New cyanamidonitrate complexes with imidazole (iz) and its methyl derivatives (meiz) of the type $[M(NO_2NCN)_2L_4]$ (with M = Ni, L = iz, 1-, 2-, 4-meiz; M = Co, L = iz, 1-, 4-meiz) and $[CoL_4](NO_2NCN)_2$ (with L = iz, 2-meiz) have been prepared and characterized by spectroscopic methods. The crystal structures of $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ and $[Co(NO_2NCN)_2(iz)_4]$ have been determined by X-ray crystallography. The metal(II) environment is practically octahedral, composed of four tertiary nitrogens from imidazole ligands and two nitrile nitrogens from cyanamidonitrate groups. According to the spectral results, similar molecular structures can be assumed for all remaining $[M(NO_2NCN)_2L_4]$ compounds. On the other hand, compounds $[CoL_4](NO_2NCN)_2$ consist of tetrahedral complex cations $[CoL_4]^{2+}$ which are electrostatically attracted with NO_2NCN^-. An isomeric pair, $[Co(NO_2NCN)_2(iz)_4]$ and $[Co(iz)_4](NO_2NCN)_2$, of octahedral and tetrahedral structure, respectively, were characterized. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Cobalt(II); Cyanamidonitrate; Electronic spectra; Imidazole ligands; IR spectra; Nickel(II); X-ray crystallography

1. Introduction

Previously, particular attention was paid to the investigation of coordination compounds with anionic ligands of non-linear pseudohalide type because of their interesting structure and physical properties [1–3]. The non-linear pseudohalide anion, cyanamidonitrate NO_2NCN^-, has until now only been sporadically studied [4–7]. In previous papers [8,9] we described new cyanamidonitrate–copper(II) complexes of the type $[Cu(NO_2NCN)_2L_4]$, where L = imidazole (iz), 1-, 2- or 4-methylimidazole (meiz), as well as $[Cu(NO_2NCN)_2(iz)_2]$. Whereas the L_4 compounds consist of molecular units in which the central Cu^{II} atoms are pseudo-octahedrally coordinated by N(meiz) and N(nitrile) atoms, in the iz_2 compound cyanamidonitrates act as bridges using N(nitrile) and O atoms as donors. However, considering the presence of four potential donor atoms, cyanamidonitrate as ligand has a variety of coordination possibilities, depending on the type of the central atom, especially with respect to its hardness [4].

We have therefore studied the coordination behaviour of cyanamidonitrate in the presence of the same neutral ligands of imidazole type, but with nickel(II) and cobalt(II) as central atoms. We have prepared nine new cyanamidonitrate compounds of Ni^{II} and Co^{II} with imidazole and its methyl derivatives and investigated them by means of infrared (IR) and electronic spectroscopy; in the case of $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ and $[Co(NO_2NCN)_2(iz)_4]$ the crystal structures were solved.

2. Experimental

2.1. Materials

The following chemicals were purchased: $Ni(NO_3)_2\cdot 6H_2O$ p.a., $Co(NO_3)_2\cdot 6H_2O$ p.a. (Chemapol, Czech Republic), imidazole, 1-methylimidazole, 2-methylimidazole, 4-methylimidazole (Merck). Potassium cyanamidonitrate (KNO_2NCN) was prepared from *N*-methyl-*N*-nitroso-*N′*-nitroguanidine according to the procedure described by Harris [10].

2.2. Preparation of the compounds

2.2.1. $[Ni(NO_2NCN)_2(iz)_4]$

Solutions of 1.25 mmol of $Ni(NO_3)_2\cdot 6H_2O$ in 3 cm^3 of water and of 2.5 mmol of KNO_2NCN in 8 cm^3 of water were

mixed and poured into a solution of 5.0 mmol of iz in 8 cm^3 of methanol. From the solution a microcrystalline product was obtained which was filtered off, washed with diethyl ether and dried over KOH. Yield, 72%.

2.2.2. $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$

Solutions of 1.25 mmol of $Ni(NO_3)_2 \cdot 6H_2O$ in 3 cm^3 of water and of 2.5 mmol of KNO_2NCN in 5 cm^3 of water were mixed and poured into a solution of 5.0 mmol of 1-meiz in 10 cm^3 of methanol. From the light-green solution crystals were isolated and treated as before. Yield, 58%.

2.2.3. $[Ni(NO_2NCN)_2L_4]$ (L = 2-meiz, 4-meiz)

Solutions of 1.25 mmol of $Ni(NO_3)_2 \cdot 6H_2O$ in 3 cm^3 of water and of 2.5 mmol of KNO_2NCN in 6 cm^3 of water were mixed and poured into a solution of 5 mmol of ligand L in 10 cm^3 of methanol. The formed turbid green solutions were filtered; the next day, crystals were isolated and treated as before. Yield, 55% (2-meiz), 64% (4-meiz).

2.2.4. $[Co(NO_2NCN)_2(iz)_4]$, $[Co(iz)_4](NO_2NCN)_2$

Solutions of 2.5 mmol of $Co(NO_3)_2 \cdot 6H_2O$ in 3 cm^3 of water and of 5.0 mmol of KNO_2NCN in 10 cm^3 of water were mixed and poured into a solution of 10 mmol of iz in 3 cm^3 of methanol. Next day, from the red–violet solution, crystals of $[Co(NO_2NCN)_2(iz)_4]$ formed on the side of the beaker and a microcrystalline suspension of $[Co(iz)_4](NO_2NCN)_2$ precipitated on the bottom. Yield, 50% $[Co(NO_2NCN)_2(iz)_4]$, 30% $[Co(iz)_4](NO_2NCN)_2$.

2.2.5. $[Co(NO_2NCN)_2L_4]$ (L = 1-meiz, 2-meiz, 4-meiz)

Solutions of 2.5 mmol of $Co(NO_3)_2 \cdot 6H_2O$ in 3 cm^3 of water and of 5.0 mmol of KNO_2NCN in 10 cm^3 of water were mixed and poured into a solution of 10 mmol of ligand L in 3 cm^3 of methanol. From the formed solutions of pink–red (1-meiz) or violet (2-meiz, 4-meiz) colour, compounds in crystalline or microcrystalline state were obtained and treated as before. Yield, 72% (1-meiz), 80% (2-meiz), 74% (4-meiz).

2.3. Analyses

Metal was determined chelatometrically after decomposition of the compounds by action of H_2SO_4 and $K_2S_2O_8$. The elemental analyses were carried out using a Carlo-Erba C, H, N analyser. The analytical data are listed in Table 1.

2.4. X-ray structure analysis and refinement

A summary of the crystal data and their collection for $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ (**1**) and $[Co(NO_2NCN)_2(iz)_4]$ (**2**) is given in Table 2. The final unit-cell parameters were obtained by least-squares on $2\sin\theta/\lambda$ values for 23 reflections with $2\theta = 6.6$–$18.4°$ for compound **1** and 34 reflections with $2\theta = 40.2$–$44.3°$ for compound **2**. The intensities of three standard reflections, measured every 2 h, showed only small random variations. The data reduction and empirical absorption correction were performed according to North et al. [11] for compound **1** and using Stoe-REDU4 [12] for compound **2**.

Both crystal structures were solved by the Patterson method and subsequent Fourier synthesis using SHELXS-86 [13]. Refinement was made by full-matrix least-squares SHELXL-93 software [14] to an $R(F)$ value of 0.0494 and 0.0334 for compounds **1** and **2**, respectively. Non-hydrogen atoms were treated anisotropically, and hydrogen atom positions were located from difference maps and constrained: imidazole C–H = 0.93 Å, N–H = 0.86 Å; CH_3 C–H = 0.96 Å with $U(H) = 1.2U_{eq}$ (C or N).

2.5. Physical measurements

The IR spectra were recorded, using a Philips Analytical PU 9800 FTIR spectrometer, in KBr disks (4000–400 cm^{-1}) and in Nujol mulls (500–200 cm^{-1}). The electronic spectra (0.4–2.8 μm^{-1}) were obtained from solid state samples on a Perkin-Elmer Lambda 19 apparatus. Thermal decompositions were performed on a MOM derivatograph (100 mg samples; heating rate, 6°C min^{-1}).

3. Results and discussion

3.1. Description of the structures of $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ (1) and $[Co(NO_2NCN)_2(iz)_4]$ (2)

The crystal structure of compound **1** consists of discrete $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ molecules (Fig. 1). The central Ni^{II} atom is found in a crystallographic special position and appears to be octahedrally coordinated by six nitrogen donor atoms. In the equatorial plane there are four nitrogens from methylimidazole molecules, while in the axial positions there are two nitrile nitrogens from cyanamidonitrate anions. Differences in bond lengths in the equatorial plane and axial positions are within the standard deviations [Ni1–N2 = 2.093(3) Å, Ni1–N8 = 2.093(2) Å, Ni1–N14 = 2.100(3) Å] (Table 3).

The crystal structure of compound **2** (Fig. 2) is also formed by discrete $[Co(NO_2NCN)_2(iz)_4]$ molecules. There are two symmetrically independent molecules in the unit cell, each with the metal atom lying on a centre of symmetry. The orientation of two molecules expressed by the angle between two symmetrically independent cyanamidonitrate ligands is 140.4(1)°.

In both molecules, the central Co^{II} atom is pseudo-octahedrally coordinated by six nitrogen donor atoms [Co1–N1 = 2.141(2) Å, Co1–N3 = 2.130(2) Å, Co1–N5 = 2.167(2) Å for the first molecule and Co2–N8 = 2.143(2) Å, Co2–N10 = 2.121(2) Å, Co2–N12 = 2.164(2) Å for the second one] (Table 4).

In both crystal structures there is a system of hydrogen bonds and interatomic interactions. However, the correlation between the decomposition temperatures and strength of interatomic interactions is not very obvious (Tables 1, 3 and 4).

3.2. Infrared spectra

The vibration characteristics of the cyanamidonitrate anions in the studied compounds were determined by comparison of the recorded spectra with those of KNO_2NCN [4,15], as well as of the free imidazole and its derivatives [15–17]. Relevant data together with those for KNO_2NCN are listed in Table 5.

The $\nu_{asym}(NCN)$ frequency value should reflect the bonding mode of NO_2NCN^-. In the case of the bond through nitrile nitrogen, a shift of these frequencies to higher values might be expected. However, inspection of the $\nu_{asym}(NCN)$ values for the compounds under study indicates shifts not only to higher but also to lower values. The latter shifts appear just for those compounds for which coordination of the NO_2NCN group through nitrile nitrogen was proved by X-ray crystallography. The shift of the $\nu_{asym}(NCN)$ to lower frequencies was also observed in the case of $[Co(iz)_4](NO_2NCN)_2$ and $[Co(2\text{-meiz})_4](NO_2NCN)_2$ in which the non-linear pseudohalide anions are not coordinated (see Section 3.3) and can interact with cations through hydrogen bondings only. In the 2-meiz compound this band is also expressively splitted, which can hardly be explained by the bonding state of the pseudohalide. Thus, it can be stated that in the present series of compounds the $\nu_{asym}(NCN)$ frequency values are not conclusive for assessing the bonding mode of the cyanamidonitrate anion.

The $\nu_{sym}(NCN)$ frequency values are almost always very near to the values for the potassium salt so that they are not distinctly influenced by the bonding mode of the pseudohal-

[d] The band can involve an admixture of an imidazole ligand band.

ide anion. The assignment of the remaining pseudohalide vibrations is difficult because the relevant region contains many bands belonging to the imidazole ligands [15–17] and careful checking is necessary. According to the obtained values it is clear that the $\nu_{asym}(NO_2)$ and $\nu_{sym}(NO_2)$ vibrations are mostly shifted to higher and lower frequencies, respectively, in comparison with KNO_2NCN, as observed previously [8]. In the case of $[Co(iz)_4](NO_2NCN)_2$ and $[Co(2\text{-meiz})_4](NO_2NCN)_2$, these shifts, in agreement with the ionic bonding, were not observed.

In the far-IR region (up to 200 cm^{-1}) two to four bands between $\approx$540 and 225 cm^{-1} were observed, which can be assigned to the M–N stretching vibrations. In $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$ the skeleton $NiN_4'N_2''$ is present, which with respect to the unequivalency of the N′ and N″ donors shows in fact a D_{4h} symmetry. Therefore, five skeletal stretching modes can be expected, two of which are infrared active: E_u as ν(Ni–N′) and A_{2u} as ν(Ni–N″). The site symmetry in the crystal lattice splits the E_u mode into two components, so that three ν(Ni–N) values are reasonable, but four values were observed (Table 5). For elucidation of this fact, interaction of the stretching modes of the same symmetry, belonging to the structure units in equivalent sites of the unit cell (correlation field effects), must be taken into account. For $[Co(NO_2NCN)_2(iz)_4]$ surprisingly only one ν(Co–N) value was ascertained, but the relevant band is broad and can comprise several closely lying components.

In the case of compounds $[Co(iz)_4](NO_2NCN)_2$ and $[Co(2\text{-meiz})_4](NO_2NCN)_2$ bands appear in a broad frequency region from $\approx$535 cm^{-1} to lower energies. The number and position of these bands agree well with a distorted tetrahedral (C_{2v}) arrangement about the central Co^{II} atom [18,19], which is in agreement with the observed electronic d–d spectra (see below).

3.3. Solid-state electronic spectra

The electronic spectra (Table 6) of the nickel(II) compounds exhibit three spin-allowed d–d absorptions whose positions are typical for octahedral configurations [20]. From the similarity of these spectral features it can be concluded that the molecular structure of all other compounds is analogous to that of $[Ni(NO_2NCN)_2(1\text{-meiz})_4]$, which was proved crystallographically (Fig. 1). The observed d–d absorptions in increasing energy order are assigned to the transitions $^3T_{2g} \leftarrow {}^3A_{2g}$, $^3T_{1g}(F) \leftarrow {}^3A_{2g}$ and $^3T_{1g}(P) \leftarrow {}^3A_{2g}$; the last transition appears only as a broad flat shoulder. The *Dq* values for these compounds are very near to 1050 cm^{-1}, indicating a small difference between the influence of different imidazole ligands. The β values are also very similar and show an appreciable amount of covalency [21].

The ligand field spectra of $[Co(NO_2NCN)_2L_4]$ are indicative of octahedral configuration [20] and, therefore, the crystallographically solved molecular structure of $[Co(NO_2NCN)_2(iz)_4]$ (Fig. 2) can be attributed to the other spectroscopically similar compounds. The low- and

Table 6

[a] The data in parentheses relate to shoulders, whose positions are only approximately determined.

high-energy absorption bands can be assigned to the $^4T_{2g} \leftarrow {}^4T_{1g}(F)$ and $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$ transitions, respectively. The electronically forbidden transition $^4A_{2g} \leftarrow {}^4T_{1g}(F)$ probably corresponds to the shoulders between 1.95 and 1.99 μm^{-1}, as the values of the ratio $E(^4A_{2g} \leftarrow {}^4T_{1g})/E(^4T_{2g} \leftarrow {}^4T_{1g})$ are very near to 1.9 [20]. Other absorptions in the visible region appearing as shoulders can be related to spin-forbidden transitions into some doublet states, spin-orbit coupling or other effects. The Dq values are visibly higher than for the Ni^{II} complexes, which is in agreement with the positions of the respective metals in the spectrochemical series of central atoms [21], and their changes are again relatively small. The very close β values are a little lower than for Ni^{II} complexes.

On the other hand, the ligand field spectra of $[Co(iz)_4](NO_2NCN)_2$ and $[Co(2\text{-meiz})_4](NO_2NCN)_2$ are considerably shifted to the lower energies compared with the foregoing group, and this spectral behaviour is diagnostic of tetrahedral coordination of the central Co^{II} atom. Therefore, it can be concluded that this central atom is tetrahedrally coordinated by four nitrogen atoms from the imidazole-type ligands and these complex cations are electrostatically attracted to the cyanamidonitrate anions. The visible and near-IR bands can be assigned to the $^4T_1(P) \leftarrow {}^4A_2$ and $^4T_1(F) \leftarrow {}^4A_2$ transitions, respectively [20]. The ligand field parameters Dq and β are considerably lower than for the octahedral compounds, as may be expected.

The near-IR bands of the foregoing compounds are very broad and, in the case of $[Co(iz)_4](NO_2NCN)_2$, a low-energy shoulder appears. This fact reveals that the tetrahedral stereochemistry around the cobalt(II) is considerably distorted and very likely has a C_{2v} symmetry [20,22,23] in which the tetrahedral $^4T_1(F)$ state is split into three orbital levels. The particular absorptions on the low-wavenumber sides of the visible bands can be related to the low-symmetry splitting of the tetrahedral $^4T_1(P)$ state.

4. Conclusions

Two different kinds of the cyanamidonitrate compounds of the type $[M(NO_2NCN)_2L_4]$ and $[CoL_4](NO_2NCN)_2$ were isolated. In the complexes of the first type, cyanamidonitrate is coordinated to the central M^{II} atom, whereas in the second type this group forms ionic bonds.

In comparison with other non-linear pseudohalide ligands, cyanamidonitrate exhibits only slight bridging ability in spite of its rich coordination possibilities.

The coordination of this pseudohalide through the nitrile nitrogen is surprisingly not significantly manifested on the $\nu_{asym}(NCN)$ frequency values and only $\nu_{asym}(NO_2)$ and $\nu_{sym}(NO_2)$ frequencies are more regularly influenced.

The coordination polyhedra of the $[M(NO_2NCN)_2L_4]$ compounds are relatively very regular, especially in the Ni^{II} compounds, in spite of the presence of chemically different nitrogen atoms in the coordination sphere. This unequivalency is, however, revealed by the ν(M–N) frequencies in the far-IR spectra.

While with iz an isomeric pair, viz. $[Co(NO_2NCN)_2(iz)_4]$ and $[Co(iz)_4](NO_2NCN)_2$, was obtained, 2-meiz gives with Co^{II} only the compound $[Co(2\text{-meiz})_4](NO_2NCN)_2$. This effect can be connected with steric hindrance of 2-meiz ligand, having better binding possibility in distorted tetrahedral configuration.

Supplementary data

Tables of hydrogen atom parameters, anisotropic thermal parameters, complete lists of bond lengths and angles, as well as measured and calculated structure factors for the structures of compounds **1** and **2** have been deposited with the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

POLYHEDRON

Synthesis of layered dendritic carbosilanes

Chungkyun Kim, Soon Kyu Choi, Bohyun Kim *

Department of Chemistry, Dong-A University, Pusan 604-714, South Korea

Received 14 December 1999; accepted 21 February 2000

Abstract

Layered dendritic carbosilanes containing triple bonds on the peripheral layer, double bonds in the $(n-1)$th inner shell, and single bonds in the $(n-2)$th inner shell were prepared. The synthetic pathways used iterative hydrosilation, alkenylation, and alkynylation. The fourth generation G4-E96PA is composed of two generations of propylene layers (G1 and G2) and one ethenyl layer in the inner shell (G3), and 96 ethynyl groups on the periphery (G4). The dendrimers are characterized by NMR, MALDI-TOF mass spectrometry, UV, IR, SEC and elemental analysis. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Dendrimers; Carbosilanes; Platinum catalysts; Hydrosilation

1. Introduction

Dendrimers that are prepared via an iterative synthetic pathway on a central multifunctional core have recently received considerable attention [1–5]. One of the intriguing possibilities in this field is the synthesis of a spherical molecule without defects. To date, highly branched dendrimers with silicon-containing molecules have been prepared by many researchers who used the beautiful construction of molecular architecture [6–9]. We have observed a few methods for the preparation of carbosilane dendrimers possessing double and triple bonds [10–17]. A number of dendrimers containing two different rests between the progressing units and the last generation have been prepared, mostly focused on modification of peripheral dendritic properties [18–20]. However, very little is known about the synthetic approach to two and more layered dendritic macromolecules, which are composed of different generating layers in the outer and inner shells.

Platinum metal in activated carbon as a hydrosilation catalyst is very useful for the synthetic purpose, because the hydrosilation of all double and triple bonded dendrimers with chlorosilane ($HSiMe_nCl_{3-n}$) does not form side products and brings about quantitative yields. We wish to report the synthetic method and characterization of layered dendrimers with 96 phenylethynyl groups on the outermost dendritic surface.

2. Results and discussion

The synthesis of carbosilane dendrimers with two different generating layers is based on two reaction mechanisms: hydrosilation [21] of double and triple bonds with chlorosilane ($HSiMe_nCl_{3-n}$) and alkenylation as well as alkynylation of dendrimers containing Si–Cl bonds (Scheme 1). The preparation of allyl groups containing low generations G*n*-*m*A ($n=0$–2; $m=6$, 12, and 24) was achieved by the use of iterative alkenylation with allylmagnesium bromide and hydrosilation with dichloromethylsilane based on 1,2-bis(triallylsilyl)ethane as the core [16,17]. The core molecule has six allylic branches that can be prepared by the reaction of 1,2-bis(trichlorosilyl)ethane with 6 equiv. allylmagnesium bromide. The G0-6A (core) with dichloromethylsilane under a platinum catalyst quantitatively provided G1P-12Cl. The yields of all allyl group-containing G*n*-*m*A type dendrimers were almost quantitative [16,17]. However, the hydrosilation of G3-48A with dichloromethylsilane did not produce the unified fourth generation G4-96Cl.

The reaction of G1P-12Cl with lithium phenylacetylide provided G1-12PA with 12 phenylethynyl groups on the periphery. G1-12PA has two different layers, which are composed of six propylene groups in the core and 12 ethynyl groups on the first generation layer. Using the same iterative synthetic method, G2-24PA and G3-48PA (Scheme 2) were synthesized in good yields (Table 1). The platinum catalyzed hydrosilation of triple bonds in dendritic molecules (G*n*-*m*PA) with dichloromethylsilane produced the chlorinated dendrimer G*n*-E2*m*Cl comprising propylene groups on the

$(n-2)$th layer, ethenyl groups on the $(n-1)$th layer, and Si–Cl groups on the outermost periphery. For example, hydrosilation of the G1-12PA molecule with dichloromethylsilane under a platinum catalyst provided G2-E24Cl containing propylene groups in the core, ethenyl groups on the first generation layer, and 24 Si–Cl bonds on the periphery. The reaction of G2-E24Cl with lithium phenylacetylide provided G2-E24PA with 24 phenylethynyl groups on the periphery. The inner shell of G2-E24PA consisted of six propylene groups in the core and 12 ethenyl groups on the first generation layer. The platinum catalyzed hydrosilation process for triple bonded dendritic molecules with chlorosilane revealed a very high yield. Side products such as α-adducts of the hydrosilation reaction were not observed using this reaction procedure. By repetition of the hydrosilation of G*n*-*m*PA ($n=1$–3; $m=12$, 24 and 48) with dichloromethylsilane under a platinum catalyst and alkynylation with lithium phenylacetylide under reflux conditions, ethynyl group-containing dendrimers were prepared up to the fourth generation with good yields (Scheme 2 and Table 1). The formation of G5P by application of the same reaction mechanism was not possible in a uniformly ordered structure.

The identification and determination of the degree of reaction of dendritic branches are very important. In many cases, NMR spectroscopy is used for this purpose. For example, information on the transition from G2P-24Cl to G2-24A can be obtained from analysis of the ^{1}H NMR spectrum. The transition of methyl signals from G2P-24Cl at 0.77 ppm to G2-24PA at 0.43 ppm was observed. Also, the transition of methyl groups of the old generation (G*n*P-*m*Cl) to the new

Scheme 2. Planar views of G3-48PA and G4-E96PA.

generation (G*n*-*m*A) is very clearly observed by NMR spectroscopy. The transition from G2-24PA to G3-E48Cl and from G3-E48Cl to G3-E48PA was observed as the same pattern. Furthermore, the ^{13}C NMR spectroscopic attachments of the hydrosilation procedure revealed the transition from triple bond signals at 90.09 and 106.37 ppm to double bonds at 147.90 and 157.94 ppm. This evidence was observed in all dendritic transitions such as G*n*-*m*Cl to G*n*-*m*PA and G*n*-*m*PA to G*n*-E*m*Cl.

Using UV spectrometry, we observed a very interesting result. That is, the increasing number of triple bonds in G*n*-*m*PA and G*n*E-*m*PA generations ($n=2$–4; $m=24$, 48 and 96) was in direct proportion to the molar absorption (Table 1 and Fig. 1). In most cases the number of triple bonds in the

prepared dendrimers was in direct proportion to the maximal value of absorption at maximal wave number. The G*n*-E*m*PA type dendrimers showed higher molar absorptions than G*n*-*m*PA, because the former have more chromophores such as phenylethenyl groups in the inner shell (Fig. 1).

MALDI-TOF mass spectroscopy is a useful direct method for determination of the molecular weight of macromolecules. However, high mass molecules are difficult to characterize. The MALDI-TOF mass spectrum of G1-12PA showed one signal as the *m/z* value of the main signal at 1876 amu referring to $M^+ + 63$ (M + K and Na ion). G2-24PA showed one main signal at 4063 amu which refers to the M + Na ion. The MALDI-TOF mass spectrum of G3-48PA showed the M + K ion peak. However, the G2-E24PA and G3-E48PA spectra show the M^+ peak (Table 2), whereas the higher molecular weight G4-E96PA (20343 amu) was not observed in any spectrum from MALDI-TOF mass spectroscopy.

The polydispersity value (M_w/M_n) analyzed using SEC for the dendrimers G2-24PA to G4-E96PA shows that the prepared dendrimers have a very narrow range of molecular weight. As expected, the calculated molecular weights of the dendrimers were in inverse proportion to the retention time. The plot of the calculated molecular weights of G1-12PA to G4-E96PA versus retention time was a straight line (Table 2, Fig. 2). This suggests that the prepared dendrimers have regularly increased molecular weight. The characterization

of the prepared dendrimers by the use of NMR, MALDI-TOF mass spectroscopy, UV, EA, and SEC methods is well justified for our experimental purpose.

3. Experimental

All reactions were carried out under a dried N_2 atmosphere. Ether and THF were dried by sodium-benzophenone ketyl, while solvents such as toluene were dried and distilled from sodium metal. The NMR spectra were recorded on a Bruker AC-200 spectrometer. The UV spectra were measured by an HP 8452A diode array UV–Vis spectrophotometer. DSC was measured with a Setram DSC-92 at a heating range of 10°C min^{-1} in aluminum crucibles. The Pusan and Taejon Branches of the Korean Basic Science Institute (KBSI) performed elemental analysis and the MALDI-TOF mass spectroscopy (KRATOS KOMPACKT MALDI-TOF 2). The following abbreviations are used in the experiments: G*n*-*m*A refers to dendritic silanes with allyl groups; G*n*P-*m*Cl refers to dendrimers with dichloromethylsilyl groups on the periphery and propylene groups in the inner shell; G*n*-*m*PA refers to dendrimers with phenylethynyl groups on the periphery and propylene groups in the inner shell; G*n*-E*m*Cl refers to dichloromethylsilyl groups on the periphery, and ethenyl groups in the $(n-1)$th layer, and propylene groups in the $(n-2)$th layer; G*n*-E*m*PA refers to phenylethynyl groups on the periphery and ethenyl groups in the $(n-1)$th layer and propylene groups in the $(n-2)$th layer. A description of the experimental methods has appeared in the literature [10–13,16,17], but the following may serve as examples. The reaction conditions are recorded in Table 1.

3.1. General procedure for GnP-mCl type dendrimers: G0P-6Cl

A mixture of 14.30 g (88.60 mmol) of $Cl_3SiCH{=}CH_2$, 21.26 g (157.74 mmol) of $HSiMeCl_2$, and 0.10 g of a hydrosilation catalyst (10% Pt content on activated carbon) was stirred for 12 h at room temperature. The platinum catalyst was filtered off with pentane. The volatile components were removed under reduced pressure, leaving 26 g (87.56 mmol, 99%) of G0P-6Cl as a colorless crystal. The G0P-6Cl was recrystallized in pentane [16,17].

3.2. General procedure for Gn-mA type dendrimers: G0-6A

222 mmol of allylmagnesium bromide in 200 ml ether was slowly added to 8.13 g (27.38 mmol) of G0P-6Cl in 50 ml THF. After the addition, the reaction mixture was refluxed for 3 h. After the reaction was completed, salt was filtered off and washed with pentane. The volatile components were removed under reduced pressure, leaving a colorless liquid. All compounds formed were chromatographed on silica gel with chloroform. The product G0-6A was obtained as colorless oil. Yield 7.80 g (23.59 mmol, 86%) [16,17].

3.3. General procedure for Gn-mPA type dendrimers: G1-12PA

35 mmol of lithium phenylacetylide in 35 ml THF was slowly added to 2.30 g (2.25 mmol) of G1P-12Cl in 25 ml THF. After the addition, the reaction mixture was refluxed for 3 h. After the reaction was completed, salt was filtered off and washed with toluene. The volatile components were removed under reduced pressure, leaving a yellow solid. All compounds formed were chromatographed on silica gel with toluene. The product G1-12PA was obtained as yellow oil to solid. Yield 2.18 g (1.21 mmol, 54%). *Anal*. Calc. for $C_{122}H_{118}Si_8$: C, 81.00; H, 6.57. Found: C, 81.18; H, 6.51%. FT-IR (KBr, cm^{-1}): 1584 (w, $\nu_{C=C\ aromatic}$), 2165 (s, $\nu_{C\equiv C}$), 3068 (w, $\nu_{C-H\ aromatic}$). T_g (°C): 143.65. ^1H NMR (ppm, $CDCl_3$): δ 0.40 (s, 18H, MeSi(G1)), 0.48 (s, 4H, CH_2(G0)), 0.62–0.81 (m, 12H, CH_2(G0)), 0.81–1.09 (m, 12H, CH_2(G0)), 1.48–1.80 (m, 12H, CH_2(G0)), 7.18–7.68 (m, 60H, Ph). ^{13}C NMR (ppm, $CDCl_3$): δ −1.19 (MeSi(G1)), 4.82 (CH_2(G0)), 16.05 (CH_2(G0)), 18.30 (CH_2(G0)), 20.69 (CH_2(G0)), 90.03 (SiC≡), 106.26 (≡CPh), 122.66 (C_{-q}), 128.12 (C_{-o}), 128.68 (C_{-p}), 132.02 (C_{-m}).

3.4. General procedure for Gn-EmCl type dendrimers: G2-E24Cl

A mixture of 2.14 g (1.18 mmol) of G1-12PA, 4.12 g (35.18 mmol) of $HSiMeCl_2$, and 0.06 g of a hydrosilation catalyst (10% Pt content on activated carbon) was refluxed for 3 h. The platinum catalyst was filtered off with toluene. The volatile components were removed under reduced pressure, leaving 3.43 g (1.08 mmol, 91%) of G2-E24Cl as a yellow crystal. ^{1}H NMR (ppm, $CDCl_3$): δ −0.46 (s, 18H, MeSi(G1)), 0.30 (m, 24H, CH_2(G0)), 0.48 (s, 4H, CH_2(G0)), 0.74 (s, 36H, MeSi(G2P)), 1.07 (m, 12H, CH_2(G0)), 6.53 (s, 12H, CH=(G1)), 6.90–7.53 (m, 60H, Ph). ^{13}C NMR (ppm, $CDCl_3$): δ −2.99 (MeSi(G1)), 4.54 (MeSi(G2P)), 5.18 (CH_2(G0)), 16.61 (CH_2(G0)), 18.33 (CH_2(G0)), 20.42 (CH_2 (G0)), 127.51 (C_{-m}), 128.16 (C_{-p}), 128.19 (C_{-o}), 140.44 (C_{-q}), 148.84 (CH=), 157.16 (=CPh).

3.5. General procedure for Gn-EmPA type dendrimers: G2-E24PA

16 mmol of lithium phenylacetylide in 16 ml THF was slowly added to 1.71 g (0.54 mmol) of G2-E24Cl in 25 ml THF. After the addition was finished, the reaction mixture was refluxed for 3 h. After the reaction was completed, the salt was filtered off and washed with toluene. The volatile components were removed under reduced pressure, leaving a yellow solid. All compounds formed were chromatographed on silica gel with toluene. The product, G2-E24PA, was obtained as yellow oil to solid. Yield 1.52 g (0.32 mmol, 60%). *Anal*. Calc. for $C_{326}H_{286}Si_{20}$: C, 82.16; H, 6.05. Found: C, 81.71; H, 6.06%. FT-IR (KBr, cm^{-1}): 1594 (w, $\nu_{C=C}$), 2158 (s, $\nu_{C\equiv C}$), 2914 (w, $\nu_{C-H\ aliphatic}$), 3055 (w, $\nu_{C-H\ aromatic}$). T_g (°C): 137.83. ^{1}H NMR (ppm, $CDCl_3$): δ −0.48 (s, 18H, MeSi(G1)), 0.20 (s, 24H, CH_2(G0)), 0.29 (m, 4H, CH_2(G0)), 0.43 (s, 36H, MeSi(G2)), 0.99 (m, 12H, CH_2(G0)), 6.68 (s, 12H, CH=(G1)), 6.78–7.75 (m, 180H, Ph). ^{13}C NMR (ppm, $CDCl_3$): δ −2.90 (MeSi(G1)), −0.85 (MeSi(G2)), 4.98 (CH_2(G0)), 16.89 (CH_2(G0)), 18.30 (CH_2(G0)), 20.53 (CH_2(G0)), 89.18 (SiC≡), 107.58 (≡CPh), 122.62 (C_{-q}), 126.45 (C_{-p}(G1)), 127.69 (C_{-m}(G1)), 128.08 (C_{-o}(G1)), 128.20 (C_{-o}), 128.87 (C_{-p}), 132.05 (C_{-m}), 143.22 (C_{-q}(G1)), 148.02 (CH=(G1)), 157.86 (=CPh(G1)).

3.6. G3-E48Cl

Abstract

The methathesis reactions between $NbCl_5$ and lithium-2,6-dimethylphenoxide, LiO-2,6-$PhMe_2$, afford $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4 \cdot 3THF$ (**1**) and $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2 \cdot 2THF]_2$ (**2**). The complexes **1** and **2** were characterized by X-ray single crystal diffraction analyses, elemental analyses, and FT-IR, ^1H and ^{13}C NMR spectroscopy. Complex **1** exists as a monomeric binuclear lithium niobium complex which has a terminal oxo ligand, and complex **2** exists as a dimeric tetranuclear lithium niobium complex where metal atoms are linearly connected by μ_2-chloride linkages, respectively. Lithium metal is coordinated by THF molecules as a counter ion. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Heterometallic aryloxides; Lithium niobate; Monomeric compounds; Niobium; Percursors

1. Introduction

Transition metal alkoxides are not only important starting materials for studying organometallic chemistry but are also extremely attractive precursors for the preparation of metal oxides. In particular, heterometallic alkoxides are potential single-source precursors for the fabrication of bimetallic (or multimetallic) oxides owing to the significant advantages they offer to the composition control of final ceramic materials and simplification of processes [1–10]. With the development of processes such as sol-gel and metal-organic chemical vapor deposition (MOCVD), demand for molecularly defined precursors has been increased [1–10]. Therefore, there has been many studies on the preparation of heterometallic alkoxides in recent years.

In particular, lithium niobium alkoxides are in an area of intense current interest owing to their utility as precursors for electro-optic materials [11–23]. However, the chemistry of lithium niobium alkoxides remains relatively unexplored. Since the first report of the syntheses of lithium niobium(V) alkoxides, $[LiNb(OR)_6]_X$ (R = Me, Et, ^{i}Pr, ^{t}Bu) [15], a few complexes have been synthesized and characterized: $[LiNb(OEt)_6]_X$ of helical structure [16] and $[LiNbO(OEt)_4 \cdot EtOH]_2$ [1,11,17] as intermediate in a hydrolysis reaction to $[LiNb(OEt)_6]_X$. More recently, $[LiNb(OR)_6]_2$ ($R = CH_2CMe_3$, CH_2SiMe_3), dimeric molecular precursors, have been prepared and characterized [18].

Our motivation for exploring lithium niobium alkoxides concerns the development of improved molecular single-source precursors for lithium niobate, $LiNbO_3$. To obtain molecular lithium niobium complexes without any intermolecular bonds or bridging units, we have introduced bulky aryl groups containing methyl side chains [24]. Syntheses and structural characterizations of niobium(V) aryl compounds such as homoleptic niobium aryloxides, $Nb(O\text{-}2,6\text{-}PhMe_2)_5$, $[Nb(O\text{-}4\text{-}PhMe)_5]_2$, and $[Nb(O\text{-}3,5\text{-}PhMe)_5]_2$, niobium oxo aryloxides, $NbO(O\text{-}2,6\text{-}PhMe_2)_3$ and $NbO(O\text{-}2,6\text{-}Ph^tBu_2)_3$, and niobium chloro aryloxides, $NbCl(MTP)_2$ ($MTP = 2,2'\text{-}CH_2(O\text{-}2,4\text{-}C_6H_2{}^tBu_2)_2$), $[Nb(O\text{-}2,6\text{-}Ph^iPr_2)_2Cl_3]_2$, and $Nb(O\text{-}2,6\text{-}PhMe_2)_2Cl_3 \cdot THF$ (THF = tetrahydrofuran) have been reported [25–29]. However, lithium niobium aryloxides, oxo aryloxides, or chloro aryloxides have not been synthesized yet. This study reports the syntheses and structural characterizations of the first examples of a monomeric lithium niobium(V) oxo aryloxide, $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4 \cdot 3THF$ (**1**), and a dimeric lithium niobium(IV) chloro aryloxide, $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2 \cdot 2THF]_2$ (**2**).

2. Experimental

All reactions and manipulations were carried out under dry inert gas using standard Schlenk line techniques. Solvents were dried and purified by distillation from sodium benzophenone ketyl under nitrogen. Niobium chloride, lithium, and 2,6-dimethylphenol were used as received from Strem Chemicals and Aldrich Chemical Co. Lithium-2,6-dimethylphenoxide was prepared from 2,6-dimethylphenol and metallic lithium in diethyl ether. IR spectra were obtained as KBr pellet technique on a Nicolet Magna-IR 760 spectrometer. NMR spectra were registered on a Varian Gemini 300 spectrometer. Analytical data were obtained with a Thermoquest EA-1110 CHNS analyzer.

2.1. Synthesis of $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4\cdot 3THF$ (1)

A solution of $NbCl_5$ (2 g, 7.4 mmol) in THF (50 ml) was added dropwise to a solution of 4 equiv. $LiO\text{-}2,6\text{-}PhMe_2$ (3.8 g, 29.7 mmol) in THF (50 ml). The resultant mixture was stirred at ambient temperature for 24 h. After removal of THF solvent, diethyl ether (150 ml) was added, and the mixture was filtered to eliminate LiCl. After concentration to half volume, THF (50 ml) was added and the solution was layered with *n*-hexane. Complex **1** was obtained as yellow crystals with 72% (4.35 g) yield. *Anal*. Found: C, 64.74; H, 7.67. Calc. for $C_{44}H_{60}O_8LiNb$: C, 64.70; H, 7.40%. FT-IR (cm^{-1}): 3010w, 2976m, 2880m, 1594w, 1467s, 1426s, 1372w, 1273vs, 1225vs, 1088m, 1048m, 918m, 880s, 754s, 737m, 713s, 566m, 546m. ^1H NMR ($CDCl_3$, 25°C, ppm): 6.94–6.51 (m, 12H, $OC_6H_3Me_2$); 3.66 (t, 12H, OCH_2CH_2); 2.15 (s, 24H, $OC_6H_3Me_2$); 1.76 (quintet, 12H, OCH_2CH_2). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 25°C, ppm): 160.5, 128.5, 127.8, 127.2, 123.5, 121.1, 119.6, 118.9 ($OC_6H_5Me_2$); 68.2 (OCH_2CH_2); 25.4 (OCH_2CH_2); 17.0, 16.2 ($OC_6H_5Me_2$).

2.2. Synthesis of $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2\cdot 2THF]_2$ (2)

A solution of 4 equiv. $LiO\text{-}2,6\text{-}PhMe_2$ (3.8 g, 29.7 mmol) in THF (50 ml) was added dropwise to $NbCl_5$ (2 g, 7.4 mmol). After a similar procedure to the preparation of complex **1**, complex **2** was obtained as dark brown crystals in a small amount. Satisfactory C and H analyses were obtained for complex **2**. FT-IR (cm^{-1}): 3010w, 2976m, 2881m, 1587w, 1467s, 1420m, 1379w, 1266s, 1208vs, 1092m, 1044m, 891s, 767m, 730s, 571m. ^1H NMR (CD_3OD, 25°C, ppm): 6.89–6.61 (m, 12H, $OC_6H_3Me_2$); 3.73 (t, 16H, OCH_2CH_2); 2.19 (s, 24H, $OC_6H_3Me_2$); 1.87 (quintet, 16H, OCH_2CH_2). $^{13}C\{^1H\}$ NMR (CD_3OD, 25°C, ppm): 129.3, 125.5, 120.7 ($OC_6H_5Me_2$); 68.8 (OCH_2CH_2); 26.5 (OCH_2CH_2); 16.6 ($OC_6H_5Me_2$).

2.3. Crystallography of $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4\cdot 3THF$ and of $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2\cdot 2THF]_2$

Single crystals suitable for X-ray diffraction studies were grown from THF and *n*-hexane for complexes **1** and **2**. A suitable crystal of each compound was mounted inside a glass capillary under nitrogen atmosphere and sealed with a flame. Diffraction data were collected on a Bruker P4 four circle instrument, with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters and basic information about data collection and structure refinement are given in Table 1. The structures were solved by direct methods with SHELXS-86 and refined against F^2 on all data by full-matrix least-squares with SHELXL-93. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms

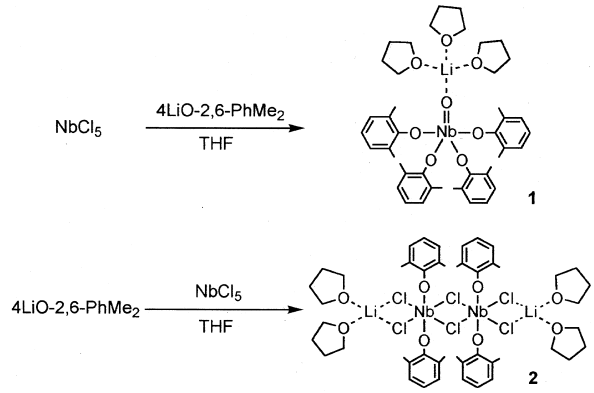
3. Results and discussion



3.1. Synthesis and characterization

The methathesis reactions of niobium chloride, $NbCl_5$, with lithium-2,6-dimethylphenoxide, LiO-2,6-$PhMe_2$, were investigated in THF at room temperature. Complexes of formula $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4 \cdot 3THF$ (**1**) and $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2 \cdot 2THF]_2$ (**2**) were obtained (Scheme 1). Complex **1** was prepared by adding a THF solution of $NbCl_5$ to a THF solution of 4 equiv. LiO-2,6-$PhMe_2$ with 72% yield. Complex **1** was formed irrespective of the ligand-to-metal molar ratio, *R*, used (from 4 to 6) and was obtained in the same yield for each ratio. The formation of a terminal oxo ligand in situ may result from the abstraction of the oxygen atom from THF by $NbCl_5$ at the initial stage of the reaction [14,23,29,30]. However, the direct reaction between $NbOCl_3 \cdot 2CH_3CN$ and 4 equiv. LiO-2,6-$PhMe_2$ did not seem to be a useful route to complex **1**. On the other hand, the addition of a THF solution of 4 equiv. LiO-2,6-$PhMe_2$ to $NbCl_5$ led to the formation of complex **2**. The reaction of $NbCl_5$ with Li-2,6-$OPhMe_2$ in 1:2–1:6 molar ratio was carried out. An amount of complex **2** was obtained with the formation of a niobium chloro-aryloxide, $NbCl_x(OR)_{5-x}$, as the major product. The maximum yield of complex **2** was $>10\%$ at $R=4$. Complexes **1** and **2** were characterized by spectroscopic and analytical techniques.

The FT-IR spectra exhibit stretching modes from ν(C–O–C) of the coordinated THF molecules at 1048 (m) and 880 (s) cm^{-1} for complex **1** and at 1044 (m) and 891 (s) cm^{-1} for complex **2** and a sharp band at 918 (m) cm^{-1} for complex **1** from ν(Nb=O) which is shifted to lower frequencies compared to ν(Nb=O), 962 cm^{-1} of the $[NbOCl_4(THF)]^-$ anion [31]. The bands at 566 (m) and 546 (m) cm^{-1} in complex **1** and at 571 (m) cm^{-1} in complex **2** are assigned to ν(Nb–O) vibrations from aryloxo ligands [32]. In the ^1H and $^{13}C\{^1H\}$ NMR spectra of complex **2** in CD_3OD, the resonance signals corresponding to only one type of 2,6-dimethylphenoxy ligand and coordinated THF molecules are observed at room temperature, while those of complex **1** in $CDCl_3$ show two types of peaks for 2,6-dimethylphenoxy ligands. The presence of two types of signals suggests magnetically non-equivalent surroundings for 2,6-dimethylphenoxy ligands.

3.2. Molecular structures of $LiNbO(O\text{-}2,6\text{-}PhMe_2)_4 \cdot 3THF$ and of $[LiNbCl_3(O\text{-}2,6\text{-}PhMe_2)_2 \cdot 2THF]_2$

To establish the solid state structures, X-ray single crystal diffraction analyses of complexes **1** and **2** were used. The ORTEP diagrams of complexes **1** and **2** are presented in Figs. 1 and 2, respectively.

Scheme 1. Syntheses of lithium niobium oxo-aryloxides and chloro-aryloxides.

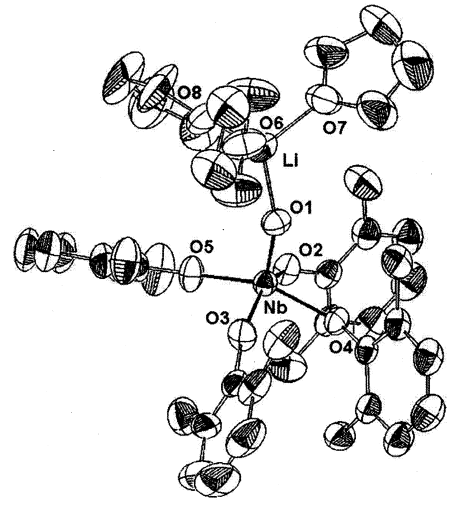


Fig. 1. ORTEP diagram of complex **1** in the solid state. The hydrogen atoms are omitted for clarity.

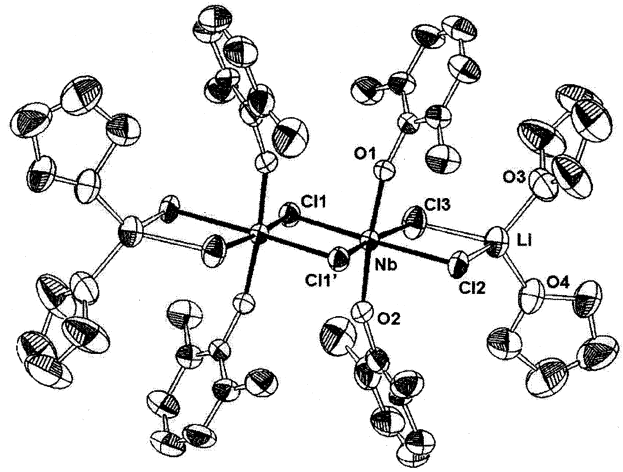

Fig. 2. ORTEP diagram of complex **2** in the solid state. The hydrogen atoms are omitted for clarity.

Complex **1** exists as a monomeric binuclear complex (Fig. 1). Selected bond lengths and angles are given in Table 2. The structure of complex **1** can be described as $[NbO(O\text{-}2,6\text{-}PhMe_2)_4]^-$ capped by an Li^+ cation which is solvated with three THF molecules. The molecular structure of com-

Nb–O1–Li	154.0(6)		

plex **1** includes niobium square pyramid and lithium tetrahedron units sharing a corner corresponding to the oxo ligand (Li–O1=Nb 154.0(6)°). The niobium is five-coordinated by a terminal oxo ligand in an axial position and four 2,6-dimethylphenoxy ligands in the basal plane of the square pyramid. The lithium is four-coordinated by three oxygen atoms of THF molecules and the terminal oxo ligand in the $[NbO(O\text{-}2,6\text{-}PhMe_2)_4]^-$ unit. The steric hindrance of the 2,6-dimethylphenoxy ligands stabilizes a low coordination number, with a terminal Nb=O bond [12,13,23].

The square pyramidal geometry around the niobium metal is severely distorted (O–Nb=O angles ranging from 101.5(2) to 106.8(2)°, *cis* O–Nb–O angles ranging from 82.8(2) to 90.7(2)°, and *trans* O–Nb–O angles ranging from 149.7(2) to 155.2(2)°), while the lithium tetrahedron is quite regular (O–Li–O angles ranging from 105.6(8) to 112.5(8)°). The average Nb–O bond length of 1.949 Å is significantly longer than those in analogous compounds such as $[LiNb(OEt)_6]_X$ (1.88 Å) [16], $[LiNb(OCH_2SiMe_3)_6]_2$ (1.893 Å) [18], and $Nb(O\text{-}2,6\text{-}PhMe_2)_5$ (1.899 Å) [25]. This is probably due to the formation of a double bond between niobium and the terminal oxygen in axial position, which results in the elongation of Nb–O bonds in *trans* positions. Interestingly, the four 2,6-dimethylphenoxy ligands in complex **1** are not identical. The bond distance Nb–O5 (1.922(5) Å) is shorter than those of the other Nb–O bonds in complex **1**. It can be assumed that the partial π interaction between the d orbital of niobium and p orbital of oxygen in Nb–O5 might cause the strong bond. The nearly linear Nb–O5–C25 angle (169.9(5)°) supports this assumption. In addition, the Nb=O1 bond length (1.730(5) Å) is longer than those in the following complexes: 1.710 Å in $[NbO(SPh)_4]^-$ [33], 1.699 Å in $NbO(N(SiMe_3)_2)_3$ [30], and 1.67–1.71 Å in six-coordinated oxo niobium complexes [34]. This probably results from the interaction between the terminal oxo ligand and lithium ion that makes the Nb=O bond relatively weaker.

Complex **2** exists as a dimeric tetranuclear complex (Fig. 2). Selected bond lengths and angles are given in Table 3. The center of the dimeric molecule is located on the crystallographic inversion center. The molecular structure of complex **2** can be described as niobium octahedra and lithium tetrahedra which are linearly connected by μ_2-chloride linkages along the Li–Nb–Nb–Li axis. The niobium is six-coordinated by four μ_2-chloride ligands and two 2,6-dimethylphenoxy ligands in *trans* positions. The lithium is four-coordinated by two μ_2-chloride ligands and two oxygen atoms of THF molecules.

The coordination environments of niobium and lithium are quite distorted (*cis* X–Nb–X (X = O or Cl) angles ranging from 83.62(4) to 104.01(3)° and X–Li–X angles ranging from 90.3(3) to 117.8(5)°). The average Nb–O bond length, 1.888 Å, is similar to those in previously known compounds but shorter than those in complex **1** by 0.06 Å [16,18,25]. The decrease in Nb–O bond length of complex **2** can be explained by the absence of an Nb=O bond. The average Nb–μ_2-Cl bond length, 2.484 Å, is significantly longer than those in chloride derivatives of niobium, probably as a consequence of interaction between the bridging chloride ligand and the lithium counter ion [14,27–29,31,34–36].

Complex **1** is the first monomeric lithium niobium(V) oxo aryloxide and complex **2** is also the first dimeric lithium niobium(IV) chloro aryloxide. Complex **1** is expected to act as a potential precursor for the fabrication of $LiNbO_3$ owing to its solubility in a variety of organic solvents and reduced sensitivity to hydrolytic processes [2]. In addition, complex **2** is an invaluable intermediate to interpret the formation of heterometallic alkoxides in organometallic chemistry. Further study will verify more detailed reaction mechanisms and reactivities of complexes **1** and **2**. In a preliminary study,

Abstract

^{31}P and ^{9}Be NMR spectra of mixtures of beryllium(II) and phosphoric acid have been interpreted to support the speciation previously proposed on the basis of potentiometric measurements. Nine ^{31}P lines were observed at ≈0.4, −3.67, −4.51, −5.57, −6.5, −7.08, −8.81, −9.3 and −11.0 ppm relative to 85% phosphoric acid as external standard. The signal in the range 0.36–0.56 was assigned to rapidly exchanging H_3PO_4, $H_2PO_4^-$ with a further contribution from $Be_3O(H_2PO_4)_6^{2-}$. The peaks at −3.67 and −4.51 ppm were ascribed to isomers of $Be(H_2PO_4)_2$. The species $Be(H_2PO_4)^+$ also gives a signal centred at −4.51 ppm. The peak at −6.5 ppm was assigned to $Be_3(OH)_3(H_2PO_4)_3$. The peaks at −5.58, −8.81 and −9.3 ppm are tentatively assigned to isomers of the complex $Be_2(OH)(H_2PO_4)^{2+}$. Signals observed at −7.08 and −11.0 ppm could not be assigned to any of the complexes proposed by potentiometry. The ^{9}Be NMR data are also consistent with the model previously proposed. ©2000 Elsevier Science Ltd All rights reserved.

1. Introduction

Complexes of beryllium(II) with phosphato ligands have been investigated previously [1] by potentiometry (25°C, 3 mol dm^{-3} $(Na)ClO_4$) using a glass electrode in the $-\log[H^+]$ range 1–4. The stoichiometry of the complexes formed is defined by Eq. (1).

$$pBe^{2+} + rH_3PO_4 \rightleftarrows Be_pH_{-q}(H_3PO_4)_r^{2p-q} + qH^+ \qquad (1)$$

On the basis of the analysis of the potentiometric data by SUPERQUAD [2] the most important species were identified as follows: $BeH_{-1}(H_3PO_4)^+$ $(111)^+$, $BeH_{-2}(H_3PO_4)_2$ (122), $Be_2H_{-2}(H_3PO_4)^{2+}$ $(221)^{2+}$, $Be_3H_{-6}(H_3PO_4)$ (361), $Be_3H_{-6}(H_3PO_4)_3$ (363) and $Be_3H_{-8}(H_3PO_4)_6^{2-}$ $(386)^{2-}$ [3]. These species constitute the 'potentiometric model' of the equilibrium system. Formation constants are given in Table 1. The present work was undertaken in order to obtain evidence to support the 'potentiometric model', especially since the model determination relies on the emf data having very high precision. We have assigned species to signals in both ^{31}P and ^{9}Be NMR spectra. Relative peak areas were compared with predictions from the 'potentiometric model'; the satisfactory agreement may be taken as an indirect but convincing demonstration of the correctness of the model proposed.

2. Notation

Reagents: Be^{2+}, H_2O and H_3PO_4.
Equilibria: $pBe^{2+} + rH_3PO_4 \rightleftarrows Be_pH_{-q}(H_3PO_4)_r^{2p-q} + qH^+, \beta_{pqr}$
$(pqr)^{2p-q} = Be_pH_{-q}(H_3PO_4)_r^{2p-q}$.
C_M = total concentration (mol dm^{-3}) of beryllium.
C_P = total concentration (mol dm^{-3}) of phosphate.
P_{pqr} = fraction of phosphorus in the species $(pqr)^{2p-q}$ $= r[Be_pH_{-q}(H_3PO_4)_r^{2p-q}]/C_P = r\beta_{pqr}[Be^{2+}]^p[H^+]^{-q}[H_3PO_4]^{r-1}/(1+\sum r\beta_{pqr}[Be^{2+}]^p[H^+]^{-q}[H_3PO_4]^{r-1})$.
B_{pqr} = fraction of beryllium in the complex $(pqr)^{2p-q}$ $= p[Be_pH_{-q}(H_3PO_4)_r^{2p-q}]/C_M = p\beta_{pqr}[Be^{2+}]^{p-1}[H^+]^{-q}[H_3PO_4]^r/(1+\sum p\beta_{pqr}[Be^{2+}]^{p-1}[H^+]^{-q}[H_3PO_4]^r)$.

[a] Ref. [6].
[b] Ref. [1].

δ_{pqr} = chemical shift (ppm) of the $(pqr)^{2p-q}$ species.
I_A, I_B, … fractional peak areas: I_A is area of peak A divided by the sum of the areas of all the peaks in the spectrum.

3. Experimental

3.1. Chemicals and analysis

Reagents were prepared and analyzed as described elsewhere [1]. The solutions were made up to constant ionic strength, 3 mol dm^{-3}, with $NaClO_4$. The $-\log[H^+]$ values of the solutions investigated ranged between 1.0 and 2.5.

3.2. NMR measurements

$^{31}P\{^1H\}$ and $^9Be\{^1H\}$ NMR spectra were recorded at 81.02 and 28.18 MHz, respectively, using a Bruker AC 200 spectrometer. The probe temperature was 23 ± 1°C. Field-frequency stabilization was established by means of a capillary tube filled with D_2O inserted coaxially in the NMR tube. All ^{31}P chemical shifts are reported in ppm toward higher frequency with respect to external 85% H_3PO_4. No corrections were made for differences in bulk susceptibilities. Since the predominant species in 85% aqueous phosphoric acid is, according to Wertz and Cook [4], the dimer $(H_3PO_4)_2$, the chemical shifts refer to this species. The ^9Be chemical shifts are relative to external 0.1 mol dm^{-3} aqueous $BeSO_4$ [5].

3.3. Spectra and composition of the solutions used

The ^{31}P spectra are shown in Fig. 1 and the ^9Be spectra in Fig. 2. The composition of the solutions is given in Table 1. The resonances were assigned by measuring the peak integrals and comparing them with the P_{pqr} and B_{pqr} values predicted according to the 'potentiometric model'. Since the concentration of the complex $Be_3H_{-6}(H_3PO_4)$ (361) is expected to be negligible in the solutions examined here, no

attempt has been made to assign an NMR signal to this species.

4. Results

4.1. ^{31}P NMR spectra

The chemical shifts of the observed signals are given in Table 2.

Peak A. The position of this peak shows a $[H^+]$-dependence which is reasonably explained in terms of a proton transfer reaction which is fast on the 81 MHz time-scale. The chemical shift, δ_A, can be expressed as in Eq. (2), where the summations are taken over all species which contribute to the peak.

$$\delta_A = \Sigma(\delta_{pqr} P_{pqr} / \Sigma P_{pqr}) \quad (2)$$

In the preliminary analysis of the data, the resonance was assigned to the species H_3PO_4 and $H_2PO_4^-$. For solutions 3, 4, 5, 11, 12, 13 and 14, peak integrals agreed within 10% with the sum $P_{001} + P_{011}$. For these solutions, the plot of δ_A versus $P_{011}/(P_{001} + P_{011})$ could be fitted with a straight line as expected in the presence of H_3PO_4 and $H_2PO_4^-$ only. However, for solutions 1, 2, 6, 7, 8, 9 and 10 the integrated intensity of peak A differs significantly from $P_{001} + P_{011}$ and the chemical shifts deviate markedly from the linear behaviour of the δ_A versus $P_{011}/(P_{001} + P_{011})$ of the first group of solutions. A detailed inspection of the 'potentiometric model' reveals the presence of the $(386)^{2-}$ complex in solutions of the second group, whilst no peak ascribable to this species can be found in the corresponding spectra. Peak A is therefore likely to be due to the three species H_3PO_4, $H_2PO_4^-$ and $Be_3H_{-8}(H_3PO_4)_6^{2-}$. This hypothesis was validated in two ways. Firstly, the comparison of peak integrals for all solutions with $P_{001} + P_{011} + P_{386}$ indicated satisfactory agreement within 6%. Secondly, δ_A, was expressed as in Eq. (3) and the most probable δ_{pqr} were calculated by processing the data by standard least-squares procedures.

$$\delta_A = (\delta_{001} P_{001} + \delta_{011} P_{011} + \delta_{386} P_{386}) / (P_{001} + P_{011} + P_{386}) \quad (3)$$

The calculations gave $\sigma(\delta_A) = 0.032$ and the best fit parameters (3σ) shown in Eq. (4).

$$\delta_{001} = 0.3_1 \pm 0.1,\ \delta_{011} = 0.69 \pm 0.06,\ \delta_{386} = 0.4_9 \pm 0.1 \quad (4)$$

Peak B, at -3.67 ppm, is ascribed to the (122) species, whereas peak C, at -4.56 ppm, has contributions from both $(111)^+$ and (122), except in solutions 11, 12 and 13; in these cases the concentration of (122) is small and the signal is generated by the $(111)^+$ species alone. In solutions 2 and 10 the ratio P_{111}/P_{122} is less than 0.1 but the corresponding spectra show both B and C with a ratio I_C/I_B greater than unity. The sum of peak areas agrees within 9% with $P_{111} + P_{122}$. The two peaks due to the (122) complex may be ascribed either to the two non-equivalent phosphorus atoms in the molecule or to isomers. Since $I_B/P_{122} = 0.30 \pm 0.15$, the explanation in terms of isomers is more likely. Fig. 1(d) illustrates the quartet nature of peaks B and C, due to coupling with the ^{9}Be nucleus ($I = 3/2$). The $^{2}J_{Be-P}$ coupling constant was estimated to be 5 ± 1 Hz. An analogous pattern of quartets has also been observed in the ^{19}F NMR spectra of fluoro complexes of beryllium [7]: in that case the fact that the fluorine atoms are bonded to the beryllium results in a much larger coupling constant, $^{1}J_{Be-F} = 34$–42 Hz.

Peaks D, G and H, which are observed as broad lines at ca. -5.57, -8.81 and -9.3 ppm, are strictly connected with each other. The appearance or disappearance of one of them is mirrored by the others. These three resonances are tenta-

Table 2
Peaks in ^{31}P NMR spectra

Peak	δ (ppm)	Assignment
A	0.36–0.56	H_3PO_4, $H_2PO_4^-$ and $Be_3H_{-8}(H_3PO_4)_6^{2-}$
B	-3.67 ± 0.04	$Be(H_2PO_4)_2$
C	-4.51 ± 0.03	$BeH_2PO_4^+$ and $Be(H_2PO_4)_2$
D	-5.57 ± 0.03	$Be_2H_{-2}(H_3PO_4)^{2+}$
E	-6.5 ± 0.2	$Be_3H_{-6}(H_3PO_4)_3$
F	-7.08	not assigned
G	-8.81 ± 0.09	$Be_2H_{-2}(H_3PO_4)^{2+}$
H	-9.3 ± 0.2	$Be_2H_{-2}(H_3PO_4)^{2+}$
I	-11.0 ± 0.2	not assigned

tively ascribed to the polynuclear complex $Be_2H_{-2}(H_3PO_4)^{2+}$; a comparison of peak areas with calculated P_{221} values is given in Table 3. The agreement can be considered acceptable in relation to the noise on the calculated peak integrals.

Peak E is observed in the spectra of solutions 2, 3, 4, 7, 13 and 14. Comparison of signal intensities with P_{pqr} values, shown in Table 4, suggests that it should be assigned to $Be_3H_{-6}(H_3PO_4)_3$.

Peaks F and I are only observed as weak signals in the spectra of solutions 13 and 14. The composition of these solutions is outside the composition range investigated by potentiometry. These peaks probably derive from species which are present in negligible amounts in the solutions studied by potentiometry, so no assignment has been attempted.

4.2. ^{9}Be NMR spectra

The spectra are characterized by signals either very close together or actually overlapping each other. The width at half height of the band at ≈ 0 ppm was estimated to be between 3 and 5 Hz. Chemical shifts observed in the ^{9}Be NMR spectra are listed in Table 5.

Peak X was assigned to the free $Be^{2+}(aq)$ ion on the basis of close agreement (within 3%) of the integrated intensity with B_{100} values calculated from the model. For the other peaks, overlap is too great to allow a quantitative evaluation of integrated intensity; the assignments of these peaks were made by searching for strong signals in spectra derived from solutions where a complex predominates. In this respect the most informative spectra are those obtained from solutions 1, 9, 10, 12 and 13; corresponding fractional concentration values are shown in Table 6.

In the spectrum of solution 2, peaks were found at -0.55, -0.69, -1.12 ppm with a shoulder at ≈ -0.35 ppm. We ascribe the resonances at -0.55 and -0.69 ppm to isomers of (122), and that at -1.12 ppm to $(386)^{2-}$ (see below). The shoulder might be assigned to $(111)^+$, but this could not be confirmed as there is no solution in which $(111)^+$ is predominant.

In solutions 12 and 13 the most intense peaks are at -0.55 and -0.69 ppm with a shoulder at about -1.1 ppm. Under these conditions we expect signals originating from $(221)^{2+}$ to be the most intense. In accordance with the findings of the preceding section we conclude that the shifts arise from isomers of the polynuclear complex $Be_2H_{-2}(H_3PO_4)^{2+}$.

In the spectra of solutions 9 and 10, three intense peaks are observed while two complexes are present in comparable amount. The shifts at -0.55, -0.69 ppm have been assigned to (122) and therefore that at -1.12 ppm is very likely to be due to $(386)^{2-}$.

As neither of the species $(111)^+$ and (363) are predicted to be predominant in any of the solutions studied, we have not attempted an assignment.

Table 3

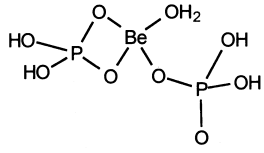
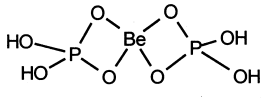
5. Discussion

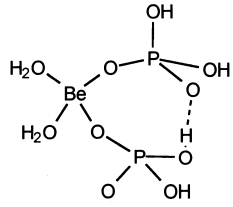


Information deduced from ^{31}P and ^{9}Be NMR spectrometry corroborates the 'potentiometric model'. The most convincing evidence comes from the agreement, within experimental

error, of the free metal and ligand concentrations calculated from the model with corresponding peak intensities.



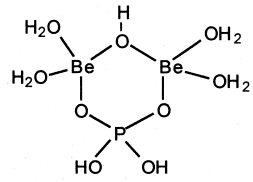
Though the sensitivity and resolution of the ^{31}P and ^{9}Be NMR spectra are not, at present, high enough to permit an independent equilibrium analysis to be performed on the NMR data, spectrometry is superior when it comes to establishing the presence of isomers. Isomerism may occur in phosphato complexes because the phosphate ligand may be either monodentate or bidentate. Thus, if $Be(H_2PO_4)_2$ is in fact a mixture of at least two isomers, as the NMR data suggest, structures (I) to (IV) are all possibilities.



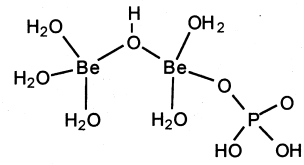
(I)

(II)

(III)

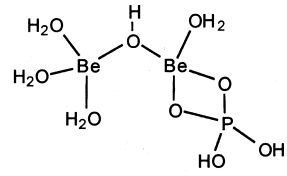


(IV)



In order to explain the appearance of two bands it has to be postulated that the ^{31}P nuclei belonging to phosphate groups in different isomers give rise to signals which are nearly 1 ppm apart. We believe that forms (III) and (IV) are the most probable. Support for this idea is provided by the fact that the stepwise equilibrium constant for $Be^{2+} + Be(H_2PO_4)_2 \rightleftarrows 2BeH_2PO_4^+$ has a value of 0.3 which is much lower than 4, the value expected purely on the basis of statistical considerations. The extra stabilization of $Be(H_2PO_4)_2$ with respect to $BeH_2PO_4^+$ can be explained by the formation of the chelate rings present in (III) and (IV). Evidence for the existence of this kind of four-membered chelate ring and its stability is provided by the work of Bruno et al. [8] on beryllium carbonato complexes. In that paper the authors also refer to an X-ray crystal structure determination which they had performed on the complex $[Be_3(OH)_3(C_5H_4NCO_2)_3]\cdot H_2O$, in which the three pyridine-2-carboxylato ligands appear to act as bidentate ligands in relation to the beryllium in the same way as they propose for the carbonate. Unfortunately this work has not, to the best of our knowledge, been published.

The isomers of stoichiometry $Be_2H_{-2}(H_3PO_4)^{2+}$ may be postulated as being derivatives of $Be_2(OH)^{3+}$, the second most important species in beryllium hydrolysis [9]. The ligand is $H_2PO_4^-$ and it may be bridging bidentate, (V), monodentate, (VI), or chelating bidentate, (VII).



The stucture of the (363) species can reasonably be assumed to derive from the trimer, $Be_3(OH)_3^{3+}$, which is the major product of beryllium hydrolysis. The stoichiometry

(V)

(VI)

(VII)

then demands that the ligands be formulated as $H_2PO_4^-$ and the complex as $Be_3(OH)_3(H_2PO_4)_3$.

It is more difficult to assign a tentative structure to the other trinuclear species, of stoichiometry $Be_3H_{-8}(H_3PO_4)_6^{2-}$. The formula $Be_3O(H_2PO_4)_6^{2-}$ was proposed [1] for this complex and the structure proposed contains both bridging and terminal phosphate groups. The slow exchange of beryllium nuclei, as indicated by the ^{9}Be spectra, would be consistent with a structure in which there is a Be_3O core which is inert on the NMR time-scale. The ^{31}P spectra are not so easy to explain. A contribution from this species to resonance A in the ^{31}P spectra is required in order to make a quantitative assignment of peak areas and chemical shifts. However, the observation of a single line is difficult to reconcile with the structure previously proposed for this species. A single line implies that the phosphorus nuclei are either all chemically equivalent or exchanging rapidly. Equivalence is possible if all the phosphato ligands are monodentate, but this seems unlikely. If rapid exchange is present then a mechanism must be operating which does not operate in the case of the 221 complex. Another possibility is that some phosphato ligands (perhaps the monodentate ones) are in slow exchange with each other, so giving a line broadening which has made the line appear to be absent.

Received 26 July 1999; accepted 15 February 2000

Abstract

The geometric isomers, *in*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)Cl]^+$ (**1a**), *in*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)OH_2]^{2+}$ (**1b**), and *in*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)(NCCH_3)]^{2+}$ (**1c**), *out*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)Cl]^+$ (**2a**), *out*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)OH_2]^{2+}$ (**2b**), and *out*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)(NCCH_3)]^{2+}$ (**2c**), where trpy is 2,2′,2″-terpyridine and 4,4′-Me_2dppi is 3,6-di-(4-methylpyrid-2-yl)pyridazine, were synthesized and characterized by UV–Vis and ^{1}H NMR spectroscopy. The *in* and *out* notation refers to the orientation of the non-imine group which is directed towards the center of the complexes in the *in* complexes and away from the center in the *out* complexes. Compounds **1a** and **2c** were additionally characterized by X-ray crystallography. Reaction of **1a** or **2a** with aqueous silver ion produces the corresponding aqua complexes, **1b** and **2b**, which after dissolution in acetonitrile produces the analogous acetonitrile complexes, **1c** and **2c**. The redox properties of **1a**, **1b**, **2a**, and **2b** were examined using cyclic voltammetry. In acetonitrile, compounds **1a** and **2a** display reversible $1e^-$ waves assigned to the Ru(III)/Ru(II) couple, while in aqueous solutions **1b** and **2b** show pH-dependent $2e^-$ waves corresponding to the formation of Ru(IV)=O complexes. Second-order rate constants, k_{cat}, for oxidation of benzyl alcohol derivatives by the Ru(IV)=O complex **2b** were determined electrochemically. Complex **1b** severely passivated the working electrode upon oxidation, and reliable catalytic rate constants could not be measured. This passivation may be related to self oxidation of the Me_2dppi ligand by the electrochemically generated Ru(IV)=O complex. ©2000 Elsevier Science Ltd All rights reserved.

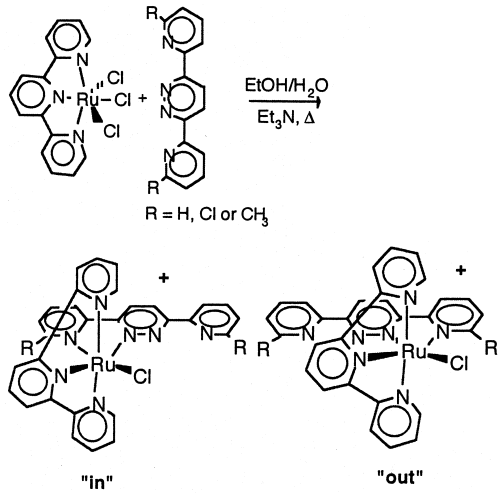
1. Introduction

High-valent ruthenium oxo complexes catalyze a variety of small-molecule oxidations [1–4]. Recently, we studied the electrocatalytic oxidation of benzyl alcohol by $[Ru(trpy)(R_2dppi)(O)]^{2+}$ (where R_2dppi is a 6,6′-disubstituted dipyridopyridazine, with R = H, CH_3, or Cl) [5]. Interestingly, the catalytic rates correlated with the steric hindrance about the metal center, but not the thermodynamic driving force for oxidation. These observations are consistent with a mechanism in which the rate-determining step involves pre-association of the substrate with the catalyst, rather than electron transfer [6–10]. During the course of this study, we found that of the two possible geometric isomers of $Ru(trpy)(R_2dppi)(L)^{n+}$ (shown below as *in* and *out*), only one could be effectively isolated. Here, using a 4,4′-disubstituted dppi ligand, we report the synthesis of both isomers, and describe their structural and catalytic properties.

2. Experimental



2.1. Materials

$RuCl_3 \cdot H_2O$ was obtained from Strem Chemical. All other chemicals were obtained from Acros and used without additional purification.

2.2. Instrumentation and measurements

^{1}H NMR spectra were recorded on either a Varian Unity Plus 500 MHz spectrometer or General Electric QE-300 spectrometer, and all spectra were referenced to TMS as an internal standard. UV–Vis spectra were recorded using a Perkin-Elmer Lamda 11 spectrophotometer.

2.3. Electrochemistry

All electrochemical experiments were performed with a Bioanalytical Systems (BAS) model CV50-W electrochemical analyzer. Cyclic voltammetry (CV) and chronocoulometry (CC) were performed at 20 ± 3°C with a normal three-electrode configuration consisting of a highly polished glassy-carbon working electrode and an AgCl/Ag reference electrode containing 1.0 M KCl. The working compartment of the electrochemical cell was separated from the reference compartment by a modified Luggin capillary. All three compartments contained a 0.1 M solution of supporting electrolyte.

Acetonitrile (Burdick and Jackson) was distilled from P_2O_5 prior to use. Tetrabutylammonium hexafluorophosphate, $TBAPF_6$ (Southwest Analytical), was used as received. Acetonitrile electrolyte solutions were prepared and stored over 80-200 mesh activated alumina (Fisher Scientific Co.) and activated 4 Å molecular sieves. Potentials are reported versus AgCl/Ag and are not corrected for the junction potential. In acetonitrile, the ferrocenium/ferrocene couple has an $E^{o\prime}$ of 0.49 V, with $E_{pa} - E_{pc} = 87$ mV; the corresponding aqueous-solution potential is 0.11 V. Digital simulations were performed using the commercial Digisim 2.1 software package from BAS [11].

2.4. Preparations

$Ru(trpy)Cl_3$ [12] and trpy [13] were synthesized according to literature procedures. 4,4′-Me_2dppi was prepared analogously to the previously described dipyridopyridine ligands from 4-methyl-2-cyanopyridine [14].

2.4.1. In-[Ru(trpy)(4,4′-Me_2dppi)Cl](PF_6) (**1a**) and out-[Ru(trpy)(4,4′-Me_2dppi)Cl](PF_6) (**2a**)

0.157 g (0.60 mmol) 4,4′-Me_2dppi and 0.283 g $Ru(trpy)Cl_3$ (0.64 mmol) were refluxed for 3 h with 0.033 g LiCl and 16 drops of *N*-ethyl morpholine. The resulting solution was filtered hot through celite, and the solvent was removed in vacuo. The residue was dissolved in 40 ml of methanol, and 0.417 g NH_4PF_6 was added. The resulting solid was collected. The remaining solution was reduced to dryness on a rotary evaporator. The solid was then re-dissolved in acetone, and 30 ml of isopropanol was added. The acetone was slowly removed using a rotary evaporator until a precipitate was formed. The resulting solid was collected and chromatographed on activated alumina using a solution of 20% CH_3CN and 80% CH_2Cl_2. The first fraction was recrystallized from acetone and diethyl ether to give 0.198 g **2a** (42.6%) and 0.082 g **1a** (17.6%). The remaining bands on the column were $[Ru(tpy)_2]^{2+}$ and other side products; no attempt was made to isolate or purify them. **2a** ^{1}H NMR (Me_2CO-d_6): δ 10.19 (1H, d, ^3J(HH) = 5.5 Hz), 8.83 (2H, d, ^3J(HH) = 8.5 Hz), 8.80 (1H, s), 8.73 (1H, d, ^3J(HH) = 9.0 Hz), 8.60 (2H, d, ^3J(HH) = 8.0 Hz), 8.46 (1H, d, ^3J(HH) = 4.5 Hz), 8.42 (1H, t, ^3J(HH) = 8.0 Hz), 8.34 (1H, d, ^3J(HH) = 8.5 Hz), 8.07 (1H, d, ^3J(HH) = 5.5 Hz), 7.99 (2H, td, ^3J(HH) = 8 Hz, ^4J(HH) = 1.5 Hz), 7.90 (2H, d, ^3J(HH) = 5.5 Hz), 7.41 (2H, td, ^3J(HH) = 5.5 Hz, ^4J(HH) = 1.5 Hz), 7.30 (2H, m), 2.45 (3H, s), 2.43 (3H, s); UV–Vis [λ_{max} (nm) (ε_{max} (dm^3 mol^{-1} cm^{-1}))]: (CH_2Cl_2) 315 (5.2×10^4), 324 (3.3×10^4), 363 (5.4×10^3), 439 (6.1×10^3), 490 (8.5×10^3), 526 (1.1×10^4). **1a** ^{1}H NMR (Me_2CO-d_6): δ 9.12 (1H, d, ^3J(HH) = 9.0 Hz), 8.98 (1H, d, ^3J(HH) = 9.0 Hz), 8.87 (1H, d, ^3J(HH) = 0.5), 8.76 (2H, d, ^3J(HH) = 8.0 Hz), 8.73 (1H, d, ^3J(HH) = 5.0 Hz), 8.62 (3H, m), 8.24 (1H, t, ^3J(HH) = 8.0 Hz), 7.98 (4H, m), 7.56 (1H, d, ^3J(HH) = 5.5 Hz), 7.46 (1H, dd, ^3J(HH) = 5.5 Hz, ^4J(HH) = 0.5 Hz), 7.34 (2H, td, ^3J(HH) = 7.0 Hz, ^4J(HH) = 1.5 Hz), 7.08 (1H, dd, ^3J(HH) = 6.0 Hz, ^4J(HH) = 1.0 Hz), 2.45 (3H, s), 2.43 (3H, s); UV–Vis [λ_{max} (nm) (ε_{max} (dm^3 mol^{-1} cm^{-1}))]: (CH_2Cl_2) 318 (4.8×10^4), 384 (6.2×10^3), 410 (5.8×10^3), 455 (5.8×10^3), 479 (7.8×10^3), 521 (1.0×10^4).

2.4.2. Out-[Ru(trpy)(4,4′-Me_2dppi)H_2O](ClO_4)$_2$ (**2b**)

0.120 g of **2a** was refluxed for 3 h with 0.127 g $AgClO_4$ in 40 ml of a 3:1 acetone:water solution. The solution was cooled in an ice bath, filtered through celite, and the acetone removed in vacuo. A bright orange–red solid precipitated from solution to give 0.091 g of **2b**. ^{1}H NMR (Me_2CO-d_6/D_2O): δ 9.55 (1H, d, ^3J(HH) = 5.5 Hz), 8.80 (2H, d, ^3J(HH) = 8.0 Hz), 8.74 (1H, s), 8.67 (1H, d, ^3J(HH) = 9.0 Hz), 8.57 (2H, d, ^3J(HH) = 8.0 Hz), 8.47 (1H, t, ^3J(HH) = 8.0 Hz), 8.39 (1H, d, ^3J(HH) = 5.0 Hz), 8.21 (1H, d, ^3J(HH) = 8.5 Hz), 8.07 (1H, dd, ^3J(HH) = 6.0 Hz,

^4J(HH) = 1.0 Hz), 8.02 (2H, td, ^3J(HH) = 8.0 Hz, ^4J(HH) = 1.5 Hz), 7.93 (2H, d, ^3J(HH) = 5.5 Hz), 7.42 (2H, td, ^3J(HH) = 5.5 Hz, ^4J(HH) = 1.0 Hz), 7.28 (1H, dd, ^3J(HH) = 5.0 Hz, ^4J(HH) = 1.0 Hz), 7.16 (1H, s), 2.81 (3H, s), 2.35 (3H, s); UV–Vis [λ_{max} (nm) (ε_{max} (dm^3 mol^{-1} cm^{-1}))] (H_2O) 308 (4.3×10^4), 329 (1.9×10^4), 425 (5.7×10^3), 491 (8.0×10^3), 585 (1.5×10^3).

2.4.3. In-[Ru(trpy)(4,4′-Me$_2$dppi)H$_2$O](PF$_6$)$_2$ (**1b**)

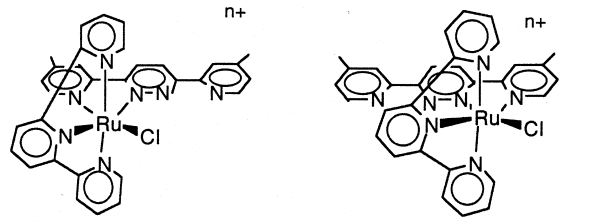
0.091 g of **1a** (0.12 mmol) was gently heated for three hours with 0.221 g (0.63 mmol) of $TlPF_6$ in a 1:1 acetone: water solution. The solution was then cooled in an ice bath, filtered, and the solvent removed in vacuo. The crude product was dissolved in acetone and precipitated with diethyl ether to give 0.087 g of **1b** (82.1%). ^{1}H NMR (Me_2CO-d_6/D_2O): δ 8.91 (1H, d, ^3J(HH) = 9.5 Hz), 8.69 (1H, d, ^3J(HH) = 9.0 Hz), 8.58 (1H, d, ^3J(HH) = 8.5 Hz), 8.54 (2H, d, ^3J(HH) = 11.0 Hz), 8.43 (2H, m), 8.31 (1H, s), 8.23 (1H, t, ^3J(HH) = 8.0 Hz), 7.90 (1H, t, ^3J(HH) = 7.5 Hz), 7.74 (2H, d, ^3J(HH) = 5.5 Hz), 7.44 (2H, d, ^3J(HH) = 6.0 Hz), 7.27 (2H, d, ^3J(HH) = 6.0 Hz), 7.23 (2H, t, ^3J(HH) = 6.0 Hz), 6.89 (1H, d, ^3J(HH) = 5.5 Hz), 2.39 (3H, s), 2.28 (3H, s); UV–Vis [λ_{max} (nm) (ε_{max} (dm^3 mol^{-1} cm^{-1}))]: (H_2O) 272 (3.0×10^4), 279 (2.9×10^4), 307 (4.7×10^4), 331 (1.5×10^4), 394 (4.0×10^3), 449 (8.6×10^3), 480 (1.0×10^4), 542 (2.4×10^3).

2.5. X-ray data collection and processing

Crystals of **1a** and **2c** were grown by slow diffusion of diethyl ether through a thin layer of methanol into an acetonitrile solution of the complex. Suitable crystals of **1a** were coated with light hydrocarbon oil, mounted on a glass fiber and placed in the −100°C nitrogen cold stream of a Siemens P4 diffractometer. A crystal of **2c** was coated in epoxy cement, and the data were collected at room temperature.

Compound **1a** yielded 6293 reflections of which 4869 (R_{int} = 0.0473) were unique in the range $1.99 < \theta < 22.50°$. Over the range $1.84 < \theta < 22.50°$ **2c** yielded 4957 (R_{int} = 0.0445) independent reflections from a total of 6370 reflections. No absorption correction was applied to **1a** while a semi-empirical model derived from psi-scans was applied to **2c**.

The data were corrected for Lorentz and polarization effects. Crystal data are given in Table 1. Scattering factors and corrections for anomalous dispersion were taken from a standard source [15].



Calculations were performed using the Siemens SHELXTL PLUS (version 5.03) system of programs, refining on F^2. The structures were solved by direct methods. The structure of **2c** contains two BF_4^- anions one of which is disordered over eight positions. The structure also contains a one-half occupancy isopropanol molecule and a one-quarter occupancy water molecule. The structure of **1a** contains two PF_6^- anions one of which is positionally disordered. The structure also contains an acetone molecule and a one-half occupancy water molecule. Hydrogen atom positions were calculated using a riding model with a C–H distance fixed at 0.96 Å and a thermal parameter 1.2 times the host carbon atom. The largest peak in the final difference map corresponded to 1.07 e$^-$ Å^{-3} and was located 1.246 Å from B(2) in **2c**. In **1a** the largest unassigned peak corresponded to 0.67 e$^-$ Å^{-3} and was located 0.710 Å from F(1A).

1a (X = Cl, n=1) **2a**
1b (X = OH_2, n=2) **2b**
1c (X = $NCCH_3$, n=2) **2c**
1d (X = O, n=2) **2d**

3.1. Syntheses

As we have noted previously, the initial reaction of R_2dppi with Ru(tpy)Cl_3 produced two isomers of [Ru(trpy)-(R_2dppi)Cl]$^+$. The major product, the *out* isomer, has the chloride ligand directed away from the center of the R_2dppi ligand, while the *in* isomer has the chloride atom pointed toward the center of the R_2dppi ligand. While both the *in* and *out* isomers were characterized crystallographically for the H_2dppi ligand, the *in* could not be isolated in appreciable quantities. In addition, the *in* complex was never detected in

the 6,6′-Me_2dppi and Cl_2dppi complexes. However, simply changing the positions of the methyl groups on the dppi ligands from the 6,6′-positions to the 4,4′-positions afforded both the *in* and *out* isomers of $[Ru(trpy)(4,4'\text{-}Me_2\text{-}dppi)Cl]^+$, isolated in a 1:4 ratio. The initial reaction mixture is first passed through a column of activated alumina to remove the $[Ru(trpy)_2]^{2+}$ impurity. The two isomers can then be separated by slow recrystallization from acetone/diethyl ether. Once in hand, the chloride species are converted in good yield to the analogous aqua complexes (**1b** and **2b**) using Ag(I) or Tl(I) ion in refluxing acetone/water. The labile aqua ligands are easily replaced by donor solvents (e.g. acetonitrile to produce **1c** and **2c**.) Ru(IV)=O complexes (**1d** and **2d**) are generated in situ electrochemically [5].

3.2. Structure analyses

*3.2.1. Structure of in-[Ru(trpy)(4,4′-Me_2dppi)Cl](PF_6)·($(CH_3)_2CO$·0.5H_2O (**1a**)*

The asymmetric unit of **1a** consists of the cation, a disordered PF_6^- anion, an acetone molecule, and a half-occupancy water molecule. A view of the cation is presented in Fig. 1, and selected bond distances and angles are given in Table 2. Consistent with the *in* geometry the chloride linkage is directed towards the center of the 4,4′-Me_2dppi ligand. The uncoordinated pyridine group is rotated away from the metal centers and is nearly coplanar with the pyridazine ring with a dihedral angle of only 4.1° and the N(6)–C(24)–C(25)–N(7) torsion angle of 173.5(3)°. As expected, placement of the methyl groups in the 4 and 4′ positions significantly reduces the steric congestion about the metal center as compared to the previously studied 6,6′-Me_2dppi complexes. The Ru(1)–Cl(1) separation is normal at 2.413(3) Å as are the remaining Ru–N separations. The Ru(1)–N(2) separation at 1.962(7) Å is slightly contracted, consistent with meridionally coordinated terpyridine. The contraction of the central pyridine is a result of the constrained bite angle of this ligand. As a result the *trans* spanning N(1)–Ru(1)–N(3) bond angle at 158.9(3)° is less than the ideal 180°. The terpyridine ligand is canted away from the 4,4′-Me_2dppi ligand with an N(2)–Ru(1)–N(4) angle of 99.2(3)°. Conversely, the *cis* angles, Cl(1)–Ru(1)–N(2) and Cl(1)–Ru(1)–N(5), at 88.1(2) and 94.2(2)°, are closer to the ideal *cis* angle of 90°.

*3.2.2. Structure of out-[Ru(trpy)(4,4′-Me_2dppi)($NCCH_3$)](BF_4)$_2$·0.5$(CH_3)_2CHOH$·0.25H_2O (**2c**)*

The asymmetric unit of **2c** contains the cation, two BF_4^- anions one-half of an isopropanol molecule and one-quarter of a water molecule. There are no unusual contacts between these moieties. Crystal data are reported in Table 1, and selected bond distances and angles are given in Table 2. A view of the cation is presented in Fig. 2. The structure reveals a Ru center in a distorted octahedral environment. The coordinated acetonitrile ligand is directed away from the 4,4′-

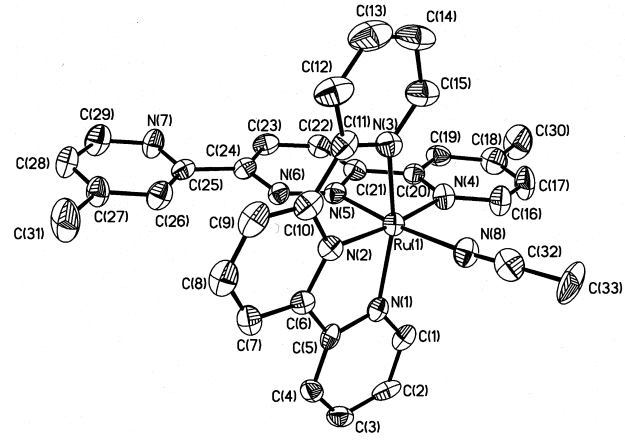

Fig. 2. Perspective view (40% probability ellipsoids) of the cation of *out*-$[Ru(trpy)(4,4'\text{-}Me_2dppi)(NCCH_3)](PF_6)_2$ (**2c**) with numbering scheme.

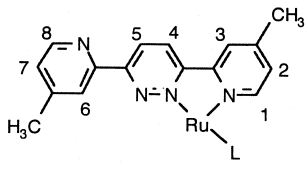
Me_2dppi ligand consistent with the *out* geometry. Like **1a**, the terpyridine group coordinates in a meridional fashion with a similar contraction of the Ru(1)–N(2) bond to 1.973(6) Å. The remaining Ru(1)–N separations fall within expected ranges. The angles around the acetonitrile group are slightly expanded with N(2)–Ru(1)–N(8) and N(4)–Ru(1)–N(8) opening to 93.9(3) and 95.5(3)°, respectively. Allowing for this expansion the N(2)–Ru(1)–N(5) angle contracts to 78.5(2)°. All other bond distances and angles fall within normal ranges.

3.3. ^{1}H NMR spectroscopy

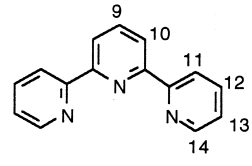
The ^{1}H NMR spectra of the complexes support the proposed geometries. The spectra of the *out* isomers exhibit a downfield resonance due to the interaction of the 4,4′-dppi proton (on C(16) from Fig. 2) and the chloride, aqua or acetonitrile ligands. This diagnostic signal permitted all the resonances to be assigned unambiguously using NOE and COSY experiments. The spectral assignments for **2a** and **2b** are shown in Table 3. The *in* isomers lack this interaction since the chloride and aqua groups are directed towards the interior of the 4,4′-Me_2dppi ligand and are not in close contact with any protons.

3.4. Isomerization



As expected for d^6 low spin complexes, **1a** and **2a** are substitutionally inert; however, once the chloride ligand is replaced by an aqua group, **1b** is prone to isomerization. Upon photolysis by visible light or reflux in methanol or acetone/water, solutions of *in*-[Ru(trpy)(4,4′-Me_2dppi)$(OH_2)]^{2+}$ readily and completely isomerize to *out*-[Ru(trpy)(4,4′-Me_2dppi)$(OH_2)]^{2+}$, but the reverse reaction was never detected, indicating that the *out* complexes are the thermodynamic products while the *in* products are the kinetic products. The mechanism for photo-isomerization likely involves excitation into a low-lying ligand-field transition [16,17]. Dissociation of the internal Ru–dppi bonds and rotation about the remaining Ru–dppi bond would interconvert the *in* isomer to the *out*, and this process could be affected thermally or photochemically. However, given that under identical conditions the chloro analogs are inert yet the relatively labile aqua species isomerize, the solvent may also play a role. Protecting the *in*-[Ru(trpy)(4,4′-Me_2dppi)$(OH_2)]^{2+}$ solutions from room light and operating at or below room temperature are enough to prevent isomerization.

3.5. Electronic absorption spectra



As tabulated in Table 4 compounds **1a** and **2a** both exhibited broad unsymmetrical bands in the visible region due to MLCT processes. The spectra also possess intense π to π* transitions in the UV region attributable to the polypyridine ligands. The λ_{max} for the MLCT transitions were 490 and 526 nm for **2a** and 479 and 521 nm for **1a**. For comparison, the λ_{max} for the analogous complex [Ru(trpy)(6,6′-Me_2dppi)Cl]$^+$, at 499 and 522 nm, are very similar to both **2a** and **1a**, a good indication of the similarity of the electronic nature of the complexes.

out-[Ru(trpy)(4,4′-Me_2dppi)OH_2]$^{2+}$ (**2b**)	0.440	20(1)	9.8	491 (8000)

[a] Obtained at pH 11 in aqueous phosphate buffer vs. SCE.
[b] Second-order rate constant obtained from analytical data as described in text.
[c] Obtained in pH 4 phosphate buffer.

The aqua complexes have similar spectra (Table 5). The low energy MLCT processes for **2b** shift to 491 nm and to 480 nm for **1b**. As with the previously studied aqua compounds, the MLCT shifts to higher energy upon substitution of the anionic chloride ligand for the neutral aqua ligand; deprotonation of the aqua ligands shifts the transitions to lower energy [18].

3.6. Electrochemistry

The cyclic voltammograms of **1a** and **2a** in acetonitrile both exhibit reversible one-electron oxidations (0.865 and 0.881 V versus Ag/AgCl, respectively). The complexes also displayed three ligand reductions. The oxidations are less anodic than that of the 6,6′-Me_2dppi complexes which had a Ru(III/II) couple at 0.98 V. The electronic nature of the ligands should be very similar, and the difference in oxidation potentials is likely a result of the different steric environments created by the two ligands. In fact, comparing the chloro complex of the 4,4′-Me_2dppi isomer (**2a**) to the unsubstituted H_2dppi complex shows that **2a** is easier to oxidize by 89 mV, fitting the expected trend now that the steric environment has been rendered more equal. In pH 11 phosphate buffer, **2b** displays a reversible two-electron oxidation at 0.44 V. **1b**, however, exhibits an oxidation wave but is accompanied by passivation of the electrode.

3.7. Electrocatalysis

The catalytic activity of **2b** towards a variety of substituted benzyl alcohol derivatives (1-phenylethanol, 1-phenyl-1-propanol and 2-methyl-1-phenyl-1-propanol) was studied to gain insight into the effects of sterics on the catalytic rate. The racemic alcohols were synthesized by a lithium aluminum hydride reduction on the corresponding commercially available ketone. These reactions proceeded cleanly, and the products required no additional purification.

The catalytic oxidation of these alcohols by *out*-[Ru(trpy)(4,4′-Me_2dppi)OH_2]$^{2+}$ was then studied in pH 11.2/phosphate buffer, with 50% t-butanol added to improve the solubility of the benzyl alcohols. Mixed solvent systems have been used by other groups for similar experiments with no adverse effects [19,20]. The addition of the t-butanol did not significantly affect the rate of catalysis of benzyl alcohol. All of the substrates were much more soluble in the modified buffer solution and yielded sigmoidally shaped voltammograms (characteristic of electrocatalysis) over the scan rate range 1 to 5 mV s^{-1}.

Data for these complexes are presented in Fig. 3. A nearly linear decrease in catalytic rate was observed as the number of carbon atoms around the alcohol group increased. The unhindered benzyl alcohol derivative has a rate constant of 19.8 $M^{-1} s^{-1}$ while the most hindered benzyl alcohol bearing the isopropyl substituent has a rate constant of only 2.7 $M^{-1} s^{-1}$. Clearly, sterics play an important factor in the catalytic mechanism since the driving force for the substrates is nearly the same. The rate constants of benzyl alcohol oxidation for the 4,4′-dppi complex can also be compared to the 6,6′-Me_2dppi isomer, which had a rate constant of 9 $M^{-1} s^{-1}$. The addition of a methyl group on the 6 and 6′ positions of the ligand retards the rate nearly identically to adding a methyl group to the substrate.

The electrocatalytic oxidation of benzyl alcohol by *in*-[Ru(trpy)(4,4′-Me_2dppi)OH_2]$^{2+}$ was also studied. This compound gave somewhat irreproducible results at a glassy carbon electrode owing to passivation upon oxidation: as much of 95% of the current is lost between the anodic and cathodic waves. Modification of the working electrode to include amide groups on the surface proved successful in reducing, but not eliminating, this passivation. With this modified electrode reversible Ru(IV/II) couples were observed and a catalytic rate constant of ~9 $M^{-1} s^{-1}$ was measured for the oxidation of benzyl alcohol. This value is nearly half

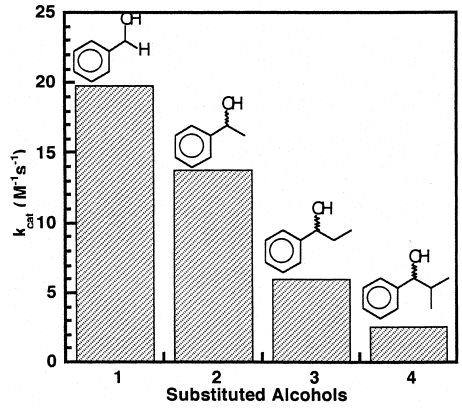

Fig. 3. Bar graph of the catalytic rate constant for the electrocatalytic oxidation of substituted benzyl alcohol derivatives by *out*-[Ru(trpy)(4,4′-Me_2dppi)OH_2]$^{2+}$.

of the corresponding *out* complex measured under identical conditions.

The smaller catalytic rate constant for the *in* versus the *out* complex and the irreversible electrochemistry on unmodified electrodes can be attributed to a variety of factors. One of these may be directly related to the previously mentioned instability of the *in* complex observed during the ligand substitution reactions. It is conceivable that an electrochemically induced *in* to *out* isomerization is possible; however, no evidence of the *out* complex was observed. A more likely explanation may be the catabolic oxidation of the 4,4′-Me_2dppi ligand and subsequent degradation of the compound. As seen in Fig. 1, the *in* complex directs what is to be the active oxo moiety towards the uncoordinated nitrogen on the pyridazine group, and intramolecular oxidation could occur upon Ru(IV)=O generation. The small rate constant measured may be more of a reflection of this process and not related to benzyl alcohol oxidation.

Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 132661 and 132662. Copies can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

Received 6 December 1999; accepted 15 February 2000

Abstract

Platinum(IV) porphyrins of the type $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ where $(p\text{-}X)_4TPP$ is a *para*-substituted tetraphenylporphyrin have been synthesized by direct oxidation of their Pt(II) precursors with Br_2. Both the Pt(II) and Pt(IV) complexes have been characterized by visible and ^1H NMR spectroscopy and their electrochemical properties. In both the oxidation and reduction processes, a substituent effect is evident, and the reduction of $Pt^{IV} \rightarrow Pt^{II}$ is identified. The oxidation and reduction potentials of the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes are compared to those of the $[Pt^{II}(p\text{-}X)_4TPP]$ precursors and $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ analogs. Addition of I_2 or I^- to Pt(II) porphyrins does not result in oxidative-addition to form Pt(IV) porphyrins. Instead, the addition of I^- to $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ results in the reduction of the platinum to form the corresponding $[Pt^{II}(p\text{-}X)_4TPP)]$. ©2000 Elsevier Science Ltd All rights reserved.

1. Introduction

An extensive amount of research has focused on metalloporphyrins owing to the critical roles they play in electron transfer, photosynthesis, and oxygen transfer processes [1]. Their reactivity is found to be dependent upon the central metal, the substituents on the porphyrin ring, and the axially coordinated ligands. Platinum porphyrins have been investigated as oxygen sensing probes [2–6], photosensitizers [7–9], potential antitumor agents [10], and molecular conductors [11,12]. Most of the recent studies have focused on Pt(II) porphyrins. Pt(IV) porphyrins of the type $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$, where X = CN, H, CH_3, and OCH_3, have been synthesized from the corresponding $[Pt^{II}(p\text{-}X)_4TPP]$ precursors through direct oxidative-addition of $Br_{2(l)}$. Stable $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes are formed with axial Br^- ligands that generate large Δ splitting values in the Pt(IV) (5d, $t_{2g}^6e_g^0$) through σ donation [13]. Considerable attention has recently been devoted to the development of platinum(IV) dichloride complexes as pro-drug antitumor agents [14–18], whereas relatively few reports have involved the study of platinum(IV) dibromide compounds [19–21]. The compounds in this paper are prepared in a fashion similar to $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes previously reported [22]. The chemical and electrochemical reactivity of Pt(II) and Pt(IV) tetraphenylporphyrins with the halogens chlorine, bromine, and iodine is discussed in this research.

2. Experimental

2.1. General

^1H NMR spectra were recorded at 270.167 MHz with a JEOL ECLIPSE spectrometer (reference δ 7.24, $CHCl_3$). UV–Vis spectra were obtained with a Beckman DU-7500 diode array instrument using quartz cells with a path length of 1.0 cm. Cyclic voltammetry was carried out by the conventional three-electrode method in CH_2Cl_2 (distilled from CaH_2) with Bu_4NPF_6 (0.10 M) as a supporting electrolyte. Electrochemical measurements were made with either a PAR 174A electrochemical analyzer or an Amel model 551 potentiostat and a model 567 function generator. The concentration of the complex was usually between $(0.5\text{–}1.0) \times 10^{-3}$ M. Ferrocene was used as an internal standard. All potentials are

referenced to the $E_{\frac{1}{2}}$ ($E_{\frac{1}{2}} = \frac{1}{2}(E_{pa} + E_{pc})$) for the $(C_5H_5)_2Fe/(C_5H_5)_2Fe^+$ couple; $E_{\frac{1}{2}}$ for ferrocene was typically $+0.48 \pm 0.02$ V versus the Ag|AgCl|NaCl(saturated) BAS reference electrode, near the 0.45 V reported for the ferrocene couple versus an SCE reference electrode [23].

Reagent grade chemicals and solvents were purchased from Aldrich Chemical Company, Fisher Scientific, and Spectrum. Platinum(II) chloride was obtained from Alfa Aesar, chlorine, from Matheson Gas Products, and bromine from Janssen Chimica. Chromatographic grade aluminum oxide, activated neutral, standard grade 150 mesh, 58 Å and silica gel (Merck grade 9385, 230-400, mesh 60 Å) were purchased from Aldrich Chemical Company. Elemental analyses were performed by Desert Analytics, Tucson, AZ.

2.2. Synthesis of $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ (X = CN, H, OCH_3, CH_3)

The synthesis of the $[Pt^{II}(p\text{-}X)_4TPP]$ complexes has been previously reported [22]. The $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes were synthesized through direct addition of Br_2 to the corresponding $[Pt^{II}(p\text{-}X)_4TPP]$ complexes. A $Br_{2(l)}/CHCl_3$ solution was prepared by the addition of 12 drops of $Br_{2(l)}$ to 10 cm^3 of $CHCl_3$, and 50 drops of the mixture were added slowly to $[Pt^{II}(p\text{-}X)_4TPP]$ (0.022 mmol) dissolved in 20 cm^3 of $CHCl_3$ at 0°C. The reaction was monitored by UV–Vis spectroscopy and judged complete in 2 h by the gradual decrease of the Soret band near 403 nm associated with $[Pt^{II}(p\text{-}X)_4TPP]$ and the appearance of the Soret band near 421 nm associated with $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$. The solution was concentrated to 5 cm^3 by rotary evaporation, and an equal volume of cold methanol precipitated the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ crystalline solid. The complex was dissolved in a minimum amount of toluene and loaded onto a 3 cm × 18 cm silica gel column. Non-reacted $[Pt^{II}(p\text{-}X)_4TPP]$ was eluted as a light orange band with toluene. $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ was collected upon elution with 2% trifluoroacetic acetic acid (TFA) in chloroform and appeared as a dark red–purple band. Concentration of the TFA/chloroform solution to 25 cm^3 and addition of an equal volume of cold methanol precipitated the red–purple $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ crystalline solid. $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ was collected by filtration and then washed with cold methanol and water. $[Pt^{IV}(p\text{-}CN)_4TPP]Br_2$ was not purified by column chromatography owing to limited solubility. Final yields were in the range of 75%. Elemental analyses gave the following results. Calc. for $[Pt(p\text{-}H)_4TPP]Br_2$ ($C_{44}H_{28}PtN_4Br_2$): C, 54.62; H, 2.92; N, 5.79; Br, 16.52. Found: C, 53.95; H, 2.81; N, 5.57; Br, 16.09%. Calc. for $[Pt(p\text{-}OCH_3)_4TPP]Br_2$ ($C_{48}H_{36}PtN_4O_4Br_2$): C, 53.00; H, 3.34; N, 5.15; Br, 14.69. Found: C, 52.64; H, 3.01; N, 4.89; Br, 14.60%.

3. Results and discussion

As reported for the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes, the UV–Vis spectra of the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes are dominated by the Soret, α, and β bands near 420, 573, and 536 nm, respectively (Table 1). These bands exhibit 20–25 nm bathochromic shifts (to longer wavelengths) with respect to the precursor $[Pt^{II}(p\text{-}X)_4TPP]$ complexes and are similar in absorption values to their $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ analogs [22]. A slight bathochromic shift of ~4 nm is detected for the Soret band for the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes compared to their chloride counterparts. Thus, there is a substantial effect on the electronic spectra of the complexes as a result of the $Pt^{II} \rightarrow Pt^{IV}$ oxidation but little effect due to variance in the halogens at the axial positions. The bathochromic shifts resulting from $Pt^{II} \rightarrow Pt^{IV}$ have been interpreted as being indicative of a decrease in metal d to porphyrin π*-bonding [24]. As was observed for $[Pt^{II}(p\text{-}X)_4TPP]$ and $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$, the Soret, α, and β bands of the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes do not display any pronounced substituent effect.

In the ^1H NMR spectra, a distinct decrease in shielding of all proton resonances is evident upon oxidation of $[Pt^{II}(p\text{-}X)_4TPP]$ to $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ (Fig. 1), and a similar trend was observed for the analogous $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes [22]. In comparing the ^1H NMR of the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ to the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes, the bromide complexes display a slight upfield chemical shift of all ^1H NMR resonances (~0.02 ppm). The upfield chemical shift may be indicative of increased electron density about the platinum center for the dibromide complexes. Increased electron density about the platinum center would allow for increased platinum–porphyrin π*-backbonding resulting in increased shielding of the porphyrin proton resonances. This would be anticipated as Pt(IV) forms a weaker bond with the bromide than with the chloride ion [25], and this feature is evident in the electrochemical results. As was the case for the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes, the J_{Pt-H} pyrrole coupling decreases from ca. 11 Hz for Pt(II) to ca. 8 Hz for Pt(IV) owing to the relative decrease in platinum 6s character (Table 2).

A porphyrin ring generally shows three or four well defined, quasireversible sites of redox activity. The LUMO of the porphyrin ring is considered to be the e_g (π*) orbital and the HOMO either an a_{2u} (π) or a_{1u} (π) orbital. In earlier

work, we were able to observe the four redox waves for $H_2(TPP)$, but the oxidation at the most positive potential was distorted and did not display good redox characteristics [22]. Substitution of the *para* protons by –CN to give $H_2(p\text{-}CN)_4TPP$ provides a ligand that does exhibit all four well defined sites of redox activity (Table 3). The substituent effect observed in other $H_2(p\text{-}X)_4TPP$ ligands is evident for $H_2(p\text{-}CN)_4TPP$ as the first oxidation is shifted by $+0.23$ V and the first reduction by $+0.16$ V relative to $H_2(TPP)$. These are substantially larger changes than observed in other $H_2(p\text{-}X)_4TPP$ ligands as, for example, the first oxidation of $H_2(p\text{-}Cl)_4TPP$ relative to $H_2(TPP)$ is only $+0.09$ V.

In several instances, the electrochemistry of the $[Pt^{II}(p\text{-}X)_4TPP]$ complexes also shows four sites of redox activity attributable to the porphyrin ring, and the substituent effect is observed in the complexes as well as the free ligands. Reaction of the $[Pt^{II}(p\text{-}X)_4TPP]$ complexes with Cl_2 produced the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes. The four sites of

[a] Electrochemistry performed in CH_2Cl_2. Scan rates were 200 mV s^{-1}. Potentials (mV) are referenced to the ferrocene/ferrocinium redox couple. Numbers in parentheses are ΔE_p (mV) and the numbers in italics are the $Pt^{IV} \rightarrow Pt^{II}$(V) reductions.
[b] Electrochemistry performed in CH_3CN.

redox activity remain, and a fifth irreversible reduction attributable to $Pt^{IV} \rightarrow Pt^{II}$ that showed a substantial substituent effect was observed. With the preparation of the corresponding $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ and $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes, the effect of the axial ligand as well as the substituents on the porphyrin ring can be studied. As was found for the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes, only the first oxidation and first reduction waves of the ligand were always well defined. Replacement of the two axial Cl^- ligands on the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes with Br^- caused only a slight negative shift (<0.05 V) in both of these waves. However, a substantial positive shift (between 0.19 and 0.31 V) in the $[Pt^{IV}(p\text{-}X)_4TPP]Br_2$ complexes relative to the $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ complexes is observed for the irreversible $Pt^{IV} \rightarrow Pt^{II}$ reduction (Table 3). Thus, the axial ligands, which are directly coordinated to the Pt(IV), have a pronounced effect on that reduction, and the effect is in the direction expected as Cl^- should form the stronger bond to Pt(IV), making $[Pt^{IV}(p\text{-}X)_4TPP]Cl_2$ more difficult to reduce [25]. The reduction process for both the Cl^- and Br^- complexes can be described by:

$$[Pt^{IV}(p\text{-}X)_4TPP]X_2 + 2e^- \rightarrow [Pt^{II}(p\text{-}X)_4TPP] + 2X^- \quad (1)$$

To illustrate, for the $[Pt^{IV}TPP]Br_2$ complex, if the potential scan is initiated at 0.00 V in the anodic direction (Fig. 2, scan A), the first porphyrin oxidation and, upon reversal of the potential scan the subsequent reduction, is observed at +0.89 V. The $Pt^{IV} \rightarrow Pt^{II}$ reduction is then observed at −0.75 V, followed by the reduction, and upon reversal of the potential scan, the subsequent oxidation of the porphyrin ring at −1.84 V. When the scan is initiated at 0.00 V in the cathodic direction (Fig. 2, scan B), the $Pt^{IV} \rightarrow Pt^{II}$ reduction and first reduction and subsequent oxidation of the porphyrin ring are again observed. However, a new irreversible oxidation at +0.25 V appears as do some small impurities associated with the porphyrin oxidation–reduction at +0.89 V. If scan A is repeated but allowed to go through two cycles (Fig. 2, scan C), the first cycle is identical to scan A but the second cycle has the oxidation at +0.25 V and the small impurities associated with the +0.89 V peak. When scan A is repeated and allowed to go through the $Pt^{IV} \rightarrow Pt^{II}$ reduction, but not the ring reduction and subsequent oxidation at −1.84 V (Fig. 2, scan D), the oxidation at +0.25 V, and impurities on the porphyrin peak are present. The cyclic voltammograms clearly indicate that the oxidation at +0.25 V and the small impurities on the +0.89 V oxidation and reduction are associated with the reduction of the Pt^{IV} and can be described by the overall process:

$$[Pt^{IV}(TPP)]Br_2 + 2e^- \rightarrow [Pt^{II}(TPP)] + 2Br^- \quad (2)$$

Either simultaneously or in a subsequent step, once the Pt(IV) is reduced, the Br^- becomes non-coordinating and is irreversibly oxidized at +0.25 V. The small peaks associated with the porphyrin ring at +0.89 V are due to the small quantity of $[Pt^{II}(TPP)]$ formed near the electrode surface. Cyclic voltammetry of the $[Pt^{IV}(p\text{-}CH_3O)_4TPP]Br_2$ complex gave similar results. Proof that the +0.25 V peak was due to Br^- was obtained when a cyclic voltammogram of tetra(*n*-butyl)ammonium bromide gave the same peak.

An attempt was made to determine whether a six-coordinate Pt(II) species might at least temporarily result from the reduction above. If reaction (2) is a two-step process:

$$[Pt^{IV}(TPP)]Br_2 + 2e^- \rightarrow [Pt^{II}(TPP)]Br_2 \quad (3)$$

$$[Pt^{II}(TPP)]Br_2 \rightarrow [Pt^{II}(TPP)] + 2Br^- \quad (4)$$

the addition of a large excess of Br^- may retard reaction (4) and reaction (3) may become partially reversible. The sup-

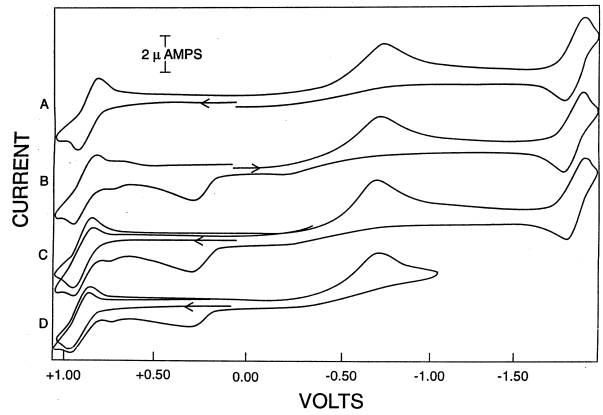

Fig. 2. Cyclic voltammograms for $[Pt^{IV}(TPP)]Br_2$ in CH_2Cl_2 at a scan rate of 100 mV s^{-1}; scan A initiated at 0.0 V in an anodic direction; scan B initiated at 0.0 V in a cathodic direction; scan C initiated at 0.0 V in an anodic direction, multiple cycles; scan D initiated at 0.0 V in an anodic direction, reversed after the Pt(IV) to Pt(II) reduction.

porting electrolyte tetra(*n*-butyl)ammonium hexafluorophosphate was replaced with tetra(*n*-butyl)ammonium bromide so that the [Br^-] was 0.10 M. The electrochemical results at scan rates to 500 mV s^{-1} were identical to the previous results and failed to reveal any evidence of a reversible nature to the $Pt^{IV} \rightarrow Pt^{II}$ reduction.

For the [Pt^{IV}(*p*-X)$_4$TPP]Br_2 complexes, the data of Table 3 illustrate that the first oxidation and the first reduction of the porphyrins do exhibit a substituent effect similar to that found for the [Pt^{IV}(*p*-X)$_4$TPP]Cl_2 complexes. The electron-donating CH_3O– and CH_3– groups shift the first oxidation and the first reduction to a more negative potential, and the electron-withdrawing –CN group shifts them toward a more positive potential. As has been observed with other Pt(II) systems, the addition of I_2 or I^- in the presence of the oxidizing agent hydrogen peroxide, H_2O_2, to Pt(II) porphyrins does not result in oxidative-addition generating Pt(IV) porphyrins [26–29]. The addition of I^- to [Pt^{IV}(*p*-X)$_4$TPP]Br_2 results in reduction of the platinum to form the corresponding Pt(II) porphyrins, [Pt^{II}(*p*-X)$_4$(TPP)]. However, addition of iodide to [Pt^{IV}(*p*-X)$_4$TPP]Cl_2 does not result in platinum reduction. This reduction process of Pt(IV) complexes by iodide has previously been observed and is believed to proceed through iodide–halide bond formation prior to the reduction in which the halogen acts as a bridging ligand [30–33]. The fact that iodide effectively reduces [Pt^{IV}(*p*-X)$_4$TPP]Br_2 and not [Pt^{IV}(*p*-X)$_4$TPP]Cl_2 is attributed to the more positive reduction potentials (by ca. 0.2 V) of the bromide species compared to their chloride counterparts. The enhanced ease of reduction of Pt(IV) bromide complexes compared to analogous Pt(IV) chloride complexes has previously been attributed to a weaker Pt(IV)–Br bond, and bromide being a good bridging ligand during the reduction process [25,28,29,34–38].

4. Conclusions

[Pt^{IV}(*p*-X)$_4$TPP]Br_2 complexes are readily accessible through direct oxidative-addition of Br_2 to [Pt^{II}(*p*-X)$_4$TPP]. The [Pt^{II}(*p*-X)$_4$TPP] porphyrins are non-reactive toward I_2 or iodide in the presence of an oxidizing agent. Iodide effectively reduces the [Pt^{IV}(*p*-X)$_4$TPP]Br_2 complexes whereas the [Pt^{IV}(*p*-X)$_4$TPP]Cl_2 complexes are unaffected. Replacement of axial Cl^- ligands on the Pt(IV) by Br^- has little effect on the electrochemistry of the complex other than to move the reduction of the Pt(IV) to considerably more positive potentials. The reduction results in the loss of the axial ligands and is described by:

$$[Pt^{IV}(p\text{-X})_4TPP]Br_2 + 2e^- \rightarrow [Pt^{II}(p\text{-X})_4TPP] + 2Br^-$$

Cyclic sweep voltammetry of the Pt(IV) complex shows the appearance of the corresponding Pt(II) complex. Use of a large excess of Br^- failed to make this reduction reversible.

Reactivity of $Mo(PMe_3)_5H_2$ towards catecholborane: synthesis and structure of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$

Received 4 October 1999; accepted 15 February 2000

Abstract

$Mo(PMe_3)_5H_2$ reacts with catecholborane (CatBH) to give $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$. Structural characterization by X-ray diffraction suggests that the complex is best represented as a borohydride complex, as opposed to a boryl-hydride derivative $Mo(PMe_3)_4(BCat)H_3$.

Keywords: Catecholborane; Reactivity

1. Introduction

Transition metal complexes, e.g. $(Ph_3P)_3RhCl$, have been used extensively as catalysts for promoting hydroboration reactions employing catecholborane (CatBH = $(C_6H_4O_2)$-BH) as a reagent [1]. A key step in the mechanism of the hydroboration reaction has been proposed to involve oxidative addition of the borane B–H bond to the transition metal center [1,2]; indeed, a variety of boryl-hydride complexes have been isolated which supports such a notion [3]. We have recently described the oxidative addition of a variety of X–H bonds (e.g. X = H [4], C [5], O [5], Hal [6]) to electron-rich molybdenum and tungsten complexes of the types $M(PMe_3)_6$, $M(PMe_3)_4(\eta^2\text{-}CH_2PMe_2)H$ and $M(PMe_3)_5H_2$. For this reason, we were interested in extending these studies by investigating the reactivity of borane derivatives towards the above complexes. In this paper, we report the reaction of $Mo(PMe_3)_5H_2$ towards CatBH.

2. Results and discussion

The dihydride $Mo(PMe_3)_5H_2$ reacts rapidly with CatBH in benzene solution to yield the red borohydride complex $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ (Scheme 1). Characterization of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ as a dihydrocatecholborate derivative is based on a structure determination by single crystal X-ray diffraction (Fig. 1), which allowed the hydrogen atoms attached to both Mo and B to be located and refined. Viewing the $[\eta^2\text{-}H_2BCat]$ ligand as occupying a single coordination site, the structure of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ may be considered to be based on a distorted octahedron, with *trans* $[\eta^2\text{-}H_2BCat]$ and hydride ligands. Such a geometry is akin to that of the tetrahydroborate derivative, $Mo(PMe_3)_4(\eta^2\text{-}H_2BH_2)H$, which was obtained by the reaction of $MoCl_3(PMe_3)_3$ with $NaBH_4$ [7]. It should, however, be noted that, in contrast to $\eta^2\text{-}BH_4$ complexes [8], structurally characterized $\eta^2\text{-}H_2BCat$ derivatives are rare [9–11]. For comparison purposes, selected average bond

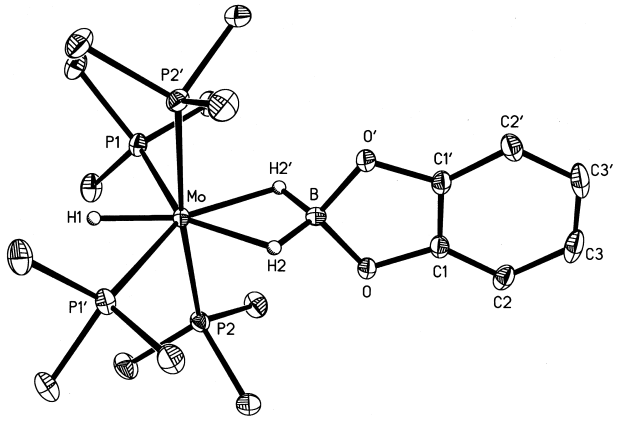

Fig. 1. Molecular structure of $Mo(PMe_3)_4(\eta^2\text{-}H_2Cat)H$.

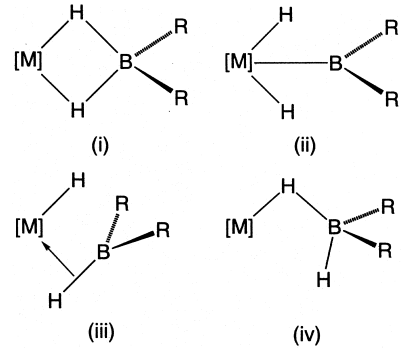

Fig. 2. Isomers of the $[MH_2BR_2]$ moiety: (i) η^2-borohydride, $\{[M](\eta^2\text{-}H_2BR_2)\}$, (ii) boryl-hydride, $\{[M](BR_2)H_2\}$, (iii) borane-hydride, $\{[M](\eta^2\text{-}H\text{–}BR_2)H\}$, and (iv) η^1-borohydride, $\{[M](\eta^1\text{-}HBHR_2)\}$.

lengths and angles for $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ and $Mo(PMe_3)_4(\eta^2\text{-}H_2BH_2)H$ are summarized in Table 1. The isolation of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ is of interest since it demonstrates that the $[Mo(PMe_3)_4H_2]$ moiety does not preferentially oxidatively add the B–H bond to yield isomeric $Mo(PMe_3)_4(BCat)H_3$. Such reactivity is in contrast to the oxidative additions that have been observed upon reaction of other H–X bonds (e.g. X = H, F, Cl, Br) with low valent molybdenum phosphine compounds giving $Mo(PMe_3)_4\text{-}H_2X_2$ [4,12]b.

Although only one structurally characterized complex identified as a catecholborate derivative is listed in the Cambridge Structural Database [9], related isomers are known, since moieties of composition $[MH_2BR_2]$ may exist, in principle, with at least four different isomeric structures (Fig. 2) [2,3,11,13]. These structures may be classified as (i) η^2-borohydride, $\{[M](\eta^2\text{-}H_2BR_2)\}$, (ii) boryl-dihydride, $\{[M](BR_2)H_2\}$, (iii) borane-hydride, $\{[M](\eta^2\text{-}H\text{–}BR_2)\text{-}H\}$, and (iv) η^1-borohydride, $\{[M](\eta^1\text{-}HBHR_2)\}$; the first three isomers exhibit identical electron counts at the metal center, whereas the last isomer possesses two electrons fewer. An issue that arises in the discussion of compounds with $[MH_2BR_2]$ moieties is the extent to which the complex may be best represented by one of the four formalisms described above. With respect to catecholborane derivatives, i.e. $[MH_2BCat]$, only η^2-borohydride, $\{[M](\eta^2\text{-}H_2BR_2)\}$, and boryl-dihydride, $\{[M](BR_2)H_2\}$, forms have been discussed in the literature [14]. The relationship between $\{[M](\eta^2\text{-}H_2BR_2)\}$ and $\{[M](BR_2)H_2\}$ bears an analogy to the metal-olefin/metallacyclopropane issue of bonding, and the factors that influence the extent to which each of these forms best represents a particular complex are subtle. For example, Cp_2NbH_3 reacts with CatBH to give *endo*-$Cp_2Nb(BCat)H_2$, whereas 9-borabicyclononane yields a structure with predominantly η^2-borohydride character $Cp_2Nb[\eta^2\text{-}H_2B(C_8H_{14})]$ [13]. Smith has also demonstrated that related catecholate tantalum complexes exist as boryl-dihydrides, namely *exo*- and *endo*-$Cp_2Ta(BCat)H_2$ [15], and *endo*-$Cp^*_2Ta[B(O_2C_6H_3Bu^t)]H_2$ [11], but, in contrast, the pentamethylcyclopentadienyl niobium complex has been suggested to be an η^2-borohydride derivative $Cp^*_2Nb[\eta^2\text{-}H_2BCat]$ [11]. In view of the frequent uncertainty associated with locating hydrogen atom positions by X-ray diffraction, the M···B separation has been used as an indicator of boryl-dihydride versus η^2-borohydride character. For comparison, selected metrical data for boryl-dihydride and η^2-borohydride complexes are listed in Table 2, from which it can be seen that the former complexes are identified by marginally shorter M···B distances. Thus, the Nb···B distance in $Cp^*_2Nb[\eta^2\text{-}H_2B(O_2C_6H_3Bu^t)]$ (2.348(4) Å) is longer than in the cyclopentadienyl boryl-dihydride derivative $Cp_2Nb(BCat)H_2$ (2.292(5) Å) [13], and is effectively

$[MH_2(BR_2)]$				
endo-$Cp_2Nb(BCat)H_2$	2.292(5)	1.62(4), 1.58(5)	1.69(4), 1.62(5)	[13]
exo-$Cp_2Ta(BCat)H_2$	2.295(11)	1.76(12), 1.78(10)	$1.45(10)_{cent}$	[15]
endo-$Cp_2Ta(BCat)H_2$	2.263(6)	1.64(6), 1.54(5)	2.11(6), 1.75(6)	[15]

identical to that in $Cp^*_2Nb(\eta^2\text{-}H_2BH_2)$ (2.35(1) Å) [11]. In this regard, the Mo···B separation in $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ (2.363(5) Å) is shorter than the corresponding value in $Mo(PMe_3)_4(\eta^2\text{-}H_2BH_2)H$ (2.468(12) Å) [7], thereby suggesting the possibility that it is closer to a boryl-dihydride representation than is $Mo(PMe_3)_4(\eta^2\text{-}H_2BH_2)H$. However, the locations of the hydrogen atoms are strongly suggestive of the η^2-borohydride formalism; for example, the Mo–H bond lengths involved in the Mo–H–B bridges (1.91(3) Å) are long, and the B–H bonds are short (1.13(3) Å), by comparison to the related values for the other complexes listed in Table 2. Comparison of the Mo···B separation in $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ with that of a bona fide single Mo–B single bond would provide decisive evidence supporting the proposed η^2-borohydride formalism, but unfortunately the Cambridge Structural Database [10] lists no structures with single Mo–B bonds in which boron is three coordinate. Nevertheless, a Mo–B single bond may be estimated to be ca. 2.19 Å on the basis that Mo and W have very similar covalent radii [16] and that the W–B bond length in $Cp_2W(BCat)H$ is 2.190(7) Å [13,17]. Thus, the Mo···B separation in $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ (2.363(5) Å) is substantially longer than would be expected for a boryl-hydride representation. Finally, further evidence counter to the boryl-hydride representation $Mo(PMe_3)_4(BCat)H_3$ is the molecular geometry, which is very different to the dodecahedral geometries observed for eight-coordinate $M(PMe_3)_4X_4$ derivatives [18].

3. Experimental

3.1. General considerations

All manipulations were performed using a combination of glovebox, high-vacuum or Schlenk techniques [19]. Solvents were purified and degassed by standard procedures. Commercially available reagents were not further purified. $Mo(PMe_3)_5H_2$ was prepared by the literature method [20].

3.2. Synthesis of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$

A solution of $Mo(PMe_3)_5H_2$ (0.43 g, 0.90 mmol) in benzene (5 ml) was treated with a solution of catecholborane (0.22 g, 1.83 mmol) in benzene (2 ml), thereby resulting in the immediate formation of a red precipitate. The mixture was filtered and the solid was washed with benzene (5 ml) and dried in vacuo. Yield of $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$: 0.41 g (87%). IR data (KBr, cm^{-1}): 2963 (w), 2905 (w), 1818 (br, w) (ν_{Mo-H}), 1584 (m), 1475 (s), 1423 (m), 1366 (w), 1276 (m), 1233 (s), 1094 (w), 1059 (m), 1007 (m), 986 (m), 937 (vs), 848 (m), 749 (m), 701 (m), 647 (m), 483 (w).

3.3. X-ray structure determination

Crystallographic data for $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$ were collected on a Bruker P4 diffractometer equipped with a SMART CCD detector. The structure was solved using direct methods and standard difference map techniques, and was refined by full-matrix least-squares procedures using SHELXTL [21]. Hydrogen atoms on carbon were included in calculated positions. Systematic absences were consistent with *Aba*2 (no. 41) or *Acam* (no. 64), of which a successful solution was obtained in the non-centrosymmetric alternative *Aba*2 (no. 41). The correct choice of space group was confirmed by PLATON [22]. Crystal data, data collection and refinement parameters for all structures are summarized in Table 3.

4. Summary

In conclusion, the dihydride $Mo(PMe_3)_5H_2$ reacts with CatBH to give $Mo(PMe_3)_4(\eta^2\text{-}H_2BCat)H$. Previous studies have indicated that catecholborate derivatives may often be better described as boryl-hydrides, but structural characterization by X-ray diffraction, which located the positions of the hydrogen atoms attached to boron, indicates that the complex is best represented as a borohydride complex.

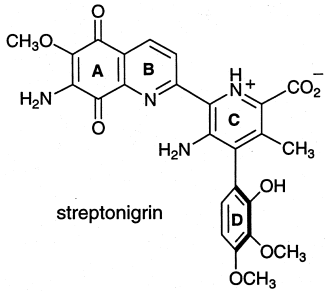
POLYHEDRON

X-ray structure of the zinc complex of the central metal chelation site of the antitumour drug streptonigrin

Georgina V. Long, Margaret M. Harding *, Peter Turner

School of Chemistry, University of Sydney, Sydney, NSW 2006, Australia

Received 15 December 1999; accepted 2 March 2000

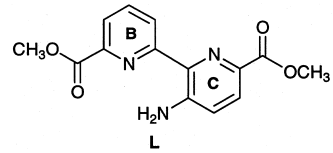


Abstract

The X-ray structure of the 1:1 complex between zinc(II) triflate and 3-amino-6,6′-bis(methoxycarbonyl)-2,2′-bipyridine is reported. This ligand contains the central chelation site present in the DNA-binding antitumour antibiotic streptonigrin. The complex is distorted octahedral involving the 2,2′-bipyridyl site and the carbonyl groups at the 6,6′-positions as well as two axial water molecules. The structure confirms that formation of similar complexes with streptonigrin is possible. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Streptonigrin; 2,2′-Bipyridyl; 6,6′-Dicarboxy-2,2′-bipyridyl; Antitumour; Zinc

1. Introduction



Streptonigrin is an aminoquinone antitumour antibiotic that is active against a range of human cancers [1–5]. A number of transition metal ions interact with the drug and have been shown to be involved in DNA strand cleavage either by direct complexation with streptonigrin or reduced streptonigrin and/or catalysing the production of hydroxyl radical close to DNA [6–19]. The exact role of the metal ions in the mechanism of action, however, is not fully understood.

streptonigrin

Streptonigrin contains many potential metal binding sites including the picolinic acid system, the 2,2′-bipyridyl system, the aminoquinone system, the 2-(3′-amino-2′-pyridyl)-quinoline system and the amino and phenolic groups on rings C and D. UV titrations have been used to establish the stoichiometries of a number of metal complexes with streptonigrin [6,7,10–15,19]. Independent NMR studies of the zinc(II) complex have shown that the structures and stabilities of the complexes are solvent dependent and that under biologically relevant conditions the 1:1 bipyridyl complex is present [20]. However, there are no X-ray crystal structures of any metal complexes of streptonigrin and the exact binding site(s) and coordination geometry of the metal centre in metal complexes of streptonigrin, which would be useful in the design of potential metal complexes for drug testing [5], are unknown.

In an effort to fully characterise the structures of the metal complexes of streptonigrin, we have reported studies on a number of model ligands that contain the key metal binding site in the drug [21–23], i.e., a 3-amino-2,2′-bipyridyl group flanked by carbonyls at the 6,6′-positions. These solution studies established the importance of the flanking carbonyls in stabilising the bipyridyl complexes [21–23] but no information about the coordination geometry at the metal centre could be obtained. We now report successful determination of the solid state structure of the zinc(II) complex of ligand **L**:

L

which contains the key metal binding site present in streptonigrin. This structure confirms our proposed solution structure [23] and provides important additional information

about the coordination sphere and coordinated ligands at the metal binding site and a molecular level structure that may be used as the basis for modelling of metal complexes of streptonigrin.

2. Results and discussion

The 1:1 zinc(II) complex of ligand **L**, complex **1**, was prepared from an acetonitrile solution of the ligand and zinc(II) triflate. In the presence of 1 equiv. of zinc(II) both the 2:1 (ligand:metal) complex and 1:1 (ligand:metal) complexes are formed [23]. Hence, excess zinc(II) was added to the solution containing this mixture of complexes and, after a period of weeks, crystals of complex **1** suitable for X-ray diffraction were obtained. Fig. 1 shows an ORTEP depiction of the structure of the complex obtained from a single-crystal X-ray diffraction analysis, and structural details are summarised in Tables 1–3. The solid state structure agrees well with solution data, in which we have previously shown [23] that the flanking carbonyls are mobile and dynamic on the NMR time scale.

The metal ion coordination is distorted octahedral, with the bipyridyl N(1), N(2) atoms and the ester carbonyl O(3) and O(4) atoms defining the equatorial coordination plane (Fig. 1). The zinc to bipyridyl nitrogen distances are unre-

[a] Generated from O(8) with $1/2-x, 1/2+y, 1/2-z$.
[b] Generated from O(10) with $1/2-x, y-1/2, 1/2-z$.
[c] Generated from O(11) with $-x, -y, -z$.

markable at 2.098(4) and 2.101(4) Å for N(1) and N(2), respectively, as are the (pseudo) axial zinc to water bond lengths of 1.981(4) and 1.946(4) Å for O(1) and O(2) respectively. The zinc to carbonyl oxygen distances, however, are relatively long at 2.437(3) and 2.377(3) Å for O(3) and O(4) respectively. The metal to carbonyl bond lengths are of course constrained by the in-plane rigidity of the equatorial coordination framework. The N(1), N(2), O(3) and O(4) atoms are co-planar, with the least-squares plane deviations ranging from −0.0164(3) to 0.0333(4) Å. The Zn distance from the equatorial coordination least-squares plane is just 0.0301(4) Å. The O(1) to O(2) line forms an angle of 3.38(7)° with the equatorial coordination least-squares plane normal.

The metal coordination geometry may also be regarded as augmented tetrahedral in which the N(1), N(2), O(1) and O(2) atoms define a distorted tetrahedral coordination geometry that is augmented by the relatively long carbonyl oxygen to zinc bonds. The N(1)–Zn(1)–N(2) bond angle is 76.1(1)° and the O(1)–Zn(1)–O(2) angle is 120.9(2)°. The Zn(1) to O(1) and Zn(1) to O(2) bond lines form angles of 25.96(7) and 33.10(7)°, respectively, with the equatorial coordination least-squares plane normal.

The least-squares planes of the pyridyl residues form an angle of 13.6(1)°, and this equatorial ligand distortion is probably a response to the close contact between the amino N(3) and the pyridyl C(4). The distance between N(3) and C(4), at 3.034(6) Å, is less than the sum of their respective van der Waals radii. As Fig. 2 suggests, there is hydrogen bonding between the amine residue and a nearby triflate counter-ion and between the aqua ligands and neighbouring counterions (Table 2).

As far as we are aware, there are no other examples of a 1:1 metal complex of a 6,6′-dicarbonylsubstituted-2,2′-bipyridyl in which both the carbonyls and the bipyridine are coordinated to the metal centre, in the CCDC database, which could be used to model potential metal complexes of streptonigrin. There are a number of related 1:1 complexes including tetrahedral nickel(II) [24] and cobalt(II) complexes [25,26], and an octahedral ruthenium(II) complex formed with a 6,6-dialkylsubstituted 2,2′-bipyridine [27]. A palladium(II) 6,6′-disubstituted 2,2′-bipyridine complex has also been reported [28]; the strong square planar stereochemical preference of palladium(II) results in drastic deviation of the overall planar geometry, with the metal at a 40° angle to the plane of the bipyridine rings.

Complex **1** was prepared as a model for metal complexes of streptonigrin. The zinc(II) complex is of particular interest as it has been proposed that a ternary Zn–streptonigrin–DNA complex is formed under certain conditions [12], although studies with oligonucleotides are consistent with an electrostatic interaction with the phosphate backbone and N7 of sterically accessible guanines [29]. While complex **1** confirms that formation of the related complex **3** with streptonigrin is feasible (Fig. 3), some structural differences are noted. Firstly, streptonigrin contains a carboxylic acid in ring C, which leads to formation of the zwitterion in solution [30] and this is an important mechanism that contributes to aqueous solubility of the drug. In ligand **L**, the acid functional group was masked as a methyl ester to allow isolation and purification of the ligand. Hence, in vivo, formation of a complex in which the carboxylate oxygen (rather than the carbonyl) coordinates to the metal cannot be ruled out, and formation of complex **2** has been proposed [2–4] (Fig. 3). Secondly, the carbonyl group on ring A in streptonigrin is not freely rotating as in ligand **L** but is held in a fixed orientation by the quinone ring. The O(3)–C(13)–C(1)–N(1)

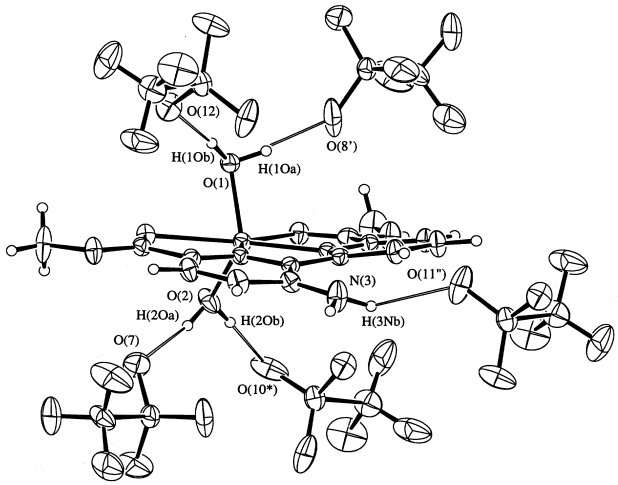

Fig. 2. An ORTEP depiction of the hydrogen bonding for complex **1**, in which O(8′) is generated from O(8) with $1/2-x, 1/2+y, 1/2-z$, O(10′) is generated from O(10) with $1/2-x, y-1/2, 1/2-z$ and O(11*) is generated from O(11) with $-x, -y, -z$.

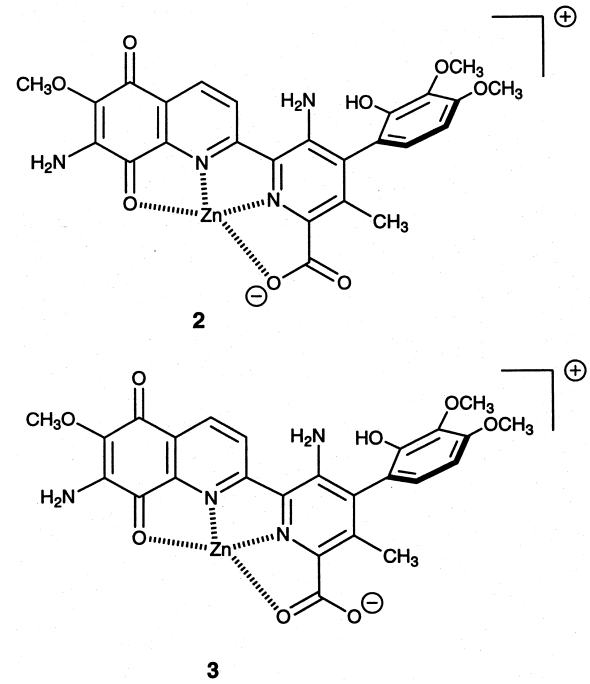

Fig. 3. Proposed complexes between streptonigrin and zinc(II) involving either the carbonyl **3** or carboxylate **2** oxygens of the acid functional group; coordination of additional water or solvent ligands to zinc(II) possible.

torsion angle is 7.6(7)° in complex **1** and these atoms are essentially coplanar, with least-squares plane deviations ranging from 0.010(3) to 0.038(5) Å. Thus, the structure of complex **1** establishes that the fixed carbonyl group of streptonigrin is unlikely to hinder formation of a streptonigrin metal complex with a similar geometry to that observed in **1**. Streptonigrin has the additional flexibility of carbonyl oxygen or oxyanion coordination, and oxyanion coordination may support the coordination of harder Lewis acids than zinc. The preparation of related metal complexes of ligand **L** and of streptonigrin are currently under investigation.

3. Experimental

3.1. Sample preparation

A mixture of the 2:1 and 1:1 zinc(II) complexes of 3-amino-6,6′-bis(methoxycarbonyl)-2,2′-bipyridine in acetonitrile was prepared as previously described [23]. Excess zinc(II) triflate (2 equiv.) was added to this solution. Crystals of the 1:1 complex **1** suitable for X-ray diffraction were grown by diffusion of benzene into the acetonitrile solution over a period of weeks.

3.2. X-ray crystallography

A very pale yellow (almost colourless) prismatic crystal having approximate dimensions of $0.30\times0.25\times0.22$ mm was attached to a thin glass fibre, and mounted on an Enraf-Nonius CAD4 diffractometer employing graphite monochromated Mo Kα radiation. Primitive monoclinic cell constants were obtained from a least-squares refinement using the setting angles of 25 reflections in the range $19.24<2\theta<24.18°$. Diffraction data were collected at a temperature of 21 ± 1°C using ω:1/3θ scans to a maximum 2θ value of 49.9°. The intensities of three representative reflections, measured every 60 min, decreased by 2.0% and a linear correction factor was accordingly applied to the data. An analytical absorption correction was applied and the data were also corrected for Lorentz and polarisation effects.

All calculations were undertaken with the teXsan [31] crystallographic software package. Neutral atom scattering factors were taken from Cromer and Waber [32]. Anomalous dispersion effects were included in F_{calc} [33] and the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [34]. The values for the mass attenuation coefficients were those of Creagh and Hubbell [35]. The structure was solved in the space group $P2_1/n$ (no. 14) by direct methods (SIR92: [36]) and expanded using Fourier techniques (DIRDIF94: [37]). Non-hydrogen atoms were modelled with anisotropic thermal parameters. The water and amine hydrogens were located and refined with distance restraints and the rest of the hydrogens were included at calculated positions with group thermal parameters (residual density was used to place the methyl hydrogens). An ORTEP projection of the molecule with 25% thermal ellipsoids is provided in Fig. 1 [38].

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition number 136086.

Abstract

A comparison between the reactivity of $[Ru_3(CO)_{12}]$ and $[Os_3(CO)_{10}(MeCN)_2]$ with 1,2-ethanedithiol ($HSCH_2CH_2SH$) and 1,3-propanedithiol ($HSCH_2CH_2CH_2SH$) is reported. The reaction of $[Ru_3(CO)_{12}]$ with 1,2-ethanedithiol at 68°C afforded $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ (**1**) in 40% yield, whereas the reaction with 1,3-propanedithiol yielded $[\{(\mu\text{-}H)Ru_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**2**) and $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2CH_2S)]$ (**3**) in 30 and 19% yields respectively. Treatment of $[Os_3(CO)_{10}(MeCN)_2]$ with 1,2-ethanedithiol gave $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}SCH_2CH_2SH)]$ (**4**) in 60% yield and with 1,3-propanedithiol it afforded $[\{(\mu\text{-}H)Os_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**5**) in 30% yield. Compounds **1** and **3** both react with equimolar amounts of PPh_3 at room temperature to give the monosubstituted products $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2S)(PPh_3)]$ (**6**) and $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2S)(PPh_3)]$ (**7**) respectively. When heated to 68°C, compound **2** transformed into **3**. The compounds have been characterized by spectroscopic studies, and in the case of **1**, **2** and **5** by X-ray crystallography. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Dithiolate complexes; Ruthenium; Osmium; X-ray structures

1. Introduction

The use of alkanedithiolates to stabilize transition metal cluster compounds by serving as chelating or bridging ligands and preventing cluster fragmentation during the course of catalytic reactions has received considerable attention [1–21]. The reactivity of polythiocycloalkanes towards metal carbonyl clusters is also of interest. It has been shown that some reactions proceed with retention of the cluster structure, while in other cases fragmentation into a dinuclear species as well as ring opening of the ligand takes place. For example, the reaction of $[Ru_3(CO)_{12}]$ with 1,2,5,6-tetrathiacyclooctane at 40°C gave a mixture of products from which the dinuclear and trinuclear complexes $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$, *anti*-$[Ru_3(CO)_7(\mu\text{-}SCH_2CH_2S)_2]$ and *syn*-$[Ru_3(CO)_7(\mu\text{-}SCH_2CH_2S)_2]$ containing the 1,2-ethanedithiolate ligand were isolated [22]. On the other hand, reactions of $[Ru_3(CO)_{12}]$ with 1,3-dithiacyclohexane, 1,3,5-trithiacyclohexane and 1,4,7-trithiacyclononane, yielded the respective complexes $[(\mu\text{-}H)Ru_3(CO)_9(\mu_3\text{-}\eta^3\text{-}1,3\text{-dithiacyclohexane})]$, $[Ru_3(CO)_9(\mu\text{-}\eta^3\text{-}1,3,5\text{-trithiacyclohexane})]$ and $[Ru_3(CO)_9(\mu\text{-}\eta^3\text{-}1,4,7\text{-trithiaheptane})]$ involving entirely different coordination modes of the ligands [23]. Recently, we have investigated the reactions of various dithiols with unsaturated triosmium clusters $[(\mu\text{-}H)Os_3(CO)_8\{Ph_2PCH_2P(Ph)C_6H_4\}]$ and $[(\mu\text{-}H)Os_3(CO)_9\{C_9H_5(R)N\}]$ (R = H or Me) [24,25] and saturated triruthenium clusters $[Ru_3(CO)_{10}(\mu\text{-dppm})]$ and $[Ru_3(CO)_{10}(\mu\text{-dppe})]$ [26], and observed several bonding modes of the dithiolate ligand depending on the cluster and the dithiol used. In the present work we report on the reactions of $[Ru_3(CO)_{12}]$ and $[Os_3(CO)_{10}(MeCN)_2]$ with 1,2-ethanedithiol and 1,3-propanedithiol and also the substitution reactions of the resulting diruthenium complexes with triphenylphosphine.

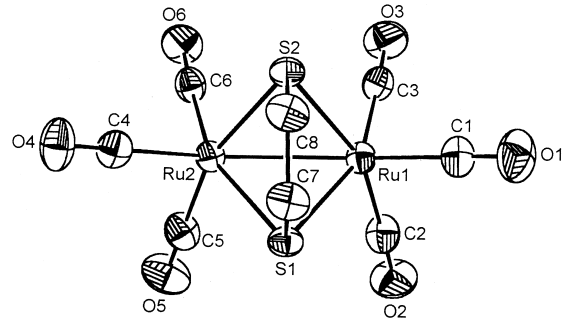
2. Results and discussion

Treatment of $[Ru_3(CO)_{12}]$ with 2 equiv. of 1,2-ethanedithiol afforded $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ (**1**) (Scheme 1) in 40% yield. This compound was previously reported from the thermal degradation of $[Ru_3(CO)_7(\mu\text{-}CO)_2(1,1,1\text{-}\eta^3\text{-}9S3)]$ (9S3 = 1,4,7-trithiacyclononane) at 68°C in 16% yield [27] as well as from the reaction of $[Ru_3(CO)_{12}]$ with 1,2,5,6-tetrathiacyclooctane at 40°C in 26% yield [22], and characterized on the basis of spectroscopic data only. We undertook an X-ray structure determination of **1** to confirm the coordination mode of the ethanedithiolate ligand.

The X-ray structure of **1** is shown in Fig. 1, and selected bond distances and angles are presented in Table 1. The molecule is based on two ruthenium atoms, each containing three linear terminal carbonyl groups and mutually bridged by both the sulfur atoms of the ethanedithiolate ligand. The molecule possesses a non-crystallographic *mm* symmetry with the $[Ru_2(CO)_6]$ unit adopting the classic 'sawhorse' arrangement. The Ru–Ru bond at 2.6790(8) Å is significantly shorter than that (2.854 Å) in the parent compound $[Ru_3(CO)_{12}]$ [28], but close to the metal–metal distance (2.710(1) Å) in the osmium analog $[Os_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ which has been reported from the pyrolysis of $[Os_3(CO)_{11}(SCH_2CH_2SCH_2CH_2)]$ as well as from the direct reaction of $[Os_3(CO)_{12}]$ with 1,4-dithiacyclohexane [29]. The ethanedithiolate ligand serves as a bidentate bridging ligand across the metal–metal bond and donates six electrons to make **1** a 34-electron valence saturated bimetallic compound, with each metal atom achieving the expected 18-electron configuration. The Ru–S–Ru bridges are symmetrical with distances Ru(1)/Ru(2)–S(1) = 2.375(2)/2.374(2) and Ru(1)/Ru(2)–S(2) = 2.370(2)/2.370(2) Å. These values are comparable to those found in *syn*-$[Ru_3(CO)_7(\mu\text{-}SCH_2CH_2S)_2]$ (2.365 Å, average) [22] and $[Os_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ (2.392 Å, average) [29]. The Ru–S–Ru angles are highly acute with the values 68.69(5) and 68.84(4)° at S(1) and S(2) respectively.



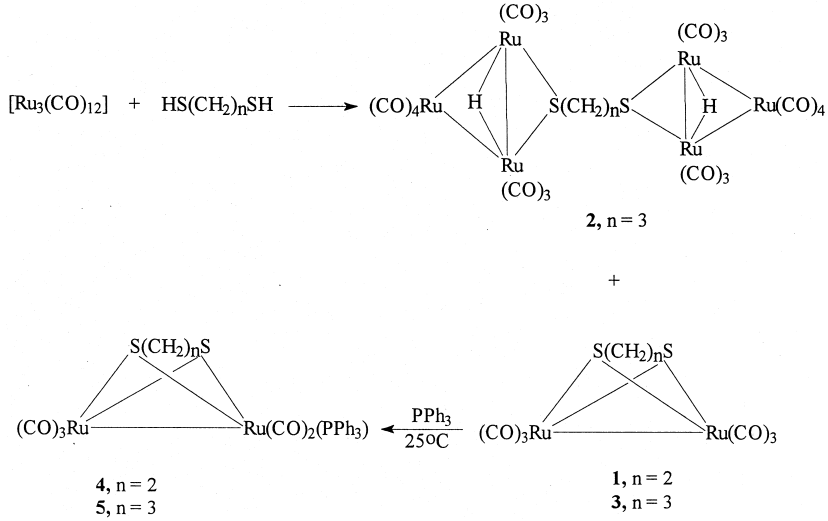


Fig. 1. Solid state structure of $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ (**1**) showing the atom labeling scheme. Hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at 40% probability level.

Ru(2)–S(1)–Ru(1)	68.69(5)	Ru(2)–S(2)–Ru(1)	68.84(4)

The reaction of $[Ru_3(CO)_{12}]$ with 1,3-propanedithiol yielded the trimetallic and dimetallic compounds $[\{(\mu\text{-}H)(Ru_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**2**) and $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2CH_2S)]$ (**3**) (Scheme 1) in 30 and 19% yields respectively. Compound **2** has been characterized by elemental analysis, IR, ^1H and ^{13}C NMR spectroscopic data and by an X-ray study.

Scheme 1.

The structure of **2** is shown in Fig. 2, and selected bond distances and angles are presented in Table 2. An interesting feature of **2** is the presence of two $\{(\mu\text{-H})Ru_3(CO)_{10}\}$ moieties linked by a propanedithiolate ligand. The overall structure of **2** is very similar to that of the methanedithiolate osmium analog $[\{(\mu\text{-H})Os_3(CO)_{10}\}_2(\mu\text{-}\eta^2\text{-}SCH_2S)]$ obtained from the reaction of $[(\mu\text{-H})_2Os_3(CO)_{10}]$ with CS_2 [30,31]. Each $\{(\mu\text{-H})Ru_3(CO)_{10}\}$ unit in **2** consists of an approximately equilateral traingle of three ruthenium atoms with Ru–Ru distances lying in a narrow range 2.8212(8)–2.8429(9) Å. These values are very similar to the Ru–Ru distances found in $[(\mu\text{-H})Ru_3(CO)_{10}(\mu\text{-}SCH_2COOH)]$ (2.827(5)–2.839(4) Å) [32]. The positions of the hydride ligands were obtained from difference maps and they are found to bridge the same edge of each triangle as the sulfur atom. Large angles for the *cis* carbonyl groups (e.g. Ru(3)–Ru(1)–C(2)/C(3) = 111.1(2)/115.4(2), Ru(1)–Ru(3)–C(8)/C(9) = 113.1(2)/116.6(2), Ru(6)–Ru(4)–C(11)/C(13) = 113.9(2)/114.0(2), Ru(4)–Ru(6)–C(18)/C(19) = 113.5(2)/116.1(2)°) are consistent with the location of the bridging hydrides along the Ru(1)–(Ru(3) and Ru(4)–Ru(6) edges in the two Ru_3 triangles. The sulfur bridges are symmetrical with distances Ru(1)/Ru(3)–S(1) = 2.386(2)/2.391(2) and Ru(4)/Ru(6)–S(2) = 2.388(2)/2.379(2) Å. These values are comparable with the Ru–S distances found in **1** and also in *anti*-$[(\mu\text{-H})Ru_3(CO)_7(\mu\text{-}\eta^2\text{-}SCH_2CH_2S)_2]$ (2.376(2)–2.384(2) Å) [22]. The $Ru_2S(1)$ and $Ru_2S(2)$ planes are inclined from the corresponding Ru_3 planes by 77.93(4) and 76.25(4)° respectively. The C–S bond distances of S(1)–C(21) = 1.839(6) and S(2)–C(23) = 1.824(6) Å are very similar to the C–S single bond distances 1.80–1.82 Å observed in several thioalkanes [33–36].

The IR, ^1H and ^{13}C NMR spectra of **2** are consistent with the proposed formulation and X-ray structure. The ^1H NMR spectrum of **2** contains a triplet at δ 2.25, a quartet at δ 2.05 and a singlet at δ −15.41 with relative intensities 2:1:1. The triplet and quartet are due to the six methylene protons in a slightly different environment, whilst the singlet is attributed to the two bridging hydrides in identical stereochemical environment. The ^{13}C NMR spectrum exhibits two resonances at

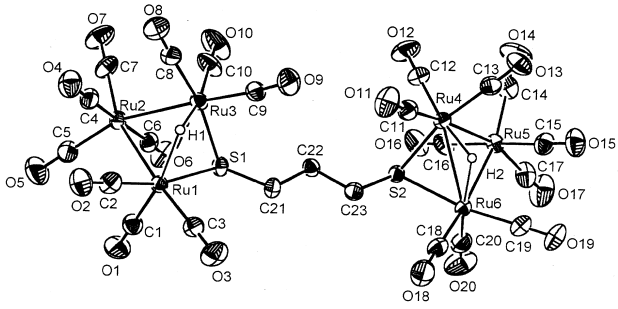

Fig. 2. Solid state structure of $[\{(\mu\text{-H})Ru_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**2**) showing the atom labeling scheme. Hydrogen atoms other than the bridging hydrides are omitted for clarity. Thermal ellipsoids are drawn at 40% probability level.

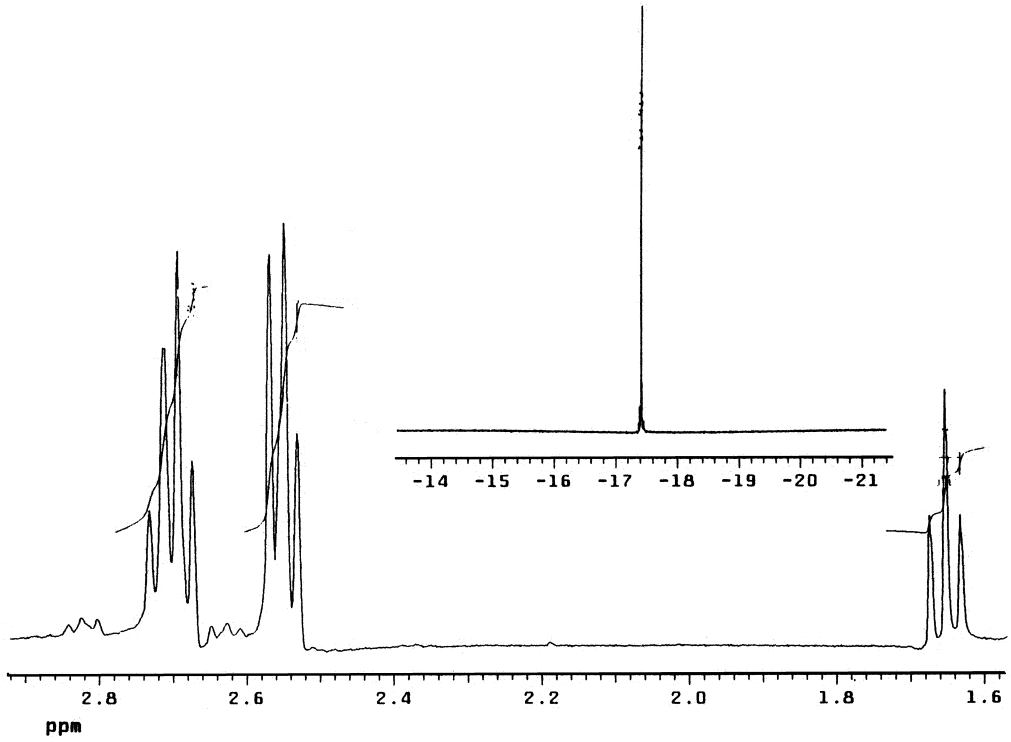

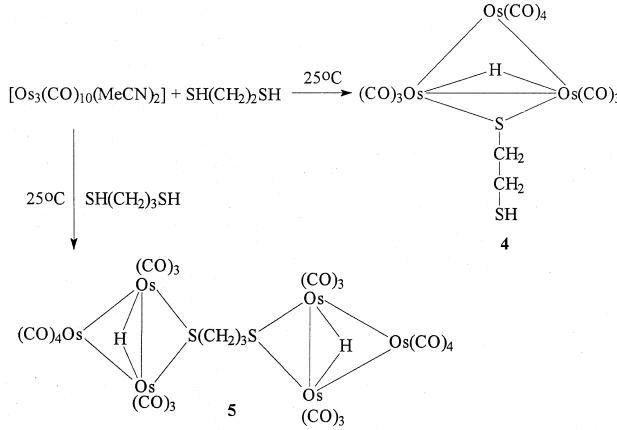

Fig. 3. ^{1}H NMR spectrum of [(μ-H)$Os_3(CO)_{10}$(μ-SCH_2CH_2SH)] (**4**) in $CDCl_3$.

The complex **3** has been characterized by elemental analysis, IR, ^{1}H NMR and mass spectroscopic data. The IR spectrum of **3** is very similar to that of **1** indicating that they are structurally similar. The ^{1}H NMR spectrum shows multiplets at δ 2.19 and 1.89 in a relative intensity of 2:1. The mass spectrum shows the molecular ion peak at *m/z* 478 as expected and the stepwise loss of six carbonyl groups is also observed. The structure of this complex is thus proposed as in Scheme 1.

The reaction of 1,2-ethanedithiol with [$Os_3(CO)_{10}$-$(MeCN)_2$] afforded [(μ-H)$Os_3(CO)_{10}$(μ-SCH_2CH_2SH)] (**4**) in 60% yield. The compound has been characterized by elemental analysis, IR, ^{1}H NMR and mass spectroscopic data. The IR spectrum of **4** in the carbonyl stretching region is very similar to that of [(μ-H)$Os_3(CO)_{10}$(μ-SR)] [37,38], suggesting that they have very similar structures. The ^{1}H NMR and mass spectra indicated the formation of a decacarbonyl compound by oxidative addition of one S–H bond while the other S–H bond remains free. The mass spectrum shows the molecular ion peak at *m/z* 950 with sequential loss of ten carbonyl ligands. The ^{1}H NMR spectrum (Fig. 3) contains four signals at δ 2.70 (dt, 2H, J = 8.0 Hz), 2.55 (t, 2H, J = 8.0 Hz), 1.65 (t, 1H, J = 8.0 Hz) and −17.42 (s, 1H). The S–H proton is observed at δ 1.65 as a triplet with J = 8.0 Hz presumably due to coupling with the adjacent methylene protons. The triplet at δ 2.55 is due to the methylene protons attached to the coordinated sulfur atom while the doublet of a triplet (deceptively appearing as a quartet) at δ 2.70 is assigned to the methylene protons adjacent to the sulfur atom of the free S–H group. The other possible structure with activation of both the S–H bonds can easily be ruled out, because such activation would result in a singlet resonance for methylene protons of the dithiolate ligand. Thus the spectroscopic data are consistent with the proposed structure for **4** (Scheme 2).

In contrast, 1,3-propanedithiol reacts with [$Os_3(CO)_{10}$-$(MeCN)_2$] at room temperature to give [{(μ-H)-$Os_3(CO)_{10}$}$_2$(μ-$SCH_2CH_2CH_2S$)] (**5**). This compound was previously structurally characterized by Lewis and coworkers [39], but no spectroscopic data were reported. We have now characterized it by both spectroscopic data and X-ray crystallography. The IR spectrum of **5** is different from that of the methanedithiolate dicluster [{(μ-H)$Os_3(CO)_{10}$}$_2$(μ-SCH_2S)] but is very similar to that of the propanedithiolate ruthenium analog **2** and the monocluster **4**. The ^{1}H NMR spectrum of **5** shows a pattern similar to

Scheme 2.

2 and contains a triplet at δ 2.44 for four equivalent methylene protons of the 1,3-propanedithiolate ligand, a quintet at δ 1.99 for the other two methylene protons and a high field singlet at δ −17.42 for the two equivalent bridging hydride ligands (one from each cluster). Compound **5** is found to be isostructural with **2**, in which two $\{(\mu\text{-H})Os_3(CO)_{10}\}$ groupings are bridged by the $SCH_2CH_2CH_2S$ ligand and each sulfur bridges two osmium atoms in separate Os_3 cluster units (Fig. 4). The molecular geometry parameters in **5** (Table 3) are comparable with the corresponding values in **2** and also with those obtained from the earlier study [39]. The Os–Os, Os–S and S–C distances (2.8441(10)–2.8652(10), 2.401(4)–2.414(4), 1.82(2)–1.83(2) Å) in **5** are virtually identical with the respective reported values (2.840(3)–2.860(3), 2.397(5)–2.424(5), 1.83(3)–1.85(4) Å) [39].

We have recently [26] found that substitution reaction of the iron-dithiolate compound $[Fe_2(CO)_6(\mu\text{-}SCH_2CH_2CH_2S]$ with tertiary phosphines gives $[Fe_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PR_3)]$. Keeping this in mind we investigated the CO substitution reaction of **1** and **3** with PPh_3 and observed that an easy reaction occurs yielding the monosubstituted compounds $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PPh_3)]$ (**6**) and $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PPh_3)]$ (**7**). Suitable single crystals could not be grown for **6** and **7** for X-ray analysis; however, they are proposed to be structurally similar to $[Fe_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PR_3)]$ on the basis of elemental analysis, IR, ^1H and $^{31}P\{^1H\}$ NMR and mass spectroscopic data. The mass spectra of **6** and **7** contain the molecular ion peaks at *m/z* 698 and 712 respectively with successive loss of five CO groups. The ^{31}P NMR spectra of **6** and **7** consist of a single resonance and do not show any significant change on varying the recording temperature. This suggests that **6** and **7** exist as single isomers. As expected, in addition to the signals for the phenyl protons of triphenylphosphine, the ^1H NMR spectra contain resonances due to dithiolate ligands. The IR spectra of **6** and **7** are very similar to that reported for $[Fe_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PR_3)]$ in which the triphenylphosphine is coordinated at an axial site of one of the metal atoms [26]. When heated to reflux in hexane compound **2** was transformed into **3** by cluster degradation.

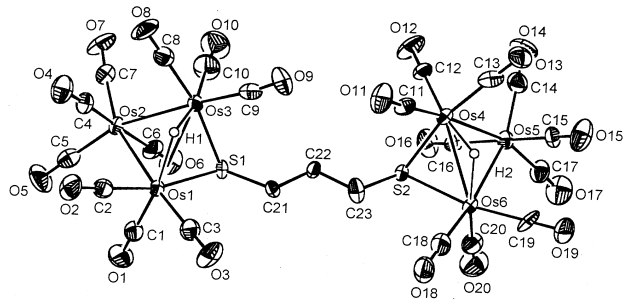

Fig. 4. Solid state structure of $[\{(\mu\text{-H})Os_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**5**) showing the atom labeling scheme. Hydrogen atoms other than the bridging hydrides are omitted for clarity. Thermal ellipsoids are drawn at 40% probability level.

This work shows that the methylene chain length of the ditholate ligands as well as the metal atoms of the clusters have an important effect on product formation when reacted with trimetallic compounds. Longer methylene chain lengths favor dimer formation whilst a short chain length results in

the formation of bidentate chelate as well as monodentate thiolate bridge.

3. Experimental

All the reactions were routinely carried out under a pre-purified nitrogen atmosphere. Reagent grade solvents were freshly distilled from appropriate drying agents. Infrared spectra were recorded on a Schimadzu FTIR 8101 spectrophotometer. NMR spectra were recorded on a Varian Unity Plus 400 spectrometer. $[Ru_3(CO)_{12}]$ was purchased from Strem Chemicals Inc. and used without further purification. $[Os_3(CO)_{10}(MeCN)_2]$ was prepared according to the known procedure [40].

3.1. Reaction of $[Ru_3(CO)_{12}]$ with 1,2-ethanedithiol

A THF solution (80 ml) of $[Ru_2(CO)_{12}]$ (0.200g, 0.312 mmol) and 1,2-ethanedithiol (0.059 g, 0.626 mmol) was refluxed for 1 h. The solvent was removed under reduced pressure and the residue chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (9:1, v/v) gave two bands. The major band afforded the known compound $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2S)]$ (0.050 g, 40%) as pale yellow crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. IR (ν(CO), hexane): 2085m, 2056vs, 2018vs, 2004s, 1995m, 1968w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.37 (s). ^{13}C {^1H} NMR ($CDCl_3$): carbonyl region, 196.2 (4C), 188.6 (2C), hydrocarbon region, 36.1 (2C). MS (*m/z*): 464, M^+, 436 $[M-CO]^+$, 408 $[M-2CO]^+$, 380 $[M-3CO]^+$, 352 $[M-4CO]^+$, 324 $[M-5CO]^+$, 296 $[M-6CO]^+$. *Anal*. Calc. for $C_8H_4O_6Ru_2S_2$: C, 20.78; H, 0.87. Found: C, 20.95; H, 0.95%.

3.2. Reaction of $[Ru_3(CO)_{12}]$ with 1,3-propanedithiol

To a THF solution (100 ml) of $[Ru_3(CO)_{12}]$ (0.400 g, 0.625 mmol) was added 1,3-propanedithiol (0.135 g, 1.25 mmol) and the reaction mixture was refluxed for 1 h. The solvent and excess thiol were removed in vacuo and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (9:1, v/v) developed two bands. The faster moving band afforded $[\{(\mu\text{-}H)Ru_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**2**) (0.120 g, 30%) as orange crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. Analytical and spectral data for **2**: (IR ν(CO), hexane): 2105m, 2067vs, 2057s, 2027vs, 2010w, 1998w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.25 (t, 4H, J=7.6 Hz), 2.05 (q, 2H, J=7.6 Hz), −15.41 (s, 2H). $^{13}C\{^1H\}$ NMR ($CDCl_3$): carbonyl region, δ 204.1 (2C), 202.6 (2C), 198.1 (4C), 192.8 (4C), 191.5 (4C), 184.5 (4C), hydrocarbon region, δ 55.1 (2C), 35.7 (1C). *Anal*. Calc. for $C_{23}H_8O_{20}Ru_6S_2$: C, 21.67; H, 0.63. Found: C, 21.82; H, 0.75%. The second band gave $[Ru_2(CO)_6(\mu\text{-}SCH_2CH_2CH_2S)]$ (**3**) (0.056 g, 19%) as pale yellow crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. Analytical and spectral data for **3**: IR (ν(CO), hexane): 2086s, 2055vs, 2018vs, 2004s, 1994s, 1966w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.19 (s, 4H), 1.89 (s, 2H). MS (*m/z*): 478, M^+, 450 $[M-CO]^+$, 422 $[M-2CO]^+$, 394 $[M-3CO]^+$, 366 $[M-4CO]^+$, 338 $[M-5CO]^+$, 310 $[M-6CO]^+$. *Anal*. Calc. for $C_9H_6O_6Ru_2S_2$: C, 22.69; H,1.27. Found: C, 22.78; H, 1.43%.

3.3. Thermolysis of **2**

A THF solution (30 ml) of **2** (0.120 g, 0.094 mmol) was refluxed for 1.5 h. The solvent was removed under reduced pressure and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (9:1, v/v) afforded **3** (0.012 g, 34%) as pale yellow crystals.

3.4. Reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with 1,2-ethanedithiol

To a dichloromethane solution (15 ml) of $[Os_3(CO)_{10}(MeCN)_2]$ (0.194 g, 0.208 mmol) was added 1,2-ethanedithiol (0.039 g, 0.414 mmol) and the reaction mixture was stirred at room temperature for 5 h. The solvent was removed by rotary evaporation and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (4:1, v/v) gave two bands. The faster moving major band gave $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}SCH_2CH_2SH)]$ (**4**) as yellow crystals (0.117 g, 60%) from hexane/CH_2Cl_2 at 20°C and the second band gave too small an amount of a compound for complete characterization. Spectral and analytical data for **4**: IR (ν(CO) hexane): 2110m, 2069vs, 2060s, 2026vs, 2021m, 2001s, 1992m, 1986w cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.70 (q, 2H, J=8.4 Hz), 2.55 (t, 2H, J=8.4 Hz), 1.65 (t, 1H, J=8.4 Hz), −17.41 (s, 1H). *Anal*. Calc. for $C_{12}H_6O_{10}Os_3S_2$: C, 15.25; H, 0.64. Found: C, 15.42; H, 0.78%. MS (*m/z*): 950 (M^+), 922 $[M-CO]^+$, 894 $[M-2CO]^+$, 866 $[M-3CO]^+$, 838 $[M-4CO]^+$, 810 $[M-5CO]^+$, 782 $[M-6CO]^+$, 754 $[M-7CO]^+$, 726 $[M-8CO]^+$, 698 $[M-9CO]^+$, 670 $[M-10CO]^+$.

3.5. Reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with 1,3-propanedithiol

1,3-Propanedithiol (0.046 g, 0.428 mmol) was added to a dichloromethane solution (15 ml) of $[Os_3(CO)_{10}(MeCN)_2]$ (0.200 g, 0.214 mmol) in CH_2Cl_2 (15 ml) and the reaction mixture was stirred at room temperature for 3 h. The solvent was removed under reduced pressure and the residue was chromatographed by TCL on silica gel. Elution with hexane/CH_2Cl_2 (4:1, v/v) gave one major band which afforded $[\{\mu\text{-}H)Os_3(CO)_{10}\}_2(\mu\text{-}SCH_2CH_2CH_2S)]$ (**5**) (0.056 g, 30%) as yellow crystals from hexane/CH_2Cl_2 at −20°C. Analytical and spectral data for **5**: IR (ν(CO), hexane): 2110w, 2070s, 2060m, 2027s, 2022m, 2000m, 1991m cm^{-1}. ^1H NMR ($CDCl_3$): δ 2.44 (t, 4H, J=7.4 Hz), 1.91 (q, 2H, J=7.4 Hz), −17.42 (s, 2H). *Anal*. Calc. for

$C_{23}H_8O_{20}Os_6S_2$: C, 15.26; H, 0.44. Found: C, 15.49; H, 0.58%.

3.6. Reaction of *1* with PPh_3

A mixture of **1** (0.050 g, 0.108 mmol) and triphenylphosphine (0.028 g, 0.107 mmol) in hexane (35 ml) was stirred at room temperature for 1 h. The color of the solution changed from yellow to orange. The solvent was rotary evaporated and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 gave a single band which afforded $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2S)(PPh_3)]$ (**6**) (0.041 g, 55%) as orange crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. Analytical and spectral data for **6**: IR (ν(CO), CH_2Cl_2): 2060vs, 2004vs, 2024vw 1985w cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.53–7.38 (m, 15H), 1.83 (m, 2H), 1.14 (m, 2H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 41.6 (s). MS (*m/z*): 698, M^+, 670 $[M-CO]^+$, 642 $[M-2CO)]^+$, 614 $[M-3CO]^+$, 586 $[M-4CO]^+$, 558 $[M-5CO]^+$. *Anal.* Calc. for $C_{25}H_{19}O_5PRu_2S_2$: C, 43.10; H, 2.75. Found: C, 43.32; H, 2.92%.

3.7. Reaction of *3* with PPh_3

A similar reaction to that above of **3** (0.030 g, 0.063 mmol) and PPh_3 (0.017 g, 0.065 mmol) in hexane (30 ml) followed by similar workup and chromatographic separation yielded $[Ru_2(CO)_5(\mu\text{-}SCH_2CH_2CH_2S)(PPh_3)]$ (**7**) (0.020 g, 44%) as orange crystals from hexane/CH_2Cl_2 at −20°C. Analytical and spectral data for **7**: IR (ν(CO), CH_2Cl_2): 2060vs, 2004vs, 1985m, 1946m cm^{-1}. ^1H NMR ($CDCl_3$): δ 7.67–7.42 (m, 15H), 1.81 (m, 2H), 1.37 (m, 2H), 0.98 (m, 2H). $^{31}P\{^1H\}$ NMR ($CDCl_3$): 42.1 (s). MS (*m/z*): 712, M^+, 684 $[M-CO]^+$, 656 $[M-2CO]^+$, 628 $[M-3CO]^+$, 600 $[M-4CO]^+$, 572 $[M-5CO]^+$. *Anal.* Calc. for $C_{26}H_{21}O_5PRu_2S_2$: C, 43.94; H, 2.98. Found: C, 44.18; H, 3.15%.

3.8. X-ray crystallography

Crystallographic data for **1** and **5** were recorded on a Delft Instruments FAST TV area detector and those for **2** were measured on a Turbo CAD4 diffractometer using monochromatized Mo Kα radiation ($\lambda = 0.71069$ Å) [41]. All data sets were corrected for absorption using DIFABS [42]. The structures were solved by direct methods (SHELXS-86) [43], developed via difference syntheses, and refined on F^2 by full-matrix least-squares (SHELXL-96) [44] using all unique data with intensities greater than zero. In all cases the non-hydrogen atoms were anisotropic. The bridging hydrides (H(1) and H(2)) in **2** were located from difference maps but not refined; all other hydrogen atoms were included in calculated positions (riding model). Compound **5** is isostructural with **2**, and so the refinement was carried out starting from the atomic coordinates for **2**. The crystallographic data are summarized in Table 4.

Table 4
Crystal data and details of data collection and structure refinement for **1**, **2** and **5** [a]

	Compound **1**	Compound **2**	Compound **5**
Chemical formula	$C_8H_4O_6Ru_2S_2$	$C_{23}H_8O_{20}Ru_6S_2$	$C_{23}H_8O_{20}Os_6S_2$

Abstract

The reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with 2-methyl-2-thiazoline at ambient temperature results in the C–H activation of the methyl substituent of the heterocyclic ligand and this gives the new compound $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}\eta^2\text{-}CH_2\overline{C{=}NCH_2CH_2S}]$ (**8**) in 55% yield. Compound **8** undergoes decarbonylation and a further C–H bond activation by thermolysis at 98°C or by treatment with trimethylamine-*N*-oxide to give the dihydrido cluster $[(\mu\text{-H})_2Os_3(CO)_9(\mu\text{-}\eta^2\text{-}CH\overline{C{=}NCH_2CH_2S}]$ (**9**) in 45% yield. Both complexes have been characterized by elemental analyses, IR and ^{1}H NMR spectroscopy, together with X-ray crystallography for **8**. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Osmium; X-ray structures; Metallation

1. Introduction

The study of the reactivity of N and S containing heterocycles with trimetallic clusters of osmium and ruthenium continues to be the subject of considerable interest; this is due to their relevance to modelling the industrially important hydrodenitrogenation (HDN) and hydrodesulfurization (HDS) processes [1–7]. We have recently reported the thiazolide clusters $[(\mu\text{-H})M_3(CO)_{10}(\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NCMe{=}CHS})]$ (**3**, M = Os; **4**, M = Ru; Scheme 1), with metallation exclusively at the 2-position, from the reactions of $[M_3(CO)_{10}L_2]$ (**1**, M = Os, L = MeCN; **2**, M = Ru, L = CO) with 4-methyl thiazole [1]. We also found that the reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with thiazole results in metallation at the 4- and 2-positions, leading to the isomeric compounds $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NCH{=}CHS})]$ (**5**) and $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}3,4\text{-}\eta^2\text{-}H\overline{C{=}NC{=}CHS})]$ (**6**) [2]. In contrast, when reacted with $[Ru_3(CO)_{12}]$, thiazole preferentially metallates at the 2-position yielding $[(\mu\text{-H})Ru_3(CO)_{10}(\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NCH{=}CHS})]$ (**7**) [3].

Scheme 1.

Pyridine and 2-substituted pyridines react with triosmium and triruthenium clusters by orthometallation to give $[(\mu\text{-H})M_3(CO)_{10}(\mu\text{-L})]$ (L = C_5H_4N, 2-MeC_5H_3N, 3-MeC_5H_3N, 2-Et-C_5H_3N) [8–17]. In comparison to the extensive orthometallation chemistry of five- and six-membered heterocyclic rings, examples of the activation of their substituent groups are comparatively rare. An example of the ethenyl group C–H bond activation rather than those at the hetero-

cyclic ring has been observed when $[Os_3(CO)_{10}(MeCN)_2]$ was reacted with 2-ethenyl pyridine leading to the formation of the open triosmium cluster $[HOs_3(CO)_{10}(NC_5H_4\text{-}C{=}CH)]$ [18]. As part of our interest in the reactivity of N and S containing heterocycles with trimetallic clusters we have investigated the reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with 2-methyl-2-thiazoline and report herein a rare example of the C–H activation of the substituent group of the ligand at ambient temperature.

2. Results and discussion

The lightly stabilized cluster $[Os_3(CO)_{10}(MeCN)_2]$ readily reacts with 2-methyl-2-thiazoline at room temperature to give the novel cluster $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}\eta^2\text{-}CH_2\overline{C{=}NCH_2CH_2S}]$ (**8**) in 55% yield (Scheme 2). The compound **8** has been characterized by microanalysis, IR and ^{1}H NMR spectroscopy as well as X-ray crystallography. The ^{1}H NMR spectrum of **8** shows four multiplets at δ 3.24, 3.37, 3.89 and 4.18 for the ring protons, which remain intact, and two coupled doublets at δ 1.81 and 2.40 for the 2-CH_2 group along with a high field singlet at δ −14.20 each integrating for one hydrogen. The coupling of 20.0 Hz between these protons and their chemical shifts imply a coordinated CH_2 group and metallation at the substituent group. The spectroscopic data indicated the activation of the C–H bond of the methyl substituent of the heterocycle and subsequent coordination of the carbon to the metal. The exact nature of the bonding of the organic ligand to the cluster was obtained by a single crystal structure determination for **8**.

The structure of a single molecule of **8** is shown in Fig. 1, and selected bond lengths and angles are given in Table 1. The molecule consists of a triangular cluster of osmium atoms with three distinct metal–metal bonds (Os(1)–Os(2) = 2.9047(8), Os(1)–Os(3) = 2.8858(8) and Os(2)–Os(3) = 2.9414(10) Å). The Os(2)–Os(3) edge which is bridged simultaneously by the hydride and the heterocyclic ligand is significantly longer than the two unbridged edges.

Scheme 2.

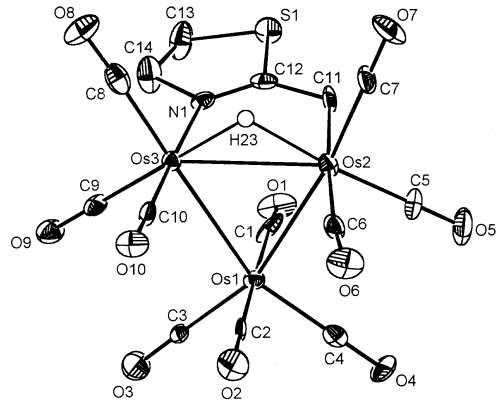

Fig. 1. X-ray structure of **8**, showing the atom labelling scheme. The ring hydrogens are omitted for clarity. Thermal ellipsoids are drawn at 40% probability level.

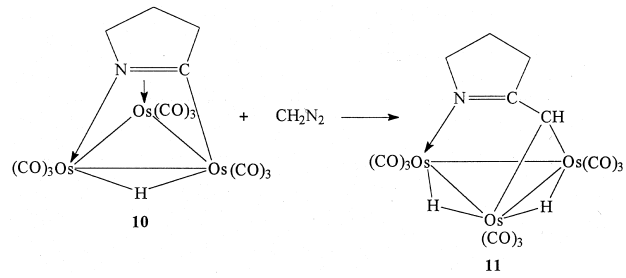
[a] Average value.
[b] Approximate value.



Similar lengthening of the doubly bridged Os–Os edges was also observed in $[(\mu\text{-}H)Os_3(CO)_{10}\{\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NC(Me){=}CHS}\}]$ (2.9340(8) versus 2.8590(7), 2.8849(8) Å), $[(\mu\text{-}H)Os_3(CO)_9\{\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NC(Me){=}CHS}\}(PPh_3)]$ (2.9674(9) versus 2.8619(13), 2.8779(9) Å) and $[(\mu\text{-}H)Os_3(CO)_8\{\mu\text{-}2,3\text{-}\eta^2\text{-}\overline{C{=}NC(Me){=}CHS}\}(PPh_3)_2]$ (2.9528(6) versus 2.8795(6), 2.9050(6) Å) [1]. The bridging hydride is located close to the plane of the Os_3 triangle, while the heterocyclic ligand is nearly perpendicular to it. The metal atoms Os(3) and Os(2) each contain three linear terminal carbonyl ligands while Os(1) is bonded to four. A notable feature of this structure is that a C–H activation of the methyl

group of 2-methyl-2-thiazoline occurs during the reaction. The organic ligand is η^2-coordinated to the longest Os(2)–Os(3) edge through a metal–carbon σ bond from C(11) to Os(2) and a two-electron donor bond from N(1) to Os(3). The Os(2)–C(11) bond length of 2.190(11) Å and Os(3)–N(1) bond length of 2.165(9) Å are comparable to those of the related compounds $[(\mu\text{-H})_2Ru_3(CO)_9(\mu_3\text{-}\eta^2\text{-}CH(Me)C{=}NCH_2CH_3)\}]$ and $[(\mu\text{-H})_2Os_3(CO)_9(\mu_3\text{-}\eta^2\text{-}CHC{=}NCH_2CH_2CH_2)]$ [19]. The C(12)–N(1) bond length of 1.284(14) Å is typical of carbon nitrogen double bonds in the related triosmium and triruthenium complexes [20–22], while the C(14)–N(1) bond length of 1.484(12) Å is close to that expected for a C–N single bond (1.47 Å) [23]. The S–C distances (1.747(11)–1.778(11), average 1.763 Å) are only slightly smaller than the value expected for a S–C single bond (1.81 Å) [23]. The Os–C(CO) distances (1.897(11)–1.954(12), average 1.923 Å) and the Os–C–O angles (171.3(10)–179.6(9), average 176.54°) are comparable to the corresponding values in triosmium decarbonyl compounds containing a 3, 3, 4 carbonyl ligand distribution and in which the heterocyclic ligand and the hydride bridge the same Os–Os edge [1,2,20,22].

Thermolysis of **8** in refluxing heptane at 98°C gives the dihydrido cluster $[(\mu\text{-H})_2Os_3(CO)_9(\mu_3\text{-}\eta^2\text{-}CHC{=}NCH_2CH_2S)]$ (**9**) in 45% yield (Scheme 1). The compound has been characterized on the basis of elemental analysis, IR and ^{1}H NMR spectroscopic data. A direct analog of **9** was obtained from the reaction of the μ_3-imidoyl compound $[(\mu\text{-H})Os_3(CO)_9(\mu_3\text{-}\eta^2\text{-}C{=}NCH_2CH_2CH_2)]$ (**10**) with diazomethane (Scheme 3) [19]. The ν(CO) frequencies of **9** are very similar to those of **11**, indicating that they have very similar distribution of the carbonyl ligands.

The aliphatic region of the ^{1}H NMR spectrum of **9** contains a doublet at δ 4.24 (J = 1.2 Hz) and three multiplets at δ 3.74, 3.47 and 3.17 in a relative intensity ratio of 1:1:1:2. The hydride region shows a doublet at δ −14.48 (J = 1.6 Hz) and a doublet of doublets at δ −14.61 (J = 1.6 and 1.2 Hz) in a relative intensity of 1:1. The doublet at δ 4.24 is due to the methyne proton and it exhibits coupling to one of the hydrides which appears as a doublet of doublets at δ −14.61. Irradiation of the methyne proton results in a collapse of the hydride doublet of doublets at δ −14.61 to a doublet. The hydride chemical shifts, their multiplicity and the long-range coupling between the methyne proton and one of the hydrides are almost identical with those reported for **11** (δ −14.30 (d, J = 1.7 Hz), −14.56 (dd, J = 1.7 and 0.8 Hz)) whose structure was established by X-ray diffraction studies [19]. The analytical data and spectroscopic features of **9** are thus in agreement with the proposed structure.

In order to examine whether the double bond of the heterocyclic ligand in **8** would exhibit the ability to coordinate to the rare metal atom yielding a μ_3-imidoyl type compound, the compound was treated with Me_3NO. Contrary to expectation, we observed a preferred reaction that involved a further C–H activation of the coordinated methylidyne ligand accompanied by a CO loss.

Scheme 3.

In conclusion, we have demonstrated herein an unusual C–H activation of the methyl substituent of 2-methyl-2-thiazoline at a triosmium centre to give $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}\eta^2\text{-}CH_2C{=}NCH_2CH_2S)]$ (**8**) which undergoes a further C–H activation to afford $[(\mu\text{-H})_2Os_3(CO)_9(\mu\text{-}\eta^2\text{-}CHC{=}NCH_2CH_2S)]$ (**9**). Decarbonylation of **8** using Me_3NO also gives **9** instead of the expected μ_3-imidoyl type product, indicating that C–H activation is more amenable than coordination of the double bond of the heterocycle to the rear metal atom.

3. Experimental

All reactions were carried out under a dry and oxygen-free atmosphere of N_2 by using standard Schlenk techniques. Reagent grade solvents were freshly distilled from the appropriate drying agents. ^{1}H NMR spectra were recorded on a Varian Unity Plus 400 MHz spectrometer. Infrared spectra were recorded on a FTIR 8101 spectrophotometer. The cluster $[Os_3(CO)_{10}(MeCN)_2]$ was prepared according to the known procedure [24].

3.1. Reaction of $[Os_3(CO)_{10}(MeCN)_2]$ with 2-methyl-2-thiazoline

To a dichloromethane solution (40 cm^3) of $[Os_3(CO)_{10}(MeCN)_2]$ (0.188 g, 0.201 mmol) was added 2-methyl-2-thiazoline (0.102 g, 1.0 mmol) and the reaction mixture was stirred at room temperature for 20 h. The solvent was removed in vacuo and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (7:3, v/v) gave one major band which afforded $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}\eta^2\text{-}CH_2C{=}NCH_2CH_2S)]$ (**8**) (0.105 g, 55%) as yellow crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. *Anal.* Found: C, 17.82; H, 0.89; N, 1.59. $C_{14}H_7NO_{10}Os_3S$ requires: C, 17.66; H, 0.74; N, 1.47%. IR (ν(CO), hexane): 2103 m, 2061 vs, 2050 vs, 2022 vs, 2002 m, 1996 m, 1990 m, 1973 w cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 1.81 (d, 1H, J = 20.0 Hz), 2.40 (d, 1H, J = 20.0 Hz), 3.24 (m, 1H), 3.37 (m, 1H), 3.89 (m, 1H), 4.18 (m, 1H), −14.24 (s, 1H).

3.2. Thermolysis of $[(\mu\text{-H})Os_3(CO)_{10}(\mu\text{-}\eta^2\text{-}CH_2C{=}NCH_2CH_2S)]$ (8)

A solution of **8** (0.070 g, 0.073 mmol) in heptane (20 cm^3) was heated to reflux for 22 h. The solvent was removed under reduced pressure and the residue was chromatographed by TLC on silica gel. Elution with hexane/CH_2Cl_2 (7:3,

v/v) developed three bands. The fast moving band gave $[Os_3(CO)_{12}]$ (0.008 g, 12%). The second band gave a too small amount (~0.002 g) for complete characterization. The third band gave $[(\mu\text{-H})_2Os_3(CO)_9(\mu\text{-}\eta^2\text{-}CHC{=}NCH_2CH_2S)]$ (**9**) (0.030 g, 45%) as yellow crystals after recrystallization from hexane/CH_2Cl_2 at −20°C. *Anal*. Found: C, 17.10; H, 0.82; N, 1.62. $C_{13}H_7NO_9Os_3$ requires: C, 16.90; H, 0.76; N, 1.51%. IR (ν(CO), CH_2Cl_2): 2103 s, 2076 vs, 2049 vs, 2019 vs, 2002 s, 1993 m, 1976 m cm^{-1}. ^1H NMR ($CDCl_3$): δ 3.21 (m, 2H), 3.47 (m, 1H), 3.74 (m, 1H), 4.24 (d, 1H, J = 1.2 Hz), −14.48 (d, 1H, J = 1.6 Hz), −14.61 (dd, 1H, J = 1.6, 1.2 Hz).

3.3. Reaction of **8** with Me_3NO

To a dichloromethane solution (20 cm^3) of **8** (0.070 g, 0.073 mmol) was added dropwise a CH_2Cl_2 solution (5 cm^3) of Me_3NO (0.011 g, 0.146 mmol) over a period of 15 min. The reaction mixture was stirred at room temperature for 20 h. A similar work-up to that above followed by a similar chromatographic separation of the residue gave **9** (0.024 g, 35%).

3.4. X-ray crystallography

Crystal data for **8**: $C_{14}H_7NO_{10}Os_3S$, M = 951.87, monoclinic, $C2/c$, a = 28.526(6), b = 7.758(2), c = 17.506(4) Å, β = 90.08(3)°, U = 3873(2) Å^3, Z = 8, D_c = 3.265 g cm^{-3}, μ(Mo Kα) = 197.98 cm^{-1}, λ = 0.71073 Å, T = 150 K, crystal size 0.22 × 0.15 × 0.12 mm.

Intensity data were recorded on a FAST area detector diffractometer [25], the structure solved by direct methods (SHELXS-86) [26], and refined on F^2 by full-matrix least-squares (SHELXL-96) [27] using all 2903 unique data and 262 parameters to final wR_2 = 0.0645 (on F^2, all data) and R_1 = 0.0286 (on F, 2484 data with $F_o^2 > 2\sigma(F_o^2)$). The bridging hydride was located from a difference map but not refined.

Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk), CCDC ref. no. 139497.

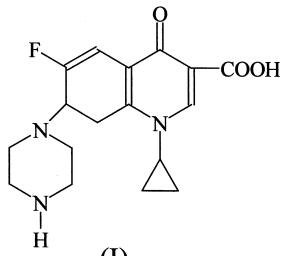
Abstract

Prototropic equilibria (protonation, hydrolytic and complexation) in iron(III) ion + ciprofloxacin (Hcipx) solutions were studied in 0.1 and 0.5 mol dm^{-3} (Na)NO_3 ionic media in the absence and in the presence of ionic surfactants: sodium dodecyl sulfate (SDS) or cetyltrimethylammonium bromide (CTAB). Experiments were carried out at 298 ± 0.2 K using glass electrode potentiometric and UV–Vis spectrophotometric measurements. The concentration of SDS in Fe^{III}–ciprofloxacin solutions was 10 mmol dm^{-3} while that of CTAB was 8 mmol dm^{-3}. The hydrolysis of the iron(III) ion was studied separately within the concentration range of iron 1–5 mmol dm^{-3} and pH 1.6–3.0. Non-linear least-squares treatment of the data indicates that in both ionic media studied the main hydrolytic products were $Fe(OH)_2^{+}$ and $Fe_2(OH)_2^{4+}$. The effect of the concentration of the nitrate ion on the stability constants of these complexes is much more pronounced than the effect of the addition of either SDS or CTAB. The successive protonation constants of ciprofloxacin anion, $cipx^{-}$, relating to the formation of Hcipx and H_2cipx^{+} species, were influenced to a significant extent by the presence of SDS and, to a considerably lesser extent, by the presence of CTAB in both studied concentrations of NO_3^{-} ionic media. The complexation between iron(III) and ciprofloxacin was studied in the concentration range of iron(III) 0.15–0.58 mmol dm^{-3}, with ligand to metal concentration ratios ranging from 3:1 to 10:1 in the pH interval 2.0–6.0. The experimental data obtained could be explained by the formation of mononuclear complexes: $Fe(cipx)_2^{+}$, $Fe(cipx)^{2+}$ and Fe(OH)cipx. In the presence of either SDS or CTAB the same complexes were formed; however, much higher formation constants were obtained with SDS, while the effect of CTAB was sluggish. The structure and mechanism of formation of iron(III)–ciprofloxacin complexes in pure ionic and in micellar media are discussed. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Ciprofloxacin; Iron(III); Solution equilibria; Surfactants



1. Introduction

Ciprofloxacin (1-cyclopropyl-6-fluoro-1,4-dihydro-4-oxo-7-(1-piperazinyl)quinolone-3-carboxylic acid), H(cipx), belongs to the class of fluorinated 4-quinolone antibiotics that find use in the treatment of urinary and respiratory infections. It exhibits strong activity against Gram-negative and some Gram-positive bacteria, although many anaerobic strains are resistant. The mechanism of its action is based on inhibition of bacterial DNA gyrase, thereby interfering with normal cell replication [1–3].

Clinical investigations have shown that concomitant intake of ciprofloxacin and iron-containing drugs (anti-anaemia or multivitamin preparations) results in reduced maximum serum concentration accompanied by the decrease in AUC (area under the concentration versus time curve), leading to decreased bioavailability of the drug, down to 30% [4–6]. The explanation for this interaction, bearing in mind the previous findings concerning some other quinolone–metal ions systems [7], is probably chelation between Fe^{3+} and the 3-carboxyl and 4-oxo functional groups of ciprofloxacin. From the formula of ciprofloxacin (I) it can be seen that it may exist in solution in diprotonated (H_2cipx^{+}), monoprotonated (Hcipx), zwitterionic ($Hcipx^{\pm}$) and anionic ($cipx^{-}$) forms. The vicinity of carbonyl and carboxyl groups makes the ciprofloxacin molecule a suitable ligand for binding hard base ions (Al^{3+}, Fe^{3+}, etc.). This property is important, not only in studying the pharmacological behaviour of ciprofloxacin in patients on parallel therapy with iron-containing drugs, but also for quantitative determination of ciprofloxacin in pharmaceutical formulations and in bio fluids (serum, saliva, urine, etc.).

(I)

Few literature data on solution equilibria between iron(III) ion and ciprofloxacin are available. Sultan and Suliman [8,9] reported the formation of $Fe(cipx)_2$ and Fe(cipx) complexes in sulfuric acid medium. The formation constant of Fe(cipx) complex was determined spectrophotometrically ($\log K = 7.76$). Lee et al. [10] characterized the formation of Fe(cipx) complex by Bjerrum ($\log K = 6.43$) and Scatchard methods ($\log K = 5.54$), while Turel et al. [11] reported the formation of $Fe(Hcipx)_3$ complex in 0.2 mol dm^{-3} KCl ionic medium ($\log \beta = 46.94$). Fratini and Schapoval [12] studied the formation of iron(III)–ciprofloxacin complexes in 1% HNO_3 medium and concluded that only Fe(cipx) complex is formed. Inspection of available literature data indicates that uncertainty exists concerning the species expected to be present in solution, particularly with regard to bis and tris complexes. There have been no reports of ternary Fe–OH–cipx or polynuclear complexes. The values of formation constants quoted for Fe(cipx) show large discrepancies, more than would be expected when account is taken of the effect of ionic medium on the formation constant concerned.

Various influences on iron(III)–ciprofloxacin solution equilibria (ionic strength, simultaneous presence of other complex-forming ligands, presence of surface-active substances) have not been studied. Of particular interest is the effect of surface-active substances on equilibria in iron(III)–ciprofloxacin solutions since in the body (gastrointestinal tract and gut, lungs, blood, etc.) various surfactants are normally present and can influence the complexation between iron(III) and ciprofloxacin. Thus, to mimic their function, in the present study, the detergents sodium dodecyl sulfate (SDS) and cetyltrimethylammonium bromide (CTAB) were used. Surfactants would have the effect of solubilizing both the quinolone and its chelate complex with iron, excluding water molecules from the complexation reaction sphere and preventing the binding of quinolone and iron(III) ion to serum proteins.

It is clear that complete equilibrium studies for the iron(III)–ciprofloxacin system are needed. Therefore, the primary aim of the present paper was to provide reliable data concerning speciation in iron(III) + ciprofloxacin + SDS (or CTAB) solutions, so that they could be used in modelling studies of the iron-based anti-anaemia drugs or multivitamin formulations, and ciprofloxacin interactions in vivo.

In the present paper, the equilibria between the iron(III) ion and ciprofloxacin in the absence and in the presence of SDS (or CTAB) were studied by potentiometry and spectrophotometry in a wide concentration range of iron to ciprofloxacin. The protonation equilibria of ciprofloxacin anion as well as the hydrolysis of iron were investigated in separate experiments.

2. Experimental

2.1. Reagents and analysis

The stock solution of iron(III) nitrate was prepared by dissolving doubly recrystallized $Fe(NO_3)_3 \cdot 6H_2O$ (p.a., Merck) in twice–distilled water. The appropriate amount of HNO_3 was added to avoid initial hydrolysis of Fe^{3+}. The iron content (0.4835 mol dm^{-3}) was determined gravimetrically by precipitation with ammonia. The concentration of the free acid (2.500 mol dm^{-3}) was determined potentiometrically using the Gran plot. The constancy of the total proton concentration with time was considered as a criterion for the absence of initial iron(III) hydrolysis and was periodically checked by titration against standard NaOH before each series of measurements.

Ciprofloxacin hydrochloride, pale yellow crystalline powder ($M_r = 385.8$) was from Bayer (Leverkusen, Germany). Standardization was performed by potentiometric titration against standard NaOH. Sodium dodecyl sulfate ($M_r = 288.4$) and cetyltrimethylammonium bromide ($M_r = 364.5$) were products of Merck (Germany). The concentrations of SDS (10.0 mmol dm^{-3}) and CTAB (8.0 mmol dm^{-3}) were higher than their critical micellar concentrations (8.2 and 0.7 mmol dm^{-3}, respectively). The sodium hydroxide solution was prepared from concentrated volumetric solutions (p.a., Merck) by diluting with freshly boiled doubly distilled water, cooled under constant flow of purified nitrogen. The alkali concentration was checked by titration against potassium hydrogen phthalate. The nitric acid solution was made from HNO_3 (Suprapure, Merck) and standardized against tris(hydroxymethyl)aminomethane. The solution of sodium nitrate was prepared from $NaNO_3$ (p.a., Merck) by dissolving the recrystallized salt in twice-deionized water. The concentration was determined by evaporation of a known volume of solution to dryness at 573 K and weighing the residue.

2.2. Equipment

Potentiometric measurements were carried out using an automatic titrator Titrilab Model 90 (Radiometer, Copenhagen) consisting of a TIM 900 titrator and ABU 901 autoburette. The titration vessel was fitted with a combined electrode (Radiometer GK 2401 B). The resolution of measurements was ± 0.1 mV or ± 0.001 pH units. A constant temperature was maintained with a VEB Prufgerate Model E3E circulating ultrathermostat. Spectrophotometric measurements were made with Beckman Model DU 60 UV–Vis double-beam spectrophotometer. Quartz cells (matching pair) with 1-cm

pathlength were used; the reference cell was filled with 0.1 or 0.5 mol dm^{-3} $NaNO_3$ solution in protonation measurements or, in complexation measurements, with a solution containing all components except iron. The pH of test solutions was measured with a glass/calomel combined electrode couple which was calibrated as hydrogen ion concentration probe according to the procedure described by Marsicano et al. [13]. Infrared (IR) spectra were taken on an IR spectrophotometer (Perkin-Elmer Model 983).

2.3. Procedure

All titrations were performed in a double-mantled, thermostated glass vessel closed with a Teflon cork. A constant temperature of 298.0 ± 0.2 K was maintained by circulating the thermostated water through the jacket. Purified and oxygen-free nitrogen gas was bubbled through the solution to provide an inert atmosphere and stirring. Additional stirring of the solution was achieved with a magnetic stirrer.

The electrochemical cell used for potentiometric measurements can be represented as RE/TS/GE, where TS is test solution and RE and GE denote reference and glass electrode, respectively. The general composition of the test solution in hydrolytic studies was M Fe^{3+}, H H^+, X SDS or CTAB, 0.1 or 0.5 mol dm^{-3} NO_3^-, where M, H and X denote total molar concentrations of corresponding species. The composition of the test solution in complexation studies was M Fe^{3+}, H H^+, X SDS, L cipx, 0.1 or 0.5 mol dm^{-3} NO_3^-, where L denotes total molar concentration of ciprofloxacin.

The potential of the glass electrode is given by the expression:

$$E = E_0 + Q \log h + E_j$$

where h is the concentration of free proton, E_0 is a constant which includes the standard potential of the glass electrode, Q is the slope of the glass electrode response and E_j is a liquid junction potential whose contribution to E was found to be negligible. E_0 was determined both before and during each titration of the test solution, according to a previously described procedure [13]. When the difference between two E_0 values was higher than 1.0 mV, the titration was rejected.

To reduce the concentration of the hydrogen ion, the alkali was added stepwise from an autoburette in small aliquots (0.005–0.01 ml). The potential was monitored after each addition of the titrant. The titration protocol was chosen in such a way that complexation reactions could proceed in the conditions as close to the true equilibrium as possible. To achieve this the potential readings were taken every 2 min until steady values to ± 0.1 mV min^{-1} were obtained. At some points titration was stopped and solution was left with no further addition of base for the next 2–3 h, with continuous monitoring of the potential. The titration was resumed only if the potential did not change more than ± 0.2 mV. No back-titrations were performed. Instead, agreement between duplicate titrations (better than 1%) served as criterion for the reversibility of the reaction.

2.4. Data treatment

Three kinds of equilibria should be considered in the present study: (a) protonation of ciprofloxacin anion (ciprofloxacinate), (b) hydrolysis of iron(III) ion and (c) general three-component equilibria:

$$p\mathrm{Fe}^{3+} + q\mathrm{H}^+ + r(\mathrm{cipx}^-) \rightleftharpoons [\mathrm{Fe}_p\mathrm{H}_q(\mathrm{cipx})_r]^{(3p+q-r)+}; \quad \beta_{p,q,r}$$

which includes the case $q = 0$, i.e. the formation of pure binary complexes of Fe^{3+}. Negative values of q denote hydroxo complexes. The equilibrium constant, $\beta_{p,q,r}$, represents the overall stability constant of the formed (p,q,r) complex. The overall protonation constants of ciprofloxacinate and stability constants of the hydrolytic complexes of iron(III) ion were determined in separate experiments. Thus, in evaluation of three-component equilibria (c), the binary models (a) and (b) were considered as known.

The mathematical analysis of the experimental data was performed with the aid of the general least-squares program Superquad [14]. In Superquad calculations the identity and stability of complexes that gave the best fit to the experimental data were determined by minimizing the error-squares sum of the potentials, U:

$$U = \sum w_i (E_{\mathrm{obs}} - E_{\mathrm{calc}})^2$$

where w_i represents a statistical weight assigned to each point of titration curve, E_{obs} and E_{calc} refer to the measured potential of the cell and the calculated one assuming the specific model and trial constants, respectively. The best model was chosen using the following criteria. (a) The lowest value of U. (b) Standard deviation in calculated stability constants less than 0.15 log units. (c) Standard deviations in potential residuals, defined as:

$$s = \frac{ewe^T}{N-k}$$

where e is a vector in potential residuals $(E_{\mathrm{obs}} - E_{\mathrm{calc}})$, w is a weighting matrix, N is the number of observations and k is the number of refinable parameters, with standard deviation in volume readings 0.0005 cm^3 and standard deviation in potential readings 0.1 mV, should be less than 3.0. (d) Goodness-of-fit statistics, χ^2 (Pearson's test) at 95% confidence level, with 6 degrees of freedom, less than 12.6. (e) Reasonably random scatter of potential residuals without any significant systematic trends. Along with Superquad the program Best [15] was also used in calculations.

The spectrophotometric data were evaluated with the aid of the program Squad [16]. In Squad calculations, the composition, stability and molar absorptivities, $\varepsilon_{p,q,r}$, of the complexes were determined by minimizing the sum, S, defined as:

$$S = \sum (A_{\mathrm{obs}} - A_{\mathrm{calc}})^2$$

where A_{obs} and A_{calc} refer to measured absorbance and that calculated according to the following equation:

$$A_{\mathrm{calc}} = \sum \beta_{p,q,r} [\mathrm{Fe}]^p [\mathrm{H}]^q [\mathrm{cipx}]^r \varepsilon_{p,q,r}$$

For Squad calculations the spectra were digitized at 3-nm intervals. Acceptance criteria for each particular model were: (a) S lower than 1.0×10^{-2}; (b) standard deviation of the fit of the spectrum (SD) less than 1.0×10^{-2}; (c) standard deviation in calculated stability constants less than 0.08 log units. All the calculations were performed on an IBM PC Pentium II 450 compatible computer.

2.5. Preparation of the complex

The iron(III)–ciprofloxacin complex was synthesized by mixing equimolar quantities (5 mmol) of sodium salt of ciprofloxacin acid and iron(III)–nitrate, which was dissolved in 10 ml of 0.1 mol dm^{-3} HNO_3. The total volume was brought up to 25 ml with doubly-distilled water. The pH of solution was then adjusted to 2.6 by the addition of an appropriate amount of solid $NaHCO_3$. The original volume was reduced to one-half by slow evaporation and was afterwards stored in a desiccator containing methanol. The complex, which crystallized after 3 days, was washed with water and methanol and dried in vacuo. Elemental analysis gave 12.14% for Fe (calc. for $Fe(cipx)(NO_3)_2\cdot2.5H_2O$, 12.5%). The nitrate content, found spectrophotometrically using diphenylamine, was 27.5% (calc. for $Fe(cipx)(NO_3)_2\cdot2.5H_2O$, 27.7%).

3. Results and discussion

In order to study speciation in the three-component system Fe^{3+}–H^+ (or OH^-)–ciprofloxacin, it is necessary first to characterize the binary equilibria, i.e. hydrolysis of iron(III) ion and protonation of ciprofloxacin anion, under exactly the same experimental conditions as for the complexation study.

3.1. Hydrolysis of iron(III) ion

Although the hydrolysis of iron has been the subject of extensive studies for almost a century, controversy still exists regarding the identity and stability of the species formed in solution. Various factors, such as the method of preparation of the solution, the degree of hydrolysis (defined as the molar ratio $m=[OH]/[Fe]$), pH range, temperature, concentration of reactants, nature and concentration of supporting ionic medium, type and rate of base addition, ageing time, have a great influence on the composition and stability of the hydrolytic complexes formed in solution of Fe^{3+}. This subject has been reviewed by, among others, Sylva [17], Baes and Mesmer [18], Flynn [19] and Blesa and Matijevic [20]. The consensus is that, at lower values of m (≤1) and low concentrations of iron (<5 mmol dm^{-3}) in the pH range 1.0–3.0, the main hydrolytic products of iron are $Fe(OH)^{2+}$, $Fe(OH)_2{}^+$ and $Fe_2(OH)_2{}^{4+}$. At very low iron concentrations (μM), Martin [21] assumed the formation of mononuclear hydrolytic complexes only, $Fe(OH)_n$ ($n=1$–3). At higher iron concentrations and $m<2$, the red cationic polymer with an OH^-:Fe ratio of 2.25–2.9 is probably the principal constituent of highly hydrolysed iron(III) solutions [19].

The data on iron hydrolysis in nitrate medium are controversial. Some authors [20,22,23] did not find the formation of any soluble hydrolytic complexes, whereas others [24–27] characterized some soluble species together with hydrolytic polymers of unknown composition. In view of these conflicting results it has been necessary to determine the composition and stability of the main iron hydrolytic species, under the same experimental conditions as for the iron–ciprofloxacin complexation study.

The experimental data obtained in the 0.1 and 0.5 mol dm^{-3} $NaNO_3$ medium at 298 K are summarized in Table 1. In the ionic media used the iron(III) hydrolyses between pH 1.6 and ca. 3.0, depending on its concentration. The maximum value of average hydroxide number, Z_{Fe}, defined as $Z_{Fe}=(h-H)/M$, before precipitation occurred was ca. 0.45. The data show that, for each concentration of the iron studied, a separate formation curve, $Z_{Fe}=Z(-\log h)$ was obtained. This indicates the formation of polynuclear hydrolytic complexes. The pH region in which hydrolysis occurs depends on the total concentration of iron. Thus, as the concentration of the iron(III) ion increases, the beginning of hydrolysis shifts towards lower pH values, while at the same time the degree of hydrolysis decreases. Possible complexation of iron(III) ion with nitrate ion from the ionic medium should appear as a constant effect because of relatively high concentration of the medium; therefore, it should not affect the number of hydroxide ions bound to iron. Although the titrations were performed in a wide pH range, for the purpose of calculations some reduction of the number of titration points was necessary. Points at low pH values, where hydrolysis is negligible, and at pH values higher than ~2.7, where solutions become turbid and colloid formation may take place, were excluded from calculations.

Reacting with water molecules, the iron(III) ion forms one or more hydrolytic complexes of the general composition $Fe_p(OH)_q{}^{(3p-q)+}$, further abbreviated as (p,q), whose overall formation constants, $\beta_{p,q}$, can be defined as:

$$\beta_{p,q}=C_{p,q}m^{-p}h^q$$

where $C_{p,q}$ denotes the equilibrium concentration of the (p,q) complex and m is the free concentration of Fe^{3+}. In the above reaction, the nitrate ions and water molecules were omitted from the coordination sphere.

First, each titration curve was processed separately using the program Best. On the basis of hydrolytic curves, $Z_{Fe}=Z(-\log h)$, the pH interval chosen was 1.6–2.7. Complexes from the initial set comprising (1, −1), (1, −2), (1, −3), (1, −4), (2, −1), (2, −2), (2, −3), (2, −4), (2, −6), (3, −3,), (3, −4), (3,−6), (6, −12), (6, −15), (6, −18), (8, −12) and (13, −32) were introduced one at a time until the minimum value of σ_{fit} [15] was obtained.

[a] M, H, SDS and CTAB denote analytical concentrations of iron(III), hydrogen ion, sodium dodecyl sulfate and cetyltrimethylammonium bromide in mmol dm^{-3}, respectively. Z_{max} is the maximal value of average hydroxide number of iron.

During the calculations all the titration parameters (M_0, H_0) were kept constant while pH values in repeated cycles of calculations were adjusted until the best possible value of σ_{fit} was obtained. The accepted set of complexes was $(1, -2)$, $(2, -2)$ and $(2, -4)$. Then all the titration curves were processed together, this time using the program Superquad. In Superquad calculations the E_0 values were allowed to float while all analytical parameters were held constant. All the complexes found in Best calculations were accepted with small differences in stability constants. Stepwise introduction of other complexes (higher polymers) from the initial set lead either in their rejection or in a much worse set of statistical parameters determining goodness of fit. No higher polymers were accepted, neither was the tridecamer. However, since residuals showed a systematic trend at the beginning and at the end of the pH interval chosen, the number of points used in the calculation was reduced, so that only the points from pH 1.7 to 2.6 ($Z_{max} \leq 0.25$) were included in the calculations. Repeated calculations ended with the rejection of the $(2, -4)$ complex. At the same time, the stability constant of the dimer $(2, -2)$ was lower, with a much better standard deviation. Other complexes remained practically unchanged. Generally, the fit was improved in terms of better scatter of residuals and lower value of *s*. The next iteration was forced with manual introduction of the binary monomer, $Fe(OH)^{2+}$. It was, however, rejected from all the models tested and consequently it was excluded from the final speciation scheme. The final results of the calculations are given in Table 2. It is seen that our results are in good agreement with available literature data. In contrast to other authors, we

[a] Protonation constants are defined as $\beta_n = [H_n cipx]/[H^+]^n[cipx]$ $(n = 1, 2)$; stability constants of hydrolytic complexes are given as $\beta_{p,q} = [Fe_p(OH)_q][H^+]^q/[Fe]^p$. Logarithms of constants are given together with standard deviations in parentheses. S, 0.1 mol dm^{-3} $NaNO_3$; S′, 0.5 mol dm^{-3} $NaNO_3$.

failed to identify the monohydroxo complex $Fe(OH)^{2+}$, probably because of its rapid further hydrolysis and polymerization.

The set of statistics obtained ($\chi^2 \leq 13.5$, $s \leq 2.3$), as well as scatter of residuals, indicates a good fit of the data. The distribution of the species over the pH range 1.0–3.0 using the program Species [28] indicates that the dimer $Fe_2(OH)_2^{4+}$ dominates over the pH range 1.7–3.0. The diol, $Fe(OH)_2^{+}$ begins to form at pH 2.0 and its concentration rapidly rises upon increasing the pH. Beyond pH 2.8, probably, the concentration of higher hydrolytic polymers sharply increases; they are the precursors of the polymer(s), which eventually precipitate(s) from the solution. Formation of either soluble or amorphous $Fe(OH)_3$ was not detected under our experimental conditions.

In addition to potentiometric measurements, the spectrophotometric measurements were also made to improve the reliability of the hydrolysis model. Spectral measurements were made on solutions in which the concentration of the iron was constant (9.67 mmol dm^{-3}) while the pH was varied between 1.357 and 2.297 (ten solutions). The spectra were taken in the 350–550 nm wavelength interval. The pH of solutions was adjusted by the addition of HNO_3 or NaOH (as appropriate). All test solutions were left to stand for 1 month before measurements were made. The pH of solutions was recorded daily. The stable readings (within ± 0.01 pH unit) were obtained after 1 week and remained stable during the next 2–3 days. Final spectra were recorded after 2 weeks. Part of the spectra obtained is shown in Fig. 1.

The spectral data were evaluated with the aid of the Squad program. In calculations the extinction coefficient of aqua iron(III) ion was set to zero in the chosen wavelength interval. The results of the calculation are given in Table 2. The calculated statistical parameters ($S = 1.5 \times 10^{-2}$, SD = 5×10^{-3}) indicate fairly good fit of the data. The results obtained are in agreement with the potentiometric ones, thus confirming the existence of (1, −2) and (2, −2) hydrolytic complexes with a high level of certainty.

Inspection of both potentiometric and spectrophotometric data reveals a pronounced effect of the concentration of the ionic medium on the stability constants of the iron(III) hydrolytic complexes ($\Delta\log\beta_{1,-1} = -0.24$ and $\Delta\log\beta_{2,-2} = -0.38$). The effect is considerably larger on the (2, −2) complex due to its higher charge. This is in agreement with the general Debye–Hückel–Onsager theory of the influence of the ionic medium on stability constants. In the case of hydrolytic complexes of iron, the additional influence arises from the lowered activity of water in more concentrated medium (0.5 mol dm^{-3} NO_3^-).

3.1.1. The effect of SDS or CTAB on the hydrolysis of iron(III) aqua ion

The experimental data obtained under the same medium and temperature conditions in the presence of SDS or CTAB are summarized in Table 1.

Under the experimental conditions chosen the iron ion hydrolyses between pH 1.5 and 2.9, depending on its concentration. The maximum value reached for the average hydroxide number, Z_{Fe}, was ca. 0.5. The data show that, for each concentration of iron studied, separate titration curves, $Z_{Fe} = Z(-\log h)$ were obtained. This indicates the formation of polynuclear complexes. It can be seen that in the presence of the surfactant the extent of hydrolysis is lowered while, at the same time, the beginning of hydrolysis is slightly shifted toward lower pH values for approximately 0.1 pH units.

The calculations indicate that the hydrolytic curves can be fitted with the same set of complexes as in the case of absence of surfactants. In Best calculations the obtained values of σ_{fit} were in the range 0.0015–0.002, thus indicating good fit of the data. Final values of the stability constants were obtained

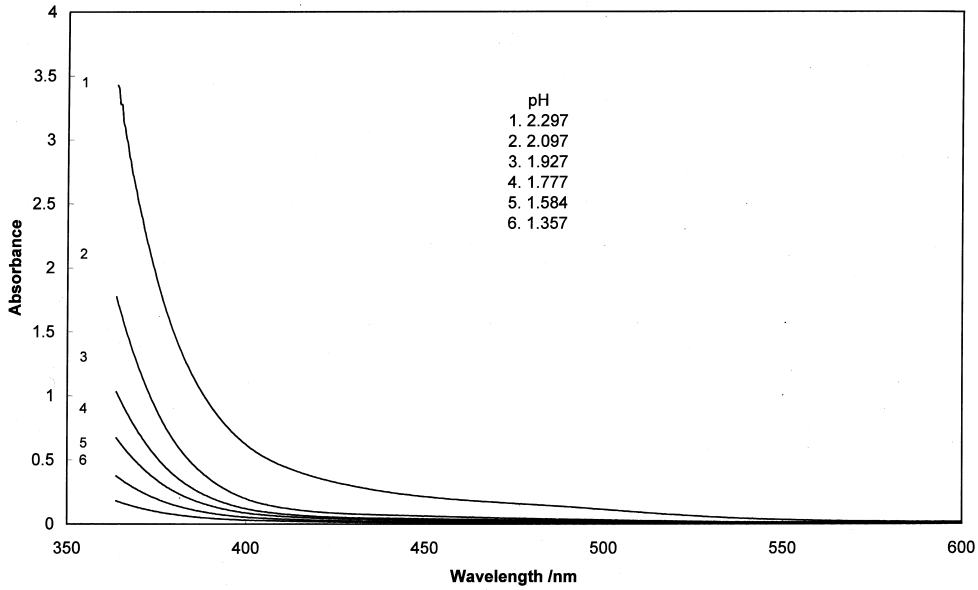

Fig. 1. Spectra of hydrolysed solutions of iron(III) ion. $C_{Fe} = 9.67$ mmol dm^{-3}.

with Superquad. The results of calculations are given in Table 2. The calculated statistical parameters of the fit satisfy all the acceptance criteria, thus confirming the existence of (1, −2) and (2, −2) hydrolytic complexes, in the presence of surfactants, with high probability. Generally, the effect of surfactants on the stability constants of iron(III) hydrolytic complexes in both concentration of the ionic medium is negligible. Probably it is due to very strong hydrolytic tendency of iron(III) ion and its high affinity towards oxygen donor from water. Thus, the change of local concentration of water caused by surfactants is insufficient to affect the hydrolysis.

3.2. Protonation of ciprofloxacin anion

Protonation constants, β_n, of ciprofloxacin anion, defined according to equilibrium:

$$n\mathrm{H}^+ + \mathrm{cipx}^- \rightleftharpoons \mathrm{H}_n\mathrm{cipx} \quad (n=1, 2)$$

were determined by glass electrode potentiometric titrations in 0.1 and 0.5 mol dm^{-3} $NaNO_3$ medium at 298 K. Three titrations were carried out with 0.5, 0.9 and 2.0 mmol dm^{-3} total ciprofloxacin concentrations, in the pH range 4.0–10.2. The experimental data were treated using the Superquad program. In total, 290 points were included in calculations. Spectrophotometric measurements were made on solutions in which the concentration of ciprofloxacin was the same (0.05 mmol dm^{-3}) while the pH values were varied between 4.0 and 9.4 (22 solutions were used). The spectra were taken in the 220–450 nm wavelength interval. Part of the obtained spectra is shown in Fig. 2. The spectra (Fig. 2a) show a high-intensity peak located at 270 nm and a broad lower energy band with two poorly resolved peaks at 320 and 340 nm. Isosbestic points exist at 345 nm and (very poorly defined) at 312 nm. For the purpose of Squad calculations the obtained spectra were digitized at every 3 nm. The calculated values of protonation constants are given in Table 2. Agreement between potentiometrically and spectrophotometrically obtained values was better than 1%.

3.2.1. Protonation of the ciprofloxacinate ion in the presence of surfactants

Protonation constants, β_n, of ciprofloxacin anion, in the presence of SDS or CTAB were determined under the same experimental conditions as in their absence. The concentration of surfactants used was 10.0 mmol dm^{-3} of SDS and 8.0 mmol dm^{-3} of CTAB, while the concentration range of ciprofloxacin was 0.5–2.0 mmol dm^{-3}. The experimental data were treated with the aid of Magec and Superquad programs. In total 180 points were included in the calculations. The results are given in Table 2. As can be seen from Table 2, protonation constants of the ciprofloxacin anion are considerably higher in the presence of SDS than in the pure ionic medium. The second protonation constant was particularly affected. It seems that the addition of SDS suppresses the dissociation of ciprofloxacin (3-carboxyl group). An explanation can be given on the basis of structural characteristics

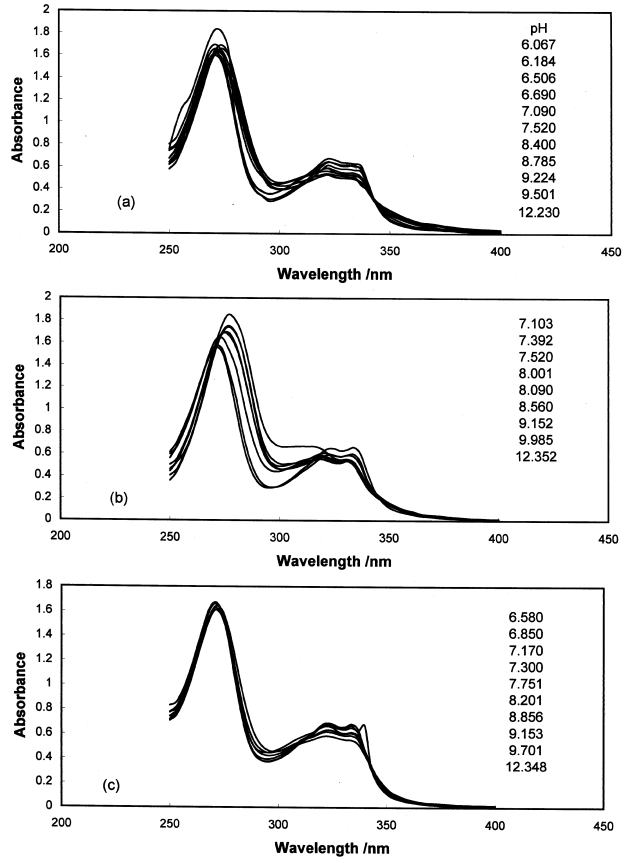

Fig. 2. Spectra of 0.05 mmol dm^{-3} solutions of ciprofloxacin. (a) No addition of surfactants, (b) +10.0 mmol dm^{-3} SDS, (c) +8.0 mmol dm^{-3} CTAB. The pH values run from top to bottom, relating to the peak at 270 nm.

of ciprofloxacin. It contains two highly polar groups (4-carbonyl and 3-carboxyl). In addition, the positively charged tertiary piperazinyl nitrogen in the ciprofloxacin cation constitutes another polar site in the molecule. These groups cause an electrostatic attraction with the SDS molecule, thus expelling water molecules around the cation and hence impeding proton transfer from cation to bulk water. Splitting off the first proton (from the 3-carboxyl group) is hindered because the hydrogen bond between the carboxyl proton and the 4-carbonyl oxygen is stabilized in the presence of SDS. On the other hand, the ciprofloxacin cation, H_2cipx^+, is additionally stabilized by electrostatic interactions with the negatively charged OSO_3^- group from SDS. CTAB exhibits a much lower effect on protonation constants due to its inefficient surrounding of the carboxylate group.

The spectrophotometric measurements in the presence of 10 mmol dm^{-3} SDS or 8 mmol dm^{-3} CTAB were made under the same experimental conditions as in their absence. Part of the spectra is shown in Fig. 2. It can be seen from Fig. 2b that the maximum of the higher energy band is shifted by approximately 10 nm towards the red, while the lower-energy band shows a blue shift with two peaks located at 315 and 320 nm, in comparison with the spectra obtained in the absence of SDS. CTAB (Fig. 2c) causes only a small red

shift of the lower-energy band. Since both low- and higher-energy bands arise from $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions in the quinolone nucleus, the observed shifts could be explained by taking into account the change of solvation of the ciprofloxacin molecule in the presence of SDS, due to its solvatophobic effect. Both electronic transitions are very sensitive to variation of solvation and this explains the change in their energies in the absence and in the presence of SDS. The evaluation of the spectral data was done with the aid of the Squad program. The results are given in Table 2. They are in satisfactory agreement with the potentiometric results.

3.3. The iron(III)–ciprofloxacin system

3.3.1. Potentiometric measurements

The experimental data obtained by e.m.f. measurements in 0.1 and 0.5 mol dm^{-3} $NaNO_3$ medium at 298 K are summarized in Table 3. In the pH range studied (2.0–6.0) the maximum apparent ligand number reached Z_c, which is defined as:

$$Z_c = \frac{C_{cipx} - \frac{[cipx^-] - [H^+] + [OH^-]}{Z_H}}{C_{Fe}}$$

where C_X denotes analytical concentration of the corresponding species, and Z_H is the proton number of ciprofloxacin. The highest concentration ratio of ciprofloxacin to Fe^{III} was 10:1. Beyond pH $\sim$5.8, solutions became turbid and drifting potential readings were obtained. No higher concentration ratios of ciprofloxacin to Fe^{III} were used because they would seriously change the constancy of the medium and, in addition, the buffering effect of ciprofloxacin would hinder the reliable potentiometric measurements.

Analysis of the formation curves, plotted as the dependence of average ligand number, Z_c, on $-\log[cipx]$, indicates the formation of mononuclear complexes only. From the maximal Z_c (ca. 1.8) values attained it can be seen that either the complex $Fe(cipx)_2$ or some mixed complexes may be important.

The equilibria in the cipx + Fe^{3+} system can be represented in a general form:

$$p(Fe^{3+}) + q(H^+) + r(cipx^-) \rightleftharpoons Fe_pH_q(cipx)_r$$

The stability constants of various (p,q,r) species formed in the above reaction can be defined as:

$$\beta_{p,q,r} = C_{p,q,r} m^{-p} h^{-q} a^{-r}$$

where $C_{p,q,r}$ denotes the equilibrium concentration of the complex, and m, h and a denote free concentrations of iron(III), proton and ciprofloxacin, respectively. Negative values of q represent hydroxo complexes. To determine the composition and stability constants of the species formed, the titration data were analysed using the programs Best and Superquad. The following complexes were selected to find the model which best fit the experimental data: (1, 0, 1), (1, 0, 2), (1, 1, 1), (1, 2, 1), (1, 1, 2), (1, −1, 1), (1, −2, 1), (1, −3, 1), (1, −1, 2), (1, −2, 2) and (1, −2, 3). More than 20 models were tested. During the calculations analytical parameters (M_0, H_0 and L_0) were held constant while E_0 values were allowed to float. The hydrolytic complexes and

[a] M, H, L, SDS and CTAB denote analytical concentrations of iron(III), hydrogen ion, ciprofloxacin, sodium dodecyl sulfate and cetyltrimethylammonium bromide in mmol dm^{-3}, respectively. Z_{max} is maximal value of average ligand number.

protonated species of ciprofloxacinate were not refined during the calculations. First, each titration curve was treated separately using the program Best. Complexes were added in the model one at a time until the lowest value of σ_{fit} was achieved (usually less than 0.003). These complexes were then used as the starting model for the Superquad calculations. The following complexes were included: (1, 0, 1), (1, 0, 2), (1, −1, 1). Then the data belonging to all titration curves, referred to one particular ciprofloxacin to iron concentration ratio, were treated together. The refined values of E_0 served as the additional criterion for model selection. If they differed from experimental values by more than 0.5 mV, the model was considered as inadequate. The results of calculations indicate that the main species in iron–ciprofloxacin solutions are the binary complexes $Fe(cipx)_2$ and Fe(cipx) as well as the mixed hydroxy complex Fe(OH)cipx. Calculated values of the stability constants are presented in Table 4. From the data presented in Tables 2 and 4 one may calculate the formation constant, K, of the Fe(cipx) complex taking Hcipx as the component instead of cipx. The obtained value, $\log K = \log \beta_{1,0,1} - \log \beta_{0,1,1} = 15.91 - 9.07 = 6.84$ is in a reasonably good agreement with literature data [9,10].

The distribution of various complexes in solution is shown in Fig. 3. As seen from the distribution diagram, the complex Fe(cipx) reaches its maximum concentration at pH ~2.5. Beyond this value it begin to hydrolyse, forming the mixed hydroxy complex Fe(OH)cipx. The concentration of the mixed complex increases upon further increasing the pH and reaches the maximum at pH ~4.3. Bis complex $Fe(cipx)_2$ starts to form at pH ~3.0 with a steep rise in concentration with increasing pH. The main complex between pH 2.0 and 3.0 is Fe(cipx) and, therefore, the colorimetric determination of ciprofloxacin using Fe^{III} as colouring agent should be carried out in this pH interval.

Table 4
Results of non-linear least-squares analysis of the data on complexation equilibria in iron(III)–ciprofloxacin solutions [a]

Species	S	S + SDS	S + CTAB	S′	S′ + SDS
Potentiometry

[a] Stability constants of complexes are defined as $\beta_{p,q,r} = [Fe_pH_q(cipx)_r]/[Fe]^p[H^+]^q[cipx]^r$. Logarithms of stability constants are given together with standard deviations in parentheses. S, 0.1 mol dm^{-3} $NaNO_3$; S′, 0.5 mol dm^{-3} $NaNO_3$; SDS, 10 mmol dm^{-3} sodium dodecyl sulfate; CTAB, 8.0 mmol dm^{-3} cetyltrimethylammonium bromide.

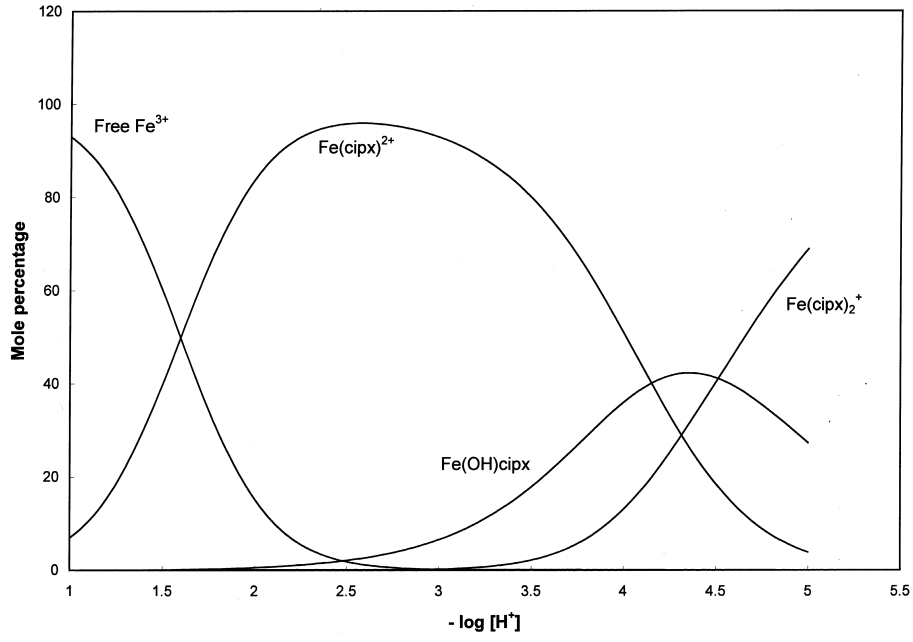

Fig. 3. The distribution of the complexes formed in iron(III) + ciprofloxacin solutions in 0.1 mol dm^{-3} $NaNO_3$ medium, at 298 K. $C_{Fe} = 1.0$ mmol dm^{-3}, $C_{cipx} = 3.0$ mmol dm^{-3}.

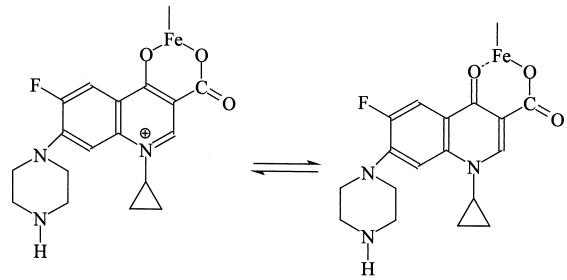
Bearing in mind the pH range in which the complex Fe(cipx) is formed, one may suppose that its formation proceeds according to reaction:

$$Fe(OH)_2^+ + H_2cipx^+ \rightleftharpoons Fe(cipx)^{2+} + 2H_2O$$

The isoelectric point of ciprofloxacin is at pH between 7.73 and 8.10 (depending on the ionic strength) so that, at pH values lower than 5.0, most ciprofloxacin exists in the cationic form. The reactive species of iron at pH 2.0–3.0 is the dihydroxo complex $Fe(OH)_2^{2+}$, so the above reaction would be more probable than that in which aqua-iron ion reacts with neutral ciprofloxacin:



$$Fe^{3+} + Hcipx \rightleftharpoons Fe(cipx)^{2+} + H^+$$

The second molecule of ciprofloxacin may be directly bound to Fe(cipx), or it may react with the mixed hydrolytic complex to produce the bis complex:

$$Fe(OH)cipx + Hcipx \rightleftharpoons Fe(cipx)_2 + H_2O$$

It seems, judging by Fig. 3, that both reactions may take place simultaneously.

In the Fe(cipx) complex, 3-carboxyl and 4-carbonyl groups are involved in coordination owing to high affinity of iron toward oxygen. The IR spectrum of ciprofloxacin at 3600–3000 cm^{-1} shows two bands, one sharp at 3250 cm^{-1} belonging to OH group and a second at 3380 cm^{-1} characteristic of N–H vibration. In the 1800–1600 cm^{-1} wavenumber region, three bands are dominant: at 1710 cm^{-1} belonging to carboxyl group, 1625 cm^{-1} belonging to ketone carbonyl (involved in hydrogen bonding) and at 1610 cm^{-1} belonging to double-bond vibration. In the 3600–3000 cm^{-1} region the complex shows only one broad band, which covers the region and is indicative of the presence of a strong hydrogen bond. In the carbonyl region two bands are seen. The third band, at 1625 cm^{-1}, disappears, indicating that keto oxygen is involved in coordination. Thus, the binding sites for iron, in the ciprofloxacin molecule, involve keto and carbonyl oxygens. Two structural isomers are possible and we believe that an equilibrium between two forms exists. The equilibrium is, however, shifted to the right because of higher resonance stability of the structure in which the double carbonyl bond is not broken (see Scheme 1).

Scheme 1.

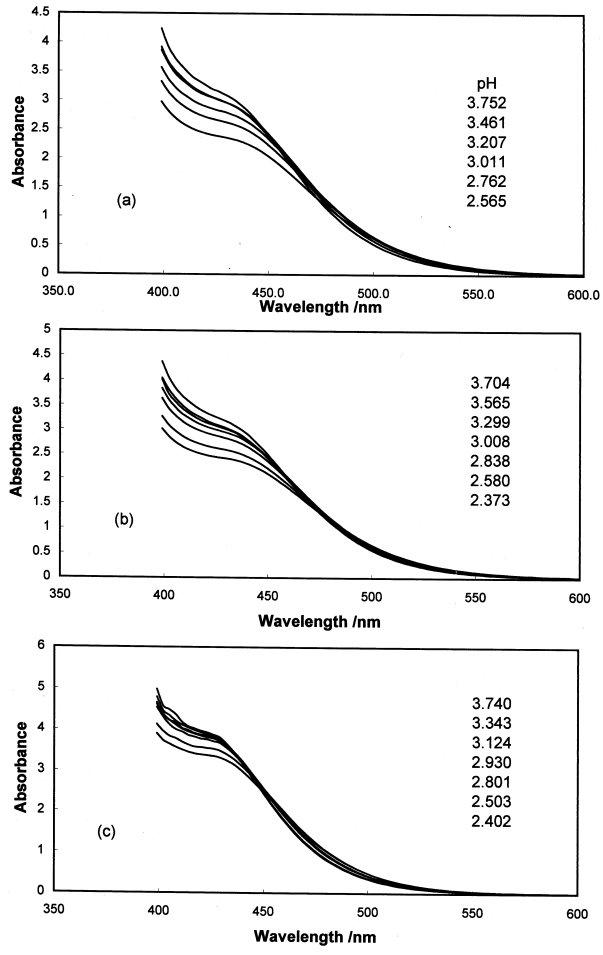


Fig. 4. Spectra of iron(III) + ciprofloxacin solutions. $C_{Fe} = 5.8 \times 10^{-4}$ mol dm^{-3}, $C_{cipx} = 1.5 \times 10^{-3}$ mol dm^{-3}. (a) No addition of surfactants, (b) + 8.0 mmol dm^{-3} CTAB, (c) + 10.0 mmol dm^{-3} SDS. The pH values run from top to bottom.

3.3.2. Spectrophotometric measurements

Spectral measurements were made on solutions in which the concentration of iron and ciprofloxacin were constant ($C_{Fe} = 5.80 \times 10^{-4}$ mol dm^{-3}, $C_{cipx} = 1.5 \times 10^{-3}$ mol dm^{-3}) while pH was varied between 2.0 and 4.0 (16 solutions). The pH of each test solution was checked daily, during 1 week. The stable values, within 0.01 pH and 0.004 absorbance units, were attained after 1 h and remained stable during a couple of days. Solutions with pH values higher than 4.5 required a longer time for equilibration, approximately 1 day. Spectra of the test solutions were recorded in the 350–600 nm wavelength interval. The experimentally obtained spectra are shown in Fig. 4. The spectra were not corrected for ciprofloxacin absorption. The spectra exhibit a high-intensity band between 360 and 390 nm. The plateau exists between 400 and 440 nm. The spectra are pH-dependent, so, upon increasing the pH, the absorbancy of the high-energy band and plateau increases.

The spectral data were evaluated with the aid of the Squad program. In calculations, the extinction coefficients of ciprofloxacinate ion, H(cipx) and H_2(cipx) were known from spectral measurements of ciprofloxacinate protonation and were fixed, while those of iron(III)–aqua ion were set to zero. To make the potentiometric and spectrophotometric measurements self-consistent, the calculations were carried

out in the following way. First, all the complexes found in appropriate potentiometric titrations were included in Squad calculations and their stability constants were fixed while the extinction coefficients were allowed to float. The Squad multiple regression option was used for these calculations. If negative values for extinction coefficients were obtained, the stability constants of the complexes were varied too, one at a time. Second, the complexes were added or excluded from the initial model also, one at a time. When the best possible fit was achieved (lowest *S* and SD values) the non-negative non-linear least-squares option of Squad was used in a final calculation cycle. With the obtained set of complexes and their stability constants, Superquad calculations of potentiometric titrations were repeated and statistical parameters of the fit re-determined. This cycling was repeated until the best possible agreement between potentiometric and spectrophotometric models was achieved. Results of the calculation are shown in Table 4. These results are in good agreement with potentiometric ones (Table 4).

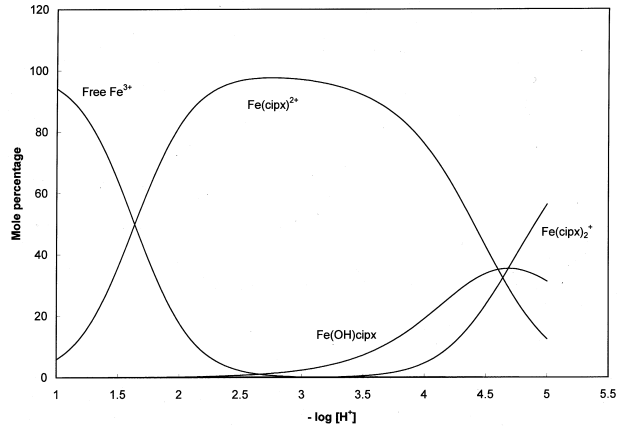
3.3.3. The effect of surfactants on the complexation equilibria in the iron(III)–ciprofloxacin system

The experimental data obtained by e.m.f. measurements in 0.1 and 0.5 mol dm^{-3} $NaNO_3$ medium at 298 K are summarized in Table 3. In the pH range studied (3.0–5.0), the maximum apparent ligand number reached was ca. 1.7. The highest concentration ratio of ciprofloxacin to Fe^{III} was 5:1. Beyond pH 5.0, solutions became turbid and drifting potential readings were obtained. In the Fe^{III} + cipx system, with the addition of SDS, formation curves are shifted towards much higher pH values in comparison with those in the absence of SDS. This indicates higher stability of the complexes formed. The results of the mathematical analysis of titration data are presented in Table 4. It can be seen that the stability of all formed complexes is significantly increased in the presence of SDS while the effect of CTAB is very moderate. The distribution diagram (Fig. 5) of the complexes indicates that the pH interval in which the complex Fe(cipx) dominates is wider while at the same time its concentration is higher relative to the hydroxy complex Fe(OH)cipx. This is an obvious advantage for the determination of ciprofloxacin.

Higher stability of the Fe(cipx) complex in the presence of SDS may be explained on the basis of its structural characteristics.

As seen from the diagram (Scheme 2), one may suppose that the SDS chain is turned with its polar head towards the positively charged iron core. In this way, the planar structure of six-membered ring involving iron is enhanced. Hydrogen bond between oxygen from sulfonyl group of SDS and hydrogens from coordinated water makes the FeO_3 core stable and the long hydrocarbon chain surrounding this core hinders hydration of iron, thus preventing its hydrolysis.

Spectral measurements were made in the presence of SDS in the same way as in its absence. However, the pH region was restricted in such a way that formation of the Fe(cipx) complex would be dominant. The obtained spectra are shown in Fig. 4. It can be observed that, in the presence of SDS, the plateau is shorter and slightly shifted toward the blue. Results of Squad calculations of the spectra are presented in Table 4. The calculated stability constants are in satisfactorily good agreement with potentiometric data.



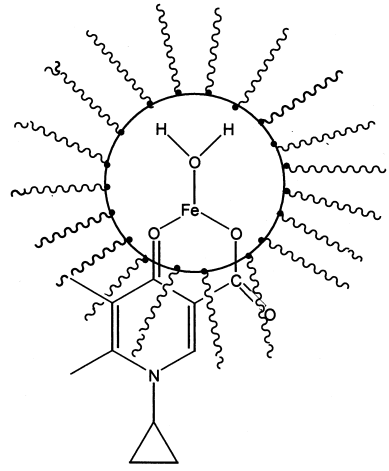


Fig. 5. The distribution of the complexes formed in iron(III) + ciprofloxacin + 10.0 mmol dm^{-3} SDS. $C_{Fe} = 1.0$ mmol dm^{-3}, $C_{cipx} = 3.0$ mmol dm^{-3}.

Scheme 2.

Consideration of the results obtained in the present work leads to the conclusion that the optimal conditions for consecutive simple complex formation in the iron(III) + ciprofloxacin system comprise relatively wide concentration ratios of ciprofloxacin to iron, ranging from 1:1 to 10:1 in the pH interval 2.0–5.0. Under these conditions, the maximum ligand number attained is 2 and, since ciprofloxacin acts as bidentate ligand, two other coordination sites are filled with water molecules.

γ-Halogenated iridium(III) acetylacetonates

V.G. Isakova, I.A. Baidina, N.B. Morozova *, I.K. Igumenov

Institute of Inorganic Chemistry, Novosibirsk, Russia

Received 20 October 1999; accepted 3 February 2000

Abstract

γ-Halogenated iridium(III) acetylacetonates of the general formula $Ir(acacX)_n(acac)_{3-n}$ (where acacX is CH_3–CO–CX–CO–CH_3, acac is CH_3–CO–CH–CO–CH_3, $n = 1,2,3$, X = F, Cl, Br, I) have been synthesized, purified and characterized. Spectroscopic and thermogravimetric studies have been carried out, as well as study of the relative volatility and thermal stability of the complexes. For a series of compounds, X-ray diffraction studies have been conducted and crystallographic characteristics have been obtained. The structures of $Ir(acac)_3$, $Ir(acacCl)_3$, $Ir(acacBr)_3$, and $Ir(acacI)_3$ complexes have been determined. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Iridium; Acetylacetonates; Halogenation

1. Introduction

One of the main questions considered in works dealing with volatile β-diketonate complexes of platinum metals is the dependence of the properties of these compounds on the structure of the chelating ligand [1,2]. The volatile β-diketonates of trivalent metals forming a sequence by consequent substitution of methyl groups in the initial acetylacetonate ligand by $–CF_3$ and $–C(CH_3)_3$ groups have now been studied in detail. The synthesis of γ-halogenated acetylacetonates of inert metals has also been described. The synthesis is based on their characteristic reaction, i.e. electrophilic substitution of methine hydrogen atoms in the acetylacetonate ring, and does not require much effort. Compounds of this type with a wide range of γ-substituents (X = Cl, Br, I, NO_2, SCN, etc.) and different numbers of substituted ligands have been obtained by Collman and coworkers and others for Co(III), Cr(III), Rh(III), and Fe(III) [3–9]. In the sequence of iridium trichelates, the complexes containing substituents in the α-position are the best studied [10–14]. Compounds of iridium containing substituents in the γ-position of the acetylacetonate ligand (like $Ir(CH_3–CO–CX–CO–CH_3)_3$ where X is a substituent) are not well known. The absence of any interest in γ-substituted iridium(III) acetylacetonates is likely to be connected with the generally accepted opinion concerning the poor volatility of these chelates. According to the limited known data, any substitution of γ-hydrogen atoms in metal acetylacetonates causes a decrease in thermal stability [16]. However, one can assume that the thermal stability of iridium γ-substituted acetylacetonates could be relatively high, similar to the higher thermal stability of the initial $Ir(acac)_3$ in comparison with the corresponding complexes of other metals [10,11,13]. In addition, the volatility of $Ir(acac)_3$ is higher than that of $Rh(acac)_3$. This means that in the sequence of Co(III)–Rh(III)–Ir(III) acetylacetonates [10], the monotonic decrease in volatility is disturbed, although this decrease is observed for the corresponding fluorinated β-diketonates, as well as for the β-diketonates of light metals. It should also be noted that, unlike acetylacetonates of trivalent metals that are well studied from the point of view of crystal chemistry [15], structural data on γ-substituted tris-complexes are absent from the literature. Taking this into account, we believe it would be interesting to study the thermal properties and determine the crystal structures of γ-substituted iridium(III) acetylacetonates.

In the present work we have synthesized for the first time γ-halogenated iridium(III) acetylacetonates described by the general formula $Ir(acacX)_n(acac)_{3-n}$, where acacX = CH_3–CO–CX–CO–CH_3, acac = CH_3–CO–CH–CO–CH_3, $n = 1,2,3$, X = F, Cl, Br, I. These complexes were studied by IR and Raman spectroscopy, thermogravimetry and differential thermal analysis; structural data for individual compounds were obtained.

2. Experimental

2.1. The synthesis of γ-halogenated iridium(III) acetylacetonates

γ-Chlorinated iridium(III) acetylacetonates were obtained by the following procedure. 250 mg of powdered $Ir(acac)_3$ were wetted with 5 ml of hydrochloric acid (1:1), then 5 ml of 30% hydrogen peroxide were added under weak heating (60°C) and mixing. After 10–15 min the precipitate became green. 5–10 min later the precipitate was separated by filtering or the mixture was dissolved in benzene, and the organic phase was separated from the inorganic phase.

γ-Bromine and iodine-substituted iridium(III) acetylacetonates were synthesized in a similar way using a 25% solution of HBr and HI.

γ-Fluorinated iridium(III) acetylacetonates were obtained by dissolving $Ir(acac)_3$ (200 mg) and XeF_2 (150 mg) in acetonitrile (a minimum amount). Then the solutions were mixed together and kept at room temperature for about 4 h. Then water was added (5 ml) in order to decompose the excess of XeF_2. The γ-fluorinated acetylacetonates formed were extracted with benzene.

The products obtained during the synthesis were isolated by chromatography on a column filled with Al_2O_3. A mixture of hexane with benzene was used as an eluent, the initial proportion being 3:1; during elution, the proportion was changed to 1:1 and then 1:3. For fluorinated compounds, the benzene concentration was increased further to pure benzene.

In all cases, the chromatograms exhibit four regions. The complexes $Ir(acacX)_3$ are the first to be eluted. The second region is represented by doubly substituted acetylacetonates and the third region contains monosubstituted iridium(III) acetylacetonates. The fourth region is small, as a rule; it is eluted with benzene and contains $Ir(acac)_3$. The elemental analysis of obtained compounds is presented in Table 1.

2.2. Devices and equipment

IR spectra were recorded with a Specord 75-IR spectrometer and Fourier spectrometer Bruker IFS-113 (200–700 cm^{-1}) in KBr tablets. Raman spectra were recorded with a DFS-24 apparatus with excitation wavelengths of the lines of He–Ne ($\lambda = 6328$ Å) and Ar ($\lambda = 4880$ Å) lasers. Thermal curves were recorded with a Q-1000 type derivatograph in He flow in open ceramic crucibles. The mass of weighed portions was 200 mg. Helium was fed into the working chamber of the derivatograph at a constant rate which was 120 ml min^{-1}. The temperature was measured at an accuracy of ± 10°C. The heating rate was 5°C min^{-1}.

2.3. X-ray diffraction patterns: crystal structure determination

For the X-ray diffraction study, crystals of $Ir(acacBr)_3$ and $Ir(acacI)_3$ were grown from solutions of the complexes in acetone. The $Ir(acacCl)_3$ crystals were grown by sublimation in a vacuum gradient furnace at a pressure of 5×10^{-2} Torr and hot zone temperature of 160°C. The crystals of $Ir(acac)_3$ were grown from acetone solution and by sublimation (vacuum gradient furnace, pressure 5×10^{-2} Torr, hot zone temperature 150°C). The crystals were orange or yellow plates. They are fairly stable in air.

A complete X-ray diffraction investigation was carried out for the complexes $Ir(acac)_3$, $Ir(acacCl)_3$, and $Ir(acacI)_3$. For $Ir(acacF)(acac)_2$, because of the poor quality of the crystals, only the elementary cell parameters were determined.

The elementary cell parameters were determined more precisely and a set of experimental intensities was obtained for the purpose of deciphering the structures with the help of a CAD-4 diffractometer (Mo Kα radiation, graphite monochromator, $\omega/2\theta$ scanning). The structures were calculated according to a standard heavy atom procedure and corrected within the anisotropic approximation; for $Ir(acacCl)_3$ the structure was corrected in anisotropic–isotropic approximation.

Table 1

The major crystallographic characteristics of the studied compounds are presented in Table 2.

3. Results and discussion

3.1. Synthesis

The synthesis of γ-halogenated iridium(III) acetylacetonates made use of the characteristic features of the chemical behaviour of iridium tris-acetylacetonate, mainly its inertness towards abstraction of the coordinated ligands. Even when boiled in concentrated solutions of hydrogen halides $Ir(acac)_3$ remains practically unchanged. The addition of hydrogen peroxide helps to dissolve the chelate, but under soft conditions we observe halogenation of the methine groups in acetylacetonate ligands without any noticeable transformation of $Ir(acac)_3$ into soluble forms. We succeeded in selecting the conditions under which $Ir(acac)_3$ is transformed practically quantitatively into γ-substituted acetylacetonates (X = Cl, Br, I), although quantitative formation of the $Ir(acacX)_3$ form seems impossible in this case because mono- and disubstituted iridium(III) acetylacetonates are likely to be formed together with the first species. Attempts to increase the synthesis temperature or the time of synthesis led to oxidation of the central ion and to the formation of soluble iridium(IV) complexes.

We did not observe fluorination of $Ir(acac)_3$ in the mixture of hydrofluoric acid and hydrogen peroxide. This confirms the electrophilic character of interaction in the systems $Ir(acac)_3$–HX–H_2O_2 which is characteristic of the acetylacetonates of inert metals [5]. Halogenation can occur with the help of free haloids evolved at the first stage of the process.

Iridium acetylacetonate was fluorinated using XeF_2. It should be noted that $Ir(acacF)(acac)_2$ was the prevailing component of the mixture, and the yield of γ-fluorinated iridium acetylacetonates was not high (owing to the preferable formation of oxidized forms of the complexes).

3.2. IR and Raman spectra

The frequencies of vibrations in the IR and Raman spectra of trisubstituted iridium(III) acetylacetonates are shown in Table 3.

The following features can be mentioned as characterizing the effect of γ-hydrogen atom substitution in the ligands by halogens: (1) in the spectra of trisubstituted acetylacetonates, the absence of the vibrations $\sigma(CH\gamma)$ at 774–792 cm^{-1} (IR), and $\sigma(CCH\gamma)$ at 1200 cm^{-1} (IR, Raman), and the very low intensity of $\nu(C–H\gamma)$ valent vibrations; (2) the appearance of additional lines corresponding to $\sigma(CCX)$ at 380–420 cm^{-1} (Raman), $\sigma(CX)$ at 455–507 cm^{-1} (Raman) and $\nu(C–X)$ at 1030–1048 cm^{-1}. The vibrations $\nu(C–X)$ are mixed with $\sigma(CH_3)$ since they are within the region of CH_3 deformations. In transfer from $Ir(acac)_3$ to mono-, di- and trisubstituted γ-halogenated acetylacetonates, the vibrational spectra exhibit a corresponding decrease in relative intensity of vibrational bands with participation of the C–X bond without any essential frequency shift accompanying the change of haloid atom.

3.3. Volatility and thermal stability

γ-Halogenated iridium(III) acetylacetonates sublime at reduced pressure (10^{-2} Torr) and a temperature of about 150°C, except for $Ir(acacBr)_3$ which decomposes under these conditions.

Differential thermal analysis was used to compare the volatility and thermal stability of the chelates under investigation. Thermogravimetric curves obtained during heating the

complexes in He flow are shown in Figs. 1 and 2. A 100% mass loss during heating of the corresponding samples to 250°C (Fig. 1) is evidence of the high sublimation ability of practically all the chelates containing F and Cl substituents in the γ-position. Aside from these complexes, only $Ir(acacI)_3$ sublimates without decomposition under the mentioned conditions (Fig. 1, curve 2). Analysis of the sublimation curves (Figs. 1 and 2) and the 50% mass loss temperatures of the compounds under consideration (Table 4) suggest that there is an insignificant difference in their volatility, although both the configuration and the nature of the substituent have a definite effect on the changes of this characteristic. For the set of Cl-substituted complexes as an example, we can see that the highest volatility is exhibited by the monosubstituted compounds and the poorest volatility by disubstituted complexes. A similar order of volatility change is observed for the sublimation of other compounds in the temperature gradient furnace. The complexes $Ir(acacCl)(acac)_2$, $Ir(acacF)(acac)_2$ and $Ir(acacI)_3$ are close in volatility. This means that $Ir(acacI)_3$ is to be more volatile than $Ir(acacCl)_3$ which is connected (as we show below) with the structural features of the complexes $Ir(acacCl)_3$ and $Ir(acacI)_3$. Superimposing sublimation and decomposition processes for other chelates (Fig. 2) and an insignificant difference in temperature intervals within the whole sequence of compounds under investigation do not allow us to outline in general the dependence of the volatility on the number and type of haloid substituents. However, there

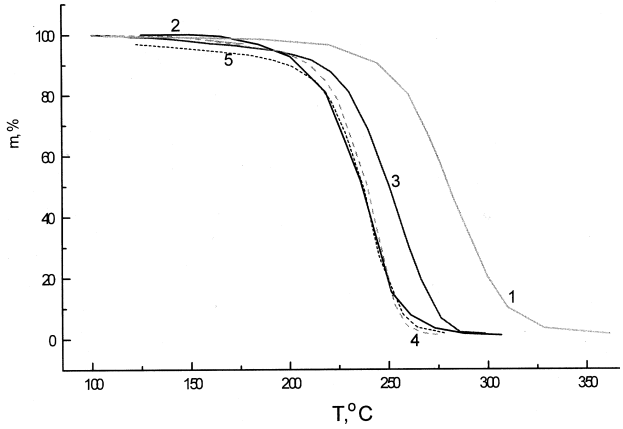

Fig. 1. Thermogravimetric curves of mass loss for $Ir(acac)_3$ (1), $Ir(acacI)_3$ (2), $Ir(acacCl)_3$ (3), $Ir(acacF)(acac)_2$ (4), $Ir(acacCl)(acac)_2$ (5).

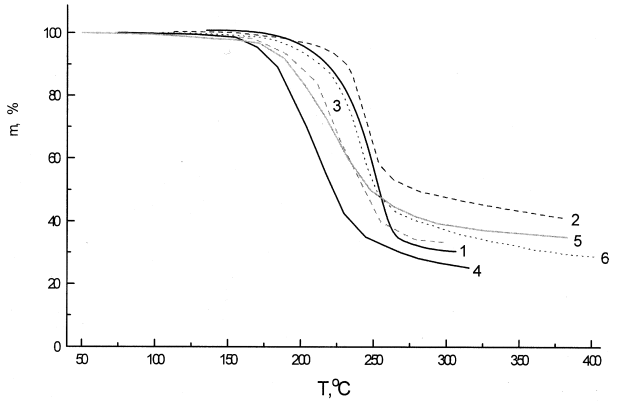

Fig. 2. Thermogravimetric curves of mass loss for $Ir(acacCl)_2(acac)$ (1), $Ir(acacI)_2(acac)$ (2), $Ir(acacI)(acac)_2$ (3), $Ir(acac)_3$ (4), $Ir(acacBr)(acac)_2$ (5), $Ir(acacBr)_3$ (6).

is no doubt that the volatility of γ-halogenated iridium(III) acetylacetonates increases, compared with the initial iridium(III) tris-acetylacetonate. The sublimation curve of the latter lies in the region of higher temperatures (Fig. 1, curve 1).

As far as thermostability is concerned, it decreases with respect to $Ir(acac)_3$ for the whole row of γ-halogenated iridium(III) acetylacetonates studied in the present work. Table 4 shows the decomposition points determined using the DTA curves. For the compounds that sublime completely under the above conditions, the temperatures were estimated under the same conditions but using tightly closed crucibles.

$Ir(acacBr)_3$ turned out to possess the poorest thermal stability, like the corresponding compounds of Co(III), Cr(III) and Rh(III) described in [3–5]. It decomposes at ~200°C. $Ir(acacI)_3$ exhibits the highest thermal stability among the I- and Br-substituted complexes. The thermal behaviour of Cl- and F-substituted iridium(III) acetylacetonates (except $Ir(acacF)_3$ which has not been investigated) resembles the behaviour of metal(III) tris-trifluoracetylacetonates. As a rule, the latter are less thermally stable in the condensed state than the corresponding acetylacetonates but possess higher volatility [12,13]. In the row of γ-halogenated iridium(III) acetylacetonates Cl- and F-substituted chelates possess the highest thermal stability.

3.4. Description of the structure

In the $Ir(acacCl)_3$ structure, two independent crystallographic iridium complexes are present. Figs. 3–6 show the packing of the complexes **I**, **II**, **III** and **IV** in the crystals.

In all the complexes, the central Ir atom has a slightly distorted octahedral coordination by six oxygen atoms belonging to three β-diketonate ligands.

The mean values of bond length Ir–O for the complexes **I**, **II**, **III** and **IV** are 2.02, 2.00, 1.99 and 2.00 Å, respectively, and the mean O–Ir–O chelate angles are 94.5, 93.7, 93.9 and 92.9°. This means that the bond lengths Ir–O and valent angles O–Ir–O in γ-halogenated iridium(III) acetylacetonates decrease, compared with $Ir(acac)_3$.

Bond lengths and valent angles of the chelate β-diketonate ligands are close to each other and agree with the literature data [15]. The mean distances Cγ–Hal in **II**, **III** and **IV** are 1.77, 1.93 and 2.12 Å, respectively. The mean angles C–Cγ–C with the methine carbon atom at the vertex are 128° with

Table 4
Thermal properties of γ-substituted iridium(III) acetylacetonates

Compound	Melting temperature (°C) (Kefler table)	Decomposition temperature (°C) (DTA, closed crucible)	*T*(50%) (°C) (DTA, open crucible)
$Ir(acac)_3$	268–270	350	310
$Ir(acacCl)(acac)_2$	253–255	280	240
$Ir(acacCl)_2(acac)$	258–259	275	265
$Ir(acacCl)_3$	278–279	290	250
$Ir(acacBr)(acac)_2$	235–236	240	
$Ir(acacBr)_2(acac)$	242–243	250	
$Ir(acacBr)_3$	dec. 200	200	
$Ir(acacI)(acac)_2$	247–248	255	
$Ir(acacI)_2(acac)$	238–240	245	
$Ir(acacI)_3$	257–260	270	245
$Ir(acacF)(acac)_2$	276–278	285	240
$Ir(acacF)_2(acac)$	265–266	275	250
$Ir(acacF)_3$		280	

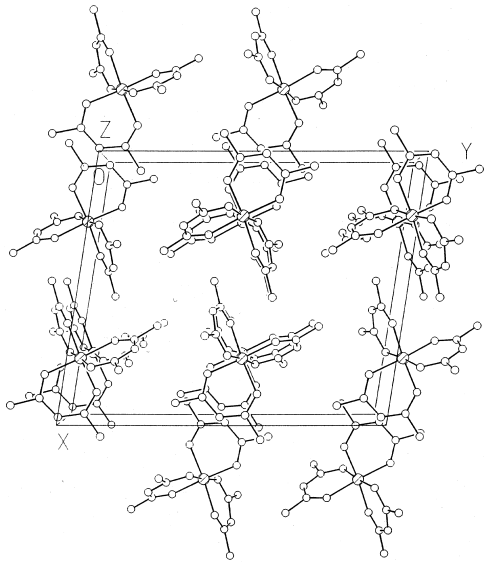

Fig. 3. Packing of $Ir(acac)_3$ complex in the crystal.

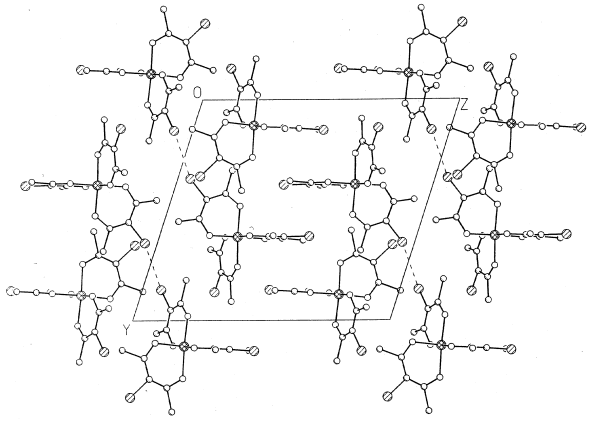

Fig. 4. Packing of $Ir(acacCl)_3$ complex in the crystal.

an accuracy of 1° in all the compounds. Chelate metal cycles in the complexes are not planar. The mean values of inflection angles of metal cycles along the O···O lines are 3° for pure iridium(III) acetylacetonate, and 4.2, 2.3, 3.2° for **II**, **III** and **IV**, respectively. In the crystals of the studied compounds, the complexes are connected by van der Waals interactions. Every iridium complex in the structures is surrounded by ten nearest neighbouring complexes. The distances between Ir atoms Ir···Ir can be estimated as >7.49 Å for **I**, 7.98–10.08 Å for **II**, and >8.10 Å for **III** and **IV**. It should be noted that compound II exhibits the shortest intermolecular contact Cl_2–Cl_4, this length being 3.26 Å. The crystal independent complexes Ir(I) and Ir(II) are connected with each other owing to this interaction in dimers. If we limit the estimate to 10 Å, intermolecular coordination numbers (ICN) of the studied structures are equal to 10.

4. Conclusions

Thus, we have synthesized and identified iridium(III) acetylacetonates and γ-halogenated Br-, I- and F-containing

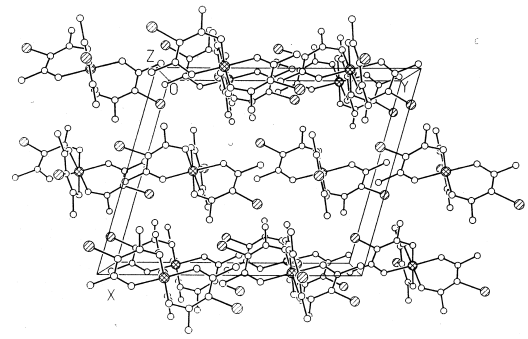

Fig. 5. Packing of $Ir(acacBr)_3$ complex in the crystal.

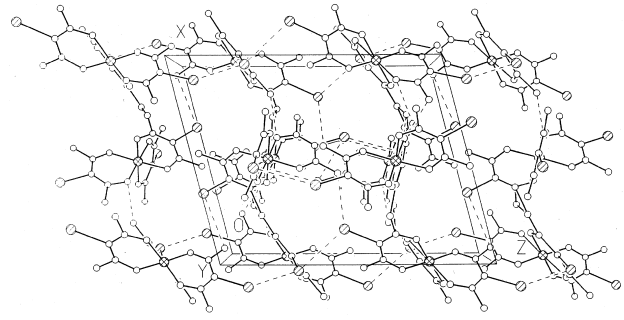

Fig. 6. Packing of $Ir(acacI)_3$ complex in the crystal.

compounds. We have investigated their spectroscopic and thermogravimetric properties. Crystal structures have been determined for a series of complexes. Monosubstituted complexes have been shown to be the most volatile and disubstituted complexes to be less volatile. The volatility of γ-halogenated iridium(III) acetylacetonates has been found to increase in comparison with the initial iridium(III) tris-acetylacetonate. The comparison with iridium(III) acetylacetonate has shown that the introduction of substituents into the γ-position does not have any substantial effect on crystallographic characteristics, except for the $Ir(acacCl)_3$ complex which is a dimer and because of this its volatility is lower than the volatility of the $Ir(acacI)_3$ complex (the complex $Ir(acacBr)_3$ decomposes during heating).

Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition numbers 136097–136100.

Abstract

Two binuclear copper(II) compounds, $Cu_2(tacn)_2(\mu\text{-ox})(ClO_4)_2$ (**I**) and $[Cu_2(bdpm)_2(H_2O)_2(\mu\text{-ox})](ClO_4)_2\cdot H_2O$ (**II**), where tacn = 1,4,7-triazacyclononane, ox = oxalate dianion, bdpm = bis(3,5-dimethylpyrazol-1-yl)methane, have been synthesized and characterized by X-ray diffraction. Each copper atom of compound **I** has a 4 + 1 + 1 elongated pseudo-octahedral environment; the copper atoms have distorted square pyramidal geometry in compound **II**. The magnetic susceptibilities (300–4 K) indicated that the binuclear copper(II) cores were antiferromagnetically coupled ($2J = -41$ cm^{-1} for compound **I**, $2J = -102$ cm^{-1} for compound **II**). The weakness of the interactions for both compounds is discussed on the basis of the structural features. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Crystal structures; Binuclear copper compounds; Magnetism; Oxalato-bridged compounds

1. Introduction

In the past decades, there has been many studies on the synthesis and magnetic coupling of metal atoms with polyatomic bridging ligands [1,2]. The oxalate dianion ($C_2O_4^{2-}$) is well known to function as a bridge ligand, and its bi-, tri-, tetranuclear, 1D, 2D and 3D network compounds have been prepared and characterized [3–22], of which some ferromagnetic interaction compounds between metal centres, particularly ferromagnets or ferrimagnets with T_c in the range of 0–50 K, have been obtained [12,13,23,24].

The simple binuclear copper(II) compounds involving a single symmetric, in-plane oxalate ion binding through two oxygen atoms to each of two metal centres have played a crucial role in the field of theoretical magnetic analysis [25–27]. Kahn and co-workers have described a theory to predict that the magnetic interactions in oxalato-bridged bicopper(II) compounds are responsible for the orientation of the magnetic orbital, sensitive to the geometry of copper. When the magnetic orbital of each copper(II) is placed on the ox plane, the absolute J value becomes the largest, resulting from the strong overlap of the magnetic orbital and the b_{2u} or b_{1g} (ox) orbital, which favours the antiferromagnetic interaction. Otherwise, the interaction becomes weak. The theory has been applied to rationalize the magnetic interactions observed for oxalate-bridged copper(II) compounds.

μ-Oxalato-dicopper(II) compounds of varying structural complexity through pronounced Jahn–Teller distortion are known. Great difficulties are faced to establish the correlation between the magnitude of the magnetic coupling and the structural factor. To address this issue, two compounds, $Cu_2(tacn)_2(\mu\text{-ox})(ClO_4)_2$ (**I**) and $[Cu_2(bdpm)_2(H_2O)_2(\mu\text{-ox})](ClO_4)_2\cdot H_2O$ (**II**) (tacn = 1,4,7-triazacyclononane, ox = oxalate dianion, bdpm = bis(3,5-dimethylpyrazol-1-yl)methane), have been prepared and characterized. Striking results have found that the structure of compound **I** possesses pseudo-octahedral coordination geometry, different from the earlier suggestion by Chaudhuri and Oder [28], and weaker antiferromagnetic interactions were observed for the two compounds. The results of the study on magneto-structural correlation for both compounds are presented and discussed in this context. The crystal structure of compound **I** has been briefly described in a preliminary communication [29].

2. Experimental

2.1. Materials and methods

1,4,7-Triazacyclononane (tacn) and bis(3,5-dimethylpyrazol-1-yl)methane (bdpm) were prepared as described in Refs. [30,31]. All other chemicals were of reagent grade and used as received.

Analyses for C, H and N were obtained using a Model 240 Perkin-Elmer analyser at the Institute of Elemental Organic Chemistry, Nankai University. The IR spectra were recorded on an FTIR-1600 spectrophotometer in KBr discs. X-band powder EPR spectra were recorded on a Bruker ER 220 D-SRC ESR spectrometer. Variable-temperature magnetic susceptibilities were measured on a Model CF-1 vibrating sample magnetometer. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms and the magnetic moments were calculated using the equation $\mu_{eff} = 2.828(\chi_M T)^{1/2}$.

2.2. Synthesis of the compounds

2.2.1. $Cu_2(tacn)_2(\mu\text{-}ox)(ClO_4)_2$ (*I*)

The blue compound was prepared according to Refs. [28,29]. The crude product was recrystallized from methanol twice. In the final stage, refrigeration allowed slow formation of crystals suitable for X-ray diffraction studied. The compound analysed satisfactorily for $Cu_2(tacn)_2(\mu\text{-}ox)(ClO_4)_2$. Yield, 43%. *Anal*. Calc. for $C_{14}H_{30}Cl_2Cu_2N_6O_{12}$: C, 25.0; H, 4.5; N, 12.5. Found: C, 24.8; H, 4.7; N, 12.2%.

2.2.2. $[Cu_2(bdpm)_2(H_2O)_2(\mu\text{-}ox)](ClO_4)_2 \cdot H_2O$ (*II*)

The preparation of compound **II** was similar to that for compound **I** with the exception that ligand, bdpm, was used in place of tacn. The compound crystallized as dark blue. Yield: 75%. *Anal*. Calc. for $C_{24}H_{38}Cl_2Cu_2N_8O_{15}$: C, 32.9; H, 4.4; N, 12.8. Found: C, 33.2; H, 4.7; N, 12.5%.

Caution! Although the perchlorate salts described in this work do not appear to be sensitive to shock, these materials, like all perchlorate salts, should only be prepared in small quantities and treated with caution.

2.3. X-ray crystallography

Crystals of dimensions $0.10 \times 0.16 \times 0.18$ mm for compound **I** and $0.08 \times 0.32 \times 0.38$ mm for compound **II** were mounted on a Siemens P4 diffractometer with graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) and used for data collection. Diffraction data were collected using ω–2θ scans at room temperature (293 K) over the range $1.8 \le \theta \le 25.0°$ for both compounds. The data for both compounds were processed using the Siemens SHELXTL crystallographic package (Version 5) [32]. Data were corrected for Lorentz polarization effects and semi-empirical absorption. The crystal data, data collection and refinement details are summarized in Table 1.

Both structures were solved by direct methods and in each case all non-hydrogen atoms were located from Fourier difference syntheses. Refinements were carried out with anisotropic thermal parameters for all non-hydrogen atoms and isotropic thermal parameters for all hydrogen atoms were fixed with ideal positions by full-matrix least-squares on F^2.

3. Results and discussion

3.1. Characterization of the compounds

The IR spectra for both compounds display the characteristic bands of the oxalate bridging ligand $\nu_{asym\ (C–O)}$ at 1650s, $\nu_{sym\ (C–O)}$ at 1356m and $\delta_{(O–C–O)}$ at 804m cm^{-1}, where s and m refer to strong and medium, respectively. This indicated that the oxalate ion is present as a bridging quadridentate ligand. For compound **I**, a sharp band at 3150 cm^{-1} was observed, indicative of the presence of N–H stretching vibrations. The ClO_4^- group vibration near 1100 cm^{-1} splitting into three sharp bands at 1142s, 1110s and 1086s cm^{-1}, and the presence of an intense band at 930 cm^{-1}, indicate coordinated perchlorate ions [33]. It can be seen that the IR spectra for compound **II** exhibit a broad band near 3400m cm^{-1}, indicative of the presence of H_2O. However, a broad band at 1100 cm^{-1}, typical for non-coordinated perchlorate ions, was present [34].

3.2. Molecular structure of $Cu_2(\mu\text{-}ox)(tacn)_2(ClO_4)_2$ (*I*)

The structure of compound **I** is made up of neutral oxalato-bridged copper(II) units, is shown in Fig. 1 with numbering scheme. Selected bond distances and angles with their estimated standard deviations are listed in Table 2.

The compound has two copper metal centres bridged by a planar bis(didentate) oxalate ligand. The geometry around each copper(II) ion is considered as an elongated octahedral environment with two nitrogen atoms of tacn and two oxygen atoms of oxalate bridge in the equatorial plane CuN2O2, and the third nitrogen atom of tacn occupying the apical position. The axial Cu–N bond distances (2.218 and 2.223 Å) are longer than those (1.996–2.014 Å) in the basal plane, as has been observed earlier [3–22]. The shortest Cu–O (perchlorate) distances are 2.770 Å (Cu1–O7) and 2.747 Å (Cu2–O9), and thus weak coordination of perchlorates to Cu(II) ions is apparent. The Cu(1) and Cu(2) atoms lie 0.043 Å and 0.049 Å from the basal planes towards the apical nitrogen. The four equatorial atoms around Cu atoms are planar. The Cu(1)–Cu(2) distance is 5.176 Å, approximately equal to the data observed (5.144–5.154 Å) [3–8]. C–O distances are in the range (1.253–1.260 Å), very close to the values found previously [3–8].

3.3. Molecular structure of $[Cu_2(bdpm)_2(H_2O)_2(\mu\text{-}ox)](ClO_4)_2\cdot H_2O$ (*II*)

The structure is made up of water molecules of crystallization, uncoordinated perchlorate anions and binuclear

[a] Symmetry transformations used to generate equivalent atoms: $-x+1$, $-y+1$, $-z+1$.

The copper coordination geometry is distorted square pyramidal with two nitrogen atoms from bdpm and two oxygen atoms from the oxalato bridging ligand in the basal plane, and the other oxygen atom from water molecular in the axial position. The Cu–Cu separation within the binuclear unit is 5.194 Å, very similar to the value for compound **I**. As far as the Cu–O distances are concerned, the average Cu–O (oxalate) (1.979 Å) is very close to the value for compound **I** (1.992 Å), much shorter than the Cu(1)–OW(water) distance (2.244 Å). The Cu–O (perchlorate) distances are 3.129 Å, much longer than those for compound **I**. The oxalate anion is almost planar, and the copper(II) ions are 0.3293 Å out of the plane towards the axial position. The bdpm ligands are in a six-membered boat coordination in compound **II**. C–O distances (1.213 and 1.275 Å) in the oxalate ion are apparently unequal, and the smaller of these values [C(1)[a]–O(1), [a] $-x+1$, $-y+1$, $-z+1$] is the shortest one found in the literatures for related species [3–22], very close to those found in oxalic acid bihydrate (1.207 and 1.281 Å, respectively) [35]. The perchlorate anions contribute to the packing by forming hydrogen bonds with coordinated and uncoordinated water molecules.

3.4. EPR spectra and magnetic properties

X-band EPR spectra of polycrystalline samples for both compounds at 110 K are similar, and close to the report earlier [28]. The $g_{\parallel}$ values (2.16 and 2.14 for compounds **I** and **II**, respectively), which are higher than $g_{\perp}$ (2.08 and 2.10 for compounds **I** and **II**, respectively) are indicative of a $d_{x^2-y^2}$ ground state.

In the 300–4 K temperature range investigated, the molar magnetic susceptibility for compound **I** increases, reaching a maximum at 35 K, and decreases, reaching a minimum at 7 K, then increases with temperature (see Fig. 3a). The magnetic moments decrease in the temperature range 7–300 K, and reach a constant about 0.36 μ_B below 7 K (Fig. 3b), indicating the presence of intramolecular antiferromagnetic interaction. A similar curve was obtained for compound **II** (Fig. 4). The single-triplet energy gap ($2J$) was deduced from least-squares fit of the experimental data to the temperature for isotropic exchange in copper(II) dimer [36] according to the Bleaney–Bowers equation modified accord-

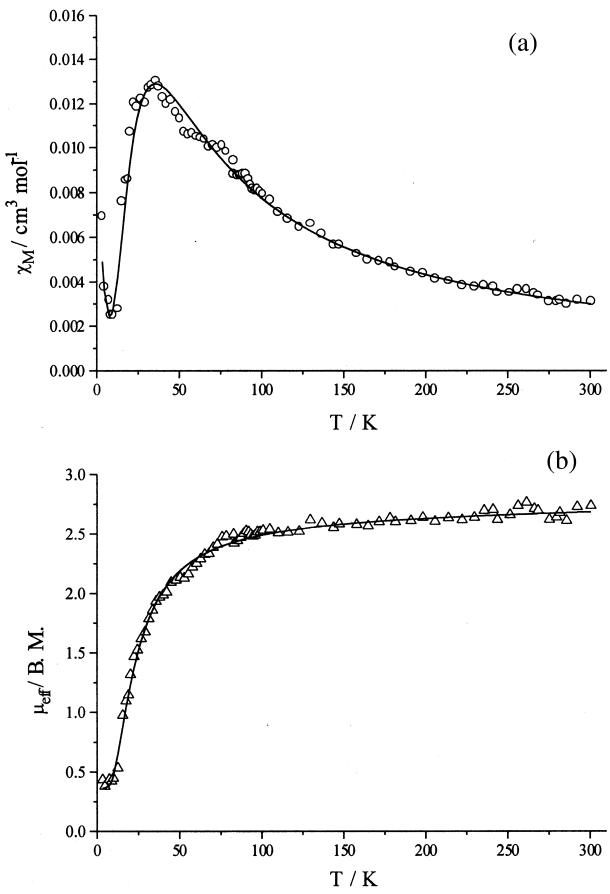

Fig. 3. Plots of χ_M (a) and μ_{eff} (b) of $Cu_2(tacn)_2(\mu\text{-ox})(ClO_4)_2$ (**I**) vs. *T*. Solid lines represent the best theoretical fit.

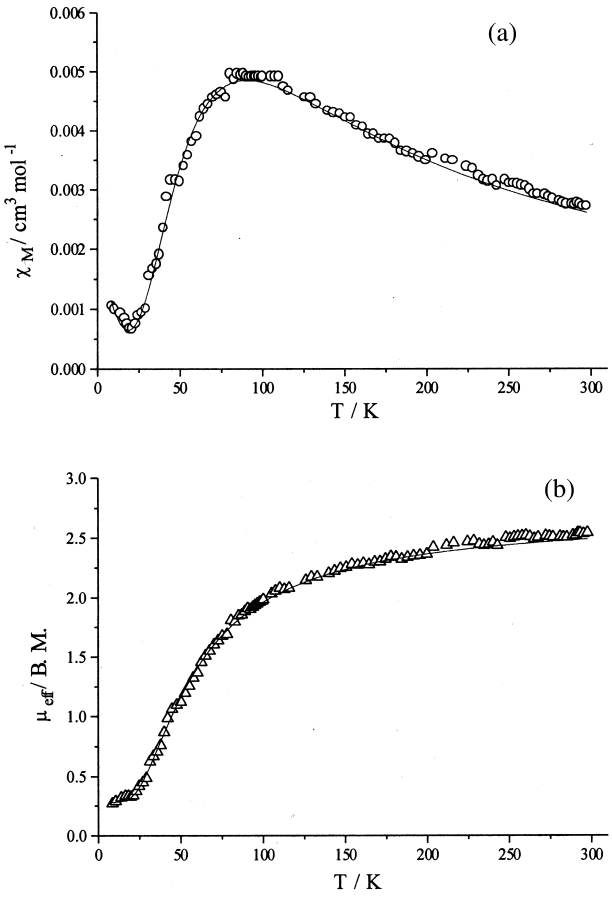

Fig. 4. Plots of χ_M (a) and μ_{eff} (b) of $[Cu_2(bdpm)_2(H_2O)_2(\mu\text{-ox})](ClO_4)_2\cdot H_2O$ (**II**) vs. *T*. Solid lines represent the best theoretical fit.

ing to Kahn and co-workers to take into account some paramagnetic impurity [37]:

$$\chi_M = \frac{2Ng^2\beta^2}{KT}\left[3+\exp\left(\frac{-2J}{KT}\right)\right]^{-1}(1-\rho)+\frac{Ng^2\beta^2}{2KT}\rho+2N\alpha$$

The symbols have their usual meanings, and ρ is the percentage non-coupled impurity. $N\alpha$ is the temperature-independent paramagnetism. The best fits, shown as the solid line in Figs. 3 and 4, afforded the parameter values $2J=-41$ cm^{-1}, $g=2.14$, $\rho=0.009$ with an agreement factor of $R=4.1\times10^{-5}$ for compound **I** and $2J=-102$ cm^{-1}, $g=2.16$, $\rho=0.01$, $R=4.4\times10^{-6}$ for compound **II** (R is defined as $\Sigma[(\chi_M)_{obs}-(\chi_M)_{calc}]^2/\Sigma(\chi_M)_{obs}^2$).

For compound **I**, the value of the singlet-triplet gap ($2J=-41$ cm^{-1}) is much weaker than those ($2J=-260$ to -300 cm^{-1}) for the compounds with non-centrosymmetric cores [38,39]. Significant weakness of the magnetic interaction can be understood according to $J_{AF}=-2S(\Delta^2-\delta^2)$ for the non-centrosymmetric dimer, Δ being the energy separation between the two single occupied molecular orbitals in the triplet state built from the magnetic orbitals, δ being the energy separation between the magnetic orbitals. With the lowering of symmetry, the δ value increases, leading to a corresponding decrease of the antiferromagnetic interaction. However, the magneto-structural correlation is still an open question and has not been quantified thoroughly. For compound **II**, the weaker antiferromagnetic interaction ($2J=-102$ cm^{-1}) is unexpected and significantly smaller than for compounds with centrosymmetric cores ($2J=-400$ to -300 cm^{-1}) [3–8]. It can be satisfactorily interpreted based on the structural data. When one looks at the structure of compound **II**, the height of the copper atom above the basal plane (0.3239 Å) is the longest in all compounds that are in a boat conformation. Furthermore, the C–O bond distances of the oxalate dianion are different (1.275 Å versus 1.213 Å), which indicates that the geometries around copper ions have somewhat deviated from square pyramid towards trigonal bipyramid. Thus the magnetic exchange interaction was reduced.

In the light of the results summarized in Table 4, three points deserve special comments on the week magnetic coupling in the μ-oxalato-bridged-dicopper(II) compounds:

Table 4

[a] The height of the copper atom above the basal plane.
[b] The distance between the intramolecular copper atoms.
[c] The C–C bond length in the oxalate bridge.

1. The bending magnitude of the basal plane of the $C_2O_4^{2-}$ bridge is sensitive to the magnetic coupling interaction. The bonding significantly reduces antiferromagnetic interaction.
2. The difference in coordination environments of copper(II) ions is able to weaken the antiferromagnetic interactions, especially in the systems in which one of the oxalate oxygen atoms is in the basal plane and the other is apical.
3. The height of metal atoms above the basal plane is significant, which permits antiferromagnetic interaction; i.e. the height reduces the overlap of both magnetic orbitals through the σ-orbital of the oxalate: the higher the distance, the weaker the interaction observed. It should be noted that the cooperative effect of all three factors is very significant to weaken the magnetic interaction in the oxalato-bridged binuclear copper(II) system.

In conclusion, the exchange interaction between the transition metal ions propagated through the oxalate bridge is strongly dependent on the geometry around the metal ions and the bridging mode of the oxalate anion. The geometry of the metal ion exerts a marked influence on the magnetic exchange interaction. Further work is necessary to study the magneto-structural correlation in the $[Cu(\mu\text{-ox})Cu]^{2+}$ system.

Supplementary data

Supplementary crystallographic data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition numbers 138285 and 138286. Least-squares plane equations, deviations of atoms (Å) and dihedral angles between planes (°) and listings of data resulting from the magnetic susceptibility measurements for compounds **I** and **II** are available from the corresponding author.

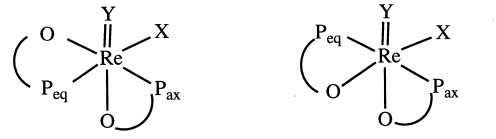
Abstract

Six-coordinate, monosubstituted and disubstituted phosphinophenol complexes $ReYX_2(PPh_3)(P\sim O)$ and $ReYX(P\sim O)_2$ (Y = O, NPh; X = Cl, Br, I) were obtained by reacting 2-diisopropylphosphinophenol (P ~ OH) with $ReOX_3(PPh_3)_2$ and $Re(NPh)X_3(PPh_3)_2$ in toluene. A mixture of the monosubstituted and disubstituted complexes $ReYX_2(PPh_3)(P\sim O)$ and $ReYX(P\sim O)_2$ was precipitated when the reactions were performed with a 2:1 ligand to metal ratio. Excess ligand (4 equiv.) was needed to obtain quantitatively the disubstituted complexes. ^1H and $^{31}P\{^1H\}$ NMR show that all monosubstituted and disubstituted complexes exist as single isomers with a *trans*-P,P 'twisted' octahedral geometry, the site *trans* to the multiple bond being filled by the oxygen donor of one P ~ O ligand. The compounds were also characterized by microanalysis, IR and mass spectrometry. ©2000 Elsevier Science Ltd All rights reserved.



Keywords: Phosphinophenols; Rhenium

1. Introduction

Because of their chemical and structural diversity and their good coordinative properties, functionalized phosphines have attracted considerable attention in strategies aimed at developing new chelates for metallic radioisotopes to develop imaging (technetium) and therapeutic (rhenium) agents in nuclear medicine.

In the recent past, studies have been conducted on the reaction of $ReOCl_3(PPh_3)_2$, $Re(NPh)Cl_3(PPh_3)_2$ and $[TcO_4]^-$ with various diphenylphosphines functionalized with nucleophilic substituents such as $Ph_2P–Z–CO_2H$ (Z = CH_2, $CH_2–CH_2$, *o*-C_6H_4) [1,2], $Ph_2PCH{=}CPh(OH)$ [3], $Ph_2PC_6H_4OH$ [4–8], $Ph_2PCH_2C_6H_4OH$ [9] and $Ph_2PC_6H_4OSiMe_3$ [10], i.e. bidentate ligands with soft phosphorus(III) donor and hard carboxo, hydroxo or phenoxo groups. Although several configurations are possible for octahedral complexes bearing three different ligands, most of the previously reported oxo and imido complexes adopt the *cis*-P_{eq},P_{ax} 'twisted' octahedral arrangement A with an O=Re–O linkage (Scheme 1), while the *trans*-P_{eq},P_{ax} arrangement B with a PhN=Re–O linkage was observed for Re-imido species. Thus these ligands favour the formation of a single isomer, which is essential for radiopharmaceutical applications.

In contrast to the relatively abundant literature on the reactions of $Ph_2PC_6H_4OH$ ligands on rhenium precursors [4–8], to our knowledge the reactivity of dialkylphosphinophenols has not yet been investigated. This may be due in part to the increased reductive character of the alkylphosphines which are known to stabilize Re(III) complexes. In order to determine the influence of an alkyl substituent on the phosphinophenol reactivity, we have studied the reaction of 2-(diisopropylphosphino)phenol (P ~ OH) on $ReOX_3$-

A (cis-P,P « twisted ») **B** (trans-P,P « twisted »)

$(PPh_3)_2$ and $Re(NPh)X_3(PPh_3)_2$ (X = Cl, Br, I) by comparison with $Ph_2P\sim OH$. Isopropyl substituents increase the steric hindrance of the phosphine (cone angle of 137° for $^iPr_2P\sim OH$ compared to 127° for $Ph_2P\sim OH$) [11] and its basicity ($pKa(PPh_3) = 2.73$; $pKa(P^iPr_3) = 9.30$)) [12]. We observe the formation of Re(V) complexes without reduction of the metal centre whose structures are controlled by the steric hindrance of the ligand.

2. Experimental

2.1. Reagents and physical measurements

All reactions were carried out in a nitrogen atmosphere using standard Schlenk techniques. Ether and toluene were dried over sodium benzophenone ketyl and distilled prior to use. Ethanol and acetonitrile were distilled on molecular sieves (3 Å). $ReOX_3(PPh_3)_2$ [13,14], $Re(NPh)X_3(PPh_3)_2$ [15], and 2-diisopropylphosphinophenol [16] were prepared by literature methods.

Infrared spectra (4000–200 cm^{-1}) were recorded as CsI pellets on a Bruker Vector 22 spectrometer. ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectra were recorded at room temperature in CD_2Cl_2, $CDCl_3$ or C_6D_6 on Bruker ARX 400 and AMX 300 WB spectrometers, using $SiMe_4$ as internal reference (^1H, ^{13}C) and H_3PO_4 (82%/D_2O) as external reference (^{31}P). All chemical shifts are reported in ppm. Desorption chemical ionization using NH_3 (DCI/NH_3) was recorded on a NERMAG R 1010 mass spectrometer. Elemental analyses were run at the Laboratoire de Chimie de Coordination du CNRS, Toulouse, France.

2.2. Synthetic work

$ReOCl_2(PPh_3)(P\sim O)$ (**1**) and $ReOCl(P\sim O)_2$ (**2**). The two complexes were obtained from the reaction of $P\sim OH$ (0.373 g, 1.77 mmol) and $ReOCl_3(PPh_3)_2$ (0.739 g, 0.89 mmol) in refluxing toluene under N_2 for 35 h. Concentration of the solution in vacuo produced a green solid. Work-up with diethyl ether and cooling of the solution gave a mixture of **1** and **2**. Purification by column chromatography using silica as support gave **1** with chloroform and **2** with diethyl ether as eluents. Recrystallization from diethyl ether at −20°C gave **1** (yield 10%) and **2** (yield 43%) as green crystals.

1. *Anal*. Calc. for $C_{30}H_{33}Cl_2O_2P_2Re$: C, 48.39; H, 4.47. Found: C, 47.82; H, 4.78%. IR (CsI): 970 cm^{-1}, ν(Re=O). MS (DCI/NH_3): *m/z* 745 $[M+H]^+$, 709 $[M-HCl+H]^+$. $^{31}P\{^1H\}$ NMR (C_6D_6, 161.98 Hz, ppm): 7.1; 24.7 (dd, $^2J_{PP} = 262$ Hz). ^1H NMR (C_6D_6, 400.14 MHz, ppm): 1.36 (dd, 6H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 15$ Hz); 1.50 (dd, 6H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 17$ Hz); 3.33 (d of septets, 2H, CH, $^3J_{HH} = 7$ Hz, $^2J_{HP} = 2$ Hz); 6.22 (dd, 1H, Ph, $^3J_{HH} = 7$ Hz, $^4J_{HP} = 4$ Hz); 6.56 (dd, 1H, Ph, $^3J_{HH} = 7$ Hz); 6.93 (dd, 2H, Ph, $^3J_{HH} = 7$ Hz); 7.03 (m, 9H, Ph); 8.04 (ddd, 6H, Ph, $^3J_{HH} = 8$ Hz, $^4J_{HH} = 1$ Hz, $^3J_{HP} = 11$ Hz).

2. *Anal*. Calc. for $C_{24}H_{36}ClO_3P_2Re$: C, 43.93; H, 5.53; Cl, 5.40; P, 9.44; Re, 28.38. Found: C, 48.85; H, 5.56; Cl, 6.55; P, 9.19; Re, 26.13%. IR (CsI): 962 cm^{-1}, ν(Re=O). MS (DCI/NH_3): *m/z* 621 $[M-HCl+H]^+$. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): 34.0; 41.6 (dd, $^2J_{PP} = 213$ Hz). ^1H NMR ($CDCl_3$, 400.14 MHz, ppm): 1.4 (dd, 12H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 17$ Hz); 1.7 (dd, 12H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 17$ Hz); 2.8 (d of septets, 1H, CH, $^3J_{HH} = 7$ Hz, $^2J_{HP} = 1$ Hz); 3.0 (d of septets, 2H, CH, $^3J_{HH} = 7$ Hz, $^2J_{HP} = 1$ Hz); 3.4 (d of septets, 1H, CH, $^3J_{HH} = 7$ Hz, $^2J_{HP} = 1$ Hz); 6.3–7.5 (m, 8H, Ph).

$ReOBr_2(PPh_3)(P\sim O)$ (**3**) and $ReOBr(P\sim O)_2$ (**4**). The same method was used as for **1** and **2**, starting from 0.380 g (1.8 mmol) of $P\sim OH$ and 0.873 g (0.9 mmol) of $ReOBr_3(PPh_3)_2$, stirred in 30 ml of refluxing toluene under N_2 for 46 h.

3. Green solid, yield 9%. *Anal*. Calc. for $C_{30}H_{33}Br_2O_2P_2Re$: C, 43.23; H, 3.99. Found: C, 44.27; H, 3.58%. IR (CsI): 969 cm^{-1}, ν(Re=O). MS (DCI/NH_3): *m/z* 835 $[M+H]^+$, 755 $[M-HBr+H]^+$. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): 8.0; 26.1 (dd, $^2J_{PP} = 260$ Hz). ^1H NMR ($CDCl_3$, 400.14 MHz, ppm): 1.55 (dd, 6H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 16$ Hz); 1.64 (dd, 6H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 16$ Hz); 3.62 (d of septets, 2H, CH, $^3J_{HH} = 7$ Hz, $^2J_{HP} = 2$ Hz); 5.9–7.8 (m, 19H, Ph). $\Lambda(CH_3CN)$: 30.3 Ω^{-1} cm^2 M^{-1} (molecular).

4. Green solid, yield 50%. *Anal*. Calc. for $C_{24}H_{36}BrO_3P_2Re$: C, 41.15; H, 5.18. Found: C, 41.40; H, 4.92%. IR (CsI): 964 cm^{-1}, ν(Re=O). MS (DCI/NH_3): *m/z* 701 $[M+H]^+$, 621 $[M-HBr+H]^+$. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): 34.1, 41.7 (dd, $^2J_{PP} = 212$ Hz). ^1H NMR ($CDCl_3$, 400.14 MHz, ppm): 1.1–1.7 (dd, 24H, CH_3, $^3J_{HH} = 7$ Hz, $^3J_{HP} = 16$ Hz); 2.8–3.1 (m, 4H, CH); 6.3–7.5 (m, 8H, Ph). $\Lambda(CH_3CN)$: 15.1 Ω^{-1} cm^2 M^{-1} (molecular).

$ReOI_2(PPh_3)(P\sim O)$ (**5**) and $ReOI(P\sim O)_2$ (**6**). The same method was used as for **1** and **2**, starting from the reaction of 0.45 g (2.14 mmol) of $P\sim OH$ and 1.185 g (1.07 mol) of $ReOI_3(PPh_3)_2$ in refluxing toluene under N_2 for 46 h. Concentration of the solution gave an oily solid. Work-up with diethyl ether and cooling the solution gave a mixture of **5** (yield 27%) and **6** (yield 9%) as a dark brown solid, which was filtered off and dried in vacuo. Purification by column chromatography as for the Cl and Br analogues gave **5** and **6** as pure compounds.

5. Brown solid, yield 27%. *Anal*. Calc. for $C_{30}H_{33}I_2O_2P_2Re$: C, 38.85; H, 3.59; I, 27.36. Found: C, 38.07; H, 3.28; I, 26.94%. ^{31}P NMR ($CDCl_3$, 161.98 MHz, ppm): 6.9; 17.4 (dd, $^2J_{PP} = 257$ Hz). MS (DCI/NH_3): *m/z* 929 $[M+H]^+$.

6. Brown solid, yield 9%. *Anal*. Calc. for $C_{24}H_{36}IO_3P_2Re$: C, 38.56; H, 4.85; I, 16.97. Found: C, 38.17; H, 4.60; I, 16.12%. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): 33.1;

42.4 (dd, $^2J_{PP}$ = 210 Hz). MS (DCI/NH_3): *m/z* 749 $[M+H]^+$.

Re(NPh)Cl_2(PPh_3)(P∼O) (**7**) and Re(NPh)Cl(P∼O)$_2$ (**8**). The same method was used as for **1** and **2**, starting from the reaction of P∼OH (0.47 g, 2.24 mmol) and Re(NPh)Cl_3(PPh_3)$_2$ (1.02 g, 1.12 mmol) in refluxing toluene (40 ml) under N_2 for 37 h.

7. Beige solid, yield 45%. *Anal*. Calc. for $C_{36}H_{38}Cl_2NOP_2Re$: C, 52.75; H, 4.67; N, 1.71. Found: C, 51.91; H, 4.73; N, 1.78%. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.98 MHz, ppm): −5.2; 27.7 (dd, $^2J_{PP}$ = 260 Hz). MS (DCI/NH_3): *m/z* 820 $[M+H]^+$.

8. Beige solid, yield 10%. *Anal*. Calc. for $C_{30}H_{41}ClNO_2P_2Re$: C, 49.27; H, 5.65; N, 1.92. Found: C, 48.95; H, 5.90; N, 1.72%. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.98 MHz, ppm): 30.7; 33.3 (dd, $^2J_{PP}$ = 224 Hz). MS (DCI/NH_3): *m/z* 732 $[M+H]^+$.

Re(NPh)Br_2(PPh_3)(P∼O) (**9**) and Re(NPh)Br(P∼O)$_2$ (**10**). The same method was used as for **7** and **8**, starting from 0.55 g (2.6 mmol) of P∼OH and 1.362 g (1.3 mmol) of Re(NPh)Br_3(PPh_3)$_2$ in 35 ml of toluene. **9** yield 56%, and **10** yield 14%.

9. *Anal*. Calc. for $C_{36}H_{38}Cl_2NOP_2Re$: C, 47.59; H, 4.22; N, 1.54. Found: C, 46.95; H, 4.08; N, 1.42%. MS (DCI/NH_3): *m/z* 910 $[M+H]^+$. $^{31}P\{^1H\}$ NMR (C_6D_6, 161.98 MHz, ppm): −6.3; 24.1 (dd, $^2J_{PP}$ = 246 Hz).

10 was obtained in 30% yield by refluxing a mixture of 0.355 g (1.7 mmol) of P∼OH and 0.44 g (0.42 mmol) of Re(NPh)Br_3(PPh_3)$_2$ in 20 ml of toluene for 46 h. Concentration of the solution gave a brown precipitate, which was recrystallized from diethyl ether (20 ml). Cooling the solution at −20°C gave **10** as a brown solid which was filtered off, washed with diethyl ether and dried in vacuo. *Anal*. Calc. for $C_{30}H_{41}BrNO_2P_2Re$: C, 46.45; H, 5.33; N, 1.81. Found: C, 46.50; H, 4.77; N, 1.64%. IR (CsI): 1026 cm^{-1}, ν(Re=O). MS (DCI/NH_3): *m/z* 776 $[M+H]^+$. $^{31}P\{^1H\}$ NMR (C_6D_6, 161.98 MHz, ppm): 30.8; 33.1 (dd, $^2J_{PP}$ = 222 Hz). ^1H NMR (C_6D_6, 400.14 MHz, ppm): 0.7–1.6 (dd, 24H, CH_3, $^3J_{HH}$ = 7 Hz, $^3J_{HP}$ = 15 Hz); 2.5–3.4 (d of septets, 4H, CH, $^3J_{HH}$ = 7 Hz, $^2J_{HP}$ = 1 Hz); 6.6–7.8 (m, 13H, Ph).

Re(NPh)I_2(PPh_3)(P∼O) (**11**) and Re(NPh)I(P∼O)$_2$ (**12**). The complexes were synthesized as for **9** and **10**, with Re(NPh)I_3(PPh_3)$_2$ (1.237 g, 1.05 mmol) and P∼OH (0.44 g, 2.09 mmol) in toluene (35 ml) for 47 h. Work-up with ether and purification by column chromatography with $CHCl_3$ and ether as eluents and recrystallization from diethyl ether at −20°C gave **11** (yield 54%) and **12** (yield 13%) as brown microcrystalline compounds.

11. *Anal*. Calc. for $C_{36}H_{38}I_2NOP_2Re$: C, 43.12; H, 3.82; N, 1.40; I, 25.31. Found: C, 41.80; H, 3.75; N, 1.35; I, 25.05%. MS (DCI/NH_3): *m/z* 1004 $[M+H]^+$. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): −6.3; 24.1 (dd, $^2J_{PP}$ = 246 Hz).

12. *Anal*. Calc. for $C_{30}H_{41}INO_2P_2Re$: C, 43.80; H, 5.02; N, 1.70; I, 15.43. Found: C, 41.92; H, 4.93; N, 1.65; I, 15.28%. MS (DCI/NH_3): *m/z* 824 $[M+H]^+$; 696 $[M-HI+H]^+$. $^{31}P\{^1H\}$ NMR ($CDCl_3$, 161.98 MHz, ppm): 31.8; 33.3 (dd, $^2J_{PP}$ = 217 Hz).

3. Results and discussion

3.1. Synthesis

$^iPr_2PC_6H_4OH$ (P∼OH) reacts readily, in refluxing toluene, on ReOX_3(PPh_3)$_2$ and Re(NPh)X_3(PPh_3)$_2$ but the reactions are sensitive to the ligand:metal ratio and care must be taken to use carefully dried and degassed solvents to prevent phosphine oxidation.

A 4:1 ligand to metal ratio gives quantitatively the disubstituted ReYX(P∼O)$_2$ complexes (Y = O, NPh; X = Cl, Br, I). However, when the reaction is performed in a stoichiometric ratio (L:M = 2:1), a mixture of monosubstituted and disubstituted ReYX_2(PPh_3)(P∼O) and ReYX(P∼O)$_2$ complexes is obtained; the ratio ReYX(P∼O)$_2$/ReYX_2(PPh_3)(P∼O) decreases as the size of the halide increases. Such a mixture of complexes was not observed with diphenylphosphinophenol whose reactions were stoichiometric, indicating that the basicity of the phosphine is not the main factor governing the reaction.

In an effort to follow the reaction, to detect intermediate compounds and to confirm that chelation of the phosphine ligand occurs with the concomitant release of both PPh_3 and Cl, we monitored the reaction of P∼OH with ReOCl_3(PPh_3)$_2$ by ^{31}P NMR (Fig. 1). The spectrum after 5 h reveals the presence of all of the expected species. Besides free PPh_3 (singlet at −4 ppm), the major species is ReOCl_2(PPh_3)(P∼O) (**1**) (pair of doublets at 7 and 25 ppm, $^2J_{PP}$ = 262 Hz), followed by ReOCl(P∼O)$_2$ (**2**) (pair of doublets at 34 and 42 ppm, $^2J_{PP}$ = 213 Hz) (vide infra). A third pair of doublets at 20.5 and 31 ppm ($^2J_{PP}$ = 220 Hz) could be assigned to the *trans*-P,P-*trans*-O,O complex ReOCl_2(P∼OH)(P∼O) containing a unidentate P∼OH ligand. The remaining signals, a pair of unresolved peaks at 21.2 and 23.2 ppm and a singlet at 27.2 ppm, which disappear quickly, could correspond to the thermodynamically unstable *cis*-P,P ReOCl(P∼O)$_2$ and the *trans*-P,P ReOCl_3(P∼OH)$_2$ species, respectively. After an extra 10 h under reflux, the spectrum shows free PPh_3, ReOCl_2(PPh_3)(P∼O) (**1**), ReOCl(P∼O)$_2$ (**2**) and ReOCl_2(P∼OH)(P∼O). 20 h later, the spectrum has become remarkably simple: besides free PPh_3, only ReOCl_2(PPh_3)(P∼O) (minor component) and ReOCl(P∼O)$_2$ (major component) are observed. Thus, ReOCl(P∼O)$_2$ is the thermodynamic product, since no further changes occur as heating is continued. Interestingly, under the same experimental conditions, using $Ph_2PC_6H_4OH$ as ligand produced quantitatively ReOCl(P∼O)$_2$.

The corresponding bromo and iodo complexes give the same final products when the reaction is run under identical conditions, starting from ReOBr_3(PPh_3)$_2$ and ReOI_3(PPh_3)$_2$, respectively. ReOBr_2(PPh_3)(P∼O) (**3**) and ReOBr(P∼O)$_2$ (**4**) form in roughly equal amounts, whereas

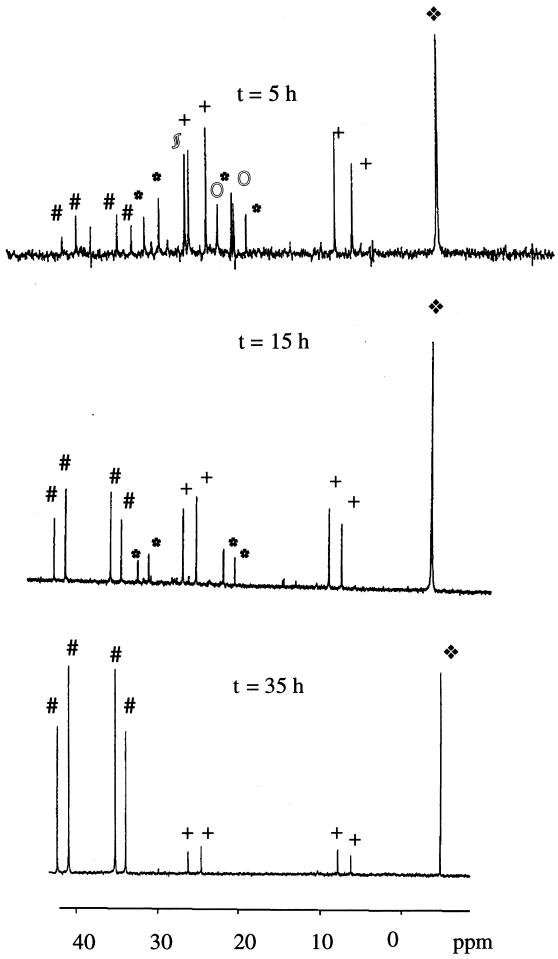

Fig. 1. Monitoring by $^{31}P\{^{1}H\}$ NMR of the reaction of P∼OH on $ReOCl_3(PPh_3)_2$ (2:1 ratio) in refluxing toluene. Spectra at $t = 5$ h (top) (Bruker AMX 300WB), 15 h (middle) and 35 h (bottom) (Bruker ARX 400). (♦) free PPh_3; +, *trans*-P,P $ReOCl_2(PPh_3)(P{\sim}O)$ (**1**); (#) *trans*-P,P $ReOCl(P{\sim}O)_2$ (**2**); (*), *trans*-P,P $ReOCl_2(P{\sim}OH)(P{\sim}O)$; (○) *cis*-P,P $ReOCl(P{\sim}O)_2$; (Ⓢ), *trans*-P,P $ReOCl_3(P{\sim}OH)_2$).

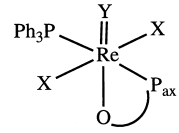
$ReOI_2(PPh_3)(P{\sim}O)$ (**5**) is predominant over $ReOI(P{\sim}O)_2$ (**6**) (∼4:1 ratio). This can be ascribed to the increasing size of the halogen.

The reaction of P∼OH with $Re(NPh)X_3(PPh_3)_2$ follows a similar pattern: a 2:1 ratio leads to a mixture of the monosubstituted and disubstituted species, whereas a 4:1 ratio is needed to obtain $Re(NPh)X(P{\sim}O)_2$.

In all cases, the monosubstituted and disubstituted complexes are successfully separated by column chromatography on silica, using $CHCl_3$ as eluent in one case and ether in the other, and recrystallized from ether.



3.2. Characterization of the compounds

3.2.1. Rhenium(V) oxo complexes

Mass spectrometry confirms the mononuclear formulation based on elemental analysis: the DCI/NH_3 spectra all exhibit the $[M+H]^+$ parent peak. In several cases, $[M-HX+H]^+$ peaks due to halide loss are also observed, suggesting that the bidentate P∼O ligand is more tightly bound than the monodentate halide. Besides the main ligand vibrations, all complexes exhibit a Re=O stretching band in the 953–970 cm^{-1} range, typical of multiply bonded Re=O complexes [17].

Table 1
$^{31}P\{^{1}H\}$ NMR data

Complex	Solvent	δ (ppm)		J_{PP} (Hz)
$ReOCl_2(PPh_3)(P{\sim}O)$ (**1**)	C_6D_6	7.1, 24.7	dd	262
$ReOCl(P{\sim}O)_2$ (**2**)	$CDCl_3$	34.0, 41.6	dd	213
$ReOBr_2(PPh_3)(P{\sim}O)$ (**3**)	$CDCl_3$	8.0, 26.1	dd	260
$ReOBr(P{\sim}O)_2$ (**4**)	$CDCl_3$	34.1, 41.7	dd	212
$ReOI_2(PPh_3)(P{\sim}O)$ (**5**)	$CDCl_3$	6.9, 17.4	dd	257
$ReOI(P{\sim}O)_2$ (**6**)	$CDCl_3$	33.1, 42.4	dd	210
$Re(NPh)Cl_2(PPh_3)(P{\sim}O)$ (**7**)	CD_2Cl_2	−5.2, 27.7	dd	260
$Re(NPh)Cl(P{\sim}O)_2$ (**8**)	CD_2Cl_2	30.7, 33.3	dd	224

$Re(NPh)Br(P{\sim}O)_2$ (**10**)	C_6D_6	30.8, 33.1	dd	222
$Re(NPh)I_2(PPh_3)(P{\sim}O)$ (**11**)	$CDCl_3$	−6.3, 24.1	dd	246
$Re(NPh)I(P{\sim}O)_2$ (**12**)	$CDCl_3$	31.8, 33.3	dd	217

Scheme 2.

The ^{31}P NMR spectrum (in C_6D_6) of $ReOCl_2(PPh_3)(P{\sim}O)$ (**1**) consists of two doublets centred at 24.7 and 7.1 ppm, respectively, with a coupling constant of 262 Hz typical of a *trans*-P,P arrangement. In the structure proposed (Scheme 2), the very stable *trans*-[O=Re–O–] core is assumed to be retained. The downfield signal corresponds to the ring P_{ax} atom as confirmed by the exchange of PPh_3 with pyridine. When pyridine is added to a C_6D_6 solution of **1** in an NMR tube, the AB signal of **1** disappears within 2 h and the *trans*-P,P coupling is lost: new singlets appear at −4 ppm for free PPh_3 and at 19 ppm for a new pyridine complex. Thus, the doublet at 7.1 ppm for **1** corresponds to the labile PPh_3 ligand, which is stereoselectively substituted by pyridine. The upfield shift from 24.7 to 19 ppm experienced by the ring P atom is consistent with the substitution of PPh_3 by pyridine, a stronger σ donor and weaker π acceptor. The stereochemistry of **1** is confirmed by the ^{1}H NMR spectrum. The two pairs of CH_3 groups appear as doublets of doublets at 1.36 ppm ($^3J_{HH} = 7$ Hz, $^3J_{HP} = 15$ Hz) and 1.50 ppm ($^3J_{HH} = 7$ Hz, $^3J_{HP} = 17$ Hz) respectively, shifted slightly from the free ligand value. The two methine protons give a doublet of septets at 3.33 ppm ($^3J_{HH} = 7$ Hz, $^2J_{HP} = 2$ Hz). A

similar multiplet is present at 2.14 ppm ($^3J_{HH}=7$ Hz, $^2J_{HP}=2$ Hz) in the free ligand indicating that the signal has moved downfield on coordination, but that the magnetic equivalence of the two protons is not affected by the bonding to rhenium. This is consistent with the isomer containing the *trans*-[O=Re–O] core, since the other isomers would contain non-equivalent isopropyl groups and, as a consequence, probably give split methine signals. The aromatic protons give rise to five multiplets in the 6.2–8.0 ppm range.

The ^{31}P NMR spectrum of $ReOCl(P\sim O)_2$ (**2**) consists of a pair of doublets (AB spin system) with signals centred at 34.0 and 41.6 ppm, and a $^2J_{PP}$ value of 213 Hz, consistent with two equivalent P atoms occupying *trans* positions in a 'twisted' octahedron (B, Scheme 1). The structure is different to that obtained for diphenylphosphinophenol complexes where the ^{31}P NMR showed two non-equivalent P atoms occupying *cis* positions in a 'twisted' octahedron (A, Scheme 1), as observed in the crystal structure of $ReOCl(Ph_2P\sim O)_2$ [8]. The *trans*-P,P structure is consistent with the ^{1}H NMR data which show the inequivalence of all the protons of the two ligands. The two methyl signals of each ligand, corresponding to 12H, are observed as doublets of doublets centred at 1.4 and 1.7 ppm, respectively, with $^3J_{HP}=17$ Hz and $^3J_{HH}=7$ Hz shifted slightly downfield from the values of 0.9 and 1.1 ppm found in the free ligand. Doublets of septets at 2.8 (1H), 3.0 (2H) and 3.4 (1H) ppm, with coupling constants $^2J_{HP}=1$ Hz and $^3J_{HH}=7$ Hz, are due to the four non-equivalent methine hydrogens that have moved downfield upon coordination, but they are not individually affected by the low symmetry of the complex. Eight multiplets between 6.3 and 7.5 ppm originate from the aromatic protons.

3.2.2. Rhenium(V) imido complexes

The phenylimido complexes **7**–**12** are stable in the solid state and in organic solvents where they are soluble (DMSO, DMF, CH_2Cl_2, $CHCl_3$, THF). The formula proposed is based on microanalyses and mass spectra (DCI/NH_3), in which the parent $[M+H]^+$ peaks and $[M-HX+H]^+$ peaks corresponding to halide loss are observed. The Re=NPh stretch of phenylimido-Re(V) complexes, difficult to detect in the IR because of overlapping ligand vibrations, is only clearly identified at 1025 cm^{-1} for **9**, in agreement with the literature [17].

The trends observed above for the oxo systems apply to the imido complexes as well. The ^{31}P NMR spectra of the $Re(NPh)X(P\sim O)_2$ complexes (X=Cl, (**8**); X=Br, (**10**); X=I, (**12**)) in $CDCl_3$ all contain doublets at ~31 and ~33 ppm with J_{PP} coupling constants of ~220 Hz, consistent with *trans*-P,P 'twisted' octahedral species. The $Re(NPh)X_2(PPh_3)(P\sim O)$ compounds **7**, **9** and **11** also adopt a *trans*-P,P structure, since their ^{31}P NMR spectra show doublets around −6 and 26 ppm ($^2J_{PP}$ of 246–260 Hz). By analogy with $ReOCl_2(PPh_3)(P\sim O)$, the peak at ~26 ppm is assigned to the P~O ligand on the basis of PPh_3 exchange. When pyridine is added to a solution of $Re(NPh)Br_2(PPh_3)(P\sim O)$, the doublets at −6 and 26 ppm are replaced by two singlets, one at −4 ppm for free PPh_3 and the other at 22 ppm for the new pyridine complex.

4. Concluding remarks

All Re(V) complexes prepared in this study contain phosphinophenolato ligands in the bidentate anionic $P\sim O^-$ form, with one phenolato oxygen atom *trans* to the multiple bond. It has been shown previously that the disubstituted $ReOX(Ph_2P\sim O)_2$ complexes with a *cis*-P,P 'twisted' octahedral structure were the only products isolated when 2 equiv. of $Ph_2P\sim OH$ were reacted on $ReOCl_3(PPh_3)_2$ in refluxing toluene. However, under the same conditions, $^iPr_2P\sim OH$ leads to monosubstituted $ReOX_2(PPh_3)(P\sim O)$ complexes, along with $ReOX(P\sim O)_2$. Therefore chelation of one P~OH ligand takes place easily but binding the second ligand is more difficult, observations that suggest that although P~OH is a stronger σ donor, its reactivity is hampered by its greater steric demand. The fact that the *trans*-P,P 'twisted' octahedral structure is favoured for all $ReOX(P\sim O)_2$ complexes indicates that the electronic effect is not the factor determining the stereochemistry of the complexes and, as a consequence, that the steric effect is important. The reaction of the phenylimido precursor with P~OH does not follow the same trends as the oxo precursor since both ligands give *trans*-P,P isomers. A possible explanation is that the imido phenyl group increases steric hindrance as a whole even for $Ph_2P\sim OH$.

Thus, the thermodynamic stability and the structural variety of the Re(V) complexes with P~O ligands, together with their presence as a single isomer, suggest that it is worth pursuing the development of these molecules as candidates for eventual applications as radiopharmaceuticals.

Abstract

The porous networks of $[Cu_2(malonato)_2(bipy)(H_2O)_2]\cdot H_2O$ (**I**) and $[Cd(malonato)(py)(H_2O)]$ (**II**) were co-assembled by rigid 4,4′-bipyridine or pyridine and the flexible malonate ion. In the network of compound **I**, 4,4′-bipy acts as a bone, separating and supporting the flexible malonate–Cu units to form a nearly strain-free square framework and a chiral square cavity in the solid state. In compound **II**, the rigid pyridine rings sustain the network by saturating the coordination sphere of Cd(II) ion to avoid a high coordination number and self-inclusion, and to prevent the two-dimensional network from forming a non-porous phase. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Rigid and flexible ligands; Self-assembly; Supramolecules; X-ray structure

1. Introduction

It is becoming increasingly clear that transition metal-based self-assembly processes can lead to functional supramolecular frameworks that exhibit potential applications as electrical conductors [1] and molecular magnets [2,3] and in inclusion chemistry [4,5], molecular recognition [6,7] and catalysis [8,9]. Previous strategies of designing open frameworks mostly focused on using rigid rod-like or tritopic ligands (e.g. cyanide, bi- or tri-pyridyl, *p*-quinone, pyrazine, trimesic acid) as spacer ligands [8–12]. Nearly all the spacer ligands used have one or several aromatic rings as the basic components [13–15]. Although this rigidity and aromatic component can assist in the design of network, it frequently limits their ability to accommodate ionic and non-ionic guest species and limits the variety of framework compositions and topologies [16]. In contrast, the assembly of inorganic polymers by flexible ligands always resulted in the formation of non-porous phases [17–20]. The exploitation of spacers with conformational freedom is expected to play important roles in self-assembly via coordination, in which the flexible components of such linkers in a coordination polymer usually lead to interpretation and self-inclusion, reflecting both the properties of the rigid aromatic ring and flexible connector [21–24]. Combining both rigid bone and flexible tissue in one system is the basic character existing throughout nature [25–28]. To investigate the parameters contributing to the assembly of materials from different molecular building blocks, we recently aimed at constructing porous polymers by co-assembling both rigid (4,4′-bipyridine or pyridine) and flexible (malonate anion) ligands with transition metal ions. Here, we report the syntheses and structural characters of two complexes $[Cu_2(malonato)_2(bipy)(H_2O)_2]\cdot H_2O$ (**I**) and $[Cd(malonato)(py)(H_2O)]$ (**II**), bearing both flexible and rigid ligands. The structure of complex **I** has been partly communicated [29].

2. Results and discussion

2.1. Structure of $[Cu_2(malonato)_2(bipy)(H_2O)_2]\cdot H_2O$ (*I*)

Complex **I** was synthesized by the reaction of $Cu(C_3H_2O_4)\cdot 2H_2O$ and 4,4′-bipyridine in H_2O–EtOH at ambient temperature. X-ray analysis reveals that the malonate ion and 4,4′-bipyridine co-assembled with Cu(II) ion in compound **I** to form a two-dimensional square network possessing two kind of squares (Fig. 1). A small planar square was constructed with Cu(II) ions and malonate ions at each

corner and side, respectively. Each Cu(II) is also bridged by one 4,4′-bipy, thus forming a large square with each edge shared by one malonate group and one 4,4′-bpy ligand. The coordination geometry about each Cu(II) is slightly distorted square pyramidal with three oxygen atoms from two different malonate ions and one nitrogen atom of 4,4′-bpy positioned in the basal plane and one water molecule occupying the apex position. The bond lengths observed in compound **I** are comparable to those found in similar structures (see Table 2) [30–35]. It is interesting that all the planar squares are distorted only to a very small extent, although the malonate ion is a typical flexible ligand. The square planar angles are 89.89(1) and 89.99(1)° in the large square and 89.25(3) and 89.35(3)° in the small one, very close to the ideal square planar. To the best of our knowledge, the square net motif in compound **I** is closest to the ideal square planar among similar 4,4′-bipy bridged networks. In the infinite network, the square planar angles are reported as ranging from 82.0 to 88.4° [8,9,15,36–41]. The ideal squares are only observed in zero-dimensional molecular cycles, for the right bond angles (90°) rule out the formation of other cyclic oligomers which must have significant ring strain [11,42]. Here, the rigid character of 4,4′-bpy is well preserved in this network and showed the co-effect of both rigid and flexible building blocks. Flexible malonate ions adopt a bridging position which enhances the stability of the two-dimensional network, adjusts the structural distortion and makes the network essentially strain-free, corresponding to the high-order square network. Rigid 4,4′-bpy functions as a bone linked by flexible tissue (small squares) to sustain and dominate the general formation of the network. The size of the squares of compound **I** have dimensions of $15.776(3) \times 15.786(2)$ Å and $4.644(2) \times 4.649(2)$ Å (Fig. 1). The two-dimensional networks are stacked parallel but in a staggered manner on each other along the *z*-axis, with an interplanar separation of 3.785 Å and angle of 45°. The packing of the two-dimensional polymers reveals that the small malonate rings in one layer fit exactly into the large rings in the next, almost as if the two rings are acting as templates for each other. The very short interplanar distance means that the networks are self-clathrated with the small squares of one layer fitting into the large squares of adjacent layers.

Complex **I** crystallizes in the chiral space group $P2_12_12_1$. It has crystallographically imposed C_2 symmetry with a half-cycle of the molecule in the asymmetric unit. Complex **I** is therefore a chiral infinite net array in the solid state. Therefore, no chiral auxiliary ligands are required [43–45]. Each edge of the small square, i.e. each pair of Cu2, has a helical structure. The overall structure of the small square in compound **I** could therefore be described as a cyclic helicate. The chirality of the small squares is succeeded by the large square of compound **I**, and forms large square cavities bearing chiral surroundings.

2.2. Structure of [Cd(malonato)(py)(H_2O)] (*II*)

Complex **II** was synthesized by the reaction of $(CdSO_4)_3 \cdot 7H_2O$, malonic acid and pyridine in aqueous solution. X-ray analysis reveals that complex **II** possesses a two-dimensional sheet structure (Fig. 2). Each Cd(II) atom is in an octahedral surrounding which is chelated by one malonate ion (forming a six-membered boat-type ring) and bound to carboxyl oxygen atoms of two adjacent six-membered boat-type rings. The apex positions are occupied by water and

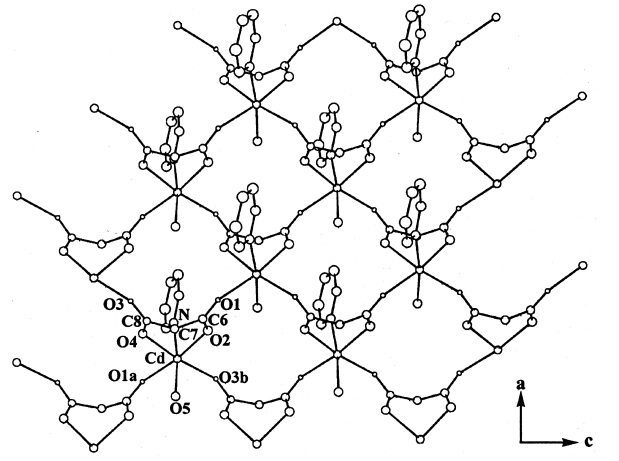

Fig. 2. Perspective view of the *ac* plane of the infinite two-dimensional layer sheet structure of compound **II**.

pyridine ligands, respectively. Every four adjacent Cd(II) atoms form a 16-membered large ring (Cd4O8C4) with size 5.71×5.58 Å. The four equatorial oxygen atoms are nearly coplanar with the Cd(II) atom and this coordination plane makes a 45° dihedral angle with the extended net plane (*ac* plane). Each equatorial coordination plane is perpendicular to four adjacent planes of bridged Cd octahedra. The N(pyridine)–Cd–O(H_2O) linkage is slightly bent (173.5(4)°) and nearly perpendicular to the equatorial coordination plane. The pyridine groups are alternatively located above and below the net plane. The malonate ion acts as a tetradentate ligand (chelate, bridge, bridge) in compound **II**. All boat-type six-membered malonato-Cd rings are arranged in one direction that lead to anisotropy of this network. Parallel layers stack along the *b*-axis and the interlayer distance is 9.105 Å (Fig. 3).

All malonate ligands in compound **II** act in the chelating mode to form a boat-type six-membered conformation and act as bridges to link adjacent metal ions, like the woof in the woven coordination polymer to form the two-dimensional network. Here, the rigid pyridine rings play an important role in sustaining this network by preventing it from intralayer shrinking, interlayer condensing, and by saturating the coordination space of Cd(II) ion to avoid a high coordination number and self-inclusion [25,30–35].

The flexibility of the malonate ion has been widely verified by X-ray structures of a series of malonate complexes [25–28,30–35,46–48]. It is also known that self-assembly of the malonate ion with metal ion always results in formation of a non-porous framework. Here, it is demonstrated that porous frameworks can be co-assembled by the flexible malonate ion accompanied by a rigid ligand. It is a new strategy for designing and constructing novel supramolecular topologies. The relation between the rigid building block and the flexible one is very important in designing frameworks with desirable topologies and architectures. In complex **I**, the rigid building block and the flexible one are co-assembled in the same layer. They are mutually linked, mutually sustained and adjusted to form a strain-free framework. The rigid and flexible blocks are separated by each other in the network of compound **I** and this is one key factor in the formation of chiral polyporous framework of compound **I**. By the bridging and chelating properties of flexible ligand malonate dianion, a chiral two-dimensional network with chiral large cavities is constructed (**I**). In complex **II**, the rigid ligand is pyridine, a terminal monodentate ligand. In contrast to compound **I**, the pyridine block is unable to separate the malonate–Cd units. But it is the rigid pyridine block that prevents the condensation of malonate–Cd network and separates the network layers. It is shown that the rigid template tends to lower the dimensionality and regularize a flexible system, whereas a flexible template decreases the structure strain in a rigid system. The co-assembly of both rigid and flexible ligands should be a very exciting strategy for the design of new materials having well-defined functions.

3. Experimental

3.1. Materials and methods

All starting materials were purchased from Aldrich or other sources and used without further purification. Elemental analyses were carried out by the Structure Research Laboratory, University of Science and Technology of China.

3.2. Preparation of $Cu(C_3H_2O_4)\cdot 2H_2O$

To a mixture of copper(II) carbonate (2.0 mmol) and hot water (20 ml), malonic acid (1.9 mmol) was added and a dark blue solution was obtained. This was filtered and condensed to 5 ml and a large amount of crystals were obtained. *Anal*. Calc. for $CuC_3H_6O_6$: C, 17.70; H, 3.47. Found: C, 17.14; H, 3.59%.

3.3. Preparation of $[Cu_2(malonato)_2(bipy)(H_2O)_2]\cdot H_2O$ (*I*)

To an aqueous solution (30 ml) of $Cu(C_3H_2O_4)\cdot 2H_2O$ (1.0 mmol) an ethanol solution (10 ml) of 4,4′-bpy (0.5 mmol) was added. The initially formed very small amount of fine precipitate was filtered off, and the clear filtrate was allowed to stand for several days at ambient temperature to give deep-blue crystals. Yields in excess of 90% were

3.4. Preparation of [Cd(py)(malonate)] (II)

To an aqueous solution of $(CdSO_4)_3\cdot 7H_2O$ (0.333 mmol) was added pyridine (1 mmol) and malonic acid (1 mmol) with stirring. The pH was adjusted to 6 using dilute NaOH solution. Diffraction-quality crystals had grown after several days. Yield (291 mg, 92%). *Anal*. Calc. for compound **II**: C, 30.77; H, 2.88; N, 4.49. Found: C, 30.87; H, 2.91; N, 4.50%.

3.5. Crystal structure determinations

Data were measured on a Rigaku AFC5R diffractometer for complex **I** and an Enraf-Nonius CAD4 diffractometer for complex **II** with graphite-monochromated Mo Kα radiation at 293 K. Cell constants and orientation matrix for data collection were obtained from least-squares refinement, using the setting angles of 20 reflections in the range $8<\theta<27.5°$ for compound **I** and $2.24<\theta<24.93°$ for compound **II**, measured by the computer-controlled diagonal-slit method of centering. Scattering factors were taken from Cromer and Waber [49]. The ω–2θ scan mode with a maximum 2θ value of 50.0° was used to collect intensity data. The data were corrected for Lorentz polarization effects. The structure was solved by direct methods (SHELXS-86) and refined by full-matrix least-squares calculation (SHELXL-93). The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included, but their positions were not refined. All calculations were performed on an INDY workstation using a Mo1EN/PC [50]. Details of crystal data, collection and refinement of the two complexes are listed in Table 1. The selected bond distances and angles of compounds **I** and **II** are presented in Tables 2 and 3.

Abstract

Copper(II)–histamine and copper(II)–L-histidine equilibrium systems were studied in fluid aqueous solution by ESR spectroscopy. Eighty-seven spectra taken in a circulating system at various ligand-to-metal concentration ratios and pH were analysed. The experimental curves were decomposed to one to four component spectra which were built up from the hyperfine lines of ^{63}Cu and ^{65}Cu, and a maximum of four non-equivalent ^{14}N nuclei. The isotropic ESR parameters (*g*-factors, hyperfine coupling constants and relaxation parameters) and the relative concentrations of the different species were optimized. New, pH-potentiometrically non-identified species were also considered in the equilibrium models. In the copper(II)–histamine system the complex $[CuLH_{-2}]$ was added to the species $[CuLH]^{3+}$, $[CuL]^{2+}$, $[CuLH_{-1}]^{+}$, $[Cu_2L_2H_{-2}]$, $[CuL_2H]^{3+}$ and $[CuL_2]^{2+}$. In the copper(II)–L-histidine system, in addition to the complexes $[CuLH]^{2+}$, $[CuL]^{+}$, $[CuLH_{-1}]$, $[Cu_2L_2H_{-2}]$, $[CuL_2H_2]^{2+}$, $[CuL_2H]^{+}$ and $[CuL_2]$, the new species $[CuLH_2]^{3+}$ and $[CuLH_{-2}]^{-}$ were found. The relative concentrations obtained from the ESR spectra are in good accordance with the concentrations calculated from the literature pH-potentiometric formation constants. The two ligands in their 'LH' states are bound differently: the histamine by the imidazole, and the L-histidine through the amino and the carboxylate groups in equatorial positions (complexes $[CuLH]$, $[CuL_2H]$ and $[CuL_2H_2]$). For the $[CuL]$, $[CuL_2H]$ and $[CuL_2]$ complexes of both histamine and L-histidine, the first 'L' ligand is coordinated equatorially by the amino and imidazole nitrogens. The second 'L' ligand in the $[CuL_2]$ complexes is either bound in the former way, or its imidazole group occupies an axial site. The carboxylate group of L-histidine is coordinated to the metal ion in each complex, in either an equatorial or an axial position. The deprotonation of the $[CuL]$ complex takes place from the imidazole ring, which is followed by the proton loss of the equatorial water molecule in the highly alkaline region. ©2000 Elsevier Science Ltd All rights reserved.

1. Introduction

The complex bis(L-histidinato)copper(II) of biological importance is a good example for the difficulties and controversy encountered in the investigation of coordination modes in solution. Histamine-like equatorial binding through the amino and imidazole nitrogen atoms of both ligands was suggested by CD [1], Raman [2] and electronic [3] spectral studies, and on the basis of 13-C and 1-H NMR relaxation evidence [4]. At the same time, other NMR [5] and visible spectral [6] data were interpreted by the histamine-like equatorial coordination of the first ligand, but the glycine-like equatorial binding of the second ligand by the amino nitrogen and carboxylate oxygen atoms. Other works showed the co-existence of both structures. Goodman et al. [7] analysed the superhyperfine (shf) structure in the high-field ^{63}Cu line of the second-derivative fluid-phase ESR spectrum. They obtained 50% relative concentration for both species. The same isomeric equilibrium was supported by CD and visible spectral evidence [8]. Valensin et al. found 24% 4N and 76% 3N isomers by 13-C and 1-H NMR relaxation measurements [9]. Pasenkiewicz-Gierula et al. [10] obtained 80% isomer of bis(histamine)-like coordination and 20% complex of mixed (histamine- and glycine-like) binding mode by ESR studies; they described the liquid-phase spectrum as that of fast-tumbling molecules of axial symmetry, fitting the anisotropic ESR parameters and the rotation correlation time.

Recently, we have developed a new computer program [11] for the decomposition of multicomponent liquid-phase

ESR spectra, which has been successfully applied to obtain the isotropic ESR parameters and the relative concentrations of the major and minor complexes in the copper(II)–glycylglycine [12] and copper(II)–L-serine [13] systems. For the bis complexes, equilibria of various coordination modes have been found.

In the present paper we report the results of an ESR study of the copper(II)–histamine and copper(II)–L-histidine systems. The aim of our work was to identify all complexes which form in fluid aqueous solution, including the possible isomers of the complex bis(L-histidinato)copper(II), and to characterize the modes of coordination for these species on the basis of their ESR parameters. We also scrutinized the real nature of 'histamine-like' coordination, since structural identification of the histidine complexes is generally based on comparison with the analogous histamine complexes. Furthermore, comparison of the corresponding histamine and histidine complexes may clarify the role of the carboxyl group in the coordination.

2. Experimental

2.1. Reagents and solutions

Reagents of analytical grade from Reanal (Hungary) were used without further purification. The neutral ligand histamine is denoted by L, while the zwitterionic L-histidine is symbolized by HL. The copper(II) concentration of the solutions was 5 mmol dm^{-3}. It seemed reasonable to make solutions in which the various species are predominant or form in as high a concentration as possible, so that we obtain the most reliable parameter values. At the same time, solutions with comparable concentrations of the species were also needed, mainly to verify the concentration distribution, although an important condition was that at most four complexes be present in a solution, since the EPR program allows decomposition of one to four component spectra. Accordingly, the ligand-to-metal concentration ratios were 1:1 and 20:1 in the case of histamine, and 1:1, 2:1, 4:1 and 20:1 for the copper(II)–L-histidine system. The optimum pH values were chosen according to the species distribution curves, which were calculated by the PSEQUAD program [14] from literature formation constants [15–20]. The pH was adjusted with HCl, then NaOH to an accuracy of 0.01 pH unit using a RADELKIS OP208/1 pH meter equipped with a RADIOMETER GK2401C combined glass electrode. The electrode was calibrated with IUPAC standard buffers from RADIOMETER.

2.2. ESR measurements

A stock solution of 20 cm^3 volume was titrated under argon atmosphere. The sample was mixed by bubbling the gas through the solution. A MASTERFLEX CL peristaltic pump ensured the circulation (14 cm^3 min^{-1}) of the solution through the capillary tube in the cavity. The ESR spectra were taken after 3 min circulation at the chosen pH at room temperature (291 K) on an upgraded JEOL JES-FE3X spectrometer with 100 kHz field modulation, using a manganese(II)-doped MgO powder for the calibration of g-measurements. A Lake Shore model 647 magnet power supply and a Stanford model SR830 DSP lock-in amplifier were applied. The field was measured by a temperature-stabilized Hall probe with an accuracy of 10^{-5} T. The spectrometer was controlled by a Pentium 100 computer. The spectrum of the capillary tube filled with distilled water was recorded together with the Mn(II)-doped MgO under the same conditions. This curve was subtracted from the spectra of the solutions.

2.3. Evaluation of spectra

The copper(II) chloride, used to make the stock solution, was a natural mixture of isotopes, therefore the spectrum of each species was calculated as the superposition of spectra containing ^{63}Cu and ^{65}Cu according to their natural abundances. The different widths of copper hyperfine lines were taken into consideration by fitting the relaxation parameters [21,22] α, β, γ, where $\sigma_{MI} = \alpha + \beta M_I + \gamma M_I^2$. The parameter g_0, the hyperfine (hf) coupling constant A_0, the nitrogen superhyperfine coupling constants a_{N0}, the above relaxation parameters, and the relative concentration of each species were varied, until the sum of the squares of differences between the calculated and measured intensities (SSQD) reached its minimum. The spectral fit is characterized by the average square deviation SQD (i.e. SSQD divided by the number of spectral points, 2000). The concentration of each species was related to the overall concentration of ESR-active species.

In the first step we evaluated those spectra which are dominated by one complex; this resulted in the ESR parameters of the major species. Next we proceeded to spectra in which the previously neglected minor complexes gain importance. Then parameters of new species were optimized, while those of known complexes were fixed. Iteration proceeded by analysing again the first spectra in which the minor components with fixed parameter sets were considered too. This procedure only allows the use of a reasonable number of adjusted parameters (no more than 20) in each consecutive step. The sensitivity of spectral fit to the various parameters was monitored by the values CNF (CNF is defined as the variation of the respective parameter that increases the SQD by the value of the square noise of the spectrum). They give the criterion for a given spectrum which parameter set(s) should be fixed (at the averages obtained from other spectra). The CNF values for the parameters of the species in low concentrations (below 10%) are large. In the computation of the average values and the standard deviations of the parameters, only the data of those spectra were considered in which the respective parameter set was optimized.

The Fermi term K was derived from two adjusted parameters: the isotropic hf coupling constant A_0 and g_0 as $K=A_0+P(g_0-g_e)$, where $P=0.036$ cm^{-1} is the dipole coefficient of the copper(II) ion and $g_e=2.0023$ is the free electron g-factor [23,24].

3. Results and discussion

3.1. Spectral fitting

The rate of interconversion between the different species is considered to be slow on the ESR time-scale, since the experimental curves could be well described as sums of individual spectra. A Lorentzian lineshape gave a satisfactory fit in all cases. Fig. 1 illustrates that the ESR spectra after the elimination of the 'glass' signal allow an excellent spectral fit. Typically, the average deviation of the calculated and measured intensities was 1.2–1.5 times as much as the noise.

3.2. Distribution of copper(II) amongst different species

Besides the good spectral fit, we rigorously insisted on another criterion, when verifying the equilibrium model for a system. A large number of spectra were analysed, and we accepted the set of species forming under the chosen conditions only if the ESR parameters of the different complexes did not show a systematic change with either the pH or the ligand concentration.

For the copper(II)–histamine system, in acidic and neutral solutions, the formation of the complexes $[CuLH]^{3+}$, $[CuL]^{2+}$, $[CuL_2H]^{3+}$ and $[CuL_2]^{2+}$ is generally accepted on the basis of pH-metric studies [15,16,25]. In equimolar solution above pH ~ 6 a deprotonated species, the complex $[Cu_2L_2H_{-2}]^{2+}$, was also shown [15,16], together with the monomer $[CuLH_{-1}]^{+}$ [16,25]. The corresponding concentration distribution curves are shown in Fig. 2. Our ESR results are in accordance with the above model (Fig. 2). The only difference is that the complex $[CuLH]^{3+}$ was formed in higher concentration than was expected on the basis of pH-metric data. Therefore, instead of the literature value of 12.88 [15], we used 13.2 as an estimate for the formation constant ($\log \beta_{111}$) of the species $[CuLH]^{3+}$ during the calculation of the distribution curves. Then the relative concentrations of the various species, obtained from the ESR spectra, agreed well with the calculated concentrations (Fig. 2). In equimolar solution over pH ~ 6, a considerable decrease in the ESR intensity was accompanied with the formation of the complex $[Cu_2L_2H_{-2}]^{2+}$. This fact confirms that the dinuclear complex is ESR inactive. The distributrion curve (Fig. 2) shows that some $[CuL_2]^{2+}$ complex is also present in addition to the dimer. The question is whether the complex $[CuLH_{-1}]^{+}$ forms [25,16], or not [15]. The spectra in the slightly alkaline pH region could not be described only with the parameters of the complex $[CuL_2]^{2+}$; they were of a mixed character. Their very low intensity, however, made the exact

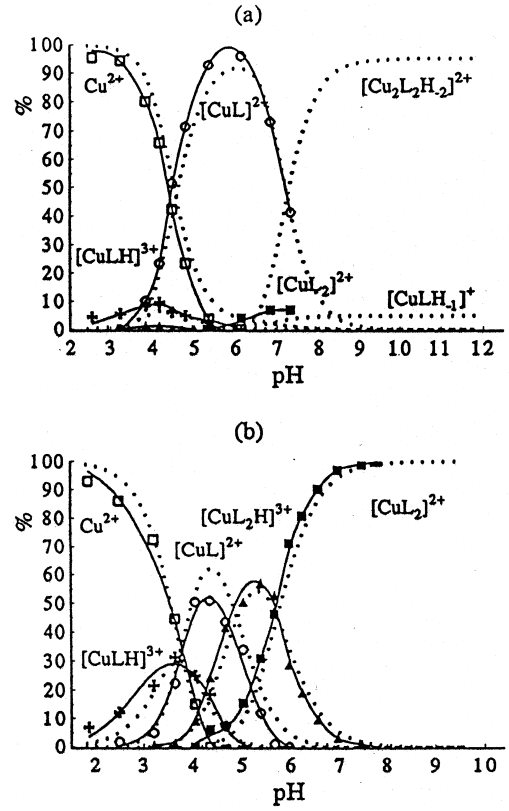

Fig. 2. Species distribution curves for the copper(II)–histamine system: (a) in equimolar solution, and (b) at a ligand-to-metal concentration ratio 20:1. The copper(II) concentration is 5 mM. Dotted lines show the concentrations of the complexes $Cu_pL_qH_r$, which were calculated from literature formation constants β_{pqr}: $\log \beta_{011}=9.81$, $\log \beta_{012}=15.84$, $\log \beta_{111}=12.88$, $\log \beta_{110}=9.56$, $\log \beta_{121}=21.82$, $\log \beta_{120}=16.06$ [15], $\log \beta_{11-1}=1.2$, and $\log \beta_{22-2}=7.0$ [16]; symbols connected by a solid line show relative concentrations from the ESR spectra.

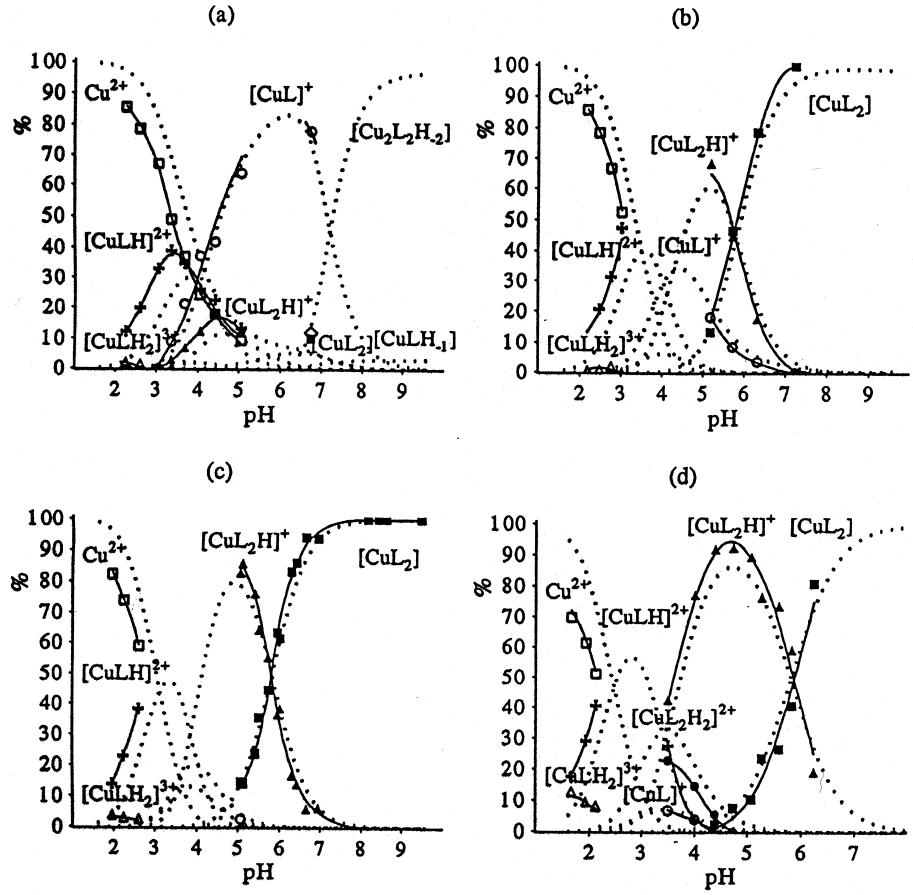

Fig. 3. Species distribution curves for the copper(II)–L-histidine system: (a) in equimolar solution; (b) at a ligand-to-metal concentration ratio 2:1; (c) at a ligand-to-metal concentration ratio 4:1; (d) at a ligand-to-metal concentration ratio 20:1. The copper(II) concentration is 5 mM. Dotted lines show the concentrations of the complexes $Cu_pL_qH_r$, which were calculated from literature formation constants β_{pqr}: $\log \beta_{011} = 9.06$, $\log \beta_{012} = 15.08$, $\log \beta_{013} = 16.62$, $\log \beta_{111} = 14.14$, $\log \beta_{110} = 10.15$, $\log \beta_{122} = 27.27$, $\log \beta_{121} = 23.83$, $\log \beta_{120} = 18.03$ [17], $\log \beta_{11-1} = 2.47$ [18,19], and $\log \beta_{22-2} = 8.0$ [20]; symbols connected by a solid line show relative concentrations from the ESR spectra.

evaluation impossible. The presence of a few per cent of the monomer $[CuLH_{-1}]^+$ really seems likely. Over pH ~ 11, a slow increase in intensity was observed in parallel with the formation of a new deprotonated ESR-active species, the complex $[CuLH_{-2}]$.

The pH-potentiometric measurements for the copper(II)–L-histidine system were interpreted in terms of the formation of the complexes $[CuLH]^{2+}$, $[CuL]^+$, $[Cu_2L_2H_{-2}]$, $[CuL_2H_2]^{2+}$ $[CuL_2H]^+$ and $[CuL_2]$ [17–20], and in equimolar alkaline solutions the presence of the complex $[CuLH_{-1}]$ was also assumed [18,19,25]. Our ESR results support the formation of all these species. In addition, we found two other complexes. In acidic solutions the ESR parameters of the aqua complex differed from those obtained in the absence of the ligand. The difference depended on the pH, and varied also with the ligand concentration. These facts suggested the coordination of the protonated amino acid $[LH_2]^+$ to the metal ion too. Completing the equilibrium model with the $[CuLH_2]^{3+}$ complex, the above anomalies ceased. As compared to the copper(II)–histamine system, another difference was that in equimolar alkaline solutions the deprotonated mono complex $[CuLH_{-1}]$ formed in a significantly higher concentration with the L-histidine ligand: we found in this region an intensity decrease of less extent than with the copper(II)–histamine system. From the amplitude ratio of the high-field copper peak to the manganese lines of the external standard in the cases of $[CuLH_{-1}]$ and $[CuL]^+$, we estimated the relative concentration of the $[CuLH_{-1}]$ complex to be about 20%, if the small linewidth change was also considered. This concentration corresponds to a formation constant of the complex larger than 1.5 [25], and closer to the other pH-metric $\log \beta_{11-1}$ of 2.47 [18,19]. Therefore we used this latter value for calculation of the concentration distribution (Fig. 3). With the above modifications in the strongly acidic and alkaline pH regions, the agreement between our relative concentrations and the pH-metric concentrations is good (Fig. 3). The relatively high concentration of the $[CuLH_{-1}]$ complex allowed us to obtain its ESR parameters, and to follow the deprotonation process leading to the formation of the $[CuLH_{-2}]^-$ complex over pH ~ 11. It should be noted that the interconversion of the deprotonated mono complexes proved to be reversible: their parameters obtained from the spectra taken during the 'ordinary' titration were in good agreement with the data gained

from the spectra recorded during the 'backward' titration of a strongly alkaline solution with HCl. That is, the copper(II)-catalysed oxidation of the ligand [25] could be neglected in argon atmosphere during the relatively short period of measuring the ESR spectra.

At excess of both ligands, in slightly acidic solution the species $[CuL_2H]$ is formed in high concentration (Figs. 2 and 3). Its ESR spectrum could be described well as a one-component curve with a 3N shf pattern, suggesting one kind of coordination in this complex.

The species $[CuL_2]$ is predominant at ligand excess in slightly alkaline media. In the case of the L-histidine complex an isomeric equilibrium was pointed out [7–10]. Our results also support the presence of different structures in this species: a much better agreement of the calculated and measured intensities could be achieved if the experimental curves were calculated as sums of two component spectra. The spectrum of lower g_0 and A_0 (spectrum 1) gave the major, while that of higher g_0 and A_0 (spectrum 2) the minor contribution to the overall curve. The SQD values were reduced by 45–50% as compared to those for the one-component model. The equilibrium was supposed to occur between the histamine-like equatorial binding of both ligands (4N coordination) and the mixed (glycine and histamine) type equatorial ligation (3N coordination) [7–10]. The question is, whether spectrum 1 is to be assigned to the 4N and spectrum 2 to the 3N molecules ('4N + 3N' model) or vice versa ('3N + 4N' model). Unfortunately, the analysis of the shf structure alone did not offer unambiguous proof for or against these models, since a spectral fit of the same quality could be obtained for them. Moreover, the '4N + 4N' model, which corresponds to a possible geometric isomerism of bis(histamine) coordination, could not be distinguished from the former models. The differences in SQD between the various models for the same spectra were 1–4%. It was striking, however, that spectrum 1 could be described well in all cases by a shf pattern of four equivalent nitrogen nuclei (models '4N + 3N' and '4N + 4N'), and spectrum 2 by the 3N pattern ('4N + 3N' model). At the same time, the assumption of a 4N splitting for the spectrum 2 (models '3N + 4N' and '4N + 4N') resulted in unreasonably low shf coupling constants (average value 8–9 G) compared to the other complexes in this system (Table 1) and to complexes of similar ligands [26]. It was only the '4N + 3N' model which resulted in reasonable shf coupling constants for both isomers. Further evidence against the '4N + 4N' model is that the CD curves indicated unambiguously the presence of the glycine-like bonded L-histidine in this complex [8]. At the same time, two additional facts support the '4N + 3N' model: (1) the 4N coordination represents a stronger ligand field which is likely to reduce g_0, compared to the 3N species (see details in Section 3.3); (2) the CD curves are highly dominated by the ligands of histamine-like binding [8], thus a higher concentration is expected for the 4N isomer. Accordingly, for the $[CuL_2]$ complex we assigned the 4N shf pattern to the major component spectrum of lower g_0 and A_0, while the 3N shf splitting was assigned to the minor component curve of higher g_0 and A_0. This model resulted in a good spectral fit also for the other spectra; the parameters and the weights of the component spectra did not depend on either the pH or the ligand concentration.

Our interpretation regarding the spectra and the coordination modes of the above complex differs in some points from that of Goodman et al. [7]. According to our data, the centres of the high-field ^{63}Cu peaks are at 3302 and 3309 G for the 3N and the 4N isomers, respectively, while this line lies at 3315 G for the $[CuL_2H]^+$ complex (at 9.5 GHz used in Ref. [7]). The same difference of 7 G in the line positions of the isomers was found in Ref. [7], however, owing to lack of accurate g_0 and A_0 Goodman et al. assigned the line at higher field to the 3N isomer, presumably because it is closer to the corresponding line of the $[CuL_2H]^+$ complex with three equatorial nitrogens (as can be seen in Fig. 5 of Ref. [7]).

The $[CuL_2]^{2+}$ complex of histamine is similar to the corresponding L-histidine complex in every respect. Its ESR spectra also indicate an isomeric equilibrium: the SQD values for the two-component models were lower by 20–25% than for the one-component description of the experimental spectra. The analysis of the superhyperfine structure led to the same conclusions, and we assigned the component spectra to the isomers in the same way as for the histidine complex. The only difference is that here the concentrations of the isomers are nearly equal.

3.3. ESR parameters and the structure of complexes

The conclusions with respect to the structure of the complexes were based upon the following statements.

A stronger ligand field in the equatorial plane tends to decrease g, and this leads to a larger value of A in the case of effective D_{4h} symmetry [23]. An increase in the ligand field is reflected in a blue shift of the visible absorption band; this effect is the largest for the amino nitrogen, intermediate for the imidazole nitrogen, smaller for the carboxylate oxygen of our ligands, and smallest for the hydroxide and water oxygen atoms [3]. More covalent metal–ligand bonds (that is, higher extent of electron delocalization from the $d_{x^2-y^2}$, d_{xy}, d_{xz} and d_{yz} orbitals to the ligands) promote the decrease in g and the parallel increase in A through reduction of the spin–orbit coupling constant too [27,28]. Stronger axial bonds, in turn, cause a moderate red shift of the d–d band [3], an increase in g and decrease in A [23].

The value of g_0 is slightly sensitive, while A_0 is highly sensitive to the geometric distortions. When a significant decrease in g_0 is accompanied with only a small increase or even a decrease in A_0, this change is a diagnostic sign of a rhombic distortion which induces a 3d–4s orbital mixing, reducing the Fermi term and hence A_0 [24].

In the case of the D_{4h} symmetry, the increase of the Fermi term indicates a less covalent in-plane σ-bond, except for those complexes in which the latter bond is highly ionic (then an opposite tendency was observed) [24].

The isotropic shf coupling constant a_{N0} is a direct measure of the unpaired spin density at the nitrogen nuclei [23]: both the stronger covalent character of the Cu–N in-plane σ-bonds (an enhanced electron delocalization from the $d_{x^2-y^2}$ orbital to the nitrogen atoms) and the larger s-character of the nitrogen hybrid orbitals in the ligand tend to increase it. This was also shown by systematic ENDOR studies [26]. With our ligands, at a similar covalency of the above metal–ligand bond, a larger shf coupling constant is expected for the imidazole, while a smaller constant is expected for the amino nitrogen donors.

For the $[CuLH_2]^{3+}$ complex of L-histidine both the amino and imidazole nitrogens are protonated, and it is only the carboxylate group that can bind to the copper(II). As compared to the aqua complex, the change of a water oxygen by a carboxylate oxygen atom induces only a slightly stronger ligand field, and hence a slight decrease in g_0, increase in A_0 and small changes in the relaxation parameters are expected. The parameters are in good accordance with the expectations (Table 1).

For the $[CuLH]^{3+}$ complex of histamine only a monodentate coordination of the ligand is possible, either by the imidazole or by the amino nitrogen. The ligation of the former is more probable, in accordance with its lower basicity (the p*K* for its protonation is ~6.2, while for the amino group it is ~9.9 [15]). The ESR parameters confirm this mode of coordination, reflecting a quite small increase in the ligand field, as compared to the aqua complex (Table 1). On the contrary, for the $[CuLH]^{2+}$ complex of L-histidine a considerable decrease in g_0 and increase in A_0, and relaxation parameters corresponding to a resolved hf structure (Table 1 and Fig. 4) reflect on a much stronger ligand field which can be attributed to a glycine-like equatorial coordination by the amino nitrogen and carboxylate oxygen atoms. This was also suggested by former Raman [2] and CD [8] studies.

The ESR parameters of the $[CuL]^{2+}$ and $[CuL]^{+}$ complexes of histamine and L-histidine, respectively, are closely identical (Table 1), suggesting a similar equatorial coordination, most likely by the amino and the imidazole nitrogen atoms. The considerable blue shift of the d–d absorption band [29], accompanied with the formation of these species, and the 2N shf pattern of the ESR spectra support this binding mode. The g_0 for the L-histidine complex is somewhat larger, while the A_0 is smaller than the corresponding data for the histamine complex, probably as a consequence of the axial binding of the carboxylate group in the former species. The tridentate coordination of L-histidine in this complex is confirmed also by CD spectroscopic evidence [8].

The deprotonation of the above species resulted in the formation of two new species: an ESR-inactive dimer, in which the monomer units are supposed to be connected by two hydroxide ions [16,18,19,25], and the corresponding monomer, which was shown by pH-potentiometry [18,19,25] and ESR spectroscopy (see above). Compared to the $[CuL]^{+}$ complex, in the $[CuLH_{-1}]$ monomer the deprotonation causes considerable changes in the parameters,

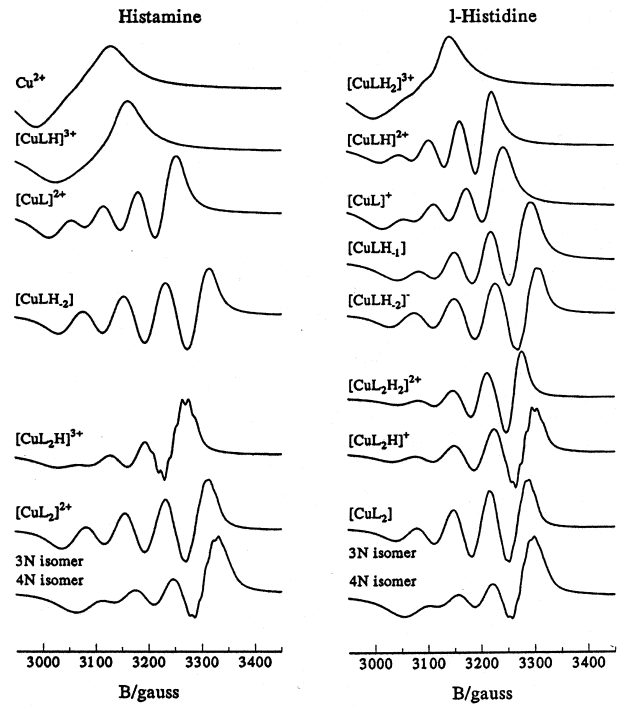

Fig. 4. Spectra of the various species in the copper(II)–histamine and copper(II)–L-histidine systems calculated from the average ESR parameters for ^{63}Cu at 9.4 GHz.

in particular, the decrease of g_0 is significant (Table 1), which indicates a much stronger ligand field. The substitution of an equatorial water molecule by a hydroxide ion modifies the ligand field only to a small extent [3], so it is more probable that the proton loss of the pirrolic nitrogen takes place in this species. The Fermi term decreases from 0.0111 to 0.0107 cm^{-1} upon the deprotonation, supporting the enhanced overall covalent character of the in-plane σ-bond [24].

The deprotonation process over pH ~ 11 is not accompanied with a change in g_0, which indicates that overall ligand field strength is not altered significantly, suggesting the proton loss of the equatorial water molecule in this step. The changes in the coupling constants, however, seem to reflect on alterations of the covalent character of various metal–ligand bonds. For the histidine complex the Fermi term has increased to 0.0117 cm^{-1}, and the decrease in the shf coupling constants is significant (Table 1), which shows a less covalent in-plane σ-bond compared to the $[CuLH_{-1}]$ complex. This is not accompanied with an increase in g_0 at all, suggesting an enhanced covalent character for the π-bonds which counterbalance the effect of the less covalent in-plane σ-bond. For the histidine complex g_0 is slightly larger, while A_0 is smaller then the corresponding data for the histamine complex, indicating the axial binding of the carboxylate group again. The coordination modes of the mono complexes are illustrated in Fig. 5.

The pH-potentiometric formation constants suggest a maximum concentration of about 30% for the $[CuL_2H_2]^{2+}$ complex of L-histidine even at a twenty-fold ligand excess, moreover, there are always three or more other species in a

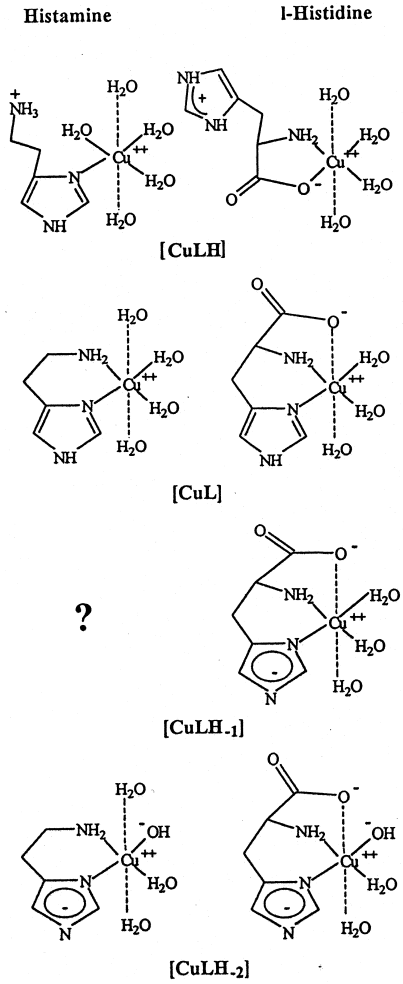

Fig. 5. Coordination modes in the mono-complexes of histamine and L-histidine (charges in formulas are omitted).

solution where this complex is formed (Fig. 3). Therefore we could obtain only limited structural information for this species. The 'bis(glycinate)' equatorial coordination through the amino nitrogen and the carboxylate oxygen atoms is most probable, while the imidazole rings remain in a protonated state. For amino acid complexes of similar coordination, *cis* and *trans* isomers were detected by ESR spectroscopy [7,13]. However, for the above reasons, we could describe the spectrum of the $[CuL_2H_2]^{2+}$ complex of L-histidine as a curve of only one species, even if two isomers were present. The parameters (Table 1) are close to the data for the analogous L-serine complex, obtained with a similar approximation [13].

The ESR parameters for the $[CuL_2H]^{3+}$ complex of histamine and the $[CuL_2H]^{+}$ complex of L-histidine are rather different, suggesting differences in the equatorial coordination, although for both spectra the three-nitrogen shf pattern proves that all three non-protonated nitrogen atoms occupy equatorial positions. The latter fact indicates that the 'L' ligand is bound equatorially through the amino and the imidazole nitrogen atoms, similarly to the [CuL] complexes. The comparison of the ESR parameters of the $[CuL_2H]$ complexes to those of the [CuL] species suggests that the 'LH' ligands bind to the [CuL] moiety differently, as in the [CuLH] complexes. In the histamine complex the ligation is monodentate, presumably through the imidazole nitrogen which alters the ligand field to a small extent, inducing only small changes in parameters (Table 1). This may be the most probable explanation for the large g_0 and small A_0 values. Two larger and one smaller shf coupling constants also support the equatorial binding of two imidazole and one amino nitrogens (Table 1). (It is worth noting that the higher a_{N0} values gained by the analysis of ESR spectra, which are assigned to the imidazole nitrogen atoms, are in good agreement with the nitrogen coupling constants for various imidazole complexes, obtained by ENDOR measurements [26].) On the contrary, for the $[CuL_2H]^{+}$ complex of L-histidine a considerable decrease in g_0 and increase in A_0 are accompanied with the coordination of the 'LH' ligand to the $[CuL]^{+}$ species, indicating a much stronger ligand field: the simultaneous equatorial bonding of the amino nitrogen and carboxylate oxygen atoms, while the 'second' imidazole nitrogen seems to remain in a protonated form. Two smaller and one larger nitrogen coupling constants support the equatorial coordination of two amino and one imidazole nitrogen atoms for the L-histidine complex too (Table 1). The CD spectra of the L-histidine complex were interpreted also in terms of the above mode of equatorial coordination [8] and the axial binding of the carboxylate group of the 'L' ligand. The proposed structures for the bis complexes are illustrated in Fig. 6.

For the 3N isomer of the $[CuL_2]$ complexes, one of the four nitrogen donors is bound in axial position. The question

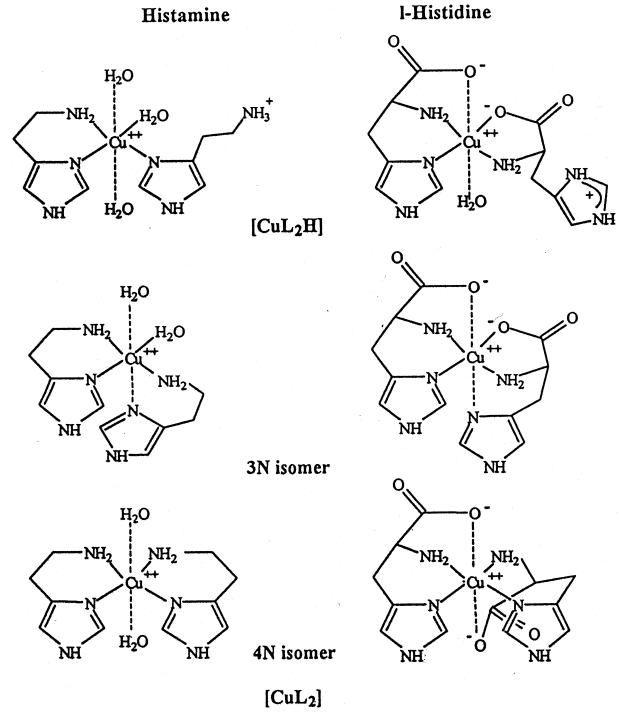

Fig. 6. Coordination modes in the bis-complexes of histamine and L-histidine (charges in formulas are omitted).

is whether an amino or an imidazole nitrogen occupies this site. For both ligands the relatively small g_0 and large A_0 of this species correspond to the equatorial coordination of one imidazole and two amino nitrogen atoms, thus the axial binding of an imidazole nitrogen is probable. The equatorial coordination of one imidazole and two amino nitrogen atoms is supported by one larger and two smaller a_{N0} coupling constants in both cases (Table 1).

The lower g_0 values for the 4N isomers of the $[CuL_2]$ complexes are in accordance with the stronger ligand fields as compared to the 3N isomers (see above); the copper hf coupling constants, however, are unexpectedly small (Table 1). We interpret this by a rhombic distortion which suggests a lower symmetry arrangement of the equatorial donor atoms, i.e. the nitrogens of the same type are in *cis* positions (Fig. 6). For such a coordination the carboxylate groups of the L-histidine ligands are on opposite sides of the equatorial plane, thus both of them can bind axially. This may be, at least in part, a probable explanation for the differences in the g_0 and A_0 values of the corresponding complexes of histamine and L-histidine (Table 1).

4. Conclusions

The good reproducibility of the ESR spectra recorded in a circulating system made it possible to take advantage of all opportunities offered by the EPR program. The decomposition of a large number of spectra has resulted in a consistent description of the copper(II)–histamine and copper(II)–L-histidine equilibrium systems. The pH-metric equilibrium model was completed by the carboxylate-coordinated complex in the strongly acidic region with the L-histidine ligand, and in equimolar alkaline solutions two deprotonated mono complexes were found for both ligands. We pointed out isomeric equilibria at excess histamine and L-histidine in nearly neutral solutions.

The nitrogen coupling constants were in good accordance with the literature ENDOR data. The accurate parameter values determined for all species gave an opportunity to study both the equatorial and the axial coordination, to decide which nitrogen donors are bound in different positions.

The main difference between histamine and L-histidine is the binding mode of the 'LH' ligand which has one of the nitrogen donors protonated. In the case of histamine a monodentate ligation occurs through the imidazole nitrogen atom, while the more basic amino group is protonated. For the L-histidine ligand a bidentate coordination takes place by the amino and the carboxylate groups; here the imidazole ring remains protonated.

For both histamine and histidine, in all complexes, which have one or two ligand(s) free from dissociable protons, the first 'L' ligand is coordinated equatorially by the amino and the imidazole nitrogens. The glycine-like equatorial coordination of the second L-histidine occurs in the minor isomer of the $[CuL_2]$ complex, while the major isomer has all nitrogens in equatorial positions with the *cis* arrangements of the nitrogens of the same kind. For the $[CuL_2]^{2+}$ complex of histamine the second amino nitrogen is bound equatorially, while the second imidazole group occupies an equatorial or an axial site with approximately equal probability.

The carboxylate group of histidine, when displaced from the equatorial positions, occupies an axial site.

cis-Dioxomolybdenum(VI) complexes with tridentate and tetradentate Schiff base ligands. Preparation, structures and inhibition of aerial oxidation of aldehydes

Janne Liimatainen, Ari Lehtonen, Reijo Sillanpää *

Department of Chemistry, University of Turku, FIN-20014 Turku, Finland

Received 4 January 2000; accepted 16 March 2000

Abstract

The synthesis and characterisation of four monomeric *cis*-dioxomolybdenum(VI) complexes involving Schiff base ligands is described. Ligands were obtained by condensation of salicylaldehyde with substituted aminoethanols. $[MoO_2(acac)_2]$ reacted with the prepared ligands forming six-coordinated *cis*-dioxoMo(VI) complexes. X-ray diffraction studies confirmed that ligands act in a tridentate manner and the sixth coordination site around Mo(VI) is occupied by methanol used as solvent. The complexes act as inhibitors in the oxidation of aldehydes by oxygen. ©2000 Elsevier Science Ltd All rights reserved.

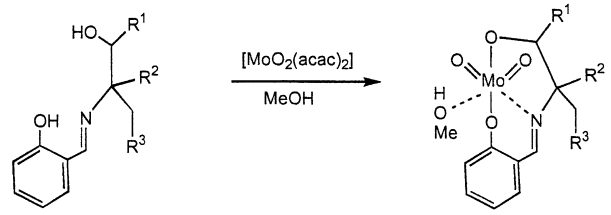
Keywords: Molybdenum complexes; Aerial oxidation of aldehydes

1. Introduction

As molybdenum is widely available to biological systems, the coordination chemistry of Mo(VI) has aroused considerable interest in view of its biochemical significance [1,2]. For example, dioxomolybdenum(VI) complexes are studied as models for oxidised forms of molybdoenzymes, e.g. aldehyde oxidase and sulfite oxidase which are supposed to contain *cis*-MoX_2 units (X = O, S) coordinated to sulfur, nitrogen and oxygen donor atoms of the protein structure [3,4]. The present view of these enzymes indicates that the formal oxidation state of molybdenum cycles between 4+ and 6+ in reactions with substrate and oxidant. The two-electron oxygen atom transfer seems to be the relevant mechanism in understanding chemical role of enzymatic reactions.

A large number of important chemical reactions are catalysed by molybdenum(VI) compounds. Several industrial processes such as ammoxidation of propene to acrylonitrile [5], olefin epoxidation [6] and olefin metathesis [7] reactions are carried out over molybdenum catalysts. Molybdenum alkoxides are also used to isomerise allylic alcohols [8].

Complexes that contain a terminally bonded oxo group dominate the high oxidation states of molybdenum. Alkoxide and phenoxide ligands are widely used ancillary groups in combination with multiply bonded oxo ligands [9]. In our previous investigations, we have studied the coordination chemistry of monomeric dioxomolybdenum complexes with simple chelating alcohols, $[MoO_2(met)_2]$, $[MoO_2(pyr)_2]$ and $[MoO_2(Hbicy)(pyr)]$ (Hmet = 2-methoxyethanol, Hpyr = tetrahydropyrane-2-methanol, H_2bicy = 1,1′-bicyclohexane-1,1′-diol) [10]. Schiff bases derived from salicylaldehyde and aminoalcohols bearing both alcoholic and phenolic hydroxyl groups and also one neutral nitrogen donor (CH=N imino group) can be used as multidentate ligands in molybdenum chemistry [11–13]. In this paper we discuss the syntheses of monomeric dioxomolybdenum(VI) complexes with tridentate or tetradentate Schiff base ligands and their role in the oxidation of benzaldehyde and butanal. Two of the ligands are optically active. Crystal structures of four new complexes are also described.



2. Results and discussion

2.1. Synthesis

In order to prepare dioxomolybdenum(VI) complexes having vacant coordination sites and/or labile ligands, we studied reactions of $[MoO_2(acac)_2]$ with Schiff base ligands

having nitrogen donor atom and two or three potential ionisable hydroxyl groups (Scheme 1). Molybdenum starting material and ligand precursors were dissolved in dry methanol in 1:1 molar ratio and the reaction mixtures were stirred at room temperature for several days. The reaction temperature proved to be vital for product composition. Syntheses carried out at higher temperatures increased the amount of side products, probably including the formation of dinuclear oxo-bridged Mo(V) species [14,15]. Compounds crystallised out from the reaction mixtures in moderate to high yields upon cooling. All compounds formed crystals, which were faint pale yellow. On acing they become more yellow and greenish in colour. The crystals are stable if stored under dry air in the dark. Spectral characterisation and X-ray crystal structure determinations showed that in spite of the variations in ligand structure, the reactions always yielded isostructural mononuclear distorted octahedral complexes of *cis*-dioxomolybdenum(VI), where the ligand is bonded to Mo(VI) in a tridentate meridional coordination mode.

2.2. Spectra

The ^{1}H NMR spectra of the ligands showed a chemical shift of about 14 ppm characteristic for aromatic OH group [16]. The ^{1}H NMR spectra of the complexes are indicative of binding of the ligands through a phenoxo, alkoxo and imine group, leaving any additional CH_2OH groups unbound. They also showed a bound CH_2O^- group in the CH_2 region. The resonances were assigned based on the splitting of resonance signal and spin coupling constants. Spectra of **3** and **4** are also consistent with an unbound CH_2OH group. The chemical shifts of imine carbon protons were about 8.3 ppm for free ligand precursors [17] and coordination of nitrogen shifted the resonance signals about 0.5 ppm downfield. The ^{1}H spectra of the complexes also showed a doublet (3.2 ppm, CH_3) and quartet (4.1 ppm, OH) of coordinated methanol. The IR spectra of the complexes show two strong absorption bands at 890–900 and 920–930 cm^{-1}, which are due to asymmetric and symmetric Mo=O stretches, respectively. Coordination of the imine centre through nitrogen is seen in the ν(C=N) (at 1626–1640 cm^{-1}), which is slightly lower than in uncoordinated bases. Both the ^{1}H NMR and IR spectra are in good agreement with those reported for comparable *cis*-MoO_2^{2+} complexes [11,12].

2.3. Structures of complexes

The molecular structures of complexes **1**–**4** are shown in Figs. 1–4, respectively, with the relevant bond distances and angles collected in Table 1. The coordination geometry around the Mo^{VI} cation is quite similar in all studied complexes. The Schiff base ligand is bonded to the *cis*-Mo(VI)O_2^{2+} ion in an *xy*-plane through a phenoxide and an alkoxide oxygen donor and an imine nitrogen atom, which is *trans* to an oxo group. A methanol molecule completes the distorted octahedral coordination sphere and is *trans* to another oxo group. In all compounds **1**–**4**, the O=Mo=O angles (105.9(2)–106.6(2)°) and the Mo=O distances (1.694(3)–1.721(3) Å) are typical for *cis*-dioxomolyb-

denum(VI) complexes [18,19]. The imine nitrogen and methanol oxygen atoms, which are *trans* to the terminal oxo-groups, bond to Mo(VI) ions with distances of 2.274(5)–2.296(3) Å for nitrogen and 2.325(3)–2.385(2) Å for oxygen, respectively. The Mo–OR distances vary from 1.920(3) to 1.952(2) Å for the alkoxide and from 1.946(2) to 1.964(3) Å for the phenoxide, respectively, these being typical values for these types of bonds in hexa-coordinated dioxomolybdenum(VI) complexes [10,19]. On the whole the structures of compounds **1**–**4** are very similar to those of dioxomolybdenum(VI) complexes with other Schiff base ligands reported by Rao et al. [12]. Complexes **2** and **4** crystallise in an asymmetric space group $P2_12_12_1$ and form an asymmetric coordination site for methanol. In **3** and **4** there is an uncoordinated OH group, which in the case of **3** forms an intramolecular H-bond with the coordinated methanol. This kind of intramolecular H-bond can direct the orientation of incoming alcohols in the reactions, which occur at this coordination site.

2.4. Oxidation of aldehydes

Dioxomolybdenum complexes, e.g. $[MoO_2(cysS\text{-}OR)_2]$ (cysS-OR = S-deprotonated L-cysteinate alkyl ester) and $[MoO_2L]$ (L = pyridine-2,6-bis(1′,1′-diphenylethanethiolate)) are known to catalyse air oxidation of organic substrates [20,21]. On the other hand, molybdenum complexes with salicylaldehyde based ligands, $[MoO_2(SAP)]$ or $[MoO_2(SSP)]$ (SAP = 2-(salicylideneamino)phenolate, SSP = 2-(salicylideneamino)benzenethiolate) do not react with Ph_3P in DMF at 60°C [22,23]. It is also suggested that those complexes are not thermodynamically capable of carrying out substrate oxidation [24]. We tested the ability of our compounds to carry out aerial oxidation of aldehydes by mixing complexes **1**–**4** with aromatic (benzaldehyde) and aliphatic (butanal) aldehydes and exposing them to dry air. Reaction mixtures under continuous air flow were kept at room temperature and the progress of the reaction was followed by HPLC or spectroscopic methods. To our surprise, these complexes did not facilitate the oxidation reaction, but they seem to inhibit it. Addition of the molybdenum complex to the acetonitrile solution of benzaldehyde prevented entirely the formation of benzoic acid. When these compounds were added to neat butanal, the oxidation reaction occurred, but it was clearly slower than in pure aldehyde. The inhibition is probably due to the fact that Mo complexes react with the radicals formed in the oxidation reaction [25]. For example, Cu complexes with phenoxyl radicals can form aldehydes and hydrogen peroxide from alcohols and oxygen but do not oxidise aldehydes to carboxylic acids, although Ni complexes can oxidise aldehydes [26,27].

2.5. Conclusion

Monomeric, octahedral complexes of *cis*-MoO_2^{2+} can be prepared by the reaction of $[MoO_2(acac)_2]$ with salicylaldehyde-based ligand precursors bearing one phenolic –OH group and one or two CH_2OH moieties. The reaction must be carried out at room temperature in order to obtain high yields and nearly colourless products. These complexes

inhibit oxidation reactions of aldehydes to carboxylic acids. In the case of aromatic aldehyde, inhibition was total and no oxidation was detected. The oxidation of aliphatic aldehydes was much slower if a small amount of the prepared complexes was present in the reaction medium.

3. Experimental

$[MoO_2(acac)_2]$ was prepared by a known method [28]. Schiff bases were synthesised by condensing salicylaldehyde with aminoalcohols in refluxing ethanol and were characterised by NMR spectroscopy and elemental analyses. Benzaldehyde and butanal were distilled before use. Other chemicals were of commercial origin and were used without subsequent purification. HPLC analyses were performed by Spectra-Physics model 3500 equipment with an LKB Bromma 2158 UVICORD SD UV-detector using H_2O–MeOH (1:1) as an eluent. IR spectra were recorded on a Mattson Galaxy FTIR spectrometer. ^{1}H NMR spectra were recorded in $(CD_3)_2SO$ using a JEOL GSX-400 spectrometer and referenced to $SiMe_4$ as internal standard. Elemental analyses were performed by a Perkin-Elmer series II analyser.

3.1. Preparation of $[MoO_2L^1(MeOH)]$ (1)

To the solution of $[MoO_2(acac)_2]$ (406 mg, 1.25 mmol) in MeOH (25 ml) was added 255 mg (1.32 mmol) of H_2L^1 and the reaction mixture was stirred at room temperature for 70 h. Supernatant liquid was decanted and concentrated to 5 ml. Compound **1** crystallised as pale yellow crystals when kept overnight at −15°C (86 mg, 20%). *Anal*. Found: C, 41.30; H, 4.85; N, 3.90. Calc.: C, 41.05; H, 4.90; N, 4.00%. NMR: δ_H 8.6 (s, 1H, imine), 7.7–6.8 (m, aromatic), 4.2 (s, CH_2O^-), 1.35 (s, 6H, CH_3), 4.1 (m, 1H, CH_3OH) and 3.2 (d, 3H, CH_3OH). IR: 1626vs, 1599s, 1557m, 1452vs, 1289s, 1235m, 1215m, 1192m, 1163m, 1145m, 1125s, 1032vs, 995m, 980m, 926vs (br), 897vs (br), 829s, 791s, 754vs, 637m, 627s, 540s (br), 517m, 478w, 446m.

3.2. Preparation of $[MoO_2L^2(MeOH)]$ (2)

$[MoO_2(acac)_2]$ (460 mg, 1.41 mmol) was dissolved in 35 ml of MeOH and 277 mg (1.44 mmol) of H_2L^2 were added. The reaction mixture was stirred at room temperature for 140 h and then filtered. The filtrate was kept at −15°C for 11 days to obtain complex **2** as pale yellow crystals in 45% yield (222 mg). *Anal*. Found: C, 41.10; H, 4.85; N, 3.95. Calc.: C, 41.05; H, 4.90; N, 4.00%. NMR: δ_H 8.7 (s, 1H, imine), 7.7–6.8 (m, aromatic), 4.4 (m, 2H, CH_2O^-), 3.9 (m, 1H, CH), 1.8 (m, 2H, CH_2), 0.9 (s, 3H, CH_3), 4.1 (m, 1H, CH_3OH) and 3.2 (d, 3H, CH_3OH). IR: 1636s, 1597s, 1559s, 1452vs, 1319w, 1289s, 1246m, 1229m, 1213m, 1152m, 1134w, 1117m, 1099m, 1074m, 1026vs, 1013vs, 980m, 955m, 930s, 909vs (br), 853s, 810s, 760vs, 733s, 710m, 644w, 633m, 619s, 544vs, 521m, 507m, 463m, 446s.

3.3. Preparation of $[MoO_2HL^3(MeOH)]$ (3)

H_3L^3 (200 mg, 0.96 mmol) was dissolved in MeOH (20 ml) and 300 mg (0.92 mmol) of solid $[MoO_2(acac)_2]$ was added. The reaction mixture was stirred for 71 h at room temperature and then decanted. The solution was then concentrated to 10 ml and it was kept at 5°C for 8 days to obtain complex **3** as pale yellow crystals in 70% yield (235 mg). *Anal*. Found: C, 37.80; H, 4.35; N, 3.90. Calc.: C, 39.25; H, 4.65; N, 3.80%. NMR: δ_H 8.5 (s, 1H, imine), 7.7–6.8 (m, aromatic), 5.1 (m, 1H, CH_2OH), 3.5–3.4 (m, 2H, CH_2O^-), 4.6 (d, 1H, CH_2OH), 4.0 (d, 1H, CH_2OH), 1.3 (s, 3H, CH_3), 4.1 (m, 1H, CH_3OH) and 3.2 (d, 3H, CH_3OH). IR: 1626s, 1595m, 1555m, 1454vs, 1329s, 1294vs, 1219m, 1192m, 1165w, 1144m, 1119m, 1055s, 1030s, 988s, 926vs, 889vs (br), 822s, 791m, 750vs, 731s, 627s, 571s, 544s, 465m, 449m.

3.4. Preparation of $[MoO_2HL^4(MeOH)]$ (4)

To H_3L^4 solution (545 mg, 2.01 mmol) in MeOH (30 ml) was added $[MoO_2(acac)_2]$ (652 mg, 2.00 mmol) as a solid and the reaction mixture was stirred at room temperature for 24 h. The mixture was filtrated and filtrate was concentrated until some crystals had formed. The solution was kept at −15°C overnight to yield complex **4** as clear, slightly greenish yellow crystals (609 mg, 71%). Crystals for X-ray analysis were grown from methanol. *Anal*. Found: C, 47.20; H, 4.50; N, 3.25. Calc.: C, 47.55; H, 4.45; N, 3.25%. NMR: δ_H 8.75 (s, 1H, imine), 7.7–6.9 (m, aromatic), 4.0–3.8 (m, 2H, CH_2OH), 5.23 (d, CHO^-), 5.16 (m, 1H, CH_2OH), 3.6 (m, 1H, CH), 4.1 (m, 1H, CH_3OH) and 3.2 (d, 3H, CH_3OH). ^{13}C NMR: δ 163 (imine), 161–119 (aromatic), 85 (bound CHO^-), 75 (CH_2OH), 59 (CH) and 49 (CH_3OH). IR: 1640s, 1603m, 1561m, 1452vs, 1339w, 1289s, 1250s, 1219s, 1155m, 1130m, 1094m, 1072m, 1030vs, 990m, 930vs, 901vs, 882vs (br), 824s, 777s, 758s, 723s, 708s, 669s, 629s, 604s, 548w, 536m, 519s, 503s, 473m, 442m.

3.5. Oxidation of benzaldehyde

15 mg samples of benzaldehyde were added to the acetonitrile (2.0 ml) solutions of studied molybdenum complexes **1**–**4** (ca. 1 mg). Reaction mixtures were stored in open vessels in dry air at room temperature for 20 h and then analysed by HPLC. However, no benzoic acid could be seen in reaction mixtures.

3.6. Oxidation of butanal

In each experiment, a sample (ca. 5 mg) of molybdenum compound was dissolved in 1 g of butanal and dry air was bubbled (2–5 $cm^3\ min^{-1}$) into the mixture at room temper-

ature. Reaction mixtures were analysed by IR spectroscopy after 1, 2 and 3 h, and in the case of compound **4** also by ^{1}H NMR. All reactions showed some formation of butyric acid, but the oxidation reaction was clearly fastest in the reference reaction, which was carried out without any Mo complex.

3.7. Crystal structure determinations

Crystal data for compounds **1**–**4**, along with other experimental details, are summarised in Table 2. Single-crystal data collections were performed at ambient temperature on a Rigaku AFC5S diffractometer using graphite-monochromatized Mo Kα radiation ($\lambda=0.71069$ Å). The unit cell parameters were determined by least-squares refinement of 25 carefully centred reflections. Data reduction and subsequent calculations were performed with teXsan for Windows [29]. The data was corrected for Lorentz and polarisation effects and for absorption (PSI-scans [30]). The structures were solved by direct methods using the SIR92 program [31] and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [32]. Non-hydrogen atoms were refined with anisotropic displacement parameters and the hydrogen atoms were included in the calculations at the fixed distances from their host atoms. Figures were drawn with Ortep-3 for Windows [33].

Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) and are available on request quoting the deposition numbers CCDC 138185–138188 for **1**–**4**, respectively.

Abstract

The reaction of $TiCl_4$ with 6 equiv. of NaSPh in the presence of organic cations such as Et_4N^+ or PPh_4^+ proceeds to yield a novel homoleptic arylthiolate Ti(IV) complex, $[Ti(SPh)_6]^{2-}$. The Et_4N salt of $[Ti(SPh)_6]^{2-}$ has been structurally determined. The coordination geometry around the metal ion is a regular octahedron in which the central titanium ion is located on the crystallographic inversion center. The infrared (IR) spectrum of compound **I** exhibits the characteristic Ti–S bond stretching vibrations of thiophenolate ligands at 480 and 430 cm^{-1}, and the ^1H NMR spectrum in CD_3CN displays characteristic Et_4N^+ resonance peaks and six thiophenolate resonance peaks which are consistent with the solid state structure. The reaction of $TiCl_4$ with 3 or 4 equiv. of NaSPh in CH_3CN yields the unexpected mixture of dark purple $[TiCl_3(CH_3CN)_3]$ and dark red $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ (**II**) complexes. Complex **II** has been structurally determined by single X-ray crystallography. The IR spectrum of complex **II** exhibits a μ_3–O stretching vibration at 600 cm^{-1} and Ti–S vibrations of the thiophenolate ligand at 481 and 429 cm^{-1}. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Oxo ligands; Thiolates; Titanium; Trimers

1. Introduction

There has been an enormous study of the transition metal complexes with aliphatic or aromatic thiolate ligands, because they exhibit a variety of structural types with various nuclearities [1–9], and certain complexes can be used as precursors for corresponding transition metal sulfide complexes [10–15]. Among the transition metal thiolate complexes, mononuclear species with homoleptic thiolate ligands are fundamental types that can be used to derive cluster and cage types of molecules or corresponding thiometalates. Such early transition metal complexes with homoleptic thiolate ligands have been reported extensively in the last few years. For example, $M(SPh)_6^{n-}$ ($n=1$, 2; M = Nb, Ta) [16], $M(SPh)_4^{2-}$ (M = Mn, Fe, Co, Ni) [17,18] and $M(S_2C_2H_4)_3^-$ (M = Nb, Ta) [19], $M(S_2C_2H_4)_3^{n-}$ ($n=1$, 2; M = Ti, Co, Cr) [20,21] have been synthesized and fully characterized. In contrast to the other groups, the types and structural pattern of group IV metal thiolate complexes have not been fully studied. Recently, Tatsumi et al. reported $Zr(^tBuS)_5^-$ and $Zr(^tBuS)_6^{2-}$ complexes [22].

Reports on titanium complexes with thiolate ligands are limited to a few complexes, including Ti(S-2,4,6-$^iPr_3C_6H_2)_4^-$, Ti(S-2,4,6-$^tBu_3C_6H_2)_4^-$ [23] and dithiolate complexes of titanium [20,21]. Recently. Giolando et al. reported on the synthesis and structural characterization of dimeric $Ti_2(SMe)_9^-$, trimeric $Ti_3(SMe)_{12}$ complexes which were obtained from the reaction of $Ti(NR_2)_4$ with RSH (R = Me, Et) [24].

We are interested in obtaining Ti(IV) homoleptic monodentate thiolate complexes, potential starting materials for corresponding thiotitanates. Here, we report the synthesis and structural characterization of the homoleptic arylthiolate titanium complex $[Ti(SPh)_6]^{2-}$ (**I**) and the trimeric $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ (**II**).

2. Experimental

All manipulations were performed using standard Schlenk line techniques under dinitrogen atmosphere. Diethyl ether was distilled after being refluxed with sodium–benzophenone. Acetonitrile was distilled after being refluxed over CaH_2 before use. $TiCl_4$, Et_4NBr and PPh_4Cl were purchased from Aldrich and used as received. Sodium thiophenolate

(NaSPh) was prepared from the reaction of sodium and thiophenol in diethyl ether.

2.1. $[Et_4N]_2[Ti(SPh)_6]$ (**I**)

A 250-ml Schlenk flask was charged with 2.26 g (17.23 mmol) of NaSPh, 1.10 g (5.30 mmol) of Et_4NBr and a stirring bar. To this mixture was added 50 ml of CH_3CN via a cannula with stirring at ambient temperature and 0.29 ml (2.65 mmol) of $TiCl_4$ was injected using a syringe. The color of the solution turned to dark red immediately. After 2 h, the solution was filtered through a fine porosity fritted funnel; to the dark red filtrate, 50 ml of diethyl ether was added and the resulting solution was left to stand at ambient temperature. Finally, dark red crystalline materials were obtained in 80% yield. Calc. for $TiS_6N_2C_{52}H_{70}$: C, 64.83; H, 7.27; N, 2.92; S, 19.97. Found: C, 64.91; H, 7.34; N, 3.01; S, 21.52%. FT-IR (cm^{-1}): ν(Ti–SPh); 480, 430. ^1H NMR in acetonitrile-d_3: δ (CH_3 in Et_4N^+); 1.18 (t, 24H), δ (CH_2 in Et_4N^+); 3.21 (q, 16H), δ (C_6H_5 in SPh ligand); 6.97–7.42 (m, 30H). The Ph_4P^+ salt was also obtained by a similar synthetic procedure in 80% yield. Calc. for $TiS_6P_2C_{84}H_{70}$: C, 73.05; H, 5.07. Found: C, 73.23; H, 5.12%. IR (KBr disc) (cm^{-1}): ν(Ti–SPh), 480 and 420.

2.2. $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ (**II**)

2.2.1. Method A

A 250-ml Schlenk flask was charged with 1.39 g (10.60 mmol) of NaSPh and a stirring bar. To this flask 30 ml of CH_3CN was added via a cannula with stirring at ambient temperature, and 0.29 ml (2.65 mmol) of $TiCl_4$ was injected using a syringe. The color of the solution turned to dark red. After 2 h, the solution was filtered through a fine porosity fritted funnel. To the red filtrate 100 ml of diethyl ether was added and the resulting solution was stood at ambient temperature. Dark purple crystals and dark red crystals were isolated and dried under vacuum. Finally, a 1:1 mixture of dark purple crystals of $TiCl_3(CH_3CN)_3$ and dark red crystals of $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ were obtained (see below). The total yield was approximately 70% (based on Ti). ^1H NMR in DMF-d_7: δ (CH_2 in CH_3CN in ligand and free CH_3CN); 1.95 (br, 27H), δ (CH_3 in Et_2O); 3.382 (q, 4H), δ (CH_3 in Et_2O); 1.068 (t, 6H), δ (C_6H_5 in SPh ligand); 7.126–7.277 (m, 15H).

2.2.2. Method B

$TiCl_4$, 0.18 ml (1.68 mmol), was injected using a syringe into a 250-ml Schlenk flask containing 20 ml of CH_3CN. To this solution 0.01 ml (0.56 mmol) of H_2O diluted in 10 ml of CH_3CN was added and the solution was stirred at ambient temperature for 10 min. The solution was transferred via a cannula to a 250-ml schlenk flask charged with 0.88 g (6.72 mmol) of NaSPh and 20 ml of CH_3CN. After 2 h, the solution was filtered through a fine porosity fritted funnel; then to the red filtrate 100 ml of diethyl ether was added and the resulting solution was stood at ambient temperature. Finally, a dark red powder of $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ was obtained in 74% yield.

Calc. for $Ti_3S_3O_2N_6Cl_4C_{34}H_{43}$: C, 43.03; H, 4.53; N, 8.85; S, 10.14. Found: C, 43.24; H, 4.24; N, 8.76; S, 12.01%. FT-IR (cm^{-1}): ν(Ti–O), 600.5; ν(CH_3CN), 2310.3, 2280; ν(Ti–SPh), 481, 429. ^1H NMR in DMF-d_7: δ (CH_3 in CH_3CN ligand and free CH_3CN); 1.92–1.97 (m, 18H), δ (CH_2 in Et_2O); 3.28 (q, 4H), δ (CH_3 in Et_2O); 1.06 (t, 6H), δ (C_6H_5 in SPh ligand); 7.252–7.285 (m, 15H).

2.3. X-ray crystallography

Single X-ray diffraction data for both crystals are presented in Table 1. Diffraction data were collected at ambient temperature on a Bruker P4 four circle diffractometer using Mo Kα radiation. Intensity data were collected by using a θ–2θ step scan technique and for all data sets the condition of the crystal was monitored by measuring 2 standard reflections. The solutions of both structures were carried out by a combination of heavy atom Patterson techniques, direct methods and Fourier techniques. The refinement of the structures by full-matrix least-squares methods was based on 2640 unique reflections ($2\theta = 45°$, $I > 2\sigma$) for compound **I**, and 4361 unique reflections ($2\theta = 22.5°$, $I > 2\sigma$) for compound **II**. Anisotropic temperature factors were used for all non-hydrogen atoms in compounds **I** and **II**, except solvent molecules packed in the lattice for compound **II**. At the current stage of refinement on 312 parameters for compound **I** and 459 parameters for compound **II** with all atoms present in the asymmetric units, $R = 0.0383$, $Rw = 0.0989$ for compound **I** and $R = 0.0715$, $Rw = 0.1982$ for compound **II**.

Table 1
Crystallographic data for $[Et_4N]_2[Ti(SPh)_6]$ (**I**) and $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ (**II**)

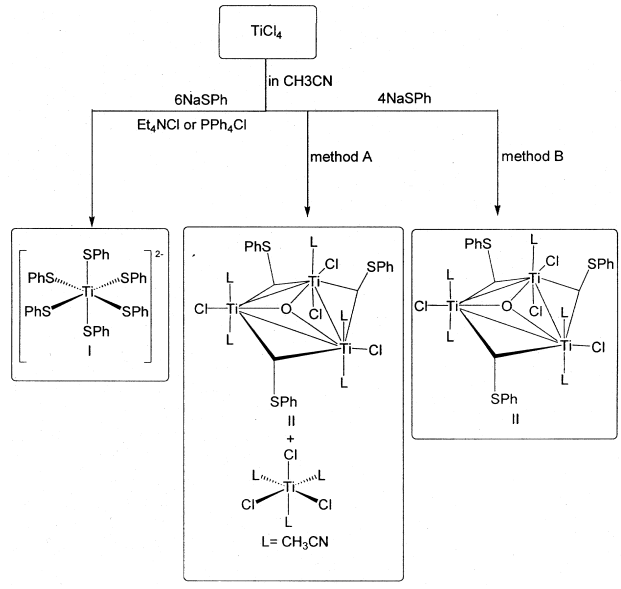
2.4. Other physical measurements



^{1}H NMR spectra (300 MHz) were obtained with a Varian Gemini 300 spectrometer. IR spectra were measured with a Nicolet Magna IR-760 spectrophotometer. C, H and N analyses were obtained with a Thermoquest EA-1110 CHNS analyzer.

3. Results and discussion

3.1. Synthesis and spectroscopic results

The reactions between titanium tetrachloride and sodium thiophenolate were investigated in CH_3CN at room temperature with different stoichiometries. The Et_4N^+ salts of compound **I** could be obtained from the reaction of $TiCl_4$ with 6 equiv. of NaSPh in CH_3CN solution in the presence of Et_4NBr. Upon the addition of solvent, the solution of the reaction mixture immediately turned to a deep red color, and was stirred for 2 h at ambient temperature under N_2 atmosphere. The solution was then filtered and dark red crystals of Et_4N^+ 'salts' were isolated with 80% yield by the slow diffusion of diethyl ether into the filtrate solution. The Ph_4P^+ 'salts' were also obtained in 70% yield using a similar method. The red crystals of compound **I** were very sensitive to air and moisture and even decomposed in a dry N_2 glove box within several days. The reaction of $TiCl_4$ with 4 equiv. of NaSPh in CH_3CN at ambient temperature produced a 1:1 mixture (as evidenced by ^{1}H NMR spectroscopy) of dark purple $[TiCl_3(CH_3CN)_3]$ and dark red $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ complexes. Both complexes were identified by single crystal X-ray analysis.

The synthesis of compound **I** was accomplished by the simple ligand exchange reaction of chloride by thiophenolate group (Scheme 1). The precipitation of NaCl facilitated the completion of the reaction. This method afforded a simple and convenient route to obtain the monomeric titanium thiolate complex in high yield. When the reaction stoichiometry of 1:4 ($Ti:PhS^-$) was used to obtain the cluster type Ti–thiolate complex, the hydrolyzed complex **II** was inadvertently produced. In this reaction, titanium was reduced to +3 oxidation state with the concomitant oxidation of PhS^- to 1/2PhSSPh. This kind of reduction mechanism was reported earlier in the synthesis of $[Ph_4P]_2[Nb(SPh)_6]$ [16]. The oxygen in complex **II** presumably came from a trace of water in the CH_3CN solution. In fact, complex **II** could be obtained in excellent yield (74%) when the stoichiometric amount of water (3:1 molar ratio with $TiCl_4$ and H_2O) was added to the reaction medium. A similar reaction was reported by Müller's group [26] in which the reaction system $3TiCl_4$:$6S(SiMe_3)_2$:$3/2O_2$ led to a $[Ti_3O(S_2)_6Cl_6]^{2-}$ complex in which the oxygen atom came from the inert gas containing small amounts of O_2. Further study will verify a more detailed reaction mechanism.

Scheme 1.

The IR spectrum of $[Et_4N]_2[Ti(SPh)_6]$ exhibited the characteristic thiophenolate ligand Ti–S bond stretching vibrations at 480 and 430 cm^{-1}, which is typical of most metal thiolate complexes. The ^{1}H NMR spectrum in CD_3CN displayed the characteristic Et_4N^+ resonance peaks and six thiophenolate resonance peaks, which is consistent with the solid state structure. In the IR spectra the μ_3–O stretching vibration in the $[Ti_3O(SPh)_3Cl_4(CH_3CN)_5]\cdot CH_3CN\cdot(C_2H_5)_2O$ (**II**) complex was observed at 600 cm^{-1}, and doublet peaks at 2310 and 2280 cm^{-1} were assigned to the C≡N vibrations in the CH_3CN ligand. Also the Ti–S vibrations in the thiophenolate ligand were observed at 481 and 429 cm^{-1}. The ^{1}H NMR spectrum in DMF-d_7 displayed the characteristic CH_2 (δ 3.382) and CH_3 (δ 1.608) resonance peaks from one diethyl ether molecule and three thiophenolate resonance peaks (δ 7.126–7.277). In the ^{1}H NMR spectra of the product, which was prepared by method A, a broad single resonance peak at δ 1.95 due to five coordinated CH_3CN, free CH_3CN molecule in complex **II** and coordinated CH_3CN in $TiCl_3(CH_3CN)_3$ were observed. The integral ratio of those peaks compared to the thiophenolate ligands suggested that $TiCl_3(CH_3CN)_3$ and complex **II** existed as a 1:1 mixture. However, the ^{1}H NMR spectra for the product prepared by method B suggested that only complex **II** was produced by this method.

3.2. X-ray structures

The structures of compounds **I** and **II** were determined; the ORTEP diagrams of the anion in complex **I** and complex **II** are shown in Figs. 1 and 2.

The selected bond distances and angles of anion in complex **I** are presented and compared with those of the $[Ti(S_2C_2H_4)_3]^{2-}$ anion [21] in Table 2. The coordination geometry around the metal ion is a regular octahedron in which the central titanium ion is located on the crystallo-

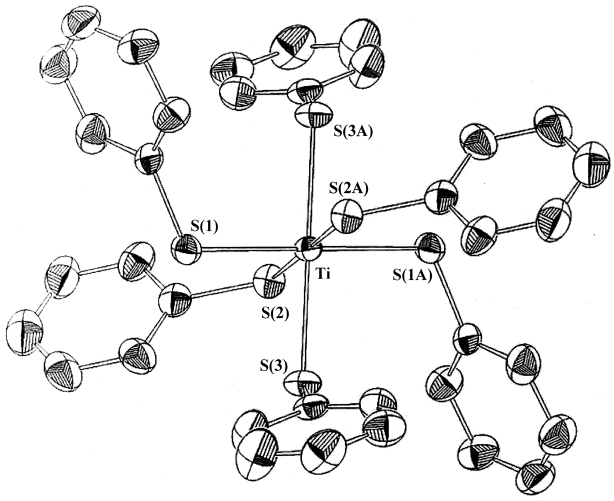


Fig. 1. Structure and labeling of the anion **I** in the $[Et_4N]_2[Ti(SPh)_6]$ complex. Thermal ellipsoids as drawn by ORTEP represent the 40% probability surfaces. Symmetry-generated atoms have the suffix 'A'.

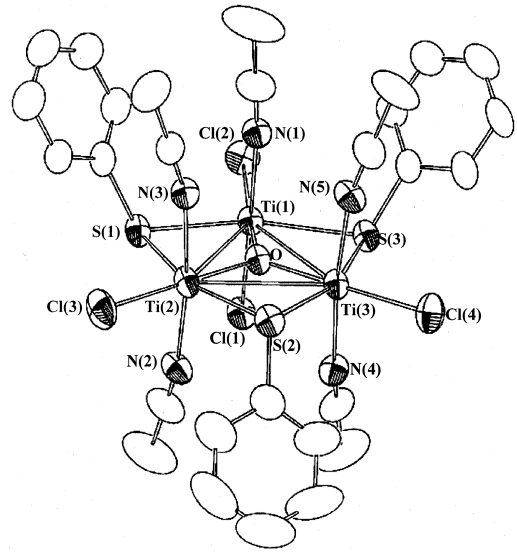

Fig. 2. Structure and labeling of complex **II**. Thermal ellipsoids as drawn by ORTEP represent the 40% probability surfaces.

Table 2
Selected bond lengths (Å) and angles (°) for anion in complex **I** and $[Ti(edt)_3]^{2-}$

	I	$[Ti(edt)_3]^{2-}$ [a]

[b] The numbers in parentheses represent the individual standard deviations.

graphic inversion center. The titanium–sulfur distances range from 2.424 to 2.443 Å, which are typical for metal–sulfur bonds in transition metal thiolate complexes. The slightly longer Ti–S distance (mean 2.432 Å) than that of $[Ti(S_2C_2H_4)_3]^{2-}$ (mean 2.428 Å) is mainly due to the chelating effect of dithiolate ligands in the $[Ti(S_2C_2H_4)_3]^{2-}$ complex. The S–M–S angles are 84.05, 84.44 and 95.51°, respectively.

The selected bond distances and angles of complex **II** are presented in Table 3. In complex **II**, the oxygen atom bridges three Ti atoms with μ_3-mode and all four atoms exist nearly in the plane. The distance of Ti–O (1.922 Å) is comparable to that of $(CpTi)_6(\mu_3\text{-}S)_4(\mu_3\text{-}O)_4$ (1.97 Å) [25]. The bond angles of Ti–O–Ti (119.87°) and the three nearly identical distances of three Ti–O bonds suggest that the oxygen atom

is located at the center of triangular geometry formed by three titanium atoms. Each titanium is contained within a pseudo-octahedral geometry in which two sulfur atoms, a chloride atom and an oxygen atom form the equatorial plane. All CH_3CN ligands are located in the axial position (O–Ti–N 90.68°) and all Cl ligands are located in the equatorial position (O–Ti–Cl 175.5°), except Cl(1) which is in the axial position (O–Ti(1)–Cl(1) 97.8°). The Ti–Ti distances in complex **II**, which range from 3.322 to 3.332 Å, are slightly longer than those in $[Ti_3O(S_2)_6Cl_6]^{2-}$ (3.14–3.18 Å) [26].

The reactivity characteristics of the anion in complex **I** and its conversion to titanium sulfide complexes as a precursor are currently under investigation in our laboratory.

Supplementary data

The full crystallographic data are available from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 IEZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition numbers 136711 (**I**) and 136712 (**II**).

Received 31 January 2000; accepted 20 March 2000

Abstract

Results of equilibrium and spectral studies have shown that, in the systems of uridine (Urd) or uridine 5′-monophosphate (UMP) with the diamines (PA) ethylenediamine, 1,3-diaminopropane or putrescine, molecular complexes of the type $(Urd)H_x(PA)$ and $(UMP)H_x(PA)$ are formed. Overall stability constants of the adducts and equilibrium constants of their formation have been determined. The tendency towards complex formation increases with growing length of the PA. The pH range of adduct formation is found to coincide with that in which the PA is protonated, whereas Urd or its monophosphate is deprotonated. The NH_3^+ groups from PA and N(3) atoms and phosphate groups from the nucleosides have been identified as the centres of non-covalent interactions. Overall stability constants of the Cu(II) complexes with Urd and UMP have been determined. It was found that, in the $Cu(Urd)^+$ and $Cu(Urd)(OH)_x$ complexes, the reaction of metallation mainly involves N(3) atoms from the pyrimidine bases. Results of the spectral and equilibrium studies of the Cu/UMP system indicate coordination involving the N(3) atom and the phosphate groups from UMP, whereas in the complexes $Cu(UMP)(OH)_x$, appearing at high pH, the involvement of the N(3) atom has been excluded and the main sites of metallation are oxygen atoms from carbonyl groups, besides those from hydroxyl groups. The mode of coordination of Cu(II) complexes with Urd or UMP, including diamines, was also determined.

1. Introduction

It has been established beyond doubt that the interactions of metal ions with nucleic acids and their fragments determine the character of many chemical processes occurring in living organisms, in particular in the processes of genetic information transfer [1–3]. One of the basic problems so far unresolved is the coordination of metal ions in complexes with nucleosides and nucleotides as well as the character of the interactions of this group of bioligands with polyamines (PA) occurring in living cells. The donor atoms N(1) or N(7) are the potential sites of coordination of purine nucleosides, and N(3) in the systems with pyrimidine bases [4–6].

An additional effective coordination site in nucleotides are the donor oxygen atoms from phosphate groups. Determination of the structure of the complexes in solutions is indispensable for the understanding of the anti-tumour effect of platinum complexes. The participation of metals in the processes of replication and transcription of nucleic acids is essential. The metal ion interactions with the bioligands discussed induce changes in their conformations [7,8]. The scope and character of the changes correspond to the mode of coordination and stabilities of the complexes formed with either metal ions or PA. In general, the hard metals from the main groups enter into coordination with donor oxygen ions, whereas the soft transition group metals prefer coordination with nitrogen atoms [1,2,9]. The complexing abilities of the nucleosides change in the order: Guo > Ado ≥ Cyd > Urd ≥ Thd [10–12]. With respect to affinity with metal ions, uridine (Urd) and uridine 5′-monophosphate (UMP) are the least reactive fragments of the nucleic acids. Analysis of the hitherto published works on this subject indicates considerable differences in estimations of the thermodynamic stability of the complexes formed of Cu(II) with this nucleoside (e.g. $\log \beta_{110} = 2.77$ [13], $\log \beta_{110} = 4.57$ [14]), or leads to much controversy on the mode of coordination, which according to some authors involves only the oxygen atoms from the nucleotide [15] and according to others the nitrogen atoms

PII S0277-5387(00)00375-2

as well [13,16]. These ambiguities prompted us to study the systems mentioned above as one of the steps towards elucidating the character of interactions in the complexes.

This paper presents results of the equilibrium and spectral studies of the interactions of uridine (Urd) and uridine 5′-monophosphate (UMP) with diamines (PA) in metal-free systems as well as of studies of the complexation reactions in binary and ternary systems of these bioligands with Cu(II).

2. Experimental

Uridine (Urd) and uridine 5′-monophosphate (disodium salt), purchased from Fluka, and uridine 5′-monophosphate (UMP) and putrescine hydrochloride (Put·2HCl), from Sigma, were used without further purification. All diamines (PA) were used in the form of hydrochlorides. The dihydrochlorides of ethylenediamine (en) or 1,3-diaminopropane (tn) were obtained by mixing one chemical equivalent of the amine suspended in methanol, with two chemical equivalents of a water–methanol solution of HCl. The salts precipitated were dried over P_4O_{10}. The results of the elemental analysis were in agreement with theoretically calculated values ($\pm 0.5\%$). Copper(II) nitrate (from POCh, Poland) was purified by recrystallisation from water. The concentration of copper ions was determined by the complexometric method [17]. Potentiometric titration was performed on a Titrino 702 Metrohm equipped with an autoburette with a previously calibrated [18] glass electrode 6.233.100 Metrohm. All potentiometric titrations were made at 20 ± 1°C at a constant ionic strength of 0.1 M (KNO_3) in an atmosphere of neutral gas (helium) at metal:ligand ratios between 1:2.5 and 1:5; $C_{Cu} = 0.0003$ M, for Urd and UMP $C = 0.0008$–0.0017 M. The titrant was 0.15229 M CO_2-free NaOH. For the calculation of stability constants with the SUPERQUAD program [19], fragments of the titration curves up to pH of about 7 in the binary systems with Urd and about 7.5 in the binary systems with UMP were used (in the conditions of the potentiometric measurements at higher pH values a precipitate started to appear). Moreover, for the calculations we have also used some of the curves for the binary systems with Urd and UMP, for which the precipitate was found to dissolve (at pH of about 9) while the total amount of the metal remained in the solution. In the metal-free systems, the concentration of both ligands was the same and equal to 0.01 M. In the ternary systems, as in the binary systems with metal ions, the concentration of copper(II) was $C_{Cu} = 0.0003$ M, while the concentration of both ligands was $C_L = 0.0003$ or 0.0008 M. Distributions for particular systems and simulated titration curves were calculated using the HALTAFALL program [20]. Measurements of ^{13}C, ^{31}P, ^{15}N NMR and IR were performed in D_2O, and the pD of the solution was adjusted by NaOD and DCl, taking into account that $pD = pH + 0.40$ [21]. The concentration of the ligands used for NMR measurements was 0.05–0.1 M (1 M for ^{15}N NMR) at the M:L molar ratio of 1:70. NMR spectra were recorded on Gemini 300 Varian and Unity 300 Varian instruments using dioxane as an internal standard for ^{13}C NMR spectra, nitromethane for ^{15}N NMR, and orthophosphoric acid for ^{31}P NMR spectra. The ligand concentration for IR was 0.3–0.5 M; the M:L ratio of concentrations varied from 1:1 to 1:5. The IR spectra were recorded on an IFS 113v Bruker spectrometer, in the cells KRS-5. Samples for UV–Vis studies were prepared in H_2O at the M:L ratio 1:1 and at a Cu(II) concentration of 0.05 M. The spectra were recorded on a UV 160 Shimadzu spectrometer using a 1-cm cell. EPR studies were carried out at 77 K, using glass capillary tubes for water:glycol (3:1); the concentration of Cu(II) was 0.005 M, and the M:L ratio was 1:1. The spectra were recorded on an SE/X 2547 Radiopan instrument.

3. Results and discussion

3.1. Urd, UMP/PA metal-free systems

The protonation constants of Urd and UMP are given in Table 1 and are consistent with literature data [14,15,22,23]. For UMP only two constants of protonation have been determined from computer analysis of the titration data: $\log K_1 = 9.50$ and $\log K_2 = 5.63$. The fully protonated UMP occurs only in very acidic medium, so accurate determination of the third protonation constant by the potentiometric method is impossible; however, a value approximated from literature data is $\log K_3 \approx 0.7 \pm 0.3$ [24].

Non-covalent interactions of Urd or UMP with PA in metal-free systems lead to a change in the acid–base character of the bioligands [25,26]. Because the formation of molecular complexes in the systems studied is accompanied by release of protons, the processes could be observed by the potentiometric method:

$$H_x(\text{Nuc}) + H_y(\text{PA}) \rightleftharpoons (\text{Nuc})H_{(x+y-n)}(\text{PA}) + nH^+$$

Table 1 presents the stoichiometry of complexes and overall stability constants of the adducts. In the systems Urd/en and Urd/tn, molecular complexes are not formed. In the systems with Put, the complexes form in the pH range in which the amine is protonated, while molecules or fragments of the nucleic acids are at least partly deprotonated. These results support the earlier proposed model [25–27] with ion–dipole interactions. Fig. 1 presents distribution curves of molecular complexes in the Urd/Put and UMP/Put systems.

The complexes of Urd with Put start forming from about pH 8, and at pH 10 about 40% of the components occur as adducts. The acidity range in which Urd forms molecular complexes with PA is markedly shifted towards higher pH (protonation constant for Urd is 9.2) than the corresponding ranges in which the complexes with adenosine (Ado) or cytidine (Cyd) are formed (protonation constants, log *K*, of 3.9 and 4.5, respectively). The process of H^+ release from Ado and Cyd occurs at lower pH and adducts form from pH about 3 [26,27]. Moreover, the pH range of molecular com-

plex formation in the system Urd/Put is significantly shifted with respect to that in the system UMP/Put (Fig. 1) (the deprotonation of the nucleoside takes place only at high pH). High basicity of the N(3) atom implies a considerable decrease in the equilibrium constant of (Urd)H_2(Put)$^+$ adduct formation with respect to that of (Urd)H(Put) formation. The equilibrium constants (K_e) for the formation of the adducts calculated from the overall stability constants and the protonation constants ($\log K_e = \log \beta_{(Urd)Hx(Put)} - \log \beta_{HxPut}$) are 2.17 and 1.19 for $x = 1$ and 2, respectively, (Table 1). This decrease can be explained by partial neutralization of the nucleoside donor nitrogen atoms by the proton cloud (which is possible because the protonation constants of bioligands are similar), which weakens the electrostatic interaction with a protonated molecule of Put.

Analysis of the results of equilibrium studies indicates that apart from the charge, also the ligand structure has a significant influence on the interactions. The results obtained for the systems of Urd and UMP, supported by those obtained for the systems with Ado and Cyd as well as adenosine and cytidine monophosphates [25–28] suggest that increasing chain length of amine usually leads to a greater tendency for adduct formation. The interactions of ethylenediamine or 1,3-diaminopropane with Urd are not detectable. However, such complexes form in the systems with Put, which corresponds to the different character of this biogenic amine occurring in living organisms.

The character of bioligand interactions in metal-free systems was confirmed by the results of ^{13}C NMR studies. The NMR signals were assigned to particular atoms on the basis

Scheme 1.

of literature data [29–33]. The numbering of the carbon atoms in uridine monophosphate and polyamines is shown in Scheme 1.

At pH from about 9 to 10, i.e. in the range of occurrence of $(Urd)H_2(Put)^+$ and (Urd)H(Put) molecular complexes the changes in the ^{13}C NMR spectra indicate that the interaction centers are the nitrogen N(3) atoms of the pyrimidine rings from uridine.

At pH 10 the chemical shifts of C(2) and C(4) atoms of Urd are 1.52 and 2.03 ppm, respectively, much higher than for C(5) and C(6) atoms and also much higher compared to the changes in the pH range at which no adducts are formed (Fig. 1(a), Table 2). The pattern of signal shifts for Put indicates that such centres in PA are the protonated $–NH_2$ groups (Table 2).

A similar agreement between the results of the potentiometric studies and the results of ^{13}C and ^{31}P NMR investigation was also found for the systems with UMP (Table 2). Formation of the $(UMP)H_3(en)$ adduct occurring in the pH range from 4 to about 8 (at pH ~6, about 65% of components occur in the form of molecular complex) involves interaction of PA and a negatively charged phosphate group (evidenced by the chemical shift of the ^{31}P NMR signal which is about 0.18 ppm, and small shifts of the ^{13}C NMR signals of the carbon atoms of ribose) (Table 2). The shifts of ^{13}C NMR signals of ribose carbon atoms are considerably higher in the range of the $(UMP)H_3(en)$ domination (i.e. at pH 6), when compared to the range in which the $(UMP)H_2(en)^-$ complex occurs, i.e. pH 6–10.5 (at pH 9, about 55% of the total amount of bioligands is bound in the adducts). With increasing pH, the change in the ^{13}P signal decreases, while that of the carbon atoms in the vicinity of N(3), i.e. C(2) and C(4) from UMP, increases (Table 2). Moreover, the shift of the ^{31}P NMR signal from the phosphate group is small at about pH 10, which means that in the molecular complex $(UMP)H_2(en)^-$ the ligands interact mainly through the N(3) atom and the protonated amine groups of the PA. A similar type of interaction with no involvement of the phosphate group has been observed for the AMP/Spm system [33].

In the system of UMP and tn in which, according to the potentiometric studies, three adducts are formed, significant chemical shifts of the signals in the ^{31}P NMR spectrum were observed at pH corresponding to the dominance of the form $(UMP)H_4(tn)^+$, i.e. in the pH range below 6 (where 85% of the components is in the form of the adduct). In this range of acidity, also the shifts of the signals attributed to ribose carbon atoms were observed (there is no change in the signal positions from C(2) and C(4) atoms), which confirms that only the phosphate group is involved in formation of this adduct. At higher pH where the adduct $(UMP)H_3(tn)$ dominates (Fig. 2), in the ^{13}C NMR spectrum the signals assigned to the carbon atoms of ribose, as well as to C(2) and C(4) of the base, are shifted.

Moreover, a change of the ^{31}P NMR spectrum is observed (Table 2). This change points to the possibility of interactions through the phosphate group and the nitrogen atom N(3). The $(UMP)H_3(tn)$ species is an intermediary form between

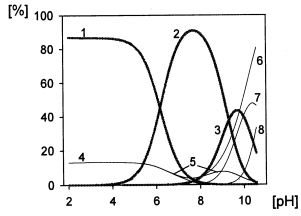

Fig. 2. Distribution diagrams for the UMP/tn system: 1, $(UMP)H_4(tn)^+$; 2, $(UMP)H_3(tn)$; 3, $(UMP)H_2(tn)^-$; 4, $H_2(UMP)^-$; 5, $H_2(tn)^{2+}$; 6, UMP^{3-}; 7, $H(tn)^+$; 8, tn; $C_{UMP} = C_{tn} = 0.01$ M.

the compound with interactions mainly through the phosphate group, as discussed above ($(UMP)H_4(tn)^+$ complex), and the molecular complex $(UMP)H_2(tn)^-$ formed at high pH, where the main reaction center is the N(3) atom of the nucleotide. At pH about 10 (40% of the substances occur as diprotonated adduct) only the shifts of the ^{13}C NMR signals due to C(2) and C(4) atoms by 3.92 and 5.35 ppm, respectively, were observed, while the signal in the ^{31}P NMR spectrum was practically unchanged (a shift by only 0.03 ppm).

The shift of the ^{31}P NMR signal (e.g. 0.44 ppm at pH 6) for the UMP/Put system in acidic medium — i.e. in the pH range of the adduct $(UMP)H_4(Put)^+$ occurrence (pH ~4–6) (Fig. 1(b)) — indicates the involvement of the phosphate group in formation of this molecular complex. In the same pH range, ^{13}C NMR spectra also reveal a change in the signal assigned to ribose carbon atom C(5′) (0.1 ppm), which confirms the above conclusion. With increasing pH (in the range of pH from 6.5 to ca. 10.5), the shift of C(2) and C(4) signals increases, which means that in these conditions in which both adducts [i.e. $(UMP)H_3(Put)$ and $(UMP)H_2(Put)^-$] are formed, the ligands interact mainly through the N(3) atom from the pyrimidine base (the ^{31}P NMR signals shift only by 0.01 and 0.05 ppm) and the protonated amine groups of PA. At pH 8 and pH 10, 85% and 50% of the total amount of components, respectively, is bound in the adducts (Fig. 1(b)).

3.2. Cu(II)/Urd or UMP binary systems

Results of the computer analysis of the potentiometric titration data for the systems Cu(II)/Urd and Cu(II)/UMP are shown in Table 1. The protonated complex of Urd and Cu(II) forms in solution already at low pH values (Fig. 3(a)). This complex species has been described previously [14,22]. The binuclear complex of type M_2L_2 starts to form at pH 6 and at higher pH disappears and practically the total amount of metal ions is bound in the hydroxo complexes formed.

The value of the $Cu(UMP)^-$ complex stability constant is significantly higher than that of the $Cu(Urd)^+$ species, suggesting a different mode of coordination (Table 1). The $Cu(UMP)^-$ complex starts forming from about pH 5.5 (Fig. 3(b)). In the basic medium, the hydroxo compounds dominate and from pH 9 they bind practically all the copper ions available.

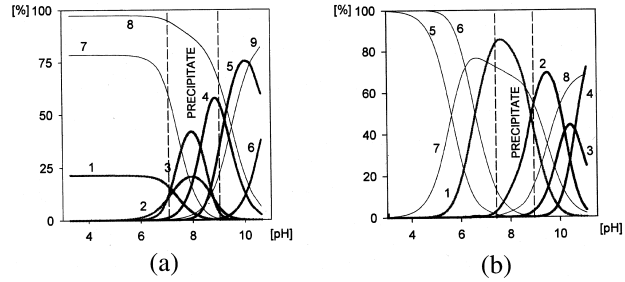

Fig. 3. Distribution diagrams for the systems: (a) Urd/Cu(II): 1, $Cu(Urd)H^{2+}$; 2, $Cu(Urd)^+$; 3, $(Cu)_2(Urd)_2^{2+}$; 4, $Cu(Urd)(OH)$; 5, $Cu(Urd)(OH)_2^-$; 6, $Cu(Urd)(OH)_3^{2-}$; 7, Cu^{2+}; 8, H(Urd); 9, Urd^-; $C_{Cu} = 0.0003$ M, $C_{Urd} = 0.0008$–0.0017M. (b) UMP/Cu(II): 1, $Cu(UMP)^-$; 2, $Cu(UMP)(OH)^{2-}$; 3, $Cu(UMP)(OH)_2^{3-}$; 4, $Cu(UMP)(OH)_3^{4-}$; 5, $H_2(UMP)^-$; 6, Cu^{2+}; 7, $H(UMP)^{2-}$; 8, UMP^{3-}; $C_{Cu} = 0.0003$ M, $C_{UMP} = 0.0008$–0.0017 M.

The mode of coordination of the complexes was determined on the basis of the equilibrium studies and spectral analysis. The λ_{max} of 713 nm for the $Cu(Urd)^+$ complex at pH 6.5 points to the monofunctional coordination of N1 type, which agrees with the results of the earlier studies of the systems with Ado and Cyd [27,34]. As follows from the results of the EPR study, an increase in the number of coordinated donor atoms is accompanied by a decrease in the value of $g_{||}$ and an increase in $A_{||}$, which has been observed for the chromophores $Cu–N_x$ ($x = 1$–6) and $Cu–N_xO_y$ ($x = 0$–4, $y = 0$–4) [35,36]. The values of $g_{||} = 2.3333$ and $A_{||} = 164$ at pH ~6.1 for the $Cu(Urd)^+$ complex indicate the coordination through a single nitrogen atom (Table 3, Fig. 4(b)). On the other hand, an increase in the $g_{||}$ value with decreasing pH (in the range in which only the $CuHUrd^{2+}$ complex

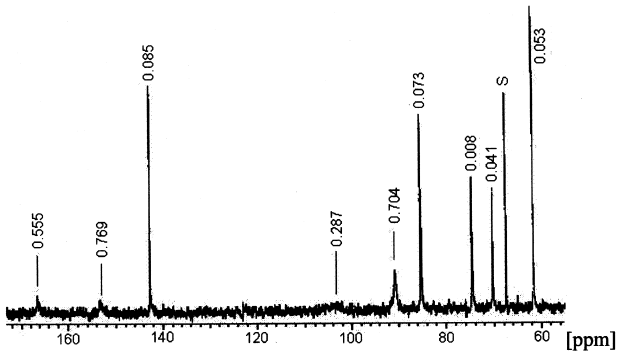

Fig. 5. ^{13}C NMR spectra of the Cu(II)/Urd system at pD = 6, C_{Urd} = 0.1 M, C_{Cu} = 0.0013 M, with changes in the signal position relative to those in the spectrum of a metal-free system at the same pD. The greatest changes are for C(2) 0.555 ppm and C(4) 0.769 ppm, and also for C(1′) 0.704 ppm.

occurs) indicates a weakening of the Cu–N interaction in the protonated complex.

The results of the EPR study also confirm the presence of the dimer $Cu_2(Urd)_2^{2+}$. A disappearance of the signal is observed at about pH 7 (Fig. 4(c)), due to spin coupling in the binuclear complex.

The changes in NMR signals were analysed taking into account the limitations of this method following from the presence of paramagnetic ions in the systems studied. In order to minimize the NMR signal broadening, the spectra were recorded for very low concentrations of the metal. As observed for analogous systems [13,15,16,18,19], significant changes of the shifts were found to occur only in the pH ranges of complex formation (the ranges have been determined from potentiometric studies). Fig. 5 presents an example of the ^{13}C NMR spectrum obtained by the method of decoupling of the complex of Cu(II) with Urd. This technique was also used to determine the coordination mode in similar systems with paramagnetic species [30,31,37]. The conclusions on the sites of coordination following from NMR studies have been verified by the UV–Vis and EPR results as well as comparative analysis of the equilibrium study data. Good correlation between results of independent methods makes it possible to make reliable inference about the coordination mode.

In the system Cu/Urd, at pH ~6, at which the $Cu(Urd)^+$ and $Cu_2(Urd)_2^{2+}$ forms exist, the ^{13}C NMR spectrum shows the shift of the C(2), C(4) and C(5) signals by 0.77, 0.56 and 0.29 ppm, respectively, which indicates coordination through the N(3) atom of the nucleoside (Table 4). At pH 4 (i.e. in conditions at which only the $CuHUrd^{2+}$ complex is formed) the shifts are much lower (changes for C(2) and C(4) atoms are only 0.018 and 0.008 ppm, respectively).

In the whole pH range considered, the positions of the IR stretching vibration bands assigned to the carbonyl groups (1652 and 1692 cm^{-1} for C(2)=O and C(4)=O, respectively) are not changed in the spectra of the system Cu(II)/Urd relative to their positions in the spectra of metal-free Urd, which testifies to the lack of interactions of these groups of the bioligand with metal ions. On the other hand, the observed changes in the positions of the β N(3)–H band (at 1524 cm^{-1}) support the above conclusion of coordination through N(3) atoms in both complexes. The IR bands were assigned on the basis of literature data [38,43,44].

At pH of about 10–11 (i.e. in the range of occurrence of $Cu(Urd)(OH)_x$ complexes), the position of the UV–Vis band indicates a coordination with the contribution of the nitrogen atom from Urd and oxygen atoms from OH^- groups. In order to draw more reliable conclusions on the mode of coordination in the complex studied, a series of absorption measurements was performed for the systems Cu(II)/acetylacetone and Cu(II)/acetylacetone/NH_3 (also with possible N_xO_y type of chromophore). In the pH range of the Cu(acac) complex domination (i.e. for the coordination of O2 type), λ_{max} = ~680 nm, while, in the range of domination of the $Cu(acac)_2$ complex (O4 chromophore), λ_{max} = 630 nm. In the ternary system Cu/acac/NH_3, at Cu:acac ratio 1:1, the band of λ_{max} = 663 nm was recorded irrespective of ammonia concentration, which indicates a coordination with the O2N1 chromophore. In spite of different types of ligands, the position of the band corresponding to $Cu(Urd)(OH)_x$ species (λ_{max} = 660 nm), suggests the interaction of copper ions with the N(3) atom of the nucleoside and oxygen atoms from hydroxyl groups. The suggested involvement of N(3) is confirmed by the shifts of ^{13}C NMR signals from the atoms C(2) and C(4) located in the neighborhood of the donor atom, 0.18 and 0.42 ppm, respectively (Table 4). The above conclusion is also confirmed by supplementary ^{15}N NMR study. The shifts of the signal attributed to N(3) atom is

Table 4
Differences between ^{13}C NMR chemical shifts for the ligands in the Urd/Cu and UMP/Cu systems in relation to metal-free systems

	7.0	0.676	1.183	–	0.000	0.809	0.091	0.026	0.064	0.140	4.183
	10.0	0.243	0.060	0.046	0.061	0.121	0.015	0.000	0.060	0.015	0.038

0.123 ppm (the shift of the signal from N(1) atom is only 0.001 ppm). The ^{15}N NMR signal positions were assigned on the basis of literature data [39,40]. The involvement of oxygen atoms from carbonyl groups should be excluded on the basis of IR study in which no signal shifts were observed for the complex relative to the band positions for a free ligand.

In the ^{13}C NMR spectra of the systems of Cu(II) with UMP at pH ~7, the range at which the Cu(UMP)$^-$ complex dominates, the greatest changes in the chemical shift were found for the signals of C(2) and C(4) atoms, 0.68 and 1.18 ppm, respectively (Table 4). These shifts suggest the coordination through the oxygen atoms of the carbonyl groups or the nitrogen atom of the base. The question was solved by IR study. No shifts of the IR bands corresponding to the carbonyl groups (C(2)=O and C(4)=O) were observed, which excludes the involvement of the oxygen atoms from these groups in the Cu(UMP)$^-$ complex. As already mentioned, the value of the stability constant for Cu(UMP)$^-$, significantly higher than that of Cu(Urd)$^+$, suggests the involvement of an additional coordination site in the complex with the nucleotide. The change in the ^{13}C NMR signal ascribed to C(5′) at pH 7 is 0.14 ppm, and the chemical shifts of the phosphorus signal in the ^{31}P NMR spectrum, 4.18 ppm (Table 4), indicate that this additional site of interaction in Cu(UMP)$^-$ are the phosphate groups of the nucleotide. In conclusion, the above results point to coordination of N1O1 type.

The mode of coordination of Cu(UMP)(OH)$_x$ complexes (formed at pH above 9 in the condition when precipitate dissolves) was found to be substantially different from that of the Cu(UMP)$^-$ complex. At pH ~10 no shifts in the position of ^{31}P NMR signals were observed, which excludes the involvement of the phosphate group in the interactions (Table 4). On the other hand, analysis of the changes in IR band positions for Cu(UMP)(OH)$_x$ species indicates that only the oxygen atom from the C(2)=O group from the nucleotide is involved in the coordination. The stretching band at 1692 cm^{-1} is shifted, whereas that corresponding to C(4)=O at 1652 cm^{-1} remains unchanged (Fig. 6).

Moreover, the ^{13}C NMR signal from the C(2) atom is shifted by 0.24 ppm, while the signal attributed to C(4) is shifted by only 0.06 ppm (Table 4). The fact that Cu(II) interacts with the oxygen atom C(2)=O and does not interact with N(3) is confirmed by additional ^{15}N NMR study. The shifts of the signals attributed to N(3) and N(1) (unavailable for coordination) are practically the same (0.7 ppm). Moreover, the position of the absorption band at pH >9 (λ_{max}=674 nm) as well as the EPR parameters (Table 3) support the above conclusion concerning the coordination of metal ions only through the oxygen atoms from UMP and those from hydroxyl groups, in the absence of interactions with nitrogen atoms.

3.3. Cu(II)/Urd/PA ternary systems

Table 5 presents the stability constants of complexes formed in ternary systems comprising Cu(II) ions, nucleosides and the PA studied. The change in the size of the ring in the mixed-ligand complex related to the increasing length of the PA is manifested as a decrease in the thermodynamic stability of the coordination complexes.

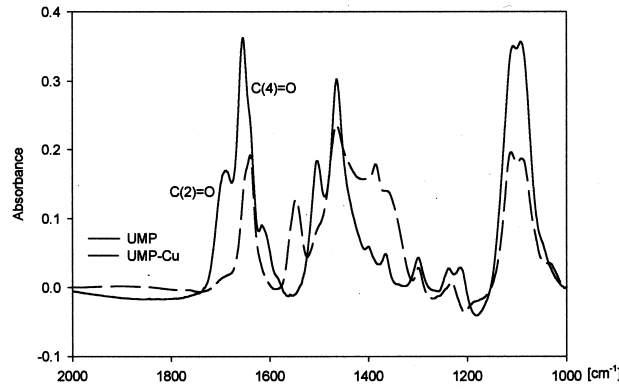

Fig. 6. The changes in IR spectra for the Cu(II)/UMP system in relation to free UMP at pH above 10.0.

The most stable compound, Cu(Urd)(en)$^+$, starts forming from pH of about 4.5, while the compounds with tn and Put form from pH of about 6.5 and 8, respectively (Fig. 7). The concentration of the Cu(Urd)(Put)$^+$ species is relatively low, which is consistent with a tendency of Put to assume a monofunctional coordination and to form protonated complexes [41,42].

Analysis of the chemical shifts of ^{13}C NMR signals indicate that the coordination site in Urd is the N(3) atom in all studied ternary systems. For example, the shifts of the signals corresponding to C(2) and C(4) atoms from the Urd molecule in the system Cu/Urd/en, at pH 6.5, are 0.202 and 0.235 ppm, respectively. The analogous shifts for the system Cu/Urd/tn are 1.115 and 0.930 ppm (pH 9), and for the system Cu/Urd/Put they are 0.829 and 1.204 ppm at pH 8. The above conclusions are in good agreement with the results of EPR and UV–Vis studies (Table 6).

The equilibrium constants of formation of the complexes Cu(PA)$^{2+}$ + Urd$^-$ ⇋ Cu(Urd)(PA)$^+$, calculated from the stability constant values of binary and mixed-ligand complexes ($\log K_e = \log \beta_{Cu(Urd)(PA)} - \log \beta_{Cu(PA)}$), are 6.65, 5.32 and 2.90 for the complexes Cu(Urd)(en)$^+$, Cu(Urd)tn$^+$ and Cu(Urd)(Put)$^+$, respectively. Taking into consideration the fact that the mode of Urd interaction (as discussed above) is the same in all studied systems, a significantly lower log K_e value for the Cu(Urd)(Put)$^+$ complex formation suggests monofunctional coordination of PA. In turn, the equilibrium constants of formation of the complexes Cu(Urd)(PA)$_2^+$ ($\log K_e = \log \beta_{Cu(Urd)(PA)2} - \log \beta_{Cu(PA)}$) (PA=en or tn), equal to 8.3 and 7.1, suggest difunctional interaction of the second molecule of en and tn. Although the overlapping of the domination range makes it difficult to identify the coordination mode of some species, in certain complexes, e.g. Cu(Urd)(en)$_2^+$, the N5-type of coordination was determined ($g_{||}$=2.218, $A_{||}$=179). The position of the band with λ_{max}=648 nm in the electronic spectrum also suggests this type of chromophore (probably formation

of a square pyramidal complex occurs), as can be inferred from analysis of the spectra of analogous systems [35]. The change in $g_{||}$, and in particular in $A_{||}$ value, at pH 10.5, thus in the area of domination of the $Cu(Urd)(en)_2(OH)$ hydroxo complex, testifies to the presence of the N5O1 chromophore. Similarly, analysis of the electronic spectrum of Cu/Urd/tn indicates N3 or N3O1 coordination in $Cu(Urd)(tn)^{+}$ and $Cu(Urd)(tn)(OH)_x$, respectively. A particularly important result is the confirmation of the monofunctional coordination of Put in $Cu(Urd)H(Put)^{2+}$, for which the values of $g_{||}=2.263$, $A_{||}=158$ and $\lambda_{max}=649$ (Table 6) indicate N2 coordination.

3.4. Cu(II)/UMP/PA ternary systems

Protonated complexes in the system Cu/UMP/Put start forming from about pH 5.5 (Fig. 8). The shortest of the diamines, en, practically does not form compounds of this kind, while the medium-length one, tn, forms both heteroligand complexes of the MLL′ type and protonated species. The stability constants of the complexes forming in the system Cu/UMP/diamine are given in Table 5.

The formation of $Cu(UMP)(en)^{-}$ from pH of about 5.5 is accompanied by a shift of the ^{31}P NMR signal (at pH 8 by about 0.1 ppm). Moreover, in the ^{13}C NMR spectrum, the positions of the peaks corresponding to the C(2) and C(4) atoms are shifted (0.127 and 0.075 ppm, respectively, at pH ~8), which suggests that besides a coordination involving

Table 6
EPR data for PA/Urd and UMP/Cu(II) complexes

Complexes	PH	EPR		UV–Vis (λ_{max})	Coordination
		$g_{\|\|}$	$A_{\|\|}$		
$Cu(Urd)H_2(en)_3^{3+}$	6.5	2.212	185	550	5–6N
$Cu(Urd)(en)_2^{+}$	9	2.218	179	648	5N
$Cu(Urd)(en)_2(OH)$	10.5	2.218	198	600	5NO
$Cu(Urd)(tn)^{+}$	9	2.234	188	601	3N
$Cu(Urd)(tn)_2(OH)_x$	10.5	2.235	196	602	3NO
$Cu(Urd)H(Put)^{2+}$	8	2.263	158	649	2N

$Cu(UMP)(tn)^{-}$	8.5	2.232	189	592	3NO
Cu(UMP)H(Put)	8	2.265	161	611	2NO

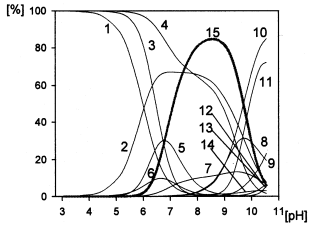

Fig. 8. Distribution diagrams for the Cu/UMP/Put system: 1, $H_2(UMP)^{-}$; 2, $H(UMP)^{2-}$; 3, Cu^{2+}; 4, $H_2(Put)^{2+}$; 5, $Cu(UMP)^{-}$; 6, $CuHPut^{3+}$; 7, $Cu(Put)^{2+}$; 8, $H(Put)^{+}$; 9, Put; 10, UMP^{3-}; 11, $Cu(Put)_2^{2+}$; 12, $Cu(UMP)(OH)_2^{3-}$; 13, $Cu(UMP)(OH)_3^{4-}$; 14, $Cu(UMP)(OH)^{2-}$; 15, Cu(UMP)H(Put); $C_{Cu} = 0.0003$ M, $C_{UMP} = C_{Put} = 0.0008$ M.

the phosphate group also the N(3) atom of the nucleotide is involved in coordination. The values of the EPR parameters (at pH 6, $g_{||} = 2.219$, $A_{||} = 198$) confirm the presence of the N3O1 chromophore (both nitrogen atoms from the PA), which is also confirmed by the position of the visible band with $\lambda_{max} = 629$ nm.

For the systems with tn, the EPR parameters (Table 6) and the significant shifts of NMR signals assigned to the phosphorus atom and C(2) and C(4) atoms indicate N3O coordination involving both the phosphate groups, the N(3) atom from the pyrimidine ring and the PA donor atoms. This mode of coordination is also implied by the position of the electron band with $\lambda_{max} = 592$ nm (pH 8.5).

According to the parameters of the EPR and visible spectra, the heteroligand complex Cu(UMP)H(Put) has a coordination mode type N2O ($g_{||} = 2.217$, $A_{||} = 196$, $\lambda_{max} = 565$, at pH 8). Taking into account the values of the chemical shifts of NMR signals of phosphorus and carbon atoms from the pyrimidine ring (in the complex Cu(UMP)H(Put) the shifts for phosphorus and C(2) and C(4) atoms are 0.672, 0.542 and 0.899 ppm, respectively, at pH 8), it is reasonable to assume a coordination involving the phosphate group of the nucleotide, N(3) atom from the pyrimidine ring and one donor atom from the amine.

As follows from the above discussion, the presence of PA changes the coordination character of UMP. In the Cu/UMP binary system, at high pH, the N(3) atom from pyrimidine ring and a phosphate group do not take part in complexation. On the other hand, in the Cu/UMP/Put system, these groups are involved in coordination, similar to the systems with en and tn.

Abstract

The hexadentate ligand *N*,*N*′,*N*″-tris(2-pyridylmethyl)-*cis*,*cis*-1,3,5-triaminocyclohexane (tachpyr) forms stable metal complexes from the salts $M(ClO_4)_2 \cdot 6H_2O$ (M = Zn^{2+} and Cd^{2+}) and $Hg(ClO_4)_2$ in methanol or ethanol. The complexes $[Zn(tachpyr)](ClO_4)_2 \cdot CH_3OH$ (**1**·CH_3OH), $[Cd(tachpyr)](ClO_4)_2$ (**2**) and $[Hg(tachpyr)](ClO_4)_2$ (**3**) have been isolated, and their solid state structures have been determined and analyzed. The coordination sphere changes from octahedral to trigonal-prismatic geometry with increasing metal radius. The trigonal twist angles (α) are 43.7(2)° in compound **1**·CH_3OH, range between 11.0(4)° and 21.7(2)° in compound **2** and range between 3.1(3)° and 5.5(2)° in compound **3**. To accommodate larger metal ions there is also a slight outward expansion of the triaminocyclohexane nitrogens, which leads to a reduction in the average cyclohexyl ring C–C–C–C torsion angles (β) with concomitant flattening of the ring. The torsion angles (β) in **1**·CH_3OH are 52.3(6)° and 52.4(6)°, range between 46.1(9)° and 52.7(9)° in compound **2** and range between 45.1(6)° and 52.9(7)° in compound **3**. ©2000 Elsevier Science Ltd All rights reserved.

1. Introduction

Ligands that are preorganized or predisposed to bind metal ions form particularly thermodynamically or kinetically stable complexes [1–4]. We previously reported an efficient synthesis of a novel hexadentate ligand, *N*,*N*′,*N*″-tris(2-pyridylmethyl)-*cis*,*cis*-1,3,5-triaminocyclohexane (referred to as tachpyr; Fig. 1) [5], based on *cis*,*cis*-1,3,5-triaminocyclohexane (tach) which is a versatile face-capping N_3 ligand and can form complexes with a large number of first-row transition metal ions with varied charges and sizes [6–10]. In studying the complexation properties of the tachpyr ligand, we reported the preparation and structure of the first metal complexes of this chelator, $[Ga(tachpyr)](NO_3)_3$ and $[In(tachpyr)](NO_3)_3$ [10]. The tachpyr ligand readily makes metal complexes by a ring flip from an open all-equatorial conformation to a closed all-axial conformation (Fig. 1), encapsulating metal ions ranging in size from Ga^{3+} (six-coordinate ionic radius of 0.76 Å) through many first-row transition elements [11] to In^{3+} (radius 0.94 Å) in alcoholic or aqueous media. Study of the interaction of Fe(II) and Fe(III) with tachpyr, which affords mono and diimino Fe(II) complexes by oxidative dehydrogenation of one or two of the aminomethylene group(s) of tachpyr in the presence of oxygen, has also been reported [12].

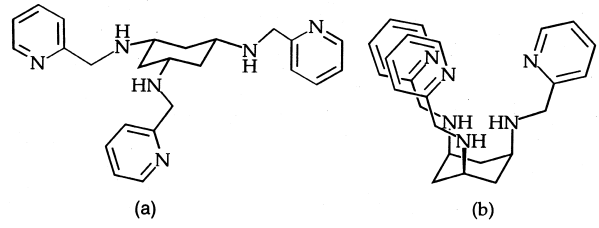

Fig. 1. Structures of tachpyr: open (a) and closed (b) conformation.

Since the group IIB metal ions (Zn^{2+}, Cd^{2+} and Hg^{2+}) do not have an electronic preference for either an octahedral or a trigonal prismatic coordination geometry, their tachpyr complexes may reveal effects of metal radius and ligand conformational preferences on geometry. Herein we report the preparation, characterization and structures of these complexes.

2. Experimental

Caution! Although we have not encountered any problems, it should be noted that perchlorate salts are potentially explosive and should be handled with care.

2.1. Materials and methods

Diethyl ether was distilled from Na/K. Anhydrous grade MeOH and CH_3CN and the salts $Zn(ClO_4)_2\cdot 6H_2O$, $Cd(ClO_4)_2\cdot 6H_2O$ and $Hg(ClO_4)_2$ were obtained from Aldrich. Anhydrous grade EtOH was obtained from Pharmco. Tachpyr was prepared as previously reported [5].

Proton NMR spectra were obtained at 360 MHz with a Bruker AM360 instrument. Chemical shifts are reported in ppm on the δ scale relative to TMS (DMSO-d_6 or CH_3CN-d_3 solutions). Proton chemical shifts are annotated as follows: ppm (multiplicity or spin system, coupling constant if measurable, integral, assignment). Fast atom bombardment (FAB-MS) mass spectra were obtained on an Extrel 4000. Elemental analyses were performed by Atlantic Microlabs (Atlanta, GA).

2.1.1. Preparation of zinc(II) tachpyr diperchlorate methanol solvate (*1*·CH_3OH)

To a colorless solution of $Zn(ClO_4)_2\cdot 6H_2O$ (0.0906 g, 2.43×10^{-4} mol) in anhydrous EtOH (3 ml) was added a yellow solution of tachpyr (0.0986 g, 2.45×10^{-4} mol) in anhydrous MeOH (3 ml), affording a pale yellow precipitate. After standing for 2 h, the pale yellow precipitate was isolated by decanting the supernatant and washed with Et_2O and MeOH. The product was dried under reduced pressure, affording 22.0% yield (0.0370 g, 5.28×10^{-5} mol) as a white solid. *Anal*. Calc. for $C_{24}H_{30}Cl_2N_6O_8Zn\cdot CH_3OH$: C, 42.97; H, 4.90; N, 12.03. Found: C, 42.91; H, 4.67; N, 12.19%. ^{1}H NMR (360 MHz, DMSO-d_6, 25°C): δ 8.11, 7.81, 7.63, 7.50 (t, d, d, t, 4H, $^3J=7.8$ and 5.7 Hz, $^4J=1.3$ Hz, C_5H_4N); 4.71 (dd, *A*XY, 1H, $^3J=8.5$ and 8.4 Hz, N*H*–CH_2-py); 4.14 (m (two dd), A*XY*, 2H, NH–C*H*$_2$–py); 3.26 (br s, *A*MM′XX′, 1H, cyclohexyl methine H′s); 2.34 (br d, A*MM*′XX′, 1H, equatorial cyclohexylmethylene H diastereotopic), 1.90 (br d, AMM′*XX*′, 1H, axial cyclohexylmethylene H′s, diastereotopic). MS (FAB/glycerol): 465 (M−2ClO_4^-).

2.1.2. Preparation of cadmium(II) tachpyr diperchlorate (*2*)

To a colorless solution of $Cd(ClO_4)_2\cdot 6H_2O$ (0.088 g, 2.1×10^{-4} mol) in anhydrous EtOH (8 ml) was added a yellow solution of tachpyr (0.084 g, 2.1×10^{-4} mol) in anhydrous MeOH (8 ml) affording a brown suspension immediately. After standing for 2 h, feather-shaped crystals precipitated. The product was isolated by decanting the supernatant, washing the residue with Et_2O and then drying under reduced pressure, affording a white solid in 51% yield (76.3 mg, 1.07×10^{-4} mol). *Anal*. Calc. for $C_{24}H_{30}CdCl_2N_6O_8$: C, 40.37; H, 4.24; N, 11.77. Found: C, 40.12; H, 4.22; N, 11.48%. ^{1}H NMR (360 MHz, CH_3CN-d_3, 25°C): δ 8.80, 7.99, 7.55, 7.49 (d, t, t, d, 4H, $^3J=7.8$ and 5.5 Hz, C_5H_4N); 4.21 (dd, *A*MX, 1H, $^2J=15.8$ Hz, $^3J=15.8$ Hz, NH–C*H*$_2$–py, diastereotopic), 4.01 (dd, A*M*X, 1H, $^2J=15.8$ Hz, $^3J=5.5$ Hz, NH–C*H*$_2$–py, diastereotopic); 3.55 (br d (dd), AM*X*, 1H, $^3J=15.8$ and 5.5 Hz, N*H*–CH_2–py); 3.46 (br s, *A*MM′XX′, 1H, cyclohexylmethine H); 2.28 (br d, A*MM*′XX′, 1H, equatorial cyclohexylmethylene H′s), 2.02 (br d, AMM′*XX*′, 1H, axial cyclohexylmethylene H′s, diastereotopic). MS (FAB/glycerol): 614 (M−ClO_4^-).

2.1.3. Preparation of mercury(II) tachpyr diperchlorate (*3*)

To a solution of $Hg(ClO_4)_2$ (0.038 g, 9.4×10^{-5} mol) prepared by sonication (5 min) in anhydrous EtOH (4 ml) was added a yellow solution of tachpyr (0.038 g, 9.4×10^{-5} mol) in anhydrous EtOH (2 ml), affording a yellowish-white precipitate. The yellowish-white precipitate was isolated by decanting the supernatant. The residue was washed with Et_2O (4 ml) and dried under reduced pressure, giving a pale yellow solid. The crude product was dissolved in CH_3CN (5 ml), and Et_2O was diffused into it, forming a mixture of yellow precipitate and white crystals. The white crystals were isolated manually and re-dissolved in CH_3CN (5 ml). Et_2O was diffused into a CH_3CN solution of the crude product, forming prisms which were isolated by decanting the supernatant and dried under reduced pressure, affording a 52% yield (39.1 mg, 4.87×10^{-5} mol). *Anal*. Calc. for $C_{24}H_{30}Cl_2HgN_6O_8$: C, 35.94; H, 3.77; N, 10.48. Found: C, 36.24; H, 3.72; N, 10.39%. ^{1}H NMR (360 MHz, DMSO-d_6, 25°C): δ 9.13, 8.06, 7.68 (d, t, m (2H), 4H, $^3J=7.9$ and 5.7 Hz, C_5H_4N); 4.91 (br d (dd), *A*MX, 1H, $^3J=13.7$ and 3.5 Hz, N*H*–CH_2–py); 4.35 (dd, A*M*X, 1H, $^2J=13.9$ Hz, $^3J=13.7$ Hz, NH–C*H*$_2$–py); 3.94 (dd, AM*X*, 1H, $^2J=13.9$ Hz, $^3J=3.5$ Hz, N*H*–CH_2–py); 3.44 (brs, *A*MM′XX′, 1H, cyclohexylmethine H); 2.44 (br d, A*MM*′XX′, 1H, equatorial cyclohexylmethylene H′s), 1.94 (br d, AMM′*XX*′, 1H, axial cyclohexylmethylene H′s, diastereotopic). MS (FAB/glycerol): 603 (M−2ClO_4^-).

2.2. X-ray data collection, structure solution and refinement for compounds *1*·CH_3OH, *2* and *3*

Single crystals suitable for X-ray crystallography of compounds **1**·CH_3OH, **2** and **3** were grown by diethyl ether diffusion into the acetonitrile solution of the corresponding metal complexes. Transparent single crystals were mounted on fibers and transferred to the goniometer. The crystals were cooled to −100°C during data collection by using a stream of cold nitrogen gas. Data collection was made on a Siemens SMART diffractometer with a CCD area detector, using graphite monochromated Mo Kα radiation. SHELXTL, version 5, software was used for solutions and refinement [13]. Absorption correction was carried out using the program SADABS [14]. The model was refined by full-matrix least-squares on F^2. A summary of data collection parameters is given in Table 1.

The structures were solved by direct methods. The cyclohexyl group and three nitrogens bonded to it in compound **2** were found to be disordered and resolved into two orientations with N1–C6 at 60% occupancy and N1′–C6′ at 40% occupancy. The two orientations differ in a twist of the chair conformation of the cyclohexyl ring. High thermal motion was also observed for anions, as is often found for perchlorate ions. Disorder models were not resolvable for these molecules. Although there is some evidence in the structure of compound **3** for the disorder observed for compound **2**, the slight elongation of thermal ellipsoids for N2, N3 and some of the cyclohexyl carbon atoms could not be resolved into a reasonable disorder model. The slight elongation of thermal ellipsoids could affect quantitative parameters, although the overall structure is clear. For the three structures, the geometrically constrained hydrogen atoms were placed in calculated positions and allowed to ride on the bonded atom with $B=1.2U_{eq}(C)$. Refinement of non-hydrogen atoms (except for C5′ in compound **2**, which could not be refined anisotropically) was carried out with anisotropic temperature factors. Selected bond lengths and angles of compounds **1**$\cdot CH_3OH$, **2** and **3** are presented in Table 2.

3. Results and discussion

3.1. Synthesis and solution behavior

The complexes [Zn(tachpyr)]$(ClO_4)_2\cdot CH_3OH$ (**1**$\cdot CH_3OH$), [Cd(tachpyr)]$(ClO_4)_2$ (**2**) and [Hg(tachpyr)]$(ClO_4)_2$ (**3**) were prepared by the reactions of the respective metal ion perchlorate salts $M(ClO_4)_2\cdot 6H_2O$ [M=Zn(II) and Cd(II)] or $M(ClO_4)_2$ [M=Hg(II)] and the ligand (1:1) in a mixture of methanol and ethanol. Colorless crystals of compounds **2** and **3** were obtained with reasonable yield

[b] Symmetry transformations used to generate equivalent atoms: $-y-3/2, -z-1, x+1/2$.

(>50%); however, the yield of colorless crystalline compound **1**·CH$_3$OH was poor (<25%).

The formation of complexes and the rigidity of coordination spheres of compounds **1**, **2** and **3** were investigated by proton NMR studies of Zn(II) and Hg(II) (DMSO-d_6 solvent) and Cd(II) (CH$_3$CN-d_3 solvent) complexes. The formation of metal complexes was easily confirmed by changes in the chemical shift and splitting patterns of the cyclohexyl protons relative to free tachpyr (Fig. 1a). The three 2-pyridylmethyl arms of tachpyr are assumed to coordinate M(II) in either the Λ or Δ configuration [15]. Proton NMR studies indicated that this configuration is static on the NMR time scale at room temperature, as shown by the chemically inequivalent methylene protons, (cyclohexylamine)NH–CH_2–pyridyl, which form an AMX (or AXY) spin system (H$_A$ is the amine hydrogen on tach).

3.2. Structural studies

X-ray structures of compounds **1**·CH$_3$OH), **2** and **3** are depicted in Figs. 2–4, respectively. Crystals of compounds **1**·CH$_3$OH, **2** and **3** consist of the di-cations $[LZn]^{2+}$, $[LCd]^{2+}$ and $[LHg]^{2+}$, respectively, and perchlorate anions. The Zn(II) complex (**1**·CH$_3$OH) crystallizes in the cubic space group $P2_13$, whereas the Cd(II) complex (**2**) and the Hg(II) complex (**3**) are essentially isostructural and

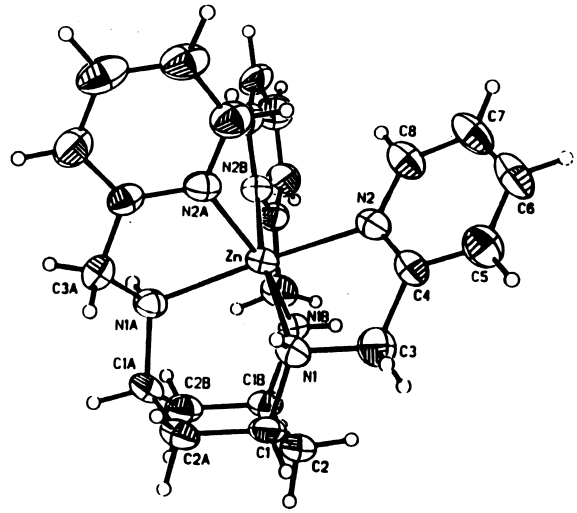

Fig. 2. Molecular structure of the metal complex cation of [Zn(tachpyr)](ClO$_4$)$_2$·CH$_3$OH (**1**·CH$_3$OH).

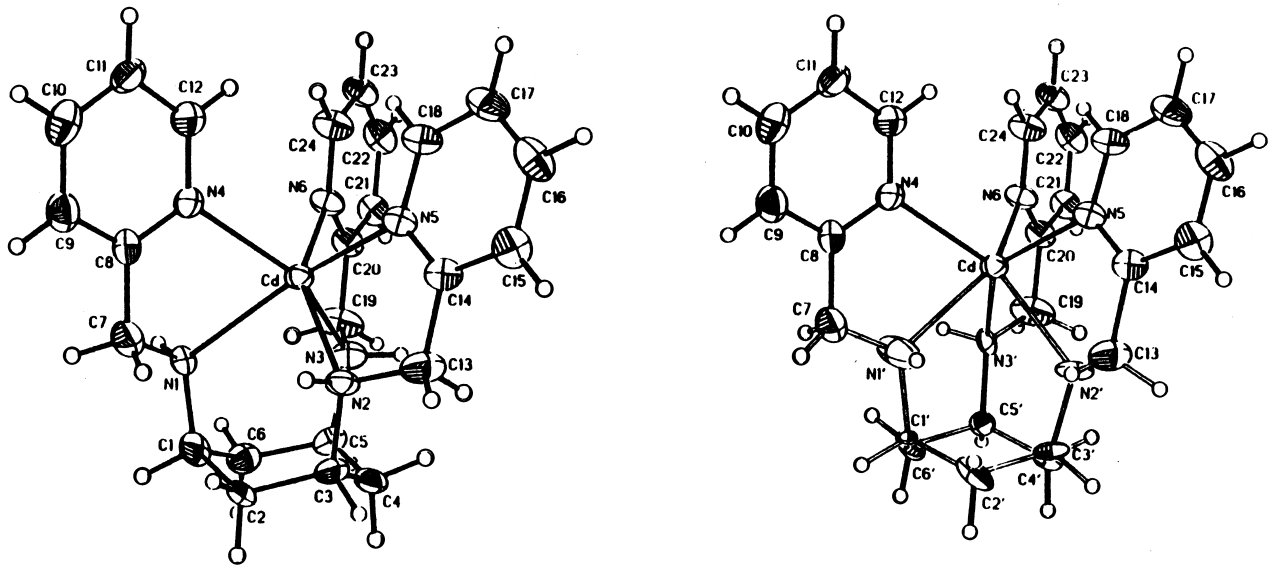

Fig. 3. Molecular structure of the metal complex cation of $[Cd(tachpyr)](ClO_4)_2$ (**2**) showing two disordered molecules with N1–C6 at 60% occupancy (left) and N1′–C6′ at 40% occupancy (right).

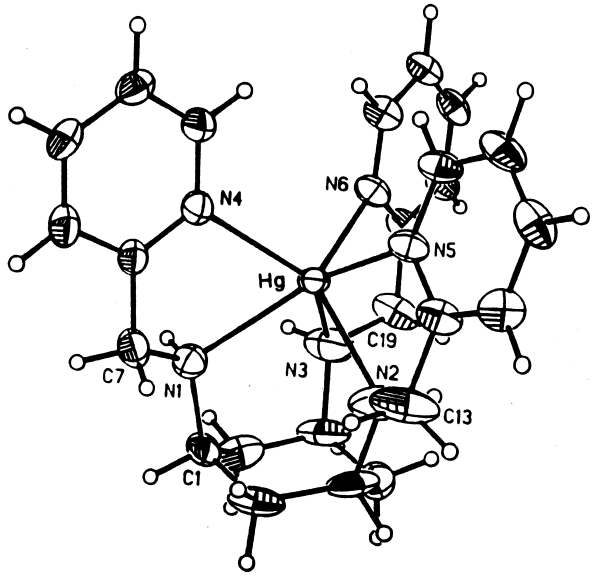

Fig. 4. Molecular structure of the metal complex cation of $[Hg(tachpyr)](ClO_4)_2$ (**3**).

crystallize in the monoclinic space group $P2_1/c$. Interestingly, the disorder obvious in the structure of the Cd(II) complex is not resolvable for the Hg(II) complex.

Tachpyr provides six nitrogens which can coordinate to metal ions, including group IIB [Zn(II), Cd(II) and Hg(II)]. Since these metal ions do not have an electronic preference for either an octahedral or a trigonal-prismatic configuration, the structures of their tachpyr complexes should reflect the conformational preference of tachpyr and non-bonded repulsions between donor groups. The coordination sphere of MN_6 in compound $\mathbf{1}\cdot CH_3OH$ is best described as a distorted octahedron, whereas that of compound **2** is classified as an intermediate between octahedral and trigonal-prismatic and that of compound **3** is close to trigonal-prismatic. The average twist angle (α) (Fig. 5) of compound **1** is 43.7(2)°, while those of compound **2** (disorder models 1 and 2) are 20.8(4) and 11.4(9)°, and that of compound **3** is 5(1)°. Without a major perturbation caused by the metal ion, the tachpyr ligand seems to have a ligand conformation preference for an octahedral geometry.

As the six-coordinate ionic radius increases from Zn^{2+} (0.88 Å) to Cd^{2+} (1.09 Å) and then to Hg^{2+} (1.16 Å) [16,17], the 2-pyridylmethyl arms straighten out to accommodate the longer metal–nitrogen bonds, two nitrogens on the same pendant arms come closer to being eclipsed, and the coordination geometry of the metal complexes approaches trigonal-prismatic. Similar trends have been observed in tricationic tachpyr complexes of Ga^{3+} (0.76 Å) and In^{3+} (0.93 Å) [10] and in di-cationic tachpyr complexes of Ni^{2+} (0.83 Å) and Mn^{2+} (high-spin, 0.97 Å) [11]. These structural features have also been reported in the complexes of *N*,*N*′,*N*′-tris(2-pyridylmethyl)-1,4,7-triazacyclononane [18,19].

The bond lengths M–N are larger for compounds **2** and **3** than for $\mathbf{1}\cdot CH_3OH$ (Table 3), reflecting the difference in six-coordinate ionic radii from Zn^{2+} in $\mathbf{1}\cdot CH_3OH$ to Cd^{2+} and Hg^{2+} in compounds **2** and **3**, respectively. The bond lengths of Zn–N (tach amine) and Zn–N (pyridyl) in $\mathbf{1}\cdot CH_3OH$ are 2.160(3) and 2.165(4) Å, which compare well with those

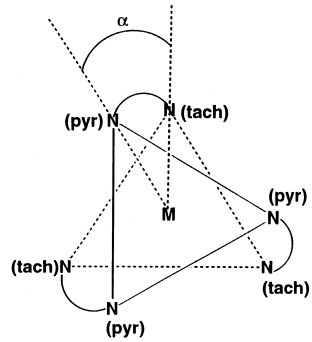

Fig. 5. The twist angle defined for the coordination sphere of $M(tachpyr)^{2+}$.

Table 3
Comparison of structural parameters in [Zn(tachpyr)]$(ClO_4)_2 \cdot CH_3OH$ (**1**·CH_3OH), [Cd(tachpyr)]$(ClO_4)_2$ (**2**) and [Hg(tachpyr)]$(ClO_4)_2$ (**3**)

Parameters	**1**·CH3OH	**2**		**3**
		Disorder model 1	Disorder model 2	
M–N bond distances (Å)				
M–N (tach amine)	2.160(3)	2.302(6)–2.400(5)	2.332(13)–2.422(9)	2.335(6)–2.487(6)
M–N (pyridyl)	2.165(4)	2.352(4)–2.361(4)	2.352(4)–2.361(4)	2.334(4)–2.461(4)
Twist angle α (°)	43.7(2)	19.6(2)–21.7(2) av. 20.8(4)	11.0(4)–12.0(8) av. 11.4(9)	3.1(3), 5.0(3), 5.5(2) av. 5(1)
C–C–C–C torsion angles of cyclohexyl framework (°)	52.3(6), 52.4(6) av. 52.35(3)	46.1(9)–52.7(9) av. 49(2)	49(1)–52(1) av. 49(4)	45.1(6)–52.9(7) av. 49(2)

of other ZnN_6 complexes. Typical Zn–N distances in zinc hexamine complexes are 2.143(5) Å (Zn–N (amine)) and 2.215(5) Å (Zn–N (pyridyl)) in $[Zn(ampy)_3]^{2+}$ (ampy = (2-pyridylmethyl)amine) [20] and an average Zn–N distance of 2.23 Å in $[LZn]^{2+}$ (L = 1,4,7-tris(*o*-aminobenzyl)-1,4,7-triazacyclononane) [21].

There are small differences in M–N bond lengths between compounds **2** and **3** (Table 3). The bond lengths of M–N in compound **3** are slightly longer than those in compound **2**, consistent with a difference in the six-coordinate ionic radii of Hg^{2+} and Cd^{2+} of 0.07 Å. The bond lengths of Cd–N in compound **2** and Hg–N in compound **3** are typical of metal hexamine complexes. The bond lengths of Cd–N (tach amine) in compound **2** range between 2.302(6) and 2.422(6) Å (average 2.36(2) Å), and those of Hg–N (tach amine) in compound **3** range between 2.335(6) and 2.487(6) Å (average 2.420(9) Å). The bond lengths of Cd–N (pyridyl) in compound **2** range between 2.352(4) and 2.361(4) Å (average 2.357(7) Å), and those of Hg–N (pyridyl) in compound **3** range between 2.334(4) and 2.461(4) Å (average 2.391(7) Å). These bond lengths of Cd–N and Hg–N compare well with those of other CdN_6 and HgN_6 polyhedra reported in the literature. Typical Cd–N distances in cadmium hexamine complexes are 2.34(2)–2.42(2) Å (Cd–N in $[Cd(en)_3]^{2+}$ (en = ethylenediamine) [22]) and 2.338(3) Å (Cd–N (amine)) and 2.343(4)–2.370(4) Å (Cd–N (pyridyl)) in $[Cd(bispicam)_2]^{2+}$ (bispicam = bis(2-pyridylmethyl)amine) [23]. Typical Hg–N distances in HgN_6 complexes are 2.350(4)–2.404(4) Å (Hg–N (amine)) and 2.352(4)–2.557(5) Å (Hg–N (pyridyl)) in $[Hg(bispicam)_2]^{2+}$ [24] and an average Hg–N distance of 2.43 Å in $[LHg]^{2+}$ (L = 1,4,7-tris(*o*-aminobenzyl)-1,4,7-triazacyclononane) [21].

Another effect of metal ion radius on the structures of the tachpyr metal complexes is a distortion of the cyclohexyl ring, as manifested in the C–C–C–C torsion angles (β) (Table 3). The torsion angles (β) in compound **1**·CH_3OH range between 52.3(6) and 52.4(6)° (average 52.35(3)°); in compound **2** they range between 46.1(9) and 52.7(9)° (average 49(2)°), and in compound **3** they range between 45.1(6) and 52.9(7)° (average 49(2)°). As the metal ion radius increases, increased distortion of the cyclohexane framework by the expansion of the cyclohexyl nitrogens away from the axial positions is effected to accommodate the metal. There is no significant difference in the distortion of the C–C–C–C torsion angles (β) between compounds **2** and **3**, which is consistent with the six-coordinate ionic radii of compounds **2** and **3**, which are similar.

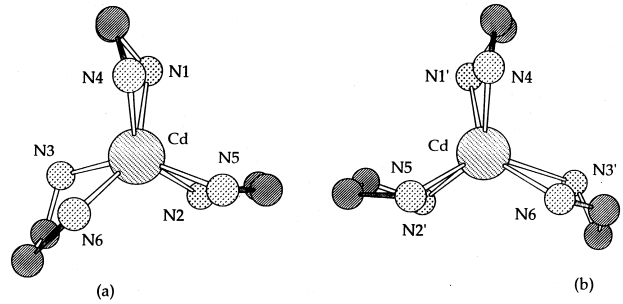

Fig. 6. Isomers of [Cdtachpyr]$(ClO_4)_2$: (a) $\Delta(\lambda\lambda\lambda)$ (isomer 1, 60%); (b) $\Lambda(\delta\delta\delta)$ (isomer 2, 40%).

The disorder in compound **2** indicates the presence of two different stereoisomers formed by two different twist directions (clockwise and counter-clockwise) of the twist of pendant arms. The counter-clockwise twist of the pendant arms forms a $\Delta(\lambda\lambda\lambda)$ isomer, and a clockwise twist of the pendant arms generates a $\Lambda(\delta\delta\delta)$ isomer. The $\Delta(\lambda\lambda\lambda)$ and $\Lambda(\delta\delta\delta)$ isomers are not enantiomers of each other (Fig. 6) since the $\Lambda(\delta\delta\delta)$ isomer has a lesser twist (average angle 11.4(9)°) and thus is closer to a trigonal-prismatic geometry than the $\Delta(\lambda\lambda\lambda)$ isomer (average angle 20.8(4)°). As expected, the presence of two different stereoisomers was not detected in the investigation by proton NMR at room temperature.

The structure of compound **3** can be defined as a $\Lambda(\delta\delta\delta)$ isomer, which is the most stable isomer among the four diastereomers ($\delta\delta\delta$, $\delta\delta\lambda$, $\delta\lambda\lambda$ and $\lambda\lambda\lambda$) due to a combination of steric and entropic factors [15]. Repulsive effects between puckered rings favor a $\Lambda(\delta\delta\delta)$ isomer; however, the entropy consideration that $\delta\delta\lambda$ and $\delta\lambda\lambda$ isomers are three times as probable as the $\delta\delta\delta$ and $\lambda\lambda\lambda$ isomers also plays a role [15].

4. Conclusions

Group IIB metal complexes with the ligand *N*,*N*′,*N*″-tris(2-pyridylmethyl)-*cis*,*cis*-1,3,5-triaminocyclohexane (tachpyr)

exhibit effects of metal radius on coordination geometry and ligand conformation. The tachpyr ligand forms a nearly octahedral complex with Zn(II), while it forms a complex intermediate between octahedral and trigonal-prismatic with Cd(II) and a slightly distorted trigonal-prismatic complex with Hg(II). Studies of the complexation chemistry of tachpyr and a variety of pendant-arm derivatives of tachpyr with first-row transition metal ions are in progress.

Supplementary data

Abstract

The solid state structure of the 1,2,3,5-dithiadiazolyl *p*-IC_6H_4CNSSN (**3**) is described. The molecules associate in dimer pairs, across an inversion centre, in an unusual *trans*-cofacial manner. The separation between the heterocyclic rings is 3.121 Å. The intradimer sulfur contacts (3.696 Å) are larger than those observed in dithiadiazolyls that associate in the more usual *cis*-cofacial manner. Individual *p*-IC_6H_4CNSSN molecules are linked into zigzag chains through weak I···S interactions (3.82 Å); each half of a [*p*-$IC_6H_4CNSSN]_2$ dimer is a member of separate chains that run in opposite directions. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Dithiadiazolyl radicals

1. Introduction

In recent years, 1,2,3,5-dithiadiazolyl (DTDA) radicals have been studied as building blocks for the design and synthesis of molecular magnets [1–5] and conductors [6–9]. The steric and electronic effects of the substituent R can be used to modify the molecular structure and hence the physical behaviour of the radical. In the solid state the majority of DTDA radicals associate as spin-paired dimers through the formation of out-of-plane intermolecular S···S interactions (Fig. 1) with a typical intermolecular separation in the range 3.0–3.2 Å. Crystal engineering of DTDAs has focused on obtaining materials in which the radicals are aligned into infinite chains or stacked in columns; one of the principal tools used to achieve this has been to use nitrile groups as structure-influencing supramolecular synthons [1,2,8,9]. The idea behind this strategy stemmed from the structure of *p*-iodobenzonitrile [10] and the cyanogen halides [11], which associate as ribbon-like chains through weak X···CN interactions. Similarly, cyano-functionalised DTDAs (e.g. compounds **1** and **2**) also associate as chains through CN···S interactions [1,2,8].

Halogen atoms can also have a marked effect on the molecular packing, although only fluorinated systems have received extensive study [1–4,12,13]. Partial fluorination of the aryl group can lead to the disruption of the dimerisation process; for example, [2,3-$F_2C_6H_3CNSSN]_2$ associates as an unusual twisted dimer [12], whereas 2,5-$F_2C_6H_3CNSSN$ assembles in uniform stacks with an unusually long interannular spacing [3.544(3) Å] [12]. Total fluorination results in more dramatic changes; both *p*-NCC_6F_4CNSSN (**2**) [1–3] and *p*-BrC_6F_4CNSSN [4] do not associate as dimers and consequently are paramagnetic at room temperature. The latter compound associates in columns, whereas the combination of fluorine atoms and a nitrile group in compound **2** leads to a compound that assembles with a chain-like structure [1,2]. Upon cooling to below 36 K, one polymorph of compound **2** undergoes a transition to a weakly ferromagnetic state [3]. This is the highest ferromagnetic ordering temperature reported to date for a non-metallic molecular magnet.

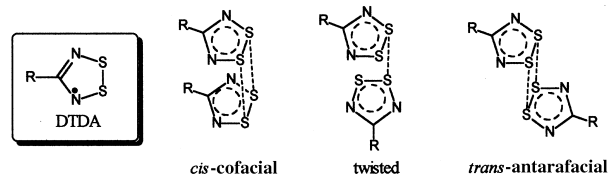

Fig. 1. Modes of dimerisation for DTDA radicals.

We are currently investigating the effect of the heavier halogen atoms on the supramolecular structures of dithiadiazolyl radicals. As part of this work, we decided to make *p*-iodophenyl-DTDA (**3**). In particular, we were keen to determine the structure-influencing properties of the iodine

PII S0277-5387(00)00384-3

atom and to see whether it would also promote the assembly of the molecules into chains, as is observed for *p*-iodobenzonitrile and cyano-functionalised DTDAs (**1** and **2**).

2. Results and discussion

Compound **3** was prepared from *p*-iodobenzonitrile using a slightly modified version of the proven metal amidine route (Scheme 1). We have found that sodium bis(trimethylsilyl)amide gives slightly higher yields with iodo-, bromo- and chloro-substituted aromatic nitriles than lithium bis(trimethylsilyl)amide, which is usually employed in dithiadiazolyl synthesis [14]. Crystals suitable for X-ray diffraction were grown by vacuum sublimation as described in Section 4. The asymmetric unit of compound **3** (Fig. 2) contains one molecule of unexceptional geometry. The bond lengths and angles of the heterocycle (Table 1) are similar to those of other members of this class [14]. Within each molecule the aryl and dithiadiazolyl rings are essentially coplanar with a slight twist angle between the dithiadiazole ring [root mean square (r.m.s.) $\Delta = 0.0077$ Å] and the aryl ring [r.m.s. $\Delta = 0.0089$ Å] of 8°. However, compared with other DTDAs, the mode of association in compound **3** is unusual. Two *p*-IC_6H_4CNSSN molecules associate in a *trans*-cofacial manner across an inversion centre (Fig. 3). The only other example of a DTDA radical adopting this mode of association is the 2,2′dimethylbiphenylene radical (**4**), which was reported very recently [5]. The distance between the heterocycles within dimers of compound **3** (measured from the mid-point of the rings) is 3.121 Å. This is significantly shorter than that in compound **4** (3.24 Å) and is similar to those observed in DTDAs that associate in the *cis*-cofacial or *trans*-antarafacial modes. However, the intradimer sulfur contacts in compound **3** [d(S1···S2A) and d(S2···S1A) = 3.696 Å] are long when compared with the equivalent distance in DTDAs that associate in a *cis*-cofacial or *trans*-antarafacial manner (typically 3.0–3.2 Å) and are similar to those in compound **4** [3.68(2) Å]. Each dimer pair also has two sets of intradimer sulfur–nitrogen interactions [d(S1···N2A), d(S1A···N2) = 3.116 Å] and [d(S2···N1A), d(S2A···N1) = 3.152 Å]. The asymmetry in these interactions results from a further interaction between one of the sulfurs with the iodine atom of an adjacent molecule (see below).

As noted by Oakley and co-workers [5], the *trans*-cofacial mode of dimerisation adopted by compounds **3** and **4** lies close to the transition state for the proposed photochemical isomerisation of 1,3,2,4- to 1,2,3,5-DTDAs (Scheme 2)

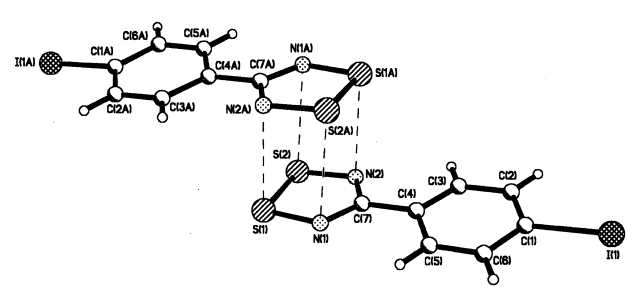

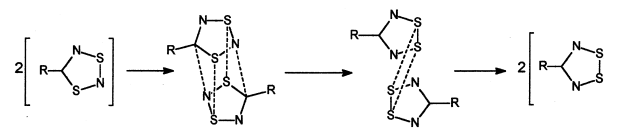

Fig. 3. Dimerisation in compound **3** illustrating the *trans*-cofacial mode of association.

Scheme 2.

[14]. Indeed, the molecular structures of compounds **3** and **4** show many similarities with that of 5,5′-(1,4-phenylene)bis(1,3,2,4-dithiadiazolyl) (**5**), which contains short S···S (3.214 Å) and S···N (3.346 Å) interactions between parallel CN_2S_2 rings [15].

Individual *p*-IC_6H_4CNSSN molecules in compound **3** are linked in a chain-like motif through a weak interaction between the iodine atom and one of the sulfurs of an adjacent molecule [d(I1···S2) = 3.82 Å]. The I···S distance is significantly longer than a conventional S–I bond [16] but is within bonding contact when compared with the sum of the van der Waal's radii of iodine and sulfur (which lies in the range 3.4–4.1 Å, depending on the orientation of the contact vector relative to the bonds) [17]. The distance between the iodine atom and the other sulfur atom of the disulfide bond [d(I1···S1) = 4.068 Å] is long and lies at the limit of the van der Waal's radius for a I···S contact, indicative of a very weak interaction. Each half of a [*p*-$IC_6H_4CNSSN]_2$ dimer is a member of separate chains that run in opposite directions. Adjacent molecules within the molecular chains occupy orthogonal positions such that the chains have a 'zigzag' alignment (Fig. 4). Analogous Cl···S interactions are seen in the structure of [*p*-$ClC_6H_4CNSSN]_2$, although in this derivative the molecules dimerise in a *cis*-cofacial manner [18]. The zigzag arrangement of the molecules in compound **3** contrasts with DTDAs **1** and **2** and the parent *p*-iodobenzonitrile, all of which form linear chains.

In addition, it is well known that compounds containing carbon–iodine bonds can undergo metal-catalysed coupling reactions, with carbon–carbon bond formation. Thus, it is possible that compound **3** could be utilised in similar reactions, providing a new synthetic route to biphenylbis(dithiadiazolyl) derivatives.

3. Conclusions

From the results reported here we see that the iodine atom has a marked effect on the supramolecular structure of compound **3**. As anticipated, the iodine substituent promotes the assembly of the molecules into chains by interacting with the sulfur atom of an adjacent molecule. The *trans*-cofacial mode of dimerisation observed in compound **3** is unusual, and we speculate that the molecules dimerise in this way to alleviate steric hindrance between two iodine atoms that would occur if the molecules associated in a *cis*-cofacial manner. However, it is less obvious why the *trans*-antarafacial or twisted geometries are disfavoured in this instance.

4. Experimental

All reactions and manipulations were carried out under an atmosphere of dry nitrogen using standard double-manifold and glove box techniques. Solvents were dried, distilled and degassed prior to use. *p*-Iodobenzoyl chloride (Aldrich), sodium bis(trimethylsilyl)amide (Aldrich), triphenylantimony (Aldrich), phosphorus pentoxide (Fisher) and sulfur dichloride (Fluka) were all obtained commercially and used as received.

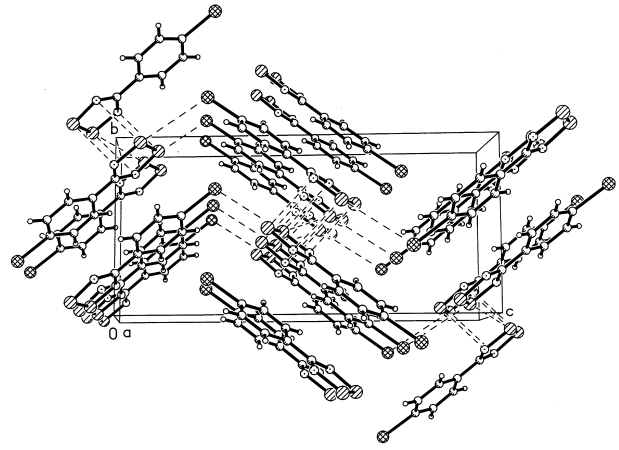

Fig. 4. Molecular packing of compound **3** parallel to crystallographic *a*-axis.

4.1. p-Iodobenzonitrile

Finely powdered *p*-iodobenzoyl chloride (5.32 g, 0.02 mol) was slowly added to ice-cold 0.880 ammonia solution (20 ml). The mixture was then stirred for 2 h and allowed to warm to room temperature. The resulting precipitate, *p*-iodobenzamide, was filtered, washed with water and dried. The *p*-iodobenzamide was then transferred to a 250-cm^3 round-bottom flask fitted with a side-arm and stopcock, together with a cold finger. An excess of phosphorus pentoxide was added to the flask and the reactants were thoroughly mixed. The flask was then heated in vacuo (130°C). Under these conditions the *p*-iodobenzonitrile product sublimes directly from the reaction mixture onto the cold finger as white needles. The *p*-iodobenzonitrile is then recovered and purified by a further vacuum sublimation (2.68 g, 59% yield; m.p. 124–126°C, lit. 124–125°C) [9]. ν_{max} (cm^{-1}): 2225 (C≡N), 1578, 1475, 1390, 1054, 1010, 894, 541. δ_H (250 MHz; $CDCl_3$; Me_4Si): 7.85 (2H, d, J 8.3 Hz) 7.37 (2H, d, J 8.3 Hz). δ_c (250 MHz; $CDCl_3$; Me_4Si): 138.86, 133.53, 118.57, 112.09, 100.68. m/e 228.9 (m^+), 102.0, 75.0.

4.2. 4-Iodophenyl-1,2,3,5-dithiadiazolyl

Sodium bis(trimethylsilyl amide) (1.673 g, 0.01 mol) and *p*-iodobenzonitrile (2.29 g, 0.01 mol) were stirred together in diethyl ether (50 cm^3) at room temperature for 18 h. Sulfur dichloride (1.3 cm^3, 0.02 mol) was slowly added, with cooling in an ice-bath, to produce an immediate orange precipitate which was stirred for 12 h, filtered off, washed with diethyl ether (3×10 cm^3) and pumped to dryness. The crude product was then reduced in situ by adding dichloromethane (50 cm^3) and triphenylantimony (0.176 g, 0.0005 mol). After 12 h, the dichloromethane was removed in vacuo. The residue was placed in a gradient sublimer (25–120°C, 10^{-3} torr). Under

these conditions, the product forms as deep red–black blocks (0.56 g, 18% yield; m.p. 172.5°C). Found: C, 27.13; H, 1.32; N, 9.05. $C_7H_4IN_2S_2$ requires: C, 27.37; H, 1.31; N, 9.12%. ν_{max} (cm^{-1}): *m/e* 307.1 (m^+), 261.1, 229.1, 180.0, 134.1, 102.1, 77.9.

4.3. Crystal data

$C_7H_4IN_2S_2$ (M = 307.14) crystallises as deep red blocks; crystal dimensions 0.20 × 0.10 × 0.10 mm. Monoclinic, $a = 5.7193(7)$, $b = 8.6096(11)$, $c = 18.320(2)$ Å, $\beta = 97.054(2)°$, $U = 895.26(19)$ $Å^3$, $Z = 4$, $D_c = 2.279$ Mg m^{-3}, space group $P2_1/n$ (a non-standard setting of $P2_1/c$, C_{2h}^5, No. 14), Mo Kα radiation ($\bar{\lambda} = 0.71073$ Å), μ(Mo Kα) = 3.984 mm^{-1}, $F(000) = 580$. Data collected were measured on a Bruker Smart CCD area detector with Oxford Cryosystems low-temperature system. Cell parameters were refined from the setting angles of 111 reflections (θ range 2.24–28.31°). Reflections were measured from a hemisphere of data collected of frames each covering 0.3 degrees in omega. Of the 5746 reflections measured, all of which were corrected for Lorentz and polarisation effects and for absorption by semi-empirical methods based on symmetry-equivalent and repeated reflections (minimum and maximum transmission coefficients of 0.5030 and 0.6914), 1474 independent reflections exceeded the significance level $|F|/\sigma(|F|) > 4.0$. The structure was solved by direct methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were placed geometrically and refined with a riding model and with U_{iso} constrained to be 1.2 times U_{eq} of the carrier atom. Refinement converged at a final $R = 0.0478$ ($wR_2 = 0.1125$, for all 2139 data, 109 parameters, mean and maximum δ/σ 0.000, 0.000) with allowance for the thermal anisotropy of all non-hydrogen atoms. Minimum and maximum final electron density was −1.464 and 1.772 e $Å^{-3}$. A weighting scheme $w = 1/[\sigma^2(F_o^2) + (0.0587P)^2 + 0.00P]$, where $P = (F_o^2 + 2F_c^2)/3$ was used in the latter stages of refinement. Complex scattering factors were taken from the program package SHELXTL [19] as implemented on a Viglen Pentium computer.

Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition number 137/938.

POLYHEDRON

Synthesis and characterization of a novel macrocyclic ligand containing catechol donor groups and its oxovanadium(IV) complex

Tingli Ma [1]*, Takahiko Kojima, Yoshihisa Matsuda [2]*

Department of Chemistry and Physics of Condensed Matter, Graduate School of Sciences, Kyushu University, Hakozaki, Fukuoka, 812-8581, Japan

Received 14 December 1999; accepted 27 March 2000

Abstract

A novel macrocyclic ligand containing catechol moieties, 9,10,21,22-tetrahydroxy-7,12,19,24-tetraoxo-2,3,4,5:8,9,10,11:14,15,16,17:20,21,22,23-tetrabenzena-1,6,13,18-tetraazacyclotetracosane ($\mathbf{H_4L}$), was designed and synthesized. For comparison, an acyclic ligand, 1,4-bis(2,3-dihydroxybenzammido)benzene ($\mathbf{H_4L^a}$), was also synthesized. Their oxovanadium(IV) complexes K(ppn)[VO(L)] and K_2[VO(L^a)] were prepared and characterized by IR, UV–Vis and ESR spectroscopies. The ESR spectra of the complexes measured at 77 K in diethyl sulfoxide–ethanol revealed unusual rhombic characteristics of the complexes, suggesting the coordination geometry of the complexes was distorted square-pyramidal. Based on these data, the complex is proposed to possess a bowl-like structure capped by the VO^{2+} moiety with a hydrophobic cavity. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Catechols; Macrocyclic ligands; Oxovanadium complexes; ESR parameters; Distorted square-pyramid; Hydrophobic cavities

1. Introduction

Macrocyclic ligands have been recognized as a strong framework to construct attractive compounds in terms of their structures and functionality. Their versatile utility has been proven in molecular and ion recognition [1], catalysis, and bioinorganic chemistry to mimic the structure and function of metalloproteins [2,3]. For these macrocyclic ligands, coordination to metal ion(s) is made through amine or imine nitrogens, ether oxygens and so on. Besides these electrostatically neutral ligands, highly charged macrocyclic ligands also show intriguing properties; for example, deprotonated tetraamide ligands having a charge of −4 prepared by Collins et al. have been shown to stabilize high-valent metal ions such as Ni(III) [4], Mn(V) [5–8], Fe(IV) [9–12] and so on. On the other hand, for highly and negatively charged macrocyclic ligands other than those mentioned above, the research groups of Vögtle [13,14], Martell [15,16], and Raymond [17–20] have reported catechol-containing macrocycles in which such catechol moieties are linked tightly together with amide bonds. They have utilized these ligands to encapsulate the Fe(III) ion based on the well-known strong interaction between Fe(III) and catechols.

Furthermore, Raymond and co-workers have explored the perspective of the coordination chemistry of catechol-based multidentate ligands, including vanadium ions. They prepared a number of oxovanadium(IV) complexes with their ligands; however, no report has appeared concerning catechol-containing macrocycles in which such catechol moieties are connected by aromatic amines. The use of an aromatic amine as a spacer connected by amide bonds in a vanadyl coordination sphere will allow us to access a new bowl-like hydrophobic cavity capped with vanadyl unit as a template, which is reminiscent of a calixarene due to the distortion around the amide moiety (Chart 1).

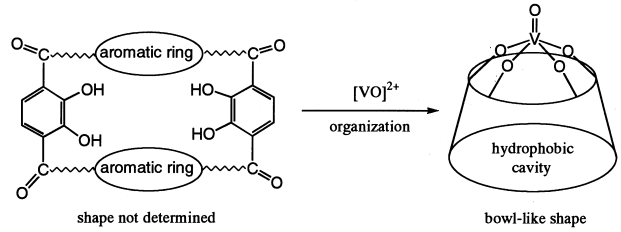

Chart 1

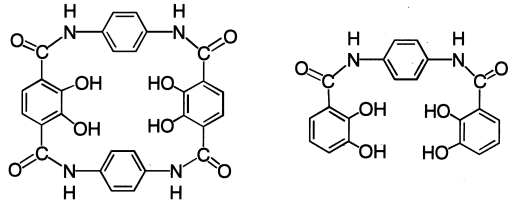

In order to construct such a vanadyl complex having hydrophobic cavity, we designed and synthesized a macrocyclic ligand ($\mathbf{H_4L}$) containing two catechol donor groups bridged by *p*-phenylenediamine (Chart 2(a)) and its oxovana-

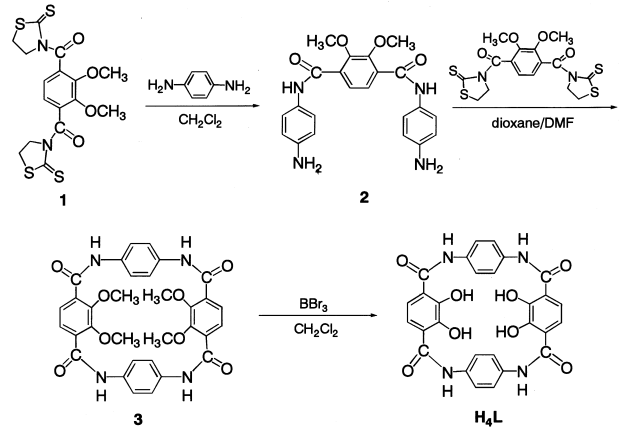
2. Materials and methods

2,3-Dimethoxyterephthalic acid bis(2-mercaptothiazolide) (**1**) was prepared by the method described in the literature [21]. 3-(2,3-Dimethoxybenzoyl)-1,3-thiozolidine-2-thione (**4**) was synthesized in accordance with a published procedure [22]. Vanadyl acetylacetonate ($VO(acac)_2$), was recrystallized from acetone. All solvents were dried by standard methods before use. All reactions were performed in an inert atmosphere in a glove box.



^{1}H NMR spectra were measured at 295 K on JEOL GX 400 MHz and EX 270 MHz spectrometers at 400 and 270 MHz, respectively. The chemical shifts were determined in ppm relative to TMS as an internal reference. IR spectra (4000–400 cm^{-1}) were recorded on a Shimadzu FT-IR-8600 spectrometer by the KBr method. UV–Vis absorption spectra were measured on a JASCO Ubest-50 spectrophotometer. Electron spin resonance (ESR) spectra were obtained on a JEOL JES-FE3X spectrometer at 300 or 77 K. C, H, and N analyses were carried out at the Service Center of the Elemental Analysis of Organic Compounds, Kyushu University.

2.1. Preparation of the ligands and the complexes

2.1.1. Synthesis of the macrocyclic ligand (*H_4L*) (Scheme 1)

*2.1.1.1. 2,3-Dimethoxy-1,4-[bis(4-amino-phenylene-diamide)] benzene (**2**).* To a solution of *p*-phenylenediamine (1.72 g, 15.90 mmol) in 300 ml of CH_2Cl_2, **1** (2.27 g, 5.30 mmol) was added and the solution was stirred at ambient temperature for 2.5 days. The solvent was removed to obtain crude **2** as orange oil. The crude product was dissolved in THF and precipitated by addition of diethyl ether. The resulting solid was filtered and washed three times with CH_2Cl_2 to remove unreacted starting materials. A yellow crystal of **2** was obtained by recrystallization from DMF/ether (1.50 g, 61%, based on **1**).

^{1}H NMR (DMSO-d_6): δ 9.90 (s, 2H, NH), 7.35 (dd, J=8.6, 3.6 Hz, 2H, ArH(amine)), 7.33 (s, 2H, ArH(cat)), 6.53 (dd, J=8.6, 3.6 Hz, 2H, ArH(amine)), 5.10 (bs, 4H, NH_2), 3.87 (s, 6H, OCH_3). (+)FAB-MS: m/z 406 $[M]^+$, 407 $[M+H]^+$. *Anal.* Calc. for $C_{22}H_{22}N_4O_4$: C, 65.02; H, 5.46; N, 13.79. Found: C, 64.82; H, 5.35; N, 13.50%.

Scheme 1.

*2.1.1.2. 9,10,21,22-Tetramethoxy-7,12,19,24-tetraoxo-2,3,4,5:8,9,10,11:14,15,16,17:20,21,22,23-tetrabenzena-1,6,13,18-tetraazacyclotetracosane (**3**).* To a solution of **2** (0.50 g, 1.23 mmol) in 500 ml of distilled dioxane and 100 ml of DMF, equimolar **1** and 1 ml of Et_3N were added at room temperature. The mixture was refluxed for 3 days. Filtration gave brown solids, which were washed with CH_2Cl_2 and hot THF. The brown powder was dissolved in DMF and insoluble material was filtered off. The yellow powder was obtained by repeated reprecipitation with DMF/ether. Recrystallization from DMSO gave **3** as yellow microcrystals (0.53 g, 36%).

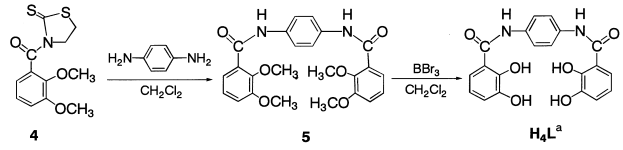
^{1}H NMR (DMSO-d_6): δ 10.36 (bs, 4H, NH), 7.73 (bs, 8H, ArH(amine)), 7.39 (bs, 4H, ArH(cat)), 3.90 (bs, 12H, OCH_3). ^{1}H NMR (DMF-d_7): δ 10.40 (s, 4H, NH), 7.91 (s, 8H, ArH(amine)), 7.55 (s, 4H, ArHcat), 4.03 (s, 12H, OCH_3). (+)FAB-MS: m/z 597 $[M+H]^+$. *Anal.* Calc. for $C_{32}H_{28}N_4O_8$: C, 64.42; H, 4.70; N, 9.40. Found: C, 63.98; H, 4.49; N, 9.66%.

2.1.1.3. 9,10,21,22-Tetrahydroxy-7,12,19,24-tetraoxo-2,3,4,5:8,9,10,11:14,15,16,17:20,21,22,23-tetrabenzena-1,6,13,18-tetraazacyclotetracosane (H_4L*).* To a degassed solution of **3** (0.50 g, 0.84 mmol) in 80 ml of CH_2Cl_2 was added 5.60 ml of BBr_3 via a syringe at 0°C. The yellow suspension formed was stirred for 5 days at ambient temperature. After slow addition of distilled H_2O at 0°C, the mixture was brought to the boil. Brown precipitate was filtered from the hot aqueous suspension. The solid was successively washed with H_2O and MeOH, and was recrystallized from DMSO/2-propanol to yield **H_4L** as yellow microcrystals (0.39 g, 86%).

^{1}H NMR (DMSO-d_6): δ 12.00 (bs, 4H, OH), 10.60 (bs, 4H, NH), 7.75 (bs, 8H, ArH(amine)), 7.50 (bs, 4H, ArH(cat)). IR (KBr, cm^{-1}): 3550(m), 1655(w), 1560(w), 1516(s), 1437(m), 1408(m), 1331(bs), 1290(sh, w), 1231(s), 1142(m), 1030(w), 929(m),

831(s), 737(w), 650(w), 509(s), 412(m). UV–Vis (DMSO): λ_{max} = 338 nm. *Anal*. Calc. for $C_{28}H_{20}N_4O_8$: C, 62.22; H, 3.73; N, 10.37. Found: C, 61.93; H, 3.95; N, 10.10%.

2.1.2. Synthesis of the acyclic ligand ***H_4L^a*** *(Scheme 2)*



*2.1.2.1. N,N′-Bis(2,3-dimethoxybenzoyl)-1,4-phenylene-diamine (**5**).* To a solution of *p*-phenylenediamine (1.04 g, 9.60 mmol) dissolved in 50 ml of CH_2Cl_2 was added a solution of 3-(2,3-dimethoxybenzoyl)-1,3-thiazolidine-2-thione (**4**), (5.45 g, 19.20 mmol) in 200 ml of CH_2Cl_2 and the mixture was refluxed for 3 days. The reaction mixture was cooled and washed with 2×100 ml of 0.10 M NaOH, and then with 100 ml of brine, and dried over anhydrous $MgSO_4$. CH_2Cl_2 was removed by a rotary evaporator to give yellow oil. This oil was chromatographed on a silica column eluted with $CHCl_3$/MeOH (95/5) to afford a white powder of **5**. Recrystallization from $CHCl_3$/hexane gave colorless needles (84%).

^{1}H NMR ($CDCl_3$): δ 10.02 (s, 2H, NH), 7.78 (dd, *J* = 7.8, 1.5 Hz, 2H, ArH), 7.69 (s, 4H, ArH), 7.20 (dd, *J* = 8.1, 7.8 Hz, 2H, ArH), 7.09 (dd, *J* = 8.1, 1.5 Hz, 2H, ArH), 3.99 (s, 6H, OCH_3), 3.92 (s, 6H, OCH_3). EI-Mass: *m*/*e* 436 [M]. *Anal*. Calc. for $C_{24}H_{24}N_2O_6$: C, 66.06; H, 5.51; N, 6.42. Found: C, 65.79; H, 5.56; N, 6.34%.

*2.1.2.2. N,N′-Bis(2,3-dihydroxybenzoyl)1,4-phenylene-diamine (**H_4L^a**).* The ligand **H_4L^a** was prepared by a similar procedure to that of **H_4L** (96%). ^{1}H NMR (DMSO-d_6): δ 11.77 (bs, 2H, OH), 10.37 (s, 2H, NH), 9.39 (bs, 2H, OH), 7.70 (s, 4H, ArHamine), 7.47 (dd, *J* = 8.1, 1.3 Hz, 2H, ArHcat), 6.98 (dd, *J* = 7.8, 1.3 Hz, 2H, ArHcat), 6.78 (dd, *J* = 8.1, 7.8 Hz, 2H, ArHcat). IR (KBr, cm^{-1}): 3480(m), 1647(m), 1596(w), 1560(s), 1454(s), 1408(m), 1329(s), 1275(s), 1281(w), 1175(s), 858(w), 750(s), 831(s), 738(m), 577(m), 521(w), 444(m). UV–Vis (DMSO): λ_{max} = 338 nm. (+)FAB-MS: *m*/*e* 381 $[M+H]^+$. *Anal*. Calc. for $C_{20}H_{16}N_2O_6 \cdot EtOH$: C, 61.96; H, 5.16; N, 6.57. Found: C, 61.93; H, 5.22; N, 6.53%.

2.1.3. Syntheses of the oxovanadium complexes

2.1.3.1. K(ppn)[VO(L)]. An ethanolic solution of KOH (4.20 ml, 0.40 M, 1.60 mmol) was added to a solution of **H_4L** (0.23 g, 0.42 mmol) in 20 ml of degassed EtOH. After stirring for 15 min at ambient temperature, $VO(acac)_2$ (0.11 g, 0.42 mmol) in EtOH was added. The mixture was refluxed for 18 h to give a green suspension. The solid material was filtered, washed with water and EtOH (3×50 ml), and then dried in vacuo to give a deep green powder of $K_2[VO(L)]$ (0.20 g, 60%). One of the K^+ cations was substituted for the ppn^+ cation by the following procedure, where ppn^+ stands for the bis(triphenylphosphoranylidene) ammonium ion: $K_2[VO(L)]$ (0.20 g, 0.29 mmol) was suspended in 150 ml of DMSO and (ppn)Cl (0.44 g, 0.58 mmol) was added. The mixture was stirred for 12 h at 85°C. After solid material was filtered off, the filtrate was evaporated under vacuum, and the solid residue obtained was recrystallized from DMF/ether to give green microcrystals.

Scheme 2.

IR (KBr, cm^{-1}): 1650(w), 1514(s), 1439(m), 1406(w), 1325(s), 1261(w), 1115(s), 1032(m), 949(m), 804(s), 723(s), 692(s), 548(m), 534(s), 502(m). UV–Vis (DMF): 334 nm, 464 nm. (+)FAB-MS: *m*/*e* 538 $[ppn]^+$, (−)TOF-MS 642 $[KVOL]^-$. *Anal*. Calc. for $C_{64}H_{46}N_5O_9VP_2K \cdot DMF \cdot H_2O$: C, 63.26; H, 4.36; N, 6.61; V, 4.00. Found: C, 62.69; H, 4.65; N, 6.40; V, 4.32%.

2.1.3.2. $K_2[VO(L)^a]$. The ligand **H_4L^a** (0.50 g, 1.30 mmol) was added to 0.50 M KOH (10.50 ml, 5.20 mmol) in EtOH and the nitrogen gas was bubbled through the solution. A solution of $VO(acac)_2$ (0.35 g, 1.30 mmol) in 200 ml of EtOH was added dropwise into the basic ligand solution. This mixture was stirred for 20 h at room temperature and the solvent was removed under reduced pressure. The resulting green solid was dissolved in 5 ml of MeOH and the solution was loaded onto a Sephadex LH-20 column eluted with MeOH. The green band was collected and the solvent was removed by evaporation. The resulted green solid was dissolved into MeOH and vapor diffusion of Et_2O gave 0.22 g (31%) of $K_2[VO(L^a)]$ as blue–green powder.

IR (KBr, cm^{-1}) 1655(s), 1589(m), 1516(s), 1439(s), 1408(w), 1344(s), 1258(s), 1228(s), 1169(w), 1061(w), 953(m), 847(w), 799(w), 764(m), 677(m), 580(w), 505(m), 419(m). UV–Vis (EtOH): 293 nm, 573 nm, 660 nm. (−)FAB-MS: *m*/*e* 482 $[M-K^+]^-$. *Anal*. Calc. for $C_{20}H_{12}O_7N_2VK_2 \cdot CH_3OH$: C, 45.57; H, 2.91; N, 5.07; V, 9.38. Found: C, 45.86; H, 2.62; N, 5.30; V, 9.59%.

3. Results and discussion

3.1. Syntheses of the ligands and the complexes

To prepare the macrocyclic ligand, first, we attempted the direct cyclization of 2,3-dimethoxyterephthaloyl chloride and *p*-phenylenediamine under high dilution conditions in the presence of triethylamine. The yield of macrocycle **3** was only 3%, accompanied by the formation of a larger size macrocyclic compound [23]. By a stepwise method, modifying the procedures described by Raymond and co-workers [21], **3** was obtained in 11% total yield [23]. Our stepwise synthetic strategy is depicted in Scheme 1; the total yield was improved up to 49%. The purification in each step also became simple because of the lack of troublesome formation

of oligomers or by-products. Removing the methyl group with BBr_3 affords the ligand **H_4L** which is stable both as solid and in solution, but air-sensitive in alkaline solution. The solubility of **3** and **H_4L** toward chloroform at room temperature is significantly low. In strong polar organic solvents, such as DMSO and DMF, they are relatively soluble.

The acyclic biscatecholamide ligand **H_4L^a** was synthesized according to Scheme 2 [24]. Although the total yield (87%) of this synthetic method is slightly lower than that by a procedure recently published [25], in which 2,3-dimethoxybenzoyl chloride is used as a starting material, the handling described in Scheme 2 is easy due to the stability and robustness of the starting material.

Two oxovanadium complexes were prepared anaerobically by the ligand substitution reaction of $VO(acac)_2$ under basic conditions. The composition of these vanadyl complexes was confirmed by elemental analysis and mass spectroscopy. The complexes were stable as solids, but were air-sensitive in solution. The solubility of the macrocyclic complex is low toward organic solvent. Efforts to obtain single crystals of these complexes for X-ray diffraction analysis have been unsuccessful so far despite numerous attempts with a variety of cations and solvent systems.

3.2. Characterization of the complexes

3.2.1. Infrared spectroscopy

IR spectral data of the complexes prepared are shown in Table 1. The V=O stretching frequencies for the complexes $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$ were observed at 949 and 953 cm^{-1}, respectively. They are lower frequencies compared to those of reported oxovanadium complexes (1100–960 cm^{-1}) [26]. The relatively low frequency indicates that the V=O bond is weakened by strong σ and π electron donation of catechol moieties to the antibonding orbital of the V=O group. A similar decrease in V=O stretching frequency has been reported for $K_2[VO(cat)_2]$ (970 cm^{-1}) [27] and $K_2[VO(bencam)]$ (955 cm^{-1}) (bencam: 1,3-bis[2-(2,3-dihydroxybenzamido)ethyl]benzene) [22], respectively. Other infrared bands associated with the anions, $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$, were those due to ν(C–O) of the catechol moieties at 1261 and 1258 cm^{-1}, and ν(V–O) of the vanadium–catechol bonds at 503 and 505 cm^{-1}, respectively [28].

3.2.2. Electronic absorption spectra

The UV–Vis spectra of $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$ are displayed in Fig. 1, and the numerical data are shown in Table 1. For oxovanadium(IV) complexes, three d–d bands corresponding to the $b_2(d_{xy}) \rightarrow e(d_{xz},d_{yz})$, $b_2(d_{xy}) \rightarrow b_1(d_{x^2-y^2})$, and $b_2(d_{xy}) \rightarrow a_1(d_{z^2})$ transitions are expected for a square-pyramidal structure [28]. The electronic spectrum of $[VO(L^a)]^{2-}$ measured in EtOH exhibited d–d bands assignable to those transitions at 660 and 573 nm, respectively, as shown in Fig. 1 (bottom, a). For comparison, $[VO(cat)_2]^{2-}$ and $[VO(bencam)]$ have been reported to exhibit the corresponding bands at 656 and 540 nm in NaOH aqueous solution, and 650 and 528 nm(sh) in MeOH, respectively, suggesting idealized C_{4v} symmetry at the metal center in each complex [22, 27]. In contrast to these complexes, the spectrum of the macrocyclic complex $[VO(L)]^{2-}$ shows considerable difference in the UV–Vis spectrum. An intense band at 334 nm and a d–d band of VO^{2+} at 464 nm as a shoulder were observed as shown in Fig. 1 (top, b). The intense band (334 nm) is assigned to a π–π^* transition of the aromatic ring of the ligand. However, no band was observed in the range from 650 to 500 nm; it is considered that a blue shift in the $b_2 \rightarrow b_1$ transition was caused by strong equatorial σ-donors [29]. An electron-rich environment

about the vanadium center provided by equatorial dicatecholate ligands is further evidence for elevating the energy of the b_1 orbital. The extinction coefficient could not be determined because of the low solubility of the complexes.

3.2.3. ESR spectroscopy

At ambient temperature, intense ESR signals were observed for the complexes prepared in this work. The spectrum of $[VO(L)]^{2-}$ measured in a mixture of DMF/CH_2Cl_2 (80:20) is shown in Fig. 2. This spectrum displays the typical eight-line pattern of the d^1 vanadium(IV) center due to hyperfine splitting by the ^{51}V nucleus ($I=7/2$) as expected. The signals are centered at $g=1.973$, with an isotopic hyperfine splitting constant of 81×10^{-4} cm^{-1}.

For $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$, the ESR spectra were measured at 77 K in the frozen solution of DMSO/EtOH (80:20) and $MeOH/CH_2Cl_2$ (80:20), respectively. The spectra are shown in Figs. 3 and 4. The g and A values obtained by simulation are given in Table 2 together with the related complexes. The parameters for $[VO(L)]^{2-}$ were determined to be $g_x=1.979$ ($A_x=53\times10^{-4}$ cm^{-1}), $g_y=1.983$ ($A_y=48\times10^{-4}$ cm^{-1}), and $g_z=1.950$ ($A_z=158\times10^{-4}$ cm^{-1}), as for $[VO(L^a)]^{2-}$, $g_x=1.984$ ($A_x=53\times10^{-4}$ cm^{-1}), $g_y=1.987$ ($A_y=50\times10^{-4}$ cm^{-1}), and $g_z=1.954$ ($A_z=155\times10^{-4}$ cm^{-1}). These values exhibit $g_z<g_x, g_y$ and $A_z>A_x, A_y$ and are lying in the expected range for catecholato oxovanadium complexes. The ESR spectra of vanadium(IV) can be classified into two groups, that is, those with a $d_{x^2-y^2}$ ground state displaying $g_z<g_x$, $g_y<2$ and $A_z>A_x, A_y$, and those with a d_{z^2} ground state $g_x, g_y<g_z\cong2$ and $A_z\ll A_x, A_y$. The former parameters are associated with square-pyramidal geometry and the latter parameters are attributable to a geometry distorted octahedral to trigonal prism [29,30]. Based on this claim, these values observed for $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$ indicated that these complexes have a square-pyramidal geometry. Moreover, rhombic features ($g_x\neq g_y\neq g_z$, $A_x\neq A_y\neq A_z$) were observed in the ESR spectra of both $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$. Such a rhombicity has not been observed for other catecholato complexes reported thus far.

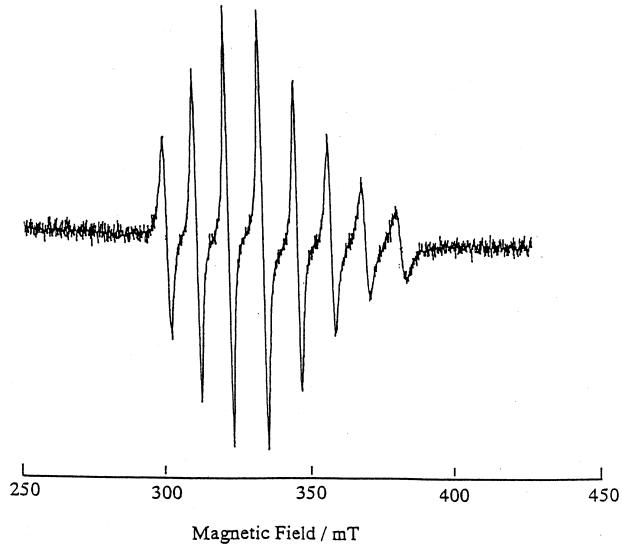

Fig. 2. ESR spectrum of $[VO(L)]^{2-}$ in DMF/CH_2Cl_2 (80/20) solution at ambient temperature.

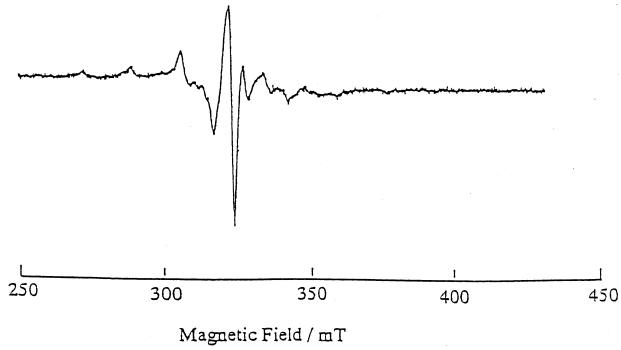

Fig. 3. ESR spectrum of $[VO(L)]^{2-}$ in DMSO/EtOH (80/20) solution at 77 K.

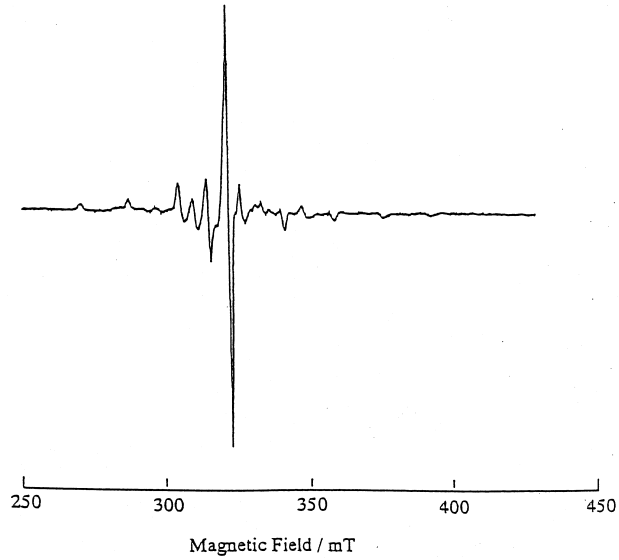

Fig. 4. ESR spectrum of $[VO(L^a)]^{2-}$ in $MeOH/CH_2Cl_2$ (80/20) solution at 77 K.

In general, the rhombicity in the equatorial components is observed for the complexes of mixed donor atoms in equatorial planes, such as [VO(salen)] (salen: N,N′-ethylenebis(salicylideneiminate)) and [VO(busaln)] (busaln: butylsalicylideneiminate) [31]. In spite of the fact that four donors in the equatorial plane of complexes in this study are all oxygen atoms, the unique rhombic nature was observed. It can be explained by the fact that the basal plane formed by four oxygen atoms in the complexes is apparently rectangular, rather than square as observed in $[VO(cat)_2]^{2-}$ and [VO(bencam)]. Moreover, the spectrum of the macrocyclic complex shows a relatively stronger rhombic property than that of $[VO(L^a)]^{2-}$. This suggests that distortion from a square in the basal plane for $[VO(L)]^{2-}$ becomes clearer than that for $[VO(L^a)]^{2-}$.

According to the results mentioned above, it can be presumed that the coordination geometry around the vana-

dium(IV) ions in $[VO(L)]^{2-}$ and $[VO(L^a)]^{2-}$ is distorted square-pyramidal.

4. Conclusions

We have synthesized a novel macrocyclic ligand containing two catechol moieties linked by two aromatic amines, *p*-phenylenediamine, and its oxovanadium(IV) complex. The complex showed rhombic distortion in square-pyramidal structure and its rhombicity was larger than those of catechol-bound oxovanadium(IV) complexes reported so far, and than the complex with an acyclic analog. This rhombic distortion around the vanadium is assumed to result in a bowl-like structure of the ligand which is organized by the vanadium coordination. Such a structural motif is reminiscent of calixarenes for molecular recognition chemistry. Thus, the formation of $[VO(L)]^{2-}$ described here can be considered as a metal-templated formation of a hydrophobic receptor [32].

Abstract

On mixing concentrated aqueous solutions of pdta, Cu(II) and Mn(II) in the ratio 1:1:1 at pH 4.5, single crystals of the complex $[Mn(H_2O)_6][Cu(pdta)]\cdot 2H_2O$ (**1**) (pdta = 1,3-propylenediamine-*N*,*N*,*N*′*N*′-tetraacetate) were obtained. X-ray structural analysis revealed that in the anion $[Cu(pdta)]^{2-}$ the coordination polyhedron around the Cu(II) ion can be described as a tetragonaly distorted CuN_2O_4 octahedron, whereas the cation $[Mn(H_2O)_6]^{2+}$ can be described as a very regular MnO_6 octahedron. Thermogravimetric analysis shows that at 110°C compound **1** loses its eight water molecules yielding the anhydrous compound [MnCu(pdta)] (**2**). Variable-temperature magnetic susceptibility measurements indicate that no magnetic interactions are present in **1** while weak antiferromagnetic interactions occur in **2**.

1. Introduction

A great deal of attention has been devoted to diamino-polycarboxylato complexes [1–5] and especially to the edta family (edta = ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetate) [6]. The complexes formulated as $M'M(edta)(H_2O)_4\cdot 2H_2O$ (M and M′ are divalent first-row transition metal ions) belong to a series of ferrimagnetic systems in which both the 1-d character and the cationic ordering are well stabilized [7–9]. The structure may be roughly described as infinite zig-zag chains involving alternating metal ions. One of them (M′) is surrounded by four water molecules and two oxygen atoms, belonging to bridging carboxylate groups, while the other (M) exhibits hexacoordination through the edta ligand. In the heterometallic complexes (M ≠ M′), a clear preference of the cations to be coordinated into either the 'hydrated' or 'chelated' form has been confirmed by a study comparing their visible spectra with those of homometallic complexes [10], as well as potentiometric measurements [11,12]. These studies show unambiguously that the Mn(II) ion will be in the 'hydrated' position when sufficient Cu(II) ion is present to occupy the 'chelated' position. Thus $MnCu(edta)\cdot 6H_2O$ is formed by infinite zig-zag chains built up with alternating 'hydrated' and 'chelated' octahedra bridged by carboxylate groups [13]: $-Mn(H_2O)O_2-Cu(edta)-Mn(H_2O)O_2-Cu(edta)-$... Owing to the selective occupation of both sites, distinct spin sublattices are expected to result in so-called ferrimagnetic 1-d behaviour [14,15]. Similar structural and magnetic behaviour has been observed in other edta-like metal complexes [16,17]. On the other hand, by conducting the synthesis under conditions of high temperature and pressure, three-dimensional crystalline polymers have been obtained [18–20]. In these, the removal of some water molecules from the parent hexahydrates results in an intercrossing of the chains through carboxylate bridges, with the consequent increase in dimensionality of the system. This strategy has also been used in the oxamido systems such as $MnCu(obbz)\cdot 5H_2O$ [21–23] and $MnCu(obze)\cdot 6H_2O$ [24,25]. Partial dehydration yields the three-dimensional

compounds MnCu(obbz)·H_2O and MnCu(obze)·$2H_2O$ which order ferromagnetically at 14 and 5 K, respectively.

In this work, we present the synthesis and structural determination of the complex [Mn(H_2O)$_6$][Cu(pdta)]·$2H_2O$ (**1**), (pdta = 1,3-propylenediamine-*N*,*N*,*N*′,*N*′-tetraacetate). Study of the thermal and magnetic properties, including those of the dehydrated compound [MnCu(pdta)] (**2**), is also reported.

2. Experimental

2.1. Preparation of the complexes [Mn(H_2O)$_6$][Cu(pdta)]·$2H_2O$ (**1**) and [MnCu(pdta)] (**2**)

H_4pdta (1,3-propylenediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid) was synthesized as previously reported [26]. A concentrated aqueous solution of H_4pdta (pH was fixed at 4.5 with NaOH solution) was mixed with a concentrated aqueous solution of Cu(NO_3)$_2$·$3H_2O$ and Mn(NO_3)$_2$·$4H_2O$ with a ratio H_4pdta:Cu(II):Mn(II) = 1:1:1. Finally, the pH of the mixed solution was also fixed at 4.5. Addition of ethanol to the solution resulted in the precipitation of a blue polycrystalline dust. The precipitate was filtered off and washed several times with ethanol. Blue crystals suitable for X-ray crystallography were grown by liquid–liquid diffusion [27,28] using water as solvent and ethanol as precipitant.

Compound **1** loses its eight water molecules when heated at $120 < T < 170$°C, yielding the dehydrated compound **2**. Thermogravimetrical analysis revealed a loss of weight of 26% that closely corresponds to 8 mol of water per molecular unit. Afterwards, the weight remained constant. This loss of water also became clear from the disappearance of the bands characteristic of water in the IR spectra. Elemental analyses were performed on a Carlo Erba 1106 automatic analyser. Copper and manganese were determined by atomic absorption. Found: C, 23.09; H, 5.17; N, 4.76; Cu, 10.94; Mn, 9.65. Calc. for $C_{11}H_{30}N_2O_{16}CuMn$ (**1**): C, 23.39; H, 5.35; N, 4.96; Cu, 11.25; Mn, 9.73%.

2.2. Instrumentation

The IR spectrum was taken on a Perkin-Elmer 1750 FTIR spectrophotometer as KBr pellets in the 4000–300 cm^{-1} region. Magnetic susceptibility measurements were carried out with a fully automated AZTEC DSM5 pendulum-type susceptometer equipped with a TBT continuous-flow cryostat and a Brüker BE15 electromagnet, operating at 1 T. The apparatus was calibrated with mercury tetrakis(thiocyanato)cobaltate(II). The corrections for the diamagnetism of compounds **1** and **2** were estimated from Pascal constants as -280×10^{-6} (**1**) and -210×10^{-6} (**2**) $cm^3\ mol^{-1}$ and were substracted from the experimental molar susceptibility to obtain the paramagnetic molar susceptibilities. Thermal analyses were performed by using a Setaram B70 thermobalance. The samples were heated at 1°C min^{-1} either under N_2 flow or air atmosphere.

2.3. Diffraction data

A prismatic blue crystal of complex **1** of approximate dimensions $0.1\times0.1\times0.1$ mm was used for data collection at 293 K. Diffraction data were taken with an Enraf-Nonius CAD-4 diffractometer using graphite-monochromated Mo Kα radiation. The cell parameters were determined from least-squares refinements of 25 well centred reflections in the range $12 < \theta < 20°$. A total of 2677 independent reflections were collected (in the range $2 < 2\theta < 64°$). Three reference reflections monitored throughout data collection showed no significant sign of crystal deterioration. The usual corrections for Lorentz and polarisation effects were carried out, but no absorption corrections.

The crystal was orthorhombic, space group *Pnna*, $a = 11.893(9)$, $b = 13.337(6)$, $c = 13.790(6)$ Å, $V = 2187(2)$ Å^3 (by least-squares refinement from 25 automatically centred reflections in the range $12 < \theta < 20°$), $M_r = 564.85$, $Z = 4$, $D_c = 1.72$ g cm^{-3}, $F(000) = 1168$. Mo Kα radiation, $\lambda = 0.71069$ Å, μ(Mo Kα) = 16.28 cm^{-1}.

The structure was solved by direct methods using SHELXS86 [29], and refined by least-squares methods using SHELXL93 [30]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located from a difference synthesis and refined with an overall isotropic thermal parameter. The refinement converged to $R_1 = 0.0383$ and $wR_2 = 0.1729$. Molecular plots were produced using SCHAKAL [31].

Crystal data are given in Table 1, while important bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. X-ray structure

The structure of **1** consists of [Cu(pdta)]$^{2-}$ and [Mn(H_2O)$_6$]$^{2+}$ complex units and water molecules of crystallization linked by electrostatic forces and an extensive hydrogen bond network. A perspective view is given in Fig. 1 along with the numbering scheme adopted.

In the molecule [Mn(H_2O)$_6$][Cu(pdta)]·$2H_2O$, pdta is a hexadentate ligand, the donor atoms being O(1) and O(3) and N(1). The coordination polyhedron around the Cu ion can be described as a tetragonally distorted CuN_2O_4 octahedron: two O(1) (two different carboxylates) and two N(1) atoms form the equatorial plane and two O(3) atoms of another two carboxylates fill the axial sites. The two O(1) and two N(1) atoms lie approximately in a plane. The maximum deviation from the plane is 0.135(2) Å (O(1)).

The coordination polyhedron around the Mn(II) ion can be described as a very regular MnO_6 octahedron (d(Mn–O) between 2.16 and 2.19 Å). The pdta ligand prefers to form a

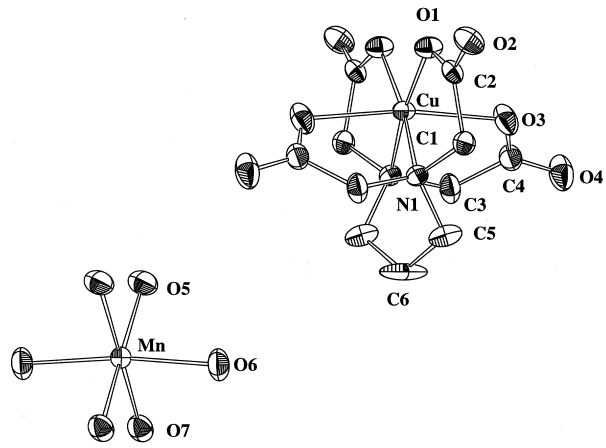

Fig. 1. Perspective view of complex **1** with the atom-numbering scheme. Hydrogen atoms have been omitted for simplicity.

There are two crystallographically independent glycine rings: one is in the plane of the six-membered chelate rings and forms part of a girdle about the copper atom; the other lies in a plane nearly perpendicular to the plane of the octahedron. The former glycine ring (Cu, N(1), C(1), C(2), O(1)) is nearly planar and O(2) deviates by about 0.243(4) Å from the least-squares plane, while the latter ring (Cu, N(1), C(3), C(4), O(3)) shows significant departure from planarity and O(4) is 0.383(5) Å out of the plane of the chelate ring. The six-membered chelate ring adopts a twisted-boat form: the atoms N(1) and C(5′) are 0.525(3) and 0.618(4) Å out of the plane defined by Cu, C(5), C(6) and N(1′). The other two non-coordinated water molecules in **1** are linked to the pdta ligand and coordinated waters by hydrogen bonds.

A similar distorted CuN_2O_4 octahedron is found in the complexes $K_2[Cu(edta)]$ [33] and $Ca[Cu(edta)]$ [34,35]. In $H_2[Cu(edta)]\cdot H_2O$ [36], the edta ligand is pentadentate and in the complex $[Co(edta)]^-$ the coordination octahedral of the Co(III) is more regular, as expected [37].

3.2. Thermogravimetric study

The thermogravimetric curve of complex **1** is shown in Fig. 2. It can be seen how the weight loss starts at ca. 40°C and stops at 110°C, a plateau being observed between this temperature and 170°C. At this stage, the weight loss is ca. 26%, a value which corresponds to eight water molecules per molecular unit. The lack of the characteristic stretching vibrations of water in the IR spectrum of this dehydrated phase supports its formulation as [MnCu(pdta)] (**2**).

The proximity of the carboxylate groups could account for the easy loss of the coordinated water molecules. The carboxylate-assisted water loss is a well known phenomenon [18–25,38]. In this sense, the water-oxygens of the coordination sphere of the manganese(II) ion would be substituted by the carboxylate-oxygen atoms. That is, the complex

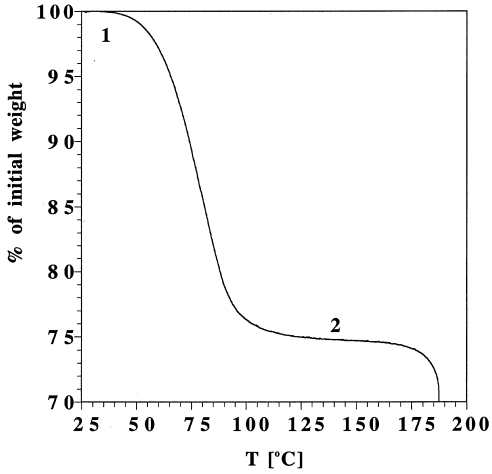

Fig. 2. Thermogravimetric curve of **1**.

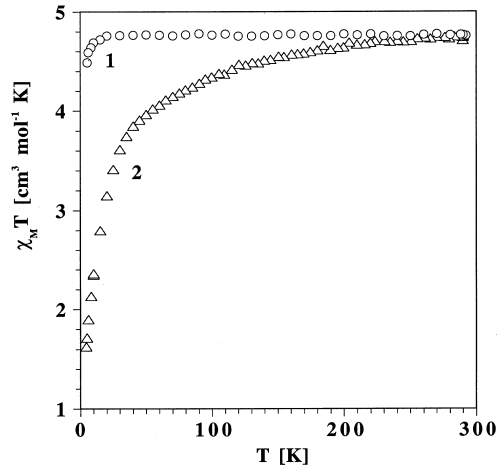

Fig. 3. Thermal dependence of the $\chi_M T$ product for **1** and **2**.

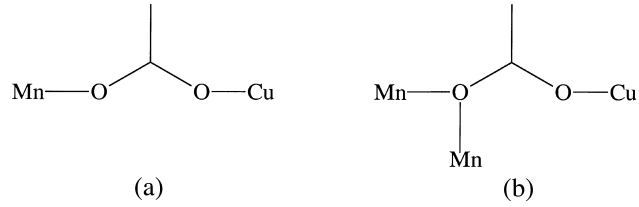
$Cu(pdta)^{2-}$ would act as a ligand towards the manganese(II) ion through its free carboxylate-oxygens in the dehydration process. A two- or three-dimensional solid would result from the polymerization of the metal ions through carboxylato bridging.



3.3. Magnetic properties

The thermal dependence of the $\chi_M T$ product (χ_M being the molar magnetic susceptibility) for **1** and its dehydrated species **2** is depicted in Fig. 3. The $\chi_M T$ value for **1** is practically constant and equal to 4.77 cm^3 mol^{-1} K from room temperature until 10 K, as expected for a pair of non-interacting Mn(II)–Cu(II). Then, it decreases smoothly at lower temperatures most likely due to a small zero field splitting of the $^6A_1$ ground state of the complex $[Mn(H_2O)_6]^{2+}$. In fact, this magnetic behaviour is matched satisfactorily through the axial $S=5/2$ zfs Hamiltonian

$$\boldsymbol{H}=D[\boldsymbol{S}_z^2-\tfrac{1}{3}S(S+1)+g\beta\boldsymbol{H}\boldsymbol{S}]$$

with $g(Mn)=1.99$ and $D=|0.4|$ cm^{-1} and keeping constant $g(Cu)=2.05$. Consequently, it is suggested that no magnetic coupling is present in complex **1**. In contrast to that, the magnetic curve of compound **2** exhibits a continuous decrease from room temperature, attaining a value of 1.6 cm^3 mol^{-1} K at 4.3 K, revealing that an antiferromagnetic coupling occurs.

During the dehydration process, the crystals of **1** crack and consequently, the crystal structure of **2** could not be determined. However, some structural information can be inferred from the magnetic study. If the polymerization process involves the formation of the carboxylate-bridging Mn(II) and Cu(II) shown in Scheme 1(a), as the only magnetic pathway, we would deal with a bimetallic system with alternating local $S=1/2$ (Cu(II)) and $S=5/2$ (Mn(II)) spins which would exhibit a ferrimagnetic-like behaviour: the $\chi_M T$ curve would present a minimum and a further increase at lower temperatures; the value of $\chi_M T$ at the minimum is predicted to be greater than 3 cm^3 mol^{-1} K, the value corresponding to an antiferromagnetically coupled Cu(II)–Mn(II) pair. Given that the magnetic properties of **2** do not agree with this description, other structural elements such as that indicated in Scheme 1(b) have to be involved. The occurrence of the antiferromagnetic interactions between Mn(II) ions bridged by a single carboxylate-oxygen atom (Scheme 1(b)) would cancel the magnetic moment of the Mn(II)–Mn(II) pair in agreement with the magnetic curve of **2**.

Scheme 1.

Additional support for this conclusion comes from the fact that the four free carboxylate-oxygens of the $Cu(pdta)^{2-}$ are not enough to keep the six-coordination of Mn(II) (the situation where Scheme 1(a) would be the only structural unit present) and thus sharing of some of these oxygen atoms would be required as shown in Scheme 1(b).

Supplementary data

Tables of atomic coordinates and equivalent isotropic displacement parameters, complete bond lengths and angles, least-squares mean planes, anisotropic displacement parameters, thermal parameters and observed and calculated structure factors (4 pages) are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, the deposit number being 133983.

Abstract

The reactions of imidazole (Him) with *N*-salicylidenearoylhydrazine copper(II) complexes have been studied and a number of ternary copper(II) complexes, $[Cu(L)Him]\cdot nH_2O$, $[Cu(HL)X\cdot Him]\cdot nH_2O$ and $[\{Cu(L)\}_2Im]\cdot nH_2O$, have been prepared and characterized (HL and L refer, respectively, to mono- and dinegative *N*-salicylidenearoylhydrazine anions and X is a mononegative monodentate ligand). The X-ray crystal and molecular structure of [(*N*-salicylidene-*p*-chlorobenzoylhydrazine)imidazole]copper(II) monohydrate, $[Cu(Sp\text{-}ClBzh)Him]\cdot H_2O$, and [(*N*-salicylidene-*p*-methylbenzoylhydrazine)imidazole]copper(II) hemihydrate, $[Cu(Sp\text{-}CH_3Bzh)Him]\cdot 1/2H_2O$, were measured. The *p*-chloro complex $[Cu(Sp\text{-}ClBzh)Him]\cdot H_2O$ is monomeric with the Cu(II) in a distorted square planar environment and is coordinated to the tridentate hydrazone via phenoxy oxygen, azomethine nitrogen and enolimide oxygen, the fourth coordination site is occupied by the imidazole nitrogen. The *p*-methyl complex $[Cu(Sp\text{-}CH_3Bzh)Him]\cdot 1/2H_2O$ was found to be a centrosymmetric dimer, the monomeric unit being bridged through the phenoxy oxygen. The Cu(II) is in a square pyramidal environment and is bounded in the equatorial plane with the enolimide oxygen, azomethine nitrogen and phenoxy oxygen of the hydrazone ligand while the fourth site is occupied by the symmetry related phenoxy oxygen of the other unit; the axial fifth coordination site is occupied by the imidazole nitrogen. The magnetic susceptibility measurements at different temperatures (5–298 K) have been recorded and are discussed. The binuclear imidazolate complexes show antiferromagnetic exchange coupling interactions, the measured $-J$ values are within the range 17.0–20.0 cm^{-1}, while the imidazole complexes do not show any appreciable exchange interactions. ©2000 Elsevier Science Ltd All rights reserved.

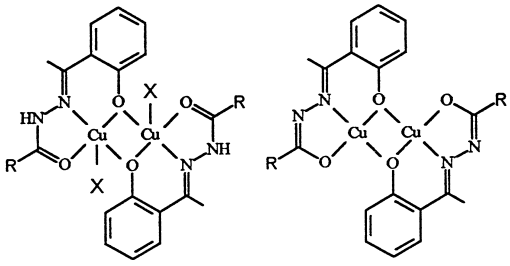
1. Introduction



N-salicylideneacylhydrazines (**1**) (hereafter abbreviated as H_2L) and their corresponding copper(II) complexes have been reported to show a wide spectrum of biological activities [1–7]. For better understanding of their mode of action within biological systems, the coordination chemistry of this class of acylhydrazones as well as the molecular structure of a number of copper(II) complexes have been extensively studied [8–12]. *N*-salicylideneacylhydrazines can act as either mononegative or dinegative ONO tridentate ligands, forming with copper(II) salts either monomeric (**2**) or dimeric copper(II) complexes (**3** and **4**). The tendency for dimerization via phenoxy oxygens is to achieve the most favourable coordination number four or five of the central copper(II).

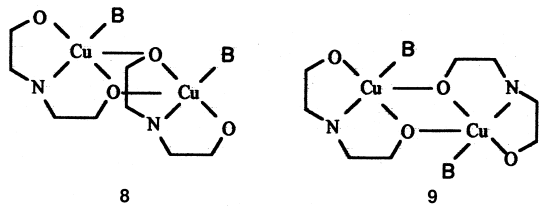
3 4



A large number of dimeric copper(II) complexes with other ONO tridentate Schiff base dianions have also been prepared and their magnetic properties have been investigated [11–20]. The reactivity of dimeric copper(II) complexes of ONO tridentate Schiff base anions (**5**) towards monodentate neutral Lewis bases continues to attract considerable attention [21–26]. The reactions of dimeric copper(II) complexes of type **5** with different Lewis bases, B, have been studied and they were found to give either monomeric square planar monobase adducts (**6**), with the rupture of Cu–O bridges, or five-coordinate (usually square pyramidal) dimeric bis adducts. Two types of dimeric adduct (**7** and **8**) have been characterized. In **7** the Lewis base donor atom occupies the apical site and is perpendicular to the square planar $CuNO_3$ plane, while in **8** the Lewis base donor atom is in the basal plane and the fifth coordination site is occupied by the two bridged oxygens. Furthermore, the two Lewis bases may attain either *cis* (**8**) or *trans* configuration (**9**) depending on the nature of the donor atom of B as well as the steric requirements of the ONO tridentate ligands [26].

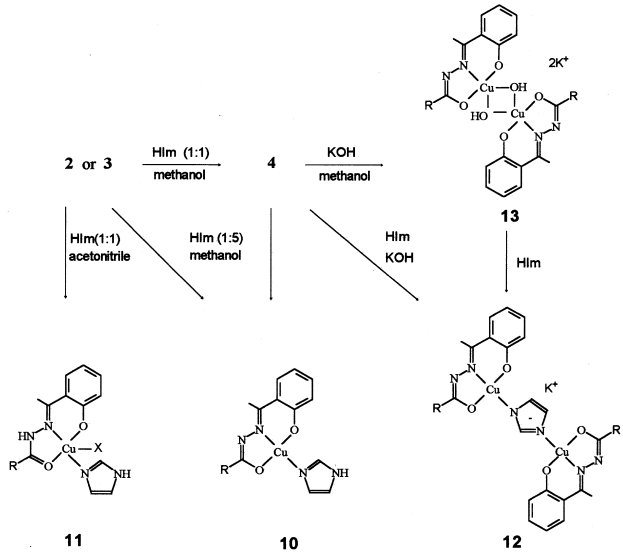
6 7

8 9

As ternary adduct formation may play an important role in the in vivo activity of *N*-salicylidenearoylhydrazine copper(II) complexes through binding with biological ligands containing an imidazole ring, this paper is devoted to study of the reactivity of some copper(II) complexes of the types $[Cu(HL)X\cdot H_2O]$ (**2**), $[\{Cu(HL)X\}_2]$ (**3**) and $[\{Cu(L)\}_2]$ (**4**) towards imidazole (Him), aiming to prepare a series of new imidazole and imidazolate copper(II) ternary complexes. The spectral and magnetic properties of the isolated ternary complexes have been examined and the X-ray crystal and molecular structures of $[Cu(Sp\text{-}ClBzh)Him]\cdot H_2O$ and $[\{Cu(Sp\text{-}CH_3Bzh)Him\}_2]\cdot H_2O$ have been determined. This may enable better understanding of the mode of interaction between these *N*-salicylideneacylhydrazine copper(II) complexes with biological ligands in vivo. Hereafter, *N*-salicylidenebenzoylhydrazine and the corresponding *p*-methyl-, *p*-methoxy- and *p*-chlorobenzoylhydrazines are abbreviated respectively as H_2SBzh, $H_2Sp\text{-}CH_3Bzh$, $H_2Sp\text{-}CH_3OBzh$ and $H_2Sp\text{-}ClBzh$.

2. Results and discussion

2.1. Synthesis



In methanol, the reaction of hydrated mononuclear copper(II) complexes $[Cu(HL)X\cdot H_2O]$ (**2**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4; $X=Cl$) and $[Cu(HSBzh)NO_3]\cdot H_2O$ as well as the anhydrous binuclear complexes $[\{Cu(HL)X\}_2]$ (**3**, $R=C_6H_5$ and *p*-$CH_3C_6H_4$; $X=Cl$) and $[\{Cu(HL)\}_2]\cdot 2NO_3$ [27] with 1 equiv. of imidazole resulted in the deprotonation of the hydrazone residue and afforded the neutral dimeric copper(II) complexes $[\{Cu(L)\}_2]$ (**4**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4). However, in the presence of a large excess of imidazole (4.0–5.0 equiv.) the reaction proceeded with the formation of the corresponding ternary imidazole adducts $[Cu(L)Him]$ (**10**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4). These adducts were also obtained from the reaction of the neutral dimeric copper(II) complexes $[\{Cu(L)\}_2]$ (**4**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4) with large excess of imidazole in methanol. In principle the imidazole adducts $[Cu(L)Him]$ may be either monomeric square planar (type **6**) or may dimerize to form the dimeric bis adduct of the type **7**, **8** or **9**.

In acetonitrile, the reaction of the monomeric copper(II) complexes $[Cu(HL)Cl\cdot H_2O]$ (**2**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4) with 1 equiv. imidazole or dimeric $[\{Cu(HL)Cl\}_2]$ (**3**, $R=C_6H_5$, *p*-$CH_3C_6H_4$) complexes with 2 equiv. of imidazole gave the chloro imidazole complexes of the stoichiometric composition $[Cu(HL)(Cl)Him]$ (**11**, $R=C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4). Similarly, the reaction of imidazole with either $[Cu(HSBzh)NO_3]\cdot H_2O$ or $[\{Cu(HSBzh)\}_2]\cdot 2NO_3$, in acetonitrile, also gave the corresponding copper(II) nitrate adducts $[Cu(HSBzh)NO_3\cdot Him)]$ (**11**, $R=C_6H_5$;

X = NO_3). The thiocyanate imidazole complexes [Cu(HL)-SCN·Him] (**11**, R = C_6H_5 and *p*-$CH_3OC_6H_4$; X = SCN) were similarly prepared.

In the presence of KOH, the reaction of the dimeric copper(II) complexes [{Cu(L)}$_2$] (**4**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4) with imidazole using 1:1 molar ratio in methanol proceeded by the deprotonation of imidazole, giving finally the corresponding imidazolate bridged copper(II) complexes K[LCu·Im·CuL] (**12**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$). These complexes can also be obtained by the reaction of the di-μ-hydroxo copper(II) complexes K[{Cu(L)OH}$_2$]$\cdot n H_2O$ (**13**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$) [27] with imidazole using 1:1 molar ratio in methanol or by the reaction of the hydroxo derivative (**13**) with the copper(II) imidazole adduct [Cu(L)Him] (**10**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ or *p*-ClC_6H_4). In this reaction the coordinated hydroxide can act as a proton acceptor, and can affect the deprotonation of the imidazole ring, and the two copper(II) centres are bridged by the imidazolate anion. The analytical data for all the isolated imidazole and imidazolate copper(II) complexes are given in Table 1.

2.2. Infrared spectra

The IR spectra of the ternary imidazole complexes [Cu(L)Him] (**10**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4), Table 2, show an intense band in the 3114–3130 cm^{-1} region due to ν(N–H) of the coordinated imidazole besides a series of bands at ca. 3050, 2995, 2930 and 2850 cm^{-1} which can be attributed to ν(C–H) as well as ν(C–H) + ν(N–H) coupled vibrations. The spectra lack absorptions due to both amide I (ν(C=O)) and amide II (δ(N–H) + ν(C–N)) bands, confirming the deprotonation of the enolimide hydrazone tautomer. The spectra, however, show strong absorption at ca. 1625 cm^{-1} due to the ν(–N=C–C=N–) of the deprotonated hydrazone ligand. The spectra also show the amide III band (ν(C–O)) at ca. 1340 cm^{-1}. The spectra of the chloro, nitrato and thiocyanato imidazole complexes [Cu(HL)X·Him] (**11**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$CH_3OC_6H_4$ and *p*-ClC_6H_4; X = Cl, NO_3 and SC*N*), Table 2, show the imidazole ν(*N*–H) as well as the aroylhydrazone ν(*N*–H) at ca. 3200 and 3100 cm^{-1}, respectively. The ν(C–H) patterns in the spectra of these complexes are more or less similar to that recorded for [Cu(L)Him] (**10**). The spectra also show the coordinated ν(C=O), amide I, band within the range 1630–1615 cm^{-1} while the ν(N=C) + ν(C=C) band appears at 1615–1590 cm^{-1}. In addition, the spectra are char-

acterized by a very intense band at 1550 cm^{-1} which can be attributed to δ(*N*–H) of the aroylhydrazone ligand. The amide III ν(C–O) band of [Cu(HL)X·Him] (**11**) complexes appear at higher frequencies (1307–1350 cm^{-1}) compared to those recorded for the [Cu(L)Him] (**10**) complexes. This may be due to the higher delocalization in the aroylhydrazone residue of the [Cu(L)Him)] complexes which in its turn decreases the C–N double bond character relative to that in [Cu(HL)X·Him].

The spectra of the nitrate complex [Cu(HSBzh)-NO$_3$·Him] (**11**, R = C$_6$H$_5$) show a split band at 1500 cm^{-1} due to ν(N=O) besides two bands at 1350 and 1065 cm^{-1} due to ν_{asy}(NO$_2$) and ν_{sy}(NO$_2$), respectively. The frequency difference $\Delta\nu = [\nu(N{=}O) - \nu_{asy}(NO_2)] = 150$ cm^{-1} is in agreement with the unidentate coordination mode of the nitrate anion [28–30]. The thiocyanate ν(NCS) in the spectra of [Cu(HL)SCN·Him] (**11**, R = C$_6$H$_5$ and *p*-CH$_3$OC$_6$H$_4$; X = SCN) appear as one intense band at ca. 2075 cm^{-1} indicating a unidentate mode of coordination, most probably through the nitrogen atom [29]. The spectra of the bridged imidazolate copper(II) complexes K[CuL·Im·CuL] (**12**, R = C$_6$H$_5$, *p*-CH$_3$C$_6$H$_4$ and *p*-CH$_3$OC$_6$H$_4$) lack absorption due to both aroylhydrazone and imidazole ν(N–H).

2.3. X-ray crystal and molecular structure of [Cu(Sp-ClBzh)-(Him)]·H$_2$O and [{Cu(Sp-CH$_3$Bzh)Him}$_2$]·H$_2$O

From all the prepared imidazole and imidazolate adducts, only the hydrated imidazole adducts [Cu(Sp-ClBzh)-Him]·H$_2$O and [{Cu(Sp-CH$_3$Bzh)Him}$_2$]·H$_2$O gave crystals suitable for X-ray diffraction studies. The crystal data and structure refinement parameters for these adducts are given in Table 3. The structure of [Cu(Sp-ClBzh)-Him]·H$_2$O together with the atom numbering scheme are shown in Fig. 1, and some selected bond distances and bond angles are given in Table 4. In this complex, the dinegative tridentate *N*-salicylidene-*p*-chlorobenzoylhydrazine is coordinated to Cu(II) through the deprotonated phenolic oxygen O(1), azomethine nitrogen N(1) and deprotonated enolimide oxygen O(2) forming respectively five- and six-membered chelate rings. The fourth coordination site is occupied by the imidazole nitrogen atom N(3). The copper(II) is in a distorted square planar arrangement and lies approximately in the ligand plane and shows a slight deviation of 0.099 Å from the best fit least-squares plane through the four donor atoms and Cu(II) atoms. The distortion from regular square planar is seen in the departure from 180° of the angles O(1)–Cu–O(2) (171.17°) and N(1)–Cu–N(3) (172.05°) and from 90° of the bite angles N(1)–Cu–O(2) (81.11°), N(1)–Cu–O(1) (93.57°), O(1)–Cu–N(3) (92.92°) and O(2)–Cu–N(3) (92.99°). This distortion may be imposed by the rigidity of the formed two chelate rings. The bond distances and angles recorded for the coordinated Schiff base in [Cu(Sp-ClBzh)Him]·H$_2$O as well as those involving the Cu(II) atom, Table 4, are more or less similar to those

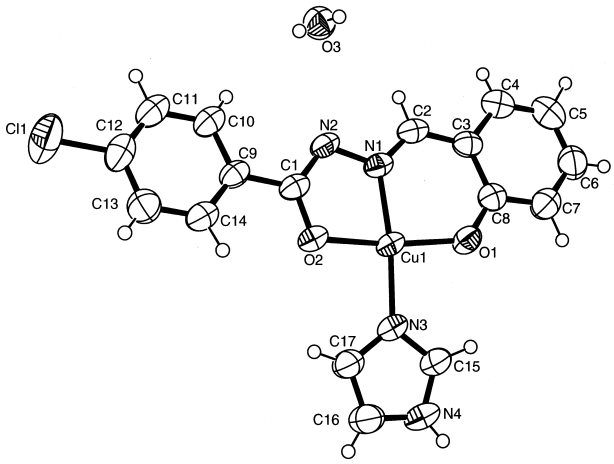

Fig. 1. X-ray structure of [Cu(Sp-ClBzh)Him]·H_2O.

reported for other *N*-salicylidenacylhydrazine copper(II) complexes [8–12]. The imidazole is planar and lies at an angle of 0.78° to the plane of best fit through the copper coordination sphere. The bond distance between the imidazole nitrogen N(3) and the copper(II) atom (1.953(2) Å) is comparable with other four coordinated copper(II) complexes containing imidazole molecule [22,23,31–34].

The crystal lattice is stabilized through the intermolecular hydrogen bonds between the two water hydrogens and the uncoordinated hydrazidic nitrogen of one molecule and the phenolic oxygen of the neighbouring molecule. The water oxygen, on the other hand, acts as a hydrogen bond acceptor forming a hydrogen bond with the N–H imidazole hydrogen from a third molecule as shown in Fig. 2. The intermolecular hydrogen bond distances and angles are listed in Table 5.

Different from [Cu(Sp-ClBzh)Him]·H_2O which exists in monomeric units where copper(II) is four coordinate and is situated in a square planar environment, the structure of [Cu(Sp-CH_3Bzh)Him]·1/2H_2O consists of dimeric units, Fig. 3, in which each Cu(II) atom is five-coordinated through the deprotonated phenolic oxygen O(1), azomethine nitrogen N(1) and deprotonated enolimide oxygen O(2) of the dinegative tridentate ligand. The phenolic oxygen O(1) of the salicylidene part of the tridentate ligand is bound in the basal plane of the Cu(II) coordination pyramid and acts as bridging atom forming the apex of an adjacent second pyramid. Accordingly, dimerization is achieved by sharing of the phenolic oxygen O(1) atom from each ligand through two copper atoms with intramolecular Cu–O(1) distance of 1.911 Å and intermolecular Cu–O1′ distance of 2.577 Å. The Cu–Cu separation is 3.257 Å and each copper atom lies approx-

imately in the ligand plane showing a slight deviation of 0.153 Å. The basal plane of the pyramid is completed with the N(3) atom from the imidazole molecule. The coordination polyhedron around the copper(II) is better described as a (4+1) distorted square pyramidal. This is in agreement with the value 0.15 of Addison et al.'s parameter τ [35] calculated from $\tau=(\beta-\alpha)/60$, where α is O(1)–Cu–O(2) (173.58°) and β is N(1)–Cu–N(3) (164.16°). The molecule is characterized by a two-fold axis perpendicular to the CuO1Cu′O1′ plane resulting in centrosymmetric dimers. In this dimeric structure, the imidazole molecules are in *trans* positions with respect to each other and perpendicular to the Cu_2O_2 plane with angles O(1)–Cu–N(3) and O(2)–Cu–N(3) of 91.78 and 94.18° respectively. The presence of two imidazole rings in a *trans* position may be attributed to the steric effect imposed by the crystal packing formed as a result of hydrogen bonds. Similar behaviour was reported for the urea adduct of *N*-salicylidene α-amino acidato copper(II) complex. The bond lengths and angles between Cu(II) and the donor atoms, Table 6, do not differ significantly from the values reported for other similar complexes [8–12].

The hydrogen bonds, Table 7, mainly determine the crystal packing. The water molecule acts as hydrogen donor towards the two uncoordinated nitrogen atoms N(2) of two different dimers in the unit cell, while the oxygen atom acts as hydrogen acceptor and is linked to two different N(4)–H imidazole hydrogens of two other different dimers in the cell. The whole of the hydrogen bond system leads to an infinite three-dimensional array as shown in Fig. 4.

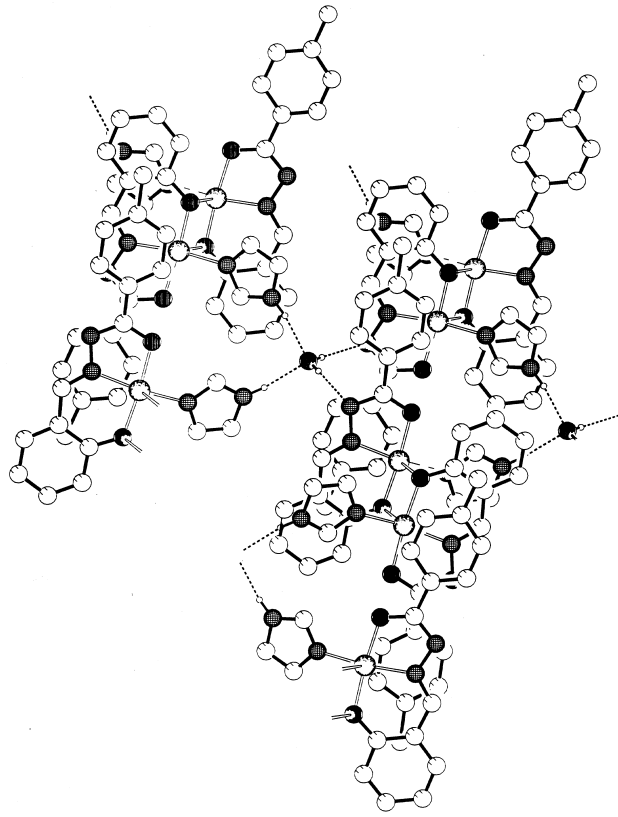

Fig. 4. Hydrogen bonds in $[\{Cu(Sp\text{-}CH_3Bzh)Him\}_2]\cdot H_2O$.

From the previous X-ray structure analyses, it is quite apparent that the reaction of imidazole with the dinuclear copper(II) complexes (**4**) may afford either monomeric ternary adducts as shown in $[Cu(Sp\text{-}ClBzh)Him]\cdot H_2O$, Fig. 1, or dimeric adducts as shown by $[\{Cu(Sp\text{-}CH_3Bzh)Him\}_2]\cdot H_2O$, Fig. 3, depending on the nature of the substituents on the tridentate *N*-salicylidenearoylhydrazine ligand. In such conjugated ligands, the electron-withdrawing substituents as in **4** ($R = p\text{-}ClC_6H_4$) result in a decrease of the negative charge on the phenoxy oxygen and the Cu–O bridges become more susceptible to bond rupture, eventually giving the monomeric square planar adduct $[Cu(SpClBzh)Him]\cdot H_2O$. On the other hand, the presence of electron-donating substituents in **4** ($R = p\text{-}CH_3C_6H_4$) increases the strength of the Cu–O bridges so they can withstand bond rupture, and in this case the reaction proceeds with the formation of a dinuclear ternary adduct.

2.4. Magnetic properties of imidazole and imidazolate ternary complexes

At room temperature, the ternary imidazole copper(II) adducts of the general formula $[Cu(L)Him]\cdot nH_2O$ and

Table 7
Intermolecular hydrogen bond distances and angles dimeric $[\{Cu(Sp\text{-}CH_3Bzh)(Him)\}_2]\cdot H_2O$

X–H···Y	Symmetry transformation	X···Y (Å)	X–H (Å)	H···Y (Å)	X–H–Y (°)
N(4)–H···O(3)	*x*, *y*, *z*	2.786	0.86	1.951	168.5

O(3)–H···N(2)	*x*, $-1+y$, *z*	2.837	0.76	2.095	176.3

[Cu(HL)X·Him], Table 1, show normal magnetic moments (1.82–1.88 μ_B), within the range expected for magnetically diluted mononuclear copper(II) complexes. Different from other dimeric copper(II) complexes with dinegative tridentate *N*-salicylidene Schiff bases which show subnormal magnetic moments due to strong antiferromagnetic exchange coupling [18–21], the dimeric imidazole copper(II) complex $[\{Cu(Sp\text{-}CH_3Bzh)Him\}_2]\cdot H_2O$ shows normal magnetic behaviour ($\mu_{eff}=1.88$ μ_B). The variation of molar magnetic susceptibility over the temperature range 4.2–295 K, Fig. 5, reveals no substantial deviation from Curie's behaviour characteristic for magnetically isolated copper(II) centres. A plot of $1/\chi$ versus temperature gave $\theta=-0.80$ K indicating very weak antiferromagnetic intermolecular interaction. This magnetic behaviour can be attributed to the orientation of the di-μ-oxo bridge relative to the CuO_2N_2 plane. As shown in Fig. 3, the Cu–N(3) are approximately perpendicular to the Cu_2O_2 plane with the N(3)–Cu(1)–O(1) bond angle of 91.78°, and the di-μ-oxo bridge is placed in the *xz* plane. Accordingly the magnetic orbitals of the copper ions ($d_{x^2}-d_{y^2}$) which point towards the CuN_2O_2 plane are oriented parallelly with no possible significant overlap. This does not mean that there is no interaction between the two copper atoms. Actually, for this peculiar geometry ferromagnetic and antiferromagnetic contributions compensate each other and the singlet and triplet states arising from this possible interaction are accidentally degenerate [36]. The geometry of this dimer is an example of dimeric adducts of type **9** which differs from the fairly common four-coordinate square planar dimers (type **5**) or five-coordinate square pyramidal bis adducts of the type **7**, where the two oxo bridges are in the *xy* plane and accordingly show strong antiferromagnetic exchange coupling [18–21].

The ternary imidazolate copper(II) complexes K[LCu·Im·CuL] (**12**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$), also show normal magnetic moments (1.82–1.88 μ_B) at room temperature. However, the variation of molar magnetic susceptibility χ_M measured for the imidazolate complexes (**12**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$), within the temperature range 4.2–297 K suggests antiferromagnetic exchange coupling. A plot of χ_M versus *T* for K[(CuSBzh)$_2$Im] (**12**, R = C_6H_5), Fig. 6, shows a maximum around ca. 40 K. This behaviour is typical of antiferromagnetic coupled dinuclear imidazolate bridged copper(II) complexes [37–53]. Similar behaviour was also observed for the other imidazolate complexes (**12**, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$). The variable temperature susceptibility data were fitted to the Bleany–Bowers equation [54]:

$$\chi_M=(1-X_p)\frac{2N_L g^2\mu_B^2}{kT}\frac{\exp(2J/kT)}{1+3\exp(2J/kT)}+X_p\frac{2N_L g^2\mu_B^2}{4kT}S(S+1)+2N_\alpha$$

$$\chi_M=(1-X_p)\frac{2N_L g^2\mu_B^2}{k(T-\theta)}\frac{\exp(2J/kT)}{1+3\exp(2J/kT)}+X_p\frac{2N_L g^2\mu_B^2}{4k(T-\theta)}S(S+1)+2N_\alpha$$

where N_α is the temperature independent paramagnetism, X_p is the fraction of monomeric impurity, and θ is a correction term for interdimer interactions [55,56] and the recorded *J*,

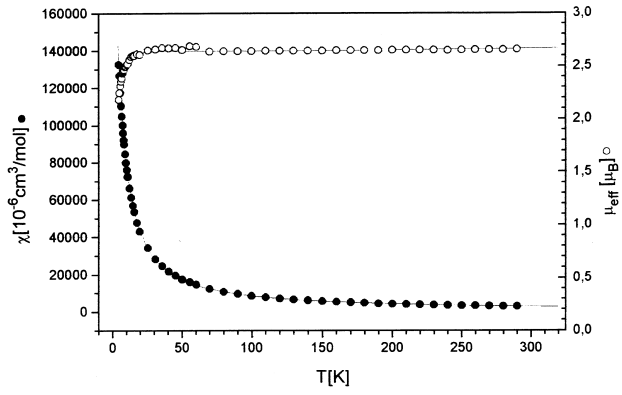

Fig. 5. Magnetic susceptibilities χ (●) and magnetic moments (○) vs. temperature for $[\{Cu(Sp\text{-}CH_3Bzh)Him\}_2]\cdot H_2O$.

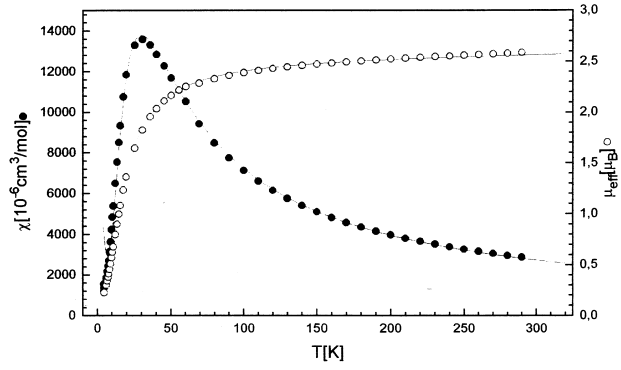

Fig. 6. Magnetic susceptibilities χ (●) and magnetic moments (○) vs. temperature for K[{Cu(SBzh)}$_2$Im]. Solid lines represent the best least-squares fit to Eq. (1), with $J=-17.2$, $g=2.11$, $\theta=-1.26$ and $X_p=2.0$.

g, θ and X_p values are listed in Table 8. The recorded J values are within the range (0 to -88 cm^{-1}) reported for other antiferromagnetic μ-imidazolate copper(II) complexes [39–53]. A comparison of the J values given in Table 8 with the values reported for other imidazolate complexes of known structures [53], reveals that the J values of the prepared imidazolate complexes (**12**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$CH_3OC_6H_4$) are more or less similar to that reported for $[Cu_2(Gly\text{-}GlyO)_2Im]$, where Gly-GlyO refers to glycylglycinate(-2), suggesting an average value of ca. 158° for the $Cu–N_{im}–N_{im}$ angle. Unfortunately, the absence of a complete X-ray molecular structure for any of the prepared imidazolate complexes, due to the lack of suitable crystals, makes any further discussion of their magnetic properties irrelevant.

Table 8
The best fit magnetic parameters for $K[\{CuL\}_2Im]$ (**12**, R = C_6H_5, *p*-$CH_3C_6H_4$ and *p*-$OCH_3C_6H_4$) complexes

Complex	J (cm^{-1})	g	θ	X_p (%)
$K[\{CuSBzh\}_2Im]$	−17.2	2.11	−1.26	2.0
$K[\{CuSp\text{-}CH_3Bzh\}_2Im]\cdot 2H_2O$	−18.9	2.19	0.19	2.2
$K[\{CuSp\text{-}OCH_3Bzh\}_2Im]\cdot 2H_2O$	−19.7	2.11	0.00	2.6

3. Experimental

3.1. Materials used

Hydrazine hydrate (B.D.H.) (99%), ethylbenzoate (Aldrich), *p*-methyl ethylbenzoate (B.D.H.), *p*-methoxy ethylbenzoate (Aldrich), *p*-chloro ethylbenzoate (B.D.H.), salicylaldehyde (Prolabo) and imidazole were used without further purification. Dry methanol was purified according to the standard method; acetonitrile was dried over P_2O_5 and then distilled, while all the other solvents were used without further purification. Copper(II) nitrate trihydrate was prepared from cupric carbonate (B.D.H.) according to the standard method while copper(II) chloride dihydrate (Merck) and copper acetate monohydrate (B.D.H.) were reagent grade and used as received. The copper(II) complexes $[Cu(HL)X\cdot H_2O]\cdot nH_2O$ (**2**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4; X = Cl, NO_3 or SCN), $[\{Cu(HL)X\}_2]$ (**3**, R = C_6H_5; X = Cl), $[\{CuL\}_2]$, (**4**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4) and $[\{(CuL\cdot OH)\}_2]\cdot nH_2O$ were prepared as previously described [27].

3.2. Preparation of $[Cu(L)Him]\cdot nH_2O$ (**10**, $R = C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4)

To a suspension of the $[\{Cu(L)\}_2]$ complex (**4**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ or *p*-ClC_6H_4) (0.01 mol) in methanol (30 ml), a sufficient amount of solid imidazole (0.05 mol) was added and the reaction mixture was heated until complete dissolution of the $[\{Cu(L)\}_2]$ then heated under reflux for ca. 1 h during which the imidazole–copper complex $[Cu(L)Him]\cdot nH_2O$ was precipitated. The isolated complex was filtered, washed with diethyl ether and then dried in a vacuum.

3.3. Preparation of $[Cu(HL)Cl\cdot Him]$ (**11**, $R = C_6H_5$, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4; $X = Cl$)

To a suspension of $[\{Cu(HL)Cl\}_2]\cdot nH_2O$ (**3**, R = C_6H_5, *p*-$CH_3C_6H_4$, *p*-$OCH_3C_6H_4$ and *p*-ClC_6H_4 or *p*-$OCH_3C_6H_4$) (0.01 mol) in acetonitrile (30 ml), an equivalent amount of solid imidazole (0.02 mol) was added. The reaction mixture was stirred at room temperature for ca. 2 h during which the green $[Cu(HL)Cl\cdot Him]$ was formed. The formed complex was filtered, washed with warm acetonitrile then dried in a vacuum.

3.4. Preparation of $[Cu(HSBzh)NO_3\cdot Him]$ (**11**, $R = C_6H_5$; $X = NO_3$)

A solution of $[Cu(HSBzh)NO_3]\cdot H_2O$ [27] (0.01 mol) in acetonitrile (70 cm^3) was treated with an equivalent amount of imidazole (0.01 mol) and the reaction mixture was stirred at room temperature for 1 h during which a green precipitate was formed. The isolated product was filtered, washed with methanol and then dried in vacuum.

3.5. Preparation of $[Cu(HL)Him\cdot SCN]$ (**11**, $R = C_6H_5$ and *p*-$OCH_3C_6H_4$; $X = SCN$)

These complexes were prepared from $[Cu(HL)SCN]$ [27] using the same procedure described for the corresponding chloro complexes.

3.6. Preparation of $K[\{Cu(L)\}_2Im]$ (**12**, $R = C_6H_5$, *p*-$CH_3C_6H_4$, and *p*-$CH_3OC_6H_4$)

A suspension of $[\{CuL\}_2]$ (**4**, R = C_6H_5, *p*-$CH_3C_6H_4$ or *p*-$OCH_3C_6H_4$) (0.01 mol) in dry methanol (50 ml) was treated with a large excess of KOH (ca. 0.05 mol). The resulting mixture was heated under reflux for about 1 h then filtered. To the clear filtrate an equivalent amount of imidazole (0.01 mol) was added and the reaction mixture was further refluxed for ca. 1 h, then evaporated till dryness. The isolated crude product was recrystallized from an acetonitrile–toluene mixture.

3.7. Physical measurements

The IR spectra were recorded on a Perkin-Elmer 1430 Data system spectrophotometer and/or Perkin-Elmer FTIR spectrometer (PARAGON 100 PC). Frequency readings were calibrated with polystyrene film. Solid samples were examined as KBr discs. Magnetic susceptibilities of powdered dried samples were recorded on a Faraday-type magnetometer using a sensitive computer controlled D-200 Cahn RG

microbalance in the temperature range 4.2–298 K. The magnetic field applied was ~1.5 T. Details of the apparatus have been described elsewhere [57–58]. Experimental susceptibility data were corrected for the underlying diamagnetism.

3.8. X-ray crystal and molecular structure

Suitable crystals were sealed in a fine focus glass capillary tube and mounted on a Nonius CAD-4 [59] diffractometer. Intensity data were collected at room temperature in the ω–θ scan mode, using graphite-monochromatized Mo Kα radiation. Lattice constants were determined by full-matrix least-squares refinement. The solution of the crystal structures was carried out using both SHELXS-86 [60] and SHELXL-93 [61] programs. The SHELXL-93 program was also used for structure refinement and for the evaluation of data. The StoeREDU4 [62] and StoeX-RED [63] programs were used for computing data reductions. The graphics plotting of the molecular and crystal structures were carried out using the PLUTON-93 [64] program as well as the ORTEP [65] method. The form factors for Cu(0) were taken from the international tables [66] and those for the other atoms are included as saved values in used programs.

Supplementary data

Atomic coordinates, equivalent isotropic displacement parameters, hydrogen coordinates, isotropic displacement parameters, anisotropic displacement parameters and complete list of bond distances and bond angles of [Cu(Sp-ClBzh)(Him)·H_2O and [{Cu(Sp-CH_3Bzh)Him}$_2$]·H_2O have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC 137464 and 137465, respectively.

Abstract

The nitrosyl complex in *trans*-[RuCl(pdma)(bpy)(NO)][PF_6]$_2$ (pdma = 1,2-phenylenebis(dimethylarsine), bpy = 2,2′-bipyridine) reacts at room temperature with stoichiometric NaN_3, followed by an excess of a neutral ligand L_1 in 2-butanone under reflux, to afford high yields of the mono-substituted derivatives *trans*-[RuCl(pdma)(bpy)L_1]PF_6 (L_1 = pyridine (py) **1**, triphenylphosphine (PPh_3) **2**, *N*-methylimidazole (mim) **3**, acetonitrile (MeCN) **4**, dimethylsulfoxide (dmso) **5** or pyrazine (pyz) **6**). The related compound *trans*-[RuCl(pdma)(phen)(NO)][PF_6]$_2$ (phen = 1,10-phenanthroline) reacts similarly to yield *trans*-[RuCl(pdma)(phen)L_1]PF_6 (L_1 = py **8**, PPh_3 **9**, mim **10** or pyz **11**). The pyrazine complexes in **6** and **11** react with MeI at room temperature in acetone to afford *trans*-[RuCl(pdma)(L–L)(mpyz$^+$)][PF_6]$_2$ (mpyz$^+$ = *N*-methylpyrazinium, L–L = bpy **7** or phen **12**, respectively). **3** reacts with an excess of a neutral ligand L_2 in the presence of stoichiometric $AgCF_3CO_2$ in water/acetone under reflux to afford high yields of the di-substituted derivatives *trans*-[Ru(pdma)(bpy)mim(L_2)][PF_6]$_2$ (L_2 = mim **13**, py **14** or MeCN **15**) and **2** reacts similarly with $AgCF_3CO_2$ in water/MeCN to give *trans*-[RuCl(pdma)(bpy)PPh_3(MeCN)][PF_6]$_2$ (**16**). The complexes in **1**–**16** exhibit intense $d_\pi(Ru^{II}) \rightarrow \pi^*(L–L)$ and $d_\pi(Ru^{II}) \rightarrow \pi^*(L_1/L_2)$ (L_1/L_2 = py, pyz or mpyz$^+$) metal-to-ligand charge-transfer absorption bands in the near-UV–visible region and are mildly photosensitive in solution. Solar irradiation leads to isomerization; for example **3** is converted into *cis*-[RuCl(pdma)(bpy)mim]PF_6 (**17**) over a period of ca. 100 h exposure to diffuse sunlight in acetone. Single crystal X-ray structures have been determined for **1**, **2**·DMF, **3**, **12**·3MeCN, **14**·DMF and **17**. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Photoisomerization; Ruthenium

1. Introduction

It has recently become apparent that ruthenium(II) complexes of N-heterocyclic chelating ligands such as 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) or 2,2′:6′,2″-terpyridine have potential for applications as components of photoactive molecular-level devices [1,2]. Of particular current interest is the discovery that relatives of the prototypical complex $[Ru^{II}(bpy)_3]^{2+}$ can act as efficient sensitizers when covalently attached to the surfaces of semiconducting nanocrystalline metal oxide electrodes in photovoltaic cells [3,4]. The utility of organotransition metal complexes in these and related devices rests upon the fact that photon absorption by metal-to-ligand charge-transfer (MLCT) chromophores can induce sequential, intramolecular electron or energy-transfer processes. The design of potentially useful MLCT-based molecular devices requires optimization of both electronic and stereochemical properties, and a particular emphasis on structurally well defined systems has emerged recently [5–7]. With functionalized octahedral MLCT chromophores, a *trans* disposition of attached donor/acceptor ('quencher') units is likely to be advantageous in order to achieve phenomena such as long-lived charge-separation. One approach to the preparation of such assemblies involves controlled ligand substitutions at *trans* octahedral metal centres.

Although 'chromophore-quencher' complexes based on *trans*-$\{Ru^{II}(bpy)_2\}^{2+}$ centres have been prepared [8], these undergo extremely facile photoinitiated ligand dissociation

PII S0277-5387(00)00369-7

and isomerization reactions. In attempts to identify alternative systems suitable for the preparation of stable *trans* MLCT chromophoric assemblies, we have chosen to explore the derivative chemistry of ruthenium(II) complexes of the chelating ligand 1,2-phenylenebis(dimethylarsine) (pdma). The precursor *trans*-$[Ru^{II}Cl(pdma)_2(NO)]^{2+}$ [9] readily undergoes nitrosyl substitution reactions to afford mono- and dinuclear derivatives containing the non-chromophoric *trans*-$\{Ru^{II}Cl(pdma)_2\}^+$ core [10,11], but subsequent chloride substitutions are remarkably difficult [10]. We have recently reported the mixed-chelates *trans*-$[Ru^{II}Cl(pdma)(L–L)(NO)]^{2+}$ (L–L = bpy or phen) [12], which were designed to act as versatile synthetic precursors to functionalized *trans* assemblies via stepwise axial ligand substitutions. The reactivity of these complexes and the photostability of the resulting products are the subjects of the present report.

2. Experimental

2.1. Materials and procedures

The compound $RuCl_3 \cdot 2H_2O$ was supplied by Johnson Matthey plc and pdma was obtained from Dr P.G. Edwards, University of Wales College of Cardiff. The salts *trans*-$[RuCl(pdma)(L–L)(NO)][PF_6]_2$ (L–L = bpy or phen) were prepared according to published procedures [12]. All other reagents were obtained commercially and used as supplied. All reactions were conducted under an argon atmosphere. Products were dried overnight at room temperature in a vacuum desiccator ($CaSO_4$) prior to characterization.

2.2. Instrumentation

^{1}H NMR spectra were recorded on a Varian Gemini 200 spectrometer and all shifts are referenced to $SiMe_4$. The complex fine splitting of the pyridine or 2,2′-bipyridine proton resonances is ignored and the signals are reported as simple doublets or triplets. Elemental analyses were performed by the Microanalytical Laboratory, University of Manchester. Infrared spectra were obtained as KBr discs with an ATI Mattson Genesis Series FTIR instrument. FAB mass spectra were recorded using a Kratos Concept spectrometer with a 6–8 keV Xe atom beam and 3-nitrobenzyl alcohol as matrix.

Cyclic voltammetric measurements were carried out using an EG&G PAR model 173 potentiostat/galvanostat with a model 175 universal programmer. A single-compartment cell was used with the saturated calomel reference electrode (SCE) separated by a salt bridge from the platinum-bead working electrode and platinum-wire auxiliary electrode. Acetonitrile (HPLC grade) was used as received and tetra-*n*-butylammonium hexafluorophosphate, twice recrystallized from ethanol and dried in vacuo, was used as supporting electrolyte. Solutions containing ca. 10^{-3} mol dm^{-3} analyte (0.1 mol dm^{-3} electrolyte) were deaerated by purging with N_2. All $E_{1/2}$ values were calculated from $(E_{pa}+E_{pc})/2$ at a scan rate of 200 mV s^{-1}.

2.3. Preparations

2.3.1. *trans*-[RuCl(pdma)(bpy)py]PF_6 (1)

A solution of *trans*-$[RuCl(pdma)(bpy)(NO)][PF_6]_2$ (50 mg, 0.056 mmol) and NaN_3 (3.7 mg, 0.057 mmol) in pyridine (10 cm^3) was stirred at room temperature for 2 h, then heated at reflux for 1 h. Addition of aqueous NH_4PF_6 yielded a deep red precipitate which was filtered off, washed with water and dried. Yield: 39 mg, 87%. *Anal*. Found: C, 37.4; H, 3.65; N, 5.10. Calc. for $C_{25}H_{29}As_2ClF_6N_3PRu$: C, 37.4; H, 3.65; N, 5.25%. ^{1}H NMR (200 MHz, CD_3CN): δ 9.27 (2H, d, J = 5.8 Hz, $H^{6,6'}$), 8.55 (2H, d, J = 8.0 Hz, $H^{3,3'}$), 8.17 (2H, t, $H^{4,4'}$), 8.05 (2H, m, C_6H_2), 7.82 (2H, t, $H^{5,5'}$), 7.73–7.65 (5H, m, $pyH^{2,4,6}$ and C_6H_2), 6.93 (2H, t, $pyH^{3,5}$), 1.78 (6H, s, 2AsMe), 1.62 (6H, s, 2AsMe). *m/z*: 658 ($[M-PF_6^-]^+$) and 579 ($[M-PF_6^- - py]^+$).

2.3.2. *trans*-[RuCl(pdma)(bpy)PPh_3]PF_6 (2)

A solution of *trans*-$[RuCl(pdma)(bpy)(NO)][PF_6]_2$ (51 mg, 0.057 mmol) and NaN_3 (3.7 mg, 0.057 mmol) in acetone (5 cm^3) was stirred at room temperature for 2 h. A solution of PPh_3 (594 mg, 2.27 mmol) in 2-butanone (10 cm^3) was added, the acetone was removed in vacuo, and the solution was heated at reflux for a further 2 h. The solvent was reduced to a small volume in vacuo and diethyl ether was added to give a golden-coloured precipitate which was filtered off, washed with diethyl ether, and dried. The product was purified by reprecipitation from acetonitrile/diethyl ether to afford a yellow solid. Yield: 45 mg, 80%. *Anal*. Found: C, 46.35; H, 3.80; N, 3.20; P, 6.05. Calc. for $C_{38}H_{39}As_2ClF_6N_2P_2Ru$: C, 46.3; H, 4.00; N, 2.85; P, 6.30%. ^{1}H NMR (200 MHz, CD_3CN): δ 8.34 (2H, d, J = 8.2 Hz, $H^{6,6'}$), 8.24 (2H, d, J = 5.2 Hz, $H^{3,3'}$), 8.07–7.98 (4H, m, $H^{4,4'}$ and C_6H_2), 7.77 (2H, m, C_6H_2), 7.32–7.23 (5H, m, $H^{5,5'}$ and $3PhH^4$), 7.13–7.04 (6H, m, $3PhH^{3,5}$), 6.93 (6H, m, $3PhH^{2,6}$), 1.74 (6H, s, 2AsMe), 1.54 (6H, s, 2AsMe). *m/z*: 841 ($[M-PF_6^-]^+$) and 578 ($[M-PF_6^- - PPh_3]^+$). A reaction was also carried out using the above method, but instead of heating at reflux after the addition of PPh_3, the solution was stirred at room temperature for 93 h. This afforded 26 mg of **2** (46%, pure by ^{1}H NMR).

2.3.3. *trans*-[RuCl(pdma)(bpy)mim]PF_6 (3)

A solution of *trans*-$[RuCl(pdma)(bpy)(NO)][PF_6]_2$ (50 mg, 0.056 mmol) and NaN_3 (3.7 mg, 0.057 mmol) in acetone (5 cm^3) was stirred at room temperature for 2 h. *N*-Methylimidazole (mim, 5 cm^3) was added, the acetone was removed in vacuo, and the solution was heated at ca. 100°C for 1 h. After cooling to room temperature, addition of aqueous NH_4PF_6 and water afforded a red precipitate which was filtered off, washed with water and dried. Reprecipitation from acetone/diethyl ether gave a deep red solid. Yield: 42 mg, 94%. *Anal*. Found: C, 36.2; H, 3.75; N, 7.05. Calc. for

$C_{24}H_{30}As_2ClF_6N_4PRu$: C, 35.75; H, 3.75; N, 6.95%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.53 (2H, d, J = 5.2 Hz, $H^{6,6'}$), 8.72 (2H, d, J = 8.0 Hz, $H^{3,3'}$), 8.21 (2H, t, $H^{4,4'}$), 8.12 (2H, m, C_6H_2), 7.76 (2H, t, $H^{5,5'}$), 7.67 (2H, m, C_6H_2), 7.31 (1H, s, $C_3H_3N_2$), 6.95 (1H, s, $C_3H_3N_2$), 6.36 (1H, s, $C_3H_3N_2$), 3.54 (3H, s, Me), 1.83 (6H, s, 2AsMe), 1.72 (6H, s, 2AsMe). *m/z*: 660 ($[M-PF_6^-]^+$) and 577 ($[M-PF_6^- - mim]^+$).

2.3.4. trans-[RuCl(pdma)(bpy)(MeCN)]PF_6 (4)

This was prepared in a similar manner to **1** by using acetonitrile in place of pyridine. The reaction was cooled to room temperature, and the solvent removed in vacuo. The resulting yellow/orange oil was dissolved in acetone (3 cm^3), and addition of aqueous NH_4PF_6 afforded an orange precipitate which was filtered off, washed with water and dried. Reprecipitation from acetone/diethyl ether yielded an orange solid. Yield: 36 mg, 82%. *Anal*. Found: C, 35.8; H, 4.00; N, 5.00. Calc. for $C_{22}H_{27}As_2ClF_6N_3PRu \cdot 0.5C_3H_6O$: C, 35.55; H, 3.80; N, 5.30%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.50 (2H, d, J = 5.9 Hz, $H^{6,6'}$), 8.73 (2H, d, J = 7.4 Hz, $H^{3,3'}$), 8.27 (2H, t, $H^{4,4'}$), 8.14 (2H, m, C_6H_2), 7.83 (2H, t, $H^{5,5'}$), 7.69 (2H, m, C_6H_2), 2.28 (3H, s, Me), 1.67 (12H, s, 4AsMe). ν(C≡N) 2267 w cm^{-1}. *m/z*: 620 ($[M-PF_6^-]^+$) and 578 ($[M-PF_6^- - MeCN]^+$).

2.3.5. trans-[RuCl(pdma)(bpy)dmso]PF_6 (5)

This was prepared and purified in an identical manner to **3**, but using dmso in place of mim, to afford a yellow solid. Yield: 33 mg, 74%. *Anal*. Found: C, 32.7; H, 3.90; N, 3.40; S, 3.40. Calc. for $C_{22}H_{30}As_2ClF_6N_2OPRuS$: C, 32.95; H, 3.75; N, 3.50; S, 4.00%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.55 (2H, d, J = 4.8 Hz, $H^{6,6'}$), 8.72 (2H, d, J = 7.4 Hz, $H^{3,3'}$), 8.34 (2H, t, $H^{4,4'}$), 8.09 (2H, m, C_6H_2), 7.90 (2H, t, $H^{5,5'}$), 7.69 (2H, m, C_6H_2), 2.96 (6H, s, 2Me), 1.93 (12H, s, 4AsMe). ν(S=O) 1085 m cm^{-1}. *m/z*: 657 ($[M-PF_6^-]^+$) and 579 ($[M-PF_6^- - dmso]^+$).

2.3.6. trans-[RuCl(pdma)(bpy)pyz]PF_6 (6)

This was prepared in an identical manner to **2**, but using pyrazine (181 mg, 2.26 mmol) in place of PPh_3. Reprecipitation from acetone/diethyl ether afforded a red solid. Yield: 37 mg, 78%. *Anal*. Found: C, 36.7; H, 3.50; N, 7.05. Calc. for $C_{24}H_{28}As_2ClF_6N_4PRu \cdot 0.5C_3H_6O$: C, 36.75; H, 3.75; N, 6.75%. ^{1}H NMR (200 MHz, CD_3CN): δ 9.18 (2H, d, J = 5.6 Hz, $H^{6,6'}$), 8.57 (2H, d, J = 8.0 Hz, $H^{3,3'}$), 8.20 (2H, t, $H^{4,4'}$), 8.05 (2H, m, C_6H_2), 7.99 (2H, d, J = 4.6 Hz, pyz), 7.86 (2H, d, J = 4.6 Hz, pyz), 7.73–7.66 (4H, m, $H^{5,5'}$ and C_6H_2), 1.77 (6H, s, 2AsMe), 1.66 (6H, s, 2AsMe). *m/z*: 659 ($[M-PF_6^-]^+$) and 579 ($[M-PF_6^- - pyz]^+$).

2.3.7. trans-[RuCl(pdma)(bpy)($mpyz^+$)][PF_6]$_2$ (7)

A solution of **6** (50 mg, 0.062 mmol) in DMF (1.5 cm^3) and MeI (0.5 cm^3) was stirred at room temperature for 24 h. The excess MeI was removed in vacuo, and addition of aqueous NH_4PF_6 afforded a purple precipitate which was filtered off and washed with water. The crude product was dissolved in acetone and the solution was filtered to remove an insoluble tan residue. Addition of diethyl ether to the filtrate gave a purple precipitate which was filtered off and washed with diethyl ether. Repeated recrystallization from acetonitrile/diethyl ether yielded the purple product. Yield: 11 mg, 18%. *Anal*. Found: C, 32.0; H, 3.55; N, 5.95. Calc. for $C_{25}H_{31}As_2ClF_{12}N_4P_2Ru \cdot 0.5C_2H_3N$: C, 31.7; H, 3.35; N, 6.40%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.22 (2H, d, J = 4.8 Hz, $H^{6,6'}$), 8.99 (2H, d, J = 5.3 Hz, $mpyz^+$), 8.89 (2H, d, J = 8.2 Hz, $H^{3,3'}$), 8.40 (2H, t, $H^{4,4'}$), 8.21 (4H, m, C_6H_2 and $mpyz^+$), 7.85 (2H, t, $H^{5,5'}$), 7.77 (2H, m, C_6H_2), 3.98 (3H, s, Me), 1.90 (6H, s, 2AsMe), 1.88 (6H, s, 2AsMe). *m/z*: 819 ($[M-PF_6^-]^+$) and 579 ($[M-2PF_6^- - mpyz]^+$).

2.3.8. trans-[RuCl(pdma)(phen)py]PF_6 (8)

This was prepared and purified in an identical manner to **1** by using *trans*-[RuCl(pdma)(phen)(NO)][PF_6]$_2$ (100 mg, 0.108 mmol) in place of *trans*-[RuCl(pdma)(bpy)(NO)][PF_6]$_2$. A red solid was obtained. Yield: 80 mg, 89%. *Anal*. Found: C, 39.3; H, 3.70; N, 5.05. Calc. for $C_{27}H_{29}As_2ClF_6N_3PRu$: C, 39.2; H, 3.55; N, 5.10%. ^{1}H NMR (200 MHz, CD_3CN): δ 9.66 (2H, d, J = 5.2 Hz, $H^{2,9}$), 8.72 (2H, d, J = 8.2 Hz, $H^{4,7}$), 8.24 (2H, s, $H^{5,6}$), 8.11–8.01 (4H, m, $H^{3,8}$ and C_6H_2), 7.86 (2H, d, J = 6.4 Hz, $pyH^{2,6}$), 7.72 (2H, m, C_6H_2), 7.49 (1H, t, pyH^4), 6.84 (2H, t, $pyH^{3,5}$), 1.87 (6H, s, 2AsMe), 1.69 (6H, s, 2AsMe). *m/z*: 682 ($[M-PF_6^-]^+$) and 603 ($[M-PF_6^- - py]^+$).

2.3.9. trans-[RuCl(pdma)(phen)PPh_3]PF_6 (9)

This was prepared and purified in an identical manner to **2** by using *trans*-[RuCl(pdma)(phen)(NO)][PF_6]$_2$ (100 mg, 0.108 mmol) in place of *trans*-[RuCl(pdma)(bpy)(NO)][PF_6]$_2$. A yellow solid was obtained. Yield: 88 mg, 80%. *Anal*. Found: C, 47.2; H, 3.95; N, 3.00; P, 6.00. Calc. for $C_{40}H_{39}As_2ClF_6N_2P_2Ru$: C, 47.55; H, 3.90; N, 2.75; P, 6.15%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.09 (2H, d, J = 4.6 Hz, $H^{2,9}$), 8.75 (2H, d, J = 7.2 Hz, $H^{4,7}$), 8.27 (2H, s, $H^{5,6}$), 8.23 (2H, m, C_6H_2), 7.82 (4H, m, $H^{3,8}$ and C_6H_2), 7.31 (3H, t, $3PhH^4$), 7.08 (6H, t, $3PhH^{3,5}$), 6.75 (6H, t, $3PhH^{2,6}$), 1.94 (6H, s, 2AsMe), 1.70 (6H, s, 2AsMe). *m/z*: 864 ($[M-PF_6^-]^+$) and 602 ($[M-PF_6^- - PPh_3]^+$).

2.3.10. trans-[RuCl(pdma)(phen)mim]PF_6 (10)

This was prepared and purified in an identical manner to **3** by using *trans*-[RuCl(pdma)(phen)(NO)][PF_6]$_2$ (200 mg, 0.217 mmol) in place of *trans*-[RuCl(pdma)(bpy)(NO)][PF_6]$_2$. A red solid was obtained. Yield: 158 mg, 82%. *Anal*. Found: C, 38.85; H, 4.20; N, 6.35. Calc. for $C_{26}H_{30}As_2ClF_6N_4PRu \cdot C_3H_6O$: C, 39.25; H, 4.10; N, 6.30%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.94 (2H, d, J = 5.0 Hz, $H^{2,9}$), 8.81 (2H, d, J = 8.2 Hz, $H^{4,7}$), 8.32 (2H, s, $H^{5,6}$), 8.14 (4H, m, $H^{3,8}$ and C_6H_2), 7.70 (2H, m, C_6H_2), 7.22 (1H, s, $C_3H_3N_2$), 6.85 (1H, s, $C_3H_3N_2$), 6.33 (1H, s, $C_3H_3N_2$), 3.42 (3H, s, Me), 1.92 (6H, s, 2AsMe), 1.81 (6H, s,

2AsMe). *m/z*: 684 ([M−PF_6^-]$^+$) and 603 ([M−PF_6^-−mim]$^+$).

*2.3.11. trans-[RuCl(pdma)(phen)pyz]PF_6 (**11**)*

This was prepared and purified in an identical manner to **6** by using *trans*-[RuCl(pdma)(phen)(NO)][PF_6]$_2$ (100 mg, 0.108 mmol) in place of *trans*-[RuCl(pdma)-(bpy)(NO)][PF_6]$_2$. A red solid was obtained. Yield: 80 mg, 89%. *Anal*. Found: C, 37.75; H, 3.60; N, 6.50. Calc. for $C_{26}H_{28}As_2ClF_6N_4PRu$: C, 37.7; H, 3.40; N, 6.75%. ^{1}H NMR (200 MHz, CD_3CN): δ 9.68 (2H, d, J=4.4 Hz, $H^{2,9}$), 8.76 (2H, d, J=6.0 Hz, $H^{4,7}$), 8.26 (2H, s, $H^{5,6}$), 8.13–8.02 (4H, m, $H^{3,8}$ and C_6H_2), 7.89 (4H, m, pyz), 7.73 (2H, m, C_6H_2), 1.86 (6H, s, 2AsMe), 1.73 (6H, s, 2AsMe). *m/z*: 683 ([M−PF_6^-]$^+$) and 603 ([M−PF_6^-−pyz]$^+$).

*2.3.12. trans-[RuCl(pdma)(phen)(mpyz$^+$)][PF_6]$_2$ (**12**)*

This was prepared and purified in an identical manner to **7**, but using **11** (50 mg, 0.061 mmol) in place of **6**. A deep purple solid was obtained. Yield: 29 mg, 48%. *Anal*. Found: C, 32.8; H, 3.05; N, 5.50. Calc. for $C_{27}H_{31}As_2ClF_{12}N_4P_2Ru$: C, 32.85; H, 3.15; N, 5.65%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.66 (2H, d, J=5.2 Hz, $H^{2,9}$), 8.99 (4H, m, $H^{4,7}$ and mpyz$^+$), 8.44 (2H, s, $H^{5,6}$), 8.27–8.12 (6H, m, $H^{3,8}$, C_6H_2 and mpyz$^+$), 7.79 (2H, m, C_6H_2) 3.93 (3H, s, Me), 1.99 (6H, s, 2AsMe), 1.97 (6H, s, 2AsMe). *m/z*: 843 ([M−PF_6^-]$^+$), 698 ([M−2PF_6^-]$^+$) and 602 ([M−2PF_6^-−mpyz$^+$]$^+$).

*2.3.13. trans-[Ru(pdma)(bpy)(mim)$_2$][PF_6]$_2$ (**13**)*

A solution of **3** (50 mg, 0.062 mmol), $AgCF_3CO_2$ (13.8 mg, 0.062 mmol) and mim (0.2 cm^3) in acetone (5 cm^3) was heated at reflux for 75 min. Water (5 cm^3) was added, and reflux was continued for a further 3 h. The reaction mixture was then filtered through celite to remove AgCl, and addition of aqueous NH_4PF_6 and water yielded an orange precipitate, which was filtered off, washed with water, and dried. Reprecipitation from acetone/diethyl ether afforded an orange solid. Yield: 50 mg, 81%. *Anal*. Found: C, 34.0; H, 3.45; N, 8.50. Calc. for $C_{28}H_{36}As_2F_{12}N_6P_2Ru$: C, 33.7; H, 3.65; N, 8.45%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.61 (2H, d, J=4.8 Hz, $H^{6,6'}$), 8.78 (2H, d, J=8.0 Hz, $H^{3,3'}$), 8.36 (2H, t, $H^{4,4'}$), 8.25 (2H, m, C_6H_2), 7.91 (2H, t, $H^{5,5'}$), 7.78 (2H, m, C_6H_2), 7.22 (2H, s, 2$C_3H_3N_2$), 6.96 (2H, s, 2$C_3H_3N_2$), 6.25 (2H, s, 2$C_3H_3N_2$), 3.49 (6H, s, 2Me), 1.80 (12H, s, 4AsMe). *m/z*: 852 ([M−PF_6^-]$^+$), 707 ([M−2PF_6^-]$^+$), 624 ([M−2PF_6^-–mim]$^+$) and 543 ([M−2PF_6^-−2mim]$^+$).

*2.3.14. trans-[Ru(pdma)(bpy)(mim)py][PF_6]$_2$ (**14**)*

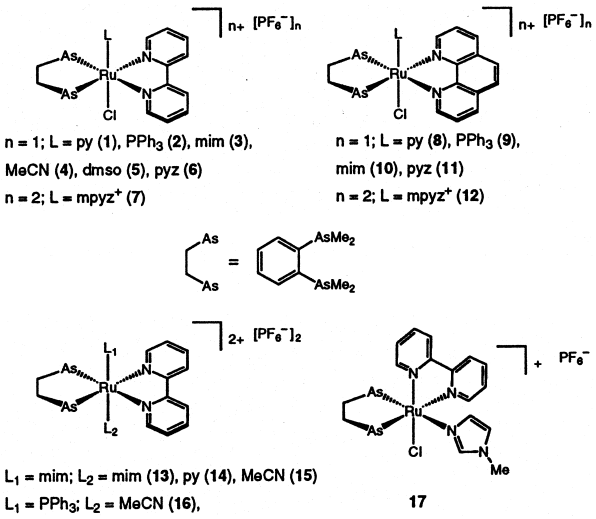
This was prepared and purified in an identical fashion to **13** but using pyridine (0.4 cm^3) in place of mim. A yellow/orange solid was obtained. Yield: 43 mg, 66%. *Anal*. Found: C, 36.5; H, 3.65; N, 6.65. Calc. for $C_{29}H_{35}As_2F_{12}N_5P_2Ru\cdot C_3H_6O$: C, 36.5; H, 3.95; N, 6.65%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.69 (2H, d, J=4.6 Hz, $H^{6,6'}$), 8.76 (2H, d, J=8.0 Hz, $H^{3,3'}$), 8.35 (2H, t, $H^{4,4'}$), 8.29–8.24 (4H, m, $pyH^{2,6}$ and C_6H_2), 7.96 (2H, t, $H^{5,5'}$), 7.82–7.76 (3H, m, pyH^4 and C_6H_2), 7.22–7.12 (3H, m, $pyH^{3,5}$ and $C_3H_3N_2$), 6.97 (1H, s, $C_3H_3N_2$), 6.15 (1H, s, $C_3H_3N_2$), 3.47 (3H, s, Me), 1.91 (6H, s, 2AsMe), 1.80 (6H, s, 2AsMe). *m/z*: 849 ([M−PF_6^-]$^+$), 703 ([M−2PF_6^-]$^+$), 624 ([M−2PF_6^-−py]$^+$) and 543 ([M−2PF_6^-−py–mim]$^+$).

*2.3.15. trans-[Ru(pdma)(bpy)(mim)MeCN][PF_6]$_2$ (**15**)*

This was prepared in an identical fashion to **13** but using acetonitrile (0.4 cm^3) in place of mim, with no reprecipitation of the crude product. An orange solid was obtained. Yield: 52 mg, 88%. *Anal*. Found: C, 32.7; H, 3.50; N, 7.70. Calc. for $C_{26}H_{33}As_2F_{12}N_5P_2Ru$: C, 32.65; H, 3.50; N, 7.30%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.46 (2H, d, J=5.4 Hz, $H^{6,6'}$), 8.87 (2H, d, J=8.0 Hz, $H^{3,3'}$), 8.45 (2H, t, $H^{4,4'}$), 8.26 (2H, m, C_6H_2), 7.93 (2H, t, $H^{5,5'}$), 7.79 (2H, m, C_6H_2), 7.20 (1H, s, $C_3H_3N_2$), 7.01 (1H, s, $C_3H_3N_2$), 6.20 (1H, s, $C_3H_3N_2$), 3.50 (3H, s, $C_3H_3N_2$–*Me*), 2.24 (3H, s, Me), 1.94 (6H, s, 2AsMe), 1.90 (6H, s, 2AsMe). *m/z*: 811 ([M−PF_6^-]$^+$), 666 ([M−2PF_6^-]$^+$), 625 ([M−2PF_6^-−MeCN]$^+$) and 544 ([M−2PF_6^-−MeCN−mim]$^+$).

*2.3.16. trans-[Ru(pdma)(bpy)(PPh_3)(MeCN)][PF_6]$_2$ (**16**)*

This was prepared and purified in an identical manner to **15** by using **2** (50 mg, 0.051 mmol) in place of **3**. A yellow solid was obtained. Yield: 37 mg, 64%. *Anal*. Found: C, 41.95; H, 3.75; N, 3.70; P, 7.85. Calc. for $C_{40}H_{42}As_2F_{12}N_3P_3Ru$: C, 42.25; H, 3.70; N, 3.70; P, 8.20%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 8.92 (2H, d, J=5.0 Hz, $H^{6,6'}$), 8.65 (2H, d, J=7.6 Hz, $H^{3,3'}$), 8.30 (4H, m, $H^{4,4'}$ and C_6H_2), 7.89 (2H, m, C_6H_2), 7.74 (2H, t, $H^{5,5'}$), 7.40 (3H, t, $3PhH^4$), 7.15 (6H, t, $3PhH^{3,5}$), 6.76 (6H, t, $3PhH^{2,6}$), 2.22 (3H, s, Me), 1.96 (6H, s, 2AsMe), 1.66 (6H, s, 2AsMe). *m/z*: 991 ([M−PF_6^-]$^+$), 845 ([M−2PF_6^-]$^+$), 583 ([M−2PF_6^-−PPh_3]$^+$) and 542 ([M−2PF_6^-−PPh_3−MeCN]$^+$).



*2.3.17. cis-[RuCl(pdma)(bpy)mim]PF_6 (**17**)*

A solution of **3** (40 mg, 0.050 mmol) in acetone (20 cm^3) was exposed to sunlight for 100 h, during which time the isomerization was completed (as shown by ^{1}H NMR spectroscopy on a smaller sample in acetone-d_6). The addition of diethyl ether gave a precipitate which was filtered off, washed with diethyl ether and dried to afford a deep red solid. Yield: 31 mg, 78%. *Anal*. Found: C, 35.9; H, 4.00; N, 7.05. Calc. for $C_{24}H_{30}As_2ClF_6N_4PRu$: C, 35.75; H, 3.75; N, 6.95%. ^{1}H NMR (200 MHz, CD_3COCD_3): δ 9.96 (1H, d, J=6.0 Hz, bpy), 8.97 (1H, d, J=5.4 Hz, bpy), 8.56 (2H, t, bpy), 8.12 (1H, t, bpy), 8.10–7.99 (2H, m, C_6H_2), 7.93–7.80 (3H, m, bpy and $C_3H_3N_2$), 7.65–7.58 (2H, m, C_6H_2), 7.46 (1H, t, bpy), 7.09 (1H, s, $C_3H_3N_2$), 6.74 (1H, s, $C_3H_3N_2$), 3.71 (3H, s, $C_3H_3N_2$–*Me*), 1.92 (3H, s, AsMe), 1.56 (3H, s, AsMe), 1.48 (3H, s, AsMe), 0.74 (3H, s, AsMe). *m/z*: 661 ([M−PF_6^-]$^+$) and 579 ([M−PF_6^-−mim]$^+$).

2.4. X-ray crystallography

Crystals of **1**, **3**, **12**·3MeCN and **17** were grown by slow diffusion of diethyl ether vapour into acetonitrile solutions of the complex salts at 4°C. Those of **2**·DMF and **14**·DMF were obtained in similar manner, but using DMF solutions. The approximate dimensions (mm) of the crystals chosen for diffraction studies were as follows: **1** (0.15×0.15×0.10), **2**·DMF (0.40×0.10×0.10), **3** (0.40×0.20×0.05), **12**·3MeCN (0.15×0.15×0.05), **14**·DMF (0.30×0.20×0.05), **17** (0.10×0.10×0.05).

Data collection details are as follows: for **1**, **2**·DMF and **3** data were collected on a Siemens SMART CCD area-detector diffractometer. Empirical absorption corrections were applied by using multiple measurements of equivalent reflections, and the data were integrated by using SAINT [13]. For **12**·3MeCN, **14**·DMF and **17** data were collected on a Nonius Kappa CCD area-detector diffractometer controlled by the Collect software package [14]. The data were processed by Denzo [15] and corrected for absorption by using the empirical method employed in Sortav [16,17] from within the MAXUS suite of programs [18].

The structures of **1**, **2**·DMF and **3** were solved by direct methods and refined by full-matrix least-squares on all F_o^2 data using Siemens SHELXTL 5.03 [13]. The same approach was used for **12**·3MeCN, **14**·DMF and **17**, but using SHELXS-90 [19] and SHELXL-97 [20]. In all cases, all non-hydrogen atoms were refined anisotropically with hydrogen atoms included in idealized positions with thermal parameters riding on those of the parent atom. Static disorder is present in the PF_6^- anions of **1** and **17**, and in the axial ligands of **14**·DMF (50% occupancy by py and mim in both positions).

Representations of the complex cations in **1**, **2**·DMF, **3**, **12**·3MeCN, **14**·DMF and **17** are given in Figs. 1–6. Crystallographic data and refinement details are presented in Table 1, and selected bond distances and angles in Table 2.

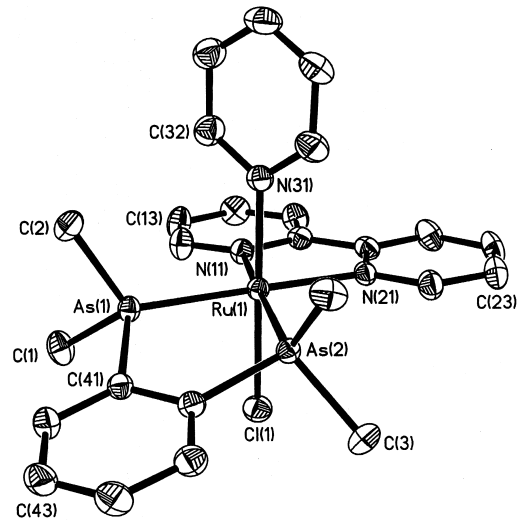


Fig. 1. Structural representation of the complex cation in the salt **1**, with hydrogen atoms omitted (50% probability ellipsoids).

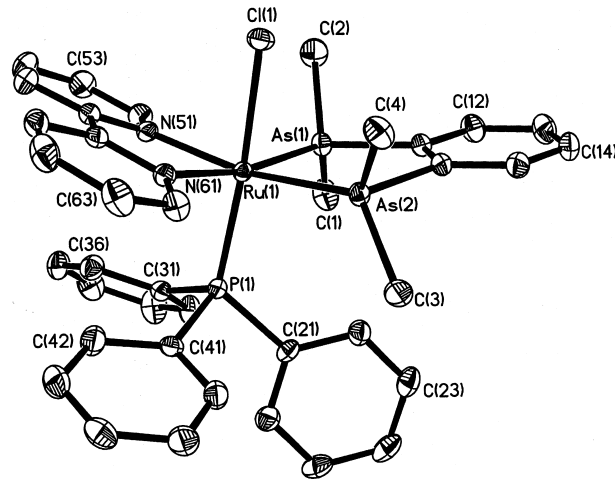

Fig. 2. Structural representation of the complex cation in the salt **2**·DMF, with hydrogen atoms omitted (50% probability ellipsoids).

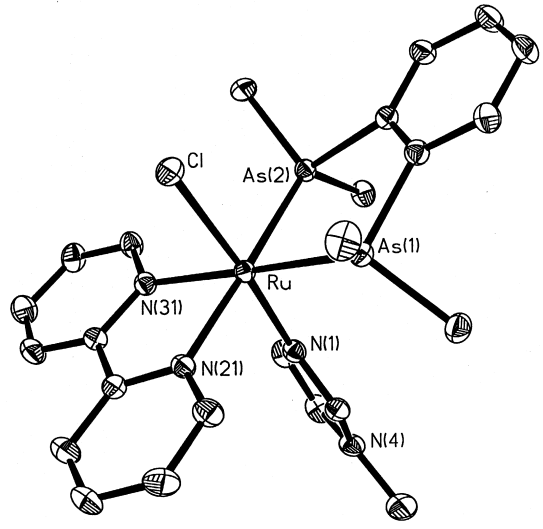

Fig. 3. Structural representation of the complex cation in the salt **3**, with hydrogen atoms omitted (50% probability ellipsoids).

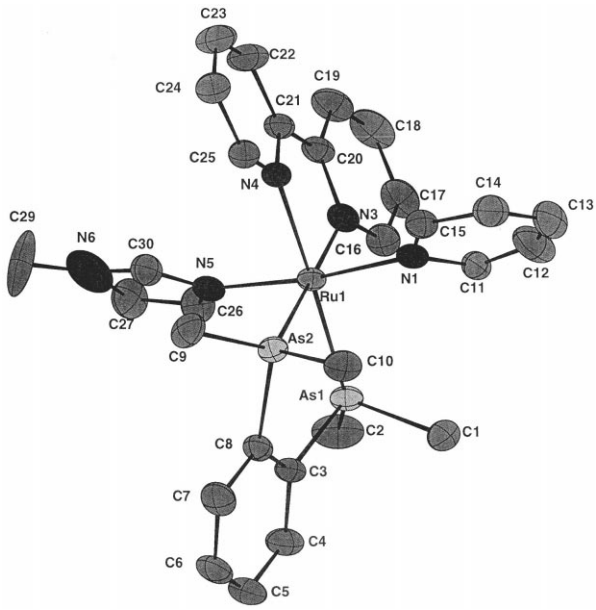

Fig. 4. Structural representation of the complex cation in the salt **12**·3MeCN, with disorder removed and hydrogen atoms omitted (50% probability ellipsoids).

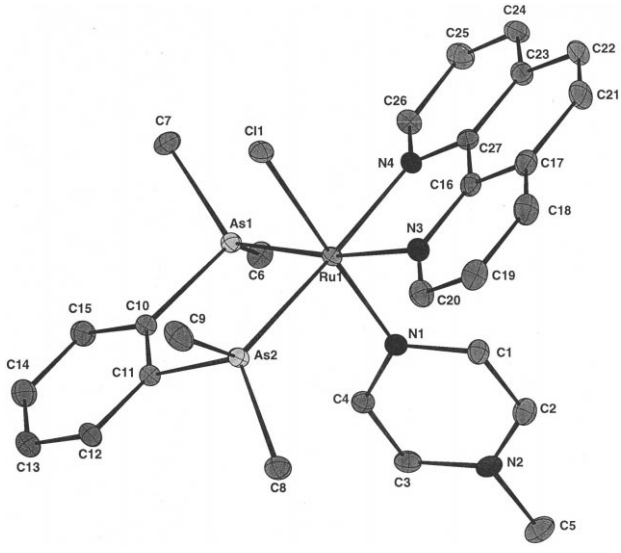

Fig. 5. Structural representation of the complex cation in the salt **14**·DMF, with hydrogen atoms omitted (50% probability ellipsoids).

3. Results and discussion

3.1. Synthesis and characterization

It is well established that sufficiently electrophilic, linearly coordinated nitrosyl ligands react with nucleophiles [21,22], and the reaction with azide ion is a versatile means to convert ruthenium(II) nitrosyls into substituted derivatives via dinitrogen or solvento intermediates [10,11,23–25]. The ν(NO) values in *trans*-[$Ru^{II}Cl(pdma)(L–L)(NO)][PF_6]_2$, 1878 cm^{-1} (L–L = bpy) and 1874 cm^{-1} (L–L = phen) [12], are indicative of relatively electron-deficient nitrosyl ligands [21,22], and these complexes hence react readily with stoi-

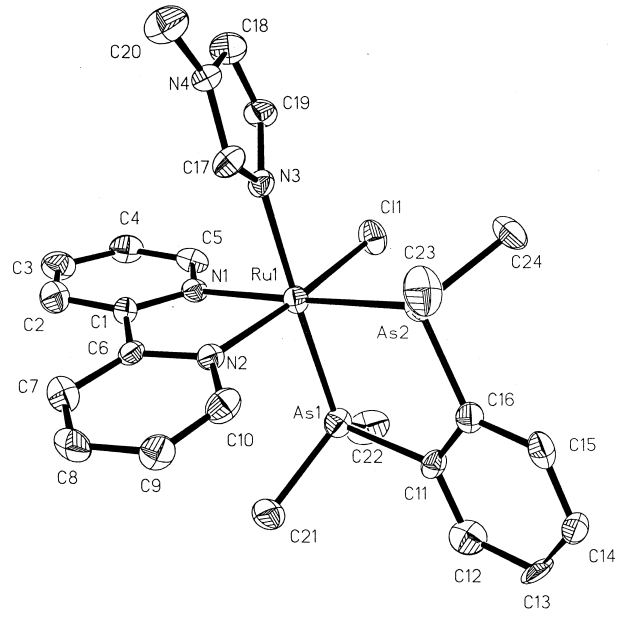

Fig. 6. Structural representation of the complex cation in the salt **17**, with hydrogen atoms omitted (50% probability ellipsoids).

chiometric azide at room temperature in acetone. The resulting intermediates, most likely *trans*-[$Ru^{II}Cl(pdma)(L–L)N_2]^+$, react with a range of neutral ligands to give clean substitution of the position formerly occupied by NO^+. These reactions take place only slowly at room temperature, but occur much more rapidly upon heating at ca. 80°C in 2-butanone.

Unlike the related complexes *trans*-[$Ru^{II}Cl(pdma)_2L]^+$ (L = py, mim, etc.) [10], the pdma/L–L *trans* mixed-chelates react with neutral ligands in the presence of $AgCF_3CO_2$ to substitute the chloride ligands, although heating is required to give reasonably efficient reactions. For example, **15** was also isolated from a reaction at room temperature, but in a yield of only 14%. The efficacy of these substitution reactions depends to varying degrees upon the nature of the starting complex and the incoming ligand. The best results were obtained with salt **3**, from which the derivatives **13**–**15** were prepared. The presence of the *trans* geometry in the salts **1**–**16** is confirmed by the ^{1}H NMR spectra which each show a single AA′BB′ pattern for the pdma ligand, either one or two singlets for the AsMe groups and four signals for bpy or phen.

3.2. Photoisomerization reactions

Previous studies have shown that *trans*-{$Ru^{II}(L–L)_2\}^{2+}$ (L–L = bpy or phen) complexes readily photoisomerize to their more stable *cis* isomers [8,26]. By contrast, when L–L = pdma, no evidence for photoinstability has been found [10]. Given these observations, it is perhaps unsurprising that the new *trans*-{Ru(pdma)(L–L)$\}^{2+}$ (L–L = bpy or phen) complexes show an intermediate degree of photostability. ^{1}H NMR experiments in d_6-acetone show that salts **1**–**16** undergo complete isomerization to their *cis* forms, with partial decomposition in some cases, following exposure to

diffuse sunlight for ca. 100 h. The isomerized samples show no reversion to their *trans* forms after extended periods in the dark. The ^{1}H NMR spectra of the *cis* isomers are characterized by increased numbers of signals due to reduced symmetry, together with shifts of as much as 1 ppm for some of the resonances. In particular, the lowest field bpy/phen doublets are shifted downfield and some of the AsMe signals shift upfield, upon *trans* → *cis* isomerization. In the case of the two forms of $[Ru^{II}Cl(pdma)(bpy)mim]PF_6$ (**3** and **17**), the isomerization was further confirmed by X-ray structural studies (see later).

3.3. UV–visible studies

Electronic absorption spectra for all of the new complex salts were recorded in acetonitrile and results are presented in Table 3. All show relatively intense, broad $d_\pi(Ru^{II}) \rightarrow \pi^*$(bpy/phen) MLCT bands [27,28] in the region 360–460 nm. For the series *trans*-$[Ru^{II}Cl(pdma)(bpy)L_1][PF_6]_n$ ($n = 1$ or 2, **1**–**5** and **7**), the MLCT energy decreases as the overall electron donor strength of L_1 increases, in the order L_1 = dmso < $PPh_3 \approx mpyz^+$ < MeCN < py < mim. This ordering reflects a steady destabilization of the Ru-based HOMO. Similar trends are observed for the phen complexes in **8**–**10** and **12** and for the *trans*-$[Ru(pdma)(bpy)mim(L_2)][PF_6]_2$ series **13**–**15**. The disubstituted derivatives **13**–**15** all have higher MLCT energies than their parent complex in **3** because mim, py and MeCN are less basic than chloride. For the same reasons, substitution of the chloride ligand in **2** by MeCN to give **16** produces a blue shift of ca. 0.25 eV.

The complexes containing py or pyz co-ligands also show $d_\pi(Ru^{II}) \rightarrow \pi^*$(py/pyz) MLCT bands which in many cases overlap with the $d_\pi(Ru^{II}) \rightarrow \pi^*$(bpy/phen) absorptions. In the complexes in **7** and **12**, $d_\pi(Ru^{II}) \rightarrow \pi^*(mpyz^+)$ bands are observed at especially low energy owing to the strongly π-accepting nature of the $mpyz^+$ ligand. The spectra of the

isomeric pair of complexes in **3** and **17** are somewhat different, with the $d_\pi(Ru^{II}) \rightarrow \pi^*(bpy)$ band maximum occurring at higher energy by ca. 0.19 eV in the *cis* isomer. Besides their MLCT bands, all of the complexes also show one or more intense UV absorptions due to intraligand $\pi \rightarrow \pi^*$ excitations.

3.4. Electrochemical studies

All of the new complex salts were studied by cyclic voltammetry in acetonitrile and results are presented in Table 3. All exhibit reversible or quasi-reversible $Ru^{III/II}$ oxidation waves, together with ligand-based reduction processes which

range from reversible to irreversible. Within the series *trans*-$[Ru^{II}Cl(pdma)(bpy)L_1][PF_6]_n$ ($n = 1$ or 2, **1**–**7**) the $Ru^{III/II}$ $E_{1/2}$ values become more positive as the overall electron donor strength of L_1 decreases, in the order $L_1 = mim > py > MeCN > pyz > mpyz^+ \approx PPh_3 > dmso$. As expected, this trend parallels that observed in the $d_\pi(Ru^{II}) \rightarrow \pi^*(bpy)$ MLCT data (see earlier). The $Ru^{III/II}$ $E_{1/2}$ values of the phen complexes in **8**–**12** are essentially identical to those of their bpy counterparts, and the same dependence upon L_1 is evident. Similarly, in the disubstituted complex salts *trans*-$[Ru^{II}(pdma)(bpy)mim(L_2)][PF_6]_2$ (**13**–**15**) the $Ru^{III/II}$ $E_{1/2}$ values shift to more positive potentials as the electron donor strength of L_2 decreases in the order $mim > py > MeCN$. The complex in **16** has an especially anodic $Ru^{III/II}$ $E_{1/2}$ due to the combined π-electron-withdrawing abilities of the MeCN and PPh_3 ligands. The cyclic voltammograms of **3** and **17** are essentially identical, showing that isomerization does not affect the redox properties of these complexes.

3.5. Structural studies

Single-crystal X-ray structures were determined for **1**, **2**·DMF, **3**, **12**·3MeCN, **14**·DMF and **17**. Representations of the complex cations are shown in Figs. 1–6. The complexes in **1**, **2**·DMF and **3** show the expected *trans* arrangement of the pdma and bpy ligands. In **2**·DMF, the steric bulk of the PPh_3 causes the pdma and bpy ligands to bend slightly towards the chloride, giving an average E–Ru–Cl (E = As or N) bond angle of 84.25(9)°. The corresponding average bond angles in **1** and **3** are 88.3(1) and 88.7(1)°, respectively, showing very little distortion of the octahedral coordination geometries. The Ru–Cl bond distances increase in the order **1** < **3** < **2**·DMF, with a difference of ca. 0.04 Å between **1** and **2**·DMF. This trend reveals the structural *trans*-effect (STE) order with respect to *trans* chloride of $py < mim < PPh_3$.

The structure of **14**·DMF confirms that the *trans* geometry of **3** is maintained upon substitution of the chloride with a pyridine ligand, and the *trans* structure is also found in **12**·3MeCN. In the latter salt, the Ru–N($mpyz^+$) distance (2.019(2) Å) is ca. 0.1 Å shorter than the average Ru–N(phen) distance, owing to a greater degree of π-back donation to the $mpyz^+$ ligand. The complex in $[Ru^{II}(NH_3)_5(mpyz^+)]I_3$ exhibits a still shorter Ru–N($mpyz^+$) distance (1.95(1) Å) [29], indicating that the presence of the strongly basic ammine ligands gives rise to more extensive $Ru^{II} \rightarrow mpyz^+$ back-bonding than is found in **12**·3MeCN.

The structure of **17** confirms that the isomerization of **3** has taken place, with the chloride ligand now *trans* to a bpy N atom. The cation in **17** is chiral and only one absolute configuration at Ru is found in the crystal. The Ru–Cl bond distance in **17** is ca. 0.01 Å shorter than that in **3**, showing that mim has a slightly larger STE than bpy with respect to chloride. Also, the Ru–N(bpy) bond distances are 2.056(4) Å (*trans* to chloride) and 2.101(4) Å (*trans* to pdma), showing that the pdma ligand exerts a rather greater STE on bpy than does chloride. The Ru–As bond distances of 2.3836(7) Å (*trans* to bpy) and 2.3686(7) Å (*trans* to mim) indicate that the STE of bpy on pdma is slightly larger than that of mim.

4. Conclusion

Stepwise substitutions of the axial nitrosyl and chloride ligands are readily achieved in the mixed-chelates *trans*-$[Ru^{II}Cl(pdma)(L–L)(NO)][PF_6]_2$ (L–L = bpy or phen). However, the resulting products are mildly photosensitive in solution and isomerize irreversibly to their *cis* forms. The preparation of chromophore-quencher complexes based on *trans*-$\{Ru^{II}(pdma)(L–L)\}^{2+}$ centres is therefore unlikely to be a worthwhile objective.

Supplementary data

Supplementary data (fractional atomic coordinates, anisotropic thermal parameters, and full listings of bond lengths and angles) are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition numbers CCDC 139504 (**1**), CCDC 139505 (**2**·DMF), CCDC 139506 (**3**), CCDC 139507 (**12**·3MeCN), CCDC 139508 (**14**·DMF) and CCDC 139509 (**17**).

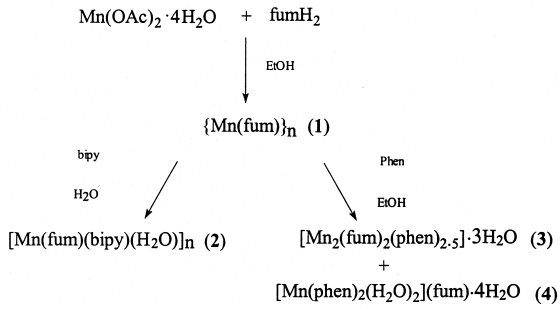
Abstract

The reaction of fumaric acid with $Mn(CH_3COO)_2\cdot 4H_2O$ gives the polymeric complex $\{Mn(fum)\}_n$ (**1**). Complex **1** reacts with 2,2′-bipyridine in ethanol to yield $[Mn(fum)(bipy)(H_2O)]_n$ (**2**). Reaction of **1** with 2 equiv. of 1,10-phenanthroline produces $[Mn_2(fum)_2(phen)_{2.5}]\cdot 3H_2O$ (**3**) and $[Mn(phen)_2(H_2O)_2](fum)\cdot 4H_2O$ (**4**). The molecular structures of **2** and **4** were determined by X-ray crystallography. In **2** the fumarate anions link the manganese ions so that each is seven coordinate, being bonded to a bidentate bipyridine, two bidentate carboxylates and one H_2O molecule. In **4** the asymmetric unit contains a $[Mn(phen)_2(H_2O)_2]^{2+}$ cation, half of each of two independent fumarate anions and four lattice H_2O molecules. The cations and anions are interconnected by water molecules hydrogen bonded to both coordinated water molecules and fumarate oxygens. The fumarate complexes, the metal free ligands and a number of simple manganese salts were each tested for their ability to inhibit the growth of *Candida albicans*. Only the 'metal free' 1,10-phenanthroline and its fumarate complexes exhibit fungitoxic activity ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Manganese(II) complexes; Fumaric acid; Crystal structures; Fungitoxic activity

1. Introduction



The yeast *Candida albicans* is a commensal of the human body and is considered to be an important fungal pathogen. Opportunistic infection can lead to the development of vaginal candidosis (thrush), a condition from which over 75% of women suffer at some stage in their lifetime. Systemic candidosis is often fatal in immunocompromised patients [1–4]. The state-of-the-art drugs currently used to treat *Candida* infections are often ineffective because of problems with resistance or toxicity and subsequently the search for novel anti-fungal agents has gathered momentum [5]. A number of publications has appeared in the literature highlighting the fungicidal activity of novel transition metal complexes, see for example Ref. [6]. Recently, we have shown that a range of cobalt carboxylate complexes inhibit the growth of *Candida albicans* [7]. Whereas metal complexes of aliphatic monocarboxylic acids have been extensively studied, relatively few papers describing the structures of their diacid equivalents have been published [8]. Rarer still are reports documenting the structures of complexes of unsaturated aliphatic diacids. We have previously described the synthesis, X-ray crystal structures and catalytic activity of a number of manganese(II) complexes containing saturated aliphatic α,ω-dicarboxylic acid ligands [9–13]. Herein we report the synthesis and structural characterisation of two new manganese(II) complexes of fumaric acid. In addition the in vitro anti-*Candida* activities of the compounds are discussed.

2. Results and discussion

Synthetic routes to complexes **1**–**4** are shown in Scheme 1. $\{Mn(fum)\}_n$ (**1**) was prepared in high yield by reacting

Scheme 1.

manganese(II) acetate tetrahydrate with fumaric acid. Reaction of **1** with excess 2,2′-bipyridine gave $[Mn(fum)(bipy)(H_2O)]_n$ (**2**). When an ethanolic suspension of complex **1** was reacted with 1,10-phenanthroline in a 1:2 molar ratio $[Mn_2(fum)_2(phen)_{2.5}]\cdot 3H_2O$ (**3**) was obtained in high yield. The filtrate from this reaction, when left standing, produced yellow crystals of $[Mn(phen)_2(H_2O)_2](fum)\cdot 4H_2O$ (**4**).

The X-ray structure of **2** is shown in Fig. 1 and selected bond lengths and angles for the complex are given in Tables 1 and 2, respectively. The structure consists of zig-zag polymeric chains running approximately parallel to the *b* axis and in which the monomer is the asymmetric unit $[Mn(fum)(bipy)(H_2O)]$. The *trans*-fumarate anions link the manganese ions so that each is seven coordinate, being bonded to a bidentate bipyridine, two bidentate carboxylates and one H_2O molecule (Fig. 1). The geometry at the manganese ions is quite irregular, the four Mn–O(carboxylate) distances are quite different from each other (Table 1), with that to O(21) being particularly long (2.388(1) Å); unexpectedly, the shortest bond is to the coordinated water molecule (Mn–O1w 2.174(1) Å).

The polymeric chains themselves are linked into sheets in the *ab* plane by hydrogen bonding (Fig. 2) involving coordinated H_2O on one chain and two of the fumarate oxygen atoms on a neighbouring chain (Table 2).

Finally, the two-dimensional sheets are linked by weak π–π stacking of bipyridine groups in adjacent sheets (Fig. 2) (interplanar stacking distance, ~3.8 Å). This long π–π distance may be enforced by the steric constraints of the relatively rigid fumarate dianion.

The X-ray structure of **4** is shown in Fig. 3 and selected bond lengths and angles are listed in Tables 3 and 4, respectively. The asymmetric unit contains a $[Mn(phen)_2(H_2O)_2]^{2+}$ cation, half of each of two independent fumarate anions and four lattice H_2O molecules. The manganese is six coordinate in a *cis*-conformation. One of the fumarate anions (containing O21 and O22) is hydrogen bonded in a 'bidentate' way to both the coordinated water molecules (O1w and O2w). Since this fumarate lies on a centre of symmetry, it acts as a hydrogen-bonded bridge between two neighbouring cations. The second fumarate anion is linked to the cation via a single hydrogen bond (to O2w); this anion also lies on a centre of symmetry, bridging two cations. The lattice therefore contains polymeric, hydrogen-bonded chains of alternating cations and anions.

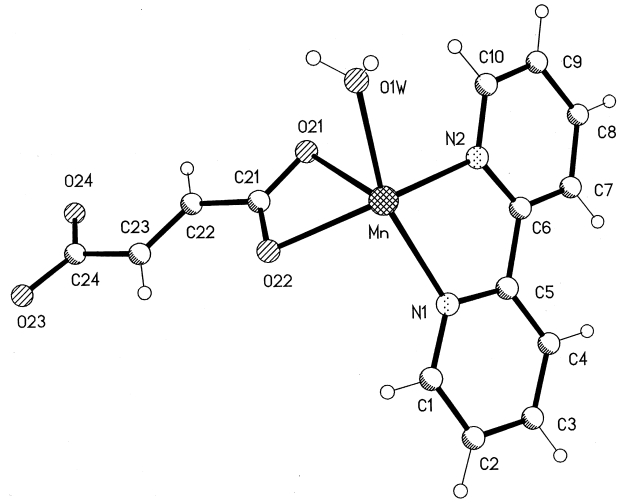

Fig. 1. The asymmetric unit of $[Mn(fum)(bipy)(H_2O)]_n$ (**2**).

The four uncoordinated lattice water molecules show extensive hydrogen bonding, to the anion oxygen atoms, the coordinated water and other lattice water molecules (Fig. 4). This results in a complicated hydrogen-bonded network that extends throughout the lattice. The cations and anions are

interconnected by water molecules hydrogen bonded to both coordinated water molecules and fumarate oxygens.

The IR spectrum of **1** contains prominent $\nu_{OCOasym}$ and ν_{OCOsym} stretching bands around 1575 and 1387 cm^{-1}, respectively. The relatively large value of Δ_{OCO} ($\nu_{OCOasym} - \nu_{OCOsym}$) calculated for the complex (188 cm^{-1}) is close to the value expected for a unidentate coordination mode of the carboxylate moiety [14]. Its relative insolubility in most common solvents suggests that it may have a polymeric structure. Indeed, we have found in previous studies that the saturated aliphatic dicarboxylic acids usually give polymeric complexes when reacted with manganese(II) acetate [9–13]. Complex **1** is sparingly soluble in ethanol and its molar conductivity ($\Lambda_M = 0.43$ S cm^2 mol^{-1}) suggests that it is a non-electrolyte in this solvent. The Δ_{OCO} value for complex **2** (114 cm^{-1}) is as expected for a chelating coordination mode of the carboxylate moieties [14]. The molar conductivity value for an aqueous solution of complex **2** ($\Lambda_M = 163$ S cm^2 mol^{-1}) suggests that it forms a 1:1 electrolyte in water and dissociates to give the cationic $[Mn(bipy)]^{2+}$ and the anionic fum^{2-} species, respectively. Complex **3** was isolated as a powder which was only sparingly soluble in methanol and chloroform. The value of Δ_{OCO}

possibly results from the extensive hydrogen bonding that exists between the carboxylate oxygens and both the coordinated and uncoordinated water molecules within the crystal. The room temperature magnetic moments of powdered samples of complexes **1**, **2**, **3** and **4** (5.65, 5.89, 5.99 and 5.76 BM respectively) were in the range expected for manganese complexes where there is no significant exchange interaction between metal centres [15].

The fumarate complexes, the metal-free ligands and a number of simple manganese salts were each tested for their ability to inhibit the growth of *Candida albicans* (Table 5). Fumaric acid exhibits negligible fungitoxic activity. The simple manganese(II) salts are essentially inactive also. The fumarate complex **1** does not show fungistatic activity at all against the *Candida*. Both the uncoordinated 2,2′-bipyridine and its fumarate derivative (complex **2**) are also ineffective against the pathogen. However, the phenanthroline complexes **3** and **4** both exhibit discrete anti-*Candida* activity causing 69 and 67% inhibition of cell growth respectively. Significantly the 'metal free' 1,10-phenanthroline itself shows the greatest activity causing 77% inhibition of cell growth. However, we believe that the so-called metal-free

Table 5
Anti-*Candida* activity [a]

Test compound	% Cell growth Isolate
Control	100
Fumaric acid	106 ± 8
1,10–phenanthroline	23 ± 2
2,2′–bipyridine	114 ± 6
$MnCl_2$	110 ± 5
$Mn(NO_3)_2$	133 ± 7
$Mn(OAc)_2$	117 ± 10
$Mn(SO_4)$	98 ± 9
[Mn(fum)] (**1**)	98 ± 10
$[Mn(fum)(bipy)(H_2O)]_n$ (**2**)	115 ± 6

[a] The compounds were tested at concentrations of 10 μg cm^{-3} of aqueous RPMI medium. Complexes **1**–**4** were insoluble in water and were used as suspensions. Yeast cells were grown for 24 h at 37°C. Results are presented as % cell growth and the effectiveness of the compounds is compared to the growth of the control (no compound added).

1,10-phenanthroline is probably coordinating to metal ions (other than the manganese) that are present in trace amounts in the growth medium and that it is these resulting metal–phenanthroline complexes that are responsible for the high anti-*Candida* activity. Studies are currently underway in our laboratories to examine this theory.

In conclusion, it would appear that fumaric acid whether coordinated or uncoordinated to manganese does not possess any anti-*Candida* properties. Furthermore, the presence of the NN-donor 2,2′-bipyridine does not improve the activity of the complex. The 1,10-phenanthroline molecule is a potent anti-*Candida* agent and upon reaction with the manganese fumarate yields complexes with comparable fungitoxic activity.

3. Experimental

Chemicals were purchased from commercial sources and used without further purification. IR spectra were recorded

in the region 4000–400 cm^{-1} on a Nicolet-400 Impact spectrometer. Magnetic susceptibility measurements were made using a Johnson Matthey magnetic susceptibility balance. $[HgCo(SCN)_4]$ was used as a reference. Conductivity readings were obtained using a Ciba Corning model check-mate 90 conductivity meter. Satisfactory microanalytical data for the complexes were reported by the Microanalytical Laboratory, University College Cork, Ireland.

3.1. $\{Mn(fum)\}_n$ (1)

To a solution of $fumH_2$ (3.15 g, 27.14 mmol) in ethanol (100 cm^3) was added manganese(II) acetate (5.94 g, 24.44 mmol), and the reaction mixture was refluxed for 2 h. The product formed as a colourless solid. The reaction mixture was allowed to cool to room temperature and then the product was filtered. The material was washed with two portions of ethanol and then dried in air. Yield 3.72 g (90.06%). Complex **1** was sparingly soluble in warm EtOH and MeOH, and insoluble in distilled H_2O, acetone, ether and chloroform. *Anal*. Found: C, 28.20; H, 1.31. Calc.: C, 28.43; H, 1.19%. IR: 3449.25, 3086.57, 2361.19, 1575.37, 1467.91, 1387.31, 1199.25, 991.04, 809.70, 688.81, 594.78 cm^{-1}. $\mu_{eff} = 5.65$ BM. $\Lambda_M(EtOH) = 0.43$ S cm^2 mol^{-1}.

3.2. $[Mn(fum)(bipy)(H_2O)]_n$ (2)

Complex **1** (0.5 g, 2.96 mmol) and 2,2′-bipyridine (1.25 g, 8.00 mmol) were stirred in deionised water (100 cm^3) for 4 h to give a pale green solution. On standing for several days at room temperature the product formed as yellow crystals. The crystals were filtered off, washed with deionised water and ethanol and then air dried. Yield 0.77 g (84.05%). Complex **2** was sparingly soluble in warm distilled H_2O, and insoluble in EtOH, MeOH, acetone, ether and chloroform. *Anal*. Found: C, 48.75; H, 3.42; N, 8.14. Calc.: C, 48.99; H, 3.52; N, 8.16%. IR: 3415.67, 3106.7, 3079.85, 1689.55, 1608.86, 1588.81, 1555.22, 1494.21, 1474.63, 1441.04, 1387.31, 1320.15,1246.27, 1219.40, 1158.96, 1105.22, 1058.21, 1004.48, 977.61, 802.99, 762.69, 735.82, 682.09, 647.76, 628.36, 561.19, 486.53 cm^{-1}. $\mu_{eff} = 5.89$ BM. $\Lambda_M(H_2O) = 163$ S cm^2 mol^{-1}.

3.3. $[Mn_2(fum)_2(phen)_{2.5}]\cdot 3H_2O$ (3) and $[Mn(phen)_2(H_2O)_2](fum)\cdot 4H_2O$ (4)

Complex **1** (1.00 g, 5.92 mmol) and 1,10-phenanthroline (2.12 g, 10.69 mmol) were refluxed in ethanol (150 cm^3) for 2 h. Upon cooling to room temperature the resulting yellow suspension was filtered to give a yellow powder and a yellow filtrate. The yellow product (**3**) was washed with ethanol and then air dried. Yield 1.86 g (37.29%). Complex **3** was sparingly soluble in warm MeOH and chloroform, and insoluble in distilled H_2O, EtOH, acetone and ether. *Anal*. Found: C, 54.23; H, 3.31; N, 8.63. Calc.: C, 54.17; H, 3.59; N, 8.31%. IR: 3449.13, 1602.24, 1514.93, 1420.90, 1205.97, 1151.60, 1105.22, 991.04, 970.22, 843.28, 809.70, 775.40, 729.10, 675.37, 634.32 cm^{-1}. $\mu_{eff} = 5.76$ BM. $\Lambda_M(MeOH) = 1.52$ S cm^2 mol^{-1}.

Upon standing at room temperature for 7 months yellow crystals of complex **4** precipitated from the filtrate. The crystals were filtered, washed with acetone and then dried in air. Yield 0.27 g (0.07%). Complex **4** was sparingly soluble in warm MeOH and insoluble in distilled H_2O, EtOH, acetone, chloroform and ether. *Anal*. Found: C, 56.35; H, 4.02; N, 9.67. Calc.: C, 52.75; H; 4.74; N, 8.79%. IR: 3388.81, 1575.37, 1514.93, 1427.61, 1360.45, 1212.69, 1089.51, 850.00 cm^{-1}. $\mu_{eff} = 5.99$ BM. $\Lambda_M(MeOH) = 0$ S cm^2 mol^{-1}.

3.4. X-ray crystallography

Crystal data for $[Mn(fum)(bipy)(H_2O)]_n$ (**2**) and $[Mn(phen)_2(H_2O)_2](fum)\cdot 4H_2O$ (**4**) are summarised in Table 6. Data sets for both complexes were collected using a Siemens SMART CCD diffractometer and were corrected for Lorentz, polarisation and absorption effects. The structures were solved by direct methods [16] and refined by full-matrix least-squares on F^2 using all the data. All the non-hydrogen atoms were refined with anistropic atomic displacement, hydrogen atoms were inserted at calculated positions with their isotropic displacement parameters riding on U_{ij} of their carrier atoms (except for those on the water molecules which were located from difference Fourier maps and their positions either allowed to refine (for complex **2**) or were not further refined (for complex **4**)). The programmes used in the final structure refinement are contained in the SHELXL-97 package [17].

3.5. Anti-Candida susceptibility testing

Candida albicans isolate was obtained commercially from Oxid Culti-loops (ATCC 10231). The isolate was stored on Sabouraud dextrose agar (SDA) plates at 4°C.

Suspensions of the test complexes were prepared by grinding them to a fine powder (0.02 g) followed by addition to sterile distilled water (100 cm^3). This process yielded stock suspensions of 200 μg cm^{-3}. These suspensions were furthered diluted to 100 μg cm^{-3}.

RPMI-1640 broth medium (Sigma R 7755) was used for the anti-*Candida* susceptibility testing. The medium (1 dm^3) was supplemented with L-glutamine (0.3 g) and morpholinepropanesulfonic acid (MOPS) (34.6 g) and was then adjusted to pH 7.0 using sterile NaOH (0.2 M). The broth microdilution reference method was used, NCCLS publication M27-P [18]. Prior to testing, yeast cells were grown on Sabouraud dextrose agar (SDA) at 37°C for 24 h. Cell suspensions were prepared in sterile phosphate buffered saline (5 cm^3) to a density of 1 McFarland standard. A 1:100 dilution of these cell suspensions were made in RPMI-1640 medium so that the cell concentration of the final inoculum was 3.5×10^4–5.0×10^5 cells cm^{-3}. The prepared cell sus-

Abstract

In the pH range 1.91–5.24, an aqueous solution of the complex $[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+}$ (**1**) oxidises ascorbic acid quantitatively to dehydroascorbic acid and is itself reduced to Mn^{II}. In the presence of excess ascorbic acid, the reaction follows first-order kinetics. The first-order rate constant k_0 measured in the presence of excess ascorbic acid increases linearly with increasing concentration of the reductant but decreases as more and more 2,2′-bipyridine is added. k_0 also increases with $[H^+]$ but tends to saturate at higher $[H^+]$. The proposed rate-determining step involves simultaneous transfer of one electron and one proton from the ascorbate ion to $[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_3(H_2O)_4]^{4+}$, an aquated form of **1**. Subsequent rapid reactions via a dinuclear $\{Mn_2O_2\}^{3+}$ intermediate lead to the final products. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Kinetics; Manganese(IV); Ascorbic acid; Electroprotic reactions

1. Introduction

In the recent past, kinetics of redox reactions of three dinuclear higher-valent manganese complexes have been determined to elucidate the reaction mechanism [1–8]; this is of interest because these complexes are related [9–11] to the oxygen evolving complex (OEC) in photosystem II [12–14]. However, we are not aware of any kinetic studies on manganese complexes with nuclearity greater than two.

The crystallographically characterised trimer $[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+}$ (**1**) (Fig. 1) [15] has three important features which are known or assumed for the OEC: (a) oxo-bridged manganese ions in higher oxidation state, (b) two sets of Mn–Mn distances ~2.7 and ~3.3 Å [16], and (c) terminal aqua ligands bound to high-valent manganese [17,18]. Complex **1** is a useful catalyst in the oxidation of olefins and hydrocarbons by potassium peroxymonosulfate [19].

UV–Vis spectra of the complex in aqueous solution do not change within a few hours and illustrate the stable nature of the complex in water, in spite of the high-valency state of the three manganese ions. Measurement of the kinetics of its redox reactions may elucidate the mechanistic pathways for the reactions of the multinuclear complexes; hence this study.

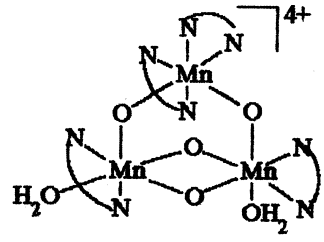

Fig. 1. Graphic drawing of the complex ion $[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+}$; bipy is 2,2′-bipyridine.

The reducing agent ascorbic acid (H_2A) is of importance as a hydroxylase cofactor [20] and as an antioxidant [21]. Brown et al. utilised ascorbic acid as a source of reducing equivalent in a multicomponent system that promotes the photo-reduction of water [22]. Metal complexes generally oxidise ascorbic acid (H_2A) to dehydroascorbic acid (A) with a net transaction of two electrons, but this change is almost always accomplished in one-electron steps [23–25]. In one important exception, a ferriporphyrin dimer [25] oxidises ascorbic acid by a two-electron pathway, thus avoiding free-radical generation.

2. Experimental

L-Ascorbic acid (Aldrich) was used without further purification. Complex **1** $(ClO_4)_4 \cdot 5H_2O$ was prepared in small batches [15], by slow evaporation of a pH 1.9 (HNO_3) solution containing 50–100 mg of the dimer $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4](ClO_4)_3 \cdot 2H_2O$ in a lot. The C, H, N analyses were found satisfactory for characterisation of the complex. Its spectral features agree with those reported earlier in the range 500–900 nm [15,26]. All other materials [4] and preparation [26] of the complex $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4](ClO_4)_3 \cdot 2H_2O$ have been described earlier.

Kinetics was measured in the presence of excess ascorbic acid at 15.0°C, I 1.0 mol dm^{-3} ($NaNO_3$). The reactions were monitored by the loss in absorbance at 370 nm with a stopped-flow spectrophotometer (HITECH SF-51), interfaced to an Apple II GS personal computer for data acquisition and analyses of absorbance–time data for rate constants. The reaction mixtures contained excess c_{bipy} ($c_{bipy} = [Hbipy^+] + [bipy]$) and were thus lightly buffered. Solution pH were measured with an Orion 710A2 pH/ion meter and an Orion Ross combination (model 81-02) electrode. The $[H^+]$ values were evaluated as described earlier [27].

The reaction stoichiometry was determined in the presence of excess ascorbic acid under the kinetic conditions. After complete reaction, an excess of $Fe(NO_3)_3$ solution was added to oxidise the remaining ascorbate quantitatively. The Fe^{II} thus produced generated $[Fe(bipy)_3]^{2+}$ with excess bipy present in the reaction media and was measured spectrophotometrically at 522 nm ($\varepsilon_{max}^{522} = 8.5 \times 10^3$ dm^3 mol^{-1} cm^{-1}) [1].

Table 1
Stoichiometric measurements for the oxidation of ascorbic acid by the trinuclear Mn_3^{IV} complex; T 25°C; concentrations in mmol dm^{-3}

[a] Average of 4–5 independent experiments, standard deviation 2–6%. [Complex] 0.10 mmol dm^{-3}; I 1.0 mol dm^{-3} ($NaNO_3$); T 15.0°C. Parenthetical values were calculated using Eq. (5).

3. Results and discussion

Measurement of unreacted ascorbic acid (Table 1) indicated a 3:1 stoichiometry according to Eq. (1).

$$[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+} + 2H^+ + 3H_2A \rightarrow 3Mn^{II} + 4bipy + 6H_2O + 3A \quad (1)$$

The reaction followed excellent first-order kinetics at least up to 90% completion. The first-order rate constants k_0 (Table 2) increased with increasing concentration of ascorbic acid ($c_{asc} = [H_2A] + [HA^-]$) without any suggestion of rate saturation even for $c_{asc} = 40$[complex]; a plot of k_0 versus c_{asc} is a good straight line ($r = 0.992$) passing through the origin. k_0 decreased with increasing c_{bipy} but increased with increasing $[H^+]$ tending to saturate at higher $[H^+]$ (Fig. 2). However, k_0 decreased with increasing c_{bipy} and a plot of k_0 versus $1/c_{bipy}$ is a good straight line passing through the origin (Fig. 3, $r = 0.995$).

Ascorbic acid (H_2A, $pK_a = 4.03$ [28]) and ascorbate anion (HA^-, $pK_a' = 11.3$ [29]) coexist in the experimental pH

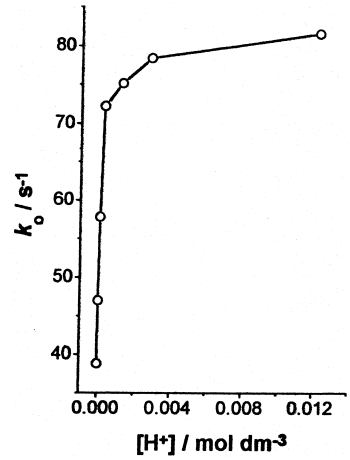

Fig. 2. Dependence of k_0 on $[H^+]$: [complex] 0.10 mmol dm^{-3}, c_{bipy} 5.0 mmol dm^{-3}, c_{asc} 1.0 mmol dm^{-3}, I 1.0 mol dm^{-3}, T 15.0°C.

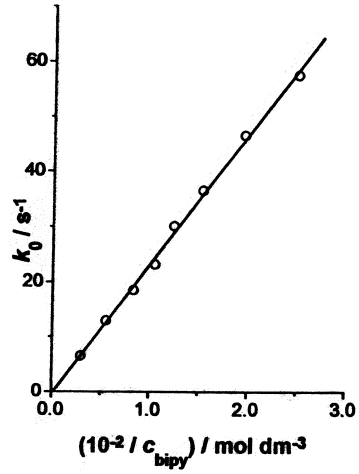

Fig. 3. Linear dependence of k_0 on $(c_{bipy})^{-1}$: [complex] 0.10 mmol dm^{-3}, c_{asc} 1.0 mmol dm^{-3}, pH 4.50, I 1.0 mol dm^{-3}, T 15.0°C.

range 1.91–5.24. The rate of oxidation of ascorbic acid generally decreases with increasing acidity, because H_2A is $\sim 10^4$ times less active [30] than HA^-. An increase in k_0 with $[H^+]$ in the present case, therefore, strongly suggests involvement of the trinuclear complex in a protic equilibrium, generating a kinetically more reactive form of the oxidising agent at lower pH. The equilibrium (2) seems to be a reasonable choice. It predicts increased rate with decreasing pH and also with decreasing c_{bipy}, provided **2** is kinetically much more active than **1**.

$$[\underset{\mathbf{1}}{Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2}]^{4+} + H^+ + 2H_2O$$

$$\overset{K_H}{\rightleftharpoons} [\underset{\mathbf{2}}{Mn_3^{IV}(\mu\text{-}O)_4(bipy)_3(H_2O)_4}]^{4+} + Hbipy^+ \qquad (2)$$

$$[\underset{\mathbf{2}}{Mn_3^{IV}(\mu\text{-}O)_4(bipy)_3(H_2O)_4}]^{4+} + HA^- \overset{k}{\rightarrow} \text{product} \qquad (3)$$

However, the concentration of HA^-, the active reductant presumed in Eq. (3), is too low at lower pH and the consequent decrease in rate is not compensated fully by the increased concentration of **2**. The rate therefore tends to saturate.

The UV–Vis spectra of **1** change reversibly with a change in $[Hbipy^+]$ as brought about by a change in pH at a constant c_{bipy} (spectra 1–4 in Fig. 4). The spectra do not change if both pH and c_{bipy} are changed, keeping $[Hbipy^+]$ constant. For example, spectrum number 3 in Fig. 4, recorded at $[Hbipy^+] = 3.62$ mmol dm^{-3} (c_{bipy} 5.0 mmol dm^{-3}, pH 4.0), did not change when c_{bipy} and pH were both changed to 8.0 mmol dm^{-3} and 4.50, respectively, keeping $[Hbipy^+]$ fixed at 3.62 mmol dm^{-3}. The spectral changes thus lend support for the presumed equilibrium (Eq. (2)) but the changes are too small to be used in the evaluation of the equilibrium constant.

The absence of a clear isosbestic point in Fig. 4, as would be expected for a fully reversible process, may be a result of interference by an equilibrium other than Eq. (2). One pos-

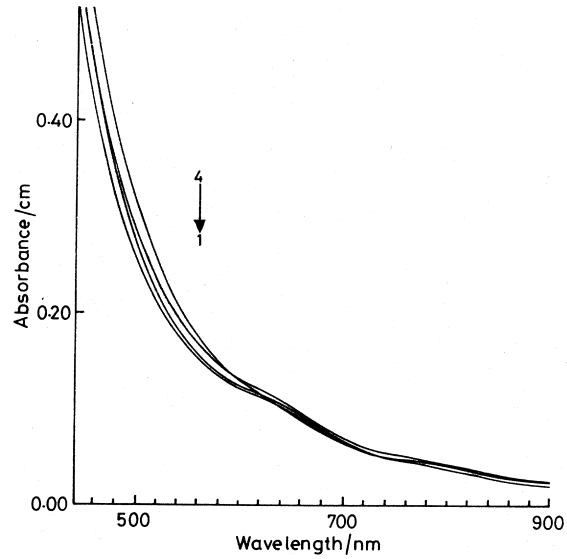

Fig. 4. Spectra of an aqueous solution of **1**: [complex] 0.20 mmol dm^{-3}, T 25.0°C, pH 3.0 (1), 3.5 (2), 4.0 (3), and 4.5 (4), c_{bipy} 5.0 mmol dm^{-3} for (1–4). Spectrum 3 does not change if pH and c_{bipy} are changed simultaneously to 4.5 and 8.0 mmol dm^{-3}, respectively, keeping $[Hbipy^+]$ constant at 3.62 mmol dm^{-3}. The observed spectral changes are reversible.

sibility is deprotonation of coordinated water at the higher pH, generating hydroxo aqua species. Such a deprotonated species may affect the spectra but not the kinetics since conjugate bases are in general kinetically less active oxidants than the parent aqua complexes. Moreover, in the pH-window of this study, the concentration of the hydroxo species is likely to be too low to be kinetically significant. It might be mentioned in this context that no hydroxo aqua form could be detected kinetically [5] for the complex ion $[Mn_2^{IV}(\mu\text{-}O)_2(\mu\text{-}O_2CMe)(bipy)_2(H_2O)_2]^{3+}$ up to pH 5.5.

The kinetic results of the present study suggest that the trinuclear complex is reduced only after the dissociation of one ligand molecule from the cluster. This means that the cluster containing four bipy molecules is not reduced or is reduced much more slowly. Similar situations were observed with some dinuclear manganese complexes. For example, $[Mn_2^{III,IV}(\mu\text{-}O)_2(L)_4]^{3+}$ (L = 1,10-phenanthroline or 2,2′-bipyridine) ions are reduced at a much slower rate than $[Mn_2^{III,IV}(\mu\text{-}O)_2(L)_3(H_2O)_2]^{3+}$. Similarly, the reduction of $[Mn_2^{IV}(\mu\text{-}O)_2(\mu\text{-}O_2CMe)(bipy)_2(H_2O)_2]^{4+}$ is much slower than the reduction of $[Mn_2^{IV,IV}(\mu\text{-}O)_2(\mu\text{-}O_2CMe)(bipy)(H_2O)_4]^{4+}$ [4,7]. In yet another report, it was concluded that the first step in the formation of **1** from $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4]^{3+}$ is a rapid generation of an active intermediate, which in subsequent redox changes produces **1**. This proposed intermediate is the diaqua species $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_3(H_2O)_2]^{3+}$ [31]; the parent complex is inactive in the redox changes. Aqua complexes exhibit greater activity also in several redox reactions of mononuclear chelates [27,32] of high valent manganese. There may be four possible reasons for the higher reactivity: (i) replacement of a chelating ligand by the weaker donor H_2O makes the metal centre more open and more electron-defi-

cient, thus increasing its strength as an oxidant; (ii) there are more H_2O molecules in the aquated species, e.g. **2**, hence hydrogen bonding with H_2O may stabilise the oxidant–reductant precursor better in **2** than in **1**; (iii) the metal–OH_2 bonds can stretch more easily than the metal–bipy bonds; metal–OH_2 bonds are more numerous in **2**, which therefore has a lower Frank–Condon barrier during structural rearrangements subsequent to electron transfer; (iv) the reductant can approach **2** closer than the parent species **1**.

The effect of pH on the redox potential of **1** in aqueous ligand buffer has not yet been measured experimentally, but a cyclic voltammogram in phosphate buffer shows that **1** becomes a stronger oxidant as the pH is lowered [15], because the reduction involves simultaneous transfer of one electron and one proton. The authors of this work did not consider the possibility of ligand loss at lower pH and the question as to how the thermodynamic oxidising strength changes with aquation remains unanswered. Moreover, the tacit assumption that phosphate is just an innocent buffer may be incorrect [13].

One can derive Eq. (4) for the reaction sequence represented by Eqs. (2) and (3).

$$k_0 = \frac{kK_H[H^+][HA^-]}{[Hbipy^+]+K_H[H^+]} = \frac{kK_HK_a(K_1+[H^+])c_{asc}}{(K_a+[H^+])\{c_{bipy}+K_H(K_1+[H^+])\}} \quad (4)$$

Eq. (4) transforms to Eq. (5) provided the inequality Eq. (6) holds:

$$k_0(K_a+[H^+]) = kK_HK_ac_{asc}(K_1+[H^+])/(c_{bipy}) \quad (5)$$

$$c_{bipy} \gg [K_H(K_1+[H^+])] \quad (6)$$

Here K_a and K_1 are the proton dissociation constants of H_2A and $[Hbipy^+]$ respectively. Their literature values are $K_a = 9.33\times10^{-5}$ mol dm^{-3} at 15°C, I 1.0 mol dm^{-3} [28,33] and $K_1 = 3.8\times10^{-5}$ mol dm^{-3} at 25°C, I 1.0 mol dm^{-3} [34,35][3].

A plot of $k_0(K_a+[H^+])$ versus $(K_1+[H^+])/c_{bipy}$ at a fixed c_{asc} is an excellent straight line ($r = 0.999$) passing through the origin and supports the proposed sequence and associated kinetic assumptions. From the slope of the plot, the value for kK_H is $(4.52\pm0.25)\times10^6$ dm^3 mol^{-1} s^{-1}. Assuming the diffusion controlled limit of the rate constant to be 10^{10} dm^3 mol^{-1} s^{-1} for the reaction of **2** with HA^-, one can evaluate a lower limit for K_H of 4.5×10^{-4}. The inequality Eq. (6), under our experimental conditions, i.e. $[H^+] \geq 3.16\times10^{-4}$ mol dm^{-3} and $c_{bipy} \geq 5.0\times10^{-3}$ mol dm^{-3} imposes an upper limit of $K_H \leq 14$, i.e. $k \geq 3\times10^5$ dm^3 mol^{-1} s^{-1}.

[3] The value of K_1 shows weak dependences on temperature and ionic strength. For example, variation of T in the range 20–25°C and I in the range 0–0.33 mol dm^{-3} causes 17% variation in K_1 ($(3.7–4.46)\times10^{-5}$ dm^3 mol^{-1}) [35]. The effect of such changes is nominal on the kK_H value, which changes only 11% with a 20% change in the value of K_1.

K_H values are known for a few other multinuclear manganese complexes such as $[Mn_2^{III,IV}(\mu\text{-}O)_2(phen)_4]^{3+}$ (35 ± 10) [3], $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4]^{3+}$ (139 ± 10) [36] and $[Mn_2^{IV}(\mu\text{-}O)_2(\mu\text{-}O_2CMe)(H_2O)_2(bipy)_2]^{4+}$ (26.3) [5]. The equilibrium affects insignificantly the spectral properties and kinetics for $[Mn_2^{IV}(\mu\text{-}O)_2(phen)_4]^{4+}$, $[Mn_3^{IV}(\mu\text{-}O)_4(phen)_4(H_2O)_2]^{4+}$, and $[Mn_4^{IV}(\mu\text{-}O)_6(bipy)_6]^{4+}$; K_H values for these complexes are therefore not known. The overall charge and nuclearity of the clusters and basicity of the ligands should control K_H but the individual effects appear difficult to assess.

The rate of oxidation of $S_2O_3^{2-}$ by the $[Mn_3^{IV}(\mu\text{-}O)_4(phen)_4(H_2O)_2]^{4+}$ ion (**1′**), the 1,10-phenanthroline analogue of **1**, exhibits a first-order dependence on $[H^+]$ but it is independent of c_{phen} [37]. Complex **1′** suffered no ligand loss in the experimental range pH ≥ 4 and the $[H^+]$-dependence arose from a rate determining, coupled one-electron one-proton transfer step. Such an electroprotic mechanism operates [1] in the reduction of the dinuclear complex $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4]^{3+}$ by HA^- and in the advancement of the 'S-states' in Kok's cycle for photosystem II [38]. A similar electroprotic mechanism may be envisioned for chemical reduction of **2** by the ascorbate ion, which supplies both an electron and a proton (Eq. (7)).

$$[Mn_3^{IV}(\mu\text{-}O)_4(\underset{\mathbf{2}}{bipy})_3(H_2O)_4]^{4+} + HA^- \xrightarrow{k} [Mn_2^{IV}Mn^{III}(\mu\text{-}O)_3(\mu\text{-}OH)(bipy)_3(H_2O)_4]^{4+} + A^- \quad (7)$$

Reaction (7) is favoured strongly by the enhanced acidity of HA^- on oxidation (pK ca. −0.4 for HA^-) [39] and the enhanced basicity expected for **2** after reduction; it is known [1] that the base strength of the oxo groups in $[Mn_2^{III}(\mu\text{-}O)_2(bipy)_4]^{2+}$ is $\sim10^9$ times greater than that in $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4]^{3+}$.

In connection with the question of intimate mechanism, a relevant question is why complex **2**, in spite of the presence of four coordinated water molecules, does not utilise an inner-sphere path for the electron transfer. Plausibly, the replacement of coordinated H_2O from the Mn^{IV} (d^3) centre is much slower than the electroprotic reaction. It is interesting to mention here that the known [18] rates of water-exchange by the manganese cluster of the S_3 state of photosystem II are much less than the lower limit of k in Eq. (7).

The overall reaction (3) must be a multistep process. The observed exponential profile along with the absence of any absorbance drop immediately after mixing indicate that the first act of electron transfer is rate-determining. Subsequent steps are rapid and therefore kinetically silent. In search of any such intermediate, we recorded the spectra of **1**, mixed with different amounts of ascorbic acid (Fig. 5) and thus noticed the generation of the binuclear complex $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_4]^{3+}$ (**3**) as an intermediate, which subsequently decayed in the presence of excess ascorbic acid. The spectrum

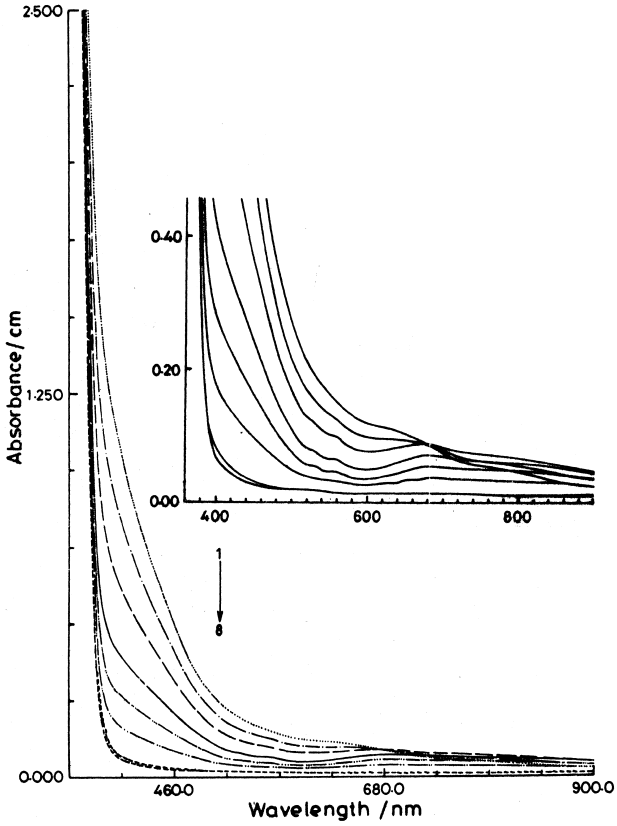

Fig. 5. Spectra of equilibrium mixtures of complex **1** (0.20 mmol dm^{-3}) with different concentrations (mmol dm^{-3}) of ascorbic acid in c_{bipy} 20.0 mmol dm^{-3}, pH 4.50. c_{asc} 0 (1), 0.10 (2), 0.15 (3), 0.30 (4), 0.40 (5), 0.50 (6), 0.60 (7), 0.80 (8).

3 in Fig. 5 recorded with $c_{asc}/[\mathbf{1}] = 0.75$ shows strong resemblance to that of the $Mn^{III}Mn^{IV}$ dimer **3** and manifests all the characteristic UV–Vis spectral features [26,40] for **3**, like a broad maximum at ~830 nm as a shoulder of a band at 684 nm and two other shoulders at 559 and 527 nm. The ratio of absorbance at 683, 559, and 527 nm (1:0.8:0.95) in this spectrum is almost the same (1:0.8:0.9) as that for **3**. The final absorbance (0.080) at 683 nm corresponds to near quantitative (103%) conversion of **1** to **3**, according to Eq. (8):

$$4[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+} + 2H^+ + 8bipy + 3H_2A \rightarrow 6[Mn_2(\mu\text{-}O)_2(bipy)_4]^{3+} + 12H_2O + 3A \quad (8)$$

3

It is known [1] that excess ascorbic acid reduces **3** to Mn^{II} according to Eq. (8a)

$$2[Mn_2^{III,IV}(\mu\text{-}O_2)(bipy)_4]^{3+} + 3H_2A + 2H^+ \rightarrow 4Mn^{II} + 8bipy + 4H_2O + 3A \quad (8a)$$

Eqs. (8) and (8a) when properly combined [8 + 3 × (8a)] yield Eq. (1), the stoichiometric equation for quantitative reduction of **1** by excess H_2A.

A reaction, Eq. (9), analogous to Eq. (8) occurs when complex **1** is stored for 24 h in the ligand buffer [40]. We verified, however, that reaction (9) is very slow and does not interfere with the reduction of **1** by ascorbic acid:

$$2[Mn_3^{IV}(\mu\text{-}O)_4(bipy)_4(H_2O)_2]^{4+} + 4H^+ + 4bipy + 3R \rightarrow 3[Mn_2(\mu\text{-}O)_2(bipy)_4]^{3+} + 6H_2O + 3R^+ \quad (9)$$

In all probability, **3** is an intermediate for reaction (3). One observation needs to be addressed at this point. The known [1] first-order rate constant for the reduction of the $Mn^{III}Mn^{IV}$ dimer by HA^- is comparable to that measured by us for the trinuclear complex. One can thus expect a sequence of first-order consecutive reactions, not a simple first-order profile as observed. This apparent anomaly might have two reasonable sources: (i) the ascorbate radical generated during the reduction of Mn_3^{IV} species reduces the dinuclear species more rapidly than, and in addition to, HA^-; (ii) the $Mn^{III}Mn^{IV}$ dimer first produced is not **3**, it is rather a bis(bipyridine) species $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_2(H_2O)_4]^{3+}$, which changes to an equilibrium mixture of the corresponding tris(bipyridine) and tetrakis(bipyridine) complexes. The bis(bipyridine) and the tris(bipyridine) species are more aquated than **3** and hence kinetically more active and reduced rapidly, perhaps before they can transform to the kinetically less active tetrakis(bipyridine) complexes. It might be noted here that the structure of **1** also requires that an aquated form of **3** be produced on reduction of **1**. If, for example, the Mn^{IV} centre at the top of the structure **1** is removed by reduction, then $[Mn_2^{III,IV}(\mu\text{-}O)_2(bipy)_2(H_2O)_4]^{3+}$ should be generated. Such possibilities cannot be verified by the UV–Vis spectral studies mentioned above; complex **3** and its aqua derivatives have similar spectra [2,26], and inter conversions are likely to be rapid in the time-scale for spectral measurements.

This work presents a systematic study of redox kinetics of a trinuclear oxo-bridged Mn_3^{IV} species. It shows the importance of the binuclear $Mn^{III}Mn^{IV}$ species as intermediate in the redox reactions leading to the formation and collapse of higher-valent manganese clusters. The study also reiterates the importance of ligand dissociation equilibria in such chemical changes and upholds the possibility that multinuclear manganese complexes undergo proton coupled electron transfer, a process of proven importance [9] in photosystem II.

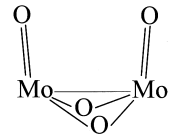
Received 16 December 1999; accepted 21 March 2000

Abstract



Simple synthetic routes for the preparation of octanuclear oxomolybdenum(V) clusters with stoichiometry $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = 4-methylpyridine (4-MePy) (**a**), 4-ethylpyridine (4-EtPy) (**b**), 4-*tert*-butylpyridine (4-Bu^{t}Py) (**c**), pyridine (Py) (**d**), 3-methylpyridine (3-MePy) (**e**), 3,5-lutidine (3,5-Lut) (**f**)) are described. Crystal structures of **e** and **f** were investigated by X-ray diffraction. The puckered ring structure made up of eight molybdenum atoms linked together by pairs of methoxy groups and pairs of oxo groups was recognized in both. The solubility of the compounds in pyridines was employed for the substitution of coordinated pyridine for a different pyridine. The octanuclear clusters have been found to react in pyridines at elevated temperatures to oxomolybdenum(V,VI) clusters with the formula $[Mo_{10}O_{26}L_8]$. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Oxomolybdenum(V) compounds; Clusters; $Mo_2O_4^{2+}$ unit; Pyridine; Alkyl-substituted pyridines

1. Introduction

The title compounds belong to a group of oxomolybdenum(V) clusters built of $Mo_2O_4^{2+}$ units (Scheme 1). The $Mo_2O_4^{2+}$ moiety is frequently encountered in Mo(V) chemistry. Its geometry is virtually independent of other ligands. Molybdenum to bridging oxygen distances are 1.9–2.0 Å. The bent Mo(μ-O)$_2$Mo bridge enables a close approach of two molybdenum atoms. The short distance 2.5–2.7 Å is indicative of a single metal–metal bond which accounts for the diamagnetism of the $Mo_2O_4^{2+}$ compounds [1]. The substantial *trans* influence due to the strong bonding between molybdenum and the terminal oxygen (distances span the range 1.6–1.8 Å) leads to weakening of the bond between molybdenum and the *trans* positioned ligand or in the extreme case to a vacancy at this coordination site [2].

The linkage of dimers into larger aggregates is achieved via oxygen donor groups which can serve not only as terminal but also as μ, μ_3 or μ_4-bridging ligands, with the polyhedra sharing common corners, edges or faces [3]. The properties of clusters are essentially the properties of $Mo_2O_4^{2+}$ units. Although the literature abounds with data on the $Mo_2O_4^{2+}$ clusters which occur among the coordination compounds, alkoxides and even organometallic compounds, the overwhelming majority are anionic species [1]. A variety of structural types is exhibited among them. We limit the scope to compounds which bear resemblance to oxomolybdenum(V) clusters with pyridines. Linking two dimers in such a way that the octahedra share common edges leads to a stable tetranuclear framework $[Mo_4O_4(\mu\text{-}O)_2(\mu_3\text{-}O)_2(\mu\text{-}OR)_2]^{2+}$ ($OR^- = OCH_3^-$, $OC_2H_5^-$, O-*i*-Pr^-) to which peripheral ligands can be attached to, for example N-donor ligand pyridine in $[Mo_4O_8(O\text{-}i\text{-}Pr)_4Py_4]\cdot 2Py$ (O-*i*-Pr^- = $OC_3H_7^-$) [4].

Scheme 1. $Mo_2O_4^{2+}$ unit.

The structure of $[Mo_8O_{16}(OCH_3)_8(PMe_3)_4]$ [5] is analogous to structures of the octanuclear clusters described in this paper. Four $Mo_2O_4^{2+}$ units are joined together by pairs of methoxy bridges, forming a pattern of alternating short Mo–Mo distances, 2.557–2.578 Å, with longer Mo···Mo contacts, 3.441–3.474 Å. The ring is bent. The cluster was obtained from a methanol solution of *fac*-[Mo(CO)$_3$-

PII S0277-5387(00)00377-6

$(PMe_3)_3]$ in the presence of oxygen and sunlight. Planar conformation of the ring was found in the anionic $[Mo_8O_{16}(OCH_3)_8(C_2O_4)]^{2-}$ [6] and $[Mo_8O_{16}(OC_2H_5)_8(C_2O_4)]^{2-}$ [7], both known as $(n\text{-}C_4H_9)_4N^+$ salts. The planarity is imposed by the oxalate anion which occupies the central cavity and is bonded to four molybdenum atoms. Another Mo_8 complex $[Mo_8O_{12}(OH)_6(OC_2H_5)_4Cl_6(HOC_2H_5)_4]$ [8] has a $Mo_8(\mu_3\text{-}O)_4(\mu\text{-}O)_8$ core encapsulated by terminal oxo, hydroxy, chloro and ethanol ligands. The structure of the central core is closely related to the structure of MoO_2.

Among the oxomolybdates(VI) different octanuclear cores were observed. Two tetranuclear units are either connected by two vertices as in $[Mo_8O_{20}(OCH_3)_4\{(OCH_2)_3CCH_3\}_2]^{2-}$ [9] or by two edges as in $[Mo_8O_{24}(OCH_3)_4]^{4-}$ [10]. The structure found in a Mo(V)/Mo(VI) compound, $((n\text{-}C_4H_9)_4N)_4[Mo_4O_8(OCH_3)_2(MoO_4)_2(HMoO_4)_2]\cdot CH_3OH\cdot H_2O$, may be viewed as a tetranuclear framework with four tetrahedral MoO_4^{2-} appended, two as terminal ligands and two as chelates [11]. A heterometallic mixed valence $[Mg_2Mo_8O_{22}(OCH_3)_6(HOCH_3)_4]^{2-}$ [12] has two tetranuclear units fused along two edges forming a central cavity which is occupied by two $\{Mg(OCH_3)_2\}$ moieties.

We observed before that in the reaction of $(PyH)_2[MoOCl_5]$ with a mixture of pyridine, methanol and acetonitrile $[Mo_8O_{16}(OCH_3)_8Py_4]$ is formed [13]. Although the compound was obtained in crystalline form, the yields were low and highly irreproducible.

Reactions of $(PyH)_2[MoOCl_5]$ with the mixture of methanol and pyridine or its alkyl substituted derivatives under varying conditions have led to oxomolybdenum(V) clusters with coordinated methoxide ions and pyridines, i.e. pentanuclear $[Mo_5O_{11}(OCH_3)_4Py_4]\cdot CH_3OH$ [14], tetranuclear $[Mo_4O_8(OCH_3)_2Cl_2Py_4]\cdot 2Py$ and $[Mo_4O_8(OCH_3)_4(4\text{-}MePy)_4]$, hexanuclear $[Mo_6O_{12}(OCH_3)_6Py_4]$, decanuclear $[Mo_{10}O_{26}Py_8]\cdot 7Py$ [15] and octanuclear $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = 4-MePy, 4-EtPy, 4-Bu^{t}Py, Py, 3-MePy, 3,5-Lut) with $Mo_2O_4^{2+}$ building blocks as a common structural motif. The aim of our research was to define conditions which would lead solely to $[Mo_8O_{16}(OCH_3)_8L_4]$. Knowledge of the factors which influence the formation of octanuclear clusters may provide insight into the processes that eventually lead to their formation. To support our assumptions that octanuclear clusters can be used as precursors in the synthesis of high nuclearity clusters with chemical evidence, systematic investigation of their reactivity was undertaken.

2. Experimental

2.1. General comments

$(NH_4)_2[MoCl_5(H_2O)]$ [16] and $(PyH)_2[MoOCl_5]$ [17] were synthesized according to published procedures. Solvents were reagent grade and they were used without additional purification. They were obtained from the following sources: Merck (pyridine, 3,5-lutidine, methanol and nitromethane), Acros Organics (4-ethylpyridine and 4-*tert*-butylpyridine), BDH Chemicals (3-methylpyridine and 4-methylpyridine).

Infrared spectra of Nujol (4000–400 cm^{-1} range) and hexachlorobutadiene (4000–1200 cm^{-1} range) mulls between CsBr plates were measured on a Perkin-Elmer 1720 X Fourier transform IR spectrometer. Far IR spectra of Nujol mulls (700–100 cm^{-1} range) on a polyethylene foil were measured on a Perkin-Elmer 2000 Fourier transform IR spectrometer. Elemental analyses were obtained by a Perkin-Elmer 2400 CHN analyser at University of Ljubljana (Department of Organic Chemistry).

2.2. Syntheses

2.2.1. Synthesis of $[Mo_8O_{16}(OCH_3)_8(4\text{-}MePy)_4]$ (**a**)

10 mmol (3.27 g) of $(NH_4)_2[MoCl_5(H_2O)]$ was added to the mixture of 10 ml of 4-methylpyridine, 10 ml of nitromethane and 75 ml of methanol. The yellow–green mixture was refluxed (approximately 15 min) until it changed into a red colour. The orange microcrystalline product was filtered off. The yield was 750 mg (37%).

2.2.2. Synthesis of $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = 4-MePy (**a**), 4-EtPy (**b**), 4-Bu^{t}Py (**c**), 3-MePy (**e**))

1 mmol (450 mg) of $(PyH)_2[MoOCl_5]$ was added to the mixture of 5 ml of ligand and 15 ml of methanol in the case of **b** and **c**. The solution was refluxed (approximately 15 min) until an orange compound started to precipitate out of the reaction mixture. The product was filtered off. The yields were 75 mg (35%) for **b** and 118 mg (52%) for **c**.

For **a**, slightly different amounts were used; 1.5 mmol (675 mg) of $(PyH)_2[MoOCl_5]$ was added to the mixture of 5 ml of 4-methylpyridine and 20 ml of methanol. The yield was 92 mg (30%).

Orange, rod-shaped ($0.05\times0.05\times0.40$ mm) single crystals of **e** were obtained in 10% yield from the mixture of 1 mmol (450 mg) of $(PyH)_2[MoOCl_5]$, 5 ml of 3-methylpyridine and 25 ml of methanol which was left at ambient conditions for 4 h.

2.2.3. Synthesis of $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = 4-EtPy (**b**), Py (**d**), 3-MePy (**e**), 3,5-Lut (**f**))

0.152 mmol (250 mg) of $[Mo_8O_{16}(OCH_3)_8(4\text{-}MePy)_4]$ was added to 10 ml of the ligand. After 15 min of stirring the solution was filtered and methanol (100, 80, 150 and 65 ml in the case of **b**, **d**, **e** and **f**, respectively) was added to the red filtrate. Orange, rod-shaped crystals started to grow in the mixture. After a few hours the product was filtered off. The yields were 190 mg (74%) for **b**, 200 mg (83%) for **d**, 150 mg (60%) for **e** and 105 mg (40%) for **f**.

Suitable crystals for X-ray structural analysis of **f** ($0.06\times0.06\times0.40$ mm) were also obtained by a described procedure.

Note: the yield of $[Mo_8O_{16}(OCH_3)_8Py_4]$ is improved compared to the published procedure [13].

2.3. IR and elemental analysis data

2.3.1. $[Mo_8O_{16}(OCH_3)_8(4\text{-}MePy)_4]$ (**a**)

IR data (cm^{-1}): 3042(w), 2966(sh), 2926(m), 2820(w), 2815(w), 1623(s), 1505(w), 1440(m), 1425(m), 1232(m), 1214(m), 1169(w), 1154(w), 1072(m), 1069(m), 1032(s), 999(vs), 967(vs), 949(s), 874(w), 817(s), 764(s), 734(m), 722(m), 670(w), 579(vs), 550(m), 522(m), 500(vs), 411(m), 363(m), 336(m), 317(m), 281(m). *Anal*. 2.4. X-ray structural determination

Data were collected on an Enraf Nonius CAD-4 diffractometer with graphite-monochromated Mo Kα radiation ($\lambda=0.71069$ Å) at room temperature. Crystal data parameters are given in Table 1. For **e** a total of 3412 reflections were measured ($\theta_{max}=27.98°$; $0\le h\le24$, $-8\le k\le24$, $-9\le l\le9$) and reduced to a unique set of 1731 reflections ($R_{int}=0.062$); for **f** a total of 16062 reflections were measured ($\theta_{max}=24.96°$; $-21\le h\le21$, $-21\le k\le21$, $-8\le l\le7$) and reduced to a unique set of 2374 reflections ($R_{int}=0.11$). Cell parameters for **e** were determined from 50 reflections from the 6.03–14.4° θ range and for **f** from 50 reflections from the 6.0–11.8° θ range. Data collection followed routine procedures. All data were corrected for Lorentz and polarization effects. In neither case was absorption correction applied. Structures were solved by direct methods using SIR-92 [18]. All non-hydrogen atoms were refined using anisotropic thermal parameters. The program used was XTAL 3.4 [19]. The hydrogen atoms were inserted in calculated positions. The least-squares refinement on F for **e** converged at $R=0.024$ and $R_w=0.024$ for 154 least-squares parameters and 850 data ($F_o>3\sigma(F_o)$ (the weighting

scheme used was $w = W_F \times W_S$, where $W_F(F_o < 79) = (F_o/79)^2$, $W_F(F_o > 100) = (100/F_o)^{0.4}$ and $W_F(79 < F_o < 100) = 1$; $W_S(\sin\theta < 0.36) = (0.36/\sin\theta)^{0.80}$, $W_S(\sin\theta > 0.54) = (\sin\theta/0.54)^4$ and $W_S(0.36 < \sin\theta < 0.54) = 1$). The final difference synthesis maximum and minimum were $+0.491$ and -0.367 e Å^{-3}. The least-squares refinement for **f** converged at $R = 0.038$ and $R_w = 0.043$ for 163 least-squares parameters and 858 data ($F_o > 3\sigma(F_o)$) (the weighting scheme used was $w = W_F \times W_S$, where $W_F(F_o < 46) = (F_o/46)^{1.5}$, $W_F(F_o > 130) = (130/F_o)^{1.5}$ and $W_F(46 < F_o < 130) = 1$; $W_S(\sin\theta < 0.24) = (0.24/\sin\theta)^{2.2}$, $W_S(\sin\theta > 0.43) = (\sin\theta/0.43)^1$ and $W_S(0.24 < \sin\theta < 0.43) = 1$). The final difference synthesis maximum and minimum were $+0.576$ and -0.488 e Å^{-3}.

3. Results and discussion

3.1. Infrared spectra

Apart from the ligand absorptions the IR spectra of all $[Mo_8O_{16}(OCH_3)_8L_4]$ are similar; characteristic absorptions are given in Table 2. The complexity of the spectra in the 1630–400 cm^{-1} region due to the superposition of ligand absorptions with the $[Mo_8O_8(\mu\text{-}O)_8(\mu\text{-}OCH_3)_8]$ absorptions prevents the unambiguous assignment of bands. Bands around 2930 and 2820 cm^{-1} observed in the spectra of all compounds can be associated with the C–H stretching modes of the methoxy groups; the observed bands are comparable to the absorption at 2930 cm^{-1} in $((n\text{-}C_4H_9)_4N)_2[Mo_8O_{16}(OCH_3)_8(C_2O_4)]$ [6] and at 2820 cm^{-1} in $((n\text{-}C_4H_9)_4N)_2[V_8O_8(OCH_3)_{16}(C_2O_4)]$ [7]. The C–O stretching vibrations of the alkoxy groups usually absorb in the 1150–1000 cm^{-1} region [20]; a strong absorption around 1000 cm^{-1} found in the spectra of $[Mo_8O_{16}(OCH_3)_8L_4]$ can be tentatively assigned as C–O stretching vibration. Two bands around 970 and 950 cm^{-1} are assigned to the Mo=O$_t$ stretching vibrations, the appearance of two bands stems from a different chemical environment of two molybdenum atoms of the $Mo_2O_4^{2+}$ pair, one being in a square pyramidal and the other one in an octahedral environment. Strong bands at ~575 and ~500 cm^{-1} in the spectra of all $[Mo_8O_{16}(OCH_3)_8L_4]$ are attributed to the bridging methoxy groups [21]. The low frequency bands around 365, 335, 315 and 283 cm^{-1} are also typical for the $[Mo_8O_8(\mu\text{-}O)_8(\mu\text{-}OCH_3)_8]$ framework.

3.2. Description of structures

Structures of **e** and **f** are almost identical to the structures of $[Mo_8O_{16}(OCH_3)_8Py_4]$ [13] and $[Mo_8O_{16}(OCH_3)_8(PMe_3)_4]$ [5]. Comparison of bond lengths and angles in **d**, **e** and **f** with the appropriate bond lengths and angles in $[Mo_8O_{16}(OCH_3)_8(PMe_3)_4]$ shows that the ring geometry does not change with the coordination of pyridines instead of trimethylphosphine.

Relevant geometric parameters of **d**, **e** and **f** are presented in Table 3. The asymmetric unit in **e** is shown in Fig. 1. The asymmetric units are related by a crystallographic $\bar{4}$ axis in the centre of the molecule (Fig. 2), the overall molecular symmetry is thus S_4.

Eight molybdenum atoms, alternately bridged by two oxygen atoms or two methoxy groups, form a cyclic 'tiara' framework $[Mo_8O_8(\mu\text{-}O)_8(\mu\text{-}OCH_3)_8]$ [6]. Short Mo–Mo distances, 2.558(1) Å for **e** and 2.561(2) Å for **f**, alternate with longer distances, 3.433(1) Å for **e** and 3.433(2) Å for **f**. The deviation from planarity of the bridging unit $Mo_2(\mu\text{-}O)_2$ is shown by the fold angle which is 148.8(8)° in **e** and 148.4(3)° in **f**. One molybdenum atom (Mo2) of the $Mo_2O_4^{2+}$ pair is in a square pyramidal environment and the other one (Mo1) to which the pyridine ligand is bonded, is in a distorted octahedral environment as shown in Fig. 2. The dimensions of the $Mo_2O_2(\mu\text{-}O)_2$ unit in both are the same, within experimental error, as in other $Mo_2O_4^{2+}$ compounds. Alkyl-substituted pyridine coordinates to Mo1 at a distance of 2.26(1) Å in **e** and 2.29(1) Å in **f**. The values are comparable to those reported for $[Mo_4O_8(O\text{-}i\text{-}Pr)_4Py_4]\cdot 2Py$ (2.229(3)–2.269(3) Å) [4]. The aromatic ligands are oriented outward from the central cavity whose perimeter may be defined by the O3···O3^{i} (4.343(7) Å for **e** and 4.30(1) Å for **f**) and O3···O3^{ii} (5.062(7) Å for **e** and 5.02(1) Å for **f**) distances (symmetry codes for **e**: (i) $1-y, -1+x, 2-z$, (ii) $2-x, -y, z$; symmetry codes for **f**: (i) $y, -x+1/2, -z+1/2$, (ii) $-x+1/2, -y+1/2, z$). In both the rings are stacked one upon another along the *z*-axis, in **f** in such a way that parallel to the one-dimensional chain of molecules channels of void space are formed. The shortest intermolecular contact O4···C4^{iii} (3.35(1) Å (symmetry code: (iii) $3/2-x, 1/2-y, -1/2+z$) between bridging oxygen and aromatic

carbon in **e** is longer than the sum of the van der Waals radii (3.22 Å) [22]. The shortest intermolecular contact O1···C6^{iv} (symmetry code: (iv) $x, y, 1+z$) between terminal oxygen and methyl carbon from 3,5-lutidine in **f** is 3.30(2) Å.

3.3. Reactivity

In the mixtures of $[MoOCl_5]^{2-}$, methanol and pyridine or its alkyl-substituted derivative, a rapid substitution of chloro ligands with methoxide ions takes place. The methoxide ions are formed in the protolytic reaction between pyridine and methanol. Owing to their high reactivity, the substituted derivatives of $[MoOCl_5]^{2-}$ react further to $Mo_2O_4^{2+}$; by subsequent linkage of dimers more stable clusters are formed. Attempts to isolate any of the substituted mononuclear or dinuclear species from what is probably a very complex mixture have failed so far. Reactive molybdenum(III) species, i.e. $[MoCl_5(H_2O)]^{2-}$, were also found to react with the mixture of methanol and pyridines in the presence of nitromethane to oxomolybdenum(V) clusters. Nitromethane might be playing a key role in the oxidation of molybdenum(III) to molybdenum(V), in its absence no oxidized species were detected [16].

In spite of the limited knowledge of the extent to which factors such as the molar ratios of the reactants, their concentration and temperature influence the reaction course, we have found that $[Mo_8O_{16}(OCH_3)_8L_4]$ is formed in the absence of water and when the ratio of methanol versus pyridine is in favour of methanol not only at room temperature but also at

boiling temperatures of the reaction mixtures. Among the oxomolybdenum clusters, $[Mo_4O_8(OCH_3)_2Cl_2Py_4]\cdot 2Py$, $[Mo_4O_8(OCH_3)_4(4\text{-MePy})_4]$, $[Mo_6O_{12}(OCH_3)_6Py_4]$ [15] and $[Mo_5O_{11}(OCH_3)_4Py_4]\cdot CH_3OH$ [14], which were also obtained from similar reaction systems, octanuclear compounds are the most reactive. In view of the apparent coordinative unsaturation of the pentacoordinated molybdenum, the ease of further reactions seems plausible. The diamagnetism is a property that the octanuclear compounds have in common with other oxomolybdenum(V) clusters with pyridines; in contrast to others they are sparingly soluble in methanol, nitromethane and pyridines. Solutions are not stable, slow decomposition takes place with time. The solubility in pyridines was employed for recrystallization and also for substitution of coordinated ligand for another ligand added in a huge excess.

$$[Mo_8O_{16}(OCH_3)_8L_4] + 4L' \rightarrow [Mo_8O_{16}(OCH_3)_8L'_4] + 4L \quad (1)$$

The recrystallized product or product with substituted ligand was precipitated from the solution by the addition of methanol. For example, 4-methylpyridine in $[Mo_8O_{16}(OCH_3)_8(4\text{-MePy})_4]$ was substituted for pyridine, 3-methylpyridine, 3,5-lutidine and 4-ethylpyridine, whereas with 4-*tert*-butylpyridine the substitution did not take place. The limiting factor of this reaction seems to be solubility.

Recrystallization of $[Mo_8O_{16}(OCH_3)_8(4\text{-MePy})_4]$ from 4-methylpyridine resulted in a partial decomposition of the starting material, namely the mixture of crystals of $[Mo_8O_{16}(OCH_3)_8(4\text{-MePy})_4]$ and $[Mo_4O_8(OCH_3)_4(4\text{-MePy})_4]$ [15] was obtained.

$$[Mo_8O_{16}(OCH_3)_8(4\text{-MePy})_4] + 4(4\text{-MePy}) \rightarrow 2[Mo_4O_8(OCH_3)_4(4\text{-MePy})_4] \quad (2)$$

We assume that the ring cleavage in solutions is followed by the aggregation of smaller fragments into stable and unsoluble clusters. It is reported in the literature that by reacting a mixed valence hexanuclear $[Mo_6O_{10}(O\text{-}i\text{-Pr})_{12}]$ with pyridine, $[Mo_4O_8(O\text{-}i\text{-Pr})_4Py_4]$ was obtained. It was shown by NMR studies that the chain of six metal centres linked together was cleaved into fragments with preserved Mo–Mo bonds and mononuclear molybdenum(VI) units [23].

Further evidence is also given by the reactions in pyridines at elevated temperatures where partial oxidation to Mo(VI) took place.

$$[Mo_8O_{16}(OCH_3)_8L_4] + L \rightarrow [Mo_{10}O_{26}L_8] \quad (3)$$

The oxidizing agent is probably oxygen. The mixed valence $[Mo_{10}O_{26}L_8]$ contains two molybdenum(VI) centres, the rest of the molybdenum atoms are part of $Mo_2O_4^{2+}$ units, as proved by X-ray crystallography [15]. Since no precaution was taken to eliminate traces of water inherent in pyridines the formation of μ_3-O ligands found in $[Mo_{10}O_{26}L_8]$ could have its origin in hydrolysis and not in C–O bond cleavage. We believe that $[Mo_{10}O_{26}L_8]$ is not the only product. By analogy, employing the same procedure only with a different pyridine, decanuclear clusters with substituted ligands were obtained.

$$[Mo_8O_{16}(OCH_3)_8L_4] + L' \rightarrow [Mo_{10}O_{26}L'_8] \quad (4)$$

4. Concluding remarks

From a seemingly simple reaction system of $[MoOCl_5]^{2-}$, methanol and pyridines, neutral oxomolybdenum(V) clusters of different nuclearity have been isolated. At present the processes giving rise to them remain obscure and are topics for future research.

Supplementary data

Tables of atomic coordinates, bond lengths, bond angles and thermal parameters are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk). The CCDC reference numbers are 137764 for **e** and 137765 for **f**. Observed and calculated structure factors are available from the authors upon request.

Abstract

Reaction of 2-(phenylazo)pyridine (pap) with $[Os(PPh_3)_3Br_2]$ afforded a mixed ligand complex of the type $[Os(PPh_3)_2(pap)Br_2]$. The structure of this complex was determined by X-ray crystallography. The PPh_3 ligands are *trans* and the bromides are in *cis* positions. The pap ligand is coordinated to osmium as a bidentate N,N-donor forming a five-membered chelate ring. The complex is diamagnetic (low-spin d^6, $S=0$) and in dichloromethane solution shows intense MLCT transitions in the visible region. The two bromides were replaced from the coordination sphere of $[Os(PPh_3)_2(pap)Br_2]$ under mild conditions by a series of anionic ligands L (where L = quinolin-8-olate (q), picolinate (pic), oxalate (Hox), 1-nitroso-2-naphtholate (nn) and acetyl acetonate (acac)) to afford complexes of the type $[Os(PPh_3)_2(pap)(L)]^+$, which were isolated and characterized as the perchlorate salt. The structure of the $[Os(PPh_3)_2(pap)(acac)]ClO_4$ complex was determined by X-ray crystallography. The PPh_3 ligands occupy *trans* positions and the acetylacetonate anion is coordinated to osmium as a bidentate O,O-donor forming a six-membered chelate ring. The $[Os(PPh_3)_2(pap)(L)]^+$ complexes are diamagnetic and show multiple MLCT transitions in the visible region. $[Os(PPh_3)_2(pap)Br_2]$ shows an osmium(II)–osmium(III) oxidation at 0.49 V versus SCE. The same oxidation is displayed by the $[Os(PPh_3)_2(pap)(L)]^+$ complexes within 0.69 to 0.96 V versus SCE. Two successive one-electron reductions of the coordinated pap ligand are also observed in all the complexes below −0.90 V versus SCE. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Osmium; Triphenylphosphine; 2-(Phenylazo)pyridine; Synthesis; Structures; Reactivities

1. Introduction

The chemistry of osmium has been receiving considerable attention [1–18], largely because of the variety of reactivities exhibited by its complexes. Most of these reactions require direct contact of the reactant with the metal center. As osmium is usually coordinatively saturated in its complexes, such direct links can only be established via dissociation of relatively weak metal–ligand bonds. Osmium complexes having potentially labile ligands are of particular importance in this regard. In the present work, which has emerged from our interest in the chemistry of osmium in different coordination environments [19–23], we have chosen an $OsBr_2$ moiety as the reactive fragment, because the Os–Br bonds are known to undergo dissociation under rather mild conditions [24,25]. To satisfy the remaining four coordination sites of osmium in this $OsBr_2$ moiety, two π-acid ligands, i.e. 2-(phenylazo)pyridine (pap, **1**) and triphenylphosphine (PPh_3), have

pap, 1

been utilized. 2-(Phenylazo)pyridine is well known for its strong π-acidity [26–28], by virtue of which it stabilizes the lower oxidation states of a metal. Triphenylphosphine also favors the lower oxidation states of a metal via dπ–dπ interaction. Coordination by these π-acid ligands has been planned in order to stabilize the bivalent state of osmium, which in turn is expected to favor dissociation of the Os–Br bonds. The targeted complex, $[Os(PPh_3)_2(pap)Br_2]$, has been synthesized and the reactivity of the $OsBr_2$ fragment towards displacement by a group of bidentate ligands (L) of different types has been studied. An account of the chemistry of $[Os(PPh_3)_2(pap)Br_2]$ and $[Os(PPh_3)_2(pap)(L)]^+$ complexes is reported here with special reference to synthesis, structure and redox properties.

2. Experimental

2.1. Materials

Osmium tetroxide was purchased from Arora Matthey, Calcutta, India and was converted into $[NH_4]_2[OsBr_6]$ by reduction with HBr [29]. $[Os(PPh_3)_3Br_2]$ was synthesized from $[NH_4]_2[OsBr_6]$ using a literature method [30]. Triphenylphosphine, acetylacetone (Hacac), oxalic acid (H_2ox) and 1-nitroso-2-naphthol (Hnn) were purchased from Loba Chemie, Mumbai, India. Picolinic acid (Hpic) and quinoline-8-ol (Hq) were purchased from E. Merck (India). 2-(Phenylazo) pyridine was prepared by following a literature procedure [31]. All other chemicals and solvents were reagent grade commercial materials and were used as received. Purification of acetonitrile and dichloromethane, and preparation of tetrabutylammonium perchlorate (TBAP) for electrochemical work were performed as reported in the literature [32,33].

2.2. Preparation of the complexes

2.2.1. $[Os(PPh_3)_2(pap)Br_2]$

To a mixture of $[Os(PPh_3)_3Br_2]$ (100 mg, 0.09 mmol) and 2-(phenylazo)pyridine (16 mg, 0.09 mmol), 2-methoxyethanol (30 cm^3) was added. The resulting mixture was refluxed for 2 h. A red crystalline precipitate started to separate during reflux. After cooling the solution to room temperature, the precipitate was collected by filtration, washed thoroughly with ethanol and dried in air. The yield was 52 mg (56%).

2.2.2. $[Os^{II}(PPh_3)_2(pap)(L)]ClO_4$ (L = pic, q, Hox, nn, acac) complexes

The $[Os^{II}(PPh_3)_2(pap)(L)]ClO_4$ (L = pic, q, Hox, nn, acac) complexes were synthesized using a general procedure. Yields varied in the range of 60–65%. Specific details are given for one complex.

$[Os(PPh_3)_2(pap)(acac)]ClO_4$. $[Os(PPh_3)_2(pap)Br_2]$ (100 mg, 0.10 mmol) was dissolved in dichloromethane (20 cm^3) and to this solution was added acetylacetone (10 mg, 0.10 mmol) followed by ethanol (30 cm^3) and triethylamine (10 mg, 0.10 mmol). The solution was boiled for a few minutes in air to remove dichloromethane as much as possible and then it was heated at reflux for 48 h. After being cooled to room temperature, a saturated aqueous solution of $NaClO_4$ (0.5 cm^3) was added to it. $[Os(PPh_3)_2(pap)(acac)]ClO_4$ precipitated as a red solid and was collected by filtration, washed with ice-cold water and dried in vacuo over P_4O_{10}. Purification of the product was done by thin layer chromatography on a silica-gel plate, using 1:1 benzene–acetonitrile as the eluant. A red band separated and was extracted with acetonitrile. On evaporation of the acetonitrile solution, $[Os(PPh_3)_2(pap)(acac)]ClO_4$ was obtained as a red microcrystalline solid. The yield was 64 mg (61%).

In the case of HL = Hq and Hnn, 2-methoxyethanol was used as solvent instead of ethanol and triethanolamine was used as base instead of triethylamine.

2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Perkin-Elmer 240C elemental analyzer. Infrared spectra were obtained on a Perkin-Elmer 783 spectrometer with samples prepared as KBr pellets. Electronic spectra were recorded on a Shimadzu UV 1601 spectrophotometer. Magnetic susceptibilities were measured using a PAR 155 vibrating sample magnetometer fitted with a Walker Scientific L75FBAL magnet. ^1H NMR spectra were obtained on a Bruker AC-200 NMR spectrometer using TMS as the internal standard. Solution electrical conductivities were measured using a Philips PR 9500 bridge with a solute concentration of 10^{-3} M. Electrochemical measurements were made using a PAR model 273 potentiostat. A platinum disk or graphite working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in a three-electrode configuration. A RE 0089 X-Y recorder was used to trace the voltammograms. Dinitrogen gas was purified by successively bubbling it through alkaline dithionite and concentrated sulfuric acid and all electrochemical measurements were performed under this dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potentials.

2.4. Crystallography

Single crystals of $[Os(PPh_3)_2(pap)Br_2]$ were obtained directly from the synthetic reaction carried out in 2-methoxyethanol. Selected crystal data and data collection parameters are given in Table 1. Data were collected on a Siemens Smart CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by frame using ω scans within the angular range $1.48° < \theta < 26.37°$. X-ray data reduction and structure solution and refinement were done using the SHELXTL package. The structure was solved by direct methods.

Single crystals of $[Os(PPh_3)_2(pap)(acac)]ClO_4$ were grown by slow diffusion of hexane into a dichloromethane solution of the complex. Selected crystal data and data collection parameters are given in Table 1. Data were collected on a Siemens Smart CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by frame using ω scans within the angular range $1.57° < \theta < 26.37°$. X-ray data reduction and structure solution and refinement were done using the SHELXTL package. The structure was solved by direct methods.

3. Results and discussion

3.1. Synthesis and characterization

3.1.1. $[Os(PPh_3)_2(pap)Br_2]$

Smooth displacement of one PPh_3 from $[Os(PPh_3)_3Br_2]$ by 2-(phenylazo)pyridine in refluxing 2-methoxyethanol affords the $[Os(PPh_3)_2(pap)Br_2]$ complex in decent yield. The composition of the complex was confirmed by its elemental (C, H, N) analytical data (Table 2). The complex is diamagnetic, which corresponds to the +2 oxidation state of osmium (low-spin d^6, $S=0$) in this complex. As 2-(phenylazo)pyridine is an unsymmetrical bidentate ligand, this $[Os(PPh_3)_2(pap)Br_2]$ complex may, in principle, exist in four geometrical isomeric forms (**2**–**5**). To find out

the actual stereochemistry of $[Os(PPh_3)_2(pap)Br_2]$, its structure was determined by X-ray crystallography. The

structure is shown in Fig. 1 and selected bond parameters are listed in Table 3. The pap ligand is coordinated to osmium in the usual manner with a bite angle of 76.6(2)°. The two PPh_3 ligands are mutually *trans*, while the two bromides occupy mutually *cis* positions. The structure determination thus shows that $[Os(PPh_3)_2(pap)Br_2]$ has stereochemistry 2. The $N_2P_2Br_2$ coordination sphere around osmium is distorted from ideal octahedral geometry, as reflected in the bond parameters centering osmium. The Os–P and Os–Br bond distances are quite normal, as observed in other complexes containing these bonds [23,24]. While the Os–N1 length is also normal [24], the Os–N3 bond is noticeably short and the azo N2–N3 distance is longer than the uncoordinated azo distance [34,35]. The short Os–N3 distance and increase in N2–N3 bond order reflect the considerable π-interaction between osmium(II) and the azo function.

The ^1H NMR spectrum of $[Os(PPh_3)_2(pap)Br_2]$ was recorded in $CDCl_3$ solution. The spectrum is rather complex in nature owing to overlapping of signals and hence assignment of all the signals in this region to specific protons has not been possible. However, two doublets (1H each) observed at 8.22 and 7.87 ppm are assigned to the two pyridine-protons of pap at positions 6 and 3, respectively (see **1**). The other resonances appear within 6.7 to 7.5 ppm and intensity measurement of these signals corresponds to the remaining number (37) of protons present in the complex. The IR spectrum of $[Os(PPh_3)_2(pap)Br_2]$ shows many vibrations in the 1600–400 cm^{-1} region. Strong vibrations observed at 740, 690, and 522 cm^{-1} indicate the presence of the $Os(PPh_3)_2$ moiety [36]. A sharp and strong vibration at 1310 cm^{-1} is assigned to the $\nu_{N=N}$ stretch [37]. The $[Os(PPh_3)_2(pap)Br_2]$ complex is poorly soluble in solvents such as acetonitrile, acetone, ethanol, etc. and moderately soluble in solvents such as dichloromethane, chloroform, *N*,*N*-dimethylformamide, etc., producing intense red solution. The electronic spectrum of the complex has been recorded in dichloromethane solution. The complex shows intense absorptions in the visible and UV region (Table 2).

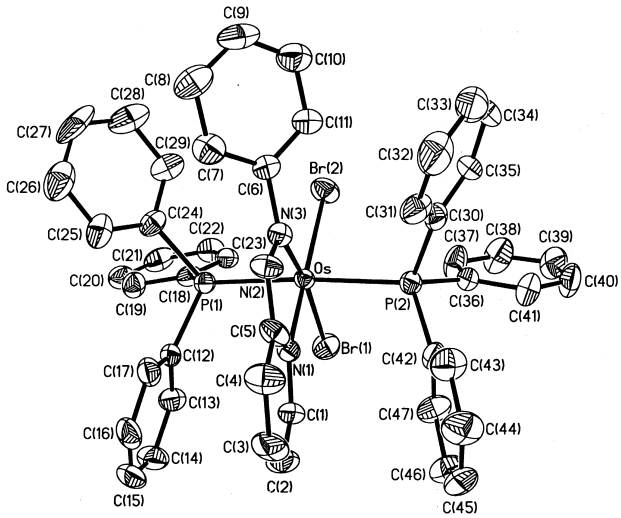

Fig. 1. Structure of $[Os(PPh_3)_2(pap)Br_2]$.

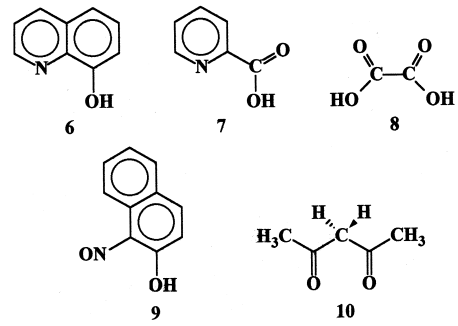

Table 3
Selected bond distances and bond angles for $Os(PPh_3)_2(pap)Br_2$ and $[Os(PPh_3)_2(pap)(acac)]ClO_4$

$[Os(PPh_3)_2(pap)Br_2]$		$[Os(PPh_3)_2(pap)(acac)]ClO_4$	
Os–P1	2.417(2)	Os–P1	2.4485(10)
Os–P2	2.430(2)	Os–P2	2.4740(9)
Os–N1	2.031(5)	Os–O1	2.082(2)
Os–N3	1.978(5)	Os–O2	2.096(2)
Os–Br1	2.5872(7)	Os–N1	2.033(3)
Os–Br2	2.5602(7)	Os–N3	1.977(3)
N2–N3	1.314(7)	O1–C13	1.297(5)
		O2–C15	1.280(4)
		N2–N3	1.329(4)
N1–Os–N3	76.6(2)	N3–Os–N1	76.29(12)
N1–Os–Br1	170.5(2)	N3–Os–O1	171.77(11)
N3–Os–Br2	175.05(14)	N1–Os–O2	175.89(10)
P1–Os–P2	175.10(6)	P1–Os–P2	172.77(3)
		O1–Os–O2	87.89(10)

The absoptions in the UV region are attributable to transitions within the ligand orbitals, whereas the absorptions in the visible region are probably due to allowed metal-to-ligand charge-transfer transitions.

3.1.2. $[Os(PPh_3)_2(pap)(L)]ClO_4$

One major objective of undertaking this present work has been to scrutinize the reactivity of the $OsBr_2$ fragment of $[Os(PPh_3)_2(pap)Br_2]$ towards displacement by ligands of different types. This was carried out by reacting $[Os(PPh_3)_2(pap)Br_2]$ with five selected acidic ligands, i.e. quinoline-8-ol (Hq, **6**), picolinic acid (Hpic, **7**), oxalic acid (H_2ox, **8**), 1-nitroso-2-naphthol (Hnn, **9**) and acetylacetone (Hacaac, **10**). The reactions proceed smoothly in

ethanol/2-methoxyethanol medium (a little dichloromethane was necessary initially to take $[Os(PPh_3)_2(pap)Br_2]$ into alcoholic medium) in the presence of a base to afford the expected complexes of the type $[Os(PPh_3)_2(pap)(L)]^+$ (L = q, pic, Hox, nn and acac). It is interesting to note here that during the reaction with oxalic acid, only one proton is lost and the monoanionic oxalate ion (Hox) coordinates to osmium. The complex cations were isolated as perchlorate salts in the solid state. Microanalytical data of these five complexes agree well with their compositions (Table 2). These complexes are diamagnetic which shows that the +2 state of osmium is retained in them. Several geometric iso-

mers are possible for these complexes. The structure of $[Os(PPh_3)_2(pap)(acac)]ClO_4$ was determined by X-ray crystallography. The structure is shown in Fig. 2 and selected bond distances and angles are presented in Table 3. The coordination sphere around osmium is $N_2O_2P_2$ which is slightly distorted octahedral in nature, as reflected in all the bond angles with osmium as the central atom. The acetylacetonate anion is coordinated to osmium as a O,O-donor with a bite angle of 87.89°. The two PPh_3 ligands are mutually *trans* as observed in the parent $[Os(PPh_3)_2(pap)Br_2]$ complex. Distances within the $Os(PPh_3)_2(pap)$ fragment are comparable to those observed in the $[Os(PPh_3)_2(pap)Br_2]$ complex [23]. The bond lengths in the Os(acac) fragment are also normal [21,38]. The other four $[Os(PPh_3)_2(pap)(L)]^+$ complexes have the same $Os(PPh_3)_2(pap)$ fragment and hence they are assumed to have similar structures with the PPh_3 ligands in mutually *trans* positions. Synthesis of the $[Os(PPh_3)_2(pap)(L)]^+$ complexes from $[Os(PPh_3)_2(pap)Br_2]$ is therefore stereoretentive.

^{1}H NMR spectra of the $[Os(PPh_3)_2(pap)(L)]ClO_4$ complexes, recorded in $CDCl_3$ solution, show many signals in the aromatic region and the spectra are complex in nature. In the $[Os(PPh_3)_2(pap)(acac)]ClO_4$ complex, two sharp methyl resonances are observed at 1.67 and 1.58 ppm due to the coordinated acac, and the central C–H proton signal of the same ligand appears at 5.09 ppm. Infrared spectra of the $[Os(PPh_3)_2(pap)(L)]ClO_4$ complexes are mostly similar to the spectrum of the parent $[Os(PPh_3)_2(pap)Br_2]$ complex. Some additional vibrations are observed in all the $[Os(PPh_3)_2(pap)(L)]ClO_4$ complexes, of which the two intense ones observed near 1100 and 625 cm^{-1} indicate the presence of perchlorate ion. The $\nu_{CO(carboxylate)}$ vibration is observed at 1700 cm^{-1} in the L = pic complex and at 1650 cm^{-1} in the L = Hox complex. In the L = nn complex the ν_{NO} vibration is observed at 1256 cm^{-1}. The $[Os(PPh_3)_2(pap)(L)]ClO_4$ complexes are soluble in acetonitrile solution, producing brown solutions. Conductivity measurements in acetonitrile solution show that all these complexes behave as 1:1 electrolytes (Λ_M = 145–160 Ω^{-1} cm^2 M^{-1}), as expected. Electronic spectra of the $[Os(PPh_3)_2(pap)(L)]ClO_4$ complexes, recorded in acetonitrile solution (Table 2), show several intense absorptions in the visible and UV region as before.

3.2. Cyclic voltammetric properties

Electrochemical properties of all the complexes were studied by cyclic voltammetry. Voltammetric data are given in Table 2 and selected voltammograms are shown in Fig. 3. Cyclic voltammetry on $[Os(PPh_3)_2(pap)Br_2]$ in dichloromethane solution shows a reversible oxidative response at 0.49 V (all potentials are referenced to SCE) and two quasi-reversible reductive responses at −1.03 and −1.40 V. The oxidation is assigned to osmium(II)–osmium(III) oxidation. The one-electron nature of this oxidation was established by comparing its current heights with those of standard ferrocene–ferrocenium couple under identical experiment. The reductions are assigned to reductions of the coordinated 2-(phenylazo)pyridine ligand. The 2-(phenylazo)pyridine ligand is known to accept successively two electrons in its lowest unoccupied molecular orbital which is largely azo in nature [39]. Both of these reductions are indeed observed in $[Os(PPh_3)_2(pap)Br_2]$. Cyclic voltammetry on the $[Os(PPh_3)_2(pap)(L)]^+$ complexes in acetonitrile solution also shows a reversible osmium(II)–osmium(III) oxidation and two reductions of the coordinated pap (Table 2, Fig. 3). The potential of the osmium(II)–osmium(III) oxidation varies significantly (0.69–1.01 V) as L is varied. Reductions of the coordinated pap are observed below −0.9 V.

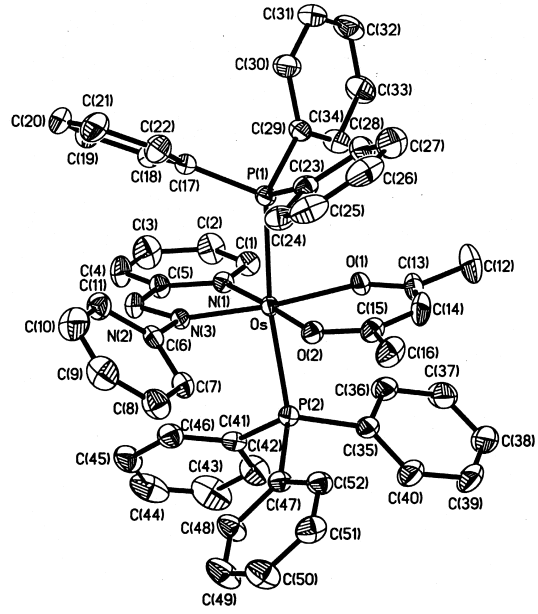

Fig. 2. Structure of $[Os(PPh_3)_2(pap)(acac)]ClO_4$.

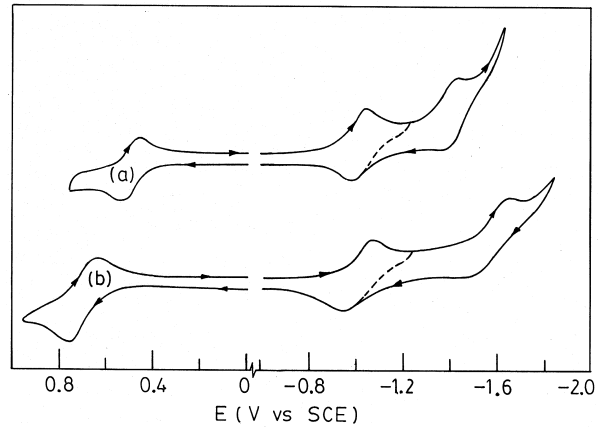

Fig. 3. Cyclic voltammograms of (a) $[Os(PPh_3)_2(pap)Br_2]$ in dichloromethane solution (0.1 M TBAP) and (b) $[Os(PPh_3)_2(pap)(Hox)]ClO_4$ in acetonitrile solution (0.1 M TBAP) at a scan rate of 50 mV s^{-1}.

4. Conclusion

The Os–Br bonds in the $[Os(PPh_3)_2(pap)Br_2]$ complex are found to be displaceable by bidentate chelating ligands

under relatively mild conditions. Hence this complex appears to be suitable as a building unit for the preparation of complexes of higher nuclearity and such possibilities are currently being explored.

Supplementary data

POLYHEDRON

Dinuclear ruthenium(II) and/or osmium(II) complexes of bipyridyl ligands bridged by rigid spacers: synthesis, characterization, electrochemical behavior and luminescence properties

Anvarhusen K. Bilakhiya, Beena Tyagi, Parimal Paul *

Discipline of Silicates and Catalysis, Central Salt and Marine Chemicals Research Institute, Bhavnagar 364 002, India

Received 18 November 1999; accepted 23 March 2000

Abstract

New bridging ligands, 1,4-bis[4-(4′-methyl)-2,2′-bipyridyl)imine]benzene (BL^1) and 4,4′-bis[4-(4′-methyl)-2,2′-bipyridyl)-imine]benzene (BL^2), and their dinuclear complexes of the type $[(bpy)_2Ru\text{-}BL\text{-}Ru(bpy)_2]^{4+}$, $[(bpy)_2Os\text{-}BL\text{-}Os(bpy)_2]^{4+}$ and $[(bpy)_2Ru\text{-}BL\text{-}Os(bpy)_2]^{4+}$ (where $BL = BL^1$ and BL^2) have been synthesized and characterized. Mononuclear model complexes $[(bpy)_2RuL^1]^{2+}$, $[(bpy)_2OsL^1]^{2+}$ and $[(bpy)_2RuL^2]^{2+}$, where L^1 = [4-(4′-methyl)-2,2′-bipyridyl)imine]-4-aminobenzene and L^2 = [4-(4′-methyl)-2,2′-bipyridyl)imine]-4-aminodiphenylene, have also been synthesized. Ligands and metal complexes were characterized on the basis of elemental analysis, FAB mass, IR and ^1H NMR data. All metal complexes exhibit characteristic MLCT absorption and luminescence bands in the visible region. Cyclic and square wave voltammograms of all complexes exhibit metal-based oxidations (M(II) → M(III)) in the potential ranges +1.20 to +1.23 V for Ru(II) and +0.75 to +0.82 V for Os(II). Ligand-based reductions occurred in the potential range −1.28 to −1.90 V. Mixed-valence species of the dinuclear complexes were generated by the addition of a standard solution of ammonium cerium(IV) nitrate. The excited state life-time of all complexes were measured in acetonitrile and also in a methanol–ethanol (4:1) mixture at room temperature. The homodinuclear complexes exhibit significantly long life-times, which are attributed to delocalization of excited electron on the conjugated bridging unit. In heterodinuclear complexes the Ru-based emission life-time decreased significantly; this quenching process takes place via energy transfer from Ru(II) to Os(II) center through spacers. The rate constants for energy transfer are calculated. ©2000 Elsevier Science Ltd All rights reserved.

1. Introduction

In the past few years, there has been explosive growth in the field of supramolecular chemistry of ruthenium(II) and osmium(II) with polypyridyl ligands because of their rich electrochemical and excited-state properties which predict their utility in a variety of photoredox applications [1–9]. Such systems can be developed by covalent linking of prefabricated molecular components (building blocks) with spacers having bidentate donor sets [3,4]. A suitable choice of the building blocks and spacers, and an appropriate designing of the structure can, in fact, allow the occurrence of energy/electron transfer along the supramolecular array [3,4,9–14]. Bis(bipyridyl)ruthenium(II)/osmium(II) exhibit suitable redox and excited-state properties to play the role of building blocks for the construction of photoactive supramolecular systems [15]. However, the key component of the supramolecular systems is the bridging ligands; the size, shape and electronic nature of the bridge controls the interactions between the units, and thereby properties of the molecule as a whole. There are number of reports of homo- and heterodinuclear complexes using 2,2′-bipyridyl-based dinucleating spacers, the bidentate donor sites of which are bridged by various aliphatic/aromatic moieties of different size and shape [16–31].

We were interested to study long-range metal–metal interactions by using spacers, the bidentate chelating sites of which are bridged by rigid aromatic moieties of various lengths. To develop such systems we synthesized two new spacers in which two 4-methyl-2,2′-bipyridyl donor sites are bridged by –CH=N–C_6H_4–N=CH– (BL^1) and –CH=N–C_6H_4–C_6H_4–N=CH– (BL^2) moieties, which make complete

conjugations between the chromophores. Homo- and heterodinuclear complexes of Ru(II) and Os(II) have been synthesized by the reaction of BL^1/BL^2 with the building blocks *cis*-$[M(bpy)_2Cl_2]$ [M = Ru(II) and Os(II)]. Heterodinuclear complexes have been synthesized following a new route which excluded the possibility of the presence of homodinuclear complexes as impurity. We also synthesized mononuclear complexes of ligands having one 4-methyl-2,2′-bipyridyl donor site connected to the bridging unit and these have been used as model compounds to compare their properties to that of the corresponding dinuclear complexes. Herein, we report the synthesis, characterization, electrochemical and luminescence properties of these novel complexes.

2. Experimental

2.1. Materials

2,2′-Bipyridyl (bpy), 4,4′-dimethyl-2,2′-bipyridyl, ammonium hexachloroosmate(IV), ammonium hexafluorophosphate, ammonium tetrafluoroborate and ammonium cerium(IV) nitrate were purchased from Aldrich. *p*-Phenylenediamine and 4,4′-diphenylenediamine were purchased from S-D Fine Chemicals. Neutral alumina was obtained from National Chemicals Co. Hydrated ruthenium trichloride was purchased from Arora Matthey. 4′-Methyl-2,2′-bipyridyline-4-carbaldehyde [21], *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ [32] and *cis*-$[Os(bpy)_2Cl_2]\cdot 2H_2O$ [33] were prepared according to the literature methods.

2.2. Physical measurements

Elemental analysis (C, H, N) were performed on a model 2400 Perkin-Elmer elemental analyzer. FAB mass spectra were recorded on a JEOL SX 102/DA-6000 mass spectrometer using xenon (6 kV, 10 mA) as the FAB gas. The accelerating voltage was 10 kV and the spectra were recorded at room temperature. *m*-Nitrobenzyl alcohol was used as the matrix. Infrared (IR) spectra were recorded on a Perkin-Elmer spectrum GX FT-IR spectrophotometer as KBr pellets. ^{1}H NMR spectra were recorded on a model DPX 200 Bruker FT-NMR instrument. The UV–Vis spectra were recorded on a model 8452A Hewlett-Packard diode array spectrophotometer. NIR spectra were recorded on a model UV-3101PC UV–Vis–NIR (Shimadzu) spectrophotometer. Electrochemical experiments were performed with a model 273A EG&G Princeton Applied Research potentiostat. All experiments were conducted in an argon atmosphere with a glassy-carbon working electrode, SCE electrode as reference and 0.1 mol dm^{-3} $[NBu^n_4][BF_4]$ as supporting electrolyte. Luminescence spectra were recorded on a Perkin-Elmer LS-50B spectrofluorimeter in acetonitrile and in methanol–ethanol (4:1) solutions at room temperature.

Flash photolysis experiments were carried out with an Applied Photophysics SP-Quanta Ray GCR-2 (10) Nd–YAG laser using the third harmonic output of 355/532 nm with a pulse width of 8 ns. A DHS2 dichroic harmonic separator was used to separate the third harmonic from the second harmonic and the fundamental of the Nd–YAG laser. The output was directed towards the sample using prisms. The oscilloscope is optically triggered using the photodiode. The monitoring source was a 250 W pulsed xenon lamp which was focused on the sample, at right-angles to the incident laser beam, using lenses and an adjustable iris positioned in front of the sample holder. The beam emerging from the sample was focused on to a Czerny Turner monochromator using a pair of lenses. The monochromator was fitted with a stepper motor control in order to drive the monochromator to the desired wavelength. The detection was carried out using a Hamamatsu R-928 photomultiplier tube. The signals were captured using a Hewlett-Packard 54201A 100 MHz digital storage oscilloscope. The data were transferred to the computer and analyzed using a software developed in-house. Experiments were performed in acetonitrile/methanol–ethanol (4:1) solutions under argon atmosphere.

2.3. Synthesis of ligands

2.3.1. Preparation of 1,4-bis[4-(4′-methyl)-2,2′-bipyridyl)-imine]benzene (BL^1)

The compound 4′-methyl-2,2′-bipyridyline-4-carbaldehyde (mbca) (396 mg, 2 mmol) and *p*-phenylenediamine (108 mg, 1 mmol) were added to ethanol (25 cm^3) and the mixture was heated at reflux for 8 h. During reflux a yellow microcrystalline compound was separated from the solution. After isolation of this compound by filtration, the filtrate was kept at room temperature over night, during which another crop of the same compound separated from the solution. The combined product was washed with ethanol and diethyl ether and dried. Yield 82%. Found: C, 76.67; H, 5.28; N, 17.74. Calc. for $C_{30}H_{24}N_6$: C, 76.90; H, 5.16; N, 17.93%. IR (cm^{-1}): 1621 ($\nu_{C=N}$). ^{1}H NMR ($CDCl_3$): δ 2.48 (s, 6H), 7.20 (dd, 2H, J = 5.0, 1.0 Hz), 7.37 (s, 4H), 7.90 (dd, J = 5.3, 1.3 Hz), 8.31 (s, 2H), 8.60 (d, 2H, J = 5 Hz), 8.63 (s, 2H), 8.82 (d, 2H, J = 4.4 Hz), 8.83 (s, 2H).

2.3.2. Preparation of [4-(4′-methyl)-2,2′-bipyridyl)imine]-4-aminobenzene (L^1)

The compound 4′-methyl-2,2′-bipyridyline-4-carbaldehyde (198 mg, 1 mmol) was dissolved in ethanol (4 cm^3) at ~60°C and the hot solution was added dropwise to a hot (~60°C) ethanolic solution (4 cm^3) of *p*-phenylenediamine (130 mg, 1.2 mmol) and the mixture was kept at the same temperature for 0.5 h, during which shining yellow crystals were deposited. The compound was isolated by filtration and washed with ethanol and diethyl ether. Yield 70%. Found: C, 74.65; H, 5.42; N, 19.18. Calc. for $C_{18}H_{16}N_4$: C, 74.98; H, 5.59; N, 19.43%. IR (cm^{-1}): 3435, 3317, 3207 (ν_{NH_2}), 1631 ($\nu_{C=N}$). ^{1}H NMR ($CDCl_3$): δ 2.46 (s, 3H), 3.80 (s, 2H),

6.73 (d, 2H, $J=8.0$ Hz), 7.17 (d, 1H, $J=4.2$ Hz), 7.24 (d, 2H, $J=8.2$ Hz), 7.86 (d, 1H, $J=4.2$ Hz), 8.27 (s, 1H), 8.57 (d, 1H, $J=6.0$ Hz), 8.59 (s, 1H), 8.72 (s, 1H), 8.76 (d, 1H, $J=6.0$ Hz).

2.3.3. Preparation of 4,4′-bis[4-(4′-methyl)-2,2′-bipyridyl)-imine]diphenylene (BL^2)

This ligand was synthesized following the same procedure as described for BL^1. The only difference is that *p,p′*-diphenylenediamine was taken instead of *p*-phenylenediamine. Yield 76%. Found: C, 79.09; H, 5.15; N, 15.11. Calc. for $C_{36}H_{28}N_6$: C, 79.39; H, 5.18; N, 15.43%. IR (cm^{-1}): 1626 ($\nu_{C=N}$). ^1H NMR ($CDCl_3$): δ 2.48 (s, 6H), 7.20 (dd, 2H, $J=4.3, 1.3$ Hz), 7.39 (d, 4H, $J=8.4$ Hz), 7.72 (d, 4H, $J=8.4$ Hz), 7.92 (dd, 2H, $J=5.0, 1.5$ Hz), 8.29 (s, 2H), 8.60 (d, 2H, $J=4.8$ Hz), 8.75 (s, 2H), 8.81 (s, 2H), 8.83 (d, 2H, $J=5.2$ Hz).

2.3.4. Preparation of [4-(4′-methyl)-2,2′-bipyridyl)imine]-4′-aminodiphenylene (L^2)

This ligand was synthesized following the same procedure as described for L^1. The only difference is that *p,p′*-diphenylenediamine was taken instead of *p*-phenylenediamine. Yield 70%. Found: C, 78.60; H, 5.59; N, 15.21. Calc. for $C_{24}H_{20}N_4$: C, 79.09; H, 5.53; N, 15.37%. IR (cm^{-1}): 3414, 3340, 3231 (ν_{NH_2}), 1639 ($\nu_{C=N}$). ^1H NMR ($CDCl_3$): δ 2.47 (s, 3H), 3.77 (s, 2H), 6.78 (d, 2H, $J=8.4$ Hz), 7.21 (d, 1H, $J=4.2$ Hz), 7.34 (d, 2H, $J=8.4$ Hz), 7.46 (d, 2H, $J=8.4$ Hz), 7.61 (d, 2H, $J=8.4$ Hz), 7.90 (d, 1H, $J=4.2$ Hz), 8.29 (s, 1H), 8.58 (d, 1H, $J=6.0$ Hz), 8.63 (s, 1H), 8.79 (s, 1H), 8.81 (d, 1H, $J=6.0$ Hz).

2.4. Synthesis of metal complexes

*2.4.1. Preparation of $[(bpy)_2Ru(L^1)][PF_6]_2\cdot H_2O$ (**1**)*

A mixture of *cis*-$Ru(bpy)_2Cl_2\cdot 2H_2O$ (520 mg, 1 mmol) and L^1 (288 mg, 1 mmol) in ethanol–water (2:1, 45 cm^3) was refluxed for 10 h. The volume of the reaction mixture was reduced to about 20 cm^3 by rotary evaporation, then an aqueous solution (10 cm^3) of NH_4PF_6 (815 mg, 4 mmol) was added. The precipitate was filtered off and washed with water and diethyl ether. The compound was purified by column chromatography packed with neutral alumina, with acetonitrile–toluene (2:1) as eluent. The solvent was removed by rotary evaporation and the residue was redissolved in a minimum volume (10 cm^3) of acetonitrile and precipitated by the addition of diethyl ether. The precipitate was filtered off and vacuum dried. Yield 75%. Found: C, 45.02; H, 3.20; N, 10.92. Calc. for $C_{38}H_{34}F_{12}N_8OP_2Ru$: C, 45.20; H, 3.39; N, 11.09%. IR (cm^{-1}): 3409, 3221 (ν_{NH_2}), 1619 ($\nu_{C=N}$), 841 (PF_6^-). ^1H NMR (CD_3CN): δ 2.56 (s, 3H), 4.53 (s, 2H), 6.71 (d, 2H), 7.27 (m, 1H), 7.30 (d, 2H), 7.40 (m, 4H), 7.54 (d, 1H), 7.67–7.81 (m, 6H), 8.05 (t, 4H), 8.49 (d, 5H), 8.69 (s, 1H), 8.87 (s, 1H).

*2.4.2. Preparation of $[(bpy)_2Os(L^1)][PF_6]_2\cdot H_2O$ (**2**)*

cis-$Os(bpy)_2Cl_2\cdot 2H_2O$ (305 mg, 0.5 mmol) and L^1 (144 mg, 0.5 mmol) were refluxed in 2-methoxyethanol–water (4:1, 20 cm^3) for 8 h. The volume of the solution was reduced to dryness by rotary evaporation and the residue was dissolved in water (5 cm^3). The solution was filtered and to the filtrate an aqueous solution (5 cm^3) of NH_4PF_6 (408 mg, 2 mmol) was added. The precipitate thus obtained was isolated by filtration and washed with water and diethyl ether. The complex was purified following the same procedure as described for complex **1**. Yield 62%. Found: C, 41.28; H, 3.20; N, 10.06. Calc. for $C_{38}H_{34}F_{12}N_8OP_2Os$: C, 41.54; H, 3.12; N, 10.20%. IR (cm^{-1}): 3408, 3220 (ν_{NH_2}), 1618 ($\nu_{C=N}$), 843 (PF_6^-). ^1H NMR (CD_3CN): δ 2.65 (s, 3H), 4.44 (s, 2H), 6.70 (d, 2H), 7.09 (m, 2H), 7.27–7.33 (m, 4H), 7.42 (d, 2H), 7.52–7.59 (m, 6H), 7.78 (t, 4H), 8.45 (s, 1H), 8.47 (d, 4H), 8.68 (s, 1H), 8.83 (s, 1H).

*2.4.3. Preparation of $[(bpy)_2Os(mbca)][PF_6]_2\cdot H_2O$ (**3**)*

This complex was synthesized by the reaction of *cis*-$Os(bpy)_2Cl_2\cdot 2H_2O$ (305 mg, 0.5 mmol) and 4′-methyl-2,2′-bipyridyline-4-carbaldehyde (mbca) (100 mg, 0.5 mmol) in 2-methoxyethanol following the same procedure as described for compound **2**. Yield 80%. Found: C, 37.90; H, 2.63; N, 8.16. Calc. for $C_{32}H_{28}F_{12}N_6O_2P_2Os$: C, 38.10; H, 2.80; N, 8.33%. IR (cm^{-1}): 1704 ($\nu_{C=O}$), 841 (PF_6^-). ^1H NMR (CD_3CN): δ 2.67 (s, 3H), 7.28–7.35 (m, 5H), 7.57 (d, 1H), 7.60–7.71 (m, 5H), 7.87–7.95 (m, 5H), 8.49 (d, 5H), 8.79 (s, 1H), 10.11 (s, 1H).

*2.4.4. Preparation of $[(bpy)_2Ru\text{-}BL^1\text{-}Ru(bpy)_2][PF_6]_4\cdot 2H_2O$ (**4**)*

A mixture of *cis*-$Ru(bpy)_2Cl_2\cdot 2H_2O$ (260 mg, 0.5 mmol) and BL^1 (117 mg, 0.25 mmol) in ethanol–water (2:1, 30 cm^3) was refluxed for 16 h. The volume of the reaction mixture was reduced to about 10 cm^3 by rotary evaporation and filtered. To the filtrate an aqueous solution (5 cm^3) of NH_4PF_6 (408 mg, 2 mmol) was added. The orange precipitate thus obtained was filtered off and washed with water and diethyl ether. The compound was dissolved in a minimum volume of acetonitrile (10 cm^3) in a small beaker which was kept inside a bottle containing diethyl ether (50 cm^3). The bottle was closed and vapor diffusion was allowed for 48 h. The microcrystalline compound thus deposited was collected by filtration and the recrystallization procedure was repeated three times, which gave complex **4** in pure form. Yield 68%. Found: C, 43.76; H, 3.29; N, 10.07. Calc. for $C_{70}H_{60}F_{24}N_{14}O_2P_4Ru_2$: C, 43.98; H, 3.16; N, 10.26%. IR (cm^{-1}): 1620 ($\nu_{C=N}$), 842 (PF_6^-). ^1H NMR (CD_3CN): δ 2.57 (s, 6H), 7.28 (d, 2H), 7.37–7.44 (m, 8H), 7.49 (s, 4H), 7.72–7.89 (m, 12H), 8.06 (t, 8H), 8.51 (m, 12H), 8.77 (s, 2H), 8.94 (s, 2H).

*2.4.5. Preparation of $[(bpy)_2Os\text{-}BL^1\text{-}Os(bpy)_2][PF_6]_4\cdot H_2O$ (**5**)*

This complex was synthesized by the reaction of *cis*-$Os(bpy)_2Cl_2\cdot 2H_2O$ (305 mg, 0.5 mmol) and BL^1 (117 mg,

0.25 mmol) in ethanol–water (2:1, 30 cm^3) following the same procedure as described for compound **4**. Yield 60%. Found: C, 40.34; H, 2.93; N, 9.57. Calc. for $C_{70}H_{58}F_{24}N_{14}OP_4Os_2$: C, 40.59; H, 2.82; N, 9.47%. IR (cm^{-1}): 1620 ($\nu_{C=N}$), 843 (PF_6^-). ^1H NMR (CD_3CN): δ 2.65 (s, 6H), 7.20 (d, 2H), 7.28–7.36 (m, 8H), 7.48 (s, 4H), 7.61–7.71 (m, 12H), 7.87 (t, 8H), 8.48 (d, 10H), 8.68 (s, 2H), 8.75 (s, 2H), 8.90 (s, 2H).

2.4.6. Preparation of $[(bpy)_2Ru\text{-}BL^1\text{-}Os(bpy)_2][PF_6]_4\cdot H_2O$ (6)

A mixture of complexes **1** (252 mg, 0.25 mmol) and **3** (252 mg, 0.25 mmol) was dissolved in acetonitrile (15 cm^3); ethanol (50 cm^3) was added to the solution and heated at reflux for 8 h. The volume of the solution was reduced to about 20 cm^3 and an aqueous solution (10 cm^3) of NH_4PF_6 (815 mg, 4 mmol) was added. The precipitate was filtered off and washed with water and diethyl ether. The product was purified following the same procedure as described for compound **4**. Yield 60%. Found: C, 42.62; H, 2.92; N, 9.59. Calc. for $C_{70}H_{58}F_{24}N_{14}OP_4RuOs$: C, 42.41; H, 2.95; N, 9.89%. IR (cm^{-1}): 1620 ($\nu_{C=N}$), 843 (PF_6^-). ^1H NMR (CD_3CN): δ 2.56 (s, 3H), 2.65 (s, 3H), 7.27–7.43 (m, 10H), 7.48 (s, 4H), 7.67–7.86 (m, 12H), 8.05 (t, 8H), 8.34–8.52 (m, 12H), 8.76 (s, 1H), 8.79 (s, 1H), 8.91 (s, 1H), 8.96 (s, 1H).

2.4.7. Preparation of $[(bpy)_2Ru(L^2)][PF_6]_2\cdot H_2O$ (7)

This complex was prepared following the same procedure as described for compound **1**. Yield 78%. (Found: C, 48.38; H, 3.63; N, 10.21. Calc. for $C_{44}H_{38}F_{12}N_8OP_2Ru$: C, 48.67; H, 3.53; N, 10.32%. IR (cm^{-1}): 3411, 3220, (ν_{NH_2}), 1619 ($\nu_{C=N}$), 841 (PF_6^-). ^1H NMR (CD_3CN): δ 2.57 (s, 3H); 4.32 (s, 2H); 6.73 (d, 2H); 7.24 (d, 2H), 7.30–7.48 (m, 7H), 7.56 (d, 2H), 7.66–7.84 (m, 7H), 8.07 (t, 4H), 8.54 (d, 5H), 8.82 (s, 1H), 9.01 (s, 1H).

2.4.8. Preparation of $[(bpy)_2Ru\text{-}BL^2\text{-}Ru(bpy)_2][PF_6]_4\cdot 2H_2O$ (8)

This complex was synthesized by the reaction of *cis*-$Ru(bpy)_2Cl_2\cdot 2H_2O$ and BL^2 following the same procedure as described for compound **4**. The complex was purified by column chromatography packed with neutral alumina and eluted with acetonitrile–toluene (2:1). The solvent of the desired fraction was evaporated to dryness by rotary evaporation and the orange residue was redissolved in acetonitrile and precipitated by addition of diethyl ether. Yield 72%. Found: C, 45.56; H, 3.27; N, 9.74. Calc. for $C_{76}H_{64}F_{24}N_{14}O_2P_4Ru_2$: C, 45.93; H, 3.24; N, 9.87%. IR (cm^{-1}): 1618 ($\nu_{C=N}$), 841 (PF_6^-). ^1H NMR (CD_3CN): δ 2.56 (s, 6H), 7.22–7.41 (m, 14H), 7.53 (d, 2H), 7.62 (d, 2H), 7.73–7.87 (m, 12H), 7.95–8.07 (m, 8H), 8.34–8.51 (m, 12H), 8.80 (s, 2H), 8.95 (s, 2H).

2.4.9. Preparation of $[(bpy)_2Os\text{-}BL^2\text{-}Os(bpy)_2][PF_6]_4\cdot 2H_2O$ (9)

cis-$Os(bpy)_2Cl_2\cdot 2H_2O$ (305 mg, 0.5 mmol) and BL^2 (136 mg, 0.25 mmol) in 2-methoxyethanol–water (4:1, 20 cm^3) was heated under reflux for 12 h in an inert atmosphere. The volume of the solution was reduced to dryness under vacuum and the residue was dissolved in water (5 cm^3), filtered and to the filtrate aqueous NH_4PF_6 (408 mg, 2 mmol) was added. The precipitate thus formed was isolated by filtration and washed with water and diethyl ether. The compound was purified following the same procedure as described for compound **8**. Yield 60%. Found: C, 42.36; H, 3.08; N, 8.96. Calc. for $C_{76}H_{64}F_{24}N_{14}O_2P_4Os_2$: C, 42.15; H, 2.98; N, 9.05%. IR (cm^{-1}): 1618 ($\nu_{C=N}$), 841(PF_6^-). ^1H NMR (CD_3CN): δ 2.67 (s, 6H), 7.20–7.55 (m, 18H), 7.60–7.74 (m, 12H), 7.84–8.03 (m, 8H), 8.47–8.51 (m, 12H), 8.78 (s, 2H), 8.91 (s, 2H).

2.4.10. Preparation of $[(bpy)_2Ru\text{-}BL^2\text{-}Os(bpy)_2][PF_6]_4\cdot H_2O$ (10)

This complex was prepared by the reaction of compounds **7** and **3** following the same procedure as described for compound **6**. Purification of this complex was performed on an alumina column, similar to that described for compound **8**. Yield 68%. Found: C, 44.14; H, 3.09; N, 9.35. Calc. for $C_{76}H_{62}F_{24}N_{14}OP_4RuOs$: C, 44.34; H, 3.03; N, 9.53%. IR (cm^{-1}): 1618 ($\nu_{C=N}$), 841 (PF_6^-). ^1H NMR (CD_3CN): δ 2.58 (s, 3H), 2.67 (s, 3H), 7.20–7.55 (m, 18H), 7.64–7.75 (m, 8H), 7.81–7.85 (m, 8H), 8.03–8.11 (m, 4H), 8.28–8.51 (m, 12H), 8.79 (s, 1H), 8.81 (s, 1H), 8.92 (s, 1H), 8.97 (s, 1H).

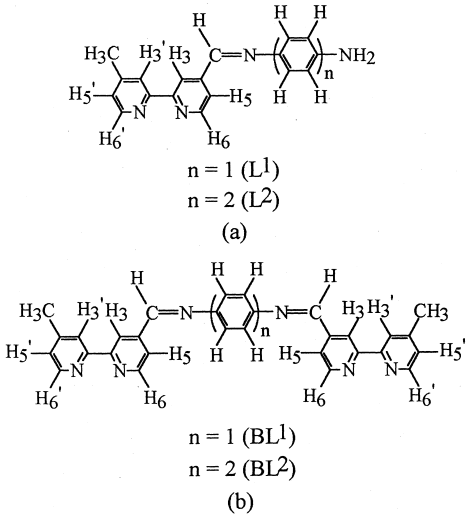
2.5. Oxidation with Ce(IV)

Ru(II) complexes (1×10^{-5} M) were oxidized in 2:3 (v/v) acetonitrile–nitric acid (6%) solution by adding ammonium cerium(IV) nitrate (5×10^{-3} M) dissolved in HNO_3 (6%). The Os(II) complexes were oxidized in acetonitrile–water (5:1) solution following a similar procedure to that described for Ru(II). The oxidation was performed by monitoring the change in absorbance in the visible region.

3. Results and discussion

3.1. Synthesis of ligands

The ligands BL^1 and BL^2 were synthesized by the reaction of 4′-methyl-2,2′-bipyridyline-4-carbaldehyde with *p*-phenylenediamine/4,4′-diphenylenediamine (1:2 molar ratio) in refluxing ethanol. In both cases yellow crystalline compounds were obtained in pure form with excellent yield. For L^1 and L^2 the reaction between aldehyde and diamines (1:1 molar ratio) was conducted under mild conditions of 60°C for 0.5 h; at this temperature L^1 and L^2 were almost insoluble in ethanol and separated from the solution as shin-



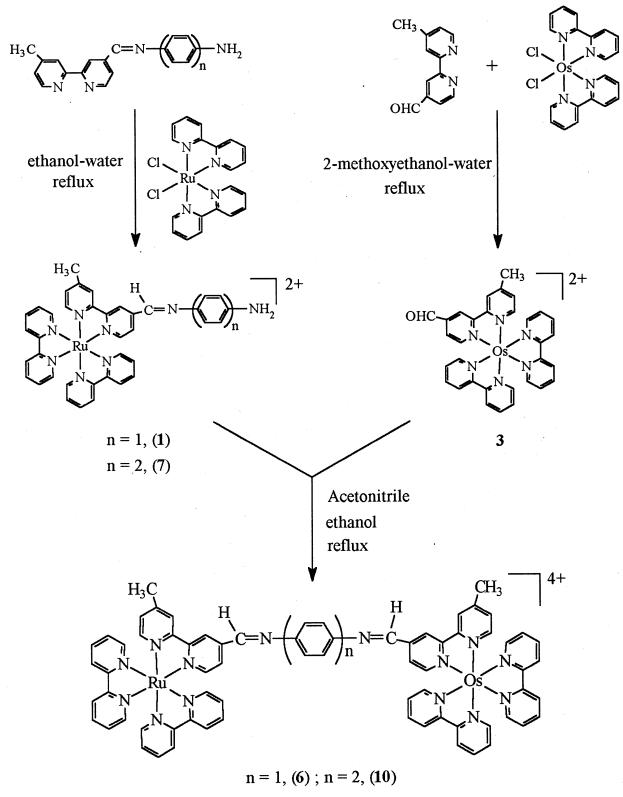


Fig. 1. Ligands used in the preparation of mononuclear (a) and binuclear (b) complexes.

ing yellow crystals. It may be noted that the experimental conditions for the synthesis of L^1 and L^2 is important; reverse sequence of addition of reactants, higher temperature and/or longer reaction time yielded significant amounts of bridging ligand (BL^1/BL^2), for which the separation from L^1/L^2 is difficult. All four ligands gave satisfactory elemental analysis. The ligands L^1, L^2, BL^1 and BL^2 are shown in Fig. 1.

3.2. Synthesis of metal complexes

The mononuclear and homodinuclear metal complexes were prepared by the reaction of the building blocks *cis*-$[M(bpy)_2Cl_2]\cdot 2H_2O$ [M = Ru(II), Os(II)] with appropriate ligand in refluxing ethanol–water or 2-methoxyethanol–water followed by the addition of NH_4PF_6. But we found difficulty for the synthesis of pure heterodinuclear complexes following the conventional route, which involves the preparation of mononuclear complexes, $[Ru(bpy)_2BL^1]^{2+}$/$[Ru(bpy)_2BL^2]^{2+}$, followed by the reaction of this mononuclear complex with *cis*-$[Os(bpy)_2Cl_2]\cdot 2H_2O$. We noticed that $[Ru(bpy)_2BL^1]^{2+}/[Ru(bpy)_2BL^2]^{2+}$, obtained by the reaction of *cis*-$[M(bpy)_2Cl_2]$ and BL^1/BL^2, were always contaminated with a small amount of the binuclear complex, separation of which was difficult. We synthesized heterodinuclear complexes following a different route, which is shown in Scheme 1. This procedure ruled out the possibility of contamination by the homodinuclear complex as impurity. Most of the complexes were purified by column chromatography using deactivated alumina (5% H_2O) as packing material and acetonitrile–toluene mixture as eluent. A few complexes were purified by repeated crystallization following the vapor diffusion method. The homo- and heterodinuclear complexes are shown in Fig. 2.

All complexes gave satisfactory C, H and N analysis. The FAB mass data of the dinuclear complexes are shown in Table 1. Elemental analysis and FAB mass data confirmed the composition of the complexes.

Scheme 1.

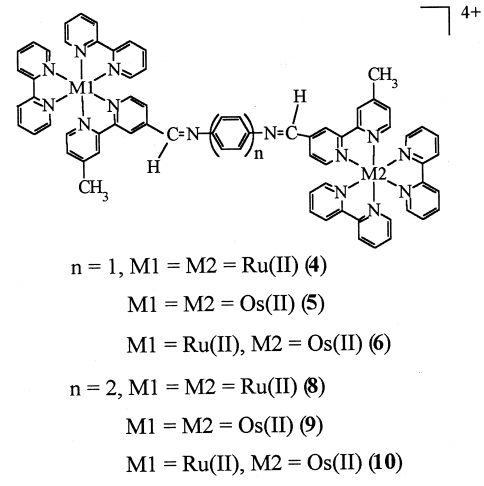

Fig. 2. Structural drawings of homo- and heterodinuclear complexes of Ru(II) and Os(II).

3.3. Infrared spectra

The IR spectra of the ligands L^1 and L^2 exhibit three peaks in the region 3207–3435 cm^{-1}, which are assigned to N–H stretchings of the NH_2 group [34]. The $\nu_{(C=N)}$ vibrational peak of all four ligands appeared in the range 1620–1640 cm^{-1} [34]. In the metal complexes the NH_2 and $\nu_{(C=N)}$ peaks appeared in the range 3220–3408 and 1618–1620 cm^{-1}, respectively. Complex **3** shows a strong band at 1704 cm^{-1}, which is assigned to $\nu_{(C=O)}$ [35]. All complexes show a strong band in the region 841–843 cm^{-1} due to PF_6^-.

3.4. ^1H NMR spectra

The ^1H NMR spectra of the ligands and their metal complexes were recorded in $CDCl_3/CD_3CN$ and the data are presented in Section 2. The CH_3 protons of all ligands appeared as a singlet in the region δ 2.46–2.48 [21]. The NH_2 of L^1 and L^2 appeared as a broad singlet at δ 3.80 and 3.77, respectively [34]. In all ligands the resonances for protons of the two pyridyl rings of the bipyridyl moieties are divided into two sets [21]. As CH_3 is an electron-donating group and –CH=N– is an electron-deficient center, the more shielded sets of resonances are due to the protons associated with pyridyl rings having CH_3 substituents. Therefore, the signals at δ 7.30 (dd), 8.60 (d) and 8.63 (s) of BL^1 are assigned to H_6', H_5' and H_3' (see Fig. 1 for numbering scheme), respectively. The other set of signals at δ 7.90 (dd), 8.82 (d) and 8.83 (s) are due to H_6, H_5 and H_3 protons, respectively. The assignment of these signals is made on the basis of multiplicity, coupling constants and other reported data in the literature [36]. The ligand BL^2 exhibits similar spectra except for two doublets at δ 7.39 (J = 8.4 Hz) and 7.72 (J = 8.4 Hz), which appeared for biphenyl moiety in place of a singlet at δ 7.34 for phenylene moiety of BL^1. The ^1H NMR data thus suggest that the two halves of the bridged ligands are magnetically identical in solution. The ligands L^1 and L^2 are unsymmetrical and, therefore, the phenyl moiety of L^1 appeared as two doublets at δ 6.73 (J = 8.0 Hz) and 7.24 (J = 8.2 Hz); the biphenylene moiety of L^2 showed four doublets at δ 6.78, 7.34, 7.46 and 7.61 (J = 8.4 Hz for all four doublets). The most shielded doublets can be assigned to the CH *ortho* to NH_2 (on the basis of ^1H NMR data of free diamines).

In the mononuclear and homodinuclear complexes the CH_3 protons exhibited a singlet, whereas in the dinuclear complexes it showed two singlets. The CH_3 attached to Ru(II) and Os(II) chromophores appeared in the ranges δ 2.56–2.58 and δ 2.65–2.67, respectively. The low-field shift of CH_3 resonances of all complexes compared to free ligands is due to ligand-to-metal σ donation, which resulted in deshielding of protons associated with pyridyl rings [37]. Complexes **1**, **2** and **7** show a broad singlet at δ 4.53, 4.44 and 4.32, respectively, which are assigned to NH_2. The CHO of compound **3** appeared as a singlet at δ 10.11.

In the aromatic region, a large number of peaks overlapped; exact assignment of peaks is therefore extremely difficult without performing other NMR techniques. Octahedral metal centers with bidentate ligands generally show stereoisomerism [38,39]; thus, in this case, there is a strong possibility of formation of stereoisomers. The resonance of CH_3 for different stereoisomers may show the same or very close (not resolved) chemical shifts, as they are in remote positions with respect to the metal centers. But the protons, which are close to the coordinated nitrogens, are expected to show different chemical shifts for different stereoisomers [39]. This isomerism, therefore, gives additional complication to the ^1H NMR, in particular the aromatic region. However, from the analysis of the spectra it appears that in all complexes H_3 protons appeared as doublets in the region δ 8.3–8.5, H_4 as doublets of doublets (dd) in the region δ 7.6–7.9; H_5 and some of the H_6 protons as multiplets (overlapped) in the region δ 7.2–7.4 (usual numbering of bpy is used). The phenylene protons of complexes **4**–**6** exhibit a singlet at δ 7.48. The biphenylene moiety of complexes **8**–**10** show two doublets in the region δ 7.5–7.7. In general, after coordination chemical shifts of most of the protons, viz. H_3, H_4 and H_5 of bpy and substituted bpy, of the ligands show slight down-field shift, as expected because of ligand-to-metal σ donation [37,39]. But H_6 shows significant up-field shift, which is definitely due to ring current effect. The facing of H_6 protons towards the ring current zone of the pyridyl ring of the neighboring ligands results in strong shielding effect on these protons [37,39,40].

3.5. UV–Vis spectra

The absorption spectra of all complexes were recorded in acetonitrile, and the data are summarized in Table 2. The spectra of complexes **4**–**6** are illustrated in Fig. 3. The low-energy absorption bands in the visible region (450–700) of all complexes are due to metal-to-ligand charge transfer

Table 2

(MLCT) transitions ($d\pi\rightarrow\pi^*$) [9,21,26,29]. For Os(II) complexes the broad band in the 600–700 nm region is due to the spin forbidden MLCT transitions [9,29,36,41]. Each metal ion is coordinated to two bpy ligands and a substituted bpy moiety of the bridging ligand; therefore, two types of MLCT bands, $d\pi\rightarrow\pi^*$ (BL) and $d\pi\rightarrow\pi^*$ (bpy), are expected. These bands are closely spaced and overlapped. However, it is observed that the λ_{max} of the MLCT bands of the complexes containing BL^1 are significantly red shifted (10–20 nm) compared to that of the similar complexes containing BL^2. This observation is consistent with the fact that the MLCT bands move to the lower energy as the metal–metal separation decreases [42]. This behavior suggests that the acceptor orbital of the MLCT transition is located on the substituted bpy moieties belonging to the bridging ligand. The electrochemical studies also suggested that the first reduction is associated with the bridging ligand. Therefore, the lowest energy spin allowed MLCT bands can be assigned to $d\pi\rightarrow\pi^*$ (BL). The high-energy bands which appeared around 290 and 246 nm are ligand-centered charge transfer (CT) due to $\pi\rightarrow\pi^*$ transitions [9,21,29]. There are slight differences in the λ_{max} of MLCT bands [6 nm for Ru(II) and 2 nm for Os(II)] between dinuclear complexes and the corresponding mononuclear model complexes, indicating weak or no electronic interaction between the metal centers [29,30].

3.6. Electrochemistry

The square-wave and cyclic voltammograms of all new complexes were recorded in acetonitrile and the results are listed in Table 3. Cyclic voltammograms of complexes **9** and **10** are shown in Fig. 4. An analysis of the electrochemical data revealed that: (1) Ru(II) → Ru(III) oxidation occurred in the potential range +1.20 to +1.23 V; (2) Os(II) → Os(III) oxidation occurred in the potential range +0.75 to +0.82 V; (3) in the homodinuclear complexes two one-electron metal-centered oxidations take place at closely spaced (indistinguishable) potentials; (4) heterodinuclear complexes exhibit two one-electron oxidations at well-separated potentials; (5) Os(II) is easier to oxidize than Ru(II); (6) all reductions are ligand-based and occurred in the potential range −1.28 to −1.90 V.

Among three ligand-based reductions, the first two are one-electron processes and the third wave is a closely spaced two one-electron processes (based on current height). Similar reductions pattern have also been noted in many binuclear complexes [21,28,43]. Each metal-containing unit of these complexes can be viewed as a mixed-ligand complex as the coordination sites of the bridging ligands have properties different to those of bpy because of the presence of substituents at 4 and 4′ positions. The methyl group is electron donating; therefore, methyl-substituted bpy reduces at a more negative potential compared with bpy [16,44,45]. However, the bridging unit between the chromophores also influences the reduction potentials [29]. It has been observed that, if the bridging unit is a saturated aliphatic chain ($-CH_2-CH_2-$), it does not affect reduction potential significantly [4]. But an unsaturated bridging unit, in particular, with complete conjugation between two chromophores shifts the reduction peak significantly to a less negative potential even in the presence of methyl substituent in the bpy units [4,21]. It seems that, in the dinuclear complexes, the positive shift of the first reduction potential by conjugation effect of the bridging unit dominates over the negative shift due to the methyl substituent in

Scheme 2.

the bpy moieties. Therefore, the first two one-electron reductions in the dinuclear complexes are assigned to the reduction of substituted bpy units of the bridging ligands, BL^1/BL^2. The third peak corresponding to two unresolved one-electron reductions is associated with bpy ligands. The sequential electron transfer processes in the heterodinuclear complexes are illustrated in Scheme 2. It may be noted that there are no significant differences between oxidation potentials of the dinuclear complexes and corresponding mononuclear model complexes containing L^1 and L^2 ligands. Ligand-based first reduction of dinuclear complexes, however, show slight anodic shift. These observations indicate a weak or no electronic interaction between the chromophores.

3.7. Mixed-valence properties

The mixed-valence species were generated by partial oxidation of dinuclear complexes by the addition of ammonium cerium(IV) nitrate dissolved in 6% HNO_3. The oxidation of Ru(II) was carried out in deoxygenated 2:3 (v/v) acetonitrile–nitric acid (6%) solution, whereas oxidation of Os(II) was performed in acetonitrile–water (5:1, v/v) solution under inert atmosphere. Addition of a standard Ce(IV) solution caused remarkable changes in the MLCT bands. For homodinuclear complexes the MLCT bands decreased linearly with increasing addition of oxidant. However, on exposing the solution to air the MLCT band starts increasing and within 10–15 min this band returns to its original position. This observation indicates that the oxidation and reduction processes are reversible and the complexes remain intact when metal ions are oxidized. For heterodinuclear complexes, addition of one equivalent of oxidant resulted in the disappearance of Os-based absorption, as expected because Os(II) oxidizes at a lower potential than Ru(II). For all mixed-valence species [Ru(II)–Ru(III) and Ru(II)–Os(III)] absorption spectra up to 1400 nm were recorded but no intervalence charge transfer bands with significant ε value were observed. Similar observations were also noted in homo- and heterobimetallic complexes containing bicyclo-

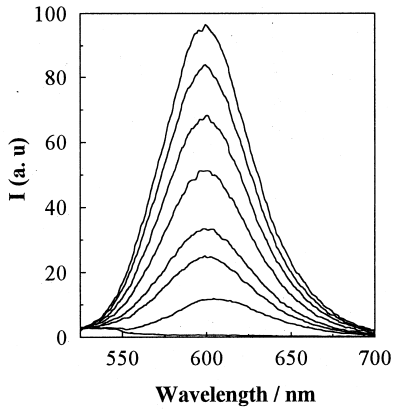

Fig. 5. Change in the emission spectra for an acetonitrile–nitric acid (6%) (2:3; v/v) solution of complex **8** upon addition of ammonium cerium(IV) nitrate.

octane as spacer [29]. But energy transfer took place in heterodinuclear complex of Ru(II) and Os(II) [29].

Oxidation of the dinuclear complexes caused a decrease in the luminescence intensity. In heterodinuclear complexes, addition of one equivalent of oxidant resulted in complete quenching of Os-based luminescence. For homodinuclear complexes, the intensity of luminescence decreased with increasing the amount of added oxidant, and completely disappeared when two equivalents were added, as shown in Fig. 5.

3.8. Luminescence

All of the Ru(II) and/or Os(II) complexes exhibit the characteristic MLCT emission band at room temperature in acetonitrile and in MeOH–EtOH (4:1) solutions. The luminescence data are summarized in Table 4. The band intensity in acetonitrile solution was significantly low compared with that in MeOH–EtOH mixture with equimolar solutions. In acetonitrile solution λ_{max} (em) shows a slight red shift [2–5 nm for Ru(II) and 6–10 nm for Os(II)] compared to that in MeOH–EtOH solution.

Emission life-times of all complexes were measured at room temperature in de-aerated acetonitrile and 4:1 (v/v) MeOH–EtOH solution; the data are presented in Table 4. Luminescence decay of compound **4** in acetonitrile is illustrated in Fig. 6. There is no significant difference in life-time in acetonitrile and MeOH–EtOH solutions. The life-times of mononuclear and homodinuclear complexes are significantly high compared with some other reported data for dinuclear complexes bridged by saturated organic moieties such as bicyclo-2,2,2-octane, adamantane and diadamantane [4,29–31]. But our values are comparable to those reported by Meyer's group [21] and Schmehl's group [26] for some dinuclear complexes with ethene and 1,4-ethynyl benzene as spacers, respectively. This long life-time can be attributed to delocalization of excited electron across the bridging units to a significant extent [21]. However, in the heterodinuclear complexes, the emission life-time of the Ru-based unit is significantly short. This could be due to the quenching of the Ru-based emission by Os-based unit via energy transfer. The rate constant for energy transfer from Ru-based unit to Os-based unit can be calculated from the equation [3,29]:

$$k_{en} = \frac{1}{\tau} - \frac{1}{\tau^0}$$

where τ and τ^0 are the luminescence life-times of the Ru-based component in the heterodinuclear complex $[(bpy)_2Ru\text{-}BL\text{-}Os(bpy)_2]^{4+}$, and in the homodinuclear model complex $[(bpy)_2Ru\text{-}BL\text{-}Ru(bpy)_2]^{4+}$, respectively. The rate constants for energy transfer thus calculated for the heterodinuclear complexes **6** and **10** are 5.9×10^6 and 3.2×10^6 s^{-1} in acetonitrile and 6.8×10^6 and 3.4×10^6 s^{-1} in MeOH–EtOH (4:1) mixture, respectively. The results indicate that BL^1 transfers electronic energy more efficiently than BL^2. This is obviously due to the short length of BL^1 compared to BL^2. Similar energy transfer processes have been reported for many Ru(II)–Os(II) dinuclear complexes with different type of spacers [29–31]. The rate constants are high ($>1\times10^8$ s^{-1}) when the M–M distance is short

and the spacers provide complete conjugation between the metal centers [4]. Recently it has been reported that in dinuclear Ru(II)–Os(II) complexes with polyphenylene spacers energy transfer takes place even if the metal–metal separation is as great as around 40 Å [9]. It may be noted that even an interaction of a few reciprocal centimeters, which can not be noticed in spectroscopic and electrochemical experiments, is sufficient to cause fast intercomponent energy and electron transfer processes [10,29,30].

The transient absorption difference spectrum of complex **8** in deoxygenated acetonitrile solution is shown in Fig. 7. It was recorded following excitation at 532 nm and after 150 ns of the flash. This spectrum exhibits strong bleaching around 450 nm. This is due to bleach of the MLCT band, found in many other Ru(II) complexes [8,21,23]. It also shows a weak positive absorption band around 530 nm, which could be due to a $\pi_1^* \rightarrow \pi_2^*$ transition of a ligand localized excited state [22].

4. Conclusions

Two novel bridging ligands made of two 4-methyl-2,2′-bipyridyl chelating units separated by rigid spacers having complete conjugations have been synthesized. Homo- and heterodinuclear complexes of these ligands have been prepared and characterized. For the synthesis of heterodinuclear complexes a new synthetic strategy has been employed which eliminated the possibility contamination by homodinuclear complex as impurity. Electrochemical studies and UV–Vis data of these complexes suggest a weak or no interaction between the metal centers. Mixed-valence species of the dinuclear complexes did not show intervalence charge transfer band. However, addition of oxidant gradually decreased luminescence intensity, and the band disappeared when two equivalents of oxidant were added. Laser flash photolysis experiments of the homodinuclear complexes show a long excited state life-time. It appears that the excited electron is delocalized on the bridging ligand. In heterodinuclear complexes, energy transfer takes place from the Ru-based unit to the Os-based unit and the rate constants indicate that BL^1 transfers energy more efficiently than BL^2.

We are grateful to the Department of Science and Technology (DST), Government of India, for the financial support. A.K.B. gratefully acknowledges CSIR for awarding a Senior Research Fellowship (SRF). Our sincere thanks to Professor P. Natarajan and Dr P. Ramamurthy for providing us with the facilities of the National Center for Ultrafast Processes (NCUFP) to perform laser flash photolysis experiments. Our thanks are due to RSIC (CDRI), Lucknow for providing FAB mass spectra. Our sincere thanks to Dr P.K. Ghosh and Dr R.V. Jasra for their keen interest and encouragement. We also thank Dr S. Muthusamy and Dr P. Subramanian for recording NMR spectra.

Abstract

Syntheses are reported of five rhenium(III) cluster complexes with acetamidate ligands: $[(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2]$ (**1**), $[(C_2H_5)_4N][Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(\mu\text{-}2,3\text{-}NHCOCH_3)]\cdot 2.5(C_4H_{10}O)$ (**2**), $[(C_4H_9)_4N]_2[Re_3Cl_{10}(\mu\text{-}1,2\text{-}NHCOCH_3)]$ (**3**), $[(C_4H_9)_4N]_2[\{Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(OH)\}_2]\cdot 1.7(C_4H_{10}O)$ (**4**), and $(C_4H_9)_4N[Re_3Cl_9(H_2O)(\mu\text{-}1,2\text{-}NHCOCH_3)]\cdot C_3H_6O$ (**5**). The acetamidate ligands in these complexes arise via reactions of acetonitrile–rhenium halide species (either dirhenium or trirhenium chloride clusters) and water. Coordination activates the nitrile to hydrolysis; proton loss and chelation of the acetamidate ligand with displacement of chloride ion leads to the products. Initial formation of a rhenium(III) acetonitrile complex can be assisted using a halide acceptor, Ag^+, to generate an open coordination site on the metal. The reaction with $K_4Mo_2Cl_8$ and Ag^+ ion in acetonitrile gives $Mo_2Cl_4(NCCH_3)_4$ (**6**). The use of MALDI mass spectrometry in support of synthetic efforts and as a characterization tool is described, and the molecular structures of **1**–**6** were established using X-ray crystallography. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Trirhenium(III) clusters; Rhenium clusters; Acetamidate; Dimolybdenum(II); MALDI; Mass spectroscopy

1. Introduction

Determinations of the structures of $Cs_3Re_3Cl_{12}$ [1], $(Re_3Cl_9)_x$ [2] and $K_2Re_2Cl_8\cdot 2H_2O$ [3] and the realization in the early 1960s [4] that a quadruple bond links the metal atoms in $[Re_2Cl_8]^{2-}$ were instrumental in bringing the metal cluster area to the attention of the chemical community. Since then, the chemistry of metal clusters has been intensively investigated. Rhenium cluster species, in particular, have been a subject of numerous studies [5].

Five new complexes of rhenium(III) that contain acetamidate ligands are described in this paper. The ligand in these compounds was formed by nucleophilic attack of water on a coordinated acetonitrile. We also describe synthesis and structural characterization of a molybdenum(II) acetonitrile complex and its failure to undergo a similar reaction.

The use of modern mass spectrometric techniques in this study is also noted. Most projects in the metal cluster area have relied on elemental analysis to determine the formulas of new species and single crystal X-ray diffraction studies to identify structures. Both have limitations: elemental analyses are often not definitive and it is frequently difficult to obtain diffraction quality crystals. In addition, neither technique typically provides the important rapid feedback of information on the progress of the reaction, the presence of intermediates, and the occurrence of secondary products, information that is usually very helpful in guiding a synthetic chemist during a synthetic procedure and often essential for developing mechanistic hypotheses to understand the chemistry involved.

We have been interested in the use of mass spectrometry in the analysis of metal cluster syntheses. Using modern ionization techniques, specifically MALDI (matrix assisted laser desorption/ionization) and ESI (electrospray ionization), it is now possible to obtain data on many compounds not previously amenable to mass spectrometric analysis. Both techniques are easy to use and can potentially provide rapid feedback on, for example, the identity and purity of a crude product from a reaction mixture. Obtaining mass spectra of some representative compounds to establish a database for reference is an important initial step to using these techniques. In this context, we reported on MALDI mass spectra of several rhenium halide clusters in a recent paper [6].

In an initial stage of the investigations described in that paper, ESI spectra were obtained on a well characterized compound, $Cs_3Re_3Cl_{12}$. The procedure selected used acetonitrile as a solvent. These spectra indicated the presence of complexes containing one or two acetamidate ligands in solution. The results led to the investigation described here.

Several papers have appeared recently that describe work related to the results reported here. The first described $[(C_4H_9)_4N]_2[Re_2Cl_6(\mu\text{-}NHCOC_6H_5)]\cdot 0.5CH_2Cl_2$, a compound prepared from $[(C_4H_9)_4N]_2Re_2Cl_8$ and benzonitrile in ethanol [7]. From the same group came the report of a related study that produced the compound $[(C_4H_9)_4N]_2$-$[Re_2Cl_5(\mu\text{-}NHCOCH_3)(\mu\text{-}NC(OH)CH_3)]\cdot 3CH_2Cl_2$ in a similar reaction using acetonitrile. A dppm derivative of this species was also described [8]. Compound **1** reported here is yet a third species that originates from a reaction of this dinuclear precursor. Compound **1** is structurally different from the compounds reported earlier in that it is dimeric via chloride bridges. There are also differences in the synthetic methodology which bear further comment. Finally, a recent paper describing the formation of a tetrarhenium(III) cluster is also noted. Again, the formation of this ligand involved hydration of the acetonitrile being used as a solvent [9].

2. Experimental

2.1. Materials

Literature procedures were used to synthesize $Cs_3Re_3Cl_{12}$ [1] and $K_4Mo_2Cl_8\cdot 2H_2O$ [10]. Silver tetrafluoroborate (98%), $AgPF_6$ (98%), $[(C_4H_9)_4N]_2Re_2Cl_8$, $Re_2(CO)_{10}$, $[(C_4H_9)_4N]Cl\cdot H_2O$ (98%), and various solvents were obtained from commercial sources. In one case a sublimed sample of $(Re_3Cl_9)_x$ was used, but in most syntheses the commercial material (obtained from Pressure Chemical Co.) was used directly without further purification with no obvious problems being encountered. Tetraethylammonium chloride monohydrate (98%) was recrystallized from anhydrous ethanol/diethyl ether prior to use. Acetonitrile and dichloromethane were dried by refluxing over CaH_2 and acetone was dried by refluxing over $CaSO_4$. Tetrahydrofuran, diisopropyl ether, and diethyl ether were dried by refluxing over Na/benzophenone and distilled immediately prior to use. All manipulations were carried out under an atmosphere of dry nitrogen using standard Schlenk techniques.

2.2. X-ray crystallographic and spectroscopic measurements

Crystallographic data were collected on a Siemens P4 diffractometer using a CCD detector. Table 1 provides details on the six structural determinations carried out in this study. Electronic spectra were measured on a Cary 4Bio spectrophotometer. Proton NMR spectra were recorded on a Bruker AC 300 spectrometer operating at 300 MHz. Matrix assisted laser desorption/ionization (MALDI) mass spectra were recorded on a Bruker Reflex II mass spectrometer equipped with a N_2 laser operating with an accelerating voltage of -20 kV and a reflectron voltage of -21.2 kV. Spectra were obtained in the negative ion mode. In the positive mode, only peaks due to the cation were present; no rhenium species were detected. All spectra were obtained using a dithranol as the matrix and are the sum of 50 shots. Samples for MALDI analysis were dissolved in acetonitrile and then mixed with an acetonitrile solution of the matrix prior to deposition onto the target. Ion signals were assigned based on *m/z* values and the match of experimental and calculated isotopic patterns. In this regard, it is noted that the isotopes of rhenium (^{185}Re and ^{187}Re) and chlorine (^{35}Cl and ^{37}Cl) result in highly definitive patterns for rhenium chloride species. ESI spectra were obtained using a Micromass Autospec triple sector mass spectrometer equipped with a Mark II electrospray source. The accelerating and sampling cone voltage were 4000 V, the needle voltage 3948 V, and nitrogen was used as the nebulizer and bath gas. The solution of $Cs_3Re_3Cl_{12}$ in acetonitrile was sprayed at the rate of either 32 or 15 $\mu l\ m^{-1}$.

2.3. Synthesis of $[(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2]$ (**1**)

A 50 ml flask equipped with a Teflon coated stir bar was charged with 28 mg (0.143 mmol) of $AgBF_4$ in 15 ml acetonitrile. Another 50 ml flask was charged with 82 mg (0.072 mmol) of $[(C_4H_9)_4N]_2Re_2Cl_8$, and 10 ml of acetonitrile. Deionized water (0.05 ml, 2.8 mmol) was added to the flask containing $[(C_4H_9)_4N]_2Re_2Cl_8$, then the $AgBF_4$ solution was added. A copious amount of precipitate (AgCl) formed immediately. The reaction mixture was stirred at room temperature for 12 h; then the volatile materials were removed under dynamic vacuum. The residue that remained was extracted with 8 ml of acetonitrile, giving a blue solution and lightly colored solid. The blue solution was filtered three times by means of filter-tipped cannulas, then concentrated to approximately 4 ml and filtered into a Schlenk tube. The solution was carefully layered with diethyl ether. On standing, dark blue prism-shaped crystals of $[(C_4H_9)_4N]_2$-$[\{Re_2Cl_6(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2]$ (**1**) formed (21% yield of the purified product). Initial characterization and assessment of purity was based on a mass spectrum (see Section 3; discussion). The structure of this compound was determined by X-ray crystallography.

Using less than 2 equiv. of silver in this reaction (with otherwise similar conditions) resulted in diminished yields with starting material being recovered.

^1H NMR spectrum (CD_2Cl_2): singlet, 3.05 ppm, plus resonances arising from the tetrabutylammonium cation. Vis (CH_2Cl_2): 651 nm ($\varepsilon = 2780\ M^{-1}\ cm^{-1}$). MALDI MS: *m/z* = 643.6 (calc. 643.74), $[Re_2Cl_6(NHCOCH_3)]^-$; *m/z* = 605.7 (calc. 605.78), $[Re_2Cl_5(NHCOCH_3)]^-$.

*2.4. Synthesis of [$(C_2H_5)_4N$][Re_3Cl_8(μ-1,2-NHCOCH$_3$)(μ-2,3-NHCOCH$_3$)] · 2.5$C_4H_{10}O$ (**2**)*

A 100 ml flask was charged with 185 mg (0.211 mmol) of $(Re_3Cl_9)_x$ and 35 mg (0.211 mmol) of $[(C_2H_5)_4N]Cl \cdot H_2O$. The contents of the flask were dissolved in acetonitrile (50 ml), with immediate formation of Re_3Cl_9(acetonitrile)$_3$ as noted by the dark red color of the solution [11]. Deionized water (0.4 ml, 22 mmol) was added. A 16-gage needle, attached to a dry N_2 line, was introduced through a rubber septum in the sidearm of the flask. The top end of the condenser was connected to a bubbler containing a saturated aqueous solution of $AgNO_3$. The needle was positioned at the bottom of the flask and the solution was purged with N_2 with the exit gas passing through the $AgNO_3$ solution. When the solution was heated to reflux temperature a white precipitate (AgCl) was observed in the $AgNO_3$ bubbler, indicating evolution of HCl. Heating was continued for 2.5 h; at this point the solution was a dark purple color. The solution was concentrated to 10 ml, filtered, and diethyl ether was layered above the acetonitrile solution. Crystals that grew over the course of several days were collected and weighed. The calculated yield of $[(C_2H_5)_4N][Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(\mu\text{-}2,3\text{-}NHCOCH_3)] \cdot 2.5C_4H_{10}O$ (**2**) was 51%. The identity of this sample was established by comparison of the negative ion MALDI mass spectra of this species and a sample with a different cation obtained by the non-systematic procedure described next.

^{1}H NMR spectrum (CD_3CN): 2.32 (s) ppm, plus resonances associated with the cation. UV–Vis (CD_3CN): 316 nm (ε = 4700 M^{-1} cm^{-1}), 325 nm (sh), 447 nm (sh) and 539 nm (ε = 700 M^{-1} cm^{-1}). MALDI MS: *m/z* = 958.7 (calc. 958.68), $[Re_3Cl_8(NHCOCH_3)_2]^-$; *m/z* = 923.8 (calc. 923.8), $[Re_3Cl_7(NHCOCH_3)_2]^-$.

2.5. Alternative synthesis: $[(C_4H_9)_4N][Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(\mu\text{-}2,3\text{-}NHCOCH_3)]\cdot 2.5C_4H_{10}O$ (**2′**)

A 50 ml flask was charged with 99 mg (0.071 mmol) of $[(C_4H_9)_4N]_2[Re_3Cl_9S]$ [12], and 15 ml of acetonitrile. Some, but not all, of the material dissolved. A solution containing $[Re(CO)_3(CH_3CN)_3]PF_6$, prepared in situ from 29 mg (0.071 mmol) of $Re(CO)_5Br$, 10 mg (0.071 mmol) of $AgPF_6$, and 20 ml of acetonitrile [13], was then transferred into the flask by means of a filter-tipped cannula. The reaction mixture was stirred overnight at room temperature. The red–brown solution was filtered into a 100 ml flask. This solution was evaporated to dryness under dynamic vacuum. The residue was redissolved in acetone (5 ml), and approximately 2 ml of the acetone solution was filtered into a 12 mm O.D. tube and layered with diethyl ether. Dark red prism-shaped crystals of $[(C_4H_9)_4N][Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(\mu\text{-}2,3\text{-}NHCOCH_3)]\cdot 2.5C_4H_{10}O$ (**2′**) grew over the course of several weeks. The isolated yield of **2′** was low. The compound was identified by X-ray diffraction.

2.6. Synthesis of $[(C_4H_9)_4N]_2[Re_3Cl_{10}(\mu\text{-}1,2\text{-}NHCOCH_3)]$ (**3**)

A 100 ml flask was charged with 81.0 mg (0.0586 mmol) of $Cs_3Re_3Cl_{12}$ and 50 mg (0.180 mmol) of $[(C_4H_9)_4N]Cl\cdot H_2O$. Acetonitrile (20 ml) was added and the contents of the flask were stirred for 10 min. Deionized water (0.10 ml, 5.5 mmol) was added and the contents of the flask were stirred vigorously for 90 min. A solution of $AgBF_4$ (34.2 mg, 0.176 mmol, in 15 ml acetonitrile) was then added dropwise via cannula over 30 min. The reaction mixture was stirred for 6 h at room temperature, yielding a purple solution and a light colored precipitate (AgCl). The solid was separated by filtration and discarded; the purple solution was concentrated to about 6 ml under vacuum. Approximately 1.5 ml of the concentrated solution was then filtered into a Schlenk tube. Diethyl ether was carefully layered above the acetonitrile solution. Dark purple prism-shaped crystals of $[(C_4H_9)_4N]_2[Re_3Cl_{10}(\mu\text{-}1,2\text{-}NHCOCH_3)]$ (**3**) formed on standing. Mass spectroscopic data and X-ray crystallography were used to characterize **3**.

^{1}H NMR spectrum (CD_3CN): singlet, 2.2 ppm, plus resonances arising from the tetrabutylammonium cation. UV–Vis (CH_2Cl_2): 524 nm ($\varepsilon = 620$ M^{-1} cm^{-1}). MALDI MS: $m/z = 935.6$ (calc. 935.60), $[Re_3Cl_9(NHCOCH_3)]^-$; $m/z = 900.7$ (calc. 900.7), $[Re_3Cl_8(NHCOCH_3)]^-$.

2.7. Alternative synthesis of **3**

Sublimed $(Re_3Cl_9)_x$ (0.0295 g, 0.034 mmol) was added to 20 ml of a 1.0 M solution of HCl in anhydrous diethyl ether (in which the rhenium complex partially dissolves). Solid $[(C_4H_9)_4N]Cl\cdot H_2O$ (0.0440 g, 0.16 mmol) was added; immediately, an oil separated from the solution. The solvent was decanted, and the oil was dissolved in methylene chloride. A solid product precipitated from this solution when diethyl ether was added. In one attempt to recrystallize this compound, the crude product was dissolved in a minimum amount of acetonitrile and the solution layered with diethyl ether. The crystalline product that formed was filtered and dried; analysis using mass spectroscopy (MALDI) identified the anion of this species. A single crystal diffraction study confirmed the identity of the product as **3**.

2.8. Preparation of $[(C_4H_9)_4N]_2[\{Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(OH)\}_2]\cdot 1.7(C_4H_{10}O)$ (**4**)

A 100 ml flask was charged with 80.3 mg (0.058 mmol) of $Cs_3Re_3Cl_{12}$ and 50 mg (0.180 mmol) of $[(C_4H_9)_4N]Cl\cdot H_2O$. Acetonitrile (40 ml) was added and the contents of the flask were stirred for 20 min. Deionized water (0.20 ml, 11 mmol) was added and stirring was continued for an additional 80 min. Then a solution of $AgBF_4$ (46.4 mg, 0.238 mmol, in 45 ml acetonitrile) was added over 10 min. An additional 25 ml acetonitrile was used to rinse the flask that contained the $AgBF_4$ solution, and this was also added to the reaction mixture. The contents of the reaction flask were stirred overnight at room temperature, resulting in a purple solution and a copious amount of a light-colored precipitate (AgCl). The solution was filtered by means of a filter-tipped cannula into a 125 ml flask, then the solvent was removed under dynamic vacuum. The residue that remained was dissolved in 3 ml acetone. This solution was filtered into a Schlenk tube and carefully layered with diethyl ether. Dark red opaque plate-shaped crystals of $[(C_4H_9)_4N]_2[\{Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(OH)\}_2]\cdot 1.7C_4H_{10}O$ (**4**) formed in the tube over several weeks. The compound was identified by X-ray diffraction. The isolated yield of compound **4** was low and additional data on this compound were not obtained. An aquo complex, $(C_4H_9)_4N[Re_3Cl_9(H_2O)(\mu\text{-}1,2\text{-}NHCOCH_3)]$ (**5**) is presumably an intermediate in the formation of **4**. In one instance, a very small amount of a crystalline sample of **5** was obtained and characterized by X-ray diffraction.

2.9. Preparation of $Mo_2Cl_4(NCCH_3)_4$ (**6**)

A 125 ml flask was charged with 77.8 mg (0.123 mmol) of $K_4Mo_2Cl_8\cdot 2H_2O$. Acetonitrile (45 ml) was added and the resulting slurry was stirred vigorously for 20 min. Deionized water (0.15 ml, 8.3 mmol) was added. A solution of $AgBF_4$ (0.97 mg, 0.493 mmol) in acetonitrile (30 ml) was added over 45 min, producing a blue solution and a light colored precipitate (AgCl). The reaction mixture was stirred overnight at room temperature, then the blue solution was separated from the precipitate by means of a filter-tipped cannula. Removal of solvent from the solution affords a 99% yield of a waxy solid, $Mo_2Cl_4(NCCH_3)_4$ (**6**).

To obtain crystalline samples of **6**, the blue solution obtained after filtration was concentrated to approximately 12 ml, and ca. 5 ml of this solution was filtered into a vapor

diffusion tube. The sidearm on the vapor diffusion tube was filled with diisopropyl ether. Dark blue plate-shaped crystals grew on the walls of the tube as diisopropyl ether diffused into the acetonitrile solution over several weeks. These crystals were identified by X-ray diffraction. This complex has been reported previously [14] but it had not been structurally characterized.

UV–Vis (CH_3CN): 602 nm, in accord with published data [14].

3. Results and discussion

Initial evidence that acetamidate complexes are formed in an acetonitrile solution of a rhenium(III) complex was obtained from a negative ion ESI spectra of $Cs_3Re_3Cl_{12}$ using acetonitrile as a solvent (Fig. 1). Seen in these spectra are peaks with *m/z* values at 924 and 959 corresponding to $[Re_3Cl_n(NHCOCH_3)_2]^-$ ($n=7$, 8) and at 901 and 936, corresponding to $[Re_3Cl_n(NHCOCH_3)]^-$ ($n=8$, 9). The first set of peaks became more prominent as the solution of $Cs_3Re_3Cl_{12}$ aged while peaks associated with the $[Re_3Cl_{12}]^{3-}$ cluster at 912, 878, and 843 (corresponding to $[Re_3Cl_n]^-$, $n=10$, 9, 8) [6] diminished and eventually disappeared from the spectrum. The acetamidate ligands in these species were presumably formed by nucleophilic attack of water (or OH^-) at a coordinated nitrile. Water had not been specifically added as a reagent but it was assumed to be present in the reaction system, either in the acetonitrile (although this solvent had been dried using standard procedures) or in the lattice of the rhenium compound. References to $Cs_3Re_3Cl_{12}$ do not mention the presence of water, but the synthesis of this species involves aqueous chemistry and traces of water would probably be overlooked in analysis of analytical and crystallographic data.

Hydration of coordinated nitriles has been studied using a variety of metals [7,15]. Typical procedures for these reactions utilize basic conditions to effect OH^- addition to the carbon of the nitrile, followed by protonation. The key mechanistic step is nucleophilic attack at the ligand, enhanced by coordination to a metal ion. Most studies involve monometallic complexes but, in one instance, catalysis of the hydration reaction using a dipalladium complex (giving acetamide) was observed [16]. Rhenium(III) nitrile complexes have been known for over 30 years [17]. Prior to the recent work cited above [7–9], however, nucleophilic attack by water at the nitrile ligand in a rhenium(III) complex was observed in one instance [18]. This reference is to an interesting reaction in which the final product is a complex with carboxylate rather than amidate ligands. The activation of nitriles to nucleophilic attack in rhenium(IV) compounds is noted, however; amines and alcohols add to the coordinated nitrile in $ReCl_4(NCR)_2$ ($R=CH_3$, C_6H_5) [17].

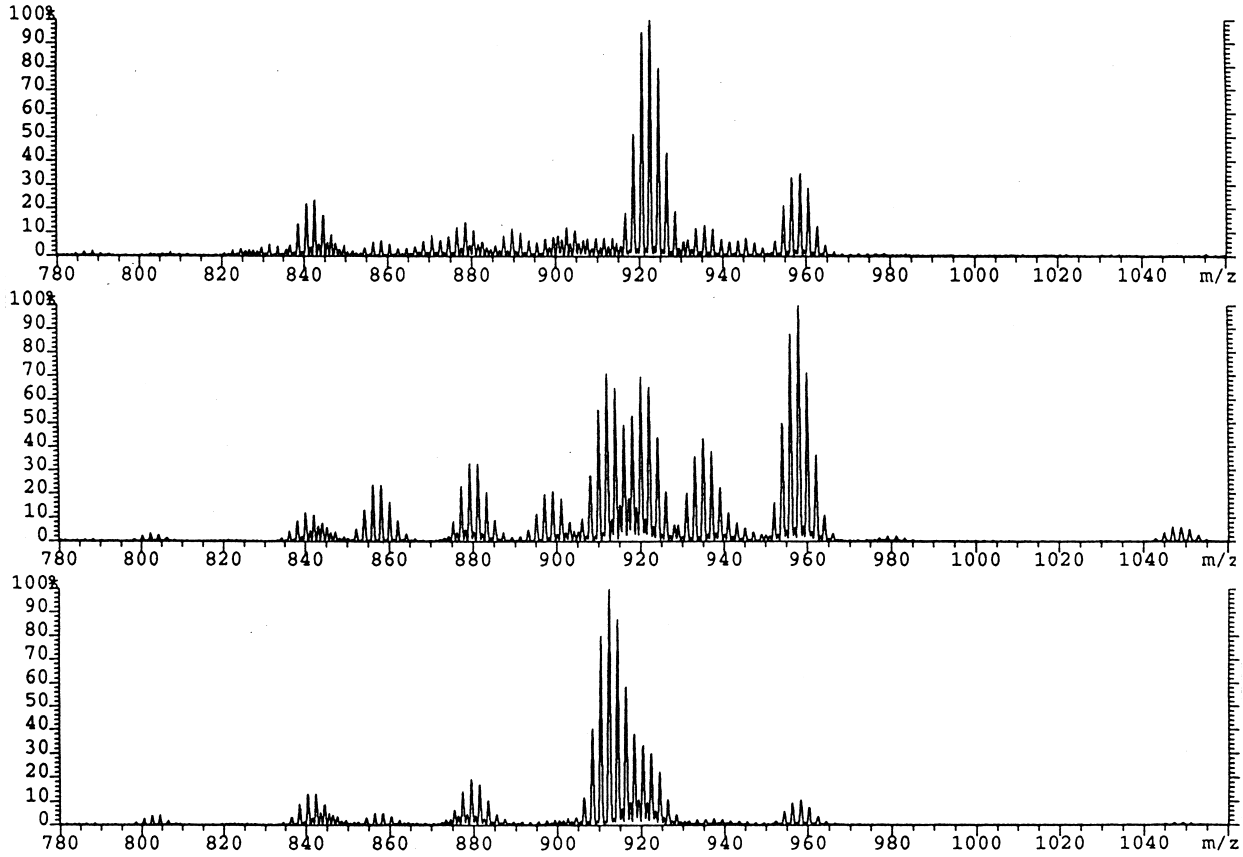

Fig. 1. ESI (electrospray) mass spectra of $Cs_3Re_3Cl_{12}$ using acetonitrile as a solvent at different times: bottom, immediately after preparing the solution; middle, after 1 day; top, after 10 days.

To prepare $[(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2]$ (**1**) a procedure was selected that involved initial addition of 2 equiv. of Ag^+ to an acetonitrile solution of $[(C_4H_9)_4N]_2Re_2Cl_8$. The intent was to form in situ a nitrile complex, $Re_2Cl_6(NCCH_3)_2$, that would then be susceptible to further reaction with water. A halide acceptor was assumed to be needed since replacement of halide ion by acetonitrile is not itself a favorable reaction. There are numerous examples in the literature in which silver ion assists in reactions in which other ligands replace a coordinated halide ion with insoluble AgCl being formed [19]. The targeted intermediate, the nitrile complex, has not been reported before, but compounds with similar stoichiometry are known with other ligands, notably phosphines [5]. The reaction between $AgPF_6$ and $[(C_4H_9)_4N]_2Re_2Cl_8$ occurs readily as judged by the immediate precipitation of AgCl. Subsequently, work-up of the reaction mixture by standard techniques led to $[(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}HNCOCH_3)\}_2]$ (**1**) in 21% isolated yield. The overall reaction is represented in Eq. (1):

$$2[(C_4H_9)_4N]_2Re_2Cl_8 + 4Ag^+ + 2CH_3CN + 4H_2O \rightarrow 4AgCl(s) + 2H_3O^+ + 2(C_4H_9)_4N^+ + [(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2] \quad (1)$$

The role of Ag^+ in this reaction is open to question. Silver ion was not a component of the reported reactions between $[(C_4H_9)_4N]_2Re_2Cl_8$ and benzonitrile [7] or acetonitrile [8] in ethanol. We have found that in the absence of ethanol, however, $[(C_4H_9)_4N]_2Re_2Cl_8$ and CH_3CN do not react appreciably over 3 days (room temperature). So, Ag^+ appears to be essential in this reaction if ethanol is not used as a solvent.

Further observations confirming the importance of Ag^+ are noted. An ESI spectrum of $[(C_4H_9)_4N]_2Re_2Cl_8$ run several hours after preparing a solution of this compound in acetonitrile contains peaks associated with the $[Re_2Cl_8]^{2-}$ ion only, indicating no reaction in this short time period. (In contrast, acetamidate complexes are noted in the ESI spectrum of $Cs_3Re_3Cl_{12}$ within an hour, vide supra.) Indirect evidence is provided in experiments with less than 2 equiv. of Ag^+. Over 1 day, these reactions produced a mixture of starting material and product, in a ratio suggesting that when Ag^+ had been expended the reaction did not proceed measurably further. Note in Eq. (1) that 2 equiv. of this reagent are needed for complete reaction, with 2 equiv. of AgCl precipitating.

The mechanism postulated [7] for the conversion of a nitrile to an acetamidate ligand appears logical: initial coordination of acetonitrile to a rhenium atom, addition of water to the nitrile carbon, hydrogen migration and deprotonation to yield a monodentate acetamidate ligand. Chelation through oxygen to the second metal atom with displacement of another chloride ion then gives the product.

The interesting aspect of this synthesis is that when acetonitrile is the solvent (and no ethanol is present) the reaction did not occur. Since activation of the nitrile requires its initial coordination to rhenium, it is attractive to conclude that such a complex must form if ethanol is used as a solvent.

Based on our results, it would appear that the formation of such an intermediate is not favored in acetonitrile. In the absence of ethanol and without Ag^+, a nitrile complex could form in two ways, and in both instances a solvent could presumably influence the process. Solvation could influence the direct replacement of a chloride ion by the nitrile. This kind of reaction is known for other ligands such as phosphines but not for nitriles. Second, the nitrile could coordinate to $[Re_2Cl_8]^{2-}$ in an axial position, that is, *trans* to the metal–metal bond. Complexes with the stoichiometry $[Re_2Cl_8(L)_2]^{2-}$ are known; for example, in some reported crystal structure studies on octahalodirhenium complexes water is present as an axial ligand [20]. In other cases axially coordinated water is not present, however, and it is reasonable to suppose that the interaction between axial ligand and metal is weak. Ethanol could affect the extent to which such a complex is formed.

In our early experiments water was not added as a reagent. Water presumably was present in the starting material or in the solvent. Hoping to intercept an intermediate nitrile complex, efforts were made to exclude water. Solvents were carefully dried and the rhenium starting material was heated in vacuum at about 100°C in an attempt to remove traces of water. In each instance, however, only the acetamidate-containing product **1** was obtained. The conclusion reached is that hydration must be both favorable and very rapid.

Structural characterization of **1** was achieved by a single crystal X-ray diffraction study. The structure of the anion of **1** is shown in Fig. 2. Two dirhenium moieties are linked via bridging chloride ions, The rhenium–rhenium bond distance in each half of the anionic species is short (2.229 Å), the bond distance being similar to values found in $[(C_4H_9)_4N]_2Re_2Cl_8$ (2.222 Å) [21] and in $[(C_4H_9)_4N]_2$-

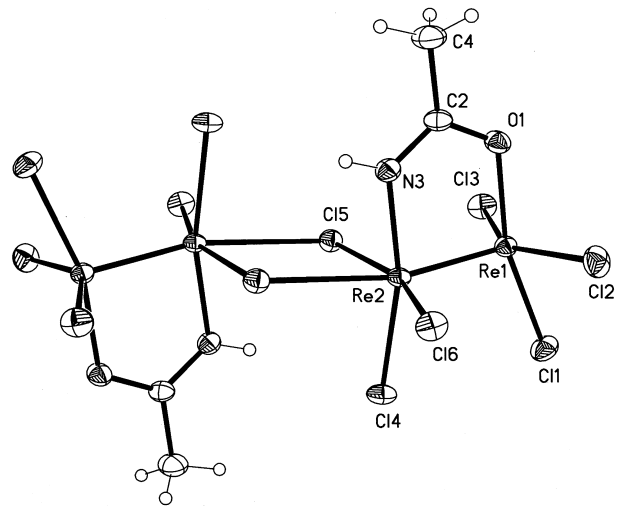

Fig. 2. Structure of the anion of $[(C_4H_9)_4N]_2[\{Re_2Cl_6(\mu\text{-}1,2\text{-}HNCOCH_3)\}_2]$ (**1**).

$[Re_2Cl_6(\mu\text{-}C_6H_5CONH)]\cdot 0.5CH_2Cl_2$ (2.2209 Å) [7], and representative of a quadruple bond [3,4].

The geometry of ligand substitution for each metal atom in the starting material is similarly retained; three chloride ligands and the oxygen or nitrogen of the acetamidate lie in a square planar arrangement about the metal. There is an eclipsed orientation of the ligands on the two rhenium atoms. Specific parameters (bond lengths and bond angles) are unexceptional.

A structure determination of **1** was done several times using good crystals from several different syntheses. In each case, an analysis assuming an ordered structure gave a better fit of data than a disordered model. The structure placed oxygen and nitrogen atoms in the dirhenium unit so that the two halves of the anion are linked through chloride bridges to rhenium atoms to which the nitrogen atoms of the coordinated acetamidate ligands are attached. Noted in passing is the structure of $[(C_4H_9)_4N]_2[Re_2Cl_6(\mu\text{-}C_6H_5CONH)]\cdot 0.5CH_2Cl_2$ in which oxygen and nitrogen atoms were also not disordered [7].

Related dirhenium species with bridging carboxylate ligands having the general formulas $Re_2(O_2CR)_4X_2$, $Re_2(O_2CR)_3X_3$, and $Re_2(O_2CR)_2X_4$ (where R is an organic group in a carboxylate ligand and X represents Cl, Br, or I) are known [5]. Dirhenium acetamidate complexes are formed by reactions of $Re_2(O_2CCH_3)_4Cl_2$ with amides at elevated temperatures [22,23]. Compounds with a 2-hydroxypyridinate ligand, structurally resembling amidate complexes, are also known [18,24].

Trirhenium complexes having acetamidate ligands were also prepared in this study. Here, the role of Ag^+ in the synthesis was less equivocal, and methods both with and without this halide acceptor are reported. Again, the synthetic strategy involves the formation of a nitrile complex as the key intermediate. In this context, the reaction occurring with $(Re_3Cl_9)_x$, acetonitrile, and water was straightforward. Polymeric $(Re_3Cl_9)_x$ dissolves readily in acetonitrile giving a deep red solution of $Re_3Cl_9(NCCH_3)_3$ [11]. On heating, the solution rapidly turns purple. Hydrogen chloride is produced in the reaction; this was detected by purging the reaction system with N_2 and passing the exit gases passed through a saturated aqueous solution of silver nitrate in which a white precipitate of AgCl is seen to form. The reaction is complete in 2.5 h; no further HCl evolution is detected. Addition of tetraethylammonium chloride and subsequent work-up gave a 51% yield of $(C_2H_5)_4N[Re_3Cl_8\text{-}\mu\text{-}1,2\text{-}(HNCOCH_3)\text{-}\mu\text{-}2,3\text{-}(HNCOCH_3)]$ (**2**) (Eq. (2)).

$$Re_3Cl_9(CH_3CN)_3 + 2H_2O + [(C_2H_5)_4N]Cl \rightarrow CH_3CN + 2HCl + (C_2H_5)_4N[Re_3Cl_8 \times (\mu\text{-}1,2\text{-}HNCOCH_3)(\mu\text{-}2,3\text{-}HNCOCH_3)] \quad (2)$$

The same anion was isolated (with a different cation) from a quite different reaction. The compound, $(C_4H_9)_4N[Re_3Cl_8(\mu\text{-}1,2\text{-}HNCOCH_3)(\mu\text{-}2,3\text{-}HNCOCH_3)]$ (**2′**), was formed in low yield in a reaction of $[(C_4H_9)_4N]_2[Re_3Cl_9S]$ [12] with $[Re(CO)_3(CH_3CN)_3]PF_6$. The abstraction of sulfide ion from $[(C_4H_9)_4N]_2[Re_3Cl_9S]$ by $[Re(CO)_3(CH_3CN)_3]^+$ is probably a key step in the process. The structure of **2′** was established by a single crystal X-ray diffraction study. The anion (Fig. 3) has two acetamidate ligands bridging axial positions on opposite sides of the plane defined by the $Re_3(\mu\text{-}Cl_3)$ fragment, resulting in one of the three rhenium atoms in the anion being coordinated by two acetamidate ligands at its two axial positions.

Compound **3**, $[(C_4H_9)_4N]_2[Re_3Cl_{10}(\mu\text{-}1,2\text{-}HNCOCH_3)]$, was obtained in a two step reaction. Here, $(Re_3Cl_9)_x$ was first allowed to react with a 1.0 M solution of anhydrous HCl in diethyl ether; then tetrabutylammonium chloride was added. The product obtained in this reaction is $[(C_4H_9)_4N]_4[\{Re_3Cl_{11}\}_2]$, the anion of which has two $[Re_3Cl_{11}]^{2-}$ subunits linked via chloride bridges [25]. When acetonitrile was used in a purification step, compound **3** formed. Water was presumably introduced into the reaction mixture when the tetraalkylammonium salt was added. It is reasonable to assume that the halide bridge is readily broken by acetonitrile yielding $[(C_4H_9)_4N]_2[Re_3Cl_{11}(NCCH_3)]$. At this point, hydrolysis and elimination of HCl leads to the observed product. Again, reaction with only a trace of water being present speaks to the facile character of the hydration step in this reaction.

The structure of the anion of **3** is shown in Fig. 4. The similarity to structures of other known trirhenium species is apparent [5]; the anion of **3** contains a triangle of rhenium atoms, linked by metal–metal bonds and bridging halide ligands. Each metal atom has, in addition, three terminal ligands. The acetamidate ligand bridges axial positions of two rhenium atoms and chloride ions occupy the remaining terminal positions.

Compound **3** was also obtained in a reaction that used Ag^+ to generate an open coordination site on rhenium. Silver tetrafluoroborate was added to $Cs_3Re_3Cl_{12}$ and acetonitrile, with AgCl precipitating immediately. The mechanism of forma-

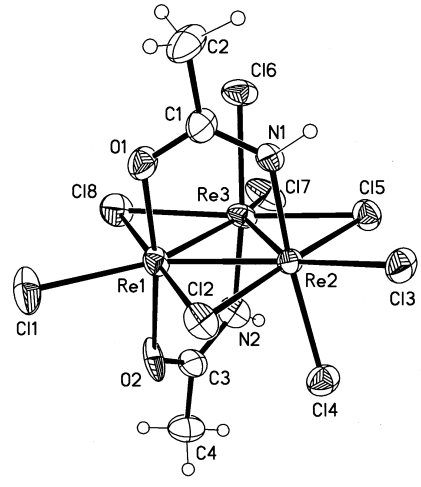

Fig. 3. Structure of the anion of $[(C_4H_9)_4N][Re_3Cl_8(\mu\text{-}1,2\text{-}HNCOCH_3)\text{-}(\mu\text{-}2,3\text{-}HNCOCH_3)]\cdot 2.5(C_4H_{10}O)$ (**2′**).

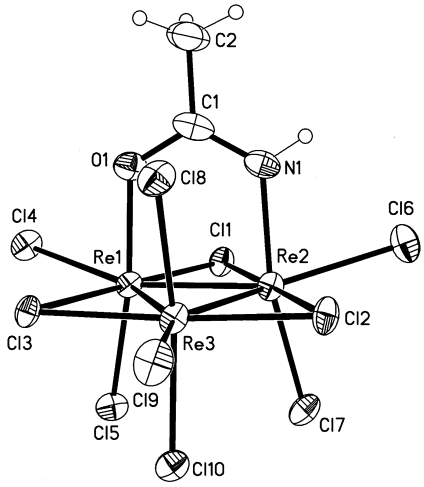

Fig. 4. Structure of the anion of $[(C_4H_9)_4N]_2[Re_3Cl_{10}(\mu\text{-}1,2\text{-}HNCOCH_3)]$ (**3**).

tion is presumably the same as was postulated for **1**: initial loss of chloride ion from the rhenium coordination sphere and coordination of acetonitrile followed by reaction with water, loss of H^+, and chelation gives the product.

An attempt to synthesize a trirhenium species containing two acetamidate ligands via a route involving chloride abstraction using Ag^+ ions was unsuccessful, however. The reaction of $[(C_4H_9)_4N]_3Re_3Cl_{12}$ with 4 equiv. of $AgBF_4$ produced a small amount of an acetamidate compound identified as $[(C_4H_9)_4N]_2[\{Re_3Cl_8(OH)(\mu\text{-}1,2\text{-}NHCOCH_3)\}_2]\cdot 1.7(C_4H_{10}O)$ (**4**). The anion of this species (Fig. 5) consists of two trirhenium fragments bridged through hydroxide ligands, each trirhenium fragment containing a single chelating acetamidate ligand. It is reasonable to suppose that **3** is initially formed in this system and that further reaction with additional Ag^+ resulted in coordination of water rather than acetonitrile, forming $(C_4H_9)_4N[Re_3Cl_9(H_2O)(\mu\text{-}1,2\text{-}NHCOCH_3)]\cdot C_3H_6O$ (**5**) (Fig. 6), a compound also isolated and structurally characterized in this study. Loss of H^+ followed by dimerization via bridging hydroxide ligand groups gives **4**.

Structural parameters for the trirhenium species mirror closely the parameters of known trirhenium complexes. In particular the Re–Re distances are representative, with dimensions appropriate for double bond character (**2**, 2.4650(8) and 2.4669(8) Å; **3**, 2.4702(5) and 2.5062(5) Å; **4**, 2.4437(3) and 2.4511(3) Å; **5**, 2.4489(13) and 2.4557(14) Å). Particularly, note the values for **4** that identify it as a rhenium(III) complex and confirm that this species contains bridging OH^- ligands and not bridging oxide ligands. Oxo and hydroxo ligands would otherwise not be readily differentiated in the structure determination.

An attempt to extend this study to molybdenum chemistry did not result in formation of an acetamidate complex. The reaction of $K_4Mo_2Cl_8$ with $AgPF_6$ in acetonitrile/water gave the blue crystalline species $Mo_2Cl_4(NCCH_3)_4$ (**6**) in good yield (Fig. 7). Although $[Re_2Cl_8]^{2-}$ and $[Mo_2Cl_8]^{4-}$ are isoelectronic species, molybdenum(II) here apparently does

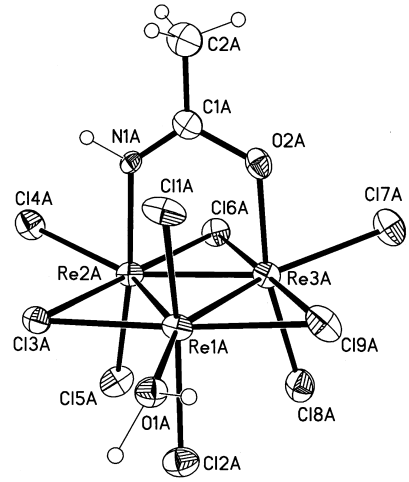

Fig. 6. Structure of the anion of $(C_4H_9)_4N[Re_3Cl_9(H_2O)(\mu\text{-}1,2\text{-}NHCOCH_3)]\cdot C_3H_6O$ (**5**).

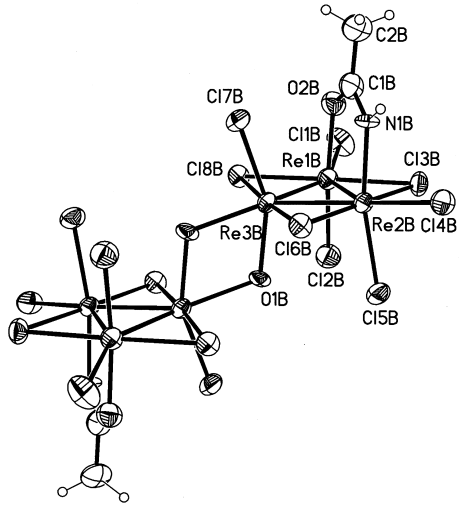

Fig. 5. Structure of the anion of $[(C_4H_9)_4N]_2[\{Re_3Cl_8(\mu\text{-}1,2\text{-}NHCOCH_3)(OH)\}_2]\cdot 1.7(C_4H_{10}O)$ (**4**).

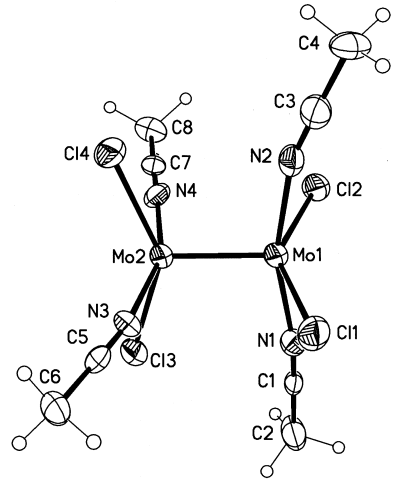

Fig. 7. Structure of $Mo_2Cl_4(NCCH_3)_4$ (**6**).

not activate the nitrile toward hydration. The factors that govern this must be subtle, however. Hydrolysis of a related complex, $[Mo_2(NCCH_3)_8]^{4+}$ to give $[Mo_2(NCCH_3)_6(\mu\text{-}NHCOCH_3)]^{3+}$ has recently been reported [26].

Compound **6** has been made previously but not structurally characterized [14]; however, a closely related compound, $Mo_2Cl_4(NCC_6H_5)_4$ has the same structure [27]. The structural motif in **6** has also been seen numerous times in the chemistry of quadruply bonded dimolybdenum complexes with the formula $Mo_2X_4L_4$, where L is a neutral donor ligand and X is a halogen [5,28].

In our earlier study on MALDI spectra of $Cs_3Re_3Cl_{12}$ and $[(C_4H_9)_4N]_2Re_2Cl_8$, two tentative conclusions were reached [6]. Mass spectra were useful in defining the nuclearity of the anion. Spectra obtained using this technique on these rhenium cluster species are fairly simple, containing only a few ion signals generated either by loss of a ligand group (Cl^-) or adduction of a matrix molecule, and in each case the nuclearity was retained. Second, loss of halide ions to create a detectable species with a -1 charge was a common occurrence. MALDI experiments typically detect ions with unitary charges. Ions that have higher charges are usually not detected, and a chemically logical means of reduction of the charge is seen to occur. For rhenium halide complexes, halide loss seems to be a common occurrence. In other systems, including some boron hydride anions when prepared as Na^+ salts [25], cation–anion aggregation is seen.

Proof of the effectiveness of MALDI in characterization must come, of course, in its use with unknown species. A broader goal of our research is to use MALDI spectra to predict the identity of new products. The match of MALDI data on **1**, **2**, and **3** with predicted spectra is preliminary evidence for the efficacy of this technique.

The MALDI spectrum of **2** (in which the anion has a single negative charge) contained only two sets of peaks, identified with the species $[Re_3Cl_8(HNCOCH_3)_2]^-$ ($[\mathbf{P}]^-$, $m/z=$ 958.7) and $[Re_3Cl_7(HNCOCH_3)_2]^-$ ($[\mathbf{P}-Cl]^-$ $m/z=$ 923.8), **P** here representing the parent anion. The spectrum obtained for **3** also matched predictions. In this instance, the compound contains a dinegative ion and, as in the previous study [6], loss of a chloride to give a -1 ion occurs. The spectrum for **3** contained peaks for the two ions $[Re_3Cl_9(HNCOCH_3)]^-$ ($[\mathbf{P}-Cl^-]^-$, $m/z=935.6$) and $[Re_3Cl_8(HNCOCH_3)]^-$ ($m/z=900.7$). The MALDI spectrum of compound **1** introduces a new, but not unexpected, dimension. In this compound, the dinegative ion is made up of two dinuclear fragments linked by chloride bridges, and the highest mass ion pattern corresponds to half of this whole unit, $[Re_2Cl_6(HNCOCH_3)]^-$ ($[\mathbf{P}/2]^-$, $m/z=643.7$). Presumably, the halide bridges also represent a weak link in this molecule, and cleavage of the $Re_2(\mu\text{-}Cl)_2$ unit of the compound is the most facile route to a monocharged species. Further examples are required to learn whether facile cleavage of a M–X–M bridge is a general result. Many cluster species aggregate in one dimension (chains) or in two dimensions (sheets), and it will be important to know whether these structural features can be established using MALDI.

ESI spectroscopy, although only used in one instance in this study, offer the possibility of more information. In results reported here, an intermediate (the mono-acetamido complex) as well as the eventual product (the bis-acetamido complex) was detected in a reaction mixture at early stages in the reaction. The ESI MS data provided evidence as to the progress of the reaction (which required more than 1 day and less than 10 days). MALDI requires removal of solvent to obtain a sample for analysis; in most instances use of this technique will be restricted to products. This allows MALDI to be used to determine whether a starting material and/or a desired product is present in a crude mixture. This simple analytical procedure, taking about 30 min to perform, will be of significant assistance in moving ahead in a synthetic project. Still, as noted, further examples and more data are needed to strengthen the case for the use of MALDI as a routine tool in characterization.

Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) and are available on request quoting the deposition numbers CCDC 140534 through CCDC 140539 (in order, structures **1**–**6**).

Acknowledgements

We are pleased to acknowledge the support for this work provided by the Research Corporation. Instrumentation (both mass spectrometers and the X-ray diffractometer) was obtained with partial support from NSF to the UW Department of Chemistry in the form of major instrumentation grants. We thank Kevin C. Moore (UW La Crosse) for assistance in rechecking reactions of $[(C_4H_9)_4N]_2[Re_2Cl_8]$.

Abstract

Cobalt(II), nickel(II), copper(II), zinc(II), cadmium(II) and lead(II) complexes of isatin 3-hexamethyleneiminylthiosemicarbazone, $[M(Ishexim)_2]$, as well as a thallium(I) complex, [Tl(Ishexim)], have been prepared by electrochemical synthesis. The crystal structures of $[Zn(Ishexim)_2]$ and $[Pb(Ishexim)_2]$ have been solved, and the metal complexes have been characterized by their ^1H and ^{13}C NMR, IR, UV–Vis and mass spectra. Coordination of the Ishexim anions is via the imine nitrogen and thiolato sulfur atoms with evidence for weak interaction of the amide oxygen with the isatin portion of the ligand. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Thiosemicarbazone; Isatin; Crystal structures; Zinc; Lead; Hexamethyleneimine; Metal(II) complexes

1. Introduction

The 3-thiosemicarbazones of isatin have been of interest since 1-methylisatin-3-thiosemicarbazone was found to be active in the treatment of smallpox [1–3] some forty years ago. It has been suggested that thiosemicarbazone drugs may act to inhibit virus growth by binding to copper ions which are constituents of the virus [4]. Therefore, a study of metal complexes for a wide range of thiosemicarbazones has been pursued in numerous studies [5]. Although substitution at N4-position of the thiosemicarbazone moiety (Fig. 1) was found to reduce anti-smallpox activity of isatin thiosemicarbazones [6], two butyl groups attached at the N4-position provides a compound with demonstrated activity against ectromelia (a vaccina virus unaffected by Marboran™) and also against type 2 polio, which is an enterovirus and quite unrelated to the vaccina family [7].

Metal complexes of N4-2-pyridyl- [6], N4-phenyl- [8], N4-ethyl- [9] and N4-dimethylthiosemicarbazones derived from isatin [10] have been studied. More recently, a study of the spectroscopic properties of the copper(II) complexes of eight N4-substituted thiosemicarbazones of isatin was communicated [11]. In this latter communication the crystal structure of the isatin 3-hexamethyleneiminylthiosemicarbazone, HIshexim, was reported, but none of the copper(II) complexes produced crystals of a quality sufficient for structural studies. In this study we report a structural and spectroscopic study of metal complexes of HIshexim prepared by electrochemical oxidation of the various metals.

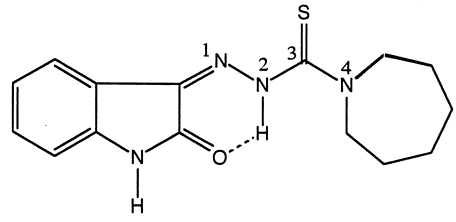

Fig. 1. Representation of HIshexim and numbering for the thiosemicarbazone moiety.

2. Experimental

HIshexim was prepared by reaction of equimolar amounts of 3-hexamethyleneiminylthiosemicarbazide, synthesized following the procedure developed by Holmberg and Psilanderhielm [12] and modified by Scovill [13], with isatin (Aldrich, 98%) at room temperature in absolute ethanol with a catalytic amount of conc. H_2SO_4. The product precipitated as a yellow powder in less than 1 h, and was collected by suction filtration and washed with cold absolute ethanol

PII S0277-5387(00)00383-1

(yield, 76%). Complexes were prepared by electrochemical oxidation of the metals in a solution of HIshexim (0.056 g, 0.19 mmol) in CH_3CN (40 ml) containing 10 mg of tetramethylammonium perchlorate for 1 h at 5 mA and a potential of 10–20 V. A loss of 5.5 mg (Co), 5.5 mg (Ni), 6.1 mg (Zn), 10.5 mg (Cd), 11.8 mg (Cu), 38.1 mg (Tl) and 19.3 mg (Pb) from the anode resulted during the preparation of the complexes. The yields for the complexes and their percentage yield based on metal consumed were as follows: [Co(Ishexim)$_2$], 37 mg, 60%; [Ni(Ishexim)$_2$], 48 mg, 77%; [Cu(Ishexim)$_2$], 17 mg, 28%; [Zn(Ishexim)$_2$], 45 mg, 72%; [Cd(Ishexim)$_2$], 58 mg, 87%; [Tl(Ishexim)], 48 mg, 78%; [Pb(Ishexim)$_2$], 43 mg, 57%. During the reaction the solutions turned from yellow to the color of the various solids, which formed on slow evaporation of the solvent. The initial product, an amorphous dark brown solid, of the electrochemical oxidation of copper analyzes as [Cu(Ishexim)]. Found: C, 49.2; H, 4.7; N, 15.5. Calc.: C, 49.4; H, 4.7; N, 15.4%. This was not characterized further, but crystals formed on slow evaporation of the MeCN solvent analyze as [Cu(Ishexim)$_2$], Table 7.

Elemental analyses were performed with a Carlo Erba 1108 microanalyser. The magnetic susceptibilities were measured with a Digital Measurements system MSB-MKI calibrated with tetrakis(isothiocyanato)cobaltate(II) ion. ^{1}H and ^{13}C NMR spectra were recorded in deuterated $(CD_3)_2SO$ with a Brucker WM-300 spectrometer. Infrared spectra were recorded from 4000–400 cm^{-1} with a Mattson Instruments Cygnus 100 FTIR spectrometer using KBr pellets. UV–Vis spectra were recorded as Nujol mulls adhered to filter paper with a Cary 5E spectrophotometer. Electrospray mass spectral data were obtained with 5×10^{-4} M solutions (MeOH) by flow injection into a Hewlett-Packard 1100 series MSD. The carrier solvent was 50% MeOH in H_2O. Electrospray ionization conditions were as follows: nitrogen drying gas flow, 10.0 l min^{-1}; nebulizer pressure, 40 psig; drying gas temperature, 350°C; capillary voltage, 4 kV. The capillary exit voltage was varied from 0 to 150 V. The ESR spectrum of [Cu(Ishexim)$_2$] was acquired in 3 mm Pyrex tubes with a Brucker EMX spectrometer using a conventional insert Dewar at liquid nitrogen temperature.

Orange prismatic crystals of [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] were mounted on glass fibers and used for data collection on an Enraf-Nonius CAD4 automatic diffractometer. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the range $21.25<\theta<45.11°$ for [Zn(Ishexim)$_2$] and $22.945<\theta<45.420°$ for [Pb(Ishexim)$_2$]. Data were collected using the ω-scan technique and corrected for Lorentz and polarization effects [14]. A semi-empirical absorption correction, Ψ-scan, was made for both crystals [15]. The structure was solved by direct methods [16] and subsequent difference Fourier maps, and refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement factors [17]. All hydrogen atoms for [Zn(Ishexim)$_2$] were located from difference Fourier maps and refined isotropically and those for [Pb(Ishexim)$_2$] were located in their calculated positions (C–H 0.93–0.97 Å) and refined using a riding model. Atom scattering factors were taken from Ref. [18] and molecular graphics are from ZORTEP [19].

3. Results and discussion

3.1. Structural studies

The crystal data for [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] are shown in Table 1; Table 2 has selected bond distances and Table 3 selected bond angles. Perspective views of [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] are shown in Figs. 2 and 3, respectively. Both compounds are thermochromic; the change for [Pb(Ishexim)$_2$] is an irreversible change from orange to red at ca. 240°C and [Zn(Ishexim)$_2$] is reversible from yellow–orange to deep orange at ca. 100°C.

In [Zn(Ishexim)$_2$] the two Ishexim ligands are coordinated by the imine nitrogen and thiolato sulfur atoms of the thiosemicarbazonato moiety. Additional coordination is by the amide oxygen of the isatin moiety, O11, of one of the ligands, which has a longer bond distance, 2.452(3) Å, than the Zn–S bond distances. However, the oxygen, O21, of the second ligand is at a greater distance from the zinc center, 2.532(3) Å, and is not formally coordinated (i.e. this distance is longer than 1.3 times the sum of the covalent radii, $1.3\times\{1.20(Zn)+0.73(O)\}=2.509$ Å, and is not considered a bond by our X-ray program) as shown in Fig. 2. The geometrical parameter τ, i.e. $\tau=(\beta-\alpha)/60$, where α and β are N12–Zn–N23 and S1–Zn–O11 bond angles, respectively, has a value of 0.2. This suggests that [Zn(Ishexim)$_2$] has a square pyramidal geometry with a 20% distortion towards a trigonal bipyramid. The axial position can be considered to be occupied by S2 with O11, N12, S2 and N22 making up the basal plane. The angles involving S2 range from 122.20(10)° for S2–Zn–N12 to 81.77(9)° for S2–Zn–N22, the latter affected by the rigidity of the thiosemicarbazone moiety.

Intermolecular hydrogen bonding by the NH of the isatin moiety for each ligand (i.e. N11H and N21H in the two ligands) to the oxygens of the isatin moiety on two different molecules, O11A and O21B, yields a molecular chain. As would be expected, the hydrogen bonding distances and angles for N11H···O11A and N21H···O21B are quite similar (Table 4). The rms plane deviations for the two isatin moieties in [Zn(Ishexim)$_2$] are minimal (Table 5) and are at an angle of 101.3(5)° to each other. The thiosemicarbazone moieties, S1–C19–N14–N13–N13–C12 and S2–C29–N24–N23–N22–C22, have greater deviations; their rms plane deviations are 0.0304 and 0.0491 Å, and the two planes are at an angle of 79.65(20)°. The planar portion, N12–S2–N22, of the approximately trigonal bipyramidal arrangement of the donor atoms has a rms plane deviation of 0.0000 and the Zn atom is 0.3642(20) Å from this plane.

N14–C19	1.343(4)	1.340(6)
N24–C29	1.347(5)	1.343(7)
O11–C11	1.229(4)	1.231(6)
O21–C21	1.226(4)	1.211(7)

[a] Although M–O distances are shown, only O11 is coordinated in [Zn(Ishexim)$_2$] and neither oxygen in [Pb(Ishexim)$_2$].

For [Pb(Ishexim)$_2$] the two oxygens are at a greater distance from the Pb(II) center than either the nitrogen or sulfur donor atoms, suggesting that the oxygens are weakly interacting with the lead center as is indicated in Fig. 3. For [Pb(Ishexim)$_2$], τ = 0.04, suggesting a square pyramidal geometry with only a 4% distortion towards a trigonal bipyramid and the lone pair on the lead atom in the apical position. The geometry of the complex shows that the lone pair on the lead is stereochemically active, and the enormous deviation from the trigonal bipyramidal geometry can be explained as the result of the electrostatic repulsion of this electron pair. The N_2S_2 basal plane has S1–Pb–S2 and N12–Pb–N22 angles of 89.78(5) and 132.65(12)° and there is a deviation by as much as 0.5 Å from the plane of the four donor atoms. Another four coordinate lead-thiosemicarbazone complex [20], [Pb(Ac4M)OAc] (Ac4M = anion of 2-acetylpyridine N(4)-methylthiosemicarbazone), has Pb–N12 and Pb–S1 distances of 2.482(7) and 2.730(3) Å compared to averages of 2.628(4) and 2.7064(14) Å for [Pb(Ishexim)$_2$]. [Pb(Ac4M)OAc] is regarded as derived from a trigonal bipyramid with S1 occupying an axial position and N12 an equatorial position, which helps to account for the differences in bond distances. The N12–Pb–S1 chelate angle in [Pb(Ac4M)OAc] is 69.1(2)°, which is larger than 67.52(9) and 66.35(9)° found for N12–Pb–S1 and N22–Pb–S2 in [Pb(Ishexim)$_2$] consistent with the S1 of the former compound being in an axial position.

The metal–ligand bonds of [Pb(Ishexim)$_2$] are about 0.3 Å longer than the analogous bonds of [Zn(Ishexim)$_2$], as

Table 3
Selected bond angles (°) for [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] [a]

	[Zn(Ishexim)$_2$]	[Pb(Ishexim)$_2$]

O21–C21–C22	127.2(4)	128.4(5)

[a] Although angles for the oxygens with the metals are shown, only O11 is coordinated in [Zn(Ishexim)$_2$] and neither oxygen in [Pb(Ishexim)$_2$].

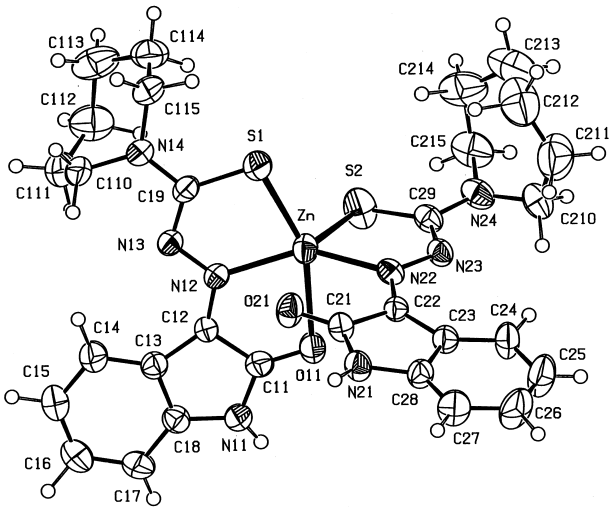

Fig. 2. Ortep diagram of [Zn(Ishexim)$_2$] at 50% probability.

would be expected based on the larger ionic radius of Pb, and the bond distances to nitrogen and to sulfur are not very different for [Pb(Ishexim)$_2$]. Differences in the bonding to the metal center between the two ligands of a complex are much greater for [Pb(Ishexim)$_2$] than for [Zn(Ishexim)$_2$]; the Pb–N and Pb–S bond distances differ by about 0.05 and 0.04 Å, respectively, but Zn–N and Zn–S by only 0.004 and 0.001 Å, respectively.

Intermolecular hydrogen bonding by the NH of the isatin moiety occurs for each ligand (i.e. N11H and N21H in the two ligands). N11H is bifurcated between an oxygen of the isatin moiety on another molecule, O11C, and a thiolato sulfur of the thiosemicarbazone of the second ligand in the same molecule, S2C. N21H hydrogen bonds to hydrazinic nitrogen of another molecule, N13D. The hydrogen bonding interactions are weaker for [Pb(Ishexim)$_2$] than for [Zn(Ishexim)$_2$], Table 4. The rms plane deviations for the two isatin moieties in [Pb(Ishexim)$_2$] are greater than for [Zn(Ishexim)$_2$], but the amide oxygen is included in the former, but not the latter (Table 5). The angle between the two isatin planes is 89.45(11)° for [Pb(Ishexim)$_2$] compared to 101.3(5)° for [Zn(Ishexim)$_2$]. The thiosemicarbazone moieties, S1–C19–N14–N13–N13–C12 and S2–C29–N24–N23–N22–C22, have rms plane deviations of 0.0292 and 0.0678 Å, and the two planes are at an angle of 116.68(52)°.

Table 6 shows a comparison of the bond distances and angles of HIshexim [11] with the average of the two ligands in [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$]. Since formation of the monoanionic ligands causes C19–S1 to convert from a formal double bond to a single bond, changes in its bond distance would be expected to be greatest among the various ligand bonds. The change from 1.672(4) Å for HIshexim to 1.711(4) and 1.726(6) Å for [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$], respectively, is not, however, to the bond distance usually associated with a C–S single bond. For example, [Pd(6MAchexim)Cl] and [Pt(6MAchexim)Cl], where 6MAchexim is the monoanion of 6-methyl-2-acetylpyridine 3-hexamethyleneiminylthiosemicarbazone, have C–S bond distances of 1.769(4) and 1.782(10) Å [21]. However, in both [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] there is not a significant change in the imine bond, C12–N12, even though N12 is coordinated in both complexes. Even the

Table 6
A comparison of HIshexim bond distances (Å) and angles (°) with the average of the two ligands in [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$]

	HIshexim	[Zn(Ishexim)$_2$]	[Pb(Ishexim)$_2$]
C12–N12	1.305(5)	1.306(4)	1.304(6)
N12–N13	1.362(6)	1.337(4)	1.342(6)
N13–C19	1.375(4)	1.364(5)	1.357(7)
C13–S1	1.672(4)	1.711(4)	1.726(6)
C19–N14	1.339(6)	1.345(5)	1.342(7)
C11–O11	1.236(7)	1.228(4)	1.221(7)
C12–N12–N13	115.4(4)	118.4(3)	116.2(4)
N12–N13–C19	119.8(4)	113.4(3)	113.8(4)
N13–C19–N14	114.6(4)	113.9(4)	114.4(5)
N13–C19–S1	121.5(4)	126.0(3)	126.6(4)
N14–C19–S1	123.9(3)	120.0(3)	119.0(4)
N11–C11–O11	127.7(4)	127.0(4)	126.1(5)
C12–C11–O11	126.3(4)	126.8(4)	127.9(5)

weakly interacting amide oxygens cause a greater change in C11–O11 in the complexes. However, the N12–N13–C19 bond angle is much smaller at about 113.6° for the complexes compared to 119.8(4)° for HIshexim, and C12–N12–N13 is also different in the complexes. Both N–C–S bonds undergo significant changes in the complexes, but C12–C11–O11 is not changed by more than three times the combination of the estimated standard deviations of the angles.

3.2. Spectral studies

The colors, partial elemental analyses and magnetic susceptibilities of the seven complexes formed electrochemically from HIshexm are listed in Table 7. All but [Tl(Ishexim)] have two ligands per metal center and the yellow and orange colors are in part due to the original color of the ligand, the formation of a conjugated thiosemicarbazone moiety on loss of N3H and L → M charge transfer bands.

The assignments for N11*H* and N13*H* in the ^{1}H NMR spectrum of HIshexim were previously reported as 11.258 and 13.504 ppm [11]. Assignments for the resonances that undergo change in the diamagnetic metal complexes formed from HIshexim are listed in Table 8. Loss of the N13H hydrogen on coordination results in the absence of a resonance above 13 ppm in the spectra of the metal complexes and N1*H* ranges from 10.673 ppm in [Tl(Ishexim)] to 11.018 ppm in [Cd(Ishexim)$_2$]. The difference between the ^{1}H NMR spectrum of HIshexim and its metal complexes involves the protons of the hexamethyleneiminyl ring. Listed in Table 7 are the hydrogens attached to the α-carbon atoms of the ring, which are different owing to restricted rotation about the C–N bond connecting the ring to the thioamide carbon. This bond distance is more consistent with a double bond than a single bond. In HIshexim the distance of this bond is 1.339(6) Å [11], and its distance in [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] averages 1.345(5) and 1.342(7) Å, respectively. In the complexes these resonances are downfield from their position in the spectrum of HIshexim. There are differences in the complexes between the hydrogens attached to the two β-carbons and γ-carbons, which is probably due to the different environment for the two ligands in a complex.

In the ^{13}C spectrum of isatin [22] the amide carbon, C11, is assigned at 159.4 ppm and the ketonic carbon, C12, at

[a] Not recorded.

184.4 ppm. In the the eight isatin N(4)-substituted thiosemicarbazones [11], the ketonic (now azomethine) carbon signal is at significantly higher field (i.e. 131.5–134.8 ppm), the exact position being dependent on the nature of the substituent of the thiosemicarbazone moiety. Its resonance in the spectrum of HIshexim is 134.8 ppm and C11 is at 162.9 ppm and C19 at 178.5 ppm, Table 8. In the spectra of the complexes the thioamide and amide carbons, C19 and C11, respectively, are found downfield from their position in the spectrum of HIshexim, suggesting coordination by the thiolato sulfur and amide oxygen. In the spectra of the complexes the imine carbon, C12, is found upfield indicating coordination of the imine nitrogen. The lone exception is [Tl(Ishexim)] which shows C12 essentially unshifted, but has a significantly larger shift of C19 and a larger shift of C11. Like the ^{1}H NMR spectra the complexes have more peaks for the carbons of the hexamethyleneiminyl ring than does HIshexim.

The IR bands, Table 9, assigned to ν(CO), ν(CN) and ν(CS) generally undergo shifts from their positions in the spectrum of HIshexim to lower energy on coordination to the metal ions. These shifts indicate coordination of the amide oxygen, imine nitrogen and thiolato sulfur atoms for most of the complexes. In the spectrum of [Cu(Ishexim)$_2$], ν(CO) is found at higher energy than in the spectrum of HIshexim, suggesting that the oxygen is not strongly coordinated in this complex. The shifts in these bands for [Tl(Ishexim)], which are generally comparable to those of the remaining complexes with divalent metal ions, suggest that the thiolato sulfur atom may be bridging to adjacent Tl centers rather than the amide oxygen.

The UV–Vis spectra of HIshexim and the complexes are included in Table 9. The highest energy $\pi \rightarrow \pi^*$ band is at lower energy in the spectrum of [Zn(Ishexim)$_2$] and higher energy for [Pb(Ishexim)$_2$] compared to HIshexim. The $\pi \rightarrow \pi^*$ band at 35780 cm^{-1} in the spectrum of HIshexim is

[a] Species suggested to be lost.

at higher energy in the spectra of the complexes, suggesting it likely arises from one of the functional groups that is coordinating rather than the aromatic ring. In the spectrum of HIshexim the band at 27820 cm^{-1} is very broad and likely involves n→π* transitions for the C=O, C=N and C=S functions. The two lowest energy bands in the spectra of the complexes are assigned to L→M charge transfer transitions with the lowest energy band probably associated with the thiolato sulfur donor.

The positive ion mass spectra of the complexes, Table 10, show a cluster of ions with significant intensity centered at *m/z* for their molecular ions, $(M+1)^+$, with the exception of [Ni(Ishexim)$_2$] and [Cd(Ishexim)$_2$]. The other significant cluster of peaks in their spectra occurs at $(M-302)^+$, due to loss of an Ishexim ligand. The loss of this ligand appears to be a one-step process because there is little indication of its partial decompostion (i.e. ions between M−1 and M−302) except for [Zn(Ishexim)$_2$] which shows $(M-16)^+$ and $(M-32)^+$ fragments due to loss of oxygen and either sulfur or oxygens from both ligands. [Tl(Ishexim)] also shows a $(M-16)^+$ fragment. [Cu(Ishexim)$_2$], [Zn(Ishexim)$_2$] and [Pb(Ishexim)$_2$] all show a signficant peak at *m/z* 301, suggesting loss of the metal as well as one of the Ishexim ligands.

[Cd(Ishexim)$_2$], based on its various spectral properties, is expected to have a similar stereochemistry to that of [Zn(Ishexim)$_2$]. [Tl(Ishexim)] is probably four coordinate with the thiolato sulfur serving as the bridging donor atom based on its large downfield shift of *C*(S) in its ^{13}C NMR spectrum and the large decrease in energy of ν(CS) on coordination. The IR spectrum of [Cu(Ishexim)$_2$] shows that ν(CO) is shifted to higher energy compared to HIshexim, suggesting that the amide oxygens of the two ligands are not coordinated. Consistent with CuN_2S_2 coordination is the d→d composite band at 16640 cm^{-1} [23], and its EPR parameters of $g_\parallel = 2.190$, $g_\perp = 2.059$, $g_{av} = 2.103$ and $A_\parallel = 162$ G for the solid at liquid nitrogen temperature. The *g*-values are considerably higher than those of a CuN_2S_2 center such as [Cu(Buhexim)] (Buhexim = dianion of 2,3-butanedione bis{3-hexamethyleniminylthiosemicarbazone}), which has $g_\parallel = 2.104$, $g_\perp = 2.030$, $g_{av} = 2.055$. Therefore, the parameters for [Cu(Ishexim)$_2$] suggest that the carbonyl oxygens interact more strongly with the copper center at the lower temperature. Copper(II) complexes with N_2S_2 coordination generally have $g_\parallel = 2.145$ [24]. The resolution of the $g_\parallel$ feature is presumably due to the bulkiness of the ligand; at room temperature we are unable to assign $g_\parallel$.

For [Co(Ishexim)$_2$] assignment of the bands at 8300 and 16810 cm^{-1} to $^4T_{1g}(F) \rightarrow {}^4T_{2g}$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$, respectively, allows calculation [25] of $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ as 17600 cm^{-1}, $B = 633$ cm^{-1}, $\beta = 0.65$ and $D_q = 930$ cm^{-1}, which are reasonable parameters for approximately octahedral $CoO_2N_2S_2$ coordination. In contrast, assignment of 10910 cm^{-1} to $^3A_{2g} \rightarrow {}^3T_{2g}$ and either 14540 or 17520 cm^{-1} as $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ for [Ni(Ishexim)$_2$] does not give reasonable values for *B*, β and D_q for an octahedral $NiO_2N_2S_2$ center. This suggests, based on $\nu(CO) = 1665$ cm^{-1}, indicating oxygen coordination, and $\mu = 3.4$ BM, that [Ni(Ishexim)$_2$] is six coordinate and more tetragonally distorted than [Co(Ishexim)$_2$] [26,27].

Supplementary data

Crystallographic data for $C_{30}H_{34}N_8O_2S_2Zn$, [Zn(Isheixm)$_2$], CCDC 134850, and $C_{30}H_{34}N_8O_2S_2Pb$, [Pb(Isheixm)$_2$], CCDC 134851 have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-1003/m. Copies of available material can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

1-Alkyl-2-(naphthyl-β-azo)imidazoles (β-NaiX, X = Me (**3a**), Et (**3b**), and CH_2Ph (**3c**)) have been synthesized and reacted with K_2PtCl_4 in boiling MeCN–water (1:1, v/v) and Pt(β-NaiX)Cl_2 (**4**) are isolated as orange–brown products. IR spectra support *cis*-$PtCl_2$ configuration and the structural configuration has been carried out by the X-ray diffraction study of Pt(β-NaiEt)Cl_2 (**4b**). The treatment of aqueous silver nitrate solution, followed by the addition of pyridine bases (Rpy) and $NaClO_4$ to an acetonitrile solution of Pt(β-NaiX)Cl_2 under boiling conditions has yielded [Pt(β-NaiX)$(Rpy)_2$]$(ClO_4)_2$ (**5–7**). The structure has been established by spectroscopic data (IR, UV–Vis, ^{1}H NMR). The redox properties of the complexes exhibit azo reductions. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Naphthylazoimidazoles; Platinum(II); PtN_4 coordination; Electrochemistry; X-ray structures

1. Introduction

The chemistry of the arylazoimidazoles (**1**) of palladium(II) was developed recently by our group [1–5]. The ligand is isoelectronic with α-diimine and the active function is the azoimine group (–N=N–C=N–), abbreviated as *N,N′* (N(imine) refers to *N* and N(azo) refers to *N′*). They form Pd(*N,N′*)Cl_2 complexes [1]. The reactivity of the Pd–Cl group is exhibited by the synthesis of mixed ligand complexes of dioxolene [2,3], dithiocarbamato and xanthate complexes [4]. Reactions of pyridine bases (Rpy) substitute the chelating ligand followed by isomerization to synthesize *trans*-Pd$(Rpy)_2Cl_2$ [5]. The parallel development for platinum(II) has remained unexplored and has prompted us to undertake the present work.

Platinum(II) chemistry of azoles, pyridines and bipyridines is of recent interest for their medicinal [6–8] and photochemical [9] activity. Research into platinum(II) compounds is mostly dedicated to synthesize new compound analogues of cisplatin [10–17]. The rich chemistry of azoimidazoles and the importance of platinum(II) chemistry have attracted our attention. In this work we use new ligands 2-(naphthyl-β-azo)imidazole (**2**) and 1-alkyl-2-(naphthyl-β-azo)imidazole (β-NaiX, **3**). Platinum(II) complexes, Pt(β-NaiX)Cl_2 (**4**), have been synthesized and characterized by spectroscopic techniques and, in one case, structural confirmation has been carried out by X-ray diffraction study. The reaction of Pt(β-NaiX)Cl_2 with pyridine bases (Rpy) has also been studied and the products [Pt(β-NaiX)-$(Rpy)_2$]$(ClO_4)_2$ are characterized by spectroscopic and cyclic voltammetric data.

2. Experimental

2.1. Materials

Imidazole (Loba-chemie Indo-Austranal Co., India), β-naphthylamine, pyridine (py), benzyl chloride ($PhCH_2Cl$), acetonitrile (Merck), 4-methylpyridine (4-Mepy), 4-(*N,N*-dimethyl)pyridine (4-NMe_2py) (Lancaster, UK) and

$H_2PtCl_6 \cdot xH_2O$ (Arrora Matthey, India) were reagent grade. K_2PtCl_4 was prepared by a published procedure [18]. All other solvents were used as previously described. CH_3I and EtI were prepared before use by a literature procedure [19].

2.2. Instrumentation

Instrumentation is described in Ref. [20].

2.3. Synthesis of ligands

2-(Naphthyl-β-azo)imidazole was prepared following the procedure as described for 2-(arylazo)imidazoles [1]. The details are given as follows: to an aqueous solution of imidazole (3.0 g, 0.044 mol) and Na_2CO_3 (7.0 g, 0.066 mol) at 0–5°C was added, dropwise with continuous stirring, a diazotized solution of β-naphthylammine (6.5 g, 0.045 mmol) (prepared by adding a $NaNO_2$ (3.2 g) solution into a 1 M HCl (50 cm^3) suspension of β-naphthylamine at 0–5°C and filtering). The temperature was controlled at ice cold conditions. The orange compound thus precipitated was filtered, washed with cold water and extracted with 2N HCl (15 $cm^3 \times 4$). The solution was neutralized with Na_2CO_3 and the pH regulated to 7. The precipitate was filtered, washed and dried. Yield: 8.4 g (86%).

2.4. Alkylation of 2-(naphthyl-β-azo)imidazole: synthesis of 1-methyl-2-(naphthyl-β-azo)imidazole (β-NaiMe)

To a dry THF solution (30 cm^3) of 2-(naphthyl-β-azo)imidazole (β-NaiH) (2.0 g, 9.05 mmol) NaH (50% paraffin) (0.8 g) was added in small portions and stirred at cold conditions for 1 h. Methyl iodide (1.3 g, 9.15 mmol) was added slowly for a period of 1 h and then refluxed over a steam bath for an additional 3 h. The solution was filtered, evaporated, extracted with $CHCl_3$ solution (3×15 cm^3), washed with 10% NaOH solution and finally with distilled water (3×20 cm^3). It was chromatographed over silica gel prepared in benzene and the desired compound was eluted by acetonitrile–benzene (1:11, v/v). Orange crystalline needles were separated on slow evaporation. Yield: 0.94 g (44%).

Other ligands were prepared by an identical procedure using ethyl iodide and benzyl chloride. Yields: 30–45%. Melting points of the compounds: β-NaiMe (**3a**), 176 ± 2°C; β-NaiEt (**3b**), 122 ± 1°C; β-NaiCH_2Ph (**3c**), 140 ± 2°C.

2.5. Preparation of dichloro[1-methyl-2-(naphthyl-β-azo)imidazole]platinum(II) (*4a*)

To a MeCN–water (1:1, v/v; 40 cm^3) solution of K_2PtCl_4 (0.85 g, 2.05 mmol) 1-methyl-2-(naphthyl-β-azo)imidazole (β-NaiMe) (0.4 g, 1.7 mmol) in the same solvent (5 cm^3) was added dropwise and the mixture was refluxed for 24 h. The brown precipitate which gradually appeared on slow evaporation of the solvent in air was recovered by filtration and washed with cold MeCN–water (1:1, v/v). The dried mass, dissolved in minimum CH_2Cl_2, was chromatographed over a silica gel column. The pure product was eluted as an orange–brown band by C_6H_6–MeCN (3:1, v/v) and evaporated in air. Yield: 0.62 g (73%).

Other complexes were prepared under identical conditions and the yield varied in the range 65–75%.

2.5.1. Preparation of bis(pyridine)[1-methyl-2-(naphthyl-β-azo)imidazole]platinum(II) perchlorate

Route A: A suspension of Pt(β-NaiMe)Cl_2 (0.2 g, 0.4 mmol) in 50 cm^3 MeCN and pyridine (0.065 g, 0.082 mmol) was refluxed continuously for 72 h. The solution colour changed from orange–brown to greenish–brown. The solution was filtered and the filtrate evaporated to half of its original volume. A saturated $NaClO_4$ solution (5 ml) was added into it and the precipitated brown mass filtered and dried. The product, dissolved in minimum CH_2Cl_2, was chromatographed over a silica gel column by a light green band (small amount). The solution was evaporated in air and the product was collected. Yield: 10%.

Route B: To a MeCN solution (20 cm^3) of Pt(β-NaiMe)Cl_2 (0.2 g, 0.4 mmol) was added an aqueous solution (5 cm^3) of $AgNO_3$ (0.06 g, 0.86 mmol); this was refluxed for 2 h and the precipitated AgCl filtered off through a G-4 crucible. To this filtrate an acetonitrile solution of pyridine (0.065 g, 0.82 mmol) was added dropwise, then refluxed over a steam bath for a further 4 h and slowly evaporated in air to half of its original volume. An aqueous saturated solution of $NaClO_4$ was added to this solution at cold conditions and the brown precipitate filtered, and washed with cold MeCN–water (1:1, v/v). The product was purified as before. Yield of the brown product: 56%.

Other products were prepared similarly with varying yields in the range 50–65%.

2.5.2. X-ray crystal structure and analysis

A crystal suitable for the X-ray diffraction study of dichloro[1-ethyl-2-(naphthyl-β-azo)imidazole]platinum(II) (Pt(β-NaiEt)Cl_2, **4b**) was grown by diffusion of hexane into CH_2Cl_2 solution at room temperature. The crystal size was $0.32 \times 0.29 \times 0.20$ mm^3. X-ray diffraction data (Table 1) were collected at 293(2) K with the Siemens SMART CCD using graphite-monochromatized Mo Kα radiation ($\lambda =$ 0.71073 Å). Unit cell parameters were determined from least-squares refinement of setting angles of 3254 reflections with 2θ in the range 10–31°. A summary of the crystallographic data and structure refinement parameters is given in Table 1. Of 8213 collected reflections 3652 unique reflections were recorded using the ω-scan technique. Data were corrected for Lorentz polarization effects and for linear decay. Semi-empirical absorption corrections based on ψ-scans were applied [21]. The structure was solved by heavy atom methods using SHELXS-97 [22] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined

[b] $wR=[\Sigma w(F_o^2-F_c^2)/\Sigma wF_o^4]^{1/2}$; $w=1/[\sigma^2(F_o^2)+(0.0473P)^2+14.3394P]$, $P=(F_o^2+2F_c^2)/3$.
[c] GOF (goodness of fit) is defined as $[w(F_o-F_c)/(n_o-n_v)]^{1/2}$, where n_o and n_v denote the numbers of data and variables, respectively.

using the riding model. In the final difference Fourier map the residual maxima and minima were 0.831 and −0.794 e Å^{-3}. All calculations were carried out using SHELXL-97 [23].

3. Results and discussion

3.1. Synthesis

2-(Naphthyl-β-azo)imidazole (β-NaiH, **2**) is synthesized by coupling the β-naphthyldiazonium ion with imidazole at pH 7. 1-Alkyl-2-(naphthyl-β-azo)imidazoles (β-NaiX) are synthesized by the alkylation of β-NaiH with alkyl halide (MeI, EtI, $PhCH_2Cl$) in dry THF in the presence of NaH. The complexes are abbreviated as β-NaiX where X = Me (**3a**), Et (**3b**), and CH_2Ph (**3c**). The active function is the azoimine group, –N=N–C=N–, and is designated as an *N*,*N*′-chelator (N(imidazole) refers to *N* and N(azo) refers to *N*′). They react with K_2PtCl_4 under reflux in MeCN–water (1:1, v/v) for 24 h and the products Pt(*N*,*N*′)Cl_2 (**4**) have been purified by chromatography. The complexes are characterized by elemental analyses and IR, UV–Vis, ^{1}H NMR data. The structure has been confirmed by the X-ray structure of Pt(β-NaiEt)Cl_2 (**4b**).

3.2. Structural studies

A view of the molecule Pt(β-NaiEt)Cl_2 (**4b**) is shown in Fig. 1 and selected bond lengths and bond angles are listed in Table 2. The entire molecule is essentially planar with the exception of the ethyl group. The atomic arrangement Pt, N(1), N(3), Cl(1), Cl(2) forms a good square plane (deviation ~0.0004 Å). The chelate plane consisting of Pt, N(3), C(1), N(2), N(1) is planar (deviation with maximum of 0.003 Å) and the chelate bite angle N(1)–Pt(1)–N(3) is 77.4(2)°. Other angles around Pt are supported by square planar geometry (Table 2). The Pt–N(1) (N(1) refers to N(azo)) and Pt–N(3) (N(3) refers to N(imidazole)) dis-

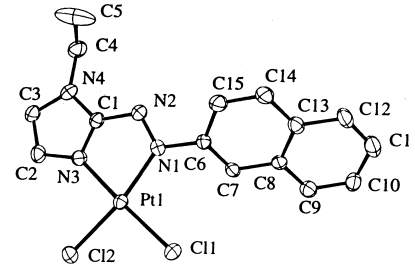

Fig. 1. Single-crystal X-ray structure of Pt(β-NaiEt)Cl_2 showing atom numbering scheme. For clarity, all hydrogen atoms have been omitted.

Table 2
Selected bond distances (Å) and angles (°) for Pt(β-NaiEt)Cl_2 along with their estimated standard deviations

Distances (Å)		Angles (°)	
Pt(1)–N(1)	2.039(4)	N(1)–Pt(1)–N(3)	77.4(2)
Pt(1)–N(3)	1.983(4)	Cl(1)–Pt(1)–Cl(2)	89.7(1)
Pt(1)–Cl(1)	2.290(1)	N(1)–Pt(1)–Cl(2)	170.3(1)
Pt(1)–Cl(2)	2.278(1)	N(1)–Pt(1)–Cl(1)	100.0(1)
N(1)–N(2)	1.280(5)	N(3)–Pt(1)–Cl(1)	177.4(1)
		N(3)–Pt(1)–Cl(2)	92.9(1)

tances are 2.039(4) and 1.983(4) Å respectively. The shortening of Pt–N(imidazole) accounts for the greater affinity of platinum to imidazole-N [24] than that of azo-N. Dichloro{2-(phenylazo)pyridine}platinum(II) also shows a longer Pt–N(py) (2.010 Å) bond than Pt–N(azo) (1.988 Å) [26]. Thus, imidazole-N has a special fascination to Pt(II) compared with other platinum metals and pyridine-N. This is the reverse of our earlier results for ruthenium(II) complexes [25]. The N(1)–N(2) distance is 1.280(5) Å and is comparable with the previously reported azo distances in metal-azo compounds [25,27]. Pt–Cl distances are supported by data from other platinum(II) complexes [28]. The naphthyl ring does not lie in a plane to the chelate ring; it makes an angle 43.88° with the metallated azoimine motif and suggests a stereochemically non-equivalent C–H function [25].

3.3. Spectral studies

The alkylation is supported by the elimination of a broad band at ca. 3400 cm^{-1} in β-NaiH. The ν(N=N) and endocyclic ν(C=N) appear at 1420 and 1580 cm^{-1}, respectively. In Pt(β-NaiX)Cl_2 (**4**), ν(N=N) is shifted to 1380–1390 cm^{-1} and is corroborated with N(azo) coordination [1]. The presence of two Pt–Cl stretches at 335–340 and 290–305 cm^{-1} is in agreement with the *cis*-$PtCl_2$ configuration [29].

The solution electronic spectra of β-NaiX (**3**) in CH_2Cl_2 exhibit intense absorptions at 390, 375 and 260 nm. In the complexes, the bands below 400 nm are discarded due to intraligand charge transitions. Multiple transitions are observed at around 608, 548, 475 and 415 nm (Table 3), which are different from aryl analogues [30]. The presence of a naphthyl ring may provide a large number of accessible energy states for transition in the metallated azo fragment [31].

The structures of the ligands and complexes are supported by ^{1}H NMR data. The signals are assigned on the basis of spin–spin interaction, and comparative integration between aliphatic and aromatic regions. β-NaiH exhibits a broad concentration-dependent resonance at 10.4 ppm corresponding to the N–H proton, which is eliminated on shaking with D_2O. Alkylated derivatives (β-NaiX) do not exhibit this resonance, which supports 1-alkylation. β-NaiMe (**3a**) shows δ(Me) at 4.07 ppm; β-NaiEt (**3b**) gives a triplet at 1.50 for $–CH_3$ and a quartet for $–CH_2–$ at 4.47 ppm; β-NaiCH_2Ph (**3c**) exhibits a sharp singlet at 5.73 ppm corresponding to methylene ($–CH_2–$) protons (Table 4). This is in agreement with our earlier observation [25]. The aromatic region shows a broad singlet at the most downfield position and is assigned to 8-H, and the downfield shifting is due to the closest position of the azo function [1]. The broadening may be due to the spin–spin interaction of 8- and 15-H. The next higher field doublet refers to 10-H. Other naphthyl protons (11- 15-H) appear as multiplets in the upfield position. Imidazole 4- and 5-H appear as separate doublets at 6.9–7.2 and 6.8–7.0 ppm, respectively.

In complexes Pt(β-NaiR)Cl_2 (**1**), imidazoles 4- and 5-H suffer maximum downfield shifting ($\Delta\delta$ = 0.2–0.4 ppm). This supports the platinaphilicity of the imidazole unit. This is corroborated by the shorter Pt–N(imidazole) (1.983 Å) compared to Ru–N(imidazole) (2.04 Å) bond length [25]. Metal ion coordination affects naphthyl protons in different ways. The characteristic features are 8- and 15-H shifts in the downward direction relative to the free ligand position of which 8-H suffers serious downfield movement ($\Delta\delta \cong 0.5$ ppm for 8-H and 0.05 ppm for 15-H). Other naphthyl protons move haphazardly and the spectral data are collected in Table 4. The marked difference in the signals of 8- and 10-H is due to their stereochemical orientation. The 8-H is assigned as stereochemically nearer to the metal centre than 10-H (*vide supra*) and may be the reason for downfield shifting. Another important difference of the spectra from the free ligand is the appearance of coupling with ^{195}Pt ($I = 1/2$, abundance 33.7%) for 4-H and 8-H. The coupling constant $^3J_{(Pt–H)}$ is 25–28 Hz for 4-H and 15–18 Hz for 8-H (Fig. 2).

3.4. Reaction with pyridines

The reaction of pyridine bases (Rpy) with the suspension of Pt(β-NaiX)Cl_2 in MeCN (route A) for a prolonged period (72 h) under reflux followed by the addition of saturated $NaClO_4$ solution has synthesized [Pt(β-NaiX)$(Rpy)_2$]$(ClO_4)_2$ in low yield (<10%). The reaction in $AgNO_3$(aq) solution (route B) followed by the addition of Rpy to Pt(β-NaiX)Cl_2 and $NaClO_4$ has yielded the same product [Pt(β-NaiX)$(Rpy)_2$]$(ClO_4)_2$ in high yield (<55%) within 6 h only. Both reactions have yielded very small amounts of unidentified green product. The conductance measurement (Λ_M = 160–180 Ω^{-1} cm^2 M^{-1}) suggests a 1:2 electrolytic nature of the complex in MeCN. Microanalytical data support the composition of the complex (Table 2). The reaction of Rpy with palladium(II) analogues under identical conditions ended with the release of chelating ligand and formation of *trans*-Pd$(Rpy)_2Cl_2$ [5].

Infrared spectra (KBr disc) exhibit a broad medium-intense band centred at 3445 cm^{-1} which is absent in the parent complex and refers to $\nu(H_2O)$ [32]. The complexes show three structured consecutive transmissions at 1120–1080 and two transmissions at 640–625. They correspond to $\nu(ClO_4)$ and support the significant coordination of ClO_4^- in the solid state [33]. The ν(N=N) appears at 1420–1425 cm^{-1} and is higher than that of the parent chloro complex. This shows a weaker azo coordination to platinum(II) in [Pt(β-Naix)$(Rpy)_2$]$(ClO_4)_2$ (**5**) than parent complexes (**4**).

The solution electronic spectra of these complexes differ markedly from Pt(β-NaiR)Cl_2 (**4**) (Table 2). Four transitions in the visible region of the parent complex are shifted to the longer wavelength region. The main transitions are observed at 800–810, 710–740, 440–480 nm along with a weak shoulder at 520–540 nm. The transitions below 400 nm are not considered. Thus, nucleophilic association decreases

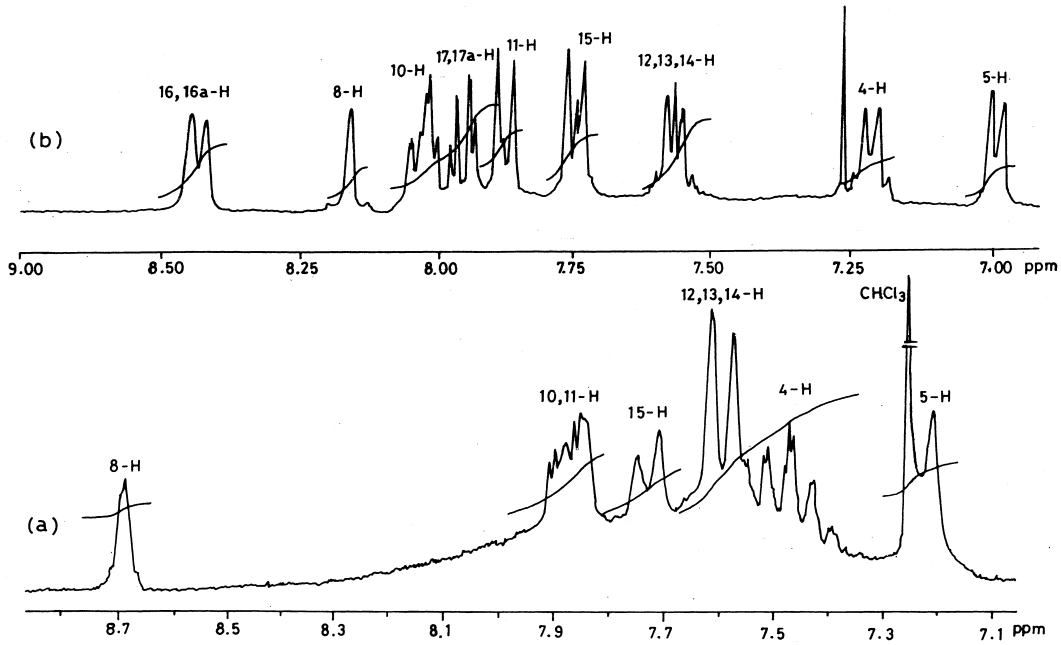

Fig. 2. ^{1}H NMR spectra of (a) Pt(β-NaiEt)Cl_2 (**4b**) and (b) [Pt(β-NaiEt)$(py)_2$]$(ClO_4)_2$ (**5b**) in $CDCl_3$ at 300 MHz.

the energy difference between the ground and excited states and may be the reason for longer wavelength transitions.

The structure and stereochemistry of [Pt(β-NaiX)$(Rpy)_2$]$(ClO_4)_2$ are established by ^{1}H NMR spectral data (Table 4) and on comparison with the spectra of the parent complexes. The distinguishable observation is the appearance of a doublet at the most downfield position, which significantly moves with the substituent in the pyridine ring. Thus, it is assigned to *ortho* H to pyridine-N (16,16a -H). The resonance corresponding to *meta*/*para* H to pyridine-N (17,17a -H) (18,18a -H) appears at the upfield side. This difference may be due to the coordination of Rpy to the platinum(II) centre. Upfield signals are assigned to the resonances of imidazole 4- and 5-H protons. Naphthyl protons appear as singlet (8-H), doublet (10-H) and others are multiplet. In general, naphthyl protons appear in the upfield position relative to the corresponding signals in the parent complex. Imidazole 4-H, naphthyl 8-H and *ortho* pyridine-H (16,16a -H) exhibit significant coupling with ^{195}Pt (Fig. 2) and support the coordination to platinum(II) [34].

3.5. Redox studies

Redox properties of the complexes were examined cyclic voltammetrically using a glassy carbon milli working electrode in MeCN in the presence of tetrabutylammonium perchlorate (n-NBu_4ClO_4) as supporting electrolyte. The potentials are expressed with reference to the saturated calomel electrode (SCE). Voltammetric data are set out in Table 3. The complexes exhibit two/three reductive responses negative to SCE. Pt(β-NaiX)Cl_2 show two consecutive reductions at less negative potentials than that of the free ligand (Table 3). The first reduction is more reversible than the second one, as evident from the peak-to-peak separation (ΔE_p). It is believed that the peaks correspond to the reduction of the organic ligand and the aof electrons are accommodated at the LUMO possibly characterized by the azoimine function. This conjecture is based on the report of our systematic studies on the ruthenium(II) and palladium(II) complexes [1–4,20,32] of the azoimine system. In pyridine derivatives, [Pt(β-NaiX)$(Rpy)_2]^{+2}$, the reduction potentials are shifted towards the more positive side. This is expected due to better stabilization of the LUMO in a PtN_4 environment where donor centres are sp^2-N. The first two couples are reversible to quasi-reversible, as expected ($\Delta E_p = 60$–90 mV), and the reduced species on further electron acceptance does not appear to be stable and, on scan reversal, no definite anodic response is observed. The last response may be localized on the pyridine derivative (Rpy) and is unstable.

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk, on request. The deposition number is 137584.

Abstract

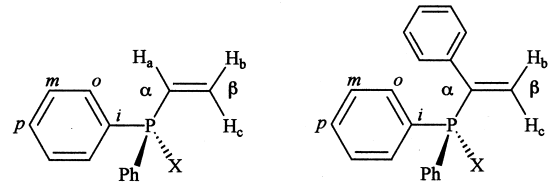
Copper(I) chloride complexes containing bifunctional phosphine/alkene ligands of the form $CuCl(Ph_2PCH{=}CH_2)_n$ ($n=1$, 3) and $CuCl(Ph_2PCPh{=}CH_2)_2$ have been synthesized, with the latter being characterized by single crystal X-ray diffraction. Complexes decompose rapidly on reaction with hydroborating agents $NaBH_4$ and $Na[B(OMe)_3H]$, although the thermally unstable $Cu(BH_4)(Ph_2PCPh{=}CH_2)_2$ may be observed by NMR spectroscopy. The complexes show considerable resistance to thermally initiated alkene polymerization, the only significant reactivity for diphenylvinylphosphine complexes being trace ligand dissociation and subsequent aerobic oxidation to $Ph_2P(O)CH{=}CH_2$. Similar dissociation/oxidation is not observed for $CuCl(Ph_2PCPh{=}CH_2)_2$. Lewis acid initiated polymerization, using $Et_2O\cdot BF_3$, results in the facile formation of copper(I) coordinated polymeric phosphine ligands for diphenylvinylphosphine complexes, but again no reactivity is induced in the more sterically hindered α-styrenyl analogue. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Phosphine; Alkene; Polymerization; Hydroboration; Copper(I) complexes

1. Introduction

The coordination chemistry of copper has been the subject of extensive research over several decades [1]. Despite such thorough activity, the structure and reactivity of copper complexes remains the focus of considerable research effort [2,3]; copper biochemistry and the stoichiometric use of organocopper reagents in synthesis are particularly significant [4,5]. The stabilization of copper(I) by tertiary phosphines forms some of the earliest studies of coordination chemistry [6,7]. Subsequent work has demonstrated a diversity of structure and stoichiometry derived from the absence of electronic factors in the d^{10} electronic configuration. Thus, whilst monophosphine complexes commonly adopt cubane or stepped tetrameric solid state structures [8,9], more sterically demanding phosphines can favour the formation of dimeric and even monomeric complexes [10,11]. The bridging halide ligands which occur in monophosphine complexes may be cleaved by the use of greater phosphine:copper(I) stoichiometries; once again the absence of ligand field control leads to the isolation of numerous products in which the copper salt, phosphine, reaction solvent and experimental conditions are all influential. The reactivity of copper chloride systems with triphenylphosphine is illustrative of this reagent and condition-based diversity. In addition to $[CuCl(PPh_3)]_4$ formed directly from CuCl or by the phosphine reduction of $CuCl_2\cdot 2H_2O$ [12], $CuCl(PPh_3)_2$ or $(Ph_3P)_2CuCl_2$-$Cu(PPh_3)/CuCl(PPh_3)_3$ may be isolated from 1:2 metal:ligand reactions in chloroform and thf, respectively [13,14]. $CuCl(PPh_3)_3$ can also be formed from 1:3 reactions in a variety of solvents or molten PPh_3 [14,15]. Whilst numerous tertiary phosphine complexes of copper(I) are reported, the present work focuses on structure and reactivity in the presence of ancillary alkene functionalities. Thus, as part of recent investigations of the phosphine/alkene complexes [16,17] we report the synthesis of diphenylvinyl- and diphenyl-α-styrenyl-phosphine complexes of copper(I), their potential for thermal and catalysed alkene polymerization, and reactivity towards hydroborating agents.

2. Results and discussion



2.1. Synthesis of complexes

The reaction of copper(I) chloride with 1 equiv. of $Ph_2PCH{=}CH_2$ in CH_2Cl_2 affords the monophosphine com-

plex CuCl($Ph_2PCH{=}CH_2$) (**1**), Table 1. Whilst reports exist of bidentate diphenylvinylphosphine complexes of silver(I) [18], IR spectroscopic evidence is indicative of non-bonded alkene functions in **1**. Thus, although **1** has not been structurally characterized, analogy with known complexes suggests the formation of tetrameric solid state species [8]. ^{1}H NMR spectroscopy is in accord with the presence of pendant alkene moieties. However, whilst vinylic proton resonances occur at broadly similar chemical shifts and with similar couplings to those of free ligand and metal complexed systems [19], it is notable that the chemical shifts of the terminal vinyl protons H_b and H_c, Scheme 1, are less separated than in comparable systems. These resonances are in fact overlaid and lie at chemical shifts which are reversed relative to their normal field positions, Table 2. Whilst the assignment of these overlaid and coupled resonances is readily elucidated by ^{1}H 2D COSY NMR spectroscopy, Fig. 1, the origin of this anomalous behaviour is less clear. Since the overlying of H_b and H_c principally originates from the larger than normal downfield shift of H_c, it must be speculated that additional deshielding interactions occur through this moiety. However, as this effect is not reflected in additional ^{1}H NMR spectroscopic coupling or shifted $^{13}C\{^1H\}$ chemicals shifts for the associated β-carbon, Table 3, it must be considered as a minor effect.

responding to the solvate **2**·0.5thf. Evidence for this formulation is provided by ^{1}H NMR spectroscopy which identifies non-bonded thf at $\delta = 1.82$ (t) and 3.70 (t) in $CDCl_3$, and thermogravimetric analysis which yields a mass loss of 4.5% (4.7%) in the temperature range 50–60°C.

In contrast to the formation of **2**, the reaction of CuCl and 3 equiv. of $Ph_2PCPh{=}CH_2$ results in the isolation of $CuCl(Ph_2PCPh{=}CH_2)_2$ (**3**) on recrystallization from CH_2Cl_2/Et_2O. The increased cone angle of the α-styrenyl ligand evidently favours bis-complex formation on steric grounds. Such changes in stoichiometry from reactant to product are not unusual, the facile modification of metal:ligand stoichiometry has been observed in other copper(I) phosphines, for example the shift from $Cu(NO_3)(PPh_3)_3$ to $Cu(NO_3)(PPh_3)_2$ on recrystallization [20]. Phenyl substitution in **3** relative to the vinyl complexes **1** and **2** results in a significant simplification of the ^{1}H NMR features associated with the alkene moiety, with protons centred at the β-carbon being reduced to phosphorus-coupled doublets, Table 2.

Since phosphine oxidation forms a facile deactivation pathway for both phosphine ligands and complexes at ambient or elevated temperatures [21,22], the phosphine oxides $Ph_2P(O)CH{=}CH_2$ (**4**) and $Ph_2P(O)CPh{=}CH_2$ (**5**) have been prepared by peroxydisulfate oxidation of the corresponding phosphines. Analytical and spectroscopic data again confirm the integrity of these products, Tables 1–3. Attempts to assign the $^{13}C\{^{1}H\}$ NMR resonances of **4** using proton-coupled ^{13}C NMR spectroscopy result in complex spectra as a consequence of extensive $^{2}J(CH)$ and $^{3}J(CH)$ coupling. $^{1}H/^{13}C\{^{1}H\}$ 2D COSY NMR spectroscopy provides in simpler route to such interpretation, Fig. 3, from which $^{13}C\{^{1}H\}$ and ^{13}C NMR resonances, as well as $^{n}J(CP)$ and $^{n}J(CH)$ couplings, can be assigned. The latter couplings are typical of phosphorus(V) interaction with aromatic and alkene sp^2 carbons.

2.2. Thermal and Lewis acid catalysed polymerization studies

The thermal effects of heating complexes **1**–**3** to 100°C in deuterated toluene have been followed using $^{31}P\{^{1}H\}$ NMR spectroscopy. In inert atmospheres no evidence for chemical change can be observed for **1**–**3** over 8 h. Under similar conditions in air, **1** and **2** show trace oxidation ($<5\%$) to free **4** ($^{31}P\{^{1}H\}$ C_7D_8 $\delta = 18.7$), although no loss of integrity is recorded for the more sterically hindered α-styrenyl complex **3**. Since vinyl and α-styrenyl substituted phosphine ligands are readily distinguish from their saturated or polymerized analogues in $^{31}P\{^{1}H\}$ NMR spectroscopy by the respective presence and absence of diamagnetic deshielding [16], it is evident that these complexes display no propensity for thermally initiated alkene polymerization.

Early reports have demonstrated that both free $Ph_2PCH{=}CH_2$ [23] and its silver(I) complexes [18] undergo Lewis acid catalysed alkene polymerization. Thus,

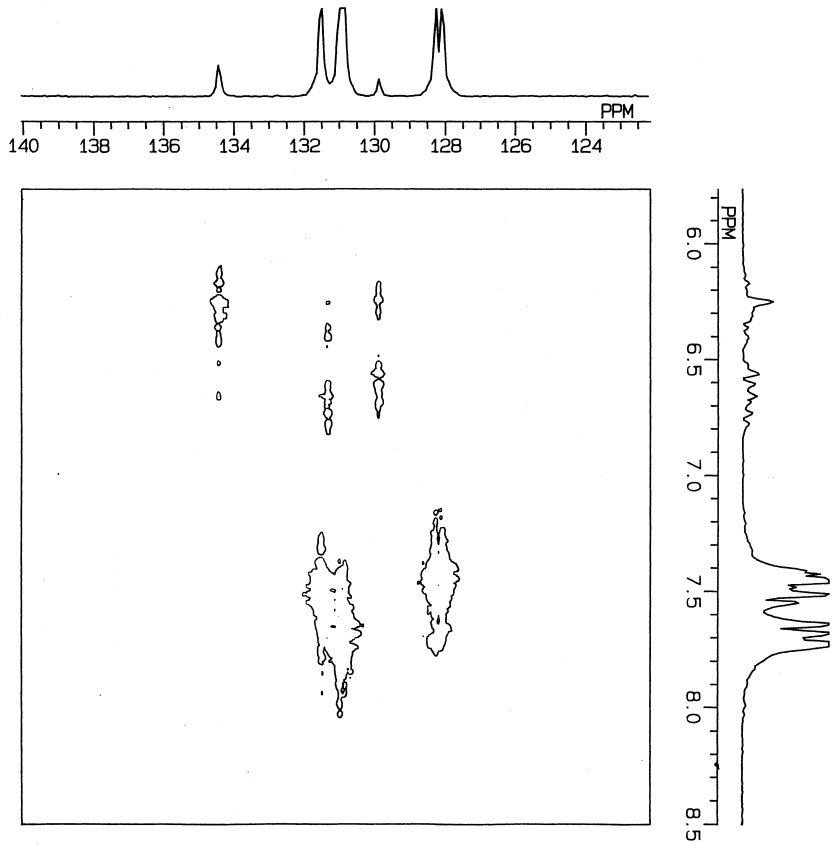

Fig. 3. $^{1}H/^{13}C\{^{1}H\}$ 2D COSY NMR spectrum of $Ph_2P(O)CH{=}CH_2$ (**4**) in $CDCl_3$.

$Et_2O \cdot BF_3$ catalysed polymerization studies have been performed in $CDCl_3$ and followed using NMR spectroscopy. The exposure of **1** to $Et_2O \cdot BF_3$ over ca. 1 h results in the precipitation of $[CuCl(Ph_2PCH–CH_2–)_n]$ (**6**) (C 54.0 (54.3); H 4.2 (4.2)) in ca. 80% yield. The corresponding reaction of **2** affords precipitates of variable hydrocarbon content consistent with concomitant ligand polymerization and dissociation. Since $[CuCl(Ph_2PCH–CH_2–)_n]$ (**6**) (and its corresponding product obtained from **2**) are insoluble in common NMR solvents, spectroscopic evidence to support polymerization is limited. No IR band corresponding to $\nu(C{=}C)$ can be located, however, such absorbances are often weak and difficult to assign even in authentic diphenylvinylphosphines. Thus interpretation is limited to elemental analysis consistent with the formation of **6**. Whilst it is obvious that **2** would provide identical elemental analysis, the considerable solubility of **2**, $Et_2O \cdot BF_3$ and the common decomposition product **4**, in $CDCl_3$ preclude the presence of these materials. The composition of the remaining reaction solution material is complex and dynamic. $^{31}P\{^{1}H\}$ NMR spectroscopy identifies five principal components, although their relative proportions vary with time and decrease overall relative to numerous other species. After 1 day a copper(I) phosphine complex ($\delta = -5.4$ and 2.5 ppm), the $[Ph_2PCH{=}CH_2 \cdot BF_3]$ adduct ($\delta = 1.7$ ppm) and additional products $\delta = 17.1$ ppm (dd $J = 62.5$ and 1187.6 Hz) and $\delta = 22.3$ ppm (dd $J = 58.9$ and 183.9 Hz) are all observed. The propensity for rapid phosphine exchange, plus the complex vinylic and ethylene resonances present in ^{1}H NMR spectra, make detailed interpretation impossible. However, further BF_3 reactivity beyond simple Lewis acid behaviour is certainly possible. Fluoride and tetrafluoroborate complexes of copper(I) phosphines are known [24], whilst the formation of BF_4^- complexes from the reaction of $Et_2O \cdot BF_3$ and $PdCl_2P_2$ complexes is well established [25].

$CuCl(Ph_2PCPh{=}CH_2)_2$ (**3**) is inert under the conditions which produce reactivity in **1** and **2**; **3** is recovered unchanged from exposure to $Et_2O \cdot BF_3$. In view of the ease with which styrene undergoes thermal and catalysed polymerization relative to ethene, the greater stability of **3** is notable. Since neither structural nor spectroscopic characterization of **3** suggests anomalous behaviour compared to **1**, **2** or $CuCl(PPh_3)_n$, it must be suggested that coordination to the relatively crowded $CuClP_2$ centre and the presence of the α-phenyl moiety are sufficient to inhibit reactivity.

2.3. Reactivity of copper complexes towards hydroborating agents

Although $Cu(BH_4)$ decomposes below ambient temperature, in the presence of tertiary phosphine and/or phenanthroline ligands, $NaBH_4$ reacts with copper(I) salts to form

stabilized complexes. The system is particularly sensitive to the nature of the phosphine employed with only triarylphosphines, PPh_2Me and various chelating phosphines containing PPh_2 fragments affording products with extended lifetimes at, or above, ambient temperature [26]. Since initial reports in this area, several strands of activity have been pursued, focusing on both structure and reactivity. Interest centres on the relationship between stoichiometry and tetrahydroborate bonding [27], and on the application of transition metal tetrahydroborates to regioselective reduction [28]. Substituted tetrahydroborates have allowed further modification of reduction reactivity, and have afforded the stable hexameric hydride $[CuH(PPh_3)]_6$ from the reaction of $Na[B(OMe)_3H]$ and $CuCl(PPh_3)$ [29], although the latter reaction is again critically dependent on the phosphine present.

Since the range of tertiary phosphines which stabilize copper(I) tetrahydroborates and hydrides is limited, it is inevitable that the isolation of $Ph_2PCH{=}CH_2$ and $Ph_2PCPh{=}CH_2$ complexes will be, at best, difficult. Indeed the reaction of **1**–**3** and $Na[B(OMe)_3H]$ at $-10°C$ proceeds through a transient red intermediate to afford metallic copper and free $Ph_2PCH{=}CH_2$ or $Ph_2PCPh{=}CH_2$; the coloration of the intermediate is consistent with that of $[CuH(PPh_3)]_6$. At lower temperatures reaction and decomposition progress more slowly, but there is no evidence for the formation of a kinetically stable hydride. **1** and **2** also form unstable products on reaction with $NaBH_4$, metallic copper and free $Ph_2PCH{=}CH_2$ being identified. Once again the reactivity of **3** contrasts with that of **1** and **2**. Reaction of **3** with a slight excess of finely ground $NaBH_4$ in $CDCl_3$ at $-10°C$ affords complete conversion to $Cu(BH_4)(Ph_2PCPh{=}CH_2)_2$ (**7**). The long-term instability of **7** has prevented elemental analysis; however, NMR is consistent with the formulation presented. ^1H NMR data are clearly indicative of a change of $Ph_2PCPh{=}CH_2$ environment with modifications in both chemical shift and $^3J(PH)$ couplings for H_b and H_c (^1H ($CDCl_3$) $\delta = 6.16$ (d, $^3J(PH) = 25.7$ Hz), 5.38 (d, $^3J(PH) = 12.6$ Hz)), and since there is no evidence for free phosphine, it is reasonable to assume the 1:2 copper:phosphine stoichiometry is maintained. The BH_4^- moiety is observed in ^1H and $^{11}B\{^1H\}$ NMR (^1H ($CDCl_3$) $\delta = 1.59$ (q, $^1J(^{11}BH) = 24.3$ Hz), $^{11}B\{^1H\}$ ($CDCl_3$) $\delta = -36.5$). $^{31}P\{^1H\}$ NMR spectroscopy is less informative owing to the facility of copper(I) complexes to undergo rapid ligand exchange, a feature which is typified by the observation of a single resonance for $Cu(BH_4)(PPh_2Me)_3$ and PPh_2Me mixtures [28]. In **7** a single new $^{31}P\{^1H\}$ NMR spectroscopic resonance is recorded at 1.0 ppm. Supporting evidence for the presence of coordinated BH_4^- is provided by solid state IR spectroscopy, from which bands at 2381 and 2011 cm^{-1} are identified. These are less separated than the terminal and bridging $\nu(Cu–H_t)$ and $\nu(Cu–H_b)$ bands of most pseudo-tetrahedral $Cu(\eta^2\text{-}BH_4)P_2$ systems, but are certainly indicative of BH_4^- coordination [30].

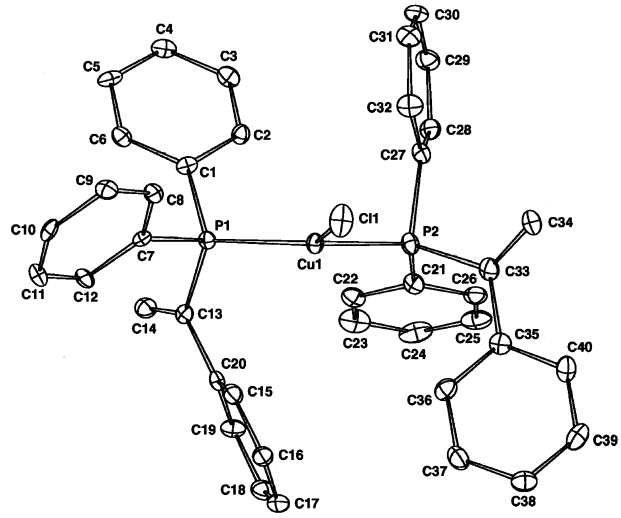

Fig. 4. Single crystal X-ray diffraction structure of $CuCl(Ph_2PCPh{=}CH_2)_2$ (**3**).

2.4. Single crystal X-ray diffraction characterization of $CuCl(Ph_2PCPh{=}CH_2)_2$ (3)

Whilst numerous copper(I) phosphine complexes have been crystallographically characterized, the majority of studies have focused on elucidating the relationship between complex structure and phosphine steric/electronic parameters in $[CuClP]_n$ complexes [1]. Structural determinations of $CuClP_2$ donor sets are less common; only $CuCl[P(o\text{-}tolyl)_3]_2$ [31] and two forms of solvated $CuCl(PPh_3)_2$ [9,14] have been reported. Thus, suitable crystals of **3**, formed by recrystallization from CH_2Cl_2/Et_2O, were studied by X-ray diffraction. Structural characterization, Fig. 4, indicates a three coordinate copper(I) structure with P-bound ligands and pendant styrene moieties. No local symmetry is observed at the metal centre; however, NMR spectroscopic evidence consistently demonstrates the equivalence of phosphine ligands in solution. Thus, in the absence of ligand field influences, solid state asymmetry is clearly dependent on steric and packing factors.

Bond lengths in **3** are broadly similar to those of $CuCl(PPh_3)_2$, Table 4. Bond angles indicate an almost planar arrangement around the copper centre. The steric repulsion of the phosphine ligands is demonstrated by the large P–Cu–P angle, with considerable asymmetry being apparent from the two P–Cu–Cl angles. Once again similar features have been observed in $CuCl(PPh_3)_2$, although the deviations from an idealized trigonal planar geometry are more pronounced in **3**.

3. Conclusions

Copper(I) forms complexes with diphenylvinyl- and diphenyl-α-styrenyl-phosphine in which phosphine ligands adopt P-bound coordination. Pendant alkene moieties are thermally stable, but vinyl functions polymerize in the pres-

ence of boron trifluoride. Phenyl substitution of the α-carbon renders the alkene less susceptible to polymerization, but also affords a tetrahydroborate complex that is sufficiently stable to allow NMR characterization.

4. Experimental

4.1. Single crystal X-ray diffraction

Crystal data for $[CuCl(Ph_2PCPh{=}CH_2)_2]$ (**3**), $C_{40}H_{34}ClCuP_2$. Crystal dimensions $0.05\times0.05\times0.2$ mm. $M=675.60$, monoclinic, space group $P2_{1/C}$. $a=9.207(2)$, $b=9.894(2)$, $c=36.510(7)$ Å, $\beta=93.80(3)°$, $V=3318.5(12)$ Å^3, $Z=4$, $D_{calc}=1.352$ g cm^{-3}, $T=293(2)$ K, λ(Mo Kα) $=0.71073$ nm, μ(Mo Kα) $=0.863$ mm^{-1}; observed data 4748, unique no. of observed data 3115 ($I>2\sigma(I)$), $R=0.0566$, $wR=0.1352$. Max./min. final difference $+0.472/-0.390$ e Å^{-3}. Intensity data were recorded on a FAST TV area detector following previously described procedures [32]. The structure was solved by direct methods (SHELXS-86) and refined by full matrix least squares on F^2 (SHELX-92), with all non-hydrogen atoms being refined anisotropically. Hydrogen atoms were assigned fixed positions and thermal parameters defined by their respective carbon atoms.

4.2. Spectroscopy

All reactions were carried out under nitrogen using dry degassed solvents using previously described methods [33]. ^{1}H, ^{13}C{^{1}H}, ^{13}C and ^{31}P{^{1}H} NMR spectra were obtained at 270.05, 67.8 and 81.1 MHz, respectively, in $CDCl_3$ and/or C_7D_8, on a JEOL GSX-270 instrument. Standard acquisition parameters were used in each case, although 8–10 s pulse delays were found necessary to obtain reasonable ^{13}C{^{1}H} and ^{13}C NMR spectra. ^{1}H/^{13}C{^{1}H} 2D COSY NMR spectra were obtained using the pulse sequence ($\pi/2$, ^{1}H)–($t^1/_2$)–Δ_1–($\pi/2$, ^{1}H; $\pi/2$, ^{13}C)–Δ_2, where $\Delta_1={}^1/_2J$ and $\Delta_2={}^1/_4J$ and $J=120$ Hz [19].

4.3. Ligand synthesis

$Ph_2PCH{=}CH_2$ was prepared by the Grignard route from commercial $CH_2{=}CHMgBr$ and Ph_2PCl. $Ph_2PCPh{=}CH_2$ was similarly prepared using Grignard formed by the reaction of α-bromostyrene and magnesium turnings. Syntheses followed conventional procedures [34]. In each case the ^{1}H and ^{31}P{^{1}H} NMR data are comparable with literature values [35].

4.4. Complex synthesis

Two synthetic routes were utilized, i.e. the stoichiometric reaction of copper(I) chloride or the reduction of hydrated copper(II) chloride in the presence of excess phosphine. Whilst both routes are acceptable, the former is preferable in terms of yield and control of metal:ligand stoichiometry. Thus the following is typical; 2.00 g copper(I) chloride (2.02 mmol) is slurried in dry dichloromethane (45 cm^3). One equivalent of $Ph_2PCH{=}CH_2$ (ca. 4.5 g, 2.1 mmol) is added and the reactants stirred until the insoluble salt is consumed. The solution is then filtered and **1** precipitated by the addition of hexane. Separation of the resulting solid by filtration and drying in vacuo affords **1** in 95% yield.

4.5. Phosphine oxide synthesis

4.5.1. $Ph_2P(O)CH{=}CH_2$

$Ph_2PCH{=}CH_2$ (1.08 g; 5.1 mmol) was dissolved in CH_2Cl_2 (25 cm^3) and slurried with Oxone® for 1 day, after which the solution was filtered and concentrated to dryness affording $Ph_2P(O)CH{=}CH_2$ in quantitative yield. ^{1}H, ^{13}C{^{1}H} and ^{31}P{^{1}H} NMR: see Tables 2 and 3. IR (KBr): ν(O=P) 1174 cm^{-1}. MS (EI) $m/e=228$ (100%). $Ph_2P(O)CPh{=}CH_2$: The compound was similarly prepared and characterized by ^{1}H and ^{31}P{^{1}H} NMR spectroscopy (see Table 3). IR (KBr): ν(O=P) 1189 cm^{-1}. MS (EI) $m/e=305$ (100%).

4.6. Thermal polymerization studies

The following is typical: **1** (4.3 mg) was dissolved in dry degassed C_7D_8 (2.0 cm^3) and placed in a sealed 4.0 mm

NMR tube under nitrogen. The solution was heated to 100°C for periods of 1 h for up to 8 h. After each hour the tube was cooled to ambient temperature and the NMR spectrum recorded.

4.7. BF_3 initiated polymerization studies

An NMR sample of **1** (6.3 mg) was prepared in $CDCl_3$ as above and $Et_2O \cdot BF_3$ (10 μl) added under nitrogen. The NMR spectrum was obtained after 1 h, 1 day and 7 days at ambient temperature, precipitated material being removed by filtration and dried in vacuo. Additional $CDCl_3$ was added to the remaining solution to maintain constant volume.

4.8. Reactions with $NaBH_4$ and $NaB(OMe)_3H$

$NaBH_4$ (5.0 mg; 0.13 mmol) was placed in a dry 4.0 mm NMR tube under nitrogen and cooled to −10°C. A solution of **1** (23.3 mg; 0.11 mmol) was prepared in $CDCl_3$ (2.0 cm^3), precooled to −10°C and transferred to the NMR tube under nitrogen. NMR spectra were obtained after 1 h and 1 day.

Supplementary data

Crystallographic data for structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 134113. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Received 30 November 1999; accepted 28 March 2000

Abstract

Unique diiodo(bipiperidinethiuramdisulfide)zinc(II) (**1**) and diiodo(bipiperidinethiuramdisulfide)cadmium(II) (**2**) were prepared by the oxidation of the corresponding bis-dithiocarbamates with iodine and the crystal structures of the compounds are reported. Metal ions are situated at the centre of a tetrahedral arrangement of two sulfur atoms of the piperidine thiuramdisulfide and two iodide ions. Two sets of significantly different C–S distances clearly correspond to single- and double-bonded C–S distances. The disulfide S–S distance in [Zn(bipiptds)I_2] is long compared to the distance in [Cd(bipiptds)I_2]. The two C=S bonds of the disulfide in the present complexes are on the same side, as a requirement for coordination with metal ions. IR spectral studies are in keeping with the thioureide distances. ©2000 Elsevier Science Ltd All rights reserved.

Keywords: Disulfides; Thioureides; Dithiocarbamates; Tetrahedral coordination

1. Introduction

Dithioacid complexes of the ML_2 (M = Zn or Cd, LH = X-CS_2H or X_2PS_2H) type are coordinatively unsaturated; this leads to the formation of compounds of higher coordination number either by the addition of one or two molecules of a Lewis base or by polymerization of ML_2. Zinc dithiocarbamates and their adducts with primary and secondary amines have previously been prepared [1–3] and some of the complexes are very active accelerators for the vulcanization of rubber by sulfur [4] and the low temperature vulcanization of latex [5]. As a continuation of our efforts to understand the reactivity of dithiocarbamates [6–8], the reaction of I_2 with M(pipdtc)$_2$ (pipdtc$^-$ = $C_5H_{10}NCS_2^-$) (M = Zn, Cd) was carried out. Interesting four-coordinate [M(bipiptds)I_2] resulted. The chemistry and crystal structure of the [Zn(bipiptds)I_2] (**1**) and [Cd(bipiptds)I_2] (**2**) are reported.

2. Experimental

All the reagents and solvents employed were commercially available analytical grade materials used as supplied, without further purification. IR spectra were recorded on a JASCO IR-700 spectrophotometer (range 4000–400 cm^{-1}) as KBr pellets. Electronic spectra were recorded using a JASCO UVIDEC-650 spectrophotometer with chloroform as the solvent.

2.1. X-ray crystallography

Details of the crystal data, data collection and refinement parameters are summarized in Table 1. ORTEP plots of the molecules **1** and **2** are given in Figs. 1 and 2. Intensity data were collected on a Philips PW1100 diffractometer using graphite monochromated Mo Kα radiation (λ = 0.71069 Å). The intensity of a standard reflection measured for every 100 reflections showed no significant change. The absorption correction was performed with the DIFABS [9] program using the method of Walker and Stuart [10]. Structure was solved by direct methods using SIR92 [11] and was refined by

SHELX 76 [12] and SHELX 93 [13]. All the non-hydrogen atoms were refined anisotropically.

2.2. IR and UV–Vis spectra

IR spectra were recorded on a JASCO IR-700 spectrophotometer (range 4000–400 cm^{-1}) as KBr pellets. UV–Vis spectra were recorded on a JASCO UVIDEC-650 with pure chloroform as the reference.

2.3. Preparation of the complexes

(a) Bis(piperidinedithiocarbamato)M(II) (M = Zn, Cd) complexes were prepared by the general methods reported earlier [8].

(b) Iodine (1 mmol) in chloroform (50 ml) was added dropwise to the solution containing M(pipdtc)$_2$ (1 mmol) in chloroform (20 ml) over a period of 2 h with continuous stirring. Light turbidity appeared in the solution after some time, which was removed by filtration. The filtrate was left undisturbed at room temperature. After 2 days pale yellow crystals separated from the solution. The crystals were filtered, washed with chloroform and then dried.

3. Results and discussion

3.1. Spectral studies

Both the zinc and cadmium complexes are of pale yellow colour. The electronic spectra contained only charge transfer bands in the 260–320 nm range for both complexes. IR spectra of both compounds showed weak disulfide bands around 480 cm^{-1}. The ν(C–S) bands appeared around 750 cm^{-1}. The thioureide band was observed around 1475 cm^{-1}.

3.2. Single-crystal X-ray studies

Unit cell constants and data collection parameters for the crystals are given in Table 1. Selected bond lengths and angles for the crystal structures **1** and **2** are given in Tables 2 and 3.

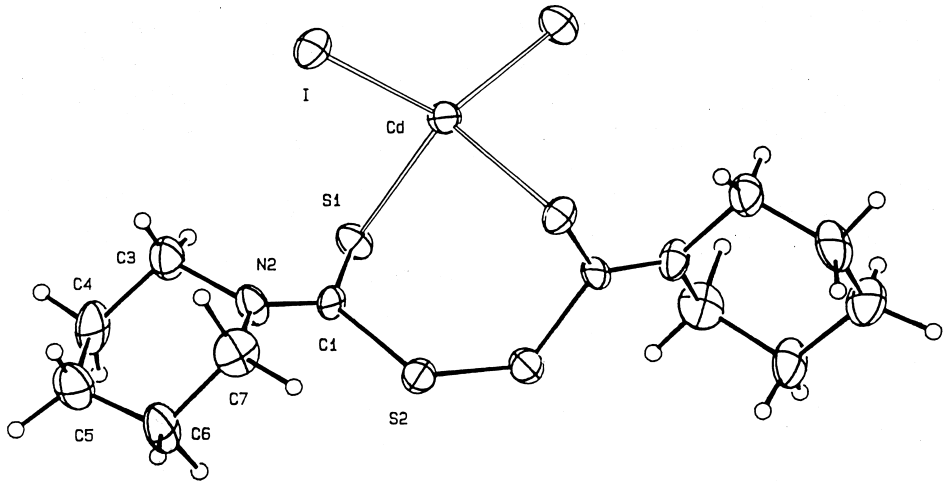

Fig. 2. ORTEP plot of [Cd(bipiptds)I_2].

The unit cell contains eight and four molecules in **1** and **2** respectively. The thiuramdisulfide of piperidinedithiocarbamate and two iodide ions are involved in complex formation with the metal ions. Both the metal ions are in near tetrahedral environment. Two sets of significantly different C–S distances are observed (mean C–S distances: 1.684(18), 1.793(14); 1.687(10) and 1.823(9) Å) for the compounds **1** and **2**, respectively. These distances clearly correspond to single- and double-bonded C–S bonds in each. The two C=S bonds of the disulfides in the present complex are on the same side, as a requirement for coordination with metal.

The Zn–S and Cd–S distances are 2.445(4) and 2.654(3) Å, respectively, which are significantly longer compared to the distances observed in the dithiocarbamate complexes. The M–S interactions, therefore, are relatively weak in [M(bipiptds)I_2] compared to their parent dithiocarbamates. The Zn–I and Cd–I bond distances are 2.552(2) and 2.699(1) Å respectively in keeping with the ionic radii of the central ions. The I–Zn–S and I–Cd–S angles are 107.1(1) and 103.1(1)° respectively, which indicate the near tetrahedral environment around the metal ions.

The disulfide S–S distance in [Cd(bipiptds)I_2) is 1.998(5) Å which is close to the distances observed in free disulfides [14–16]. In the case of [Zn(bipiptds)I_2], the S–S distance is 2.251(6) Å which is longer than those observed in free disulfides. Very significant increase observed in the disulfide S–S bond distance in the present compound is due to the larger strain involved in forcing the two C=S bonds to assume a *cis* form in order to coordinate to the zinc ion. The C–N thioureide distances observed in [Zn(bipiptds)I_2] (1.314(18) Å) and [Cd(bipiptds)I_2] (1.312(14) Å) are similar to those observed in other dithiocarbamate complexes, which confirms the considerable double-bond character associated with the thioureide bonds. The IR spectroscopic data support the structural determinations because ν(C–N) bands occur at 1478 and 1474 cm^{-1} for [Zn(bipiptds)I_2] and [Cd(bipiptds)I_2], respectively, indicating the partial double-bond nature.

Coordination of iodide ions to M(II) ions takes place by a concomitant oxidation of the dithiocarbamate moiety into the corresponding disulfide as per the following reaction:

POLYHEDRON

Studies on α-$C_3S_5^{2-}$ ($dmit^{2-}$) and its dinuclear Ni(II) complex: spectroscopic and structural characterization

Jonathan G. Breitzer, Thomas B. Rauchfuss *

School of Chemical Sciences and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana, IL 61801, USA

Received 22 November 1999; accepted 14 March 2000

Abstract

The optical properties of the $dmit^{2-}$ ion ($dmit^{2-}$ = 4,5-dimercapto-1,3-dithiol-2-thiolate) have been characterized under a range of conditions. The oxidatively sensitive anion is highly solvatochromic: λ_{max} = 504 (H_2O), 514 (MeOH), 568 (MeCN), and 632 nm (DMF). With a shift in absorption maximum of 4000 cm^{-1} (DMF versus H_2O), $dmit^{2-}$ is possibly the most solvatochromic species known. The dianion is monoprotonated by NH_4^+ and binds CS_2 to form a thioxanthate ($C_3S_5 \cdot CS_2^{2-}$). ^{13}C NMR measurements of ^{13}C-enriched $dmit^{2-}$ demonstrated that $C_3S_5 \cdot CS_2^{2-}$ exchanges with free CS_2 via an associative pathway involving binding of a second molecule of CS_2. Titration with acid showed that the M_2dmit (M = Na, Cs) dissolves to give the dianion in protic solvents, rather than $Hdmit^-$. The conversion of α-$C_3S_5^{2-}$ to its β-isomer ('Steimecke rearrangement') occurs very slowly with purified Na_2dmit, in contrast to the literature method. The salt $(NBu_4)_2[Ni(dmit)_2]$ is also highly solvatochromic but its behavior does not follow any simple pattern. Treatment of $(NBu_4)_2[Ni(dmit)_2]$ with 1/3 equiv. of $[Ni(NCMe)_6](BF_4)_2$ gave the dinuclear compound $(NBu_4)_2[Ni_2(dmit)_3]$, the first Ni–$dmit^{2-}$ complex with a Ni/$dmit^{2-}$ ratio that is not 1:2. The binuclear salt crystallizes as the CH_2Cl_2 solvate as dark purple prisms. The planar $Ni(dmit)_2^{2-}$ is bridged to Ni(dmit) via two sulfur atoms; the anion features a short Ni–Ni distance of 2.71 Å. ©2000 Elsevier Science Ltd All rights reserved.

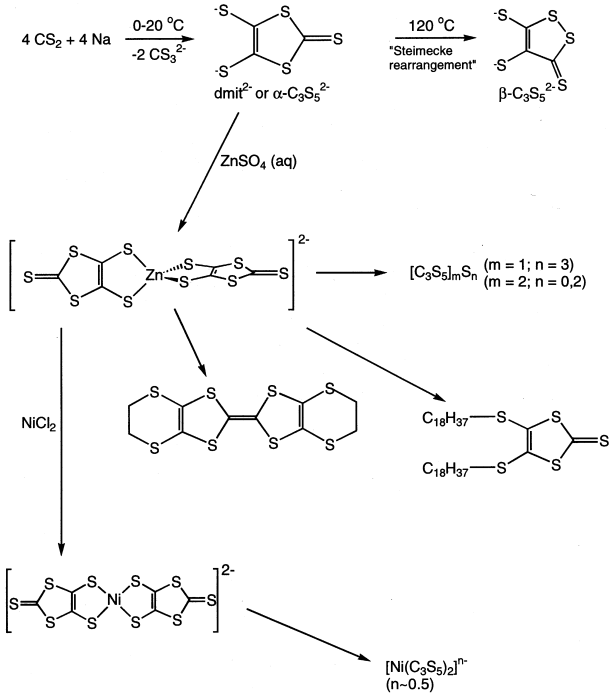
1. Introduction

The inorganic heterocycle 4,5-dimercapto-1,3-dithiole-2-thione, with formula $C_3S_5^{2-}$ referred to here as $dmit^{2-}$, is the basis for a substantial amount of research. The anion is of interest primarily as a precursor to electronic and photonic materials. This extensive research has been facilitated considerably by the efficient synthesis of $dmit^{2-}$ by the alkali metal reduction of carbon disulfide [1–3]. In this preparation, a mixture of carbon disulfide and dimethylformamide is treated with sodium to give an equimolar mixture of the $dmit^{2-}$ and trithiocarbonate ions. Separation of the two anions is readily achieved by treating the mixture with an aqueous solution of Zn^{2+}, which selectively complexes to the $dmit^{2-}$ (Scheme 1).



The chemistry of $dmit^{2-}$ can be roughly divided into three branches:

1. Organic derivatives, which are commonly related to the preparation of tetrathiafulvalenes [4], but have been extended to Langmuir–Blodgett films [5].
2. Binary carbon sulfides, illustrated by our recent synthesis of $[C_8S_8]_n$ [6,7].
3. Coordination compounds, illustrated by $[Ni(dmit)_2]^{2-}$ and organometallic derivatives, e.g. $Cp_2Ti(dmit)$ [8–10].

The third area, coordination complexes of $dmit^{2-}$, especially those of nickel, has recently been particularly active. Since 1990, over 200 publications have appeared on derivatives of $[Ni(dmit)_2]^{n-}$ ($0 < n < 2$). This explosion of interest is attributable to the discovery that certain salts of $[Ni(dmit)_2]^{n-}$ are metallic. A representative investigation in this area is the recent electrocrystallization of $[Ni(dmit)_2]^{0.3-}$ with Li(15-crown-5)$^+$ as the counterion. The resulting material was found to be both an electrical and a lithium-ion conductor; such materials are sought for cathode materials in lithium-ion batteries [11]. In addition to displaying metallic conductivity, eight $[M(dmit)_2]^{n-}$ salts (M = Ni, Pd) are superconductors; they are the only transition-metal coordination compounds that have been found to display this property [12]. These remarkable electrical properties are attributed to the sulfur-rich exterior of these complexes that results in relatively strong intra- and inter-stack interactions. Recent work has shown that $[Ni(dmit)_2]^{2-}$ exhibits a large third-order optical non linearity; hence appli-

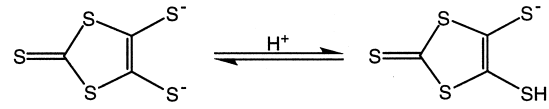
Scheme 1. Synthesis and reactions of $[Zn(dmit)_2]^{2-}$ and $[Ni(dmit)_2]^{2-}$.

cations of these materials can be envisioned in the area of photonics [13].



While the organic and coordination chemistries of $dmit^{2-}$ have been examined extensively [14], little attention has been paid to the properties of the dianion itself, as well as some fundamental aspects of its coordination chemistry. The UV–Vis spectrum of $dmit^{2-}$ has been reported previously [15,16], but it appears that both of these reported spectra are not of actual $dmit^{2-}$, but rather the product of air oxidation. A separate report will describe the redox properties of $dmit^{2-}$ and related thioanions [17].

In this paper, the spectroscopic properties of $dmit^{2-}$ are examined, and conclusions about the chemistry of this species are drawn from these properties. As indicated above, the $[Ni(dmit)_2]^{n-}$ system has been heavily examined for various oxidation states of nickel; this paper reports the first homoleptic Ni–dmit complex in which the dmit/Ni^{2+} ratio is other than 2:1 and illustrates a new bridging mode for the $dmit^{2-}$ ligand [18–22].

2. Results and discussion

2.1. Acid–base properties of $dmit^{2-}$

One of the surprising properties of $dmit^{2-}$ that has not been systematically investigated is its apparent solvatochromism (vide infra). Prior to investigating this property, we needed to determine whether the wide variety of absorption maxima exhibited by $dmit^{2-}$ in various solvents is due to actual solvatochromism or to protonation of $dmit^{2-}$ in protic solvents. DMF solutions of Na_2dmit and Cs_2dmit (the Cs salt crystallizes well and is less hygroscopic than the sodium salt [23]) are deep blue, having a λ_{max} at 632 nm ($\varepsilon = 5510\ M^{-1}\ cm^{-1}$). A DMF solution of Cs_2dmit turns red immediately on treatment with an excess of NH_4Br, with an absorption maximum (510 nm) close to that of a methanolic solution of Na_2dmit (514 nm), as shown in Fig. 1. We assign the red color in DMF to the monoprotonated species $dmitH^-$ (Eq. 1), rather than the diprotonated species, because H_2dmit, which is deep yellow in solution, decomposes, eliminating H_2S to form C_6S_8, an insoluble solid [25].

(1)

Based on the similarity of the optical properties of $dmitH^-$ in DMF and $dmit^{2-}$ in methanol, we originally concluded that $dmit^{2-}$ is so basic ($pK_a > 15$) that it actually exists as $dmitH^-$ in water and methanol. Subsequent investigations established, however, that $dmit^{2-}$ indeed exists as a dianion in water and methanol [24]. A solution of Cs_2dmit in oxygen-free water ($\lambda_{max} = 504$ nm) has similar spectroscopic properties to those of a methanolic solution of Na_2dmit. No color change was observed after treatment with a large excess of NaOH; this observation alone would mean that either $dmit^{2-}$ exists as such in water, or that $dmit^{2-}$ is extremely basic (i.e. $Hdmit^-$ is not deprotonated by NaOH).

To distinguish these possibilities, an aqueous Cs_2dmit solution was titrated (anaerobically) with HCl, monitoring by UV–Vis spectroscopy (Fig. 2). Isobestic behavior was observed at ≤ 1 equiv. of HCl; the solution was yellow and homogeneous at that point. Only upon addition of > 1 equiv. of HCl did a precipitate form; this precipate is either $H_2C_3S_5$ or its decomposition product C_6S_8 [25]. Based on the data from the titration of $dmit^{2-}$ with HCl, we conclude that $dmit^{2-}$ exists as the dianion in both protic (water, methanol) and aprotic solvents (DMF). The conclusion that $dmit^{2-}$ exists as the dianion in both protic and aprotic solvents means that the variation of color in different solvents is actually due

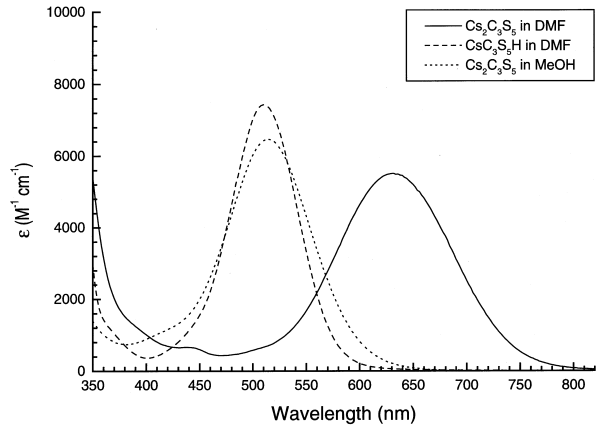


Fig. 1. Comparison of UV–Vis spectra of Na_2dmit in MeOH solution and NaHdmit in DMF solution, and UV–Vis spectrum of Na_2dmit in DMF solution.

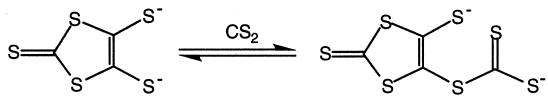
to solvatochromism, and it is only coincidence that $dmitH^-$ in DMF and $dmit^{2-}$ in water/methanol have similar absorption maxima.

2.2. Optical properties of $dmit^{2-}$

The free anion, $dmit^{2-}$, can be made soluble in water and non-protic solvents, and is oxygen sensitive in all of them. The color of $dmit^{2-}$ in solution is dependent on the solvent, ranging from red in water and methanol to blue in DMF. The most convenient preparation of the free anion involves the addition of excess NaOMe to a methanolic suspension of the thioester, $C_3S_5[C(O)Ph]_2$ [26], giving Na_2dmit as a red solution (Eq. 2) ($\lambda_{max}=514$ mm, $\varepsilon=5710\ M^{-1}\ cm^{-1}$), having an absorption maximum at 514 nm.

$$C_3S_5[C(O)Ph]_2 + 2NaOMe \rightarrow Na_2C_3S_5 + 2MeOC(O)Ph \quad (2)$$

Fig. 3 shows the UV–Vis spectrum of Na_2dmit in methanol before and after exposure to air for a few seconds. The yellow coloration for $dmit^{2-}$ solutions ($\lambda_{max}=438$ nm) indicates oxidation. The red color of authentic Na_2dmit in methanol ($\lambda_{max}=514$ nm) has been described by Svenstrup, Matsubayashi and others [4,27], and these results were confirmed by us. The absorption maximum of Na_2dmit in ethanol has however been listed by Reuter and Gattow to be 412 nm [15], which may actually be this yellow oxidized species. Removing the solvent from a methanolic Na_2dmit solution and adding dry, oxygen-free acetonitrile results in a purple solution ($\lambda_{max}=568$ nm). As shown in Fig. 4, this solution also turns yellow within seconds on exposure to air ($\lambda_{max}=472$ nm). Singh and Singh [16] recently listed the absorption of Na_2dmit in acetonitrile to be 475 nm; again, based on the similarities of the listed absorption maxima, the compound they examined appears to have been an oxidized derivative of $dmit^{2-}$.



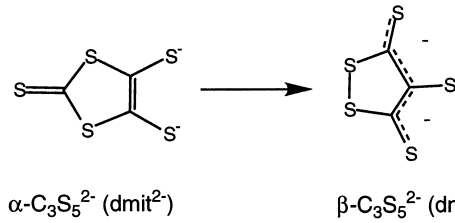
Because the energy of the absorption maximum increases with increasing solvent polarity, the effect is characterized as hypsochromism. The difference between the absorption maxima for $dmit^{2-}$ in water and in DMF corresponds to 4020 cm^{-1}; this response to solvent polarity is comparable to (or exceeds) the most solvatochromic compounds known. One such compound is a merocyanine dye [28] with a difference in absorbance maxima of 9500 cm^{-1}, but this is between toluene and water, which is a greater range of polarity than is available for $dmit^{2-}$ due to solubility constraints.

2.3. The $dmit^{2-}$–CS_2 system

In the most widely used synthetic route to $dmit^{2-}$, CS_2 is reduced with sodium metal in DMF solution. The $dmit^{2-}$ anion is not isolated directly; instead, it is usually coordinated to Zn^{2+} and isolated as the salt, $(R_4N)_2[Zn(C_3S_5)_2]$. Prior to the addition of zinc, however, the $dmit^{2-}$ solution is bright red. Such a solution should be anhydrous and highly basic, considering the presence of the Na_2CS_3 byproduct and the excess Na. It is therefore inconceivable that such a solution would contain a significant amount of the protonated species, $dmitH^-$. Another explanation is required to explain the red color of the reaction mixture, rather than the blue color ($\lambda_{max}=632$ nm) observed for M_2dmit in DMF (M = Na, Cs).

We initiated a series of experiments based on the hypothesis that the red coloration of the crude (but anhydrous) reaction solutions is due to adducts of CS_2 and $dmit^{2-}$. CS_2 is known to form adducts with a variety of nucleophiles, including thiolates [29–31], and CS_2 is usually used in a large excess in the synthesis of $dmit^{2-}$. Furthermore, the CS_2 adduct of β-$C_3S_5^{2-}$ (an isomer of $dmit^{2-}$, see Scheme 1) has been crystallographically characterized [32]. We found that the addition of CS_2 to a DMF solution of Cs_2dmit effected an immediate color change from blue to the red color of the synthesis solution ($\lambda_{max} = 490$ nm).

We further investigated the nature of the CS_2–$dmit^{2-}$ reaction through ^{13}C NMR studies using ^{13}C-enriched $dmit^{2-}$. Due to the high cost of $^{13}CS_2$, we first modified the synthesis of $dmit^{2-}$ so that it uses CS_2 more efficiently. Fig. 5 shows a ^{13}C NMR spectrum of a DMF-d_7 solution of ^{13}C-enriched $dmit^{2-}$. ^{13}C NMR resonances are observed at δ 209 and 144, which are assigned to the thiocarbonyl and the alkenyl centers, respectively. Upon treatment of this solution with an excess of unlabeled CS_2 (δ 193), a new species was formed, having signals at δ 214 (*C*=S) and broad signals at δ 172 and 122. The latter two peaks are assigned to the now-inequivalent alkenyl carbon centers of the CS_2 monoadduct of $dmit^{2-}$ (Eq. 3).



(3)

The broadness of these alkenyl peaks is attributed to an exchange of the trithiocarbonate and thiolate functions.

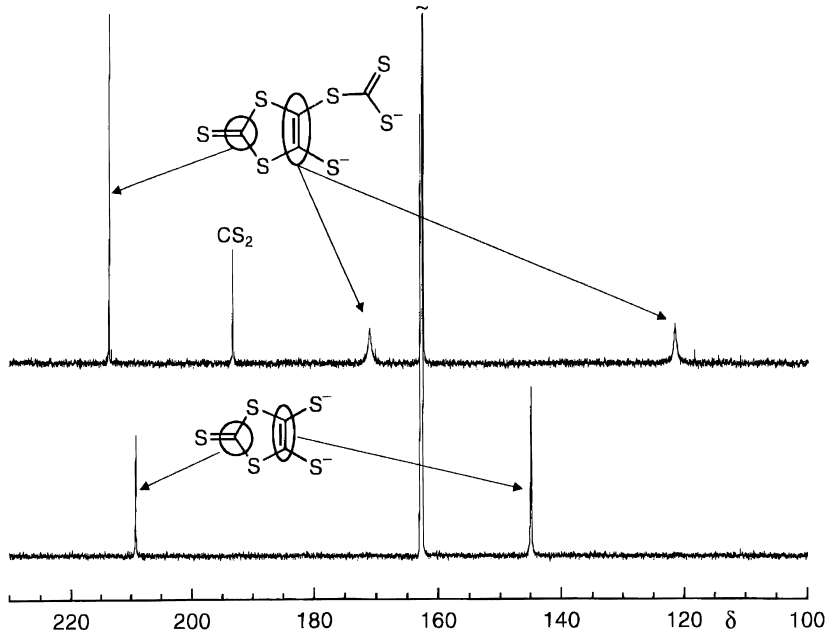
The excess CS_2 was then removed from the DMF solution by distillation under reduced pressure. The ^{13}C NMR spectrum of the resulting purplish solution shows the absence of free CS_2 and resonances corresponding to both $dmit^{2-}$ and $C_3S_5 \cdot CS_2^{2-}$.

2.4. Comments on the Steimecke rearrangement

It is well known that a mixture of sodium and carbon disulfide in DMF, when heated to 120°C, produces an isomer of $dmit^{2-}$, which we previously termed [25] β-$C_3S_5^{2-}$ (Eq. 4).

(4)

It was of interest to know whether this isomerization mechanism is intramolecular or whether other species are involved. UV–Vis spectroscopy would be suitable for monitoring this isomerization because of the different optical properties of the two isomers: the λ_{max} of $dmit^{2-}$ in DMF is 632 nm (blue color, as stated above), while the λ_{max} of β-$C_3S_5^{2-}$ in DMF is 530 nm (red color). A DMF solution of Na_2dmit remained unchanged after 24 h at 120°C, based on UV–Vis measurements. This initial experiment was conducted at a concentration (6×10^{-5} M) appropriate for UV–Vis spectroscopy. Recognizing the possibility that the rearrangement might be bimolecular, the experiment was repeated at a concentration (0.8 M) closer to that typically used in a reaction mixture [25]; however, the characteristic color change required approximately 15 days at 120°C. Evidently a catalyst, which we have not identified, is present in the reaction mixture when the Steimecke rearrangement is carried out.



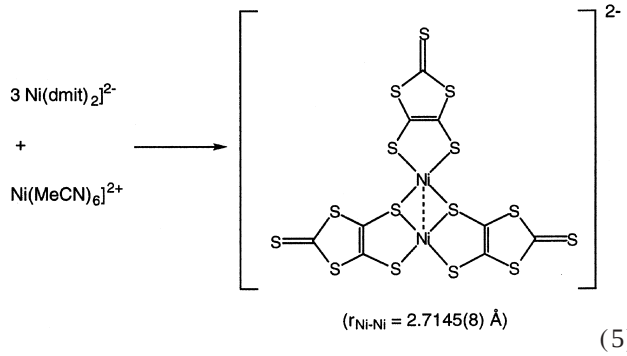


Fig. 5. 125 MHz ^{13}C NMR spectra (DMF-d_7) of Cs_2dmit (bottom), Cs_2dmit with excess CS_2 added (middle), and with most of the CS_2 removed (top).

2.5. Comments on the optical properties of $[Ni(dmit)_2]^{2-}$

We began this aspect of the work by examining the solution properties of $[Ni(dmit)_2]^{2-}$, the precursor to many conductive materials [33,34]. Spectrophotometric measurements show that $(NBu_4)_2[Ni(dmit)_2]$ is highly solvatochromic. The position of its absorption maximum does not, however, correlate with the $E_T(30)$ or the E_T^N solvent index of Reichardt and Harbusch-Goernert [35] of the solvent. THF ($E_T^N = 0.207$) solutions are blue, with a λ_{max} of 596 nm. DMF ($E_T^N = 0.386$) solutions are green, with a λ_{max} of 626 nm. This would seem to indicate that the compound is bathochromic; however, the trend reverses for acetonitrile (E_T^N index = 0.46, λ_{max} = 596 nm, blue solution) and methanol (E_T^N index = 0.762, λ_{max} = 554 nm, purple solution). There may be other factors affecting the absorption maximum besides solvatochromism, such as dimerization or ligation of a solvent.

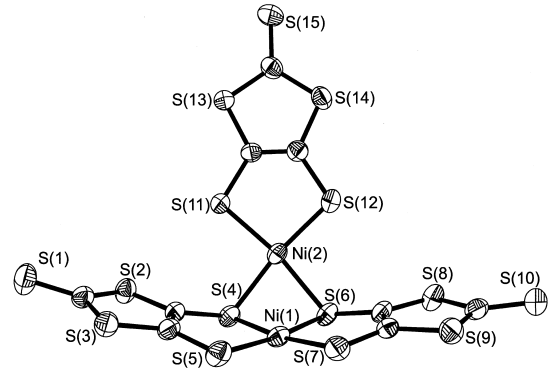
2.6. Synthesis and structure of $[Ni_2(dmit)_3]^{2-}$

While the $[Ni(dmit)_x]^{n-}$ system has been investigated for many values of *n*, variations in *x*, the Ni/dmit ratio, have not been reported. Treatment of an acetonitrile solution of $(NBu_4)_2[Ni(dmit)_2]$ with 1/3 equiv. of $[Ni(MeCN)_6]^{2+}$ gave a red solution containing the salt $(NBu_4)_2[Ni_2(dmit)_3]$ (Eq. 5).

(5)

In contrast to $[Ni(dmit)_2]^{2-}$, solutions of the dinickel compound are sensitive to oxygen. This finding is somewhat counterintuitive because the negative charge is delocalized over a larger molecule. A major product of air oxidation of this compound was characterized crystallographically to be $(NBu_4)[Ni(dmit)_2]$, which is well known [36–38].

The structure of $(NBu_4)_2[Ni_2(dmit)_3]$ was established by single crystal X-ray diffraction (Fig. 6). The anion is binuclear with two bridging dmit ligands such that the complex has idealized C_s symmetry. Bond lengths and angles are listed in Table 1. The noteworthy feature is the Ni–Ni distance of 2.7145(8) Å. An example of a compound with an unsupported Ni–Ni bond is $[Ni(C_{10}H_{14}N_8)]_2$ [39], with a Ni–Ni bond distance of 2.788(2) Å. This establishes that the nickel–nickel distance observed in this work is close enough to be characterized as a bond. The ethanedithiolate derivative $[Ni_2(S_2C_2H_4)_3]^{2-}$ [40] has a wider average Ni–S–Ni angle



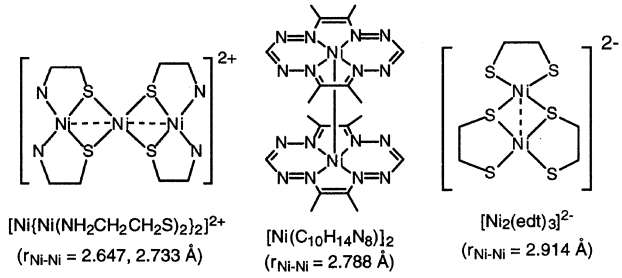


Fig. 6. The molecular structure of the anion, $[Ni_2(dmit)_3]^{2-}$, with thermal ellipsoids at the 50% probability level.

Table 1
Selected bond lengths (Å) and angles (°) for the anion in $(Bu_4N)_2[Ni_2(C_3S_5)_3]\cdot CH_2Cl_2$

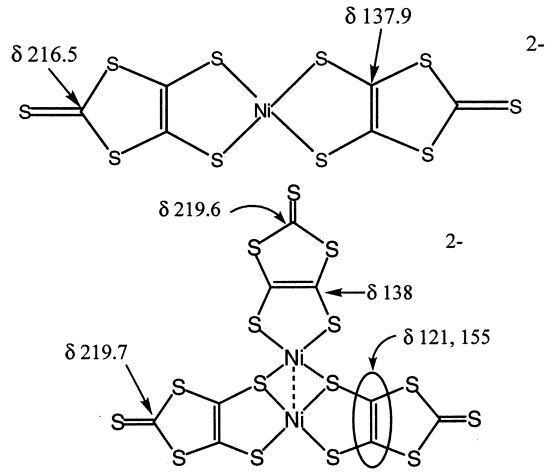
		S(4)–Ni(2)–S(6)	77.63(5)

(83.4°) than that observed here (75.8°) and a correspondingly longer Ni–Ni distance (2.914(1) Å).

Although not completely analogous in structure, an example of a short Ni–Ni bond distance bridged by a thiolate is the cation $[Ni\{Ni(NH_2CH_2CH_2S)_2\}_2]^{2+}$ [41]. Here, the two nickel–nickel distances are 2.733 and 2.647 Å, the range of these distances indicates the 'softness' of the Ni–Ni interaction. An explanation is required for an apparently attractive interaction involving a pair of filled $3d_{z^2}$ orbitals. Under lower symmetry, the $3d_{z^2}$ orbitals mix with empty $4p_z$ orbitals. This mixing lowers the energies of the $3d_{z^2}$ orbitals, resulting in a weak bonding interaction overall. The idealized symmetry environment around the nickel atoms in $[Ni_2(dmit)_3]^{2-}$ is C_s, which would also allow for mixing of the $3d_{z^2}$ and $4p_z$ orbitals on the nickel centers.

Although no compound has been structurally characterized in which $dmit^{2-}$ bridges two metal centers in an analogous fashion to $[Ni_2(dmit)_3]^{2-}$, there are other examples of bridging $dmit^{2-}$ ligands, such as in the $Cp^*_2Fe^+$ salt of $[Fe(dmit)_2]_2^{2-}$ [20].



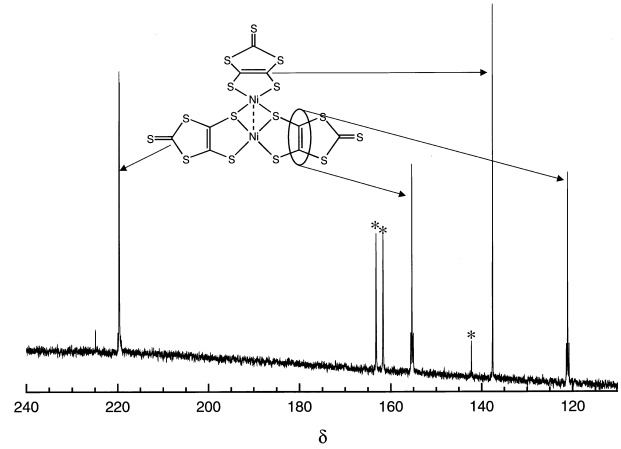
$[Fe(dmit)_2]_2^{2-}$

In this anionic dimer, the iron atoms are in a square pyramidal environment. Only one thiolate sulfur from the $dmit^{2-}$ ligand functions as a bridging ligand. The Fe–S bond lengths, both within and between $[Fe(dmit)_2]^-$ units, are all 2.24 ± 0.01 Å.

^{13}C NMR measurements were conducted on solutions of $[Ni_2(dmit)_3]^{2-}$ in order to establish its solution structure. Due to the lack of nOe effects and limited solubility, these measurements were carried out using a 10 mm sample tube and $dmit^{2-}$ that was ~16% ^{13}C. The ^{13}C NMR spectrum of $(NBu_4)_2[Ni(dmit)_2]$ features resonances at 216.5 and 137.9 [42].

On the basis of the crystallographic results, one would expect five resonances for $[Ni_2(dmit)_3]^{2-}$: three for the ethylenic carbon atoms and two for the thiocarbon atoms. The ^{13}C NMR spectrum is shown in Fig. 7. Due to the ^{13}C enrichment, ^{13}C–^{13}C coupling is evident as satellites around two of the peaks. The assignments for the peaks are as follows:

The peaks at δ 121 and 155 can be assigned to the alkenyl carbons in the $Ni(dmit)_2$ moiety because the satellites indicate coupling to a carbon in a different environment. The peak at δ 138 has no satellites, so it can be assigned to the other alkenyl carbons. The thione carbons are in such similar environments that their chemical shifts differ by only 0.1 ppm.



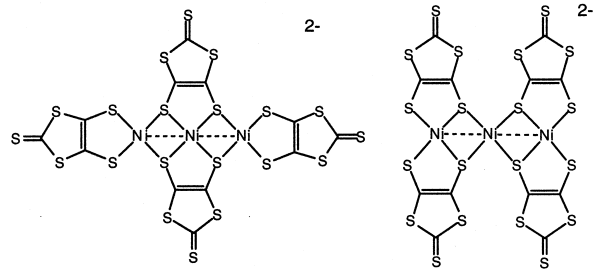


Fig. 7. 125 MHz ^{13}C NMR spectra (CD_2Cl_2) of $(Bu_4N)_2[Ni_2(dmit)_3]$. The peaks labeled with asterisks are assigned to a higher nuclearity impurity discussed in Section 2.7.

2.7. Higher oligomers of Ni–dmit^{2-}

Inspection of the ^{13}C NMR spectrum of $[Ni_2(dmit)_3]^{2-}$ reveals two additional peaks at δ 162 and 163. We attribute these to the alkenyl carbon atoms in a higher-nuclearity derivative of $Ni(dmit)_2^{2-}$. Two possible structures of this impurity are shown below.

A **B**

Both of these structures would have two types of ethylenic carbons. The ethanedithiolate analog of **B** is known [43]. However, **A** appears to be the more plausible in this case due to the lack of ^{13}C–^{13}C coupling in its NMR spectrum. The ^{13}C NMR spectrum of $(Bu_4N)_2[Ni_2(dmit)_3]$ in acetone-d_6 shows no evidence for this higher-nuclearity impurity.

Combining MeCN solutions of $Ni(dmit)_2^{2-}$ and $[Ni(MeCN)_6](BF_4)_2$ in a 1:1 ratio produced a greenish solid, which analyzed as $(Bu_4N)_2[Ni_{15}(dmit)_{16}]$. A similar study was carried out on the nickel complex of the β-$C_3S_5^{2-}$. Treatment of $(Bu_4N)_2[Ni(\beta\text{-}C_3S_5)_2]$ with $[Ni(MeCN)_6](BF_4)_2$ resulted only in an insoluble product; no intermediate products were detected. The black solid analyzed as NiC_3S_5, and preliminary electrical measurements on a pressed pellet of this solid showed it to be insulating.

3. Summary

The following are the principal conclusions of this study.

1. The $dmit^{2-}$ ion is strongly solvatochromic, having an absorption that shifts to higher energy with increasing

solvent polarity. Its color in solution ranges from red in water and methanol to blue in DMF.
2. Aqueous and alcoholic solutions of $dmit^{2-}$ indeed consist of the dianion, not the monoprotonated monoanion, $Hdmit^{-}$. The extreme solvatochromism combined with the oxygen sensitivity has been the source of previous confusion in this area.
3. CS_2 reversibly binds $dmit^{2-}$ to give the thioxanthate ($C_3S_5 \cdot CS_2^{2-}$). This adduct exchanges with free CS_2.
4. DMF solutions of pure $dmit^{2-}$ undergo the Steimecke rearrangement much more slowly than in the reaction mixture used for β-$C_3S_5^{2-}$ synthesis.
5. The well known anion $[Ni(dmit)_2]^{2-}$ reacts with a source of Ni^{2+} to form $[Ni_2(dmit)_3]^{2-}$, which features a short Ni–Ni distance ($\sim$2.71 Å).

4. Experimental

4.1. Materials and methods

$^{13}CS_2$ was obtained from Cambridge Isotopes (Cambridge, OH, USA). $[Ni(MeCN)_6](BF_4)_2$ was prepared from Ni metal and $NOBF_4$ [44]. The $C_3S_5(COPh)_2$ was prepared from the treatment of $(Bu_4N)_2[Zn(C_3S_5)_2]$ [2] with benzoyl chloride [1]. Unless otherwise noted, reactions and work-ups were conducted under nitrogen using degassed solvents. Electronic spectra were collected using an HP8452 diode-array spectrophotometer. A 1 cm path length cell was used.

4.2. Synthesis

4.2.1. Preparation of ^{13}C-enriched $(Bu_4N)_2[Zn(C_3S_5)_2]$

The usual methods for the preparation of $dmit^{2-}$ [2,45] were revised so as to make the most efficient use of $^{13}CS_2$, which is expensive. The $^{13}CS_2$ was diluted with five portions of isotopically normal CS_2. An alloy was prepared from potassium metal (0.94 g, 0.0233 mol) and sodium metal (0.515 g, 0.0224 mol), and was chilled to 0°C. Distilled DMF (10 ml) was added, followed by ^{13}C-enriched CS_2, prepared as above (2.41 ml, 0.0401 mol). The mixture took on a yellow color immediately, which progressed through orange to a deep red within 15 min. The reaction mixture was allowed to warm to room temperature over the course of 24 h, after which the mixture became a purplish-blue, porous semisolid. Residual alkali metal was oxidized with isopropanol (20 ml), followed by a few milliliters of ethanol. After 0.5 h, most of the alcohols were removed by evaporation. The purple DMF solution was treated with a solution of $ZnSO_4 \cdot 7H_2O$ (1.44 g, 5.01 mmol) in water (50 ml), chilled to 0°C, and treated with a solution of Bu_4NBr (3.24 g, 10.1 mmol) in water (50 ml). A fine red powder formed, which was collected. This was recrystallized by dissolution in $\sim$20 ml of acetone, diluting with a similar volume of methanol, and successively concentrating and diluting with methanol until red crystals formed, which were washed with ether. Yield: 2.32 g, 49% based on CS_2.

4.2.2. Preparation and characterization of $dmit^{2-}$

$Cs_2C_3S_5 \cdot 1.5H_2O$ was prepared from $C_3S_5(COPh)_2$ and $CsOH \cdot H_2O$ according to the method of Gasiorowski et al. [24]. The ^{13}C NMR spectrum was collected of a solution of the ^{13}C-enriched $Cs_2C_3S_5$ (0.06 g, 0.12 mmol in $\sim$0.8 ml of DMF-d_7). UV–Vis spectroscopic characterization was carried out by charging a sealed cuvette with a DMF solution (10 ml, 0.12 mM) of $Cs_2C_3S_5 \cdot 1.5H_2O$ in an inert atmosphere chamber. ^{13}C NMR (DMF-d_7): δ 209, 145. UV–Vis, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$): 628 (5500). The solution used for the UV–Vis measurement (4 ml, 1.2×10^{-4} M) was treated with 0.02 g (0.2 mmol) of NH_4Br, which did not fully dissolve. UV–Vis, λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$): 510 (7430).

4.2.3. ^{13}C NMR monitoring of the $dmit^{2-} + CS_2$ reaction

The solution of 0.06 g (0.12 mmol) of ^{13}C-enriched Cs_2dmit used for the ^{13}C NMR spectroscopic characterization (see above) was treated with 0.08 ml of isotopically normal CS_2 (1.3 mmol), causing the color to turn from blue to orange–red immediately. ^{13}C NMR (DMF-d_7): δ 213, 193 (CS_2), 171 (br), 122 (br). Most of the CS_2 was then removed by subjecting the red solution briefly to a dynamic vacuum, causing the color to turn from orange–red to purple. ^{13}C NMR (DMF-d_7): δ 213, 171, 122. See Fig. 5.

4.2.4. $(Bu_4N)_2[Ni_2(C_3S_5)_3] \cdot CH_2Cl_2$

The ^{13}C-labeled nickel coordination compound, $(Bu_4N)_2[Ni(*C_3S_5)_2]$ (*C = 16% ^{13}C), was prepared from $(Bu_4N)_2[Zn(*C_3S_5)_2]$ according to literature procedures [1]. A solution of 0.1790 g (0.1910 mmol) of $(Bu_4N)_2[Ni(*C_3S_5)_2]$ in acetonitrile (20 ml) was treated with a solution of $[Ni(NCCH_3)_6](BF_4)_2$ (0.0321 g, 0.064 mmol) in CH_3CN (0.5 ml). Within seconds, the color of the solution changed from green to red. The MeCN was removed by evaporation, and the residue extracted into CH_2Cl_2 in $\sim$0.5 ml. Dilution with diethyl ether ($\sim$1 ml) produced dark purple crystals. Yield: 0.1454 g, 96%. *Anal*. Calc. for $C_{42}H_{74}N_2Cl_2Ni_2S_{15}$: C, 39.52; H, 5.84; N, 2.19. Found: C, 39.54; H, 6.03; N, 2.07%. ^{13}C NMR (CD_2Cl_2): δ 121 (s, 16% d, $J_{C-C} = 0.6$ Hz), 138 (s), 155 (s, 16% d, $J_{C-C} = 0.6$ Hz), 162 (s), 163 (s), 219.6 (s), 219.7 (s). ^{13}C NMR (acetone-d_6): δ 121 (s, 16% d, $J_{C-C} = 0.6$ Hz), 138 (s), 156 (s, 16% d, $J_{C-C} = 0.6$ Hz), 220 (s).

4.2.5. Titration of $Cs_2C_3S_5$ with HCl

$Cs_2C_3S_5$ (32.0 mg, 69.2 μmol) was dissolved in deionized, oxygen-free water (12.46 ml) to make a 5.56 mM 'stock' solution. This solution was treated with 1 equiv. of HCl in steps of 0.1 equiv. After each step, a UV–Vis spectrum was collected by diluting a small aliquot of the reaction mixture to about 0.06 mM in a 1 cm path length cuvette fitted with a valve to exclude air. In calculating the equivalents added, the

total amount of $Cs_2C_3S_5$ was adjusted for the aliquots used for the measurements.

4.2.6. Attempted Steimecke rearrangement of Na_2dmit

Sodium metal (0.0247 g, 1.07 mmol) was allowed to react with 8 ml of MeOH. To this solution was added the thioester $C_3S_5(COPh)_2$. This yellow slurry was allowed to react for 30 min at ambient temperature, then the methanol was removed by evaporation. The pink residue was washed with ether (4×15 ml) to remove the methyl benzoate byproduct. Anhydrous DMF (7.5 ml) was added to the residue, resulting in a blue solution of the $dmit^{2-}$ salt and solid NaOH. An aliquot (15 ml) of the solution was decanted from the NaOH and added to DMF (7.5 ml) in a 1 cm path length cell (conc. 5.9×10^{-5} M). No change, either in appearance or UV–Vis spectroscopic properties, was observed after 3.8 h at 100.5°C. 0.8 M solution of $Na_2{}^-$dmit ($\sim$1 ml), prepared in a similar manner, was then flame-sealed in a Pyrex tube and maintained at 12 °C. No color change was observed after 21 h. After 15 days, the color was deep brown.

4.2.7. Crystallographic analysis of $(Bu_4N)_2[Ni_2(C_3S_5)_3]\cdot CH_2Cl_2$

A CH_2Cl_2 solution of $(Bu_4N)_2[Ni_2(C_3S_5)_3]\cdot CH_2Cl_2$ was layered with diethyl ether. A black, prismatic crystal of approximate dimensions $0.14\times0.14\times0.18$ mm was selected for analysis and mounted on a glass fiber with Paratone-E (Exxon). Intensity data were collected at 198(2) K using a Siemens CCD area detector utilizing Mo Kα radiation ($\lambda=0.71073$ Å). The completeness of data collection in the range $2\theta=3.22$ to 56.56° was 96.5%. The data were corrected for absorption using the empirical method with maximum and minimum transmission factors of 0.9901 and 0.8546, respectively. The data merged to form a set of 14320 independent reflections with $R_{int}=0.0734$. The space group, $P2_1/n$ (no. 14), was selected on the basis of systematic conditions and was verified by subsequent refinement. The structure was solved by direct methods and refined by full-matrix least-squares methods on F^2. Hydrogen atom positions were calculated using a riding model. All non-hydrogen atoms were refined anisotropically. The SOF for one of the butyl groups was refined between two positions. The largest peak and hole in the difference map was 0.529 and -0.509 e Å^{-3}, respectively. Additional crystal data: $a=17.7947(5)$, $b=14.4605(4)$, $c=23.7863(6)$ Å; $\beta=102.38°$; $V=5978.9(3)$ Å^3; $Z=4$; $\rho(\text{calc})=1.418$ Mg m^{-3}; $\mu=1.274$ mm^{-1}; index ranges $-18\le h\le23$, $-19\le k\le19$, $-31\le l\le14$; number of data and parameters 14320 and 595, respectively; final R_1/wR_2 ($I>2\sigma(I)$) 0.0665/0.1032; GoF = 1.077.

Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk) on request, quoting the deposition number CCDC 133733.

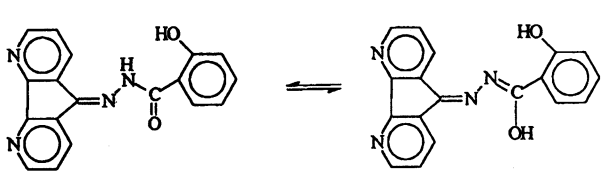
Received 18 January 2000; accepted 28 March 2000



Abstract

Transition metal complexes $M(HL)_2 \cdot nH_2O$ (M(II) = Mn, $n = 2$ (**1**); Co, $n = 3$ (**2**); Ni, $n = 4$ (**3**); Cu, $n = 3$ (**4**); Zn, $n = 2$ (**5**); Pb, $n = 0$ (**6**)) of 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L), have been prepared by the reaction of H_2L with the metal(II) acetates in EtOH–DMF. X-ray diffraction studies showed that the ligand in the solid state has a *pseudo*-helical structure in the keto-form. In complexes $Mn(HL)_2(H_2O)_2$ (**1**) and $Co(HL)_2(DMF)_2$ (**2a**), the ligand coordinates to the metal ion as a mononegative ion in the enol-form with the enolic oxygen and azomethine nitrogen atoms of the aroylhydrazone group forming a five-membered chelate ring, while the phenolic hydroxyl group and pyridyl-N atoms of the diazafluorene moiety are free. The metal atoms are in octahedral geometry with N_2O_4 from two ligands HL in the equatorial plane and the axial sites occupied by solvent molecules. The structures were also characterized by IR and ^1H NMR spectroscopy. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Diazafluorenone aroylhydrazone; Transition metal aroylhydrazone complexes; Crystal structures; Enolization; ^1H NMR spectroscopy; IR

1. Introduction

Aroylhydrazones have attracted much attention from chemists in recent years because of their biological activities [1–3], strong tendency to chelate to transition metals [4,5], lanthanide metals [6,7], and main group metals [8,9], forming complexes with the aroylhydrazone acting as a neutral or mononegative bidentate ligand, or even as a dianionic ligand depending on the aroyl substituents and the reaction conditions [10,11]. Recently, a series of ruthenium complexes with ferrocenyl aroylhydrazones have been reported [12] in which the aroylhydrazone moiety behaves as a neutral ligand and chelates to the Ru ion in the keto-form via the carbonyl oxygen and azomethine nitrogen atoms. 4,5-Diazafluorene-9-one and its derivatives are also strong chelating agents [13,14] and have been used as ligands to form Ru complexes [15].

abilities of the diazafluorene moiety and of the hydrazone group toward transition metals, the condensed products 4,5-diazafluorene-9-one aroylhydrazones have been designed and synthesized. We have reported the crystal structure of the first such compound, 4,5-diazafluorene-9-one isonicotinylhydrazone, in 1996 [16]. Here we present a new ligand, 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L) and six of its transition metal complexes, with the crystal structures of two of them described to identify the coordination mode of the ligand.

2. Experimental

2.1. Reagents

Metal(II) acetates and other analytical grade reagents were available commercially. Salicyloylhydrazine was prepared by the condensation of methyl salicylate with hydrazine hydrate in ethanol. 4,5-Diazafluorene-9-one was obtained by the method described in the literature [17].

2.2. Synthesis of 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L)

The reaction mixture of 4,5-diazafluorene-9-one (1.82 g, 5.0 mmol) in ethanol (40 cm^3) and salicyloylhydrazone (1.52 g, 5.0 mmol) in warm ethanol (40 cm^3) was refluxed for 4 h and filtered. The yellow precipitate was collected, washed with cold ethanol, and dried in vacuo, m.p. 315°C. Analytical data and yield are listed in Table 1. Pale-yellow single crystals suitable for X-ray analysis were prepared by slow evaporation of a solution of the compound in EtOH–DMF in air.

2.3. Syntheses of complexes *1–6*

All complexes were prepared by a similar procedure: a solution containing hydrated $M(OAc)_2$ (0.25 mmol) (M = Mn, Co, Ni, Cu, Zn, and Pb) and the ligand $H_2L{\cdot}H_2O$ (0.17 g, 0.50 mmol) in 30 cm^3 of EtOH–DMF (2:1, v/v) was refluxed for 6 h. The precipitates thus produced were collected, washed several times with warm ethanol and dried in vacuo. The formula, formula weight, color, yield, and elemental analysis data are also listed in Table 1.

Dark red single crystals of complexes **1** and **2a** suitable for X-ray diffraction analyses were obtained by slow evaporation of a solution of **1** in DMF and by diffusion of Et_2O into a solution of **2** in DMF, respectively.

2.4. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 240C analytical instrument. IR spectra were obtained on a Nicolet FTIR-170SX spectrophotometer in KBr pellets in the 4000–400 cm^{-1} region. ^1H NMR data were recorded on a Bruker Aspect AM500 spectrometer at 45°C in DMSO-d_6 with TMS as internal standard.

2.5. Crystal structure determination

Intensity data were collected on a Bruker SMART CCD for H_2L and **1**, and on a Siemens P4 diffractometer by the $\omega - 2\theta$ scan technique for **2a**, both with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Absorption corrections were applied. The crystal data, data collection and refinement parameters are summarized in Table 2.

The coordinates of the metal atoms were determined by direct methods and the remaining non-hydrogen atoms were located from successive difference Fourier syntheses. The structures were refined by full-matrix least-squares method with anisotropic thermal parameters for all the non-hydrogen atoms. The positions of the hydrogen atoms were placed in idealized positions isotropically and used in structural factor calculations but not refined for the ligand and **1**, while those for **2a** were found from the difference Fourier map and refined isotropically except those in DMF, which were generated geometrically. All calculations were performed on IBM PC computer with the Siemens SHELXTL program package [18].

3. Results and discussion

3.1. Synthesis

The ligand 4,5-diazafluorene-9-one salicyloylhydrazone was prepared by condensation of 4,5-diazafluorene-9-one with salicyloylhydrazine in molar ratio 1:1 as shown in Eq. (1). It is insoluble in weakly polar or non-polar solvents such as ether, benzene and alkanes; soluble to some extent in moderately polar solvents such as methanol, ethanol and acetonitrile, and easily soluble in strongly polar solvents DMF and DMSO. When reacted with transition metal acetates in mixed solvents EtOH–DMF, the ligand enolizes and chelates to the metal ions forming complexes **1**–**6** (Eq. (2)). In contrast to ligands of the type salicylaldehyde benzoylhydrazone, where the hydroxyl group is attached to the same phenyl group as the $N_{azomethine}$ atom, this ligand is a bidentate rather than a tridentate chelator [10,11]. In ligand H_2L with the hydroxyl group substituted on the amide side of the aroylhydrazone, the hydroxy proton is less prone to dissociate in neutral or mildly acidic conditions. The result also shows that the coordinating activity of the aroylhydrazone moiety is stronger than the two pyridyl nitrogens in diazafluorene, so that the former chelates to the metal atom and the latter are free, obviously caused by increased electronegativity of an oxygen atom in the hydrazone moiety. The fact that the ligand 4,5-diazafluorene-9-one thiosemicarbazone coordinates to a transition metal via the N:S atoms [19], rather than the N:N atoms of the diazafluorene moiety, is also an effect of the more electron donating sulfur atom.

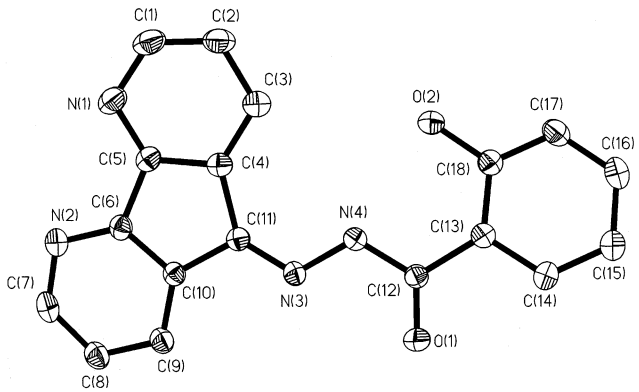

Fig. 1. Molecular structure of the ligand 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L) with thermal ellipsoids at 30% probability level.

All the complexes dissolve only in DMF and DMSO. They are stable in the solid state and decompose above 320°C. Elemental analyses showed that they conform to the formula $M(HL)_2{\cdot}nH_2O$.

$$H_2L{\cdot}H_2O + M(OAc)_2{\cdot}nH_2O \rightarrow M(HL)_2{\cdot}nSol \quad (2)$$

3.2. Structures

The molecular structure of the ligand H_2L is shown in Fig. 1, while those of complexes **1** and **2a** are depicted in Figs. 3 and 5, respectively. The selected atomic distances and bond angles are listed in Tables 3–5. A comparison of relevant structural parameters is shown in Table 6. The ligand in the solid state exists in the keto-form (C=O distance 1.219(2) Å), as also identified by IR absorption (vide infra). The atoms $N_{azomethine}$–N_{amide}–C–O in the acylhydrazone moiety, both in the free ligand and in complexes **1** and **2a**, are arranged in a *syn*-position and situated nearly in a plane with the torsion angles $N_{azomethine}$–N_{amide} versus C–O_{amide} in range of 5–9° only. In addition to that, the sp^2 hybridization of the carbon atoms C(11) (C_{FLU}) in diazafluorene ring (FLU) and C(12) (C_{amide}) of the amide group affords the whole ligand molecule nearly planar with the two aromatic moieties FLU and the phenolic ring (PhOH) forming a dihedral angle of only 16°. Because of this *quasi*-coplanarity, the ligand molecule is asymmetric with one of the pyridyl ring (Py-I) of FLU situated in *syn*-position with the amide oxygen O(1) (O_{amide}), while the hydroxyl group of PhOH is oriented toward the other pyridyl group (Py-II). In addition, the proton of the hydroxyl group in PhOH forms intermolecular hydrogen bond with the nitrogen atom of Py-I of a neighboring molecule with

$N_{Py\text{-}I}\cdots OH$ distance of 2.808 Å. The difference between the two pyridyl rings Py-I and Py-II in a FLU group is also depicted by ^1H NMR studies which will be described below. The hydrogen donor and acceptor behavior of the ligand affords a one-dimensional *pseudo*-helical chain structure as depicted in Fig. 2. Similar structure has been reported for the chiral ligand methyl 2-pyridylmethylidenehydrazinecarbodithioate [20]. Otherwise, the structural data of the ligand are comparable to those of a similar compound [16].

Both **1** and **2a** are centrosymmetric neutral molecules of the composition $M(HL)_2(solvent)_2$, where M = Mn, solvent = H_2O for **1** and M = Co, solvent = DMF for **2a,** with the center of symmetry sitting on the metal ion. The metal atoms in both complexes are hexacoordinated by N_2O_4 in a distorted octahedral geometry with $N_{azomethine}$ and O_{amide} atoms from two enolic mononegative HL groups in the equatorial plane, forming restricted bite angles $N_{azomethine}$–M–O_{amide} of 72.01(7)° for **1** and 75.51(8)° for **2a**, while the O atoms from the solvent molecules occupy the axial sites.

[a] The O_{amide} atom becomes enolic oxygen in the complexes, but is a carbonyl oxygen in the ligand.

[b] O_{sol} denotes the oxygen atom of the solvent attached to the metal, from H_2O in **1** and DMF in **2a**.

[c] The carbon atom in the pyridyl group in diazafluorene *cis* to the amide oxygen atom in the aroylhydrazone is represented by $C_{Py\text{-}I}$, while that *trans* to the amide oxygen is $C_{Py\text{-}II}$.

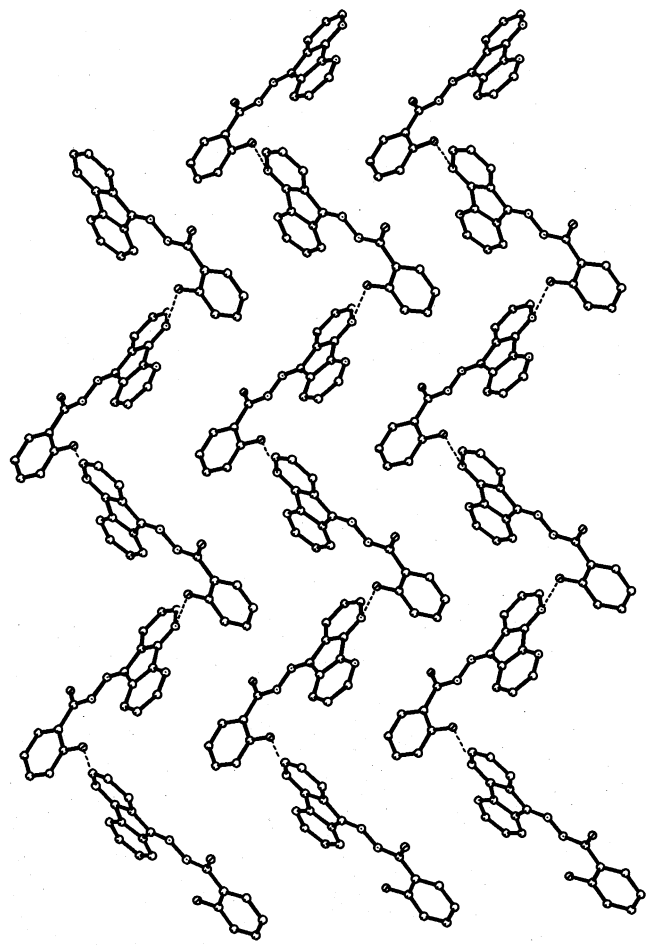

Fig. 2. *Pseudo*-helical structure of the ligand 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L) showing the intermolecular hydrogen bond $N_{Py\text{-}I}\cdots HOPh$.

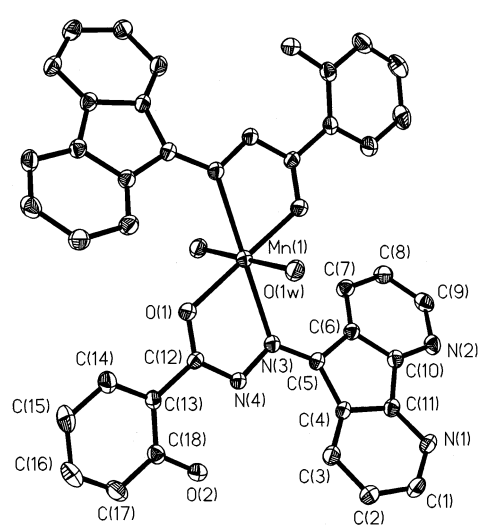

Fig. 3. Molecular structure of $Mn(HL)_2{\cdot}2H_2O$ (**1**) with thermal ellipsoids at 30% probability level.

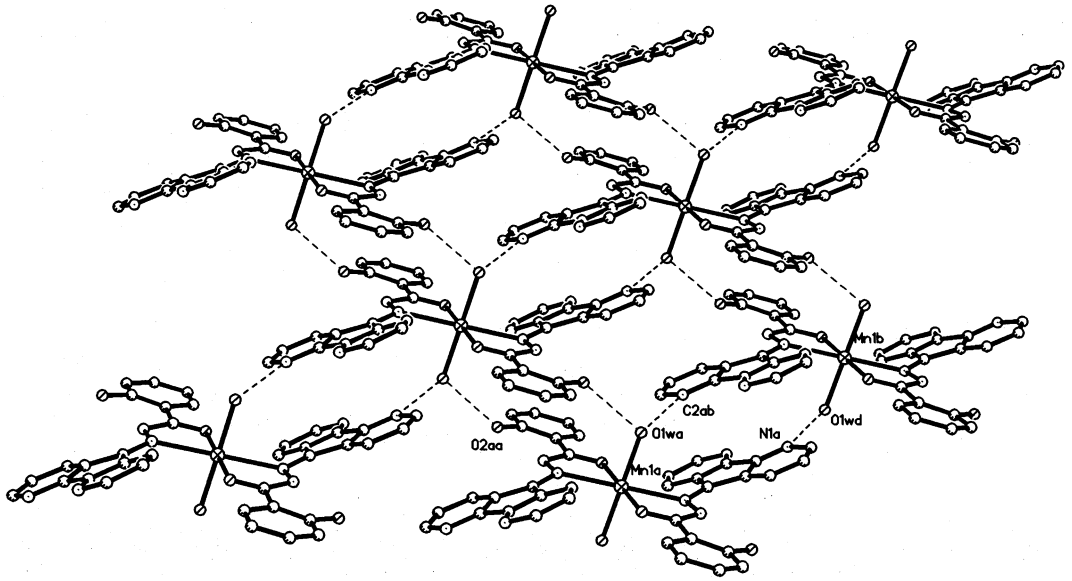

Fig. 4. Crystal packing of $Mn(HL)_2{\cdot}2H_2O$ (**1**) showing the layered structure formed by intermolecular hydrogen bonds $N_{Py\text{-}I}\cdots HOH$ (2.831 Å) and $HOH\cdots OHPh$ (2.805 Å).

The in-plane bond distances of **1** showed that the Mn–O_{amide} bond (2.067(2) Å) is somewhat shorter and the Mn–$N_{azomethine}$ bond (2.415(2) Å) is somewhat longer than those of other Mn(II) complexes in which the aroylhydrazone moiety is either in the enolic form [21] (2.190(5) and 2.280(5) Å, respectively) or in the ketonic form [22,23] (average 2.28 and 2.27–2.33 Å, respectively), where the Mn(II) ion is hepta-coordinated in pentagonal bipyrimidal geometry. As there is no similarly enolic coordinated cobalt complexes of aroylhydrazones in literature for comparison, we will look at a few of the ketonic complexes $[Co(H_2L^A)(H_2O)(MeOH)]^{2+}$ $[H_2L^A = 2,5\text{-}C_6H_3N(C(CH_3)NNHC(O)NH_2)_2]$, $[Co(H_2L^B)(H_2O)(NO_3)]^{+}$ $[H_2L^B = 2,5\text{-}C_6H_3N(C(CH_3)NNHC(O)Ph)_2]$, and $[Co(H_2L^C)(H_2O)_2]^{2+}$, $[H_2L^C = 2,5\text{-}C_6H_3N(C(CH_3)NNHC(O)(2\text{-}Py))_2]$, and found that the Co–$O_{amide}$ bond (2.025(2) Å) in **2a** is again shorter than the average value of that bond (2.227 Å) in these complexes, while the Co–$N_{azomethine}$ bond (2.212(2) Å) is slightly longer (average 2.195 Å) [24–26]. Therefore, the geometry of the central metal atom has much larger effect on the structural parameters than the actual coordination mode of the hydrazones.

The five-membered chelate rings $\overline{MNNCO}$ in the equatorial plane in both complexes are nearly planar with mean deviation from least-square planes of 0.0368 Å for **1** and 0.0860 Å for **2a**. They form dihedral angles of 32.7 and 30.1° for **1** and **2a**, respectively, with the FLU ring and 4.8 for **1** and 2.5° for **2a** with the PhOH ring, indicating that a certain degree of delocalization could occur throughout the molecule, which can be interpreted by the lengthening of bonds C_{FLU}–$N_{azomethine}$ and shortening of bond C–N_{amide}, as compared to the free ligand (see Table 6). The shortening of the latter is an evidence of enolization, as expected. The lengthening of the former is reasonable for coordination of the atom $N_{azomethine}$ to the metal atom with the formation of a chelate ring. Notably, the bond $N_{azomethine}$–N_{amide} also increases (by 0.02 Å) in the complexes, a further indication of delocalization over the whole ligand molecule, particularly within the chelate ring.

On close examination of the structural parameters in Table 6, it will be noticed that the C–O_{amide} bond of 1.265(3) Å (**1**) and 1.263(3) Å (**2a**) in the complexes with elongation of 0.04–0.05 Å, as compared to the free ligand, can not be considered long as would be

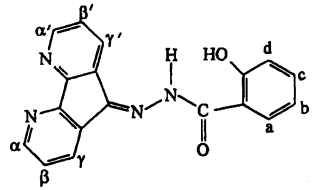
expected for enolization of the ligand. The evidence for the enolization should further be provided by the spectroscopic data, such as a disappearance of the carbonyl absorption in IR, which is indeed the case for the complexes **1**–**6** (Table 7), and should also be accompanied by the balance of electric charge in the molecules. Carbonyl distances of 1.24–1.25 Å have been reported for the keto-coordination of an aroylhydrazone [10], which are only 0.1–0.2 Å shorter than in **1** and **2a**. Therefore, the length of the C–O bond may not be a sufficient criterion for the identification of coordination modes; other effects such as coordination geometry of the central atom influence the bond distances even more significantly.

An interesting feature is observed in the five-membered central ring in FLU of the free ligand, the two C_{FLU}–C_{Py} bonds C(11)–C(10) and C(11)–C(4) are not equivalent: the former to $C_{Py\text{-}I}$ (*syn* to amide) is 0.02 Å shorter than the latter to $C_{Py\text{-}II}$ (*anti* to amide), which could have been caused by the asymmetry of the ligand. This difference disappears on coordination to the metal ions and the complexes lose chirality. Such a phenomenon is also reflected in the bond angles around the sp^2 hybridized C_{FLU}: the two outer angles $N_{azomethine}$–C_{FLU}–C_{Py} differ by 14° in the ligand, nearly twice as much in the complexes (8.5°). Such change of symmetry of the FLU ring could partially be induced by the co-planarity of the two aromatic moieties: it is larger in the ligand than in the complexes.

In both complexes, the planes of the diazafluorene moiety of two neighboring molecules are parallel to each other (dihedral angle 0°), with the center to center distance of 3.706 Å in **1** and 4.137 Å in **2a**, implying weak interactions, which stabilize the complexes. The molecules of **1**, as shown in Fig. 4, are further connected by intermolecular hydrogen bonds $N_{Py\text{-}II}\cdots OH_2$ (2.831 Å) with one molecule and $PhHO\cdots OH_2$ (2.805 Å) with another. Having two H_2O molecules in *trans*-positions and with a center of symmetry for the molecules of **1**, a total of eight hydrogen bonds exist in the complex. The resulting layered network is composed of four molecules forming two linked rings, one within the other, with the size of the inside cavity about 7.2 × 11.0 Å, composed of two HL ligands and two water molecules with four hydrogen bonds. The outer ring involves four Mn atoms, four HL ligands providing two PhOH and two FLU moieties, and four H_2O molecules.



Complex **2a** with two molecules of DMF in the axial sites does not possess interactions other than the rather weak π···π stacking mentioned above, due to the absence of hydrogen bond donors.

3.3. IR spectroscopy

Infrared spectral studies showed that both the ligand and the complexes contained solvated water molecules as shown by the broad bands in region 3200–3500 cm^{-1}, where the NH stretching absorption of the ligand is also buried under. Notably, the carbonyl absorption at 1684 cm^{-1} in the ligand has disappeared in all the complexes. Instead, strong bands of the $C–O_{enol}$ absorptions appeared in range 1046–1068 cm^{-1} [27] (see Table 7): a convincing evidence for the enolization of the keto-form of the ligand to the enol-form when coordinated to transition metals in protic solvents. The moderately strong aromatic C–OH absorption (1280 cm^{-1}) of the phenolic group in the free ligand is still present in the complexes (1236–1250 cm^{-1}) [28], which is shifted to lower frequencies, indicating that the hydrogen bonding involving the hydroxyl group in the ligand might not be so effective in the complexes.

The coordination of the azomethine nitrogen atom to the metal ions was indicated by the displacement of $\nu_{(C=N)}$ from 1604 cm^{-1} in the ligand to 1588–1602 cm^{-1} in the complexes, which overlapped with the band ν(C=N–N=C). This result shows that the contribution of C=N stretching has been reduced as the nitrogen atom is involved in bond formation with the metal ion. The strong absorption at 1567 cm^{-1} in all the complexes for the C⋯N stretching vibration in the FLU ring [29] has not changed much, both in frequency

and in intensity, from the free ligand (1565 cm^{-1}), implying the non-coordination of this fragment. All of this evidence indicates that the ligand coordinates to the metal center through the depronated enolic aroylhydrazone group while the FLU and the PhOH moieties are free. Interestingly, although these two moieties are two different aromatic groups with three and four adjacent protons, respectively, there appeared only one very strong and sharp C–H out-of-plane bending absorption in range 744–751 cm^{-1}, which is characteristic for the fluorene group, since this band is always resent in all compounds containing this moiety [29].

3.4. ^1H MNR spectroscopy

The relevant ^1H NMR spectral data of the ligand and complex **6** in DMSO-d_6 are listed in Table 8, together with the assignments and coupling constants. NMR spectra were not measured for the other complexes due either to the paramagnetic nature or to their low solubilities. The proton signals of H_N and H_{OH} of the free ligand appeared at 11.582 and 12.050 ppm, respectively (not listed in Table 8), indicating that the ketonic form exists not only in the solid state, but also in strongly polar non-protic solvent. The disappearance of the H_N signal in **6** shows that H_2L has deprotonated and coordinated to the metal ion in the enolic form. The chemical shifts of the phenolic proton (14.055 pm in **6**), and Hγ and Hγ′ have shifted to a lower field after complexation, while all the other signals shifted somewhat to a higher field due to the heavy atom effect of lead. The data showed clearly the asymmetry of the ligand with the two protons Hγ and Hγ′ nearest to the $N_{azomethine}$ have the largest difference. We have tentatively assigned protons on Py-I to the α-series and those on Py-II to the α′-series, a result caused probably by the *cis*-situated $N_{azomethine}$ atom [19].

4. Summary

This work showed that 4,5-diazafluorene-9-one salicyloylhydrazone adopts a *pseudo*-helical structure formed from intermolecular hydrogen bonding, which would be interesting if chiral complexes could be prepared from it. However, when reacted with transition metals, two of the ligand monoanions lie in the equatorial plane of the complexes with the two axial sites occupied by two solvent molecules, yielding centrosymmetric complexes. The weaker coordinating FLU moiety is not involved in complex formation, and the protic solvent H_2O molecules connect the molecules of **1** with intermolecular hydrogen bonds to form a layered network when accompanied by π···π interaction. With DMF as the axial ligand as in complex **2a**, no hydrogen bonding is possible so that only π···π stacking interaction exists in the complex. By proper selection of axial ligands, it should be possible to obtain low dimensional or 3D supramolecular compounds containing aroylhydrazones, which could have applications in biological systems. It should also be possible to obtain chiral coordination complexes by selection of aroylhydrazones to avoid the generation of molecular symmetry. Furthermore, these mononuclear complexes can still act as building blocks to construct polynuclear complexes by chelating on the diazafluorene side, which would be of interest for their potential multi-redox and long range energy transfer properties. Further work is in progress.

5. Supplementary material

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request. The deposition numbers for 4,5-diazafluorene-9-one salicyloylhydrazone (H_2L), $Mn(HL)_2{\cdot}2H_2O$ (**1**), and $Co(HL)_2{\cdot}2DMF$ (**2a**) are 137883, 137885 and 137884, respectively.

Abstract

Rhodium sulfosalicylate, prepared from 5-sulfosalicylic acid, distinguishes itself from most rhodium carboxylates by its high solubility in water. Magnetic resonance, infrared, ultraviolet, and visible spectroscopic techniques were used for structure determination and the resulting spectra suggested that the molecule bears the characteristic binuclear structure (two rhodium atoms complexing four equatorial ligand molecules) described for other transition metal carboxylates. Titrimetry, with a standardized base solution, indicated the presence of four free sulfonic acid functions in the molecule. Thermo analytical procedures (TG/DTG and DSC) indicated a loss of six water molecules by the complex at temperatures below 200°C. The X-ray diffraction powder pattern for rhodium sulfosalicylate shows the end product of thermal decomposition as being metallic rhodium. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Rhodium(II) complexes; Rhodium(II) carboxylates; Rhodium sulfosalicylate; Thermogravimetric analysis; Spectroscopic analysis; Anticancer drugs

1. Introduction

The study of antineoplastic properties of transition metal complexes prompted by Rosenberg's discovery of the antitumor activities of cisplatine [1] led to syntheses and antitumor evaluations of several metal complexes, including rhodium carboxylates [2]. Some authors attempted the modification of biological activities of these octahedral $Rh_2(Le_4)\cdot 2La$ complexes (Le stands for equatorial ligands while La represents axial ligands) by replacing the solvent molecules, usually occupying the two axial sites, with other species [3]. One reason for attempting these modifications was to reduce the toxicity exhibited by most rhodium carboxylates. As toxic effects seem to correlate with the lipophilic character of active complexes, several authors synthesized hydrophilic carboxylates, including citrate [4], ketogluconate, and glucuronate [5]. Souza et al. [6] evaluated the solubilizing effect of isonicotinic acid molecules as axial ligands in rhodium propionate. The reported tumor inhibitory activity of water-soluble rhodium complexes, citrate in particular, prompted the synthesis of rhodium sulfosalicylate. The complex was characterized by thermo analytical and spectroscopic methods. A volumetric technique indicated the presence of four free sulfonic acid moieties.

2. Material and methods

2.1. Synthesis

A mixture containing 0.2 mmol of rhodium propionate prepared previously [3] and 4 mmol of 5-sulfosalicylic acid (Merck) was heated for 30 min at about 120°C in a glass tube submerged in glycerin, with occasional stirring. The dark-green melt, generated by the fusion of the ligand, was cooled and transferred to a beaker with small portions of cold water. After 24 h, the solution was filtered on a sintered glass filter in order to isolate crystals of unreacted rhodium propi-

PII: S0277-5387(00)00394-6

onate. Rhodium sulfosalicylate was further isolated from the parent carboxylate by repeated extraction of the aqueous solution with ethyl ether. Extractions were continued until the ether phase was colorless. The aqueous phase was evaporated on a steam bath, and the green solid rhodium sulfosalicylate was washed with acetone, filtered, and dried at 105°C for 3 h.

2.2. Instrumental analyses

Carbon and hydrogen content of the new carboxylate was determined by standard microanalytical procedures using a Perkin–Elmer PE2400CHN elemental analyzer. The sulfur content was established by the Schöniger combustion flask technique.

Thermoanalytical determinations — TG/DTG and DSC measurements — were performed on Shimadzu TGA50 and DSC50 instruments, respectively. TG/DTG curves were obtained from a 5 mg sample in a platinum crucible, under a current of air (flow rate 50 ml min^{-1}), and a heating rate of 10°C min^{-1}. DSC curves were obtained from 2 mg samples in aluminum crucibles, under nitrogen current (flow rate 50 ml min^{-1}), and a heating rate of 5°C min^{-1}.

Infrared spectra were recorded on a Bomen MB102 FTIR spectrophotometer from KBr pellets (2000–1200 cm^{-1}) and Nujol mulls (4000–200 cm^{-1}). UV–Vis spectra were obtained on a Hitachi U-3000 spectrophotometer, using 10^{-4} and 10^{-3} mol l^{-1} methanol solutions.

X-ray powder patterns were obtained on a Philips PW-1710 diffractometer from a product isolated at 360°C, using Cu Kα radiation ($\lambda = 1.541$ Å).

^{1}H and ^{13}C NMR spectra were generated for 5-sulfosalicylic acid and for rhodium sulfosalicylate on a Bruker Avance DPX300 300 MHz/52 mm spectrometer from deuterated water solutions stirred for 24 h and concentrated by evaporation.

The volumetric determination of the pK_a of rhodium sulfosalicylate was performed with 20 mg samples, dissolved in 10 ml of water. The solutions were titrated with drop wise addition of potassium hydroxide (2.83×10^{-3} mol l^{-1}). The titration curve — pH versus added base solution — was plotted from data generated using a portable Corning pH meter.

3. Results and discussion

Elemental analyses of rhodium sulfosalicylate afforded the following values: C, 29.30; H, 2.67; S, 10.30%. This is consistent with the molecular formula $C_{28}H_{20}O_{24}S_4Rh_2.6H_2O$, M_W 1182.60. The theoretical composition of hexahydrated rhodium sulfosalicylate is: C, 28.44; H, 2.73; S, 10.84%. The probable structure of the new complex is shown in Fig. 1. The yield was 75%.

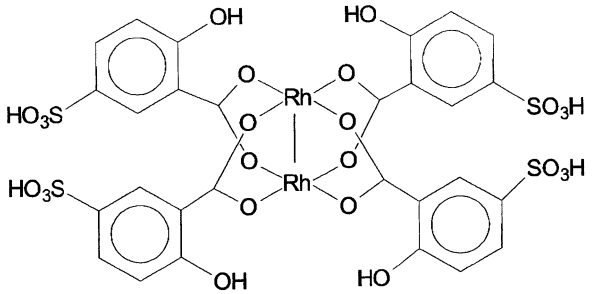

Fig. 1. Structure proposed for rhodium 5-sulfosalicylate.

3.1. Thermal analyses

TG/DTG procedures indicated that hexahydrated rhodium sulfosalicylate maintained structural integrity up to 40°C and suffered progressive dehydration above this temperature. The loss of six molecules of water was calculated from the endothermal with peak temperature at 57°C and $\Delta H = 81$ kJ mol^{-1}) that appears on the DSC curve (Fig. 2). A sample of the complex, previously dried at 200°C, was equally submitted to DSC. The resulting curve was similar to the one obtained from the hydrated complex, which suggests that the water molecules were quickly recovered from the atmosphere upon cooling. They are, presumably, essential to the stability of the complex.

The TG/DTG curve for rhodium sulfosalicylate indicated that the anhydrous complex starts decomposing at 200°C. The breakdown proceeds slowly during the

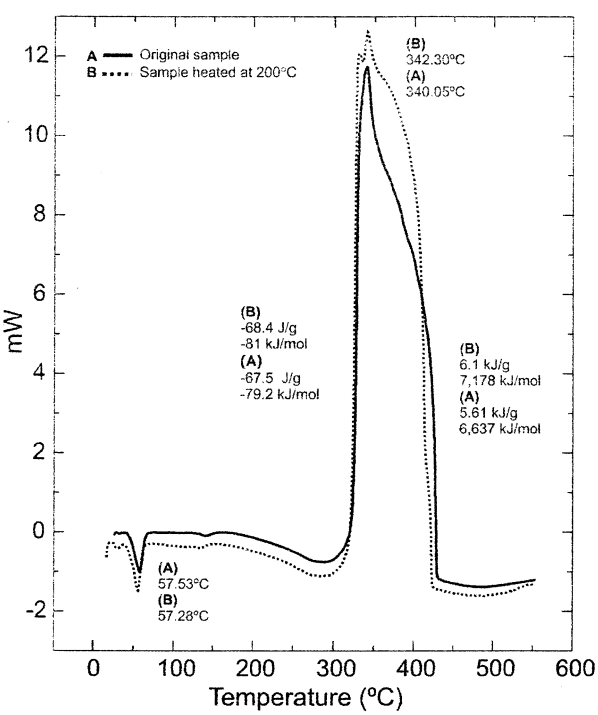

Fig. 2. DSC curves for heated and unheated samples of rhodium 5-sulfosalicylate.

dehydration, accelerating after 330°C. Stoichiometric calculations suggest that the final decomposition product, at about 360°C, is metallic rhodium. The chemical nature of the material was confirmed by X-ray powder diffratometry [7]. It is inferred that the decomposition of the anhydrous complex results in carbonization. The formation of elementary carbon and the metals cation reactive properties are factors that favor the reduction of rhodium to its metallic form, Rh^0. The thermal decomposition process of rhodium sulfosalicylate, peaking at 340°C, is highly exothermic ($\Delta H = -6637$ kJ mol^{-1}).

3.2. Infrared spectrophotometry

Some peak assignments are based on published spectra of sulfosalicylic acid [8–11] (Table 1) and are reliable. Bands associated with deformations in the plane of the OH group (δ_{OH}), stretching vibrations for C–O, and asymmetric stretching of the SO_3^- group occur at very close frequencies, between 1250 and 1140 cm^{-1}, and are difficult to assign accurately.

Bands assigned to O–H stretching vibrations of the hydrated sulfonyl group, between 2800 and 1650 cm^{-1}, approximately, are broad. That phenomenon may be related to the presence of small quantities of water, which promote the ionization of the sulfonyl groups, originating ionic species $-SO_3^- H_3O^+$.

Evidences for the coordination of 5-sulfosalicylic acid to rhodium through its carboxyl groups comes from the analysis of the C–O stretching modes in the acid and complex spectra. The band associated to the stretching vibration of the acids carboxyl group (ν_{COOH}), at 1432 cm^{-1}, unfolds, in the complexes' spectrum, into asymmetrical ($\nu_{asCOO} = 1588$ cm^{-1}) and symmetrical ($\nu_{sCOO} = 1440$ cm^{-1}) stretching vibrations. According to Deacon et al. [12,13], metallic carboxylates whose spectra display Δ values (ν_{asCOO}–ν_{sCOO}) higher than 200 cm^{-1} are monodentate. The value of $\Delta = 148$ cm^{-1} observed in the spectrum of rhodium sulfosalicylate suggests the occurrence of a bridged or chelated bidentate coordination.

3.3. UV–Visible spectroscopy

The spectra of rhodium sulfosalicylate in the ultraviolet and visible regions are similar to those of other rhodium carboxylates described in the literature [14]. Major absorption bands between 200 and 900 nm, and their respective absorptivity values, are listed in Table 2. Norman and Kolari [15] assigned the bands at 584 nm (band 1) and 434 nm (band 2), in the visible region, to the electron dipole allowed transitions $\pi^*_{(Rh-Rh)} \rightarrow \sigma^*_{(Rh-Rh)}$ ($2e_g \rightarrow 2a_u$, in D_{4h}), and $\pi^*_{(Rh-Rh)} \rightarrow \sigma^*_{(Rh-O)}$ ($2e_g \rightarrow 2b_{2u}$, in D_{4h}), respectively. Their assignments are based in a correspondence among calculated and experimental energy values, as well as in an observed influence of axial ligands on the energy levels of the bands. Dubicki and Martin [16] have also evaluated the relationship between ligands and carboxylate UV spectra. They stated that while band 1 is affected strongly by the nature of the axial ligands, band 2 is practically unaffected.

3.4. Magnetic resonance spectroscopy

Band assignment for ^1H and ^{13}C magnetic resonance spectra for 5-sulfosalicylic acid and rhodium sulfosalicylate in D_2O (Tables 3a and 3b) were accomplished with the aid of published data for sulfosalicylic acid

Table 2

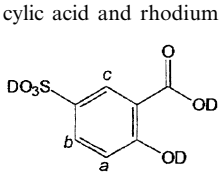
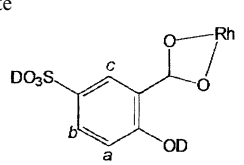
[17,18]. Reference peaks were those of deuterated water, at 4.6 ppm (^{1}H NMR), and of methanol, at 49.9 ppm (^{13}C NMR).

3.5. pK determination



Titration of rhodium sulfosalicylate with potassium hydroxide is illustrated in Fig. 3. Application of the Boltzman correction to the experimental points generated the sigmoid curve. The pK_a value for rhodium sulfosalicylate (6.2) was found graphically as the inflection point of the curve.



It should be noted that the experimental points in Fig. 3 tend to increase beyond the neutralization of the sulfonic groups. This can be attributed to the partial reaction with carboxylate functions, freed after a presumed progressive decomposition of the complex in alkaline media. The disintegration proposition is strengthened by the color change — from the typical green to yellow — which occurs at this stage.

From the volume of alkali solution consumed at the point of inflection of the curve, the stoichiometry of the reaction was determined to be:

$$R\text{–}(SO_3H)_4 + 4KOH \rightarrow R\text{–}(SO_3K)_4 + 4H_2O \quad (1)$$

Received 7 December 1999; accepted 5 April 2000

Abstract

Six oxovanadium(IV) complexes with *N*,*N*′-ethylenebis(amino acid) of general formula, $[VO(XeX)(H_2O)]\cdot nH_2O$, where e and X represent ethylene group and (*S*)-α-amino acid, respectively; and X = G (Gly) **1**, (*S*)-A (Ala) **2**, (*S*)-V (Val) **3**·$2H_2O$, (*S*)-P (Pro) **4**, ^{m}G or G^{m} (Sar or *N*-methylglycine) **5**·H_2O and (*S*)-M (Met) **6**) were prepared. These complexes were characterized by means of TG, DTA, and XRD, and the thermal decomposition processes of these complexes up to 650°C were investigated. The thermal studies showed that the dehydration processes for **3** and **5** having water of crystallization were endothermic, whereas decompositions of all the complexes were exothermic. Calcinations of these complexes at 650°C resulted in the formation of vanadium(V) oxide V_2O_5. Choosing **1** as a leading example of the oxovanadium(IV) complexes, an over all reaction scheme for the thermal decomposition was proposed on the basis of IR and MS analyses of both the solid and the volatile decomposition products at different temperatures. © 2000 Elsevier Science Ltd. Keywords: Oxovanadium(IV) complexes; *N*,*N*′-Ethylenebis(amino acid); TG-DTA

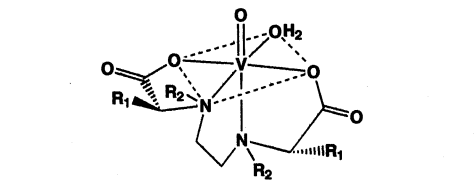
1. Introduction

After the pioneering investigations revealing that both vanadium(IV) and (V) ions have an insulin-mimetic activity [1,2], much attention has been given to research concerning insulin-mimetic vanadium complexes. It is known that the vanadium ions, especially those of an oxidation state of +4 (i.e. vanadyl or oxovanadium) and +5 (vanadate), can adopt various coordination numbers and geometries [3], and to date a variety of vanadium complexes have been prepared [4]. However, since it has been pointed out that oxovanadium(IV) is less toxic than vanadate [5], it seems that a current strategy of investigation involving vanadium ions in the field of biochemistry and physiology is inclined to designing a new functional vanadium(IV) complex with a higher insulin-mimetic activity [6–9].



Recently, it has been reported that the complexes with a $VO(N_2O_2)$ coordination mode, such as oxovanadium(IV)–picolinate complexes with a metal-to-ligand ratio of 1:2, also exhibit insulin-mimetic effects [10]. So far we know, however, that the oxovanadium(IV) complexes with a tetradentate ligand in 1:1 molar ratio, in which the ligand especially has a structure type of *N*,*N*′-ethylenebis(amino acid) (XeX′: e = ethylene group, X and X′ = α-amino acid), have not been well recognized. It is a bright prospect to consider using α-C and/or *N*-substituent groups of XeX′, since they can lead the various characteristics of $VO(N_2O_2)$ type complexes. Furthermore, it is expected that the stability of the oxovanadium(IV) complex with mono-tetradentate will be much greater than that of the complex with a bis-bidentate ligand. Next, our efforts have been utilized to improve a new synthetic route to obtain these XeX′ ligands, and we were successful in both preparing and characterizing a variety of oxovanadium(IV)–(XeX′) complexes [11–14].

In the course of our fundamental studies on vanadium chemistry, it was discovered that little attention

Fig. 1. Schematic description of oxovanadium(IV) complexes with *N*,*N*′-ethylenebis(amino acids), [VO(XeX)(H_2O)].

has been paid to the thermal analyses of oxovanadium-(IV) complexes containing α-amino acid as ligands [15]. Some of the studies involving vanadium complexes are as follows. Thermal decomposition behavior of oxovanadium(IV) complexes with salicylic acid and nuclear-substituted salicylic acids was investigated [16,17]. Thermogravimetric studies on vanadium(IV) and (V) complexes with bidentate chelating ligands such as quinoline, pyrazole and dibenzoylmethane derivatives were carried out [18]. More recently, characterization and thermal analyses of oxovanadium(IV) complexes of the tetradentate Schiff bases [19] and the vanadium(II) oxalate [20] were reported.

In this paper, as a series of our continuing investigation in vanadium chemistry, we report on a thermal study performed on the oxovanadium(IV) complexes with *N*,*N*′-ethylenebis(amino acids).

2. Experimental

2.1. Preparation of oxovanadium(IV) complexes and physical measurements

All reagents and solvents were of analytical grade and used without purification. The oxovanadium(IV) complexes with *N*,*N*′-ethylenebis(amino acids) of a general formula [VO(XeX)(H_2O)]·$n$$H_2O$ (X = α-amino acid and; e = ethylene group and n = 0, 1 and 2), were prepared according to the previously reported method [11,12]. A schematic description of the six complexes is illustrated in Fig. 1, and the abbreviated formula used in this text are as follows: [VO(GeG)(H_2O)] (**1**), G = Gly (glycine); [VO(AeA)(H_2O)] (**2**), A = (*S*)-Ala (alanine); [VO(VeV)(H_2O)]·2H_2O (**3**), V = (*S*)-Val (valine); [VO(PeP)(H_2O)] (**4**), P = (*S*)-Pro (proline); [VO(^{m}GeG^{m})(H_2O)]·H_2O (**5**), ^{m}G or G^{m} = Sar (sarcosine or *N*-methylglycine); [VO(MeM)(H_2O)] (**6**), M = (*S*)-Met (methionine). All the complexes were purified by recrystallization from hot water, and were identified by elemental analysis and IR spectra. The analytical data, some physical data, and the IR data for these complexes are collected in Table 1.

2.2. Thermal analyses

TG and DTA curves were obtained by heating up to 650°C, using a Shimadzu DT-40. The heating rate was 5°C min^{-1} in a dynamic atmosphere of N_2. A small portion (ca. 15–20 mg) of the sample was used for the TG, and the highly sintered α-Al_2O_3 was the thermally inert reference material used for the DTA.

2.3. Analyses of solid and gaseous products obtained by the calcinations

Powder diffractograms of the calcination products were obtained by means of a Shimadzu XD-610 with a source of Cu Kα radiation. For identification purposes, diffraction patterns [(I/I_0) versus d spacing (Å)] of the products were matched with the relevant data on JCPDS cards. The IR spectra of the calcined products at various temperatures were prepared as KBr disks and recorded with the aid of a Shimadzu FT-IR 4300. Mass spectra (MS) of gas phase decomposition products were obtained with a JEOL AV505W in the electron-impact positive-ion mode.

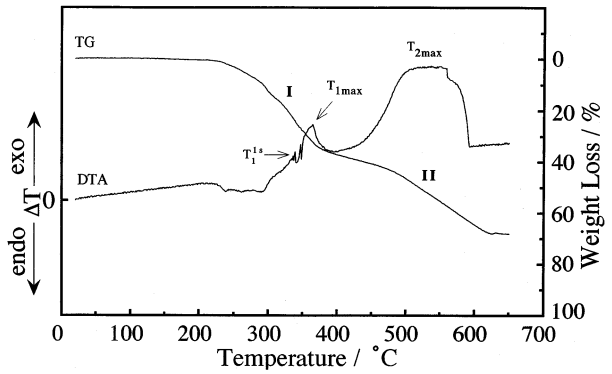

Fig. 2. TG and DTA curves for compound [VO(GeG)(H_2O)] (**1**).

3. Results and discussion

3.1. Dehydration and decomposition processes

Fig. 2 shows the simultaneous DTA and TG curves for [VO(GeG)(H_2O)] (**1**) as a typical example of the thermal analysis of oxovanadium(IV) complexes, and the DTA curves for all the complexes studied are presented in Fig. 3. For convenience, each weight loss (WL) step monitored on the TG curve is designated in Roman numerals, and the corresponding peak temperature on the DTA curve is denoted as T_{1max}, T_{2max}, and so on. In addition, the superscripts 's' and 'sh' in the peak temperature signify small peak and shoulder peak, respectively. The reaction temperatures along with the WL obtained from both TG and DTA curves are summarized in Table 2.

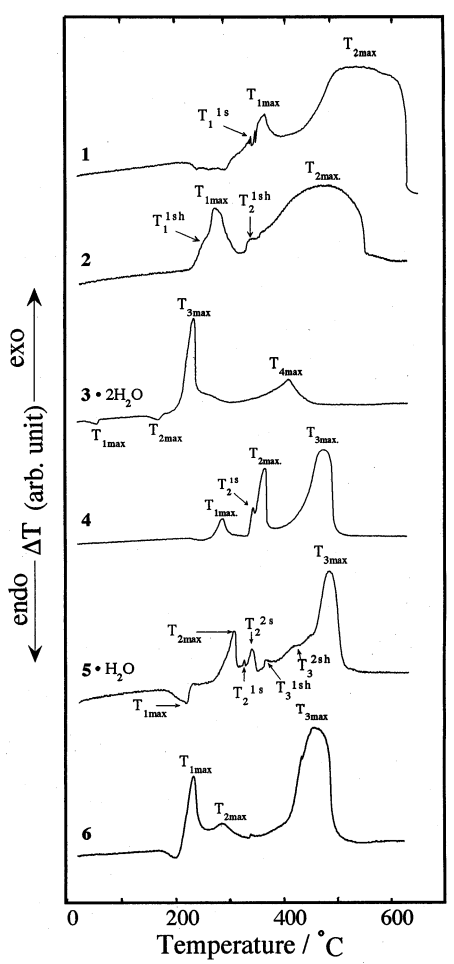

Fig. 3. DTA curves for oxovanadium(IV) complexes (see text for roman numerals).

TG studies revealed that the decomposition of the oxovanadium(IV) complexes could be classified into two categories, which depend on whether a water of crystallization exists or not (see Table 1 for each formula of the complexes). The decomposition of the complexes **3** and **5** occurred in two main stages. The first stage involved a stepwise dehydration to the anhydrous state, followed by the decomposition of the complexes to stable final products. On the other hand, complexes **1**, **2**, **4** and **6** showed only decomposition steps. Although the ambiguous endothermic peaks were shown just before the exothermic decomposition processes in each DTA curve for **1**, **4** and **6**, and since there were no well-defined weight losses in the corresponding TG curves, it has been considered that these ambiguous subtle changes in the DTA curves may not be classified as one of the peaks resulting from some endothermic processes.

As shown in Table 2, the observed WL values that were found in both the dehydration and decomposition processes are in good agreement with the calculated values. In conjunction with the TG curves, it is obvious that the endothermic peaks correspond to each dehydration step, and the exothermic peaks correspond to the decomposition (see Fig. 3). Complex **3** began to lose the first of the two water molecules of crystallization at 34°C, then the second hydrated water was lost at 168°C, which was just before the subsequent decomposition stage. Since complex **5** has one water molecule of crystallization, the corresponding endothermic peak was observed solely at 218°C. When the dehydration stages were completed for complexes 3 and **5**, as well as the rest of each complex, rather complicated peaks were observed in the decomposition temperature region around 230–540°C, which may explained the multiplicities by the postulate that the decomposition process also occurs step by step. For each of the complexes, after the complete decomposition, the TG curve tends to be a continuous horizontal plateau.

The crystallographic characterizations of the oxovanadium(IV) used in the present study were carried out previously, and the coordination geometry of each complex was revealed [12,14]. It is worth noting, however, that the thermal analyses for complexes **3** and **5** could also distinguish the different types of hydrated water molecules, and the observations were consistent with the X-ray crystallographic studies on the com-

[b] Calculated as V_2O_5.

plexes. Considering the fact that water of crystallization is just packed in the crystal lattice and is not bound to any other atom, upon heating the complex it should be easily liberated at a relatively low temperature region. In fact, for both the complexes **3** and **5**, the dehydration temperatures for the loss of such water molecules of crystallization were observed below 220°C, and in which such temperatures were lower than those of the corresponding decomposition temperatures. Consequently, it is reasonably concluded that the other type of hydrated water molecule, i.e. the coordinated water molecules, which are strongly bonded to the oxovanadium(IV) cation, are expected to be difficult to liberate and the loss of such water molecules could be involved in the decomposition stages. This assumption is supported by the observations that any of the complexes **1**, **2**, **4** and **6**, which have no water molecules of crystallization, have not shown any endothermic peaks.

In addition, for all the oxovanadium(IV) complexes studied here, an attempt to correlate the decomposition temperature with such the intermolecular distances as V–O (vanadyl oxygen), V–O (coordinated water oxygen) and V–O (carboxylate oxygen) was made. It is concluded, however, that no significant dependence was found between the thermal studies and the crystallographic characterization of the oxovanadium(IV) complexes.

*3.2. Characterization of thermal decomposition process for [VO(GeG)(H_2O)] (**1**)*

Since **1** has the simplest amino acid moiety in the ligand, and choosing this complex as a leading complex of [VO(XeX)(H_2O)], an effort was made to reveal an overall thermal decomposition process for the complexes prepared in this study. First, in order to identify the solid products remaining after the decomposition, the calcined products of **1** at 650°C in a dynamic atmosphere of N_2 were subjected to an XRD study. As seen in Table 3, it is clear that the observed XRD data matched the reference data (JCPDS 41-1426) very well, and it was found that the final decomposition product of **1** is to be V_2O_5. This conclusion is consistent with the results of the TG analysis (see Table 2); i.e. the theoretical value (35.1%) for the final residual weight of the decomposed sample, which is calculated based on the formula of V_2O_5, is in agreement with the experimental value (32.8%). Furthermore, the fact that the calcication product of **1** was V_2O_5 is the same result as previously reported on thermal studies involving oxovanadium(IV) complexes [16,18,19].

IR and MS analyses of the calcined solid- and gas-phase products of **1** were carried out, so as to characterize the overall thermal decomposition process. Fig. 4 exhibits the IR spectra taken over the frequency range of 4000–700 cm^{-1} of **1** and its calcined solid products

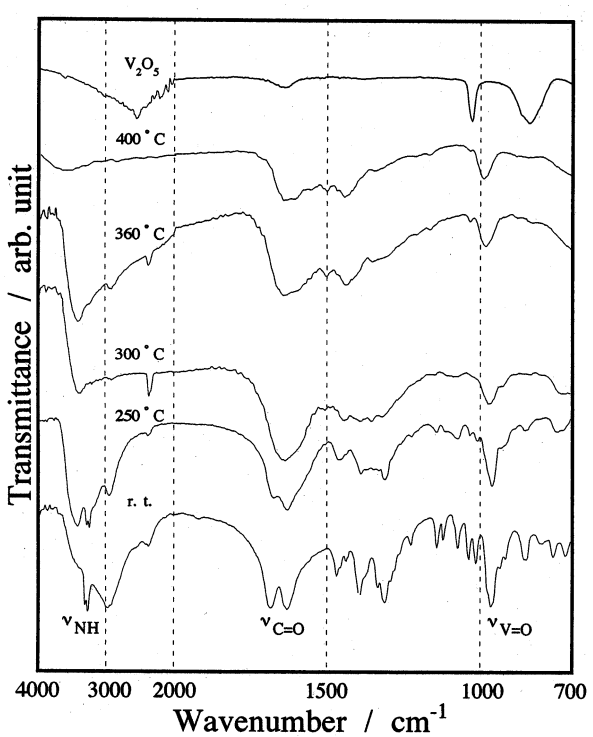

Fig. 4. IR spectra taken for [VO(GeG)(H_2O)] (**1**), its solid decomposition products obtained at the temperature indicated and V_2O_5 as the final decomposition product.

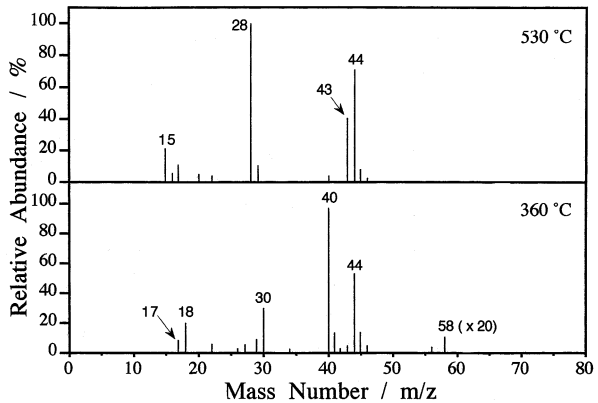

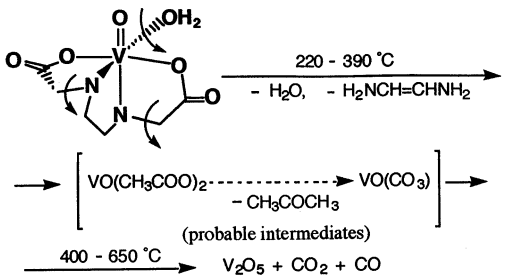

Fig. 5. MS spectra of the volatile products obtained in the pyrolysis of [VO(GeG)(H_2O)] (**1**) at the temperature indicated.

after heating to various temperatures for 10 min. As shown in these IR spectra, it is interesting to note that sharp absorptions at 3310 and 3280 cm^{-1}, which have been observed in the original complex and are due to ν(NH) vibrations [21], disappear around 300°C, and no peaks assignable to the ν(NH) are found in the IR spectrum at 400°C. On the other hand, strong and broad peaks at 1680 and 1630 cm^{-1} [ν(CO)] and a medium-strong absorption at 980 cm^{-1} [ν(VO)], which are observed at r.t., still remains clearly evident at 400°C. Moreover, the IR spectrum of V_2O_5, which was obtained as the final product, is not compatible with that taken at 400°C. Therefore, it is reasonably safe to conclude that a part of the ligand in the complex, especially the moiety containing the NH group, decomposes during the early stages of the pyrolysis, and that vanadium oxidation occurs in the last step in the range 400–650°C.

Support for the above IR results were furnished by MS analyses. Mass spectra of the volatile products obtained in the pyrolysis at 360°C, at which the first stage of the thermal decomposition of **1** occurred, show a molecular ion peak at m/z 58 as shown in Fig. 5. This peak can be considered a $NH_2CH{=}CHNH_2$ molecule, which might be generated as a result of the cleavage of the C_α–N bonds of the ligand. It is, therefore, reasonable to conclude that this base peak leads such fragment ions and molecular peaks as observed at m/z 44 ($CH_2{=}CHNH_3^+$), 40 ($CH_2C{=}N^+$), 30 ($CH_2{=}NH_2^+$), 18 (NH_4^+) and 17 (NH_3). In these fragment ions, the first iminium ion is known to be a very prominent fragment ion, which is commonly observed in the fragmentation of amino acid derivatives [22]. Moreover, it should be emphasized that the peak at m/z 18 in the same MS obviously includes the H_2O molecule.

On the other hand, the mass spectra of the volatiles evolved near the T_{2max} present peaks at m/z 44, 43 and 28 with relatively high intensities. The peaks at m/z 44 and 28 are easily recognized as molecular ion peaks of

Scheme 1.

CO_2 and CO, respectively. Those peaks at m/z 43 (CH_3CO^+) and 15 (CH_3^+) can be considered fragment ion peaks that subsequently arise from the molecular ion of acetone. Although the corresponding base peak was not found in the spectra, the above results make it possible to assume that the CH_3COCH_3 molecule was present in the gaseous product of the second decomposition stage around 530°C.

In summary, in conjunction with the above experimental results and our previous X-ray structural analysis of **1** [12,14], the probable pathway of the thermal decomposition can be rationalized as shown in Scheme 1.

Species such as oxovanadium(IV) acetate and oxovanadium(IV) carbonate were not detected directly in the present study. However, it has been elucidated that metal acetate complexes decompose thermally to corresponding oxides evolving CO_2 and CO, via formation of oxovanadium(IV) carbonate as an intermediate [23]. Therefore, as proposed in Scheme 1, the pathway for the thermal decomposition of **1** might be reasonably accepted. The oxidation of the vanadium from +IV to +V state is probably caused by intermolecular atomic rearrangements during fragmentation in the thermal decomposition.

Although attempts to characterize the other oxovanadium(IV) complexes were not made, their thermal decompositions may proceed in a similar manner as above, even though a part of the bis(amino acid) ligands is different from one another.

Abstract

The oxidation–reduction reactions of aromatic amines {*o*-aminophenol (*o*-AP), *o*-phenylenediamine (*o*-PDA) and *p*-phenylenediamine (*p*-PDA)} with Co(III)–, Mn(III)–, and Cu(II)–oxalate complexes have been investigated in homogeneous and heterogeneous systems. The kinetics of the redox reaction of both systems have been studied spectrophotometrically. The redox products were identified and characterised by diffuse reflectance spectroscopy (DRS), and mass spectrometry. The redox reactions follow first-order kinetics with respect to each of the reactants and first order in [amines] in homogeneous and heterogeneous (supported complexes on Amberlite IRA 904 anion-exchange resin) phases, respectively. However, the specific oxidation rate of the amines is found to follow the order, *p*-PDA > *o*-AP > *o*-PDA. The effect of the oxalate anion on the reaction rate of both systems was examined. There is a significant difference in the behaviour of the oxidation of *o*-AP and *o*-, *p*-PDA with all the metal complexes in both systems. Moreover, the oxidation of *o*-AP and *o*-, *p*-PDA appears to follow the outer- and inner-sphere mechanistic classification, respectively. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Aromatic amines; Amberlite anion-exchange resin; Oxalate anions; Metal–oxalate complexes; Oxidation; Homogeneous and heterogeneous

1. Introduction

The oxidation of aromatic amines in human erythrocytes is very useful for producing phenoxazine compounds via the intervention of human oxyhaemoglobin [1]. One of the main objectives has been the elucidation of the oxidation product of the aromatic amines, which has been shown to be a phenoxazine [2–4]. The phenoxazine, also known as questiomycin A, is related to the naturally occurring antibiotic actinomycin D [5,6] that is used clinically for the treatment of certain types of cancer [7].

The oxidation of *p*-PDA in an aqueous sulphuric acid medium by Mn(III) acetate has been examined [8]. The reaction followed second-order kinetics, first order with respect to [amines] and [Mn(III)]. The reaction shows a positive salt effect. In aqueous solution, the redox reaction between *p*-PDA and Ag(I) ions has also been envisaged [9–11]. An induction period was dependent on pH and the concentration of *p*-PDA, but not on the Ag(I) ion concentration. Furthermore, the effect of pH on the equilibrium in the *p*-PDA–ferricyanide redox system has been discussed [12–14]. The equilibria were established very rapidly at all pH values. Finally, the oxidation of *o*-aminophenol (*o*-AP) by O_2 to amino 3-*H*-phenoxazine-3-one (APX) can be catalysed by cobalt(II) salts, cobalt(II)–phthalocyanine derivatives and copper compounds [15–18]. Some tris-oxalato complexes are also known to be strong oxidising agents in aqueous solution [19]. The kinetics of reduction of tris-oxalato–cobaltate(III) by amines have been investigated [20,21] in aqueous acidic media. The specific rate constants and the corresponding activation parameters have been evaluated at constant ionic strength.

The oxidative condensation mechanism of amines involves a $6e^-$ oxidation coupling process [22,23]. It has been suggested that the reaction occurs via a sequence of three consecutive $2e^-$ oxidations, alternating with conjugate addition of the amine moiety to benzoquinoneimine type intermediates, followed by a tautomerisation step to afford a phenoxazine compound. A sequence for the inner- or outer-sphere mechanisms may be seen in Refs. [24,25].

We have carried out a systematic study of the kinetics and mechanism of such redox systems in heterogeneous (supported metal oxalate complexes on Amberlite IRA 904 anion-exchange resin) and homogeneous systems. A related study reported the kinetics and mechanism of the sorption of the same amines into Amberlite IRA 904 anion-exchange resin in chloride form [26]. An important result from that work is that the rate of diffusion into the particle is accelerated by the presence of supported metal oxalate complexes. Moreover, the overall redox reaction is controlled by a combination of intraparticle reaction and intraparticle diffusion. The latter can never be the sole rate-determining step.

2. Experimental

2.1. Materials

All the materials used in the present work such as amines {*o*-aminophenol (*o*-AP), *o*-phenylenediamine (*o*-PDA) and *p*-phenylenediamine (*p*-PDA)} and the Amberlite IRA-904 anion-exchange resin (spherical-shaped beads of quaternary ammonium styrene divinylbenzene copolymer) were supplied by the Sigma-Aldrich Company Ltd., UK. The stock solutions of the amines (0.01 M) were prepared in an ethanol–water mixture as follows: 10% for *o*-AP and 20% for both *o*- and *p*-PDA, and were diluted to obtain the suitable concentration of the amine. In all cases, the percentage of ethanol is not more than 2% in the amine solution during the redox reactions of all amines. The $K_3[Mn(C_2O_4)_3]$ (**I**), $K_3[Co(C_2O_4)_3]$ (**II**), and $K_2[Cu(C_2O_4)_2]$ (**III**) complexes were prepared by standard methods [27–30]. The UV–Vis absorption spectra of the 0.01 M solutions of complexes **I** and **II** in aqueous solution and complex **III** (in aqueous potassium oxalate) agreed with the literature [27–30].

2.2. Resin support with transition metal–oxalate complexes

The anion-exchange resin was immersed in doubly distilled water and the highly diluted solutions of the metal–oxalate complexes were added dropwise with continuous stirring in the dark until a slight excess of the complexes was detected by UV–Vis spectrophotometry. The resin was collected and washed by distilled water, and then it was air dried in the dark.

2.3. Apparatus

The spectrophotometric measurements were performed with a Shimadzu 2100S spectrophotometer equipped with a TCC-260 temperature controller, and a Perkin Elmer Lambda 19 UV–Vis/NIR spectrometer, equipped with temperature control. The mass spectrometric experiments were recorded on a Micromass Platform quadrupole mass analyser. APCI (atmospheric pressure chemical ionisation) spectra were recorded under operating conditions of: a capillary 3.5 kV, HV lens 0 kV, cone voltage 20 V, source temperature 150°C, probe temperature 450°C, ES eluent; 100% acetonitrile at 200 μl min^{-1}, nitrogen drying gas 250 l h^{-1} and APCI sheath gas 50 l h^{-1}. A Crison 501 pH meter was used and calibrated just before the measurements were recorded. Diffuse reflectance spectroscopy (DRS) measurements of the resins were recorded on the Perkin Elmer Lambda 19 UV–Vis/NIR spectrometer.

2.4. Kinetic measurements

The heterogeneous redox reaction between the amines (*o*-AP, *o*-PDA, and *p*-PDA) and a known amount of Amberlite IRA 904 supported with complexes **I**–**III** was carried out at four temperatures (range 25–45°C) $\pm$ 0.1°C in aqueous/trace ethanol solution. The reaction was performed using a thermostatted shaker, where the rate of shaking was constant for all reactions. After a set interval of time, the container was removed from the thermostat and the reaction was quenched quickly by suction. The homogeneous redox reaction was carried out in the spectrophotometer cell at controlled temperatures (25–50°C precision $\pm$ 0.1°C). The concentration of the oxidation product of the amines in homogeneous and heterogeneous systems was monitored spectrophotometrically at 435 nm for *o*-AP, 420 nm for *o*-PDA [15,24] and 510 nm for *p*-PDA [31], except with complex **II** where the reactions were monitored at 435 and 450 nm for *o*- and *p*-PDA, respectively [32].

3. Results and discussion

3.1. Analysis of the supported resin and oxidation products of the amines

DRS was utilised to observe the influence of the supported complexes and the oxidation reaction of the amines on the Amberlite IRA 904 anion-exchange resin (Fig. 1). The observed absorption bands at $\lambda = 604$ and

420 nm shown in Fig. 1(b) are attributed to the strong support of complex **II** on the resin after ion exchange [19,27]. Additionally, the absorption band at $\lambda = 604$ nm for complex **II** disappears and the band at $\lambda = 435$ nm becomes apparent (Fig. 1(b,c)). These results provide good evidence for the reduction of the metal ion in the redox system and strong adsorption of the oxidation product on the Amberlite resin after the redox reaction.

Mass spectrometry APCI was used for the molecular weight determination of the oxidation product of the redox reaction (Fig. 2). This showed that the oxidation product of *o*-AP, *p*-PDA and *o*-PDA exhibited a molecular ion consistent with the formation of dimers and a trimer as follows: $[M]^+ = 215$, 319 and 211 for the oxidation product of *o*-AP, *p*-PDA and *o*-PDA, respectively. These ions were consistent with the molecular formulae $[C_{12}H_{11}N_2O_2]^+$, $[C_{18}H_{19}N_6]^+$ and $[C_{12}H_{11}N_4]^+$. These ions are consistent with the protonated forms of the oxidation products of the amines, as shown in Schemes 1–3. These analyses are consistent with literature values [24,33], and are appropriate for the reaction of the complexes **I**–**III** with the amines to produce benzoquinoneimine and benzoquinonediimine compounds.

3.2. Schematic representations of the diverse reactions

The oxidative condensation process involves a $4e^-$ oxidation for *o*-AP to produce 2-aminophenoxazine-3-ol (APZ) (Scheme 1). However, the $6e^-$ oxidation is described for the oxidation of *o*-PDA and *p*-PDA to get 2,3-diaminophenazine (DAP) and 2,2′-diaminoazabenzene (AB), respectively (Schemes 2 and 3). Generally, the first $2e^-$ oxidation is a result of the reduction of the metal–oxalate complexes **I**–**III** [23,32]. This means that two equivalents of the metal complexes are initially reduced by one equivalent of the various amines. Since the benzoquinone imines react with another molecule of the amines to afford the dimeric or trimeric oxidation products, the reaction sequence of the expected oxidation products is shown in Schemes 1–3.

3.3. Kinetic parameters of the redox reactions

All the redox reactions between the amines (*o*-AP, *o*-PDA and *p*-PDA) and a known amount of the Amberlite IRA 904 supported complexes **I**–**III** obeyed first-order kinetics with respect to [amine]. The plot of

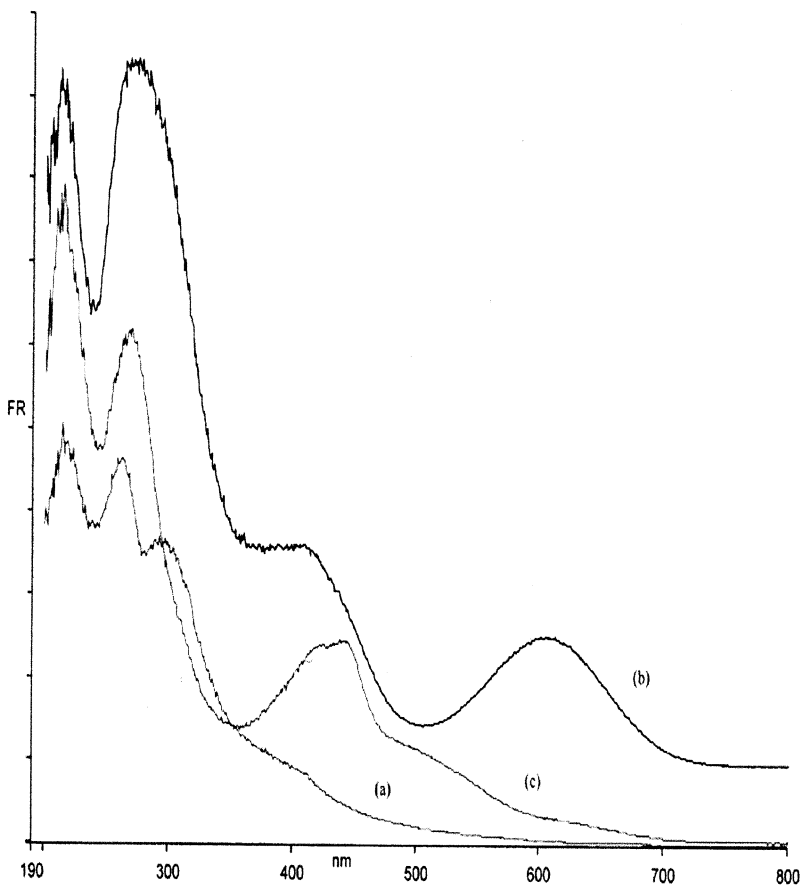

Fig. 1. Diffuse reflectance spectra of Amberlite IRA 904 anion-exchange resin (a) before supporting with complex, (b) after supporting with the Co(III)–oxalate complex, and (c) after the redox reaction with the amines used in this work at 25°C.

Scheme 3.

the logarithm of the $A_f/A_f - A_t$ versus time (Fig. 3) gives a straight line passing through the origin whose slope is equal to the observed rate constant (k_{obs}) according to the following equation [34]:

$$\ln(A_f/A_f - A_t) = k_{obs}wt$$

where A_f is the absorbance at infinite time, A_t is the absorbance at time t and w is the mass (g) of dry supported resin.

The true rate constants (k_t) per gram of dry resin (pgdr), which are independent of the amount of supported resin, were calculated and are summarised in Table 1.

The homogeneous redox reactions were performed under pseudo first-order conditions, with a large excess of the amine, except in the case of the reaction of complex **II** with *o*-AP and *o*-PDA where there was a large excess of the complex. In both cases, the reaction rate was determined by following the oxidation product of the amines at the characteristic absorption band as shown in Fig. 4. The rate equation in most cases can generally be written as follows:

$$\text{Rate} = k_{true}[\text{amine}]^m[\text{complex}]^n$$

The partial order with respect to [amine] and [complex] was obtained under pseudo first-order conditions. A plot of $\ln k_{obs}$ (k_o) against ln[amine] or ln[complex] gave a straight line whose slope and intercept are the order (m and n) of the [reactants] and k_{true} (k_t), respectively (Fig. 5(a,b)). The values of m and n were determined to be $1.0(\pm 0.1)$. Hence, the k_t values of this second-order reaction are listed in Table 2.

According to the data shown in Tables 1 and 2, the true rate constant of the homogeneous and heteroge-

[a] Standard deviations were in the range $1–7 \times 10^{-2}$ for all rate constants.

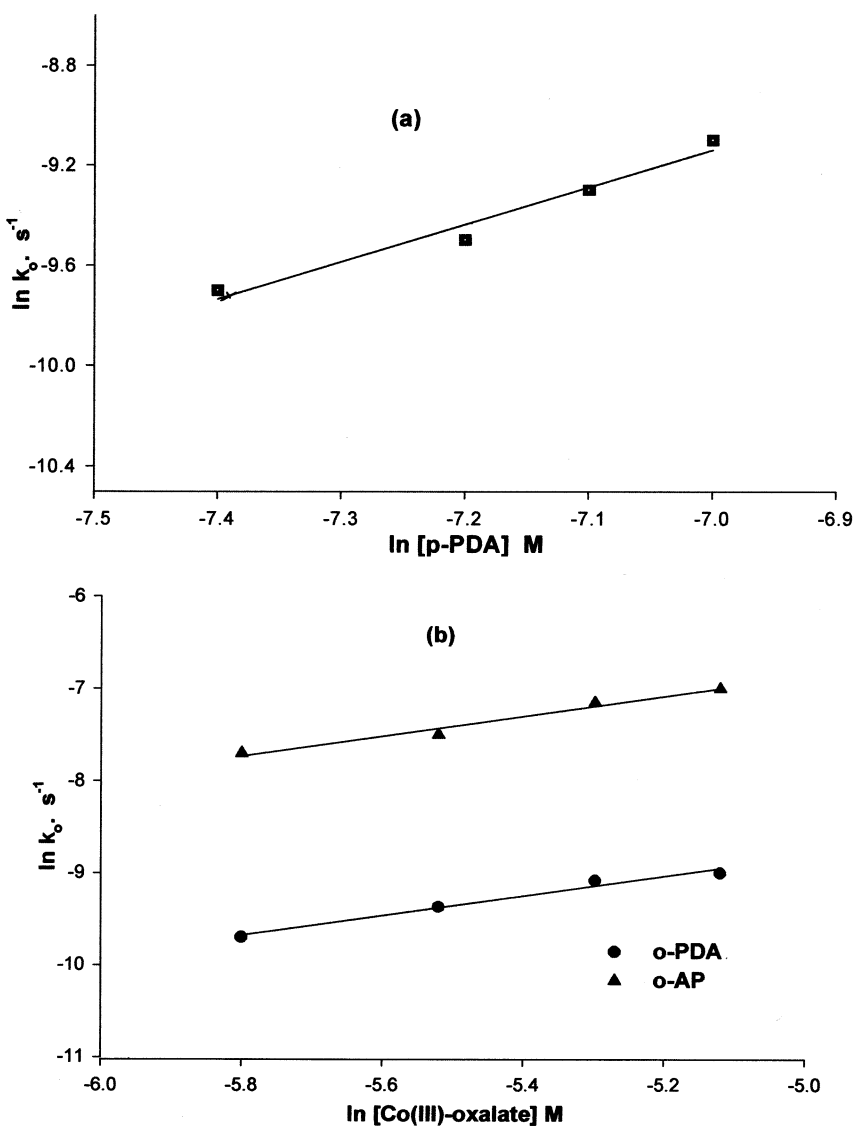

Fig. 5. Logarithmic plot of the relationship between the observed rate constant and (a) the [*p*-PDA] at constant of Co(III)–oxalate complex (7×10^{-5} M) and (b) the varied [Co(III)–oxalate] at constant amines concentration (2×10^{-4} M) at 40°C.

neous oxidation of amines has the following order pattern:

p-PDA > o-AP > o-PDA

which is attributed to the effects of the electron donating and electron density of the amine substituents. This is the same trend as observed with our previous work carried out on the oxidation of these amines by transition metal complexes incorporated with mesoporous silica materials [35].

Also, the oxidation activity of the metal–oxalate complexes increases in the following order:

III < II < I

The stability constant of the oxalate complexes decreases in the following sequence: **II** ≥ **I** ≫ **III** [28], but the reduction potential of Mn(III) → Mn(II) is larger than that of Co(III) → Co(II) in the reaction medium [36]. Hence, the reduction potential of the metal has more effect on the reactivity than the stability constant of these metal complexes.

3.4. Activation parameters of the redox reactions

The dependence of reaction rate of the redox reactions on the temperature is shown for one example of a heterogeneous reaction in Fig. 6.

The activation energy (E) was deduced from an Arrhenius plot, exemplified for a homogeneous case in Fig. 7. The other activation parameters $\Delta G^{\neq}$, $\Delta H^{\neq}$ and $\Delta S^{\neq}$ were calculated from Eyring's equation and are listed in Tables 1 and 2.

From these results, it can be seen that $\Delta S^{\neq}$ and E of amines for complexes **I**–**III** follow the same sequence as the rate constant of the reaction as follows: p-PDA > o-AP > o-PDA, except only in the cases of amine oxidation reaction with complexes **II** and **III** supported on the Amberlite resin, which show an inverse sequence. This may be due to the high negative $\Delta S^{\neq}$ value suggesting that the transition state is charged and rigid [37,38].

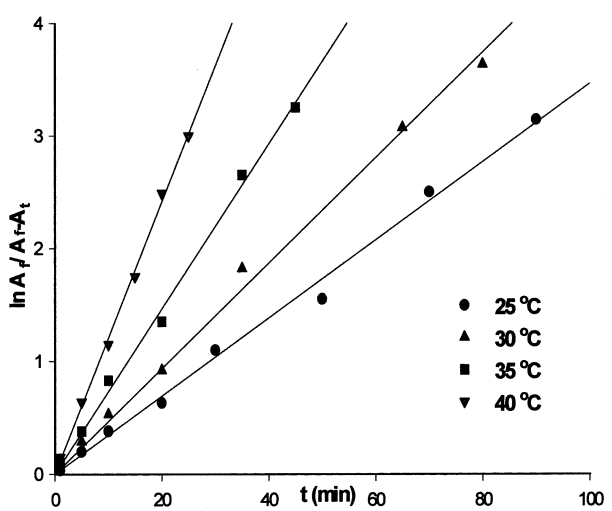

Fig. 6. Integrated first-order rate equation of the heterogeneous oxidation reaction between p-PDA (7.35×10^{-4} M) and the Mn(III)–oxalate complex supported on Amberlite IRA-904 (0.4 g) anion-exchange resin at different temperatures.

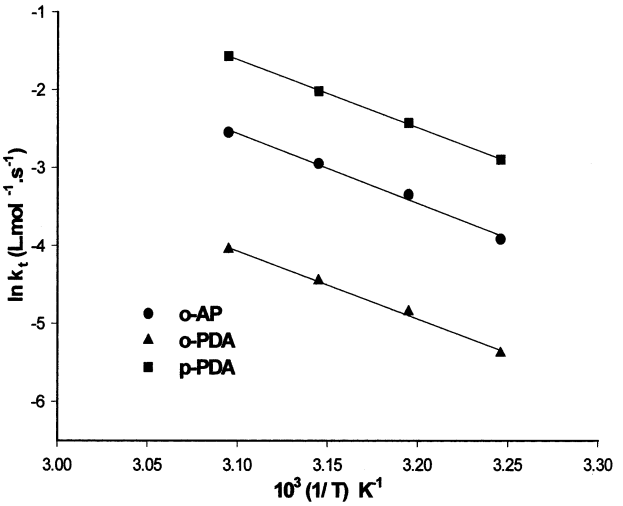

Fig. 7. Arrhenius plot of the redox reaction between amines and the Cu(II)–oxalate complex in solution.

On the other hand, the activation energy (E) of the redox reaction of the metal–oxalate complexes with amines (o-AP, o-PDA and p-PDA) increases in the following order with slight deviation in the case of the complex **I** in the heterogeneous system:

I < II < III

Hence the greater the reduction potential of the metal ion, the more facile is the metal–oxalate complexes to be reduced, and the smaller is the activation energy. Moreover, the value of $\Delta H^{\neq}$ of activation is in the range of chemical reaction control [39]. Also, this value shows that the electron transfer reaction steps may include the substitution reaction process [40]. The $\Delta G^{\neq}$ value is found to be in the range 74–95.7 kJ mol^{-1} (Tables 1 and 2), which is within the range of values for the oxidation of these amines by the iron(III)–oxalate complex $[Fe(C_2O_4)_3]^{3-}$ [41]. The above observations are consistent with the mechanisms of the redox reactions being the same in the homogeneous and heterogeneous systems.

3.5. Effect of oxalate ions on the redox reactions

The effect of added oxalate anion on the redox reaction rate has been studied in solution as well as in the heterogeneous system. This study was done after establishing an absence of any effect of oxalate anion concentration on the resin supported metal oxalate complexes by DRS measurements.

As shown in Fig. 8, an increase in the concentration of oxalate ion causes an inhibition in the reaction rate in the cases of o-PDA and p-PDA. The presence of the

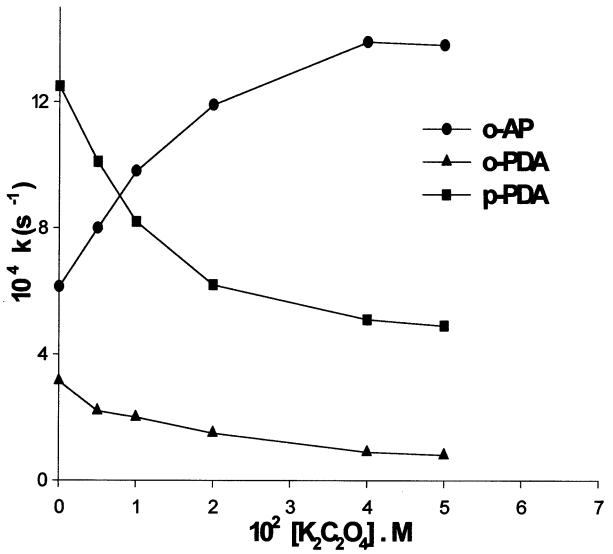

Fig. 8. Illustration of the effect of the oxalate ion concentration on the rate constant k (pgdr) for heterogeneous redox reaction between amines (7.35×10^{-4} M) and the Cu(II)–oxalate complex supported on Amberlite IRA 904 anion-exchange resin at 30°C.

oxalate ions in the reaction medium causes the reaction to shift towards the side of the reacting species. This causes the reacting species to be even more stable than the activated complexes and that renders the reaction less facile [42]. This result suggests the oxidation of *o*-PDA and *p*-PDA may follow a stepwise inner-sphere mechanism. On the contrary, in the case of redox reaction of *o*-AP with metal oxalate complexes, the rate of the reaction increases with increasing concentration of oxalate ions until at a particular concentration, the rate is constant. This means that the presence of oxalate ions in the reaction medium causes stabilisation of the activated complex and accelerates the reaction rate. The oxidation of *o*-AP by the metal oxalate complexes may follow the outer-sphere mechanism.

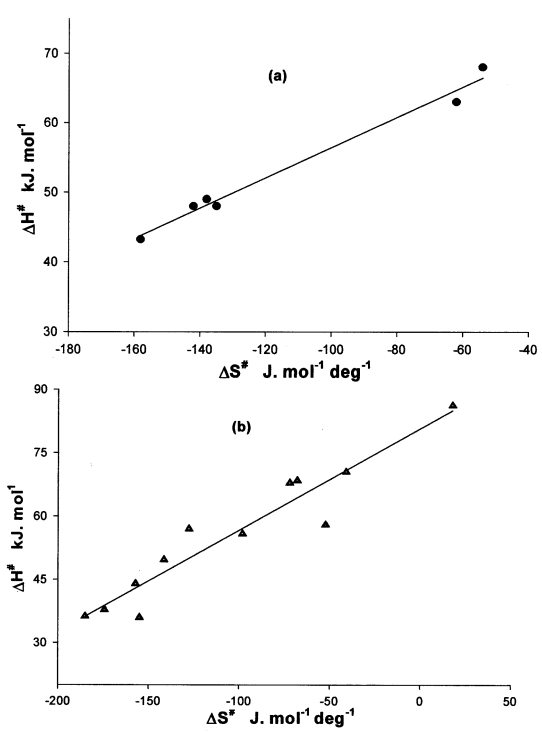

Fig. 9. Isokinetic relationship plot of heterogeneous and homogeneous redox reaction between metal–oxalate complexes and amines (a) *o*-AP and (b) *o*- and *p*-PDA used in this work.

3.6. Isokinetic relationship

These results suggest two different types of the oxidation reaction mechanisms. To confirm that, the isokinetic temperature (β) was tested by plotting a graph of $\Delta H^{\neq}$ versus $\Delta S^{\neq}$ (Fig. 9(a,b)) for the heterogeneous and homogeneous oxidation reactions of *o*-AP, *o*-PDA and *p*-PDA with metal oxalate complexes, which provide correlation coefficients of 0.95 and 0.90, respectively, on a linear relationship (Fig. 9(a,b)). It is evident that there is a significant difference in the redox reaction mechanism in the case of *o*-AP as opposed to those of *o*-PDA and *p*-PDA.

The value of the isokinetic temperature β was found to be 218 and 240 K, respectively. These values are below the mean experimental temperature, thereby suggesting that these are entropy-controlled reactions [43].

3.7. The reaction mechanism

In view of the experimental findings, it would seem appropriate to discuss the mechanism of the redox reaction. The *outer-sphere mechanism* of the redox reaction between *o*-AP and metal–oxalate complexes is proposed as follows in the following reaction scheme (Eqs. (1)–(8)) [44–46]. In all types of mechanism (L = 0 or $C_2O_4^{2-}$ in the cases of the second and third oxidation state of transition metal, respectively):

$$[ML(C_2O_4)_2]^{n-} + AP \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \{[ML(C_2O_4)_2]^{n-}\cdots AP\} \quad (1)$$

(formation of the encounter pair)

$$\{[ML(C_2O_4)_2]^{n-}\cdots AP\} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} \{[ML(C_2O_4)_2]\text{–}AP^{n-}\} \quad (2)$$

(restructuring of the encounter complex to set up the electron transfer)

$$\{[M\,L(C_2O_4)_2\,] - AP\}^{n-} \xrightarrow[slow]{k_3} [M\,L(C_2O_4)]^{(n-1)-} + HC_2O_4^{-} + AP^{\cdot} \xrightarrow[\text{Oxidation product}]{rapid\ \downarrow k_4} \quad (3)$$

$$dx/dt = k_3\{[ML(C_2O_4)_2]\text{–}AP\}^{n-} \quad (4)$$

Under pre-equilibrium conditions:

$$dx/dt = k_3K_1K_2[ML(C_2O_4)_2]^{n-}[AP] \quad (5)$$

where $K_1 = k_1/k_{-1}$ and $K_2 = k_2/k_{-2}$.

Applying the steady-state approximation for the intermediate:

$$\begin{aligned} &d\{[ML(C_2O_4)_2]\text{–}AP\}^{n-}/dt \\ &= k_2\{[ML(C_2O_4)_2]^{n-}\cdots AP\} \\ &\quad - k_{-2}\{[ML(C_2O_4)_2]\text{–}AP\}^{n-} \\ &\quad - k_3\{[ML(C_2O_4)_2]\text{–}AP\}^{n-} = 0 \end{aligned} \tag{6}$$

$$\text{i.e. } \{[ML(C_2O_4)_2]\text{–}AP\}^{n-} = \frac{k_2K_1[ML(C_2O_4)_2]^{n-}[AP]}{k_{-2}+k_3} \tag{7}$$

$$dx/dt = \frac{k_3k_2K_1[ML(C_2O_4)_2]^{n-}[AP]}{k_{-2}+k_3} \tag{8}$$

The *inner-sphere mechanism* of the redox reaction between *o*-PDA and *p*-PDA, and metal–oxalate complexes is also suggested as follows in the following reaction scheme (Eqs. (9)–(16)) [44,47,48]:

$$[ML(C_2O_4)_2]^{n-} + PDA \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \{[ML(C_2O_4)_2]^{n-}\cdots PDA\}$$

(formation of the encounter pair) (9)

$$\{[ML(C_2O_4)_2]^{n-}\cdots PDA\} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} [ML(C_2O_4)PDA]^{(n-1)-} + HC_2O_4^-$$

(formation of the inner-sphere complex) (10)

$$[M\,L(C_2O_4)\,PDA]^{(n-1)-} \xrightarrow[slow]{k_3} [M\,L(C_2O_4)]^{(n-1)-} + PDA \quad (rapid \downarrow k_4)$$

Oxidation product (11)

$$dx/dt = k_3[ML(C_2O_4)PDA]^{(n-1)-} \tag{12}$$

Applying a pre-equilibrium approximation:

$$dx/dt = k_3K_1K_2\frac{[ML(C_2O_4)_2]^{n-}[PDA]}{[HC_2O_4^-]} \tag{13}$$

where $K_1 = k_1/k_{-1}$ and $K_2 = k_2/k_{-2}$

Applying the steady state approximation for the intermediate:

$$\begin{aligned} &d[ML(C_2O_4)PDA]^{(n-1)-}/dt \\ &= k_2\{[ML(C_2O_4)_2]^{n-}\cdots PDA\} \\ &\quad - k_{-2}[ML(C_2O_4)PDA]^{(n-1)-}[HC_2O_4^-] \\ &\quad - k_3[ML(C_2O_4)PDA]^{(n-1)-} = 0 \end{aligned} \tag{14}$$

i.e. $[ML(C_2O_4)PDA]^{(n-2)-}$

$$= \frac{k_2K_1[ML(C_2O_4)_2]^{n-}[PDA]}{k_{-2}[HC_2O_4^-]+k_3} \tag{15}$$

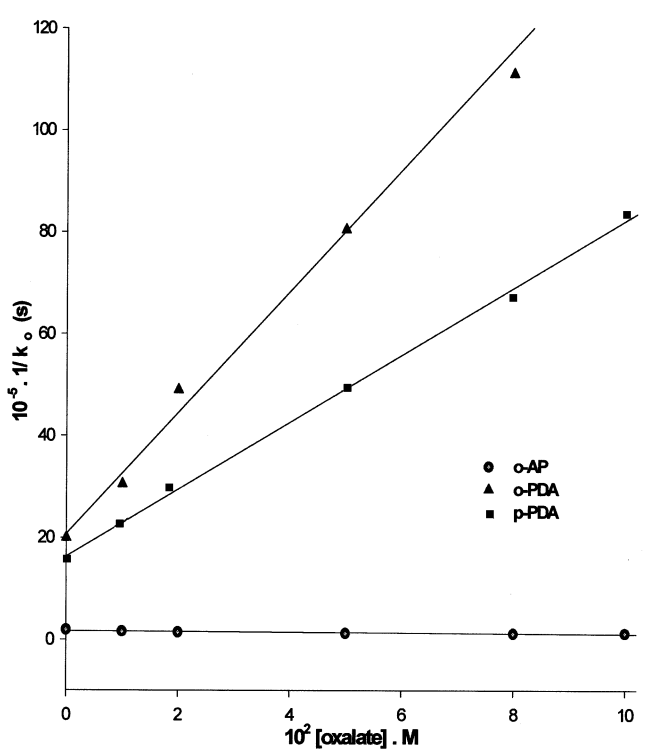
$$dx/dt = \frac{k_3k_2K_1[ML(C_2O_4)_2]^{n-}[PDA]}{k_{-2}[HC_2O_4^-]+k_3} \tag{16}$$

From the two suggested mechanisms, the $[C_2O_4^{2-}]$ appearing in the denominator of the rate expression for the inner-sphere mechanism only, provides an explanation for a slight inverse dependence on $[C_2O_4^{2-}]$ in the oxidation of *o*-PDA and *p*-PDA. In each mechanism, the reaction rate is proportional to $[ML(C_2O_4)_2]^{n-}$ and [amine]. This means that the reaction follows second-order kinetics in the homogeneous system, and first-order for kinetics for $[MLC_2O_4)_2]^{n-}$ and [amine], and first-order kinetics for [amine] in the heterogeneous system.

From Eq. (16), we can derive the following relationship:

$$\frac{1}{k} = \frac{k_{-2}[HC_2O_4^-]}{k_3k_2K_1} + \frac{k_3}{k_2K_1} \tag{17}$$

By applying the relationship $1/k_{obs}$ versus [oxalate], a plot of Eq. (10) gives a good linear relationship in the case of the oxidation reaction of *o*-PDA and *p*-PDA, which provides correlation coefficients of 0.994 and 0.996, respectively. In contrast, a poor straight line with



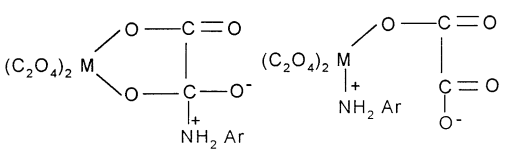


Fig. 10. Illustration of the relationship $1/k_{obs}$ vs. [oxalate] of the homogeneous redox reaction between the amines and the Co(III)–oxalate complex at 40°C.

a correlation coefficient of 0.75 and an inverse linear relationship was found in the oxidation of *o*-AP, as shown in Fig. 10. It is evident that the redox reaction mechanism in the oxidation of *o*-AP is different to those of *o*-PDA and *p*-PDA. The rate equation of the outer-sphere mechanism of *o*-AP oxidation is independent of [oxalate]. Thus, the effect of oxalate represents the medium effect on the oxidation reaction of *o*-AP in both redox systems. On contrary, the reaction rate of the oxidation of *o*-PDA and *p*-PDA was significantly affected with [oxalate] anion. This suggests that the inner-sphere mechanism is predominant to those amines oxidation reaction.

Generally, these tris-oxalato complexes may be considered to be kinetically inert, especially for the d^6 complex of Co(III), and thus be improbable candidates for an inner-sphere mechanism. However, it is known that $[Co(C_2O_4)_3]^{3-}$ does undergo racemisation, oxygen exchange and aquation under ambient conditions. Several possibilities exist for an inner-sphere complex which are consistent with discussion about these coordination sphere modifications [49,50]:

Only the last of these might release oxalate, and would obviously result in rate retardation by this anion. However, it is reported that the rate of oxygen exchange is also depressed by oxalate, and so the other alternatives may be valid [51].

4. Conclusion

It can be concluded that the kinetics and the activation parameters of the redox reaction are in good agreement with both the behaviour of the redox reactants in solution and the heterogeneous system. The effects of added anions on the redox reaction can be used to differentiate between the inner- and outer-sphere mechanisms that are ascertained as the detailed pathway for the electron transfer process in complex systems.

Abstract

Diphosphinepalladium nitrite complexes of the type $[Pd(NO_2)_2L_2]$ (L_2 = dppm, dppe, dppp) have been prepared by treatment of $[PdCl_2(CH_3CN)_2]$ with silver nitrite, followed by addition of the appropriate diphosphine. The nitrite complexes are fluxional in solution at 298 K, but on cooling to 220 K signals due to three species could be detected. These have been assigned to the N-bonded, the O-bonded, and the mixed coordination compounds. Treatment of $[PdCl_2(dppe)]$ with two equivalents of $TlPF_6$, followed by addition of $Na^{15}NO_2$, produced $[Pd(^{15}NO_2)_2(dppe)]$, whose ^{31}P NMR spectrum allowed identification of the three isomers. The analogous platinum complex $[Pt(NO_2)_2(dppe)]$ exists as a single isomer, which is static at 298 K, and a $^{15}NO_2$-labeling experiment indicated that it contains N-bonded nitrite ligands. © 2000 Elsevier Science Ltd. Keywords: Palladium; Platinum; Nitrite; Diphosphines; Isomerism; Fluxionality

1. Introduction

The phenomenon of linkage isomerism, which is exhibited by ambidentate ligands such as thiocyanate, nitrite, and dimethylsulfoxide, has been known for many years, and it is discussed in most inorganic textbooks. The thiocyanate ligand, for example, usually acts as an S-donor towards soft metal centers, but as a N-donor towards smaller, hard metals. Steric effects may also be important, particularly for the bulkier dimethylsulfoxide. Although one form is often considerably more thermodynamically stable than the other, rearrangement of the kinetic product into the thermodynamic one may be slow. Such is the case for the classic example of $[Co(NH_3)_5(NO_2)]Cl_2$ [1], where conversion of the nitrito to the corresponding nitro complex takes place over several days at ambient temperature. Nitrito to nitro isomerization of octahedral cobalt(III) complexes may be base-catalyzed [2], whereas the reverse process has been shown to be catalyzed by acid [3]. Isomerization may proceed in liquid ammonia [4] or even in the solid state [5,6]. Reversible nitro–nitrito linkage isomerization at a ruthenium center may be redox-induced [7–9]. For the chromium complex $[Cr(\eta^5\text{-}C_5H_5)(NO)_2(NO_2)]$, a mixture of linkage isomers was found, the nitrito form predominating, but exchange between the two forms was slow on the NMR timescale [10].

Palladium nitrite complexes, in particular, exhibit reactivity in a number of areas, including the oxidation of alkenes to ketones [11], in carboxylation reactions [12], and in oxygen transfer reactions [13]. Oxygen transfer reactions catalyzed by nickel nitrite complexes have been suggested to involve intermediate O-bonded nitrite ligands [14]. Interconversion between N- and O-bonded nitrites may be important in many of these reactions, but such rearrangements are typically slow, at least under ambient conditions.

We have prepared a series of palladium nitrite complexes of the type $[Pd(NO_2)_2L_2]$ (L_2 = dppm, dppe, dppp), which exhibit broad ^{31}P NMR resonances at ambient temperature. This behavior suggests that they are fluxional at this temperature and that the energy barrier between the different forms is quite low. We have employed variable temperature NMR spectroscopy, as well as ^{15}N-labeling experiments, in order to establish the nature of this behavior. The results of these studies will be presented here.

2. Results and discussion

Treatment of $[PdCl_2(CH_3CN)_2]$ with excess silver nitrite in CH_3CN solution produced $[Pd(NO_2)_2(CH_3CN)_2]$, along with a precipitate of AgCl [15–18]. Following filtration, addition of one molar equivalent of the appropriate diphosphine gave a complex of the type $[Pd(NO_2)_2L_2]$ (L_2 = dppm, dppe, dppp). Each of these complexes contains two monodentate nitrite ligands, which are forced to adopt a *cis* configuration due to the presence of the chelate ring. In each case, when the ^1H NMR spectrum was recorded in $CDCl_3$ solution, the resonances expected for the diphosphine ligand were observed, but no resonances could be detected in the $^{31}P\{^1H\}$ NMR spectrum at ambient temperature. Upon cooling to 220 K, however, ^{31}P signals were observed in each case (Table 1). The $^{31}P\{^1H\}$ NMR spectrum of $[Pd(NO_2)_2(dppm)]$ at 220 K is shown in Fig. 1. It contains signals due to three species; two of these must contain equivalent P atoms and give rise to singlet resonances, whereas the third has non-equivalent P atoms and produces a pair of doublets (AB quartet). When the $^{31}P\{^1H\}$ NMR spectrum was recorded in CD_2Cl_2 solution at temperatures between 180 and 250 K, there was no discernible change in the relative concentrations of the three components. We propose that the three sets of resonances are due to the linkage isomers shown in Fig. 2.

Several palladium nitrite complexes containing monodentate phosphines have been prepared [19,20]. Using ^{15}N-labeling experiments, the nitrite ligand was shown to be coordinated through nitrogen in each case, but no fluxional behavior was reported. The complex *trans*-$[Pd(NO_2)_2(PMePh_2)_2]$ was prepared by treatment of $K_2[Pd(NO_2)_4]$ with $PMePh_2$ [21], and we have prepared this complex by an alternative route, namely, treatment of $[PdCl_2(PMePh_2)_2]$ with silver nitrite. We have found that *trans*-$[Pd(NO_2)_2(PMePh_2)_2]$ is not fluxional in solution, as shown by sharp resonances in its ^{31}P NMR spectrum over the temperature range 220–298 K. The diphosphinepalladium complex $[PdPh(NO_2)(dppe)]$ has been reported, but no ^{31}P NMR data were provided [11].

Treatment of the platinum complex $[PtCl_2(dppe)]$ with $AgNO_2$ resulted in the formation of the expected $[Pt(NO_2)_2(dppe)]$, which is static in solution. The reaction takes place in a stepwise fashion, with $[PtCl(NO_2)(dppe)]$ (δP 28.2 br d, ^1J(Pt,P) = 2923 Hz, ^2J(P,P) = 8 Hz; δP 37.8 d, ^1J(Pt,P) = 3707 Hz) being formed when one molar equivalent of $AgNO_2$ was added. Addition of a second equivalent of $AgNO_2$ resulted in complete conversion to $[Pt(NO_2)_2(dppe)]$ (δP 27.9, ^1J(Pt,P) = 3052 Hz).

In order to assign the linkage isomers, we carried out ^{15}N-labeling experiments. When up to ten equivalents of $Na^{15}NO_2$ was added to a CH_3CN solution of $[PtCl_2(dppe)]$, mixtures of $[PtCl(^{15}NO_2)(dppe)]$ and $[PtCl_2(dppe)]$ only were obtained. In order to ensure complete conversion to the bis(nitrite)platinum species, $[PtCl_2(dppe)]$ was first treated with $TlPF_6$ in acetone, followed by addition of two equivalents of $Na^{15}NO_2$.

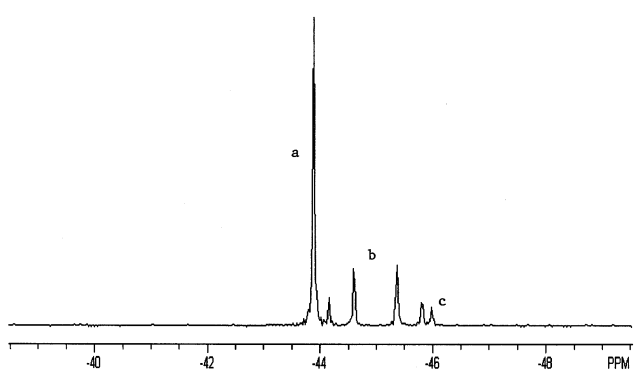

Fig. 1. $^{31}P\{^1H\}$ NMR spectrum of $[Pd(NO_2)_2(dppm)]$ (a), $[Pd(NO_2)(ONO)(dppm)]$ (b) and $[Pd(ONO)_2(dppm)]$ (c) recorded in $CDCl_3$ solution at 220 K.

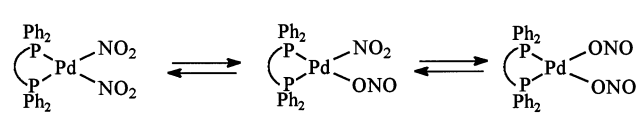

Fig. 2. Equilibria involving N- and O-bonded nitrite complexes.

This generated [Pt($^{15}NO_2$)$_2$(dppe)] quantitatively. Its ^{31}P NMR spectrum contained a central doublet at 27.9 ppm (^2J(P,N) = 65 Hz) and, consistently, the ^{15}N NMR spectrum exhibited a doublet at 464 ppm with a separation of 65 Hz. These data confirmed that the two nitrite ligands were coordinated to platinum through nitrogen. (The ^{31}P and ^{15}N NMR spectra should both exhibit AA′XX′ coupling patterns [22], but the magnitudes of most of the coupling constants were small and only the separation of the main doublet could be ascertained.)

The corresponding palladium complex [Pd($^{15}NO_2$)$_2$(dppe)] was prepared by the same method. Its ^{31}P NMR spectrum was again very broad at ambient temperature, but cooling to 220 K allowed identification of three species. The major species exhibited a broad doublet (actually part of an AA′XX′ system) centered at 54.5 ppm (^2J(P,N) = 56 Hz), indicating that the mode of coordination of the two nitrites was through nitrogen, namely, [Pd($^{15}NO_2$)$_2$(dppe)]. A second species exhibited a doublet of doublets at 58.5 ppm (^2J(P,P) = 16 Hz, ^2J(P,N) = 64 Hz) and a doublet at 55.1 ppm (^2J(P,P) = 16 Hz). This was consistent with [Pd($^{15}NO_2$)(O^{15}NO)(dppe)], the signal at δP 58.5 being due to the P atom lying *trans* to N. Only a trace of [Pd(O^{15}NO)$_2$(dppe)] was observed, which exhibited a single resonance at 59.3 ppm. Thus, the three linkage isomers could be identified at low temperature, but interconversion between the three was rapid at 298 K.

In each case, [Pd(NO_2)$_2$L$_2$] is the major species, with the dinitritopalladium complex being least favored. The dinitropalladium derivative is present in the greatest concentration for the bulkiest ligand dppp, perhaps unexpectedly because the –NO_2 group is more sterically demanding than the –ONO fragment, but the other two cases do not follow this trend. In contrast, the analogous thiocyanate complexes were isolated as [Pd(SCN)$_2$(dppm)], [Pd(SCN)(NCS)(dppe)] and [Pd(NCS)$_2$(dppp)], respectively [23]. Here it appears that the more sterically demanding –SCN ligands are favored with the less bulky diphosphine ligands. It should be noted, however, that this study was of solid state structures, and it does not necessarily follow that these are the more stable species in solution.

The difference in solution behavior between the monodentate phosphine complexes *trans*-[Pd(NO_2)$_2$L$_2$] (L = PPh_3, $PMePh_2$, PMe_2Ph, PEt_3) and those where L_2 = dppm, dppe or dppp may be attributed to the high *trans*-influence [24] of the phosphine ligand. When monodentate phosphines are employed, they adopt a mutually *trans* arrangement, causing the nitrite ligands to be *trans* to each other. In the diphosphine complexes, however, the nitrite ligands are forced to lie *trans* to tertiary phosphino groups. The greater *trans*-influence of the latter weakens the palladium–nitrite bond, thereby allowing isomerization between N- and O-bonded ligands more readily. The stronger Pt–N bonds in [Pt(NO_2)$_2$(dppe)] may preclude ligand rearrangement even though the nitrites lie *trans* to phosphino groups.

3. Summary

The results described above provide evidence that palladium nitrite complexes may exchange readily between N- and O-bonded forms when the nitrite group lies opposite a ligand with a high *trans*-influence [24]. This is in contrast to a number of platinum and palladium complexes that have been reported previously to be coordinated through nitrogen exclusively. Formation of oxygen-bound palladium nitrite complexes may be the first step in many palladium-catalyzed oxygen transfer reactions, and this study provides evidence that such species do exist and, indeed, may make up a significant proportion of the metal complex in solution, even at low temperatures.

4. Experimental

[$PdCl_2(CH_3CN)_2$] and [Pd(NO_2)$_2$(CH_3CN)$_2$] were prepared as described previously [11]. All reactions were carried out under an argon atmosphere and in the absence of light. $AgNO_2$ and Na$^{15}NO_2$ were purchased from Aldrich and Cambridge Isotope Laboratories, respectively, and used as received. NMR spectra were recorded on a Bruker ARX-500 spectrometer. ^{1}H chemical shifts were measured in ppm relative to the residual solvent signal, and ^{31}P and ^{15}N shifts were determined relative to external H_3PO_4 and $MeNO_2$, respectively, positive shifts representing deshielding. Elemental analyses were performed by Atlantic Microlab Inc., Norcross, GA. The ratios of isomers of [Pd(NO_2)$_2$L$_2$] were obtained by integration of the ^{31}P{^{1}H} NMR spectra (gated decoupled).

4.1. Preparation of [Pd(NO_2)$_2$(dppm)]

[$PdCl_2(CH_3CN)_2$] (0.10 g, 0.39 mmol) was dissolved in CH_3CN (30 ml) and $AgNO_2$ (0.18 g, 1.2 mmol) was added. The reaction mixture was allowed to stir for 12 h. The solution was filtered and dppm (0.15 g, 0.39 mmol) was added to the filtrate. The mixture was stirred for a further 5 min, then the solvents were removed. The residue was extracted with CH_2Cl_2 and filtered. The solvent was removed and the resulting solid was dried in vacuo to leave the product as a pale yellow solid (0.22 g, 99%). *Anal.* Calc. for $C_{25}H_{22}N_2O_4P_2Pd$: C, 51.52; H, 3.81. Found: C, 51.10; H, 3.92%. ^{1}H NMR ($CDCl_3$): δ 4.05 (t, ^2J(P,H) = 10.3 Hz, 2H, PCH_2); 7.4–7.75 (m, 20H, P(C_6H_5)$_2$).

[$Pd(NO_2)_2$(dppp)] was prepared analogously, and isolated as a colorless powder in 43% yield. *Anal.* Calc. for $C_{27}H_{26}N_2O_4P_2Pd$: C, 53.08; H, 4.30. Found: C, 52.99; H, 4.23%. ^{1}H NMR ($CDCl_3$): δ 2.1 (br, 2H, PCH_2CH_2); 2.4 (br, 4H, PCH_2); 7.4–7.7 (m, 20H, $P(C_6H_5)_2$).

4.2. Preparation of [$Pd(NO_2)_2$(dppe)]

[$PdCl_2(CH_3CN)_2$] (0.10 g, 0.39 mmol) was dissolved in CH_3CN (30 ml) and $AgNO_2$ (0.18 g, 1.2 mmol) was added. The reaction mixture was allowed to stir for 12 h. The solution was filtered, then dppe (0.15 g, 0.39 mmol) was added. A precipitate formed, which was collected by filtration. It was washed with CH_3CN and ether, then dried in vacuo to leave the product as a colorless powder (0.16 g, 71%). *Anal.* Calc. for $C_{26}H_{24}N_2O_4P_2Pd$: C, 52.31; H, 4.03. Found: C, 51.80; H, 4.06%. ^{1}H NMR ($CDCl_3$): δ 2.21–2.35 (m, 4H, PCH_2); 7.4–7.5 (m, 20H, $P(C_6H_5)_2$).

4.3. Preparation of [$Pt(NO_2)_2$(dppe)]

[$PtCl_2$(dppe)] (0.15 g, 0.23 mmol) was dissolved in CH_3CN (30 ml). $AgNO_2$ (0.14 g, 0.90 mmol) was added and the mixture was allowed to stir for 48 h. The solution was filtered and the solvent was removed. The resulting solid was extracted with CH_2Cl_2 and filtered. The solvent was removed again to leave the product as a colorless solid (0.12 g, 77%). *Anal.* Calc. for $C_{26}H_{24}N_2O_4P_2Pd$: C, 45.54; H, 3.50. Found: C, 45.47; H, 3.60%. ^{1}H NMR ($CDCl_3$): δ 2.20–2.50 (m, 4H, PCH_2); 7.5–7.8 (m, 20H, $P(C_6H_5)_2$).

4.4. Preparation of [$Pd(NO_2)_2(PMePh_2)_2$]

[$PdCl_2(PMePh_2)_2$] (0.10 g, 0.17 mmol) was dissolved in CH_2Cl_2 (30 ml), and $AgNO_2$ (0.080 g, 0.52 mmol) and methanol (2 ml) were added. The reaction mixture was allowed to stir for 24 h, the solvents were removed and the residue was extracted with CH_2Cl_2 and filtered. The solvent was removed again and the sample was dried in vacuo to leave the product as a colorless solid (0.086 g, 83%).

4.5. Preparation of $^{15}NO_2$-labeled complexes

In a typical experiment, [MCl_2L_2] (ca. 0.02 g) was dissolved in acetone. $TlPF_6$ (two molar equivalents) was added and the reaction was allowed to stir for 2 h. After this time, $Na^{15}NO_2$ (two molar equivalents) was added and the mixture was allowed to stir for a further 2 h. The acetone was removed, and the solid was extracted with CH_2Cl_2. The solvent was removed again and the product was dried in vacuo.

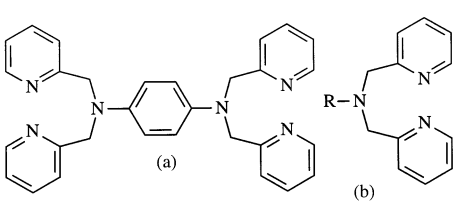
Received 2 February 2000; accepted 14 April 2000



Abstract

Ni(II) and Fe(II) complexes of the new ligand *N*,*N*-bis(2-pyridylmethyl)aniline (phdpa) of the general formula $[M(phdpa)_2](ClO_4)_2$ have been prepared and characterised. $[Ni(phdpa)_2](ClO_4)_2 \cdot 0.5\ H_2O$ was characterised by X-ray crystallography. For comparison, the X-ray structure of $[Ni(medpa)_2](ClO_4)_2$ (where medpa is bis(2-pyridylmethyl)methylamine) has been determined. The ligand in both $[Ni(phdpa)_2](ClO_4)_2$ and $[Ni(medpa)_2](ClO_4)_2$ exhibit *cis–facial* geometry. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Our recent work with the redox-active bis-tridentate ligand, *N*,*N*,*N*′,*N*′-tetrakis(2-pyridylmethyl)benzene-1,4-diamine (tpbd) (Scheme 1(a)) has resulted in the isolation of a series of transition metal complexes of varied M:L ratio. Mononuclear complexes were obtained with zinc, $(tpbd)ZnCl_2$ [1], and ruthenium, $[(tpbd)Ru(tpbd)]^{2+}$ [1],dinuclear complexes with palladium, $[ClPd(tpbd)PdCl]^{2+}$ [1], and copper, $[(H_2O)_2Cu(tpbd)Cu(H_2O)_2]^{4+}$ [2], and proposed oligomeric/polymeric complexes with iron and nickel, $[M(tpbd)]_n^{2n+}$, M = Fe or Ni, and copper, $[(tpbd)Cu(\mu\text{-}L)_2Cu]_n^{2n+}$ or $[(tpbd)Cu(\mu\text{-}L)_2Cu]L^{2+}$, L = Cl or NO_3 [1]. Structural characterisation of these insoluble polymeric complexes has been hampered by the lack of success in growing crystals suitable for X-ray structural determination, and NMR studies have afforded only limited information. In order to assist in establishing the structures of these polymers we have prepared the Ni(II) and Fe(II) complexes of the new tridentate ligand *N*,*N*-bis(2-pyridylmethyl)aniline (phdpa) (Scheme 1(b)) in the expectation that these might act as monomeric structural models for the putative polymeric tpbd complexes. The tertiary nitrogen atoms of tpbd are expected to be weaker Lewis bases compared with the aliphatic nitrogens in the known related ligands, i.e. bis(2-pyridylmethyl)amine (dpa) and bis(2-pyridylmethyl)methylamine (medpa) (Scheme 1) due to the electron withdrawing effect of the phenylene group on the attached nitrogen atom's lone pair. Prediction of the coordination mode (*trans*/*cis fac* versus *mer*) of phdpa is complicated due to a number of parameters (i.e. σ-donor strength, π-acceptor strength, geometry of the ligand/metal, etc.) which are affected by substituting H or CH_3 by a phenyl group in the dpa derived ligands.

Scheme 1. Schematic representation of (a) tpbd and (b) dpa, R = H; medpa, R = Me; phdpa, R = ph.

Structurally characterised bis-dpa complexes with Cu(II) [3], Fe(II) [4], Ni(II) [5], Mn(II) [6], Zn(II) [6] and Cd(II) [6] and bis-medpa with Fe(II) [7] exhibit *cis–facial* coordination, whereas, to the best of our knowledge, only one *mer* six-coordinated coordinated metal complex with dpa-derived ligands has been synthesised; a di-μ-oxo dimer of Cr(III) with two squarate molecules as monodentate ligands [8].

2. Experimental

2.1. Physical measurements

UV–Vis absorption spectra were recorded on a Shimadzu UV-3100 spectrophotometer. FAB mass spectrometry was carried out on a Kratos MS50TC instrument. NMR spectra were recorded on a Bruker AC 250. Elemental analyses were carried out by the Microanalytical Laboratory of the H.C. Ørsted Institute, Copenhagen.

2.2. Materials

All commercially available chemicals were used without any prior purification, apart from aniline, which was freshly distilled. *N*,*N*-Bis(2-pyridylmethyl)-methylamine (medpa) was used as medpa·3HClO$_4$ as described elsewhere [9], and [Ni(tpbd)]$_n$(ClO$_4$)$_{2n}$ and [Fe(tpbd)]$_n$Cl$_{2n}$ were prepared as previously reported [1].

2.3. *N*,*N*-Bis(2-pyridylmethyl)aniline, phdpa

A solution of 2-(chloromethyl)pyridine hydrochloride (6.00 g, 36.6 mmol) in water (3 ml) was neutralised by addition of NaOH (1.46 g, 36.6 mmol) in water (7 ml) at 0°C. Aniline (1.70 g, 18.3 mmol) was added to the vigorously stirred solution at 0°C over a period of 2 h, followed by methylene chloride (5 ml). Over 7 days NaOH (1.46 g, 36.6 mmol) in water (7 ml) was added in small portions and the pH was kept below 9. The reaction was stirred for another 7 days. The pH was adjusted to 8 with NaOH or HCl, and the phases were separated. The aqueous phase was extracted with CH_2Cl_2 (3 × 30 ml) and the combined organic extracts were washed with water (10 ml), dried over anhydrous sodium sulfate and evaporated to dryness. The crude product was purified by a Soxhlet apparatus using petrol (b.p. 60–80°C). Yield 2.4 g, 47.6% of pale yellow crystals. *Anal*. Found: C, 78.34; H, 6.33; N, 15.26. Calc. for $C_{18}H_{17}N_3$: C, 78.52; H, 6.22; N, 15.26%. FABMS, *m*/*z*: 276 (M^+, 100%). ^{1}H NMR ($CDCl_3$): $\delta = 4.83$ (s, 4H, CH_2), 6.72 (m, 3H, ph-$H^2 + H^4$), 7.17 (m, 4H, py-H^5 + ph-H^3), 7.24 (d, 4H, py-H^3, $J = 6.9$ Hz), 7.61 (dt, 4H, py-H^4, $J = 7.8$, 1.8), 8.59 (m, 2H, py-H^6). ^{13}C NMR ($CDCl_3$): $\delta = 57.56$ (CH_2), 112.85 (ph-C^2), 117.55 (ph-C^4), 121.14, 122.35 (py-C^3, py-C^5), 129.65 (ph-C^3), 137.17 (py-C^4), 148.61 (ph-C^1), 150.12 (py-C^6), 159.29 (py-C^2).

Caution! The following perchlorate compounds should be handled as potential explosives.

2.4. [(Bis(*N*,*N*-bis(2-pyridylmethyl)methylamine)nickel-(II)]diperchlorate, [Ni(medpa)$_2$](ClO$_4$)$_2$

Ni(ClO$_4$)$_2$·6H$_2$O (160 mg, 0.440 mmol) and medpa·3HClO$_4$ (453 mg, 0.880 mmol) were suspended in water (40 ml). 2 M NaOH was added dropwise until all material was dissolved. The purple solution was allowed to stand for 2 days before the product was isolated as purple crystals. Yield 157 mg, 52.2%. *Anal*. Found: C, 45.66; H, 4.10; N, 12.12. Calc. for $C_{26}H_{30}Cl_2N_6NiO_8$: C, 45.64; H, 4.42; N, 12.12%. UV–Vis (CH_3CN): λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 259 (12 490), 556 (18), 815 sh, 936 (13). FABMS, *m*/*z*: 583 ([Ni(medpa)$_2$ClO$_4$]$^+$, 18%), 370 ([Ni(medpa)ClO$_4$]$^+$, 100), 271 ([Ni(medpa)]$^+$, 95).

2.5. [(Bis(*N*,*N*-bis(2-pyridylmethyl)aniline)nickel(II)]-diperchlorate, [Ni(phdpa)$_2$](ClO$_4$)$_2$

Ni(ClO$_4$)$_2$·6H$_2$O (33.2 mg, 0.091 mmol) in MeOH (1 ml) was added to phdpa (50 mg, 0.182 mmol). Precipitation began after a few minutes. The purple crystals were isolated by filtration. Yield 65.4 mg, 89%. *Anal*. Found: C, 52.43; H, 4.39; N, 10.03. Calc. for $C_{36}H_{34}Cl_2N_6NiO_8$: C, 52.33; H, 4.39; N, 10.17%. UV–Vis (CH_3CN): λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 250 (15 400), 305 (2100), 573 (15), 824 sh, 941 (13). FABMS (*m*/*z*): 707 ([Ni(phdpa)$_2$ClO$_4$]$^+$, 7%), 432 ([Ni(phdpa)ClO$_4$]$^+$, 100). Crystals for X-ray structure determination were obtained by recrystallisation from MeOH/water.

2.6. [(Bis(*N*,*N*-bis(2-pyridylmethyl)aniline)iron(II)]-diperchlorate, [Fe(phdpa)$_2$](ClO$_4$)$_2$

This synthesis was carried out under an inert atmosphere. Fe(ClO$_4$)$_2$·6H$_2$O (33 mg, 0.091 mmol) in abs. ethanol (1.5 ml) was added to a solution of phdpa (50 mg, 0.182 mmol) in abs. ethanol (4 ml). Immediate precipitation of the pale yellow product, which was filtered under argon. Yield 56.4 mg, 73.7%. *Anal*. Found C 53.95; H 4.59; N 9.98. Calc. for $C_{36}H_{34}Cl_2FeN_6O_8$: C 53.68; H 4.25; N 10.43. UV–Vis (CH_3CN): λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 248 (22 970), 300 sh, 1025 (br, 9). FABMS, *m*/*z*: 705 ([Fe(phdpa)$_2$ClO$_4$]$^+$, 2%), 605 ([Fe(phdpa)$_2$ − H]$^+$, 1), 430 ([Fe(phdpa)ClO$_4$]$^+$, 13).

2.7. X-ray structural determination

The structures were determined at room temperature using graphite monochromatised radiation. Data were collected on a Siemens SMART diffractometer [10]. Crystal data and experimental parameters are presented in Table 1. The data were corrected for Lorentz-polarisation effects and for absorption [10]. The structures were solved by direct methods using SIR-97 [11] and refined by least-squares techniques using programs from the KRYSTAL [12] package. Atomic scattering factors were taken from elsewhere [13].

2.7.1. $[Ni(phdpa)_2](ClO_4)_2 \cdot H_2O$

The complex crystallises in the centrosymmetric monoclinic space group $P2_1/n$ with eight molecules in the unit cell. All non-hydrogen atoms were refined anisotropically, hydrogen atoms of the water molecule were located from a difference map and refined isotropically, hydrogen atoms of the ligands were kept fixed in calculated positions (C–H = 0.95 Å). The perchlorate ions containing Cl3 and Cl4 were both disordered and were each modelled as two ideal tetrahedra, occupation factors and a common Cl–O distance were refined. Anisotropic displacement factors for the disordered perchlorate ions were described by **T** and **L** tensors [14].

2.7.2. $[Ni(medpa)_2](ClO_4)_2$

The complex crystallises in the non-centrosymmetric monoclinic space group $P2_12_12_1$ with four molecules in the unit cell. All non-hydrogen atoms were refined anisotropically, while hydrogen atoms were placed in fixed calculated positions (C–H = 0.95 Å).

3. Results and discussion

3.1. Ligand synthesis

The ligand phdpa was prepared by nucleophilic substitution of 2-(chloromethyl)pyridine with aniline in a two-phase system (water/methylene chloride) and was isolated as an off-white crystalline product in acceptable yields. All Rdpa (R = H, Me or Ph) complexes were prepared by reaction of the ligand with the relevant metal perchlorate in 2:1 ratios. In the case of $[Ni(medpa)_2](ClO_4)_2$, the perchloric acid ligand salt medpa·3HClO$_4$ was neutralised with base after the addition of nickel perchlorate. A preparation of this complex, but no crystal structure has been reported earlier [15].

3.2. Nickel complexes

The X-ray structures of $[Ni(phdpa)_2](ClO_4)_2$ and $[Ni(medpa)_2](ClO_4)_2$, show a *cis–facial* arrangement of the ligands, which is the case in almost all octahedral complexes with bis(2-pyridylmethyl)amine derived ligands [3–7]. Both structures consist of $[Ni(Rdpa)_2]^{2+}$ cations, perchlorate anions and, for R = phenyl, water of crystallisation. The two almost identical cations in the asymmetric unit of $[Ni(phdpa)_2](ClO_4)_2$ have approximate two-fold symmetry as is shown in Fig. 1, coordination at the nickel atom is roughly octahedral, with two tridentate ligands coordinating in *cis–fac* configuration. Principal bond lengths and angles for $[Ni(Phdpa)_2](ClO_4)_2$, $[Ni(Medpa)_2](ClO_4)_2$ and, for comparison, $[Ni(dpa)_2](ClO_4)_2$ [5], are summarised in Table 2. The medpa structure consists of

$[Ni(medpa)_2]^{2+}$ cations and perchlorate anions. A view of the cation is shown in Fig. 2. Again the nickel atom is octahedrally coordinated with *cis–fac* configuration so that the cation has approximate two-fold symmetry.

The average $Ni–N_{amine}$ distances increases with the size of the alkyl substituent, 2.106(4), 2.196(3) and 2.278(1) Å for dpa, medpa and phdpa, respectively; however, there is no significant difference between the corresponding average $Ni–N_{py}$ distances, 2.083(3), 2.111(2) and 2.096(1) Å.

The electronic spectra for $[Ni(Rdpa)_2](ClO_4)_2$ and $[Ni(tpbd)]_n(ClO_4)_{2n}$ are shown in Fig. 3. Absorption maxima are listed in Table 3. The green colour of $[Ni(tpbd)]_n(ClO_4)_{2n}$, caused by the broad band below 450 nm, centred at 312 nm (sh), is believed to arise from transitions in the phenylene backbone. This feature is not as pronounced in the UV–Vis spectrum of the corresponding complex with the less conjugated ligand, phdpa. A shift towards higher energy is observed of the low energy field spin-allowed d–d* transition bands in the $[Ni[dpa)_2]^{2+}$ (797 and 877 (sh) nm) compared with the corresponding Ni(II) complexes with substituted dpa ligands (ca. 820 (sh) and ca. 930 nm). This is due to a stronger ligand field nature of dpa compared with medpa, phdpa and tpbd in nickel(II) complexes. There is little difference in the electronic spectra of the complexes of *N*-alkylated DPA. Thus very similar geometries are expected.

3.3. Iron complexes

The pale yellow high-spin (HS) iron(II) complex, $[Fe(phdpa)_2](ClO_4)_2$, is relatively stable in air both as a solid and in solution. In the corresponding yellow medpa complex, $[Fe(medpa)_2]^{2+}$, HS behaviour was verified by magnetic susceptibility measurements [15]. In contrast the red dpa complex, $[Fe(dpa)_2]^{2+}$, is low-spin (LS) [15]. X-ray structures of $[Fe(dpa)](BF_4)_2$ [4] and $[Fe(medpa)_2](ClO_4)_2$ [7] reveal a *cis–facial* coordination geometry in both cases.

Electronic spectra of acetonitrile solutions of $[Fe(dpa)_2]^{2+}$, $[Fe(medpa)_2]^{2+}$, $[Fe(phdpa)_2]^{2+}$ and $[Fe(tpbd)]_n^{2n+}$ all have absorption maxima at 251–262 nm, due to ligand π–π* transitions. LS behaviour of $[Fe(dpa)_2]^{2+}$ is evident from the medium intensity d–d* transition band at 531 nm. Spectra of $[Fe(medpa)_2]^{2+}$, $[Fe(phdpa)_2]^{2+}$ and $[Fe(tpbd)]_n^{2n+}$ show medium intensity absorption bands in the area from 300 to 410 nm.

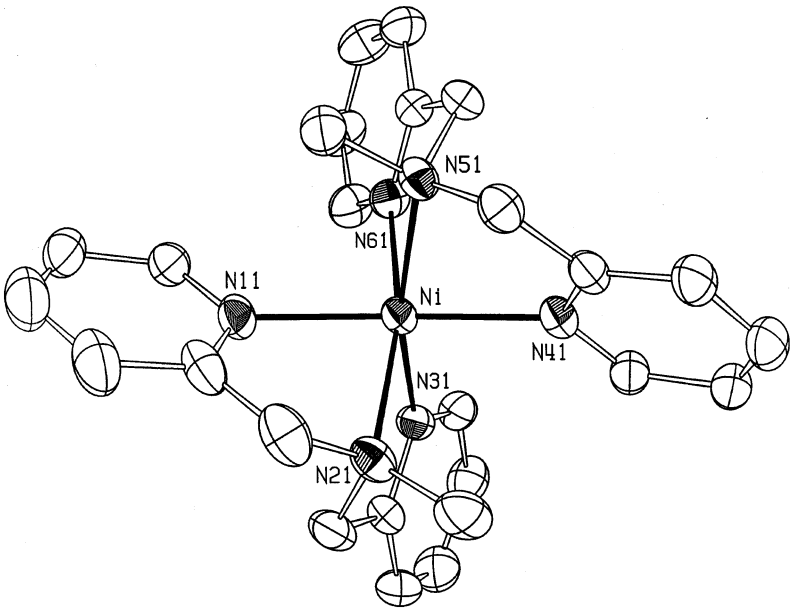

Fig. 2. ORTEP drawing of the $[Ni(medpa)_2]^{2+}$ cation. Ellipsoids are drawn at the 30% probability level.

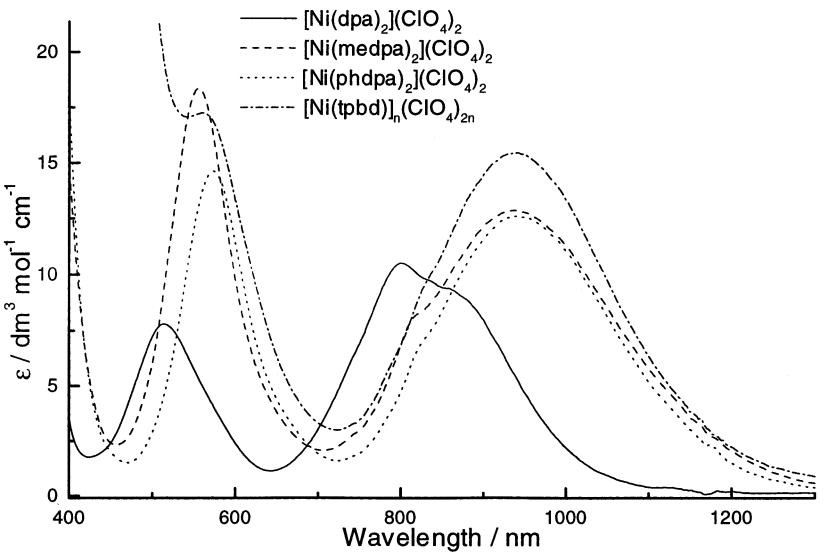

Fig. 3. UV–Vis spectra of the nickel complexes in CH_3CN solutions.

Such bands are generally believed to stem from MLCT from the iron(II) centre to pyridine ligands [16]. $[Fe(medpa)_2](ClO_4)_2$ and $[Fe(phdpa)_2](ClO_4)_2$ show comparable absorption characteristics in the area from 920 to 1075 nm. This further consolidates the strong field nature of dpa compared with the substituted analogues which was observed in the Ni(II) complexes. Due to the similarity of the spectra of $[Fe(phdpa)_2]^{2+}$ and $[Fe(tpbd)]_n^{2n+}$ with the spectrum of $[Fe(medpa)_2]^{2+}$ it is believed that the former two have analogous *cis–fac* geometries. Absorption maxima are listed in Table 3.

Table 3
UV–Vis absorption maxima for acetonitrile solutions of $[Ni(dpa)_2]^{2+}$, $[Ni(medpa)_2]^{2+}$, $[Ni(phdpa)_2]^{2+}$ and $[Ni(tpbd)]_n^{2n+}$

Complex	λ_{max} (ε/dm^3 mol^{-1} cm^{-1})
$[Ni(dpa)_2](ClO_4)_2$	514 (8), 801 (10), 859 sh
$[Ni(medpa)_2](ClO_4)_2$	556 (18), 815 sh, 936 (13)
$[Ni(phdpa)_2](ClO_4)_2$	573 (15), 824 sh, 941 (13)
$[Ni(tpbd)]_n(ClO_4)_{2n}$	561 (17), 827 sh, 937 (15)
$[Fe(dpa)_2](ClO_4)_2$	382 sh, 431 (8990)
$[Fe(medpa)_2](ClO_4)_2$	363 sh, 921 (8), 1024 sh
$[Fe(phdpa)_2](ClO_4)_2$	300 sh, 363 sh, 1025 (9) broad
$[Fe(tpbd)]_nCl_{2n}$	312 sh, 360 sh, 414 sh

4. Conclusions

Comparable ligand field properties are found in nickel(II) and iron(II) complexes of medpa, phdpa and tpbd in contrast to the much stronger donating ligand dpa.

The ligands are coordinated in a *cis–fac* fashion in $[Ni(phdpa)_2]^{2+}$ and $[Ni(medpa)_2]^{2+}$. UV–Vis results indicate similar coordination modes in phdpa and tpbd, suggesting a *cis–fac* binding of each end of tpbd in the polymeric $[Ni(tpbd)]_n^{2n+}$ and $[Fe(tpbd)]_n^{2n+}$.

5. Supplementary material

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre as CCDC No. 139600 for $[Ni(phdpa)_2](ClO_4)_2 \cdot 0.5H_2O$ and CCDC No. 139601 for $[Ni(medpa)_2](ClO_4)_2$. Copies of the data can be obtained, free of charge, on application from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

Formation of a mixed-valence Ru(IV)–Fe(II) binuclear complex via the reaction of $[Ru^{III}(edta)(H_2O)]^-$ and $[Fe^{III}(CN)_6]^{3-}$ in aqueous solution

Matthew S. Ward [a], Debabrata Chatterjee* [b,1], Rex E. Shepherd* [a,2]

Received 22 November 1999; accepted 25 April 2000

Abstract

The combination of $[Ru^{III}(edta)(H_2O)]^-$ ($edta^{4-}$ = ethylenediamine-*N*,*N*,*N*′*N*′-tetraacetate) and $[Fe^{III}(CN)_6]^{3-}$ in aqueous solution results in the rapid formation of $[Ru^{III}(edta)(NC)Fe^{III}(CN)_5]^{4-}$ (**1**), which has been isolated and characterized by physical methods. An aqueous solution of complex **1** shows two characteristic absorption maxima in the visible spectral region located at 420 and 620 nm. Examination of the same solution after 72 h shows that a spectral change has occurred, forming a species with a new band maximum at 870 nm. Spectral (IR, UV–Vis, ^1H and ^{13}C NMR spectra showing a paramagnetic complex, and time-dependent magnetic susceptibility data) provide evidence for the formation of a mixed-valence $[Ru^{IV}(edta)(NC)Fe^{II}(CN)_5]^{4-}$ complex **2** by the process, which causes the appearance of the 870 nm band. The results are compared with the known reactions between $[Ru^{III}(NH_3)_5(H_2O)]^{3+}$ and $[Fe(CN)_6]^{3-}$, which have been reported by Taube and co-workers (V.G. Poupopoulu, Z.W. Li, H. Taube, Inorg. Chim. Acta 225 (1994) 173) to sequentially form $\{[Ru^{III}(NH_3)_5(H_2O)]^{3+}, [Fe^{III}(CN)_6]^{3-}\}$ ion-pairs, converting to a (Ru^{III}–CN^- bridged-Fe^{III}) binuclear complex (an analogue of **1**, and upon intramolecular electron transfer, the (Ru^{IV}–CN^- bridged-Fe^{II}) binuclear complex (an analogue of **2**). The events reported for the conversion of **1** into **2** ensue without appreciable accumulation of ion pairs as both $[Ru^{III}(edta)(H_2O)]^-$ and $[Fe^{III}(CN)_6]^{3-}$ are anionic. Magnetic susceptibility data imply that both **1** and **2** are paramagnetic $S = 1$ ions. The d electron manifold filling is $d^2_{xy}d^2_{xz}d^1_{yz}$ in **1** and $d^2_{xy}d^1_{xz}d^1_{yz}$ in **2**, whereas a filling of $d^2_{xy}d^2_{xz}d^0_{yz}$ seems to account for the prior observations with the $[Ru^{IV}(NH_3)_5(NC)Fe^{II}(CN)_5]$ system studied by Taube and co-workers. © 2000 Elsevier Science Ltd. 1. Introduction

The chemistry of binuclear complexes containing the $[Ru^{III}(NH_3)_5]$ moiety has been a topic of continued interest, especially in the context of the electron transfer process as the electron acceptor from metal centers that are bridged to it by small molecules [1–10]. Only a few studies have been carried toward the preparation and electron transfer studies with the related $[Ru^{III}(edta)]$ acceptor moiety in place of the more commonly studied $[Ru(NH_3)_5]$ analogues [11,12]. The suitability of such studies is prompted by the unusually high substitution lability of $[Ru^{III}(edta)(H_2O)]^-$, which renders this complex as a substitutionally labile and kinetically accessible Ru^{III} center, as noted by Creutz in former studies [13,14] and described in detail in a recent review [15].

Moreover, the Ru–edta complexes undergo easy intercoversion between low-spin Ru^{II}/Ru^{III} redox changes (d^6/d^5) without significant needs for structural changes that limit electron transfer steps. Less is known about the Ru^{III}/Ru^{IV} redox changes as the latter may occur only by including an oxo or hydroxy group at the solvent position on the Ru center in complexes such as $[Ru^{III}(edta)(H_2O)]^-$. However, rather facile Ru^{IV}/Ru^{II} conversions are obtained by the oxidation of alcohols by Ru^{IV}(polyaminopolycarboxylate) complexes — changes being sufficiently rapid to allow electrochemical detection of enhanced currents of the Ru^{IV}/Ru^{II} waves [16]. Thus, there is some indication that formation of Ru^{IV} species within polyaminopolycarboxylate

PII: S0277-5387(00)00414-9

environments is sufficiently facile that the Ru^{IV} oxidation state might be readily obtained from a $[Ru^{III}(edta)]$ center as a stable product electronic state if the Ru^{III} site were bridged to an electron sink via an inner-sphere bridging ligand. The bridging ligand might also prevent hydrolysis reactions at the Ru center, which in forming an oxo group out of a solvent or hydroxy group could lead to non-bridged products, e.g. in displacement of the second metal site from the Ru^{IV} product species.

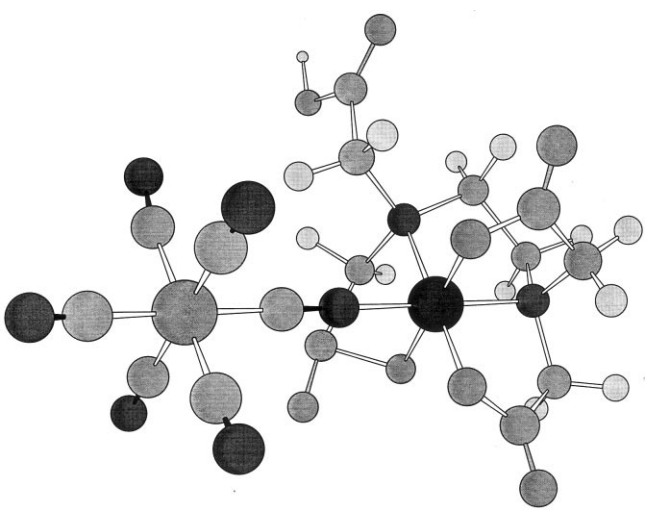
The chemistry of $[Ru^{III}(edta)(H_2O)]^-$ and derivative complexes has been a continuing area of study by Chatterjee et al. [17–21]. In particular, the cyano-bridged complexes, $[Ru^{III}(L)(NC)Fe^{II}(CN)_5]^{5-}$, L = $edta^{4-}$ and $hedta^{3-}$ (ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetate and *N*-hydroxyethylethylenediamine-*N*,*N*′,*N*′-triacetate) have been characterized previously in Chatterjee's laboratories [22,23]. The characterization of such cyano-bridged (III, II) ions of the general formulation $[Ru^{III}(edta)(NC)M(CN)_5]^{5-}$ for $M = Ru^{II}$, Os^{II} and Fe^{II} were recently described in studies by Olabe and co-workers [24]. Analogous pentaammine complexes of the formulation $[Ru^{III}(NH_3)_5(NC)Ru^{II}(CN)_5]^-$ have been characterized by Shepherd and co-workers [3b], Vogler and Kisslinger [33] and Ludi [34].

We have observed a slow spectral change that occurs for the related (III, III) ion, $[Ru^{III}(edta)(NC)Fe^{III}(CN)_5]^{4-}$ (**1**), that changes its visible spectral maxima from 420 and 620 nm to a new value of 870 nm over a period of more than 72 h. Since a related species, $[Ru^{III}(NH_3)_5(NC)Fe^{III}(CN)_5]$, has been reported to undergo intramolecular electron transfer forming a reputed $[Ru^{IV}(NH_3)_5(NC)Fe^{II}(CN)_5]$ complex [25], we examined the $[Ru^{III}(edta)(NC)Fe^{III}(CN)_5]^{4-}$ (**1**) complex by several physical methods to deduce if the related $[Ru^{IV}(edta)(NC)Fe^{II}(CN)_5]^{4-}$ (**2**) species is generated in the step producing the 870 nm transition.

2. Experimental

2.1. Reagents

K[Ru(edtaH)Cl] was prepared according to the published procedure [26]. In aqueous solution the $[Ru^{III}(edtaH)Cl]^-$ ion undergoes rapid aquation, forming the reactive $[Ru^{III}(edtaH)(H_2O)]$ complex, which is the dominant form in solution in the pH range 5.0–6.0 [27]. Synthesis and characterization of the binuclear complex $K_4[Ru^{III}(edta)(NC)Fe^{III}(CN)_5]$ (**1**) was carried out (in Durgapur) as described previously [22]. All reagents were of analytical grade. Double distilled water or deionized distilled water was used throughout the spectral and stopped-flow experiments. Concentrations are as reported in the main text and figures.



Samples for the NMR work and magnetic susceptibility studies were independently prepared (in Pittsburgh) by the following procedures. Complex **1** was prepared by dissolving 1.01×10^{-3} mol each of $K_3Fe(CN)_6$ (0.333 g) and $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$, prepared for a previous study [19], in 100.00 ml of distilled deionized water. The solution was swirled for nearly 5 min using magnetic stirring via a rice-sized stirring bar added to the volumetric flask. This sample was then stored, wrapped in aluminum foil and kept in a dark cabinet at room temperature for a period of 14 days to assure complete reaction in forming complex **2**. The solution was rotary evaporated to near dryness and then the sample was pumped in a vacuum desiccator to remove any remaining free water. A small amount of this product was redissolved in D_2O (Aldrich) to prepare the sample for ^1H and ^{13}C NMR studies. The ^1H NMR spectrum was taken immediately to avoid any problems with H/D exchange. The ^1H NMR resonances were absent due to paramagnetism of the product as discussed in the main text.

Samples of **1** for the magnetic susceptibility studies were first prepared at 9.712×10^{-3} M by combining 0.07995 g of $K_3Fe(CN)_6$ and 0.11686 g of $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$ in a 25.00 ml flask. Magnetic measurements were made and compared with a 9.716×10^{-3} M solution of $K_3Fe^{III}(CN)_6$ (0.07997 g in 25.00 ml). These two samples were left unprotected from air, but were stored in the dark. Measurements of the magnetic susceptibility varied non-systemmatically with time. This prompted a repeat experiment in samples protected from air by purging the deionized water with N_2, transferring the water by syringe techniques to a flask containing 0.05749 g of $K_3Fe^{III}(CN)_6$ and 0.08415 g of $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$ in a septum-sealed and prepurged 25.00 ml flask. Adding the purged water solvent produced a 6.984×10^{-3} M solution of **1**. This sample was transferred by syringe methods to a purged sample tube of the magnetic susceptibility device. A blank solution of 7.004×10^{-3} M $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$ was also prepared under N_2. The magnetic susceptibilities of both complexes of **1** and the $[Ru^{III}(edtaH)(H_2O)\cdot 4H_2O$ blank remained constant with time. All values of magnetic susceptibility were obtained in cgs units in accordance with the equations supplied in the Johnson–Matthey Susceptibility Balance Instruction Manual. The magnetic susceptibility of **1** was consistent with the anticipated $S = 1$ complex, and of $S = 1/2$ for the parent Ru^{III} complex.

2.2. Instrumentation

Microanalyses were carried out using a Carlo Erba elemental analyser. UV–Vis spectra were recorded with a GBC Cintra 10 spectrophotometer using quartz cells. Infrared spectra were recorded on a Carl Zesis Specord

M80 spectrophotometer. Cyclic voltammetric studies were performed in Durgapur using a Princeton Applied Research Model 174A electrochemical instrument. The working electrode was a glassy carbon probe with a standard calomel reference. All potentials are corrected to the NHE scale. NMR spectra were examined on Bruker 300 MHz NMRs in Pittsburgh using standard techniques. The spectra revealed that no detectable resonance for the edta portion of complexes **1** or **2** could be observed due to the local paramagnetism of the Ru^{III} center in **1** and the Ru^{IV} center in **2**, nor could a ^{13}C NMR signal be detected for the cyano carbons of the Fe^{II} center in complex **2** due to the Ru^{IV} paramagnetism and/or rapid electron transfer between metal centers, which delocalizes the paramagnetic properties of **2**. The paramagnetism as a function of time was recorded in solution using a Johnson–Matthey magnetic susceptibility balance. The N_2-protected sample gave constant readings of the magnetic susceptibility for over 72 h, the time period for which spectral conversion of **1** to **2** is noted by the changes in the UV–Vis spectra.

Scheme 1. Energy minimized structure via MM2 calculations for the [Ru(edta)NCFe(CN)$_5$] binuclear species **1**.

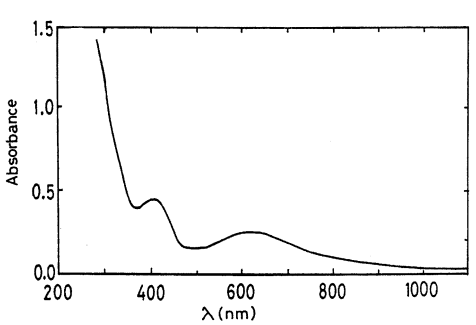


Fig. 1. UV–Vis spectrum of the Ru^{III}–Fe^{III} starting complex **1**; [complex **1**] = 2.45×10^{-4} M, room temperature, $\mu = 0.50$ (KCl); pH 5.5; 1.00 cm cell.

2.3. Kinetic studies

Fast kinetics experiments for the substitution reaction that forms **1** were performed with a Hi-Tech SF-51 stopped flow spectrophotometer interfaced to an Apple IIe data analysis system. Slow reactions were followed by conventional techniques using the GBC Cintra-10 spectrophotometer. Both instruments were thermostated to ± 0.1°C. Rate constant data represent the average of three runs that were reproducible to $\times 4\%$. Acetic acid–acetate buffers were used to maintain the desired pH in the kinetic experiments, whereas KCl was used to control the ionic strength. pH readings were made with a Digisun pH meter calibrated with standard buffers.

An energy minimized representation of the cyano-bridged [Ru(edta)NCFe(CN)$_5$] structural unit is shown in Scheme 1. The atom locations were obtained by energy minimization on the MM2 program using CHEM-PRO-3D software and assigning the metal centers to octahedral coordination with a linear cyano bridge. The system was minimized on the {Ru(III)–Fe(III)} binuclear complex.

3. Results and discussion

3.1. Formation of the Ru^{III}–Fe^{III} binuclear complex 1

Reaction of $[Ru^{III}(edta)(H_2O)]^-$ with $[Fe(CN)_6]^{3-}$ in aqueous solution results in the rapid formation of $[Ru^{III}(edta)(NC)Fe^{III}(CN)_5]^{4-}$ (**1**), which was isolated and characterized previously [22]. The absorption spectrum of **1** in aqueous solution has two bands as shown in Fig. 1. The band at 420 nm ($\varepsilon_{420} = 1600 \pm 40$ M^{-1} cm^{-1}) is characteristic of the ferricyanide moiety within complex **1** as $[Fe(CN)_6]^{3-}$ has the same band at 417 nm and $[Fe(CN)_5(H_2O)]^{2-}$ absorbs at 394 nm [28,29]. The band at 620 nm ($\varepsilon_{620} = 1020 \pm 30$ M^{-1} cm^{-1}) is assigned to a metal-to-metal charge transfer (MMCT) transition analgous to the same assignment for the pentaammine system, $[Ru^{III}(NH_3)_5(NC)Fe^{III}(CN)_5]$ (**3**), by Taube and co-workers, where the band appears at 540 nm ($\varepsilon_{540} = 900$ M^{-1} cm^{-1}) [25]. The observed shift from 540 nm for the $[Ru^{III}(NH_3)_5]$ environment to that of 620 nm for the $[Ru^{III}(edta)]$ environment is attributed to the stabilization of the higher Ru^{IV} state in the photo-oxidized electronic configuration by the anionic carboxylate donors of the $edta^{4-}$ ligand in **2** compared with lesser stabilization of Ru^{IV} by ammines alone in **3**.

The infrared spectrum of the Ru^{III}–Fe^{III} complex **1** exhibited bands at 2130 and 2090 cm^{-1} of the cyanide stretching region [30]. These are, respectively, assigned to the five terminal and one bridging cyano groups in **1**. The 2130 cm^{-1} stretch is virtually the same as for

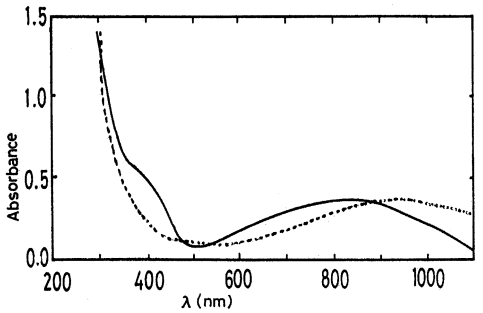

Fig. 2. UV–Vis spectrum of Ru^{IV}–Fe^{II} complex **2**; solid curve before ascorbate reduction, [complex **2**] = 1.25×10^{-4} M, room temperature, $\mu = 0.50$ (KCl), pH 5.5, 1.00 cm cell; dashed curve, Ru^{III}–Fe^{II} complex **5** formed via ascorbate reduction, [complex **5**] = 1.25×10^{-4} M after reduction with 2.0×10^{-3} M ascorbate at pH 5.5 and other conditions the same as before reduction.

$K_3[Fe^{III}(CN)_6]$ at 2135 and 2130 cm^{-1} [31]. A cyclic voltammogram on complex **1** exhibited two reversible waves at 0.06 V for the $Ru^{III/II}$ wave and 0.60 V for the $Fe^{III/II}$ wave versus NHE. The $Fe^{III/II}$ wave is more positive than the 0.36 V value for the $[Fe^{III/II}(CN)_6]^{3-/4-}$ couple due to the influence of the withdrawing effect of the coordinated, positive Ru^{III} center at potentials approaching the $Fe^{III/II}$ wave.

Thus, UV–Vis, IR and electrochemical data establish complex **1** as the Ru^{III}–Fe^{III} binuclear complex that retains the oxidation states of the $[Ru^{III}(edta)(H_2O)]^-$ and $[Fe^{III}(CN)_6]^{3-}$ reactants that form **1** in the substitution process that occurs immediately upon mixing. The energy-minimized structural drawing clearly shows that there is minimal steric interaction between the cyano ligands of the Fe center and the chelate functionalities of the $edta^{4-}$ ligand of the Ru center. All bonds and angles that were determined for the energy minimized structure were those common to M(edta) and $M'(CN)_6$ structural moieties, and hence, unexceptional, emphasizing the absence of steric strain between the metal centers in **1** and its redox isomer **2** (to be described later in the text).

The kinetic progress of the substitution process was followed directly by monitoring the appearance of the 640 nm band in stopped-flow experiments that combined these two reactants. The rate was observed to be first-order in each $[Ru^{III}(edta)(H_2O)]^-$ and $[Fe(CN)_6]^{3-}$ reactant. Rate measurements were made at pH 5.2 (acetate buffer) and $\mu = 0.50$ (KCl). The substitution reaction has a formation rate constant, k_{obs}, of 10 ± 2 M^{-1} s^{-1} at 25°C. This is 10-fold slower than the substitution of $[Fe^{II}(CN)_6]^{4-}$ on $[Ru^{III}(edta)(H_2O)]^-$ in forming the known Ru^{III}–Fe^{II} binuclear complex [22]. Therefore, the mechanism to generate **1** does not involve any outer-sphere electron transfer pathway that precedes the simple substitution step of Eq. (1).

$$Ru^{III}(edta)(H_2O)]^- + [Fe^{III}(CN)_6]^{3-} \xrightarrow{k_{obs}} [Ru^{III}(edta)(NC)Fe^{III}(CN)_5]^{4-}\ (\mathbf{1}) \quad (1)$$

The substitution of $[Fe(CN)_6]^{3-}$ on $[Ru^{III}(edta)(H_2O)]^-$ is strikingly more rapid than for the substitution process of $[Fe(CN)_6]^{3-}$ on $[Ru^{III}(NH_3)_5(H_2O)]^{3+}$ ($k = 5.9 \times 10^{-5}$ s^{-1} [25]). The former process obeys second-order kinetics for the formation of **1**, whereas the pentaammine complex **3** is produced by the slow first-order rearrangement of the ion-pair. Clearly, the difference in charge for the $[Ru^{III}(edta)(H_2O)]^-$ versus $[Ru^{III}(NH_3)_5(H_2O)]^{3+}$ reactants is a key factor in the different mechanisms of the formation of **1** and **3**, the latter using the strong ion-pair pathway that is imposed by the $(3+)(3-)$ attractions that are absent in forming **1** via two anions [25]. The rates of substitution on the Ru^{III} center in the labilized $[Ru^{III}(edta)(H_2O)]^-$ complex is rather rapid [15]. By contrast, the inherently slow substitution of $[Ru^{III}(NH_3)_5(H_2O)]^{3+}$ allows a sufficiently long time that all the Ru^{III} species will have formed ion pairs prior to any step that will produce **3**. Thus, only ion-paired species exist as available precursor species in forming **3**. But in forming **1**, the transition state species that proceed to produce **1** are those collisions of $[Fe(CN)_6]^{3-}$ with $[Ru^{III}(edta)(H_2O)]^-$ molecules that are in the act of dissociation of the coordinated water in I_a pathways [15] at the time of approach of the $[Fe^{III}(CN)_6]^{3-}$ ion. That is, no pool of ion-paired species act as the reactant species that forms **1**. Hence, second-order kinetics are followed, distinguishing this process that produces **1** from the pathway that forms **3**.

3.2. Formation of the Ru^{IV}–Fe^{II} binuclear complex 2

Taube and co-workers observed a slow change in complex **3**, converting **3** into a Ru^{IV}–Fe^{II} complex **4** [25]. We examined complex **1** as a function of time in order to seek evidence for a similar change in **1** transforming into another Ru^{IV}–Fe^{II} complex **2**. Indeed, over a 72 h period, the bands in the visible spectrum at 420 and 620 nm decreased with time, while concurrently, a new band appeared at 870 nm as shown in Fig. 2. The extinction coefficient at 870 nm for **2** is 3020 ± 30 M^{-1} cm^{-1}. Acetone was added to precipitate **2** as its K^+ salt after 6 days to assure completion of the reaction. The infrared spectrum of complex **2** showed new IR bands at 2120 and 2040 cm^{-1}. Note that these values differ from the Ru^{III}–Fe^{III} species **1** with stretches at 2130 and 2090 cm^{-1}, but also differ from the value of 2080 cm^{-1} reported for the Ru^{III}–Fe^{II} complex [22]. The band at 2040 cm^{-1} is virtually the same as reported for the F_{1u} modes of $K_4[Fe(CN)_6]$ [31]. This feature indicates an Fe^{II}-cyano chromophore is present in **2**.

Based upon the similarity of the infrared stretch of the product species to that of Fe^{II}–CN stretches, the appearance of a totally different near-IR band in the visible spectrum concomitant with the loss of features

assignable to the Ru^{III}–Fe^{III} species, and magnetic information to be described later, we assign the changes mentioned in the sample of **1** over the 72 h period as being those due to the formation of a Ru^{IV}–Fe^{II} complex **2** in analogous processes that convert the pentaammine Ru^{III}–Fe^{III} species **3** into the pentaammine Ru^{IV}–Fe^{II} complex **4**. The kinetics of the process was determined from the time dependence of the appearance of the 870 nm band, and by the decay of the 620 m band, both yielding the same rate. A rate constant of $k_{obs} = 2.0 \times 10^{-5}$ s^{-1} at 25°C, pH 5.5 and $\mu = 0.50$. The initial concentration of **1** was 2.0×10^{-4} M. The rate constant for this process is an order of magnitude faster than the 1.6×10^{-6} s^{-1} value reported by Taube and co-workers for the conversion of **3** into **4**. This difference is attributed to the greater reducing power of the Ru^{III} center in the $edta^{4-}$ environment compared with the pentaammine environment, and the stabilizing influence of the carboxylate donors toward the Ru^{IV} product species. Removal of an electron from the positively charged $[Ru^{III}(NH_3)_5]^{3+}$ center comes at a greater rearrangement cost than for the transfer of an electron away from the anionic $[Ru^{III}(edta)]^{-}$ site, resulting in the latter process having a lower kinetic barrier (and a faster intramolecular electron transfer rate).

3.3. Reduction of binuclear complexes *1* and *2* by ascorbic acid

Addition of ascorbic acid to an aqueous solution of the Ru^{IV}–Fe^{II} complex **2** produced an immediate reduction that resulted in the known mixed-valence $[Ru^{III}(edta)(NC)Fe^{II}(CN)_5]^{5-}$ complex **5** that has been characterized in previous studies [22]. The spectral changes occur with the appearance of a new band at 945 nm that is characteristic of **5**.

The rate of reduction of complexes **1** and **2** were studied in stopped-flow experiments under conditions where [ascorbate] $= 2.0 \times 10^{-3}$ M as a pseudo-first order excess reagent, pH 5.50, $\mu = 0.50$ and $T = 25.0$°C. The conditions were chosen to match those of van Eldik's study of the reduction of $[Fe^{III}(CN)_6]^{3-}$ by ascorbate [32] in order to make direct comparison with results from the ascorbate reduction of **1** and **2**. Under identical experimental conditions the reduction of $[Fe^{III}(CN)_6]^{3-}$ has a rate constant of 2.16 s^{-1} [32]. The reduction of the Ru^{III}–Fe^{III} complex **1** yielded a reduction rate constant of 1.95 ± 0.08 s^{-1} (kinetic data was reproducible to $\pm$ 4%) with the ascorbate reagent. This implies that the reduction of the Ru^{III}–Fe^{III} complex **1** is Fe^{III} centered in forming complex **5**.

Reduction of the Ru^{IV}–Fe^{II} complex **2** by ascorbate in forming complex **5** proved difficult to follow spectrophotometrically as the absorbance change in going from a maximum at 870 nm to a new species with its maximum at 945 nm was not large. The best fit among several kinetic traces yielded a value of 105 ± 10 s^{-1} (kinetic data was reproducible to no better than $\pm$ 10% in this system) for the ascorbate reduction of **2** to **5**. Recalling that the measured rate constant for the ascorbate/**1** reaction under the same conditions is only 1.95 s^{-1}, the ascorbate reduction clearly identifies the redox capability of complex **2** as a more potent oxidant than complex **1**. Also, given that the reduction of the Fe^{III} site of complex **1** occurs with a rate nearly identical to that of an isolated Fe^{III} center in $[Fe^{III}(CN)_6]^{3-}$, the reduction of **2** at an approximately 50 times faster rate by ascorbate must be occurring at the Ru center. Since the product is a Ru^{III} species, this implies that the oxidation state of the Ru site is higher than Ru^{III} in complex **2**. Therefore, one is forced to conclude that species **2** has the redox assignment of Ru^{IV}–Fe^{II} as has been the tacit nature of our prior discussion, which has been presented before full proof of the Ru^{IV} oxidation state within **2** has been given.

3.4. Magnetic susceptibility study on the *1* to *2* conversion process

A freshly prepared sample of complex **1** was prepared at 9.712×10^{-3} M by a 1:1 combination of $[Ru^{III}(edta)(H_2O)]^{-}$ and $[Fe^{III}(CN)_6]^{3-}$ reactants. This sample was allowed to react in the dark for 14 days to assure complete conversion to **2** before being concentrated by rotary evaporation and dessication to achieve a sample of **2** with low water content. This sample was redissolved in D_2O at ca. 0.020 M for the ^1H and ^{13}C NMR studies described later. Another preparation was studied at 6.984×10^{-3} M on freshly prepared **1** that was purged with N_2 as described in the Section 2 and transferred immediately to the sample tube of a Johnson–Matthey magnetic susceptibility balance. Since the manipulations were accomplished much slower than the time to form **1**, as shown by the stopped-flow experiments, it is clear that the sample in the susceptibility balance tube is **1** at the start of the magnetic studies.

Magnetic susceptibility data were obtained as a function of time with calibration of the instrument against $K_3[Fe^{III}(CN)_6]$ and the $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$ monomer complexes. Equal molar amounts of the two standards gave the same calculated net spin per complex of $S = 1/2$ ($n = 1$ unpaired electron for each standard complex).

In the experiments of Taube and co-workers on the pentaammine Ru^{III}–Fe^{III} complex **3**, which converts to the Ru^{IV}–Fe^{II} complex **4**, a decrease in the solution magnetic moment was initially observed, but a complete study of the magnetic changes was prevented by the precipitation of product **4** when the solubility was exceeded. Since our product species **2** is a 4− anion, the probability that precipitation would cause problems

was greatly lowered. Thus, we attempted to observe the slow electron transfer process that was detected by the change from 420 and 620 nm maxima of **1** to the new 870 nm maximum of **2** by means of changes in the magnetic susceptibility. This would occur if the change in spin states happens as in Eq. (2):

$$\{Ru^{III}\ (S=1/2);\ Fe^{III}\ (S=1/2)\}\ (\text{net}\ S=1) \rightarrow \{Ru^{IV}\ (S=0)\ \text{LS};\ Fe^{II}\ (S=0)\ \text{LS}\}\ (\text{net}\ S=0) \quad (2)$$

The study of the magnetic susceptibility as a function of time for over a period of 72 h on samples protected from exposure to O_2 from the air showed that no net spin change occurs on the same time frame that produces the changes in the visible electronic spectrum. Calibrated against the two standard complexes, equimolar amounts of the $K_3[Fe(CN)_6]$ and $[Ru^{III}(edtaH)(H_2O)]\cdot 4H_2O$ were allowed to react, first forming **1** via the substitution route. The magnetic susceptibility data when compared with the equimolar standards imply an effective net spin of $S=0.75$ ($n=1.5$) rather than the anticipated values of $S=1$ ($n=2$) for complex **1**. However, the net spin is definitely not zero for a diamagnetic complex.

The reduced number of available free spins that were determined in the experiment may arise from difficulties in making significant diamagnetic corrections for the ligand contributions for the paramagnetically dilute sample (6.98×10^{-3} M), or may arise from the existence of a spin-crossover equilibrium between $S=1$ and $S=0$ forms of **1** near room temperature. The later explanation is rejected as the exact same net spin amount in the sample was retained as the complex converted to the redox isomer **2**. It is nearly impossible to believe that the two redox isomers would both be spin-crossover complexes resting at exactly the same position in the spin equilibrium. Such an unbelievable coincidence would require a spin-crossover {Ru(III)–Fe(III)} system that exhibits an identical spin-crossover equilibrium at the Ru^{IV} center by itself in the {Ru(IV)–Fe(II)} redox isomer with the spin crossover equilibrium as modulated by the local $edta^{4-}$ environment around the Ru^{IV} site exactly mimicing the delocalization and through-space coupling in the original redox isomer **1**. A simpler explanation is surely correct.

Rather, the experimental difficulties of measuring the dilute paramagnetism contribution on a sample with a large diamagnetic correction to the measurable magnetic susceptibility is a much more logical explanation for an observed constant net spin effective value of $S=0.75$ ($n=1.5$) rather than the anticipated $S=1$ and $n=2$ ideal values. The important point for the measurement is that upon mixing and formation of **1** there remains a substantial paramagnetism that is closer in magnitude to that of a species of two unpaired electrons than to a species of zero unpaired electrons. The sample tube containing the components that form **1** is more paramagnetic than for the sample tube and N_2-purged solvent alone. Furthermore, as the changes in the electronic spectrum occur in forming the redox isomer **2**, there is no change in the samples paramagnetism. The number of unpaired electrons is conserved although an electronic rearrangement has occurred.

This is explained only if the Ru^{IV} species is generated as a high-spin complex, wherein the d^4 center has the filling of $d^2_{xy}d^1_{xz}d^1_{yz}$ (taking the unique axis along the Ru(NC)Fe bond as the z axis in the system). Thus, the electron transfer process must occur as in Eq. (3):

$$\{Ru^{III}\ (S=1/2);\ Fe^{III}\ (S=1/2)\}\ (\text{net}\ S=1) \rightarrow \{Ru^{IV}\ (S=1)\ \text{HS};\ Fe^{II}\ (S=0)\ \text{LS}\}\ (\text{net}\ S=1) \quad (3)$$

Supporting evidence for the paramagnetic nature of complex **2** was obtained indirectly in attempts to obtain the ^1H and ^{13}C NMR spectra of **2**. Neither of these spectra revealed suitable lines for the proton resonances of the edta portion of the ^1H NMR spectrum or for the CN^- carbons of the ^{13}C NMR spectrum. The conclusion from the ^1H NMR results is that paramagnetic broadening of the edta ligand resonances is present in complex **2**. This is consistent with the retention of a net spin of $S=1$ during the electron transfer process, as described in Eq. (3), but not as in Eq. (2). Thus, none of the glycinato or ethylenediamine backbone protons is sufficiently removed from the paramagnetic center to allow for its detection by the ^1H NMR method.

In a separate attempt to obtain the ^{13}C NMR spectrum of complex **2**, it was hoped that the ferrocyanide-like end of the binuclear complex **2** might offer enough electronic isolation that ^{13}C resonances would appear, similar to those of the $[Fe^{II}(CN)_6]^{4-}$ complex, but perhaps shifted by the charge and induction of the $[Ru^{IV}(edta)]$ portion of **2** that is linked by the cyano bridge. No ^{13}C NMR resonances for the cyano ligands were detected after overnight signal averaging. Thus, although the infrared data from the CN^- stretches in **2** support an $[Fe^{II}(CN)_5(CN)\ldots]$ chromophore, there is sufficient ground state electronic delocalization that the CN^- ligands sense the presence of a paramagnetic center nearby, which broadens the signal via relaxation processes. These relaxation processes prevent a ^{13}C resonance being detected for the $[Fe^{II}(CN)_5(CN)\ldots]$ portion of complex **2**. This means that there is sufficient resonance character (delocalization) in the ground state wave function, although predominantly $\Psi(Ru^{IV}\text{–}Fe^{II})$ in character, has a small component of $\Psi(Ru^{III}\text{–}Fe^{III})$ character that is sufficient to cause ^{13}C relaxation processes that prevent detection of the cyano ^{13}C resonances in species **2**.

4. Conclusions

Reaction of $[Ru^{III}(edta)(H_2O)]^-$ with $[Fe^{III}(CN)_6]^{3-}$ initially forms a binuclear complex **1** of net spin $S = 1$ as a $[Ru^{III}–Fe^{III}]$ entity that has ferricyano-like CN^- stretches, reduces with ascorbate with a rate virtually the same as an isolated ferricyanide chromophore to a known complex of electronic assignment $[Ru^{III}–Fe^{II}]$, species **5**, and has electronic transitions similar to ferricyanide at 420 nm. The initially formed complex **1** undergoes a slow intramolecular electron transfer reaction that makes a $[Ru^{IV}–Fe^{II}]$ complex **2**. The product species **2** exhibits infrared stretches similar to the ferrocyanide complex, and reduction with ascorbate occurs at a rate 50-fold faster than for an Fe^{III}–cyano centered reduction, implying the more potent Ru^{IV} center is the one reduced, again creating complex **5**, but by a different pathway.

Finally, the magnetic susceptibility data shows that the net spin state of $S = 1$ is conserved in the electron transfer process that converts **1** into complex **2**. The ^1H and ^{13}C NMR data on species **2** confirm the paramagnetism that is maintained without net change during the electron transfer process. This will be the outcome if the ligand field symmetry around the Ru site is lowered from pseudo octahedral in the parent $[Ru^{III}(edta)(H_2O)]^-$ complex by the addition of the $(NC)Fe^{III}(CN)_5$ chromophore. Upon electron transfer, the Ru^{IV} center will have the filling of $d^2_{xy}d^1_{xz}d^1_{yz}$ as long as the splitting between the d_{xz} and the d_{yz} orbitals is less than the pairing energy. In the case of the $[Ru^{IV}(edta)(NC)Fe^{II}(CN)_5]^{4-}$ complex, the differences among the carboxylate and en-backbone donors appears to be too small to force a large splitting that would have produced the low-spin $d^2_{xy}d^2_{xz}d^0_{yz}$ configuration. This would have been accompanied by the decrease in magnetic susceptibility, as the {Ru^{IV} ($S = 0$) LS; Fe^{II} ($S = 0$) LS} complex would be created. Interestingly, although the Taube group could not follow the entire electron transfer process due to precipitation problems, they have suggested that a decrease in net spin occurs in the reaction of the pentaammine system where $[Ru^{III}–Fe^{III}]$ **3** converts to the $[Ru^{IV}–Fe^{II}]$ complex **4** [25]. The ammine environment is a stronger ligand field that could cause a larger splitting among the $d_{xy}d_{xz}d_{yz}$ levels, as discussed above, but it is also possible that in forming the Ru^{IV} oxidation state in the pentaammine system, the $Ru^{IV}–NH_3$ bonding allows for dissociation of a proton forming the strongly π-donating coordinated amide group that stabilizes Ru^{IV} in the **4** system. This coordination of an amide to stabilize Ru^{IV}, as mentioned as a possibility by the authors in Ref. [25], although they could not examine the product complex in detail.

Amido coordination with its strong π donation would come with a large increase in ligand field splitting for complex **4** compared with only bond distance shortening via carboxylate ligands in complex **2**. Therefore, the slight differences that have been observed between the behavior of the Ru^{IV} moiety in the Taube complex **4** compared with our observations on the edta complex **2** are reasonably reconciled on the basis of different ligand field factors between the two systems.

POLYHEDRON

Synthesis and characterisation of mixed-ligand platinum(II)–sulfoxide complexes, [PtCl(DMSO)(L)], for potential use as chemotherapeutic agents (HL = *N*,*N*-dialkyl-*N*′-(3-*R*-benzoyl)thiourea)

C. Sacht *, M.S. Datt

Received 7 February 2000; accepted 26 April 2000

Abstract

A novel series of mixed-ligand platinum(II) complexes of the type [PtCl(DMSO)(L)], where HL = *N*,*N*-diethyl-*N*′-(3-*R*-benzoyl)thiourea, *N*,*N*-di(2-hydroxyethyl)-*N*′-(3-*R*-benzoyl)thiourea or *N*-morpholino-*N*′-(3-*R*-benzoyl)thiourea (R = H, Cl, NO_2, CH_3O, CH_3), have been synthesised and characterised by elemental analysis, IR spectroscopy and ^1H and ^{195}Pt NMR spectroscopy. The spectroscopic data are consistent with the complexes containing an O, S chelated ligand and an S-bonded sulfoxide ligand which is in a *cis* arrangement to that of the sulfur donor atom of the chelated ligand. Trends in the NMR spectra can be correlated with the electronic effects of the substituents on the phenyl ring of the acylthiourea ligands. © 2000 Elsevier Science S.A. All rights reserved.

1. Introduction

The successful use of inorganic complexes as chemotherapeutic agents is best exemplified by cisplatin and its analogue carboplatin, which have been used clinically since 1971 and 1981, respectively [1]. Because of the beneficial clinical efficacy of cisplatin, the past 30 years have witnessed tremendous effort and progress in trying to understand the mechanism of action of this metal-based anticancer drug [1]. Moreover, the clinical success of cisplatin has sparked considerable interest and research in the search for improved metal-based drugs for the use as chemotherapeutic agents [1,2]. Several approaches have been taken over the past three decades and some of these include the synthesis of cisplatin analogues, variation of the metal ion as well as the preparation of platinum complexes that are not structurally analogous to cisplatin [1,2]. Recent reports in the literature have revealed that the latter approach has yielded some exciting and successful results and two of these complexes are currently undergoing Phase I clinical trials, such as ZD0473 (*cis*-amminedichloro(2-methylpyridine)platinum(II)) and BBR3464, a trinuclear 4+ charged platinum(II) complex, introduced by Farrell et al., the structure of which is best described as two *trans*-$[PtCl(NH_3)_2]^+$ units bridged by a non-covalent tetra-amine *trans*-$[Pt(NH_3)_2\{NH_2(CH_2)_6NH_2\}_2]^{2+}$ unit [1,2]. These results are encouraging and thus this approach continues to be a promising strategy in the design of metal-based drugs. This can be achieved by the variation of either the firmly bound non-leaving ligands or the labile leaving groups or both. The non-leaving ligands could influence both the target selection and reactivity of the metal ion. For instance, the ligands may determine whether the compound may enter a hydrophobic environment like membranes, approach charged biomolecules like DNA or fit into the ligand binding pocket of a particular protein. The leaving groups will be exchanged for more nucleophilic biomolecules and thereby infer a biological lesion. Or

PII: S0277-5387(00)00419-8

the metal complex may require an exchange of one or more of the labile ligands by water in order to become activated. These factors are also influenced by the non-leaving ligand.

In our laboratory we have focused on preparing a series platinum(II) complexes of the type [Pt(acylthioureato)Cl(RR′SO)], in which we have varied both the non-leaving ligands and the labile leaving groups attached to the platinum(II) centre [3]. We have used the acylthiourea ligand system, $R^1C(O)NHC(S)NR^2R^2$, as the R^1 and R^2 groups can be readily varied to give a wide range of ligand systems with different physical and chemical properties, which could be used to fine-tune the biological activity of the resultant complexes. We have reported recently the synthesis and characterisation of the following [Pt(acylthioureato)Cl(RR′SO)] complexes with the acylthiourea ligands: *N*,*N*-di(2-hydroxyethyl)-*N*′-benzoylthiourea, *N*,*N*-diethyl-*N*′-benzoylthiourea and *N*,*N*-adipoylbis(*N*′,*N*′-diethylthiourea) and the sulfoxides: dimethylsulfoxide (DMSO), methylphenylsulfoxide (MPSO), *R*-methyl(*p*-tolyl)-sulfoxide (*R*-MTSO) and *S*-methyl(*p*-tolyl)sulfoxide (*S*-MTSO) [3]. We have since extended this series by preparing [Pt(acylthioureato)Cl(DMSO)] complexes using *N*,*N*-diethyl-*N*′-(3-*R*-benzoyl)thiourea, *N*,*N*-di-(2-hydroxyethyl)-*N*′-(3-*R*-benzoyl)thiourea and *N*-morpholino-*N*′-(3-*R*-benzoyl)thiourea ligands, where R = H, Cl, NO_2, OCH_3 and CH_3. Variation of the amine attached to the thiocarbonyl functionality and substitutents on the phenyl ring could influence the lipophilicity/hydrophilicity and electronic properties of the complexes and thus also affect the lability of the leaving groups which could control the reactivity and biological activity of the complexes. To this end, we herein report the synthesis and full characterisation of this novel series of platinum(II) complexes.

2. Experimental

2.1. Materials and physical methods

The potassium tetrachloroplatinate (Johnson Matthey), DMSO (Merck), 3-substituted benzoyl chlorides (Aldrich), benzoyl chloride (SaArchem) were used as supplied. The diethyl amine, morpholine and acetone were dried and distilled before use. All other solvents were commercial grade and used as received. The known complexes *cis*-[$PtCl_2(DMSO)_2$] [4], [PtCl(DMSO)(*N*,*N*-diethyl-*N*′-benzoylthioureato)] and [PtCl(DMSO)(*N*,*N*-di(2-hydroxyethyl)-*N*′-benzoylthioureato)] [3] were prepared by literature procedures. The IR spectra were recorded as KBr disks on Perkin–Elmer FT IR spectrum 2000, between 4000 and 250 cm^{-1}. ^1H NMR (1D and 2D) spectra were recorded at 400.13 MHz on a Bruker 400AMX spectrometer at 30 ± 1°C. All samples were prepared using deuterated solvents purchased from Aldrich Chemical Company, and 5 mm NMR tubes were used throughout. Chemical shifts are reported in parts per million (ppm) relative to the central line of the solvent proton resonance of known shifts relative to TMS, and coupling constants are reported in hertz (Hz). ^{195}Pt NMR spectra were recorded at 86.02 MHz on a Bruker 400AMX spectrometer at 30 ± 1°C using 70–100 KHz spectral widths and 13 μs pulses with 1 s pulse delay. Between 2048 and 16 000 transients, with a line broadening factor of 10 Hz, gave good spectra. All ^{195}Pt shifts are quoted relative to external H_2PtCl_6 (500 mg in 1 ml 30% (v/v) D_2O/1 M HCl). Melting points were determined on a Reichert hot-stage microscope and are uncorrected. Differential scanning calorimetry (DSC) was performed on a Perkin–Elmer Delta series 7 instrument, under a nitrogen atmosphere. The temperature range for the DSC experiments was 50–250°C. Elemental analyses were carried out at the microanalytical unit at the University of Cape Town, South Africa. Thin-layer chromatography (TLC) was performed on silica sheets $60F_{254}$ (Merck, Darmstadt). Reverse phase TLC was performed on glass backed RP-$C18F_{254}S$ plates (Techware). Flash chromatography was performed on silica gel 60 (Merck, Darmstadt).

2.2. Preparation of ligands

The ligands were prepared according to the method of Douglass and Dains [5]. The synthesis of *N*,*N*-di(2-hydroxyethyl)-*N*′-benzoylthiourea (**L3a**) has been reported recently [6,7]. The preparation of *N*,*N*-diethyl-*N*′-(3-*R*-benzoyl)thioureas and *N*-morpholino-*N*′-(3-*R*-benzoyl)thioureas (**L1a**–**d**; **L2a**–**d**), where R = H, Cl, NO_2 and OCH_3, have also been described recently [8–10]. The analytical data and selected IR data for the new ligands are given below.

N,*N*-Di(2-hydroxyethyl)-*N*′-(3-nitrobenzoyl)thiourea, **L3c**: (70%), m.p. 138–141°C. *Anal.* required for $C_{12}H_{15}N_3O_5S$: C, 46.00; H, 4.82; N, 13.41; S, 10.23. Found: C, 46.23; H, 4.85; N, 13.48; S, 9.93%. IR (KBr pellet, cm^{-1}): *ν*(N–H) 3175 (vs, br), *ν*(C=O) 1697 (vs, sh).

N,*N*-Di(2-hydroxyethyl)-*N*′-(3-methoxybenzoyl)-thiourea, **L3d**: (77%), m.p. 103–106°C. *Anal.* required for $C_{13}H_{18}N_2O_4S$: C, 52.33; H, 6.08; N, 9.39; S, 10.74. Found: C, 53.11; H, 6.29; N, 9.42; S, 10.40%. IR (KBr pellet, cm^{-1}): *ν*(N–H) 3232 (vs, br), *ν*(C=O) 1688 (vs, sh).

N,*N*-Di(2-hydroxyethyl)-*N*′-(3-chlorobenzoyl)-thiourea, **L3b**: (69%), m.p. 132–134°C. *Anal.* required for $C_{12}H_{15}ClN_2O_3S$: C, 47.60; H, 4.99; N, 9.25; S, 10.59. Found: C, 47.72; H, 5.09; N, 9.33; S, 10.58%. IR (KBr pellet, cm^{-1}): *ν*(N–H) 3180 (s, br), *ν*(C=O) 1693 (vs, sh).

N,*N*-Di(2-hydroxyethyl)-*N*′-(3-methylbenzoyl)-thiourea, **L3e**: (75%), m.p. 136–138°C. *Anal.* required for $C_{13}H_{18}N_2O_3S$: C, 55.29; H, 6.42; N, 9.92; S, 11.35. Found: C, 56.12; H, 6.57; N, 9.48; S, 11.36%. IR (KBr pellet, cm^{-1}): ν(N–H) 3192 (s, br), ν(C=O) 1693 (vs, sh).

N-Morpholino-*N*′-(3-methylbenzoyl)thiourea, **L2e**: (72%), m.p. 141–142°C. *Anal.* required for $C_{13}H_{16}N_2O_2S$: C, 59.06; H, 6.10; N, 10.60; S, 12.13. Found: C, 59.12; H, 6.15; N, 10.58; S, 11.75%. IR (KBr pellet, cm^{-1}): ν(N–H) 3150 (m), ν(C=O) 1657 (vs, sh).

N,*N*-Diethyl-*N*′-(3-methylbenzoyl)thiourea, **L1e**: (55%), m.p. 96–97°C. *Anal.* required for $C_{13}H_{18}N_2OS$: C, 62.36; H, 7.25; N, 11.19; S, 12.81. Found: C, 62.37; H, 7.28; N, 11.21; S, 12.20%. IR (KBr pellet, cm^{-1}): ν(N–H) 3311 (s, sh), ν(C=O) 1646 (s, sh).

2.3. Preparation of platinum(II) sulfoxide complexes

The complexes were prepared according to the following general procedure.

A solution of *N*,*N*-dialkyl-*N*′-(3-*R*-benzoyl)thiourea (0.50 mmol) in 10 ml acetonitrile–7 ml ethanol was added dropwise to a stirred solution of *cis*-$[PtCl_2(DMSO)_2]$ (0.50 mmol) in 1.5 ml acetonitrile–2.5 ml dimethylsulfoxide. Sodium acetate (0.063 g, 0.77 mmol) in 1.5 ml water was then added. The solution was allowed to stir for 48 h. The yellow solution was concentrated to ca. 10 ml and water (40 ml) was added whereupon the solution became opaque. The opaque solution was placed in the fridge (4°C) overnight. The yellow precipitate was collected by filtration, washed with water, a little ethanol and dried in vacuo over silica gel. In some cases ,column chromatography is required in order to obtain the pure product.

3. Results and discussion

3.1. Ligand synthesis and characterisation

The ligands were prepared according to the method of Douglass and Dains [5] and were obtained in yields ranging from 55–77%. The synthesis involves the reaction of a 3-substituted benzoyl chloride with potassium thiocyanate in acetone followed by condensation of the 3-*R*-benzoylisothiocyanate with the appropriate secondary amine. The ligands were purified by recrystallisation from ethanol and characterised by elemental analysis, ^{1}H NMR and IR spectroscopy. The analytical and spectroscopic data are consistent with the proposed structures given in Fig. 1.

The assignments of the ^{1}H NMR spectra of the *N*,*N*-diethyl-*N*′-(3-*R*-benzoyl)thiourea, *N*,*N*-di(2-hydroxyethyl)-*N*′-benzoylthiourea and *N*-morpholino-*N*′-(3-*R*-benzoyl)-thiourea ligands were in general straightforward, except for the assignments of the H_4 and H_6 protons which were confirmed by 2D [^{1}H, ^{13}C] HMBC experiments. The chemical shift data are given in Table 1. The data for the ligands that have been reported already are included for comparison. The numbering scheme for the thioamide protons are as given in Tables 3–5.

A notable feature of the ^{1}H NMR spectra of the ligands is the observation of separate resonances for the methylene protons (H_α) attached to the nitrogen of the respective thioamides. The magnetic inequivalence of these methylene protons can be ascribed to the restricted rotation around the C–N bond between the thiocarbonyl and the amine nitrogen due to the partial double bond character of this bond.

The ^{1}H NMR spectra of the *N*,*N*-di(2-hydroxyethyl)-*N*′-(3-*R*-benzoyl)thiourea ligands in DMSO-d_6 show inequivalent proton resonances for the hydroxyl protons. The lower field signal is broad and unresolved, while the higher field signal is a well-resolved triplet. This inequivalence of the hydroxyl protons is due to the presence of an intramolecular hydrogen bond between one hydroxyl moiety and the amide N–H [6].

The proton resonances for the phenyl ring and N–H protons are significantly affected by the presence of electron-withdrawing and electron-releasing substituents on the benzoyl moiety. As shown in Table 1, on increasing the electron withdrawing ability of the *R*-group there is a downfield shift of the proton resonances, the most pronounced shifts being observed for the ligands **L1c**, **L2c** and **L3c** which contain the nitro substituent.

3.2. Synthesis of [PtCl(DMSO)(L)] complexes

The complexes were prepared according to the general method described by Eqs. (1) and (2), where HL represents an acylthiourea ligand. The structural formulae for the complexes are given in Fig. 1.

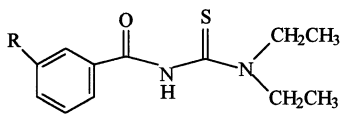
$$K_2PtCl_4 + 3DMSO \rightarrow cis\text{-}[PtCl_2(DMSO)_2] \quad (1)$$

$$cis\text{-}[PtCl_2(DMSO)_2] + HL \xrightarrow{Base} [PtCl(DMSO)(L)] + cis\text{-}[Pt(L)_2] \quad (2)$$

As indicated by Eq. (2), it was found, for ligands **L1a**–**e** and **L2a**–**e**, that in addition to the formation of the desired complex, [PtCl(DMSO)(L)], the corresponding neutral *cis*-$[Pt(L)_2]$ complex was also formed as a minor product. This was evident from both the TLC and the ^{1}H NMR spectra. Integration of the proton resonances indicated that the *cis*-$[Pt(L)_2]$ was present as the minor product (ca. 5–15%). The *cis*-$[Pt(L)_2]$ complexes have a higher mobility on silica gel (R_f ca. 0.8) compared to the [PtCl(DMSO)(L)] complexes (R_f 0.5–0.6) and consequently the complexes were readily separated using flash column chromatography. The

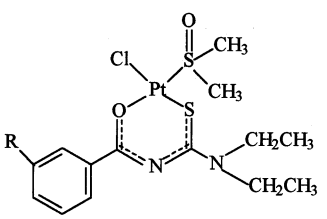
platinum complexes containing the *N*,*N*-di(2-hydroxyethyl)-*N*′-(3-*R*-benzoyl)thiourea ligands were isolated by filtration free of the *cis*-[Pt(L)$_2$] complex. This is most likely due to the *cis*-[Pt(L)$_2$] complex being more hydrophilic than the [PtCl(DMSO)(L)] complex.

The analytical data, ^{195}Pt NMR chemical shifts and relevant IR data for the [PtCl(DMSO)(L)] complexes are given in Table 2. The ^{1}H NMR data for all the platinum complexes are given in Tables 3–5.



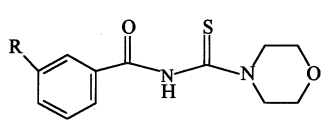
3.3. Characterisation of [PtCl(DMSO)(L)] complexes

3.3.1. Infrared spectra



The IR spectra of the platinum(II) sulfoxide complexes are very similar. Notable features of the infrared spectra of the platinum complexes are the disappearance of the N–H stretching vibrations and shifts of the ν(C=O) peaks to higher frequencies upon complexation of the acylthiourea ligands. A shift to a higher frequency would also be expected for the C=S stretch vibration, but this vibration could not be assigned unambiguously. The strong IR band in the region of 1130–1150 cm^{-1} is assigned to the ν(SO) stretching frequency. The ν(SO) peak is shifted to a higher frequency upon complexation, relative to the uncoordinated dimethylsulfoxide, which is indicative of a sulfoxide bonded through the sulfur atom [4,11].

3.3.2. NMR spectra



In accordance with the IR spectra, the N–H signal, observed for the ligands in the 8–11 ppm region, disappears upon complexation. A downfield shift is

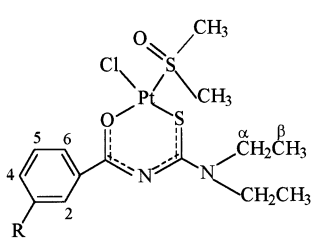
[a] Spectra were recorded in DMSO-d_6.
[b] Ref. [6].

observed for the H_2 and H_6 aromatic protons and an upfield shift for the H_3, H_4 and H_5 proton resonances relative to that of the free ligand, with the exception of the H_4 proton resonances for complexes **1c**, **2c** and **3a**–**d** which undergo downfield shifts.

The ^{1}H NMR chemical shift for the methyl protons of the coordinated dimethylsulfoxide are shifted 1 ppm downfield relative to free dimethylsulfoxide, which is typical for sulfur bonded sulfoxides [3,4]. The assignment of the mode of coordination of the dimethylsulfoxide was further supported by the presence of platinum satellites due to vicinal coupling of the methyl protons of the dimethylsulfoxide with the platinum centre, ^{195}Pt (33.7%, $I = 1/2$). The $^3J(^{195}Pt–^1H)$ coupling constants were approximately 23 Hz, which is the same order of magnitude found for sulfur bonded sulfoxides [4]. The data are consistent with that reported for the [PtCl(L)(RR′SO)] complexes with *N*,*N*-dialkyl-*N*′-benzoylthiourea ligands, which were confirmed by the crystal structure of the [PtCl(*N*,*N*-diethyl-*N*′-benzoylthioureato)(MPSO)] complex [3]. The methylphenyl sulfoxide (MPSO) is sulfur bonded to the platinum and *cis* to the sulfur of the *N*,*N*-diethyl-*N*′-benzoylthiourea ligand. Variation of the electronic properties of the benzoyl moieties appears to have little affect on the ^{1}H NMR chemical shift position of the methyl protons of the coordinated sulfoxide.



All the [Pt(acylthioureato)Cl(DMSO)] complexes show ^{195}Pt chemical shifts in the -3200 to -3300 ppm region. This chemical shift range is characteristic of complexes with the coordination sphere [PtSOSCl] [3]. The 3-substitution of the benzoyl moiety of these complexes results in a small but significant difference in the ^{195}Pt chemical shifts for the [Pt(acylthioureato)Cl(DMSO)] complexes, demonstrating the sensitivity of the ^{195}Pt nucleus to subtle electronic changes on

the benzoyl moiety [11]. The electron-withdrawing affect of the nitro- and chloro- substituents results in notable downfield shifts of the ^{195}Pt signal: NO_2 ($\Delta\delta$: 10–14 ppm) > Cl ($\Delta\delta$: 6–7 ppm) > $OCH_3 \approx H \approx CH_3$, which is consistent with the mesomeric/inductive effects expected for a 3-substituted benzoyl group and parallels the trend observed for the ^{1}H NMR data. No significant effect was observed with variation of the thioamide moiety.

The sensitivity of the ^{195}Pt NMR signal to changes in the benzoyl substituent indicates that these groups influence the electron density at the platinum centre and are therefore expected to have an influence on the substitution reaction kinetics of these complexes. Since the rate of substitution of the dimethylsulfoxide and chloride ligands is of utmost importance in gaining insight into the reactivity and mode of binding of these complexes to DNA detailed studies are underway cur-

rently to evaluate the substitution kinetics of these complexes. In the meanwhile, preliminary substitution reaction kinetic studies of [PtCl(DMSO)(*N*,*N*-diethyl-*N*′-(3-*R*-benzoyl)thioureato)] and the anionic nucleophile azide have revealed that the rate of substitution of the chloride leaving group is influenced by the electronic properties of the R group on the phenyl ring. The rate of substitution decreases in the order of $NO_2 > Cl > OCH_3 \approx H \approx CH_3$. These results are in agreement with the ^{195}Pt NMR results, which provide evidence that the electron-withdrawing substituents on the phenyl ring results in a decrease in the electron density at the Pt centre thereby making it more susceptible to nucleophilic attack. The substitution of the chloride-leaving group was established from the ^{1}H NMR spectrum of the complex. In the presence of the azide anion a significant upfield shift was observed for the protons of the coordinated DMSO and there was no significant appearance of free DMSO at 2.5 ppm.

It is also noteworthy to mention that preliminary in vitro cytotoxicity studies against a HeLa cell line have shown that both the benzoyl substituent and the thioamide moiety play an important role in determining whether the complexes exhibit any anticancer activity. The [PtCl(DMSO)(*N*,*N*-diethyl-*N*′-benzoylthioureato)], and [PtCl(DMSO)(*N*,*N*-di(2-hydroxyethyl)-*N*′-benzoylthioureato)] complexes did not exhibit any cytotoxic behaviour, whereas a notable concentration-dependent anti-proliferative effect was observed for the HeLa cell line treated with the [Pt(acylthioureato)Cl(DMSO)] complexes containing the *N*,*N*-diethyl-*N*′-(3-nitrobenzoyl)thiourea, *N*-morpholino-*N*′-(3-nitrobenzoyl)thiourea or *N*-morpholino-*N*′-(3-methoxybenzoyl)thiourea ligands [12]. These preliminary results are most encouraging in that they support our hypothesis that the acylthiourea ligand could play an important role in the biological activity of this series of complexes and can thus be used to fine-tune their anti-tumour behaviour. Detailed studies are thus currently underway to investigate the biological activity of this series of complexes and to try and establish a structure–activity relationship.

POLYHEDRON

Interaction between iron(II) tetrasulfophthalocyanine and the neurotransmitters, serotonin and dopamine

Joshua Oni, Tebello Nyokong *

Department of Chemistry, Rhodes University, Grahamstown 6140, South Africa

Received 4 February 2000; accepted 8 May 2000

Abstract

This work reports on the kinetics of interaction of iron(II) tetrasulfophthalocyanine, $[FeTSPc]^{4-}$, with dopamine (DA) and serotonin (5-HT). The interaction results in the coordination of dopamine and serotonin to $[FeTSPc]^{4-}$, followed by internal electron transfer and the formation of $[(DA^{+})Fe^{I}TSPc]^{4-}$ and $[(5\text{-}HT^{+})\ Fe^{I}TSPc]^{4-}$ complexes, respectively. The rate constants for the coordination of dopamine or serotonin to $[FeTSPc]^{4-}$ and the formation of the $Fe^{I}TSPc$ species were found to be $k_f = 6.8$ and 9.3 $dm^3\ mol^{-1}\ s^{-1}$, respectively. The equilibrium constants were 2.2×10^3 and 1.5×10^3 $dm^3\ mol^{-1}$, respectively, for the interaction of dopamine or serotonin to $[FeTSPc]^{4-}$. © 2000 Elsevier Science Ltd. Keywords: Iron; Phthalocyanine; Dopamine; Serotonin; Coordination

1. Introduction

There has been an extensive interest in developing methods for the analysis of neurotransmitters [1–6]. Both dopamine and serotonin are important neurotransmitters in the mammalian central nervous system [7]. Brightly coloured complexes are known to form when iron(III) interacts with dopamine and these are often used for qualitative analysis of dopamine [8,9]. Following coordination of dopamine to iron(III), internal electron transfer occurs with the formation of iron(II) and semiquinone [9]. Some members of the catecholamine family such as 6-hydroxydopamine react directly with iron(III) to form iron(II) and semiquinone via outer sphere electron transfer without first forming a complex with iron(III) [10]. This work examines the interaction of iron(II) tetrasulfophthalocyanine with dopamine (DA) and serotonin (5-HT) (Fig. 1). We examine the spectroscopic behaviour of iron phthalocyanine in the presence of dopamine and serotonin.

Metallophthalocyanine (MPc) complexes are well known catalysts for the oxidation or reduction of a wide variety of molecules [11]. The catalytic behaviour of MPc complexes is dependent on the nature of the central metal ion. MPc complexes that contain redox active central metals, such as CoPc and FePc, show better catalytic activity than those that exhibit ring based redox behaviour such as CuPc [11]. The catalytic activity of MPc complexes often involve electron transfer processes which in many cases are mediated by axial ligation (to the MPc complex) of the species to be catalysed [12–14]. Nickel(II) tetraaminophthalocyanine (NiTAPc) has been shown to exhibit electrocatalytic behaviour towards the oxidation of dopamine when adsorbed onto a glassy carbon electrode [2]. The electrocatalytic behaviour was attributed to an electron transfer from dopamine to the $Ni^{III}TAPc$ species.

Because of the role played by iron(III) in the analysis of dopamine, and the biological importance of studying the mechanism of the interaction of neurotransmitters with porphyrins and porphyrin-type molecules, such as phthalocyanines, we chose the water soluble iron(II) tetrasulfophthalocyanine ($[FeTSPc]^{4-}$) complex for the study of the interaction with dopamine and serotonin. $[Fe^{II}TSPc]^{4-}$ may be oxidised to $[Fe^{III}TSPc]^{4-}$ or reduced to $[Fe^{I}TSPc]^{4-}$ by electrochemical [15] and chemical means.

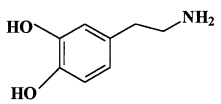
Axial ligand exchange reactions in MPc complexes are dissociative with the formation of a highly reactive five-coordinate intermediate [16,17] (Eqs. (1) and (2)):

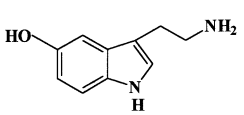
$$(L)_2MPc \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} (L)MPc + L \quad (1)$$

$$E + (L)MPc \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} (L)(E)MPc \quad (2)$$



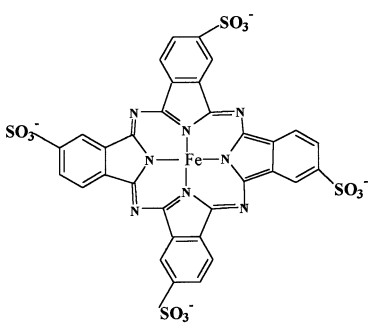
where L is the leaving ligand and E is the entering ligand.

Axial ligand coordination in MPc complexes may be accompanied by electron transfer between MPc complexes and the ligands. In this work, we use UV–Vis spectroscopy to monitor the interaction of $[FeTSPc]^{4-}$ with serotonin and dopamine.



2. Experimental

2.1. Materials



Dopamine (4-(2-aminoethyl)benzene-1,2-diol) hydrochloride and serotonin (5-hydroxytryptamine) creatinine sulfate monohydrate were purchased from Sigma. Sodium salts of the tetrasulfophthalocyanine complexes of iron(II), cobalt(II) and nickel(II) (Na_4[FeTSPc], Na_4[CoTSPc] and Na_4[NiTSPc]) were synthesised and purified according to established procedures [18]. The complexes were characterised by IR and UV–Vis spectroscopy and by elemental analysis. Solid complexes formed between $[FeTSPc]^{4-}$ and serotonin or dopamine were obtained following evaporation of water from an aqueous solution containing the respective species, following the change of colour from blue to green. The solid products were characterised by elemental analysis, IR, UV–Vis and NMR spectroscopies.

2.1.2. $[FeTSPc]^4$, serotonin complex

Anal. Calc. for $C_{46}H_{37}N_{13}S_5O_{24}Na_4Fe$ (including one H_2O of cystallisation): C, 37.73; H, 2.55; N, 13.27. Found: C, 37.79; H, 4.69; N, 15.29%. UV–Vis (H_2O) λ_{max} (log ε): 663 (3.58) nm. IR ν_{max}/cm^{-1} (KBr disks): 3367, 2930, 1707, 1637, 1545, 1456, 1414, 1344, 1102, 1028, 701, 601.

UV–Vis spectra was recorded with the Cary 500 UV–Vis/NIR spectrophotometer. Infrared spectra (KBr discs) were recorded with the Perkin–Elmer spectrum 2000 FTIR spectrophotometer. Nuclear magnetic resonance (^1H NMR) data in D_2O was recorded with the Bruker EMX 400 NMR spectrometer

2.2. Kinetics and equilibria

Kinetic and equilibrium studies were run at 20 ± 0.5°C and monitored with the Cary 500 UV–Vis NIR spectrophotometer. We monitored the appearance of the spectra due to the product formed following the addition of serotonin or dopamine to solutions of $[FeTSPc]^{4-}$ in water (unbuffered pH 6.3). Typically, a known volume of the aqueous solution of $[FeTSPc]^{4-}$ was added to a 1 cm path length spectrophotometric cell and deaerated using nitrogen. Then a known volume of aqueous solution of either serotonin or dopamine was added to the cell and the changes in absorbance monitored with time. For kinetic studies, concentrations of the $[FeTSPc]^{4-}$ were kept constant at 2.0×10^{-5} mol dm^{-3}, while dopamine concentrations were varied from 1.7×10^{-4} to 8.3×10^{-4} mol dm^{-3} and serotonin concentrations ranged from 6.7×10^{-5} to 4.7×10^{-4} mol dm^{-3}. The extinction coefficient of 4.8×10^4 mol^{-1} dm^3 cm^{-1} was used for the calculation of $[FeTSPc]^{4-}$ concentration. Since the concentrations of dopamine and serotonin were larger than that of $[FeTSPc]^{4-}$, pseudo-first order conditions were assumed for kinetic studies.

3. Results and discussion

3.1. Spectroscopic characterisation

Electronic absorption spectra of $[MTSPc]^{4-}$ complexes have been well studied [19,20] These complexes exist as dimers in equilibrium with the monomers in aqueous solutions, the spectra of $[MTSPc]^{4-}$ thus con-

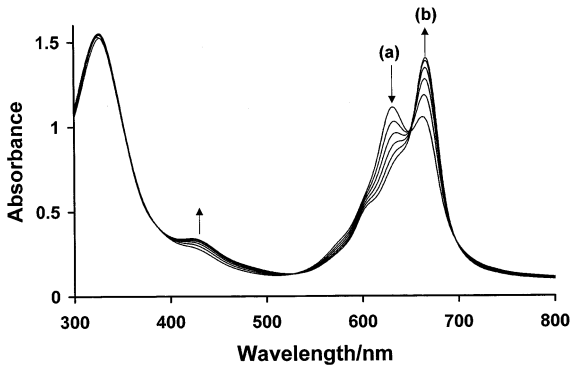

Fig. 2. Electronic absorption spectral changes observed on addition of dopamine to aqueous solutions of $[FeTSPc]^{4-}$. Spectra before (a) and spectra 5 min after (b) addition of 3.3×10^{-5} mol dm^{-3} dopamine.

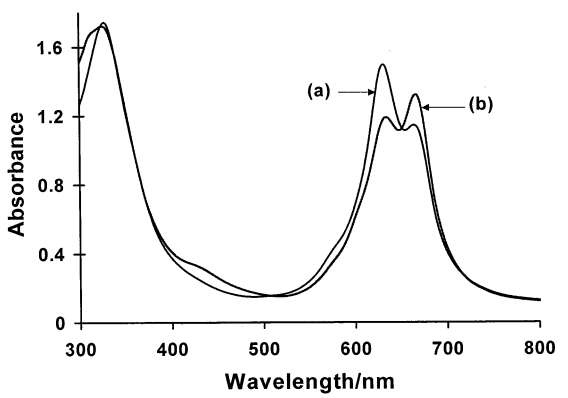

Fig. 3. Electronic absorption spectral changes observed on addition of serotonin to aqueous solutions of $[FeTSPc]^{4-}$. Spectra before (a) and spectra 1 min after (b) addition of 2.7×10^{-4} mol dm^{-3} serotonin.

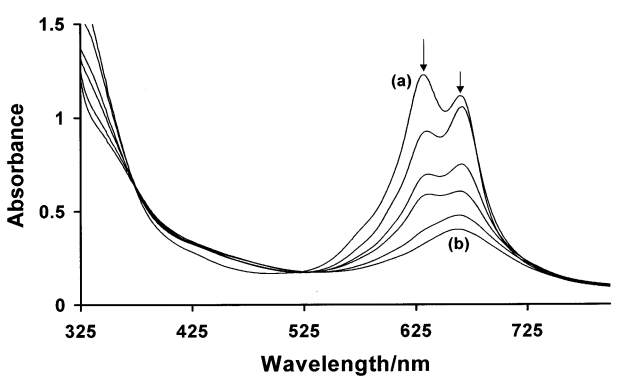

Fig. 4. Electronic absorption spectral changes observed following addition of serotonin to aqueous solutions of $[FeTSPc]^{4-}$. (a) Spectra after 1 min and (b) spectra after 20 min of addition of 2.7×10^{-4} mol dm^{-3} serotonin.

sist of two peaks in the Q band region. The high energy absorption band near 620 nm is associated with the dimeric species and the low energy band near 670 nm is due to the monomeric species [19]. For $[FeTSPc]^{4-}$ in water, the peak due to the monomeric species is observed at 665 nm and the dimeric peak at 633 nm. The Soret or B band peak is observed at 327 nm. Fig. 2 shows spectral changes observed on addition of dopamine to solutions of $[FeTSPc]^{4-}$ in water. The peak due to the monomeric species at 665 nm is enhanced greatly with a small shift in wavelength to 667 nm, whereas the peak due to the dimeric species at 633 nm disappeared. These changes were only observed at concentrations of DA less than 1×10^{-4} mol dm^{-3}. The increase in the monomeric peak occurred with clear isosbestic points at 651, 529 and 389 nm.

Equilibrium data were determined by standard spectroscopic techniques using Eq. (3):

$$\log[(A_{eq} - A_0)/(A_\infty - A_{eq})] = \log K + n\log[DA] \quad (3)$$

where A_{eq} is the equilibrium absorbance at 667 nm, A_0 is the absorbance at 665 nm before the addition of DA and A_∞, the absorbance after complete shifting of the equilibrium to the monomeric side, was determined from the final absorbance at 667 nm (Fig. 2). From the plot of $\log[(A_{eq} - A_0)/(A_\infty - A_{eq})]$ versus log[DA], an equilibrium constant of $K = 5.4 \pm 0.4 \times 10^5$ dm^3 mol^{-1} was determined for the shifting of the dimer–monomer equilibrium to the monomeric side.

Spectral changes observed on addition of serotonin to solutions of $[FeTSPc]^{4-}$ are shown in Fig. 3. Contrary to the observation above for dopamine, disappearance of the peak due to the dimeric species was not complete on addition of 5-HT to $[FeTSPc]^{4-}$, the peaks due to both the monomeric and dimeric species were observed regardless of the concentration of serotonin added. There was however, a reduction in the intensity of the peak due to the dimeric species and an increase in the monomeric peak on initial addition of serotonin to $[FeTSPc]^{4-}$. Also the increase in the intensity of the monomeric peak occurred without any measurable shift in the wavelength. The peak due to the monomeric species did not show an increase with time that was observed for DA (Fig. 2) regardless of the concentration of 5-HT added.

The enhancement in the peak due to the monomeric species on addition of either DA or 5-HT to $[FeTSPc]^{4-}$ shows that the dimer–monomer equilibrium for the $[FeTSPc]^{4-}$ species is shifted towards the monomeric side. The dimer–monomer equilibrium in $[MTSPc]^{4-}$ complexes can be affected by ionic strength [20] and by axial ligation [21,22]. The spectral changes observed with time, on addition of 5-HT to $[FeTSPc]^{4-}$ solutions are shown in Fig. 4.

The spectral changes in this case involved the decrease in both the dimeric and monomeric peaks and the formation of a broad peak at 663 nm. The new peak was formed with isosbestic points at 521 and 374 nm. Fig. 5 shows spectral changes observed on addition of DA concentrations larger than 1×10^{-4} mol dm^{-3}

to solutions of $[FeTSPc]^{4-}$. Under these conditions pseudo-first-order conditions apply and were assumed for kinetic studies below. Spectral changes in Fig. 5 consisted of the decrease in the intensity of the peak due to the monomeric species at 667 nm accompanied by a shift to 659 nm and no further decrease in intensity. These spectral changes occurred with isosbestic points at 545, 454 and 305 nm. The peak at 428 nm decreased in intensity and a new broad feature developed near 500 nm. The Soret band shifted to higher energies. Accompanying the spectral changes shown in Figs. 4 and 5 were changes in the colour of the solution from blue to green. The spectral and colour changes are similar to those observed on reduction of the $[Fe^{II}TSPc]^{4-}$ species to $[Fe^{I}TSPc]^{4-}$ using sodium borohydride. Thus the final spectra in Figs. 4 and 5 are due to the reduction of the central metal in $[Fe^{II}TSPc]^{4-}$ with the formation of the $Fe^{I}TSPc$ species, as a result of the electron transfer from DA or 5-HT. Ligation of species such as NO_2^- or cysteine to $[CoTSPc]^{4-}$ has been shown to be accompanied by oxidation of $[Co^{II}TSPc]^{4-}$ to the $[Co^{III}TSPc]^{4-}$ species [21,22]. Axial ligation, followed by electron transfer, has also been suggested for the interaction of the neurotransmitter, NO with iron porphyrins [23]. It has been shown before that coordination of DA to Fe^{III} results in the formation of an Fe^{III}(DA) complex involving the use of both oxygen atoms in DA [9]. This is followed by internal electron transfer forming Fe^{II} and a semiquinone, hence the dissociation of the complex [9]. We suggest in this work that axial ligation of DA or 5-HT to $[FeTSPc]^{4-}$ occurs prior to internal electron transfer resulting in the formation of $(DA^+)Fe^{I}TSPc$ and $(5\text{-}HT^+)Fe^{I}TSPc$ species, respectively. The one-electron oxidation product of DA is likely to be a semiquinone.

The fact that the final spectra following addition of DA or 5-HT to $[Fe^{II}TSPc]^{4-}$ is observed at different wavelengths shows that the final $Fe^{I}TSPc$ species formed are slightly different. This can be explained by differences in the complexes formed due to ligation of DA or 5-HT, with the formation of $[(DA^+)Fe^{I}TSPc]^{4-}$ and $[(5\text{-}HT^+)Fe^{I}TSPc]^{4-}$, respectively.

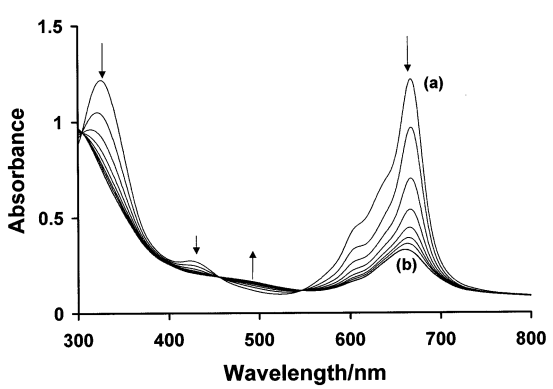

Fig. 5. Electronic absorption spectral changes observed following addition of large concentrations of dopamine to aqueous solutions of $[FeTSPc]^{4-}$. (a) Spectra after 2 min and (b) spectra after 20 min of addition of 3.3×10^{-4} mol dm^{-3} dopamine.

IR spectra of the solid complex formed following evaporating water from a solution containing $[FeTSPc]^{4-}$ and DA as explained in Section 2, showed a new peak at 819 cm^{-1} which could not be identified with either DA or $[FeTSPc]^{4-}$. Fe–O vibrations are observed in the 800–830 cm^{-1} region for oxoiron porphyrin complexes [24]. The vibration at 819 cm^{-1} is thus in the range for Fe–O vibrations, suggesting the presence of an Fe–O bond in the complex between $[FeTSPc]^{4-}$ and DA. Also a new vibration at 3419 cm^{-1} was observed for the complex between DA and $[FeTSPc]^{4-}$. This band is due to indole N–H vibrations and gives evidence of cyclisation in DA following its oxidation. Prominent vibrations due to DA at 1931 and 1500 cm^{-1} and between 800 and 1000 cm^{-1} disappeared on formation of a complex between $[FeTSPc]^{4-}$ and DA.

For the complex between $[FeTSPc]^{4-}$ and 5-HT, no new peaks were evident in the 800–830 cm^{-1} region where Fe–O vibrations are expected, this could be due to overlap with serotonin vibrations. The indole N–H vibration is observed at 3475 cm^{-1} for serotonin. Upon interaction between serotonin and $[FeTSPc]^{4-}$, this band disappeared and a sharp new band was observed at 2927 cm^{-1}.

^{1}H NMR spectra of MPc complexes is characterised by weak multiplets near 9.30 and 8.60 ppm due to the α and β protons of the phthalocyanine ring [25,26]. The ^{1}H NMR spectra of dopamine showed a multiplet at 6.95 ppm due to the aromatic protons of the ring, and two sets of triplets due to side chain protons at 3.30 and 2.90 ppm. The ^{1}H NMR spectra observed following interaction between $[FeTSPc]^{4-}$ and DA showed no changes in the 3.30 and 2.90 resonances of DA, but showed a small shift in the resonances of the aromatic protons (6.95–6.80 ppm). This shift is probably a result of changes in the electronic effects of the ring following cyclisation of DA. There was also an improvement in the resolution of the resonances due to the phthalocyanine ring following the interaction between DA and $[FeTSPc]^{4-}$. This could be due to improved solubility of the axially ligated $Fe^{I}TSPc$ species. For serotonin, the resonances for the protons of the fused aromatic rings were observed at different positions (6.85, 7.06, 7.25 and 7.38 ppm) due to their different environments. The side chain protons gave resonances at 3.29 and 4.19 ppm, while the protons due to the creatinine unit were observed at $\delta = 3.08$ ppm. Upon interaction between 5-HT and $[FeTSPc]^{4-}$, significant changes in the ^{1}H NMR spectra were observed. The spectra broadened and in general the resonances due to the protons

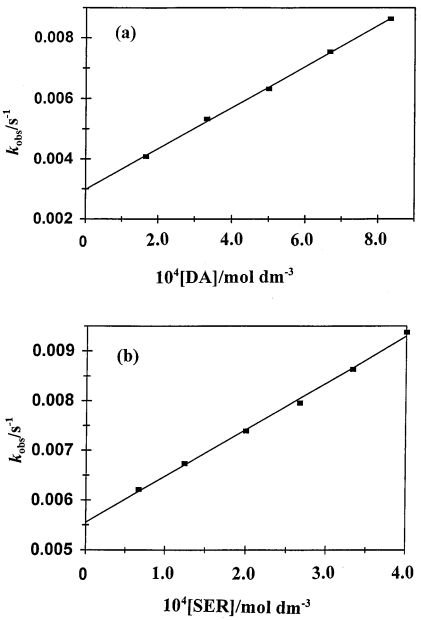

Fig. 6. Plots of the observed rate constants, k_{obs} (s^{-1}) versus concentration for the coordination of (a) dopamine and (b) serotonin to $[FeTSPc]^{4-}$.

of the fused rings shifted upfield, except for the resonance at 7.38 ppm which shifted downfield to 7.45 ppm. The resonances due to the side chain protons and due to creatinine unit remained unchanged. The shifting and broadening of the 5-HT resonances may be a result both of its coordination to $[FeTSPc]^{4-}$ and its oxidation.

3.2. Interactions between dopamine and serotonin with other MPc complexes

Addition of DA or 5-HT to solutions of $[CoTSPc]^{4-}$ or $[NiTSPc]^{4-}$ resulted in small changes in the spectra of $[MTSPc]^{4-}$ species. A small increase in the peak due to the monomer peak and a small decrease in the dimer peak were observed. There was no evidence for the formation of the reduced $[CoTSPc]^{4-}$ or $[NiTSPc]^{4-}$ species. The differences in the behaviour of $[NiTSPc]^{4-}$ in the presence of DA or 5-HT when compared to $[FeTSPc]^{4-}$ may be explained by the fact that for the $[NiTSPc]^{4-}$ complex, reduction or oxidation occurs at the phthalocyanine ring and not at the central metal [27]. Also NiPc complexes are square planar and do not favour axial ligation. For $[Co^{II}TSPc]^{4-}$ complexes, reduction occurs at the central metal forming $[Co^{I}TSPc]^{4-}$, and hence this complex would be expected to behave in a manner similar to $[FeTSPc]^{4-}$ on interaction with DA or 5-HT. However reduction of the $[Co^{II}TSPc]^{4-}$ to $[Co^{I}TSPc]^{4-}$ was not observed in the presence of DA or 5-HT.

3.3. Kinetic studies for the interaction of $[FeTSPc]^{4-}$ with DA or 5-HT

Kinetic data for the coordination of DA or 5-HT to $[FeTSPc]^{4-}$ were obtained by monitoring the formation of the peak due to $[(DA^{+})Fe^{I}TSPc]^{4-}$ or $[(5\text{-}HT^{+})\text{-}Fe^{I}TSPc]^{4-}$ complexes with Q bands at 659 and 663 nm, respectively, under conditions of Figs. 4 and 5. For DA coordination, the formation of the $[(DA^{+})\text{-}Fe^{I}TSPc]^{4-}$ species was monitored following the complete shift of the monomeric side, hence the starting spectra in Fig. 5 is that of the monomeric species, thus avoiding influences due to the dimeric species. For the coordination of serotonin, the presence of the dimeric species cannot be ruled out. For both complexes, plots of the logarithm of absorbance versus time were linear showing that the reaction was first order in $[FeTSPc]^{4-}$. The slopes of these plots gave the observed rate constant, k_{obs} and plots of k_{obs} versus the concentration of DA or 5-HT were linear (Fig. 6) showing that the coordination was first order in both DA and 5-HT. As discussed above, the axial ligand substitution reactions in MPc complexes are dissociative resulting in a highly reactive five-coordinate intermediate [16,17]. It is expected that the monomeric form of $[FeTSPc]^{4-}$ is coordinated to water molecules in aqueous solutions forming the $[(H_2O)_2FeTSPc]^{4-}$ species. The coordination of DA or 5-HT to $[(H_2O)_2FeTSPc]^{4-}$ may then be represented by Eqs. (4) and (5):

$$(H_2O_2)Fe^{II}TSPc \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} (H_2O)Fe^{II}TSPc + H_2O \quad (4)$$

$$(H_2O)Fe^{II}TSPc + DA \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} (H_2O)(DA^{+})Fe^{I}TSPc \quad (5)$$

The rate law for axial ligand exchange reactions in MPc complexes shown by reactions 4 and 5 is generally given by Eq. (6):

$$k_{obs} = k_f[DA] + k_r \quad (6)$$

where k_f, the rate constant for the forward reaction is given by $k_1k_2/(k_{-1}[H_2O])$ and k_r is the rate constant for the reverse reaction. Least-square analysis of the data presented in Fig. 6 gave $k_f = 6.8 \pm 0.2$ dm^3 mol^{-1} s^{-1} from the slope and $k_r = 3.0 \pm 0.1 \times 10^{-3}$ s^{-1} from the intercept, for the coordination of DA. For serotonin $k_f = 9.3 \pm 0.3$ dm^3 mol^{-1} s^{-1} and $k_r = 5.6 \pm 0.1 \times 10^{-3}$ s^{-1} were obtained. Using these values of rate constants, the value of the equilibrium constant for DA coordination to $[FeTSPc]^{4-}$ was estimated to be $K = 2.3 \times 10^3$ dm^3 mol^{-1} from the relationship, $K_1 = k_f/k_r$. For 5-HT, the equilibrium constant was determined to be $K = 1.7 \times 10^3$ dm^3 mol^{-1}. The values for the equilibrium and rate constants are in the range reported for axial ligand exchange reactions in FePc complexes [28].

Similar to the kinetic studies, for DA coordination, the equilibrium data was determined following com-

plete shifting of the equilibrium to the monomeric side, and the spectral changes for the decrease in the peak due to the monomeric species were followed. For the interaction between DA and $[FeTSPc]^{4-}$, the equilibrium for the formation of the $[(DA^{+})Fe^{I}TSPc]^{4-}$ was studied by monitoring the decrease in the peak due to the monomeric species at 667 nm (Fig. 5) using Eq. (3), where A_{eq} is the equilibrium absorbance at 667 nm and A_0 is the starting absorbance (at 667 nm) of the monomeric, $[FeTSPc]^{4-}$ species. A_{∞}, the absorbance after complete formation of the $[(DA^{+})Fe^{I}TSPc]^{4-}$ complex, was determined from the final absorbance at 659 nm. Fig. 7(a) shows the plot of $\log[(A_{eq}-A_0)/(A_{\infty}-A_{eq})]$ versus log[DA]. A linear plot with a slope near unity ($n=0.9\pm0.2$) was obtained, showing that only one mole of DA was coordinated to the $[FeTSPc]^{4-}$ species. The linearity of the plot confirms the coordination of DA to the $[FeTSPc]^{4-}$ complex. Least-square analysis gave an equilibrium constant of $K=2.2\pm0.1\times10^{3}$ dm^{3} mol^{-1}, in agreement within experimental error with the value calculated from the kinetic data above.

For the coordination of 5-HT to $[FeTSPc]^{4-}$, the equilibrium data was determined by using the spectra due to the formation of the reduced $[(5\text{-}HT^{+})\text{-}Fe^{I}TSPc]^{4-}$ species. Thus in this case, A_{eq} is the equilibrium absorbance at 665 nm, A_0 is the absorbance at 665 nm before addition of 5-HT and A_{∞}, the absorbance after complete formation of the $[(5\text{-}HT^{+})\text{-}Fe^{I}TSPc]^{4}$ complex, was determined from the final absorbance at 663 nm. The plot of $\log[(A_{eq}-A_0)/(A_{\infty}-A_{eq})]$ versus log[5-HT] is shown in Fig. 7(b), a linear plot with a slope $n=0.9\pm0.1$ was obtained and the value of K was determined to be $K=1.5\pm0.2\times10^{3}$ dm^{3} mol^{-3}, again in agreement with the value determined using k_f/k_r.

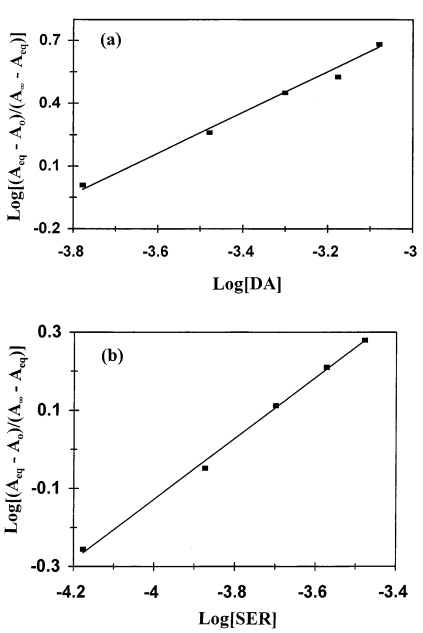

Fig. 7. Plot of $\log[(A_{eq}-A_0)/(A_{\infty}-A_{eq})]$ versus (a) log[dopamine] and (b) log[serotonin] for the coordination to $[FeTSPc]^{4-}$.

In conclusion, we have shown in this work that DA and 5-HT interact with $[FeTSPc]^{4-}$ resulting in the reduction of the latter to the $Fe^{I}TSPc$ species. There was spectroscopic evidence for the coordination of DA and 5-HT to the $[FeTSPc]^{4-}$ species. Studies on the interaction of DA and 5-HT with metallophthalocyanine and metalloporphyrin complexes are of importance since they may provide means for the analysis of these neurotransmitters.

Abstract

Cocondensation reaction of MoO_3 with hexamethyldisilazane, followed by work-ups produced the nitrido molybdenum(VI) compounds, $[MoN(OSiMe_3)_3(NH_3)]_2$ (**1**), $[MoN(OSiMe_3)_3(py)]$ (**2**), and a very unusual μ_2-oxo-μ_2-nitrido tetranuclear molybdenum(VI) compound, $[Mo_2N_2O(OSiMe_3)_4(py)_2]_2{\cdot}2py$ (**3**). When **1** is reacted with excess methanol it results in another oxonitrido Mo(VI) compound, $Mo_4N_4O_2(OH)_8(H_2O)(MeOH)_3$ (**4**). The compounds were characterized by elemental analyses, FT-IR, ^1H and ^{13}C NMR, mass spectrometry, and by single-crystal X-ray diffraction for **1** and **3**. Compound **1** is dimeric in the solid state with two bridging siloxo groups; however, in toluene solution and at ambient temperature, the dimer readily dissociates into the monomer. The molecular geometry changes rapidly via a pseudorotation process as deduced from the variable temperature ^1H and ^{13}C NMR study. However, as the temperature is lowered, monomer↔dimer equilibrium is attained. The $\Delta G^{\neq}$ for the pseudorotation of **1** is 13.1 kcal mol^{-1} and $\Delta G^{\neq}$ for the monomer↔dimer association is 9.9 kcal mol^{-1}. Compound **2** is also fluxional, but remains monomeric in toluene solution down to 190 K. The $\Delta G^{\neq}$ for the pseudorotation of **2** is 12.2 kcal mol^{-1}. In contrast, **3** is tetranuclear in the solid state and is not fluxional in solution. Instead, it is slowly disproportionated to **2** and, presumably, an oxonitrido Mo(VI) pyridine adduct. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Numerous nitrido transition metal complexes accompanying various organic and/or inorganic ligands have been reported for the past several decades [1]. Nitride ion (N^{3-}), isoelectronic with the oxide ion (O^{2-}), is the strongest π bonding ligand and forms a unique class of compounds with interesting characteristics and properties [2]. Recently, research results on these compounds such as non-linear optical (NLO) and luminescence property [3], olefin metathesis catalysis [4], N-atom transfer reaction [5], and theoretical calculation [6] have emerged. However, until recently, little attention has been paid to the transition metal nitrido alkoxide and siloxide chemistry [7,9,18,19]. Quite recently Mo(N)(O-*t*-Bu)$_3$ together with the sterically bulky monomeric tris(alkylarylamido) Mo(III) complex was shown to accelerate the dinitrogen cleavage reaction [8]. There is an interesting analogy between cyclic and linear nitrido transition metal complexes, conjugated organic polyenes and cyclic aromatic compounds [9]. These research results warrant further synthetic effort and reactivity study of nitrido transition metal complexes.

We utilized cocondensation reactions to generate highly energetic coordinatively unsaturated molybdenum trioxide fragments that in turn reacted further with organosilanes. The cocondensation reactions, in many cases, generated hard-to-obtain and structurally interesting, and sometimes unique, compounds due to the intrinsic kinetic and energetic nature of the reaction [10]. For example, we were able to prepare a series of thermally unstable molybdenum oxoalkoxides and oxosiloxides through this synthetic route, the results are reported elsewhere [11].

In this paper, we wish to report the reaction, product characterization including two X-ray structures, and dynamic solution behavior of the products isolated from the MoO_3-hexamethyldisilazane cocondensation reaction. Until recently, although many transition metal nitrido complexes have been reported, only a handful of compounds have been subjected to solution studies. In this context, the solution NMR results described here may shed some light on the understanding of the energetics in the fundamental structural chemistry. In addition, we report an alternative high yield synthesis for **1** by using a conventional synthetic route.

2. Experimental

2.1. General considerations

All manipulations were performed either under an argon atmosphere using standard Schlenk techniques or in an argon-filled Vacuum Atmospheres® glovebox. Solvents were dried rigorously using appropriate literature procedures and stored over 4 Å molecular sieves just prior to use. Hexamethyldisilazane was purchased from Petrarch and used as received. MoO_3 (Matheson Coleman and Bell) was used without further purification. $MoO_3 \cdot 2H_2O$ was prepared as a crystalline yellow solid by the literature method [12]. IR spectra were obtained on a Mattson Sirius® 100 FT-IR or on a Nicolet 5XDB FT-IR with 2 cm^{-1} resolution. Nujol mull or KBr pellet with 3–5 wt.% sample loading was employed. Elemental analyses were performed by Galbraith Laboratories, Knoxville, TN, USA. NMR spectra were taken on a Bruker AM-400 spectrometer that was equipped with a temperature controller. Mass spectrometry was performed on a Finnigan 4000-23 spectrometer with a 4500 ion source by using pulsed-ion–positive-ion–negative-ion chemical ionization (PIPINICI) with methane as the secondary ion generator and by using 70–100 eV ionization potential. Mass data reported are based on ^{98}Mo for mononuclear species and on ^{96}Mo for dinuclear species. The cocondensation reaction was carried out using the equipment that has previously been described [13]. MoO_3 was sublimed from a resistively heated niobium tube with five to six holes punched in from the upper side. Cocondensation occurred over a period from 0.5 to 1.5 h. Yield based on MoO_3 condensed on the wall of the reactor was determined by taking the mass difference before and after the reaction.

2.2. Preparation of $[MoN(OSiMe_3)_3(NH_3)]_2$ (1): method 1 (from the cocondensation reaction)

MoO_3 (1.574 g, 10.94 mmol) was cocondensed at 77 K with $HN(SiMe_3)_2$ (48.6 g, 301 mmol). When the reactor was warmed to ambient temperature, the volatile was stripped off using dynamic vacuum at 10^{-3} Torr overnight. A yellow–green solid (2.558 g) was obtained. A 1.193 g portion of the solid was dissolved in 30 ml of hexane and filtered twice through a coarse glass frit to give a yellow–brown solution. The solution volume was reduced to 10 ml by a vacuum line in a Schlenk tube and placed in a freezer at 253 K. A colorless needle-shaped crystalline solid was formed overnight. Decanting the solution, followed by washing with cold hexane (5 ml) and vacuum drying at ambient temperature gave a colorless crystalline solid (0.180 g). Crystallization of the decanted solution gave another crop of the product (0.112 g). The total yield was 14.5% based on the cocondensed MoO_3. *Anal.* Calc. for $C_{18}H_{60}N_4O_6Si_6Mo_2$: C, 27.4; H, 7.66; N, 7.60; Mo, 24.3. Found: C, 27.4; H, 7.75; N, 7.05; Mo, 24.0%. ^1H NMR 400 MHz (in benzene-d_6, 293 K, referenced to the solvent protio peak at 7.15 ppm): δ 0.38 (s, 27H, Me_3SiO), 1.97 (s, br, 3H, NH_3). ^{13}C NMR 100.614 MHz (in benzene-d_6, 293 K, referenced to the solvent ^{13}C peak at 128.00 ppm): δ 2.17 (Me_3SiO). IR data (KBr): 3401 (m), 3350 (m), 3234 (m), 3156 (m), 2954 (s), 2899 (m), 2726 (vw), 2667 (vw), 2098 (vw), 2000 (vw), 1932 (vw), 1876 (vw), 1612 (m), 1434 (m), 1402 (m), 1384 (m), 1313 (m), 1249 (s), 1215 (m), 1049 (s), 942 (s), 867 (sh), 844 (vs), 815 (s), 750 (s), 713 (sh), 684 (m), 632 (m), 481 (s), 473 (s). Mass data (m/z [% intensity, assignment]): 308 [5, $MoO_2(OSiMe_3)_2^-$], 379 [100, $MoN(OSiMe_3)_3^-$].

2.3. Method 2 (solution preparation)

$MoO_3 \cdot 2H_2O$ (0.189 g) was placed in a 25 ml round-bottomed flask along with a Teflon-coated magnetic stir bar. To this solution was added 7.0 ml of $HN(SiMe_3)_2$ and the mixture was heated to 358 K while stirring. The yellow solid dissolved in 15 min to give a pale yellow homogeneous solution. Further heating resulted in color change from yellow to orange and then finally to red–brown. The solution was stirred for 5 h at this temperature. The volatile was pumped off using a dynamic vacuum line to give a colorless plate-shaped crystalline solid slightly contaminated with a red–brown thick oil (0.363 g). Pure compound may be obtained by crystallization from the hexane solution at 253 K. Yield 87%. IR, ^1H and ^{13}C NMR results confirmed that the product is identical to the one described above.

2.4. Preparation of deuterated ammonia adduct of 1

ND_3 gas was bubbled through a hexane solution of **1** in a Schlenk flask for 5 min. The flask was sealed and placed in a freezer at 253 K overnight. The colorless crystalline solid formed was isolated the same way as **1**.

IR data (KBr): 3136 (m, br), 2954 (m), 2901 (m), 2538 (w), 2491 (w), 2370 (w), 2318 (w), 1612 (w, br), 1434 (m), 1402 (m), 1313 (m), 1310 (w), 1250 (s), 1052 (s), 1019 (m), 939 (s), 846 (vs), 819 (sh), 751 (s), 684 (m), 631 (m).

2.5. Preparation of $MoN(OSiMe_3)_3(py)$ (2)

$[MoN(OSiMe_3)_3(NH_3)]_2$ (**1**) (0.419 g) was dissolved in 5 ml of pyridine to give a dark yellow solution. The volatile was pumped off under dynamic vacuum at ambient temperature to give a pale yellow solid (0.452 g). *Anal. Calc.* for $C_{14}H_{32}N_2O_3Si_3Mo$: C, 36.8; H, 7.07; N, 6.14; Mo, 21.0. Found: C, 36.0; H, 6.83; N, 5.79; Mo, 20.9%. ^{1}H NMR 400 MHz (in toluene-d_8, 297 K, referenced to the solvent protio peak at 2.09 ppm): δ 0.26 (s, 27H, Me_3SiO), 6.54 (m, 2H, py), 6.88 (m, 1H, py), 8.38 (m, 2H, py). ^{13}C NMR 100.614 MHz (in toluene-d_8, 297 K, referenced to the solvent ^{13}C peak at 20.40 ppm): δ 1.39, 124.41, 137.97, 150.61. IR data (KBr): 3143 (w, br), 2959 (s), 2898 (m), 2837 (w), 2788 (w), 1993 (vw), 1932 (vw), 1870 (vw), 1606 (m), 1446 (s), 1399 (m), 1384 (m), 1355 (w), 1320 (w), 1219 (w), 1185 (vw), 1150 (w), 1069 (m), 1057 (s), 1044 (m), 1015 (m), 963 (s), 904 (vs), 882 (vs), 872 (vs), 838 (vs), 749 (s), 700 (m), 685 (m), 638 (m), 630 (sh), 486 (m), 458 (m). Mass data (m/z [% intensity, assignment]): 379 [100, $MoN(OSiMe_3)_3^-$].

2.6. Preparation of $[Mo_2N_2O(OSiMe_3)_4(py)_2]_2{\cdot}2py$ (3)

To the brown hexane solution after compound **1** was isolated (vide supra) was added 2.0 ml of pyridine to give a brown precipitate. The brown precipitate was filtered off twice through a coarse glass frit. The resulting filtrate was placed in a freezer at 253 K. Many block crystals formed overnight were filtered, washed with cold hexane (5 ml) and dried in dynamic vacuum to give a yellow crystalline solid (0.162 g). The yield was 8.45% based on the cocondensed MoO_3. *Anal.* Calc. for $C_{54}H_{102}Mo_4N_{10}O_{10}Si_8$: C, 39.1; H, 6.19; N, 8.44; Mo, 23.1. Found: C, 38.5; H, 6.50; N, 7.95; Mo, 22.6%. ^{1}H NMR 400 MHz (in toluene-d_8, 297 K, referenced to the solvent protio peak at 2.09 ppm): δ 0.06 (s, 36H, Me_3SiO), 0.25 (s, 36H, Me_3SiO), 6.80 (m, 12H, py), 7.01 (m, 6H, py), 8.82 (m, 12H, py). ^{13}C NMR 100.614 MHz (in toluene-d_8, 297 K, referenced to the solvent ^{13}C peak at 20.40 ppm): δ 1.41 (Me_3SiO), 2.36 (Me_3SiO), 123.83 (py), 130.58 (py), 150.69 (py). IR data (KBr): 3146 (vw), 3111 (sh), 3089 (sh), 3074 (m), 3041 (vw), 3020 (vw), 2999 (vw), 2954 (m), 2896 (m), 2827 (vw), 2802 (vw), 2470 (vw), 2087 (vw), 1990 (vw), 1953 (vw), 1872 (w), 1629 (w), 1598 (s), 1580 (w), 1573 (w), 1482 (m), 1444 (s), 1401 (m), 1384 (m), 1353 (w), 1313 (w), 1246 (vs), 1215 9s), 1150 (m), 1072 (m), 1051 (m), 1036 (s), 1026 (m), 1005 (s), 911 (vs), 835 (vs), 751 (s), 697 (s), 659 (vs), 650 (vs), 630 (s), 622 (s), 459 (s), 451 (s), 434 (vs). Mass data (m/z [% intensity, assignment]): 308 [62, $MoO_2(OSiMe_3)_2^-$], 379 [100, $MoN(OSiMe_3)_3^-$], 453 [5, $Mo(OSiMe_3)_3(HNSiMe_3)^-$], 527 [1, $Mo(OSiMe_3)_3(HNSiMe_3)_2^-$], 612 [1, $Mo_2O_4(OSiMe_3)_4^-$], 685 [2, $Mo_2O_3(OSiMe_3)_5^-$], 754 [1, $Mo_2N_2(OSiMe_3)_6^-$].

2.7. Preparation of $[Mo_4N_4O_2(OH)_8(H_2O)(CH_3OH)_3]$ (4)

Compound **1** (0.185 g) was dissolved in 2.0 ml of toluene. Addition of dried methanol (0.50 ml) to this solution caused a white precipitate to form in a few minutes. The mixture was set aside for a day at ambient temperature. The volatile was thoroughly pumped off for 2 days under dynamic vacuum at 10^{-3} Torr to give a white powder (0.085 g, yield 100%). *Anal.* Calc. for $C_3H_{22}N_4O_{14}Mo_4$: C, 4.99; H, 3.07; N, 7.76; Mo, 53.2. Found: C, 4.24; H, 3.06; N, 7.35; Mo, 54.0%. ^{1}H NMR 400 MHz (in DMSO-d_6, 297 K, referenced to the solvent protio peak at 2.49 ppm): δ 2.29 (s, 3H, CH_3OH), 3.16 (s, 9H, CH_3OH), 5.70 (s, br, OH, H_2O). IR (Nujol mull): 3157 (vs, br), 2733 (sh), 2684 (sh), 1676 (w), 1616 (w), 1400 (s), 1304 (m), 1158 (w), 1018 (s), 886 (vs), 857 (s), 720 (vs), 673 (s), 534 (m), 467 (m), 454 (m).

2.8. Preparation of deuterated methanol adduct of 4

The same procedure as described above was used. Compound **1** (62.4 mg) when reacted with CD_3OD (0.20 ml) gave 31.9 mg of a white solid after drying under dynamic vacuum. Selected IR data (Nujol mull): 1020 (s), 721 (vs), 669 (s).

3. Results and discussion

3.1. Synthesis and characterization

Vaporization of molybdenum trioxide under high vacuum and its condensation with an excess coreactant at 77 K (liquid nitrogen temperature) is expected to generate matrix-isolated four-coordinate, pseudo-tetrahedral $(MoO_3)_x$ species, where $x = 1–5$ [15]. The most abundant species are known to be trimer or tetramer, depending on the experimental condition of mass spectral studies [15]. Upon warming the cocondensate, the highly energetic coordinatively unsaturated oxo molybdenum species react with organosilane to produce various species. One of the initially formed products could be a ligand coordinated species such as $MoO_3[HN(SiMe_3)_2]_x$, where $x = 1$ or 2. However, as the temperature increases, the trimethylsilyl groups can migrate to the more nucleophilic oxygen sites of MoO_3,

presumably due to the oxophilicity of the silyl group. Here, the bond energies for N–Si versus O–Si play an important role [16]. Previously, this kind of reaction was observed by Nugent et al. [17]. They rationalized this facile rearrangement due to the differences in N–Si and O–Si bond energies and the relief of steric repulsion in the congested bis(trimethylsilyl)amido group. However, Lam et al. reported that CrO_2Cl_2 reacted with HMDS produced $CrO_2[N(SiMe_3)_2]_2$, but MoO_2Cl_2 reacted with HMDS instead produced $Mo(NSiMe_3)_2(OSiMe_3)_2$ [18].

Hexamethyldisilazane, when reacted with MoO_3, is expected to generate, depending on the reaction condition, various metal-bound moieties, such as bis(trimethylsilyl)amido, trimethylsilylamido, trimethylsilylimido, ammonia, amido, imido, and nitrido groups. In particular, the nitride ion (N^{3-}), isoelectronic to oxide ion (O^{2-}), can function as a strong π bonding ligand showing structural diversity [1,2].

In our case, the most abundant isolable molecular product was the fully silylated nitrido compound, $[MoN(OSiMe_3)_3(NH_3)]_2$ (1) (Eq. (1)).

$$MoO_3 + HN(SiMe_3)_2 \rightarrow [MoN(OSiMe_3)_3(NH_3)]_2 + Mo_2N_2O(OSiMe_3)_4 \quad (1)$$

The coordinated ammonia is definitely from the degraded HMDS. The identity of ammonia in **1** was confirmed by several lines of evidence. First, the ^1H NMR spectrum of **1** in deuterated benzene showed a broad singlet at 1.80 ppm. Secondly, the ^{13}C NMR spectrum showed a single peak that is assigned to Me_3SiO and therefore the peak at 1.80 ppm in the ^1H NMR spectrum is from a non-carbon moiety. Thirdly, the IR spectrum of **1** showed four stretches at 3156, 3234, 3350, and 3401 cm^{-1}, of which two or three bands can be assigned to the N–H stretches of the coordinated NH_3[2].

To make positive identity, the deuterated ammonia adduct of **1** was prepared. In the IR spectrum of the ND_3-**1**, these peaks shifted to 2318, 2370, 2491, and 2538 cm^{-1}, while maintaining the identical peak pattern. The ν(H/D) ratio is $1.35 + 0.01$. (The differences in peak positions are 850 ± 13 cm^{-1}.) The most convincing evidence came from the X-ray crystallographic work in which all three hydrogen atoms were observed around the nitrogen atom (vide infra).

[2] K. Nakamoto, Infrared and Raman Spectra of Inorganic and Coordination Compounds, Wiley, New York, 1986, pp. 191–196. (b) As one of the referees pinpointed, there must be only two (A_1, E) stretching modes for the local C_{3v} symmetry and three modes at lower symmetry (C_1 or C_s) for the coordinated ammonia in **1**. We fully agree with the referee's opinion that the nitrido moiety of **1** can partially be hydrolyzed to give imido- or less likely amido-containing by-product(s). However, because the presence of the coordinated ammonia was definitely confirmed by the X-ray work, we did not further follow the reactivity and IR studies for **1**.

The pyridine adduct $MoN(OSiMe_3)_3(py)$ (**2**) was quantitatively prepared by replacing the coordinated ammonia with pyridine shown in Eq. (2).

$$[MoN(OSiMe_3)_3(NH_3)]_2 + py \ (xs) \rightarrow 2MoN(OSiMe_3)_3(py) + 2NH_3 \quad (2)$$

Recently this compound was prepared in 27% yield by reacting MoO_2Cl_2(dme) (dme = dimethoxyethane) with hexamethyldisilazane, followed by pyridine addition, and its X-ray structure was reported by Chiu et al. [19]. This compound showed only one type of Me_3SiO in the ambient temperature ^1H and ^{13}C NMR spectra.

Another product after isolation of **1** was the mixed oxo-bridged nitrido molybdenum siloxy species, i.e. $[Mo_2N_2O(OSiMe_3)_4]$. This four-coordinate oxo-bridged species is further stabilized by pyridine and was isolated as a crystalline material from the hexane solution. See Eqs. (1) and (3). Attempts to prepare this compound by reacting **1** with excess pyridine, as shown in Eq. (4), was unsuccessful, instead the pyridine adduct **2** was isolated (vide supra). Compounds **1** and **2** showed interesting fluxional behavior in toluene solution (vide infra).

$$2Mo_2N_2O(OSiMe_3)_4 + py \ (xs.) \rightarrow [Mo_2N_2O(OSiMe_3)_4(py)_2]_2 \quad (3)$$

$$2[MoN(OSiMe_3)_3(NH_3)]_2 + py \ (xs.) \not\rightarrow [Mo_2N_2O(OSiMe_3)_4(py)_2]_2 + 2(Me_3Si)_2O + 4NH_3 \quad (4)$$

The reaction of $Mo(N)(O\text{-}t\text{-}Bu)_3$ with less bulky alcohols produced alcoholysis products [7a]. To test the alcoholysis reaction for **1**, we performed the reaction with various alcohols. ^1H NMR tube reactions of **1** with ROH (R = H, Me, Et, *i*-Pr, *n*-Bu, *t*-Bu) in a hydrocarbon solvent showed quantitative generation of Me_3SiOR and white microcrystalline precipitates. The reaction rate seems to be inversely proportional to the bulkiness of the R group of ROH. For example, it took 38 h for the completion of the reaction with EtOH, but 1 week for the reaction with *t*-BuOH at ambient temperature. As observed, **1** reacted with excess methanol and produced a hydroxo oxonitrido compound, as shown in Eq. (5).

$$4[MoN(OSiMe_3)_3(NH_3)] + 15MeOH \rightarrow Mo_4N_4O_2(OH)_8(MeOH)_3(H_2O) + 12Me_3SiOMe + H_2O + 4NH_3 \quad (5)$$

The presence of a nitrido group in the product was deduced from the presence of a strong Mo≡N stretch at 1018 cm^{-1}. The two IR bands at 720 and 670 cm^{-1} might be due to the asymmetric and symmetric Mo–O–Mo stretches. The presence of the coordinated methanol and water was confirmed by ^1H NMR and elemental analysis. The IR spectrum of the deuterated

methanol adduct showed a similar spectral pattern, indicating the IR peak assignment for the oxonitrido Mo skeleton is correct (see Section 2).

Since the yield of **1** from the cocondensation reaction was merely 14.5%, we continued further to develop an alternative high yield synthesis. A high yield one-pot synthesis of **1** was achieved by reacting $[MoO_3]\cdot 2H_2O$ [12] with hexamethyldisilazane without employing additional solvent at 358 K (85°C, typically 60–80% yield, see Eq. (6)). Therefore, the preparation of the pyridine adduct **2** starting from this compound is a better synthetic protocol in terms of yield than the one (27%) described by Chiu et al. [19].

$$MoO_3\cdot 2H_2O + HN(SiMe_3)_2 \text{ (xs.)} \rightarrow [MoN(OSiMe_3)_3(NH_3)]_2] \quad (6)$$

3.2. IR spectroscopy

The characteristic trend of the Mo≡N IR stretches [2] of the title compounds is noteworthy. Compound **1** in the solid state showed a strong sharp peak at 1049 cm^{-1}, assignable to the Mo≡N stretch (ND_3-**1** showed the band at 1052 cm^{-1}). Compound **2** showed the band at 1057 cm^{-1} in the solid state (Chiu et al. reported the band at 1059 cm^{-1} in hexane solution [19]). Compound **3** showed the band at 1036 cm^{-1}. However, the deca (oxo/hydroxo) tetranitrido Mo complex **4** showed the band at 1018 cm^{-1} (1020 cm^{-1} for the deuterated methanol adduct). Compound **2** showed the highest stretching frequency and then **1**, **3**, and **4** followed in descending order. Clearly this trend reflects the relative Mo≡N bond strength. The Mo≡N bond in monomeric **2** is the strongest since there is no *trans* ligand competing with the Mo≡N triple bond, as observed in the X-ray structure [19]. Compound **1** is ranked second because only the datively bonded [20] bridging siloxy group (2.65 Å, vide infra), which is *trans* to the nitrido group, minimally competes with the Mo≡N bond. Then, because **3** and **4** possess bent Mo≡N→Mo bonds and also *trans* ligands, the Mo≡N stretches were even lower. Compound **4** is assumed to have more basic oxygen atoms (oxo and hydroxo groups) compared with **3**. Therefore, they compete more for π bonding with the Mo≡N bonds, thereby giving the lowest frequency value. The Mo≡N band positions in these closely related compounds are internally consistent and, consequently, show the subtle relative order of the bond strength.

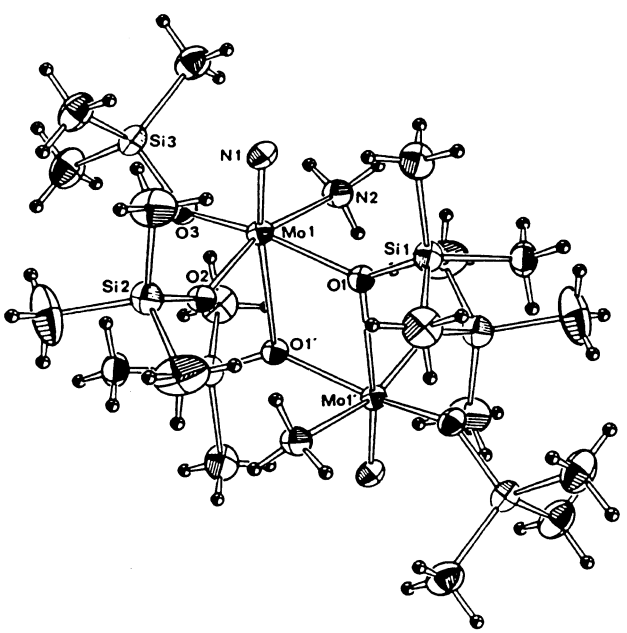

Fig. 1. ORTEP drawing of **1** showing 20% thermal ellipsoids for the non-hydrogen atoms. Selected bond distances (Å) and angles (°): Mo1–N1, 1.626(6); Mo1–O3, 1.920(5); Mo1–O2, 1.922(4); Mo1–O1, 1.981(4); Mo1–N2, 2.272(6); Mo1–O1′, 2.669(4).

3.3. Molecular structures

Transition metal nitrido complexes show various structural types [1,2]. There appeared monomeric complexes with coordination numbers ranging from 4 to 6 depending upon the bulkiness of the attached ligand [21]. The entities with coordination number five showed two possible structures, namely tetragonal pyramid (TP) and trigonal bypyramid (TBP). Di-, tri-, and tetranuclear complexes can possess either nitrido-bridged or ligand-bridged geometry with coordination number 5 or 6. Some complexes show a nitrido-bridged linear chain structure, examples are the five-coordinate nitrido alkoxides, $MN(OR)_3$ (where M = Mo, W; R = *i*-Pr, *t*-Bu) in solid state [7a–c].

When the hypothetical four-coordinate nitridoalkoxide is further supported by a coordinating ligand, either a monomeric five-coordinate structure or a dimeric six-coordinate structure is expected. The association mode is also either through nitrido- or ligand-bridges. A tetrameric rectangular nitrido structure is exclusively observed for the nitrido molybdenum halide complexes [22].

A brief description of structures [14] of the title complexes was published elsewhere [11c]. Herein, we only wish to describe the information that is relevant and necessary for the subsequent solution NMR discussion. Title complex **1**, shown in Fig. 1, is the first structurally characterized siloxo-bridged dinuclear nitrido molybdenum compound. (Chisholm et al. reported the *t*-$BuMe_2SiO$-bridged dinuclear tungsten compound, but no X-ray structure was reported [9].)

The molecule possesses crystallographically imposed C_i symmetry and is composed of two fragments of five-coordinate $Mo(N)(OSiMe_3)_3(NH_3)$ (TP structure). The nitrido group is situated at the apical position with a Mo–N distance of 1.626(6) Å. The Mo–O distance of

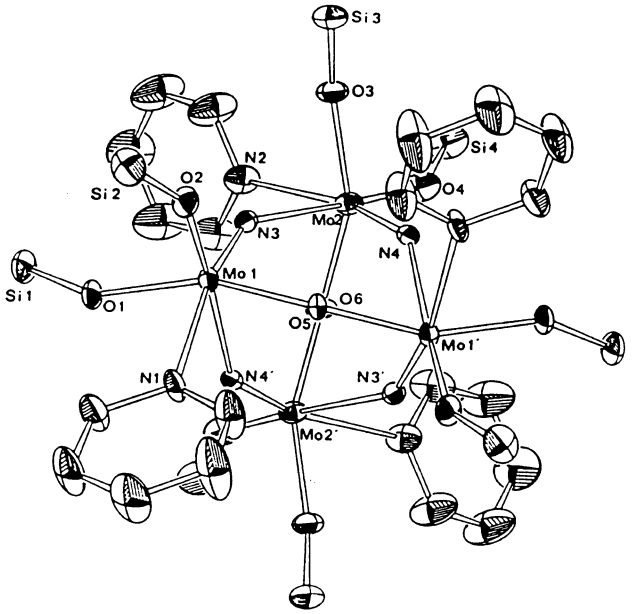

Fig. 2. ORTEP drawing of **3** showing 20% thermal ellipsoids. Hydrogen and methyl carbon atoms are omitted for clarity. Selected bond distances (Å) and angles (°): Mo1–N3, 1.680(7); Mo1–O5, 1.904(3); Mo1–O2, 1.915(6); Mo1–O1, 1.922(6); Mo1–N4′, 2.155(7); Mo2–N4, 1.685(7); Mo2–O6, 1.911(3); Mo2–O3, 1.914(6); Mo2–O4, 1.902(7); Mo2–N3, 2.157(7).

the terminal siloxy group *trans* to ammonia is 1.922(4) Å and the one *trans* to the bridging siloxy group is 1.920(5) Å. The bond distance of the bridging siloxy group is 1.981(4) Å, which is 0.06 Å longer than those of the terminal ones. This discrepancy clearly shows the bonding competition of the siloxo oxygen of the bridging siloxy moiety by the two Mo atoms.

The long Mo1–O1′ distance (2.669(4) Å) indicates a weak dative bond [20] exists in the dimer. This weak bond is easily broken in hydrocarbon solution even at ambient temperature, as evidenced by a sharp singlet from $OSiMe_3$ in the ^1H and ^{13}C NMR spectra (vide infra). This weak bond in the solid state results from the *trans* influence [23] exerted by the strongly π bonding Mo≡N group.

The molecule has a $Mo_2N_4(\mu_2\text{-}O)_2O_4$ core that was observed in the nitrosyl compound $Mo_2(NO)_2(O\text{-}i\text{-}Pr)_6(HNMe_2)_2$ [24]. A similar structure composed of an alkoxy bridge, but with TBP structure, was observed in the alkylidyne tungsten complex, $[W(\equiv CMe)(O\text{-}t\text{-}Bu)_3]_2$ [7b,c], and nitrosyl chromium alkoxide, $Cr_2(NO)_2(O\text{-}i\text{-}Pr)_6$ [25]. $Mo_2(NO)_2(OR)_6$, where R = *t*-Bu, *i*-Pr, Np, shows fluxionality in NMR spectroscopy with a 2:1 ratio of alkoxy groups at frozen-out temperature [26].

Although we were unable to grow X-ray quality crystals of **2**, recently Chiu et al. reported the X-ray structure [19]. The structure was shown to be monomeric and is in a distorted tetragonal pyramidal environment with an apical Mo≡N bond [19]. For this compound, we were able to confirm that monomeric nature persists in hydrocarbon solution by using the VT solution NMR study (vide infra).

An ORTEP drawing of **3** is given in Fig. 2. This is the first example, to our knowledge, of a transition metal cage compound supported both by μ_2-O and μ_2-N bridges [27].

The molecule possesses C_2 point group symmetry. The bridging N and O atoms are placed on the plane that contain two Mo atoms and the centeroid of the Mo_4 tetrahedron. This perfect Mo_4 tetrahedron clearly shows the bridging nature of N and O atoms in the molecule. The asymmetric bond distances of Mo–N of nitrido groups [1.69(1) and 2.15(1) Å] are similar to the values observed for the cyclic halide tetramers of $[MoNX_3(L)]_4$ [22]. In contrast to the asymmetric bond distances for Mo≡N, the molecule possesses two totally symmetric Mo–O [1.91(1) Å] bridges. In a mono oxo bridged imido Mo compound $Mo_2(=NH)_2(\mu\text{-}O)_2(Np)_6$ [28a], a Mo–O distance of 1.956(4) Å was reported. This bridging bond is slightly longer than ours because it is *trans* to the doubly bonded imino group. The Mo–N(py) bond distance (2.47 Å avg.) is quite long compared with those of other molybdenum compounds including **2** (2.287 Å, *cis* to Mo≡N bond [19]), which is again a consequence of *trans* influence [23] of the nitrido group. This molecule can be viewed as a paired entity of the five-coordinate oxo-bridged dinuclear fragments formed in a cross-wise manner exclusively through the bent Mo≡N → Mo bonds. For the stability of **3** in a hydrocarbon solution at ambient temperature, refer to Section 3.4.

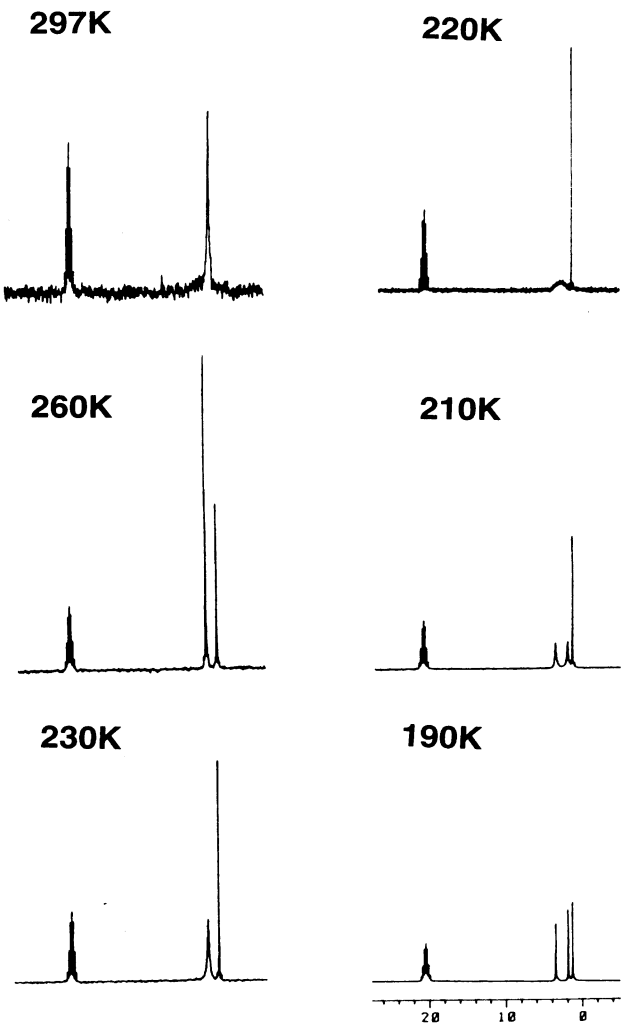
3.4. Variable temperature NMR work

To understand the solution structures, a variable temperature NMR study of **1**–**3** was undertaken. Variable temperature ^{13}C NMR spectra of **1** in toluene-d_8 are shown in Fig. 3.

At 297 K, a sharp single resonance was observed in both ^1H and ^{13}C NMR spectra. (Proton NMR is not shown.) This is in contrast to the solid state dimeric structure as determined by single crystal diffraction work in which three types of trimethylsiloxy group are present. This can be understood by the fact that the weak dative bond between Mo and the bridging siloxo group (2.67 Å) is easily broken in solution (vide supra). Again the NMR observation does not fit with the tetragonal pyramidal structure (half of the solid state structure).

Only two situations are consistent with this NMR observation; the solution structure is either a frozen mononuclear trigonal bypramid (TBP) with three equatorial siloxy groups or a tetragonal pyramid (TP) structure rapidly interconverting through trigonal bypyramidal (TBP) intermediacy on the NMR time scale. It is

well known that the energy gap between TBP and tetragonal pyramidal (TP) structures is very narrow [6a]. Therefore, it is quite likely that the latter is a more plausible description. Lowering the solution temperature confirms this. At 273 K, the singlet becomes broad ($fwhh = 19$ Hz for the ^{1}H NMR) and, at 260 K, it splits into two peaks with an integral ratio of 1:2. The more sensitive ^{13}C NMR peak also becomes a doublet with 1:2 intensity ratio at 273 K. This indicates that the tetragonal pyramidal structure was frozen at this temperature and the TBP structure is slightly lower in energy than the tetragonal pyramidal one (see Scheme 1).



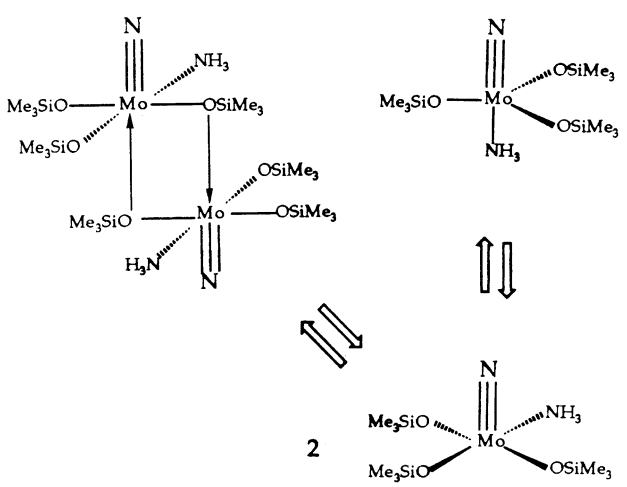


Fig. 3. Variable temperature ^{13}C NMR spectra of **1** in toluene-d_8. Asterisks denote methyl carbon of toluene solvent.

Scheme 1.

Calculation of rate constant for this well known pseudorotation process [28] using the equation [30], $k = 2.22\ \Delta\nu$, for these uncoupled exchanging carbons ($\Delta\nu = 140$ Hz) gave $k = 311\ s^{-1}$. By using the well established relationship between k and $\Delta G^{\neq}$ [29] (Eq. (7)),

$$\Delta G^{\neq} = 4.58 T_c[10.32 + \log(T_c/k)]\ \text{cal mol}^{-1} \quad (7)$$

where $T_c = 279$ K, $k = 311\ s^{-1}$, $\Delta G^{\neq} = 13.1$ kcal mol^{-1} was obtained. This value is about 10 kcal mol^{-1} higher than the theoretically calculated energy for the TBP↔TP interconversion (Berry pseudorotation) of transition metal-nitrido compounds [6a]. This discrepancy may be, albeit in part, due to the steric hindrance arising from site exchange of the bulky trimethylsiloxy groups.

Further cooling of the solution of **1** revealed the monomer↔dimer equilibrium. At around 215 K, the peak with intensity 2 coalesced and further lowering the temperature showed that two peaks with equal intensity appeared ($\Delta\nu = 160$ Hz in ^{13}C NMR) down to the limiting lowest temperature of the solvent, i.e. 190 K. Using the same equations, we can obtain the rate constant and activation free energy values for this rare monomer↔dimer equilibrium: $k = 355\ s^{-1}$ and $\Delta G^{\neq} = 9.9$ kcal mol^{-1}. This final NMR observation and the interpretation is totally consistent with the solid state molecular structure (vide supra) (see Scheme 1). Interestingly, the NMR spectra of **1** in CD_2Cl_2 showed that only two peaks with an integral ratio of 2:1 persist down to 190 K, the same behavior observed for **2** (vide infra). This is presumably due to the solvent effect.

Compound **2** was also subjected to a VT NMR study (in toluene-d_8) to compare its behavior with that of **1**. In a similar condition, the ^{1}H and ^{13}C NMR spectra showed a singlet as the temperature lowered and coalesced at around 253 K. Below this temperature two peaks with an intensity ratio of 1:2 grew up and the spectral pattern did not change down to the solvent limiting temperature of 190 K. The peak separation of 64 Hz in the ^{1}H NMR spectrum gave $k = 142\ s^{-1}$ and $\Delta G^{\neq} = 12.2$ kcal mol^{-1}. This value is somewhat lower than that of **1**. The reason that **2** did not form a dimer is quite obvious from the solid state X-ray structure [19]. In **2**, the coordinated pyridine molecule exerts bulkiness and the metal center is more crowded than **1**.

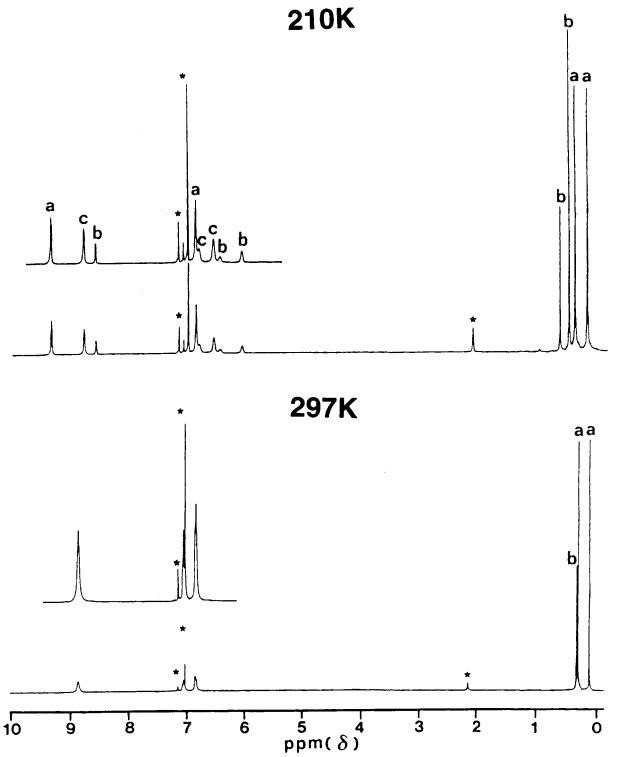

Fig. 4. Variable temperature ^{1}H NMR spectra of **3** in toluene-d_8. Asterisks denote protio peaks of toluene solvent.

Another interesting feature of the ^{1}H NMR pattern with regard to that of **1** is in the reversal of the peak intensity (2:1 for **1** and 1:2 for **2** from downfield side). This may be ascribed to the diamagnetic anisotropy exerted by the ring current effect of the coordinated pyridine compared the coordinated ammonia. The NMR spectral patterns of **1** and **2** are totally reversible in the temperature range.

The ^{1}H VT NMR spectra of tetranuclear oxonitrido complex **3** are shown in Fig. 4.

The spectrum at 297 K shows two peaks with equal intensity in the Me_3SiO region. However, with time, another peak in the downfield side grew up with concomitant intensity decreases in the two upper field peaks. Lowering the temperature made the downfield peak at 0.273 ppm coalesce and the peak split into two peaks with 1:2 intensity ratio. This behavior is exactly the same as observed for **2** (vide supra), therefore this species can be safely assigned to **2**.

The peak intensity and pattern of the remaining two peaks at 0.061 and 0.247 ppm with 1:1 intensity remained unaltered. These peaks can be assigned to **3** and are consistent with the solid state X-ray structure in which two types of siloxy groups present; one *trans* to bridging oxygen and the other *trans* to nitrido moiety (vide supra). The low temperature NMR spectra obtained with time confirmed these assignments. With the elapse of time, the two upfield equal intensity peaks were decreased with the concomitant intensity increases in the downfield 1:2 intensity peaks.

Even more interesting is the presence of three types of pyridine peaks that are frozen out in ^{1}H and ^{13}C NMR spectra [30]. Down to 270 K, only a single type of pyridine was observed, indicating fast exchange in the NMR time scale. However, below this temperature the pyridine resonance become broad and at around 230 K three types of pyridines have emerged. The far downfield resonance marked as (a) in Fig. 4 is assigned to **3**. The other two types are from the disproportionation reaction; the resonance marked (b) can be assigned to **2** and those marked (c) belong to a purely inorganic Mo (VI) cluster-pyridine adduct, which does not contain a siloxy group. This slow disproportionation reaction can be written as in Eq. (8).

$$3[Mo_2N_2O(OSiMe_3)_4(py)_2]_2\cdot 2py \rightarrow 8MoN(OSiMe_3)_3(py) + [Mo_2N_2O_3(py)_4]_2 + 2py \quad (8)$$

The assignments were easily made by comparison with the VT NMR spectra of authentic **2** and the time-dependent intensity behavior (increases and decreases) of the VT NMR spectra of **3**. This disproportionation is not due to hydrolysis because no hexamethyldisiloxane or trimethylsilanol, the expected hydrolysis products, were observed in the aged solution spectra. In addition, no precipitate was formed and no peak from trimethylsiloxy resonance was observed for the aged solution other than those from **2** and **3**.

It is interesting to note that trimethylsiloxy groups can easily migrate from one metal center to another even at ambient temperature. This implicates that **3** is thermally unstable. The addition of pyridine did not alter the reaction course and rate of this disproportionation reaction.

4. Conclusions

The cocondensation reaction of molybdenum trioxide with hexamethyldisilazane produced several structurally interesting nitrido (oxo) molybdenum (6+) siloxides of which some interesting complexes were isolated and characterized. These complexes show subtle differences in dynamical solution structures in hydrocarbon and render some insight into the energetics of the well known pseudorotation and the monomer↔dimer association processes.

5. Supplementary material

X-ray data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge,

CB2 1EZ, UK on request quoting the reference codes, KANNIW (for **1**) and KANNOC (for **3**).

Acknowledgements

We thank Mr Roger Konhert for the help in the VT NMR work and Mr Brian Arbogast for the mass spectral work.

Abstract

The complexes *fac*-$[M(CO)_3L^3]$ (M = Mo or W, $L^3 = MeC(CH_2SMe)_3$, $MeC(CH_2SeMe)_3$ or $MeC(CH_2TeMe)_3$) have been prepared from $[M(CO)_3(MeCN)_3]$ and characterised by analysis, FAB mass spectrometry, IR, ^1H, $^{13}C\{^1H\}$, ^{77}Se, ^{125}Te and ^{95}Mo NMR spectroscopies. The complexes are prone to decomposition in solution into tetracarbonyls, and attempts to isolate $[Cr(CO)_3L^3]$ have been unsuccessful. The complexes *cis*-$[Cr(CO)_4\{\eta^2\text{-}MeC(CH_2SMe)_3\}]$, *cis*-$[Mo(CO)_4(\eta^2\text{-}MeC(CH_2SeMe)_3\}]$ and the robust $[M(CO)_4(S_3)]$ (M = Cr, Mo or W, S_3 = 1,4,7-trithiacyclononane or 1,4,7-trithiacyclodecane) have been similarly characterised. © 2000 Elsevier Science Ltd. 1. Introduction

We have been exploring the chemistry of tridentate seleno- and telluro-ether ligands with a variety of metal centres including both homoleptic and halocomplexes with Pd(II), Pt(II), Rh(III) and Ir(III) [1,2], Ru(II) [3], Rh(I) and Ir(I)-olefin and diene complexes [4], and homoleptic Cu(I) and Ag(I) [2]. Carbonyl complexes have received less attention and reports are currently limited to our studies of *fac*-$[M(CO)_3(\text{tridentate})]^+$ (M = Mn or Re) [5]. Here we report studies of Group 6 carbonyl derivatives of $MeC(CH_2SeMe)_3$ (tse) and $MeC(CH_2TeMe)_3$ (tte) (Fig. 1) and we include corresponding studies with $MeC(CH_2SMe)_3$ (tth) and two S_3-donor macrocycles [9]aneS_3 (1,4,7-trithiacyclononane) and [10]aneS_3 (1,4,7-trithiacyclodecane) to permit comparisons between the Group 16 donors. These complexes are the first triselena- or tritellura-ligand complexes of these metal carbonyls, but several trithioether systems have been described in the literature. These include $[Mo(CO)_3([14]aneS_4)]$, $[Mo(CO)_3([16]aneS_4)]$, $[\{Mo(CO)_3\}_2([18]aneS_6)]$ and $[\{W(CO)_4\}_2([18]aneS_6)]$ in which the thioether is assigned as either tri- or bi-dentate [6,7]. Yoshida and co-workers [8] have reported the preparation of $[Mo(CO)_2(L)]$ (L = 3,3,7,7,11,11,15,15 - octamethyl - 1,5,9,13 - tetrathiacyclohexadecane) and the bis-dinitrogen derivative $[Mo(N_2)_2(L)]$ [9], both of which have been structurally characterised. $[Mo(CO)_3([9]aneS_3)]$ is well established and has been structurally characterised [10], showing *fac* tridentate ligation of the thioether, Mo–S = 2.504(6)–2.543(7) Å, Mo–C = 1.93(2)–1.97(2) Å. Indeed this species is involved in the template synthesis of [9]aneS_3 [11] and similar routes yield C-func-

tionalised derivatives of [9]aneS_3 [12]. Other trithioether complexes have been reported [13–15]. The results of the present studies may also be compared with those from our previous work on [$M(CO)_4$(bidentate)] (bidentate = various dithio-, diseleno- and ditelluro-ethers) [16].

2. Results and discussion

2.1. Tripodal ligand complexes

Although Group 6 carbonyl complexes are often regarded as among the more stable low valent complexes, the *fac*-[$M(CO)_3L^3$] of $L^3 = MeC(CH_2SMe)_3$ (tth), $MeC(CH_2SeMe)_3$ (tse) and $MeC(CH_2TeMe)_3$ (tte) proved surprisingly difficult to isolate in the pure state, and prone to decomposition in solution, and as a result considerable care was necessary both in the syntheses and in obtaining reliable spectroscopic data. For M = Mo or W, the starting materials in each case were the nitrile complexes [$M(CO)_3(MeCN)_3$] [17] made in situ from the hexacarbonyls in MeCN, which were treated with the ligand tth. After stirring at room temperature overnight, the solvent was removed in vacuo, the complex extracted with dry CH_2Cl_2, filtered and the solvent removed. The resulting solid was washed with diethyl ether which extracts any tetracarbonyl complex present, leaving the [$M(CO)_3$(tth)] in moderate yield. The identity of the products as *fac*-tricarbonyls follows from the two $\nu(CO)$ stretches at ca. 1930 and 1810 cm^{-1} (Table 1) (theory $a_1 + e$), the FAB mass spectra which show parent ions with the correct isotope patterns, and microanalysis. The solids appear stable under nitrogen for several weeks, but the complexes are surprisingly unstable in solution. A freshly prepared $CDCl_3$ solution of [$Mo(CO)_3$(tth)] exhibits a simple ^1H NMR spectrum with singlets at δ 1.15 (MeC), 2.1 (MeS) and 2.45 (CH_2); however, on standing some brown solid precipitates and new resonances appear, some of which can be

associated with uncoordinated tth (δ 0.95, 2.0 and 2.5). The $^{13}C\{^1H\}$ NMR spectrum obtained from CH_2Cl_2–$CDCl_3$ solution at 300 K is also more complex than expected for $[Mo(CO)_3(tth)]$, and changes with time. The $^{13}C\{^1H\}$ NMR spectrum was also obtained at 240 K which slowed, but did not stop the decomposition. From a freshly prepared solution immediately cooled to 240 K, the major $^{13}C\{^1H\}$ resonances are attributable to $[Mo(CO)_3(tth)]$ and occur at δ 221.0 (CO), 44.3 (CH_2), 41.6 (C), 27.7 (MeS) and 24.0 (MeC). Much weaker features at δ 44.2 (CH_2), 18.0 (MeS), are associated with free tth, and other features at 216, 208 (CO), 44.1 and 18.5 (MeS) are attributed to the tetracarbonyl *cis*-$[Mo(CO)_4(\eta^2\text{-tth})]$, (the MeC and C resonances are not resolved from those in the tricarbonyl). After the solution had stood for some hours at room temperature, the $^{13}C\{^1H\}$ NMR resonances associated with the *fac*-tricarbonyl had greatly diminished and the free tth and the tetracarbonyl were the major species present. A ^{95}Mo NMR spectrum of freshly prepared $[Mo(CO)_3(tth)]$ solution at 300 K[1] had $\delta = -1138$, but this disappeared on standing, and a new resonance at -1283 grew in. The latter value is close to that observed [16] for $[Mo(CO)_4(MeSCH_2CH_2CH_2SMe)]$ (-1294), consistent with the generation of a tetracarbonyl complex. Confirmation came from an IR spectrum of the final solution used to record the $^{13}C\{^1H\}$ NMR spectrum, which showed ν(CO) at 2024, 1911, 1885(sh) and 1858 cm^{-1}, which may be compared with similar values 2023, 1910, 1895(sh), 1856 cm^{-1} in $[Mo(CO)_4(MeSCH_2CH_2CH_2SMe)]$ [16]. It is thus clear that whilst pure *fac*-$[Mo(CO)_3(tth)]$ can be isolated, it decomposes readily in solution into *cis*-$[Mo(CO)_4(\eta^2\text{-tth})]$, tth and an unidentified brown solid. The analogous *fac*-$[W(CO)_3(tth)]$ was isolated as a pale brown solid and thoroughly characterised (Table 1), and shows similar but slower decomposition to tth and a tetracarbonyl complex in CH_2Cl_2 solution. Pyramidal inversion at sulfur is fast on the NMR timescales in thioether complexes of Group 6 carbonyls [16,18] but exchange between the free and coordinated MeS groups in the tetracarbonyls is not observed in the NMR spectra.

The instability of the *fac*-tricarbonyl complex was greatest in the chromium–tth system. The reaction of $[Cr(CO)_3(MeCN)_3]$ in situ in MeCN with tth gave a yellow solution which contained *fac*-$[Cr(CO)_3(tth)]$, identified by ν(CO) modes at 1926, 1812 cm^{-1}. However repeated attempts to isolate a pure sample of the solid *fac* complex have been unsuccessful, either from this solution, or using pre-isolated $[Cr(CO)_3(MeCN)_3]$ in benzene [15]. Work up of such solutions gave some green solid, large amounts of yellow $[Cr(CO)_4(\eta^2\text{-tth})]$ which was isolated and is described below, and free tth. An alternative route via $[Cr(CO)_6]$, tth and $NaBH_4$ in ethanol [19], which was successful for the macrocyclic thioethers (below), gave only green decomposition products in this case. The instability of *fac*-$[Cr(CO)_3(tth)]$ is in keeping with the facile decomposition of the heavier analogues W < Mo (≪ Cr), but is surprising when compared with the recently isolated *fac*-$[Cr(CO)_3\{MeSi(CH_2SMe)_3\}]$ [15] which has been structurally characterised.

The $[M(CO)_3L^3]$ (M = Mo or W, L^3 = tse or tte) were isolated as pale brown (Mo) or brown (W) powders from reaction of the appropriate $[M(CO)_3(MeCN)_3]$ with the ligand in MeCN, any tetracarbonyl impurity being washed out with diethyl ether. The IR and NMR spectroscopic data are given in Table 1. *fac*-$[Cr(CO)_3(tse)]$ was made in solution from $[Cr(CO)_3(MeCN)_3]$ and identified in situ by ν(CO) bands at 1923, 1812 cm^{-1}, but as with the tth analogue we have not so far been able to isolate a pure solid sample due to its facile decomposition to the tetracarbonyl. The $[Mo(CO)_3(tse)_3]$ partially decomposes in CH_2Cl_2 solution at 300 K to *cis*-$[Mo(CO)_4(\eta^2\text{-tse})]$, tse (identified by a combination of ^1H, $^{13}C\{^1H\}$ NMR and IR spectroscopies) and an unidentified brown precipitate. Decomposition is very slow at 240 K and at this temperature the $^{13}C\{^1H\}$ NMR data (Table 1) and a single ^{77}Se resonance at δ 81 (free tse has δ = 23) are assignable to the *fac*-tricarbonyl. The *fac*-$[W(CO)_3(tse)]$ behaves similarly. The complexes of the tritelluroether *fac*-$[M(CO)_3(tte)]$ (M = Mo or W) are the most stable of the series, showing no decomposition in CH_2Cl_2 at 240 K during the several hours taken to record $^{13}C\{^1H\}$ NMR spectra. At ambient temperatures in CH_2Cl_2, some decomposition is evident after several hours with weak features in the NMR spectra attributable to tetracarbonyls and some dark precipitate, but in contrast to the other systems, the free ligand (tte) is not present in detectable amounts. It is also notable that only a single *fac*-tricarbonyl species is present in the telluroether complexes. Previous studies of $[M(CO)_4(bidentate)]$ (bidentate = dithio-, diseleno- or ditelluroether) [16] have shown that whilst pyramidal inversion at the Group 16 atom is fast at 300 K (on the NMR timescale) for dithioethers and for some diselenoethers, the barriers are much higher for tellurium inversion, and thus we would expect to see invertomers in the last case. For a *fac*-

[1] Previous studies [16,18] have shown that ^{95}Mo NMR resonances in related complexes broaden rapidly when the samples are cooled, probably due to the substantial quadrupole moment, and spectra are best obtained at ambient temperatures.

$[M(CO)_3\{MeC(CH_2TeMe)_3\}]$ complex two invertomers are expected with *sym* or *anti* methyl groups [5], but only a single form with one δ(Te) and one δ(^{13}C–TeMe) was found (the *sym* isomer). It would appear that only the *sym* invertomer (with a propeller-like arrangement of Me groups) is present in significant amounts in the tte, and probably the tse complexes. We note that in the $[M(CO)_3L^3]^+$ (M = Mn or Re) [5] and $[Ru(L^3)_2]^{2+}$ [3] the NMR spectra, and in several cases X-ray crystallographic data have identified only *sym* invertomers, and $[M(CO)_3\{MeSi(CH_2SMe)_3\}]$ are also *sym* in the solid state [15].

We have described detailed studies of $[M(CO)_4$(bidentate)] elsewhere [16], and the tetracarbonyl complexes formed by η^2-coordination of the tripodal ligands are not fundamentally different. For comparison we describe two examples, *cis*-$[Cr(CO)_4(\eta^2$-tth)] and *cis*-$[Mo(CO)_4(\eta^2$-tse)]. The chromium complex was isolated during attempts to prepare the tricarbonyl from $[Cr(CO)_3(MeCN)_3]$, and $[Mo(CO)_4$(tse)] from reaction of $[Mo(CO)_4((MeCN)_2]$ and tse. The spectroscopic data (Table 1) are, as expected, very similar to those of the corresponding *cis*-$[M(CO)_4\{MeE(CH_2)_3EMe\}]$ (M = Cr E = S, M = Mo E = Se) [16], which also contain six-membered chelate rings, with extra NMR features due to the free arm of the tripodal ligand. In contrast to the *fac*-$[M(CO)_3(L_3)]$ these tetracarbonyls appear stable both in the solid state and in solution.

2.2. S_3 macrocycles

In contrast to the tripodal complexes described above, the macrocyclic thioether complexes proved quite robust, although rather poorly soluble in most solvents. Reaction of $[Cr(CO)_6]$ with one molar equivalent of L (L = [9]aneS$_3$ or [10]aneS$_3$) in degassed EtOH solution at room temperature in the presence of an excess of $NaBH_4$, gave the *fac*-$[Cr(CO)_3L]$ in moderate yields as pale yellow solids (heating led to decomposition). This route is similar to that reported by Chatt and co-workers for the preparation of phosphine substituted complexes of Cr(0), Mo(0) and W(0) carbonyls [19]. Attempts to prepare $[Cr(CO)_3$([9]aneS$_3$)] or $[Cr(CO)_3$([10]aneS$_3$)] from a 1:1 mixture of $[Cr(CO)_6]$ and thioether in MeCN were not successful, yielding unreacted starting materials and green solutions from which no tractable product could be isolated. The literature route to $[Mo(CO)_3$([9]aneS$_3$)] is via the $[Mo(CO)_3(NCMe)_3]$ intermediate [9,10], and we have successfully repeated this reaction. However, we also found that this compound can be prepared from $[Mo(CO)_6]$ and [9]aneS$_3$ in refluxing EtOH solution containing $NaBH_4$. Reaction of $[Mo(CO)_6]$ with [10]aneS$_3$ in refluxing MeCN yields $[Mo(CO)_3$([10]aneS$_3$)] as a light brown solid. The preparation of the tungsten analogues was achieved by reaction of $[W(CO)_3(NCMe)_3]$ in MeCN in situ with [9]aneS$_3$ or [10]aneS$_3$ at room temperature (heating these solutions resulted in decomposition).

These Group 6 carbonyl compounds are poorly soluble in most organic solvents, although they show sufficient solubility in DMSO to enable spectroscopic characterisation, and in contrast to the complexes of the acyclic tripodal ligands, they show no tendency to decompose to tetracarbonyls. The FAB mass spectra show highest mass peaks with the correct isotopic distributions corresponding to $[M(CO)_3L]^+$, and other peaks arising from fragmentation via loss of CO are also observed. For *fac* compounds two CO stretching vibrations ($a_1 + e$) are predicted in the IR spectrum, although strictly the [10]aneS$_3$ complex does not have C_{3v} symmetry. Typically the complexes show two strong bands, although the low frequency band shows an additional shoulder. The data for our sample of $[Mo(CO)_3$([9]aneS$_3$)] are in accord with the literature (KBr: ν(CO) = 1915, 1783 cm^{-1}) [10,11].

$^{13}C\{^1H\}$ NMR spectra were recorded in DMSO solution and the data for the compounds are presented in Table 1. For the complexes of [9]aneS$_3$, a single resonance is seen in the CO region, and a single methylene carbon resonance occurs around + 30 ppm, confirming a symmetrically bound [9]aneS$_3$ ligand. For the complexes of [10]aneS$_3$, two CO resonances (1:2 ratio), and three methylene carbon resonances (4:2:1 ratio) are observed, as expected for tridentate coordination via the macrocycle. In the case of the tungsten complexes, satellites due to coupling to ^{183}W ($I = 1/2$, 14.3%) are also seen on each of the CO resonances, giving $^1J_{WC}$ approximately 180 Hz. This compares with 126 Hz in $[W(CO)_6]$ [20]. ^{95}Mo ($I = 5/2$, 15.7%) NMR spectra were also recorded for the Mo(0) compounds. These show single resonances at − 1345 and − 1311 ppm respectively for $[Mo(CO)_3$([9]aneS$_3$)] and $[Mo(CO)_3$([10]aneS$_3$)]. These shifts are ca. 500 ppm to high frequency of $[Mo(CO)_6]$ (δ(^{95}Mo) = − 1856) [21] indicating decreased electron density on Mo(0) in the thioether compounds. It is notable that in the $[Mo(CO)_3L_3]$ (L_3 = tth, tse or tte) the δ(^{95}Mo) shifts progressively to high frequency with *trans* donor Te < Se < S, consistent with increasing σ-donation as Group 16 is descended [5]. The two macrocyclic trithioether complexes are significantly more shielded that the tth complex.

3. Experimental

Physical measurements were made as described previously [16]. The $M(CO)_6$, [9]aneS$_3$ and [10]aneS$_3$ (Aldrich) were used as received. The ligands tth [22], tse [23], and tte [24] were made by literature methods.

3.1. *fac*-[Mo(CO)$_3$(tth)]

$Mo(CO)_6$ (0.2 g, 0.76 mmol) was refluxed in dry degassed MeCN (50 cm^3) under argon for 16 h. to give $[Mo(CO)_3(MeCN)_3]$. The ligand tth (0.17 g, 0.8 mmol) was added and the mixture stirred under argon for a further 16 h. An IR spectrum of the solution showed the absence of $[Mo(CO)_3(MeCN)_3]$. The solvent was removed in vacuo, and the resulting oil dissolved in CH_2Cl_2 (20 cm^3), and filtered through Celite. The solvent was removed in vacuo, and the solid washed with diethyl ether (20 cm^3) to remove any tetracarbonyl complex. The pale brown powder was rinsed with *n*-pentane (10 cm^3) and dried in vacuo (yield 0.15 g, 52%). *Anal*. Found: C, 34.1; H, 4.7. Calc. for $C_{11}H_{18}MoO_3S_3$: C, 33.8; H, 4.7%. FAB MS (3-NOBA matrix): found $m/z = 392$; calc. for $[^{98}Mo(CO)_3\{MeC(CH_2SMe)_3\}]^+$ $m/z = 392$. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.15 (Me), 2.1 (MeS), 2.45 (CH_2).

3.2. *fac*-[Mo(CO)$_3$(tse)]

This was made analogously as a pale brown powder (yield 0.19 g, 47%). *Anal*. Found: C, 25.2; H, 3.3. Calc. for $C_{11}H_{18}MoO_3Se_3$: C, 24.9; H, 3.4%. FAB MS (3-NOBA matrix): found $m/z = 532$, 448; calc. for $[^{98}Mo(CO)_3\{MeC(CH_2^{80}SeMe)_3\}]^+$ $m/z = 536$, $[^{98}Mo\{MeC(CH_2^{80}SeMe)_3\}]^+$ $m/z = 452$. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.3 (Me), 2.1 (MeSe), 2.7 (CH_2).

3.3. *fac*-[Mo(CO)$_3$(tte)]

This was made analogously as a pale brown powder (yield 0.23 g, 45%). *Anal*. Found: C, 20.0; H, 2.9. Calc. for $C_{11}H_{18}MoO_3Te_3$: C, 19.5; H, 2.7%. FAB MS (3-NOBA matrix): found $m/z = 678$, 594; calc. for $[^{98}Mo(CO)_3\{MeC(CH_2^{130}TeMe)_3\}]^+$ $m/z = 686$, $[^{98}Mo\{MeC(CH_2^{130}TeMe)_3\}]^+$ $m/z = 602$. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.3 (Me), 2.1 (MeTe), 2.8 (CH_2).

3.4. *fac*-[W(CO)$_3$(tth)]

$W(CO)_6$ (0.2 g, 0.57 mmol) was refluxed in dry degassed MeCN (50 cm^3) under argon for 4 d to give $[W(CO)_3(MeCN)_3]$. The ligand tth (0.13 g, 0.6 mmol) was added and the mixture stirred for a further 16 h, at which time an IR spectrum showed the absence of $[W(CO)_3(MeCN)_3]$. The solvent was removed in vacuo, the residue dissolved in CH_2Cl_2 and the solution filtered through Celite. The solvent was again removed in vacuo, the pale brown solid washed with diethyl ether (10 cm^3) and *n*-pentane (20 cm^3) and dried in vacuo (yield 0.44 g, 52%). *Anal*. Found: C, 27.3; H, 4.0. Calc. for $C_{11}H_{18}O_3S_3W$: C, 27.6; H, 3.8%. FAB MS (3-NOBA matrix): found $m/z = 478$; calc. for $[^{184}W(CO)_3\{MeC(CH_2SMe)_3\}]^+$ $m/z = 478$. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.1 (Me), 2.2 (MeS), 2.6 (CH_2).

3.5. *fac*-[W(CO)$_3$(tse)]

This was made analogously (yield 0.14 g, 39%). *Anal*. Found: C, 21.5; H, 3.1. Calc. for $C_{11}H_{18}O_3Se_3W$: C, 21.3; H, 2.9%. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.3 (Me), 2.05 (MeSe), 2.8 (CH_2).

3.6. *fac*-[W(CO)$_3$(tte)]

This was made analogously (yield 0.24 g, 55%). *Anal*. Found: C, 17.3; H, 2.3. Calc. for $C_{11}H_{18}O_3Te_3W$: C, 17.3; H, 2.4%. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.5 (Me), 2.0 (MeTe), 2.2 (CH_2).

3.7. *cis*-[Cr(CO)$_4$(η^2-tth)]

This was made from $[Cr(CO)_3(MeCN)_3]$ and tth in benzene, following the method used [15] for $[Cr(CO)_3\{MeSi(CH_2SMe)_3\}]$. The product was extracted in diethyl ether, the solvent removed and the yellow solid washed with *n*-pentane. *Anal*. Found: C, 38.5; H, 4.3. Calc. for $C_{12}H_{18}CrO_4S_3$: C, 39.1; H, 4.9%. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.12 (Me), 2.2, 2.4 (MeS), 2.6, 2.7 (CH_2).

3.8. *cis*-[Mo(CO)$_4$(η^2-tse)]

$Mo(CO)_6$ (0.2 g, 0.76 mmol) was refluxed in dry degassed MeCN (50 cm^3) under argon for 8 h. to give $[Mo(CO)_4(MeCN)_2]$ (identified in situ by IR spectroscopy). The ligand tse (0.28 g, 0.8 mmol) was added and the mixture stirred for a further 16 h. The solvent was removed in vacuo and the resulting oil dissolved in CH_2Cl_2 (20 cm^3) and filtered through Celite. The solvent was removed in vacuo, the residue dissolved in diethyl ether (10 cm^3) and filtered. The solvent was again removed in vacuo, and the solid washed with *n*-pentane, and died in vacuo. *Anal*. Found: C, 25.3; H, 3.0. Calc. for $C_{12}H_{18}MoO_4Se_3$: C, 25.8; H, 3.2%. FAB MS (3-NOBA matrix): found $m/z = 560$, 532; calc. for $[^{98}Mo(CO)_4\{MeC(CH_2^{80}SeMe)_3\}]^+$ $m/z = 564$, $[^{98}Mo(CO)_3\{MeC(CH_2^{80}SeMe)_3\}]^+$ $m/z = 536$. ^{1}H NMR (300 MHz, $CDCl_3$, 300 K): δ 1.2 (Me), 2.1, 2.45 (MeSe), 2.7, 2.8 (CH_2).

3.9. *fac*-[Cr(CO)$_3$([9]aneS$_3$)]

To a degassed solution of [Cr(CO)$_6$] (0.049 g, 0.22 mmol) and NaBH$_4$ (0.038 g, 1.0 mmol) in dry EtOH (25 cm^3) was added [9]aneS$_3$ (0.040 g, 0.22 mmol). The resulting mixture was stirred at room temperature (r.t.) for ca. 24 h, during which time a yellow solution was produced. The reaction volume was reduced to ca. 15 cm^3 in vacuo to give a white solid and yellow solution. Following filtration, the filtrate was concentrated in vacuo and diethyl ether was added to give a yellow solid, which was filtered, washed with H$_2$O and dried in vacuo (yield 0.028 g, 40%). *Anal*. Found: C, 33.7; H, 4.7. Calc. for C$_9$H$_{12}$CrO$_3$S$_3$: C, 34.2; H, 3.8%. FAB MS (3-NOBA matrix): found $m/z = 316$, 232; calc. for [^{52}Cr(CO)$_3$([9]aneS$_3$)]$^+$ $m/z = 316$, [^{52}Cr([9]aneS$_3$)]$^+$ $m/z = 232$. ^{1}H NMR (300 MHz, d_6-DMSO, 300 K): δ 3.0–2.6 (br m CH$_2$).

3.10. *fac*-[Cr(CO)$_3$([10]aneS$_3$)]

Method as for [Cr(CO)$_3$([9]aneS$_3$)] above, but using [Cr(CO)$_6$] (0.023 g, 0.1 mmol), NaBH$_4$ (0.018 g, 0.46 mmol) and [10]aneS$_3$ (0.020 g, 0.1 mmol), giving a pale yellow precipitate, which was recrystallised from MeNO$_2$ (yield 0.020 g, 59%). *Anal*. Found: C, 33.1; H, 4.1. Calc. for C$_{10}$H$_{14}$CrO$_3$S$_3$·MeNO$_2$: C, 33.7; H, 4.3%. FAB MS (3-NOBA matrix): found $m/z = 330$, 274, 246; calc. for [^{52}Cr(CO)$_3$([10]aneS$_3$)]$^+$ $m/z = 330$, [^{52}Cr(CO)-([10]aneS$_3$)]$^+$ $m/z = 274$, [^{52}Cr([10]aneS$_3$)]$^+$ $m/z = 246$. ^{1}H NMR (300 MHz, d_6-DMSO, 300 K): δ 3.25–2.85, 2.50 (br, m, CH$_2$).

3.11. *fac*-[Mo(CO)$_3$([9]aneS$_3$)]

Method 1: [Mo(CO)$_6$] (0.059 g, 0.22 mmol) was added to a stirred solution of [9]aneS$_3$ (0.040 g, 0.22 mmol) in dry, degassed MeCN (25 cm^3). The solution was gently refluxed under N$_2$ for 6 h. After cooling the solution was concentrated in vacuo to ca. 3 cm^3. Subsequent addition of diethyl ether afforded a light yellow/brown precipitate that was filtered, washed with diethyl ether and dried in vacuo (yield 0.030 g, 38%).

Method 2: [Mo(CO)$_6$] (0.059 g, 0.22 mmol), [9]aneS$_3$ (0.040 g, 0.22 mmol) and NaBH$_4$ (0.025 g, 0.67 mmol) were heated to reflux for 5 h in dry, degassed EtOH (25 cm^3) under N$_2$. The yellow solution that formed was stirred at r.t. for a further 12 h. After concentrating the solution in vacuo, diethyl ether was added to afford a light yellow precipitate which was filtered, washed with H$_2$O and dried in vacuo (yield: 0.025 g, 31%). FAB MS (3-NOBA matrix): found $m/z = 363$; calc. for [^{98}Mo(CO)$_3$([9]aneS$_3$)]$^+$ $m/z = 362$. ^{1}H NMR (300 MHz, d_6-DMSO, 300 K): δ 3.1–2.8 (br m CH$_2$).

3.12. *fac*-[Mo(CO)$_3$([10]aneS$_3$)]

[Mo(CO)$_6$] (0.068 g, 0.26 mmol) was added to a stirred solution of [10]aneS$_3$ (0.050 g, 0.26 mmol) in dry, degassed MeCN (30 cm^3). The solution was gently refluxed under N$_2$ for 18 h. After cooling the solution was concentrated in vacuo to ca. 3 cm^3. Subsequent addition of diethyl ether afforded a light yellow precipitate that was filtered, washed with diethyl ether and dried in vacuo (yield 0.060 g, 62%). *Anal*. Found: C, 31.8, H, 3.4. Calc. for C$_{10}$H$_{14}$MoO$_3$S$_3$: C, 32.0; H, 3.7%. FAB MS (3-NOBA matrix): found $m/z = 376$; calc. for [^{98}Mo(CO)$_3$([10]aneS$_3$)]$^+$ $m/z = 376$. ^{1}H NMR (300 MHz, d_6-DMSO, 300 K): δ 3.1–2.6 (m, CH$_2$).

3.13. *fac*-[W(CO)$_3$([9]aneS$_3$)]

[W(CO)$_6$] (0.100 g, 0.28 mmol) was refluxed in dry MeCN (50 cm^3) under argon for 4 days to give *fac*-[W(CO)$_3$(MeCN)$_3$]. After cooling to r.t. [9]aneS$_3$ (0.051 g, 0.28 mmol) was added and the reaction mixture stirred under argon for 3 days during which time a pale brown solid was deposited. The solution was then concentrated in vacuo and diethyl ether was added to give a fawn solid that was filtered, washed with diethyl ether and dried in vacuo (yield 0.037 g, 26%). *Anal*. Found: C, 24.1; H, 2.4. Calc. for C$_9$H$_{12}$O$_3$S$_3$W: C, 24.1; H, 2.7%. FAB MS (3-NOBA matrix): found $m/z = 448$, 365; calc. for [^{184}W(CO)$_3$([9]aneS$_3$)]$^+$ $m/z = 448$, [^{184}W([9]aneS$_3$)]$^+$ $m/z = 364$. ^{1}H NMR (300 MHz, d_6-DMSO, 300 K): δ 2.9–2.5 (m, CH$_2$).

3.14. *fac*-[W(CO)$_3$([10]aneS$_3$)]

Method as for [W(CO)$_3$([9]aneS$_3$)] above, but using [W(CO)$_6$] (0.100 g, 0.28 mmol) and [10]aneS$_3$ (0.055 g, 0.28 mmol), giving a light brown precipitate which was recrystallised from CHCl$_3$ (yield 0.040 g, 30%). *Anal*. Found: C, 23.7; H, 2.3. Calc. for C$_{10}$H$_{14}$O$_3$S$_3$W·CHCl$_3$: C, 22.7; H, 2.6%. FAB MS (3-NOBA matrix): found $m/z = 461$; calc. for [^{184}W(CO)$_3$([10]aneS$_3$)]$^+$ $m/z = 462$. ^{1}H NMR (300 MHz, CDCl$_3$, 300 K): δ 3.20–2.85 (m, CH$_2$).

Received 29 February 2000; accepted 4 May 2000

Abstract

The Raman spectroscopic data for a series of 50 phthalocyaninato and/or porphyrinato rare earth complexes including monomeric Tb[T(4-Cl)PP]acac, and sandwich-type $RE(Pc')_2$ [RE = Ce, Eu, Gd, Tb, Y; Pc′ = Pc, $Pc(OC_5H_{11})_8$, $Pc(OC_8H_{17})_8$, $Pc(C_7H_{15})_8$], $RE(Nc^*)_2$ [RE = La, Ce, Pr, Nd, Eu, Gd, Tb, Er, Y; Nc* = $Nc(^tBu)_4$, $Nc(SC_{12}H_{25})_8$], (Pc)RE(Pc*)RE(Pc*) [RE = Eu, Tb, Er; Pc* = $Pc(OC_5H_{11})_8$], (Pc)Eu(Pc*)Er(Pc*) [Pc* = $Pc(OC_8H_{17})_8$], Eu(Pc)(Pc*) [Pc* = $Pc(OC_5H_{11})_8$, $Pc(C_7H_{15})_8$], Eu(Por)(Pc′) [Por = TPP, TPyP, T(4-Cl)PP, T(4-OMe)PP, T(4-^{t}Bu)PP; Pc′ = Pc, $Pc(C_7H_{15})_8$], Eu(Por)(Nc) [Por = TPyP, T(4-Cl)PP], HEu(Por)(Pc), Ce(TPyP)(Pc), $RE_2(Por)_2(Pc)$ [RE = Ce, Eu; Por = TPP, TPyP, T(4-Cl)PP, T(4-^{t}Bu)PP], and $RE_2(Por)(Pc')_2$ [RE = Eu, Ce, Y; Por = TPP, TPyP, T(4-Cl)PP, T(4-OMe)PP, T(4-^{t}Bu)PP, OEP; Pc′ = Pc, $Pc(OC_8H_{17})_8$, $Pc(C_7H_{15})_8$], and (TPyP)RE(Pc*)RE′(Pc*) [RE ≠ RE′ = Eu, Y; Pc* = $Pc(C_7H_{15})_8$] have been collected in the solid state using a Raman microprobe and excitation at 632.8 nm (and in some cases, 780 nm). The Raman characteristics for unsubstituted and substituted (na)phthalocyaninato mono-radical anions $Pc'^{\bullet -}$ (Pc′ = Pc, Pc*), $Nc^{*\bullet -}$ and dianions Pc'^{2-} (Pc′ = Pc, Pc*) are thus comparatively described. The intense band at ca. 1500 cm^{-1} was confirmed to be the marker band for $Pc'^{\bullet -}$ and Pc'^{2-} anions. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Sandwich type phthalocyaninato double-deckers, in which the large conjugated π systems are held in close proximity by rare earth ions, have attracted great attention due to their application in organic materials science [1,2]. These sandwiches have recently been found to be good candidates for potential applications in the fields of molecular electronics, molecular optronics, and molecular iono-electronics [3–12]. As the bulk characteristics of a molecular material are largely related to the properties of individual molecules, various modifications have been made on these sandwiches with the aim of improving their performance as advanced materials. Thus there has been intense research into substituted bis(phthalocyaninato), bis(naphthalocyaninato), heteroleptic bis(phthalocyaninato), and mixed porphyrinato–phthalocyaninato metal complexes, especially since the beginning of the 1990s [13–23]. As fully summarised in our recent paper concerning the IR spectroscopic characteristics of sandwich porphyrinato and/or phthalocyaninato rare earth complexes [24], IR spectroscopy is a versatile technique for studying the intrinsic properties of the sandwiches [25–29]. For the bis(phthalocyaninato) complexes $M(Pc')_2$ (M = RE, Th, U, Zr, Hf, Bi, Sn; Pc′ = Pc, Pc*) [30–34] and porphyrinato–phthalocyaninato double-deckers M(Por)(Pc′) (Pc′ = Pc, Pc*; M = RE, Th, U, Zr, Hf) [35,36], the IR peak around 1310–1330 cm^{-1} has been confirmed to be the diagnostic band for the $Pc'^{\bullet -}$ and Pc'^{2-} anions

(for a list of abbreviations, see the Appendix). Raman spectroscopy is potentially another valuable tool for analysing the extent of charge (de)localisation in porphyrin or phthalocyanine π radicals. However, it has so far not been as extensively used for characterising the sandwich-type porphyrinato and/or phthalocyaninato metal complexes as the IR technique [37,38]. Since 1989, Aroca has described the resonance Raman spectra of lutetium and ytterbium bis(phthalocyaninato) compounds in thin solid films [39]. Meanwhile, Homborg and co-workers also reported the synthesis and structures of a series of bis(phthalocyaninato) rare earth complexes together with their vibrational (IR and Raman) spectroscopic characterisations [30,31,40–42]. In 1994, Tran-Thi et al. compared the FT-Raman spectra (excited at 1064 nm) for several sandwich phthalocyaninato and porphyrinato Gd and Ce compounds and proposed that the intense band at 1500 cm^{-1} is the marker band to estimate the hole (de)localisation within the Pc moiety [37]. We are currently developing novel synthetic methods for a series of sandwich porphyrinato and/or phthalocyaninato rare earth compounds and are investigating the ring–ring interaction between or among the macrocycles (porphyrinato and phthalocyaninato ligands) through electrochemical and spectroscopic methods [13,14,16–23,43–46]. In this paper we describe and compare the Raman spectroscopic characteristics for the (na)-phthalocyanine ligand in various examples of double- and triple-decker sandwich complexes containing phthalocyanine(s), naphthalocyanine(s) and porphyrins.

2. Experimental

The sandwich-type rare earth complexes were prepared according to the reported procedures [13–26,45,60]. Raman spectra were recorded with a Renishaw Raman Microprobe, equipped with a Spectra Physics model 127 He–Ne laser excitation source emitting at a wavelength of 632.8 nm and a Renishaw diode laser emitting at 780 nm, and a cooled charge-coupled device (CCD) camera. An Olympus BHZ-UHA microscope was attached and was fitted with three objective lenses (× 10, × 20, × 50). For these experiments, the × 10 objective was employed giving a spot size on the sample of about 5 μm. Laser power at the sample was ca. 0.08 mW. Sample preparation consisted simply of placing a very small amount of the solid on a clean stainless steel plate on the microscope stage. Spectra of excellent quality were generally obtained in ca. 3 min. Some porphyrin-containing samples suffered from strong fluorescence, as noted in the text.

3. Results and discussion

3.1. Raman characteristics of homoleptic double-deckers $RE(Pc)_2$, $RE(Pc^*)_2$, and heteroleptic double-deckers $RE(Pc)(Pc^*)$

Although sandwich phthalocyaninato metal compounds have not been as extensively studied by the Raman technique as by the IR method, both Aroca and Homborg have paid considerable attention to both the Raman and IR spectroscopic properties of bis(phthalocyaninato) rare earth complexes [30,31,39–42]. In their systematic work on the vibrational spectra and structures of thin films of metal bis(phthalocyaninato) complexes, Aroca noticed the difference between the Q-state excitation (676.4 nm) resonance Raman spectra of green $RE(Pc')_2$ and blue $HRE(Pc')_2$. The strong band around 680 cm^{-1} and a medium strong band around 740 cm^{-1} assigned to macrocycle (Pc) breathing and Pc ring modes, respectively, appear in the resonance Raman spectra of the green species [39,47–50]. For the lower symmetry blue species $HRE(Pc')_2$, an additional peak at about 730 cm^{-1} was observed between these two bands [39,47]. Closely similar characteristics have also been observed by Homborg in the resonance Raman spectra of $La(Pc)_2$ [51] and $[M^{III}(Pc)_2]^-$ (M = La, Ce, Bi, Y, In) [30,31]. By using the 647.1 nm laser line to excite the Raman spectra of a series of bis(phthalocyaninato) rare earth complexes, Homborg proposed that the Q band-enhanced resonance Raman spectra have almost the same signature for the Pc^{2-} and $Pc^{\bullet -}$ ligands. However, with excitation wavelengths further from resonance, in particular between 457 and 514 nm, three strong vibrational peaks were observed at about 1110, 1170 and 1595 cm^{-1} for all the radical anion-containing double-deckers $M^{III}(Pc)_2$ (M = La, Nd, Gd, Ho, Lu, Bi, Y, In) [30,31,51,52], and these were thus attributed to the typical $Pc^{\bullet -}$ marker bands. Further studies revealed that removing an electron from $M(Pc)_2$ (M = Y, In, Ho, Pr) to form $[M(Pc)_2]^+$ does not change the corresponding resonance Raman bands significantly [31,53,54]. Using instead a long wavelength laser line at 1064 nm (in near-resonance with the intramolecular charge transfer transition of the neutral species) to excite the Raman spectra of $M^{III}(Pc)_2$ (M = La···Lu except Ce, Pm; Y, In) [31,51] and $[M^{III}(Pc)_2]^+$ (M = La···Lu except Ce, Pm; Y, In) [31,53], Homborg found that the band assigned to the Pc skeletal mode vibration around 1515 cm^{-1} experiences a successive blue-shift from La to Lu. Moreover, in the resonance Raman spectra of both $M^{III}(Pc)_2$ and $[M^{III}(Pc)_2]^+$, the appearance of only one set of the $Pc^{\bullet -}$ bands in $M^{III}(Pc)_2$ (M = La···Lu except Ce, Pm; Y, In) [31,51,52] indicates strong ring–ring interaction and hole delocalisation over both the Pc chromophores on the time scale of Raman spectroscopy. Through detailed work on the

FT-Raman spectra (1064 nm excitation) for a series of phthalocyanine-containing sandwiches, Tran-Thi et al. found a significant upshift of a redox-sensitive Raman band at ca. 1500 cm^{-1} after oxidation of Pc^{2-}, the extent of which was used to judge the (de)localisation of the unpaired electron in the sandwiches [37]. According to his proposal that an upshift of over 15 cm^{-1} is the indication of the localisation of the hole in the Pc ring, the hole in both $Gd(Pc)_2$ and Gd(TPP)(Pc) is predominantly located on the Pc ligand. This conclusion for $Gd(Pc)_2$ is in contrast with that deduced from IR measurements [24] and that of Homborg also from Raman measurements [30,31,51–54].

The sandwich phthalocyaninato and/or porphyrinato rare earth double-deckers contain a large number of atoms and are expected to have many normal vibrational modes. For example, even the unsubstituted $RE(Pc)_2$ complex has 113 atoms and 333 normal modes. Assuming a C_{4v} point group, the Raman-active modes are $44A_1$, $42B_1$, $42B_2$, and $83E$, and IR-active modes include $44A_1$ and $83E$ vibrational fundamentals [39]. It has been clearly shown that despite the large number of IR-active modes, the experimental IR spectra of sandwich phthalocyaninato rare earth double-deckers $RE(Pc)_2$ are composed of a small number of fundamentals, including the following main IR absorption groups corresponding to characteristic vibrations of phthalocyanine molecules. The aromatic C–H wagging vibration around 730 cm^{-1}, the aromatic C–H bending vibration at 1115 cm^{-1}, and two isoindole stretching vibrations at 1320 and 1450 cm^{-1} are observed for these double-decker compounds [24]. According to their work for both IR and Raman vibrational properties of bis(phthalocyaninato) rare earth compounds, Aroca and co-workers pointed out that groups of characteristic phthalocyanine vibrations could be clearly distinguished in the IR and resonance Raman spectra [39]. Aromatic C–H vibrations are responsible for the IR and resonance Raman spectra of Pc molecules in the region of 1000–1300 cm^{-1}, which are correlated with phthalonitrile and indole frequencies, except for the pyrrole ring vibration band at about 1140 cm^{-1}. Vibrational frequencies in the range 1320–1650 cm^{-1} are derived from isoindole ring stretches and the aza group stretch, for which the pyrrole stretching vibrations at ca. 1330 and 1510 cm^{-1}, and *ortho*-disubstituted benzene stretchings at ca. 1560, 1590 and 1610 cm^{-1} can be distinguished by frequency and relative intensity. The spectral region from 1000 to 400 cm^{-1} has main contributions from the dihedral plane deformation involving the aromatic C–H groups (wagging and torsion vibration) which is normally seen in the IR spectra, and ring radial vibrations of the isoindole moieties and the macrocycle which show strong Raman signals. The assignment to different symmetry types was thus carried out according to the following principles. A vibration that gives signals in both IR and Raman but with stronger relative intensity in the Raman was assigned to the A_1 type. The reverse was assumed to be the case for E type. A number of new frequencies appearing in the Raman spectra are most likely related to A_2, B_1 and B_2 type in view of the Herzberg–Teller mechanism.

In our experiments, the 632.8 nm laser line, which is in close resonance with the Q absorption band of bis(phthalocyaninato) rare earth compounds (λ_{max}: ca. 670–690 nm), was used to excite the Raman spectra. The proposed partial assignment of observed values in the Raman spectra of homoleptic $RE(Pc')_2$ and heteroleptic RE(Pc)(Pc*) is given in Table 1. The results for the Raman shifts of $Eu(Pc)_2$ are comparable to those of Aroca and Homborg for a series of $RE(Pc)_2$ [30,31] when they used 676.4 and 647.1 nm excitation, respectively. As expected, neither the introduction of substituted groups onto the phthalocyanine ring nor the variation in sandwiched metal seems to induce significant changes in the resonance Raman spectra. For instance, the Raman spectra for both heteroleptic Eu(Pc)(Pc*) and homoleptic $Eu(Pc^*)_2$ [Pc* = $Pc(OC_5H_{11})_8$, $Pc(OC_8H_{17})_8$, $Pc(C_7H_{15})_8$] are similar to their analogue $Eu(Pc)_2$, while the resonance Raman spectrum for $Eu[Pc(C_7H_{15})_8]_2$ resembles closely that for $Y[Pc(C_7H_{15})_8]_2$. However, when tetravalent cerium is involved in double-decker phthalocyaninato compounds, significant band shifts and intensity changes, especially for the marker band of Pc ring at ca.1500 cm^{-1}, take place in the Raman spectrum of $Ce^{IV}(Pc')_2$ (Pc′ = Pc, Pc*) compared with those of $RE^{III}(Pc')_2$ (Pc′ = Pc, Pc*). It is worth noting that the band at ca. 1500 cm^{-1} for the phthalocyanine ring is attributed to a ν_3 porphyrin-like mode which contains nearly equal C=C (pyrrole) and C=N (aza group) character according to Tran-Thi [37]. Fig. 1 compares the Raman spectra of $Gd^{III}[Pc(OC_8H_{17})_8]_2$ and $Ce^{IV}[Pc(OC_8H_{17})_8]_2$. In the Raman spectrum of the latter, the ν_3 porphyrin-like mode of the phthalocyanine ring gives a band near 1500 cm^{-1} and the most intense band is located at 1174 cm^{-1}, which is assigned to an aromatic C–H bend. When the tetravalent cerium in the bis(phthalocyanine) compound is substituted with tervalent rare earth ions, dramatic changes occur in the Raman spectra. The former band with contributions from both C=C (pyrrole) and C=N (aza group) stretches, upshifts to 1515 cm^{-1}. These changes are considered to result from (i) the intrinsic difference between the monoanion radical $Pc^{\bullet-}$ in $RE^{III}(Pc')_2$ and dianion Pc^{2-} in $Ce^{IV}(Pc')_2$ and (ii) the different degree of resonance of the excitation laser line (632.8 nm) with the Q absorption of tervalent rare earth (Eu, Gd, Tb, Y) phthalocyaninato double-deckers (λ_{max}: ca. 670–690 nm) and tetravalent cerium bis(phthalocyaninato) complexes (λ_{max}: 649 nm) [13–15,20,23,44]. This result is in good

[a] $Eu(Pc)_2$ (**1**), Eu(Pc)[$Pc(OC_5H_{11})_8$] (**2**), Eu(Pc)[$Pc(C_7H_{15})_8$] (**3**), Eu[$Pc(OC_5H_{11})_8]_2$ (**4**), Gd[$Pc(OC_8H_{17})_8]_2$ (**5**), Tb[$Pc(OC_8H_{17})_8]_2$ (**6**), Eu[$Pc(OC_8H_{17})_8]_2$ (**6′**) (λ_{ex} = 780 nm), Y[$Pc(C_7H_{15})_8]_2$ (**7**), Eu[$Pc(C_7H_{15})_8]_2$ (**8**), $Ce(Pc)_2$ (**9**), Ce[$Pc(OC_8H_{17})_8]_2$ (**10**).

accordance with the conclusions of Aroca and Tran-Thi [37,55,56] and with the experimental data reported by Homborg [30,31,51,57–59]. When trying to use the Langmuir–Blodgett films of $RE(Pc')_2$ as tobacco smoke sensors, Aroca and co-workers found that the radical-containing green form $RE(Pc')_2$ was reduced after chemisorption of the tobacco side stream smoke to the blue form $[RE(Pc')_2]^-$, which showed a different pattern of relative intensities in the surface-enhanced Raman spectrum (612 nm excitation) compared to the original green sample [56]. Most significantly, the band at 1513 cm^{-1} for green $Pr[Pc(^tBu)_4]_2$ shifts to 1493 cm^{-1} for blue $\{Pr[Pc(^tBu)_4]_2\}^-$.

It is worth noting that the use of the 780 nm excitation laser line does not induce any significant change in the Raman spectra of $RE[Pc(OC_8H_{17})_8]_2$. The Raman spectrum of $Eu[Pc(OC_8H_{17})_8]_2$ (λ_{ex}: 780 nm) is just identical with that measured by means of the 632.8 nm laser line (Table 1). This result is consistent with those of Homborg on $RE(Pc)_2$ [30,31,51,52] and is probably due to the fact that neither laser line is in close resonance with the electronic absorption band of $RE[Pc(OC_8H_{17})_8]_2$. When Homborg used excitation wavelengths even farther removed from the Q absorption, namely between 457 and 514 nm, an intense band at ca. 1595 cm^{-1} for all the radical anion-containing double-deckers $M^{III}(Pc)_2$ (M = La, Nd, Gd, Ho, Lu, Bi, Y, In) [30,31,51,52] was also observed.

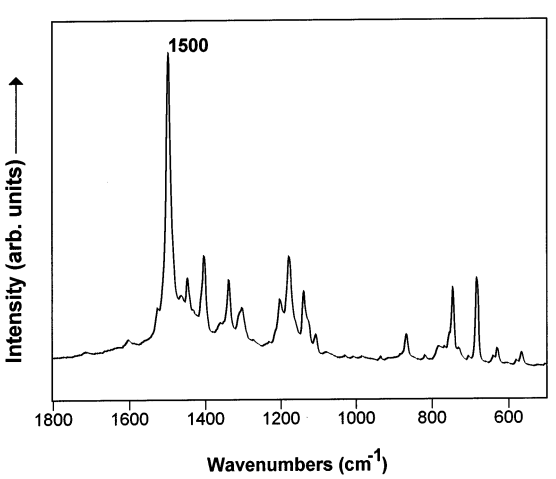

Fig. 2. Raman spectrum of (Pc)Eu[$Pc(OC_8H_{17})_8$]Eu[$Pc(OC_8H_{17})_8$].

3.2. Raman characteristics of homo-dinuclear triple-deckers (Pc)RE(Pc*)RE(Pc*) and hetero-dinuclear triple-deckers (Pc)Eu(Pc*)Er(Pc*)

Our Raman results for triple-decker (Pc)RE(Pc*)-RE(Pc*) (RE = Eu, Tb, Er) and (Pc)Eu(Pc*)Er(Pc*) [Pc* = $Pc(OC_8H_{17})_8$] are collected in Table 2 and assigned based on the partial assignment for the double-deckers $RE(Pc')_2$. Fig. 2 shows the Raman spectrum of triple-decker $Eu_2(Pc)(Pc^*)_2$ [Pc* = $Pc(OC_8H_{17})_8$], which is typical of this class. To a large degree, these spectra are quite similar to that of $Ce^{IV}[Pc(OC_8H_{17})_8]_2$ instead of to those of other tervalent rare earth bis(phthalocyaninato) compounds. The most intense band for all four of these triple-deckers is the one attributed to the ν_3 porphyrin-like mode which has contributions from C=C (pyrrole) and C=N (aza group) stretches around 1500 cm^{-1} as in $Ce^{IV}(Pc')_2$. This is due to the similar electronic structure of phthalocyanine rings in $RE_2^{III}(Pc^{2-})(Pc^{*2-})_2$ and $Ce^{IV}(Pc^{*2-})_2$ and the correspondingly similar electronic absorption properties for these two kinds of sandwiches. The most intense electronic absorptions in triple-deckers $RE_2^{III}(Pc^{2-})(Pc^{*2-})_2$ and double-deckers $Ce^{IV}(Pc^{*2-})_2$ are their Q bands around 639–643 and 649 nm, respectively, both of which are in close resonance with the excitation line (632.8 nm). This contrasts with the results for $RE^{III}(Pc')_2$ which have Q band maxima between 670 and 690 nm. The similarity of the Raman spectra of $RE_2^{III}(Pc^{2-})(Pc^{*2-})_2$ and $Ce^{IV}(Pc^{*2-})_2$ confirms that the existence of the monoanion radical $Pc^{\bullet-}$ in $RE^{III}(Pc')_2$ is responsible for the different Raman characteristics between the double-deckers $RE^{III}(Pc^*)_2$ and $Ce^{IV}(Pc^*)_2$ mentioned above. This conclusion is consistent with those derived from the IR measurements [24].

3.3. Raman characteristics of $RE(Nc^*)_2$ [Nc* = $Nc(^tBu)_4$, $Nc(SC_{12}H_{25})_8$]

In contrast to the situation of bis(phthalocyaninato) rare earth compounds, neither the synthesis nor the spectroscopic characterisation of bis(naphthalocyaninato) rare earth compounds has been extensively studied. Before our work on both the synthesis and the IR spectroscopic characterisation for the substituted $RE[Nc(^tBu)_4]_2$ [43,60], $Eu[Nc(SC_{12}H_{25})_8]_2$ [43], and RE(TPyP)(Nc′) [8], only the synthesis, electronic absorption, and electrochemical properties of unsubstituted naphthalocyanine-containing $Lu(Nc)_2$, Lu(Pc)-(Nc), and $Lu_2(Nc)_3$ had been described by L'Her, Simon and Ishikawa [61–67]. Recently L'Her and coworkers briefly described the IR spectroscopic results for $Lu(Nc)_2$ and Lu(Pc)(Nc) [62]. However, there has been no previous report on the Raman spectroscopic properties of sandwich naphthalocyaninato rare earth complexes.

By analogy to the Raman characteristics of sandwich phthalocyaninato rare earth compounds, the Raman characteristics of $RE(Nc^*)_2$ [Nc* = $Nc(^tBu)_4$,

$Nc(SC_{12}H_{25})_8]$ and $[Eu(Nc^*)_2]^+$ [$Nc^* = Nc(^tBu)_4$] were partially assigned and are summarised in Table 3. Fig. 3 shows the Raman spectrum of $Tb(Nc^*)_2$ [$Nc^* = Nc(^tBu)_4$]. Due to the similar electronic structure and electronic absorption properties among the whole series of naphthalocyaninato double-decker complexes, all these compounds show similar Raman characteristics. Moreover, the fact that the Raman spectrum of $Eu(Nc^*)_2$ is similar to that of $[Eu(Nc^*)_2]^+$ indicates that removing an electron from $Eu(Nc^*)_2$ does not change the corresponding Raman marker bands significantly. This is also comparable with the result of Homborg on the resonance Raman spectra of $RE(Pc)_2$ and $[RE(Pc)_2]^+$ [31,53]. Probably because the excitation laser line (632.8 nm) used in this experiment is far away from resonance with the most intense Q absorption band of $RE(Nc^*)_2$ (767–799 nm), the *ortho*-disubstituted benzene quadrant stretchings around 1590 cm^{-1} appear as the most intense band instead of those from pyrrole C=C group and C=N aza group stretchings at 1510 and 1520 cm^{-1}. This postulate is confirmed by exciting the Raman spectra with the 780 nm laser line, which is in resonance with the Q absorption band of naphthalocyaninato rare earth double-deckers. The Raman spectra of $Tb(Nc^*)_2$ [$Nc^* = Nc(^tBu)_4$] excited at the two wavelengths are compared in Fig. 3. With excitation by 780 nm light, the peak at ca. 1520 cm^{-1} becomes the most intense band in that region of the

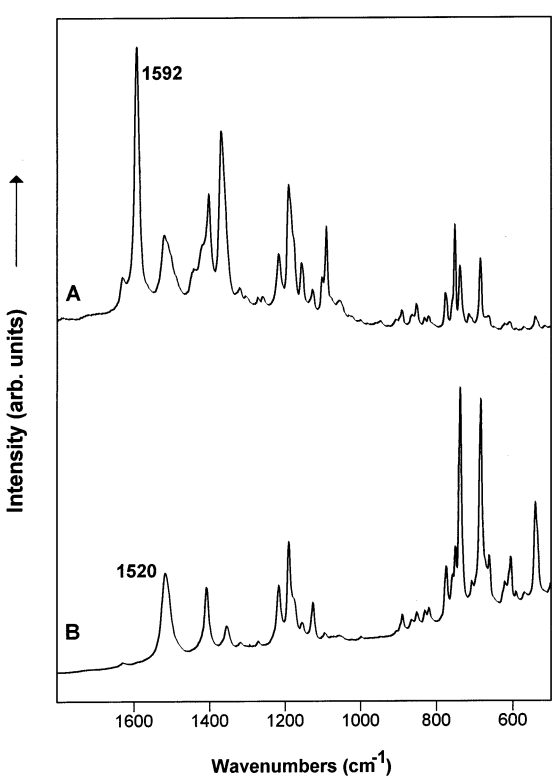

Fig. 3. Raman spectra of $Tb[Nc(^tBu)_4]_2$ with excitation at (A) 632.8 and (B) 780 nm.

resonance Raman spectra of $RE(Nc^*)_2$ [RE = Tb, Er; $Nc^* = Nc(^tBu)_4$] and no band around 1590 cm^{-1} attributed to the *ortho*-disubstituted benzene quadrant stretchings was observed. This result is consistent with the above-mentioned result for $RE(Pc^*)_2$ [RE = Eu, Nd; $Pc^* = Pc(OC_8H_{17})_8$] and those of Homborg on $RE(Pc)_2$ [30,31,51,52]. The other frequencies are assigned to the various vibrational fundamentals based on the work on phthalocyaninato double- and triple-deckers detailed above.

3.4. Raman characteristics of RE(Por)(Pc′) (Pc′ = Pc, Pc), HEu(TPyP)(Pc), and Eu(Por)(Nc)*

We begin this section by noting that for the purpose of comparison, the Raman spectrum of monomeric Tb[T(4-Cl)PP]acac excited at 632.8 nm was also recorded and the data are included in Table 4. The spectrum of this complex is comparable to the preresonance Raman spectrum of Zn(TPP) excited at 1064 nm reported by Tran-Thi et al. [37]. As also noted by Tran-Thi, the porphyrin ligand and the Pc ligand can be easily distinguished by both the frequencies of their respective characteristic Raman bands and their different intensity patterns. The band in the region near 1500 cm^{-1} for the Pc moiety played an important role in this respect. Furthermore, the Q_y absorption bands of phthalocyanines are generally at longer wavelengths and thus are in closer resonance to the 632.8 nm laser line than are those of porphyrins, so the phthalocyanine contributions appear to dominate the Raman spectra in the mixed Por–Pc′–RE sandwich compounds, as described below.

The characteristic Raman bands for RE(Por)(Pc′) (Pc′ = Pc, Pc*) (λ_{max}: 467–476 nm), HEu(TPyP)(Pc) (λ_{max}: 640 nm), and RE(Por)(Nc) (λ_{max}: 630 nm) are organised in Table 4. The characteristic Raman spectroscopic patterns of Ce(TPyP)(Pc) are similar to those of Ce(TPP)(Pc) reported by Tran-Thi [37] but with minor band-shifts and different relative intensities probably due to the different excitation wavelengths. The Raman marker band for Pc^{2-} appears as an intense band at 1493 cm^{-1}, which downshifts about 7 cm^{-1} compared with that in $Ce(Pc')_2$ but corresponds well with that in the triple-deckers $RE_2(Por)_2(Pc)$ and $RE_2(Por)(Pc')_2$ as will be discussed below. It is reasonable that the Raman spectrum of HEu(TPyP)(Pc) is very similar to that of Ce(TPyP)(Pc) due to their identical macrocycle oxidation level and hence electronic structure and electronic absorptions. When the protonated HEu(Por)(Pc) is oxidised to Eu(Por)(Pc′) (Pc′ = Pc, Pc*) which contains phthalocyanine monoanion radical $Pc^{\bullet -}$, the previously intense band at 1493 cm^{-1} for Pc^{2-} in Ce(TPyP)(Pc) and HEu(TPyP)(Pc) remains as a very weak band. Meanwhile, a relatively intense band appears in the region of 1513–1518 cm^{-1}. The

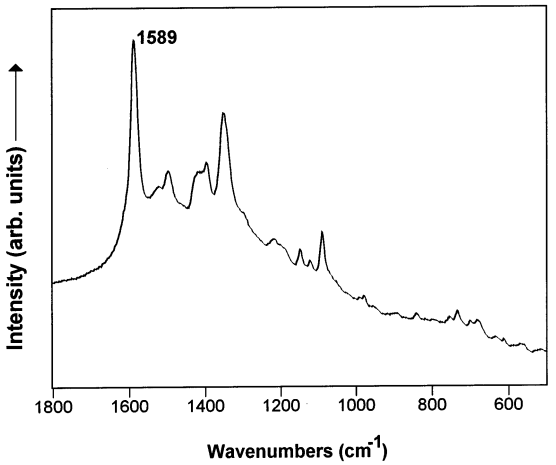

Fig. 4. Raman spectrum of Eu(TPyP)(Nc).

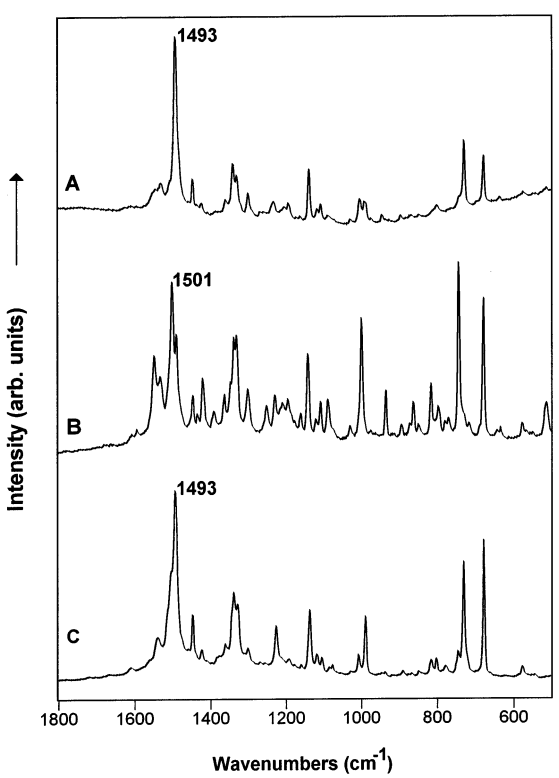

Fig. 5. Raman spectra of (A) (TPyP)Ce(Pc)Ce(TPyP), (B) (Pc)Ce(TPyP)Ce(Pc), and (C) [T(4-^{t}Bu)PP]Eu(Pc)Eu(Pc).

spectrum for Eu[T(4-Cl)PP](Pc) was of poor quality due to the strong fluorescence under the conditions of our Raman measurements.

The Raman spectrum of Eu(TPyP)(Nc) is exhibited in Fig. 4. The spectra for the compounds Eu(Por)(Nc) [Por = TPyP, T(4-Cl)PP] are obviously dominated by the contributions from the naphthalocyanine monoanion radical, $Nc^{\bullet -}$. Except for slight band-shifts and slightly different relative intensities, the Raman spectroscopic patterns of Eu(Por)(Nc) are virtually the same as those of $RE(Nc^*)_2$ [$Nc^* = Nc(^tBu)_4$].

As expected from the change in the Raman spectra of $RE(Nc^*)_2$ induced by the change of excitation source, similar changes took place in the Raman spectrum of Eu(TPyP)(Nc) when 780 nm light was applied. The peak at ca. 1528 cm^{-1} gains intensity and becomes the most intense band in the resonance Raman spectrum of Eu(TPyP)(Nc), while the most intense band at 1587 cm^{-1} under 632.8 nm excitation, attributed to the *ortho*-disubstituted benzene quadrant stretchings, loses most of its intensity and appears as a very weak band.

3.5. Raman characteristics of $RE_2(Por)_2(Pc)$, $RE_2(Por)_2(Pc^*)$, $RE_2(Por)(Pc)_2$, $RE_2(Por)(Pc^*)_2$, $(Por)RE(Pc^*)RE'(Pc^*)$

The Raman characteristic bands together with partial assignment according to the above-described conclusions for $RE_2(Por)_2(Pc)$ (λ_{max}: 600–610 nm), $RE_2(Por)(Pc)_2$ (λ_{max}: 615–620 nm), $RE_2(Por)(Pc^*)_2$, and $(Por)RE(Pc^*)RE'(Pc^*)$ (λ_{max}: 610–660 nm) are summarised in Table 5. Fig. 5 compares the Raman spectra of (TPyP)Ce(Pc)Ce(TPyP), (Pc)Ce(TPyP)Ce(Pc), and [T(4-^{t}Bu)PP]Eu(Pc)Eu(Pc). The similarity among these three clearly suggests that the spectra for all these kinds of triple-deckers are dominated by Pc^{2-} contributions. There is no obvious band that can be ascribed to the Por moiety. In both series of triple-deckers (Por)RE(Pc)RE(Por) and (Por)RE(Pc)RE(Pc), the ν_3 porphyrin-like mode (of the Pc moiety) shows a strong band at ca. 1493 cm^{-1}, while for (Pc)Ce(TPyP)Ce(Pc), this mode displays a strong band at 1501 cm^{-1} along with a shoulder at 1490 cm^{-1}. All these results are in good correspondence with those of Tran-Thi for solution-state FT-Raman spectra (1064 nm) of (TPP)RE(Pc′)RE(TPP) [RE = Ce, Gd, Pc′ = Pc, $Pc(OMe)_8$] and (Pc)Ce[T(4-OMe)PP]Ce(Pc), apart from a blue shift by an average of 3–4 cm^{-1}. It is interesting that the characteristic pattern of the Raman spectra for these three kinds of triple-deckers are so similar despite the widely differing excitation wavelength used in our experiments.

For the purpose of comparison, the Raman spectra of (TPP)Gd(Pc)Gd(TPP) and (TPP)Gd(Pc)Gd(Pc) with excitation at 780 nm were also recorded and the data are included in Table 5. It is reasonable that they are quite similar to those of their analogues excited with 632.8 and 1064 nm as described above.

As can be expected from the above results on phthalocyaninato rare earth double-deckers, the introduction of alkyl or alkoxyl substituents onto the periphery of phthalocyanine rings in triple-deckers (Por)RE(Pc)RE′(Pc) does not cause significant changes in the Raman spectra. Furthermore, the close similarity among the Raman spectra of (TPyP)Y(Pc*)Y(Pc*), (TPyP)Y(Pc*)Eu(Pc*), and (TPyP)Eu(Pc*)Y(Pc*) [$Pc^* = Pc(C_7H_{15})_8$] indicates that variation of rare earth

metals in the triple-decker does not change significantly the electronic structure of phthalocyanine ligands in these triple-deckers. The strong fluorescence of (OEP)Eu[Pc(OC_8H_{17})$_8$]Eu[Pc(OC_8H_{17})$_8$] and the consequent poor quality of the Raman spectrum for this compound prevents us from further comparison of the effects of different porphyrin ligands on the Raman characteristics of phthalocyanine in the triple-deckers.

4. Conclusions

1. When the laser excitation is in close resonance with the Q band absorption of phthalocyanine-containing sandwich rare earths, the band at ca. 1500 cm^{-1} with contributions from both C=C (pyrrole) and C=N (aza group) stretches, is a good Raman marker band for the phthalocyanine dianion Pc'^{2-} (Pc′ = Pc, Pc*) in double-deckers $Ce^{IV}(Pc')_2$ [Pc′ = Pc, Pc(OC_8H_{17})$_8$] and triple-deckers (Pc)RE(Pc*)RE(Pc*) [Pc* = Pc(OC_8H_{17})$_8$]. In $Pc'^{\bullet -}$ radical anion-containing double-deckers $RE^{III}(Pc')_2$ (Pc′ = Pc, Pc(OC_5H_{11})$_8$, Pc(OC_8H_{17})$_8$, Pc(C_7H_{15})$_8$], this band blue-shifts to ca. 1515 cm^{-1}.
2. When the laser excitation is far away from resonance with the Q band absorption of double-decker naphthalocyaninato rare earth complexes, the strongly enhanced Raman band at ca. 1590 cm^{-1}, which is assigned to the benzene quadrant stretch of the Nc ring, is a typical feature of naphthalocyanine monoanion radical, $Nc^{*\bullet -}$, in RE(Nc*)$_2$ [Nc = Nc(^{t}Bu)$_4$, Nc($SC_{12}H_{25}$)$_8$].
3. The marker band of Pc^{2-} in double-deckers Ce^{IV}(TPyP)(Pc) and HEu(TPyP)(Pc), and triple-deckers (Por)RE(Pc)RE(Por), (Por)RE(Pc′)RE(Pc′) (Pc′ = Pc, Pc*) is located at ca. 1493 cm^{-1}, but is at 1501 cm^{-1} along with a shoulder at 1490 cm^{-1} for (Pc)Ce(TPyP)Ce(Pc). For $Pc'^{\bullet -}$ radical–anion in double-deckers RE^{III}(Por)(Pc′) (Pc′ = Pc, Pc*), the band appears at 1515 cm^{-1}.
4. In the Raman spectra of $RE^{III}(Pc')_2$ (Pc′ = Pc, Pc*), only the $Pc'^{\bullet -}$ π radical anion marker bands instead of those for both $Pc'^{\bullet -}$ and Pc'^{2-} are observed, which suggests that the hole in the double-decker phthalocyaninato rare earth compounds delocalises over both phthalocyanine rings on the Raman timescale. This result is in line with the conclusion deduced from the IR measurements [24] and also in good accordance with the fact that both $[Eu(Nc^*)_2]^+$ and Eu(Nc*)$_2$ [Nc* = Nc(^{t}Bu)$_4$] showed quite similar Raman marker bands in their Raman spectra as described above. For a wider assessment on the question of the nature of the (na)phthalocyanine ligands in the various sandwich complexes, and the physical techniques (EPR, X-ray crystallography, UV–Vis) applied to the problem, our review can be consulted [38].
5. The Raman microscope is a rapid and convenient experimental technique for recording the solid state Raman spectra of porphyrinato and (na)phthalocyaninato rare earth complexes.

Abstract

The hydroxo-complexes $[\{Pd(\mu\text{-}OH)(N–N)\}_2][ClO_4]_2$ (N–N = bpzm:bis(pyrazol-1-yl) methane: **a**-compounds, bpzm*:bis(3,5-dimethylpyrazol-1-yl)methane; **b**-compounds) react with a wide variety of weak protic electrophiles H(LL) in a 1:2 molar ratio to give the mononuclear cationic palladium(II) derivatives of general formula $[Pd(LL)(N–N)][ClO_4]$ [LL = 2-pyridine-methoxo (OCH_2-py) (**1a**,**b**); picolinate (pic) (**2a**,**b**); 8-hydroxiquinolinate (oxin) (**3a**,**b**)] or the dinuclear complexes $[\{Pd(N–N)\}_2(\mu\text{-ox})][ClO_4]_2$ [ox = oxalate: (**4a**,**b**)] and $[\{Pd(\mu\text{-}LL)(N–N)\}_2][ClO_4]_2$ [LL = pyrazolate (pz) (**5a**,**b**); *p*-thiocresolate (SC_6H_4Me-*p*) (**6a**,**b**); triazolate (tz) (**7b**); thiophenolate (SPh) (**8b**)] when reacting with oxalic acid, azoles or thiols in the same molar ratio. In a related reaction, deprotonation of secondary amines by the hydroxo-complexes in the presence of carbon disulfide leads to the corresponding dithiocarbamate complexes $[Pd(S_2CNR_2)(N–N)][ClO_4]$ [R = Me (**9a**,**b**), Et (**10a**,**b**) C_5H_{10} (**11a**,**b**)]. The hydroxo complexes also promote the nucleophilic addition of water to pyridine-2-carbonitrile and mononuclear complexes containing pyridine-2-carboxamidate ligands are formed (**12a**,**b**). The new compounds have been characterized by partial elemental analyses, conductance measurements and spectroscopic (IR, ^1H and ^{13}C NMR) methods. The crystal structures of compounds **6b** and **11a** have been determined by X-ray diffraction analysis. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

The recent surge of interest in the chemistry of hydroxo complexes of the nickel group elements is undoubtedly related to their wide reactivity and potential relevance to catalysis [1]. The syntheses of the binuclear ionic complexes $[\{M(C_6F_5)_2(\mu\text{-}OH)\}_2]^{2-}$ (M = Ni, Pd, Pt) [2–4] and $[\{M(N–N)(\mu\text{-}OH)\}_2]^{2+}$ (M = Pd or Pt; N–N = bipy or phen [5]; M = Pd; N–N = α-diimine [6]; M = Pd; N–N = bpzm:bis(pyrazol-1-yl) methane, bpzm*:bis(3,5-dimethylpyrazol-1-yl)methane [7]) have been reported. Their use as precursors in synthetic work is based on the considerable nucleophilicity of the bridging OH groups, which is consistent with their high-field proton resonances. Thus, previous work demonstrated that di-μ-hydroxo complexes are useful precursors for the preparation of an interesting variety of complexes [7–16], by means of a simple acid–base reaction with protic electrophiles. We also realized that deprotonation of amines or alcohols by the hydroxo-complex in the presence of carbon disulfide leads to the formation of the corresponding dithiocarbamate or xanthate complexes, respectively [9,17]. Moreover, the reaction of the hydroxo-bridged

nickel complex with malononitrile leads to the formation of an unprecedented dicyanomethanide-bridged anionic complex [18].

On the other hand, although the chemistry of metal poly(pyrazol-1-yl)borato complexes has been studied extensively in recent years [19], comparable development of the isoelectronic, but neutral poly(pyrazol-1-yl)alkanes has received little attention [20]. Most of the published material concerns first-row transition metals [21] and some ruthenium(II) examples [22], while coordination to metals having the d^8 configuration is rare and it basically includes complexes of rhodium(I) [23] and some derivatives of dimethylgold(III) [24] and methyl or dimethylplatinum(II) [25] with tris(pyrazol-1-yl)alkanes. The interaction of the bis(pyrazol-1-yl)alkanes with palladium(II) is still largely unexplored [26], and only a few cationic allylic complexes have been reported [27]. In this sense, we have described recently the synthesis of the precursors $[Pd(N–N)(CH_3CN)_2][ClO_4]_2$ and $[Pd(N–N)(\mu\text{-}OH)]_2[ClO_4]_2$ (N–N = bpzm:bis(pyrazol-1-yl)methane, bpzm*:bis(3,5-dimethylpyrazol-1-yl)methane) [7].

Following our systematic study of the reactivity shown by hydroxo-complexes of the nickel group elements, we have now investigated the former complexes $[Pd(N–N)(\mu\text{-}OH)]_2[ClO_4]_2$ [7] in reactions towards a wide variety of protic electrophiles and related reactions like that against amines in the presence of carbon disulfide. The addition of water to pyridine-2-carbonitrile in the presence of the above hydroxo-palladium complexes has also been studied.

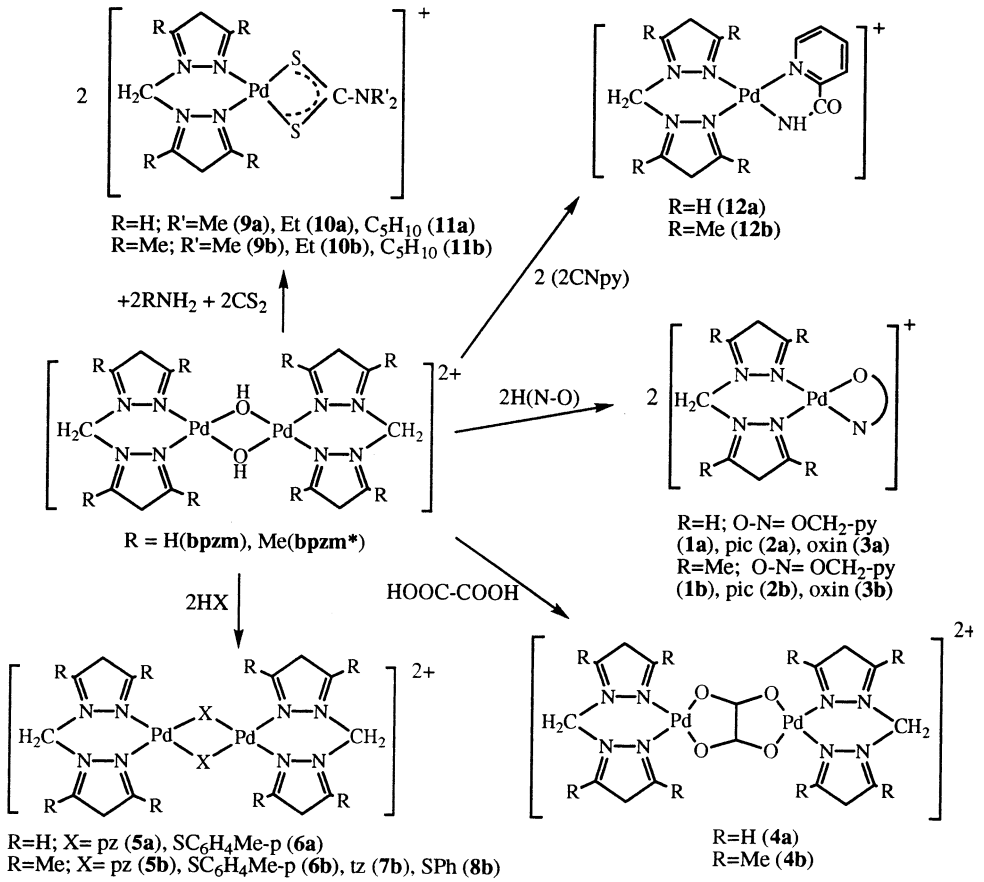
2. Experimental

2.1. Materials and physical measurements



C, H, N and S analyses were carried out with a Carlo Erba model EA 1108 microanalyzer. IR spectra were recorded on a Perkin–Elmer 16PC FT IR spectrophotometer using Nujol mulls between polyethylene sheets. NMR data were recorded on a Bruker AC 200E or a Varian Unity 300 spectrometer. Decomposition points were determined on a Reichert microscope provided with heating plate. Conductance measurements were performed with a Crison 525 conductimeter (in acetone; $c=10^{-3}$ M). Mass spectrometric analyses were performed on a Fisons VG Autospec double-focusing spectrometer, operated in positive mode. Ions were produced by fast atom bombardment (FAB) with a beam of 25-Kev Cs atoms. The mass spectrometer was operated with an accelerating voltage of 8 kV and a resolution of at least 1000.

The bis(pyrazol-1-yl)alkane precursors $[Pd(N–N)(\mu\text{-}OH)]_2[ClO_4]_2$ were prepared by a procedure described elsewhere [7]. The protic ligands were obtained commercially and used without further purification and all the solvents were dried by standard methods before use.

2.2. Preparation of the complexes

2.2.1. Complexes *1a*–*6a*

The complexes were obtained by treating $[\{Pd(\mu\text{-}OH)(bpzm)\}_2][ClO_4]_2$ with the corresponding protic ligand (molar ratio 1:2; 1:1 in **4a**) in acetone according to the following general method. To an acetone (15 ml) suspension of $[\{Pd(\mu\text{-}OH)(bpzm)\}_2][ClO_4]_2$ (0.10 g, 0.13 mmol) was added the stoichiometric amount of ligand

Scheme 1.

(0.26 mmol, 0.13 mmol in **4a**). The solution was stirred at room temperature (r.t.) for 15 min, then concentrated under reduced pressure until ca. one fifth of the initial volume. Slow addition of diethyl ether caused the precipitation of the title complexes, which were filtered off, washed with ether and air-dried.

[Pd(O–CH_2-py)(bpzm)][ClO_4] (**1a**) was obtained in 66% yield. *Anal.* Calc. for $C_{13}H_{14}ClN_5O_5Pd$: C, 32.2; H, 3.1; N, 15.2. Found: C, 32.0; H, 3.3; N, 15.1%. M.p. (dec.) = 150°C. $\Lambda_M = 117\ \Omega^{-1}\ cm^2\ mol^{-1}$. IR ($cm^{-1}$): 1604 (C=N str).

[a] In acetone.
[b] In DMSO.

2.2.2. Complexes ***1b–8b***

The complexes were obtained by treating [{Pd(μ-OH)(bpzm*)}$_2$][ClO$_4$]$_2$ with the corresponding protic ligand (molar ratio 1:2, 1:1 in **4b**) in acetone according to the following general method. To an acetone (15 ml) suspension of [{Pd(μ-OH)(bpzm*)}$_2$][ClO$_4$]$_2$ (0.10 g, 0.12 mmol) was added the stoichiometric amount of ligand (0.24 mmol, 0.12 mmol in **4b**). The solution was refluxed for 1 h, then concentrated under reduced pressure until ca. one fifth of the initial volume. Slow addition of diethyl ether caused the precipitation of the title complexes, which were filtered off, washed with ether and air-dried.

Scheme 3.

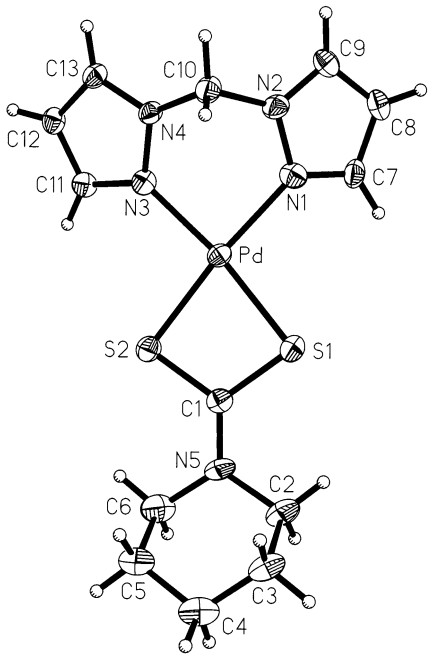

Fig. 1. Molecular structure of complex **11a**.

2.2.4. Hydration of coordinated aminonitriles: complexes *12a* and *12b*

In separate experiments, to a suspension of the precursors [{Pd(μ-OH)(bpzm*)}$_2$][ClO$_4$]$_2$ (0.10 g, 0.12 mmol) and [{Pd(μ-OH)(bpzm)}$_2$][ClO$_4$]$_2$ (0.10 g, 0.13 mmol) in acetone–H$_2$O (15:1 ml) was added pyridine-2-carbonitrile in stoichiometric amount (1:2). The resultant clear solution was stirred at r.t. for 15 min and then concentrated under reduced pressure until ca. one fifth of the initial volume. Slow addition of diethyl ether caused the precipitation of the yellow complexes, which were filtered off, washed with ether and air-dried.

[Pd(HNCO-py)(bpzm)][ClO$_4$] (**12a**) was obtained in 90% yield. *Anal.* Calc. for $C_{13}H_{13}ClN_6O_5Pd$: C, 32.8; H, 2.7; N, 17.7. Found: C, 32.7; H, 2.7; N, 17.5%. M.p. (dec.) = 194°C. $\Lambda_M = 112\ \Omega^{-1}\ cm^2\ mol^{-1}$. IR (cm^{-1}): 3172 (N–H str), 1642 (C=O str).

[Pd(HNCO-py)(bpzm*)][ClO$_4$] (1**2b**) was obtained in 89% yield. *Anal.* Calc. for $C_{17}H_{21}ClN_6O_6Pd$: C, 38.4; H, 3.9; N, 15.8. Found: C, 38.5; H, 4.1; N, 15.7%. M.p. (dec.) = 284°C. $\Lambda_M = 120\ \Omega^{-1}\ cm^2\ mol^{-1}$. IR (cm^{-1}): 3204 (N–H str), 1650 (C=O str).

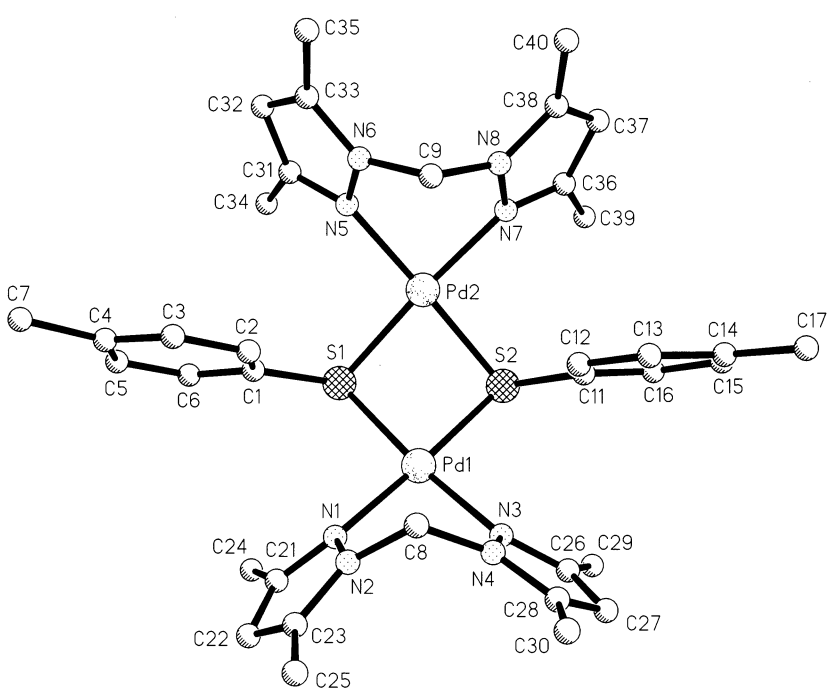

Fig. 2. Molecular structure of complex **6b**.

2.3. X-ray structural analysis of complexes $[Pd(S_2CNC_5H_{10})(bpzm)][ClO_4]$ (**11a**) and $[\{Pd(\mu\text{-}SC_6H_4Me\text{-}p)(bpzm^*)\}_2][ClO_4]_2$ (**6b**)

Crystals were mounted on glass fibers and transferred to the diffractometer (Siemens P4 with LT2 low-temperature attachment) as summarized in Table 1. The structure was solved by direct methods (**6b**·$(CH_3)_2CO\cdot H_2O$) or by the heavy atom method (**11a**) and refined anisotropically on F^2 (program SHELXL-93) [28]. For compound **6b**·$(CH_3)_2CO\cdot H_2O$ both perchlorate anions and the methyl groups of the acetone molecule are disordered over two positions. Hydrogen atoms for the water molecule were not found and the others included using a riding model. For compound **11b**, two independent molecules were found in the asymmetric unit with one of the perchlorate anions disordered over two sites.

3. Results and discussion

3.1. Reactivity of $[Pd(N–N)(\mu\text{-}OH)]_2[ClO_4]_2$ (N–N = bpzm and bpzm*)

The markedly basic character of complexes $[Pd(bpzm)(\mu\text{-}OH)]_2[ClO_4]_2$ and $[Pd(bpzm^*)(\mu\text{-}OH)]_2[ClO_4]_2$ is consistent with their chemical reactivity, exhibited towards a wide variety of protic acids H(LL) and summarized in Scheme 1. Its efficiency as precursors in coordination chemistry comes from their ability to yield the new complexes in one clean step, with the concomitant release of water.

Thus, the hydroxo-complexes react in acetone under mild to strong conditions with weak protic acids H(LL) to give mono- or binuclear species, depending on whether the deprotonated acid $(LL)^-$ is *exo*- or *endo*-bidentate. These reactions can be considered as an initial proton abstraction by the hydroxo-palladium complex, which provides $(LL)^-$ and the metal substrate subsequently, trapped by the anion to form the new complexes. In a similar way, the preparation of the dithiocarbamato-complexes (**9a**–**11a** and **9b**–**11b**) should involve a first step of amine deprotonation, followed by nucleophilic attack of R_2N^- to carbon disulfide present in the reaction medium to form the dithiocarbamate anion.

In previous work we pointed out marked differences in reactivity between the hydroxo-complexes studied [6,16], although it was always under the general pattern described above. Sometimes these differences can be explained on the basis of the distinct activation of the OH groups, and other reasonable explanations are provided by the relative lability of the backbone ligands (bpzm and bpzm* in this paper), easily displaced from the coordination sphere if a competitive insoluble product is forming, or when strong steric requirements of the incoming ligand are operating. In this sense, the unequal behavior showed by the hydroxo-complexes object of our study in this paper was not unexpected, and can be regarded as a consequence of the differences both steric and electronics between the ligands bpzm and bpzm*.

Thus, when $[Pd(bpzm)(\mu\text{-}OH)]_2^{2+}$ reacts in acetone with HO–N donor ligands in short time (15 min) under mild conditions, the new complexes **1a**–**3a** were obtained in good yield. If the same reactions are stirred for longer periods, dissociation of complexes occurs with the formation of insoluble species $[Pd(O–N)_2]$ and solutions containing the cationic complex with two bpzm units (Scheme 2).

This dissociation reactions are strongly dependent on the solvent employed, being faster when increasing its donor properties. On the other hand, reactions involving the bis(3,5-dimethylpyrazol-1-yl) methane (bpzm*) precursor and O–N-donor ligands did not present this behavior and the expected complexes were obtained normally, even requiring stronger conditions. In this case the presence of methyl groups in bpzm* may increase the donor capability of this ligands respect bpzm, as it can avoid the dissociation mechanism by solvent attack through the *z*-axis of the square-planar complexes.

The attemps to obtain the corresponding thiolate and azolate complexes from $[Pd(bpzm)(\mu\text{-}OH)]_2[ClO_4]_2$ and $[Pd(bpzm^*)(\mu\text{-}OH)]_2[ClO_4]_2$ revealed once more, differences in reactivity between them. Thus, reactions of the bpzm precursor with triazole and activated thiols yield insoluble species where the bpzm ligand was not detected, probably labilized from the coordination sphere as a consequence of the formation of polimeric compounds.

In contrast, the reactivity presented for both precursors against carbon disulfide and secondary amines was the same, yielding the corresponding dithiocarbamate complexes **9a**–**11a** and **9b**–**11b** as explained in Section 2.

3.2. Hydration of coordinated aminonitriles

The activation of nitriles with respect to attack by nucleophiles in the coordination sphere of metal ions has attracted considerable interest [29–31] and we have recently described the nucleophilic attack of OH^- and MeO^- on benzonitrile coordinated to Pt(II) [4]. We also reported the use of the hydroxo-complex $[\{Ni(C_6F_5)_2(\mu\text{-}OH)\}_2]^{2-}$ in the formation of complexes containing amidate ligands [32]. In acetone–H_2O, the precursors $[Pd(bpzm)(\mu\text{-}OH)]_2[ClO_4]_2$ and $[Pd(bpzm^*)(\mu\text{-}OH)]_2[ClO_4]_2$ react smoothly with pyridine-2-carbonitrile (CNpy) leading to the formation of the corresponding complexes with pyridine-2-carboxamidate ligand (compounds **12a** and **12b** in Scheme 1).

3.3. Characterization

The new compounds are air-stable, yellow–orange solids, and measurements of their molar conductivity in acetone solutions indicate that the complexes behave as 1:1 (**1**–**3** and **9**–**12**) or 1:2 (**4**–**8**) electrolytes [33], in accordance with the proposed formulae. The most significant IR absorption bands of the new complexes are collected in Section 2. The IR spectra of the complexes also show the characteristic bands of the ligands bpzm and bpzm* at ca. 1520, 770 and 640 cm^{-1} and 1556, 790 and 680 cm^{-1}, respectively, together with the bands attributed to the anion perchlorate at 1070 and 624 cm^{-1}.

The ^{1}H and ^{13}C NMR data are listed in Table 2 and Scheme 3 shows the labeled ligands. The ^{1}H spectra exhibit the expected resonances for the corresponding anionic ligands, together with the corresponding resonances of the pyrazolyl groups. As we reported in a previous paper [7], the two pyrazolyl groups were identical or spectroscopically different depending on the asymmetry of complexes, and one or two sets of pyrazolyl signals were respectively observed. Regarding to the methylene NMR-signals showed by the compounds, we found the expected patterns reported for bis(pyrazol-1-yl)methane ligands [7,22,26,27]. The assignment was made by comparison with our previous data and by means of different NMR experiments ($^{1}H-^{13}C$ heteronuclear correlations for ^{13}C assignment).

Further evidence for the dinuclearity of complexes **4a**–**6a** and **4b**–**8b** comes from the FAB mass spectrometry (see Section 2). Spectra of the new bridged compounds show a similar pattern of fragmentation which includes, as the most outstanding feature, the peaks corresponding to $[Pd_2(N–N)_2(L)_2(ClO_4)]^+$, $[Pd_2(N–N)_2(L)_2]^+$ and $[Pd_2(N–N)(L)_2(ClO_4)]^+$ (N–N = bpzm or bpzm*; L = pz, taz, SPh and SC_6H_4Me-p). This technique becomes an excellent tool to characterize the μ-oxalate compounds **4a** and **4b**, whose marked insolubility prevent their proper characterization by NMR spectroscopy. The abundances of the signals around the parent ion are consistent with the natural isotopic abundances. Additional peaks are observed, indicating further fragmentation and formation of some adducts with the matrix [34].

3.4. Crystal structures of complexes *11a* and *6b*

The crystal structure of **11a** consists of cationic mononuclear palladium complexes and perchlorate anions. Two molecules of the complex appear in the asymmetrical unit, as shown in Fig. 1. The planar coordination around palladium is slightly distorted. Bond distances and angles are similar to those found in other palladium(II) complexes with dithiocarbamate ligands [35], and a selection is presented in Table 3. The angle S(2)–Pd–S(1) is appreciably smaller than 90° (76.3°) as a consequence of geometrical restrictions of the chelate ring, and, as expected, the S–Pd–N angles are over 90° (95.9 and 98.7°) [36].

The dinuclearity of complex **6b** was unambiguously established by single-crystal X-ray diffraction. Selected geometrical features are given in Table 3. The structure consists of binuclear $[\{Pd(\mu\text{-}SC_6H_4Me\text{-}p)(bpzm^*)\}_2]^+$ cations (Fig. 2) joining ClO_4^- anions by electrostatic interactions and one molecule of crystallization of $(CH_3)_2CO$ and H_2O. The geometry about each palladium atom is approximately planar-square, with predictable narrowing of the S–Pd–S (80.04 and 80.14°) and N–Pd–N (86.2 and 85.3°) angles in both centers to accommodate the bridged structure, as usual in bridging arylthiolates [37].

On the other hand, it is well known that, depending on the units $M(\mu\text{-}SR)_2M$ being planar or bend and the relative positions of substituents, there are five possible geometrical isomers [38]. In our complex, the structure presents a bend $Pd(\mu\text{-}SC_6H_4Me\text{-}p)_2Pd$ unit with *syn–endo* geometry and a dihedral angle between $N_2Pd(1)S_2$ and $S_2Pd(2)N_2$ of 52.6°.

4. Supplementary data

Crystallographic data have been deposited with the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) and are available on request quoting the deposition Nos. CCDC 140465 and 140466.

Abstract

Reactions of $(PyH)_2[MoOCl_5]$ with methanol and 3,5-lutidine or 3-methylpyridine carried out under conditions of solvothermal synthesis at 130°C have resulted in two Mo(V, VI) clusters containing the same molybdenum oxide framework, $[Mo_{10}O_{26}(3,5\text{-Lut})_8]\cdot 2(3,5\text{-Lut})$ (3,5-Lut = 3,5-lutidine (C_7H_9N)) (**i**) and $[Mo_{10}O_{26}(3\text{-MePy})_8]\cdot(3\text{-MePy})$ (3-MePy = 3-methylpyridine (C_6H_7N)) (**ii**), and in a novel $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-MePy})_8]$ (**iv**). $[Mo_{10}O_{26}(3\text{-MePy})_8]$ (**iii**) was also obtained by oxidizing $(NH_4)_2[MoCl_5(H_2O)]$ in a mixture of methanol, 3-methylpyridine and nitromethane. X-ray structural analyses revealed $Mo_2O_4^{2+}$ unit as a common structural motif in both cluster types. In **i**–**iii** ten molybdenum atoms are grouped into four Mo_2^{V} pairs with Mo–Mo bonds and two Mo(VI) sites. The oxomolybdenum core of **iv** is composed of six Mo_2^{V} pairs connected through oxo and methoxo bridges. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Solvothermal synthesis; Crystal structures; Oxomolybdenum(V) coordination compounds; Mo(V, VI) compounds; Alkyl-substituted pyridines

1. Introduction

A decanuclear oxomolybdenum(V, VI) cluster with stoichiometry $[Mo_{10}O_{26}L_8]$ (L = 3,5-Lut, 3-MePy) and a new, dodecanuclear $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-MePy})_8]$ are two more examples of the vast family of high-nuclearity oxoalkoxymolybdate complexes with oxygen, nitrogen and sulfur donor ligands that has emerged in the past two decades. The molecular building approach based on the assembly of preorganized templates combined with the technique of hydrothermal synthesis has led to polyoxometalates of very complex stoichiometries, some with finite oxometalate core structures, and some with infinite chains, sheets or lattice frameworks [1]. The organic components added to the reaction mixture have been found to play a key role in the design of novel oxide-based composite materials: with the appropriate selection of the organic template its structural information can be imprinted onto the inorganic framework [2]. $(NH_4)_7[NaMo_{16}(OH)_{12}O_{40}]\cdot 4H_2O$, a class of superclusters $[Na(H_2O)_3H_{13}Mo_{42}O_{109}\{(OCH_2)_3CR\}_7]^{9-}$ or $[MoO_3H_{14}Mo_{42}O_{109}\{(OCH_2)_3CR\}_7]^{9-}$ ($(OCH_2)_3$-CR = trisalkoxy group) [3,4] with $Mo_2O_4^{2+}$ as a common structural motif in all, $[\{Cu(pyrd)\}_4(\gamma\text{-}H_4Mo_8O_{26})]$ (pyrd = pyridazine) [5] and $[\{Cu_3(4,7\text{-phen})_3\}_2\{Mo_{14}O_{45}\}]$ (4,7-phen = 4,7-phenanthroline) [6] where the molybdate cluster is entrained within a scaffolding provided by the coordination cation polymer, are just a few examples. A curious feature of the latter is the presence of two distinct types of molybdenum cluster $[Mo_6O_{19}]^{2-}$ and $\beta\text{-}[Mo_8O_{26}]^{4-}$ which are linked through $[Cu_3(4,7\text{-phen})_3]^{3+}$ in a two-dimensional structure.

In the literature two molybdate(VI) pyridine compounds are reported. $(PyH)_4[Mo_8O_{26}Py_2]$, which is built of pyridinium cations and discrete $[Mo_8O_{26}Py_2]^{4-}$ an-

PII: S0277-5387(00)00430-7

ions, was the first isopolymolybdate(VI) containing a ligand other than oxygen [7]. The polymeric structure of $[MoO_3Py]$ is believed to consist of oxide layers separated by organic layers with nitrogen directly coordinated to molybdenum [8].

We found that $(PyH)_2[MoOCl_5]$ reacts with methanol and pyridines through a series of reactions, starting with the facile replacement of chloro ligands, followed by dimerization into $Mo_2O_4^{2+}$ moieties, which eventually link into larger, stable assemblies. The properties of the neutral oxomolybdenum(V) clusters are similar to those of $Mo_2O_4^{2+}$ units. The puckered $Mo(\mu_2\text{-}O)_2Mo$ ring, whose two molybdenum atoms are a short distance apart (2.5–2.7 Å), allows the formation of a localized single metal–metal bond which accounts for the experimentally-observed diamagnetism [9]. From the identity of the isolated clusters, i.e. $[Mo_4O_8(OCH_3)_2Cl_2Py_4]\cdot 2Py$ [10], $[Mo_5O_{11}(OCH_3)_4Py_4]\cdot CH_3OH$ [11], $[Mo_6O_{12}(OCH_3)_6Py_4]$ [10], $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = pyridine, 3-methylpyridine, 4-methylpyridine, 4-ethylpyridine, 4-*tert*-butylpyridine, 3,5-lutidine) [12,13] and $[Mo_{10}O_{26}Py_8]\cdot 7Py$ [10], we could infer that the nuclearity of the clusters and the degree of substitution of chloro ligands are highly dependent on the reaction conditions. In order to obtain the 'final' product of the polymerization, some of the reaction systems were tested under the conditions of the solvothermal synthesis. Herein we report on two types of oxomolybdenum cluster obtained by employing this technique.

2. Experimental

2.1. General comments

$(NH_4)_2[MoCl_5(H_2O)]$ [14] and $(PyH)_2[MoOCl_5]$ [15] were synthesized according to published procedures. Solvents were reagent grade and they were used without additional purification. They were obtained from the following sources: Merck (3,5-lutidine, methanol and nitromethane) and BDH Chemicals (3-methylpyridine).

IR spectra of Nujol (4000–400 cm^{-1}) and hexachlorobutadiene (4000–1200 cm^{-1}) mulls between CsBr plates were measured on a Perkin–Elmer 1720 X FT-IR spectrometer. Far IR spectra of Nujol mulls (700–100 cm^{-1}) on a polyethylene foil were measured on a Perkin–Elmer 2000 FT-IR spectrometer.

2.2. Preparations

2.2.1. Preparation of $[Mo_{10}O_{26}(3,5\text{-}Lut)_8]\cdot 2(3,5\text{-}Lut)$ (i)

A 50 mg (0.11 mmol) sample of $(PyH)_2[MoOCl_5]$ was added to a mixture of 2 ml of methanol and 7 ml of 3,5-lutidine. The sealed glass tube was heated in an autoclave under autogenous pressure at 130°C for 146 h. Dark, red crystals were obtained in 30% yield (8 mg).

Anal. Calc. for $C_{56}H_{72}Mo_{10}N_8O_{26}$ (dried sample): C, 30.13; H, 3.25; N, 5.02. Found: C, 30.37; H, 3.27; N, 5.08%.

IR data (cm^{-1}): 1608(m), 1600(m), 1310(w), 1252(w), 1184(w), 1157(s), 1038(m), 974(m), 961(vs), 945(m), 922(w), 868(m), 796(m), 779(m), 757(vs), 740(vs), 720(vs), 702(vs), 649(w), 617(m), 537(sh), 516(m), 494(m), 413(w).

2.2.2. Preparation of $[Mo_{10}O_{26}(3\text{-}MePy)_8]\cdot(3\text{-}MePy)$ (ii)

A 428 mg (0.95 mmol) sample of $(PyH)_2[MoOCl_5]$ was added to a mixture of 5 ml of methanol and 15 ml of 3-methylpyridine. A total of 2 ml of water was added to the solution. The sealed glass tube was heated in an autoclave under autogenous pressure at 130°C for 104 h. Dark, almost black crystals were obtained in 9% yield (18 mg).

IR data (cm^{-1}): 1614(m), 1584(m), 1251(w), 1201(s), 1135(s), 1111(s), 1068(s), 1037(w), 957(vvs), 946(vvs), 935(m), 910(w), 825(w), 798(vs), 752(vvs), 741(vs), 726(m), 707(vs), 696(vs), 661(m), 618(vs), 534(sh), 520(sh), 502(s), 484(s), 453(m), 419(sh), 408(sh).

2.2.3. Preparation of $[Mo_{10}O_{26}(3\text{-}MePy)_8]$ (iii)

A 90 mg (0.273 mmol) sample of $(NH_4)_2[MoCl_5(H_2O)]$ was added to a mixture of 2.2 ml of 3-methylpyridine, 2.2 ml of nitromethane and 6.6 ml of methanol. After stirring for 30 min, 0.2 ml of water was added to the solution. The solution was left for 3 days under ambient conditions. Red, plate-shaped crystals were obtained in 24% yield (14 mg).

Anal. Calc. for $C_{48}H_{56}Mo_{10}N_8O_{26}$: C, 27.19; H, 2.66; N, 5.28. Found: C, 26.92; H, 2.48; N, 5.02%.

IR data (cm^{-1}): 1612(m), 1583(w), 1198(m), 1130(m), 1111(m), 1066(m), 1037(w), 958(vvs), 948(sh), 823(w), 796(vs), 753(vs), 741(vs), 725(sh), 706(vs), 661(m), 621(s), 519(sh), 500(s), 487(sh), 452(w).

2.2.4. Preparation of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (iv)

A 428 mg (0.95 mmol) sample of $(PyH)_2[MoOCl_5]$ was added to a mixture of 5 ml of methanol and 15 ml of 3-methylpyridine. The sealed glass tube was heated in an autoclave under autogenous pressure at 130°C for 96 h. Black crystals were obtained in 28% yield (55 mg).

Anal. Calc. for $C_{50}H_{62}Cl_2Mo_{12}N_8O_{30}$: C, 24.24; H, 2.52; N, 4.52. Found: C, 24.53; H, 2.52; N, 4.46%.

IR data (cm^{-1}): 2811(w), 1612(m), 1582(m), 1200(m), 1133(m), 1113(m), 1065(s), 1047(s), 962(vvs), 938(vs), 826(w), 794(m), 761(vs), 747(s), 704(vs), 692(vs), 672(m), 661(m), 617(m), 543(w), 508(vs), 480(sh), 437(w), 419(m), 392(w), 366(w), 347(w), 332(w), 307(m), 290(sh), 269(m).

2.3. X-ray structural determination

Crystal data parameters are given in Table 1. Data for compound **i** were collected on a Nonius FAST area detector diffractometer. A total of 10 359 reflections were measured ($\theta_{max} = 22.76°$; $-13 \le h \le 13$, $-14 \le k \le 14$, $-15 \le l \le 15$) and reduced to a unique set of 5250 reflections ($R_{int} = 0.071$). The program used for data collection was MADNES [16]. The structure was solved by direct methods. The program used for structure solution and refinement was SHELXTL-96 [17]. All non-hydrogen atoms were refined using anisotropic thermal parameters. The least-squares refinement on F^2 for **i** converged at $R = 0.0599$ and $R_w = 0.1282$ for 523 parameters, 18 restraints and 4896 data ($I > 2\sigma(I)$) (the weighting scheme used was $w = 1/\{\sigma^2(F_o^2) + (0.03P)^2 + 35.0P\}$ where $P = (F_o^2 + 2F_c^2)/3$).

Data for compounds **ii**–**iv** were collected on an Enraf–Nonius CAD-4 diffractometer. For **ii** a total of 12 909 reflections were measured ($\theta_{max} = 24.99°$; $-14 \le h \le 0$, $-15 \le k \le 15$, $-26 \le l \le 26$) and reduced to a unique set of 6452 reflections ($R_{int} = 0.0379$); for **iii** a total of 17 768 reflections were measured ($\theta_{max} = 28.12°$; $-15 \le h \le 15$, $-17 \le k \le 0$, $-30 \le l \le 30$) and reduced to a unique set of 8489 reflections ($R_{int} = 0.072$); for **iv** a total of 23 729 reflections were measured ($\theta_{max} = 24.98°$; $-48 \le h \le 48$, $-48 \le k \le 48$, $-14 \le l \le 4$) and reduced to a unique set of 7124 reflections ($R_{int} = 0.092$). Cell parameters for **ii** were determined from 100 reflections in the 9.01–14.29° θ range, for **iii** from 50 reflections in the 8.15–13.1° θ range and for **iv** from 75 reflections in the 8.20–14.17° θ range. Data collection followed routine procedures. All data were corrected for Lorentz and polarization effects. No absorption corrections were applied. Structures were solved by direct methods using SIR-92 [18]. All non-hydrogen atoms were refined using anisotropic thermal parameters. The program used was XTAL 3.4 [19]. The hydrogen atoms were inserted in calculated positions. The least-squares refinement on F for **ii** converged at $R = 0.033$ and $R_w = 0.042$ for 451 parameters and 4529 data ($F_o > 3\sigma(F_o)$) (the weighting scheme used was $w = W_F W_S$, where $W_F(F_o < 32) = (F_o/32)^1$, $W_F(F_o > 76) = (76/F_o)^1$ and $W_F(32 < F_o < 76) = 1$, and $W_S(\sin\theta < 0.4) = (0.4/\sin\theta)^1$, $W_S(\sin\theta > 0.54) = (\sin\theta/0.54)^1$ and $W_S(0.4 < \sin\theta < 0.54) = 1$). The least-squares refinement for **iii** converged at $R = 0.088$ and $R_w = 0.089$ for 415 parameters and 3492 data ($F_o > 3\sigma(F_o)$) (the weighting scheme used was $w = W_F W_S$, where $W_F(F_o < 40) = (F_o/40)^1$, $W_F(F_o > 90) = (90/F_o)^1$ and $W_F(40 < F_o < 90) = 1$, and $W_S(\sin\theta < 0.33) = (0.33/\sin\theta)^{2.0}$, $W_S(\sin\theta > 0.43) = (\sin\theta/0.43)^3$ and $W_S(0.33 < \sin\theta < 0.43) = 1$). The least-squares refinement for **iv** converged at $R = 0.047$ and $R_w = 0.050$ for 460 parameters and 3744 data ($F_o > 3\sigma(F_o)$) (the weighting scheme used was $w = W_F W_S$, where $W_F(F_o < 146) = (F_o/146)^1$, $W_F(F_o > 268) = (268/F_o)^1$ and $W_F(146 < F_o < 268) = 1$, and $W_S(\sin\theta < 0.32) = (0.32/\sin\theta)^{3.0}$, $W_S(\sin\theta > 0.48) = (\sin\theta/0.48)^1$ and $W_S(0.32 < \sin\theta < 0.48) = 1$).

3. Results and discussion

3.1. Description of structures

3.1.1. Crystal structures of $[Mo_{10}O_{26}(3,5\text{-Lut})_8]\cdot 2(3,5\text{-Lut})$ (i), $[Mo_{10}O_{26}(3\text{-MePy})_8]\cdot(3\text{-MePy})$ (ii) and $[Mo_{10}O_{26}(3\text{-MePy})_8]$ (iii)

X-ray structural analyses have shown that compounds **i**–**iii** contain discrete neutral molecules com-

posed of a common oxomolybdenum framework. The same structure has been identified before for $[Mo_{10}O_{26}Py_8]\cdot 7Py$ [10]. Some of the principal dimensions of the $[Mo_{10}O_{10}(\mu_2\text{-}O)_8(\mu_3\text{-}O)_6(\mu_4\text{-}O)_2]$ core for compounds **i**–**iii** are given in Table 2. Geometric parameters for **i** are listed in Table 3. The structure of **i** is shown in Fig. 1. The centrosymmetric molecules contain eight Mo(V) atoms, two Mo(VI) atoms, 26 oxo groups and eight nitrogen donor ligands. The eight Mo(V) centers form four binuclear units with single Mo–Mo bonds, in which the average Mo–Mo distances are 2.579(2), 2.585(9) and 2.585(3) Å for **i**–**iii**, respectively. Two oxygen atoms adopt a μ_4-bridging mode. The coordination of O(μ_4) to one Mo(VI) and three Mo(V) sites is unsymmetrical. In **i**, for example, the distances to the Mo(V) centers are 1.970(7), 1.982(7) and 2.309(7) Å and the distance to Mo(VI) is 2.613(8) Å. The two hexavalent molybdenum atoms can be clearly distinguished from the Mo(V) centers which are part of the $Mo_2O_4^{2+}$ units. The distorted octahedral environment of each Mo(V) atom consists of five oxygen atoms and one nitrogen atom. The coordination environment of each Mo(VI) site is composed solely of oxygen atoms at distances ranging from 1.675(8) to 2.613(8) Å in **i**. One terminally bound oxo group, two doubly bridging, two triply bridging and a quadruply bridging oxo group constitute the highly distorted octahedral environment of Mo(VI). The weak interaction between Mo(VI) and O(μ_4), 2.613(8) Å in **i** manifests a strong *trans* influence of a terminally bound oxygen. The structure may be alternatively viewed (Fig. 2) as a parallel alignment of the Mo–Mo vectors of four $Mo_2O_4^{2+}$ units forming a fourfold pattern with the Mo=O groups of each dimer perpendicularly oriented towards its adjacent neighbors. The front and back face

of the geometric shape thus obtained are capped with two Mo(VI) moieties. Fig. 3 shows how the polyhedra are assembled together.

The structure of **i** also contains 3,5-lutidine molecules of crystallization. Compound **ii** contains a disordered solvent of crystallization. The shortest contact between two cluster molecules in **ii** is between a 3-methylpyridine carbon and a terminally bound oxygen, C24···O2^{ii} (symmetry code: (ii) $-x, 1-y, 1-z$) at a distance of 3.166(10) Å. The shortest contact in **iii** formed between C11 and O7^{ii} is 3.10(4) Å (symmetry code: (ii) $-x, 1-y, 1-z$).

The decanuclear anion found in $(NBu_4)_4[Mo_{10}O_{28}(SCH_2CH_2O)_2(HOCH_3)_2]\cdot 2CH_3OH$, which also features molybdenum in two oxidation states, has a different structure [22]. It consists of six Mo(VI) and four Mo(V) atoms which are part of two Mo_2^V units.

*3.1.2. Crystal structure of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-MePy})_8]$ (**iv**)*

The centrosymmetric cluster consists of a $[Mo_{12}O_{12}(\mu_2\text{-O})_4(\mu_3\text{-O})_{10}(\mu_4\text{-O})_2(\mu_2\text{-OCH}_3)_2]^{2+}$ framework to which are attached two chloro and eight 3-methylpyridine ligands. An extensive list of bond lengths and angles is given in Table 4, while values for different bonding modes of the ligands are listed in Table 5. An ORTEP III [20] picture of **iv** is given in Fig. 4. The 12 molybdenum atoms are arranged into six Mo_2^V pairs with Mo–Mo distances of 2.562(2), 2.590(2) and 2.682(2) Å. The oxygen atoms are of five distinct types. Twelve are terminal oxo groups with characteristic Mo–O distances in the range 1.643(9)–1.681(6) Å and two are methoxy oxygen donors adopting a doubly bridging mode with Mo–O distances 2.054(9) and 2.219(10) Å. Four oxygen atoms coordinate in a μ_2 fashion and ten in a μ_3 fashion. An unusual structural

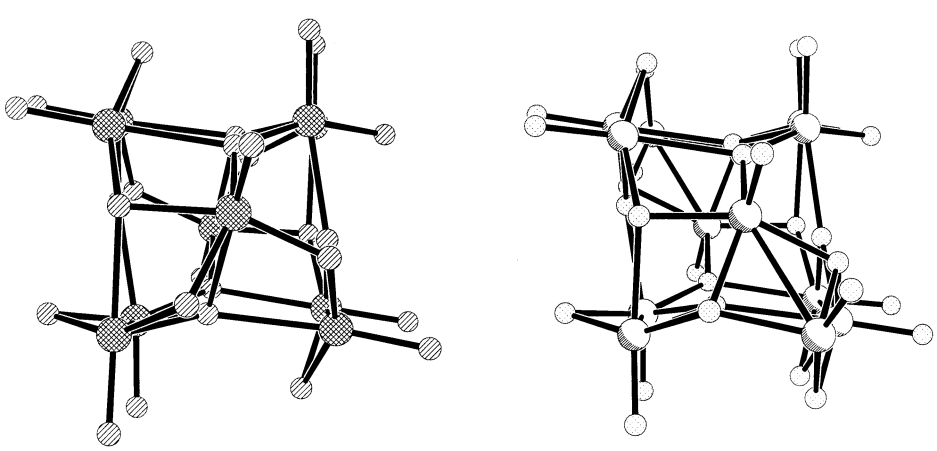

Fig. 2. Alternative view of cluster molecules in **i** (left) and **iv** (right). Carbon atoms are omitted.

^{iii} Symmetry code: $1-x$, $1-y$, $1-z$.

feature is a quadruply bridging oxygen atom labeled O8, surrounded by four molybdenum atoms (Mo1, Mo2, Mo3 and Mo5) which lie at the vertices of a distorted tetrahedron. Among the Mo–O(μ_4) distances, 1.987(5), 1.990(8), 2.405(6) and 2.625(8) Å, the two longer bonds are formed as expected, i.e. *trans* to two terminal Mo=O groups. In view of these long Mo–O distances, the Mo sites are highly distorted octahedra that may be alternatively described as square pyramidal sites with weak axial interactions *trans* to the multiply bonded apical oxygen. Some molybdenum atoms have one, two or three terminally bound ligands. Although the structure of **iv** represents a hitherto unknown structural type, it bears some resemblance to $[Mo_{10}O_{26}L_8]$ (L = Py, 3,5-Lut (**i**), 3-MePy (**ii**, **iii**)). The analogy becomes obvious by noting that four of the six $Mo_2O_4^{2+}$ units are aligned with their Mo–Mo vectors parallel to each other, similar to the previously described $[Mo_{10}O_{26}L_8]$ cluster type with the front and rear faces in **iv** capped with two $Mo_2O_4^{2+}$ units (Fig. 2). A polyhedral representation of **iv** is given in Fig. 5.

The core of **iv** may be compared with the $Mo_{12}^{V}O_{40}$ core found in an organometallic cation, $[(C_5Me_5Rh)_8Mo_{13}O_{40}]^{2+}$ [23]. Six $Mo_2O_4^{2+}$ units, assembled together with a tetrahedral T_d symmetry, form a cage whose center accommodates a Mo(VI) site. In the analogous $(NH_4)_7[NaMo_{16}(OH)_{12}O_{40}]\cdot 4H_2O$ and $(Me_2NH_2)_6[H_2Mo_{16}(OH)_{12}O_{40}]$ complexes the central cavity hosts a sodium cation or two protons [3]. These anions may be rewritten as $[(Mo^{VI}O_3)_4Mo_{12}^{V}(OH)_{12}O_{28}]^{8-}$ where four faces of the $Mo_{12}^{V}O_{40}$ core are capped with four $Mo^{VI}O_3$ units.

3.2. IR spectra

In the IR spectra of the $[Mo_{10}O_{26}L_8]$ clusters (L = 3,5-Lut (**i**), 3-MePy (**ii**, **iii**)), a number of intense bands were observed in the region for stretching frequencies of terminal Mo=O groups. Not only do the molybdenyl groups in a centrosymmetric decanuclear cluster adopt five distinct coordination environments, they also differ in the oxidation state of molybdenum. The positions of the bands in the $[Mo_{10}O_{26}L_8]$ clusters also differ. Furthermore, the spectra of **ii** and **iii** are not the same, even though the main difference is the content of the solvent of crystallization. In the former, apart from two common absorption bands at ~ 957 and ~ 946 cm^{-1},

Table 5
Selected bond distances (Å) for $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (**iv**) [a]

Mo–Mo	2.562(2), 2.590(2), 2.682(2)
Mo–N	2.223(8)–2.251(11)
Mo–O_t	1.643(9)–1.681(6)
Mo–O(μ_2)	1.897(9)–1.951(5)
Mo–O(μ_3)	1.954(7)–2.304(6)
Mo–O(μ_4)	1.987(5)–2.625(8)
Mo–OCH_3(μ_2)	2.054(9), 2.219(10)
Mo–Cl	2.344(6)

bands of medium intensity at 935 and 910 cm^{-1} have appeared.

The spectrum of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (**iv**) displays absorption bands at 962 and 938 cm^{-1}, which are similar to absorptions at 961 and 942 cm^{-1} found in another oxomolybdenum(V) compound $[Mo_4O_8(OCH_3)_2Cl_2Py_4]\cdot 2Py$ [10]. A complex pattern of bands in the far-IR region prevents the unambiguous assignment of the Mo–Cl stretching vibration for **iv**. In $[Mo_4O_8(OCH_3)_2Cl_2Py_4]\cdot 2Py$ these were found at 351 and 320 cm^{-1} [10]. The absorption at 2811 cm^{-1} in **iv** can be ascribed to the C–H stretching vibration of the methoxy group. The observed band is comparable to the absorption at 2820 cm^{-1} in $[(n\text{-}C_4H_9)_4N]_2[V_8O_8(OCH_3)_{16}(C_2O_4)]$ [24].

3.3. Synthetic considerations

From previous studies of the reactions of $(PyH)_2[MoOCl_5]$ with methanol and pyridine or its alkyl-substituted analogues we have recognized a number of factors which have a determining influence over numerous processes taking place in solution which eventually lead to final products [10]. Traces of water have been found to change the reaction course, always leading to Mo(V, VI) clusters which no longer contain neither chloro ligands nor methoxide groups, i.e. $[Mo_{10}O_{26}L_8]$. The sensitivity towards water makes the reactions irreproducible and difficult to control. The domain of the solvothermal synthesis provides a more stable and reproducible environment for the reaction systems described. Exploiting the advantageous conditions offered by this technique, such as the reduced

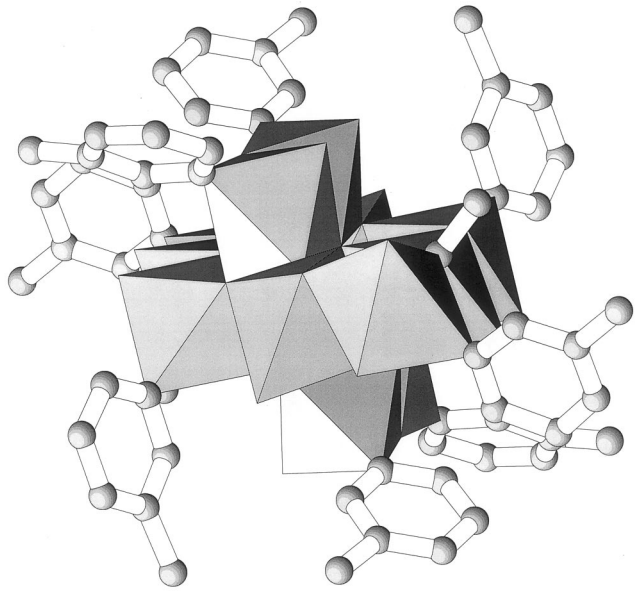

Fig. 5. ATOMS [21] polyhedral representation of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (**iv**).

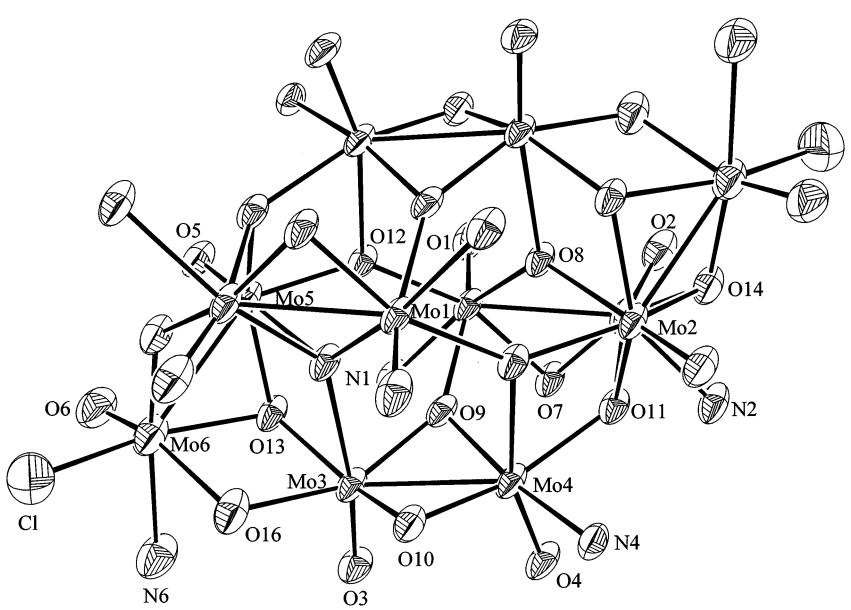

Fig. 4. ORTEP III [20] drawing of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (**iv**) with the atomic naming scheme shown. Thermal ellipsoids are drawn at the 30% probability level. Carbon atoms are omitted for clarity.

viscosity of the solvent resulting in enhanced crystal growth [4], enabled new species to be prepared in the crystalline form, as shown by the isolation of $[Mo_{12}O_{28}(OCH_3)_2Cl_2(3\text{-}MePy)_8]$ (**iv**).

Note that the same structural types occur in different contexts, i.e. $[Mo_4O_8(OCH_3)_4(4\text{-}MePy)_4]$ [10], $[Mo_4O_8(O\text{-}i\text{-}Pr)_4Py_4]\cdot 2Py$ [25] and $((n\text{-}C_4H_9)_4N)_4[Mo_4O_8(OCH_3)_2(C_4O_4)_2(C_4O_4H)_2]\cdot CH_3OH$ [26], which all consist of the tetranuclear framework $[Mo_4O_4(\mu_2\text{-}O)_2(\mu_3\text{-}O)_2(\mu_2\text{-}OR)_2]^{2+}$ (OR = alkoxy group) made of two $Mo_2O_4^{2+}$ building blocks fused together. Also, in $[Mo_8O_{16}(OCH_3)_8(PMe_3)_4]$ [27] and $[Mo_8O_{16}(OCH_3)_8L_4]$ (L = pyridine or alkyl-substituted pyridine) [13], the linkage of four $Mo_2O_4^{2+}$ moieties through pairs of methoxy bridges results in a cyclic $[Mo_8O_8(\mu_2\text{-}O)_8(\mu_2\text{-}OCH_3)_8]$ array. Apart from the well-known stability of the $Mo_2O_4^{2+}$ dimer, the occurrence of some $Mo_2O_4^{2+}$ assemblies in diverse fields suggests their remarkable stability. A series of decanuclear clusters $[Mo_{10}O_{26}L_8]$ (L = Py, 3-MePy, 3,5-Lut) with a common $[Mo_{10}\text{-}O_{10}(\mu_2\text{-}O)_8(\mu_3\text{-}O)_6(\mu_4\text{-}O)_2]$ core, and $(NH_4)_7[NaMo_{16}(OH)_{12}O_{40}]\cdot 4H_2O$ and $(Me_2NH_2)_6[H_2Mo_{16}(OH)_{12}O_{40}]$, which both contain $[(Mo^{VI}O_3)_4Mo^{V}_{12}(OH)_{12}O_{28}]^{8-}$ [3], illustrate the same trend. Additionally both cluster types were obtained through both conventional and solvothermal synthesis, suggesting they can be formed under various conditions.

4. Supplementary material

Tables of atomic coordinates, bond lengths, bond angles and thermal parameters are available from the Cambridge Crystal Data Centre, quoting the CCDC reference numbers 140809, 140810, 140811 and 140812 for complexes **i**–**iv**, respectively. Observed and calculated structure factors are available from the authors upon request.

Abstract

A series of nine ternary Co(II), Ni(II) and Cu(II) complexes with some aromatic diamines and dianion of terephthalic acid (tpht) have been synthesized and characterized by elemental analysis, magnetic susceptibility measurements, IR and diffuse-reflectance spectroscopy. All compounds were obtained as microcrystalline solids, stable in air and insoluble in common solvents. Two of them, $[M(tpht)(dipya)(H_2O)_2]\cdot 3H_2O$ [M = Co(II), Ni(II); dipya = 2,2′-dipyridylamine], were obtained as single crystals and their crystal structures have been determined by X-ray structure analysis. Both structures consist of discrete $[M(tpht)(dipya)(H_2O)_2]^{2+}$ complex units with two H_2O molecules in the *trans* position. Three additional H_2O molecules together with coordinated H_2O and O atoms from COO groups make a three-dimensional network of hydrogen bonds. Terephthalato ligands are coordinated by only one COO group, which acts as a chelating ligand. Central metal ions are in a distorted octahedral environment. Based on the above-mentioned analysis and known crystal structures, the possible structures and geometry of the complexes are discussed. All Co(II) and Ni(II) complexes are pseudooctahedral and mononuclear, with only one of the tpht COO groups coordinated in a chelate mode. Cu(II) complexes have probably distorted octahedral geometry with bridging role of tpht ions and monodentate or strongly asymmetric coordination of COO groups. © 2000 Elsevier Science Ltd. Keywords: Transition metal complexes; Terephthalate ions; Aromatic diamines; Crystal structures; Spectral data

1. Introduction

Among anions of benzenedicarboxylic acids as possible polydentate and bridging ligands, phthalate (pht) or hydrogen phthalate ions are the most widely used in coordination chemistry (see for example [1–3] and references therein). On the contrary, very few complexes with isophthalate ion have been described so far [4,5].

Interest for terephthalato (tpht) complexes arose in 1985, when an unexpected strong antiferromagnetic interaction was found in $[Cu_2(\mu\text{-tpht})(bipy)_2(H_2O)_2](ClO_4)_2$, where bipy = 2,2′-bipyridine [6]. Very soon after, it was shown [7] that moderately strong magnetic interactions can exist, even if two Cu(II) magnetic centers are 11.3 Å away from each other. Most articles concerning ternary complexes with tpht ligands concentrated on Cu(II) complexes and their magnetic

PII: S0277-5387(00)00435-6

properties, and on quantum-chemical studies of the relative orientation of magnetic orbitals which influences exchange interaction through the bridging ligand [6–13]. Nevertheless, several tpht complexes containing some other transition metals were also described [14,15].

Besides the Cu(tpht)·3H_2O itself [16], numerous tpht complexes were structurally characterized [5,7,8,10–14,17]. As a rule, the complexes are binuclear and bridging tpht ligands are coordinated in a bis-monodentate manner [7,8,12,13]. Moreover, bis-bidentate, [8,17] bridging, [14,16], as well as combined [11] modes of coordination are encountered. It seems that the number of polymeric complexes [10,11,14,16] is smaller than the number of binuclear complexes.

To the best of our knowledge, only a few systematic studies about transition metal complexes with tpht ions have been undertaken so far. In a paper by Bakalbassis et al. [9], five ternary Cu(II) complexes containing some polyamines are described. In addition, several ternary Co(II) and Ni(II) complexes with 1,10-phenanthroline, 2,2′-bipyridine and its derivatives, as diamine ligands, and tpht [18,19] or substituted tpht ions have been characterized [20].

In this study we report synthesis and characterization of nine ternary Co(II), Ni(II) and Cu(II) complexes containing dianion of terephthalic acid and 2,2′-dipyridylamine (dipya), 1,10-phenanthroline (phen) or 2,2′-bipyridine as aromatic diamine ligands.

2. Experimental

2.1. Preparation and characterization of the complexes

With the exception of aromatic diamines, which were of purum quality, the other reagents were of analytical grade and were used without further purification. All complexes were prepared in a similar way using the following procedure.

An aqueous solution of $M(NO_3)_2 \cdot xH_2O$ (M = Co, Ni and Cu, $x = 6$ or 3, $n = 5.0 \times 10^{-3}$ mol in 200 cm^3 of H_2O) and a solution of 5.0×10^{-3} mol diamine ligand in 20 cm^3 of EtOH were mixed firstly. Then a solution of Na_2tpht (5.0×10^{-3} mol in 75 cm^3 of H_2O) was added dropwise at room temperature for about 2 h under continuous magnetic stirring. The instantly formed microcrystalline precipitate was filtered off after standing overnight, washed several times with small portions of water, EtOH and Et_2O and dried at room temperature. Formulae of the complexes, together with their color, yield and analytical data are listed in Table 1. Further on in the text, the complexes will be denoted by the corresponding numbers in Table 1.

Elemental analysis was carried out by standard analytical micromethods. The metal content was determined by dry combustion of samples followed by heating at 800–1000°C and weighing of the residual metal oxide (as MO). Total content of water of crystallization was confirmed by thermal analysis performed on a Perkin–Elmer model TGS-2 thermobalance (heating rate: 10°C min^{-1}, sample mass: less than 10 mg,

[a] Abbreviations: tpht, dianion of terephthalic acid; dipya, 2,2′-dipyridylamine; phen, 1,10-phenanthroline; bipy, 2,2′-bipyridine.
[b] Temperature for complete dehydration is given in large brackets.

furnace atmosphere: dry nitrogen with flow rate of 60 $cm^3\ min^{-1}$). Only complex **6** dehydrates in two steps, indicating clearly the presence of a loosely bound lattice H_2O (0.3 mol) and coordinated H_2O (1 mol) molecules. The dehydration of other complexes is very similar: they lose H_2O in a single step and it was not possible to distinguish between coordinated and lattice H_2O.

Magnetic susceptibility measurements were made at room temperature using an MSB-MK1 magnetic susceptibility balance (Sherwood Scientific Ltd., Cambridge, UK). The data were corrected for diamagnetic susceptibilities. Infrared spectra in the 4000–400 cm^{-1} range were recorded on a Bomem MB-100, Hartmann Braun FT IR spectrophotometer using KBr pellets. Diffuse-reflectance spectra were obtained on an SPM-2 quartz monochromator (Zeiss, Jena). Spectra were taken at room temperature in the interval 10.0–45.0 kK using MgO as the reference compound and the reflection cell of the R-45/0 type.

2.2. Structure determination of complexes *1* and *2*

Single crystals were prepared by slow diffusion of two, A and B, solutions through a glass filter. The solution A contained 5.0×10^{-4} mol of each $Co(NO_3)_2 \cdot 6H_2O$ [or $Ni(NO_3)_2 \cdot 6H_2O$] and dipya in a H_2O–EtOH mixture, whereas B was a solution of Na_2tpht ($c = 0.1$ mol dm^{-3}) in water. The first crystals appeared within a 1 h period, but the single crystals of a suitable size were filtered off after about 7 days.

Data were collected on an Enraf–Nonius CAD-4 diffractometer using Mo Kα radiation ($\lambda = 0.71069$ Å) and $\omega/2\theta$ scan in 2.10–26.97° θ range for Co and 2.11–27.97° θ range for the Ni complex. The intensities of the Ni complex were corrected for absorption by the integration method ($T_{min} = 0.826$, $T_{max} = 0.930$) [21]. The structures were solved by heavy atom and difference Fourier methods and refined on F^2 by full-matrix least-squares method. All H atoms were found in ΔF maps and refined isotropically. The procedures for unit cell determination and data collection, as well as details of structure solution and refinement, were similar to those described in a recent paper [22].

2.2.1. Complex *1*: $[Co(tpht)(dipya)(H_2O)_2] \cdot 3H_2O$

A red, cubic crystal of $0.29 \times 0.29 \times 0.28$ mm size was chosen for data collection. Crystal data: $C_{18}H_{23}CoN_3O_9$, $M_r = 484.32$, triclinic system, space group $P\bar{1}$, $a = 10.103(3)$, $b = 10.970(3)$, $c = 11.242(4)$ Å, $\alpha = 105.82(2)$, $\beta = 109.15(2)$, $\gamma = 107.55(2)°$, $V = 1022.3(6)$ Å^3, $Z = 2$. A total number of 4767 reflections was collected, which after averaging gave 4429 independent observations (3980 with $I > 2\sigma(I)$, $R_{int} = 0.0256$). Final agreement indices for 372 refined parameters were: $S = 1.054$, $wR(F^2) = 0.0873$, $w = 1/[\sigma^2(F_o^2) + (0.0565P)^2 + 0.1173P]$ with $P = (F_o^2 + 2F_c^2)/3$, for all data; $R = 0.0302$ for data with $I > 2\sigma(I)$.

2.2.2. Complex *2*: $[Ni(tpht)(dipya)(H_2O)_2] \cdot 3H_2O$

A light-blue, prismatic crystal of $0.35 \times 0.16 \times 0.08$ mm size was used for data collection. Crystal data: $C_{18}H_{23}N_3NiO_9$, $M_r = 484.10$, triclinic system, space group $P\bar{1}$, $a = 10.076(1)$, $b = 10.963(1)$, $c = 11.242(2)$ Å, $\alpha = 105.77(2)$, $\beta = 109.33(2)$, $\gamma = 107.66(1)°$, $V = 1016.4(2)$ Å^3, $Z = 2$. A total number of 5319 reflections was collected, which after averaging gave 4895 independent observations (3870 with $I > 2\sigma(I)$, $R_{int} = 0.0413$). Final agreement indices for 372 refined parameters were: $S = 1.008$, $wR(F^2) = 0.0980$, $w = 1/[\sigma^2(F_o^2) + (0.0585P)^2]$ with $P = (F_o^2 + 2F_c^2)/3$ for all data; $R = 0.0357$ for data with $I > 2\sigma(I)$.

3. Results and discussion

3.1. Synthesis and formulae of complexes

All complexes were obtained as microcrystalline products from diluted solutions containing diamine ligand, M(II) and tpht ions in a 1:1:1 molar ratio. The general formula (Table 1) is $M(tpht)(diamine) \cdot xH_2O$ (M = Co, Ni, Cu) with $x = 1$–5. In comparison with Co and Ni complexes, all Cu complexes contain a smaller number of water of crystallization. The compounds are insoluble in common polar and non-polar solvents and this fact suggests that some of them could be polymeric.

It should be pointed out that complexes **2**, **4**, **5**, and **8** have empirical formulae identical to the previously described phthalato complexes, while complexes **3**, **6** and **9** have very similar empirical formulae [2,23–25]. (There are no data about pht compounds analogous to complex **7**.) The only significant difference was found in complex **1**, which in Co–pht–dipya system has been reported [24] as anhydrous substance, i.e. it should be similar to **3** not to **2**. Therefore, it seems that formulae are mainly determined by bulkiness of the constituents present, not by the position of COO groups in dicarboxylato ligands. These observations also indicate that similarities in the geometry and coordination mode of the tpht ion could be expected (vide infra).

It is interesting to note that the use of different synthetic routes (and stoichiometry) results in binuclear complexes: $[Cu_2(\mu\text{-}tpht)(bipy)_2(H_2O)_2](ClO_4)_2$, [6] $[Ni_2(\mu\text{-}tpht)_2(bipy)_4](ClO_4)_2$ [17] and $[Co_2(\mu\text{-}tpht)L_4](ClO_4)_2$ with L = bipy, phen or Me_2bipy [19].

3.2. Crystal structures of complexes *1* and *2*

As follows from crystal data given in Section 2, these complexes are isostructural and only the Co complex will be described in detail. Selected bond distances and

angles listed in Table 2 show that main differences are in coordination polyhedra where, for example, all Ni–ligand bond distances are shorter. The other bond distances and angles are very similar and in most cases agree within the 3σ range.

The structure (Fig. 1) consists of discrete [Co(tpht)(dipya)$(H_2O)_2$] complex units and three lattice H_2O molecules. The dipya acts as a usual chelating ligand, while the tpht ion is coordinated by only one of its COO groups which chelates the central metal atom. Thus, the compound belongs to the rare tpht complexes where only one of the COO groups is coordinated. Since in the other known example, Cu(tpht)·$3H_2O$, the COO group bridges two Cu(II) ions [16]. Compounds described here can be regarded as the new structural type of tpht complexes.

The analogy with pht-compounds continues and the complex is similar to [Ni(pht)(dipya)$(H_2O)_3$]·$2H_2O$, where only one of the (*ortho*) COO groups is coordinated, but in a monodentate manner [23].

Crystal packing is governed by a three-dimensional network of hydrogen bonds which are in the range of 2.723(4)–3.093(4) Å and with O–H···O angles between 151(6) and 178(4)°. The H_2O molecules act as double H bond donors, while O7 and O9 are also H bond acceptors. The amine N atom (N3) is a H bond donor too. All carboxylate O atoms are H bond acceptors (O3 and O4: 3 ×, O1 and O2: 1 ×). Such an extended system of H bonds increases the stability of crystal lattice and together with its non-electrolyte character can explain the high insolubility of the complexes.

All aromatic rings, as well as the equatorial plane are reasonably planar with deviation less than 5σ. The angle between two pyridine rings is 17.66(7)°. If one neglects the two axial H_2O molecules, the whole molecule does not deviate significantly from planarity. For example, dihedral angles between the benzene ring and the equatorial plane, as well as the plane of coordinated and uncoordinated COO group are 10.35(5), 7.1(2) and 161.8(2)°, respectively.

Co (or Ni) is in a distorted octahedral environment (Table 2). Chelating behavior of the C1O1O2 group causes the main distortion with the O1–Co–O2 angle of only 60.35(5)°. The coordination geometry is similar to that in [Ni_2(μ-tpht)$_2$(bipy)$_4$]$(ClO_4)_2$ [17] and in the previously mentioned [Ni(pht)(dipya)$(H_2O)_3$]·$2H_2O$ [23].

3.3. Spectral and magnetic properties

The reflectance spectra of Co and Ni complexes are in accordance with octahedral or pseudooctahedral geometry of the metal site. In both cases, three spin-allowed transitions [assigned as $^4T_{1g}(F)$ to $^4T_{2g}$ (ν_1),

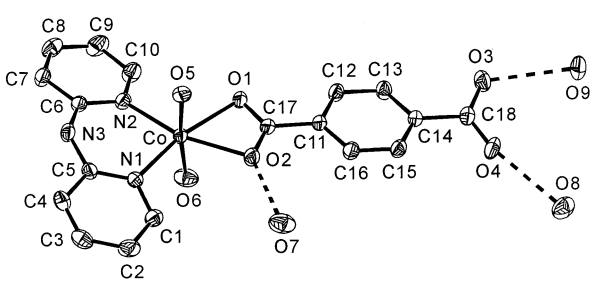

Fig. 1. Numbering of atoms and view of the [Co(tpht)(dipya)$(H_2O)_2$]·$3H_2O$ complex (40% probability displacement ellipsoids) [26]. Only part of H bonds (within an asymmetric unit) is shown as dashed lines.

9	Cu(tpht)(bipy)·$1.8H_2O$	1.90	14.0	1576	1370	206

$^4A_{2g}(F)$ (ν_2) and $^4T_{1g}(P)$ (ν_3) for Co(II), and $^3A_{2g}$ to $^3T_{2g}$, (ν_1), $^3T_{1g}(F)$ (ν_2) and $^3T_{1g}(P)$ (ν_3) for Ni(II) complexes] are expected [27]. The lowest energy transitions, ν_1, belong to the near-IR region and were outside the measurement limit of the instrument.

The highest energy transition $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$, characteristic for octahedral Co(II) complexes, is presented in the 21.6–22.4 kK region (Table 3). The second (ν_2) band, corresponding to the forbidden two-electron transition, appeared as a shoulder in the 16.6–16.8 kK region. It was also possible to notice two more spin forbidden transitions (near 11.0 and 20.0 kK) originated in the ^2G state.

The two bands presented in the spectra of Ni(II) complexes lie in the ranges 10.8–11.2 kK (ν_2) and 25.6–26.5 kK (ν_3).

The spectra of all Cu(II) complexes show usual, broad and asymmetric bands in the 13.2–14.0 kK region (Table 3). In complex **3** there is a band at 23.2 kK, which is also observed in the other Cu(II)–dipya complexes [28] and probably belongs to the charge transfer. It is well known that electronic spectra of Cu(II) complexes are a poor indication for their geometry [29]. However, criteria established by Hathaway and Billing [30] suggest that Cu(II) ions are in an elongated tetragonal–octahedral or *cis*-distorted octahedral ligand field with D_{4h} or C_{2v} symmetry, respectively. This can be interpreted as the presence of the $CuN_2O_2O'_2$ chromophore originated from chelate coordination of two COO groups.

Although phen and bipy are planar with extended π-bonds system, while dipya does not belong to that type of ligand, no systematic shifts of transition maxima have been observed.

In addition to the d–d bands mentioned, the reflectance spectra of all complexes exhibit very broad and intensive maxima in the range 27.0–40.0 kK. By comparison with ligand spectra, these bands were identified as intraligand transitions.

As expected, all Co and Ni complexes are high-spin and μ_{eff} values (Table 3) are characteristic for (pseudo)octahedral complexes (Co, 4.7–5.2 BM; Ni, 2.9–3.4 BM [29]). This supports previous conclusions about the geometry of central atoms.

The usual magnetic moments of simple Cu(II) complexes lie between 1.75 and 2.20 BM [29] and the observed μ_{eff} values (Table 3) are also in this range. The μ_{eff} values are significantly greater than the spin-only value (1.73 BM), indicating the presence of intense orbital contribution.

No strong magnetic interactions were observed at room temperature in any case. At least for complexes **1** and **2** such behavior is not surprising, since the only possible interactions could be of a very weak, intermolecular type.

The presence of coordinated and/or lattice H_2O molecules caused the appearance of strong and broad ν(O–H) stretching bands centered at 3452–3267 cm^{-1}. In accordance with the different number of H_2O molecules, the shape and position of these bands were different. Characteristic vibrations of aromatic nucleus [ν(C=C), ν(C=N)] for bipy and phen complexes are near 1580 and 1445 cm^{-1}, bzw. 1590, 1503 and 1430 cm^{-1}, respectively, while ν(C–H) deformation vibrations are about 765 cm^{-1} (bipy) and 726 cm^{-1} (phen). Both facts confirm coordination of these ligands.

The IR spectra of dipya complexes exhibit very similar features. Strong absorption bands ν(NH) near 3200 cm^{-1}, overlapped with ν(O–H) stretching, were seen. Also ν(C=C) or ν(C=N) vibrations of aromatic nucleus, which are around 1600 cm^{-1} in uncoordinated ligand shift to about 1650 cm^{-1} and verify the coordination of dipya.

The most salient feature in the IR spectra was the existence of two very strong and broad bands in the 1580–1360 cm^{-1} region, attributed to the ν_{as}(COO) and ν_s(COO) stretching vibrations of the tpht ligand. Positions of these bands, together with their difference, $\Delta\nu$, are listed in Table 3.

Coordination modes of COO groups and their distinction by IR spectroscopy are well documented in many general textbooks [29,31]. Practically all predictions are based on an extensive study published by Deacon and Phillips [32]. The procedure requires comparison of $\Delta\nu$ data with the appropriate value ($\Delta\nu_i$) for

purely ionic salt. In this case, $\Delta\nu_i$ was found to be 170 cm^{-1} for K_2tpht [9].

It is evident (Table 3) that $\Delta\nu$ values for Co and Ni complexes are smaller than $\Delta\nu_i$. Such behavior is in accordance with the presence of chelating COO groups in **1** and **2** and can be extended to the rest of Co and Ni complexes. Very similar intensity and the shape of COO bands also support this conclusion. $\Delta\nu$ values for Cu complexes are greater than $\Delta\nu$ for the Co and Ni complexes, and significantly greater than $\Delta\nu_i$. At first sight, this can be interpreted as monodentate coordination of COO groups. However, the situation with Cu complexes is always complicated since O–Cu bonds have high covalent character and, due to plasticity of Cu(II) coordination sphere, chelating or bridging COO groups are always coordinated asymmetrically. Therefore, the presence of such COO groups can not be excluded [33].

Under the synthetic conditions used in this work, prepared Co(II) and Ni(II) complexes containing tpht ions are mononuclear and pseudooctahedral, with only one of the COO groups coordinated in a chelate mode. It is quite surprising to find that the tpht can form mononuclear complexes, because previous experience shows that bi- or polynuclear complexes are always formed. On the other hand, Cu(II) complexes probably have bridging tpht ions and monodentate or asymmetric chelate coordination of COO groups with distorted octahedral geometry. The complexes described are very similar to the analogous pht compounds [1–3] where, as a rule, Co(II) and Ni(II) complexes are also mononuclear, whereas binary and ternary Cu(II) complexes are polymeric.

4. Supplementary data

Supplementary crystallographic data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition Nos. 136142 and 136141 for the structures of complexes **1** and **2**, respectively.

POLYHEDRON

Magneto–structural studies of monohydroxo-bridged dicopper(II) complexes $M[Cu_2L_2(OH)]\cdot 2H_2O$ ($M = Na^+$ (**1**) and K^+ (**2**); H_2L = 2,6-bis[*N*-(phenyl)carbamoyl]pyridine). Effect of Cu–OH–Cu bridge angle on antiferromagnetic coupling

Abstract

Using a tridentate bis-amide ligand 2,6-bis[*N*-(phenyl)carbamoyl]pyridine (H_2L), in its deprotonated form, two new monohydroxo-bridged dicopper(II) complexes $M[Cu_2L_2(OH)]\cdot 2H_2O$ ($M = Na^+$ (**1**) and K^+ (**2**)) have been prepared and characterised by a number of methods, including X-ray crystallography. Each copper(II) ion is terminally coordinated by one pyridyl and two amide nitrogen donors. The two copper(II) centres are bridged by a hydroxo group, with each copper(II) centre assuming a distorted square planar geometry. The observation of short Cu–N_{py} and long Cu–N_{amide} bonds is caused by the steric requirement of the ligand. Interestingly, each cation Na^+/K^+ is coordinated to four different $[Cu_2L_2(OH)]^-$ units through the amide *O*-donors, in an uncommon distorted tetrahedral coordination environment. Temperature-dependent magnetic susceptibility measurements revealed that the compounds have $S = 0$ ground state with singlet–triplet energy separation, $2J = -334$ and -296 cm^{-1} for **1** and **2**, respectively. The larger Cu–OH–Cu bridge angle in **1** (131.1(6)°) causes better antiferromagnetic exchange coupling than that in **2** (125.7(6)°). © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

During the past few years we have been investigating the coordination chemistry of peptide ligands containing pyridine-2-carboxamide (bidentate [1,2] and tetradentate [3–6]) and pyridine-2,6-dicarboxamide (tridentate [7,8]) functionality, in their deprotonated form. We have demonstrated that sterically and/or electronically demanding pyridine amide ligands can dictate the geometry and coordination number of such complexes. For example, the rigid tridentate dianionic bis-amide ligand L(2-) (H_2L = 2,6-bis[(*N*-phenyl)carbamoyl]pyridine) imposes tetragonally compressed geometry (two unusually short M–N_{py} axial bonds compared to four equatorial M–N_{amide} bonds) around highly stabilised Fe(III) ($S = 1/2$) [7], Co(III) ($S = 0$) [7], Ni(II) ($S = 1$) [8] and Ni(IV) ($S = 0$) [8] centres in their bis-chelate complexes. The present work stems from our interest in studying the coordinative behaviour of L(2-) toward copper(II). Here we report the synthesis and X-ray structural characterisation of two monohydroxo-bridged copper(II) complexes, $M[Cu_2L_2(OH)]\cdot 2H_2O$ ($M = Na^+$ (**1**) and K^+ (**2**)). The synthetic reaction between $Cu(O_2CMe)_2\cdot H_2O$ and Na_2L afforded compound **1** whose structural analysis revealed that each Na^+ ion is coordinated by four amide *O*-donors, in an uncommon distorted tetrahedral arrangement. As a first step towards generalisation of the existence of such a structural feature we decided to investigate the synthetic reaction with K^+ salt of L(2-) as well. Temperature-dependent magnetic studies on solid samples of **1** and **2** give us a unique opportunity to pinpoint the structural effect on the magnetic properties of the copper(II) centres in these complexes.

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and used as received. Solvents were dried as reported previously [3,7,8]. The ligand 2,6-bis[*N*-(phenyl)carbamoyl]pyridine was prepared as before [7].

2.2. Synthesis of copper(II) complexes

2.2.1. $Na[Cu_2L_2(OH)]\cdot 2H_2O$ (1)

To a bluish green N_2-purged DMF solution (10 cm^3) of $Cu(O_2CMe)_2\cdot H_2O$ (0.25 g, 1.25 mmol) was added a light yellow DMF solution (10 cm^3) of H_2L (0.4 g, 1.25 mmol) treated with NaH (0.09 g, 3.75 mmol). The resulting moss green solution was stirred for 8 h at 298 K in air. The solvent was then distilled off under reduced pressure and the resulting solid was dissolved in EtOH. The green solution thus obtained was filtered and concentrated to a small volume. Addition of CH_3CO_2Et afforded moss green crystals of **1** (yield 0.25 g, ca. 48%). *Anal.* Found: C, 54.5; H, 3.6; N, 9.9. Calc. for $C_{38}H_{31}Cu_2N_6NaO_7$: C, 54.8; H, 3.8; N, 10.2%. IR (KBr disc, selected peaks): 3610 (sharp) and 3420 (broad) cm^{-1} [ν(OH)]. Conductivity (DMF, $\approx 10^{-3}$ mol dm^{-3} solution at 298 K): $\Lambda_M = 58\ \Omega^{-1}\ cm^2\ mol^{-1}$. Absorption spectra [$\lambda_{max}$/nm ($\varepsilon$, $dm^3\ mol^{-1}\ cm^{-1}$)]: (DMF solution) 305 (20 880) and 590 (490); (Nujol mull) 320 and 580. Slow diffusion of CH_3CO_2Et to the concentrated DMF solution of the product deposited shining block-like crystals suitable for structural studies.

2.2.2. $K[Cu_2L_2(OH)]\cdot 2H_2O$ (2)

A similar procedure as that for **1** was followed with H_2L (0.6 g, 1.89 mmol), KH (0.23 g, 5.67 mmol), and $Cu(O_2CMe)_2\cdot H_2O$ (0.38 g, 1.89 mmol). The product is well formed dark green crystals (yield 0.48 g, ca. 59%). *Anal.* Found: C, 54.9; H, 3.5; N, 10.0. Calc. for $C_{38}H_{31}Cu_2KN_6O_7$: C, 54.8; H, 3.8; N, 10.2%. IR (KBr disc, selected peaks): 3600 (sharp) and 3420 (broad) cm^{-1} [ν(OH)]. Conductivity (DMF, $\approx 10^{-3}$ mol dm^{-3} solution at 298 K): $\Lambda_M = 62\ \Omega^{-1}\ cm^2\ mol^{-1}$. Absorption spectra [$\lambda_{max}$/nm ($\varepsilon$, $dm^3\ mol^{-1}\ cm^{-1}$)]: (in DMF) 300 (16 950) and 603 (480); (Nujol mull) 330 and 600 (sh). X-ray quality crystals were obtained following the same procedure as that for **1**.

2.3. Measurements

Elemental analyses were obtained from the National Chemical Laboratory, Pune, India. Solution electrical conductivity measurements were carried out with an Elico (Hyderabad, India) Type CM-82 T conductivity bridge. Spectroscopic data were obtained by using the following instruments: infrared, Perkin–Elmer M-1320; electronic, Perkin–Elmer Lambda 2.

2.4. Magnetism

Variable-temperature solid-state magnetic susceptibility measurements were done by the Faraday technique using a locally-built magnetometer [6,7]. All measurements were made at a fixed main field strength of ≈ 10 kG. Susceptibilities were corrected for diamagnetic contribution [9].

2.5. Crystallography

Moss green block-shaped crystals of **1** and **2** were used for data collection (θ–2θ scan technique) using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) on an Enraf–Nonius CAD4-Mach diffractometer. Lattice parameters were obtained from least-squares analyses of 25 machine-centred reflections. Intensity data were corrected for Lorentz-polarisation effects; analytical absorption corrections were also applied. All calculations were performed using the XTAL 3.2 program package [10]. The structures were solved by direct methods and expanded by Fourier-difference syntheses. All refinements were performed by full-matrix least-squares on *F*. We could not locate hydrogen atoms of OH bridge and of two water molecules of crystallisation, to give any chemical significance. The positions of the hydrogen atoms were calculated assuming ideal geometries, but not refined. Except for O atoms, which were refined isotropically, all other atoms were refined with anisotropic thermal parameters. Pertinent crystallographic parameters are summarised in Table 1.

3. Results and discussion

3.1. Synthesis and properties

The reaction between $Cu(O_2CMe)_2\cdot H_2O$ and Na_2L in DMF at 298 K did not yield a bis-chelate complex $[Cu^{II}L_2]^{2-}$. However, all our attempts led only to the isolation of a dark green crystalline solid of composition $Na[Cu_2L_2(OH)]\cdot 2H_2O$ (**1**), irrespective of the mole ratio used (1:1 or 1:2). The product from a similar reaction with K_2L gave a dark green complex of composition $K[Cu_2L_2(OH)]\cdot 2H_2O$ (**2**). The absence of ν(N–H) in the IR spectra confirms that the ligand is coordinated in the deprotonated form. The absorptions observed at $\sim 3600\ cm^{-1}$ (sharp) and $\sim 3400\ cm^{-1}$ (broad) are due to ν(OH) vibrations, with the former one due to hydroxo bridge and the latter due to water of crystallisation. Identical IR spectra of **1** and **2** reveal that they are isostructural. Elemental analysis, IR, and

solution electrical conductivity data (expected range for a 1:1 electrolyte: 65–85 Ω^{-1} cm^2 mol^{-1} [11]) are in agreement with the above formulation for **1** and **2**. The electronic spectra, measured both in the solid state (dispersed in mineral oil mull) and in DMF solution are closely similar, implying that the stereochemistry of the copper(II) centre does not change on dissolution in DMF. In DMF **1** and **2** exhibit a crystal-field transition at $\sim$600 nm, with an additional LMCT transition at $\sim$300 nm of $OH^- \rightarrow$Cu(II) origin.

3.2. Description of molecular structure of $M[Cu_2L_2(OH)]\cdot 2H_2O$ ($M = Na^+$ (**1**) and K^+ (**2**))

Complexes **1** and **2** were found to be isostructural (cf. IR spectra). In the dimeric $[Cu_2L_2(OH)]^-$ unit of **1** and **2** (Fig. 1), each copper(II) ion is terminally coordinated by two amide nitrogens and one pyridyl nitrogen of L(2-). The dianionic ligand L(2-) adopts a *mer* configuration, as before [7,8]. The two copper atoms are bridged by an OH group with a Cu–OH–Cu angle of 131.1(6)° in **1** and 125.7(6)° in **2**. In both structures the CuN_3O planes are coplanar within experimental error. At each copper site, significant deviation of the bond angles involving the chelation by L(2-) is observed (Table 2). The coordination geometry about each copper is distorted square planar, with hydroxide oxygen *trans* to the pyridyl nitrogen. Due to the strong donor capacity of deprotonated amide N donors providing two negative charges on the equatorial plane, it is expected to have shorter Cu–N_{amide} bond lengths. In contrast, Cu–N_{py} bond lengths are considerably shorter

($\sim$0.1 Å) than Cu–N_{amide} bond lengths (Table 2). We believe that the observed opposite behaviour is the result of steric predominance over electronic effects. A similar bonding situation was observed before [12–15]. To the best of our knowledge, only three unsupported monohydroxo-bridged copper(II) dimers with bidentate/tridentate terminal coordination are reported in the literature [16–18]. Within such complexes the geometry around copper(II) centres is invariably distorted octahedral, square-pyramidal or trigonal bipyramidal. Note that in the reported examples of monohydroxo-bridged copper(II) dimers with square planar coordination [19], the copper(II) centres are additionally bound to the tetradentate binucleating ligands. To the best of our knowledge, the structures of **1** and **2** represent the first

structurally characterised monohydroxo-bridged dicopper(II) complexes with terminal amide coordination.

Interestingly, in the crystal packing of **1** and **2** each Na^+or K^+ ion is bound through four amide *O* donors from four different $[Cu_2L_2(OH)]^-$ modules. Each $[Cu_2L_2(OH)]^-$ module is in turn surrounded by four Na^+/K^+ ions, giving rise to a 3D array of cation–anion interactions [20,21]. The network structure of compound **2** is displayed in Fig. 2. Interestingly, copper(II) and other metal complexes with deprotonated salicylamide ligands 1,2-(2-hydroxybenzamido)benzene and 1,2-(2-hydroxybenzamido)ethane act as multidentate ligands due to coordination by both amidate *N* and amide *O* donors [22,23]. In fact, they give rise to multi-dimensional structures, including coordination of K^+ counterions by amide *O* donors, as observed here. However, it should be noted that coordination of Na^+/K^+ ions solely by *O* donors as in **1** and **2** is novel. In fact, in **1** and **2** the sodium/potassium ions are forced to have an uncommon MO_4 distorted tetrahedral geometry due to hydrophobic pocket created by an ensemble of four dimeric anions. Sodium and potassium enolates of pinacolone [24] and cyclic aluminophosphonate [25], potassium hydrogen DL-methylsuccinate [26] and potassium hydrogen bis(homophthalate) [27] exhibit similar MO_4 coordination. The present structures represent, to the best of our knowledge, the first examples where each Na^+/K^+ ion is coordinated by only amide oxygen donors in a distorted tetrahedral coordination environment. Moreover, two water molecules present in **1** and **2** are involved in an intermolecular hydrogen bonding (O(1w)···O(2w) 3.029(9) Å for **1** and 3.297(8) Å for **2**) and they are not in contact distances with either cop-

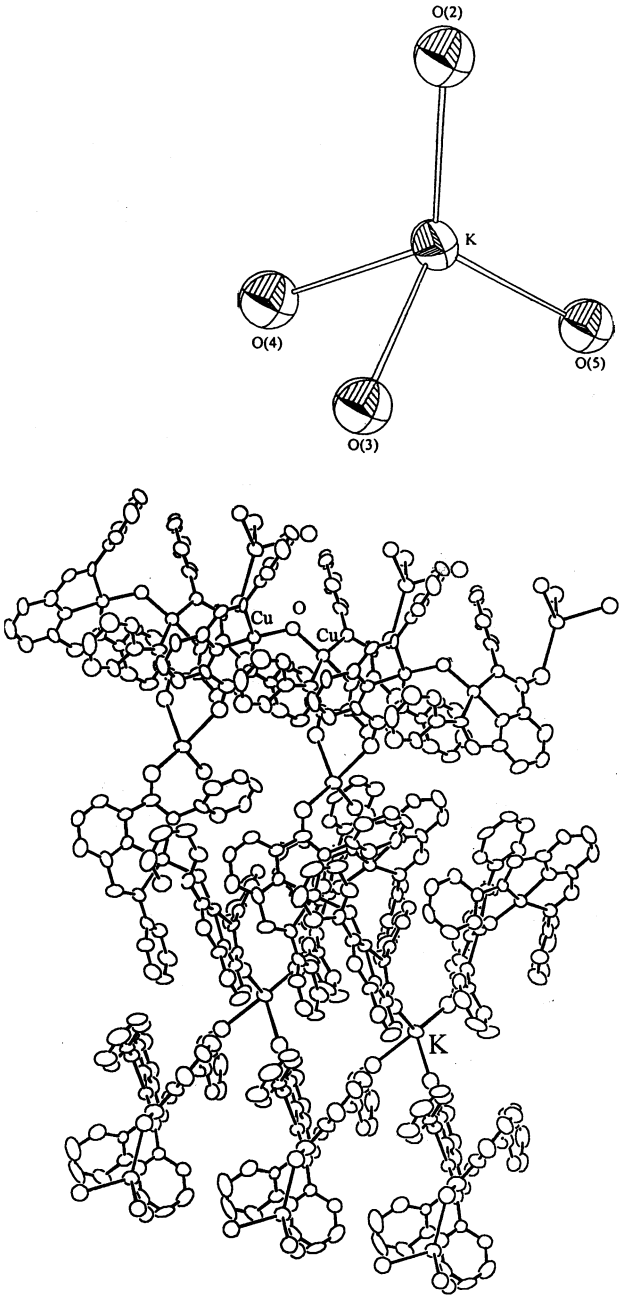

Fig. 2. The 3D network of cation–anion interactions in $K[Cu_2L_2(OH)]\cdot 2H_2O$ (**2**).

per(II) (for **1** Cu(1)–O(1w) 6.382, Cu(1)–O(2w) 6.612, Cu(2)–O(1w) 8.621 and Cu(2)–O(2w) 9.341 Å; for **2** Cu(1)–O(1w) 6.435, Cu(1)–O(2w) 7.162, Cu(2)–O(1w) 9.006 and Cu(2)–O(2w) 8.604 Å) or sodium/potassium ions (for **1** Na–O(1w) 5.560 and Na–O(2w) 5.720 Å; for **2** K–O(1w) 5.184 and K–O(2w) 6.995 Å). The structural data reveal that the water molecules are present in the lattice as separate entities.

Although in each ligand the two *N*-phenyl rings and the pyridine ring are planar, the two phenyl rings, however, make an angle of ~108 and ~108° to each other in **1** and ~113 and ~116° to each other in **2**. In **1** the two phenyl rings make angles of ~58 and ~134° at the Cu(1) site and ~57 and ~126° at the Cu(2) site, with the central pyridine ring. The corresponding angles for **2** are ~53 and ~132° at the Cu(1) site and ~52 and ~127° at the Cu(2) site. This explains the observation of distorted square planar stereochemistry at the copper(II) centre and associated bonding parameters. A close match between electronic and steric requirement of each L(2-) has restricted each copper(II) centre to have distorted square planar geometry and due to the presence of four surrounding $[Cu_2L_2(OH)]^-$ units every Na^+/K^+ ion has been forced to be coordinated by only four amide oxygen donors. We believe that the 3D network structure observed here is the outcome of mutual synergism between the cations and the anions.

3.3. Magnetism

The presence of a hydroxo bridge between two copper(II) centres is well known to lead to antiferromagnetic exchange between the metal centres [16–19] and the temperature-dependent (25–300 K) magnetic measurements on powdered samples of **1** and **2** were carried out accordingly. The magnetic behaviour (Fig. 3) is typical of strong antiferromagnetic coupling between pairs of copper(II) centres. The μ_{eff} per Cu (300 K) values are 1.30 and 1.35 μ_B for **1** and **2**, respectively. The experimentally observed χ_M values (per dimer) may be expressed (the Cu···Cu separations between interdimers: 7.88–15.90 Å for **1** and 8.03–15.99 Å for **2**) using the modified [28,29] Bleaney–Bowers expression (1),

$$\chi_M = 2N\beta^2g^2/3kT[1 + 1/3\exp(-2J/kT)]^{-1}(1-\rho) + (N\beta^2g^2/2kT)\rho + 2N_\alpha \quad (1)$$

which includes a very small corrective term, ρ, for non-coupled copper(II) impurity and N_α is the temperature-independent paramagnetism. The singlet–triplet energy gap is expressed in terms of $2J$ and other symbols have their usual meanings. Keeping N_α fixed at 60×10^{-6} cm^3 mol^{-1}, the J, g and ρ parameters were determined by minimising $R = \Sigma(\chi_m^{obs} - \chi_m^{calc})^2/\Sigma(\chi_m^{obs})^2$. Non-linear regression analyses [28,29] of the data using Eq. (1) gave good data fits: $J = -167$ cm^{-1}, $g = 2.039$, $\rho = 0.033$ and $R = 3.127 \times 10^{-8}$ for **1**; $J = -149$ cm^{-1}, $g = 2.034$, $\rho = 0.038$ and $R = 5.580 \times 10^{-8}$ for **2**.

The coordination geometry of copper(II) centres in **1** and **2** is almost square planar (cf. X-ray structures) and the bridging hydroxide group occupies an equatorial position. Hence in both cases the copper(II) ground state is $d_{x^2-y^2}$. For this type of geometry a stronger antiferromagnetic interaction is expected as the bridging angle approaches 180°, since the copper(II) $d_{x^2-y^2}$ orbitals are then more favourably positioned to overlap in a σ fashion with the bridging moiety [30]. The strong antiferromagnetic coupling observed in **1** and **2** must be due to the angle Cu–OH–Cu being towards linear (131.1(6)° for **1** and 125.7(6)° for **2**) and rather short Cu–O bond lengths (1.876(1) and 1.899(1) Å for **1**, and 1.874(1) and 1.913(1) Å for **2**); magnetic exchange interaction can take place effectively through the OH bridge. Compared with **2** the larger antiferromagnetic coupling in **1** must be associated with its larger Cu–OH–Cu bond angle, as they are otherwise identical. In fact, an increase in Cu–OH–Cu bridge angle by ~5° causes an increase in the extent of antiferromagnetic

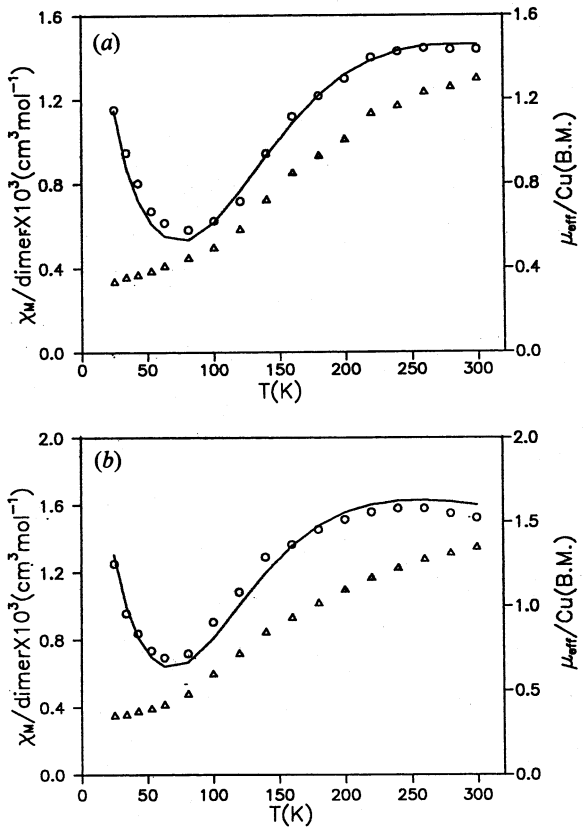

Fig. 3. Temperature dependence of the molar susceptibility (○) and of the magnetic moment (△) of solid (a) $Na[Cu_2L_2(OH)]\cdot 2H_2O$ (**1**) and (b) $K[Cu_2L_2(OH)]\cdot 2H_2O$ (**2**). The solid lines represent the result of the fitting calculation.

exchange coupling by $\sim 20\ cm^{-1}$. The *J* values obtained here are comparable to monohydroxo-bridged copper(II) complexes $[Cu_2(dien)_2(OH)(OClO_3)_3]$ (dien = diethylenetriamine) and $[Cu_2(dpm)_2L(OH)][ClO_4]_3 \cdot 2H_2O$ (dpm = di(2-pyridy)methane; L = 1,1,2,2-tetrakis(2-pyridyl)-ethylene) with the $d_{x^2-y^2}$ ground state [31,32]. It must be noted, however, that the former complex has a supported perchlorate bridge. In essence, the present investigation has given us a unique opportunity to compare the extent of antiferromagnetic magnetic exchange coupling as a function of Cu–OH–Cu bridge angle, brought about by crystal-packing effects.

4. Conclusion

Even though L(2-) imposes tetragonally compressed geometry around metal centre in bis-chelate complexes [7,8], in full agreement with our expectation $[Cu^{II}L_2]^{2-}$ was not formed; however, monohydroxo-bridged copper(II) dimers $M[Cu_2L_2(OH)] \cdot 2H_2O$ ($M = Na^+$ (**1**) and K^+ (**2**)) were isolated. The amide function in L(2-) not only interacts with the Cu(II) centre via the *N*-atom, but also binds to Na^+ or K^+ ion via the *O*-atom. The observation of distorted tetrahedral coordination of Na^+/K^+ is a bonus to the present structural analysis. As expected, the Cu(II) centres are strongly antiferromagnetically coupled and the extent of exchange coupling is dependent on the Cu–OH–Cu bridge angle.

5. Supplementary data

Full tables of bond lengths and angles, tables of non-hydrogen and hydrogen atomic coordinates, anisotropic thermal parameters for non-hydrogen atoms are available upon quoting the CCDC deposition numbers 138917 and 138918 for **1** and **2**, respectively. POLYHEDRON

Magnetic interactions in dicopper(II) complexes of a new endogenous alkoxo bridging ligand with exogenous pyrazolate, azide and acetate bridges. X-ray structure of $[Cu_2L(\mu\text{-}C_3H_3N_2)(OClO_3)(H_2O)](ClO_4)\cdot H_2O$ (HL = 1,3-bis[*N*-methyl-*N*-(2-pyridylethyl)amino]propan-2-ol)

Abstract

Using a new dinucleating ligand, 1,3-bis[*N*-methyl-*N*-(2-pyridylethyl)amino]propan-2-ol (HL), in its deprotonated form, three new binuclear copper(II) complexes $[Cu_2(L)(\mu\text{-}X)(ClO_4)(H_2O)](ClO_4)\cdot H_2O$ ($X = C_3H_3N_2^-$ (prz), N_3^- and $MeCO_2^-$) have been synthesized. The crystal structure of pyrazolate (prz) compound was determined and revealed that the complex contains an endogenous bridging alkoxide ligand and an exogenous bridging prz ligand. A water molecule is coordinated to a copper(II) center and is hydrogen-bonded to the alkoxide O atom. A perchlorate ion is 'semi-coordinated' to another copper(II) center as a monodentate ligand and is hydrogen-bonded to a second water molecule. The coordination geometry around both copper centers resembles a distorted square pyramid. The magnetochemical characteristics of these compounds were determined by temperature-dependent magnetic studies, revealing their antiferromagnetic behavior [$-2J$ (in cm^{-1}) values: 550 ± 25 for prz, 360 ± 10 for azide and 100 ± 10 for acetate]. The ground state magnetic orbital involved in spin coupling is similar ($d_{x^2-y^2}$) in these complexes. Differences in the magnetic behavior have been rationalized in terms of the bridging ligand orbital complementary/countercomplementary concept. Spectroscopic properties of these complexes are also reported. © 2000 Elsevier Science Ltd. All rights reserved.

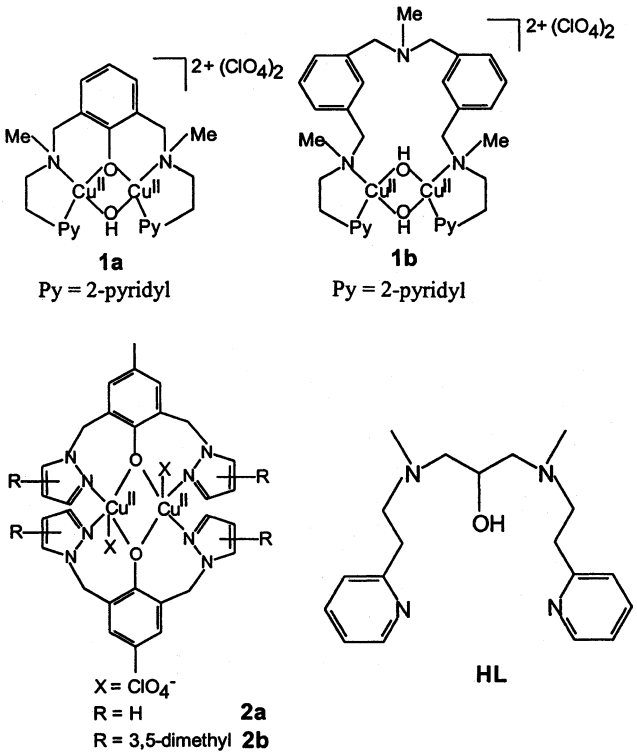
1. Introduction

Continuing interest in the copper(II) complexes of binucleating ligands derives from their structural and magnetic properties [1–4] and their ability to model the active site in dicopper-containing proteins [5,6]. As part of our activity in the chemical modeling of tyrosinase, we investigated magnetic interactions in structurally characterized copper(II) dimers [7] involving (i) two dissimilar bridging ligands, a μ-phenoxo- and a μ-hydroxo- **1a** and (ii) a symmetrically dibridged species, a bis(μ-hydroxo)- **1b**. As the terminal coordination in **1a** and **1b** is invariant, we identified the effect of the Cu_2O_2 ring planarity on the trend of antiferromagnetic coupling. Very recently we have structurally characterized a bis(μ-phenoxo)dicopper(II) compound **2a** and from a systematic comparative studies between **2a** and **2b** the effect of Cu_2O_2 ring planarity caused by pyrazole ring methyl substituents on the extent of antiferromagnetic coupling has been identified [8].



The present work stems from our interest in investigating the magnetic exchange interactions associated with an endogenous alkoxo-bridged dicopper(II) system, derived from a new tailor-made ligand with identical terminal coordination as that in **1a**/**1b**, with variable exogenous bridging ligands. Here we have synthesized

PII: S0277-5387(00)00391-0

and characterized a group of three dicopper(II) complexes of HL, in its deprotonated form, with additional exogenous bridging by pyrazolate (prz), azide or acetate. The prz complex has been subjected to X-ray structural analysis. Temperature-dependent magnetic properties and the observed magneto-structural trend have been presented. It is worth mentioning here that among reported [9–14] endogenous alkoxo-bridged copper(II) systems with ligands derived from 2-hydroxy-1,3-diaminopropane backbone having terminal N-coordination, a six-membered chelate ring forming dinucleating ligand as that considered here is rare [14].

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and used as received. Solvents were dried as reported previously [8,15]. Copper(II) perchlorate hexahydrate was prepared as before [8].

2.2. Syntheses

2.2.1. 1,3-Bis[N-methyl-N-(2-pyridylethyl)amino]-propan-2-ol (HL)

A solution of 2-(2-methylaminoethyl)pyridine (1 g, 7.35 mmol) in MeOH (25 cm^3) was added slowly to a vigorously stirred solution of Et_3N (0.743 g, 7.35 mmol) in MeOH (12 cm^3) at $\sim$10°C. To the resulting mixture a solution of 1,3-dichloro-2-propanol (0.483 g, 3.75 mmol) in MeOH (25 cm^3) was added dropwise over a period of $\sim$15 min. The solution was then stirred at $\sim$10°C for 2.5 h. After stirring at room temperature (r.t.) for 2 days the solvent was removed at reduced pressure and the ligand was extracted with $CHCl_3$ (25 cm^3). The $CHCl_3$ layer was then washed with water and finally dried over anhydrous Na_2SO_4. After removal of Na_2SO_4 the solvent was removed to afford pale yellow oil (yield 0.110 g, 87%). ^1H NMR ($CDCl_3$): δ 2.4 (6H, s, CH_3), 2.9 (8H, s, CH_2CH_2), 3.15 (4H, s, CH_2), 3.9 (1H, quintet, 2-CH), 6.53–7.51 (6H, m, aromatic protons) and 8.56 (2H, d, pyridine 6-H protons).

2.2.2. $[Cu_2L(prz)(ClO_4)(H_2O)](ClO_4)\cdot H_2O$ (3a)

A solution of Et_3N (0.185 g, 1.83 mmol) in EtOH (3 cm^3) was added to a solution of HL (0.200 g, 0.61 mmol) in EtOH (4 cm^3). Solid pyrazole (0.40 g, 0.615 mmol) was added to this mixture. Addition of a solution of $Cu(ClO_4)_2\cdot 6H_2O$ (0.452 g, 1.22 mmol) in EtOH (3 cm^3) to the above magnetically stirred solution resulted in a blue solution. After 1 h of stirring the solution was kept in the air at r.t. for slow evaporation. The solid thus precipitated was filtered, washed with cold EtOH and dried under vacuum. The compound was recrystallized by slow vapor diffusion of diethyl ether to a MeCN solution (yield 0.220 g, 48%). Found: C, 35.2; H, 4.4; N, 11.0. Calc. for $C_{22}H_{34}N_6Cl_2O_{11}Cu_2$: C, 34.9; H, 4.5; N, 11.1%. IR (KBr disc, selected peaks): 3540, 3460 [ν(OH)]; 1110, 1090, 1060 and 625 cm^{-1} [$\nu(ClO_4)$]. Conductivity (MeCN, $\sim 10^{-3}$ mol dm^{-3} solution at 298 K): $\Lambda_M = 260\ \Omega^{-1}\ cm^2\ mol^{-1}$. Absorption spectrum [MeCN solution, λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1})]: 605 (450), 353 (3 420), 290 (sh) and 260 (15 450); (Nujol mull) 990 (sh), 620 (sh) and 360 (sh).

2.2.3. $[Cu_2L(N_3)(ClO_4)(H_2O)](ClO_4)\cdot H_2O$ (3b)

A similar procedure as that described for **3a** was followed with HL (0.202 g, 0.615 mmol), Et_3N (0.125 g, 1.23 mmol), NaN_3 (0.40 g, 0.615 mmol) and $Cu(ClO_4)_2\cdot 6H_2O$ (0.456 g, 1.23 mmol). The compound was recrystallized by slow diffusion of diethyl ether to a MeCN solution (yield 0.260 g, 58%). Found: C, 31.0; H, 4.2; N, 13.1. Calc. for $C_{19}H_{31}N_7Cl_2O_{11}Cu_2$: C, 31.1; H, 4.2; N, 13.2%. IR (KBr disc, selected peaks): 3480 [ν(OH)]; 2050 [$\nu(N_3)$]; 1140, 1120, 1080, 630 and 625 cm^{-1} [$\nu(ClO_4)$]. Conductivity (MeCN, $\sim 10^{-3}$ mol dm^{-3} solution at 298 K): $\Lambda_M = 225\ \Omega^{-1}\ cm^2\ mol^{-1}$. Absorption spectrum [MeCN solution, λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1})]: 609 (620), 420 (sh), 367 (3 950), 290 (sh) and 261 (14 350); (Nujol mull) 1 000 (sh), 620 and 420.

2.2.4. $[Cu_2L(O_2CMe)(ClO_4)(H_2O)](ClO_4)\cdot H_2O$ (3c)

This complex was prepared following a similar method to that for **3a** and **3b** using ligand HL (0.200 g, 0.610 mmol), Et_3N (0.185 g, 1.83 mmol), $NaO_2CMe\cdot 3H_2O$ (0.083 g, 0.610 mmol) and $Cu(ClO_4)_2\cdot 6H_2O$

(0.452 g, 1.22 mmol). The compound was recrystallized by layering of *n*-hexane to an acetone solution (yield 0.120 g, 44%). Found: C, 33.5; H, 4.4; N, 7.6. Calc. for $C_{21}H_{34}N_4Cl_2O_{13}Cu_2$: C, 33.6; H, 4.5; N, 7.5%. IR (KBr disc, selected peaks): 3440 [ν(OH)]; 1555 and 1440 [$\nu(MeCO_2)$]; 1150, 1120, 1080, 630 and 625 cm^{-1} [$\nu(ClO_4)$]. Conductivity (MeCN, $\sim 10^{-3}$ mol dm^{-3} solution at 298 K): $\Lambda_M = 255\ \Omega^{-1}\ cm^2\ mol^{-1}$. Absorption spectrum [MeCN solution, λ_{max}/nm (ε/$dm^3\ mol^{-1}\ cm^{-1}$)]: 656 (280), 360 (sh), 290 (sh) and 262 (16 150); (Nujol mull) 1000 (sh), 660 and 370 (sh).

CAUTION! Perchlorate and azide salts of metal complexes are potentially explosive and should be handled in small quantities with care.

2.3. Measurements

Elemental analyses were obtained from the Department of Inorganic Chemistry, Indian Association for the Cultivation of Science, Calcutta. Solution electrical conductivity measurements were carried out with an Elico (Hyderabad, India) Type CM-82 T conductivity bridge. Spectroscopic data were obtained by using the following instruments: infrared spectra, Perkin–Elmer M-1320; electronic spectra, Perkin–Elmer Lambda 2; ^{1}H NMR spectra, PMX-60 JEOL (60 MHz) spectrometer.

2.4. Magnetic studies

Variable-temperature solid-state magnetic susceptibility measurements were carried out using the Faraday technique with a locally built magnetometer [7,15]. All measurements were made at a fixed main field strength of ≈ 10 kG. Susceptibilities were corrected for diamagnetic contribution, by using literature tabulations [16].

2.5. Crystal structure determination and refinement

The blue rectangular plate-like single crystal ($0.2 \times 0.1 \times 0.05$ mm) of **3a** was mounted on a glass fiber and coated with epoxy resin. Intensity and lattice parameter measurements were made on an Enraf–Nonius CAD4-Mach diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.710\ 73$ Å). Unit cell parameters were determined by a least-squares fit of 25 reflections (2θ, 12.0–27.1°). Data were collected at 293 K using the θ–2θ scan technique to a maximum 2θ value of 45.0°. 6040 reflections measured out of which 2830 ($I > 3\sigma(I)$) were used in all calculations.

2.5.1. Crystal data

$C_{22}H_{34}Cl_2N_6O_{11}Cu_2$, $M = 756.5$, monoclinic, space group $P2_1/n$, $a = 8.548(2)$, $b = 13.599(2)$, $c = 25.883(2)$ Å, $\beta = 97.81(1)°$, $V = 2981(6)$ Å^3, $Z = 4$, $D_{calc} = 1.686$ g cm^{-3}, $\mu = 16.7\ cm^{-1}$, $F(000) = 1552$.

Intensity data were corrected for Lorentz-polarization effects. The structure was solved by direct methods and refined by full-matrix least-squares and Fourier techniques. The positions of the hydrogen atoms were calculated assuming ideal geometry, and their positions and thermal parameters were not refined. All other atoms were refined with anisotropic thermal parameters. The final cycle of refinement included 388 variable parameters. The refinement on F converged to a final $R = 0.059$, $R_w = 0.069$ and goodness-of-fit = 3.871, with the largest difference peak and hole 1.19 and -1.30 e Å^{-3}, respectively. The quantity minimized was $\Sigma w(|F_o| - |F_c|)^2$ with $w = 1$. All calculations are performed using the XTAL3.2 program package [17].

3. Results and discussion

3.1. Syntheses

The new dinucleating ligand HL was synthesized in high yield from the reaction between 1,3-dichloro-2-propanol and 2-(2-methylaminoethyl)pyridine in a 1:2 molar ratio, in cold (~ 10°C) MeOH in the presence of Et_3N. The dicopper(II) complexes were prepared by the stoichiometric reaction between $Cu(ClO_4)_2{\cdot}6H_2O$, HL and exogenous ligand (pyrazole + Et_3N)/NaN_3/$MeCO_2Na$, in a 2:1:1 molar ratio in an ethanolic medium. While the azide complex is a green solid the acetate and prz complexes are blue in color.

In the IR spectra for all three compounds, broad bands at $\sim 3500\ cm^{-1}$ are seen, associated with O–H stretch of water of crystallization or coordinated water or both. For the prz complex this band is split. A strong band at $\sim 1100\ cm^{-1}$ and a medium intensity band at $\sim 620\ cm^{-1}$ are characteristic of the presence of ionic perchlorate. However, for all three compounds, the $\nu_3(ClO_4)$ vibration at $\sim 1100\ cm^{-1}$ shows significant splitting, suggesting the presence of a low-symmetry perchlorate, possibly acting as a 'semi-coordinated' ligand [8]. The X-ray structure determination for the prz complex shows the presence of a coordinated perchlorate and a coordinated water molecule, in addition to the presence of a water molecule of crystallization (vide infra). The azide complex has an intense IR band at 2050 cm^{-1} assignable to $\nu_{asym}(N_3)$ vibration of μ-1,1-azido bridge [18]. For the acetate complex bands at 1555 and 1440 cm^{-1} are assignable to the ν_{asym}(OCO) and ν_{sym}(OCO) vibrations of the bridging acetate [15]. Barring the characteristic absorption region due to the exogenous ligand, the IR spectra of the present complexes are closely similar, revealing that they are isostructural. The solution electrical conductivity data in MeCN revealed their 1:2 electrolytic behavior (expected range for 1:2 electrolytes in MeCN: 220–300 $\Omega^{-1}\ cm^2\ mol^{-1}$ [19]), implying weak coordi-

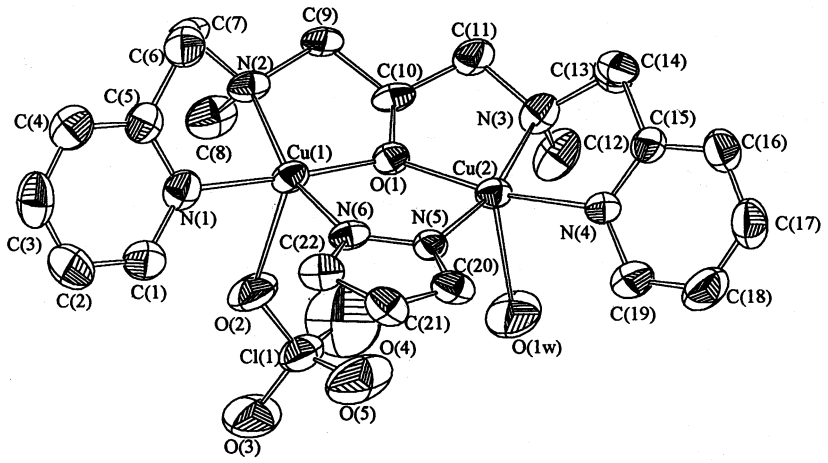

Fig. 1. Perspective view of the cation $[Cu_2(L)(prz)(OClO_3)(H_2O)]^+$ in complex **3a**. The thermal ellipsoids are at the 50% probability level. Hydrogen atoms are omitted.

nation of perchlorate ion in the sold state. Based on the above facts and microanalytical data, we propose the composition of these three new complexes as $[Cu_2L(X)(OClO_3)(H_2O)](ClO4)\cdot H_2O$ [$X = C_3H_3N_2^-$ (prz) (**3a**), N_3^- (**3b**), $MeCO_2^-$ (**3c**)], which was finally confirmed by the X-ray structural analysis of **3a**.

3.2. Description of the crystal structure of $[Cu_2L(\mu\text{-}prz)(OClO_3)(H_2O)]$–$(ClO_4)\cdot H_2O$

A perspective drawing of the complex together with the atom-labeling scheme is shown in Fig. 1. Table 1 contains pertinent bond distances and angles. The crystal structure of **3a** comprises $[Cu_2L(\mu\text{-}prz)(OClO_3)(H_2O)]^+$ cation, ClO_4^- anion and water of crystallization in the ratio of 1:1:1. The cation features each copper(II) center coordinated by one common alkoxide bridge, one pyridyl and one aliphatic nitrogen, besides from exogenous ligand coordination (prz, perchlorate and water) in an asymmetric manner. The geometry around each copper(II) is best described as square-pyramidal with a small trigonal-bipyramidal component (τ) of 0.24 for Cu(1) and 0.07 for Cu(2) [$\tau = (\beta - \alpha)/60$, with α and β being the two largest coordination angles). In a perfect square-pyramidal geometry τ equals 0, while it is 1 in a perfect trigonal-bipyramidal geometry [20]. The two copper centers, alkoxo O-atom and two prz nitrogen atoms are almost coplanar (the angle between the planes Cu(1)–O(1)–Cu(2) and Cu(1)–N(6)–N(5)–Cu(2) is 1.94°). The Cu(1) and Cu(2) atoms sit above the mean plane of three N-atoms and one alkoxide O-atom by 0.15 and 0.19 Å towards axial coordination, respectively. An additional water molecule is hydrogen-bonded to 'semi-coordinated' ClO_4^- and the coordinated H_2O molecule is hydrogen-bonded to the alkoxide O atom.

The Cu–N(amine) distances are longer than that observed for complexes **1a** and **1b**; however, the Cu–N(pyridyl) distances are comparable [7]. The Cu–N(prz) and the Cu···Cu distances both are on the higher end but Cu–O(alkoxide) distances are on the lower end of that reported for closely similar prz bridged compounds [12,13]. Interestingly, the Cu–OR–Cu bridge angle is on the higher end [12,13].

3.3. Absorption spectra

To gain insight into the coordination geometry of the present complexes, the absorption spectral behavior was investigated in MeCN solution as well as in the solid state (dispersed in mineral oil mull). In the solid state, a broad d–d transition is observed at 620 nm (for **3a** and **3b**) and at 656 nm (for **3c**), which is indicative of a square-based geometry around copper(II) [21]. A measurable red shift in the case of **3c** could be due to

Plots of χ_M (left scale) per dinuclear complex and μ_{eff}/Cu (right scale) vs. T for (a) $[Cu_2(L)(prz)(OClO_3)(H_2O)](ClO_4)\cdot H_2O$ (**3a**) and $[Cu_2(L)(N_3)(OClO_3)(H_2O)](ClO_4)\cdot H_2O$ (**3b**). The circles are susceptibility data and triangles are magnetic moment data; the line is the calculated fit based on the parameters given in the text.

the fact that the copper(II) centers are slightly more distorted toward trigonal-bipyramidal (cf. X-ray structure of **3a**). In going from solid state to solution the visible band position for **3a** and **3b** is ~10–15 nm blue shifted, due to the dissociation of the perchlorate ion (cf. conductivity data); thus giving rise to a square-planar geometry of the Cu(II) center. For **3c** no measurable shift in the position of this band was observed. Here dissociation of perchlorate ion must be associated with solvent coordination, retaining its five-coordinate square-based geometry. In solution compounds **3a**–**3c** show distinct features between 260–450 nm. The bands between 280 and 370 nm are assignable to LMCT transitions, based on their extinction coefficients. The characteristic band at 420 nm for **3b**, which does not change on dissolution in MeCN, is due to the $N_3^- \rightarrow$ Cu(II) CT transition [14]. For these complexes intraligand transitions are observed at ~260 nm.

3.4. Magnetism

The magnetic properties of the present complexes are clearly of interest owing to the presence of an invariant alkoxide bridge and variable exogenous bridge. Therefore, they were subjected to magnetic susceptibility measurements in the temperature range 25–300 K for **3a** and **3b** and in the range 34–300 K for **3c**. The μ_{eff}/Cu values (at 300 K) are 0.96, 1.31 and 1.73 μ_B for **3a**, **3b** and **3c**, respectively. Plots of molar susceptibility and effective magnetic moment versus temperature for **3a** and **3b** are illustrated in Fig. 2 and similar plots for **3c** are in Fig. 3. For **3a** a rise in susceptibility at high temperatures, with the Néel point clearly far above r.t., indicates the presence of very strong antiferromagnetic exchange coupling. The maximum in susceptibility at ca. 250 K for **3b** and at ca. 100 K for **3c** is indicative of medium-strength and comparatively weak intramolecular antiferromagnetic coupling in **3b** and **3c**, respectively. The observed magnetic susceptibility data were fitted to the modified Bleaney–Bowers [22] Eq. (1) by allowing for the presence of monomeric impurity [7,8], where ρ is the mole-fraction of

$$\chi_M = 2N\beta^2g^2/3kT[1 + 1/3\exp(-2J/kT)]^{-1}(1-\rho) + N\beta^2g^2\rho/2kT + 2N_\alpha \quad (1)$$

the non-coupled copper(II) impurity. In this expression, N, g, and k have their usual meaning; $2J$ is the energy difference between the singlet and triplet states; χ_M is the molar susceptibility per dimer. The values of g and temperature-independent paramagnetic susceptibility (N_α) were kept fixed at 2.10 [typical value for a tetragonal Cu(II)] and 60×10^{-6} cm^3 mol^{-1} during fitting procedure. The best-fit parameters of J and ρ using Eq.

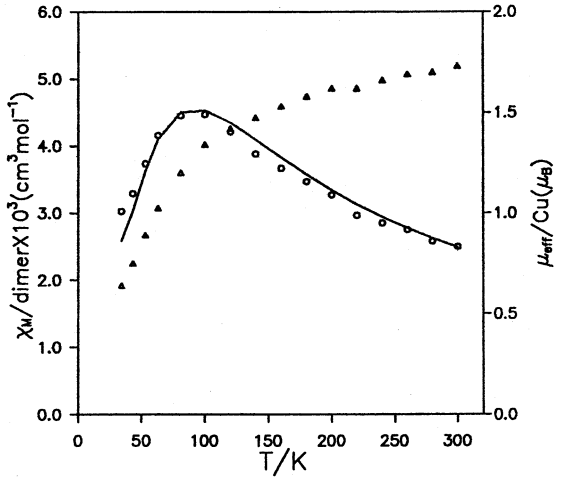

Fig. 3. Plot of χ_M (left scale) per dinuclear complex and μ_{eff}/Cu (right scale) vs. T for $[Cu_2(L)(O_2CMe)(OClO_3)(H_2O)](ClO_4)\cdot H_2O$ (**3c**). The circles are susceptibility data and triangles are magnetic moment data; the line is the calculated fit based on the parameters given in the text.

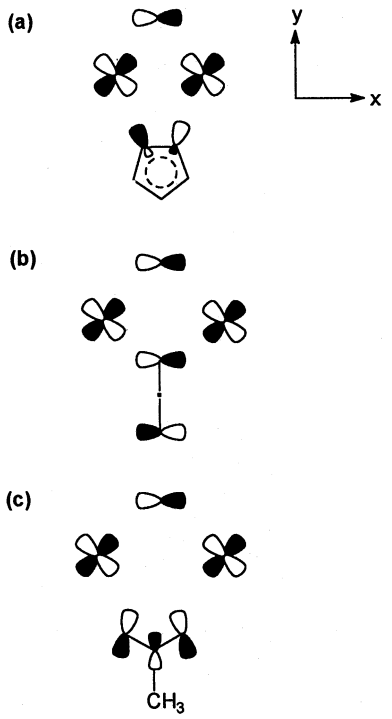

Fig. 4. Bridging ligand orbital interactions with $d_{x^2-y^2}$ orbitals of copper for various dibridged systems: (a) complementarity of alkoxide/prz, (b) countercomplementarity of alkoxide/1,1-azide and (c) countercomplementarity of alkoxide/acetate. Only the antisymmetric combination of copper magnetic orbitals is illustrated.

(1) were obtained by a nonlinear least-squares fitting procedure [7,8]. The quality of fit was estimated by the R index defined as $R = \Sigma(\chi_M^{expt} - \chi_M^{calc})^2/\Sigma(\chi_M^{expt})^2$. The following parameters were obtained: $J = -275$ cm^{-1}, $\rho = 0.0039$ and $R = 3.92 \times 10^{-9}$ for **3a**; $J = -183$ cm^{-1}, $\rho = 0.0610$ and $R = 2.66 \times 10^{-7}$ for **3b**; $J = -56$ cm^{-1}, $\rho = 0.0700$ and $R = 4.33 \times 10^{-7}$ for **3c**. Given the presence of a considerable amount of paramagnetic impurities (particularly in **3b** and **3c**) the calculated J values are far too accurate. Based on the data, we put a range of $-2J$ values as: 550 ± 25 cm^{-1} (**1**), 360 ± 10 cm^{-1} (**2**) and 100 ± 10 cm^{-1}. However, the analyses correspond to excellent agreement between observed and calculated magnetic data (Figs. 2 and 3). The strong antiferromagnetic coupling observed for the prz complex is due to (i) the planarity of the Cu(1)–O(1)–Cu(2)–N(5)–N(6) unit and (ii) an enhanced Cu–OR–Cu bridge angle of $\sim 126°$ (cf. X-ray structure). As before [10], we note that small changes in the coordination geometry at the copper(II) ions can bring about a profound effect on the extent of antiferromagnetic exchange coupling.

3.5. Magnetostructural correlations

Based on the X-ray structure of **3a** and closely similar spectral properties of **3a**–**3c** [cf. (i) IR spectra of **3a**–**3c**, (ii) identical d–d band position of **3a** and **3b** (the copper(II) centers in **3c** might have slightly more trigonal bipyramidal components, compared with **3a** and **3b**)] we could assume that the present complexes have predominantly square-based copper(II) centers. According to theoretical predictions made by Hoffmann and co-workers [23], strong antiferromagnetic interactions arise in any dimer when the energy separation between the highest d-like molecular orbitals, viz. symmetric (ϕ_s) and antisymmetric (ϕ_a) combinations of magnetic orbitals is large, irrespective of which combination of the orbitals is lower in energy. In the case of an alkoxide bridge [24–27] the intervening oxygen p_x orbital interacts with the ϕ_a orbital and exerts no effect on it (Fig. 4). Nishida and co-workers [24–27] and Reed and co-workers [11] have indicated that in a dicopper complex with two different bridging groups (endogenous alkoxide and exogenous X groups), the bridging groups act 'complementary' or 'countercomplementary' in inducing antiferromagnetic interaction depending on the symmetries of their HOMOs which interact with metal d-like orbitals. Based on the above considerations, we provide here a rationale of the observed magnetic behavior of **3a**–**3c** (Fig. 4).

For the prz complex **3a** both bridging ligands provide orbital interaction pathways that act in concert (bridging ligand orbital complementarity) to increase the energy of ϕ_a. For **3b** the energy of ϕ_a orbital is lowered, because the highest occupied orbital of an azide ion in the μ-1,1-mode does not have the correct symmetry (in the antibonding sense) to interact with ϕ_a orbital. For **3c** the acetate bridge has no net overlap with the ϕ_a orbitals; therefore, no net change in energy of ϕ_a is expected with this orbital combination. However, the energy of ϕ_s orbital is raised, because the highest occupied orbital of an acetate ion has the correct symmetry (in the antibonding sense) to interact with ϕ_s orbital (not shown in Fig. 4). Thus, effectively the gap between ϕ_a and ϕ_s decreases (countercomplementary) in **3b** and **3c**, thereby diminishing the antiferromagnetic interaction. Even though μ-1,1-N_3^- bridge exerts a ferromagnetic contribution [28], which in the present case does not entirely compensate the strong antiferromagnetic contribution due to the alkoxo-bridge. Similar situations have been encountered with phenolato-bridged dicopper(II) compounds [29,30]. The observed trend between **3b** and **3c** is comparable with that observed for a closely related system, albeit not structurally characterized, with terminal five-membered chelate ring [12]. However, here we observe a more pronounced antiferromagnetic pathway of exchange coupling. We note that the $2J$ values for phenoxo-/hydroxo complex **1a** and bis(hydroxo) complex **1b** are -440 and -258 cm^{-1}, respectively [7].

Some interesting general trends emerge from the present results. (i) Within the endogenous alkoxo

bridge, with variation in the exogenous bridging groups the order of the strength of the exchange interaction is **3a** > **3b** > **3c**. (ii) Within the endogenous alkoxo bridge, a six-membered chelate ring (an ethylpyridine compared to a methylpyridine [12]) gives a more negative J, a factor that is presumably due to increased terminal ligand flexibility. It should be noted however that the present ligand has N-methyl groups instead of NH groups present in the reported system [12]. This ligand flexibility probably provides a more favorable superexchange pathway.

4. Concluding remarks

Using a new dinucleating ligand with an endogenous alkoxo bridging unit, three dicopper(II) complexes have been synthesized with additional mono-anionic exogenous bridging ligand prz (structurally characterized), azide and acetate. Temperature-dependent magnetic susceptibility studies show that (i) there is antiferromagnetic exchange between pairs of copper(II) ions in each case resulting in $S = 0$ ground state; (ii) the magnitude of the antiferromagnetic exchange depends on the identity of the exogenous bridge (prz > azide > acetate). The concept of complementary versus countercomplementary effect has been used to explain the magnetic behavior of the complexes.

5. Supplementary material

Further details of the structure determination, including atomic coordinates, bond lengths and angles, thermal parameters of all non-hydrogen atoms for the structure is available on request as supplementary material from The Director, Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) (CCDC deposition number, 138906).

POLYHEDRON

Photoredox reactions of oxomolybdenum(V) with phosphines

Ralph A. Isovitsch [1], Jerome G. May, Frank R. Fronczek, Andrew W. Maverick *

Department of Chemistry, Louisiana State University, Baton Rouge, LA 70803-1804, USA

Received 24 September 1999; accepted 21 March 2000

Abstract

The fluorescent molybdenum(V)–oxo complex $MoOCl_4(H_2O)^-$, and oxomolybdenum(V)–phosphine complexes derived from it, undergo thermal and photochemical reactions in acetonitrile with the series of phosphines PEt_3, PEt_2Ph, $PEtPh_2$, and PPh_3. PEt_3 reacts spontaneously to form several products: crystalline $(PPh_4)[Mo^{III}Cl_4(PEt_3)_2]$ and $(PPh_4)_2[Mo^{V}OCl_5]\cdot 2CH_2Cl_2$; and a maroon oil that contains $OPEt_3$, $Mo^{IV}OCl_2(PEt_3)_3$ and $Mo^{IV}Cl_4(PEt_3)_2$. The Mo(III) and $OPEt_3$ products show that oxygen atom transfer has occurred. PEt_2Ph and $PEtPh_2$ show no significant redox activity with oxomolybdenum(V) in the dark, but irradiation ($\lambda > 320$ nm, CH_3CN solution) leads to reduction of Mo(V) and production of the corresponding phosphine oxides. The molybdenum(III) product, *cis-mer*-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$, was isolated from the PEt_2Ph experiment. PPh_3 is not oxidized under these conditions; instead, spectral evidence suggests that photoinduced ligand substitution occurs, producing $MoOCl_3(PPh_3)_2$. Selective irradiation of the longer-wavelength Mo(V) absorption bands leads to similar photoredox reactions, but much more slowly. X-ray analyses of two reaction products, $(PPh_4)_2[Mo^{V}OCl_5]\cdot 2CH_2Cl_2$ and *cis-mer*-$Mo^{III}Cl_3(OPEt_2Ph)_2(PEt_2Ph)$, are reported. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Complexes that contain a transition metal with a multiply bonded main-group element have been the subject of intense study [1]. The importance of such complexes is reflected in the large array of such reagents in organic chemistry: oxo derivatives of chromium(VI), $KMnO_4$, OsO_4, RuO_4 and others are known to transfer oxygen atoms to organic substrates. Metal–oxo complexes are also believed to be important in metalloenzymes that catalyze the transfer of an oxygen atom to or from a substrate [2]. Thermal oxygen-atom transfer has also been studied in a variety of inorganic systems [3,4].

The photophysics and photochemistry of metal complexes with multiply bonded main-group elements have received less attention. Most such studies have been based on early electronic-structure investigations of monooxo complexes of Mo(V), Cr(V), and V(IV) [5]. A variety of d^2 M≡N and MO_2 complexes have been studied more recently. For example, the rhenium(V)–nitrido cations $[ReN(R_2PCH_2CH_2PR_2)_2Cl]^+$ (R = Me, Et, Ph, cyclohexyl) phosphoresce in solution with lifetimes of 0.3–2 μs [6] and Che and co-workers have explored the photophysical properties of $[Os^{VI}N(2,3\text{-diamino-}2,3\text{-dimethylbutane})_2Cl]^{2+}$ and $[Os^{VI}N(NH_3)_4]^{3+}$ [7]. The dioxo species are exemplified by *trans*-$[ReO_2(py)_4]^+$, which shows a phosphorescence lifetime of 10 μs in CH_3CN at room temperature [8].

Photochemical experiments have also been carried out with these d^2 systems. The 'd–d' lowest-energy excited states also possess M → MN π* (or M → MO π*) character, making the N (or O) atom more basic. This principle has been demonstrated by excited-state protonations of the rhenium(V) nitrido [6] and dioxo [9] complexes, and by the sensitivity of the ReO_2^+ phosphorescence lifetimes to hydrophilic/hydrophobic environments [10]. Photoredox reactions have also been observed, beginning with the report that ReO_2^{+}* reduces methylviologen and other acceptors [11]. The resulting $Re^{VI}O_2^{2+}$ species, which can also be generated

PII: S0277-5387(00)00395-8

electrochemically, oxidizes organic substrates such as silanes and secondary alcohols. An analogous dioxorhenium(VI) complex has been isolated and its properties studied [12]. Finally, photochemical oxygen atom transfer reactions have been reported from two phosphorescent *trans*-dioxoosmium(VI) complexes to phosphines, sulfides, and alkenes [13].

We have focused on photoredox reactions of molybdenum. We first studied the two-electron photooxidation of $Mo(NCS)_6^{3-}$ to a molybdenum(V) oxo dimer, $(SCN)_3MoO(\mu\text{-}O)_2MoO(NCS)_3^{4-}$ [14]. We also showed that one of the simplest molybdenum(V) oxo complexes, $MoOCl_4(NCCH_3)^-$, shows d–d fluorescence in acetonitrile solution with a lifetime (110 ns) sufficient for reaction with one-electron oxidants and reductants [15]. In the present work we explore the photochemistry of oxomolybdenum(V) with the series of phosphines PEt_3, PEt_2Ph, $PEtPh_2$ and PPh_3 as oxygen atom acceptors, with the goal of achieving photochemical oxygen atom transfer. We find that PEt_3, PEt_2Ph and $PEtPh_2$ are oxidized to the corresponding phosphine oxide, with PEt_3 reacting spontaneously and PEt_2Ph and $PEtPh_2$ requiring irradiation. Molybdenum-containing reduction products were isolated in the reactions with PEt_3 and PEt_2Ph. The only photochemical activity observed with PPh_3 appears to be ligand substitution.

2. Experimental

2.1. Materials and procedures

All reactions and manipulations were performed using standard dry-box techniques. Anhydrous solvents were obtained from Aldrich Chemical Co. PEt_3, PEt_2Ph, and $PEtPh_2$ were obtained from Organometallics, Inc. The phosphines were free of phosphine oxides, as determined by GC–MS and ^{31}P NMR. $(PPh_4)[MoOCl_4(H_2O)]$ was prepared according to the literature procedure [16].

A Perkin–Elmer 1760X spectrometer was used to record FT-IR spectra; samples were thin films or KCl pellets. Electronic absorption spectra were recorded on an Aviv 14DS spectrophotometer. Fluorescence measurements utilized a Spex Fluorolog 2 model F112X instrument, with Hamamatsu R406 (S-1) PMT. ^{31}P NMR spectra were recorded on Bruker 250 and 300 MHz spectrometers operating at 101.2 and 121.4 MHz, respectively, with samples dissolved in CD_3CN; chemical shifts are reported in ppm referenced to 85% H_3PO_4.

2.2. Thermal reaction of $MoOCl_4(H_2O)^-$ with PEt_3

A green solution of $(PPh_4)[MoOCl_4(H_2O)]$ (0.31 g, 0.51 mmol) was prepared in 25 ml of CH_2Cl_2. To this was added 0.072 g (0.61 mmol) PEt_3, causing an immediate color change to maroon. The mixture was stirred for 1 h and then flooded with pentane. The resulting yellow suspension was left to stand overnight, and the greenish–yellow solid collected. The filtrate was evaporated to give a maroon oil, whose analysis is described in Section 3.

2.3. $(PPh_4)_2[MoOCl_5]\cdot 2CH_2Cl_2$

The greenish–yellow solid isolated from the $MoOCl_4(H_2O)^-/PEt_3$ reaction (see above) contained crystals suitable for X-ray analysis (see below). This compound is stable for extended periods in inert atmosphere, but in moist air, it shows green surface discoloration over a period of several weeks. *Anal.* Calc. for $C_{50}H_{44}Cl_9MoOP_2$: C, 52.78; H, 3.90; Cl, 28.04. Found: C, 54.05, 54.49; H, 4.60, 4.54; Cl, 27.91, 27.79%. Although the microanalytical data were poor for this compound, the X-ray (see below), UV–Vis (see Section 3), EPR (spectra for this material are similar to those for $(PPh_4)[MoOCl_4(H_2O)]$), and XANES analyses (see Section 6) all support the Mo(V) oxidation state assignment.

2.4. Irradiation of Mo(V)–phosphine mixtures

Solutions prepared from $(PPh_4)[MoOCl_4(H_2O)]$ (3.2 mM) and the desired phosphine (4 equiv.) in CH_3CN were irradiated in Pyrex vessels using a 150-W xenon arc lamp, with or without Corning colored-glass longpass filters. Reaction progress was monitored by removing aliquots at 1-day intervals for UV–Vis analysis. The reaction was judged complete when no further change was noted in the UV–Vis spectra. The solvent was then evaporated from the reaction mixture and the resulting residue analyzed. Control mixtures were prepared and analyzed identically, with the flasks tightly wrapped in aluminum foil to eliminate light.

2.5. ^{31}P NMR analysis of reaction products

After a thermal (dark) or photochemical reaction, the solvent was removed under vacuum, and the residue dissolved in CD_3CN for measurement of its ^{31}P NMR spectrum. In all cases, resonances were observed in these spectra for PPh_4^+ and unreacted phosphine. Phosphine oxides were identified as products in these mixtures, by comparison either with literature data ($OPEt_3$ [17]) or with samples prepared separately from the phosphines and NaOCl(aq) (chemical shifts for the reaction products sometimes differed from reference values by 1–2 ppm, and the resonances were typically broad; we attribute these effects to the presence of paramagnetic complexes, e.g. Mo(III) or Mo(V), in the solutions). In the photochemical experiments, the production of phosphine oxide was also confirmed by GC–MS analysis.

[b] $R=\Sigma\|\|F_o\|-\|F_c\|\|/\Sigma|F_o|$.
[c] $R_w=[\Sigma w(|F_o|-|F_c|)^2/\Sigma wF_o^2]^{0.5}$; $w=4F_o^2/[\sigma^2(I)+(0.02F_o^2)^2]$.

2.6. X-ray analyses

Diffraction data (see summary in Table 1) were collected on an Enraf–Nonius CAD4 diffractometer fitted with Mo Kα source and graphite monochromator, using the $\theta-2\theta$ scan method. Final unit cell constants were determined from the orientations of 25 centered high-angle reflections. The intensities were corrected for absorption using ψ scan data for five reflections. The MOLEN [18] set of programs was used for structure solution and refinement.

3. Results

3.1. Thermal reaction of $MoOCl_4(H_2O)^-$ with PEt_3

Addition of 1.2 equiv. of PEt_3 to $MoOCl_4(H_2O)^-$ dissolved in dichloromethane produced an immediate change in color from green to maroon, as illustrated by the electronic spectral changes in Fig. 1. Treatment of the reaction mixture with pentane produced three different substances: a greenish–yellow crystalline material, an orange crystalline material, and a maroon oil that is soluble in pentane and CH_2Cl_2 (similar changes occurred when the reaction was carried out with a larger excess of PEt_3, or when it was performed in CH_3CN solvent).

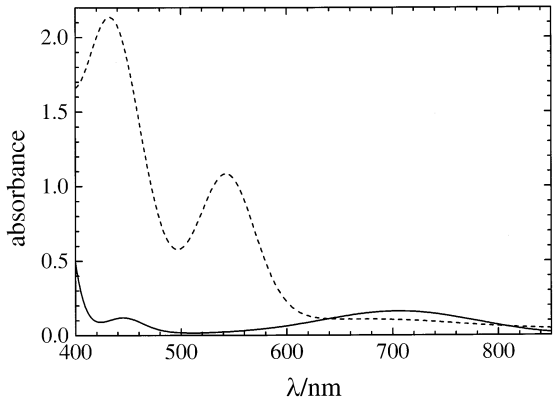

Fig. 1. Electronic absorption spectra illustrating the reaction of $MoOCl_4(H_2O)^-$ with PEt_3 in CH_2Cl_2. (—) $MoOCl_4(H_2O)^-$; (---) immediately after addition of PEt_3.

3.1.1. Greenish–yellow material

This was obtained in crystalline form by the above procedure; it was identified as $(PPh_4)_2[Mo^VOCl_5]\cdot 2CH_2Cl_2$ by X-ray analysis. An ORTEP [19] drawing of the $MoOCl_5^{2-}$ ion in this structure appears in Fig. 2; distances and angles in the anion are listed in Table 2. The unit-cell parameters closely match those of a number of other compounds (located by means of the Cambridge Crystallographic Database [20]; two isostructural examples are $(PPh_4)_2[W^VOCl_5]\cdot 2CH_2Cl_2$ and $(PPh_4)_2[Re^VOCl_5]\cdot 2CH_2Cl_2$ [21].

The $MoOCl_5^{2-}$ ion lies on a center of symmetry, with one position ('O1Cl3') half-occupied by Cl3 and the other half by O1. We were unable to resolve separate positions for Cl3 and O1. As a result, the refined Mo–O1Cl3 distance is shorter than the other Mo–Cl distances and longer than a typical Mo≡O distance (this is similar to the results obtained in previous studies of MoO/MoCl disorder [22]). The largest residual electron density, 1.39 e Å^{-3}, is 0.5 Å from the Mo position. This peak, the size of the Mo ellipsoid, and the orientation of its long axis nearly along the

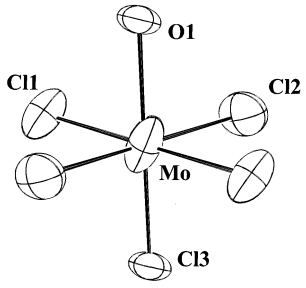

Fig. 2. ORTEP drawing of the $MoOCl_5^{2-}$ anion in $(Ph_4P)_2[MoOCl_5]\cdot 2CH_2Cl_2$, with ellipsoids at the 40% probability level. The O1 and Cl3 atoms are shown separately, but the two positions are superimposed by the crystallographically imposed inversion center; they are modeled as 50% Cl, 50% O ('O1Cl3'), with one set of coordinates and displacement parameters.

Table 2
Selected interatomic distances (Å)

$(Ph_4P)_2[MoOCl_5]\cdot 2CH_2Cl_2$			
Mo–Cl1	2.387(1)	Mo–Cl2	2.362(2)
Mo–Cl/O3	2.230(2)		
cis-mer-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$			
Mo–Cl1	2.417(2)	Mo–P1	2.532(2)
Mo–Cl2	2.424(2)	Mo–O1	2.182(4)
Mo–Cl3	2.430(2)	Mo–O2	2.106(4)

Mo–O1Cl3 vector are evidence that the Mo atom in a single molecule is displaced slightly out of the equatorial Cl_4 plane, and actually occupies two different but unresolved positions as a result of the disorder (because this displacement is likely to occur in the direction of the O atom, it will tend to minimize the apparent difference between Mo≡O and Mo–Cl distances). There is evidence that the disorder in the structure may be more complex than our model describes: the B_{eq} value for the overlapped O1Cl3 atom, 4.32(5) $Å^2$, is somewhat smaller than those for Cl1 and Cl2 (6.55(4) and 5.56(4) $Å^2$, respectively), suggesting that the O atom is distributed into the Cl1 and Cl2 sites with some smaller populations. We attempted to refine this more complex disorder model, but we obtained no significant improvement in the fit to the data.

We considered alternative models for this structure that would not require disordered O and Cl ligands. For example, both the Mo(VI) complex *trans*-$MoO_2Cl_4^{2-}$ and the Mo(IV) complex $MoCl_6^{2-}$ are centrosymmetric, and isostructural $(Ph_4P)_2[MO_2Cl_4]\cdot 2CH_2Cl_2$ [23] and $(Ph_4P)_2[MCl_6]\cdot 2CH_2Cl_2$ compounds [24] have been reported. However, when we attempted to fit the X-ray data with Mo(VI) or Mo(IV) models, the results were unsatisfactory. When we refined the anion as Mo(VI) (i.e. *trans*-$MoO_2Cl_4^{2-}$, with a fully occupied O atom), B_{eq} for the O atom refined to a value near zero, R_w was worse (0.099), and two peaks of density 2 e $Å^{-3}$ (0.4 Å from the O position) were present in the resulting difference map. With a Mo(IV) model ($MoCl_6^{2-}$), on the other hand, one of the three crystallographically independent Mo–Cl distances was still unexpectedly short (Mo–Cl3 2.23 Å, vs. 2.38 Å for the other two), and the B_{eq} value for Cl3 was somewhat larger than those of Cl1 and Cl2. The R_w value for this model was also high (0.067).

Our characterization of this compound as containing Mo(V) is further supported by the similarity of its electronic (see below) [15,25–27] and ESR [28] and XANES [29] spectra (see Section 6) to those for other Mo(V) compounds. The IR spectrum of the solid shows a band at 946 cm^{-1}, providing additional support for the presence of the Mo–oxo unit (compare 985 and 950 cm^{-1} for the bipyridinium and triphenylphosphonium salts of $MoOCl_5^{2-}$, respectively [27,30], and 980 cm^{-1} for $(Ph_4P)[MoOCl_4(H_2O)]$ [31].

Therefore, X-ray analysis and spectroscopic data support the description of the greenish–yellow crystalline plates as $(PPh_4)_2[Mo^VOCl_5]\cdot 2CH_2Cl_2$.

In a previous crystal-structure study of K_2MoOCl_5, the geometry of the $MoOCl_5^{2-}$ anion was found to be similar to that described here [32]. Though the species that forms when molybdenum(V) dissolves in concentrated HCl(aq) is often described as $MoOCl_5^{2-}$, Boorman and co-workers [26] showed that the principal constituent of these solutions is $MoOCl_4(H_2O)^-$. To illustrate the difference between the two anions, we prepared a solution of $(PPh_4)_2[MoOCl_5]\cdot 2CH_2Cl_2$ in CH_2Cl_2; it was deep yellow in color, showing electronic absorption bands at 697 and 440 nm [33]. However, when this solution was shaken with conc. HCl(aq), its color changed immediately to green, and the absorption bands shifted to 715 and 441 nm. The latter values are very similar to those for solutions prepared directly from $(PPh_4)[MoOCl_4(H_2O)]$ in CH_2Cl_2 (716 and 447 nm).

3.1.2. Orange crystalline material

The orange product of the Mo(V)/PEt_3 reaction crystallized as needles along with the greenish–yellow plates of $(PPh_4)_2[MoOCl_5]\cdot 2CH_2Cl_2$. X-ray analysis of one of the orange needles identified it as the molybdenum(III) salt $(PPh_4)[MoCl_4(PEt_3)_2]$. The production of this molybdenum(III) compound shows that reduction of $MoOCl_4(H_2O)^-$ by PEt_3 has occurred. $(PPh_4)[MoCl_4(PEt_3)_2]$, and analogs with PEt_2Ph and $PEtPh_2$, have been made and studied in solution by ^1H NMR by Poli and Gordon [34] and the crystal structures of these derivatives have been reported by Cotton and Vidyasagar [35]. The unit-cell parameters and atomic coordinates we obtained for $(PPh_4)[MoCl_4(PEt_3)_2]$ are essentially identical to those of Cotton and Vidyasagar.

3.1.3. Maroon oil

The pentane-soluble maroon oil contains several species. The ^{31}P NMR spectrum of this material (recorded immediately after isolation to minimize decomposition; see Table 3) shows signals attributable to $OPEt_3$ and *cis-mer*-$MoOCl_2(PEt_3)_3$ (δ 9.4 ppm [d, $^2J_{P-P}$ 18 Hz], 17.2 ppm [t, 18 Hz]). The resonances assigned to the latter oxomolybdenum(IV) complex are very similar to those of $MoOCl_2(PEt_2Ph)_3$ [22,36,37]. Also, the formation of *cis-mer*-$MoOCl_2(PEt_3)_3$ in our experiment is indicated by an IR absorption in the reaction products at 963 cm^{-1} [ν(MoO)]; the analogous band in $MoOCl_2(PMe_3)_3$ occurs at 960 cm^{-1} [38] (another similar pattern was present at 10.5 [d, 20 Hz] and 38.9 ppm [t, 20 Hz], but its much lower intensity precluded identification). The most intense peak in the ^{31}P NMR

Table 3
Products observed in reaction of oxomolybdenum(V) with phosphines

Phosphine	Dark reaction			Irradiation		
	^{31}P NMR [a]	X-ray [b]	Electronic spectrum [c]	^{31}P NMR [a]	X-ray [b]	Electronic spectrum [c]
PEt_3	$OPEt_3$, *cis-mer*-$Mo^{IV}OCl_2(PEt_3)_3$	$Mo^{III}Cl_4(PEt_3)_2^-$, $Mo^{V}OCl_5^{2-}$	$Mo^{IV}Cl_4(PEt_3)_2$	not performed

$PEtPh_2$		$Mo_2^{V}O_4Cl_4^{2-}$		$OPEtPh_2$		*fac*-$Mo^{V}OCl_3(PEtPh_2)_2$
PPh_3	no reaction					*fac*-$Mo^{V}OCl_3(PPh_3)_2$

[a] Identified by ^{31}P NMR spectroscopy; see Section 2 for details. Phosphine oxides were also identified by GC–MS analysis.
[b] Identified by X-ray crystallography.
[c] Identified by electronic absorption spectroscopy.

spectrum is attributable to $OPEt_3$; PEt_3 and *cis-mer*-$MoOCl_2(PEt_3)_3$ appear to be present in smaller amounts. We believe the maroon color of this oil is due to the molybdenum(IV) complex $MoCl_4(PEt_3)_2$, as outlined in Section 4 (see below).

Thus, Mo(V) exhibits redox activity with PEt_3, including oxygen atom transfer reactions. Since rapid redox reactions occur even without irradiation, we did not study the effects of light on this system.

3.2. Irradiation of Mo(V) with PEt_2Ph, $PEtPh_2$, and PPh_3

The other phosphines showed little or no reactivity with Mo(V) in the dark. Therefore, we explored their photochemical reactions in acetonitrile solution. In the following paragraphs, the starting material is referred to as oxomolybdenum(V) for simplicity. The Mo(V) source, $MoOCl_4(H_2O)^-$, is ordinarily converted to $MoOCl_4(NCCH_3)^-$ in acetonitrile solution [15], but further spectral changes (in both absorption and fluorescence; see below) on addition of phosphines suggest that at least some additional ligand substitution is occurring, possibly making $MoOCl_4(phosphine)^-$. Solid $MoOCl_4(phosphine)^-$ salts appear not to have been reported previously in the literature, and we were unable to isolate well-defined solids from these Mo(V)–phosphine mixtures.

3.2.1. PEt_2Ph

On addition of PEt_2Ph (4 equiv.) to oxomolybdenum(V) in acetonitrile, the solution changed from green to brown–green. The absorption maxima for the brown–green solution are at 674 and 446 nm. No fluorescence was observed from these Mo(V)–PEt_2Ph solutions. On irradiation, the color changed gradually to deep red–brown; see spectra in Fig. 3. After irradiation, one maximum was present at 405 nm with a shoulder at 475 nm. GC–MS analysis of the reaction mixture, after as little as 1 day of irradiation, showed that both PEt_2Ph ($m/e = 166$) and $OPEt_2Ph$ ($m/e = 182$) were present. At the end of the irradiation, the ^{31}P NMR spectrum showed intense peaks due to $OPEt_2Ph$ and unreacted PEt_2Ph. A reduced Mo product was also isolated, as follows.

Removal of solvent from the product mixture gave a brown–red oil, which dissolved readily in CH_2Cl_2. Treatment of this CH_2Cl_2 solution with pentane produced orange–yellow crystals, which were shown by X-ray analysis to be the unusual mixed-ligand molybdenum(III) complex *cis-mer*-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$ (see data in Tables 1 and 2, and ORTEP plot in Fig. 4). This compound is similar to $MoI_3(PMe_2Ph)_2(OPMe_2Ph)$, which was also produced by reduction of a higher-valent molybdenum compound [39].

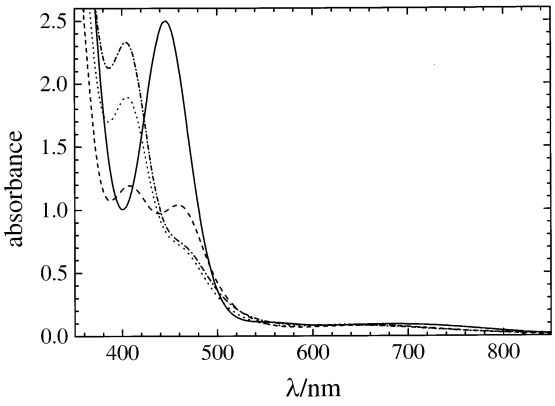

Fig. 3. Electronic absorption spectra illustrating the photochemical reaction of oxomolybdenum(V) with PEt_2Ph in CH_2Cl_2. Irradiation times: (—) initial spectrum, (---) 1 day, (···) 2 days, (-·-·-) 3 days.

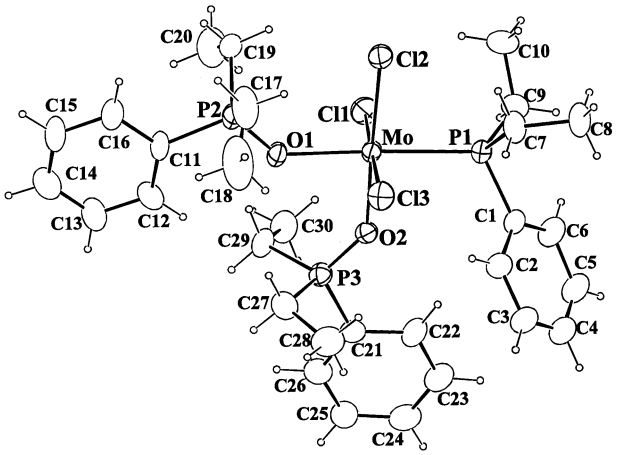

Fig. 4. ORTEP drawing of *cis-mer*-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$, with ellipsoids at the 30% probability level.

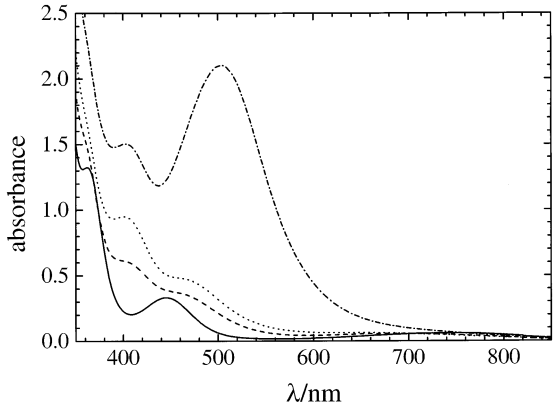

Fig. 5. Electronic absorption spectra illustrating the photochemical reaction of oxomolybdenum(V) with $PEtPh_2$ in CH_2Cl_2. Irradiation times: (—) initial spectrum, (---) 1 day, (···) 2 days, (-·-·-) 3 days.

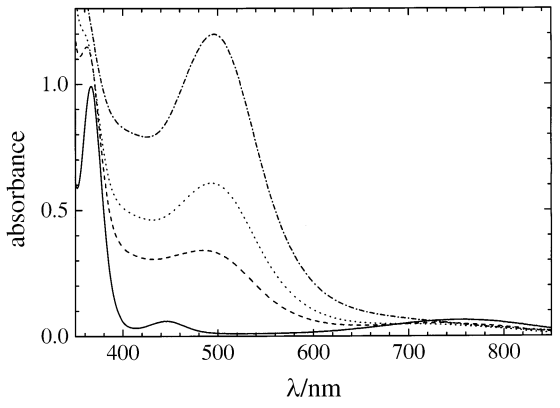

Fig. 6. Electronic absorption spectra illustrating the photochemical reaction of oxomolybdenum(V) with PPh_3 in CH_2Cl_2. Irradiation times: (—) initial spectrum, (---) 1 day, (···) 2 days, (-·-·-) 3 days.

Thus, irradiation of oxomolybdenum(V) with PEt_2Ph causes oxidation of PEt_2Ph and reduction of molybdenum, as judged by the production of $OPEt_2Ph$ and the Mo(III) product *cis-mer*-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$.

3.2.2. $PEtPh_2$

Irradiation of oxomolybdenum(V) in CH_3CN with 4 equiv. of the less nucleophilic $PEtPh_2$ produced a change in color similar to that for irradiation with PEt_2Ph. The initial color of the Mo(V)–$PEtPh_2$ mixture was brown–green, with maxima at 446 and 741 nm. This solution was also fluorescent, with λ_{max} (ca. 930 nm) slightly blue-shifted relative to $MoOCl_4(NCCH_3)^-$, and it was also noticeably less intense. During 3 days of irradiation, the solution turned deep red–brown, with final absorption maxima at 403 and 503 nm (see spectra in Fig. 5). Evaporation of solvent from the irradiated solution left a brown–red oil. Both $PEtPh_2$ and $OPEtPh_2$ were present in this residue, as shown by GC–MS (*m*/*e* 214, 230) and ^{31}P NMR (see Table 3) analysis.

Reduced Mo species were expected to form along with the oxidation product $OPEtPh_2$. However, we were unable to isolate such species. Instead, the UV–Vis and IR spectra of the brown–red oil were similar to those of *fac*-$MoOCl_3$(dppe) [40]. No new ^{31}P NMR signals were observed.

Thus, irradiation of oxomolybdenum(V) with $PEtPh_2$ causes photooxidation to $OPEtPh_2$. The major electronic spectral changes are associated with formation of Mo(V) complexes, likely including $MoOCl_3(PEtPh_2)_2$; this indicates that ligand substitution is an important component of the photoinduced reactions.

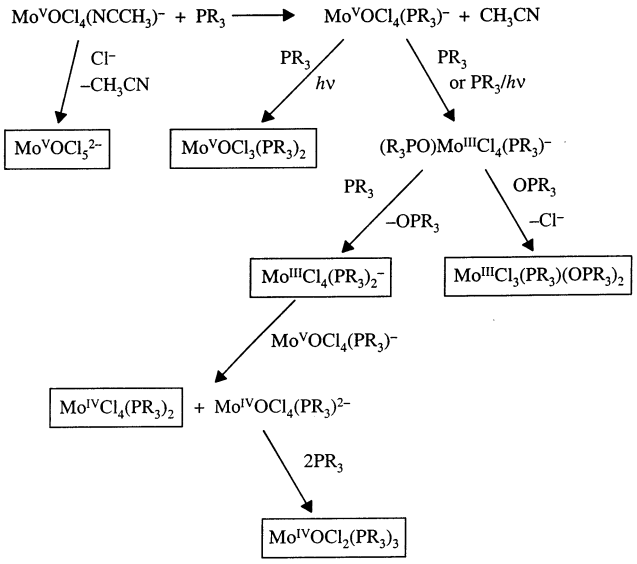
3.2.3. PPh_3

Addition of PPh_3 to oxomolybdenum(V) produced green–brown solutions, with absorption maxima at 446 and 754 nm, and fluorescence λ_{max} 935 nm (the latter value slightly blue-shifted relative to $MoOCl_4(NCCH_3)^-$). Irradiation of these solutions produced a change in color similar to that noted in the irradiations with PEt_2Ph and $PEtPh_2$: after 3 days the solution had turned deep red–brown (see spectra in Fig. 6).

After removal of solvent, the residue was washed with benzene to remove excess PPh_3. A red–brown solid remained, which showed an absorption maximum of 472 nm in CH_3CN and ν(MoO) at 972 cm^{-1}. The similarity of these features to those for *fac*-$MoOCl_3$(dppe) [40] suggests that the major product in our reaction is *fac*-$MoOCl_3(PPh_3)_2$. Thus, we believe the principal photoreaction in the Mo^VO–PPh_3 system is ligand substitution. No redox products ($OPPh_3$ or isolable reduced molybdenum products) were observed in these irradiated mixtures.

3.3. Reactivity of Mo(V) with PEt_2Ph, $PEtPh_2$, and PPh_3 in the dark

To confirm that the reactions discussed above were indeed photochemical, identical solutions were placed



in the dark for 3–4 days and their spectra monitored. Only minor changes occurred, as follows.

3.3.1. PEt_2Ph

The electronic spectrum of the solution changed slightly (final λ_{max} 441 and 640 nm) after 3 days. ^{31}P NMR analysis of the products showed a small signal due to $OPEt_2Ph$ (also present were weak resonances at 20.2 (t) and 15.0 ppm (d), with a pattern similar to that mentioned above for *cis-mer*-$MoOCl_2(PEt_2Ph)_3$). The presence of some $OPEt_2Ph$ (integration ratio $OPEt_2Ph$:PEt_2Ph ca. 1:40) indicates a small amount of thermal oxidation over the course of the dark reaction. As a control experiment, we prepared a similar solution without Mo; this solution also produced a small amount of $OPEt_2Ph$ on standing in the dark. We believe both processes are likely due to traces of O_2 entering the flasks.

3.3.2. $PEtPh_2$

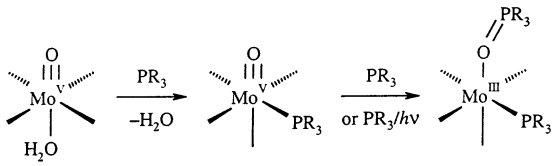
When a Mo(V)–$PEtPh_2$ mixture was allowed to stand for 3 days in the dark, there was essentially no change in its electronic absorption spectrum. Removal of solvent left a brown–green solid, which showed no resonances attributable to $OPEtPh_2$ in its ^{31}P NMR spectrum. Dissolution of this solid in a minimum of CH_2Cl_2, followed by flooding with pentane, gave a solution that slowly deposited a small quantity of orange crystals. These crystals were identified by X-ray analysis as the molybdenum(V) dimer $(PPh_4)_2$-$[Mo_2O_4Cl_4]\cdot CH_2Cl_2$ [41]. Thus, although some ligand substitution occurs in this system, we found no products (e.g. $OPEtPh_2$, or reduced Mo species) that suggested redox processes.

Scheme 1. Proposed routes for formation of molybdenum complexes in the oxomolybdenum(V)–phosphine reaction (phosphine, represented by PR_3, is PEt_3, PEt_2Ph, $PEtPh_2$, or PPh_3). Species in boxes have been identified by spectroscopic methods or by X-ray crystallography.

3.3.3. PPh_3

A dark experiment with Mo(V) and PPh_3 produced no detectable changes after 4 days. The electronic absorption maxima were unchanged. Removal of solvent gave a green solid; this material showed only PPh_4^+ and PPh_3 in its ^{31}P NMR spectrum.

4. Discussion



In this work, we attempted to exploit the attractive photophysical properties of $MoOCl_4(NCCH_3)^-$ for use in photochemical oxygen atom transfer. For example, photoreduction of a molybdenum(V)–oxo complex via O atom transfer would yield molybdenum(III). Since some Mo(III) complexes are already known to undergo photoinitiated two-electron oxidation to Mo(V) [14,42] our ultimate goal was to construct a Mo(III)–Mo(V) cycle for use in photochemical two-electron transformations of substrate molecules.

The products we have observed, and proposed routes for their formation, are shown in Scheme 1.

We began our studies with triethylphosphine, because it is the best electron donor in the series PEt_3, PEt_2Ph, $PEtPh_2$, PPh_3, and we expected it to be the most reactive (for example, in the reduction of $MoO_2(S_2CNEt_2)_2$ by this series of phosphines, PEt_3 gives the highest thermal oxygen atom transfer rate constant [43]). Treatment of $MoOCl_4(H_2O)^-$ with PEt_3 in CH_2Cl_2 leads to an immediate change in color from green to maroon. Similar color changes occur when the reaction is performed in CH_3CN, except that the maroon solution gradually turns yellow–orange. In either solvent, numerous products form: $Mo^{V}OCl_5^{2-}$, $Mo^{III}Cl_4(PEt_3)_2^-$, and $OPEt_3$ have been clearly identified, and two additional products appear to be $Mo^{IV}OCl_2(PEt_3)_3$ and $Mo^{IV}Cl_4(PEt_3)_2$ (identified by ^{31}P NMR and UV–Vis spectroscopy, respectively).

Several pieces of evidence argue in favor of the initial step, rapid substitution of phosphine *cis* to the oxo group: the previously documented rapid aquation of $MoOCl_5^{2-}$ (as discussed above) and solvation of $MoOCl_4(H_2O)^-$ in CH_3CN [15], and the initial spectral changes observed on mixing PEt_2Ph, $PEtPh_2$, or PPh_3 with Mo(V).

In the next step, we propose that a molecule of PR_3 reacts with the oxo group of the molybdenum(V)–oxo complex, producing coordinated phosphine oxide and reducing the Mo center to the trivalent state. These initial steps are illustrated in Scheme 2 (reaction of $Mo^{V}O$ with PR_3 is spontaneous for PEt_3, but requires irradiation for PEt_2Ph and $PEtPh_2$). The Mo(III)–OPR_3

Scheme 2. Possible initial steps in the reactions of oxomolybdenum(V) with phosphines.

complex is likely to react readily with an additional molecule of phosphine, releasing the phosphine oxide and giving $Mo^{III}Cl_4(PR_3)_2^-$ as the product.

The other Mo(V) and Mo(IV) products may form as follows. Comproportionation of a molecule of $Mo^{V}OCl_4(PEt_3)^-$ with $Mo^{III}Cl_4(PEt_3)_2^-$ would produce two molybdenum(IV) complexes: $MoOCl_4(PEt_3)^{2-}$ and $MoCl_4(PEt_3)_2$. Substitution of two PEt_3 ligands for Cl^- in $MoOCl_4(PEt_3)^{2-}$ would produce $MoOCl_2(PEt_3)_3$. The chloride ions released in this substitution would be free to react with $MoOCl_4(PEt_3)^-$ to produce $MoOCl_5^{2-}$.

The visually most striking feature of the $MoOCl_4(H_2O)^-/PEt_3$ reaction is the deep maroon color (λ_{max} 546 nm; see Fig. 1) produced almost immediately on mixing the reactants. We were unable to isolate the maroon material by evaporation of the solvent from the pentane solution: this procedure left a brown residue that gave a brown solution in CH_2Cl_2. The maroon color is unlikely to be due to *cis-mer*-$MoOCl_2(PEt_3)_3$, since such complexes are reported to be blue [22]. We believe a more likely explanation of the maroon color is the non-oxo Mo(IV) complex $MoCl_4(PEt_3)_2$. This would be closely related to the Mo(III) anion $MoCl_4(PEt_3)_2^-$ already observed in this system, and other *trans*-$MoCl_4(PR_3)_2$ complexes have been reported to be maroon [37,44], though no electronic absorption spectral data have been published.

Thus, PEt_3 reacts with Mo(V) to give the oxygen atom transfer products of Scheme 1, and other products. The rapid redox activity exhibited with PEt_3, even without irradiation, led us to explore the use of less basic phosphines as oxygen atom accepting substrates. Fewer products were observed in the reactions with other phosphines, but they are also consistent with Scheme 1.

Irradiation of Mo(V) with PEt_2Ph produces $OPEt_2Ph$ and the molybdenum(III) complex $MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$. The formation of these products can be explained by referring to Scheme 1. Displacement of one chloride ligand in $Mo^{III}Cl_4(OPEt_2Ph)(PEt_2Ph)^-$ by $OPEt_2Ph$ would give $MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$, one of the species we have isolated in crystalline form (this route would also yield the *cis-mer* isomer of the mixed phosphine–phosphine oxide complex, as observed in the X-ray structure).

Irradiation of Mo(V) with $PEtPh_2$ produces a change in color similar to that noted with PEt_2Ph. Spectroscopic evidence shows that $OPEtPh_2$ is produced, but the nature of the reduced molybdenum product(s) is unknown.

Irradiation of Mo(V) with PPh_3, the phosphine in the series that is most difficult to oxidize, does not appear to lead to redox reactions. Instead, we believe the major photoprocess is ligand substitution, to give $MoOCl_3(PPh_3)_2$.

The major electronic spectral changes during the irradiations with $PEtPh_2$ and PPh_3 consist of decreasing absorbance beyond 700 nm, increasing (but still weak) absorbance in the 650–700 nm region, and sharply increasing absorbance near 500 nm. The fact that these changes occur with PPh_3, which shows no photoinduced redox activity, suggests that they are due to another process, such as ligand substitution. We have been unable to isolate pure compounds from these irradiated solutions. However, the similarity of these spectral features to those of $MoOCl_3$(dppe) (λ_{max} 496 nm in CH_3CN) [40] suggests that a photoinduced ligand substitution process is important in these systems, with the major product being $MoOCl_3(PR_3)_2$. Because of the complexity and low overall efficiency of the photochemical reactions, and because the most prominent spectral changes appear to reflect photosubstitution rather than the more interesting photoredox reaction, we did not attempt to determine quantum yields for these processes.

Reaction of Mo(V) with PEt_2Ph in the dark also produced a small amount of $OPEt_2Ph$, as indicated by its ^{31}P NMR spectrum. However, the ratio of phosphine oxide to phosphine in the dark reaction is much smaller (by a factor of ca. 25) than in the photochemical reaction.

4.1. Longer-wavelength irradiation of Mo(V) with phosphines

For the photochemical experiments described above, we used Pyrex-filtered xenon-arc light. We also wished to ascertain whether these reactions proceeded via the lowest-energy $^2E(d_{xz}, d_{yz})$ excited state. Therefore, we repeated the Mo(V)/PEt_2Ph and Mo(V)/$PEtPh_2$ irradiations (those that showed definite photoredox activity) using the following Corning colored glass filters: 3–67 ($\lambda > 530$ nm transmitted), 0–51 ($\lambda > 390$ nm) and 0–52 ($\lambda > 360$ nm) [45]. The 3–67 filter allows irradiation in only the lowest-energy absorption band (ca. 750 nm; $^2B_2(d_{xy}) \rightarrow {}^2E(d_{xz}, d_{yz})$), and the other two filters allow irradiation in the first two bands (ca. 450 nm also; $^2B_2(d_{xy}) \rightarrow {}^2B_1(d_{x^2-y^2})$). The starting Mo(V) concentration was kept as high as possible (0.03–0.07 M) in these experiments, in order to maximize the absorbance of the solutions: typical initial absorbances near 450 and

750 nm were 0.5–1, so that 70–90% of the excitation light was absorbed. For example, the Mo(V)/PEt_2Ph mixture was irradiated for 6 days using the 3–67 filter. Although the electronic spectrum of the irradiated solution was almost unchanged, ^{31}P NMR analysis showed the production of a small amount of $OPEt_2Ph$ ($OPEt_2Ph$:PEt_2Ph ratio approximately four times as great as for the dark reaction). Also, irradiation of the Mo(V)/$PEtPh_2$ mixture using the 0–51 filter for 4 days produced slight changes in the electronic spectrum, similar to those observed after 1 day of irradiation in Fig. 5. Thus, these photochemical redox reactions occur, at least to some extent, from the lowest-energy fluorescent excited state. The photochemical reactivity appears to be greater on higher-energy irradiation, but this cannot be established quantitatively because of the difficulty of obtaining quantum yield data (see above).

5. Conclusions

We have examined the chemistry and photochemistry of oxomolybdenum(V) using the series of phosphines PEt_3, PEt_2Ph, $PEtPh_2$ and PPh_3 as potential oxygen atom acceptors. The reaction with PEt_3 occurs spontaneously, producing $[MoOCl_5]^{2-}$, $[MoCl_4(PEt_3)_2]^-$, and a multicomponent maroon oil that contains $OPEt_3$ and the molybdenum(IV) oxo complex $MoOCl_2(PEt_3)_3$. PEt_2Ph and $PEtPh_2$ require irradiation to react with Mo(V), producing the corresponding phosphine oxides and reduced Mo complexes, along with ligand-substitution products. Irradiation of oxomolybdenum(V) with PPh_3 leads only to ligand substitution. The order of reactivity we observe is consistent with the electronic properties of the phosphines: PEt_3 is most electron-rich at P and therefore the easiest to convert to its oxide, and PPh_3 is the most difficult to oxidize.

6. Supplementary material

XANES spectra for $(Ph_4P)_2[MoOCl_5]\cdot 2CH_2Cl_2$ and related compounds, and an ORTEP illustration of the Ph_4P^+ and CH_2Cl_2 portions of the $(Ph_4P)_2[MoOCl_5]\cdot 2CH_2Cl_2$ structure, are available from the authors. Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-134165 ($(Ph_4P)_2[MoOCl_5]\cdot 2CH_2Cl_2$) and CCDC-134166 (*cis-mer*-$MoCl_3(OPEt_2Ph)_2(PEt_2Ph)$). Copies of the data can be obtained, free of charge, on application to: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

[31] D. Garner, L.H. Hill, F.E. Mabbs, D.L. McFadden, A.T. McPhail, J. Chem. Soc., Dalton Trans. (1977) 853.
[32] V.V. Tkachev, O.N. Krasochka, L.O. Atovmyan, J. Struct. Chem. USSR 17 (1976) 807. In this case, the $MoOCl_5^{2-}$ anion was not disordered, and showed Mo–O 1.61(1) Å, equatorial Mo–Cl 2.369(7)–2.397(7) Å, and *trans* axial Mo–Cl 2.587(6) Å.
[33] In addition to the two species already mentioned ($MoOCl_5^{2-}$ and $MoOCl_4(H_2O)^-$), the five-coordinate complex $MoOCl_4^-$ may also be important in the chemistry of Mo(V) in noncoordinating solvents (the equilibrium $MoOCl_5^{2-} \rightleftarrows MoOCl_4^- + Cl^-$ was originally studied by Boorman et al. [26]). Thus, for example, the CH_2Cl_2 solution prepared from $(PPh_4)_2[MoOCl_5]{\cdot}2CH_2Cl_2$ is spectroscopically similar to a solution of $(PPh_4)[MoOCl_4]$ (prepared by heating $(PPh_4)[MoOCl_4(H_2O)]$ under vacuum at ca. 80°C for 30 h) in CH_2Cl_2 (λ_{max} 691, 442 nm). Addition of $(PPh_4)Cl$ (to suppress dissociation of $MoOCl_5^{2-}$) or $SOCl_2$ (to react with traces of H_2O and therefore convert any $MoOCl_4(H_2O)^-$ present back to $MoOCl_4^-$/$MoOCl_5^{2-}$) to these Mo(V)/CH_2Cl_2 solutions caused blue shifts in the absorption band near 700 nm and substantial weakening in the band near 440 nm. For example, a solution of $(PPh_4)_2[MoOCl_5]{\cdot}2CH_2Cl_2$ in CH_2Cl_2, treated with added $SOCl_2$ (ca. 5% v/v) and $(Ph_4P)Cl$ (2 equiv., excess) has a much weaker yellow color; the absorption bands in the visible region are shifted to 686 and 447 nm, the latter band being much less intense than in the initially prepared solution. Thus, although CH_2Cl_2 solutions prepared from $(PPh_4)_2[MoOCl_5]{\cdot}2CH_2Cl_2$ are clearly different in spectroscopic properties from those of other well-recognized oxomolybdenum(V) species, these solutions may contain $MoOCl_4^-$ and small amounts of $MoOCl_4(H_2O)^-$ in addition to $MoOCl_5^{2-}$.

Received 28 January 2000; accepted 5 April 2000

Abstract

The syntheses of the cobalt(III) and copper(II) complexes with the hexadentate nitrogen ligand 1,10-bis(2-pyridylmethyl)-1,4,7,10-tetraazadecane (bpteta) are reported. NMR spectra and X-ray structure determination have shown that these octahedral complexes have a β-*cis* configuration with pyridine nitrogen atoms mutually *cis* and *trans* to amine nitrogen atoms. A large distortion due to the Jahn–Teller effect is observed in the case of the copper(II) compound. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Copper(II); Cobalt(III); NMR spectroscopy; Pyridylmethyl-tetraazadecane

1. Introduction

Tetradentate N_4 or hexadentate N_6 ligands containing pyridylmethyl groups are able to form di- or tetranuclear complexes in which biologically interesting metallic ions are present at different oxidation states and are studied for their relevance as models for enzymes [1,2]. The hexadentate nitrogen ligand 1,10-bis(2-pyridylmethyl)-1,4,7,10-tetraazadecane was described for the first time by Arulsamy et al. [2], who obtained $ML(ClO_4)_2$ complexes ($M = Fe^{2+}$, Mn^{2+}, Ni^{2+}) and tetranuclear iron(III) compounds. The stability constants of the complexation of metallic ions (Cu^{2+}, Ni^{2+}, Co^{2+}, Zn^{2+}) with this ligand have been determined by Kim et al. [3,4]. Surprisingly, none of these authors has described either copper or cobalt coordination with this ligand. In this report, we examine the isomeric identification of diamagnetic octahedral cobalt(III) complexes using two-dimensional NMR spectroscopy, ESR spectra and electrochemical behavior for the copper(II) compound. Structural determinations have been carried out for both these complexes.

2. Experimental

2.1. Materials and methods

All the solvents were purified by conventional procedures [5] and distilled prior to use. All the reagents were commercially available (Aldrich) and used without further purification.

Elemental analyses (C, H and N) were carried out on a Perkin–Elmer 2400 C, H, N element analyzer in our university. The metal percentage was performed on an ICP AES Liberty Series II Varian apparatus. The UV–Vis spectra were recorded on a Perkin–Elmer Lambda 6 spectrophotometer. IR spectra were obtained using KBr sample pellets. Magnetic susceptibilities were determined at room temperature (r.t.) (20°C) using $Hg-Co(SCN)_4$ as a calibrant; diamagnetic susceptibility corrections were calculated from Pascal's constants [6].

All NMR spectra were recorded in D_2O at r.t. with a Bruker AC 250 or a Bruker DRX 500 spectrometer. Chemical shifts for ^1H and ^{13}C NMR spectra were referenced to residual solvent.

The crystal data were collected at 173 K on a Kappa CCD diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). For both compounds, X-ray experimental data are given in Table 1.

Three standard reflections measured every hour during the entire data collection period showed no significant trend. The raw data were collected for Lorentz polarization and absorption factor (psi scans of seven reflections). The structure was solved by the heavy atom method. After refinement of the non-hydrogen atoms, difference-Fourier maps revealed maxima of residual electron density close to positions expected for hydrogen atoms. Hydrogen atoms were refined at calculated positions with a riding model in which the C–H vector was fixed at 0.95 Å with isotropic temperature factors. A final Fourier difference map revealed no significant maxima. All calculations were performed on a DEC Alpha 3000 computer using the Nonius OPENMOLEN package [7]. Neutral atom scattering factor coefficients and anomalous dispersion coefficients were taken from a standard source [8].

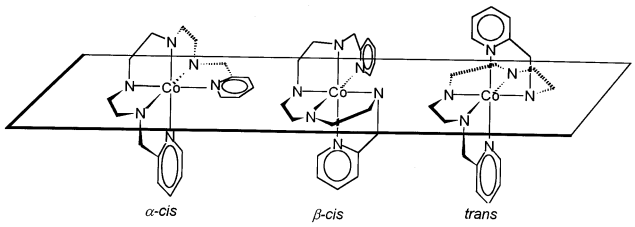
The cyclic voltammetry experiments were carried out with a conventional three electrode cell using an EG&G PAR model 362 scanning potentiostat and a Kipp & Zonen BD91 X-Y recorder. A platinum disk (2 mm diameter) working electrode and a platinum wire auxiliary electrode were used. The reference was a saturated calomel electrode. Acetonitrile was purified using standard methods, while tetraethylammonium perchlorate was recrystallized from water before use. The copper(II) complex (10^{-3} mol l^{-1}) was dissolved in deoxygenated acetonitrile containing tetraethylammonium perchlorate (0.1 mol l^{-1}). All solutions were kept under nitrogen during electrochemical measurements.

The ESR spectra in acetonitrile were obtained in the X-band at 77 K and at r.t. with a Varian E109 spectrophotometer. The g values were measured relative to the strong pitch.

2.2. Syntheses

The ligand 1,10-bis(pyridylmethyl)-1,4,7,10-tetraazadecane tetrahydrochloride monohydrate was prepared according to the method described by Arulsamy et al. [2], which involved the condensation of pyridine-2-carboxaldehyde with triethylenetetramine and then the reduction of the obtained imine by sodium borohydride. The compound was identified by elemental analyses and ^{1}H NMR spectra.



Caution! Perchlorate salts of metal complexes with organic ligands are potentially explosive and should be handled with care.

2.3. Cu(bpteta)(ClO$_4$)$_2$

The complex was synthesized in a similar manner as the manganese or nickel complexes described by Arulsamy et al. [2]. Yield: 71%; m.p. = 188°C. $C_{18}H_{28}Cl_2CuN_6O_8$ (590.91 g mol^{-1}): Calc. C, 36.59; H, 4.78; N, 14.22; Cu, 10.7. Found: C, 36.54; H, 4.30; N, 13.86; Cu, 10.4%. IR: $\nu(ClO_4^-) = 1086$ cm^{-1}. Magnetism: $\chi_M = 1630 \times 10^{-6}$ uem cgs, $\mu = 1.97$ BM. Electronic spectrum: $\lambda = 615$ nm, $\varepsilon = 107$ l mol^{-1} cm^{-1}.

2.4. Co(bpteta)(ClO$_4$)$_2$Cl·H$_2$O

Sodium acetate (4 mmol) was added to bpteta·4HCl·H$_2$O (1 mmol) in absolute ethanol. The mixture was stirred, brought to the boil (10 min), and filtered. 1 mmol of Co(ClO$_4$)$_2$·6H$_2$O was then added to the filtrate, the solution was stirred under air bubbling over 10 h in order to completely oxidize the Co(II) into Co(III). Yield 32%; m.p. = 212°C. $C_{18}H_{30}Cl_3CoN_6O_9$ (639.77 g mol^{-1}): Calc. C, 33.76; H, 4.69; N, 13.13; Co, 9.2. Found: C, 33.93; H, 4.41; N, 12.93; Co, 8.9%. IR: $\nu(ClO_4^-) = 1086$ cm^{-1}. Electronic spectrum: $\lambda = 464$

Scheme 1.

nm, $\varepsilon = 142$ l mol^{-1} cm^{-1}. The diamagnetism of the cobalt complex is indicative of a complete oxidation of cobalt(II) into cobalt(III).

3. Results and discussion

3.1. NMR spectra

The ^{1}H NMR spectrum of the ligand reveals four well-resolved signals for the pyridine moiety with typical values of coupling constants (see Table 2) [9], one multiplet for the equivalent methylen groups and a singlet for the two pyridyl moieties.

The 1D and 2D NMR spectra which have allowed the determination of the geometry of cobalt(III) complexes with tetradentate or pentadentate ligands containing nitrogen and/or sulfur donor atoms [10] have been used to determinate the configuration of the cobalt complex. Octahedral metal complexes containing a hexadentate N_6 ligand can exist in α-*cis*, β-*cis* or *trans* configurations which have one, two or three ethylen groups, respectively, in the same plane (Scheme 1).

Therefore the ^{1}H NMR spectrum of the cobalt compound must reveal several resonances for each proton. By combined use of COSY and decoupling methods, it is possible to assign all ^{1}H resonances for the both pyridine moieties. The decoupling experiments and the coupling constants are the key elements for the determination of the proton resonances. Any ambiguities are resolved via the COSY experiment (Fig. 1).

The complete ^{1}H assignment is extended to the ^{13}C resonances by reference to the ^{1}H-^{13}C HMBC and ^{1}H-^{13}C HMQC data. The ^{1}H NMR spectrum of the cobalt compound shows a slight deshielding for H^{1}, H^{2}, H^{3}, H^{4}, H^{13} and H^{14} pyridine protons compared with those of the ligand according to electronic density

[a] Split triplet.

decreasing due to the Co(III) metallic cation. On the other hand, shielding for the H^{15} signal (-0.26 ppm) which resonates at 7.44 ppm as a triplet and a very large shielding for H^{16} (-1.82 ppm) which resonates at 6.88 ppm as a doublet with the typical $J_{1,2}$ (5.9 Hz) coupling in the pyridine moiety are also observed. The presence of these two pyridine protons in the interatomic ring currents anisotropic contributions of the other pyridine induces this shielding. This effect for H^{15} and H^{16} involves a β-*cis* configuration which is the only one inducing this shielding for these two protons of the complex.

From this configuration we can assign all resonances from the ^{1}H-^{13}C HMQC and ^{1}H-^{13}C HMBC spectra. The singlet at 4.50 ppm in the ligand was replaced in the cobalt compound by two AB patterns at 4.45 and 5.34 ppm with a J(AB) of 18.3 Hz for H^5 and at 4.30 and 4.40 ppm with the same J(AB) of 18.3 Hz for H^{12}. These proton resonances are confirmed by the HMBC spectrum, which shows a correlation between H^5, H^{12} and $H^{4'}$, $H^{13'}$, respectively, and a very weak correlation between H^4 and H^{13}.

There is also a correlation between this ^{1}H resonance (H^5 and H^{12}) and two carbons at 59.6 and 54.2 ppm. This carbon must be part of the ethylenediamine chain, since the HMQC experiment correlates a proton resonance to these ^{13}C resonances at 3.11/3.80 ppm and 3.36/3.95 ppm which are assigned to H^6 and H^{11}. The non-equivalence of the two protons of each methylen group is due to the shielding effect of the neighboring five-membered ring (Co, N, $C^{4'}$, C^5, N for H^6 protons and Co, N, C^{12}, $C^{13'}$, N for H^{11} protons) anisotropic bond contributions. Finally, H^7, H^8, H^9 and H^{10} protons are assigned by a similar way using simultaneously 1D and 2D experiments. From which, weak but distinguishable, correlations are observed for the high field ^{1}H resonance in the HMBC spectrum which confirm the assignment of the three ethylenediamine protons.

From this study, we can deduce the β-*cis* configuration of the cobalt compound. Only the presence of protons in the interatomic ring current anisotropic contribution allows one to elucidate the configuration of the complex with this type of hexadentate ligand. Moreover, no splitting was observed for any proton or carbon signal indicating only one isomer.

This β-*cis* configuration was confirmed by X-ray analyses.

3.2. X-ray crystallography

Each structure consists of $[Mbpteta]^{n+}$ cations M = Co^{3+} or Cu^{2+} which are well separated from anions. Principal bond distances and angles are listed for the two complexes in Tables 3 and 4. A view of the cobalt and the copper cations is given in Figs. 2 and 3.

N(2)–Cu–N(6)	95.95(8)		

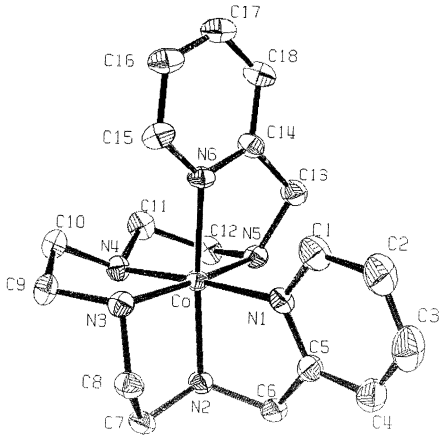

Fig. 2. View of the $[Co(bpteta)]^{3+}$.

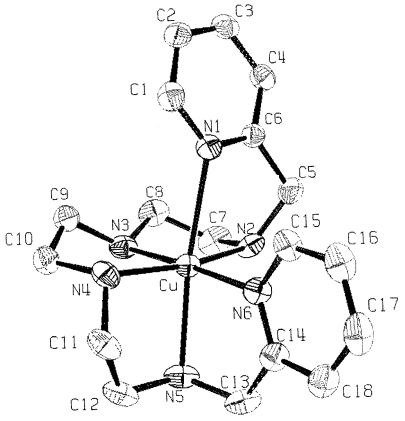
The $[Cobpteta]^{3+}$ cation has a slightly distorted octahedral coordination geometry whereas the copper cation exhibits a strong distortion of the octahedral geometry with a large elongation along the *z* axis. The ligand encircles the metal atom through the six ligating nitrogen atoms. Though several isomers can be obtained with this hexadentate ligand, only those obtained with the first transition metal series (Fe(II) [2], Co(III), Ni(II) [2] or Cu(II)) have the pyridine nitrogen atom in the *cis* position.

The $[Cobpteta]^{3+}$ cation is very similar to those of iron(II) and nickel(II) described by Arulsamy et al. [2]; however the octahedral polyhedron around the cobalt is less distorted than those around the iron and nickel: the N–Co–N angles being nearer 90° for the *cis* nitrogen donor atom and 180° for the *trans* nitrogen donor atom. The cobalt–nitrogen bond lengths are practically the same for the ligating of pyridine and amine nitrogen atoms and are consistent with those found in the CoN_6 chromophore [11–13]. However all the metal–nitrogen bond lengths in the cobalt complex are shorter than those in the nickel or iron complexes, in agreement with the radius of Co(III). One perchlorate ion in the cobalt(III) compound is ordered and the Cl–O bond lengths and the O–Cl–O angles are consistent with those reported in the literature [2], but the latter is disordered.

The $[Cubpteta]^{2+}$ cation can be described as pseudo-octahedral with a $N_{pyridine}$–Cu–$N_{pyridine}$ angle of 93.2°. Four bond lengths are nearly equal in the distorted square with three Cu–N_{amine} and one Cu–$N_{pyridine}$ whereas a strong Jahn–Teller distortion is observed along the *z* axes with an increasing bond length of 0.45 Å for the Cu–$N_{pyridine}$ and of 0.30 Å for the Cu–N_{amine}.

3.3. Electrochemical measurements

The cyclic voltammogram of the free ligand presents a reduction peak at a strong negative potential ($E_{1/2} = -0.50$ V versus SCE). The copper complex voltammogram shows an oxidation peak at 0.50 V indicative of the presence of copper(III) in solution. As the separation of the anodic and the cathodic peaks potential ($\Delta E_p = E_{p_a} - E_{p_c}$) is around 0.13 V, the Cu(III)/Cu(II) redox system appears quasi-reversible ($E_{1/2} = 0.43$ V). Unfortunately, several attempts to prepare the solid Cu(III) complex have failed.



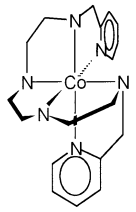


Fig. 3. View of the $[Cu(bpteta)]^{2+}$.

3.4. ESR spectra

The ESR spectrum of the copper complex dissolved in acetonitrile was recorded at r.t. (Fig. 4(a)): an isotropic ESR signal is obtained at $g_{iso} = 2.140$ with $A_{iso} = 71.10^{-4}$ cm^{-1}. The values of $g_{\parallel}$ (2.257), $A_{\parallel}$ (184.10^{-4} cm^{-1}), $g_{\perp}$ (2.081) and $A_{\perp}$ (14.10^{-4} cm^{-1}) are obtained from the spectrum recorded at 77 K (Fig. 4(b)). The values are typical of a strong tetragonally elongated octahedral copper (II) compound.

In conclusion, chromatography experiments and NMR spectroscopy indicate that only one isomer is obtained with the 1,10-bis(2-pyridylmethyl)-1,4,7,10-tetraazadecane.

β-cis

X-ray crystallography has shown that the geometry of these β-*cis* octahedral complexes is more and more

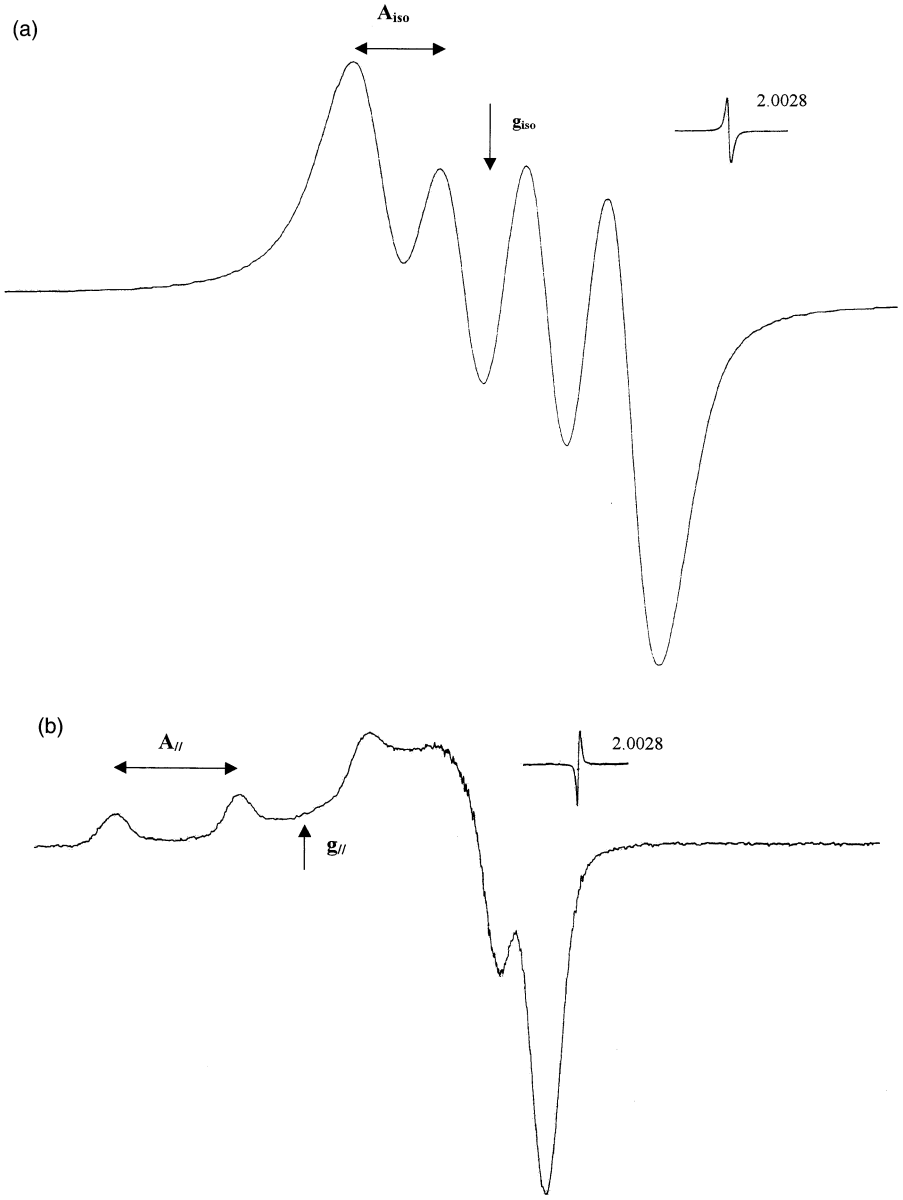

Fig. 4. ESR spectra of [Cu(bpteta)](ClO$_4$)$_2$.

distorted in the following order of the metal ion: Co(III), Fe(II), Ni(II), Cu(II).

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 135906 for the copper complex and no. CCDC 135907 for the cobalt compound. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail, deposit@ccdc.cam.ac.uk).

Acknowledgements

We thank Professor J.G. Fischer and Dr A. De Cian (Université Louis Pasteur, Strasbourg, France), for the single-crystal X-ray analyses.

Received 24 February 2000; accepted 7 April 2000

Abstract

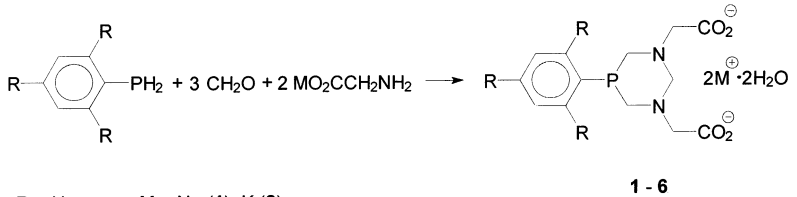
One-step syntheses of a number of water-soluble sodium and potassium phosphino amino acid salts from primary arylphosphines (2,4,6-$R_3C_6H_2$)PH_2 (R = H, Me, Pr^i), formaldehyde and sodium or potassium glycinate, with unsubstituted and 2,4,6-trisubstituted aryl substituents on the phosphorus atom are reported. The structures of the disodium and dipotassium 1,3-di(carboxylatomethyl)-5-aryl-1,3,5-diazaphosphorinanes were established on the basis of IR and ^1H, ^{13}C and ^{31}P NMR data.
© 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Water-soluble phosphines; Phosphino amino acid salts; Disodium or dipotassium 1,3-di(carboxylatomethyl)-5-aryl-1,3,5-diazaphosphorinanes

1. Introduction

The advantage of homogeneous over heterogeneous catalysis with respect to activity (relative to metal content), selectivity (particularly enantioselectivity), mildness of reaction conditions, freedom from diffusion problems, sensitivity towards catalyst poisons, variability of steric and electronic properties of the catalysts and mechanistic understanding of processes are well established [1]. However, the problem of separating the expensive catalysts from the products is often a major obstacle to industrial applications [1]. The main way of overcoming this problem is to 'heterogenize' a homogeneous catalyst by utilizing a liquid–liquid (usually water–organic solvent) biphasic system, in which solutions of the catalyst and of the substrate are separated by a phase barrier [2]. This approach generated intense interest in water-soluble ligands, especially phosphines [2–5].

Recently we described the synthesis of novel water-soluble [6,7] and chiral water-soluble [8] phosphines by the reaction of bis(hydroxymethyl)phenylphosphine, formaldehyde and *o*-aminobenzoic acid or the potassium salt of optically active phenylglycine, respectively. A number of their water-soluble complexes with transition metals were also reported [6,7]. It is of interest to vary the steric demand of the ligands, because the stereoselectivity of catalytic reactions is very sensitive to the nature of the ligands attached to the transition metal.



We now report the synthesis of water-soluble phosphino amino acids based on phenylphosphine ($PhPH_2$) and the bulky primary arylphosphines mesitylphosphine ($MesPH_2$) and 2,4,6-triisopropylphenylphosphine ($TippPH_2$) and alkali metal salts of glycine.

2. Results and discussion

To prepare the desired disodium or dipotassium 1,3-di(carboxylatomethyl) - 5 - aryl - 1,3,5 - diazaphosphorinanes we developed a new one-step synthesis directly from the primary phosphine, formaldehyde and amino acid salts (Eq. 1).

1 - 6

R = H, M = Na (**1**), K (**2**)
R = Me, M = Na (**3**), K (**4**)
R = Pr^i, M = Na (**5**), K (**6**)

(1)

This route allowed us to avoid handling air-sensitive hydroxymethylphosphines. This is especially important for bulky $MesPH_2$ and $TippPH_2$, because they react with two and even three molecules of formaldehyde to give mainly monosubstituted secondary phosphines (Eq. 2).

n = 2, 3	R = H	>95%	
n = 2	R = Me	28%	72%
n = 3	R = Pr^i	16%	84%

(2)

After heating the reaction mixtures of primary phosphine and formaldehyde to 120–130°C, the ^{31}P NMR signal of the primary phosphine disappeared, and the signal of the secondary phosphine appeared (R = Me: −79.6 ppm, $^1J(PH) = 221.9$ Hz; R = Pr^i: −89.1 ppm, $^1J(PH) = 214.5$ Hz) together with a minor signal (16–28%) for the tertiary bis(hydroxymethyl)arylphosphine (R = Me: −22.2 ppm; R = Pr^i: −27.5 ppm). The formation of hemiacetals from $P(CH_2OH)_3$ and formaldehyde has already been demonstrated [9]. In a second step, the secondary phosphines were reacted with sodium or potassium glycinate to yield the cyclic phosphines **1**–**6**, but the overall yields were noticeably lower than that of the one-step reaction.

Compounds **1**–**6** are white, air-stable microcrystalline powders. The IR spectra of **1**–**6** exhibit strong bands for the carboxylate group (1600 cm^{-1}), water of crystallization (3200–3400 cm^{-1}), and also absorption bands for the backbone vibrations of heterocylic bonds [10]. In the ^{31}P NMR spectrum, only one signal was found in the characteristic region of 1,3,5-diazaphosphorinanes [11] (Table 1). The chemical shifts of **1**–**6** are correlated with the donor ability of the aromatic substituents on the phosphorus atom, decreasing in the series R = H > Me > Pr^i. Elemental analysis data were also in agreement with the formation of the hydrated salts **1**–**6**.

The ^{13}C and ^1H NMR spectra are consistent with the heterocylic phosphine structure [8,11,12]. In the ^{13}C NMR spectrum, signals for the methylene groups of the P–CH_2–N, N–CH_2–N and N–CH_2–CO_2 fragments were observed (Table 2). The signal for the methylene carbon atom of the P–CH_2–N and N–CH_2–CO_2 fragments afforded the coupling constants $^1J(CP)$ and $^3J(CP)$.

It was shown previously that ^1H NMR data provide additional information on the conformational behavior of heterocyclic phosphines [11,12]. The ^1H NMR spectra of **1**–**6** are more complex than their ^{13}C and ^{31}P NMR spectra and that of the previously described 1,3,5-diazaphosphorinanes [11], due to overlap of the signals of the $(AB)_2(CD)X$ spin system of cyclic and exocyclic methylene groups. 2D COSY NMR spectra were used for the assignment of multiplets and to establish the order of spin–spin coupling.

In the ^1H NMR spectra, readily identified signals of the aryl substituents on the phosphorus atom and of the N–CH_2–N fragment are observed. The chemical shifts of the N–CH_2–N hydrogen atoms depend on the solvent. The chemical shift of the low-field doublet did not change, but that of the high-field signal moved to higher field ($\Delta\delta = -0.56$ ppm) on changing the solvent from water to methanol (see Section 3.3). This high-field signal was interpreted as a doublet of doublets with a four-bond coupling to phosphorus and could be

assigned to the equatorial proton in a chair conformation according to the W rule [11].

The methylene protons of the N–CH_2–CO_2 fragments gave rise to two doublets (**1**–**5**) or the singlet (**6**) of an AB spin system. Raising the temperature from 25 to 98°C did not lead to the coalescence of these signals; this indicates that the AB spin system is due not to the non-fluxional behavior of corresponding six-membered ring substituents but to magnetically inequivalent N–CH_2–CO_2 protons.

The most interesting signals of P–CH_2–N protons with stereospecific geminal PH coupling constant represent $(AB)_2X$ spin systems (Table 3). Both H^A and H^B protons were registered as doublets of doublets, but their coupling constants ^2J(PH) were noticeably different. $^2J(PH^A)$ and $^2J(H^AH^B)$ were approximately equal ($\sim$13 Hz), but the $^2J(PH^B)$ values were smaller than 6.1 Hz, ranging from 4.0–4.5 (**1**, **2**) to 5.7–6.1 Hz (**3**–**6**). 1,3-Diaryl-5-phenyl-1,3,5-diazaphosphorinanes in organic solvents have similar ^1H NMR spectra [11]. Thus, the ^1H NMR data in water, methanol, and other organic solvents are similar. It was shown previously [11,12] by ^1H NMR spectroscopy, measurement of the dipole moment and X-ray analysis that 1,3-diaryl-5-phenyl-1,3,5-diazaphosphorinanes exist mainly in chair conformation with an equatorial phenyl group on the phosphorus atom. The stereospecific coupling constant $^2J(PH^B)$ increased with decreasing X–P–C–H (X = lone pair) torsion angle [11,12]. Hence, the increase in this coupling constant for **1**–**6** in comparison with 1,3-diaryl-5-phenyl-1,3,5-diazaphosphorinanes and from **1**, **2** to **3**–**6** can be explained by an increasing content of the conformer with an axial substituent on the phosphorus atom. NMR measurements at different magnetic fields (400 and 250 MHz), $^1H\{^{31}P\}$ NMR data and 2D COSY experiments confirmed the assignment of the coupling constants.

Changing from an organic solvent to water led to a decrease in the ^{31}P NMR chemical shifts by approximately 10 ppm (for methanol/water) and minor changes in the ^1H NMR spectra. Hence, the structure and fluxional behavior of these heterocyclic compounds do not dramatically change in water in comparison with common organic solvents.

The phosphines **5** and **6** form suspensions in water, and their water solubility does not exceed 0.01 M, in accordance with the hydrophobic properties of the bulky substituent on the phosphorus atom. The salts of 1,3-di(carboxylatomethyl)-5-phenyl(or mesityl)-1,3,5-diazaphosphorinanes **1**–**4** show high water solubility; 1 M solutions in water can be obtained, in the range practical for catalytic application.

3. Experimental

All experiments were carried out under purified dry argon. NMR spectra: Avance DRX 400 (Bruker), WM-250 (Bruker), standards: ^1H NMR (400 MHz, 250 MHz): C_6H_6, ^{13}C NMR (100.6 MHz): internal solvent, ^{31}P NMR (162 MHz): external 85% H_3PO_4. The IR spectra were recorded as KBr mulls on a Perkin–Elmer FT-IR spectrometer System 2000 in the range 350–4000 cm^{-1}. The melting points were determined in sealed capillaries and are uncorrected.

Table 3
Selected ^1H NMR data of phosphines **1**–**6**

3.1. Preparation of disodium 1,3-di(carboxylatomethyl)-5-phenyl-1,3,5-diazaphosphorinane dihydrate (**1**)

A solution of 0.98 g of sodium hydroxide (25 mmol) in 10 ml of dry methanol was added dropwise to a stirred mixture of 1.34 g (12 mmol) of phenylphosphine, 1.10 g (36 mmol) paraformaldehyde, 1.83 g (24 mmol) of glycine and 5 ml of dry methanol. The mixture became transparent and was noticeably warm. The resulting solution was kept at room temperature (r.t.) and stirred for 12 h and was then concentrated to about 3–4 ml. After 0.5–1 h, a fine white solid was collected on a thick glass filter, washed twice with 1:1 MeOH–Et_2O and then with Et_2O and dried in vacuum to give 3.83 g of **1**, yield 84%. M.p. > 250°C (with decomposition).

^{1}H NMR (400.1 MHz, D_2O): δ 7.51 (t, 2H, ^3J(HH) = 6.7 Hz, ^3J(PH) = 6.7 Hz, *o*-H, Ph), 7.31–7.36 (m, 3H, *m*-H, *p*-H of Ph), 4.72 (s, H_2O), 3.53 (d, 1H, ^2J(HH) = 11.4 Hz, N–CH_2–N), 3.41 (dd, 1H, ^2J(HH) = 11.4, ^4J(PH) = 1.5 Hz, N–CH_2–N), 3.30 (t, 2H, ^2J(HH) = 13.4, ^2J(PH) = 13.4 Hz, P–CH^A–N), 3.17 (dd, 2H, ^2J(HH) = 13.4, ^2J(PH) = 4.5 Hz, P–CH^B–N), 3.18 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2), 3.16 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2). ^{13}C NMR (100.6 MHz, D_2O): δ 178.75 (s, 2C, CO_2), 136.85 (d, 1C, ^1J(CP) = 12.4 Hz, *ipso*-C of Ph), 131.84 (ddd, 2C, ^1J(CH) = 160.9, ^2J(CP) = 15.2 Hz, ^2J(CH) = 7.1 Hz, *o*-C of Ph), 129.47 (dd, 2C, ^1J(CH) = 161.8, ^3J(CP) = 5.4 Hz, *m*-C of Ph), 129.31 (d, 1C, ^1J(CH) = 162.0 Hz, *p*-C of Ph), 75.98 (t, 1C, ^1J(CH) = 143.3 Hz, N–CH_2–N), 60.54 (td, 2C, ^1J(CH) = 136.8, ^1J(CP) = 6.4 Hz, P–CH_2–N), 51.05 (td, 2C, ^1J(CH) = 141.1, ^3J(CP) = 10.1 Hz, N–CH_2–CO_2). ^{31}P NMR (162 MHz): in MeOH: δ −55.5; in H_2O: δ −62.1. IR ($\tilde{\nu}$/cm^{-1}, KBr): 1594 (CO, Ph, H_2O), 3427 (H_2O). $C_{13}H_{19}N_2Na_2O_6P$ (376.27): Calc.: C, 41.49; H, 5.09; N, 7.44; P, 8.23. Found: C, 42.32; H, 4.91; N, 7.60; P, 8.40%.

3.2. Preparation of dipotassium 1,3-di(carboxylatomethyl)-5-phenyl-1,3,5-diazaphosphorinane dihydrate (**2**)

Phosphino amino acid salt **2** was synthesized by a procedure analogous to that of **1** with KOH instead of NaOH. Yield 62%. M.p. > 250°C (with decomposition).

The NMR data of **2** are similar to those of **1** (Tables 1–3). IR ($\tilde{\nu}$/cm^{-1}, KBr): 1607 (CO, Ph, H_2O), 3374 (H_2O). $C_{13}H_{19}K_2N_2O_6P$ (408.49): Calc.: C, 38.22; H, 4.69; N, 6.85; P, 7.58. Found: C, 38.92; H, 4.57; N, 6.98; P, 7.72%.

3.3. Preparation of disodium 1,3-di(carboxylatomethyl)-5-mesityl-1,3,5-diazaphosphorinane dihydrate (**3**)

(A) The phosphino amino acid salt **3** was synthesized by a procedure analogous to that for **1** with $MesPH_2$ instead of $PhPH_2$. Yield 72%.

(B) 0.26 g (8.8 mmol) of paraformaldehyde was reacted with 0.67 g (4.4 mmol) of mesitylphosphine with heating (125–130°C), and the mixture was diluted with 5 ml of dry methanol. To the stirred mixture of the hydroxyalkylphosphine, 0.13 g (4.4 mmol) of paraformaldehyde, 0.66 g (8.8 mmol) of glycine and 5 ml of dry methanol and a solution of 0.35 g (8.8 mmol) of sodium hydroxide in 5 ml of dry methanol was added dropwise. The reaction mixture became transparent and was noticeably warm. The resulting solution was kept at r.t. and stirred for 12 h and then was concentrated to about 3–4 ml. After 0.5–1 h the white fine solid was collected on a thick glass filter, washed twice with 1:1 MeOH–Et_2O and then with Et_2O and dried in vacuum to give 0.72 g of **3**, yield 39%. M.p. > 250°C (with decomposition).

^{1}H NMR (400.1 MHz, D_2O): δ 6.84 (s, 2H, *m*-H of Mes), 4.72 (s, H_2O), 3.67 (d, 1H, ^2J(HH) = 12.0 Hz, N–CH_2–N), 3.55 (dd, 1H, ^2J(HH) = 12.0, ^4J(PH) = 2.6 Hz, N–CH_2–N), 3.58 (dd, 2H, ^2J(HH) = 12.7, ^2J(PH) = 5.7 Hz, P–CH^B–N), 3.51 (t, 2H, ^2J(HH) = 12.7, ^2J(PH) = 12.7 Hz, P–CH^A–N), 3.43 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2), 3.28 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2), 2.39 (s, 6H, *o*-CH_3 of Mes), 2.15 (s, 3H, *p*-CH_3 of Mes). ^{1}H NMR (400.1 MHz, CD_3OD): δ 6.68 (s, 2H, *m*-H of Mes), 4.79 (s, H_2O), 3.67 (d, 1H, ^2J(HH) = 10.2 Hz, N–CH_2–N), 3.19–3.21 (m, 4H, P–CH_2–N), 3.12 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2), 3.04 (d, 2H, ^2J(HH) = 16.2 Hz, N–CH_2–CO_2), 2.89 (dd, 1H, ^2J(HH) = 10.2, ^4J(PH) = 4.2 Hz, N–CH_2–N), 2.40 (s, 6H, *o*-CH_3 of Mes), 2.08 (s, 3H, *p*-CH_3 of Mes). ^{13}C NMR (100.6 MHz, D_2O): δ 178.87 (s, 2C, CO_2), 143.42 (d, 2C, ^2J(CP) = 11.6 Hz, *o*-C of Mes), 140.00 (s, 1C, *p*-C of Mes), 130.57 (d, 2C, ^1J(CH) = 160.8 Hz, *m*-C of Mes), 128.77 (d, 1C, ^1J(CP) = 21.3 Hz, *ipso*-C of Mes), 75.58 (t, 1C, ^1J(CH) = 146.7 Hz, N–CH_2–N), 59.69 (td, 2C, ^1J(CH) = 133.1 Hz, ^1J(CP) = 10.6 Hz, P–CH_2–N), 51.45 (td, 2C, ^1J(CH) = 139.3, ^3J(CP) = 9.0 Hz, N–CH_2–CO_2), 23.31 (qd, 2C, ^1J(CH) = 115.9, ^3J(CP) = 14.0 Hz, *o*-CH_3 of Mes), 20.45 (q, 1C, ^1J(CH) = 127.3 Hz, *p*-CH_3 of Mes). ^{31}P NMR (162 MHz): in MeOH: δ −57.7; in H_2O: δ −66.0. IR ($\tilde{\nu}$/cm^{-1}, KBr): 1606 (CO, aryl, H_2O), 3407 (H_2O). $C_{16}H_{25}N_2Na_2O_6P$ (418.35): Calc.: C, 45.94; H, 6.02; N, 6.69; P, 7.40. Found: C, 46.1; H, 5.98; N, 6.66; P, 7.31%.

3.4. Preparation of dipotassium 1,3-di(carboxylatomethyl)-5-mesityl-1,3,5-diazaphosphorinane dihydrate (**4**)

(A) Compound **4** was synthesized by a procedure analogous to that for **3** (given in Section 3.3 (A)) with KOH instead of NaOH. Yield 63%.

(B) Compound **4** was synthesized by a procedure analogous to that for **3** (given in Section 3.3 (B)) with KOH instead of NaOH. Yield 45%.

M.p. > 250°C (with decomposition).

The NMR data of **4** are similar to those of **3** (Tables 1–3). IR ($\tilde{\nu}$/cm^{-1}, KBr): 1606 (CO, aryl, H_2O), 3382 (H_2O). $C_{16}H_{25}K_2N_2O_6P$ (450.57): Calc.: C, 42.65; H, 5.59; N, 6.21; P, 6.87. Found: C, 42.9; H, 5.9; N, 6.8; P, 6.6%.

*3.5. Preparation of disodium 1,3-di(carboxylatomethyl)-5-(2,4,6-triisopropylphenyl)-1,3,5-diazaphosphorinane dihydrate (**5**)*

The phosphino amino acid salt **5** was synthesized by a procedure analogous to that for **1** with $TippPH_2$ instead of $PhPH_2$. Yield 46%. M.p. > 250°C (with decomposition).

^{1}H NMR (400.1 MHz, CD_3OD): δ 7.51 (s, 2H, *m*-H of Tipp), 5.36 (s, H_2O), 4.10 (dsept, 2H, $^3J(HH) = 6.8$, $^2J(PH) = 6.8$ Hz, *o*-CH(CH$_3$)$_2$), 3.85 (d, 1H, $^2J(HH) = 10.0$ Hz, N–CH$_2$–N), 3.39 (dd, 2H, $^2J(HH) = 11.8$, $^2J(PH) = 6.0$ Hz, P–CH^B–N), 3.11 (dd, 2H, $^2J(HH) = 11.8$, $^2J(PH) = 11.8$ Hz, P–CH^A–N), 3.28 (d, 2H, $^2J(HH) = 16.2$ Hz, N–CH$_2$–CO$_2$), 3.21 (d, 2H, $^2J(HH) = 16.2$ Hz, N–CH$_2$–CO$_2$), 3.00 (dd, 1H, $^2J(HH) = 10.0$, $^4J(PH) = 4.0$ Hz, N–CH$_2$–N), 2.83 (sept, 1H, $^3J(HH) = 6.9$ Hz, *p*-CH(CH$_3$)$_2$) 1.71 (d, 12H, $^3J(HH) = 6.8$ Hz, *o*-CH(CH_3)$_2$), 1.68 (d, 6H, $^3J(HH) = 6.8$ Hz, *p*-CH(CH_3)$_2$). ^{13}C NMR (100.6 MHz, CD_3OD): δ 178.02 (s, 2C, CO_2), 157.16 (d, 2C, $^2J(CP) = 12.9$ Hz, *o*-C of Tipp), 152.1 (s, 1C, *p*-C of Tipp), 126.14 (d, 1C, $^1J(CP) = 25.9$ Hz, *ipso*-C of Tipp), 123.14 (d, 2C, $^1J(CH) = 152.8$ Hz, *m*-C of Tipp), 77.61 (t, 1C, $^1J(CH) = 159.0$ Hz, N–CH$_2$–N), 62.41 (td, 2C, $^1J(CH) = 134.4$, $^1J(CP) = 9.4$ Hz, P–CH$_2$–N), 52.87 (td, 2C, $^1J(CH) = 139.6$, $^3J(CP) = 8.1$ Hz, N–CH$_2$–CO$_2$), 35.50 (d, $^1J(CH) = 127.6$ Hz, *p*-*C*H(CH$_3$)$_2$), 32.91 (dd, $^1J(CH) = 127.0$, $^3J(CP) = 21.0$ Hz, *o*-*C*H(CH$_3$)$_2$), 25.37 (q, 4C, $^1J(CH) = 125.6$ Hz, *o*-CH(*C*H$_3$)$_2$), 24.20 (q, 2C, $^1J(CH) = 125.7$ Hz, *p*-CH(*C*H$_3$)$_2$). ^{31}P NMR (162 MHz): in MeOH: δ −69.7; in H_2O: δ −77.1. IR ($\tilde{\nu}$/cm^{-1}, KBr) 1598 (CO, aryl, H_2O), 3424 (H_2O). $C_{22}H_{37}N_2Na_2O_6P$ (502.51): Calc.: C, 52.58; H, 7.42; N, 5.57; P, 6.16. Found: C, 52.3; H, 7.76; N, 5.28; P, 5.83%.

*3.6. Preparation of dipotassium 1,3-di(carboxylatomethyl)-5-(2,4,6-triisopropylphenyl)-1,3,5-diazaphosphorinane dihydrate (**6**)*

The phosphino amino acid salt **6** was synthesized by a procedure analogous to that for **2** with $TippPH_2$ instead of $PhPH_2$. Yield 54%. M.p. > 250°C (with decomposition).

The NMR data of **6** are similar to those of **5** (Tables 1–3). IR ($\tilde{\nu}$/cm^{-1}, KBr): 1606 (CO, aryl, H_2O), 3382 (H_2O). $C_{22}H_{37}K_2N_2O_6P$ (534.73): Calc.: C, 49.42; H, 6.97; N, 5.24; P, 5.79. Found: C, 49.2; H, 7.04; N, 5.55; P, 4.90%.

POLYHEDRON

Magnetic properties of two 1D complexes with mixed bridging ligands

You Song, Dun-Ru Zhu, Kou-Ling Zhang, Yan Xu, Chun-Ying Duan, Xiao-Zeng You *

State Key Laboratory of Coordination Chemistry, Coordination Chemistry Institute, Center for Advanced Studies in Science and Technology of Microstructures, Nanjing University, Nanjing 210093, PR China

Received 15 December 1999; accepted 11 April 2000

Abstract

The crystal structure of a 1D chain complex, $[Cu(SCN)(deae)]_n$ (**1**) (Hdeae = *N*,*N*-diethylamino ethanol), with mixed bridges was determined. The structure is composed of a dimeric Cu(II) unit with two bridging μ^3-η^2-aminoethanolato ligands, while the units are bridged by end-to-end thiocyanato groups to form a 1D chain. The variable temperature magnetic susceptibility of **1** and $[Cu(SCN)(dmae)]_n$ (**2**) (Hdmae = *N*,*N*-dimethylamino ethanol) in the temperature 5–300 K have been interpreted in terms of simple dimer model approximation ($H = -2JS_A \cdot S_B$). The magnetic behaviors show that the aminoethanolato bridges mediate a moderately strong antiferromagnetic exchange interaction with the fitting values $g = 1.96(3)$, $J = -175(3)$ cm^{-1} for **1** and $g = 2.016(7)$, $J = -205.4(7)$ cm^{-1} for **2**, respectively. © 2000 Elsevier Science Ltd. 1. Introduction

Low-dimensional magnetic compounds as important precursors of molecular magnets have attracted great interest in the past two decades [1]. The pseudohalide bridging ligands (NCO^-, NCS^-, N_3^-) have been utilized extensively in preparing extended structures, because they can bridge between paramagnetic centers with versatile binding modes to form a one-dimensional chain (1D) [2–4] or 2D [5] and 3D [6] network compounds. Many compounds with uniform bridging ligands have been reported [2,3], but those with more than one kind of bridging ligand [4] are studied rarely. Variation of the bridging groups has a great advantage in the modification of the magnetic coupling interactions.

N,*N*-Dialkylamino ethanol (Hdaae) is a kind of effective bridging ligand, which can bridge between paramagnetic centers to form cluster compounds with acetate [7] and 1D chain complexes with pseudohalide ligands [4c]. However, to our knowledge, detailed magnetic properties of the compounds with daae bridging ligands have not yet been reported. As an extension of our study on alternating chain systems, we report here, a new Cu(II)-containing 1D alternating chain complex, $[Cu(SCN)(deae)]_n$ (Hdeae = *N*,*N*-diethylamino ethanol) (**1**), with mixed di-μ_2-thiocyanato and di-μ_2-oxo bridging ligands, and the magneto-structural correlation of this kind of compound.

2. Experimental

2.1. Materials

All chemicals were commercial products of reagent grade and used without purification.

2.2. Preparation

2.2.1. $[Cu(SCN)(deae)]_n$ (1)

The synthesis procedure was lightly modified as described previously [4c]. To 10 ml of stirred ethanolic

Electronic reflectance spectra ($BaSO_4$ pellet, nm): 500–1200 (broad d–d bond: $\lambda_{max} = 660$ nm).

2.2.2. [Cu(SCN)(dmae)]$_n$ (2)

This complex was prepared in a similar way to that of **1**, except for the use of Hdeae (1.5 mmol, 0.13 g, 0.15 ml) instead of Hdeae, yielding 82 mg, 77.2%. *Anal.* Found: C, 28.33; H, 4.78; N, 13.15. Calc. for $C_5H_{10}CuN_2OS$: C, 28.63; H, 4.80; N 13.35%. IR: ν_{max} (cm^{-1}): 2800s (CH_3, CH_2), 2100vs (SCN^-). Electronic reflectance spectra ($BaSO_4$ pellet, nm): 500–1140 (broad d–d bond: $\lambda_{max} = 680$ nm).

2.3. Physical measurements

CHN analysis was determined on a Perkin–Elmer 240C elemental analyzer. The infrared spectra were recorded on a Nicolet-170 SX FT-IR spectrometer with KBr discs in the 4000–400 cm^{-1}. Solid electronic reflectance spectra were obtained on a Hitachi U3400 spectrophotometer in 400–1500 nm. Magnetic susceptibility in the temperature range 5–300 K on microcrystalline samples was carried out with a Quantum Design MPMS SQUID system.

2.4. X-ray crystallography

$C_{14}H_{28}Cu_2N_4O_2S_2$, $M_r = 475.6$, monoclinic, space group $P2_1/n$, $a = 7.991(5)$, $b = 13.681(6)$, $c = 9.411(4)$ Å, $\beta = 100.15(5)°$, $V = 1012.7(9)$ Å^3, $Z = 2$ for **1**.

Suitable X-ray-quality crystals of **1** were obtained as described above. The diffraction experiments (crystal size $0.40 \times 0.30 \times 0.20$ mm) were carried out on a Siemens P4 four-circle diffractometer with monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation using the $\theta - 2\theta$ ($2.66 \leq \theta \leq 25.00°$) scan mode with a variable scan speed 5–50° min^{-1} in ω. The data were corrected for Lorentz and polarization effects during data reduction using XSCANS [8].

The structures were solved by direct method and refined on F^2 by full-matrix least-squares methods using SHELXTL version 5.0 [9]. All the non-hydrogen atoms were refined anisotropically. All the hydrogen atoms were placed in calculated positions with assigned fixed isotropic thermal parameters at 1.2 times the equivalent isotropic U of the atoms to which they are attached (1.5 times for the O–H and methyl groups) and allowed to ride on their respective parent atoms. The contributions of these hydrogen atoms were included in the structure-factor calculations. All computations were carried out on a PC-586 computer using the SHELXTL-PC program package [9]. The final R_1 (wR_2) value was 0.0766 (0.1699) for 120 parameters and 1760 observed reflections [$I \geq 2\sigma(I)$]. The goodness-of-fit on F^2 is 1.143.

3. Results and discussion

3.1. Description of the structure [Cu(SCN)(deae)]$_n$ (1)

Each complex of this kind consists of an alternating chain in which two neighboring Cu(II) ions are bridged by two alkoxo oxygen atoms from two different aminoethanolate ligands, while the dimer units are linked by two end-to-end thiocyanato bridging ligands. Between the neutral chains, there are no any other linkages but the van der Waals forces. The geometry of a chain, in which the thiocyanates bridge between dimer units, with the copper coordination spheres is showed in Fig. 1. The structure of [Cu(SCN)(dmae)]$_n$ (**2**) is described as reported previously [4c]. For complex **1**, the geometry of a discrete dimer unit is illustrated in Fig. 2. Selected bond distances and angles relevant to the copper coordination spheres are listed in Table 1.

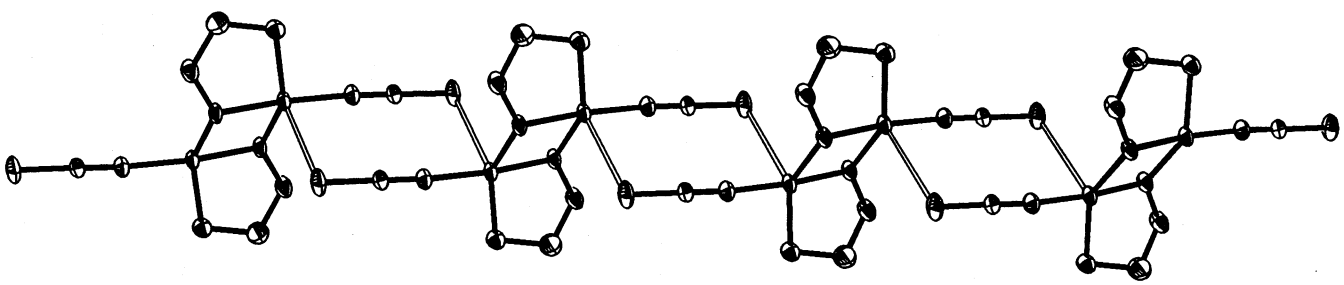

Fig. 1. View of the 1D chain with alternating thiocyanatoes and aminoethanolatoes bridging ligands. Displacement ellipsoids are drawn at the 30% probability level: methyl and ethyl groups have been omitted for clarity.

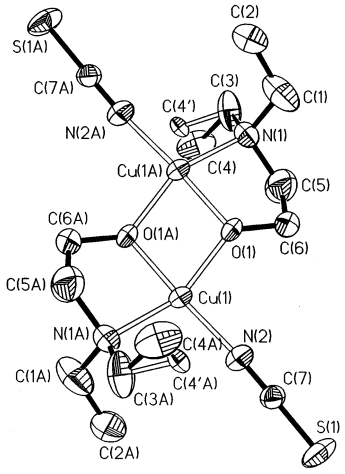

Fig. 2. View of the structure of $[Cu(SCN)(deae)]_2$ (**1**) with numbering scheme adopted. Ellipsoids are drawn at 50% probability: hydrogen atoms have been omitted for clarity.

Table 1

[a] Methyl and ethyl groups have been omitted for clarity. Symmetry code A, $-x$, $-y+1$, $-z+1$; B, $-x+1$, $-y+1$, $-z+1$.

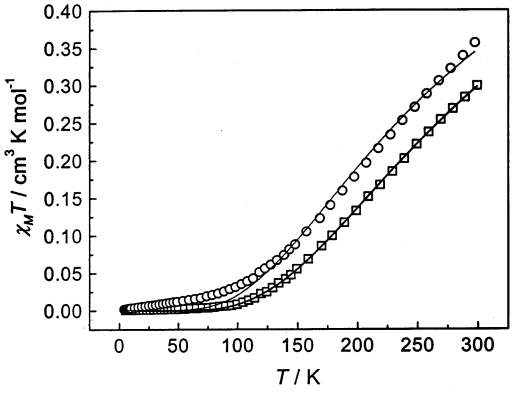

Fig. 3. Temperature dependence of the magnetic susceptibility on the form of the $\chi_M T$ versus T curve: (○) and (□) experimental points of **1** and **2**; (—) theoretical curve.

In the dimer unit, each copper(II) ion exhibits an extremely distorted square-pyramidal geometry with the mean deviations of 0.2565 Å from their basal plane. A nitrogen atom and two bridging oxygen atoms of two $deae^-$ ligands and a nitrogen atom of a bridging thiocyanato group coordinate to the copper(II) ion in the basal plane with metal-donor distances in the ranges of 1.908–2.078 Å, which are comparable with those of $[Cu(SCN)(C_4H_{10}NO)]_n$ [4c], $Cu_9(CHCl_2COO)_{10}(C_4H_{10}NO)_6(OH)_2$ and $Cu_4(CHCl_2COO)_4(C_4H_{10}NO)_4$ [7]. The other bridging thiocyanato group coordinates to the Cu(II) ion in the axial position via the S atom. Around the Cu(1) atom, the S(1B) (symmetry code B: $-x+1$, $-y+1$, $-z+1$) at the axial position is 2.950(2) Å away, which is comparable to very weak S–Cu(II) bond distances of 2.933(1)–3.174(2) Å reported previously [5a] and Cu(1) is displaced by 0.2134 Å from its basal plane, O(1)O(1A)N(2)N(1A). The Cu(II)···Cu(II) separation in the dimer unit is 2.979(2) Å, which is comparable to that of $[Cu(SCN)(C_4H_{10}NO)]_n$ [4c], but the shortest intrachain and interchain Cu(II)···Cu(II) distances are 5.792 and 7.526 Å, respectively. They are longer than those of $[Cu(SCN)(C_4H_{10}NO)]_n$ [4c] (5.375 and 4.987 Å) because the ethyl groups of $deae^-$ replace the methyl groups of $dmae^-$.

3.2. Magnetic properties

Variable-temperature magnetic susceptibility measurements of **1** and **2** performed on a crystalline sample from 300 to 5 K are shown in Fig. 3 in the form $\chi_M T$ versus T. The experimental data were corrected for inherent diamagnetism using Pascal's constants [10] and for temperature-independent paramagnetism (TIP).

In the whole temperature range, **1** and **2** show similar magnetic behavior. Two domains are clearly distinguished. At 299 K, the values of product $\chi_M T$ per two Cu(II) ions unit of $[Cu(SCN)(deae)]_2$ and $[Cu(SCN)(dmae)]_2$ are 0.36 and 0.30 cm^3 K mol^{-1}, respectively, which are less than the spin-only value of 0.75 cm^3 K mol^{-1}, indicating that a significant antiferromagnetic coupling contribution is involved. When the system cools down, the product $\chi_M T$ for **2** decreases quickly and reaches a critical point at about 100 K with $\chi_M T = 0.009$ cm^3 K mol^{-1}, but that of **1** decreases more smoothly than **2**, which suggest the presence of a strongly antiferromagnetic interaction. In the lower temperature domain $\chi_M T$ exhibits a plateau at 0.005 cm^3 K mol^{-1} for **1** and 0.001 cm^3 K mol^{-1} for **2**, indicative of an effective zero spin per unit in this temperature range.

The data can be interpreted in terms of a one-dimensional chain model with alternating coupling constants J_1 and J_2 and a simple dimer model with intermolecular coupling interaction in accordance with the structures of **1** and **2**. However, reasonable fitting results cannot be obtained using the former model ($H = -2J\,\Sigma[S_{2i}\cdot S_{2i-1} + \alpha S_{2i}\cdot S_{2i+1}]$ [11]. This could be attributed to the limitation of the chain model because it cannot be used to explain the behavior in the very low

temperature range [12]. For the latter model, two bridging thiocyanato groups linking adjacent Cu(II) ions in the axial position can not result in the effective magnetic exchange pathway between the dimer units because the single electron does not occupy in the d_{z^2} orbital. As well as, there is no any magnetic exchange pathways between chains besides the very weak van der Waals effect in **1** and **2**. Therefore, the intrachain Cu(II) ions by the extended bridging thiocyanato and interchain Cu(II) ions magnetic coupling interactions can be neglected and the magnetic behavior can be represented using the simple dimer model.

We assume that there is only one kind of exchange coupling (J), which exists only between the two Cu(II) ions bridged by two alkoxo oxygen atoms in the dimer units. The magnetic system can be interpreted by using the Heisenberg–Dirac–van Vleck $S_A = S_B = 1/2$ spin-coupled dimer model ($H = -2JS_A \cdot S_B$). The expression of magnetic susceptibility of **1** and **2** is

$$\chi_M = \frac{2Ng^2\beta^2}{kT} \times \frac{1}{3 + e^{-2J/kT}} \times (1-\rho) + \frac{Ng^2\beta^2}{2kT}\rho \qquad (1)$$

where N, g, β, k, ρ and T have their usual meanings. The least-squares fits to the magnetic susceptibility data to give the parameters: $g = 1.96(3)$, $J = -175(3)$ cm^{-1} and $R = 7.17 \times 10^{-5}$ ($R = \Sigma[(\chi_M T)_{calc} - (\chi_M T)_{obs}]^2 / \Sigma(\chi_M T)^2_{obs}$) for **1**, and $g = 2.016(7)$, $J = -205.4(7)$ cm^{-1} and $R = 2.46 \times 10^{-6}$ for **2**, respectively, fixing $\rho = 0$. The J values indicate the moderately strong antiferromagnetic exchange coupling within the copper(II) dimer units. The correction term $(1-\rho)$ attempts to take into account the paramagnetic impurities in copper(II)-containing compounds, but the fitting results give $g = 2.09(6)$, $J = -175(3)$ cm^{-1}, $\rho = 0.12(5)$ and $R = 6.67 \times 10^{-5}$ for **1**, and $g = 2.05(1)$, $J = -205.5(7)$ cm^{-1}, $\rho = 0.030(9)$ and $R = 2.08 \times 10^{-6}$ for **2**, respectively. As a matter of fact, the paramagnetic impurities often influence on the magnetic measurement for copper(II)-containing compounds, but it is suggested that the former fitting for **1** is identical to its magnetic properties rather than the latter with too large paramagnetic impurities.

Usually, in the square-pyramidal configuration of a central Cu(II) ion, the unpaired electron occupies the $d_{x^2-y^2}$ orbital. For example of the Cu(II) dimer unit of complex **1**, two alkoxo oxygen atoms [O(1) and O(1A)] of two different aminoethanolato ligands bridge between paramagnetic centers of Cu(1) and Cu(1A) in the equatorial plane involving the magnetic $d_{x^2-y^2}$ orbitals of two Cu(II) ions. The Cu(1)···Cu(1A) distance of 2.979(2) Å being comparable to that of the hydroxide-bridged systems (2.847–3.000 Å) [13] and the bridge angle falling in the antiferromagnetic realm would be expected for moderately strongly antiferromagnetic exchange between Cu(II) ions with non-orthogonal magnetic orbitals and two magnetically active oxygen bridges [13].

4. Supplementary material

Crystallographic data (including structure factors) for structures **1** and **2** reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-137230 and CCDC-137231, respectively. Further details on the structure determinations can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336 033; e-mail: deposit@ccdc.cam.ac.uk; or www: http://www.ccdc.cam.ac.uk). Structure factors are available upon request from author You Song.

Abstract

Two new copper(I) complexes of di-2-pyridyl ketone (DPK); $[(DPK)H][CuI_2]$ (**1**) and $[(DPK)H][(Cu\{NCS)_2]$ (**2**) have been prepared and characterized by spectroscopic and crystallographic methods. Both complexes are colored and exhibit very broad and strong MLCT bands in the visible region. The IR spectra of these complexes are measured and discussed. The structure determination of complex **1** shows that it consists of discrete $[(DPK)H]^+$ cation contains N–H···N hydrogen bonds, and polymeric $[CuI_2]^-$ anion. In the anion, each copper atom is in a distorted tetrahedral environment with Cu–I bond lengths from 2.570(4) to 3.072(4) Å. The structure of complex **2**, which is similar to **1**, features uncoordinated N-protonated di-2-pyridyl ketone cations and corrugated layers of $[Cu(NCS)_2]_n$, in which the copper atom is in a distorted tetrahedral CuS_2N_2 chromophore; Cu–N bond lengths are 1.954(2) and 1.958(2) Å, and Cu–S distances are 2.4120(8) and 2.4501(7) Å. © 2000 Elsevier Science Ltd. 1. Introduction

Di-2-pyridyl ketone (DPK) has the ability to coordinate initially via one of the two modes, either through the two nitrogen atoms of the pyridine rings or through one nitrogen atom and the carbonyl group of the ligand. At present, evidence shows that in aqueous solution, the former mode is favored. The observed reaction is hydration of the carbonyl forming a diol group [1]. The metal promoted hydration of DPK has been of interest for some time since the ligand has the ability to undergo a reaction after initial coordination to a transition metal ion. Another interesting aspect of DPK can be found in reported solid state structures of metal–DPK (1:2) complexes [2–4]. These structures show that one of the oxygen atoms from the newly formed diol on the ligand also interacts with the metal atom, thereby making the ligand tridentate in character rather than bidentate. Recently, DPK has been used to produce different copper(II) clusters [5,6], e.g. $[Cu_4(DPK{\cdot}CH_3O)_4(CH_3O)_2](ClO_4)_2$ (DPK·CH_3OH = monomethylated diol of di-2-pyridyl ketone) [5] and $[Cu_8(DPK{\cdot}OH)_8(O_2CCH_3)_4](ClO_4)_4{\cdot}9H_2O$ (DPK·H_2O = the hydrated gem-diol form of di-2-pyridyl ketone) [6]. Also, it has been found [7] that copper(I)–PPh_3–DPK complexes are efficient photocatalysts for norbornadiene–quadricyclane conversion, which is important as a solar energy storage process [8,9].

Previously, we have shown that when a mixture of excess $Cu^{I}I$ or $Cu^{I}NCS$ and 2-benzoylpyridine (2-Bzpy) in an ethanol medium stands over ca. 2 weeks in contact with air, an intramolecular oxidative cyclization occurs with the formation of the ionic compounds [9-oxo-indolo[1,2-*a*]pyridinium]$^+[CuX_2]^-$ [10,11]. In the present study we have undertaken the reactions

between $Cu^{I}X$ dissolved in excess NaX or KX and DPK to investigate the coordination behavior of DPK when combined with a copper(I) ion and to compare the compounds resulted in this case with those of 2-Bzpy. Such reactions afforded solid complexes only for the iodide and thiocyanate salts, for which good quality crystals have been isolated. The results of these reactions along with the structural characterization of both complexes as elucidated by spectroscopic and crystallographic methods are reported in the present paper.

2. Experimental

Di-2-pyridyl ketone was purchased from Aldrich and other chemicals are of analytical grade quality.

2.1. Preparation of complexes

2.1.1. [(DPK)H][CuI_2] complex **1**

An aqueous solution of $Cu(NO_3)_2\cdot3H_2O$ (2 mmol) was mixed with an aqueous solution of NaI in presence of L(+)-ascorbic acid. The precipitated CuI was washed several times with water and then dissolved by addition of a concentrated aqueous solution of NaI and filtered. To the filtrate, an ethanol solution of DPK (4 mmol) was added and the final mixture was allowed to stand in a cool place for ca. 1 week. The complex was deposited as black crystals suitable for X-ray diffraction. Yield 20%. *Anal*. Found: C, 26.2; H, 1.7; Cu, 12.8; I, 51.0, N, 5.6. Calc. for $C_{11}H_9CuI_2N_2O$; C, 26.3; H, 1.6; Cu, 12.6; I, 50.5; N, 5.6%. IR (KBr pellet, w = weak, m = medium, s = strong, v = very, cm^{-1}); 2749m, ν(N–H···N), 1685vs, ν(C=O), 1599s, 1577s, 1514s, 1453ms, 1436m, 1342m, 1328m, 1303m, 1270vs, 1255m, 1222s, 1161s, 1091ms, 1040m, 1009s, 947wm, 930m, 827ms, 786wm, 749vs, 663s, 633m, 611wm (pyridyl ring vibrations).

2.1.2. [(DPK)H][$(CuNCS)_2$] complex **2**

This complex was prepared according to the procedure given above in which $Cu^{I}NCS$ was dissolved in excess KNCS, filtered and mixed with an ethanol solution of DPK. The complex was separated as black long needle-like crystals upon allowing the final mixture to stand open in air over several days. Yield 70%. *Anal*. Found: C, 36.3; H, 1.8; Cu, 30.1; N, 13.4; S, 14.7. Calc. for $C_{13}H_8N_4OCu_2S_2$: C, 36.5; H, 1.9; Cu, 29.7; N, 13.1; S, 15.0%. IR (KBr pellet, cm^{-1}); 2100vs, ν(CN), 1672s, ν(C=O), 1589s, 1569s, 1504m, 1450m, 1431m, 1348(w), 1315(m), 1300(m), 1270(vs), 1246(ms), 1223(s), 1155(s), 1088(m), 1035m, 1005s, 963wm, 922m, 821ms, 765wm, 727wm, 653ms, 629wm (pyridyl ring vibrations).

2.2. Physical measurements

The experimental procedures and instruments used for different physical measurements are as described previously [12]

2.3. X-ray crystallography

Details of crystal parameters, data collection and structure refinement are given in Table 1. Raw intensities collected on a Rigaku AFC7R four-circle diffractometer at room temperature (293 K) were corrected for absorption using the DIFABS program [13]. Patterson superposition yields the positions of all non-hydro-

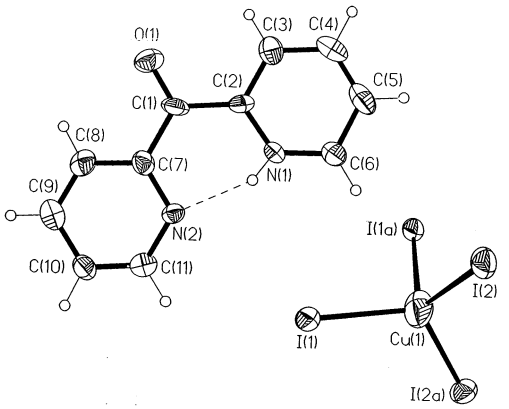

Fig. 1. The structure of the cation and coordination about Cu in the anion in $[(DPK)H]\cdot[CuI_2]$ (**1**) along with atom numbering scheme.

gen atoms, which were subjected to anisotropic refinement. All hydrogens are generated geometrically (C–H bonds fixed at 0.96 Å) but H(1) attached to N(1) in complex **1**, which was found on the difference Fourier map and allowed to ride on their respective parent atoms; they were assigned the same isotropic temperature factors ($U = 0.08$ Å^2) and included in the structure–factor calculations. Computations were performed using the SHELTXL/PC program package [14,15] on a PC 486 computer. Analytic expressions of atomic scattering factors were employed, and anomalous dispersion corrections were incorporated [16]. The residual maxima in the last difference map all lie in the neighborhood of the I atom.

3. Results and discussion

Two new copper(I) complexes have been isolated from the reactions between copper(I) iodide or copper(I) thiocayanate dissolved in excess of the respective potassium or sodium salt. Similar reactions in the case of chloride and bromide salts yielded no solid compounds, even upon allowing the mixtures to stand over several months. In case of the cyanide and azide salts, the mixture turned dark brown, from which a black material deposited on the walls of the container or black massive gelatinous material is formed, respectively. We could not obtain, however, defined solid compounds in both cases. Both complexes **1** and **2** are black, diamagnetic and sufficiently stable, over more than 1 year, against air oxidation when well dried. They are insoluble in water, methanol and ethanol, but slightly soluble in acetone with a change in color to pale green–yellow.

3.1. Structures

Fig. 1 illustrates the essential structural features of complex **1** which consists of a packing of $[(DPK)H]^+$ cations and polymeric $[CuI_2]^-$ anion; bond distances and bond angles are given in Table 2. DPK is thus protonated at the nitrogen atom N(1) giving rise to a hydrogen bond of the type N(1)–H···N(2) [N(1)–H(1) = 0.81(2), N(2)···H(1) = 1.95(1) Å], and hence a cation is formed. Di-2-pyridyl ketone, therefore, does not enter the coordination sphere of the copper atom, this represents a novelty in the chemistry of this class of polyfunctional molecules. The C(1)–O(1) bond length of 1.21(2) Å is significantly shorter than the corresponding distances in chromium or ruthenium complexes of hydrated DPK [average 1.392 Å] [1]. Thus the existence of a pyridyl ring in DPK instead of a phenyl ring in 2-benzoylpyridine, prevents the intramolecular oxidative cyclization of DPK, and instead a protonation occurs at a nitrogen atom with the formation of a hydrogen bond between the two pyridyl nitrogen atoms. In the polymeric CuI_2^- species, the copper and iodine atoms constitute columns of edge-

sharing CuI_4 tetrahedra running parallel to the *b* axis (Fig. 2) with three Cu–I bond lengths of 2.618 Å (average) and a long Cu–I distance of 3.074(5) Å. These Cu–I distances (Table 2), however, are much longer than those reported [2.394(2) and 2.383(1) Å] in the previously described linear CuI_2-species [17], but closely corresponded to the distances observed in CuI complexes in which Cu is bound to two iodines in the dimeric Cu_2I_2 units, e.g. av. = 2.686 Å in [CuI(quinoline)$_2$]$_2$ [18], av = 2.655 Å in {CuI(3-Me-pyridine)$_2$]$_2$ [19]. Compared to complexes in which Cu links four iodine atoms, the Cu–I distances in the present CuI_2^- species are shorter than those (av. = 2.711 Å) in the complex $(Cu_4I_6)K_2$(15-crown-5) [20] and (av. = 2.72 Å) in $[Cu(NH_3)_4][CuI_2]_2$ [21]. The structure of the present CuI_2^- species is very similar to that found in the structure of [9-oxo-indolo[1,2-*a*]pyridinium]$^+$[CuI_2]$^-$, except that the four Cu–I bond lengths are comparable to each other [from 2.682 to 2.705 Å] and the angles I(1)–Cu(1)–I(2a) [114.6(1)°] and Cu(1)–I(2)–Cu(1a) [75.7(1)°] are much smaller [10] than in the present species (Table 2).

The principle structure features of complex **2** are illustrated in Fig. 3; bond distances and bond angles are given in Table 3. The structure consists of uncoordinated N-protonated di-2-pyridyl ketone cations and corrugated layers of $[(CuNCS)_2]_n$ at $y = 1/4$, along the *b*-axis of the unit cell (Fig. 4). Each copper atom in the layer attains an approximate tetrahedral CuS_2N_2 coordination. The Cu–N bond lengths of 1.954(2) and 1.958(2) Å, and the Cu–S distances of 2.4120(8) and 2,4501(7) Å fall within the range of those reported previously for related compounds [22,23]. The structure of this $[(CuNCS)_2]_n$ species differs from that of $[Cu(NCS)_2]_n^-$ species found in the structure of [(9-oxo-indolo[1,2-*a*]pyridinium]$^+$[$Cu(NCS)_2$]$^-$ [11]. In the later species, one independent thiocayanato group functions as a μ-N,S,S bridging tridentate ligand in which a sulfur atom links two different copper atoms and the nitrogen atom binds a third copper atom, giving rise to a puckered layer. The second thiocyanato group acts as a N-monodentate ligand.

3.2. IR spectra

The IR spectra of complexes **1** and **2** exhibit a broad band of medium intensity centered around 2749 cm^{-1} assignable to ν(N–H···N) [22]. The spectrum of free DPK does not contain such a band. The carbonyl stretching frequency which appears at 1682 cm^{-1} in the spectrum of free DPK is not influenced at all and appeared at 1685 cm^{-1} in the spectrum of **1**, suggesting that the C=O group does not participate in the bonding formation. In complex **2**, this frequency is shifted slightly to a lower frequency and appeared at 1678 cm^{-1}. This slight shift may be attributed to the packing of DPK molecules in the complex. It is well known that coordination via the lone pair of electrons of the nitrogen atom of the pyridine can shift the ring vibrations to higher frequencies [23]. The blue shifts of such bands, however, caused by complex formation by pyridine are smaller for transition metal atoms than for H^+ ion [24]. In accordnace with this, the bands due to the pyridyl rings in the range 1600–400 cm^{-1} experience large shifts in complexes **1** and **2** where a H^+ protonates one

nitrogen atom of the two pyridyl rings forming a hydrogen bond with the other, when compared with corresponding bands in free DPK. The IR spectrum of complex **2** shows a very strong and sharp band at 2100 cm^{-1}, associated with the ν(CN) of the thiocyanate group. This result is not consistent with the μ-N,S bridging mode determined by the X-ray structure analysis given above. This value, however, is not uncommon and has been observed for many other complexes containing this mode of bonded thiocayanate groups [25,26].

3.3. Electronic spectra

The electronic spectra of the solid complexes **1** and **2** mulled in Nujol (Fig. 5) exhibit very strong bands in the visible region, a very broad band covers the 350–600 nm range for **2** and at least two bands centered around 435 and 590 nm for **1**. These intense charge transfer bands may be due to XLCT (X = anion) transitions since the ligand is protonated and not coordinated in both complexes. These CT bands in both complexes, however, are significantly shifted to lower energies when compared with CT bands in corresponding complexes of 2-benzoylpyridine which appear in the range 330–480 nm [10,11]. This may be attributed to the presence of two pyridyl rings in DPK which would decrease the HOMO–LUMO gap when compared with 2-benzoylpyridine. The positions of these bands, however, are similar to those observed in the case of copper(I) complexes of pyrazine [27,28].

In CuIX ligand systems containing a ligand that permits CT transitions, or a copper–copper distance of less than 2.8 Å, emission spectra of different origins are observed usually [29–31]. Accordingly, complexes **1** and **2** are expected to demonstrate visible evidence of emission. However, neither **1** nor **2** display emission at room temperature. This result is similar to those re-

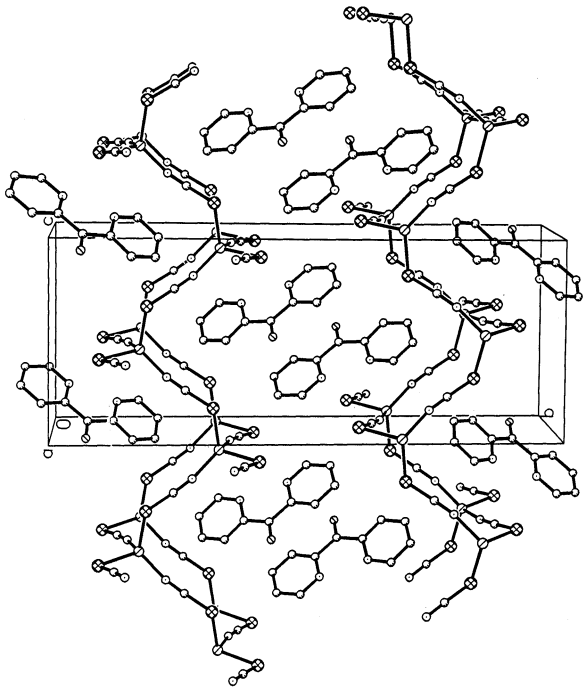

Fig. 4. A perspective view showing the packing of [(DPK)H]-[$Cu(NCS)_2$] (**2**) in the unit cell.

ported for $Cu^{I}CN$ and $Cu^{I}NCS$ complexes of 2-benzoylpyridine [11] and $Cu^{I}I$–quinaldate complexes [32]. The non-emitting character of these complexes may be affected by the electron withdrawing carbonyl group which alters the energy levels of the aromatic ring to make excitation of greater energy or to make other radiationless mechanisms more efficient.

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, CB2 IEZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk) quoting the deposition numbers 121782 and 121742 for complexes **1** and **2**, respectively.

Received 28 January 2000; accepted 13 April 2000

Abstract

The novel hexanuclear oxoclusters of the general formula $R[Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**1**–**7**), where $R = CH_3NH_3$ (**1**), C_5H_5NH (**2**), $(CH_3)_2CHNH_3$ (**3**), $(CH_3)_3CNH_3$ (**4**), $C_5H_{11}NH$ (**5**), $(C_2H_5)_3NH$ (**6**), and $C_6H_5NC_{11}H_{13}O_2$ (**7**) have been obtained by the reactions of the binuclear oxomolybdenum(V) complex $[Mo_2O_3(acac)_4]$ (acac = acetylacetonate ion) with a variety of alkyl or aryl amines or corresponding alkyl or aryl ammonium chlorides in methanol. The formation of 3,5-diacyl-2,6-dimethyl-1-pheny-l-pyridinium cation in **7** is explained by the cyclization via Hantzsch condensation of acetylacetone, formaldehyde and aniline. The molecular structures of complexes **5**, **6** and **7** have been determined by a single-crystal X-ray diffraction study. In all salts the anion is of hexanuclear nature in which molybdenum atoms are bridged by oxo-oxygen and methoxo-oxygen atoms. Six Mo-octahedra are fused through edges, thus allowing the formation of localized metal–metal bonds between three pairs of molybdenum atoms. © 2000 Elsevier Science Ltd. All rights reserved.

1. Introduction

Organic derivatives of isopolymolybdate anions have been extensively studied as models for the investigation of the interactions between organic molecules and catalytic metal oxide surfaces, as well as in the catalytic photo-oxidation of organic compounds [1–10]. The isopolymolybdate complexes containing alkoxo ligands are particularly known and investigated as models for selective hydrolysis of ethylene oxide to monoethylene glycol and for oxidation of primary and secondary alcohols [11–14]. However, whereas in all known cases high nuclearity molybdenum complexes usually contain either Mo(VI) ions or mixed valence Mo(VI)/Mo(V) clusters, the complexes of isopolymolybdates(V) containing more than four Mo(V) atoms with organic ligands are still relatively unknown [15]. The rare examples are $[Mo_6O_6Cl_6(\mu_3\text{-}O)_2(\mu\text{-}OC_2H_5)_6(\mu\text{-}Cl)_2]$ [16], $[(n\text{-}C_4H_9)_4N]_2[Mo_8O_{16}(OC_2H_5)_8(C_2O_4)]$ [17], $[Mo_8O_{16}(OCH_3)_8\{P(CH_3)_3\}_4]$ [18] and $[Mo_6O_{15}(PO_4)_4]^{12-}$ [19,20].

In continuation of our previous research on molybdenum(V) complexes, we have synthesized novel hexanuclear oxocluster salts with different cations: $R[Mo_6O_{12}(OCH_3)_4(acac)_3]$, where $R = CH_3NH_3$ (**1**), C_5H_5NH (**2**), $(CH_3)_2CHNH_3$ (**3**), $(CH_3)_3CNH_3$ (**4**), $C_5H_{11}NH$ (**5**), $(C_2H_5)_3NH$ (**6**), and $C_6H_5NC_{11}H_{13}O_2$ (**7**). They were prepared by the reactions of $[Mo_2O_3(acac)_4]$ with a variety of alkyl or aryl amines or corresponding alkyl or aryl ammonium chlorides in methanol.

The molecular structures of complexes **5**, **6** and **7** have been determined by a single-crystal X-ray diffraction study thus proving the hexanuclear nature of the anion in all prepared salts. The coordination octahedra within the hexanuclear anions are interconnected by sharing common edges, thus allowing the formation of localized metal–metal bonds between three pairs of molybdenum ions in such a way that they follow the alkoxide structural pattern found in the tetranuclear molybdenum(V) complexes $[Mo_4Cl_4O_6(O^nPr)_4(HO^nPr)_2]$ [21,22], $[Mo_4O_8(O^iPr)_4(py)_4]$ [23], $[Mo_4Cl_4O_8(OEt)_2(HOEt)_2]^{2-}$ [24] and $[Mo_4Cl_4O_6(OEt)_4(HOEt)_2]$ [25], as

well as in the tetranuclear β-diketonato complexes $[Mo_4O_6S_2(R'COCHCOCH_3)_2(OSCR'')_2]$ ($R' = -CH_3$ or $-C_6H_5$ and $R'' = -C_6H_5$, $-CH_3$, $-C(CH_3)_3$ or $-CH_2CH(CH_3)_2$) [26].

In preparing **7** by reacting $[Mo_2O_3(acac)_4]$ with aniline, we did not obtain anilinium but 3,5-diacyl-2,6-dimethyl-1-phenylpyridinium salt showing that the formation of the cation occurred via Hantzsch condensation [27,28] in which aniline, formaldehyde and acetylacetone form an intermediate, which on further oxidation produces a cyclic product.

2. Experimental

All chemicals were of reagent grade and used as purchased. Methanol was dehydrated on magnesium and distilled immediately before use. The starting acetylacetonato complex $[Mo_2O_3(acac)_4]$ was prepared as described in the literature [29,30]. C, H and N analyses were provided by the Analytical Services Laboratory of Institute Rudjer Bošković. Molybdenum was determined according to the method described in the literature [31]. Infrared spectra were recorded in KBr with an FT-IR 1600 Fourier transform spectrophotometer in the 4500–450 cm^{-1} region. Thermogravimetric (TG) analyses were measured on a Mettler TG 50 thermobalance using aluminum crucibles under oxygen atmosphere with a heating rate of 5°C min^{-1}. For all experiments the temperature ranged from 30 to 600°C. The results were developed by applying the GrafVare 2.1. program.

2.1. General procedures for the synthesis of complexes

Method A. $[Mo_2O_3(acac)_4]$ (0.25 g, 0.4 mmol) was suspended in dry methanol (25 ml) and appropriate amine (0.4 mmol) was added. The mixture was gently warmed for 1.5 h. An orange–red crystalline product was obtained from solution left at room temperature (r.t.) for 5–10 days. It was filtered off, washed with cold methanol and dried. Yields are based on $[Mo_2O_3(acac)_4]$.

Method B. $[Mo_2O_3(acac)_4]$ (0.25 g, 0.4 mmol) and appropriate organoammonium chloride (0.4 mmol) were suspended in dry methanol (25 ml). The mixture was gently warmed for 1 h. Within minutes the suspension cleared to an orange solution from which a small amount of pale orange solid precipitated. The by-product was collected by filtration, washed with cold methanol and dried. The filtrate was left at r.t. for 5–10 days. An orange–red crystalline product was filtered off, washed with cold methanol and dried. IR and elemental analyses showed that compounds (**1**–**7**) were identical to those prepared by method A.

2.1.1. Methylammonium μ_3-methoxo-tri-μ-methoxo-tri-μ_3-oxo-tri-μ-oxo-tris(acetylacetonato)hexaoxohexamolybdate(V), $(CH_3NH_3)[Mo_6O_{12}(OCH_3)_4(acac)_3]$ (1)

Yield: 0.05 g, 31.3% (method A, obtained from the reaction with CH_3NH_2), and 0.03 g, 18.8% (method B, obtained from the reaction with $CH_3NH_2{\cdot}HCl$). *Anal.* Calc. for $C_{20}H_{39}Mo_6NO_{22}$ ($M_r = 1221.162$): C, 19.67; H, 3.22; Mo, 47.14; N, 1.15. Found: C, 19.98; H, 3.68; Mo, 46.85; N, 1.55%. TG: 70.48% MoO_3 (Calc. 70.72%). IR data (KBr, cm^{-1}): 3212 (m), 2924 (m), 2815 (m), 1572 (s), 1512 (s), 1428 (m), 1361 (s), 1271 (m), 1048 (m), 960 (s), 740 (m), 704 (m), 669 (m), 546 (m), 484 (m).

2.1.2. Pyridinium μ_3-methoxo-tri-μ-methoxo-tri-μ_3-oxo-tri-μ-oxo-tris(acetylacetonato)hexaoxohexamolybdate(V) 2,5-diethyl-3,6-dimethyl-1,4-benzenedicarboxylic acid solvate (1/1), $(C_5H_5NH)[Mo_6O_{12}(OCH_3)_4(acac)_3]{\cdot}C_{12}H_{18}O_4$ (2)

When the product **1** was separated by filtration and the resulting filtrate left to stand for further 5 days new red crystals of **2** were obtained. Yield: 0.01 g, 5.1% (method A), and 0.01 g, 5.1% (method B). *Anal.* Calc. for $C_{36}H_{57}Mo_6NO_{26}$ ($M_r = 1495.466$): C, 28.91; H, 3.84; Mo, 38.49; N, 0.94. Found: C, 28.27; H, 4.02; Mo, 37.93; N, 1.58%. TG: 57.46% MoO_3 (Calc. 57.75%). 2.1.7. 3,5-Diacyl-2,6-dimethyl-1-phenylpyridinium μ_3-methoxo-tri-μ-methoxo-tri-μ_3-oxo-tri-μ-oxo-tris-(acetylacetonato)hexaoxohexamolybdate(V), $[C_{17}H_{18}NO_2][Mo_6O_{12}(OCH_3)_4(acac)_3]$ (7)

Yield: 0.03 g, 15.7%, (method A, from the reaction with $C_6H_5NH_2$; the product **7** was not obtained by method B). *Anal.* Calc. for $C_{36}H_{51}Mo_6NO_{24}$ ($M_r = 1457.42$): C, 29.67; H, 3.53; Mo, 39.50; N, 0.96. Found: C, 30.16; H, 4.21; Mo, 39.14; N, 1.15%. TG: 59.65% MoO_3 (Calc. 59.26%). IR data (KBr, cm^{-1}): 3073 (w), 2921 (m), 2821 (m), 1711 (m), 1686 (m), 1574 (s), 1516 (s), 1458 (m), 1429 (m), 1363 (s), 1272 (m), 1053 (s), 1026 (m), 970 (s), 959(s), 940 (m), 748 (m), 672 (m), 515 (m), 476 (m).

2.2. X-ray crystallography

A summary of crystallographic data is given in Table 1. Intensity data for all structures were corrected for Lorentz-polarization effects, but not for absorption. Accurate cell constants were determined by full-matrix least-squares refinement of the carefully centered and randomly selected reflections (35 reflections in the range $9.1 \leq \theta \leq 19.2°$ for **5**, 28 in the range $10.0 \leq \theta \leq 14.7°$ for **6** and 28 in the range $10.0 \leq \theta \leq 17.4°$ for **7**). Cell refinement, data collection procedure and Lp corrections were performed by STADI4 [32] and X-RED [33] programs.

The structure solution and refinement were performed through direct, Fourier and full-matrix least-squares methods performed by SHELXS-96 [34] and SHELXL-97 [35] for **6** and **7** and by NRCVAX program package [36] for **5**. Hydrogen atoms were generated by stereochemical constraints and refined by applying a riding model (C–H 0.95 Å and $U_{iso}(H) = 1.2\ U_{eq}(Csp^2$ or $Csp^3)$ in **5**; Csp^3–H 0.96 Å, Csp^2–H 0.93 Å and $U_{iso}(H) = 1.2\ U_{eq}$ (Csp^2) or 1.5 for Csp^3 in **6** and **7**).

The presence of a 'heavy' hexanuclear Mo core in the complex anion and the holes generated in the crystal structures by ions in order to accommodate small organic cations have been limiting factors in the refinement of organic cations. Therefore, due to possible positional disorder, the ring atoms of the piperidinium cation in **5** as well as C and N atoms of triethylammonium cation in **6** have not been properly resolved. In both structures they were refined isotropically. The H atom belonging to the nitrogen atom in **6** was found in different Fourier maps at the last stage of refinement at the N–H distance of 0.98 Å. Since it was not well defined, it was generated at an ideal geometrical position and allowed to ride on the parent N atom. In **7**, all non-H atoms were refined anisotropically. The molecular graphics have been performed by the PLATON98 program [37].

Fig. 1. shows an ORTEP drawing of the complex anion in the structure of triethylammonium derivative **6**.

Fig. 2 represents 3,5-diacyl-2,6-dimethyl-1-phenylpyridinium cation in the structure of $[C_{17}H_{18}NO_2]$-$[Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**7**). The same atomic numbering scheme as that in Fig. 1 has been applied for the atoms in the anions of **5** and **7**.

3. Results and discussion

3.1. Synthesis and characterization of complexes

Complexes of general formula $R[Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**1**–**7**) have been prepared by using $[Mo_2O_3(acac)_4]$ as starting reagent in the reaction with a variety of alkyl or aryl amines of cyclic, acyclic, primary, secondary and tertiary type: (i) CH_3NH_2; (ii) $(CH_3)_2CHNH_2$; (iii) $(CH_3)_3CNH_2$; (iv) $C_5H_{11}NH$; (v) $(C_2H_5)_3N$ and (vi) $C_6H_5NH_2$. The obtained complexes were characterized as novel oxocluster salts containing hexanuclear anions and different organoammonium cations.

However, while the reaction products with secondary and tertiary amines were of the expected nature, those

with primary amines were not. In the reaction of methylamine or methylammonium chloride with $[Mo_2O_3(acac)_4]$, two different salts of hexanuclear molybdenum(V) clusters were obtained: methylammonium salt **1** as a less soluble reaction product and compound **2** as the pyridinium salt, which cocrystalize together with terephthalic acid derivative. After **1** was separated and the resulting filtrate was left to stand for 5 days, the new red crystalline product was precipitated. The appearance of dicarboxylic acid was not expected but it may be explained by the condensation of a variety unidentified by-products present in the solution. In the analogous reactions with *i*-propylamine or *t*-butylamine (or *i*-propylammonium or *t*-butylammonium chloride), besides of **3** and **4**, the similar red crystalline products were also obtained but the resulting crystals were stable in solution only for 2–3 h. The obtained amounts however were insufficient for chemical analyses, and the crystals were of very small size, fragile and not suitable for X-ray data collections.

In the reaction of $[Mo_2O_3(acac)_4]$ with aniline, only one product was obtained and it was identified as

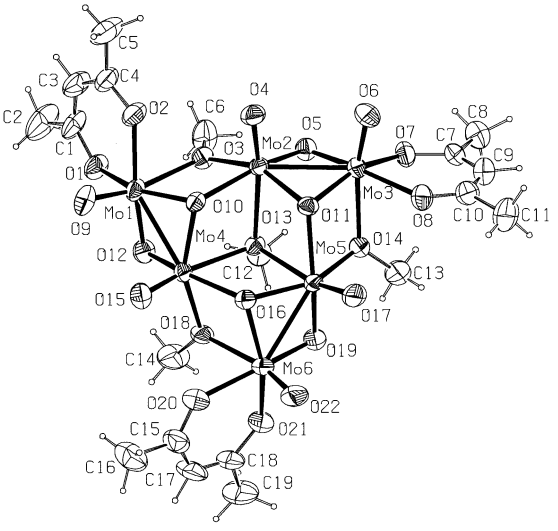

Fig. 1. The ORTEP drawing with crystallographic atom numbering scheme of the $[Mo_6O_{12}(OCH_3)_4(acac)_3]^-$ anion in the structure of $[(CH_3CH_2)_3NH][Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**6**). Thermal ellipsoids represent 50% probability.

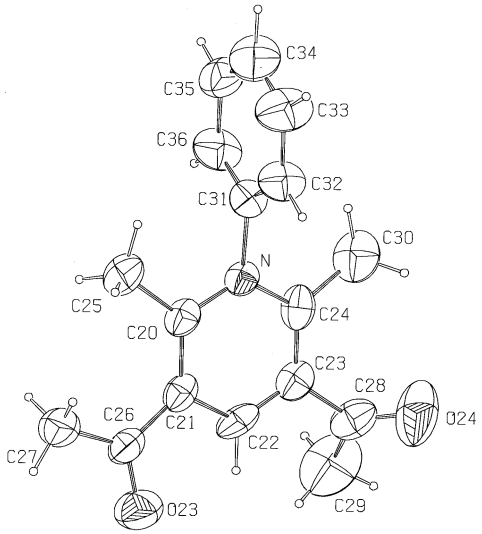

Fig. 2. The ORTEP drawing with crystallographic atom numbering scheme of 3,5-diacyl-2,6-dimethyl-1-phenylpyridinium cation in the structure of $[C_{17}H_{18}NO_2][Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**7**). The thermal ellipsoids represent 50% probability.

$[C_{17}H_{18}NO_2][Mo_6O_{12}(OCH_3)_4(acac)_3]$ (**7**). The formation of such a pyridinium derivative (Fig. 2) may only be explained by the Hantzsch condensation of 2,4-pentandione with formaldehyde in the presence of amine, and it has already been observed and described in the literature [27,28]. It is reasonable to suppose that the intermediate formaldehyde was produced in situ from molybdenum catalyzed oxidation of methanol [11–14], while the β-diketone was the by-product of the same reaction. Further aromatization of a cyclic product, N-substituted dihydropyridine, is most probably the result of oxidation due to the presence of oxygen [38,39]. This mechanism was supported by further experiment: if the reaction was carried out in the atmosphere of dry nitrogen, the corresponding pyridinium salt was not obtained thus proving that such a catalytic cycle is indispensably dependent upon the presence of oxygen.

Additionally, it should be mentioned that such a product was obtained only if freshly distilled dry methanol was used in the reaction. Otherwise the traces of water inhibit the formation of formaldehyde due to the hydrolysis of methoxo groups. According to the elemental and spectroscopic analyses, the colourless solids obtained from the reaction carried out in aqueous methanol gave the corresponding ammonium octamolybdates with $[Mo_8O_{26}]^{4-}$ anions. The octamolybdate(VI) compounds have been identified chemically as well as by IR spectra and some of them by single-crystal X-ray structure analysis [40]. In addition, more species are present in solution but they do not precipitate together owing to their different solubility. All products from **1** to **7** were considerably unstable in methanol solution and their decomposition was accompanied by colour changes of their solutions, after 2 or 3 weeks, from bright orange to dark green and finally blue.

Complexes **1**–**7** were insoluble in almost all common organic solvents except their slight solubility in methanol, but they were extraordinarily soluble in water. However, in all cases the dissolution in water was accompanied by fast (1 or 2 min) oxidation of molybdenum(V) to molybdenum(VI) showing colour change from orange red to colourless.

The complexes were also characterized by IR spectroscopy. The single strong absorption found at about 960 cm^{-1} is characteristic of ν(Mo=O), while the bands at 740 and 705 cm^{-1} were assigned to the double and triple bridging oxo groups (MoOMo and Mo_3O), respectively. Also, the bands at about 665 and 545 cm^{-1} correspond to the vibrations of doubly and triply bridging methoxo groups ($Mo(OCH_3)Mo$ and Mo_3OCH_3), respectively. The remaining frequencies in the IR spectra were definitely due to the vibrations within the cation and ligands.

Samples of all complexes **1**–**7** showed similar thermographic behaviour. A weight loss between r.t. and 100°C observed only in the case of *t*-butyl salt **4** could be attributed to the loss of a solvated methanol molecule, while significant weight losses between 200–450°C observed for all samples are indicative of their decomposition. Thermal decompositions should proceed through complex intermediates finally resulting in the solid residues (in oxygen atmosphere) identified as MoO_3. The agreements between calculated and experimental mass losses are within experimental error, thus proving the formulation of each particular complex.

3.2. Structural studies

Compounds **5**, **6** and **7** have been structurally characterized by X-ray single-crystal diffractometry. The composition and structure of **2** was also confirmed by X-ray structural analysis, but owing to the poor quality of the obtained single crystal, the final refinement could not be performed (its unit cell parameters were determined as: $a = 22.813(3)$, $b = 13.045(1)$, $c = 31.957(5)$ Å, $\beta = 103.57(2)°$, $V = 9244.8(17)$ Å^3, monoclinic space group, $I2/a$, $Z = 8$). All of them contain different cations but the same hexameric cluster anion $[Mo_6O_{12}(OCH_3)_4(acac)_3]^-$. Such an anion contains six Mo(V) ions each coordinated by six oxygen atoms in the form of a distorted octahedron. These oxygens originate from different ligands: terminal-oxo oxygens, bridging and triply bridging oxo and methoxo groups or from acetylacetonato ligands. As can be seen from Fig. 1, its structure can be considered as a metal-oxide core surrounded by organic ligands.

Polynuclear Mo(V) oxo complexes containg more than four Mo(V) centres and with Mo(V) d-electrons

engaged in the formation of Mo(V)–Mo(V) single bonds are rare and can be regarded as high-nuclearity species [15]. The Mo(V) chloro–oxo complex $[Mo_6O_6Cl_6(\mu_3\text{-}O)_2(\mu\text{-}OC_2H_5)_6(\mu\text{-}Cl)_2]$ [16] with six Mo(V) centres is the only example known so far. The investigated hexametallic clusters with the unique Mo(V) oxo core moiety represent the first example of such types of high-nuclearity oxomolybdenum(V) clusters. Such a structural motif arranged as edge-sharing MoO_6 octahedra minimizes the distortion of each molybdenum coordination sphere as well as steric interactions between the ligands. The six Mo ions do not have the same coordination environment: three of them, Mo1, Mo3 and Mo6 are surrounded by one terminal oxygen, one bridging oxygen, one triply bridging oxygen, one methoxy bridging oxygen atom, and two oxygen atoms from bidentate acetylacetonate ligands, while the another three Mo atoms, Mo2, Mo4 and Mo5 are surrounded by one terminal oxygen, one bridging oxygen, two triply bridging oxygen, one methoxo bridging oxygen atom, and one triply bridging methoxo group (Fig. 1). Such metal centre aggregations enable three pairs of metal–metal bonding with Mo–Mo bond lengths in the range 2.593(2)–2.598(2) Å in **5**, 2.595(1)–2.608(1) Å in **6** and 2.597(2)–2.603(1) Å in **7**. The diamagnetic behaviour of our complexes is confirmed by these Mo–Mo single bonds (Table 2).

The coordination octahedra around all six molybdenum atoms are significantly distorted in all three structures. These distortions are most evident within the octahedra with an angle occupied by triply bridging μ_3-O oxygen atoms (Table 3).

The Mo–O bond distances are listed in Table 2. They depend upon the nature of the bridging role of any single oxygen atom and upon the *trans* influence of $Mo{=}O_t$ and $Mo{-}O_b$ bonds. The $Mo{=}O_t$ distances are within expected values ranging between 1.651(9) and 1.694(8) Å for all three structures. The Mo–O (doubly bridging) bond length values vary between 1.887(7) and 1.935(8) Å in **5**; 1.901(4) and 1.937(4) Å in **6** and 1.903(8) and 1.950(7) Å in **7**. The Mo–O (triply bridging) bond length values vary between 1.990(7) and 2.139(6) Å in **5**, 2.004(4) and 2.119(4) Å in **6** and 1.999(7) and 2.159(7) Å in **7**.

Three of four OCH_3 groups form a double bridge between two Mo atoms, while one methoxo-O atom acts as a triple bridge between three Mo atoms. The Mo–O bond length values in comparison to the doubly bridging methoxo-O atoms are considerably different and depend upon the position within particular Mo coordination ocahedra. Out of six, three bonds *trans* to $Mo{=}O_t$ are remarkably longer than the others (Table 2). The $Mo{-}O(OCH_3)$ (triply bridging) bond lengths be-

tween O13 atom and Mo4, Mo5 and Mo6 atoms are among the longest ones varying in the range 2.260(6)–2.315(7) Å for all three structures. It seems that such a triply-bridging role for one methoxo-oxygen atom is the first example observed in the structural chemistry of Mo(V) complexes. However, as far as we know there are only two such examples in the chemistry of Mo(VI): (i) $[Mo_4O_{10}(OMe)_4(Me_2CNHO)_2]$ [41] with Mo–O(OCH_3) (triply bridging) bond lengths varying from 2.360(3) to 2.304(3) Å and (ii) $[NBu^n_4][Mo_4O_{10}(NO)(OMe)(Me_2CNO)_2]$ [42] with this bond ranging from 2.209(7) to 2.481(7) Å. Otherwise, oxo-oxygens as a triple bridge between three Mo atoms are frequently established in the structures of different polyoxomolybdates.

The Mo–O(acac) bond lengths are within the expected range of values. They exhibit a pattern of three shorter (2.041(9)–2.099(8) Å in **5**, 2.042(5)–2.061(5) Å in **6** and 2.058(8)–2.074(9) Å in **7**) and three longer (2.099(8)–2.137(7) Å in **5**, 2.113(5)–2.141(5) Å in **6** and 2.089(8)–2.131(8) Å in **7**) bond distances, again depending upon the position in the structure, i.e. either *cis* or *trans* to terminal or bridging oxo-oxygen atoms (Table 2).

In the structure of the triethylammonium derivative **6**, an intramolecular hydrogen bond is formed between the NH group of the cation and the terminal O4 atom of the anion [N–H 0.91 Å; H···O4 2.317 Å; ∠N–H···O4 150.9°; N···O 3.14(2) Å]. Also, the observed intra- and intermolecular hydrogen bonds of the type C–H···O seem to be additional stabilizing factors in all three crystal structures.

Abstract

Zinc(II), cadmium(II) and mercury(II) coordination compounds derived from tris(2-benzimidazolylmethyl)amine (ntb) were characterised by ^{1}H and ^{13}C NMR in solution, IR and X-ray single crystal diffraction for $[Zn(ntb)Cl]_2[ZnCl_4]\cdot 4EtOH$, $[Cd(ntb)(\mu_2\text{-}NO_3)]NO_3\cdot 2DMSO$ and $[Hg(ntb)Cl]_2[HgCl_4]\cdot 4EtOH$. The complexes derived from zinc(II), cadmium(II) and mercury(II) halides form $[M(ntb)X]^+$ cations, where the metal ions are pentacoordinated and have a distorted trigonal bipyramidal geometry, with tetrahedral anions $[MX_4]^{2-}$. In the $[Cd(ntb)(\mu_2\text{-}NO_3)]NO_3\cdot 2DMSO$ complex, by analogy with the Zn(II) and Hg(II) compounds, the NO_3^- could be considered as the fifth apical substituent in a distorted trigonal bipyramid geometry. In all complexes the ligand is coordinated to the metal through the imidazolic nitrogen atoms and has a weak coordination with the tertiary amine. The counter ion (halide or nitrate) remains bonded to the metal ion in solution and in the solid state as was evidenced by NMR and X-ray diffraction. The structures presented interactions between the coordinated counterion and the nearest C–H of the aromatic rings. All cations show an approximate *C*3 symmetry. The distortions found in the solid state were attributed to intermolecular hydrogen bonding and stacking between the benzimidazolic rings of neighbouring molecules. © 2000 Elsevier Science Ltd. 1. Introduction

The coordination compounds of tripodal ligands have been widely investigated, since they may serve as models for the active site of metalloproteins [1–3]. Due to the great flexibility and polyfunctionality of the tripodal tris(2-benzimidazolylmethyl)amine ligand (**1**), the actual coordination geometry for the metal ions can not always be unambiguously assigned. Most of its reported complexes have been characterised by means of various spectroscopic techniques [4–8], but for some of them the structure has been completely characterised [9–19].

In this context we have been investigating coordination compounds of diamagnetic metal ions with ligand **1** in solid state, and when possible, by X-ray crystallography, as well as in solution by NMR, in order to get information on intra- and intermolecular interactions between the ligand and the metallic centers. Therefore, we have prepared compounds with the zinc(II) (**2**–**4**), cadmium(II) (**5**–**7**) and mercury(II) (**8**–**10**) chlorides, bromides and nitrates. These were characterised by spectroscopic techniques and by ^{1}H and ^{13}C NMR, and compounds **2**, **7** and **8** were also characterised by X-ray diffraction.

2. Experimental

2.1. Materials

The metal salts (J.T. Baker) were used without further purification. Ligand **1** was prepared as previously described [20].

2.2. Synthesis of complexes: general procedure

All coordination compounds were synthesised following the same procedure, as described for compound **2**.

2.2.1. $[Zn(ntb)Cl]_2[ZnCl_4]\cdot 4EtOH$ (**2**)

Tris(2-benzimidazolylmethyl)amine (0.102 g, 0.25 mmol) was dissolved in 10 ml of hot ethanol and added to a solution of $ZnCl_2$ (0.034 g, 0.25 mmol) in 10 ml of ethanol. Crystals were obtained by slow evaporation of an ethanol solution. *Anal*. Calc. for $C_{48}H_{42}Cl_6N_{14}Zn_3$: C, 47.10; H, 3.43; N, 16.03. Found: C, 46.89; H, 3.36; N, 15.87%. The crystals suffered cracking within minutes when taking them out of the solution obviously by loss of crystal solvent. For this reason the elemental analysis of this compound was carried out on a powder sample and the following calculated composition does not include alcohol molecules. Colourless crystals (90 mg, 86%) were isolated 2 days later.

2.2.2. $[Zn(ntb)Br]_2[ZnBr_4]$ (**3**)

The resulting powder (101 mg, 81%) was filtered off, washed and dried in vacuo. *Anal*. Calc. for $C_{48}H_{42}Br_6N_{14}Zn_3$: C, 38.67; H, 2.82; N, 13.16. Found: C, 39.07; H, 3.26; N, 12.95%.

2.2.3. $[Zn(ntb)NO_3]NO_3\cdot 3H_2O$ (**4**)

A white powder (137 mg, 85%) was obtained. The solid was separated by filtration and dried in vacuo. *Anal*. Calc. for $C_{24}H_{21}N_9O_6Zn\cdot 3H_2O$: C, 44.40; H, 4.17; N, 19.31. Found: C, 44.27; H, 4.34; N, 18.71%.

2.2.4. $[Cd(ntb)Cl]_2[CdCl_4]$ (**5**)

The white precipitate (89 mg, 79%) was collected by filtration, washed with ethanol, and dried in vacuo. *Anal*. Calc. for $C_{48}H_{42}Cd_3Cl_6N_{14}$: C, 42.2; H, 3.08; N, 14.36. Found: C, 42.8; H, 3.96; N, 13.86%.

2.2.5. $[Cd(ntb)Br]_2[CdBr_4]$ (**6**)

The white powder (116 mg, 79.0%) was filtered off, washed and dried in vacuo. *Anal*. Calc. for $C_{48}H_{42}Br_6Cd_3N_{14}$: C, 35.33; H, 2.59; N, 12.02. Found: C, 35.22; H, 2.41; N, 12.09%.

2.2.6. $[Cd(ntb)(\mu_2\text{-}NO_3)]NO_3\cdot 2DMSO$ (**7**)

A white powder was obtained which was recrystallised from DMSO. The elemental analysis of this compound was carried out on a powder sample and the following calculated composition does not include DMSO molecules (104 mg, 65%). *Anal*. Calc. for $C_{24}H_{21}CdN_9O_6$: C, 44.94; H, 3.35; N, 19.51. Found: C, 44.63; H, 3.32; N, 19.49%.

2.2.7. $[Hg(ntb)Cl]_2[HgCl_4]\cdot 4EtOH$ (**8**)

Colourless crystals (97 mg, 48%) were isolated 3 days later. The elemental analysis of this compound does not include ethanol molecules. *Anal*. Calc. for $C_{48}H_{42}Cl_6Hg_3N_{14}$: C, 35.38; H, 2.60; N, 12.03. Found: C, 35.29; H, 2.65; N, 12.02%.

2.2.8. $[Hg(ntb)Br]_2[HgBr_4]$ (**9**)

Colourless crystals (97 mg, 48%) were isolated by filtration. *Anal*. Calc. for $C_{48}H_{42}Br_6Hg_3N_{14}$: C, 30.4; H, 2.23; N, 10.34. Found: C, 29.49; H, 1.76; N, 10.37%.

2.2.9. $[Hg(ntb)NO_3]NO_3$ (**10**)

A white precipitate (0.167 g, 91.0%) was filtered off, washed and dried in vacuo. *Anal*. Calc. for $C_{24}H_{21}HgN_9O_6$: C, 39.38; H, 2.89; N, 17.22. Found: C, 39.61; H, 2.99; N, 17.18%.

2.3. Physical measurements

IR spectra were recorded with a Nicolet FT-IR 740 spectrophotometer using KBr pellets in the 4000–400 cm^{-1} region. Elemental analyses were performed on a Fisons EA 1108 elemental analyser. ^1H and ^{13}C NMR data (67.80 MHz) were obtained in DMSO-d_6 on a Jeol GSX-270 spectrometer.

2.4. X-ray crystallographic study

Suitable single crystals of compounds **2**, **7** and **8** were mounted on a glass fibre in a small amount of perfluoroether oil. Data were collected at 193 K on a Siemens P4 diffractometer equipped with a Siemens CCD area detector, using 10 s exposure per frame in a hemisphere scan mode. Data reduction was performed with the program SAINT, and an empirical absorption correction was applied using SADABS. Pertinent crystal data and other crystallographic parameters are listed in Table 1. Computations were performed with the SHELX-97 [21] package on a personal computer.

3. Results and discussion

3.1. Spectroscopic characterisation

The IR spectrum of the free ligand **1** presents two bands associated to the ν(C=N) and ν(C–N) vibrations at 1536 and 1438 cm^{-1}, respectively; these bands shifted to ca. 1545 and ca. 1450 cm^{-1} in all complexes due to the coordination of the nitrogen atoms to the

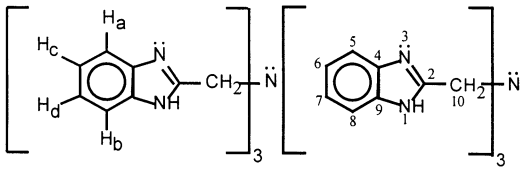
metal ions. For complexes **4**, **7** and **10** a strong absorption at 1384 cm^{-1} for the uncoordinated nitrate ion did not allow us to observe the vibrations associated with the coordinated nitrate [22].

In the ^{1}H NMR spectra of compounds **2**–**10** (Table 2), the imidazolic N–H tautomeric equilibrium present in the free ligand is absent, indicating that the imine group is coordinated to the metal ion. The fact that the band associated with the methylene groups shifts to higher frequencies indicates that the tertiary amine nitrogen atom is also bonded to the metal centre. Therefore, we can assume that the ligand is tetradentate. For each metal family, there is a chemical shift to higher frequencies of H_a depending on the nature of the anion, indicating that the anion remains linked to the metal and stays close to the H_a. The deshielding effect of these intramolecular interactions is stronger for Br followed by Cl and to a lesser extent for NO_3.



Tha ^{13}C NMR spectra of these compounds also show the effect of coordination of the ligand to the metal centre, i.e. the C4, C5 and C6 signals become different to those observed for C7, C8 and C9 (Table 2) e.g. in benzazole N–BH_3 adducts [23].

3.2. Solid state structures

From the studied compounds three of them crystallised **2**, **7** and **8** and their X-ray structures were obtained. This allowed us to compare the coordination behaviour of the ligand in the solid state with that in solution. $[Zn(ntb)Cl]_2[ZnCl_4]{\cdot}4EtOH$ (**2**) and $[Hg(ntb)Cl]_2[HgCl_4]{\cdot}4EtOH$ (**8**) are crystallographically isostructural and present similar structures (Fig. 1, Table 1). The ntb behaves as a tetradentate ligand where the three imidazolic nitrogen atoms are coordinated to the M(II) with M–N distances ranging from 2.009(4) to 2.067(4) Å for Zn and 2.217(6) to 2.294(7) Å for Hg (Table 3). The fourth position is occupied by a chloride atom with a normal M–Cl bond length (Zn–Cl, 2.280(1) Å; Hg–Cl, 2.415(2) Å). There is also an interaction of the tertiary N(1) of the amine to the metal ion (Zn(1)–N(1) = 2.549(4) Å), which is in the range of those reported for analogous zinc(II) ntb complexes, i.e. 2.518 Å [9] and 2.540 Å [18], where a bipyramidal geometry is proposed, while a longer bond distance (Zn(1)–N(1) 2.590 Å [10]) is observed for a tetrahedral structure. The bond length Hg(1)–N(1) = 2.810(6) Å is shorter than those reported for other Hg(II)–N bonds (2.87(2) and 2.84(2) Å [24]), which is an indication of the coordination of the quaternary nitrogen in this complex. The distorted geometry in the cations $[M(ntb)X]^+$ is reflected in the bond angles around the metal centres, which are more in agreement with a trigonal bipyramidal than with a distorted tetrahedral geometry [10,15,18] (see Table 3). The complexes contain isolated tetrahedral $[MX_4]^{2-}$ anions.

The structures are stabilised by intramolecular hydrogen bonds between the aromatic hydrogen atoms H7A, H17A and H27A of the benzimidazole groups and the M–Cl chloride (for Zn: H7A···Cl 2.729, H17A···Cl 2.735 and H27A···Cl 2.836; for Hg: H7B···Cl 3.043, H17A···Cl 2.927 and H27A···Cl 3.266 Å). These

interactions are responsible for the chemical shifts observed by NMR for H_a.

The ligand presents an almost non-crystallographic threefold axis in compounds **2** and **8**, as shown in Fig. 1. The lack of symmetry in the complexes is attributed to intermolecular stacking: the phenylene ring of one molecule is stacked with an imidazolic ring of a neighbouring molecule (Fig. 2). The distances between the centroids of five- and six-membered rings are 3.708 and 3.633 Å for Zn and Hg, respectively [25][1].

[1] The distance between the planes in graphite is 3.354 Å.

The crystal structure of $[Cd(ntb)(\mu_2\text{-}NO_3)]NO_3 \cdot 2DMSO$ (**7**) shows that the geometry around the metal ion does not fit with any regular geometry for hexacoordinated systems. An analogy of this cadmium compound with the zinc and mercury compounds could be proposed if the N8 of the nitrate is considered the fifth apical substituent in a distorted trigonal bipyramid geometry as shown in Fig. 3. The bond lengths and angles are listed in Table 3.

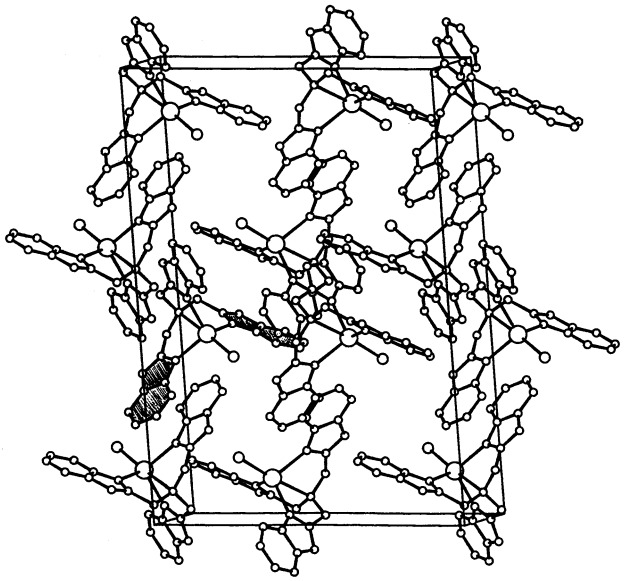

Fig. 2. View of the packing in compounds **2** and **8**. The phenylene ring of one molecule is stacked with an imidazolic ring of a neighbouring molecule (grey shading).

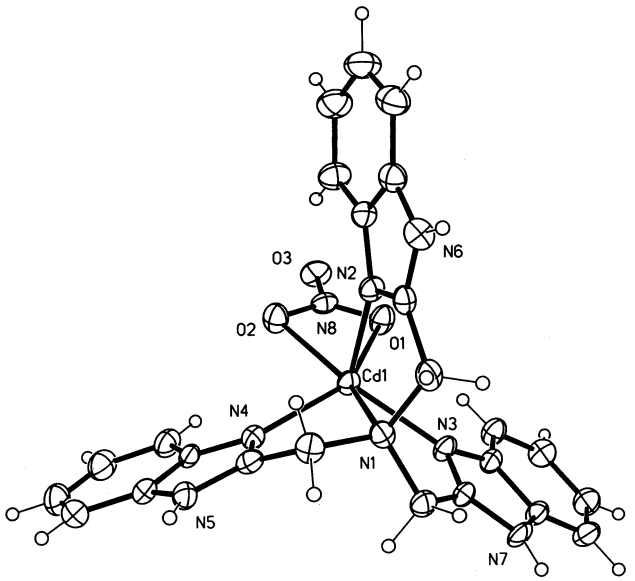

Fig. 3. View of the solid state structure of cadmium cation in compound **7**.

Weak hydrogen bonds between the imidazole protons and the oxygen atom of the nitrate group are observed in the crystal packing. In addition, intermolecular stacking is observed between the benzimidazole rings of **7** with the shortest separation between the centroid of the benzene rings being 4.245 Å.

A regular variation for angles N–M–N for these three compounds when moving from Zn(II) to Hg(II) (Table 3) is observed: the angles decrease in that order due to the M–N1 bond. The nature of the coordinated ion (Cl^-, NO_3^-) does not contribute to this effect.

4. Conclusions

The diamagnetic nature of the metals allowed a study of the coordination behaviour of these compounds in solution. The Zn(II), Cd(II) and Hg(II) halide complexes contain distorted trigonal bipyramidal cations $[M(ntb)X]^+$ and tetrahedral anions $[MX_4]^{2-}$. On the other hand, the hexacoordinated $[Cd(ntb)(\mu_2\text{-}NO_3)]NO_3 \cdot 2DMSO$ complex may be considered to have trigonal bipyramidal geometry. The ligand is coordinated to the metal through the imidazolic nitrogen atoms and has a weak coordination with the tertiary amine. The counterion (halide or nitrate) remains bonded to the metal ion in solution and in the solid state as was evidenced by NMR spectroscopy and X-ray diffraction. The compounds presented interactions between the coordinated counterion and the nearest C–H of the

aromatic rings stabilising the complexes. The distortions found in the solid state were attributed to stacking interactions between aromatic rings of different molecules. From NMR it is clear that in solution the ligand is tetracoordinated as it was also found in the solid state.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-138103–138105. Copies of the data can be obtained free of charge on application to: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

POLYHEDRON

Binuclear copper(II), nickel(II), cobalt(II) and zinc(II) complexes of the macrocycle 1,4,7,16,19,22-hexaaza[9.9]metacyclophane (L). Crystal structure of $[Cu_2LCl_4]_{0.5}\cdot[Cu_2LCl_3]ClO_4\cdot$dmf and the copper complex catalysed hydrolysis of the phosphotriester 2,4-dinitrophenyldiethylphosphate

Abstract

Copper(II), nickel(II), cobalt(II) and zinc(II) complexes of the 22-membered hexa-aza macrocycle 1,4,7,16,19,22-hexaaza[9.9]metacyclophane (L) have been prepared and characterised. The crystal structure of a copper(II) chloro complex has been determined. The complex exists in two forms, one form (Type 1) with an inversion centre has both copper atoms in essentially square pyramidal stereochemistry with an N_3Cl_2 donor set and a Cu···Cu distance of 5.82 Å. The other form (Type II) has one square pyramidal copper with an N_3Cl_2 donor set and one planar copper with an N_3Cl donor set. The Type II Cu···Cu distance is 6.13 Å. The structure is best described as $[Cu_2LCl_4]_{0.5}\cdot[Cu_2LCl_3]ClO_4\cdot$dmf (dmf = *N*,*N*-dimethylformamide). The copper(II) complex catalyses the hydrolysis of the phosphotriester 2,4-dinitrophenyldiethylphosphate to give diethyl phosphate and the mechanism of the reaction is discussed. © 2000 Elsevier Science Ltd. Keywords: Binucleating hexa-aza macrocycle; Copper(II); Nickel(II); Cobalt(II); Zinc(II); Crystal structures; Phosphotriester; Hydrolysis

1. Introduction

Recently there has been considerable interest in the area of binucleating macrocycles capable of incorporating two metal centres [1]. In part, this interest has arisen due to the occurrence of binuclear metal centres in several enzymes such as purple acid phosphatase [2] (**1**) and urease [3]. In addition, several marine natural products have been shown recently to involve binucleating macrocycles [4] and binuclear copper(II) centres are well established in marine oxygen carrying proteins such as hemocyanin [5]. For this reason we have been interested in the coordination chemistry of binucleating ligand systems. In the present paper we describe the synthesis of a series of metal complexes of the hexa-aza macrocycle (**2**) = L including the crystal structure of a binuclear copper(II) complex. In the context of binuclear phosphatases, the binuclear copper complex of L has catalytic activity above pH 7 for the hydrolysis of the water soluble phosphotriester 2,4-dinitrophenyldiethylphosphate (**3**) to give diethyl phosphate. The nature of the catalytically active complex is discussed.

(2) L

(3)

The chemistry of L has attracted a number of previous studies. Martell and co-workers [6–9] have studied host–guest interactions between *ortho*-, pyro- and triphosphate anions and the mono and dinuclear copper(II) complexes of L by potentiometric methods. Ternary complexes are formed in aqueous solution as a result of coordinate bonding, hydrogen bond formation and electrostatic attraction between host and guest. The ligand also forms binary complexes with the nucleotides AMP, ADP and ATP due to electrostatic attraction and hydrogen bonding interactions. The protonated forms of L are capable of recognising the nucleotides in solution and the strength of the binding follows the order ATP > ADP > AMP. The mono- and dinuclear copper(II) complexes of L also form stable ternary complexes with ADP and ATP in solution although the formation constants are somewhat less than those of the macrocycle alone. The conversion of ATP to ADP and orthophosphate at 70°C has been shown to occur with the rates of hydrolysis increasing with decreasing pH. The presence of copper(II) ions has an inhibitory effect on the hydrolysis of ATP by L.

2. Experimental

2.1. Synthesis

2.1.1. $L \cdot 6HBr \cdot 5H_2O$

The macrocycle 1,4,7,16,19,22-hexa-aza[9.9]metacyclophane L (**2**) was prepared by the non-template [2 + 2] condensation of 1,5-diamino-3-azapentane with *iso*-phthalaldehyde to give the macrocyclic tetra-imine which was reduced with sodium borohydride essentially as described previously [7,8]. The hexahydrobromide salt was prepared by the addition of concentrated hydrobromic acid to a solution of the free base macrocycle in methanol and was recrystallised three times from aqueous methanol (40:190). Yield 9.56 g, 61%. m.p. 164–168, FAB MS (m/z), 655 ($LH_4Br_3^+$), 573 ($LH_3Br_2^+$), 491 (LH_2Br^+), 411 (LH^+). IR (cm^{-1}) 3450s (H_2O), 2800–2940m (C–H), 2450m (NH_2^+), 1590s (arom C–C), 1450s (C–H), 710, 810s (*m*-substituted Ph). $\delta(^1H)$ (ppm from sodium 3-trimethylsilyl-1-propane sulfonate in D_2O) 7.4 s (2H, arom.), 7.5 s (6H, arom.) 4.2 s (8H, CH_2–Ph), 3.2–3.4 m (16H, CH_2). *Anal*. Found: C, 29.6; H, 5.7; Br 48.8; N, 8.35. Calc. for $C_{24}H_{38}N_6 \cdot 6HBr \cdot 5H_2O$: C, 29.2; H, 5.5; Br 48.6; N, 8.5%. The free base form of the ligand was prepared by the addition of a concentrated potassium hydroxide solution to an aqueous solution of the HBr salt followed by extraction with dichloromethane. The stepwise protonation constants for the free base L have been determined previously to be 9.43(2), 8.68(2), 7.94(1), 7.07(1), 3.77(2) and 3.36(2) [8].

2.1.2. $[Cu_2LCl_4](Cu_2Cl_4)_{0.33}(EtOH)_{0.165}$

Copper(II) chloride dihydrate (0.99 g, 4.82 mmol) was dissolved in ethanol (20 cm^3) and added dropwise to a boiling solution of the free base ligand L (1.20 g, 2.93 mmol) in ethanol (20 cm^3). A fine blue–green precipitate began to form when half of the copper solution had been added. The complex was filtered off, washed with ethanol, then diethyl ether and dried in vacuo at 50°C (yield 1.70 g, 75%). *Anal*. Found: C, 37.5; H, 5.1; N, 10.8. Calc. for $C_{24}H_{38}N_6Cu_2 \cdot (Cu_2Cl_4)_{0.33} \cdot (C_2H_5OH)_{0.165}$: C, 37.6; H, 5.1; N, 10.8%. IR (KBr) 3434(OH), 3186 (NH), 1614 (aromatic) cm^{-1}. In DMF solution, the complex has λ_{max} 692 nm (ε = 304 $dm^3\ mol^{-1}\ cm^{-1}$) and 437 nm (ε = 116 $dm^3\ mol^{-1}\ cm^{-1}$) and a molar conductance (Λ_M) of 46 S $cm^2\ mol^{-1}$ per dimer at 25°C.

2.1.3. $[Cu_2L](ClO_4)_4 \cdot H_2O$

(**CAUTION**: Perchlorate salts are potentially explosive and should be handled with care.)

A solution of $L \cdot 6HBr \cdot 5H_2O$ (0.55 g, 0.56 mmol.) in distilled water (50 cm^3) was stirred with a suspension of excess $CuCO_3$ (0.2 g, 1.68 mmol) at room temperature (r.t.) for 3–4 h. The excess $CuCO_3$ was removed by filtration to leave a deep blue filtrate. Treatment of the filtrate at 0°C with $NaClO_4$ (0.3 g, 2.8 mmol in 5 cm^3 H_2O) resulted in precipitation of a blue solid which was removed by filtration and dried briefly in a desiccator over a silica gel. Yield 0.3 g, 60%. *Anal*. Found (%): C, 30.63; H, 4.13; N, 8.87. Calc. for $C_{24}H_{40}Cl_4N_6O_{17}Cu_2$ (M_r = 953.21): C, 30.22; H, 4.20; N 8.81%. IR (cm^{-1}), 3450s (νOH, H_2O), 3280m (νNH), 2900–2950w (νCH), 1450m (δCH), 1070, 1105, 1135vs (ν_3 ClO_4), 730m, 795m (*m*-Ph), 640, 650s (ν_4 ClO_4). In aqueous solution, the complex has λ_{max} 646 nm (ε = 308 $dm^3\ mol^{-1}\ cm^{-1}$) and Λ_M = 440 S $cm^2\ mol^{-1}$ per dimer (4:1

electrolyte). The solid complex possesses a μ/μ_B value (per Cu) of 1.53 at 18°C.

2.1.4. $[Zn_2LCl_4]\cdot 2H_2O$

Anhydrous zinc(II) chloride (0.86 g, 6.3 mmol) was dissolved in ethanol (20 cm^3) and added dropwise to a boiling ethanolic solution of the free base L (1.3 g, 3.2 mmol). A flocculent white precipitate formed immediately but slowly dissolved. On complete addition of the ligand, a white solid began to form. The solution was cooled and the complex filtered off, washed with ethanol then diethyl ether and dried in vacuo for 24 h at 50°C (yield 1.65 g, 73%). *Anal.* Found: C, 40.2; H, 5.4; N, 11.2. Calc. for $C_{24}H_{38}N_6Zn_2Cl_4\cdot 2H_2O$: C, 40.1; H, 5.9; N, 11.7%. IR (KBr), 3475 (OH), 3217 (NH), 1615 (aromatic) cm^{-1}. In DMF solution the complex has $\Lambda_M = 30$ S cm^2 mol^{-1} per dimer at 25°C.

2.1.5. $[Ni_2LCl_4](NiCl_2)_{0.167}\cdot H_2O$

Nickel(II) chloride hexahydrate (1.23 g, 5.2 mmol) in ethanol (20 cm^3) was added dropwise to a refluxing solution of the free base L (1.07 g, 2.4 mmol) in ethanol (30 cm^3). A pale-green precipitate formed during the addition. The solution was cooled and the complex filtered off, washed with ethanol and dried in vacuo for 24 h at 50°C (yield 1.35 g, 73%). *Anal.* Found: C, 40.5; H, 5.7; N, 11.5. Calc. for $C_{24}H_{44}N_6O_2Ni_2Cl_4\cdot(NiCl_2)_{0.167}\cdot H_2O$: C, 40.6; H, 5.7; N, 11.8%. IR (KBr) cm^{-1}, 3434–3194 (OH and NH), 1635 (aromatic and OH). In aqueous solution the complex has λ_{max} 390 nm ($\varepsilon = 33$ dm^3 mol^{-1} cm^{-1}) and 628 nm ($\varepsilon = 20$ dm^3 mol^{-1} cm^{-1}). In DMF solution the complex has $\Lambda_M =$ 67 S cm^2 mol^{-1} per dimer at 25°C.

2.1.6. $[Co_2LCl_2](CoCl_4)_{0.25}(Cl)_{1.5}$

Anhydrous cobalt(II) chloride (0.65 g, 4.98 mmol) was dissolved in ethanol (20 cm^3) and added dropwise to a boiling solution of the ligand (1.02 g, 2.49 mmol) in ethanol (20 cm^3) under argon. A blue precipitate formed and was filtered off and washed with ethanol (3×10 cm^3) then diethyl ether (1×10 cm^3). The complex was dried in vacuo for 24 h at 50°C (yield 1.31 g, 75%). *Anal.* Found: C, 41.45; H, 5.4, N, 11.8. Calc. for $C_{24}H_{38}N_6Co_2Cl_2\cdot(CoCl_4)_{0.25}(Cl)_{1.5}$: C, 41.0; H, 5.4; N, 11.95%. IR (KBr), 3397 (OH), 3235 (NH), 1616 (aromatic). In DMF solution the complex has λ_{max} 524 nm ($\varepsilon = 112$ dm^3 mol^{-1} cm^{-1}) 609 nm ($\varepsilon = 122$ dm^3 mol^{-1} cm^{-1}), 661 nm ($\varepsilon = 143$ dm^3 mol^{-1} cm^{-1}) and 802 nm ($\varepsilon = 18$ dm^3 mol^{-1} cm^{-1}) and $\Lambda_M = 3.4$ S cm^2 mol^{-1} per dimer at 25°C.

2.2. Crystal structure determination of $[Cu_2LCl_4]_{0.5}[Cu_2LCl_3]ClO_4\cdot dmf$

Crystals suitable for X-ray diffraction were grown by diffusion of diethyl ether into a solution of the chloro-complex prepared in DMF containing added sodium perchlorate. Small dark blue blocks were obtained. The diffraction measurements were carried out at 220 K.

2.2.1. Crystal data

$C_{39}H_{64}N_{10}Cu_3Cl_6O_5$, $M = 1156.5$, primitive monoclinic, $a = 10.504(4)$, $b = 38.68(2)$, $c = 12.962(6)$ Å, $\beta = 110.35(3)°$, $U = 4937(3)$ $Å^3$, space group $P2_1/c$ (no. 14), $Z = 4$, $D_{calc} = 1.556$ g cm^{-3}, $F(000) = 2388$. Approximate crystal dimensions $0.30 \times 0.20 \times 0.15$ mm, μ(Mo Kα) = 16.57 cm^{-1}.

2.2.2. Data collection and processing

Rigaku AFC7S diffractometer, ω–2θ scan type, graphite monochromated Mo Kα radiation; 8688 reflections measured (max $2\theta = 45.1°$) of which 6275 were unique ($R_{int} = 0.045$). No decay correction was required. Corrections for absorption (trans. factors: 0.7596–1.0000) were required. Corrections were made for Lorentz and polarisation effects.

2.2.3. Structure analysis and refinement

Direct methods were employed [10] and expanded using Fourier techniques [11]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. The final cycle of full-matrix least-squares refinement was based on 4241 observed reflections ($I > 3\sigma(I)$) and 568 variable parameters and converged (largest parameter shift was 0.04 times its e.s.d.) with unweighted agreement factors of $R = 0.048$ and $R_w = 0.055$. The weighting scheme was based on counting statistics and included a factor ($\rho = 0.027$) to downweight the intense reflections. The maximum and minimum peaks in the final difference Fourier map corresponded to 0.68 and -0.49 e A^{-3}, respectively. All calculations were carried out using the TEXSAN [12] crystallographic software package of the Molecular Structure Corporation.

2.3. Kinetic measurements

The water-soluble phosphotriester 2,4-dinitrophenyldiethylphosphate was prepared as described previously [13]. The release of 2,4-dinitrophenolate was monitored by the absorbance increase at 360 nm using a Perkin–Elmer lambda-14 spectrophotometer in 1 cm quartz cells. Plots of $\ln(A_\infty - A_t)$ versus time (t) were linear for at least two half-lives. All measurements were made at 25 ± 0.1°C. Solutions of varying pH were prepared by the adjustment of a 4.65×10^{-3} mol dm^{-3} solution of copper(II), 2.52×10^{-3} mol dm^{-3} L and 0.1 mol dm^{-3} KCl to the required pH by the addition of NaOH or HCl. Reactions were initiated by the addition of 2 μdm^3 of a solution of 2,4-dinitrophenyldiethylphosphate in acetonitrile to 2 cm^3 of the metal complex solution in a 1 cm cuvette. The final phosphotriester concentration was 2×10^{-4} mol dm^{-3}. For

slow reactions (pH < 7) absorbance data were collected over one half-life and the final value of A_∞ was obtained after 2 weeks at r.t. Above pH 7, absorbance data were collected for up to three half-lives. The absorbance versus time curves were fitted to a first order rate equation using a linear least-squares method. Rate constants could be replicated to within 5%. The quoted rate constants are the average of duplicate runs.

Infra-red spectra were recorded on a Perkin–Elmer Paragon 1000 FT spectrometer as KBr pellets. Cyclic voltammetric measurements were recorded using a PAR model 170 electrochemistry system with built in sweep generator and $X-Y$ plotter. A standard three-electrode system was employed comprising Pt disc working electrode, Pt wire counter electrode and a Ag/AgCl reference electrode. Potentials are reported relative to the Ag/AgCl electrode. The solvent was dry deoxygenated acetonitrile (distilled from P_2O_5 onto 4 Å molecular sieves) and the electrolyte was 0.1 M tetra-*n*-butylammonium hexafluorophosphate. All metal salts and other solvents/materials were used as supplied.

3. Results and discussion

The 22-membered hexa-aza macrocycle 1,4,7,16,-19,22-hexa-aza[9.9]metacyclophane L (**2**) was readily prepared by the [2 + 2] condensation of 1,5-diamino-3-azapentane with isophthalaldehyde followed by sodium borohydride reduction. The macrocycle could not be readily recrystallised and it was found most convenient to purify the ligand as the hexahydrobromide salt which could be recrystallised from aqueous methanol. The free base was then prepared by the addition of a concentrated KOH solution to an aqueous solution of the hexahydrobromide followed by extraction into dichloromethane.

Complexes with Cu(II), Ni(II), Co(II) and Zn(II) could be prepared by the reaction of the metal chlorides with the free base ligand in ethanol or by use of the metal carbonate with the ligand hydrobromide salt. Analytical data was not consistent with the formation of simple binuclear chloro-complexes. The percentage of carbon, hydrogen and nitrogen was consistently lower than expected. Similar problems were also encountered with the larger 28-membered metacyclophane [14]. Chloride analysis indicated a higher percentage of chloride than predicted, which could be explained by the presence of bridging metal-chloro clusters or the presence of tetrachlorometallate anions. In view of the large size of the metal complex, it is not surprising that large anions are required to stabilise the structure. In addition, it is also known that large macrocyclic complexes of this type readily incorporate solvent molecules within their structure [15].

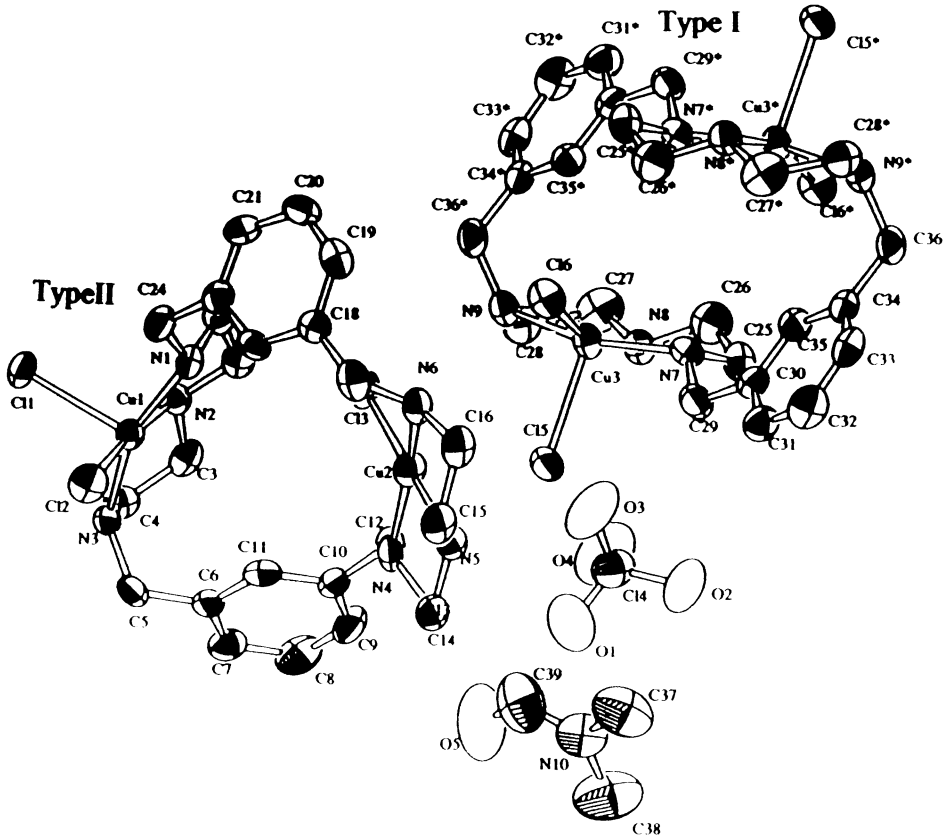

Fig. 1. ORTEP of the complex, $[Cu_2LCl_4]_{0.5}\cdot[Cu_2LCl_3]ClO_4\cdot$dmf with the atomic numbering scheme.

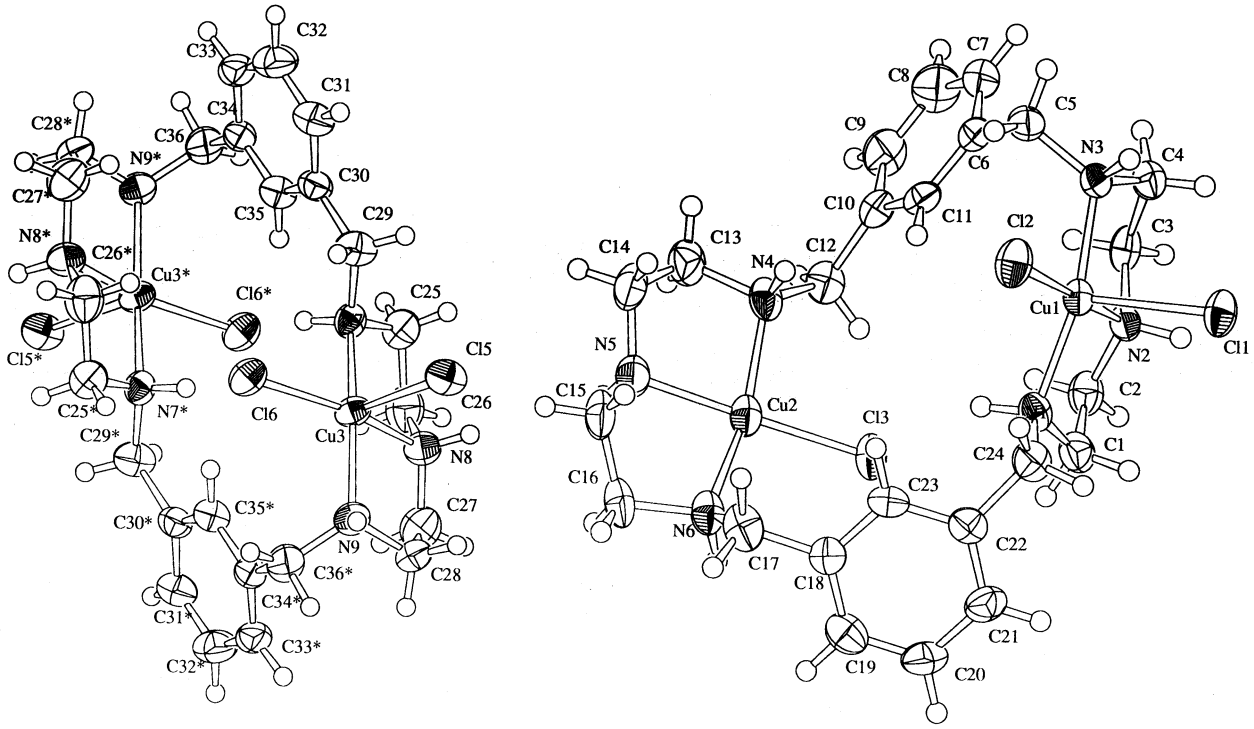

Fig. 2. Close up of the structure of the Type I (a) and Type II (b) dicopper units in the structure of $[Cu_2LCl_4]_{0.5}\cdot[Cu_2LCl_3]ClO_4\cdot dmf$.

3.1. Crystal structure of $[Cu_2LCl_4]_{0.5}[Cu_2LCl_3]ClO_4\cdot dmf$

The crystal structure (Fig. 1) shows the presence of two different binuclear copper complexes. One third of the complex has the Type 1 structure and two thirds the Type II structure. These two structures will be discussed separately.

3.1.1. Type I

The complex lies on a crystallographic centre of inversion (at 1, 0, 1/2) and displays C_i symmetry. The bond lengths and angles of half of this molecule relate to the other half as a result of this centre of symmetry. The copper centres can best be described as square pyramidal; three nitrogen donors from the macrocycle and one chloride make up the base of the pyramid (Fig. 2(a)). The copper atom is somewhat displaced from the basal plane towards the apical chloride as is frequently observed in square pyramidal complexes. The apical chloride is directed away from the macrocyclic cavity to form a long bond with a copper centre in the Type II structure. The copper–nitrogen bond distances fall within the range 2.021–2.045 Å, values which are fairly typical for five-coordinate secondary amine complexes of copper(II) where the mean value found in the Cambridge data file is 2.029 Å. The copper–chloride bond distance is 2.287 Å which is quite normal for the basal chloride, but the bond to the apical chloride (2.491 Å) is quite long and there is probably a small degree of electron withdrawal from the bond to form a bridge to the Type II structure. The Cu–Cu distance within the Type I structure is 5.82 Å. Bond lengths and angles for the Type I structure are summarised in Table 1.

Table 1
Assorted bond lengths (Å), angles (°) and Cu···Cu separation for the Type I dicopper unit

Cu(3)–Cl(6)	2.287(2)	Cl(6)–Cu(3)–Cl(5)	102.95(8)
Cu(3)–Cl(5)	2.491(2)	N(7)–Cu(3)–Cl(6)	90.6(2)
Cu(3)–N(8)	2.021(6)	N(8)–Cu(3)–Cl(5)	96.1(2)
Cu(3)–N(7)	2.043(6)	N(8)–Cu(3)–Cl(6)	160.8(2)

Cu(1)···Cu(2)	6.13		

3.1.2. Type II

As with the Type I structure one of the copper centres has square pyramidal stereochemistry; however, the other copper centre is best described as square planar or Jahn–Teller distorted square pyramidal (Fig. 2(b)), the apical chloride bridging from the Type I structure. The Cu–N bond distances are similar to those observed in the Type I structure although somewhat shorter distances occur in the Jahn–Teller distorted copper centre (Table 2). The planar character of this centre is reflected in the donor–copper–donor angles which are close to the ideal 90 or 180°. The Cu–Cu distance observed in the Type II structure is 6.13 Å.

The structure also includes one dmf molecule and a perchlorate anion to balance the charge on the four coordinate copper in the Type II structure. The *N*,*N*-dimethylformamide is not hydrogen bonded to any of the components of the structure and the bond lengths and angles are quite normal.

The crystal structure of the related sulfato complex $Cu_2L(SO_4)_2$ has been determined recently [6]. Crystals were prepared by slow diffusion of acetone into an aqueous solution of L·6HBr and copper(II) sulfate in a 1:2 molar ratio adjusted to pH 6.3 with KOH. The macrocycle binds two copper(II) ions via the two diethylenetriamine moieties which provide three nitrogen donors to each metal ion. The copper has square pyramidal stereochemistry with the coordination sphere being completed by one sulfate oxygen in an equatorial site and another sulfate oxygen from a different sulfate anion in the apical site. The Cu–N distances range from 1.99(1) to 2.06(1) Å and are typical of interactions of this type [16–19]. The equatorial Cu–O bond distance is 1.947(8) Å while the axial Cu–O bond distance is considerably longer at 2.262(10) Å consistent with the expected Jahn–Teller distortion. As the sulfate anions bridge the two copper centres in neighbouring molecules the crystal has an extended polymeric structure.

The solid state structure of $Cu_2L(SO_4)_2$ establishes that the macrocycle has a chair conformation with one dien moiety flipped down and the other flipped up. This conformation may not necessarily be that adopted in solution.

3.2. Electrochemical studies on $[Cu_2L(solv)_x]^{2+}$ ($solv = CH_3CN$ or H_2O)

Cyclic voltammograms recorded on solutions of freshly made up solutions of $[Cu_2L](ClO_4)_4$ in dry deoxygenated acetonitrile show a quasi-reversible oxidation wave to Cu(III) centred at $+0.99$ V (vs. Ag/AgCl) and a broad quasi-reversible reduction wave to Cu(I) centred at ~ -0.1 V. Exposure of the solution to air over a period of 12 h, however, results in the slow appearance of a new quasi-reversible oxidation wave to Cu(III) at $\sim +0.72$ V. At the same time the reduction wave to Cu(I) moves more negative towards -0.5 V and becomes largely irreversible. The deliberate addition of a few drops of water resulted in the new waves becoming dominant. It is concluded that the acetonitrile-solvated complex $[Cu_2L(NCCH_3)_x](ClO_4)_4$ ($x = 1$–4) is immediately formed upon dissolution of the presumed complex, $[Cu_2L(OClO_3)_x](ClO_4)_{4-x}$, which then slowly aquates in the air to give the aqua complex, $[Cu_2L(OH_2)_x](ClO_4)_4$ ($x = 1$–4), the rate-determining process of which is the diffusion of atmospheric moisture into the acetonitrile solvent in the electrochemical cell. On the basis of the observed potentials it can be concluded that replacement of CH_3CN by H_2O in the coordination sphere of the copper results in stabilisation of the Cu(III) state to the extent of ~ 0.23 eV and correspondingly destabilises the Cu(I) state to the extent of 0.5 eV.

3.3. Other metal complexes

The nickel(II) complex isolated is green in colour and presumably has octahedral stereochemistry at each nickel ion. This view is supported by the d–d spectrum which displays two bands at 390 nm ($\varepsilon = 33$ dm^3 mol^{-1}) and 628 nm ($\varepsilon = 20$ dm^3 mol^{-1} cm^{-1}) in the wavelength range 350–900 nm.

The d–d spectrum of the cobalt(II) complex excludes tetrahedral geometry and is consistent with a trigonal bipyramidal stereochemistry of the type observed in $[Co(Et_4dien)Cl_2]$ [20] which exhibits three bands between 950 and 520 nm with absorption coefficients in the range 20–100 dm^3 mol^{-1} cm^{-1}. The low conductivity of the complex in dmf solution also suggests that two chlorides are bound to each cobalt.

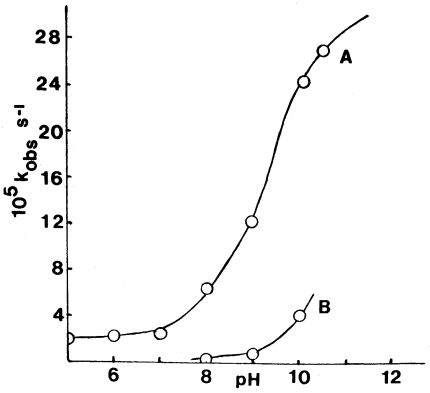
3.4. Kinetic studies

Recent investigations [13,21] have established that simple aqua-hydroxo copper(II) complexes such as $[Cu(tmen)(OH)OH_2)]^+$ (tmen = *N*,*N*,*N*′,*N*′-tetramethylenediamine) are excellent catalysts for the hydrolysis of phosphodiesters and phosphotriesters. Red kidney bean purple acid phosphatase [2] (**1**) is a binuclear Fe^{III}–Zn^{II} metalloenzyme resembling the mammalian Fe^{III}–Fe^{II} version. As a result, we were interested to establish whether the binuclear copper(II) complex of L exhibited any equivalent, or even enhanced, catalytic activity in such reactions to those of related mononuclear copper(II) systems.

Measurements were made using the water-soluble phosphotriester 2,4-dinitrophenyldiethylphosphate (**3**). In order to avoid complications due to general base catalysis which can arise from the use of buffers, the copper(II) complex of L was employed as the buffer

Table 3
The pH dependence of the hydrolysis of 2,4-dinitrophenyldiethylphosphate by the binuclear copper complex at 25°C and $I = 0.1$ mol dm^{-3}

pH	$10^5\ k_{obs}$ (s^{-1})	pH	$10^5\ k_{obs}$ (s^{-1})
5.05	1.9	8.00	6.3
5.52	2.5	8.50	8.5
6.01	2.2	9.00	12.2
6.52	1.85	9.48	23.6
7.00	2.15	10.06	24.3
7.50	2.5	10.5	26.8



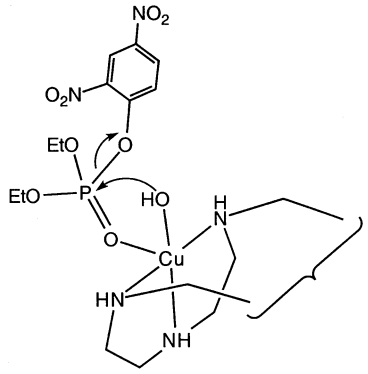


Fig. 3. Plot of k_{obs} versus pH for the binuclear copper(II) L-catalysed hydrolysis of 2,4-dinitrophenyldiethylphosphate (curve A). Curve B is the plot for the uncatalysed reaction. Measurements were made at 25°C and $I = 0.1$ mol dm^{-3} KCl.

and the pH adjusted by the dropwise addition of acid or base. The concentration of the copper complex was 2.5×10^{-3} mol dm^{-3} and the phosphotriester 2×10^{-4} mol dm^{-3}. The kinetic measurements are summarised in Table 3. The pH-rate profile is sigmoidal (Fig. 3) suggesting that the catalytically active species have a pK of ca. 9. The pH-rate profile for the uncatalysed reaction was calculated from the expression $k_{obs} = k_o + k_{OH}[OH^-]$ where k_o is the rate constant for the spontaneous water hydrolysis and k_{OH} relates to base hydrolysis. At 25°C and $I = 0.1$ mol dm^{-3}, $k_o = 1.2 \times 10^6$ s^{-1} and $k_{OH} = 0.305$ dm^3 mol^{-1} s^{-1} [13]. Using the formation constants reported by Martell and co-workers [8] for copper(II) complexes of the ligand L it is possible to construct the speciation diagram shown in Fig. 4. Formation of the dihydroxo complex $[Cu_2L(OH)_2(OH_2)_{x-2}]^{2+}$ occurs with a pK of ca. 9 and its formation mirrors the hydrolysis rate profile observed. The aqua complex $[Cu_2L(OH_2)_x]^{4+}$ also appears to exert a significant catalytic effect at pH 6 where it is the predominant species. At pH 6, in the presence of the metal complex $k_{obs} = 2.20 \times 10^{-5}$ s^{-1} while the uncatalysed reaction has $k = 1.2 \times 10^{-6}$ s^{-1}, a rate enhancement of some 20-fold. Although the rate enhancement observed with the aqua complex is not

(4)

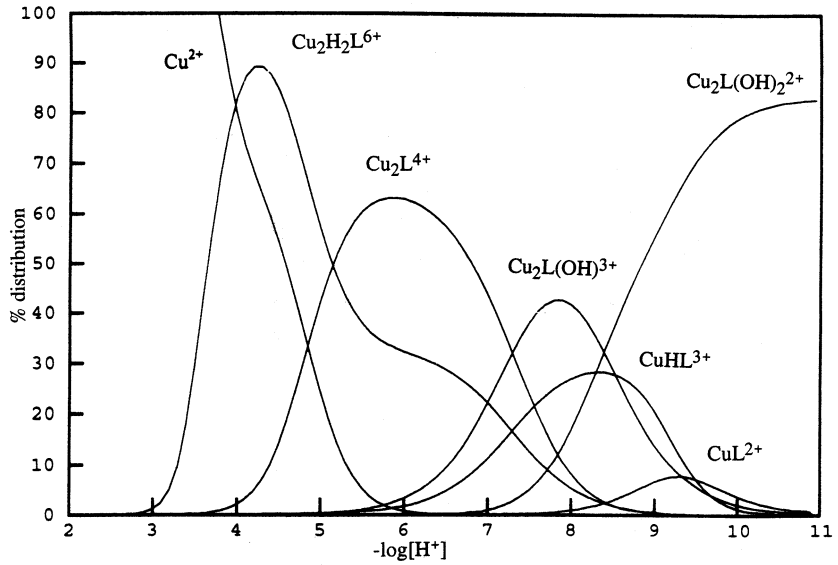

Fig. 4. Speciation curves for the copper(II) complexes of L at a 2:1 copper to ligand ratio at 25°C (constructed from the data of Martell et al. [8]).

large, the effect on the half-life of the phosphate ester is quite substantial. At pH 6 the half-life of the ester is ca. 160 h which is reduced to some 8 h in the presence of the copper complex.

In copper complexes of this type, it appears that a square pyramidal stereochemistry on copper tends to be favoured. As the distance between the copper centres in the complexes is quite large (5.8–6.0 Å), a co-operative mechanism involving both centres appears unlikely. Hydrolysis almost certainly takes place at a single copper site by formation of a ternary complex with the phosphotriester via the P=O group which then undergoes intramolecular attack by a coordinated water molecule or hydroxide ion (**4**). Such a mechanism is now well recognised in a variety of such reactions catalysed by copper(II) complexes [13,21].

4. Supplementary material

Supplementary crystallographic data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition no. CCDC 138257.

POLYHEDRON

The spectroscopic characterisation of *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ and an investigation of their halogen exchange reactions in solution and the vapour

Abstract

Infrared spectra of the iron carbonyl halides, *cis*-$Fe(CO)_4X_2$ (X = I, Br, Cl) and *cis*-$Fe(CO)_4XY$ (XY = IBr, ICl), have been studied in the 4000–150 cm^{-1} region. Solution ^{13}C NMR, mass spectrometry and matrix isolation infrared studies have provided evidence of cross halogenation reactions of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ to yield *cis*-$Fe(CO)_4IBr$ in both the solution and the vapour phases and have facilitated the characterisation of the mixed halide species for the first time. Improved structural data for *cis*-$Fe(CO)_4I_2$ and the first for *cis*-$Fe(CO)_4Br_2$ have been obtained using iron K-edge X-ray absorption fine structure (XAFS) spectroscopy. © 2000 Elsevier Science Ltd. Keywords: Iron carbonyl halides; NMR; XAFS spectroscopy; Halogen exchange reactions; Matrix isolation

1. Introduction

Iron carbonyl halides, and in particular *cis*-$Fe(CO)_4I_2$, have been well studied using infrared [1–9], Mössbauer [10–13], ^{13}C NMR [14] and photoelectron [15,16] spectroscopies along with mass spectrometric [17] and calorimetric studies [18]. Whilst the *cis*-$Fe(CO)_4X_2$ (X = I, Br, Cl) complexes are well documented, little or no attention has been given to the mixed halide complexes such as *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ since the original reports of their synthesis in 1940 [19]. Of the *trans* complexes, only *trans*-$Fe(CO)_4I_2$ has been obtained in solution [1,5,8,9,20], the solid [9] and in a matrix [21], with the only reports of *trans*-$Fe(CO)_4Br_2$ [22] and *trans*-$Fe(CO)_4Cl_2$ [23] being limited to matrix isolation experiments. Previous work on the *cis*-$Fe(CO)_4X_2$ complexes has concentrated on the infrared spectra and in particular the ν_{CO} region with assignments of the four fundamental frequencies now being generally agreed upon [1,2,5,6]. Work has also been carried out on the infrared spectra of the metal–carbon and metal–halogen stretching vibrations (ν_{MC} and ν_{MX}) and the metal–carbon–oxygen deformation modes, δ_{MCO} [6–9]. Whilst Bennett and Clark [7] did not distinguish between the ν_{MC} and δ_{MCO} vibrations, Pankowski and Bigorgne [8,9] assigned some of those for *cis*-$Fe(CO)_4I_2$. In neither report were the ν_{MX} modes of *cis*-$Fe(CO)_4I_2$ identified. To our knowledge, only *cis*-$Fe(CO)_4I_2$ has been characterised by solution ^{13}C NMR spectroscopy, yielding two equally intense carbonyl resonances at room temperature [14]. Structural data on these compounds is limited to *cis*-$Fe(CO)_4I_2$ using Fe K-edge X-ray absorption fine structure (XAFS) spectroscopy [24], although *trans*-$Fe(CO)_4Cl_2$ [23] and *trans*-$Fe(CO)_4Br_2$ [22] have been characterised by Fe K-edge XAFS from the co-condensation of $FeCl_2$ or $FeBr_2$ into a carbon monoxide matrix. The mass spectra of *cis*-$Fe(CO)_4X_2$ showed fragmentation involving the loss of both carbon monoxide and halogen [17].

Therefore, the aim of this work was to characterise *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ for the first time, and to improve the structural data available for *cis*-$Fe(CO)_4I_2$ and also to provide the first structural data for *cis*-$Fe(CO)_4Br_2$.

2. Experimental

All compounds were prepared from iron pentacarbonyl and the appropriate halogen or interhalogen by literature methods [19,25]. *cis*-$Fe(CO)_4Br_2$ and *cis*-$Fe(CO)_4I_2$ were vacuum sublimed before further analysis. Infrared spectra were acquired using a Bruker IFS66 FTIR spectrometer. Mid-infrared (MIR) spectra (4000–400 cm^{-1}) were recorded as Nujol mulls or as solutions in NaCl or KBr windowed cells with a KBr beamsplitter and DTGS detector at 1 cm^{-1} resolution. Far-infrared (FIR) spectra (600–150 cm^{-1}) were recorded as Nujol mulls between polythene sheets (1 mm) using a 6 μm Mylar beamsplitter and DTGS detector at 2 cm^{-1} resolution. ^{13}C NMR spectra were recorded in $CDCl_3$ at 20°C on a JEOL JNM-GX270 FT NMR spectrometer at 67.8 MHz with the chemical shifts reported relative to TMS. Mass spectra were recorded using a VG SXP-1000 quadrupole mass spectrometer at 70 eV.

Matrix isolation IR spectroscopy was carried out by co-condensation of *cis*-$Fe(CO)_4X_2$ with a large excess of matrix gas on a caesium iodide window held at 15 K during deposition and 9 K during data acquisition by an APD Cryogenics DE-204SL Displex closed cycle refrigerator. No heating of the samples was necessary and deposition times were typically 20–30 min. The IR spectra were acquired on a Bruker IFS 66 FTIR spectrometer as above. Light was excluded from the samples to prevent conversion to the *trans*-species [1,5,8,9]. Details of the XAFS matrix isolation experiments, performed at the Daresbury Laboratory Synchrotron Radiation Source (SRS), have been described previously [24] and were similar to the infrared matrix isolation experiments described above except that (i) the deposition substrate was aluminium, (ii) deposition was monitored by observing the increase in the Fe K-absorption edge (2.5–4 h) and (iii) the co-condensed gas was methane at an approximate rate of 1 mmol h^{-1}. The Fe K-edge spectra were collected in fluorescence mode (NaI/Tl scintillator detector) on station 9.2 of the Daresbury Laboratory SRS (operating at 2 GeV with circulating currents of ca. 200 mA) using a Si(220) double crystal monochromator detuned by ca. 50% to remove harmonic contamination. Four to seven spectra were collected for each sample, averaged and calibrated using the first maximum in the first derivative of the Fe K-edge of Fe foil (7111.2 eV [26]). Background subtraction was carried out using PAXAS [27] by fitting the pre-edge region to a quadratic polynomial, subtracting this from the data and approximating the atomic component of the post-edge region with a high (typically sixth) order polynomial. This approximation was optimised in order to minimise the low-*r* features in the Fourier transforms by an iterative process. In the case of *cis*-$Fe(CO)_4Br_2$ it was necessary to truncate the data at 12.5 $Å^{-1}$ due to unnormalised glitches. Fitting of the experimental data was carried out with EXCURV98 [28–30] making use of the single and multiple scattering curved wave theory with linear Fe–C–O units, a von-Barth ground state and a Hedin–Lundqvist exchange potential. The same potentials and phase-shifts were used for all samples and included both bromine and iodine backscatterers as well as carbon and oxygen around a central absorbing iron atom.

3. Results and discussion

3.1. IR solution studies in the ν_{CO} region

In the ν_{CO} region, *cis*-$Fe(CO)_4X_2$ complexes have four IR active modes, and in line with previous studies [3–6], the *z* axis is taken to bisect the two Fe–X bonds which lie in the *yz* plane, the two CO ligands *trans* to each other (also called axial) lie in the *xz* plane and the 2 CO ligands *cis* to each other (equatorial) lie in the *yz* plane. Assuming no coupling, the ν_{CO} modes of the CO ligands *trans* to each other transform as $A_1^{(2)}$ and B_1, whereas the ν_{CO} modes of the CO ligands *cis* to each other transform as $A_1^{(1)}$ and B_2, and this is shown schematically below. The $A_1^{(2)}$ mode is expected to be very weak, but its intensity will be enhanced by coupling with the $A_1^{(1)}$ mode.

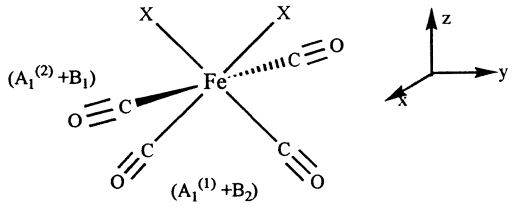

Fig. 1(a) shows the cyclohexane solution infrared spectrum of *cis*-$Fe(CO)_4I_2$ in the ν_{CO} region, and the 2129.8 cm^{-1} band can readily be assigned to the $A_1^{(2)}$ mode on the basis of its relative intensity. In agreement with Noack's findings [1] we observed only three bands instead of the expected four and he suggested that the fourth absorption was either weak at 2047 cm^{-1} or accidentally degenerate with the strong band at 2084 cm^{-1}. The overlapping of the $A_1^{(1)}$ and B_1 modes was later confirmed by Johnson et al. [5] and Butler and Spendjian [6] with the use of $C^{18}O$ and ^{13}CO isotopic exchange experiments, respectively, and it is clear from our spectra that the band at 2085 cm^{-1} is asymmetric, indicating the presence of more than one band. The solution infrared data for *cis*-$Fe(CO)_4I_2$ in the ν_{CO} region are given in Table 1 and are in good agreement with those previously reported [1,2,5,6]. In the spectrum of *cis*-$Fe(CO)_4Br_2$ (Fig. 1(b), Table 1), the four fundamental absorption bands were resolved, and in this case the relative intensity of the peaks allows for the unam-

biguous assignment of the 2149.5 and 2107.7 cm^{-1} bands to the $A_1^{(2)}$ and B_1 modes, respectively. The assignment of the two remaining peaks at 2097.4 and 2073.6 cm^{-1} to the $A_1^{(1)}$ and B_2 modes, respectively, is based on the work of Johnson et al. [5] and Butler and Spendjian [6] on the basis of the values of the principal and interaction force constants required to fit the data. As to be expected [3,31–34] the ν_{CO} modes of *cis*-$Fe(CO)_4Br_2$ are at higher wavenumbers than those of *cis*-$Fe(CO)_4I_2$, but all the modes are not affected by the same amount, with the $A_1^{(2)}$ and B_1 modes of the *trans* COs being more affected than the $A_1^{(1)}$ and B_2 modes of the *cis* CO ligands. This behaviour has been rationalised previously [3,31] to be due to the differing extent of metal dπ-orbital sharing by the *cis* and *trans* CO ligands.

The IR spectrum of *cis*-$Fe(CO)_4IBr$ shown in Fig. 1(c) clearly has features due to both *cis*-$Fe(CO)_4I_2$ and

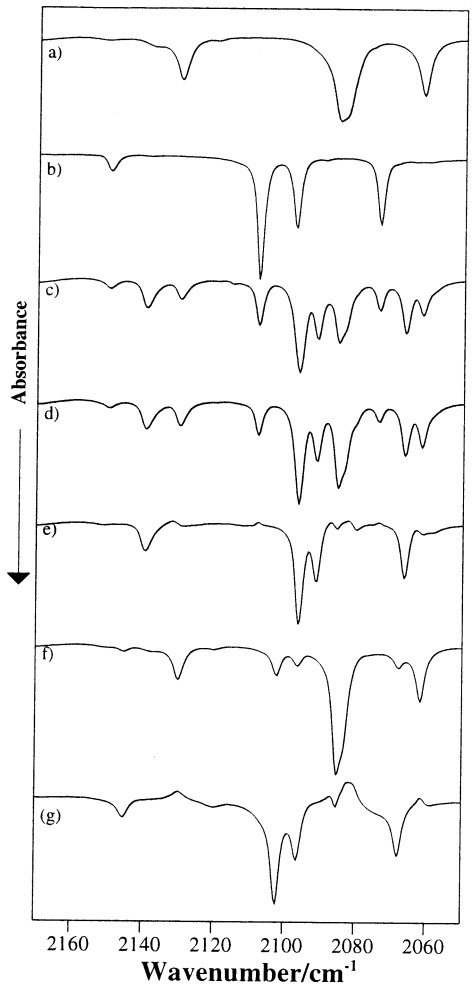

Fig. 1. Infrared spectra of *cis*-iron carbonyl halides in cyclohexane solution in the ν_{CO} region (a) *cis*-$Fe(CO)_4I_2$, (b) *cis*-$Fe(CO)_4Br_2$, (c) *cis*-$Fe(CO)_4IBr$, (d) mixture of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$, (e) *cis*-$Fe(CO)_4IBr$ (obtained by subtracting (a) and (b) from (c)), (f) *cis*-$Fe(CO)_4ICl$ and (g) *cis*-$Fe(CO)_4ICl$ (obtained by subtracting (a) from (f)).

cis-$Fe(CO)_4Br_2$, as well as new bands which are from *cis*-$Fe(CO)_4IBr$. This is confirmed in Fig. 1(e) where the spectral features of the parent molecules (Fig. 1(a)) and (Fig. 1(b)) have been subtracted from Fig. 1(c) to reveal the bands solely due to *cis*-$Fe(CO)_4IBr$, and these lie approximately midway between the comparable bands of the parent species. All four of the ν_{CO} modes are observable, but are not as well separated as in *cis*-$Fe(CO)_4Br_2$, with those at 2139.3 and 2096.0 cm^{-1} being assigned to the modes of the COs *trans* to each other, whereas those at 2091.2 and 2066.2 cm^{-1} arise from the CO ligands *cis* to each other. For the case of *cis*-$Fe(CO)_4ICl$, the main features present in Fig. 1(f) are clearly due to *cis*-$Fe(CO)_4I_2$ with a set of weaker bands assigned to *cis*-$Fe(CO)_4ICl$ shown in Fig. 1(g), which was obtained by subtraction of the spectrum of *cis*-$Fe(CO)_4I_2$ and again four modes are clearly present. No absorptions due to *cis*-$Fe(CO)_4Cl_2$ were observed in this spectrum because *cis*-$Fe(CO)_4Cl_2$ was particularly unstable in solution and very insoluble in cyclohexane.

Whilst we were able to use the SOTONVIB program [35] and the force field of Butler and Spendjian [6] to calculate the positions of the ν_{CO} modes of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ and could also generate values of the force constants for *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$, there is no unique solution in the absence of isotopic data, because it is necessary to define five force constants for *cis*-$Fe(CO)_4X_2$ and seven force constants for *cis*-$Fe(CO)_4XY$ molecules with only four observed frequencies for each molecule.

The bands due to *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ observed in the spectra of *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ posed the questions: (i) whether the starting materials IBr and ICl existed in significant equilibrium with the parent halogens to such an extent as to carry over to the final product, or (ii) whether halogen exchange occurred in solution, or a combination of the two. The degree of dissociation of IBr into I_2 and Br_2 in carbon tetrachloride has been investigated by Christian and co-workers [36] and was found to be around 8%. A far greater proportion of the parent complexes was seen in our spectra than would be expected due to dissociation of the interhalogen alone. The extent of halogen exchange between the complexes in solution was demonstrated by recording infrared spectra of a 1:1 mixture of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$. In this case a significant amount of *cis*-$Fe(CO)_4IBr$ formed instantly (Fig. 1(d)) with no time-dependent intensity changes being observed. Comparison of this spectrum with that of the material prepared from IBr shown in Fig. 1(c) is very good, showing that halogen exchange in solution produced very similar proportions of *cis*-$Fe(CO)_4I_2$, *cis*-$Fe(CO)_4Br_2$ and *cis*-$Fe(CO)_4IBr$ compared with the solution of *cis*-$Fe(CO)_4IBr$ prepared directly from $Fe(CO)_5$ and IBr. Therefore, it appears that there is indeed halogen exchange between the

complexes when in solution. Previous kinetic studies [37] on ^{14}CO exchange with *cis*-$Fe(CO)_4I_2$ have shown that all four CO ligands exchange at the same rate via a S_N2 (associative) mechanism, with a proposed seven-coordinate transition state. We have not carried out IR kinetic experiments for the halogen exchange due to the limited time resolution available, and isotopic labelling would produce complex spectra with many overlapping bands in both the mid and far infrared that would be hard to disentangle with confidence.

3.2. IR solution and mull studies in the δ_{MCO}, ν_{MC} and ν_{MX} region

For *cis*-$Fe(CO)_4X_2$ complexes, a total of 12 infrared active bands are expected in the FIR region, and these can be described as six infrared-active δ_{MCO} vibrations ($2A_1 + 2B_1 + 2B_2$), four infrared-active ν_{MC} vibrations ($2A_1 + B_1 + B_2$), and two infrared-active ν_{MX} vibrations ($A_1 + B_2$). However, as noted by Bennett and Clark [7] unambiguous assignment of the spectra is not easy, especially as the various modes lie close together in frequency, allowing the coupling of those with the same symmetry, but Pankowski and Bigorgne [8] have assigned a few of the spectral features. It is however instructive to compare the spectra for the analogous *trans*-$Fe(CO)_4X_2$ complexes as the higher symmetry results in fewer IR bands which are much easier to assign with confidence, especially in conjunction with isotopic data. The ν_{MC} (E_u, assuming D_{4h}) modes for *trans*-$Fe(CO)_4X_2$ were observed at 414 (X = I, solution [8]), 394.9 (X = Br, CO matrix [22]) and 380.4 cm^{-1} (X = Cl, CO matrix [23]), with the expected shift to lower energy for more electronegative halogen, which is the reverse of the trend observed for the ν_{CO} modes. The δ_{MCO} modes ($A_{2u} + E_u$) at 606 and 600 (X = I, solution [8,9]), 612 and 598 (X = I, CO matrix [21]), 608.7 and 589.0 (X = Br, CO matrix [22]), 606.6 and 582.3 (X = Cl, CO matrix [23]) were less sensitive to a change of halogen, but much more intense than the ν_{MC} modes. Therefore, for the *cis*-$Fe(CO)_4X_2$ complexes we might expect some relatively intense δ_{MCO} modes not very sensitive to halogen around 600 cm^{-1} and some weaker ν_{MC} modes much more sensitive to halogen at about 400 cm^{-1} in addition to ν_{MX} modes which would be very sensitive to a change in halogen.

The FIR data for the *cis*-$Fe(CO)_4X_2$ complexes are shown in Fig. 2. The data in Fig. 2(a) and Fig. 2(c) were collected as cyclohexane solutions, whereas for all the other spectra the samples were presented as Nujol

mulls. As there is little difference between the spectrum of *cis*-$Fe(CO)_4I_2$ (Fig. 2(a)) and *cis*-$Fe(CO)_4Br_2$ (Fig. 2(c)) in the 630–480 cm^{-1} region, the spectra of the mixed complexes are not shown in this region. It is clear from Fig. 2(a) to (d) that not all of the 12 IR active modes are clearly identifiable, with some being either too weak to observe, or overlapped by other bands. The ν_{MX} vibrations below 330 cm^{-1} are readily identified due to their large shifts on change of halogen, and the presence of triplets in the mixed halogen species at 245–215 cm^{-1} and 210–180 cm^{-1} for *cis*-$Fe(CO)_4IBr$ and 330–290 cm^{-1} and 210–180 cm^{-1} for *cis*-$Fe(CO)_4ICl$. The three intense features at ca. 600 cm^{-1}, which are not greatly affected by a change in halogen, can be assigned to δ_{MCO} modes on the basis of the arguments above, which is in agreement with Pankowski and Bigorgne [8] who also assigned the weaker feature at 505 cm^{-1} to a δ_{MCO} mode. The spectra between 470–350 cm^{-1} are complex with many bands being sensitive to a change of halogen. In some cases (460–420 cm^{-1} for *cis*-$Fe(CO)_4IBr$ Fig. 2(f)) triplets are clearly observed confirming that these are most probably due to the ν_{MC} modes, although it is possible that there are also some weak δ_{MCO} modes in this spectral region. Whilst it may be possible to make firmer assignments on the basis of the relative intensities expected for the ν_{MC} modes, there is the severe problem of mixing of the vibrational modes of the same symmetry, so that even assignments of the features as exclusively ν_{MC} modes should be treated with care. In particular, the ν_{MX} modes may mix with three of the ν_{MC} modes and four of the δ_{MCO} modes to cause both intensity and energy perturbations that will be different for each complex. Therefore, whilst the assignment of the δ_{MCO}, ν_{MC} and ν_{MX} modes is reasonable, we do not believe that it is possible or meaningful to assign any of the individual δ_{MCO}, ν_{MC} and ν_{MX} modes to their respective normal modes.

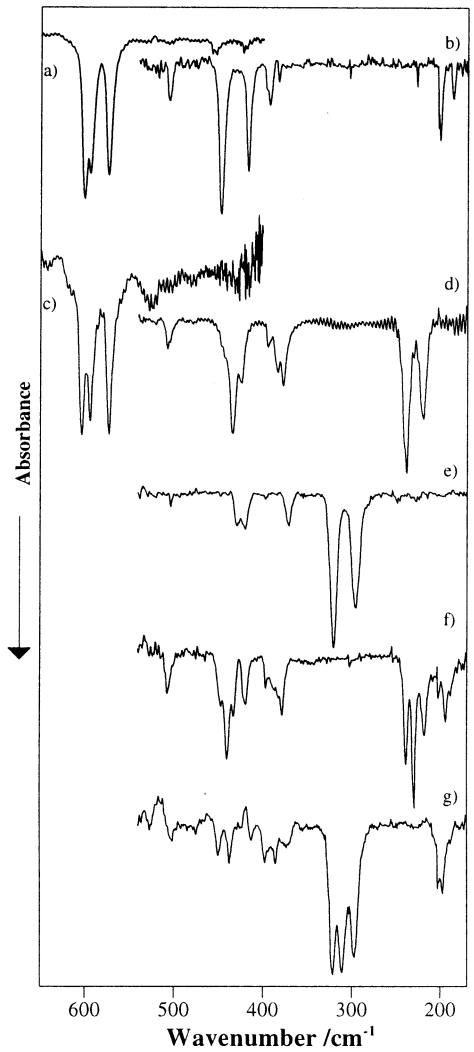

Fig. 2. Infrared spectra in the $\delta_{M\text{-}C\text{-}O}$, $\nu_{M\text{-}C}$ and $\nu_{M\text{-}X}$ regions of (a) *cis*-$Fe(CO)_4I_2$ (cyclohexane solution), (b) *cis*-$Fe(CO)_4I_2$ (Nujol mull) (c) *cis*-$Fe(CO)_4Br_2$ (cyclohexane solution), (d) *cis*-$Fe(CO)_4Br_2$ (Nujol mull) (e) *cis*-$Fe(CO)_4Cl_2$ (Nujol mull), (f) *cis*-$Fe(CO)_4IBr$ (Nujol mull) and (g) *cis*-$Fe(CO)_4ICl$ (Nujol mull).

3.3. Solution ^{13}C NMR studies

The ^{13}C NMR spectra from the *cis*-$Fe(CO)_4X_2$ (X = I, Br,) complexes yielded two equally intense resonances at 204.2 and 197.7 ppm (X = I) and 199.4 and 194.1 ppm (X = Br) in good agreement with the literature values for *cis*-$Fe(CO)_4I_2$ given in Table 3 [14]. The marked shift to lower frequency of both resonances observed for *cis*-$Fe(CO)_4Br_2$ compared with *cis*-$Fe(CO)_4I_2$ has been observed previously for related platinum and palladium carbonyl complexes [38]. Spectra of *cis*-$Fe(CO)_4Cl_2$ were unobtainable due to significant decomposition involving the loss of CO during analysis. The mixed halide complexes also proved difficult to analyse due to their lack of stability, and in the case of *cis*-$Fe(CO)_4IBr$ this problem was remedied by combining *cis*-$Fe(CO)_4Br_2$ and *cis*-$Fe(CO)_4I_2$ in a 1:1 mixture in the NMR tube just prior to spectral acquisition. For *cis*-$Fe(CO)_4IBr$ three ^{13}C NMR resonances are expected in a 2:1:1 intensity ratio; one signal for the two CO ligands *trans* to each other (axial) and one signal each for the *cis* CO ligands (equatorial) but *trans* to different halogens. Therefore, the spectrum of a 1:1 mixture of *cis*-$Fe(CO)_4Br_2$ and *cis*-$Fe(CO)_4I_2$ would be expected to contain seven peaks if the halogen exchange is slow on the NMR timescale, and this was indeed the case, as shown in Fig. 3 with the features due to the different complexes marked. This spectrum also allows for the direct assignment of the *cis*-$Fe(CO)_4IBr$ resonances at 202.6, 201.3 and 196.3 ppm due to their different intensities. Therefore, as the signal at 196.3 ppm has approximately twice the intensity of those at 202.6 and 201.3 ppm, it must arise from the axial CO ligands *trans* to each other, with those at

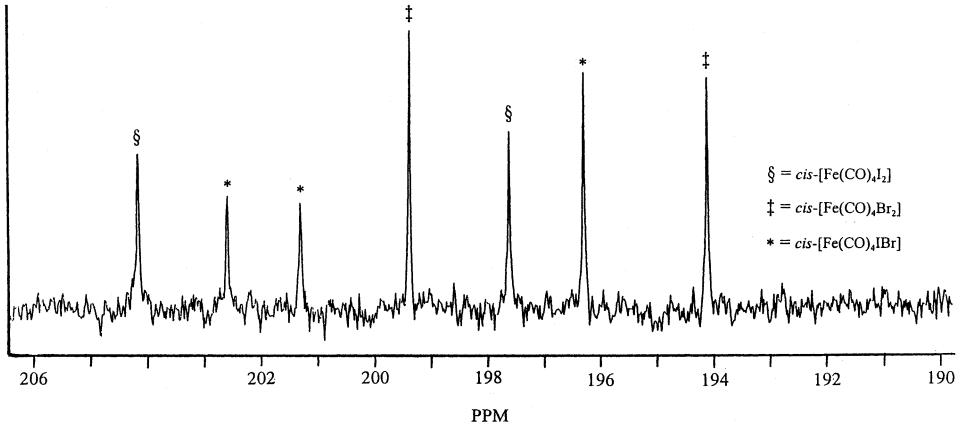

Fig. 3. $CDCl_3$ solution ^{13}C NMR of a mixture of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$.

202.6 and 201.3 ppm from the equatorial CO ligands *cis* to each other, but *trans* to I and Br, respectively. This assignment can then be extended to *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ where the 204.2 and 199.4 ppm signals can be assigned to the equatorial CO ligands *trans* to the halogen, whereas the 197.7 and 194.1 ppm features can be assigned to the axial CO ligands *trans* to CO. These assignments are the reverse of those given previously for *cis*-$Fe(CO)_4I_2$ [14], but as this was based on the coupling patterns in the analogous *cis*-$Os(CO)_4H_2$ complexes, we believe that our assignments based on the mixed halogen complexes are more likely to be the correct ones. The ^{13}C NMR spectrum of *cis*-$Fe(CO)_4ICl$ was very noisy due to the lack of sample stability, and this should be borne in mind when consulting the data in Table 3.

3.4. Matrix isolation infrared studies

Having observed halogen exchange in solution, experiments were performed to check whether halogen exchange also occurred in the vapour phase. Mass spectrometry was initially employed, firstly with *cis*-$Fe(CO)_4IBr$ to see if it was sufficiently stable as a vapour phase species, and subsequently, the vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$. All complexes gave fragmentation patterns involving the loss of both carbon monoxide and halogen as previously reported [17]. When *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ were combined in the vapour phase in the mass spectrometer, the fragmentation pattern characteristic of *cis*-$Fe(CO)_4IBr$ was observed, in addition to those characteristic of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$. Whilst this is reasonable evidence of halogen exchange in the vapour, it should be remembered that the ionisation process for mass spectrometry is very energetic, and the apparent composition may not be representative of the true vapour phase behaviour. Therefore, infrared studies of the vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ were also conducted using matrix isolation techniques. Argon and nitrogen were used as the matrix gases and the absorption bands observed in the 4000–550cm^{-1} region are given in Tables 1 and 2. As to be expected, the ν_{CO} modes are shifted to slightly higher frequency for the matrix isolated species compared with the solution data, and with the N_2 matrix data blue shifted with respect to the Ar matrix data. Because the argon matrix IR spectra of *cis*-$Fe(CO)_4Br_2$ and *cis*-$Fe(CO)_4IBr$ were complicated by site effects, the vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ was only carried out in dinitrogen matrices. Fig. 4 shows the nitrogen matrix infrared spectra in the ν_{CO} region from samples of (a) *cis*-$Fe(CO)_4I_2$, (b) *cis*-$Fe(CO)_4Br_2$, (c) *cis*-$Fe(CO)_4IBr$ and (d) the vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$. Matrix isolation experiments with *cis*-$Fe(CO)_4Cl_2$ were not possible due to extensive sample decomposition under vacuum. The spectrum showing the vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ (Fig. 4(d)) illustrates that whilst the spectral components from *cis*-$Fe(CO)_4I_2$ predominate, bands due to the formation of *cis*-$Fe(CO)_4IBr$ are clearly visible and are marked with an asterisk. Therefore, this is clear evidence that vapour phase halogen exchange is occurring between *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ resulting in the formation of *cis*-$Fe(CO)_4IBr$, and that the most likely mechanism in this case involves a seven-coordinate, halogen bridged, dimeric intermediate.

3.5. Fe K-edge XAFS studies

In order to obtain structural data for these complexes, Fe K-edge XAFS experiments were carried out on *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$, but not on *cis*-$Fe(CO)_4IBr$ because the presence of very significant proportions of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ would

[d] For *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ all the features are tabulated.

make the analysis effectively impossible. In order to obtain the XAFS data from the highest purity sample, and to reduce the problems of self-absorption by the iodine in *cis*-$Fe(CO)_4I_2$, the samples were vacuum sublimed in-situ into a methane matrix at 15 K. The experimental Fe K-edge XAFS and Fourier transforms as well as the theoretical fits for *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ isolated in methane matrices at 9 K are shown in Fig. 5, with values of the refined parameters given in Table 4. Also included in Table 4 are the literature structural values for $Fe(CO)_5$ from the most recent gas-phase electron diffraction [39] and single-crystal X-ray diffraction studies [40]. Fe K-edge XAFS data for $Fe(CO)_5$ have been obtained and analysed previously by us using EXCURV90 [23] and this data has now been refitted using EXCURV98 using the same phase shifts as for the iron carbonyl halides. Although small differences (ca. 0.01–0.02 Å) in the axial and equatorial Fe–C bond lengths have been observed in the diffraction studies [39,40], the ordering was actually reversed between the two techniques. A recent theoretical study [41] has tried to reconcile these differences, and indicates slightly longer (0.068 Å) axial Fe–C bond lengths than equatorial Fe–C bond lengths, but only when a relatively high level of theory (DZP B3LYP) was used. The differences in the axial and equatorial Fe–C bond lengths from the diffraction experiments or theory are too small to be detected by XAFS (to resolve a difference of 0.02 Å requires a data set of ca. 75 $Å^{-1}$ [42]) and therefore as expected there was no statistical improvement in the quality of the fit when two shells of CO ligands were used rather than one. However, it is clear that the agreement between Fe K-edge XAFS and the other structural methods for the Fe–C distances is

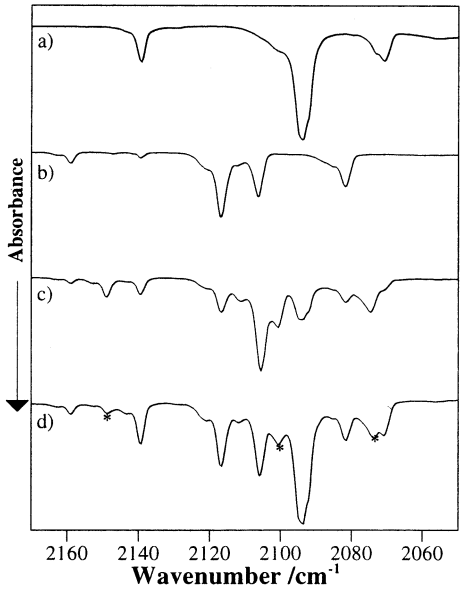

Fig. 4. Nitrogen matrix infrared spectra in the ν_{CO} region for (a) *cis*-$Fe(CO)_4I_2$, (b) *cis*-$Fe(CO)_4Br_2$, (c) *cis*-$Fe(CO)_4IBr$ and (d) vapour phase combination of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$.

better for the refinements using EXCURV98 rather than EXCURV90, therefore an even better improvement would be expected in the quality of the refined parameters for *cis*-$Fe(CO)_4I_2$ as the previous analysis made use of EXCURV88. The only structurally characterised iron(II) complex which has carbonyl ligands both *trans* to CO and *trans* to a halogen is $[Fe(CO)_3I_2(C(O)CH_3)]^-$ [43]. This has Fe–C bond lengths of 1.781 Å for CO *trans* to I, and 1.826 and 1.869 Å for the two CO ligands *trans* to each other, as well as Fe–I bond lengths of 2.632 and 2.686 Å. Although a difference of ca. 0.1 Å could just be resolved, any spread of distances would rule this out. Therefore, in the case of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ the data would only fit to one significant Fe–C shell. The shorter average Fe–C bond length for $Fe(CO)_5$ (1.81(2) Å) compared with *cis*-$Fe(CO)_4I_2$ (1.87(2) Å) or *cis*-$Fe(CO)_4Br_2$ (1.85(2) Å) is expected on the basis of the relative position of the ν_{CO} modes. The small difference between the Fe–C bond lengths for *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ are about the same as the confidence limits, and therefore their significance should not be over interpreted. Like-

wise the differences in Fe–C bond lengths between *cis*-$Fe(CO)_4Br_2$ and *trans*-$Fe(CO)_4Br_2$ (Fe–C, 1.87 Å) [22] are also probably not statistically significant. However, because our current analysis methods give better values for $Fe(CO)_5$, we believe that the bond lengths reported herein for *cis*-$Fe(CO)_4I_2$ are more accurate than those we have published previously [24]. The Fe–I bond length of 2.63(3) Å in *cis*-$Fe(CO)_4I_2$ obtained from the XAFS data is in very good agreement with those for related complexes derived from crystallography [43–49]. The accuracy of Fe–Br distances from Fe K-edge XAFS has been demonstrated previously, where the Fe–Br bond lengths from a single-crystal X-ray study [50] published after our XAFS study [51] were within 0.01 Å of our values for both the high- and low-spin states of $Fe(dppen)Br_2 \cdot 2Me_2CO$. Therefore, we believe that the Fe–Br bond length of 2.43(3) Å is accurate.

4. Conclusions

Using a range of spectroscopic techniques, this work has shown that both solution and vapour phase halogen exchange reactions occur between *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ leading to the formation of *cis*-$Fe(CO)_4IBr$. Although we have not been able to elucidate the detailed mechanism of the halogen exchange, on the basis that both solution and vapour phase exchange has been observed, it is most likely an associative mechanism with a seven-coordinate transition state probably involving halogen bridging ligands. The fact that a *cis* complex results from the halogen exchange indicates that in the absence of light this must be the thermodynamically preferred isomer. In addition, this work has provided the first spectroscopic characterisation of *cis*-$Fe(CO)_4IBr$ and *cis*-$Fe(CO)_4ICl$ and has also assisted in resolving a number of unanswered questions for the well known, *cis*-$Fe(CO)_4X_2$ (X = I, Br, Cl) complexes. An unambiguous assignment of the solution ^{13}C NMR resonances for these compounds is proposed with carbonyl groups *trans* to halogens having a higher chemical shift than those *cis* to halogens. The cross halogenation reaction of *cis*-$Fe(CO)_4I_2$ and *cis*-$Fe(CO)_4Br_2$ leading to the formation of *cis*-$Fe(CO)_4IBr$ has assisted in this characterisation. XAFS studies have provided the first structural data for *cis*-$Fe(CO)_4Br_2$ and improved structural data for *cis*-$Fe(CO)_4I_2$.

Received 14 February 2000; accepted 29 March 2000

Abstract

The synthesis and characterisation of $(PPh_4)_2[M(CN)_4O(pz)]\cdot 3H_2O$ (M = Mo or W; pz = pyrazine) are presented. The salts are reactive towards molecular oxygen, both in solution and in the solid state, with formation of $(PPh_4)_2[M(CN)_4O(O_2)]$. The X-ray crystal structure of the molybdenum compound confirmed the presence of a peroxo ligand *cis* to the M=O bond; the O–O bond distance is 1.41 Å. The IR spectra exhibit two absorption bands in the 950–850 cm^{-1} region assigned to the terminal M=O group [917 (Mo) and 933 (W) cm^{-1}] and the peroxo group [893 (Mo) and 871 (W) cm^{-1}]. The possible mechanism of molecular oxygen uptake by pyrazine complexes is discussed. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: Molybdenum complexes; Tungsten complexes; Pyrazine complexes; Peroxo ligands; Crystal structures

1. Introduction

It is well known that in aqueous solutions tetracyanodioxometallates(IV), $[M(CN)_4O_2]^{4-}$ (M = Mo, W) undergo stepwise protonation reactions

$$[M(CN)_4O_2]^{4-} + H^+ \overset{K_1}{\rightleftharpoons} [M(CN)_4O(OH)]^{3-} \quad (1)$$

$$[M(CN)_4O(OH)]^{3-} + H^+ \overset{K_2}{\rightleftharpoons} [M(CN)_4O(H_2O)]^{2-} \quad (2)$$

with the equilibrium constants given by: $\log K_1 = 13.00$, $\log K_2 = 9.70$ and $\log K_1 = 11.60$, $\log K_2 = 7.76$ for M = Mo and W, respectively [1,2]. It is also known that the $[M(CN)_4O(H_2O)]^{2-}$ ion easily undergoes a considerable number of substitution reactions. It reacts with a variety of monodentate ligands yielding complexes of general formula $[M(CN)_4O(L)]^{(n+2)-}$, where $L = CN^-$, NCS^-, F^-, N_3^-, HCN and pyridine (py) [2–5].

$$[M(CN)_4O(H_2O)]^{2-} + L^{n-} \rightarrow [M(CN)_4O(L)]^{(n+2)-} + H_2O \quad (3)$$

Bidentate ligands are coordinated according to the reaction

$$[M(CN)_4O(H_2O)]^{2-} + LL^{n-} \rightarrow [M(CN)_3O(LL)]^{(n+1)-} + H_2O + CN^- \quad (4)$$

where LL = 2,2′-bipyridyl (bipy), 1,10-phenanthroline (phen), pyridine-2-carboxylate (pic) and several Schiff bases [6]. There is also one known example of a neutral seven-coordinate complex $[M(CN)_2O(LLLL)]$ formed in the reaction

$$[M(CN)_4O(H_2O)]^{2-} + LLLL \rightarrow [M(CN)_2O(LLLL)] + H_2O + 2CN^- \quad (5)$$

where the tetradentate ligand LLLL = *N*,*N*′-bis[1-(pyridin-2-yl)ethylidene]ethane-1,2-diamine [7].

The considerable number of relatively fast reactions of $[M(CN)_4O(H_2O)]^{2-}$ with different ligands prompted us to use a similar procedure to obtain tetracyanocomplexes with pyrazine (pz), which forms a variety of complexes with different transition metals [8,9]. The pyrazine ligand seemed interesting for us due to its small dimensions, which imply that the steric factor does not interfere with its coordination and, moreover, it can act as a monodentate ligand or as a bridging ligand. We have found, however, that the only species formed under our experimental conditions was

$[M(CN)_4O(pz)]^{2-}$, in which pyrazine is monodentate. The syntheses of new complexes, with their spectroscopic and physicochemical characterisation, and their reactivity towards molecular oxygen are the subject of this report. There is only one known example of molecular oxygen uptake by a similar type of complex. The anhydrous salt $(PPh_4)_3[Mo(CN)_5O]$ has been reported [10] to react with dioxygen according to the equation

$$(PPh_4)_3[Mo^{IV}(CN)_5O] + O_2 \rightarrow (PPh_4)_2[Mo^{VI}(CN)_4O(O_2)] + (PPh_4)CN \quad (6)$$

In this paper we present the spectroscopic and physicochemical characteristics of peroxo complexes of formula $(PPh_4)_2[M(CN)_4O(O_2)]$ obtained by us in the reaction of hydrated pyrazine salts with molecular oxygen. We also discuss the mechanism of molecular oxygen incorporation, our proposal differing from that presented earlier [11].

2. Experimental

2.1. Materials

$K_3Na[M(CN)_4O_2]\cdot 6H_2O$ (M = Mo or W) were prepared as described in the literature [12], and their purity confirmed by their IR spectra. Tetraphenylphosphonium chloride [$(PPh_4)Cl$], pyrazine (pz), triphenylphosphine (PPh_3) and standard laboratory reagents were of analytical grade (Sigma, Aldrich) and used as supplied.

2.2. Syntheses

Tetraphenylphosphonium tetracyanooxopyrazinemolybdate(IV) was prepared as its trihydrate, $(PPh_4)_2[Mo(CN)_4O(pz)]\cdot 3H_2O$ (**1**), by dissolving 2.80 g (5.8 mmol) of $K_3Na[Mo(CN)_4O_2]\cdot 6H_2O$ and 1.92 g (24 mmol) of pz in 15 ml of water. The pH of the solution was adjusted to ca. 8 with 1 M HCl and a solution of 4.5 g (12 mmol) of $(PPh_4)Cl$ in 15 ml of water added. The resulting green crystals were filtered off, washed four times with water and dried in air. Yield: 5.80 g (97%). *Anal.* Found: C, 65.80; H, 4.96; N, 8.09. Calc. for $C_{56}H_{50}MoN_6O_4P_2$: C, 65.37; H, 4.90; N, 8.17%.

Tetraphenylphosphonium tetracyanooxopyrazine tungstate(IV) was prepared as its trihydrate, $(PPh_4)_2[W(CN)_4O(pz)]\cdot 3H_2O$ (**2**), by dissolving 3.3 g (5.8 mmol) of $K_3Na[W(CN)_4O_2]\cdot 6H_2O$ and 1.92 g (24 mmol) of pz in 15 ml of water. The pH of the solution was adjusted to ca. 7 with 1 M HCl. It was heated to 50°C for ca. 20 min, followed by addition of 4.5 g (12 mmol) of $(PPh_4)Cl$ in 15 ml of water. The resulting dark green crystals were filtered off, washed four times with water and dried in air. Yield: 2.46 g (38%). *Anal.* Found: C, 60.40; H, 4.77; N, 7.53. Calc. for $C_{56}H_{50}N_6O_4P_2W$: C, 60.22; H, 4.51; N, 7.52%.

Tetraphenylphosphonium tetracyanooxoperoxomolybdate(VI), $(PPh_4)_2[Mo(CN)_4O(O_2)]$ (**3**), was prepared by extraction of 1.1 g (1.07 mmol) of **1** three times with 30 ml of acetone and filtering the extracts. The resulting yellow filtrates were combined and the solvent was evaporated in air at room temperature within 20 min. The yellow crystals were washed three times with ethanol and dried in air. Yield: 0.46 g (46%). *Anal.* Found: C, 67.38; H, 4.25; N, 5.94. Calc. for $C_{52}H_{40}MoN_4O_3P_2$: C, 67.39; H, 4.35; N, 6.05%.

Tetraphenylphosphonium tetracyanooxoperoxotungstate(VI), $(PPh_4)_2[W(CN)_4O(O_2)]$ (**4**), was prepared by dissolving 0.45 g (0.4 mmol) of **2** in 30 ml of acetonitrile. After 60 min, the initially yellow solution turned colourless; it was evaporated in air at room temperature. The resulting white product was washed three times with ethanol and dried in air. Yield: 0.35 g (85%). *Anal.* Found: C, 61.34; H, 3.92; N, 5.29. Calc. for $C_{52}H_{40}N_4O_3P_2W$: C, 61.55; H, 3.97; N, 5.52%.

2.3. Reaction of $(PPh_4)_2[M(CN)_4O(O_2)]$ with molecular oxygen

The salts **3** or **4** were dissolved in acetonitrile and left in air for about 2 h. In the case of salt **4** no changes were observed and after evaporation of solvent **4** was quantitatively recovered. In the case of **3** its yellow colour disappeared, and after removal of solvent by evaporation a white product of formula $(PPh_4)_2[Mo_2O_7]$ was isolated. IR: $\nu(Mo{=}O) = 880\ cm^{-1}$, $\nu(Mo{-}O{-}Mo) = 790\ cm^{-1}$. *Anal.* Found: C, 58.06; H, 3.92; N, 0.06. Calc. for $C_{48}H_{40}Mo_2O_7P_2$: C, 58.66; H, 4.07; N, 0.00%.

2.4. Analytical methods and physical measurements

Carbon, nitrogen and hydrogen were determined by organic microanalysis. UV–Vis absorption spectra (Shimadzu 2101 PC) were recorded in the normal way. Reflectance spectra were measured in $BaSO_4$ pellets versus $BaSO_4$ as a reference (Shimadzu 2101 PC equipped with ISR-260 attachment). IR spectra were measured in KBr pellets on a Bruker IFS 48 spectrometer. ^1H NMR spectra in $CDCl_3$ were recorded on a Tesla BS-567A spectrometer. ESR spectra were measured on a Bruker ELEXSYS spectrometer at room and liquid nitrogen temperatures using diphenylpicrylhydrazide (dpph) as an internal standard. To estimate the amount of paramagnetic centres, $VOSO_4$ was used as standard.

2.5. Crystal structure determination

Crystals of **3** suitable for X-ray crystallography were selected from the recrystallised material prepared as described above. Crystal data for **3**, and a summary of

data collection and structure refinement parameters, are given in Table 1. The positions of Mo and P atoms were determined by Patterson methods; the remaining non-hydrogen atoms were located in successive difference Fourier syntheses. Hydrogen atoms were included in the structure factor calculations at idealised positions and were not refined. In the final refinement cycle all non-hydrogen atoms were refined anisotropically. The largest peaks in the final difference maps were located near the Mo atom. All calculations were performed using SHELXTL-PC [13]; scattering factors and anomalous dispersion factors were those given in SHELXTL.

3. Results

3.1. Characterisation of the complexes

The reaction of $[M(CN)_4O(H_2O)]^{2-}$ with pyrazine under appropriate conditions results in aqua ligand substitution and pyrazine coordination according to the equation

$$[M(CN)_4O(H_2O)]^{2-} + pz \leftrightarrows [M(CN)_4O(pz)]^{2-} + H_2O \quad (7)$$

The equilibrium lies strongly towards the reactants — formation of the product complex can be observed only in concentrated solutions in the presence of a large excess of pyrazine. Complexes **1** and **2** were isolated as tetraphenylphosphonium salts. The $(PPh_4)^+$ cation forms insoluble salts only with the product complex thus shifting equilibrium (7) to the right.

The results of analysis and physicochemical measurements indicate that pyrazine acts as a monodentate ligand; the possibility of its acting as a bridging ligand between two complex units can be excluded. On the basis of the crystal structure data of all known $[M(CN)_4O(L)]^{n-}$ type complexes [3,5,11], the pyrazine ligand is expected to be in the position *trans* to the M=O bond.

Both light green **1** and dark green **2** are diamagnetic. In the solid state they are stable when kept under restricted anaerobic conditions. The salts are almost insoluble in water, but soluble in polar organic solvents such as MeCN, CH_2Cl_2 and DMSO. In dilute aqueous solutions, the only species which can be detected by visible spectroscopy is the $[M(CN)_4O(H_2O)]^{2-}$ ion, even in the presence of a large excess of pyrazine. In organic solvents in the presence of air, a fast change of colour from green to yellow is observed. After evaporating the solvent, yellow **3** and white **4** were isolated, indicating that the colour change is connected with molecular oxygen uptake:

$$[M(CN)_4O(pz)]^{2-} + O_2 \rightarrow [M(CN)_4O(O_2)]^{2-} + pz \quad (8)$$

Similar colour changes were observed when solid salts **1** and **2** were kept in air. The final products of solid state reactions were found to be identical with those isolated from the solutions. They were found not to be contaminated with free pyrazine thanks to its high volatility. The salts **3** and **4** are insoluble in water and alcohols and soluble in common organic solvents, such as MeCN, $CHCl_3$, CH_2Cl_2, DMSO and DMF. As solids they are stable in air at room temperature. In solution, complex **4** is thermally stable, whereas salt **3** undergoes slow decomposition to $(PPh_4)_2[Mo_2O_7]$ as confirmed by the elemental analysis and IR spectra of the product formed.

Molecular oxygen uptake by cyano-oxo complexes of Mo(IV) was found only for anhydrous $(PPh_4)_3[Mo(CN)_5O]$, and was postulated to be impossible for hydrated salts [11]. Here we have succeeded, for the first time, in demonstrating molecular oxygen uptake by the hydrated oxotetracyano complexes and in isolating the tungsten salt analogous to $(PPh_4)_2[Mo(CN)_4O(O_2)]$ described in the literature [10].

3.2. Description of the structure of **3**

The structure of **3** is presented in Fig. 1 and selected bond distances and angles are collected in Table 2. The

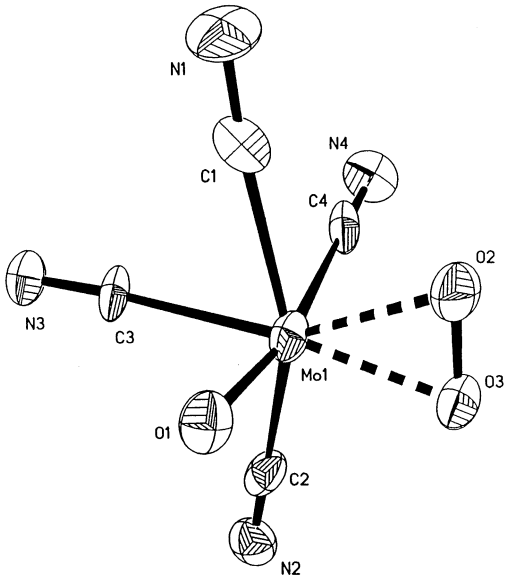

Fig. 1. Structure of the $[Mo(CN)_4O(O)_2]^{2-}$ ion in **3**.

anion has a distorted pentagonal bipyramidal geometry with the O–O group *cis* to the Mo=O bond. The O–O bond distance of 1.41 Å is typical for the peroxo group [14–17] and thus the formal oxidation state of the metal is +6.

A salt of the same formula was obtained earlier by Arzoumanian et al. [10] in the reaction of $(PPh_4)_3[Mo(CN)_5O]$ in CH_2Cl_2 with molecular oxygen and its structure was determined by X-ray crystal analysis. There are, however, some differences in the bond distances and angles between salt **3** and that described in the literature. The Mo(1)–O(1) bond distance is shorter (1.671(10) compared with 1.694(3) Å) and the Mo(1)–C(4) and Mo(1)–C(3) bond distances are longer (2.296(16) compared with 2.197(4) Å and 2.196(11) compared with 2.167(5) Å, respectively). It is difficult to compare the bond angles with the literature data due to some mistakes in the assignments of angles (e.g. the O(1)–Mo(1)–C(4) angle (O3–Mo–C4 in their numbering scheme) was reported to be 88.20°, which is impossible for atoms in *trans* positions). It seems, however, that there are probably some differences in bond angles in the structures of both salts, though the angle subtended by the peroxo ligand is the same in both determinations (43.1(4)° in **3**, 43.2(2) in Ref. [10]). The O–O bond distance in our crystal, 1.410(14) Å, is the same as that in the earlier reference, 1.416(5) Å; these distances do not differ significantly from that in the analogous complex $[Mo(CN)_3O(O_2)(hmpa)]^-$, 1.397(10) Å [10].

Table 2

3.3. IR spectra

Selected IR data for salts **1** to **4** are presented in Table 3. For comparison data for pyrazine and $(PPh_4)Cl$ are also included.

The IR spectra of salts **1** and **2** show bands at 974 cm^{-1} (**1**) and at 969 cm^{-1} (**2**) which can be assigned to the stretching vibrations of the M=O group. The pyrazine complexes have higher values of ν(M=O) than analogous six-coordinate cyano-oxo complexes of Mo(IV) and W(IV) with monodentate ligands having the nitrogen atom in the *trans* position to the M=O bond [3,5,11,18] (for $L = N_3^-$, CH_3CN, HCN band positions are at 953, 940 and 940 cm^{-1} for Mo and for $L = N_3^-$, NCS^-, py at 952, 954 and 964 cm^{-1} for W, respectively). This suggests weak bonding of pyrazine and locates the pyrazine ligand between pyridine (ν(W=O) = 964 cm^{-1}) and H_2O (ν(W=O) = 980 cm^{-1}) in the series of ligands arranged according to the decreasing value of ν(W=O), viz.

$$OH^- > CN^- > F^- > N_3^- > NCS^- > \text{pyridine} > \textit{pyrazine} > H_2O$$

given in the literature [5]. The analogous series for Mo complexes [3,10,11,19] is:

$$OH^- > CN^- > HCN > CH_3CN > N_3^- > \textit{pyrazine} > H_2O.$$

In the CN stretching region four bands are observed (Table 3). The larger number of bands with respect to analogous complexes of the $[M(CN)_4O(L)]^{n-}$ type indicates lower symmetry for the anions in **1** and **2**.

The 400–1800 cm^{-1} region is dominated by overlapping bands of $(PPh_4)^+$ and pyrazine. There are four bands assigned to coordinated pyrazine, at 1017, 1037, 1147 and 1415 cm^{-1} for salt **1** and at 1017, 1040, 1148 and 1415 cm^{-1} for salt **2**. The positions of the bands

[a] s, strong; m, medium; w, weak; v, very; sh, shoulder; b, broad.

are only slightly shifted in comparison with free pyrazine (1010, 1036, 1145 and 1408 cm^{-1} [20]) in agreement with weak bonding of pyrazine to the metal centre.

The IR spectra of **3** and **4** exhibit bands at 917 and 933 cm^{-1}, assigned to the respective M=O stretching vibrations. The bands at 893 cm^{-1} (**3**) and 871 cm^{-1} (**4**) correspond to the stretching vibrations of side on bonded peroxo group [17,21]. The positions of the ν(M=O) and ν(O–O) bands are close to those of peroxo complexes of molybdenum(VI) and tungsten(VI) without cyanide ligands [14,15,22].

In the CN stretching region the IR spectra show bands of very low intensity at 2127, 2150 and 2201 cm^{-1} for **3** and 2132, 2154 and 2199 cm^{-1} for **4**. The unusually high position of these CN vibrations in comparison with the cyano-oxo complexes of Mo(IV) and W(IV) is consistent with an increase of the formal oxidation state of the central atom resulting in the decrease of π-back donation which shifts the CN stretching band towards higher energy.

3.4. ^1H NMR spectra

^1H NMR spectra for solutions of salts **1** and **2** exhibit signals of protons of pyrazine, aromatic rings of $(PPh_4)^+$ cations and water molecules. The four pyrazine protons give a singlet at 8.48 ppm for **1** and at 8.60 ppm for **2**, in comparison with 8.60 ppm for free pyrazine [23]. One could expect that pyrazine coordinated as a monodentate ligand should exhibit two doublets of two groups of protons, positioned farther and closer to the metal centre, respectively [9]. The singlet resonances for salts **1** and **2** indicate very weak bonding of pyrazine which causes the protons of pyrazine to be chemically equivalent. The upfield shift of the signal for salt **1** shows that in $CDCl_3$ solution weakly bonded pyrazine is still coordinated whereas for salt **2** decomposition accompanied by the release of pyrazine occurs.

3.5. UV–Vis spectra

In the solid state reflection spectra show bands at 232, 270, 303 and 650 nm for salt **1** and at 229, 270, 309 and 620 nm for salt **2**. In aqueous solutions, the bands observed in the visible region at 610 and 562 nm (for salts **1** and **2**, respectively) can be attributed to the $[M(CN)_4O(H_2O)]^{2-}$ ions which are formed according to equilibrium (7). In organic solvents such as MeCN, CH_2Cl_2 and acetone fast formation of **3** and **4** is observed.

Fig. 2 presents typical spectral changes observed for a solution of **1** in dichloromethane in the presence of air, together with the spectrum of **3** in the same solvent. The decrease of the band at ca. 621 nm, characteristic of a d–d transition in **1**, and the growth of a new band at ca. 393 nm, connected with dioxygen uptake and formation of **3**, are observed. The diffuse isosbestic point (Fig. 2) indicates that two species are dominant in the system.

The reflection spectra of salts **3** and **4** consist of bands originating from the respective cations at 231 and 276 nm and at 237 and 281 nm, and bands at 420 and 336 nm which can be assigned to charge-transfer to metal (CTTM) transitions. In organic solvents the latter bands are shifted towards higher energy, e.g. in acetonitrile the band maximum is observed at 393 (**3**) and 323 nm (4) (Fig. 3) with molar absorptivity equal to 465 and 635 M^{-1} cm^{-1}, respectively.

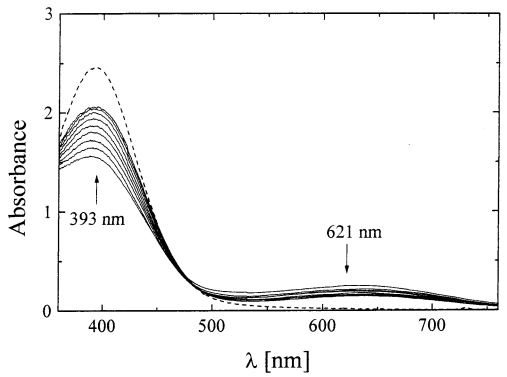

Fig. 2. Spectral changes of **1** in dichloromethane solution. The arrows show the direction of changes with time (first spectrum measured after 30 s from dissolution, time interval = 90 s). For comparison the spectrum of **3** is given (dashed curve). Conc. = 5.3×10^{-3} M, optical path = 1 cm.

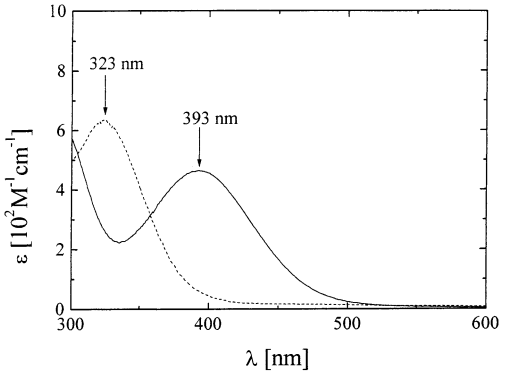

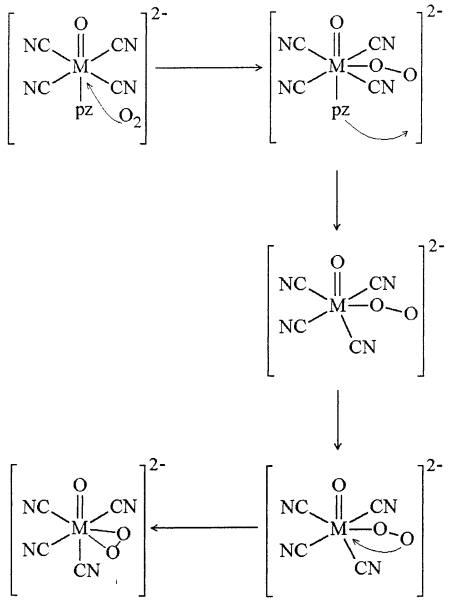

Fig. 3. Electronic spectra of **3** (solid curve) and of **4** (dashed curve) in acetonitrile.

3.6. ESR spectra

The ESR spectra for salts **3** and **4** consist of very weak signals, which are typical for paramagnetic centres M(V)–d^1 [24] with g factors (at room temperature) equal to 1.970 and 1.915, respectively. In the case of salt **3** in liquid nitrogen (77 K) an anisotropic signal is observed with $g = 1.915$ and 1.943 indicating the axial symmetry of the complex anion. The amount of M(V) centres in salts **3** and **4** is equal to 0.32 and 0.82%, respectively. This indicates that to some extent thermal charge transfer from the O_2^{2-} ligand to the metal occurs, resulting in M(V) and O_2^- formation.

4. Discussion

It was found earlier that anhydrous $(PPh_4)_3[Mo(CN)_5O]$ can react with molecular oxygen giving $(PPh_4)_2[Mo(CN)_4O(O_2)]$ [10]. It was also found that this reaction is possible only for the anhydrous salt and that hydrated salts are not reactive towards molecular oxygen [11]. We have now found that the hydrated tetracyano complexes of Mo(IV) and W(IV) of formula $[M(CN)_4O(pz)]^{2-}$ can react with molecular oxygen, both in solution and in the solid state. The presence of water molecules does not interfere with the reaction with dioxygen. This is probably caused by the fact that the weakly bonded pyrazine ligand does not participate in the network of hydrogen-bonds. Thus, the best site for nucleophilic attack of dioxygen seems to be in the vicinity of pyrazine, whereas the rest of the complex ion is surrounded by water molecules, hydrogen-bonded to cyano and oxo ligands, which hinder the reaction with O_2. It seems also that the dissociative mechanism proposed by Arzoumanian et al. [11] is not valid. In this case the incoming dioxygen should be in the *trans* position to the M=O bond, as found for all substitution reactions leading to the $[M(CN)_4O(L)]^{n-}$ ($n = 2, 3$) type complexes. In all these cases the coordinatively unsaturated $[M(CN)_4O]^{2-}$ does not undergo rearrangement in the coordination sphere and does not react with dioxygen. The associative mechanism presented in Scheme 1 seems more probable. In the first step the coordination of dioxygen occurs with the increase of coordination number to seven. Such a structure (distorted pentagonal bipyramid) was found by us earlier in $[Mo(CN)_2O(LLLL)]\cdot H_2O$ [7]. Release of pyrazine followed by a rearrangement in which a cyano group is transferred to the vacant *trans* position and the second oxygen of dioxygen is bonded to the metal centre could lead to the observed *cis*-tetracyanooxoperoxomolybdate(VI) anion.

Scheme 1. Proposed mechanism for molecular oxygen incorporation into the $[M(CN)_4O(pz)]^{2-}$ ion.

Abstract

The palladium complexes $[PdCl_2\{Ph_2P(CH_2)_nPPh_2\}]$ ($n = 1, 3, 4$) react with the bi- and tri-valent metal diethyldithiocarbamates $[M(S_2CNEt_2)_2]$ (M = Zn, Cd, Hg, Pb) and $[Mn(S_2CNEt_2)_3]$ in cold dichloromethane solution to afford salts of the general form $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]_2[MCl_4]$ in almost quantitative yield. X-ray crystal structures are reported for the salts $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]_2[MCl_4]$ ($n = 1, 4$; M = Cd: $n = 3$, M = Hg). Structural parameters, IR and NMR spectroscopic data for these salts are compared with similar data previously reported for salts of the related cation $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_2PPh_2\}]^+$. © 2000 Elsevier Science Ltd. 1. Introduction

While attempting the synthesis of heteronuclear bimetallic complexes containing bridging dithiocarbamate ligands we observed that many class b metal diethyldithiocarbamates react readily with the palladium(II) halide complexes $[PdX_2\{Ph_2P(CH_2)_2PPh_2\}]$ (X = Cl, Br) to afford halometallate salts containing the $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_2PPh_2\}]^+$ cation in essentially quantitative yield [1]. Two of these salts, $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_2PPh_2\}][MCl_2]$ (M = Cu, Ag) were characterised by X-ray diffraction methods [1]. Given the tendency of soft class b metal ions to bind strongly to S-donor ligands, the ease with which some of the softer metal ions investigated, notably Cd(II), Hg(II) and Ag(I), relinquished their dithiocarbamate ligands in favour of halide anions was somewhat unexpected. We have therefore sought to investigate the generality of this behaviour by examining the reactions of some metal dithiocarbamates with a range of other transition metal halide complexes. In the present paper we describe the synthesis and characterisation of a series of halometallate complexes containing the cations $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]^+$ ($n = 1, 3, 4$) and report X-ray crystal structures for the salts $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]_2[MCl_4]$ ($n = 1$, 4; M = Cd: $n = 3$, M = Hg). We also examine the effect of chelate ring size on the structural and spectroscopic parameters of the complex cations $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]^+$ ($n = 1$–4).

propane and 1,4-bis(diphenylphosphino)butane from Avocado and palladium chloride from Johnson Matthey. Metal dithiocarbamates were prepared from the metal nitrates and the sodium salt of the ligand in aqueous media and recrystallised from dichloromethane/petroleum spirit 60–80. Dichloro[bis(diphenylphosphino)methane]palladium(II), dichloro[1,3-bis(diphenylphosphino)propane]palladium and dichloro[1,4 - bis(diphenylphosphino)butane]palladium were prepared by dissolving palladium(II) chloride in acetonitrile under reflux and adding the stoichiometric amount of diphosphine to the filtered solution thus obtained. All complexes were recrystallised from dichloromethane. Instrumentation and other experimental details were as described in a preceding paper [1]. Analytical, IR and NMR data are given in Tables 1–3, respectively.

2.1.1. (*N*,*N*-Diethyldithiocarbamato)-[bis(diphenylphosphino)methane]palladium(II) tetrachlorozincate

Dichloro[bis(diphenylphosphino)methane]palladium (0.169 g, 0.30 mmol) and bis(*N*,*N*-diethyldithiocarbamato)zinc (0.054 g, 0.15 mmol) were stirred in dichloromethane (60 cm^3) for 1 h. The solution obtained was filtered and concentrated under reduced pressure to a small volume (ca. 5 cm^3). Diethyl ether (70 cm^3) was added to the concentrated solution and the precipitate obtained was filtered, washed with diethyl ether (3 × 10 cm^3) and dried in vacuo for 3 h. The product appears as a yellowish–white fine powder (yield 0.211 g, 94%; m.p. 148–150°C).

The following complexes were obtained by the same method and on a similar scale:

(*N*,*N* - Diethyldithiocarbamato)[bis(diphenylphosph-

ino)methane]palladium(II) tetrachlorocadmate as yellowish–white fine powder (yield 94%; m.p. 146–148°C).

(*N*,*N* - Diethyldithiocarbamato)[bis(diphenylphosphino)methane]palladium(II) tetrachloromercurate(II) as yellowish–white fine powder (yield 92%; m.p. 150–152°C).

2.1.2. (*N*,*N*-Diethyldithiocarbamato)[bis(diphenylphosphino)methane]palladium(II) tetrachloromanganate

Dichloro[bis(diphenylphosphino)methane]palladium (0.169 g, 0.30 mmol) and tris(*N*,*N*-diethyldithiocarbamato)manganese (0.075 g, 0.15 mmol) were stirred in dichloromethane (60 cm^3) for 1 h. The solution obtained was filtered and concentrated under reduced pressure to a small volume (ca. 5 cm^3). Diethyl ether (70 cm^3) was added to the concentrated solution and the precipitate obtained was filtered, washed several times with diethyl ether to remove all the tetraethylthiuram disulfide byproduct formed and dried in vacuo for 3 h. The product appears as a yellowish fine powder (yield 0.194 g, 88%; m.p. 131–133°C).

2.1.3. (*N*,*N*-Diethyldithiocarbamato)[1,3-bis(diphenylphosphino)propane]palladium(II) tetrachlorozincate

Dichloro[1,3 - bis(diphenylphosphino)propane]palladium (0.177 g, 0.30 mmol) and bis(*N*,*N*-diethyldithiocarbamato)zinc (0.054 g, 0.15 mmol) were stirred in dichloromethane (60 cm^3) for 1 h. The solution obtained was filtered and concentrated under reduced pressure to a small volume (ca. 5 cm^3). Diethyl ether (70 cm^3) was added to the concentrated solution and the precipitate obtained was filtered, washed with diethyl ether (3×10 cm^3) and dried in vacuo for 3 h. The product appears as a yellowish–white fine powder (yield 0.214 g, 92%; m.p. 167–170°C).

The following complexes were obtained by the same method and on a similar scale:

(*N*,*N*-Diethyldithiocarbamato)[1,3-bis(diphenylphosphino)propane]palladium(II) tetrachlorocadmate as yellowish–white fine powder (yield 94%; m.p. 178–180°C).

(*N*,*N*-Diethyldithiocarbamato)[1,3-bis(diphenylphosphino)propane]palladium(II) tetrachloromercurate(II) as yellowish–white fine powder (yield 94%; m.p. 163–165°C).

(*N*,*N*-Diethyldithiocarbamato)[1,3-bis(diphenylphosphino)propane]palladium(II) tetrachloroplumbate(II) as yellowish–white fine powder (yield 94%; m.p. 250–253°C).

2.1.4. (*N*,*N*-Diethyldithiocarbamato)[1,3-bis(diphenylphosphino)propane]palladium(II) tetrachloromanganate

Dichloro[1,3 - bis(diphenylphosphino)propane]palladium (0.177 g, 0.30 mmol) and tris(*N*,*N*-diethyldithiocarbamato)manganese (0.075 g, 0.15 mmol) were stirred in dichloromethane (60 cm^3) for 1 h. The solution obtained was filtered and concentrated under reduced pressure to a small volume (ca. 5 cm^3). Diethyl ether (70 cm^3) was added to the concentrated solution and the precipitate obtained was filtered, washed several times with diethyl ether to remove all the tetraethylthiuram disulfide byproduct formed and dried in vacuo for 3 h. The product appears as a yellowish fine powder (yield 0.214 g, 93%; m.p. 190–192°C).

2.1.5. (*N*,*N*-Diethyldithiocarbamato)[1,4-bis(diphenylphosphino)butane]palladium(II) tetrachlorozincate

Dichloro[1,4 - bis(diphenylphosphino)butane]palladium (0.181 g, 0.30 mmol) and bis(*N*,*N*-diethyldithiocarbamato)zinc (0.054 g, 0.15 mmol) were stirred in dichloromethane (60 cm^3) for 1 h. The solution obtained was filtered and concentrated under reduced pressure to a small volume (ca. 5 cm^3). Diethyl ether (70 cm^3) was added to the concentrated solution and the precipitate obtained was filtered, washed with diethyl ether (3×10 cm^3) and dried in vacuo for 3 h. The product appears as a yellowish–white fine powder (yield 0.218 g, 93%; m.p. 170–172°C).

The following complexes were obtained by the same method and on a similar scale:

(*N*,*N*-Diethyldithiocarbamato)[1,4-bis(diphenylphosphino)butane]palladium(II) tetrachlorocadmate as yellowish–white fine powder (yield 94%; m.p. 154–156°C).

(*N*,*N*-Diethyldithiocarbamato)[1,4-bis(diphenylphosphino)butane]palladium(II) tetrachloromercurate(II) as yellowish–white fine powder (yield 94%; m.p. 162–164°C).

(*N*,*N*-Diethyldithiocarbamato)[1,4-bis(diphenylphosphino)butane]palladium(II) tetrachloroplumbate(II) as yellowish–white fine powder (yield 93%; m.p. 158–160°C).

2.2. Crystallography

X-ray crystal structures have been determined for the complexes $[Pd(S_2CNEt_2)(Ph_2PCH_2PPh_2)]_2[CdCl_4]$. 4.0 $CHCl_3$ (**1**), $[Pd(S_2CNEt_2)(Ph_2PCH_2CH_2CH_2PPh_2)]_2$-$[HgCl_4]\cdot CH_2Cl_2\cdot H_2O$ (**2**) and $[Pd(S_2CNEt_2)(Ph_2PCH_2$-$CH_2CH_2CH_2PPh_2)]_2[CdCl_4]$ (**3**). Crystals of **1** were grown by the slow evaporation of a $CHCl_3$ solution, while crystals of **2** and **3** were obtained by the slow evaporation of $CH_2Cl_2/C_6H_5CH_3$ solutions. For the X-ray determination yellow plates of **1**, and yellow needles of **2** and **3**, were mounted on thin glass fibres using a fast setting epoxy resin. A total of 90 oscillation frames of 90 s exposure time with 2° rotation in ϕ were recorded using a Nonius Kappa CCD diffractometer, with detector to crystal distance of 25 mm. The crystals were indexed from the first ten frames using the DENZO package [2] and positional data were refined along with diffractometer constants to give the final unit cell parameters. Integration and scaling of the whole data-sets resulted in a total of 57 655 data (10 152 unique) for **1**, 16 765 data (7036 unique) for **2** and 61 497 data (6399 unique) for **3**, which were corrected for Lorentz and polarisation effects. The structures were solved using the direct methods option of SHELXS-86 [3] and developed via alternating least square cycles and difference Fourier synthesis (SHELXL-97 [4]) with the aid of the program RES2INS [5]. All non-hydrogen atoms were modelled anisotropically, while hydrogen atoms were assigned an isotropic thermal parameter 1.2 times

Refinement converged with $wR_2 = 0.1846$ which corresponds to a conventional R-factor of 0.0644 for data with $I > 2\sigma(I)$ for **1**, $wR_2 = 0.0755$ ($R_1 = 0.0295$) and $wR_2 = 0.0668$ ($R_1 = 0.0289$) for **2** and **3**, respectively. Crystal data and structural refinement parameters are given in Table 4, and selected bond angles and bond lengths are presented in Table 5.

3. Results and discussion

After the synthesis and characterisation of halometallate salts containing the $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_2PPh_2\}]^+$ cation [1] we sought to extend our investigations further by using a number of similar chelating diphosphines in place of dppe. The aim was to study the effect of varying the ring size formed upon coordination, investigate the relative coordinating abilities of these diphosphines and confirm whether the nature of the resulting products was similar to the ones already synthesised. The reaction stoichiometries were kept the same, however it was necessary to modify the solvent medium and reaction temperature. It was found that especially in the case of the dppm ligand, substantial decomposition of products occurred under reflux conditions. The reactions were therefore modified to take place in dichloromethane at room temperature. These conditions gave clean products and were therefore used for all the diphosphine starting materials employed. The products precipitated from the filtered and concentrated reaction solutions on addition of diethyl ether, and were isolated in essentially quantitative yield as air-stable powders. The complexes were characterised by elemental analyses, IR and NMR spectra, and X-ray diffraction methods. Their IR spectra displayed absorptions characteristic of coordinated dithiocarbamate ligands [ν(C–N) ca. 1525 cm^{-1}] [6] and of the tetrahedral $[MCl_4]^{2-}$ anions [ν_3(M–Cl) ca. 280 cm^{-1} (M = Zn) to ca. 220 cm^{-1} (M = Hg, Pb)] [7]. We were not able to unambiguously identify the ν_4(M–Cl) absorptions since these are relatively weak and occur very low (usually below 130 cm^{-1}), near the detection limit of the instrument employed. The proton NMR spectra are consistent with the stoichiometries and structures proposed for the complex cations. The $^{31}P\{^1H\}$ NMR spectra establish the chemical and magnetic equivalence of the two phosphorus atoms present in each complex cation, and confirm that the bis-(chelate) cations structurally characterised by X-ray diffraction methods for representative examples are common to all the complexes reported here. They also display the well-established relationship between ^{31}P chemical shifts and chelate ring size, in particular the anomalously low field resonances previously observed for chelated $Ph_2PCH_2CH_2PPh_2$ ligands, and attributed to a large deshielding effect characteristic of phosphorus nuclei in five member chelate rings [8]. This can be seen in Table 6, which includes data for both free and coordinated ligands.

X-ray crystal structure determinations were performed on representative examples of salts containing each of the three cations $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]^+$ ($n = 1$, 3 or 4). All three were found to contain square planar cations and tetrahedral $[MCl_4]^{2-}$ anions. The salient bond length and bond angle data for these structures are recorded in Table 5. For comparison purposes similar data previously collected [1] for salts containing the related $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_2PPh_2\}]^+$ cation are also included. Molecular structures showing atomic labelling schemes for compounds **1**–**3** are shown in Figs. 1–3, respectively.

Bond length and bond angle data for the four complex cations are similar to those previously reported for other dithiocarbamate and diphosphine complexes of

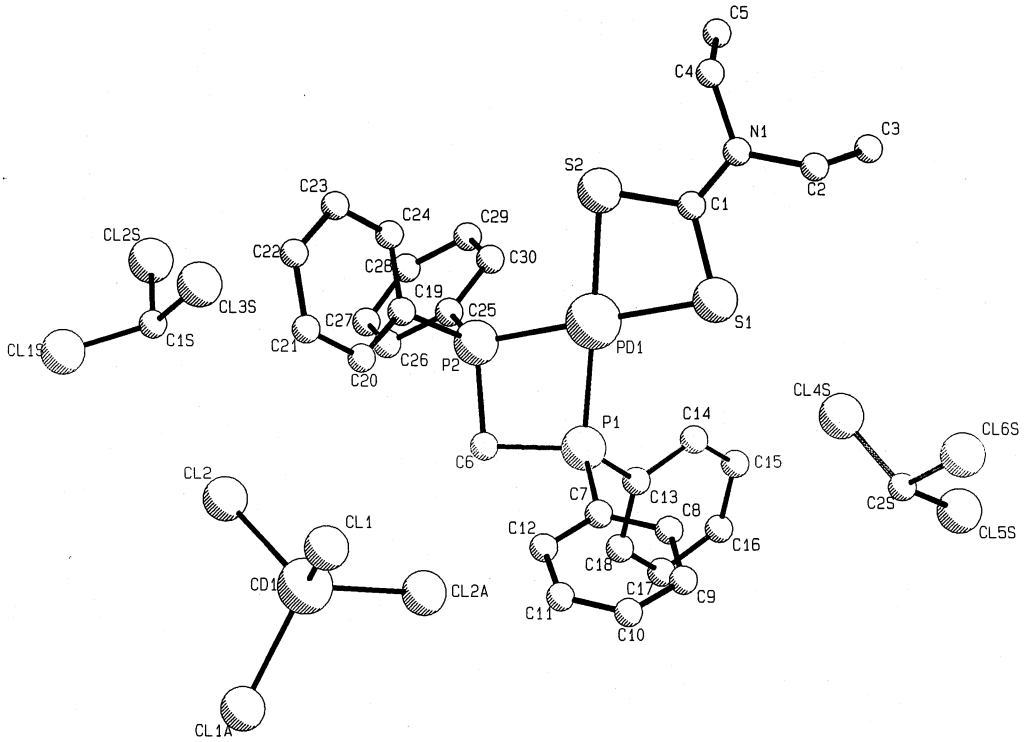

Fig. 1. Molecular structure for $[Pd(S_2CNEt_2)(Ph_2PCH_2PPh_2)]_2[CdCl_4]\cdot 4.0CHCl_3$ (**1**) showing atom labelling scheme.

palladium(II) [9]. In each case the relatively short S_2C–NEt_2 distance (ca. 1.310–1.329 Å) indicates the presence of a significant degree of double bond character arising from the $^{2-}S_2C{=}NEt_2^+$ tautomer of the dithiocarbamate ligand. The 'bite' angles of the dithiocarbamate and diphosphine ligands obviously impose considerable strain on the geometry of the square planar cation. The angles subtended at palladium by the two phosphorus donor atoms of the various diphosphines, $Ph_2P(CH_2)_nPPh_2$, increase from 72.90(5)° ($n = 1$) to 94.82(6)° ($n = 4$). However, these changes are accommodated within the coordination sphere of the palladium without any deviation from the strict planarity of the P_2PdS_2 moiety or any significant change in the coordination geometry of the dithiocarbamate ligand. In particular the angle subtended at palladium by the two sulfur atoms which reflects the narrow 'bite' angle of the dithiocarbamate ligand, remains essentially constant at 75.30–75.75°.

The tetrachlorometallate anions $[MCl_4]^{2-}$ (M = Cd, Hg) are essentially tetrahedral and display bond length and angle data similar to those previously reported for these species [10–13]. Metal chlorine distances range from 2.4482(19) to 2.4681(19) Å for M = Cd and from 2.4735(12) to 2.5093(11) Å for M = Hg. In each case the angles subtended at the metal centre by pairs of chloride ligands deviate from the ideal tetrahedral value of 109°28′ by ca. ± 5° (M = Cd) or ca. ± 7° (M = Hg).

Finally, the structures reveal the presence of a number of short contact distances between the chloride ligands of the MCl_4^{2-} anions and the phenyl hydrogens of the complex cations and the hydrogens of solvent molecules, which can be attributed to H-bonding interactions. The observed C–H···Cl distances found for complexes **1**–**3** are within the range of values associated

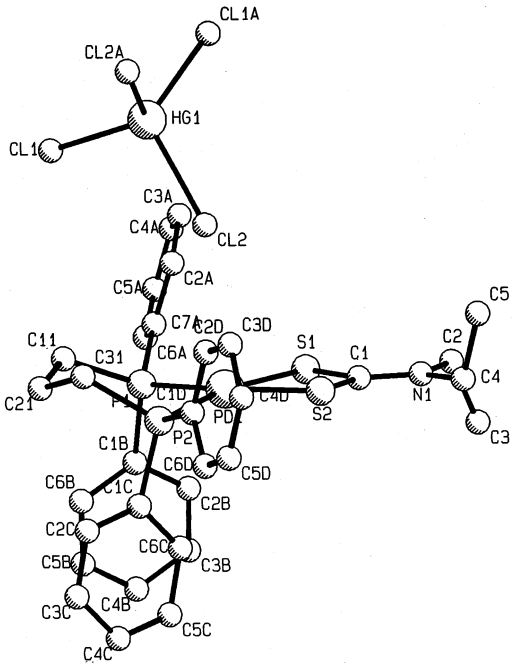

Fig. 2. Molecular structure for $[Pd(S_2CNEt_2)(Ph_2PCH_2CH_2CH_2PPh_2)]_2[HgCl_4]\cdot CH_2Cl_2\cdot H_2O$ (**2**) showing atom labelling scheme.

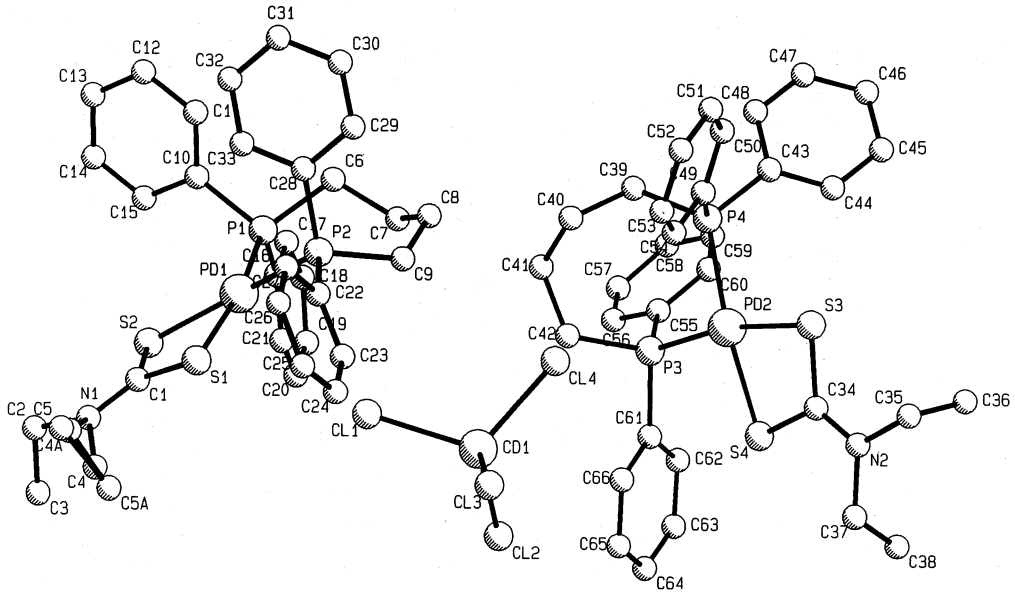

Fig. 3. Molecular structure for $[Pd(S_2CNEt_2)(Ph_2PCH_2CH_2CH_2CH_2PPh_2)]_2[CdCl_4]$ (**3**) showing atom labelling scheme.

with this type of interaction (H···Cl = 2.568–2.944 Å) [14–17]. Indeed the C–H···Cl distances are all at the lower end of the range, and suggest the presence of relatively strong C–H···Cl interactions, especially when $CHCl_3$ solvent molecules are involved.

The spectroscopic data recorded for the other complex salts of the general form $[Pd(S_2CNEt_2)\{Ph_2P(CH_2)_nPPh_2\}]_2[MCl_4]$ all appear to indicate the presence of essentially tetrahedral $[MCl_4]^{2-}$ anions similar to those found for the structurally characterised examples. Given the wide variety of cation dependent stoichiometries and coordination geometries known to exist for the various halometallate anions of zinc, cadmium and mercury [18] this observation was rather disappointing. Therefore, a small number of complexes containing cations of the general form $[Pd(S_2CNR_2)\{Ph_2P(CH_2)_nPPh_2\}]^+$ (R = Me, Bu^n, Morph) in which the identity of the dithiocarbamate ligand varied were prepared. However, IR data strongly suggested that these salts also contain tetrahedral $[MCl_4]^{2-}$ anions similar to those described above. Their characterisation was therefore not pursued further.

4. Supplementary data

Supplementary data are available from CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request quoting the deposition numbers 139279–139281.

Optically active transition metal complexes☆ Part 125. Preparation and epimerization of chiral-at-metal pentamethylcyclopentadienyl-rhodium(III) and iridium(III) half-sandwich complexes

H. Brunner *, A. Köllnberger, T. Burgemeister, M. Zabel [1]

Institut für Anorganische Chemie, Universität Regensburg, D-93040 Regensburg, Germany

Received 7 February 2000; accepted 25 April 2000

Abstract

The optically active bidentate Schiff base ligands (+)-2-*N*-[(*S*)-1-phenylethyl]pyrrolcarbaldimine NN*H and (+)-*N*-[(*S*)-1-phenylethyl]salicylaldimine ON*H react with $[Cp^*MCl_2]_2$ (M = Rh, Ir) to give the half-sandwich complexes Cp*Rh(NN*)Cl (**1**), Cp*Ir(NN*)Cl (**2**), Cp*Rh(ON*)Cl (**3**) and Cp*Ir(ON*)Cl (**4**). In all four cases two diastereomers (R_M,S_C) and (S_M,S_C) arise, differing only in the metal configuration. However, in each of the systems **1**–**4**, only the (R_M,S_C) diastereomer crystallized. X-ray structure analyses established the absolute configuration in the crystals of all four complexes. In solution the compounds epimerize via a change of the metal configuration and approach equilibria (R_M,S_C) (S_M,S_C) in which for **1** and **2** the (S_M,S_C) diastereomers dominate. Time dependent integration of ^{1}H NMR signals of the complexes **1** and **2** revealed that the epimerization is a clean first-order reaction. The half-lives in CD_2Cl_2 solution at −50°C were 19.4 min for **1** and 30.6 min for **2**. From the temperature dependence $\Delta H^{\neq}$ was determined as 62.4 kJ mol^{-1} for **1** and 44.3 kJ mol^{-1} for **2** and $\Delta S^{\neq}$ as 148 J K^{-1} mol^{-1} for **1** and 65 J K^{-1} mol^{-1} for **2**. For the compounds **3** and **4**, the kinetic data for the epimerization with respect to the metal center were derived from ^{1}H NMR coalescence experiments: half lives 35 ms for **3** at 21 ± 3° (CH_2Cl_2 solution) and 58 ms for **4** at −1.8 ± 3°C ($CHCl_3$ solution). These epimerization studies show that the metal configuration is labile in complexes **1** and **2** and extremely labile in complexes **3** and **4**. © 2000 Elsevier Science Ltd. 1. Introduction

In 1997 in this journal a communication entitled 'Diastereoselective preparation of chiral-at-metal pentamethylcyclopentadienyl iridium(III) and rhodium(III) complexes' was published by Loza et al. [1]. They claimed that in the reaction of (+)-*N*-[(*S*)-1-phenylethyl]salicylaldimine ON*H with $[Cp^*MCl_2]_2$ (M = Rh, Ir) in the presence of KO^{t}Bu only one diastereomer of the complexes **3** and **4** was formed with high diastereomeric excess. The X-ray crystallographic analysis of complex **4,** performed by the authors, was used to assign R-configuration to the only isomer observed in solution. These conclusions turned out to be unsafe, because the authors had overlooked the configurational instability of the complexes **3** and **4** at the metal center. On the basis of additional experiments we present here a rectification [2].

2.2. Ligands and precursors

The ligands (+)-2-*N*-[(*S*)-1-phenylethyl]pyrrolcarbaldimine NN*H [3,4] and (+)-*N*-[(*S*)-1-phenylethyl]-salicylaldimine ON*H [5] were prepared by condensation of pyrrol-2-carbaldehyde and salicylaldehyde, respectively, with (−)-(*S*)-1-phenylethylamine. $[Cp^*MCl_2]_2$ (M = Rh, Ir) were synthesized by a published method [6].

2.3. Cp*Rh(NN*)Cl (1)

NN*H (233 mg, 1.175 mmol) was dissolved in CH_2Cl_2 (10 ml) and NaH (25 mg, 1.05 mmol) was added at 0°C. After 1 h $[Cp^*RhCl_2]_2$ (404 mg, 0.654 mmol) was added. The solution was stirred for 20 h at room temperature. By filtering the mixture over Celite, evaporating the solvent, picking up in toluene and adding petroleum ether, red single crystal prisms could be obtained in a yield of 74%. The crystals only consisted of the (R_{Rh},S_C) diastereomer. A solution of the powdered crystals in CD_2Cl_2 was prepared at −80°C for ^{1}H NMR investigations. At this temperature the ^{1}H NMR spectrum mainly showed the diastereomer (R_{Rh},S_C), whereas measurements at 21°C gave a ratio (R_{Rh},S_C):(S_{Rh},S_C) = 13:87 (CD_2Cl_2).

Anal. Calc. for Cp*Rh(NN*)Cl, $C_{23}H_{28}ClN_2Rh$ (470.84): C, 58.67; H, 5.99; N, 5.95. Found: C, 58.87; H, 6.09; N, 5.88%. $[\alpha]_D^{23} = +74.5°$ ($c = 0.36$, $CHCl_3$). MS-FD: $m/z = 470$ (100, M). IR: 1575 cm^{-1} (vs, $\nu_{C=N}$). ^{1}H NMR (250 MHz, $CDCl_3$) of (S_{Rh},S_C)–Cp*Rh(NN*)Cl (the values of the thermodynamically less stable diastereomer (R_{Rh},S_C)–Cp*Rh(NN*)Cl are given in brackets): $\delta = 1.67$ (1.66) (s, 15H, C_5Me_5), 1.81 (1.86) (d, ^3J(H,H) = 7.0 Hz, 3H, CH_3), 5.31 (5.17) (q, ^3J(H,H) = 7.0 Hz, CH), 6.32 (6.33) (ddd, $^3J(H^3,H^4)$ = 3.7 Hz, $^4J(H^3,H^5) = 1.8$ Hz, $^4J(H^3,CH) = 0.4$ Hz, 1H, H^3-pyrr), 6.61 (6.64) (dd, $^3J(H^4,H^3) = 3.7$ Hz, $^3J(H^4,H^5) = 1.1$ Hz, 1H, H^4-pyrr), 7.23–7.44 (m, 6H, H^5-pyrr, Ph), 7.45 (m, 1H, N=CH).

2.4. Cp*Ir(NN*)Cl (2)

Cp*Ir(NN*)Cl (**2**) was synthesized in the same way as Cp*Rh(NN*)Cl (**1**). The orange crystals of **2**, which formed in a toluene/petroleum ether solution in a yield of 96%, only consisted of the (R_{Ir},S_C) diastereomer as confirmed by X-ray analyses. Crystals of **2** were dissolved in CD_2Cl_2 at −80°C and analyzed by ^{1}H NMR spectroscopy. At −80°C only the (R_{Ir},S_C) diastereomer was observed. At room temperature, the diastereomer ratio was (R_{Ir},S_C):(S_{Ir},S_C) = 12:88 (CD_2Cl_2).

Anal. Calc. for Cp*Ir(NN*)Cl, $C_{23}H_{28}ClIrN_2$ (560.15): C, 49.32; H, 5.04; N, 5.00. Found: C, 49.08; H, 5.09; N, 4.66%. $[\alpha]_D^{23} = -47.5°$ ($c = 0.40$, $CHCl_3$). MS: $m/z = 560$ (100, M). IR: 1590 cm^{-1} (vs, $\nu_{C=N}$). ^{1}H NMR (400 MHz, $CDCl_3$) of (S_{Ir},S_C)–Cp*Ir(NN*)Cl (the values of the thermodynamically less stable diastereomer (R_{Ir},S_C)–Cp*Ir(NN*)Cl are given in brackets): $\delta = 1.62$ (1.63) (s, 15 H, C_5Me_5), 1.76 (1.72) (d, ^3J(H,H) = 7.0 Hz, 3H, CH_3), 5.22 (5.16) (q, ^3J(H,H) = 7.0 Hz, CH), 6.23 (6.26) (dd, $^3J(H^3,H^4) = 3.8$ Hz, $^4J(H^3,H^5) = 1.8$ Hz, 1H, H^3-pyrr), 6.52 (6.54) (dd, $^3J(H^4,H^3) = 3.8$ Hz, $^3J(H^4,H^5) = 1.1$ Hz, 1H, H^4-pyrr), 7.04 – 7.38 (m, 6H, H^5-pyrr, Ph), 7.47 (7.48) (s, 1H, N=CH).

2.5. Cp*Rh(ON*)Cl (3)

Cp*Rh(ON*)Cl (**3**) was synthesized in the same way as Cp*Rh(NN*)Cl (**1**), except that KO^{t}Bu instead of NaH was used as the base. Red plate-like crystals of the (R_{Rh},S_C) diastereomer were obtained in a yield of 84% by crystallization from a toluene/petroleum ether solution. The 400 MHz ^{1}H NMR spectrum in $CDCl_3$ at room temperature showed broad signals (coalescence regime). Therefore, the ^{1}H NMR spectrum was measured at −80°C in CD_2Cl_2. At this temperature the diastereomer ratio was 81:19.

Anal. Calc. for Cp*Rh(ON*)Cl, $C_{25}H_{29}ClNORh$ (497.86): C, 60.31; H, 5.87; N, 2.81. Found: C, 59.93; H, 5.86; N, 2.59%. $[\alpha]_D^{23} = +25.8°$ ($c = 0.44$, $CHCl_3$). MS: $m/z = 497$ (100, M), 462 (30, M–Cl). IR: 1610 cm^{-1} (vs, $\nu_{C=N}$). ^{1}H NMR (−80°C, 400 MHz, $CDCl_3$) of the thermodynamically more stable diastereomer (the values of the thermodynamically less stable diastereomer are given in brackets): $\delta = 1.33$ (1.47) (s, 15H, C_5Me_5), 1.72 (1.81) (d, ^3J(H,H) = 7.0 Hz, 3H, CH_3), 5.57 (q, ^3J(H,H) = 7.0 Hz, 1H, CH), 6.42 (dd, $^3J(H^3,H^4) = 7.1$ Hz, $^3J(H^5,H^4) = 7.1$ Hz, 1H, H^4-sal), 6.90–7.50 (m, 8H, H^3,H^5,H^6-sal, Ph), 7.95 (7.81) (s, 1H, N=CH).

2.6. Cp*Ir(ON*)Cl (4)

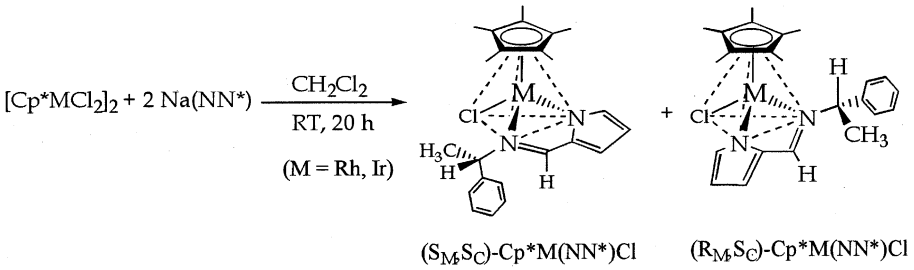
Cp*Ir(ON*)Cl (**4**) was synthesized in the same way as Cp*Rh(ON*)Cl (**3**). The orange crystals of **4**, which formed in a toluene/petroleum ether solution in a yield of 65%, only consisted of the (R_{Ir},S_C) diastereomer. The 400 MHz ^{1}H NMR spectrum at room temperature showed broad signals (coalescence regime). Therefore, the ^{1}H NMR spectrum was measured at −50°C in $CDCl_3$. At this temperature the diastereomer ratio was 85:15.

Anal. Calc. for Cp*Ir(ON*)Cl, $C_{25}H_{29}ClIrNO$ (587.17): C, 51.14; H, 4.98; N, 2.39. Found: C, 51.15; H, 5.15; N, 2.02%. $[\alpha]_D^{23} = +18.6°$ ($c = 0.43$, $CHCl_3$). MS: $m/z = 587$ (100, M). IR: 1610 cm^{-1} (vs, $\nu_{C=N}$). ^{1}H

NMR (-50°C, 400 MHz, $CDCl_3$) of the thermodynamically more stable diastereomer (the values of the thermodynamically less stable diastereomer are given in brackets): $\delta = 1.53$ (1.64) (s, 15 H, C_5Me_5), 1.97 (1.78) (d, $^3J(H,H) = 7.0$ Hz, 3H, CH_3), 5.60 (q, $^3J(H,H) = 7.0$ Hz, 1H, CH), 6.43 (dd, $^3J(H^3,H^4) = 7.1$ Hz, $^3J(H^5,H^4) = 7.1$ Hz, 1H, H^4-sal), 6.90–7.50 (m, 8H, H^3,H^5,H^6-sal, Ph), 7.86 (7.72) (s, 1H, N=CH).

2.7. X-ray

Diffraction data were collected on a STOE-IPDS diffractometer using Mo Kα radiation ($\lambda = 0.7107$ Å). The unit cells for **1**–**4** were determined from 8000 randomly selected reflections. Intensity data were collected for Lorentz and polarization effects. For the two iridium compounds absorption effects must be calculated. Crystal data and details of the structure determination are shown in Table 1. The structures **1**–**4** were solved by direct methods and SIR-97 [7]. All were refined on F^2 by the full-matrix least-squares technique (SHELXL-97 [8]). All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were calculated geometrically and a riding model was used during the refinement process.



3. Cp*Rh(NN*)Cl (1) and Cp*Ir(NN*)Cl (2)

3.1. Synthesis and X-ray structure analyses

The deprotonated ligand NN*H is reacted with $[Cp^*MCl_2]_2$ (M = Rh, Ir) to give the compounds Cp*M(NN*)Cl (M = Rh, Ir) (**1** and **2**) (Scheme 1). The

Scheme 1. Synthesis of Cp*M(NN*)Cl (M = Rh, Ir) **1** and **2**.

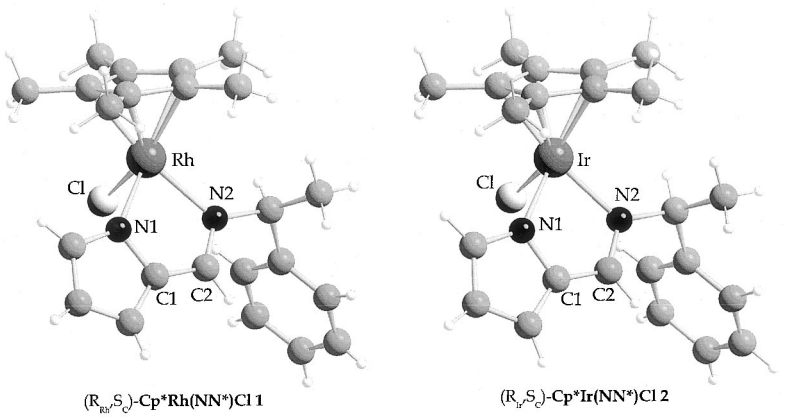

Fig. 1. Crystal structures of (R_{Rh},S_C)–Cp*Rh(NN*)Cl (**1**) and (R_{Ir},S_C)–Cp*Ir(NN*)Cl (**2**).

ligand NN*H contains an asymmetric carbon atom in S_C configuration. In the complexes **1** and **2** a new stereogenic center arises at the metal center. Consequently, there are two diastereomers (R_M,S_C) and (S_M,S_C) which differ in their ^{1}H NMR spectra. The (R_M,S_C):(S_M,S_C) ratio was 13:87 for **1** and 12:88 for **2** (CD_2Cl_2 solution) at ambient temperature obtained by integration of the Cp* signals.

Petroleum ether was added to a solution of Cp*Rh(NN*)Cl (**1**) and Cp*Ir(NN*)Cl (**2**), respectively, in toluene to obtain single crystals. The X-ray analyses showed, that the absolute configuration at the metal atom was R in both cases using the ligand priority sequence Cp* > Cl > N(imine) > N(pyrrolate) [9,10]. Thus, crystals of the two compounds only contain the (R_M,S_C) diastereomer (Fig. 1).

Table 2 summarizes selected bold lengths [Å], angles [°] and torsional angles of (R_{Rh},S_C)–Cp*Rh(NN*)Cl (**1**) and (R_{Ir},S_C)–Cp*Ir(NN*)Cl (**2**), which turn out to be very similar.

3.2. Epimerization studies

In the epimerization studies of (R_{Rh},S_C)–Cp*Rh(NN*)Cl (**1**) and (R_{Ir},S_C)–Cp*Ir(NN*)Cl (**2**) the samples stayed within the Bruker ARX 400 spectrometer. During the kinetic measurements the temperature varied from series to series by approximately ± 2°C. Within one series of measurements the temperature was much more constant. The evaluation was done by integration of the Cp* ^{1}H NMR signals.

Powdered crystals of (R_{Rh},S_C)-**1** or (R_{Ir},S_C)-**2,** dissolved at − 80°C in CD_2Cl_2, mainly showed the signals of the diastereomer (R_M,S_C) in the ^{1}H NMR spectrum as shown for Cp*Ir(NN*)Cl (**2**) in Fig. 2. In both cases on raising the temperature the signals of the (S_M,S_C)-diastereomers grew — a process which continued on further warming up. Obviously, the reason for this behavior is an epimerization at the metal center which

Table 2

leads to an equilibrium between the two diastereomers (R_M,S_C) and (S_M,S_C). Measurements at 21°C gave the equilibrium ratios (R_{Rh},S_C):(S_{Rh},S_C) = 13:87 and (R_{Ir},S_C):(S_{Ir},S_C) = 12:88.

Kinetic studies of the epimerization were made on the basis of the integration of the Cp* signals. After dissolving the powdered crystals at −80°C in CD_2Cl_2, ^{1}H NMR spectra were recorded at defined time intervals for more than 1.5 half-lives at the temperatures −35, −50 and −65°C, leaving the samples in the NMR spectrometer. The data analyzed perfectly according to first-order kinetics (Fig. 3), the half-lives for the approach to equilibrium of Cp*Rh(NN*)Cl (**1**) (Cp*Ir(NN*)Cl (**2**)) being 247 (225) min at −65°C, 19.4 (30.6) min at −50°C and 2.66 (7.63) min at −35°C (Table 3).

The Eyring-plots show the temperature dependence of the epimerization (Fig. 4), giving the activation enthalpies $\Delta H^{\neq}$ 62.4 (44.3) kJ mol^{-1} and the activation entropies $\Delta S^{\neq}$ 148 (65) J K^{-1} mol^{-1} for **1** (**2**).

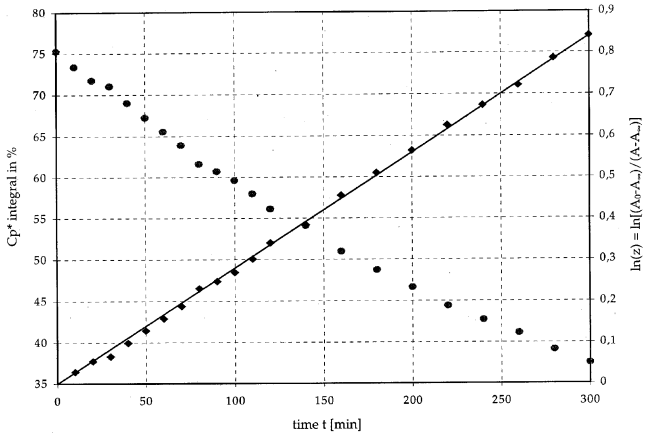

Fig. 3. The epimerization of Cp*Rh(NN*)Cl (**1**) at −65°C in CD_2Cl_2.

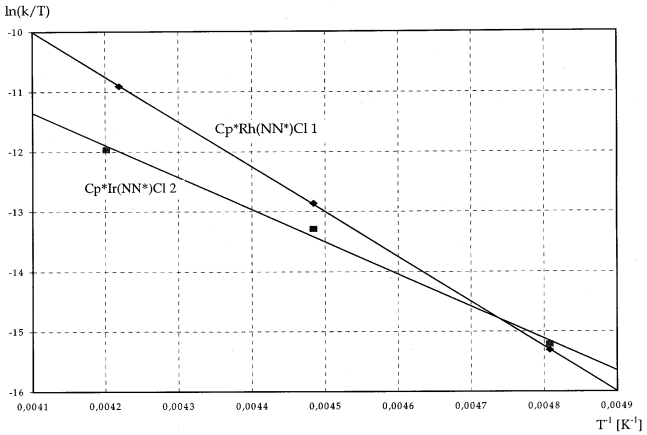

Fig. 4. Eyring-plot for Cp*Rh(NN*)Cl (**1**) and Cp*Ir(NN*)Cl (**2**).

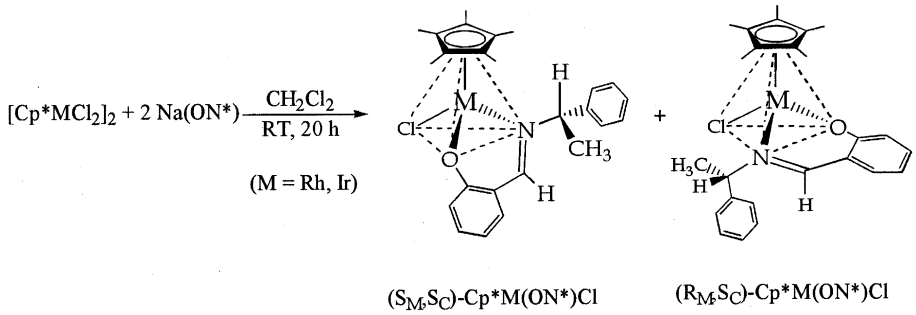
4. Cp*Rh(ON*)Cl (3) and Cp*Ir(ON*)Cl (4)

4.1. Synthesis and X-ray structure analyses



The deprotonated ligand ON*H is reacted with [Cp*MCl_2]$_2$ (M = Rh, Ir) to give the complexes Cp*M(ON*)Cl (M = Rh, Ir) **1** and **2** (Scheme 2). Again, two diastereomers are possible. The diastereomer ratio can only be determined at low temperatures. In CD_2Cl_2 solution the ratio is 81:19 for 3 at −80°C and 85:15 for **4** at −40°C in $CDCl_3$ solution.

To a toluene solution of Cp*Rh(ON*)Cl (**3**) and Cp*Ir(ON*)Cl (**4**), respectively, petroleum ether was added to obtain single crystals. In both cases the absolute configuration at the metal atom was R as shown by X-ray analyses (Fig. 5).

In Table 4 selected bond lengths [Å], angles [°] and torsional angles of (R_{Rh},S_C)–Cp*Rh(ON*)Cl (**3**) and (R_{Ir},S_C)–Cp*Ir(ON*)Cl (**4**) are summarized.

4.2. Coalescence measurements

As for Cp*Rh(ON*)Cl (**3**) and Cp*Ir(ON*)Cl (**4**), respectively, the interconversion of the two possible diastereomers is too fast, the rate constants cannot be

Scheme 2. Synthesis of Cp*M(ON*)Cl (M = Rh, Ir) **3** and **4**.

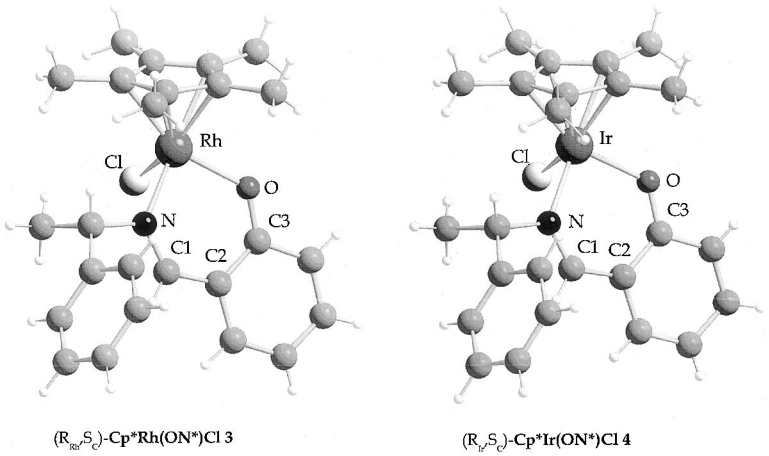


Fig. 5. Crystal structures of (R_{Rh},S_C)–Cp*Rh(ON*)Cl (**3**) and (R_{Ir},S_C)–Cp*Ir(ON*)Cl (**4**).

determined by time dependent integration of suitable ^{1}H NMR signals as in the complexes **1** and **2**. Therefore, in case of **3** and **4** the kinetic parameters were determined from the coalescence of the ^{1}H NMR spectra. At low temperatures the signals of the two diastereomers are clearly recognizable as shown for the imine protons of Cp*Rh(ON*)Cl (**3**) at −80°C in Fig. 6. On raising the temperature the signals broaden. At the coalescence temperature T_c there is a horizontal connection between the two peaks. The coalescence temperature T_c is +21°C for Cp*Rh(ON*)Cl (**3**) (Fig. 6) and −1.8°C for Cp*Ir(ON*)Cl (**4**).

Table 5
Results of the coalescence measurements of Cp*Rh(ON*)Cl (**3**) and Cp*Ir(ON*)Cl (**4**)

	Cp*Rh(ON*)Cl (**3**)	Cp*Ir(ON*)Cl (**4**)
Coalescence temperature T_c (°C)	21 ± 3	-1.8 ± 3
$\Delta\nu$ at T_c (extrapolated) (Hz)	52.60	39.04
Equilibrium constant K	0.24	0.18
Rate constant k_A (s^{-1})	24.7	13.7
Half-life τ (A) (ms)	28	50
Rate constant k_B (s^{-1})	102.8	76.9
Half-life τ (B) (ms)	6.7	8
Rate constant k (s^{-1})	127.5	90.6
^{1}H NMR parameters	400 MHz, CD_2Cl_2	400 MHz, $CDCl_3$

For a first-order reaction it is possible to compute the rate constants k_A, k_B, k, the half-lives τ_A, τ_B and the free enthalpies of activation $\Delta G_A^{\neq}$, $\Delta G_B^{\neq}$ (A = forward reaction, B = back reaction) using the equilibrium constant K, the coalescence temperature T_c, the line widths b_E [Hz] and the chemical shift difference $\Delta\nu$ [Hz] of the signals of the two diastereomers at different temperatures below T_c [2,11]. A linear extrapolation has to be made to calculate the value of $\Delta\nu$ at T_c. Table 5 summarizes the results of the coalescence measurements.

5. Discussion

As outlined in the Introduction, the complexes **3** and **4** had been prepared before and complex **4** had been characterized by an X-ray structure analysis [1]. However, the authors had characterized the complexes **3** and **4** only by room temperature ^{1}H NMR spectra. Our investigations demonstrated that the room temperature ^{1}H NMR spectra are the averaged high temperature limiting spectra (fast exchange regime of two diastereomers in diastereomer equilibria). Therefore, the authors of Ref. [2] missed to recognize the configurational lability of the complexes **3** and **4** with respect to the metal configuration. As the consequence, their overall result 'The complex **4** forms with R configuration at the metal centre exclusively, as confirmed by X-ray crystallography and comparison of the ^{1}H-NMR spectra of the reaction mixtures from the preparation with those of the crystallised material' [1] is an oversimplification and misinterpretation of the systems **3** and **4**. The X-ray structure analyses of the complexes **3** and **4** unequivocally establish the stereochemistry in the solid state. However, metal configurations in solution cannot be assigned because of the configurational instability at the metal center. The complexes **1** and **2** demonstrate how questionable such assignments can be. Although

Scheme 3. (η^6-C_6H_6)Ru(NN*)Cl and (η^6-C_6H_6)Ru(ON*)Cl (only one diastereomer shown).

for both **1** and **2**, there is a major isomer dominating the minor isomer by about 90:10 in the diastereomer equilibrium established in solution, it is the minor diastereomer which crystallizes in both cases. Thus, the major diastereomers are converted into the less soluble minor diastereomers in a second-order asymmetric transformation [12].

(η^5-C_5H_5)Rh and (η^5-C_5H_5)Ir complexes are isolobal with the corresponding (η^6-C_6H_6)Ru and (η^6-C_6H_6)Os complexes [13]. Therefore, a comparison of their configurational stability at the metal atom seems appropriate. Whereas the compound (η^6-C_6H_6)Ru(ON*)Cl (Scheme 3) undergoes fast epimerization in solution [14], the half-life of the equilibration of the diastereomers of (η^6-C_6H_6)Ru(NN*)Cl (Scheme 3) was determined to be 9.2 min at 27°C in $CDCl_3$ solution [15]. Thus, the rhodium complexes **1** and **3** seem to be more labile in the configuration at the metal center than the corresponding ruthenium counterparts.

6. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Centre. Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition nos. 139215–139218.

Abstract

Four new metal complexes with an octadentate macrocyclic ligand [L = 1,4,7,10-tetrakis(2-carbamoylethyl)-1,4,7,10-tetraazacyclododecane] were synthesized and characterized by elemental analyses, IR and MS. These complexes have the general formula: $M(L)(NO_3)_2{\cdot}nH_2O$ [M = Co (**1**), Ni (**2**), $n = 2$; M = Cu (**3**), Zn (**4**), $n = 1$]. The structures of complexes **1**, **2** and **3** have been determined by X-ray diffraction. $[Co(L)(NO_3)](NO_3){\cdot}2H_2O$ (**1**) crystallizes in the triclinic space group $P\bar{1}$. The refinement converges with $R = 0.045$ and $R_w = 0.057$ for 3233 reflections with ($I > 2.5\sigma(I)$). The Co has an octahedral geometry, and was coordinated with four amine nitrogen atoms of macrocyclic ligand and two or one acylate oxygen atoms derived from amide pendant groups. Two water molecules crystallize in the lattice cell and two kinds of hydrogen bonds exist between the coordinated acylate group and the water molecules: N(6)–H(27)···O(11) 2.158, N(8)–H(40)···O(12) 2.158 Å or exist between the uncoordinated acylate group and the nitrate ion: N(5)–H(21)···O(8) 2.452, N(7)–H(33)···O(5) 2.256 Å. $[Ni(L)(NO_3)](NO_3){\cdot}2H_2O$ (**2**) crystallizes in the monoclinic space group $C2/c$. The refinement converges with $R = 0.044$ and $R_w = 0.059$ for 2726 reflections with ($I > 3\sigma(I)$). The crystal of complex **2** has high symmetry with a C_{2v} symmetric operation. The central Ni atom is coordinated to four amine nitrogen atoms of macrocyclic skeleton and two acylate oxygen atoms of pendant amide groups. The polyhedron of the central atom can be described as a pseudo-octahedron. Two water molecules crystallized in the cell lattice. $[Cu(L)](NO_3)_2{\cdot}H_2O$ (**3**) crystallizes in the monoclinic space group $P2_1/n$. The refinement converges with $R = 0.037$ and $R_w = 0.048$ for 3174 reflections with ($I > 2.5\sigma(I)$). Complex **3** has a five-coordinated pyramid. The bond lengths of Co–O (av.) 2.088(3), Ni–O 2.089(2) Å are almost equal, and are shorter than Cu–O 2.137(3) Å. On the other hand, the bond lengths of Co–N (av.) and Ni–N (av.) are 2.194(3) and 2.153(2) Å, respectively. Both of them are longer than Cu–N (av.) 2.0465(3) Å. The potentiometric experiments in aqueous solution showed that the stability constants of three complexes were in the range of $\log K_{ML} = 17.11–15.00$. The DNA cleavage results showed that the cobalt complex can effectively cleave supercoiled DNA to form nicked or linear DNA by performing single strand and double strand scissions under aerobic conditions in the presence of hydrogen peroxide as co-oxidant. Electron paramagnetic resonance results with the aid of DMPO as trapping agent demonstrated that the cleavage mechanism possibly occurred via hydroxy radical attacking. © 2000 Elsevier Science Ltd. 1. Introduction

Cyclen-based macrocyclic metal complexes have been of interest for many years. With the recent elucidation of more and more biological activities of these complexes, researchers have started to concentrate on their antitumor and anti-HIV activities [1–3].

A variety of pendant arm ligands, such as CH_2CH_2COOH [4], $CH_2CH_2PO_3H_2$ [5], CH_2CH_2OH [6], $CH_2C_6H_4COOH$ [7], $CH_2C_6H_5$ [8], CH_2CH_2CN [9], $CH_2CH_2NH_2$ [10], $CH_2CH(OH)C_6H_5$ [11], $CH_2CH_2CONH_2$ [12], $CH_2CH(OH)CH_3$ [13] and CH_2CONH(naphthyl)CH_3 [14], have been prepared. These ligands possess divergent steric and electronic properties

and coordination environments. Several types of tetraazamacrocyclic lanthanide complex have been developed, which are inert to the dissociation of metal ions, and can hydrolyze the phosphodiester backbone of RNA as free complexes in solution [15] as well as conveniently attach to antisense oligonucleotides [16–18]. These complexes have at least one coordination site available for binding a small molecule or substrate. Since the Morrow group reported their results on the specific cleavage of RNA with tetraazamacrocyclic lanthanide complexes [19], a wide range of metal complexes have become available for the scission of nucleic acids. One of the most effective metal-based nucleases is the copper complex of 1,10-phenanthroline, which has been extensively studied and used for mapping protein and drug binding sites on DNA as well as for studying DNA structure [20]. Ligands with pendant amide groups are particularly interesting. Because they can form complexes in which the NH_2 group can remain protonated and the metal coordination to the CH_2CONH_2 group occurs through the carbonyl oxygen, or the NH_2 group can be deprotonated and so act as a deprotonated amide nitrogen, thus providing a strong metal binding site. This coordination behavior is very similar to that of the CONH group in small peptides. This kind of ligand has the advantage of having carbonyl oxygen and amide nitrogens as donor atoms at the same time. This characteristic was found in the complexes with 1,4,7-tri(carbamoylmethyl)-1,4,7-triazacyclonanone [21]. In order to screen new metal complexes for cancer chemotherapy, we synthesized these four complexes. However, compared with other analogous complexes reported with ligands: 1,4,7,10-tetrakis(benzyl)-1,4,7,10-tetraazacyclododecane [8] or 1,4,7,10-tetrakis(2-cycanoethyl)-1,4,7,10-tetraazacyclododecane [22], four metal complexes showed little activities against P388 or A549 tumor cell lines in vitro. In the research on the antitumor mechanism of these complexes, we found unexpectedly that complex **1** can effectively cleave supercoiled DNA into nicked and linear DNA in the presence of hydrogen peroxide at different concentrations.

Scheme 1. Synthetic route of L and its complexes.

2. Results and discussion

2.1. Spectrum analyses

The ligand and complexes were synthesized according to Scheme 1. All metal complexes dissolved well in water, DMF, DMSO and CH_3OH, but were insoluble in ether or acetone. The characteristic absorption of the ionic nitrate can be found in the IR spectrum of four complexes at ca. 1385 cm^{-1} [23]. Two vibration bands of the acylate of N–H pendant groups exist in the ligand at ca. 3155 and 3379 cm^{-1}. When the ligand coordinated with metal ions, this band was overlapped with O–H vibration absorption of the water molecule and only existed as a broader band at ca. 3377, 3411, 3408 and 3348 cm^{-1} for Co, Ni, Cu and Zn, respectively. The carbonyl group C=O of the amide of the ligand has a characteristic absorption at 1672 cm^{-1}, but in Co and Ni complexes this band shifted to 1676 cm^{-1} after the two carboxamide oxygen atoms coordinated to the central metal ions. However, this band is absent and strong bands are observed in Cu and Zn complexes at lower wavelengths: ca. 1666 and 1670 cm^{-1}, respectively. In the case of Cu and Zn complexes, the carboxamide oxygen atom also coordinated to the central metal ions then decreased the electronic density of the delocalized double bond. The absorption bands shifted to low wavelengths. The same phenomenon was observed in $[Cr(L'–H)]^{2+}$ reported by Weyhermüller et al. [21].

In the EI MS spectrum of complex **4** the base peak is m/z 71 $[CHCH_2CONH_2]^+$. Other peaks correspond to the loss of one or more pendant groups, which are m/z 503 $[M^+ - 2CHCH_2CONH_2]$, 429 $[M^+ - 3CH_2CH_2CONH_2]$, 369 $[M^+ - 3(CH_2CH_2CONH_2)–NO_3]$, 357 $[M^+ - 4CH_2CH_2CONH_2]$ and 295 $[M^+ - 4(CH_2CH_2CONH_2)–NO_3]$. The molecular peak does not exist because the pendant group $CH_2CH_2CONH_2$ is easily lost under EI source conditions. However, the FAB MS spectrum of complex **2** shows different characteristics to the above-mentioned. The molecular peak: M^+ m/z 639 $[Ni(L)(NO_3)_2]^+$ easily lost the non-coordination ionic nitrate to form the peak $[Ni(L)(NO_3)]^+$ m/z 577, which can lose the coordinating nitrate further to form a fragment peak at m/z 515 corresponding to $[Ni(L)]^+$. Then the ligand decomposes with the loss of several pendant groups to generate fragmentation peaks: m/z 443, 299, 229.

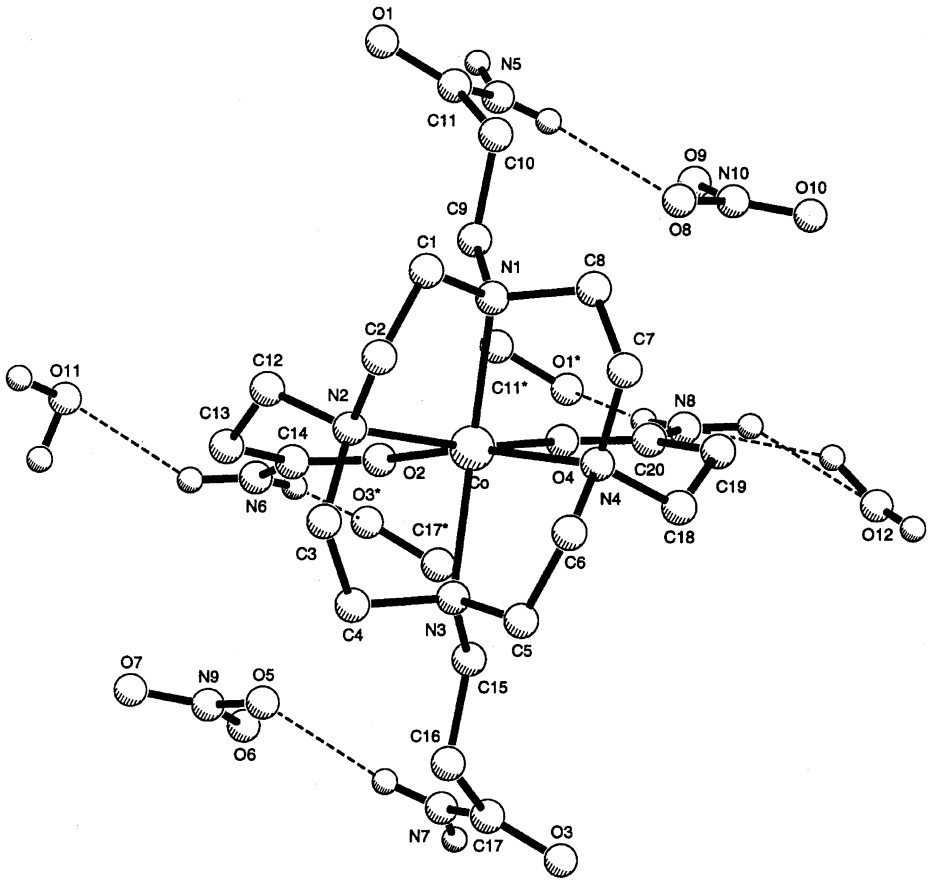

Fig. 1. The ORTEP drawing of the cation part in complex **1** with ellipsoid 40%.

2.2. Structural analyses

The ORTEP drawings for crystal structures of complexes **1**, **2** and **3** are depicted as Figs. 1–3, respectively. The crystallographic data and important parameters are given in Table 1. The selected bond distances and bond angles of two crystals are listed in Tables 2–4, respectively.

Complex **1** consists of ion pairs. In the cationic part, the central Co atom was surrounded by four imino nitrogen and two acylato oxygen atoms, which were defined as an octahedral polyhedron. Two water molecules crystallize in the lattice cell and two kinds of hydrogen bonds exist between the coordinated acylate group and water molecules: N(6)–H(27)···O(11) 2.158, N(8)–H(40)···O(12) 2.158 Å, or exist between an uncoordinated acylate group and a nitrate ion: N(5)–H(21)···O(8) 2.452, N(7)–H(33)···O(5) 2.256 Å. The four nitrogen atoms of the macrocycle are coplanar with a mean deviation 0.3337 Å and the Co atom departed from this plane −0.974 Å. Two oxygen atoms have similar distances separated from this plane −2.556 Å. The bond lengths between Co and O(2), O(4) are 2.087(3) and 2.089(3) Å. Co–N distances exist in the range 2.169(3)–2.222(3) Å, which are longer than
