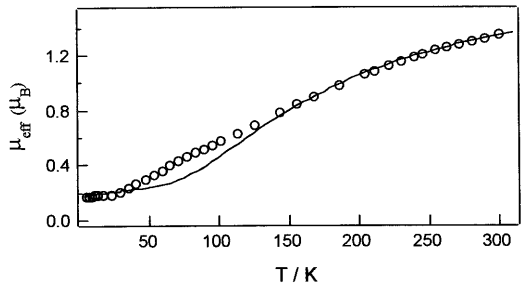

Fig. 3. Plots of magnetic moment (O) per Cu for complex **1**. The solid line shows the best fit for parameters (see text).

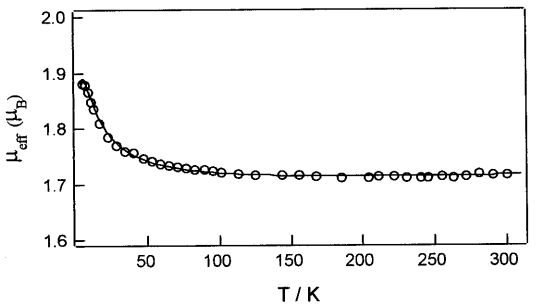

Fig. 4. Plots of magnetic moment (O) per Cu for complex **2**. The solid line shows the best fit for parameters (see text).

shown) is due to monomer impurity, a common phenomenon in such dinucleated systems.

There are a number of factors contributing to the medium sized negative J values obtained for **1**. The primary influence is the symmetry and disposition of the magnetic orbitals on each Cu centre in relation to the bridging phenoxide and methoxide oxygen orbitals. The Cu···Cu distance and Cu–O–Cu angles then play important roles, while effects such as steric strain around Cu and the trigonal planar versus pyramidal geometry around the phenolate oxygen atom play minor, but sometimes important roles. A review of {Cu(μ-*O*-alkoxo)$_2$Cu} [12] and {Cu(μ-*O*-alkoxo-μ-*O*-phenoxo)Cu} [13] systems in which the co-ligands allow non-strained square-pyramidal geometry around each Cu, show that very large negative J values are quite common, the compounds often approaching diamagnetic behaviour at room temperature ($J \geq -500$ cm^{-1}). Complex **1** has r(Cu···Cu) = 3.002(1) Å, Cu–O(CH$_3$)–Cu = 102.4(1)° and Cu–O(Ph)–Cu = 93.4(1)° and the sum of the angles around the phenoxo oxygen, O(1), is 337.9°, the pyramidal distortion arising through steric strain. As in [Cu$_2$(bmbp)(OCH$_3$)](ClO$_4$)$_2$ [10], the coordination geometry around Cu(1) and Cu(2) is closer to trigonal bipyramidal than to square pyramidal, with the apical ligands being OCH_3^- and N(amine), and the phenoxo O(1) bridging atom being in the trigonal plane. Thus, the Cu(1)d$_{z^2}$–O(2)–Cu(2)d$_{z^2}$ pathway will yield weaker antiferromagnetic coupling than in related Cu(1)d$_{x^2-y^2}$–O(2)–Cu(2)d$_{x^2-y^2}$ systems, and the Cu–O(Ph)–Cu pathway will contribute little to J, perhaps even a ferromagnetic contribution, vide infra. Nishida et al. [14] have shown that the bmbp$^-$ analogue of **4**, which has a longer r(Cu…Cu) value of 3.55 Å because of the acetate bridge, also has a lower than normal J value (-80 cm^{-1}), largely because of negligible overlap via the O(phenoxo).

Interestingly, complex **2**, which possesses only the O(phenoxo) bridge, shows weak ferromagnetic coupling, in agreement with the EPR triplet state spectrum. A characteristic increase in μ_{Cu} occurs at low temperature on account of thermal population of the $S = 1$ state (Fig. 4). The best fit parameters are $g = 1.95$, $J = +5.4$ cm^{-1}, $N_\alpha = 60 \times 10^{-6}$ cm^3 mol^{-1} and % monomer = 2%. It was found that inclusion of a small ϑ value of -0.2 K in to the $(T - \vartheta)$ term of susceptibility improved the fitting of the plateau in the μ_{eff} values noted below 6 K. This suggests some weak intermolecular effects are occurring in **2**. In the absence of a crystal structure, one can only speculate on the reason for weak ferromagnetic coupling in **2**. The related singly-bridged complex [Cu$_2$(bmbp)(Cl)$_2$](ClO$_4$) showed $J = 0$ cm^{-1} [14]. It is likely that **2** also has the O(phenoxo) bridge occupying the common apical positions of the square pyramidal chromophores adopted by each Cu. The lack of a methoxo bridge in **2** compared with **1** relieves the strain and allows a change in coordination geometry. We have observed more strongly antiferromagnetically coupled effects in other phenoxo-only bridged dinucleated complexes but in such cases the phenoxo oxygen provided good overlap with the Cud$_{x^2-y^2}$ orbitals [15].

Finally, complex **3** is uncoupled, as expected because of the lack of any endogenous bridging group.

3.2. Electrospray ionization mass spectrometry (ESI MS)

The labile complexes **1**, **2** and **3** give ESI mass spectra significantly more complicated than complexes **4** and **5**. Perusal of the species observed in spectra recorded in methanol (Table 3) support an increase in the state of protonation of ions in going from complex **1** to **3**. Hydroxide (and methoxide for **1**)-containing ions were observed as base peaks for complexes **1** and **2**, but not detected for **3**. Also, a tendency for ions bearing two perchlorates was seen in the spectra of **3**, suggesting a stronger association than ion pairing, i.e. coordination. Notably, dominant ions in the spectra of **3** include only one copper ion. Loss of copper is not unexpected from the protonated species **3**. The ESI mass spectra of methanol solutions of **1** show that the cation present in the solid state structure is observed only as a minor peak at m/z 364.1 along with [(bpbp)Cu$_2$(OH)]$^{2+}$ at m/z 357.1 as the major ion. Variation in source conditions show that the hydroxide ion is present in solution

Table 3
Distribution and intensity of ions in the ESI mass spectra of complexes **1**, **2** and **3**

m/z	Assignment	**1**	**2**	**3**
364.1	$(bpbp)Cu_2(OCH_3)]^{2+}$	20		
357.1	$(bpbp)Cu_2(OH)^{2+}$	100	100	
365.8	$(bpbp)Cu_2(OH)(H_2O)^{2+}$		75	
399.2	$(bpbp)Cu_2(ClO_4)^{2+}$		70	10
367.7	$(bpbpH)Cu(ClO_4)^{2+}$			100
815.3	$(bpbp)Cu_2(OH)(ClO_4)^{+}$	20		
833.3	$(bpbp)Cu_2(OH)(H_2O)(ClO_4)^{+}$		5	
897.3	$(bpbp)Cu_2(ClO_4)_2^{+}$		18	7
734.2	$(bpbpH)Cu(ClO_4)^{+}$			15
836.2	$(bpbpH)Cu(ClO_4)_2^{+}$			20
936.3	$(bpbpH_2)Cu(ClO_4)_2^{+}$			3

and not generated in the gas phase. The ESMS spectrum of **1** recorded in acetonitrile show no signal at the m/z value expected for $[(bpbp)Cu_2(OCH_3)]^{2+}$, rather the base peak is always at m/z 357.1 due to $[(bpbp)Cu_2(OH)]^{2+}$. This result suggests that the dominant solution species is the hydroxide complex, despite the fact that crystallization of a methoxide-bridged complex occurs in the presence of methanol. Crystal packing forces probably drive the crystallisation of a methoxide complex, despite the higher pK_a for methanol compared with water. Collision activation of the $[(bpbp)Cu_2(OCH_3)]^{2+}$ ion results in one daughter ion, $[Cu_2(bpbp)]^{2+}$ at m/z 348.5, which corresponds to the loss of neutral radical methoxide with concomitant reduction of a copper centre by one electron.

The ESI mass spectrum of the acetate complex **4** shows the expected cation $[Cu_2(bpbp)(CH_3CO_2)]^{2+}$, as the base peak at m/z 379.0 and its ion pair $[Cu_2(bpbp)(CH_3CO_2)](ClO_4)^{+}$ as the base peak at m/z 857.4. Also, isoelectronic species were detected; $[Cu_2(bpbp)(OH)]^{2+}$, $[Cu_2(bpbp)(OH)(H_2O)]^{2+}$, and $[Cu_2(bpbp)(OH)](ClO_4)]^{2+}$, demonstrating that there is a considerable exchange of the acetate ligand in solution. By contrast, the ESI mass spectrum of the less labile complex **5** is very simple by comparison with peaks for $[Cu_2(bpbp)(C_3H_3N_2)]^{2+}$ and its ion pair, $[Cu_2(bpbp)(C_3H_3N_2)](ClO_4)^{+}$ at m/z 382.1 and m/z 865.3, respectively.

4. Conclusions

Labile complexes with the $[Cu_2(bpbp)]^{2+}$ core and an ancillary methoxide ligand (antiferromagnetic green complex **1**) or two ancillary water ligands (ferromagnetic brown complex **2**) were isolated depending on the pH of reaction solutions. From acidic solutions below pH **2**, a blue dinuclear complex, **3**, in which the phenol group of the dinucleating is uncoordinated, is isolated and the magnetic properties confirm this arrangement. The series show an interesting variation in magnetic coupling between the copper ions, from antiferromagnetic for **1**, ferromagnetic for **2** and uncoupled for **3**. Complex **1** can be used for substitution reactions in which the methoxide is replaced by bridging groups. Unfortunately investigations into the possible biomimetic activity of these complexes in the promotion or catalysis of the hydrolysis of nitriles, amides and esters have not yielded observations of unusual reactivity.

Abstract

The $K_8[P_2VMoW_{16}O_{62}]\cdot 31H_2O$ heteropolyoxometalate complex was synthesized and investigated by electrochemistry measurements and IR, UV–Vis and EPR spectroscopy. The substitution of one $W{=}O_d$ unit by the VO^{2+} group was inferred from the shift of the $\nu_{as}(M{=}O_{a,d})$ and $\nu_{as}(M{-}O_{b,c}{-}M)$ vibrational bands (M = W, Mo) and the appearance of $\nu_{as}(V{=}O_d) \approx 960\ cm^{-1}$ vibration in the IR spectrum of the complex and from the electrochemistry studies. The three transitions in the electronic spectra were assigned to $^2B_2 \rightarrow {}^2E$ (13 700 cm^{-1}), $^2B_2 \rightarrow {}^2B_1$ (16 490 cm^{-1}) and $^2B_2 \rightarrow {}^2A_1$ (23 140 cm^{-1}), indicating a six coordination of the vanadium(IV) ion in an axial C_{4v} environment. EPR spectrum of the complex obtained at room temperature shows resolved hyperfine features in the parallel and perpendicular regions typical for monomeric V^{4+} ion. EPR parameters ($g_{\|} = 1.940$, $g_{\perp} = 1.982$, $A_{\|} = 178.5$, $A_{\perp} = 62.9$ G) and the values of LCAO–MO coefficients ($\beta_1^2 = 0.863$, $\beta_2^2 = 0.875$ and $\beta_3^2 = 0.935$) correspond to a dominant ionic character of the σ and π V–O bondings and to an important delocalization of the electrons towards the $O_{b,c}$ atoms. © 2000 Elsevier Science Ltd. 1. Introduction

Heteropolyoxometalates (HPOM) are intensely studied for their use in catalysis, biology and materials science. When these polyanions contain vanadium and molybdenum atoms near the tungsten and oxygen atoms, they exhibit important catalytic activities for redox reactions [1]. In this paper we investigate the $K_8[P_2VMoW_{16}O_{62}]\cdot 31H_2O$ complex by electrochemical and spectroscopic methods. This complex has an α-Dawson–Wells structure [1,2] with one tungsten atom substituted by one easier molybdenum atom and another tungsten atom replaced by one vanadium ion (Fig. 1). The two phosphorus atoms are tetrahedrally coordinated in the center of the investigated heteropolyoxometalate complex.

Usually, the oxygen atoms of α-Dawson–Wells structure coordinate octahedrally the vanadium and molybdenum ions, similarly to the fundamental WO_6 units [3,4]. The MoO_6 and VO_6 substitute WO_6 octahedra in a 6W belt or in a 3W cap regions of the α-Dawson–Wells structure [3]. On the other hand, these could be in the vicinity, sharing a corner oxygen atom or an edge, or could be nonadjacent. Previous studies revealed the affinity of the molybdenum ion to coordinate in the 'cap' region [3,5] and the affinity of vanadyl ions for the 'belt' region of the complex [5]. Also, the vanadium ion is more easily reducible (to V^{4+}) compared to molybdenum ion (to Mo^{5+}) [6]. The electron trapped on the vanadium ion is slightly delocalized, more into the V–O–Mo bond than into the V–O–W bond [7].

$K_{10}[P_2MoW_{16}O_{61}]\cdot 19H_2O$ (obtained as described in [8]) in 50 ml acetate buffer solution (pH 4.7) at 60–70°C, under vigorous stirring for 1 h. After cooling at room temperature (r.t.), KCl saturated solution was added to blue polyoxometalate complex solution.

The dark blue precipitate was collected on a medium frit, dried for 30 min under vacuum, washed with saturated KCl solution and dried again under vacuum. The chemical analysis was carried out by atomic absorption methods after the complex decomposition by boiling with 6 M NaOH solution. The chemical analysis data are: *Anal*. Calc.: H_2O, 11.14; K, 6.21; Mo, 1.95;P, 1.24; V, 1.02; W, 58.68%. Found: H_2O, 11.05; K, 6.16; Mo, 1.87; P, 1.26; V, 1.00; W, 58.42%.

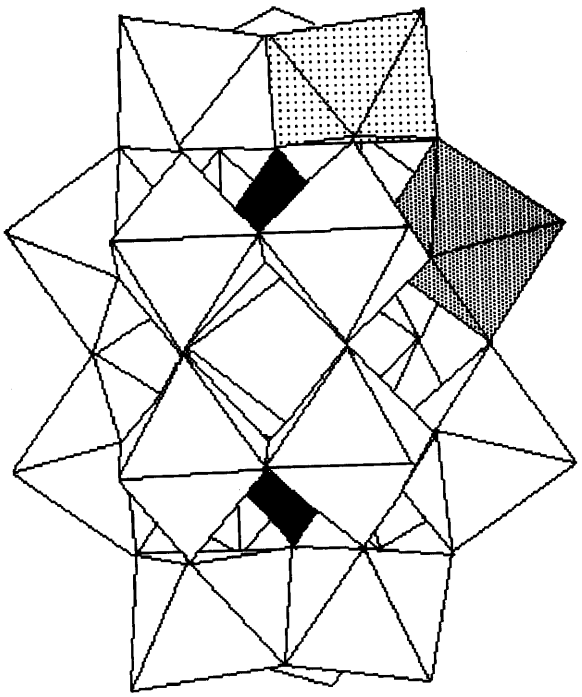

Fig. 1. The structure of the $K_8[P_2VMoW_{16}O_{62}]\cdot 31H_2O$ heteropolyoxometalate (Shaded octahedron in the 'belt' position represents VO_6 site. Pointed octahedron in the 'cap' position represents the MoO_6 site).

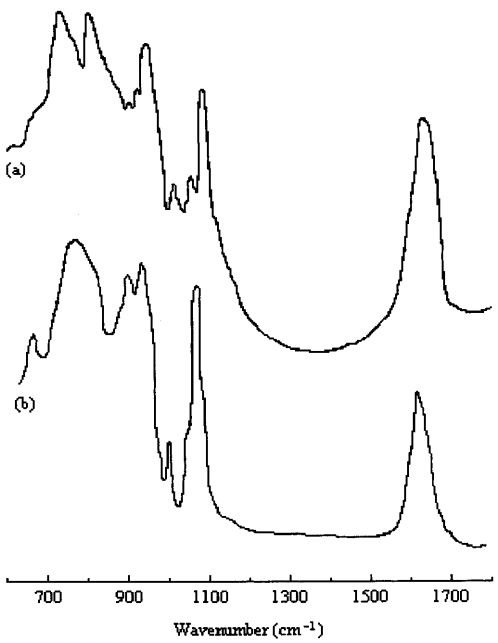

Fig. 2. IR spectra of the ligand (a) and vanadium–HPOM complex (b).

2.2. Physical measurements

UV and visible electronic spectra were performed in $\lambda = 200$–800 nm range in aqueous solutions, using a standard Specord UV–Vis spectrometer. IR spectra were obtained in KBr pellets in the 4000–400 cm^{-1} range with a Carl Zeiss Jena model UR-20 spectrophotometer. Cyclic voltammetry experiments were performed using a computer-controlled potentiostat AUTOLAB 10. A conventional three-electrode cell was used. The working electrode (WE) was a vitreous carbon disk ($\phi = 3$ mm), the reference electrode was a saturated calomel electrode (SCE, $\varepsilon^0 = 0.244$ V NHE) and the counter electrode was a platinum plate ($S = 1$ cm^2). The WE was polished before use on abrasive paper 1200, followed with a paste of Al_2O_3 (Struers, Denmark). The electrolyte solutions were prepared from distilled water and heteropolyoxometalates. All measurements were performed in phosphates buffer at pH 3. EPR measurements were performed at 9.4 GHz (X band) using a standard JEOL-JES-3B equipment at r.t.

3. Results and discussion

3.1. IR spectra

By compairing the IR frequencies of the monolacunary $K_{10}[P_2MoW_{16}O_{61}]\cdot 19H_2O$ ligand with those of the vanadium–polyoxometalate complex, we have obtained information concerning the coordination of the vanadium ion at the polyoxometalate. Fig. 2 presents the main part of the IR spectra and the most important IR absorption bands and their assignments are shown in Table 1.

The shoulder at ≈ 960 cm^{-1} in the IR spectrum of the complex is due to the stretching vibration of a vanadyl group, whose oxygen is a terminal atom [7,9].

The bands of the $\nu_{as}(W{=}O_d)$ and $\nu_{as}(Mo{=}O_d)$ strechings vibrations [10] are supperposed in the IR spectrum of the ligand. One of the two shoulders (at 910 cm^{-1})

Table 1
Some IR bands (cm^{-1}) of the ligand and vanadium–HPOM complex [a]

Band	Ligand (cm^{-1})	V(IV)–HPOM (cm^{-1})
$\nu(H_2O)$	3500 (s,b)	3470 (s,b)
		3570 (s,b)

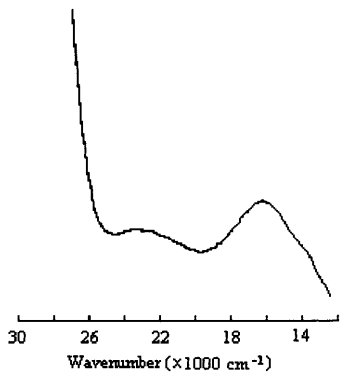

Fig. 3. Visible electronic spectra of the vanadium–HPOM complex in 10^{-2} mol l^{-1} aqueous solution.

is red-shifted with ~ 13 cm^{-1} due to the coordination of the vanadyl group at the polyoxometalate [11].

In the IR spectrum of the complex the streching vibration of the tricentric W–O_c–W bonds of the edge-sharing WO_6 octahedra [12] appears as shoulder and is shifted with 5 cm^{-1} to lower frequencies than the corresponding value in the IR spectrum of the ligand.

Due to the coordination of the vanadium ion at O_a and O_b atoms, the shape of the spectra is modified in the 700–850 cm^{-1} region [13]. IR spectrum of the monolacunary ligand presents two distinct bands, one at 807 cm^{-1} (with a shoulder at 839 cm^{-1}) assigned to ν_{as}(W–O_b–W) vibration and another at 730 cm^{-1} corresponding to ν_{as}(W–O_a) vibration, while in the IR spectrum of the complex there is only a broad band with some features at 840, 795 and 745 cm^{-1}.

The frequency of the ν_{as}(W–O_a) vibration is shifted with 15 cm^{-1} to smaller frequencies in the IR spectrum of the complex. This is due to the coordination of the vanadyl group at the ligand which also affects the neighboring octahedra of the structure [14].

The WO_6 octahedra from the equatorial regions have three O_b atoms and one O_c, O_a and O_d atom, while the WO_6 octahedra from the polar regions have two O_b, two O_c, one O_a and one O_d atoms. The value of the ν_{as}(W–O_b–W) vibration and the shape of its band are more affected by the vanadium coordination than those of ν_{as}(W–O_c–W) vibration. We conclude that the vanadium ion coordinates in the region with more O_b atoms (the equatorial region) of the α-Dawson–Wells structure.

The three absorption bands assigned to ν_{as}(P–O_a) vibrations [7,15] correspond to distorted PO_4 tetrahedra whose symmetry decreases to C_s. These frequencies are red-shifted with 2–6 cm^{-1} comparatively to the ligand spectrum. The shoulder at ≈ 1054 cm^{-1} arrises from the nonequivalent character of the two PO_4 distorted tetrahedra [16]. The shifts of the ν_{as}(P–O_a) frequencies and the lowering of the local symmetry around the phosphorus atoms are due to the vanadium coordination at O_a type atoms.

The frequency of the deformation band of the water molecules changes because of the raising of basic character of the O_d atom bounded to the vanadium ion [17]. The terminal O_d oxygen could be involved in hydrogen bonds with the neighbouring water molecules [18]. This fact is confirmed by the shape of the ν_{as}(OH) vibration band, which spreads in the 3100–3700 cm^{-1} range and presents two separate shoulders, at 3460 and 3570 cm^{-1}, respectively. The first shoulder, which is also less intense, corresponds to the coordination water involved in hydrogen bonds, while the other is due to the crystalization water.

The IR spectrum of vanadium–HPOM complex indicates the coordination of the vanadyl ion at O_a, O_b and O_c type oxygen atoms, in the equatorial region of Dawson–Wells structure.

3.2. Electronic spectra

The visible electronic spectrum of the complex in aqueous solution (Fig. 3) presents typical absorptions for vanadium(IV) ion in C_{4v} local symmetry [19,20]. In terms of the Ballhausen and Gray molecular orbital theory [21], these bands can be assigned to the transitions indicated in Table 2 and are consistent with the $d_{xy} < d_{xz,yz} < d_{x^2-y^2} < d_{z^2}$ energetical orbital ordering [22].

The absorption band centered at $\approx 13\,700$ cm^{-1} is due to the transition into V=O_d double bond. The second absorption band ($\approx 16\,490$ cm^{-1}) is a measure of the nonaxial ligand field strength. The smaller value

comparative to the other vanadium–HPOM complexes [19] indicates the presence of one important ligand field in the oxy plane (ortogonal to V=O_d direction).

For the assignment of the band centered at $\approx 23\ 140\ cm^{-1}$, there are two posibilities: this can arise from a $d_{xy} \rightarrow d_{z^2}$ transition [22] or can be a heteronuclear charge-transfer transition ($V^{4+} \rightarrow W^{6+}$, Mo^{6+}) [23]. For some vanadium–heteropolyoxometalates, M.T. Pope [24] and E. Cadot [19] have assigned the bands at $\approx 20\ 000$ and $\approx 25\ 000\ cm^{-1}$ to the charge-transfer transitions, owing to their important intensity comparative to d–d transitions. Because in the present case the absorption at $\approx 23\ 140\ cm^{-1}$ is less intense than the other two bands and also than the charge-transfer band appearing up to $25\ 000\ cm^{-1}$ (responsible for the intense colour of the anion), we attribute this band to a d–d transition [25].

The UV electronic spectra of the vanadium complex and of the ligand are similar in shape and number of bands (Fig. 4). The band centered at $47\ 040\ cm^{-1}$ in the ligand spectrum is assigned to p_π–d_π transitions into the W=O and Mo=O bonds [26]. The shift of the maximum of this band for the complex is due to the distortions introduced by the weaker vanadium(IV) ion into its neighbouring MO_6 octahedra (M = W, Mo).

Table 2
UV–Vis spectral features (cm^{-1}) of the vanadium–HPOM complex [a]

Electronic transition	ν (cm^{-1})
$^2B_2(d_{xy}) \rightarrow {}^2E(d_{xz,yz})$	13700 (sh)
$^2B_2(d_{xy}) \rightarrow {}^2B_1(d_{x^2-y^2})$	16490 (s)
$^2B_2(d_{xy}) \rightarrow {}^2A_1(d_{z^2})$	23140 (m)
$d_\pi \rightarrow p_\pi \rightarrow d_\pi$ (M–O–M′)	34000 (m)
$p_\pi \rightarrow d_\pi$(M=O)	47440 (s)

[a] sh, shoulder; s, strong; m, medium.

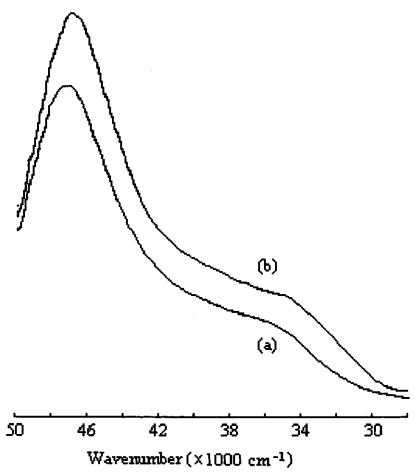

Fig. 4. UV spectra of the ligand (a) and vanadium–HPOM complex (b) obtained in 5×10^{-5} mol l^{-1} aqueous solution.

The broad bands centered at $\approx 34\ 040\ cm^{-1}$ for the ligand and at $\approx 34\ 000\ cm^{-1}$ for the complex (Fig. 4) are due to electron transition between the energetic levels of the M–O–M′ tricentric bonds (M, M′ = Mo, W) [27]. The two shoulders arrising from different M–O–M′ bonds are more resolved in the vanadium complex spectrum.

3.3. Electrochemistry

To establish the electrochemical behaviour of the $K_8[P_2VMoW_{16}O_{62}]\cdot 31H_2O$ heteropolyoxometalate, the cyclic voltammograms of the heteropolyanions: α_2-$[P_2W_{17}O_{61}]^{10-}$ (abbreviated P_2W_{17}), α_2-$[P_2MoW_{16}O_{61}]^{10-}$ (abbreviated P_2MoW_{16}) and α_2-$[P_2VMoW_{16}O_{62}]^{8-}$ (abbreviated P_2VMoW_{16}) were performed at different potential scan rates (Fig. 5).

The four pairs of peaks in the case of voltammograms obtained for P_2W_{17} (Fig. 5a) showed clearly three reduction reversible processes (peaks I, II, and III) confirmed by a linear dependence between the peak current (I_{pc}) logarithm and the scan rate logarithm, and by the fact that the peak potentials are independent of scan rates. In the case of peak IV, the behaviour is less clear due to the fact that the maximum corresponding to anodic peak is in cathodic current range. For the four pairs of peaks the charge transfer and protonation reactions are the same with those confirmed by literature [28–31]:

$$\alpha_2\text{-}[P_2W_{17}O_{61}]^{10-} + 1e^- \rightarrow \alpha_2\text{-}[P_2W_{16}W^{5+}O_{61}]^{11-} \text{ (peak I)} \quad (1)$$

$$\alpha_2\text{-}[P_2W_{16}^{6+}W^{5+}O_{61}]^{11-} + 1e^- \rightarrow \alpha_2\text{-}[P_2W_{15}^{6+}W_2^{5+}O_{61}]^{12-} \text{ (peak II)} \quad (2)$$

$$\alpha_2\text{-}[P_2W_{15}^{6+}W_2^{5+}O_{61}]^{12-} + 2e^- + 2H^+ \rightarrow \alpha_2\text{-}[H_2P_2W_{15}^{6+}W_2^{5+}O_{61}]^{12-} \text{ (peak III)} \quad (3)$$

$$\alpha_2\text{-}[H_2P_2W_{15}^{6+}W_2^{5+}O_{61}]^{12-} + 2e^- + 2H^+ \rightarrow \alpha_2\text{-}[H_4P_2W_{15}^{6+}W_2^{5+}O_{61}]^{12-} \text{ (peak IV)} \quad (4)$$

The voltammetric behaviour of the compound P_2MoW_{16} (Fig. 5b) is similar to that of the P_2W_{17} anion but the peak for Mo^{6+}–Mo^{5+} appears at a potential about +0.2 V SCE and the corresponding reaction is:

$$\alpha_2\text{-}[P_2Mo^{6+}W_{16}^{6+}O_{61}]^{10-} + 1e^- \rightarrow \alpha_2\text{-}[P_2Mo^{5+}W_{16}^{6+}O_{61}]^{11-} \quad (5)$$

For the P_2VMoW_{16} compound (Fig. 5c) a new peak for the V^{5+}–V^{4+} appears at +0.36 V SCE and the corresponding reaction is:

$$\alpha_2\text{-}[P_2V^{5+}Mo^{6+}W_{16}^{6+}O_{62}]^{7-} + 1e^- \rightarrow \alpha_2\text{-}[P_2V^{4+}Mo^{6+}W_{16}^{6+}O_{62}]^{8-} \quad (6)$$

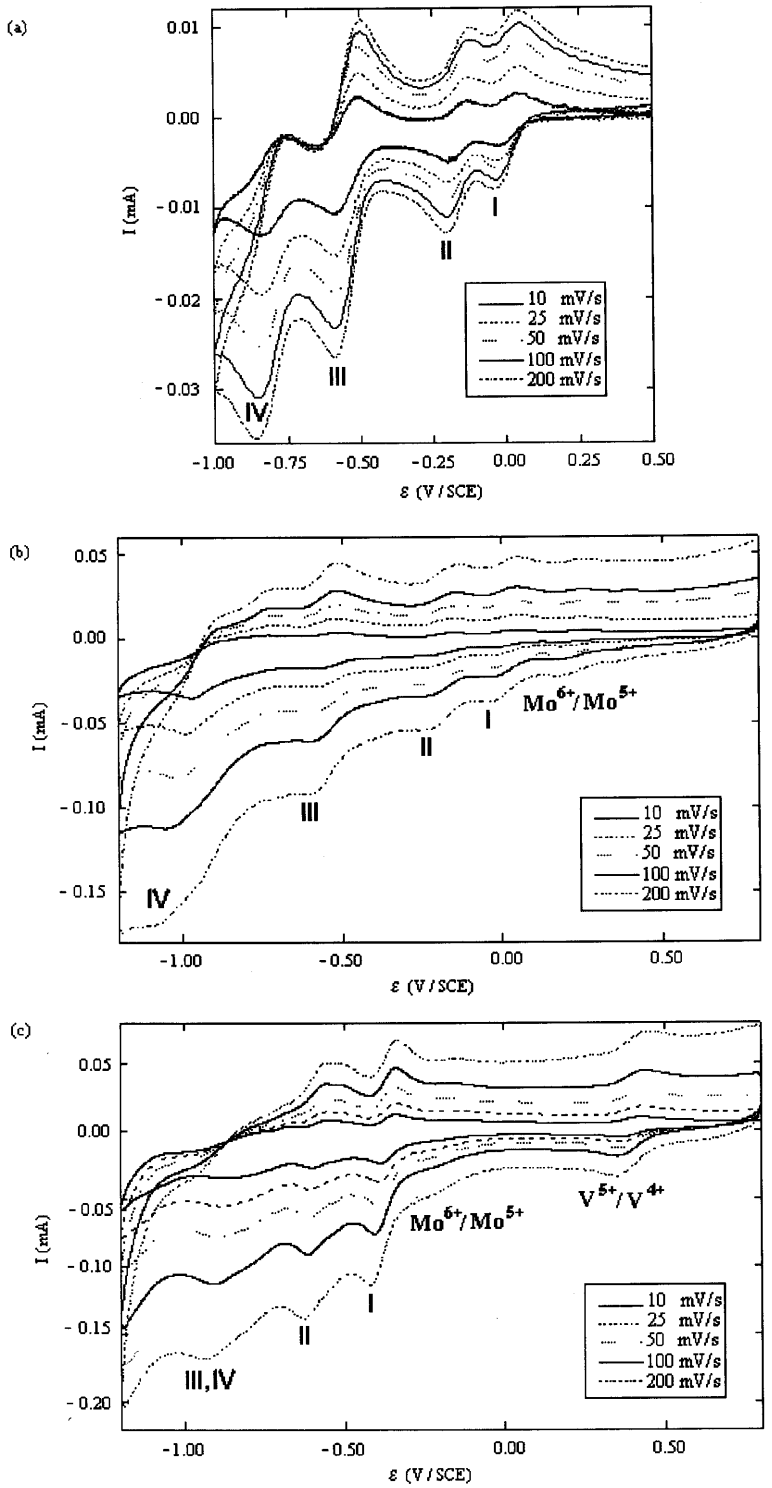

Fig. 5. Experimental cyclic voltammograms of 10^{-3} M $K_{10}P_2W_{17}O_{61}$ (a), 2×10^{-3} M $K_{10}P_2MoW_{16}O_{61}$ (b) and 2×10^{-3} M $K_8P_2VMoW_{16}O_{62}$ (c) complexes at different scan rates at pH 3.

Our results are in good agreement with those proposed by Pope [32]. Both iso and heteropolyoxometalates containing vanadium, molybdenum or tungsten shows the ability to form reduced species only when the metal atom is coordinated by the oxygen terminal atom. The presence of the three cations (vanadium, molybdenum and tungsten) in the same polyoxometalate structure leads first to electrochemical reductions of

vanadium (V^{5+}), this being more easy reducible, then to that of molybdenum (Mo^{6+}) and finally to that of tungsten (W^{6+}) [33,34].

Voltammetric study of P_2VMoW_{16} in acid media showed the modification of the electrochemical behaviour compared with that of the P_2W_{17} anion because of the vanadium and molybdenum addenda presence.

The electrochemical signal of vanadium is very distinct and creates favorable views for using it as a redox mediator for electrochemical polyoxometalate modified electrodes.

3.4. EPR spectra

The powder EPR spectrum of the complex recorded at r.t. (Fig. 6, normal line) is typical for mononuclear oxovanadium species in an axial environment. This spectrum can be described by an axial spin Hamiltonian for a d^1 system Eq. (7) [27]:

$$H = \beta[g_{\|}B_zS_z + g_{\perp}(B_xS_x + B_yS_y)] + A_{\|}S_zI_z + A_{\perp}(S_xI_x + S_yI_y) \quad (7)$$

The spectrum exhibits eight components, both in the perpendicular and in the parallel bands, due to the metallic hyperfine coupling of the electron spin with the nuclear spin ($I = 7/2$) of the 99.75% natural abundant ^{51}V isotope. The absence of Mo^{5+} and W^{5+} EPR signals confirms that all the molybdenum and tungsten atoms are in the $+6$ oxidation state [35]. The best fitting simulated EPR parameters are: $g_{\|} = 1.940$, $g_{\perp} = 1.982$, $A_{\|} = 178.5$, $A_{\perp} = 62.9$ G, with the line widths $\Delta B_{pp}(\|) = 52$ and $\Delta B_{pp}(\perp) = 38$ G in the parallel and perpendicular bands, respectively. The principal axis of g and A tensors have been presumed coincident, with the $g_{\|}$ and $A_{\|}$ directions parallel to the V=O_d bond. Differences between the experimental and simulated spectra indicate a small rhombic distortion of the VO_6 octahedron.

The electronic ground state for V^{4+} ion in a C_{4v} local symmetry is the antibonding B_2 molecular orbital, formed by the d_{xy} orbital of the vanadium ion. The LCAO–MO approach gives the spin Hamiltonian parameters (Eq. (8)) [21,37]:

$$g_{\|} = g_0 - \frac{8\beta_1^2\beta_2^2\lambda}{\Delta E(d_{xy} \rightarrow d_{x^2-y^2})}$$

$$g_{\perp} = g_0 - \frac{2\beta_2^2\beta_3^2\lambda}{\Delta E(d_{xy} \rightarrow d_{xz,yz})}$$

$$A_{\|} = -P\left[\beta_2^2\left(K + \frac{4}{7}\right) + (g_0 - g_{\|}) + \frac{3}{7}(g_0 - g_{\perp})\right]$$

$$A_{\perp} = -P\left[\beta_2^2\left(K - \frac{2}{7}\right) + \frac{11}{14}(g_0 - g_{\perp})\right] \quad (8)$$

where λ is the spin-orbit coupling constant for the vanadium(IV) ion, $P = 2.0023\beta_e g_N \beta_N \langle r^{-3} \rangle$ is the dipolar interaction term, K is the isotropic Fermi contact term, β_1^2, β_2^2 and β_3^2 are the fractional contributions of $d_{x^2-y^2}$, d_{xy}, $d_{xz,yz}$ vanadium orbitals to the molecular orbitals. Using $P = 0.0128$ [38] and $\lambda = 170$ cm^{-1} [39], we obtained $\beta_1^2 = 0.863$, $\beta_2^2 = 0.875$ and $\beta_3^2 = 0.935$ for the in-plane σ-bonding, in-plane π-bonding and out-of-plane π bonding, respectively.

The out-of-plane π bonding has a dominant ionic character, with the unpaired electron spending more time into the $d_{xz,yz}$ orbitals of the vanadium ion. The not too high values of β_1^2 and β_2^2 coefficients suggest that the VO_6 and MoO_6 octahedra could share a corner, as previous studies of polyoxometalates with vanadyl and molybdenum ions have indicated [19]. The calculation was made by considering all the possibilities for the signs of $A_{\|}$ and $A_{\perp}$, but only the case $A_{\|} < 0$,

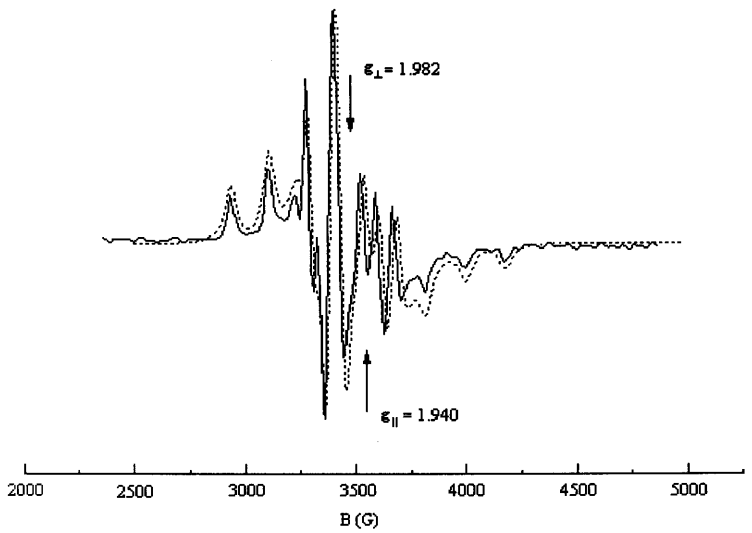

Fig. 6. Experimental (normal line) and simulated (dashed line) EPR spectra of the powder vanadium–HPOM complex, at room temperature.

$A_{\perp} < 0$ gives rise to acceptable values for the molecular orbital coefficients (for $A_{\parallel} > 0$, $A_{\perp} > 0$ and $A_{\parallel} > 0$, $A_{\perp} < 0$ we obtained the negative $\beta_2^2 = -1.003$ and $\beta_2^2 = -2.060$ values respectively and for $A_{\parallel} < 0$, $A_{\perp} < 0$, the $\beta_2^2 = 1.932$ exceed the $\beta_2^2 = 1$ superior limit). This fact together with the low $K = 0.785$ value are in good agreement with the presence of a negative charge on the $O_{b,c}$ oxygen atoms, resulted from the delocalization of the unpaired electron of the vanadium(IV) ion [24,36,38].

4. Conclusions

The spectroscopic and electrochemical investigations of $K_8[P_2VMoW_{16}O_{62}]\cdot 31H_2O$ complex indicate the coordination of the vanadyl group at the monolacunary α-Dawson–Wells fragment. The vanadium(IV) ion is six coordinated by oxygen atoms in a C_{4v} local environment, with a $^2B_2(d_{xy})$ ground state. EPR parameters obtained from the simulated spectrum confirm the axial symmetry. The values of the molecular orbital coefficients for the in-plane σ and π bondings show the electron delocalization towards the oxygen atoms from $V–O_{b,c}$ bonds.

Abstract

Mixed-ligand tris-chelates, $[Ru(bpy)_2(RaaiR')](ClO_4)_2 \cdot H_2O$ (bpy = 2,2′-bipyridine; RaaiR′ = 1-alkyl-2-(arylazo)imidazole) have been synthesized by a silver-assisted route $[Ru(bpy)_2Cl_2 + RaaiR' + AgNO_3 + NaClO_4/Ru(bpy)_2Cl_2 + [Ag(RaaiR')_2](ClO_4)]$. The structures of the complexes have been supported by the single-crystal X-ray diffraction study and the stereochemistry are assessed by ^1H NMR spectral data. All the complexes show two metal-to-ligand charge transfer (MLCT) transitions in the visible region at ca. 400 and 500 nm and their emission spectra are also described here. Cyclic voltammetric studies exhibit high-potential $Ru^{III/II}$ (1.4 V vs. SCE) and three successive ligand reductions at negative to SCE in acetonitrile solution. The difference in the first metal and successive ligand redox potentials are linearly correlated with the ν_{CT} of MLCT band. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Azoimine; Ru–bipyridine; Tris-chelates; X-ray structures; Electrochemistry; Emission spectra

1. Introduction

For the past several years we have been engaged [1–11] in the exploration of the chemistry of arylazoimidazoles (RaaiR′) (**1**–**3**). The ligand behaves as N,N′-chelator with azoimine, –N=N–C=N–, function. Dichloro-bis(arylazoimidazoles)-ruthenium(II), $Ru(RaaiR')_2Cl_2$, have been structurally characterized in two isomeric forms although the complexes, in principle, may exist in five isomeric forms [11]. The present study is concerned with the heteroleptic tris-chelates of ruthenium(II)-bipyridine and RaaiR′. The chemistry of ruthenium–bipyridine complexes has been widely studied during the last few years [12–33]. Recently there has been a growing interest [20–30] in modifying the properties of Ru–bpy complexes by substituting ligands of other donor centres, altering the steric and electronic properties of the ligands, differently substituted polypyridines, other heterocycles, etc. Herein we wish to report the synthesis, structural characterisation, redox activities, absorption and emission spectroscopic properties of ruthenium complexes of 1-alkyl-2-(arylazo)imidazoles (RaaiR′) with $Ru(bpy)_2$–core.

2. Experimental

2.1. Materials

$RuCl_3 \cdot nH_2O$ was obtained from Arrora Matthey, Calcutta and was digested thrice with concentrated HCl

before use [1]. 1-Alkyl-2-(arylazo)imidazoles (RaaiR′) and $[Ag(RaaiR')_2](ClO_4)$ were synthesized as before [3]. *Cis*-$Ru(bpy)_2Cl_2$ was prepared by a published procedure [34]. The purification of dry solvents for electrochemical spectral work and preparation of $[Bu_4N][ClO_4]$ were done as described earlier [1]. All other chemicals and solvents used for the preparative work were of reagent grade and were used as received.

2.2. Instrumentation

Infra-red spectra were obtained on KBr discs (4000–200 cm^{-1}) with JASCO FTIR model 420 spectrophotometer. Solution electronic spectra were received on a Shimadzu UV 160A spectrophotometer and solution emission spectra were recorded with Hitachi F-4500 fluorescence spectrophotometer. The room temperature (298 K) spectra were taken in MeOH–EtOH (1:4, v/v) mixture using a 1 cm pathlength quartz cell. The spectra at 77 K were recorded in liquid nitrogen. Quantum yields were calculated using Eq. (1) [35].

$$\varphi_s = \varphi_{std} \frac{A_{std} I_s \eta_s^2}{A_s I_{std} \eta_{std}^2} \quad (1)$$

where φ_s = quantum yield of unknown sample; φ_{std} = quantum yield of $Ru(bpy)_3^{2+}$: 0.089 at 298 K [36] and 0.35 at 77 K [37] in MeOH–EtOH (1:4, v/v) at λ_{ex} = 450 nm; A_s and A_{std} are the solution absorbencies at the excitation wavelength (λ_{ex}); I_s and I_{std} are the integrated emission intensities and η_s and η_{std} are the refractive indices of the solvent.

Solution electrical conductivity of the complexes were collected from a Systronics digital conductivity meter model 304 with a solute concentration of ca. 10^{-3} mol dm^{-3}. ^1H NMR spectra in $CDCl_3$ were obtained on a Brucker 300 MHz FT NMR spectrometer using $SiMe_4$ as internal standard. The magnetic susceptibilities of the samples were measured on a PAR 155 vibration sample magnetometer. Electrochemical measurements were carried out using EG&G PAR Versastat computer controlled model 270 electrochemical system. All experiments were done under a dinitrogen atmosphere in a three-electrode configuration by using glassy carbon disc milli-electrode and Pt-wire auxiliary electrode. All results were collected at 298 ± 1 K and are referenced to a saturated calomel electrode. The reported potential and the instrument are internally IR compensated.

2.3. Preparation of complexes

2.3.1. Bis(2,2′-bipyridine)[1-methyl-2-(phenylazo)imidazole]ruthenium(II) perchlorate, monohydrate $[Ru(bpy)_2(HaaiMe)](ClO_4)_2 \cdot H_2O$ (**4a**)

(i) To a suspension of *cis*-$Ru(bpy)_2Cl_2$ (1 mmol) in acetone (15 ml) was added aqueous solution of $AgNO_3$ (2 mmol) and was refluxed for 15 min, AgCl so precipitated was filtered off by G-4 crucible. The acetone solution (10 ml) of HaaiMe (0.2g, 1.08 mmol) was then added and the resulting mixture was heated to reflux for 1 h under nitrogen atmosphere. The solution volume was then evaporated to half of its original volume by N_2 bubbling and an aqueous solution of $NaClO_4$ (ca. 1 g in 20 ml water) was added. The reddish brown precipitate thus obtained was filtered and dried in vacuo over P_4O_{10}. The dry mass was then dissolved in minimum volume of CH_2Cl_2 and was subjected to column chromatography on a silica gel column (60–120 mesh). A reddish brown band was eluted with C_6H_6–MeCN (3:2, v/v). This was collected and evaporated. Crystals were collected by layering a solution of the complex in CH_2Cl_2 with hexane. Yield, 68%. *Anal*. Found (Calc.): (**4a**): C, 38.02 (38.24); H, 3.19 (3.43); N, 13.85 (13.73)%; IR: ν(N=N) 1316 cm^{-1}, $\nu(ClO_4^-)$ 1089, 623 cm^{-1}.

Other complexes were also prepared following the same general route as discussed above and the yields were varied 60–75%. *Anal*. Found (Calc.): $[Ru(bpy)_2(p$-MeaaiMe)$](ClO_4)_2 \cdot H_2O$ (**4b**): C, 39.29 (39.04); H, 3.48 (3.61); N, 13.38 (13.50)%; IR: ν(N=N) 1314, $\nu(ClO_4^-)$ 1088, 622 cm^{-1}. $[Ru(bpy)_2(p$-ClaaiMe)$]$ $(ClO_4)_2 \cdot H_2O$ (**4c**): C, 36.50 (36.68); H, 3.31 (3.17); N, 13.33 (13.17)%; ν(N=N) 1318, $\nu(ClO_4^-)$ 1090, 625 cm^{-1}. $[Ru(bpy)_2$-(HaaiEt)$]$ $ClO_4)_2 \cdot H_2O$ (**5a**): C, 38.89 (39.04); H, 3.49 (3.61); N, 13.39 (13.50)%; ν(N=N) 1311, $\nu(ClO_4^-)$ 1086, 624 cm^{-1}. $[Ru(bpy)_2(p$-MeaaiEt)$](ClO_4)_2 \cdot H_2O$ (**5b**): C, 46.28 (46.45); H, 3.92 (3.79); N, 13.08 (13.27)%; ν(N=N) 1312, $\nu(ClO_4^-)$ 1087, 626 cm^{-1}. $[Ru(bpy)_2(p$-ClaaiEt)$](ClO_4)_2 \cdot H_2O$ (**5c**): C, 37.32 (37.48); H, 3.48 (3.35); N, 12.79 (12.96)%; ν(N=N) 1313, $\nu(ClO_4^-)$ 1089, 625 cm^{-1}. $[Ru(bpy)_2(HaaiCH_2Ph)](ClO_4)_2 \cdot H_2O$ (**6a**): C, 42.89 (43.05); H, 3.47 (3.59); N, 12.68 (12.56)%; ν(N=N) 1310, $\nu(ClO_4^-)$ 1087, 626 cm^{-1}. $[Ru(bpy)_2(p$-MeaaiCH$_2$Ph)$](ClO_4)_2 \cdot H_2O$ (**6b**): C, 43.93 (43.71); H, 3.66 (3.75); N, 12.44 (12.36)%; ν(N=N) 1309, $\nu(ClO_4^-)$ 1088, 625 cm^{-1}. $[Ru(bpy)_2(p$-ClaaiCH$_2$Ph)$](ClO_4)_2 \cdot H_2O$ (**6c**): C, 41.61(41.45); H, 3.41 (3.35); N, 12.28 (12.09)%; ν(N=N) 1313, $\nu(ClO_4^-)$ 1090, 626 cm^{-1}.

2.3.2. Reaction of *cis*-$Ru(bpy)_2Cl_2$ with $[Ag(RaaiR')_2](ClO_4)$

General procedure [38] for synthesis of $[Ru(bpy)_2(p$-MeaaiMe)$](ClO_4)_2 \cdot H_2O$. To a methanolic suspension of *cis*-$Ru(bpy)_2Cl_2$, $[Ag(MeaaiMe)_2](ClO_4)$ in acetone was added and refluxed for 1 h under nitrogen atmosphere. Solution was filtered through a G-4 sintered glass funnel. Insoluble AgCl was filtered, the solution was evaporated to dryness and washed thoroughly with cold water (20 $cm^3 \times 4$). The dried mass was dissolved in methanol and an aqueous solution of $NaClO_4$ (ca. 1 g in 15 cm^3) was added. The reddish brown product was filtered and purified as before (yield: 74%).

All other complexes were prepared similarly (yield: 70–80%).

CAUTION! Perchlorate salts of metal complexes are generally explosive. Care should be taken in handling the samples.

2.4. X-ray crystal structure and analysis

Crystal suitable for X-ray work was grown by slow diffusion of hexane–benzene (1:1, v/v) into a dichloromethane solution of $[Ru(bpy)_2(p\text{-MeaaiCH}_2\text{-Ph})](ClO_4)_2.H_2O$ (**6b**). Crystal size was $0.1 \times 0.2 \times 0.2$ mm^3. Data were collected on a Siemens SART CCD diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K. Crystal data and collection parameters are listed in Table 1. The data were corrected for absorption effects by empirical method using azimuthal scan data. Systematic absences led to the identification of space group $P\bar{1}$ (triclinic crystal system). Of the 10 532 collected reflections, 5889 with $I > 2\sigma(I)$ were used for structure solution. The structure was solved by conventional heavy-atom method and refined by full-matrix least-square method on all F_o^2 data using the SHELXTL 5.03 package on silicon graphics Indigo-R4000 computers. Hydrogen atoms were included in calculated positions and refined with isotropic thermal parameters which were ~ 1.04 (aromatic (H)) times the equivalent isotopic thermal parameters of their parent carbon atoms. Atomic coordinates (SHELXTL 5.03 program system; Siemens analytical X-ray instruments, Madison, WI, 1995) and isotropic thermal parameters are available as Section 4.

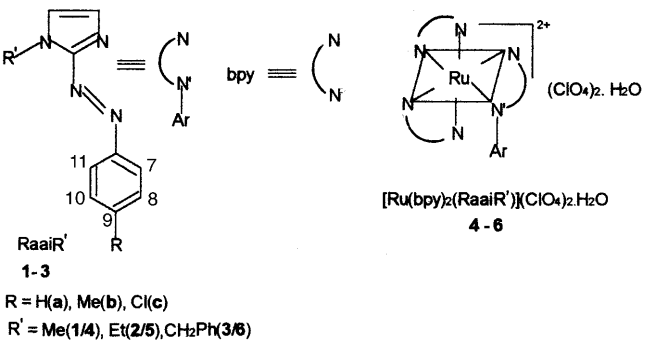
3. Results and discussion



3.1. Synthesis

1-Alkyl-2-(arylazo)imidazoles (RaaiR′) are unsymmetric N,N′-chelating ligands [1] and the donor centres are abbreviated as N(imidazole), N and N(azo), N′. The complexes are isolated as perchlorate salt, $[Ru(bpy)_2(RaaiR')](ClO_4)_2$, by nucleophilic substitution of chloride from *cis*-$Ru(bpy)_2Cl_2$ by RaaiR′ via Ag^+-assisted route. The same reaction is also carried out by reacting $Ag(RaaiR')_2^+$ with *cis*-$Ru(bpy)_2Cl_2$ [18,19].

$$cis\text{-}Ru(bpy)_2Cl_2 + RaaiR' \xrightarrow[(2)\ NaClO_4]{(1)\ Ag^+,\ MeOH,\ reflux} [Ru(bpy)_2(RaaiR')](ClO_4)_2 + 2AgCl\downarrow \quad (2)$$

$$cis\text{-}Ru(bpy)_2Cl_2 + Ag(RaaiR')_2^+ \xrightarrow[(2)\ NaClO_4]{(1)\ MeOH,\ reflux} [Ru(bpy)_2(RaaiR')](ClO_4)_2 + RaaiR' + 2AgCl\downarrow \quad (3)$$

Reaction (3) has been particularly useful for the synthesis of heteroleptic tris-chelate. The products were purified by chromatographic process. Although the tris-chelate may exist in different isomeric forms [19] but they have not been separated by chromatographic separation process and the mixed chelate cation $[Ru(bpy)_2(RaaiR')]^{2+}$ may exist in one chiral structure (**4**–**6**).

The composition of the compounds was formulated by elemental analyses. The complexes are expectedly diamagnetic (d^6) and 1:2 electrolyte in MeCN. The mixed tris-chelate cation $[Ru(bpy)_2(RaaiR')]^{2+}$ can have one chiral structure (**4**–**6**).

3.2. Molecular structure

View of the molecular unit $[Ru(bpy)_2(p\text{-Meaai-CH}_2\text{Ph})]^{2+}$ is shown in Fig. 1 and the bond parameters are given in Table 2. The distorted RuN_6 octahedron is due to the coordination from two N-donor centres of a 1-benzyl-2-(*p*-tolylazo)imidazoles and four N-donor centres of two bpy units. Molecular packing view down the *b* axis shows trapped benzene at

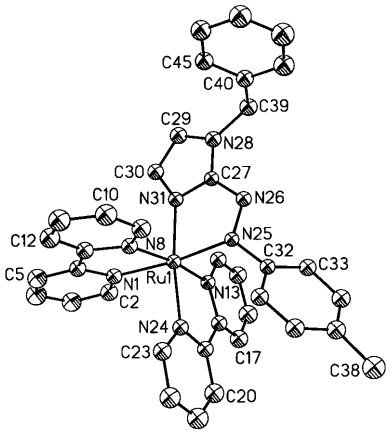


Fig. 1. Single crystal structure of $[Ru(bpy)_2(p\text{-}MeaaiCH_2ph)]^{2+}$ showing the atom numbering scheme. For clarity, all hydrogen atoms have been omitted.

special position and disorder in ClO_4 unit. The three atomic groups Ru, N(1), C(6), C(7), N(8); Ru, N(4), C(19), C(18), N(13) and Ru, N(25), N(26), C(27), N(31) separately constitute three chelate planes (mean deviation < 0.02 Å). The planes are mutually orthogonal (dihedral angle 86–90°). The N(1)–Ru–N(25), N(8)–Ru–N(13), N(24)–Ru–N(31) angles are 173.3(2), 171.7(2), 172.1(2)°, respectively. The angles are deviated from *trans*-angular value (180°), this deviation originates undoubtedly from the acute chelate bite angles: N(1)–Ru–N(8), 78.0(2); N(13)–Ru–N(24) 78.6(2); N(25)–Ru–N(31), 76.5(2)°. The chelate ring constituted by azoimine (N(25)–Ru–N(31)) group has experienced heavy perturbation and is responsible for the deviation from octahedral geometry. The N–N distance is 1.296(6) Å and is longer than the free azo bond length [8] (1.25 Å). The increase in bond length is undoubtedly due to coordination of N(azo) that can lead to a decrease in the N–N bond order due to both σ- and

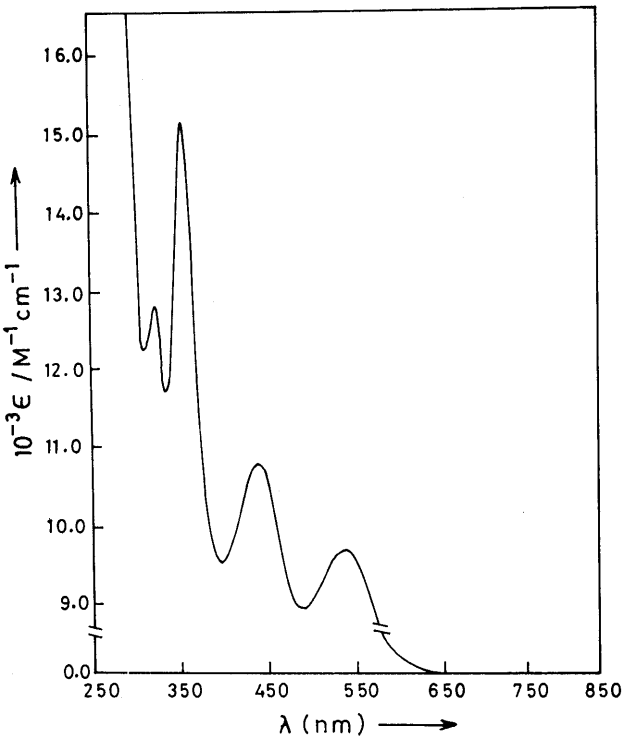

Fig. 2. Absorption spectra of $[Ru(bpy)_2(p\text{-}ClaaiCH_2Ph)](ClO_4)_2$ in methanol at 298 K.

π-acceptor character of the ligands — the latter character having a more pronounced effect and may be the reason for elongation [1]. The pendent *p*-tolyl ring is planar and is inclined at angle 57.1° with the chelate azoimine group N(25)–Ru–N(31).

The average Ru–N(bpy) distance (2.07 Å) is longer than Ru–N(imidazole) (2.038(4) Å) and Ru–N(azo) (2.023(4) Å) distances. The shortening of Ru–N(azo) distance as opposed to Ru–N(imidazole)/Ru–N(bpy) is the indication of metal–ligand π-interaction that is localised in the M–azo fragment [39–41].

3.3. Spectra and bonding mode

The complexes exhibit characteristic IR transmission [1,14,18,33] for ν(N=N), 1360; ν(C=N), ~ 1596; $\nu(H_2O)$, ~ 3400; $\nu(ClO_4^-)$, ~ 1100 and 625 cm^{-1}. The solution spectral studies of the complexes within 200–900 nm (Table 3, Fig. 2) reveal the free ligand absorption < 400 nm and are not considered further. The transitions in the visible region are of typical metal to ligand charge transfer type (MLCT) in the range 400–510 nm with high absorption coefficients ($\sim 10^4$ dm^3 $mol^{-1}cm^{-1}$). The spectra of the complexes are very similar to that of other $[Ru(bpy)_2(L)]^{2+}$ (L = bpy, aryl(2-pyridylmethylene)amine [19]/2-(arylazo)pyridine [42]) in intensity and profile pattern. The MLCT transitions may be compared with reported results [1,37] and is concluded that the absorption at 400–420 nm is

attributed to d(Ru)→π*(bpy) and at 500–510 nm is diagnostic feature in d(Ru)→π*(RaaiR′) transition.

The emission spectral behaviour of the complexes have been studied at room temperature (298 K) and 77 K using MeOH–EtOH (1:4, v/v) solution or glass. The emission spectra in frozen glass are sharper and considerably more intense relative to solution spectra. The emission peaks and quantum yields are given in Table 1 and a representative spectrum is shown in Fig. 3. The spectral behaviour is basically similar to the reported mononuclear analogues, $[Ru(bipy)_2(L)]^{n+}$ (L = phenolic Schiff bases, $n=1$ [16]; 3,5-bis(benzimidazole-2-yl)pyrazole, $n=2$ [33]; aryl-(2-pyridylmethylene)amine, $n=2$ [19]). The complexes on excitation at the wavelengths where their two MLCT absorption maxima are observed, exhibit three to four luminiscent bands in the range 400–600 nm. The peak of the longer wavelength band, which lies between 550 and 590 nm at 298 K, remains unchanged with the energy of excitation radiation. However, the peak positions of the luminescent bands observed at 420–500 nm are affected by the irradiation wavelength; they undergo a blue shift on lowering of the excitation wavelength. The emission band occurring at the longer wavelength part has the characteristic of emission from the ^{3}MLCT excited state, which corresponds to a spin forbidden Ru→bpy transition [3]. In solution, at room temperature, all the complexes are weak emitters with their quantum yields in the range 1.0×10^{-3} to 1.5×10^{-3}. On the other hand, in frozen glass the longer wavelength peak observed at 520–560 nm shows a significant increase of quantum yield 0.028–0.035. The blue shift of the emission band and the enhancement of intensity on lowering of temperature are typical of MLCT emitters [43,44]. The emission observed between 420 and 500 nm is highly unusual and is not expected for ruthenium complexes. It could be either due to emission from the ^{1}MLCT state or from an impurity, free ligand or similar [45]. The fact that peak positions are affected by the excitation wavelength and may suggest that scattered light is the cause of this observation.

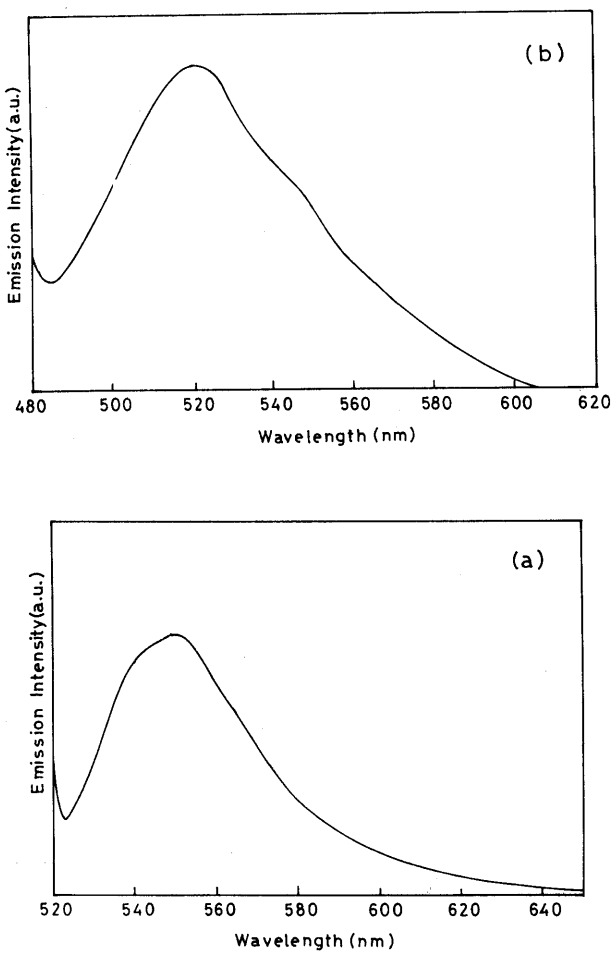

Fig. 3. Emission spectra of $[Ru(bpy)_2(p\text{-}ClaaiCH_2Ph)](ClO_4)_2$ in methanol–ethanol (1:4) (a) at 298 K and (b) frozen glass at 77 K.

3.4. ^{1}H NMR spectra

The ^{1}H NMR spectra were collected in $CDCl_3$. The proton numbering pattern is shown in structure **1** and spectral data are given in Table 4. The N–Me signal appears at 4.3 ppm and is downfield shifted by 0.3 ppm compared to free ligand values (free ligand δ(Me): 4.0 ppm) [1]. N–CH_2CH_3 shows usually a quartet and triplet for –CH_2– and –CH_3 groups respectively in free ligand. In the present complexes methylene protons –CH_2–, appear as AB type complex multiplet (Fig. 4) with geminal coupling constant ca. 24 Hz. The $[Ru(bpy)_2(RaaiCH_2Ph)]^{2+}$ compounds show quartet (AB type, Fig. 4) for methylene, –CH_2–(Ph), protons at ca. 5.8 ppm ($J=18.0$ Hz). The complex does not possess neighbouring chiral centres but there exist a distorted coordination around the metal ion (vide supra, X-ray structure, Fig. 1). This overall distortion leads to the molecular dissymmetry [1,2]. The imidazolic 4- and 5-H protons appear at 7.0–7.2 and 6.8–7.0 ppm, respectively. The coordination of N(3) to ruthenium(II) may lead to downfield shifting of 4-H signal [3–7]. The aryl protons 8,10-H resonate symmetrically at a single position and are perturbed by the substituents at C-9 position. The signal movement is in accordance with the electronic effects of the group. The protons 7-H and 11-H resonate asymmetrically, indicative of a magnetically inequivalent environment. The 11-H is assigned as stereochemically nearer than 7-H to the metal centre. Bipyridine protons are assigned as reported elsewhere [33].

3.5. Redox studies and correlation with electronic spectra

The redox properties of the complexes were examined cyclic voltammetrically at a glassy carbon working

[c] Doublet.
[d] Triplet.

electrode and the potentials are reported with reference to SCE. The voltammograms display $Ru^{III/II}$ couple at the positive side and the ligand reductions at the negative side to SCE. The results are in Table 3, and a representative voltammogram is shown in Fig. 5.

In the potential range + 0.5 to 1.8 V at the scan rate 50 mV s^{-1} in MeCN a reversible to quasireversible (peak-to-peak separation $\Delta E = 70–120$ mV) oxidative response is observed corresponding to the redox reaction (Eq. (4)).

$$[Ru(bpy)_2(RaaiR')]^{3+} + e \rightleftharpoons [Ru(bpy)_2(RaaiR')]^{2+} \quad (4)$$

$$[Ru(bpy)_2(RaaiR')]^{2+} + e \rightleftharpoons [Ru(bpy)_2(RaaiR'^{-})]^{2+} \quad (5)$$

$$[Ru(bpy)_2(RaaiR')]^{2+} + e \rightleftharpoons [Ru(bpy)(bpy^{-})(RaaiR'^{-})]^{2+} \quad (6)$$

$$[Ru(bpy)(bpy^{-})(RaaiR'^{-})]^{2+} + e \rightleftharpoons [Ru(bpy^{-})(bpy^{-})(RaaiR'^{-})]^{2+} \quad (7)$$

The i_{pa}/i_{pc} ratio (i_{pa} = anodic peak current and i_{pc} = cathodic peak current) is close to 1.0, as expected for reversible couples. The $Ru^{III/II}$ redox potential ($E_{1/2}$ = 1.4 V, Table 2) is expectedly higher than that of $Ru(RaaiR')_2Cl_2$ (0.6–0.9 V vs. SCE) [1]. Some $Ru^{III/II}$ formal potential data in tris-chelates $[Ru(bpy)_2(L)]^{2+}$ for L = N,N-bidentate neutral donor are as follows: $Ru(bpy)_3^{2+}$ in CH_2Cl_2 1.29 V [46]; $[Ru(bpy)_2(2\text{-(arylazo)pyridine})]^{2+}$ in MeCN 1.60 V [42]; $[Ru(bpy)_2\text{-(camphorquinonemono–oximato)}]^{+}$ in MeCN 0.85 V [18]. The relative values of the potential support the π-acidity order [1,47] bipyridine < arylazoimidazoles < arylazopyridines. Thus azoimidazole ligands stabilise (with respect to oxidation) Ru(II) better than bipyridine but less effectively than azopyridines.

In the potential range − 0.5 to − 2.4V three successive reductive responses are observed under similar conditions. The literature reports on the redox properties of *cis*-$Ru(bpy)_2Cl_2$ [46], $[Ru(bpy)_2(L)]^{2+}$ (L = 2-(arylazo)pyridines [42], aryl-(2-pyridylmethylene)amine [19]), and $Ru(RaaiR')_2Cl_2$ [1] suggest the cathodic responses those are due to reductions of the coordinated ligands. Redox data in Table 2 reveal that the first reduction potential of the coordinated ligand occurs at a much less negative potential than that of other two responses. The first reduction may be expected to involve the ligand having the most stable lowest unoccupied molecular orbital (LUMO) [18–21]. We believe that this is for arylazoimidazole than bpy and it is due to the acceptance of electron at the azo function (Eq. (5)). The present values are less negative by 0.1–0.2 V than previously reported azo reduction potential in $Ru(RaaiR')_2Cl_2$ [1]. This may be due to coligand effect of π-acidic bpy groups. The first reduction in $[Ru(bpy)_2(2\text{-(arylazo)pyridine})]^{2+}$ has been observed [42] at ca. − 0.5 V and in $[Ru(bpy)(aryl\text{-(2-pyridyl methylene)amine})]^{2+}$ at ca. − 1.0 V [19]. This is certainly due to π-acidity of the ligands, 2-arylazopyridines > 2-arylazoimidazoles > aryl-(2-pyridyl methylene)-amine. In the potential range − 1.4 to − 1.8 V two reductive responses are observed. These are referred to the reduction of bpy in $Ru(bpy)_2$ motif (Eqs. (6) and (7)) [48]. The one-electron nature of these processes was assigned from the comparison of current height with couple (Eq. (4)). The potential is sensitive to the substituent in the aryl ring and is linearly related with Hammett σ values of the substituent. It is interesting to note that the potential, ruthenium(III)/ruthenium(II) and first bound ligand reduction potential correlate linearly (with the slope less than unity). This observation is justified with the extent of perturbation of the ligand π*-orbital due to direct bonding of the substituent in the ligand frame. The effect is more pronounced in the ligand than the metal centre.

It is observed that the MLCT absorption energies for the complexes $[Ru(RaaiR')(bpy)_2]^{2+}$ show a linear cor-

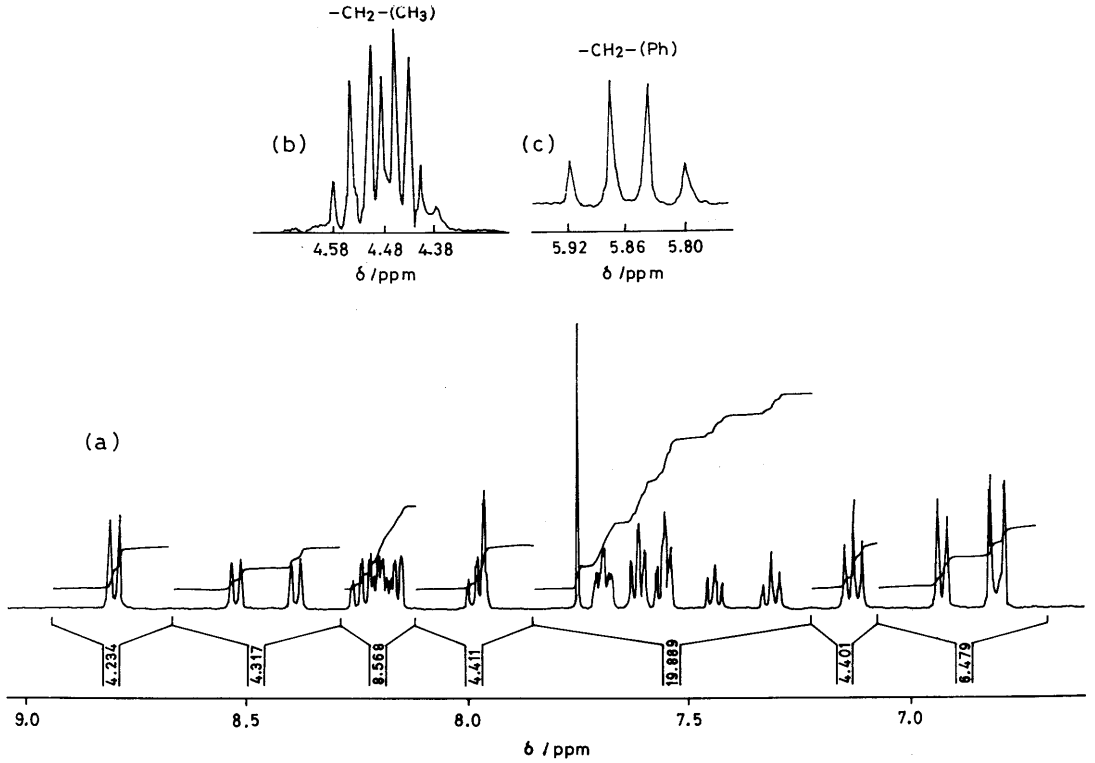

Fig. 4. ^{1}H NMR spectra of (a) aromatic region of $[Ru(bpy)_2(HaaiMe)](ClO_4)_2$ (**4a**), (b) methylene part ($–CH_2–(CH_3)$) of $[Ru(bpy)_2(HaaiEt)](ClO_4)_2$ (**5a**) and (c) methylene part ($–CH_2–(Ph)$) of $[Ru(bpy)_2(p\text{-}MeaaiCH_2Ph)](ClO_4)_2$.

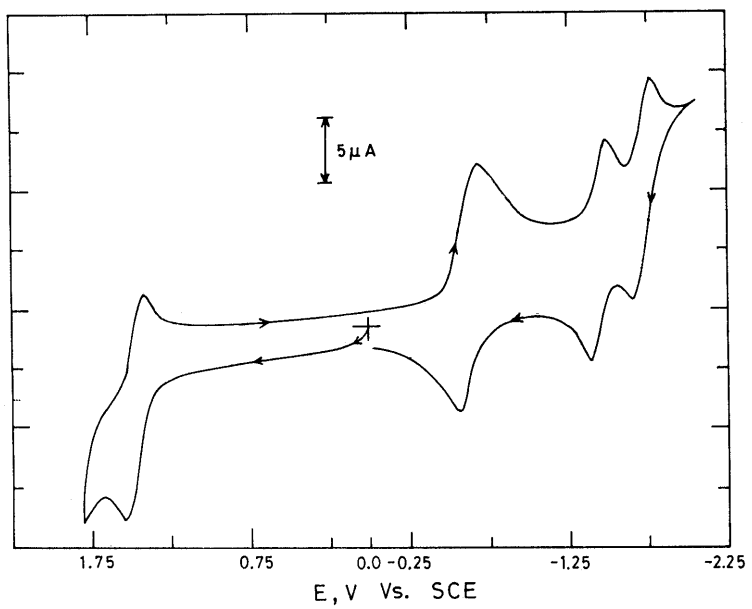

Fig. 5. Cyclic voltammogram of $[Ru(bpy)_2(p\text{-}MeaaiCH_2ph)](ClO_4)_2$ in acetonitrile at GC-milli electrode (0.1 M Bu_4NClO_4) at 298 K using SCE as reference.

relation with $\Delta E°$ values. The difference in potential between the $Ru^{III/II}$ couple and the first ligand reduction couple ΔE_1° ($= E_{1/2}^{M}$ (Eq. (4)) $- E_{1/2}^{L1}$ (Eq. (5))) is linearly related (Eq. (8)) with the longer wavelength MLCT transition (ca. 500 nm). Similarly the potential difference ΔE_2° ($= E_{1/2}^{M}$ (Eq. (4)) $- E_{1/2}^{L1}$ (Eq. (5))) is linearly

$$\nu_1 = 1.39\Delta E_1^\circ - 0.46 \quad (8)$$

correlated with the MLCT transition at ca. 400 nm. (Eq. (9)). The plots are not exactly parallel but their

trend (slopes of same sign) support equivalent intramolecular redox process.

$$v_2 = 1.67\Delta E_2^{\circ} - 1.82 \quad (9)$$

Therefore, the low-energy MLCT transition (ca. 500 nm) for these complexes involves excitation to the π* (RaaiR′) and high-energy transition (ca. 400 nm) is associated with electron excitation to the π* (bpy). It may also be noted that other examples of ruthenium(II) complexes with similar ligands, e.g. the 2,2′-bipyridine [14–16], 2-(arylazo)pyridines [42], 2-(arylazo)imidazoles [1] and aryl-(2-pyridyl methylene)amine [19] also show similar relationships.

4. Supplementary data

Supplementary data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 142090. Copies of this information are available free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

Financial support from the Council of Scientific and Industrial Research (CSIR), New Delhi is gratefully acknowledged. We thank Dr B.B. De, University of Massachusetts, Lowell, USA, for recording some NMR spectra. Our sincere thanks are also due to Professor S. Bagchi, Department of Chemistry, Burdwan University, Burdwan, for helpful discussion.

Received 11 February 2000; accepted 8 June 2000

Abstract

Two new cyano-bridged dinuclear complexes $[Cu(dmen)_2Fe(CN)_5(NO)]$ (**1**) and $[Cu(dmpn)_2Fe(CN)_5(NO)]$ (**2**) (where dmen = 2-dimethylaminoethylamine and dmpn = 1 dimethylamino-2-propylamine) have been synthesized. The complexes have been characterized by elemental analyses, spectroscopic studies and magnetic moment measurements, and the structures were determined using single-crystal X-ray diffraction. In both complexes the copper(II) ion is coordinated by five nitrogen atoms and has distorted square-pyramidal geometry. The iron(II) center is in a distorted octahedral environment and is linked to copper(II) through a cyano-bridge. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Copper–iron complexes; Cyano-bridge; Crystal structures; IR spectra

1. Introduction

Interaction of ferrocyanide with copper proteins was studied and it is suggested that outer sphere charge-transfer (CT) complexes are formed during the electron transfer between two metals. The binding in such complexes is proposed to occur via electrostatic interaction and hydrogen bonding, but direct information is not available [1]. In some cases CT complexes without electron transfer take place as is the case for ferrocyanide with bovine superoxide dismutase, copper substituted carbonic anhydase [2,3] and also in the complex of copper(II) with tris(2-aminoethylamine) [4]. It is well known that the cyanide ion may coordinate through the carbon atom acting as a monodentate ligand or through both the carbon and nitrogen atoms acting as a bridging ligand [5,6]. Recently, there has been a growing interest in the field of coordination polymers based on hexacyanometalate $[M(CN)_6]^{3-}$ as a building block, due to the generation of anomalous structures, magnetic behavior and electron transfer properties [7–11]. Electron transfer is a fundamental and important chemical process with important applications in the field of photosynthesis, disease control and catalysis. Previously, we have reported synthesis and thermally induced electron transfer properties of some cyano-bridged complexes [12]. Zhan and others have reported few cyano-bridged complexes by controlling the reaction conditions [13–17].

Several works have been carried out with the $[Fe(CN)_5(NO)]^{2-}$ anion [18–20], but the interesting polymeric network using nitroprusside as building block was developed very recently [21–23]. Tang and co-workers [21] reported an antiferromagnetic 2D polymeric complex $[Cu_2(oxpn)Fe(CN)_5(NO)]_n$ (oxpn = *N*,*N*′-bis(3-aminopropyl)oxamide) in which the copper(II) and iron(III) centers are bridged by both oxpn and cyanide. Recently, Wei and co-workers [22] reported a double complex $[Ni(bpy)_3][Fe(CN)_5(NO)]\cdot 3H_2O$ and an antiferromagnetic 1D polymeric complex $[Ni(en)_2Fe(CN)_5(NO)]\cdot H_2O$, in which the nickel(II) and iron(II) centers are linked by two cyanide groups. Fur-

thermore, Zhan et al. [23] reported three complexes of general formula $[Cu(L)_2\{Fe(CN)_5(NO)\}_2][Cu(L)_2]\cdot nH_2O$ [where L = ethylenediamine, 1,2-diaminopropane and 1,3-diaminopropane and $n = 0–2$] in which the anionic moiety proceeds with the formation of a trinuclear zigzag chain. Attempts have been made to clarify the structural correlation with the magnetic property of dinuclear complexes with the $[Fe(CN)_5(NO)]^{2-}$ anion. In an attempt to achieve this goal, we have synthesized two new cyano-bridged heterometallic complexes $[Cu(dmen)_2Fe(CN)_5(NO)]$ (**1**) and $[Cu(dmpn)_2Fe(CN)_5(NO)]$ (**2**), which have been characterized by X-ray analysis, IR, ESR, electronic spectroscopy and magnetic measurements.

2. Experimental

2.1. Materials

All chemicals and solvents used for synthesis were of reagent grade. 2-Dimethylaminoethylamine and 1-dimethylamino-2-propylamine (Fluka), $Cu(NO_3)_2\cdot3H_2O$ (Lancaster) and $Na_2[Fe(CN)_5(NO)]\cdot2H_2O$ (Aldrich) were used as received.

2.2. Physical measurements

Elemental analyses were carried out using a Perkin–Elemer 2400 II elemental analyzer. Infrared spectra were recorded on a Perkin–Elemer 883-Infrared spectrophotometer in the range 4000–200 cm^{-1} as KBr pellets. Electronic spectra were recorded from an aqueous solution on a Hitachi U-3400 (UV–Vis–NIR) spectrophotometer. ESR spectra of the crystalline compound were recorded at X-band frequency using a Bruker ESP 300E automatic spectrometer. Magnetic susceptibility measurements in the temperature range 2–300 K were carried out using MPMS SQUID magnetometer.

2.3. X-ray crystallography

The air-stable crystals of **1** and **2** were mounted on glass fiber. Crystallographic data for **1** and **2** are listed in Table 1 and selected bond lengths and angles are listed in Table 2. The data were measured at 293(2) K on a Syntex $P2_1$ four-circle diffractometer fitted with graphite-monochromated Cu Kα radiation, $\lambda = 1.54178$ Å. The stability of the crystals was checked by measuring standard reflections at fixed intervals during the data collection. However, no significant loss of intensity was noted for the crystals. All the reflections collected were independent, satisfied the $I > 2\sigma(I)$ criterion of observability and were used in the subsequent structure determination and refinement. The structures were solved by direct methods using SHELXTL-PLUS [24] and

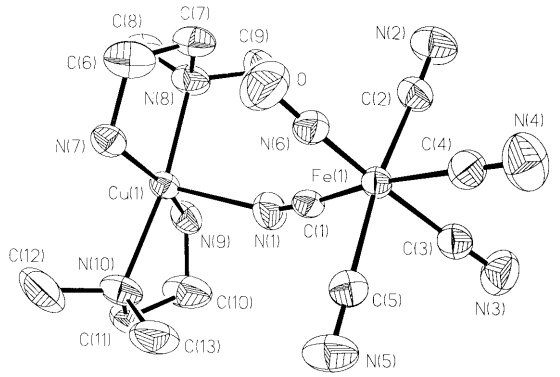

Fig. 1. View of $[Cu(dmen)_2Fe(CN)_5(NO)]$ (**1**) with atom numbering scheme.

refined by a full-matrix least-squares procedure based on F^2 using SHELXL-93 [25].

2.4. Synthesis of the complexes

$[Cu(dmen)_2Fe(CN)_5(NO)]$ (**1**): a 10 ml aqueous solution of $Na_2[Fe(CN)_5(NO)]\cdot 2H_2O$ (0.29 g, 1 mmol) was added slowly to an aqueous solution of $[Cu(dmen)_2](NO_3)_2$ (0.36 g, 1 mmol) and the mixture was kept in a dark place. The deep blue square-shaped crystals of **1** appeared after 2 days, from which crystals suitable for X-ray analysis were separated. The crystals were collected by suction filtration, washed with water and dried in air. *Anal*. Found: C, 34.5; H, 5.4; N, 30.5. Calc. for $C_{13}H_{24}CuFeN_{10}O$: C, 34.2; H, 5.3; N, 30.7%.

$[Cu(dmpn)_2Fe(CN)_5(NO)]$ (**2**): the synthesis was carried out using the same procedure as in **1**, by using $[Cu(dmpn)_2](NO_3)_2$. The blue prismatic crystals of **2** appeared after 1 day. *Anal*. Found: C, 37.0; H, 5.9; N, 28.8. Calc. for $C_{15}H_{28}CuFeN_{10}O$ requires: C, 37.2; H, 5.8; N, 28.9%.

3. Results and discussion

3.1. IR spectra

The characteristic IR active bands for ν(NH) of the NH_2 groups appeared at 3275, 3231 and 3151 cm^{-1} for complex **1** and at 3246, 3230 and 3137 cm^{-1} for complex **2**. In general, IR absorption bands in the region 2200–1900 cm^{-1} are due to the presence of CN^- and NO^+ stretching vibrations [22]. The low intensity bands that appeared at 2162 and 2154 cm^{-1} for **1** and **2**, respectively, was assigned to the intermetallic bridging ν(C≡N), and the high intensity band that appeared at 2143 and 2144 cm^{-1} for **1** and **2**, respectively, was assigned to the terminal ν(C≡N) stretching mode. Our results suggest that the contribution of the terminal cyanide group is high. The band of ν(NO) appeared at 1928 and 1916 cm^{-1} for **1** and **2**, respectively, in accordance with the literature [22].

3.2. Electronic spectra

The binuclear complexes exhibit two broad peaks at 673 and 545 nm for **1** and at 675 and 549 nm for **2**. The high-energy peaks are assigned as a d–d transition of copper(II) ions and the low-energy absorptions are assigned to iron(II)–copper(II) [3,4,23] charge transfer.

3.3. ESR spectra

The ESR spectra for the complexes show a symmetric feature with the g values, $g_\parallel = 2.21$, $g_\perp = 2.06$ and there is no change on lowering the temperature for compound **1** except a simple decrease in intensity. For compound **2** some ill-defined hyperfine splits were observed. The ESR spectra of the complexes are typically the same as the copper(II) ion, and the data suggest square-pyramidal geometry with $g_\parallel > g_\perp > g_e$ in both cases, and the unpaired electron occupies the $d_{x^2-y^2}$ orbital.

3.4. Magnetic measurements

Both the complexes follow the Curie law due to the presence of copper(II) ion, and the plot of $\chi_M T$ versus T remains invariant. In each case the $\chi_M T$ values are 0.5, typical for one unpaired electron of copper(II) ion with a g value of 2.06–2.21. Magnetic results indicate that exchange interaction between copper(II)–iron(II) is absent in both the complexes as the $[Fe(CN)_5(NO)]^{2-}$ anion is diamagnetic. This is also supported by the reported complexes $[Cu_2(oxpn)Fe(CN)_5(NO)]_n$ and $[Ni(en)_2Fe(CN)_5(NO)]\cdot H_2O$ [21,22], which were found to exhibit an antiferromagnetic behavior due to the interaction of M(II) [Cu, Ni] ions through oxpn in the former and cyano-bridge in the latter, but the exchange interaction between the M(II)–Fe(II) through cyano-bridge is negligible.

3.5. Description of structures

The crystal structures of **1** and **2** with atom numbering schemes are presented in Figs. 1 and 2, respectively. The copper(II) ions in both the complexes are pentacoordinated. The coordination number five is very common and possesses either square-based pyramid (SP) or trigonal-bipyramid (TBP) geometry. Recently some complexes have been reported in which the copper(II) ion adopts geometry that is intermediate between SP and TBP [4,11]. Several parameters are used to specify the geometry, one of which is the parameter τ [26]. The

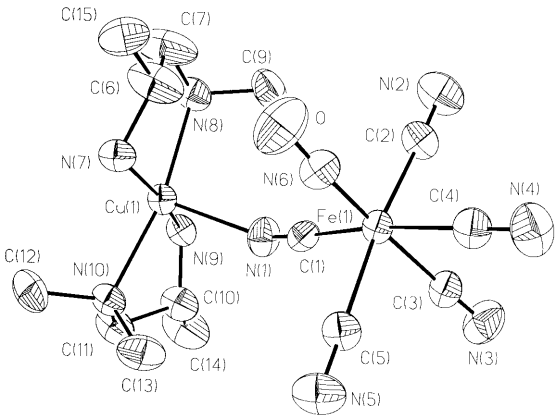

Fig. 2. View of $[Cu(dmpn)_2Fe(CN)_5(NO)]$ (**2**) with atom numbering scheme.

value of τ is 0.15 for **1** and 0.023 for **2**, which indicates that the coordination environment of the copper atom in both complexes is distorted square-pyramidal. The distortion towards TBP geometry is smaller for **2** than for **1**. The basal plane is constructed by the coordination of two primary nitrogen atoms [Cu(1)–N(7), Cu(1)–N(9) are 2.003(4) and 1.989(4) Å for **1** and 1.989(3) and 1.988(3) Å for **2**] and two tertiary nitrogen atoms [Cu(1)–N(8), Cu(1)–N(10) are 2.097(4) and 2.120(4) Å for **1** and 2.123(4) and 2.133(3) Å for **2**] and the nitrogen atom of the cyanide group occupies the axial position [Cu(1)–N(1) is 2.234(5) Å for **1** and 2.223(4) Å for **2**]. The axial Cu(1)–N(1) bond is elongated, as in the case of $[Cu_2(oxpn)Fe(CN)_5(NO)]_n$ and $[Cu(en)_2\{Fe(CN)_5(NO)\}][Cu(en)_2]$ [21,23], in which the values are 2.25(1) and 2.477(3) Å, respectively. The deviation of the Cu(1) from the mean basal plane N(7) N(8) N(9) N(10) is 0.24(1) Å for **1** and 0.25(1) Å for **2**. The bond angles and bond distances of **1** and **2** do not differ significantly and compare well with the related pentacoordinated complexes [4,10,11].

In both cases the iron(II) atom is in a distorted octahedral arrangement with a coordination of four carbon atoms of cyanide groups occupying the equatorial positions, whereas a carbon atom of cyanide group and a nitrogen atom of nitrosyl group from $[Fe(CN)_5(NO)]^{2-}$ anion, occupying the axial positions. According to MO theory, $M–NO^+$ will be nearly linear which is proved by the bond angles of Fe–N–O 176.6(4) and 176.3(4)° for **1** and **2**, respectively. The bond angles of Fe–C–N (ranging from 175.7 to 179° for **1** and from 176.2 to 178.4° for **2**) are nearly linear. The bond angle of C(1)–N(1)–Cu(1) for **1** and **2** are 146.5(4) and 147.5(3)°, respectively, indicating a nonlinear linkage between the nitrogen atom of the cyanide ligand and the copper(II) atom. The average Fe–C and C–N bond distances are 1.934 and 1.148 Å for **1** and 1.944 and 1.135 Å for **2**, respectively. The N(6)–O distances for **1** and **2** are 1.143(4) and 1.144(4) Å, respectively. All of these bond distances are comparable with those found in reported multinuclear complexes of $[Fe(CN)_5(NO)]^{2-}$ [21–23] and also in accordance with other nitroprusside metal salts [19].

4. Supplementary data

Supplementary data have been deposited with the CCDC under deposition numbers 139244 and 139243. Abstract

Zirconocene complexes carrying sterically bulky tri-substituted cyclopentadienyl ligands, $(\eta^5\text{-4-R-1,2-Ph}_2\text{C}_5\text{H}_2)_2\text{ZrCl}_2$ [R = phenyl (**3**), cyclohexyl (**4**)], were synthesized by the reaction of $ZrCl_4$ with lithio salt of 1,2,4-triphenylcyclopentadiene (**1**) or 4-cyclohexyl-1,2-diphenylcyclopentadiene (**2**), respectively. The single-crystal X-ray structure analysis reveals that both complexes crystallize in C_2-symmetric conformation in solid state. When activated with methylaluminoxane (MAO), complexes **3** and **4** polymerize ethylene with moderate activities to produce ultra-high-molecular-weight polyethylenes with high melting transition temperatures at low Al/Zr ratios. Under ambient conditions, both systems of **3**–MAO and **4**–MAO show relatively high activities in propylene oligomerization. The molecular weight of the polypropylene produced from the **3**–MAO system is lower than that from the **4**–MAO system. In comparison with **4**, complex **3** is more active in both ethylene and propylene polymerization. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Zirconocene; Crystal structures; Catalysis; Olefin polymerizations

1. Introduction

Group 4 metallocenes have attracted extensive research attention in recent years because of their application as catalysts in olefin polymerization [1–4]. In the development of new metallocene catalysts, modification of the cyclopentadienyl ligand is an effective means of optimizing catalyst activity as well as polymer properties such as molecular weight, stereoregularity and microstructure, etc. [5–10]. Recently, unbridged zirconocenes bearing trisubstituted cyclopentadienyl or mono-substituted indenyl ligands have drawn much attention because some of this type of zirconocenes produce semi-isotactic polypropylene elastomers [11–16]. The design of this type of catalyst was based on the consideration that the conformation conversion of the metallocene molecule could be controlled by the introduction of appropriate substituents on the cyclopentadienyl or indenyl ligand to block the rotation of the ligand during polymerization, so that the stereospecificity of the polymer could be controlled. It was believed that the π-stacking between the aryl substituents plays a crucial role in blocking the conversion between the *rac*-like and *meso*-like conformations of the catalyst molecule [13,17]. On the other hand, it has been demonstrated that modification of the ligand with phenyl substituent whether on the ligand ring [8,12–19] or even on the bridging moiety [20] has a considerably strong influence on the catalytic properties of metallocenes due to the special steric and electronic characteristics of phenyl group. In these respects, we have concentrated our efforts on designing a series of unbridged sterically hindered metallocenes containing phenyl substituents and investigating their polymeriza-

PII: S0277-5387(00)00484-8

tion behavior. The present paper describes the synthesis and structure characterization of two new C_2-symmetric unbridged zirconocenes (η^5-4-R-1,2-$Ph_2C_5H_2)_2ZrCl_2$ [R = phenyl (**3**), cyclohexyl (**4**)], as well as their catalytic properties for ethylene and propylene polymerizations.

2. Results and discussion

2.1. Synthesis

1,2,4-Triphenyl-1,3-cyclopentadiene (**1**) was synthesized by a modified literature procedure [21]. Treatment of 3,4-diphenyl-2-cyclopenten-1-one with phenyl lithium in THF formed the intermediate 1-hydroxy-1,3,4-triphenyl-2-cyclopentene, which was then converted into **1** by dehydration with *p*-toluenesulfonic acid monohydrate (Scheme 1). Pure **1** was obtained as pale yellow needles by recrystallization from 1:3 CH_2Cl_2–hexane in a good yield (70%). THF was used as solvent because of the good solubility of 3,4-diphenyl-2-cyclopenten-1-one and the increased reactivity of the addition of phenyllithium to the keto group of α–β unsaturated ketone. 4-cyclohexyl-1,2-diphenyl-1,3-cyclopentadiene (**2**) was prepared in a similar manner to **1** by the reaction of 3,4-diphenyl-2-cyclopenten-1-one with cyclohexyl magnesium chloride. Compound **2** was obtained in low yields (less than 30%) presumably due to that the bulky cyclohexyl Grignard reagent disfavors 1,2-addition to the keto group of the α–β unsaturated ketone. Pure **2** was obtained by column chromatography as a yellow oil which solidified slowly at room temperature. Attempts to prepare **2** with cyclohexyl lithium instead of cyclohexyl magnesium chloride were unsuccessful. ^{1}H NMR spectroscopic analysis indicates that both **1** and **2** were obtained in single isomer form (as depicted in Scheme 1). The chemical shifts of the cyclopentadiene ring protons of **2** (δ 3.47 and 6.31 ppm) are shifted up-field 0.5–0.8 ppm compared with those (δ 3.95 and 7.06 ppm) of **1** due to the electronic donating effect of the cyclohexyl substituent.

Scheme 1.

The ligand precursor **1** is well soluble in toluene, while only slightly soluble in other common organic solvents. Therefore, **1** was deprotonated with butyllithium in toluene. The produced lithium salt was easily isolated from solvent as white precipitate in ca. 90% yield. Interestingly, the ligand precursor **2** has a pretty good solubility in hexane. The lithium salt of **2** was therefore prepared in hexane in high yields ($\sim$95%) with convenient isolation and purification. THF was found to be an unsuitable solvent for the lithiation reaction due to low yield and difficulty in isolation. The zirconocene dichlorides **3** and **4** were prepared from the reaction of two equivalents of lithium salt of corresponding ligand with $ZrCl_4$ in toluene. The reaction mixture was heated at 60–70°C for hours until a bright yellow solution was formed, which indicates the completion of the reaction. Pure complexes **3** and **4** were obtained by recrystallization of the crude products from hexane–toluene in high yields (80% for **3** and 74% for **4**). Both **3** and **4** were found to be stable to air and moisture for several days.

^{1}H and ^{13}C NMR spectra reveal that **3** and **4** both exhibit C_{2v} symmetry in solution due to the rapid rotation of the cyclopentadienyl ligands around the Cp–Zr axis and all phenyl groups in both complexes are in free rotating fashion at room temperature. In complex **3**, the down-field shift of the Cp ring proton resonance (δ 6.75 ppm) compared to that (δ 6.64 ppm) in **4** is in agreement with the result mentioned above for their ligand precursors **1** and **2**. In ^{13}C NMR spectra, down-field shifts of the resonances (δ 125.1 and 125.4 ppm in **3**, 128.0 ppm in **4**) assigned to the Cp ring carbons linked to phenyl groups compared to resonances of other Cp ring carbons were also observed due to the electron-withdrawing effect of the phenyl substituents.

2.2. X-ray crystal structures analyses

The molecular structures of **3** and **4** determined by X-ray diffraction are shown in Figs. 1 and 2, respectively. Selected bond distances and angles are given in Table 1. The geometry about zirconium in **3** or **4** can be described as pseudo-tetrahedral and the whole molecule adopts a C_2-symmetric conformation. The two adjacent phenyl substituents at each Cp ring lie in the front open side of the zirconocene molecule, one of which is staggered nearly over one of the two Cl atoms and the other is oriented away from the corresponding phenyl group at another Cp ring. The third phenyl substituent at each Cp ring in **3** and the cyclohexyl group in **4** are arranged backwards from the front side of the metallocene.

In complex **3**, the Cl–Zr–Cl # angle of 94.08(9)° is a typical value for unbridged zirconocenes [22,23]. The Cent–Zr–Cent angle (Cent is the centroid of Cp ring)

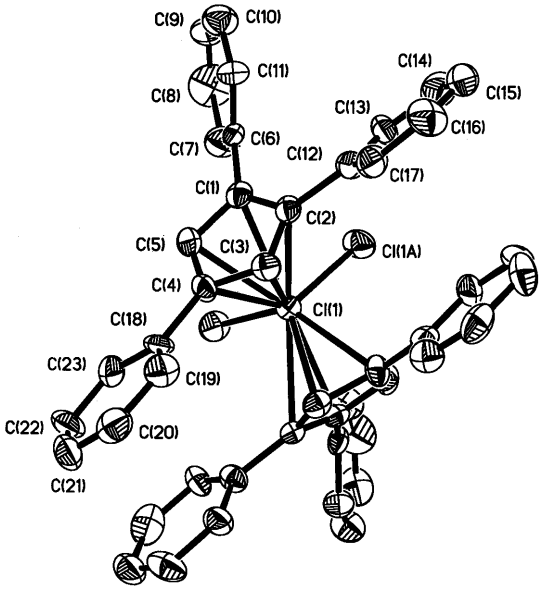

Fig. 1. ORTEP plot of complex **3** at 50% probability ellipsoids. The solvent molecules and hydrogen atoms were omitted for clarity reasons.

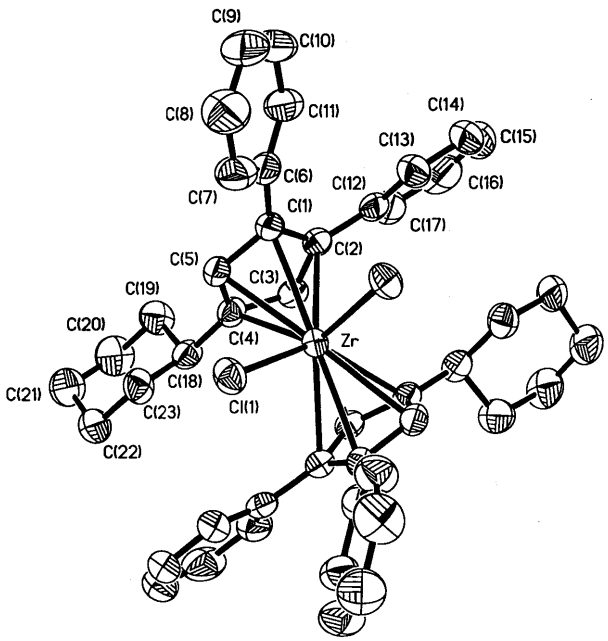

Fig. 2. ORTEP plot of complex **4** at 50% probability ellipsoids. The solvent molecules and hydrogen atoms were omitted for clarity reasons.

129.3° is almost identical to that (129.7°) observed in $[\eta^5\text{-}C_5H_3\text{-}1,3\text{-}(CMe_3)_2]_2ZrCl_2$ [24], smaller than the one of 131.3° for bis(2-phenylindenyl)zirconium dichoride [12], but much larger than that of 119.4° found in [bis(η^5-7,9-diphenylcyclopenta[*a*]acenaphthadienyl)] zirconium dichloride [19]. The angle (φ) between two Cp ring planes (56.6°) is larger than the one (51.4°) observed for $(Me_3CCp)_2ZrCl_2$ and analogous metallocenes [25]. The angles between the Cp and the phenyl planes are separately 56.9, 33.3 and 24.1°. Compared with the value (less than 10°) of the angle between the phenyl and indenyl planes in bis(2-phenylindenyl)zirconium dichloride [13], the angle (24.1°) between the Cp plane and the phenyl ring at the 4-position in **3** is quite large. This angle is also larger than those for complexes $(1,2\text{-}Me_2\text{-}4\text{-}Ph\text{-}C_5H_2)ZrCl_2$ (18.8, 13.6°) [15], while close to that (22.5°) in $(1,2\text{-}Me_2\text{-}4\text{-}p\text{-}tolyC_5H_2)_2ZrCl_2$ [13].

The Zr–Cl bond distance of 2.441(3) Å is in a normal range for zirconocene dichloride [25]. The distance from Zr atom to the centriod of cyclopentadienyl ring (2.245 Å) is longer than those (2.215–2.223 Å) found in analogous bulky zirconocene compounds [19,26]. The C(1)–C(2) bond has the longest bond length [1.458(9) Å] among five wedges of the Cp ring. It seems likely that the two adjacent phenyl substituents sterically force the C–C bond longer. The bond lengths for C(1)(sp^2)–C(6)(sp^2) [1.495(9) Å] and C(2)(sp^2)–C(12)(sp^2) [1.510(9) Å] are longer than that of C(4)(sp^2)–C(18)(sp^2) [1.490(9) Å], which might be attributed to that the bonds C(1)–C(6) and C(2)–C(12) are in more sterically congest environments.

The structure of **4** is similar to that of **3** with the substituted cyclohexyl group at each Cp ring adopting a

Cp_2ZrCl_2	300	1.09	0.47	132.9
	1000	2.26	0.43	131.9
	1500	3.69	0.42	131.5

[a] Polymerization conditions: catalyst 1.7 μmol, volume of toluene 50 ml, time 1 h, temp. 18°C, ethylene pressure 6 bar.
[b] kg PE (mol Zr)$^{-1}$ h^{-1}.
[c] Measured in decahydronaphthalene at 135°C.
[d] Determined with DSC at a heating rate of 10°C min^{-1}.

twist-chair conformation. The Cl–Zr–Cl angle of 93.71(4)° is smaller than that for **3**. The Cent–Zr–Cent (131.6°) is nearly equal to the value of 131.5° for (1,2-Me_2-4-Ph-C_5H_2)$_2$$ZrCl_2$ [15] and close to those (130.3 and 131.0°) in bis(2-phenyl-4,5,6,7-tetrahydroindenyl)(2-cyclohexylindenyl)zirconium dibromide [13]. In comparison with complex **3**, the Cent–Zr–Cent angle in **4** is increased by 2.3° and the angle between the Cp ring planes (53.1°) is reduced by 3.5°. The angles between the substituted phenyl and Cp planes (42.6 and 30.8°) are quite different from those (56.9 and 33.3°) for complex **3**. Obviously, the bulky cyclohexyl groups demand more space at the back part of the zirconocene molecule and result in these differences.

The Zr–Cl bond length [2.4303(7) Å] is also a typical value. The distance (2.251 Å) of Zr–Cent is somewhat larger than that in **3**. The bond lengths for C(1)(sp^2)–C(6)(sp^2) [1.479(4) Å] and C(2)(sp^2)–C(12)(sp^2) [1.488(4) Å] are smaller than those for C(1)(sp^2)–C(6)(sp^2) [1.495(9) Å] and C(2)(sp^2)–C(12)(sp^2) [1.510(9) Å] in **3**, probably due to stronger π-binding resulted from the smaller angle between the substituted phenyl and Cp planes in **4**.

2.3. Polymerization

Complexes **3** and **4** were studied as ethylene polymerization catalysts. For comparison purposes, some polymerization experiments were also carried out with Cp_2ZrCl_2 as catalyst under the same conditions (Table 2). Upon activation with MAO, both **3** and **4** polymerize ethylene with moderate activities at lower Al/Zr ratios. Unlike Cp_2ZrCl_2, the catalytic activities of **3** and **4** do not decrease very much when the Al/Zr ratio changes from 1500 to 300, which suggests that the concentration of cationic active species formed by the activation of MAO does not change very much with the change in Al/Zr ratios. In addition, the samples of polyethylene produced by **3** and **4** show high molecular weights and melting transition temperatures. These results could be explained on the basis of steric effects of the complexes. X-ray structures of **3** and **4** exhibit that the bulky substituents at the Cp ring construct a sterically crowded environment around the metal center, which could weaken the interaction between cationic zirconium center and anionic cocatalyst and therefore could efficiently prevent the active catalyst from bimolecular deactivation. Therefore, a smaller amount of MAO is needed to keep the catalyst in the active state. On the other hand, the large steric hindrance of the complexes could effectively block the chain termination by β-H transfer, thus long polymer chains could be formed.

The results in Table 2 also reveal that replacement of the phenyl group (in **3**) at the 4-position of Cp ring by a cyclohexyl group (in **4**) leads to a decrease in catalytic activities. As can be seen from their structures, complex **3** has a smaller angle of Cent–Zr–Cent and a larger angle of Cp–Cp than **4**. This means that the steric hindrance of **4** in the front side of Zr atom is larger and the coordination gap aperture for the monomer is smaller, and hence the catalytic activity of **4** is lower than that of **3**. Obviously, the steric effect of the ligands in **3** and **4** seems to play a predominant role in ethylene polymerization. Otherwise, the electron donating effect of the cyclohexyl group should increase the catalytic activity of **4**.

Complexes **3** and **4** were also tested for propylene polymerization under ambient conditions. From two typical experiments, 2.5 g of colorless oily propylene oligomer (catalytic activity: 1470 kg PP (mol Zr)$^{-1}$ h^{-1} was obtained from **3**, and 1.2 g of similar product (catalytic activity: 706 kg PP (mol Zr)$^{-1}$ h^{-1} was obtained from **4**. From the ^{1}H NMR spectra of the oligomer samples, resonances (δ 4.65, s; 4.72, s) for vinylidene end group were observed as the only signals in the unsaturated end group region, which indicates that β-H elimination is the single detectable chain termination pathway. The number average molecular weights (M_n) of propylene oligomers produced by **3** and **4** were calculated by end group analysis. It was found that the molecular weight of the propylene oligomer (M_n: 1.89×10^3 g mol^{-1}) produced by **3** is lower than that (M_n: 2.52×10^3 g mol^{-1}) of the sample from **4**. ^{13}C NMR spectra revealed that the polypropylene samples produced by **3** and **4** are highly regioregular and no 2,1-insertion takes place during the polymerization reaction. The reason for the lower catalytic activity of **4** would be the same as above mentioned for ethylene polymerization. Compared with **3**, the increased steric hindrance of **4** would result in a decline in the rates of chain propagation and chain termination, while the decrease in the chain termination rate seems to be more

remarkable, and thus longer polymer chains are produced.

It was demonstrated that the stereospecificity of polypropylene could be improved by introducing a bulky substituent at the appropriate position of the Cp ring to restrict the rotation of the ligand ring, e.g. polypropylene with high isotacticity (49.8%) was produced by *rac*-(1-Me-3-^{t}BuC_5H_3)$_2$ZrCl_2–MAO [15]. At ambient conditions, the lack of stereospecificity for **3** and **4** suggests that the bulky substituents at their Cp rings could not efficiently block the rapid rotation of the Cp rings to make the catalyst molecule maintain an isospecific coordination site-switching model with a long enough life-time during the polymerization [27,28]. On the other hand, it has been reported that high stereoregularity could be obtained with analogous complex bis(2-aryindenyl)zirconium dichloride [12–14]. In this case, the phenyl group and the rigid indenyl moiety have been believed to be two crucial factors for generating appropriate π-stacking and establishing a balance between two conformational isomers (from *rac* to *meso*) of the catalyst [12–14,17]. In the present case, there seems to be no effective π-stacking interaction in both **3** and **4** during polymerization. Investigations on the propylene polymerization under different conditions are currently underway in our laboratory.

3. Experimental

3.1. General procedures and material

All reactions with moisture- and air-sensitive compounds were carried out under argon with use of Schlenk techniques. Toluene and THF were refluxed over sodium benzophenone ketyl and distilled prior to use. Hexane and CH_2Cl_2 were refluxed and distilled from CaH_2 under nitrogen. Polymerization grade ethylene and propylene were further purified by passage through columns of 10 Å molecular sieves and MnO. 3,4-Diphenyl-2-cyclopenten-1-one was prepared by a known procedure [29]. Methylaluminoxane (MAO, 10 wt.% solution in toluene, $M = 800$ g mol^{-1}, Al = 5.3 wt.%) was purchased from Witco. Cyclohexylmagnesium chloride (2.0 M in diethyl ether), phenyllithium (1.8 M in cyclohexane–ether) and ^{n}BuLi (1.6 M in hexanes), $ZrCl_4$, and Cp_2ZrCl_2 were purchased from Aldrich. NMR spectra were recorded on Varian Unity-400 (FT 400 MHz, ^{1}H; 100 MHz, ^{13}C) spectrometer. Elemental analyses were carried out on Perkin–Elmer 240 C elemental analyzer. Viscosity-average molecular weights of the polyethylenes were determined in decahydronaphthalene at 135°C using Schott Gerate Mod. AVS/T2 Ubbelohde viscosimeter. Melting transition temperatures (T_m) of the polyethylenes were determined by DSC (Du Pont 910 differential scanning calorimeter) at a heating rate of 10°C min^{-1}.

3.2. 1,2,4-Triphenyl-1,3-cyclopentadiene (1)

To a solution of phenyl lithium (25 ml, 1.8 M in cyclohexane–ether, 0.045 mol) was added dropwise a solution of 3,4-diphenyl-2-cyclopenten-1-one (10 g, 0.043 mol) in THF (70 ml) at −10°C. The deep reddish solution was allowed to warm to r.t. and stirred for 6 h. After quenching with 40 ml of ice–water, the organic layer was separated and the aqueous phase was extracted with diethyl ether (2 × 30 ml). The combined organic phases were stirred with *p*-toluenesulfonic acid monohydrate (1 g) for 2 h. The mixture was neutralized by addition of 30 ml acqueous NH_4Cl and then the organic solution was dried over $MgSO_4$. After removal of the solvent, pure **1** was obtained as a pale yellow needle solid by recrystallization from hexane–CH_2Cl_2 (3:1). Yield 7.73 g (61.1%). ^{1}H NMR ($CDCl_3$, 400 MHz): δ 3.95 (s, 2H, C_5H_3), 7.06 (s, 1H, C_5H_3), 7.1–7.6 (m, 15H, Ph) ppm.

3.3. 4-Cyclohexyl-1,2-diphenyl-1,3-cyclopentadiene (2)

THF (40 ml) was added to a dry 200 ml Schlenk flask under argon. Cyclohexylmagnesium chloride (21.5 ml, 2.0 M in diethyl ether, 0.043 mol) was added, followed by dropwise addition of a solution of 3,4-diphenyl-2-cyclopenten-1-one (10 g, 0.043 mol) in THF (50 ml) at −10°C. The mixture was allowed to warm to r.t. and stirred for 5 h. After the solution was quenched with 40 ml of ice water, the organic layer was extracted with diethyl ether (2 × 30 ml). The combined organic phases were treated with concentrated HCl (3 × 20 ml). The mixture was washed with saturated NH_4Cl (aq). After drying with $MgSO_4$ and filtering, the solvent was evaporated under reduced pressure. Pure **2** was obtained as yellow–brown oil by chromatography over silica gel (eluent: hexane–CH_2Cl_2 (15:1), which was gradually made more polar to a ratio of 6:1). Yield: 3.26 g, 25.3%. ^{1}H NMR ($CDCl_3$, 400 MHz): δ 0.95–1.98 (br m, 10H, Cy), 2.40 (br m, 1H, Cy), 3.47 (s, 2H, C_5H_3), 6.31 (s, 1H, C_5H_3), 7.02–7.40 (m, 10H, Ph).

3.4. Bis(1,2,4-triphenylcyclopentadienyl)zirconium dichloride (3)

1,2,4-Triphenyl-1,3-cyclopentadiene (0.88 g, 2.99 mmol) was dissolved in toluene (40 ml). ^{n}BuLi (2.0 ml, 1.6 M, 3.20 mmol) was added dropwise at −78°C to give a creamy suspension. The mixture was stirred for 18 h at r.t. After the solvent had been removed by filtration, the solid residue was washed with hexane (20 ml) and then suspended in toluene (40 ml). $ZrCl_4$ powder (0.34 g, 1.46 mmol) was added slowly at −15°C and the suspension was allowed to warm to r.t. The mixture was stirred over night and heated to 70°C for further 18 h. The precipitate was filtered off and the solution was

concentrated in vacuo. Recrystallization from toluene–hexane (1:3) afforded **3** as a yellow crystalline powder. Yield: 0.89 g (80.3%). ^{1}H NMR ($CDCl_3$, 400 MHz): δ 6.75 (s, 4H, Cp), 7.00–7.20 (m, 30H, Ph). ^{13}C NMR ($CDCl_3$, 100 MHz): δ 116.1, 125.1, 125.4 (Cp), 127.4, 127.6, 127.8, 129.0, 129.5, 130.8, 131.9, 133.0 (Ph). $C_{46}H_{34}Cl_2Zr$ (748.85): *Anal.* Calc. C, 73.78; H, 4.58. Found: C, 73.98; H, 4.65%.

3.5. Bis(4-cyclohexyl-1,2-diphenylcyclopentadienyl)zirconium dichloride (4)

To a solution of 4-cyclohexyl-1,2-diphenyl-1,3-cyclopentadiene (0.78 g, 2.65 mmol) in hexane (30 ml) was added BuLi (1.8 ml, 1.6 M in hexane, 2.88 mmol) at −78°C. The mixture was allowed to warm to r.t. and stirred overnight. The solvent was removed by filtration and the solid was suspended in toluene (50 ml) and cooled to −15°C. $ZrCl_4$ (0.30 g, 1.3 mmol) was added to the suspension. The mixture was stirred overnight at r.t. and for 18 h at 70°C. The resulting suspension was filtered to remove precipitate. The solution was concentrated in vacuo and pure **4** was given as green–yellow micro-crystals by recrystallization from toluene–hexane (1:3). Yield: 0.73 g (73.8%). ^{1}H NMR ($CDCl_3$, 400 MHz): δ 0.71–0.82, 1.02–1.10, 1.37–1.61 (br m Cy, 20H), 1.78 (br m, Cy, 2H), 6.64 (s, 4H, Cp), 7.26–7.44 (m, 20 H, Ph). ^{13}C NMR ($CDCl_3$, 100 MHz): δ 25.6 (double intensity), 33.2, 36.2 (Cy), 117.4, 127.3, 128.0 (Cp), 128.7, 129.8, 133.3, 133.6 (Ph). $C_{46}H_{46}Cl_2Zr$ (760.95): *Anal.* Calc. C, 72.61, H, 6.09. Found: C, 72.99, H, 6.18%.

3.6. X-ray structural determination of complex 3

Crystals of **3** with two CH_2Cl_2 solvent molecules were obtained by recrystallization from a solution of hexane–CH_2Cl_2 (4:1). A yellow crystal suitable for X-ray diffraction sealed in a glass capillary was used. Data were collected on a Siemens P_4 four-circle diffractometer with a graphite monochromator using Mo Kα radiation. The structure was solved by direct methods and refined by full-matrix least-squares methods on F^2. The hydrogen atoms were located by combination of difference Fourier map and HYDROHEN program. All calculations were performed using SHELX-93 [30]. Crystallographic data and parameters are summarized in Table 3.

3.7. X-ray structural determination of complex 4

A yellow crystal of **4** with one CH_2Cl_2 solvent molecule crystallized from hexane–CH_2Cl_2 (5:1) was mounted in a thin-walled glass capillary under nitrogen. Data collection was performed using a standard Siemens SMART CCD diffractometer with graphite-monochromated Mo Kα radiation. Hydrogen atoms were located by combination of difference Fourier map and HYDROGEN program. Except for CH_2Cl_2 molecular, all non-hydrogen atoms were refined with anisotropic thermal parameters, while hydrogen atoms were refined isotropically. The disorder CH_2Cl_2 molecule founded in the lattice as a solvent of recrystallization exhibited high thermal parameters. The disorder CH_2Cl_2 was refined as 50/50 disordered. All calculations were performed using SHELX crystallographic package [31]. Crystallographic data and parameters are summarized in Table 3.

3.8. Polymerizations

A dry 250 ml steel reactor equipped with a magnetic stirrer was evacuated and pressurized with ethylene to 1.0 bar. Toluene and appropriate amount of MAO were added to the reactor through a septum port via syringe. After the solution was saturated with ethylene for 30 min, a solution of catalyst (1.7 μmol) in toluene was injected (total volume of the polymerization solution is 50 ml after the addition of catalyst). The vessel was repressurized to the required pressure with ethylene as soon as the catalyst was injected and the pressure was maintained by continuously feeding monomer. After the mixture was stirred for the desired reaction time, the reactor was vented and the polymerization was terminated by injecting acidified methanol [HCl (3 M)–methanol = 1:1]. The polymer was stirred in acidified methanol overnight, washed with water and methanol, dried in vacuo at 60°C. Polymerization of propylene was performed under ambient conditions (1 bar, temperature 20°C, time 1 h, Al/Zr = 1000/1, catalyst = 1.7 μmol). The procedure was similar to that for ethylene polymerization. After the reaction mixture was treated with acidified methanol and stirred overnight, the organic layer was separated and the aqueous phase was extracted with toluene. The organic layers were combined and dried over $MgSO_4$. After the solvent was removed, the propylene oligomer was obtained as a colorless oil.

4. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 140596 and 140597. Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 29 February 2000; accepted 26 June 2000

Abstract

The reaction of dipyrrylmethane with an equimolar mixture of ferrocenecarboxaldehyde and benzaldehyde in dry acetonitrile in the presence of a catalytic amount of trichloroacetic acid leads to the formation of 5-ferrocenyl-15-phenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**1**) with a yield of 27%. The metallation of **1** with $Zn(OAc)_2 \cdot 2H_2O$ and $MnCl_2 \cdot 4H_2O$ gives Zn·**1** and MnCl·**1**, respectively. Cyclic voltammograms of **1**, Zn·**1** and MnCl·**1** show reversible one-electron oxidation processes for the oxidation of ferrocene at 0.29, 0.22, and 0.37 V, respectively. Variable temperature ^{1}H NMR spectra of **1** in toluene-d_8 show two distinct singlets of equal intensities and line widths for NH protons. From the plot of $\ln(k/T)$ versus $1/T$ according to the Eyring equation, gave straight line with $\Delta G^{\ddagger} = 51$ kJ mol^{-1}. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Ferrocenylporphyrin; π-Conjugation; Electrochemical communication; Intramolecular hydrogen bonding; NH tautomerism

1. Introduction

Many discrete molecules in which two photo- and redox-active sites are linked by π-conjugation have been developed with great interest for applications in molecular electronic devices [1,2]. In particular, porphyrins [3,4] or ferrocenes [5] are the most frequently used molecules for this purpose. However, examples of covalently linked π-conjugates of these two units are quite rare [6,7]. These facts and the recent demonstration on the significant substituent effect on electronic properties in porphyrins prompted us to explore new porphyrin–ferrocene conjugates. Herein we describe the synthesis, structure and conjugated feature of 5-ferrocenyl-15-phenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**1**).

2. Experimental

2.1. Materials

Solvents were purified according to standard methods where applicable [8]. Tetra-*n*-butylammonium perchlorate (TBAP) was synthesized and purified by procedure described in the literature [9]. 3,3′-Diethyl-4,4′-dimethyl-2,2′-dipyrrylmethane was synthesized according to procedures described in the literature [10]. All other reagents were purchased from Aldrich Chemical Co. or Sigma Chemical Co. and were used as received.

2.2. Preparations

5-Ferrocenyl-15-phenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**1**) was synthesized by a procedure similar to that described by Osuka et al. for the preparation of 5,15-diarylporphyrins [11]. The ferrocenecarboxaldehyde (0.79 g, 3.7 mmol) and benzaldehyde (0.39 g, 3.7 mmol) were dissolved in dry acetonitrile (84 ml) containing trichloroacetic acid (0.56 g,

3.4 mmol). The mixture was stirred for 30 min under nitrogen. Then, the 3,3′-diethyl-4,4′-dimethyl-2,2′-dipyrrylmethane (1.8 g, 7.4 mmol) in acetonitrile (20 ml) was added through cannula under positive nitrogen pressure. After stirring for 60 h under nitrogen in the dark, *p*-chloranil (2.93 g, 12 mmol) in THF (100 ml) was added and stirred for 5 h under same conditions. The solvent was evaporated to dryness, and the residual solid was suspended on aqueous NaOH solution (10%, 100 ml) to dissolve the hydroquinone impurities. After stirring for 2 h, filtered on a glass frit, washed with water and then methanol. The crude products were separated and purified by flash chromatography (SiO_2, 3.8×25 cm, $CHCl_3$). The first red band was 5,15-diphenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**2**), and the second olive green band was the desired 5-ferrocenyl-15-phenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**1**). Recrystallization from toluene–methanol mixture gave purple crystals of **1**·0.5C_6H_5Me (0.70 g, 27% based on the amount used dipyrrylmethane). *Anal.* Calc. for $C_{48}H_{50}N_4Fe{\cdot}0.5C_6H_5Me$ (MW 784.87): C, 78.81; H, 6.93; N, 7.14. Found: C, 77.58; H, 6.93; N, 7.19. ^{1}H NMR (δ ppm, $CDCl_3$) 9.86 (s, 2H, *meso*-H), 8.25 (d, 1H, phenyl), 7.75 (m, 3H, phenyl), 7.64 (d, 1H, phenyl), 7.25–7.16 (m, 2.5H, phenyl of C_6H_5Me), 4.70 (t, 2H, ferrocenyl), 4.60 (t, 2H, ferrocenyl), 3.90 (m, 8H, CH_2CH_3), 3.72 (s, 5H, ferrocenyl), 3.35 (s, 6H, CH_3), 2.39 (s, 6H, CH_3), 2.35 (s, 1.5H, C_6H_5Me), 1.72 (t, 6H, CH_2CH_3), 1.66 (t, 6H, CH_2CH_3), −1.06 (s, 1H, NH), −1.32 (s, 1H, NH). 2.3. Physical measurements

Elemental analyses (C, H, and N) were performed by Fisons EA 1110 analyzer. ^{1}H NMR spectra were recorded on a Bruker Spectrospin 400 instrument with chemical shifts being referenced against the signal of the deuterated NMR solvents. Electronic spectra were measured on a Shimadzu UV-3100S spectrophotometer. Thermogravimetric analyses were performed under nitrogen atmosphere at a heating rate of 10°C min^{-1} with DuPont TGA 2050 instrument. Electrochemical measurements were carried out on a BAS-100W system. Cyclic voltammetry was performed with 1×10^{-3} mol dm^{-3} solution of sample in dry CH_2Cl_2 containing 0.1 mol dm^{-3} of $(n\text{-}C_4H_9)_4NClO_4$ as supporting electrolyte. The potentials were determined with reference to the Ag–AgCl electrode at room temperature. Under these conditions ferrocene shows a reversible one-electron oxidation wave ($E_{1/2} = 0.37$ V).

2.4. X-ray crystallography

A purple crystal of **1**·0.5 C_6H_5Me with dimensions $0.5 \times 0.4 \times 0.25$ mm, obtained from toluene–methanol solution, was mounted on a thin glass fiber and intensity data were collected on an Enraf–Nonius CAD4 diffractometer equipped with monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Unit cell parameters were determined from a least-squares fit of 25 accurately centered reflections ($22.45 < 2\theta < 27.22$). These dimensions and other parameters, including conditions of data collection, are summarized in Table 1. Data were collected at 293 K in the ω–2θ scan mode. Three intense reflections were monitored every 200 reflections to check stability. Of the 9932 unique reflections measured, 6198 were considered observed ($F_o > 4\sigma(F_o)$) and were used in subsequent structure analysis. Data were corrected for Lorentz and polarization effects. Empirical absorption correction using the ψ scan technique was applied. Maximum and minimum transmissions were 99.83 and 96.21%, respectively. The SHELXS-86 program was utilized for the direct method. The structure refinements were performed with the SHELXL-93 program on F^2 data. Anisotropic thermal parameters for all non-hydrogen atoms were included in the refinements. All hydrogen atoms bonded to carbon atoms were included in calculated positions. This C–H bond distance was fixed and U values were assigned based approximately on the U value of the attached atom. The other hydrogens (N–H) were included in located positions with $U = 0.08$ Å^2. The toluene molecule is

(a)

(b)

Fig. 1. Molecular structure of **1**, monomeric (a), and dimeric (b) structure.

refined with the regular hexagon model ($d_{C-C} = 1.39$ Å). A final difference Fourier map revealed several random features (< 0.627 eÅ^{-3}). The full-matrix least-squares refinement finally converged with $R_1 = 0.0780$ (based on F) and $wR_2 = 0.2032$ (based on F^2) for observed reflections ($F_o > 4\sigma(F_o)$).

3. Results and discussion

Compound **1** was synthesized by condensation of dipyrrylmethane with an equimolar mixture of benzaldehyde and ferrocenecarboxaldehyde. Pure **1** was separated from crude mixtures by column chromatography, and 5,15-diphenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (**2**) was also obtained as a side-product in 28% yield but 5,15-diferrocenyl-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin was not formed, because of steric demand.

The X-ray study of **1** shows that an asymmetric cell consists of one toluene solvent molecule and two ferrocenylporphyrins to form a dimer owing to a π–π interaction between the porphyrin planes. As shown in Fig. 1, the linked cyclopentadienyl (Cp) ring of the ferrocene substituent and the porphyrin plane twisted with dihedral angles of 47.1(3) and 49.3(3)°. The unusually small dihedral angles caused by large steric hindrance of β-pyrrolic methyl group imply that there might be a chance for a weak π-overlap between the Cp and the porphyrin rings. Furthermore, large steric hindrance of the β-pyrrolic methyl groups not only prevents the ferrocenyl moiety from rotating around the *meso* carbon but also results in distortion of the porphyrin ring. The C–C distance (1.50 Å) between the Cp and *meso* carbon of porphyrin is not significantly shorter than the pure single bond distance (1.52 Å) found in the 5,15-diferrocenylporphodimethene [12]. However, It should be considered that this bond distance of other ferrocenyl porphyrin complexes characterized by our and other

group was in the range of 1.477(5) ~ 1.498(8) Å which are significantly shorter than 1.52(1) Å. [6a,13] The conjugated feature of **1** was further explored by spectroscopic and electrochemical means. Selected bond distances and angles are listed in Table 2.

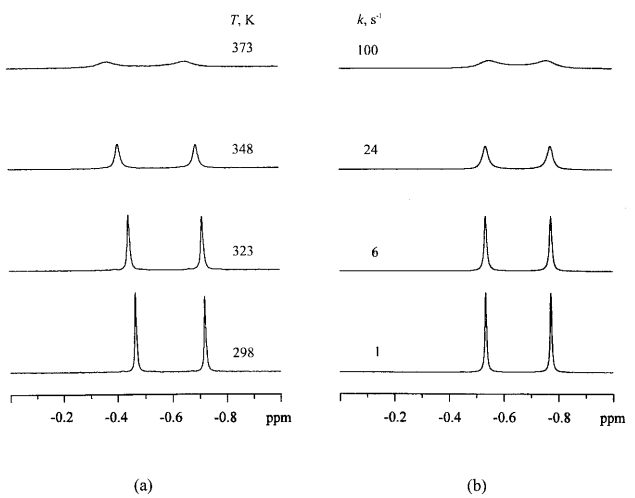
[b] Two-electron process.



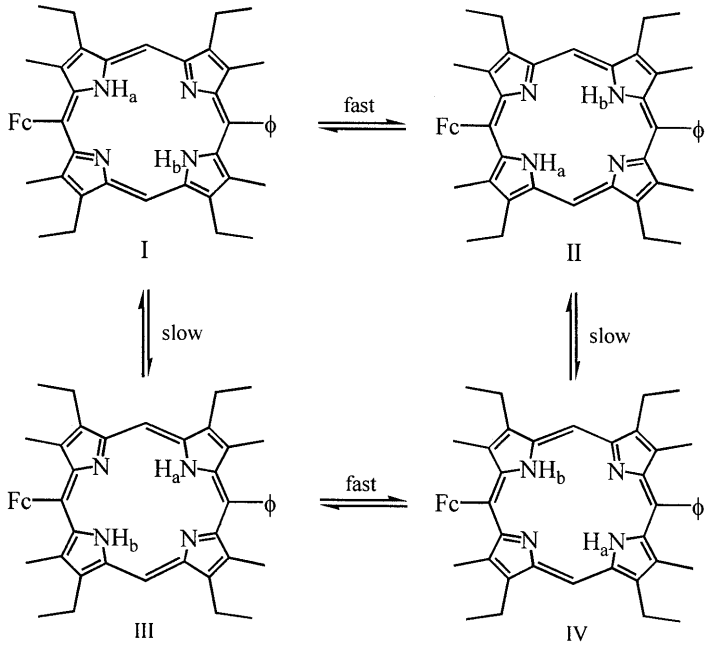


Fig. 2. Variable temperature ^1H NMR spectra for the nitrogen-bonded inner protons of porphyrin **1** in dry toluene-d_8. (a) observed and (b) calculated.

Electrochemical properties of **1** and its metal complexes Zn·**1** and MnCl·**1** in dichloromethane solution are summarized in Table 3. The ferrocenyl groups of compounds **1** and Zn·**1** undergo a reversible one-electron transfer process at 0.29 and 0.22 V, respectively. The values of half-wave oxidation potentials indicate that the ferrocenyl groups in these compounds are more susceptible for the oxidation than the free ferrocene. The easier ferrocenyl oxidation might be considered as a consequence of the great electron releasing ability of the porphyrin ring. In the case of MnCl·**1**, the higher oxidation state of Mn(III) is expected to reduce the electron releasing tendency of the porphyrin ring and thus make the ferrocene oxidation difficult. In fact, the oxidation potential of MnCl·**1** shifts to positive direction. The foregoing electrochemical analyses show that the oxidation of the ferrocene subunit is strongly affected by porphyrin ring as well as the central metal through extended π-conjugation.

^1H NMR data further support the strong electronic interaction of the ferrocenyl group with the porphyrin ring. In the case of **1** in chloroform, an electron withdrawing effect of ferrocenyl group through π-conjugation with the porphyrin ring was suggested to account for the large downfield shift of β-pyrrolic methyl protons adjacent to ferrocenyl group (3.35 ppm) compared to those adjacent to phenyl group (2.39 ppm). Furthermore, the chemical shifts for *meso* CH (9.86 ppm) and NH (−1.06 and −1.32 ppm) protons of **1** are quite different from the chemical shift for *meso* CH (10.22 ppm) and NH (−2.41 ppm) protons of **2**. This indicates that the ring current in **1** might be partially reduced due to the ring distortion [14]. Notably, the large downfield shift of NH for **1** compared to **2** can be interpreted by the N–H···N intramolecular hydrogen bonding [15].

The NH tautomerism in porphyrin is an intramolecular proton transfer process coupled with migration of double bonds. The two NH protons of the porphyrin **1** are situated on different chemical environments. Variable temperature ^1H NMR spectra of **1** in toluene-d_8 show two distinct singlets of equal intensities and line widths for NH protons as shown in Fig. 2. The chemical shifts are −0.47 and −0.72 ppm at 298 K. The presence of ferrocenyl substituent at only C5 position renders the two nitrogen-bonded protons magnetically nonequivalent at room temperature. The coalescence of the two NH peaks was unobserved up to the higher temperature limit of 373 K and only line broadening occurred, indicating that the exchange rate is very slow. This observation can be explained by considering that one kind of intramolecular N–H···N hydrogen bonding is prevailing against the other due to a rectangular

Scheme 1. Schematic representation of NH tautomerism.

elongation of porphyrin core. The X-ray analysis shows that **1** has two sets of short (2.69 and 2.72 Å) and long (3.12 and 3.16 Å) N···N distances and the short N···N distances lie in the known range (2.71 Å) observed for the N–H···N hydrogen bonding units of porphyrin [15]. Thus, the tautomerisations between tautomer I and III as well as between II and IV are not energetically favorable (Scheme 1) [16]. Based on the assumption that exchange is only responsible for the temperature-dependent line broadening, the rate constants for exchange can be determined. From plot of $\ln(k/T)$ versus $1/T$ according to Eyring equation [17], a straight line with $\Delta G^{\ddagger} = 51$ kJ mol^{-1} was obtained. This is similar to values reported in the literatures [18]. The exchange rate for NH protons depends on the solution conditions. When anhydrous chloroform is employed as a NMR solvent for **1**, the coalescing of the two NH peaks is not observed up to the higher temperature limit of 328 K. This is similar to the result observed in dry toluene as shown in Fig. 3. However, two NH signals are coalesced below room temperature in chloroform containing trace amount of residual water. It implies that the NH tautomerism of **1** in wet chloroform may be mediated by the trace amount of water in solvent. In dilute solution (0.04 mmol dm^{-3}) of porphyrin, the signal of NH protons is a singlet at 298 K. However, in concentrated solution (0.5 mmol dm^{-3}), the signals of NH protons split into two peaks because the rate of exchange becomes slower. Such result suggests that the rate of dynamic exchange of NH protons is accelerated in proportion to the water concentration of solution.

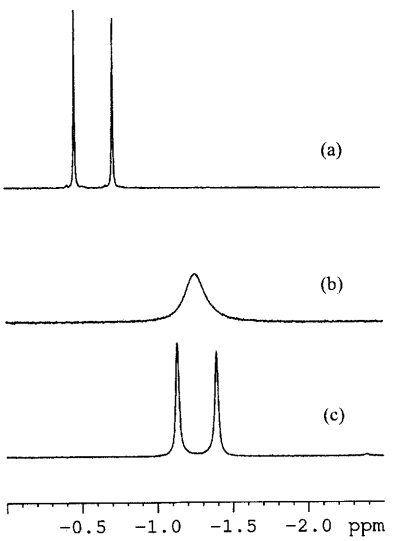

Fig. 3. ^{1}H NMR spectra of **1** in various solvent conditions at 298 K. (a) H_2**1**·0.5C_6H_5Me in anhydrous toluene-d_8, (b) H_2**1** in wet chloroform-*d*, and (c) H_2**1** in anhydrous chloroform-*d*.

Abstract

The reaction of *trans*-$[Ni(ampy)_2(NO_3)_2]$ (**1**) (ampy = 2-aminomethylpyridine) with $K_3[Fe(CN)_6]$ affords a cyano-bridged bimetallic system, $[Ni(ampy)_2]_3[Fe(CN)_6]_2 \cdot 6H_2O$ (**2**). The crystal structure of compound **1** has been solved. It crystallizes in the monoclinic space group $P121/c1$ and consists of neutral mononuclear entities with the nickel atom located on an inversion center. The nickel atom exhibits a (pseudo)octahedral stereochemistry with the two nitrato ligands coordinated in *trans* positions. The Ni–N bond distances vary from 2.0690(15) to 2.0811(15) Å, while the *trans*-Ni–O distances are 2.1665(13) Å. The cryomagnetic investigation of compound **1** reveals an intermolecular ferromagnetic coupling ($\theta = +3.7$ K), which is mediated by the π–π stacking interactions between the mononuclear entities. Compound **2** is a soft ferromagnet with $T_c = 7.5$ K and a coercive field of 330 G at 2 K. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

In the past decade or so, we have been facing a spectacular revival of the chemistry generated by the hexacyanometallate anions [1,2]. This is due to the discovery of the spontaneous 3-D long-range magnetic ordering exhibited by the Prussian Blue (PB) analogues, $M'_q[M(CN)_6]_m \cdot nH_2O$ and $C^IM'^{II}[M^{III}(CN)_6] \cdot nH_2O$ [3–9]. It has been found that, for certain combinations of paramagnetic metal ions in the cubic PB framework, room-temperature molecule-based magnets can be obtained [7,10]. The interesting magnetic and photomagnetic properties of these materials gave a strong impulse to the development of an extremely rich coordination chemistry, which is based on self-assembly processes involving $[M(CN)_6]^{q-}$ templates and $[M'L_x(H_2O)_y]^{m+}$ assembling cations. The presence of ancillary (usually polydentate) ligands, L, in the coordination sphere of the assembling cation influences the topology of the spin carriers in the lattice, and, consequently, the magnetic properties. The M′(II)–M(III) pairs are chosen in order to achieve the strict orthogonality of the magnetic orbitals, which affords a ferromagnetic interaction between the nearest-neighbor metal ions (M′(II) = Cu(II), Ni(II); M(III) = Cr(III), l.s.–Fe(III)).

For the particular Ni(II)–Fe(III) pair, a survey of the recent literature reveals numerous polynuclear complexes, with interesting structures and physical properties. Depending on the nature of the ancillary ligands attached to the nickel ion, discrete entities or 1-D, 2-D and 3-D bimetallic assemblies are obtained. One

Ni(II)–Fe(III) pentanuclear cluster, $[(Ni(bpm)_2)_3(Fe(CN)_6)_2]\cdot 7H_2O$ (bpm = bis(1-pyrazolyl)methane), has been characterized [11]. Its low nuclearity permitted accurate calculation of the value of the exchange coupling constant between cyano-bridged Ni(II) and low-spin Fe(III) ions ($J_{NiFe} = +5.3\ cm^{-1}$). Three types of compound exhibiting extended structures have been characterized in the Ni^{2+}–polydentate ligand–$[Fe(CN)_6]^{3-}$ system. They have the following stoichiometries: (a) $[Ni(LL)_2]_3[Fe(CN)_6]_2$ (Ni_3Fe_2) with a 1-D rope-ladder structure (LL = ethylenediamine) [12,13]; (b) $PPh_4[Ni(LL)_2][Fe(CN)_6]$ (NiFe) with a 1-D zig-zag chain structure (LL = propylenediamine) [14]; (c) $[Ni(LL)_2]_2[Fe(CN)_6]X$ (Ni_2Fe) with a 2-D square sheet structure (LL = 1,1-dimethylethylenediamine, propylenediamine; $X = ClO_4^-$, BF_4^-, PF_6^-, $CF_3SO_3^-$, $C_6H_5COO^-$, NO_3^-) [15–18]. By using tetradentate macrocyclic ligands, two $[Ni(MAC)]_3[Fe(CN)_6]_2$ compounds have been obtained, both with a 2-D honeycomb-like structure (MAC = cyclam, 1,4,8,11-tetraazacyclotetradecane [19]; 3,10-dimethyl-1,3,5,8,10,12-hexaazacyclotetradecane [20]). Finally, when the tripodal tetradentate ligand tris(2-aminoethyl)amine (tren) is used, the self-assembly between $[Ni(tren)]^{2+}$ and $[Fe(CN)_6]^{3-}$ ions leads to a cyano-bridged compound, $[Ni(tren)]_3[Fe(CN)_6]_2.6H_2O$, with a 3-D structure [21].

Beyond the beauty of their solid-state architectures, all these compounds played a very important role in gaining insights into the magnetostructural correlation of the cyano-bridged heteropolynuclear complexes. Magnetic ordering occurs in all compounds exhibiting 2-D and 3-D structures. As a matter of fact, it has been observed that the incorporation of an organic ligand in the $M'^{n+}/[M(CN)_6]^{q-}$ systems leads to materials undergoing magnetic phase transitions at lower temperatures than the PB analogue.

We report here on the magnetic properties of a new $Ni(II)_3Fe(III)_2$ cyano-bridged bimetallic complex, $[Ni(ampy)_2]_3[Fe(CN)_6]_2\cdot 6H_2O$, as well as on the crystal structure and magnetic properties of its mononuclear precursor, *trans*-$[Ni(ampy)_2(NO_3)_2]$ (ampy = 2-aminomethylpyridine) (Table 1).

2. Experimental

2.1. Synthesis

The chemicals were purchased from Aldrich and all manipulations were performed using materials as received.

trans-$[Ni(ampy)_2(NO_3)_2]$ (**1**) was prepared by mixing an aqueous solution of $Ni(NO_3)_2\cdot 6H_2O$ (10 ml, 1 mmol) with 2 mmol of 2-aminomethylpyridine. The slow evaporation of the resulting mixture led to a highly crystalline blue material. IR data (KBr, cm^{-1}): 3337m, 3283m, 3258m, 2927w, 2858vw, 1607m, 1569w, 1496w, 1416m, 1383vs, 1315s, 1287m, 1180w, 1147w, 1117w, 1100w, 1035m, 939vw, 886vw, 774m, 725w, 638w, 571w. Elemental analyses: Found: C, 35.6; H, 4.1; N, 14.4%; Calc.: C, 36.08; H, 4.00; N, 14.71%.

$[Ni(ampy)_2]_3[Fe(CN)_6]_2\cdot 6H_2O$ (**2**): an aqueous solution containing compound **1** (30 ml; 1 mmol) was added to an aqueous solution of $K_3[Fe(CN)_6]$ (20 ml; 0.6 mmol). The resulting brown precipitate was filtered off and washed with water. IR data (KBr, cm^{-1}): 3424vs, 3355vs, 3286vs, 2920w, 2144s, 2114s, 1606vs, 1484m, 1442s, 1380m, 1155m, 1077m, 1023vw, 771s, 638m. Elemental analyses: Found: C, 42.7; H, 4.4; N, 24.3; Fe, 7.9; Ni, 13.1%; Calc.: C, 42.48; H, 4.22; N, 24.78; Fe, 8.23; Ni, 12.98%.

$[Ni(ampy)_2]_3[Co(CN)_6]_2\cdot 6H_2O$ (**3**) was obtained following the same procedure as for compound **2**. Violet powder. IR data (KBr, cm^{-1}): 3421vs, 3355vs, 3281vs, 2924m, 2854m, 2154vs, 2124vs, 1606vs, 1570m, 1484m, 1441s, 1379m, 1283m, 1154m, 1111w, 1076m, 1021vs, 932m, 811w, 770s, 731w. Elemental analyses: Found: C, 41.7; H, 4.2; N, 24.2; Co, 8.1; Ni, 12.1%; Calc.: C, 41.92; H, 4.36; N, 24.45; Co, 8.57; Ni, 12.81%.

2.2. Physical measurements

The IR spectra (KBr pellets) were measured on a BIO-RAD FTS 135 spectrometer. UV–Vis spectra (diffuse reflectance technique) were recorded with a VSU2 spectrophotometer with MgO as a standard. Magnetic measurements were carried out on a Quantum Design MPMS-5S SQUID magnetometer.

2.3. Crystallography

The data collection for **1** was made at room temperature on an Enraf–Nonius CAD4 diffractometer with a

graphite-monochromatized Mo Kα radiation ($\lambda =$ 0.71073 Å). The $\omega-2\theta$ scan technique was used ($\theta_{max} =$ 25.00°). A total of 1434 reflections were collected, of which 1351 independent reflections ($R_{int} = 0.0080$). The coordinates of the heavy atoms were determined from direct methods and the positions of all non-hydrogen atoms were found by usual Fourier techniques. The refinement of the structure was done by full-matrix least-squares techniques) on F^2 (SHELX-97) and converged to R_1 ($I > 2\sigma(I)$) = 0.0261, wR_2 (all data) = 0.0730, Goodness-of-fit = 1.152, largest difference peak and hole 0.273 and -0.614 Å^{-3}.

3. Results and discussion

The synthesis of the cyano-bridged polynuclear compound, $[Ni(ampy)_2]_3[Fe(CN)_6]_2 \cdot 6H_2O$, is based on the observation that bis-chelated Ni(II) complexes, $[Ni(chelate)_2X_2]$, are very good candidates for self-assembly processes with $[M(CN)_6]^{3-}$ templates. These processes consist in the replacement of the weakly bound anions, X^-, with bridging cyano groups. Therefore, the first step in our work was the synthesis of a bis-chelated nickel(II) complex with 2-aminomethylpyridine (ampy) as a bidentate ligand. Indeed, the reaction between $Ni(NO_3)_2 \cdot 6H_2O$ with ampy in a metal:ligand molar ratio of 1:2 leads to the mononuclear complex $[Ni(ampy)_2(NO_3)_2]$ (**1**).

Let us discuss first the crystal structure and the magnetic properties of the nickel(II) precursor. The structure in itself has nothing exceptional and consists of neutral mononuclear $[Ni(ampy)_2(NO_3)_2]$ entities. However, the crystal structure proves that this compound, with only two molecules of chelating ligands and two potentially free coordination sites, is a suitable starting material in synthesizing cyano-bridged Ni(II)–Fe(III) polynuclear complexes. The nickel atom lies on an inversion center and the nitrato ligands occupy the *trans* positions (Fig. 1). Selected bond distances and angles are given in Table 2. The nickel atom is coordinated to four nitrogen atoms of the chelating ampy ligands and two oxygen atoms, from two nitrato ligands, in a distorted octahedral geometry. The distortion of the octahedron arises mainly from the short bite of the ampy ligands (79.92(6)°). The Ni–N distances are very close; Ni–N(py) = 2.0811(15) and Ni–N(NH_2) = 2.0690(15) Å). The Ni–O bond lengths are slightly longer (2.1665(13) Å) in comparison with the Ni–N. Compound **1** crystallizes as one of the five possible isomers, [22], namely the α-*trans* isomer (*trans*-NO_3, *trans*-py, *trans*-NH_2).

The solid-state electronic spectrum of **1** is typical for a (pseudo)octahedral Ni(II) complex, showing the expected d–d bands at: 989, 644, and 422 nm. These bands are assigned to following transitions: $^3A_{2g} \rightarrow {}^3T_{2g}$ and $^3A_{2g} \rightarrow {}^3T_{1g}$, and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$, respectively.

Surprisingly, the cryomagnetic investigation of **1** reveals an intermolecular ferromagnetic coupling. The magnetic properties are shown in Fig. 2 in the form of $\chi_M T$ versus T plot. The value of the $\chi_M T$ product at room temperature (1.202 cm^3 mol^{-1} K) corresponds to the expected value for non-interacting Ni(II) ions. By lowering the temperature, $\chi_M T$ increases, reaching a maximum value at 30 K (1.283 cm^3 mol^{-1} K), then abruptly decreases to a value of 0.93 cm^3 mol^{-1} K at 5 K.

In order to understand the magnetic behavior of **1**, we have analyzed the packing diagram of the molecules in the crystal. The most interesting structural feature, at the supramolecular level, consists in the stacking interactions involving the pyridyl moieties of neighboring mononuclear entities. The weak intermolecular π–π overlap leads to infinite chains (Fig. 3) and thus provides an exchange pathway. Weak magnetic interactions across π-stacking have been already observed with several compounds [23–25]. In one case, namely between Mn(II) ions, the intermolecular interaction was found to be ferromagnetic [23]. The magnetic behavior

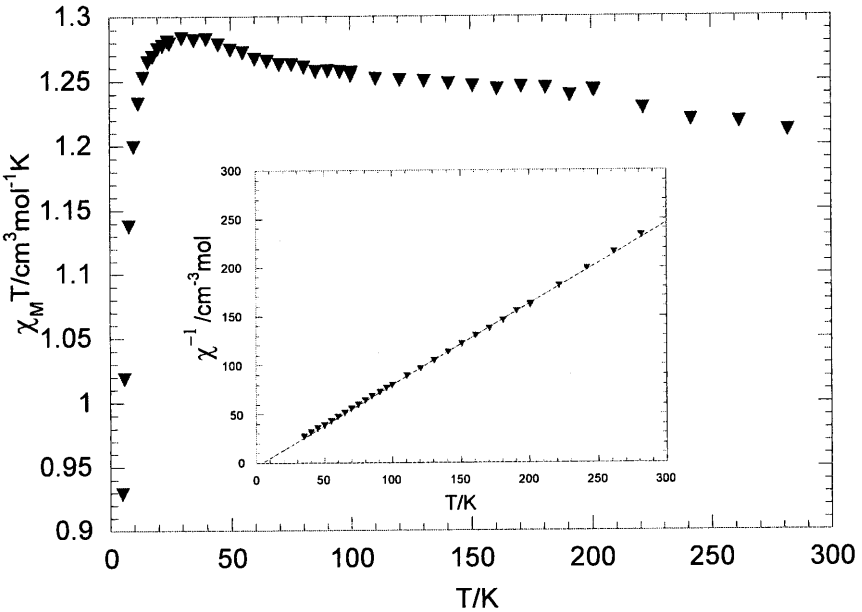

Fig. 2. Temperature dependence of $\chi_M T$ and χ_M^{-1} (inset) for compound **1**.

of **1** below 30 K could be explained by the onset of long-range antiferromagnetic ordering and/or by a zero-field splitting of the ground state of the Ni(II) ion. The data between 300 and 30 K have been fitted through the Curie–Weiss law, $\chi^{-1} = (T - \theta)/C$ (see the inset in Fig. 2). The fit leads to $\theta = +3.7$ K, $C = 1.205$ cm^3 mol^{-1} K, and $g = 2.19$. Given that $\theta = zJ'S(S+1)/3k$ and $S = 1$, it follows that $zJ' = 3.8$ cm^{-1}. As the packing of **1** shows, z is equal to 2 and, consequently, $J' = +1.9$ cm^{-1}. By fitting with the Curie–Weiss law the data below 30 K, one obtains $\theta = -1.7$ K.

The bimetallic assembly, $[Ni(ampy)_2]_3[Fe(CN)_6]_2 \cdot 6H_2O$ (**2**), has been obtained as brown crystals by the reaction of **1** with $K_3[Fe(CN)_6]$ in water. The infrared spectrum shows two characteristic bands of the CN^- groups in the region between 2100 and 2200 cm^{-1}, indicating both their terminal and bridging functions. The band located at 2144 cm^{-1} is assigned to the bridging cyano groups, while the other one (2114 cm^{-1}) is assigned to the terminal cyano ligands. The diffuse reflectance electronic spectrum shows a shoulder at 920 nm and one band at 520 nm. These are characteristic for the Ni(II) ions in a (pseudo)octahedral environment and are assigned to the $^3A_2 \rightarrow {}^3T_2$ and $^3A_2 \rightarrow {}^3T_1$ spin-allowed transitions (assuming the O site symmetry) [26]. The band located at 440 nm is due to a ligand-to-metal charge transfer within the $\{Fe(CN)_6\}$ chromophore. The cobalt(III) derivative, $[Ni(ampy)_2]_3[Co(CN)_6]_2 \cdot 6H_2O$ (**3**), exhibits a very similar infrared spectrum with compound **2**, with bridging and terminal cyano groups (ν(CN) = 2154, and 2124 cm^{-1}).

The magnetic properties of compound **2** have been investigated in the temperature range 2–300 K. The $\chi_M T$ versus T plot is given in Fig. 4. At room tempera-

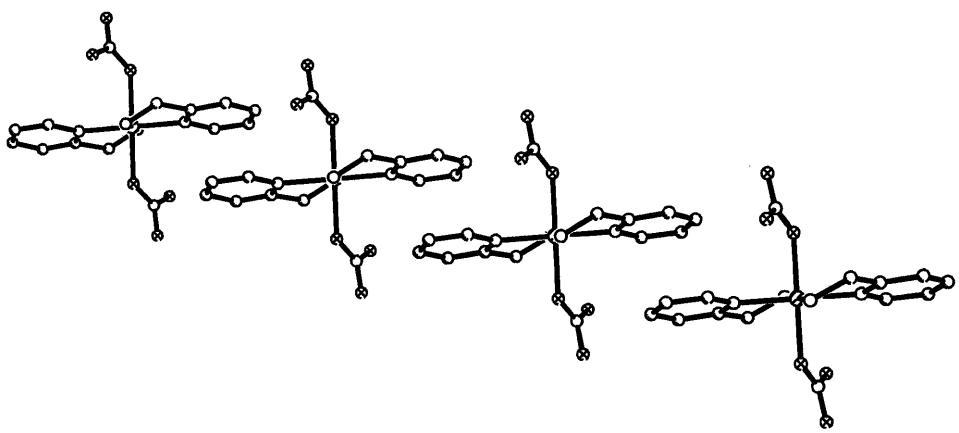

Fig. 3. Packing diagram for compound **1** showing the π–π stacking interactions.

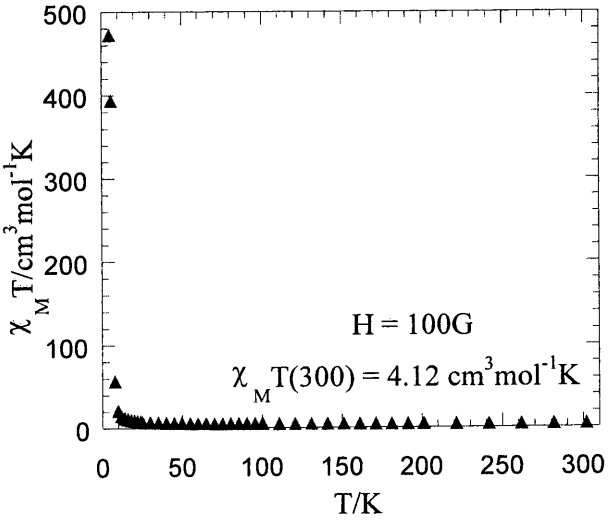

Fig. 4. $\chi_M T$ versus T plot for compound **2**.

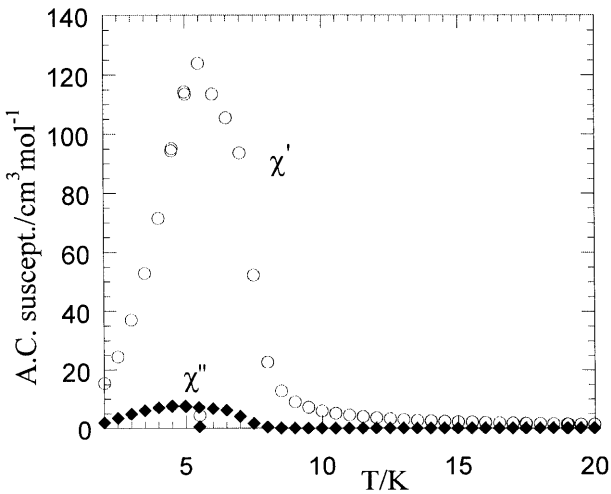

Fig. 5. In-phase(χ') and out-of-phase (χ'') ac magnetic susceptibility as a function of temperature for compound **2**.

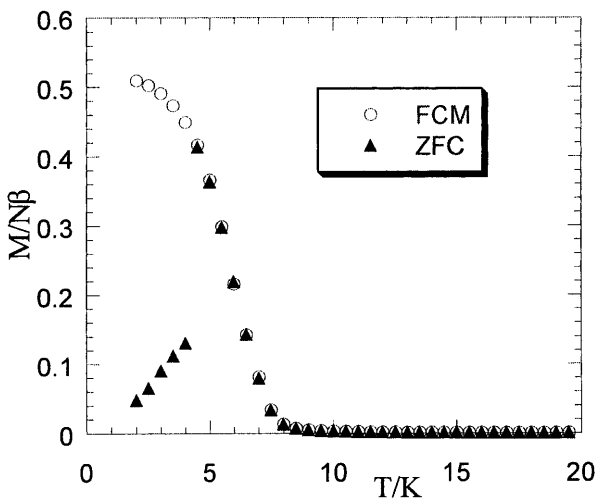

Fig. 6. Temperature dependence of the FCM and ZFCM curves for compound **2**.

ture, the value of the $\chi_M T$ product is 4.12 $cm^3\ mol^{-1}$ K (per Ni_3Fe_2), being close to the value expected for an uncoupled Ni_3Fe_2 system (4.13 $cm^3\ mol^{-1}$ K, with $g = 2.1$). Down to 30 K, $\chi_M T$ is constant, then diverges reaching a maximum value of 470 $cm^3\ mol^{-1}$ K at 2 K. This behavior suggests that a long-range ferromagnetic ordering occurs. The ferromagnetic interaction is rationalized by the strict orthogonality of the e_g(Ni(II)) and t_{2g}(low spin-Fe(III)) orbitals [27].

The ferromagnetic transition in compound **2** is further confirmed by ac magnetic susceptibility measurements in the temperature range 2–20 K ($\nu_{ac} = 125$ Hz, $H_{ac} = 1$ G) (Fig. 5). The in-phase (real) component, χ', increases sharply when the sample is cooled below 9 K, reaching a maximum around 5.5 K. The out-of-phase (imaginary) χ'' component shows a broad hump with maximum at 5 K. The non-zero value of χ'' is another indication of the bulk magnetic ordering in **2**. Usually, the T_c temperature is defined as the inflexion point in the increasing part of the χ' curve, as well as the point where χ'' becomes non-zero. In our case the two points are coincident, $T_c = 7.5$ K.

The magnetization studies are also in line with the ferromagnetic nature of **2** (Fig. 6). The field-cooled magnetization (FCM) curve, which is obtained on cooling the sample within a field of 10 G, exhibits a break at $T_c = 7.5$ K and begins to saturate below 4 K. The zero-field-cooled magnetization (ZFCM) curve, measured upon cooling down in zero field, shows also a break at $T_c = 7.5$ K. The field dependence of the magnetization, $M = f(H)$, was measured at 2 K up to 50 kG (Fig. 7). The material begins to saturate at high fields, but not completely ($M = 7.2\ N\beta$ at 50 kG, the theoretical saturation value being $M_s = 8\ N\beta$). The M versus H curve shows hysteresis behavior (see the inset in Fig. 7), which is observed upon cycling the applied field.

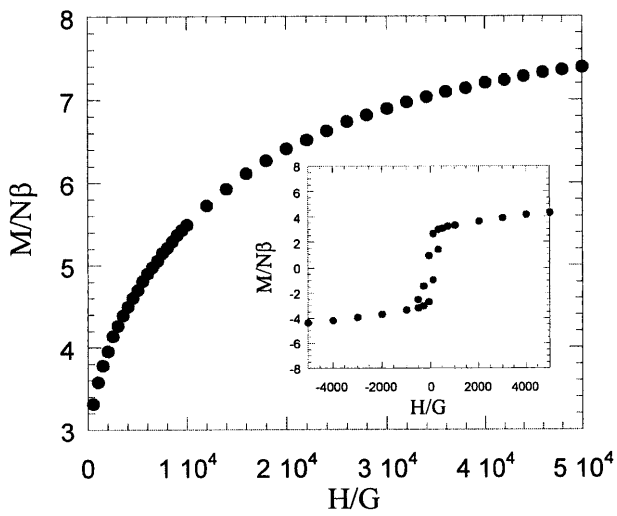

Fig. 7. Magnetization and hysteresis loop (inset) at 2 K as a function of the applied field for compound **2**.

Table 3
$Ni(II)_3Fe(III)_2$ cyano bridged complexes with long-range magnetic ordering

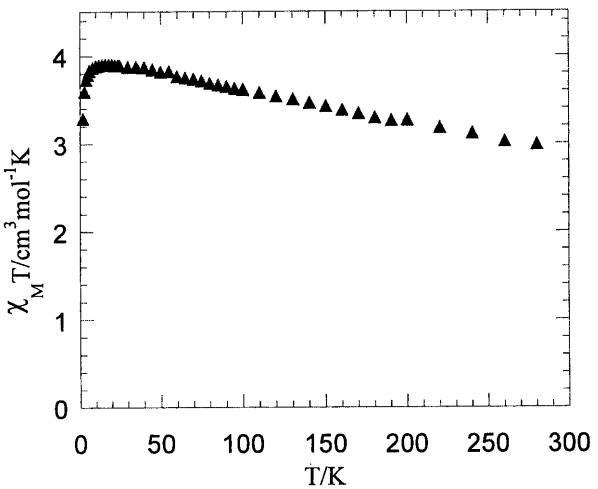

Fig. 8. $\chi_M T$ versus T plot for compound **3**.

According to the value of the coercive field, $H_c = 330$ G, compound **2** may be considered as a soft magnet.

Compound **3**, $[Ni(ampy)_2]_3[Co(CN)_6]_2 \cdot 6H_2O$, is most probably isostructural with compound **2**. Such families of isostructural $[M(CN)_6]^{3-}$–M′(II)-chelate bimetallic compounds (M = Fe(III), Cr(III), Co(III)) are already known [13,30]. The cryomagnetic investigation of the Co(III) derivative, since $[Co(CN)_6]^{3-}$ is diamagnetic, gives information about the pure Ni(II)–Ni(II) exchange interactions. The magnetic properties of compound **3** are shown in the form of $\chi_M T$ versus T plot (Fig. 8). The value of the $\chi_M T$ product at room temperature (2.92 cm^3 mol^{-1} K) corresponds to three uncoupled Ni(II) ions. By lowering the temperature, $\chi_M T$ increases reaching a maximum value (3.90 cm^3 mol^{-1} K) at 18 K. Below this temperature, $\chi_M T$ decreases. Such a behavior is characteristic of dominant ferromagnetic interactions to which antiferromagnetic interactions are superimposed.

Only a few cyano-bridged polynuclear complexes with the stoichiometry $[Ni(polydentate\ ligand)_x]_3[Fe(CN)_6]_2 \cdot nH_2O$ and extended structures have been reported so far (Table 3). Some of them have been structurally characterized.

The analysis of the magnetic properties of the compounds presented in Table 3 shows that the critical temperatures are always lower than for the corresponding PB analogue, $Ni_3[Fe(CN)_6]_2 \cdot xH_2O$ ($T_c = 23$ K, [31]). To date, this seems to be true for all the systems obtained by introducing an organic ligand in PB-like phases, irrespective of the nature of the paramagnetic metal ions.

4. Supplementary material

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 142419. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

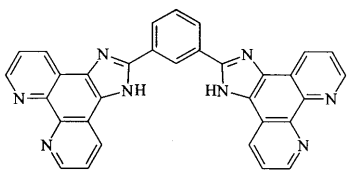
Abstract



1,3-Bis([1,10]phenanthroline-[5,6-*d*]imidazol-2-yl)benzene ($mbpibH_2$) and its $(bpy)_2Ru^{2+}$ complexes (bpy = 2,2′-bipyridine) have been synthesized and characterized. The electrochemical and spectroscopic studies of the mono- and dinuclear complexes have shown that there is very little or no interaction between the linked metal centers. The absorption spectra of the mono- and dinuclear complex are both strongly dependent on the solution pH. The deprotonation of the bridging ligand $mbpibH_2$ also induces a pertubation on the spectral and redox properties of the dinuclear complex. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Bpy ligands; Polypyridine ligands; Ruthenium(II) complexes

1. Introduction

Photoinduced energy- and electron-transfer in supramolecular systems have attracted much current attention in connection with the design of molecular electronic devices [1–3]. Ruthenium(II) complexes of polypyridine-type ligands are excellent building blocks for the construction of such devices due to their rich photochemical and photophysical properties [4]. Thus, it is not surprising that the number of investigations concerning the photochemical and photophysical behavior of dinuclear or polynuclear ruthenium(II) polypyridine complexes is rapidly growing [5–16]. In most cases, the spacer between the metal centers is a polychelating ligand and it plays an important role in the polynuclear complex, since the interaction between the bridged units, and thereby the properties of the polynuclear complex, are critically dependent on the size, shape and electronic nature of the spacer.

Recently, protonation has been shown to induce the switching of fluorescence, redox properties, and electron transfer reactions [17–21]. This motivated us to design a new phen-based bridging ligand: 1,3-bis([1,10]-phenanthroline-[5,6-*d*]imidazol-2-yl)benzene ($mbpibH_2$) (Chart 1). A unique feature of this bridging ligand is its two imidazole intervening fragments, which can undergo reversible acid–base interversion by protonation and deprotonation to induce a large energy perturbation. Although several diruthenium(II) complexes containing imidazole fragment have been reported [10,22–25], in most cases the imidazole ring is coordinated to the metal ion and not protonated. We describe here the synthesis, electrochemical and spectroscopic properties of ruthenium(II) complexes containing the ligand $mbpibH_2$.

2. Experimental

2.1. Materials and preparations

The compounds *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ [26] and 1,10-phenanthroline-5,6-dione [27] were synthesized according to literature methods. Other materials were commercially available and of reagent grade.

(**Caution**: perchlorate complexes are potential explosives. These complexes must be handled in small quantities and with great care.)

2.1.1. Synthesis of 2-(3-formylphenyl)imidazo[4,5-f]-[1,10]phenanthroline (mfmp)

A mixture of isophthalic aldehyde (0.201 g, 1.5 mmol), 1,10-phenanthroline-5,6-dione (0.315 g, 1.5 mmol), ammonium acetate (2.31 g, 30 mmol) and glacial acetic acid (30 cm^3) was refluxed for about 2 h, and then cooled to room temperature (r.t.) and diluted with water (ca. 60 cm^3). Dropwise addition of concentrated aqueous ammonia gave a yellow precipitate, which was collected and washed with water. The crude product in ethanol was purified by silica gel filtration (60–100 mesh, ethanol). The principal yellow band was collected. A yellow crystalline solid was obtained by slow evaporation of the solution, then were dried in vacuo. Yield 0.369 g, 76% (Found: C, 74.0; H, 3.9; N, 16.9. $C_{20}H_{12}N_4O$ requires C, 74.1; H, 3.7; N, 17.3%). ν (cm^{-1}) 3374m, 3064s, 1693s 1609m, 1546m, 1507m, 1400m, 805s, 737s and 674m. ^{1}H NMR data (300 M, DMSO-d_6): δ 13.94 (s, 1H), 10.17 (s, 1H), 9.04 (d, 2H, $J = 4.5$), 8.94 (d, 2H, $J = 8$), 8.81 (s, 1H), 8.62 (d, 1H, $J = 7.8$), 8.04 (d, 1H, $J = 7.5$), 7.84 (q, 3H). FABMS: $m/z = 325$ ($C_{20}H_{12}N_4O$ requires 324).

2.1.2. Synthesis of 1,3-bis([1,10]phenanthroline-[5,6-d]-imidazol-2-yl)benzene (mbpibH$_2$)

A mixture of 1,10-phenanthroline-5,6-dione (0.63 g, 3 mmol), ammonium acetate (4.62 g, 60 mmol), isophthalic aldehyde (0.201 g, 1.5 mmol) and glacial acetic acid (50 cm^3) was refluxed for about 2 h and then cooled to r.t. The precipitate was collected and washed with H_2O. The crude product was recrystallized from DMF and produced a greenish yellow powder. Yield 0.347 g, 45% (Found: C, 74.3; H, 3.8; N, 21.5. $C_{32}H_{18}N_8$ requires C, 74.7; H, 3.5; N, 21.8%) ν (cm^{-1}) 3403s, 3065m, 1616m, 1559m, 1501m, 1452s, 1398m, 807s, 737s and 672m. ^{1}H NMR data (300 M, DMSO-d_6): δ 14.05 (s, 2H), 9.24 (s, 1H), 9.07 (d, 4H, $J = 4.5$), 9.05 (d, 4H, $J = 8$), 8.42 (d, 2H, $J = 7.8$), 7.89 (t, 5H, $J = 7.7$). FABMS: $m/z = 515$ ($C_{32}H_{18}N_8$ requires 514).

2.1.3. Synthesis of [Ru(bpy)$_2$(mbpibH$_2$)](ClO$_4$)$_2\cdot 3H_2O$ (**1**)

A mixture of $[Ru(bpy)_2Cl_2]\cdot 2H_2O$ (0.261 g, 0.5 mmol), mfmp (0.162 g, 0.5 mmol), methanol (20 cm^3) and water (10 cm^3) was refluxed under argon for 5 h to give a clear red solution. The solvent was removed by rotory evaporation, and the residue was dissolved in glacial acetic acid (5 cm^3). This solution was then added dropwise under argon to a mixture of 1,10-phenanthroline-5,6-dione (0.084 g, 0.4 mmol) and ammonium acetate (0.616 g, 8 mmol) in glacial acetic acid (5 cm^3). The mixture was refluxed under argon for 2 h. After neutralization with concentrated aqueous ammonia, a red precipitate was obtained by dropwise addition of aqueous $NaClO_4$ solution. The product was purified by column chromatography on alumina with acetonitrile as eluent and dried in vacuo. Yield: 0.248 g, 55% (Found: C, 51.03; H, 3.12; N, 13.98. $RuC_{52}H_{40}N_{12}Cl_2O_{11}$ requires C, 52.88; H, 3.39; N, 14.24%) ν (cm^{-1}) 3389w(br), 3064w, 1603m, 1559m, 1465m, 1082vs (ClO_4), 807m, 765s, 723m and 625s. ^{1}H NMR data (500 M, DMSO-d_6): δ 14.08 (s, 1H), 9.34 (s, 1H), 9.05 (d, 4H, $J = 7.5$), 9.00 (d, 2H, $J = 7$), 8.89 (d, 2H, $J = 8$), 8.85 (d, 2H, $J = 8.5$), 8.53 (d, 1H, $J = 6.5$), 8.27 (d, 1H, $J = 6.5$), 8.22 (t, 2H, $J = 8$), 8.11 (t, 2H, $J = 8$), 7.89 (d, 2H, $J = 5.5$), 7.85 (m, 4H), 7.79 (d, 2H, $J = 6$), 7.71 (m, 1H), 7.67 (d, 2H, $J = 5.5$), 7.60 (t, 2H, $J = 6.5$), 7.39 (t, 2H, $J = 6.5$). FABMS: $m/z = 1028$ [$M - ClO_4$] and 928 [$M - 2ClO_4$].

2.1.4. Synthesis of [(bpy)$_2$Ru(mbpibH$_2$)Ru(bpy)$_2$](ClO$_4$)$_4\cdot 3H_2O$ (**2**)

A solution of $[Ru(bpy)_2Cl_2]\cdot 2H_2O$ (0.25 g, 0.58 mmol) in ethylene glycol was heated for 30 min. Solid mbpibH_2 (0.149 g, 0.29 mmol) was added to the reddish–violet solution, and the resulting mixture was refluxed for 12 h. During the period, the solution turned dark red. The solution was cooled to r.t., and 60 cm^3 H_2O was added. After filtration, a dark red precipitate was obtained by dropwise addition of aqueous $NaClO_4$ solution. The product was purified by column chromatography on alumina with 4:1 acetonitrile–ethanol (v/v) as eluent. Yield: 0.404 g, 80.2%. (Found: C, 47.90; H, 3.14; N, 12.38; $Ru_2C_{72}H_{56}N_{16}C_{14}O_{19}$ requires C, 48.21; H, 3.12; N, 12.49%). ν (cm^{-1}) 3483w(br), 3071m, 1602m, 1549m, 1444m, 1082vs (ClO_4), 807m, 765s, 723m and 625s. ^{1}H NMR data (500 M, DMSO-d_6): δ 9.37 (s, 1H), 9.10 (d, 4H, $J = 8.5$), 8.85 (d, 4H, $J = 8.5$), 8.81 (d, 4H, $J = 8$), 8.40 (d, 2H, $J = 7.5$), 8.20 (t, 4H, $J = 8$), 8.09 (t, 4H, $J = 8$), 7.89 (d, 4H, $J = 5.5$), 7.88 (d, 4H, $J = 5.6$), 7.81 (dd, 4H, $J_1 = 5.5$, $J_2 = 2.5$), 7.63 (d, 4H, $J = 5.5$), 7.59 (t, 5H, $J = 6.5$), 7.38 (t, 4H, $J = 6.5$). ESMS [CH_3OH, m/z] 769.7 ([$M - 2ClO_4$]$^{2+}$), 478.8 ([$M - 3ClO_4$]$^{3+}$), 446.9 ([$M - 4ClO_4 - H$]$^{3+}$), 335.7 ([$M - 4ClO_4$]$^{4+}$).

2.1.5. Synthesis of [(bpy)$_2$Ru(mbpib)Ru(bpy)$_2$](ClO$_4$)$_2\cdot 5H_2O$ (**3**)

A solution of complex **2** (0.15 g, 0.084 mmol) in methanol was added to a sodium methoxide solution,

which was made in situ by dissolving sodium metal (0.04 g, 1.7 mmol) in methanol (10 cm^3). The solution was heated while stirring for 1 h and then cooled to 0–5°C in a refrigerator. A red microcrystalline solid was collected by filtration. Yield: 0.109 g, 85%. (Found: C, 53.06; H, 3.78; N, 13.62; $Ru_2C_{72}H_{58}N_{16}Cl_2O_{13}$ requires C, 53.09; H, 3.56; N, 13.77%). ^1H NMR data (500 M, DMSO-d_6): δ 9.43 (s, 1H), 9.02 (d, 4H, $J = 8$), 8.87 (d, 4H, $J = 8$), 8.83 (d, 4H, $J = 8.5$), 8.33 (d, 2H, $J = 7.5$), 8.20 (t, 4H, $J = 8.5$), 8.08 (t, 4H, $J = 8$), 7.89 (d, 4H, $J = 5$), 7.74 (d, 4H, $J = 5.5$), 7.71 (t, 4H, $J = 5.5$), 7.61 (d, 4H, $J = 6$), 7.60 (t, 4H, $J = 6$), 7.45 (t, 1H, $J = 8$), 7.38 (t, 4H, $J = 6.5$). ESMS [CH_3OH, m/z] 669.7 ($[M - 2ClO_4]^{2+}$), 447.0 ($[M - 2ClO_4 + H]^{3+}$).

2.2. Physical measurements

Microanalyses (C, H and N) were carried out with a Perkin–Elmer 240Q elemental analyzer. Infrared spectra were recorded on a Nicolet 170SX-FTIR spectrometer as KBr discs. UV–Vis spectra were measured on a Shimadzu MPS-2000 spectrophotometer. Emission spectra were obtained for each complex in CH_3CN at r.t. with a Hitachi F-4500 spectrofluorometer and ^1H NMR spectra were recorded on a Bruker ARX-300 NMR spectrometer and a Varian-500 NMR spectrometer with $(CD_3)_2SO$ as solvent at r.t. and $SiMe_4$ as an internal standard. Fast atomic bombardment mass spectra (FABMS) were obtained on a VG ZAB-HS spectrometer in a 3-nitrobenzyl alcohol matrix. Electrospray mass spectra (ESMS) were recorded on a LCQ system (Finnigan MAT, USA) using methanol as mobile phase. The spray voltage, tube lens offset, capillary voltage and capillary temperature were set at 4.50 kV, 30.00 V, 23.00 V and 200°C, respectively, and the quoted m/z values are for the major peaks in the isotope distribution.

Cyclic voltammetry was performed on an EG&G PAR Model 173 potentiostat/175 universal programmer. The supporting electrolyte was 0.1 mol dm^{-3} tetrabutylammonium perchlorate in acetonitrile freshly distilled from phosphorus pentaoxide and deaerated by purging with nitrogen. A standard three-electrode system was used comprising a platinum microcyclinder working electrode, platinum-wire auxiliary electrode and a saturated calomel reference electrode (SCE).

The pH measurements were made with a TOA mode HM-20E pH meter standardized with buffers of pH 4.01 and 6.86. To facilitate dissolution of samples in aqueous solutions a minimal volume of acetonitrile was added. The readings of the pH meter in this mixture are referred to as apparent pH unless otherwise stated. Spectrophotometric titrations were performed in buffer solution, The titration experiment were conducted with Gilson P20 Pipetman microburettes by using a 2.0 mol dm^{-3} NaOH aqueous solution. Buffer systems and pH ranges employed were as follows: $HClO_4$–$NaClO_4$, pH 0–2; Robinson-Britton buffer, pH 2–11 [28]. The pK values of the protonation and deprotonation in the complexes were calculated by using the equation:

$$\mathrm{pH} = \mathrm{p}K - \log\frac{A - A_o}{A_f - A}$$

where A_o and A_f are the initial and final absorbances, respectively. Some A_o and A_f values were evaluated from the graphical method of Coleman et al. [29], because two closely spaced protonation or deprotonation equilibria exist in this system.

The luminescence lifetime measurements were done with an excimer laser (Lambda Physics EMG 201MSC)-pumped dye laser (Lambda Physics model FL2002) system. The nominal pulse width and the line width of the dye-laser output were 10 ns and 0.18 cm^{-1}, respectively. The excitation wavelength was fixed at 455 nm, The emission of a sample was collected by two lenses into a monochromator, detected by a photomultiplier and processed by a Boxcar Average (EG&G model 162) in line with a microcomputer.

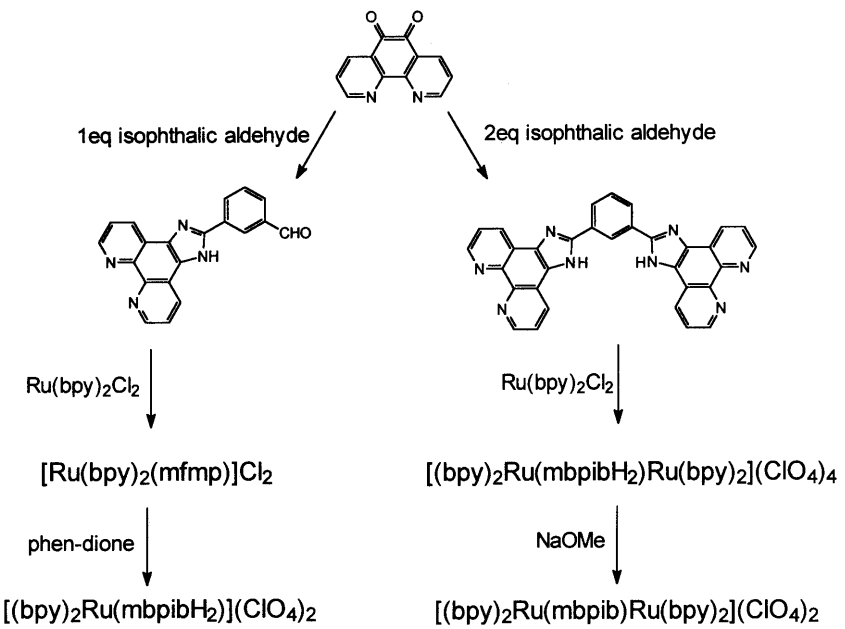
3. Results and discussion

3.1. Synthesis

An outline of the synthesis of the ligands and complexes is presented in Scheme 1. The ligands were synthesized on the basis of the method for imidazole ring preparation established by Steck et al. [30]. The ligand mfmp and $mbpibH_2$ were obtained through condensation of 1,10-phenanthroline-5,6-dione with isophthalic aldehyde in refluxing glacial acetic acid containing ammonium acetate at a molar ratio of 1:1 or 2:1, respectively. The ligand $mbpibH_2$ is hardly soluble in common organic solvents, but partly soluble in hot DMF and DMSO. The low solubility of $mbpibH_2$ in most solvents prevents efficient synthesis of the mononuclear complex **1** since it is much more soluble than the ligand $mbpibH_2$. Even when the reaction between $Ru(bpy)_2Cl_2$ and $mbpibH_2$ was run in a 1:1 molar ratio in glycerol, only the dinuclear complex was formed. Therefore, to prepare the mononuclear complex **1**, we carried out the condensation of 1,10-phenanthroline-5,6-dione with the precoordinated mfmp in $[(bpy)_2Ru(mfmp)]^{2+}$ to avoid the formation of the dinuclear complex (Scheme 1). Deprotonation was achieved by reaction of sodium methoxide with the dinuclear complex in methanol. The deprotonated complex completely reverted to the corresponding protonated complex by the addition of acid. All these compounds were characterized by IR, FABMS, ESMS, ^1H NMR and elemental analyses.

3.2. ^1H NMR spectra

The ^1H NMR spectra of the bridging ligand mbpibH_2 and two representative complexes **2** and **3** in $(CD_3)_2SO$ solvent are shown in Fig. 1. The observed ^1H NMR spectra indicate that each half of the ligand is equivalent due to the presence of internal symmetry. In the ^1H NMR spectrum of free mbpibH_2 the proton signals at δ 14.05, 9.24, 9.07, 9.05, 8.42 and 7.89 can be easily assigned to H(NH), H_d, H_a, H_c, H_e and H_b/H_f, respectively, according to $^1H-{}^1H$ COSY experiments and comparison with those of oligopyridine. The proton on the nitrogen atom of the imidazole resonates at ca δ 14.05 for the free ligand mbpibH_2 as a broad singlet, but it is unobserved for the ruthenium complexes because of quickly exchanging between the two nitrogens of the imidazole ring.



It is easy to assign the chemical shifts of the protons of the bridging ligand mbpibH_2 in its complexes, bearing in mind the free mbpibH_2 data. On coordination to two ruthenium ions to form complex **2**, the protons on the mbpibH_2 all experience shifts by comparison with those of free mbpibH_2: H_c and H_d show 0.05 and 0.13 ppm downfield shifts, H_b, H_e and H_f show 0.08, 0.02 and 0.30 ppm upfield shifts, respectively, while H_a experiences surprising upfield shifts of 1.19 ppm. Similar behaviors have been observed for the mononuclear complex **1** and its ^1H NMR spectrum exhibits two distinct sets of aromatic resonances for both coordinated and uncoordinated parts of mbpibH_2, which is especially clear for H_a. The dramatic upfield shifts of H_a may be due to the effect of the ring current of the bpy ligands.

Deprotonation of the dinuclear complex has a strong influence on the resonance frequency of the protons in the bridging ligand (Fig. 1). Resonances for H_a, H_b, H_c, H_d, H_e and H_f appear at δ 7.74, 7.71, 9.02, 9.43, 8.33 and 7.45, respectively. Shifts in the bpy resonances are small but nevertheless significant. The shift in the resonance positions of mbpibH_2 protons can be explained by the increased electron density in the imidazole ring, which probably also affects the electron density in the phen ring and phenyl ring of mbpibH_2. Also, the change in the overall charge of the compound is likely to influence the resonance frequencies. A similar example has been reported [31].

3.3. Electrochemistry

The electrochemical behaviors of the complexes have been studied in CH_3CN by cyclic voltammetry. Results are collected in Table 1. Due to the poor solubility of free mbpibH_2, it has not been possible to study its electrochemical behavior. Each complex exhibits well shaped oxidation (one) and reduction (three) waves in the sweep range from -1.8 to $+1.6$ V, as shown in Fig. 2 for the dinuclear complex $[(bpy)_2Ru(mbpibH_2)Ru(bpy)_2]^{4+}$. This pattern is common to most d^6 metal polypyridyl complexes where the redox orbitals are localized on the individual ligands [32].

For all of the three complexes, the first reduction potential may be assigned to the bridging ligand mbipbH_2 by comparison with the reduction potential of $[Ru(bpy)_3]^{2+}$ in CH_3CN [33]. It is concluded that reductions of the three complexes occur first on the mbipbH_2 ligand and then on each bpy ligand. Coordi-

Scheme 1.

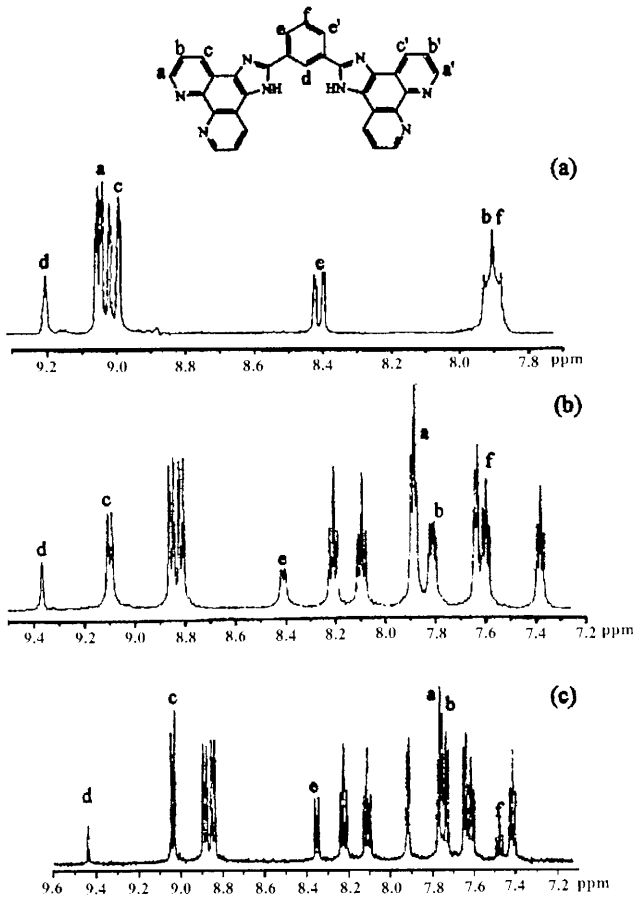


Fig. 1. ^{1}H NMR spectra of $mbpibH_2$ (a), $[(bpy)_2Ru(bpibH_2)Ru(bpy)_2]^{4+}$ (b) and $[(bpy)_2Ru(bpib)Ru(bpy)_2]^{2+}$ (c) in the aromatic region between $\delta = 7.0$ and $\delta = 9.6$ ppm [$(CD_3)_2SO$ solvent, TMS reference].

nation of the second $[Ru(bpy_3)]^{2+}$ ion to the remote nitrogen atoms of the mononuclear $[(bpy)_2Ru(mbpibH_2)]^{2+}$ causes a shift to more positive values in the reduction potential of the $mbpibH_2$ ligand, reflecting the stabilization of the $mbpibH_2$ π^* orbital in the dinuclear complex.

For dinuclear complexes, investigation of the oxidation behavior is very useful to determine the extent of electronic interaction between the metal units. In the absence of any metal–metal interaction, one would anticipate that symmetric bimetallic complexes should exhibit metal-based oxidations at the same potential for both metal centers. If there is metal–metal communication through the bridging ligand, such symmetric bimetallic complex would be expected to exhibit two oxidations since the oxidation of one metal center will be influenced by the oxidation of the other. In the current study, only a single anodic wave is observed for complex **2**. No difference in the oxidation potential was observed between the mononuclear and the dinuclear complex (Table 2). Coulometry indicates that two electrons are involved in this process. From the separation between the anodic and cathodic peak potential (65 mV), it is concluded that two simultaneously independent one-electron processes are involved in this oxidation. This indicates that in the present system the electrostatic interaction between metal sites plays a negligible role, which is attributed to the large distance of separation between the two $Ru(bpy)_2$ units and free rotation around the C–C bond of $mbpibH_2$. Upon deprotonation of the dinuclear complex, the oxidation potential of complex **3** shifts to a more negative potential (about 70 mV).

Table 1
Redox potentials for the ruthenium(II) complexes [a]

Complex	$E_{1/2}$, V (ΔE, mV) [b]

3.4. Electronic absorption spectra

Absorption spectra were obtained in CH_3CN for all complexes at room temperature (Fig. 3), and the ab-

Table 2
Absorption spectral data for the ruthenium(II) complexes [a]

Complex	λ_{max}, nm (ε, M^{-1} cm^{-1})
1	457 (9800), 285 (70 350), 244 (28 000)
2	457 (21 600), 285 (119 450), 243 (41 600)
3	461 (20 050), 427 (18 050), 339 (49 700), 288 (105 200), 243 (45 850)

[a] In CH_3CN, $T = 298 \pm 1$ K.

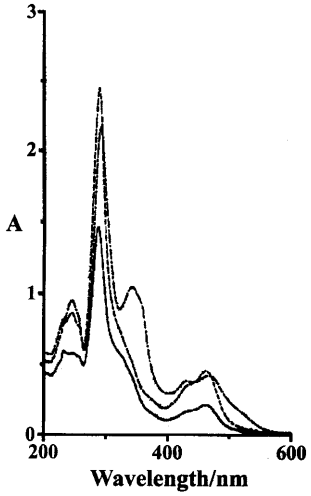

Fig. 3. Absorption spectra of complex **1** (solid line), complex **2** (dotted line) and complex **3** (dashed line) in CH_3CN at room temperature.

sorption data listing energy maxima and the absorption coefficients are summarized in Table 2. The absorption spectra of complexes having a polyunsaturated bridging ligand represent a composite of intraligand ($\pi \rightarrow \pi^*$) and metal to bridging ligand charge transfer (MLCT). By comparison with the spectrum of $[Ru(bpy)_3]^{2+}$ [34], the lowest energy band at 458 nm is assigned to metal–ligand charge transfer (MLCT) transition and consists of overlapping $Ru(d\pi) \rightarrow mbpibH_2(\pi^*)$ and $Ru(d\pi) \rightarrow bpy(\pi^*)$ transitions. The lowered symmetry removes the degeneracy of the π^* levels, which results in the appearance of broad MLCT bands.

When the mononuclear complex **1** is treated with another ruthenium center to form the dinuclear complex, the MLCT absorption maximum around 458 nm remained almost unaltered, except that it becomes twice as intense compared with the mononuclear complex (Fig. 3). This is in sharp contrast to a π-accepting bridging system such as bbdb [bbdb = 1,4-bis(4′-methyl-2,2(bipyridin-4-yl)buta-1,3-diene] [35], dpp [dpp = 2,3-bis(2-pyridyl)pyrazine] [36]. A shift to longer wavelength of the MLCT band compared with that of the mononuclear complex has been reported when the latter containing such a π-accepting ligand forms a dinuclear complex. It suggests that in the present $mbpibH_2$ system the metal–metal interaction is very small, which is consistent with the electrochemistry results. Similar cases were observed between $[Ru(bpy)_2(tpbq)]^{2+}$ and $[(bpy)_2Ru(tpbq)Ru(bpy)_2]^{4+}$ [tpdq = 2,2′,3,3′-tetra(2-pyridyl)-6,6′-biquinoxaline] [37].

Deprotonation of $mbpibH_2$ in the dinuclear complex induces a marked change in the absorption spectrum. Compared with the absorption spectrum of complex **2**, the deprotonated dinuclear complex **3** exhibits the MLCT absorption maxima at 427 and 461 nm, which are much broader with a tail extending out to nearly 600 nm. The red shift of the MLCT band may be explained by an increase in the σ-donor properties of the deprotonated ligand [31]. The band at 339 nm is attributed to the $\pi-\pi^*$ (mbpib) transition in comparison with the absorption spectrum of complex **2**, which suggests that the deprotonated bridging ligand has a larger extent of π delocalization.

The influence of pH on the absorption spectral behavior has been studied for complexes **1** and **2**. The changes that occur for **1** in buffer over the pH range 2–11 are shown in Fig. 4. From pH 2.30 to 6.05, the MLCT band at 458 nm decreases and has a small red-shifts. A further increase of pH from 6.05 to 7.51 leads an increase of the minimum at 380 nm and the band at 500 nm, but a further decrease of the 460 nm

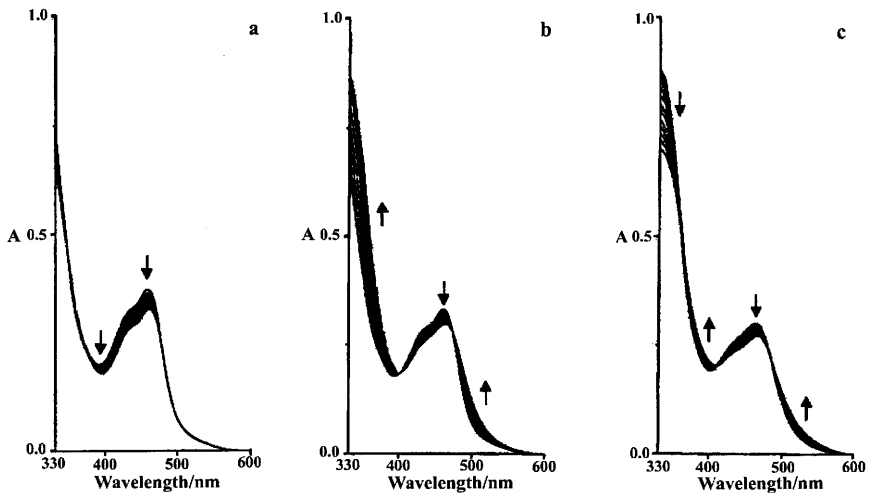

Fig. 4. Absorption spectra of complex **1** (1.00×10^{-5} mol dm^{-3}) at 20°C in buffer at various pH values: (a) pH 2.32 → 6.05; (b) pH 6.05 → 7.51; (c) pH 7.51 → 11.

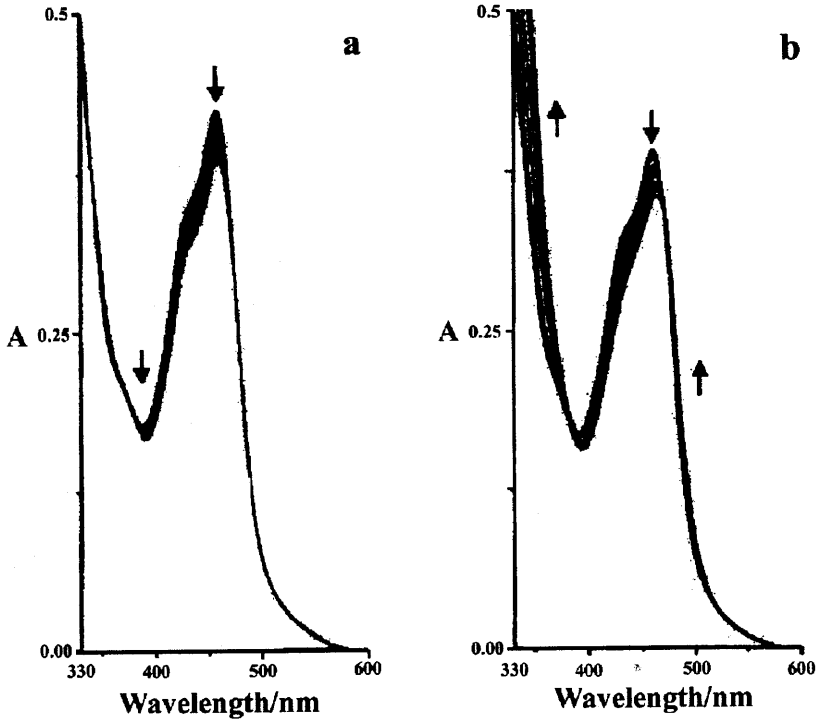

Fig. 5. Absorption spectra of complex **2** (1.00×10^{-5} mol dm^{-3}) at 20°C in buffer at various pH values: (a) pH 2.90→6.49; (b) pH 6.49→9.86.

band, and two well-defined isosbestic points at 400 and 470 nm can be seen. In the range pH 7.51–11 the MLCT band at 465 nm still decreases and shifts to a longer wavelength (470 nm), three well-defined isosbestic points at 360, 410 and 485 nm can be seen. Above the spectral changes are attributed to the following acid–base equilibria. The pK values obtained are $pK_{b1} = 3.43$, $pK_{b2} = 6.45$ and $pK_{a1} = 9.48$.

$$[(bpy)_2Ru(mbpibH_4)]^{4+} \overset{K_{b1}}{\rightleftharpoons} [(bpy)_2Ru(mbpibH_3)]^{3+} \quad (1)$$

$$[(bpy)_2Ru(mbpibH_3)]^{3+} \overset{K_{b2}}{\rightleftharpoons} [(bpy)_2Ru(mbpibH_2)]^{2+} \quad (2)$$

$$[(bpy)_2Ru(mbpibH_2)]^{2+} \overset{K_{a1}}{\rightleftharpoons} [(bpy)_2Ru(mbpibH)]^{+} \quad (3)$$

The bridging ligand $bpibH_2$ has two protonated sites and two depronated sites. The first protonation ($pK_{b2} = 6.45$), according to the spectral changes, should take place at the imidazole group of uncoordinated subunit. On the contrary, only the dissociation of the imidazole group in the coordinated subunit was observed in the pH range 2–11. This result is rationalized by the fact that the pK_a of the imino NH protons of free benzimidazole derivatives is usually around 14. Therefore, it shows clearly that in complex **1** the imidazole of the coordinated subunit is a stronger acid or a weaker base in comparison with that of the uncoordinated subunit.

The dinuclear complex **2** in buffer (pH 2.07) exhibits a MLCT band at 458 nm. The pH dependence of the absorption spectra is shown in Fig. 5. Since the two imidazole groups in $mbpibH_2$ only act as intervening units and are uncoordinated to metal ion, the spectral changes of complex **2** can be attributed to the acid–base equilibria analogous with those of complex **1**. The pK values obtained are 3.23 and 9.28.

3.5. Emission spectra

The steady-state emission spectra of the three complexes in MeCN are shown in Fig. 6. The observed bands correspond to emission from what is assumed to be a Ru(II)-based ^{3}MLCT excited state, similar to that observed for $[Ru(bpy)_3]^{2+}$ [38]. The emission band

Table 3
Emission spectral data for ruthenium(II) complexes [a]

Complex	λ_{max} (nm)	τ (ns)	Φ_{em} ($\times 10^2$) [b]
1	618	520	5.2
2	618	880	10.2
3	623	545	5.8

[a] In CH_3CN, $T = 298 \pm 1$ K.
[b] Quantum yields of the complexes were determined by a relative method using $[Ru(bpy)_3]^{2+}$ ($\Phi_{em} = 0.062$) as the standard.

maxima, quantum yields and selected excited-state lifetimes of the ruthenium complexes are given in Table 3.

The mono- and dinuclear complexes in CH_3CN all emit at the same wavelength (618 nm). It is interesting to observe that the emission intensity of the dinuclear complex **2** is nearly twice that of the mononuclear complex **1**. At the same time, the excited state lifetime (τ) at room temperature for the dinuclear complex **2** is larger than that observed for the mononuclear complexes **1** (Table 3). In the $[(bpy)_2Ru(mbpibH_2)Ru(bpy)_2]^{4+}$ dinuclear system, the MLCT state is greatly stabilized relative to the ligand field state. This prevents thermal population of the LF state in the dinuclear complex at room temperature. On the other hand, the metal–metal interaction is very weak in the $mbpibH_2$ system. The two reasons result in the emission intensity and lifetime of the chromophore in the dinuclear complex **2** being enhanced relative to the mononuclear complex **1** when measured at room temperature. Deprotonation of the dinuclear complex **2** results in decreasing of the emission intensity (Fig. 6), with less than 60% of the original emission intensity remaining. The emission wavelength also shifts to a longer wavelength (623 nm). This may be involved in the rapid radiationless decay [4]. It has been known that the energy of the metal-centered (MC) excited states depends on the ligand field strength, which in turn depends on the σ-donor and π-acceptor properties of the ligands [4]. The negative charge on the deprotonated imidazol substituent may be delocalized over the whole π framework, which decreases the σ-donor and increases the π-acceptor capacity of the $mbpib^{2-}$ ligand, resulting in weakening of the ligand-field strength around the metal center and in turn lowering the metal σ* orbitals [39–41].

4. Conclusions

A new bridging ligand $mbpibH_2$ [$mbpibH_2$ = 1,3-bis([1,10]phenanthroline-[5,6-*d*]imidazol-2-yl)benzene] and its mono- and dinuclear complexes have been synthesized and characterized. Electrochemical and spectroscopic data clearly suggest that in $mbpibH_2$ system the properties of each metal-based component are essentially maintained and the metal–metal interaction is very weak between the linked metal centers. The longer lifetime and larger emission intensity of the bimetallic chromophore make it a useful component in the design of supramolecular complexes. In addition, since the bridging ligand enables the mono- and dinuclear complexes to act not only as a diprotic acid, but also as a diprotic base, the two complexes show quite interesting proton-dependent photophysical properties.

Abstract

A series of hexanuclear manganese(III) metallamacrocycles were synthesized using *N*-acylsalicylhydrazides (H_3xshz) (where H_3xshz = H_3ashz, *N*-acetylsalicylhydrazide; H_3pshz, *N*-propionylsalicylhydrazide; H_3hshz, *N*-hexanoylsalicylhydrazide; H_3lshz, *N*-lauroylsalicylhydrazide), where the pentadentate ligands bridged the metal ions. The triple deprotonated *N*-acylsalicylhydrazidate (xshz^{3-}) could bridge the metal ions by using a hydrazide N–N group and form the hexanuclear manganese metallamacrocycle with a hole in the center. Depending on the ligands used, the tripled hydrophobic tails of different lengths are attached at both chiral faces of the metallamacrocycles. In the complex $[Mn_6(ashz)_6(DMF)_6]$ (**2**), both sides of the hole are closed by the three methyl groups of the ligands. In the complex $[Mn_6(pshz)_6(DMF)_6]$ (**3a**), one ethyl side chain of the ligands is located inside the hole. In complexes $[Mn_6(hshz)_6(DMF)_6]$ (**4**) and $[Mn_6(lshz)_6(MeOH)_6]$ (**5**), three alternating long alkyl side chains aligned at an approximately right angle to the plane of the metallamacrocycle in one direction, while the other three alkyl side chains aligned in the opposite direction. The stability of the metallamacrocycles in the solution was addressed using ^{1}H NMR spectroscopy. Three phenyl protons of the bridging ligands in the metallamacrocycles were observed in the upfield region. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Metallamacrocycles; Hexanuclear clusters; Manganese complexes; Pentadentate ligands; Hydrophobic aliphatic tripled tails

1. Introduction

Self-assembly is one of the most efficient methods for the synthesis of the variety of supramolecular species [1,2]. Recently, several research groups have been synthesizing and characterizing new types of inorganic cluster that can serve as inorganic counterparts of the macrocyclic organic host molecules, where the metal centers are connected by the bridging ligand. Depending on the metal ions, the bridging ligands and the additional ligands used, the self-assembled metallamacrocycles were obtained by the cyclic repeat of the metal ions and the bridging ligands. Macrocyclic squares [3], mercuracarborand cyclic species [4], metal analogue of calix[4]arene [5], and other types of metallamacrocycle [6–8] have appeared as new types of the macrocyclic inorganic host molecule, where the bidentate bridging ligands connect two metal centers.

Another type of metallamacrocycle, known as metallacrowns [9,10], has also emerged as inorganic host molecules. The tetradentate ligands, salicylhydroximate (shi^{3-}), not only serve as a bridging ligand between the metal centers, but also form the five-membered chelate ring using a hydroximate group and the six-membered chelate ring using a iminophenolate group. The chelation gave the metallamacrocycles additional stabilization. Depending on the chelation mode of the ligands around the metal center, the metal centers of the metallamacrocycle could have two different configurations,

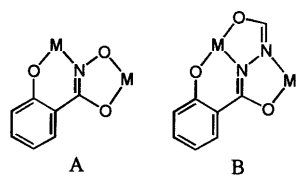

Fig. 1. (A) Binding site of shi^{3-}: 6-, 5-membered chelating rings. (B) Binding sites of fshz^{3-}: 6-, 5-, 5-membered chelating rings.

the planar configuration and the propeller configuration [9a,c].

We have recently synthesized a new type of metallamacrocycle [11], where the pentadentate ligand, *N*-formylsalicylhydrazide (H_3fshz), bridged the metal ions using a hydrazide N–N group (instead of a hydroximate N–O group of the salicylhydroximate) and formed three chelate rings in each metal center (Fig. 1). In addition, the chelation mode of the ligands enforced the metal centers only into the propeller configuration. The metallamacrocycle $[Mn(III)_6(fshz)_6(MeOH)_6]$ (**1**) [11], prepared by using a trianionic pentadentate ligand $fshz^{3-}$, has a large, vacant and hydrophobic hole in the center of the metallamacrocycle. The chiralities of the metal center in metallamacrocycle **1** alternate between Λ and Δ forms. As a result of the alternation, two faces of the donut-shaped hexanuclear manganese metallamacrocycle have opposite chiralities to each other.

In this study, we synthesized a series of pentadentate ligands with various lengths of hydrophobic alkyl chains and their corresponding hexanuclear manganese metallamacrocycles. We report here the general method of synthesizing the series of pentadentate ligands and the features of the corresponding hexanuclear manganese metallamacrocycles with tripled hydrophobic tails. These metallamacrocycles have been characterized using X-ray crystallography and spectroscopic methods.

2. Experimental

2.1. Materials

The following were used as received with no further purification: Salicylhydrazide, dimethylsulfoxide-d_6 (DMSO) and acetone-d_6, acetic anhydride, propionic anhydride, hexanoyl chloride, lauroyl chloride and triethylamine from Aldrich, Inc.; manganese acetate tetrahydrate from Yakuri; acetone, diethylether, chloroform, hexane, methanol (MeOH), ethanol (EtOH), dimethylformamide (DMF) and tetrahydrofuran (THF) from Carlo Erba.

2.2. Instrumentation

The Elemental Analysis Laboratory of the Korean Institute of Basic Science performed C, H, N and Mn determinations. Infrared spectra were recorded as KBr pellets in the range 4000–600 cm^{-1} on a Bio-Rad FTIR spectrometer. Absorption spectra were obtained using a Perkin Elmer Lambda spectrometer. NMR spectra were obtained using a Varian-300 spectrometer. Positive-ion FAB mass spectra were obtained using a JEOL HX110A/HX110A tandem mass spectrometer in a 3-nitrobenzyl alcohol matrix. Room temperature (r.t.) magnetic susceptibilities of well-ground solid samples were measured by using an Evans balance. The measurements were calibrated against a $Hg[Co(SCN)_4]$ standard.

2.3. Synthesis

2.3.1. Ligand synthesis

2.3.1.1. N-Acetylsalicylhydrazide (H_3ashz). Salicylhydrazide (2.017 g, 13.3 mmol) was added to acetic anhydride (8.00 ml) at an ambient temperature. A white suspension was immediately obtained. The suspension was diluted with diethylether, filtered, and rinsed with diethylether (2.453 g, 95% yield). M.p. = 174–176°C. IR (KBr pellet): 3187, 1605, 1573, 1487, 1235, 753 cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ 11.90, 10.54, 10.18 (br s, br s, s, 3H, Hs at amides and phenolic OH), 7.90 (dd, 1H, $J = 7.9$, 1.5 Hz, H at phenyl), 7.44 (td, 1H, $J = 7.8$, 1.6 Hz, H at phenyl), 7.03–6.91 (m, 2H, Hs at phenyl), 1.96 (s, 3H, H at methyl). ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 168.29, 167.06, 159.21, 134.36, 128.78, 119.39, 117.65, 115.02, 20.81. *Anal.* Calc. for $C_9H_{10}N_2O_3$: C, 55.67; H, 5.19; N, 14.43. Found: C, 55.74; H, 5.22; N, 14.69%.

2.3.1.2. N-Propionylsalicylhydrazide (H_3pshz). The ligand, *N*-propionylsalicylhydrazide was prepared in an analogous manner to that used for *N*-acetylsalicylhydrazide. Propionic anhydride (8.00 ml) was used. 91% yield. M.p. = 148–151°C. IR (KBr pellet): 3333, 3302, 3201, 2976, 1675, 1640, 1607, 1485, 1236, 752 cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ 11.93, 10.54, 10.12 (s, s, s, 3H, Hs at amides and phenolic OH), 7.91 (dd, 1H, $J = 7.9$, 1.5 Hz, H at phenyl), 7.44 (td, 1H, $J = 7.7$, 1.5 Hz, H at phenyl), 6.99–6.91 (m, 2H, Hs at phenyl), 2.25 (q, 2H, $J = 7.6$ Hz, H at –CH_2–), 1.09 (t, 3H, $J = 7.6$ Hz, H at –CH_3). ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 172.14, 167.19, 159.27, 134.35, 128.71, 119.36, 117.66, 114.98, 26.81, 9.96. *Anal.* Calc. for $C_{10}H_{12}N_2O_3$: C, 57.69; H, 5.81; N, 13.45. Found: C, 57.48; H, 5.68; N, 12.75%.

2.3.1.3. N-Hexanoylsalicylhydrazide (H_3hshz). Hexanoyl chloride (2.76 ml, 19.7 mmol) was added to a solution of chloroform (100 ml) containing water (0.36 ml, 19.7 mmol) and triethylamine (5.5 ml, 39.4 mmol) at 0°C. The reaction mixture was slowly warmed to ambient temperature. Another hexanoyl chloride (2.76 ml, 19.7 mmol) was added to the mixture. Then, salicylhydrazide (2.500 g, 16.4 mmol) was added to the reaction mixture. The resulting reaction mixture was stirred at ambient temperature for 1 day. The white suspension was diluted with hexane (200 ml), filtered, and rinsed with water (50 ml × 3) and hexane (50 ml × 5). 3.450 g of the product was obtained (84% yield). M.p. = 163–

165°C. IR (KBr pellet): 3323, 3195, 2963, 2935, 1610, 1576, 1490, 1235, 756 cm^{-1}. ^1H NMR (300 MHz, DMSO-d_6): δ 11.89, 10.48, 10.07 (s, s, s, 3H, Hs at amides and phenolic OH), 7.83 (dd, 1H, $J = 7.9$, 1.3 Hz, H at phenyl), 7.36 (td, 1H, $J = 7.7$, 1.4 Hz, H at phenyl), 6.95–6.83 (m, 2H, Hs at phenyl), 2.14 (t, 2H, $J = 7.4$ Hz, H at $-CH_2-$), 1.49 (m, 2H, H at $-CH_2-$), 1.22 (m, 4H, H at $-CH_2-CH_2-$), 0.80 (t, 3H, $J = 6.8$ Hz, H at $-CH_3$). ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 172.57, 168.41, 160.69, 135.57, 129.90, 120.55, 118.87, 116.10, 34.70, 32.46, 26.29, 23.43, 15.40. *Anal.* Calc. for $C_{13}H_{18}N_2O_3$: C, 62.38; H, 7.25; N, 11.90. Found: C, 62.17; H, 7.18; N, 11.73%.

2.3.1.4. N-Lauroylsalicylhydrazide (H_3lshz). The ligand *N*-lauroylsalicylhydrazide was prepared in an analogous manner to that used for *N*-hexanoylsalicylhydrazide. Lauroyl chloride (2.76 ml, 19.7 mmol) was used. 93% yield. M.p. = 145–147°C. IR (KBr pellet): 3328, 3195, 2919, 2850, 1604, 1576, 1490, 1234, 751 cm^{-1}. ^1H NMR (300 MHz, DMSO-d_6): δ 11.97, 10.56, 10.15 (br s, br s, s, 3H, Hs at amides and phenolic OH), 7.91 (dd, 1H, $J = 7.9$, 1.5 Hz, H at phenyl), 7.44 (td, 1H, $J = 7.8$, 1.5 Hz, H at phenyl), 7.00–6.90 (m, 2H, Hs at phenyl), 2.22 (t, 2H, $J = 7.3$ Hz, H at $-CH_2-$), 1.54 (m, 2H, H at $-CH_2-$), 1.26 (m, 16H, H at $-(CH_2)_8-$), 0.86 (t, 3H, $J = 6.6$ Hz, H at $-CH_3$). ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 171.28, 167.12, 159.48, 134.32, 128.69, 119.30, 117.64, 114.89, 33.53, 31.70, 29.42, 29.35, 29.18, 29.13, 28.96, 25.43, 22.49.14.28. *Anal.* Calc. for $C_{19}H_{30}N_2O_3$: C, 68.23; H, 9.04; N, 8.38. Found: C, 67.97; H, 9.02; N, 8.39%.

2.3.2. Synthesis of metallamacrocycles

*2.3.2.1. [Mn(fshz)(MeOH)]$_6$ (**1**).* The metallamacrocycle, [Mn(fshz)(MeOH)]$_6$, was synthesized as previously described [11]. ^1H NMR (acetone-d_6): δ −10.14, −21.64, −34.94 (Hs at phenyl); 3.03 (Hs for H_2O).

*2.3.2.2. [Mn(ashz)(DMF)]$_6$ (**2**).* A 0.588 g (3.0 mmol) sample of *N*-acetylsalicylhydrazide was dissolved in 30 ml of DMF and 0.735 g (3.0 mmol) of manganese(II) acetate tetrahydrate was dissolved in 30 ml of DMF in another flask. The two solutions were mixed and the combined solution was allowed to stand for 4 days, whereupon dark brown rectangular crystals were obtained (0.935 g, 90.7% yield). *Anal.* Calc. for [Mn(ashz)(DMF)]$_6$·2DMF ($C_{78}H_{98}Mn_6N_{20}O_{26}$) (fw = 2061.38): C, 45.45; H, 4.79; Mn, 15.99; N, 13.59. Found: C, 45.32; H, 5.20; Mn, 16.55; N, 14.25%. ^1H NMR (acetone-d_6): δ −10.03, −20.40, −33.12 (Hs at phenyl); 37.94 (H at C9); 8.01, 2.95, 2.79 (Hs for DMF); 2.99 (Hs for H_2O). FABMS, m/z: $[Mn_6(ashz)_6 + H]^+$, 1477.6. UV–Vis ($CHCl_3$) $\lambda_{max}(\varepsilon)$: 249 nm (36 500 M^{-1} cm^{-1}); 298 nm (20 100 M^{-1} cm^{-1}); 364 nm (10 600 M^{-1} cm^{-1}). μ_{eff}: 11.84 μ_B (4.83 μ_B/metal).

*2.3.2.3. [Mn(pshz)(DMF)]$_6$ (**3a**).* A 0.365 g (2.0 mmol) sample of *N*-propionylsalicylhydrazide was dissolved in 15 ml of DMF and 0.49 g (2.0 mmol) of manganese(II) acetate tetrahydrate was dissolved in 15 ml of DMF in another flask. The two solutions were mixed and the combined solution was allowed to stand for 4 days, whereupon dark brown rectangular crystals were obtained (0.58 g, 87.0% yield). *Anal.* Calc. for [Mn(pshz)(DMF)]$_6$ ($C_{78}H_{96}Mn_6N_{18}O_{24}$) ($F_w = 1999.35$): C, 46.86; H, 4.84; Mn, 16.49; N, 12.61. Found: C, 46.56; H, 5.58; Mn, 16.18; N, 13.23%. ^1H NMR (acetone-d_6): δ −2.76(br); −10.10, −20.26, −32.90 (Hs at phenyl); 49.90 (H at C9); 8.10, 2.99, 2.82 (Hs for DMF); 3.11 (Hs for H_2O). UV–Vis (acetone) $\lambda_{max}(\varepsilon)$: 328 nm (27400 M^{-1} cm^{-1}); 372 nm (17 500 M^{-1} cm^{-1}); 467 nm (2460 M^{-1} cm^{-1}). μ_{eff}: 11.13 μ_B (4.55 μ_B/metal).

*2.3.2.4. [Mn(pshz)(EtOH)]$_6$ (**3b**).* A 0.10 g (0.5 mmol) sample of *N*-propionylsalicylhydrazide was dissolved in 5 ml of DMF and 0.123 g (0.5 mmol) of manganese(II) acetate tetrahydrate was dissolved in 5 ml of DMF in another flask. The two solutions were mixed and the combined solution was allowed to stand for 4 days, whereupon dark brown rectangular crystals were obtained (0.10 g, 67% yield). *Anal.* Calc. for [Mn_6(pshz)$_6$(EtOH)$_5$] ($C_{70}H_{84}Mn_6N_{12}O_{23}$) ($F_w = 1791.13$): C, 46.94; H, 4.73; Mn, 18.40; N, 9.38. Found: C, 46.25; H, 4.51; Mn, 18.46; N, 9.36%. UV–Vis (THF) $\lambda_{max}(\varepsilon)$: 239 nm (233 000 M^{-1} cm^{-1}); 278 nm (193 000 M^{-1} cm^{-1}); 327 nm (45 600 M^{-1} cm^{-1}); 369 nm (26 700 M^{-1} cm^{-1}); 439 nm (3850 M^{-1} cm^{-1}); 739 nm (2640 M^{-1} cm^{-1}).

*2.3.2.5. [Mn(hshz)(DMF)]$_6$ (**4**).* A 0.250 g (1.0 mmol) sample of *N*-hexanoylsalicylhydrazide was dissolved in 15 ml of DMF and 0.245 g (1.0 mmol) of manganese (II) acetate tetrahydrate was dissolved in 15 ml of DMF in another flask. The two solutions were mixed and the combined solution was allowed to stand for 5 days, whereupon dark brown rectangular crystals were obtained (0.352 g, 93.8% yield). *Anal.* Calc. for [Mn(hshz)(DMF)]$_6$ ($Mn_6C_{96}H_{132}N_{18}O_{24}$) ($F_w$ = 2251.84): C, 51.21; H, 5.91; Mn, 14.64; N, 11.20. Found: C, 51.04; H, 5.88; Mn, 14.00; N, 11.25. ^1H NMR (acetone-d_6): δ -12.0(shoulder); −10.63, −20.61, −32.56 (Hs at phenyl); 54.73 (H at C9); 8.43, 3.102, 2.926 (Hs for DMF); 3.351 (Hs for H_2O); 1.30, 0.51 (Hs for alkyl chains). UV–Vis (THF) $\lambda_{max}(\varepsilon)$: 239 nm (247 000 M^{-1} cm^{-1}); 278 nm (208 000 M^{-1} cm^{-1}); 369 nm (24 000 M^{-1} cm^{-1}); 456 nm (4060 M^{-1} cm^{-1}). UV − Vis (acetone) $\lambda_{max}(\varepsilon)$: 326 nm (31 000 M^{-1} cm^{-1}); 374 nm (19 200 M^{-1} cm^{-1}); 458 nm (2200 M^{-1} cm^{-1}). μ_{eff}: 11.59 μ_B (4.73 μ_B/metal).

*2.3.2.6. [Mn(lshz)(MeOH)]$_6$ (**5**).* A 0.668 g (2.0 mmol) sample of *N*-lauroylsalicylhydrazide was dissolved in 80 ml of MeOH and 0.490 g (2.0 mmol) of manganese(II) acetate tetrahydrate was dissolved in 20 ml of MeOH in another flask. When the two solutions were mixed precipitate formed immediately. After a day of stirring, the solution was filtered to obtain 0.56 g of undissolved powder. The filtrate was allowed to stand for 3 days, whereupon dark brown rectangular crystals were obtained (0.10 g, 11.9% yield). The undissolved powder obtained from the early stage of the reaction was added to 200 ml of MeOH. After a week of the stirring, most of powders were dissolved. Slow evaporation of the solution yielded the same dark rectangular crystals (0.34 g, 40.6% yield). *Anal.* Calc. for [Mn(lshz)(MeOH)]$_6$ ($Mn_6C_{120}H_{186}N_{12}O_{24}$) ($F_w$ = 2510.49): C, 57.41; H, 7.47; Mn, 13.13; N, 6.70. Found: C, 57.06; H, 8.07; Mn, 13.77; N, 7.03%. ^{1}H NMR (acetone-d_6): δ −10.44, −20.35, −31.18 (Hs at phenyl); 52.95 (H at C9); 3.837(Hs for H_2O); 5.792, 1.296, 0.915 (Hs for alkyl chains). UV–Vis (THF) $\lambda_{max}(\varepsilon)$: 239 nm (249 000 M^{-1} cm^{-1}); 278 nm (214 000 M^{-1} cm^{-1}); 368 nm (24 000 M^{-1} cm^{-1}); 466 nm (4020 M^{-1} cm^{-1}); 742 nm (360 M^{-1} cm^{-1}). UV–Vis (acetone) $\lambda_{max}(\varepsilon)$: 328 nm (34 200 M^{-1} cm^{-1}); 375 nm (21 900 M^{-1} cm^{-1}); 465 nm (3500 M^{-1} cm^{-1}). μ_{eff}: 11.63 μ_B (4.75 μ_B/metal).

2.4. Crystallographic data collection and refinement of structures

Because crystals of **2**–**5** lose their structural solvents of crystallization within 1 min, they were mounted in a glass capillary with the mother liquor to prevent the loss of the structural solvents during data collection. Preliminary examination and data collection for crystals of **2**–**4** were performed with Mo Kα radiation (λ = 0.71069 Å) on an Enraf–Nonius CAD4 computer-controlled κ-axis diffractometer equipped with a graphite crystal, incident-beam monochromator. Cell constants and orientation matrices for data collection were obtained from least-squares refinement, using the setting angles of 25 reflections. Data were collected at r.t. using the ω scan technique. Three standard reflections were monitored every hour, but no intensity variations were monitored. Lorentz and polarization corrections were applied to the data; however, no corrections were made for absorption. Preliminary examination and data collection for the crystal of **5** were performed with Mo Kα radiation (λ = 0.71069 Å) on a Siemens SMART CCD equipped with a graphite crystal, incident-beam monochromator. Data were collected at r.t. Lp correction and absorption correction were applied to the data. All structures were solved by direct methods using SHELXS-86 [12] and refined by full-matrix least-squares calculations with SHELX-97 [13].

*2.4.1. Complex [Mn(ashz)(DMF)]$_6$ (**2**).*

All non-hydrogen atoms except one solvent molecule were refined anisotropically; hydrogen atoms were allowed to ride on geometrically ideal positions with isotropic temperature factors 1.2 times those of the attached non-hydrogen atoms. One DMF molecule coordinated to the ring metal ion is statically disordered. This disordered site was refined with two partially occupied DMF molecules (0.47 occupancy site: O4C, C101, N3C, C111, C121; 0.53 occupancy site: O4C, C102, N3C, C112, C122). Two solvent sites were identified; one of them performed very poorly. Refinement without any geometrical restraint or with disordered modelling produced bad geometry. So the geometry of this solvent molecule was restrained the same as the geometry of the other solvent molecule.

*2.4.2. Complex [Mn(pshz)(DMF)]$_6$ (**3a**).*

All non-hydrogen atoms (except disordered sites) were refined anisotropically; hydrogen atoms were allowed to ride on geometrically ideal positions with isotropic temperature factors 1.2 times those of the attached non-hydrogen atoms. All ethyl side chains of the ligands were disordered. These disordered sites were refined with partial occupancy. One disordered ethyl side chain showed abnormal bond distances (C9A–C10A 1.73; C9A–C11A 1.86 Å). The restrained refinement with an ideal geometry gave similar result. Two solvent sites were identified, one of them performed very badly. Refinement without any geometrical restraint or with disordered modelling produced bad geometry. So the geometry of this solvent molecule was restrained the same as the geometry of the other solvent molecule.

*2.4.3. Complex [Mn(hshz)(DMF)]$_6$ (**4**).*

All non-hydrogen atoms were refined anisotropically; hydrogen atoms were allowed to ride on geometrically ideal positions with isotropic temperature factors 1.2 times those of the attached non-hydrogen atoms. Two solvent sites were identified; one of which yield an abnormal bond distance (1.78 Å) between O1DE–C1DE. So the geometry of this solvent molecule was restrained the same as the geometry of the other solvent molecule.

*2.4.4. Complex [Mn(lshz)(MeOH)]$_6$ (**5**).*

All non-hydrogen atoms were refined anisotropically; hydrogen atoms were allowed to ride on geometrically ideal positions with isotropic temperature factors 1.2 times those of the attached non-hydrogen atoms. In the crystal structures, only portions of the long alkyl side chains could be identified in the difference Fourier map. The remaining terminal carbon atoms were disordered. During the least-squares refinement of the crystal **5**, the alkyl side chains of the ligands were restrained as an

ideal geometry. Seven solvent sites were identified and refined as methanol molecules but some of them might be part of the unconnected long alkyl side chains.

Crystal and intensity data are given in Table 1.

3. Results and discussion

In this study, a series of potential pentadentate ligands, *N*-acylsalicylhydrazides (H_3xshz) (–$COCH_3$, *N*-acetylsalicylhydrazide; –$COCH_2CH_3$, *N*-propionylsalicylhydrazide; –$CO(CH_2)_2CH_3$, *N*-hexanoylsalicylhydrazide; and, –$CO(CH_2)_{10}CH_3$, *N*-lauroylsalicylhydrazide) were synthesized by the coupling of the salicylhydrazide and the corresponding acyl chloride or acyl anhydrides. The triple deprotonated *N*-acylsalicylhydrazidate (xshz^{3-}) with a linear aliphatic chain were able to bridge the metal ions using a hydrazide N–N group and form the isostructural hexanuclear manganese metallamacrocycle. Depending on the ligands used, the tripled hydrophobic aliphatic tails of different lengths are attached at both chiral faces of the hexanuclear manganese metallamacrocycle (Fig. 2).

3.1. Crystal structure of $[Mn(ashz)(DMF)]_6$ (2)

Hexanuclear manganese metallamacrocycle $[Mn(ashz)(DMF)]_6$, **2** were able to be synthesized using manganese(II) acetate tetrahydrate as a metal source and ashz^{3-} as a trianionic pentadentate ligand. An ORTEP diagram of complex **2** is shown in Fig. 3. This neutral hexanuclear manganese metallamacrocycle is similar to the previously reported hexanuclear manganese metallamacrocycle $[Mn(fshz)(DMF)]_6$ (**1**) (Tables 2 and 3) [11]. Complex **2** with noncrystallographic local pseudo-C_{3i} symmetry is in the crystallographic inversion center. As in complex **1**, the pentadentate ligand *N*-acetylsalicylhydrazidate also bridges the ring metal ions using a hydrazide N–N group. An iminophenolate group (O1 and N1 atoms) and an iminoacetyl group (N1 and O3 atoms) of the ligand are coordinated to the metal ion in the meridional mode to form the six-membered and five-membered chelating rings. A hydrazidate group (O2 and N2 atoms) occupies two of the three remaining coordination sites of the octahedral

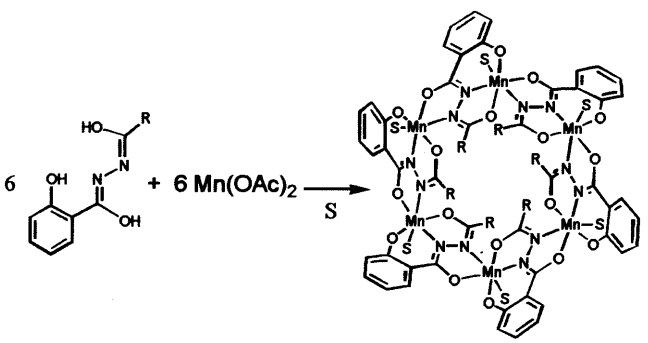

Fig. 2. Synthesis of metallamacrocycles.

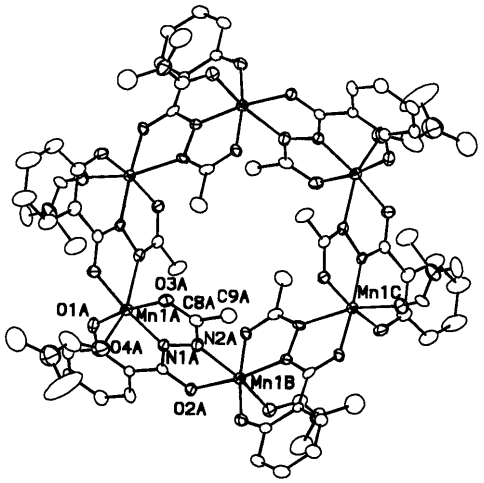

Fig. 3. An ORTEP drawing of complex **2**, $[Mn(ashz)(DMF)]_6$. The complex is in the crystallographic inversion center. A, B, and C in manganese ions could be related to each other by using a noncrystallographic S_6 symmetry operation. Hydrogen atoms have been omitted for clarity.

[b] Ref. [11].
[c] Symmetry transformation used to generate equivalent atoms: $1-x, -y+2, -z$

manganese ions to form the five-membered chelating ring. A solvent molecule DMF (O4 atom), coordinated at the Jahn–Teller elongation axis, finishes the octahedral geometry of the manganese ion (Table 2). The binding mode of the ligand enforces the stereochemistry of the metal ions only into a propeller configuration in the complex **2**. The resulting chiralities of the metal centers in complex **2** alternate between Λ and Δ forms. The alternation of the chiralities of the metal centers generates two chiral faces with opposite chiralities in the hexanuclear manganese metallamacrocycle. Complex **2** also has a vacant, hydrophobic hole in the center of the metallamacrocycle. The approximate dimensions of the hydrophobic hole are similar to those in the previously reported complex **1**, $[Mn(fshz)(DMF)]_6$ (Table 3). However, in complex **2** the entrance of the hole at each face is closed by three methyl groups of the *N*-acetyl side chains of the ligands. The diameter of the entrance of the hole, formed by the pseudo-C_3 symmetry-related three methyl carbon atoms (C9), is about 1.3 Å smaller than that of the entrance of the hole formed by the pseudo-C_3 symmetry-related three C8 carbon atoms (Table 3).

3.2. Crystal structure of $[Mn(pshz)(DMF)]_6$ (3a)

Hexanuclear manganese metallamacrocycle $[Mn(pshz)(DMF)]_6$ (**3a**) could be synthesized using manganese(II) acetate tetrahydrate as a metal source and $pshz^{3-}$ as a trianionic pentadentate ligand. An ORTEP diagram of complex **3a** is shown in Fig. 4. This neutral hexanuclear manganese metallamacrocycle is also similar to the previously reported hexanuclear manganese metallamacrocycle $[Mn(fshz)(DMF)]_6$ (**1**) and $[Mn(ashz)(DMF)]_6$ (**2**). Complex **3a** with noncrystallographic local pseudo-C_{3i} symmetry is also in the crystallographic inversion center. In the crystal structure, ethyl side chains of the ligands (three ethyl side chains in the asymmetric unit) are disordered. In the complex **3a**, only one entrance of the hole is blocked by three ethyl groups of the *N*-propionyl side chains of the ligands. At the other entrance of the hole, one ethyl group is located on the inside of the hole and the remaining two ethyl groups are at the face of the hole. When the ethyl group located in the inside of the hole was omitted during crystallographic refinement, the difference Fourier map showed about 1.5 residual electron density per $Å^2$. In addition, the hole of the metallamacrocycle

Table 3
Selected lengths (Å) and hole sizes (Å) for **1**, **2**, **3a**, **4** and **5**

	1 [a]	**2**	**3**	**4**	**5**

Mn1A···Mn1C	8.031	8.208	8.256	8.183	8.268
Hole size [b]	6.89	7.10	7.15	7.07	7.17
C8A···C8C	5.026	5.226	5.405	5.235	5.355
Hole size	2.70	2.93	3.14	2.94	3.08

[a] Ref. [11].
[b] The hole was formed by the three pseudo-C_3 symmetry-related atoms and the size of the hole was calculated by the subtraction of the Van der Waals radii of the constituting atoms.

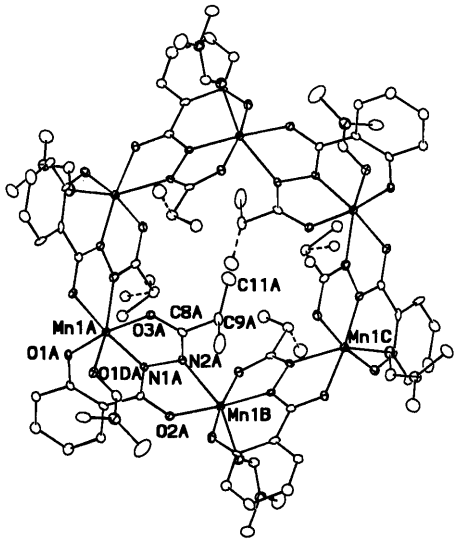

Fig. 4. An ORTEP drawing of complex **3a**, $[Mn(pshz)(DMF)]_6$. The complex is in the crystallographic inversion center. A, B, and C in manganese ions could be related to each other by using a noncrystallographic S_6 symmetry operation. The dotted lines are for the disordered ethyl groups. Hydrogen atoms have been omitted for clarity.

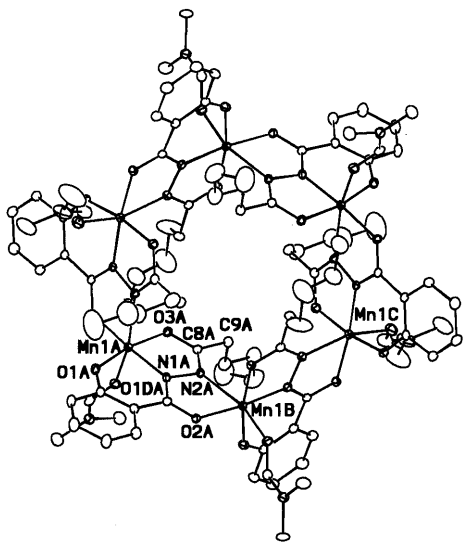

Fig. 5. An ORTEP drawing of complex **4**, $[Mn(hshz)(DMF)]_6$. The complex is in the crystallographic inversion center. A, B, and C in manganese ions could be related to each other by using a noncrystallographic S_6 symmetry operation. Hydrogen atoms have been omitted for clarity.

expanded slightly. The diameter of the entrance formed by the pseudo C_3 symmetry related three C8 atoms in the complex **3a** increased approximately 0.4 Å compared to the corresponding diameter in the complex **1** (Table 3). The incorporation of the ethyl group resulted in the expansion of the hole. This shows that the hexanuclear manganese metallamacrocycle has some degree of flexibility.

3.3. Crystal structure of $[Mn(hshz)(DMF)]_6$ (4)

Hexanuclear manganese metallamacrocycle $[Mn(hshz)(DMF)]_6$ (**4**) could be synthesized using manganese(II) acetate tetrahydrate as a metal source and $hshz^{3-}$ as a trianionic pentadentate ligand. An ORTEP diagram of complex **4** is shown in Fig. 5. The complex has two sets of tripled hydrophobic tails at each face of the donut shaped metallamacrocycles. In the crystal structure, three alternating pentyl side chains aligned at an approximately right angle to the plane of the metallamacrocycle in one direction, while the other three alternating pentyl side chains aligned in the opposite direction (Fig. 6).

3.4. Crystal structure of $[Mn(lshz)(MeOH)]_6$ (5)

Hexanuclear manganese metallamacrocycle $[Mn(lshz)(MeOH)]_6$ (**5**) could be synthesized using manganese(II) acetate tetrahydrate as a metal source and $lshz^{3-}$ as a trianionic pentadentate ligand. The crystal structure showed three crystallographically independent, but chemically identical, molecules. In the crystal structure, only a portion of the long alkyl side chains could be identified. Depending on the alkyl side chains in the three crystallographically independent molecules, three to seven carbon atoms among eleven could be found in the difference Fourier map. The remaining terminal carbon atoms were disordered. An ORTEP drawing of one of these molecules (complex **5**) is shown in Fig. 7. The three alternating hydrophobic alkyl chains aligned at an approximately right angle to the plane of the metallamacrocycle, and the other three alkyl chains aligned in the opposite direction as in

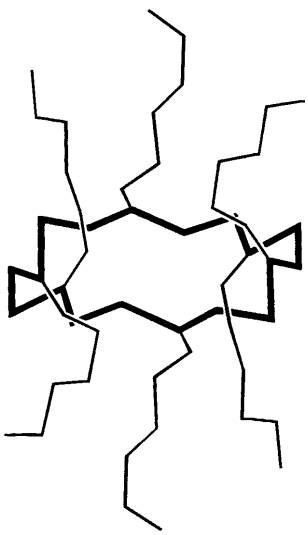

Fig. 6. Side view of complex **4**, $[Mn(hshz)(DMF)]_6$. Cyclic $(Mn–N–N–)_6$ linkage is drawn in bold. The alternating side chains aligned at an approximately right angle to the plane of the metallamacrocycle.

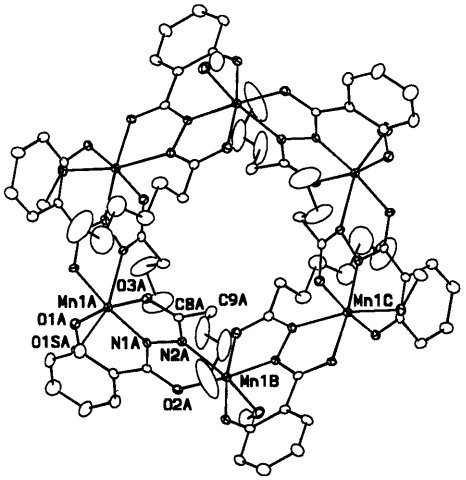

Fig. 7. An ORTEP drawing of complex **5**, $[Mn(lshz)(MeOH)]_6$. Only parts of the alkyl chains could be identified in the difference Fourier map. A, B and C in manganese ions could be related to each other by using a noncrystallographic S_6 symmetry operation. Hydrogen atoms have been omitted for clarity.

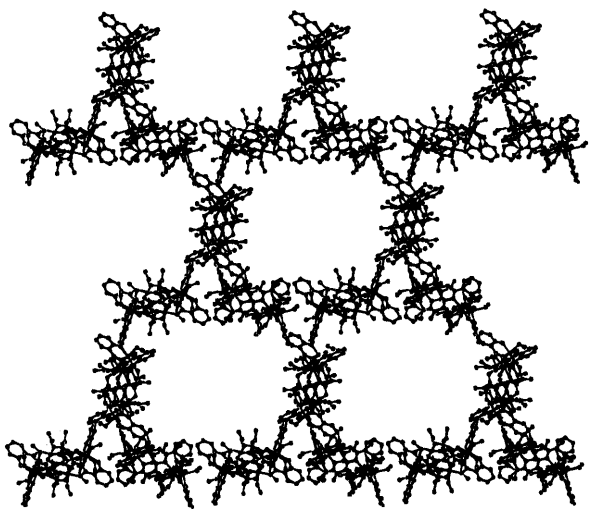

Fig. 8. Packing diagram of complex **5**, $[Mn(lshz)(MeOH)]_6$. Complex **5** serves as unit for the gigantic hexagonal packing of the hexanuclear metallamacrocycles. Only the part of the alkyl chains (C9 and C10 atoms) are represented in this packing diagram. The disordered hydrophobic alkyl chains of the hexanuclear metallamacrocycles are gathered at the centers of the gigantic hexagonal network.

complex **4**. In the crystal packing structure, the hexanuclear metallamacrocycle **5** serves as a unit for the gigantic hexagonal packing of the metallamacrocycles. The disordered hydrophobic alkyl chains of the hexanuclear metallamacrocycles are gathered at the centers of the gigantic hexagon (Fig. 8).

The charge balance of the metallamacrocycles in the crystal structures suggests that the oxidation state of the manganese ion is $+3$. The oxidation state of the manganese ion is also confirmed by room temperature magnetic susceptibililty measurement. The magnetic moments per metal center in the metallamacrocycles are in the range of 4.55 to 4.83 μ_B. The values correspond to the spin-only value, 4.9, for the high spin manganese(III) d^4 ions.

The methanol solution of the complex **2** in a 3-nitrobenzyl alcohol matrix gave a peak at m/z 1477.6 in the FABMS. This peak corresponds to the hexanuclear metallamacrocycle ion $[Mn_6(ashz)_6 + H]^+$. A similar peak at m/z 1393.5 in complex **1**, corresponding to the hexanuclear metallamacrocycle ion $[Mn_6(fshz)_6 + H]^+$, was previously reported [11]. The solution integrity of the metallamacrocycle was confirmed using paramagnetically shifted ^1H NMR spectroscopy. In the ^1H NMR spectra of all hexanuclear manganese metallamacrocycles in acetone-d_6, three distinctive peaks around -10, -20 and -33 ppm were observed (Fig. 9). These peaks were tentatively assigned to the phenyl protons of the bridging ligands. Similar upfield peaks of the manganese metallacrowns were observed and assigned to the phenyl protons of the salicylhydroximate (shi^{3-}) ligand using deuterium exchange experiments [9g]. The peaks around 38–55 ppm were observed for all complexes with alkyl side chains. The peak at 37.9 ppm was assigned to the methyl protons in the complex **2**, and the peak at 49.9, 54.7, and 53.0 ppm was

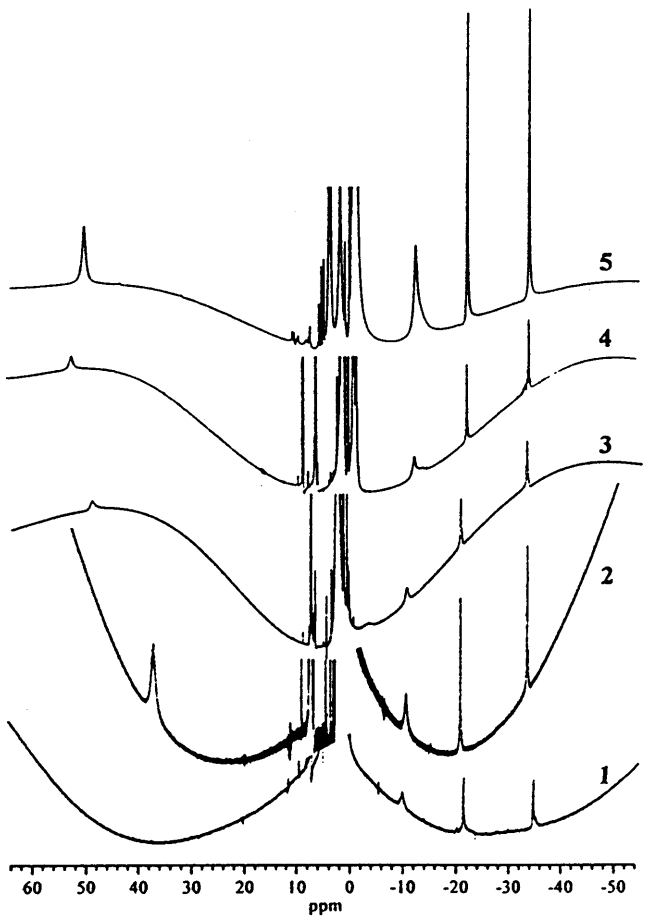

Fig. 9. ^1H NMR spectra of macrocyclic hexanuclear manganese complexes, **1**–**5** in acetone-d_6.

assigned to the methylene protons at the C9 position for the complex **3a**, **4** and **5**, respectively. However, no corresponding peak was observed in the complex **1** (Fig. 9) [11].

All hexanuclear manganese metallamacrocycles with various lengths of hydrophobic aliphatic linear chains are isostructural. The introduction of the side chain to the ligand does not disturb the formation of the hexanuclear manganese metallamacrocycle. Depending on the ligand used, two sets of triple hydrophobic tails of different lengths aligned at a right angle to the plane of the metallamacrocycle in opposite directions to each other. In general, the metallamacrocycle is only slightly soluble in various organic solvents. This might come from the large molecular weight of the metallamacrocycle. However, the solubility of the metallamacrocycle with long hydrophobic alkyl side chains is reasonably good in organic solvent. The ligands with the various functional groups might yield the isostructural metallamacrocycles with the interesting functional groups.

All metallamacrocycles are stable in the solid state. Even in solution, the metallamacrocycles were fairly stable. The ^{1}H NMR spectra of the metallamacrocycles did not change for at least a few months. The stability of the metallamacrocycles might come from the formation of the three chelating rings around the metal ions. The variation of the diameters of the holes (Table 3) implies that the metallamacrocycles have some degree of flexibility. Five donor atoms (from two chelating pentadentate ligands) and an additional donor atom (from a solvent molecule) have coordinated each metal center in the metallamacrocycle. In addition to the stability and flexibility of the metallamacrocycles, the presence of the replaceable solvent site suggests that the hexanuclear manganese metallamacrocycles could be used as a building block for the molecular frameworks [14] or a new type of molecular recognition agent.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 136344 and 136347. Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

Solvothermal synthesis and structure of iron tellurido carbonyl clusters

Birinchi K. Das [1], Mercouri G. Kanatzidis *

Department of Chemistry, Michigan State University, East Lansing, MI 48824, USA

Received 27 May 2000; accepted 7 June 2000

Abstract

Three compounds prepared solvothermally from a mixture of $Fe_3(CO)_{12}$, Na_2Te_2, and Ph_4PBr in the 1:5:6 molar ratio are described. The compound $(Ph_4P)_2[Fe_6Te_{14}(CO)_{12}]\cdot 2H_2O$ (**1**) was obtained by heating the reaction mixture in water at 130°C for 16 h. With 0.5 ml ethanol as the solvent for a reaction carried out at 110°C for 12 h, $(Ph_4P)_2[Fe_4Te_6(TeC_2H_5)_2(CO)_8]$ (**2**) was obtained. $(Ph_4P)_2[Fe_2Te_3(CO)_6]$ (**3**) was obtained as the only product in 4 h with 0.5 ml methanol heated at 80°C. These high-yield preparations illustrate vividly how strongly the identity of product is dependent on the conditions of a solvothermal reaction. X-ray structural studies reveal a variety of coordination modes for the Te_x^{2-} ligands present in these anionic polynuclear clusters.

Keywords: Solvothermal synthesis; Polytelluride; Iron telluride; Iron cluster; Iron carbonyl; Carbonyl clusters

1. Introduction

The solvothermal preparation of metal carbonyl clusters containing polytelluride ligands is now well demonstrated as a synthesis technique [1]. A host of products can be obtained in high yield from reactions involving a mixture of a metal carbonyl compound, an alkali metal polytelluride and a suitable quaternary ammonium or phosphonium cation in an appropriate molar ratio. The improved solvent properties under hydrothermal (or solvothermal for nonaqueous solvents) conditions help in crystal growth [2] and thus in this preparative method lengthy purification procedures can often be avoided by way of the simple filtration of the only desired solid product. By developing this technique we have been successful in obtaining several anionic metal tellurido carbonyl clusters, both homo as well as heterometallic, in very good yield and high level of purity and crystallinity [3]. The nature of exact product formed is highly dependent on the various reaction parameters such as molar ratio of the reactants, solvent, and the temperature and duration of the reaction. We have already published our results on the unusual cluster anions $[M_4Te_6(TeCH_3)_2(CO)_8]^{2-}$ (M = Fe, Ru) [3e], $[Fe_2MTe_3(CO)_{11}]^{2-}$ (M = Mo, W) [3d], $[Fe_3W_2Te_8(TeCH_3)(CO)_{12}]^{3-}$ [3d], $[Fe_4Te_2(CO)_{14}]^{2-}$ [3b], $[HFe_3Te(CO)_9]^-$ [3b], $[Ru_4Te_2(CO)_{10}]^{2-}$ [3a], and $[Ru_5Te(CO)_{14}]^{2-}$ [3a]. The potency of the solvothermal reactions in generating metal clusters is also illustrated by our isolation of $[Fe_2(AsS)(CO)_6]^-$ and $[Fe_5As_2(CO)_{17}]^{2-}$ from reactions involving $Fe_3(CO)_{12}$, $NaAsO_2$, and Ph_4PBr [3c]. The sulfur atom in the former complex is derived from $Na_2S_2O_4$ which was added into the reaction mixture in order to reduce As^{3+} to As^0. In this paper we describe the solvothermal preparation and structural characterization of two new compounds $(Ph_4P)_2[Fe_6Te_{14}(CO)_{12}]\cdot 2H_2O$ (**1**) and $(Ph_4P)_2[Fe_4Te_6(TeC_2H_5)_2(CO)_8]$ (**2**) along with $(Ph_4P)_2[Fe_2Te_3(CO)_6]$ (**3**) which was previously isolated as $[(K.crypt)_2][Fe_2Te_3(CO)_6]\cdot 0.5en$ by reacting $Fe(CO)_3(\eta^4$-butadiene) with K_2Te_4 and crypt (4,7,13,16,21,24 - hexaoxa - 1,10 - diazabicyclo[8,8,8]hexacosane) in ethylenediamine (en) [4]. The present report highlights how an identical mixture consisting of $Fe_3(CO)_{12}$, Na_2Te_2 and Ph_4PBr under three different sets of reaction

conditions leads to the formation of three entirely different anionic iron-tellurido carbonyl clusters of nuclearities six, four and two.

2. Experimental

Solids were handled in an inert atmosphere glove box. Triiron dodecacarbonyl (Strem Chemicals Inc) and tetraphenylphosphonium bromide (Lancaster) were used as received. Sodium ditelluride was prepared by reacting stoichiometric amounts of the elements in liquid ammonia.

Solution IR spectra were recorded using a cell with NaCl windows on a Nicolet IR/42 FT Spectrometer. For obtaining the solid-state spectra also the same instrument was used. A Varian VXR-300 NMR spectrometer was used to obtain the ^{1}H NMR spectrum of **2**. ^{125}Te NMR spectra were obtained on a Varian VXR-500 spectrometer operating at approximately 157.9 MHz for ^{125}Te resonances. Spectral data were referenced to a signal for $TeCl_4$, dissolved in D_2O–HCl, at 1237 ppm with respect to Me_2Te at 0.0 ppm [5]. Elemental analyses for P, Fe and Te were performed by Energy Dispersive Spectroscopy (EDS) of X-rays using a JEOL JSM-6400V Scanning Electron Microscope. Instruments and experimental procedures of single crystal X-ray work are described in a separate section below.

2.1. Preparation of $(Ph_4P)_2[Fe_6Te_{14}(CO)_{12}]\cdot 2H_2O$ (1)

A mixture of 50 mg $Fe_3(CO)_{12}$ (0.1 mmol), 150 mg Na_2Te_2 (0.5 mmol) and 250 mg Ph_4PBr (0.6 mmol) was loaded into a thick-walled Pyrex tube of 9 mm outer diameter. The tube was frozen in liquid N_2 after adding 0.3 ml water (under nitrogen) into it and subsequently it was flame-sealed under vacuum. The sealed tube was heated at 130°C and the solid product was isolated after 16 h by washing with MeOH several times. The dark brown crystals of **1** were separated from the needle-shaped crystals of elemental tellurium by suspending the mixture in bromoform which is lighter than the Te crystals, but heavier than the triclinic plate-like crystals of **1**. Yield: 145 mg (ca. 90% based on Fe). EDS analysis gave a P:Fe:Te ratio close to the expected ratio of 1:3:7. IR data: (ν_{CO}, cm^{-1}; KBr pellet) 1978(sh), 1965(s), 1942(w), 1936(m), 1927(m).

2.2. Preparation of $(Ph_4P)_2[Fe_4Te_6(TeC_2H_5)_2(CO)_8]$ (2)

A mixture of 50 mg $Fe_3(CO)_{12}$ (0.1 mmol), 150 mg Na_2Te_2 (0.5 mmol) and 250 mg Ph_4PBr (0.6 mmol) was loaded into a thick-walled Pyrex tube of 9 mm outer diameter. The tube was frozen in liquid N_2 after adding 0.5 ml ethanol into it and subsequently it was flame-sealed under vacuum. The sealed tube was heated at 110°C and the dark brown crystals of **2** were isolated after 12 h by washing with MeOH. Yield: 127 mg (77% based on Fe). EDS analysis gave a P:Fe:Te ratio close to the expected ratio of 1:2:4. IR data: (a) (ν_{CO}, cm^{-1}; KBr pellet) 1948(s), 1997(s) (b) (ν_{CO}, cm^{-1}, DMF solution) 1971(w), 1945(m), 1907(vs). ^{1}H NMR (δ, ppm; DMSO-d_6 solution) 2.79(quartet), 1.61(triplet). UV–visible spectral data: (nm, DMF solution) 331(sh), 438(sh), 565(sh).

2.3. Preparation of $(Ph_4P)_2[Fe_2Te_3(CO)_6]$ (3)

A mixture of 50 mg $Fe_3(CO)_{12}$ (0.1 mmol), 150 mg Na_2Te_2 (0.5 mmol) and 250 mg Ph_4PBr (0.6 mmol) was loaded into a thick-walled Pyrex tube of 9 mm outer diameter. The tube was frozen in liquid N_2 after adding 0.5 ml methanol into it and subsequently it was sealed under vacuum. The sealed tube was heated at 80°C and the red brown, hexagonal plate-like crystals of **3** were isolated after 4 h by washing with small aliquots of MeOH. Yield: 130 mg (65% based on Fe). EDS analyses carried out on well defined crystals showed expected P:Fe:Te ratios. IR data: (a) (ν_{CO}, cm^{-1}; KBr pellet) 2024(w), 2018(w), 1993(s), 1951(s), 1914(s), 1903(s), 1892(vs), 1882(sh); (b) (ν_{CO}, cm^{-1}, DMF solution) 2002(m), 1973(m), 1923(s), 1908(s). UV–Vis spectrum in DMF solution: λ_{max}, 515 nm ($\varepsilon = 7230\ M^{-1}\ cm^{-1}$). ^{125}Te NMR spectral data (δ, ppm; DMSO-d_6 solution): 241, −32, −613.

2.4. X-ray crystallography

The single crystals used for X-ray diffraction experiments were chosen from the products formed during the solvothermal reactions employed for preparing the compounds. Intensity data of **1** were collected on a Rigaku AFC-6S diffractometer using Mo Kα ($\lambda =$ 0.7107 Å). A crystal sealed inside a glass capillary was used as the specimen for doing the experiments at room temperature. For the crystal of **2** also, similar arrangements were made. To collect the intensity data on **3**, a glass fiber mounted crystal was cooled with a cold stream of nitrogen gas and it was seen that no ice crystals had developed over the crystal surfaces during the data collection process. Intensities of three standard reflections were measured repeatedly after every 200 reflections in all three cases during the collection of intensity data. No significant decay of intensities was observed, however. The structures were solved by direct methods using SHELXS-86 [6] and were refined on a VAXstation 3100/76 computer by least squares techniques using the TEXSAN crystallographic software package [7]. Intensity data were corrected for absorption effects using the empirical method of Walker and Stuart [8]. These corrections were applied to the data by

using the refined parameters obtained after refining the non-hydrogen atom structure isotropically to convergence. For all structures the non-hydrogen atoms barring the carbon atoms belonging to the tetraphenylphosphonium cations were refined anisotropically and the carbon-bonded hydrogen atoms were placed at calculated positions, but not refined. The hydrogen atoms belonging to the water molecules in **1** were ignored. Relevant crystal data on **1**, **2**, and **3** are presented in Table 1. Positional coordinates and geometric data on the structurally important portions of **1**, **2**, and **3** have been deposited (see below).

3. Results and discussion

The preparative reaction explored in this work has been classified previously as *oxidative decarbonylation* wherein chalcogenide fragments oxidatively replace some or all of the CO ligands of a neutral metal carbonyl compound [1b,9]. However, partial substitution of CO ligands may also occur without any concomitant oxidation of the central metal atom as shown by the report on the $[M(CO)_4Te_4]^{2-}$ (M = Cr, Mo, W) anions, which were prepared by reacting $M(CO)_6$ with K_2Te_4 [9]. On the other hand, Se_3^{2-} anions were shown to completely decarbonylate $Mn_2(CO)_{10}$ at 100°C in DMF so as to form $[Mn(Se_4)_2]^{2-}$ [10]. However, under solvothermal (albeit more drastic) conditions we have invariably observed only partial decarbonylation reactions which have resulted in the isolation of several anionic metal-chalcogenido clusters including $[Mn_3(Q_2)_2(QCH_3)(CO)_9]^{2-}$ (Q = S, Se, Te), [1b,11], $[Re_4(Te_2)_3(TeCH_3)(CO)_{12}]^{3-}$ (this compound was prepared from $CpRe(CO)_3$ and as such no CO ligands have been removed during the reaction) [1b,11]) $[Fe_4Se_2(Se_2)(CO)_{12}]^{2-}$ [3f], $[Fe_8Te_8(Te_2)(CO)_{20}]^{2-}$ [3f], and $[Ru_6(Te_2)_7(CO)_{12}]^{2-}$ [3g]. These and other routes to the synthesis of metal carbonyl clusters containing main-group element based ligands have been extensively reviewed [1,9,12].

In the present reactions, Na_2Te_2 has been used to decarbonylate $Fe_3(CO)_{12}$ in the presence of the large Ph_4P^+ cations. Syntheses, molecular structures and properties of **1**, **2**, **3** are discussed below under separate headings.

3.1. $[Fe_6Te_{14}(CO)_{12}]^{2-}$

Compound **1** has been obtained as the only insoluble crystalline species other than the crystals of elemental tellurium using a 1:5:6 reaction mixture of $Fe_3(CO)_{12}$,

Na_2Te_2 and Ph_4PBr at 130°C in water. The same compound has also been found to form at 110°C, which is incidentally the temperature at which the ruthenium analogue of **1** was prepared [3g], but the product in the present instance is microcrystalline in nature. The tellurium crystals are conveniently separated from the desired product by taking advantage of their different densities with respect to that of the heavy organic liquid bromoform where compound **1** is not soluble. Crystals of **1** are fairly stable in air and these have appreciable solubility only in DMF and DMSO among common organic solvents. The $[Fe_6Te_{14}(CO)_{12}]^{2-}$ anion in **1** is isostructural (Fig. 1) with $[Ru_6Te_{14}(CO)_{12}]^{2-}$ and the powder X-ray diffraction patterns of both compounds are nearly superimposable. The structural relationship of the $\{Ru_6(Te_2)_7\}^{2-}$ core in the latter with the pyrite structure type has been emphasized earlier [3g] and the same arguments are valid in the case of compound **1** as well. The ethane-like staggered geometry of the central μ_3,μ_3-Te_2 fragment is a notable feature of this type of structure. This ditelluride ligand in **1** and its ruthenium analogue have nearly the same Te–Te distance. Other

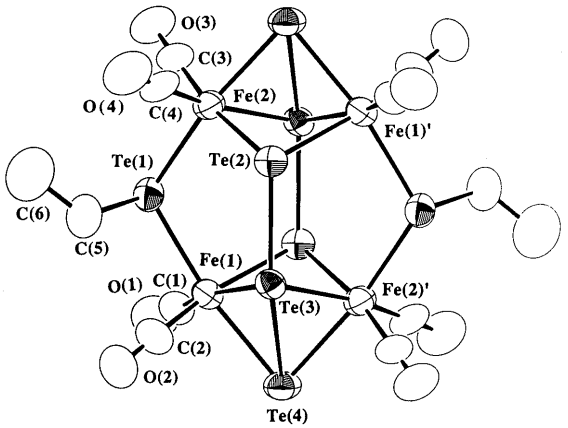

Fig. 2. An ORTEP view of the $[Fe_4Te_6(TeC_2H_5)_2(CO)_8]^{2-}$ cluster anion in **2**.

Te–Te distances are also comparable in magnitude. Selected bond distances and angles are given in Table 2.

The Fe–C bonds in **1** (ca. 1.77 Å) are uniformly shorter compared to those in $[Ru_6Te_{14}(CO)_{12}]^{2-}$ (ca. 1.9 Å) and this difference is reflected appropriately in the carbonyl region IR spectra of the compounds. While the two pairs of ν(CO) doublets in **1** center around 1967 and 1929 cm^{-1}, those in the ruthenium compound appear at ca. 1997 and 1950 cm^{-1}. Although three ^{125}Te NMR signals were reported [3g] to occur for $[Ru_6Te_{14}(CO)_{12}]^{2-}$ at -1606, -2978, and -3616 ppm, no such signals could be recorded under similar conditions for **1**. The dark brown crystals of **1** dissolve slowly in DMF to give a dark solution, which may not contain much of $[Fe_6Te_{14}(CO)_{12}]^{2-}$ as evidenced by the rather poorly defined IR spectrum of the solution. It is likely to behave in deuterated DMF in a similar manner and during the long hours of ^{125}Te signal acquisition, the sample must have decomposed to a mixture of unknown species. Solution IR spectra of $[Ru_6Te_{14}(CO)_{12}]^{2-}$ were not reported. The above results, however, indicate a difference in solution stability between the iron and ruthenium clusters having identical solid state structures. Perhaps due to the same inherent reasons we were previously unable to isolate the iron analogues of the pseudo-octahedral ruthenium clusters $[Ru_5(\mu_4\text{-Te})(CO)_{14}]^{2-}$ and $[Ru_4(\mu_4\text{-Te})_2(CO)_{10}]^{2-}$ [3a].

3.2. $[Fe_4Te_6(TeC_2H_5)_2(CO)_8]^{2-}$

The synthesis and characterization of two chemical analogues of **2** have been previously reported [3e]. In spite of the triclinic symmetry of the crystals of **2**, the structure of the $[Fe_4Te_6(TeC_2H_5)_2(CO)_8]^{2-}$ anion (Fig. 2) present in this compound is closely related to the $[M_4Te_6(TeCH_3)_2(CO)_8]^{2-}$ anions [3e] present in its analogues described below. Selected bond distances and angles are given in Table 3. The compound $(Me_4N)_2[Fe_4Te_6(TeCH_3)_2(CO)_8]$ was made using a set of near identical conditions ($Fe_3(CO)_{12}/Na_2Te_2/Me_4NBr$ in a 1:5:6 ratio, 110°C, 12 h, 0.5 ml MeOH) with those of **2**, while $(Ph_4P)_2[Ru_4Te_6(TeCH_3)_2(CO)_8]$ was prepared at a lower temperature. In the formation of these two structurally unique compounds a novel telluride alkyla-

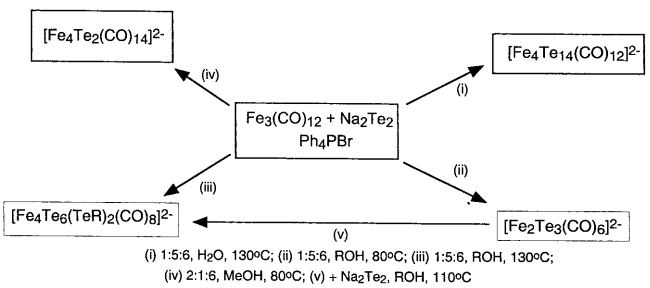
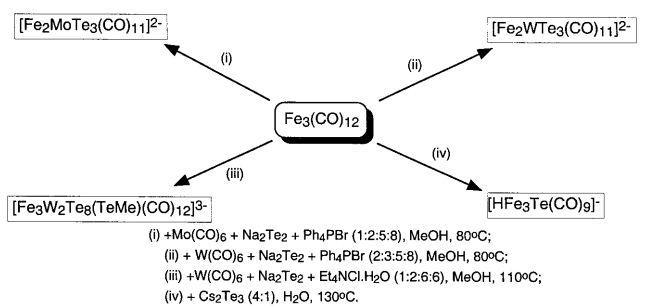
tion reaction was found to occur in methanolic media. In order to learn more about the mechanistic pathway involved in this process the present reaction involving a 1:5:6 mixture of $Fe_3(CO)_{12}$, Na_2Te_2, Ph_4PBr in *ethanol* was carried out. Isolation of **2**, with its $TeCH_2CH_3$ ligand, has thus established the involvement of the alcoholic media in the telluride alkylation process.

The ethyl group is easily identified in the ^1H NMR spectrum of **2**. Although it was not possible to observe a ^{125}Te NMR spectrum of the present compound, considering the fact that its methyl analogue $[Fe_4Te_6(TeCH_3)_2(CO)_8]^{2-}$ was found to display four instead of the expected three signals, the solution stability of $[Fe_4Te_6(TeC_2H_5)_2(CO)_8]^{2-}$ is also suspect [1,3e]. The solution IR spectrum of the later displays three ν(CO) bands and the spectrum in the carbonyl stretching region is nearly identical with that of the former [3e]. The color of the solution of **2** in DMF or DMSO is yellowish green and the UV–Vis spectral behavior of the solution is similar to that of $(Me_4N)_2[Fe_4Te_6(TeCH_3)_2(CO)_8]$.



3.3. $[Fe_2Te_3(CO)_6]^{2-}$

The simpler cluster anion $[Fe_2Te_3(CO)_6]^{2-}$ was previously made from the reaction of $Fe(CO)_3(\eta^4$-butadiene) with the soluble Te_4^{2-} ions in ethylenediamine [4]. This compound is structurally quite novel because of the presence of a dangling tellurium atom from a η^1,μ_2-Te_2^{2-} ligand. Following the isolation and structural characterization of the alkylated tetranuclear clusters we saw the obvious structural relationship between $[Fe_2Te_3(CO)_6]^{2-}$ and $[M_4Te_6(TeR)_2(CO)_8]^{2-}$ and it was found interesting to probe if the former could be involved in the formation of the latter. By carrying out methanothermal reactions at lower temperatures and for shorter duration, it was possible to isolate red-brown hexagon-shaped crystals of a single product that was moderately soluble in methanol. This is unlike other tetraphenylphosphonium salts of iron-carbonyl telluride anions are sparingly soluble in methanol. The IR spectrum for the carbonyl stretching vibrations of this product differed somewhat from the one reported for $[(K.crypt)_2][Fe_2Te_3(CO)_6]\cdot 0.5en$ (**4**) and as a result, its crystal structure was determined. Notwithstanding this minor difference, the X-ray structure of **3** (Fig. 3) shows that the anionic cluster contained in our crystal is essentially the same with that of the K.crypt-compound. The residuals for the X-ray diffraction analysis on $(Ph_4P)_2[Fe_2Te_3(CO)_6]$ (**3**) are, however, considerably better than those of **4** and thus more accurate geometrical parameters of $[Fe_2Te_3(CO)_6]^{2-}$ are now available.



An ORTEP representation of the $[Fe_2Te_3(CO)_6]^{2-}$ cluster anion present in **3** is shown in Fig. 3. The Fe–Fe distance of 2.651(2) Å in **3** is longer than the corresponding distance (2.614(4) Å) in **4**. Similarly, the Te–Te distance in the ditelluride ligand is also longer (2.736(2) and 2.705(3) Å). The non-bonding Te(2)···Te(3) distances are however significantly differ-

ent (by 0.09 Å) in the two structures, the distance in **3** being longer at 3.307(2) Å. Selected bond distances and angles are given in Table 4. We have previously noticed [3b,e] short, non-bonding contacts between tellurium atoms in similar clusters and from a comparison of those results with the present ones it appears to us that such distances may be quite sensitive to crystal packing effects. Thus Te–Te bonding interactions are likely to be significant only when the distances are about 3.1 Å or shorter. Another structural difference of note in **4** and **3** is that in the latter, all the Fe–C distances are roughly equal ($\sim$ 1.76 Å), but these are found in the range of 1.683–1.814 Å in the former. This difference could explain the small departures between the number and positions of the ν(CO) vibrations in the IR spectrum. Our work, on the other hand, proves that compound **3** is a true intermediate in the reaction that leads to the formation of the tetranuclear clusters, as evidenced by our isolation of $(Ph_4P)_2[Fe_4Te_6(TeCH_3)_2(CO)_8]$ in the reaction between **3** and Na_2Te_2 at 110°C [3e]. The dangling tellurium atom in $[Fe_2Te_3(CO)_6]^{2-}$ thus acts as a center of high reactivity as shown by the conversion of two $[Fe_2Te_3(CO)_6]^{2-}$ clusters into $[M_4Te_6(TeR)_2(CO)_8]^{2-}$ [1a,3e].

We have already noted the moderate solubility of **3** in methanol. This compound gives reddish solutions in most of the polar organic solvents. The DMF solution displays a moderately intense absorption band at 515 nm that is of as yet unknown origin. Bands of similar origin were also observed for the clusters $[Fe_2MoTe_3(CO)_{11}]^{2-}$ and $[Fe_2WTe_3(CO)_{11}]^{2-}$ at 509 nm [3d].

Scheme 1.

Scheme 2.

These solutions are stable in an inert atmosphere. The carbonyl region of the IR spectrum recorded for a DMF solution of **3** is much more simplified. From its similarity with the solution spectrum previously reported for **4**, and from the fact that $(Ph_4P)_2[Fe_2Te_3(CO)_6]$ (**3**) can be recovered from a solution of **3** in DMF by adding diethyl ether, leaves no doubt that the dinuclear $[Fe_2Te_3(CO)_6]^{2-}$ cluster anion remains intact in solution. Moreover, three ^{125}Te resonances are observable for a solution of **3** in DMSO-d_6 corresponding to the three different types of tellurium environment.

4. Summary and conclusions

The synthetic results obtained from our studies are summarized in Schemes 1 and 2. These highlight the usefulness of the solvothermal technique in the synthesis of anionic metal chalcogenido carbonyl clusters. Of particular note is the extensive chemistry that has been generated on this type of reaction for the $Fe_3(CO)_{12}/Te_x^{2-}$ system. Clearly, the right set of conditions must be used for synthesizing a particular cluster compound solvothermally. Thus in the present reactions involving $Fe_3(CO)_{12}$, Na_2Te_2, and Ph_4PBr in the 1:5:6 molar ratio, the hexanuclear cluster **1** containing as many as fourteen tellurium atoms (as ditelluride ligands) is the product when water is the solvent of choice; on the other hand, the tetranuclear cluster **2** with ethyl tellurolate ligands (in addition to mono and ditellurides) is obtained just by changing the solvent to ethanol. In methanol, the cluster species formed is $[Fe_4Te_6(TeCH_3)_2(CO)_8]^{2-}$. Observation of telluride alkylation reactions in alcoholic media suggests the participation of the solvents in these reactions. This fact also indicates why compound **1** cannot form in alcoholic solvents. That a non-alcoholic solvent is necessary for the preparation of **1** is also confirmed by our isolation of **1** using CH_3CN.

Solvothermal preparation of **1** and its ruthenium analogue $[Ru_6Te_{14}(CO)_{12}]^{2-}$ as well as **2** and its chemical analogues $[Fe_4Te_6(TeCH_3)_2(CO)_8]^{2-}$ and $[Ru_4Te_6(TeCH_3)_2(CO)_8]^{2-}$ proves that the syntheses described are rational and reproducible and not mere serendipities. Thus this method can provide planned routes to the preparation of desired products. For the isolation of intermediate compounds, the reaction temperature must be controlled as shown by our isolation of **3**.

Choice of the starting metal carbonyl compound also appears to play an important role in the formation of a particular complex. For example, the double cubane cluster [13] $[Fe_8Te_{10}(CO)_{20}]^{2-}$ is obtained by reacting $Fe(CO)_5$ with Na_2Te_2 [3f], but the same cluster anion has never been found to form in reactions where $Fe_3(CO)_{12}$ is the starting carbonyl compound, except in the isolated instance of its formation as a byproduct

along with $[Fe_2MoTe_3(CO)_{11}]^{2-}$ [3d]. Similarly, compound **1** is not obtainable from $Fe(CO)_5$. Furthermore, reactant ratios do play a crucial role in determining the nature of the product formed. Thus, while a 2:3:5 mixture of $Fe_3(CO)_{12}$, $W(CO)_6$ and Na_2Te_2 leads to the formation of $[Fe_2WTe_3(CO)_{11}]^{2-}$, a change of the ratio to 1:2:6 results in the isolation of the cluster $[Fe_3W_2Te_8(TeCH_3)(CO)_{12}]^{3-}$ [3d]. For obtaining the tellurium-poor species $[Fe_4Te_2(CO)_{14}]^{2-}$ we must use an $Fe_3(CO)_{12}$: Na_2Te_2 ratio of 2:1, and to make $[HFe_3Te(CO)_9]^-$, the $Fe_3(CO)_{12}$:Cs_2Te_3 ratio of 4:1 must be used [3b]. Slight change in reactant ratio and reaction time during the preparation of the former resulted in the formation of yet another cluster anion $[Fe_5Te_4(CO)_{14}]^{2-}$. However, values of x in the range of 2–4 in the telluride fragment Te_x^{2-} of the starting alkali telluride appears to have no influence on the identity of products. This is only to be expected because the chalcogenide species (Q_x^{2-}) formed in solutions prepared by dissolving a solid alkali metal chalcogenide may correspond to $x = 1$–6, depending on the conditions. Synthetic methods of the type described here may also be useful for the synthesis of other molecular organometallic and coordination compounds.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 145390 and 145392. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction of bis(β-dionato)oxovanadium(IV) chelates, $VO\beta_2$, with substituted benzoylhydrazines, $XbhH_2$, was explored in alcoholic solutions and oxovanadium(V) compounds with Schiff bases as ligands were obtained in high yield. These VOL(OR) compounds have alkoxide as coligand and the asymmetic tridentate Schiff base ligands, L^{2-}, bind to the oxovanadium core through the carbonyl oxygens and the imine nitrogen. Substituents attached to benzoylhydrazines affect the electron density about the oxovanadium core. While electron attracting substituents appear to favour monomeric square pyramidal chelates, the derivatives having electron repelling groups seem to encourage formation of dimeric structures and alkoxo bridged dimers are obtained. The crystal structures of the products of the reaction of bis(1-phenyl-1,3-butanedionato)oxovanadium(IV), $VO(bzac)_2$, with *o*-nitrobenzoylhydrazine (*o*-O_2NbhH_2) and *m*-methoxybenzoylhydrazine (*m*-CH_3ObhH_2) that are reported demonstrate the influence of the substituents as well as the role of the solvent. © 2000 Elsevier Science Ltd. 1. Introduction

Vanadium exists in a plethora of oxidation states and its coordination compounds play an important role in nitrogen activation and fixation and other biologically important reactions [1–3]. This revelation has stimulated interest in the stereochemistry and reactivity of its coordination compounds that contain the diazo and hydrazido group because they may provide some understanding of the mechanism of metalloenzymatic reduction of dinitrogen. Substituted aroylhydrazones possessing a suitably disposed amino group, whilst often bind directly to the metal [4], they may also interact with compounds containing carbonyl groups, for example salicylaldehydes and β-diones [5–10]. Such reactions have been exploited adroitly to form Schiff bases that are capable of confining metal atoms and controlling their properties and functionality [11]. Regarding β-diones and the oxovanadium(IV) core, the 1-phenyl-1,3-propanedione [6–9] has been gainfully employed in studies involving the Schiff bases resulting from the condensation reaction with aroylhydrazines [4–9]. Recent studies have indicated that solvent interactions with the moieties resulting from the ligation of such tridentate Schiff bases to the oxovanadium(IV) core have significant repercussions on the structure of the resulting chelates since solvent molecules or solvent fragments participate as coligands [6–9]. Other β-diones have not been utilised in similar studies, even though seemingly minor changes in ligand structure incurred by groups within the β-dionato moiety have a profound effect on the stereochemistry, the spacing of the energy levels, the redox potentials and other distinctive physicochemical properties of the β-dionato chelates [12]. The effects of substituents attached to the phenyl ring of benzoylhydrazines on the electron distri-

PII: S0277-5387(00)00483-6

bution of the Schiff bases have not been explored sufficiently. Further, the reactivity of the bis(β-dionato)oxovanadium(IV) chelates, $VO\beta_2$, has not been probed adequately in the preparation of tridentate Schiff base ligands, even though the $VO\beta_2$ chelates have been engaged successfully in ligand addition and ligand exchange reactions and are often used as starting material in syntheses [13,14].

This investigation was undertaken in order to explore the reactivity of certain bis(β-dionato)oxovanadium(IV) chelates with aroylhydrazines, to assess the influence of the reaction medium in the formation of products, to appraise the effect of substituents in the structure and the spectroscopic properties of the chelates formed, to assay the possibility of oxygen bridge creation and formation dimeric structures and to determine the stereochemistry of the resulting compounds. In this work the preparation of some β-dionate(benzoyl)hydrazonato(2-)oxovanadium(V) chelates is reported, the structures of [ethoxo(4-phenyl-2,4-butanedione(2′-nitrobenzoyl)hydrazonato(2-))oxo-vanadium(V)] and the anticoplanar bis[μ_2-methoxo(4-phenyl-2,4-butanedione(3′-methoxybenzoyl)hydrazonato(2-))oxovanadium(V)] are described and the results of the investigation are presented and discussed.

2. Experimental

2.1. Preparation and characterisation of the *VO(βbh)OR* compounds

The β-diones, βH, namely 2,4-pentanedione (acetylacetone, acacH), 1-phenyl-1,3-butanedione (benzoylacetone, bzacH), 1-phenyl-4,4,4-trifluoro-1,3-butanedione (trifluorobenzoylacetone, bztfH) and 1-thenyl-4,4,4-trifluoro-1,3-butanedione (trifluorothenoylacetone, thtfH), were purchased from Sigma–Aldrich. The bis(β-dionato)oxovanadium(IV) chelates ($VO\beta_2$), that were used as starting materials, were prepared and purified as described in the literature [15,16]. The compound $(n\text{-}C_4H_9)_4NVO_3$ was prepared by established procedures [17]. The substituted aroylhydrazines, $XbhH_2$, were procured from Fluka. Certain Schiff bases resulting from the reaction of benzoylacetone or trifluorobenzoylacetone with substituted benzoylhydrazines were prepared by literature methods [18] and characterised. The synthesis of the new vanadium chelates was accomplished as follows:

In a 200 cm^3 conical flask containing a magnetic follower are placed 10 mmol of $VO\beta_2$ and ~ 80 cm^3 alcohol and the mixture is stirred at ambient temperature until complete dissolution. Then 20 mmol of aroylhydrazine (also dissolved in the same alcohol) are added while stirring and the colour of the reaction mixture changes from brown to red–brown. The stirring continued for an additional 20 h. The VO(Xbh)OR compounds precipitated as red–brown solids. Recrystallisation was achieved by redissolving the solid in alcohol and allowing crystals to grow under refrigeration.

The chelates prepared, their stoichiometry and melting points are given in Table 1.

2.2. X-ray crystallographic analysis of *[VO(o-O_2Nbhbzac)OC_2H_5]* and of *[VO(m-CH_3Obhbzac)(μ_2-OCH_3)]$_2$*

Intensities of X-ray reflections within two octants of the reciprocal sphere were collected by means of a four-circle Philips-STOE computer-controlled X-ray diffractometer employing graphite-filtered Mo Kα radiation. The orientation matrix and refined unit cell dimensions of the crystal of [ethoxo(4-phenyl-2,4-

butanedione(2′-nitrobenzoyl)hydrazonato(2-))oxovanadium(V)], [VO(o-O_2Nbhbzac)OC_2H_5] and of bis[μ_2-methoxo(4-phenyl-2,4-butanedione(3′-methoxybenzoyl)-hydrazonato(2-))oxovanadium(V)], [VO(m-CH_3Obhbzac)(μ_2-OCH_3)], were obtained from independent reflections of high intensity ($12 \le \theta \le 15°$). Details of crystal analysis, data collection and structure refinement are given in Table 2, together with the final values for the unit cells. All intensities were corrected as usual for Lorentz and polarization effects. In view of the low μ value no correction for absorption deemed necessary. In both cases the vanadium position was deduced by direct methods employing the SHELXS-86 and the SIR-97 programs [19,20] and used to compute a first-approximation electron-density synthesis, which revealed the position of all remaining atoms except the hydrogens. After least-squares refinements with the non-hydrogen atoms, the hydrogen atoms were also located in the difference Fourier map using the SHELX-97 program [21]. The figures of the clinographic projection were produced with the DIAMOND and ATOMS programs [22]. Refinement was carried out by full-matrix least-squares, with unit weight to all reflections.

3. Results and discussion

Many oxometallates undergo condensation reactions in which polyatomic groups replace the oxygen ligand. For example, the diazenido and the hydrazido groups are attached to molybdenum by employing oxomolybdenum compounds as precursors [23]. In the case of bis(β-dionato)oxovanadium(IV) chelates, the mixing of alcoholic solutions of $VO\beta_2$ and a substituted benzoylhydrazine, $XbhH_2$, is accompanied by a change in colour (suggesting commencement of a reaction) and formation of a precipitate as the main product. The elemental analysis of the recrystallised precipitate revealed the presence of nitrogen while the stoichiometry disclosed dependence on the alcohol employed as solvent. Interestingly, the yield is maximised when the metal-to-benzoylhydrazine molecule is 1:2 and the reaction mixture is accessible to atmospheric oxygen. Further, in a series of reactions using the same alcohol as solvent and the same $XbhH_2$ but different chelate $VO\beta_2$, the composition of the main product suggested abstraction of a β-ketoenol and entrapment of a aroylhydrazine molecule by the vanadium atom. The diamagnetic behaviour of the new compounds indicated absence of unpaired electrons while the lack of absorption in the electronic excitation spectra at wavenumber below $\sim 2.50\ \mu m^{-1}$ reaffirmed the absence of electrons localised in the d orbital manifold [12,13]. These observations suggested an oxidative displacement reaction in the oxovanadium core converting the metal to vanadium(V) with sacrificial species one of the ligated β-dionato anions and formation of chelates corresponding to the general formula VOL(OR), where OR^- is an alkoxide and L^{2-} denotes the Schiff base resulting from the partial addition-elimination reaction of the β-dionato anion with an aroylhydrazine. To verify this hypothesis, aroylhydrazones and either 1-phenyl-1,3-butanedione (bzacH) or trifluorobenzoylacetone (bztfH) were employed to obtain Schiff bases which were subsequently

reacted with $(n\text{-}C_4H_9)_4NVO_3$ to produce chelates. The later reaction afforded products identical to those obtained by the reaction of the appropriate $VO\beta_2$ chelates with aroylhydrazines. Interestingly the yield of the one-pot synthesis was appreciably higher. Further information regarding the structure of the new compounds was acquired from their electronic absorption spectra.

3.1. Electronic excitation spectra

In the electronic excitation spectra of the VOL(OR) chelates no absorptions attributable to the ligand field excitations happen. The lack of paramagnetic interactions and the absence of ligand field transitions indicate oxidation of the metal to vanadium(V) and disallow any inference about the ordering of the d orbitals. A strong broad band (or envelope) is observed at ~ 2.50 μm^{-1} and is solvent depended. The absorption in this region, for energy and intensity reasons, should be attributed to a charge transfer excitation most likely from a π ligand orbital to the manifold of the d metal orbitals. The influence of the solvent in this band is clearly evident in the spectra of the monomers in which shifts and alterations of band shape are notable upon change of solvent. Actually in the spectra of the monomers obtained from 1,2-dichloroethane solutions this LMCT excitation affords an envelope with no definite maximum. From the shape of the envelope and the preliminary analysis the occurrence of a band with maximum at ~ 2.0 μm^{-1} is deduced. In the spectra of the monomers obtained employing acetonitrile or DMSO as solvent, a well-formed band is evident at ~ 2.3 μm^{-1}. This shift suggests change of the ordering of the d orbitals effected by the occupation of the vacant coordination site. Further information regarding bonding in the chelates under consideration were sought from the infrared spectra.

3.2. Infrared spectra

In the IR spectra of the compounds resulting from the reaction of the substituted benzoylhydrazines with bis(β-dionato)oxovanadium(IV) chelates, the absence of absorptions above 3100 cm^{-1} implied that the hydrazino group, $-NHNH_2$, has taken part in an addition–elimination reaction and that proton transfer has taken place. The marginal shift in the diminished band that turns out at $\sim 1578 \pm 10$ cm^{-1} and is associated with the stretching vibration of a carbonyl group of the β-dionato anion [13] suggested that carbonyl oxygen remains bonded to vanadium since the C–O bending mode appears as a rather strong band around 1160 cm^{-1}. Further, the intense band occurring at $\sim 970 \pm 30$ cm^{-1} and assigned to the V=O stretching vibration [23–25] indicated that the V=O core stays intact, while the variation in frequency to the V=O stretching vibration suggests that the $d_\pi - p_\pi$ overlap between the vanadium and the oxygen atoms is influenced by the substituents and the coligands. The implication of these observations is that the condensation reaction of hydrazine does not involve the oxo ligand. Further, it transpires that while one of the β-dionato anions, β^-, participates in the condensation reaction, the other becomes the sacrificial species of the oxidative displacement reaction.

In addition to IR absorptions originating from V=O core and the β-dione fragment of the Schiff base, the bands may be distinguished in those arising from the entrapped hydrazine species and in those emerging from the alkoxy group. The presence of substituents attached to the β-dionato moiety and the existence of groups appended to the phenyl ring of the aroylhydrazine engender absorption bands and spectral shifts. Whenever the β-diones employed are non-symmetric the site of the attack becomes important. In the case of $bzac^-$ the phenyl ring renders the adjacent carbonyl group immune to the attack while in ($bztf^-$) the strong electron attracting ability of the trifluoro group ensures that the attack is targeted in the carbonyl neighbouring the phenyl ring. In the ensuing Schiff bases, the =NH proton is prone to form intermolecular and intramolecular hydrogen bonds as the bands observed at ~ 3400 (broad) and 1630 cm^{-1} indicated. These bands are not present whenever the bis(β-dionato)oxovanadium(IV) is employed, as the β-dione source and the chelates are obtained in the one-pot synthesis. In the chelates prepared the intense absorption observed at $\sim 1600 \pm 10$ cm^{-1} probably emanates from the azomethine (C=N) stretching mode [26] while the high intensity band occurring at $\sim 1520 \pm 15$ cm^{-1} and is tentatively assigned to the $>C{=}N{-}N{=}CPhO(^-)$ entity indicates extensive delocalisation. The prototropic $>C{=}NNHCOPh$ entity in the Schiff base apparently undergoes hydrogen abstraction from the tautomeric form, $>C{=}N{-}N{=}C(OH)Ph$, to produce the electron-rich hydrazido(2-) species because no band could be associated with vibrations of either the N–H or the O–H bonds. The process of hydrogen abstraction is accomplished presumably with the aid of atmospheric oxygen that facilitates the oxidation of the metal to vanadium(V). Taking into consideration the strongly electron-attracting nature of the metal and the availability of electron density at the nitrogen atoms the wholly reasonable assumption may be made that they may be involved in bonding interactions. On the basis of previous structural data and the geometry of the resulting Schiff base, the nitrogen atom engaged in the condensation reaction is presumed to be bonded to the metal atom. This assumption is further supported by the relatively weak bands at around 475 ± 10 cm^{-1} that are assigned to the stretching vibrations of the V–N bonds [27]. The stretching vibrations of the V–O

bonds appear as rather medium intensity bands around 525 ± 20 cm^{-1}. Some of the metal–ligand absorptions are not related to the Schiff base and are solvent dependent. For instance, in the IR spectra of the product of the reaction of *m*-methoxybenzoylhydrazine with $VO\beta_2$ in methanol a very broad feature centred around 340 cm^{-1} propounded the possibility of additional metal–oxygen bonds and suggested the likely occurrence of dimeric structures [27]. The broad feature appears to consist of a number of overlapping peaks attributable to deformations of bridging V–O–V bonds and vibrational coupling of low frequency modes that complicate the assignments in this region. The notion of the existence of dimeric structures was enhanced by the shift of the bands due to the C–O vibrations to higher wave-numbers by 10–30 cm^{-1} that suggested absence of additional bonding interactions of the carbonyl oxygens. The oxo ligand was not implicated in the formation of the dimeric species, because the shift of the band due to the V=O stretching vibration was imperceptible [23–25]. Since neither the infrared spectra nor the elemental analyses revealed the presence of water molecules, the alkoxo groups were implicated in the formation of dimeric species. Confirmation of their existence and details of the structures of representative compounds of the new chelates were acquired from the X-ray diffraction study.

3.3. Description of the structures

The X-ray diffraction study of [ethoxo(4-phenyl-2,4-dione(2′ - nitrobenzoyl)hydrazonato(2 -)oxovanadium-(V)], [VO(*o*-NO_2bhbzac)OC_2H_5], disclosed that in the unit cell there are four vanadium atoms. The positional parameters, the interatomic distances and the bond angles (Table 3) reveal that the coordination environment in which the vanadium atoms exist is approximately square pyramidal with the oxo ligand engaging the apical position. The oxygen of the ethoxy group, the carbonyl oxygens and the nitrogen of the primary amino group that reacted with the β-dione, are in the immediate vicinity of vanadium. While the aforementioned oxygen and nitrogen atoms are virtually in the same plane (the basal plane), the central atom is above the basal plane by 0.480(2) Å and is directed towards the oxo ligand. The $V–O_{oxo}$ interatomic distance at 1.580(2) Å is in accord with other pentacoordinate oxovanadium compounds (Table 4). These data reaffirm the indications of coordination unsaturation suggested by the solvent shifts in the electronic excitation spectra. The Schiff base ligand forms a six-membered and a five-membered chelate ring and the interatomic distances within the C(2)–N(2)–N(1)–C(11) group reassert that no hydrogen is bonded to the nitrogen atoms and that extensive electron delocalisa-

tion has taken place. The planar aromatic rings form a dihedral angle of 34.53(5)°. A clinographic projection of [VO(*o*-NO_2bhbzac)OC_2H_5] and its labelling scheme is shown in Fig. 1.

The X-ray diffraction study of bis[μ_2-methoxo-(4-phenyl-2,4-dione(3′-methoxybenzoyl)hydrazonato-(2-))oxovanadium(V)], [VO(*m*-CH_3Obhbzac)OCH_3]$_2$, disclosed that in the unit cell there are only two vanadium atoms. The positional parameters (Table 4) show that the coordination environment in which the vanadium atoms exist resembles closely that of the metal in [VO(*o*-NO_2bhbzac)OC_2H_5] and other [VO(L)OR] chelates. The vanadium atoms are separated by a distance of only 3.370(2) Å, suggesting the possibility of a dimeric structure. The oxo ligand binds to one vanadium atom but exists at a distance of 4.750(2) Å from the other vanadium centre, implying absence of bonding interactions. However, at a distance of 2.360(2) Å from the vanadium centre the position *trans* to the oxo ligand is engaged by the oxygen of another alkoxo ligand. The methoxo group is strongly ligated to one vanadium centre and interacts with the other forming a bridge. The resulting distorted octahedral structures of the oxovanadium centres are bridged by one shared edge leading to the creation of a $\{VO(\mu_2\text{-}OR)_2VO\}^{4+}$ core. As the oxygen atom of the alkoxo group becomes involved in covalent interactions with the other vanadium atom, the $V–O_{alkox}$ distance increases and the change in electron density should affect the interactions of the nitrogen atom in *trans* position. A diminution of the distance of the nitrogen atom in *trans* position from the vanadium centre is envisaged and, indeed, such a trend becomes apparent when the interatomic distances listed in Table 5 are considered. The compounds described in this work do not follow exactly the expected trend.

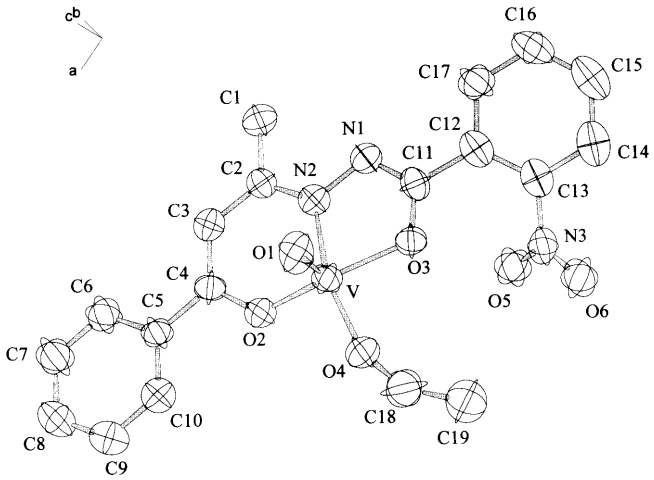

Fig. 1. A clinographic projection and labelling scheme of [ethoxo(4-phenyl-2,4-butanedione(2′-nitrobenzoyl)hydrazonato(2-))oxovanadium(V)]. The ATOMS drawing shows the thermal ellipsoids at the 50% probability level. Hydrogen atoms are omitted for clarity.

In the binuclear compound [VO(*m*-CH_3Obhbzac)-OCH_3]$_2$, the $\{VO(\mu_2\text{-}OR)_2VO\}^{4+}$ core forms a parallelepiped and the mutual steric requirements of the

[a] Symmetry transformations used to generate equivalent atoms: $-x,-y+1,-z+1$.

metal coordination spheres exert strong influence on the V···V separation, the hybridisation of the bridging oxygen, and hence the bridge angle about oxygen which is 106.61(7)°. Since the C(19)–O(5)–V angles exceed 120°, it transpires that the hybridisation of the oxygen is rather near sp^2. Dimeric vanadium chelates with a $\{VO(\mu_2\text{-}OR)_2VO\}^{4+}$ core may exist in five possible configurations classified according to the orientation of the vanadyl groups in respect to the plane defined by the vanadium centres and the bridging oxygen atoms [32]. The configurations are *syn*-orthogonal, *anti*-orthogonal, *syn*-coplanar, *anti*-coplanar, and twist. It has been suggested [33] that, when several structures differing very little in energy are possible, the centrosymmetric structure is preferred by crystal packing requirements. In dimeric vanadium chelates with a $\{VO(\mu_2\text{-}OR)_2VO\}^{4+}$ core, the *anti*-structures are favorites. In the [VO(*m*-CH_3Obhbzac)(μ_2-OCH_3)]$_2$ chelate, the atoms of the ligands are symmetrically disposed relative to the centre of the $\{VO(\mu_2\text{-}OR)_2VO\}^{4+}$ core and the disposition of the oxovanadium groups is anti-coplanar, a configuration sporadically encountered in dimeric oxovanadium compounds [34,35]. A clinographic projection of [VO(*m*-CH_3Obhbzac)OCH_3]$_2$ is shown in Fig. 2.

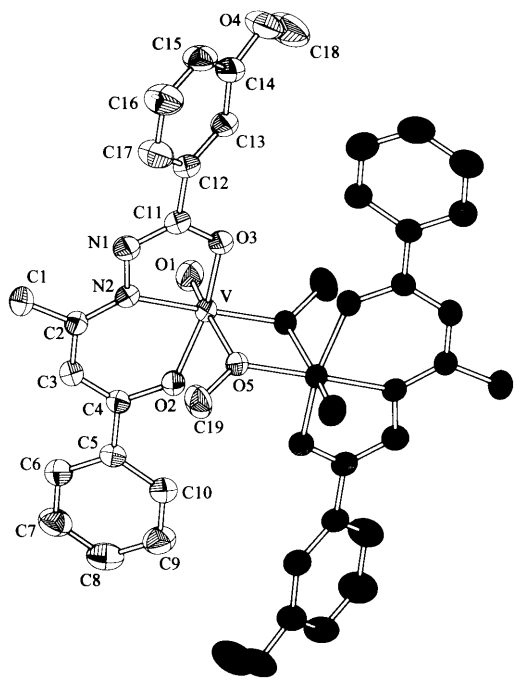

Fig. 2. A clinographic projection and labelling scheme of bis-[methoxo(4-phenyl-2,4-butanedione(3′-methoxybenzoyl)hydrazonato-(2-))-oxovanadium(V)]. The DIAMOND drawing shows the thermal ellipsoids at the 50% probability level. Hydrogen atoms are omitted for clarity.

4. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 134611 and 134612 for bis[μ_2-methoxo(4-phenyl-2,4-dione(3′ - methoxybenzoyl)hydrazonato(2 -))oxovanadium(V)] and [ethoxo(4-phenyl-2,4-dione(2′-nitrobenzoyl)hydrazonato(2-)oxovanadium(V)], respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of mononuclear complexes ML^1 (M = Ni, Cu) where $L^1 = N,N'$-bis[2-hydroxy-3-(piperidin-1-ylmethyl)-5-methylbenzyl]alkyldiimine (alkyl = ethylene L^{1a}, propylene L^{1b}, butylene L^{1c}) and ML^2 (M = Ni, Cu) where $L^2 = N,N'$-bis[2-hydroxy-3-(piperidin-1-ylmethyl)-5-bromobenzyl]alkyldiimine (alkyl = ethylene L^{2a}, propylene L^{2b}, butylene L^{2c}) have been synthesized and characterized by C, H, N analysis, IR, electronic and ESR spectra. The crystal structures of the complexes NiH_2L^{1a} (**1**) and CuH_2L^{1a} (**6**) were determined and the geometry around the metal ion is square planar. Electrochemical studies of the complexes show a quasi-reversible single redox wave at negative potential in the range 0 to -1.3 V. For nickel complexes (**1**–**5**) $E_{pc} = -1.0$ to -0.80 V and for copper complexes (**6**–**9**) $E_{pc} = -0.90$ to -0.72 V. The ESR spectra of nickel complexes are inactive due to square planar nature of the complexes whereas copper complexes show an ESR spectrum characteristic of square planar complex with nuclear hyperfine spin 3/2. Copper complexes show a normal magnetic moment value of $\mu_{eff} = 1.70$–1.75 B.M. which is close to the spin-only value of 1.73 B.M. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Binucleating ligand; Nickel complexes; Copper complexes; Crystal structures; Redox chemistry

1. Introduction

The role of metal ions at the active site of proteins has been the focus of many studies by both synthetic and biological chemists. The metal ions [1,2] such as copper, nickel, manganese, cobalt and zinc are involved in biological processes like electron transfer, dioxygen binding (Fe, Cu) and catalysis (Mn, Fe, Cu, and Ni). The enzymes that depend on nickel [3] are urease, carbon monoxide dehydrogenase, hydrogenase and methyl-*S*-coenzyme-*M*-methyl reductase. The proteins such as cytochrome *C* oxidase, copper/zinc superoxide dismutase, tyrosinase, hemocyanin and laccase contain a copper ion [4]. Synthetic chemists have synthesized many copper and nickel containing mono and polynuclear complexes using several types of ligand [5] such as, pendant arm [6], acyclic and macrocycles, porphyrins [7], polydentate Schiff bases [8], polyaza macrocycles [9], scorpionate ligands [10], etc. in order to understand the function, structure and properties of active sites in proteins.

In an earlier work we synthesised homobinuclear copper(II) complexes [11] using ligands H_2L^1 where $L^1 = N,N'$-bis[2-hydroxy-3-(piperidin-1-ylmethyl)-5-methylbenzyl]alkyldiimine (alkyl = ethylene L^{1a}, propylene L^{1b}). The present work deals with the synthesis of mononuclear complexes ML^1 (M = Ni, Cu) using ligands H_2L^{1a}, H_2L^{1b} and H_2L^{1c} where $L^{1c} = N,N'$-bis[2-hydroxy-3-(piperidin-1-ylmethyl)-5-methylbenzyl] butylenediimine (Scheme 1) and ML^2 (M = Ni, Cu) where $L^2 = N,N'$-bis[2-hydroxy-3-(piperidin-1-ylmethyl)-5-bromobenzyl]alkyldiimine (alkyl = ethylene L^{2a}, propylene L^{2b}, butylene L^{2c}). In the present work we have synthesized mononuclear complexes using the binucleating ligands as we are interested in studying the effect of a single metal ion in the ligand environment.

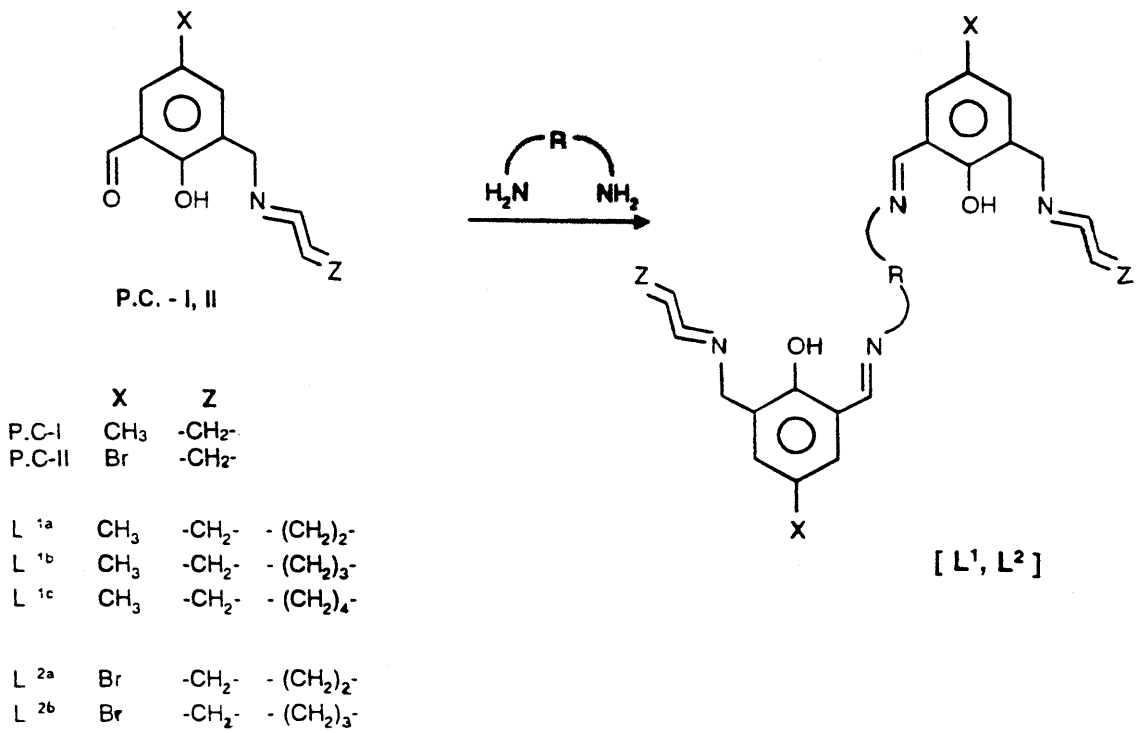
This will form the basis for the synthesis and studies of heterobinuclear complexes and to compare their properties. The spectral, electrochemical and magnetic properties of the complexes and crystal structure of nickel complex **1** and copper complex **6** have been discussed.



2. Experimental

2.1. Physical measurements

Elemental analyses for the complexes were obtained on a Carlo Erba Model 1106 elemental analyzer. ^{1}H NMR spectra (90 MHz) of the ligands were recorded using FX-80-Q. Fourier transform NMR spectrometer. Electronic spectra were recorded on a Hewlett-Packard 8452A spectrophotometer in the range 250–820 nm. The IR spectra were recorded on a Hitachi 270–50 spectrophotometer in the range 400–4000 cm^{-1}. The cyclic voltammograms were obtained on an apparatus comprising a PAR Model 173 potentiostat/galvanostat, 175 universal programmer, 176 current follower and 179 coulometer. For cyclic voltammetry three electrode system was used in which the counter and working electrodes were platinum foils and the reference electrode was Ag/AgCl. Ferrocene/ferricinium(1 +) couple was used as an internal standard. Room temperature (r.t.) magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. The apparatus was calibrated by the use of Ni. The effective magnetic moment was calculated using the relation $\mu_{Cu} = 2.83\sqrt{\chi_{Cu}T}$, where χ_{Cu} is the molar magnetic susceptibility per Cu. X-band ESR spectra were recorded on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference.

2.2. Crystal structure determination

Parallelopiped shaped orange and green coloured crystals were obtained for complex **1** and **6** by growing with DMF–ethanol by slow evaporation method at r.t. Intensity data were measured on a Siemens SMART CCD [12] area detector diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data collection covered over a hemisphere of reciprocal space by a combination of three sets of exposures; each set had a different ϕ angle (0, 88 and 180°) for the crystal and each exposure of 30 sec covered 0.3° in ω. The crystal-to-detector distance was 4 cm and the detector swing angle was $-35°$. Crystal decay was monitored by repeating 30 initial frames at the end of data collection and analyzing the duplicate reflections; it was found to be negligible. The structures of the complexes were solved using SHELXS-97 [13], a package for crystal structure solution using direct methods. The non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full-matrix least-squares calculation based on F^2 using SHELXL-97 [14]. Some of the hydrogen atoms were geometrically fixed and allowed to ride on the parent carbon atoms, and other

Scheme 1.

hydrogen atoms were located from the difference Fourier map and refined isotropically. Geometrical parameter calculations were performed using PARST [15].

2.3. Materials

5-Methylsalicylaldehyde was prepared by the literature method [16]. TBAP, used as the supporting electrolyte in electrochemical measurements was purchased from Fluka and recrystallized from methanol–water mixture. (Caution! TBAP is potentially explosive; hence, care should be taken in the handling of this compound). DMF (HPLC) was obtained from SD Fine Chemicals. All other chemicals and solvents were of analytical grade and were used as received.

2.4. Synthesis of precursor compounds

2.4.1. Synthesis of 4-methyl-2-formyl-6-(piperidin-1-ylmethyl)phenol (precursor compound **I**)

Piperidin (2.0 ml, 20 mmol) was added to a solution of paraformaldehyde (0.60 g, 20 mmol) dissolved in acetic acid (30 ml) and stirred for 24 h. Then 5-methylsalicyaldehyde (2.72 g, 20 mmol) was added and stirring was continued for another 24 h. The resulting compound was refluxed for 8 h and then neutralized with saturated Na_2CO_3 and extracted with $CHCl_3$. The $CHCl_3$ extract was evaporated at r.t. The resulting product was filtered, washed with methanol and recrystallized from MeOH by slow evaporation. Yield: 3 g (61%). M.p: 171°C. Selected IR data (ν cm^{-1} using KBr): 3350, 1680, 1490. ^1H NMR(δ ppm in $CDCl_3$): 2.15(s, 3H), 2.35(m, 4H), 3.45–4(m, 6H), 7.0–7.5(d, 2H), 9.8(s, H).

2.4.2. Synthesis of 4-bromo-2-formyl-6-(piperidin-1-ylmethyl)phenol (precursor compound **II**)

This precursor compound was synthesized by following the above procedure used for the synthesis of precursor compound **I** using 5-bromosalicyaldehyde instead of 5-methylsalicyaldehyde. The product was recrystallized from MeOH by slow evaporation. Yield: 4 g (70%). M.p: 185°C. Selected IR data(ν cm^{-1} using KBr): 3250, 1680, 1450. ^1H NMR (δ ppm in $CDCl_3$): 2.28(t, 4H), 3.65–4.2(m, 6H), 7.15–7.5(d, 2H), 9.8(s, H).

2.5. Synthesis of ligands

Synthesis of (*N*,*N*′ - bis - 2 - hydroxy - 3 - (piperidin - 1-yl - methyl) - 5 - methylbenzyl]ethylenediimine) (H_2L^{1a}): Ethylenediamine (0.07 ml, 10 mmol) was added to a solution of precursor compound **I** (4.7 g, 20 mmol) in methanol with stirring and refluxed for 2 h. The resulting product obtained on evaporation of the solvent at r.t. was filtered, washed with methanol and recrystallized from $CHCl_3$–MeOH (40 ml, 1:2). Yield: 4 g (81%). M.p: 193°C. Selected IR data (ν cm^{-1} using KBr): 3320, 1625, 1450. ^1H NMR(δ ppm in $CDCl_3$): 2.25(s, 6H), 2.24–2.55(m, 12H), 3.12–4.13(m, 12H), 6.85–6.90(d, 4H), 8.45(s, 2H). The X-ray crystal structure of this ligand has been reported [17].

The ligands H_2L^{1b} and H_2L^{1c} were prepared by following the above procedure used for the synthesis of H_2L^{1a} using the appropriate diamines.

2.5.1. H_2L^{1b}

Yellow coloured compound. Yield: 4.6 g (72%). M.p: 195°C. Selected IR data (ν cm^{-1} using KBr): 3340, 1625, 1510. ^1H NMR(δ ppm in $CDCl_3$): 1.12(s, 2H), 2.18(s, 6H), 2.3–2.55(m, 12H), 3.12–4.12(m, 12H), 6.67–6.89(d, 4H), 8.35(s, 2H).

2.5.2. H_2L^{1c}

Yellow coloured compound. Yield: 4.8 g (75%). M.p: 175°C. Selected IR data (ν cm^{-1} using KBr): 3290, 1635, 1480. ^1H NMR(δ ppm in $CDCl_3$): 1.17(s, 4H), 2.25(s, 6H), 2.34–2.56(m, 12H), 3.2–4.7(m, 12H), 6.75–6.86(d, 4H), 8.32(s, 2H).

2.5.3. H_2L^{2a}

Yellow coloured compound. Yield: 4 g (82%). M.p.: 165°C. ^1H NMR (δ ppm in $CDCl_3$): 2.21 (s, 6H), 2.4–2.65 (m, 14H), 3.4–4 (m, 16H), 6.95–7.10(d, 4H).

2.5.4. H_2L^{2b}

Yellow coloured compound. Yield: 3.4 g (69%). M.p: 155°C. ^1H NMR (δ ppm in $CDCl_3$): 1.15(s, 2H), 2.15(s, 6H) 2.37–2.65(d, 14H), 3.35–4.2(m, 16H), 6.89–6.95(d, 4H).

2.6. Synthesis of complexes

2.6.1. $[NiH_2L^{1a}](ClO_4)_2$ ($R = -(CH_2)_2-$) (**1**)

Ligand H_2L^{1a} (0.98 g, 2 mmol) and NaOH (0.16 g, 4 mmol) was dissolved in $CHCl_3$–MeOH (40 ml, 1:3) and added to a solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.73 g, 2.1 mmol) in MeOH (20 ml) and refluxed for 1 h. Orange coloured crystals appeared. The crystalline product was collected by filtration and washed with MeOH. Recrystallized from CH_3CN–MeOH (40 ml, 1:3). *Anal.* Calc. for $C_{30}H_{40}N_4O_2Ni \cdot (ClO_4)_2$: C, 42.58; H, 4.75; N, 7.51. Found: C, 42.48; H, 4.62; N, 7.38%. Selected IR data (ν cm^{-1} using KBr) 3260, 1625, 1590, 1110, 625. UV–Vis [λ_{max} nm (ϵ M^{-1} cm^{-1})] in DMF: 552(228), 420(510), 270(11403). The X-ray structure of the complex has been studied and discussed in this paper (Fig. 1).

All nickel complexes given below were prepared by following the procedure used for the synthesis of complex **1** using Ni(II) perchlorate and appropriate ligands.

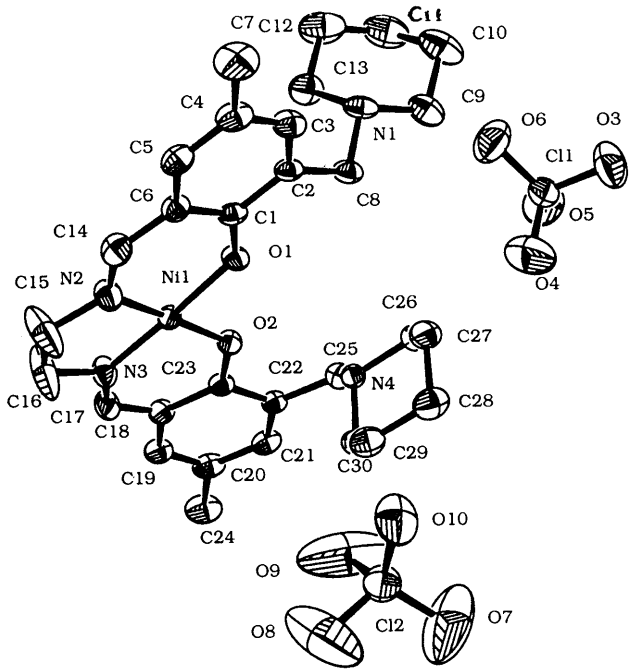


Fig. 1. ORTEP plot of $[NiH_2L^{1a}](ClO_4)_2$ (**1**) with atomic numbering scheme.

*2.6.2. $[NiH_2L^{1b}](ClO_4)_2$ ($R = -(CH_2)_3-$) (**2**)*

Anal. Calc. for $C_{31}H_{42}N_4O_2(ClO_4)$: C, 50.17; H, 5.69; N, 7.89. Found: C, 49.87; H, 5.43; N, 7.65%. Selected IR (ν cm^{-1} using KBr): 3220, 1625, 1590, 1100, 620. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 595(236), 410(10688), 338(21376).

*2.6.3. $[NiH_2L^{1c}](ClO_4)_2$ ($R = -(CH_2)_4-$) (**3**)*

Anal. Calc. for $C_{32}H_{44}N_4O_2(ClO_4)$: C, 52.76; H, 5.98; N, 8.12. Found: C, 52.62; H, 5.75; N, 8.05%. Selected IR (ν cm^{-1} using KBr): 3300, 1620, 1580, 1100, 628. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 615(234), 340(18378).

Anal. Calc. for $C_{28}H_{36}N_4O_2{\cdot}(ClO_4)_2$: C, 46.93; H, 5.02; N, 7.82. Found: C, 46.85; H, 4.95; N, 7.79%. Selected IR data (ν cm^{-1} using KBr): 3330, 1640, 1100, 625. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 580(217), 392(11689).

*2.6.6. $[CuH_2L^{1a}](ClO_4)_2$ ($R = -(CH_2)_2-$) (**6**)*

Ligand H_2L^{1a} (0.98 g, 2 mmol) and NaOH (0.16 g, 4 mmol) was dissolved in $CHCl_3$–MeOH (40 ml, 1:3) and added to a solution of $Cu(ClO_4)_2{\cdot}6H_2O$ (0.75 g, 2.1 mmol) in MeOH (20 ml) and refluxed for 1 h. Green coloured crystals appeared. The crystalline product was collected by filtration, washed with MeOH and recrystallized from CH_3CN–MeOH (40 ml, 1:3). *Anal*. Calc. for $C_{30}H_{40}N_4O_2{\cdot}(ClO_4)_2$: C, 48.06; H, 5.34; N, 7.47. Found: C, 47.98; H, 5.25; N, 7.38%. Selected IR data (ν cm^{-1} using KBr): 3330, 1640, 1100, 625. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 570(506), 375(4726). The X-ray structure of this complex is discussed in this paper.

All the other copper complexes given below were prepared by following the procedure used for the synthesis of complex **6**, by using copper(II) perchlorarte and appropriate ligands.

*2.6.7. $[CuH_2L^{1b}](ClO_4)_2$ ($R = -(CH_2)_3-$) (**7**)*

Anal. Calc. for $C_{31}H_{42}N_4O_2{\cdot}(ClO_4)_2$: C, 43.24; H, 4.89; N, 7.20. Found: C, 43.13; H, 4.95; N, 7.24%. Selected IR data(ν cm^{-1} using KBr): 3330, 1640, 1100, 625. UV–Vis[λ_{max} nm($\in$ M^{-1} cm^{-1})] in DMF: 620(457), 372(4673), 280 (9532).

*2.6.8. $[CuH_2L^{2a}](ClO_4)_2$ ($R = -(CH_2)_2-$) (**8**)*

Anal. Calc. for $C_{27}H_{34}N_4O_2{\cdot}(ClO_4)_2$: C, 45.82; H, 4.81; N, 7.92. Found: C, 45.75; H, 4.78; N, 7.86%. Selected IR data (ν cm^{-1} using KBr): 3330, 1640, 1100, 625. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 580(217), 392(11689).

*2.6.9. $[CuH_2L^{2b}](ClO_4)_2$ ($R = -(CH_2)_3-$) (**9**)*

Anal. Calc. for $C_{28}H_{36}N_4O_2{\cdot}(ClO_4)_2$: C, 46.90; H, 4.99; N, 7.76. Found: C, 46.85; H, 4.92; N, 7.66%. Selected IR data (ν cm^{-1} using KBr): 3330, 1640, 1100, 625. UV–Vis [λ_{max} nm ($\in$ M^{-1} cm^{-1})] in DMF: 680(210), 380(10689).

3. Results and discussion

3.1. X-ray structural study of the complexes

Structure of the $[NiH_2L^{1a}](ClO_4)_2$ (**1**) and $[CuH_2L^{1a}](ClO_4)_2$ (**6**): An ORTEP [18] view with crystallographic numbering scheme of complexes **1** and **6** are shown in Figs. 1 and 2. Crystallographic data and structure determination parameters are given in Table 1. Selected bond distance and angles are given in Table 2. The two structures presented in this paper are isostructural. The near equality of the bond lengths and angles of the phenyl and piperidin rings of complexes **1** and **6** indicates that the replacement of Ni by the Cu ion has not produced any extra deformation of the coordination geometry and ring system. As shown in Figs. 1 and 2, the Ni(II) and Cu(II) ions have slightly distorted square-planar coordination. The displacement

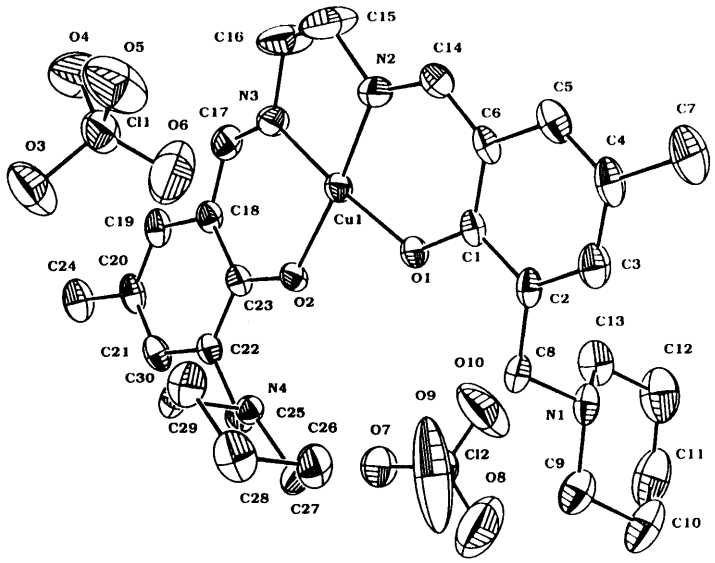

Fig. 2. ORTEP plot of $[CuH_2L^{1a}](ClO_4)_2$ (**1**) with atomic numbering scheme.

of the Ni(II) and Cu(II) ions from the best plane through the donor atoms O1, O2, N2 and N3 is −0.0004 (5) and 0.0007 Å, respectively. The coordination bond angles have values between 85.3(1) (N2–Ni1–N3) and 95.3(1)° (N2–Ni1–O1) for complex **1** and 84.5(2) (N2–Cu1–N3) and 93.6(2)° (N2–Cu1–O1) for complex **6**, their sum being 360.2(1) for **1** and 360.5(2)° for **6**. The Ni–O [1.838(3) and 1.855(2) Å] and Cu–O [1.901(4) and 1.878(4) Å] distances are equal within experimental error. There is a slight distortion of the coordination plane around the ions which can be quantified by the dihedral angle between the N2–Ni1–N3 and O1–Ni1–O2 planes [4.6(1)°] for **1** and N2–Cu1–N3 and O1–Cu1–O2 planes [7.5(2)°] for **6**.

The piperidin rings adopt chair conformation. The best plane passes through the central C atoms, leaving the N and C atoms above and below the plane. The deviations of N and C atoms are −0.485(3) and 0.318(6) Å, −0.491(4) and 0.311(8) Å for **1** and **6**, respectively. The deviations for the ring consisting of atoms C9–C13, N1 and C11 are −0.485(4) and 0.307(6), for the ring consisting of atoms C26–C30, N4 and C28 are −0.504(4) and 0.344(7) Å for **1** and **6**, respectively. The N1 and N4 atoms of the piperidin rings are protonated as shown by the degree of pyramidalization. N1 deviates from the C8, C9, C13 plane by 0.447(3) for **1** and 0.439(4) Å for **6**, and N4 deviates from the C25, C26, C30 plane by −0.423(4) for **1** and −0.429(4) Å for **6**. These two positive charges are stabilized by two lattice perchlorate anions. The hydrogen (H1–N4) of N4 is involved in intramolecular N–H···O hydrogen bonding between N4 of piperidin ring and phenoxy O2.

IR spectra of the complexes **1**–**9** shows ν(C=N) peak [19] at 1620–1640 cm^{-1}. The complexes show a broad peak at 1100 and 620 cm^{-1} characteristic of the perchlorate ion. The presence of the perchlorate ion is evident from the X-ray structure of the complexes **1** and **6** The electronic spectra of the complexes show three main transitions [20]: a weak band observed in the range 540–650 nm, due to d–d transition of the metal ion. Nickel complexes show a single d–d band in the range 550–650 nm characteristic of square planar [21] geometry around the metal ion. Copper complexes also show a d–d band in the range 550 to 620 nm characteristic of square planar geometry around the metal ion. An increase in the λ_{max} of the d–d transition of the complexes starting from **1** to **3** is observed as the number of methylene group in the imine linkage in-

creases [22]. The same trend has been observed for nickel(II) complexes **4** and **5** and copper(II) complexes **6** and **7**. A moderately intense peak observed in the range 400–350 nm is due to ligand to metal charge transfer transition and the very intense peak observed in the range 350–250 nm is due to ligand to ligand charge transfer transition.

3.2. Electrochemistry

Electrochemical properties of the complexes **1**–**9** were studied by cyclic voltammetry in DMF in the range + 1.2 to − 1.3 V. All the complexes **1**–**9** show a single redox wave at negative potential in the range − 0.70 to − 1.2 V. At positive potential, nickel complexes **1**–**5** show a single redox wave in the range + 0.5 to + 0.90 V. Generally, the electrochemical properties of the complexes depend on the chelate ring size [23], axial ligation [24] and substitution pattern in the chelate ring [25].

3.3. Reduction process at negative potential

The cyclic voltammogram of nickel complexes (**1**–**5**) and copper complexes (**6**–**9**) at negative potential show a single electron transfer process in the range − 0.70 to − 1.2 V. The data are given in Table 3. The reduction process is quasi-reversible in nature as is evident from the criteria: the $E_{1/2}$ value is independent of scan rate, the ΔE_p increases with increasing scan rate (10, 20, 50, 100, 150 mV s^{-1}) and is always greater than 60 mV. Repeated scanning lead to a gradual decrease in current, suggesting that the newly formed species is chemically unstable at room temperature. At a lower scan rate (10 mV s^{-1}) the oxidation process becomes irreversible. The peak currents i_{pc} and i_{pa} were not equal. Controlled potential electrolysis experiment indicates that the couple corresponds to a one-electron transfer process. Thus a quasi-reversible one-electron transfer occurred at the electrode surface, $M^{II} \rightleftharpoons M^{I}$ (M = Cu, Ni). The reduction potential of nickel complexes [23,26] of ligand L^{1a-c} (**1**–**3**) shifts anodically from $E_{pc} = -1.0$ to − 0.85 V ($E_{1/2} = -0.91$ to − 0.75 V) (vs Fc/Fc^+) as the number of methylene groups in the imine linkage is increased. A similar trend has been observed for copper complexes [27] of ligand L^{1a} (complex **6**) ($E_{1/2} = -0.84$ V) and L^{1b} (complex **7**) ($E_{1/2} = -0.71$ V) (vs Fc/Fc^+). This is because as the number of methylene group increases, the flexibility of the complex increases and the reduction process is shifted to a less negative potential.

The reduction potential for nickel complex **4** of ligand L^{2a} is observed at less a negative potential ($E_{pc} = -0.92$ V) (vs Fc/Fc^+) than complex **1** of ligand L^{1a} ($E_{pc} = -1.0$ V) (vs Fc/Fc^+). This is because complex **4**, which contains an electron-withdrawing [4] substituent (Br) at the *para* position to the phenoxide oxygen in the phenyl ring, reduces at less negative potentials than complex **1**, which contains an electron-donating substituent (CH_3) at the *para* position. A similar trend has been observed for the copper complex of ligand L^{1b} and L^{2b}. This may be due to the lesser electron density on the metal centre as a result of the poor electron donating nature of the bromine [28] at the *para* position.

Table 3
Electrochemical data for the complexes (reduction at cathodic potential) [a]

Number	Complex	E_{pc} (V)	E_{pa} (V)	ΔE_p (mV)	$E_{1/2}$ (V)
1	$[NiH_2L^{1a}](ClO_4)_2$	−1.0	−0.83	170	−0.91

Table 5
ESR and magnetic data (room temperature) for the complexes

Number	Complex	$g_{\|}$	$g_{\perp}$	$A_{\|} \times 10^{-4}$ cm^{-1}	μ_{eff} (B.M)
6	$[CuH_2L^{1a}](ClO_4)_2$	2.22	2.16	160	1.69
7	$[CuH_2L^{1b}](ClO_4)_2$	2.21	2.10	140	1.72
8	$[CuH_2L^{2a}](ClO_4)_2$	2.18	2.05	120	1.73
9	$[CuH_2L^{2b}](ClO_4)_2$	2.22	2.12	160	1.75

3.4. Oxidation process at positive potential

Cyclic voltammogram of nickel complexes **1**–**5** at positive potential show a single redox wave in the potential range [29] +0.50 to +0.90 V. The data are summarized in Table 4. The oxidation process is quasi-reversible in nature as is evident from the criteria: the $E_{1/2}$ value is independent of scan rate, the ΔE_p increases with increasing scan rate (10, 20, 50, 100, 150 mV s^{-1}) and is always greater than 60 mV. The peak currents I_{pa} and I_{pc} were not equal. Controlled potential electrolysis experiment indicates that the wave corresponds to one electron transfer process. The oxidation potential of nickel complexes **1**–**3** of ligand L^{1a-c} shifts towards a more positive value [23] (from $E_{pa} = +0.50$ to +0.85 V) as the number of methylene groups in the chelate ring of the complex increases. A similar trend has been observed for nickel complexes of ligand L^{2a} (complex **4**) and L^{2b} (complex **5**). This is because, as the chelate ring size of the ligand increases, the hole size provided for the coordinated ion also increases, thereby experiencing more difficulty for encompassing the smaller Ni(III) ion. Consequently, the Ni(II)/Ni(III) oxidation process of complexes with a large chelate ring size is shifted to a more positive value.

3.5. ESR and magnetic study

The ESR spectra of nickel complexes were recorded in a solution state using DMF as solvent at liquid nitrogen temperature. The data are given in Table 5. The ESR spectra of nickel complexes [30] are inactive characteristic of square-planar geometry around the metal ion. All the copper complexes (**6**–**9**) show an ESR spectrum typical of square-planar copper(II) complex [31] with nuclear hyperfine spin 3/2, three of the four expected hyperfine signals are seen, with the fourth being hidden under the $g_{\perp}$ line. For all the copper complexes the copper hyperfine $A_{\|}$ splitting falls in the range $120–160 \times 10^{-4}$ cm^{-1}, indicative of an electron interacting with only one copper nucleus. The relation $g_{\|} > g_{\perp}$ is typical of axially symmetric Cu(II) having one unpaired electron in a $d_{x^2-y^2}$ orbital. For the copper complex **7**; $g_{\|} = 2.21$, $g_{\perp} = 2.10$, $A_{\|} = 140 \times 10^{-4}$ cm^{-1}.

Magnetic moment of the complexes was observed at room temperature and the data are given in Table 5. All the nickel complexes are diamagnetic in nature due to square planar [30] geometry around the metal ion. Copper complexes (**6**–**9**) show μ_{eff} value in the range 1.70–1.75 B.M. which is close to the spin only value of 1.73 B.M. expected for copper complexes [30] with single unpaired electron located in an essentially $d_{x^2-y^2}$ orbital.

4. Supplementary material

Full crystal data and structure refinement details, atomic coordinates and equivalent isotrophic displacement parameters, full interatomic distances and angles, anisotrophic displacement parameters, hydrogen coordinates and isotrophic displacements parameters for complexes **1** and **6** are available from the Cambridge Crystallographic Data Centre, CCDC Nos. 140078 and 140079 for **1** and **6**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK

Received 28 April 2000; accepted 5 July 2000

Abstract

The chelating properties of 4-(*p*-methylphenyl)-3,5-bis(pyridin-2-yl)-1,2,4-triazole (MBPT) were investigated through the study of the crystal structures of $[Co(MBPT)_2(H_2O)_2](ClO_4)_2{\cdot}4H_2O$ (**1**), $[Ni(MBPT)_2(H_2O)_2](ClO_4)_2$ (**2**) and MBPT and the analysis of IR and ESIMS spectra. The metal atom is in a distorted octahedral environment. Two bidentate chelating ligands (MBPT) coordinate to metal center equatorially and two water molecules coordinate axially. Each MBPT coordinates via one triazole nitrogen atom and one pyridine nitrogen atom. The magnetic measurements show that the complexes are high-spin species in the 75–300 K range. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Substituted 1,2,4-triazoles have been actively studied as bridging ligands between transition metal(II) ions coordinating through their N1 and N2 atoms, since their complexes have interesting structures and specific magnetic properties [1–9]. It is interesting to note that some complexes containing substituted 1,2,4-triazole ligands have the spin-crossover properties, which could be used as molecular-based memory devices, displays and optical switches [10,11]. However, complexes containing triaryltriazole ligands have been rarely studied so far. We have synthesized some triaryltriazole compounds [12–14], which could be acted as doubly-bidentate chelating ligands because of their structural similarity to 4-amino-3,5-bis(pyridin-2-yl)-1,2,4-triazole (ABPT) [15]. It may be expected that the triaryltriazoles resulting from the substitution of 4-amino group of the ligand (ABPT) by a *p*-substituted aryl group would allow a variable structural chemistry of their complexes. Recently we have reported the crystal structure of a Ag(I) complex with 4-(*p*-methylphenyl)-3,5-bis(pyridin-2-yl)-1,2,4-triazole (MBPT), one of the triaryltriazole ligands [16]. As a continuation of our investigation of the ligand MBPT, we present here the syntheses and crystal structures of new cobalt(II) and nickel(II) complexes with MBPT and of MBPT itself. The spectroscopic and magnetic properties are also discussed in this paper.

2. Experimental

2.1. Synthesis of the compounds

All chemicals used were of analytical grade. Solvents were purified by conventional methods.

2.1.1. 4-(p-Methylphenyl)-3,5-bis(pyridin-2-yl)-1,2,4-triazol MBPT

The ligand (MBPT) was synthesized according to a similar method [14], m.p.196–198°C. Colorless single

crystals suitable for X-ray analysis were obtained from acetone upon slow evaporation at r.t. (*Anal.* Found: C, 72.37; H, 5.04; N, 22.64. Calc. for $C_{19}H_{15}N_5$: C, 72.82; H, 4.82; N, 22.35%). IR (cm^{-1}) $\nu(CH_3)$ 2954.7(w), 2918.9(w); ν(py ring) 1584.8(s), 1568.3(m), ν(ph) 824(s), 801.6(s); ^1H NMR δ: 2.41(s, Me), 7.18–7.34(m, 6H), 7.86–7.88(m, 2H), 8.22–8.24(m, 2H), 8.44–8.47(m, 2H).

2.1.2. Complex $[Co(MBPT)_2(H_2O)_2](ClO_4)_2\cdot 4H_2O$ (1)

To a solution of MBPT (0.6 mmol), in boiling EtOH (10 cm^3), was added a solution of $Co(OAc)_2\cdot 4H_2O$ (0.6 mmol) in EtOH (5 cm^3). The mixture was filtered into an EtOH solution containing $NaClO_4$ (1.5 mmol). The yellow crystalline solid that formed was isolated, washed with H_2O and dried in vacuo to yield 0.27 g (90%) of the perchlorate. Light-brown single crystals suitable for X-ray analysis were obtained from a methanol solution. (*Anal.* Found: C, 45.83; H, 4.56; N, 13.97. Calc. for $C_{38}H_{42}Cl_2CoN_{10}O_{14}$: C, 45.98; H, 4.26; N, 14.11%). IR (cm^{-1}): ν(O–H): 3454 (m, b); ν (CH_3): 2925.8(w); ν(py ring): 1606.6(s), 1591(m), 1572.7(w); ν(Cl–O): 1099.3(s), 929.2(w), 625.5(s).

2.1.3. Complex $[Ni(MBPT)_2(H_2O)_2](ClO_4)_2$ (2)

Complex **2** was prepared in 83% yield by a procedure similar to complex **1** but using $Ni(OAc)_2\cdot 4H_2O$ instead of $Co(OAc)_2\cdot 4H_2O$. The pale purple single crystals suitable for X-ray diffraction were obtained by evaporation from methanol solution. (*Anal.* Found: C, 49.35; H, 3.89; N, 15.09; Calc. for $C_{38}H_{34}Cl_2NiN_{10}O_{10}$: C, 49.59; H, 3.72; N, 15.22%). IR (cm^{-1}): ν(O–H): 3422.8 (m, b); $\nu(CH_3)$: 2925.6(w); ν(py ring): 1608.9(s), 1587.9(m), 1572.7(w); ν(Cl–O): 1097.7(s), 930(w), 625.4(s).

2.2. Physical measurements

Elemental analyses were performed with a Perkin–Elmer 240 instrument. IR spectra were recorded on a Nicolet 170SX FTIR instrument (KBr discs) in the 4000–400 cm^{-1} region. Electronic spectra were obtained with a Shimadzu UV3100 spectrophotometer in MeOH solution. The ^1H NMR spectra of MBPT were measured with a Bruker AM 500 spectrometer at ambient temperature in [$^2H_6$] $(CD_3)_2C{=}O$ using TMS as internal reference. Electrospray ionization mass spectra (ESIMS) were recorded with a Finnigan mat APISSQ 710 mass spectrometer, with methanol mobile phase and the flow rate of the mobile phase was 0.2 ml min^{-1}. The spray voltage was 4.5 KV and the capillary temperature was 200°C. The capillary voltage was 7.4 V for complex **1** and 28.7 V for complex **2**. Magnetic susceptibility of powder sample was collected with a CAHN 2000 magnetobalance and corrected using Pascal's constants (75–300 K).

2.3. X-ray crystallography

The well-shaped single crystals of MBPT, **1** and **2** were selected for X-ray diffraction study. The unit cell parameters and intensity data were collected at 293(2) K on a Siemens SMART CCD diffractometer with a detector distance of 4 cm and frame exposure time of 30 s using a graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. The structures were all solved by direct methods and refined on F^2 by full-matrix least-squares procedures using SHELXTL software [17]. All non-hydrogen atoms were anisotropically refined. All H atoms were located from a difference map and refined isotropically. Details on crystal data of MBPT, **1** and **2** are summarized in Table 1.

3. Results and discussion

3.1. Syntheses

The triaryltriazole ligand MBPT reacts with $M(OAc)_2\cdot 4H_2O$ ($M = Co^{II}$, Ni^{II}) and $NaClO_4$ in 2:1:2 molar ratio to form a neutral monomeric hexacoordinate complex of formula $[M(MBPT)_2(H_2O)_2](ClO_4)_2\cdot nH_2O$ ($M = Co^{II}$, $n = 4$; $M = Ni^{II}$, $n = 0$) which is stable in air. The elemental analysis is satisfactory and indicates that the complex contains one metal atom, two MBPT ligands, and six or two water molecules for complex **1** or **2**. The ligand MBPT does not seem to have any binucleating tendency towards cobalt and nickel [15].

3.1.1. Description of the structure of MBPT

For ligand MBPT the molecular structure with the atom-numbering scheme is shown in Fig. 1 and selected bond lengths and bond angles are listed in Table 2. Bond lengths and angles in the structure are comparable with those reported for related structures [12–14]. The substituted pyridyl groups and the phenyl ring lie in a propeller arrangement around the central 1,2,4-triazole ring. The dihedral angle between the phenyl and triazole rings is 53.9(3)°. The two pyridyl rings form dihedral angles of 32.0(3) and 48.0(3)° with the triazole ring.

3.1.2. Description of the structure of complex 1

The crystal structure of **1** consists of $[Co(MBPT)_2(H_2O)_2]^+$ cations, two ClO_4^- anions, and four lattice water molecules, held together by hydrogen bridges. This is consistent with the elemental analysis results. There is an inversion centre at the centre of the cation. A projection of the structure is presented in Fig. 2, together with the atomic labelling system; lattice water molecules O(2w) and O(3w) are omitted for clarity. Relevant interatomic distances and angles are given in Table 3.

The cobalt atom is surrounded by four nitrogen atoms from two MBPT ligands in the equatorial plane and two oxygen atoms from two water molecules in the axial positions to form a distorted octahedral geometry. The MBPT ligand coordinates to cobalt atom via N(1) atom of a pyridyl ring and N(2) atom of the triazole moiety leaving N(4) atom of another pyridyl ring and N(3) atom of the triazole moiety uncoordinated, which is similar to the coordination mode in complex $[Ag(MBPT)(PPh_3)_2]ClO_4$ [16] and of the reported ligand (ABPT) in the mononuclear compounds [18–22]. The Co–N and Co–O distances are within the range observed for octahedral complex [23]. It is, however, noticeable that the Co–N bond to the triazole nitrogen is 0.051 Å shorter than that to the pyridyl nitrogen. This feature can be compared with those observed for the ABPT complexes [18–22]. The ligand MBPT is non-planar. The pyridyl ring of which the nitrogen is involved in coordination makes an angle of 5.6(5)° with the triazole ring, whereas the non-coordinating pyridyl ring makes 39.4(6)° with respect to the triazole plane. The same feature has been found in other mononuclear ABPT compounds. In the present compounds, however, the coordinating or non-coordinating pyridyl ring and the triazole ring are somewhat less or more twisted than those [dihedral angle: 17.0(1) or 25.2(2)°, respectively] observed for the $[Ag(MBPT)(PPh_3)_2]ClO_4$ complex [16]. On the other hand, in the free ligand MBPT, the two pyridyl rings form dihedral angles of 32.0(3) and 48.0(3)° with the triazole ring (vide ante). It appears that on complexation, a small triazole-pyridyl twist angle is required to bring the ligand in the favored conformation to obtain the coordination around the metal centre.

The packing of cations and anions in the unit cell is depicted in Fig. 3. The perchlorate ions are highly disordered (67:33) and are connected to the water ligands by O(1w)–H1B···O(1) hydrogen bridges [O(1w)···O(1) = 2.827(8) Å and O(1w)–H1B···O(1) = 168(4)°]. In addition, there are also three kinds of

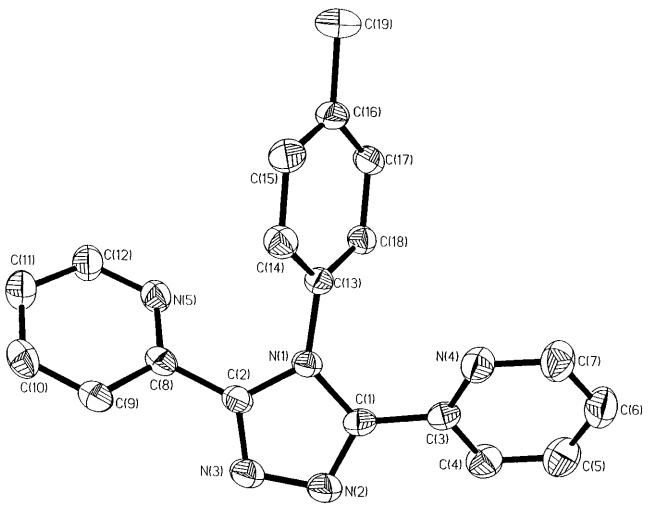

Fig. 1. The molecule of ligand MBPT with the atom-numbering scheme.

Table 2
Selected bond distances (Å) and angles (°) for MBPT

N(1)–C(1)	1.373(2)	N(3)–C(2)	1.311(3)
N(1)–C(2)	1.369(2)	N(4)–C(3)	1.335(3)
N(1)–C(13)	1.446(2)	N(4)–C(7)	1.331(3)
N(2)–C(1)	1.311(3)	N(5)–C(8)	1.339(3)
N(2)–N(3)	1.379(2)	N(5)–C(12)	1.334(3)
N(1)–C(1)–N(2)	110.3(2)	N(4)–C(3)–C(1)	117.3(2)

hydrogen bond interaction in the complex **1**: O(1w)–H1A···O(3w), O(3w)–H3A···O(2w), O(2w)–H2A···N(4). The distance of O(1w)···O(3w) is 2.625(5) Å [O(1w)–H1A···O(3w) = 160(3)°], which is shorter than those in ice [2.752(8) and 2.765(2) Å] [24]. It is clear that there is very strong hydrogen bonding between O(1) of coordinated water molecule and the lattice water molecules O(3). Moreover, O(3) interacts with another lattice water molecule, O(2), with an O···O distance of 2.810(7) Å [O(3w)–H3A···O(2w) = 132°]. Furthermore, O(2) is involved in hydrogen bonding with N(4) of the non-coordinating pyridyl group [O(2w)···N(4) = 3.264(6) Å and O(2w)–H2A···N(4) = 138.1(3)°].

3.1.3. Description of the structure of complex **2**

The structure of complex **2** is similar to that of **1** but does not contain lattice water molecules. The bond lengths and angles in the structure are in the normal range [15]. The Ni–N bond to the triazole nitrogen is 0.065 Å shorter than that to the pyridyl nitrogen. The dihedral angle between the coordinating or non-coordinating pyridyl ring and the triazole ring is 2.5(3) or 25.5(3)°, respectively. The pyridine rings are oriented at an angle of 26.2(3)° with each other. The perchlorate ion is highly disorder (56:44) and is involved in intramolecular O–H···O [O(1w)···O(2A) = 2.87(1) Å; O(1w)–H1A···O(2A) = 157°] hydrogen bonding and intermolecular C–H···O [C(18)···O(1A) = 3.43(2) Å; C(18)–H(18A)···O(1A) = 163°] hydrogen bonding thereby participating in the packing.

3.2. Spectral characterization

In the IR spectrum of the complex **1** (or **2**), there are several broad, medium bands around 3454 (or 3423), 3250 (or 3279), 3191 (or 3110) and 3072 (or 3075) cm^{-1}, mainly attributed to H–O–H stretching vibrations, suggesting the existence of hydrogen bonding interactions [25]. This is in agreement with the results of X-ray analysis. The bands due to the ionic perchlorate groups are around 1099 (or 1098)(s), 929 (or 930)(w), 626 (or 625) cm^{-1}(s), which can be assigned as the IR-allowed ν_3 mode, IR-forbidden ν_1 mode and the nondegenerate ClO_3 symmetrical bending frequency, ν_3, respectively [26]. The IR spectrum of the complexes can also be closely related to that of free MBPT. One of the most diagnostic changes occurs in the region between 1610 and 1560 cm^{-1}. The spectrum of free MBPT shows a strong band at 1584.8 cm^{-1} and a medium band at 1568.3 cm^{-1}, attributable to the pyridine ring vibrations. Upon pyridine coordination to a metal the higher band is shifted by about +15 wavenumbers [27]. So in the spectrum of the complex **1** (or **2**), a band at 1606.6 (or 1608.9) cm^{-1}(s) and two bands at 1591 (or 1587.9)(m) and 1572.7 (or 1572.7) cm^{-1}(w) can be assigned to one coordinated and one uncoordinated pyridine ring, respectively. This means that in this 2:1 complex, each MBPT ligand uses one pyridine nitrogen and one triazole nitrogen for chelate binding, as was confirmed by the structure determination.

In the UV–Vis spectrum of the complex **1** (or **2**) in methanol solution, two intense bands at 259 (or 247) and 284 (or 293.5) nm are attributed to the MBPT $\pi-\pi^*$ and $n-\pi^*$ transitions in contrast to those (243.5 and 275 nm) in the free MBPT–methanol solution. Three bands at 531.5, 667.5 and 1133.9 nm corresponding to d–d transitions, are observed for complex **1**, whereas only a band at 532.5 nm for complex **2**.

The structures of the complex **1** and **2** in solution were also studied by electrospray ionization mass spectrometry (ESIMS) [28–30]. Fig. 4(a) displays the positive ESI mass spectrum of the complex **1** in methanol solution. Four main peaks were observed. The peak at m/z 783.9 is $[Co(MBPT)_2(ClO_4)]^{1+}$ ion and that at m/z 499.1 is $[Co(MBPT)_3]^{1+}$. The peak at m/z 358.1 is

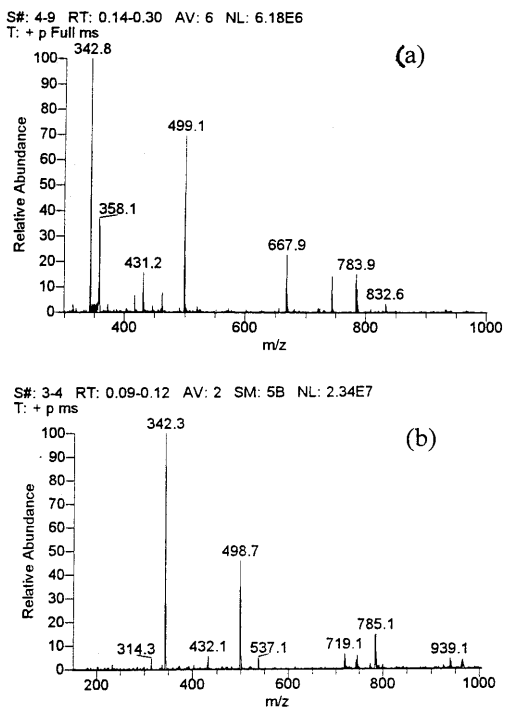

Fig. 4. Positive ion ESI mass spectrum of $[M(MBPT)_2(H_2O)_2](ClO_4)_2{\cdot}nH_2O$. (a) $M = Co^{II}$, $n = 4$ for **1**; (b) $M = Ni^{II}$, $n = 0$ for **2**.

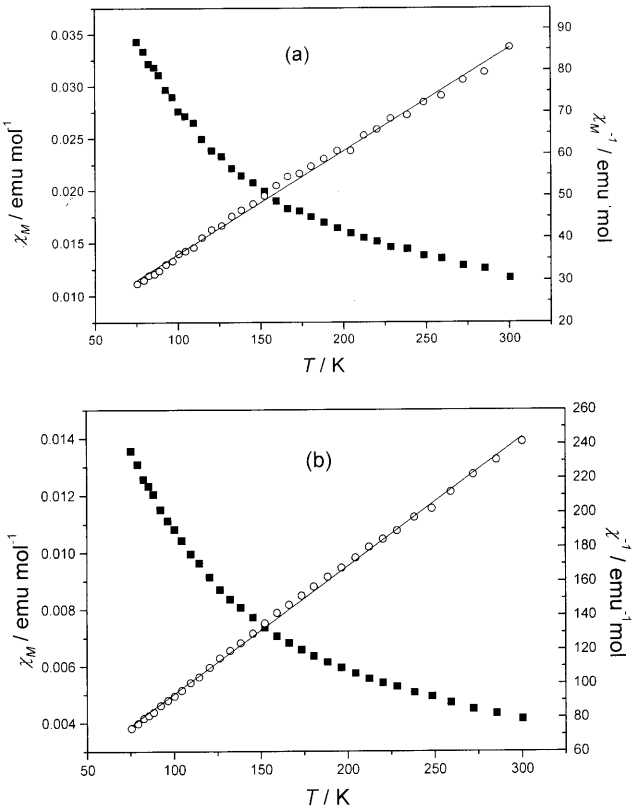

Fig. 5. The magnetic behavior of the complexes: χ_M () and χ_M^{-1} (○) vs. T plot. (a) For **1** and (b) for **2**.

probably due to $[Co(MBPT)_2(CH_3OH)]^{1+}$, which is one $[Co(MBPT)_2]$ structure unit containing a solvent molecule in it. The base peak at m/z 342.8 is $[Co(MBPT)_2]^{1+}$. Compared to that of $Co(bpy)_3(ClO_4)_3$ [29], the spectrum of the complex **1** in solution showed no sign of the presence of Co(III) complex. It clearly indicates that there is no chemical reduction/oxidation reaction in the solution and that the complex **1** is also stable in methanol solution. Fig. 4(b) displays the positive ESI mass spectrum of the complex **2** in methanol solution. Four main peaks were also observed. The peak at m/z 785.1 is $[Ni(MBPT)_2(ClO_4)]^{1+}$ ion and that at m/z 498.7 is $[Ni(MBPT)_3]^{1+}$. The base peak at m/z 342.3 is $[Ni(MBPT)_2]^{1+}$ and the peak at m/z 314.3 is $(MBPT+1)^{1+}$.

3.3. Magnetic properties

The temperature variation of the magnetic susceptibility in the form of χ_M and χ_M^{-1} versus T is shown in Fig. 5(a) and (b) for **1** and for **2**, respectively. The effective magnetic moments per molecule unit at 75–300 K range are 4.54–5.30 for **1** and 2.86–3.15 for **2**, respectively, which are in the normal range observed for a octahedral high-spin mononuclear Co(II) complex (μ_{eff} = 4.3–5.2 BM) and for a Ni(II) complex (μ_{eff} = 2.9–3.3 BM) [31]. However, the μ_{eff} values are slightly larger than the spin-only moments of 3.88 BM for **1** and of 2.83 BM for **2**. Over the whole temperature range (75–300 K), the magnetic behaviors of **1** and **2** can be interpreted by Curie–Weiss law with Curie values and Weiss constants of 4.07(5) and −47(2) for **1** and of 1.33(1) and −25(1) for **2**, respectively. The negative Weiss constants of **1** and **2** are expected for the zero-field splitting behaviors in lower temperature domain.

4. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 137157,137158 and 137159. Abstract

Two N'-2-pyridylmethyl and N'-2-hydroxypropyl derivatives of H_5dtpa (diethylene-N,N',N''-triamine-N,N,N',N'',N''-pentaacetic acid), $H_4L^1 = N'$-(2-pyridylmethyl)-$N,N,N''N''$-diethylenetriaminetetraacetic acid and $H_4L^2 = N'$-(2-hydroxypropyl)-$N,N,N''N''$diethylenetriaminetetraacetic acid were synthesized. Their protonation constants were determined by potentiometric titration in 0.10 mol dm^{-3} Me_4NNO_3 and by NMR pH titration at 25.0 ± 0.1°C. Stability and selectivity constants were determined to evaluate the possibility of using the corresponding gadolinium(III) complexes as magnetic resonance imaging contrast agents. Low stability or selectivity constants indicate higher possibility for releasing free Gd^{3+} ion and free ligand as well from gadolinium(III) complexes. The formations of lanthanide(III), copper(II), zinc(II) and calcium(II) complexes were investigated quantitatively by potentiometry. The stability constants of lanthanides(III) complexes with H_4L^1 and H_4L^2 increase from La(III) to Nd(III) and then plateau at Sm(III) and Gd(III), before increasing again to Yb(III). The stability constant of the gadolinium(III) complex is larger than those of Ca(II), Zn(II) and Cu(II) complexes for these two ligands. The selectivity constants and modified selectivity constants of H_4L^1 and H_4L^2 for Gd^{3+} over endogenously available metal ions were calculated. Effectiveness of these two ligands in binding divalent and trivalent metal ions in biological media is assessed by comparing pM values at physiological pH 7.4. Spin-lattice relaxivity R_1 for the Gd(III) complex was also determined. The observed relaxivity values of $[GdL^1]^-$ and $[GdL^2]^-$ became invariant with respect to pH changes over the range of 2–10 and 3–10, respectively. ^{17}O NMR shifts showed that the $[DyL^1]^-$ and $[DyL^2]^-$ complexes have 1.50 and 2.51 inner-sphere water molecules, respectively. Water proton spin-lattice relaxation rates for the $[GdL^1]^-$ and $[GdL^2]^-$ complexes were also consistent with inner-sphere gadolinium(III) coordination. © 2000 Elsevier Science Ltd. 1. Introduction

Synthesis and characterization of new gadolinium-(III) complexes of poly(aminocarboxylates) ligands, as contrast agents, by magnetic resonance imaging (MRI) have been of great interest in recent years. Among paramagnetic contrast agents, stable water-soluble gadolinium(III) chelates have the ideal properties of high water relaxivity, chemical stability, and low toxicity in vivo. At present, the octachelating ligands, (carboxymethyl)iminobis(ethylenenitrilo) tetraacetic acid (H_5dtpa), N,N''-di(methylcarbamoylmethyl) diethylenetrinitrilo-N,N',N''-triacetic acid (H_3dmdtta), 10-(2-hydroxypropyl)-1,4,7,10-tetraazacyclododecane-1,4,7-triacetic acid (H_3hpdotra), 1,4,7,10-tetraazacyclododecane-$N,N',N''N'''$-tetraacetic acid (H_4dota), ethoxybenzyltriaminepentaacetic acid (H_5eob-dtpa), and benzyloxyproponic tetraacetic acid) (H_5bopta) are effective MRI contrast agents when complexed with a trivalent gadolinium ion [1–3]. These gadolinium(III) chelates possess sufficient paramagnetism and high stability. The toxic effect of uncomplexed Gd^{3+} and free pro-ligand, arising from dissociation of the metal complex, is one of the major concerns in MRI [4,5]. The

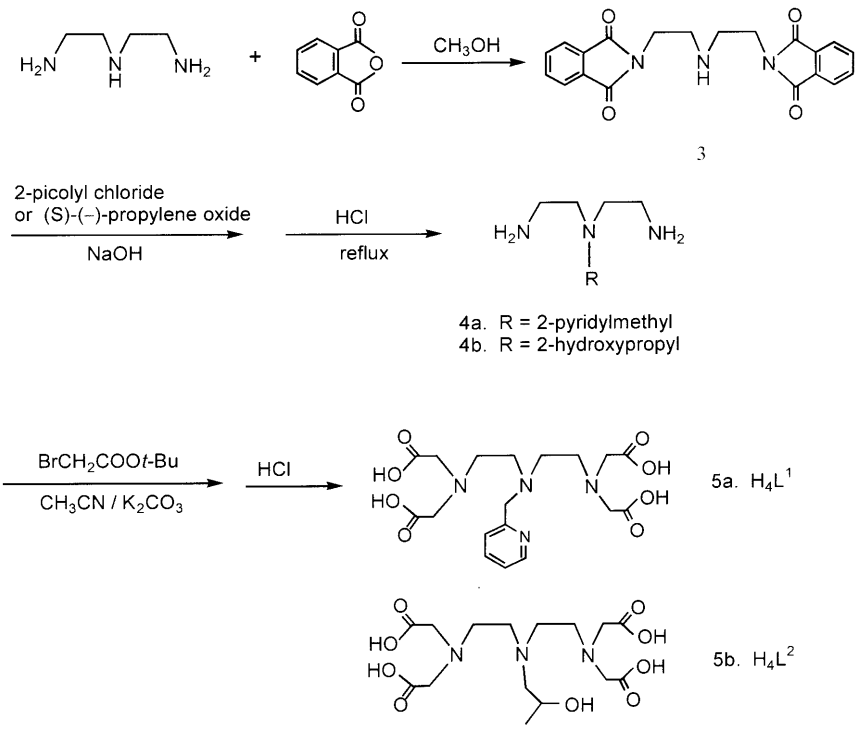
acute toxicity of gadolinium(III) complexes of poly(aminocarboxylates) correlates well with the selectivity of the latter for Gd^{3+}. The release of Gd^{3+} is related to the stability constants of the gadolinium(III) chelates [6,7]. The characterization of the complex of gadolinium(III) with bis(amide) derivatives of H_5dtpa had been investigated in a series of our studies [8–11]. In the continuing search for gadolinium(III) chelates for MRI, we have modified the carboxylate group by introducing *N*′-2-pyridylmethyl and *N*′-2-hydroxypropyl, and explored both the protonation constants of the ligands and the stability constants of the metal complexes. This report describes the synthesis of two *N*′-2-pyridylmethyl and *N*′-2-hydroxypropyl derivatives of H_5dtpa (Scheme 1). Their protonation constants, thermodynamic and conditional stability constants of complexes with lanthanides(III), Cu^{2+}, Zn^{2+}, and Ca^{2+} and their selectivity for Gd^{3+} over endogenously available metal ions are discussed. ^{17}O NMR shifts of the $[DyL^1]^-$ and $[DyL^2]^-$ complexes and water proton spin-lattice relaxivity, R_1, of the $[GdL^1]^-$ and $[GdL^2]^-$ are also discussed in this paper.

2. Experimental

2.1. Materials

Gadolinium chloride (> 99.9%) was obtained from Aldrich Chemical Co. and oven dried at 110°C for at least 24 h before use. All other reagents used for the synthesis of the ligands were purchased from commercial sources unless otherwise noted. Proton NMR spectra and elemental analyses were used to confirm the composition of the products.



2.2. Preparations

2.2.1. Synthesis of *N*,*N*-bis(phthalimide)diethylenetriamine (**3**)

To a 500 cm^3 two-necked round-bottom flask diethylenetriamine (27.164 g, 263.30 mmol) and CH_3OH (250 cm^3) were added. The solution was heated to 60°C in an oil bath and phathalic anhydride (65.15 g, 439.85 mmol) was added. The reaction mixture became slurry within 20 min, and the mixture was stirred for 4 h. The pare yellow slurry was filtered of onto a Büchner funnel, washed with acetone (4×50 cm^3) and with MeOH (4×50 cm^3), and then vacuum dried to give 50.04 g (52.3%) of a white solid, m.p.: 181.0–181.3°C. *Anal.* Calc for $C_{20}H_{17}N_3O_4$ ($f_w = 363.37$): C, 66.12; H, 4.72; N, 11.56. *Anal.* Found: C, 66.17; H, 4.75; N, 11.37. ^1H NMR ($CDCl_3$), δ(ppm): 7.69 (m, 8H, ArH), 3.76 (t, 4H, backbone), 2.95 (t, 4H, backbone).

2.2.2. Synthesis of *N*′-(2-pyridylmethyl)diethylenetriamine (**4a**)

N,*N*-Bis(phthalimide)diethylenetriamine (**3**) (5.0 g, 13.76 mmol) was suspended in 50 cm^3 of water, with stirring, and the pH was adjusted to between 11.5 and

Scheme 1.

12.0 by addition of NaOH (2.0 mol dm^{-3}). The reaction mixture was kept at room temperature and 2-picolyl chloride (2.26 g, 13.76 mmol) was added. Then the mixture was stirred for 15 h. The mixture was evaporated by rotary evaporation to give a dark red oil, and then 6 N HCl (100 cm^3) was added and heated at reflux for 24 h to remove the protection group. The crude product was purified on an AG 50W × 8 cation exchange resin column (200–400 mesh, H^+ form, 100 cm^3 of resin, 4.2 cm column diameter). The column was eluted consecutively with 500 cm^3 of water, 250 cm^3 of 0.5 mol dm^{-3} HCl, 250 cm^3 of 1.0 mol dm^{-3} HCl, 250 cm^3 of 1.5 mol dm^{-3} HCl, 250 cm^3 of 2.0 mol dm^{-3} HCl, 250 cm^3 of 2.5 mol dm^{-3} HCl, 250 cm^3 of 3.0 mol dm^{-3} HCl and 250 cm^3 of 3.5 mol dm^{-3} HCl. The product was eluted with the 3.5 mol dm^{-3} HCl fractions, while the earlier fractions contained inorganic salts (NaCl) and impurities. All fractions containing the product were evaporated to dryness by rotary evaporation and coevaporated three times with 150 cm^3 of water to remove the excess HCl. After vacuum drying, 1.58 g (38.7%) of pure **4a** ·3HCl was obtained as a dark yellow hygroscopic powder. ^{1}H NMR (D_2O), δ(ppm): 8.64, 8.45, 7.92, 7.88 (m, 5H, pyH), 4.19 (s, 2H, N–CH_2-py), 3.20 (t, 4H, backbone), 2.98 (t, 4H, backbone).

2.2.3. Synthesis of N′-(2-pyridylmethyl)-N,N,N″N″-diethylenetriaminetetraacetic acid (*5a*, H_4L^1)

To a solution of **4a** (1.58 g, 5.5 mmol) and potassium carbonate (10 g, 72.35 mmol) in CH_3CN (150 cm^3), *tert*-butylbromoacetate (4.38 g, 22.45 mmol) was added. The reaction mixture was heated at reflux for 36 h. The potassium carbonate was removed by filtering the reaction mixture through a Büchner funnel and was washed with CH_3CN (20 cm^3). The filtrate was evaporated to dryness by rotary evaporation. To the residue H_2O was added and extracted with chloroform (3 × 50 cm^3). The chloroform phase was evaporated under reduced pressure, and 2 mol dm^{-3} HCl (50 cm^3) added. The solution was stirred for 6 h at ambient temperature, stripped to dryness, and the acid treatment repeated three times (until ^{1}H NMR showed complete removal of the *tert*-butyl group). The residue was dissolved in 50 cm^3 of distilled water, and the solution was loaded onto an AG 50W × 8 cation exchange resin column (200–400 mesh, H^+ form, 100 cm^3 of resin, 4.2 cm column diameter). The column was eluted consecutively with 500 cm^3 of water, 250 cm^3 of 0.5 mol dm^{-3} HCl, 250 cm^3 of 1.0 mol dm^{-3} HCl, 250 cm^3 of 1.5 mol dm^{-3} HCl, 250 cm^3 of 2.0 mol dm^{-3} HCl, 250 cm^3 of 2.5 mol dm^{-3} HCl and 500 cm^3 of 3.0 mol dm^{-3} HCl. The product was eluted with the 3.0 mol dm^{-3} HCl fractions. All fractions containing the product were evaporated to dryness by rotary evaporation and coevaporated three times with 150 cm^3 of water to remove the excess HCl. The product was dissolved in 50 cm^3 of distilled water and alkalized with ammonia water to pH 11.0, and the solution applied to AG1 × 8 anion exchange resin column (200–400 mesh, HCO_2H form, 60 cm^3 of resin, 3.0 cm column diameter) and the product eluted with 500 cm^3 of water, 500 cm^3 of 0.1 mol dm^{-3} formic acid, 500 cm^3 of 0.2 mol dm^{-3} formic acid, 500 cm^3 of 0.3 mol dm^{-3} formic acid, 500 cm^3 of 0.4 mol dm^{-3} formic acid and 500 cm^3 of 0.5 mol dm^{-3} formic acid. The product was eluted with the 0.5 mol dm^{-3} formic acid to yield 1.76 g (47%) of a brown hygroscopic powder. ^{1}H NMR ($CDCl_3$), δ(ppm): 8.71, 8.52, 8.03, 7.94 (m, 5H, pyH), 4.12 (s, 2H, N–CH_2-py), 3.81 (s, 8H, –CH_2–COOH), 3.44 (t, 4H, backbone), 3.00 (t, 4H, backbone).

2.2.4. Synthesis of N′-(2-hydroxypropyl)diethylenetriamine (*4b*)

N,*N*-Bis(phthalimide)diethylenetriamine (**3**) (4.72 g, 12.99 mmol) was suspended in 25 cm^3 of water, with stirring, and the pH was adjusted to between 11.5 and 12.0 by addition of NaOH (2.0 mol dm^{-3}). The reaction mixture was cooled to 2–5°C, and 1.0 cm^3 (0.86 g, 14.81 mmol, 14% excess) of (S)-(−)-propylene oxide was added. The reaction mixture was stirred for 12 h at room temperature. The mixture was evaporated by rotary evaporation to give a pale yellow oil, and then 6 mol dm^{-3} HCl (100 cm^3) was added and heated at reflux for 24 h to remove the protection group. The crude product was purified on an AG 50W × 8 cation exchange resin column (200–400 mesh, H^+ form, 100 cm^3 of resin, 4.2 cm column diameter). The column was eluted consecutively with 500 cm^3 of water, 500 cm^3 of 0.5 mol dm^{-3} HCl, 500 cm^3 of 1.0 mol dm^{-3} HCl, 500 cm^3 of 1.5 mol dm^{-3} HCl, 500 cm^3 of 2.0 mol dm^{-3} HCl, 500 cm^3 of 2.5 mol dm^{-3} HCl and 500 cm^3 of 3.0 mol dm^{-3} HCl. The product was eluted with the 2.5 mol dm^{-3} and 3.0 mol dm^{-3} HCl fractions. All fractions containing the product were evaporated to dryness by rotary evaporation and coevaporated three times with 150 cm^3 of water to remove the excess HCl. After vacuum drying, 1.58 g (45%) of pure **4b** ·3HCl was obtained as a white hygroscopic powder. ^{1}H NMR (D_2O), δ(ppm): 4.09 (m, 1H, –CH–OH), 3.37 (m, 8H, backbone), 3.08 (m, 2H, N–CH_2–CH(OH)–), 1.17 (d, 3H, –CH(OH)–CH_3).

2.2.5. Synthesis of N′-(2-hydroxypropyl)-N,N,N″N″-diethylenetriaminetetraacetic acid (*5b*, H_4L^2)

To a solution of **4b** (1.58 g, 5.84 mmol) and potassium carbonate (10 g, 72.35 mmol) in CH_3CN (150 cm^3), *tert*-butylbromoacetate (4.67 g, 23.94 mmol) was added. The reaction mixture was heated at reflux for 36 h. The potassium carbonate was removed by filtering the reaction mixture through a Büchner funnel and was washed with CH_3CN (20 cm^3). The filtrate was evapo-

rated to dryness by rotary evaporation. To the residue H_2O was added and extracted with chloroform (3×50 cm^3). The chloroform phase was evaporated under reduced pressure, and 2 mol dm^{-3} HCl (50 cm^3) added. The solution was stirred for 6 h at ambient temperature, stripped to dryness, and the acid treatment repeated three times (until ^1H NMR showed complete removal of the *tert*-butyl group). The residue was dissolved in 60 cm^3 of distilled water, and the solution was loaded onto an AG $50W \times 8$ cation exchange resin column (200–400 mesh, H^+ form, 100 cm^3 of resin, 4.2 cm column diameter). The column was eluted consecutively with 500 cm^3 of water, 500 cm^3 of 0.5 mol dm^{-3} HCl, 500 cm^3 of 1.0 mol dm^{-3} HCl, 500 cm^3 of 1.5 mol dm^{-3} HCl, 500 cm^3 of 2.0 mol dm^{-3} HCl and 500 cm^3 of 2.5 mol dm^{-3} HCl. The product was eluted with the 2.5 mol dm^{-3} HCl fractions. All fractions containing the product were evaporated to dryness by rotary evaporation and coevaporated three times with 150 cm^3 of water to remove the excess HCl. The product was dissolved in 50 cm^3 of distilled water and made alkaline with ammonia water to pH 11.0. Finally, the solution was applied to an AG 1×8 anion exchange resin column (200–400 mesh, HCO_2H form, 60 cm^3 of resin, 3.0 cm column diameter) and eluted with 500 cm^3 of water, 500 cm^3 of 0.1 mol dm^{-3} formic acid, 500 cm^3 of 0.2 mol dm^{-3} formic acid, 500 cm^3 of 0.3 mol dm^{-3} formic acid, 500 cm^3 of 0.4 mol dm^{-3} formic acid, 500 cm^3 of 0.5 mol dm^{-3} formic acid and 500 cm^3 of 0.6 mol dm^{-3} formic acid. The product was eluted with the 0.6 mol dm^{-3} formic acid to yield 1.9 g (74.2%) of a white hygroscopic free acid. *Anal.* Calc for $C_{15}H_{27}N_3O_9 \cdot 2.5\ H_2O$ ($f_w = 438.41$): C, 41.09; H, 7.36; N, 9.59. *Anal.* Found: C, 41.05; H, 7.44; N, 9.63. ^1H NMR (D_2O, pD 3.63), δ(ppm): 3.92 (m, 1H, –CH–OH), 3.79 (s, 8H, $–CH_2–COOH$), 3.41 (t, 4H, backbone), 3.09 (m, 4H, backbone), 2.68 (m, 2H, $N–CH_2–CH(OH)–$), (d, 3H, $–CH(OH)–CH_3$).

2.3. NMR experiments

Solutions of ligand (15 mmol dm^{-3}) for NMR pH titration were made up in D_2O, and p*D* was adjusted with DCl or CO_2-free NaOD. Proton NMR spectra were measured in D_2O solution on Varian Unity Plus 400 and XL-200E spectrometers. The final p*D* values of the ligand solutions were determined with a microelectrode. The final p*D* was obtained from the equation $pD = pH + 0.40$ [12]. The hydrogen electrode used in the present study allows a reliable and accurate determination of the proton activity over an extended pH range.

The ^{17}O NMR spectra were recorded by a Varian Gemini 300 spectrometer at 25°C. The induced ^{17}O shift (d.i.s.) measurements were determined with respect to D_2O as external standard. The hydration number of $[DyL^1]^-$ and $[DyL^2]^-$ was determined by the method of Alpoim et al. [13]. An equimolar solution of Dy^{3+} and ligand was prepared, and a stoichiometric amount of standardized NaOH was added so that the complex was fully formed. Six solutions of differing dysprosium concentrations were prepared by serial dilution of the stock solution.

2.4. Solution preparations

Stock solutions of trivalent lanthanides, Ca^{2+}, Zn^{2+} and Cu^{2+} were prepared between 0.010 and 0.025 mol dm^{-3} from nitrate salts with demineralized water (obtained by a Millipore/Milli-Q system) and standardized by titration with Na_2edta (disodium salt of ethylenedinitrilotetraacetic acid) or atomic absorption spectrophotometry. A stock solution was prepared by dissolving reagent grade Na_2edta (4.65 g) and diluting it to 250 cm^3 with demineralized water. This was used as a titrant to standardize the solution of lanthanides(III) and Ca^{2+}. Stock lanthanide(III) complex solutions (henceforth identified as LnL and having a concentration range of 1.5–0.5 mmol dm^{-3}) were prepared by mixing equimolar amounts of stock solution of lanthanides(III) and ligand. A slight excess (2%) of ligand was used to ensure total complexation of lanthanides(III).

2.5. Potentiometric measurements

Potentiometric titrations were performed with an automatic titrator system to determine the protonation constants of the H_4L^1 and H_4L^2, and the stability constants of the metal complexes. The autotitrating system consists of a 702 SM Titroprocessor, a 728 stirrer and a PT-100 combination pH electrode (Metrohm). The pH electrode was calibrated using two standard buffer solutions and all calibrations and titrations were carried out under a CO_2-free nitrogen atmosphere, to avoid any contact with carbon dioxide in a sealed glass vessel (20 cm^3) thermostatted at 25.0 ± 0.1°C, and an ionic strength of 0.10 mol dm^{-3} Me_4NNO_3. The concentrations of the metal–ion and ligand solutions were maintained between 2.0 and 1.0 mmol dm^{-3}. A CO_2-free 0.100 mol dm^{-3} NaOH solution was used as the titrant to minimize ionic strength change during the titration. The purity of the ligand was also confirmed by potentiometric titration with standard NaOH. Oxygen and carbon dioxide were excluded from the reaction mixtures by maintaining a positive pressure of purified nitrogen in the titration cell. Each titration was performed at least three times. Since the lanthanides(III) chelate is completely or almost completely formed at low pH, their stability constant could not be determined from the normal potentiometric titration method. Therefore, these stabil-

Table 1
Protonation constants of the ligands H_4L^1, H_4L^2, H_3dtpa-bp, H_3dmdtta and H_5dtpa at 25.0 ± 0.1°C in aqueous Me_4NNO_3 ($I = 0.10$ mol dm^{-3})

[a] Data were obtained from Ref. [14].
[b] Ref. [18].

ity constants were evaluated by a ligand–ligand competition potentiometric titration in this study [14,15]. A 1:1:1 molar ratio of lanthanides(III), ligand and a reference ligand with a known metal chelate stability was titrated. A good reference ligand for the lanthanide(III) systems was found to be H_4edta. $^7H_4$edta forms complexes with lanthanides(III) ions and the stability constants are accurately known.

The potentiometric equilibrium studies were carried out on solutions of H_4L^1 and H_4L^2, in the absence of metal ions and then in the presence of each metal ion which the M:L ratio was 1:1. The E data were obtained after additions of 0.005 cm^3 increments of standard 0.100 mmol dm^{-3} NaOH solution, and after stabilization in this direction, equilibrium was then approached from the other direction by adding standard 0.100 mol dm^{-3} acid solution. The equilibria were slow to attain and it was necessary to take about 10 min for each point of the titration where the ligand–ligand competition took place. However, complexation was usually rapid (3–5 min per point to give a stable pH reading) in the Cu(II), Ca(II) and Zn(II) studies. The same values of the stability constants were obtained either by using the direct or the back titration.

2.6. Computational method

The protonation constants of the H_4L^1 and H_4L^2 were calculated using a FORTRAN computer program PKAS [16] written for polyprotonic weak acid equilibria. The overall stability constants of the various metal complexes formed in aqueous solution were determined from the titration data with the FORTRAN computer program BEST [16]. The average difference between observed and calculated log [H$^+$] was < 0.04 throughout all titration. A value of 13.78 was employed for the pK_w at 25°C. The species distribution diagrams were calculated with the FORTRAN program SPE and SPEPLOT [16].

2.7. Relaxation time measurement

The Gd(III) chelate solution was prepared by combining equal molar amounts of the stock $GdCl_3$ and the ligand solution. The Gd(III) chelate solutions under various pH values were prepared by combining the buffer solution with an appropriately diluted Gd(III) complex solution in a 1:1 (v/v) ratio. The following buffer systems (all 0.10 mol dm^{-3}) were used: chloroacetic acid–NaOH (pH 2 and 3), acetic acid–NaOH (pH 4 and 5), PIPES (PIPES = piperazine-*N*,*N*′-bis-2-ethanesulfonic acid)–NaOH (pH 6.0 and 6.8) and ammonia–HCl (pH 9 and 10). These buffer solutions were used to maintain constant ionic strength (i.e. 0.10 mol dm^{-3}). The 0.10 mol dm^{-3} buffers were sufficient to maintain the solution pH within the desired range in most cases. The buffered Gd(III) chelate solutions were all allowed to equilibrate for at least 3 h. The pH of these solutions was determined immediately before relaxation time T_1 measurements.

Relaxation times T_1 of aqueous solutions of gadolinium(III) complexes of with H_4L^1 and H_4L^2 were measured to obtain relaxivity R_1. All measurements were made using a NMR spectrometer operating at 20 MHz and 37.0 ± 0.1°C (NMS 120 Minispec, Bruker). Before each measurement the spectrometer was tuned and calibrated. The value of R_1 was measured from eight data points generated by an inversion-recovery pulse sequence. The slope of plot of $1/T_1$ versus concentration gives R_1 in dm^3 mmol^{-1} s^{-1}.

3. Results and discussion

3.1. Protonation constants

The potentiometric titration curves for H_4L^1 and H_4L^2 are deposited as supplementary material (Figs. 1S and 2S). Table 1 summarizes the protonation constants of the H_4L^1, H_4L^2, H_3dtpa-bp(*N*,*N*″-2-bis(2-pyridylmethyl)diethylenetriamine-*N*,*N*′,*N*″-triacetic acid),

H_3dmdtta and H_5dtpa [7]. The titration curves of H_4L^1 and H_4L^2 all show the increase between pH 8.5 and 3.0 (moles of base per mol ligand present equals 2). This is due to the difference between the second ($\log K_2$) and third protonation constant ($\log K_3$), i.e. 8.77 and 4.91, 8.15 and 3.17, respectively. The $\log K_1$ (first protonation constant) and the $\log K_4$ (fourth protonation constant) values of H_4L^1 and H_4L^2 are 9.67 and 10.68, 2.98 and 2.75, respectively. The cumulative protonation constant of H_4L^1 is significantly higher than those of the H_4L^2, H_3dtpa-bp and H_3dmdtta and is a slightly higher than that of the H_5dtpa.

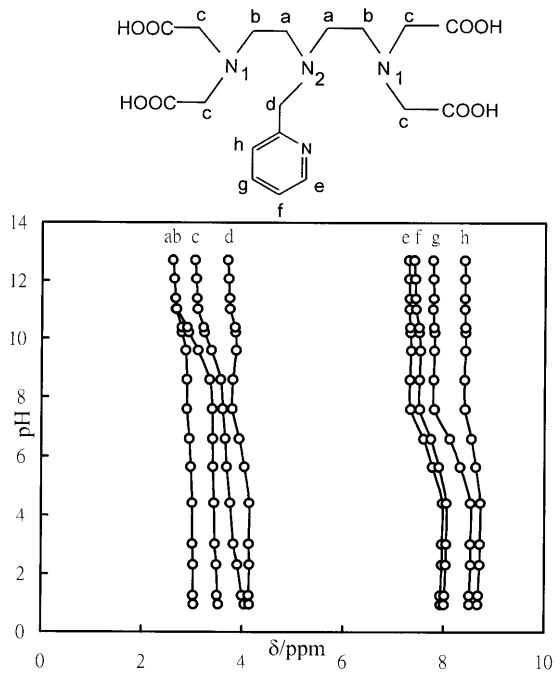

Fig. 1. Proton NMR titration curves for H_4L^1.

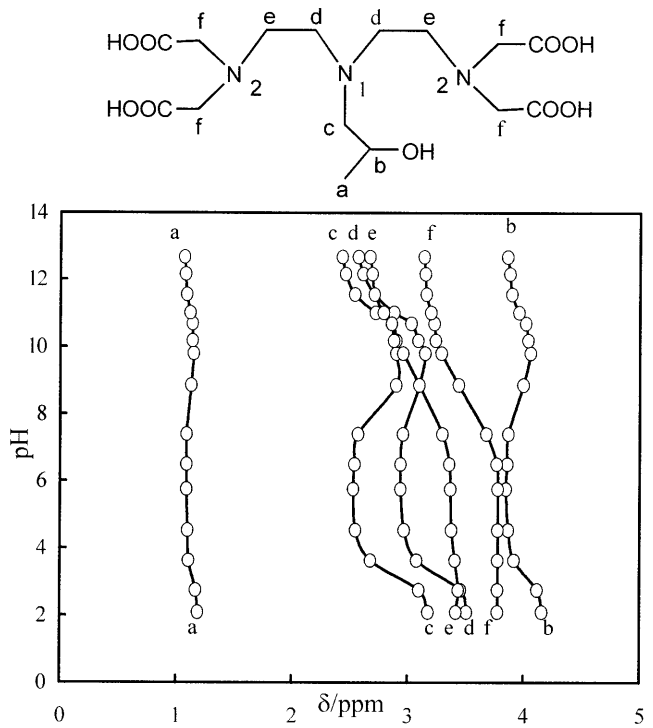

Fig. 2. Proton NMR titration curves for H_4L^2.

The replacement of the one central acetate group in H_5dtpa by the one 2-pyridylmethyl group results in a decrease in $\log K_1$ (i.e. 0.82 unit), increase in $\log K_2$ (i.e. 0.17 unit), $\log K_3$ (i.e. 0.63 unit), $\log K_4$ (i.e. 0.34 unit), and ΣpK_a value (i.e. 0.32 unit), and by the one 2-hydroxypropyl group results in an increase in $\log K_1$ (i.e. 0.19 unit), decrease in $\log K_2$ (i.e. 0.45 unit), $\log K_3$ (i.e. 1.11 unit), and ΣpK_a value (i.e. 1.36 unit).

3.2. NMR pH titration

The macroscopic protonation constants of the ligands in Table 1 are measured by the potentiometric titration technique. However, the microscopic protonation scheme is obtained by NMR spectroscopy coupled with pH titration. The proton NMR spectra of H_4L^1 and H_4L^2 as a function of pH have been deposited as supplementary material (figures 3S and 4S). Coalescence of the triplets corresponding to the ethylenic group occurs about pH > 10.0 for the H_4L^1. Plots of the proton chemical shift values (δ) of the methylenic resonance of H_4L^1 and H_4L^2 as a function of pH are shown in Figs. 1 and 2. There are four inflections centered for H_4L^2 at pH about 10.5, 8.0, 3.0 and 2.5. For H_4L^1 the chemical shift changing to lower of higher frequency in the region pH 11.0–8.3 reveals that the first and the second observed protonation occurred on the terminal nitrogen atoms, which is the first and second protonation sites. In the range pH 7.0–4.0 the chemical shift changing to lower of higher frequency shows that the third protonation occurred on the central 2-pyridylmethyl nitrogen atom. At about pH 3.0 the chemical shift changing to lower of higher frequency was also observed for the one of the carboxylate groups, which is the fourth protonation site. For H_4L^2 the chemical shift changing to lower of higher frequency in the region pH 12.0–10.2 indicates that the first observed protonation occurred on the central nitrogen atom, which is also common to H_5dtpa and bis(amide) of H_5dtpa derivatives system [7,8]. In the range of about pH 9.8–7.5 the chemical shift changing from lower of higher frequency was also observed for one of the terminal nitrogen atoms which is the second protonation site. In the range pH 3.5–2.5 the chemical shift changing from lower of higher frequency shows that the third protonation occurred on the remaining terminal nitrogen atom. At about pH 2.5 the chemical shift changing from lower of higher frequency also occurred on the central hydroxyl oxygen atom, which is the fourth protonation site. These values correlate quite

well with the protonation constants of the H_4L^1 and H_4L^2 given in Table 1. This reflects stepwise protonation of the amino groups of the H_4L^2 and stepwise protonation of the amino groups and pyridyl nitrogen atom of the H_4L^1 with the formation of the species HL^{3-}, H_2L^{2-} and H_3L^-. The first protonation constant of H_4L^2 is higher than that of H_4L^1 because the first protonation site of H_4L^2 occurs on the central nitrogen atom and the H_4L^1 occurs at one of the terminal nitrogen atoms. These results seem to reveal that the methyl substituent increases the basicity of Lewis base whereas the acetate group does not. The third protonation constant of H_4L^1 is significant higher than that of corresponding value for H_4L^2 because of the protonation site of H_4L^1 being a pyridyl nitrogen atom. The species distribution curves for H_4L^1 and H_4L^2 have been deposited as supplementary material (Figs. 5S and 6S) the dominant species are the diprotonated ligand (H_2L^{2-}) between pH 5.5–8.0 and 4.0–7.5, respectively.

3.3. Thermodynamic stability constants

The metal chelate thermodynamic stability constants (K_{ML}) are expressed as in Eq. (1) where M represents the free, unhydrolyzed aquametal ion,

$$K_{ML} = [ML]/[M][L] \quad (1)$$

L is the uncomplexed, totally deprotonated form of the ligand and ML is the normal unprotonated and unhydrolyzed complex. The potentiometric titration curves for the complexes of Cu^{2+}, Ca^{2+} and Zn^{2+} with H_4L^1 and H_4L^2 have been deposited as supplement any material (Figs. 1S and 2S). The lanthanides(III) reacts strongly with H_4L^1 and H_4L^2 and at a considerably lower pH than the divalent metals. The stability constants of the complexes of lanthanides(III) with H_4L^1 and H_4L^2 were derived from the competition reaction H_4edta (not shown). In Table 2, the thermodynamic stability constants of Gd^{3+}, Cu^{2+}, Ca^{2+} and Zn^{2+} chelates are presented for the linear poly(aminocarboxylates) H_4L^1, H_4L^2, H_3dtpa-bp, H_3dmdtta and H_5dtpa [7,17,18].The similar stability constants of the complexes of Gd^{3+}, Cu^{2+} and Zn^{2+} with the H_4L^1 and H_5dtpa may indicate similar ligand basicities. The stability constants of $[GdL^2]^-$ are lower than those of $[GdL^1]^-$ and $[Gd(dtpa)]^{2-}$ and similar to that of $[Gd(deata)]^-$ (i.e. $\log K_{GdL} = 17.79$) (deata = *N*,*N*-bis-(2-aminoethyl) ethylamine-*N*′,*N*′,*N*″,*N*″tetraacetic acid) [19]. In other words, the hydroxyl group for DTPA-HP ligand does not coordinate to Gd(III) metal ion. The lower stability constants of the H_4L^2 and H_3dmdtta chelates when compared to the H_5dtpa and H_4L^1 chelates are assigned to the weaker donor ability of the hydroxyl and amide groups and the lower basicity of the ligands.

Plots of the thermodynamic stability constants ($\log K_{LnL}$) for $[LnL^1]^-$ and $[LnL^2]^-$ chelates (Ln = La^{3+}, Ce^{3+}, Nd^{3+}, Sm^{3+}, Gd^{3+}, Dy^{3+}, Ho^{3+}, Yb^{3+} and Lu^{3+}) versus lanthanide(III) ionic radius are displayed in Fig. 3. The ligand H_4L^1 forms stronger complexes with lanthanides than H_4L^2, primarily because of higher protonation constants of H_4L^1 ligand. The stability constants for $[LnL^1]^-$ and $[LnL^2]^-$ increase from La(III) to Nd(III) and then plateau at Sm(III) and Gd(III), before increasing again to Yb(III). This is a

common effect in Ln(III) solution chemistry [20]. The progressive increase in stability constants for $[LnL^1]^-$ and $[LnL^2]^-$ along the Ln(III) cation series is characteristic of ligands H_4L^1 and H_4L^2 those are higher basicity, less steric hindrance or more flexible and reveal increasing stability with enhancing the charge density of Ln(III) cation.

pZn	13.31	10.82	10.84	9.06	13.39

3.4. Conditional stability constants and selectivity constants

The conditional stability constant of a metal chelate ($K_{ML'}$) under physiological conditions (pH 7.4) is more important than the thermodynamic stability constant for biological studies. The former shows the extent of metal chelation at a pH 7.4 and can be calculated by taking regard of the thermodynamic stability constant and the stepwise ligand protonation constants [7].

Table 2 summarizes the conditional stability constants of the complexes of Gd^{3+}, Cu^{2+}, Ca^{2+} and Zn^{2+} with the five poly(aminocarboxylates), H_4L^1, H_4L^2, H_3dtpa-bp, H_3dmdtta and H_5dtpa at pH 7.4. Their order is $[Gd(dtpa)]^{2-} \approx [GdL^1]^- > [GdL^2]^- > [Gd(dtpa\text{-}bp)] \approx [Gd(dmdtta)]$. This suggests the conditional stability constants of the gadolinium(III) complexes are dependent on the ligand basicity. Fig. 4 shows the pH dependence of the conditional stability for the complexes, $[GdL^1]^-$, $[GdL^2]^-$ and $[Gd(dtpa)]^{2-}$. The results for $[GdL^1]^-$ and $[Gd(dtpa)]^{2-}$ are very similar. The conditional stability constants at pH > 11.0 for $[GdL^1]^-$ and $[Gd(dtpa)]^{2-}$ differ by a factor of $10^{0.87}$, similar to that at pH 7.4 ($10^{0.61}$). This reveals that the stability of $[GdL^1]^-$ is similar to that of $[Gd(dtpa)]^{2-}$ at pH 7.4 and 11.0, respectively. But for $[GdL^2]^-$ and $[Gd(dtpa)]^{2-}$ the conditional stability constant at pH > 11 differ by a factor of $10^{2.98}$ which is less than that at pH 7.4($10^{3.76}$). This indicates that the stability of $[GdL^2]^-$ is less significant than those of $[Gd(dtpa)]^{2-}$ and $[GdL^2]^-$ at pH 7.4.

The merit of comparing pM values $\{pM = -\log[M_f]\}$[21] rather than stability constants of the metal complexes is that the pM values give repression to the influence of ligand basicity and metal chelate protonation. The calculation of $[M_f]$ takes into consideration the protonation constants of the ligand and the stability constants of protonated metal complexes [19] The larger the pM value, the higher the affinity of that ligand for the metal ion under the specified conditions. The relative order of the stability constants may change if a different set of conditions (concentration and pH) is used to calculate the pM values. The results given in Table 3 reveal that the H_4L^1 and H_5dtpa are much stronger gadolinium(III) chelating agents than H_4L^2, H_3dtpa-bp and H_3dmdtta. The pM values of $[GdL^1]^-$ and $[GdL^2]^-$ are larger than those of $[CaL^1]^{2-}$ and $[CaL^2]^{2-}$, $[CuL^1]^{2-}$ and $[CuL^2]^{2-}$, and $[ZnL^1]^{2-}$ and $[ZnL^2]^{2-}$, respectively. However, the competition among Gd^{3+}, Ca^{2+}, Cu^{2+} and Zn^{2+} with H_4L^1 seems to favor Gd^{3+} at pH 7.4, indicating that the $[GdL^1]^-$ complex should be stable enough to avoid interference by Ca^{2+}, Cu^{2+} and Zn^{2+}. The stability constants for $[GdL^1]^-$ and $[Gd(dtpa)]^{2-}$ chelates are larger than those of the corresponding $[GdL^2]^-$ and $[Gd(dtpa\text{-}bp)]$ chelates, therefore the pGd values for $[GdL^2]^-$ and

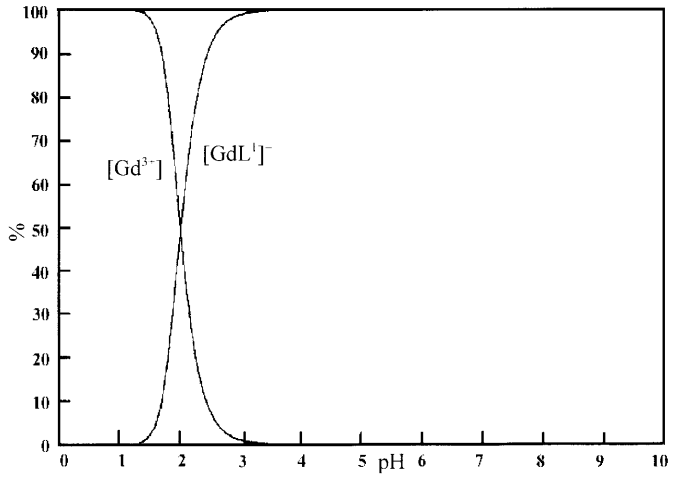

Fig. 5. Species distribution curves for 1.0×10^{-3} mol dm^{-3} $[GdL^1]^-$ system containing a 1:1 molar ratio of Gd(III) to H_4L^1. $T = 25.0 \pm 0.1$°C; $I = 0.10$ mol dm^{-3} (Me_4NNO_3); %, percent relative to 1.0×10^{-3} mol dm^{-3} total H_4L^1 species is 100%.

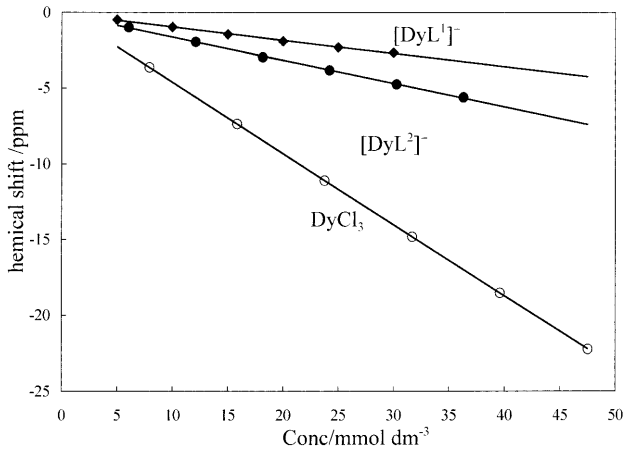

Fig. 6. The Dy(III)-induced water ^{17}O NMR shift versus Dy(III) chelate concentration for solution of (1) $[DyL^1]^-$ (◆); (2) $[DyL^2]^-$ (●); and (3) $DyCl_3$ (○) in D_2O at 25 ± 0.1°C.

[Gd(dtpa-bp)] chelates are ca. 3.55 and 2.74, 3.76 and 3.26 log units less than those of $[GdL^1]^-$ and $[Gd(dtpa)]^{2-}$, respectively. The reason is that H_4L^1 and H_5dtpa have high protonation constants, and therefore formation of their complexes is subject to stronger hydrogen ion competition. However, the p*Gd* value for $[GdL^1]^-$ is only about 0.21 log unit slightly less than that of $[Gd(dtpa)]^{2-}$, because the protonation constant of H_4L^1 is similar to that of H_5dtpa.

Species distribution curves of $[GdL^1]^-$ shown in Fig. 5, generated from the potentiometric data given in Table 2, indicate that there is still some free Gd^{3+} at pH 1, but by pH 3 the complex is fully formed. $[GdL^2]^-$ has been deposited as supplementary material (Fig. 7S). However, the $[GdL^1]^-$ and $[GdL^2]^-$ chelates are dominant species at physiological pH 7.4.

The logarithmic selectivity constant [7] of H_4L^1, H_4L^2, H_3dtpa-bp, H_3dmdtta and H_5dtpa for Gd^{3+} over Zn^{2+}, Ca^{2+} and Cu^{2+} is the difference between $\log K_{GdL}$ and $\log K_{ML}$ ($M = Zn^{2+}$, Ca^{2+} or Cu^{2+}), i.e. $\log K$(Gd–Zn), $\log K$(Gd–Ca) and $\log K$(Gd–Cu) are also listed in Table 2. From the selectivity constants, the $\log K$(Gd–Zn Gd–Ca and Gd–Cu) values of H_4L^1 are similar to that of H_5dtpa but higher than those of H_4L^2, H_3dmdtta and H_3dtpa-bp. Therefore, the H_4L^1 and H_5dtpa show more favorable selectivity toward Gd^{3+} over Zn^{2+}, Cu^{2+} and Ca^{2+} than do H_4L^2, H_3dmdtta and H_3dtpa-bp. The Gd(III) complexes of H_3dmdtta and H_3dtpa-bp have similar stability constants, but H_3dtpa-bp has a much lower selectivity for Gd(III) over Zn(II), which in turn leads to a high toxicity because of Gd(III) displacement by endogenous Zn(II) [7]. However, the selectivity constants ($\log K$(Gd/Zn)) of Gd(III) complexes with H_4L^2 and H_3dtpa-bp are similar and the toxicity of these two complexes should be similar too.

The modified selectivity constant ($K_{sel'}$) for Gd^{3+} over other endogenous metal ions (Cu^{2+}, Ca^{2+} and Zn^{2+}) and H^+ for a ligand can be calculated [14] and is obtained by the incorporation of ligand equilibria with Cu^{2+}, Ca^{2+}, Zn^{2+} and H^+. Table 2 shows the modified selectivity constants of H_4L^1, H_4L^2, H_3dtpa-bp, H_3dmdtta and H_5dtpa at pH 7.4. The concentrations of Ca^{2+}, Cu^{2+} and Zn^{2+} used were 2.5, 1.0×10^{-3} and 5.0×10^{-2} mmol dm^{-3}, respectively [7]. The $\log K_{sel'}$ of H_4L^1 (7.29) is a slightly higher than that of H_5dtpa (7.04), less than that of H_3dmdtta(9.03), but significantly higher than those of H_4L^2 (6.26) and H_3dtpa-bp (5.32). Thus, H_4L^1 forms the gadolinium(III) complex that is more stable than $[GdL^2]^-$ and [Gd(dtpa-bp)] toward transmetallation with endogenous metal ions at pH 7.4.

3.5. Dy(III)-induced ^{17}O water NMR shifts

The Dy(III)-induced water ^{17}O NMR shift versus Dy(III) chelate concentration for a solution of $DyCl_3$, $[DyL^1]^-$ and $[DyL^2]^-$ in D_2O at 25°C were shown in Fig. 6. For the H_4L^1 and H_4L^2 ligands the slopes are -88.2 ($r^2 = 0.9972$) and -154.0($r^2 = 0.9993$) ppm, respectively. The hydration number of dysprosium(III) ion has been proposed as being eight [21–23]. Under the conditions applied in the present study, the slope per Dy(III)-bound water molecule is -58.7 ppm. It can be concluded that the $[DyL^1]^-$ and $[DyL^2]^-$ complexes contain 1.50 and 2.62 inner-sphere water molecules per Dy(III) ion. The number of Ln(III)-bound water molecules in these complexes provides information on the coordination mode of the ligand. For the $[GdL^1]^-$ complex the coordination sites of Gd(III) ion is occupied by one water molecule and eight sites are available for the ligand molecule. By the

binding of three amine nitrogen atoms, four carboxylates and one 2-pyridylmethyl nitrogen atom to the H_4L^1 backbone, a similar coordination mode is found for the coordination sites of the previously studied, the bis(amide) of H_5dtpa derivative is attained [8,9,24,25]. However, two co-ordination site of Gd(III) are occupied by two water molecules and seven sites are available for the H_4L^2 ligand molecule. Therefore, the 2-hydroxypropyl oxygen atom may not coordinate to Gd(III) metal ion in the $[GdL^2]^-$ chelate. This result is also aligned with the conclusion of the thermodynamic stability studies of $[GdL^2]^-$.

3.6. Relaxometric studies of the Gd(III) complex

The rate of the chemical exchange of water from the coordination water to the bulk water could influence the inner sphere relaxation mechanism. The paramagnetic contribution of the solvent longitudinal relaxivity is obtained by the following equation [26]:

$$R_1 = Nq/[55.6\ (T_{1M} + \tau_M)] \quad (2)$$

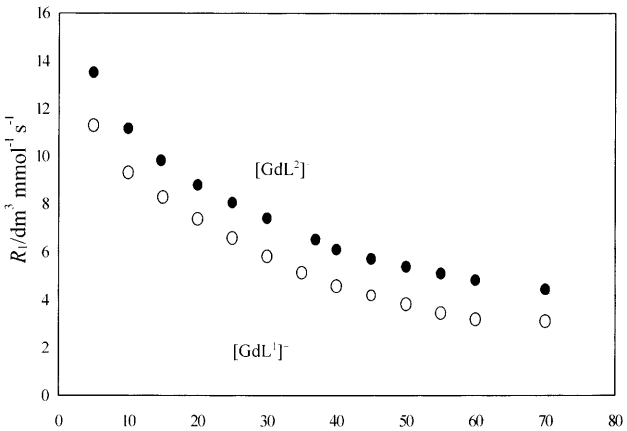

Fig. 7. Temperature dependence of the longitudinal relaxation rate for 0.5–2.0 mmol dm^{-3} solution of $[GdL^1]^-$ (○) and $[GdL^2]^-$ (●) measured at 20 MHz, pH 7.

Table 4
Relaxivities R_1 of gadolinium(III) complexes at 37.0 ± 0.1°C and 20 MHz

Complex	pH	R_1 relaxivity [a]/mmol dm^{-3} s^{-1}
$[GdL^1]^-$	6.7 ± 0.1	4.24 ± 0.03
	limiting [a]	4.27 ± 0.02
$[GdL^2]^-$	6.7 ± 0.1	6.17 ± 0.04
	limiting [a]	6.26 ± 0.03
[Gd(dmdtta)]	7.6 ± 0.1	3.89 ± 0.03
	limiting [a]	4.65 ± 0.05
$[Gd(dtpa)]^{2-}$	7.6 ± 0.1	3.89 ± 0.03
	limiting [a]	4.65 ± 0.05

[a] Average of relaxivity values over the pH range 2–10.

where N represents the molar concentration of the gadolinium(III) complex, q is the number of water molecules bound per metal ion, T_{1M} is the relaxation time of the bound water protons and τ_M is the residence lifetime of the bound water. Because of the opposite temperature dependence of T_{1M} and τ_M two cases can be considered: (1) fast chemical exchange ($T_{1M} \gg \tau_M$); R_1 increases with decreasing temperature and (2) slow chemical exchange ($T_{1M} \ll \tau_M$); R_1 decreases by decreasing the temperature. Fig. 7 shows the temperature dependence of the relaxivity for the complexes $[GdL^1]^-$ and $[GdL^2]^-$ at 20 MHz. A monoexponential decrease of the observed relaxivity upon increasing the temperature in the range 5–70°C was found for the $[GdL^1]^-$ and $[GdL^2]^-$ complexes. This is characteristic of the fast chemical exchange behavior which occurs when the residence lifetime of the coordinated water molecule (τ_M) is much shorter than the relaxation time of the bound water proton (T_{1M}).

Table 4 shows the spin-lattice relaxivity R_1 values of $[GdL^1]^-$, $[GdL^2]^-$, $[Gd(dtpa)]^{2-}$, and [Gd(dmdtta)]. The R_1 value of $[GdL^1]^-$ is similar to those of Gd(III) complexes with H_5dtpa and bis(amide) of H_5dtpa derivatives, but the $[GdL^2]^-$ is higher than those of $[Gd(dtpa)]^{2-}$, $[GdL^1]^-$ and [Gd(dmdtta)] under the same experimental conditions [7–10]. The relaxivity of a paramagnetic metal complex consists of two components: the inner-sphere and outer-sphere relaxivities. Since the basic skeleton of these ligands studied and the shapes and sizes of their gadolinium(III) complexes are similar, it is assumed that the outer-sphere relaxivities are similar. Thus, the observed relaxivity is primarily attributed to the variation in the inner-sphere contribution. The inner-sphere relaxivity is mainly dependent on the hydration number of the gadolinium(III) complex. A larger hydration number results in a higher relaxivity R_1. However, the q value of the complex of gadolinium(III) with H_4L^1 is similar to those of $[Gd(dtpa)]^{2-}$ and [Gd(dmdtta)] [14,25] leading to an almost identical R_1 value. The relaxivity R_1 of $[GdL^2]^-$ is 6.17 mmol dm^{-3} s^{-1}, higher than those of $[GdL^1]^-$, [Gd(dmdtta)] and $[Gd(dtpa)]^{2-}$, and this is undoubtedly due to the larger hydration number of the gadolinium(III) complex.

The relaxivities R_1 for the complexes $[GdL^1]^-$ and $[GdL^2]^-$ at differing pH values are shown in Fig. 8. The relaxivity R_1 curves of $[GdL^1]^-$ and $[GdL^2]^-$ complexes exhibit no pH dependence over the pH range 2–10 and 3–10, respectively. Therefore, no ligand dissociation of gadolinium(III) complexes occurred with a varying pH range of 3–10 in the solution. It is concluded that the hydration number remains constant in this pH range. When the pH range is less than 3 the $[GdL^2]^-$ complex undergoes partial dissociation. The observed relaxivity trend is qualitative agreement with the q values of the Gd(III) complexes. The dissociation of the complex

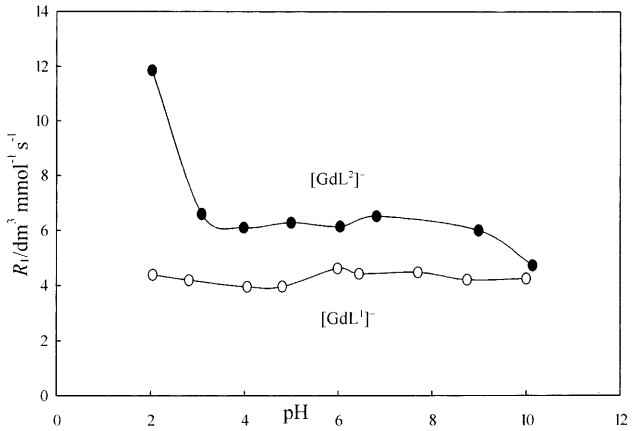

Fig. 8. pH dependence of the relaxivity for the complexes (1) $[GdL^1]^-$ (○) and (2) $[GdL^2]^-$ (●) all in 0.10 mol dm^{-3} buffers at 20 MHz and $T = 37.0 \pm 0.1$°C.

appeared to be more complete for $[GdL^2]^-$ than for $[GdL^1]^-$ in the lower pH range.

The most important prerequisites for potential use as MRI contrast agents are high relaxivity and high stability of the paramagnetic metal chelate. The Gd(III) complex of H_4L^1 is quite stable in aqueous solution, does not dissociate at physiological condition (pH 7.4) and does not exchange with Ca(II), Cu(II) and Zn(II) to an appreciable extent. However, The Gd(III) complex of H_4L^2 is not very stable and may exchange with Cu(II) and Zn(II) in aqueous solution. In conclusion, thermodynamic and relaxometric properties of $[GdL^1]^-$ chelate make it an attractive complex for the development of a new contrast agent for MRI.

4. Supplementary material

Seven figures showing potentiometric titration curves, NMR spectra, and special distribution curves are available on request from the authors (Y.-M.W.).

Abstract

The dichloromanganese(IV) complexes with various bidentate and tetradentate Schiff base ligands, $Mn^{IV}(L')_2Cl_2$ and $Mn^{IV}(L)Cl_2$ have been obtained by the reactions of chloromanganese(III) complexes, $Mn^{III}(L')_2Cl$ and $Mn^{III}(L)Cl$ with hydrogen chloride or by the reactions of acetatomanganese(III) complexes, $Mn^{III}(L')_2OAc$, with chlorine as deep green crystals, where L′H denotes bidentate Schiff base ligands *N*-R-salH (*N*-alkyl-salicylideneamine) and R can be *n*-C_3H_7, *n*-C_6H_{13}, *n*-C_8H_{17}, or *n*-$C_{12}H_{25}$, and LH_2 denotes tetradentate Schiff base ligands X-salenH_2 (*N*,*N*′-disubstituted-salicylideneethylenediamine) or X-salpnH_2 (*N*,*N*′-disubstituted-salicylidenepropanediamine) and X can be H and 5-Br. X-ray structure analysis of the present dichloromanganese(IV) complexes has revealed that two chloride ions coordinate to the central manganese ion in a *trans*-form. © 2000 Elsevier Science Ltd. Keywords: Dichloromanganese(IV) complexes; Bidentate Schiff base ligands; Tetradentate Schiff base ligands; Crystal structures; Photosystem II

1. Introduction

The chemistry of high-valent manganese complexes, Mn(III) and Mn(IV), is interesting in relation to the biological redox systems involving manganese ions, such as oxygen-evolving center (OEC) of Photosystem II in green plants [1–10]. In the OEC of PS II, chloride ions exist near manganese ions as co-factors and it is suspected that the chloride ion may act in proton release, charge neutralization in water splitting or as a ligand to the manganese ions and facilitation of electron transfer [11–15]. However, the details have not yet been made clear. We have reported previously on the preparation and physico-chemical properties of a series of dichloromanganese(IV) complexes [16–18] and their reactivities with water [19,20]. However, their molecular structures have not yet been determined.

In this paper, we describe the molecular structures of a series of dichloromanganese(IV) complexes with bidentate and tetradentate Schiff base ligands, $Mn^{IV}(L')_2Cl_2$ and $Mn^{IV}(L)Cl_2$, respectively, together with those of the acetatomanganese(III) complexes with bidentate Schiff base ligands, $Mn^{III}(L')_2OAc$, which are starting complexes for the preparation of manganese(IV) complexes.

The structures of all $Mn^{IV}(L')_2Cl_2$ are found to be a distorted octahedron, where two bidentate Schiff base ligands (L′) coordinate to the manganese ion in a *trans*-fashion to form an equatorial plane(ONON) and two chloride ions occupy a *trans* axial position. These complexes have a high symmetry and their Cl–Mn–Cl angles are 180.0°. On the other hand, the structures of $Mn^{IV}(L)Cl_2$ are also a *trans*-distorted octahedron, where tetradentate Schiff base ligands (L) coordinate to the manganese ion by a N_2O_2 donor set to form an equatorial plane and two chloride ions occupy a *trans* axial position. However, the angles of Cl–Mn–Cl are found to be 174.5(1)° for Mn^{IV}(salen)Cl_2, 167.9(1)° for Mn^{IV}(5-Br-salen)Cl_2, and 172.6(2)° for Mn^{IV}(5-Br-salpn)Cl_2, where both chloride ions lean toward the chelate ring formed by –N–Mn–N–$(CH_2)_{2/3}$–.

The bond lengths of Mn–Cl observed for all the manganese(IV) complexes are found to be shorter than those for the corresponding chloromanganese(III) complexes, which can be explained by the stabilization effect of chloride ions at higher oxidation states of transition metal elements.

2. Experimental

2.1. Physical measurements

IR spectra were recorded on a Shimadzu Model IR-470 infrared spectrophotometer. Elemental analyses were made on a Yanaco Model CHN-CORDER MT-5.

2.2. Preparation of bidentate and tetradentate Schiff base ligands

All of the bidentate and tetradentate Schiff base ligands were prepared and identified according to the literature [16–18].

2.3. Preparation of manganese(III) complexes with bidentate Schiff base ligands

The acetatobis(*N*-dodecylsalicylideneaminato)manganese(III) complex, Mn^{III}(*N*-Dod-sal)$_2$OAc was prepared by the reaction of bidentate Schiff base ligand, *N*-dodecylsalicylideneamine, *N*-Dod-salH (Dod = *n*-$C_{12}H_{25}$) (0.58 g, 2.0 mmol) and a half molar amount of manganese(III) acetate dihydrate, $Mn^{III}(OAc)_3{\cdot}2H_2O$ (0.27 g, 1.0 mmol) in methanol at 60°C. After 2 h, the resulting precipitates were collected on a glass filter and recrystallized from acetonitrile (MeCN). Other acetatomanganese(III) complexes, Mn^{III}(*N*-R-sal)$_2$OAc, were obtained in the same manner, where R can be *n*-C_3H_7 (Pr), *n*-C_6H_{13} (Hx). The yields of these complexes were about 70%. Single crystals of Mn^{III}(*N*-Pr-sal)$_2$OAc, Mn^{III}(*N*-Hx-sal)$_2$OAc, and Mn^{III}(*N*-Dod-sal)$_2$OAc were used for X-ray crystallographic determination. *Anal.* Calc. for $C_{22}H_{27}MnN_2O_4$ {Mn^{III}(*N*-Pr-sal)$_2$OAc}: C, 60.27; H, 6.21; Mn, 12.53; N, 6.39. The chlorobis(*N*-alkylsalicylideneaminato)manganese(III) complexes, Mn^{III}(*N*-R-sal)$_2$Cl (R = Pr, Hx, Oct, and Dod) were prepared and identified according to the literature [16–18].

2.4. Preparation of manganese(III) complexes with tetradentate Schiff base ligands

Chloro(*N*,*N*′ - di - X - salicylideneethylenediaminato)-manganese(III) complexes, Mn^{III}(X-salen)Cl and chloro(*N*,*N*′-di-5-bromosalicylidenepropanediaminato)-manganese(III) complex, Mn^{III}(5-Br-salpn)Cl were prepared and identified according to the literature [16–18].

2.5. Preparation of dichloromanganese(IV) complexes with bidentate Schiff base ligands

Dichlorobis(*N* - dodecylsalicylideneaminato)manganese(IV) complex, Mn^{IV}(*N*-Dod-sal)$_2$Cl$_2$. To 2-propanol (150 ml) containing Mn^{III}(*N*-Dod-sal)$_2$OAc (1.38 g, 2 mmol) or Mn^{III}(*N*-Dod-sal)$_2$Cl (1.41 g, 2 mmol), a concentrated HCl solution (36%, 0.59 g, 6 mmol) was added drop by drop with stirring at 0°C. The solution changed from greenish brown to deep green with precipitation of deep green crystals. The mixture was stirred for 30 min at 0°C. The crystalline precipitates were collected on a glass filter, washed with 2-propanol and *n*-hexane, and recrystallized from a mixed solvent of dichloromethane (CH_2Cl_2) and *n*-hexane (1:1) in a refrigerator. Other dichloromanganese(IV) complexes with bidentate Schiff base ligands, Mn^{IV}(*N*-R-sal)$_2$Cl$_2$, were obtained in a similar way, where R can be *n*-C_3H_7 (Pr) or *n*-C_8H_{17} (Oct). The yields of these manganese(IV) complexes were about 40%. Dichlorobis(*N*-alkyl-salicylideneaminato)manganese(IV) complexes were also successfully obtained using a Cl_2 solution of 2-propanol instead of a conc. HCl solution. Their yields were about 70%. This means that the manganese(IV) complexes are formed by dispropotionation of the manganese(III) complex when HCl was used. Single crystals of Mn^{IV}(*N*-Pr-sal)$_2$Cl$_2$ (**4**), Mn^{IV}(*N*-Oct-sal)$_2$Cl$_2$ (**5**), and Mn^{IV}(*N*-Dod-sal)$_2$Cl$_2$ (**6**) were used for X-ray crystallographic determination. *Anal.* Calc. for $C_{20}H_{24}Cl_2MnN_2O_2$ {Mn^{IV}(*N*-Pr-sal)$_2$Cl$_2$}: C, 53.35; H, 5.37; Mn, 12.20; N, 6.22. IR spectrum on KBr pellets (cm^{-1}): 2910(s), 2825(s), 1615(s), 1597(m), 1542(m), 1464(m), 1452(s), 1403(w), 1302(s), 1251(w), 1212(w), 1148(m), 1120(w), 1027(w), 909(m), 818(m), 753(m), 637(w), 581(w), 511(w), 480(w), 449(w), 420(w).

2.6. Preparation of dichloromanganese(IV) complexes with tetradentate Schiff base ligands

Dichloro(*N*,*N*′-disalicylideneethylenediaminato)manganese(IV) complex, Mn^{IV}(salen)Cl_2. A diethyl ether solution saturated with Cl_2 was added to a solution of dichloromethane containing Mn^{III}(salen)Cl. The solution changed from brown to deep green, which was concentrated under reduced pressure to yield deep green crystals. They were recrystallized from a mixed solvent of CH_2Cl_2 and *n*-hexane (1:1) in a refrigerator to yield Mn^{IV}(salen)Cl_2·1/2CH_2Cl_2. Moreover, in order to obtain single crystals of Mn^{IV}(salen)Cl_2, they were recrystallized from acetone under slightly reduced pressure, but mixed crystals of Mn^{III}(salen)Cl and Mn^{IV}(salen)Cl_2 were obtained. The yield of this manganese(IV) complex was low (ca. 20%), compared with those for the $Mn^{IV}(L')_2Cl_2$. Single crystals of the mixed crystals of Mn^{III}(salen)Cl and Mn^{IV}(salen)Cl_2 (**7**) were used for X-ray crystallographic determination. *Anal.* Calc. for $C_{16.5}H_{15}Cl_3MnN_2O_2$ {Mn^{IV}(salen)Cl_2·1/2CH_2Cl_2}: C, 45.60; H, 3.48; Mn, 12.64; N, 6.45. Found: C, 45.17; H, 3.55; Mn, 12.68; N, 6.49%. IR spectrum on KBr pellets (cm^{-1}): 2907(w), 1623(s), 1598(m), 1537(m), 1461(w), 1444(s), 1382(w), 1324(w), 1289(s), 1198(w), 1148(w), 1139(w), 1042(w), 1031(w), 901(m), 799(m), 762(m), 750(m), 735(w), 630(m), 584(w), 466(m).

In a similar way, Mn^{IV}(5-Br-salen)Cl_2 was prepared and identified. Single crystals of Mn^{IV}(5-Br-salen)Cl_2 (**8**) were used for X-ray crystallographic determination. *Anal.* Calc. for $C_{16}H_{12}Br_2Cl_2MnN_2O_2$ {Mn^{IV}(5-Br-salen)Cl_2}: C, 34.94; H, 2.20; Mn, 9.99; N, 5.09. Found: C, 34.91; H, 2.11; Mn, 10.2; N, 4.98%. IR spectrum on KBr pellets (cm^{-1}): 2952(w), 2905(w), 1625(s), 1592(m), 1523(m), 1455(s), 1435(m), 1430(m), 1418(m), 1369(m), 1277(s), 1192(w), 1178(w), 1135(w), 1076(w), 1041(w), 825(m), 802(m), 690(m), 683(m), 657(m), 595(w), 548(w), 486(m), 465(w).

Dichloro(*N*,*N*′-di-5-bromosalicylidenepropanediaminato)manganese(IV) complex, Mn^{IV}(5-Br-salpn)Cl_2. The concentrated HCl solution (36%, 0.59 g, 6 mmol) was added to a MeCN solution of Mn^{III}(5-Br-salpn)Cl (1.06 g, 2 mmol). The solution changed from brown to deep green with precipitation of deep green crystals. They were collected on a glass filter, washed with *n*-hexane, and recrystallized from a mixed solvent of CH_2Cl_2 and *n*-hexane (1:1) in a refrigerator. The yield of this complex was 20%. Single crystals of Mn^{IV}(5-Br-salpn)Cl_2 (**9**) were used for X-ray crystallographic determination. *Anal.* Calc. for $C_{17}H_{14}Br_2Cl_2MnN_2O_2$ {Mn^{IV}(5-Br-salpn)Cl_2}: C, 36.21; H, 2.50; Mn, 9.74; N, 4.97. Found: C, 36.37; H, 2.57; Mn, 9.86; N, 4.95%. IR spectrum on KBr pellets (cm^{-1}): 2905(w), 1612(s), 1528(m), 1455(s), 1432(m), 1378(m), 1289(s), 1196(w), 1181(w), 1131(w), 1070(w), 1062(w), 822(m), 808(m), 692(m), 685(m), 648(m), 542(w), 511(w), 454(m).

2.7. X-ray crystallographic measurements

X-ray structure analyses were taken on a Rigaku AFC-7R automatic four-circle X-ray diffractometer.

Single crystals of the manganese(III) complexes and dichloromanganese(IV) complexes were obtained by recrystallization from MeCN and from a mixed solvent of CH_2Cl_2 and *n*-hexane or acetone, respectively. The crystals were mounted on a glass capillary. All the data were collected on a Rigaku AFC-7R four circle automated diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) for **1**, **2**, **5**, **6**, **7** and **9** and Cu Kα radiation ($\lambda = 1.54178$ Å) for **3**, **4** and **8** at 23°C. Unit-cell parameters were obtained from least-squares fit of 25 reflections, $23.85 < 2\theta < 28.10°$ for **1**, $22.79 < 2\theta < 34.06°$ for **2**, $21.81 < 2\theta < 44.48°$ for **3**, $47.32 < 2\theta < 54.67°$ for **4**, $20.74 < 2\theta < 29.26°$ for **5**, $20.54 < 2\theta < 29.53°$ for **6**, $52.58 < 2\theta < 56.70°$ for **8**, $20.50 < 2\theta < 29.34°$ for **9**, and 16 reflections, $20.82 < 2\theta < 28.36°$ for **7**. Three standard reflections were measured every 150 reflections; they showed no systematic decay throughout data collection. The data were corrected for Lorentz and polarization effects. All the calculations were carried out using the TEXSAN [21] crystallographic software package. The structures of the complexes were solved using direct method for **1** (MITHRIL-84) [22], **5** (MULTAN-88) [23], **6** (SAPI-91) [24], **4**, **7**, **8**, **9** (SHELX-86) [25] or Patterson method for **2** (DIRDIF-92 PATTY) [26], **3** (SAPI) and expanded using Fourier techniques [27]. These structures were refined by the full-matrix least-squares technique with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were introduced in calculated positions but not refined. Crystallographic data for the complexes are summarized in Tables 1–3.

3. Results and discussion

Previously, we have demonstrated that some of the dichloromanganese(IV) complexes with bidentate Schiff base ligands can generate molecular oxygen by oxidation of water, which may be considered as possible models for OEC in PSII [19,20]. In this case, chloride ions, which are proposed to be an important co-factor

of the OEC, function to stabilize an oxidation state of manganese(IV). However, a series of dichloromanganese(IV) complexes with Schiff base ligands has been found to be usually unstable toward moisture even in the solid state and decomposes to the reduced manganese complexes. This may be caused by displacement of the coordinated chloride ions with water molecules. We have obtained single crystals of dichloromanganese(IV) with Schiff base ligands under absolutely moisture-free conditions.

3.1. Structure of $Mn^{III}(L')_2OAc$

Molecular structures of Mn^{III}(*N*-Pr-sal)$_2$OAc (**1**) and Mn^{III}(*N*-Hx-sal)$_2$OAc (**2**) and Mn^{III}(*N*-Dod-sal)$_2$OAc (**3**) are shown in Figs. 1–3, respectively. Selected bond lengths and angles are listed in Table 4. All the manganese(III) complexes, $Mn^{III}(L')_2OAc$ have a mononuclear distorted octahedral structure which comprises *cis*-form coordination of two Schiff base ligands and bidentate acetato moiety. Furthermore, these complexes belong to a $C2$ point group where a $C2$ axis passes through two carbon atoms of the acetato ligand to a manganese ion. In addition, a crystallographic $C2$ axis exists in the complexes of R = Hx and Dod. Since a significant Jahn–Teller distortion could not be observed in these complexes, the structures are considered to be trigonal bipyramidal rather than octahedral.

3.2. Structure of $Mn^{IV}(L')_2Cl_2$

Molecular structures of Mn^{IV}(*N*-Pr-sal)$_2Cl_2$ (**4**), Mn^{IV}(*N*-Oct-sal)$_2Cl_2$ (**5**) and Mn^{IV}(*N*-Dod-sal)$_2Cl_2$ (**6**) are shown in Figs. 4–6, respectively. Selected bond lengths and angles are listed in Table 5. Complex **4** crystallized in the monoclinic space group $P2_1/a$. The manganese ion located on the center of symmetry in a N_2O_2 plane. Two chloride ions occupied a *trans* axial position and two bidentate Schiff base ligands occupied an equatorial plane. Adoption of this configuration places to all the coordination atoms (Cl, N, O) *trans*-position each other: Two chloride ions and Schiff base ligands are equivalent and two bond lengths of Mn–Cl, Mn–O and Mn–N are equal. The Mn–O (1.849(6)–1.851(3) Å) and Mn–N (2.024(6)–2.039(5) Å) bond lengths are typical for several observed octahedral manganese(IV) complexes with Schiff base ligands [28–39]. The phenyl ring of the Schiff base ligand is parallel with the other one.

Complexes **5** and **6** crystallized in the monoclinic space group $C2$. The manganese ion located in a N_2O_2 plane, belonging to a $C2$ symmetry including two chloride ions and two Schiff base ligands. Adoption of this configuration places the donor atoms (Cl, N, O) to *trans*-position each other. In these cases, the two phenyl rings are bending to the same direction, forming an umbrella. Therefore, the two bond lengths of Mn–Cl are no longer equivalent: The bond length between Mn and Cl which is coordinated to the manganese ion from the top position of umbrella is slightly longer than the other. The bond lengths of Mn(1)–Cl(1) and Mn(1)–Cl(2) are 2.270(2) and 2.248(2) Å for complex **5** and 2.272(3) and 2.243(3) Å for complex **6**. Moreover, the bond lengths of Mn(1)–Cl(1) of complexes **5** and **6** are also longer than that of complex **4** (2.258(2) Å), whereas the bond lengths of Mn(1)–Cl(2) are shorter. This may be caused by the difference between the interaction of the bottom chloride ion with a phenyl group. For complexes **5** and **6**, the chloride ion placed in the bottom position of the umbrella is just wrapped

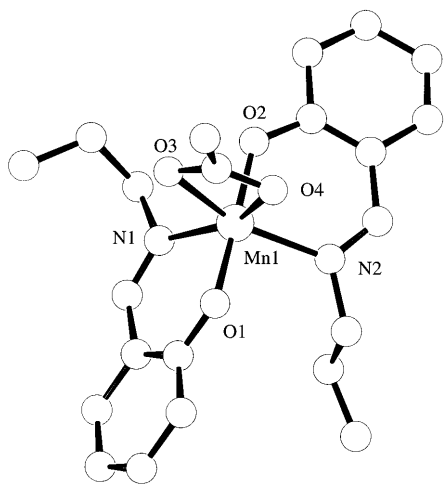

Fig. 1. The molecular structure of Mn^{III}(*N*-Pr-sal)$_2$OAc (**1**) with hydrogen atoms omitted for clarity.

with two phenyl rings, which may have the affect of pressing it up toward the central manganese ion, whereas for complex **4** two chloride ions may interact with only one phenyl ring. The angles between a mean plane of N_2O_2 and phenyl ring are 41.52 for complex **5** and 42.12° for complex **6** and the torsion angles of two phenyl rings are 20.76 for complex **5** and 21.06° for complex **6**, respectively. The Cl–Mn–Cl angles of these three complexes are 180.0°, and their O–Mn–O and N–Mn–N angles are close to 180.0°. Complex **4** is found to be the most symmetric among these complexes.

3.3. Structure of $Mn^{IV}(L)Cl_2$

Molecular structures of Mn^{IV}(salen)Cl_2 (**7**), Mn^{IV}(5–Br-salen)Cl_2 (**8**), and Mn^{IV}(5-Br-salpn)Cl_2 (**9**) are shown in Figs. 7–9, respectively. Their selected bond lengths and angles are listed in Table 6. Complex **8** crystallized in the orthorhombic space group $Pna2_1$. Its molecular structure has a distorted octahedral

Table 4

N(1)–Mn(1)–N(2)	110.4(1)	O(2)–Mn(1)–O(2)*	59.6(1)
$Mn^{III}(N\text{-Dod-sal})_2OAc$ (**3**)			
Mn(1)–O(1)	1.846(5)	Mn(1)–O(2)	2.201(7)
Mn(1)–N(1)	2.109(7)		
O(1)–Mn(1)–O(1)*	179.2(4)		
O(1)–Mn(1)–N(1)	88.8(3)	O(1)–Mn(1)–N(1)*	90.8(3)
O(1)–Mn(1)–O(2)	89.7(3)	O(1)–Mn(1)–O(2)*	91.0(3)
N(1)–Mn(1)–N(2)	109.7(4)	O(2)–Mn(1)–O(2)*	59.4(4)

configuration, in which the N_2O_2 donor set of the salen coordinated to the manganese ion to form an equatorial plane and the manganese ion displaced on a mean plane of N_2O_2 by 0.082 Å. Two chloride ions occupied a *trans* axial position and leaned toward the chelate ring formed by –N–Mn–N–$(CH_2)_2$– and the angle of Cl(1)–Mn(1)–Cl(2) was 167.9(1)°. This may be caused by the electronic repulsion between the chloride ions and the phenolic oxygen atoms, because electron negativity of oxygen atom is larger than that of nitrogen atom. Although one phenyl ring of the salen forms a co-plane with the mean plane of N_2O_2 (2.68°), the other one clearly deviates from this plane about 18.45°. Thus

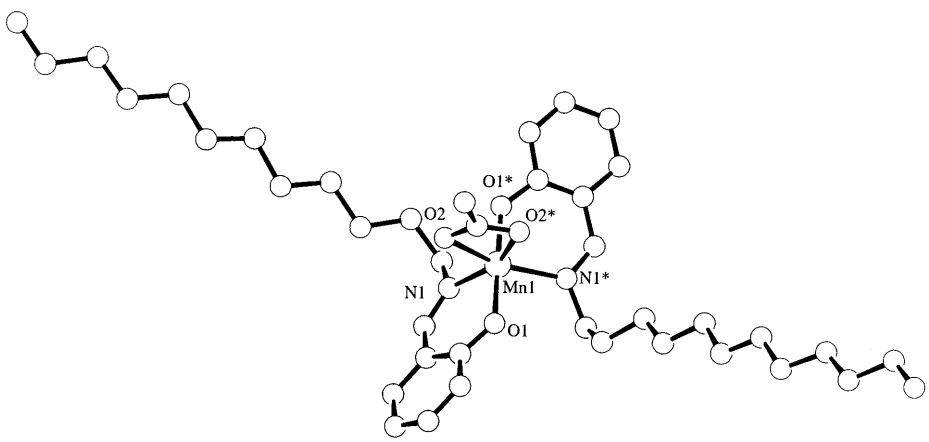

Fig. 3. The molecular structure of $Mn^{III}(N\text{-Dod-sal})_2OAc$ (**3**) with hydrogen atoms omitted for clarity.

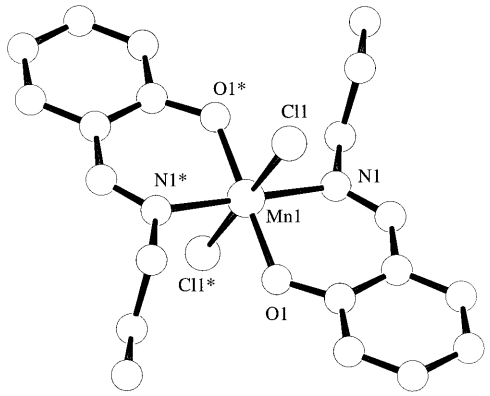

Fig. 4. The molecular structure of $Mn^{IV}(N\text{-Pr-sal})_2Cl_2$ (**4**) with hydrogen atoms omitted for clarity.

two chloride ions are no longer equivalent, which reflects difference in the Mn–Cl bond lengths: The bond length of Mn(1)–Cl(1) is 2.342(4) Å, of which the Cl(1) is coordinated to the manganese ion from the opposite site of the deviated phenyl ring, which is longer than the bond length of Mn(1)–Cl(2), 2.190(4) Å.

Complex **9** crystallized in the monoclinic space group $P2_1/c$. This complex consists of crystallographically independent two molecules. The molecular structure of complex **9** is very similar to that of $Mn^{IV}(salpn)Cl_2$ reported previously [28], in which the 5-Br-salpn coordinated to the manganese ion to form an equatorial plane by the N_2O_2 donor set and two chloride ions occupied a *trans* axial position. The central manganese ion displaced on a mean plane of N_2O_2 by 0.005 Å. Like complex **8**, two chloride ions leaned toward the chelate ring formed by –N–Mn–N–$(CH_2)_3$– and the angle of Cl(1)–Mn(1)–Cl(2) was 172.6(2)°. However, the two phenyl rings of the 5-Br-salpn are bent in the same direction, forming an umbrella, which is very similar to those observed for $Mn^{IV}(N\text{-Dod-sal})_2Cl_2$ and $Mn^{IV}(N\text{-Oct-sal})_2Cl_2$ mentioned above. The angle between one phenyl ring and a mean plane of N_2O_2 is 13.81° and the other angle is 28.81°. Moreover, the torsion angle between two phenyl rings are 42.58°, which is larger compared to those for complexes **5** and **6**. Thus, the bond lengths of Mn(1)–Cl(1) and Mn(1)–Cl(2) are not equivalent: the former is 2.281(4) and the latter 2.241(4) Å, where Cl(1) and Cl(2) denote a chloride ion coordinated to the manganese ion from the top and bottom of the umbrella, respectively. Moreover, a mean Mn–Cl bond length (2.261 Å) of this

complex is slightly shorter than that of complex **8** (2.266 Å) and that of $Mn^{IV}(salpn)Cl_2$ (2.2715 Å). This difference in the bond lengths of Mn–Cl may be caused by the difference in interaction between a chloride ion and a phenyl ring. The chloride ion placed in the bottom position is just wrapped with two phenyl rings, which may act to press it up toward the central manganese ion.

Complex **7** crystallized in the monoclinic space group $P2_1$ as mixed crystals with $Mn^{III}(salen)Cl$, which included one acetone molecule as a crystalline solvent. The molecular structure of this complex is very similar to that of complex **8**. The manganese ion displaced on a mean plane of N_2O_2 by 0.031 Å. Two chloride ions

O(1)–Mn(1)–O(2)	84.7(4)	O(1)–Mn(1)–N(1)	90.8(4)
O(1)–Mn(1)–N(2)	173.2(4)	O(2)–Mn(1)–N(1)	175.5(4)
O(2)–Mn(1)–N(2)	88.6(4)	N(1)–Mn(1)–N(2)	95.9(4)

occupied a *trans* axial position leaned toward the chelate ring formed by –N–Mn–N–$(CH_2)_2$– and the Cl(1)–Mn(1)–Cl(2) angle was 174.5(1)°. One phenyl ring of the salen is almost co-planar (4.00°) with a mean plane of N_2O_2 but the other one deviates by 16.13°. Thus, like complex **8**, two chloride ions are not equivalent: the bond lengths of Mn–Cl are 2.299(3) for Mn(1)–Cl(1) and 2.277(4) Å for Mn(1)–Cl(2), where the Cl(1) is placed at the position of the deviated phenyl ring.

All of the dichloromanganese(IV) complexes with tetradentate Schiff base ligands have a distorted octahedral structure. Comparison of the bond lengths of Mn–Cl and Mn–O between complexes **7** and **8**, and those between complex **9** and Mn^{IV}(salpn)Cl_2 has revealed that the introduction of 5-bromo substituent to the phenyl group induced shortening both bond lengths. Moreover, the Cl(1)–Mn(1)–Cl(2) angle has been found to be smaller in the complexes having 5-bromo substituent than in the non-subsituted complexes. These may be affected by both electron-withdrawing and steric effects of 5-bromo group.

4. Conclusions

X-ray crystallographic analyses have revealed that the dichloromanganese(IV) Schiff base complexes have a distorted octahedral structure, in which two chloride ions occupied a *trans* position and the N_2O_2 donor set of the Schiff base ligands coordinated to the central manganese ion to form an equatorial plane. Moreover, a configuration of the phenyl rings of the Schiff base ligands reflects the bond lengths and angles of Mn–Cl coordination environment.

5. Supplementary data

Supplementary data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 142065–142073 for complexes **1**–**9**, respectively. Copies of this information are available free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of multi-component ESR spectra of fluid aqueous solutions containing glycyl-L-histidine and copper(II) at 1:1 and 20:1 concentration ratios, taken in a circulating system at various pH, have been analysed simultaneously. The isotropic ESR parameters (g-factors, hyperfine coupling constants for the ^{63}Cu and ^{65}Cu isotopes and maximum four non-equivalent ^{14}N nuclei, and relaxation parameters) and the formation constants of the various complexes were optimized. In the acidic region, the new species $[CuLH_2]^{3+}$, has been shown and the formation of the pH-metrically identified species $[CuLH]^{2+}$, $[CuL]^{+}$ and $[CuLH_{-1}]$ has been supported. The coordination in the first three complexes is reminiscent of that in simple dipeptides: it is likely to take place at first by the carboxylate O, then by the amino N and peptide O, and then by the amino N, deprotonated peptide N and carboxylate O atoms in equatorial positions, respectively, while the imidazole ring remains protonated. In the species $[CuLH_{-1}]$, the non-protonated imidazole nitrogen displaces the carboxylate oxygen from the equatorial coordination. In the alkaline region of the equimolar solutions the spectra could be described consistently in terms of the formation of four species: three of them, the complex $[Cu_2L_2H_{-3}]^{-}$ and the two coordination isomers of the complex $[CuLH_{-2}]^{-}$ are ESR-active, while the tetramer $[Cu_4L_4H_{-8}]^{4-}$ is ESR-inactive. For the complex $[CuLH_{-2}]^{-}$, one of the isomers is the species $[CuLH_{-1}(OH)]^{-}$, while the other one has the imidazole ring deprotonated. At ligand excess the region pH 7–10 is dominated by the pH-metrically identified complexes $[CuL_2]$ and $[CuL_2H_{-1}]^{-}$. In these species the first ligand is bound equatorially by the amino, deprotonated peptide and imidazole nitrogen atoms. The second dipeptide is co-ordinated either by the amino nitrogen in equatorial and the peptide oxygen in axial position (4N isomer), or vice versa (3N isomer) in both bis complexes. © 2000 Elsevier Science Ltd. 1. Introduction

Owing to their biological importance, the copper(II) complexes of glycyl-L-histidine [1–5] and related peptide ligands [6–9] have been extensively studied. The compositions and the formation constants of most species are known, though the formation of the various oligonuclear complexes is under debate, and the divergences in the literature formation constants of the bis complexes are unusually high. The coordination modes are less understood, since a new donor group, the imidazole ring, further increases the variety of possible structures, as compared to the simple dipeptides. Some authors stressed the similarities between the coordination properties of glycyl-L-histidine and simple dipeptides: in strongly alkaline solutions the proton loss of the equatorial water molecule was suggested to dominate, resulting in the formation of the $[CuLH_{-1}(OH)]^{-}$ complex [1,3,5,10]. Other authors [2] assumed the deprotonation of the pyrrolic NH group and the formation of the tetrameric complex $[Cu_4L_4H_{-8}]^{4-}$. For the bis complexes it is generally accepted that one of the peptide nitrogens is deprotonated, i.e. the correct formulae for these complexes are $[Cu(LH_{-1})(LH)]$ and $[Cu(LH_{-1})L]^{-}$, respectively [1–5] and a tridentate equatorial ligation of the deprotonated dipeptide is

proposed. The other ligand is suggested to be bound by the imidazole nitrogen atom [1–3,8,9] in both bis complexes, i.e. the previous studies have led to the conclusion that even the non-protonated amino group of the 'L' ligand does not bind to the copper. At the same time, for the analogous $[Cu(LH_{-1})L]^{-}$ (and also $[CuL]^{+}$) complexes of the simple dipeptides, fairly stable structures are formed by the simultaneous coordination of the amino nitrogen and the peptide oxygen atoms [11].

ESR spectroscopy can provide valuable evidence on the coordination modes. In the case of minor species and/or isomeric equilibria this requires the decomposition of overlapping multi-component spectra. Previous studies were based upon the analysis of the resolved nitrogen superhyperfine structure of the high-field ^{63}Cu peak in the isotropic ESR spectra. The measured band was described in terms of two component bands [12–14]. Recently we have developed a new program [15] for the overall analysis of multi-component (up to four components) ESR spectra which was used to determine the ESR parameters and the relative concentrations of minor and major species in several copper(II)–dipeptide [16] and amino acid [17,18] systems.

Very recently we applied a basically new approach to analyse the multi-component isotropic ESR spectra: instead of the separate simulation of experimental curves we carry out a simultaneous fit for a whole series of a maximum of 36 spectra. The method allows determination of both the formation constants and the ESR parameters for a maximum of ten active species with a great confidence [19]. In the present work we report on the ESR-spectroscopic study of the copper(II)-glycyl-L-histidine system. We aimed to identify all the complexes including possible coordination and geometric isomers forming in liquid aqueous solutions, to obtain their formation constants, and to characterize the coordination modes on the basis of the ESR parameters.

2. Experimental

2.1. Reagents and solutions

The glycyl-L-histidine ligand–denoted by HL in its neutral form from FLUKA and other reagents from Reanal (Hungary) were of analytical grade and were used without further purification. The copper(II) concentration of the solutions was 2 or 5 mmol dm^{-3} at a ligand-to-metal concentration ratio 1:1, and 5 mmol dm^{-3} at a 20-fold ligand excess. The optimum conditions for the ESR measurements (concentrations and pH) were chosen according to the requirement that even the less stable species form in as high concentration as possible to obtain the most reliable parameters. Preliminary species distribution curves were calculated by the PSEQUAD program [20] from literature formation constants [1,2]. The pH was adjusted with HCl, then NaOH to an accuracy of 0.01 pH units using a Radelkis OP208/1 pH meter equipped with a Radiometer GK2401C combined glass electrode. The electrode was calibrated with IUPAC Standard Buffers from Radiometer.

2.2. ESR measurements

The ESR spectra were recorded at r.t. (291 K) under argon atmosphere in a circulating system. All the details are given in our previous work [18].

2.3. Evaluation of spectra

Before the analysis, the 'glass signal' (the curve of the capillary tube filled with distilled water, together with the manganese peaks) was subtracted from the spectra. Since the copper(II) chloride, used to make the stock solution, was a natural mixture of isotopes, the spectrum of each species was calculated as the sum of spectra containing ^{63}Cu and ^{65}Cu weighted by their abundance in nature. The different widths of copper hyperfine lines were taken into consideration by fitting the relaxation parameters α, β, γ, where $\sigma_{MI} = \alpha + \beta M_I + \gamma M_I^2$. The parameter g_o, the hyperfine (hf) coupling constant A_o, the nitrogen superhyperfine (shf) coupling constants a_{No}, the above relaxation parameters, and the formation constant of each ESR-active complexes were varied, until the overall sum of the squares of differences between the calculated and measured intensities (overall SSQD) reached its minimum. The quality of fit for each spectrum was shown by the average square deviation SQD (i.e. SSQD divided by the number of spectral points, 500). The sensitivity of the spectral fit to the various parameters was characterized by the CNF value. It is defined as the variation of the respective parameter that increases the overall SQD by the value of the average square noise, while the other parameters are kept constant. (The overall SQD is the sum of the SQD values over the whole series of spectra under analysis. The square noise obtained from the lowest- and the highest-field parts of each spectrum was averaged over the whole series, resulting in the average square noise.)

The series of 40 spectra has been evaluated by the 2D_EPR program [19]. Since in this system more than ten ESR-active species are forming (see below), the experimental curves were evaluated in two steps. At first, all the spectra of equimolar solutions in the pH range 2.5–12.2 and the curves taken at ligand excess between pH 2.5 and 6.4 were analysed simultaneously, fitting the ESR parameters and the formation constants of each ESR-active species, except for the complex $[CuL_2H_{-1}]^{-}$. In the second step the same spectra of

equimolar solutions, though only below pH 7, and the same spectra at ligand excess together with additional curves up to pH 10 (a series of 23 spectra) were evaluated simultaneously: now the data for both bis complexes and those for the mono species forming in acidic solutions (see below) were optimized. The parameters obtained for the same complexes agreed excellently: the divergences in g_o, in the parameters of field dimension, and in the formation constants were less than 0.0002, 0.3 G and 0.05 log units, respectively. Here we report their averages.

For the determination of the formation constant of the inactive species, the difference of the analytical and the calculated total copper(II) concentration was minimized.

The coupling constants and the relaxation parameters of field dimension are given in gauss (G) units throughout the paper; $1\ G = 10^{-4}$ T.

3. Results and discussion

3.1. Spectral fitting

The rate of interconversion between the various complexes was regarded to be slow on the ESR time-scale, since the experimental curves could be well described as sums of individual spectra. A Lorentzian lineshape gave a good fit in all cases: the average deviation of the calculated and measured intensities was 1.4–1.9 times as much as the noise. The spectral fit was fairly sensitive to the formation constant of each species in our model: the CNF values were 0.05–0.08 log units. The typical CNF for the g_o was $2–10 \times 10^{-4}$, while for the A_o it was 0.2–1 G. In the cases of aqua, the $[CuLH_2]^{3+}$ and $[CuLH]^{2+}$ complexes, and particularly the dimeric species of very broad spectral lines, higher CNF values (0.001–0.004 for g_o and 2–4 G for A_o) were found. The CNF values for the relaxation parameters were typically 0.2–5 G, the highest values were the α parameters of the above-mentioned four species again. In the case of the shf coupling constants, the CNF was 0.5–1.6 G (4–15% of a_{No}), with the exception of the $[CuLH]^{2+}$ complex, where the fit was only slightly sensitive to a_{No}. For isomer 1 of the $[CuLH_{-2}]^{-}$ complex the CNF values of the coupling constants and the relaxation parameters were intermediate between those of the above two groups of complexes.

3.2. Verification of the equilibrium model

According to the pH-potentiometric studies [1–9] in the acidic region the aqua complex is displaced by the mono complexes $[CuLH]^{2+}$, $[CuL]^{+}$ and $[CuLH_{-1}]$. In strongly acidic media, however, these four species proved to be insufficient for the consistent description of ESR spectra: it was necessary to also imply the complex $[CuLH_2]^{3+}$, otherwise the parameters for the aqua complex differed significantly from those obtained in the absence of the ligand, and the SQD values increased by 5–10% at ligand excess. The formation constants obtained from the ESR analysis for the above pH–potentiometrically identified species agree well with the literature values (Table 1), and so the concentration distribution curves in the acidic pH region are in good accordance with those calculated from the pH–potentiometric formation constants averaged over the data at 25°C [1,2,4] (Fig. 1).

The pH–potentiometric studies gave a controversial description for the alkaline region of equimolar solutions. According to Brookes and Pettit [1] the $[CuLH_{-1}]$ complex is displaced by the species $[Cu_2L_2H_{-3}]^{-}$, then $[CuLH_{-2}]^{-}$ with increasing pH. Other authors did not take into consideration the dimer [2–6]. Sóvágó and co-workers [2] regarded the deprotonation of the $[CuLH_{-1}]$ complex as the proton loss of the pyrrolic nitrogen, leading to the formation of the species $[Cu_4L_4H_{-8}]^{4-}$, but they did not report the formation constant for the tetramer. For other, related systems an ESR-inactive tetramer and an ESR-active monomer were shown [8,9] under similar conditions.

For the glycyl-L-histidine ligand in moderately alkaline media, where the proton loss of the $[CuLH_{-1}]$ complex starts, the measured ESR curves contain a non-resolved component spectrum which can be as-

signed to the dimeric complex $[Cu_2L_2H_{-3}]^{-}$. Omitting this species the spectral fit is poor, particularly in the region pH 9–10 (Fig. 2), where the SQD is increased by 80–100%. This species was proposed also for dipeptides with non- and weakly co-ordinating side-chains [21].

Upon a further raise in pH the spectra revealed a considerable decrease in intensity (Fig. 3) in parallel with the deprotonation of the complexes $[CuLH_{-1}]$ and $[Cu_2L_2H_{-3}]^{-}$, suggesting the formation of an ESR-inactive species: the tetramer $[Cu_4L_4H_{-8}]^{4-}$ which was suggested previously on the basis of spectroscopic evidence [2,8,9]. For the satisfactory description of the spectra of the monomer species over pH 11 a two-component model proved to be necessary: this resulted in a 20–40% reduction of the SQD compared to the one-component model (Fig. 3) which indicates a coordination isomerism in the case of the species $[CuLH_{-2}]^{-}$.

At ligand excess, in nearly neutral and moderately alkaline media the species $[CuL_2]$ and $[CuL_2H_{-1}]^{-}$ have been shown by the pH–potentiometry [1–9]. The ESR spectra reveal several kinds of coordination again

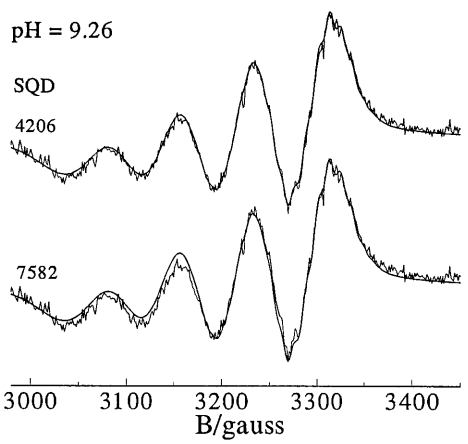

Fig. 2. Experimental ESR spectrum taken in equimolar (5 mM) solution at pH 9.26 together with the calculated curve, taking into consideration the $(Cu_2L_2H_{-3})^{-}$ complex (upper spectra), or omitting the dimer species (lower curves).

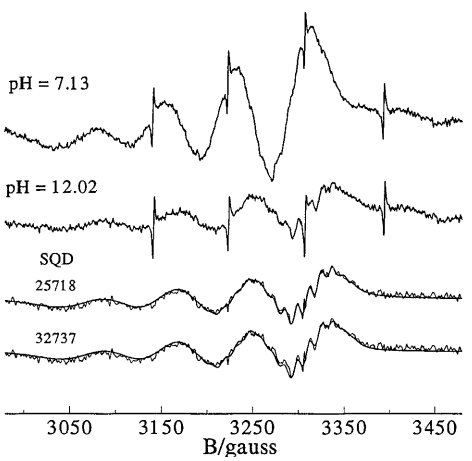

Fig. 3. ESR spectra in equimolar (5 mM) solution at pH 7.13 and 12.02. At higher pH the curves from top to bottom are the measured spectrum, then the corrected curve after subtracting the 'glass signal', together with the spectrum calculated as the sum of two component spectra, and finally the corrected curve together with a one-component calculated spectrum.

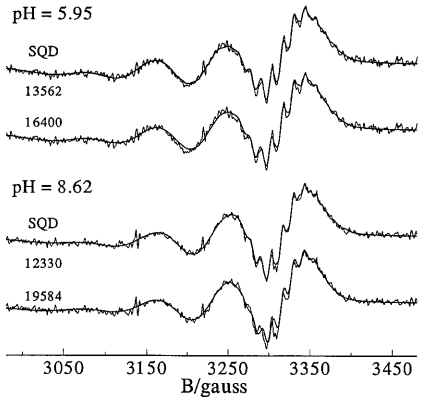

Fig. 4. ESR spectra taken at twenty-fold ligand excess at pH 5.95 and 8.62, at the maximum concentration of the $[CuL_2]$ and $[CuL_2H_{-1}]^-$ complexes, respectively, together with the curves calculated assuming two component spectra, one with a three-nitrogen, the other with a four-nitrogen shf splitting (upper spectra), or as one spectrum with a four-nitrogen shf pattern (lower curves).

for both complexes. The best spectral fit could be achieved with the assumption of two component spectra, where the ESR curve of higher g_o and A_o is described by a three-nitrogen shf pattern, while the other one by a four-nitrogen splitting ('3N + 4N' model). At ligand excess over pH 5.5, where the total concentration of the bis complexes exceeds 60%, the SQD increased by 20–50%, if one of the bis complexes was described by a one-component curve. (The spectral fit for the various models is shown in Fig. 4.)

When a 4N shf pattern ('4N + 4N' model) was applied to both component spectra of the bis complexes, the SQD values increased by about 3–4% up to pH 6.5 (near the maximum concentration of the $[CuL_2]$ complex, Fig. 1), then by 8–10% over pH 7 (where the $[CuL_2H_{-1}]^-$ complex is the major or the predominant species, Fig. 1). In the case of the $[CuL_2]$ complex, a slight impairing of the spectral fit cannot exclude alone the '4N + 4N' model. The '3N + 4N' model, in turn, was supported for this species also by the close similarity of the ESR parameters and the absorption spectra to those of the $[CuL_2H_{-1}]^-$ complex. The formation constants for the various copper(II)-glycyl-L-histidine complexes are summarized in Table 1, while their ESR parameters can be found in Table 2.

It should be noted that all the above bis and deprotonated mono complexes together with the tetramer proved to be insufficient for the consistent description of ESR spectra taken at ligand excess over pH 10. New deprotonation processes (the proton loss from the pyrrolic nitrogens or/and the second peptide nitrogen of bis complexes) may occur, resulting in even more species of similar parameters and relatively low concentration, which does not allow for an exact analysis.

3.3. Coordination modes of various species

3.3.1. Mono complexes and oligomers

For the $[CuLH_2]^{3+}$, $[CuLH]^{2+}$ and $[CuL]^+$ complexes of glycyl-L-histidine the parameters g_o and A_o (Table 2) are nearly equal to the corresponding data for the $[CuLH]^{2+}$, $[CuL]^+$ and $[CuLH_{-1}]$ complexes of glycylglycine [16] and glycyl-L-serine [18], respectively. This suggests that the imidazole ring remains protonated in the above species, and the coordination is similar to the corresponding complexes of the simple dipeptides (Fig. 5).

In the case of the $[CuLH_{-1}]$ complex the three-nitrogen shf pattern of the spectrum indicates that the carboxylate oxygen is replaced by the imidazole nitrogen atom in the equatorial coordination (Fig. 5). The tridentate equatorial ligation by nitrogen donors was proved by crystallographic studies [22] in solid state, and it was stated [22] that the carboxylate group of the equatorially co-ordinated dipeptide cannot bind to the same metal ion. In solution this structure was supported also by visible spectral evidence [2,8,9].

The ESR spectrum of unresolved hf structure (Fig. 6) for the complex $[Cu_2L_2H_{-3}]^-$ reflects on a magnetic dipole interaction between the paramagnetic centres, corresponding to the dimer structure. The coupling in the glycyl-L-histidine complex seems to be weaker than in the complexes of simple dipeptides that are diamagnetic [18,21].

For the $[CuLH_{-2}]^-$ complex it is rather difficult to assign the spectra of the isomers. Most likely the deprotonation takes place from either the pyrrolic nitrogen or the equatorial water molecule. For the analogous complexes of simple dipeptides only the latter process is possible, and mixed hydroxo complexes are formed. For these species a striking feature of the ESR spectra is the well-resolved shf splitting by equivalent nitrogen donors [10,16,18,23]. It is the spectrum of isomer 2 that shows a similar character; hence we assigned it to the mixed hydroxo complex. Accordingly, isomer 1 was regarded to have the pyrrolic nitrogen deprotonated (Fig. 5).

The tetramer $[Cu_4L_4H_{-8}]^{4-}$ is diamagnetic which indicates a strong co-operation between the copper(II) ions. This is likely to take place through the deprotonated imidazole rings which act as bidentate ligands connecting the neighbouring copper(II) ions, and simultaneously increase the number of equatorial nitrogen donors to four around the metal ions. The latter structure was assumed to explain the low wavelength of the d–d absorption band in equimolar solutions near pH

12 in the case of glycyl-L-histidine [2] and of related ligands [8,9].

3.3.2. Bis complexes

It is generally accepted that in the bis complexes only one of the peptide nitrogens is deprotonated, and the deprotonated ligand is bound to the copper(II) as in the ($CuLH_{-1}$) complex [1,2,8,9]. For the other ligand a monodentate coordination through the imidazole nitrogen has been suggested for both bis complexes [1,2,8,9]. The amino group was assumed to be protonated in the $[CuL_2]$ complex, and then to lose the proton simultaneously with the amino group of the free ligand, without binding to the copper(II). The arguments for this are (1) the deprotonation pK of the $[CuL_2]$ complex (7.5–8.4 from the data in Table 1) can be regarded nearly identical with the pK (8.2) for the deprotonation of the amino group in the free ligand, (2) for the glycyl-L-histidyl-glycine the deprotonation enthalpy of the $[CuL_2]$ complex is near the corresponding value for the amino group of the free ligand, and (3) the absorption [2,8,9] and CD [8] spectra of the $[CuL_2]$ and $[CuL_2H_{-1}]^{-}$ complexes are closely similar.

At the same time, many examples show that the coordination of the amino group is favoured if it can take part in a five-membered chelate ring by the bidentate binding of the ligand, even if the other group contains only a relatively weak oxygen donor, and only an equatorial–axial coordination can occur. (1) In a comprehensive ESR study of the copper(II)–histamine and L-histidine systems we have pointed out that the monodentate coordination of the histamine in its 'LH' form really takes place by the imidazole nitrogen; in the corresponding L-histidine complexes, however, a bidentate coordination by the amino and carboxylate groups occurs, with the proton loss of the amino group at significantly lower pH than in the free ligand [18]. (2) In the $[Cu(LH_{-1})L]^{-}$ complexes of simple dipeptides the amino group of the 'L' ligand, together with the peptide oxygen, binds to the metal ion at a relatively low pH where it is in a protonated state in the free ligand [11,16,19]. It occupies either the fourth equatorial position, while the oxygen is co-ordinated axially, or, in the other isomer, the above donors are interchanged [16,19]. This mode of coordination is supported by visible absorption data too [23].

As we have observed great similarities in the important features of the ESR spectra for the $[CuL_2H_{-1}]^{-}$ complex of simple dipeptides and of glycyl-L-histidine, we assume the same coordination modes, with the only

difference in the nature of the third donor atom of the deprotonated dipeptide (Fig. 5). The analogies are as follows. The ESR analysis indicates isomeric equilibria in both cases. One of the isomers is characterized by a relatively high g_o and low A_o, in accordance with the 2N [16,19] or 3N (this work) superhyperfine splitting of spectra, which suggest that from the nitrogens, only those of the 'LH$_{-1}$' ligand are co-ordinated equatorially. For the other isomer, the low g_o indicates a much stronger ligand field which shows, in agreement with the 3N [16,19] and 4N [this work] shf patterns, respectively, that all the possible nitrogen donors are bound equatorially. The A_o of this isomer is unexpectedly low for such a low g_o, indicating a considerable rhombic distortion of the ligand field. Besides, the nitrogen donors have proved to be equivalent (Refs. [16,19] and Table 2).

The wavelengths of the visible absorption maxima are in good accordance with the suggested structures. For the 4N isomer $\lambda_{max} \cong 540$ nm is calculated from the

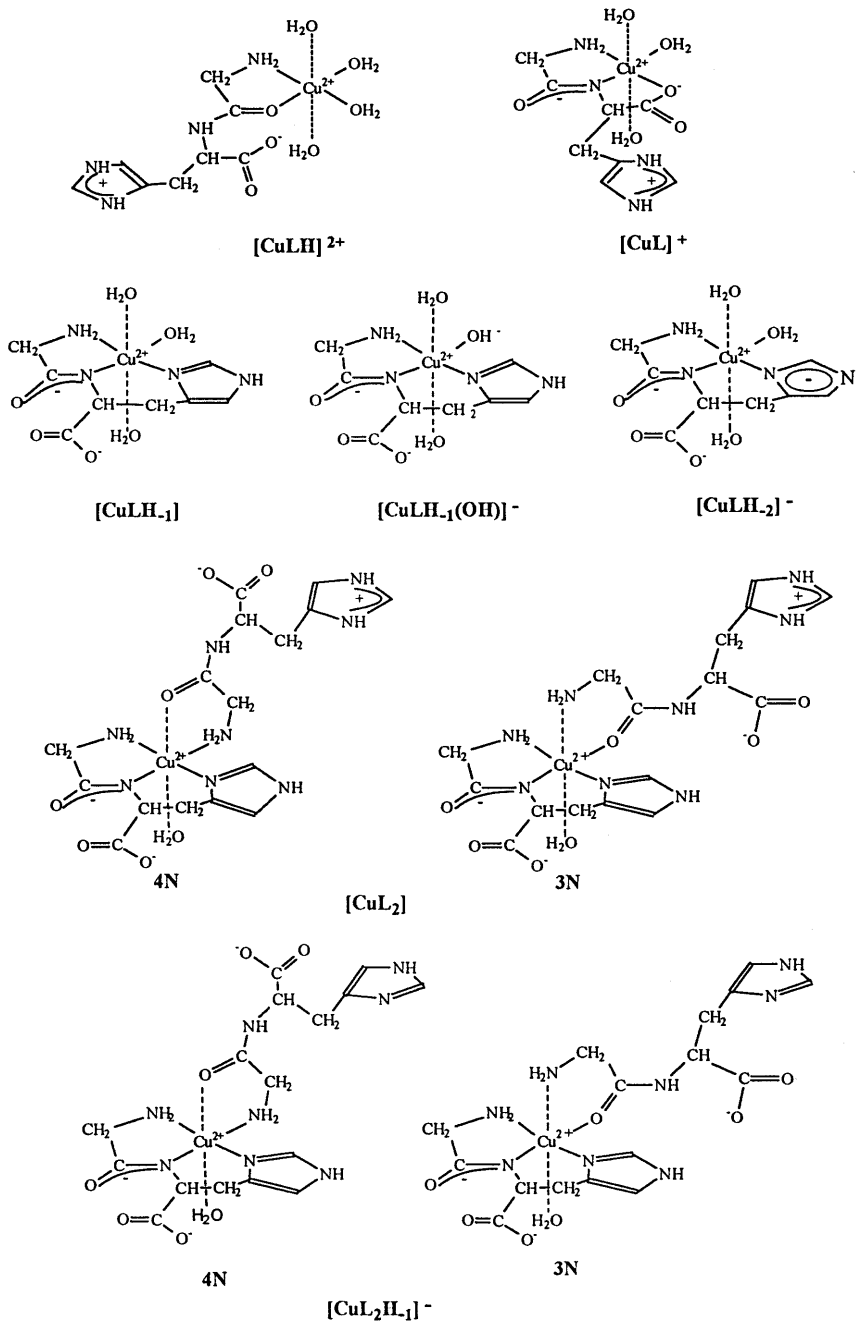

Fig. 5. Structures proposed for the various copper(II)-glycyl-L-histidine complexes.

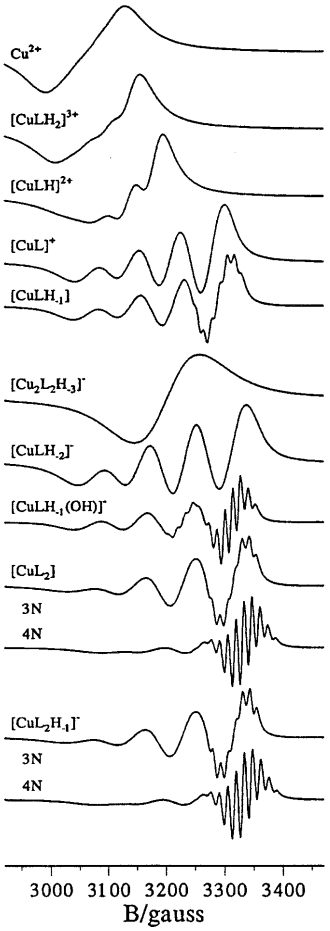

Fig. 6. ESR spectra of the various ^{63}Cu(II)-glycyl-L-histidine complexes.

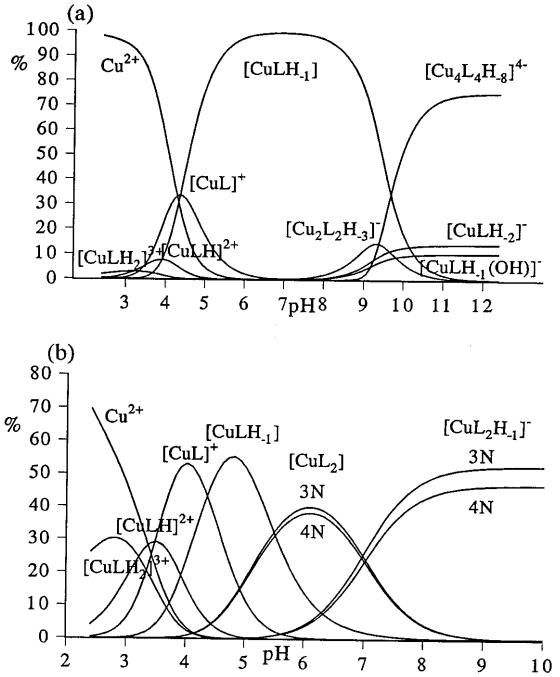

Fig. 7. Distribution of copper(II) amongst various species, including isomers, calculated from the formation constants obtained by the ESR method. The copper(II) concentration is 5 mM, the ligand-to-metal concentration ratio is (a) 1:1, (b) 20:1.

modified Billo-rule [24] while for the 3N isomer it is $\cong$ 593 nm. The experimental values are near the average of the above wavelengths: approximately 575 nm for the glycyl-L-histidine [2], 556 nm for the glycyl-L-histidyl-glycine [8] and 568 nm for the glycyl-histamine [9] complex. This is in agreement with the expectation when the measured curve is composed from a 540 and a 593 nm band of nearly equal intensity. It is worthy of note that the concentrations of the isomers were found nearly equal, and the molar absorption coefficients of the monomer species are of similar magnitude [2,8,9].

For the $[CuL_2]$ complex the close similarity of all the known characteristics (ESR parameters, the concentration ratio of the isomers, other spectroscopic data [2,8,9]) to those of the $[CuL_2H_{-1}]^-$ complex suggest the same modes of coordination (Fig. 5). The proposed structure is in good accordance with the deprotonation pK of the $[CuL_2]$ complex, too. We found pK 7.0 for both isomers, which is close to the value of 6.8, obtained for the imidazole group in the free ligand [1–8]. This supports the concept that the change in the protonation state of the imidazole group does not affect the structures of the isomers, i.e. it does not take part in the coordination sphere of either of these species. Another possible explanation is that in the $[CuL_2]$ complex the 'LH' ligand is bound by the imidazole nitrogen, while the amino group remains protonated. The lower deprotonation pK in the complex compared to the free ligand indicates the coordination of the amino group in the $[CuL_2H_{-1}]^-$ complex. This, however, would be accompanied by altered ESR parameters and d–d energies. The accidental coincidence of all these data of the corresponding isomers is improbable (Table 2).

The ESR spectra for the various copper(II)–glycyl-L-histidine complexes are illustrated in Fig. 6, and the concentration distribution curves including also the isomers are shown in Fig. 7.

4. Conclusions

Below pH 10 the presence of the side-chain imidazole group in the glycyl-L-histidine complexes only slightly affects the mode of coordination compared to the simple dipeptides: it is bound to the metal ion only in the $[CuLH_{-1}]$ complex, and in the 'LH_{-1}' ligand of the bis complexes; in these species it displaces the carboxylate group from the third equatorial site. The 'LH' and 'L' ligands in the $[CuL_2]$ and $[CuL_2H_{-1}]^-$ complexes, respectively, are ligated through the amino nitrogen and the peptide oxygen donors, either with the first in equatorial and the second in axial position, or vice

versa. Above pH 10, the deprotonation of the pyrrolic nitrogen causes dramatic changes in the coordination. In equimolar solution, the equilibrium of three species occurs up to pH 12: the monomer $[CuLH_{-2}]^{-}$ with a deprotonated imidazole ring, the corresponding tetramer $[Cu_4L_4H_{-8}]^{4-}$ and also the mixed hydroxo complex $[CuLH_{-1}OH]^{-}$ are formed.

Abstract

Reactions of benzilbisthiosemicarbazone (LH_6) with nickel, cobalt and iron chloride and nitrate give different complexes depending on the salts used and the working conditions. Reactions from nickel chloride give three complexes, **1**, **2** and **3** when the solvent or the pH is modified. Complex **1** is obtained in ethanol under reflux, and in methanol, independently of temperature and also with basic medium. Complex **2** is formed by working in ethanol at room temperature. The ligand acts as a dianion in both complexes. In the presence of hydrochloric acid, the new isolated complex **3** presents the neutral form of the ligand. Reaction from nitrate yields only complex **1**. Reactions with iron chloride give two new complexes with different formulae and grade of deprotonation in the ligand. For complex **4**, obtained at room temperature, LH_6 acts as an anion with a ligand–iron ratio of 2:1 and in its neutral form with a 1:1 ratio in complex **5**, working under reflux. Reactions with iron nitrate yield complex **6**, with the ligand in an intermediate situation, as anion but a nitrate remains. Complexes **7** and **8**, with a 1:1 cobalt–ligand molar ratio are isolated from reactions with cobalt nitrate; both contain nitrate and ethanol or water to complete the co-ordination sphere. Attempts to get a macrocyclic thiosemicarbazone from reaction of benzil and LH_6 in the presence of nickel or iron salt gave the complexes obtained, in absence of the dicarbonyl molecule. Electrochemical behaviour of complexes studied by cyclic voltammetry show metal-centred reduction processes for all of them. The reduction/oxidation potential values depend on the structures of complexes. Nickel complexes exhibit waves corresponding to Ni(III)–Ni(II) process. Electrochemical response of iron complexes depends on the presence of chloride ions. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

The investigation of metal complexes with sulfur-containing Schiff bases is a subject of current and growing interest and it has been shown that many of them present anticancer activity [1,2]. A particular important group of such ligands includes those containing thiosemicarbazone moieties, because complexes formed with many of the first row transition metals have shown a wide range of biological properties [3–5].

It has been shown that a NNS tridentate system is present in most of the thiosemicarbazones with carcinostatic potency [6] and that copper and iron complexes usually have higher activity than the free ligands [7,8]. The chemical properties of these complexes, namely concerning their behaviour in redox reactions, relate to those observed in biological systems. For some copper complexes, a lower reduction potential seems to be related to an increased antifungal activity and with their potential abilities as SOD–mimic complexes [8–

11]. Recently, iron-based SOD mimics have been reported [12–14]. The most successful mimics were obtained using macrocyclic pentadentate ligands [12]. However, these structures are quite different from the distorted trigonal bipyramidal geometry of the active site structure of Fe–SODs [15]. Some iron complexes with tripodal tetradentate ligand have activity [16]. The mimetic activity is related to the reduction potential values in the Fe(III)–Fe(II) process. The values observed in most Fe–SOD are between 0.2 and 0.4 V (versus NHE) [17]. The factors that influence the accessibility of several oxidation states for nickel are currently studied, because it is related to the bio-inorganic role of this metal ion in several redox enzymes [18,19]. Further interest in the co-ordination chemistry of nickel (I) and cobalt (I) arise from the role of these complexes in several catalytic reactions, such as electrocatalytical [20–22] and photocatalytical [23,24] reduction of CO_2. The incorporation of both soft and hard donor atoms in the co-ordination environment of the metal ion may be crucial in the stabilisation of oxidation numbers $+1$ and $+3$ for nickel [25].

Several studies on metal complexes of ligands derived from benzil and thiohydrazides with cobalt (II), zinc (II) and nickel (II) chloride and copper (II) salts have been made in our group [26,27]. Copper complexes have also been studied as SOD mimetic types [28,29]. In this paper we report the details of the synthesis, the spectroscopic characterization and the electrochemical behaviour of complexes obtained from benzilbisthiosemicarbazone (Fig. 1) and nickel (II), cobalt (II) and iron (III) salts. We have also investigated the influence of the counter-ion and the pH of the reaction medium in the behaviour of the ligand in reactions with metal chloride or nitrate.

2. Experimental

2.1. Reagents

Nickel(II) and cobalt(II) chloride and nitrate hexahydrate, iron(III) chloride hexahydrate and iron (III) nitrate nonahydrate were commercial products of highest chemical grade (Fluka). Solvents were purified according to standard procedures.

Benzilbisthiosemicarbazone LH_6 was prepared following the method previously reported [26].

2.2. Synthesis of nickel complexes

2.2.1. $NiC_{16}H_{14}N_6S_2$ (1)

A solution of nickel (II) chloride (0.20 g, 0.8 mmol) in methanol (10 cm^3) was added to a suspension of LH_6 (0.30 g, 0.8 mmol) in 20 cm^3 of the same solvent. The mixture was stirred for 3 h at room temperature. The reddish solid formed was filtered off, washed with methanol and dried in vacuo (yield 73%). ^{13}C NMR (DMSO-d_6): δ(ppm) 127.7, 128.8, 129.4, 131.6 (CPh), 153.8 (CN), 179.7 (CS). ^1H NMR (DMSO-d_6): δ(ppm) 7.6 (s, NH_2), 7.1–7.3 (m, HPh).

The same solid was obtained in ethanol under reflux [27]; in the presence of LiOH (0.028 g, 0.8 mmol) under reflux; and from nickel nitrate in ethanol at room temperature.

2.2.2. $NiC_{32}H_{30}N_{12}S_4$ (2)

This complex was prepared in the same way using ethanol and at room temperature (yield 63%) [27].

2.2.3. $NiC_{16}H_{16}N_6S_2Cl_2$ (3)

This complex was obtained following the same procedure, but in the presence of 10 cm^3 of hydrochloric acid (12 M) in methanol and under reflux (yield 58%).

2.2.4. Reactions with benzil

Working in the conditions described, but in the presence of benzil (0.17 g, 0.8 mmol) in methanol. The mixture was (a) refluxed with stirring for 3 h; (b) refluxed for 3 h in the presence of lithium hydroxide (0.034 g, 0.8 mmol); and (c) refluxed for 3 h in the presence of 10 cm^3 of hydrochloric acid (12 M). A reddish brown solid **1** was formed in procedures (a) and (b) but a brown solid **3** was formed following (c).

2.3. Synthesis of iron (III) complexes

2.3.1. $FeC_{32}H_{29}N_{12}S_4$ (4)

A solution of iron (III) chloride (0.23 g, 0.8 mmol) in 10 cm^3 of methanol was added to a suspension of LH_6 (0.30 g, 0.8 mmol) in 20 cm^3 of the same solvent. The mixture was stirred for 6 h at room temperature. The solid formed was filtered off, washed with methanol and dried in vacuo (yield 31%).

2.3.2. $FeC_{17}H_{20}N_6S_2OCl_3$ (5)

The reaction took place in the same conditions, but heating the mixture under reflux for 6 h gave a green solution, which was concentrated until a dark brown solid was formed (yield 43%). A reaction in the presence of hydrochloric acid in the reaction medium, enabled the reagents to be isolated. The reaction in the presence of LiOH (0.034 g, 0.8 mmol) in methanol under reflux for 2 h gave a yellow solid (yield 21%) [30].

[a] Found (calcd)%.

2.3.3. Reactions with benzil

Following the same procedure described for nickel (II) chloride. Using procedures (a) and (c), the reagents were recovered, but in the presence of lithium hydroxide the yellow solid obtained above was isolated.

2.3.4. $FeC_{16}H_{20}N_7S_2O_6$ (6)

A solution of iron (III) nitrate (0.52 g, 1.3 mmol) in ethanol (10 cm^3) was added to a suspension of LH_6 (0.46 g, 1.3 mmol) in 40 cm^3 of ethanol. Immediately the colour of the solution changed to dark brown, then the mixture was stirred for 8 h. The dark solid was filtered off, washed with ethanol and dried in vacuo (yield 27%).

2.4. Synthesis of cobalt(II) complexes

2.4.1. $CoC_{18}H_{21}N_7S_2O_4$ (7)

A solution of cobalt(II) nitrate (0.54 g, 1.8 mmol) in ethanol (25 cm^3) was added to a suspension of LH_6 (0.66 g, 1.8 mmol) in 40 cm^3 of ethanol. Immediately the solution changed to a dark brown colour. The mixture was stirred for 8 h. The dark solid was filtered off, washed with ethanol and dried in vacuo (yield 66%).

2.4.2. $CoC_{16}H_{21}N_7S_2O_6$ (8)

The same procedure was followed, as above, but heating the mixture under reflux with stirring for 8 h (yield 82%).

2.5. Physical measurements

Microanalyses were carried out using a Perkin–Elmer 2400 II CHNS/O elemental analyser. IR spectra in the 4000–400 cm^{-1} range were recorded as KBr pellets on a Bomen-100 spectrophotometer and in the range 550–200 cm^{-1} on a Bruker IFS 66V.

UV–Vis spectra in solution were registered on an Ati-Unicam UV2 spectrophotometer and the solid reflectance spectra on a Pye-Unicam SP-8-100. Conductivity data were measured using freshly prepared DMF solutions (ca. 10^{-3}M) at 25°C with a Metrohm Herisau model E-518 instrument.

^{1}H and ^{13}C NMR spectra were recorded on a Bruker AMX-300 spectrophotometer, using DMSO-d_6 as a solvent and Me_4Si as an internal standard.

Fast atom bombardment mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzylalcohol (*m*NBA) as the matrix.

EPR spectra were obtained with a Bruker ER 200D spectrometer operating in the X-band and calibrated with a DPPH standard ($g = 2.0036$). Portions of the samples were placed inside a quartz probe cell and subjected to brief out-gassing at room temperature (in high vacuum conditions) prior to record the spectra.

[a] Several bands.
[b] Solvent molecules (water, methanol or ethanol).

Electrochemical measurements were performed with a BAS CV 27 voltammograph and a BAS A-4 XY register, using a carbon glassy (ϕ 5 mm) as working electrode, a platinum wire as auxiliary and a double junction, with porous ceramic wick, Ag–AgCl as reference electrode. In all cases, ferrocene was used as an external standard under the experimental conditions employed, redox couple ferricinium–ferrocene ($E_{1/2} = +0.48$ V; $\Delta E_p = 60$ mV). Cyclic voltammetry studies of ligands and complexes were carried out in 0.01 M solutions in dimethylformamide containing 0.1 M $[NBu_4]$ $[PF_6]$ and lithium chloride as supporting electrolytes. The range of potential studied was from $+1.5$ to -2.5 V. All solutions were purged with nitrogen steam for 5 min before measurements and the working electrode was polished before each experiment with diamond paste. The procedure was performed at room temperature and nitrogen atmosphere was maintained over the solution during the measurements.

3. Results and discussion

Analytical data are summarised in Table 1. From these data it can be deduced that the formulae of complexes depends on the working conditions.

For nickel reactions, three complexes were obtained: **1** ($NiLH_4$) and **2** ($Ni(LH_5)_2$), in which the ligand acts as an anion and complex **3** ($NiLH_6Cl_2$) with LH_6 in its neutral form. The last one is only obtained in the presence of hydrochloric acid, while complex **1** appears independently of the salts used, the solvent (methanol or ethanol), under reflux and in the presence of a basic medium.

Attempts to get the macrocyclic ligand from the reaction of LH_6 and benzil in the presence of nickel chloride, under the working conditions described in the experimental section, were unsuccessful. The complexes isolated from the nickel salt and benzilbisthiosemicarbazone were the same in basic or acid medium.

The nature of iron complexes is very dependent on the working conditions: temperature, salt used or the reaction medium. From the iron chloride reactions in methanol, two complexes **4** ($Fe(LH_5)(LH_4)$) and **5** ($FeLH_6Cl_3CH_3OH$) are obtained depending on the temperature. Complex **4** presents a 1:2 iron–ligand molar ratio with LH_6 acting as an anion, but complex **5** has chloride ions and the ligand is in its neutral form. In comparison with the nickel reaction, no complex is obtained by working in the presence of hydrochloric acid, while in the basic medium an iron macrocyclic complex was formed [30]. Moreover, from the nitrate reaction a new complex **6** ($FeLH_4NO_3{\cdot}3H_2O$), which has a nitrate ion, is isolated.

As in the case of nickel, attempts to get the macrocyclic ligand from the reaction of benzil and LH_6 in the presence of iron chloride, under the working conditions described in the experimental section, were unsuccessful. A macrocyclic complex was obtained working in the presence of lithium hydroxide. This complex was obtained in the absence of benzil as shown in a previous study [30].

From cobalt nitrate reactions, the obtained complexes **7** ($CoLH_5NO_3CH_3CH_2OH$) and **8** ($CoLH_5NO_3{\cdot}3H_2O$) present the ligand as partially deprotonated as in complex **6**, in contrast to the complex obtained from chloride [27]. In both cobalt complexes, solvent molecules are bonded to cobalt, ethanol in complex **7** and water in complex **8**.

The conductivity data (Table 1) indicate that all complexes are non-electrolytes, although complexes **5**, **7** and **8** show a partial solvolysis [31].

3.1. Nickel complexes

Mass spectra of all complexes show a peak at 413 amu corresponding to the $[LH_5Ni]^+$ fragment. The spectrum of complex **3** does not exhibit the molecular ion peak, but since it is a molecular complex the chloride ions must be bonded to the metal.

^{1}H NMR spectra of complexes **1** and **2** exhibit the amine and aromatic hydrogen in the same range as the free ligand. This is diagnostic of the diamagnetism for complexes, which indicates a square-planar symmetry for them in DMSO solution.

The spectrum of complex **2** confirms the presence of two non-equivalent ligand molecules. Its spectrum exhibits signals in the same position as complex **1** and the free ligand. This data indicates that one of the ligands is replaced by the DMSO. The ^{13}C NMR spectrum supports the partial substitution of one of the ligands by the solvent. The ^{13}C NMR spectrum of **1** shows a signal corresponding to the thioamide group in the same position as the free ligand, but the imine group is shifted to a lower field. These data support both azomethine groups and the primary amines being bonded to the nickel ion, as was proposed from the previous spectral data [27].

The IR spectrum of **3** shows several bands between 3398 and 3098 cm^{-1} corresponding to N–H stretching vibrations, which indicates that the ligand is present in its neutral form according to the analytical data. The shifts of the other bands in this spectrum are similar to those of complex **1**, so the behaviour of the ligand must be the same. The bands present in the far infrared spectrum of complex **3** support that the imine and thioamide nitrogen atoms are bonded to the metal ion. This spectrum shows two additional bands assignable to ν(Ni–Cl) with respect to complexes **1** and **2**, which confirm the chlorine–nickel bonds (Table 2). Electronic spectrum in DMF solution shows absorption bands at 707 nm ($\varepsilon = 333$ mol^{-1} dm^3 cm^{-1}) and 744 nm ($\varepsilon =$ 304 mol^{-1} dm^3 cm^{-1}) and three more intense bands at 430, 416 nm ($\varepsilon = 310^3$ mol^{-1} dm^3 cm^{-1}) and 312 nm ($\varepsilon = 12.244$ mol^{-1} dm^3 cm^{-1}) and in solid state at 540 and 680 nm with a shoulder at 740 nm, which are consistent with a distorted octahedral environment for the nickel [32].

3.2. Iron complexes

The reactions of iron salts with LH_6 gave three new complexes with different stoichiometry and variable grades of deprotonation in the ligand (Table 1).

From the chloride reaction, complexes **4** and **5** show both variables. The mass spectrum of **4** presents a pattern similar to that of complex **2**, which had the same stoichiometry. The IR spectrum is also close, with poorly resolved bands. Therefore, the same co-ordination behaviour of the thiosemicarbazone must be expected in both complexes, in which one ligand acts as dianion bonding through two imine nitrogen atoms and the terminal amine groups, and the other by the amine

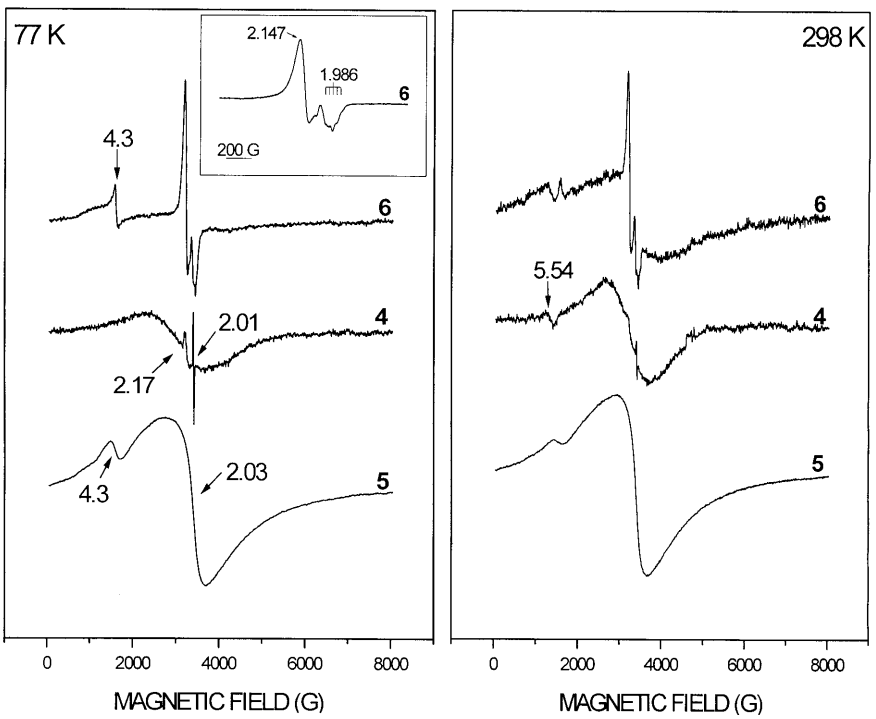

Fig. 2. EPR spectra of iron complexes in solid state, recorded at 77 and 298 K.

group [27]. Analytical data for complex **5** agree with a 1:1 molar ratio and the presence of methanol and chloride ions. Its IR spectrum confirms that the ligand acts in its neutral form and is bonded by the azomethine nitrogen atoms to the iron ion. The bands in the far IR confirm this behaviour, as do the bonds to the iron by the methanol molecule and the chloride ions.

Complex **6**, which is obtained from iron nitrate, presents an intermediate situation. The ligand acts as an anion, but a nitrate ion remains. The mass spectrum shows a peak corresponding to $[LH_4Fe]^+$. The infrared spectrum confirms the presence of the nitrate group as a ligand (mono or bidentate) and the water molecules, so it is more difficult for the assignment of the amine vibrations. By comparison with the cadmium nitrate complex in which recent X-ray data confirm a monodentate behaviour for this group [33], we propose that the nitrate is bonded by only one oxygen. The band assigned to the imine group is shifted to lower frequency, which indicates that these nitrogen atoms are involved in the bond to the iron. The iron co-ordination sphere is completed by four oxygen atoms, one from the nitrate group and the other from water molecules (Fig. 3(c)). The bands present in the far IR confirm the bond Fe–N(NC) and several Fe–O bonds (Table 2).

Electronic spectra in solution show an intense band at 400 nm ($\varepsilon = 10^3$ mol^{-1} dm^3 cm^{-1}) with a shoulder at 766 nm ($\varepsilon = 180$ mol^{-1} dm^3 cm^{-1}). The reflectance spectrum of **4** only shows a peak at 320 nm and several shoulders at lower energy. Spectra of complexes **5** and **6** show bands at 610 and 550 nm with a shoulder at lower energy in each absorption band, which support a distorted octahedral geometry for the iron ion. Electronic spectra in solution show charge transfer bands that obscure d–d bands [32].

3.2.1. EPR spectra

The EPR spectra of the iron(III) complexes in solid state, recorded at 77 and 298 K, are shown in Fig. 2. In all cases an overall intensity decrease is produced when the spectra are recorded at 298 K related to those recorded at 77 K.

The spectrum of complex **6** exhibits resonances in the low field region showing a peak at $g' = 4.3$ and a relatively broad absorption in the $g' = 9.0$–4.0 range. This is typical of high-spin iron(III) complexes in rhombically distorted low-symmetry positions [34]. For these cases the zero-field splitting terms remove the degeneracy of the spin sextet resulting in three Kramer's doublets; transitions within these states give rise to resonances in the low field region of the spectra [34]. Observation of a relatively broad resonance in this region and a narrower line at $g' = 4.3$ is consistent with the existence of a certain dispersion in the zero-field splitting terms. This could be caused by strain effects in the solid-state crystallites, giving rise to a relatively large spreading of the g resonant values [34]. In addition, complex **6** exhibits a signal at $g_\perp = 2.147$, and $g_\parallel = 1.986$ which is resolved by a hyperfine splitting of five lines in the parallel component, with $A = 29$ G, which shows intensity decreasing from the central line to the outermost components of the pattern (the inset of Fig. 2 shows details of this signal obtained in a shorter range run). This signal is typical of low-spin iron(III) complexes in a distorted octahedral environment with axial symmetry. Analysis of the g tensor values suggests that the axial ligands are weaker than the equatorial ones and that the d_{xy} orbital is lower in energy [35,36]. On the other hand, the hyperfine splitting pattern shown by this signal is consistent with a partial delocalization of the unpaired electron density into two equivalent nitrogen atoms through a superhyperfine interaction. Considering the infrared results, the nitrogen atoms responsible of this effect might be those of the imine groups. Besides, in the spectrum recorded at 298 K, the presence of a relatively broad signal with g value close to g_e is observed. This signal can be attributed to the low-spin iron(III) system, the broadening arising from the effects of magnetic exchange interactions within adjacent iron(III) species in the crystallites or a relatively fast high-low spin configurational equilibrium [36].

A similar broad signal prevails in complexes **4** and **5** indicating the presence of low-spin iron(III) configurations in them. In the former case the presence of high-spin iron(III) is apparent only in the spectrum recorded at 298 K (revealed by a peak at $g' = 5.54$), suggesting a greater relative stability of the low-spin configuration for complex **4**, while complex **5** shows the coexistence of low- and high-spin states of the iron(III) signal at low recording temperatures. In the case of complex **4** a narrower iron(III) signal in the low-spin state is evidenced by a signal at $g_1 = 2.142$, $g_2 = 2.110$ and unresolved g_3 in the spectrum recorded at 77 K. A narrow signal at $g = 2.01$, with relatively low intensity, is also observed in the spectrum of this complex. This could probably arise from location of unpaired electrons in the organic ligands of the complex or from the presence of impurity radicals.

3.3. Cobalt complexes

As it was mentioned in the experimental section and from the analytical data, two new complexes were obtained from the nitrate reaction with LH_6 (Table 1). Both complexes differ in the solvated molecules, but the ligand presents the same grade of deprotonation. The mass spectra show the peak corresponding to the $[LH_5Co]^+$ ion. IR spectra confirm the presence of the nitrate ion and the solvent molecules. The band assigned to thioamide IV remains in the same position as

in the free ligand, which indicates that this group is not involved in the bonding to the cobalt ion. The presence of solvent molecules does not permit the assignment of the NH and imine vibrations, but the bands in the far IR region indicate that the ligand is bonded by the imine nitrogen atoms (Table 2) [4].

The solid state electronic spectra of complexes **7** and **8** show bands at 580 and 500 nm with a shoulder at 690 and 680 nm, respectively, these data are consistent with a pentacoordinated or a distorted octahedral geometry for the cobalt ion [32].

An example of the different structures proposed for complexes is shown in Fig. 3, where the output of the calculation carried out using the Hyperchem program is plotted.

3.4. Electrochemical behaviour

The cyclic voltammogram of the ligand in DMF shows only two irreversible cathodic waves at -1.44 and -1.75 V, which can be attributed to the reduction of the groups present in the ligand.

3.4.1. Nickel complexes

Cyclic voltammogram of complex **1** shows the same pattern in glassy carbon electrode as in platinum [27]. The electrochemical behaviour of complex **3** differs from that complex **1**, in the same conditions, and depends on the potential range explored. On scanning from 0.0 to -2.5 V, the cyclic voltammogram (Fig. 4(a)) shows two waves in the cathodic scan at -1.10 and -1.67 V, respectively, corresponding to successive reductions of the Ni (II) ion [37–39], and in the reverse scan two anodic peaks at -1.61 and -1.05 V. Analysis of the first redox couple in the interval 25–800 mV s^{-1} shows a lineal variation of i_{pc} versus $v^{1/2}$. Small dependence of the potential peak with the scan rate is observed, and the i_{pa}–i_{pc} ratio is close to the unity. These results suggest a diffusion controlled quasirreversible Ni(II)–Ni(I) process. The more negative redox couple shows similar features, except that the potential peak values are independent of the scan rate, so this couple corresponds to a reversible process. When the positive potential limit is increased to $+1.5$ V (Fig. 4(b)), complex **3** exhibits an irreversible oxidation at $+0.87$ V, which generates a new unknown species which is turned into an irreversible reduction at -0.67 V [39–41].

Reduction potentials values of complexes **1** and **3** are similar, although slightly more negative for the latter complex due to the lower number of unsaturations for complex **3**. It is more difficult to have access to the $+1$ state for nickel in the complex with the ligand in its neutral form and two chloride ions bonded to the metal ion. The values of the oxidation process show that it is easier to oxidize complex **3** than complex **1**. This fact agrees with the presence of two chloride ligands in complex **3**. Chloride is a good π-donor, which will stabilise the higher oxidation state [41–43].

3.4.2. Iron complexes

Voltammetric studies of complexes **4**, **5** and **6** were carried out in dimethylformamide as solvent and using tetrabutylammonium hexafluorophosphate (TBAHFP)

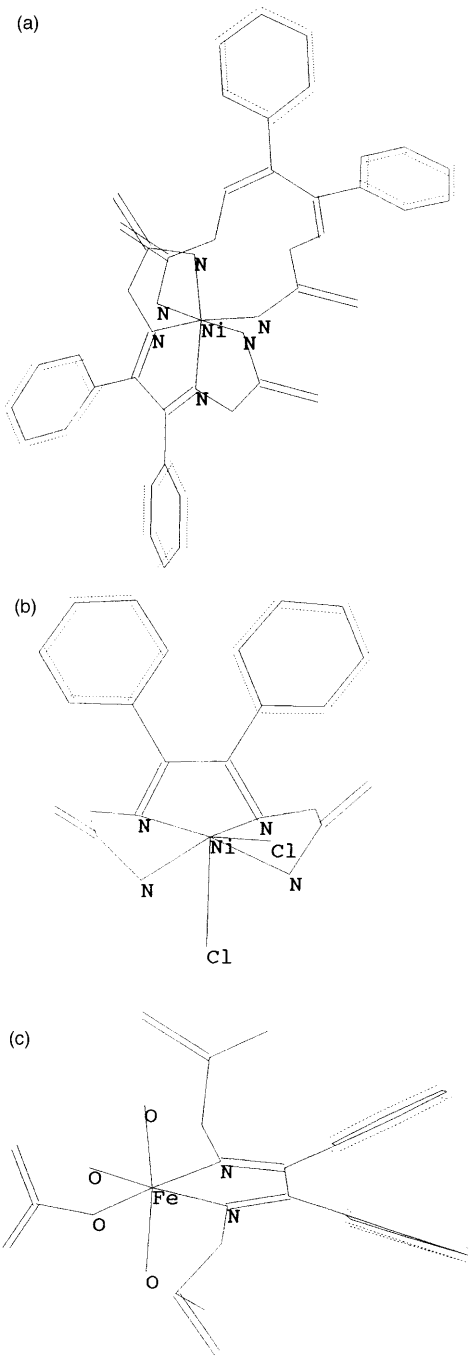

Fig. 3. Possible structures for (a) complex **2**; (b) complex **3**; (c) complex **6**.

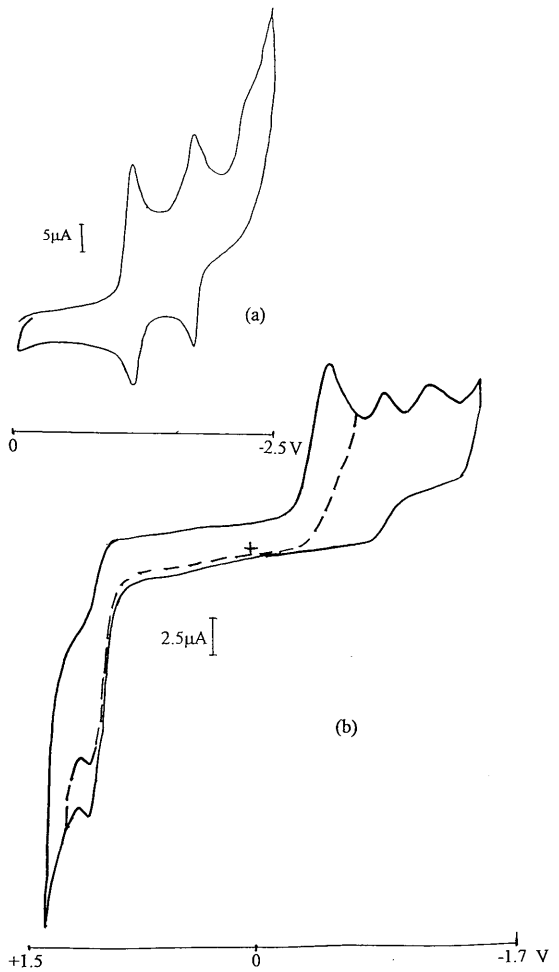

Fig. 4. Cyclic voltammogram for complex **3**; (a) potential range 0.0 to −2.5 V; (b) potential range +1.5 to −2.5 V, $v = 100$ mV s^{-1}.

and lithium chloride as electrolytes. In addition, voltammetric response in TBAHFP was recorded with successive additions of LiCl until ca. 0.1 M.

In the solutions containing TBAHFP, complexes **4**, **5** and **6** show different electrochemical behaviour. The cyclic voltammogram of complex **4** shows waves attributed to the ligand and poorly defined waves at less negative potentials. Using 2.10^{-2} M solutions the cyclic voltammogram obtained shows two waves in the range from +1 to −1.7 V. The peak at −0.75 V could be attributed to a Fe(III)–Fe(II) process. This behaviour could be explained considering the two ligands around the metal ion, without flexibility to accommodate the structural changes that accompany the reduction process. Cyclic voltammogram of complex **5** exhibits metal centred waves and other ones corresponding to the ligand reduction processes. In the range from +1 to −1 V a quasirreversible process attributed to the Fe(III)–Fe(II) couple at +0.19 V and a reduction wave at −0.72 V are observed (Fig. 5(a)). Cyclic voltammetric response of complex **6** shows poorly defined peaks due to the reduction of different species of iron(III) (Fig. 6(a)).

The three complexes show a different behaviour after the addition of LiCl. The voltammogram of complex **4** does not change, but those of complexes **5** and **6** are modified by the presence of chloride ions (LiCl). A gradual addition of chloride ions yielded a better defined cyclic voltammogram of complex **5**, which has chloride ions in its formula; a fully reversible Fe(III)–Fe(II) process is observed, although the potential values are shifted to +0.04 V. At the level of 0.1 M LiCl a well defined voltammogram is obtained (Fig. 5(b)). For complex **6**, a dramatic change in the voltammogram is produced by successive additions of LiCl, suggesting strong interaction of the complex with the anion by the replacement of the co-ordinated nitrate ion by chloride. From the first addition, a clear reversible process attributed to the Fe(III)–Fe(II) couple at +0.03 V and two peaks at more negative potential are observed (Fig. 6(b)). The features of the voltammogram depend on chloride content in the solution. A new peak at −0.62 V arises and its intensity increases when the concentration of chloride increases, so it can be related to the reduction of mixed species containing iron, ligand and chloride, $[Fe(LH_5)Cl_3)]^-$, $[Fe(LH_5)_2)]^+$, which are responsible of the electrochemical response observed in these conditions as previously described [44]. The redox process Fe(III)–Fe(II) would be accompanied by slow loss of nitrate, and therefore addition of chloride ions will improve this and hence more reversible electrochemical behaviour is observed. The voltammogram obtained at the level of 0.1 M LiCl is shown in Fig. 6(c).

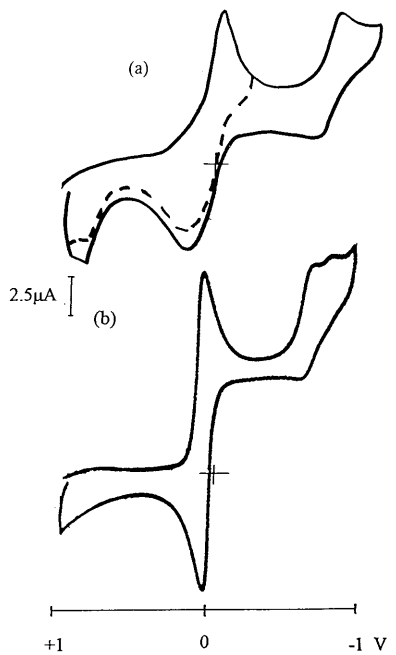

Fig. 5. Cyclic voltammogram for complex **5**; (a) in TBAHFP; (b) at the level of 0.1 M LiCl, $v = 100$ mV s^{-1}.

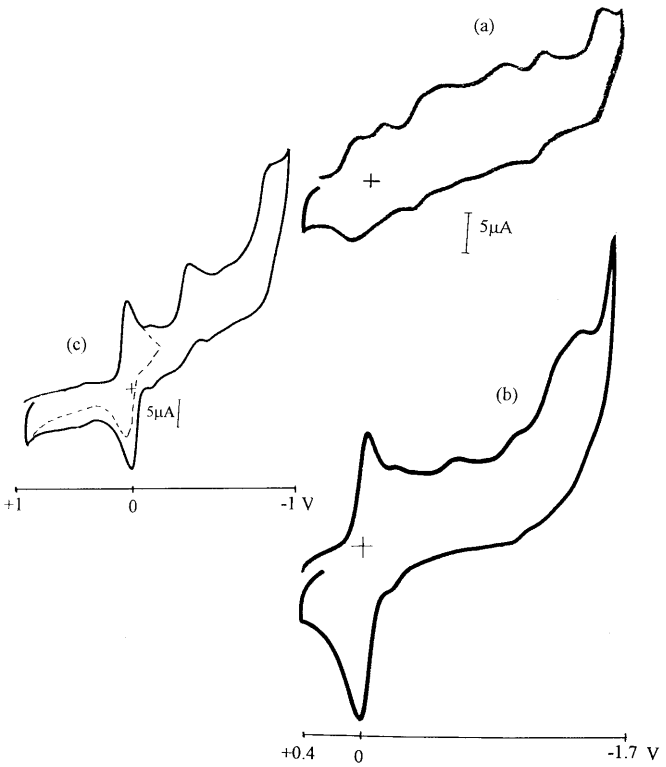

Fig. 6. Cyclic voltammogram for complex **6**; (a) in TBAHFP; (b) in TBAHFP after the addition of 0.1 ml of LiCl 0.1 M; (c) in TBAHFP at the level of 0.1 M of LiCl, $v = 100$ mV s^{-1}.

3.4.3. Chloride medium

The pattern of the cyclic voltammograms of complexes **5** and **6** are almost the same of that obtained from the addition of LiCl described above.

The reduction potential values of complexes **5** and **6** in LiCl are in the range of the Fe–SOD mimic observed [17]. Therefore, these compounds might be SOD mimetic.

3.4.4. Cobalt complexes

Voltammetric behaviour of cobalt complexes **7** and **8** was studied in the potential range from $+1$ to -2.5 V. The electrochemical behaviour of both complexes is very close according to the same geometry proposed from the spectroscopic data for these complexes. Both complexes exhibit waves only in the negative range of potential. Cyclic voltammogram of **7** (Fig. 7) shows an irreversible reduction wave at -1.85 V attributed to the insaturations of the ligand. In addition, it exhibits a cathodic wave at -0.97 with the anodic counterpart at -0.91 V corresponding to a cobalt(II) centred reduction process [45]. Study of the dependence of the voltammetric parameters with scan rate in the interval 25–800 mV s^{-1} show a lineal relationship of i_{pc} with $v^{1/2}$. The peak potential shows a small dependence with the scan rate. The ratio i_{pa}–i_{pc} is close to unity. From these data, it can be deduced that this redox couple is related to a quasirreversible process controlled by diffusion. The potential values are slightly shifted with respect to those obtained from the cobalt chloride complex in the same conditions, because in this complex chloride ions were bonded to the cobalt ion [27].

Abstract

SnO_2 or doped SnO_2 thin films can be used as transparent conductors in various optoelectronic devices such as screens or solar cells. They usually present high optical transmittance, low resistivity and high chemical and mechanical stability. The synthesis and single crystal X-ray diffraction analysis of new tin (IV) modified alkoxides $Sn(OEt)_2(\eta^2\text{-acac})_2$ (**1**) and $Sn_4(\mu_3\text{-O})_2(\mu_2\text{-OEt})_4(OEt)_6(\eta^2\text{-acac})_2$ (**2**) (acacH = 2,4 pentanedione) are reported. **1** crystallizes in the monoclinic system (space group $P2_1/n$) while **2** crystallizes in the triclinic system (space group $P\bar{1}$). The asymmetric unit of the molecular species $Sn(OEt)_2(\eta^2\text{-acac})_2$ contains two monomers which are slightly different. $Sn_4(\mu_3\text{-O})_2(\mu_2\text{-OEt})_4(OEt)_6(\eta^2\text{-acac})_2$ is a tetranuclear species in which Sn atoms are connected together by two triply bridging oxo ligands and four bridging ethoxo groups. Six terminal ethoxo groups and two chelating β-diketonato ligands are completing the coordination of the metal atoms. Their behaviour towards hydrolysis–condensation reactions is discussed. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Alkoxide; Tin; Tin dioxide; Sol–gel; β-Diketonate

1. Introduction

Tin dioxide thin films can be used as transparent conductors in various optoelectronic devices such as screens or solar cells. They usually present high optical transmittance, low resistivity and high chemical and mechanical stability. SnO_2 films have been previously prepared using chemical vapor deposition (CVD) [1], spray pyrolysis [2,3], or the sol–gel process [4–8]. One of the advantages of the sol–gel process is that the required temperature, which can be quite low, should allow deposition on thermosensitive substrates such as organic substrates. Tin alkoxides precipitate easily upon controlled addition of water. To avoid this precipitation one can stabilize the alkoxide precursors by substitution of alkoxo groups with less hydrolysable ones, β-diketone for instance. There is only one tin alkoxide modified with β-diketone which is structurally known, namely $[Sn(OPr^i)_3(acac)]_2$ [9], while three alkoxides have been structurally characterized, $Sn(OBu^t)_4$, $[Sn(OPr^i)_4(HOPr^i)]_2$ [10] and $[Sn(OBu^i)_4(HOBu^i)]_2$ [11]. T. Toupance have recently published F-doped SnO_2 materials by the sol–gel route using $Sn(OR^1)F(R^2COCHCOR^2)_2$ (R^1 = *tert*-amyl, isopropyl, ethyl; R^2 = methyl, *tert*-butyl) as precursors [12]. In this article we report the synthesis and structural characterization of tin (IV) modified alkoxides with β-diketone: $Sn(OEt)_2(\eta^2\text{-acac})_2$ and $Sn_4(\mu_3\text{-O})_2(\mu_2\text{-OEt})_4(OEt)_6(\eta^2\text{-acac})_2$ (acacH = 2,4 pentanedione). Their behaviour towards hydrolysis–condensation reactions is discussed and they are compared as potential precursors for film deposition.

2. Results and discussion

β-Diketones, especially acetylacetone, are often used in order to stabilize metal alkoxides towards hydrolysis reactions during the sol–gel process [13]. The system $Sn(OBu^t)_4$–EtOH–acacH is of great interest for the elaboration of tin oxide and it has previously been used to prepare Sb^{3+} doped SnO_2 thin films for example [8].

The complexes $Sn(OEt)_2(\eta^2\text{-acac})_2$ (**1**) and $Sn_4(\mu_3\text{-}O)_2(\mu_2\text{-}OEt)_4(OEt)_6(\eta^2\text{-acac})_2$ (**2**) have been successfully prepared and isolated by reacting acetylacetone with the product of ethanolysis of $Sn(OBu^t)_4$ in a ratio acacH–Sn = 1:1. Two kinds of crystals were grown in the toluene solution, corresponding to compounds **1** and **2**. Species **1** could also be prepared by reacting acetylacetone and the product of ethanolysis of $Sn(OBu^t)_4$ in a ratio acacH–Sn = 2:1. The infrared spectrum for **1** shows two vibration bands at 1573 and 1534 cm^{-1} in the C=O region corresponding to terminal acetylacetonato ligands. The ^1H NMR spectrum at room temperature shows a singlet at 5.54 ppm attributed to the CH of the acac ligands, a quadruplet at 3.94 ppm for the CH_2, a triplet at 1.22 ppm for the CH_3 of the ethoxo groups and two singlets at 2.14 and 2.03 ppm for the methyls of the acac groups with a ratio OEt–acac = 1. The presence of two discrete and equivalent resonances associated with the CH_3 of the acetylacetone is consistent with a *cis* configuration for the alkoxide groups [7]. This was confirmed by single crystal X-ray diffraction (Fig. 1). Crystallographic data and selected bond lengths and angles are reported in Tables 1 and 2. The molecular species $Sn(OEt)_2(\eta^2\text{-acac})_2$ looks like a monomer but the asymmetric unit contains two monomers, A and B, which are different from a crystallographic point of view. The O–C–C angles of the alkoxo groups are slightly different, these angles are O11–C110–C111 = 124.7(7)° and O12–C120–C121 = 113.9(5)° for monomer A while O21–C210–C211 = 113.4(4)° and O22–C220–C221 = 114.3(5)° for monomer B. The angles around the metal atoms are also different: for example between the two ethoxo groups, O11–Sn1–O12 = 97.46(13)° for A and O22–Sn2–O21 = 101.20(12)° for B. Compound **1** presents two terminal ethoxo groups and two chelating β-diketonato ligands. The tin atom is hexacoordinated with a distorted octahedral environment. Sn–O bond lengths are varying between 1.960(3) and 2.113(2) Å with Sn–OR_t bonds shorter than Sn–η^2O bonds, which are quite similar to the Sn–O bonds in $[Sn(acac)(OPr^i)_3]_2$ [9]. The alkoxo groups are in a *cis* position surrounding the tin atom. They have the same position as the chlorine atoms in $SnCl_2(acac)_2$ [14] while the methyl groups in $Sn(CH_3)_2(acac)_2$ are in a *trans* position [15]. The *cis* configuration of compound **1** is more stable than the *trans* configuration. RO^- ligands, as well as Cl^-, act as σ- and π-donors and π-bonding is most easily accomplished if the two alkoxo groups are located in *cis* positions. Compound **2** was also prepared by reacting acetylacetone with the ethanolysis product of $Sn(OBu^t)_4$ in a ratio acacH–Sn = 1:2. The infrared spectrum shows two vibration bands in the C=O region at 1561 and 1539 cm^{-1} corresponding to terminal

β-diketonato groups. The ^{1}H NMR spectrum at room temperature shows a singlet at 5.60 and 5.58 ppm corresponding to the CH of the acac ligands, a quadruplet at 3.7 ppm for the CH_2, a triplet at 1.25 ppm for the CH_3 of the ethoxo groups and a singlet at 2.13 ppm for the methyles of the acac groups with a ratio OEt–acac = 5. The ^{119}Sn NMR spectrum has been measured. The compound displays several resonances with chemical shifts in the regions of δ −694, −646, −607 and −568 ppm. The tin atoms supporting the acetylacetone Sn2 and Sn2a have a more negative chemical shifts (δ = −694, −646 ppm) than Sn1 and Sn1a (δ = −607, −568 ppm). The values for Sn2 and Sn2a are in the same region as the values measured in the complexes $Sn(acac)_2(OR)_2$ (R = Me, Bu, OPr^i) ($\delta\approx-690$, −650 ppm), $Sn(acac)(OPr^i)_3$ ($\delta\approx-680$ ppm) and $Sn(bzac)(OPr^i)_3$ (bzac = benzoylacetone) ($\delta\approx-697$, −595 ppm) [9]. Correlations of ^{119}Sn chemical shift values with tin coordination numbers have been previously reported [7,16–18]. According to the data published in the literature the chemical shifts of compound **2** are consistent with six-coordinated species. This was confirmed by single-crystal X-ray diffraction analysis on **2** (Fig. 2). Crystallographic data and selected bond lengths and angles are reported in Tables 1 and 3. $Sn_4(\mu_3\text{-O})_2(\mu_2\text{-OEt})_4(OEt)_6(\eta^2\text{-acac})_2$ (**2**) is a tetrameric species. Sn atoms are connected together by two triply bridging oxo ligands and four bridging ethoxo groups. Six terminal ethoxo groups and two chelating β-diketonato ligands are completing the coordination of the metal atoms. The tin atoms are hexacoordinated with a distorted octahedral environment. The four Sn atoms are nearly co-planar. There are two kinds of tin, either connected to one chelating acetylacetonato, three alkoxo and one oxo groups for Sn2 and Sn2a or four alkoxo and two oxo groups for Sn1 and Sn1a. Sn–O bond lengths are in the range 1.926(18)–2.187(15) Å. The metal oxygen framework of **2** is similar to that adopted by $[Ti(OR)_4]_4$ species such as $[Ti(OMe)_3(OEt)]_4$ [19], $[Ti(OMe)_4]_4$ [20] or $[Ti(OEt)_4]_4$ [21]. If the solid-state structure was remaining in the solution we would expect only one ^{119}Sn resonance for Sn2 and one for Sn1. The presence of four resonances probably means that a reorganization occurs in solution with the formation of different isomers of **2**.

Compounds **1** and **2** are both soluble in ethanol and possess hydrolysable ligands. They are thus potential precursors for the preparation of tin dioxide through

the sol–gel process. Hydrolysis reactions have been conducted and various parameters have been analysed, such as the h values (degree of hydrolysis $h = [H_2O]/[M(OR)_n]$), the aging of the sols and the influence of the substitution of alkoxo groups with β-diketonato ligands. Pure tin alkoxide solutions led to clear sols for h values up to 3 and gels for h values between 3 and 8. For higher h values the precipitation starts immediately. Solutions of modified alkoxides **1** and **2** give slightly different results. Clear sols are obtained with $3 < h < 8$ and can be stable for weeks. For $h > 8$, turbid gels are obtained while precipitation occurs for high h values (50). TGA and X-ray diffraction analysis on the powder resulting from hydrolysis with $h = 50$ show that complete elimination of the remaining ligands occurs at 365°C and crystallisation of pure SnO_2 Cassiterite starts at about 350°C (Fig. 3). Films (thickness ≈ 0.6–1.3 μm) were deposited using both spin and dip-coating methods on glass substrates. They present high transmission in the visible (99%). They generally show a very smooth and homogeneous surface.

3. Conclusion

New tin oxide precursors for the sol gel process, $Sn(OEt)_2(\eta^2\text{-}acac)_2$ (**1**) and $Sn_4(\mu_3\text{-}O)_2(\mu_2\text{-}OEt)_4(OEt)_6(\eta^2\text{-}acac)_2$ (**2**), could be isolated and characterized by single crystal X-ray diffraction. These species are of great interest because ethanol is one of the most commonly used solvent for the sol–gel process. The presence of β-diketonato ligands in the coordination sphere

of the metal induces the stabilization of the precursors toward hydrolysis reaction, thus permitting the preparation of stable sols or gels with higher hydrolysis ratios.

4. Experimental

4.1. General procedures and measurements

All reactions were conducted under an inert atmosphere using Schlenk tubes and vacuum-line techniques. Solvents were purified by standard techniques. The compound $Sn(OBu^t)_4$ was prepared according to the literature [10] and purified by sublimation under vacuum. [$Sn(OEt)_4$] was obtained by alcoholysis of the pure $Sn(OBu^t)_4$ at room temperature. Infrared spectra were recorded on a Perkin Elmer Paragon 500 spectrometer as Nujol mulls. ^1H NMR spectra were recorded on a Brüker AM300 spectrometer and ^{119}Sn NMR spectra on a Brüker DRX500 spectrometer with $Sn(CH_3)_4$ as standard. Powder X-ray diffraction patterns were obtained on a Siemens D5000 diffractometer. TGA analysis were recorded with a Setaram TGDTA92 thermobalance, using Al_2O_3 crucible and heating rates of 5°C min^{-1}.

4.2. Preparation of $Sn(OEt)_2(\eta^2\text{-acac})_2$ (1) and $Sn_4(\mu_3\text{-}O)_2(\mu_2\text{-}OEt)_4(OEt)_6(\eta^2\text{-acac})_2$ (2) — method A

EtOH (1.5 ml, 25.7 mmol) was added to a solution of $Sn(OBu^t)_4$ (0.64 g, 1.56 mmol) in toluene (10 ml). The reaction medium was stirred for 30 min and evaporated to dryness. [$Sn(OEt)_4$] was dissolved in toluene (20 ml) and 2,4-pentanedione (0.16 ml, 1.56 mmoles) was added. The solution was stirred for 20 h and filtrated. Crystallization occurred at room temperature. Two kinds of crystals were simultaneously obtained, yellow prisms (**1**) and small colourless crystals (**2**).

4.3. Preparation of $Sn(OEt)_2(\eta^2\text{-acac})_2$ (1) — method B

2,4-pentanedione (0.24 ml, 2.34 mmol) was added to a solution of $Sn(OBu^t)_4$ (0.48 g, 1.17 mmol) in toluene (10 ml). The reaction medium was stirred for 4 hours and ethanol (0.14 ml, 2.34 mmol) was slowly added. **1** crystallized in toluene at room temperature (0.09 g, 19%).

FT-IR (cm^{-1}): $\nu = 1573$ s, 1534 s; 1279 m, 1194 w, 1155 w, 1101 s, 1058 m, 1025 m, 938 m, 900 w (C–O + C–C); 789 m, 733 w, 680 w, 650 w; 606 w, 579 w, 445 w, 415 m (M–O); ^1H NMR ($CDCl_3$, 20°C, ppm): $\delta = 5.54$ (s, 2H, $(CH_3CO)_2CH$), 3.94 (q ($J = 7$), 4H, OCH_2CH_3), 2.14, 2.03 (s, 12H, $(CH_3CO)_2CH$), 1.22 (t ($J = 7$ Hz), 6H, OCH_2CH_3).

4.4. Preparation of $Sn_4(\mu_3\text{-}O)_2(\mu_2\text{-}OEt)_4(OEt)_6(\eta^2\text{-acac})_2$ (2) — method C

EtOH (1.5 ml, 25.7 mmol) was added to a solution of $Sn(OBu^t)_4$ (0.64 g, 1.56 mmol) in toluene (10 ml). The reaction medium was stirred for 30 min and evaporated to dryness. The white powder was dissolved in toluene (20 ml) and 2,4-pentanedione (0.08 ml, 0.78 mmol) was added. The solution was stirred for 20 h and evaporated to dryness. **2** crystallized in hexane at 4°C (0.116 g, 26%).

FT-IR (cm^{-1}): $\nu = 1561$ s, 1539 s, 1351 m; 1283 w, 1153 w, 1101 s, 1063 s, 1033 m, 940 w, 894 m, 828 w (C–O + C–C); 807 w, 723 w, 679 w, 650 w; 616 w, 591 w, 548 m, 464 w, 417 m (M–O); ^1H NMR ($CDCl_3$, 20°C, ppm): $\delta = 5.60$, 5.58 (s, 2H, $(CH_3CO)_2CH$), 3.7 (q ($J = 6.9$), 20H, OCH_2CH_3), 2.13 (s, 12H, $(CH_3CO)_2CH$), 1.25 (t ($J = 6.9$ Hz), 30H, OCH_2CH_3); ^{119}Sn NMR ($CDCl_3$, 20°C, ppm): $\delta = -694$, -647.8, -646, -645.7, -608.3, -606.8, -568.1.

4.5. Crystal-structure determination of 1 and 2

Data collections for **1** and **2** were performed on a NONIUS Kappa CCD diffractometer with Mo Kα radiation ($\lambda = 0.71069$ Å) using the program Denzo [22]. Intensities were collected by the ω–2θ scan technique. All diagrams and calculations were performed using MAXUS [23]. Hypotheses were determined using

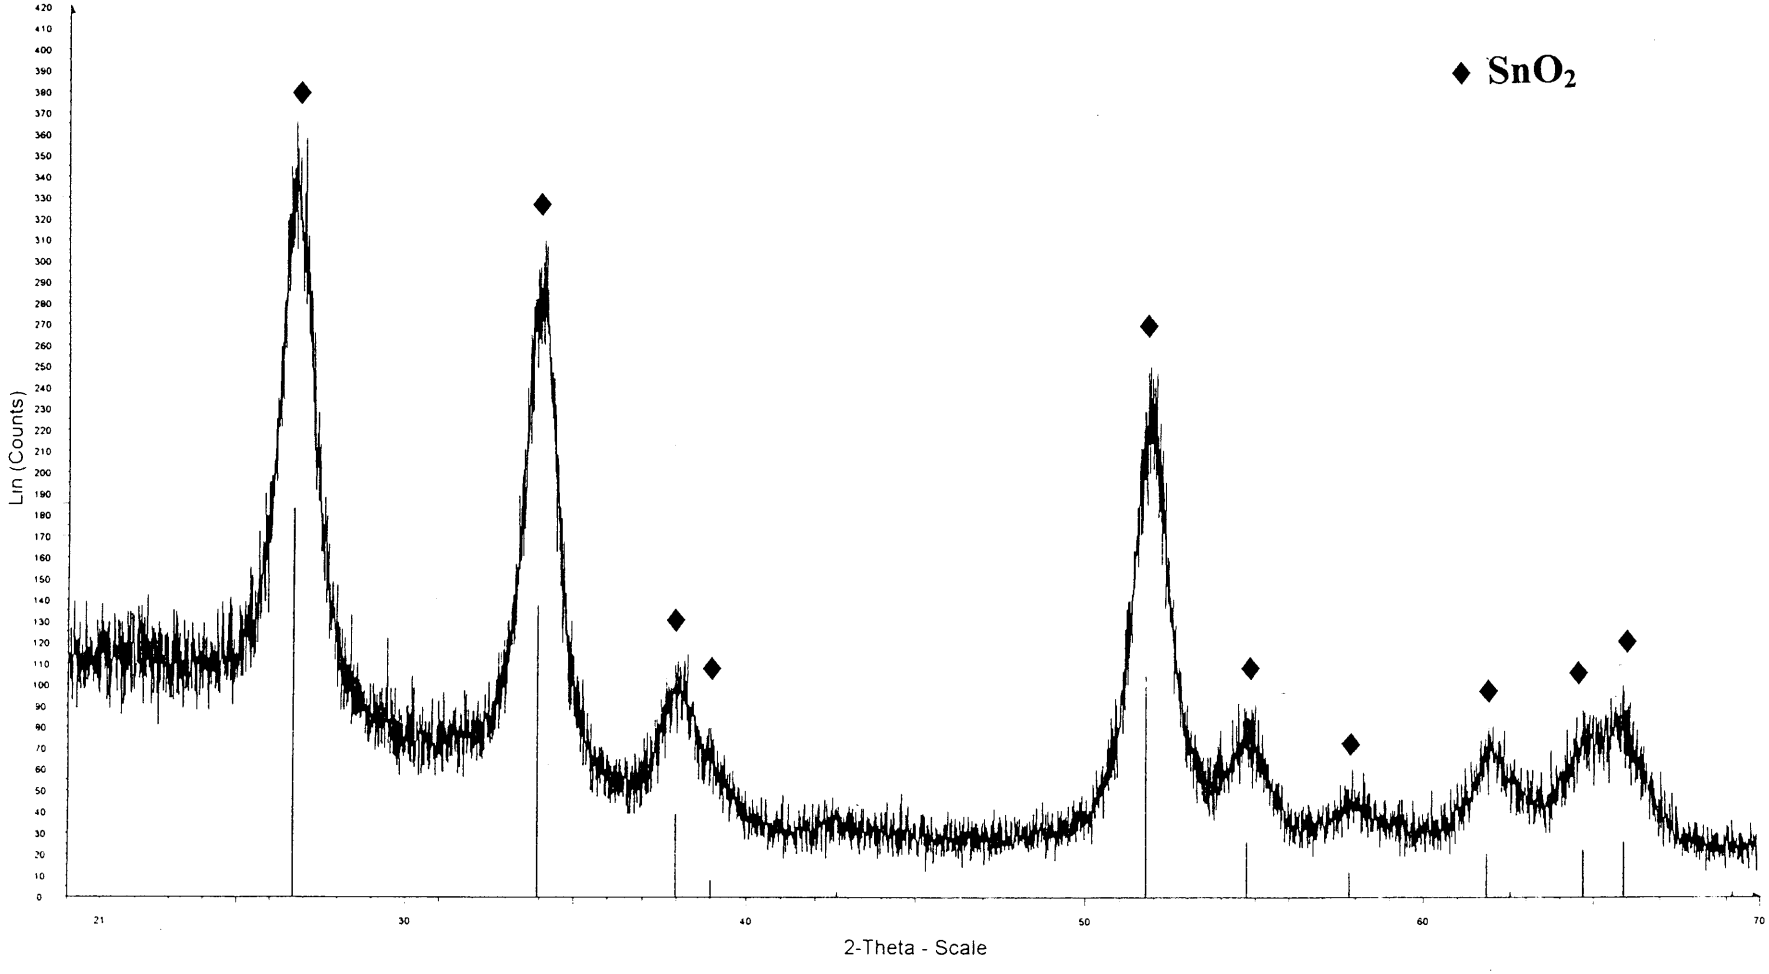

Fig. 3. Powder X-ray diffraction pattern of the xerogel prepared with complete hydrolysis of the precursor and thermal treatment at 500°C.

SIR-97 [24]. Refinement of F^2 against *all* reflections were performed using SHELXL-97 [25]. The weighted R-factor wR and goodness-of-fit S are based on F^2, conventional R-factors R are based on F, with F set to zero for negative F^2.

5. Supplementary material

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 141250 and 141251. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

The preparation of the first examples of sulfimide complexes of platinum; the X-ray crystal structure of $[Pt(Ph_2SNH)_4]Cl_2$

Abstract

The reactivity of *S*,*S*-diphenylsulfimide, Ph_2SNH, (**1**) towards platinum complexes has been investigated. Solutions of **1** and $[PtCl_2(PMe_2Ph)_2]$ show an equilibrium between the starting materials and *cis*-$[PtCl(Ph_2SNH)(PMe_2Ph)_2]Cl$; addition of $[NH_4][BF_4]$ generates pure *cis*-$[PtCl(Ph_2SNH)(PMe_2Ph)_2][BF_4]$ (**2**). Four equivalents of **1** react with $[PPh_4]_2[PtCl_4]$ over a period of days to give crystalline $[Pt(Ph_2SNH)_4]Cl_2$ (**3**); the crystal structure of **3** confirms the expected square planar geometry with significant H-bonding interactions between the cation and the chlorides. © 2000 Elsevier Science Ltd. 1. Introduction

We have long been interested in the ability of sulfur (and selenium)–nitrogen species to react with transition metal centres [1]. In our earlier work on such systems we tended to concentrate upon the reactivity of S–N species that were either completely devoid of substituents (eg. S_4N_4, $[S_3N_3]^-$ etc.) or had only hydrogen present in addition to the sulfur and nitrogen (e.g. $S_4N_4H_4$). In more recent studies we looked at the properties of substituent-capped long-chain species such as $Me_3SiNSNSNSNSiMe_3$, though in such cases the substantial disruption of the latter during reaction means that only unsubstituted S–N ligands are found in the products [2]. In our most recent work, however, we have prepared a range of complexes of a class of S–N ligand that bears organic groups and retains them upon coordination. Specifically we have investigated the reactivity of *S*,*S*′-diphenylsulfimide, Ph_2SNH (**1**), towards a number of metal centres.

These studies have generated a range of unexpected results, such as the unique isomerism of *trans*-$[CuCl_2(Ph_2SNH)_2]$ [3] and the concerted, directed hydrogen bonding between both sets of triple N–H units on either side of the $[Co(Ph_2SNH_2)_6]^{2+}$ cation and the chloride counterions [4]. The interesting ligand properties of **1** were further illustrated by its reactivity towards $Pt(MeCN)_2Cl_2$; now a nucleophilic attack of the sulfimide upon the coordinated nitrile is seen giving rise to the novel $Ph_2SNC(Me)NH$ ligand [5]. The key feature of this reaction is that the latter fragment cannot be formed by simple reaction of the sulfimide with MeCN in the absence of the platinum centre. Although the latter reaction was of great interest and has great potential as a source of new hybrid sulfimide/nitride fragments as free systems, the unexpected reaction of **1** with MeCN meant that simple coordination chemistry with Pt went unobserved.

One aspect of our current interests centres upon making direct contrast between the coordinating ability of **1** and of underivatised S–N species such as S_4N_4. In the previous work alluded to above, platinum complexes proved to be amongst the most versatile reagents for such reactions; thus we have an interest in observing the simple coordination chemistry of **1** with this metal. Here we report on the results of the first such studies and reveal that **1** is not only more reactive towards simple Pt species than underivatised S–N systems but that the products also exhibit interesting H-bonding structures that bode well for their use in constructing extended arrays.

2. Experimental

2.1. General

All reactions were performed under an atmosphere of dry nitrogen using dried, degassed solvents (CH_2Cl_2 and MeCN from calcium hydride, Et_2O from sodium–benzophenone). *S*,*S*′-Diphenylsulfimide was prepared by our recently reported variation of the literature method [6]; $[PPh_4]_2[PtCl_4]$ was prepared by addition of $[PPh_4]Cl$ to $K_2[PtCl_4]$ in water, $[PtCl_2(PMe_2Ph)_2]$ by addition of PMe_2Ph to $[PtCl_2(COD)]$.

2.2. Preparations

2.2.1. *[PtCl(Ph$_2$SNH)(PMe$_2$Ph)$_2$][BF$_4$] (**2**)*

A solution of $[PtCl_2(PMe_2Ph)_2]$ (50 mg, 0.09 mmol) in CH_2Cl_2 (10 ml) was treated with a solution of **1** (23 mg, 0.11 mmol) in the same volume of CH_2Cl_2. After stirring for 1 h the colourless solution was treated with solid $[NH_4][BF_4]$ (10 mg, 0.1 mmol) and the resulting mixture stirred vigorously overnight. Filtration followed by reduction of the volume in vacuo and slow diffusion of diethylether yielded a mass of well-formed colourless crystals of **2**. ^{31}P NMR of solutions before crystallisation showed an effectively quantitative yield of the product: AX spectrum, δ_A −12.7 $^1J(^{31}P-^{195}Pt)$ 3651 Hz; δ_B −20.0 ppm $^1J(^{31}P-^{195}Pt)$ 3141 Hz. Microanalysis: *Anal*. Found: C, 41.6; H, 1.4; N, 4.1. Calc. for $C_{28}H_{33}BClF_4NP_2PtS$: C, 42.3; H, 1.8; N, 4.2%. IR: in addition to peaks due to the PMe_2Ph ligands, bands also seen at 3307(m, *v*(N–H)), 1065 (s, br), 517 (m), 284(m, *v*(Pt–Cl)).

Treatment of a solution of **2** in CH_2Cl_2 with $[^nBu_4N]Cl$ resulted in the rapid establishment of an equilibrium between **2** and $[PtCl_2(PMe_2Ph)_2]$ (as shown by ^{31}P NMR).

2.2.2. *[Pt(Ph$_2$SNH)$_4$]Cl$_2$ (**3**)*

A solution of $[PPh_4]_2[PtCl_4]$ (0.1 g, 0.1 mmol) in CH_2Cl_2 (20 ml) was treated with solid **1** (0.1 g, 0.5 mmol); after stirring the solution was left to stand. Overnight a small crop of pale yellow crystals appeared; the mixture was allowed to stand for one week during which time the amount of crystalline material increased. At this point the solution was decanted from the crystals which were washed with CH_2Cl_2 and dried in vacuo. Yield: 83 mg, 79% based upon Pt. Microanalysis: *Anal*. Found C, 53.2; H, 3.9; N, 4.7. Calc. For $C_{48}H_{44}N_4S_4PtCl_2$ C, 53.8; H, 4.1; N 5.2%.

2.3. X-ray crystallography

Data were collected for **3** (using a Bruker SMART diffractometer with graphite monochromated Mo Kα radiation) using small slices: 11 178 data collected, 3293 data used ($R_{int} = 0.1197$). Data were corrected for Lorentz and polarisation effects and an empirical absorption correction was applied resulting in transmission factors ranging from 0.842 to 1.00.

Structure analysis and refinement: the structure was solved by direct methods and refined by full-matrix least-squares against F^2 leading to $R_1 = 0.0376$, $wR_2 = 0.0494$ with $I > 2\sigma(I)$. The maximum/minimum residual electron densities in the final ΔF map were 0.991 and -1.068 e Å^{-3}; calculations were performed using SHELXTL [7].

3. Results and discussion

The unexpected observation that **1** reacts with $Pt(MeCN)_2Cl_2$ to generate $[Pt(Ph_2SNH)(Ph_2SNC(Me)NH)Cl]Cl$ [5] diverted attention away from the possible simple coordination chemistry that **1** could show towards platinum. Attention to such chemistry is made worthwhile for two reasons. Firstly, we have used platinum as one of the main metal centres for reaction with binary S–N species such as S_4N_4. Contrast between the reactivity of such species and **1** is thus best achieved by looking at such complexes. Secondly, we have already noted a propensity for strong H-bonding from coordinated **1** to counterions; such interactions may well be utilised in the formation of extended array systems. As platinum has a well-defined square-planar geometry one would expect to see a significant contrast between the H-bonding arrangement in its homoleptic complexes of **1** and the aforementioned arrangement in $[Co(Ph_2SNH_2)_6]Cl_2$.
