Abstract

Two new cobalt(III) complexes with *S*-benzyl-β-*N*-(5-methylpyrazole-3-yl)methylenedithiocarbazate (H_2L), $[Co(HL)_2]NO_3 \cdot EtOH$ (**1**) and $[Co(HL)(L)] \cdot H_2O$ (**2**), have been synthesised and characterised using single-crystal X-ray diffraction and spectroscopic (electronic, IR and NMR) techniques. The structure of **1** consists of $[Co(HL)_2]^+$ cation and NO_3^- anion linked by an ethanol solvent molecule, that of **2** consists of neutral monomeric species [Co(HL)(L)] with one mole water of crystallisation where the two ligand molecules are uniquely non-equivalent. In both the complexes the coordination geometry about cobalt is distorted octahedral and the two ligands are in the *mer* configuration (S and tertiary N atom *cis* to each other and the iminic N atoms *trans*). © 2002 Elsevier Science Ltd. Keywords: Co(III) complexes; Pyrazole; Dithiocarbazate; Synthesis; Spectroscopy; X-ray crystal structures

1. Introduction

Recent studies [1–4] have attempted a correlation between the structural nature of transition metal ion complexes of heterocyclic thiosemicarbazones and *S*-alkyl/aryl dithiocarbazates and their wide spectrum therapeutic uses. This has prompted further research in this specific area with the great expectation that structural variation of the ^{4}N substituent on the thiosemicarbazone moiety as well as modification of the heterocyclic ring might prove beneficial and will lead to dramatic enhancement of the biological activity of such new metal ion complexes which might also provide unique structural information. As a part of our comprehensive efforts [5–10] towards synthesis and structural characterisation of the new materials containing *N*-heterocycles with proven bioactivity, we report, herein, the synthesis, spectroscopy and crystallographic characterisation of two new cobalt(III) complexes with the title ligand (H_2L), viz. $[Co(HL)_2]NO_3 \cdot EtOH$ (**1**) and $[Co(HL)(L)] \cdot H_2O$ (**2**).

2. Experimental

All the materials used at different stages for the preparation of the cobalt(III) complexes reported were of GR/AR quality and were used without further purification. Spectrograde solvents were used for spectral and conductance measurements. Solvent DMSO-d_6 (Sigma) was used for recording NMR data.

2.1. Synthesis of ligand S-benzyl-β-N-(5-methylpyrazole-3-yl)methylenedithiocarbazate (H_2L)

The title ligand, H_2L (Fig. 1), has been synthesised and thoroughly characterised for the first time as reported earlier [7].

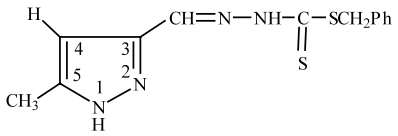

Fig. 1. *S*-Benzyl-β-*N*-(5-methylpyrazole-3-yl)methylenedithiocarbazate (H_2L).

2.2. Synthesis of $[Co(HL)_2]NO_3\cdot EtOH$ (**1**)

To a boiling ethanolic solution (40 cm^3) of the ligand (0.29 g, 1 mmol) was added a solution (10 cm^3) of $Co(NO_3)_2\cdot6H_2O$ (0.14 g, 0.5 mmol) in the same solvent, followed by the addition of 0.5 cm^3 HNO_3 (1:1) to make the solution acidic (pH ~ 3); the mixture was stirred for 30 min in water-bath temperature. Upon slow evaporation, microcrystalline complex was obtained (ca. 80%). A recrystallisation from water–ethanol (1:14 v/v) afforded needle shaped reddish brown crystals.

2.3. Preparation of $[Co(HL)(L)]\cdot H_2O$ (**2**)

A hot ethanolic solution (30 cm^3) of the ligand (0.29 g, 1 mmol) was mixed with a solution of $CoBr_2\cdot6H_2O$ (0.16 g, 0.5 mmol) in the same solvent and the resulting clear reddish brown solution was stirred for 30 min around 90 °C. Upon slow evaporation, well-shaped crystals were obtained (yield: ca. 75%). The composition of the complex, as evidenced from elemental analyses, did not contain the expected bromide ion, and was established by X-ray analysis.

2.4. Physical measurements

Elemental analyses (C, H and N) were carried out at IACS, Kolkata with a Perkin–Elmer CHNS/O analyser 2400. The cobalt content of the complexes was determined gravimetrically as anhydrous $CoSO_4$. The molar conductance values of the complexes were measured in methanolic solution with a Systronics model 304 digital conductivity meter. The electronic spectra of the complexes in DMF solution (ca. 30 °C) were recorded in a Hitachi model UV 2000 spectrophotometer (250–1100 nm). IR spectra (4000–200 cm^{-1}) were recorded in a Perkin–Elmer model 833 infrared spectrophotometer with KBr pellets and magnetic measurements were made in the polycrystalline state in a PAR 155 sample vibrating magnetometer at IACS, Kolkata. NMR spectra were recorded in DMSO-d_6 with a Bruker AM300L(300 MHz) super conducting FTNMR.

2.5. Structure determination

Suitable crystals of **1** and **2** were used for X-ray diffraction data collection on a Siemens P4S diffractometer using Mo–Kα radiation. The relevant crystal data are summarised in Table 1. The data were corrected for Lorentz and polarisation effects and empirical absorption corrections were carried out using ψ-scan data of some selected reflections. The structures were solved by direct methods and refined by full-matrix least-squares based on $|F_{obs}|^2$ using the program SHELXL-97 [11]. The non-hydrogen atoms were refined

anisotropically while the hydrogen atoms, except those of a water molecule in structure **2**, were included in their idealised positions. The water hydrogen atoms in **2** were located from a difference electron density map and were restrained to maintain a fixed distance from the oxygen atom. Neutral atom scattering factors were taken from Cromer and Weber [12] and anomalous dispersion effects were included in F_{calc} [13].

3. Results and discussion

Satisfactory C, H and N analyses were obtained (Table 2) for both **1** and **2** for the empirical composition $C_{28}H_{32}CoN_9O_4S_4$ and $C_{26}H_{27}CoN_8OS_4$, respectively. Both the cobalt(III) complexes reported are diamagnetic at room temperature, while $[Co(HL)_2]NO_3{\cdot}EtOH$ (**1**) is an 1:1 electrolyte ($\Lambda_m = 78.2$ $\Omega^{-1}\,cm^2\,mol^{-1}$), the $[Co(HL)(L)]{\cdot}H_2O$ (**2**) is a non-electrolyte ($\Lambda_m = 17.0$ $\Omega^{-1}\,cm^2\,mol^{-1}$).

3.1. Vibrational, electronic and NMR spectra

Assignments of the selected characteristic IR bands of H_2L and its cobalt(III) complexes are given in Table 3. The characteristic IR bands (4000–200 cm^{-1}) for the free ligand (H_2L) when compared with those of its complexes provide significant indications regarding the bonding sites of the primary ligand molecule and the information are in conformity with our earlier results [7]. A negative shift in ν(C=N) (1580 cm^{-1}) in the spectrum of the free ligand to approximately 1560 cm^{-1} in its complexes is consistent with coordination of the azomethine nitrogen to the central cobalt(III) ion; the IR band at approximately 470 cm^{-1} is then assignable to ν(Co–N) [14]. A second band around 1600 cm^{-1}, assignable to ν(C=N) is expected in the spectra of the complexes, since the anionic ligand while coordinated to Co(III) generates a double bond between ^{2}N and ^{3}C (i.e. $-^1N-^2NH-^3C(S)-SCH_2Ph$) as the proton attached to ^{2}N atom of dithiocarbazate moiety is lost during complexation. An intensive strong band at 845 cm^{-1} in the free ligand spectrum is due to ν(C=S) which has been found to shift to lower frequency by ~ 50 cm^{-1} in the complexes, pointing to the coordination of the thiol sulfur to cobalt(III) atom; moreover, a new band at 375 and 390 cm^{-1} in complexes **1** and **2**, respectively, is assignable to ν(Co–S). The free ligand band at 1535 and 650 cm^{-1} assignable to the ν(C=N) (ring) and the inplane deformation of the pyrazole ring, respectively, are shifted to higher wave number ($\delta\nu = 25$ cm^{-1} in **1**, 40 cm^{-1} in **2** and $\delta\nu = 15$ cm^{-1} in **1**, 20 cm^{-1} in **2**, respectively); these data suggest that the tertiary ring nitrogen atom (^{2}N) as a possible bonding site in terms of earlier findings on crystallographic studies [7,15–18].

The electronic spectra (in DMF) of complexes **1** and **2** show bands (Table 3) in the regions 32 365–37 245 and 22 730–23 530 cm^{-1} and are attributed to intraligand charge transfer ($n \rightarrow \pi^*$) and d–d transition ($^1A_{1g} \rightarrow {}^1T_{2g}$) of a d^6 system, respectively [18]. However, diffuse reflectance spectra exhibit four bands in the region 8860–8895, 9650, 11 725 and 23 255–23 475 cm^{-1} which may be assigned as $^1A_{1g} \rightarrow {}^3T_{1g}$, $^1A_{1g} \rightarrow {}^3T_{2g}$, $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ transitions, respectively, in an octahedral symmetry.

Table 4 gives selected ^{1}H and ^{13}C NMR assignments for the ligand and the cobalt(III) complexes in order to compare the coordinated, anionic ligand species in the complex with the free ligand molecule (H_2L). The ^{1}H

Table 4
NMR data of ligand and its cobalt(III) complexes; values given (in δ ppm) relative to TMS

Compound	Imino proton	Pyrazole ring protons			Methine proton	Benzyl proton	^{13}C assignments		
		1	**4**	**5**(CH_3)			Thioamide carbon	Azomethine carbon	^{3}C (pyrazole)
H_2L	12.93, 8.81	13.20	6.31	2.21	7.41	4.45	202.0	136.6	142.5
$[Co(HL)_2]NO_3{\cdot}EtOH$	–	14.28	6.77	2.25	8.93	4.53	209.6	146.7	153.1
$[Co(HL)(L)]{\cdot}H_2O$	–	14.27	6.77	2.24	8.94	4.49	209.7	146.6	153.2

NMR spectra of the complexes (Table 4) when compared with those of the free ligand point out: (i) $-SCH_2-$ peak showing slightly downfield shift ($\delta =$ 4.45–4.53) is ascribed to coordination of the thiol sulfur to Co(III) resulting in reduced electron density at $-SCH_2-$; (ii) maximum downfield shift occurs with the methine proton appearing at approximately $\delta = 8.93$ in the complex molecule(s) corresponding to $\delta = 7.41$ ppm in the free ligand as expected due to coordination of the azomethine nitrogen to the central Co(III); and (iii) the shifting of ^{4}CH (the pyrazole ring) from $\delta = 6.77$ in the complexes is reasonable with the proposition that ^{2}N (pyrazole) coordinates with Co(III) ion. Comparison of the ^{13}C NMR spectra of the uncomplexed ligand with its cobalt complexes shows that the thioamide carbon shifts slightly downfield by $\delta = 7.6$ (e.g. $\delta = 202.0$ in free ligand to ca. $\delta = 209.6$ in complexes) showing a coordination through thioamide sulfur. The significant downfield shift occurs with azomethine carbon appearing at approximately $\delta = 146.7$ in the complex molecules corresponding to approximately $\delta = 136.6$ in the free ligand as expected due to coordination of the azomethine nitrogen to the central cobalt atom and the maximum downfield shifting of ^{3}C ring (pyrazole) carbon from $\delta = 142.5$ (free ligand) to approximately $\delta =$ 153.3 in complexes is quite reasonable with the proposition that neighbouring ^{2}N (pyrazole) coordinates strongly with the central atom.

3.2. Crystal structures of $[Co(HL)_2]NO_3{\cdot}EtOH$ (1) and $[Co(HL)(L)]{\cdot}H_2O$ (2)

ORTEP [19] diagrams of $[Co(HL)_2]NO_3{\cdot}EtOH$ (**1**) and $[Co(HL)(L)].H_2O$ (**2**) together with the atom numbering schemes are shown in Fig. 2 (a) and (b). In both the complexes the Co(III) atom is coordinated, as slightly distorted octahedron, to two deprotonated ligands through the thiol sulfur atoms [S(1A), S(1B)], the tertiary pyrazolyl nitrogen atoms [N(1A), N(1B)], and the hydrazinic nitrogen atoms [N(3A), N(3B)]. The crystallographic asymmetric unit in complex **1** consists of a $[Co(HL)_2]^+$ cation, a NO_3^- anion and a molecule of ethanol of crystallisation. The corresponding unit in complex **2** consists of a neutral [Co(HL)L] moiety and a molecule of water of crystallisation. During complexation in **2**, the secondary pyrazolyl nitrogen, N(2A), of one of the ligands has been deprotonated resulting in an extra negative charge which renders it unnecessary to have a counter anion like NO_3^- as in complex **1**, or as the Cl^- ion in another complex with the same ligand reported earlier [7]. The nitrate ion and the ethanol of crystallisation in complex **1** show some degree of disorder; two of the oxygen atoms of the nitrate group [O(1) and O(2)] and the carbon atoms [C(1S) and C(2S)] of the ethanol molecule vibrate between two alternate sets of positions, identified by the suffices A and B.

The bond distances and angles around the Co(III) atoms for both the complexes are shown in Table 5. In both complexes, two molecules (designated as A and B) of the tridentate *S*-benzyl-β-*N*-(5-methylpyrazole-3-yl)methylenedithiocarbazate ligand (H_2L) coordinate to the Co(III) atom to form four five-membered chelate rings [Co–S(1A)–C(5A)–N(4A)–N(3A), Co–S(1B)–C(5B)–N(4B)–N(3B), Co–N(1A)–C(3A)–C(4A)–N(3A) and Co–N(1B)–C(3B)–C(4B)–N(3B)].

The bond distances and angles involving the Co(III) atoms in both the complexes compare well with those observed in other similar structures [20–22]. The endocyclic angle N(1)–N(2)–C(1) in ligand A of complex **2** is 106.7(3)°; the corresponding angle in ligand B is 112.0(3)° while those in complex **1** are 111.2(4)° and 111.0(4)°, respectively. This clearly indicates the deprotonation of the secondary pyrazolyl ring nitrogen of ligand A in complex **2**. It is interesting to note that in complex **2**, the Co–N(1A) bond is approximately 0.02 Å shorter than the Co–N(1B) bond, this can be reasonably attributed to the stronger coordination of the harder base N(1A), owing to deprotonation of the adjacent N(2A), with the hard acid Co(III). As a corollary to this, the Co–S(1A) bond in complex **2**, which is *trans* to the Co–N(1A) bond [N(1A)–Co–S(1A) angle is 166.5(1)°], is observed to be shorter by approximately 0.03 Å than the Co–S(1B) bond.

In both the complexes, the two almost planar ligand molecules approach the central Co(III) atom in orthogonal orientation; the interligand diheral angle is

88.87(4)° in complex **1** and 87.70(4)° in complex **2**. The two azomethine nitrogen atoms [N(3A) and N(3B)] are *trans* to each other while the sulfur atoms [S(1A) and S(1B)] are in the *cis* position. The pyrazole rings, C(1)–C(2)–C(3)–N(1)–N(2), and the two five-membered chelate rings, Co–N(1)–C(3)–C(4)–N(3) and Co–S(1)–C(5)–N(4)–N(3), are individually planar with very small dihedral angles between the two planes. In complex **1**, the maximum dihedral angle of 7.5(1)° is between the pyrazole ring and its second neighbouring chelate ring, Co–S(1A)–C(5A)–N(4A)–N(3A); in complex **2**, the same pair of rings have the maximum dihedral angle of 6.0(1)°.

Table 6 gives the details of the hydrogen bonding patterns in the two structures. In complex **1**, the pyra-

Abstract

The reaction of the Ni(II) complex of 5,14-dihydro-6,8,15,17-tetramethyldibenzo[b,i][1,4,8,11]tetraazacyclotetradecine with succinyl dichloride leads to di- and monosubstituted derivatives bearing β,γ-unsaturated-γ-lactonic rings at the *meso* positions of the macrocycle. An aminolytic cleavage of these lactonic substituents gives rise to open-chain pendant groups containing the corresponding amide functions. A range of new complexes have been synthesized in this way with use of primary and secondary aliphatic and heterocyclic amines. The new products have been characterized by elemental analyses, ^{1}H, ^{13}C NMR, IR and ESI-MS spectral data. Single crystal X-ray studies revealed that the saddle-shaped molecules of [5,14-dihydro-7,16-bis(2-oxo-3*H*-furan-5-yl)-6,8,15,17-tetramethyldibenzo[b,i][1,4,8,11]tetraazacyclotetradecinato(2-)-κ^4N]nickel(II) act as receptors with molecules of toluene forming 1:1 supramolecular complexes. © 2002 Elsevier Science Ltd. Keywords: Dibenzotetraaza[14]annulenes; Macrocyclic Ni(II) complexes; Succinyl dichloride; Crystal structures; Solid state supramolecular complexes

1. Introduction

Recent studies on the chemistry of Ni(II) complexes of dibenzotetraaza[14]annulenes have revealed their diverse reactivity involving *meso* positions of the ring [1]. Some of these transformations were found to differ remarkably from that typical for the corresponding non-coordinated organic molecules [2–6]. These observations well support common opinion suggesting influence of the metal center on the coordinated ligand reactivity [7,8]

Herein we report on the metal center mediated reactivity of the dibenzotetraaza[14]annulene Ni(II) complex **1** towards succinyl dichloride, leading to *meso* di- and monosubstituted products, equipped with 2-oxo-3*H*-furan-5-yl substituents (**2a** and **2b**, Scheme 1). It has further been found that these β,γ-unsaturated-γ-lactonic groups easily undergo an aminolytic cleavage giving the open-chain amide-type pendant substituents. The procedure proved to be applicable to a wide variety of primary and secondary amines, thus showing its practical significance in the preparation of purpose-designed ligand superstructures. Schemes 1 and 2 outline the reactions performed.

Apart from being studied as fairly reactive coordinated ligands, dibenzotetraaza[14]annulene complexes have been recently appreciated as versatile supramolecular receptors. Thus, the host–guest inclusion complexes with toluene [9], benzene [10] as well as with molecules of C_{60} and C_{70} [11,12] have been described. In this paper we report crystallographic results showing

that molecules of [5,14-dihydro-7,16-bis(2-oxo-3*H*-furan - 5 - yl) - 6,8,15,17 - tetramethyldibenzo[b,i][1,4,8,11]-tetraazacyclotetradecinato(2-)-κ^4N]Ni(II) (**2a**) forms the 1:1 solid state inclusion complex with molecules of toluene.

2. Experimental

2.1. Materials and equipment

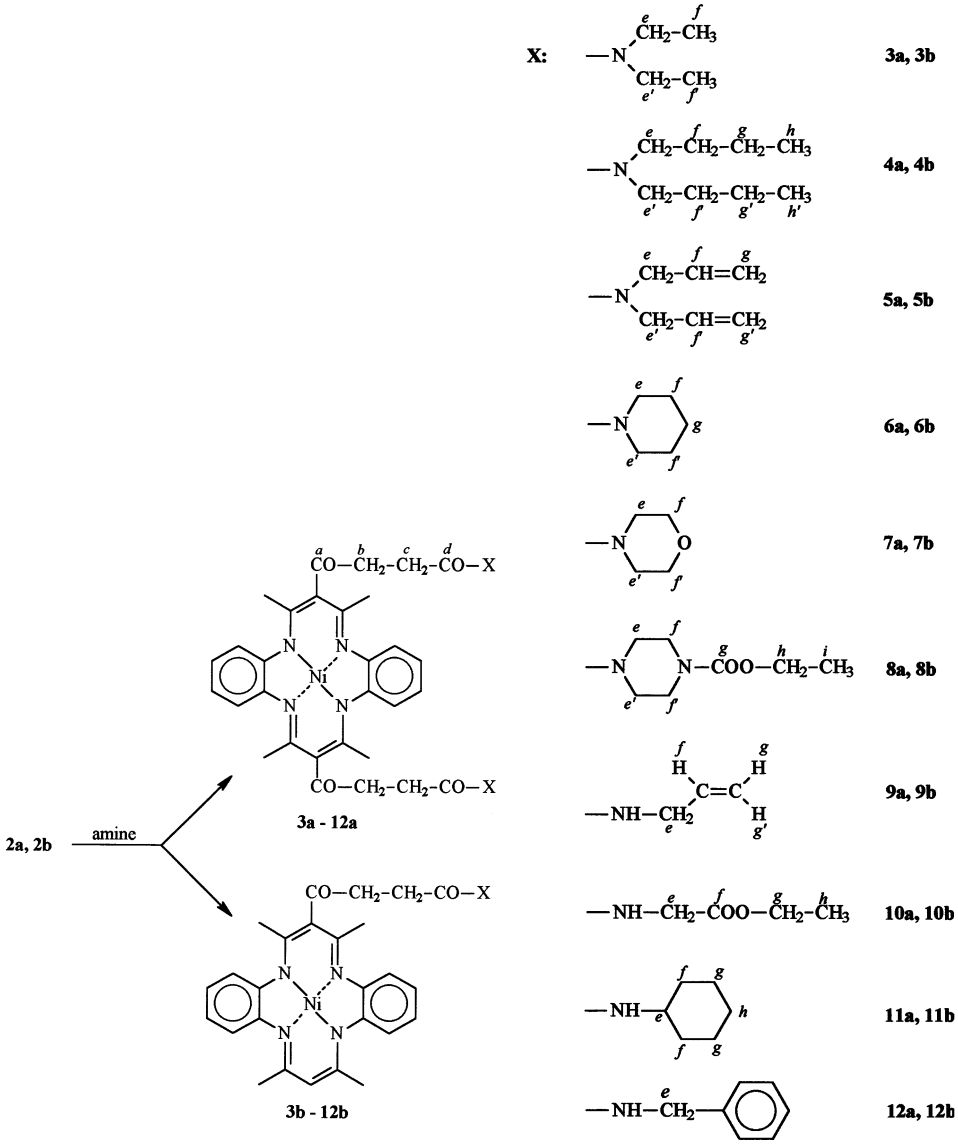
Elemental analyses were performed with the use of an Euro-EA (EuroVector) microanalyser. The IR spectra were recorded in KBr and hexachlorobutadiene with a BRUKER IFS 48 spectrometer. ^{1}H and ^{13}C NMR spectra were run on a BRUKER AMX. instrument operating at 500 MHz, with TMS as internal standard. ESI-MS and MALDI-TOF spectra were taken on Finnigan MAT 95 and Voyager-Elite (PerSeptive Biosystems Inc.) mass spectrometers, respectively. The parent complex **1** was prepared by a procedure described in the literature [13]. All solvents were dried using standard methods and freshly distilled before use. Amines were purchased from commercial sources (Fluka, Aldrich) and used as received. 1-Ethoxycarbonylpiperazine was prepared according to Ref. [14]. Succinyl dichloride (Fluka) was distilled before use. Silica gel 60 (Fluka) (0.063–0.2 mm) and aluminum oxide 507 C (Fluka) were used for the column chromatography.

Scheme 1.

2.2. Synthesis of the complexes *2a* and *2b*

Succinyl dichloride (1 ml, 2.5 mmol) was added to a solution of the complex **1** (1 g, 2.5 mmol) and triethylamine (3 ml) in dry toluene (80 ml). The deep green reaction mixture was refluxed for 2 h with stirring and was protected from moisture. The reaction mixture was left aside to cool, triethylamine hydrochloride was filtered off and the filtrate was evaporated to dryness under reduced pressure. The green residue dissolved in a small quantity of methylene dichloride was chromatographed on a column of silica gel. Two fractions—the monosubstituted complex **2b** and the disubstituted **2a** were eluted successively using toluene–methylene chloride (1:1) and methylene dichloride–acetone (20:1) as eluents. The deep-violet crystals suitable for X-ray measurements were obtained by recrystallization of the complex **2a** from toluene.

2.3. Synthesis of the complexes *3–12* (general procedure)



A deep green slurry consisting of the complex **2a** or **2b** (1 mmol), appropriate amine (10 mmol) and toluene (50 ml) was heated under gentle reflux for 1 h. Further procedures had to be adapted to the solubilities of the products, therefore two different methods have been employed.

Method A (for separation of the products **3**–**8** and **9b**–**12b**): the reaction mixture was evaporated to dryness under reduced pressure and the green residue was chromatographed on a column of Al_2O_3 using toluene–acetone (10:1) as eluent. The main fraction was separated to afford the corresponding amide-type product.

Method B (for separation of the products **9a**–**12a**): unlike the products described above, the disubstituted complexes **9a**–**12a** appeared in the reaction mixture as abundant, sparingly soluble, green precipitates. They were filtered off, washed thoroughly with toluene, acetone, water and acetone again. The green products thus obtained gave satisfactory results for elemental analyses.

2.4. Crystallography

Single crystal X-ray diffraction data were collected on a KUMA4CCD κ-axis diffractometer with the use of graphite monochromated Mo Kα radiation applying ω–2θ and ω scan techniques. The crystal was positioned at 65 mm from the KM4CCD camera. 576

Scheme 2.

frames were measured at 0.8° intervals with a counting time of 25 s. The data were corrected for Lorentz, polarization effects and variation of the reference frame. No absorption correction was applied. Data reduction and analysis were carried out with the Kuma diffraction (Wroclaw, Poland) programs. The structure was solved by direct methods [15] and refined using SHELXTL [16]. The refinement was based on F^2 for all reflections except those with very negative F^2. Weighted R factors wR and all goodness-of-fit S values are based on F^2. Conventional R factors are based on F with F set to zero for negative F^2. The $F_o^2 > 2s(F_o^2)$ criterion was used only for calculating R factors and is not relevant to the choice of reflections for the refinement. The R factors based on F^2 are about twice as large as those based on F. Anisotropic temperature factors were used to describe the thermal motions of non-hydrogen atoms (with the exception of toluene atoms). Most of the hydrogen atoms were located in idealized averaged geometrical positions, allowed to ride on the heavy atoms and rotate around C–C bonds. The toluene molecule is difficult to refine. Although its shape is clearly seen from differential maps we were unable to refine the carbon atoms using anisotropic ADPs. Additionally, we had to reduce atomic site occupation factors and constrain the ring. All this is due to really weak interactions of toluene with the host molecule. It tends to escape from crystals although the crystals seem to keep the structure and this is why some larger variation of reference frames (ca. 6% in total) had to be corrected for. Atomic scattering factors for C, H and O were derived from wave functions tabulated in Tables 6.1.1.4 and 4.2.4.2 from Ref. [17]. The average standard deviation for bonds is ca. 0.015 Å which means that

3. Results and discussion

3.1. Syntheses

The reaction of the complex **1** and succinyl dichloride in a 1:3 molar ratio was performed in boiling toluene in the presence of triethylamine. In this way the di- and monosubstituted products **2a** and **2b** were obtained in 56 and 15% yields, respectively (Scheme 1). A 1:1 molar ratio of the reagents gave rise to the mixture of approximately equal amounts of the parent complex **1**, di- and monosubstituted products **2a** and **2b**. Aminolysis was accomplished by refluxing of the complexes **2a** and **2b** in toluene with an excess of the appropriate amines for 1 h to afford amide products in yields ranging from 65 to 92%. Analytical data and physical properties of the new complexes **2**–**12** are collected in Table 1.

Succinyl dichloride, similarly to other dicarboxylic acid dichlorides, is commonly considered to be a typical difunctional electrophilic reagent, often used in organic synthesis as a powerful linker in the preparation of dimers and polymeric products [18,19]. However, we have recently observed anomalous behavior of oxalyl dichloride in the reaction with dibenzotetraaza[14]annulene Ni(II) complexes [5]. The key step of the mechanism was postulated to involve a chloro-α-dioxo intermediate, formed as a result of electrophilic attack of oxalyl dichloride at the methine position of the macrocycle. Reactivity of this intermediate was found to be crucial for the final product formation.

Our experiments with succinyl dichloride showed that reaction with the complex **1** led to monomeric products **2a** and **2b**, equipped with β,γ-unsaturated-γ-lactonic rings at the *meso* positions. The reaction seems to proceed via a two-step mechanism involving acylation of the *meso* methine carbon by one of two electrophilic centers of succinyl dichloride, followed by intramolecular *O*-acylation within chlorosuccinoyl groups. Enolization of the ketomethylene part of the chlorosuccinoyl group presumably takes place prior to the lactonic ring closure. The procedure used was found to give a reasonable yield without recourse to the high dilution technique. Moreover, the reaction failed when applied to the corresponding dibenzotetraza[14]annulene ligand, allowing the starting material only to be recovered from the reaction mixture. In view of the above, we suppose that the metal center promotion takes place in the course of the reaction. It seems reasonable to believe in this case again, that reactivity of the open-chain monoacylated intermediate is essential for the

formation of the final product. One could assume further that intramolecular interactions of pendant chlorosuccinoyl groups with the metal center prevents the intermolecular acylation that could result in a polymer formation. The saddle-like structure of the macrocyclic ring seems to additionally enhance this tendency. Such reasoning, taking into account the metal center role, is in fact not very far from that presented by Collman [20] and Nonhebel and Smith [21] in their first papers on the acylation of transition metal β-diketonates. It should be mentioned here that we have already reported similar reactivity involving glutaryl dichloride [6] and that analogous intramolecular lactonization was also observed in the metal centered reaction of both succinyl and glutaryl dichlorides with molybdenum and tungsten organometallic complexes [22].

The new complexes **3**–**12** have been synthesized in the course of the reactions of the products **2a** and **2b** with primary and secondary amines. The reaction can be explained in terms of nucleophilic attack of the base on the carbonyl carbon within the *meso* substituents of the macrocycle. The β,γ-unsaturated-γ-lactones are known to be susceptible to aminolytic cleavage usually leading to the open-chain amides [23,24], although pyrrolidine derivatives have also been isolated in some cases in the reactions with primary amines [25,26]. Our experiments showed the first type of the reactivity to be unique for the lactonic substituents of the complexes **2a** and **2b**. The open-chain amide-type derivatives **3**–**12** have been achieved in fair yields ranging from 65 to 92%. The structure assignment of the new complexes is based on elemental analyses, ^{1}H and ^{13}C NMR, IR and MS data. The ^{1}H and ^{13}C NMR signals and their detailed assignments as well as analytical, MS and IR data of the products **2**–**12** are summarized in Tables 1–3.

[1,4,8,11]tetraazacyclotetradecinato(2-)-κ^{4}N]Ni(II) toluene solvate (**2a**·toluene) crystallizes in the monoclinic *Cc* space group with one molecule in the independent part of the unit cell. The molecule adopts a saddle-shaped conformation in which phenylene rings and pentanediiminato fragments are tilted in opposite directions to relieve steric constrain (Fig. 1). The distortion from planarity is typical of 6,8,15,17-substituted dibenzotetraaza[14]annulenes and their metal complexes [27–29]. The structure consists of columns of stacked molecules **2a**, mixed with the molecules of toluene locked in cavities formed by the host moieties (Figs. 2 and 3). The molecules of toluene are well fitted sitting at the top of one saddle host molecule along N2–Ni1–N4 bonds and being topped by the other one—the closest in the stack. The nearest C(toluene)···Ni contacts are close to 3.5 Å. All Ni–N bond lengths are quite typical ranging from 1.79 to 1.89 Å. Also the values of the valence angles around the central Ni ion are close to 90° (from 84 up to 95°). The geometry of the saddle is defined by a number of angles between the best planes calculated for particular molecular fragments. It appears that the angle between the aromatic rings and the central planar N1N2N3N4Ni1 fragment is equal approximately 32°, whereas the C1C3C11 and C18C25C26—the other walls of cavities—have angles equal to 41.5 and 35° with the central NNNNNi plane. The best planes of the lactonic rings are almost perpendicular to the delocalized fragments of the macrocyclic ring and the central NNNNNi fragment. The atoms defining the best least-squares planes as well as the angles between them are defined in Table 4. Numerical values of the most important structural parameters are given in Table 5.

The 'upper' and 'lower' halves of the molecule **2a** (as seen in the Fig. 1) appeared to differ slightly. This seems likely to be due to asymmetric intermolecular interactions involving the guest molecule (toluene) (in particular weak CH···N and CH···π bonds). The most striking differences in the bond lengths are those for C1C3, C3C8 and C16C18, C18C23. The first pair of bonds being approximatley 1.41 and 1.44 Å whereas the other pair are equal to 1.39 and 1.39 Å. Also the possibly symmetric bonds to the nitrogens are different (C1N1 = 1.34 and N2C8 = 1.29 Å whereas the topologically equivalent bonds to N3 and N4 are equal to 1.36 and 1.37 Å, respectively. Furthermore, the β,γ-unsaturated-γ-lactonic *meso* substituents have different C=O (1.27 and 1.12 Å) and double C=C bonds (1.34 and 1.25 Å).

4. Conclusions

The reaction of the Ni(II) complex of dibenzotetraaza[14]annulene **1** with succinyl dichloride afforded new derivatives equipped with β,γ-unsaturated-γ-lactonic groups at the *meso* positions. The intramolecular cyclization of the succinoyl groups seems to involve a metal-center mediated mechanism, supported additionally by the non-planar conformation of the macrocyclic framework. The lactonic substituents of **2a** and **2b** proved to be useful synthons of amide-type ligand superstructure. The X-ray crystallography showed that the saddle-shaped molecules of **2a** form solid state 1:1 supramolecular complexes with toluene.

5. Supplementary material

Crystallographic data (excluding structural factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 157217. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EW, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Magneto-structural studies and thermal analysis of *n*-ethylpyridinium ($n = 2$, 3, 4) tetrabromocuprate(II) complexes

Antonio Luque *, Jon Sertucha, Oscar Castillo, Pascual Román

Departamento de Química Inorgánica, Universidad del País Vasco, Apartado 644, E-48080 Bilbao, Spain

Received 18 June 2001; accepted 24 September 2001

Abstract

Three *n*-ethylpyridinium salts of the tetrabromocuprate(II) anion [$n = 2$ (**1**), 3 (**2**) and 4 (**3**)] were prepared by air evaporation of an ethanolic solution of the aromatic amine base, HBr and $CuBr_2$ in a molar ratio 2:2:1. The compounds were characterized by elemental analysis, IR, UV–Vis and ESR spectroscopies, thermal analysis and variable-temperature magnetic susceptibility measurements. The crystal structures of **2** and **3** were determined by means of single-crystal X-ray diffraction methods. The $[CuBr_4]^{2-}$ anion (with C_2 symmetry for **2**) is connected to two organic cations through N–H···Br hydrogen bonds to form cation–anion–cation motifs which are held together by means of offset face-to-face interactions between the aromatic rings to give zig–zag one-dimensional chains in **2** and a dimeric entity in **3**. The dimeric units of **3** are joined by means of weak Br···Br contacts to give one-dimensional chains as well. The X-band ESR spectra show quasi-axial signals which are clearly resolved operating at Q-band, with $g_{\parallel} \gg g_{\perp} > 2.0$, characteristic of a flattened $[CuBr_4]^{2-}$ tetrahedral complex. The magnetic susceptibility measurements of powdered samples show that compounds behave as low-dimensional magnetic systems with weak antiferromagnetic exchange interactions. Thermal decomposition of the compounds yield copper(II) oxide and metallic Cu as stable final residues in synthetic air and dinitrogen atmospheres, respectively. © 2002 Elsevier Science Ltd. Keywords: Crystal structures; Magnetic properties; Thermal properties; Tetrabromocuprate(II); *n*-Ethylpyridinium

1. Introduction

We report herein on the preparation and solid-state properties of the compounds (2-ethylpyridinium)$_2$[$CuBr_4$] (**1**), (3-ethylpyridinium)$_2$[$CuBr_4$] (**2**) and (4-ethylpyridinium)$_2$[$CuBr_4$] (**3**). This work is a part of our studies of hybrid organic/inorganic materials based on organoammonium salts of copper(II) halides, in which we are attempting to analyse the influence of the organic cation features (size, shape and nature and position of the substituent) on the packing interactions that govern the crystal organisation and, as a consequence, the properties of this kind of complex [1–3]. In these compounds, structural units are held together by means of hydrogen-bonds and aromatic–aromatic interactions. These non-covalent interactions control many molecular recognition and self-assembly processes in both solution and solid-state, exercise important effects on the organization and properties of natural and artificial systems [4], and play an important role on the properties of many materials in areas such as biology [5], crystal engineering [6] and material science [7].

2. Experimental

2.1. Reagents and physical measurements

All chemicals were procured commercially and used without subsequent purification. Microanalyses of carbon, nitrogen and hydrogen were performed on a Perkin–Elmer 2400 C-, H-, N-analyser. Copper analysis was made on a Perkin–Elmer 360 atomic absorption/flame emission spectrometer. The densities were measured by flotation in $CHBr_3$–CCl_4 mixtures [8]. IR spectra were recorded in the 4000–200 cm^{-1} range on

a IR Perkin–Elmer 283 spectrometer as Nujol suspensions. UV–Vis spectra were recorded on a Shimazu 260 spectrometer. Thermoanalytical measurements were made on a Setaram Tag 24 S16 thermobalance (TG/DTA) using dynamic synthetic air and dry dinitrogen atmospheres (flow rate of 50 $cm^3\ min^{-1}$) and a heating rate of 5 °C min^{-1}. ESR polycrystalline spectra were measured on a Bruker ESP300 spectrometer, operating at X- (ca. 9.5 GHz) and Q-band (ca. 34 GHz). Magnetic susceptibility measurements were performed on polycrystalline samples of the compounds with a Quantum Design SQUID susceptometer covering the temperature range 2–300 K and using an applied magnetic field $H = 0.1$ T. Diamagnetic corrections terms were estimated from Pascal's constants [9] and experimental magnetic susceptibility data were also corrected for temperature-independent paramagnetism (60×10^{-6} $cm^3\ mol^{-1}$ per Cu^{II}) and magnetisation of the sample holder.

2.2. Syntheses

All manipulations were carried out in an open atmosphere; exposure to air (O_2) is necessary for the synthesis of bromocuprate(II) complexes in HBr media, since preparation under anaerobic conditions led to the formation of mixed-valence Cu(II)/Cu(I) compounds [10]. Copper(II) bromide (1.00 g, 4.4 mmol) dissolved previously in ethanol, was added dropwise to a stirred ethanolic solution containing equimolecular amounts of concentrated HBr (1 ml, 8.8 mmol) and the corresponding aromatic amine. After heating for approximately 4 h at 60 °C, the resulting black solutions were filtered off and then allowed to stand at room temperature. Overnight, the complexes were obtained as black polycrystalline powders which were filtered off, washed with diethylether and dried in a dinitrogen stream. For compounds **2** and **3** polyhedral dark-violet crystals suitable for single-crystal X-ray crystallographic studies were grown by slow diffusion of *n*-hexane (20 ml) into a ethanol solution (5 ml) of the complexes (0.2 mmol) transferred previously to a 15-mm diameter glass tube. Crystals were filtered off, washed with diethylether and dried in a stream of dry dinitrogen. Crystals were essentially opaque due to the absorption of light in the visible region (ca. 560 nm) and showed metallic lustre. They were found to be quite stable to light and X-ray exposure, but after 3 weeks they lost crystallinity and gradually showed green powder on their surfaces. All our attempts to obtain single-crystals of the compound **1** were unsuccessful and led to the crystallization of twinned specimens with a density value of 2.06(1) g cm^{-3}.

2.2.1. (2-Ethylpyridinium)$_2$[CuBr$_4$] (**1**)

Yield 1.93 g, 75% based on copper. *Anal.* Found: C, 28.1; H, 3.3; N, 4.7; Cu, 10.6. Calc. for $C_{14}H_{20}Br_4CuN_2$: C, 28.1; H, 3.4; N, 4.7; Cu, 10.6%. Main IR data (cm^{-1}): 3200w, 3060m, 3050w, 2970m, 1635s, 1615vs, 1600s, 1505vs, 1445m, 1390w, 1215m, 1185m, 1035s, 795s, 760s, 650m, 230w, 220w and 210w. UV–Vis [EtOH/HBr, λ_{max} nm (ε, $M^{-1}\ cm^{-1}$)]: 560 (500), 335 (2800), 250 (10500), 215 (9000).

2.2.2. (3-Ethylpyridinium)$_2$[CuBr$_4$] (**2**)

Yield 1.93 g, 75% based on copper. *Anal.* Found: C, 28.1; H, 3.3; N, 4.6; Cu, 10.6. Calc. for $C_{14}H_{20}Br_4CuN_2$: C, 28.1; H, 3.4; N, 4.7; Cu, 10.6%. Main IR data (cm^{-1}): 3215w, 3170w, 3120w, 3050m, 2980w, 1625m, 1605s, 1545s, 1430m, 1385m, 1225m, 1195m, 1120s, 800s, 740s, 675f, 230w, 220w and 210w. UV–Vis [EtOH/HBr, λ_{max} nm (ε, $M^{-1}\ cm^{-1}$)]: 565 (500), 340 (2550), 275 (7950), 215 (2150).

2.2.3. (4-Ethylpyridinium)$_2$[CuBr$_4$] (**3**)

Yield 1.85 g, 70% based on copper. *Anal.* Found: C, 28.2; H, 3.3; N, 4.7; Cu, 10.5. Calc. for $C_{14}H_{20}Br_4CuN_2$: C, 28.1; H, 3.4; N, 4.7; Cu, 10.6%. Main IR data (cm^{-1}): 3205w, 3065m, 3045m, 2970m, 1635vs, 1620s, 1595s, 1500vs, 1435m, 1380w, 1225m, 1195s, 1030s, 815vs, 770s, 655m, 490m, 230w, 220w and 210w. UV–Vis [EtOH/HBr, λ_{max} nm (ε, $M^{-1}\ cm^{-1}$)]: 570 (450), 340 (2900), 255 (12500), 220 (9500).

The purity and homogenity of the samples of **1**–**3** used for physical measurements were checked by IR spectroscopy, elemental analysis and by the comparison between the observed X-ray powder diffraction patterns and those generated from the single crystal X-ray data (for compounds **2** and **3**). The magnetic and thermal data were reproducible between different preparations.

2.3. X-ray single-crystal analysis

Diffraction data were performed with an Enraf–Nonius CAD4 automatic four-circle diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) (**2**) and Cu Kα radiation ($\lambda = 1.54180$ Å) (**3**) and operating in the ω–2θ scan mode. Crystal parameters and refinement results for both compounds are summarised in Table 1. The data were processed and corrected for Lorentz-polarization and absorption effects [11]. Crystal structures were solved by the SIR-92 program [12] and refined by full-matrix least-squares on F^2 including all reflections (SHELXL-93) [13]. Scattering factors for neutral atoms and anomalous dispersion were taken from the literature [14]. All calculations were performed using the WINGX crystallographic software package [15]. Anisotropic thermal parameters were given to all the non-hydrogen atoms. All hydrogen atoms were located on a Fourier difference map but

only the pyridinic hydrogen atoms in **2** and those attached to the nitrogen atoms of **3** were refined isotropically.

3. Results and discussion

3.1. Crystal structures of *2* and *3*

The crystal structures of compounds **2** and **3** contain the same basic structural unit that consists of a discrete $[CuBr_4]^{2-}$ anion (a) bonded by two organic cations (c), as seen in Fig. 1. The c–a–c molecular units are built through the formation of N–H···Br hydrogen bonds from the pyridinium nitrogen atoms to the bromine atoms on the anions. The molecular unit of compound **2** has a C_2 symmetry and the copper atom sits on a crystallographic twofold axis. Selected bond lengths and angles, and hydrogen contacts are listed in Table 2.

As far as the geometry of the $[CuBr_4]^{2-}$ anions is concerned, the Cu–Br bond lengths are in the range 2.36–2.40 Å, being similar to those usually found for analogous compounds [1–3,16,17]. The tetrabromocuprate(II) anions present a compressed tetrahedral geometry with two bond angles distinguishing their high values (124°–140°) from the rest (96°–101°). These values show that the geometry is intermediate between square-planar (D_{4h}) and regular tetrahedral (T_d). A quantitative description of the distortion from the tetrahedral geometry has been evaluated by the Muetterties and Guggenberger [18] method [$\Delta D=0$ for regular tetrahedron and $\Delta D=100$ for a D_{4h} geometry] and the obtained values are listed in the Table 2. It has been pointed out that hydrogen bonding interactions are among the factors which determine a deviation from T_d symmetry in the tetrahalocuprate(II) anions to a near D_{2d} symmetry [1,17]. Presumably, this is due to a reduction of the effective charge on the halide ions, thus reducing the electrostatic repulsion between the bromide ions within the $[CuBr_4]^{2-}$ species. Two different types of hydrogen bonds are found (see end of the Table 2). The first cation [N(11)–C(18)] in **3** shares its N–H proton between two Br acceptors. The N···Br distances are approximately equal suggesting that the cation has established two nearly symmetric bifurcated hydrogen bonds. The two aromatic cations of **2** and the second pyridinic cation [N(21)–C(28)] in **3** only form a monofurcated hydrogen-bond with one bromine atom. The two aromatic cations around the tetrabromocuprate(II) anion are not coplanar and make dihedral angles of 52° and 81° for **2** and **3**, respectively.

In both cases the c–a–c molecular entities are held together by means of offset face-to-face aromatic stacking interactions between the rings of adjacent units. The most significant parameters of these interactions are listed in Table 3. The packing patterns of the com-

pounds are quite different. In the crystal structure of **2**, anions and cations are packed forming infinite zig–zag one-dimensional chains (Fig. 2a) with a…cac… sequence and an M···M···M angle of 120.5° between three successive copper atoms along the chain. The intrachain Cu···Cu distances is 11.96 Å. There are no other important interactions in the crystal structure, the centroid–centroid distance between parallel aromatic cations from two neighbouring is longer than 5 Å and the shortest interchain Br···Br contact is 4.31 Å. In **3**, the c–a–c molecular entity is connected to an inversion-related counterpart through face-to-face interactions involving the first aromatic ring [N(11)–C(16)] and forming a dimeric group with a Cu···Cu distance of 11.53 Å (Fig. 2b). The separation between the planes of the second aromatic cations [N(21)–C(26)] from adjacent dimeric units is longer than 3.8 Å and no graphite-like interactions may be considered. However, a Br(3)···Br(3) contact of 4.06 Å links the dimers together into chains along the [$\bar{1}$01] direction. The Cu–Br···Br angle is 141.9°. These chains are essentially isolated in

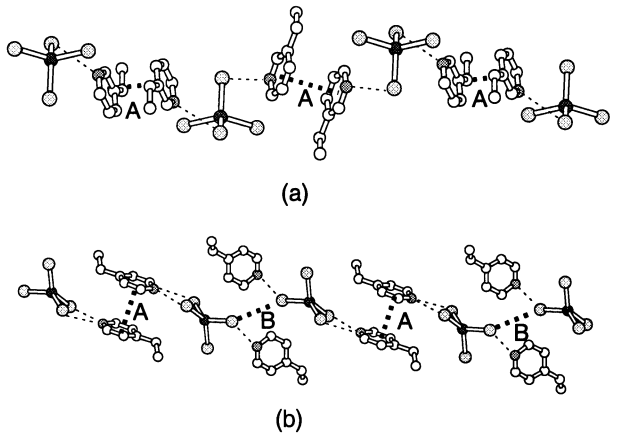

Fig. 2. (a) Fragment of the one-dimensional chain formed by the anions and cations in **2**. A denotes π-stacking interaction (see Table 3). Hydrogen bonds (dotted lines). (b) Alternated one-dimensional chain in **3**. A and B denote π-stacking interaction and Br···Br contact, respectively.

the crystal structure and the shortest interchain Br···Br and Cu···Br distances are 4.46 and 6.06 Å, respectively. So it is quite likely that the interchain interactions are only due to electrostatic effects.

3.2. Infrared and UV–Vis spectroscopies

The infrared spectra of the complexes are consistent with the structural data presented above. The IR spectra of the salts in the range 3300–600 cm^{-1} are dominated by the internal vibrations of the pyridinic ring and the aromatic and alkyl C–H bend peaks [19]. The far-IR region shows three weak bands at 230, 220 and 210 cm^{-1} due to the Cu–Br stretching vibrations, which are similar to those observed for other tetrabromocuprate(II) salts [20]. The UV–Vis spectra show strong bands below 280 nm, assigned to the $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions of the *n*-ethylpyridinium cations which are not affected by the complex anion [21]. Two weak bands appear around 340 and 565 nm which, according to the literature, are associated with ligand-to-metal charge-transfer transitions [22], since the d–d transitions are expected in the near-IR region in the case of the $[CuBr_4]^{2-}$ chromophore [23]. The broad band at 565 nm is responsible for the compounds' dark-violet colour.

3.3. ESR spectroscopy and magnetic susceptibility

ESR spectra of the compounds were recorded at room temperature on powdered samples at both X- and Q-bands. The X-band spectra show a quasi-axial signal which is clearly resolved operating at Q-band (Fig. 3). The axial spectra are consistent with the compressed tetrahedral stereochemistry of the $[CuBr_4]^{2-}$ chromophore and the relation $g_{\parallel} \gg g_{\perp} > 2.0$ indicates a $b_1(d_{x^2-y^2})$ ground state [17].

Variable temperature magnetic susceptibility measurements (2.0–300 K) were carried out on powdered samples of the complexes taken from the same uniform batches used for the chemical and structural characterizations. The room temperature magnetic moments range from 1.83 to 1.85μ_B and are typical for one non-interacting d^9 copper(II) ion. The magnetic susceptibility data for all compounds follow a Curie–Weiss law at $T > 40$ K (Table 4). Thermal variations of reciprocal susceptibility and the $\chi_m T$ product of **2** are shown in Fig. 4. The overall appearance of the $\chi_m T$ versus T curves are indicative of weak antiferromagnetic interactions between the Cu(II) centres. The χ_m versus T curve of compound **3** exhibits a maximum at 5 K (Fig. 5).

Considering the structural features of compound **2**, the experimental data were analysed using the Heisenberg model with exchange interaction between pairs of Cu(II) ions with spins S_i and S_j of the form:

$$H = -2\sum_{i>j} J_{ij} S_i S_j \quad (1)$$

where we assumed interactions between nearest neighbour copper ions on a chain (i.e. $J_{ij} = J$ for $j = i \pm 1$ and $J_{ij} = 0$ otherwise). In order to evaluate the magnitude of the exchange coupling constant we have used the polynomial expression developed by Hall to describe the results graphically presented by Bonner and Fisher [24] for a uniformly spaced chain of spins with $S = 1/2$:

$$\chi_m = \frac{Ng^2b^2}{kT}\left[\frac{A + Bx + Cx^2}{1 + Dx + Ex^2 + Fx^3}\right] \quad (2)$$

where $x = |J|/kT$, N and k are the Avogadro and Boltzmann constants, β is the Bohr magneton, $A = 0.250$, $B = 0.150$, $C = 0.3009$, $D = 1.9862$, $E = 0.6885$ and $F = 6.0626$. The least-squares best-fit results are listed in Table 4. R is the agreement factor defined as $R = \Sigma_i[(\chi_m)_{obs}(i) - (\chi_m)_{calc}(i)]^2/\Sigma_i[(\chi_m)_{obs}(i)]^2$. The calculated g and J values are in good agreement with those deduced from the ESR spectra and Curie–Weiss fit, respectively. At high temperatures ($|J|/kT \ll 1$) Eq. (2) becomes a Curie–Weiss law with $\Theta = 1.38 \times J/k$, and from the observed Θ value a J/k exchange parameter of -0.80 K should be expected, practically the calculated one. Therefore, as expected, the 1D Heisenberg model gives a good representation for the magnetic behaviour of this compound. The overlap between adjacent aromatic rings and the hydrogen bond interactions most likely provides the exchange pathways for the small antiferromagnetic coupling observed. In this respect, weak magnetic couplings across aromatic (pyrazolyl and 2,2′-bipyridine rings) π-stacking interactions have been reported [25] and hydrogen bonding has been demonstrated extensively to be a powerful tool for generating magnetic interactions and for propagating them in both inorganic [26] and organic solids [27].

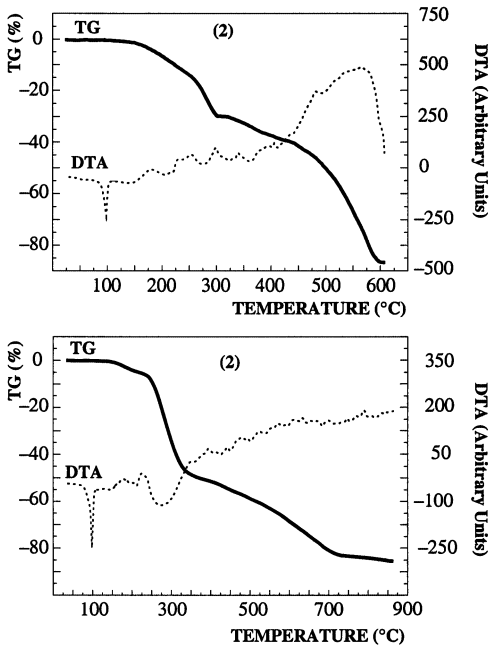

Fig. 6. Thermoanalytical curves (TG and DTA) for compound **2** in air (top) and dinitrogen (bottom) atmospheres.

In the case of **3**, the dimeric units are held together in a one-dimensional chain by means of Br···Br contacts and consequently we have analysed its magnetic data through an antiferromagnetic Heisenberg alternating chain model [28] which was derived through the Hamiltonian of Eq. (3)

$$H = -2J\Sigma[S_{2i}S_{2i-1} + \alpha S_{2i}S_{2i+1}] \quad (3)$$

where α is the alternating parameter and $S_{2i-1} = S_{2i} = S_{2i+1} = 1/2$. The expression derived for the susceptibility is

$$\chi_m = \frac{Ng^2b^2}{kT}\left[\frac{A + Bx + Cx^2}{1 + Dx + Ex^2 + Fx^3}\right] \quad (4)$$

where $x = |J|/kT$ and the coefficients A–F, all functions of α, are found in the above-referenced paper by Hatfield and co-workers [28]. The best-fit parameters are given in the Table 4.

From the point of view of the magnetic properties of copper(II)–bromide compounds, the examination of the Br···Br contacts is important [29]. The unpaired electron density in Cu(II) halide complexes is substantially delocalized out onto the orbitals of the halide ions. This is particularly true for bromide complexes, since the smaller difference in the energy between the copper d and Br p orbitals (as compared to the chloride complexes) enhances the delocalization. Hence, substantial overlap of the magnetic orbitals can occur and lead to the establishment of unusual and, on the surface, unexpected magnetic exchange pathways [30]. Although it has been observed experimentally [31,32] and confirmed theoretically [33] that the strength of these interactions, which are invariable antiferromagnetic, decrease rapidly with the Br···Br distance d, typically as d^{-10}, exchange couplings in excess of $|J/K| = 50$ K have been observed [31]. The magnitude of the interaction depends also on the geometry of the superexchange pathway through such parameters as the mean *trans* angle of the distorted $CuBr_4$ tetrahedra and the dihedral angle between the two Cu–Br···Br planes [34,35].

3.4. Thermal analysis

The thermal behaviour of the compounds have been deduced from its TG/DTA curves in both synthetic air and dinitrogen atmospheres. The data show the occurrence of three consecutive steps: melting point, organic cation pyrolysis and inorganic residue evolution (Fig. 6). No phase transitions were observed in the thermal evolution of the compounds **1**–**3** from room temperature to their melting points at 110 (**1**), 100 (**2**) and 85 °C (**3**). The melting enthalpies are 35 (**1**), 30 (**2**) and 25 kJ mol^{-1} (**3**). The melting points, the enthalpies and the density values are in the order **1** > **2** > **3**. The melt-

ing processes do not show significant dependence on the nature of the environmental gas, but the decomposition pathway of the liquid and the final residues are affected by the surrounding atmosphere. Under air atmosphere, the compounds decompose endothermically at 140 (**1**), 120 (**2**) and 155 °C (**3**) with the oxidation of the organic units to give copper(II) bromide followed by a strong exothermic loss of bromine to yield copper(II) oxide as final product above 610 °C. No other peak belonging to Cu or another copper oxide were found in the X-ray powder patterns of the final stable residues. In dinitrogen atmosphere, all degradation processes are endothermic and they lead, without stable intermediate species, to powdered metallic copper as the final product above 700 °C. No peaks corresponding to $CuBr_2$ or CuBr could be identified. These results suggest that organic cation pyrolysis under inert atmosphere can produce, direct or indirectly, the reduction of Cu(II) to Cu(0). It has been suggested that the thermal degradation of organoammonium halometalate complexes in inert atmospheres is an excellent method of obtaining powdered metals of great reactivity [36].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 164530 for compound **2** and 164531 for compound **3**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 3 July 2001; accepted 25 September 2001

Abstract

A synthesis of new chiral dihalo palladium(II)-(**5**, **7**) and nickel(II) (**6**, **8**) complexes bearing the ligands *N*,*N*′-bis{(−)-(*cis*)-myrtanyl}butylene-2,3-diimine (BMDI, **3**) and the conformationally constrained bisoxazoline ligand ((1*R*,2*S*)-*inda*-*box*, **4**) is described. Reaction of [(TMEDA)Pd(CH_3)Cl] (TMEDA: *N*,*N*,*N*′,*N*′-tetramethylethylenediamine) with **4** followed by chloride abstraction with $NaB(Ar_f)_4$ in the presence of CH_3CN afforded the solvent stabilized, monoalkyl complex [(**4**)Pd($NCCH_3$)(CH_3)]$B(Ar_f)_4$ (**9**) (Ar_f: 3,5-bis(trifluoromethyl)benzene). The solid state structure of the dichloro palladium(II) complex [{(1*R*,2*S*)-*inda*-*box*}$PdCl_2$] (**7**) was determined by X-ray structure analysis. © 2002 Elsevier Science Ltd. Keywords: Palladium; Nickel; Chirality; Bidentate nitrogen ligands; Crystal structures

1. Introduction

Numerous publications describing the coordination chemistry of phosphorous donor ligands and the application of their complexes in homogeneous catalysis have been disclosed [1]. In contrast, less has occurred for the organic nitrogen ligands, maybe because their complexes have not been used extensively for synthetic organic applications.

Recently, some research groups have highlighted the use and application of nitrogen donors, particularly because they are more easily obtained from the 'chiral pool' [2]. These reports included the application of different transition metal coordinating catalysts, which are based on the chiral and C_2-symmetric bisoxazoline ligands, in the field of catalytic asymmetric organic synthesis such as enantioselective C–C bond forming reactions [3], oxidation [4], reduction [5], and carbonylation of alkenes [6]. Furthermore, chiral and achiral Pd(II) and Ni(II) complexes bearing bidentate nitrogen donors have attracted interest due to their application as catalysts for homo- and copolymerization of linear and cyclic olefins with carbon monoxide [7,8] and for polymerization of functionalized olefins [9].

As an extension to our studies on both the coordination chemistry of chiral and C_2-symmetric heteroatom-containing ligands and the catalytic application of their metal complexes [10,11], we report here on the synthesis of new chiral diimine-palladium(II) and nickel(II) complexes containing the nitrogen ligands bis(myrtanyl)diimine (BMDI) and the C_2-symmetric bisoxazoline ligand (1*R*,2*S*)-*inda*-*box* [12]. The solid state structure of the chiral and C_2-symmetric palladium(II) complex [{(1*R*,2*S*)-*inda*-*box*}$PdCl_2$] (**7**) was determined by X-ray structure analysis.

2. Experimental

2.1. Materials

All reactions were carried out under argon by using standard Schlenk techniques. [$(PhCN)_2PdCl_2$] [13], [(DME)$NiBr_2$] (DME: 1,2-dimethoxyethane) [14], and [(TMEDA)$Pd(CH_3)Cl$] (TMEDA: *N*,*N*,*N*′,*N*′-tetra methylethylenediamine) [15] were prepared according to literature procedures. (−)-(*cis*)-Myrtanylamine and bisoxazoline ([3*aR*-[2(3′*aR**, 8′*aS**),3′*a*β, 8′*a*β]]-(+)-2,2′-methylenebis [3*a*, 8*a*-dihydro-8H-indeno[1,2-*d*]oxazole]) were purchased from Aldrich. The hydrocarbon and ether solvents were purified by distillation over $LiAlH_4$. CH_2Cl_2 was distilled from CaH_2. MeCN and Me_2CO were dried over K_2CO_3 and $CaSO_4$, respectively. Reagent grade chemicals were used as received unless otherwise stated.

2.2. Physical measurements

Elemental analyses were performed at the Pharmacology Department, University of Helsinki (EA 1110 CHNS-O CE instrument). ^1H and ^{13}C NMR spectra were recorded on a Varian Gemini 200 spectrometer operating at 200 MHz and at 50.286 MHz, respectively. Infrared spectra were measured on BIO-RAD FTS-7 FT-IR spectrometer using KBr pellet. Mass spectra (EI) were acquired with a JEOL JMS-SX102 mass spectrometer.

2.3. Synthesis of compounds

2.3.1. (BMDI) (**3**)

To a solution of 2,3-butandione (1.0 g, 11.6 mmol) was added with continuous stirring a solution of (−)-(*cis*)-myrtanylamine (3.56 g, 23.2 mmol) in MeOH (50 ml) at room temperature. A white precipitate started to form after 15 min. After stirring for 3 h the product was filtered, washed with methanol (2 × 3 ml) and dried under vacuum.

Yield: 2.1 g (51%), m.p.: 73 °C. Found: C, 80.95; H, 11.67; N, 7.77. *Anal*. Calc. for $C_{24}H_{40}N_2$: C, 80.83; H, 11.30; N, 7.85%. ^1H NMR (200 MHz, $CDCl_3$): δ 3.46–3.37 (m, 2 H, N–CH_2), 2.58–2.31 (m, 2H, N–CH_2), 2.05 (s, 6H,), 1.98–1.86 (m, 14H), 1.65–1.50 (m, 2H, ring), 1.20 (2, 6H, $H_{Me-myrt.}$), 1.06 (s, 6H, $H_{Me-myrt.}$), 0.98 (m, 2H). ^{13}C NMR (200 MHz, $CDCl_3$): δ 168 (C=N), 59.1 (C–N), 13.2 (Me-bridge). IR (KBr, cm^{-1}): 1639 (m) (C=N).

2.3.2. [(BMDI)$PdCl_2$] (**5**)

A filtered solution of the ligand (**3**) (1.02 g, 2.87 mmol) in acetone (50 ml) was added to a filtered solution of $(PhCN)_2PdCl_2$ (1.0 g, 2.61 mmol) in acetone (50 ml) with continuous stirring. Upon addition, an orange–yellow solid was formed. After 5 h stirring, the precipitate was filtered, washed with acetone (2 × 5 ml), Et_2O (2 × 10 ml) and dried in vacuum.

Yield: 0.87 g (63%), m.p. (dec.): 230 °C. Found: C, 53.75; H, 8.01; N, 5.28. *Anal*. Calc. for $C_{24}H_{40}N_2PdCl_2$: C, 53.99; H, 7.55; N, 5.24%. EI MS; *m*/*e* (rel. int.): 467 (10.0%, $M^+ - 2Cl$), 356 (30%, $M^+ - Pd2Cl$). ^1H NMR (200 MHz, $CDCl_3$): δ 3.87 (m, 2H, N–CH_2), 2.80 (m, 2H, N–CH_2), 2.34 (8H,), 2.05–1.85 (m, 12H) 1.44 (m, 2H, ring), 1.19 (s, 6H, $H_{Me-myrt.}$), 1.07 (s, 6H, $H_{Me-myrt.}$), 0.98 (m, 2H). ^{13}C NMR (200 MHz, $CDCl_3$): δ 179 (C=N), 60.1 (C–N), 15.3 (Me-bridge). IR (KBr, cm^{-1}): 1635 (m) (C=N).

2.3.3. [(BMDI)$NiBr_2$] (**6**)

A filtered solution of the ligand BMDI (**3**) (1.27 g, 3.56 mmol) in CH_2Cl_2 (50 ml) was added to a suspension of (DME)$NiBr_2$ (1.0 g, 3.23 mmol) in the same solvent (50 ml) with continuous stirring. Upon addition, a red–orange solid was formed. Stirring was continued for 5 h, and the precipitate was filtered, washed with acetone (2 × 5 ml), Et_2O (2 × 10 ml) and dried in vacuum.

Yield: 1.43 g (77%), m.p.(dec.): 110 °C. Found: C, 49.81; H, 7.42; N, 4.93. *Anal*. Calc. for $C_{24}H_{40}N_2NiBr_2$: C, 50.12; H, 7.01; N, 4.87%. EI MS; *m*/*e* (rel. int.): 495 (30.0%, $M^+ - Br$), 412 (100.0%, $M^+ - 2Br$), 354 (30%, $M^+ - Ni2Br$). IR (KBr, cm^{-1}): 1636 (m) (C=N).

2.3.4. [{(1*R*,2*S*)-inda-box}$PdCl_2$] (**7**)

A filtered solution of the bisoxazoline ligand (**4**) (0.95 g, 2.87 mmol) in CH_2Cl_2 (50 ml) was added to a filtered solution of $(PhCN)_2PdCl_2$ (1.0 g, 2.61 mmol) in acetone (50 ml) with continuous stirring. Upon addition, a white solid was formed. After stirring for 18 h the precipitate was filtered, washed with acetone (2 × 5 ml), Et_2O (2 × 10 ml) and dried under vacuum. Orange crystals suitable for X-ray analysis were formed by crystallization from acetone.

Yield: 0.60 g (45%), m.p. (dec.): 183 °C. Found: C, 49.37; H, 3.85; N, 5.57. Anal. Calc. for $C_{21}H_{18}N_2O_2PdCl_2$: C, 49.68; H, 3.57; N, 5.52%. ^1H NMR (200 MHz, $CDCl_3$): δ 8.60 (m, 2H, $CH_{2\text{-bridge}}$), 7.39–7.26 (m, 8H, $H_{arom.}$), 5.38 (dt, 2H, 13 Hz), 6.27 (d, 2H, 6Hz) 3.38 (d, 4H). IR (KBr, cm^{-1}): 1652 (m) (C=N).

2.3.5. [{(1*R*,2*S*)-inda-box}$NiBr_2$] (**8**)

To a suspension of (DME)$NiBr_2$ (0.60 g, 1.94 mmol) in CH_2Cl_2 (50 ml) was added a filtered solution of the ligand (**4**) (0.77 g, 2.33 mmol) in the same solvent (50 ml) with continuous stirring. Upon addition, the colour changed from orange to red. Stirring was continued for 12 h at room temperature. After which, the precipitate was filtered, washed with acetone (2 × 5 ml), Et_2O (2 × 10 ml) and dried in vacuum.

Yield: 0.62 g (58%), m.p. (dec.): 200 °C. Found: C, 44.24; H, 3.63; N, 4.58. Anal. Calc. for $C_{21}H_{18}N_2O_2NiBr_2 \cdot H_2O$: C, 44.49; H, 3.56; N, 4.94%. EI MS; *m/e* (rel. int.): 468 (25.0%, $M^+ - Br$), 388 (50.0%, $M^+ - 2Br$), 330 (20%, $M^+ - Ni2Br$). IR (KBr, cm^{-1}): 1670 (m) (C=N).

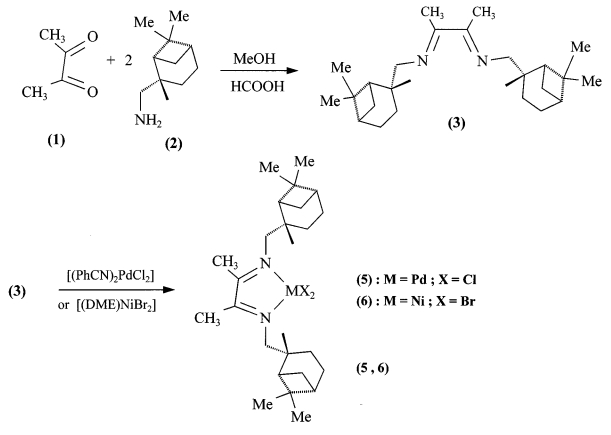

Fig. 1. Synthesis of the ligand BMDI (**3**) and its palladium(II)- and nickel(II) dihalide complexes (**5** and **6**).

*2.3.6. [{(1R,2S)-inda-box}Pd(NCCH$_3$)(CH$_3$)]·B(Ar$_f$)$_4$ (**9**)*

To a solution of [(TMEDA)Pd(CH_3)Cl] (0.17 g, 0.61 mmol) in toluene (20 ml) and CH_2Cl_2 (15 ml) was added with continuous stirring a solution of the ligand (**4**) (0.20 g, 0.61 mmol) in CH_2Cl_2 (30 ml). After 28 h stirring, the product was precipitated with diethylether and filtered. The residue was dissolved in CH_2Cl_2 (35 ml) and CH_3CN (15 ml) and $NaB(Ar_f)_4$ (0.44 g, 0.49 mmol) was added. After stirring for 24 h, the mixture was filtered and the solvent was evaporated to dryness. The isolated yellow product was extracted with CH_2Cl_2 (10 ml), filtered and dried in vacuum.

Yield: 0.41g (62%), m.p. (dec.): 83 °C. Found: C, 47.27; H, 2.92; N, 3.25. *Anal.* Calc. for $C_{56}H_{36}N_3O_2BF_{24}Pd \cdot 3H_2O$: C, 47.69; H, 3.00; N, 2.98%. *2.4. X-ray structure determinations for **7***

Crystal data of compound (**7**) were collected on a Rigaku AFC7S single-crystal diffractometer at 193(2) K using graphite monochromatized Mo Kα radiation (0.71073 Å). The intensities were corrected for Lorentz and polarization effects [16]. An experimental absorption correction (psi-scan) was performed [17]. The structure was solved by direct methods (SHELX-97) [18]. All non-hydrogen atoms were refined anisotropically and hydrogen atoms isotropically on calculated positions. Final calculations were performed with SHELX-97 and SHELXTL/PC [19] program systems. The cell parameters and specific data collection parameters are summarized in Table 1.

3. Results and discussion

3.1. Ligand and complexes synthesis

The condensation reaction of the commercially available 2,3-butandione (**1**) with 2 equiv. of the enantiomerically pure amine (−)-*cis*-myrtanylamine (**2**) in MeOH at 25 °C afforded the bidentate diimine ligand, *N*,*N*′-bis((−)-*cis*-myrtanyl)butylene-2,3-diimine (BMDI, **3**) in a moderate yield (Fig. 1). The presence of a medium to strong band at around 1639 cm^{-1} in the IR-spectra of the Schiff base ligand and the disappearance of the peak due to the carbonyl group of the starting material indicate the formation of the desired diimine. The ^{13}C NMR spectrum of the diimine **3**, exhibits a resonance at 168 ppm which can be ascribed to the imine group (C=N). A singlet at 13.2 ppm has also been observed which can be attributed to the methyl groups in the backbone of the ligand.

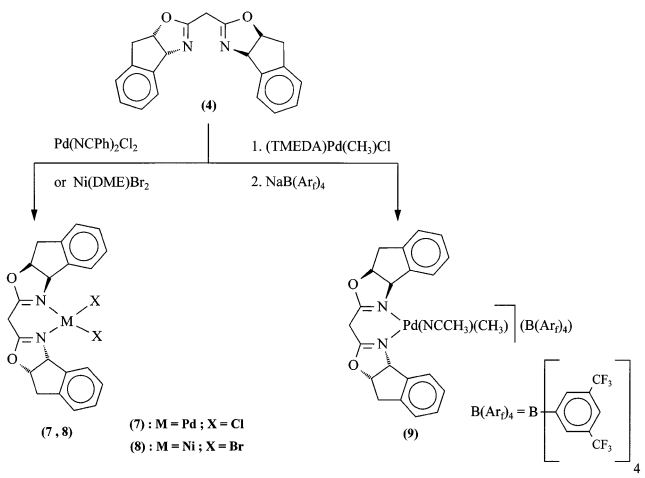

Fig. 2. Synthesis of the dihalide and the monocationic, monoalkyl complexes (**7**, **8**, **9**) of the bisoxazoline ligand (**4**).

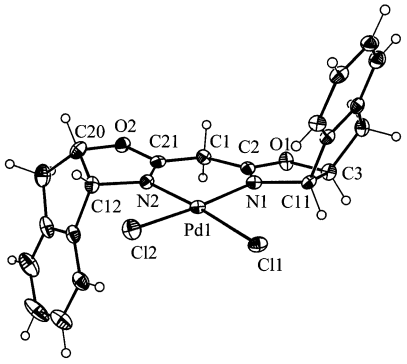

Fig. 3. Molecular structure of complex **7** with 30% probability thermal ellipsoids depicted.

Table 2
Selected bond lengths (Å) and bond angles (°) for complex **7**

Bond lengths			
Pd1–N1	2.046(4)	Cl2–Pd1–Cl1	87.47(6)
Pd1–N2	2.055(5)	C2–N1–Pd1	126.1(4)
Pd1–Cl2	2.2905(17)	C21–N2–Pd1	125.8(4)
Pd1–Cl1	2.2945(16)	C12–N2–Pd1	127.4(4)
		C11–N1–Pd1	126.9(3)
Bond angles			
N1–Pd1–N2	89.97(18)	C21–C1–C2	116.9(5)
N1–Pd1–Cl2	174.21(14)	O1–C2–C1	112.2(5)
N2–Pd1–Cl2	91.69(14)	O2–C21–C1	112.7(5)
N1–Pd1–Cl1	91.32(14)	N1–C2–C1	129.5(5)
N2–Pd1–Cl1	175.20(15)	N2–C21–C1	130.0(6)

The square-planar palladium(II) dihalide complexes [(BMDI)$PdCl_2$] (**5**) and {(1*R*,2*S*)-*inda-box*}$PdCl_2$ (**7**) as well as the nickel(II) complexes (BMDI)$NiBr_2$ (**6**) and {(1*R*,2*S*)-*inda-box*}$NiBr_2$ (**8**) were prepared in moderate yields by treating the complexes [$(NCPh)_2PdCl_2$] or [(DME)$NiBr_2$] with the corresponding ligands in acetone or CH_2Cl_2 at room temperature (Figs. 1 and 2).

Pd(II) complexes, like **5** and **7**, can be used as catalysts for CO/alkene copolymerization after conversion of the dichlorides to the solvent stabilized cationic species (Fig. 2) [20]. The monoalkyl complex [{(1*S*,2*R*)-*inda-box*}$Pd(NCCH_3)(CH_3)]\cdot B(Ar_f)_4$ (**9**) was prepared by the reaction of [(TMEDA)$Pd(CH_3)Cl$] with **4** in CH_2Cl_2 followed by chloride abstraction with $NaB(Ar_f)_4$ in the presence of CH_3CN.

To confirm the identity of the complexes prepared in the present study, a variety of techniques including elemental analysis, mass spectroscopy (EI), infrared spectroscopy, ^1H and ^{13}C NMR have been used. In addition, complex **7** was a subject to single-crystal X-ray diffraction study. The isolated complexes are microcrystalline and stable at atmospheric conditions, except compound **9** which is moisture sensitive. Compared to the palladium(II) complexes, the corresponding dibromo nickel(II) complexes (**6** and **8**) showed lower solubility in deuterated organic solvents such as $CDCl_3$, CD_3CN, and CD_3COCD_3.

3.2. Crystal structure of complex (7)

Suitable crystals of the chiral and C_2-symmetric palladium(II) complex [Pd(*inda-box*)Cl_2] (**7**) (Fig. 3) were obtained by crystallization from acetone. Selected bond lengths and angles are given in Table 2. The palladium atom is at the center of approximately square-planar arrangement with two chlorine atoms (Cl1 and Cl2) and two nitrogen atoms (N1 and N2) of the bidentate ligand. The compound crystallizes in the monoclinic space groups $P2_1$ (No. 4) with $a = 7.633(2)$ Å, $b = 8.807(2)$ Å, $c = 14.664(3)$ Å, $\beta = 97.22(3)°$, $V = 978.0(4)$ Å^3 and $Z = 2$.

The results of X-ray analysis indicate the desired C_2-symmetric form for complex **7** in the solid state. This is also the case in solution, since only one set of resonances for protons related by a C_2-symmetric axis can be detected. The significant bond lengths and angles in **7** are similar for the ones reported for the structures of the C_2-symmetric [(1,2-bis(*N*-indolinyl)ethane)$PdCl_2$] [21] and [(2,2′-bipyridine)$PdCl_2$] [22] which indicates electronic similarity of the nitrogen sites in both complexes.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 166715. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Novel trinuclear disilver(I)–copper(II) complexes, $[Ag(PPh_3)_2]_2[Cu(mtm)_2]$ (**1**) and $[Ag_2(dppm)_2][Cu(mtm)_2]$ (**2**) (mtm = [bis(methylthio)methylene]malonate, dppm = bis(diphenylphosphino)methane) have been prepared and characterized by a single-crystal X-ray structure analysis. In the complex **1**, a silver atom is coordinated to each of the two carboxylate oxygens with different bond distances of 2.325(5) Å (Ag–O(1)) and 2.653(6) Å (Ag–O(2)). In the case of the complex **2**, two silver atoms are bridged by two dppm ligands separated by 3.0130(9) Å and Ag(1) has bonded to O(5) (2.442(5) Å). Interestingly, Ag(2) has bonded to O(4) (2.325(5) Å) which is not a coordinated carboxylate oxygen bonded to copper(II) atom. Interaction between silver(I)–thioether group was not observed in **1** and **2**. © 2002 Published by Elsevier Science Ltd.

Keywords: Trinuclear complexes; Single crystal structures; Copper(II); Silver(I); Carboxylate; Thioether

1. Introduction

Since Coucouvanis and coworkers synthesized an interesting class of polynuclear adducts between $M(PPh_3)_2$ (M = Ni, Cu) and anionic metal complexes in 1974 [1], some derivatives have been reported. For example, Kawamura and coworkers have reported the structures of Pt and Pd derivatives containing tri(*n*-butyl)phosphine silver complexes [2]. Very recently, our group has reported the structure of $[Ag(PR_3)_2]_2[Ni(mnt)_2]$ (R = Me, Et, Cy and mnt = maleonitriledithiolate) and $[Ag_2L_2][Ni(mnt)]_2$ (L = dppf and dppm) [3]. The structures reported so far having $[M(PR_3)_2[M'(L)_2]$ type formulae contain only mnt as a ligand except one example. In 1998, Healy and coworkers have reported the structure using thiosalicylate having O and S donor set during their electrochemical reactions [4].

The study on the bonding modes of the potentially multidentate ligands provide various synthetic routes for synthesizing magnetic materials, catalysts and biological model compounds. Ylidenemalonate ligands containing both sulfur and oxygen exhibit versatile coordination chemistry and are capable of forming polymeric and molecular metal complexes having interesting structural and magnetic properties [5,6]. In particular, the ligand mtm (mtm = [bis(methylthio)methyl-

PII: S0277-5387(01)00951-2

ene]malonate) has been shown to be useful in linking two different metal ions to afford a ferrimagnetic compound. The heterobimetallic layered compounds of manganese(II) and copper(II) metal ions [5], and the polymeric (μ-oxo)diferric chain complex, all of which include the ligand mtm, have shown unique magnetism [6]. Such sulfur-containing ligands with diverse potentials have prompted our interest in synthesizing new multinuclear metal complexes, not only to search out the novel strategy to design multinuclear magnetic materials, but also to investigate their coordination modes and structural properties. Here, we report the synthesis of novel heterotrinuclear complexes of $[Ag(PPh_3)_2]_2$-$[Cu(mtm)_2]$ and $[Ag_2(dppm)_2][Cu(mtm)_2]$ and their unique structural properties.

2. Experimental

2.1. Materials and instrumentation

Triphenylphosphine (Aldrich) and dppm (bis(-diphenylphosphino)methane) (Aldirch) were used as received without further purification. The mtm ligand was synthesized by slight modification of literature methods [7a]. Infrared spectra were recorded in a Nicolet Avatar 360 FT-IR spectrometer. Elemental analyses were performed at the Korea Basic Science Institute Seoul Branch Lab.

2.1.1. $[Ag(PPh_3)_2]_2[Cu(mtm)_2]$ (1)

$CuSO_4$ (0.08 g, 0.5 mmol) and $(NH_4)_2SO_4$ (0.07 g, 0.5 mmol) were added to a solution of $Ba(mtm)\cdot 2H_2O$ (0.34 g, 1 mmol) in water (200 ml). The mixture was stirred for 2 h. The precipitate $BaSO_4$ was removed by filtration, the filtrate was treated with Ag_2SO_4 (0.16 g, 0.5 mmol), and the mixture was stirred for 24 h in the dark. The resulting pale green precipitate was collected on a sintered glass filter and washed successively with water (100 ml), ethanol (20 ml) and ether (20 ml) and dried in vacuo. To this pale green solid suspended in $CHCl_3$ (50 ml) was added PPh_3 (0.52 g, 2 mmol). The mixture was stirred for 24 h. Unreacted solid was removed by filtration, and the resulting blue solution was concentrated to approximately 10 ml under reduced pressure and layered with ether. Blue crystals formed after 24 h were collected on a sintered glass filter. They lost their crystallinity when removed from the mother liquor. Washing with ether and hexane produced blue solids. Yield is 69% based on PPh_3. Elemental analysis was performed after vacuum drying at room temperature (r.t.). *Anal.* Calc. for $[Ag(PPh_3)_2]_2[Cu(mtm)_2]$: C, 57.95; H, 4.16; S, 7.36. Found: C, 57.65; H, 4.25; S, 7.32%. IR (cm^{-1}, KBr disc) 3051(s), 2918(m), 1629(vs), 1586(sh), 1480(s), 1433(s), 1303(vs), 1096(s), 748(s), 592(s), 506(s).

2.1.2. $[Ag_2(dppm)_2][Cu(mtm)_2]$ (2)

The procedure was similar to that used to prepare compound **1**, except that 2 equiv. of dppm were used in place of PPh_3. Recrystallization with CH_2Cl_2/acetone/ether solvent system yielded blue needle crystals (yield 65%). They lost their crystallinity when removed from the mother liquor. Elemental analysis was performed after vacuum drying at r.t. *Anal.* Calc. for $[Ag_2(dppm)_2][Cu(mtm)_2]$: C, 50.99; H, 3.86; S, 8.78. Found: C, 51.02; H, 3.92; S, 8.57%. IR (cm^{-1}, KBr disc) 3050(m), 2918(m), 1612(vs, sh), 1483(m), 1434(s), 1098(s), 778(s), 740(s), 693(s) 586(m), 511(m), 474(m).

2.1.3. X-ray analysis of $[Ag(PPh_3)_2]_2[Cu(mtm)_2]\cdot 2CHCl_3$ (1) and $[Ag_2(dppm)_2][Cu(mtm)_2]\cdot 2CH_2Cl_2\cdot$acetone (2)

X-ray crystallographic data were collected in an Enarf–Nonius CAD 4 automatic diffractometer with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) at ambient temperature for compound **1**, $[Ag(PPh_3)_2]_2$-$[Cu(mtm)_2]\cdot 2CHCl_3$, and a Siemens three-circle diffractometer with a CCD area detector (SMART system) [8] under nitrogen flow using a LT-2 low-temperature system at 233 K for compound **2**, $[Ag_2(dppm)_2]$-$[Cu(mtm)_2]\cdot 2CH_2Cl_2\cdot$acetone. The structures were solved by the direct methods (SHELXS-97) and were refined by full-matrix least-squares techniques (SHELXL-97) [9]. Crystal parameters and procedural information corresponding to data collection and structure solution are given in Table 1.

3. Results and discussion

The reaction of $CuSO_4$ along with $(NH_4)_2SO_4$ and barium salts of [bis(methylthio)methylene]malonate (mtm) in distilled water gives a deep green solution at room temperature. The addition of silver sulfate to this deep green solution affords a pale green precipitate. Treatment of this compound with PPh_3 in chloroform results in the formation of a blue solution from which $[Ag(PPh_3)_2]_2[Cu(mtm)_2]\cdot 2CHCl_3$ (**1**) has been crystallized. The molecular structure of **1** as determined by single-crystal X-ray structure analysis is shown in Fig. 1. Relevant bond distances and angles are listed in Table 2. The copper(II) ion is coordinated in a square-planar geometry by four carboxylate oxygens from two mtm ligands (see Scheme 1). Each of the two Ag (I) cations is coordinated in a distorted tetrahedral arrangement by two PPh_3 ligands and two carboxylate oxygens (Ag–O(1) = 2.325(5) Å) and (Ag–O(2) = 2.653(6) Å) that form a bridging to the Cu(II) center. As a result, the interaction of the $Ag(PPh_3)_2^+$ cations with the $Cu(mtm)_2^-$ complex anions occurs at the CuO_4 moiety. The plane which is made up of C(2), C(2_1), C(3), C(4), S(1), S(2) of mtm ligand is bent by 65° from

the mean square-plane calculated by copper and four carboxylate oxygen atoms resulting in an overall chair-like conformation.

The reaction of the pale green precipitate with 2 equiv. of bis(diphenylphosphino)methane (dppm) led to the formation of trinuclear complex $[Ag_2(dppm)_2]$-$[Cu(mtm)_2]$ (**2**). The crystal structure of complex **2** is shown in Fig. 2. Selected bond distances and angles are listed in Table 3. In striking contrast to the complex **1** described above, this complex has an unsymmetric structure. The two silver atoms, bridged by two dppm ligands and separated by 3.0130(9) Å, show some weak Ag–Ag bonding character [10]. One silver (Ag(1)–O(5) = 2.442(5) Å) is coordinated to a carboxylate oxygen that bridges to the Cu(II) center, while the other silver (Ag(2)–O(4) = 2.325(5) Å) is coordinated by the carbonyl oxygen that is not coordinated to the copper(II) atom. The coordination geometry

Scheme 1.

around the copper(II) atom is distorted square planar. The resulting chelation mode forms a seven-membered ring made up of two Ag(I), three oxygens, one carbon and one Cu(II). It is remarkable that the addition of PPh_3 into the $[Cu(mtm)_2]^{2-}$ moiety produced the symmetric complex **1**, while the addition of dppm to the same moiety resulted in the formation of the unusual unsymmetric complex **2**. Such tactic could be employed for synthesizing symmetric and unsymmetric complexes by switching the phosphine ligands. Two dppm molecules should react with two Ag(I) to produce an $Ag_2(dppm)_2^{2+}$ adduct [11], which is then, unlike the case of complex **1**, unsymmetrically coordinated to two oxygens (O(4) and O(5)) of the carboxylates of $[Cu(mtm)_2]^{2-}$. For complex **1**, each silver(I) is coordinated by two PPh_3 ligands to afford two $Ag(PPh_3)_2^+$ units and these $Ag(PPh_3)_2^+$ units are then coordinated symmetrically to two oxygens of CuO_4 moiety.

Another important feature in the molecular structures is the binding modes in complexes **1** and **2**. It has been well documented that the silver(I) ion is able to form coordination complexes with a variety of donor atoms (e.g. S, P, N and O) [12], and the complexes of silver(I) with carboxylic acid can adopt various bonding modes which may be monomeric or extended to dimeric, olygomeric or polymeric one through a carboxylate bridging [13]. Moreover, the thioether function of the mtm ligands is a non-innocent donor set to the coordination process [7b]. For example, the mtm ligand and its derivatives containing both two sulfur and two oxygen donors may coordinate to Pt(II) ion via one of the three distinct modes of O,O′-, O,S′-, and S,S′-chelation [7]. For both complexes **1** and **2** only O,O′-chelation to Cu(II) has been observed. The Cu(II) ion is regarded on the borderline in the hard–soft acid–base concept [14] and can interact with both oxygen and sulfur of the mtm ligand during the reaction. It is noted that in our work only oxygen donor atoms coordinated to Cu(II) ion. It is very interesting

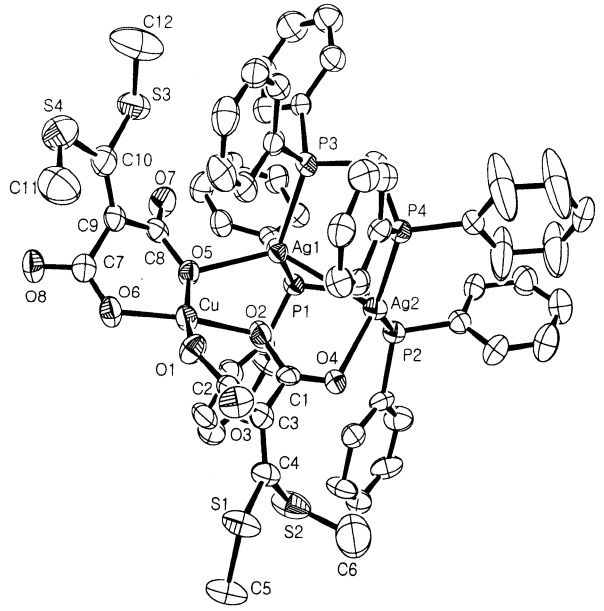

Fig. 2. ORTEP drawing of $[Ag_2(dppm)_2][Cu(mtm)_2]\cdot 2CH_2Cl_2\cdot$acetone (**2**) showing the atomic labeling scheme and thermal ellipsoids at the 50% level. The hydrogen atoms and solvent molecules are omitted for clarity.

to observe that, in complexes **1** and **2**, the silver(I) cation coordinated to two oxygens instead of two sulfurs, even though the high preference of Ag(I) for sulfur has been reported with the mixed cyclic ether 1,4-thioxane [12]. Complexes **1** and **2** also possess unusual coordination modes between Ag^+ cations and $[Cu(mtm)_2]^{2-}$. The complex **1** involves silver(I) cations bound to two oxygens coordinated to Cu(II) cation, whereas the complex **2** has bridging through both the oxygen of carbonyl moiety and the oxygen coordinated to Cu(II) center. The bidentate dithiolene ligand containing sulfur donor atom is often used to produce polynuclear complexes. For example, the dithiolene complexes of Group 10 metals react with Ag(I) to form mixed-metal complexes of the type $[M(mnt)_2\{Ag(PR_3)_2\}_2]$ (M = Ni, Pd, Pt; mnt = maleonitriledithiolate) [1–3]. These structures show slightly longer Ag–S distances than the normal and shorter M–Ag distances than van der Waals contact. These results imply bonding interaction between M and Ag atoms. In the structures of these mixed-metal complexes the silver atoms are located above and below the MS_4 planes. Entirely different from the complexes of the $[M(mnt)_2\{Ag(PR_3)_2\}_2]$ described above, our trinuclear adducts of $[Cu(mtm)_2][Ag(PPh_3)_2]_2$ (**1**) and $[Cu(mtm)_2][Ag_2(dppm)_2]$ (**2**) do not exhibit bonding interaction between Cu(II) centers and Ag(I) (Ag–Cu = 3.4845(15) in **1** and Ag(1)–Cu = 5.0060(11) in **2**).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 157084 and 157085 for compounds **1** and **2**, respectively. Abstract

Treatment of the Schiff base ligands 2-$ClC_6H_4C(H)=NCH_2(C_4H_7O)$ (**a**) and 3,4-$(MeO)_2C_6H_3C(H)=NCH_2(C_4H_7O)$ (**b**) with palladium(II) acetate in toluene or glacial acetic acid gave the dinuclear cyclometallated complexes $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}(\mu\text{-}OAc)]_2$ (**1a**) and $[Pd\{3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)\}(\mu\text{-}OAc)]_2$ (**1b**) with the ligand bonded to the palladium atom through the imine nitrogen and the C6 carbon atom. The ^1H and $^{13}C-\{^1H\}$ NMR spectra of the complexes show the occurrence in solution of three pairs of enantiomers. The acetato-bridged cyclometallated complex $[Pd\{3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)\}(\mu\text{-}OAc)]_2$ (**1c**) was prepared from the enantiopure ligand (*R*)-3,4-$(MeO)_2C_6H_3(H)=NCH_2(C_4H_7O)$ (**c**). The NMR spectra of **1c** showed the existence of only two diastereomers in the solution. The reaction of **1a** and **1b** with aqueous sodium chloride gave the chloro-bridged complexes $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}(\mu\text{-}Cl)]_2$ (**2a**) and $[Pd\{3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)\}(\mu\text{-}Cl)]_2$ (**2b**) after a metathesis reaction. The reaction of **2a** with PPh_3 in acetone gave the mononuclear cyclometallated complex $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}(Cl)(PPh_3)]$ (**3a**) in a bridge-splitting reaction. Treatment of **3a** with silver triflate gave the cyclometallated complex $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}(PPh_3)][CF_3SO_3]$ (**4a**) in which the palladium atom is bonded to four different atoms C, N, O and P. When complex **2a** was reacted with silver triflate in acetone complex $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}((CH_3)_2CO)][CF_3SO_3]$ (**5a**) was obtained with the ligand as [C,N,O] coordinated. The reaction of complexes **2a** and **2b** with the diphosphine dppp in a complex–phosphine 1:1 molar ratio gave the dinuclear cyclometallated complexes $[\{Pd[2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)](Cl)\}_2(\mu\text{-}Ph_2P(CH_2)_3PPh_2)]$ (**8a**) and $[\{Pd[3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)](Cl)\}_2(\mu\text{-}Ph_2P(CH_2)_3PPh_2)]$ (**5b**) with the diphosphine bridging the two palladium atoms. Reaction of complexes **2a** and **2b** with the phosphines dppp and *cis*-dppe in a 1:2 molar ratio gave the mononuclear complexes $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}\{Ph_2P(CH_2)_3Ph_2\text{-}P,P\}][ClO_4]$ (**6a**), $[Pd\{3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)\}\{Ph_2P(CH_2)_3Ph_2\text{-}P,P\}][ClO_4]$ (**3b**) and $[Pd\{2\text{-}ClC_6H_2C(H)=NCH_2(C_4H_7O)\}(cis\text{-}Ph_2PCH=CHPh_2\text{-}P,P)][Cl]$ (**4b**). The treatment of **2a** with the triphosphine bis(2-diphenylphosphinoethyl)phenylphosphine in 1:2 molar ratio, followed by treatment with sodium perchlorate gave $[Pd\{3,4\text{-}(MeO)_2ClC_6H_3C(H)=NCH_2(C_4H_7O)\}\{(PPh_2CH_2CH_2)_2PPh\text{-}P,P,P\}][ClO_4]$ (**7a**) in which the palladium atom is bonded to the triphosphine through the three phosphorus atoms and to the Schiff base ligand through one carbon atom and the imine nitrogen. © 2002 Elsevier Science Ltd. 1. Introduction

The study of cyclometallated compounds has attracted much attention over the last three decades [1–5]. They present numerous applications in organic and organometallic synthesis [6], in insertion reactions [7], in optical resolution [8], in the determination of the enantiomeric excess [9], in the synthesis of new metal mesogenic compounds [10], biologically active compounds [11,12], in catalytic materials [13], in the building of new self assembly supramolecular species [14], and to promote unusual coordination environments [15].

Our interest in cyclometallated complexes has been, in part, focused on the study of compounds derived from potentially [C,N,X] (X = O, S, N) terdentate ligands, such as semicarbazones [16,17], thiosemicarbazones [18,19] or Schiff bases [20–23] which react with palladium(II) and platinum(II) or palladium(0) to give cyclometallated complexes with two fused rings at the metal. In spite of the large number of [C,N,N] derivatives reported [24], relatively few [C,N,O] derivatives are known [25].

Semicarbazones are known to react readily with $M_2[PdCl_4]$ (M = Li, K) to give mononuclear cyclometallated complexes; however, complexes derived from thiosemicarbazones show tetranuclear structures.

In the present paper we report the synthesis of new cyclometallated compounds derived from the potentially terdentate Schiff bases 2-$ClC_6H_4C(H)$=NCH_2-(C_4H_7O) (**a**) and 3,4-$(MeO)_2C_6H_3C(H)$=$NCH_2(C_4H_7O)$ (**b**). We have found that direct reaction with Pd(II) or Pd(0) salts did not yield the expected complex with the ligand in a [C,N,O] terdentate fashion. Thus, in an oxidative addition reaction, treatment of **a** with $[Pd_2(dba)_3]$, in benzene under reflux, gave an untreatable mixture which was not further investigated, and reaction of **a** or **b** with palladium(II) acetate, in glacial acetic acid, only yielded the dimeric acetato-bridged complexes **1a** and **1b** with the corresponding ligand as [C,N] bidentate. However, the vacant site produced in the coordination sphere of the palladium atom, upon reaction of the cyclometallated halogen-bridged dimer complexes with a Ag(I) salt, promotes formation of the Pd–O bond. The reactivity of the cyclometallated complexes with mono-, di- and triphosphines is reported, and we also describe a new type of stereoisomerism arising from the folded open-book disposition of the cyclometallated ligands in the acetato-bridged dimers **1a** and **1b**.

2. Experimental

Safety note: Caution: perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of these materials should be prepared and handled with great caution.

2.1. General procedures

Solvents were purified by standard methods [26]. Chemicals were reagent grade. The phosphines PPh_3, *cis*-Ph_2PCH=$CHPPh_2$ (*cis*-dppe), $Ph_2P(CH_2)_3PPh_2$ (dppp) and $(Ph_2PCH_2CH_2)_2PPh$ (triphos) were purchased from Aldrich-Chemie. Microanalyses were carried out using a Carlo–Erba elemental analyzer, model 1108. IR spectra were recorded as Nujol mulls or KBr discs on a Perkin–Elmer 1330 and on a Mattson spectrophotometers. NMR spectra were obtained as $CDCl_3$ solutions and referenced to $SiMe_4$ (^1H, $^{13}C-\{^1H\}$) or 85% H_3PO_4 ($^{31}P-\{^1H\}$) and were recorded on a Bruker AC-2005 spectrometer. All chemical shifts were reported downfield from standards. The FAB mass spectra were recorded using a Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix. Conductivity measurements were made on a CRISON GLP 32 conductivimeter using 10^{-3} mol dm^{-3} solutions in dry acetonitrile.

The syntheses of 2-$ClC_6H_4C(H)$=$NCH_2(C_4H_7O)$ (**a**) and 3,4-$(MeO)_2C_6H_3C(H)$=$NCH_2(C_4H_7O)$ (**b**) were performed by heating chloroform solutions of the appropriate quantities of tetrahydrofurfurylamine and 2-chlorobenzaldehyde or 3,4-dimethoxybenzaldehyde, respectively, in a Dean–Stark apparatus under reflux. Schiff base ligand (*R*)-3,4-$(MeO)_2C_6H_3C(H)$=NCH_2-(C_4H_7O) (**c**) was prepared similarly using enantiopure (*R*)-tetrahydrofufurylamine. IR (ν_{max}/cm^{-1}) (C=N) 1640s (**a**), 1645s (**b**, **c**). $^{13}C-\{^1H\}$ NMR for ligand **a**: (50.28 MHz, $CDCl_3$): δ 158.9 (C=N); δ 135.0 (C1); δ 129.6 (C6); δ 131.1 (C2); δ 126.8 (C5); δ 128.3, 131.4 (C3, C4); δ 78.3 (C8); δ 68.1 (C11); δ 65.8 (C7); δ 29.2, 25.7 (C9, C10). $^{13}C-\{^1H\}$ NMR for ligand **b, c**: δ 161.9 (C=N); δ 151.3, 149.2 (C3, C4); δ 129.4 (C1); δ 123.1 (C6); δ 110.3, 108.8 (C2, C5); δ 78.5 (C8); δ 68.1 (C11); δ 65.7 (C7); δ 29.3, 25.6 (C9, C10); δ 55.8 (OCH_3).

2.2. Syntheses

2.2.1. *[Pd{2-$ClC_6H_3C(H)$=$NCH_2(C_4H_7O)$}(μ-OAc)]$_2$ (1a)*

A pressure tube containing 2-$ClC_6H_4C(H)$=NCH_2-(C_4H_7O) (**a**) (150 mg, 0.67 mmol), palladium(II) acetate (150 mg, 0.67 mmol) and 25 cm^3 of dry toluene was sealed under argon. The resulting mixture was heated at 60 °C for 3 h. After cooling to room temperature (r.t.) the orange precipitate formed was filtered off and dissolved in chloroform. The red solution obtained was filtered through Celite to remove the black palladium formed. The solvent was removed under vacuum to give an orange solid which was chromatographed on a column packed with silica gel. Elution with dichloromethane–methanol (1%) afforded the final product after concentration. Yield 44%. *Anal.* Found: C, 43.2; H, 4.2; N, 3.6. Calc. for $C_{28}H_{32}N_2O_6Cl_2Pd_2$: C, 43.3; H, 4.1; N, 3.6%. IR: ν(C=N), 1610s cm^{-1}; ν_{as}(COO), 1560s cm^{-1}; ν_s(COO), 1410s cm^{-1}. $^{13}C-\{^1H\}$ NMR: (50.28 MHz, $CDCl_3$): δ 171.6, 171.7 (C=N); δ 156.9, 156.7 (C6); δ 143.2, 143.0 (C1); δ 131.0 (C2); δ 124.6, 124.7 (C5); δ 130.1, 130.2, 130.3, 130.4 (C3, C4); δ 76.6 (C8); δ 68.5 (C11); δ 63.6, 61.6 (C7); δ 29.1, 28.4, 25.9, 25.5 (C9, C10); δ 173.0 (CH_3COO); δ 24.4 (CH_3COO). FAB MS: m/z = 776 $[M]^+$; 717 $[M-AcO]^+$.

Complexes **1b** and **1c** were prepared similarly.

*2.2.2. [Pd{3,4-(MeO)$_2$C$_6$H$_2$C(H)=NCH$_2$-(C$_4$H$_7$O)}(μ-OAc)]$_2$ (**1b**)*

Yield 56%. *Anal*. Found: C, 46.2; H, 5.2; N, 3.3. Calc. for $C_{32}H_{42}N_2O_{10}Pd_2$: C, 46.4; H, 5.1; N, 3.4%. IR: ν(C=N), 1608m cm^{-1}; ν_{as}(COO), 1570s cm^{-1}; ν_s(COO), 1415s cm^{-1}. ^{13}C–{^{1}H} NMR: (50.28 MHz, $CDCl_3$): δ 173.8, 173.7, 172.5, 172.4 (C=N); δ 149.3, 149.0 (C6); δ 149.4, 146.0 (C3, C4); δ 137.8, 137.4 (C1); δ 114.1, 109.9 (C2, C5); δ 76.9 (C8); δ 68.3, 67.8 (C11); δ 62.7, 60.1 (C7); δ 29.1, 28.6, 25.8, 25.4 (C9, C10); δ 181.1, 180.0 (CH_3COO); δ 24.4, 24.3 (CH_3COO); δ 56.2, 55.7 (OCH_3).

*2.2.3. (R)-[Pd{3,4-(MeO)$_2$C$_6$H$_2$C(H)=NCH$_2$-(C$_4$H$_7$O)}(μ-OAc)]$_2$ (**1c**)*

Yield 65%. *Anal*. Found: C, 45.7; H, 5.4; N, 3.2. Calc. for $C_{32}H_{42}N_2O_{10}Pd_2$: C, 46.4; H, 5.1; N, 3.4%. IR: ν(C=N), 1608m cm^{-1}; ν_{as}(COO), 1570s cm^{-1}; ν_s(COO), 1415s cm^{-1}. ^{13}C–{^{1}H} NMR: (50.28 MHz, $CDCl_3$): δ 173.8, 172.4 (C=N); δ 149.3 (C6); δ 149.4, 146.0 (C3, C4); δ 137.8, 137.4 (C1); δ 114.1, 109.9 (C2, C5); δ 76.9 (C8); δ 68.3, 67.8 (C11); δ 62.7, 60.1 (C7); δ 29.1, 28.6, 25.8, 25.4 (C9, C10); δ 181.1, 180.0 (CH_3COO); δ 24.4, 24.3 (CH_3COO); δ 56.2, 55.7 (OCH_3).

*2.2.4. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}(μ-Cl)]$_2$ (**2a**)*

An aqueous solution of NaCl (ca. 10^{-2} M) was added dropwise to a solution of **1a** (200.0 mg, 0.257 mmol) in 10 cm^3 of acetone. The resulting mixture was stirred for 6 h. The yellow precipitate formed was filtered off, washed with water and dried under vacuum. Yield 86%. *Anal*. Found: C, 39.9; H, 3.3; N, 3.7. Calc. for $C_{24}H_{26}N_2O_2Cl_4Pd_2$: C, 39.5; H, 3.6, N, 3.8%. IR: ν(C=N), 1615s cm^{-1}. ^{13}C–{^{1}H} NMR: (50.28 MHz, $CDCl_3$): δ 174.4 (C=N); δ 155.2 (C6); δ 143.3 (C1); δ 131.1 (C2); δ 125.4 (C5); δ 131.3, 131.7 (C3, C4); δ 76.7 (C8); δ 68.2 (C11); δ 63.7 (C7); δ 28.9, 25.8 (C9, C10). FAB MS: $m/z = 765$ $[M + Cl]^+$; 693 $[M - Cl]^+$.

Complex **2b** was prepared similarly as a yellow solid.

*2.2.5. [Pd{3,4-(MeO)$_2$C$_6$H$_2$C(H)=NCH$_2$-(C$_4$H$_7$O)}(μ-Cl)]$_2$ (**2b**)*

Yield 91%. *Anal*. Found: C, 43.4; H, 4.3; N, 3.7. Calc. for $C_{28}H_{36}N_2O_6Cl_2Pd_2$: C, 43.1; H, 4.6, N, 3.6%. IR: ν(C=N), 1610m cm^{-1}. FAB MS: $m/z = 780$ $[M]^+$; 745 $[M - Cl]^+$.

*2.2.6. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}(Cl)(PPh$_3$)] (**3a**)*

PPh_3 (22.0 mg, 0.082 mmol) was added to a suspension of **2a** (30.0 mg, 0.041 mmol) in acetone (15 cm^3). The mixture was stirred for 12 h and the white precipitate formed filtered off, dried under vacuum and recrystallized from chloroform–hexane. Yield 74%. *Anal*. Found: C, 57.1; H, 4.9; N, 2.3. Calc. for $C_{30}H_{28}NOCl_2PdP$: C, 57.5; H, 4.5; N, 2.2%. IR: ν(C=N), 1620m cm^{-1}. ^{13}C–{^{1}H} NMR: (50.28 MHz, $CDCl_3$): δ 175.0 (d, C=N, $JPC = 4.2$ Hz); δ 160.0 (C6); δ 145.0 (C1); δ 131.3 (C2); δ 124.8 (C5); δ 131.0, 131.9 (C3, C4); δ 77.5 (C8); δ 67.9 (C11); δ 65.6 (C7); δ 28.8, 25.8 (C9, C10). P-phenyl: δ 135.4 (d, C_o, $JPC = 12.1$ Hz); δ 128.0 (d, C_m, $JPC = 11.3$ Hz); δ 130.8 (d, C_p, $JPC = 2.8$ Hz); δ 130.7 (d, C_i, $JPC = 42.5$ Hz). FAB MS: $m/z = 627$ $[M]^+$; 590 $[M - Cl]^+$.

*2.2.7. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}-(PPh$_3$)][CF$_3$SO$_3$] (**4a**)*

A suspension of **3a** (24.0 mg, 0.020 mmol) in acetone (15 cm^3) was treated with silver trifluoromethanesulfonate (5.2 mg, 0.020 mmol) and stirred for 24 h. The resulting solution was filtered through Celite to eliminate the AgCl precipitate and the solvent removed to give a yellow solid, which was recrystallized from chloroform–hexane. Yield 60%. *Anal*. Found: C, 50.1; H, 3.7; N, 2.1. Calc. for $C_{31}H_{28}NO_4F_3ClSPdP$: C, 50.3; H, 3.8; N, 1.9%. IR: ν(C=N), 1620m cm^{-1}. ^{13}C–{^{1}H} NMR: (50.28 MHz, $CDCl_3$): δ 173.6 (d, C=N, $JPC = 3.5$ Hz); δ 151.3 (C6); δ 145.5 (C1); δ 127.7 (C2); δ 126.3 (C5); δ 128.7 (C3, C4); δ 81.9 (C8); δ 69.7 (C11); δ 61.7 (C7); δ 28.4 (C9, C10). P-phenyl: δ 134.9 (d, C_o, $JPC = 12.1$ Hz); δ 129.0 (d, C_m, $JPC = 10.6$ Hz); δ 131.8 (d, C_p, $JPC = 2.8$ Hz); δ 132.4 (d, C_i, $JPC = 48.2$ Hz). FAB MS: $m/z = 592$ $[M - CF_3SO_3]^+$. Specific molar conductivity, $\Lambda_m = 156.4$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

*2.2.8. [{Pd[2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)](Cl)}$_2$-(μ-Ph$_2$P(CH$_2$)$_3$PPh$_2$)] (**8a**)*

$Ph_2P(CH_2)_3PPh_2$ (dppp) (17.0 mg, 0.041 mmol) was added to a suspension of **2a** (30.0 mg, 0.041 mmol) in acetone (15 cm^3). The mixture was stirred for 12 h and the precipitate formed filtered off and dried under vacuum to give a white solid which was recrystallized from chloroform–hexane. Yield 51%. *Anal*. Found: C, 49.1; H, 4.3; N, 2.3. Calc. for $C_{51}H_{52}N_2O_2Cl_4Pd_2P_2.CHCl_3$: C, 49.5; H, 4.2; N, 2.2%. IR: ν(C=N), 1623m cm^{-1}.

Compound **5b** was prepared similarly as a white solid.

*2.2.9. [{Pd[3,4-(MeO)$_2$C$_6$H$_2$C(H)=NCH$_2$-(C$_4$H$_7$O)](Cl)}$_2$(μ-Ph$_2$P(CH$_2$)$_3$PPh$_2$)] (**5b**)*

Yield 55%. *Anal*. Found: C, 55.1; H, 5.0; N, 2.3. Calc. for $C_{55}H_{62}N_2O_6Cl_2Pd_2P_2$: C, 55.4; H, 5.2; N, 2.3%. IR: ν(C=N), 1615m cm^{-1}.

*2.2.10. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}-(Ph$_2$P(CH$_2$)$_3$Ph$_2$–P,P)][ClO$_4$] (**6a**)*

$Ph_2P(CH_2)_3Ph_2$ (dppp) (34.0 mg, 0.082 mmol) was added to a suspension of **2a** (30.0 mg, 0.041 mmol) in

acetone (20 cm^3). The mixture was stirred for 1 h, after which an excess of sodium perchlorate was added. The complex was then precipitated out by addition of water, filtered off and dried in vacuo. Recrystallization from chloroform–hexane gave the final compound as a white solid. Yield 85%. *Anal*. Found: C, 55.1; H, 4.2; N, 3.0. Calc. for $C_{39}H_{39}N_2O_5Cl_2P_2Pd$: C, 54.8; H, 4.6; N, 3.3%. IR: ν(C=N), 1617m cm^{-1}. Specific molar conductivity, $\Lambda_m = 113.5$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

Complex **3b** was synthesized similarly as a yellow solid.

2.2.11. [Pd{3,4-(MeO)$_2$C$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}-(Ph$_2$P(CH$_2$)$_3$Ph$_2$–P,P)][ClO$_4$] (3b)

Yield 85%. *Anal*. Found: C, 56.1; H, 5.0; N, 1.9. Calc. for $C_{41}H_{44}NO_7ClPdP_2$: C, 56.8; H, 5.1; N, 1.6%. IR: ν(C=N), 1615m cm^{-1}. Specific molar conductivity, $\Lambda_m = 140.3$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

2.2.12. [Pd{3,4-(MeO)$_2$C$_6$H$_2$C(H)=NCH$_2$(C$_4$H$_7$O)}-(cis-Ph$_2$PCH=CHPh$_2$–P,P)][Cl] (4b)

cis-$Ph_2PCH{=}CHPh_2$ (*cis*-dppe) (30.0 mg, 0.074 mmol) was added to a suspension of **2b** (29.0 mg, 0.037 mmol) in acetone (20 cm^3). The mixture was stirred for 1 h. The complex was then precipitated out by addition of water, filtered off and dried in vacuo. Recrystallization from chloroform–hexane gave the final compound as a white solid. Yield 62%. *Anal*. Found: C, 48.8; H, 4.5; N, 2.0. Calc. for $C_{40}H_{40}NO_3ClP_2Pd{\cdot}2CHCl_3$: C, 49.2; H, 4.1; N, 1.4%. IR: ν(C=N), 1606m cm^{-1}. Specific molar conductivity, $\Lambda_m = 90.3$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

Complex **7a** was synthesized as a yellow solid using a similar procedure to the one described for complex **6a**.

2.2.13. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}-{(PPh$_2$CH$_2$CH$_2$)$_2$PPh–P,P,P}][ClO$_4$] (7a)

Yield 95%. *Anal*. Found: C, 52.0; H, 4.5; N, 1.5. Calc. for $C_{46}H_{46}NO_5Cl_2P_3Pd{\cdot}CHCl_3$: C, 52.1; H, 4.4; N, 1.3%. IR: ν(C=N), 1615m cm^{-1}. $^{13}C-\{^1H\}$ NMR: (50.28 MHz, $CDCl_3$): δ 168.8 (d, C=N, $JPC = 5.0$); δ 139.6 (C1); δ 135.4 (C2); δ 124.5 (C5); δ 77.7 (C8); δ 67.9 (C11); δ 63.1 (C7); δ 28.8, 25.8 (C9, C10). FAB MS: $m/z = 862.2$ $[M - ClO_4]^+$. Specific molar conductivity, $\Lambda_m = 146.3$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

2.2.14. [Pd{2-ClC$_6$H$_3$C(H)=NCH$_2$(C$_4$H$_7$O)}-((CH$_3$)$_2$CO)][CF$_3$SO$_3$] (5a)

A suspension of **2a** (30.0 mg, 0.041 mmol) in acetone (8 cm^3) was treated with silver trifluoromethanesulfonate (22.0 mg, 0.082 mmol) and stirred for 24 h. The resulting solution was filtered through Celite to eliminate the AgCl precipitate and the solvent removed to give a hygroscopic yellow solid which was recrystallized from dichloromethane–hexane and stored under nitrogen. Yield 65%. *Anal*. Found: C, 36.1; H, 3.3; N, 2.1. Calc. for $C_{16}H_{19}NO_5F_3ClSPd$: C, 35.8; H, 3.6; N, 2.6%. IR: ν(C=N), 1608m cm^{-1}. $^{13}C-\{^1H\}$ NMR: (50.28 MHz, $CDCl_3$): δ 174.1 (C=N); δ 151.3 (C6); δ 143.3 (C1); δ 131.4 (C2); δ 126.1 (C5); δ 132.0, 129.8 (C3, C4); δ 79.6 (C8); δ 70.1 (C11); δ 62.4 (C7); δ 28.5, 25.6 (C9, C10); δ 31.2, 29.7 ($CH_3C{=}O$). Specific molar conductivity, $\Lambda_m = 240.2$ ohm^{-1} cm^2 mol^{-1} (in acetonitrile).

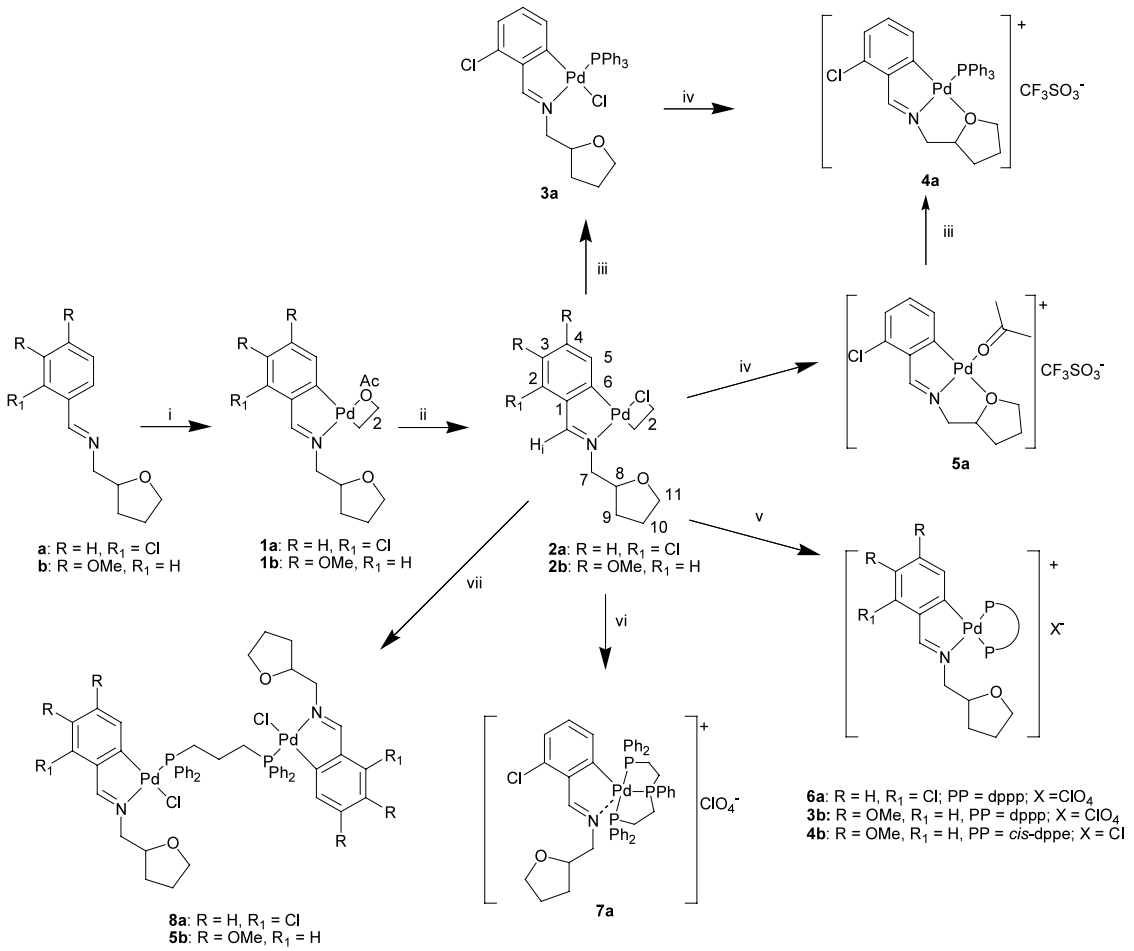
3. Results and discussion

For the convenience of the reader the compounds and reactions are shown in Scheme 1. The compounds described in this paper were characterized by elemental analysis (C, H, N) and by IR spectroscopy (data in Section 2) and by ^1H, $^{31}P-\{^1H\}$ (see Table 1) and, in part, $^{13}C-\{^1H\}$ NMR spectroscopy and FAB mass spectrometry (Section 2).

Reaction of the Schiff base ligands 2-$ClC_6H_4C(H){=}NCH_2(C_4H_7O)$ (**a**) and 3,4-$(MeO)_2C_6H_3C(H){=}NCH_2(C_4H_7O)$ (**b**) with palladium(II) acetate in toluene gave the dinuclear cyclometallated complexes [Pd{2-$ClC_6H_3C(H){=}NCH_2(C_4H_7O)$}(μ-OAc)]$_2$ (**1a**) and [Pd{3,4 - $(MeO)_2C_6H_2C(H){=}NCH_2(C_4H_7O)$}(μ - OAc)]$_2$ (**1b**), respectively, which were fully characterized. The IR spectra of **1a** and **1b** showed the ν(C=N) stretch at 1610 and 1608 cm^{-1}, respectively, shifted to lower wavenumbers (as compared to the free ligand) due to N-coordination of the imine [27,28]. The IR spectra also showed strong bands assigned to the symmetric and asymmetric ν(COO) vibrations, in agreement with those expected for bridging acetate ligands [29] (see Section 2). The resonance corresponding to the HC=N proton in the ^1H NMR spectra was shifted to lower frequency consequent upon coordination of the imine group to the palladium atom *via* the lone pair of the nitrogen atom [30]. The assignment of the aromatic proton resonances unequivocally showed that metallation had taken place at the C6 carbon atom for both compounds (see Table 1).

A noticeable feature of the ^1H NMR spectra of **1a** and **1b** is the number of signals for the HC=N and aromatic protons. Four singlets for the HC=N protons were assigned in each case. For complex **1a** a multiplet was assigned to the H^3, H^4 and H^5 resonances, whereas for complex **1b** two singlets were assigned to each one of the H^2 and H^5 protons. We reasoned that the splitting could be caused by the presence of the *syn* and *anti* conformations, as acetato-bridged dimers exist in a folded arrangement which gives rise to two isomers: the *anti* isomer with C_2 symmetry and the *syn* isomer with C_s symmetry (see Fig. 1). By far, the *anti* disposition is the most frequent [31].

If both isomers were present two resonances would be expected for the HC=N protons and three for the



acetate MeCOO protons (one for the *anti* isomer and two for the *syn* separated by approximately 0.2 ppm [32]). However in the ^{1}H NMR spectra of **1a** and **1b** only two resonances, separated by approximately 0.02 ppm, were assignable to the acetate methyl groups.

Therefore, we believe that the number of signals found may be due to the presence of several diastereoisomers in solution.

Because the syntheses of ligands **a** and **b** were performed by heating a chloroform solution of (*R*,*S*)-tetrahydrofurfurylamine with 2-chlorobenzaldehyde or 3,4-dimethoxybenzaldehyde, as appropriate, the ligands would in fact be equimolar mixtures of both enantiomers and the cyclopalladated compounds **1a** and **1b** would yield a mixture of three pairs of enantiomers (see Fig. 2).

The NMR spectra of each pair of enantiomers are identical, but obviously different from those of their correspondent diastereoisomers. One set of signals is expected for enantiomers **I** and **II**, and another set for enantiomers **III** and **IV**; however, **V** and **VI** should give two groups of resonances for the protons of each cyclometallated unit of the acetate dimer. Thus, four signals could be assigned to the HC=N protons in the ^{1}H NMR spectra of the complexes, two resonances for the aromatic protons and two for the acetate methyl protons. The intensities of the signals for **V** and **VI** are the same as those for the **I**–**IV** enantiomers. Due to their similar solubility we were not able to separate the three pairs of enantiomers. Surprisingly, none of the other derivatives of ligands **a** and **b** showed splitting of the NMR signals. We attribute these findings to the folded structure of the acetato-bridged complex which brings close together the cyclometallated units. The asymmetric C8 carbon atom of one unit is situated close to the neighboring cyclometallated ligand, thus experiencing a different chemical environment in each diastereomer. Since the folded structure brings the HC=N proton close to the C8 carbon, the chemical differences between the diastereoisomers are most evident in the HC=N resonances.

In order to confirm this we synthesized the enantiopure ligand **c** by reaction of (*R*)-tetrahydrofufurylamine with 3,4-dimethoxybenzaldehyde. The ^{1}H NMR spectra

^{31}P NMR: in $CDCl_3$ unless otherwise stated. Measured at 80.9 MHz (ca. ± 20 °C); chemical shifts (δ) in ppm (± 0.1) to high frequency of 85% H_3PO_4. ^1H NMR: in $CDCl_3$. Measured at 200 MHz (ca. ± 20 °C); chemical shifts (δ) in ppm (± 0.01) to high frequency of $SiMe_4$. Coupling constants in Hz. s, singlet; d, doublet; dd, doublet of doublets; t, triplet; m, multiplet; br, broad.

[a] ^3JHH.

[b] $\delta(CH^{acetate}) = 2.14$, 2.11[s, 6H] (compound **1a**); 2.14, 2.13[s, 6H] (compound **1b**).

[c] ^4JHH.

[d] JPH.

[e] δ [$(CH_2)_2CO$] = 2.5 br, ppm.

[f] JPP.

[g] C4–(OMe).

of **c** was identical to the one recorded for **b**. The cyclometallated acetato-bridged complex **1c** was prepared following an analogous procedure to that used for **1b**. The ^1H NMR spectrum of **1c** showed only two resonances for the HC=N proton at δ 7.44 and 7.30, indicating the presence of only two distinct diastereoisomers in solution (**I** and **III**).

The $^{13}C-\{^1H\}$ spectra of the complexes showed the signals assigned to the C6, C=N, and C1 resonances shifted to higher frequency confirming that metallation had occurred [20]. The signals exhibited the splitting due to the mixture of diastereoisomers (see Section 2). Four signals were observed for the C=N carbon atom due to the three pairs of enantiomers present in solution, as opposed to only two signals for the C=N carbon in the spectrum of complex **1c**.

The mass FAB spectrum of **1a** showed a cluster of peaks, centered at 776 and 717 amu which correspond to $[M]^+$ and $[M-AcO]^+$, respectively. The isotopic pattern is in good agreement with the expected dinuclear structure.

The reaction of **1a** and **1b** with aqueous sodium chloride gave the chloro-bridged complexes [Pd{2-$ClC_6H_3C(H)=NCH_2(C_4H_7O)$}(μ-Cl)]$_2$ (**2a**) and [Pd{3,4-$(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)$}(μ-Cl)]$_2$ (**2b**), respectively, which were fully characterized (see Table 1 and Section 2). The IR spectra showed the absence of the ν(COO) bands. The ^1H NMR spectra of **2a** and **2b** showed the HC=N resonance at δ 8.21 and δ 7.75, respectively. The aromatic proton resonances of **2a** were at δ 7.23 (H^3) and δ 6.97 (H^4, H^5), as multiplets, whereas two singlets were observed for the H^2, H^5 resonances at δ 6.80 and 6.89, respectively, for compound **2b**. In the $^{13}C-\{^1H\}$ spectra the C=N, C1 and C6 carbon resonances were shifted to higher frequency as compared to the free ligands. The FAB mass spectra showed the peaks which were assigned to the $[M]^+$ and $[M-Cl]^+$ fragments; a similar fragmentation of cyclometallated chloro-bridged complexes has been reported [33].

Reaction of **2a** with PPh_3 in acetone gave the mononuclear cyclometallated complex [Pd{2-$ClC_6H_3C(H)=NCH_2(C_4H_7O)$}(Cl)($PPh_3$)], **3a**, in a typical bridge-splitting reaction. In the ^1H NMR spectra the HC=N and H^5 resonances showed coupling to the phosphorus nucleus [δ 8.62 ($JPH = 8.3$ Hz) and δ 6.25 ($JPH = 6.4$ Hz), respectively]; in the $^{31}P-\{^1H\}$ spectrum the resonance of the coordinated phosphine was a singlet at δ 43.0; these findings are in agreement with a phosphorus *trans* to nitrogen arrangement [34–37]. The FAB mass spectrum showed peaks centered at 627 and 590 amu for the $[M]^+$ and $[M-Cl]^+$ fragments, respectively.

Treatment of **3a** with silver triflate gave the complex [Pd{2-$ClC_6H_3C(H)=NCH_2(C_4H_7O)$}($PPh_3$)][$CF_3SO_3$] (**4a**) after the removal of the AgCl precipitate formed. The most noteworthy differences in the ^1H NMR spectrum of **4a** as compared to **3a**, were in the THF proton resonances, although overlapping of these resonances made an exact assignment difficult, especially in the

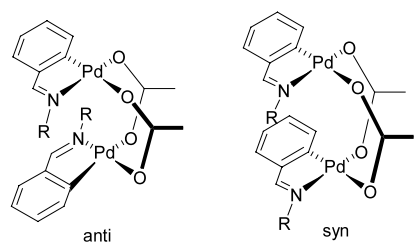

Fig. 1.

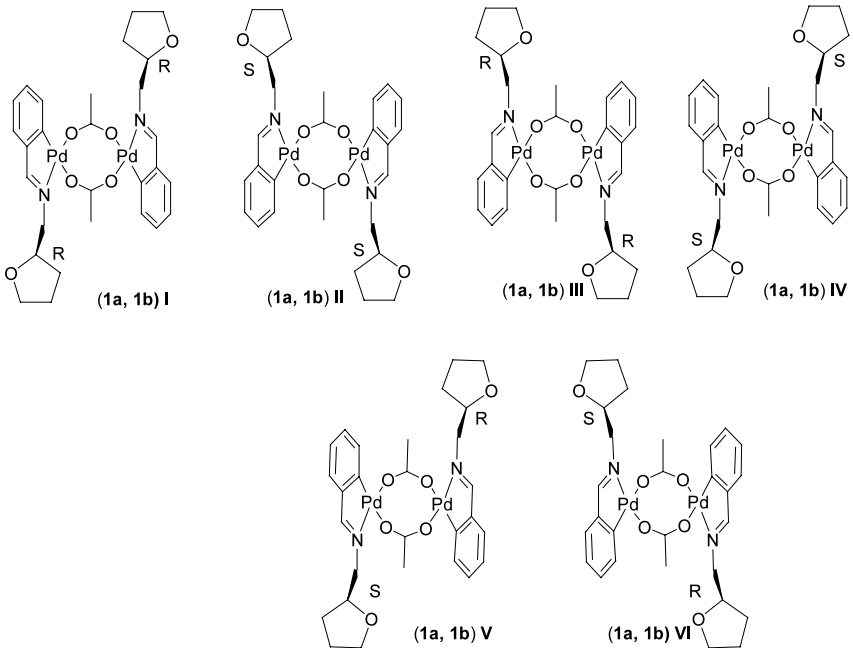

Fig. 2.

splitting pattern shown by the H^7, H^8, and H^{11} protons. Furthermore, the $^{13}C-\{^1H\}$ spectrum of **4a** showed the signal assigned to C8 at δ 81.9, downfield shifted consequent upon Pd–O bond formation (cf. δ 78.6, **a**, and δ 77.5, **3a**). Compound **4a** is a 1:1 electrolyte, as shown by molar conductivity measurements. The FAB-mass spectrum showed a set of peaks centered at 592 amu for the $[M-CF_3SO_3]^+$ fragment.

Pd–O bond formation could also be achieved by reacting **2a** with silver triflate in acetone which gave the complex $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}((CH_3)_2CO)][CF_3SO_3]$ (**5a**) after AgCl removal. The IR spectra supports the presence of the $[CF_3SO_3]^-$ anion, which contains the characteristic stretching bands of the free anion [38], approximately 1274, 1251, 1170 and 1031 cm^{-1}. The ^1H NMR spectrum showed the HC=N resonance at δ 8.07 and the signals corresponding to the H^2, H^3 protons and H^4 as multiplets at δ 6.98 and 6.92, respectively. The splitting pattern and chemical shift resonances for the THF ring are clearly different from those observed in the spectrum of **2a**. In the $^{13}C-\{^1H\}$ spectrum of **4a** the C8 resonance appeared at δ 79.6, downfield shifted upon Pd–O bond formation. Molar conductivity measurements were in agreement with the ionic nature of the complex.

Treatment of complexes **2a** and **2b** with $Ph_2P(CH_2)_3PPh_2$, dppp, in a complex/phosphine 1:1 molar ratio gave the dinuclear cyclometallated complexes $[\{Pd[2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)](Cl)\}_2(\mu\text{-}Ph_2P(CH_2)_3PPh_2)]$ (**8a**) and $[\{Pd[3,4\text{-}(MeO)_2C_6H_2C(H)=NCH_2(C_4H_7O)](Cl)\}_2(\mu\text{-}Ph_2P(CH_2)_3PPh_2)]$ (**5b**) which were fully characterized (see Section 2 and Table 1). The $^{31}P-\{^1H\}$ NMR spectra only showed a singlet resonance in accordance with the centrosymmetric nature of this dinuclear complexes.

In the ^1H NMR spectra of complex **5b**, the C(4)–OCH_3 resonance was shifted towards lower frequency by approximately 0.8 ppm, as compared complex **2b**, due to the shielding effects of the phosphine phenyl ring, in agreement with a N–Pd–P *trans* geometry [16,21,39]. This arrangement was confirmed by the coupling of the HC=N and H^5 proton resonances to the phosphorus nucleus.

Reaction of complexes **2a** and **2b** with the diphosphines $Ph_2P(CH_2)_3Ph_2$, dppp, and $Ph_2PCH=CHPh_2$, *cis*-dppe, in a 1:2 molar ratio gave the mononuclear complexes $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}\{Ph_2P(CH_2)_3Ph_2\text{-}P,P\}][ClO_4]$ (**6a**), $[Pd\{2\text{-}(MeO)_2C_6H_3C(H)=NCH_2(C_4H_7O)\}\{Ph_2P(CH_2)_3Ph_2\text{-}P,P\}][ClO_4]$ (**3b**) and $[Pd\{2\text{-}ClC_6H_3C(H)=NCH_2(C_4H_7O)\}(cis\text{-}Ph_2PCH=CHPh_2\text{-}P,P)][Cl]$ (**4b**) as air-stable solids which were fully characterized (see Table 1 and Section 2).

The $^{31}P-\{^1H\}$ NMR spectra showed two doublets for the two unequivalent phosphorus nuclei. The resonance at lower frequency was assigned to the phosphorus nucleus *trans* to the phenyl carbon atom in accordance with the higher *trans* influence of the latter with respect to the C=N nitrogen atom [40]. The *H*C=N resonance was only coupled to the ^{31}P nucleus *trans* to nitrogen. This was confirmed by selective decoupling experiments on the ^{31}P atoms. The H^5 resonance showed coupling to both phosphorus atoms. Measurements of the specific molar conductivity have shown the complexes to be 1:1 electrolytes.

Reaction of **2a** with the triphosphine bis(2-diphenylphosphinoethyl)phenylphosphine in 1:2 molar ratio, followed by treatment with sodium perchlorate gave [Pd{2-$ClC_6H_3C(H)$=$NCH_2(C_4H_7O)$}{$(PPh_2CH_2CH_2)_2PPh$-*P*,*P*,*P*}][ClO_4] (**7a**). The phosphorus resonances in the $^{31}P-\{^1H\}$ NMR spectrum were downfield shifted from their values in the free phosphine suggesting coordination of the three phosphorus atoms to the metal centre. A triplet resonance at δ 89.3 was assigned to the central ^{31}P nucleus, *trans* to the phenyl carbon atom, and a doublet at δ 45.4 was assigned to the two equivalent mutually *trans* phosphorus nuclei. The latter signal appeared at lower frequency in accordance with the high *trans* influence of the phosphine ligand [11]. The resonance of the proton in the *ortho* position to the metallated carbon appeared as a triplet showing coupling to the central ^{31}P atom [J(PH) 7.8 Hz]; no coupling was observed to the terminal phosphorus nuclei. These data are in accordance with a disposition in which the metallated ring is nearly perpendicular to the plane defined by the three phosphorus atoms; these observations were confirmed by selective decoupling experiments. The shift of the ν(C=N) stretching vibration to lower wavenumbers [27,28] as well as the upfield shift of the HC=N proton resonance in the ^1H NMR spectra [30] indicates the existence of palladium–nitrogen interaction in solution. These results strongly agree with those previously obtained by us in related pentacoordinated palladium(II) species, and hence we propose a similar disposition of the triphos ligand in this case [15]. The C=N signal in the $^{13}C-\{^1H\}$ spectrum at δ 168.8 coupled to the central phosphorus ($JPC = 5.0$ Hz) was also indicative of Pd–N interaction.

Molar conductivity measurements have shown that complex **7a** is a 1:1 electrolyte. The FAB mass spectrum showed a set of peaks centered at 862 amu assigned to the $[M - ClO_4]^+$ fragment.

Synthesis and enhanced photosensitization ability of a 4-carboxy-2,2′:6′,2″-terpyridine complex of ruthenium(II)

Charles Mikel [1], Pierre G. Potvin *

Department of Chemistry, York University, 4700 Keele Street, North York, Ont., Canada M3J 1P3

Received 20 April 2001; accepted 2 October 2001

Abstract

The new ligand 4-carboxy-4′-*p*-tolyl-2,2′:6′,2″-terpyridine (HttpyA) was prepared in complexed form via the methyl ester (ttpyE), which was elaborated from methyl isonicotinate in two-steps and in good yields. The homoleptic complex $[Ru(ttpyE)_2](PF_6)_2$ was prepared, characterized, and hydrolyzed to produce the diacid complex, $H_2[Ru(ttpyA)_2]^{2+}$. Once ionized to the neutral $[Ru(ttpyA)_2]^0$, there are no long-range electrostatic repulsions with the electron acceptor methyl viologen (MV^{2+}), and the surface COO^- groups are suitably disposed for a close-range, 1:1 supramolecular pre-association with MV^{2+}. $H_2[Ru(ttpyA)_2]^{2+}$ was indeed a significantly better photosensitizer in effecting electron transfer to MV^{2+} in CH_3CN than was the non-carboxylated dicationic analogue, $Ru(ttpy)_2^{2+}$ (ttpy is 4′-*p*-tolyl-2,2′:6′,2″-terpyridine). © 2002 Elsevier Science Ltd. Keywords: Photoinduced electron transfer; Cyclic voltammetry; Supramolecular pre-association; Ruthenium(II) complexes; 2,2′:6′,2″-Terpyridine; 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid

1. Introduction

The photophysical and photochemical properties of the 2,2′-bipyridine-4,4′-dicarboxylate complexes of Ru(II) have been studied in some detail [1], in part because of the Coulombic advantages available to ionizable complexes in photo-induced electron transfers to cationic electron acceptors such as methyl viologen (MV^{2+}). Another manifestation of this advantage is the photo-induced injection of electrons into semiconductors even if the sensitizer excited states are extremely short-lived [2], and this has been attributed to attractive surface interactions involving COO^- groups on the sensitizer surface.

Terpyridines are superior to bipyridines in terms of symmetry and synthetic simplicity, but ionizable terpyridine complexes are relatively unknown. We are particularly interested in complexes able to enter into supramolecular associations with MV^{2+} through negatively charged groups on the ligand periphery. If it occurs prior to photoexcitation, this affords an additional, entropic advantage over dicationic sensitizers. Molecular models suggested that placing a COO^- group at the 4-position of each ligand in a bis(terpyridine) Ru(II) complex would afford a geometry and an inter-carboxylate distance conducive to a 1:1 association with MV^{2+} (Fig. 1).

The previously reported preparations of carboxyterpyridine ligands are either arduous or ill-suited for our objective [3]. We wish to report the facile Kröhnke synthesis [4] of a novel methyl terpyridine-4-carboxylate ligand (ttpyE), preparation of its Ru(II) complex $[Ru(ttpyE)_2]^{2+}$ and its hydrolyzed form $H_2[Ru(ttpyA)_2]^{2+}$, and the testing of the latter in photo-induced electron transfer to MV^{2+}.

2. Experimental

2.1. Preparation of methyl 2-acetylisonicotinate (*1*)

Methyl isonicotinate (8.2 g, 60.0 mmol) was added to a solution of excess paraldehyde (40 g) in CH_3CN (140

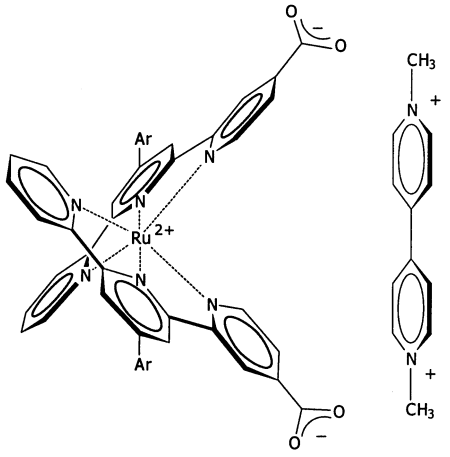
ml) at room temperature (r.t.). To this solution was added $FeSO_4 \cdot 7H_2O$ (0.28 g, 1.00 mmol), TFA (7 g) and 70% ^{t}BuOOH (15 g), and the mixture was heated to reflux for 4 h. This was freed of solvent under reduced pressure, and the residue was taken up in saturated aqueous Na_2CO_3 (100 ml), then extracted with $PhCH_3$ (3×75 ml). The combined organic fractions were dried ($MgSO_4$) and freed of solvent under reduced pressure. The dark brown residue was purified on a short column (silica, 30:70 P.E.–EtOAc). The main fraction was freed of solvent under reduced pressure, and the yellow residue was recrystallized from pentane to give white needles (9.8 g, 91%). The ^{1}H NMR spectrum agreed with that in the literature [5].

2.2. Preparation of N-[2-oxo-2-(2-(4-methoxycarbonylpyridyl))ethyl]pyridinium iodide (2a)

Methyl 2-acetylisonicotinate (**1**, 0.24 g, 1.34 mmol) was added to a warmed solution of I_2 (0.35 g, 1.38 mmol) in anhydrous pyridine (10 ml) and the resulting solution was heated to reflux under argon for 3 h. The precipitate which formed upon cooling was collected by vacuum filtration and washed with $CHCl_3$ (25 ml) and Et_2O (25 ml), and then dried, yielding a tan powder (0.300 g, 58% as **2a**). ^{1}H NMR (DMSO-d_6): δ 9.08 (d, 1H, H-6), 8.95 (d, 2H, H-2′), 8.72 (t, 1H, H-4′), 8.34 (s, 1H, H-3), 8.28 (t, 2H, H-3′), 8.21 (d, 1H, H-5), 6.51 (s, 2H, CH_2), 3.94 (s, 3H, OCH_3) ppm. FAB MS m/z (%): 257 (70) [M − I]. The product was contaminated with a small quantity ($< 6\%$) of the free acid analogue **2b** identified by additional ^{1}H NMR signals at 12–13 (bs), 9.10 (d) and 8.25 (d) ppm, as well as a FAB MS peak at m/z (%) 243 (30) [M − I].

2.3. Preparation of 4-methoxycarbonyl-4′-p-tolyl-2,2′:6′,2″-terpyridine (ttpyE)

3-*p*-Tolyl-1-(2-pyridyl)-2-propenone (**3**) [6] (0.18 g, 0.81 mmol) and **2a** (0.40 g, nominally 1.0 mmol as pure **2a**) were added to a solution of excess NH_4OAc (2.0 g) in CH_3OH (2 ml) and the resulting solution was heated to reflux for 4 h. The precipitate which formed upon cooling was collected by filtration, and triturated successively with CH_3OH (2×5 ml), $CHCl_3$ (2×5 ml) and Et_2O (2×5 ml). The $CHCl_3$ extract was set aside while the remaining solid was dried, then taken up in $SOCl_2$ (10 ml) and heated to reflux under argon for 1 h. The reaction mixture was freed of excess $SOCl_2$ in vacuo and the residue was taken up in dry CH_3OH and heated to reflux under argon for 1 h. Once the excess CH_3OH was removed under reduced pressure, the residue was taken up in 1:1 Et_3N–$CHCl_3$ (25 ml) and combined with the $CHCl_3$ extract from the original filtration. This was filtered on a short column (alumina–*N*-$CHCl_3$). The collected fraction was freed of solvent and recrystallized ($CHCl_3$–CH_3OH) to give tan flakes (0.226 g, 73%). Melting point (m.p.): 181–2 °C. ^{1}H NMR ($CDCl_3$): δ 9.17 (1H, s, H-3′/5′), 8.87 (1H, d, $J = 4.9$, H-6), 8.77 (1H, s, H-5′/3′), 8.75 (1H, d, $J = 1.4$, H-3), 8.74 (1H, d, $J = 4.5$, H6″), 8.70 (1H, d, $J = 7.9$, H3″), 7.91 (1H, dt, $J = 1.6$, 7.9, H4″), 7.89 (1H, d, $J = 4.9$, H-5), 7.82 (2H, d, Ar-H-2(6)), 7.37 (1H, dd, $J = 4.9$, 7.7, H-5″), 7.33 (2H, d, Ar-H-3(5)), 4.05 (3H, s, OCH_3), 2.45 (3H, s, Ar-CH_3) ppm. ^{13}C NMR ($CDCl_3$): δ 166.0, 157.6, 156.2, 155.2, 155.1, 150.3, 149.9, 149.1, 139.2, 138.4, 136.9, 135.4, 129.7, 127.2, 123.9, 122.7, 121.5, 120.7, 119.1, 118.9, 52.8, 21.3 ppm. FAB MS m/z (%): 382 (100) [M + H], 364 (10) [M − CH_3]. Elemental analysis: *Anal.* Calc. for $C_{24}H_{19}N_3O_2$ (M_W 381.42) (%): C, 75.57; H, 5.03; N, 11.02. Found: C, 75.45; H, 5.03; N, 10.94%.



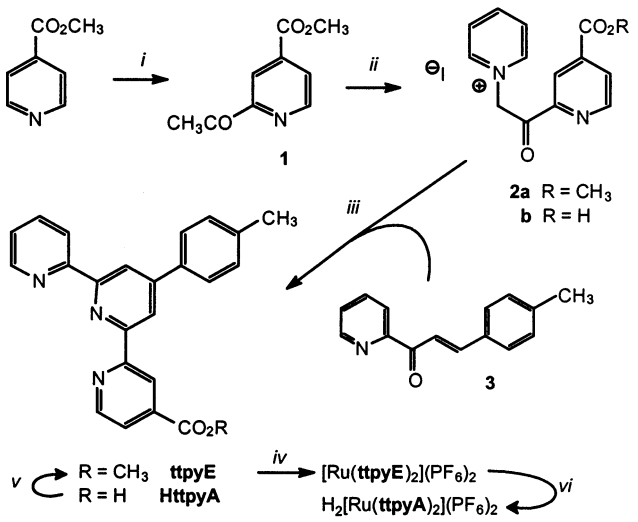


Fig. 1. Two-point supramolecular association of a 4-carboxylated terpyridine complex with MV^{2+} (Ar is *p*-tolyl).

2.4. Preparation of [Ru(ttpyE)$_2$](PF$_6$)$_2$

The ligand (ttpyE) (32.5 mg, 0.085 mmol) was added to a solution of $RuCl_3$ (8.8 mg, 0.034 mmol as the trihydrate) in CH_3OH and the resulting solution was heated to reflux for 16 h. The reaction mixture was rid of solvent in vacuo. The resulting residue was re-dissolved in a minimal quantity of CH_3CN, filtered to remove unreacted starting materials, and treated with an excess of a saturated aqueous solution of NH_4PF_6. The collected precipitate was purified by column chromatography (silica, 14:1:0.5 CH_3CN–satd. aq. KNO_3–H_2O). The minor, purple-colored, fore-fraction was discarded. The major, red-colored, fraction was collected and freed of solvent under reduced pressure, redissolved in a minimal quantity of CH_3CN, and again precipitated with NH_4PF_6, as above. The collected red powder (33 mg, 85% based on $RuCl_3 \cdot 3H_2O$) crystallized as red plates using vapor diffusion methods (CH_3CN–acetone). ^{1}H NMR (CD_3CN): δ 9.16 (1H, s, H-3′/5′), 9.10 (1H, s, H-3), 9.03 (1H, s, H-5′/3′), 8.60 (1H, d, H-3″/6″), 8.15 (2H, d, Ar-H-2(6)), 7.96 (1H, dd, H-4″/

Scheme 1. Reagents and conditions: (i) 70% aq. ^{t}BuOOH (2 equiv.), TFA (1 equiv.), $FeSO_4$ (1/60 equiv.), paraldehyde (22 equiv. of CH_2O), r.t. in CH_3CN, 4 h; (ii) I_2 (1 equiv.), reflux in pyridine, 3 h; (iii) NH_4OAc (24 equiv.), reflux in MeOH, 1 h; (iv) reflux in $SOCl_2$, 1 h, then reflux in MeOH, 1 h; (v) 0.4 equiv. $RuCl_3$, reflux in MeOH, 16 h; (vi) 2:5 0.78 N aq. 5″), 7.59 (4H, m, Ar-H-3(5), H-5, H-6), 7.42 (1H, d, H-6″/3″), 7.18 (1H, dd, H-5″/4″), 3.98 (3H, s, OCH_3), 2.55 (3H, s, Ar-CH_3) ppm. ^{13}C NMR (CD_3CN): δ 164.5, 160.3, 158.9, 156.3, 155.9, 154.4, 153.4, 149.8, 142.1, 139.6, 139.3, 134.6, 131.2, 128.7, 128.5, 127.0, 125.5, 124.2, 122.9, 122.6, 53.8, 21.3 ppm. FAB MS m/z (%): 1008 (100) [$M-PF_6$], 863 (90) [$M-2PF_6$]. Elemental analysis: *Anal.* Calc. for $C_{48}H_{38}F_{12}N_6O_4P_2Ru$ (M_W 1153.87): C, 49.96; H, 3.32; N, 7.28. Found: C, 49.57; H, 3.37; N, 7.17%.

2.5. Preparation of $H_2[Ru(ttpyA)_2](PF_6)_2$

$[Ru(ttpyE)_2](PF_6)_2$ (11.0 mg, 9.5 μmol) was dissolved in DMF (5 ml) to which was added 2 ml of 0.775 N NaOH. This was heated at reflux overnight, cooled, then neutralized with excess 60% aq. HPF_6. The collected precipitate was washed with H_2O and dried under vacuum to give a red powder (10.1 mg, 94%). ^{1}H NMR (CD_3CN + TFA-*d*): δ 9.14 (1H, s, H-3′/5′), 9.08 (1H, s, H-3), 9.01 (1H, s, H-5′/3′), 8.64 (1H, d, H-3″/6″), 8.13 (2H, d, Ar-H-2(6)), 7.94 (1H, t, H-4″/5″), 7.56 (4H, m, H-5, H-6, Ar-H-3(5)), 7.41 (1H, d, H-6″/3″), 7.17 (1H, t, H-5″/4″), 2.52 (3H, s, CH_3) ppm. MALDI-MS m/z (%): 790.2 (11) [$M-2PF_6-CO_2-2H$], 747.1 (100) [$M-2PF_6-2CO_2-2H$].

2.6. Electrochemistry

Cyclic voltammetry was run at 298 K in CH_3CN containing 0.1 M $^{n}Bu_4NPF_6$, with a Pine Instruments RDE-3 potentiostat and Houston Instruments model 100 X-Y recorder, and used a three-electrode system, consisting of a quasi-reference Ag/AgCl wire electrode and working and auxiliary electrodes of Pt wire. The CH_3CN was dried via distillation over P_2O_5. Ferrocene served as a reference (Fc/Fc^+ +0.45 V vs. SSCE in CH_3CN) [7].

2.7. Electron transfer measurements

Sample solutions (2.5 ml) containing $H_2[Ru(ttpyA)_2](PF_6)_2$ (3.77×10^{-5} M) or $[Ru(ttpy)_2](PF_6)_2$ (3.99×10^{-5} M), $MV(PF_6)_2$ (MV, 9.45×10^{-3} M) and triethanolamine (5×10^{-2} M) in CH_3CN were prepared in 3 ml cuvettes for measurements and data treatment as detailed elsewhere [8]. The absorbance due to $MV^{\bullet+}$ (λ_{max} 600 nm, ϵ_{max} 10 060 M^{-1} cm^{-1} [9]) was monitored over time first under irradiation, then in the dark, and this cycle was repeated twice more with each sample. After converting the absorbance data to $MV^{\bullet+}$ concentrations, the average maximum $MV^{\bullet+}$ yields were measured, and the average initial growth rates were converted to first-order constants (k_{init} = rate/$[MV^{2+}]_0$). The pseudo-first-order rate constants for the formation (k_f) and quenching (k_q) of $MV^{\bullet+}$ were obtained from application of the kinetic model [8]:

$$d[MV^{\bullet+}]_t/dt = k_f[MV^{2+}]_0 - (k_f + k_q + k_{d1})[MV^{\bullet+}]_t - k_{d2}[MV^{\bullet+}]_t^2 \quad (1)$$

using k_d parameter values measured from a prior analysis of the subsequent aerobic decays in the dark (where $k_f = k_q = 0$).

3. Results and discussion

The Kröhnke synthesis [4] of ttpyE (Scheme 1) necessitated the preparation of ketone ester **1** as a means of introducing the desired functionality. The acetylation of methyl isonicotinate provided **1** in near quantitative yield through a modification of a recently reported procedure [5].

In the Kröhnke method, the desymmetrizing functionality on unsymmetrical terpyridines is normally introduced as part of a propenone synthon, but this approach failed in the present case. Indeed, attempted formation of the requisite propenone by Claisen condensation of **1** with *p*-tolualdehyde under basic conditions resulted in hydrolysis of the ester group. The alternate approach, via pyridinium salt **2a**, was, therefore, adopted and this represents one of the few examples of a Kröhnke synthesis employing a functionalized pyridinium salt [10]. Ester **1** was converted in 58% yield to salt **2a** which, without purification, was condensed with the known propenone **3** [6] in the presence of excess NH_4OAc to afford ttpyE. Despite rigorous con-

trol of all reaction conditions, the crude product contained variable but small quantities ($<6\%$) of a polar material that we suppose was the product of hydrolysis, the acid HttpyA, but this was easily separated by trituration with $CHCl_3$. The presence of residual hydrolyzed material was traced back to a contamination of **2a** by a variable but small quantity ($<6\%$) of acid salt **2b** (detected by ^1H NMR and FAB MS). This proved to be inseparable from the ester salt **2a**, but the presence of **2b** was inconsequential, as we were able to convert the putative HttpyA to ttpyE to improve the overall yield of pure ttpyE to 73%.

The putative HttpyA was too insoluble to undergo complexation under standard conditions. The insolubility is likely because it adopts a zwitterionic form, a problem encountered with other carboxyl-bearing tridentates [11]. Instead, the diester form $[Ru(ttpyE)_2](PF_6)_2$ was prepared in 85% isolated yield from ttpyE and $RuCl_3$, followed by anion exchange and column chromatography. The use of $Ru(DMSO)_4Cl_2$ [12] resulted in a lower yield (63%) [13]. Although the NMR spectra of both ttpyE and $[Ru(ttpyE)_2](PF_6)_2$ were complicated by low symmetry, COSY spectra allowed for the assignment of all H resonances. The most notable effect of complexation was the 1.3 ppm upfield migrations of H-6 and H-6″ (and smaller migrations for H-5 and H-5″) amidst generally downfield shifts, due to the ring current of the perpendicular ligand.

The room temperature electronic spectra and cyclic voltammogram of $Ru(ttpyE)_2^{2+}$ were obtained and compared to those of the parent complex $Ru(ttpy)_2^{2+}$ (Table 1). Two quasi-reversible reduction waves were found. When compared to $Ru(ttpy)_2^{2+}$, $Ru(ttpyE)_2^{2+}$ shows more positive potentials for all waves, more so for the first reduction wave ($\Delta E_{1/2}^{2+/+}$ 210 mV) than for the oxidation wave ($\Delta E_{1/2}^{3+/2+}$ 140 mV), and this is consistent with the electron-withdrawing ester groups stabilizing the ligand-centred π* (LUMO) level to a larger extent than the metal-centred d (HOMO) orbital. There is a rough correlation among Ru(II) terpyridine complexes between MLCT energies and $E_{1/2}^{3+/2+} - E_{1/2}^{2+/+}$, [14] which $Ru(ttpyE)_2^{2+}$ also obeys. The smaller $E_{1/2}^{3+/2+} - E_{1/2}^{2+/+}$ gap with $Ru(ttpyE)_2^{2+}$ is reflected in the red shift of the MLCT absorbance to one of the longest wavelengths measured in such complexes, accompanied by a broadening of the MLCT envelope due to the lower symmetry here than in $Ru(ttpy)_2^{2+}$, and the consequent loss of orbital degeneracy. The effects of ester groups were therefore very similar here as in a 4,4′-disubstituted 2,2′-bipyridine complex, [15] and are analogous to the effects of other electron-withdrawing substituents in tpy complexes [16].

The hydrolysis of $[Ru(ttpyE)_2](PF_6)_2$ by NaOH, followed by acidification with HPF_6, afforded the diacid complex $H_2[Ru(ttpyA)_2](PF_6)_2$ as a red powder in 94% yield. Except for the absence of an ester OCH_3 signal, its ^1H NMR spectrum was very similar to that of $[Ru(ttpyE)_2](PF_6)_2$.

The dilute CH_3CN solutions of this complex used in UV–Vis spectroscopy and in the photochemical experiments (vide infra) were homogeneous but, in concentrated solutions appropriate for crystallization and NMR, this acidic complex developed a precipitate that was subsequently insoluble in the usual solvents for Ru(II) complexes (CH_3CN, DMF) and only sparingly soluble in MeOH or H_2O. Similarly, the evaporation of solutions of $H_2[Ru(ttpyA)_2](PF_6)_2$ and redissolution left an insoluble residue. The residue could be solubilized in methanolic HCl or with TFA, and a drop of TFA-*d* in the CD_3CN sample for NMR prevented that precipitation. We believe that this insoluble material resulted from the loss of the elements of HPF_6, as had occurred with the PF_6^- salts of previous carboxyl-bearing Ru(II) complexes [17]. Since the pK_a values governing the deprotonations of each COOH group are likely very similar, this would probably generate the neutral $[Ru(ttpyA)_2]^0$. We cannot exclude the formation of a singly deprotonated $H[Ru(ttpyA)_2]PF_6$ but we note that COO^- groups are unable to hydrogen-bond with the solvent whereas COOH groups can. When, during synthesis, the acidification step following the NaOH digestion was omitted, the product was similarly insoluble and could only be analyzed in TFA solutions, i.e. in a protonated and charged state. Since the COO^- groups lie on the outer surface of the complex, they remain accessible for close-range electrostatic interactions with external cations, even if the complex is electrostatically indifferent at long range (or, in the case of $H[Ru(ttpyA)_2]PF_6$, repulsive). As they are disposed on one side of the complex, the COO^- groups on one molecule can interact with the opposite, positively

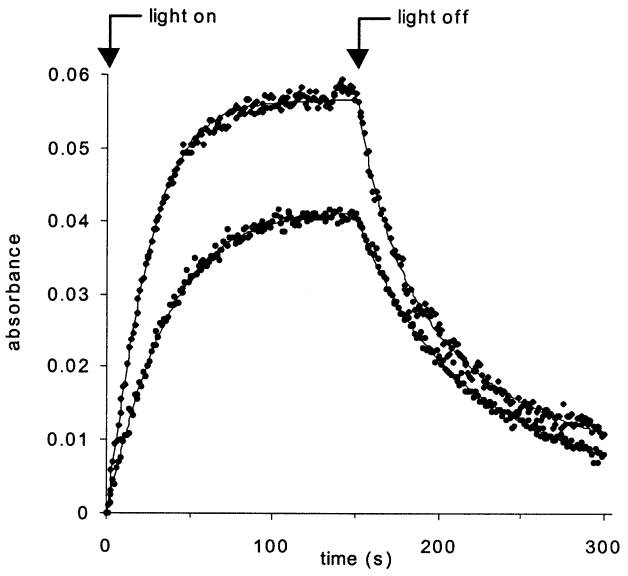

Fig. 2. Typical time courses of the absorbance at 600 nm with $H_2[Ru(ttpyA)_2](PF_6)_2$ (upper trace) and $[Ru(ttpy)_2](PF_6)_2$ (lower trace). Samples were in CH_3CN at 4×10^{-5} M and contained 9.45×10^{-3} M $MV(PF_6)_2$ and 0.05 M TEOA. The solid lines are the least-squares fits according to Eq. (1).

charged hemisphere of another, and the insolubility may therefore reflect the formation of an infinite chain of electrostatically ordered molecules, e.g. $\{[Ru(ttpyA)_2]\}_n$.

Although no satisfactory analytical sample of $H_2[Ru(ttpyA)_2](PF_6)_2$ could thus be prepared, its purity (as shown by its ^1H NMR spectrum) and its stability in dilute solutions were more than adequate for the photochemical experiments (vide infra).

The electronic spectrum of $H_2[Ru(ttpyA)_2](PF_6)_2$ was very similar to that of the diester, but with a blue shift of the MLCT λ_{max}. A similar shift had been recorded for a 2,2′-bipyridine-4,4′-dicarboxylic acid complex [1]. This attests to the weaker electron-withdrawing effect of COOH groups.

Methodology developed earlier [8] was used to comparatively assess the abilities of $H_2[Ru(ttpyA)_2](PF_6)_2$ and $[Ru(ttpy)_2](PF_6)_2$ to sensitize the production of cation radical ($MV^{\bullet+}$) from the electron acceptor (MV^{2+}) by oxidative quenching, under continuous irradiation in CH_3CN and with triethanolamine (TEOA) as sacrificial reductant. Fig. 2 presents typical results and Table 1 reports the pertinent findings: under continuous irradiation, there is an initial rapid rise of $[MV^{\bullet+}]$ (monitored at 600 nm), followed by a steady-state plateau. The rate of rise (rate constant k_{init}) and the steady-state yield of $MV^{\bullet+}$ were significantly higher than with $[Ru(ttpy)_2](PF_6)_2$. Kinetic analysis according to Eq. (1) suggested that this improvement arose from a 66% increase in the rate of $MV^{\bullet+}$ formation (larger k_f) while the $MV^{\bullet+}$ quenching rate constant (k_q) was, within experimental error, similar.

In the presence of TEOA, $H_2[Ru(ttpyA)_2](PF_6)_2$ should be in a deprotonated form. While the effects of $COOH/COO^-$ groups on the excited-state lifetimes (τ) of bpy complexes is ambiguous, [1,20] it is generally agreed that electron-withdrawing groups lengthen τ [1,15,16,20,21]. COO^- groups are weakly electron-withdrawing and therefore not expected to significantly increase τ beyond that previously measured for $[Ru(ttpy)_2]^{2+}$ (τ 0.95 ns in nitrile solvent [22]). Instead, the COO^- groups must play another role.

It may be that the TEOA-deprotonated complex is the neutral $[Ru(ttpyA)_2]^0$ (or $H[Ru(ttpyA)_2]PF_6$) and that this remains soluble at the low concentration employed in the photochemical experiments. If so, the improvement in photosensitization ability can be attributed to a simple electrostatic advantage over $[Ru(ttpy)_2]^{2+}$ of the kind invoked with other carboxylated complexes, [1] wherein the electrostatic repulsions experienced by photoexcited $[Ru(ttpy)_2]^{2+}$ in its encounters with MV^{2+}, repulsions that the solvent can poorly abate, are absent (or reduced) with TEOA-deprotonated $H_2[Ru(ttpyA)_2](PF_6)_2$. But, just as the insolubility of the material that $H_2[Ru(ttpyA)_2](PF_6)_2$ spontaneously deposits at higher concentrations is believed to result from intermolecular electrostatic interactions involving the surface COO^- groups, it is likely that the TEOA-generated COO^- groups here remain intimately associated with the co-generated $HTEOA^+$ ions through electrostatic and hydrogen bonding, both attractive interactions that can occur at close enough range to overcome the repulsions with the more distant metal centre. In this case, the TEOA-deprotonated complex is better described as a $(HTEOA)PF_6$ adduct, $(HTEOA)_2[Ru(ttpyA)_2](PF_6)_2$ or $H(HTEOA)[Ru(ttpyA)_2](PF_6)_2$. We had earlier obtained an analogous bis-$NaPF_6$ adduct with a diacidic complex [23]. There is no electrostatic advantage over $[Ru(ttpy)_2]^{2+}$ with such adducts, but they can undergo cation exchange with MV^{2+}. At the very least, such cation exchange provides encounters between the excited state and MV^{2+}. At best, the two COO^- moieties constitute a two-point binding site for MV^{2+} in 1:1 supramolecular interaction, as illustrated in Fig. 1. We have earlier described an analogous supramolecular association between MV^{2+} and a deprotonated tetra-acidic complex [17]. More importantly, such cation exchange or supramolecular association can occur prior to the photoevent and, once photoexcitation has taken place, would render the electron transfer a unimolecular process, thereby entropically enhancing the rate of transfer and reducing the dependence on τ. After the electron transfer has taken place, the electrostatic attractions with the photoproduct $MV^{\bullet+}$ are weaker and further weakened by enhanced repulsions from the Ru(III) centre. This promotes a dissociation that allows $MV^{\bullet+}$ to avoid the reverse electron transfer and accumulate. This notion of

electrostatic or supramolecular assistance of photosensitization is under further investigation in this and other systems.

Abstract

The electrochemical reduction of copper(II) complexes with salen Schiff-base ligands derived from ethylenediamine or (*R*,*R*) or (*S*,*S*)-1,2-diphenylethylenediamine and 5-methoxy, 5-bromo and 5-nitrosalicylaldehyde have been studied by cyclic voltammetry in the potential range +1 to −2.3 V in dimethyl sulfoxide (DMSO) as a solvent. The resulting voltammograms consist of a single quasi-reversible one-electron transfer attributable to the couple [Cu(II)L]/[Cu(I)L]$^-$. Trends in cathodic peak potential (E_{pc}) values are observed which can be correlated with the electronic effects of the 5-substituents of the Schiff-base ligands. Changes in the basicity of the ligand groups are determinant for such electrochemical trends. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Salen Cu(II) complexes; Schiff-base ligands; Cyclic voltammetry; Hammett substituent constants

1. Introduction

Transition metal complexes with tetradentate Schiff-base ligands have been extensively investigated as catalysts for a number of organic redox reactions and electrochemical reduction processes [1–5]. Salen complexes have also been recently used as catalytically active materials to develop surface-modified electrodes for sensoring applications [6,7]. Cyclic voltammetry has been a useful tool to investigate the mechanisms of catalysis by Schiff-base metal complexes as well as to study the structure–reactivity relationships in these compounds [3,5,8]. We have previously studied the syntheses and spectroscopic characterisation of copper(II) complexes of salen Schiff bases derived from ethylenediamine, (1*R*,2*R*)- and (1*S*,2*S*)-1,2-diphenylethylenediamine, and 5-nitro, 5-bromo and 5-methoxysalicylaldehyde [9]. Electronic spectra of these complexes in the d–d region suggest that the ligand field strength varies as a function of the 5,5′-substituents according to the sequence $NO_2 < Br < H < OCH_3$. Hence, it should be expected that the thermodynamic stabilities of such complexes follow a similar order which, in turn, should influence both their electrochemical properties and potential catalytic behaviour. Properties of these complexes, as potential catalysts for epoxidation of olefins are being tested at present in our laboratory. In connection with such studies, herein, we report an electrochemical study of the above mentioned Schiff-base ligands and their respective copper(II) complexes in dimethyl sulfoxide (DMSO) as a solvent. Copper(II) complexes whose electrochemical characterisation has been reported previously [10,11] have been included in this report in order to parallel both Schiff-base ligand series, the ethylenediamine and the 1,2-diphenylethylenediamine derivatives.

2. Experimental

Reagent grade chemicals were obtained from Aldrich and were used as provided. HPLC grade DMSO was

dried over molecular sieve previously dried at 105 °C under vacuum, redistilled and stored under N_2 over molecular sieve before use. The Schiff bases and copper(II) complexes under study have been prepared previously [9]. For comparative purposes, the redox couple Cu(II)/Cu(I) of $Cu(ClO_4)_2$ in DMSO was also considered. Moreover, in the cases of sparing solubility in DMSO, dimethylformamide (DMF) was used. Cyclic voltammetry was carried out under pure dry nitrogen in a three-electrode cell with a vitreous carbon working electrode, a platinum counter electrode and an aq. saturated AgCl/Ag reference electrode ($E = -0.0474$ V vs. the saturated calomel electrode). Supporting electrolyte was 0.05 M n-Bu_4NClO_4 (TBAP). Cyclic voltammograms were scanned at room temperature (r.t.) in the potential range of $+1$ to -2.3 V, at sweep rates (v) between 25 and 1000 mV s^{-1}, and were recorded with a Metrohm VA-693 potentiostat equipped with a VA-694 stand and connected to a personal computer. Oxidative CV measurements were not performed because, according to literature data on copper(II) complexes with similar coordination spheres [8], the CV wave for the process Cu(II)/Cu(III) falls at potentials near $+1.48$ V, i.e. outside the potential range allowed by the electrode–solvent system here used. Coulometric measurements were carried out at r.t., under pure dry nitrogen, with a Princeton Applied Research (PARC) model 173 potentiostat coupled to a PARC model 179 digital coulometer, with a platinum mesh working electrode, a platinum coil counter electrode and an aq. saturated AgCl/Ag reference electrode. Controlled-potential electrolysis measurements were performed at r.t., under pure dry nitrogen, with a Wenking POS 88 potentioscan, using an electrochemical cell modified for spectrophotometric measurements (optical path length, 1 cm). Here a platinum coil working electrode, a platinum coil counter electrode and an aq. saturated AgCl/Ag reference electrode were used. Absorption spectra were recorded in the visible region on a UV3 Unicam spectrometer.

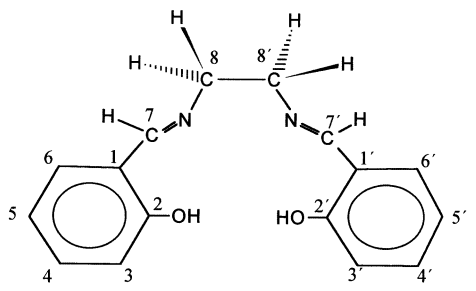

Fig. 1. Atom labelling scheme for salen copper(II) complexes.

3. Results and discussion

The ligands and metal complexes under study were labelled as shown in Table 1 by use of the atom-labelling scheme given in Fig. 1. The voltammetric parameters obtained for the ligands and their respective copper(II) complexes are listed in Table 2. Moreover, typical voltammograms of a given ligand and its respective copper(II) complex are shown in Fig. 2.

3.1. Schiff-base ligands

For all Schiff-base ligands studied, except compounds **4** and **4R** (nitro derivatives), cyclic voltammograms at 100 mV s^{-1} consist of a single cathodic peak at potentials ranging from -1.6 to -2.0 V; no anodic wave occurs in the reverse scan. This behaviour was observed for a wide range of scan rates from 25 to 1000 mV s^{-1}. Hence, such a reduction process should correspond to a totally irreversible electron transfer. Voltammograms of compounds **4** and **4R** show the above-mentioned cathodic peak at -1.13 V (Table 2). Additionally, they exhibit CV waves in the range -1.4 to -1.8 V, which may be ascribed to the reduction of the nitro groups [15]. Coulometric measurements of compound **2** in DMSO indicate that the cathodic wave observed corresponds to a two-electron transfer. In fact, the shapes of the cathodic waves suggest that they would consist of two overlapped one-electron processes. A similar result has previously been reported for this compound in DMF, but in the presence of 2 equiv. of acetic acid [12]. Such a requirement would arise from the fact that both the dielectric constant and the dipole moment of DMF are smaller than those of DMSO. For all Schiff bases under study, this irreversible reduction peak would be ascribed to an intramolecular reductive coupling of the two imine groups to yield a piperazine [12–14]. Such a process would involve self-protonation reactions where the phenolic hydroxyl groups act as proton donors.

Table 2
Cyclic voltammetric parameters for the Schiff-base ligands and their copper(II) complexes, and calculated values for $\Delta \log \beta = \log \beta(\mathrm{Cu(II)L}) - \log \beta(\mathrm{Cu(I)L^-})$

Ligand		*Complex*					
	E_{pc} (V)		E_{pc} (V)	$E_{1/2}$ (V)	ΔE_p (mV)	i_{pa}/i_{pc}	$\Delta \log \beta$
Ethylenediamine derivatives							
1	−1.97	Cu1	−1.26	−1.19	130	0.50	21.4
2	−1.79	Cu2	−1.23	−1.17	115	0.73	20.9
3	−1.62	Cu3 [a]	−1.14	−1.07	140	0.46	19.4
4	−1.13	Cu4	−0.91	−0.86	111	0.27	15.6

2R	−1.85	Cu2S	−1.22	−1.17	101	0.97	20.9
3R	−1.69	Cu3R	−1.08	−1.05	91	0.80	18.5
4R	−1.13	Cu4R	−0.95	−0.91	94	0.88	16.3
$Cu(ClO_4)_2$ [b]			0.01	0.05	91	0.97	

[a] For Cu**3**, the solvent was DMF.
[b] CV parameters of $Cu(ClO_4)_2$ correspond to the couple Cu(II)/Cu(I). For the couple Cu(I)/Cu^0 $E_{pc} = -0.57$ V and $E_{1/2} = -0.26$ V.

On the other hand, in each series of ligands, the cathodic peak potential (E_{pc}) corresponding to the intramolecular reductive coupling of the imine groups varies as can be expected from the electronic effects of the substituents at positions 5,5′. Thus, E_{pc} becomes less negative according to the sequence $OCH_3 < H < Br < NO_2$, i.e. in order of an increase in both electron-withdrawing and π-acceptor qualities of the substituents. In fact, for both ethylenediamine and 1,2-diphenylethylenediamine derivatives, Hammett type relationships were found between the E_{pc} values and the appropriate *para*-substituent parameters [16]. Such correlations are shown in Fig. 3. However, since the substituents at positions 5,5′ are indeed *para*- to the respective phenolic hydroxyl groups, the occurrence of these Hammett type correlations would indicate that the E_{pc} for the reductive coupling of the imine groups actually varies as a function of the acidity of the hydroxyl group through the ligand series. This fact agrees with a mechanism involving self-protonation reactions for the electrochemical reduction of the imine groups in the Schiff bases under study.

3.2. Copper(II) complexes

The cyclic voltammetric curves for the electrochemical reduction of the studied copper(II) complexes (Table 2) exhibit a redox couple at potentials in the range of −0.91 to −1.28 V, which can be attributed to the reduction of the metal centre [10,11]. Voltammograms of complexes Cu4 and Cu4R show additional CV waves in the range of −1.5 to −1.8 V, which correspond to the reduction of the nitro groups. Moreover, for all complexes studied, the cathodic wave corresponding to the irreversible two-electron reduction of the imino groups is no longer observed. This fact indicates that, owing to the lack of transferable hydroxylic protons, the reduction potentials of the dianionic ligands have been shifted beyond the lower limit of the potential interval considered in the experimental measurements [12].

On the other hand, the ΔE_p data listed in Table 2, though being much larger than the theoretical value for an electrochemically reversible one-electron process, at least suggest that the reduction of copper(II) in the complexes under study should correspond to a one-electron charge transfer. Actually, this possibility has been corroborated through coulometric measurements on the system Cu2 in DMSO. The exceedingly large ΔE_p val-

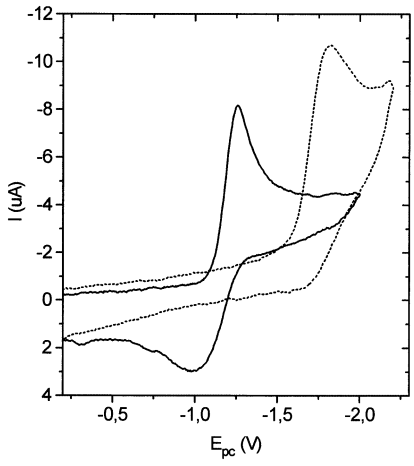

Fig. 2. Cyclic voltammograms recorded for the reduction of 1.0 mM ligand **2** (----) and 1.0 mM complex Cu2 (—) at a vitreous carbon electrode in DMSO containing 0.05 M TBAP. Scan rate, 0.1 V s^{-1}.

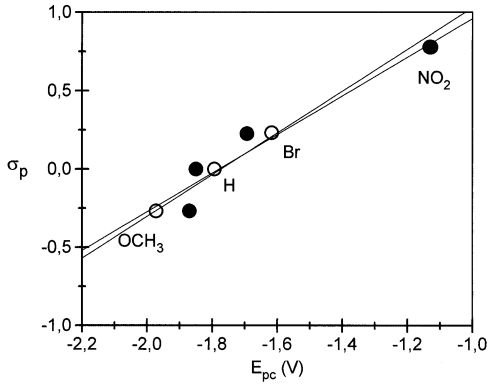

Fig. 3. Correlation between the E_{pc} values for Schiff-bases and the respective σ substituent constants (for *p*-substitution). Ethylenediamine derivatives (○) $r = 0.998$; 1,2-diphenylethylenediamine derivatives (●) $r = 0.960$.

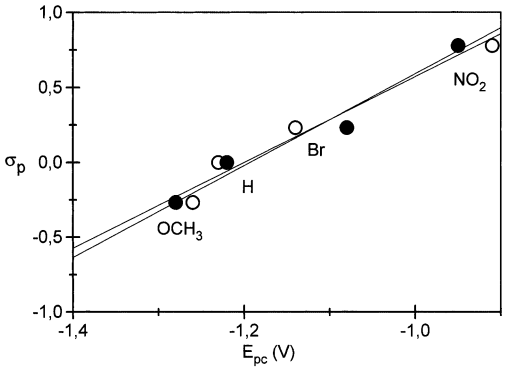

Fig. 4. Correlation between the E_{pc} values for copper(II) complexes with Schiff-base ligands and the respective σ substituent constants (for *p*-substitution). Ethylenediamine derivatives (○) $r = 0.982$; 1,2-diphenylethylenediamine derivatives (●) $r = 0.983$.

ues for the electrochemical reduction of copper(II) in these complexes would be due to both a quasi-reversible behaviour of the couple $[Cu(II)L] + e^- = [Cu(I)L]^-$ under the v conditions here adopted and the non-aq. nature of the systems [8,17]. For all complexes, CV measurements at different v, in the range 25–1000 mV s^{-1}, indicate that the E_{pc} values are only slightly dependent upon the v. Furthermore, in all cases a linear relationship between the cathodic peak current (i_{pc}) and the square root of the v ($v^{1/2}$) was observed. This fact implies that these electrochemical processes are mainly diffusion-controlled.

As can be noticed in Table 2, the E_{pc} and $E_{1/2}$ values for the copper complexes are more negative by 1.1–1.7 V compared with the respective values for the $Cu(ClO_4)_2$ couple in DMSO. This indicates that, for the Schiff-base ligands herein studied, the chelates of copper(II) are considerably more stable than the respective chelates of copper(I). Accordingly, the differences between the logarithms of the formation constants (β) of these complexes were estimated through the expression:

$$\Delta\log\beta = \log\beta(Cu(II)L) - \log\beta(Cu(I)L^-) = (E^{\circ\prime} - E)/0.059$$

where $E^{\circ\prime}$ stands for the reduction potential of the reference Cu(II)/Cu(I) redox couple and E for the reduction potential of the couple $[Cu(II)L]/[Cu(I)L]^-$. In such calculations, the approximation $E^{\circ\prime} - E = E_{pc}[Cu(ClO_4)_2] - E_{pc}[Cu(II)L]$ was taken. The parameters $\Delta\log\beta$ thus calculated are included in Table 2. As can be seen in this table, E_{pc} becomes less negative in the sequence $OCH_3 < H < Br < NO_2$ and, hence, $\Delta\log\beta$ decreases according to $OCH_3 > H > Br > NO_2$, i.e. in a sequence of increasing electron-withdrawing effects of the substituents at positions 5,5′. Similar results have been reported previously for analogous copper(II) and nickel(II) systems, and have been interpreted by assuming that the strong electron-withdrawing effects stabilise the lower oxidation state [8]. However, another possibility would be that, owing to the decrease in donor ability of the ligand groups (mainly the phenoxy groups) the stabilities of both [Cu(II)L] and $[Cu(I)L]^-$ decrease through the above mentioned sequence, but for the latter to a lesser extent. This would be a consequence of an increase in the flexibility of the coordination sphere over such a series, which should favour the stability of the copper(I) complex. Moreover, for both metal complex series, Hammett type relationships were found between E_{pc} and the appropriate *para*-substituent parameters [16] which reflect the variation of the electrode potential as a function of the electron-withdrawing ability of the substituents at positions 5,5′. Such correlations are shown in Fig. 4. These results indicate that the decrease in basicity of the phenoxy group through the sequence $OCH_3 > H > Br > NO_2$ would be determinant for the electrochemical trends observed.

On the other hand, since the $\Delta\log\beta$ data indicate that, for each system the Cu(II) complex should be considerably more stable than the Cu(I) one, a less negative electrode potential for the couple $[Cu(I)L]^-/Cu^0$ than for the couple $[Cu(II)L]/[Cu(I)L]^-$ should be expected. Hence, it should also be expected that the electrochemical reduction of the copper(II) complexes occurs through a two-electron charge transfer, i.e. by an EE or EC mechanism. Reduction of [Cu(II)L] to Cu^0 has not been observed, not even in the coulometric experiments. Thus, the copper(I) complexes would behave as kinetically inert to both cathodic heterogeneous charge transfer and disproportionation. Nevertheless, if the solution resulting from the coulometric experiment on the complex Cu2 is allowed to stand overnight under pure dry nitrogen, a partial recovery of its original colour is observed. This suggests that, at least for the mentioned complex, disproportionation of $[Cu(I)L]^-$ occurs to a some extent. This fact has been confirmed by means of spectroelectrochemical measure-

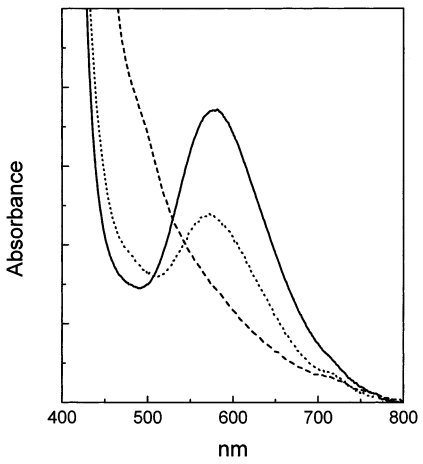

Fig. 5. Absorption spectrum in the d–d band region of 1 mM Cu2 in DMSO containing 0.05 M TBAP, (—) before electrochemical reduction; (----) after reduction; and (···) allowed to stand for 15 h after reduction, under pure dry nitrogen, at r.t.

ments on the complexes Cu2 and Cu4. Results obtained for Cu2 are shown in Fig. 5. Such results can be related with the i_{pa}/i_{pc} data listed in Table 2. Accordingly, for complexes with 8,8′-diphenyl substituted Schiff-base ligands the ratio of i_{pa}/i_{pc} takes values close to one, as required for a reversible or quasi-reversible charge transfer without coupled chemical reactions. Instead, for complexes with Schiff-base ligands derived from ethylenediamine $i_{pa}/i_{pc} < 1$ is always observed. This fact suggests that the electrochemical reduction of these complexes involves an EC mechanism consisting of a reversible or quasi-reversible one-electron heterogeneous charge transfer followed by an irreversible chemical reaction, i.e. the disproportionation of $[Cu(I)L]^-$. It has previously been suggested that the ratio i_{pa}/i_{pc} smaller than unity observed for complex Cu2 in DMF can be attributed to the presence of traces of water in the solvent-supporting electrolyte [10]. Accordingly, additional experiments performed in our laboratory have shown that, on increasing the water concentration of the Cu1S system from traces to 5 M, the peak-current ratio decreases from 1.01 to 0.87. However, as can be seen in Table 2, peak-current ratios for complexes with Schiff-base ligands derived from ethylenediamine are smaller than 0.87. Thus, the somewhat different behaviour of copper(II) complexes with 8,8′-diphenyl substituted Schiff-base ligands can be ascribed to a greater kinetic inertness to disproportionation of the respective copper(I) complexes. Since the disproportionation reaction of Cu(I) complexes should involve a bimolecular process, it could be assumed that such a greater kinetic inertness arises from the occurrence of steric hindrance effects involving the phenyl substituents in the transition state.

Abstract

A series of ruthenium(II) polypyridine complexes were synthesized with a tertiary aliphatic amine ligand, $[Ru(4,4'\text{-}X_2bpy)_2(DMAEPy)]^{2+}$ (**1a**; X = H, **2**; X = CF_3), $[Ru(tpy)(N\text{–}N)Cl]^{+}$ (**3a**; N–N = DMAEPy, **3c**; N–N = DEAEPy) and $[Ru(tpy)(DMAEPy)(MeCN)]^{2+}$ (**4**) where DMAEPy = 2-(2′-dimethylaminoethyl)-pyridine, DEAEPy = 2-(2′-diethylaminoethyl)-pyridine, tpy = 2,2′:6′,2″-terpyridine and bpy = 2,2′-bipyridine. The spectroscopic, electrochemical and photochemical properties of these complexes are studied and compared to those of the corresponding primary-amine complexes $[Ru(bpy)_2(AEPy)]^{2+}$ (**1b**) and $[Ru(tpy)(AEPy)Cl]^{+}$ (**3b**) where AEPy = 2-(2′-aminoethyl)-pyridine. The MLCT bands in the UV–Vis absorption spectra of the tertiary-amine complexes were blue-shifted (8–9 nm), and their redox potentials for the $Ru^{II/III}$ couples were more positive than expected (90–100 meV) compared to the corresponding primary-amine complexes. Irradiation of an acetonitrile solution of the complexes causes selective photochemical ligand substitution of the tertiary-amine ligand even under aerated conditions, giving the corresponding solvento complex $[Ru(4,4'\text{-}X_2bpy)_2(MeCN)_2]^{2+}$ or $[Ru(tpy)(MeCN)_2Cl]^{+}$. © 2002 Elsevier Science Ltd. Keywords: Tertiary amines; Ruthenium complexes; Photochemistry; Electrochemistry

1. Introduction

Oxidative dehydrogenation of amines is an important metabolic process in vivo. In the case of amine oxidase (EC 1.4.3.6) it is known that Cu^{II} is present at the active site and plays an important role in amine dehydrogenation [1]. The inorganic chemistry of the oxidative dehydrogenation of primary and secondary aliphatic amines coordinated to ruthenium(II) has been also investigated by many researchers [2]. Meyer and co-workers reported that primary-amine complexes such as $[Ru(bpy)_2(en)]^{2+}$ (en = ethylenediamine), underwent four-electron oxidation either electrochemically or chemically, giving the corresponding diimine complexes $[Ru(bpy)_2(dim)]^{2+}$ (dim = 1,2-diiminoethane) [3]. Formation of these diimine complexes is initiated by the oxidation of the central Ru^{II} to Ru^{III}, and oxidation of the amine ligand couples to the deprotonation process from the amine. Ford and co-workers reported that the oxidation of $[(NH_3)_4Ru(AMPy)]^{2+}$ (AMPy = 2-(2′-aminomethyl)-pyridine) gives the stable Ru^{III} complex at low pH, while on increasing the pH oxidation of the AMPy ligand takes place, and the imine complex $[(NH_3)_4Ru(IMPy)]^{2+}$ (IMPy = 2-(2′-iminomethyl)-pyridine) is produced [4]. Photochemical oxidation of the primary-amine complexes has also been reported: irradiation of an aerated water or acetonitrile solution of $[Ru(bpy)_2(en)]^{2+}$ or $[Ru(bpy)_2(tn)]^{2+}$ (tn = 1,3-propylenediamine) gives the corresponding α,α′-diimine complexes [5].

Although metal complexes that are coordinated by a tertiary amine, such as triethylamine or triethanolamine, are important intermediates in photocat-

[a] Calculated values are in parentheses.

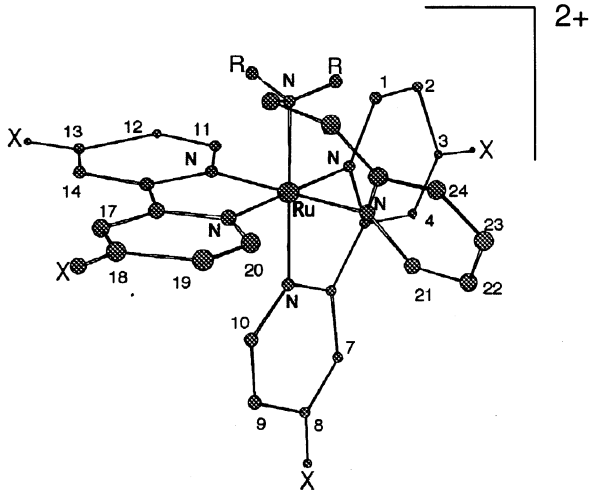
alytic reactions [6–8], only a few ruthenium polypyridine complexes with a tertiary-amine ligand have been isolated [9,10]. Information on the photochemical and electrochemical properties of the tertiary amine complexes is therefore very limited [10]. For example, we reported that $[Ru(tpy)(bpy)(py)]^{2+}$ (tpy = 2,2′:6′,2″-terpyridine, bpy = 2,2′-bipyridine, py = pyridine) photocatalyzes selective hydride reduction of an $NAD(P)^+$ model compound, and the tertiary-amine complex $[Ru(tpy)(bpy)(NEt_3)]^{2+}$ is presumed to be an important intermediate [6]. However, little information is available on the properties of the amine complex because it is not stable enough to be isolated.

We report here that five new tertiary-amine complexes were synthesized successfully using bidentate tertiary-amine ligands such as 2-(2′-dimethylaminoethyl)-pyridine (DMAEPy) and 2-(2′-diethylaminoethyl)-pyridine (DEAEPy), i.e. $[Ru(4,4'\text{-}X_2bpy)_2(DMAEPy)]^{2+}$ (**1a**; X = H, **2**; X = CF_3), $[Ru(tpy)(N–N)Cl]^+$ (**3a**; N–N = DMAEPy, **3c**; N–N = DEAEPy) and $[Ru(tpy)(DMAEPy)(MeCN)]^{2+}$ (**4**). Electrochemical and photochemical properties of the complexes are also reported.

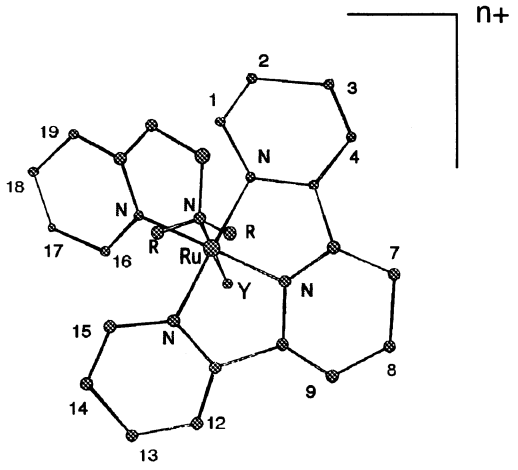
DMAEPy DEAEPy AEPy

2. Experimental

2.1. Physical measurements and instrumentation



Proton NMR spectra were recorded on JEOL 500 NMR (500 MHz) and Bruker ARX-400 NMR (400 MHz) spectrometers at 25 °C. Both COSY and NOESY NMR techniques were used for unambiguous assignment of the resonances of the complexes. Electrospray ionization mass spectra (ESI-MS) were measured using a Hitachi M-1200 mass spectrometer with an M-1206 ES probe. The positive ion ESI-MS spectra were measured with 10–30 V drift voltages by a procedure reported elsewhere [11]. Electronic absorption spectra were recorded using an Otsuka–Denshi Photal MCPD-2000 multi channel spectrometer with a D_2/I_2 mixed lamp (± 1 nm resolution). The cyclic voltammograms of the complexes were measured in an acetonitrile solution containing tetra-*n*-buthylammonium tetrafluoroborate (0.1 M) as a supporting electrolyte using an ALS/CHI CHI-620 electrochemical analyzer with a Pt disk working electrode, a $Ag/AgNO_3$ (0.01 M) reference electrode and a Pt counter electrode.



2.2. Materials

Acetonitrile was distilled over P_2O_5 three times, and then once over CaH_2 just before use. Tetra-*n*-buthylammonium tetrafluoroborate was recrystallized from ethyl acetate-benzene, and then dried in vacuo at 120 °C over night prior to use. The ligands: 2-(2′-dimethylaminoethyl)-pyridine (DMAEPy); 2-(2′-diethylaminoethyl)-pyridine (DEAEPy) [12] and the complexes: *cis*-$Ru(bpy)_2Cl_2\cdot 2H_2O$ [13]; $Ru(tpy)Cl_3$ [14]; *cis*-$Ru(4,4'\text{-}CF_3bpy)_2Cl_2$ [15]; $[Ru(bpy)_2(AEPy)](PF_6)_2$ (**1b**) [3] were prepared according to literature methods. The purities of the synthesized complexes were confirmed by ^1H NMR and ESI-MS and elementary analysis (Table 1). The structures of the complexes are illustrated in Scheme 1.

2.2.1. *[Ru(bpy)$_2$(DMAEPy)](PF$_6$)$_2$ (1a)*

An $EtOH/H_2O$ (1/1:v/v, 28 ml) solution containing *cis*-$Ru(bpy)_2Cl_2\cdot 2H_2O$ (0.505 g, 0.971 mmol) and DMAEPy (0.279 g, 1.86 mmol) was refluxed under an Ar atmosphere for 2 h. The color of the solution changed from purple to reddish orange. After the reaction mixture was cooled to room temperature (r.t.), the solution was concentrated to ~ 5 ml under reduced pressure and then a saturated NH_4PF_6 aqueous solution was added to it. The precipitated orange solid of **1a** was collected by filtration, recrystallized from

2.2.2. *[Ru(4,4′-CF_3bpy)$_2$(DMAEPy)](PF$_6$)$_2$ (**2**)*

An acetonitrile solution (30 ml) containing *cis*-Ru(4,4′-CF_3bpy)$_2Cl_2$ (0.197 g) and $AgPF_6$ (0.137 g, 0.54 mmol) was refluxed under Ar in the dark for 4 h. After the reaction mixture was cooled to r.t., precipitated AgCl was filtered out using celite layer. The solvent was evaporated under vacuum. One ml of saturated NH_4PF_6 solution was added to the solution and cooled at a refrigerator over night. Precipitated brown solid of [Ru(4,4′-CF_3bpy)$_2$(MeCN)$_2$](PF$_6$)$_2$ was collected by filtration and then washed with cold methanol. An EtOH/H_2O (1/1:v/v, 4 ml) solution containing the brown solid (0.0548 g) and DMAEPy (0.0293 g) was refluxed under an Ar atmosphere for 55 h. After the reaction mixture was cooled to r.t., a saturated NH_4PF_6 aqueous solution was added to it. The complex **2** was collected as brown solid by filtration. It was recrystallized from MeCN–diethyl ether. Yield: 40%. ^{1}H NMR (acetone-d_6): δ 9.69 (d, $J = 6.2$ Hz, H-1); 9.47 (s, H(4, 17)); 9.28 (s, H(7, 14); 9.15 (d, $J = 5.9$ Hz, H-20); 8.66 (d, $J = 5.9$ Hz, H-10); 8.23 (d, $J = 5.9$ Hz, H-19); 8.17 (d, $J = 6.2$ Hz, H-2); 7.96 (dd, $J = 7.7$, 7.0 Hz, H-23); 7.93 (d, $J = 6.6$ Hz, H-11); 7.81 (d, $J = 7.7$ Hz, H-24); 7.78 (d, $J = 5.9$ Hz, H-9); 7.57 (d, $J = 6.6$ Hz, H-21); 7.38 (d, $J = 6.6$ Hz, H-12); 6.97 (dd, $J = 7.0$, 6.6 Hz, H-22); 3.67-3.76 (m, CH_2CH_2, 4H); 2.80 (s, CH_3, 3H); 1.92 (s, CH_3, 3H).

2.2.3. *[Ru(tpy)(DMAEPy)Cl](PF$_6$) (**3a**)*

An EtOH/H_2O (2/1:v/v, 36 ml) solution containing Ru(tpy)Cl_3 (0.207 g, 0.47 mmol), DMAEPy (0.147 g, 0.98 mmol) and LiCl (0.200 g, 4.7 mmol) was refluxed under an Ar atmosphere for 8 h. After the reaction mixture was cooled to r.t., the solution was slowly concentrated to half volume under reduced pressure at r.t. A saturated NH_4PF_6 aqueous solution was added to it, and then the precipitated black solid was collected by filtration. The complex **3a** was isolated by column chromatography with basic alumina and 2:1 toluene/CH_3CN eluent to remove a by-product $[Ru(tpy)_2]^{2+}$. It was recrystallized from acetone–diethyl ether. Yield: 30%. ^{1}H NMR (acetone-d_6): δ 9.94 (d, $J = 5.9$ Hz,

H-16); 8.62 (d, $J = 8.1$ Hz, H-7, 9); 8.61 (d, $J = 8.1$ Hz, H-4, 12); 8.52 (d, $J = 5.5$ Hz, H-1, 15); 8.10 (dd, $J = 7.6$, 7.7 Hz, H-18); 8.08 (dd, $J = 7.6$, 8.1 Hz, H-3, 13); 8.02 (t, $J = 8.1$ Hz, H-8); 7.79 (d, $J = 7.7$ Hz, H-19); 7.64 (dd, $J = 5.5$, 7.6 Hz, H-2, 14); 7.56 (dd, $J = 5.9$, 7.6 Hz, H-17); 3.35–3.38 (m, CH_2CH_2, 2H); 2.50–2.53 (m, CH_2CH_2, 2H); 1.54 (s, $N(CH_3)_2$, 6H).

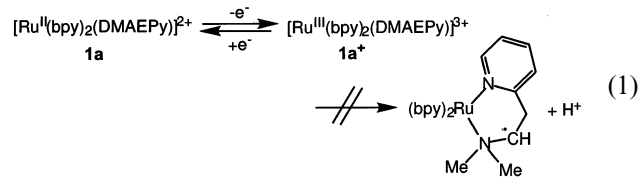
2.2.4. [Ru(tpy)(AEPy)Cl](PF$_6$) (**3b**) and [Ru(tpy)(DEAEPy)Cl](PF$_6$)·CH$_3$COCH$_3$ (**3c**)

These complexes were synthesized using procedures analogous to the method for **3a**, except for use of AEPy or DEAEPy instead of DMAEPy. **3b**: Yield: 14%. ^{1}H NMR (acetone-d_6): δ 10.25 (d, $J = 5.9$ Hz, H-16); 8.53 (d, $J = 8.1$ Hz, H-4, 12); 8.50 (d, $J = 8.1$ Hz, H-7, 9); 8.42 (d, $J = 5.5$ Hz, H-1, 15); 8.08 (dd, $J = 7.5$, 7.7 Hz, H-18); 8.00 (d, $J = 7.9$, 8.1 Hz, H-3, 13); 7.91 (t, $J = 8.1$ Hz, H-8); 7.71 (d, $J = 7.7$ Hz, H-19); 7.59 (dd, $J = 5.9$, 7.5 Hz, H-17); 7.56 (dd, $J = 5.5$, 7.9 Hz, H-2, 14); 3.14–3.19 (m, CH_2CH_2, 2H); 2.98 (brs, NH_2, 2H); 2.46–2.54 (m, CH_2CH_2, 2H). **3c**: Yield: 13%. ^{1}H NMR (acetone-d_6): δ 9.84 (d, $J = 5.9$ Hz, H-16); 8.62 (d, $J = 8.1$ Hz, H-4, 12); 8.61 (d, $J = 8.1$ Hz, H-7, 9); 8.56 (d, $J = 5.5$ Hz, H-1, 15); 8.06 ~ 8.12 (m, H-3, 13, 18, 3H); 7.99 (t, $J = 8.1$ Hz, H-8); 7.79 (d, $J = 7.7$ Hz, H-19); 7.67 (dd, $J = 5.5$, 7.7 Hz, H-2, 14); 7.50 (dd, $J = 5.9$, 7.5 Hz, H-17); 3.53–3.57 (m, CH_2CH_2, 2H); 2.72–2.76 (m, CH_2CH_2, 2H); 2.10 (q, $J = 7.0$ Hz, $N(CH_2CH_3)_2$, 4H); 2.08 (s, CH_3COCH_3, 6H); 0.43 (t, $J = 7.0$ Hz, $N(CH_2CH_3)_2$, 6H).

2.2.5. [Ru(tpy)(DMAEPy)(MeCN)](PF$_6$)$_2$·1/2H$_2$O (**4**)

This complex was synthesized in a manner similar to the reported method for [Ru(tpy)(bpy)(MeCN)](PF$_6$)$_2$ except for use of DMAEPy instead of bpy [16] Yield: 40%. ^{1}H NMR (acetone-d_6): δ 9.36 (d, $J = 5.9$ Hz, H-16); 8.79 (d, $J = 8.1$ Hz, H-7, 9); 8.75 (d, $J = 8.1$ Hz, H-4, 12); 8.58 (d, $J = 5.5$ Hz, H-1, 15); 8.35 (t, $J = 8.1$ Hz, H-8); 8.29 (dd, $J = 7.7$, 8.1 Hz, H-3, 13); 8.19 (dd, $J = 7.5$, 7.7 Hz, H-18); 7.87 (d, $J = 7.7$ Hz, H-19); 7.79 (dd, $J = 5.5$, 7.7 Hz, H-2, 14); 7.68 (dd, $J = 5.9$, 7.5 Hz, H-17); 3.41–3.46 (m, CH_2CH_2, 2H); 2.86 (brs, 1/2H$_2$O); 2.69–2.74 (m, CH_2CH_2, 2H); 2.10 (s, CH_3CN, 3H); 1.68 (s, $N(CH_3)_2$, 6H).

3. Results and discussion



3.1. Synthesis and characterization

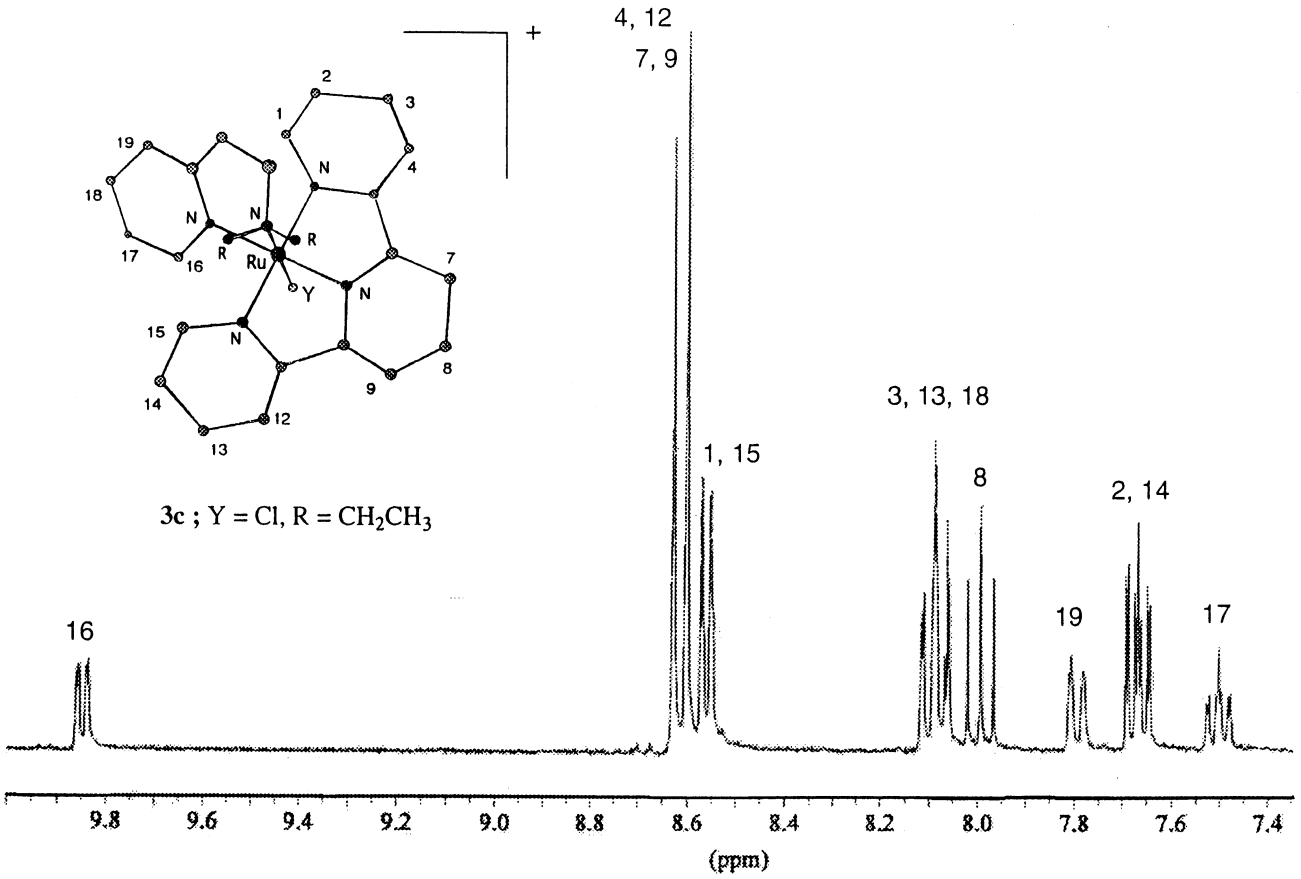
We successfully synthesized and purified tertiary-amine complexes **1a**, **2**, **3a**, **3c** and **4** using the bidentate tertiary-amine ligands DMAEPy and DEAEPy (Scheme 1). Complexes with the corresponding monodentate tertiary amine, such as triethylamine, are not stable enough to be isolated. This result clearly shows that use of bidentate tertiary-amine ligands is a good method for synthesis of metal complexes with a relatively bulky tertiary amine. Another tertiary amine complex, $[Ru(bpy)_2(DEAEPy)]^{2+}$ was also synthesized, although it could not be isolated using the same procedure as for **1a** because it decomposed very fast, even at room temperature. Similarly, $[Ru(bpy)_2(N,N,N',N'$-tetraethylethylenediamine$)]^{2+}$ was not stable, but $[Ru(bpy)_2(tmen)]^{2+}$ (tmen = N,N,N',N'-tetramethylethylenediamine) with the methyl group of the tertiary-amine ligand was isolated easily [10]. Steric repulsion between the hydrogen at position 1 on the bpy ligand (see the structures of **1** and **2** illustrated in Scheme 1) and the ethyl group of the amine ligand could cause these complexes to be unstable.

There are two possible structural isomers for each of **3a**, **3c** and **4**, in which the tertiary amine part of the bidentate ligand is in the *cis* or *trans* position relative to the monodentate ligand. As an example, the aromatic region of the ^{1}H NMR spectrum of **3c** is illustrated in Fig. 1. The resonance at 9.84 ppm, which is attributable to the proton at the position 16, is shifted down significantly by 1.38 ppm in magnetic field compared to the corresponding proton on 'free' DEAEPy, while the other aromatic protons on the DEAEPy ligand are only shifted slightly from the values for 'free' DEAEPy. If **3c** were the *cis* isomer, the chemical shift of the proton at position 16 should be observed at higher fields because of the shielding effect of the tpy ligand [17]. On the other hand, the chemical shift of the ethyl protons of the DEAEPy ligand was observed at ~0.5 ppm higher field than that of 'free' DEAEPy. It is plausible that the pyridine rings of the tpy ligand of the *trans* isomer shield the ethyl group magnetically. It follows that **3c** must be the *trans* isomer. The other complexes **3a**, **3b** and **4** had similar ^{1}H NMR characteristics. The structure of $[Ru(tpy)(DMAMPy)Cl]^+$ (DMAMPy = 2-(2′-dimethylaminomethyl)-pyridine) was recently determined by X-ray crystallographic analysis [18], showing that the dimethylamino group and the Cl ligand are in *trans* positions relative to each other. This complex has similar ^{1}H NMR characteristics to those of **3** and **4** described here.

3.2. Electrochemistry and UV–Vis absorption spectra

Fig. 2(A) illustrates the cyclic voltammogram (CV) of **1a** measured for an acetonitrile solution. A reversible redox wave attributable to a $Ru^{II/III}$ couple was observed at $E_{1/2} = 0.88$ V (Eq. (1)).

(1)



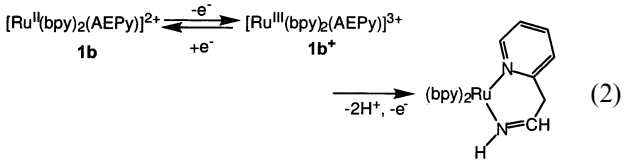


Fig. 1. Aromatic region of the ^{1}H NMR spectrum of **3c** measured in acetone-d_6 at 25 °C.

Addition of a base such as pyridine did not affect the reversibility. This finding is in sharp contrast to the corresponding primary-amine complex **1b**, for which oxidation is irreversible as shown in Fig. 2(B). Meyer and co-workers have reported that oxidation of primary-amine complexes occurs on the central Ru^{II} to give Ru^{III}, and is followed by rapid deprotonation from the primary amine ligand and additional one-electron oxidation to give the corresponding imine complex (Eq. (2)) [3].

(2)

It is well known that oxidation of 'free' tertiary amines such as NEt_3 and $N(CH_2CH_2OH)_3$ causes the loss of two electrons and also one proton from the α-carbon of the amine, to give the iminium cation (Eq. (3))[19,20].[2] The stability of the oxidized complex $\mathbf{1a}^+$ implies that deprotonation from the DMAEPy ligand on Ru^{III} is too slow, even in the presence of the base, to be converted to the corresponding iminium cation, at least during the CV measurement.

$$NEt_3 \xrightarrow{e^-} (NEt_3)^{+\bullet} \xrightarrow{-H^+} Et_2N\dot{C}HCH_3 \xrightarrow{e^-} Et_2N^+{=}CHCH_3 \quad (3)$$

In contrast to the oxidation, the one-electron reduction wave of **3a** was irreversible (this is the solid line in Fig. 2(C)). The chloride ligand of $\mathbf{3a}^-$ is substituted with the solvent molecule to give the acetonitrile complex **4**, for which the CV is shown as the dotted line in Fig. 2(C) (Eq. (4)).

$$[\underset{\mathbf{3a}}{Ru(tpy)(DMAEPy)Cl}]^+ \xrightarrow{e^-} [\underset{\mathbf{3a}^-}{Ru(tpy^{-\bullet})(DMAEPy)Cl}]^+$$
$$\xrightarrow{MeCN} [\underset{\mathbf{4}^-}{Ru(tpy^{-\bullet})(DMAEPy)(MeCN)}]^+ + Cl^- \quad (4)$$

Similar ligand substitution reactions occurred for the other chlorido complexes **3b** and **3c**. On the other hand, reversible waves attributable to (bpy/bpy$^{-\bullet}$) were observed for **1a** and **2**.

The redox potentials of the $Ru^{II/III}$ couples of **3a** and **3c** are more positive than that of **3b**, and reduction of **1a** also occurred at a more positive potential than for **1b** even though DMAEPy and DEAEPy have stronger electron donating abilities than AEPy, as shown in Table 2.

[2] The $Ru^{II/III}$ couple of **3b** is also reversible even though the primary amine AEPy coordinates to the Ru center. The central Ru^{III} of $\mathbf{3b}^+$ is probably unable to oxidize the AEPy ligand because the redox potential for $Ru^{II/III}$ in **3b** is much more negative than that in **1b** (Table 2).

For all complexes the lowest energy absorption band is attributable to the metal-to-X_2bpy ligand charge transfer (MLCT) transition, as summarized in Table 2. The UV–vis absorption spectra of the DMAEPy and DEAEPy reveal some unexpected features in comparison to the AEPy complexes. The tertiary-amine complexes have higher energy MLCT bands than those of the primary amine complexes, i.e. E_{MLCT}(**1a**) > E_{MLCT}(**1b**), E_{MLCT}(**3a**) and E_{MLCT}(**3c**) > E_{MLCT}(**3b**). These observations might be caused by distortion of the

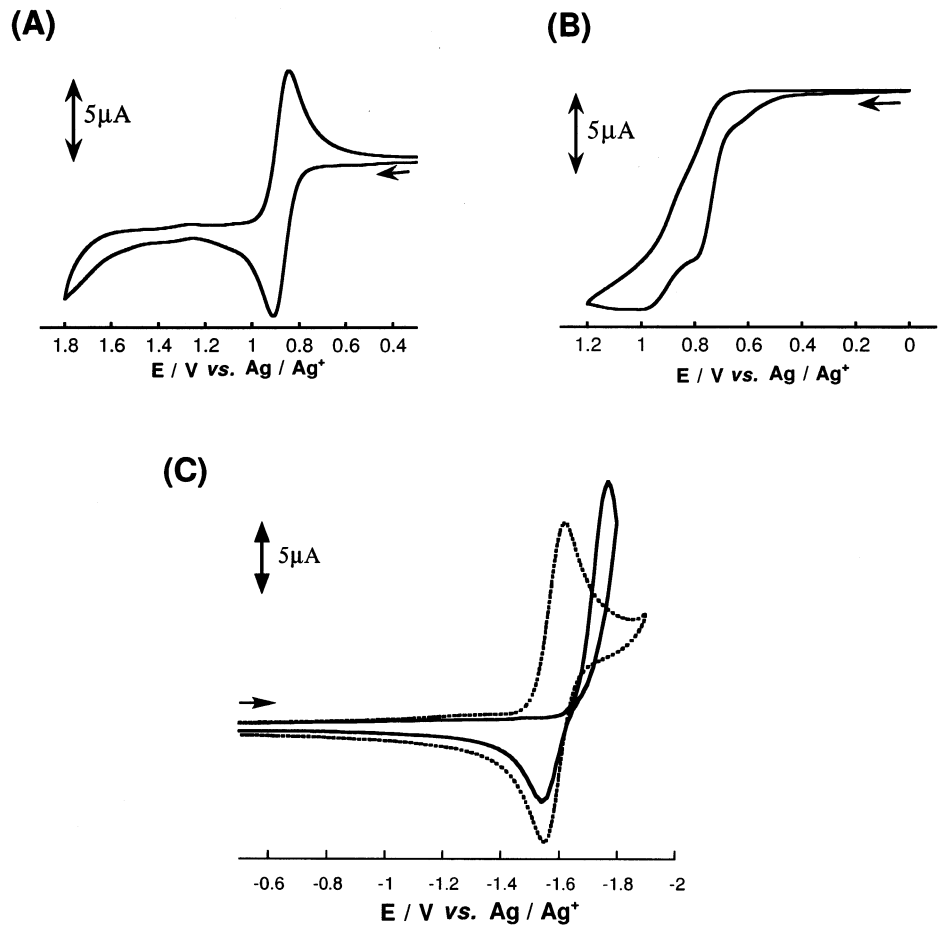

Fig. 2. Cyclic voltammograms for (A) **1a**, (B) **1b**, and (C) **3a** (the solid line) and **4** (the dotted line) in acetonitrile solutions containing $Bu^n_4NBF_4$ (0.1 M) under an Ar atmosphere at scan rates of (A, B) 0.05 V s^{-1} and (C) 0.2 V s^{-1}.

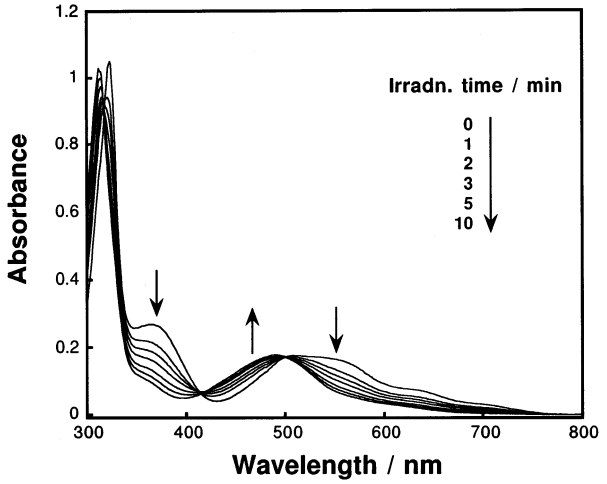

Fig. 3. UV–Vis absorption spectral change in an acetonitrile solution containing **3a** (0.039 mM) during irradiation.

complexes due to the steric bulkiness of the alkyl amine parts components of DMAEPy and DEAEPy [10].

3.3. Photochemistry

Irradiation of acetonitrile solutions containing **1a**, **2**, **3a** and **3c** caused quantitative substitution of the tertiary amine ligands with the solvent molecules. As an example, Fig. 3 shows the UV–vis absorption spectral change in an acetonitrile solution containing **3a** (0.039 mM) during irradiation with a high pressure Hg lamp through a $CuSO_4$ aqueous solution filter. Irradiation caused a rapid hypsochromic shift of the MLCT absorption maximum from 509 to 490 nm, accompanied by a set of isosbestic points. Immediately after irradiation the solution underwent ESI-MS analysis: the peak corresponding to the $[Ru(tpy)(MeCN)_2Cl]^+$ ($m/z =$ 452) was observed, but another possible product, $[Ru(tpy)(^1\eta\text{-DMAEPy})(MeCN)Cl]^+$, was not detected at all. Similar experimental results were obtained for other tertiary-amine complexes. The photochemical ligand substitution reaction also occurred even in the presence of a base or under aerated conditions. These observations clearly demonstrate that irradiation of the tertiary-amine complexes causes quantitative photochemical ligand substitution (Eq. (5)), but that oxidation of the tertiary-amine ligands does not proceed.

$$[Ru(tpy)(\underset{\mathbf{3a}}{DMAEPy})Cl]^+ \xrightarrow[MeCN]{h\nu} [Ru(tpy)(MeCN)_2Cl]^+ + DMAEPy \quad (5)$$

This results is in sharp contrast to the case of the primary-amine complexes $[Ru(bpy)_2(AMPy)]^{2+}$ and $[Ru(bpy)_2(en)]^{2+}$ (AMPy = 2-(2′-aminomethyl)-pyridine), for which irradiation under aerated conditions causes oxidation of the primary-amine ligand to give the corresponding imine complex [5,21,22]. Deprotonation from the α-carbons of the DMAEPy ligand on the central Ru^{III} of the MLCT excited states should be too slow, even in the presence of the base, for conversion to the corresponding iminium cation.

Abstract

Uranyl dimethylmalonato complexes with different metal to ligand ratios and connectivity, 1:2 monomeric, dimeric and 2:3, 3:4 infinite chain structures have been prepared and characterised by elemental analysis, thermal analysis, IR and ^{13}C CPMAS NMR spectroscopy, and X-ray crystallography. The different structural types are isolated by the use of different counter-cations. Two new kinds of binding mode of malonate with uranyl have been identified, tridentate (μ_2 1,3-bidentate and 1,5-bidentate) and tetradentate (1,3-bidentate with both carboxylate groups). A basis for the prediction of structural type from the results of ^{13}C CPMAS NMR spectroscopy is proposed. The structures of the crystallographically characterised products can be rationalised in terms of templating by the counter-cations, which appears to be influenced by the size of the counter-cations and the tendency to maximise hydrogen bonding in the lattice. © 2002 Elsevier Science Ltd. Keywords: Uranyl; Dimethylmelonate; Counter-cation; CPMAS ^{13}C NMR; X-ray crystallography

1. Introduction

In the solid state, pentagonal bipyramidal geometry appears to be favoured in malonato complexes of uranyl crystallised with NH_4^+, Sr^{2+} or Ba^{2+} [1–3]. In each case, one malonate is terminally 1,5-bidentate to a uranium atom, giving rise to a six-membered ring. The second malonate is also 1,5-bidentate through both carboxylate groups to the same uranium atom, but the other oxygen atom from one carboxylate group μ_1 bridges to the neighbouring uranium atom, producing an infinite chain of $[UO_2(C_3H_2O_4)_2]_n^{2n-}$. In the equatorial plane the U–O bonds are similar, with U–O distances between 2.31(1) and 2.41(1) Å and O–U–O angles ranging from 68.2(4) to 75.3(3)°. The conformations of the six-membered rings are different with different cations, and this is attributed to the size of the cations and the incorporation of non-bonded carboxylate oxygen atoms into the coordination spheres of Sr^{2+} or Ba^{2+}. For the ammonium derivative, the nitrogen atoms, carboxylate oxygen atoms and H_2O molecules are involved in numerous short contacts between 2.74 and 3.08 Å. Most of these contacts are probably involved in hydrogen bonding, which link the uranyl malonate chains into a three-dimensional network.

Although numerous investigations involving crystal structures of actinide complexes have provided data on coordination geometry and spatial arrangements, there is no coherent data set allowing identification of the

PII: S0277-5387(01)00964-0

effects of counter-cations and of systematic subtle change of the proligand. Therefore, we have initiated a study of the interactions between uranyl and malonates to delineate structural types and to assess spectroscopic methods for their characterisation. By varying appropriate substituent groups of the selected proligand, malonic acid, we might produce predictable trends in the properties of the resulting malonate complexes. Ultimately, it should be possible to predict the properties of similar homologous series. Malonates were selected as the ligand series because some crystallographic information was already available. Previously we have reported the synthesis and structural characterisation of monomeric and dimeric uranyl dimethyl malonato compounds [4]. In the present studies, dimethylmalonic acid was used as proligand and the counter-cations varied to explore further possible effects on structural diversity and bonding modes.

2. Experimental

2.1. Materials

All chemicals were reagent grade, purchased from Strem Chemicals, Aldrich or Lancaster and used without further purification.

2.2. Physical methods

Elemental analyses were performed by the Microanalysis Lab, Department of Chemistry, The University of Manchester. IR spectra were recorded on an ATI Mattson Genesis Series FTIR Spectrometer. TG/DT analyses were made on a Seiko (TG/DTA 220) thermal analyser at a heating rate of 10 °C min^{-1} and an air flow rate of 100 cm^3 min^{-1}. High resolution solid state ^{13}C NMR spectra were recorded using a Varian Associates Unity 300 spectrometer operating at 75.4 MHz using the cross polarisation-magic angle spinning (CP-MAS) technique. The acquisition time was 0.05 s, the spectral width was 30007.5 Hz, the contact time was 1.5 ms, the recycle time was 5 s and the spinning speed was approximately 4 kHz. The chemical shift scale was referenced by setting the CH_3 peak in a sample of solid hexamethylbenzene, run using the same conditions, to 16.5 ppm.

2.3. Syntheses

2.3.1. Preparation of tetramethylethylenediammonium tris(dimethylmalonato) bis[dioxouranate(VI)]

$(C_6H_{18}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ (**1**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 10 cm^3 H_2O) was added to a solution of dimethylmalonic acid and tetramethylethylenediamine (0.52 g, 4 mmol and 0.60 cm^3, 4 mmol in 30 cm^3 H_2O). A yellow crystalline product formed after a week, and was collected by filtration and dried in air, yield 70%. *Anal.* Found: C, 23.90; H, 3.55; N, 2.65; U, 45.22. Calc. for $C_{21}H_{36}N_2O_{16}U_2$: C, 24.05; H, 3.46; N, 2.67; U, 45.40%. TG/DTA (°C): 231(−22.4%, *endo*, cation + ligand = 22.9%), 410 (53.2%, *exo*, UO_3 = 52.7%). IR (KBr disk), ν (cm^{-1}): 3458 vs (br), 1601 vs, 1571 w, 1520 m, 1478 m, 1416 m, 1384 m, 1200 s, 930 vs, 721 s, 602 m.

2.3.2. Preparation of dimethylpiperazinium di-aqua tetrakis(dimethylmalonato) tris[dioxouranate(VI)] trihydrate

$(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 3H_2O$ (**2**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 10 cm^3 H_2O) was added to a solution of dimethylmalonic acid and dimethylpiperazine (0.52 g, 4 mmol and 0.56 cm^3, 4 mmol in 30 cm^3 H_2O). EtOH (5 cm^3) was added. A yellow crystalline product, formed after a week, was collected by filtration and dried in air, yield 85%. *Anal.* Found: C, 21.00; H, 3.40; N, 1.76; U, 46.95. Calc. for $C_{26}H_{50}N_2O_{27}U_3$: C, 20.3; H, 3.3; N, 1.8; U, 46.5%. 2.3.3. Preparation of ethylenediammonium aqua bis(dimethylmalonato) dioxouranate(VI) monohydrate

$(C_2H_{10}N_2)[UO_2(C_5H_6O_4)_2\ (H_2O)]\cdot H_2O$ (**3**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 15 cm^3 H_2O) was added to a solution of dimethylmalonic acid and ethylenediamine (0.51 g, 4 mmol and 0.28 cm^3, 4 mmol in 35 cm^3 H_2O). A yellow crystalline product formed after few days and was collected by filtration and dried in air, yield 85%. *Anal.* Found: C, 23.03; H, 4.16; N, 4.38; U, 37.65. Calc. for $C_{12}H_{26}N_2O_{12}U$: C, 22.94; H, 4.17; N, 4.46; U, 37.88%. TG/DTA (°C): 140 (−2.8%, *endo*, $-H_2O$ = 2.9%), 187 (*endo*), 330 (46.0%, UO_3 = 45.5%). IR (KBr disk) ν (cm^{-1}): 3476 s (br), 1615 s (br), 1586 w, 1549 w, 1468 m, 1414 s, 1357 m, 1204 m, 910 vs, 695 m, 593 m.

2.3.4. Preparation of bis[hexaaminecobalt(III) bis(dimethylmalonato) dioxouranate(VI)] di-chloride heptahydrate

$\{[Co(NH_3)_6][UO_2(C_5H_6O_4)_2]\}_2Cl_2\cdot 7H_2O$ (**4**): the preparation has been reported previously [4].

2.3.5. Preparation of piperazinium bis(dimethylmalonato) dioxouranate(VI) pentahydrate

$(C_4H_{12}N_2)[UO_2(C_5H_6O_4)_2]\cdot 5H_2O$ (**5**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 15 cm^3 H_2O) was added to a solution of dimethylmalonic acid and piperazine (0.51 g, 4 mmol and 0.76 g, 4 mmol in

35 cm^3 H_2O). A yellow crystalline product formed after few days and was collected by filtration and dried in air, yield 75%. *Anal.* Found: C, 23.94; H, 4.95; N, 3.91; U, 33.58%. Calc. for $C_{14}H_{34}N_2O_{15}U$: C, 23.73; H, 4.84; N, 3.95; U, 33.60%. TG/DTA (°C): 24 (-2.2%, *endo*, $-H_2O = 2.5\%$), 119 (-12.3%, *endo*, $-4H_2O = 12.7\%$), 194 (*exo*), 257 (*exo*), 317 (*exo*), 452 (41.2%, *exo*, $UO_3 = 40.4\%$). IR (KBr disk) ν (cm^{-1}): 3478 vs (br), 1608 vs, 1585 w, 1539 m, 1466 w, 1414 m, 1386 m, 1327 m, 1201 m, 1089 w, 905 vs, 710 s, 594 s.

2.3.6. Preparation of triethylenediammonium bis(dimethylmalonato) dioxouranate(VI)

$(C_6H_{14}N_2)[UO_2(C_5H_6O_4)_2]$ (**6**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 15 cm^3 H_2O) was added to a solution of dimethylmalonic acid and 1,4-diazabicyclo[2.2.2] octane (triethylenediammonium) (0.51 g, 4 mmol and 0.44 cm^3, 4 mmol in 35 cm^3 H_2O). A yellow crystalline product formed after few days and was collected by filtration and dried in air, yield 70%. *Anal.* Found: C, 29.08; H, 4.00; N, 4.20; U, 37.02. Calc. for $C_{16}H_{26}N_2O_{10}U$: C, 29.23; H, 4.07; N, 4.35; U, 36.94. TG/DTA (°C): 255 (-37.7%, *exo*, cation + ligand = 37.9%), 404 (45.0%, *exo*, $UO_3 = 44.4\%$). IR (KBr disk) ν (cm^{-1}): 3471 m (br), 1591 vs, 1530 m, 1413 m, 1359 mw, 1192 m, 912 s, 714 m, 593 m.

2.3.7. Preparation of tetraethylethylenediammonium tris(dimethylmalonato) bis[dioxouranate(VI)]

$(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ (**7**): a solution of uranyl nitrate hexahydrate (1.00 g, 2 mmol in 10 cm^3 H_2O) was added to a solution of dimethylmalonic acid and tetraethylethylenediammonium (0.52 g, 4 mmol and 0.88 cm^3, 4 mmol in 30 cm^3 H_2O). A yellow crystalline product formed after a week and was collected by filtration and dried in air, yield 75%. *Anal.* Found: C, 27.45; H, 4.10; N, 2.69; U, 43.50. Calc. for $C_{25}H_{46}N_2O_{17}U_2$: C, 27.18; H, 4.01; N, 2.54; U, 43.10%. IR (KBr disk), ν (cm^{-1}): 3419 br, w, 1606 s, 1571 w, 1550 w, 1520 s, 1471 m, 1430 w, 1409 w, 1360 w, 1334 w, 1197 m, 930 vs, 716 m, 602 w, 574 w.

2.3.8. Preparation of propanediammonium aqua bis(dimethylmalonato) dioxouranate(VI) monohydrate

$(C_7H_{20}N_2)[UO_2(C_5H_6O_4)_2(H_2O)]\cdot 2H_2O$ (**8**): the preparation has been reported previously [4].

2.4. Crystallography

The crystallographic data for compounds **2**, **3** and **7** are listed in Table 1. The intensities for **2** were measured on a Rigaku AFC5R diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) in ω–2θ mode at 17 °C. The cell parameters were refined by least squares from the angular positions of 25 for carefully centred reflections. An empirical absorption correction was applied, based on azimuthal scans of three reflections. The data were corrected for Lorentz and polarization effects. The structure was solved by direct methods with SIR-92 [5], and expanded using Fourier techniques with DIRDIF-94 [6]. Disordered solvent molecules were refined isotropically, whilst all other, non-hydrogen atoms were refined anisotropically. Hydrogen atoms were added in calculated positions. All calculations were performed using the TEXSAN [7] crystallographic software package (Molecular Structure Corporation).

The diffraction data for **3** and **7** were measured on a Rigaku Raxis II diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 20 °C. The structures were solved by conventional direct methods for **3** and Patterson methods for **7** and were refined by the full-matrix least-squares method on all F^2 data with SHELXTL 5.03 package [8]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were fixed in calculated positions.

3. Results and discussion

3.1. Crystal structures

Selected bond lengths and angles for **3**, **7** and **2** are given in Tables 2–4, respectively. The anionic structure of **3** is shown in Fig. 1. The uranium atom has pentagonal bipyramidal geometry. The two-malonate groups are both terminal 1,5-bidentate on the same uranyl ion with the fifth equatorial position of the uranium atom occupied by a H_2O molecule, forming a monomeric anion structure. The uranyl group is nearly linear with an O(1)–U–O(2) angle of 177.57(12)° and normal U–O distance [1.770(3) Å]. The U–O distances in the equatorial plane are separated into three groups, 2.311(2) Å for O(5), average 2.363(3) Å for O(3) and O(7), and average 2.430(3) Å for O(9) and O(11). The adjacent equatorial O–U–O angles range from 69.75(8) to 75.15(9)°. The deviations of the donor atoms from the mean equatorial plane are from -0.079 Å for O(5) to 0.117 Å for O(9). The packing diagram along crystallographic *b* axis is shown in Fig. 2. Several short contacts between a N atom and carboxylic oxygen atoms [2.725(4)–2.921(4) Å] suggest that cation–anion interactions are via H-bonding, which links the monomeric structures into a three-dimensional framework.

The anionic structure of the asymmetric unit for **7** is shown in Fig. 3. It has two crystallographically distinct uranyl groups and three ligands. Both U atoms have a hexagonal bipyramidal environment. The two ligands which form the central $(UO_2)_2(DMMA)_2$ unit are both 1,3-bidentate through one carboxylate group to one U atom and one of the oxygen atoms bridges μ_2 to the

other U atom, and another carboxylate group is monodentate to the other U atom as well, forming a bridging structural unit with two uranyl groups and two ligands. These structural units are linked together by the third ligand through bis(1,3-bidentate) bonding of two carboxylate groups, forming infinite chains. The two uranyl groups are quite normal with O–U–O angle 178.1(2)° and U–O distance averaging 1.751(4) Å for U(1), 178.6(2)° and 1.752(4) Å for U(2). The equatorial U–O distances for U(1) are quite different, with 2.380(3) Å for O(11), 2.431(3) Å for O(3), 2.471(3) Å for O(7), average 2.503(3) Å for O(4) and O(9) and 2.544(4) Å for O(10), and the adjacent equatorial O–U–O angles range from 50.18(11)° (1,3-bidentate) to 68.13(12)°. The deviations of donor atoms from the mean equatorial plane for U(1) are significant, from −1.270 Å for O(3) to 0.602 Å for O(4), which accounts for the first experimental observation of donor atoms well outside the equatorial plan for uranyl. Similarly the equatorial U–O distances for U(2) are also quite different, 2.311(4) Å for O(13), average 2.453(3) Å for O(5), O(6) and O(9), 2.505(3) Å for O(7) and 2.559(4) Å for O(8), and the adjacent equatorial O–U–O angles range from 50.23(11)° (1,3-bidentate) to 69.03(12)°. Compared with U(1), U(2) has a more planar environment. The deviations of donor atoms from the equatorial plane are within ±0.08 Å. The packing diagram along crystallographic a axis is shown in Fig. 4. The short contacts [2.738(7)–2.764(7) Å] between N and carboxylate O atoms suggest cation–anion interactions via H-bonding, linking the infinite chains into a two-dimensional network.

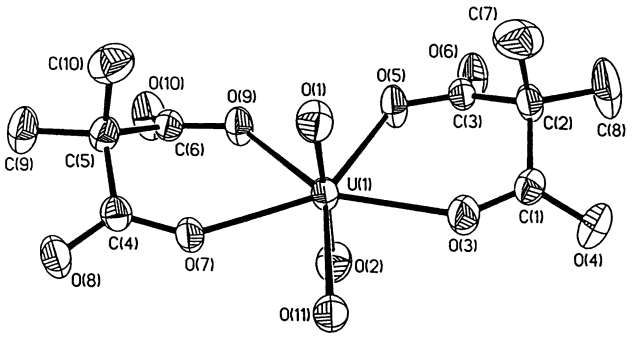

Fig. 1. An ORTEP drawing of the anionic structure for **3**, ellipsoids are drawn at the 50% probability level.

In the case of **2**, the uranium containing fragment in the asymmetric unit bonds together to form an infinite chain. U(1) lies on a centre of symmetry. The anionic structure in the asymmetric unit is shown in Fig. 5. The compound has two crystallographically unique uranyl groups. U(1) has hexagonal bipyramidal geometry, with two *trans* equivalent H_2O ligands and two dimethyl-

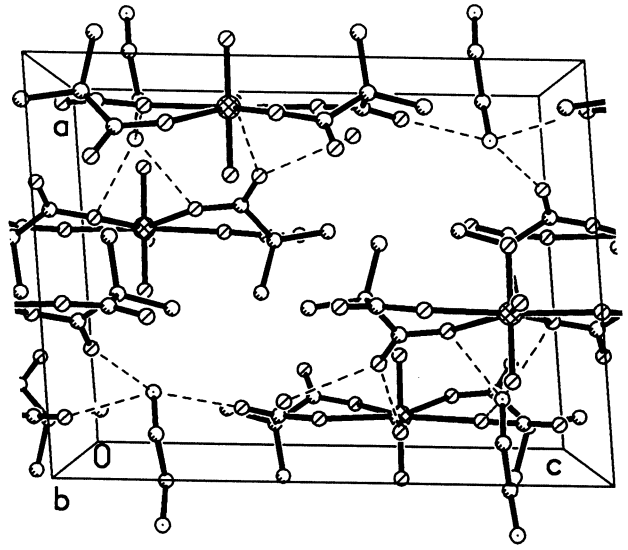

Fig. 2. Packing diagram along crystallographic *b* axis for **3**.

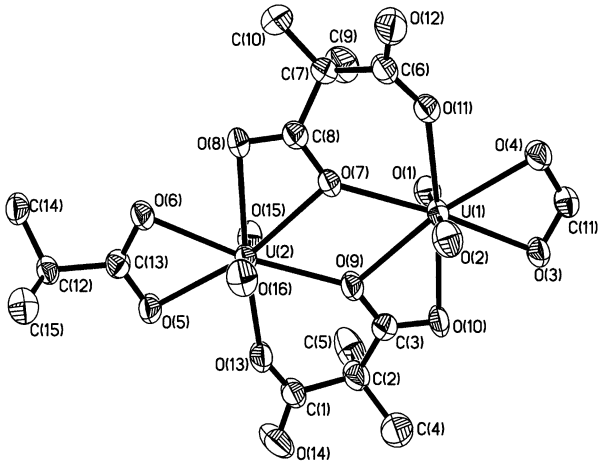

Fig. 3. An ORTEP drawing of the anion part of the asymmetric unit for **7**, ellipsoids are drawn at the 50% probability level.

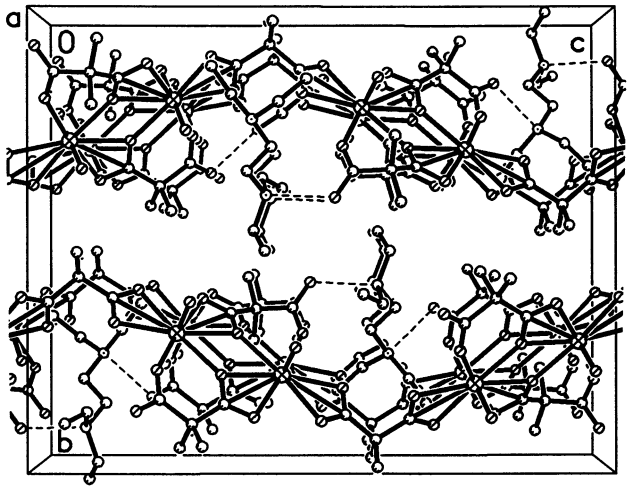

Fig. 4. Packing diagram along crystallographic *a* axis for **7**.

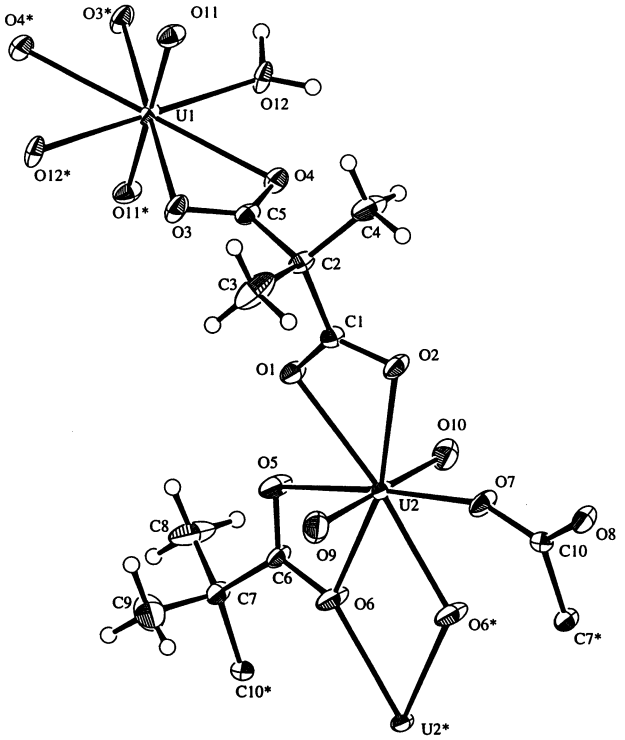

Fig. 5. An ORTEP drawing of the anion part of the asymmetric unit for **2**, ellipsoids are drawn at the 50% probability level.

malonate ligands that are each 1,3-bidentate. U(2) also has hexagonal bipyramidal geometry. Two symmetric crystallographically equivalent U(2) atoms are bridged together by two μ_2 carboxylate oxygen atoms from two crystallographically equivalent ligands (μ_2 1,3- and 1,5-bidentate arrangement). The infinite structure in the lattice is formed by bis(1,3-bidentate) dimethylmalonate ligands linking U(1) and U(2). The uranyl groups are nearly linear with normal U–O distance [average 1.751(5) Å for U(1) and 1.744(6) Å for U(2)]. The equatorial U–O distances for U(1) range from 2.471(5) to 2.493(5) Å with average 2.479(5) Å and the adjacent equatorial O–U–O angles range from 51.9(2)° (1,3-bidentate) to 64.1(2)°. The deviations from the mean equatorial plane for U(1) are within ± 0.025 Å. The equatorial U–O distances for U(2) are quite different, ranging from 2.327(5) Å for O(7) to 2.528(5) Å for O(5) with 2.415(5) Å for O(6), 2.492(5) Å for O(1) and 2.445(5) Å for O(2), average 2.456(5) Å and the adjacent equatorial O–U–O angles range from 50.1(2)° (1,3-bidentate) to 70.6(2)°. The deviations from the mean equatorial plane for U(2) are significant with -0.31 Å for O(1) and 0.13 Å for O(2). The packing diagram along crystallographic *c* axis is shown in Fig. 6. The short non-bonded contacts indicate that the oxygen atoms from non-bonded carboxylate groups, H_2O and EtOH molecules may be involved in H-bonding linking the chains in three dimensions. The distance of 2.732(9) Å between a non-bonded carboxylate O atom and a N atom implies that the cation–anion interactions are via H-bonding.

3.2. Infrared spectra

Compounds **3**–**6** and **8** [4] have very similar IR spectra, ν(OH) and ν(NH) between 3418 and 3478; ν_{as}(COO) between 1520 and 1654; ν_s(COO) between 1313 and 1478; ν_{as}(OUO) between 903 and 912; δ(C=O) between 695 and 721 and π(C=O) between 574 and 609 cm^{-1}. The IR spectra of compounds **1**, **2** and **7** differ mainly in the presence of a shifted ν_{as}(OUO) at 930, 932 and 930 cm^{-1}, respectively. Crystallographic studies confirmed that compounds **3**, **4** [4] and **8** [4] have pentagonal bipyramidal uranium centres and compounds **2** and **7** have hexagonal bipyramidal uranium centres. This seems to suggest that for the group of compounds studied, ν_{as}(OUO) at around 930 indicates the presence of a hexagonal bipyramidal uranium centre and ν_{as}(OUO) at around 900 indicates the presence of a pentagonal bipyramidal uranium centre. Thus compounds **5** and **6**, with ν_{as}(OUO) values at 905 and 912 cm^{-1}, respectively, are most likely to have pentagonal bipyramidal uranium centres and by contrast, compound 1 probably has a hexagonal bipyramidal uranium centre.

3.3. Thermal analysis

Compounds **1**, **6** and **7** first lost their counter-cations and one ligand, then the remaining ligands to give the final product, UO_3, at about 450 °C.

Compound **2** first lost its solvent molecules, then counter-cations and one ligand, finally the remaining ligands to give the final product, UO_3, at about 400 °C.

Compounds **3**, **5** and **8** [4] lost their final H_2O molecules at 106–140 °C. Since **3** and **8** [4] have a monomeric anion structure with one coordinated H_2O molecule, it is likely that **5** has a similar monomeric anion structure with a coordinated H_2O molecule.

3.4. ^{13}C CPMAS NMR spectroscopy

3.4.1. Compounds of known structure

^{13}C CPMAS NMR spectroscopy has been widely used to study the interactions of metals with ligands [9,10]. Unfortunately very little work has been done for uranium complexes [11,12]. Based on the specific patterns of carbonyl chemical shifts, compounds with known crystal structures can be used as model compounds to study the relationship between structural types and ^{13}C CPMAS NMR spectroscopic data. The ^{13}C CPMAS NMR spectra of **3**, **7** and **2**, together with the expanded carbonyl regions, are shown in Figs. 7–9.

3.4.1.1. Structure type 1: monomeric anion structure with no symmetry (see Fig. 1). Compound **3** has a monomeric anion structure with no crystallographically imposed symmetry, and in principle should give four carbonyl peaks. Experimentally only two peaks were observed at 183.3 and 180.9 ppm with approximately equal intensities (see Fig. 7), suggesting that the four carbonyls fall into two groups of two closely similar environments. Evidently the deviation from C_2 rotational symmetry is small. The peak at 48.4 ppm is assigned to the quaternary carbons (C_q) in the ligand and the broad peak at 34 ppm is assigned to the CH_2 carbons in the counter-cation. The CH_3 carbons in the ligand are assigned to the group of four closely spaced peaks at 24.0, 22.7, 21.0 and 18.7 ppm, indicating that all four CH_3 carbons are different.

3.4.1.2. Structure type 2: monomeric anion structure with C_2 rotational symmetry. Compound **8** [4] also has a monomeric anion structure but with a C_2 axis along the U(1)–O(6) direction. It is required to have two non-equivalent carboxylate groups, in agreement with the ^{13}C CPMAS NMR spectrum which shows two carbonyl peaks at 189.0 and 184.4 ppm, and two CH_3 peaks at 24.1 and 20.6 ppm. The peak at 48.7 ppm is assigned to C_q in the ligand, the broad peak at 52.5 ppm is assigned to the CH_2N cation carbons, the peaks at 42.6 and 39.8 ppm are assigned to the NCH_3 cation carbons, and the shoulder at ca. 19 ppm to the CCH_2C cation carbon.

3.4.1.3. Structure type 3: dimeric anion structure. Compound **4** [4] has a dimeric anion structure and shows three carbonyl peaks at 188.0, 184.2 and 182.5 ppm with an approximate intensity ratio of 1:1:2. It is likely that this pattern arises from non-equivalent carbonyl carbons in the bridging ligand (188.0 and 184.2 ppm) and equivalent carbonyls in the terminal 1,5-bidentate ligand (182.5 ppm). The peak at 51.5 is assigned to C_q and the peaks at 25.6 and 23.3 ppm to CH_3 carbons in the ligand, the CH_3 peak showing a barely resolved splitting indicating different CH_3 environments.

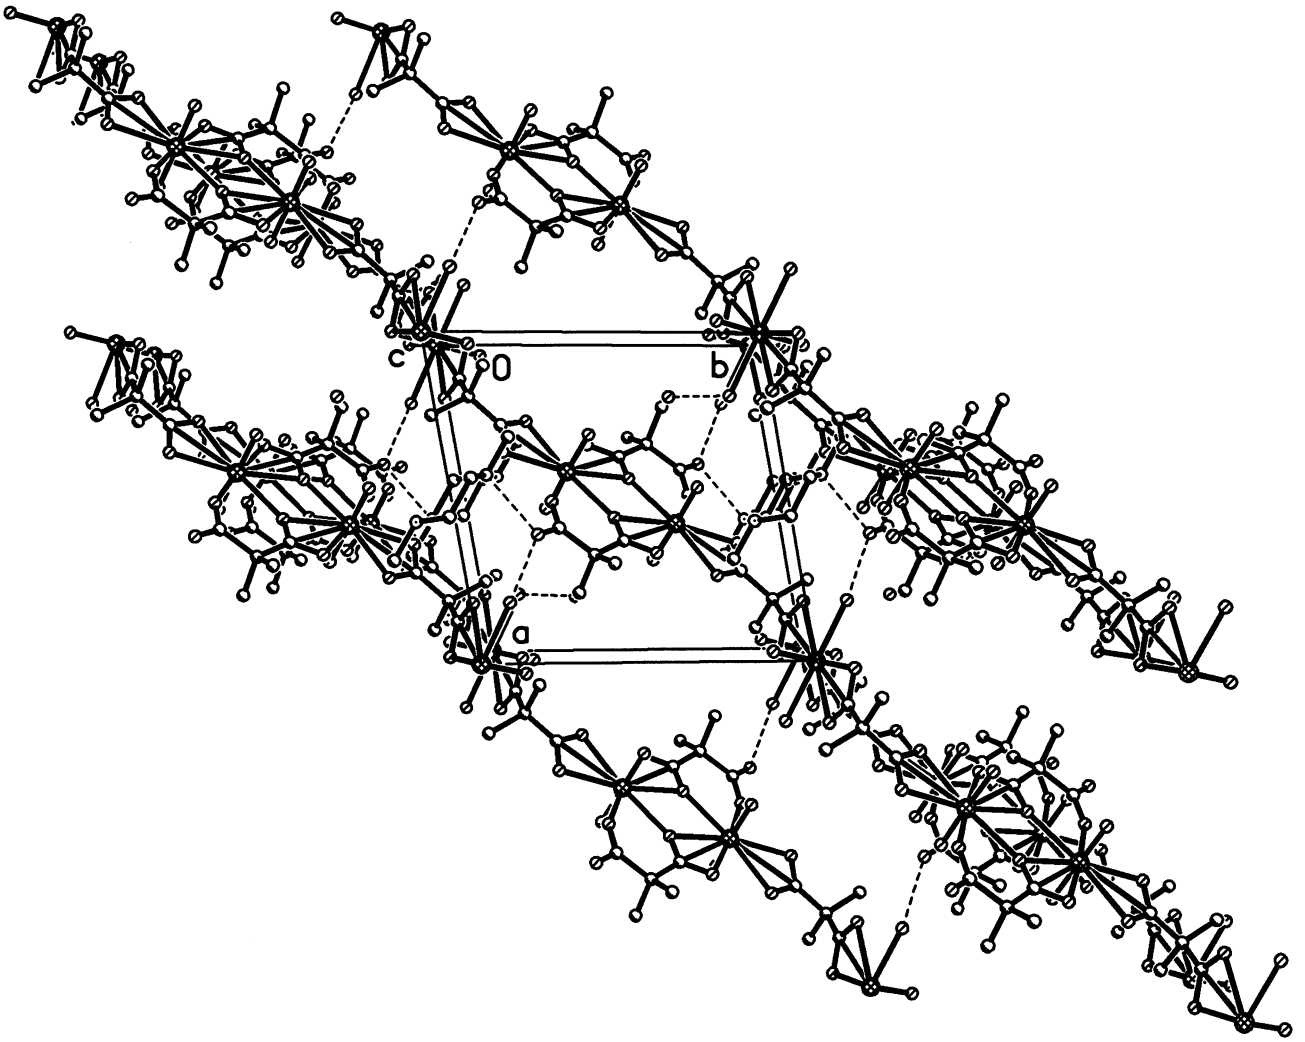

Fig. 6. Packing diagram along crystallographic *c* axis for **2**.

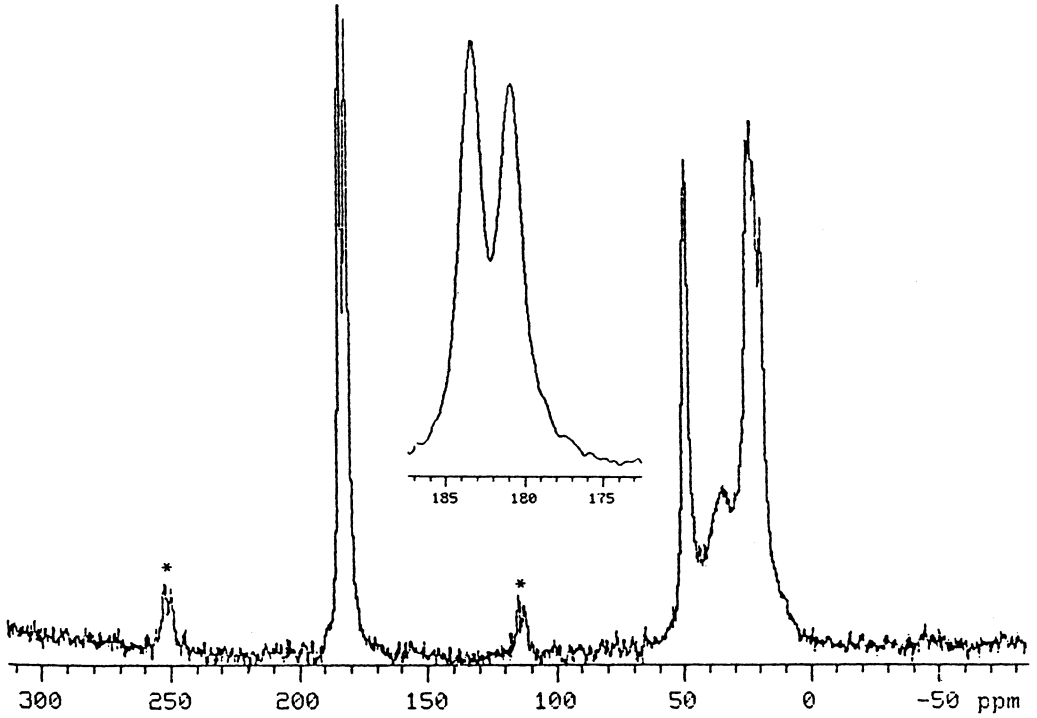

Fig. 7. ^{13}C NMR CPMAS spectrum with carbonyl expansion for **3** (* spinning sidebands).

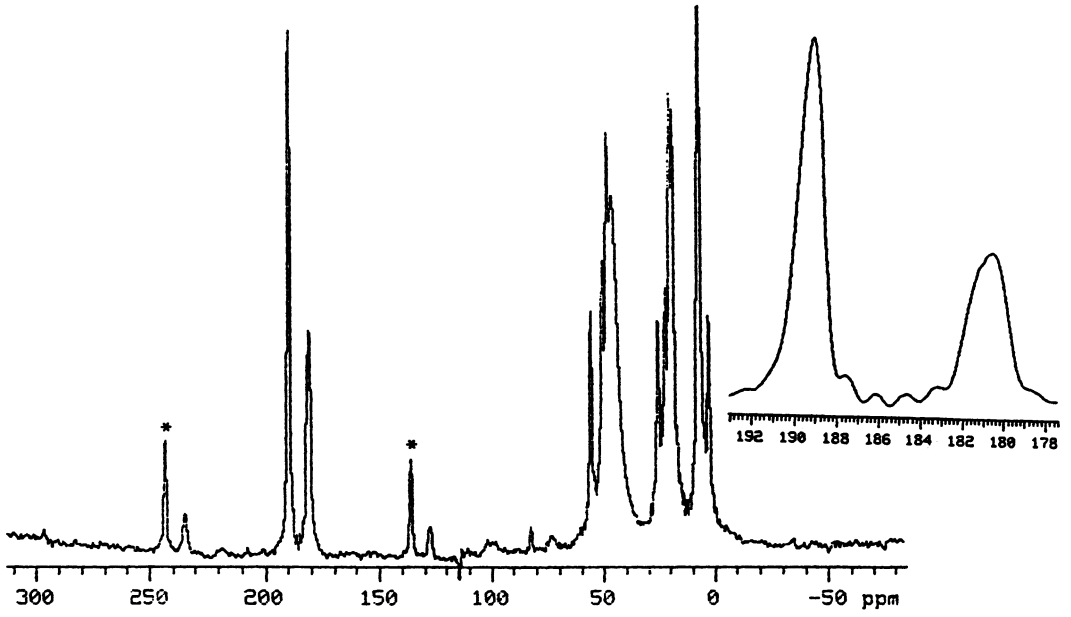

Fig. 8. ^{13}C NMR CPMAS spectrum with carbonyl expansion for **7** (* spinning sidebands).

3.4.1.4. Structure type 4: novel infinite chain (2:3) structure (see Fig. 3). Compound **7** has a novel 2:3 ratio infinite chain anion structure. It shows two well separated carbonyl peaks at 189.4 and 180.7 ppm with approximately 2:1 intensity ratio (see Fig. 8). These are tentatively assigned to 1,3-bidentate carboxylate groups (C(3), C(8), C(11) and C(13) in Fig. 2) and to monodentate carboxlate groups (C(1) and C(6) in Fig. 3), respectively. The peaks at 25.3, 21.9, 19.9 and 18.5 ppm with relative intensities approximately 1:1:2:2 arise from CH_3 carbons in the ligand, the first two being assigned to the [C(14), C(15)) pair and the last two to the (C(4), C(5)) and (C(9), C(10)] pairs. The sharp peaks at 55.7, 50.3 and 48.3 ppm are assigned to C_q in the ligands; evidently all three C_q in the repeat unit are non-equivalent. The broad peak at 46.4 ppm is assigned

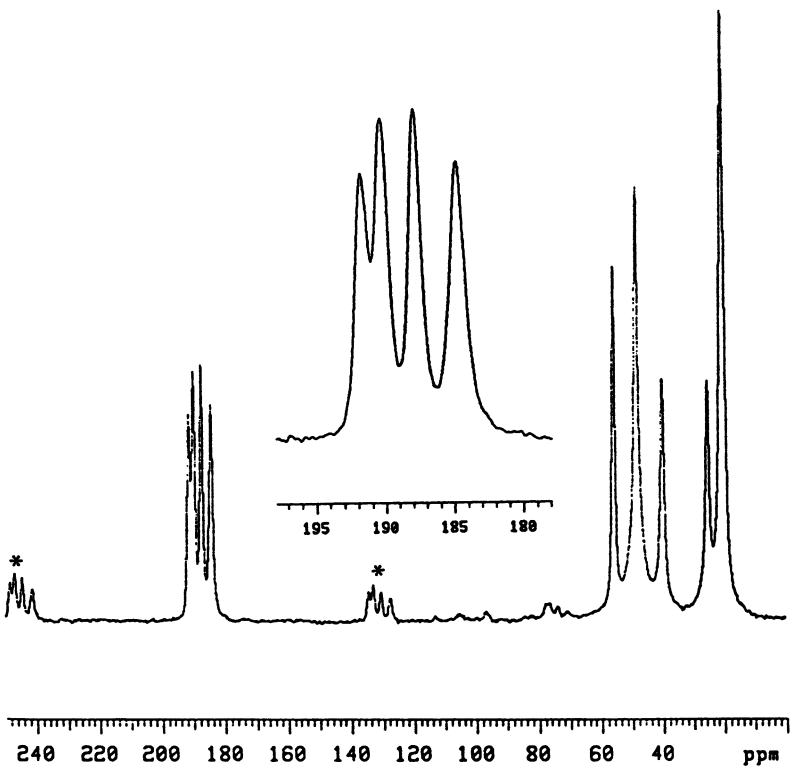
to the CH_2 carbons in the counter-cation and then peaks at 6.7 and 2.4 ppm are assigned to CH_3 carbons in the counter-cation.

3.4.1.5. Structure type 5: novel infinite chain (3:4) structure (see Fig. 5). Compound **2** possesses a novel 3:4 ratio infinite chain anion structure. Four carbonyl peaks of equal intensity are observed at 191.6, 190.1, 187.7 and 184.6 ppm (see Fig. 9) as expected from the stoichiometry and symmetry of the asymmetric unit (Fig. 5). The peak at 56.2 ppm is assigned to C_q in the ligands, the peaks at 48.9 and 40.1 to CH_2 and CH_3 carbons, respectively, in the counter-cation, and the peaks at 25.5 and 20.9 ppm to CH_3 carbons in the ligands.

3.4.2. Structural predictions

There are three major factors which influence the carbonyl chemical shifts in the solid state: (i) the chemical structure of the anion, including factors such as $U-O_{eq}$ distances, conformations of chelate rings and H-bonding involving carboxylate oxygen atoms; (ii) the chemical structure of the cation; (iii) crystallographic symmetry and solid-state packing. Unfortunately, there are at present insufficient data to separate the contributions of all these factors. For the five compounds of known crystal structure, the ^{13}C carbonyl peaks span some 10 ppm and the number of peaks observed is consistent with the number of structurally distinct carbonyl groups. However the chemical shifts do not seem to show a regular relationship with the type of bonding. For example, compounds **3** (Fig. 7) and **8** [4] both have anions of similar structure with 1,5-bidentate ligands, but the carbonyl shifts of **3** are 180.8 and 183.3 ppm and those of **8** [4] are 184.4 and 189.0 ppm. Evidently subtle differences in anion, cation or crystal structure may have a significant effect on the chemical shifts. Nevertheless, tentative predictions of the structure of those compounds not characterised by X-ray diffraction have been made on the basis of comparisons of their carbonyl CPMAS NMR spectra (not shown) with those of the compounds of known structure:

1. The spectrum of compound **1** is similar to that of **7**, having two well-separated carbonyl peaks at 190.1 and 181.8 ppm of relative intensity 2:1. Its structure is predicted to be type 4 (2:3 novel infinite chain), see Scheme 1.
2. The spectrum of compound 5 has three carbonyl peaks at 185.6, 183.9 and 182.2 ppm with intensity ratio approximately 1:2:1. The form of this spectrum resembles that of **4** [4], though the peaks are more closely spaced and the order of intensities is different. The structure of **5** is tentatively identified as a dimer.
3. The spectrum of compound **6** is similar to that of **4** [4], having three carbonyl peaks at 186.7, 184.3 and 179.1 ppm with relative intensity 1:1:2. Its structure is predicted to be type 3 (dimer), see Scheme 1.



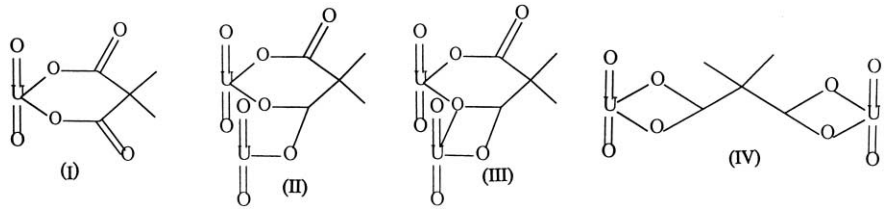


Fig. 9. ^{13}C NMR CPMAS spectrum with carbonyl expansion for **2** (* spinning sidebands).

Scheme 1. Bonding modes of malonate with uranyl.

These predictions are consistent with the elemental analysis and IR spectroscopic results.

3.5. Bonding modes of malonate with uranyl

Two bonding modes for malonate with the uranyl ion have been previously published [2]. These are bidentate (terminal 1,5-bidentate) (I), and tridentate (1,5-bidentate and μ_1 3-monodentate) (II), see Scheme 1. Two new type of bonding modes have been identified in this study, shown in Scheme 1, tridentate (μ_2 1,3-bidentate and 1,5-bidentate) (III) and tetradentate (1,3-bidentate through both carboxylate groups) (IV).

3.6. Effects of counter-cations and H-bonding

Infinite chain structures have previously been found for uranyl bis(malonato) complexes with different cations (Sr^{2+}, Ba^{2+} and NH_4^+) [2–4]. However, in the present studies, it appears that the steric bulk of the organic cations (ionic radii: Sr^{2+} 1.12 Å, Ba^{2+} 1.34 Å; N–N distances about 2.88 Å for piperazinium and about 3.76 Å for ethylenediammonium calculated from CSD relevant structures) prevents uranyl bis(malonate) units from bridging to form infinite chains, instead forming monomeric or dimeric structures with ethylenediammonium, piperazinium, triethylenediammonium and propanediammonium (**3**, **5**, **6** and **8** [4]). In addition the use of protonated amines as counter-cations encourages extensive H-bonding between counter-cations and the anions (ligating H_2O molecules and non-ligating O atoms of carboxylate groups). The hydrophobic effect of counter-cations probably is another factor, which may influence the equilibria in solutions and the resultant products in solid state.

When changing piperazine to dimethylpiperazine, ethylenediamine to tetramethylethylenediamine or tetraethylethylenediamine, 2:3 or 3:4 oligomeric compounds with infinite chain structures are formed. It is obvious that oligomeric compounds are favoured by methylation of the cations because that restricts the possibilities for H-bonding between cations and anions (complexes) and thereby encourages bridging between the anion and the ligand.

On the basis of these results, it appears that: (i) monomer formation is favoured by use of protonated, primary acyclic amines as counter-cations; (ii) dimer formation is directed by protonated alicyclic or secondary diamines; and (iii) protonated tertiary cyclic or alicyclic amines give rise to polymeric chains.

4. Conclusions

Eight uranyl dimethylmalonato compounds have been synthesised and characterised by elemental analysis, thermal analysis, IR and CP/MAS ^{13}C NMR spectroscopy and five of them by X-ray crystallography. Monomeric, dimeric and infinite chain motifs have been identified. ^{13}C CPMAS NMR has been shown to be a useful method to distinguish structural types and predict structures for related non-crystalline compounds.

So far unrecognised structural diversity for uranyl dicarboxylate complexes can be achieved by varying counter-cations and slightly modification of the substituent groups on the proligand. Two new kinds of bonding mode of malonate for uranyl have been identified in this study, tridentate (μ_2 1,3- and 1,5-bidentate) and tetradentate (1,3-bidentate through both carboxylate groups).

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 166052–166054. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction of aliphatic diamine with malonic or substituted malonic acid and uranyl nitrate in the ratio 2:2:1 in aqueous media leads in most cases to one predominant product, usually with a metal–ligand ratio of 1:2, but in a few cases it leads to oligomers with metal–ligand ratios of 2:3, 3:4 and 3:5. The crystalline products are salts with diprotonated diamines as cations, but crystals can also be formed with salts of hexaaminecobalt(III). Representative structures have been determined by single crystal X-ray diffraction for: $(C_4H_{12}N_2)[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 1.5H_2O$ (**5**); $(C_4H_{14}N_2)[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 2H_2O$ (**7**); $(C_4H_{12}N_2)[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot H_2O$ (**9**); $(C_{10}H_{26}N_2)[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot 2H_2O$ (**10**); $(C_{10}H_{26}N_2)[(UO_2)_3(C_7H_{10}O_4)_5]\cdot 2H_2O$ (**11**) and $\{[Co(NH_3)_6][UO_2(C_4H_4O_4)(C_5H_6O_4)]\}_2Cl_2\cdot 6H_2O$ (**20**). Compounds **5**, **7**, **9** and **10** possess similar, monomeric anion structures. The anion in **11** has an infinite zigzag chain structure containing three distinct types of U centres, linked by three kinds of bridging ligands. Compound **20** has a dimeric anion structure. Three new types of bonding mode have been identified in this study, tridentate (μ_2-1,3-bidentate and 1,5-bidentate), tetradentate (1,3-bidentate through both carboxylate groups) and tridentate (1,3-bidentate through one carboxylate group and 1-monodentate through the other). Several types of carbonyl environments have been identified by X-ray crystallography in the present and recent previous work [Zhang et al., Polyhedron 21 (2002) 69; Zhang et al., J. Alloys Compounds 271 (1998) 139; Tilley et al., unpublished data] and a general correlation between isotropic chemical shift values in the ^{13}C CPMAS NMR spectra and the carbonyl type has been identified. © 2002 Elsevier Science Ltd. Keywords: Uranyl; Malonato complexes; CPMAS ^{13}C NMR; X-ray crystallography

1. Introduction

Our earlier work on malonato and substituted malonato complexes of uranyl has indicated that considerable structural diversity is present in solids which have been isolated from the ternary system uranyl/proligand/diamine in aqueous solution [1–3]. Thus, when using malonic acid (H_2MA), although a pentagonal bipyramidal geometry is produced based upon 1,5-bidentate ligation by the dianion, monomeric or dimeric complexes may be formed in addition to the well known chain polymeric anions found when $[NH_4]^+$ or Group II cations are employed [4–6]. In contrast, with dimethylmalonic acid (H_2DMMA) as proligand, as well as similar monomeric and dimeric complexes, the equatorial coordination number can increase to six with the concomitant formation of polymeric anions even using diprotonated diamines as counter-cations. The purposes

PII: S0277-5387(01)00965-2

of this further study are to investigate the effects of both intermediate and greater bulk within the malonic acids by using methylmalonic (H_2MMA), diethylmalonic (H_2DEMA) and phenylmalonic (H_2PMA) acids, to extend the range of diamine pro-cations and hence to search for other new structural types. The effect of unsymmetrical substitution within the malonate ligand will also be investigated. There have been indications in our previous work that ^{13}C CPMAS NMR spectroscopy might be able to identify bonding modes in uranyl-malonato complexes from the number and nature of the carboxylate carbon resonances and the present study will add further to this database of spectroscopic information.

2. Experimental

2.1. Materials

All chemicals were reagent grade, purchased from Strem Chemicals, Aldrich or Lancaster and used without further purification.

2.2. Physical methods

Elemental analyses were performed by the Microanalysis Lab, Department of Chemistry, The University of Manchester. IR spectra were recorded on an ATI Mattson Genesis Series FTIR Spectrometer. TG/DT analyses were made on a Seiko (TG/DTA 220) thermal analyser at a heating rate of 10 °C min^{-1} and an air flow rate of 100 cm^3 min^{-1}. High resolution solid state ^{13}C NMR spectra were recorded using a Varian Associates Unity 300 spectrometer operating at 75.4 MHz using the cross polarisation-magic angle spinning (CP-MAS) technique. The acquisition time was 0.05 s, the spectral width was 30007.5 Hz, the contact time was 1.5 ms, the recycle time was 5 s and the spinning speed was approximately 4 kHz. The chemical shift scale was referenced by setting the CH_3 peak in a sample of solid hexamethylbenzene, run using the same conditions, to 16.5 ppm.

2.3. Syntheses

In general, a solution of uranyl nitrate hexahydrate was added to a solution of a ligand and a diamine in the molar ratio of 1:2:2. The yellow crystalline product formed after a week, and was collected by filtration and dried in air.

2.3.1. Synthesis of hexaaminecobalt(III) tris(malonato)hydromalonato bis[dioxouranate(VI)] dihydrate

$[Co(NH_3)_6][(UO_2)_2(C_3H_2O_4)_3(C_3H_3O_4)]\cdot 2H_2O$ (**1**): a solution of uranyl nitrate hexahydrate (0.50 g, 1 mmol in 5 cm^3 H_2O) was added to an aqueous solution of malonic acid (0.21 g, 2 mmol in 25 cm^3 H_2O), fresh sodium hydroxide solution (0.32 g, 8 mmol) and hexaaminecobalt(III) chloride (0.27 g, 1 mmol) in the ratio of 1:4:1. An orange, solid product formed after 1 h and was collected by filtration and dried in air, yield 85%. *Anal.* Found: C, 12.27; H, 3.00; N, 7.32; Co, 4.99; U, 41.85. 7. The cell parameters were refined by least-squares from the angular positions of 15 (for **5**), 22 (for **9**) and 25 (for **7**) carefully centred reflections, respectively. An empirical absorption correction was applied, based on azimuthal scans of three reflections. The data were corrected for Lorentz and polarisation effects. Linear decay correction factors were applied for **5**. The structure for **7** was solved with SIR-92 [7], **9** with ORIENT [8] by direct methods and **5** with PATTY [9]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were added in calculated or difference map positions. Neutral atom scattering factors were taken from Cromer and Waber [10]. Anomalous dispersion effects were included in F_{calc} [11]; the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley [12]. The values for the mass attenuation coefficients were those of Creagh and Hubbell [13]. All calculations were performed using the TEXSAN [14] crystallographic software package (Molecular Structure Corporation). The diffraction data for **10**, **11** and **20** were measured on a Rigaku Raxis IIc diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 20 °C. The structures were solved by conventional direct methods for **10** and **20**, and Patterson methods for **11** and were refined by the full-matrix least-squares method on all F^2 data with the SHELXTL 5.03 package [15]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were fixed in calculated positions.

3. Results and discussion

3.1. Crystal structures

3.1.1. Crystal structures for compounds *5*, *7*, *9* and *10*

Compounds **5**, **7**, **9** and **10** have similar monomeric structures. Their selected bond lengths and angles are listed in Tables 2–5. The asymmetric unit of **5** contains two pairs of ions and three H_2O molecules. Both anions are monomeric structures with two terminal 1,5-bidentate methylmalonates and the seventh coordination positions of U atoms being occupied by H_2O molecules. The anion structures for **5** are shown in Fig. 1. Both uranyl groups are nearly linear with ordinary U–O distances. The U–O distances in the equatorial plane for U(1) are separated into two groups with average 2.331(7) Å for O(1), O(4), O(5) and O(8), and 2.430(7) Å for the water molecule O(11); similarly for U(2) with average 2.331(8) Å for O(12), O(15), O(16) and O(19), and 2.440(7) Å for the water molecule O(22). The presence of short O–O [2.667(10) Å] and O–N [2.659(12)–3.121(12) Å] contacts suggests that H_2O molecules, carboxylate oxygen atoms and cations are involved in extensive H-bonding and that cation–anion interactions are via H-bonding.

The anion structure for **7** is shown in Fig. 2. The asymmetric unit consists of half the molecule, related to the other half by twofold symmetry. The uranyl group is quite normal with O–U–O angle 177.2(6)° and U–O distance 1.778(8) Å. The U–O distances in the equato-

rial plane are 2.381(8) Å for O(4), 2.386(10) Å for O(1) and 2.39(1) Å for O(6). The water molecules and carboxylate oxygen atoms, O(1), O(2) and O(3) are involved in extensive H-bonding and lead the monomeric structures into a three-dimensional framework. The short contacts, 2.942 Å for a N atom to O(2) and 2.745 Å for it to O(3) indicate that the cation–anion interactions are via H-bonding.

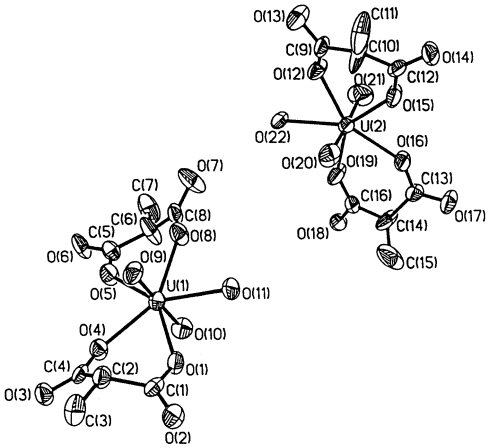

Fig. 1. An ORTEP drawing of the anionic structures for $(C_4H_{12}N_2)$-$[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 1.5H_2O$ (**5**) (50% probability ellipsoids).

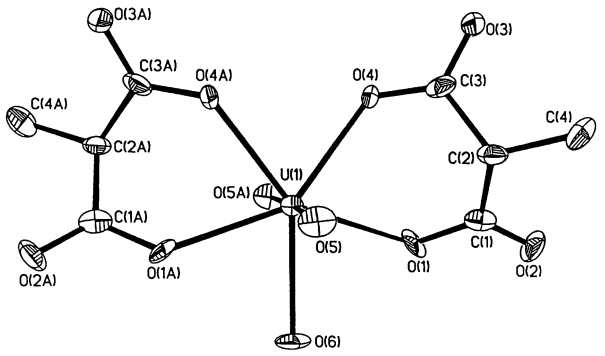

Fig. 2. An ORTEP drawing of the anionic structure for $(C_4H_{14}N_2)$-$[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 2H_2O$ (**7**) (50% probability ellipsoids).

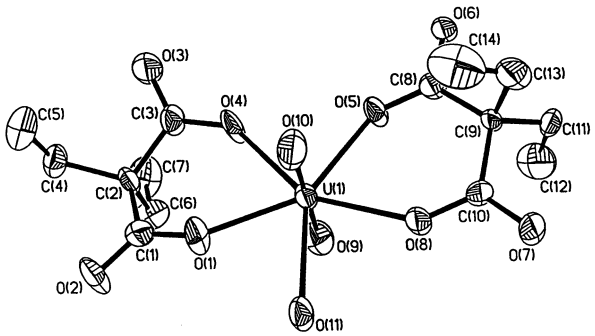

Fig. 3. An ORTEP drawing of the anionic structure for $(C_4H_{12}N_2)$-$[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot H_2O$ (**9**) (50% probability ellipsoids).

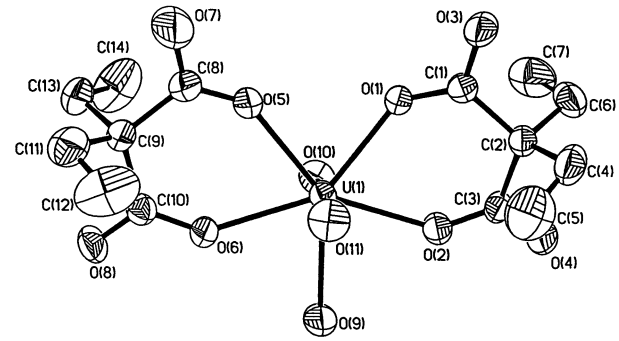

Fig. 4. An ORTEP drawing of the anionic structure for $(C_{10}H_{26}N_2)[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot 2H_2O$ (**10**) (50% probability ellipsoids).

The monomeric anion structure for **9** is shown in Fig. 3. The uranyl ion is almost linear with an average U–O distance of 1.752(7) Å. The equatorial U–O distances are separated into two groups with average 2.334(7) Å for O(1), O(4), O(5) and O(8), and 2.507(5) Å for the coordinated water molecule O(11). Several short contacts between O and O atoms [from 2.881(11)–2.895(10) Å] suggest that the carboxylate O atoms, lattice and coordinated H_2O molecules are involved in H-bonding.

The asymmetric unit for **10** contains a whole molecule. The monomeric anion structure for **10** is shown in Fig. 4. The uranyl ion is unusual, with two different U–O distances [1.776(3) and 1.792(3) Å]. The equatorial U–O distances range from 2.273(3) Å for O(5), average 2.350(3) Å for O(1) and O(2), 2.394(3) Å for O(6) and 2.485(3) Å for the coordinated H_2O molecule O(9). H-bonding between a N atom and O(3), a N atom and O(4), O(4) and O(9) links the monomeric structures into a one-dimensional chain along the crystallographic *b* axis.

*3.1.2. Crystal structure for compound **11***

Selected bond lengths and angles for **11** are listed in Table 6. The anionic structure for **11** is shown in Fig. 5. The anion part of the asymmetric unit has five ligands and three uranyl groups. U(2) and U(3) are linked together by two bridging ligands which are both 1,3-bidentate through one carboxylate group to one U atom and one of the oxygen atoms bridges μ_2 to the other U atom. Another carboxylate group is monodentate to the other U atom as well, forming a structural unit with two uranyl groups and two ligands. Both U atoms have a hexagonal bipyramidal environment. U(1) has a pentagonal bipyramidal environment with a terminal 1,5-bidentate ligand. U(1) and the structural unit containing U(2) and U(3) are linked together by two kinds of linear ligands, tetradentate (1,3-bidentate through both carboxylate groups) and tridentate {1,3-bidentate to the structural unit [U(2), U(3)] and 1-monodentate through the other carboxylate group to

U(1)}, forming an infinite zigzag chain. The three uranyl groups are quite normal with average U–O distances 1.756(6) Å for U(1), 1.751(6) Å for U(2), 1.746(5) Å for U(3) and O–U–O angles 178.2(2)° for U(1), 177.9(3)° for U(2) and 178.5(2)° for U(3). The equatorial U–O distances range from 2.308(5) Å to 2.447(5) Å for U(1), 2.284(5) Å to 2.590(4) Å for U(2) and 2.338(5) Å to 2.510(5) Å for U(3) and the O–U–O angles in the equatorial planes range from 52.3(2)° (1,3-bidentate) to 82.3(2)° for U(1), 49.70(14)° (1,3-bidentate) to 71.3(2)° for U(2) and 49.7(2)° (1,3-bidentate) to 70.8(2)° for U(3). The deviations of donor atoms from the equatorial planes are quite different, between −0.30 Å [O(7)] and 0.33 Å [O(4)] for U(1), and from −0.10 Å [O(14)] to 0.08 Å [O(13)] for U(2) and within ±0.08 Å for U(3). The terminal 1,5-bidentate ligand on U(1) is so puckered that no typical conformation can be assigned to it and the two tridentate bridging ligands are fairly planar. There are extensive H-bonding interactions between N atoms and non-bonded carboxylate oxygen atoms [2.654(8)–2.723(8) Å] within the infinite one-dimensional chains.

3.1.3. Crystal structure for compound *20*

Selected bond lengths and angles for **20** are listed in Table 7. The asymmetric unit for **20** consists of half of the U complex anion, together with two half $[Co(NH_3)_6]^{3+}$ ions, with each of the Co atoms on a centre of symmetry. In each case, the other halves are generated by inversion. In addition, the asymmetric unit contains a Cl^- ion and three water molecules. The anionic structure is shown in Fig. 6. The dimethylmalonate ligand is terminal whilst the methylmalonate ligand links to the adjacent uranium atom through a third oxygen atom of one carboxylate group to give a dimeric, centrosymmetric structure for the anion. The uranyl unit is quite normal with U–O distances averaging 1.782(6) Å and an axial O–U–O angle 176.5(3)°. The equatorial U–O distances range from 2.312(6) Å for O(4) to 2.431(6) Å for O(8). Short intermolecular contacts indicate H-bonding interactions among the water molecules, the carboxylate oxygen atoms, chlorine atoms and the ammonia ligands in the countercation which links the dimeric structures into a

three-dimensional framework. Each hexaaminecobalt(III) ion has two symmetry-related Cl^- ions on each side. The Cl^- ions are involved in H-bonding and also play a charge balancing role. The extensive short O–N contacts [2.872(12)–3.232(10) Å] suggest that the cation–anion interactions are via H-bonding.

Crystals were obtained for **15** and were shown to be monoclinic, $C2/c$, $a = 36.608(7)$, $b = 13.602(3)$, $c = 30.649(6)$ Å, $\alpha = 105.51(3)°$, $Z = 8$, $V = 14706(6)$ A^3, $F(000) = 7536$, but only a low resolution refinement ($R_1 = 0.060$, $wR_2 = 0.186$) could be obtained. However, a monomeric structure containing two adjacent $\{UO_2\}$ centres was apparent. Both centres had pentagonal bipyramidal geometry with two chelating 1,5-bidentate malonate ligands. The coordination of one U was completed with a H_2O molecule and the second U by a single oxygen atom of a phenyl malonate, the other carboxylic group taking part in H-bonding interactions with other complexes in the lattice. This is consistent with the structure proposed below on the basis of spectroscopic and analytical data.

3.1.4. U–O bond lengths

The average U–O_{ax} and U–O_{eq} distances of pentagonal (P) and hexagonal (H) bipyramidal uranium centres for the uranyl compounds which have been crystallographically characterised in the present work and others in this series[1–6] are shown in Fig. 7. This scatter diagram gives two well defined and well separated footprints with U–O_{eq} distances ranging from 2.34 to 2.38 Å for P and 2.45 to 2.49 Å for H. For C.N. 8 (H), U–O_{ax} remains fairly constant as U–O_{eq} varies, in contrast to C·N. 7 (P) where the correlation of the equatorial and axial U–O distances is not obvious. The two 'bottom left hand' points which separate from the rest of the C·N. 7 data correspond to the unusually short U–O_{ax} distances in **5** and $Ba[UO_2(C_3H_2O_4)_2]\cdot 3H_2O$. Compared to the average U–O distances for the uranyl malonato compounds discussed here, the average U–O distances for uranyl carboxylato compounds [16], especially those for uranyl dicarboxylato compounds [17] are less well correlated. This would be expected since these data are from a variety of sources (different ligands and different types of complexes) and of variable quality.

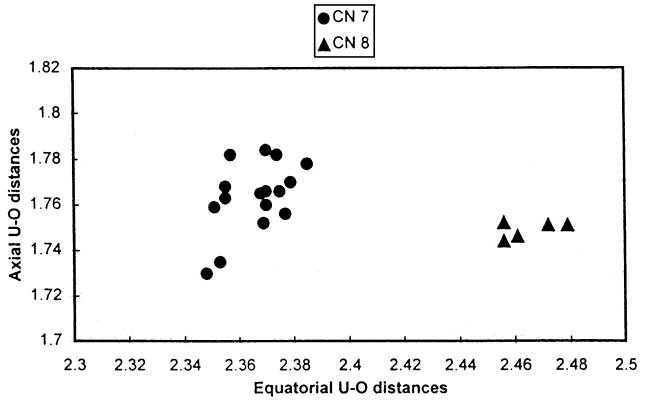

Fig. 7. Average U–O distances for uranyl malonato and substituted malonato compounds.

3.2. Structural comparisons

A variety of structural types [monomeric, dimeric for 1:2 (M:L) ratio compounds; infinite chains for 2:3, 3:4 and 3:5 (M:L) ratio compounds] for uranyl malonato and substituted malonato compounds has been identified by X-ray crystallography and these will be discussed by structural types.

3.2.1. Dimeric structure

The dimeric compounds $\{(C_6H_{18}N_2)[UO_2(C_3H_2O_4)_2]\}_2\cdot(CH_3OH)_2$, $\{(C_4H_{12}N_2)[UO_2(C_3H_2O_4)_2]\}_2\cdot 6H_2O$ and $\{[Co(NH_3)_6][UO_2(C_5H_6O_4)_2]\}_2Cl_2\cdot 7H_2O$ have centrosymmetric dimeric anion structures and have been described previously [2,3]. Compound **20** is very similar to $\{[Co(NH_3)_6][UO_2(C_5H_6O_4)_2]\}_2Cl_2\cdot 7H_2O$ [2] except one of the dimethylmalonate ligands is replaced by a methylmalonate ligand. They have very similar IR and TG/DTA results. The similarities and differences between these two compounds are summarised in Table 8. From a structural point of view, these two dimeric complexes are very similar. The only obvious differences are that **20** has axial and equatorial U–O distances about 0.02 Å longer and an O(10)–U(1)–O(8)–C(8) torsion angle about 2° wider.

3.2.2. Monomeric structures

Compounds **5**, **7**, **9**, **10** and $(C_6H_{16}N_2)[UO_2(C_3H_2O_4)_2(H_2O)]\cdot 2H_2O$ [3], $(C_2H_{10}N_2)[UO_2(C_5H_6O_4)_2(H_2O)]\cdot 2H_2O$ [1] and $(C_7H_{20}N_2)[UO_2(C_5H_6O_4)_2\cdot(H_2O)]\cdot 2H_2O$ [1] have monomeric anion structures and their similarities and differences are summarised in Table 9. The monomeric compounds have U–O_{ax} distances between 1.747(7) and 1.782(6) Å and except for **7**, U–O(malonate) distances between 2.320(6) and 2.365(3) Å, U–O(H_2O) distances between 2.435(7) and 2.507(7) Å and O–U–O angles from 110° to 118°. Compound **7** has a relatively shorter U–O(H_2O) distance [2.39(1) A], longer U–O(malonate) distances [2.384(10) Å] and narrower C–C–C angle (108°). All the malonate ligands have boat or skew boat conformations. Compound **7** and $(C_7H_{20}N_2)[UO_2(C_5H_6O_4)_2\cdot(H_2O)]\cdot 2H_2O$ both have a C_2 axis along the U–O(H_2O) direction and a more planar equatorial coordination environment than the others.

3.2.3. Infinite chain structures

Compounds $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ [1], $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$ [1] and

11 are sub-stoichiometric products (metal–ligand = 2:3, 3:4 and 3:5) and they all possess infinite chain structures containing a similar 2:2 structural unit (two uranyl groups linked together by two μ_2 bridging ligands, 1,3-bidentate to one uranyl group and 1,5-bidentate to the other). In the case of $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$, the structural units are linked together by linear tetradentate ligands (1,3-bidentate through both carboxylate groups) forming the infinite chain structure. For $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$, the structural unit is centrosymmetric and the two uranyl groups and the two bridging ligands are equivalent. There is a second type of uranyl group *trans*-coordinated by two H_2O molecules. The two kinds of uranyl groups are linked together by linear tetradentate ligands (1,3-bidentate through both carboxylate groups) forming the infinite chain structure. For **11**, there is a third uranyl group with 1,5-bidentate coordination by a ligand. The structural units and the third uranyl groups are linked by two kinds of linear bridging ligands, a tetradentate (1,3-bidentate through both carboxylate groups) and a tridentate (1,3-bidentate through one carboxylate group and 1-monodentate through the other) forming the zigzag infinite chain structure.

3.3. Effects of substituent groups, size of counter-cations and H-bonding

With malonic acid and mono-substituted malonic acids (methylmalonic acid and phenyl malonic acid) as ligands, only compounds with a ratio of metal–ligand of 1:2 have been isolated and monomeric and dimeric structures dominate the products. This seems to suggest that mono-substitution of the ligands has little effect on the coordination of uranyl by malonate. In those cases the structural types are mainly controlled by the size of counter-cations. With ethylenediammonium, piperazinium and triethylenediammonium as counter-cations, di-substituted malonates all give products with metal–ligand ratio of 1:2. On increasing the size of the counter-cations, for example tetramethyl- or tetraethyl-ethylenediammonium and dimethyl-piperazinium, a variety of 2:3, 3:4 and 3:5 sub-stoichiometric compounds with polymeric structures are formed. These could be solely effects of counter-cations or combined effects of counter-cations and di-substituted groups of malonate.

Many short O–N contacts clearly indicate the strong H-bonding that would be expected from protonated amines. The tendency to maximise the H-bonding between ligands and protonated amines undoubtedly have a bearing on the solid state structure, including the role of the ligands, since carboxylate oxygen atoms have been involved in the H-bonding. Thus, the size of the protonated amines may not necessarily be as significant as the H-bonding networks they can accommodate.

3.4. Bonding modes of malonate with uranyl

Two bonding modes for malonate with the uranyl ion have been previously published [5,6]. These are bidentate (terminal 1,5-bidentate) (I), and tridentate (bridging 1,5-bidentate and μ_1 3-monodentate) (II). Three new types of bonding mode have been identified in this study, tridentate (μ_2 1,3-bidentate and 1,5-bidentate) (III), tetradentate (1,3-bidentate through both carboxylate groups) (IV) and tridentate (1,3-bidentate through one carboxylate group and 1-monodentate through the other) (V). These bonding modes are summarised in Scheme 1.

3.5. Infrared spectra

IR spectroscopy has been of limited value in indicating metal–ligand bonding for this group of uranyl compounds because the ligands coordinated to uranyl have low symmetry and the multiple features of anti-

symmetric and symmetric carboxylate stretching frequencies makes it almost impossible to identify the nature of the carboxylate groups with confidence. However, the coordination number of $\{UO_2\}^{2+}$ may be determined from the value of ν_{as}(OUO).

All of the compounds in this and previous work[1–3] except $(C_6H_{18}N_2)[(UO_2)_2(C_5H_6O_4)_3]$, $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$, $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ and **11** have very similar IR spectra, ν(OH) and/or ν(NH) at 3418–3478; ν_{as}(COO) at 1520–1654; ν_s(COO) at 1313–1478; ν_{as}(OUO) at 900–922, δ(C=O) at 695–721 and p(C=O) at 574–609 cm^{-1}. The IR spectra of those four compounds differ mainly in the presence of a shifted ν_{as}(OUO) at 930, 932, 930, 931 and 919 cm^{-1}, respectively. Crystallographic studies [1–3] confirmed that uranyl malonato compounds with pentagonal bipyramidal uranium centres $(\{(C_6H_{18}N_2)[UO_2(C_3H_2O_4)_2]\}_2\cdot(CH_3OH)_2$, $(C_6H_{16}N_2)[UO_2(C_3H_2O_4)_2(H_2O)]\cdot 2H_2O$, $\{(C_4H_{12}N_2)[UO_2(C_3H_2O_4)_2]\}_2\cdot 6H_2O$, **5**, **7**, $(C_2H_{10}N_2)[UO_2(C_5H_6O_4)_2(H_2O)]\cdot 2H_2O$, $(C_7H_{20}N_2)[UO_2(C_5H_6O_4)_2\cdot(H_2O)]\cdot 2H_2O$, **9** and **10**) have ν_{as}(OUO) at 900–920 cm^{-1} and compounds with hexagonal bipyramidal uranium centres $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$ and $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ have ν_{as}(OUO) both at 932 and 930 cm^{-1}. This seems to suggest that for the group of compounds studied, ν_{as}(OUO) at around 930 cm^{-1} may indicate the presence of a hexagonal bipyramidal uranium centre and ν_{as}(OUO) at 900–920 cm^{-1} may indicate the presence of a pentagonal bipyramidal uranium centre. Evidently **11** has both pentagonal and hexagonal bipyramidal uranium centres and it has ν_{as}(OUO) at 931 and 919 cm^{-1}. Thus, $(C_6H_{18}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ most likely has hexagonal bipyramidal uranium centres, together with 2:3 (M:L) stoichiometry suggesting an infinite chain anionic structure as has $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$. By contrast, the

Scheme 1. Bonding modes for malonate with the uranyl ion (I–V) and associated carbonyl environments (a, a′, a″, b, c, d, e). Type I, terminal 1,5-bidentate; type II, tridentate (bridging 1,5-bidentate and μ_1 3-monodentate); type III, tridentate (μ_2-1,3-bidentate and 1,5-bidentate); type IV, tetradentate (1,3-bidentate through both carboxylate groups); and type V, tridentate (1,3-bidentate through one carboxylate group and 1-monodentate through the other).

rest of the 1:2 (M:L) non-X-ray characterised compounds probably have pentagonal bipyramidal uranium centres, suggesting monomeric or dimeric structures.

3.6. Thermal analysis

The main use of TG/DTA in this work has been to identify the nature of H_2O molecules in those compounds isolated from aqueous solution. Three main types of H_2O are present in the structurally characterised compounds in this series, viz. ligand, weakly bound in the lattice, strongly bound in the lattice. For monomeric bis(malonato) complexes, where the fifth equatorial coordination position comprises a H_2O ligand and there is a characteristic endothermic process at >100 °C. Weakly bound lattice H_2O is generally lost in an endothermic process at <90 °C. However, there is some overlap between the temperature ranges over which ligand and strongly bound H_2O is removed. Compounds $\{(C_4H_{12}N_2)[UO_2(C_3H_2O_4)_2]\}_2\cdot 6H_2O$, **5**, **5a**, $(C_4H_{12}N_2)[UO_2(C_5H_6O_4)_2]\cdot 5H_2O$, **9** and **16** all have a metal–ligand ratio of 1:2 with the same counter-cation, piperazinium. The decomposition temperatures decrease with larger substituent groups on the malonate, about 205 °C for malonate and methylmalonate, 190 °C for dimethylmalonate, 180 °C for diethylmalonate and 150 °C for phenylmalonate as ligands. Thus, there are several general features of the thermal analysis for this group of compounds: (i) the final residue for the compounds with organic counter-cations is UO_3 at about 480 °C and U_3O_8 at over 570 °C. (ii) The final residue for the compounds with hexaaminecobalt(III) as counter-cation at over 570 °C is Co_2O_3 and U_3O_8. (iii) Hydrated compounds (except with phenylmalonate as ligand) lose their solvent molecules first, then counter-cations or one ligand or cation plus one ligand and finally the remaining ligands. (iv) Hydrated compounds with phenylmalonate as ligand lose their solvent molecules first, then phenyl groups, cations plus ligands, finally the remaining ligands. (v) The temperature, above or below 100 °C, at which compounds lose their final water molecules may be used to identify the presence of coordinated water molecules.

3.7. ^{13}C CPMAS NMR spectroscopy

As indicated in the preceding paper, based on the specific patterns of carbonyl chemical shifts, compounds with known crystal structures can be used as model compounds to study the relationship between structural types and ^{13}C CPMAS NMR spectroscopic data.

3.7.1. Compounds of known structure

$(C_6H_{16}N_2)[UO_2(C_3H_2O_4)_2(H_2O)]\cdot 2H_2O$ has a monomeric structure [3] and the ^{13}C NMR spectrum contains two carbonyl peaks (at 179.2 and 176.1 ppm) with a 1:3 intensity ratio, which suggests that the chemical environment of one carbonyl atom is different from the other three. That is consistent with the unusually short U–O distance, U(1)–O(7). The broad peak at 47.1 ppm is assigned to the CH_2 carbons in the counter-cation and the broad peak at 40.2 ppm to the CH_2 carbons in the ligands. $(C_4H_{12}N_2)[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 1.5H_2O$ (**5**) has a pair of monomeric anion structures in the asymmetric unit (see Fig. 1) and the ^{13}C NMR spectrum contains two carbonyl peaks (at 179.9 and 177.8 ppm) of approximately equal intensity. The peaks at 45.9 and 43.8 ppm are assigned to CH_2 carbons in the counter-cation, those at 41.5 and 37.9 ppm to the CH carbons in the ligands and those at 17.3, 14.2, 9.8 and 8.5 ppm to the CH_3 carbons. $(C_4H_{14}N_2)[UO_2(C_4H_4O_4)_2(H_2O)]\cdot 2H_2O$ (**7**) has a monomeric anion structure with a C_2 axis along the U–O(H_2O) direction (see Fig. 2). The two U–O(malonate) distances are not significantly different. The ^{13}C CPMAS NMR spectrum has one carbonyl peak at 178.1 ppm, demonstrating the near equivalence of the carbonyl carbons. The peak at 46.7 ppm is assigned to the CH_2 carbons in the counter-cation, those at 40.0 and 30.0 ppm to the CH carbons and those at 8.7 and 4.1 ppm to the CH_3 carbons. $(C_4H_{12}N_2)[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot H_2O$ (**9**) has a monomeric anion structure with no crystallographically imposed symmetry (see Fig. 3). Experimentally only two carbonyl peaks are observed in the ^{13}C NMR spectrum (184.8 and 182.4 ppm), with an intensity ratio of approximately 1:3. The peak at 58.4 ppm is assigned to the C_q carbons in the ligands, those at 34.7 and 33.1 ppm to the CH_2 carbons and the peak at 8.3 ppm to the CH_3 carbons. $(C_{10}H_{26}N_2)[UO_2(C_7H_{10}O_4)_2(H_2O)]\cdot 2H_2O$ (**10**) has a monomeric anion structure with no crystallographically imposed symmetry (see Fig. 4). As in the cases of **2**, **13** and **21**, two carbonyl peaks were expected on the basis of X-ray crystallography. Experimentally, four carbonyl peaks at 185.0, 182.1, 179.8 and 177.6 ppm of approximately equal intensities were observed in the ^{13}C NMR spectrum. The peak at 58.2 is assigned to CH_2N carbons in the counter-cations, that at 43.6 ppm to the C_q carbons in the ligands, that at 30.5 ppm to the CH_2CH_3 carbons in the counter-cations, and those at 9.2, 7.3, 5.0 and 2.8 ppm to the CH_3 carbons.

$(C_{10}H_{26}N_2)[(UO_2)_3(C_7H_{10}O_4)_5]\cdot 2H_2O$ (**11**) possesses a rather complicated 3:5 ratio infinite chain anion structure. A single uranium atom, with one 1,5-bidentate ligand, and the dimeric structural unit encountered in compounds $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ [1] and $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$ [1] are linked together by two distinct types of ligands, one tetradentate (1,3-bidentate through both carboxylate groups) and the other tridentate (1,3-bidentate to the dimeric unit and 1-monodentate to the single uranium atom to form a zigzag, 3:5 infinite chain. This com-

–H_2MA = malonic acid, H_2MMA = methylmalonic acid, H_2DMMA = dimethylmalonic acid, H_2DEMA = diethylmalonic acid, H_2PMA = phenylmalonic acid.

[a] The values in brackets are solution ^{13}C NMR data from Aldrich [18].

[b] Carbonyl type is in Scheme 1.

pound has six carbonyl peaks in the ^{13}C CPMAS NMR spectrum at 190.5, 187.3, 184.5, 183.0, 180.2 and 175.3 ppm, indicating that the six kinds of carbonyl groups in the asymmetric unit can be distinguished by ^{13}C CP-MAS NMR. The peaks at 61.1, 59.6, 58.2 and 57.5 ppm are assigned to the four non-equivalent C_q carbons in the ligands, those two broad peaks at 43.8 and 30.6 ppm to the CH_2 carbons and those at 9.3, 7.4, 4.9 and 2.7 ppm to the CH_3 carbons.

Several types of carbonyl environments identified by X-ray crystallography are shown in Scheme 1(I–V). The isotropic chemical shifts (ICS) of carbonyl carbons for the ligands and some structurally characterised compounds are summarised in Table 10. For the ligands generally, there are differences of 2–4 ppm between solid and solution NMR but overall the trend in values is reasonably consistent (see Table 10). In the solid state, $\delta_{C=O}$ moves to higher values with an increase in the number of substituent alkyl groups (electron withdrawal leads to the carbonyl carbon being more deshielded) on the malonate. The occurrence of two values of $\delta_{C=O}$ for H_2PMA could be the effect of solid state packing.

Because monomeric structures only have 1,5-bidentate ligands, carbonyl type a (see Scheme 1) should have ICS values of 176–186 ppm. The ICS for dimeric and 1:2 (M:L) infinite chain structures suggests that a, a′ should be at 176–182 ppm which is within the range defined from monomeric structures and the bridging carbonyl type b should be at 173–176 ppm. The ^{13}C CPMAS NMR spectrum of $(C_{10}H_{26}N_2)[(UO_2)_2(C_5H_6O_4)_3]$ indicates that carbonyl types c and d have ICS values over 189 ppm and type a″ at 181 ppm. The data from $(C_6H_{16}N_2)[(UO_2)_3(C_5H_6O_4)_4(H_2O)_2]\cdot 2(C_2H_5OH)$ and **11** confirm that carbonyl types c and d have ICS values over 189 ppm. The ICS at 175.3 ppm for **11** could be the characteristic ICS for carbonyl type e. Thus, there is a rough correlation between ICS value and the carbonyl type: a, a′, a″ 176–186 ppm; b, e 173–176 ppm; c, d >189 ppm.

3.7.2. Structural predictions

The structural characterisation of the compounds in this series which have not been determined by single crystal X-ray diffraction can be attempted using a combination of ^{13}C MAS NMR and IR spectroscopy, together with the thermal and microanalytical data. Inspection of Tables 11 and 12 indicates that these spectroscopic and physical properties lead to a consistent interpretation of monomeric or dimeric structures based on a pentagonal bipyramidal coordination geometry at U for most of these compounds. The exceptions are **11** and **14**, which may have polymeric structures with a mixture of hexagonal and pentagonal equatorial geometry.

These data provide an opportunity to test the principles suggested in Part I of this paper. Table 14 summarises the known or spectroscopically inferred structures and provides a comparison with predicted ones based purely on counter-cations. In 11 out of 21 cases, the predicted and actual or inferred structural types are the same and, of the ten examples where there is disagreement, the predicted connectivity is more complex than actually observed in all cases. Since the

Table 11

principles defined in Part I of this paper exclude any effects of ligand chemistry, this level of disagreement is not surprising. In spite of the large size and aromaticity of the phenyl-substituted ligand, the structures of the phenylmalonato complexes (**12**–**19**) are predicted even better than those of complexes with other ligands. The tendency to overpredict structural complexity perhaps reflects a preference for simpler structural types with large cations and bulky ligands, and suggests that structures with high connectivity may be the exception rather than the rule.

4. Conclusions

The reaction of aliphatic diamine with malonic or substituted malonic acid and uranyl nitrate in the ratio 2:2:1 and in aqueous media leads in most cases to one predominant product, often crystalline, and with a range of stoichiometries and structures throughout the series (see Table 13). ^{13}C MAS NMR spectroscopy gives resonances for the carboxylate carbon ligands in the range 172–192 ppm which appear to be characteristic of structural type. Metal–ligand ratios are 1:2 for malonate and methylmalonate ligands and only differ from this in a few cases when larger substituent groups are present (i.e. dimethylmalonate, diethylmalonate, phenylmalonate). Thus, the stoichiometry of products is affected primarily by the bulk of the ligand and not by the bulk of the dipositive counter-cation, but the latter's bulk and ability to form hydrogen bonds affects the nuclearity of the anionic product. In the case of

phenylmalonate, although the compounds form slowly from solution, we have been unable to obtain diffraction quality crystals of sufficient quality to complete a structural refinement, but the spectroscopic and analytical data are indicative of simple monomeric or dimeric species based on pentagonal bipyramidal geometry. Direct evidence for the influence of the bulk of the substituents on the ligand comes from the mixed ligand complex with methyl- and dimethyl-malonates, which is dimeric and the bulkier ligand is terminal whilst the mono-substituted ligand is bridging. However, the choice of counter-cation does not appear to dictate the production of a given structural type, viz. monomer, dimer, polymeric chain. The tendency to maximise H-bonding in the lattice undoubtedly has a significant effect on the structure in the solid state. Although more than thirty uranyl malonato compounds have been studied (see Table 13) there remains no evidence for the isolation of oligomeric anions, $\{UO_2(\text{ligands})\}_n^{x-}$, of intermediate nuclearity, i.e. where $2 < n < \infty$, despite the identification of several new types of bonding mode for malonate with uranyl.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 166055–166060. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Synthesis, structure and redox properties of isomeric $[RuCl_2(L)_2]$ (L = *N*-aryl-1,2-arylenediimine) complexes formed by the oxidative dimerization of coordinated aromatic amines

Abstract

The di-arylamino complex $[RuCl_2(ArNH_2)_2L]$ ($ArNH_2$ = aromatic monoamine and L = *N*-aryl-1,2-diimino arene) reacts spontaneously with aqueous H_2O_2 to produce two isomers of $[RuCl_2(L)_2]$ via oxidative dimerization of the two coordinated aromatic amines. The geometries of two isomers are *cis* with respect to two chlorides and are *trans*, *cis*(tc) and *cis*, *cis*(cc) in the following sequence: NH(imine), HN(imine) and ArN(imine), ArN(imine). Of the above two, the tc-$[RuCl_2(L)_2]$ forms good X-ray quality crystals. The structure of a representative has been solved by X-ray diffraction. The geometry of the cc-$[RuCl_2(L)_2]$ is, however, revealed by the spectral data. The tc-isomer possesses a C_2-symmetry axis and the two-coordinated diimine ligands are magnetically equivalent. As a result, a single NH resonance in tc-$[RuCl_2(L)_2]$ appeared at approximately δ 12.40. By contrast, the cc-isomer is unsymmetrical and a complex pattern of ^1H NMR was observed in this case. Thus, there were two NH resonances observed in the range approximately δ 14.11–11.88. A semi-empirical extended Hückel MO calculations on a representative example showed strong metal–ligand overlap. A highly intense electronic transition that appeared in the visible range spectra of the complexes was assigned to a transition involving two molecular orbitals with considerable metal and ligand contributions. Both the isomers of the complex showed a high potential anodic response (0.8 V) due to the Ru^{III}/Ru^{II} couple. The trivalent congeners $[RuCl_2(L)_2]^+$ were generated in solution which showed characteristic rhombic EPR for the low spin d^5 ions. The distortion parameters have been computed using the observed *g* values. The axial distortion (Δ) in each case is found to be stronger than the rhombic (V) distortion. © 2002 Elsevier Science Ltd. Keywords: Ruthenium promoted reactions; Dimerization of aromatic amines; 1,2-Diimine; Structures; Redox

1. Introduction

Metal complexes of redox non-innocent dioxolene ligand series together with their nitrogen analogues are of considerable interest [1–3] because of their exceptionally rich redox and spectroscopic behavior, which originate from a strong degree of orbital mixing between metal ($d\pi$) and ligand ($p\pi$) frontier orbitals. Since the first report [4] of the ruthenium complex of bqdi, $[Ru(bqdi)_3](PF_6)$ (benzoquinonediimine) by Warren, the ruthenium complexes of bqdi and its redox partners have been the focus of many recent studies [5,6].

As a part of our ongoing work [7,8] in the area of metal promoted assembly of diimine complexes based on oxidation of aromatic amines we report herein the synthesis [7c], characterization, crystal structure and redox properties of isomeric $RuCl_2(L)_2$ (L = *N*-aryl-1,2-arylenediimine). The diimine ligand L is generated in situ by the oxidative dimerization of two coordinated aromatic amines (Scheme 1). It is proposed that the metal ion mediates these transformations by holding the amine residues in close proximity and also by taking part in the redox processes. In the present study two di-arylamino complexes [7b] of ruthenium of gen-

Scheme 1.

eral formula $[RuCl_2(ArNH_2)_2(L)]$ were chosen for the study of oxidation reaction. Oxidative deprotonation [9] of coordinated aromatic amines leading to the formation of metal–imido complexes was known in the literature. However, oxidative dimerization of coordinated amines of above type has been noted by us only in the recent past [7]. Furthermore, the transformation described in this work represents an example of an oxidation reaction, which led to the oxidation of internal substrate. Such reactions are important but are scanty [10].

2. Experimental

The solvents and chemicals used for synthesis were of analytical grade. The supporting electrolyte tetraethylammonium perchlorate (TEAP) and solvents for electrochemical work were obtained as before [11].

2.1. Physical measurements

A Shimadzu UV 2100 UV–Vis spectrophotometer was used to record electronic spectra. The IR spectra recorded with a Perkin–Elmer 783 spectrophotometer. ^1H NMR spectra in $CDCl_3$ were recorded with a Bruker Advance DPX300 spectrophotometer. $SiMe_4$ was used as internal standard. A Perkin–Elmer 240C elemental analyzer was used to collect microanalytical data (C,H,N). Electrochemical measurements were performed under dry nitrogen with an EG&G PARC model 273A potentiostat/galvanostat based electrochemistry system. All potentials, reported in this work, are referenced to the saturated calomel electrode (SCE) and are uncorrected for junction contributions. EPR measurements were made with a Varian 109C E-line X-band spectrometer fitted with a flat cell. Spectra were calibrated with the help of DPPH ($g = 2.0037$). Electronic spectra were recorded on a JASCO V-570 spectrophotometer.

2.1.1. Synthesis of dianiline dichloro N-phenyl-1,2-benzoquinone diimine ruthenium(II) $[RuCl_2(L^a)(PhNH_2)_2]$ (**1a**)

A sample of $RuCl_3 \cdot 3H_2O$ (0.25 g, 0.95 mmol) was added to 0.5 ml of aniline, and the mixture was heated on an oil bath at 140 °C for 30 min. The brown color changed gradually to violet and then an intense red solution resulted. The crude mass was extracted with dichloromethane and was washed thoroughly with 1 M hydrochloric acid and finally washed with water. The acid free solution was dried over anhydrous sodium sulfate. Hexane was then layered over the red solution and after 2 days shiny brown crystals were obtained. Yield 60%. Calc. for $C_{24}H_{24}Cl_2N_4Ru$ (540): C, 53.33; H, 4.44; N, 10.37. *Anal.* Found: C, 53.46; H, 4.50; N, 10.52%.

A similar reaction using *p*-toluidine instead of aniline afforded (**1b**) in 65% yield. Calc. for $C_{28}H_{32}Cl_2N_4Ru$ (596): C, 56.37; H, 5.37; N, 9.39. *Anal.* Found: C, 56.48; H, 5.27; N, 9.50%.

2.1.2. Synthesis of dichloro bis(N-phenyl-1,2-benzoquinone diimine)ruthenium(II), tc-$[RuCl_2(L^a)_2]$ and cc-$[RuCl_2(L^a)_2]$ (**2a**)

To a dichloromethane solution of $[RuCl_2(PhNH_2)_2(L^a)] \cdot CH_2Cl_2$ (0.108 g, 0.2 mmol), 0.5 ml 30% weight/volume hydrogen peroxide solution was added and the mixture was stirred at room temperature for 30 min. An intense blue color resulted, which was evaporated at room temperature. The crude product, thus obtained, was purified on a TLC plate. Two intense blue bands moved with a 25% chloroform–acetonitrile mixture. The two geometrical isomers were collected by evaporation of the solvent at room temperature. The first blue isomer (tc-) was crystallized by slow diffusion of dichloromethane tetrahydrofuran solution of the complex into hexane. Analysis and yields of the two isomers are given below:

tc-$[RuCl_2(L^a)_2]$ (first blue), yield (35%). Calc. for $C_{24}H_{20}N_4Cl_2Ru$ (537): C, 53.63; H, 3.72; N, 10.43. *Anal.* Found: C, 53.65; H, 3.43; N, 10.52%.

cc-$[RuCl_2(L^a)_2]$ (second blue), yield (35%). Calc. for $C_{24}H_{20}N_4Cl_2Ru$ (537): C, 53.63; H, 3.72; N, 10.43. *Anal.* Found: C, 54.02; H, 3.33; N, 10.62%.

The tc and cc isomers of $[RuCl_2(L^b)_2]$ (**2b**) were similarly prepared following the above procedure.

tc-$[RuCl_2(L^b)_2]$, yield 32%. Calc. for $C_{28}H_{28}N_4Cl_2Ru$ (592): C, 56.76; H, 4.73; N, 9.46. *Anal.* Found: C, 56.85; H, 4.32; N, 9.45%.

cc-$[RuCl_2(L^b)_2]$, yield 32%. Calc. for $C_{28}H_{28}N_4Cl_2Ru$ (592): C, 56.76; H, 4.73; N, 9.46. *Anal.* Found: C, 56.76; H, 4.35; N, 9.36%.

2.2. Crystal structure determination

The crystallographic data for the compound tc-$[RuCl_2(L^a)_2]$ (**2a**) are collected in Table 1. Slow diffusion of a dichloromethane–THF solution of tc-$[RuCl_2(L^a)_2]$ in hexane yielded thin needle like crystals ($0.50 \times 0.05 \times 0.04$ mm^3). Intensity data were collected on a SMART CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.7107$

Å). A total of 13 424 unique reflections were collected and 5719 with $I \geq 2\sigma(I)$ were used in the refinement [12]. Refinement of positional and anisotropic thermal parameters for all non-hydrogen atoms converged to $R = 0.0698$. The final Fourier difference maps showed residual extrema at 0.591, -0.570 e Å^{-3}.

3. Results and discussion

3.1. The starting compounds and synthesis

Hydrated ruthenium(III) chloride reacts [7b] with neat $ArNH_2$ at 130 °C to yield the brown complex, $[RuCl_2(ArNH_2)_2L]$ [$ArNH_2$ = aniline, L = L^a and $ArNH_2$ = *p*-toluidine, L = L^b, Eq. (1)], which was used as the starting complex for carrying out the synthesis.

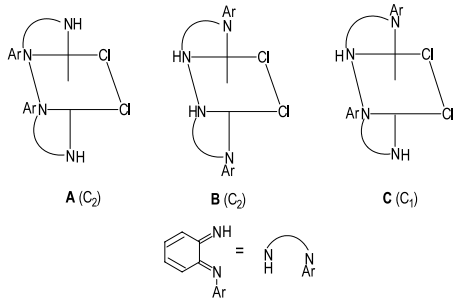
$$RuCl_3\cdot nH_2O \xrightarrow[130-135\ ^\circ C]{ArNH_2} \underset{\mathbf{1}}{[RuCl_2(ArNH_2)_2L]} \quad (1)$$

$ArNH_2$	**L**	**1**
aniline	L^a	1a
p-toluidine	L^b	1b

The complex **1** is poorly soluble in common organic solvents. A suspension of **1** in CH_2Cl_2, however, reacts instantaneously [7c] with 5% aqueous H_2O_2 at room temperature (300 K) to afford $[RuCl_2L_2]$ (**2**) (Eq. (2)):

$$[RuCl_2(ArNH_2)_2L] \xrightarrow{H_2O_2} [RuCl_2L_2] \quad (2)$$

Preliminary work up followed by chromatographic purification yielded the two geometrical isomers of $[RuCl_2L_2]$ (vide infra). In this reaction, the two coordinated amine residues have undergone oxidative coupling to give a 1,2-diamino ligand. This transformation, **1** → **2** is a combination of many operations: (i) isomerization of the starting complex **1** in order to bring two $ArNH_2$ in close proximity (*trans* → *cis*); (ii) oxidative coupling of two $ArNH_2$ residues to *ortho*-semidine (C–N bond making); and (iii) further oxidative dehydrogenation, *ortho*-semidine → 1,2-diimine (diamine → diimine).



3.2. Formulation and spectral characterization of isomeric $[RuCl_2(L)_2]$

The crude product, obtained from the reaction (1), contained two major blue fractions, which were separated on a preparative TLC plate. These were obtained in almost identical yields (ca. 35% each). FAB mass spectra of these two compounds are nearly identical which indeed confirm that these two are isomers. Due to the unsymmetric nature of L, there exist [13] five geometrical possibilities for $[RuCl_2L_2]$. The present complexes are characterized by two sharp and medium Ru–Cl stretches in the region 310–350 cm^{-1} (Table 2). Thus, the $RuCl_2$ fragments in these complexes are *cis* and three geometries A–C are possible (Scheme 2). The relative orientations (*trans*/*cis*) of the coordinated imine nitrogen atoms [N(H), N(H)] and aryl substituted imine nitrogen atoms [N(Ar), N(Ar)] in the isomeric $[RuCl_2(L)_2]$ are *trans*, *cis* and *cis*, *cis* respectively (vide infra). We shall refer these two isomers as tc- (first blue) and cc- (second blue) isomers. Of the above two com-

Scheme 2.

pounds, the tc-$[RuCl_2(L^a)_2]$ formed suitable crystals for X-ray structure determination. The geometry of the cc-isomer was however, revealed by the spectral data.

The complexes showed well resolved ^1H NMR spectra in $CDCl_3$ at 300 MHz, chemical shift data are listed in (Table 2) and the spectra of two representatives are shown in Fig. 1. The spectrum of the tc-isomer is simpler than that of the cc-isomer. Each kind of proton in the tc-isomer gave rise to only one signal (singlet or multiplet), which indicates that the two L ligands in this isomer are magnetically equivalent. By contrast, the corresponding cc-isomer showed two signals for each kind of protons. In this geometry the two ligands are magnetically inequivalent and their spectral pattern is as expected. For comparison, while the tc-$[RuCl_2L_2]$ showed only one NH resonance [7d] at δ 12.40, the

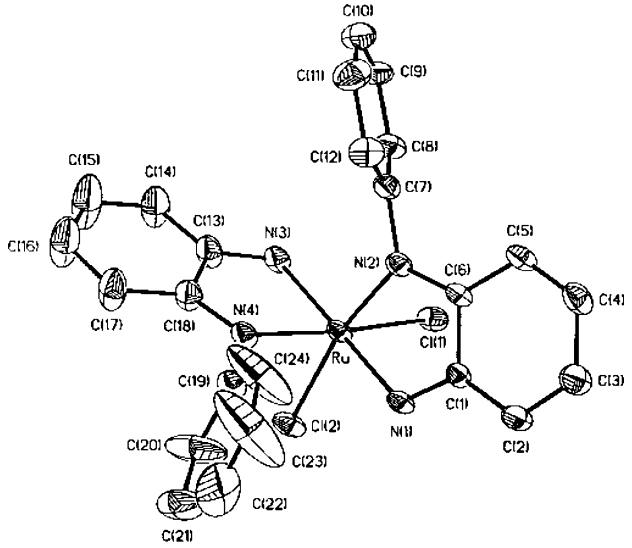

Fig. 2. Molecular structure and atom numbering scheme for tc-$[RuCl_2(L^a)_2]$.

corresponding cc-$[RuCl_2L_2]$ displayed two such resonances at approximately δ 14.11 and 11.88. The two isomers of the complex with methyl substituted ligand, $[RuCl_2(L^b)_2]$ showed two (tc-) and four (cc-) methyl resonances, respectively, in the range δ 2.38–1.94. The ^1H NMR together with the IR spectral data, thus confirms the geometries of the two isomers of $[RuCl_2L_2]$.

3.3. Crystal structure, tc-[$RuCl_2(L^a)_2$]

The first blue fraction of $RuCl_2(L^a)_2$ formed suitable X-ray quality crystals for structure determination. A view of the molecule is shown in Fig. 2, which shows that one of the *N*-phenyl rings is disorder. Selected bond parameters are collected in (Table 3). The coordination sphere involves $RuCl_2N_4$. Two chlorides are *cis* to each other and the aryl substituted imine nitrogens are also in relative *cis* positions. The imine C–N bond lengths, average 1.316 Å are within the range of values expected for the diimine oxidation state of L [5e,7]. These bonds are much shorter than the two C–N single bonds, viz. C(7)–N(2) and C(19)–N(4), average 1.434 Å. Moreover, the C–C lengths (average 1.348 Å) at positions that would have localized double bond for the diimine form of the ligands are significantly shorter than the other C–C lengths (average 1.432 Å) in the same ring. The Ru–Cl lengths in this complex compare well with the corresponding lengths in the related complexes. The overall gross structural features of this conforms well with those of a related osmium(II) complex [7a], tc-[$OsBr_2(L^a)_2$]. Moreover, the average of Ru–N lengths in the present complex (average 1.995 Å) significantly smaller than Ru^{II}–N single bonds. For comparison, the Ru–N bond distances [10,11] in Ru^{II}–NH_3 and Ru^{II}–bpy (bpy = 2,2′-bipyridine) lie in the range 2.14–2.06 Å; which are appreciably longer than [9,12] Ru(II)–N(azo) lengths (ca. 1.98 Å) in [$RuCl_2(pap)_2$] complex where very strong metal (dπ) and ligand (pπ) interactions were noted. Thus the short Ru–N distances in the tc-[$RuCl_2(L^a)_2$] complex confirms strong dπ–pπ interactions. This effect has also been reflected in the high metal based anodic potentials (vide infra).

3.4. Electronic spectra and redox properties

From the crystallographic data it is obvious that in the ruthenium complexes, under consideration, there exist strong metal–ligand dπ–pπ interactions. In order to have some insight into the nature of redox and spectroscopically relevant orbitals, a standard extended Hückel MO calculation using the crystallographic parameters was performed on tc-[$RuCl_2(L^a)_2$] using the CACAO programme [14] by Mealli and Proserpio. A partial energy level scheme is shown in Fig. 3. In this complex, the molecular orbitals, LUMO and HOMO-1 are heavily mixed orbitals where as HOMO is almost a pure ruthenium orbital. Pictorial representations of these three molecular orbitals are deposited as supplementary information.

The electronic spectral data are collected in (Table 4). Two representative spectra of isomeric (tc- and cc-) [$RuCl_2(L^a)_2$] are shown in Fig. 4. There are two major transitions in the range 1600–250 nm. The lowest energy transitions, occurring in the near IR region, is weak (λ, ca. 950 nm; ε, ca. 950 M^{-1} cm^{-1}) and broad compared to the next highly intense transition (λ, ca. 600 nm; ε, ca. 23 100 M^{-1} cm^{-1}) in the visible region. However, the intensity of NIR transition for the present complex is too intense for a d–d transition. This transition may be ascribed to HOMO Ru(dπ) → LUMO transition. The next highly intense transition at approximately 590 nm is due to a transition between two heavily mixed metal–ligand orbitals, LUMO and HOMO-1. This type of transitions are known to exist in other related complexes [7d,15] and their intensities are

generally very high. For example, a similar transition at approximately 620 nm was noted [7a] for a related osmium complex, $[OsBr_2(L^a)_2]$. The spectral patterns of the two isomers of $[RuCl_2(L)_2]$ are nearly identical except the minor differences in band positions and intensities.

The redox properties of the ruthenium complexes have been studied by cyclic voltammetry with a platinum-working electrode in the range 1.8 to −1.5 V. Voltammetric data are collected in (Table 5) and representative voltammograms are displayed in Fig. 5. All the potentials are referenced to the saturated calomel electrode (SCE). Both the isomers of $[RuCl_2(L)_2]$ show almost identical voltammograms. The difference in geometry seems to have negligible effects on the redox potentials. The complexes exhibited a reversible anodic response near 0.80 V and two irreversible cathodic responses in the potential range −0.60 to −1.60 V. The oxidation process in these complexes occurs at HOMO, which is primarily a metal orbital. One-electron coulometric oxidation of both the isomers of $[RuCl_2(L^a)_2]$ afforded reddish–brown solutions. The voltamograms of the electrogenerated trivalent complexes are superposable (initial scan cathodic) on those of the corresponding isomers of $[RuCl_2(L^a)_2]$ (initial scan anodic) showing that the metal redox processes are reversible. The EPR of the Ru(III) complexes were studied in acetonitrile–toluene glass at 77 K, which display rhombic EPR spectra with three distinct resonances (Table 6). The spectrum of a representative example cc-$[RuCl_2(L^a)_2]^+$ is shown in Fig. 6. The trivalent ruthenium complexes may also be generated by the chemical oxidation of the bivalent complexes by Br_2. Unfortunately, the oxidized complexes are not stable

enough for their isolation. They revert to the parent divalent complexes rapidly. The observed rhombicity of the EPR spectra in the present cases is understandable in terms of the gross molecular symmetry of these complexes, containing three non-equivalent axes. The distortion parameters have been computed [16] using the observed g values. The axial distortion (Δ, which split t_2 into a and e) is indeed much stronger than the rhombic distortion (V, which splits e). Thus the EPR spectral data of the complexes indicate significant distortion from ideal octahedral arrangements which indeed in line with the observed structure of the parent bivalent complexes.

In conclusion it may be stated that the present work further demonstrates that aromatic primary amines are susceptible to metal mediated oxidative dimerization processes via the formation of a C–N bond. The isomeric complexes, $RuCl_2L_2$, thus formed, represent an interesting family of ruthenium–diimines that show strong metal d(π)–ligand p(π) interactions. Chemical reactions including the chloride substitution at $[RuCl_2(L)_2]$ are now under scrutiny.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 160040. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction of [$Pt_2Me_4(\mu\text{-}SMe_2)_2$] with the ligand 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ (**L**) yielded the cyclometallated platinum(II) compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)SMe_2] (**1**), in which the imine acts as a [C,N]-bidentate ligand. Compounds [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)DMSO] (**2**) (DMSO = dimethyl sulfoxide) and [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)PPh_3] (**3**) were obtained from a displacement reaction of SMe_2 for DMSO or PPh_3, respectively. Oxidative addition of methyl iodide to compounds **1**–**3** produced, respectively, [$PtMe_2I$(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)SMe_2] (**4a**/**4b**) as two isomers, [{$PtMe_2I$(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)}$_2$] (**5**) and [$PtMe_2I$(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)PPh_3] (**6**). Platinum(II) metallacycles can be cleaved upon reaction with an excess of PPh_3 or with the diphosphine dppe to yield, respectively, compounds [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)$(PPh_3)_2$] (**7**) and [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)dppe] (**8**) in which the imine acts as a monodentate [C] ligand. Analogous compounds could not be obtained for platinum(IV) since in this case neither PPh_3 nor dppe can cleave the metallacycle. The reaction of **4a**/**4b** with dppe produced [{$PtMe_2I$(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)}$_2$dppe] (**11**), a binuclear compound in which the diphosphine bridges two platinum(IV) moieties with the imine acting as a [C,N]-bidentate ligand. All compounds were characterised by analytical and spectroscopic techniques and compound **3** was also characterised crystallographically. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

Cyclometallated complexes of the Group 10 elements have generated considerable interest due to their numerous applications and interesting properties. Previous results showed that the reactions with phosphines could be taken as a criterion for the stability of metallacycles [1]. Moreover, it has been shown that steric crowding in the co-ordination sphere of the metal favoured the cleavage of metallacycles upon reaction with triphenylphosphine. In particular, the presence of a fluorine [2–4] or a chlorine [5,6] atom in the position adjacent to the M–C(aryl) bond seems to be decisive. On the other hand, both palladium(II) [7] and platinum(II) [6,8,9] metallacycles are cleaved easily with diphosphines such as 1,2-bis(diphenylphosphino)-ethane, which can be explained by the chelating nature of this ligand. Nevertheless, examples in which the formation of either compounds containing a bridging diphosphine [10] or ionic compounds with a chelate diphosphine [11] is favoured over cleavage of the metallacycles have also been reported.

In this paper we report new cyclometallated platinum compounds containing the imine 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ and their reactions with phosphines in order to analyse the factors governing the cleavage of the formed metallacycles.

2. Results and discussion

The reaction of $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ with ligand 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ (**L**) yielded the cyclometallated platinum(II) compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2$-C_6H_5) SMe_2] (**1**) by *ortho* metallation with loss of methane, as reported for analogous systems [3,4]. Compound **1** reacted with an excess of dimethylsulfoxide (DMSO) or with PPh_3 in a 1:1 molar ratio to yield respectively compounds [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2$-C_6H_5)DMSO] (**2**) and [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2$-C_6H_5)PPh_3] (**3**) which result from a displacement reaction of SMe_2 for DMSO or PPh_3. The reaction of compound **2** with PPh_3 gave compound **3** which indicates the lability order $SMe_2 > DMSO > PPh_3$ for these platinum(II) compounds. Compounds **1**–**3**, shown in Scheme 1, were characterised by elemental analysis and NMR spectroscopies. In the ^1H NMR spectra, the methyl group bound to platinum is coupled to the fluorine atom in position five of the aryl ring, thus revealing a through-space interaction; additional coupling to the phosphorous atom is observed for compound **3**. The methyl, the imine and the methylene hydrogens are coupled to ^{195}Pt and the values of the coupling constants are characteristic of this kind of cyclometallated platinum(II) compounds. For compound **2**, the $J(H{-}Pt)$ value of the protons of DMSO [12] and the $\delta(^{195}Pt)$ value [13] indicate that DMSO is S-bonded to platinum; this is further confirmed by a strong band at 1110 cm^{-1} in the IR spectrum. A process involving oxidative cycloplatination and sulfur deoxygenation has been reported in the reaction between (*E*)-2-methyl-1-phenylbutan-1-one oxime and *cis*-$[PtCl_2(DMSO)_2]$ in refluxing methanol [14]; however, compound **2** was recovered unchanged when treated under such conditions. The presence of the PPh_3 ligand in **3** is confirmed by ^{31}P NMR spectroscopy and the value of the coupling constant to platinum ($J(P{-}Pt) = 2631$ Hz) is in the expected range for a phosphine with a fluorinated aryl group in *trans*. In the ^{19}F NMR spectra, three distinct resonances appear in the aromatic region and the values of the coupling constants are in the range expected for analogous compounds [15].

Compound **3** was also characterised crystallographically. Suitable crystals were grown from acetone solution. The crystal structure is composed of discrete molecules separated by van der Waals interactions. A view of the molecule is shown in Fig. 1. Selected bond lengths and angles are given in Table 1. As expected from spectroscopic characterisation, the methyl group is *trans* to the nitrogen atom, the C=N group is *endo* to the cycle and the imine adopts an (*E*)-configuration, the torsion angle C(6)–C(7)–N–C(8) being $-173.99(4)°$. The platinum atom displays a tetrahedral distorted planar co-ordination and the following displacements (Å) are observed from the least-squares plane of the co-ordination sphere: Pt, -0.0264; P, 0.1658; N, -0.1785; C(1), 0.2074; C(15), -0.1683. The metallacycle is approximately planar; the largest deviation from the mean plane determined by the five atoms is -0.0628 Å for C(1). The dihedral angle between the metallacycle and the co-ordination plane is larger (10.24°) than those reported for [PtMe(2,3,4-$C_6HF_3CH{=}NCH_2C_6H_5$)PPh_3] (4.6°) [3] and [PtMe-(2,3,4-$C_6HF_3CH{=}NCH_2CH_2NMe_2$)] (0.28°) [4]. A larger deviation from coplanarity reduces the steric interaction between the methyl group and the fluorine substituent

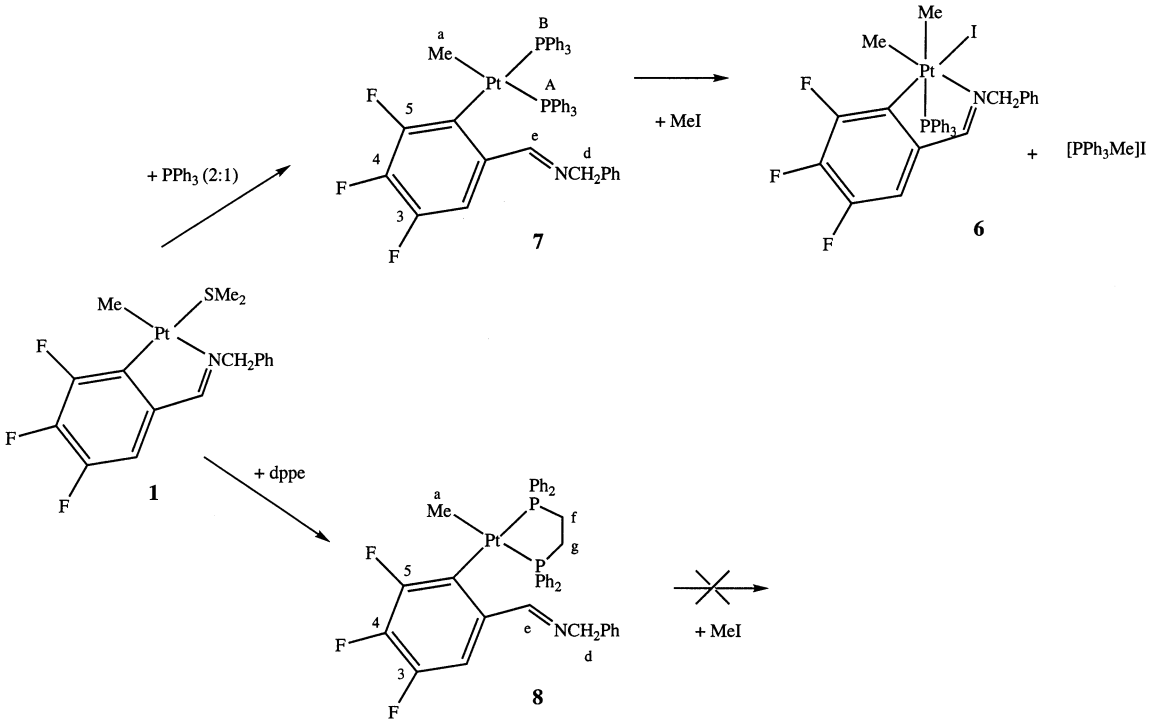
in a position adjacent to the Pt–C(aryl) bond. Nevertheless, the distance C(15)···F(1) of 2.929 Å can be taken as an indication of a short contact between the methyl group and the fluorine, which are close enough for the van der Waals radii to overlap. The coupling between the methyl protons and ^{19}F in the NMR spectrum implies that this interaction persists in solution. Bond lengths and angles are well within the range of values obtained for analogous compounds [3,4,16]. The 'bite' angle C(1)–Pt–N of 79.08(17) is characteristic of cyclometallated platinum(II) complexes [17].

Oxidative addition of methyl iodide to compound **1** carried out in $CDCl_3$ at NMR scale produced a mixture of two isomers of platinum(IV) compound $[PtMe_2I(3,4,5\text{-}C_6HF_3CH{=}NCH_2C_6H_5)SMe_2]$ (**4a**/**4b**) in nearly equal amounts together with a very small amount (less than 5% of the reaction mixture) of compound **5** (see below). The spectral parameters for compounds **4** are in good agreement with those reported in the literature for analogous compounds [18] and are assigned to the isomers depicted in Scheme 2, which differ only in having a SMe_2 or an I *trans* to the axial methyl. For both isomers only the equatorial methyl is coupled to the fluorine at position five of the aryl ring. Oxidative addition of methyl iodide to compound **2** gave compound **5** as a pale yellow solid which was characterised by NMR and FAB spectroscopies. Of the two methyl resonances—both coupled to platinum—the one at lower field is assigned to the equatorial methyl which is also coupled to the fluorine atom F^5. The absence of coordinated S– or O–DMSO in the ^1H and IR spectra points to an iodide bridged platinum(IV) dimer, a structure that is confirmed by FAB mass spectrometry. Moreover, since resonances due to SMe_2 are not observed, the formation of dimethylsulfide from DMSO within the co-ordination sphere of platinum as described in the literature for analogous systems[14] can be ruled out. The low affinity of the DMSO ligand for platinum(IV) has already been shown in the reaction of *cis*-$[PtMe_2(DMSO)_2]$ with methyl iodide which yields the platinum(IV) tetramer $[\{PtMe_3(\mu_3\text{-}I)\}_4]$ [19]. The $\delta(^{195}Pt)$ value obtained for **5** (-2700 ppm) is similar to that reported in the literature for the tetramer (-2769 ppm) [20]. Oxidative addition of methyl iodide to compound **3** produced cyclometallated platinum(IV) compound $[PtMe_2I(3,4,5\text{-}C_6HF_3CH{=}NCH_2C_6H_5)(PPh_3)]$ (**6**) which was characterised by elemental analyses and NMR spectra. Two methyl resonances appear at $\delta = 1.38$ ($^2J(Pt–H) = 60$ Hz) and $\delta = 2.20$ ($^2J(Pt–H) = 69$ Hz) both coupled to ^{195}Pt and ^{31}P ($^3J(P–H) = 8$ Hz). The small value of the coupling constant of the axial methyl with platinum suggest a *trans* arrangement of this group and the PPh_3 ligand, as reported previously for analogous compounds [8]. The equatorial methyl is also coupled to the fluorine atom at position five of the aryl ring. The $J(P–Pt)$ value is in the range expected for platinum(IV) compounds, which is considerably reduced compared to that of the platinum(II) compound. Alternatively, compound **6** could be prepared upon reaction of com-

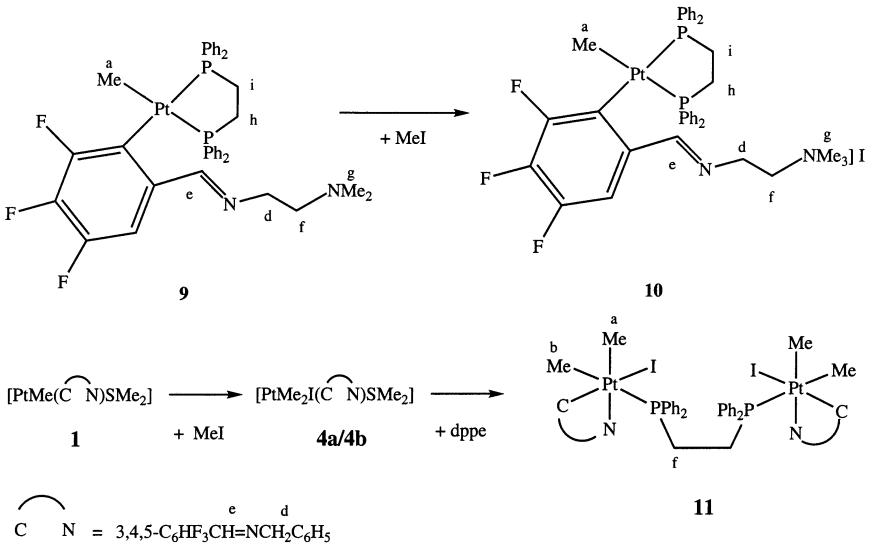


pounds **4a**/**4b** or **5** obtained in situ in acetone with the equivalent amount of triphenylphosphine and all preparative methods lead to the same stereoisomer in which the bulky triphenylphosphine is in an axial position. The lability order $DMSO > SMe_2 > PPh_3$ is deduced for platinum(IV) compounds.

Cleavage of the metallacycle in platinum(II) compounds was achieved upon reaction of compound **1** with two equivalents of PPh_3 or with one equivalent of the bidentate phosphine 1,2-bis(diphenylphosphino)ethane (dppe) to yield, respectively, compounds [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)(PPh_3)$_2$] (**7**) and [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)dppe] (**8**) (see Scheme 3) which were obtained as white solids and characterised by elemental analyses and NMR spectroscopies. In both cases, the methyl resonance is coupled to two non-equivalent phosphorus atoms and the value of the coupling constants with ^{195}Pt are reduced (^2J(Pt–H) = 65 Hz (**7**) or 67 Hz (**8**)) when compared to that of cyclometallated compound **3** (83 Hz). Moreover, the imine proton is not coupled to ^{195}Pt and the ^{31}P NMR spectra show two sets of resonances due to two non-equivalent phosphorus atoms, both coupled to platinum. These results indicate that two phosphorus atoms are present in the co-ordination sphere of platinum(II) and therefore the imine is acting as a monodentate ligand through the aryl carbon. As observed previously for analogous compounds [3,4], the ^3J(Pt–F^5) values are much larger (412 Hz (**7**) and 385 Hz (**8**)) than those obtained for cyclometallated compounds **1** (140 Hz), **2** (98 Hz) and **3** (87 Hz). The large value of the coupling constant may arise from a perpendicular orientation of the aryl group to the co-ordination plane [21]. The methyl group consistently does not couple with the fluorine in position five of the aryl ring.

In spite of the easy cleavage of the metallacycle reported above for platinum(II) compounds, cyclometallated platinum(IV) compound **6** did not react further with triphenylphosphine even when large excesses were used. Other attempts to obtain triphenylphosphine platinum(IV) derivatives in which the imine acts as a monodentate [C] ligand were also unsuccessful. For instance, the reaction of platinum(II) compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)(PPh_3)$_2$] (**7**) with methyl iodide gave a mixture of cyclometallated platinum(IV) compound **6**, characterised as above, and the phosphonium salt [PPh_3Me]I, for which ^{1}H and ^{31}P NMR data are consistent with the values given in the literature [22]. In this process, oxidative addition of methyl iodide took place along with co-ordination of the dangling imine nitrogen to platinum and dissociation of the phosphine, which gave the phosphonium salt. This result can be related to the higher affinity of platinum(IV) for nitrogen than for phosphorus donor ligands due to its harder nature.

Scheme 2.



Scheme 3.

On the other hand, compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)dppe] (**8**) did not react with methyl iodide even after 48 h when evidence of decomposition was observed. For the purpose of comparison, the reaction with methyl iodide was also tested for compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2NMe_2$)(dppe)] (**9**) obtained from [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2NMe_2$)] [4] in which the terdentate imine 3,4,5-$C_6HF_3CH{=}NCH_2CH_2NMe_2$ acts as a monodentate [C] ligand. The reaction of compound **9** with methyl iodide is shown in reaction 1 and produced the ionic compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2NMe_3$)(dppe)]I (**10**) resulting from methylation of the amine group. NMR data are similar to those obtained for **9** except for the fact that the amine protons are shifted towards higher fields ($\delta = 3.43$ ppm) and integrate nine hydrogen atoms. An analogous process in which methyl iodide is added to the dangling NMe_2 moiety but not to the platinum centre has been described for compound [PtMe(3-$C_6H_3ClCH{=}NCH_2CH_2NMe_2$)(dppe)] [6].

In view of these results, the reaction of compounds **4a**/**4b**—obtained in situ from **1**—with dppe in the ratio 2:1 was also tested. A yellow non-electrolyte solid was obtained and was characterised as binuclear platinum(IV) compound [{$PtMe_2I$(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)}$_2$(dppe)] (**11**) by NMR and FAB Mass spectra. Compound **11** could not be isolated in a pure form due to decomposition processes during attempted crystallisation in several solvents. In the ^{1}H NMR spectrum two methyl resonances appear at $\delta = 1.05$ (^2J(Pt–H) = 59 Hz) and $\delta = 1.83$ (^2J(Pt–H) = 69 Hz) both coupled to ^{195}Pt and to one phosphorus atom (J(Pt–P) ca. 7–8 Hz), and the equatorial methyl also coupled to the fluorine atom at position five of the aryl ring. As in compound **6**, these values suggest a *trans* arrangement of the axial methyl and the phosphorus atom and a *fac*-PtC_3 stereochemistry. The imine proton is also coupled to ^{195}Pt (^{3}J(Pt–H) = 47 Hz) indicating that the metallacycle has not been cleaved. Two resonances appear in the ^{31}P NMR spectrum at $\delta = -10.4$ (J(Pt–P) = 1049 Hz) and $\delta = -10.9$ (J(Pt–P) = 1048 Hz); these values are characteristic of phosphines bound to platinum(IV) and *trans* to a methyl group [9], and can only be assigned to two different conformations of compound **11**. When larger amounts of diphosphine were used the main products are compound **11** and free diphosphine or its oxide. No evidence of formation of compounds containing chelate diphosphine was observed in the ^{1}H or in the ^{31}P NMR; the formation of such compounds requires dissociation of either nitrogen or iodide, and it is likely that such processes are not favoured for platinum(IV) compounds.

In conclusion, while platinum(II) metallacycles derived from imine 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ can be opened up using a diphosphine or an excess of a monodentate phosphine, platinum(IV) metallacycles are much more resistant to cleavage. Moreover, oxidative addition to platinum(II) compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)(PPh_3)$_2$] (**7**) in which the imine acts as a [C] ligand favours the co-ordination of the

imine nitrogen to yield a [C,N] platinum(IV) cyclometallated compound. These results could be explained by the higher affinity of platinum(IV) for nitrogen donor ligands when compared to the softer platinum(II).

3. Experimental

^{1}H, ^{19}F, $^{31}P-\{^{1}H\}$ and ^{195}Pt NMR spectra were recorded by using Varian Gemini 200 (^{1}H, 200MHz), Varian 300 (^{19}F, 282.2 MHz; ^{195}Pt, 64.2 MHz) and Bruker 250 (^{31}P, 101.25 MHz) spectrometers, and referenced to $SiMe_4$ (^{1}H), CCl_3F (^{19}F), H_3PO_4 (^{31}P) and H_2PtCl_6 (^{195}Pt). δ values are given in ppm and J values in Hz. IR spectra were recorded as KBr disks on a Nicolet 520 FT-IR spectrometer. Conductivity measurements were carried out to a Crison 2000 equipment. Microanalyses and FAB mass spectra were performed by the Serveis Científico-Tècnics de la Universitat de Barcelona.

3.1. Preparation of the compounds

Compounds $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ [23] and [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2NMe_2$)] [4] were prepared as reported.

The ligand 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ (**L**) was prepared by the reaction of 0.5 g (3.1×10^{-3} mol) of the corresponding aldehyde with an equimolecular amount (0.33 g) of benzylamine in refluxing ethanol. The mixture was refluxed for 2 h, and the solvent was removed in a rotary evaporator to yield a yellow oil. Yield 0.65 g (83%). ^{1}H NMR ($CDCl_3$): $\delta = 4.82$ [s, H^d]; 7.42 [m, aromatics]; 8.24 [s, H^e]. ^{19}F NMR ($CDCl_3$): $\delta = -140.09$ [dd, $J(F^a-F^b) = 20$, $J(F^a-H) = 8$, F^a]; -163.14 [tt, $J(F^a-F^b) = 20$, $J(F^b-H) = 6$, F^b].

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)SMe_2] (**1**) was obtained by the reaction of 100 mg (1.74×10^{-4} mol) of compound $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ with 87.6 mg (3.52×10^{-4} mol) of the ligand 3,4,5-$C_6H_2F_3CH{=}NCH_2C_6H_5$ in acetone (20 ml). After continuous stirring during 16 h, the solvent was removed in a rotary evaporator and the resulting orange solid was washed with hexane (2×10 mL) and dried under vacuum. Yield 140 mg (77%). ^{1}H NMR (acetone-d^6): $\delta = 1.13$ [d, $^{2}J(Pt-H) = 80$, $J(F-H) = 6$, Me^a]; 1.90 [s, $^{3}J(Pt-H) = 36$, Me^c]; 5.19 [s, $^{3}J(Pt-H) = 13$, H^d]; {7.28–7.38 [m], aromatics}; 8.96 [s, $^{3}J(Pt-H) = 56$, H^e]. ^{19}F NMR (acetone-d^6): $\delta = -122.61$ [dt, $J(Pt-F^5) = 140$, $J(F^5-F^4) = 23$, $J(F^5-F^3) = J(F^5-H) = 5$, F^5]; -146.95 [m, F^3]; -159.89 [ddd, $J(Pt-F^4) = 100$, $J(F^4-F^5) = 24$, $J(F^4-F^3) = 20$, $J(F^4-H) = 7$, F^4]. *Anal.* Found: C, 39.4; H, 3.6; N, 2.9. Calc. for $C_{17}H_{18}F_3NSPt$: C, 39.23; H, 3.49; N, 2.69%.

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)-DMSO] (**2**) was obtained by adding two drops of DMSO to 50 mg (9.6×10^{-5} mol) of compound **1** in dichloromethane (20 ml). After continuous stirring during 1 h, the solvent was removed in a rotary evaporator and the oily residue was washed with diethylether (3×5 ml). The obtained yellow solid was dried in vacuum. Yield 35 mg (68%). ^{1}H NMR ($CDCl_3$): $\delta = 0.95$ [d, $^{2}J(Pt-H) = 80$, $J(F-H) = 6$, Me^a]; 2.78 [s, $^{3}J(Pt-H) = 20$, Me^c], 5.28 [s, $^{3}J(Pt-H) = 5$, H^d]; {7.14 [m, 1H]; 7.30–7.41 [m, 5H], aromatics}; 8.62 [s, $^{3}J(Pt-H^e) = 62$, H^e]. ^{19}F NMR ($CDCl_3$): $\delta = -120.91$ [dt, $J(Pt-F^5) = 98$, $J(F^5-F^4) = 22$, $J(F^5-F^3) = J(F^5-H) = 7$, F^5]; -142.97 [dt, $J(F^3-F^4) = 18$, $J(F^3-F^5) = J(F^3-H) = 7$, F^3]; -156.46 [m, $J(Pt-F^4) = 43$, $J(F^4-F^5) = 22$, $J(F^4-F^3) = 18$, $J(F^4-H) = 6$, F^4]. ^{195}Pt NMR ($CDCl_3$): $\delta = -3982$ [s]. IR (KBr): 1110 cm^{-1} (ν(SO)). FAB(+) MS (NBA, m/z): 521 ($[M-Me]^+$); 443 ($[M-Me-SOMe_2]^+$). *Anal.* Found: C, 37.6; H, 3.4; N, 2.6. Calc. for $C_{17}H_{18}F_3NOPtS$: C, 38.06; H, 3.38; N, 2.61%.

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)-PPh_3] (**3**) was obtained from the reaction of 50 mg (9.6×10^{-5} mol) of compound **1** with the equimolecular amount (25 mg) of PPh_3 in acetone (20 ml). After continuous stirring during 2 h, the solvent was removed in a rotary evaporator and the resulting yellow solid was washed with hexane (2×5 ml), and diethylether (2×5 ml) and dried under vacuum. Yield 55 mg (80%). ^{1}H NMR (acetone-d^6): $\delta=0.97$ [dd, ^2J(Pt–H) = 83, ^3J(P–H) = 9, J(F–H) = 6, Me^a]; 4.22 [s, ^3J(Pt–H) = 8, H^d]; {6.79 [m, 1H]; 7.40 [m], 7.64 [m], aromatics}; 8.63 [s, ^3J(Pt–H^e) = 55, H^e]. ^{19}F NMR (acetone-d^6): $\delta=-122.62$ [m, J(Pt–F^5) = 87, J(F^5–F^4) = 24, J(P–F^5) = J(F^5–F^3) = J(F^5–H) = 7, F^5]; -146.01 [m, F^3]; -159.80 [m, F^4]. ^{31}P NMR (acetone-d^6): $\delta=29.79$ [dd, J(Pt–P) = 2631, J(P–F^5) = 10, J(P–F^4) = 7]. *Anal.* Found: C, 54.7; H, 3.8; N, 2.0. Calc. for $C_{33}H_{27}F_3NPPt$: C, 55.00; H, 3.78; N, 1.94%.

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)-$(PPh_3)_2$] (**7**) was obtained as a white solid by an analogous procedure using 100 mg (1.9×10^{-4} mol) of PPh_3. Yield 80 mg (85%). ^{1}H NMR (acetone-d^6): $\delta=$ 0.27 [dd, ^2J(Pt–H) = 65, ^3J(P^A–H) = 8, ^3J(P^B–H) = 7, Me^a]; {4.74 [d], 4.87 [d], J(H–H) = 13, AB pattern, H^d}; 7.13–7.24 [m, aromatics]; 9.40 [s, H^e]. ^{19}F NMR (acetone-d^6): $\delta=-113.96$ [ddd, J(Pt–F^5) = 412, J(F^5–F^4) = 30, J(P–F^5) = 15, J(F^5–F^3) = 3, F^5]; -148.54 [m, F^3]; -164.33 [ddt, J(F^5–F^4) = 30, J(F^4–F^3) = 19, J(P–F^4) = J(F^4–H) = 7, F^4]. ^{31}P NMR (acetone-d^6): $\delta=25.38$ [d, J(Pt–P^A) = 1908, J(P^A–P^B) = 15, P^A]; 26.01 [td, J(Pt–P^A) = 2311, J(P^B–P^A) = J(P^B–F^5) = 15, J(P^B–F^4) = 8, P^B]. *Anal.* Found: C, 61.9; H, 4.3; N, 1.4. Calc. for $C_{51}H_{42}F_3NP_2Pt$: C, 62.32; H, 4.31; N, 1.44%.

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2C_6H_5$)-(dppe)] (**8**) was obtained as a white solid by an analogous procedure using 38 mg (9.5×10^{-5} mol) of dppe. Yield 70 mg (85%). ^{1}H NMR (acetone-d^6): $\delta=$ 0.48 [t, ^2J(Pt–H) = 67, ^3J(P^A–H) = ^3J(P^B–H) = 6, Me^a]; 2.44 [m, H^{f,g}]; 4.36 [s, H^d]; {7.12–7.32 [m], 7.45–7.55 [m], 7.70–7.79 [m], 7.89–7.98 [m], aromatics}; 8.65 [s, H^e]. ^{19}F NMR ($CDCl_3$): $\delta=-114.20$ [dd, J(Pt–F^5) = 385, J(F^5–F^4) = 27, J(P–F^5) = 11, F^5]; -147.38 [m, F^3]; -163.92 [ddt, J(F^5–F^4) = 29, J(F^4–F^3) = 20, J(P–F^4) = J(F^4–H) = 8, F^4]. ^{31}P NMR (acetone-d^6): $\delta=46.58$ [s, J(Pt–P^A) = 1718, P^A]; 47.36 [m, J(Pt–P^B) = 2287, P^B]. *Anal.* Found: C, 57.4; H, 4.4; N, 1.6. Calc. for $C_{41}H_{36}F_3NP_2Pt$: C, 57.48; H, 4.24; N, 1.63%.

Compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2$-NMe_2)(dppe)] (**9**) was obtained as a white solid by an analogous procedure from 50 mg (1.14×10^{-4} mol) of the compound [PtMe(3,4,5-$C_6HF_3CH{=}NCH_2CH_2$-NMe_2)] and 45 mg of dppe. Yield 80 mg (84%). ^{1}H NMR (acetone-d^6): $\delta=0.46$ [t, ^2J(Pt–H) = 68, ^3J(P^A–H) = ^3J(P^B–H) = 7, Me^a]; 2.15 [s, Me^g]; {2.20–2.45 [m], 3.26 [t, J(H–H) = 7, H^{d,f,h,i}} 7.14–7.76 [m, aromatics]; 8.52 [s, H^e]. ^{19}F NMR ($CDCl_3$): $\delta=-109.17$ [dd, J(Pt–F^5) = 390, J(F^5–F^4) = 30, J(P–F^5) = 16, F^5]; -144.31 [m, F^3]; -161.64 [m, F^4]. ^{31}P NMR (acetone-d^6): $\delta=46.37$ [s, J(Pt–P^A) = 1718, P^A]; 47.27 [dd, J(Pt–P^B) = 2274, J(P^B–F^5) = 16, J(P^B–F^4) = 8, P^B]. $\Lambda_M=2.3\ \Omega^{-1}\ cm^2\ mol^{-1}$ (10^{-3} M in acetone). *Anal.* Found: C, 53.9; H, 4.7; N, 3.2. 3.2. X-ray structure analysis: data collection

A prismatic crystal ($0.1 \times 0.1 \times 0.2$ mm) was selected and mounted on a MAR345 diffractometer with an image plate detector. Unit cell parameters were determined from automatic centring of 6890 reflections ($3 < \theta < 31°$) and refined by least-squares method. Intensities were collected with graphite monochromatized Mo Kα radiation. 7346 reflections were measured in the range $2.37 < \theta < 24.95°$, 4108 of which were non-equivalent by symmetry (R_{int} (on I) = 0.021). A total of 3820 reflections were assumed as observed applying the condition $I > 2\sigma(I)$. Lorentz polarisation and absorption corrections were made.

3.3. Structure solution and refinement

The structure was solved by direct methods, using SHELXS computer program [24], and refined by the full-matrix least-squares method, with the SHELXL-97 computer program [25] using 4108 reflections (very negative intensities were not assumed). The function minimised was $\Sigma\, w||F_o|^2 - |F_c|^2|^2$, where $w = [\sigma^2(I) + (0.0374P)^2 + 3.1998P]^{-1}$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. f, f' and f'' were taken from the International Tables of X-ray Crystallography [24]. 20 H were located from a difference synthesis and refined with an overall isotropic temperature factor and 7 H atoms were computed and refined, using a riding model, with an isotropic temperature factor equal to 1.2 times the equivalent temperature factor of the atom to which they are linked. Further details are given in Table 2.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC No. 167426. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Phthalocyanines are established gas sensitive materials. We have successfully recorded backscatter conversion electron Mössbauer spectra (CEMS) of iron(II) phthalocyanine. Further, we have shown that the introduction of nitrogen dioxide, a typical analyte for these materials, into the detector system can be achieved without deleterious effects. The method allows surface sensitive spectra of these materials to be recorded under normal sensor operating conditions of temperature and pressure. The high vacuum conditions of other surface sensitive techniques used to study materials of this type are not required by this method.

Keywords: Iron(II) phthalocyanine; Backscatter Mössbauer spectroscopy; Gas sensing

1. Introduction

Phthalocyanines are well-known for their gas sensing properties [1–5]. When electron acceptor gases such as NO_2 interact with solid organic or organometallic compounds with delocalised π-electron systems, charge transfer between the solid and the absorbed gas is believed to lead to charge-carrier generation and large increases in electrical conductivity. Metal phthalocyanines have a high chemical and physical stability and show large conductivity increases which allow electrophilic gases such as NO_2 to be detected in the parts per million (ppm) range. However, the exact mechanisms for the gas sensing actions are not well understood [6] and hence our interest in iron(II) phthalocyanine (FePc) as a model system which can be studied by Fe-57 Mössbauer spectroscopy. Although iron phthalocyanine is not an optimised gas sensor it nevertheless has gas sensing properties which are typical of metal phthalocyanines. It exhibits polymorphism due to relatively weak intermolecular forces allowing a variety of stacking arrangements. In the α-form iron lies at the centre of a square of four nitrogen atoms coordinated to the metal whereas in the β-polymorph there are additionally two other longer nitrogen bonds in the octahedral positions from neighbouring molecules [7,8]. Transmission Mössbauer and variable temperature studies of the α- and β-phases of FePc have been reported elsewhere [9]. This paper presents the results from a series of backscatter conversion electron Mössbauer spectroscopy (CEMS) experiments, designed to observe in-vitro behaviour of the surface of a sample of iron(II) phthalocyanine when exposed to reactive gases.

2. Experimental

Crude FePc has been prepared in the laboratory based on the method of Tomoda et al. [10] by the

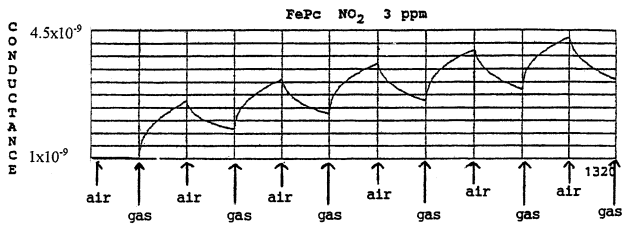

Fig. 1. Conductance response of FePc to 3 ppm NO_2.

reaction of iodine and iron powder in ethanol, followed by the addition of a mixture of phthalonitrile and 1,5-diazabicyclo[4,3,0]non-5-ene. The α-FePc phase was prepared by vacuum sublimation onto a water-cooled finger[8]. The β-FePc phase was isolated as purple needle-like crystals from crude FePc by entrainer sublimation [11]. The response of FePc to NO_2 was verified using a conventional interdigitated electrode. The sensor consisted of a 3 mm × 3 mm × 0.5 mm alumina substrate with an electrode pattern on one side and a platinum heater on the other. Approximately 500 nm films of FePc were vacuum sublimed onto the interdigitated electrode pattern. The sensor was exposed to two minutes of air, followed by two minutes of gas and this sequence repeated. The results of gas exposure were plotted as conductance against time during cyclic exposure to air and gas with typical results shown in Fig. 1.

3. Mössbauer spectroscopy

Conventional transmission Mössbauer spectra have been recorded for both phases and the experimental arrangement, computer fitting strategies and results have been previously reported [9]. Backscatter Mössbauer spectroscopy can be performed following the resonant absorption of the 14.4 keV γ-ray by an Fe-57 nucleus by either detecting the re-emitted 14.4 keV γ-ray photon, or the 6.3 keV X-ray photon (conversion X-ray Mössbauer spectroscopy (CXMS)), or from the internal conversion at 7.3 keV or by detecting the associated KLL Auger electrons at 5.3 keV (CEMS), all of which result from the decay of the $I = \pm 3/2$ excited iron nucleus. The backscatter radiations are detected as a function of the conventional Doppler velocity to enable hyperfine interactions to be studied. Of particular interest in this work is the relative surface sensitivities of CXMS and CEMS and the detector design which enables in-vitro gas sensing experiments to be designed. Krakowski and Miller [12] have estimated theoretically that 65% of the 7.3 keV conversion electrons detected (from iron) would have arisen from within 45 nm of the surface. However, Swanson and Spijkerman have shown experimentally that 65% originate within 60 nm and 95% within 300 nm of the surface [13]. Detection of the conversion electrons therefore yields chemical information which is extremely surface sensitive (≤ 0.3 μm). Conversion X-rays have a much greater penetration depth ($\sim$ 10 μm) and yield chemical information which is characteristic of the near surface region.

The detector used for the backscatter experiments was a gas flow proportional counter where the sample material (fluorescor) was mounted inside the chamber behind the HT wire of the counter (Fig. 2). An informed choice of gas mixture in the detector allows the preferential detection of either the conversion electron or X-ray. Thus, a gas mixture of helium 95% and methane 5% was used for CEMS and argon 95%/methane 5% for CXMS. The gas flow detector was chosen in preference to the channeltron, which has a superior signal to noise performance but which operates under high vacuum, because it offered the potential for introducing reactive gas into the detector while recording a Mössbauer spectrum and thus mimicked sensor operating conditions. The aim of the experiment was to place an FePc sample in the backscatter detector and to allow NO_2 to flow through the detector so that in-vitro spectra could be accumulated before, during and after exposure to NO_2. The experiments were carried out at ambient temperature and pressure, normal gas sensor operating conditions. Cylinders containing 90 ppm NO_2 normally contain oxygen to prevent dissociation. However, the presence of oxygen would oxidize the anode wire in the CEMS detector and so was removed and replaced with helium which is the normal ionizing gas in the chamber. To ensure that dissociation had not occurred, tests using Drager tubes confirmed NO_2 in the range 80–90 ppm. A simple gas flow arrangement as shown in Fig. 3 combined the diluted reactive gas with the conventional ionization sensing gas to create within the detector 15-20 ppm of NO_2. Once conditions had stabilised, a backscatter Mössbauer spectrum was accumulated in the conventional way.

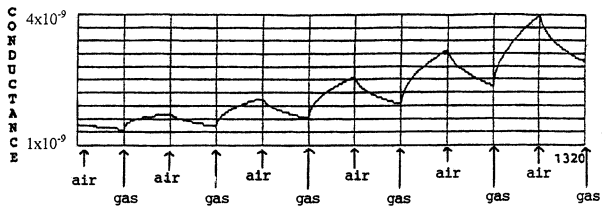

Fig. 4. Change in conductivity of FePc during exposure in 2 min intervals to 1–5 ppm NO_2.

4. Results and discussions

4.1. Gas sensing

The α-FePc film was exposed to 1–5 ppm NO_2, 3 ppm NO_2 and 5 ppm NO_2, diluted down from 90 ppm by mass flow controllers to show that the film would act as a sensor and to determine appropriate gas concentration levels. Fig. 4 shows the exposure to 1–5 ppm NO_2. The observed response is fast and approximately exponential and conductivity increases with increasing concentration of NO_2. The recovery is also fast but not to the original starting point with a gradual increase in the baseline with continued cyclic exposure. This response is characteristic of all metal phthalocyanines which behave as p-type semiconductors when exposed to electron acceptor gases [14].

4.2. Mössbauer spectroscopy

Previously published variable temperature studies ([9] and references therein) have shown that the α-FePc has a Debye temperature, θ_D of 143 K and a recoil free fraction at room temperature f_{300} of 0.14. The corresponding results for β-FePc are $\theta_D = 199$ K and $f_{300} = 0.36$. The starting point for a series of backscatter experiments was to record the spectra from the mixed phase FePc powder which was pressed onto double-sided sellotape to form a sample within the detector.

A similar CEMS backscatter spectrum was obtained for the purified β-phase as shown in Fig. 5. An attempt was made to obtain a backscatter spectrum from the α-phase but no emission could be detected after 6 days of accumulation. This in part can be explained by the low recoil free fraction of the α-phase. The fitting parameters for the backscatter spectra are compared to transmission parameters in Table 1.

To investigate the effect on the anode wire, the NO_2 flow experiment was repeated with a stainless steel sample. Identical spectra were recorded with and without NO_2 confirming that the operation of the detector is not affected by the NO_2. Transmission spectra were recorded of β-FePc and powder which had been exposed to 90 ppm NO_2 for 48 h. Identical spectra were recorded indicating that NO_2 had not chemically reacted with the bulk β-FePc.

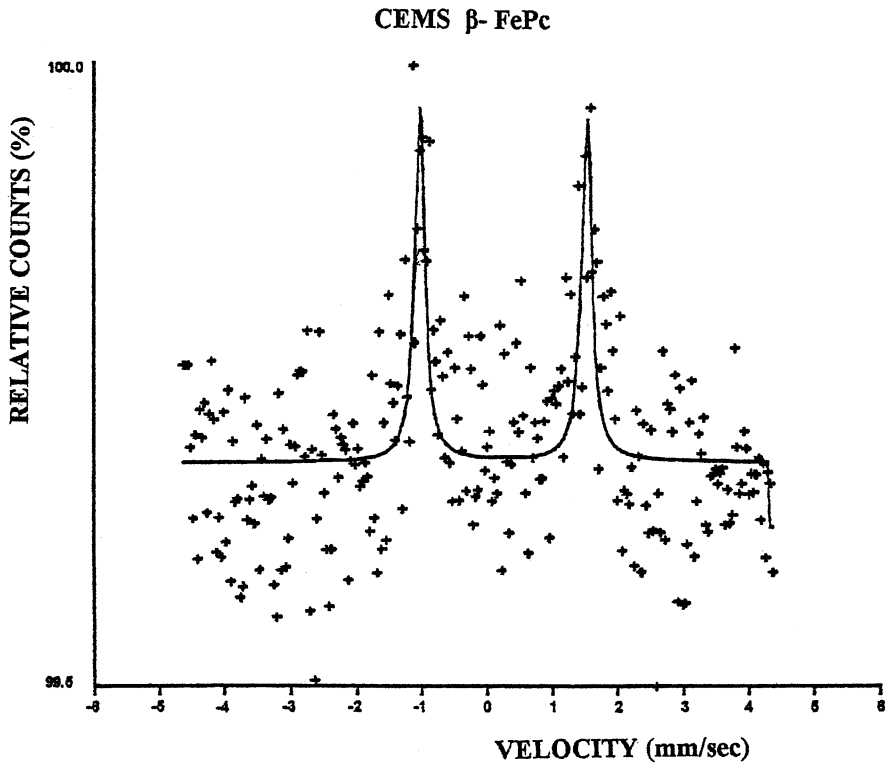

Fig. 5. CEMS Mössbauer spectrum of β-FePc.

Table 1
CEMS and transmission Mössbauer parameters of FePc

Sample	Isomer shift ± 0.02 mm s^{-1} (αFe)	Quadrupole split ± 0.02 mm s^{-1}
CEMS Crude FePc RT	0.39	2.61
Transmission-α RT	0.35	2.39
Transmission-β RT	0.37	2.53
CEMS β-FePc	0.37	2.56

Thus, we have demonstrated the ability to record backscatter spectra at ambient temperatures and pressure. We have also confirmed that the sample gas, NO_2 can be introduced to the backscatter detector with no deleterious effect on its operation. We now propose to collect backscatter spectra, CEMS and CXMS, in an attempt to elucidate the interaction between the sample gas and the phthalocyanine. Initial experiments suggest that long collection times are required and this may in part be due to adsorption of NO_2 on the FePc surface, and other surface characterisation techniques will be used to explore this possibility. ^{57}Fe enriched FePc might also be used and this might also allow spectra from β-FePc to be collected.

Determining substrate selectivity and regiochemistry of nitrilium phosphanylid tungsten complexes in cycloaddition reactions with terminal alkynes

Rainer Streubel *, Nils Hoffmann, Frank Ruthe, Peter G. Jones

Institut für Anorganische und Analytische Chemie der Technischen Universität Braunschweig, PO Box 3329, D-38023 Braunschweig, Germany

Received 3 August 2001; accepted 5 October 2001

Dedicated to Professor Kurt Dehnicke on the occasion of his 70th birthday

Abstract

Here we report reactions of intermediate nitrilium phosphanylid complexes, formed via reactions of a 2*H*-azaphosphirene complex, and 2-furanocarbonitrile, 2-thiopheno-carbonitrile or 2-cyano-1,5-dimethyl-pyrrole, and different alkynes. These examples show the dependencies of substrate selectivity and regiochemistry of this new reactive intermediate. Furthermore, we report on an unusual ^{13}C NMR coupling phenomena within the 2*H*-1,2-azaphosphole ring. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: P-Ligands; 2*H*-Azaphosphirene complexes; 2*H*-1,2-Azaphosphole complexes; Cyclisation; 1,3-Dipoles

1. Introduction

Recently, we developed the generation and trapping of the transient nitrilium phosphanylid complexes **II** as a novel and highly efficient synthesis of five-membered P-heterocycle complexes. Such intermediates are usually generated via thermal ring opening of 2*H*-azaphosphirene complexes **I** [1] or, more recently, via decomposition of 7-phosphanorbornadiene complexes **III** [2] in the presence of nitriles. Intermediates **II** can be trapped with a wide variety of different π-systems such as alkynes, [3] nitriles [4] and phosphaalkynes [5] to give complexes **IV** (Scheme 1). Furthermore, we showed that, in the case of complexes **I**, formal nitrile–nitrile exchange reactions of **II** occurred intermediately via [1 + 1]-addition of transiently formed terminal phosphanediyl complexes with a nitrile (*transylidation reactions*), thus offering novel applications of this method in heterocyclic synthesis [6].

Although we recently reported on trapping reactions of derivatives of **II** with various alkynes in some detail, the regiochemistry of **II** in [3 + 2]-cycloaddition reactions with acetylene ethylcarboxylate was only deduced from ^{13}C NMR spectroscopic data of the 2*H*-1,2-azaphosphole complexes thus obtained [6]. It is noteworthy that the metal complex fragment of the 2*H*-azaphosphirene complexes played an important role in such three-component reactions [6]. Whereas reactions of 2*H*-azaphosphirene chromium and tungsten complexes are in general selective, the analogous reactions of molybdenum are not and, furthermore, the products displayed lower stabilities towards chromatographic work-up procedures. We also showed that the reaction courses significantly depended on the alkyne substituents, thus leading to 2*H*-1,2-azaphosphole complexes if the employed alkyne has electron-withdrawing groups as substituents, as in dimethyl acetylenedicarboxylate or ethyl acetylenecarboxylate [6].

Since our interest in exploiting this three-component reaction methodology, we have started a new series of reactions using hetarene-substituted nitriles. Here we report first reactions using the 2*H*-azaphosphirene tungsten complex **1**, 2-furanonitrile (**2a**), 2-thiophenonitrile (**2b**) and 2-cyano-1,5-dimethyl-pyrrole (**2c**) as nitrile components and phenylacetylene (**3a**),

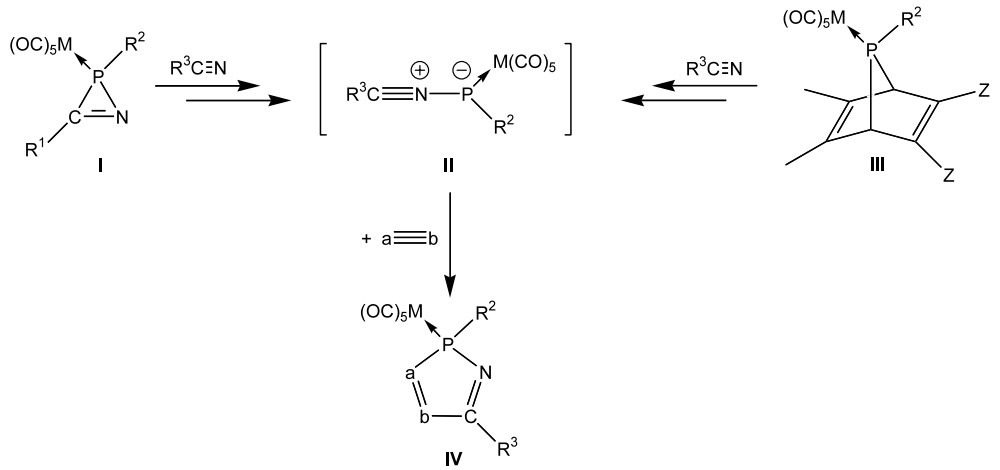
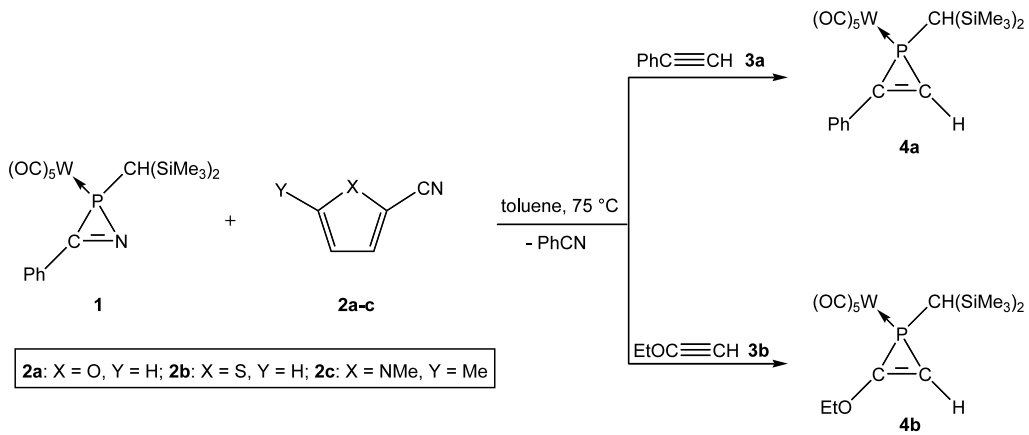
ethoxyacetylene (**3b**), acetylene ethylcarboxylate (**3c**) as trapping reagents.



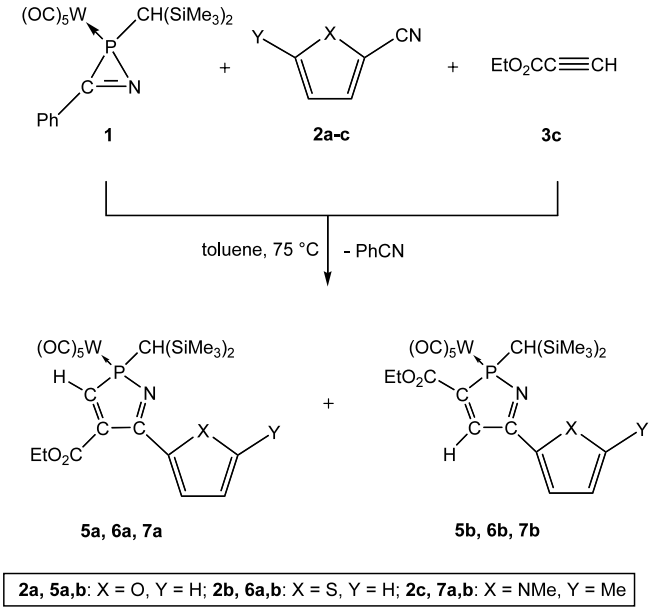
2. Results

Reactions of the 2*H*-azaphosphirene tungsten complex **1** [7] with the nitriles **2a**–**c** and phenylacetylene (**3a**) furnished exclusively the 1*H*-phosphirene complex **4a** [8] as the only phosphorus-containing product, which was readily identified by ^{31}P NMR spectroscopy (Scheme 2).



Using complex **1**, nitriles **2a**–**c** and ethoxyacetylene (**3b**), having an electron-donating group, the reactions afforded selectively the 1*H*-phosphirene complex **4b**; [9] neither was evidence for 2*H*-1,2-azaphosphole complex formation obtained in this case (Scheme 2).

The three-component reactions of complex **1**, nitriles **2a**–**c** and ethyl acetylenecarboxylate (**3c**) led to the formation of the regioisomeric 2*H*-1,2-azaphosphole complexes **5a**,**b** (ratio 3:1), **6a**,**b** (ratio 5:1) and **7a**,**b** (ratio 8:1) (Scheme 3); formation of a 1*H*-phosphirene complex was not observed in these reactions. Selected NMR data are given in Table 1. Whereas the 2*H*-1,2-azaphosphole complexes **5a**,**b** and **7a** were obtained in pure form, the derivatives **6a**,**b** were characterized as mixtures. Complex **7b** could not be characterized, because of the very low amounts formed; nevertheless, its identity can be deduced from its ^{31}P NMR spectrum.



In all cases, the 4-ethoxycarbonyl-substituted 2*H*-1,2-azaphosphole complexes **5a**, **6a** and **7a** were formed predominantly, as established unambiguously by the X-ray structure analysis of the 2*H*-1,2-azaphosphole complex **7a**. The outcome of these reactions was completely unexpected, especially with regard to the ^{13}C NMR data of the regioisomeric 2*H*-1,2-azaphosphole complexes. The 4-ethoxy-carbonyl-substituted 2*H*-1,2-azaphosphole complex **7a** showed a greater phosphorus-coupling constant magnitude for the C^4-atom than for the C^3-atom of the 2*H*-1,2-azaphosphole ring, which was unambiguously shown through DEPT-NMR experiments. Assuming that there are no other contributions than through-bond couplings in this ring system, this would mean that the $|^{(1+4)}J(P,C^3)|$-value is

Scheme 1. 2*H*-azaphosphirene complexes **I**, 7-phosphanorbornadiene complexes **II**, nitrilium phosphanylid complexes **III** and phosphorus heterocycles **IV** (**I**–**IV**, R^1–R^3 = organic substituents).

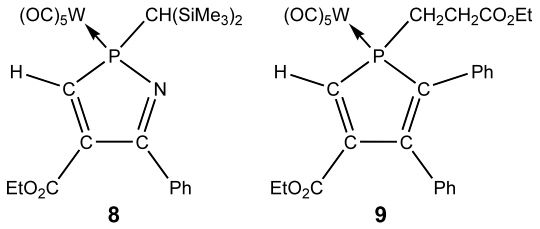

Fig. 1. Comparison of related 2*H*-1,2-azaphosphole and phosphole complexes.

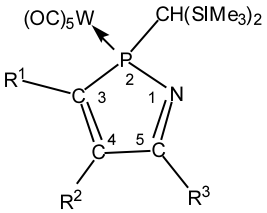

Table 2
Selected bond lengths in Å for compound **7a**

Bond	Compound **7a**
W–C1	2.009 (3)
W–P	2.5098(6)
P–C13	1.807(2)
P–N1	1.7042(19)
C13–C14	1.337(3)
N1–C15	1.312(3)
C14–C15	1.503(3)
C15–C20	1.439(3)

smaller than the $|^{(2+3)}J(P,C^4)|$-value, which is completely counterintuitive! Remarkable are also the significantly different $|^2J(P,H)|$- and $|^3J(P,H)|$-values determined by ^{1}H NMR spectroscopy, which therefore also provide structural information concerning the regioisomerism of complexes **5**–**7**. A comparison of the ^{1}H NMR data of complexes **6a**, **8** [10] and **9** [11] shows $|^2J(P,H)|$-values of 31.8 Hz (**6a**), 32.7 Hz [10] (**8**) and 33.3 Hz [11] (**9**) as the most valuable information; this is especially the case if the derivatives are closely related with respect to the nature of the substituents at C^4 and C^5 (Fig. 1). All other NMR and analytical data of the complexes **5a**,**b**, **6a**,**b** and **7a** are in agreement with the proposed structures.

The molecular structure of the diethyl ether solvate of complex **7a** (Fig. 2) shows bond lengths in the 2*H*-1,2-azaphosphole ring, which are typical for localized C_{sp^2}=C_{sp^2} (1.337(3) Å) [12] and N_{sp^2}=C_{sp^2} (1.312(3) Å) [12] double-bonds and are close to the values observed for {pentacarbonyl[2-bis(trimethylsilyl)methyl-4-ethoxycarbonyl-5-phenyl-2*H*-1,2-azaphosphol-κ*P*]-tungsten(0)} [6] (Table 2). The interplanar angle in **7a** of 14.8° should enable only weak, if any, electronic interactions between the two ring systems.

3. Conclusions

These results provide new insights into substrate selectivity and the regiochemistry of nitrilium phosphanylid complexes **II** in [3 + 2]-cycloaddition reactions. Concerning the substrate selectivity this can understood in terms of favored reactions of intermediately formed terminal phosphanediyl complexes **I**, which are in some kind of equilibrium with nitrilium phosphanylid complexes **II**, with electron-rich alkynes and disfavored reactions of **I** with electron-poor alkynes. Regarding our earlier assignments cf. [6,10] of the ^{13}C NMR data of ethoxycarbonyl-substituted 2*H*-1,2-azaphosphole complexes and the associated regio-chemistry of **II** this means that they were most probably erroneous.

As we already pointed out for HOMO-dipole LUMO-dipolarophile-directed reactions of derivatives of **II** with nitriles [4], the reactions are regioselective, but in contrast to our former conclusions, the selectivity seems to be mainly determined by steric rather than electronic factors. This would also explain the formerly observed lower regioselectivity of C-phenyl-substituted nitrilium phosphanylid complexes, cf. [4]. New findings obtained very recently from reactions of derivatives of **II** with a *P*-chloro phosphaalkene [13] also substantiate this new conclusion.

The concertedness of [3 + 2]-cycloaddition reactions of nitrilium phosphanylid complexes will be subject of further investigations.

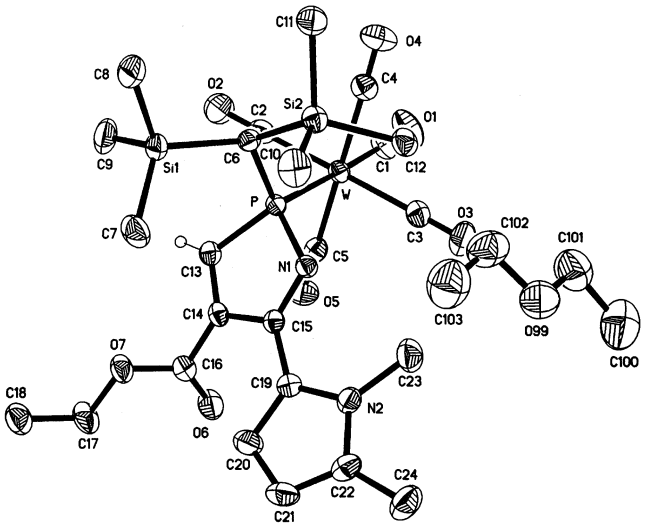

Fig. 2. Molecular structure of **7a** in the crystal. Ellipsoids represent 50% probability levels; hydrogen atoms, except for C(13)–H are omitted for clarity. Selected bond lengths (Å) and angles (°): W–C(1) 2.009(3), W–P 2.5098(6), P–N(1) 1.7042(19), P–C(13) 1.807(2), N(1)–C(15) 1.312(3), C(13)–C(14) 1.337(3), N(2)–C(19) 1.393(3); C(1)–W–P 178.19(9), W–P–C(13) 108.19(8), P–N(1)–C(6) 104.58(10), N(1)–P–C(13) 93.36(10), C(6)–P–W 117.4(8).

4. Experimental

4.1. General procedures

All reactions and manipulations were carried out under an atmosphere of deoxygenated dry nitrogen, using standard Schlenk techniques with conventional glassware, and solvents were dried according to standard procedures. NMR spectra were recorded on a Bruker AC-200 spectrometer (200 MHz for ^{1}H; 50.3 MHz for ^{13}C; 81.0 MHz for ^{31}P) using [D]chloroform and [D_6]benzene as solvent and internal standard; shifts are given relative to ext. tetra-methylsilane (^{1}H, ^{13}C) and 85% H_3PO_4 (^{31}P). Mass spectra were recorded on a Finigan Mat 8430 (70 eV); apart from *m*/*z*-values of the molecule ions, only *m*/*z*-values having intensities of more than 20% are given. Infrared spectra were recorded on a Biorad FT-IR 165 (selected data given). UV–Vis spectra were recorded on a Hewlett–Packard HP 8452. Melting points were obtained on a Büchi 535 capillary apparatus. Elemental analyses were performed using a Carlo Erba analytical gas chromatograph. The κP-notation in the nomenclature is intended to differentiate between P- and N-coordination of the appropriate heterocycle to the metal.

4.2. General procedure for the preparation of complexes 5–7

To the 2*H*-azaphosphirene complex **1** (0.62 g, 1 mmol), dissolved in 10 ml of toluene, 5 mmol of the nitriles **2a**–**c** and 2 mmol of the alkynes **3a**–**c** were added and, in each case, the solutions were heated at 75 °C for 5 h with slow stirring. Afterwards, all volatile components were removed in vacuo and the products separated by low-temperature column chromatography (SiO_2, −15 °C, 10 × 2 cm, *n*-pentane–diethyl ether 70/30).

4.3. {Pentacarbonyl[2-bis(trimethylsilyl)methyl-4-ethoxycarbonyl-5-(2-furanyl)-2H-1,2-azaphosphole-κP]tungsten(0)} (5a)

8.8 Hz, PC^{3}C), 159.8 (s, PNC^5), 165.8 (d, ^2J(P,C) = 17.5 Hz, CO_2Et), 196.8 (d, ^2J(P,C) = 6.7 Hz, *cis*-CO), 199.3 (d, ^2J(P,C) = 20.8 Hz, *trans*-CO); ^{31}P{^{1}H} NMR ($CDCl_3$) δ 94.8 (s, ^1J(P,W) = 232.4 Hz); UV–Vis (CH_3CN) λ (ln ε) 232 (4.78), 248 (4.58), 270 (4.20), 282 (4.00), 290 (3.91), 374 (4.15); IR (KBr) 2069 (s), 1986 (s), 1976 (s), 1934 (s), 1919 (s) cm^{-1} (CO); 1726 (s) cm^{-1} (CO_2); MS (70 eV, EI, ^{184}W); *m*/*z* 732 (16) [M$^+$], 704 (22) [(M–CO)$^+$], 676 (100) [(M–2CO)$^+$], 648 (48) [(M–3CO)$^+$], 620 (4) [(M–4CO)$^+$], 592 (70) [(M–5CO)$^+$], 517 (12) [(M–5CO–$SiMe_3$)$^+$], 408 (11) [(M–W(CO)$_5$)$^+$], 73 (40) [($SiMe_3$)$^+$]; *Anal.* Calc. for $C_{24}H_{33}N_2O_7PSi_2W$: C, 39.35; H, 4.54; N, 3.82. Found: C, 38.95; H, 4.43; N, 3.67%.

4.8. Crystal structure determination of **7a**·Et_2O, $C_{28}H_{43}N_2O_8PSi_2W$

Crystal data: triclinic, space group $P\bar{1}$, a = 1103.18(12), b = 1125.48(12), c = 1649.94(16) pm, α = 82.051(2), β = 71.975(2), γ = 65.999(2)°, U = 1.7794(3) nm^3, Z = 2, μ = 3.403 mm^{-1}, T = −130 °C. Data collection: a yellow crystal (ca. 0.35 × 0.13 × 0.11 mm) was used to record 29 869 intensities on a Bruker SMART 1000 CCD diffractometer (Mo Kα radiation, $2\theta_{max}$ 60°); 10 717 reflections were independent (R_{int} 0.0566). An absorption correction based on multiple scans was applied, with transmissions 0.72–1.00. Structure refinement: the structure was solved by the heavy-atom method and refined anisotropically on F^2 (program SHELXL-97, G.M. Sheldrick, University of Göttingen) to wR_2 0.0549, R_1 0.0307 for 392 parameters and 200 restraints; S = 0.953, max $\Delta\rho$ 1.178 e Å^{-3}. The hydrogen atoms were included using a riding model or rigid methyl groups, except for H13, which was freely refined.

5. Supplementary material

Atomic coordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Any request to the CCDC for this data should quote the full literature citation and the reference number 163567. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@chemcrys.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 9 April 2001; accepted 9 October 2001

Abstract

A series of new cationic platinum(II) complexes of the type $[Pt(L)(R'R''S)Cl]NO_3$ (where L = homopiperazine or 1-methylhomopiperazine and R′R″S = dimethylsulfide, diethylsulfide, dipropylsulfide, diisopropylsulfide, dibutylsulfide, diphenylsulfide, dibenzylsulfide, methylphenylsulfide, or methyl *p*-tolylsulfide) were synthesized and characterized by elemental analysis and infrared, ^1H and ^{195}Pt nuclear magnetic resonance spectroscopy. Among the complexes synthesized, $[Pt^{II}(homopiperazine)(diphenylsulfide)Cl]NO_3$ was examined by single-crystal X-ray diffraction. The slightly distorted square plane of the platinum complex included the amino groups of the homopiperazine molecule in a *cis* orientation, the sulfur atom of diphenyl sulfide, and a chloride ion. The homopiperazine molecule adopts a boat conformation and forms five- and six-membered chelating rings with platinum. Hydrogen bonding plays an important part in holding the crystal together. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Platinum(II); Homopiperazines; Disubstituted sulfides; Synthesis; Crystal structure

1. Introduction

The wide success of cisplatin in the treatment of a variety of human cancers [1], especially those of the testes, ovaries, head, and neck [2–5], has encouraged the search for new cisplatin derivatives in an effort to improve the therapeutic index of its compounds, which is reduced by dose-limiting toxic effects, namely, nephrotoxicity, myelotoxicity, neurotoxicity, nausea, and vomiting [6,7]. The clinical effectiveness of cisplatin has been improved by replacing the labile chloro ligands with other leaving groups of intermediate lability so as to alter the pharmacokinetics as well as by substituting stable amine ligands with cyclic or acyclic alkylamines [8]. Carboplatin (diammine-1,1-cyclobutanedicarboxylatoplatinum(II) [9,10], one of a number of cisplatin analogs developed in this way, is now used clinically. Many other compounds that have 1,2-diaminocyclohexane as a carrier ligand and chloride or carboxylate ion as a leaving group, such as oxaliplatin (*trans* - l - 1,2 - diaminocyclohexaneoxalatoplatinum(II) and L-NDDP [liposome-entrapped bis(neodecanoato)-(*trans*-1R,2R-diaminocyclohexane)platinum(II)] are now in clinical trials [10–12].

Platinum antitumor complexes like cisplatin and its analogs are neutral complexes that obey the general formula $[cis\text{-}Pt(Am)_2(X)_2]$ in which Am is an amine ligand having at least one NH group and X is a moderately strongly bound anionic leaving group, such as chloride [13,14]. These complexes are bifunctional in nature, which is probably necessary to form an intrastrand cross-link between two adjacent guanine bases in DNA [15,16]. However, two cationic classes of

PII: S0277-5387(01)00967-6

platinum complexes having antitumor properties have been described, both of which are much more soluble in water than the neutral complexes are. Such complexes have the general formula [*cis*-$Pt(NH_3)_2$(N-het)Cl]Cl (N-het = heterocyclic amine) or [Pt(diam)(R′R″SO)Cl]NO_3 (diam = bidentate diamine, R′R″SO = substituted sulfoxide) [17,18]. On the other hand, related monofunctional cationic complexes like [Pt(dien)Cl]Cl and $[Pt(NH_3)_3Cl]Cl$ are antitumor inactive [19,20]. Eventually, compounds having the formula [Pt(diam)-(R′R″SO)Cl]NO_3 or [Pt(diam)Cl_2] will form the same adduct with 5′GMP and d(GpG) [21]. In principle, the same adducts can be expected with DNA, therefore, the mechanisms of action of both types of compounds might well be related to each other but are unlikely to be the same as that of cisplatin [21].

Hollis et al. [17] reported on a series of cationic platinum(II) complexes whose antitumor activity violates some of the rules of classical structure-activity relationships. However researchers have known of cationic diammineplatinum(II) complexes with substituted sulfoxide for the past 2 decades [22,23]. It has been reported that these complexes have antitumor activity in certain tumor models [24,25]. We have been developing platinum complexes with diamines such as diaminocyclohexane as a carrier ligand and disulfides as leaving groups [26]. Complexes containing thioether groups can reduce cisplatin-induced nephrotoxicity when administered simultaneously with cisplatin [27]. Hence we report here the synthesis and characterization of cationic platinum(II) complexes of the type [PtL(R′R″S)Cl]NO_3 along with the crystal structure of [Pt^{II}(homopiperazine)(diphenylsulfide)Cl]NO_3.

2. Experimental

2.1. Chemicals

K_2PtCl_4 was purchased from Johnson Matthey, Seabrook, MA. Homopiperazine, 1-methylhomopiperazine, dimethylsulfide, diethylsulfide, dipropylsulfide, diisopropylsulfide, dibutylsulfide, diphenylsulfide, dibenzylsulfide, methylphenylsulfide, and methyl *p*-tolylsulfide were purchased from Aldrich Chemical Co., Milwaukee, WI. Silver nitrate was obtained from Fisher Scientific Co., Houston, TX. All chemicals obtained from commercial sources were used as supplied.

2.2. Physical measurements

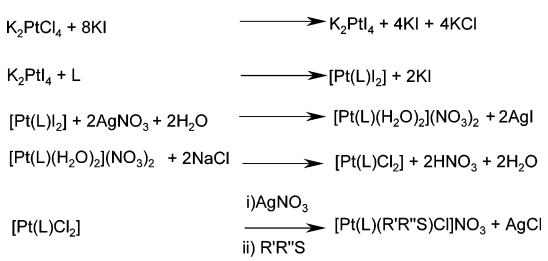
Elemental analyses of the complexes were performed by Robertson Laboratory Inc., Madison, NJ. Infrared (IR) spectra in the range of 600–4000 cm^{-1} and far-IR spectra in the range of 150–600 cm^{-1} were recorded in KBr and polyethylene pellets, respectively, on a Perkin–Elmer 2000 spectrophotometer. ^1H nuclear magnetic resonance (NMR) spectra in MeOH-d_4 and ^{195}Pt NMR spectra in methanol were recorded using a Bruker Advance 300 spectrometer. ^1H spectra were recorded with a 5-mm tunable probe at 300.13 MHz, ^{195}Pt spectra were recorded at 43.055 MHz, and the shifts were measured relative to an external standard of 2.2 M Na_2PtCl_6 in D_2O at 0.00 ppm.

2.3. Preparation of {Pt(hpip)[$(CH_3)_2S$]Cl}NO_3 (hpip = homopiperazine) (complex **1**)

K_2PtCl_4 (20.76 g, 50 mmol) was dissolved in 250 ml of deionized water and filtered. KI (83.0 g, 0.5 mol) in 100 ml of water was added to it, and the reaction mixture was stirred for 10 min. Next, homopiperazine (8.5 g, 100 mmol) was added dropwise to the mixture while stirring to obtain a yellow precipitate of [Pt(hpip)I_2]. The stirring was continued for a further 30 min, and the precipitate was then collected by filtration. This compound was stirred in 100 ml of dimethylformamide, filtered, washed with water, ethanol, and acetone, and dried under vacuum (yield, 95%). [Pt(hpip)I_2] (12.38 g, 20 mmol) was suspended in an aqueous solution of silver nitrate (6.72 g, 39.8 mmol) in 250 mL of water. The reaction mixture was stirred for 24 h at room temperature (r.t.) in the dark. The AgI precipitate was filtered off, and a solution of NaCl was added dropwise to the filtrate with constant stirring until a yellow precipitate of [Pt(hpip)Cl_2] formed. The precipitate was filtered and recrystallized from dimethylformamide. The yellow crystals obtained were washed with water and acetone and dried under vacuum (yield, 75%). An equivalent amount of $AgNO_3$ (0.338 g, 2 mmol) dissolved in 100 ml of hot methanol was added to a slurry of [Pt(hpip)Cl_2] (0.872 g, 2 mmol) in 100 ml of methanol. An equivalent amount of dimethylsulfide (0.15 mg, 2 mmol) in 20 ml of methanol was added to this mixture. The reaction mixture was then stirred overnight in the dark. The AgCl precipitate was filtered off and the filtrate was evaporated to dryness under reduced pressure. A yellow solid was obtained, which was recrystallized from methanol and ether. Finally, the light yellow compound, [Pt(hpip)$(CH_3)_2S$)Cl]NO_3, was obtained, which was then dried under vacuum (yield, 70%).

Complexes **2**–**18** (Table 2) were prepared in a similar manner.

Complex **11** [Pt^{II}(hpip)(diphenylsulfide)Cl]NO_3 (100 mg) was dissolved in 100 ml of methanol, after which the volume of the solution was reduced to 50 ml and filtered. The filtrate was allowed to evaporate slowly at r.t. Within 2 weeks, colorless needle-shaped crystals were separated from the solution, which were used for X-ray crystallography.



2.4. Single crystal X-ray crystallographic study

The experimental details of the X-ray data collection, the structure solution and refinement of the title compound are compiled in Table 1. A single crystal of [Pt^{II}(homopiperazine)(diphenylsulfide)Cl]NO_3 was coated with a thin layer of epoxy cement and glued to the end of a glass fiber. The fiber was mounted on the goniometer of a Bruker SMART 1K diffractometer equipped with a CCD area detector at 298 K. The orientation matrix and all data were collected at this temperature. The diffractometer is equipped with graphite monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å) and the data was corrected for Lorentz and polarization effects. Absorption correction was applied using the program SADABS [28]. No appreciable decay of the crystal was detected during data collection.

Table 1
Crystal data and structure refinement for [Pt^{II}(homopiperazine)-(diphenylsulfide)Cl]NO_3

Empirical formula	$C_{17}H_{20}ClN_3O_3PtS$
Formula weight	576.96
Temperature (K)	293(2)
Wavelength (Å)	0.71073
Crystal system	monoclinic
Space group	$P2_1/c$
Unit cell dimensions

Absorption coefficient (mm^{-1})	7.546
$F(000)$	1112
Crystal size (mm)	$0.318 \times 0.242 \times 0.163$
θ Range for data collection (°)	1.17–23.33
Limiting indices	$-19 \le h \le 17$, $-9 \le k \le 9$, $-12 \le l \le 13$
Reflections collected	8122
Independent reflections	2740 ($R_{int} = 0.0785$)
Refinement method	Full-matrix least-squares on F^2
Data/restraints/parameters	2740/0/235
Goodness-of-fit on F^2	1.057
Final R indices [$I > 2\sigma(I)$] [a]	$R_1 = 0.0400$, $wR_2 = 0.1035$
R indices (all data)	$R_1 = 0.0416$, $wR_2 = 0.1110$
Largest difference peak and hole (e Å^{-3})	1.865 and −1.319

[a] $R_1 = \Sigma||F_o|-|F_c||/\Sigma|F_o|$. $R_w = [\Sigma\, w(F_o^2-F_c^2)^2]/\Sigma[w(F_o^2)^2]^{1/2}$. $w = [\sigma^2(F_o^2)+(0.0833P)^2]^{-1}$. $P = (F_o^2+2F_c^2)/3$. $a = 0.0833$, $b = 0$.

Scheme 1.

The structure was solved using direct methods with the SHELXTL software package [28]. Scattering factors were taken from the literature [29]. Heavy atoms were located initially to set the correct phases for the model. All other atoms were located by successive Fourier maps and were refined using the full-matrix least-squares method on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions ($d_{C-H} = 0.96$ Å) and allowed to ride on the adjacent carbon atom. Refinement of positional and anisotropic parameters led to convergence.

3. Results and discussion

3.1. Synthesis of platinum complexes

The procedure used in the synthesis of complexes is shown in Scheme 1. [$PtLCl_2$] was prepared according to the method described by Dhara [30], which was adopted because it is rapid and easy and provides a much higher yield than when K_2PtCl_4 is treated directly with homopiperazines. K_2PtCl_4 mixed with an excess of KI produced K_2PtI_4 in solution. K_2PtI_4 was then reacted with one equivalent of hpip or mhpip (1-methylhomopiperazine) to precipitate [$PtLI_2$]. The reaction of [$PtLI_2$] with $AgNO_3$ led to the formation of [$PtL(H_2O)_2$]$(NO_3)_2$ in solution, which was further converted to [$Pt^{II}LCl_2$] by treating it with a NaCl solution. Finally [$Pt^{II}(L)Cl_2$] was reacted with one equivalent of $AgNO_3$ and subsequently with thioethers to form the required compounds of the type [Pt(L)(R′R″S)Cl]NO_3 in solution, while the insoluble AgCl was separated by filtration. The yellow solid [Pt(L)(R′R″S)Cl]NO_3 was obtained [26] upon removal of the solvent.

3.2. Characterization of platinum complexes

The complexes were characterized by elemental analysis and IR, ^{1}H NMR, and ^{195}Pt NMR spectroscopy. The composition of each complex as determined by elemental analysis showed good agreement between the theoretical and actual values. The analytical results are summarized in Table 2. The results of characterization by IR and ^{195}Pt NMR are shown in Table 3.

The IR spectra of the complexes in general showed a broad absorption between 3204 and 3009 cm^{-1}, which was due to the ν_{N-H} stretching vibrations of coordinated homopiperazine and 1-methylhomopiperazine. The intense band observed in the region 1331–1385 cm^{-1} was due to the ν_{S-C} stretching vibrations in all the complexes [31–33]. The ν_{Pt-S} stretching vibrations

Table 2
Elemental analysis of $[Pt^{II}(L)(R'R''S)Cl]NO_3$

Complex	Complex name	Observed (calculated)		
		C (%)	H (%)	N (%)
1	$[Pt^{II}$(hpip)(dimethylsulfide)Cl$]NO_3$	18.50 (18.72)	3.94 (4.01)	9.20 (9.36)

7	$[Pt^{II}$(hpip)(diisopropylsulfide)Cl$]NO_3$	25.56 (25.85)	5.05 (5.09)	8.29 (8.22)
8	$[Pt^{II}$(1-mhpip)(diisopropylsulfide)Cl$]NO_3$	27.31 (27.47)	5.03 (5.38)	8.20 (8.01)
9	$[Pt^{II}$(hpip)(dibutylsulfide)Cl$]NO_3$	29.01 (31.41)	5.55 (6.04)	7.77 (6.04)
10	$[Pt^{II}$(hpip)(dibutylsulfide)Cl$]NO_3$	30.09 (30.41)	5.84 (5.83)	7.55 (7.60)
11	$[Pt^{II}$(hpip)(diphenylsulfide)Cl$]NO_3$	35.02 (35.26)	3.92 (3.80)	7.37 (7.26)
12	$[Pt^{II}$(1-mhpip)(diphenylsulfide)Cl$]NO_3$	36.76 (36.46)	4.14 (4.08)	7.08 (7.09)
13	$[Pt^{II}$(hpip)(dibenzylsulfide)Cl$]NO_3$	37.74 (37.59)	4.28 (4.14)	6.92 (6.80)
14	$[Pt^{II}$(1-mhpip)(dibenzylsulfide)Cl$]NO_3$	38.58 (38.68)	4.57 (4.54)	6.68 (6.77)
15	$[Pt^{II}$(hpip)(methylphenylsulfide)Cl$]NO_3$	27.86 (27.87)	3.87 (3.87)	8.13 (8.06)
16	$[Pt^{II}$(1-mhpip)(methylphenylsulfide)Cl$]NO_3$	29.69 (29.41)	4.20 (4.18)	7.77 (7.92)
17	$[Pt^{II}$(hpip)(methyl *p*-tolylsulfide)Cl$]NO_3$	30.02 (29.40)	4.24 (4.14)	7.82 (7.91)
18	$[Pt^{II}$(1-mhpip)(methyl *p*-tolylsulfide)Cl$]NO_3$	30.69 (30.87)	4.41 (4.44)	7.62 (7.72)

L = homopiperazine (hpip) or 1-methylhomopiperazine (1-mhpip).

were observed around 350–400 cm^{-1}, which were close to the values reported for such compounds [26,27,34,35]. The absorption for ν_{Pt-Cl} stretching vibrations were seen around 300 cm^{-1} [26,27,36].

The ^1H NMR spectra, which are shown in Table 4, were most informative with respect to the structures of the complexes. Platinum coordination at S atom of substituted disulfides in all complexes leads a downfield shift of S–CH protons relative to the free ligands. Hence, evidence of ^1H NMR spectra suggests the coordination of platinum(II) with sulfur atom.

The ^{195}Pt NMR data shown in Table 3 further confirmed the structures of these platinum complexes. The singlet observed in the range of -3178 to -3415 ppm indicated the coordination of amino nitrogens of homopiperazine, and 1-methylhomopiperazine to the two adjacent corners of square planar platinum(II), while the other two positions were bound to the chloride and sulfur atoms of the thioether group. Such chemical shifts are characteristic for the square planar platinum(II) complexes in which platinum(II) is bound by two nitrogen atoms, one sulfur atom, and one chlorine atom [26,27,37]. Fig. 1 shows the general structure of the complexes.

3.3. Crystal structure

Fig. 2 shows a view of the crystal structure of $[Pt^{II}$(hpip)(diphenylsulfide)Cl$]NO_3$. Selected bond lengths and bond angles are given in Table 5. In this molecule, the coordination environment around the platinum atom is a slightly distorted square planar one, with the angles ranging from 77.1(2) to 96.69(6)°. The distortion is caused by limitation in the bite distances of the chelating ligand.

In the platinum square plane, two adjacent corners are occupied by the two nitrogen atoms of the homopiperazine ligand, whereas the remaining two *cis* positions are coordinated with one chloride ion and one sulfur atom of the diphenylsulfide. All Pt–N, Pt–Cl, and Pt–S bond lengths are in the range normally

Chemical shift in ppm; ^{1}H NMR spectra were recorded in deuterated methanol. s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet.

observed for platinum(II) complexes. The average Pt–N bond length of 2.041(5) Å is consistent with those found in homopiperazine containing complexes. For instance, this length is 2.02(10) Å in [Pt^{II}(hpip)-(pentadecanoate)$_2$] [38], 1.99(2) Å in Pt^{II}(1-methylhomopiperazine)(methylmalonato)]·$2H_2O$ [34], and 2.027(6) Å in [Pt^{II}(hpip)Cl_2] [39]. The Pt(1)–Cl(1) bond length of 2.3021(17) Å is normal as compared with the values observed in other Pt(II) dichloride complexes, e.g. 2.309 (2) Å in [Pt^{II}(hpip)Cl_2] [39] and 2.315(2) Å in [Pt(piperidine)Cl_2]·H_2O [40]. The Pt–S bond distance of 2.284(15) Å is not significantly different from the 2.279(7) Å observed in the sulfide complex [Pt(μ-SC_5H_9NM)Br [41].

Homopiperazine is in boat conformation and forms five- and six-membered chelating rings with platinum. The coordination structure of platinum with two ring nitrogens of homopiperazine is considerably strained, and the N(1)–Pt(1)–N(2) bond angle is contracted to 77.1(2)° due to geometric constraints imposed by the ligand. This angle is close to that reported for [Pt^{II}(hpip)Cl_2] (76.9 (3)°) [39], Pt^{II}(1-methylhomopiperazine)(methylmalonato)]·$2H_2O$ (77.8(8)° [36], and

S(1)–Pt(1)–Cl(1)	96.69(6)	C(3)–N(2)–Pt(1)	109.2(4)

[Pt^{II}(hpip)(pentadecanoate)$_2$] (76.3(4)°) [38]. In addition, the contraction of the N1–Pt–N2 bond angle is compensated for with expansion of the N(2)–Pt(1)–S(1), N(1)–Pt(1)–Cl(1) and S(1)–Pt(1)–Cl(1) bond angles to 92.53(15)°, 93.67(16)° and 96.69(6)°, respectively. The Pt(1)–N(1)–C(1) and Pt(1)–N(1)–C(5) bond angles in the present study are 107.3(4)° and 107.9(4)°, respectively, these angles are 107.7(4)° and 109.0(4)°, respectively, in [Pt^{II}(hpip)Cl_2] [39], 105.9(8)° and 112.1(7)°, respectively, in [Pt^{II}(hpip)(pentadecanoate)$_2$] [38], and 104.3(14)° and 109.5(14)°, respectively, in Pt^{II}(1-methylhomopiperazine)(methylmalonato)]·$2H_2O$ [36]. The molecules in the crystal show a system of N–H···O hydrogen bonds (Fig. 3).

In summary, we have synthesized and characterized a series of new platinum(II) complexes containing homopiperazine or 1-methylhomopiperazine as nonleaving amine ligands and different sulfide groups as leaving ligands. The crystal structure of [Pt^{II}(hpip)(diphenylsulfide)Cl]NO_3 was determined by X-ray crystallography.

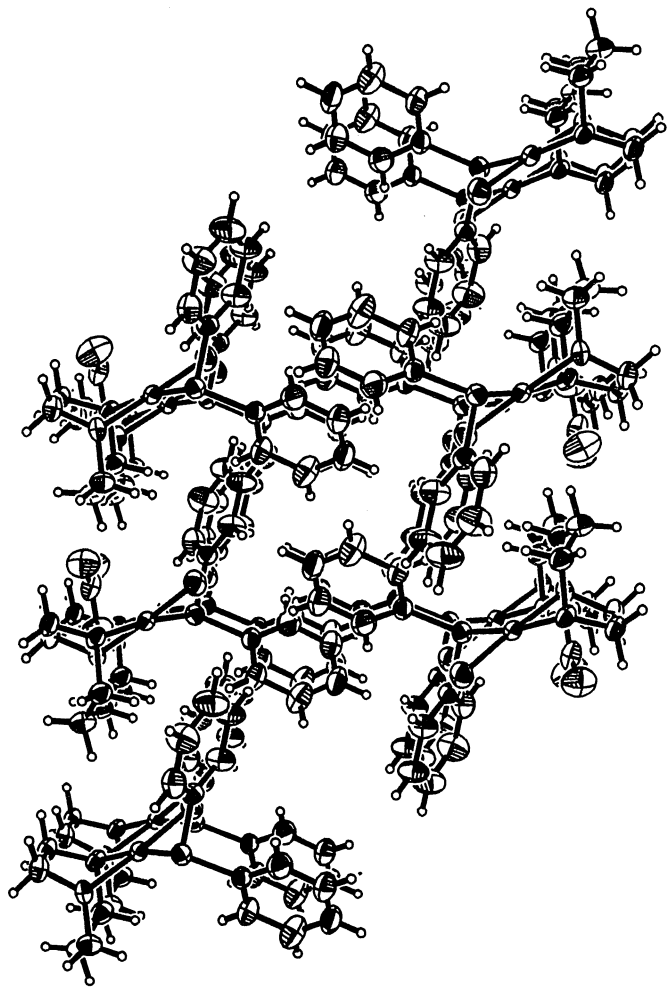

Fig. 3. Packing diagram of [Pt^{II}(homopiperazine)(diphenylsulfide)-Cl]NO_3. Orientation is along the 0 1 0 axis. Thermal ellipsoids drawn at 50% probability.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC No. 160939. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Interaction of sulfur dioxide and cyanide with cobalt(II) tetrasulfophthalocyanine in aqueous media

Mamothibe Thamae, Tebello Nyokong *

Department of Chemistry, Rhodes University, Grahamstown 6140, South Africa

Received 13 August 2001; accepted 9 October 2001

Abstract

Kinetic and equilibrium studies for the coordination of cyanide or sulfur dioxide to the cobalt(II) tetrasulfophthalocyanine ($[CoTSPc]^{4-}$) complex are reported. The equilibrium constant for the coordination of the cyanide under pH 11 conditions and an oxygen atmosphere, and the formation of $[(CN^-)_2Co(III)TSPc]^{5-}$ species, was found to be 2.1×10^1 dm^3 mol^{-1} and the rate constant, k_f was found to be 7.4 dm^3 mol^{-1} s^{-1}. Similarly, the coordination of SO_2 to $[CoTSPc]^{4-}$ occurred with an equilibrium constant of 8.7×10^1 dm^3 mol^{-1} and a rate constant of 2.1×10^2 dm^3 mol^{-1} s^{-1}, at pH 11. These rate and equilibrium constants represent the coordination of the second cyanide or sulfur dioxide ligands to the $[CoTSPc]^{4-}$ species. Coordination of the first ligand occurred faster than that of the second ligand in both cases. The coordination is accompanied by the oxidation of the central Co(II) metal with the formation of a Co(III) tetrasulfophthalocyanine species. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Cobalt; Phthalocyanine; Cyanide; Sulfur dioxide; Kinetics; Equilibria

1. Introduction

Analysis of cyanide and sulfur dioxide is of environmental importance. The oxidation of sulfur dioxide to higher oxidation states of sulfur is also of industrial importance. Metalloporphyrin (MP) complexes are known to react with SO_2 to give sulfonato metalloporphyrin complexes [1–3]. Coordination of SO_2 to metallophthalocyanine (MPc) complexes, FePc and CoPc, has been implicated during electrocatalytic oxidation of sulfur dioxide by these complexes [4]. Our reports on the photolysis of tin(IV) mono- and di-phthalocyanine ($(L)_2Sn(IV)Pc(-2)$ and $Pc(-2)Sn(IV)Pc(-2)$, respectively, where Pc(-2) is the phthalocyaninato dianion) complexes in the presence of SO_2 showed the reduction of the $(L)_2Sn(IV)Pc(-2)$ species to $[(L)_2Sn(IV)Pc(-3)]^-$, and the oxidation of the diphthalocyanine to $[Pc(-1)Sn(IV)Pc(-2)]^+$ [5,6]. Electron transfer reactions between SO_2 and MPc complexes could be useful in converting harmful sulfur complexes to their less harmful analogues.

There is a need to develop complexes that may act as antidotes for cyanide intoxication. Metalloporphrins and metallophthalocyanine complexes have sharp spectral features such as strong Q bands in the visible region for the MPc complexes and strong Soret or B bands for the MP complexes. The MPc and MP com-

plexes may thus be used as sensitive spectrophotometric reagents for the detection of analytes. Interactions between cyanide and porphyrin complexes have been reported [7,8]. Reactions catalysed by MPc complexes are often mediated by axial ligation of the species to be catalysed. Kinetic and equilibrium studies for the coordination of cyanide to FePc [9,10], $FePc(Cl)_{16}$ [11] and RuPc [12] in non-aqueous media have been reported. Coordination of cyanide under these conditions occurred in a step-wise manner, with coordination of the first cyanide occurring much faster than that of the second one. The coordination of each cyanide ligand gave distinct spectroscopic changes [9]. Axial ligand substitution reactions in metallophthalocyanine and metalloporphrin complexes are dissociative with the formation of a highly reactive five-coordinate intermediate [9,13,14], prior to coordination of the ligands.

In this work, we investigate the interaction of cobalt(II) tetrasulfophthalocyanine ($[CoTSPc]^{4-}$), (Fig. 1) with cyanide and sulfur dioxide in aqueous basic media. We report on the kinetics and equilibria of this interaction. Studies on the coordination of cyanide or sulfur dioxide to MPc complexes have been mainly undertaken in non-aqueous media. The possibility of electron transfer from the $[CoTSPc]^{4-}$ species following the coordination of sulfur dioxide or cyanide is explored.

2. Experimental

2.1. Materials

Cobalt(II) tetrasulfophthalocyanine ($[CoTSPc]^{4-}$) was prepared and purified according to reported procedures [15]. The complex gave satisfactory spectroscopic and elemental analysis. $[CoTSPc]^{4-}$ complexes containing axially ligated cyanide or SO_2 were prepared by adding cyanide or SO_2 to aqueous solutions of $[CoTSPc]^{4-}$, allowing the reaction to proceed until there was a definite change in spectra, then evaporating off the solvent. Potassium cyanide (Merck) and SO_2 (Messer Grieshem) were used as received. Dimethyl sulfoxide (DMSO) was dried on alumina and 0.01 or 0.1 mol dm^{-3} (ionic strength, $\mu = 0.5$ mol dm^{-3} $NaClO_4$) tris(hydroxymethyl)aminomethane (Tris) buffer was employed for buffered solutions, pH 7.4 and 11. SO_2 stock solutions were prepared by bubbling SO_2 gas into aqueous solutions, the flasks containing SO_2 were closed with a tight fitting stopper. SO_2 concentrations were determined by treatment with standard iodine, followed by titration with standard aqueous sodium thiosulfite [16]. Potassium hexacyanoferrate, $K_3[Fe(CN)_6]$ was purchased from Merck and used as received. Distilled deionised Millipore water was employed for all studies in aqueous media, and dimethyl sulfoxide, DMSO in non-aqueous media. Cyanide determinations in non-aqueous media were done using silver nitrate [16].

UV–Vis spectra were recorded with the Cary 500 UV–Vis/NIR spectrophotometer. Infrared spectra (KBr discs) were recorded with the Perkin Elmer Spectrum 2000 FTIR spectrophotometer.

2.2. Kinetics and equilibria

Kinetic and equilibrium studies were run at 20 ± 0.5 °C and monitored with the spectrophotometer. We monitored the appearance of the spectra due to the products formed following the addition of cyanide or SO_2 solutions to $[CoTSPc]^{4-}$ dissolved in an appropriate buffer. Typically, a known volume of the solution of $[CoTSPc]^{4-}$ was added to a 1-cm path length spectrophotometric cell. Then a known volume of the aqueous solution of either cyanide or SO_2 in an appropriate buffer was added to the cell and changes in absorbance monitored with time. A comparison was made between the experiments performed in the presence of residual oxygen or when nitrogen or oxygen were bubbled through the solutions prior to kinetic studies. Spectroscopic changes were also recorded in DMSO. The concentration of the $[CoTSPc]^{4-}$ complex in water was estimated from the published molar extinction coefficient of 5.8×10^4 dm^3 mol^{-1} cm^{-1} [17]. The concentration of $[CoTSPc]^{4-}$ was kept constant at 1.0×10^{-5} mol dm^{-3}, while cyanide concentrations were varied from 2.5×10^{-3} to 8.7×10^{-2} mol dm^{-3}, and SO_2 concentrations from 2.0×10^{-3} to 1.6×10^{-2} mol dm^{-3}. Since the concentrations of cyanide and SO_2 were much larger than that of $[CoTSPc]^{4-}$, pseudo first-order conditions were assumed for kinetic studies.

3. Results and discussion

3.1. Interaction of cyanide with $[CoTSPc]^{4-}$

Electronic absorption spectra of $[CoTSPc]^{4-}$ complexes have been described in terms of the monomer dimer equilibrium [17,18]. This equilibrium is affected by conditions such as ionic strength, pH and temperature. The monomer peak for the $[CoTSPc]^{4-}$ species under pH 11 buffer conditions is observed as a broad shoulder near 666 nm, while the dimer peak is observed at 627 nm. On addition of cyanide to solutions of $[CoTSPc]^{4-}$ in pH 11 buffer, spectral changes shown in Fig. 2(a) were observed. pH 11 was chosen deliberately since at this pH it is expected that the CN^- species exist mainly in solution, hence avoiding complicating effects of HCN species. pK_a for $[HCN]/([CN^-][H^+]$ is 9.14 [8]. Spectral changes shown in Fig. 2(a) consisted of a decrease in the dimer peak at 627 nm, and an increase

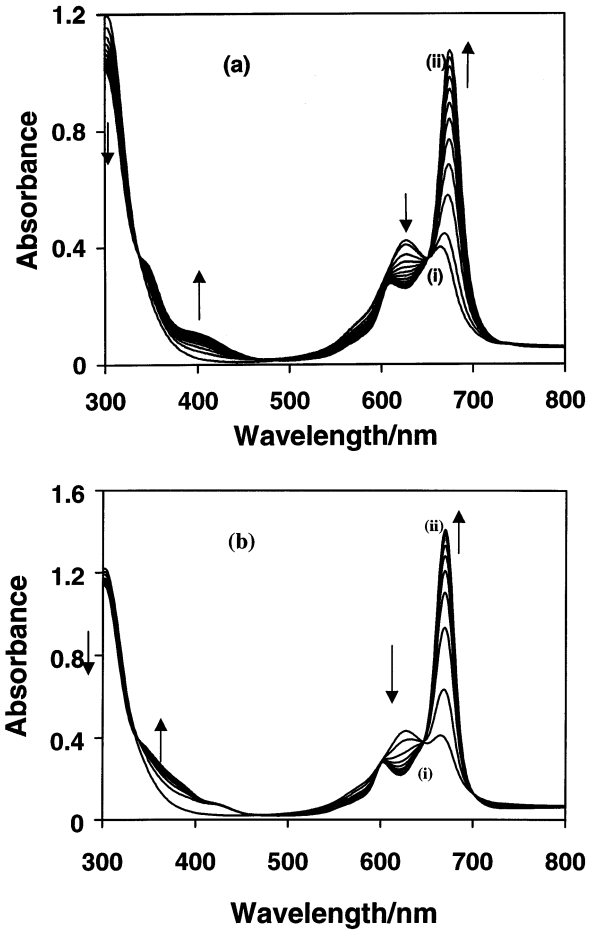

Fig. 2. Electronic absorption spectral changes observed on addition of (a) cyanide (1.8×10^{-4} mol dm^{-3}); (b) ferrocyanide (3.3×10^{-2} mol dm^{-3}) to solutions of $[CoTSPc]^{4-}$) in a pH 11 buffer. (i) Spectrum before addition of cyanide and (ii) final spectrum 2.5 min following the addition of cyanide.

accompanied by a shift in the monomer peak from 666 to 670 nm and finally to 676 nm. There were also new peaks at 610, 404 and 348 nm. The split in the Soret band with the shifting of one of the split peaks to wavelengths near 400 nm, is characteristic of cyanide coordination in MPc complexes [19,20]. Isosbestic points were observed at 652, 458 and 337 nm. The original spectrum before addition of cyanide did not go precisely through the isosbestic point at 458 nm, suggesting that there are more than two species in solution. The shifting of the monomer peak from 666 to 670 nm and finally to 676 nm also shows that there are more than two species in solution. The solution changed from blue to green as the spectral changes shown in Fig. 2(a) progressed. No further spectral changes were observed following the formation of the species with a Q band at 676 nm.

Weber and Busch [21] reported on the interaction of cyanide with $[Co(II)TSPc]^{4-}$ and concluded that a cyanocobalt phthalocyanine did not form when solutions of cyanide were added to $[Co(II)TSPc]^{4-}$, but that cyanocobalt(III) phthalocyanine complex was formed when ferricyanide was employed as a source of cyanide. Fig. 2(b) shows spectral changes obtained on addition of ferricyanide to solutions of $[Co(II)TSPc]^{4-}$ under pH 11 buffer conditions. Spectral changes similar to those shown in Fig. 2(a) were obtained, except that the monomer peak shifted only from 666 to 670 nm, with no further shift to 676 nm, which was observed in Fig. 2(a). There was evidence of coordination of cyanide by the split in the Soret band with a formation of a broad band near 400 nm as was observed in Fig. 2(a). Thus, these results show that cyanide coordination is observed when either cyanide or ferricyanide are added to the solutions of $[CoTSPc]^{4-}$ in basic media. Stable cyanocobalt(III) phthalocyanine complexes have been reported from addition of cyanide to other CoPc complexes [19,20] in non-aqueous media. Literature reports have thus shown that coordination of cyanide to Co(II)Pc complexes result in the oxidation of the central metal with the formation of Co(III)Pc complexes [19,20]. Autooxidation of $[CoTSPc]^{4-}$ is known to depend on the nature of the axial ligands [21,22].

The fact that the final Q band maxima in Fig. 2(a,b) are different yet in both cases coordination of cyanide occurs, as evidenced by split in the Soret band, suggests that different levels of axial ligand coordination occurs in the two situations. Since the final Q band maxima on addition of ferricyanide to $[CoTSPc]^{4-}$ is at the same wavelength as the Q band observed when cyanide is first added to the $[CoTSPc]^{4-}$ species, we propose that on addition of ferricyanide, only one cyanide ligand is coordinated, since further spectral changes to 676 nm were not observed. While in the case where cyanide (instead of ferricyanide) was added to the $[Co(II)TSPc]^{4-}$ solutions, Fig. 2(a), the first spectral changes with a Q band located at 670 nm are due to the coordination of the first cyanide in a similar manner (and with a similar Q band maxima) to when ferricyanide is added. The further shifting of the spectra to 676 nm in the case of addition of cyanide is due to the coordination of the second cyanide and the formation of the $[(CN^-)_2Co(III)TSPc]^{5-}$ species. The coordination of cyanide to CoPc complexes is known to result in dicyano complexes [19,20]. The coordination of the first cyanide to other MPc complexes (e.g. $(L)_2FePc$) is known to occur much faster than the coordination of the second cyanide [11]. In general coordination of the first axial ligands in MPc complexes occurs much faster than the coordination of the second ligands [9–12]. The fact that gradual spectral changes were not observed for the formation of the monocyano species with a Q band maxima at 670 nm on addition of cyanide, under aqueous conditions, even though gradual changes were observed when ferricyanide was employed as a source of cyanide, may be a result of the extent of cyanide availability in the latter. Gradual evolution of the 670

nm band was not observed even on addition of very small amounts of cyanide. Instantaneous formation of the species with a Q band centered at 670 nm was observed under all circumstances.

In order to confirm the step-wise coordination of cyanide to the $[CoTSPc]^{4-}$ species, we monitored spectral changes of this complex in the presence of cyanide using DMSO as a solvent. Spectral changes observed, Fig. 3, clearly showed the stepwise coordination of cyanide to the $[CoTSPc]^{4-}$ species. In DMSO the $[CoTSPc]^{4-}$ is in the monomeric form only. The spectral changes shown in Fig. 3(a) consisted of a decrease in the Q-band (located at 663 nm) accompanied by an isosbestic shift to 670 nm. When the solution that resulted in spectral changes of Fig. 3(a) is left for longer periods, or when larger cyanide concentrations, (0.03 mol dm^{-3}) were added to $[CoTSPc]^{4-}$ solutions, spectral changes of Fig. 3(b) were observed, which consisted of a shift of the Q band from 670 to 680 nm. Thus, in organic media, stepwise spectral changes were observed corresponding to the stepwise coordination of cyanide.

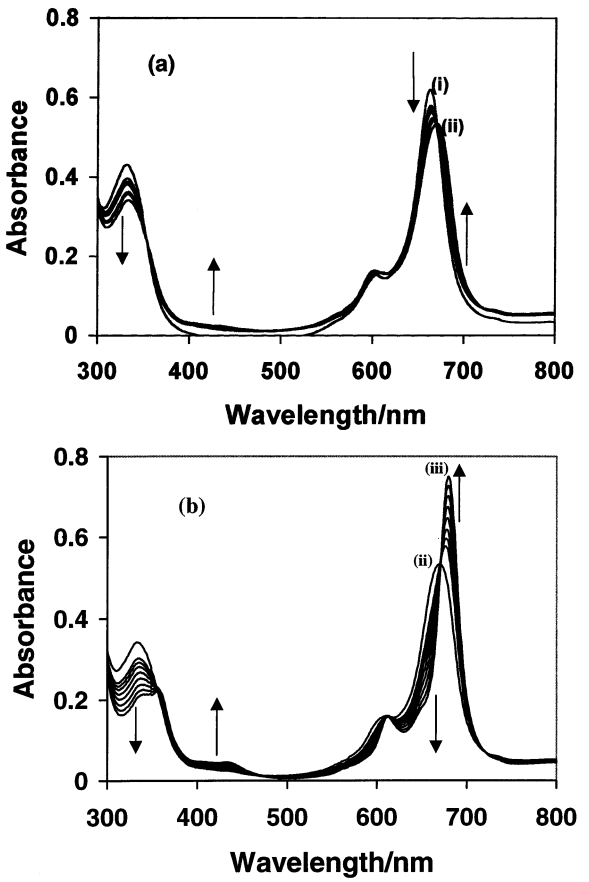

Fig. 3. Electronic absorption spectral changes observed on addition of cyanide (6.7×10^{-3} mol dm^{-3}) to solutions of $[CoTSPc]^{4-}$) in DMSO. (i) Spectrum before addition of cyanide, (ii) final spectrum 2.5 min following the addition of cyanide and (iii) spectra 6 h after the addition of cyanide. (a) and (b) represent the spectral changes for the coordination of the first and second cyanides, respectively.

Fig. 3(a) corresponds to the coordination of the first cyanide and Fig. 3(b) to the coordination of the second cyanide. The fact that these stepwise coordinations are observed in organic media and not in aqueous solutions is a result of the slower kinetics in the former.

It is suggested that coordination of cyanide to the $[Co(II)TSPc]^{4-}$ species occurs simultaneously with the oxidation of Co(II) to Co(III) and hence the formation of the $[(CN^-)_2Co(III)TSPc]^{5-}$ species in aqueous solutions. As mentioned above, oxidation of Co(II) to Co(III) occurs on addition of cyanide to CoPc complexes [19,20]. Addition of bromine to aqueous solutions of $[Co(II)TSPc]^{4-}$ resulted in the formation of the Q band at 670 nm (due to the formation of the $[Co(III)TSPc]^{3-}$ species) and the disappearance of the dimer band. Central metal oxidation in the $[Co(II)TSPc]^{4-}$ complex results in the disappearance of the dimer peak and the shifting of the Q band to longer wavelengths [13,23,24]. Addition of a reducing agents (e.g. sodium borohydride) at the end of the reaction between cyanide and $[CoTSPc]^{4-}$ and the formation of a species with a Q band located at 676 nm, resulted in regeneration of the original spectrum in Fig. 2(a), confirming that oxidation accompanies the coordination of cyanide to the $[Co(II)TSPc]^{4-}$ species and that cyanide binds reversibly to $[CoTSPc]^{4-}$.

The slight deviation from the isosbestic point at 458 nm of the spectra before addition of cyanide in Fig. 2(a) may be attributed to the presence of more than two species in solution, these being the dimer, monomer, monocyano and dicyano species.

The ligation of cyanide to $[CoTSPc]^{4-}$ was evidenced by IR spectra of the solid complex produced when cyanide was added to solutions of $[CoTSPc]^{4-}$ and then evaporating off the solvent. ν_{CN^-} was observed at 2130 cm^{-1}. This value is larger than that reported by Weber and Busch for the formation of cyanocobalt(III) phthalocyanine complex using ferricyanide as a source of cyanide [21], but is in the range reported for ν_{CN^-} (2120 cm^{-1}) in dicyanoiron phthalocyanine [11].

Earlier studies [13] have shown that bubbling oxygen through a solution of $[CoTSPc]^{4-}$ resulted in an increase in the monomer peak of the spectra of this complex, followed by a further shift to longer wavelengths. These spectral changes were attributed to formation of an adduct between oxygen and $[CoTSPc]^{4-}$. We did not observe any spectral changes for $[CoTSPc]^{4-}$ in the absence of cyanide, showing that residual oxygen present in water is not enough to oxidize $[CoTSPc]^{4-}$ in the absence of cyanide.

The relatively strong ligands, cyanide [21] and imidazoles [21,23] are known to facilitate central metal oxidation in $[CoTSPc]^{4-}$ by atmospheric oxygen. The spectral changes observed when oxygen was deliberately bubbled into the solution containing $[CoTSPc]^{4-}$ and cyanide are similar to those observed in the pres-

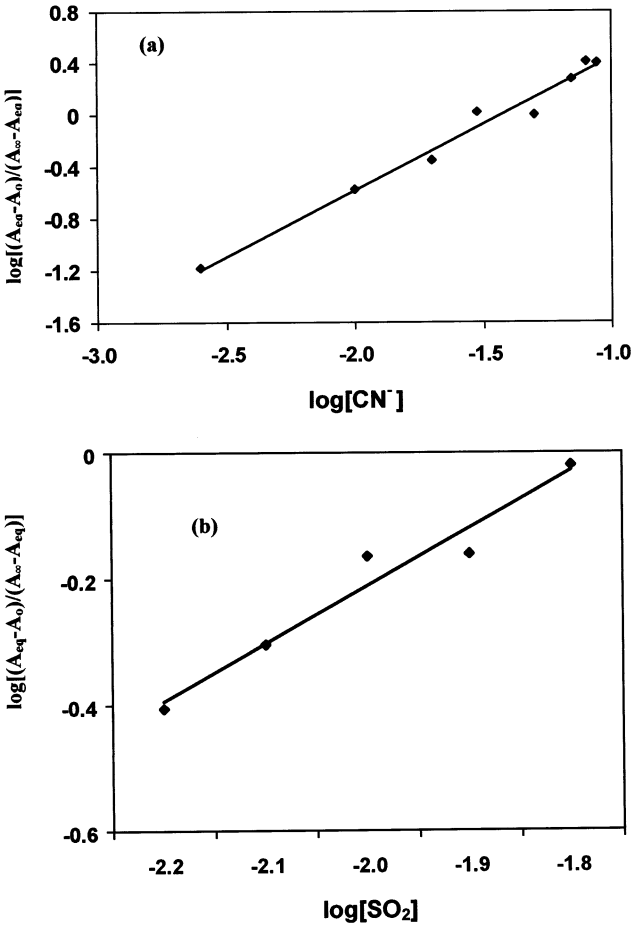

Fig. 4. Plots of $\log[(A_{eq}-A_0)/(A_\infty-A_{eq})]$ vs. (a) $\log[CN^-]$ and (b) $\log[SO_2]$. pH 11 buffer.

ence of residual oxygen, and as will be shown below, the rate of formation of products is much faster when oxygen is bubbled, clearly showing that oxygen is involved in the oxidation of $[CoTSPc]^{4-}$ on coordination of cyanide.

Assuming that two molecules of water are initially ligated to the $[CoTSPc]^{4-}$ forming $[(H_2O)_2CoTSPc]^{4-}$ as has been suggested before [18], the following mechanism for the coordination of cyanide to $[CoTSPc]^{4-}$ is suggested, Eqs. (1) and (2):

$$[(H_2O)_2Co(II)TSPc]^{4-} + CN^- \xrightarrow{O_2} [(H_2O)(CN^-)Co(III)TSPc]^{4-} + H_2O + O_2^- \quad (1)$$

$$[(H_2O)(CN^-)Co(III)TSPc]^{4-} + CN^- \rightarrow [(CN^-)_2Co(III)TSPc]^{5-} + H_2O \quad (2)$$

Eq. (1) is a result of the fast coordination of the first cyanide ligand with a Q band maxima cented at 670 nm in Fig. 2. Eq. (2) is proposed for the coordination of the second cyanide with gradual spectral changes in Fig. 2(a) and the final formation of a Q band at 676 nm.

We followed the kinetics and equilibria for the formation of the new species following addition of cyanide to $[CoTSPc]^{4-}$, by monitoring the spectra due to the product, $[(CN^-)_2Co(III)TSPc]^{5-}$, with a Q band at 676 nm, Fig. 2(a). The equilibrium data were analysed by standard spectrophotomeric method using Eq. (3):

$$\log[(A_{eq}-A_0)/(A_\infty-A_{eq})] = \log K + n\log[CN^-] \quad (3)$$

where A_{eq} is the equilibrium absorbance at 676 nm, A_0 is the absorbance at 676 nm before addition of cyanide. A_∞ was determined from the final absorbance at 676 nm in Fig. 2(a), following complete formation of the $[(CN^-)_2Co(III)TSPc]^{5-}$ complex. From the plot of $\log[(A_{eq}-A_0)/(A_\infty-A_{eq})]$ versus $\log[CN^-]$, Fig. 4(a), an equilibrium constant of $K = 2.1 \pm 0.1 \times 10^1$ dm^3 mol^{-1} was determined for the formation of $[(CN^-)_2Co(III)TSPc]^{5-}$ when oxygen was deliberately bubbled through the solution. A lower value of the equilibrium constant of $K = 6.0 \pm 0.1$ dm^3 mol^{-1} (Table 1) was observed when no oxygen was bubbled into solution (i.e. in the presence of residual oxygen in water). The number of moles of electrons transferred of near unity ($n = 0.9 \pm 0.1$) was obtained from the slope of the plot shown in Fig. 4(a) showing the coordination of one molecule of cyanide at this stage. As has been discussed above, the coordination of the second cyanide is responsible for the formation of a species with a Q

Table 1
Equilibrium and rate constants for the coordination of cyanide and SO_2 to MPc complexes

Complex	Ligand	Conditions [a]	K (dm^3 mol^{-1})	k_f (dm^3 mol^{-1} s^{-1})	k_r (s^{-1})	Ref. [b]

The data are for the coordination of second cyanide or sulfur dioxide ligands.
[a] Ionic strength = 0.5 M $NaClO_4$ for aqueous solutions. 0.01 mol dm^{-3} Tris buffer employed.
[b] tw = this work.
[c] Oxygen bubbled.
[d] Residual oxygen (no oxygen bubbled).

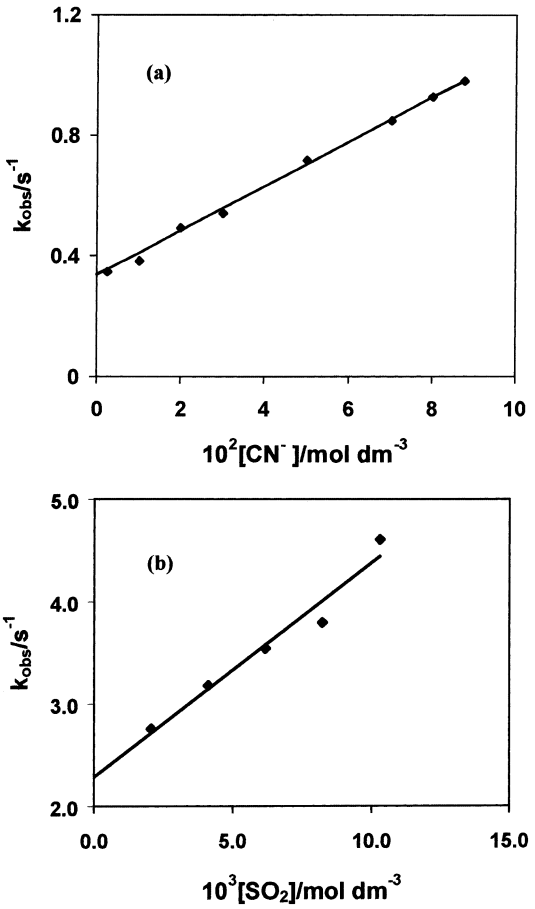

Fig. 5. Plots of k_{obs} (s^{-1}) vs. concentration for the coordination of (a) cyanide, (b) sulfur dioxide to $[CoTSPc]^{4-}$ species. pH 11 buffer.

band at 676 nm, hence the determined equilibrium constant is for the formation of $[(CN^-)_2Co(III)TSPc]^{5-}$ species by Eq. (2). The value of the equilibrium contant could be slightly affected by the initial formation of the monocyano species.

The plot of the observed rate constant (k_{obs}) versus cyanide concentration was linear, Fig. 5(a)) for the data shown in Fig. 2(a), showing that the coordination is first order in cyanide and obeys the following rate law, which is typical of coordination of axial ligands to MPc complexes:

$$k_{obs} = k_f[CN^-] + k_r \quad (4)$$

where k_f is the rate constant for the formation of $[(CN^-)_2Co(III)TSPc]^{5-}$ and is given by $k_1k_2/k_{-1}[CN^-]$. k_r is the rate constant for the dissociation of the complex. Least-square analysis of the data gave $k_f = 7.4 \pm 0.2$ dm^3 mol^{-1} s^{-1} from the slope and $k_r = 0.34 \pm 0.01$ s^{-1} from the intercept for the case when oxygen was bubbled through the solution, and $k_f = 5.9 \pm 0.2$ dm^3 mol^{-1} s^{-1} and $k_r = 0.96 \pm 0.01$ s^{-1}, in the presence of residual oxygen (i.e. no oxygen bubbled through the solution). Using the k_f and k_r values, the equilibrium constants were estimated to be $K \sim 2.2 \times 10^1$ and 6.0 dm^3 mol^{-1}, respectively, for situations when oxygen was bubbled or in the presence of residual oxygen. These values are in good agreement with the values determined from equilibrium data.

Rates and equilibrium constants are higher when oxygen was bubbled through the solution, hence showing that the formation of the oxidized $[(CN^-)_2Co(III)TSPc]^{5-}$ species is depended on oxygen. As has been mentioned above, it has been reported in the literature that cyanide facilitates central metal oxidation in $[CoTSPc]^{4-}$ by atmospheric oxygen [21]. The kinetics were not affected by varying the concentration of Tris buffer employed.

Table 1 compares the equilibrium and rate constants for the coordination of cyanide to $[CoTSPc]^{4-}$ complex, to the constants reported for the coordination of cyanide to FePc complexes. Table 1 shows that the rate constants for the coordination of cyanide to the $[CoTSPc]^{4-}$ complex in aqueous solutions is larger than those reported for the coordination of cyanide to FePc complexes in DMSO. The differences in the rate and equilibrium constants may be caused by the presence of different ring substituents, the nature of the central metal and also by differences in the solvents employed. Coordination of axial ligands (e.g. pyridine) to FePc was found [25] to occur faster than its coordination to CoPc complexes in DMSO solutions, suggesting faster axial ligand exchange reactions in FePc complexes compared to CoPc complexes. As has been mentioned above, in the presence of DMSO coordination of cyanide to $[CoTSPc]^{4-}$ occurred slower in DMSO (hence the observation of a stepwise cyanide coordination) than in water, thus the nature of the solvent plays an important role. The rate constants for the coordination of axial ligands to MPc complexes are a measure of the ease of dissociation of the bond between the central metal and the leaving ligand. As mentioned above, in aqueous solutions $[CoTSPc]^{4-}$ contains water molecules in axial positions (forming $[(H_2O)_2CoTSPc]^{4-}$), whereas the reported data for coordination of cyanide to FePc, DMSO was employed as a solvent, giving the $(DMSO)_2FePc$ species. The observation of higher rate constants for coordination of cyanide to $[CoTSPc]^{4-}$ in water when compared to its coordination to FePc in DMSO may reflect the ease of dissociation of the Co-water bond in the former complex, compared to the dissociation of the Fe–DMSO bond in the later. When DMSO is in the axial position, the metal–DMSO bond gets extra stability from π back-bonding due to the DMSO ligand, making it difficult to replace the DMSO compared to the replacement of water. The relative strength of the Fe–DMSO bond compared to the Co–water bond may be one of the reasons for a larger rate constants for the coordination of cyanide to the $[CoTSPc]^{4-}$ complex when compared to its coordination to FePc complexes. The rate

constants for the coordination of cyanide to CoPc in non-aqueous solutions have not been reported. The rate constant reported for the coordination of cyanide to the $[CoTSPc]^{4-}$ species is much lower than the rate constant of 3×10^4 dm^3 mol^{-1} s^{-1} reported for the coordination of cyanide to cobalt tetraphenyl porphyrin [26].

3.2. Interaction of sulfur dioxide with $[CoTSPc]^{4-}$

Fig. 6 shows spectral changes observed when sulfur dioxide solutions were added to solutions of $[CoTSPc]^{4-}$ under pH 11 buffer conditions in presence of residual oxygen (no oxygen bubbled). We chose basic solutions for this study in order to allow for comparison with the studies for cyanide coordination discussed above. The spectral changes shown in Fig. 6 are similar to those observed in Fig. 2(a) for the addition of cyanide to $[CoTSPc]^{4-}$ species, except that the final spectra showed a Q band at 673 nm, and not 676 nm, observed for cyanide coordination. The monomer peak shifted from 666 to 670 nm and finally to 673 nm, with clear isosbestic points at 710, 649, 502 and 341 nm. Similar spectral changes were observed in pH 7.4 buffer. The similarities between spectral changes on addition of SO_2 to $[CoTSPc]^{4-}$ to the changes observed on coordination of cyanide above, suggests that similar processes are taking place in both cases. Thus, coordination of SO_2 to $[CoTSPc]^{4-}$ is proposed for changes observed in Fig. 6, in a similar manner to coordination of cyanide, with coordination of the first SO_2 occurring fast, resulting in the Q band shift to 670 nm, and then the final spectral changes leading to the observation of the Q band at 673 nm, being due to the coordination of the second SO_2 molecule resulting in the formation of a disulfite complex, since SO_3^- is the prominent form of SO_2 in basic media. The exact nature of the complex formed is under investigation. However, the step-wise coordination of SO_2 to the $[CoTSPc]^{4-}$ species was confirmed by the observation of spectral changes (in DMSO) similar to those shown in Fig. 3 for the coordination of cyanide.

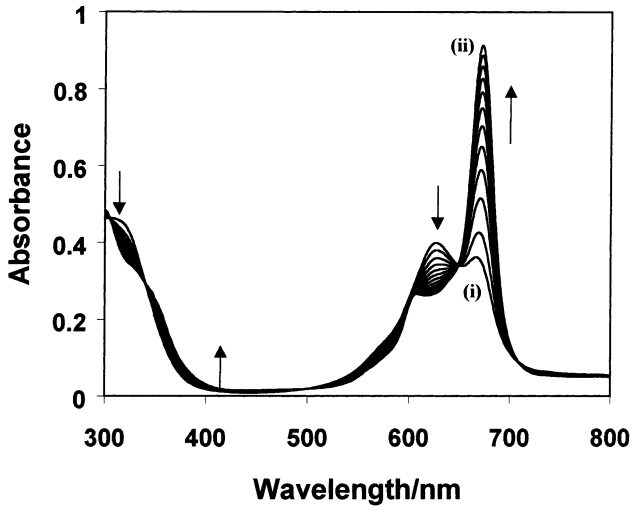

Fig. 6. Electronic absorption changes observed on addition of SO_2 (2.1×10^{-3} mol dm^{-3}) to solutions of $[CoTSPc]^{4-}$ in pH 11 buffer (i) spectrum before addition of sulfur dioxide and (ii) final spectrum, 2.5 min following the addition of SO_2.

In comparison with cyanide, it is likely that the coordination of SO_2 is also accompanied by electron transfer and oxidation of $[Co(II)TSPc]^{4-}$ to the $[Co(III)TSPc]^{3-}$ species. Earlier studies [27] showed that photochemical reduction of tin(IV) phthalocyanine complexes, $(OH)_2SnPc$ or $(Cl)_2SnPc$ in the presence of SO_2 resulted in the ring reduction of these SnPc complexes, whereas oxidation of Pc(-2)Sn(IV)Pc(-2) to the Pc(-1)Sn(IV)Pc(-2) species was observed on addition of sulfur dioxide [5].

The fact that the final spectra peak is observed at different wavelengths for cyanide ($\lambda_{Q\,band} = 676$ nm) and SO_2 ($\lambda_{Q\,band} = 673$ nm) coordination to $[CoTSPc]^{4-}$ confirms that different complexes are formed due to axial ligation.

Metalloporphyrin complexes are known to react with SO_2 to form porphyrin sulfate complexes [28,29], with the IR spectra of monocoordinated sulfate groups being observed at 1147, 1098 and 464 cm^{-1} [30]. IR spectra of the solid product formed following evaporation of the solvent from a solution containing SO_2 and $[CoTSPc]^{4-}$ showed an IR band at 1104 cm^{-1}. However, the IR spectra were complicated by the presence of vibrations from the SO_3^- groups attached to the phthalocyanine ring in the $[CoTSPc]^{4-}$ complex.

Equilibrium data for the formation of the SO_2 complex were determined as explained above using Eq. (3), with CN^- replaced by SO_2. We monitored the increase in the monomer peak in Fig. 6. In Eq. (3), A_{eq} is the equilibrium absorbance at 673 nm; A_0 is the absorbance at 673 nm before addition of SO_2. A_{∞}, the absorbance after complete formation of the complex, was determined from the final absorbance at 673 nm. From the plot of $\log[(A_{eq} - A_0)/(A_{\infty} - A_{eq})]$ versus $\log[SO_2]$, Fig. 4(b), an equilibrium constant of $K = 8.7 \pm 0.3 \times 10^1$ dm^3 mol^{-1} was determined for the formation of the proposed $[(SO_3^-)_2CoTSPc]^{5-}$ complex. The value of n was found to be near unity ($n = 1.1 \pm 0.1$) showing that the coordination of one molecule of SO_2, results in the observed spectral evolution with a Q band centred at 673 nm in Fig. 6. The plot of k_{obs} versus $[SO_2]$ for the data shown in Fig. 6 was linear, Fig. 5(b) with $k_f = 2.1 \pm 0.2 \times 10^2$ dm^3 mol^{-1} s^{-1} and $k_r = 2.3 \pm 0.2$ s^{-1}, under pH 11 conditions. Again using these values equilibrium constant was estimated to be $K \sim 9.0 \times 10^1$ dm^3 mol^{-1} in agreement with the value determined from equilibrium data. The plot in Fig. 5(b) confirms that a rate law similar to that shown by Eq. (4) is obeyed for

the coordination of SO_2 to the $[CoTSPc]^{4-}$ species and that the coordination is first-order in SO_2. Equilibrium and rate constants for the reaction between SO_2 and $[CoTSPc]^{4-}$ at pH 11 are shown in Table 1, and are compared with those obtained at pH 7.4. Similar rate constants are obtained at these two pH values. The equilibrium constant at pH 7.4 was slightly higher than that obtained at pH 11, but the difference was not significant. As discussed above, in basic media, it is expected that the predominant species for SO_2 is the SO_3^- species. Thus, at both pH 7.4 and 11, the same species (SO_3^-) is expected to coordinate to the $[CoTSPc]^{4-}$ complex, $pK_a = 1.81$ and 6.9 for H_2SO_3.

The rate and equilibrium constants for the coordination of cyanide to the $[CoTSPc]^{4-}$ complex are much lower than those obtained for the coordination of SO_2 (as SO_3^-). Due to the strong π acceptor abilities of cyanide which makes it easier to coordinate to the $[CoTSPc]^{4-}$ species by stabilization of the resulting complex through π back-bonding, one would have expected cyanide to exhibit larger rate and equilibrium constants compared to SO_2.

In conclusion we have shown in this work that cyanide and SO_2 coordinate to the $[CoTSPc]^{4-}$ species. The coordination is accompanied by oxidation of the central Co(II) metal forming a Co(III) species. The rate constants reported here for cyanide coordination to the $[CoTSPc]^{4-}$ complex are larger than those reported for the coordination of cyanide to FePc and RuPc complexes in non-aqueous media. The values of the forward rate constants are larger than the values for the reverse reactions for the coordination of both cyanide and SO_2, showing that the interaction between $[CoTSPc]^{4-}$ and these pollutants is highly favoured. This is an important observation since complexes which can react with these harmful molecules and hopefully counteract their toxic effects, are needed.

Abstract

The synthesis and characterization of three new alkoxo-bridged dinuclear copper(II) compounds are described, all having the general formula $[Cu_2(L)_2(RO^-)_2](ClO_4)_2(ROH)_y(H_2O)_z$, in which L = b2b (bis(2-benzimidazolyl)-2-butane) and b3b (bis(2-benzimidazolyl)-3-butane), ROH = MeOH, EtOH, 1-PrOH, $y = 1$ or 2, $z = 0$ or 3. The X-ray structure has been solved from two compounds; $[Cu_2(b2b)_2(OCH_3)_2](ClO_4)_2(CH_3OH)_2(H_2O)_3$ (**1**) and from compound $[Cu_2(b3b)_2(C_3H_7O)_2](ClO_4)_2(C_3H_7OH)_2$ (**3**). These two compounds consist of dinuclear Cu(II) units with bridging methoxo group for **1** and an unique bridging propoxo group for **3** with two ligands linked to each copper via N, providing square–planar CuN_2O_2 chromophores. The latter one is the first dinuclear Cu(II) X-ray structure with bridging propoxo groups. Both dinuclear compounds are diamagnetic. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Copper(II); Alkoxo-bridged; Magnetism; Benzimidazoles; Crystal structures

1. Introduction

The co-ordination chemistry of azoles acting as ligands in copper(II) compounds in the context of modeling biological systems has gained much interest in the past decades [1–4]. In this respect bis(2-benzimidazoles) have received much attention for their wide-ranging antivirus activity [5,6] their importance in selective ion exchange resins [7,8] and the possibility to form supramolecular aggregates with d^{10} metal ions [9].

Previously, spectroscopic and magnetic properties, as well as some structures of copper(II) co-ordination compounds with bis(2-benzimidazolyl)alkanes and some substituted bis(2-benzimidazolyl)alkanes have been reported [10–18] by others and by us. In an earlier study, we synthesized and characterized copper(II) dinuclear alkoxo-bridged compounds with these bis(2-benzimidazolyl)alkanes [12,13]. So far only methoxo- and ethoxo-bridged Cu(II) dinuclear compounds were obtained. When using higher alcohols, like 1-propanol, only mononuclear species were obtained [15]. To the best of our knowledge so far no X-ray structures of Cu(II) propoxo-bridged compounds are reported; in fact with transition metals only one Fe(III) dinuclear propoxo-bridged X-ray structure has been solved [19]. To investigate whether there is an influence in varying the steric properties, a methyl group was introduced on two different positions in the alkyl chain, obtaining the ligands bis(2-benzimidazolyl)-2-butane (abbreviated as b2b), where a chiral C atom is present and bis(2-benz-

PII: S0277-5387(01)00903-2

imidazolyl)-3-butane (abbreviated as b3b), which has a twofold symmetry axis. With Cu(II) and Co(II) halides, monomeric compounds with a tetrahedral geometry were obtained [20]. However, with other anions dinuclear species were formed. In this paper, we describe the synthesis and characterization of three new copper(II) alkoxo-bridged compounds with the general formula $[Cu_2(L)_2(RO^-)_2](ClO_4)_2(ROH)_y(H_2O)_z$, in which L = b2b and b3b, ROH = MeOH, EtOH, 1-PrOH, $y = 1$ or 2, $z = 0$ or 3. The X-ray structure has been solved from two compounds, i.e. $[Cu_2(b2b)_2(OCH_3)_2](ClO_4)_2(CH_3OH)_2(H_2O)_3$, a methoxo bridged Cu(II) dinuclear compound and $[Cu_2(b3b)_2(C_3H_7O)_2](ClO_4)_2(C_3H_7OH)_2$, which appears to be the first reported X-ray structure with a Cu-bridging propoxo group.

2. Experimental

2.1. Syntheses

All chemicals were used as received without further purification. The ligands b2b and b3b were synthesized as described before [20].

The coordination compounds were prepared according to the following general procedure: 1.2 mmol of the $Cu(ClO_4)_2$ and 1.2 mmol of the ligand were each dissolved in 10 ml of alcohol. The ligand solution was then added slowly to the Cu(II)-salt solution and filtered to remove any undissolved material. Usually, after a few days to at most 2 weeks, the product separates as crystals. These were isolated by filtration and dried in air, and characterized by elemental analysis and spectroscopic methods. Yield for both compounds was approximately 40%.

[a] tbz, bis(2-benzimidazolyl)propane); mtbz, bis(1-methyl-2-benzimidazolyl)propane; b2b, bis(2-benzimidazolyl)-2-butane; b3b, bis(2-benzimidazolyl)-3-butane.

2.2. Physical measurements

C, H, N determinations were performed on a Perkin–Elmer 2400 Series II analyzer. Metal analysis was performed by complexometric titration technique.

Ligand-field spectra were obtained on a Perkin–Elmer Lambda900 spectrophotometer using the diffuse-reflectance technique, with MgO as a reference.

X-band powder EPR spectra were obtained on a JEOL RE2× electron spin resonance spectrometer, using DPPH ($g = 2.0036$) as a standard.

FTIR spectra were obtained on a Perkin–Elmer Paragon 1000 FTIR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1})

Magnetic susceptibility measurements (5–250 K) were carried out using a Quantum Design MPMS-5 5T SQUID magnetometer (measurements carried out at 1000 G). Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants.

2.3. Crystal structure determination and refinement of the structures

2.3.1. General

A crystal was selected for and mounted to the glass fiber using the oil-drop method, data were collected on a Rigaku AFC-7S diffractometer (graphite-monochromated Mo Kα radiation, ω–2θ scans). The intensity data were corrected for Lorentz and polarization effects, for absorption (psi-scan absorption correction) and extinction. The structures were solved by direct methods. The programs TEXSAN [21], SHELXS-97 [22], SHELXL-97 [23] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. The weighted R factor, wR, and goodness-of-fit S are based on F^2, the conventional R factor is based on F, with F set to zero for negative F^2. All non-H atoms were refined anisotropically.

2.3.2. Specific details for structure **1**

The H atoms of the disordered water molecule and the H atom of the lattice methanol O_2 atom were not located. The other H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. The disordered perchlorate anion was refined on two positions as a rigid group.

2.3.3. Specific details for structure **3**

The H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. The disordered methyl group on the propyl chain was refined in two positions (50/50).

Crystal data and numerical details of the structure determination of compounds **1** and **3** are given in Table 1.

3. Results and discussion

angle information given in Table 2. The unit cell contains one dinuclear methoxo-bridged copper(II) unit, two perchlorate molecules, two methanol molecules and three water molecules. The perchlorate anions and the water molecules are disordered.

The dinuclear unit has a center of symmetry located between two copper ions. Due to the chiral center in the ligand at C3, each molecule has two enantiomers of the ligand. The Cu–Cu distance within the dinuclear unit is 2.9854(13) Å; the ligand b2b acts as a didentate ligand with N(11) and N(21) as coordinating atoms.

The Cu atoms are square–planar coordinated with the basal plane formed by the two nitrogens of the ligand and two oxygens of two methoxo ligands. The angles (O(1)–Cu(1)–N(11) 173.26(15)°, O(1)a–Cu(1)–N(21) 172.20(15)°) deviate nearly 8° from linearity; the angle of the Cu–O–Cu bridge is 103.21(14)°. Axial ligands are not present at semi-coordinating distance (Cu–O distances are > 5 Å).

The Cu–Cu distance and the Cu–O–Cu angle can be well compared with other compounds with bis(benzimidazole)alkanes for which the X-ray structure is known (see Table 3).

The lattice structure is stabilized by stacking between the benzimidazole groups of different units (shortest ring–ring distances of 3.861 Å) and by a hydrogen-bonding network primarily consisting of the methanol oxygen atom to a water molecule (O2···O4 2.695 Å), and to an imidazole nitrogen atom (O2···N13 2.749 Å). Additional weaker H-bonds involve an oxygen atom of the perchlorate molecule (O2···O22 3.219 Å) and oxygen atoms of water molecules to oxygen of perchlorate molecules (O4···O22 2.975 Å, O4···O21 3.156 Å), and to imidazole nitrogen atom (O3···N23 2.654 Å, O31···N23 3.149 Å). Due to the disorder of the perchlorate and water molecule and as not all H-atoms could be located, no specific details of these hydrogen bondings have been obtained.

3.2. Description of crystal structure of $[Cu_2(b3b)_2(C_3H_7O)_2(ClO_4)_2](C_3H_7OH)_2$ (3)

The structure of the dinuclear cationic unit is depicted in Fig. 2, with relevant bond length and bond angle information given in Table 4. The unit cell con-

Table 5

$[Cu_2(b3b)_2(C_3H_7O)_2](ClO_4)_2(C_3H_7OH)_2$ (**3**) [b]	brown–violet	26.5	17.8	48.6	5.5	10.2	10.7

[a] b2b, bis(2-benzimidazolyl)-2-butane; b3b, bis(2-benzimidazolyl)-3-butane.
[b] X-ray crystal structure solved.

tains two-dinuclear methoxo-bridged copper(II) unit, two perchlorate molecules and two propanol molecules. The methyl group of the bis-benzimidazole was found to be disordered and has been refined in two positions (ratio 1:1). No axial coordination or semi-coordination is observed (Cu···O > 3.5 Å).

The dinuclear unit has a center of symmetry located between two copper ions. The Cu–Cu distance within the dinuclear unit is 3.003(3) Å; the ligand b3b acts as a didentate ligand with N(13) and N(23) as coordinating atoms.

The Cu atoms are square–planar coordinated with the basal plane formed by the two nitrogens of the ligand and two oxygens of two propoxo ligands. The angles (O1a–Cu1–N13 173.6(3)°, O1–Cu1–N23 173.3(3)°) deviate nearly 8° from linearity; the angle of the Cu–O–Cu bridge is 102.9(3)°. The Cu–Cu distance and the Cu–O–Cu angle can be well compared with other compounds with bis(benzimidazole)alkanes for which the X-ray structure is known (see Table 3).

The lattice structure is stabilized by stacking between the benzimidazole groups of different units (shortest ring–ring distances of 3.750 Å) and by a hydrogen-bonding system between the oxygen of the uncoordinating propanol molecule and the perchlorate anion and between the nitrogens of the benzimidazole ligand and the oxygens of the propanol molecule and the oxygens of the perchlorate molecules. The shortest contact being N···O 2.729 Å. Relevant details of this hydrogen bonding system are included in Table 4.

3.3. Electronic spectra

The diffuse-reflectance spectra of the powdered solids are given in Table 5.

From this table it is observed that the ligand field bands for compounds **1**, **2** and **3** are at $17.8–19.0 \times 10^3$ cm^{-1}, which are normal ligand field transitions for a CuN_2O_2 or a $CuN_2O_2(O)_x$ chromophore [24,25]. These bands are also comparable with the transitions found earlier for compounds with the chromophore $N_2Cu(OR)CuN_2$ [12,13]. In addition, a second very strong and sharp band is found for all these compounds at $28.4–26.6 \times 10^3$ cm^{-1}, which is characteristic for dinuclear copper(II) compounds, with a square–planar $Cu_2O_2N_4$ chromophore and has been assigned to an (O) → (Cu) charge-transfer band [12,13,26,27].

3.4. Magnetic properties

X-band EPR spectra of polycrystalline powders were taken at room temperature. All the alkoxo-bridged compounds are EPR silent and show even no traces of signals of monomeric impurities, a phenomenon often seen in other bis(benzimidazole)alkane compounds [12,13].

The magnetic susceptibility was measured as powders between 5 and 300 K and these measurements show a diamagnetic behavior below room temperature (above approximately 360 K, the compounds decompose). This diamagnetism results from strong antiferromagnetism and is in accordance with earlier magnetic investigations of alkoxo-bridged bis(benzimidazole)alkane compounds [12,13,28].

4. Concluding remarks

The results discussed above have shown that with the two new bis(benzimidazole) ligand b2b and b3b in the presence of weakly coordinating anions in alcoholic solution dinuclear copper(II) alkoxo-bridged compounds are formed. It appears that these ligands are basic enough to dehydronate the alcohol. The Cu–Cu distances and the Cu–O–Cu angles of the compounds, as determined by single-crystal X-ray analysis, are in the range known for other alkoxo-bridged compounds with bis(benzimidazolyl)alkane ligands. The spectroscopic and magnetic properties of our compounds also agree with theoretical expectations. Finally, the first X-ray structure of a Cu(II) dipropoxo-bridged dinuclear compound is reported.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-159159 and no. CCDC-159160 for structures **1** and **3**, respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033, e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Synthesis and characterization of some new acetato complexes of molybdenum(IV), (V) and (VI). Crystal structures of $Na_2[Mo_2O_4(OCOCH_3)_6]\cdot NaOCOCH_3\cdot CH_3COOH$ and $K[MoO_2(OCOCH_3)_3]\cdot CH_3COOH$

Received 20 July 2001; accepted 11 September 2001

Abstract

The acetato complexes of molybdenum(VI), (V) and (IV): $[MoO_2(OCOCH_3)_2]$ (**1**), $Na_2[Mo_2O_4(OCOCH_3)_6]\cdot NaOCOCH_3\cdot CH_3COOH$ (**2**), $K[MoO_2(OCOCH_3)_3]\cdot CH_3COOH$ (**3**), $[Mo_2O_3(OCOCH_3)_4]$ (**4**), $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]\cdot 16H_2O$ (**5**) and $[Mo_3O_2(OCOCH_3)_6(H_2O)_3]Cl_2\cdot 14H_2O$ (**6**) have been prepared and characterized by chemical analyses, ESR and IR spectroscopy. The crystal structures of **2** and **3** have been determined by single-crystal X-ray crystallography. Both complexes contain octahedrally coordinated molybdenum atoms with bonds formed to two terminal oxo-oxygen atoms and four oxygen atoms from the acetate ligands. In **2** two acetate ligands are monodentately bonded to each molybdenum atom while the third one together with its centrosymmetrical pair acts as a bridging ligand between two molybdenum atoms. In **3** two acetate ligands are monodentately and one bidentately bonded to molybdenum. In both structures the acetic acid molecules are not involved in bonding to molybdenum but act as bridges over both (in **2**) or only one oxygen atom (in **3**) connecting centrosymmetrically related sodium and potassium ions, respectively. © 2002 Elsevier Science Ltd. 1. Introduction

The dimeric molybdenum(II) acetate, $[Mo_2(OCOCH_3)_4]$, prepared by the method described by E. Bannister and G. Wilkinson in 1960, was the first isolated acetato complex of molybdenum. However, the reaction yield was poor, amounting to 20% [1,2]. In 1978 A. Bino et al. showed that as well as $[Mo_2(OCOCH_3)_4]$, different trinuclear molybdenum(IV) compounds could be separated from the same solution by ion exchange chromatography [3]. A few years later, the same authors reported the isolation of six new complexes of the general formula $[Mo_3O_x(CCH_3)_{2-x}(OCOCH_3)_6(H_2O)_3]^{2+}$ containing a trinuclear cation capped either by oxygen atoms or alkylidyne ligands [4]. These findings opened a new area in the chemistry of molybdenum and so far a number of acetato complexes containing the trinuclear molybdenum(IV) core with different bridging units have been described [5].

The structural type of triangular metal–metal bonded cluster compounds basically depends upon the applied preparative procedure [6,7]. For instance, the reaction of MoO_4^{2-} with $Mo(CO)_6$ (or $Cr(CO)_6$) results in the formation of the most commonly found cluster of an

PII: S0277-5387(01)00973-1

incomplete cubane type such as in $[Mo_3O_4(OCOCH_3)_8]^{4-}$ [8–11] or the monooxo-capped cluster as in the $[Mo_3O(OCOCH_3)_8]^{2-}$ anion [12]. In addition, the trimolybdenum clusters with two capping oxygen atoms (μ_3-O) of the general formula $[Mo_3O_2(OCOCH_3)_6X_3]^{2+}$ were prepared in the reaction of $Mo(CO)_6$ with acetic acid and acetic anhydride [3,4], or by reducing sodium molybdate in acetic anhydride with the use of $W(CO)_6$ [13], $[Mo_2(OCOCH_3)_4]$ [6] or zinc [7] as reducing agents. Until now, the molecular structures of some of these clusters such as $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]\cdot 16H_2O$ [13], $[Mo_3O_2(OCOCH_3)_6(H_2O)_3]Br_2\cdot H_2O$ [4,14], $[Mo_3O_2(OCOCH_3)_6(H_2O)_3](CF_3SO_3)_2\cdot CF_3SO_3H\cdot H_2O$ [4,6,14] and $[Zn_2(OCOCH_3)_3][Mo_3O_2(OCOCH_3)_6(OCH_3)_3]\cdot 2H_2O$ [7] have been determined by single-crystal diffraction method.

However, in spite of many examples of such acetato complexes of molybdenum(IV) very little is known about such complexes with molybdenum in its higher oxidation states $+5$ and $+6$. Rare examples are dimeric complexes in which two molybdenum atoms are bridged either by one, $[Mo_2O_3(OCOR)_4]$ [15], or by two oxygen atoms $(NH_4)_2[Mo_2O_4(OCOCH_3)_4(H_2O)_2]$ [16]. Their structures, however, have been postulated only on the basis of chemical analyses and spectroscopic data. As far as we are aware of, the crystal structures of $[\{Mo_2ClO_3(OCOCH_3)_3\}_2]\cdot(CH_3CO)_2O$ [17] and of those of the general formula $[Mo_2(NTo)_2\{S_2P(OEt)_2\}_2(OCOCH_3)S(SR)]$ (To = *p*-tolyl) [18–20] are the only known examples of molybdenum acetates with molybdenum in its higher oxidation states.

In this paper we describe the preparation and characterization of the following acetato complexes of molybdenum(VI), (V) and (IV): $[MoO_2(OCOCH_3)_2]$ (**1**), $Na_2[Mo_2O_4(OCOCH_3)_6]\cdot NaOCOCH_3\cdot CH_3COOH$ (**2**), $K[MoO_2(OCOCH_3)_3]\cdot CH_3COOH$ (**3**), $[Mo_2O_3(OCOCH_3)_4]$ (**4**), $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]\cdot 16H_2O$ (**5**) and $[Mo_3O_2(OCOCH_3)_6(H_2O)_3]Cl_2\cdot 14H_2O$ (**6**). Whereas, the complexes **1**–**4** and **6** are described here for the first time, for the known complex **5** we suggest a different procedure for its preparation. However, while all syntheses are of interest to understand more fully the reaction of MoO_4^{2-} with an excess of acetic anhydride, the identification of the reaction products helps to explain how the reduction of molybdenum depends upon the reaction conditions, starting materials and the type of reducing agents.

All prepared complexes were characterized by chemical analyses, ESR and IR spectroscopy, **2** and **3** additionally by single-crystal X-ray crystallography. Our X-ray determination of the structures **5** and **6** confirmed that they belong to the structural type already known from the literature [13,14].

2. Experimental

All reagents were of reagent grade and used as purchased. The starting compound $(NH_4)_2[Mo_2O_4(OH)_4(H_2O)_2]$ was prepared as described in the literature [21]. The Analytical Services Laboratory of Rudjer Bošković Institute, Zagreb, provided C and H analyses. Molybdenum [22], Na [23], K [24] and chlorine [23] were determined according to the methods described in literature. Infrared spectra were recorded with an FTIR 1600 Fourier transform spectrophotometer in the 4500–450 cm^{-1} region. The KBr discs of **2** and **3** were prepared in the dry box. Magnetic measurements were made by the standard Gouy method. pH measurements were done using a Mettler MP220 pH meter. The ESR spectra were recorded on a polycrystalline sample on a Varian E-109 spectrometer operating at 100 kHz modulation. DPPH (α,α′-diphenil-β-picrylhydrazyl) was used as an internal reference. All measurements were made at room temperature (r.t.). Paramagnetic (Mo^{5+}) concentration was determined by double integration of the spectrum and compared with the standard Varian strong pinch [25].

2.1. Synthesis and characterization of complexes

2.1.1. Dioxobis(acetato(O,O′))molybdenum(VI), $[MoO_2(OCOCH_3)_2]$ (1)

$MoO_3\cdot 2H_2O$ (2 g, 11.1 mmol) was added in several portions to the mixture of AcOH (10 ml) and Ac_2O (10 ml) and the suspension was heated for 2 h at 80 °C. The unreacted MoO_3 was filtered off and the obtained filtrate evaporated to the third of its volume. The resulting precipitate obtained upon standing of the solution at r.t. for 1 week was filtered off in dry atmosphere, rinsed with CCl_4 and stored in a dessicator.

Yield: 2.1 g, 78%. *Anal.* Calc. for $C_4H_6MoO_6$ (M_r = 246.026): C, 19.53; H, 2.46; Mo, 39.00. Found: C, 19.41; H, 2.61; Mo, 38.93%. IR data (KBr, cm^{-1}): 1575 (s), 1441 (s), 1431 (s), 1349 (m), 992 (m), 950 (s), 669 (m), 656 (m).

2.1.2. Sodium di-μ-oxo-bis(μ-acetato(O,O′))tetrakis-(acetato(O))-dioxodimolybdate(VI) sodium acetate acetic acid solvate (1/1/1), $Na_2[Mo_2O_4(OCOCH_3)_6]\cdot NaOCOCH_3\cdot CH_3COOH$ (2)

$Na_2MoO_4\cdot 2H_2O$ (3 g, 12.4 mmol) was dissolved in Ac_2O (15 ml) and the solution warmed up just below the boiling temperature until all the sodium molybdate was dissolved. The solution was cooled to r.t., the mixture allowed to settle overnight and the resulting precipitate filtered off. The resulting filtrate was left at r.t. and after a few days the obtained crystalline product was filtered off in dry atmosphere, rinsed with CCl_4 and dried in a dessicator.

Yield: 2.1 g, 42.3%. *Anal.* Calc. for $C_{14}H_{21}Mo_2Na_3O_{18}$ ($M_r = 738.16$): C, 22.78; H, 2.87; Mo, 25.99; Na, 9.34. Found (since the crystals rapidly lost AcOH they were left in a dessicator until they were a constant weight and the analysis was then performed using the unsolvated sample): C, 23.75; H, 2.98; Mo, 25.73; Na, 8.65%. IR data (KBr, cm^{-1}): 1557 (s, br), 1452 (s, br), 1272 (s), 1059 (m), 988 (m), 948 (s), 732 (s, br), 639 (m).

*2.1.3. Potassium bis(acetato(O))(acetato(O,O'))-dioxomolybdate(VI) acetic acid solvate (1/1), $K[MoO_2(OCOCH_3)_3]\cdot CH_3CO_2H$ (**3**)*

The preparation was performed as described above by dissolving K_2MoO_4 (3 g, 15.1 mmol) in Ac_2O (15 ml).

Yield: 2.3 g, 46.3%. *Anal.* Calc. for $C_6H_9KMoO_8$ ($M_r = 344.172$): C, 20.94; H, 2.64; K, 11.36; Mo, 27.88. Found (since these crystals were also rapidly losing AcOH the same analytical procedure was used as in **2**): C, 20.45; H, 2.34; K, 11.21; Mo, 27.39%. IR data (KBr, cm^{-1}): 1560 (s, br), 1444 (s, br), 1349 (s), 1049 (m), 990 (s), 949 (m), 885 (m, br), 638 (m).

*2.1.4. μ-Oxo-tetrakis(acetato(O,O'))-tetraoxodimolybdenum(V) $[Mo_2O_3(OCOCH_3)_4]$ (**4**)*

$(NH_4)_2[Mo_2O_4(OH)_4(H_2O)_2]$ (2 g, 5.1 mmol) was dissolved in Ac_2O (30 ml) and the solution warmed up for 3 h at 90 °C. The obtained olive brown product was filtered off, rinsed with CCl_4 and dried in a dessicator.

Yield: 1.8 g, 75%. *Anal.* Calc. for $C_8H_{12}Mo_2O_{11}$ ($M_r = 476.054$): C, 20.18; H, 2.54; Mo, 40.31. Found: C, 19.57; H, 2.52; Mo, 39.95%. IR data (KBr, cm^{-1}): 1538 (s, br), 1446 (s, br), 981 (s), 739 (s, br), 655 (m).

*2.1.5. Hexakis(μ-acetato(O,O'))di-μ_3-oxo-aquadihydroxytrimolybdenum(IV) hexadecahydrate (**3** Mo–Mo) $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]\cdot 16H_2O$ (**5**) and hexakis(μ-acetato(O,O'))di-μ_3-oxo-triaqua-trimolybdenum(IV) chloride tetradecahydrate (**3** Mo–Mo) $[Mo_3O_2(OCOCH_3)_6(H_2O)_3]Cl_2\cdot 14H_2O$ (**6**)*

2.1.5.1. Procedure A. A mixture of $Na_2MoO_4\cdot 2H_2O$ (or K_2MoO_4) (0.5 g, 2 mmol), $SnCl_2\cdot 2H_2O$ (0.46 g, 2 mmol) and Ac_2O (20 ml) was warmed at 125 °C under Ar atmosphere for 15 h during which time a dark brown supernatant liquid and red precipitate were formed. The precipitate was isolated by filtration, rinsed with dry CCl_4 and dried in dessicator. It was hydrolysed in water (5 ml) and the obtained solution (pH approximately 5) left to evaporate slowly in an open vessel at r.t. After 2 days red crystals of **5** were filtered off and dried.

2.1.5.2. Procedure B. A mixture of M_2CO_3, where M = Na, K, Rb, Cs (2 mmol), $MoO_3\cdot 2H_2O$ (0.36 g, 2 mmol), $SnCl_2\cdot 2H_2O$ (0.46 g, 2 mmol) and Ac_2O (20 ml) was warmed at 125 °C under Ar atmosphere for 3 days until a dark brown solution was obtained. The solution was evaporated by vacuum distillation to one-third of its volume and cooled to r.t. Acetone (30 ml) was added and the obtained red powdered mixture was isolated by filtration, rinsed with CCl_4 and dried in a dessicator. It was hydrolysed in water (5 ml) and the resulting solution was left to evaporate slowly in air. After about 3 days crystals of **6** came out from the solution if the pH of the solution was maintained at about 3. However, if the pH was about five crystals of **5** instead of **6** were obtained. IR and elemental analyses proved that compound **5** prepared by procedure B was identical to that prepared by procedure A.

Compound **5**: Yield: 0.23 g, 45.6% (prepared by procedure A). Yield: 25–30% (prepared by procedure B). *Anal.* Calc. for $C_{12}H_{22}Mo_3O_{17}$ ($M_r = 726.112$): C, 19.85; H, 3.05; Mo, 39.64. Found (since the crystals were losing water of crystallization they were left in a dessicator until they were a constant weight so that the analysis was performed using an unsolvated sample): C, 19.4; H, 3.55; Mo, 39.10%. IR data (KBr, cm^{-1}): 3616 (m), 3475 (s, br), 1636 (m, br), 1556 (s), 1454 (s), 1354 (m), 1051 (w), 689 (s), 644 (m), 588 (m).

Compound **6**: Yield: 30–35%. *Anal.* Calc. for $C_{12}H_{24}Cl_2Mo_3O_{17}$ ($M_r = 799.034$): C, 18.04; H, 3.03; Cl, 8.87; Mo, 36.02. Found (since the crystals were losing water of crystallization the same procedure was used as in the case of **5**): C, 18.41; H, 3.25; Cl, 8.18; Mo, 36.66%. IR data (KBr, cm^{-1}): 3616 (m), 3447 (s, br), 2936 (w), 1636 (m, br), 1560 (s), 1454 (s), 1354 (m), 1052 (w), 893 (w), 691 (s), 644 (s), 591 (m).

2.2. X-ray crystallography

The well-developed, colourless single crystals of **2** and **3** were very difficult to handle due to rapid decomposition when exposed to air. They were stable if kept in a closed flask in mother liquor. They had to be transferred directly from the flask into a capillary and sealed. Data were collected at r.t. on a four-circle PW 1100 diffractometer (Stoe upgraded) with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) [26]. Lattice constants were obtained by least-squares refinement from the settings of 42 reflections ($10.3 \leq \theta \leq 18.8°$) for **2** and 38 reflections ($10.9 \leq \theta \leq 18.5°$) for **3**. Three reference reflections were monitored every 90 min. Both crystals were stable at the beginning of the data collection but the final decay amounted to 9 and 8% for **2** and **3**, respectively. The data were corrected for decay, Lorentz and polarization effects using the X-RED [27] program. Crystal data, experimental conditions, details of structure determination and final refinement parameters are given in Table 1.

In both structures the molybdenum atoms were located by the Patterson method and all non-hydrogen atoms in the subsequent difference Fourier maps. Refinement, in which non-hydrogen atoms were treated anisotropically, was performed by the full-matrix least-squares method based on the F^2 values against all reflections. The last Fourier maps revealed positions of all H atoms but some of them with poor geometry. Methyl-H was therefore calculated at positions that maximized the sum of their electron density, i.e. the torsion angles were refined while keeping the angles and distances fixed (C–H 0.96 Å and $U_{iso} = 1.5\ U_{eq}$). In both **2** and **3** the hydrogen atom bonded to the AcOH oxygen atom was found in the Fourier maps. In **2** it was kept fixed during the refinement with an occupancy of 0.5 since it belongs with 50% probability to either one of the centrosymmetrically related acetate ions thus forming AcOH–acetate pairs, while in **3** it was refined (Tables 2 and 3).

All calculations were done by SHELXS [28] and SHELXL [29], and the molecular graphics with PLATON [30].

3. Results and discussion

3.1. Synthesis and characterization of complexes

3.1.1. Synthesis of molybdenum(VI) complexes

$[MoO_2(OCOCH_3)_2]$ (**1**) was obtained by refluxing molybdenum(VI) oxide with the 1:1 mixture of acetic acid and acetic anhydride, $Na_2[Mo_2O_4(OCOCH_3)_6]\cdot NaOCOCH_3\cdot CH_3COOH$ (**2**) and $K[MoO_2(OCOCH_3)_3]\cdot CH_3CO_2H$ (**3**) were prepared by dissolving sodium and potassium molybdate, respectively, in acetic anhydride. As far as we know complexes **2** and **3** are the first structurally characterized examples of molybdenum acetato complexes with molybdenum in its +6 oxidation state. All complexes were extremely sensitive to moisture not only in the solid state but also in solution. The crystals of **1** exposed to light and moisture also showed photochromic behaviour changing colour from pale yellow to blue. Its ESR spectrum (Fig. 1) clearly

showed partial change of the Mo oxidation number from +6 to +5 [31].

3.1.2. Synthesis of molybdenum(V) complex

An olive green molybdenum(V) complex $[Mo_2O_3(OCOCH_3)_4]$ (**4**) was prepared by the reaction of $(NH_4)_2[Mo_2O_4(OH)_4(H_2O)_2]$ [21] with acetic anhydride. The diamagnetism of the complex is characteristic of an oxo bridged molybdenum(V) dimer, but due to its insolubility in all common solvents we were not able to prepare crystals suitable for X-ray analyses.

3.1.3. Synthesis of molybdenum(IV) complexes

The reduction of sodium or potassium molybdate with $SnCl_2{\cdot}2H_2O$ in hot acetic anhydride gave a mixture of a red powder and a colourless substance. Red crystals of $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]{\cdot}16H_2O$ (**5**) were obtained if the precipitate was dissolved in water and the solution left to evaporate slowly. The same complex could be obtained by heating the mixture of MoO_3 and corresponding carbonate M_2CO_3 (M = Na, K, Rb, Cs) in acetic anhydride with $SnCl_2{\cdot}2H_2O$. However, the structural type of the obtained cluster depends upon the pH of the solution i.e. upon the amount of carbonate left over in the reaction solution. The crystals of $[Mo_3O_2(OCOCH_3)_6(H_2O)(OH)_2]{\cdot}16H_2O$ (**5**) and $[Mo_3O_2(OCOCH_3)_6(H_2O)_3]Cl_2{\cdot}14H_2O$ (**6**) were obtained from aqueous solution at pH 5 and 3, respectively. For both complexes the oxidation number +4 of molybdenum (actually +3.93 and +3.95 for **5** and **6**, respectively) was determined by titration with standard Ce(IV) solution [32]. The trimeric nature of **5** and **6** was also confirmed by X-ray diffraction [13,14].

Table 3
Selected bond lengths (Å) and angles (°) for **3**

Bond lengths	
Mo–O1	1.692(2)
Mo–O2	1.696(2)
Mo–O3	1.989(2)

O5–Mo–O8	81.32(8)

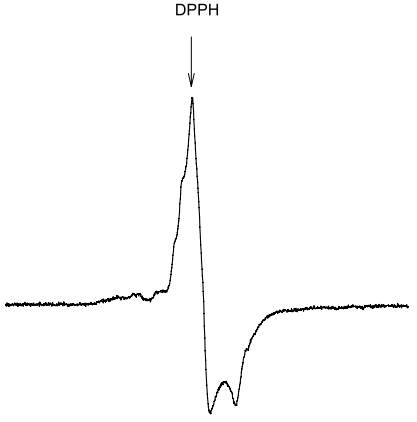

Fig. 1. EPR spectrum of $[MoO_2(OCOCH_3)_2]$.

The complexes were also characterized by IR spectroscopy. The strong bands characteristic of $\nu(Mo–O_t)$ were found at 995–950 cm^{-1} for the *cis*-dioxomolybdate(VI) unit and 938 cm^{-1} for μ-oxomolybdenum(V). Other characteristic strong bands appearing around 1575–1540 and 1455–1440 cm^{-1} (broad) were attributed to $\nu_{asym}(OCO)$ and $\nu_{sym}(OCO)$, respectively. The strong absorption found at 739 cm^{-1} is characteristic of $\nu(Mo–O_b)$, while those at 690 and 644 cm^{-1} were attributed to $\nu(Mo–O_3)$.

3.2. Structural studies

Structures of both $Na_2[Mo_2O_4(OCOCH_3)_6]{\cdot}NaOCOCH_3{\cdot}CH_3COOH$ (**2**) and $K[MoO_2(OCOCH_3)_3]{\cdot}CH_3COOH$ (**3**) contain octahedrally coordinated molybdenum atoms bonded to two terminal oxo-oxygen atoms and four oxygen atoms from the acetate ligands.

The crystal structure of **2** is built up of centrosymmetrical dinuclear complex $[Mo_2O_4(OCOCH_3)_6]^{2-}$ anions (Fig. 2) interconnected by sodium cations and centrosymmetrical pairs of acetate–acetic acid (Fig. 3). The terminal Mo=O bond lengths amount to 1.680(2) and 1.699(2) Å. Two acetate ligands are monodentately bonded to each molybdenum atom at 2.023(2) and 2.028(2) Å, while the third one together with its centrosymmetrical pair acts as a bridge with Mo–O distances of 2.169(2) and 2.222(2) Å. They are the longest Mo–O bonds due to the *trans* influence of the terminal oxo-oxygen atoms. The octahedron is distorted with angles at Mo atom ranging from 79.32(6) (involving two oxygens from the bridging acetate) to 102.41(9)° (formed by two oxo-oxygen atoms).

The crystal structure of **3** is built up of mononuclear complex $[MoO_2(OCOCH_3)_3]^-$ anions (Fig. 4) interconnected by potassium cations and acetic acid molecules. The Mo=O bonds are similar as in **2** (1.692(2) and 1.696(2) Å). The Mo–O bonds from the bidentately bonded acetate ligand are *trans* to the oxo-oxygen

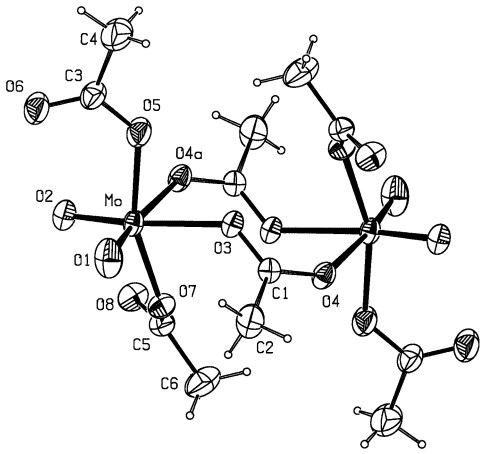

Fig. 2. Drawing of the $[Mo_2O_4(OCOCH_3)_6]^{2-}$ anion in **2** with the atom labelling scheme. The thermal ellipsoids are at the 50% probability level. Symmetry operations: $a = -x, -y, -z+1$.

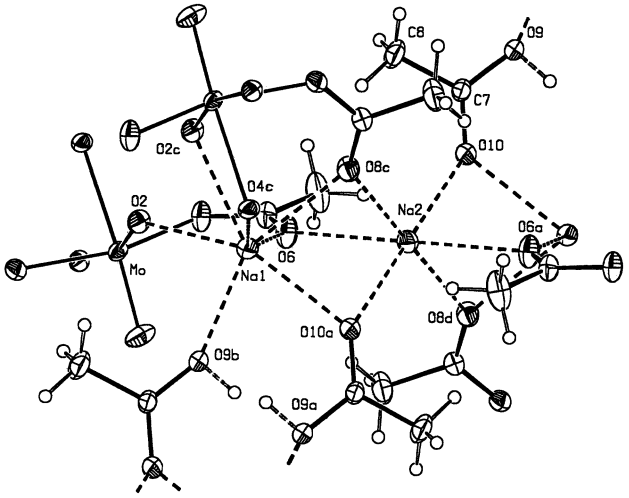

Fig. 3. The coordination polyhedron around the two sodium atoms is shown by dashed lines. Only the oxygen atoms within the sodium coordination sphere and the acetic acid–acetate ion atoms are labelled. The H atom on O9 is of 50% probability and the bond is shown by double broken lines. Symmetry operations: $a = 1-x, 1-y, -z$; $b = -1+x, y, z$; $c = -x, -y, -z$; $d = 1+x, 1+y, z$.

atoms and are again the longest ones (2.233(2) and 2.270(2) Å), even longer than in **2**. The two monodentately bonded acetates form Mo–O bonds of 1.989(2) and 2.021(2) Å, respectively. The coordination octahedron is even more distorted than in **2** with O–Mo–O angles ranging from 57.18(8) to 108.0(1)°, the largest angle is again that one involving the oxo-oxygen atoms and the smallest one involving oxygens from the bidentately bonded acetate ligand. In the chemistry of molybdenum there are not many examples of such structures with an acetato ligand bidentately bonded to one molybdenum atom. Actually molybdenum(IV) complexes $[Mo\{C_7H_2(CCH_3)_4\}(OCOCH_3)_2]$ [33] and $[Mo(OCOCH_3)(\eta^3\text{-}C_3H_5)_3]$ [34] are the only such examples with the Mo-to-acetate–oxygen bond lengths ranging from 2.144(2) to 2.264(2) Å. They are longer comparing to those in **2** and **3**.

By searching the Cambridge Structural Database for all Mo–O(acetate) bonds, 69 structures with 215 Mo–O bonds were found ranging from 2.057 to 2.264 Å. Only two molybdenum complexes with mondentately bonded acetate ligands were found: in one of them, $(Bu_4N)_2[Mo_6(\mu_3\text{-}Cl)_8(OCOCH_3)_6]$ [35], six acetate ligands are bound to a hexanuclear cluster with Mo–O distances ranging from 2.085 to 2.093 Å, while in the other one, $[Mo(H_2CPz)(CO)_2(NO)(OCOCH_3)]$, CPz = 3,5-dimethylpyrazol-1-yl [36], the acetate ions in two independent molecules are bonded with Mo–O distances of 2.095 and 2.152 Å. Therefore, the Mo–O bonds involving the monodentate acetate ligands in **2** and **3** are the shortest Mo–O(acetate) bonds found so far.

In both structures the acetic acid molecules are not involved in bonding to molybdenum but act as bridges either over both (as in **2**, Fig. 3) or over only one oxygen atom (as in **3**, Fig. 5) connecting centrosymmetrically related sodium and potassium ions, respectively. In **2** the acetic acid molecule and the acetate ion are centrosymmetrically related and connected by a hydrogen bond O9–H···O9($-x, 1-y, -z$) of 2.422(3) Å (O9–H 0.92, H···O9 1.51 Å, O9–H···O9 170.2°) with a positionally disordered hydrogen atom. The acetic acid molecule in **3** is linked to a neighbouring acetate ion by a hydrogen bond O10–H···O6 ($2-x, 1-y, -z$) of 2.638(4) Å (O10–H 0.71(4), H···O6 2.01(4) Å, O10–H···O6 148(1)°).

In **2** the two crystallographically independent sodium ions Na1 and Na2 are surrounded by seven and six oxygen atoms, respectively, with distances Na···O ranging from 2.316 (2) to 2.604 (2) Å, while the larger

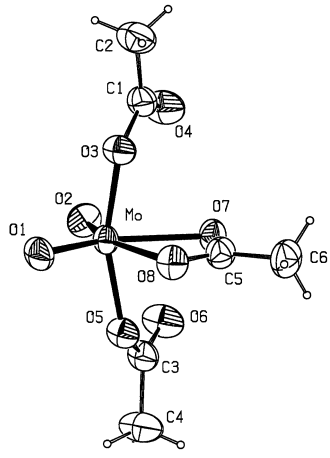

Fig. 4. Drawing of the $[MoO_2(OCOCH_3)_3]^-$ anion in **3** with the atom labelling scheme. The thermal ellipsoids are at the 50% probability level.

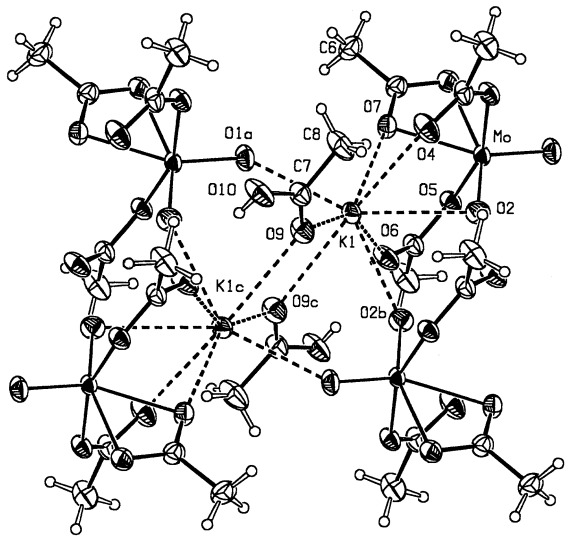

Fig. 5. The coordination polyhedron around the potassium atom is shown by dashed lines. Only the oxygen atoms within the potassium coordination sphere and the acetic acid atoms are labelled. Symmetry operations: $a = 1 + x, y, z$; $b = 1 - x, 1 - y, -z$; $c = 2 - x, 1 - y, -z$.

potassium ion in **3** is eight-coordinated with K···O distances from 2.778(2) to 3.047(3) Å.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 166269 and 166270 for compounds **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The complex originally reported to be '$Cr_{12}O_{12}(pivalate)_{15}$' has been examined by a number of spectroscopic techniques in order to elucidate the chromium valence states. By charge balance arguments, the complex could, for example, contain nine Cr(III) and three Cr(IV) centers, contain 11 Cr(III) and one Cr(VI) center or could possess three protons, not detected by X-ray crystallography, and 12 Cr(III) centers. While a recent neutron diffraction study has suggested the existence of three additional and disordered deuterons (and thus 12 Cr(III) centers), the complex has been studied by several complementary spectroscopic techniques which confirm the formula to be $Cr_{12}O_9(OH)_3(pivalate)_{15}$. © 2002 Elsevier Science Ltd. 1. Introduction

In 1991, Batsanov et al. reported the synthesis and X-ray diffraction (XRD) structure of a complex they tentatively assigned the formula '$Cr_{12}O_{12}(pivalate)_{15}$' [1]. Charge balance requirements necessitate that the complex be mixed valent containing Cr(III) and higher oxidation state chromium centers or that all the chromium centers be trivalent and three additional protons be present that could not be located by X-ray crystallography. To establish the chromium oxidations states, we set out to obtain a higher resolution X-ray structure and to characterize the complex by a series of spectroscopic techniques. While this work was in progress, Winpenny and co-workers [2] reported that the complex's formula should be $Cr_{12}O_9(OH)_3(pivalate)_{15}$ based on variable temperature magnetic susceptibility studies, high-field EPR studies, and most importantly neutron diffraction studies. The last technique disclosed the presence of three disordered half-weight deuterons bound to six of the μ_3-oxo ligands. Herein are reported our complementary spectroscopic studies, which confirm the formula as $Cr_{12}O_9(OH)_3(pivalate)_{15}$.

2. Experimental

2.1. Materials and physical measurements

The starting polymer $[Cr(OH)(O_2CC(CH_3)_3)_2]_n$ was prepared as described previously [1]. All chemicals were used as received; all operations were performed in air unless otherwise noted. Infrared spectra (mineral oil mulls) were recorded on a Perkin–Elmer 283B spectrophotometer, and ^1H NMR spectra were obtained using a Bruker AM-360 or a Bruker AM-500 spectrometer at 23 °C. Chemical shifts are reported on the δ scale (shifts downfield are positive) using the solvent

deuterio-component signal(s) as reference. Evans method solution susceptibility measurements [3] were performed using hexamethyldisiloxane as a chemical shift reference; diamagnetic contributions were corrected using Pascal's constants. A Hewlett–Packard 8451A spectrophotometer was used to record UV–Vis spectra. FAB and EI mass spectra were obtained using a VG Autospec high-resolution mass spectrometer. FAB mass spectra of the dodecanuclear complexes (**1** and **3**) were collected on mixtures made from 1.5 μl of the complex in *n*-propanol (10 μg ml^{-1}) and 1.5 μl of thioglycerol containing 1% trifluoroacetic acid. The FAB mass spectrum of **2** was collected on a 10 μg ml^{-1} solution of the complex in 3-nitrobenzyl alcohol. EPR spectra were collected on a Varian E-12 spectrophotometer equipped with an Oxford ESR 900 cryostat. X-ray photoelectron spectroscopy (XPS) measurements were performed using a Kratos Analytical Axis 165 XPS with monochromatic Al Kα radiation (1486.6 eV). The analyzer pass energy employed for high resolution spectra was 40 eV with 0.1 eV per step. The Cr-containing powder sample was placed onto carbon tape mounted on an analysis stub. The stub was then inserted into the chamber. The base pressure during XPS analysis remained below 10^{-9} Torr. A charge neutralizer was employed to supply electrons for charge compensation. The XPS spectra were referenced to aliphatic carbon in the C 1s region as 285.0 eV and carboxylate carbon to 289.3 eV. Data analysis and fitting using standard Shirley background correction was performed using Spectral Data Processor software (XPS International). Elemental analyses were performed by Galbraith Laboratories (Knoxville, TN).

2.2. $Cr_{12}O_9(OH)_3(O_2CC(CH_3)_3)_{15}\cdot 3\ 1/6\ HOPr\cdot 4H_2O$ (1)

$[Cr(OH)(O_2CC(CH_3)_3)_2]_n$ (2.0 g) was placed in a quartz boat within a reaction tube and heated under a slow purge of Ar in a 400 °C tube furnace for 1 h. The green sublimate, which was deposited in the end of the reaction tube, was taken up in a minimum amount of Et_2O, and an equal volume of MeCN was added. The solution was allowed to concentrate slowly, yielding dark green crystals. The crystals were collected by filtration and recrystallized from *n*-propanol producing dark green crystals of **1** in an average yield of 0.35 g (23% yield based on Cr). *Anal.* Calc. (Found) for $C_{84.50}H_{171.33}O_{49.17}Cr_{12}$: C, 39.06 (39.14); H, 6.65 (7.14); Cr, 24.01 (24.06%). Selected IR data (cm^{-1}): 1584 (s), 1564 (s), 1548 (s), 1233 (s), 690 (s), 624 (s), 467 (s). Visible spectrum (*n*-propanol): $\lambda_{max} = 444$ nm (ε/Cr = 69), $\lambda_{max} = 616$ nm (ε/Cr = 89).

2.3. $[Cr_3O(O_2CC(CH_3)_3)_6(H_2O)_3]^+$ (2)

Pivalic acid (1.02 g, 9.98 mmol) and 0.560 g (9.98 mmol) of potassium hydroxide were combined in 35 ml of stirred and gently warmed tetramethylene sulfone; stirring with low heat was continued until all the solid dissolved. To this solution, a solution of 2.00 g (7.51 mmol) chromium(III) chloride hexahydrate in 25 ml of warm tetramethylene sulfone was added. The reaction mixture was heated at reflux for 4.5 h and then allowed to cool to r.t. The resulting green solid was dissolved in acetone, filtered, and allowed to concentrate slowly to produce dark green crystals of the chloride salt of **2** in 22% yield (based on Cr). *Anal.* Calc. (Found) for $C_{30}H_{60}O_{16}Cr_3Cl$: C, 39.08 (38.59); H, 7.38 (7.24); Cl, 3.66 (4.03), Cr, 16.09 (15.75). Selected IR data (cm^{-1}): 1594 (s), 1487 (m), 1460 (s), 1432 (s), 1379 (s), 1297 (w), 1231 (s), 1148 (w), 1110 (w), 1035 (w), 942 (w), 906 (w), 789 (w), 724 (w), 670 (w), 623 (m), 490 (w), 469 (m). Visible spectrum (acetone): $\lambda_{max} = 441$ and 590 nm.

2.4. $Cr_{12}O_{12}(O_2CC(CH_3)_3)_{12.46}(O_2CCCl_3)_{2.54}\cdot HOPr\cdot 4H_2O$ (3)

$Cr_{12}O_9(OH)_3(O_2CC(CH_3)_3)_{15}\cdot 3\ 1/6\ HOPr\cdot 4H_2O$ (**1**) (0.25 g, 0.096 mmol) was dissolved in 35 ml of *n*-propanol. To this stirred solution was added 0.35 g, 2.2 mmol of Cl_3CCO_2H. The reaction mixture was heated at reflux for 9.5 h. The resulting solution was cooled, and slow concentration of the solution produced dark green crystals in 83% yield (0.20 g, 0.079 mmol). *Anal.* Calc. (Found) for $C_{79.38}H_{152.14}O_{50}Cr_{12}Cl_{7.62}$: C, 34.00 (34.04); H, 5.58 (5.57); Cl, 9.64 (9.63); Cr, 22.25 (22.25). Selected IR data: 1700 (m), 1650 (m), 1578 (s), 1234 (s), 1772 (w), 853 (m), 836 (m), 783 (w), 758 (w), 720 (m), 689 (s), 624 (s), 585 (m). Visible spectra (*n*-propanol): $\lambda_{max} = 446$ (ε/Cr = 42) and 611 nm (ε/Cr = 55).

2.5. X-ray crystallography and structure solution

X-ray crystallographic intensity data for complex **1** were collected on a green, hexagonal-shaped crystal, $0.1 \times 0.20 \times 0.20$ mm (Table 1). The crystal was mounted in a glass capillary, and intensity data were collected at −100 °C on a Siemens SMART diffractometer with a CCD area detector and with graphite-monochromated Mo Kα radiation in the range $\theta = 1.39°$–$27.87°$. The space group *R*32 was assigned on the basis of extinctions. A total of 22 694 reflections were collected of which 5575 were unique and 3520 were considered observed [$I > 1\sigma(I)$]. The structure was solved by direct methods using the computing package SHELXTL, Version 5 [4], and refined by full-matrix least-squares minimization of $w(F_o^2 - F_c^2)^2$ with anisotropic thermal parameters for all non-hydrogen

atoms. Final R factors were 0.0896 and 0.2233 for R_1 and wR_2, respectively.

In the refinement of **1**, solvent and ligand disorder was noted. The ligand t-butyl groups, in general, exhibited high thermal motion and were refined isotropically. Rotational disorder was resolved for one unique ligand and atoms C(8)–C(10) were refined in two alternate orientations with 50% occupancy each.

The solvent and water molecules exhibited very diffuse peaks making it difficult to refine effectively these atoms. The final refinement was nest modeled on two disordered n-PrOH molecules and nine disordered water molecules per formula unit. The high thermal motion and disorder of the solvent and ligand molecules on the periphery of the cluster resulted in high R values for the overall refinement. Nonetheless, the Cr and O atoms of the cluster were well behaved in the refinement, and the geometrical parameters of the core of the cluster gave reasonable e.s.d. Only this portion of the structure will be discussed.

3. Results and discussion

3.1. Synthesis

The original synthesis of **1** by Bastanov et al. involved heating the starting polymer $[Cr(OH)(O_2CC(CH_3)_3)_2]_n$ in a 400 °C bath under a flow of argon; the resulting sublimate underwent extensive purification via a series of extractions and crystallizations. The yield after recrystallization from n-propanol, but before suitable crystals for X-ray crystallography were obtained from α-methylnapthalene, was approximately 37% [1]. A synthesis and purification involving fewer steps was desirable. In initial attempts to develop an alternate synthesis of **1**, the starting polymer was refluxed in a high-boiling-point solvent, tetramethylene sulfone (b.p. 285 °C). However, the subsequent reaction gave rise to the basic carboxylate trimer $[Cr_3O(O_2CC(CH_3)_3)_6(H_2O)_3]^+$ (**2**).

As an alternative, the starting polymer was heated to 400 °C in a reaction tube in a tube furnace under a flow of argon. Under these conditions, released pivalic acid was flushed from the reaction tube, and **1** deposited at the end of the tube, readily separating from the chromic oxide byproduct left in the quartz boat. Now the sublimate only had to be recovered by rinsing the reaction tube with an appropriate solvent; recrystallization from n-propanol gave crystals suitable for XRD studies. Winpenny and co-workers [2] have shown recently that a single recrystallization step (also using n-propanol) is all that is necessary after the first step of the original Bastanov procedure.

In order to test whether hydroxide bridges were present in **1**, an effort was made to substitute the pivalate ligands with another carboxylate with a very different electron donating ability. It was anticipated that substitution of the electron-donating t-butyl group of pivalate with the electron-withdrawing CCl_3 group of trichloroacetate might alter the acidity of any bridging hydroxide groups and give rise to a dodecamer bearing a negative charge. The addition of the more acidic acid, trichloroacetic acid, to a refluxing solution of **1** in n-propanol resulted in partial substitution of the pivalate ligands with trichloroacetate. The reaction presumably occurs in the same manner as for similar metal carboxylate assemblies [5] where the more acidic acid is believed to protonate the carboxylate ligand (from the weaker acid). The newly generated carboxylate replaces the newly formed acid. Why only partial substitution occurred is unclear as increasing the ratio of trichloroacetic acid to **1** and increasing the reaction time had little effect on the reaction.

3.2. Description of structure

In the structure of the Cr_{12} by Bastanov et al., the compound was found to crystallize in the space group $P2_1/c$ [1]. Partially because of the large number of atoms, the structure was refined to a precision of $R=$

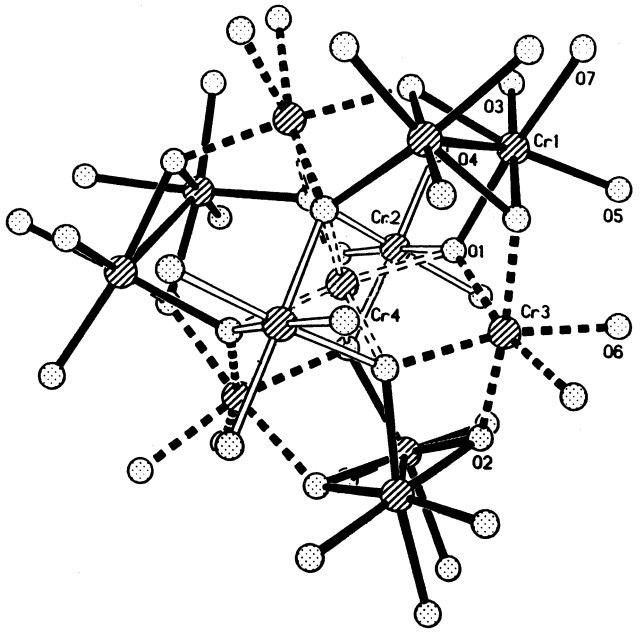

Fig. 1. Body-centered pentacapped trigonal antiprism core of $Cr_{12}O_9(OH)_3(pivalate)_{15}$ (**1**) with atom labels.

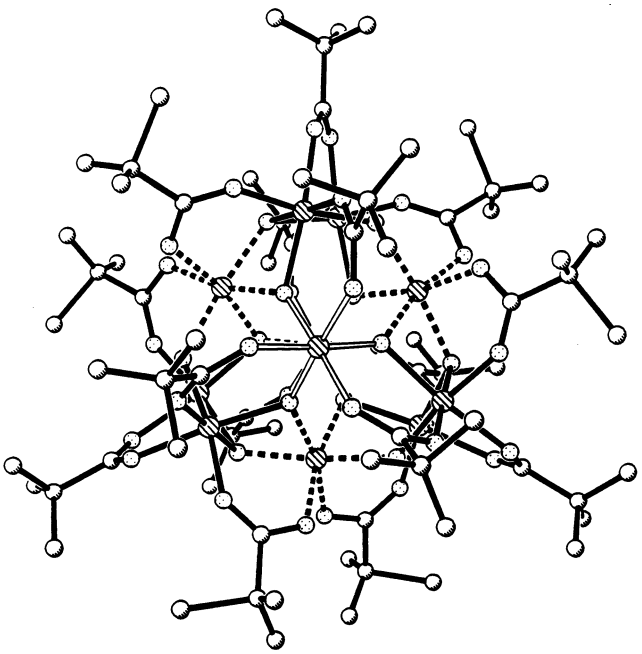

Fig. 2. Structure of $Cr_{12}O_9(OH)_3(pivalate)_{15}$ (**1**) viewed approximately along the C_3 axis.

0.059 ($R_w = 0.067$). It was hoped that obtaining crystals of the complex from another solvent could give rise to crystals with a different space group and whose molecular structure could be refined to a greater degree of precision. Greater precision might allow for the average Cr–O bond distances for the various chromium centers to be distinguished as would be expected if chromium existed in multiple oxidation states in the complex. The space group of **1** recrystallized from *n*-propanol was *R*32 with the molecule lying on a 32 site, imposing D_3 symmetry on the molecule. Consequently, the molecule possessed only four unique chromium sites with the others being generated by the symmetry elements. The molecule is nearly identical in terms of its metric parameters to the α-methylnaphthalene solvate. The formula found for the molecule from X-ray crystallography is the same as reported by Bastanov et al. [1]; three additional, disordered protons corresponding to the three additional deuterons found in the neutron diffraction study [2] could not be located. The 12 chromium centers are arranged in a body-centered pentacapped trigonal antiprism with a twist angle of 16.8° (Fig. 1), compared with 15.3° in the α-methylnaphthalene solvate [1]. The six chromium centers of type Cr1 form the trigonal antiprism. Two chromium centers (type Cr2) form caps 1.284 Å above the triangular bases, while three chromium centers, type Cr3, form caps 1.147 Å above the lateral faces. A unique center, Cr4, lies at the center of the trigonal antiprism. All 15 pivalate ligands are bidentate, bridging between two chromium atoms (Fig. 2).

The octahedron for each of the six Cr1 type chromium centers is completed by one pivalate bridge to a second Cr1 center, spanning the lateral edge of the prism, two μ_3-oxide bridges, which also coordinate to the Cr3 type centers on the adjacent lateral faces, one pivalate bridging to a type Cr2 center, one pivalate bridging to a Cr3 center, and one μ_4-oxide, which is also coordinated to a Cr2, a Cr3, and the Cr4 type center. The octahedron of each of the Cr2 type centers is completed by the pivalate bridging to each of the three type Cr1 centers forming a trigonal face and three μ_4-oxide ligands which bridge between a Cr1, Cr3, and Cr4 center. Octahedral coordination about the Cr3 centers is composed of two pivalate bridges, one each to opposing Cr1 centers such that they span the diagonal of a lateral face, two μ_3-oxide bridges which also coordinate Cr1 centers of the lateral face, and two μ_4-oxide bridges. The Cr4 center lying at the center of the prism is in an extremely novel environment, being surrounded by six μ_4-oxide bridges and capable of supporting a high valent chromium center theoretically.

Tables 2 and 3 list the important bond angles and bond distances for **1**. Examination of the bond lengths reveals all Cr–(μ_n-O) bond lengths to be virtually identical (1.982–2.027 Å). For example, the Cr–(μ_4-O(1)) bond lengths are 1.986(5) Å for the Cr1 type chromiums (corners of the antiprism), 1.994(5) Å for the Cr2 type chromiums (trigonal caps), 2.027(5) Å for the Cr3 type chromiums (lateral face caps), and 1.985(4) Å for the Cr4 type chromium lying at the center of the prism. The values for Cr1, Cr2, and Cr4 are all equivalent within the 3σ criterion. The value for the Cr3 type chromiums (lateral face caps) is considerably larger,

lying outside the 3σ difference. This difference is not, however, suggestive of Cr(IV) or Cr(VI) as bond lengths for Cr(IV)–O or Cr(VI)–O bonds would be shorter than the comparable Cr(III)–O bond length. The origin of the long Cr3–(μ_4-O) bond length is probably steric; the Cr3 centers have two μ_4-O interactions and two μ_3-O interactions, which prevent the center from fitting more closely into the $Cr_{12}O_9(OH)_3$ core. The Cr–(μ_4-O) bond lengths observed are consistent with reported Cr(III) to μ_4-oxide bond lengths in the range of 1.97–2.04 Å [6,7].

The observed Cr–(μ_3-O) bond lengths are 1.974(7) and 1.985(5) Å for the Cr1 type chromium centers and 1.982(6) Å for the Cr3 type chromium centers. These Cr–(μ_3-O) bond distances are slightly elongated relative to those cited for Cr(III)–(μ_3-O) bonds; Cr(III) to μ_3-oxide bond lengths are known to be in the range of 1.85–1.95 Å, although nearly all examples contain planar Cr_3O units rather than pyramidal [8–12]. Though elongated relative to Cr(III)–(μ_3-O) bonds, the observed bond lengths are not suggestive of Cr(IV)–(μ_3-O) or Cr(VI)–(μ_3-O) as these would be shorter than comparable Cr(III) bonds. These μ_3-'oxo' groups are the ones bound to the half-occupancy deuterons in the neutron diffraction study [2]. Thus, the long bond distances and pyramidal geometry are consistent with these sites being on average a mixture of μ_3-oxo and μ_3-hydroxo.

Evaluation of the Cr–(μ-$O_2CC(CH_3)_3$) bond lengths reveals these to be also virtually identical. The Cr–(μ-$O_2CC(CH_3)_3$) bond lengths are 1.940(8), 1.961(5), and 2.017(7) Å, for an average of 1.97(3) Å for the Cr1 type chromiums (corners of the antiprism), 1.985(6) Å for the Cr2 type chromiums (trigonal caps), and 1.989(6) Å for the Cr3 type chromiums (lateral face caps). Using the average value for the Cr1 type chromium atoms, all values are equivalent within the 3σ criterion. This value is consistent with the range of 1.97–2.01 Å reported for μ-carboxylates bound to chromium(III) [8,9,13]. Therefore, the crystallographic data is consistent with all chromium atoms being trivalent. It should be noted that examination of the Bastanov structure also reveals all Cr–O bond lengths to be virtually identical, in the range of 1.95–2.02 Å [1].

X-ray crystallographic data were collected on the trichloroacetic acid derivative $[Cr_{12}O_{12}(O_2CC(CH_3)_3)_{12.46}(O_2CCCl_3)_{2.54}]\cdot 4HOPr\cdot 4H_2O$ (**3**). Unfortunately, the partially substituted complex possessed extensive disorder making refinement very difficult; a

satisfactory structure solution for publication has not been obtained. The best refinement to date reveals the body-centered pentacapped trigonal antiprism core of $Cr_{12}O_{12}$ is maintained (Royer et al., unpublished results).

3.3. NMR spectroscopy

Paramagnetic ^{1}H NMR spectroscopy has been demonstrated to be of utility in the characterization of chromium(III) assemblies [9,13–17] For the d^3 chromic ion in an octahedral crystal field, one unpaired electron lies in each of the t_{2g} orbitals, which are directed between the chromium–ligand bonds. Hence, a π-delocalization mechanism is responsible for the paramagnetic shift in these chromium complexes [18]. The ^{1}H NMR spectrum of **1** contains one large, broad resonance centered at approximately 0.5 ppm (Fig. 3), readily assigned to the pivalate methyl hydrogens, the only hydrogen atoms in the complex. Although examination of the crystal structure reveals three distinct pivalate ligands, the ligands all bridge between two chromium centers and, therefore, have would be expected to have virtually identical chemical shifts if all the chromium centers involved are trivalent. The very small paramagnetic shift is not surprising considering that no good mechanism is available for unpaired electron density to be delocalized onto the ligand; the possibility of a π-delocalization mechanism playing a significant role in electron delocalization from the metal orbitals to the methyl groups of the ligand is negated by the quaternary carbon separating the carboxylate π-system from the methyl protons. Evans method solution susceptibility measurements revealed a magnetic moment per chromium of 3.20 B.M. This is significantly less than the expected spin-only value of 3.87 B.M. if all the centers are Cr(III), suggesting the Cr(III) centers within **1** are antiferromagnetically coupled. This is consistent with the results of variable temperature magnetic susceptibility studies that indicate the complex possesses antiferromagnetically coupled centers and an $S = 6$ ground state [2]. The ^{1}H NMR spectrum for **3** contained one paramagnetically broadened signal centered at 0.8 ppm, again assigned to the methyl protons of the pivalate ligands.

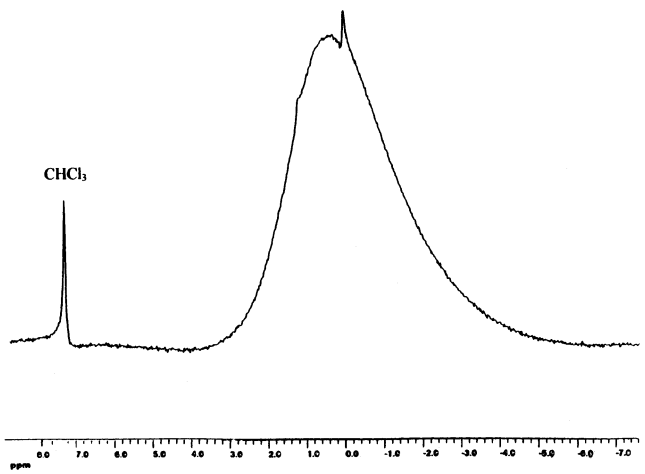

Fig. 3. ^{1}H NMR spectrum of **1** in *n*-propanol.

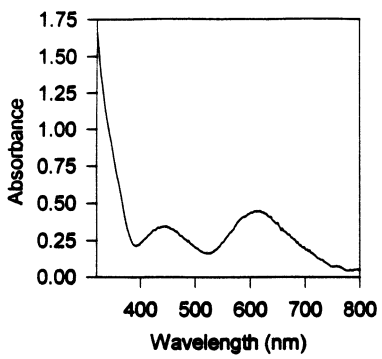

Fig. 4. Electronic spectrum of **1** in *n*-propanol.

The ^{1}H NMR spectrum of **2** contained one paramagneticaly broadened signal centered at 1.2 ppm assigned to the methyl protons of the pivalate ligands; again the lack of an appreciable paramagnetic shift is attributed to a lack of significant π-delocalization of the electron density. Evans method solution susceptibility measurements revealed a magnetic moment per chromium of 3.37 B.M. indicating the chromium atoms within **2** are antiferromagnetically coupled. This value is typical for Cr_3O complexes [8].

3.4. UV–vis spectroscopy

The electronic spectrum of complex **1** in *n*-propanol is shown in Fig. 4. The spectrum contains two major features, with maxima at 444 (ε/Cr = 69) and 616 nm (ε/Cr = 89), and two small shoulders between approximately 750–800 nm. The two strong, broad features at 444 and 616 nm are consistent with spin-allowed d–d transitions for chromic ions in a pseudo-octahedral environment. The two small shoulders between 750 and 800 nm are assigned tentatively to spin-forbidden (spin-flip) transitions that gain intensity from exchange coupling. Notably, there are no features assignable to chromium(IV) [19]. In terms of chromium(VI), oxo to chromium charge transfer bands would be expected, but no such features are observed. Therefore, the electronic spectrum is consistent with **1** possessing 12 chromic ions. The electronic spectrum of complex **3** in *n*-propanol is nearly identical to that of **1**, containing two major features with maxima at 446 and 611 nm.

The electronic spectrum of a saturated solution of complex **2** in acetone contains two major features with maxima at 441 and 590 nm, consistent with spin-allowed d–d transitions for chromic ions in a pseudo-oc-

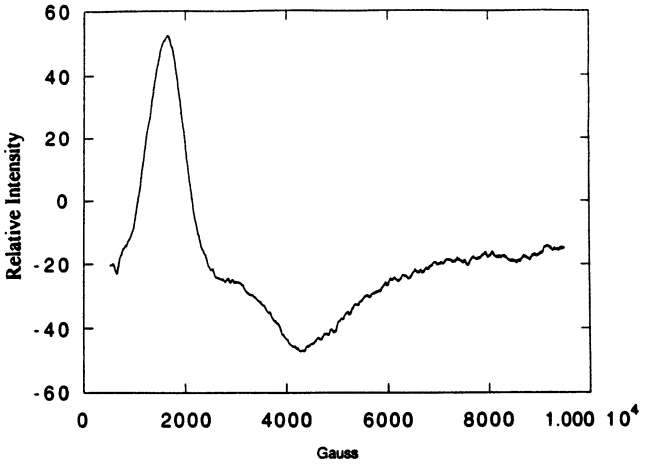

Fig. 5. X-band EPR spectrum of *n*-propanol glass of **1** at 100 K.

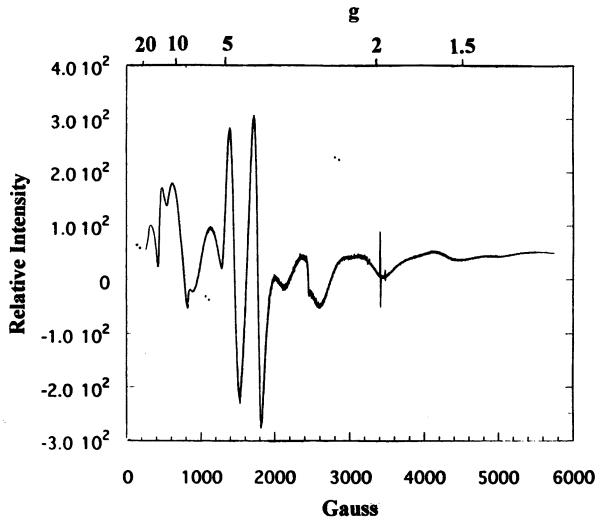

Fig. 6. X-band EPR spectrum of *n*-propanol glass of **1** at ~4 K.

tahedral environment, and three small shoulders at 358, 667, and 715 nm, assigned tentatively to spin-forbidden (spin-flip) transitions which gain intensity from exchange coupling. Because of the poor solubility of the trimer in common solvents, spectra were obtained on saturated solutions, preventing the calculation of extinction coefficients. The spectrum is nearly identical to that of other basic carboxylate type chromic assemblies with terminal oxygen ligands [8].

3.5. EPR spectroscopy

X-band EPR data were collected for complex **1** at 100 K (Fig. 5) and at approximately 4 K (Fig. 6). Twelve Cr(III) centers would give rise to an integer spin system, while the presence of three Cr(IV) or one Cr(VI) in the complex would give rise to half-integer spin systems. The 100 K spectrum, obtained as a saturated *n*-propanol glass, contained one major feature at $g = 3.78$. The 4 K spectrum, also obtained as a saturated *n*-propanol glass, was considerably more complex. Winpenny and co-workers have reported previously the EPR spectrum of the complex at 10 K at 34.11 and 89.21 GHz [2]. The higher field spectrum was simulated successfully assuming an $S = 6$ state. The X-band spectrum at 4 K is consistent with the higher field spectra and the existence of an integer spin-system and, thus, all 12 Cr centers being Cr(III).

3.6. Mass spectrometry

The EI mass spectrum of complex **1** (Fig. 7) contains the molecular ion (2336 mass to charge ratio) with m-(pivalic acid)$_n$ fragmentation signals, where $n = 1$–4, at mass values 2234 (54% intensity relative to the parent ion), 2132 (17%), 2029 (13%), 1928 (36%), respectively. The FAB mass spectrum of **1** confirmed the molecular ion at 2336 mass. This mass is consistent with the exact mass calculated for the complex formula $[Cr_{12}(OH)_3O_9(O_2CC(CH_3)_3)_{15}]$ having three additional protons relative to the originally proposed formula. Although the protonation of species to give positive ions in FAB MS is commonly observed, the mass to charge ratio of 2336 representative of $[Cr_{12}(OH)_3O_9(O_2CC(CH_3)_3)_{15}]$ is reproducible in both the EI and FAB spectra, and signals at 2331, representative of the originally proposed $[Cr_{12}O_{12}(O_2CC(CH_3)_3)_{15}]$, are not observed. The isotopic distribution for the mass ion at 2336 in the FAB spectrum agrees well with values calculated for the formula of the triprotonated complex, $[Cr_{12}(OH)_3O_9(O_2CC(CH_3)_3)_{15}]$, as shown in Fig. 8. Bastanov et al. reported that the mass spectrum of the complex contained the molecular ion and fragments from loss of one to five pivalate ligands. However, the technique used and the mass-to-charge ratios were not reported [1]. Given that the use of two standard techniques gives rise to the molecular ion corresponding to the hydroxide-containing formulation, interpretation of the report of Bastanov et al. (as Bastanov et al. use the formula based on 12 oxide ligands rather than nine oxide ligands and three hydroxo ligands, presumably the molecular ion mass they expect should be three units smaller) is difficult. Winpenny and co-workers have reported electrospray mass spectrometric studies on CH_2Cl_2–methanol solutions of the complex indicate that species of the form $Cr_{12}O_{12-x}(OH)_x(pivalate)_{15}$ were the only significant species present [2]; unfortunately, no other details were presented.

The EI mass spectrum of complex **3** (Fig. 9) reveals the nature of the disorder problem observed in the X-ray studies. While a feature consistent with the triprotonated formula, $[Cr_{12}(OH)_3O_9(O_2CC(CH_3)_3)_{12}(O_2CCCl_3)_3]$ (2519 m/z, 63% intensity relative to the most intense feature) was observed, higher mass ions corresponding to carboxylate ratios ($O_2CC(CH_3)_3$:

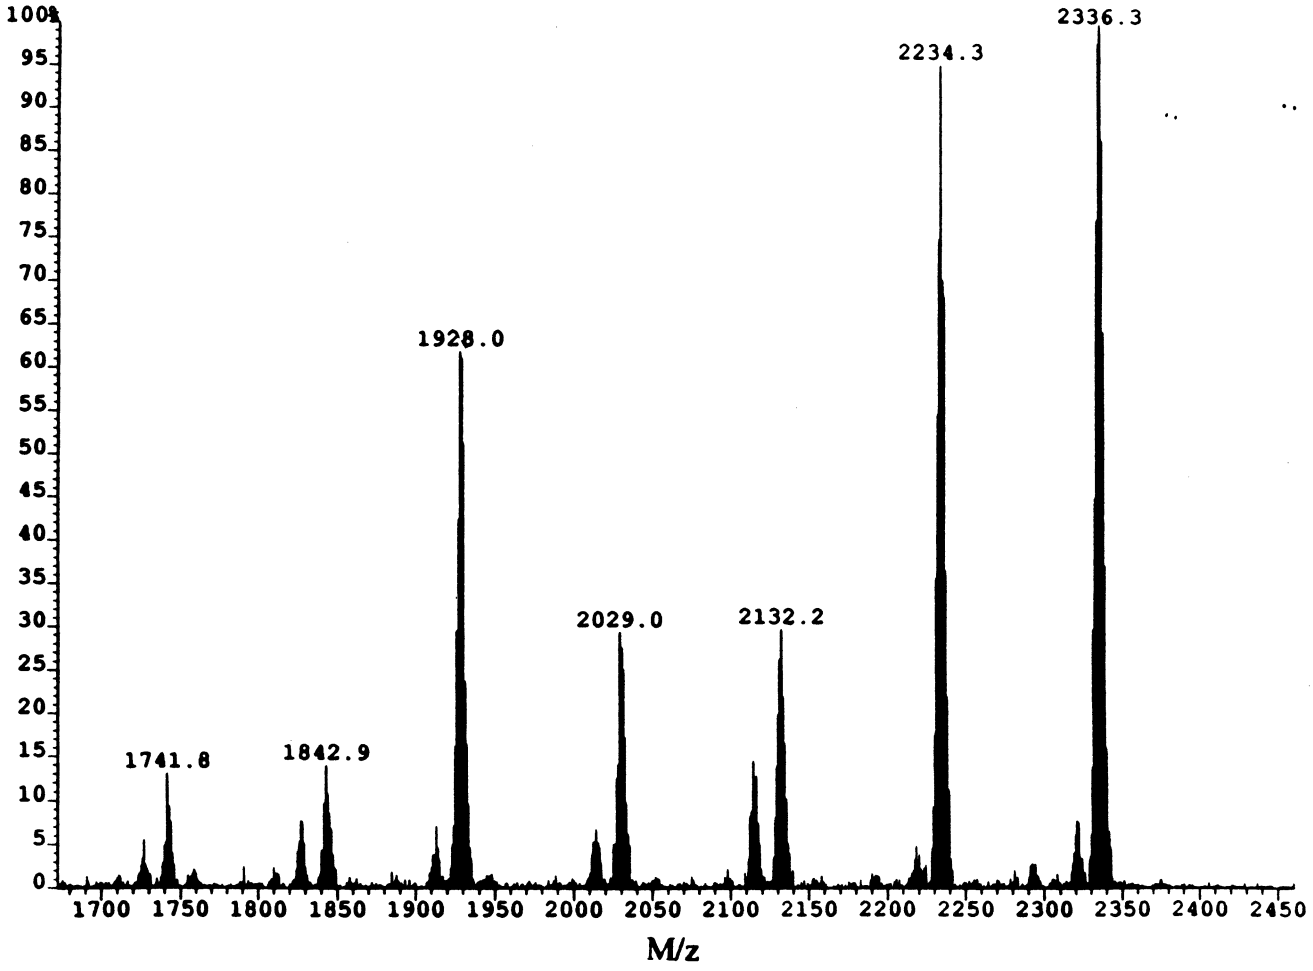

Fig. 7. EI mass spectrum of **1**.

O_2CCCl_3) of 11:4 (2581 m/z, 25%), and 10:5 (2641 m/z, 5%), as well as lower mass ions for ratios of 15:0 (2336 m/z, 31%), 14:1 (2397 m/z, 70%), and 13:2 (2458 m/z, 100%) were also observed. Each of these species produced additional signals resulting from both loss of one pivalate ligand loss or one trichloroacetate ligand. Evaluation of the relative abundance for each of these features revealed an average of 2.08 O_2CCCl_3 ligands in the complex. This difference, from the average number of 2.54 O_2CCCl_3 ligands in the complex from elemental analysis, could be the result of differing gas-phase stability of the various species and/or preferential loss of O_2CCCl_3 or $O_2CC(CH_3)_3$. The isotopic distribution for the mass ion at 2519 also agrees well with that calculated for the formula of the triprotonated complex, $Cr_{12}(OH)_3O_9(O_2CC(CH_3)_3)_{12}(O_2CCCl_3)_3$ (not shown).

The FAB mass spectrum for complex **2** contains the molecular ion, $[Cr_3O(O_2CC(CH_3)_3)_6]^+$ (778 mass), consistent with the proposed structure after loss of the three terminal water ligands. Loss of terminal water

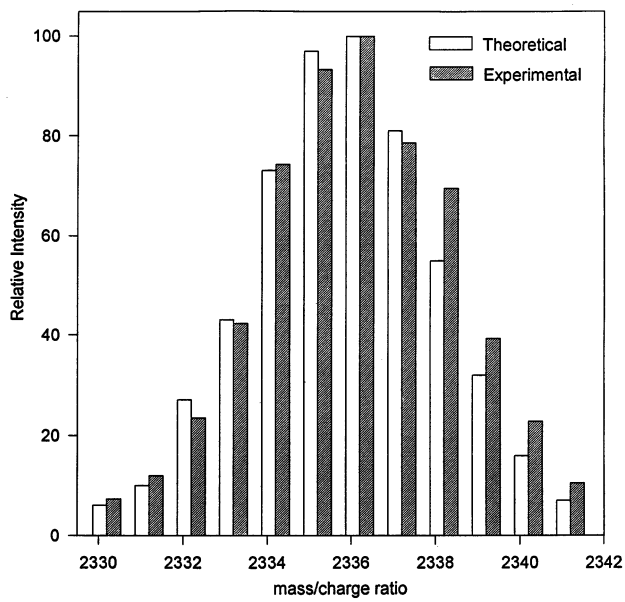

Fig. 8. Comparison of experimental and theoretical isotopic distribution pattern for molecular ion of **1**.

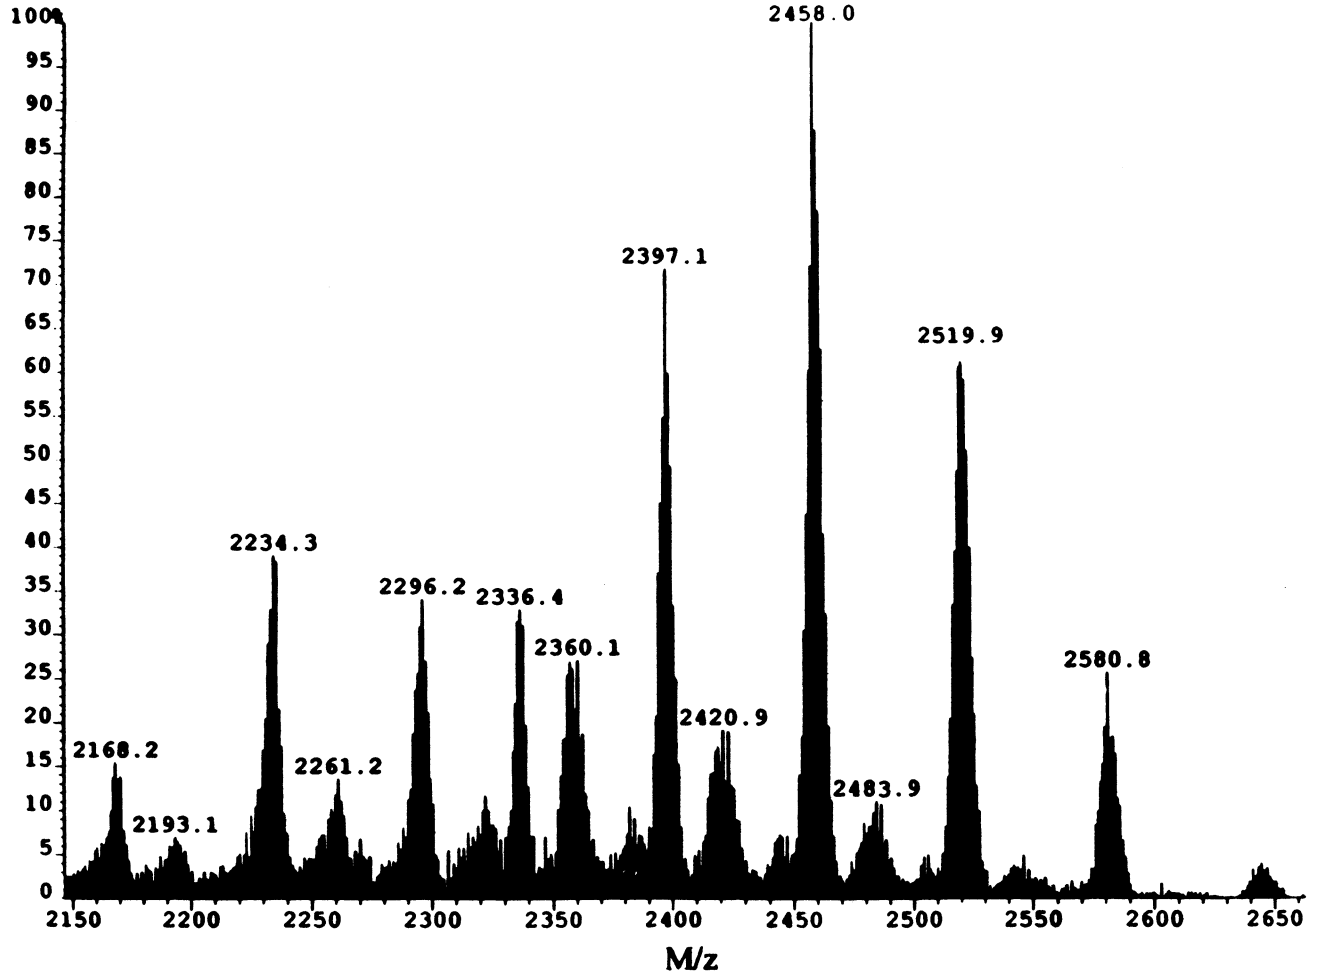

Fig. 9. EI mass spectrum of **3**.

molecules in FAB MS has been observed for other similar trinuclear complexes [20–22]. The spectrum also contains features from m-(pivalic acid)$_n$ fragmentation, where $n = 1–3$; this type of fragmentation has also been observed previously [20,21].

3.7. Photoelectron spectroscopy

The Cr 2p region was analyzed in the high-resolution mode, and the resulting spectrum is shown in Fig. 10. The binding energy value for the $2p_{3/2}$ feature is 576.2 eV (FWHM 3.8 eV). This value is indicative of a mid-range valence state of chromium (Cr^{+3} or Cr^{+4}) [23,24]. There appears to be some small ($< 10\%$) quantity of Cr metal present, probably the result of secondary electron reduction of the Cr under irradiation. This does not affect attribution of the oxidized Cr states. It can be concluded that there is no high valence chromium (Cr^{+6}) in the sample. Distinguishing between the Cr^{+3} and Cr^{+4} states is problematic. The separation between the two would be small (~ 0.5 eV). However, the peak analysis fits a single Gaussian–Lorentzian feature and is entirely consistent with all Cr^{+3} metal centers.

3.8. Infrared spectroscopy

As XPS demonstrated the presence of only chromic ions in **1**, three protons that cannot be observed by X-ray crystallography are necessary for charge balance. Either the triply bridging oxide ligands or bridging pivalate groups could be protonated. The IR spectrum of **1** contains stretches at 1584 (s), 1564 (s), and 1548 (s) cm^{-1} consistent with the symmetric and asymmetric C–O stretches of a bridging carboxylate. There is no evidence for the protonated form, pivalic acid. Thus, the spectrum is consistent with the neutron diffraction studies that indicated the partial protonation of the six symmetry-related triply-bridging oxide ligands. The possible presence of hydroxide ligands is masked by the presence of n-propanol and water solvate. The asymmetric Cr–O stretches expected at approximately 500–600 cm^{-1} are difficult to assign in these systems due to the presence in this region of modes from coordinated

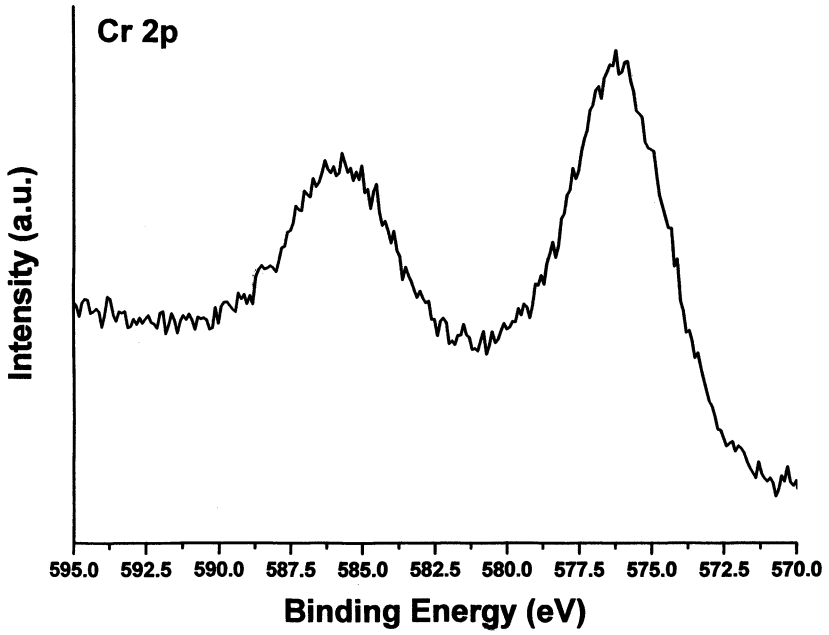

Fig. 10. X-ray photoelectron spectrum of **1**.

carboxylates [25]. The spectrum of the mixed-carboxylate complex (**3**) also displays no absorption in the region of the CO stretches of carboxylic acids.

3.9. Bond valence sum analysis

Finally the simple method of determining oxidation states of metal ions in a coordination complex termed bond valence sum (BVS) analysis was utilized [26]. The analysis in addition to bond lengths from the crystal structure only requires the value of a constant for each bond type (i.e. Cr(III)–O). For compound **1**, only Cr–O bonds are present, and fortunately the necessary constants, R_0, has previously been determined for Cr(II), Cr(III), and Cr(IV) [27]; an average value for approximation of the valence state when the Cr valence is unknown (1.724) has also been determined [27]. The range of calculated valances for the four unique chromium centers in complex **1** is from 2.85 to 3.03, strongly supporting the all Cr(III) oxidation state assignment.

4. Supplementary material

Crystallographic data for the structural analysis of **1** have been deposited with the Cambridge Crystallographic Data center, CCDC No. 164780. Copies of this material may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Mixed-ligand complex formation equilibria of Pd(Me_2en)–CBDCA–DNA constituent have been investigated (Me_2en = *N*,*N*′-dimethylethylenediamine, CBDCA = cyclobutane dicarboxylic acid). The results show ring opening of CBDCA and monodentate complexation of the DNA constituent. Stoichiometries and stability constants of the complexes were determined at 25 °C and at constant 0.1 M ionic strength. The kinetics of base hydrolysis of glycine methyl ester in presence of $Pd(Me_2en)^{2+}$ complex was studied in aqueous solution at different temperatures, and in dioxane–water solutions of different compositions at 25 °C. © 2002 Elsevier Science Ltd. Keywords: Palladium(II) complexes; Bioligands; Glycine methyl ester hydrolysis

1. Introduction

cis-Platin, *cis*-diammine dichloroplatinum(II), is one of the most effective anticancer agents that are clinically active to solid tumors [1,2]. Cytotoxicity of this drug is regarded as the consequence of making a covalent 1,2-intrastrand adduct with N_7 of the guanine base of DNA.

Carboplatin, *cis*-diammine(1,1-cyclobutanedicarboxylate)platinum(II), is a widely used second-generation platinum anticancer drug [3]. It has less side effects than *cis*-platin [4]; for example, it does not cause the loss of high frequency hearing, or have significant renal or neural toxicity. This is attributed to lower reactivity of carboplatin due to the presence of the bidenate-chelated bis(carboxylato)ligand [5]. Some workers have suggested that carboplatin is merely a pro-drug for *cis*-platin [6], whereas others have postulated a ring-opening reactions [7] of carboplatin followed by reaction with guanosine 5′-monophosphate (5′-GMP) forming *cis*-[$Pt(NH_3)_2$(CBDCA-O)(5′-GMP)]. The ring opening reaction with DNA constituent was investigated from the kinetic point of view through studies of [Pd(amine)(CBDCA) with inosine 5′-monophosphate [8].

In order to save the inert kinetics of Pt(II) complexes and on the basis of the remarkable analogy of Pt(II) and Pd(II) coordination chemistry a variety of Pd(II) complexes have proved useful as models to obtain a reasonable view on the thermodynamic aspects of the reactions for closely related Pt(II) ones.

Work in our laboratory has focused on studies of complex formation of model (amine)palladium(II) complexes with bioligands [9–13]. We have recently studied the reaction of $[Pd(Me_2en)(H_2O)_2]^{2+}$ with amino acid, peptide and DNA constituent [14], and now we are concentrating our effort to study the ring opening of chelated CBDCA and monodentate chelation of DNA components in the Pd(Me_2en)–CBDCA–DNA system. Also, the hydrolysis of glycine methyl ester through

PII: S0277-5387(01)00958-5

complex formation with $[Pd(Me_2en)(H_2O)_2]^{2+}$ was also investigated in dioxane–water solutions of different composition and at different temperatures.

2. Experimental

The complex $[Pd(Me_2en)Cl_2]$ was prepared as described [14]. The diaqua-complex $[Pd(Me_2en)(H_2O)_2](NO_3)_2$ was prepared in solution by stirring the chloro-complex with 2 equiv. of $AgNO_3$ overnight (with careful protection from light). The precipitated AgCl was removed by filtration and the filtrate was made up to the required volume in a standard flask. The glycine methyl ester hydrochloride was purchased from Fluka and converted to the corresponding hydronitrate by stirring with 1 equiv. of $AgNO_3$, filtering off the precipitated AgCl and making up to the desired volume in a standard flask. The ligands used were cyclobutane dicarboxylic acid, methylamine, imidazole, potassium dihydrogen phosphate (KH_2PO_4) and DNA constituents as inosine, uracil, uridine, thymine, thymidine. These materials were obtained from Sigma Chemicals Co.

Potentiometric measurements were made using a Metrohm 686 titroprocessor equipped with a 665 Dosimat. The electrode and titroprocessor were calibrated with standard buffer solutions prepared according to NBS specifications [15]. The pH meter readings were converted into hydrogen concentration by titrating a standard acid solution (0.01 M), the ionic strength of which was adjusted to 0.1 M with $NaNO_3$, with standard base (0.10 M) at 25 °C. The pH is plotted against p[H]. The relationship $pH - p[H] = 0.05$ was observed. The kinetics of hydrolysis was monitored using the titroprocessor operated with (SET) mode.

2.1. Kinetic measurements

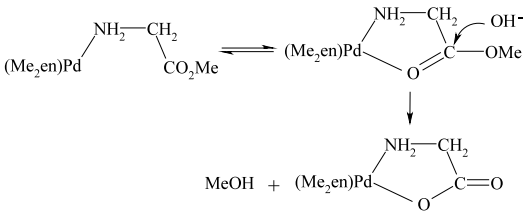
Hydrolysis kinetics of glycine methyl ester (MeGly) in the presence and absence of $[Pd(Me_2en)(H_2O)_2]^{2+}$ was investigated by pH-stat techniques [16]. Hydrolysis of MeGly (1.25 mM) in the presence of the Pd(II) complex of equimolar molar concentration was studied at different temperatures (20–35 °C) and at 25 °C in dioxane–water solutions of different compositions. All solutions have a constant ionic strength 0.1 M $NaNO_3$.

After equilibrating $[Pd(Me_2en)(H_2O)_2]^{2+}$ solution at the required temperature under nitrogen flow, a solution of ester was added and the pH brought to the desired value by the addition of 0.05 M NaOH solution. The hydrolysis was then followed by the automatic addition of 0.05 M NaOH solution to maintain the given pH. The data fitting was performed with the OLIS KINFIT set of programs as described previously [17].

2.2. Equilibrium measurements

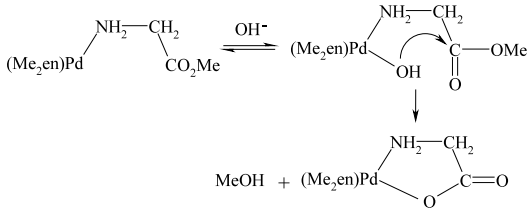
The acid dissociation constants of the ligands were determined by titrating 40 ml of ligand solution (1.25 mM). The formation constants of the complexes Pd(Me_2en)–(CBDCA)–(DNA) were determined by titrating solution mixtures of $[Pd(Me_2en)(H_2O)_2](NO_3)_2$ (1.25 mM), CBDCA and DNA constituents in concentration ratios of 1:1:1, 1:2:1 and 1:1:2. The titrating solution mixtures had a volume of 40 ml. The titrations were carried out at 25 °C by circulating thermostated water into the appropriate reaction cell and a slow and constant stream of N_2 passed over the test solution. The ionic strength was adjusted by $NaNO_3$ (0.1 M). A 0.05 M NaOH solution was used as titrant.

The equilibrium constants evaluated from the titration data (summarized in Table 1) are defined by Eqs. (1) and (2), where M, C, D and H stand for the $[Pd(Me_2en)(H_2O)_2]^{2+}$ ion, cyclobutane dicarboxylate, DNA constituent and proton, respectively.



$$lM + pC + qD + rH \rightleftharpoons [M_lC_pD_qH_r] \quad (1)$$

$$\beta_{lpqr} = \frac{[M_lC_pD_qH_r]}{[M]^l[C]^p[D]^q[H]^r} \quad (2)$$



The calculations were obtained from ≈ 150 data points in each titration using the computer program [18] MINIQUAD-75. The stoichiometries and stability constants of the complexes formed were determined by trying various possible composition models. The model selected gave the best statistical fit and was chemically consistent with the titration data without giving any systematic drifts in the magnitudes of various residuals, as described elsewhere [18]. The accepted model was tested by comparing the experimental titration data with the theoretically simulated curve calculated from the acid dissociation constants of the ligand and formation constants of the complexes. The species distribution diagrams were obtained using the program SPECIES [19] under the experimental conditions used. The hydrolysis of the coordinated ester $[Pd(Me_2en)(ester)]^{2+}$ is monitored over the pH range 4.2–4.8. In this pH range the hydrolysis of free ester is negligible, as the free ester starts to hydrolyze above pH 10 [20]. The results are summarized in Tables 2–6.

3. Results and discussion

The hydrolysis of coordinated glycine methyl ester may proceed by mechanism (3) and/or mechanism (4). The first mechanism involves an initial rapidly established equilibrium in which the carbonyl oxygen of the ester group coordinates, followed by a rate-determining attack by OH^- (Eq. (3)).

(3)

(4)

The second mechanism involves rapid equilibrium formation of a Pd–OH complex, followed by intramolecular OH^- attack (Eq. (4)).

The kinetic data, the volume of base added to keep the pH constant versus time, could be fitted by one exponential as shown in Fig. 1. Various other kinetic

[a] pK_w are 14.28, 14.72, 15.13, 15.46 and 15.70 for 12.5, 25.0, 37.5, 50.0 and 62.5% dioxane in water, respectively. These data were taken from Ref. [23].

models were tested without leading to satisfying fits of the data. Plots of k_{obs} versus the hydroxide ion concentration is linear, Fig. 2. The rate expression can therefore be given in the form, Fig. 5. The k_o term arises from the attack by water.

$$\text{Rate} = k_{obs}[\text{Pd(DME)(ester)}]$$

$$k_{obs} = k_o + k_{OH}[\text{OH}] \quad (5)$$

The linear dependence of rate on the OH^- concentration is consistent with the direct attack of OH^- ion on the coordinated ester carbonyl group as given in mechanism (3). On the other hand mechanism (4) requires that the plot of k_{obs} versus the hydroxide ion concentration is not linear. The catalysis ratio ($C = k_{OH}/k_{OH}^{ester}$) is calculated and found to be approximately

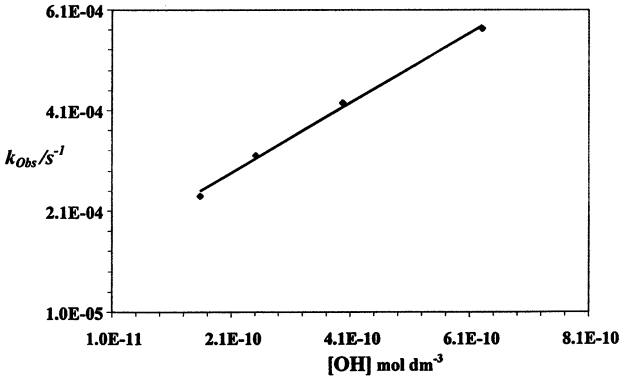

Fig. 2. Plots of k_{obs} vs. [OH^-] for the hydrolysis of coordinated glycine methyl ester in water solution at 25 °C.

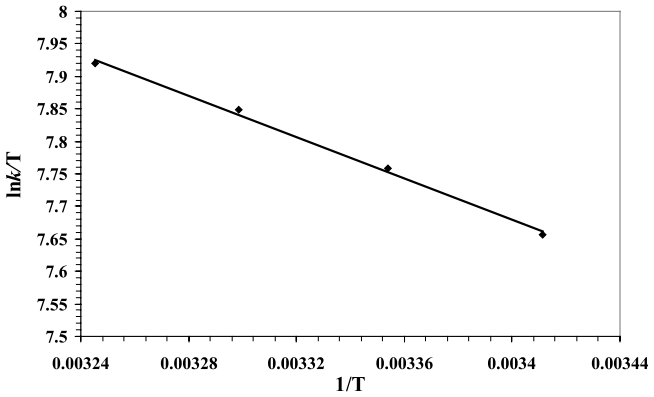

Fig. 3. Plots of $\ln k_{OH}$ vs. $1/T$ for the hydrolysis of coordinated of glycine methyl ester.

10^7, Table 5. The relatively high catalysis ratio is also consistent with the proposed mechanism.

The activation parameters for the hydrolysis of coordinated ester were determined using the Eyring plot of ($\ln k_{OH}/T$) versus $1/T$, Fig. 3, from which the values of $\Delta H^{\pm} = 13.2 \pm 0.4$ kJ mol^{-1}, $\Delta S^{\pm} = -88.7 \pm 0.5$ J K^{-1} mol^{-1} were calculated. For base hydrolysis of free glycine methyl ester the activation parameters were found [23] to be $\Delta H^{\pm} = 39.7$ kJ mol^{-1} and $\Delta S^{\pm} = -117$ J K^{-1} mol^{-1}. The enhanced rate for base hydrolysis of the ester incorporated in the complex is therefore due to contributions from a decreased $\Delta H^{\pm}$ and an increased $\Delta S^{\pm}$. The large increase in $\Delta S^{\pm}$ implies desolvation between the ground and transition states and is indicative of a mechanism involving nucleophilic attack by external OH^- on the complexed ester group as shown in mechanism (3).

Comparative values of k_{OH} [24] at 25 °C for the glycine methyl ester incorporated in $[Pd(en)L]^{2+}$ and $[Pd(Bpy)L]^{2+}$ are 6.3×10^4 and 2.0×10^5 dm^3 mol^{-1} s^{-1}, respectively. The k_{OH} value for $[Pd(Me_2en)L]^{2+}$ is lower than those of other Pd(II) complexes. This may be due to the steric interaction between the ester and the methyl substituent group of the amine. The high reactivity of $[Pd(Bpy)L]^{2+}$ complex is due to π-acceptor property of the pyridine ring, leading to an increase of electrophilicity of the metal center.

It is known that solutions in biochemical micro-environments such as active sites of enzymes and side chain in proteins have dielectric constant values of 30–50 [25–27]. It was suggested that these properties approximately correspond to those (or can be simulated by those) existing in the water–dioxane mixtures. Consequently, investigation of amino acid ester hydrolysis in water–dioxane mixture is of biological significance.

In order to examine the effect of organic solvent on the hydrolysis of the ester, the rate constants for the hydrolysis of free and coordinated ester were determined in various dioxane–water solutions of different compositions. The rate constant values are given in Table 5. The rate constant k_{OH} increases with increasing amount of dioxane. This may be explained on the premise that as the dioxane content increases the dielectric constant of the solution medium decreases. This will favor the interaction of negatively charged OH^- ion with the electropositive carbonyl carbon atom of

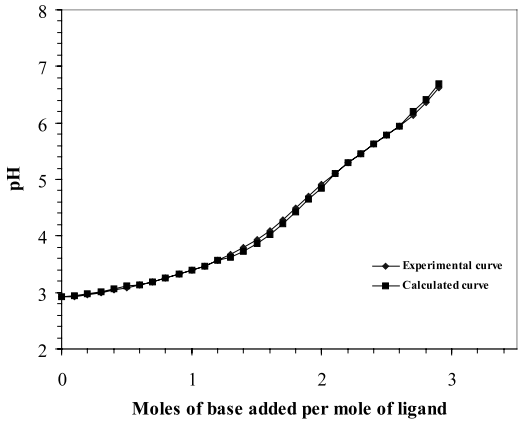

Fig. 4. Potentiometric titration curve of the Pd(DME)–CBDCA–inosine system.

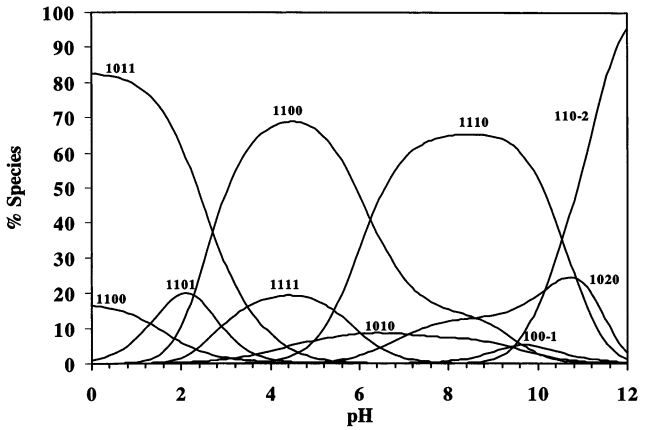

Fig. 5. Species distribution of various species as a function of pH in the Pd(DME)–CBDCA–inosine system (at concentration of 1.25 mM of each).

the ester. Consequently the hydrolysis will proceed faster.

3.1. Equilibrium studies

The potentiometric data of the system consisting of $[Pd(Me_2en)(H_2O)_2]^{2+}$, CBDCA and DNA constituent were fitted assuming the formation of the complexes of 1110 with uracil, uridine, thymine and thymidine. In addition to 1110 species inosine forms the species 1111. This result was verified by comparing the experimental potentiometric data with the theoretically calculated curve. Fig. 4 represents such a comparison for the inosine system. The experimental data coincide with the theoretical curve. This supports the formation of the quaternary complex.

The pyrimidines uracil, uridine, thymine and thymidine have only basic nitrogen (N_3). Consequently the pyrimidines ligate in the deprotonated form through this site and they do not form protonated complexes. Inosine has two binding centers N_1 and N_7 nitrogens. The pH-dependent binding of these *N*-donors has already been reported. The results showed that inosine forms the complexes 1110 and 1111. The species 1111 is formed in the acidic pH region and it corresponds to a N_7 coordinated complex, while the N_1 nitrogen is in a protonated form. The pK_a of the protonated form ($\log \beta_{1111} - \log \beta_{1110}$) amounts to 5.43. The lowering of pK_a of N_1H upon coordination was reported previously [28].

The ring opening reaction of carboplatin with 5′-GMP was characterized by NMR [29]. These studies conclude that CBDCA is attached through one carboxylate oxygen and 5′-GMP through N_7 of the purine base. Also such a reaction for [Pd(en)(CBDCA)] with thiourea, inosine 5′-monophosphate or iodide was mechanistically investigated [8].

It should be recognized that further studies are necessary to elucidate the ring opening of chelated CBDCA by DNA constituents, especially multinuclear NMR measurements. These aspects will be considered in future investigations.

Estimation of the concentration distribution of the various species in solution provides a useful picture of metal ion binding. To illustrate the main features observed in the species distribution plots in these systems the speciation diagram obtained for the $Pd(Me_2en)$–CBDCA–inosine system is shown in Fig. 5. The $Pd(Me_2en)$–CBDCA species (1100) predominates with a formation degree of 68% at pH 4.4. The $Pd(Me_2en)$–inosine species (1010) reaches the maximum concentration of 8% at pH 6.4. The quaternary species $Pd(Me_2en)$–CBDCA–inosine species (1110) attains a maximum of 60% in the pH range 7.6–8.8. This reveals that in the physiological pH range the ring opening of chelated CBDCA by DNA is quite feasible.

Received 15 June 2001; accepted 5 October 2001

Abstract

We report the synthesis, single-crystal X-ray structure, IR, TGA–DTA and fluorescence of a black MOF crystal $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$, which has two channels. One channel along the [001] direction was formed by a metal–oxygen octatomic ring and the another one along the [010] direction was shaped by 4′4-bipy. © 2002 Elsevier Science Ltd. Keywords: Metal-organic frameworks (MOF); Synthesis; Crystal structures; TGA–DTA

1. Introduction

Enormous efforts have recently been made in synthesizing new coordination polymers with 1-D, 2-D, 3-D structures [1]. Incorporation of both organic and inorganic components in these compounds has created a new dimension in the search for functional materials that have desired structure and properties [2]. The significance of composite metal-organic frameworks organic/inorganic micro/meso porous solid-state material engineering [3], is based on their potential applications in catalysis [4], magnetism [5], photochemistry [6] and ion-exchange [7]. Using the organic ligands and inorganic ions for design and research of novel structures with micro/meso pores is our interest. The poly-functional rod-like ligand 4,4-bipy is an effective tether for construction of extended solids with diverse topologies [8], such as linear chain $[Cu(4,4'\text{-bipy})]^{+1}$, zigzag chain $\{Zn(SPh)_2(\mu\text{-bipy})\}_n$ [9], square or rectangular grids [M(bipy)] ($M = Zn^{2+}$ or Fe^{2+}; bipy = 4,4′-bipyridyl) [10], ladder $[Zn(4,4'\text{-bipy})(H_2O)_3(ClO_4)]^{+1}$ [11], diamondoid [12], honeycomb [13], T-shaped [14], brick wall [15] and molecular bilayer [16], etc.

Zubieta and coworkers have synthesized a series of molybdenum oxide organo-diamine compounds, such as: (i) a simple counter-ion compound as in $[4,4'\text{-bipyH}_2][Mo_7O_{22}]$ [17]; (ii) ligands covalently bound to the molybdenum oxide skeleton, as in $[MoO_3(4,4'\text{-bipy})]$ or $[Mo_3O_9(2,2'\text{-bpy})_2]$ [18] and the cross-linking 1-D molybdenum oxide chains and through hydrogen bonding of the pendant and protonated arm of the ligands forming a 2-D sheet, as in $[Mo_4O_{13}(Hbpa)_2]$ [19]; (iii) $[Co(2,2'\text{-bpy})Mo_3O_{10}]$ [20], the ligand to heterometal forming part of a bimetallic molybdenum oxide backbone; (iv) the compound $[\{Cu(4,4'\text{-bipy})\}_4Mo_{15}O_{47}]$ [21], which contains spacer ligands in a polymeric coordination complex cation providing charge compensation for the negatively charged metal oxide.

In this work we used the hydrothermal technique to obtain the title polymer and characterized the structure and physical properties of the polymer, which has a 3-D molecular network formed by the 4,4′-bipy ligands covalently bound to the 2-D molybdenum oxide square grids in the diagonal positions.

2. Experimental

Chemicals were used as purchased. The crystal was synthesized by the hydrothermal technique. Infrared spectra were recorded on a Nicolet Magna 750 FT–IR spectrophotometer using KBr pellets. Elemental analyses were performed by Elementar (Germany) Vario EL III. The differential thermal analysis was measured by the Universal V2.4F TA Instrument. Fluorescence was obtained by RF-540 fluorometry.

2.1. Preparation of the compound $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$ (1) and $(NH_4)_4(Mo_8O_{26})(4,4'\text{-bipy})_6$ (2)

$(NH_4)_6Mo_7O_{24}\cdot 4H_2O$ (1.25 g, 1.01 mmol) and distilled water (6 ml) were added to a 25 ml Teflon Lined Parr Autoclave. The autoclave was sealed and heated under static condition for 96 h at 200°; the velocity of heat up was 1° per 3 min from room temperature (r.t.). To facilitate crystal growth, the reaction was cooled to r.t. over 50 h. Black cube crystal $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$ (0.265 g, 28.8%) was obtained and thoroughly washed with H_2O and C_3H_6O; at same time, we also got 0.20 g (27.35%) of red crystal $(NH_4)_4(Mo_8O_{26})(4,4'\text{-bipy})_6$ in this reaction.

IR (KBr pellet, cm^{-1}): $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$. $\nu_{Mo=O}$ 806(s), $\nu_{\mu\text{-}Mo\text{–}O}$ 924(m), $\nu_{\mu\text{-}Mo\text{–}N}$ 955(s); $(NH_4)_4(Mo_8O_{26})(4,4'\text{-bipy})_6$ Mo–O stretching region, 939(s), 912(s), 903(s), 841(w), 806(m), 712(s).

2.3. The TG–DTA and fluorescence

The thermogravimetric (TG) and differential thermal analyses (DTA) were performed using an Universal V2.4F TA Instrument. TGA–DTA were run with a temperature ramp of 10.0 °C min^{-1} between 20 and 700 °C. For compound **1** there is an endothermal peak at 420° and an exothermal peak at 495°. For compound **2**, there are three endothermal peaks at 140, 250, 390° and an exothermal peak at 495°. Using the RF-540 fluorometry with 320 nm Xe light as a pumping beam, starting at 350 nm and stopping at 600 nm, with a step of 1.00 nm and a dwell of 0.20 ns, we got fluorescence at 450 nm for compound $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$ (**1**) and the count of this compound was about 3.5×10^3.

2.4. Crystal structure determination

The crystal data for compounds **1** and **2** are summarized in Table 1, together with some experimental details. Intensity data for the two compounds were obtained on a Siemens Smart/CCD area-detector diffractometer with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Data reductions and cell refinements were performed with SMART CCD software [22]. The structures were solved by direct methods with the SHELXTL-97 program [23]. Absorption corrections were carried out using SADABS [24]. Selected bond distances and angles of the title compound are shown in Table 2.

3. Results and discussion

3.1. Crystal structure of $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$ (1) and $(NH_4)_4(Mo_8O_{26})(4,4'\text{-bipy})_6$ (2)

Compound **1** is a 3-D polymer and an ORTEP drawing of a portion of the polymeric structure is shown in Fig. 1. The Mo atom is coordinated by five O atoms

and one N atom from the 4,4-bipy molecule in a distorted octahedral geometry [the angles of O1–Mo1 to other O atoms around Mo1 are 99.3(7)–99.7(3)°, and the angle of O1–Mo1–N1 is 179.6(9)°], O(1) is a terminal oxo-oxygen. At the same time, the structure of $\{(Mo_4O_{12})(4,4'\text{-bipy})_2\}_n$ has a number of unusual and interesting features. Firstly, it contains a 2-D square grid formed by fused metal–oxygen octatomic rings as shown in Fig. 2. As far as we know, the metal–oxygen octatomic ring that formed the square grid in the MOF has not been reported previously, the dimensions of the square grid are 3.7×3.7 Å^2 and the length from Mo1a to Mo1c is 5.27 Å. Secondly, there are two N atoms of 4,4′-bipy molecules and two oxygen atoms in the diagonal position of the square grid. Thus a 3-D metal-organic framework is formed by the 4,4′-bipy connecting the 2-D square grids, the distance between the square grids being 11.987 Å. A channel with the dimensions of 11.98×5.27 Å^2, ignoring the space occupied by O and 4,4′-bipy, is shown in Fig. 3.

The anion of structure **2** is the β-isomer of $(Mo_8O_{26})^{4-}$, which has approximately C_{2h} symmetry and has eight edge-sharing MoO_6 octahedra. From the packing drawing (Fig. 4), the 4,4′-bipy molecule and NH_4^+ cation are dissociated from the $(Mo_8O_{26})^{4-}$ anion.

3.2. Thermal stability

Compound **1** underwent a two-step weight loss process and is thermally stable up to 350 °C, The on-set temperature of the weight losses are approximately 350 °C, the decomposition process being complete at approximately 495 °C. The demonstrated thermal sta-

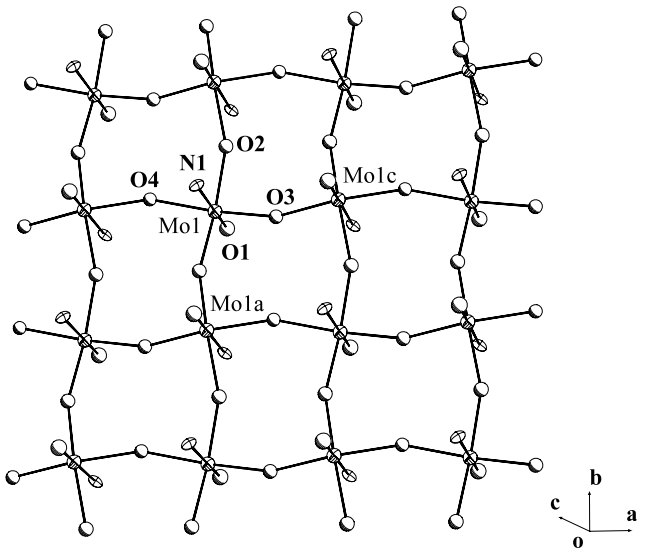

Fig. 2. 2-D square grids formed by the Mo–O octatomic ring.

bility of the polymer could be, at least partially, attributed to the weak π–π interactions between adjacent 4,4′-bipy molecules [25], which are parallel to each other. The distance between any two adjacent 4,4′-bipy is 5.270 Å which is subject to a weak π–π interaction that stabilizes the structure. The oxygen ligands may also enhance the stability of the structure. The weight loss curves clearly indicate that no water molecules are

incorporated in the compounds through inclusion. The same situation has been noted in the hydrothermal synthesis of other compounds under similar experimental conditions [26]. Compound **2** has no weak π–π interactions between the 4,4′-bipy molecules; it underwent a four-step weight loss process and is thermally stable up to 100 °C, the on-set temperature of weight losses (actual weight loss 1.8%, Calculated for $4NH_4^+$ 1.1%). The decomposition process is completed at approximately 490 °C. The fluorescence in compound **1** may be caused by the π–π interaction of the 4,4′-bipy molecules.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 162635 and 162634 for compounds **1** and **2**. Abstract

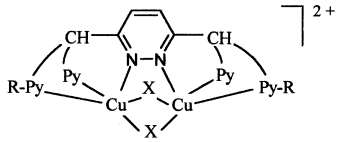
The syntheses, voltammetry and autoxidation of the binuclear copper(I) complex, $Cu_2(bdpdz)Cl_2$, (bdpdz = 3,6-bis-(di-2-pyridylmethyl)pyridazine) are reported. The complex catalyses the aerobic oxidation of 3,5-di-*tert*-butylcatechol, $DTBCH_2$, to 3,5-di-*tert*-butyl-*o*-benzoquinone. At constant catalyst concentration (5×10^{-5} M) the initial rate of oxygen uptake increases with increasing amounts of substrate reaching an asymptotic value. At constant $DTBCH_2$ (1×10^{-3} M) the reaction rate depends linearly on the concentration of catalyst with a rate constant k' equal to 8.8×10^{-3} s^{-1}. The relevance of the oxidation of $DTBCH_2$ by the copper(I)–dioxygen adduct becomes evident from the kinetic data reported in this work. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Copper(I) complexes; Autoxidation; Kinetic data; Catalytic activity



1. Introduction

The oxidation of catechol and in particular, 3,5-di-*tert*-butylcatechol ($DTBCH_2$), using copper(II) complexes as catalysts, has been studied widely as a model reaction for the catecholase activity of tyrosinase [1–10]. The reaction mechanism proposed by several authors includes an initial step leading to the formation of a reduced copper(I) complex as the active species towards molecular oxygen. The copper–oxygen adduct then would react with the catechol to give the quinone, or be oxidised to copper(II), which in turn reacts with the catechol in a ping–pong mechanism giving the corresponding quinone [11]. In this way the properties of the copper(I) complex should be as important as those of the copper(II) complex to determine the catalytic activity, depending on the rate-determining step.

We have reported the catalytic activity of copper(II) complexes with the ligand 3,6-bis-(di-2-pyridylmethyl) pyridazine, (bdpdz), and its methyl derivatives in the oxidation reaction of $DTBCH_2$ using methanol as a solvent [12]. Our results suggest an initial equilibrium between the copper(II) complex and the catechol instead of an irreversible reaction to give the reduced copper(I) species. This species is the active one towards molecular oxygen.

In this work we report the syntheses, characterisation and autoxidation of the copper(I) complex, $Cu_2(bdpdz)Cl_2$, and its catalytic activity in the oxidation of $DTBCH_2$ by molecular oxygen. The electrochemical behaviour of solutions of CuCl with the ligand in methanol is also studied in order to gain information about the species present in solution, relevant to the reaction mechanism.

2. Experimental

2.1. Reagents

All reagents and solvents were of high purity grade and were purchased from commercial sources and used as received unless noted otherwise. 3,6-bis(di-2-pyridylmethyl) pyridazine, (bdpdz) was prepared as reported elsewhere [13].

The copper(I) complex, $Cu_2(bdpdz)Cl_2$, was prepared under anaerobic conditions by reaction of CuCl (2 mmol) dissolved in acetonitrile (4 ml) with the ligand (1mmol) dissolved in methanol (25 ml). The red–brown solid was filtered, washed with cold methanol and vacuum dried. Elemental analysis: Calc. for $Cu_2(bdpdz)Cl_2$: C, 50.81; H, 3.28; Cu, 20.68; N, 13.68. *Anal.* Found: C, 49.13; H, 3.15; Cu, 20.30; N, 12.3%.

2.2. Measurements

The C, H, N elemental analyses were performed at CEPEDEQ (University of Chile) on a Fison–Carlo Erba EA 1108 model analyser. Electronic spectra were recorded on a Perkin–Elmer Lambda 11 spectrophotometer using methanol (Chrom AR HPLC, Mallinckrodt) as solvent.

Electrochemistry was performed in methanol solution using 0.05 M $NaNO_3$ as electrolyte. The cyclic voltammograms were recorded at a glassy carbon electrode, with a saturated calomel reference electrode and a Pt wire as an auxiliary electrode, on a BAS CV 50W voltammetric analyzer. All potential values are reported versus SCE. The voltammograms were obtained for solutions of the prepared complex and also for mixtures of solutions of CuCl and the ligand in the appropriate ratio.

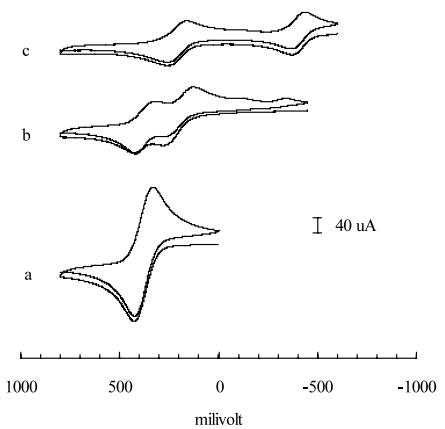

Fig. 1. Cyclic voltammogram of solutions of: (a) CuCl: 2×10^{-3} M. (b) CuCl: 2×10^{-3} M and L: 1×10^{-3} M. (c) CuCl: 2×10^{-3} M and L: 2×10^{-3} M.

Kinetic measurements were done following the oxygen uptake with a YSI (model 53) oxygen monitor, in a sealed thermostatted (28 °C) reaction cell. The oxygen concentration was adjusted to the desired value in the reaction cell. The copper(I) solution was injected by syringe into the stirred solution and the O_2 uptake was recorded. Kinetic data were obtained using a solution of the prepared complex as catalyst and also an in situ solution prepared by mixing solutions of CuCl and the ligand in the appropriate molar ratio. Both systems give the same results.

3. Results and discussion

Before studying the catalytic reaction of the complex, $Cu_2(bdpdz)Cl_2$, with $DTBCH_2$ it was of outmost importance to know the nature of the species in solution, because equilibrium of different species with varying stoichiometries is conceivable. In order to have an insight of the actual species present in solution we undertook a voltammetric study of solutions of CuCl and the ligand in methanol.

3.1. Electrochemistry

Fig. 1(a) shows the cyclic voltammogram of a solution of CuCl. It is compared with solutions of CuCl and the ligand in a 2:1, (Fig. 1(b)), and 1:1 ratios, (Fig. 1(c)). Fig. 1(a) shows the oxidation peak at 425 mV and the reduction peak at 330 mV for the Cu(I)/Cu(II) couple. Fig. 1(b) shows the first oxidation peak at 270 mV and a second one at 425 mV. The reverse scan shows a reduction peak at 330 mV, a second one at 130 mV and a third one at -345 mV. The quasi-reversible $E_{1/2} = 378$ mV couple (peak-to-peak separation equal to 95 mV) can be identified with the Cu(I)/Cu(II) redox pair. To understand the rest of the peaks, it is necessary to analyse Fig. 1(c). This voltammogram (1:1 ratio) can be explained by one-electron redox processes of the $L_2Cu(I)–Cu(I)$ species, formed by the reaction:

$$2Cu(I) + 2L \rightarrow L_2Cu(I)–Cu(I)$$

The oxidation peak at -375 mV corresponds to the formation of the mixed valence complex $L_2Cu(I)–Cu(II)$. The oxidation peak at 250 mV corresponds to the oxidation of the mixed valence complex to the dicupric species, $L_2Cu(II)–Cu(II)$. The corresponding

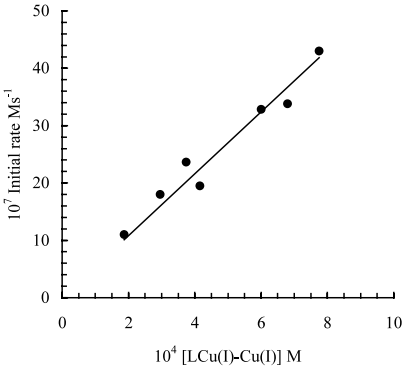

Fig. 2. Dependence of the initial rate of autoxidation of the copper(I) complex with its concentration.

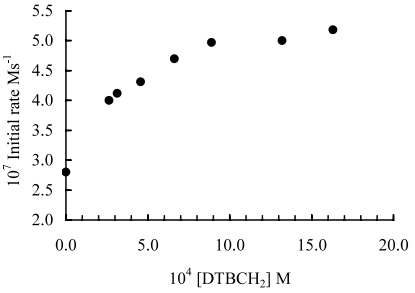

Fig. 3. Dependence of the initial rate of oxygen consumption on the concentration of $DTBCH_2$ at constant concentration of copper(I) complex equal to 5×10^{-5} M.

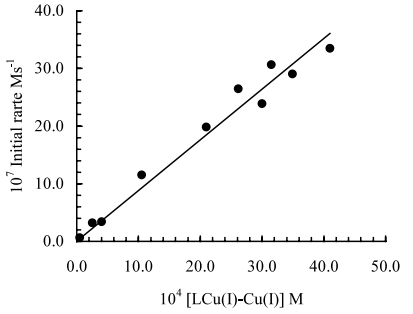

Fig. 4. Dependence of the initial rate of oxygen uptake with the concentration of copper(I) complex at constant concentration of $DTBCH_2$, 1×10^{-3} M.

reductions in the reverse scan appear at 150 and -445 mV.

The absence in the voltammogram of Fig. 1(b) of the oxidation peak at -375 mV is indicative of the non-existence of the $L_2Cu(I)–Cu(I)$ species when the ratio Cu(I)/L = 2:1. Then, the signal at 270 mV may be explained by the process:

$$LCu(I)–Cu(I) \rightarrow 1/2L_2Cu(II)–Cu(II) + Cu(I) + 1e$$

This species would generate the corresponding reduction at 130 mV.

$$L_2Cu(II)–Cu(II) + 1e \rightarrow L_2Cu(I)–Cu(II)$$

The fact that the signal corresponding to the reduction of the solvated cupric ion persists is indicative that the reaction:

$$1/2L_2Cu(II)–Cu(II) + Cu(II) \rightarrow LCu(II)–Cu(II)$$

is slow at the time scale of the voltammetric scan. The peak at -345 mV corresponds to the process:

$$1/2L_2Cu(II)–Cu(II) + Cu(I) + 1e \rightarrow LCu(I)–Cu(I)$$

A solution of the prepared cuprous complex gives a voltammogram identical to the one obtained for a mixture of solutions of CuCl and the ligand in a 2:1 ratio.

In conclusion it can be assessed that in the two to one copper to ligand ratio the species in solution is mainly LCu(I)–Cu(I) and not $L_2Cu(I)–Cu(I)$.

3.2. Kinetic studies

The kinetic data for the autoxidation of the cuprous complex were obtained following the initial oxygen uptake by the reaction mixture in methanol at 28 °C. The kinetic results were obtained using a solution of the in situ generated cuprous complex. Solutions of the solid prepared complex gave the same results.

The observed initial rate is linearly dependent on the copper(I) complex concentration with an experimental rate constant $k = 5.4 \pm 0.5 \times 10^{-3}$ s^{-1} (Fig. 2).

The addition of variable amounts of $DTBCH_2$ (0.2 to 4×10^{-3} M.) increases the rate of oxygen consumption (Fig. 3). When a 5×10^{-5} M solution of complex is used the rate tends to an asymptotic value of $5 \pm 0.2 \times 10^{-7}$ M s^{-1}, at concentration of $DTBCH_2$ above 8×10^{-4} M.

At a constant value of 1×10^{-3} M in $DTBCH_2$ the oxygen consumption has a linear dependence with the copper(I) complex (Fig. 4). A value of $k' = 8.8 \pm 1 \times 10^{-3}$ s^{-1} is obtained for this set of values.

In a previous paper we reported a kinetic study of this reaction, followed spectrophotometrically by the formation of the quinone [12]. The initial rate of quinone formation was found to be slower than the oxygen consumption observed in this work.

The following mechanism can account for the set of data given above:

$$Cu(I) - Cu(I) + O_2 \underset{k_{-1}}{\overset{k_1}{\rightleftarrows}} Cu(II) - O_2^{2-} - Cu(II) \quad (1)$$

$$Cu(II) - O_2^{2-} - Cu(II) \xrightarrow{k_2} Cu(II) - Cu(II) + O_2^{2-} \quad (2)$$

$$Cu(II) - O_2^{2-} - Cu(II) + DTBCH_2 \xrightarrow{k_2} DTB + Cu(I) - Cu(I) + H_2O_2 \quad (3)$$

Reaction (3) would account for the difference in reaction rates for the formation of the DTBQ and oxygen uptake. This reaction would also explain the observed dependence of the rate of oxygen consumption on the concentration of $DTBCH_2$.

Taking steps (2) and (3) as competitive reactions and applying the steady state to the oxygen adduct; the kinetic law for the initial oxygen consumption becomes:

$$V_{O_2} = \frac{k_1k_2[\text{Cu(I)}-\text{Cu(I)}][O_2] + k_1k_3[\text{Cu(I)}-\text{Cu(I)}][\text{DTBCH}_2][O_2]}{k_{-1}+k_2+k_3[\text{DTBCH}_2]} \quad (4)$$

At high $DTBCH_2$ concentration the rate of step (3) would be high enough to make reaction (1) to be rate-determining and the consumption becomes independent of $DTBCH_2$ concentration, as shown in Fig. 3.

At low $DTBCH_2$ concentration, it is possible to assume $k_3[\text{DTBCH}_2] \ll (k_{-1}+k_2)$. Therefore, at constant Cu(I)–Cu(I) concentration (5×10^{-5} M) a plot of V_{O_2} versus the concentration of $DTBCH_2$ should give a linear dependence, as was found. These data permit to estimate:

$$\frac{k_1k_2}{k_1+k_2} = 66\pm6 \text{ M s}^{-1}$$

$$\frac{k_1k_3}{k_{-1}+k_2} = 1.0\pm0.08\times10^5 \text{ s}^{-1}$$

In the absence of $DTBCH_2$, only steps (1) and (2) would be operative. In these conditions the kinetic law for the initial consumption of oxygen is:

$$V_{O_2} = \frac{k_1k_2[\text{Cu(I)}-\text{Cu(I)}][O_2]}{k_{-1}+k_2} \quad (5)$$

From the slope of Fig. 2 a value of 70 ± 7 M s^{-1} for the $k_1k_2/(k_{-1}+k_2)$ ratio was obtained. This value is the same as the one determined from the set of kinetic data with $DTBCH_2$.

The data presented above permit to estimate a value of k_3/k_2 close to 1.5×10^3. Then, for the experiments at constant concentration of $DTBCH_2$ equal to 1×10^{-3} M (Fig. 4) the $k_3[\text{DTBCH}_2]$ product is of the same order of magnitude as k_2. Under these conditions Eq. (4) applies for the rate of oxygen uptake. The plot of V_{O_2} versus the concentration of cuprous complex gives a linear dependence as expected.

The catalytic activity of the studied binuclear copper(I) complex can be compared with that of the binuclear copper(II) complexes informed by Chyn and Urbach [11], since these authors propose two alternative mechanism in which the cupric species are totally reduced by the catechol in an initial fast reaction, prior to the formation of the $Cu(II)–O_2^{2-}–Cu(II)$ adduct.

Mechanism I

$$\text{Cu(II)}-\text{Cu(II)} + \text{DTBCH}_2 \rightarrow \text{Cu(I)} - \text{Cu(I)} + \text{DTBQ} + 2\text{H}^+$$

$$\text{Cu(I)}-\text{Cu(I)} + O_2 \rightarrow \text{Cu(II)}-O_2^{2-}-\text{Cu(II)}$$

$$\text{Cu(II)}-O_2^{2-}-\text{Cu(II)} + 2\text{H}^+ \rightarrow \text{Cu(II)}-\text{Cu(II)} + H_2O_2$$

Mechanism II

$$\text{Cu(II)}-\text{Cu(II)} + \text{DTBCH}_2 \rightarrow \text{Cu(I)} - \text{Cu(I)} + \text{DTBQ} + 2\text{H}^+$$

$$\text{Cu(I)}-\text{Cu(I)} + O_2 \rightarrow \text{Cu(II)}-O_2^{2-}-\text{Cu(II)}$$

$$\text{Cu(II)}-O_2^{2-}-\text{Cu(II)} + \text{DTBCH}_2 \rightarrow \text{Cu(I)} - \text{Cu(I)} + \text{DTBQ} + H_2O_2$$

They assume that mechanism I is the correct one based on the fact that the μ-peroxo-dicopper(II) species would be rapidly protonated and would not exist long enough to oxidise $DTBCH_2$. Besides they find a zero-order dependence with respect to $DTBCH_2$ concentration. In our previous work we also informed a zero-order dependence with respect to $DTBCH_2$ [12]. However, when the concentration range is amplified, and lower concentration than 8×10^{-4} are used the consumption of oxygen begins to decrease. This fact together with the different rate in production of quinone (determined spectrophotometrically by following the absorption band at 400 nm) as stated above compared to the oxygen uptake (followed amperometrically with an oxygen sensor) permits to propose the mechanism based on steps (1) to (3).

Therefore, our results show that both mechanisms operate in parallel. This could be due to the fact that the catalytic activity was studied in methanol, while Chyn and Urbach used a solvent system of 1 to 1 methanol–water buffered at pH 6.4. In this mixed system the decomposition of the copper oxygen adduct would be faster than in pure methanol, thus promoting mechanism I.

Other authors have also shown the dependence of the catalytic activity on the substrate concentration, thus giving evidence of the existence of mechanism II [1,14]. Besides, Rockcliffe and Martell [15] have shown that a copper(I) dioxygen complex can act as an oxidising agent towards different substrates, including $DTBCH_2$. Our work together with the reported data in the literature, permits to conclude that both the solvent and the characteristics of the catalysts seem to be important in the existence of the reaction of the peroxo-dicopper(II) species with the catechol.

Solid state metathesis synthesis of metal silicides; reactions of calcium and magnesium silicide with metal oxides

Artur M. Nartowski, Ivan P. Parkin *

Department of Chemistry, Christopher Ingold Laboratory, University College London, 20 Gordon Street, London WC1H OAJ, UK

Received 17 August 2001; accepted 10 October 2001

Abstract

Reactions of transition metal oxides (V_2O_3, V_2O_5, Nb_2O_5, $LiNbO_3$, Ta_2O_5, $LiTaO_3$, MoO_3 and Li_2MoO_4) with lithium silicide (Li_2Si) and calcium silicide–magnesium silicide mix ($CaSi_2$, Mg_2Si) could be initiated by grinding, flame, filament or bulk thermal methods to produce a range of single phase transition metal silicides (VSi_2, $NbSi_2$ and $TaSi_2$) in good yields (approximately 90%). The silicides were characterised by X-ray powder diffraction, scanning electron microscopy (SEM), energy dispersive analysis by X-rays (EDAX), electron probe, FTIR and microelemental analysis. © 2002 Elsevier Science Ltd. Keywords: Silicides; Solid state metathesis; Self-propagating

1. Introduction

Transition metal silicides are hard, inert and have high electrical and thermal stability [1]. Molybdenum disilicide is widely used as a high temperature heating element [2], whilst the other metal silicides show potential as interface diffusion barriers and in large scale integrated (VLSI) circuit technology [3]. Silicides are generally unaffected by strong acids including aqua-regia. Their resistance to oxidation, particularly at high temperatures is largely due to the formation of a tenacious oxide layer that passivates the surface to further attack [4].

Silicides are usually prepared by co-reduction of SiO_2 with aluminium or carbon or by direct elemental combination at elevated temperatures [4]. Russian researchers have shown that in certain reactions silicides can be made from elemental combination reactions that are self-propagating, a technique known as Self propagating High temperature Synthesis or SHS [5]. These reactions rely on the in-built exothermicity of the elemental combination, can often be initiated at a point source and proceed by passage of a synthesis wave, also known as a solid-flame. Such work has produced a range of metal silicides, including commercial production of $MoSi_2$ for use as furnace elements [5]. SHS has some associated problems with the speed of the reaction (over in approximately 2–20 s), exceptionally high temperatures generated (>2000 °C) and low density of the product. Control of product stoichiometry and purity can also be difficult [6]. Kaner [7] has shown that a variant of the SHS process can form a range of ceramic materials including metal silicides—solid state metathesis or SSM. In SSM the reaction involves the exchange of ions between reacting solids and is driven largely by the formation of a co-produced salt. To date all SSM reactions have involved the use of a metal halide (M) starting material and a main group metal—element (E) anion Eq. (1).

$$MCl_n + Na_nE \rightarrow ME + n\,NaCl \quad (1)$$

In the case of metal silicide formation Kaner [7] has shown that reaction of $MoCl_5$ with Mg_2Si leads to the formation of $MoSi_2$, Mo metal and $MgCl_2$. The magnesium halide is readily removed from the silicide product, simply by washing with water, however, the molybdenum metal was difficult to remove. We have extended the range of compounds that can be made in SSM reactions [8]. In silicide formation we have reported on a large survey of reactions involving lan-

thanide and transition metal halides with magnesium silicide [9]. All of these reactions were undertaken in sealed quartz ampoules under vacuum. In no instance was the reaction self-propagating and consequently no synthesis wave was observed. However, over 10 h at 850 °C a metathesis reaction occurred with formation of a range of products. Unfortunately single-phase metal silicide products were not formed in the reactions. Invariably mixed phase silicide products were formed such as $NbSi_2$ and Nb_5Si_3 and in some instances the products were also contaminated with elemental metal impurity [9].

Given the relative refractory nature of metal silicides and their resistance to oxidation we report here the metathesis formation of metal silicide utilising metal oxide starting materials. In particular, we show that by using a range of siliciding reagents, such as Li_2Si and $MgSi_2/CaSi_2$ the reactions can be made to proceed in the propagation mode by means of a solid-flame and that single-phase transition metal silicides can be synthesised.

2. Experimental

All chemicals were purchased from Aldrich Chemical Co and used as supplied. All powders were of 99.9% purity or better except calcium oxide which was 80%. No purity rating was available for the $CaSi_2$ used in the experiments (Aldrich), this was also used as provided. Manipulations and weighings were carried out in a Saffron Scientific nitrogen filled glove box. Ampoules were made from quartz (0.6 cm diameter, 15 cm long, 2–3 mm walls) and were annealed and flamed dried in vacuum prior to use. Dilute HCl (5%) was used for all triturations. After treatment with acid the remaining solids were always rinsed with distilled water and dried in vacuum. X-ray powder diffraction patterns were determined on a Siemens D5000 transmission powder diffractometer using germanium monochromated Cu Kα1 radiation ($\lambda = 1.5046$ Å). Patterns were indexed using TREOR or METRIC-LS programmes. SEM–EDAX was determined on a JEOL JSM820 microscope, equipped with a Kevex Quantum Detector Delta 4, and a Hitachi SEM S-570. Infra-red spectra were recorded on a Nicolet 205 spectrometer using KBr pressed discs. Electron probe measurements were made on a JEOL EMA. Reactions were initiated in one of four ways, flame, filament, grinding and bulk initiation. Flame initiation was carried out in air using a gas torch at 1000 °C, the pre-ground reaction mixture was placed in a line on a ceramic mat and initiated at one end. This encouraged a yellow propagation wave to move through the solid. Filament initiation was carried out analogously to flame initiation except that a hot nichrome filament (800 °C) was used. Initiation using grinding occurred simply by grinding the starting powders in a glove box. Bulk initiation was used in all reactions and was accomplished by adding the pre-ground powders to an ampoule. The ampoule was sealed in vacuo and heated in a Lenton Thermal designs programmable tube-furnace to 1000 °C at a ramp rate of 20 °C a minute.

2.1. Reactions of Li_2Si with V_2O_5, $NaVO_3$, Nb_2O_5, $LiNbO_3$, Ta_2O_5, $LiTaO_3$, MoO_3, Li_2MoO_4 and Li_2WO_4 inside ampoules

The same reaction scale and procedure were used for all reactions exemplified below for the reaction of Li_2Si and Nb_2O_5.

Niobium(V) oxide (0.200 g, 0.752 mmol) and lithium silicide (0.126 g, 3.00 mmol) were ground together and placed inside of an ampoule that was evacuated and sealed. The ampoule was placed in a tube furnace that was brought from room temperature (r.t.) to 1000 °C over 1 h. At 550 °C some white residue settled at the cooler part of the ampoule whilst the solid at the hottest part of the ampoule had turned black over a 20 s period. The ampoule was annealed at 1000 °C for 12 h. After annealing the ampoule was allowed to cool to room temperature, broken open and the contents triturated with dilute HCl (3×6 ml), rinsed with distilled water (3×10 ml) and then dried in vacuum. The resultant black solid was analysed using powder XRD, SEM–EDAX, FTIR and electron probe measurements, Table 1.

3. Results and discussion

3.1. Synthesis; reaction of metal oxides with magnesium–calcium silicides

Solid state metathesis reactions between transition metal oxides and a mixture of calcium silicide–magnesium silicide produced transition metal disilicides and calcium and magnesium oxide, Table 1, Eqs. (2) and (3). The reactions were promoted by three methods of initiation, bulk, flame and filament. Bulk initiation was studied in all systems. This involved heating pre-ground powders in a sealed ampoule. A thermal flash was noted in each system somewhere between 450 and 600 °C. This corresponded to the initiation of a reaction within the bulk powder. Flame initiation was accomplished in air using a gas flame. This induced an orange propagation wave that travelled through the solid at 5 mm s^{-1}. Filament initiation involved the use of a heated nichrome wire. It was only successful for the reaction of Ta_2O_5 with $Mg_2Si/CaSi_2$ mixture. In this case the reaction also proceeded with an orange synthesis wave of velocity 4 mm s^{-1}.

Neither filament nor flame initiations were annealed. The products from all three modes of initiation were analysed as made and after trituration with dilute hydrochloric acid and water. The as made products showed the presence of calcium and magnesium oxides. These were removed by the trituration treatment. Notably the method of initiation did have a bearing on the phase composition of the product.

The ratio of magnesium silicide to calcium silicide used in the initial starting mixture (normally 2:1 Mg_2Si–$CaSi_2$) was altered to make single-phase metal disilicide products Eqs. (2) and (3). This proved to be successful for bulk initiation. Flame initiation for M_2O_5 (M = Nb, Ta) also produced a small amount (approximately 10%) of a secondary phase M_5Si_3. This phase also correlated with some unreacted magnesium disilicide reagent in the as-formed product-mix. Trituration with acids removed this magnesium disilicide but could not remove the secondary M_5Si_3 phase.

$$M_2O_5 + 2Mg_2Si + CaSi_2 \rightarrow 2MSi_2 + 4MgO + CaO \quad (M = V,\ Nb,\ Ta) \tag{2}$$

$$2LiNbO_3 + 2Mg_2Si + CaSi_2 \rightarrow 2NbSi_2 + Li_2O + 4MgO + CaO \tag{3}$$

3.2. Synthesis; reaction of metal oxides and lithium silicide

Solid state metathesis reactions were also studied between metal oxides and lithium silicide, Table 1. The reactions of lithium silicide with $LiMO_3$ (M = Nb, Ta) and Li_2MoO_4 initiated more readily than the corresponding $CaSi_2$ and Mg_2Si reactions. In these two cases simply grinding the reagents together initiated the reaction. It was observed, conversely, that binary transition metal oxides such as M_2O_5 (M = V, Nb, Ta), V_2O_3 and MoO_3 could not be initiated on grinding with lithium silicide. All of the reactions of metal oxides with lithium silicide could be initiated in bulk by heating in an ampoule; a yellow thermal flash was noted at a point between 450 and 650 °C dependent on the specific reaction. In a number of cases initiation in the bulk produced single-phase metal silicides, Eqs. (4) and (5). The reactions that initiated on grinding produced a mixture of product phases.

$$Nb_2O_5 + 4Li_2Si \rightarrow 2NbSi_2 + 4Li_2O + 1/2O_2 \tag{4}$$

$$LiMO_3 + 2Li_2Si \rightarrow MSi_2 + 2.5Li_2O + 1/2O_2 \tag{5}$$

3.3. Characterisation

The samples produced after trituration in all reactions were black. The FT–IR spectra matched commercially available samples with a broad band at approximately 600 cm^{-1}. Elemental microanalysis of the silicides using powdered tin as a combustion aid showed negligible amounts of carbon, nitrogen and hydrogen.

X-ray powder diffraction showed that all modes of initiation; bulk heating, filament and grinding produced crystalline products without recourse to annealing (Fig. 1). The formed products were mixtures of co-formed salts (MgO, CaO and Li_2O) together with metal silicide. The washing procedure using dilute acid proved very effective in removing the co-formed oxide and in most cases left a single phase of metal silicide. Hence, from flame initiated reactions single phases of VSi_2 and $TaSi_2$ could be made in seconds from the reaction. Line broadening studies using the Scherrer equation indi-

$TaSi_2$	38-483	4.7851(7)	6.56980(16)	*P*6222	hexagonal
$MoSi_2$	41-612	3.2047(2)	7.8449(8)	*I*4/*mmm*	tetrahedral

Values in parentheses are e.s.d.'s, where these are available, corresponding to the least significant digits of entries. Note 8-422 vs 30-874 and 30-875 for Nb_5Si_3 and 41-612 vs 17-917 for $MoSi_2$.

cated that crystallite sizes were 500–600 Å irrespective of the mode of initiation [10]. The reactions involving molybdenum always produced mixed phase products irrespective of the starting silicide reagents. The reactions that initiated on grinding did not give single-phase silicide products. In this case it is probable that the reaction is too rapid for the formation of a single thermodynamic product. In all cases the X-ray powder patterns of the crystalline metal silicides indexed well with values within error limits of literature measurements (Table 2) [11].

EDAX analysis of the metal silicides, as formed from the SSM reactions showed that the pre-washed material contained calcium and magnesium oxide or lithium oxide in addition to metal and silicon. Trituration with dilute acid and water proved to be effective in removing the co-formed oxides. It was not effective in removing the free metal that was identified in some of the reactions. EDAX analysis of the triturated product correlated extremely well with the phases observed by XRD and gave the expected elemental ratios for silicon and transition metal over a number of surface spots. Electron-probe line-scan analyses were consistent with the EDAX results. Notably no calcium, magnesium or free silicon could be detected in the triturated products by either electron probe or EDAX. In the reactions involving molybdenum (Li_2MoO_4, MoO_3) some free metal was noted by both techniques, in agreement with the XRD results. SEM analysis revealed that the triturated products consisted of rough irregular particles with sharp surfaces. The products showed a narrow particle size distribution within the samples (Fig. 2(a and b)).

3.4. Thermodynamic considerations

Hesses law calculations indicate that the formation of transition metal silicide products from reaction of transition metal oxide and lithium silicide or calcium–mag-

nesium silicide is exothermic (typical exothermicities 300–500 kJ mol^{-1}) [12]. The driving force for the reaction is the formation of the co-formed oxides (MgO, CaO, Li_2O). This is analogous to traditional solid state metathesis reactions that are driven by the formation of co-formed salts (NaCl, LiCl, …). The reaction exothermicity is such that once the reaction is initiated it can be self-sustaining. In traditional SSM reactions an exothermicity of 300 kJ mol^{-1} is typically required for propagation [8,9], similar to that calculated for the oxide based metathesis reactions reported here. The temperature required to initiate a metathesis reactions often correlates with a phase change of one of the reagents. In the reactions studied here for silicides this does not seem readily applicable as the Li_2Si (760 °C), Mg_2Si (1085 °C) and $CaSi_2$ (980 °C) have melting points above the temperature at which the bulk reactions were noted to initiate (450–650 °C) [12]. It is possible that metal impurities, such as magnesium in the commercial Mg_2Si may initiate some of the reactions as magnesium melts at 645 °C. The maximum reaction temperature in the reactions is approximately 1000 °C as assessed by the colour of the synthesis flame. Full thermodynamic data on specific heat capacities could not be found for the silicide products, hence, a calculated maximum reaction temperature was not obtained [12].

4. Conclusions

A range of single-phase transition metal silicides can be made from solid state metathesis recations. This is the first report of the use of metal oxides as starting materials in SSM reactions. These have proven useful in silicide synthesis, in contrast attempts using metal halides formed mixed phase silicide products. In particular crystalline metal silicide powders can be made in seconds from solid state metathesis, in air, using a gas flame to initiate the process. Under all modes of reaction initiation crystalline products were produced without recourse to annealing.

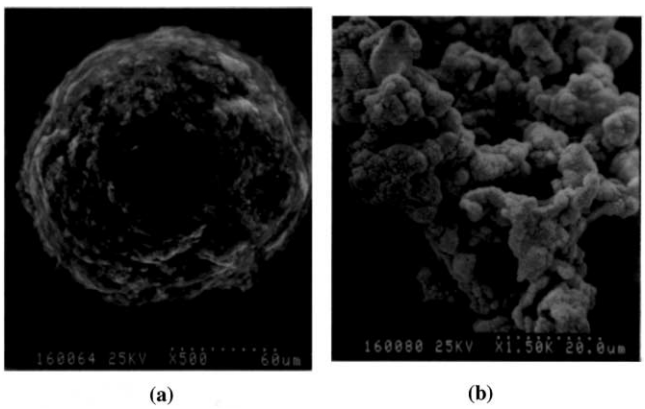

Fig. 2. SEM micrographs of $TaSi_2$ produced from SSM reaction of Ta_2O_3 and $CaSi_2/Mg_2Si$ at 1000 °C for 12 h. Reaction initiated at 500 °C.

Abstract

The crystalline $Li_2(WO)_2(OMe)_{10}\cdot MeOH$ (**I**) is formed as a side product in the process of anodic oxidation of tungsten in methanol in the presence of LiCl, which is used as a conductive additive. The structure of **I** as determined by the X-ray diffraction (XRD) method features infinite chains made up of two alternating tetranuclear species $[Li_2(WO)_2(OMe)_{10}]$ (**A**) and $[Li_2(WO)_2(OMe)_{10}(MeOH)_2]$ (**B**), linked via Li–O=W bridges involving the Li atom belonging to fragment **A** and tungstenyl group from fragment **B**. Each fragment occupies a special position in the crystallographic inversion center and has a metal–oxygen framework. All tungsten atoms have octahedral coordination, whereas all lithium vertices have five-coordinated trigonal bipyramidal environments. The H-bonds of the (A)W=O…HOMe(B) type in the crystal of **I** provide the links between the **A** and **B** fragments belonging to the different chains. © 2002 Published by Elsevier Science Ltd.

Keywords: Alkoxides; Crystal structures; Lithium; Tungsten; Methoxide

1. Introduction

Electrochemistry provides one of the most convenient synthetic routes to Mo and W alkoxides. The detailed studies of the processes of dissolution of Mo and W in alcohols in the presence of various conductive additives showed that along with the target products, i.e. the expected alkoxides, low yield side products may be often isolated from the electrolyte solutions. In most cases the latter represent heterometallic Li containing complexes. They are formed in the reactions between the Mo or W alkoxides and LiOR generated during the electrolysis of the electrolyte. The composition and structure of these complexes may vary depending on the particular metals and alcohols.

Thus, anodic dissolution of W in EtOH leads to crystallization of $WO(OEt)_4$ as the main product. However, after subsequent treatment of the mother electrolyte solution with $MeOC_2H_4OH$, the crystalline $[\{LiWO_2(OC_2H_4OMe)_3\}_2\cdot 2Li(HOC_2H_4OMe)_2]^{2+}[W_6O_{19}]^{2-}$ was isolated. Its structure comprises one neutral centrosymmetric molecule $\{Li_2W_2O_4(OR)_6\}$ and two cationic $\{Li(ROH)_2\}^+$ moieties linked into hexanuclear cationic aggregates $[\{Li_2W_2O_4(OR)_6\}\{Li(ROH)_2\}_2]^{2+}$ [1].

Electrochemical synthesis of Mo alkoxides in MeOH or EtOH yielded two side products, viz. $[LiMo_2^{V}O_2(OMe)_7\cdot MeOH]$ and $[LiMo_2^{VI}O_4(OPr^i)_4(OC_2H_4OMe)]_2$ (the latter precipitated upon the treatment of the mother liquor, from which $MoO(OEt)_4$ had been extracted, first with ^{i}PrOH, and then with methylcellosolve). In the crystals of the former, complex cationic and anionic residues, $[Li(MeOH)]^+$ and $[Mo_2O_2(OMe)_7]^-$, are linked into infinite chains via μ-OMe-groups. The anionic species represents a well-known motive in the alkoxide structural chemistry featuring M_2X_9 group, two octahedra sharing a common face. The dimeric molecule of the second side product is made up of two trinuclear $[LiMo_2O_2(OR)_5]$ fragments linked via two [Mo=O–Li] bridges [1].

The present paper reports the results of the structural study of complex $Li_2(WO)_2(OMe)_{10}\cdot MeOH$ (**I**) which was isolated in a small yield from the electrolyte, pre-

pared by the anodic oxidation of W in MeOH in the presence of LiCl [1,2]. No data on methoxotungstenates of lithium have ever been reported in literature (see discussions in [1,3]).

2. Experimental

The electrolysis was carried out for 9 h using direct current at 110 V and 0.1 A cm^{-2}, the concentration of the LiCl additive was 0.073 M, and the reaction mixture was kept at room temperature (r.t.). Upon completion of the process, the electrolyte turned dark-brown and then gradually changed to blue as the solution was left to stand for a week without atmospheric contact. After the solvent was removed in vacuo, the light-blue precipitate was treated with hexane. The most part of the precipitate was dissolved and a blue solution was formed. White non-transparent crystals of **I** were then slowly (in the course of approximately 1 week) reprecipitated on cooling to ~ 0 °C, the yield of the complex was 2–3%. The main products obtained by electrolysis—$W(OMe)_6$ and $WO(OMe)_4$ still remained in the solution.

3. Results and discussion

The structure of $Li_2(WO)_2(OMe)_{10}\cdot MeOH$ (**I**)[1] features zigzag-like infinite chains made up of two alternating fragments $[Li_2(WO)_2(\mu_3\text{-}OMe)_2(\mu\text{-}OMe)_4(OMe)_4]$ (**A**) and $[Li_2(WO)_2(\mu_3\text{-}OMe)_2(\mu\text{-}OMe)_4(OMe)_4(MeOH)_2]$ (**B**). Each of the fragments represents a tetranuclear centrosymmetric complex with coplanar metal atoms; this metal–oxygen framework is widely known in the alkoxide chemistry as the $Ti_4(OMe)_{16}$-type structure [4]. It is characterized by the presence of two distinct metal atom positions, which differ in the number of coordinated μ_3-O atoms. Indeed two of the four metal atoms are coordinated only by one μ_3-O whereas the other two are bonded to two μ_3-O atoms. In complex **I** the tungsten octahedra $[WO(\mu_3\text{-}OMe)(\mu\text{-}OMe)_2(OMe)_2]$ occupy the sites of the first kind in both fragments **A** and **B**; the lithium trigonal bipyramids $[LiO(\mu_3\text{-}OMe)_2(\mu\text{-}OMe)_2]$ and $[Li(\mu_3\text{-}OMe)_2(\mu\text{-}OMe)_2(MeOH)]$ occupy the sites of the second kind in the fragments of **A** and **B**, respectively. Table 1 lists selected bond lengths and angles within **I**. The fragments **A** and **B** are linked in the chains via Li–O=W bridges involving the Li atoms of the **A** fragments and the tungstenyl groups of the **B** fragments. The Li(1)–O(2)–W(2) angle is equal to 159.7(6)°.

Symmetry transformations: (i) $(-x, 2-y, 1-z)$; (ii) $(-x, 3-y, -z)$.

The existence of the W=O–Li bridges may be regarded as one of the most interesting features of the structure **I**. It is noteworthy that the W=O bond in the W=O–Li bridge in **I** (W(2)=O(2) 1.738(7) Å) is considerably longer than in $[WO(OMe)_4]_2$ (1.691 Å [5]), wherein the W=O bond is not involved in any additional interactions. The similar lengthening of the W=O bond is caused by its participation in the hydrogen bonding which is manifested in the long W(1)=O(1) bond in **I** (1.734(7) Å). At the same time the Li(1)–O(2) bond 2.023(15) Å does not show any lengthening as compared with other Li–O bonds in **I** (1.99–2.13 Å) or to the known Li–O distances, say, in LiOMe·2MeOH [6]. The Li–O bond lengths are in fact unaffected by the function of the O atom, which should be attributed to the predominantly ionic character of these bonds. On the other hand the lengths of the substantially covalent W–OR bonds show quite noticeable and regular increase with the increase of the number of oxygen atom neighbors (1.887–1.899 for the terminal OMe groups, 1.938–1.954 for μ_2-OMe and 2.075–2.078 Å for μ_3-OMe ligands).

The crystal structure of **I** supports the assumption that monomeric species $[LiWO(OMe)_5(MeOH)]_n$ and $[LiWO(OMe)_5(MeOH)_2]_2$ (the latter seems to be structurally analogous to the known sodium complex, $[NaWO(OEt)_5(EtOH)_2]_2$ [3]) indeed exist in the hydrocarbon solution. One may believe that elimination of one alcohol molecule and formation of the Li…O=W bridge occurs in the process of crystallization. (Fig. 1.)

[1] Crystal data for **I**: $C_{11}H_{34}Li_2O_{13}W_2$, $M = 755.96$, triclinic, space group $P\bar{1}$, $a = 8.664(5)$, $b = 10.974(8)$, $c = 13.416(11)$ Å, $\alpha = 77.88(6)$, $\beta = 72.18(5)$, $\gamma = 76.42(5)$°, $V = 1167.3(14)$ Å^3, $T = 213(2)$ K, $Z = 2$, λ(Mo Kα) = 0.71073 Å, 6165 reflections measured, 5735 unique ($R_{int} = 0.0786$) were used in all calculations. The final $wR(F^2)$ was 0.1514 for all data, $R(F)$ was 0.0550 for 4721 observed data with $I > 2\sigma(I)$.

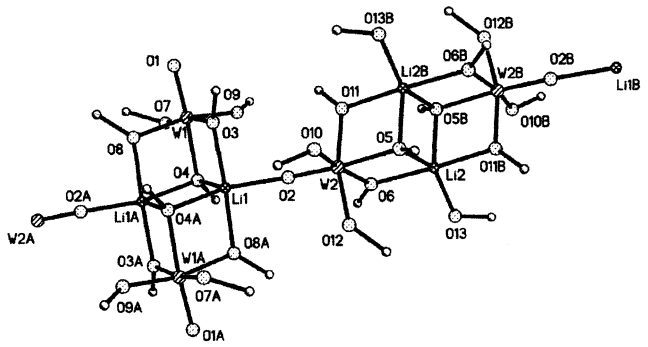

Fig. 1. The fragment of the infinite chain $[Li_2(WO)_2(OMe)_{10}\cdot MeOH]_n$ in the crystal of **I**.

The bridges of the M^{VI}=O–M^{I} type were observed previously in the structures of several Mo and W complexes. In particular such bridges were found in the above mentioned cation $\{[LiWO_2(OC_2H_4OMe)_3]_2\cdot 2Li(HOC_2H_4OMe)_2\}^{2+}$ (**2**), the neutral molecules $[LiMo_2^{VI}O_4(OPr^i)_4(OC_2H_4OMe)]_2$ (**3**) [1], and $[NaMo_2O_4(OPr^i)_5(^iPrOH)]_2$ (**4**) [3] as well as in the anionic species $[Mg_2Mo_8O_{22}(OMe)_6(MeOH)_4]^{2-}$ (**5**) [7]. It is noteworthy, however, that in all of the above mentioned literature results, in contrast to **I**, the M=O bond involved in the M=O–M bridge belongs to the MO_2 group. The lengthening of the M=O bond in all cases is similar to that observed in **I** [the M^{VI}=O(M^{I}) bond lengths are in the range of 1.72–1.76 Å]. At the same time the second M=O bond does not show any lengthening in **3** and **5**, (1.68–1.70 Å), whereas in **2** and **3** this bond is lengthened to the same extent as the one which takes part in the additional interaction. The bond angles M(VI)–O–M(I) in **1** and **3** (159.7(6) and 156.6°) are much wider than the corresponding angles in **2** and **4** (141.9 and 144.5°) which probably reflects the different degree of the sp^3–sp-rehybridization of the O atom.

It is worth mentioning, in conclusion, that the infinite chains built of the $[Ti_4(OMe)_{16}]$-type aggregates have been observed previously only in the structure of $[Na_2(MO_2)_2(OC_2H_4OMe)_6]_\infty$, M = Mo, W [3,8]. However, in these complexes the aggregates are linked via the bidentate ligand which coordinates the Na atoms of two neighboring tetranuclear fragments.

4. Supplementary material

Supplementary data for this compound are available on request from The Director, Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-3360333; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk). CCDC deposition number, 167119.

Syntheses and characterization of lead(II) salts with 4,4′-bithiazole ligand: X-ray crystal structures of $[(BTZ)_2Pb(NO_3)_2]$ and $[(BTZ)Pb(SCN)_2]_n$ (a new polymeric compound)

Received 3 August 2001; accepted 16 October 2001

Abstract

Complexes of lead(II) nitrate and lead(II) thiocyanate with 4,4′-bithiazole (BTZ) have been synthesized using a direct reaction of PbX_2 (X = nitrate and thiocyanate) and ligand. The complexes have been isolated and characterized by IR spectra and CHN elemental analysis. The structures of $[(BTZ)_2Pb(NO_3)_2]_2$ and $[(BTZ)Pb(SCN)_2]_n$ were confirmed by X-ray crystallography. The coordination polyhedron is different in the two complexes. The coordination number of Pb in $[(BTZ)_2Pb(NO_3)_2]$ is six (four by the chelating BTZ and two oxygen atoms of the two nitrate anions), whereas in $[(BTZ)Pb(NCS)_2]_n$ it is five with two different Pb environments, PbN_3S_2 (two by the chelating BTZ and three by SCN^- anions) and PbN_5 (two by BTZ and three by SCN^- anions). The coordination geometry of $[(BTZ)_2Pb(NO_3)_2]$ and $[(BTZ)Pb(NCS)_2]$ complexes show a gap around the Pb(II) ion, occupied possibly by a stereoactive lone pair of electrons on lead(II) and coordination around the lead atoms is hemidirected with a significant gap trans to chelating BTZ ligands, nitrate and thiocyanate anions. There is a π–π stacking interaction between the parallel aromatic rings belong to adjacent chains in $[(BTZ)Pb(NCS)_2]_n$ that may help to increase the 'gap' in the coordination geometry around the Pb(II) ion. © 2002 Elsevier Science Ltd. Keywords: BTZ ligands; X-ray crystallography; Pb(II) salts; π–π stacking interaction

1. Introduction

The most of the lead(II) issues are on macrocyclic ligands and recently a number of lead(II) complexes with different N-donor ligands have been synthesized and studied by X-ray crystallography [1–10]. These studies have provided a basis for a rather detailed analysis of the evidence for coordination sphere distortions, which may be a consequence of the presence of the lone pair on Pb^{2+}. It appears that in complexes of lead(II) [and probably in those of related species such as Tl(I) and Bi(III)], the nature and form of the coordination sphere is generally determined by a number of factors, possibly including lone pair–bond pair repulsions, of comparable influence, so that seemingly minor differences in ligands or in the crystal array can have quite marked effects upon the coordination stereochemistry. Since the presence of a lone pair is not directly detected but is inferred on the basis of the spatial distribution of atoms assumed to be donors to the central metal, the identification of these donor atoms is fundamental to the analysis of any particular system. In a recent report [2] on the crystal structure of $[Pb(phen)(O_2CCH_3)(O_2ClO_2)]$, the presence of a lone pair and its influence upon the coordination stereochemistry of the lead(II) ion and also π–π stacking interaction in polymeric structure was described.

In the present paper we want to show the nature of adducts formed between lead(II) salts (nitrate and thiocyanate anions) and the aromatic *N*,*N*′-bidentate ligand 4,4′-bithiazole (BTZ). This ligand is planar like 1,10-phenanthroline and 2,2′-bipyridyl, and can act as a bidentate ligand.

2. Experimental

2.1. Physical measurment

IR spectra were recorded as Nujol mulls using Perkin–Elmer 597 and Nicolet 510P spectrophotometers. Microanalyses were carried out using Carlo–Erba microanalyses.

2.2. Preparation of ligand

The BTZ ligand was prepared as described in the literature [11].

2.3. Preparation of $[(BTZ)_2Pb(NO_3)_2]$ (1)

(a) The complex $[(BTZ)_2Pb(NO_3)_2]$ was prepared by dissolving 0.331 g (1 mmol) lead(II) nitrate in distilled water and adding an alcoholic solution of BTZ (2 mmol). The resulting solution was stirred for 1 h at room temperature (r.t.); then it was allowed to stand for 2–3 days in a refrigerator. Colorless crystals of the desired product precipitated, which were filtered off, washed with C_3H_6O and ether, then air dried (yield 70%), m.p. 205 °C.

Anal. Found: C, 21.6; H, 1.2; N, 12.4. Calc. for $[(BTZ)_2Pb(NO_3)]_2$: C, 21.5; H, 1.19; N, 12.57%. The IR spectrum of the solid complex shows $\nu(NO_3)$ at 1378 cm^{-1} consistent with unidentate or unsymmetrical bidentate nitrate coordination.

(b) *Branched tube method:* 4,4′-Bithiazole (2 mmol) was placed in one arm of the branched tube and 0.331 g (1 mmol) lead(II) nitrate in the other. Methanol was carefully added to fill both arms, then the tube was sealed and the ligand-containing arm immersed in a bath at 60 °C while the other was at ambient temperature. After 15 days, white crystals, m.p. 205 °C had deposited in the cooler arm.

2.4. Preparation of $[(BTZ)Pb(NCS)_2]$ (2)

To a solution of BTZ (2 mmol) in hot MeOH was added a hot aq. solution of lead(II) nitrate (1 mmol) and excess of potassium thiocyanate. The final solution was allowed to cool slowly overnight, when crystals separated from the solution. The crystals were filtered,

washed with C_3H_6O and air dried (yield 80%), m.p. 250 °C. *Anal*. Found: C, 19.1; H, 1.2; N, 7.4. Calc. for $[(BTZ)Pb(SCN)_2]$: C, 19.3; H, 1.07; N, 7.53%. The IR spectrum of this complex shows ν(SCN) at 2040 cm^{-1}.

2.5. Crystallography

2.5.1. Crystal data and refinement details

*2.5.1.1. $[(BTZ)_2Pb(NO_3)_2]$ (**1**).* $C_{12}H_8N_6O_6PbS_4$, M 667.67, monoclinic, space group $C2/c$, a 16.8571(19), b 13.03895(16), c 8.8706(11) Å, β 109.191(3)°, V 1890.9(4) $Å^3$, D_{calc} ($Z = 4$ f.u.) 2.345 mg m^{-3}, F(000) 1264, specimen: $0.30 \times 0.15 \times 0.10$ mm, $T_{max,min}$ 1.00000, 0.54844, N 10 968, N_0 2761, R 0.0199, R_w 0.0499.

*2.5.1.2. $[(BTZ)Pb(SCN)_2]_2$ (**2**).* $C_{16}H_8N_8Pb_2S_8$, M 983.16, triclinic, space group $P\bar{1}$, a 9.672(4), b 10.592(4), c 13.386(5) Å, α 103.77(3), β 101.78(3), γ 92.65(3)°, V 1297.4(8) $Å^3$, D_{calc} ($Z = 2$ f.u.) 2.517 mg m^{-3}, F(000) 904, specimen: $0.3 \times 0.2 \times 0.2$ mm, $T_{max,min}$ 0.856, 0.4856, N 4678, N_0 4381, R 0.0618, R_w 0.1475.

2.5.2. Determination of the structures

Crystallographic measurements were made at 153(2) K using a Siemens R3m/V diffractometer. The intensity data were collected within the range $1.99° \leq \theta \leq 30.01°$ for compound **1** and $1.99° \leq \theta \leq 25.03°$ for compound **2** using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Accurate unit cell parameters and orientation matrix for data collection were obtained from least-squares refinements. Intensities of 10 968 for compound **1** and 4678 for compound **2** unique reflections were measured, from which 2649 for compound **1** and 4381 for compound **2** with $I > 2\sigma(I)$ were used in the refinement. The structures have been solved by direct methods and refined by full-matrix least-squares techniques on F^2.

The positions of hydrogen atoms were idealized and included in the calculations of the structure factors as fixed contributions. Each hydrogen atom was assigned an isotopic thermal parameter. R, R_w, with a goodness-of-fit on F^2 of 1.010, for compound **1** are 0.0199, 0.046 and for compound **2** are 0.0818, 0.1475. The final difference density map showed a maximum peak and hole of 1.809 and -1.947 e $Å^{-3}$ for compound **1**, 3.879 and -4.099 e $Å^{-3}$ for compound **2**. Corrections for the Lp as well as the empirical correction for absorption using the SADABS programs for compound **1**

and PSI-SCAN programs for compound **2** were applied. All structural calculations were carried out with a PDP—11/23+ computer using the SDP–PLUS program package [12,13].

Crystal data and structure refinement are given in Table 1. Selected bond lengths and angles are given in Tables 2 and 3. Anisotropy thermal parameters, observed and calculated structure factors, full lists of bond distances, bond angles and torsion angles are given in the Section 4. ORTEP diagrams and a perspective view of the packing in the unit cells are shown in Figs. 1–5.

3. Discussion

3.1. Synthesis

The method of synthesis of both complexes is the same and in preparing these two complexes, BTZ ligand and lead(II) nitrate have been reacted in a 2:1 ratio. In preparing $(BTZ)Pb(SCN)_2$, KSCN is used excess. The attempt to isolate $(BTZ)_2Pb(SCN)_2$ was not successful and each time the 1:1 adduct was isolated.

3.2. Crystal structure of $[(BTZ)_2Pb(NO_3)_2]$ (1)

The crystal structure of compound **1** consists of dimeric units of $[(BTZ)_2Pb(NO_3)_2]_2$. Each lead atom is chelated by the nitrogens of two BTZ ligands with a Pb–N distance of 2.617 and 2.636 Å, and the oxygen atoms of nitrate anions with a Pb–O distance of 2.729 Å. The coordination number in this complex is six (four from BTZ ligands and two from nitrate anions) and the weak interaction of lead(II) with oxygen atoms of an adjacent molecule produces dimer units in the solid state. In fact each Pb atom in this structure alone with six normal bonds forms four 'weak' Pb···O bonds. Only two of them are symmetry independent and the exact distances are Pb1···O1 = 3.045, Pb1···O1 $(-x, -y, -z) = 3.110$ Å, Pb1···O1 $(-x, y, 1/2-z) = 3.045$ and Pb1···O1 $(-x, -y, z+1/2) = 3.110$ Å (Table 2). The presence of a lone pair of electrons on the lead atom is apparently the reason why the bridging interactions cannot come closer together. If the stereochemically active lone pair was not present, it might create a

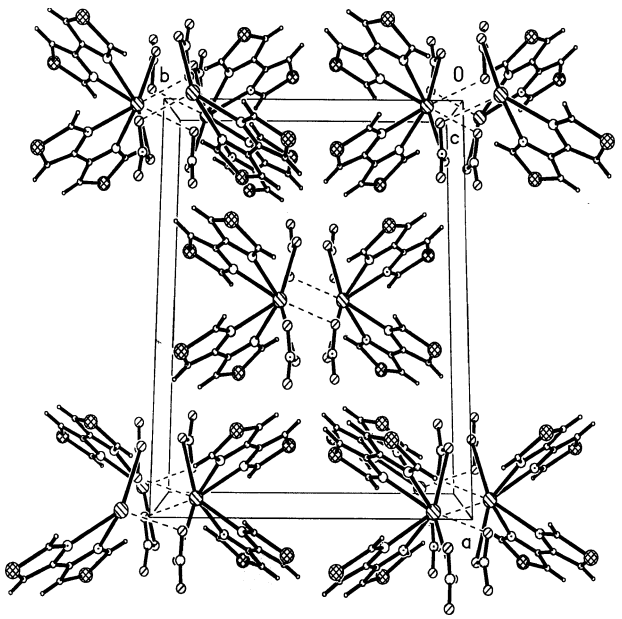

Fig. 2. The unit cell of $[(BTZ)_2Pb(NO_3)_2]_2$.

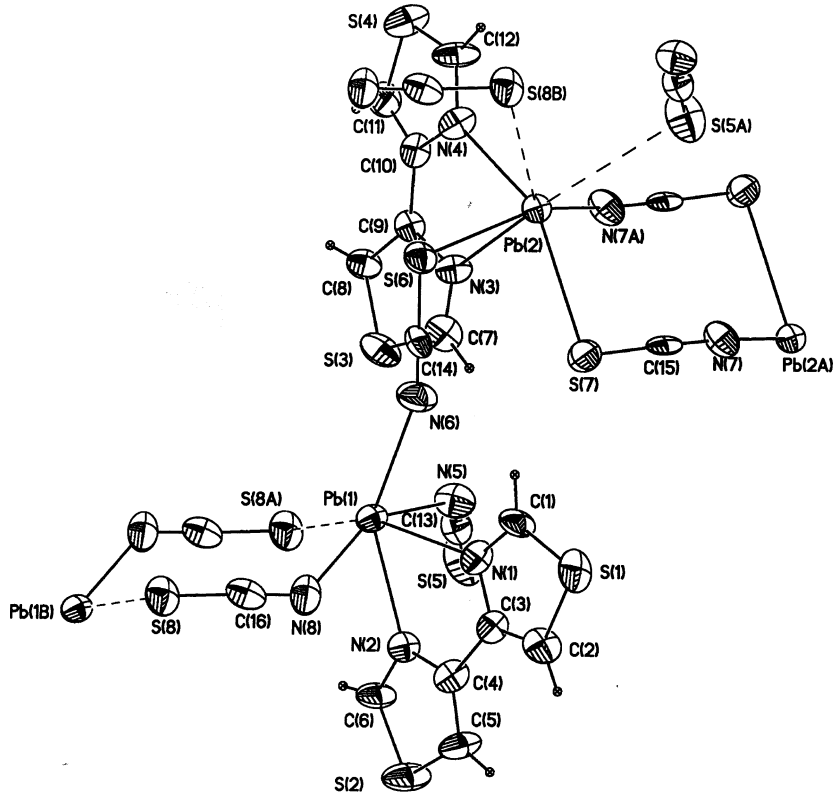

Fig. 3. ORTEP diagram of $[(BTZ)Pb(SCN)_2]_n$.

greater interaction between bridging atoms of lead(II) with the neighboring oxygens from nitrate anions. Consequently, this phenomenon could lead to more symmetry.

The arrangement of BTZ ligands and nitrate anions suggests a gap in the coordination geometry around the metal ion [O(3A)–Pb(1)–O(3) angle is 148.98°] (Table 2), occupied possibly by a stereoactive lone pair of electrons on lead(II). The observed shortening of the Pb–N bond on the side of Pb(II) ion opposite to the position of the putative lone pair (2.617 compared with 2.636 Å adjacent to the lone pair) supports the presence of this feature [4]. Hence, the geometry of the nearest

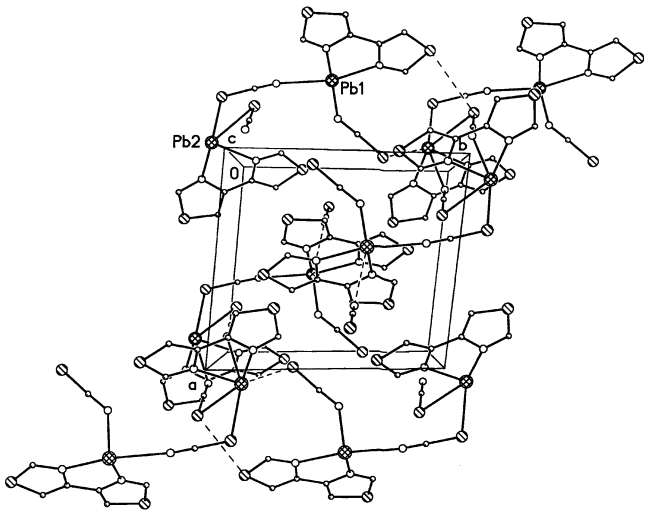

Fig. 4. The unit cell of $[(BTZ)Pb(SCN)_2]_n$.

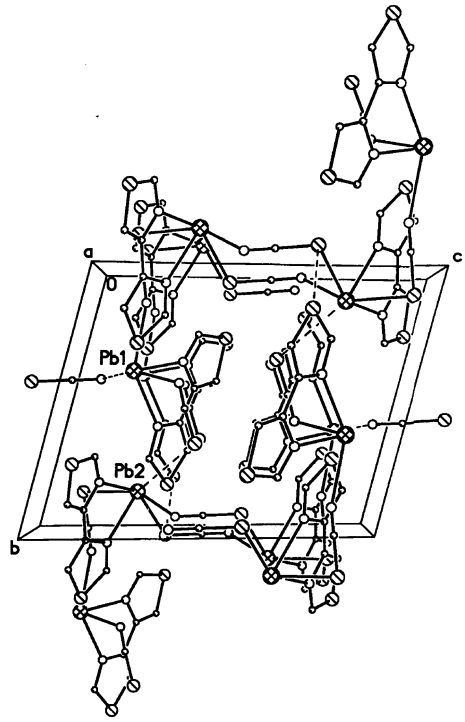

Fig. 5. Showing π–π stacking interaction in $[(BTZ)Pb(SCN)_2]_n$ with atom labelling.

coordination environment of every lead atom is likely caused by the geometrical constraints of coordinated BTZ ligands, nitrate anions and by the influence of a stereochemically active lone pair of electrons in a hybrid orbital on the metal atom. Such an environment leaves space for bonding of oxygen atoms of nitrate anions of an adjacent molecule (Fig. 2).

3.3. Crystal structure of [(BTZ)Pb(NCS)$_2$] (2)

The structure of compound **2** is polymeric as a result of thiocyanate ligand bridging (Fig. 3), with various similarities to polymeric (phen)Pb(SCN)$_2$ [10], in which the lead atoms are five coordinated with two different coordinate polyhedra, PbN_3S_2 (two by the chelating BTZ and three by SCN^- anions) and PbN_5 (two by BTZ and three by SCN^- anions).

The Pb(1) atoms are in a deformed pseudooctahedral arrangement with five nitrogen atoms, two from the bithiazole ligand and three from the thiocyanate anions (one lone pair of electrons occupying an equatorial site). The Pb(2) atoms are also in a deformed pseudooctahedral arrangement with two nitrogen atoms from the bithiazole ligand, two sulfur atoms and one nitrogen atom from the thiocyanate anions (one lone pair of electrons occupying an equatorial site).

The arrangement of the BTZ ligands and two SCN^- anions [N(2)–Pb(1)–N(6), N(7A)–Pb(2)–S(6) angles are 144.6° and 155.3°, respectively] (Table 3) suggests a gap in the coordinate geometry around the metal ions, occupied possibly by a stereoactive lone pair of electrons on the lead(II). The observed shortening of the Pb–N bond on side of the Pb(II) ion opposite to the position of the putative lone pair (2.441 compared with 2.686 Å adjacent to the lone pair) supports the presence of this feature [4]. Hence the geometry of the nearest coordination environment of every lead atom, the same as the compound **1**, is likely to be caused by the geometrical constraints of coordinated bithiazole ligands, thiocyanate anions and by the influence of a stereochemically active lone pair of electrons in an hybrid orbital on the metal atom, which occupies one equatorial coordination site of a pseudooctahedral. Such an environment leaves space for bonding of sulfur atoms (Fig. 3).

The possible stereochemically active lone pair of electrons in divalent lead compounds has recently been discussed by Shimoni-Livny et al., based on a thorough review of crystal data available in the Cambridge Structural Database (CSD) [14]. They classified lead complex coordination as holodirected or hemidirected. Holodirected refers to complexes in which the bonds to ligands are directed throughout the surface of an encompassing sphere, while hemidirected refers to those cases in which the bonds to ligands are directed throughout only part of the coordination sphere, leaving a gap in the distribution of bonds to the ligands. The latter is present in all Pb(II) compounds with coordination numbers 2–5, is quite common in Pb(II) complexes with coordination numbers 6, 7 and 8 and does not exist in lead complexes with higher coordination number, where holodirected geometry is the rule. For the structures described here, coordination around the lead atoms is hemidirected with a significant gap trans to the BTZ ligand, nitrate and thiocyanate anions. The strikingly different features of compound **2** compared to compound **1** is that there is a π–π stacking interaction (charge-transfer arrays) [15,16] between the parallel aromatic rings belong to adjacent chains, as shown in Fig. 5. It is a planar species in which the mean molecular planes are close to parallel and separated by a distance of ~3.5 Å, close to that of the planes in graphite. The 'gap' in $[(BTZ)Pb(NCS)_2]_n$ is more than that in $[(BTZ)_2Pb(NO_3)]_2$. In five reported compounds, $[Pb(phen)(CH_3COO)_2]_2$, $[Pb(phen)(NO_3)_2]_n$, $[Pb(bpy)(NO_3)_2]_n$ [10], $[Pb(phen)(CH_3COO)(ClO_4)]_n$ [2], $[Pb(phen)(CH_3COO)(NO3)]_n$ [17], and the reported compound here, $[(BTZ)Pb(SCN)_2]_n$, the ratio of ligand–metal is 1:1. There are π–π stacking interactions in all these compounds, but π–π stacking interactions are rarely observed in complexes with a ligand–metal ratio of 2:1 [10]. In both 1:1 and 2:1 complexes there is a gap but this gap is more for the 1:1 ratio. It may be that this increased gap is due to the influence of the π–π stacking of aromatic units upon Pb(II) coordination.

4. Supplementary material

Complete bond lengths and angles, co-ordinates and displacement parameters have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 162630 and 167891 for compounds **1** and **2**. Supplementary data are available on request from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

An organophosphorus ligand, namely, 1,2-bis(diphenylthiophosphinyl)ethane {$Ph_2P(S)–CH_2–CH_2–P(S)Ph_2$; $dppeS_2$} reacted with palladium(II) chloride in acetonitrile forming $[PdCl_2(dppeS_2)](CH_3CN)$ (**1**). Similarly, it reacted with mercury(II) bromide in acetone to yield $HgBr_2(dppeS_2)$ (**2**). In these compounds, Pd/Hg are bonded to two S atoms of chelating $dppeS_2$ ligand and to the respective halogen atoms. The geometry about Pd is distorted square planar with *trans*-bond angles S(1)–Pd–Cl(1) and S(2)–Pd–Cl(2) being 174.10(5)° and 172.85(5)°, respectively. The angles about Hg vary in the range 96.20(6)–124.56(4)°, suggesting highly distorted geometry about Hg. The bite angle S(1)–Hg–S(2) of the ligand is 118.85° in **2** versus 97.76° in **1**, and it demonstrates large flexibility of alkane moiety and stability of the seven-membered metallacyclic rings formed by $dppeS_2$.

1. Introduction

Organophosphorus ligands such as tertiary phosphine oxides, sulphides, or selenides (I, II below) bearing O, S, or Se donor atoms have been the focus of several investigations related to their coordination chemistry, extractive metallurgy, catalytic properties, and structural chemistry [1,2].

$$\underset{\text{I}}{R_3P=E} \qquad \underset{\text{II}}{R_2P(E)–(CH_2)_m–P(E)R_2}$$

$\{E = O, S, Se;\ R = Ph, \text{etc.} \quad m = 1, 2, \text{etc.}\}$

In view of the importance of the study of metal–sulphur interactions, the structures and spectroscopic properties of a number of metal complexes of heterocyclic thiones, thiosemicarbazones, and tertiary phosphine chalcogenides have been reported in the literature [1–11]. As a part of our interest in investigating the structural chemistry of metal–phosphine chalcogenide interactions, particularly with bis(tertiary phosphine chalcogenides), we have reported the structures of the complexes, viz. $[HgCl_2\{Ph_2P(S)–CH_2–P(S)Ph_2\}]$ [11c] (compound **3**), $[HgI_2\{Ph_2P(S)–CH_2–PPh_2\}]$ [11b] (compound **4**), $[HgCl_2\{Ph_2P(S)–CH_2–CH_2–P(S)Ph_2\}]$ [11b] (compound **5**), $[HgPh_2\{Ph_2P(S)–CH_2–CH_2–P(S)Ph_2\}]$ [11a] (compound **6**), $[Cu_2(\mu\text{-}I)_2(Ph_3PSe)_2(MeCN)_2]$ [12](compound **7**), $[Cu_2(\mu\text{-}I)_2(Ph_3PS)_2{\cdot}(CH_3CN)_2]$ [13] (compound **8**), and $[Cu_2(\mu\text{-}Cl)_2(dppeSe_2)_2]$ [13] (compound **9**; $dppeSe_2$ is selenium analogue of $dppeS_2$), $[ZnI_2(dppmSe_2)]$ [14] (compound **10**, $dppmSe_2 = Ph_2P(Se)–CH_2–P(Se)Ph_2$). As regards palladium, there are only two complexes, $PdCl_2L_2$ {$L = PhEt_2PS$, *i*-Bu_3PS}, whose crystal structures are known and none

PII: S0277-5387(01)00977-9

among bis(tertiary phsophine sulphides or selenides) [1,15,16].

In this paper, the structures of complexes of palladium(II)/mercury(II) with 1,2-bis(diphenylthiophosphinyl)-ethane are described which represent rare examples of seven-membered chelate ring formation among metal-phosphine sulphides or selenides [11b]. In a copper(I) complex, $[Cu_2Cl_2\{dppeS_2\}_2]$, $dppeS_2$ bridges two Cu atoms [13]. Furthermore, for palladium(II) it is the first structurally characterised complex with a bis(tertiary phosphine chalcogenide) [1,2,18].

2. Experimental

2.1. General materials

Palladium(II) chloride and mercury(II) bromide were of standard grade and used as such. The compound 1,2-bis(diphenylphosphino)ethane, $\{Ph_2P–CH_2–CH_2–PPh_2$, dppe$\}$, was prepared by lithiation of PPh_3 in dry tetrahydofuran followed by the reaction with dichloroethane [17]. Treatment of dppe with elemental sulphur (1:2 mole ratio) in benzene formed $Ph_2P(S)–CH_2–CH_2–P(S)Ph_2$ $\{dppeS_2\}$ [18].

2.2. Preparation of $[PdCl_2(dppeS_2)](CH_3CN)$ (1)

To a solution of palladium(II) chloride (0.100 g, 0.56 mmol) in hot acetonitrile (25 cm^3) was added to the solution of the ligand, $dppeS_2$ (0.260 g, 0.56 mmol), and the contents refluxed for 3 h. The solution was filtered and allowed to crystallise, whereupon light red-coloured crystals were formed. The crystals were separated and dried at room temperature (r.t.). Yield 70%; melting point (m.p.) 245–47 °C. *Anal.* Found: C, 49.4; H, 4.3; N, 1.97. Calc. for $C_{28}H_{27}Cl_2NPdS_2$: C, 49.4; H, 4.0; N, 2.05%. Main IR bands: 1098 cm^{-1} $\{\nu P–C\}$; 575 cm^{-1} $\{\nu P–S\}$; ligand band($dppeS_2$): 1097 cm^{-1} $\{\nu P–C\}$; 600 cm^{-1} $\{\nu P–S\}$.

2.3. Preparation of $[HgBr_2(dppeS_2)]$ (2)

To a solution of mercury(II) bromide (0.050 g, 0.14 mmol) in acetone (20 cm^3) was added the solution of the ligand, $dppeS_2$ (0.065 g, 0.14 mmol), in acetone (20 cm^3) and the contents were stirred for 1 h, followed by refluxing for half an hour. The solution was filtered and allowed to crystallise at r.t. whereupon colourless crystals were formed. The crystals were separated and dried at r.t. Yield 60%; m.p. 206–08 °C. *Anal.* Found: C, 39.2; H, 3.2. Calc., for $C_{26}H_{24}Br_2HgS_2$: C, 38.0; H, 2.9%. Main IR bands: 1110 cm^{-1} $\{\nu P–C\}$; 585 cm^{-1} $\{\nu P–S\}$; ligand band: 1097 cm^{-1} $\{\nu P–C\}$; 600 cm^{-1} $\{\nu P–S\}$.

2.4. Elemental analyses and spectroscopic techniques

The C, H, and N elemental analyses were obtained with a Carlo–Erba 1108 microanalyser. The melting points were determined with a Gallenkamp electrically heated apparatus. IR spectra were recorded using KBr pellets on a Pye-Unicam SP3-300 Infrared Spectrophotometer in the 4000–400 cm^{-1} range.

2.5. Crystal structure determinations

A red prismatic crystal of compound **1** (colourless for compound **2**) was mounted on a glass fibre and used for data collection. Cell constants and orientation matrices for data collection were obtained by least-squares refinement of the diffraction data from 25 reflections in the range of $21.513 < \theta < 45.145°$ for **1** and $4.682 < \theta < 20.743°$ for **2**, on an Enraf–Nonius CAD 4 automatic diffractometer [19]. Data were collected at 293 K using Cu Kα radiation ($\lambda = 1.54184$ Å) for **1** or Mo Kα radiation (0.71073 Å) for **2** and the ω scan technique and corrected for Lorentz and polarisation effects [20]. A semi-empirical absorption correction (ψ-scan) was made [21].

The structures were solved by direct methods [22] and subsequent difference Fourier maps and refined on F^2 by a full-matrix least squares procedure using anisotropic displacement parameters [23]. All hydrogen atoms were located from difference Fourier maps in their calculated positions (C–H, 0.93–0.97 Å) and were refined isotropically. Atomic scattering factors were used from International Tables for X-ray crystallography [24] and molecular graphics from PLATON 98 [25]. A summary of the crystal data, experimental details, and refinement results is given in Table 1.

3. Results and discussion

3.1. General comments

Reactions of $Ph_2P(S)–CH_2–CH_2–P(S)Ph_2\cdot\{dppeS_2\}$ with $PdCl_2(CH_3CN)_2$ in hot CH_3CN or with $HgBr_2$ in acetone (room temperature) formed 1:1 complexes, viz. $MX_2(dppeS_2)$, as revealed by the physical properties and analytical data. The IR spectra for the ligand and the complexes were different, and the diagnostic peak νP–S of free $dppeS_2$ at 600 cm^{-1} shifted to 575 cm^{-1} in compound **1** and to 585 cm^{-1} in compound **2**, and it clearly shows that $dppeS_2$ is coordinating to Pd(II)/Hg(II) metal centres via S donor atoms. The shift is more pronounced for Pd(II) vis-à-vis Hg(II) even though the latter is believed to be softer than the former in the terminology of the HSAB principle. The crystal structures of both the compounds are described below.

Table 1
Crystal data and structure refinement for compounds **1** and **2**

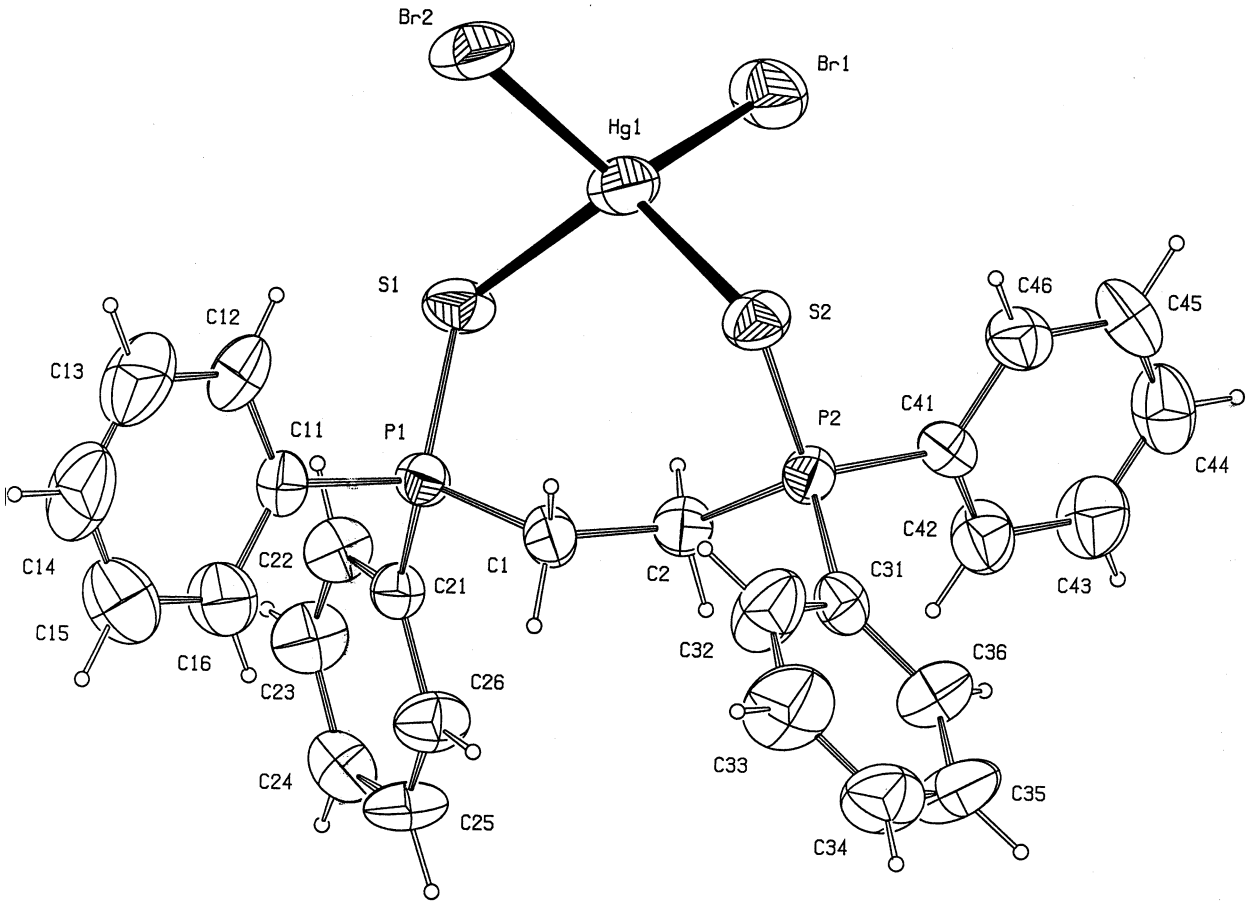
3.2. Description of crystal structures of compounds *1* and *2*

The atomic numbering schemes for [$PdCl_2$($dppeS_2$)]-(CH_3CN) (**1**) and $HgBr_2$($dppeS_2$) (**2**) are shown in Figs. 1 and 2, respectively. While Table 1 contains crystal data, experimental details, and refinement results, Table 2 contains important bond lengths and bond angles. Both compounds adopt a monoclinic crystal system similar to that of [$HgCl_2${$Ph_2P(S)–CH_2–CH_2–P(S)Ph_2$}] [11b]. The basic unit is [MX_2($dppeS_2$)] (X, M = Cl, Pd; Br, Hg) with no evidence for intermolecular interaction, and in compound **1**, CH_3CN lies in the lattice as a non-bonded molecule.

In compound **1**, palladium(II) is bonded to two S atoms of the chelating $dppeS_2$ ligand and two chlorine atoms. The *trans*-bond angles S(1)–Pd–Cl(1) and S(2)–Pd–Cl(2) are 174.10(5)° and 172.85(5)°, respectively, with the bite angle S(1)–Pd–S(2) of the ligand being 97.76°. Whereas Cl(1)–Pd–Cl(2) and S(2)–Pd–Cl(1) bond angles are close to 90°, the angle S(1)–Pd–Cl(2) of 83.19(5)° is unusually short. Thus the square planar geometry about Pd is severely distorted and is the consequence of the effect of the large bulk of the ligand and the tendency of the Pd metal to form square planar geometries. The angles at the S atom differ significantly [cf. Pd–S(1)–P(1), 113.54(7)°,



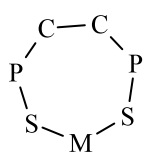


Fig. 2. Perspective view of the structure of compound $HgBr_2(dppeS_2)$ (**2**) with numbering scheme.

Pd–S(2)–P(2), 105.11(7)°]. Similarly, in compound **2** Hg is bonded to two S atoms of the chelating $dppeS_2$ ligand and two bromine atoms. The angles about Hg vary in the range 96.20(6)°–124.56(4)°, suggesting highly distorted geometry about Hg. The bite angle S(1)–Hg–S(2) of the ligand expands to 118.85(8)° in **2**, and interestingly this angle is still higher at 122.3(1)° in the analogous complex, $[HgCl_2(dppeS_2)]$ [11b] (compound **5**). This is clearly the effect of the bulky Br atoms, which has not only affected the bite angle S(1)–Hg–S(2) of the ligand, but also affected other bond angles. Note that the Br(1)–Hg–Br(2) bond angle of 124.56(4)° is much larger than the analogous Cl(1)–Hg–Cl(2) angle of 111.4(1)° in compound **5**. In the three examples of complexes of $dppeS_2$ discussed above {compounds **1**, **2**, **5**}, the flexibility of the alkane moiety is very apparent, which is tuning to the steric requirements of the metal or the anion. Thus the seven-membered metallacyclic rings (III) are interestingly stable and flexible.

III

The Pd–S bond distances, 2.3005(14) and 2.3018(13) Å, are shorter than those reported for $PdCl_2L_2$ {2.334, 2.350 Å for L = *i*-Bu_3PS, $PhEt_2PS$, respectively} [15,16]. The Pd–Cl bond distances are normal, though unequal. The P–S bond distances for **1** {2.0181(18), 2.0089(18) Å} are equal to those for the above Pd complexes [2.014, 2.013 Å, respectively [15,16]] and a bit longer than those found in **2**{1.990(3), 1.999(3) Å}. Other bond distances of the metallacyclic ring, namely P(1)–C(1) and P(2)–C(2), are also unequal, but similar for both the compounds (Table 2). In compound **2** Hg–S distances are unequal{2.678(2), 2.552(2) Å} and quite different from those for compound **5** {2.559(3), 2.546(3) Å} [11b]. The longer Hg–S distance in **2** is comparable to that observed in HgI_2L {Hg–S = 2.760 Å, L = Ph_2P–CH_2–P(S)Ph_2} [11b] for which a flattened tetrahedral structure was concluded. In **2** also, the sum of the bond angles of the trigonal plane formed by Hg, S(2), Br(1) and Br(2), is 340.77 Å [S(2)–Hg–Br(1), S(2)–Hg–Br(2), and Br(1)–Hg–Br(2)], similar to that in HgI_2L {353.7°} [11b]. The lengthening of the Hg–S(1) bond distance is reflected in the shorter P(1)–S(1) and P(1)–C(1) distances.

4. Supplementary material

Supplementary data are available from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 166375 for compound **1**, 166374 for compound **2.**

Abstract

The title complex $Zr(dshpm)_2$ has been successfully prepared by heating a 1:2 mole ratio of $Zr(OBu^n)_4$ and the free ligand in absolute ethanol. It is mononuclear and eight-coordinate in the solid state with a dodecahedral coordination sphere. The two O,N,N,O donor atom quadridentate Schiff base ligands each form 6,4,6-membered chelate rings. As expected, the change in a chelate ring sizes from 6,5,6- to 6,4,6- resulted in significantly more labile complex, as indicated by TLC and NMR of heated solutions and its subsequent chemical reactions. The 0.010 Å shorter average Zr–N bond distance was not anticipated, and appears to result from the zirconium atom's preference that the oxygen atoms occupy certain locations. Preparations of two heteroleptic complexes from the title complex were undertaken to evaluate potential of the title compound as a synthon. A new fluorine-substituted homoleptic Schiff base Zr complex was also prepared, for comparison purposes. Despite the reasonable stability of $Zr(dshpm)_2$ in air, the decomposition of labilized Hdshpm(2-) ligand on silica gel and in heated solution interfered with the purifications of the desired heteroleptic products. © 2002 Published by Elsevier Science Ltd.

Keywords: Eight-coordinate; Schiff base; Zirconium complexes; X-ray crystal structure; Synthon; Heteroleptic

1. Introduction

The recent publication of articles dealing with early transition metal eight-coordinate complexes reflects a continuing interest in this subject, especially with regard to their structural aspects [1–6] intramolecular dynamics [7–10] and ligand exchange properties [11–14]. Our current interest is in the development of a more facile route to heteroleptic (mixed ligand) bis(quadridentate) complexes for use as polymer pendent groups [15]. Commercially available entry points for the preparation of zirconium(IV) complexes include zirconium tetraalkoxides and zirconium tetrachloride, which are polymeric to some degree and/or susceptible to atmospheric hydrolysis, and tetrakis(acetylacetonato)zirconium(IV), which can exhibit varying degrees of ligand substitution.

Bis(quadridentate) Schiff base complexes of zirconium(IV), which have fused 6,5,6-membered chelate rings and two O,N,N,O donor atom sets, are sufficiently inert that chromatographic separation on silica gel can be accomplished [15]. However, we have observed that the temperatures needed to overcome this inertness cause decomposition of the freed ligands in dimethyl sulfoxide. By choosing a quadridentate Schiff base ligand capable of forming fused 6,4,6-membered chelate rings

upon coordination, we hoped to isolate a mononuclear complex with a convenient balance of ligand lability and air stability to serve as a new reaction intermediate (synthon). The increased lability would be a consequence of the greater ring strain, i.e. poorer overlaps, in the 4-membered chelate ring portion of the complex. The quadridentate Schiff base that we chose to use is *N*,*N*′ - bis(2 - hydroxybenzylidene) - 2 - hydroxyphenylmethanediamine, also called *N*,*N*′-bis(salicylidene)-2-hydroxy-α,α benzyldiamine, or more commonly *N*,*N*′-di(salicylidene) - 2 - hydroxyphenylmethanediamine, H_3dshpm. It can be made by mixing reagents found in most synthetic chemistry labs, ammonium hydroxide and salicylaldehyde, at room temperature [16,17]. This reaction is an example of one of the earliest known 'spontaneous assembly' reactions [18]. This compound allows facile modification of its structure [19–23] and is known to form complexes with other transition metals [24].

The synthesis, structural characterization and further reactions of the title complex, Zr(dshpm)$_2$, are reported here (Fig. 1).

2. Experimental

Zirconium *n*-butoxide (80% in *n*-butanol), salicylaldehyde, 3-fluorosalicylaldehyde, deuterated methylene chloride and deuterated dimethyl sulfoxide were obtained from Aldrich and used as received. The ammonium hydroxide and all solvents used were of reagent grade. Silica Gel (Merck), grade 60, 230–400 mesh, 60 Å pore size was obtained from Aldrich, and silica TLC plates were obtained from Kodak.

Prior to all TLC separations, silica plates were activated by heating at 110 °C for approximately 10 min, cooled in a desiccator for at least 5 min, and then stored for approximately 1 h or less in a glove bag filled with dry dinitrogen. Ligands and complexes were spotted while in the glove bag, and the plates returned to the oven for at least 2 min to drive away the spotting solvent.

Infrared spectra were obtained on a Perkin–Elmer FT-IR X spectrophotometer as KBr pellets using polystyrene for external calibration. ^{1}H NMR spectra for preliminary identification purposes were obtained on either a Nicolet NT-200 or a Bruker WP200 SY NMR instrument using tetramethylsilane as internal standard. ^{1}H, ^{19}F (using α,α,α-trifluorotoluene or internal referencing based on sample solvent), and all 2-D NMR spectra for detailed analyses were obtained on a Bruker Avance 400 NMR instrument.

X-ray crystallographic data for the title compound were obtained as follows: Large yellow block crystals were mounted on fine glass fibers and found to be monoclinic with systematic absences for *C* centering and a *c* glide along *b* indicating either *Cc* or *C*2/*c* as

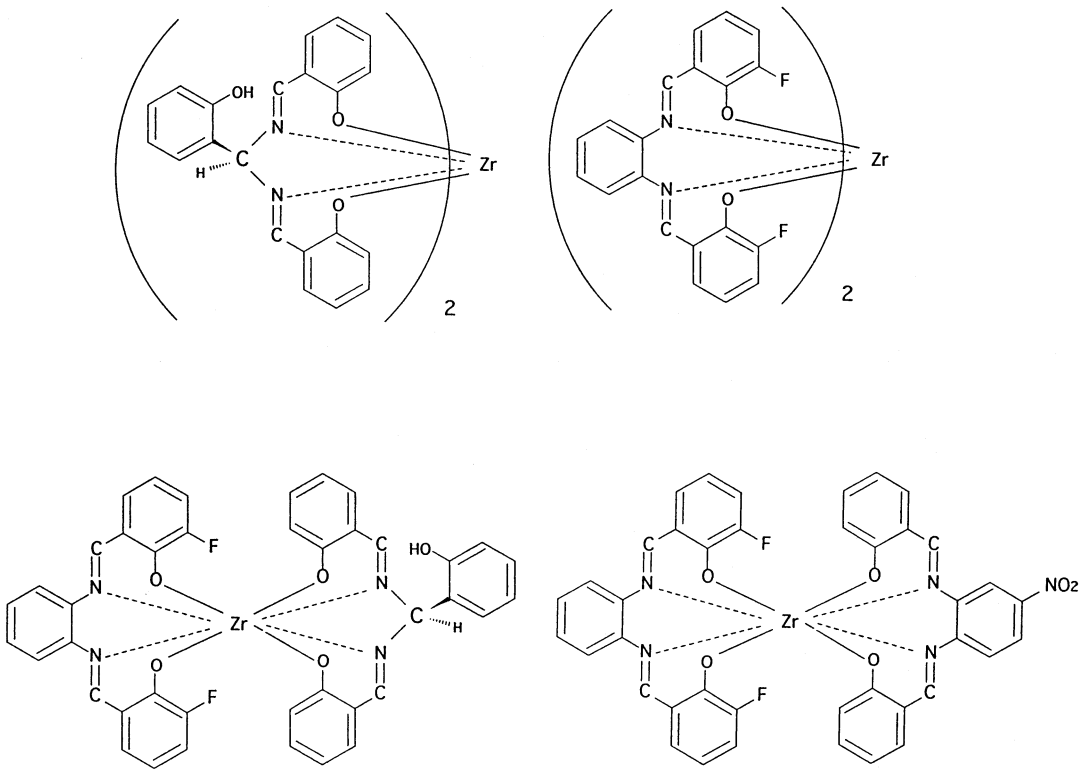

Fig. 1. Proposed structures for all new complexes in this report. Top left, Zr(dshpm)$_2$; top right, Zr(3-Fdsp)$_2$; bottom left, Zr(dshpm)(3-Fdsp); bottom right, Zr(ndsp)(3-Fdsp).

possible space groups. The latter was confirmed by the presence of a crystallographic twofold rotation axis in the Zr complex and the stability of the refinement in the centrosymmetric setting. The structure was solved by direct methods. All nonhydrogen atoms were refined anisotropically and hydrogen atoms were included as idealized isotropic contributions. All computations used the programs contained in the SHELXTL library (version 4, G. Sheldrick, Siemens XRD, Madison, WI).

2.1. *N,N′-di(salicylidene)-2-hydroxyphenylmethanediamine*, *H_3dshpm*

In a 125 ml Erlenmeyer flask was placed 20.5 g (0.168 mole) salicylaldehyde. Concentrated ammonium hydroxide was added almost to the top (ca. 115 ml), the flask stoppered and vigorously shaken. Bright yellow precipitate formed almost immediately. The flask was allowed to sit unopened for 3 days. At this point, the flask contained tamped-down, fused-looking yellow orange precipitate with a clear yellow supernate. The solution was gravity filtered, and the precipitate washed with ethyl ether. A powdery yellow solid containing some shiny orange spheres was obtained. Trituration of this product in 40 ml of absolute ethanol failed to completely remove the orange spheres. Yield, 13.0 g (66.9%).

A portion of this product was dissolved in acetone, petroleum ether added, and the volume of solvents reduced using rotary evaporation to induce recrystallization. After filtering, and washing with pertroleum ether, the fluffy yellow solid obtained lacked any visible orange component, and was only slightly soluble in methylene chloride; m.p. 159–160 °C. *Anal.* Calc. for $C_{21}H_{18}N_2O_3$: C, 72.8; H, 5.20; N, 8.09. Found: C, 72.58; H, 5.31; N, 8.09%. ^{1}H NMR (acetone-d_6): δ 13.1 (br) [1], 8.7 [2], 7.5–6.8 [12], 6.35 [1]. IR (cm^{-1}): 1628s, 1276m.

2.2. *Bis(N,N′-di(salicylidene)-2-hydroxyphenylmethanediaminato)zirconium(IV)*, *$Zr(dshpm)_2$*

A 1.69 g (4.86 mmol) portion of the yellow and orange H_3dshpm product was covered with 80 ml absolute ethanol in a 500 ml round bottom flask. Under a dinitrogen tmosphere, 0.50 ml (1.2 mmol) of $Zr(OBu^n)_4$ was then precipitated to the flask, causing the immediate formation of a cloudy, white precipitate. The flask was heated at reflux for 24 h, and filtered, to give a fine yellow powder; m.p. ca. 250 °C (slow dec.). Yield, 0.62 g (67%).

The sample submitted for elemental analysis was dried in vacuo at 100 °C for 3 days. *Anal.* Calc. for $C_{42}H_{32}N_4O_6Zr$: C, 64.7; H, 4.11; N, 7.19. Found: C, 64.56; H, 4.14; N, 6.97%. ^{1}H NMR (CD_2Cl_2): δ 9.5 (br) [2], 8.2 [2], 8.0 [2], 7.6–6.5 [28]. IR (cm^{-1}): 1638s, 1604s, 1310m, 1288m.

2.3. *N,N′-Di(3-fluorosalicylidene)-1,2-phenylenediamine*, *$H_2$3-Fdsp*

A 1:2 mole ratio of 1,2-phenylenediamine and 3-fluorosalicylaldehyde, respectively, were heated at reflux in absolute ethanol for 6 h, concentrated, and chilled to give an orange precipitate; m.p. 148–150 °C.

Anal. Calc. for $C_{20}H_{14}F_2N_2O_2$: C, 68.2; H, 3.98; N, 7.95. Found: C, 67.95; H, 3.86; N, 7.87%. ^{1}H NMR (CD_2Cl_2): δ 13.2 (br) [2], 8.9 [2], 7.5–6.9 [10]. ^{19}F NMR (CD_2Cl_2): -140.6. IR (cm^{-1}): 1620s, 1275m, 1250s, 1230s.

2.4. *Bis(N,N′-di(3-fluorosalicylidene)-1,2-phenylenediaminato)zirconium(IV)*, *$Zr(3\ Fdsp)_2$*

Under a dinitrogen atmosphere, 0.49 ml (0.52 g, 1.1 mmole) $Zr(OBu^n)_4$ were added to 0.80 g (2.3 mmole) $H_2$3-Fdsp in 50 ml absolute ethanol and heated at reflux for 1 h, suction filtered, washed with absolute ethanol, and allowed to dry to give a bright yellow powder; m.p. approximately 416 °C (422 °C dec.). Yield, 0.73 g (81%).

The sample submitted for elemental analysis was dried in vacuo at 100 °C for 3 days. *Anal.* Calc. for $C_{40}H_{24}F_4N_4O_4Zr$: C, 60.7; H, 3.06; N, 7.08. Found: C, 60.86; H, 3.03; N, 7.00%. ^{1}H NMR (CD_2Cl_2): δ 8.7 [4], 7.5–6.4 [20]. ^{19}F NMR (CD_2Cl_2): -137.4. IR (cm^{-1}): 1615s, 1320m, 1255m, 1240m.

2.5. *(N,N′-di(salicylidene)-2-hydroxyphenylmethanediaminato)(N,N′-di(3-fluorosalicylidene)-1,2-phenylenediaminato)zirconium(IV)*, *Zr(dshpm)(3-Fdsp)*

2.5.1. *Method 1*

In 200 and 100 ml portions of methylene chloride, 1.97 g (2.5 mmole) $Zr(dshpm)_2$ and 0.30 g (0.85 mmole) $H_2$3-Fdsp, respectively, were separately dissolved. The former solution was heated to reflux, and the latter added in five increments with 2 h intervals between additions, and reflux maintained overnight. TLC separation of the resulting solution (using methylene chloride eluent on silica) indicated that some unreacted Schiff base remained, whereupon 100 ml absolute ethanol was added. Reflux was maintained, periodically monitoring the reaction with TLC. A pale spot having a value of R_F clearly lower than those for the reactants or $Zr(3\text{-}Fdsp)_2$ or H_3dshpm appeared. After 22.5 h at reflux, TLC of the reaction solution revealed a spot due to $Zr(3\text{-}Fdsp)_2$, at which time the reaction was stopped. The volume was reduced by rotary evaporation to one half of its original volume, 80 ml absolute ethanol added, and concentrated again to induce precipitation. The impure product was redissolved in minimal methylene chloride and subjected to column chromatography

using methylene chloride eluent on silica gel. Fractions containing only the trailing spot (as shown by TLC) were combined, and the solvent evaporated to give a yellow product. Subsequent recrystallizations and column separations failed to produce a product having experimental elemental analyses within established limits from their theoretical values. ^{1}H NMR (CD_2Cl_2): δ 9.0 br [less than 1], 8.5 [1], 8.4 [1], 8.0 [2], 7.5–5.8 [ca. 29] ^{19}F NMR (CD_2Cl_2): -138.5, -133.5. IR (cm^{-1}): 1641s, 1616s, 1317m, 1300m, 1238m.

2.5.1.1. Derivative preparation. An impure sample of Zr(dshpm)(3-Fdsp) was mixed with *N*,*N*′-di(salicylidene)-4-nitro-1,2-phenylenediamine, H_2ndsp, in 30:70 methylene chloride and absolute ethanol, respectively, and heated at reflux. The reaction was monitored by TLC using the TLC system noted above. When the spots attributed to the starting materials were no longer apparent, the reaction solution was concentrated by rotary evaporation to give a red solid. A 0.1 g portion of this product was separated on a silica gel column using methylene chloride as eluent. Fractions having single spot TLCs which appeared to correspond with the desired product were consolidated and evaporated to give a red product. The sample submitted for elemental analysis was dried in vacuo at 100 °C for 3 days. *Anal.* Calc. for $C_{40}H_{25}F_2N_5O_6Zr$ [Zr(ndsp)(3-Fdsp)]: C, 60.0; H, 3.15; N, 8.74. Found: C, 61.24; H, 3.50; N, 8.60%. ^{1}H NMR (CD_2Cl_2): δ 8.6–8.2 [6], 7.5–5.9 [19]. These NMR signals matched those for a sample of Zr(ndsp)(3-Fdsp) prepared directly from $Zr(OBu^n)_4$ and the corresponding free Schiff base ligands, to be reported elsewhere (Found: C, 60.66; H, 3.44; N, 8.52%).

2.5.2. Attempted method 2

Under a dinitrogen atmosphere, 1:1:1 mole ratio amounts of H_3dshpm, $H_2$3-Fdsp, and $Zr(OBu^n)_4$ were heated at reflux in absolute ethanol for 7 h, until the TLC spot from H_3dshpm was no longer apparent (using a 16:1 petroleum ether to ethanol eluent). After being allowed to cool, the mixture was filtered to give a bright yellow powder.

2.5.3. Attempted method 3

Under a dinitrogen atmosphere, 1:1 mole ratio amounts of $Zr(dshpm)_2$ and $Zr(3\text{-}Fdsp)_2$ were separately dissolved in d^6-DMSO. The solutions were mixed, and heated for 20 h intervals at 40, 43, and 50 °C. Changes in the reaction solution were monitored by TLC (using a 16:1 petroleum ether–ethanol eluent), and compared with those for the separate complexes.

3. Results and discussion

The physical and spectroscopic data collected in this study are consistent with the following reaction schemes:

Reaction Scheme I.

$$3NH_3\ (aq) + 2\ \text{salicylaldehyde}\ (aq) \xrightarrow{(-3\ H_2O)} H_3\text{dshpm}\ (s)$$

$$2\ H_3\text{dshpm} + Zr(OBu^n)_4 \xrightarrow{(-4\ HOBu)} Zr(\text{dshpm})_2 \xrightarrow{(H_2\text{3-Fdsp})} Zr(\text{dshpm})(\text{3-Fdsp}) \xrightarrow{(H_2\ \text{ndsp})} Zr(\text{ndsp})(\text{3-Fdsp})$$

Reaction Scheme II.

$$\text{1,2-phenylenediamine} + 2\ \text{3-fluorosalicylaldehyde} \xrightarrow{(-2\ H_2O)} H_2\text{3-Fdsp}\ (s)$$

$$2\ H_2\text{3-Fdsp} + Zr(OBu^n)_4 \xrightarrow{(-4\ HOBu)} Zr(\text{3-Fdsp})_2$$

The 1628 and 1276 cm^{-1} infrared bands for H_3dshpm are comparable to those observed for the dsp-type ligands used in our previous studies [25,26] and are assigned to imine stretching and ring-to-oxygen stretching, respectively. The broad ^{1}H NMR signal at 13.1 ppm is assigned to exchangeable salicylidene O–H, the 8.7 ppm singlet to the two imine protons, 7.5–6.8 ppm multiplets to the 12 aromatic protons, and a singlet at 6.35 to a methine proton. The appearance of an orange component in the initial product, the variety of melting points reported [16,17,27] and the differences between the NMR spectra in deuterated acetone versus methylene chloride (of poor quality due to low solubility) indicate the presence of tautomeric forms of this material. Very similar observations were made for the ethyl ester substituted H_2dsp ligand, for which either tautomer gave the same product upon complexation [28].

3.1. Zr(dshpm)$_2$

The shift in salicylidene ring-to-oxygen vibration frequency from 1276 to 1310 cm^{-1} upon Zr complexation is analogous to those seen for all H_2dsp-type ligands studied previously by us [25,26]. The essentially non-shifted band at 1288 cm^{-1} is assigned to the phenyoxy ring-to-oxygen vibration since coordination does not take place at this site (vide infra). Either of the bands at 1638 or 1604 cm^{-1} could be assigned to an imine vibration. However, the former is more the likely, given the increase in frequency upon complexation noted above. The absence of a peak near 13.1 ppm in the ^{1}H NMR spectrum of $Zr(dshpm)_2$ is expected, as the Zr displaces the salicylidene O–H protons of each ligand.

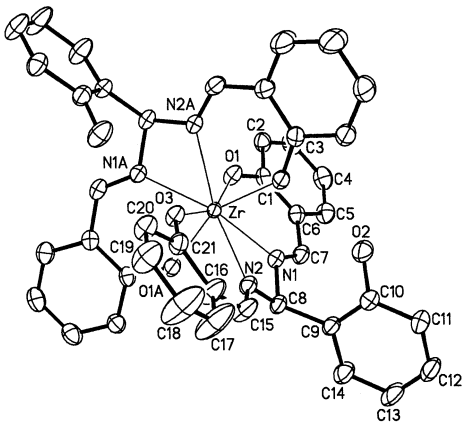

Fig. 2. Labeled thermal ellipsoid drawing for $Zr(dshpm)_2$.

The broad signal at 9.5 ppm, which integrates for a little less than two protons, is assigned to an exchangeable phenoxy proton on each ligand. The imine protons become nonequivalent upon complexation, giving singlets at 8.2 and 8.0 which each integrate for 2. The methine proton signal from each ligand occurs among the aromatic proton multiplets which extend from 7.6 to 6.5 ppm, the region integrating for 28 protons. The upfield shift upon Zr complexation, especially for the salicylidene protons *meta* to the oxygen, is comparable to those observed for all H_2dsp-type ligands studied by us [25,26]. The doublets at 7.0 and 6.8 ppm which have no apparent fine structure and integrate for one proton each, are most likely from the methine protons. If these assignments are accurate, as indicated by the 2-D COSY spectrum, then the salicylidene and/or phenyoxy rings must have different average positions in solution, e.g. an equilibrium could exist between coordinated phenoxy and salicylidene moieties, or, less likely, the short bite N–C–N moieties could span different edges in the coordination sphere in solution to create different methine proton environments.

Table 1
Selected bond lengths, bond angles, and coordination sphere parameters for $Zr(dshpm)_2$; see Fig. 2

Bond lengths (Å)					
Zr–O(1)	2.090(2)	O(1)–C(1)	1.323(5)	N(1)–C(7), imine	1.270(5)

[a] The deviation of C(8) from the N(1)–Zr–N(2) plane is away from the phenoxy group.
[b] Standard Hoard and Silverton symbolism [29]. The remaining dodecahedral edge lengths for $Zr(dshpm)_2$ are dictated by symmetry.

Results of X-ray crystallography on $Zr(dshpm)_2$ establish its solid state structure as eight-coordinate with a dodecahedral coordination sphere, point group $2/m$, and space group $C2/c$. A labeled thermal ellipsoid drawing is shown in Fig. 2. Important bond lengths, bond angles, and coordination sphere parameters are summarized in the Table 1. Comparisons with bis(*N*,*N*′-disalicylidene-1,2-phenylenediaminato)zirconium(IV), $Zr(dsp)_2$ [26] and bis(*N*,*N*′-disalicylidene-1,2-*trans*-diaminocyclohexanato)zirconium(IV), $Zr(trans\text{-}dsd)_2$ [25] which have fused 6,5,6-membered Schiff base ligands, reveal the following: While the mean Zr–O distances are approximately equal for each complex, the mean Zr–N distance for $Zr(dshpm)_2$ is approximately 0.010 Å shorter. Considering the ring strain normally associated with four-membered rings, poor bonding overlaps would justify longer bonds. In this case, the shorter bonds probably arise due to zirconium's preference for the oxygen atoms to be located in certain positions, the 'B' positions of a dodecahedron [29], which is consistent with theory for d^0 dodecahedral systems [30]. The imine bond is highly localized in $Zr(dshpm)_2$, as for the other complexes, and the methine-to-nitrogen bond lengths are ordinary. The O–Zr–O bond angles are larger for $Zr(dshpm)_2$ than for the other complexes, which indicates that the 6,4,6 ligands do not engulf the Zr as extensively. The N–Zr–N bond angle is the smallest for $Zr(dshpm)_2$, due to the limited reach of the methine diamine moiety versus those of the phenylenediamine and diaminocyclohexane moieties [25,26]. The above mentioned bond length and angle constraints produce a dodecahedron having the shortest N–N distance ('a edges'), and a Zr–N (ave.) to Zr–O (ave.) bond length ratio of 1.09. The latter is closer to the Hard Sphere Model (1.00) and Most Favorable Model (1.03) [29] than the other members of this series. The angle made between the trapezoidal O,N,N,O donor atom planes is 89.0° for $Zr(dshpm)_2$, which is comparable to those for $Zr(dsp)_2$ and $Zr(trans\text{-}dsd)_2$ [25,26]. The angle made between the phenoxy ring and the donor atom plane of the same ligand is 85.2°. The corresponding value for the other ligand is equivalent by symmetry.

In vitro tests conducted by the National Cancer Institute, Developmental Therapeutics Program (Sample and Test Identification NSC: 657558-U/0-1/38), indicated that this compound was inactive against nine cancers and HIV.

3.2. $Zr(3\text{-}Fdsp)_2$

The preparation of $Zr(3\text{-}Fdsp)_2$ was undertaken so that its spectral data could be compared with those of Zr(dshpm)(3-Fdsp) and Zr(ndsp)(3-Fdsp), see Reaction Scheme II and the final two legs of Reaction Scheme I (see Section 3). The method employed is well established [15,25,28]. The IR bands at 1615 and 1320 cm^{-1} are assigned to the imine and coordinated-oxygen-to-ring stretching vibrations, respectively [25,26], while the band at 1255 or 1240 cm^{-1} arises from a fluorine-to-ring stretching vibration. The absence of the proton NMR signal at 13.2 ppm, observed for the free ligand, is consistent with ligand coordination. The imine proton signals are virtually equivalent, and shifted upfield by approximately 0.15 ppm from that of the free ligand. Similar upfield shifts are observed in the $Zr(dsp)_2$ and $Zr(trans\text{-}dsd)_2$ systems [25,26]. Symmetrical multiplets at 7.5–7.4 ppm arise from the 1,2-phenylenediamine protons, as observed for $Zr(dsp)_2$ [26]. Nearly identical doublets at 7.1–7.0 arise from the salicylidene ring protons *para* to F and *meta* to O; less similar doublets at 6.9–6.7 arise from the salicylidene ring protons *ortho* to F and *meta* to O; and two distinct triplets at 6.5–6.4 arise from the salicylidene ring protons *meta* to F and *para* to O. Off diagonal features in the ROESY (with 400 ms mixing) and DQF COSY NMR experiments confirm these assignments and indicate interactions between the imine protons and aromatic protons of the phenylenediamine (α and β) and salicylidene (*para* to F) moieties.

3.3. Zr(dshpm)(3-Fdsp)

Method 2, the reaction of Zr butoxide and the free ligands in 1:1:1 mole ratio, has successfully been used to prepare heteroleptic complexes [15]. However, the yellow product obtained in this research was determined to be mostly $Zr(3\text{-}Fdsp)_2$, based on TLC and proton NMR analyses. Since the solubilities of $Zr(3\text{-}Fdsp)_2$ and the desired Zr(dshpm)(3-Fdsp) are very similar, recrystallization was precluded as an effective method of purification. Furthermore, since $Zr(dshpm)_2$ decomposes rapidly on a silica gel column (on the elution time scale) and is the fastest moving of the three Zr products, the Zr(dshpm)(3-Fdsp) band becomes contaminated. This precludes chromatography as a convenient method of purification. With purification proving to be difficult, Method 2 was deemed ineffective in this case.

While $Zr(3\text{-}Fdsp)_2$ withstood heating in d^6-DMSO up to 148 °C with no change in its TLC or proton NMR, $Zr(dshpm)_2$ was shown to undergo chemical change upon heating to only 40 °C. Heating a 1:1 mole ratio mixture of the two complexes, as per Method 3, resulted in labilization and decomposition of the H_3dshpm ligand at low temperature without any evidence of mixed ligand complex formation.

The relative success of Method 1 is, based upon stopping the addition of $H_2$3-Fdsp to $Zr(dshpm)_2$ as soon as $Zr(3\text{-}Fdsp)_2$ appears in the reaction solution's TLC. The approximately equal mixture of unreacted $Zr(dshpm)_2$ and Zr(dshpm)(3-Fdsp) which resulted

could be substantially purified due to the limited solubility of the former in absolute ethanol. However, despite repeated recrystallizations followed by a column separation, contamination of the desired product persisted, as reflected by the elemental analyses. The impurities, which are likely to arise from on-going labilization of Hdshpm(2-), probably contributed to our inability to grow a crystal suitable for X-ray crystallography. Fortunately, the composition of the new material could be established using IR and NMR spectroscopies, and by preparing chemical derivatives.

For the substantially purified product, infrared bands at 1641 and 1616 cm^{-1} are assigned as imine stretching vibrations arising from the Hdshpm(2-) and 3-Fdsp(2-) ligands, respectively, by analogy to the corresponding homoleptic complexes. The band at 1317 cm^{-1} and its shoulder are assigned as 'coordinated O-to-salicylidene ring' stretching vibrations for the two ligands. The band at 1238 cm^{-1} and/or its higher frequency shoulder are assigned as an aromatic ring-to-F vibration, analogous to that for $Zr(3\text{-}Fdsp)_2$. Thus, all IR assignments are consistent with the Zr(dshpm)(3-Fdsp) formulation.

While strong parallels between Zr(dshpm)(3-Fdsp) and the corresponding homoleptic complexes are readily apparent from the IR spectra of solid state samples, fewer parallels are evident from their solution ^1H NMR spectra. The absence of a signal around 13.2 ppm is consistent with the presence of coordinated ligands. Small singlets at 11.0 and 9.9 ppm match signals observed for salicylaldehyde, which is a likely decomposition by-product from the Hdshpm(2-) ligand. The broad signal at 9.0 ppm, which integrates for less than one proton, is assigned to an exchangeable phenoxy O–H and is consistent with the presence of one Hdshpm(2-) ligand. This chemical shift is 0.5 ppm upfield from the analogous signal for $Zr(dshpm)_2$, which, from examination of molecular models, could result from a nearby fluorine on the opposing 3-Fdsp(2-) ligand. The singlets at 8.5 and 8.4 ppm, which integrate for one proton each, are assigned to the imine protons of the 3-Fdsp(2-) ligand, protons which had been equivalent for $Zr(3\text{-}Fdsp)_2$ at 8.7 ppm. The singlet at 8.0 ppm, which integrates for two protons, is assigned to the imine protons of the Hdshpm(2-) ligand, protons which had been inequivalent for $Zr(dshpm)_2$ at 8.2 and 8.0 ppm. Signals in the 7.5–5.8 ppm range are assigned to the aromatic protons of the ligands. The upfield end of this range appears higher than observed for either of the homoleptic complexes, 6.4 ppm in both cases. The integration over this range, corresponding to approximately 29 protons, is higher than expected for 22 aromatic protons and one methine proton, and is consistent with the presence of some impurity, e.g. salicylaldehyde. We also note that the aromatic signals for Zr(dshpm)(3-Fdsp) appear poorly resolved in CD_2Cl_2, a poor H-bonding solvent, and appear strikingly different in d^6-DMSO, a good H-bonding solvent, while the imine proton signal at 8.0 ppm appears the same in each solvent. Furthermore, in the d^6-DMSO spectrum, the phenoxy O–H signal is a sharp singlet which integrates for one proton; the aromatic range extends down to 8.1 ppm; and, the integration of the aromatic region corresponds to 22.8 protons, which is much closer to the expected number of 23.

In addition to TLC evidence, rapid disproportionation of Zr(dshpm)(3-Fdsp) in solution to form a 1:1 mole ratio of homoleptic complexes was ruled out by observing the CD_2Cl_2 ^1H NMR spectrum of a mixture of separately prepared $Zr(3\text{-}Fdsp)_2$ and $Zr(dshpm)_2$. The spectrum showed all of the signals apparent in the spectra of the separate complexes with no perceptible shifts, i.e. with no sign of interaction.

The $^{19}F\{^1H\}$ NMR of the proposed Zr(dshpm)(3-Fdsp) product shows two proton decoupled signals, neither of which matches the ^{19}F signal from $Zr(3\text{-}Fdsp)_2$. The ^{19}F signal from a mixture of $Zr(3\text{-}Fdsp)_2$ and $Zr(dshpm)_2$ was identical with the latter. The coordinated Hdshpm(2-) ligand evidently imposes a different chemical environment on the two fluorines of the opposing 3-Fdsp(2-) ligand. $^1H\{^{19}F\}$ NMR (i.e. proton observe with decoupled ^{19}F using the above ^{19}F NMR frequencies) of the proposed Zr(dshpm)(3-Fdsp) product in CD_2Cl_2 solution indicates that each F atom couples with the nearest imine proton and nearest salicylidene protons (*ortho* and *meta*).

A plausible explanation for some of the observed NMR differences between Zr(dshpm)(3-Fdsp) and the corresponding homoleptic complexes is the presence of H bonding between the phenoxy O–H of Hdshpm(2-) and a fluorine atom on the opposing 3-Fdsp(2-). Such an interaction would render the ^{19}F NMR chemical shifts of the 3 Fdsp(2-) inequivalent. Since the above decoupling experiment established that each fluorine is coupled to the nearest imine proton, the different Zr(dshpm)(3-Fdsp) fluorine environments could explain the separate imine proton signals at 8.5 and 8.4 ppm. The imine protons for $Zr(3\text{-}Fdsp)_2$, where analogous H-bonding is not possible, gave a singlet at 8.5 ppm. However, alternate explanations for these observations, such as coordination sphere structure in solution and ligand puckering, cannot be ruled out.

3.4. Zr(ndsp)(3-Fdsp)

In light of the less-than-convincing elemental analysis for Zr(dshpm)(3-Fdsp), the inability to obtain a suitable single crystal, and the complexity of its NMR results, corroboration of its composition was sought using chemical means. In this case, the 6,4,6-chelating Hdshpm(2-) was replaced by the 6,5,6-chelating ndsp(2-). As expected, the proposed Zr(ndsp)(3-Fdsp) derivative

was demonstrated by NMR to be identical to the heteroleptic product from the 1:1:1 mole ratio reaction of H_2ndsp, $H_2$3-Fdsp, and $Zr(OBu^n)_4$. The latter had a satisfactory elemental analysis. Its NMR spectrum shows four proton signals in the imine proton region (8.6–8.3), attributed to the two imine protons and the two protons adjacent to the nitro group; the multiplet at 7.5–7.4 which integrates for five protons is attributed to the remaining phenylenediamine protons [four from 3-Fdsp(2-) and one from ndsp(2-), *meta* to the nitro group]; and the series of triplets and doublets over the 7.3–5.9 range, which each integrate for two protons each, are assigned to salicylidene ring protons, and correspond to the signals observed for the homoleptic complexes [31].

4. Conclusions

The title complex $Zr(dshpm)_2$ has been successfully prepared. Based on X-ray crystallographic results, it is mononuclear, and eight-coordinate in the solid state with a dodecahedral coordination sphere, as observed for other similar Schiff base Zr complexes [15,25,26]. The two quadridentate ligands employ O,N,N,O donor atoms to form 6,4,6-membered chelate rings, while the phenyoxy moieties are not coordinated. Although the coordination sphere dimensions of $Zr(dshpm)_2$ are closer to the Hard Sphere Model and the Most Favored Model [29] than previously studied 6,5,6- Schiff base Zr complexes [15,25,26], the change in chelate ring sizes resulted in a significantly more labile complex, as indicated by TLC, NMR of heated solutions, and chemical reactivity. The 0.010 Å shorter average Zr–N bond distance was not anticipated, and appears to result from the zirconium atom's preference that the oxygen atoms occupy certain locations.

Despite the respectable stability of the title complex in air, the decomposition of labilized ligands on silica gel and in heated solutions seriously detracts from its utility as a synthon. Complete purification of the two heteroleptic complexes prepared from it were not achieved. Zr complexes having more resilient 6,4,6-chelating ligands are expected to give more promising results.

5. Supplementary material

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Center, reference number CCDC 150144. Copies of this information can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Synthesis and spectral studies of binuclear ruthenium(II) carbonyl complexes containing bis(β-diketone) and their applications

R. Karvembu, K. Natarajan *

Department of Chemistry, Bharathiar University, Coimbatore 641-046, India

Received 5 February 2001; accepted 22 October 2001

Abstract

A series of new binuclear ruthenium(II) complexes of the type $\{[RuX(CO)(AsPh_3)_2]_2L\}$ (X = H or Cl; L = bis-β-diketone) have been synthesised by reacting $[RuHX(CO)(AsPh_3)_3]$ (X = H or Cl) with various bis(β-diketones) of the general formula [(RCO)(R′CO)CH–CH(R″)–CH(COR)(COR′)] (R = CH_3 or C_6H_5; R′ = CH_3 or C_6H_5; R″ = H, C_6H_5, 4-$(CH_3)C_6H_4$, 4-$(OCH_3)C_6H_4$ or 4-$N(CH_3)_2C_6H_4$) in 2:1 molar ratio in benzene. An octahedral structure has been tentatively proposed for all the new ligand bridged binuclear complexes. The new complexes have been subjected to the antibacterial and catalytic activity studies.

Keywords: Ruthenium(II); Binuclear; Bis(β-diketone); Triphenylarsine; Syntheses; Antibacterial activity; Catalytic study

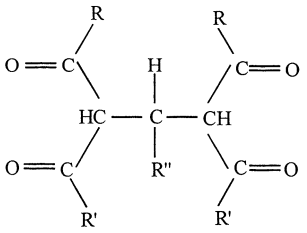
1. Introduction

Metal complexes of binucleating ligands are attractive as models for the coordination environments of metallobiomolecules. Binuclear complexes have also gained considerable interest in the recent past, because of their utility in promoting multi-electron redox reactions, in homogeneous catalysis as species capable of carrying out multi-step reactions, in photochemistry as sensitizers in energy transfer reactions and in magnetic exchange interactions.

Several bis(β-diketonato) bridged binuclear transition metal complexes are known [1–6] for its electrochemical and biological properties. Though many hydride, chloride and carbonyl complexes of ruthenium(II) containing bis(β-diketones) and tertiaryphosphine have been reported [7–11], analogues tertiaryarsine complexes are limited. In continuation of our systematic investigations on the ligand bridged binuclear ruthenium(II) and ruthenium(III) complexes [8–12], we report herein the synthesis, spectral, antibacterial and catalytic activity studies of bis(β-diketonato) bridged binuclear ruthenium(II) complexes containing triphenylarsine as one of the ligands. The general structure of the bis(β-diketone) ligands used in this study is shown in Fig. 1.

2. Experimental

2.1. Procedures and analyses



$RuCl_3 \cdot 3H_2O$ was purchased from Loba-Chemie and was used without further purification. Solvents were purified and dried according to standard procedure [13]. The starting compounds $[RuH_2(CO)(AsPh_3)_3]$ [14], $[RuHCl(CO)(AsPh_3)_3]$ [15] and bis(β-diketones) [16] were prepared by the literature methods.

C, H and N analysis were performed at the Central Salt and Marine Chemicals Research Institute, Bhavnagar. IR spectra of the complexes were recorded in KBr pellets with a Perkin–Elmer 597 infrared diffraction grating spectrophotometer in the range 4000–200 cm^{-1}. Electronic spectra were recorded in CH_2Cl_2 solution with a Systronics 119 spectrometer in the range of 800–200 nm. ^1H NMR spectra were recorded in Varian AMX 400 instrument using TMS as an internal standard. Melting points (m.p.) were recorded with a Boetius micro heating table and are uncorrected.

Fig. 1. Structure of the bis(β-diketones).

2.2. Synthesis of the complexes

To a solution of $[RuHX(CO)(AsPh_3)_3]$ (X = H or Cl) (0.1 g; 0.107–0.11 mmol) in benzene (25 cm^3), was added the appropriate bis(β-diketone) (0.015–0.032 g; 0.054–0.055 mmol) (molar ratio of ruthenium complex: bis(β-diketone) ligand was 2:1). The solution was heated under reflux for 6 h. Then, the solution was concentrated to a small volume (3 cm^3) and the new complex was separated from it by the addition of a small quantity (6 cm^3) of petroleum ether (60–80 °C). The product was filtered, washed with petroleum ether and recrystallized from CH_2Cl_2–petroleum ether (60–80 °C) mixture and dried in vacuo. Yield: 71–78%.

2.3. Antibacterial activity studies

Three pathogenic microbials were used to test the biological potential of the bis(β-diketones) and their ruthenium(II) complexes. They were (i) *Bacillus* sp. (ii) *Escherichia coli* and (iii) *Pseudomonas* sp.

The antibacterial activity of the compounds was determined by disc diffusion method [17]. The bacteria were cultured in nutrient agar medium and used as inoculam for the study. Bacterial cells were swabbed on to nutrient agar medium (prepared from NaCl 5.0 g, peptone 5.0 g, beef extract powder 3.0 g, yeast extract powder 3.0 g, agar 20.0 g in 100 cm^3 distilled H_2O; pH 7.5 ± 0.2) in Petri plates. The compounds to be tested were dissolved in DMF to a final concentration of 0.25 and 0.5% and soaked in filter paper discs (whatmann No. 4, 5 mm diameter). These discs were placed on the already seeded plates and incubated at 35 ± 2 °C for 24 h. The zones of inhibition around the discs were measured after 24 h. Streptomycin was used as a standard (Table 1).

2.4. Catalytic studies

The catalytic activity of ruthenium(II) complexes in aerial oxidation of benzaldehyde was followed spectrophotometrically by monitoring the increase in the benzoic acid absorbance as a function of time. A CH_2Cl_2 solution of the ruthenium(II) complex (2 cm^3, 1×10^{-4} M) and 2 cm^3 of 1×10^{-3} M freshly distilled benzaldehyde in CH_2Cl_2 were mixed in a 1 cm quartz cell at room temperature (r.t.; 26 °C) and the absorbance change at 279 nm was recorded.

3. Results and discussion

Bis(β-diketones) react with $[RuHX(CO)(AsPh_3)_3]$ (X = H or Cl) in 1:2 molar ratio in benzene to afford stable chelated diruthenium complexes as indicated below.

$$2[RuHX(CO)(AsPh_3)_3] + [(RCO)(R'CO)CH{-}CH(R'')-CH(COR)(COR')](H_2L) \xrightarrow[\text{Reflux, 6 h}]{\text{Benzene}} \{[RuX(CO)(AsPh_3)_2]_2L\} + 2AsPh_3 + 2H_2 \quad (X = H \text{ or } Cl)$$

The new complexes are soluble in most of the common organic solvents. Molecular weight determination (Rast method) and elemental analysis data confirm the complexes to be binuclear.

3.1. ^{1}H NMR spectra

The NMR spectral data of the complexes are presented in Table 2. The presence of a sharp singlet at 3.04–3.6 ppm in the spectra of all the complexes is assigned as due to the methine proton. The multiplet observed in the region 6.1–7.9 ppm has assigned to the protons of the phenyl groups present in triphenylarsine and bis(β-diketone). In all the hydrido complexes, the metal hydride signal corresponding to two protons has been detected in the very high upfield region (-12.0 to -20.14 ppm), suggesting the identical environment around the hydride ligand in both the metal centers. In addition to the above signals, the resonances corresponding to CH_3, OCH_3, CH_2 and $N(CH_3)_2$ were also observed in the expected region (Table 2). The above spectral observations are in good agreement with the values reported for similar bis(β-diketonato) bridged binuclear ruthenium phosphine complexes [7,11].

3.2. IR spectra

The IR spectra of all the new complexes show two to three bands in the region 1480–1600 cm^{-1}, which are characteristic of the mixed modes of vibrations arising due to the normal coordinates having contribution from ν(C=O) and ν(C=C) of the coordinated β-diketone groups [18]. This coordination is further confirmed by the absence of a band at about 1700 cm^{-1} due to free carbonyl group of bis(β-diketone) ligand. The strong absorption around 1950 cm^{-1} has been assigned to the coordinated terminal carbonyl group [11]. In hydrido complexes, the ν(Ru–H) appeared in the region 2010/2020 cm^{-1} [11] and in chloride complexes ν(Ru–Cl) absorption has been found in the 310–320 cm^{-1} region [19]. Characteristic bands of $AsPh_3$ [20] are observed in the spectra of all the complexes at 1440, 1080, 740 and 680 cm^{-1}. Thus, the IR data reveal the dibasic tetradentate behavior of bis(β-diketone) moiety in all the new complexes.

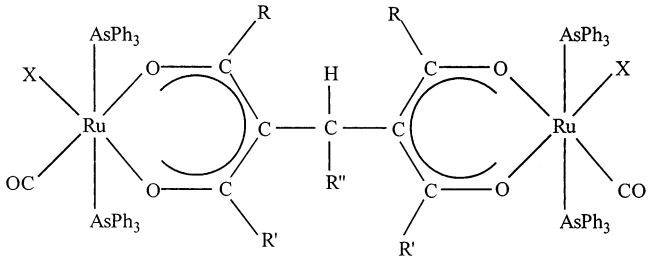

Fig. 2. Proposed structure of the Ru(II) complexes (where R, R′, R″ and X groups are as previously described).

3.3. Electronic spectra

All the new ruthenium complexes are diamagnetic, indicating the presence of ruthenium in the +2 oxidation state. The ground state of ruthenium(II) is $^1A_{1g}$ arising from the t_{2g}^6 configuration in an octahedral environment. The excited states corresponding to the $t_{2g}^5 e_g^1$ configuration are $^3T_{1g}$, $^3T_{2g,}$ $^1T_{1g}$ and $^1T_{2g}$. Hence, four bands corresponding to the transitions $^1A_{1g} \rightarrow {}^3T_{1g}$, $^1A_{1g} \rightarrow {}^3T_{2g}$, $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ are possible in the order of increasing energy.

The electronic spectra of all the complexes in CH_2Cl_2 displayed three bands in the region 220–270 nm. On the basis of high extinction coefficients ($\varepsilon = 15\,255$–$24\,360$ dm^3 mol^{-1} cm^{-1}), these bands have been assigned to charge transfer transitions arising from excitation of an electron from the metal t_{2g} level to an unfilled molecular orbital derived from the π* level of the ligands [21]. Similar assignments have been made for other octahedral ruthenium(II) complexes [22].

Thus, on the basis of elemental analysis, IR, electronic and ^{1}H NMR spectral data, the following octahedral structure has been tentatively proposed for the new binuclear ruthenium(II) complexes. The *trans* positions for the $AsPh_3$ groups have been assigned on the basis of the structures proposed for similar Ru(II) and Ru(III) phosphine complexes [7,27] (Fig. 2).

3.4. Antibacterial activity

Ligands H_2L1, H_2L2, H_2L4 and H_2L5 and their ruthenium(II) complexes yielded clear inhibition zones around the discs when treated against *Bacillus* sp. and *E. Coli* which clearly indicates the activity of the compounds. But all the compounds except {[RuCl(CO)-$(AsPh_3)_2]_2$L2} are inactive against *Pseudomonas* sp. From the results, it is concluded that the complexes possess more toxicity than their parent ligand and the toxicity increases with increase in concentration of the test solution containing new complexes. Though the complexes possess activity, it could not reach the effectiveness of the standard drug, Streptomycin. The variation in the effectiveness of different compounds against different organisms depends either on the impermeability of the cells of the microbes or differences in ribosomes of microbial cells [23] (Table 3).

3.5. Catalytic activity

The catalytic activities of {[RuH(CO)$(AsPh_3)_2]_2$L1}, {[RuCl(CO)$(AsPh_3)_2]_2$L1}, {[RuH(CO)$(AsPh_3)_2]_2$L2}, {[RuH(CO)$(AsPh_3)_2]_2$L6} and {[RuCl(CO)$(AsPh_3)_2]_2$-L6} were investigated for aerial oxidation of benzaldehyde to benzoic acid.

The course of the reaction was followed spectrophotometrically by monitoring the increase in benzoic acid absorbance at 279 nm as a function of time. Plots of the absorbance versus time are linear. The slope of the line is equal to the reaction rate constant [24], K, and the observed K values are given in Table 4. There is no

Table 4
Catalytic activity for selected complexes

Compound	K (M^{-1} s^{-1})
{[RuH(CO)($AsPh_3$)$_2$]$_2$L1}	2.103×10^{-3}
{[RuCl(CO)($AsPh_3$)$_2$]$_2$L1}	1.022×10^{-3}
{[RuH(CO)($AsPh_3$)$_2$]$_2$L2}	3.867×10^{-4}
{[RuH(CO)($AsPh_3$)$_2$]$_2$L6}	4.290×10^{-4}
{[RuCl(CO)($AsPh_3$)$_2$]$_2$L6}	5.210×10^{-5}

change in absorbance at 279 nm in the absence of complex, indicating the catalytic activity of the new complexes. The catalytic activity is found to decrease with an increase in size [25] of the X and R″ group. This may be due to the possibility of steric effect which hinders the formation of activated complex and thus reduces the rate of oxidation [26]. There is no appreciable change in rate constant with respect to R and R, moieties.

Linear coordination of Hg(II) by cysteamine

Chong-Hyeak Kim, Sean Parkin, Mohan Bharara, David Atwood *

Department of Chemistry, University of Kentucky, Lexington, KY 40506-0055, USA

Received 4 June 2001; accepted 22 October 2001

Abstract

Combination of the hydrochloride salt of cysteamine (**1**) with $HgCl_2$ in water affords the unique compound, $[Hg\{S(CH_2)_2NH_3\}_2](Cl)_2$ (**2**) in which the S–Hg–S angle is nearly linear. The ammonium portion of the molecule forms short hydrogen bonding contacts with the sulfur atoms. A related S···H bond is observed in the structure of the free ligand **1** indicating that such bonding does not require the presence of a metal. The compounds were characterized with spectroscopic (^1H NMR, IR) and physical techniques (Mp, CH-analysis) as well as X-ray diffractometry. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Cysteamine; Cysteine; Sulfur; Hydrogen bonding

1. Introduction

The affinity of the amino acid cysteine for soft heavy metals is exploited in many metal binding proteins. For example, cysteine is found in the binding sites of the mercury metalloregulatory proteins, MerR [1] and MerP [2]. Due to the abundance and importance of cysteine in biological systems a great deal of research has been conducted to understand how the amino acid interacts with metals [3].

By comparison, the chemistry of cysteamine ($HS(CH_2)_2NH_2$), having the same sulfur-containing unit as cysteine, has not been examined in as much depth. This is despite the fact that cysteamine is a fairly common medicinal agent. It is approved by the US Food and Drug Administration for the treatment of the painful disease, cystinosis where its effect is to break up excess intracellular cysteine as a soluble cysteine–cysteamine complex that can be subsequently excreted [4]. It is also one of the best radioprotective agents [5].

Recently, a small-molecule model of the binding site for MerP has been prepared which incorporates two cysteamine units. The ligand, benzene (or pyridine) diaminoethanethiol (BDET) irreversibly binds mercury (and other metals) from aqueous sources, is totally insoluble, and does not release the bound metal under harsh conditions [6]. The nature of the interaction between free cysteamine and mercury has not yet been established and so little can be inferred about the remarkable stability of the BDET–Hg complex. The purpose of the work presented herein is to obtain some insight into the BDET–Hg interaction.

$[Hg\{S(CH_2)_2NH_3\}_2](Cl)_2$ (**2**), is prepared by combining cysteamine-hydrochloride (**1**) with $HgCl_2$ in

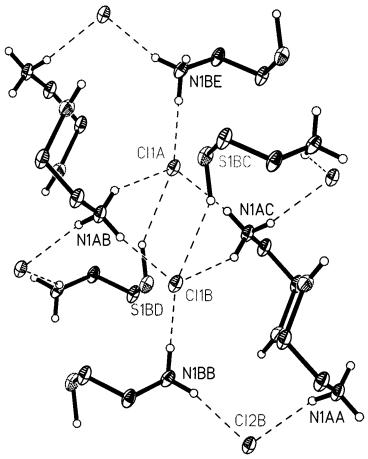

Fig. 3. ORTEP view of $[SHCH_2CH_2NH_3]Cl$ (**1**). Selected bond distances (Å) and angles (°): S(1)–H(1) 1.248, S(1)–C(1) 1.814(5), C(1)–C(2) 1.525(7), C(2)–N(1) 1.486(6); S(1)–C(1)–C(2) 114.4(4), C(1)–C(2)–N(1) 112.4(4).

water. After cooling for 2 weeks at 4 °C colorless X-ray quality crystals form in near quantitative yield. In the structure the Hg atom is coordinated to two sulfurs in a nearly linear fashion (168.53(3)°) and there are no secondary contacts to the mercury atom (Fig. 1). The structure is unique in that other related compounds feature either bridging and/or chelating cysteamine units [7]. For instance, the structures of soft metals bound by cysteamine and related molecules feature predominantly bidentate S-N coordination [8,9]. When employing cysteamine hydrochloride metals such as Cu [10] and Ag [11] form clusters with bridging (μ_2, μ_3 and μ_4) sulfur atoms. The only exception, and closest precedent to (**2**) is a rhenium-oxo compound which is coordinated by a single μ_1, cysteamine [12].

In general, structurally characterized molecules possessing a linear S–Hg–S geometry are rare [13]. This unit is observed in the cysteine compound, $Hg\{SCH_2CH(NH_3)COO\}$ $\{SCH_2CH(NH_3)COOH\}Cl{\cdot}0.5$ H_2O (**3**) (S–Hg–S = 170°) [14], and in $Hg\{SCN)_2$–Rb(SCN) (S–Hg–S = 154) [15]. The groups in $[MeHgSCMe_2CH(NH_3)](CO_2^-)$ (**4**) are also linear (C–Hg–S = 178°, Hg–S = 2.35 (**1**) Å) [16]. Most other Hg compounds that are linear have close secondary contacts [17,18]. This is true, for example, in $Hg\{SSi(O^tBu)_3\}_2$ (S–Hg–S = 180°, Hg–O ~ 2.8 Å) [19] and $Hg[(SPh)(OAc)]_2$ (S–Hg–S = 162°, Hg–O ~ 2.4–2.9 Å) [20]. Remarkably, the Hg–S distances in all of these compounds, including **2** are essentially the same at ~2.4 Å.

A unique feature that has been identified in **2**, in contrast to other synthetic mercury thiolates, is the presence of short S···H contacts (Fig. 2) [21]. The S···N distance is 3.26 Å (between S2A and N1D) implying a short hydrogen bond distance of ~2.2 Å (with the N–H fixed at 0.920 Å). This type of contact, although rare, has been found to be important in the structures of ferredoxins [22]. The common feature for **2** and the ferredoxins is the fact that the hydrogen bonding occurs in conjunction with the sulfur (either cysteamine for **2** or cysteine for the ferredoxin models) bound to the metal. It is possible that such a contact exists in MerP but the known structures are not of sufficient resolution to determine this.

In order to explore whether sulfur–hydrogen bond contacts are unique to the structure of **2** and possibly require a metal to be present, the structure of **1** was determined (Fig. 3). Hydrogen bonding is, indeed, observed for **1**, but between the S–H and a chloride. The S1BD···Cl1A distance is 3.78 Å implying a hydrogen bond contact of 2.75 Å (with an S–H distance of 1.25 Å (the hydrogens were found as peaks in the Fourier Difference map and then fixed in place)). The ammonium groups are hydrogen bonded to the chlorides (2.3–2.8 Å) but not to the sulfurs as in **2**. Clearly, chloride is the organizing force for the hydrogen bonding contacts in **1**.

2. Conclusion

With a linear S–Hg–S unit and S···H hydrogen bonding compound **2** may be viewed as a potential soluble model of the binding site of MerP in which two cysteine units coordinate a mercury atom in a linear manner [4]. It is possible that this is also occurring in the BDET–Hg complex [6]. Additionally, there is growing evidence that hydrogen bonding may be common in metal thiolate compounds. Compound **2** is the first mercury thiolate to demonstrate such bonding.

3. Experimental

3.1. General considerations

NMR data were obtained on JEOL-GSX-400 and -270 instruments operating at 270.17 and 399.78 MHz

and are reported relative to $SiMe_4$ and are in ppm. Elemental analyses were obtained on a Perkin–Elmer 2400 Analyzer. IR data were recorded as KBr pellets on a Matheson Instruments 2020 Galaxy Series spectrometer and are reported in cm^{-1}. X-ray data for **1** and **2** were collected on a Nonius Kappa-CCD unit using Mo Kα radiation. The structures were refined using the Siemens software package SHELXTL 4.0. All of the non-hydrogen atoms were refined anisotropically. The hydrogen atoms were put into calculated positions. Absorption corrections were not employed. Further details of the structure analyses are given in Table 1.

Isolation of $(SHCH_2CH_2NH_3)Cl$ (**1**): cysteamine hydrochloride (0.57 g, 5 mmol) was dissolved in hot 1-$C_4H_{10}O$ (15 ml) and filtered. The solution was allowed to stand for 2 weeks at 4 °C during which time colorless crystals formed in quantitative yield. Other alcohols, such as iso-C_3H_8O and *n*-C_3H_8O could be employed in a similar manner. Yield: 0.40 g (70%); m.p. 64–66 °C. ^1H NMR (D_2O, 200 MHz): δ 2.83 (t, 2H, CH_2N), 3.21 (t, 2H, CH_2S), 4.80 (s, residual water in the D_2O, HS, NH). IR (KBr; ν cm^{-1}): 3410w, 2955s, 2718w, 2660w, 2558w, 2504w, 1598s, 1499s, 1444m, 1423m, 1379s, 1321m, 1279m, 1244m, 1130s, 1079s, 1041s, 979m, 898s, 858s, 787w, 660w, 455m. *Anal.* Calc. for C_2H_8ClNS: C, 21.14; H, 7.10; N, 12.33; S, 28.22. Found: C, 21.33; H, 7.25; N, 12.19; S, 28.47%.

Preparation of $[Hg(SCH_2CH_2NH_3)_2](Cl)_2$ (**2**): to a stirring solution of cysteamine hydrochloride (1.14 g, 10 mmol) in deionized water (15 ml) was added mercury(II) chloride (1.36 g, 5 mmol). The resulting solution was allowed to stand for 2 weeks at 4 °C during which colorless crystals formed in near quantitative yield. Yield: 1.72 g (81%); m.p. 218–220 °C (dec.). ^1H NMR (D_2O, 400 MHz): δ 3.23 (m, 4H, CH_2N), 3.27 (m, 4H, CH_2S), 4.80 (br s, residual water in the D_2O and NH). ^{13}C NMR (D_2O, 100 MHz): δ 25.2 (CH_2S), 43.3 (CH_2N). IR (KBr; ν cm^{-1}): 3445w, 2991s, 2904s, 2720w, 2606w, 2532w, 2410w, 1604s, 1566s, 1491s, 1477s, 1420w, 1405m, 1366w, 1315m, 1264s, 1249m, 1134m, 1094m, 1077m, 1034m, 1015w, 933s, 882m, 802w, 787m, 724w, 653w, 453w. *Anal.* Calc. for $C_4H_{14}Cl_2HgN_2S_2$: C, 11.28; H, 3.32; N, 6.58; S, 15.06. Found: C, 11.39; H, 3.25; N, 6.70; S, 14.98%.

4. Conclusion

The presence of S···H contacts in **1** and **2** suggests that the thiol and sulfide form of the MerP protein are capable of hydrogen bonding. This hydrogen bonding is well-known in iron sulfide containing proteins but not established for either the MerP or MerR proteins. This may be due, in part, to the relative paucity of information on the later two proteins. Out of the synthetic mercury-sulfides known, including **3** and **4**, none are reported to have S···H contacts. Thus, compound **2** is unique in this regard.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 15748 and 157479 for compounds **1** and **2** which includes full tables of bond lengths and angles, full atom-labeled ORTEP views, unit cell views and observed and calculated structure factor tables are available upon request. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 8 August 2001; accepted 31 October 2001

Abstract

A systematic investigation of the reactions between metal ions and dipeptides containing the α-aminoisobutyric residue (Aib) was initiated. The solid complexes $[Cu(H_{-1}L)]_n$ (**1**, **2**) and $(LH_2)_n[CuCl_3]_n$ (**3**) were isolated and characterized by single-crystal X-ray crystallography, solid-state IR spectra and UV–Vis spectroscopy in solution ($H_{-1}L^{2-}$ is the dianionic form of H–Aib–Aib–OH). Of remarkable interest is the isolation of two complexes which have the same chemical formula, $[Cu(H_{-1}L)]_n$, but different structures. Complex **1** is a chain (1D) compound, while complex **2** is a 3D coordination polymer. The doubly deprotonated dipeptide behaves as a N(amino), N(peptide), O(carboxylate), O′(carboxylate) $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ ligand in **1**. In **2** the $H_{-1}L^{2-}$ ligand binds to one Cu^{II} atom at its amino and peptide nitrogens and at one carboxylate oxygen, and to a second metal at the other carboxylate oxygen, while a third Cu^{II} atom is attached to the peptide oxygen. The structure of **3** consists of zigzag $(CuCl_3)_n^{n-}$ chains and protonated dipeptides (H_2L^+) which remain uncoordinated. Two neighbouring Cu^{II} atoms are bridged by two chloro ligands, while a terminal chloro ligand completes five coordination at each metal center. The IR data are discussed in terms of the nature of bonding and known structures. The UV–Vis spectra show that the solid-state structures of **1** and **2** do not persist in H_2O. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

The interaction of metal ions with small peptides has been a subject of increasing interest over the past three decades [1–3]. Among many reasons for the development of this area are: (a) many of these reactions provide simple models for much more complex biochemical reactions and processes of great importance, e.g. the investigation of the action of metalloenzymes or the storage and transport of trace metal ions through the human body [4,5]; (b) the mode of coordination has a major influence on the conformation of a peptide molecule, a fact that influences its reactivity and ability to interact with receptor sites. Hence, complex formation can have a significant influence on the biological activity of peptides and the metal ions can be regarded as catalysts for many reactions involving peptides [6,7]; and (c) the possibility that such metal complexes possess pharmacological activity [8].

We have recently initiated a systematic study of the coordination chemistry of dipeptides and tripeptides containing the α-aminoisobutyric residue [–HNC-$(CH_3)_2$CO–, Aib]. The occurrence of high proportions of Aib in microbial polypeptide antibiotics and the unusual ion conductance of membranes and artifi-

cial bilayers composed of these peptides [9,10] have stimulated studies concerning the effect of Aib unit on the conformations available to small peptides in solution and in the solid state. Theoretical and ^{1}H NMR investigations have shown that dimethyl alkylation of the α-carbon sterically restricts the conformational freedom of peptides containing the Aib unit [11–13]. The crystal structure of several peptides containing Aib residues show that a 3_{10}- or a-helical conformation is favoured [14–16]. Despite the special properties of Aib, there is a limited number of reports concerning the coordination chemistry of Aib-based small peptides [17–21].

Our interest in this chemistry is fourfold: (i) to redress the almost complete lack of structurally characterized metal complexes with Aib-containing peptides as ligands. To the best of our knowledge, only the X-ray crystal structure of the remarkable copper(III) complex $[Cu^{III}(H_{-2}Aib_3)]\cdot 2H_2O\cdot 1.5NaClO_4$, containing the trianion of tri-α-amino-isobutyric acid as ligand, has been determined [18]. We are particularly interested in investigating how the inductive and steric properties of α-carbon methyl groups affect the structures of the complexes in the solid state and their ability to bind metals of various sizes and oxidation states. We plan to use ligands which will introduce several coordination possibilities and a variety of steric and electronic effects. (ii) To compare the solid-state and solution structures of the peptide complexes using the appropriate physical and spectroscopic techniques. (iii) To investigate the possibility of creating helical complexes (helicates) and/or one-dimensional (1D), two-dimensional (2D) and three-dimensional (3D) coordination polymers. The unique steric properties of Aib and the variety of donor sites present in peptides containing Aib would favour the formation of such complexes. Syntheses of helicates containing two or more metal ions have attracted considerable attention in recent years as examples of self-assembly reactions [22]. Transition metals coordination polymers are of great interest as magnetic, electronic and photooptical materials [23]. (iv) To test the pharmacological activity, e.g. the antitumour activity of tin(IV) complexes [8], the antiinflammatory properties of copper(II) complexes [24,25], etc. of selective peptide complexes.

We wish to report here the initial results of our studies concerning the products from the reaction between copper(II) salts and the α-aminoisobutyryl-α-aminoisobutyric acid, H–Aib–Aib–OH (LH, **I**). Emphasis is given on the characterization of the products in the solid state.

LH, I

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received.

Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Service using an EA 1108 Carlo Erba analyzer. Copper analysis was carried out by EDTA titration. M.p.s were taken on a Buchi SMP-20 capillary m.p. apparatus and are uncorrected. IR spectra (4000–500 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT spectrometer and a Jasco FT-IR 5300 spectrometer with samples prepared as KBr pellets. Solution electronic spectra (800–250 nm) were recorded on a Pharmacia-Biochrom 4060 instrument using H_2O as solvent.

2.2. Compound preparation

2.2.1. H–Aib–Aib–OH

The protected aminoacids Z–Aib–OH and *p*-TsA–Aib–OBzl were prepared according to the literature [26]. Coupling of Z–Aib–OH (0.71 g, 3 mmol) with 1.20 g (3.3. mmol) of *p*-TsA–Aib–Obzl via the PyBOP procedure [27], provided 1.05 g (85%) of Z–Aib–Aib–OBzl; m.p. 122–125 °C (recrystallized from EtOAc–petroleum ether); $R_f = 0.72$ in CH_2Cl_2–MeOH (9:1 v/v); $R_f = 0.68$ in EtOAc. The protecting groups were removed by catalytic hydrogenolysis (10% Pd on charcoal) in methanol. After 3 h the catalyst was filtered off and the solvent evaporated in vacuo. Complete removal was ensured by the addition of a few milliliters of methanol and repetition of the evaporation. The free dipeptide crystallized upon addition of AcOEt–petroleum ether. The product was further purified by column chromatography on Sephadex G-10 using AcOH (5%) as the eluant. Yield: 0.40 g (85%). $R_f = 0.53$ in *n*-BuOH:MeCOOH:Py:H_2O (4:1:1:2 v/v); m.p. 101–102 °C.

2.2.2. $[Cu(H_{-1}L)]_n$ (1)

A solution of LH (0.05 g, 0.26 mmol) in MeOH (3 ml) was added to a stirred green solution of $CuCl_2\cdot 2H_2O$ (0.02 g, 0.12 mmol) in the same solvent (8 ml). The color of the solution was immediately changed to pale blue. The pH of the solution was adjusted to ~6 with aqueous 0.1 N NaOH. The resultant dark blue solution was left for slow evaporation at room temperature. The blue residue obtained dissolved in 2 ml of a mixture

EtOH:Et_2O (50:50 v/v) and was left to a closed test tube. After 4 days, blue crystals suitable for X-ray crystallography formed; these were collected by filtration and dried in vacuo over P_4O_{10}. Yield: 34%. *Anal.* Found: C, 38.9; H, 5.6; Cu, 24.6; N, 11.0. Calc. for $C_8H_{14}O_3N_2Cu$: C, 38.5; H, 5.6; Cu, 25.4; N, 11.2%.

2.2.3. $[Cu(H_{-1}L)]_n$ (2)

LH (0.05 g, 0.26 mmol) was added to a blue solution of $[Cu_2(O_2CMe)_4(H_2O)_2]$ (0.06 g, 0.15 mmol) in H_2O (6 ml). The solid soon dissolved and EtOH (6 ml) was added to the solution. Upon slow evaporation at room temperature (r.t.), blue crystals of the product were precipitated, collected by filtration and dried in vacuo. Some of them were suitable for crystallographic studies. Yield: 37%. *Anal.* Found: C, 38.3; H, 5.5; Cu, 24.2; N, 11.0. Calc. for $C_8H_{14}O_3N_2Cu$: C, 38.5; H, 5.6; Cu, 25.4; N, 11.2%.

2.2.4. $(LH_2)_n)[CuCl_3]_n$ (3)

A solution of LH (0.02 g, 0.11 mmol) in MeOH (6 ml) was added to a stirred green solution of $CuCl_2{\cdot}2H_2O$ (0.02 g, 0.12 mmol) in the same solvent (2 ml). The pH of the resulting solution obtained was lowered to ~ 2 with aqueous 0.1 N HCl and this was left for slow evaporation at r.t. After complete evaporation, a yellow solid was obtained which was dissolved in EtOH (5 ml). Brown crystals suitable for crystallographic studies were obtained from the ethanolic solution by vapour diffusion with Et_2O. Yield: 46%. *Anal.* Found: C, 26.5; H, 4.7; Cu, 16.6; N, 7.5. Calc. for $C_8H_{17}O_3N_2Cl_3Cu$: C, 26.7; H, 4.8; Cu, 17.7; N, 7.8%.

2.3. X-ray crystallographic studies

Crystals of complexes **1**, **2** and **3** were mounted in air. Diffraction measurements were made on a Crystal Logic Dual goniometer diffractometer using graphite-monochromated Mo radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined using the angular settings of 25 automatically centred reflections in the range $11 < 2\theta < 23°$. Three standard reflections, monitored every 97

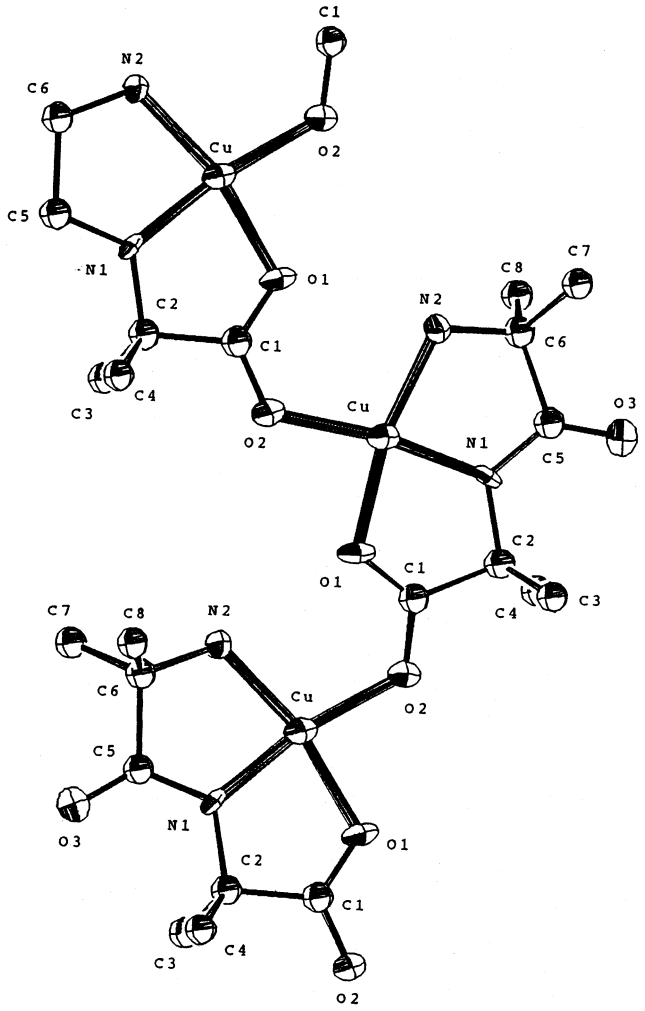

Fig. 1. A portion of one chain of complex **1** showing three metal centers.

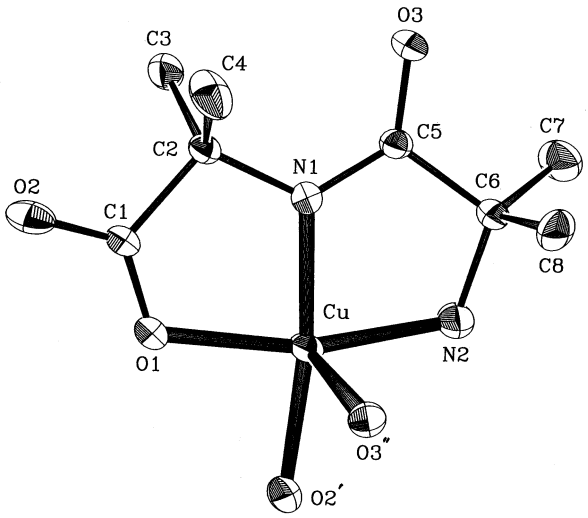

Fig. 2. Details of the structural unit in the 3D coordination polymer **2**. Atoms O(2′) and O(3″) are carboxylate and peptide oxygens, respectively, from two different neighbouring $H_{-1}L^{2-}$ ligands.

reflections, showed less than 3% intensity fluctuation and no decay. Lorenz polarization and Ψ-scan absorption corrections were applied using Crystal Logic software.

The structures were solved by direct methods using SHELXS-86 [28] and refined by full-matrix least-squares techniques on F^2 with SHELXL-93 [29]. For **2** and **3**, all hydrogen atoms were clearly visible in subsequent difference Fourier maps and refined with isotropic thermal parameters; in **1**, all hydrogen atoms were introduced at calculated positions as riding on bonded atoms. For all structures, all non-hydrogen atoms were refined using anisotropic thermal parameters.

3. Results and discussion

3.1. Syntheses

The case of blue complexes **1** and **2** is very interesting and as far as we are aware unique in metal–peptide chemistry. The two complexes have the same chemical formula, $[Cu(H_{-1}L)]_n$, but different structures. Complex **1** is a chain compound (1D) and complex **2** is a three-dimensional (3D) coordination polymer. Different inorganic starting materials were used for the preparation of the two complexes; $CuCl_2{\cdot}2H_2O$ for **1** and $[Cu_2(O_2CMe)_4(H_2O)_2]$ for **2**. Both reactions took place at pH ~ 6 in aqueous alcoholic media. The LH:Cu^{II} reaction ratio has no influence on the stoichiometry of the products. For example, complex **1** can be isolated using either a 2:1 or an 1:1 LH:$CuCl_2{\cdot}2H_2O$ ratio. The preparation of **1** and **2** is summarized in Eqs. (1) and (2), respectively.

$$n\,CuCl_2{\cdot}2H_2O + n\,LH + 2n\,NaOH \xrightarrow{MeOH/H_2O} \underset{\mathbf{1}}{[Cu(H_{-1}L)]_n} + 2n\,NaCl + 4n\,H_2O \quad (1)$$

$$[Cu_2(O_2CMe)_4(H_2O)_2] + 2n\,LH \xrightarrow{H_2O/EtOH} \underset{\mathbf{2}}{2[Cu(H_{-1}L)]_n} + 4n\,MeCO_2H + 2n\,H_2O \quad (2)$$

We believe that the solvent mixture used is the critical factor for the different structural identity of the two products.

The 1:1 reaction between $CuCl_2{\cdot}2H_2O$ and LH in $MeOH/H_2O$ under acidic conditions (pH ~ 2) yielded the ionic polymer **3**, in which the dipeptide is in its cationic form (LH_2^+) acting as a counter-ion (Eq. (3)).

$$n\,CuCl_2{\cdot}2H_2O + n\,LH + n\,HCl \xrightarrow{MeOH/H_2O} \underset{\mathbf{3}}{(LH_2)_n[CuCl_3]_n} + 2n\,H_2O \quad (3)$$

Despite our efforts, no copper(II) complexes containing the monoanionic (L^-) and neutral (LH) forms of the dipeptide could be obtained at intermediate acidity ($2 < pH < 6$) conditions.

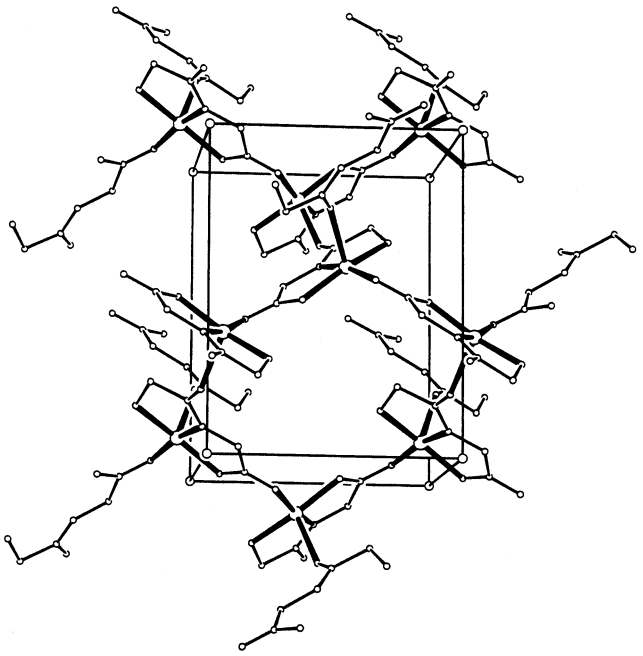

Fig. 3. A crystal packing diagram of complex **2**; the weak intermolecular hydrogen bond is not shown.

3.2. Description of structures

The structures of complexes **1**, **2** and **3** are shown in Figs. 1, 2 and 4, respectively. A crystal packing diagram of **2** is present in Fig. 3. The important metric parameters are listed in Tables 2–4.

The crystal structure of **1** consists of isolated 'flat' helical chains along the *c* axis. The helical chain develops along a twofold screw axis. The metal ion is chelated by the terminal amino [N(2)] nitrogen, the deprotonated peptide [N(1)] nitrogen and one of the carboxylate oxygens [O(1)] of the ligand. The fourth coordination site is occupied by a carboxylate oxygen [O(2)] of a neighbouring dipeptide dianion. The carboxylate bridging interaction with two neighbouring metal ions is of the *syn*, *anti* type. Thus, $H_{-1}L^{2-}$ behaves as $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ ligand or in a $[2{\cdot}1_1 1_2 1_1 1_1]$ mode (as described using 'Harris' notation [30]). According to the latter, the binding mode of a ligand is referred to as $[X{\cdot}Y_1 Y_2 Y_3 \ldots Y_n]$, where X is the overall number of metals bound by the whole ligand and each value of Y refers to the number of metal atoms attached to the different donor atoms. The ordering of Y

is listed by the Cahn–Ingold–Prelog priority rules, hence here O before N. In the case of chelating/bridging ligands, to distinguish between several alternatives, a subscript number is included to show to which metal ion the donor is attached.

A moderate distortion in the square planar environment of Cu^{II} is indicated by the observed *cis* bond angles which vary from 83.1(1) to 105.5(2)°. The deviation of the Cu^{II} atom from the best mean plane of the donor atoms N(1), N(2), O(1), O(2) is 0.10 Å. The $Cu^{II}–N_{peptide}$ bond [1.888(4) Å] is stronger than the $Cu^{II}–NH_2$ one [1.979(4) Å], as expected [1,2]. The two chelating rings are almost coplanar; the dihedral angle between the best mean planes CuN(1)C(2)C(1)O(1) and CuN(1)C(5)C(6)N(2) is 3.8°. Intermolecular hydrogen bonds involving the amino group and atoms O(1) and O(3) stabilize the crystal structure.

There is one very weak interaction between Cu and the peptide oxygen of a neighbouring chain, the dimension being Cu···O(3) $[x-y,\ y,\ z] = 2.959(1)$ Å.

Another 1D copper(II) dipeptide complex is structurally related to **1** in that it also exhibits a $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ coordination mode of the ligand, namely $[Cu(H_{-1}L')]_n$ (L′H = L-trypthophyl-glycine) [31]. However, in the latter there are $Cu^{II}–\pi$ interactions that are provided by the 'sandwich' structure involving each Cu^{II} atom and two trypthophan residues from neighbouring molecules.

Although complexes **1** and **2** have the same chemical formula, their solid-state structures are quite different. Complex **2** is a 3D coordination polymer. The doubly deprotonated dipeptide binds copper(II) via the amino [N(2)] nitrogen atom, the deprotonated peptide [N(1)] nitrogen atom and a carboxylate oxygen atom [O(1)]. In addition there are two bonds from the peptide oxygen atom [O(3)] and the second carboxylate oxygen atom [O(2)] to two other Cu^{II} atoms. Thus, each peptide dianion participates in the coordination spheres of three Cu^{II} atoms and behaves as $\eta^1{:}\eta^1{:}\eta^1{:}\eta^1{:}\mu_3$ ligand or in a $[3{\cdot}1_1 1_2 1_3 1_1 1_1]$ mode [30]. Conversely, each copper is bonded to three different peptides; this is the view emphasized in Fig. 2. The Cu···Cu distances are 5.105(1) [through the carboxylate group] and 6.097(1) Å [through the deprotonated peptide bond].

The coordination number of Cu^{II} is five and its geometry is distorted square-pyramidal. Three of the basal coordination sites are occupied by the donor atoms of the same ligand O(1), N(1), N(2) and the fourth by the second carboxylate oxygen [O(2)] of an adjacent repeating unit. In the axial coordination position lies the peptide oxygen [O(3)] of a third unit. The metal lies 0.19 Å out of the least-squares basal plane, towards O(3). As expected the axial Cu–O(3) bond is approximately 0.4 Å longer than the Cu–O bond lengths in the basal plane. The $Cu–N_{amino}$, $Cu–N_{peptide}$ and $Cu–O_{carboxylate}$ bond lengths in **2** are distinctly longer than in **1**, as expected from the higher coordination number in the former. The two individually almost planar chelate rings CuN(1)C(2)C(1)O(1) and CuN(1)C(5)C(6)N(2) are slightly twisted out of coplanarity, the dihedral angle between their least-squares plane being 6.5°. The crystal structure is stabilized by a

weak, intermolecular hydrogen bond involving the amino group and the carboxylate oxygen atom [O(1)], dimensions being: N(2)···O(1) [$-x+1/2$, $-y$, $z+1/2$] = 3.045 Å, H(N2B)···O(1) [$-x+1/2$, $-y$, $z+1/2$] = 2.510 Å and N(2)–H(N2B)···O(1) [$-x+1/2$, $-y$, $z+1/2$] = 118.4°.

The structure of **2**, as detailed in the above discussion and in Figs. 2 and 3, shows remarkable resemblance to those of $[Cu(H_{-1}L_A)]_n$, where L_AH = glycyl-L-methionine [32], glycyl-L-alanine [33], L-methionylglycine [34] and L-leucyl-L phenylalanine [35]. In all five complexes, the deprotonated peptide bond bridges two different Cu^{II} atoms through the oxygen and nitrogen atoms. This μ_2 coordination mode of the deprotonated peptide group is extremely rare in transition metal chemistry. It has also been observed in the dinuclear complex $[Pt_2(H_{-1}L_B)(NH_3)_4]\cdot(SO_4)$ [36], where L_BH = glycylglycine; however, one of the carboxylate oxygen atoms remains uncoordinated in the platinum(II) complex.

The crystal structure of **3** is composed of zigzag, polymeric chains of stoichiometry $(CuCl_3)_n^{n-}$ and protonated [at the amino nitrogen, N(2)] dipeptides which remain uncoordinated. There are two bridging chloro ligands between two neighbouring atoms, while a terminal chloro ligand [Cl(3)] completes five coordination at each metal centre. A regular alternation of two non-equivalent $Cu_2(\mu_2\text{-}Cl)_2$ units occurs in the chain. Both bridging Cu_2Cl_2 units are strictly planar with a crystallographic inversion centre in the middle of each Cu···Cu distance. The Cu···Cu separations are 3.483(1) Å through the Cl(1) bridges and 3.522(1) Å through the Cl(2) bridges. The bridging Cu–Cl bond distances range from 2.268(1) to 2.529(1) Å. As expected, the terminal Cu–Cl(3) bond distance [2.251(1) Å] is shorter than the bridging distances. These Cu–Cl distances are within the normal range observed [37] for other 1D polymeric complexes of the stoichiometry $ACuCl_3$ (A = cation).

Salts of stoichiometry $ACuCl_3$ often contain $[Cu_2Cl_6]^{2-}$ ions and large, e.g. Ph_4P^+, cations to keep the anions well separated; the $[Cu_2Cl_6]^{2-}$ ions are formed by two tetrahedra sharing an edge [38,39]. For smaller cations, the dimers become linked by long Cu–Cl bonds giving infinite chains with five- or six-coordinate Cu^{II} [38,39]. The chloro complex $CsCuCl_3$ is unique in forming infinite chains of distorted octahedra sharing opposite triangular faces [38].

The five donor atoms within bonding distances do not define a regular polyhedron around copper in **3**. Analysis of the shape-determining angles using the approach of Addison et al. [40] yields a value for trigonality index, τ, of 0.53 ($\tau = 0$ and 1 for perfect square pyramidal and trigonal bipyramidal geometries, respectively). Thus, the geometry about copper(II) is distorted significantly and can be described as either a distorted sp or a distorted tbp arrangement. With use of the tbp description, the apical sites are occupied by Cl(1) [$-x+1$, $-y$, $-z$] and Cl(2) [$-x+1$, $-y+1$, $-z$] with atoms Cl(1), Cl(2) and Cl(3) making up the equatorial plane; Cu lies 0.52 Å out of the equatorial plane. For the sp description the basal plane consists of atoms Cl(1) [$-x+1$, $-y$, $-z$], Cl(2), Cl(2) [$-x+1$, $-y+1$, $-z$] and Cl(3) with Cl(1) occupying the apical site. The four basal atoms are not coplanar; Cl(1) [$-x+1$, $-y$, $-z$] and Cl(2) [$-x+1$, $-y+1$, $-z$] lie 0.20 and 0.50 Å, respectively, above the best least-squares plane through the four atoms, while Cl(2) and Cl(3) lie 0.27 and 0.67 Å, respectively, below it. In the sp description, the bridging Cl(1) (or Cl(1) [$-x+1$, $-y$, $-z$]) atom simultaneously occupies a basal site at one Cu^{II} atom and the apical site of the neighbouring Cu^{II} atom. This is a common structural feature for dinuclear Cu^{II} units with two mono-atomic bridges. The copper(II) atom is 0.29 Å above the plane toward the apical donor atom. The distortions from the ideal tbp geometry appear greater than in the sp model; thus, the sp description is more preferred.

The presence of hydrogen bonds is a dominant feature in the crystal structure of **3** (see Fig. 4). The LH_2^+ peptide cations form dimers through the two hydrogen bonding interactions O(2)–H···O(3) [$-x+2$, $y+1/2$, $-z-1/2$] and N(2)–H(N2A)···O(1) [$-x+2$, $y+1/2$, $-z-1/2$]. Moreover, the chloro atoms of the $CuCl_3^-$ chains are hydrogen bonded to the dimeric LH_2^+ moieties through the N(1)–H···Cl(1)[(x, $-y+1/2$, $z-1/2$], N(2)–H(N2B)···Cl(3) [$-x+1$, $-y$, $-z$] and N(2)–H(N2C)···Cl(2) [x, y, z] interactions.

3.3. Spectroscopic studies

Table 5 gives diagnostic IR bands for the dipeptide LH and complexes **1**, **2** and **3**. Assignments have been made by studying extensive literature reports [34,41–48], noting spectral differences between the free, protonated and coordinated dipeptide and bearing in mind the known X-ray structures of the complexes.

The free dipeptide exists as zwitterion, as evidenced by the appearance of the typical $-NH_3^+$ and $-COO^-$ bands [34,42,45]. The simultaneous presence of the $-NH_3^+$ and characteristic –COOH bands [ν(C=O), ν(C–O), δ(OH)] in the spectrum of **3** confirms that the dipeptide is protonated, i.e. LH_2^+.

The extensive hydrogen bonding in LH and $H_{-1}L^{2-}$, and their difference in charge makes it difficult to rationalize frequency shifts upon copper(II) coordination. However, we observe the disappearance of the $\nu(NH_3^+)$, $\delta_d(NH_3^+)$ and $\delta_s(NH_3^+)$ bands associated with the zwitterionic structure in **1** and **2**, coupled with the appearance of two absorptions in the 3358–3150 cm^{-1} assigned to the antisymmetric and symmetric $-NH_2$ stretching modes. These changes and the relatively low frequency of the $\nu(NH_2)$ bands are in agree-

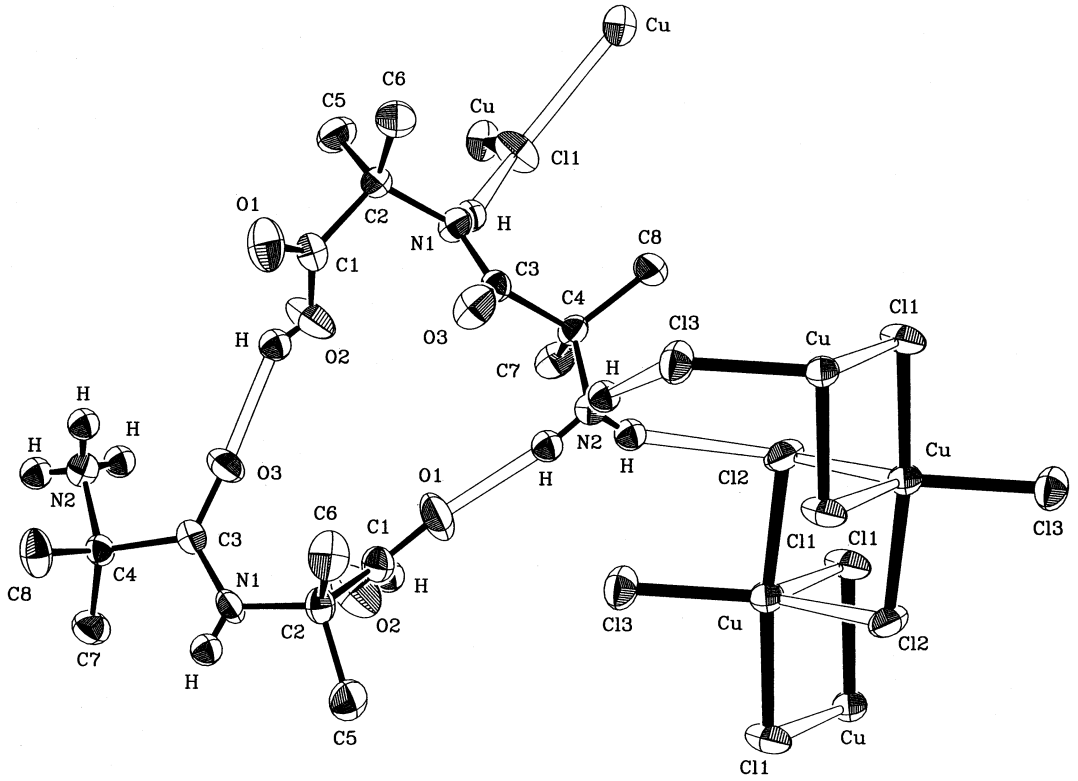

Fig. 4. A view of the structure of complex **3** showing a portion of the $(CuCl_3)_n^{n-}$ chain and two dipeptide counterions. Identical numbers are used for symmetry-generated atoms. Open bonds indicate weak coordination bonds or hydrogen bonds.

ment with the fact that the terminal amino group of $H_{-1}L^{2-}$ occupies one of the coordination sites of the metal ion [34]. The difference $\Delta[\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)]$ for complexes **1** and **2** is less than that for the corresponding free zwitterionic dipeptide as expected for the bidentate bridging mode of carboxylate ligation [46].

The IR spectrum of the free dipeptide LH shows the characteristic bands of a hydrogen-bonded, trans secondary peptide group [41,48]. As would be expected from the stoichiometry, the $\nu(NH)_{peptide}$ band is absent in the spectra of **1** and **2**. Also the amide II and III bands are replaced by a new absorption at 1400 (**1**) and 1404 (**2**) cm^{-1}, which is characteristic for deprotonated secondary (in fact tertiary) peptide complexes [41]; this replacement might be expected, since on removal of the peptide proton the band becomes a pure C–N stretch. The $\nu(CO)_{peptide}$ [amide I] band appears at 1600 (**1**) and 1576 (**2**) cm^{-1}; this large low-frequency shift is typical of peptide N-bonding [34]. It is interesting to note, however, that this mode appears at lower frequencies in **2** (compared to **1**) which has been shown by X-ray crystallography to contain a μ_2 O,N-bound deprotonated peptide group. Thus, in the solid state, there is only indirect IR evidence that the peptide group in complex **2** is bound to the Cu^{II} atoms through both its deprotonated nitrogen and peptide oxygen.

Electronic spectra of aqueous solutions of **1** and **2** have been recorded. The longest wavelength absorption band of the peptide group itself occurs near 220 nm in the free dipeptides and this is due to an $n \rightarrow \pi^*$ transition [2]. Several transitions in the 210–280 nm region appear upon coordination of Cu^{II}; these intense absorption maxima are assigned [2,34] to $N \rightarrow Cu^{II}$ ligand-to-metal charge transfer (LMCT) transitions. Data in the 285–800 nm range are as follows: complex **1**, $\lambda_{max} =$ 292, 609 ($\varepsilon = 130$ l mol^{-1} cm^{-1}) nm; and complex **2**, $\lambda_{max} = 292$, 610 ($\varepsilon = 125$ l mol^{-1} cm^{-1}) nm. The d–d visible band is suggestive of approximately square pyramidal geometry with mixed O and N donors about the metal ion as observed in other copper(II) peptide complexes [49]. The approximately 290 nm band is tentatively assigned to a $COO^- \rightarrow Cu^{II}$ charge-transfer transition [34].

From our solution data it is evident that complexes **1** and **2**, which have a different solid-state geometry, have the same chromophore in water. We believe that the polymeric structures—observed for **1** and **2** in the solid state—do not persist in solution. Possibly, one of the carboxylate oxygens and the apical peptide oxygen (in **2**) are replaced by H_2O molecules when the crystals are dissolved in water [34]. Further evidence of the disruption of the solid-state structures upon dissolution is provided by the absence of a band in the 320–370 nm range in the solution spectra [34,50]; this LMCT band, which is observed when the COO^- group is bridging between two Cu^{II} ions and considered to be a diagnos-

tic property of the Cu^{II}–OCO–Cu^{II} linkage, has been attributed to the bridging π system that is delocalized over the carboxylate group and the Cu^{II} atoms.

4. Conclusions and perspectives

The Cu^{II}/LH reaction system fulfilled its promise as a source of new interesting copper(II) complexes. The most interesting point of this work is that complexes **1** and **2** have a completely similar chemical identity, i.e. $[Cu(H_{-1}L)]_n$, but a different structural identity; **1** is a chain (1D) polymer, whereas **2** is a 3D coordination polymer. This structural difference arises from the different ligation modes of the dianion $H_{-1}L^{2-}$ in the two complexes. Our results indicate that competition and cooperation between potential binding sites in the dipeptide used are rather complicated processes and support the view that 'fine-tuning' of the synthetic and crystallization conditions can bring remarkable changes in the structure of the copper(II)/Aib-based peptide complexes.

It is clear that a plethora of new experiments is required to fulfil the goals (i)–(iv) cited in the introduction. In addition to complexes **1**–**3** described above, a number of copper(II) and diorganotin(IV) complexes with other Aib–based peptides as ligands, i.e. Aib–Gly, Aib–Ala, Aib–Leu, Aib–Phe, etc. have been characterized or are under characterization at the time of writing. The products comprise a remarkably wide variety of structural types, emphasizing the capability of the dipeptides to adopt a number of ligation modes in their mono- or dianionic forms, both terminal and bridging, and both tridentate and polydentate. The complexes obtained to date, some of which have an impressive biological activity, will be reported in due course.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 160947, 160948 and 160949 for complexes **1**, **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Several complexes of the type, $[M\{S_2CNR\}_3]$ (**1**) (M = Ga or In; R = $CH_2CH_2OCH_2CH_2$, $CH_2CH_2N(Me)CH_2CH_2$), $[MCl_2\{S_2CN(CH_2CH_2)_2O\}]$ (**2**) (M = Ga or In), $[MCl\{S_2CN(CH_2CH_2)_2O\}_2]$ (**3**) (M = Ga or In), $[Ga\{S_2CN(CH_2CH_2)_2O\}\{S_2P(OR)_2\}_2]$ (**4**) (R = Et, Pr^i) and $[M\{S_2CNR\}\{(SCH_2CH_2)_2O\}]$ (**5**) (M = Ga or In; R = $CH_2CH_2OCH_2CH_2$, $CH_2CH_2N(Me)CH_2CH_2$) have been prepared. All the complexes were characterized by elemental analysis, IR and NMR (^1H, $^{13}C\{^1H\}$) spectroscopy. ^{71}Ga NMR chemical shifts and half line widths are influenced by the coordination number of gallium and the substituents on the ligand moiety. Single crystal X-ray structures of two complexes $[M\{S_2CN(CH_2CH_2)_2O\}_3]$ (M = Ga, In) have been determined. © 2002 Published by Elsevier Science Ltd.

1. Introduction

Compounds containing metal–sulfur bonds have attracted considerable attention during the last three decades due to their synthetic and structural aspects [1], spectroscopic and theoretical features [2] and their biochemistry [3]. More recently, their relevance in catalysis [4] and materials science [5] has been demonstrated. Among the sulfur ligands, the dithiocarbamate species ($RR'NCS_2^-$) form an important family of classical anionic ligands. These anions are 3-electron donors, capable of stabilising metal centres in a variety of oxidation states [6]. Besides their extensive technological applications [6], these ligands are still of topical interest as a potential source of novel structures.

The significance of III–VI materials (particularly those of Ga and In), formed in different stoichiometries [7,8], in various electronic applications has provided a stimulus for the current interest in the chemistry of Group 13 elements with chalcogen ligands. The ligands include thiolates [9], thiocarboxylates [10], xanthates [11], dithiophosphates [12,13], monothiocarbamates [14–16] and dithiocarbamates [17–20]. The gallium–indium complexes with the latter ligands have usually been isolated as tris-chelates. The ligands in general contain simple R groups on the nitrogen atom. The tris-chelates have been employed as molecular precursors for the preparation of M_2S_3 by us [20] and others [17–19]. These developments have motivated us to study the chemistry of gallium and indium complexes with internally functionalized ligands, viz. *N*-methylpiperazine and morpholine dithiocarbamates. The results of this work are reported herein.

2. Experimental

Except for the preparation of tris-complexes, all other reactions were carried out under anhydrous conditions using Schlenk techniques. High purity metal trichlorides (Trans Metal), 2-mercaptoethylether (Aldrich), morpholine, *N*-methylpiperazine, $Me_2NCS_2Na{\cdot}3H_2O$ and $Et_2NCS_2Na{\cdot}3H_2O$ were obtained from commercial sources. $[Ga(S_2CNR_2)_3]$ (R = Me, Et, Pr^i)

[21] and morpholine and *N*-methylpiperazine dithiocarbamates [22,23] were prepared by literature methods. The infrared spectra were recorded as Nujol mulls between CsI plates on a Bomem MB-102 FT spectrometer. ^{1}H, $^{13}C\{^{1}H\}$, $^{31}P\{^{1}H\}$ and $^{71}Ga\{^{1}H\}$ NMR spectra were recorded in $CDCl_3$ solutions in 5 mm tubes on a Bruker DPX-300 NMR spectrometer operating at 300.13, 75.44, 121.44 and 91.53 MHz, respectively. Chemical shifts were referenced to the internal $CHCl_3$ peak (δ 7.26 and 77.0 ppm) for ^{1}H and ^{13}C, respectively, external 85% H_3PO_4 for ^{31}P and external $GaCl_3$ solution in D_2O (known to form $Ga(H_2O)_6^{3+}$ [24]) for ^{71}Ga.

2.1. Preparation of $[Ga\{S_2CN(CH_2)_4NMe\}_3]$ (**1a**)

To a methanolic solution (25 ml) of $GaCl_3$ (0.26 g, 1.47 mmol) (exothermic reaction), a solution of potassium salt of *N*-methylpiperazine dithiocarbamate (0.95 g, 4.43 mmol) in MeOH (25 ml) was added slowly and stirred for 3 h. The solvent was dried in vacuo and the residue was extracted with dry CH_2Cl_2 and filtered through a G-3 filtration unit using suction pump. The clear filtrate was evaporated in vacuo to give a white solid in 90% yield (0.79 g). Pertinent data are given in Table 1.

2.2. Preparation of $[Ga\{S_2CN(CH_2)_4O\}_3]$ (**1c**)

To a methanolic solution (20 ml) of $GaCl_3$ (0.37 g, 2.10 mmol), a solution of Na salt of morpholine dithiocarbamate (1.18 g, 6.37 mmol) in MeOH (25 ml) was added slowly and stirred for 3 h. The MeOH was evaporated in vacuo and the solid was extracted with dry $CHCl_3$. The solution was filtered and the clear filtrate was evaporated in vacuo to obtain a dirty white solid (1.09 g, 93%). The solid was recrystallized from dry CH_2Cl_2–C_6H_{14} in 81% yield.

In a similar manner, $[In\{S_2CN(CH_2)_4O\}_3]$ (**1d**) was prepared.

2.3. Preparation of $[GaCl_2\{S_2CN(CH_2)_4O\}]$ (**2a**)

A methanolic solution (25 ml) of Na salt of morpholine dithiocarbamate (0.60 g, 3.24 mmol) was added dropwise to a methanolic solution (20 ml) of $GaCl_3$ (0.57 g, 3.24 mmol) and the mixture was stirred for 3 h. The solution was evaporated in vacuo and the residual solid was extracted with dry $CHCl_3$. The solution was filtered and the clear filtrate evaporated to give a white solid (0.65 g, 66%).

$[InCl_2\{S_2CN(CH_2)_4O\}]$ (**2b**) was prepared using a similar method.

2.4. Preparation of $[GaCl\{S_2CN(CH_2)_4O\}_2]$ (**3a**)

To a solution (20 ml) of $GaCl_3$ (0.53 g, 3.0 mmol) in dry $CHCl_3$, a solution of $[Ga\{S_2CN(CH_2)_4O\}_3]$ (3.34 g, 6.0 mmol) in $CHCl_3$ was added and stirred for 3 h. The clear solution was evaporated in vacuo to obtain a white solid (3.80 g, 98% yield).

2.5. Preparation of $[InCl\{S_2CN(CH_2)_4O\}_2]$ (**3b**)

To a methanolic solution (20 ml) of $InCl_3$ (0.44 g, 1.99 mmol), a methanolic solution of Na salt of morpholine dithiocarbamate (0.73 g, 3.94 mmol) was added slowly and stirred for 3 h. The MeOH was evaporated in vacuo and the solid was extracted with dry $CHCl_3$. The solution was filtered and the clear filtrate was

evaporated in vacuo to obtain a white solid (0.79 g, 84%).

2.6. Preparation of $[Ga\{S_2CN(CH_2)_4O\}\{S_2P(OEt)_2\}_2]$ (4a)

To a methanolic solution (20 ml) of $GaCl_3$ (1.17 g, 6.64 mmol), a solution of Na salt of morpholine dithiocarbamate (1.22 g, 6.59 mmol) in MeOH (25 ml) was added slowly and stirred for 3 h. The MeOH was evaporated in vacuo and the solid was suspended in dry $CHCl_3$. To it a $CHCl_3$ solution of ammonium diethyldithiophosphate (2.70 g, 13.30 mmol) was added and stirred which was continued for 4 h. The mixture was filtered and the clear filtrate evaporated in vacuo to yield an oily product (3.80 g, 95%).

$[Ga\{S_2CN(CH_2)_4O\}\{S_2P(OPr^i)_2\}_2]$ (**4b**) was prepared in a similar manner.

2.7. Preparation of $[Ga\{S_2CN(CH_2)_4NMe\}\{(SCH_2CH_2)_2O\}]$ (5a)

$[GaCl\{(SCH_2CH_2)_2O\}]$, prepared by stirring a C_6H_6 solution of $GaCl_3$ (1.89 g, 10.73 mmol) and $[(NaSCH_2CH_2)_2O\}]$ [obtained from $(HSCH_2CH_2)_2O$ (1.48 g, 10.72 mmol) and Na (0.49 g, 21.3 mmol) in MeOH and then dried in vacuo] for 3 h, was treated with potassium salt of *N*-methylpiperazine dithiocarbamate (2.30 g, 10.73 mmol). The whole was stirred at room temperature (r.t.) for 3 h. Precipitated salts were filtered off and the filtrate was evaporated in vacuo to give a dirty white solid (3.90 g, 95%).

$[In\{S_2CN(CH_2)_4NMe\}\{(SCH_2CH_2)_2O\}]$ (**5b**), $[Ga\{S_2CN(CH_2)_4O\}\{(SCH_2CH_2)_2O\}]$ (**5c**) and $[In\{S_2CN(CH_2)_4O\}\{(SCH_2CH_2)_2O\}]$ (**5d**) were prepared in an identical manner.

2.8. X-ray crystallography

X-ray data of the isostructural systems $[M\{S_2CN(CH_2CH_2)_2O\}_3]$ (M = Ga, In) which crystallize with a molecule of (disordered) dichloromethane (Table 2) were collected at 173(2) K on a Siemens P3 diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) employing the ω–2θ scan technique. The unit cell parameters were determined for 25 reflections measured by random search routine. The intensity data were corrected for Lp and absorption effects. The structures were solved using direct methods. The non-hydrogen atoms were refined anisotropically. A disorder model (ring inversion) was used for the N(3)–O(3) containing six-membered ring in the Ga compound (CCDC Nos. 167589 for Ga and 167588 for In).

3. Results and discussion

Several gallium(III) and indium(III) complexes with morpholine and *N*-methylpiperazine have been prepared. The reaction of MCl_3 with 3 equiv. of sodium–potassium salt of dithiocarbamate in methanol (for Ga) or water (for In) resulted in the formation of $[M(S_2CNR)_3]$ (**1**) (R = –$CH_2CH_2OCH_2CH_2$–, –$CH_2CH_2N(Me)CH_2CH_2$–) as colourless crystalline solids (Eq. (1)). Treatment of MCl_3 with sodium salt of morpholine dithiocarbamate in 1:1 and 1:2 molar ratio afforded chloro complexes $[MCl_2\{S_2CN(CH_2CH_2)_2O\}]$ (**2**) (M = Ga (**2a**), In (**2b**)) and $[MCl\{S_2CN(CH_2CH_2)_2O\}_2]$ (**3**) (M = Ga (**3a**), In (**3b**)), respectively

(Eq. (2)). However, similar reactions with $[KS_2CN(CH_2CH_2)_2NMe]$ yielded only **1**. Treatment of **2a** with ammonium dialkyldithiophosphate gave mixed ligand complexes, $[Ga\{S_2CN(CH_2)_4O\}\{S_2P(OR)_2\}_2]$ (**4**) (Eq. (3)). Yet another series of mixed ligand complexes $[M\{(SCH_2CH_2)_2O\}\{S_2CNR\}]$ (**5**) could be isolated by the reaction of MCl_3 with sodium salt of 2-mercaptoethylether followed by addition of dithiocarbamate in 1:1:1 stoichiometry (Eq. (4)). All the complexes **1**–**5** are colorless crystalline solids. They are soluble in common organic solvents, except **2** and **3**, which are sparingly soluble in chloroform and benzene.

$$MCl_3 + 3[KS_2CN(CH_2)_4NMe] \rightarrow [M\{S_2CN(CH_2)_4NMe\}_3] + 3KCl \quad (1)$$

$$MCl_3 + n[NaS_2CN(CH_2)_4O] \rightarrow [MCl_{3-n}\{S_2CN(CH_2)_4O\}_n] + n\,NaCl \quad (n = 1, 2, 3) \quad (2)$$

$$[GaCl_2\{S_2CN(CH_2CH_2)_2O\}] + 2[NH_4S_2P(OR)_2] \rightarrow [Ga\{S_2CN(CH_2)_4O\}\{S_2P(OR)_2\}_2] + 2NH_4Cl \quad (R = Et \text{ or } Pr^i) \quad (3)$$

$$MCl_3 + [NaSCH_2CH_2)_2O] + Na/KS_2CNR \rightarrow [M\{S_2CNR\}\{(SCH_2CH_2)_2O\}] + Na/KCl \quad (4)$$

The infrared spectra of these complexes exhibited strong bands in the regions 1155–1134 and 1009–980 cm^{-1} attributable to νCNC and ν C=S, respectively [25]. Interpretation of the ν M–Cl and ν M–S absorptions have been made by comparison of the infrared spectra of the free ligands, chloro complexes and the tris-derivatives. An absorption at 372 ± 2 (in $[GaCl_{3-n}L_n]$ ($n = 1$ or 2)) [12,21] and 327 cm^{-1} (in $[InCl_{3-n}L_n]$) [13,26], absent in the spectra of free ligands and in tris-complexes have been assigned to ν M–Cl stretchings. Similarly, absorptions in the region 316–370 (for gallium complexes) and 319–375 cm^{-1} (for indium complexes) absent in the spectra of free ligands may be assigned to ν M–S absorptions [26–29]. In the spectra of mixed thiolate complexes (**5**) two–three such absorptions appeared in these regions.

The ^1H and $^{13}C\{^1H\}$ NMR spectra of these complexes exhibited characteristic resonances due to the ligand protons–carbons at room temperature (Table 3). The dithiocarbamate ligand protons in the ^1H NMR spectra of 1–5 were little affected with other substituents (metal or chloride) as each set of resonances appeared in a narrow region. The methylene proton signals appeared as triplets. In the $^{13}C\{^1H\}$ NMR spectra the quarternary carbon resonance had low intensity as expected and in a few cases could not be resolved. This signal showed substituent dependance. It was deshielded on substituting chloride with dithiocarbamate ligands as in $[MCl_{3-n}\{S_2CN(CH_2)_4O\}_n]$ (M = Ga or In). However, other resonances were little affected either on changing the metal ion (e.g. Ga or In) or the chloride ligand with dithiocarbamate. The ^{31}P NMR spectra of $[Ga\{S_2CN(CH_2)_4O\}\{S_2P(OR)_2\}_2]$ displayed a single resonance. These values can be compared with the corresponding tris-dithiophosphates, $[Ga\{S_2P(OR)_2\}_3]$ [12]. The ^1H NMR spectra of $[M\{S_2CN(CH_2CH_2)_2O\}\{(SCH_2CH_2)_2O\}]$ exhibited four triplets due to methylene protons as expected. There is little change in the chemical shift on substituting gallium with indium. However, in the $^{13}C\{^1H\}$ NMR spectra, the CS_2 carbon resonance is deshielded on replacing gallium with indium.

Although there are only a few reports on ^{71}Ga ($I = 3/2$, natural abundance 39.6%) NMR spectroscopy [30], it would be an important probe to study the behaviour of gallium with simple and chelating ligands—a relatively underdeveloped area. The ^{71}Ga NMR chemical shifts cover rather a broad range (ca. 1500 ppm) with half line width at times as great as 37 kHz [31]. In order to throw some light on the solution behaviour of gallium dithiocarbamate complexes, $^{71}Ga\{^1H\}$ NMR spectra were recorded in $CDCl_3$ (Table 3). The ^{71}Ga NMR resonance for all the tris-complexes is considerably shielded relative to the six-coordinate hexa-aquo ion, $[Ga(H_2O)_6]^{3+}$. The effect of the organic groups of dithiocarbamate ligands are reflected on the ^{71}Ga NMR chemical shifts. The resonance is deshielded with increasing steric demand of the R group (i.e. Me < Et < Pr^i). The substituents effects are also seen on the half line width of the signal (Fig. 1). The $\Delta 1/2$ decreases with decreasing size of the R group (Me, Et, Pr^i). The ^{71}Ga signal for morpholine and *N*-methylpiperazine complexes appeared close to the signal for S_2CNEt_2 derivative, but with greater half line width. The X-ray structural analyses of $[Ga\{S_2CN(CH_2)_5\}_3]$ [21] and $[Ga\{S_2CN(CH_2CH_2)_2O\}_3]$ (see later) have revealed an octahedral geometry around gallium atom. The observed ^{71}Ga NMR shifts can be interpreted in terms of octahedral geometry around gallium atom.

The X-ray structure of $[GaCl\{S_2CNMe_2\}_2]$ [21] has shown a square pyramidal environment around gallium atom. It is likely that mono–chloro complexes with other dithiocarbamate ligands have a similar structure. The ^{71}Ga NMR spectrum of $[GaCl\{S_2CN(CH_2)_4O\}_2]$ displayed a broad resonance at δ 77.2 ppm. The signal is considerably downfield shifted ($\sim$150 ppm) from the hexa-coordinated complexes and is upfield ($\sim$150 ppm) from the four-coordinate regime (sodium gallate δ 223.3 ppm). This may be interpretated in terms of penta-coordinate structure for gallium in solution. The increased line width may be attributed to the asymmetry in the electric field gradient (efg) around the gallium nucleus due to the presence of different ligands. The ^{71}Ga measurements of $[GaCl_2\{S_2CN(CH_2)_4O\}]$ were

thwarted due to poor solubility of the complex coupled with extensive line broadening of the resonance. The ^{27}Al NMR chemical shifts have also been reported to depend on the coordination number of aluminium and deviation from spherical geometry around aluminium nucleus resulted in broadening of the resonances [32,33]. Unlike ^{27}Al NMR spectroscopy, deviation of chemical shifts with changes in coordination number and signal half line widths with ligand substituents are more pronounced in ^{71}Ga NMR spectroscopy.

The structures of $[In\{S_2P(OR)_2\}\{SCH_2CH_2)_2O\}]$ (R = Et or Pr^i) established by X-ray diffraction analyses showed a dimeric structure. The 2-mercaptoethylether dianion coordinates the indium atom using both sulfur atoms and the ether oxygen atom while at the same time one of the sulfur atoms bridges the second indium atom of the dinuclear species [29]. The dithiocarbamate complexes, $[M\{(SCH_2CH_2)_2O\}\{S_2CNR\}]$ (**5**), reported here are likely to have a similar structure since the R_2NCS_2 ligands are isoelectronic and isostructural to the dithiophosphates.

The molecular structures of $[M\{S_2CN(CH_2CH_2)_2O\}_3]$ (M = Ga, In) as shown in Figs. 2 and 3 (the CH_2Cl_2 solvate molecule is omitted) have been established unambiguously by single crystal X-ray diffraction analy-

ses. Selected bond lengths and angles for the isostructural systems are given in Table 4. The six sulphur atoms from three chelating dithiocarbamate moeties in each molecule are arranged in a distorted octahedral environment around the central metal atom. The observed distortion from ideal geometry may be attributed to the small bite angle (< S–M–S being 73.5° for Ga and 69.6° for In) of the chelating dithio-ligand. Decreased ligand bite with increasing size of the metal atom results in opening of the S–C–S angle (115.9° in the Ga and 118.0° in the In derivative). The overall geometry of these complexes closely resembles those reported for related dithiocarbamates [20,34–36].

All six M–S distances are very similar and agree well with the reported values [13,34–39]. The C–S distances are also similar (close to 1.72 Å) within experimental error in the two molecules, indicating delocalization in the CS_2 skeleton. The C–N distances, which are close to 1.33 Å, are significantly shorter than the normal single bond, suggesting considerable double bond character, as expected for metal dithiocarbamates. The four-membered 'MS_2C' rings are planar while the six-membered heterocyclic rings adopt a puckered conformation; the angles between the SCS and CNC planes range from 4.6° to 9.4° for the non-disordered morpholine rings, confirming the efficient π electron conjugation.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 167589 for Ga and 167588 for In. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

We thank Drs J.P. Mittal and P. Raj for encouragement of this work. We are grateful to the Head, Analytical Chemistry Division for providing microanalyses of the compounds. Support from the Indo-German exchange program WTZ 99/060 is gratefully acknowledged.

Abstract

The crystal structures of three compounds containing bis(di-2-pyridylamine)copper(II) complex units have been determined by X-ray crystallographic methods; $[Cu(dpyam)_2(OH_2)_2](S_4O_6)$ (**1**), $[Cu(dpyam)_2(CF_3SO_3)_2]$ (**2**) and $[Cu(dpyam)_2(SO_4)]_2[Cu(dpyam)_2(OH_2)_2](PF_6)_2{\cdot}2H_2O$ (**3**). In compound **1** the anions are uncoordinated, and each Cu(II) ion involves the elongated tetragonal octahedral geometry with two water molecules occupying the axial positions. Compound **2** consists of neutral mononuclear units, the Cu(II) environment being elongated tetragonal octahedral with two unidentate triflate anions coordinating in axial positions. Two crystallographically independent molecules are found in compound **3**, one complex unit being centrosymmetric and octahedrally elongated, with two water molecules coordinated in the axial positions, the other predominately close to the distorted square-based pyramidal (4 + 1) stereochemistry of the CuN_3ON' chromophore which is best described as square-pyramidal *cis*-distorted octahedral (4 + 1 + 1*). The latter complex unit of compound **3** is the first example containing a *cis*-distorted octahedral coordination among the copper(II) complexes with divalent oxyanions. © 2002 Elsevier Science Ltd. Keywords: Crystal structures; Copper complexes; Di-2-pyridylamine complexes; Tetrathionate complexes; Trifluoromethanesulfonate complexes; Sulfate complexes; Hexafluorophosphate complexes

1. Introduction

Copper(II) complexes are known to display a large variation of non-regular stereochemistries [1]. A large number of $[Cu(chelate)_2(OXO)]^+$ cations, where the chelate is di-2-pyridyl (bpy), 1,10-*o*-phenanthroline (phen) or di-2-pyridylamine (dpyam) and OXO is monovalent oxyanions: ONO^-, HCO_2^-, $CH_3CO_2^-$ or $CH_3CH_2CO_2^-$ have been well known and characterized as having *cis*-distorted octahedral stereochemistry [1,2]. There is no crystal structure of this geometry involving the divalent oxyanion has been found for the copper(II) complexes with chelating ligands.

The copper(II) complexes of $Cu(chelate)_2(OYO){\cdot}nH_2O$ and $Cu(chelate)_2X_2$, where OYO is divalent $S_4O_6^{2-}$, $S_3O_6^{2-}$, $S_2O_6^{2-}$ or SO_4^{2-} oxyanions and X is monovalent ClO_4^-, BF_4^-, PF_6^-, NO_3^- or Br^- anions, show different geometries with four-, five- and six-fold coordination. These complexes can be characterized as monomeric or polymeric chain structures. Previous work led to the characterization of a number of bpy, phen and dpyam ligands representing a sequence of increasingly flexible chelate nitrogen ligands. The four-coordinate $[Cu(chelate)_2](PF_6)_2$, where chelate = bpy [3], phen [4] and dpyam [5] and $[Cu(dpyam)_2]X_2$, where $X = ClO_4^-$ [6] and BF_4^- [7]; the five-coordinate $[Cu(bpy)_2(OH_2)](S_2O_6)$ [8] and six-coordinate $[Cu(dpyam)_2X_2]$, where $X = NO_3^-$ [5,9] and $Br^-{\cdot}2H_2O$ [10] and $[Cu(dpyam)_2(OH_2)_2](SO_4){\cdot}7H_2O$ [7] complexes,

PII: S0277-5387(01)00993-7

belong to the mononuclear compounds, whereas the bridged $[Cu(bpy)_2(OYO)]$, where $OYO = S_4O_6^{2-}$ and $S_3O_6^{2-}$ [11], $[Cu(phen)_2(S_4O_6)]$ [12] and $[Cu(bpy)_2X]X$, where $X = ClO_4^-$ and BF_4^- [13] complexes correspond to the polymeric infinite chain structure.

Among this family of copper(II) complexes with dpyam ligand, six crystal structures of mononuclear compounds have been crystallographically characterized: $[Cu(dpyam)_2](ClO_4)_2$ [6], $[Cu(dpyam)_2](BF_4)_2$ [7], $[Cu(dpyam)_2](PF_6)_2$ [5], $[Cu(dpyam)_2(NO_3)_2]$ [5,9], $[Cu(dpyam)_2Br_2]\cdot 2H_2O$ [10] and $[Cu(dpyam)_2(OH_2)_2](SO_4)\cdot 7H_2O$ [7]. The continued interest in the more flexible dpyam ligand in this family of copper(II) complexes, has prompted us to examine more examples of three compounds containing bis(di-2-pyridylamine)-copper(II) complex units, namely diaqua-bis(di-2-pyridylamine)copper(II) tetrathionate (**1**), bis(di-2-pyridylamine)bis(trifluoromethanesulfonato-*o*)copper-(II) (**2**) and {bis[bis(di-2-pyridylamine)(sulfato-*o*,*o*′)-copper(II)][diaqua-bis(di-2-pyridylamine)copper(II) bis-(hexafluorophosphate)]}dihydrate (**3**).

These complexes were prepared and their structures determined crystallographically. Their IR, ESR and electronic spectra were investigated and discussed, along with the structural and spectral comparisons with those of the analogous complexes.

2. Experimental

All reagents were commercial grade materials and were used with out further purification. Elemental analysis (C, H, N) was performed by the Microanalytical Service of Science and Technological Research Equipment Centre, Chulalongkorn University on Perkin–Elmer PE2400 CHNS/O Analyzer. The Infrared spectra were recorded on a Biorad FTS-7/PC FTIR spectrophotometer as KBr pellets in the 4000–450 cm^{-1} region. Solid-state (diffuse reflectance) electronic spectra were recorded as polycrystalline samples on a Perkin–Elmer Lambda2S spectrophotometer over the range 8000–18 000 cm^{-1}. The X-band ESR spectra were recorded on polycrystalline samples at room temperature with a Jeol ESR JES-RE2X spectrometer.

2.1. Preparation

2.1.1. Preparation of $[Cu(dpyam)_2(H_2O)_2](S_4O_6)$ (1)

A warm solution of $Cu(BF_4)_2$ (237 mg, 1.0 mmol) in 10 ml water was added with stirring to a warm solution of dpyam (171 mg, 1.0 mmol) in 10 ml EtOH and $Na_2S_4O_6\cdot 2H_2O$ (306 mg, 1.0 mmol) in 20 ml DMSO yielding a light green solution with a small amount of the undissolved precipitates. Brownish-green crystals of **1** appeared upon slow evaporation of the filtrate at room temperature (r.t.). They were filtered off, washed with mother liquor and air-dried. Yield ca. 50%. *Anal.* Calc. for $C_{20}H_{22}CuN_6O_8S_4$: C, 36.06; H, 3.33; N, 12.62. Found: C, 36.11; H, 3.40; N, 12.58%.

2.1.2. Preparation of $[Cu(dpyam)_2(CF_3SO_3)_2]$ (2)

Compound **2** was obtained as a side product in the preparation of the dihydroxo-bridged complex $[Cu(dpyam)(OH)]_2(CF_3SO_3)_2]$ by adding a warm solution of dpyam (171 mg, 1.0 mmol) in 5 ml MeOH to a warm solution containing $Cu(CF_3SO_3)_2$ (362 mg, 1.0 mmol) in 20:10 ml of water–DMF mixed solvent and 1 ml of 1.0 N KOH solution. Greenish-brown needle-like crystals of **2** were deposited by slow evaporation at r.t. Yield ca. 85%. *Anal.* Calc. for $C_{22}H_{18}CuF_6N_6O_6S_2$: C, 37.53; H, 2.58; N, 11.94. Found: C, 37.44; H, 2.51; N, 12.01%.

2.1.3. Preparation of $[Cu(dpyam)_2(SO_4)]_2[Cu(dpyam)_2(H_2O)_2](PF_6)_2\cdot 2H_2O$ (3)

A warm solution of dpyam (342 mg, 2.0 mmol) and KPF_6 (92 mg, 0.5 mmol) in 40 ml EtOH was added with stirring to a warm solution of $CuSO_4\cdot 5H_2O$ (250 mg, 1.0 mmol) in 100 ml water. The rod-like green crystals were deposited from the solution after slow evaporation in air. Yield ca. 83%. *Anal.* Calc. for $C_{60}H_{58}Cu_3F_{12}N_{18}O_{12}P_2S_2$: C, 40.67; H, 3.53; N, 14.23. Found: C, 40.59; H, 3.58; N, 14.30%.

2.2. Crystallography

Reflection data for complexes **1**, **2** and **3** were collected at 293 K on a 1 K Bruker SMART CCD area-detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at a detector distance of 4.5 cm and swing angle of $-35°$. A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different ϕ angle (0, 88, 180°) and each exposure of 30, 15 and 35 s for **1**–**3**, respectively, covered 0.3° in ω. Data reduction and cell refinements were performed using the program SAINT [14]. An empirical absorption correction by using the SADABS [15] program was applied, which resulted in transmission coefficients ranging from 0.779 to 1.000 for **1**, 0.633 to 1.000 for **2** and 0.129 to 1.000 for **3**. The structures were solved by direct methods and refined by full-matrix least-squares method on F_{obs}^2 with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXTL-PC V 5.03 [16] software package. All hydrogen atoms in **1** and **2** were located by difference synthesis and refined isotropically, except two hydrogens from different pyridyl ring in **2**. In **3**, all hydrogen atoms, except seven atoms from the pyridyl rings, were geometrically fixed and allowed to ride on the attached atoms. Atoms O(4), O(6) and O(7) of the tetrathionate group in **1** show disorder with occupancies of 0.55 and 0.45; 0.74 and 0.26; and 0.64

and 0.36, respectively. In **3**, the PF_6^- group (F(2) and F(6)) shows disorder with site occupancies of 0.47 and 0.53; and 0.45 and 0.55, respectively. The large molecule with disorder PF_6^- anion arise to the reasonably high *R* value in **3**. The molecular graphics were created by using SHELXTL-PC. The crystal and refinement details for complexes **1**–**3** are listed in Table 1. Selected bond lengths and angles are given in Tables 2–4. Figs. 1–3 illustrates the structures of **1**–**3**, respectively, and the atom numbering scheme used.

3. Results and discussion

3.1. Description of structure *1*

The crystal structure of **1** is composed of a $[Cu(dpyam)_2(H_2O)_2]^{2+}$ cation and a $S_4O_6^{2-}$ anion (Fig. 1). The six-coordinated copper ion is equatorially bonded to two bidentate dpyam ligands [Cu–N = 1.990(7), 1.992(7), 2.013(6) and 2.047(7) Å] and axially, weakly bonded to the water oxygens [2.460(6) and 2.437(6) Å]. The coordination geometry around each copper ion can be described as an elongated tetragonal octahedral of the CuN_4O_2 chromophore with the tetragonality of 0.82. The basal CuN_4 plane is planar with r.m.s.d. of 0.006 Å, resulted by the large dihedral angles, 40.1(3) and 41.8(3)° between the pyridine rings within one dpyam ligand. The N–Cu–N bite angles of the dpyam ligands are 86.4(3)° and 85.3(3)°, respectively.

Three oxygen atoms from two tetrathionate groups show disorder, resulting in a slight distortion from the

3.2. Description of structure *2*

The crystal structure of **2** is made up of discrete neutral $[Cu(dpyam)_2(CF_3SO_3)_2]$ units (Fig. 2). The copper ion exhibits an elongated tetragonal octahedral CuN_4O_2 chromophore with four pyridyl N atoms from the dpyam ligands occupying the equatorial plane and two axial oxygen atoms from each triflate group. The four equatorial Cu–N distances are not significantly different ranging from 1.983(7) to 2.030(7) Å. The two oxygen atoms from each triflate group weakly coordinated in the axial positions with the distances of 2.471(7) and 2.498(7) Å, giving the tetragonality of the CuN_4O_2 chromophore of 0.81. The basal CuN_4 plane is planar with r.m.s.d. of 0.002 Å, attributed to the large angles between the pyridine rings of 36.6(4)° and 38.2(5)°, respectively. The bite angles of the dpyam ligands are 85.8(3)° and 85.9(3)°.

The structure contains unidentate trifluoromethanesulfonate anions which are semi-coordinated to the copper ion. The bonding parameters for the CF_3SO_3 ligand are very close to those found for previously reported unidentate coordinated triflate groups [17–20]. In the present case these anions exhibit a staggered-ethane conformation about the S–C bond. The values of the O–S–O angles are greater than the C–S–O ones as predicted on the basis of bond-pair repulsion. The slight distortion in the S–O bond lengths from the expected values of the second triflate group may due to the involvement of the uncoordinated O atoms in strong N–H···O and C–H···O hydrogen bonds. However, the mean value of the S–O bond lengths involving the coordinated oxygen atoms (1.444 Å) is somewhat

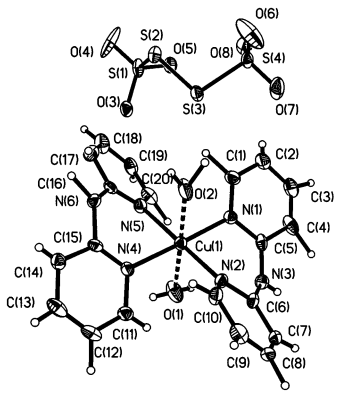

Fig. 1. The molecular structure of $[Cu(dpyam)_2(H_2O)_2](S_4O_6)$ (**1**).

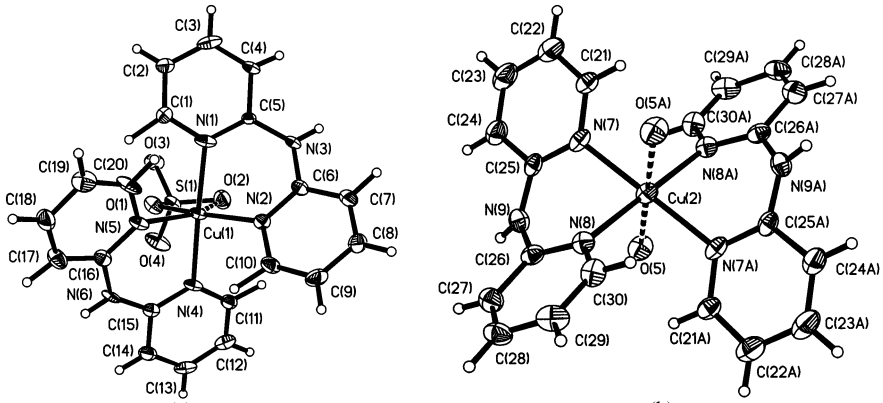

Fig. 3. The molecular structure of $[Cu(dpyam)_2(SO_4)]_2[Cu(dpyam)_2(H_2O)_2](PF_6)_2{\cdot}2H_2O$ (**3**).

longer than the average value of the uncoordinated ones (1.436 Å).

3.3. Description of structure *3*

The asymmetric unit of **3** contains two crystallographically independent units of $[Cu(dpyam)_2(SO_4)]$ and one-half $[Cu_{0.5}(dpyam)(H_2O)]$ moieties (the other half being inversion related), one hexafluorophosphate and one water molecule in the lattice. The two crystallographically independent Cu(II) ions are in totally different coordination geometries. The molecule A (Fig. 3(a)) of compound **3** involves a basic *cis*-distorted octahedral stereochemistry of the CuN_4O_2 chromophore with a marked asymmetric coordination of the sulfate anion. The Cu atom of the $[Cu(dpyam)_2(O_2SO_2)]$ unit is basically five-coordinate, but with the second O atom, O(2), of the sulfate group occupying a sixth-coordinate position at a distance greater than 2.6 Å, namely 2.981(6) Å, to give (4 + 1 + 1*)-type coordination [1,2]. The short Cu–O distance of 1.989(5) Å agrees well with the typical value of 2.00 Å [2]. However, the bidentate coordination of the sulfate group is highly asymmetric with a $\Delta O_{1,2}$ value of 0.99 Å, giving a square-pyramidal distorted octahedral stereochemistry of the six-coordinate CuN_4OO' chromophore [1,2]. The out-of-plane Cu–N(1) and Cu–N(4) distances [2.014(6) and 2.036(6) Å] are not significantly different. The in-plane Cu–N(2) and Cu–N(5) distances [2.041(6) and 2.170(6) Å] are significantly different with $\Delta N_{2,5} = 0.129$ Å and the out-of-plane N(1)–Cu–N(4) angle is 171.4(2)°. There is the in-plane angular distortion, the O(1)–Cu–N(2) and O(2)–Cu–N(5) angles are significantly $< 180°$ at 163.0(2) and 148.4(2)° and the O(1)–Cu–O(2) bite angle is significantly $< 90°$ at 53.1(2)°. However, the copper centre alternatively adopts distorted square-pyramidal stereochemistry if the weak interaction between Cu and O(2) is not considered, with atoms N(1), N(2), N(4) and O(1) forming the basal plane. The Cu atom is lifted out of the basal plane by 0.22 Å, in the direction of the N(5) atom. The basal plane has a slight tetrahedral distortion with a τ value of 0.14, which is relatively close to that of a square-pyrmidal CuN_3ON' chromophore ($\tau = 0$). However, O(2) is close enough to be involved in the off-axis weak semi-coordination to the Cu(II) ion [1,2], indicated by the geometry of the bidentate sulfate anion. The pyridine rings form dihedral angles of 25.2° and 10.6(4)° for the two dpyam ligands, respectively and the dpyam bite angles are 89.4(3)° and 88.6(2)°. The asymmetric bidentate chelating SO_4^{2-} anion shows a small deviation from tetrahedral symmetry, the S–O bonds involving coordinated and hydrogen bonded oxygen atoms, O(1) and O(3) being slightly longer (1.502(5) and 1.478(6) Å) compared to the other two bonds (1.468(5) and 1.457(6) Å), and the angle involving the coordinated oxygen atoms being slightly smaller (106.7(3)°) than the remaining angles (108.0(3)°–113.0(4)°). These correspond to the asymmetric bidentate coordination of the sulfate group [21].

In molecule B of compound **3** (Fig. 3(b)), the Cu(2) atom is in an octahedral environment with four nitrogen atoms from the two inversion related dpyam ligands occupying the basal plane (exactly planar). The axial positions in Cu(2) are occupied by the centrosymmetrically related water oxygens at 2.450(6) Å, giving the elongated tetragonal octahedral CuN_4O_2 chromophore with the tetragonality of 0.82. The Cu–N distances are not significantly different, 2.030(6) and 1.999(6) Å. As the basal plane is exactly planar, the dihedral angle between the pyridine rings is of high value, 40.9(2)° and the dpyam bite angle is 85.3(3)°. Two F atoms of the ionic PF_6^- group show disorder [F(2) and F(6)] so that the bond lengths and angles deriving from the disordered atoms are unusual [5]. The crystal structure of **3** is stabilized by a number of $(SO_4^{2-})O{\cdots}H{-}O(H_2O)$, $(SO_4^{2-})O{\cdots}H{-}N$, $N{\cdots}H{-}O(H_2O)$ and $N{-}H{\cdots}O(H_2O)$ hydrogen bonds involving both the coordinated and uncoordinated water molecules.

3.4. Structure comparison

The bis(dpyam) copper(II) complex with a divalent $S_4O_6^{2-}$ oxyanion of **1** differs from the monomeric five-coordinate $[Cu(bpy)_2(H_2O)](S_2O_6)$ [8] and the polymeric infinite chain structure of $[Cu(bpy)_2(S_4O_6)]$ [11], $[Cu(bpy)_2(S_3O_6)]$ [11] and $[Cu(phen)_2(S_4O_6)]$ [12]. The local geometry of the latter three complexes involves an elongated rhombic octahedron with a marked tetrahedral twist of the basal plane. The most relevant complexes to **1** are found in the elongated centrosymmetric octahedral geometry of $[Cu(dpyam)_2(H_2O)_2](SO_4)\cdot 7H_2O$ [7] and $[Cu(dpyam)_2(H_2O)_2](PF_6)_2$ complex unit of compound **3**, all of which display the planarity of the basal plane and the same tetragonality (0.81–0.82).

The ditriflate complex **2** is not centrosymmetric, but has a structure similar to the elongated centrosymmetric octahedral complexes $[Cu(dpyam)_2X_2]$ where $X = NO_3^-$ [5,9] and Br^- [10], the complex units $[Cu(dpyam)_2X_2]$, where $X = O$-tricyanoethyleneoate [22] and NCS^- [5] and also the related monomeric complexes $[Cu(dpyam)_2(H_2O)_2]X_2$, where $X = \frac{1}{2}(SO_4^{2-})$ [7], $\frac{1}{2}(S_4O_6^{2-})$ (**1**) and PF_6^- (**3**). The equatorial Cu–N distances in these eight complexes are not significantly different. The planarity of the basal CuN_4 plane is only possible because of the flexibility of the dpyam ligands which in these eight complexes are puckered such that the angles between the pyridine rings are quite large and comparable for all complexes [36.6° and 38.2° for **2**, 41.4° for the tricyanoethyleneoated unit, 40.0° for the thiocyanate unit, 37.4° for the nitrate complex, 39.4° for the bromide complex, 35.6° and 38.9° for the sulfate complex, 40.1° and 41.8° for **1** and 40.9° for the hexafluorophosphate complex unit of compound **3**]. The N–Cu–N bite angles within these complexes are also comparable [85.8° and 85.9°; 86.3°; 85.7°; 85.5°; 85.4°, 85.9° and 85.4°; 86.4° and 85.3°; and 85.3°, respectively]. The analogous coordination geometry has not been found in complexes with the less flexible bpy or phen ligand. These observations demonstrate a noticeable difference between the chelate functions of bpy or phen and the more flexible dpyam ligand.

However, these structures of compounds **1** and **2** and their analogous complexes above differ from those of the related complexes: (a) the compressed CuN_4 tetrahedron of $[Cu(chelate)_2](PF_6)_2$, where chelate = bpy [3] and phen [4], and $[Cu(dpyam)_2]X_2$, where $X = BF_4^-$ [7], ClO_4^- [6] and PF_6^- [5]; (b) the asymmetric *cis*-distorted CuN_4OO' octahedral complexes $[Cu(bpy)_2(NO_3)](NO_3)$ [23] and $[Cu(dpyam)_2(OXO)]Y$, where OXO = formate [24], acetate [5,24] and propionate [25–27].

The *cis*-distorted octahedral coordination in molecule A, $[Cu(dpyam)_2(SO_4)]$ of compound **3** is a rare example among copper(II) complexes with divalent oxyanions. However, the CuN_4OO' chromophore geometry is extremely asymmetric *cis*-distorted octahedral, comparable to those of the asymmetric *cis*-distorted octahedral complexes containing the dpyam ligand above. These complexes are slightly different from the less asymmetric *cis*-distorted octahedral complexes $[Cu(dpyam)_2(ONO)]X$ [28–30].

3.5. ESR, electronic and IR spectra

3.5.1. Complexes $[Cu(dpyam)_2(H_2O)_2](S_4O_6)$ (1) and $[Cu(dpyam)_2(CF_3SO_3)_2]$ (2)

The room temperature ESR spectra of **1** and **2** are of the axial type with $g_\parallel \gg g_\perp > 2.0 = 2.26 \gg 2.09 > 2.0$ for **1** and $2.18 \gg 2.06 > 2.0$ for **2**, corresponding to their elongated tetragonal octahedral CuN_4O_2 chromophores and the $d_{x^2-y^2}$ ground state [1,2].

The electronic reflectance spectra of **1** and **2** display a weak peak centred at 17 980 and 18 120 cm^{-1} and a poorly resolved shoulder at approximately 14 790 and 15 430 cm^{-1}, respectively, which correlate well with those of the most likely related complexes $[Cu(dpyam)_2(NO_3)_2]$ (17 870, 14 700(sh) cm^{-1}) [7,30], $[Cu(dpyam)_2(H_2O)_2](SO_4)\cdot 7H_2O$ (17 520, 14 500(sh) cm^{-1}) [7] and $[Cu(dpyam)_2Br_2]$ (17 200 cm^{-1}) [31].

The IR spectrum of **1** shows a strong band splitting into two peaks at 1235 and 1210 cm^{-1} and a medium band at 625 cm^{-1}, characteristic of the $S_4O_6^{2-}$ anion with a number of hydrogen bonds involved [11,12]. The IR spectrum of the triflate group in **2** indicates lowering of symmetry from C_{3v} to C_s as expected for unidentate sulfonate coordination. In C_s symmetry, the E modes are split and nine peaks would occur [17,18]. In fact, $\nu_4(E)$ is slightly split by 20 cm^{-1} (two SO_3 stretching modes at 1250 and 1230 cm^{-1} as strong absorptions) and $\nu_5(E)$ is not split (SO_3 deformation mode at 515 cm^{-1} as a strong peak), whereas no splitting is observed for $\nu_1(A_1)$ 1020, $\nu_2(A_1)$ 745 and $\nu_3(A_1)$ 625 cm^{-1}.

3.5.2. Complex $[Cu(dpyam)_2(SO_4)]_2[Cu(dpyam)_2(H_2O)](PF_6)_2\cdot 2H_2O$ (3)

The observed ESR spectrum of **3** is axial elongated with $g_\parallel \gg g_\perp > 2.0 = 2.47 \gg 2.08 > 2.0$, attributed to two different chromophore coordination. However, this feature is consistent with an elongated tetragonal octahedral CuN_4O_2 chromophore of the complex unit B and a square-pyramidal *cis*-distorted octahedral CuN_4OO' chromophore of the complex unit A in compound **3**, and a $d_{x^2-y^2}$ ground state ($g_\parallel \gg g_\perp > 2.0$) for both chromophores [1,2].

The diffuse reflectance spectra of **3** consists of two almost equally intense peaks at approximately 10 130 and 14 970 cm^{-1}, $\Delta E = 4840$ cm^{-1}, values that are typical and comparable to those reported for the *cis*-distorted octahedral stereochemistry [25–30]. This feature corresponds to the asymmetric *cis*-distorted octahedral unit A, $[Cu(dpyam)_2(O_2SO_2)]$ in compound

3. The observed electronic spectrum of **3** does not show the typical characteristic bands of the elongated tetragonal octahedral unit B, $[Cu(dpyam)_2(H_2O)_2](PF_6)_2$ in compound **3** as its weak band is superimposed under the higher intensity peaks developed from the unit A. This conclusion can be made reasonably by comparison to the weak bands found in the closely related complexes $[Cu(dpyam)_2(H_2O)_2](SO_4)\cdot 7H_2O$ [17 520(w) and 14 500(sh) cm^{-1}] and compound **1** [17 980(w) and 14 790(sh) cm^{-1}]. With a predominated $d_{x^2-y^2}$ ground state, these two observed d–d bands are consistent with the $d_{z^2} \rightarrow d_{x^2-y^2}$ and d_{xy}, d_{yz}, $d_{zx} \rightarrow d_{x^2-y^2}$ transitions for a low-energy shoulder and a higher-energy peak, respectively.

The hexafluorophosphate ion in **3** gives two IR-active bands at 845 cm^{-1} (ν_{PF},s) and 560 cm^{-1} (δ_{FPF}, s) which are in good agreement with those reported earlier for the ionic PF_6^- ion [31], while the coordinated SO_4^{2-} ion displays a strong band (ν_3) splitting into three peaks at 1165, 1150 and 1110 cm^{-1} and a medium band (ν_4) at 620 cm^{-1} attributed to the bidentately coordinated sulfate group [32–34].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 168976, 168977 and 168978 for compounds **1**, **2** and **3**. Copies of this information may be obtained free of charge from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

We describe the complete synthesis of differently substituted multifunctional metallo phthalocyanines (MPcs) (M = Ni, Zn, Co) bearing four 2′-aminophenylsulfanyl or 2-aminophenoxy moieties and four chloro atoms on peripheral positions. The synthesis started from the corresponding anhydrous metal salts and differently substituted [4-(2′-aminophenylsulfanyl)-5-chlorobenzene-1,2-dicarbonitrile] (**2a**) and [4-(2-aminophenoxy)-5-chlorobenzene-1,2-di-carbo nitrile] (**2b**), and the products were separated by HPLC. These multifunctional amino substituents serve as strong binding sites for further reactions after phthalocyanine formation, such as Schiff-bases, and provide solubility of the phthalocyanines in organic solvents (THF, $CHCl_3$ and CH_2Cl_2). The newly synthesized compounds have been characterized by elemental analysis, FTIR, ^{1}H NMR, MS (EI and FAB), UV–Vis and atomic absorption spectroscopy. Electrochemical studies reveal that CoPc (**6a**) has two metal and four ligand-based redox processes while NiPc (**4a**) and ZnPc (**5b**) show three ligand-based reduction processes. © 2002 Elsevier Science Ltd. 1. Introduction

Over the last few years, phthalocyanine's derivatives with purpose-designed functional substituents have been receiving more frequent attention due mainly to the utility of these species in a variety of new fields, such as molecular electronics [1,2], non-linear optics [3], liquid crystals [4,5], gas sensors [6], photosensitizers [7], catalysts and semiconductive materials [8,9], photovoltaic cells [10] and electrochromic displays [11,12].

The considerable interest in these macrocycles focuses our studies to this area. So we have been investigating peripherally reactive phthalocyanines having electron donating or electron withdrawing substituents on benzenoid rings of the phthalocyanines as precursors for the development of further applications [12–15]

Incorporation of functional moieties such as 2′-aminophenylsulfanyl, 2-aminophenoxy nitro and pyridyl groups to the peripheral position of the phthalocyanines can have stronger coupling ability to the macrocyclic core than do non-reactive moieties [13,16–19]. Using this strategy, it is possible to prepare reactive compounds in which the solubility, redox and electronic properties may be varied. This makes this family of the reactive phthalocyanine molecules an interesting target for the further development of new chemical reactions on phthalocyanine complexes.

In the present work, as a further part of our previous studies on phthalocyanines with octasubstituted multifunctional substituents [13], here it has been reported that, for the first time, a reproducible procedure on the preparation and characterization of novel 4,5-differently substituted functional phthalonitrile derivatives and their metallophthalocyanines carrying both 2′-aminophenylsulfanyl or 2-aminophenoxy and chloro substituents. In the substituent reactions, 4,5-bis (2′-aminosulfanylphenyl)-1,2-dicyanobenzene (**3a**) and 4,5-

bis (2′-aminophenoxy)-1,2-dicyanobenzene (**3b**), as by-products formed during the course of the reaction, were separated from **2a** and **2b** by using HPLC preparative separation.

The functions of metallophthalocyanine derivatives are almost all based on their electron transfer properties. Thus, in this study, electrochemical analysis of **4a**, **5b** and **6a** were also carried out by cyclic voltammetric measurements.

2. Results and discussion

In the present study, nucleophilic aromatic displacement reactions have been used on either one or two chloro atoms of the 4,5-dichloro-1,2-dicyanobenzene (**1**) with the –SH or –OH function of the corresponding 2′-aminothiophenyl or 2-aminophenol nucleophiles at reflux temperature in tetrahydrofuran in the presence of Cs_2CO_3 (Scheme 1). Compounds **2a** and **2b** were separated from **3a** and **3b** by preparative HPLC. Because of the more acidic –SH groups, under similar conditions, the yields of **3a** and **2a** were found to be much greater than those of **2b** and **3b**.

In our group's previous studies when K_2CO_3 was used as a base, the chloro atoms were only partially substituted. However, in the case of Na_2CO_3 base, both chloro atoms were substituted in aliphatic structured starting materials [20,21]. Selective substitution of one of the two chloro atoms by 2-aminothiophenol or 2-aminophenol for the synthesis of **2a** and **2b** was not practical without forming **3a** and **3b** disubstituted side products in the case of the strong Cs_2CO_3 base-catalyzed reaction. According to these studies, displacement of one chloro atom might be a consequence of steric hindrance of the bulky groups, the acidic capacities of the displacement groups and the strength of the bases used in these reactions [20–22].

Scheme 1. Cs_2Co_3, thf **ii**, anhydrous quinoline or ethyleneglycol, anhydrous $NiCl_2$, $Zn(O_2CMe)_2$, $CoCl_2$.

Compounds **2a** and **2b** were converted into the desired phthalocyanines (**4a**–**6a** and **4b**, **5b**) by using anhydrous high-boiling solvents and metal salts ($NiCl_2$, $Zn(O_2CMe_2)_2$, $CoCl_2$). The blue–green cyclotetramerization products were purified by flash chromatography with sephadex in tetrahydrofuran [17,23].

In the case of **3a** and **3b**, the cyclotetramerization led to the octasubstituted phthalocyanines described in our previous studies, whereas the mixture of constitutional phthalocyanine isomers were obtained by the cyclization of **2a** or **2b** at approximately 195–200 °C in a sealed tube. Purification steps were tedious. All attempts to separate these isomers by column chromatography and also HPLC methods using different solvents were unsuccessful. Their presence were determined by a slight broadening both in ^{1}H NMR and UV–Vis spectra when compared with symmetrically octasubstituted phthalocyanines [13,20–22]. The solubilities of the zinc phthalocyanines are slightly higher than those of the others.

The structures of the phthalocyanine substances (**4a**–**6a** and **4b**, **5b**) were verified by elemental analysis, IR, ^{1}H NMR, UV–Vis and mass spectroscopy.

In the IR spectra of **2a** and **2b**, both the major strong –CN and $-NH_2$ peaks are at approximately 2220 and 3350–3450 cm^{-1} and the rest of the spectra are very similar. The most instinctive indicators of the presence of **2a** and **2b** are the signals belonging to the aromatic protons *ortho* to the cyano group in the lower field region of the ^{1}H NMR. In the phthalonitriles bearing two different substituents in 4,5-positions (**2a** and **2b**), the aromatic protons *ortho* to the –CN group appear at 7.64–7.34 and 7.78–7.47 ppm as two slightly broad singlets in the down field region of the ^{1}H NMR spectrum while broad deuterium exchangeable NH_2 protons appear at 5.33 and 5.55 ppm respectively. Also, the presence of **2a** and **2b** were confirmed by the mass spectra (EI) showing molecular ion peaks at m/z: 285.0 [M^+] and m/z: 269.0 [M^+], respectively, and the major fragment ions corresponding to the loss of Cl [$M-35]^+$, C_6H_5N [$M-93]^+$, C_6H_5NS [$M-124]^+$ and C_6H_5NO [$M-108]^+$ were identified easily.

The ^{1}H NMR spectra of the phthalocyanines bearing four 2′-aminophenylsulfanyl or 2-aminophenoxy moieties and four chloro atoms are almost identical, with small changes in shifts. The broad signals in the case of **4a**, **4b** (NiPc) rather than those in **5a**, **5b** (ZnPc) were probably due to the chemical exchange associated with

Table 1
Electronic spectral data for the phthalocyanine complexes in dimethylformamid

Compound	$\lambda_{max\ (nm)}$ (10^{-4} ε dm^3 mol^{-1} cm^{-1})			
	Q-band region		Soret region	
4a	708(11.20)	634(5.60)	440 [a](4.45)	330(14.04)
4b	670(6.85)	618(3.06)	445(3.04)	329(11.24)
5a	696(12.82)	642(4.3)		355(14.68)
5b	680(7.16)	638(3.58)		367(6.53)
6a	687(7.14)	628(3.20)		317(8.65)

[a] Shoulder.

aggregation–disaggregation equilibria which occurred at high concentrations used in the NMR measurements [13,22,24,25]. Differently substituted benzo units of the phthalocyanines result in the formation of positional isomers which in turn cause the splitting of the signals for the peripheral aromatic protons in the down field aromatic region. Slightly broad signals for Ar–NH_2 exchangeable protons of the phthalocyanines appear at 5.40 and 5.47 ppm, and disappear after addition of D_2O. ^{1}H NMR signals of the phthalocyanines (**4a**, **4b** and **5a**, **5b**) at 8.02, 7.78; 8.10, 7.85 and 8.07, 7.85; 8.17, 7.90 ppm, respectively, in the down field region of the spectrum are another indication of positional isomers.

The mass spectra by the FAB technique on the newly synthesized phthalocyanines (**5b**, **6a**) confirmed the proposed structures. Molecular ions in **5b** and **6a** were identified easily at m/z: 1143.1 $[M]^+$ and m/z: 1201 $[M+1]^+$ and as well as the fragment ions corresponding to loss of Cl $[M-35]$, C_6H_7NS $[M-124]^+$, C_6H_7NO $[M-93]^+$, $2\times C_6H_7NS$ $[M-249]^+$, $[M-Zn-1]^+$, $[M-Co\ -1]^+$.

The typical UV–Vis spectra of the phthalocyanine complexes **4**–**6** exhibited characteristic Q and B bands, one in the visible region at approximately 600–750 nm (Q-band) attributed to the π–π* transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc^{2-} ring, and the other in the UV region at 300–400 nm (B-band) arising from the deeper π-levels → LUMO transition (Table 1). In the UV–Vis absorption spectra of all phthalocyanines (**4**–**6**) in dmf, the Q-band absorptions of the π–π* transition were observed as a single band of high intensity at 708, 670, 696, 680, 687 nm, respectively. There is also a shoulder at the slightly higher energy side for each phthalocyanine. In the phthalocyanines bearing 2′-aminophenylsulfanyl moieties (**4a**–**6a**) on the periphery, the wavelengths of the maximum of the Q-bands were shifted to a lower energy as a result of the electron-donating thioether substituents compared to those of phthalocyanines bearing 2′-aminophenoxy moieties (**4b** and **5b**). The position of the soret-like π–π* bands of all phthalocyanines were slightly shifted. Any increase in the concentration results in the aggregation of the phthalocyanine molecules, which are accompanied by a blue shift of the Q-band with a decrease in intensity. The extent of aggregation is slightly stronger for phthalocyanines bearing a low number of 2′-aminophenylsulfanyl or 2-aminophenoxy moieties on the periphery than those of octasubstituent ones [13].

3. Electrochemical measurements

The voltammograms of **4a**, **5b** and **6a** were recorded at different scan rates and are presented in Fig. 1. The reduction and oxidation potentials of these complexes are summarized in Table 2. The controlled potential coulometric (CPC) studies indicated that the number of electrons transferred for all electrochemical reactions of the complexes is one.

The cyclic voltammograms of complexes **6a**, **4a** and **5b** exhibited six, three and three redox processes in the $+1.10$ to -1.80 V range, respectively. Scanning the potential to the positive side, two irreversible oxidation processes of complex **6a** at 0.620 and 0.960 V are seen, and upon scanning cathodically, two reduction peaks with the corresponding anodic waves on the reverse step and two irreversible reduction waves were recorded at -0.610, -1.263, -1.037 and -1.618 V, respectively, at 0.05 V s^{-1} scan rate.

The reduction and oxidation behavior of metallophthalocyanine derivatives is due to the interaction between the phthalocyanine ring and the central metal. The redox properties of metallophthalocyanines have been studied by many authors [26–29]. First-row transition metal phthalocyanines differ from those of the main-group metal phthalocyanines due to the fact that metal 'd' orbitals may be positioned between the HOMO and LUMO of the phthalocyanine (Pc^{-2}) ligand. This has been well established by several papers published by Lever et al. [29–31]. According to these studies, the first oxidation and first reduction processes occur on the metal center in the metal phthalocyanines only for Mn, Fe and Co derivatives. According to Lever et al., for Ni, Cu and Zn phthalocyanines, redox processes take place on the phthalocyanine ring. As understood from these studies, in the case of **6a**, phthalocyanine ring oxidation occurs after the oxidation of the cobalt center, while the ring reductions follow the reduction of the central metal. So the first oxidation at 0.620 V and the first reduction at -0.610 V are attributed to the cobalt center while other redox processes are to the phthalocyanine ring system. All redox processes recorded for complexes **4a** and **5b** are also attributed to the phthalocyanine ring system. Peak potentials and differences between the first oxidation and reduction for the cobalt center and for the phthalocya-

nine rings are comparable to those given in the corresponding papers. In the case of **6a**, the phthalocyanine ring reduction recorded at a higher negative potential than the ring reduction of **4a** and **5b**. This difference may be due to the variation in the effect of the interaction between the central metal and phthalocyanine ring. Ring oxidations of **4a** and **5b** cannot be recorded with the available solvent/electrolyte range. It may be out of the solvent windows. The difference between the first reduction and oxidation of the phthalocyanine ring was given in the range 1.7–1.8 V in different studies. In the case of **4a** and **5b** first reductions were recorded at

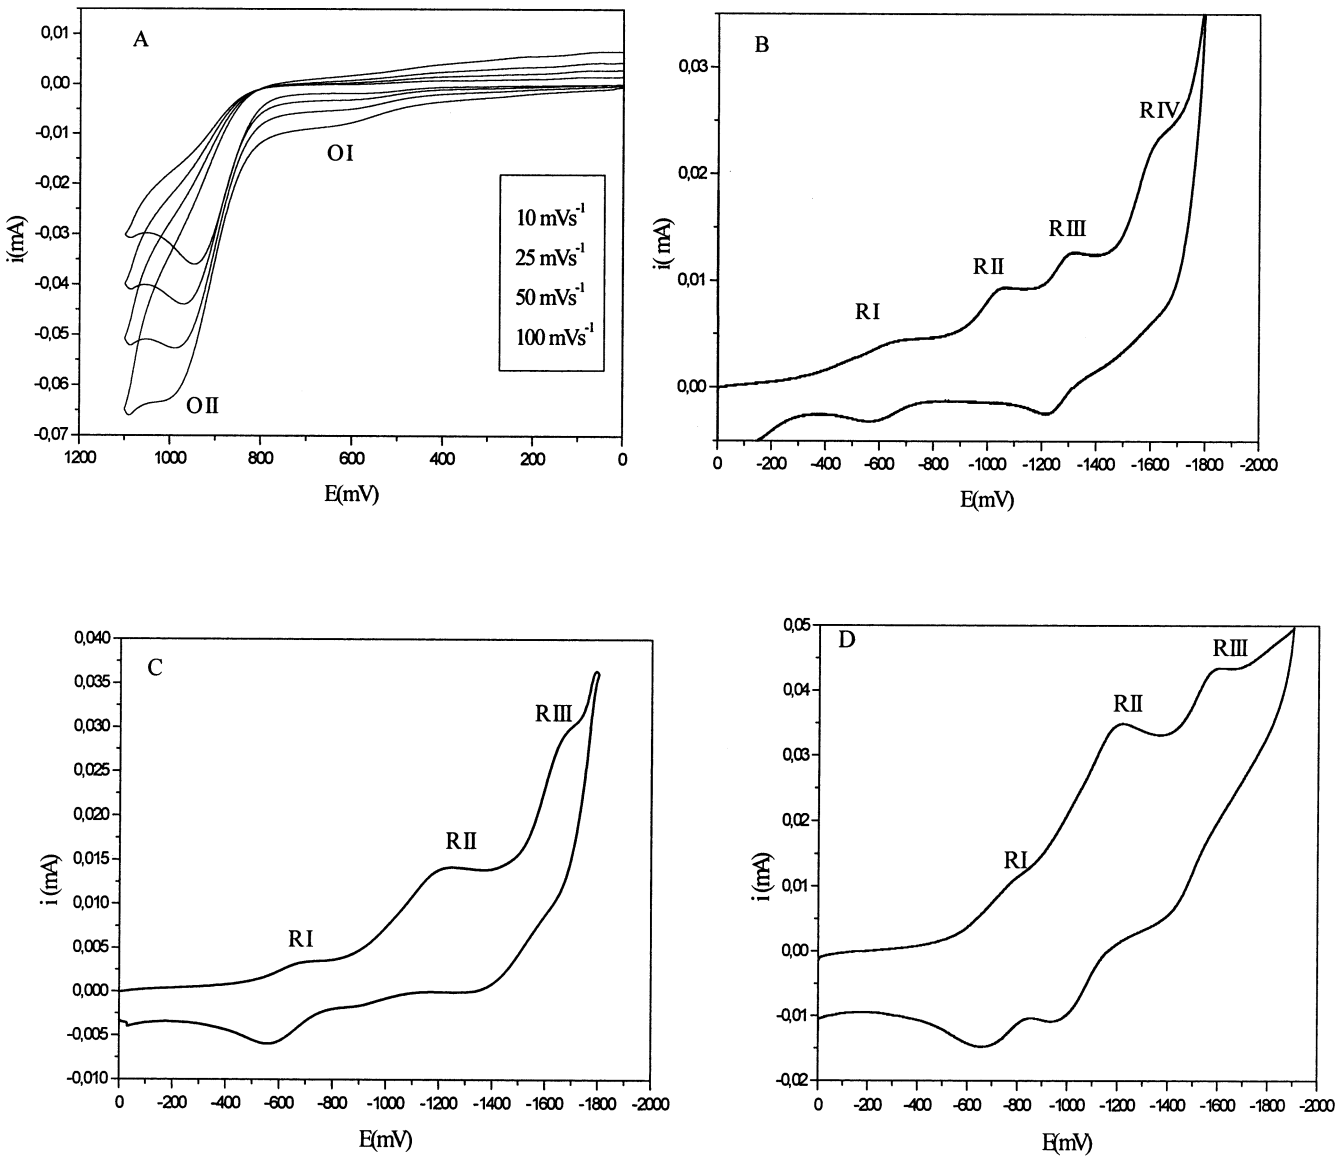

Fig. 1. Cyclic voltammograms of **4a**, **5b** and **6a** at 0.050 V s^{-1} scan rate (A and B: **6a**; C: **4a**; and D: **5b**).

Table 2

Pcs	Reduction, $E_{1/2}$ (ΔE) or E_{pc} (mV)				Oxidation, $E_{1/2}$ (ΔE) or E_{pa} (mV)	
	I. Red.	II. Red.	III. Red.	IV. Red.	I. Ox.	II. Ox.
4a	−615 (67)	−1210	−1668 (180)			
5b	−713 (63)	−1105 (112)	−1493 (73)			
6a	−609 (63)	−1037	−1263 (65)	−1618	605	950

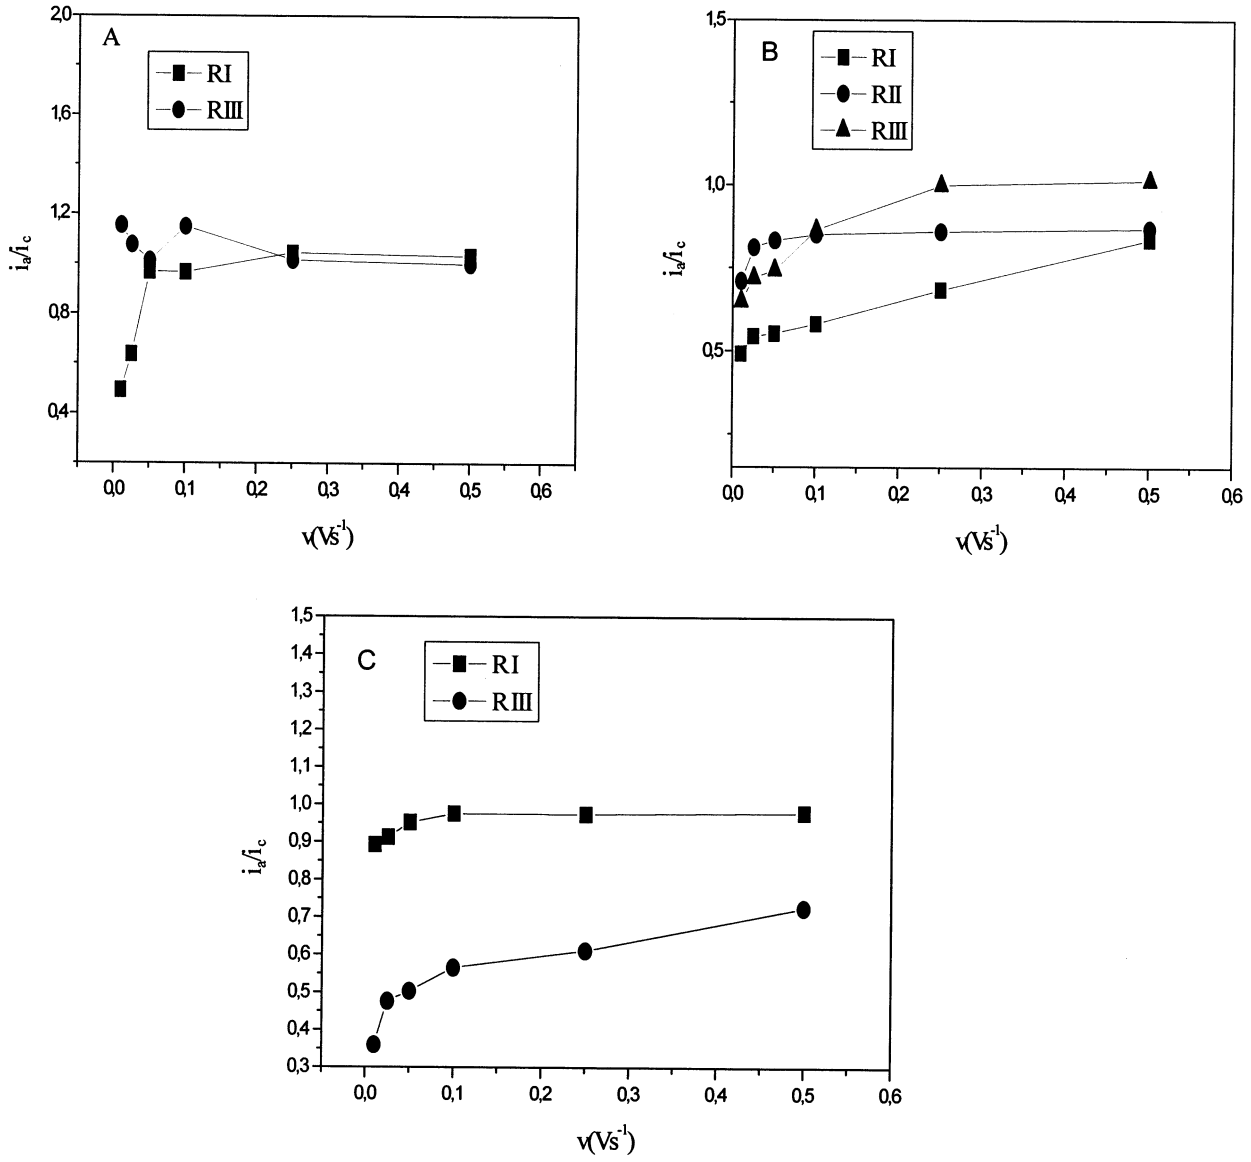

Fig. 2. The plot of $i_{pa}/i_{pc} - v$ for the reversible couple of the complexes (A: **6a**; B: **5b**; C: **4a**).

approximately -0.600 and -0.700 V, respectively. So oxidation should be observed at approximately 1.200–1.300 V which is out of our solvent/electrolyte range.

For the redox couples (peaks I and III) of **6a**, the peak separation ΔE_p, 63 and 65 mV, respectively, at 0.005 V s^{-1} scan rate, indicated that the first and third redox couples are reversible at this scan rate, but approach an irreversible case at higher scan rates (above 0.250 V s^{-1} scan rate). In the case of **5b**, at low scan rates all redox couples are reversible, but approach an irreversible case with higher scan rates. However, the third redox couple of **4b** shows quasi-reversible properties even at a very low scan rate and goes to an irreversible case at higher scan rates (Table 2). With the same approaches, the first one is also a reversible couple.

The linear dependence of the peak currents (i_{pc} (i_{pa} for oxidation)) of **6a** (except the ring oxidation process) to the scan rate is characteristic of a behavior that is associated with a diffusion process for solution species. The peak current of the ring oxidation is much bigger than the one of Co (II) oxidation and it is directly proportional to the scan rate (Fig. 1). This indicates the adsorption of the Co(II) oxidation's product on the electrode.

Fig. 2 shows the change in the ratio of the anodic to the cathodic peak current (i_{pa}/i_{pc}) of complexes **4a**, **5b** and **6a** with scan rate for the redox couples. The relationship between the i_{pa}/i_{pc} of a reversible couple with scan rate serves as a quick test for an electrochemical mechanism associated with a preceding or succeeding chemical reaction. In the case of the ratio of i_{pa}/i_{pc} at all scan rates being unity, it is a simple electron

transfer reaction. In the case of i_{pa}/i_{pc} decreasing with scan rate, it is assigned as a reversible electron transfer followed by a reversible chemical reaction. While for i_{pa}/i_{pc} increasing with scan rate, it is a chemical reaction preceding a reversible electron transfer reaction. It is shown that the i_{pa}/i_{pc} ratio is nearly unity at all scan rates for the first redox couple of **6a**. This is an indication of a simple electron transfer reaction. For redox process III, the i_{pa}/i_{pc} ratio increased with the scan rate. This indicates the existence of an irreversible chemical reaction succeeding the electron transfer reaction (Fig. 2A). The unit values of the i_{pa}/i_{pc} ratio indicated that the first couple of **4a** also shows a simple electron transfer reaction, while the third redox couple is an electron transfer reaction followed by an irreversible chemical reaction. For complex **5b**, the i_{pa}/i_{pc} ratio increased towards unity with scan rate for the first reversible couple. This indicates the existence of an irreversible chemical reaction followed by electron transfer reactions. For the other redox couples, the i_{pa}/i_{pc} ratios are near unity indicating simple electron transfer reactions.

4. Experimental

All organic solvents were dried and distilled before use. All reagents were freshly distilled or recrystallized and dried under reduced pressure before use. Melting points were determined using a Buchi melting apparatus. FTIR (KBr) were recorded on ATI a Unicom-Mattson 1000 spectrophotometer. Elemental analysis (C, H and N) was performed at the Instrumental Analysis Laboratory of TUBITAK Gebze Research Center. Electronic (UV–Vis) Absorption Spectra were recorded on a UnicamUV2 spectrophotometer. Nuclear Magnetic Resonance spectra were recorded on a Bruker (200 MHz) and Mass Spectra (IE and FAB) were recorded on a VG Zab-spectrometer. Chromatography was performed with silica gel (Merck grade 60 and sephadex) from Aldrich. The metal contents of the complexes were determined with a Hitachi 180-80 atomic absorption spectrophotometer in solution prepared by decomposition of the compounds in conc. HCI and conc. HNO_3 (3:1) solution followed by the dilution in water.

The homogeneity of the products was tested in each step by TLC (SiO_2, $CHCl_3$, DMF, methanol).

CV measurements were carried out with Princeton Applied Research Model 273 potentiostat controlled by an external PC, using the computer program HEADSTRT, utilizing a three-electrode configuration at 25 °C. ORIGIN.50 graph program was used to evaluate HEADSTRT data, to draw voltammograms and analyze them. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and was separated from the bulk of the solution by a glass bridge. The working electrode was a Pt plate with an area of 1.0 cm^2. The surface of the working electrode was polished with a H_2O suspension of Al_2O_3 before each run. Electrochemical grade 0.1 mol dm^{-3} tetrabutylammoniumperchlorate (TBAP) in extra pure DMSO was employed as the supporting electrolyte. High purity nitrogen was used for deaeration and to maintain an N_2 blanket for at least 15 min prior to each run. For controlled potential coulometric (CPC) studies, a platinum gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge, a saturated calomel reference electrode, and a model 377/12 Synchronous stirrer were used.

5. Materials and synthesis

4,5-Dicholoro-1,2-benzenedicarboxylic acid was purchased from Aldrich Chemical Co. and used as received. 4,5-Dichloro-1,2-dicyanobenzene was synthesized according to the procedure in Ref. [6], by a multi-step reaction sequence; yield 75%, m.p. 182 °C. Owing to instability of the amines **2b** and **3b**, all the preparations described below require the use of freshly prepared and purified samples of these ligands.

*5.1. 4-(2′-Aminophenyl sulfanyl)-5-chloro-benzene-1,2-dicarbonitrile (**2a**)*

2-Aminothiphenol (0.64 g, 5.1 mmol) was dissolved in 50 cm^3 dry tetrahydrofuran under nitrogen. Finely ground anhydrous cesium carbonate ($\sim$2.0 g) was added to this solution. After stirring for 0.5 h efficiently, 0.5 g (2.53 mmol) 4,5-dichloro-1,2-dicyanobenzene was added dropwise over 1 h. After the reaction mixture was stirred under nitrogen at reflux temperature for 12 h, the solution was cooled to room temperature (r.t.). Having reduced the volume of the solvent to 20 cm^3 under reduced pressure, water was added to separate any inorganic residues and the aqueous phase was extracted with chloroform (3×25 cm^3). The combined extracts were first treated with sodium carbonate (5%), then with water (3×20 cm^3) and finally dried over anhydrous sodium sulfate. The solvent was distilled off and the resulting yellow–light-brown oily residue was crystallized from toluene. The light yellow powder mixture was dissolved in a minimum amount of tetrahydrofuran and purified by preparative HPLC (on Lichrospher reverse phase-18 (5 μm)) using acetonitrile as the mobile eluent. As the first fraction 0.28 g (39%) of **2a** and as the second fraction 0.16 g (16.45%) of **2b** was obtained.

2a: m.p: 190 °C *Anal.* Calc. for $C_{14}H_8ClN_3S$: C, 58.84; H, 2.80; N, 14.71. Found: C, 59.01; H, 2.76; N,

14.26%. IR (KBr disc) ν: 2230 (–CN), 3345–3450 (Ar–NH_2); ^{1}H NMR ([d_6]-DMSO) δ: 7.64 (s, 1H, *ortho* to Cl group), 7.34 (s, 1H, *meta* to Cl), 6.90–6.62 (m, superimposed 8H, Ar–H), 5.33 (s, br, 2H, Ar–NH_2). EI/MS: m/z (%): 285.0 (25) [M^+], 249.1, 234, 217.1, 204.1, 187.0, 125, 93.1.

5.2. 4-(2′-Aminophenoxy)-5-chloro-benzene-1,2-dicarbonitrile (**2b**)

The white compound was prepared by following the same procedure as described above, starting from 0.55 g, (5.1 mmol) 2-aminophenol and (0.5 g, 2.53 mmol) 4,5-dichloro-1,2-dicyanobenzene. Crude solid was collected by suction filtration and washed copiously with cold MeOH until the washings were clear. The white–yellow product was dissolved in a minimum of thf and purified by preparative HPLC (on LiChrosorp reverse phase-18 (5 μm)) 25 × 250 mm by using acetonitrile as eluent. The first fraction was determined to be **2b** (0.14 g, 20.57%). The second band was determined as **3b** (0.09 g, 10.40%).

2b: m.p.: 178 °C, *Anal*. Calc. for $C_{14}H_8ClN_3O$: C, 62.33; H, 2.97; N, 15.58. Found: C, 62.14; H, 3.18; N, 15.02%. 5.3. 2,3,9,10,16,17,23,24-[Tetrakis (2′-aminophenyl-sulfanyl)]-tetrachloro-substituted-nickel(II) phthalocyanines (**4a**) or 2,3,9,10,16,17,23,24-[tetrakis-(2′-aminophenoxy)]-tetra-chloro-substituted-nickel(II) phthalocyanines (**4b**)

Compound **2a** (0.1 g, 0.35 mmol) or **2b** (0.07 g, 0.26 mmol) were dissolved in 0.2 cm^3 of dry quinoline in a sealed tube. Anhydrous $NiCl_2$ (0.012 g excess) was added to the reaction mixture under nitrogen atmosphere. The mixture was heated and stirred gently at 120 °C for approximately 1 h under nitrogen until the moisture was get rid of the sealed tube and then covered. After, stirring and heating for about another 3 h at 190–195 °C, the mixture was cooled to r.t. Ethanol was added to mixture in order to precipitate the crude product. The filtrated blue product was washed several times with ethanol, acetic acid and then ethanol again to remove unreacted inorganic and organic impurities (i.e. isoindoline derivative intermediates and unreacted metal salts). The crude product was further purified by acidification with HBr gas and then neutralization into the amino compound with aqueous KOH in ethanol medium. Precipitates were collected by suction of the filtrate, washed with methanol and dried in vacuo.

4a: yield 0.031g (30.72%), m.p. > 200 °C. *Anal*. Calc. for $C_{56}H_{32}Cl_4N_{12}S_4Ni$: C, 55.95; H, 2.66; N, 13.98. Found: C, 55.01; H, 2.68; N, 13.76%. IR (KBr disc) ν: 3350–3450 cm^{-1} (Ar–NH_2); ^{1}H NMR ([d_6]-DMSO) δ: 8.02 (s, 1H, *ortho* to Cl), 7.78 (s, 1H, *meta* to Cl), 7.25–6.86 (m, 16H, phenyl 4 × C_6H_4), 5.40 (s, br, 8H, Ar–NH_2).

4b: yield 0.015 g (% 20.1), m.p. > 200 °C. *Anal*. Calc. for $C_{56}H_{32}Cl_4N_{12}O_4Ni$: C, 59.10; H, 2.81; N, 14.76 Found: C, 58.84; H, 2.63; N, 14.30%. IR (KBr disc) ν: 3350–3450 cm^{-1}; ^{1}H NMR ([d_6]-DMSO) δ: 8.10 (s, 1H, C_6H_2, *ortho* to Cl), 7.85 (s, 1H, C_6H_2 *para* to Cl), 7.43–6.80 (m, 16 H, C_6H_4), 5.47 (s, Br, 8H, Ar–NH_2).

5.4. 2,3,9,10,16,17,23,24-[Tetrakis(2′-aminophenyl-sulfanyl)]-tetrachloro-substituted-zinc(II) phthalocyanines (**5a**) or 2,3,9,10,16,17,23,24-[tetrakis-(2′-aminophenoxy)]-tetrachloro-substituted-zinc(II) phthalocyanines (**5b**)

Compound **2a** (0.1 g, 0.35 mmol) or compound **2b** (0.7 g, 0.26 mmol) were dissolved in 0.2 cm^3 of anhydrous quinoline in a sealed tube under nitrogen atmosphere and ~0.017 g (0.18 5 mmol) of $Zn(OCMe)_2$ was added to the mixture. The colour of the mixture immediately turned into green–blue. The mixture was kept under nitrogen at 185–190 °C for 2 h, then the green–blue product was cooled to r.t. The subsequent procedure was carried out the same way as described in **4a** and **4b**.

5a: yield 0.025 g (24.65%), m.p. > 200 °C. *Anal*. Calc. for $C_{56}H_{32}Cl_4N_{12}S_4Zn$: C, 55.67; H, 2.65; N, 13.91. Found: C, 55.21; H, 2.58; N, 13.77%. IR (KBr disc) ν: 3350–3450 cm^{-1}; ^{1}H NMR ([d_6]-DMSO) δ: 8.17 (s, 4H, C_6H_2, *ortho* to Cl), 7.90 (s, 4H, C_6H_2 *meta* to Cl), 7.45–6.99 (m, 16H, 4 × C_6H_4), 5.65 (s, Br, 8H, Ar–NH_2); MS (FAB): m/z (%): 1143.1 (5) [M]$^+$, 1106.3 (8) [M – Cl]$^+$, 1072 [$M - 2 \times$ Cl]$^+$, 1050 [$M - C_6H_6N$]$^+$, 1033 (2), [$M - C_6H_6NO$]$^+$, 998.1 (3) [$M - C_6H_6NO$ + Cl]$^+$, 958 (3) [$M - 2 \times C_6H_6N$]$^+$, 924 (2.5) [$M - 2 \times C_6H_6NO$]$^+$, 869 (5) [$M - 3 \times C_6H_6N$]$^+$, 777.1 (10) [$M - 4 \times C_6H_6N$]$^+$, 725 (5.5) [$M - 4 \times$ C_6H_6NO]$^+$.

5.5. 2,3,9,10,16,17,23,24-[Tetrakis-(2′-aminophenylsulfanyl)]-tetrachloro-substituted-cobalt(II) phthalocyanines (6a)

Compound **2a** (0.1 g, 0.35 mmol) and anhydrous $CoCl_2$ (0.012 g, 0.083 mmol) were dissolved in 20 cm^3 of anhydrous ethylene glycol in a two round-necked bottomed flask under nitrogen atmosphere. The reaction was continued at 180 °C for approximately 6h. The dark-green–blue product formed during the reaction was poured into ethanol (30 cm^3) after cooling to r.t. to precipitate the desired product. The green–blue product was filtered off and then washed successively with water, ethanol and several times with acetic acid and finally with again ethanol. Further purification was carried out by passing HBr gas through a tetrahydrofuran solution of the product and carefully neutralized with 1 M KOH. The precipitates formed after neutralization were centrifuged, washed with ethanol and dried in vacuo. The compound is soluble in dmf, dmso, quinoline and moderately in thf.

6a: yield 0.012 g (12.07%), m.p. > 200 °C. *Anal.* Calc. for $C_{56}H_{32}Cl_4N_{12}S_4Co$: C, 55.95; H, 2.66; N, 13.98. Found: C, 55.99; H, 2.70; N, 13.44%. 6. Conclusion

The present work introduces the preparation, characterization and electrochemical properties of novel phthalocyanines, which have been peripherally substituted with four 2-aminophenylsulfanyl or 2-aminophenoxy moieties through flexible S- or O-bridges. The design strategy for functional phthalonitriles substituted by the same or different substituents is based on mainly the size and the strength of the base, and the Lewis acidity of the aromatic thiols and phenols used during the reaction. The approach described here allows us to prepare a wide number of novel phthalonitriles and phthalocyanines having mixed substituents on the periphery.

Electrochemical studies indicated that the reduction and oxidation of compounds **4a**, **5b** and **6a** were due to the interaction between the phthalocyanine ring π electron system and the central metal atoms. The voltammograms of **6a** show considerably different and interesting voltammetric behaviors compared to **4a** and **5b**, probably owning to the interaction between the cobalt ions and the platinum electrode. The absorption process occurred for the first oxidation product of the **6a**. Electrode processes of all redox reactions were diffusion controlled (except the ring oxidation of **6a**) with one-electron transfers having succeeded chemical reactions.

Synthesis and characterisation of dipyridinated magnesium phthalocyaninato(2-) complex

Jan Janczak, Ryszard Kubiak *

W. Trzebiatowski Institute of Low Temperature and Structure Research, Polish Academy of Sciences, 2 Okólna Str., P.O. Box 1410, 50-950 Wroclaw, Okolna 2, Poland

Received 17 July 2001; accepted 19 October 2001

Abstract

A new complex of dipyridinated magnesium phthalocyanine has been synthesised in crystalline form by dissolving magnesium phthalocyanine in pyridine and heating at 160 °C. The crystals are formed during the slow cooling process. $MgPc(py)_2$ crystallises in the monoclinic system, space group $P2_1/c$ with two molecules in a unit cell. The structure was solved by direct and Fourier difference methods and refined by full-matrix least-squares techniques to $R = 0.0462$, $wR = 0.1210$ and $S = 1.012$ for 3856 independent reflections and 242 refined parameters. The magnesium cation coordinates four isoindole nitrogen atoms of the almost planar phthalocyaninato(2-) ligand and axially two nitrogen atoms of pyridine molecules. The coordination polyhedron around the magnesium atom approximates to a tetragonal bypyramid with relatively long bonds between the Mg atom and the axial base ligands. The thermal analysis shows that the crystals of $MgPc(py)_2$ are stable up to ~ 180 °C, at higher temperature the release of pyridine ligands is rapid. The UV–Vis and FT–IR and Raman spectra of $MgPc(py)_2$ are discussed in relation to its structure and compared with the spectral data of magnesium phthalocyanine. © 2002 Elsevier Science Ltd. 1. Introduction

The chemistry of metallophthalocyaninato complexes (M(II)Pc) has been widely investigated [1]. Interest in these MPc complexes arise from their extensive electrochemical properties that make them useful in several fields where metalophthalocyanines find applications. Especially in the last 20 years, they have been used in industry as sensing elements, visual pigments in display devices, photochemical redox agents in solar conversion and photosensitisers for photodynamic cancer therapy [2–7]. Many of these applications depend on the nature of the metal ion incorporated at the centre of an 18π-electron phthalocyaninato(2-) macroring as well as on their solubility in a wide range solvents [8]. The studies of phthalocyanines in solutions have been hindered by their limited solubility in many solvents. Among of the four coordinate metal(II) phthalocyaninato complexes the magnesium phthalocyanine exhibits the highest solubility, especially in N- or O-donor solvents [9].

In the course of our studies of magnesium phthalocyanine we have stated, based on X-ray single crystal investigations, that in contrast to the metal(II) phthalocyaninato complexes of the metals of the d-block (Mn, Fe, Co, Ni, Cu and Zn) whose structures are stabilised by $4 + 2$ coordination of the central metal ion, MgPc in the crystal form dimerises $(MgPc)_2$ [10]. The dimers of magnesium phthalocyanine are stabilised by $4 + 1$ coordination of the magnesium ion, which is significantly deviated from the N_4-isoindole plane as a result of the intermolecular $Mg\cdots N_{azamethine}$ interaction. Additionally, we have stated that magnesium phthalocyanine in ambient atmosphere is unstable and interacting with the air molecules (O_2 as well as N_2) transforms into complexes with the composition of $(MgPc)_2O_2$ and $(MgPc)_2N_2$ [10,11]. The existence of the dimers in the crystal of magnesium phthalocyanine as subunits fully correlates with the composition of the complexes with

PII: S0277-5387(01)00988-3

dioxygen or/and dinitrogen molecules. The formation process of $(MgPc)_2X_2$ (where X = O or N) is reversible and strongly depends on the temperature. This process take place by insertion of O_2 and/or N_2 between Pc planes of the $(MgPc)_2$ moiety, since the deviated magnesium ion from the N_4-isoindole plane with an effective ~ 0.5 positive charge interacts with more electronegative atoms of O_2 or N_2 molecules [12]. Continuing the studies on magnesium phthalocyanine we have obtained a new complex of magnesium phthalocyanine with two additional pyridine molecules, which are axially coordinated to the magnesium ion.

In the present paper, details concerning the synthesis and crystal structure of $MgPc(py)_2$ are described together with its stability, vibrational and electronic properties. Additionally, the relation between five- and six-coordinated magnesium phthalocyaninato(2-) complexes is discussed. Knowledge of the structures of magnesium containing phthalocyanine and its related complexes are of considerable interest because of their relationship to chlorophyll and can aid in the understanding of photosynthesis, spectroscopy and other properties. The complete structure may be useful as the first step for a theoretical study of the excited electronic states of $MgPc(py)_2$.

2. Experimental

2.1. Preparation

The MgPc used for the synthesis of $MgPc(py)_2$ was obtained by the procedure described elsewhere [10]. The single crystals of $MgPc(py)_2$ suitable for X-ray analysis were obtained by the following procedure. About 0.2 g of powder magnesium phthalocyanine was dissolved into 25 ml of twice distilled and dry pyridine. Next, the mixture of MgPc in pyridine was inserted into an evacuated glass ampoule and heated at 160 °C for 3 h. When the MgPc was fully dissolved, the ampoule was slowly cooled (2° h^{-1}) to room temperature (r.t.). During the cooling procedure the parallelepiped violet crystals of $MgPc(py)_2$ in various sizes (0.1–2 mm) were well formed. Elemental analysis was carried out on an energy dispersive spectrometer. *Anal.* Found: C, 72.67; Mg, 3.47; N, 20.08%. Calc. for $(C_{32}H_{16}N_8)$-$Mg(C_5H_5N)_2$: C, 72.58; H, 3.77; Mg, 3.51; N, 20.14%.

2.2. X-ray data collection

A violet single crystal of $MgPc(py)_2$ having dimensions $0.38 \times 0.16 \times 0.12$ mm^3 was used for data collection on a four-circle KUMA KM-4 diffractometer equipped with a two-dimensional area CCD detector. The graphite monochromatised Mo Kα radiation ($\lambda =$ 0.71073 Å) and the ω-scan technique with $\Delta\omega = 0.75°$ for one image were used for data collection. The 960 images for six different runs covering over 90% of the Ewald sphere were performed. Initially the lattice parameters were refined on 165 reflections obtained from 40 images for eight runs with different orientations in the reciprocal space. Finally, the lattice parameters were refined by least-squares methods based on 2250 reflections. One image was monitored as a standard after every 40 images. Integration of the intensities, correction for Lorenz and polarisation effects was performed using KUMA KM-4 CCD software [13]. The face-indexed analytical absorption was calculated using the SHELXTL program system [14], max. and min. transmission factors being 0.988 and 0.962. Three thousand eight hundred and fifty-six independent reflections (a total of 10 855 reflections were integrated, $R_{int} =$ 0.0407) were used for crystal structure solution and refinement.

2.3. Structure solution and refinement

The structure was solved by direct methods using SHELXS-97 program [15]. Fourier maps calculated from the $E \geq 1.8$ gave the positions of the magnesium and most of the nitrogen and carbon atoms of the phthalocyaninato(2-) ring. The remaining non-hydrogen atoms were located successfully by difference Fourier synthesis. Initially, the structure was refined with isotropic thermal displacement parameters. The hydrogen atoms were located from the $\Delta\rho$ maps, but in the final refinement their positions were constrained using HFIX 43 with the isotropic thermal parameters of $1.2U_{eq}$ of the carbon atoms linked directly to the H-atoms. In the final refinement all non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods using the SHELXL-97 program [15]. The final unweighted and weighted agreement factors converged to $R[F^2 > 2\sigma(F^2)] = 0.0464$ and $wR(F^2) = 0.1210$, and the goodness-of-fit calculation resulted in a value of 1.012. The final difference map calculation showed no peaks of chemical significance; the largest were $+0.169$ and -0.191 e Å^{-3}. Scattering factors for neutral atoms and calculations for anomalous dispersion were as in SHELXL-97. Details of the data collection parameters, crystallographic data and final agreement factors are collected in Table 1. Selected bond lengths and angles are given in Table 2.

2.4. Spectroscopic measurements

IR spectra of the solid material (KBr pellets) were recorded at r.t. on a Bruker IFS 113 V FT–IR spectrometer (4000–400 cm^{-1}). The powder Fourier transform (FT) Raman spectrum was taken on a FRA-106 attachment to the Bruker ITS-88 spectrometer. Resolu-

tion was set to 2 cm^{-1}. A diode-pumped Nd^{3+}:YAG laser with a power of about 200 mW was used as the exciting source. Measurements of the electronic spectra were carried out at r.t. using a CARRY VARIAN/5E UV–Vis–NIR spectrometer. The UV–Vis spectra (200–1000 nm) were recorded from solution in pyridine and DMSO in 0.5 cm quartz cells.

2.5. Thermal measurements

Thermal analyses were carried out on a Lineis L81 thermobalance apparatus with Pt crucibles. Powdered Al_2O_3 has been used as a reference. The measurements on several samples have been performed under static air atmosphere on heating from r.t. to 300 °C at the heating rate of 2 °C min^{-1}.

3. Results and discussion

3.1. Synthesis and characterisation

Our preparation method of the single crystals of the dipyridinated magnesium phthalocyanine complex, $MgPc(py)_2$, presented here, is very fast and simple. A mixture of magnesium phthalocyanine with purificated pyridine was heated in an evacuated glass ampoule at 160 °C for 3 h. The molecular orbital calculations predict for the magnesium atom in magnesium porphyrin and related complexes about 0.5 positive charge [12]. This explains why during the heating process the molecule of MgPc interacts by its central magnesium atom with a lone electron pair of the nitrogen atom of the pyridine molecule. This interaction take place on both sides of the MgPc molecule and leads to the formation of the $MgPc(py)_2$ complex. During slow cooling (2° min^{-1}) violet crystals are formed. The first crystals of $MgPc(py)_2$ have been observed at about 140 °C; from this temperature point the cooling process was twice as slow (1° min^{-1}). The obtained crystals of $MgPc(py)_2$ are soluble in pyridine, DMF, DMSO an in other N- and O-donor solvents as well as in aromatic solvents like chloronaphthalene or quinoline. The complex of $MgPc(py)_2$ may also be obtained from a stirred suspension of pure MgPc in purified and dry pyridine at room temperature in approximately 2–3 days. However, at room temperature the complex of $MgPc(py)_2$ is formed only in powdered form. The elemental analysis of the powder product corresponds to the 1:2 adduct.

The crystals of $MgPc(py)_2$ are stable under dry atmosphere, but under conditions of moist atmosphere after several days they transform into a powder form. During this process, the complex of $MgPc(py)_2$ interacts

with water molecules and converts into an hydrated complex according to the equation (see Scheme 1) with the composition $MgPcH_2O{\cdot}2py$. This was proved by elemental analysis and by X-ray powder and single crystal diffraction methods. The speed of the conversion of $MgPc(py)_2 + H_2O \rightarrow MgPcH_2O{\cdot}2py$ takes place several times quicker in the solution of non-purified pyridine. It should be added that in a separate experiment part of the $MgPc(py)_2$ crystals obtained were dissolved in pyridine and then the solution was slowly evaporated to dryness in laboratory air. As a result the well described in the literature $MgPcH_2O{\cdot}2py$ crystals were obtained. Our observations are not only consistent with those observed by Fischer et al. [16] but also explain why they have obtained only the hydrated

complex from the air-exposed solution of MgPc in pyridine. Contact of $MgPc(py)_2$ with dilute acids led to demetallation, yielding metal-free phthalocyanine (H_2Pc). As can be seen from the thermogram (Fig. 1) the complex of $MgPc(py)_2$ is relatively stable up to about 180 °C. Above this temperature point the 2 equiv. $Mg–N_{(py)}$ bonds in the complex of $MgPc(py)_2$ break, giving MgPc in crystalline form. Its powder diffraction pattern indicates the β-form. There was no evidence for the formation of the 1:1 adducts (MgPcPy) by thermal dissociation. Similar observations during thermal analysis have been noticed by Cariati et al. [17] for the equivalent cocomplex ($CoPc(py)_2$). However, the $MgPc(py)_2$ complex is much more stable, since the sharp thermal dissociation of both pyridine molecules take place at the temperature about 80 °C higher than in $CoPc(py)_2$.

3.2. Description of the structure

The molecular structure of the centrosymmetric dipyridinated magnesium phthalocyaninato complex is illustrated in Fig. 2. In contrast to the molecular structure of MgPc in which the magnesium cation is significantly displaced (~ 0.5 Å) from the plane defined by four *N*-isoindole atoms of the Pc(2-) ring [10], in this dipyridinated complex the magnesium cation lies closely on the N_4-isoindole plane. The phthalocyaninato(2-) macroring is almost planar. The greatest deviations from the N_4-isoindole plane are observed for the outermost carbon atoms of the phenyl rings; the displacement of C12 and C13 are equal to 0.12(1) and 0.11(1) Å, while C4 and C5 are displaced only by 0.02(1) and 0.03(1) Å, respectively. The two nitrogen atoms of the pyridine molecules are coordinated by

their lone electron pair to the magnesium atom with an effective ~ 0.5 positive charge forming a deformed octahedral complex. The sp^3d^2 hybridisation of the magnesium atom orbitals accommodates six donor nitrogen atoms, four of which are from the phthalocyaninato(2-) macroring and two of which belong to the pyridine molecules. The planes of the pyridine molecules are almost perpendicular to the phthalocyaninato(2-) ring and are positioned above and below this plane. Thus, the coordination polyhedron around the magnesium cation approximates to a tetragonal bipyramid with relatively long bonds between the magnesium atom and the axial base ligands. The four $Mg–N_{iso}$ bonds are shorter and almost equal, while the two axial $Mg–N_{py}$ bonds are longer by ~ 0.37 Å. Thus, the magnesium atom has $4+2$ coordination. A similar correlation between the short and long M–N bonds can be found in the cobalt phthalocyaninato(2-) complex with two axially coordinated molecules of 4-methylpyridine ($Co–N_{iso} \sim 1.94$ and $Co–N_{4Mepy} \sim 2.32$ Å) [18]. In the Co(II) complex with axially coordinated 4-methylpyridine molecules, the longer axial Co–N bond is likely to be due to an unpaired electron which is essentially localised on the d_z^2-orbital of the Co^{2+}. In the absence of this electron, as in an axially coordinated Co(III) porphyrin complex, both axial Co–N bond lengths decreases to ~ 1.94 Å [19]. The strength of the axial M–N bonds in Mg and Co complexes correlate with their stability as was mentioned above. A similar relation between the bonds of Mg–N in plane and perpendicular to the plane can be found in the crystal structures of $4+2$ coordinated porphyrinato(2-) complexes [20–22]. The difference in the Mg–L bond lengths in plane and perpendicular to the plane are significantly smaller in magnesium phthalocyaninato complexes in which the axial ligands are coordinated by oxygen atoms of methanol, water or 2-methoxyenthanol molecules [23–25]. This is likely due to the steric hindrance from the structural environment of the non-bonding contacts, which play an important role in the dipyridinated magnesium phthalocyaninato(2-) complex.

All C–C and C–N bond distances (Table 2) of the phthalocyaninato(2-) ring in $MgPc(py)_2$ are normal in the sense that their values are not very different from the corresponding values found in the various metallophthalocyaninato complexes [26,27]. However, it should be noted that the good accuracy of the present structure determinations and relatively small standard deviations indicate that differences between the average values of $C–N_{iso}$ (1.367(2) Å) and $C–N_{aza}$ (1.343(2) Å) are observable. These differences indicate an accumulation of charge density on the bridged aza-nitrogen atoms as well as on the outer carbon atoms of the pyrrole rings and therefore can be explained by an important electron donation from the free-electron pair of the pyridine nitrogen atom to the magnesium hybrid orbital. A similar correlation between the $C–N_{iso}$ and $C–N_{aza}$ bond lengths can be found in the crystals of other metallophthalocyaninato complexes [28], but no comment was made on this fact.

The orientation of the coordinated pyridine plane relative to the phthalocyaninato(2-) macroring is well described by the torsion angle of N1–Mg1–N5–C17. The rotation of the pyridine ligand around the Mg1–N5 axis would reduce the steric effect, i.e. the non-bonding distances between the carbon or hydrogen atoms of the axial pyridine ligand in *ortho* positions and the atoms of the phthalocyaninato(2-) macrocycle. In particular, if the rotation angle is equal to zero, the pyridine plane is parallel to the Mg1–N1 bond (or the equivalent position rotated by 90° where the pyridine plane is parallel to the Mg1–N3 bond) making the non-bonding C–C distances greater than 3 Å and the C–H distance greater than 2.5 Å. The second orientation (the rotation angle being 45°) makes the axial pyridine ligand plane parallel to the $Mg1–N_{aza}$ axis and reduces the non-bonding distance between the azamethine nitrogen atoms of the Pc(2-) ring and the hydrogen atoms of pyridine molecule in the *ortho* positions. This conformation of $MgPc(py)_2$ is the most stable conformation, since the greatest interactions between the *ortho* H-atoms of pyridine molecules and the N_{aza} atoms of Pc(2-) exist. The intermolecular interactions and crystal packing force present in the crystal makes the rotation angle of the axial pyridine plane have a value of 26.6(2)°. The architectural arrangement of the $MgPc(py)_2$ molecules in the unit cell is illustrated in Fig. 3. The structure is composed of isolated $MgPc(py)_2$ molecules, which form alternating sheets. In one sheet the planes of the Pc(2-) macrorings are parallel to each other while between the sheets the Pc(2-) planes are perpendicular. In one sheet the neighbouring molecules have two overlapping phenyl rings which are separated by about 3.38(2) Å. This value is comparable to the van der Waals distance (~ 3.4 Å) for aromatic carbon atoms and indicates weak interactions between the delocalised π-electron systems [29].

3.3. UV–Vis spectroscopy

Fig. 4 shows the UV–Vis spectra of the dipyridinated magnesium phthalocyaninato(2-) complex in solution in pyridine (a) and in DMSO (b). The experimentally observed electronic bands are collected in Table 3, which also comprises the electronic bands for the vapour-phase absorption spectrum for MgPc as well as those calculated for magnesium phthalocyanine. The UV–Vis spectra of solid and vapour-phase metal(II) phthalocyanines as well as for MgPc have been reported several times [30–34]. In the metal(II) phthalocyaninato(2-) complexes several theoretical calculations

predict five distinct electronic bands in the spectral region between 200 and 800 nm [35–37]. The description of the bands for porphyrin have been labelled as C, L, N, B and Q [32]. We adhere to this convention in explaining our results. The spectra of $MgPc(py)_2$ recorded in both solvents are very similar. However, the electronic bands recorded in DMSO are slightly hypsochromic shifted in relation to the spectrum recorded in pyridine. It is generally known that for a given phthalocyanine its Q-band appears at a shorter wavelength in non-aromatic solvents and at a longer wavelength in aromatic solvents [38]. The Q-band corresponds to the excitation between the HOMO—A_{1g} ground state ($(a_{1u}^2)(\pi)$) and the degenerate LUMO ($e_g(\pi^*)$)—the first excited singlet state which has E_u symmetry, from the ($a_{1u}^1 e_g^1$) configuration. As can be seen from Fig. 4 in both solvents the Q-band of the $MgPc(py)_2$ complex exhibits splitting, which has been mentioned in the literature and labelled as Q_1 and Q_2 [39,40]. The splitting value of the Q-band in $MgPc(py)_2$ is equal to about 65 nm and is likely due to the vibronic coupling in the excited state as suggested in the literature [41–43]. In the spectral region between 550 and 750 nm for the spectra of $MgPc(py)_2$ in both solvents, besides the two distinctly separated Q_1 and Q_2 bands, a shoulder is observed. This shoulder between the Q_1 and Q_2 bands is also observed in the vapour-phase spectrum of magnesium phthalocyanine [32]. The Q_1 and Q_2 bands observed on the $MgPc(py)_2$ spectra are slightly shifted in relation to the MgPc spectrum and can be attributed to the substitution effect of axially coordinated pyridine molecules. The B band region is more complicated. The B (or Soret) band is associated with the excitation between the $1a_{2u}(\pi)$ and the $1e_g(\pi^*)$ states. In addition to the B band, two other bands at lower wavelengths, have been observed. The N band results mainly from a transition $b_{2u}(\pi) \rightarrow e_g(\pi^*)$ while the L band results from a combination of $a_{2u}(\pi) \rightarrow e_g(\pi^*)$ and $b_{2u}(\pi) \rightarrow e_g(\pi^*)$ transitions.

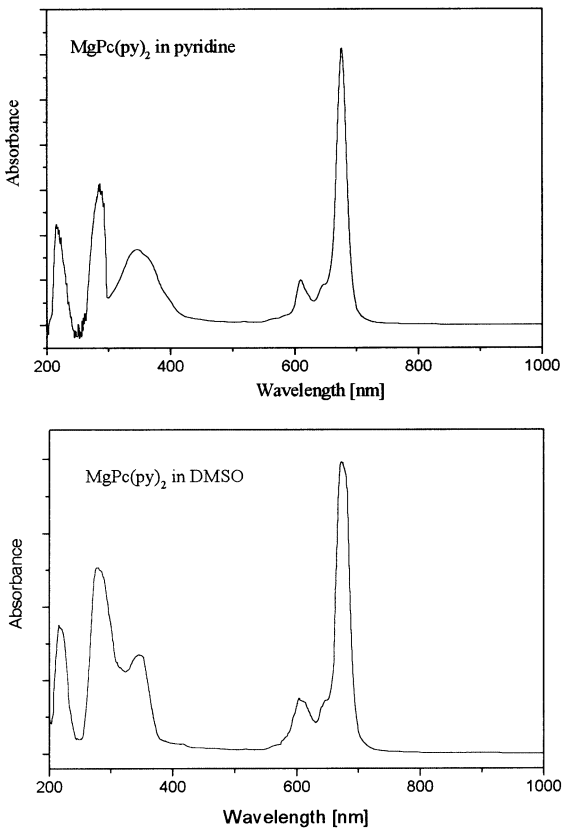

Fig. 4. UV–Vis spectrum of $MgPc(py)_2$ complex in pyridine (a) and in DMSO (b).

3.4. Vibrational spectroscopy

The equilibrium geometry of the $MgPc(py)_2$ molecule can be assumed to have a D_{2h} point group symmetry. Each $MgPc(py)_2$ molecule contains 79 atoms and 231 normal vibrational modes. The number of fundamentals of each irreducible representation are: $\Gamma = 39A_g + 31B_{1g} + 24B_{2g} + 20B_{3g} + 17A_u + 28B_{1u} + 35B_{2u} + 39B_{3u}$. IR active modes include $28B_u + 35B_{2u} + 39B_{3u}$ vibrational fundamentals, while Raman active modes include $39A_g + 31B_{1g} + 24B_{2g} + 20B_{3g}$. Seventeen modes with A_{1u} symmetry are inactive. Despite this large number of vibrational fundamentals the IR and Raman spectra of this dipyridinated magnesium phthalocyanine complex are composed of a small number of fundamentals as shown in Figs. 5 and 6. The positions of the most prominent IR and Raman bands are listed in Tables 4 and 5, respectively. The spectral data of MgPc are also

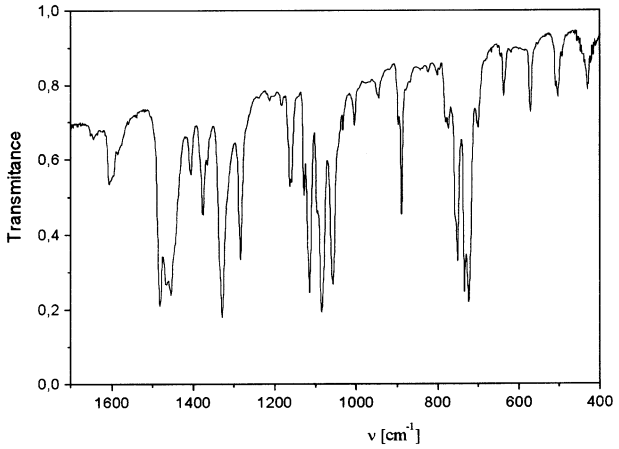

Fig. 5. Infrared spectrum of $MgPc(py)_2$ complex.

listed in the tables for comparison. The vibrational assignment of the observed IR and Raman bands can be discussed in terms of the following groups: vibrations of the macrocycle, isoindole moieties, axial pyridine ligands, C–H bending and magnesium–nitrogen vibrations.

The main IR bands correspond to the characteristic vibrations of the phthalocyanine molecule as well described in the literature for metal-free phthalocyanine and M(II)Pc complexes. In the spectral region 1500–1400 cm^{-1}, the spectrum of $MgPc(py)_2$ shows four slightly overlapped bands at frequencies of 1445, 1456, 1467 and 1482 cm^{-1}, while in the IR spectrum of MgPc in this spectral region only two bands at 1451 and 1479 cm^{-1} are observed [44,45], thus the bands at 1445 and 1467, as suggested Stymme et al. [46], could be attributed to the axially coordinated pyridine molecules. This assignment is also supported by the fact that relative strong intensity bands at about 1436 and 1478 cm^{-1} are observed in the IR spectrum of pyridine and several metallodipyridinated complexes [47]. The bands in the spectrum of $MgPc(py)_2$ at 1215, 1160, 1096 and 1033 cm^{-1} could be attributed to the axially coordinated pyridine molecules, since in this spectral region several other metallodipyridinated complexes have also displayed four bands at about 1215, 1160, 1070 and 1035 cm^{-1} [47]. The spectral region from 900 to 800 cm^{-1} shows two bands; one much more intense at 890 cm^{-1} attributed to a γ(C–H) vibration (also present in the IR spectrum of MgPc) and the second at

[a] v, very; s, strong; m, medium; w, weak.

898 cm^{-1} is attributed to the C–H out-of-plane vibration of axially coordinated pyridine molecules. In the last region, below 800 cm^{-1}, besides the bands also observed in the spectrum of MgPc ($\sim$775, 724, 638, 572, 504 and 431 cm^{-1}), two intense bands at $\sim$752 and 734 cm^{-1} and one weaker band at 701 cm^{-1} associated with the coordinated pyridine are observed. Comparing the IR spectrum of $MgPc(py)_2$ complex with the spectrum of MgPc we can see that they are very similar, excluding the bands attributed to the axially coordinated pyridine molecules as well as any reduction in vibrational degeneracy of the parent complex.

The most intense Raman band is observed at 1499 cm^{-1}. This band is assigned to the symmetric stretching vibration of the C_β–C_β bonds in the pyrrole groups.

The corresponding vibration in the Raman spectrum of MgPc complex is observed at 1506 cm^{-1} [48–50]. This assignment is supported by the fact that the corresponding vibration in the Raman spectrum of free indole is observed at 1509 cm^{-1} with a relative strong intensity [51]. In the Raman spectrum of metal-free phthalocyanine two bands are observed in this spectral region (1513 and 1534 cm^{-1}) [52]. The band at 1513 cm^{-1} assigned to the C–N stretching is not observed in the Raman spectrum of metallophthalocyanines [48–50]. Frequencies in the region $\sim$1400 cm^{-1} (1424 and 1448 cm^{-1}) could be attributed to the C–N stretching vibrations. The X-ray crystallographic studies showed that the aza C–N bonds with the average distance of 1.344(3) Å are shorter than the isoindole C–N bonds (average distance of 1.369(3) Å); thereby the stretching vibration of the aza group is expected at higher frequency than the C–N stretching vibration of the isoindole group. Thus, the band at 1448 cm^{-1} should be attributed to the C–N aza stretching vibration and the band at 1424 cm^{-1} to the C–N isoindole stretching vibration. The Raman band at 1341 cm^{-1} is a characteristic feature of the phthalocyaninato ring. It is assigned to the C_α–C_β stretching vibration of the pyrrole groups. This characteristic vibration is also present in the Raman spectrum of indole (at 1352 cm^{-1}) [51]. The breathing stretching vibration of pyrrole groups is ob-

served at 1143 cm^{-1}, while in MgPc it is at 1141 cm^{-1} and the corresponding breathing vibration of the benzene rings is observed at 947 cm^{-1} (for MgPc at 945 cm^{-1}). The Raman bands at 585 and 482 cm^{-1} in the spectrum of $MgPc(py)_2$ could be attributed to the deformation of the isoindole moieties. The equivalent Raman bands in the spectrum of MgPc are observed at 588 and 481 cm^{-1} [48,49]. The C–H in-plane bending vibrations of the isoindole groups are observed at 1024 and 1107 cm^{-1} and in the Raman spectrum of MgPc at 1030 and 1106 cm^{-1}. Similar frequencies are observed in the spectrum of metal-free phthalocyanine [52]. The $Mg–N_{isoindole}$ vibration in the Raman spectrum of $MgPc(py)_2$ is observed at 247 cm^{-1} while in the Raman spectrum of MgPc it is at 221 cm^{-1} [48,49]. A higher frequency value for the dipyridinated magnesium complex than that in MgPc is indicative of a stronger coordination, i.e. a larger force constant value. This relation is fully consistent with the X-ray single crystal structure analysis of $MgPc(py)_2$ described here and the structure of MgPc [10]. The $Mg–N_{isoindole}$ bond length in the $MgPc(py)_2$ complex is shorter (2.006(2)) Å, greater value of the force constant) than in the MgPc complex (2.026(2) Å). The Raman bands at 1320, 1181, 1156, 1112 and 947 cm^{-1} are associated with the vibrations of the axially coordinated pyridine molecules, since they are not observed in the Raman spectrum of MgPc [48,49].

4. Conclusion

Our investigations showed that the dipyridinated magnesium phthalocyanine complex could only be obtained by a solving MgPc in purified and dry pyridine. The crystals of $MgPc(py)_2$ (4 + 2 coordinated complex) are stable under dry atmosphere, while under moist conditions the $MgPc(py)_2$ complex interacts with water molecules and converts into 4 + 1 coordinated complex of $MgPcH_2O{\cdot}2py$, in which the water molecule is apically coordinated to the Mg atom and the pyridine molecules as solvated molecules are involved as acceptors in O–H···N hydrogen bonds. The $MgPc(py)_2$ complex is moderately stable up to about 180 °C. At higher temperatures $MgPc(py)_2$ loses both pyridine molecules and MgPc transforms into β-modification. This observation is in agreement with the vibrational spectroscopic data, which shows that most of the high intensity peaks of free pyridine are also seen with only minor shifts or splittings in the spectrum of $MgPc(py)_2$ complex. This fact indicates that the pyridine molecules are coordinated to the MgPc molecule without forming strong bonds. However, the Mg–N(pyridine) bonds in $MgPc(py)_2$ complex are much stronger than Co–N(pyridine) bonds in the equivalent dipyridinated cobalt phthalocyanine complex, which is stable only up to ~100 °C [17]. Additionally, we have not observed any evidence for the existence of the 1:1 complex (MgPcpy) as was suggested in the literature [45].

5. Supplementary material

Additional material comprising of atomic coordinates, anisotropic thermal parameters, a full list of bond lengths and angles for the $MgPc(py)_2$ complex have been deposited with the Cambridge Crystallographic Data Centre in CIF format as supplementary publications no. CCDC 166120. Abstract

The synthesis of a new platinum(III) 'lantern-shaped' complex with amidate bridging ligands, $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$ (**1**), is described. Complex **1** has been structurally characterized by X-ray diffraction and compared with the related compound $[Pt_2I_2\{N(H)C(Me)O\}_4]$ (**2**). The two complexes exhibit very short N···O bite distances which are similar in the two cases but the Pt(III)–Pt(III) distance is significantly shorter in **1** than in **2**. © 2002 Elsevier Science Ltd. Keywords: Platinum(III) compounds; Lantern-type complexes; Amidate bridging ligands; X-ray structure

1. Introduction

Dinuclear platinum(III) complexes represent a topic of intense research not only from a theoretical point of view but also for their potential use in catalysis and biomedicine [1–4].

Starting from the early discovery of elusive platinum-blue materials [5], various types of amides and amidates have been used as terminal and bridging ligands, respectively [6]. In particular, the use of terminal amide ligands allowed the synthesis of the first Pt(III) dimer unsupported by covalent bridges [7,8]. A great number of platinum(III) dimers supported by two amidate bridges has been reported ([1,2] and references therein), in contrast the synthesis of platinum dimers with four bridging amidate ligands proved to be much more difficult and was accomplished only recently. The first fully characterized 'lantern-type' platinum(III) dimer with amidate bridging ligands was $[Pt_2I_2\{N(H)C(Me)O\}_4]$ (**2**) and it contains four acetamidate bridges and two axial iodo ligands [9]. In this paper, we report on the synthesis and X-ray structural characterization of a corresponding complex with chloro ligands in the axial positions, $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$ (**1**), for which the Pt–Pt distance has been found to be even shorter than in the previous case.

2. Experimental

2.1. Synthesis

2.1.1. Preparation of $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$ (1)

K_2PtCl_4 (445 mg) and K_2PtCl_6 (522 mg) were dissolved in water (40 ml) and treated with an excess of pivaloamide (6.30 g). The reaction mixture was kept under stirring for approximately 16 h at 90 °C. A sticky black precipitate separated from the solution. The solution was filtered off keeping the temperature high and the solid residue carefully washed with hot water to remove unreacted pivaloamide. The solid was then extracted with acetone and the solution evaporated to dryness in a rotary evaporator. The solid residue was transferred on a filter, washed twice with small quantities of ether (the washing ether became

PII: S0277-5387(01)00992-5

blue in color) and dried. The light-green solid can be crystallized from acetone–water to yield a mixture of yellow and green crystals. The two types of crystals differ for the solvent of crystallization they incorporate, which can be either acetone (one molecule of solvent per molecule of Pt dimer, light green crystals) or water (1.5 molecules of solvent per molecule of Pt complex, yellow crystals). *Anal.* Calc. for $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]\cdot COMe_2$, $C_{23}H_{46}Cl_2N_4O_5Pt_2$: C, 30.0; H, 5.0; N, 6.1. Found: C, 30.4; H, 4.9; N, 5.9%.

2.1.2. Preparation of $[Pt_2Cl_2\{N(H)C(Me)O\}_4]$ (3)

K_2PtCl_4 (500 mg) and K_2PtCl_6 (590 mg) (molar ratio 1:1) were dissolved in water (25 ml) and treated with an excess of acetamide (3 g). The reaction mixture was kept under stirring for approximately 6 h at 90 °C. A yellow solid precipitated from the solution. The solution was filtered and the solid residue was carefully washed with water to remove unreacted acetamide, and dried. This product resulted to be insoluble in most solvents and was characterized only by IR and elemental analysis. *Anal.* Calc. for $[Pt_2Cl_2\{N(H)C(Me)O\}_4]\cdot 2H_2O$, $C_8H_{20}Cl_2N_4O_6Pt_2$: C, 13.2; H, 2.8; N, 7.7. Found: C, 12.5; H, 2.3; N, 7.7%. Fedova et al. [10] who first prepared this product by a similar procedure concluded that it had a lantern-shaped structure on the bases of XPS, IR and analytical data. No information about the isomer type was given.

2.1.3. Preparation of $[Pt_2I_2\{N(H)C(Me)O\}_4]$ (2)

This compound was obtained from the previously described chloro-complex by metathesis of the axial ligands. In a typical experiment 0.060 g of the chloro-complex, $[Pt_2Cl_2\{N(H)C(Me)O\}_4]\cdot 2H_2O$, were suspended in 5 ml of water, 0.500 g of KI were added and the reaction mixture heated at 90 °C for about 10 min, meanwhile the color turned red–brown. The filtered mother liquor, kept at 4 °C in a refrigerator, afforded red crystals of the desired compound. *Anal.* Calc. for $[Pt_2I_2\{N(H)C(Me)O\}_4]\cdot 8H_2O$, $C_8H_{32}I_2N_4O_{12}Pt_2$: C, 9.4; H, 3.2; N, 5.5. Found: C, 8.9; H, 2.9; N, 5.3%.

Table 1
Crystal data for $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]\cdot 1.5H_2O$

Empirical formula	$C_{20}H_{40}Cl_2N_4O_4Pt_2\cdot 3/2H_2O$
Formula weight (g mol^{-1})	888.66
Wavelength (Å)	1.54178
Crystal system	monoclinic
Space group	$C2/c$
a (Å)	11.364(5)
b (Å)	15.767(7)
c (Å)	18.573(9)
β (°) [$\alpha = 90°$, $\gamma = 90°$]	98.45(7)
V (Å^3)	3292(3)
Z	4
D_{calc} (g cm^{-3})	1.793
Absorption coefficient (mm^{-1})	17.434
$F(000)$	1700
Crystal size (mm)	$0.12 \times 0.08 \times 0.06$
2θ max (°)	60.02
Reflections collected	2625
Independent reflections	1560 ($R_{int} = 0.0377$)
Data/restraints/parameters	1534/0/90
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.078$, $wR_2 = 0.20$
Goodness-of-fit on F^2	1.056
Largest difference peak and hole (e Å^{-3})	3.109 and −3.631

2.2. X-ray crystal structure determination

2.2.1. $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$

Yellow crystals of **1** were obtained by crystallization from acetone–water. The intensities were collected at 293(2) K on a Philips PW 1100 four-circle diffractometer operating in the θ–2θ scan mode, using Cu Kα monochromatized radiation ($\lambda = 1.54178$). Crystal data for compound **1** are reported in Table 1.

The structure was solved by direct methods, using the SHELXTL NT program [11], completed by subsequent difference Fourier syntheses, and refined by full-matrix least-square procedures on F^2 with the SHELXL-93 program [12]. The platinum, chlorine, O(1) and O(2) atoms were anisotropically refined, while the remaining atoms necessitated isotropic treatment in order to maintain satisfactory thermal displacement parameters. Refinement of the crystal structure was severely hampered by many factors. The crystal batch had inherent handling difficulties, but repeated attempts to obtain higher quality crystals were unsuccessful. The only remotely suitable sample, a very small gem-like block, for a single-crystal structure determination was substandard. The peaks were broad and the diffracting ability of the sample fell off rapidly with increasing Bragg angle and most of the higher angle data collected (up to $\theta = 60°$) were flagged as weak and bore negative intensities. As a consequence of the poor data set (2625 reflections), convergence was inhibited, but improved by omitting reflections with negative intensity from the final refinement cycles. In addition, the crystal was sensitive towards X-rays and decomposed after prolonged irradiation, as shown by the severe decay (up to 40%) in intensity of the three reference reflections throughout the data collection. Moreover, as there were no identifiable faces and no reflections of high intensity at χ approximately 90°, correction for absorption effects was not applied. The final R factor was 0.078, wR_2 was 0.200 and the goodness-of-fit was 1.056 for all 1534 observed ($I > 2\sigma(I)$) reflections, the number of parameters was 90. As expected, the final Fourier-difference map did show four major peaks (up to 3.1 e Å^{-3}), approximately 1.1 Å far from the Pt atom. Although bond distances and angles are affected by relatively high standard deviations, the structural analysis did attain the configuration of the organic ligands attached

Table 2
Selected bond lengths (Å) and angles (°) for $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$

Bond lengths			
Pt–PtA [a]	2.448(2)	Pt–O(2)	2.06(2)

to the platinum centers and selected bond lengths and angles are listed in Table 2.

2.3. Physical measurements

Elemental analyses were obtained by an Elementar Analyzer mod. 1106 Carlo Erba instrument. IR spectra were recorded on a spectrophotometer Perkin–Elmer Spectrum One using KBr pellets, ^1H and ^{195}Pt NMR spectra were recorded on a Bruker Avance DPX 300 WB spectrometer.

3. Results and discussion

3.1. $[Pt_2I_2\{N(H)C(Me)O\}_4]\cdot 8H_2O$

The X-ray crystal structure of **2** was solved by Fedotova et al. [9].

The asymmetric unit included a quarter of complex **2** and two independent water molecules. The two crystallographically independent water molecules were randomly disordered (with a refined occupancy factor of 0.50(5)), and gave rise to a complex network of hydrogen-bonds which serve to stabilize the crystal edifice.

The X-ray study showed one symmetrical isomer for complex **2** and, as a consequence, the ^1H NMR spectrum was expected to exhibit one signal for NH's and one signal for the methyl groups. In contrast, the ^1H NMR spectrum of a sample of **2** prepared by a similar procedure showed four NH's signals at 6.02, 5.62, 5.53 and 5.41 ppm. The intensity ratios between the signals at 6.02, 5.62 and 5.41 ppm were 2:1:1, respectively; moreover this intensity pattern remained constant in different samples in which, however, the intensity of the peak at 5.53 ppm, with respect to the previous set of three signals, had changed. Therefore, it is most likely that the set of three signals belongs to the same compound in which one Pt(III) atom has N_3O coordination of the four bridging amidates and the second Pt(III) atom has NO_3 coordination. For such an asymmetric isomer only two out of the four bridging amides are equivalent and therefore three signals of 2:1:1 intensity ratios, are expected. The fourth signal at 5.53 ppm must belong to a symmetrical isomer having N_2O_2 coordination of the amidates for both Pt(III) units. The presence of two isomers, one symmetrical and one non-symmetrical was confirmed by the ^1H resonances in the region for the methyl groups. Three methyl signals were observed at 2.19, 2.18, and 2.15 ppm. A NOESY spectrum proved that two NH's signals (at 5.62 and 5.53 ppm) couple with the signal at 2.18 ppm, which therefore must be the sum of two separate methyl signals. Therefore, it is possible to assign the signals at 2.19 and 2.15 ppm, and a portion of the signal at 2.18 ppm (intensity ratio between signals at 2.19 and 2.15 ppm of 1:2) to the asymmetric isomer and the remaining portion of the signal at 2.18 ppm to the symmetric isomer.

In principle two types of symmetrical isomers are possible, one with *cis* and one with *trans* geometry. There is no way for distinguishing between the two geometries on the basis of NMR data, but the X-ray structure has shown the geometry to be *cis*.

The ratio between the symmetrical and the non-symmetrical isomers was different for different samples while, for a given sample, the intensity ratios remain constant with time. Therefore, it is possible to conclude that there is no fast interconversion between the two isomers. It is rather surprising that the symmetrical isomer, which is the only one obtained in crystalline form, is generally the less abundant in solution.

The starting chloro-complex **3** from which **2** is obtained by substitution of iodide for chloride, is insoluble in most solvents. Therefore, it is not possible to decide if it is a mixture of different isomers, as shown for **2**, or, alternatively, it is a single isomer which

partially isomerizes during the halide ion metathesis and dissolution processes.

3.2. $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$

Complex **1** crystallizes incorporating molecules of solvent. This can be either acetone (light green crystals, IR absorption band at 1710 cm^{-1}) or water (yellow crystals). The X-ray analysis of the yellow crystals showed the presence of 1.5 molecules of water per molecule of complex.

The asymmetrical unit comprises half a molecule of the diplatinum complex and the structure is generated by the inversion center ($\frac{1}{4}$, $\frac{1}{4}$, 0) at the midpoint of the Pt–Pt bond (Fig. 1). Around the Pt_2Cl_2 stick are located four uninegative ligands, producing the 'lantern-shaped' structure. The Pt–Pt distance (2.448(2) Å) (Table 2) is very short and second only to the Pt(III)–Pt(III) distance observed in the quadruply bridged acetate complex $[Pt_2(H_2O)_2\{OC(Me)O\}_4]^{2+}$ for which the Pt(III)–Pt(III) distance is 2.390(1) Å [13].

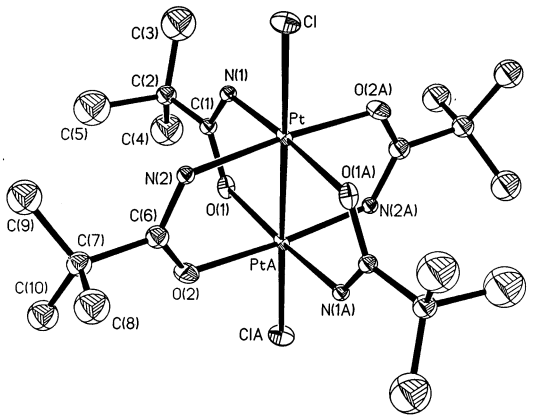

Fig. 1. View of the complex $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$ (**1**). The suffix **A** denotes atom at $\frac{1}{2}-x$, $\frac{1}{2}-y$, $-z$.

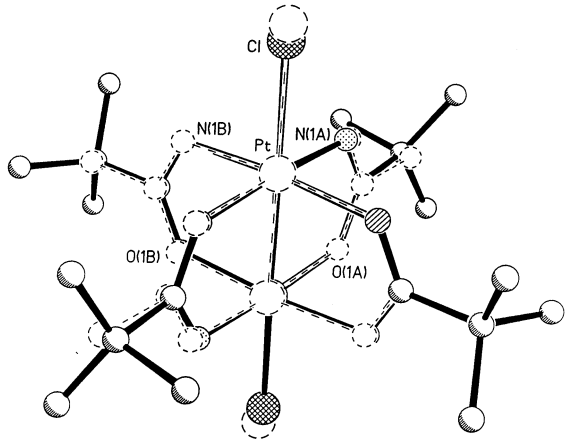

Fig. 2. Superimposition of $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]$ and $[Pt_2I_2\{N(H)C(Me)O\}_4]$ complexes.

It is worth noting that the intermetallic distance in Pt(III) dimers is very sensitive to the bite of the covalently bridging ligands, this latter distance can range from 2.94 Å, as in the case of pyrophosphate bridging ligands, to 2.23 Å, as in the case of acetate bridges ([14] and references therein). The N···O bite distance for complexes **1** and **2** (average 2.28(2) Å) is also very short and comparable to that of the acetate ligand (2.26 Å) in $[Pt_2(H_2O)_2\{OC(Me)O\}_4]^{2+}$.

The platinum coordination squares are perfectly eclipsed (maximum twist angle 1.1°) and such a conformation allows the greatest separation between the platinum atoms. The platinum atoms are displaced from the equatorial coordination planes by 0.08 Å towards the axial chlorides, such a displacement being a measure of the strength with which the four bridging ligands pull together the two metal centers. The five-membered Pt–N–C–O–PtA rings (the suffix A denotes the symmetry-related atom at $\frac{1}{2}-x$, $\frac{1}{2}-y$, $-z$) are planar to within 0.01 Å and virtually orthogonal to each other (dihedral angle of 91.9(3)°).

The structures of **1** and **2** are superimposable (Fig. 2), the weighted root mean square deviation being only 0.04 Å when the fitting is performed upon the atoms common to the two structures. In the iodo complex **2** the Pt–Pt distance is slightly longer (2.473(2) Å) than in the chloro-complex **1** (2.448(2) Å), probably as a consequence of the greater *trans* influence of the iodo ligand with respect to the chloro ligand. The bond lengths between each platinum atom and the corresponding axial halogen ligand (2.427 and 2.73 Å for **1** and **2**, respectively) are much longer than analogous bond distances in 4-coordinate platinum(II) and 6-coordinate platinum(IV) complexes (2.32 and 2.61 Å for Cl and I, respectively [7,15]). This lengthening has been ascribed to a very strong *trans* influence exerted by the intermetallic bond on the *trans* halogen ligands.

The molecules of water (1.5 molecules per platinum dimer) fill the empty spaces of the crystal lattice (Fig. 3). Only the water molecule in a special position at $\frac{1}{2}$, y, $\frac{1}{4}$ is engaged in hydrogen bonds (Fig. 4) and its oxygen atom is equidistant (3.22 Å) from the Cl and N(1) atoms (probably a water hydrogen interacts with the axial chloride and the amide hydrogen interacts with the water oxygen).

Green crystals of **1**, containing one molecule of acetone per molecule of complex, can also be obtained. They are hexagonal in shape and the space group and cell parameters are $C2$, $a = 11.389(4)$, $b = 15.810(6)$, $c = 18.549(6)$ Å, $\beta = 98.52(3)°$.

Complex **1** was also investigated by ^1H and ^{195}Pt NMR spectroscopy in $CDCl_3$. Only one signal was observed for the *tert*-butyl groups of the amidate bridges (1.17 ppm), while four signals were observed in the region of NH protons (6.13, 5.81, 5.67 and 5.52 ppm). Intensity ratios of 2:1:1 were observed for three

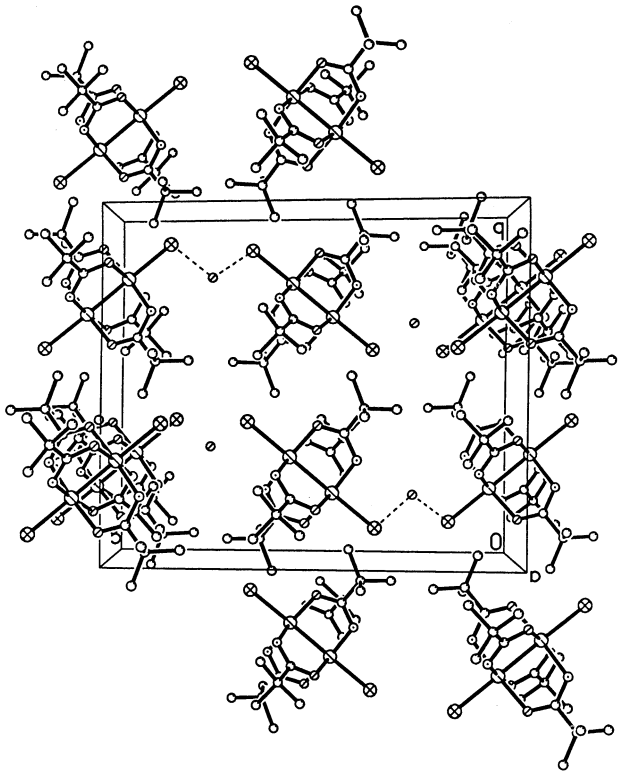

Fig. 3. Packing diagram of the unit cell for $[Pt_2Cl_2\{N(H)C(Bu^t)O\}_4]\cdot 3/2\ H_2O$.

NH's signals (6.13, 5.81 and 5.52 ppm, respectively) while the signal at 5.67 ppm had a much greater intensity. Therefore, also in the case of complex **1**, as already described for complex **2**, two isomers are present in solution: one symmetrical (NH signal at 5.67 ppm) and one non-symmetrical (NH signals at 6.13, 5.81 and 5.52 ppm). In the case of compound **1** the ratio between symmetrical and non-symmetrical isomers observed in various samples was of the order of 4:1, therefore much more in favor of the symmetrical isomer than in the case of compound **2**. The $\{^1H\}^{195}Pt$ spectrum showed a signal at $\delta = -82$ ppm (external reference H_2PtCl_6 in D_2O), the broad shape of this signal is probably due to the coordination to platinum of two N-donor ligands. The observation of only one ^{195}Pt resonance could either indicate a coincidence of chemical shift for the symmetrical and the non-symmetrical isomer, or, more probably, to a too small intensity for the signals of the non-symmetrical isomer which is present in small percentage and has unequivalent platinum atoms. This value of chemical shift falls in the range of those observed for platinum(III) dimers which, however, are spread over a wide range of values spanning from those of platinum(II) to those of platinum(IV) [2].

Also for compound **1**, as already described for **2**, the symmetrical isomer, having N_2O_2 coordination for both Pt(III) centers, has a *cis* configuration as proved by the X-ray analysis (Fig. 1).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 149290 for compound **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Alkylaluminium derivatives of 2,2′-di(hydroxymethyl)biphenyl: structural characterization of trinuclear complexes

Wanda Ziemkowska *

Faculty of Chemistry, Warsaw University of Technology, Koszykowa 75, 00-662 Warsaw, Poland

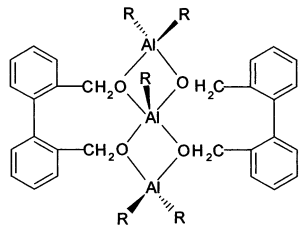
Received 9 August 2001; accepted 31 October 2001

Abstract

Reactions of 2,2′-di(hydroxymethyl)biphenyl with trimethyl-, triethyl- and tri-*iso*-butylaluminium yield tri-aluminium compounds $R_5Al_3(OCH_2C_{12}H_8CH_2O)_2$ [where R = Me (**1**), R = Et (**2**), R = *i*-Bu (**3**)]. Compounds **1**–**3** have been characterized by NMR spectroscopy, molecular weight measurements and elemental analysis. The crystal structures of the complexes **1** and **3** have been determined by X-ray crystallography. The geometry about the central aluminium atom in both compounds is a distorted trigonal-bipyramidal with two oxygen atoms occupying the axial positions. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Aluminium; Diols; Trinuclear complexes; 2,2′-Di(hydroxymethyl)biphenyl; Crystal structures; Alkylaluminium diolates

1. Introduction



The reaction of alcohols with one equivalent of trialkylaluminium affords mainly dimeric complexes $[(R_2AlOR^1)_2]$ with four-coordinate aluminium atoms [1]. Dimethylaluminium- and diethylaluminium methoxide are trimeric due to the sterically undemanding alkoxide and alkyl ligands [2]. The interaction of carbonyl-, carboxyl-, alkoxyl- and hydroxyl-functionalized alcohols with aluminium trialkyls leads to the formation of a wide variety of organoaluminium O,O′-chelated complexes depending on the reactants molar ratio, the nature of the alkyl substituent R–Al and the nature of the O,O′-bifunctional ligands [3]. The structures of products obtained in the reactions of trialkylaluminium with diols mainly fall into two categories. The first may be characterized as a bimetallic alkylaluminium diolates of the formula $R_4Al_2[diol–(H)]_2$, in which the aluminium centres are four-coordinate and two O*H* protons form intra-molecular hydrogen bonding. Only one example of this group has been recently reported, a *tert*-butylaluminium complex with 2,2-dimethylpropane-1,3-diol [4]. The second category is trimetallic compounds $R_5Al_3[diol–(2H)]_2$ [where R = Me, Et, $CH(SiMe_3)_2$] with two four-coordinate aluminium atoms and one central five-coordinate aluminium atom [5–12]. Numerous examples of similar compounds have been obtained with the salen class of N_2O_2 tetradentate ligands [13]. Although an increasing number of the complexes $R_5Al_3[diol–(2H)]_2$ have been reported, only one example of the crystal structure of a methylaluminium diolate is known for 2,4-dimethylpentane-2,4-diol [10]. Barron et al. has recently reported the structure of *tert*-butylaluminium derivatives of 2,2-dimethylpropane-1,3-diol of the formula $[(t\text{-Bu})_4XAl_3(OCH_2C(CH_3)_2CH_2O)_2]$ [where X = H, Me, Cl] [4]. *iso*-Butylaluminium diolates are unknown. It is, therefore, the goal of this paper to present the crystal structure of methyl- and *iso*-butylaluminium complexes of 2,2′-di(hydroxymethyl)biphenyl. The ethylaluminium derivative has been also synthesised and characterized by spectroscopic methods.

2. Results and discussion

The reaction of three equivalents of R_3Al [where R = Me, Et, *i*-Bu] with two equivalents of 2,2′-di(hydroxymethyl)biphenyl yields trimetallic products [1–3]. The complex **1** is formed almost quantitatively. The complexes **2** and **3** were obtained with yields of about 70 and 50%, respectively.

1 (R = Me), **2** (R = Et), **3** (R = *i*-Bu)

The complex **1** was isolated 10 days after the reaction as a colourless crystalline solid. The molecular structure of compound **1** has been determined by X-ray crystallography and is shown in Fig. 1(a). Data collection and structure analysis are presented in Table 1. Selected bond lengths and angles are given in Table 2. The molecule consists of a tetracyclic structure formed from two four-membered and two nine-membered rings. The geometry about the central aluminium atom is a distorted trigonal bipyramidal with O(2) and O(4) occupying the axial positions [O(2)–Al(1)–O(4) = 156.07°] and O(1), O(3) and C(29) defining the equatorial sites (Fig. 1(b)). The sum of the bond angles between the equatorial ligands is 359.98°. Compound **1** is the first alkylalu-

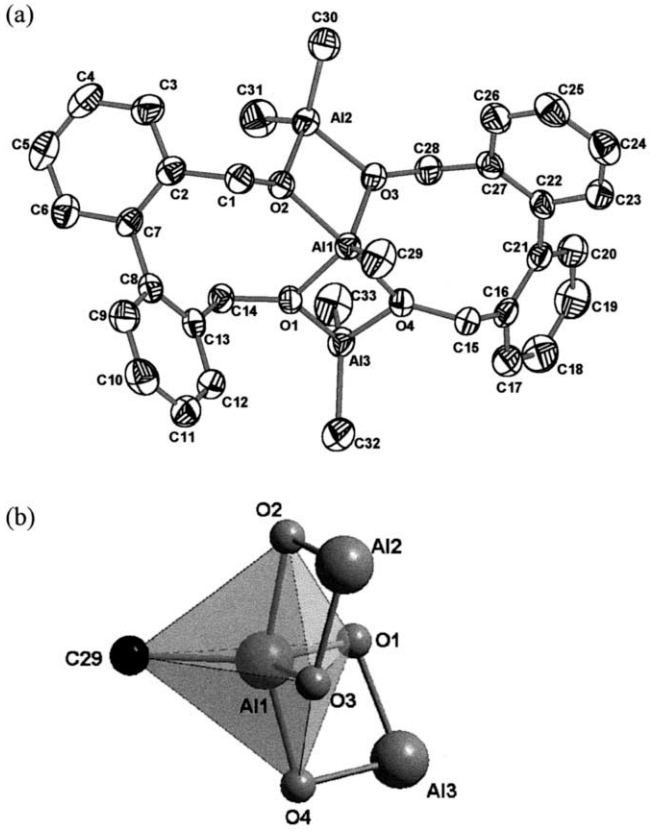

Fig. 1. $[Me_5Al_3(OCH_2C_{12}H_8CH_2O)_2]$ (**1**) (a) molecular structure. Thermal ellipsoids are given at the 50% level and hydrogen atoms are omitted for clarity. minium diolate with a trigonal-bipyramidal geometry at the central atom. The central metal atom of the trinuclear complexes noted in Section 1 adopts a square based pyramidal structure, in which four oxygen atoms occupy the basal sites. The sums of the angles about the O(1), O(2), O(3) and O(4) atoms are equal 358.21°, 356.05°, 359.42° and 358.25°, respectively, which indicates a lack of strain in the nine-membered cycles. The terminal aluminium centres in **1** are coordinated in a distorted tetrahedral fashion by two methyl groups and two oxygen atoms of the diol moiety.

The solvent plays an important role in the crystallisation of product **1**. From hexane and diethyl ether solutions the product precipitates as a powder. Single crystals suitable for X-ray structure analysis were obtained from a toluene solution and one molecule of solvent is present in the formula unit. The toluene molecules show complicated positional disorder. To avoid the loss of toluene from the lattice the X-ray measurement was performed at low temperature.

The CH_2 protons of ligands are inequivalent and appear as a pattern of four doublets in the ^1H NMR spectrum, in contrary to the earlier reported alkylaluminium diolates $Me_5Al_3(OCH_2C_6H_4CH_2O)_2$ [10], $Me_5Al_3[O(CH_2)_3O]_2$, $Me_5Al_3[O(CH_2)_4O]_2$ and Me_5Al_3-$[OCH_2C(CH_3)_2CH_2O]_2$ [9], which possess equivalent OCH_2 groups. The chemically different CH_2 groups of **1** are derived from the molecular structure with two groups below and two groups above the molecular plane.

The ethylaluminium derivative of 2,2′-di(hydroxymethyl)biphenyl **2** was separated by crystallisation from hexane, however, the crystals were unsuitable for X-ray diffraction studies. It was confirmed on the bases of NMR spectra that the structure of **2** is similar to that of complex **1**. The ^1H NMR spectrum reveals the signals of two C_2H_5Al groups *syn* and two C_2H_5Al groups *anti* (the triplets at 1.56 and 0.93, quartet at 0.60 and multiplet at -0.09 ppm) to the ethyl group bonded to the central aluminium atom.

The reaction of $(i\text{-Bu})_3Al$ with 2,2′-di(hydroxymethyl)biphenyl yields the product $[(i\text{-Bu})_5Al_3(OCH_2$-$C_{12}H_8CH_2O)_2]$ (**3**) and unidentified oligomeric products. Compound **3** was separated by crystallisation from hexane–dichloromethane. The molecular structure of **3** is shown in Fig. 2(a) and selected bond lengths and angles are given in Table 3. As with compound **1**, compound **3** consists of a tetracyclic structure with a central pentacoordinated aluminium atom. Also like compound **1**, the geometry at the central atom approximates trigonal bipyramidal with the oxygens O(1) and O(3) occupying the axial positions [O(1)–Al(1)–O(3) = 161.43°] (Fig. 2(b)). The sum of the bond angles between the equatorial ligands O(2), O(4) and C(29) is 360.0°. The oxygen atoms O(1) and O(3) are situated in the planes formed by Al(1), Al(3), C(1) and Al(1),

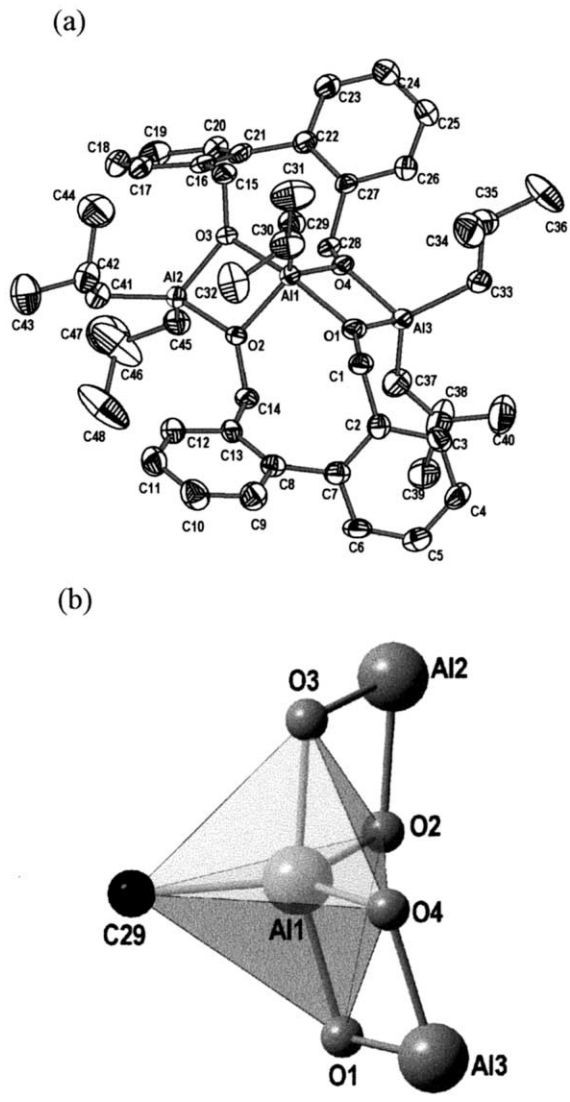

Fig. 2. $[i\text{-}Bu_5Al_3(OCH_2C_{12}H_8CH_2O)_2]$ (**3**) (a) molecular structure. Thermal ellipsoids are given at the 30% level and hydrogen atoms are omitted for clarity. (b) View of the coordination sphere of the central aluminium atom showing distorted trigonal bipyramidal geometry with two oxygen atoms occupying the axial positions.

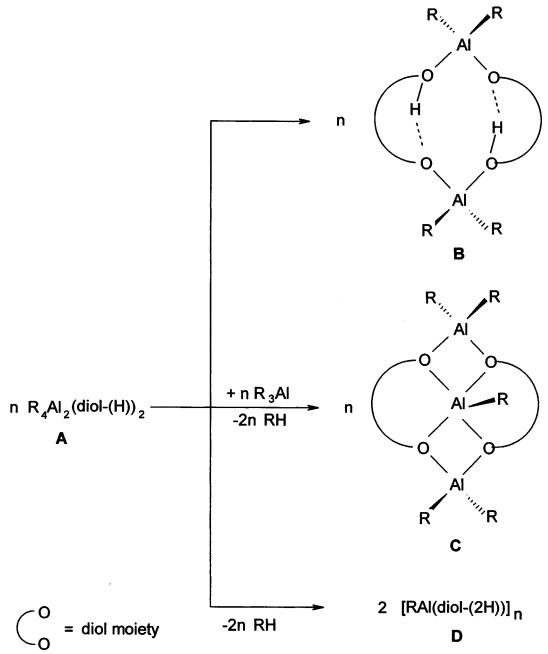
Table 3
Bond lengths (Å) and bond angles (°) for $i\text{-}Bu_5Al_3$-$(OCH_2C_{12}H_8CH_2O)_2$ (**3**)



Bond lengths			
Al(1)–O(4)	1.860(4)	Al(1)–O(2)	1.861(4)
Al(1)–O(3)	1.920(4)	Al(1)–O(1)	1.936(4)
Al(1)–C(29)	1.966(7)	Al(2)–O(3)	1.824(4)
Al(2)–O(2)	1.860(4)	Al(3)–O(1)	1.816(4)
Al(3)–O(4)	1.853(4)		
Bond angles			
O(4)–Al(1)–O(2)	111.99(19)	O(4)–Al(1)–O(3)	92.36(17)
O(2)–Al(1)–O(3)	77.03(17)	O(4)–Al(1)–O(1)	76.56(18)
O(2)–Al(1)–O(1)	93.15(18)	O(3)–Al(1)–O(1)	161.43(19)
O(3)–Al(2)–O(2)	79.48(18)	O(1)–Al(3)–O(4)	79.74(19)

Al(2), C(15) atoms, respectively, because the three X–O(1)–Y angles and the three X–O(3)–Y angles sum about 360°. The sums of the angles about the O(2) and O(4) atoms are equal to 354.4° and 352.76°, respectively. It means that the O(2) and O(4) atoms deviate slightly from the C(14), Al(2), Al(1) and C(28), Al(3), Al(1) planes, contrary to the comparable oxygen atoms in compound **1**. The terminal aluminium atoms are coordinated in a highly distorted tetrahedral fashion by two carbons of *iso*-butyl groups and two oxygen atoms of the diol moiety.

Like compounds **1** and **2**, the ^{13}C NMR spectrum of **3** shows two kinds of inequivalent CH_2O groups (signals at 63.30 and 62.70 ppm). In the ^1H NMR spectrum the doublets of $(CH_3)_2CHCH_2$ and $(CH_3)_2CHCH_2$ protons are split, because the methyl groups of the *iso*-butyl substituents are diastereotopic.

Barron et al. have recently proposed the complex $R_4Al_2(diol–(H))_2$ with two intra-molecular hydrogen bonds as an intermediate product in the reactions of diols with trialkylaluminium compounds [4]. The complex might subsequently react with trialkylaluminium yielding the trimetallic product $R_5Al_3(diol–(2H))_2$. However, the bimetallic complex $[(t\text{-Bu})_4Al_2(OCH_2C(CH_3)_2CH_2OH)_2]$ showed low reactivity towards trialkylaluminiums and long heating in refluxing toluene was necessary for the inclusion of the third aluminium atom into the molecule. Alkylaluminium derivatives described above and other earlier reported trinuclear alkylaluminium diolates have been easy obtained in the temperature range from −78 to 20 °C [5–12]. Moreover, the compound $[(t\text{-Bu})_5Al_3(OCH_2C(CH_3)_2CH_2O)_2]$ could not be formed from the reaction of $[(t\text{-Bu})_4Al_2(OCH_2C(CH_3)_2CH_2OH)_2]$ with $(t\text{-Bu})_3Al$, although only little steric interaction was found between the bulky *tert*-butyl substituent on the central metal and diol moieties [4]. On the other hand the reaction of 1,2-catechol with $(t\text{-Bu})_3Al$ smoothly yields the tri-aluminium product $[(t\text{-Bu})_5Al_3(OC_6H_4O)_2]$ [14]. It seems that the first step of the reaction of R_3Al with diol is the formation of the dimeric intermediate product $R_4Al_2(diol–(H))_2$ (**A**) with two hydroxyl groups. Then the strong intra-molecular hydrogen bonding interaction competes with the reaction of OH groups with the excess of R_3Al and inclusion of the third metal atom to give the products **B** and **C**, respectively. Although examples were not found in the literature, the reaction of the hydroxyl groups with the next alkyl groups of the intermediate product and formation of $[RAl(diol–(2H))]_n$ type complexes (**D**) cannot be excluded (Scheme 1). Final products depend on many factors, steric bulk and the nature of R–Al substituents, acidity of O*H* groups, basicity of oxygen atoms from diol moieties and presumably on the substituents on the diol.

In conclusion, trimethyl-, triethyl- and tri-*iso*-butylaluminium react with 2,2′-di(hydroxymethyl)biphenyl to give trimetallic compounds $R_5Al_3(OCH_2C_{12}H_8CH_2O)_2$ [where R = Me (**1**), Et (**2**), *i*-Bu (**3**)]. The formation of the intermediate products with two OH groups and intra-molecular hydrogen bonding was not observed. Further studies on the effects of steric and electron changes in a subunit structure on the molecular and crystal structure of aluminium diolates are in progress.

Scheme 1. Possible reaction pathways and products in the reaction of trialkylaluminiums with diols.

3. Experimental

All manipulations were carried out using standard Schlenk techniques in anhydrous solvents under an inert gas atmosphere. Me_3Al, Et_3Al, $(i\text{-Bu})_3Al$ and 2,2′-di(hydroxymethyl)biphenyl were obtained from Aldrich. ^{27}Al NMR spectra were run on a Varian VXR 300 spectrometer, (standard $Al(acac)_3 = 0.0$ ppm). ^1H NMR spectra were recorded with a Mercury-400BB spectrometer, at 400.09 MHz. Chemical shifts were referenced to the residual proton signal of C_6D_6 (7.15 ppm). ^{13}C NMR spectra were run on the same instrument at 100.60 MHz (standard, benzene $^{13}CC_5D_6$, 128 ppm). The molecular weight of the compounds was determined by cryoscopy in benzene.

3.1. The synthesis of $[Me_5Al_3(OCH_2C_{12}H_8CH_2O)_2]$ (1)

A sample (0.446 g, 6.2 mmol) of Me_3Al in 10 cm^3 of diethyl ether was placed in a 250-cm^3 two-necked flask and cooled to −78 °C. A solution of 0.856 g (4.0 mmol) of 2,2′-di(hydroxymethyl)biphenyl in 100 cm^3 of

diethyl ether was then added drop by drop within 0.5 h. The reaction mixture was allowed to warm to room temperature (r.t.) within 2 h. Evolution of gases was observed during the course of the reaction. All volatiles were then removed from 10 cm^3 of the post-reaction mixture and the residue was characterized by NMR spectroscopy. After the reaction the ^1H and ^{13}C NMR spectra showed a mixture of two isomers **1a** [major product (65%, calculated on the basis of integration of Al–CH_3 signals)] and **1**.

The mixture of **1a** and **1**: ^1H NMR (C_6D_6): δ 6.8–7.8 (16H, H arom.), **1a**: {4.62 (d, ^2J(H–H) = 12.0 Hz), 4.37 (d, ^2J(H–H) = 12.0 Hz), 4.34 (d, ^2J(H–H) = 12.0 Hz), 4.27 (d, ^2J(H–H) = 12.0 Hz) [5.2H, CH_2]}, –0.30 (s, 1.95H, AlCH_3), –0.44 (s, 1.95H, AlCH_3), –0.69 (s, 1.95H, AlCH_3), –0.76 (s, 1.95H, AlCH_3), –1.11 (s, 1.95H, AlCH_3). **1**: {4.56 (d, ^2J(H–H) = 12.0 Hz), 4.43 (d, ^2J(H–H) = 12.0 Hz), 4.26 (d, ^2J(H–H) = 12.0 Hz), 4.22 (d, ^2J(H–H) = 12.0 Hz) [2.8H, CH_2]}, –0.07 (s, 2.1H, AlCH_3), –0.78 (s, 2.1H, AlCH_3), –0.99 (s, 1.05H, AlCH_3). ^{13}C NMR (C_6D_6): δ **1a**: 141.26, 140.44, 137.42, 136.65, 130.41, 130.24, 129.87, 129.02, 128.71, 128.69, 128.18 (*C* aromat.), 66.12, 64.01, (CH_2), –11.50, –11.85 (AlCH_3) ppm, **1**: the signals are the same as for the pure **1** (see below).

Over 10 days compound **1a** undergoes complete transformation to **1**. The solvent and the slight excess of Me_3Al were distilled off and the pure product **1** was obtained (yield 1.00g, 95%). X-ray quality, colourless crystals were crystallised from toluene.

1: ^1H NMR (C_6D_6): δ 6.8–7.8 (16H, H arom), 4.56 (d, ^2J(H–H) = 12.0 Hz), 4.43 (d, ^2J(H–H) = 12.0 Hz), 4.26 (d, ^2J(H–H) = 12.0 Hz), 4.22 (d, ^2J(H–H) = 12.0 Hz) [8H, CH_2], –0.07 (s, 6H, AlCH_3), –0.78 (s, 6H, AlCH_3), –0.99 (s, 3H, AlCH_3). ^{13}C NMR (C_6D_6): δ 141.20, 139.38, 138.03, 136.35 130.50, 130.07, 129.82, 128.96, 128.52, 128.49, 128.15 (*C* aromat.), 62.98, 61.84 (CH_2), –9.32, –10.30 (AlCH_3, broadened). ^{27}Al NMR (C_6D_6): δ 150 (Al four-coordinate), 57 Al five-coordinate) ppm. 3.3. The synthesis of $[(i\text{-}Bu)_5Al_3(OCH_2C_{12}H_8CH_2O)_2]$ (3)

Compound **3** was obtained as described in Section 3.1 using 1.070 g (5.0 mmol) of 2,2′-di(hydroxymethyl)biphenyl and 1.544 g (7.8 mmol) of $(i\text{-}Bu)_3Al$. The solvent was distilled off and a thick colourless liquid was obtained. The crude material was redissolved in hexane–methylene dichloride and placed in freezer. X-ray quality, colourless crystals were formed with the yield 0.948 g, 48%.

^1H NMR (C_6D_6): δ 7.91 (d, 2H ^3J(H–H) = 7.8 Hz, *H* aromat.), 7.61 (d, 2H ^3J(H–H) = 7.6 Hz, *H* aromat.), 7.30 6.90 (m, 12H, *H* aromat.) 4.79 (d, 2H, ^2J(H–H) = 12.8 Hz, CH_2O), 4.63 (d, 2H, ^2J(H–H) = 12.8 Hz, CH_2O), 4.62 (d, 2H, ^2J(H–H) = 11.7 Hz, CH_2O) 4.38 (d, 2H, ^2J(H–H) = 11.7 Hz, CH_2O), 2.38 (m, 2H, $(CH_3)_2CHCH_2$), 1.63 (m, 2H, $(CH_3)_2CHCH_2$), 1.55 (m, 1H, $(CH_3)_2CHCH_2$), 1.37 (d, 12H, ^3J(H–H) = 6.4 Hz, $(CH_3)_2CHCH_2$), 0.92, 0.90 [(d, ^3J(H–H) = 6.4 Hz), (d, ^3J(H–H) = 6.4 Hz), (12H, $(CH_3)_2CHCH_2$)], 0.72 (m, 6H, $(CH_3)_2CHCH_2$), 0.71 (d, 4H, ^3J = 6.6 Hz, $(CH_3)_2CHCH_2$)), –0.03 (m, 4H, $(CH_3)_2CHCH_2$), –0.20 (m, 2H, $(CH_3)_2CHCH_2$). ^{13}C NMR (C_6D_6): δ 141.23, 139.54, 137.43, 136.16, 130.92, 130.69, 130.58, 130.31, 129.18, 128.60, 128.44, 128.54 (*C* aromat.), 63.30, 62.70 (CH_2O), 29.03, 28.72, 25.65 (($CH_3)_2CHCH_2$), 27.94, 26.53, 22.94 (($CH_3)_2CHCH_2$), 20.07 (($CH_3)_2CHCH_2$, broad) ppm. Molecular weight. *Anal.* Found: 779. Calc.: 790. Association degree: 0.99. Elemental *Anal.* Found: Al, 10.02; hydrolysable *iso*-butyl groups, 36.24. Calc.: Al, 10.25; *i*-Bu, 36.08 wt.%.

3.4. X-ray crystal structure analysis

Crystal data regarding structures **1** and **3** are given in Table 1. All measurements of crystals were performed on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The crystals were positioned at 65 mm from the KM4CCD camera. For compound **1** 748 frames were measured at 1.7° intervals with a counting time of 15 s. For compound **3** 288 frames were measured at 1.6° intervals with a counting time of 15 s. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis

were carried out with the Kuma Diffraction (Wroclaw) programs. The structure was solved by direct methods [15] and refined using SHELXL [16]. All hydrogen atoms were located from a differential map and refined isotropically. Scattering factors were taken from Tables 6.1.1.4 and 4.2.4.2 in Ref. [17].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 161314 and 161315 for compounds **1** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Structures and catalytic properties of triphenylphosphine oxide complexes of scandium and lanthanide triflates

Abstract

The complexes $M(OTf)_3(Ph_3PO)_4$ where M = lanthanide metals and scandium have been prepared and characterised in the solid state by single crystal X-ray diffraction, infrared spectroscopy and elemental analysis. All the complexes have the ionic structure $[M(OTf)_2(Ph_3PO)_4]^+[OTf]^-$. Single crystal X-ray structures for M = Sc, Nd and Lu are reported. In the complexes of the early lanthanides (La–Nd) the metals are seven-coordinate with one monodentate, one bidentate triflate. The smaller lanthanide ions, and scandium, have six-coordinate structures with an approximate octahedral coordination about the metal where both triflates are bound as monodentate ligands. The solution structures have been analysed by electrospray mass spectrometry, which indicates that extensive ligand redistribution occurs. The complexes catalyse the Friedel Crafts acylation, alkenylation and alkylation of activated aromatics with modest increases in selectivity compared to the same reactions using scandium triflate. © 2002 Elsevier Science Ltd. Keywords: Triflates; Triphenylphosphine oxide complexes; Single crystal X-ray diffraction; Scandium and lanthanide; Catalysis

1. Introduction

Scandium and lanthanide triflates have been extensively studied as catalysts for a variety of organic reactions in protic [1,2] and aprotic [1,3] media, and the use of $Yb(OTf)_3$ and $Sc(OTf)_3$ in particular as water tolerant Lewis acid catalysts continues to attract considerable interest.

The coordination complexes of lanthanide triflates with Ph_3PO have previously been investigated in the solid state by infrared and electronic spectroscopy and elemental analysis, and in solution by conductivity [4]. No structural data for these compounds were reported.

Coordination complexes might be expected to display lower catalytic activity than the triflates themselves as the metal ion will be less available to the substrates in the reaction. This may be compensated to some extent if the resulting catalysts were more selective. Previous studies on the catalysis of Diels Alder reactions found that ytterbium triflate complexes with polyethers were more selective than those of polyethylene glycols and that the uncomplexed ytterbium triflate had intermediate selectivity [5a], and more recently chiral coordination complexes of scandium triflate have been shown to catalyse enantioselective Michael addition reactions [5b], and aldol reactions in aqueous media [5c]. We have thus examined the structures of the triphenylphosphine oxide complexes and the catalytic properties of the scandium complex in particular, and compared its activity and selectivity to that of uncomplexed scandium triflate.

2. Results and discussion

2.1. Solid state structures

Crystals suitable for single crystal X-ray diffraction study were obtained for the Sc, Nd and Lu complexes. Crystals of poorer quality for the La and Er complexes

have also allowed us to establish the atom connectivities in these compounds. The complexes are ionic containing $[M(OTf)_2(Ph_3PO)_4]^+$ and an uncoordinated triflate anion. The smaller lanthanide ions, Er and Lu and also Sc, are six-coordinate, whilst for the larger Nd and La, one of the triflates adopts a bidentate mode giving seven-coordinate geometries about the metal. The structures of the Nd and Sc complexes are shown in Fig. 1, selected interatomic distances and bond angles are given in Table 1 and details of the data collection and refinement in Table 2.

The structures are very similar to those of the complexes of lanthanide triflates with hexamethylphosphoramide, $[Ln(OTf)_2(HMPA)_4]^+[OTf]^-\cdot CHCl_3$ [6a], where a change from bidentate to monodentate triflate coordination is found, with the lanthanum complex containing one bidentate and one monodentate triflate whilst the cerium analogue has two monodentate triflates.

The scandium and lutetium complexes form slightly distorted octahedra, with bond angles at the metal $90 \pm 5°$. The increased steric effect of the bidentate triflate in the Nd complex forces the equatorial oxygen atoms of the phosphine oxides out of plane towards the mondentate triflate. The Ln–O(P) distances increase in line with the ionic radii of the metal ion, the 12% increase mirroring almost exactly the increased ionic size from Sc to Nd [7]. The Nd–O(triflate) distances are longer than expected, presumably as a result of the increased steric congestion caused by the bidentate ligand. The bidentate S–O(Nd) lengths are significantly longer than the S–O(Nd) monodentate. In general the S–O bond distances reflect the coordination state to the metal, with S–O(metal) distances being longer than S–O(terminal), an identical effect being observed in the HMPA complexes [6b].

The change from bidentate to monodentate triflate coordination presumably occurs later in our series of complexes as a result of lower steric strain from the less bulky triphenylphosphine oxide ligand.

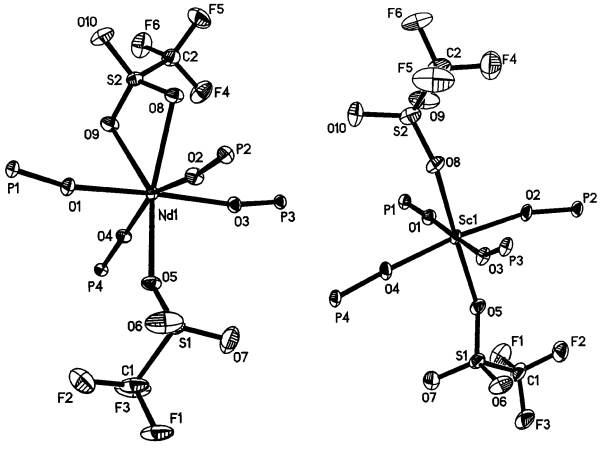

Fig. 1. The structures of the $[M(O_3SCF_3)_3(Ph_3PO)_4]^+$ cations M = Nd and Sc phenyl groups omitted for clarity.

Infrared spectroscopy in principle provides a means of identifying the coordination mode of the triflate ligand. The spectra were obtained as hexachlorobutadiene mulls and as KBr discs and showed no significant differences. This indicates that halide substitution, which is common for nitrate complexes, is not occurring here. The spectra themselves are complex with bands due to S–O and C–F not easily assigned. This is due to mixing of the vibrational modes [8], the presence of up to three different coordination modes in the same compound, and interference from phosphine oxide absorptions. It is, however, possible to deduce which complexes contain bidentate triflate by examination of their spectra. The spectra for the Nd and Sm complexes as KBr discs are shown in Fig. 2. Whilst only subtle differences are seen between the two spectra, the absorption at 1329 cm^{-1} in the Sm complex splits into two bands at 1342 and 1326 cm^{-1} in the Nd complex. Spectra for the complexes of the heavier lanthanides and scandium are essentially identical to that of the Sm complex. On this basis the transition from bidentate to monodentate coordination occurs at Nd with the complexes from Sm onwards being six-coordinate with two monodentate triflates.

2.2. Catalytic studies

Preliminary studies on the catalytic activity of several of the complexes have been carried out. Three of the phosphine oxide complexes were initially screened for activity in the acylation of anisole in nitromethane solution. The scandium complex was found to be most active, with erbium less so and the praseodymium complex showing no catalytic activity. $Sc(OTf)_3(Ph_3PO)_4$ was subsequently examined as a catalyst for the acylation, alkenylation [3a] and alkylation of activated aromatics. The reactions studied are shown in Scheme 1 and the results, together with some comparisons of the reactions using $Sc(OTf)_3\cdot 9H_2O$ as catalyst, in Table 3. The products were assigned using GC-mass spectrometry. The % conversions are based on GC measurements using benzophenone as an internal standard.

As expected, the activity of the triphenylphosphine oxide complex is considerably lower than that of the uncomplexed triflate salt. Some increase in selectivity is seen in reaction 1, whilst in reaction 3 the single substitution product is preferred when $Sc(OTf)_3(Ph_3PO)_4$ is used. These observations are presumably accounted for by the increased steric congestion around the metal centre, with extensive dissociation of the complexes accounting for the relatively modest increases in selectivity observed.

2.3. Solution properties

The solution behaviour of the complexes has been examined by electrospray mass spectrometry (ES MS) [9]. ES MS has found increasing use as a means of examining solution speciation, where the relatively mild transfer of solvated ions in solution to the gas phase in many cases occurs with little fragmentation [10]. For lanthanide complexes it is a particularly powerful tool as other methods tend to give indirect information due to the lability and paramagnetism of many of the complexes. The ES MS were recorded on methanol solutions, the results are shown in Table 4.

The low cone voltage spectra in methanol clearly show that extensive ligand redistribution reactions involving both triflate and Ph_3PO occur on dissolution and that the solid state structure is not retained. Assignments are based on the calculated mass to charge ratio and comparison of the observed and calculated isotope distribution patterns. These are particularly in-

formative when assigning signals to multiply charged ions where a characteristic compression of the isotope profile is observed. Interestingly the pseudo-parent ion, $[Ln(OTf)_2(Ph_3PO)_4]^+$, observed in the solid state is only present in small concentration in solution. The spectra obtained from the scandium complex differ from those of the lanthanides in that at low cone voltage, no metal containing ions were observed with the spectrum dominated by ions derived from dissociated Ph_3PO and ions (H^+ and Na^+) present in the solvent. Thus peaks due to $[(Ph_3PO)_nH]^+$ and $[(Ph_3PO)_nNa]^+$ ($n = 1$–4) are the main features in the positive ion spectra. At higher cone voltages scandium containing ions such as $[Sc(OTf)(Ph_3PO)_3]^{2+}$ ($m/z = 514$), $[Sc(OTf)_2(Ph_3PO)_2]^+$ ($m/z = 899$) and $[Sc(OTf)_2(Ph_3PO)_3] + (m/z = 1177)$ are seen at low intensity.

On addition of excess triphenylphosphine oxide the relative abundances of the ions in solution as measured by ES MS changes. The formation of $[Ln(Ph_3PO)_6]^{3+}$ is favoured for the lighter lanthanides and forms the base peak for the La and Nd complexes. This is expected in view of the labile nature of lanthanide complexes with monodentate ligands.

ES MS has previously been used to identify intermediates in reactions of lanthanide ions in solution [11], thus direct observation of reactions 2 and 3 using about 10 mol% $Sc(OTf)_3(Ph_3PO)_4$ as catalyst was carried out in an attempt to directly observe any catalytic intermediates. It was anticipated that species such as $[Sc(OTf)_2(Ph_3PO)_4(PhCCH)]^+$ or $[Sc(OTf)_2(Ph_3PO)_4(Me_2C_6H_4)]^+$ might be present in sufficiently high concentration to be detectable. In both solutions the base peak was due to $[Ph_3POH]^+$ with $[(Ph_3PO)_2H]^+$ of similar intensity. The main scandium containing ions are $[Sc(OTf)(Ph_3PO)_4]^{2+}$ ($m/z = 653$) and $[Sc(OTf)(Ph_3PO)_3]^{2+}$ ($m/z = 514$) with $[Sc(OTf)(Ph_3PO)_2]^{2+}$ and $[Sc(OTf)_2(Ph_3PO)_n]^+$ ($n = 1$–3) being represented by much lower intensity signals. No peaks assigned to complexes of these ions with either phenylacetylene or aromatic were observed, and thus it is not possible to deduce which, if any, of the scandium containing ions observed, are the catalytically active species.

3. Experimental

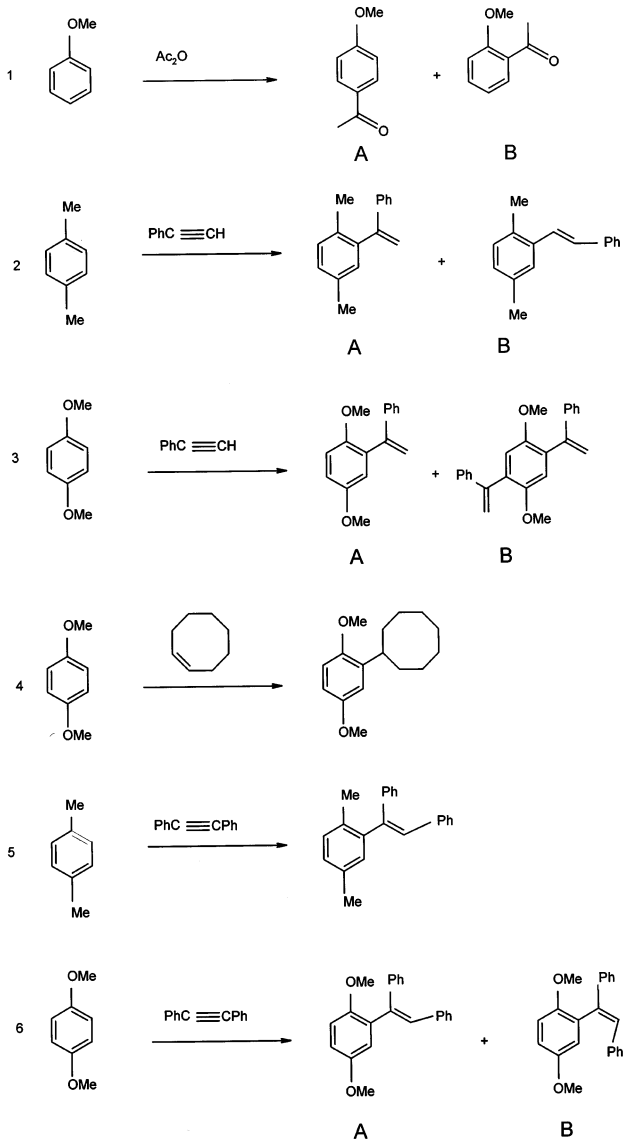
The same general method of preparation was used with the exception of the La and Sc complexes, which are detailed separately below. The lanthanide triflate and slight excess of triphenylphosphine oxide were dissolved in EtOH and heated briefly to reflux. The solution was evaporated to dryness and the excess phosphine oxide removed by stirring with a little THF. The complexes generally show a marked decrease in solubility in THF with decreasing ionic radius, with the exception of the Sc complex, which has appreciable solubility. Thus the La complex is freely soluble in THF and could not be purified in this manner, and whilst the Nd complex is sufficiently soluble for the lilac colour of Nd^{3+} to be seen in solution it can be recovered in reasonable yield. Typical yields were in the region of 80% based on metal, all compounds analysed satisfactorily as $Ln(OTf)_3(Ph_3PO)_4$. The Sc and La complexes were crystallised from EtOH as described below.

3.1. $La(OTf)_3(Ph_3PO)_4H_2O$

Hydrated La triflate (1.48 g, 1.98 mmol) and triphenylphosphine oxide (2.38 g, 8.57 mmol) were suspended in 100 ml of EtOH heated to boiling until a clear solution was obtained. The resulting solution was reduced to about 20 ml and cooled to room temperature (r.t.) when crystallisation occurred. The crystals were filtered, washed with a little Et_2O and dried at the pump to give 2.95 g (87%) of the product as a white powder.

Anal. Calc. for $C_{75}H_{62}F_9LaO_{14}P_4S_3$: C, 52.47; H, 3.70. Found: C, 52.41; H, 3.64%.

3.2. $Sc(OTf)_3(Ph_3PO)_4$



Hydrated scandium triflate (1.09 g, 1.66 mmol) in 40 ml EtOH was mixed with a solution of Ph_3PO (2.04 g, 7.35 mmol in 15 ml EtOH) The volume was reduced by boiling to 25 ml and the product crystallised on cooling to r.t. The solid was collected, washed with Et_2O and dried at the pump to give 1.61 g as a white powder. A second crop (0.29 g) was obtained on further concentration of the filtrate. Combined yield 72%.

Anal. Calc. for $C_{75}H_{60}F_9O_{13}P_4S_3Sc$: C, 56.12; H, 3.77. Found: C, 55.94; H, 3.79%.

Crystals for X-ray analysis formed spontaneously during the preparations for the Sc, La and Nd complexes. Crystals of the Er and Lu complexes were grown by slow evaporation of EtOH solutions. Whilst the bulk sample of the La complex analysed as the monohydrate the crystal chosen for X-ray analysis appears to have a higher hydration state and is probably not representative of the bulk sample.

4. Crystallography

Data for the Sc and Nd complexes were measured on a Bruker SMART diffractometer with a 2K CCD area

Scheme 1.

detector. Data for the Lu complex were measured on a Bruker P4 diffractometer. All data were collected using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Semi-empirical absorption corrections, based on comparison of Laue equivalents, were applied to the data sets. The structures were solved by direct methods and refined by full-matrix least-squares cycles on F^2 for all data, using SHELXTL [12]. All non hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were included in refinement cycles riding on bonded atoms. For all structures the uncoordinated triflate ion exhibits high anisotropic displacement values and for the Sc complex this was resolved to disordered sites.

Catalytic reactions were carried out on 5 ml of approximately 2 M solutions of the reagents in nitromethane. The reactions were heated to reflux and monitored by GC-MS using a Carlo Erba MFC 500 gc linked to a Trio 1000 mass spectrometer.

Electrospray mass spectra were obtained by the EPSRC National Mass Spectrometry Service Centre at Swansea University. The spectra were recorded on a VG Quattro II triple quadrupole mass spectrometer. Samples were loop injected into a stream of MeOH passing through a steel capillary held at high voltage ($+3.5$ kV for positive mode and -3.0 kV for negative mode). Nebulisation of the resulting spray was pneumatically assisted by a flow of nitrogen bath gas and heated source (70 °C). Declustering and molecular fragmentation were promoted by increasing the cone voltage from 8 to 50 V.

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 168629, 168630, 168631, 168632 and 168633 for complexes Lu,

Abstract

Stabilities of the mixed-ligand complexes of Cu^{2+} ion with *N*,*N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine [*N*,*N*,*N*′,*N*″,*N*″-pentamethyl-{bis(2-aminoethyl)amine}, Me_5dien] as a primary ligand and α-alaninehydroxamic acid [2-amino-*N*-hydroxypropanamid, α-Alaha] or β-alaninehydroxamic acid [3-amino-*N*-hydroxypropanamid, β-Alaha] as a secondary ligand L and their absorption and EPR spectra at various pH values are reported. The visible spectra exhibit a characteristic red shift and a shoulder at lower energies indicating a five-coordinate structure of the formed complexes. The change of the EPR spectral parameters as a function of pH reflects two modes of an equatorial–axial chelation by the aminohydroxamic acid ligand L in the $[Cu(Me_5dien)(HL)]^{2+}$ and $[Cu(Me_5dien)(L)]^{+}$ species. © 2002 Elsevier Science Ltd. Keywords: Copper(II) complexes; Mixed-ligand complexes; Five-coordinate complexes; Aminohydroxamic acids; EPR spectra; Vis spectra

1. Introduction

The aim of this paper is to summarise our results on the mixed-ligand copper(II) complexes in which polyamines play a role as a primary ligand and aminohydroxamic acid as a secondary one [1–3]. However, we have extended this paper including *N*,*N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine (Me_5dien) to investigate its complexing properties with copper(II) in binary and ternary systems. We were looking for an answer for the following question: is the geometry around copper(II) controlled first of all by polyamines? In order to find the answer we used different methods (pH-metric and spectroscopic: UV–Vis and EPR).

2. Experimental

2.1. Materials

α-Alaha and β-Alaha were prepared in our laboratory via the methyl ester of the respective amino acid as described in Ref. [4]. Me_5dien from Fluka was used without further purification and its purity was greater than 99%.

The exact concentrations of the stock solutions of the ligands used for potentiometric studies were determined by the Gran method [5]. The copper(II) chloride solution was purchased from Merck. Carbonate-free potassium hydroxide (the titrant) was prepared and standardized against a standard potassium hydrogenphtalate solution.

For clarity, the charges of the complexes are omitted in the tables. It has to be mentioned, however, that the fully deprotonated forms of aminohydroxamic acids are L^- while the *N*,*N*,*N*′,*N*″,*N*″,-pentamethyldiethylenetriamine is neutral.

2.2. Potentiometric measurements

A summary of the potentiometric experimental details is given in Table 1. The data for the Cu^{2+}–α-Alaha and Cu^{2+}–β-Alaha binary systems can be found in our early papers [4,6]. Data for the Cu^{2+}–Me_5dien binary system can be found in the literature [7], but for a comparison we had to determine stability constants under identical conditions to those of ternary systems, i.e. at 298 K and ionic strength of 0.2 M (KCl). For the binary system 1:1, 1:2 and 1:4 metal ion to ligand ratios were used. For the determination of the stability constants of the mixed-ligand complexes the concentration ratios of copper(II):Me_5dien: α-Alaha/β-Alaha were 1:1:1, 1:1:2, 1:2:1, 1:2:2, 2:1:1 and 2:2:1.

All the pH-metric titrations were carried out with carbonate-free KOH solution of known concentration (ca. 0.2 M). Titration emf data were used to calculate the hydrogen ion concentration, $[H^+]$. Stability constants $\beta_{pqrs} = [M_p(Me_5dien)_qL_rH_s]/[M]^p[Me_5dien]^q[L]^r[H]^s$ were calculated with the aid of the SUPERQUAD computer program [8]. The reported standard deviations were calculated by assuming random errors.

2.3. Spectroscopic measurements

The absorption spectra were recorded on a SPECORD M-40 spectrophotometer using 1-cm quartz cells at room temperature. The individual spectra of the copper(II) complexes were calculated. EPR measurements were performed on a Bruker 300E X-band spectrometer at 77 K in water/ethyleneglycol (4:1 v/v) solution. The metal ion concentrations for both spectroscopic measurements were 4×10^{-3} M and metal ion to ligands molar ratios were 1:1 and 1:2 for the binary systems and 1:2:1 for the Cu^{2+}–Me_5dien–α-Alaha/β-Alaha systems. pH-varied absorption spectra were obtained by the addition of 2 M KOH to the sample solutions so that the concentration (4×10^{-3} M) was not changed significantly. The pH of solutions was measured by employing an OP-208/1 Radelkis pH-meter with a Mettler–Toledo combined electrode.

3. Results and discussion

The acid dissociation constants of the ligands are given in Table 2, together with the macro- and microscopic dissociation constants of α- and β-alaninehydroxamic acids, which have been reported in our previous papers [9]. Me_5dien undergoes three acid dissociation processes during the potentiometric titration from pH 2 to 11. The pK values of these processes can be assigned to the three tertiary ammonium groups. Comparison of the pK values for Me_5dien with that of dien [2] (Table 2), shows that the substitution of hydrogen atoms of the $-NH_2$ group by $-CH_3$ groups decreases the pK values. The coordination tendencies of Me_5dien toward Cu^{2+} ions in aqueous solution were studied in the binary and ternary systems. In the course of the potentiometric titrations no precipitation at any metal ion to ligand ratios and concentrations applied in the studied pH range ($2 < pH < 11.5$). The best fits between the measured and calculated titrations curves were obtained by assuming the species given in Table 3 (for binary systems) and Table 4 (for ternary systems).

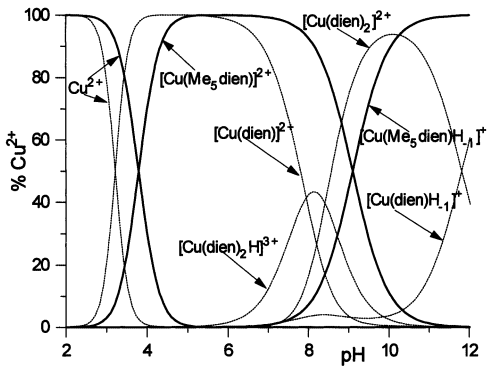

Fig. 1. Species distribution curves calculated for the Cu^{2+}–Me_5dien system (solid lines) and the Cu^{2+}–dien system (dashed lines), as a function of pH; $c_{Cu^{2+}} = 4 \times 10^{-3}$ M; Cu^{2+}:L = 1:2 molar ratio.

3.1. Cu^{2+}-complexation for binary systems

The values of the stability constants obtained for the complexes in the copper(II)–Me_5dien system are listed in Table 3 and the corresponding species distribution diagram is presented in Fig. 1. For comparison the data for the copper(II)–dien system [2] are included in the same table and figure. The studied system contains only equimolar complexes. The formation of bis complexes seems to be hindered because of a steric hindrance (as a result of the methylation of the $-NH_2$ groups in dien). In this system the concentration of the Cu^{2+} ions starts to drop at considerably higher pH values than in the case of dien. This indicates that dien is a noticeably stronger chelating agent than Me_5dien. The overall stability constants of the complexes are remarkably lower for Me_5dien species as compared to dien. However, the basicity-adjusted stability constants for 1:1 complexes, $\log K_{[Cu(am)]} - \Sigma$ pK_{am}, are −7.56 and −7.39, respectively. It means that the stabilities of these complexes are almost identical.

The Vis spectra at the maximum concentration distribution of $[Cu(Me_5dien)(H_2O)]^{2+}$ (pH 6.10) and $[Cu(dien)(H_2O)]^{2+}$ (pH 5.40) were obtained. The molar absorptivity (ε) for $[Cu(Me_5dien)(H_2O)]^{2+}$ ($\varepsilon = 225$ at $\lambda = 664$ nm) (Fig. 2) is much higher than that for $[Cu(dien)(H_2O)]^{2+}$ ($\varepsilon = 78$ at $\lambda = 614$ nm) [2]. It is difficult to correlate these results quantitatively with specific features, but they may indicate an increasing distortion of the complex geometry due to the bulkiness of the methyl groups. Similar results were obtained for Cu^{2+}–tren and Cu^{2+}–Me_6tren complexes [10].

3.2. Cu^{2+}-complexation for ternary systems

Analysis of the potentiometric titration data by the SUPERQUAD computer program allowed the determination of the main complex species in equilibrium. The overall formation constants are defined as: $\beta_{pqrs} = [M_p(Me_5dien)_qL_rH_s]/[M]^p[Me_5dien]^q[L]^r[H]^s$. The values of these constants are given in Table 4. The β_{pqrs} constant expresses the stability of the $[Cu(Me_5dien)L]^+$ species but does not represent directly the binding

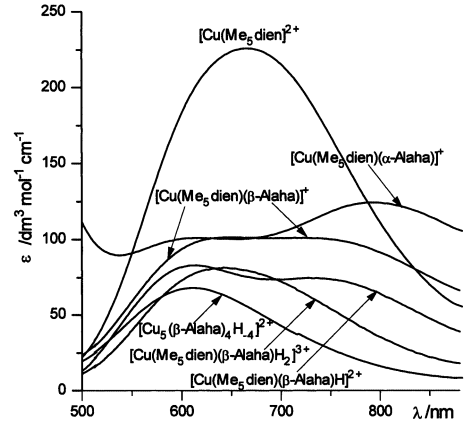

Fig. 2. Calculated electronic spectra of individual species.

strength between L and the Cu^{2+} ions. The equilibrium constant, $K_{[Cu(Me_5dien)L]}$, derived from the computed values of β_{pqrs} according to equation: $\log K_{[Cu(Me_5dien)L]} = \log \beta_{[Cu(Me_5)L]} - \log \beta_{[Cu(Me_5dien)]}$, shows how tightly L (aminohydroxamate) is bound to the simple $[Cu(Me_5dien)]^{2+}$ complex. Thus, the binding strength of α-Alaha or β-Alaha in the mixed-ligand complexes depends on the stability of the simple complex $[Cu(Me_5dien)]^{2+}$. Useful information can be obtained by considering equilibrium (1).

$$[Cu(Me_5dien)]^{2+} + [CuL]^{+} \rightleftharpoons [Cu(Me_5dien)L]^{+} + Cu^{2+} \quad (1)$$

$$\Delta\log K = \log \beta_{[Cu(Me_5dien)L]^{+}} - \log \beta_{[Cu(Me_5dien)]^{2+}} - \log \beta_{[CuL]^{+}} \quad (2)$$

Eq. (2) follows a criterion suggested by Sigel [11,12] to account for the stability of a mixed-ligand complex with respect to the corresponding simple ones. Since the aminohydroxamic acids coordinate more easily with the free Cu^{2+} ion than with the complexed metal ion, $[Cu(Me_5dien)]^{2+}$, $\Delta\log K$ should be negative. It can be seen, by viewing the $\Delta\log K$ values for different systems, that values of this factor for the Cu^{2+}–Me_5dien–α-Alaha and Cu^{2+}–Me_5dien–β-Alaha systems are low (−2.34 and −6.41, respectively). This effect of the mixed-ligand complex is due to a Cu^{2+} lower (than six) coordination number [13].

The Cu^{2+} mixed-ligand complexes of Me_5dien with α-Alaha or β-Alaha show larger $\log K_{[Cu(Me_5dien)L]}$ values, or less negative in $\Delta\log K$, compared with the corresponding dien systems (Table 5).

3.3. Cu^{2+}–Me_5dien–α-Alaha system

The stability constants obtained for the complexes formed in the Cu^{2+}–Me_5dien–α-Alaha system are given in Table 4. Concentration distribution curves for this system are presented in Fig. 3(a). From Table 4 it can be seen that the chemical model contains six simple species and two mixed-ligand ones: $[Cu(Me_5dien)(α\text{-Alaha})H]^{2+}$ and $[Cu(Me_5dien)(α\text{-Alaha})]^{+}$.

Absorption spectral data provide evidence for the presence of mixed-ligand complexes. These spectra exhibit an intense charge-transfer transition band in the near-UV region, which is not observed in the spectra of the $[Cu(Me_5dien)]^{2+}$ species (Fig. 2). In other words, the CT transition is observed when the hydroxamic ligand is coordinated. Additionally, a comparison between the species distribution curves (Fig. 3(a)) and the pH-dependent curves of the absorption (Fig. 4) clearly indicates that the spectral change shown in Fig. 3(a) is attributable to the formation and decay of the main mixed-ligand species.

The first mixed-ligand complex, $[Cu(Me_5dien)(α\text{-Alaha})H]^{2+}$, reaches a maximum concentration (ca. 70%) at pH 5.5 (Fig. 3(a)). The $pK_{[Cu(Me_5dien)(α\text{-Alaha})H]^{2+}}$ value characteristic of the deprotonation step for this complex is lower than the corresponding deprotonation constant and microscopic acid dissociation constant of the 'free' α-Alaha (Table 2) and it can be assigned to proton release from the amino group promoted by the copper(II) binding. Thus, the protonated H-α-Alaha coordinates to $[Cu(Me_5dien)]^{2+}$ by the hydroxamate group forming a five-membered chelate ring with {O, O} donor atoms and deprotonated α-Alaha gives a five-membered chelate ring but with $\{N_{amino}, N_{hydrox.}\}$ donor atoms. The proposed structures of the mentioned complexes are presented in Scheme 1(a).

In the visible region the Cu^{2+}–Me_5dien–α-Alaha system shows the existence a broad band which is assigned to the copper(II) d–d transitions. As the pH of the solution increases, the maximum in the longer wavelength region is greatly enhanced. The most evident changes are observed between pH 5.78 and 6.40 (5

and 6 spectra in Fig. 4(a)) which correspond to the formation of the $[Cu(Me_5dien)(\alpha\text{-Alaha})]^+$ species. From pH 8.50 to 9.50 absorption spectra are identical, what means that this complex is the predominant one in this pH range (see Fig. 3(a)). The studied spectra show well two noticeable maxima: at 609 nm (16 420 cm^{-1}) and at 790 nm (12 656 cm^{-1}). This absorption pattern, two peaks with one more intense being near the IR region, indicates a structural change around the Cu^{2+} ion towards five-coordinate copper(II) complexes [14–16]. Taking into account a bulky linear tridentate ligand with three tertiary amino groups (which have poor σ-donating properties [17], if compare with the amino groups of dien) we can see that such steric and electronic characters of the donors permit Me_5dien to easily form five-coordinate type copper(II) complexes with an intermediate geometry between square-pyramidal and trigonal-bipyramidal.

The analysis of the EPR spectra (Table 6) reveals a distinct difference between the spectral characteristic for the species formed between three partners: Cu^{2+}, aminohydroxamic acid and Me_5dien as compared to those for suitable simple complexes. For the ternary systems only a few spectra associated with the parallel

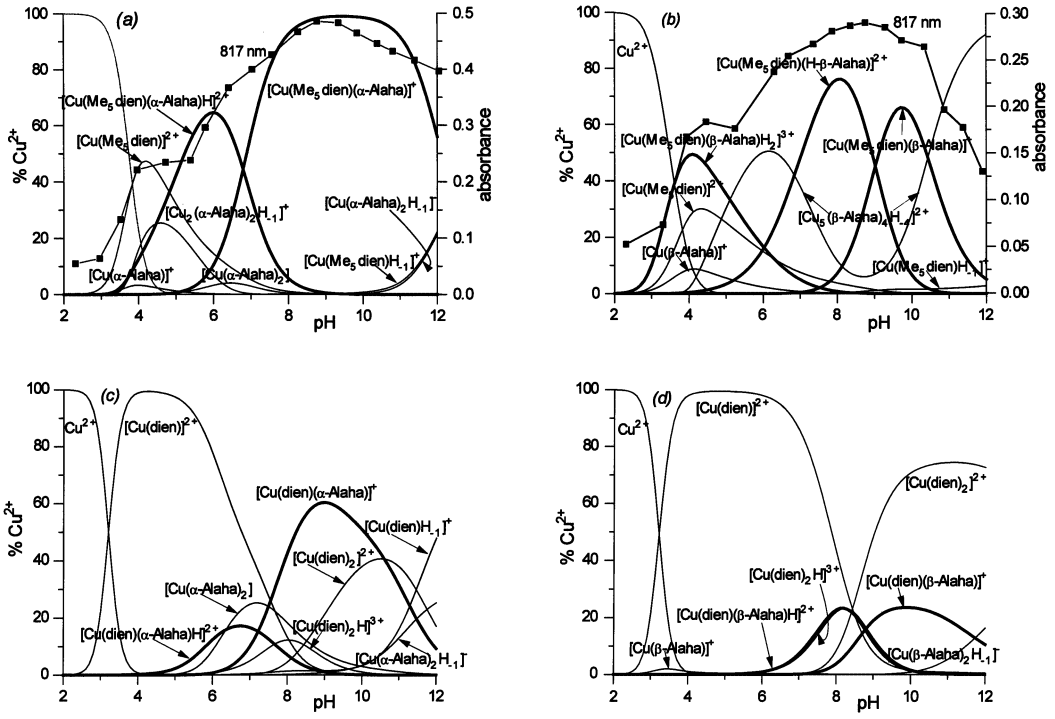

Fig. 3. Species distribution curves as a function of pH (—) and variations of visible absorption ($\lambda = 817$ nm) (···) for the Cu^{2+}–Me_5dien–α-Alaha (a) and Cu^{2+}–Me_5dien–β-Alaha (b) systems; species distribution curves as a function of pH for the Cu^{2+}–dien–α-Alaha (c) and Cu^{2+}–dien–β-Alaha (d) systems; $c_{Cu^{2+}} = 4 \times 10^{-3}$ M and Cu^{2+}:amine:L = 1:2:1 molar ratio (for all systems).

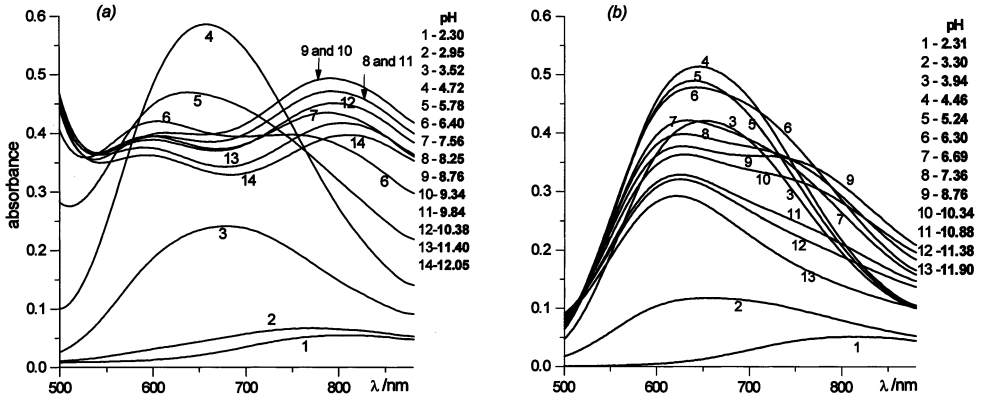

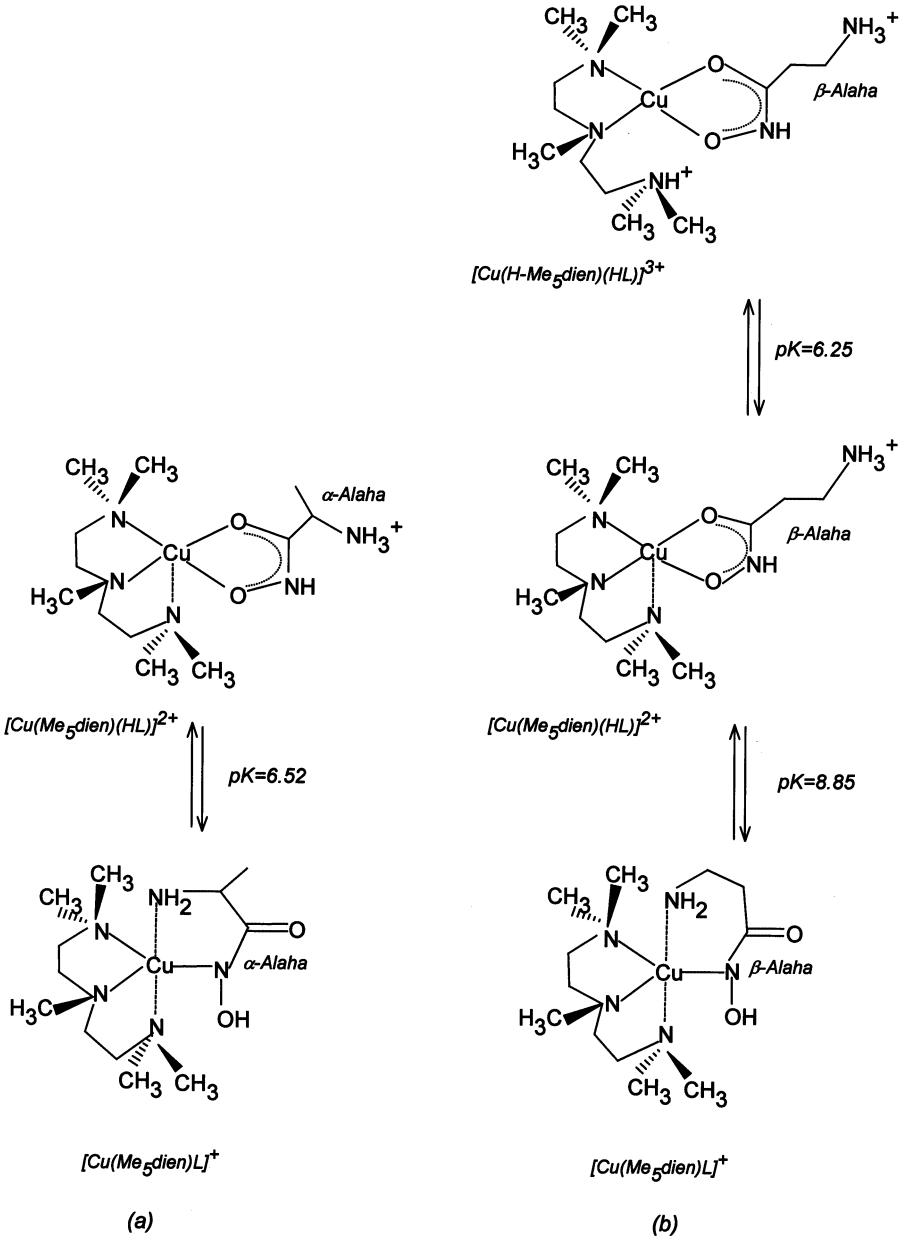

Fig. 4. pH-varied absorption spectra of the Cu^{2+}–Me_5dien–α-Alaha (a) and Cu^{2+}–Me_5dien–β-Alaha (b) systems; $c_{Cu^{2+}} = 4 \times 10^{-3}$ M and Cu^{2+}:amine:L = 1:2:1 molar ratio.

Scheme 1.

formation of the simple species are observed. At pH between 4 and 5, the spectrum has an orthorhombic character reflecting a distorted geometry of the $[Cu(Me_5dien)(H_2O)]^{2+}$ complex as a result of the effect of bulky *N*-methyl groups. This spectrum is observed for the mixed ligand system with α-Alaha alone and with β-Alaha in equilibrium with the spectrum assigned to the mixed-ligand species. The spectrum with strongly rhombically distorted parameters is typical for the complex geometry being intermediate between square-pyramidal and trigonal-bipyramidal [18,19]. The simple complexes with aminohydroxamic acids of tetragonal geometry, beside the species assigned to the first complex formed by α-Alaha and copper(II) [4] at pH 3.5, are not detected in the EPR spectra for the Cu^{2+}–Me_5dien–α-Alaha systems.

The comparison of the concentration distribution curves presented for the Cu^{2+}–Me_5dien–α-Alaha system in Fig. 3(a) together with those for the Cu^{2+}–dien–α-Alaha system (Fig. 3(c)) reveals that the coordination of α-Alaha towards $[Cu(Me_5dien)]^{2+}$ begins at a lower pH (pH ≈ 3) than towards $[Cu(dien)]^{2+}$ (pH ≈ 4.5). Additionally, Fig. 3(a) shows that the presence of Me_5dien does not suppress the formation of the dimeric $[Cu_2(\alpha\text{-Alaha})_2H_{-1}]^{+}$ species in the ternary system (in contrast to system with dien (Fig. 3(c) and [2]).

3.4. Cu^{2+}–Me_5dien–β-Alaha system

In the case of the Cu^{2+}–Me_5dien–β-Alaha system, the chemical model is different if compared to the system with α-Alaha (Table 4). Three mixed-ligand species (in addition to the simple ones) are observed in this case. Two of these are the same type, i.e. $[Cu(Me_5dien)LH]^{2+}$ and $[Cu(Me_5dien)L]^{+}$. However, in the system with β-Alaha $[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}$ is formed additionally (Fig. 3(b)).

The effect of the formed mixed-ligand species is observed distinctly in the electronic spectral changes. A comparison between the species distribution curves (Fig. 3(b)) and the pH-dependent curves of the absorption (Fig. 4(b)) clearly indicates that the spectral change shown in Fig. 3(b) is attributable to the formation and decay of the mixed-ligand species. It is analogous as it was mentioned above in the system with α-Alaha.

The $[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}$ species is observed in the pH range of 3–6 and is predominant at pH 4. Thus, all uncoordinated amino groups should be protonated. The deprotonation process of this species leads to the formation of $[Cu(Me_5dien)(\beta\text{-Alaha})H]^{2+}$ above pH 6. The deprotonation constant, $pK_{[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}}$, is 6.25. This value is lower than the deprotonation constants of the 'free' ligands (Table 2). However, the second deprotonation step, having a $pK_{[Cu(Me_5dien)(\beta\text{-Alaha})H]^{2+}}$ value equal to 8.85 which is identical with the $pK^{micro}_{\beta\text{-Alaha}}(NH_3^+)$ microconstant value [9], supports that N_{amino} of β-Alaha is not involved in the coordination sphere probably because of steric reasons. So, the first deprotonation step can be assigned to the deprotonation of Me_5dien promoted by the copper(II) binding. Thus, the proposed binding mode for these mixed-ligand species is presented on Scheme 1(b).

Table 6
EPR parameters of the binary and ternary systems

A_y			20

The anisotropic parameters are estimated on the basis of computer simulation of the experimental spectra measured at 77 K. Parameters A are given in 10^{-4} cm^{-1}.

This bonding mode may be supported by the d–d transition. The absorption curve for the $[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}$ species (Fig. 2) exhibits a maximum at about 644 nm with a ε (molar absorptivity) value of ~ 78. A maximum or a shoulder in the region of 800 nm was not observed in the spectrum for this species. So, in the $[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}$ species Me_5-dien occupies two equatorial positions only and the hydroxamic group, forming an{O, O} type chelate ring, occupies the two remaining equatorial positions. The values of its axial EPR parameters indicate involvement of two nitrogen donors and two oxygen donors in the Cu^{2+} coordination plane. Thus, two amino groups, one from Me_5dien and a second from β-Alaha, remain protonated (this type of species is not observed in the spectra recorded for the system with α-Alaha, which supports the species distribution model shown in Fig. 3).

The absorption curve for the next species, $[Cu(Me_5dien)(\beta\text{-Alaha})H]^{2+}$, which exhibits peaks at 610 nm (83) and 753 nm (75) is drastically different from that for $[Cu(Me_5dien)(\beta\text{-Alaha})H_2]^{3+}$ (Fig. 2). This spectral behaviour reveals a structural transformation around the copper(II) ion, strongly suggesting the formation of a five-coordinated mixed-ligand complex. The EPR spectra for $[Cu(Me_5dien)(\beta\text{-Alaha})H]^{2+}$ display parameters of slightly rhombic character and reveal the formation of a complex with a coordination mode of the ligands including two nitrogen and two oxygen donors in the Cu^{2+} plane (Table 6).

The values of $\log K_{[Cu(Me_5dien)LH]^{2+}} = \log \beta_{[Cu(Me_5dien)LH]^{2+}} - pK^{micro}_{NHOH}$ for $[Cu(Me_5dien)(\beta\text{-Alaha})H]^{2+}$ and $[Cu(Me_5dien)(\alpha\text{-Alaha})H]^{2+}$ are 19.29 and 19.07, respectively (Table 4). These values show that the complex formed with β-Alaha is slightly more stable than that formed with α-Alaha. The presence of the positive $-NH_3^+$ group in the side-chain (an electrostatic repulsion between the $-NH_3^+$ group and the coordinating Cu^{2+} ion) decreases the stability of these two complexes and the extent of the decrease depends on the distance between the $-NH_3^+$ group and the hydroxamate moiety [20].

Final liberation of the proton allows all the nitrogen donors to participate in the coordination sphere in the $[Cu(Me_5dien)(\beta\text{-Alaha})]^{+}$ species leading to the chelate rings twisting away followed by an apparent distortion of the geometry from square-pyramidal to trigonal-bipyramidal.

The EPR spectral characteristics for the $[Cu(Me_5dien)L]^+$ mixed-ligand complexes are observed between pH 8 and 11 for the species with α-Alaha, whereas for the complex with β-Alaha the final change of the spectrum is achieved at about pH 10.5 (Table 6). The spectra reveal an apparently stronger rhombic distortion in the case of mixed-ligand species with α-Alaha than that for the complex with β-Alaha and this effect appeared to be the highest for $[Cu(Me_5dien)H_{-1}]$ at pH 12. It is especially noteworthy that the spectrum of the ethanolic solution of the polycrystalline sample precipitated from the ethanol solution of the Cu–Me_5dien–α-Alaha system exhibits exactly the same parameters as that observed between pH 8.1 and 11 for this system in aqueous solution. This not accidental resemblance strongly supports the fact that the spectra are associated with the same thermodynamically $[Cu(Me_5dien)(α\text{-Alaha})]^+$ complex. The EPR spectral difference between both main mixed-ligand complexes may be only assigned to the dissimilar chelate rings formed by aminohydroxamic acid—a five-membered ring for the species with α-Alaha and a six-membered ring for the species with β-Alaha as is shown in the proposed structure (Scheme 1). It is remarkable that the spectral pattern consistent with a strictly trigonal-bipyramidal geometry of the complexes as observed for $[CuX(Me_6tren)^+]$, where Me_6tren is tris(2-dimethylaminoethyl)amine and X = Br, I) [21] is not reached and only an increasing distortion from square-pyramidal is observed in the following order: $[Cu(Me_5dien)(β\text{-Alaha})H]^{2+} < [Cu(Me_5dien)(α\text{-Alaha})H]^{2+}) < [Cu(Me_5dien)(β\text{-Alaha})]^+ < [Cu(Me_5dien)(α\text{-Alaha})]^+$

The basicity-adjusted stability constants, $\log K_{[Cu(Me_5dien)(α\text{-Alaha}/β\text{-Alaha})]} - \Sigma\, pK_L$, for $[Cu(Me_5dien)(α\text{-Alaha})]^+$ and $[Cu(Me_5dien)(β\text{-Alaha})]^+$ are −8.61 and −11.77, respectively (Table 5). These values show that the complex formed with α-Alaha is more stable than that formed with β-Alaha. It seems that the basicity of the coordinating donor groups is over-compensated by the chelating effect which is clearly seen in the case when the $\{N_{amino}, N_{hydrox.}\}$ donor set (provided by aminohydroxamate ligands) is involved in copper(II) chelation. Thus, due to the preference of Cu^{2+} for five- rather than six-membered chelation [22], the complex with α-Alaha is found to be more stable.

The comparison of the concentration distribution curves presented for the Cu^{2+}–Me_5dien–β-Alaha system in Fig. 3(b) together with those for Cu^{2+}–dien–β-Alaha (Fig. 3(d)) reveal that the coordination of β-Alaha towards $[Cu(Me_5dien)]^{2+}$ begins at a much lower pH (pH ≈ 2.50) than towards $[Cu(dien)]^{2+}$ (pH ≈ 6). In the latter system the presence of dien suppresses the formation of pentameric $[Cu_5(β\text{-Alaha})_4H_{-4}]^{2+}$ species whereas in the system with Me_5dien this species appears above pH 4 and reaches two maxima (ca. 50% at pH 6 and close to 100% above pH 12) and one minimum around pH 8.8 (Fig. 3(b)). In the binary system this complex is a main component in the whole pH range.

Very interesting information can be obtained from the comparison of the ternary systems with hydroxamic acids as against those with amino acids (Table 5). The relatively more favoured formation of the complexes involving the mixed bonding mode is showed by results obtained for the studied systems with dien. The order of decreasing stability ($\log K_{[Cu(dien)L]} - \Sigma\, pK_L$) is: $[Cu(dien)(α\text{ - Ala})]^+ > [Cu(dien)(β\text{ - Ala})]^+ > [Cu(dien)(α\text{-Alaha})]^+ > [Cu(dien)(β\text{-Alaha})]^+$ which corresponds to the existence of (N,O) > (N,O) > (N,N) > (N,N) chelate donors of the ligand L and (5) > (6) > (5) > (6) chelate rings of this ligand.

In the case of the systems with Me_5dien this fact is not confirmed. The order of decreasing stability ($\log K_{[Cu(Me_5dien)L]} - \Sigma\, pK_L$) is: $[Cu(Me_5dien)(α\text{-Ala})]^+ > [Cu(Me_5dien)(α\text{ - Alaha})]^+ > [Cu(Me_5dien)(β\text{ - Ala})]^+ > [Cu(Me_5dien)(β\text{-Alaha})]^+$ which corresponds to the existence of (N,O) > (N,N) > (N,O) > (N,N) chelate donors of the ligand L and (5) > (5) > (6) > (6) chelate rings of this ligand.

This order reflects that the chelate containing the pure five-membered rings are favoured over systems with the five- and six-membered rings in the mixed-ligand five coordination complexes with Me_5dien. It is well known that the formation of six-membered chelate rings generally results in a decrease of thermodynamic stability and distortion of coordination geometry of the complexes.

Our spectroscopic data show that the geometry of the mixed-ligand five-coordination complexes consisting of copper(II), Me_5dien and L is closer to trigonal-bipyramidal in the case when L = α-Alaha (see Fig. 2) and when L = β-Alaha the spectrum indicates that the geometry of this mixed-ligand complex is closer to square-pyramidal (see above).

In conclusion, both thermodynamic and structural parameters are rather sensitive functions of the sizes of linked chelate systems. On the other hand, it should be emphasised that there is not a strict relationship between the thermodynamic and structural parameters.

4. Conclusion

Studying the mixed-ligand complexes: $[Cu(en)(α\text{-Alaha})]^+$, $[Cu(dien)(α\text{-Alaha})]^+$, $[Cu(dien)(β\text{-Alaha})]^+$, $[Cu(dien)(Hisha)]^+$, $[Cu(dien)(Metha)]^+$, $[Cu(Me_5dien)(α\text{-Alaha})]^+$ and $[Cu(Me_5dien)(β\text{-Alaha})]^+$ we could see the phenomena of the plasticity of the coordination sphere of copper(II). In these complexes the geometry around the copper(II) atom is controlled first of all by the polyamine, i.e. by the number of nitrogen atoms

which may occupy coordination sites. In the case of $[Cu(en)(\alpha\text{-Alaha})]^+$ bidentate amine occupies two coordination sites and α-Alaha is coordinated in the same way as in the binary system; the mixed-ligand complex has a planar geometry and 4N coordination. The other above-mentioned complexes with tridentate amines are five-coordinate species but species with dien have a geometry slightly deviated from square-pyramidal whereas species with Me_5dien have a geometry closer to trigonal-bipyramidal probably because of steric reasons.

An increasing distortion of the $[Cu(Me_5dien)H_2O]^{2+}$ complex geometry in comparison with $[Cu(dien)H_2O)]^{2+}$ has no influence on their relative stability but results in higher stability of the mixed-ligand complexes with Me_5dien than those with dien ($\log K_{[Cu(Me_5dien)L]} > \log K_{[Cu(dien)L]}$). Murakami et al. [18] observed the same tendency for the ternary systems in which ligand L was replaced by an amino acid.

The present of additional groups in the side chain of the aminohydroxamic acids, i.e. a $CH_3–S–CH_2–$ group in methioninehydroxamic acid or an imidazole ring in histidinehydroxamic acid do not cause considerable deformations of the coordination geometry [3].

Abstract

The new 1,4-diaza-1,3-diene niobium complexes (*t*-Bu-DAD)$NbCl_3$(THF) (**2**) and (*t*-Bu-DAD)$_2$NbCl (**3**) [*t*-Bu-DAD≡(*t*-Bu)N=CHCH=N(*t*-Bu)] have been prepared in 75–82% isolated yields by replacing of two or four chlorine atoms of $NbCl_5$ by the sterically demanding *t*-Bu-DAD ligand. In addition, we also describe the ionic Nb(V) complex [(*t*-Bu-DAD)$NbCl_4$](H_3N*t*-Bu) (**6**) which was formed as a byproduct during the preparation of **2**. The new compounds have been characterized in solution by NMR measurements as well as by X-ray analyses in solid state. The structural parameters within the *t*-Bu-DAD ligand of **6** are in agreement with a chelating enediamido dianion. On the other hand the N–C and C–C bond distances of the *t*-Bu-DAD ligand of **2** are rather comparable to those found in complexes having a radical–anionic *t*-Bu-DAD ligand. The higher steric crowding at the niobium center caused by two 1,4-diaza-1,3-diene ligands in **3** leads to a significant asymmetric distortion of the 1,3-diaza-2-niobacyclopent-4-ene rings. However, none of the 1,4-diaza-1,3-diene ligands of **2**, **3** or **6** is coordinated in the sterically less demanding η2-C,N bonding mode as found in the binuclear complex (*t*-Bu-DAD)$_5Nb_2$ (**4**). © 2002 Elsevier Science Ltd. Keywords: Niobium complexes; Heterodiene; 1,4-Diaza-1,3-diene; X-ray crystal structures

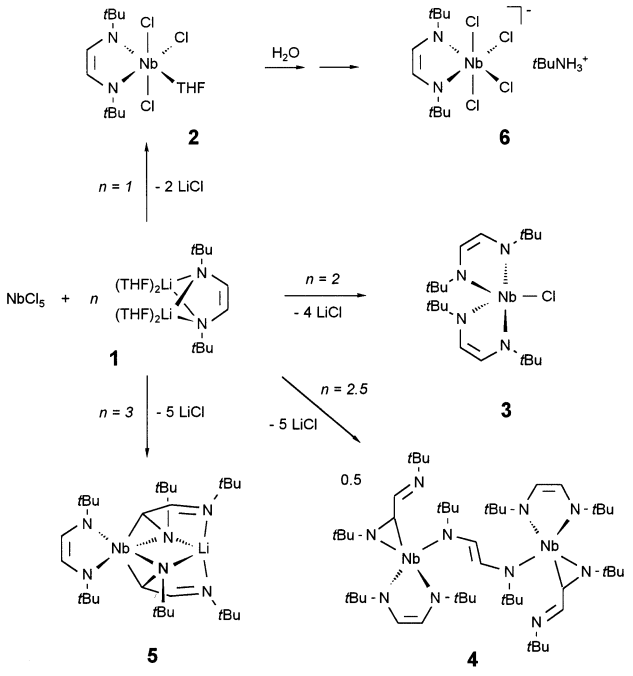
1. Introduction



1,4-Diaza-1,3-diene (DAD) metal complexes have been shown to play an important role in homogeneous catalytic reactions. Ni(DAD) complexes, for instance, are very active catalysts for the homo and copolymerization of alkenes [1], Ru(DAD) complexes were used to catalyze the hydrogenation, the hydrosilylation and the isomerization of alkenes [2], whereas in other cases Fe(DAD) complexes are effective and selective catalysts for the cyclodimerization of 1,3-dienes [3]. The structural chemistry of 1,4-diaza-1,3-diene complexes of late transition metals is dominated by the versatile coordination behavior of this type of organic ligand [4]. This versatility arises from the ability of the 1,4-diaza-1,3-dienes to use both the lone pairs of the nitrogen atoms (σ-donor) and the π system of the two C=N bonds (π-acceptor) for coordination to a metal.

Recently, we reported about the novel niobium 1,4-diaza-1,3-diene complexes **4** and **5** (Scheme 1) [5]. With regard to the stability of the early transition metals in their highest oxidation state it is not surprising, that the 1,4-diaza-1,3-diene ligands in **4** and **5** as in other 1,4-diaza-1,3-diene complexes of Group 4 and 5 metals [6] formally have been double reduced to the dianion. Nevertheless, complexes **4** and **5** are the first examples which demonstrate that other coordination types than the ordinary chelate form are also possible for 1,4-diaza-1,3-diene ligands bound to early transition metals. Most spectacular is the molecular structure of the dinuclear niobium complex **4** which shows five 1,4-diaza-1,3-diene ligands in three different bonding situations.

In this paper, we complete the series of 1,4-diaza-1,3-diene niobium complexes by the chloride complexes

(*t*-Bu-DAD)$NbCl_3$(THF) (**2**) and (*t*-Bu-DAD)$_2$NbCl (**3**) [*t*-Bu-DAD=(*t*-Bu)N=CHCH=N(*t*-Bu)] which have been prepared by replacing of two or four halogen atoms of $NbCl_5$ by the sterically demanding *t*-Bu-DAD ligand. In addition, we also describe the ionic Nb(V) complex [(*t*-Bu-DAD)$NbCl_4$](H_3N*t*-Bu) (**6**) which was formed as a byproduct during the preparation of **2**.

2. Results and discussion

2.1. Syntheses of (t-Bu-DAD)$NbCl_3$(THF) (2), (t-Bu-DAD)$_2$NbCl (3) and [(t-Bu-DAD)$NbCl_4$][t-BuNH_3] (6)

The 1,4-diaza-1,3-diene niobium chloride complex (*t*-Bu-DAD)$NbCl_3$(THF) (**2**) was synthesized by reaction of the lithium 1,4-diaza-1,3-diene compound Li_2(*t*-Bu-DAD) (**1**) [7] with 1 equiv. of $NbCl_5$ in THF according to Scheme 1. Removal of the solvent after the reaction gave a dark red residue, from which **2** could be isolated by extracting with diethyl ether as purple crystals in good yield (75%). Complex **2** is thermally stable but very air-sensitive and only sparingly soluble in diethyl ether but moderately soluble in THF. Crystals suitable for an X-ray study were obtained by cooling a saturated THF solution of 2 to −20 °C for 1 week.

A minor byproduct (about 5%) formed during the synthesis of **2** was identified as [(*t*-Bu-DAD)$NbCl_4$][*t*-BuNH_3] (**6**). This complex probably arises from the reaction of **2** with traces of water which could have contaminated the ether solution during the purification of **2** but the details of the formation of **6** are not yet understood. Complex **6** is sparingly soluble in THF and crystals of **6** suitable for an X-ray diffraction study were found during an attempt to grow crystals of **2**.

A dark brown crystalline solid of (*t*-Bu-DAD)$_2$NbCl (**3**) (see Scheme 1) was isolated in high yield (82%) by reaction of $NbCl_5$ with 2 equiv. of **1** in THF, and crystallization from pentane and ether. In contrast to **2** complex **3** is highly soluble in aliphatic and aromatic solvents and is considerable volatile. The robustness of this complex is convincingly demonstrated by the fact that the molecular ion peak in the electron impact mass spectra appears as basis peak. Single crystals of **3** suitable for an X-ray diffraction study were grown from a saturated ether solution.

2.2. X-ray diffraction studies

Single-crystal X-ray studies on the compounds **2**, **3** and **6** were carried out in order to have a complete set of structural parameters for **1**–**6** and to determine to what extent the 1,4-diaza-1,3-diene bonding mode is influenced by changing the electronic and steric situation at the metal center. The molecular structures of **2**, **3**, and **6** with their atom labeling schemes are shown in Figs. 1–3. Selected intramolecular bond lengths and angles are listed in Tables 1–3. Table 4 contains the crystal data for these complexes.

Some general comments about these structures are warranted. The structural parameters and the NMR data we have obtained for the new complexes **2**, **3** and **6** are largely consistent with a bonding situation found in most other 1,4-diaza-1,3-diene complexes of early transition metals [6]. The heterodiene ligands are bonded as *N*,*N*-chelates forming five-membered rings which have a folded geometry with the niobium atom lying out of the plane of the NC=CN backbone. Usually the lack of planarity of the metallacyclic rings in

these 1,4-diaza-1,3-diene complexes has been taken as proof of an enediamide ligand donating to a d^0 metal center and forming a metallacyclopentene ring and not a π-bonded 1,4-diaza-1,3-diene ligand. In both **2**, **3** and **6**, the ring folding moves the internal carbons, C1 and C2, of the 1,3-diaza-2-niobacyclopentene rings closer to the electrophilic niobium center. The corresponding Nb–C1 and Nb–C2 distances of 2.36–2.49 Å imply that these complexes could experience some stabilization from a weak attractive interaction between the filled π-orbital of the C1=C2 double bond and an empty metal orbital. However, the absence of any significant difference in the C1=C2 bond distances of the complexes **2** (1.414(5) Å) and **3** (1.386(6), 1.414(7) Å) and the fact that the folding angles are quite comparable (**2**: 123.2(1)°; **3**: 123.4(1)°, 122.4(2)°) and do not reflect the different coordination geometries of these two niobium complexes suggests that this type of π-interaction is probably not a major factor in determining the relative stability of the nonplanar structures.

*2.3. Solid state structures of (t-Bu-DAD)$NbCl_3$(THF) (**2**) and [(t-Bu-DAD)$NbCl_4$][H_3Nt-Bu] (**6**)*

The distorted octahedral coordination sphere about the niobium atom of complex **2** consists of the three chlorine atoms, the coordinated THF molecule, and the two nitrogen donors of a symmetrically-chelating *t*-Bu-DAD ligand. A small *trans* influence is observed when the niobium–chlorine distances are compared. The Nb–Cl1 (2.397(1) Å) and Nb–Cl2 (2.408(1) Å) bond lengths are typical and compare well to terminal Nb–Cl distances found in other Nb(V) complexes [8], while the Nb–Cl3 distance (*trans* to N1) is somewhat longer (2.465(1) Å). Surprisingly the C–N bond lengths within the *t*-Bu-DAD ligand of **2** (N1–C1 1.298(5), N2–C2 1.345(5) Å) do not fall within the range 1.38–1.42 Å, observed for related enediamide complexes that conform to the metallacyclopentene structure [6]. Accordingly the C1–C2 bond length (1.414(5) Å) is significantly longer than expected for a double bond and much closer to the C–C single bond of *t*-Bu-DAD [7b,9]. In contrast to the results of the NMR spectroscopic investigations (vide infra) which clearly demonstrate the presence of a diamagnetic d^0 enediamide niobium(V) complex these N–C and C–C bond distances are rather comparable to those found in complexes having a radical–anionic *t*-Bu-DAD ligand [10]. Furthermore it is remarkable, that the folding of the (N1, C1, C2, N2) plane relative to the (Nb, N1, N2) plane is not accompanied by a rehybridization of the nitrogen atoms to sp^3. The sum of angles at N1 (359.8(3)°) and N2 (358.4(3)°) demonstrates that the nitrogen atoms are arranged in the plane of the surrounding three atoms. This coordination geometry about the amido nitrogen atoms together with the relatively short Nb–N bond distances (Nb–N1 1.973(3), Nb–N2 1.961(3) Å) [11] suggests that these nitrogen atoms act as four-electron donors in this molecule.

On the other hand the homologous 1,4-diaza-1,3-diene niobium complex (*i*-Pr-DAD)$NbCl_3$(THF) (**7**), [*i*-Pr-DAD≡(*i*-Pr)N=CHCH=N(*i*-Pr)] (Scheme 2) [12],

exhibits ordinary Nb–N bond distances (2.048(2) and 2.057(2) Å) without any significant π-bonding contribution.

Moreover, in contrast to that of **2**, the five-membered ring (Nb–N–C=C–N) is hardly folded (6.3(2)°) and two chlorine atoms are found in the plane of the 1,4-diaza-1,3-diene. It is very surprising that an apparent unimportant change at the ligand periphery has such significant consequences for the structure of **7**. We found that these unusual structural parameters are caused by hydrogen bonds between the metal-bonded chlorine atoms and the methine hydrogen atoms of the isopropyl groups. To date there are hardly any compounds known in which chlorine atoms are covalently bound and nevertheless participate in C–H···Cl hydrogen bonds.

Complex **6** crystallizes as an ionic compound consisting of a niobate(V) anion and one *tert*-Butylammonium cation to balance the charge. The overall geometry of the [(t-Bu-DAD)NbCl$_4$]$^-$ anion and in particular the bonding parameters of the reduced heterodiene ligand are in close agreement with those of **2**. The environment about the niobium atom corresponds to a distorted octahedron with four chlorine ligands and the two N-donors of the t-Bu-DAD ligand. The *cis* chlorine–niobium–chlorine angles ranging from 82.77(4)° to 86.21(4)°, while the *trans* angle Cl1–Nb–Cl2 spans 162.54(4)°. Closer inspection of the crystal structure reveals that the *tert*-Butylammonium hydrogen atom H3 is hydrogen bonded to Cl4 (H3···Cl4 2.24(1) Å, N3–H3–Cl4 163.6(10)°). Nevertheless, the Nb–Cl4 distance (2.434(1) Å) which is not longer than those of Nb–Cl1 (2.424(1) Å), Nb–Cl2 (2.571(1) Å), and Nb–Cl3 (2.523(1) Å), implies that this interaction is rather weak. Moreover, the N–H3···Cl2 hydrogen bonding observed in **6** should not be viewed as unusual, since

there are many other examples of related N–H···Cl–M complexes [8b,13].

2.4. Solid state structure of (t-Bu-DAD)$_2$NbCl (3)

Unlike the complexes **2** and **6** the Nb atom in **3** has the coordination number five if only the lone pair donor sites of the ligands are taken into account. Moreover, the binding of the *t*-Bu-DAD ligands is slightly asymmetric, as seen by different Nb–N bond distances (Nb–N1 1.962(4), Nb–N2 2.110(3), Nb–N3 1.978(4), Nb–N4 2.111(4) Å). According to this asymmetric bonding mode only the nitrogen atoms N1 and N3 which exhibit significantly shorter Nb–N bond distances maintain a planar sp^2 environment, as seen by the summation of angles about N1 and N3 (358.6(3)° and 357.9(3)°). The nitrogen atoms N2 and N4 tend appreciably more towards pyramidality, with angle sums of 351.2(3)° and 351.4(3)°. The dihedral angle between the planes containing the atoms Nb, N1, N2 and Nb, N3, N4 is 78.0(1)°. The slightly longer niobium–chlorine bond (2.523(1) Å) in **3** can be rationalized by the presence of the two heterodiene ligands and no other halogen atoms which make the central metal less electrophilic, relative to that in **2** or **6**. Consequently, a longer bond length of the chlorine atom to the niobium atom in **3** ensues.

2 **7**

Scheme 2.

2.5. Solution structures of 2 and 3

The ^{1}H NMR spectrum of **2** in THF-d_8 at room temperature (300 MHz) exhibits the HC=CH and the *t*-Bu signal as single peaks at δ 6.44 and δ 1.51, as well as a set of the THF proton signals. Their relative intensities indicate that **2** contains one coordinated THF molecule. Furthermore, the simplicity of the ^{1}H NMR spectrum at room temperature suggests that a dynamic process is occurring that in contrast to the solid state structure renders the two ends of the 1,4-diaza-1,3-diene ligand equivalent. On cooling the sample to −80 °C the low-temperature limiting spectrum is observed, with two separate resonances for the backbone protons at δ 6.69 and 6.64 as well as two signals for the *t*-Bu protons at δ 1.58 and 1.54. This observation is consistent with a rapid (NMR time scale) exchange process involving probably the inversion of the folded 1,3-diaza-2-niobacyclopentene ring and equilibrating the geminal protons of the ligand backbone and that of the *t*-Bu groups. The final limiting low-temperature spectra is totally consistent with the observed solid-state structure of **2**.

The ^{1}H NMR spectrum of complex **3** acquired at −80 °C contains four sharp signals for the *t*-Bu hydrogens (δ 1.38, 1.21, 1.15, and 0.98) and four doublets for the HC=CH groups which is in agreement with the lack of any symmetry of the solid structure of **3**. As the temperature is raised up to ambient temperature, both the *t*-Bu and the HC=CH resonances broaden and collapse into one signal, respectively (*t*-Bu δ 1.29, HC=CH δ 6.10). These NMR results of **3** coupled with the solid state geometry suggests that the enediamide units show a dynamic behavior passing through an apparent molecular plane of symmetry. In other words, we assume that the folded 1,3-diaza-2-niobacyclopentene rings undergo a ring inversion which is rapid on the NMR time scale at room temperature [6c,6e,6l].

3. Concluding remarks

Reaction of $NbCl_5$ with Li_2(*t*-Bu-DAD) offers a convenient synthetic route for the preparation of the 1,4-diaza-1,3-diene niobium halogenide complexes **2** and **3** in consistently good isolated yields and provide the opportunity to evaluate structural changes due to the stepwise replacement of chlorides by the heterodienes. X-ray studies completed by variable-temperature NMR measurements show that the 1,4-diaza-1,3-diene ligand in **2** is strongly bound as a *N*,*N*-chelate to the metal center with structural parameters consistent with a folded 1,3-diaza-2-niobacyclopentene ring bonding description. Furthermore, comparison of the structural data of **2** and **3** shows that the lower steric requirements of only one 1,4-diaza-1,3-diene ligand in **2** enhance the metals Lewis acidity and even permit the addition of one molecule THF. The higher steric crowding caused by two 1,4-diaza-1,3-diene ligands in **3** leads to a significant asymmetric distortion of the 1,3-diaza-2-niobacyclopentene rings. However, none of the 1,4-diaza-1,3-diene ligands is coordinated in the sterically less demanding η^2-C,N bonding mode as found in **4** [5] and in Cp*Ta(η^2-*t*-Bu-DAD)(S-*t*-Bu)2 [14]. Altogether, the complete series of niobium complexes **2**–**5** confirms that the 1,4-diaza-1,3-diene bonding mode in this type of compounds is mainly influenced by the sterical situation of the metal center.

4. Experimental

4.1. General procedures

All reactions were carried out under Ar with strict exclusion of moisture using standard Schlenk techniques [15]. Solvents were dried over and distilled from Na–benzophenone ketyl under Ar, except for CD_2Cl_2, which was distilled from activated molecular sieves (3 Å). $NbCl_5$ was purchased from Aldrich. *t*-Bu-DAD [16] and Li_2(*t*-Bu-DAD) [7] were prepared according to literature procedures.

NMR spectra were recorded on a Varian Gemini 300 BB spectrometer with deuterated solvents as an internal lock. ^{1}H (300 MHz) and ^{13}C NMR (75 MHz) shifts are referenced to internal solvent resonances and reported relative to TMS. MS studies were performed on a Intectra AMD 402 instrument with 70 eV electron impact ionization. Elemental analyses were carried out at the Mikroanalytisches Laboratorium of the Chemical Department at the Martin-Luther-Universität Halle-Wittenberg.

4.2. (*t*-Bu-DAD)$NbCl_3$(THF) (**2**)

To a solution of 6.42 g of $NbCl_5$ (23.8 mmol) in 100 ml THF cooled to −60 °C was added dropwise with stirring a solution of 23.8 mmol of Li_2(*t*-Bu-DAD) in 100 ml of THF prepared by addition of 0.33 g lithium (47.6 mmol) to a solution of 4.00 g *t*-Bu-DAD (23.8 mmol) in THF. The reaction mixture was allowed to warm to room temperature (r.t.) within 2 h whereupon a red brown color developed. After stirring for a further 12 h, the solvent was removed in vacuo and the residue was extracted several times with 100 ml of Et_2O. Cooling of the extract to −20 °C overnight afforded a purple crystalline material (7.87 g, 17.9 mmol, 75%). Single crystals suitable for X-ray crystallography were obtained by slow cooling of a solution of **2** in THF. ^{1}H NMR (d_8-THF) + 20 °C: δ 6.44 (s, 2H; *H*C=C*H*), 3.62 (m, 4H; OCH_2, THF), 1.77 (m, 4H; OCH$_2$CH_2, THF), 1.51 (s, 18H; CMe_3); −80 °C: δ 6.69 (d, ^3J(H,H) = 2.0 Hz, 1H; *H*C=C*H*), 6.64 (d, ^3J(H,H) = 2.0 Hz, 1H; *H*C=C*H*), 3.62 (m, 4H; OCH_2, THF), 1.80 (m, 4H; OCH$_2$CH_2, THF), 1.58 (s, 9H; CMe_3), 1.45 (s, 9H; CMe_3); (CD_2Cl_2) + 20 °C: δ 6.31 (s, 2H; *H*C=C*H*), 4.14 (m, 4H; OCH_2, THF), 1.95 (m, 4H; OCH$_2$CH_2, THF), 1.55 (s, 18H; CMe_3). ^{13}C NMR (d_8-THF) + 25 °C: δ 102.48 (d, ^1J(C,H) = 180.2 Hz, ^2J(C,H) = 10.4 Hz; H*C*=*C*H), 68.21 (t, OCH_2, THF), 64.85 (s; *C*Me$_3$), 29.69 (q, ^1J(C,H) = 127.2 Hz; CMe_3), 26.24 (t, ^1J(C,H) = 135.3 Hz; OCH$_2$*C*H$_2$, THF); (CD_2Cl_2) 25 °C: δ 101.01 (d, ^1J(C,H) = 178.5 Hz, ^2J(C,H) = 10.6 Hz; H*C*=*C*H), 71.07 (t, ^1J(C,H) = 146.7 Hz; OCH_2, THF), 65.26 (s; *C*Me$_3$), 29.70 (q, ^1J(C,H) = 128.8 Hz; CMe_3), 25.64 (t, ^1J(C,H) = 135.3 Hz; OCH$_2$*C*H$_2$, THF). EI MS (70 eV), *m*/*z* (%): 366 (5) [M^+ − THF], 331 (8) [M^+ − Cl − THF], 310 (8) [M^+ − THF − CMe_3], 254 (24) [$C_2H_2N_2Cl_2Nb^+$], 219 (12) [$C_2H_2N_2Cl_3^+$]. *Anal.* Calc. for $C_{14}H_{28}Cl_3N_2NbO$ (439.65 g mol^{-1}): C, 38.25; H, 6.42; N, 6.37. Found: C, 37.97; H, 6.40; N, 6.52%.

4.3. (t-Bu-DAD)$_2$NbCl (3)

To a solution of 4.11 g of $NbCl_5$ (15.2 mmol) in 100 ml THF cooled to −60 °C was added dropwise with stirring a solution of 30.4 mmol of Li_2(*t*-Bu-DAD) in 100 ml of THF prepared by addition of 0.42 g Li (60.8 mmol) to a solution of 5.12 g *t*-Bu-DAD (30.4 mmol) in THF. The reaction mixture was allowed to warm to r.t. and was stirred for 12 h. The solvent was removed by evaporation in vacuum, and the product was then extracted into C_5H_{12}. The extract was concentrated to 50 ml and cooled at −20 °C overnight to give a brown crystalline solid (5.72 g, 12.3 mmol, 81%). Suitable brown–red single crystals for X-ray studies were obtained from a saturated solution of **3** in C_5H_{12} at 0 °C. ^{1}H NMR (d_8-THF, 20 °C): $\delta = 6.10$ (br s, 4H; *H*C=C*H*), 1.29 (s, 36H; C*Me*$_3$); (CD_2Cl_2, −80 °C): $\delta = 6.60$ (d, ^3J(H,H)=2.3 Hz, 1H; =C*H*), 6.48 (d, ^3J(H,H) = 2.3 Hz, 1H; =C*H*), 5.84 (d, ^3J(H,H) = 2.5 Hz, 1H; =C*H*), 5.29 (d, ^3J(H,H) = 2.5 Hz, 1H; =C*H*), 1.38 (s, 9H; C*Me*$_3$), 1.21 (s, 9H; C*Me*$_3$), 1.15 (s, 9H; C*Me*$_3$), 0.98 (s, 9H; C*Me*$_3$). ^{13}C NMR (d_8-THF, 25 °C): $\delta = 107.50$ (br, H*C*=*C*H), 59.46 (*C*Me$_3$), 31.20 (br, C*Me*$_3$). EI MS (70 eV), *m*/*z* (%): 465 (100) [M^+], 450 (15) [$M^+ -$ Me], 407 (68) [$M^+ -$ CMe$_3$], 297 (30) [$C_{10}H_{20}N_2NbCl^+$], 185 (80) [$C_2H_4N_2NbCl^+$]. *Anal.* Calc. for $C_{20}H_{40}ClN_4Nb$ (464.92 g mol^{-1}): C, 51.67; H, 8.67; N, 12.05. Found: C, 50.88; H, 8.82; N, 12.30%.

4.4. [(t-Bu-DAD)NbCl$_4$][t-BuNH$_3$] (6)

^{1}H NMR (d_8-THF, 20 °C): $\delta = 7.77$ (br s, 3H, Me$_3$CN*H*$_3$), 6.34 (br s, 2H; H*C*=C*H*), 3.38 (q, 4H; OC*H*$_2$, Et$_2$O), 1.58 (s, 18H; C*Me*$_3$), 1.46 (s, 9H; *Me*$_3$CNH$_3$), 1.11 (t, 6H; OCH$_2$C*H*$_3$, Et$_2$O). ^{13}C NMR (d_8-THF, 25 °C): $\delta = 102.02$ (H*C*=*C*H), 66.26 (O*C*H$_2$, Et$_2$O), 64.64 (*C*Me$_3$), 53.37 (*C*Me$_3$), 30.02 (C*Me*$_3$), 28.04 (C*Me*$_3$), 15.60 (OCH$_2$*C*H$_3$, Et$_2$O). *Anal.* Calc. for $C_{18}H_{42}N_3OCl_4Nb$ (551.27 g mol^{-1}): C, 39.22; H, 7.68; N, 7.62. Found: C, 39.01; H, 7.66; N, 8.10%.

4.5. X-ray crystal structure determination of 2, 3 and 6

The intensity data for the compounds **2** and **3** were collected on a Nonius CAD4 diffractometer and for compound **6** on a Nonius Kappa CCD diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.7107 Å). Data were corrected for Lorentz and polarization effects, but only for **2** and **3** for absorption [17,18]. The structures were solved by direct methods (SHELXS) [19] and refined by full-matrix least squares techniques against F_o^2 (SHELXL-97) [20]. For the compounds **3** and **6** the hydrogen atoms were located by difference Fourier synthesis and refined isotropically, the hydrogen atoms of the compound **2** were included at calculated positions with fixed thermal parameters. All nonhydrogen atoms were refined anisotropically [20]. XP (SIEMENS Analytical X-ray Instruments, Inc.) was used for structure representations. Cell constants and other pertinent data are collected and recorded in Table 4.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 165574, 165575, and 165576 for compounds **2**, **3**, and **6**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Syntheses, spectroscopic and crystal structural studies of novel imidazo[4,5-f]1,10-phenanthroline derivatives and their Eu(III) ternary complexes with dibenzoylmethane

Zu-Qiang Bian, Ke-Zhi Wang *, Lin-Pei Jin

Department of Chemistry, Beijing Normal University, Beijing 100875, People's Republic of China

Received 6 August 2001; accepted 8 November 2001

Abstract

Two novel ligands, 2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline (L1) and 3-ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline (L2), and their europium(III) complexes with dibenzoylmethanate (DBM), Eu(DBM)$_3$(L1) and Eu(DBM)$_3$(L2), were synthesized and characterized by IR, UV–Vis and fluorescence spectroscopy, and thermogravimetric and differential thermal analyses (TG–DTA). The fluorescent intensity of Eu(DBM)$_3$(L2) is 18 times that of Eu(DBM)$_3$(L1). The crystal structures of Eu(DBM)$_3$(L1) and L2 were determined by single crystal X-ray diffraction. Each europium atom is coordinated by six oxygen atoms of three bidentate DBM anions and two nitrogen atoms from one bidentate L1, forming a distorted square antiprism. Highly resolved fluorescence spectroscopy of Eu(DBM)$_3$(L1) at 77 K revealed one Eu(III) site. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Europium complexes; X-ray crystallography; Luminescence property; Dibenzoylmethane; 2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline; 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline

1. Introduction

In the past three decades, Eu(III) β-diketonates have been intensively studied with respect to their applications for luminescence and laser materials since the first successful laser action in europium β-diketonate was reported by Lempicki and Samelson in 1963 [1]. Recently, Eu(III) complexes have attracted extensive interest in electroluminescent devices owing to their inherent extremely sharp emission bands and potentially high internal quantum efficiency [2–6]. These characteristics make Eu(III) complexes promising candidates for the next generation of flat-panel display with low-voltage drive. Among the Eu(III)-β-diketonate complexes studied as an emissive layer in EL devices, Eu(III) dibenzoylmethanate ternary complexes exhibited appealing and desirable EL properties. The formation of ternary complexes by the introduction of a second ligand into Eu dibenzoylmethanate complexes could improve the volatility, thermal stability and carrier-transport ability of the europium complexes, and thus greatly enhance the photoluminescent and electroluminescent properties [3,7,8]. In order to develop novel Eu(III) complex-based materials for EL devices with improved device performance, we synthesized two novel ligands, 2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline and 3-ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, and also their europium ternary complexes with dibenzoylmethanate. The synthetic details and spectroscopic and crystal structure results are reported in this paper.

2. Experimental

2.1. Materials and methods

Dimethylformamide (DMF) was purified by distillation over P_2O_5 and *n*-hexane over CaH_2. All other

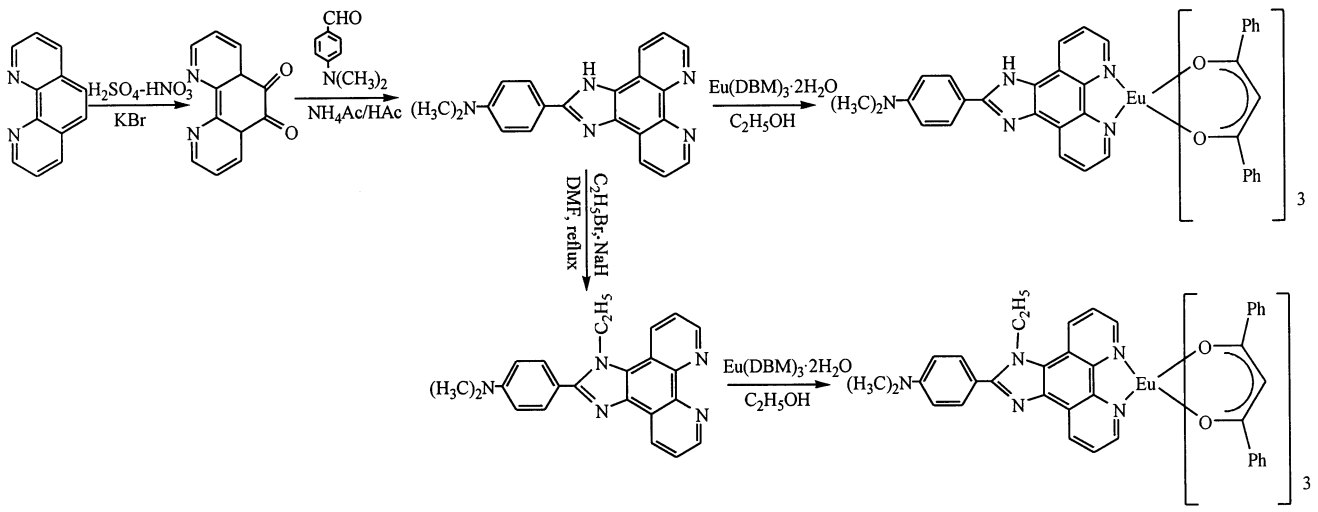
reagents were commercially available and were used without further purification. Contents of carbon, hydrogen and nitrogen were determined using a Perkin–Elmer 240 elemental analyzer. Absorption spectra were recorded with a Shimadzu UV-3100 spectrophotometer. IR-spectra were recorded on a Perkin–Elmer 200-FTIR spectrophotometer in the range of 4000–400 cm^{-1} using KBr pellets. The ^1H NMR spectra were recorded on a Varian 500 MHz instrument using d_6-DMSO as solvent and Me_4Si as internal reference. Thermogravimetric and differential thermal analyses were carried out with a LCT-1 system, at an elevation temperature rate of 10° min^{-1} in an ambient atmosphere. Luminescence spectra were performed with a Hitachi F-4500 spectrophotometer. The highly resolved emission spectra and the time-resolved fluorescence measurements were performed at 77 K using a Nd–YAG pumped dye laser with RG 10 dye as the excitation source and a Spex 1403 double grating monochromator.



2.2. Syntheses

Synthetic routes of the ligands and their Eu(III) complexes are presented in Scheme 1.

2.2.1. Synthesis of ligands

2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline (**L1**) was synthesized by condensation of 1,10-phenanthroline-5,6-dione [9] and dimethylaminobenzaldehyde, according to a slightly modified imidazole ring preparation method [10,11]. The crude product was purified by recrystallization from a mixture of EtOH and water to get yellow crystals (yield 79%). *Anal.* Found: C, 66.17; H, 5.70; N, 17.05. Calc. for $C_{21}H_{17}N_5{\cdot}0.5C_2H_5OH{\cdot}2H_2O$: C, 66.17; H, 5.55; N, 16.78%. ^1H NMR, δ: 13.42 (s, 1H), 9.02 (d, 2H), 8.91 (q, 2H), 8.12 (d, 2H), 7.82 (d, 2H), 6.90 (d, 2H), 3.02 (s, 6H) ppm. UV–Vis in ethanol, λ_{max}/nm ($\varepsilon \times 10^{-4}$/$dm^3$ mol^{-1} cm^{-1}): 235 (2.34), 292 (2.33), 338 (2.60). IR in KBr pellet: 1718(vw), 1612(vs), 1560(w), 1527(m), 1489(s), 1440(s), 1396(w), 1370(m), 1352(m), 1202(m), 1070(w), 1030(w), 953(w), 812(w), 741(s) cm^{-1}. M.p. >300 °C.

3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10–phenanthroline (**L2**) was synthesized as follows: L1 (1.7 g, 5.0 mmol) in 20 ml of DMF was allowed to react with sodium hydride (0.288 g, 6.0 mmol, 50% dispersion in mineral oil), which was washed by *n*-hexane in order to remove the mineral oil, under a N_2 atmosphere. Upon heating to 100 °C, a vigorous reaction occurred with the evolution of H_2 gas and the color of the solution changed from pale yellow to brown. After the evolution of the gas has ceased, bromoethane (1.1 g, 10 mmol) was added dropwise and the resulting solution was further refluxed for 12 h. NaBr precipitated upon cooling was removed by filtration. An addition of a large amount of ether gave a yellow precipitate of the desired ligand, which was chromatographed on a silica gel column with CH_2Cl_2–MeOH (15:1, v/v) as an eluent and recrystallized from ethanol to get yellow crystals (58% yield). Crystals suitable for X-ray analysis were obtained from the mother liquor after 2 weeks at the room temperature (r.t.). *Anal.* Found: C, 75.19; H, 5.76; N, 19.06. Calc. for $C_{23}H_{21}N_5$: C, 74.83; H, 5.79; N, 18.53%. ^1H NMR, δ: 9.06 (d, 2H), 8.94 (q, 2H), 7.86 (d, 2H), 7.64 (d, 2H), 6.92 (d, 2H), 4.72 (m, 2H), 3.03 (s, 6H), 1.49 (m, 3H) ppm. UV–Vis in ethanol, λ_{max}/nm ($\varepsilon \times 10^{-4}$/$dm^3$ mol^{-1} cm^{-1}): 237 (2.38), 288 (2.65). 2.2.2. Synthesis of complexes

Tris(dibenzoylmethanato){2-(4′-dimethylaminophenyl)imidazo[4,5 - f]1,10 - phe - nanthroline}europium(III) [$Eu(DBM)_3L1$] was synthesized as follows: $Eu(DBM)_3{\cdot}2H_2O$ [12] (0.170 g, 0.2 mmol) and L1 (0.080 g, 0.2 mmol) were refluxed in 20 ml of ethanol for 2 h. A yellow precipitate formed upon cooling was filtered and recrystallized from 30 ml of mixed solvents EtOH and THF (1:1, v/v). Crystals suitable for X-ray analysis were obtained from the mother liquor after 8 days at r.t. *Anal*. Found: C, 67.83; H, 4.14; N, 5.81. Calc. for $C_{66}H_{50}N_5O_6Eu$: C, 68.27; H, 4.34; N, 6.03%. UV–Vis in tetrahydrofuran, λ_{max}/nm ($\varepsilon\times10^{-4}$/dm^3 mol^{-1} cm^{-1}): 247 (6.08), 288 (3.51), 349 (8.02). IR in KBr pellet: 1610(s), 1594(s), 1547(vs), 1518(vs), 1479(vs), 1455(s), 1406(vs), 1359(m), 1312(m), 1284(m), 1222(w), 1199(w), 1073(m), 1024(w), 736(m), 687(m), 608(w) cm^{-1}.

Tris(dibenzoylmethanato){3 - ethyl - 2 - (4′ - dimethylaminophenyl)imidazo[4,5 - f]1,10 - phenanthroline}europium(III) [$Eu(DBM)_3$(L2)] was synthesized by following the procedure described above for $Eu(DBM)_3$(L1) except that L2 was used instead of L1. *Anal*. Found: C, 66.28; H, 4.74; N, 5.51. Calc. for $C_{68}H_{58}N_5O_8Eu$: C, 66.67; H, 4.77; N, 5.72%. UV–Vis in tetrahydrofuran, λ_{max}/nm ($\varepsilon\times10^{-4}$/dm^3 mol^{-1} cm^{-1}): 243 (4.77), 284 (3.69), 348 (4.32). IR in KBr pellet: 1595(vs); 1549(vs); 1518(vs); 1478(vs); 1457(s); 1410(vs); 1309(m); 1219(w); 1023(w); 722(m); 670(w) cm^{-1}.

2.3. X-ray crystallographic determination

X-ray data were collected in ω–2θ scan mode with a Rigaku AFC 7R diffractomer for $Eu(DBM)_3$(L1) and a CCD area detector Bruker SMART 2000 X-ray for L2 using Mo Kα radiation at 298 K. All calculations were performed using the TEXSAN [13] crystallographic software package. The intensity data were corrected for LP and empirical absorption corrections using the program DIFABS [14] were applied. Crystallographic data for the two compounds are listed in Table 1 and full details of the structure determination are given in the supporting information.

3. Results and discussion

3.1. The crystal structures of $Eu(DBM)_3$(L1) and L2

The perspective view of the molecular unit of $Eu(DBM)_3$(L1) is shown in Fig. 1. The selected bond lengths are tabulated in Table 2.

The central ion Eu(III) is eight-coordinated by six oxygen atoms of three bidentate DBM anions and two nitrogen atoms from one bidentate L1, forming a distorted square antiprism. Compared with the crystallographic data of $Eu(DBM)_3{\cdot}phen{\cdot}CH_3COCH_3$ [12] in which phen is 1,10-phenanthroline, the average Eu–O bond length of 2.35 Å for the former is equal to that for the latter and the mean Eu–N bond length of 2.60(2) Å for the former is slightly shorter than that [2.64(3) Å] for the latter although L1 is much more bulky than phen. The calculated results of the least square planes revealed that all of the atoms in the ligand L1 are almost coplanar and thus L1 is more conjugated than phen. The enhancement in coordinative ability of L1 compared to phen may be due to the presence of the electron donor dimethylamino group. In the β-diketone chelate rings, average distances for the carbon–carbon [C(28)–C(29), C(29)–C(30), C(43)–C(44), C(44)–C(45), C(58)–C(59), C(59)–C(60)] and carbon–oxygen [C(28)–O(1), C(30)–O(2), C(43)–O(3), C(45)–O(4), C(58)–O(5), C(60)–O(6)] bonds of 1.39 and 1.26 Å respectively, lie between the single- and double-bond distances, reflecting the delocalization of the π-electrons in the chelate ring system. The mean C–C–C angle is also compatible with the values reported for delocalized systems of β-diketonates [15].

The molecular structure of L2 is shown in Fig. 2. Similarly to the structure of L1, the molecular backbone of L2 mainly consists of an imidazo ring, a phenyl

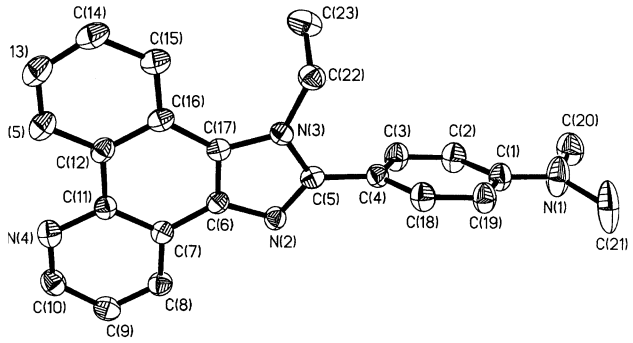

Fig. 2. Molecular structure of L2.

ring and a phenanthroline ring. The rings in the molecule do not show any unusual features and the bond lengths as well as bond angles are within the range of normal values. The only notable difference is that the moiety of imidazo[4,5-f]1,10-phenanthroline in L2 is not coplanar with the phenyl ring due to the grating of the ethyl group to the nitrogen atom on the imidazo ring in contrast to the structure of L1.

3.2. Absorption spectra

The UV spectrum of L1 showed three bands at 235, 292 and 338 nm attributed to $\pi-\pi^*$ transitions. While the former two bands were small red- or blue-shifted, the last one at the low-energy side was absent in the spectrum of L2. The difference obviously arose from the fact that L1 is more conjugated than L2, as revealed by X-ray crystal structural results. The UV spectrum of $Eu(DBM)_3{\cdot}2H_2O$ exhibited three ligand-centered $\pi-\pi^*$ transitions at 251, 280 and 355 nm which are dominant in the spectra of the two complexes [277, 288 and 349 nm for $Eu(DBM)_3(L1)$; 243, 284 and 348 nm for $Eu(DBM)_3(L2)$] so that the characteristic absorption of L1 and L2 were obscured. Interestingly, the molar extinction coefficient of the two complexes was larger than the sum of $Eu(DBM)_3{\cdot}2H_2O$ and L1 or L2, strongly supporting the occurrence of a coordination reaction between $Eu(DBM)_3{\cdot}2H_2O$ and L1 or L2.

3.3. IR spectra

The main IR data and their assignments are summarized in Table 3. The assignments are made by comparison with known related compounds and functional groups [16]. The C–H in-plane bending vibrations observed at 1396 cm^{-1} for L1, 1391 cm^{-1} for L2 and 1398 cm^{-1} for $Eu(DBM)_3{\cdot}2H_2O$ red shifted to 1406 cm^{-1} for $Eu(DBM)_3(L1)$ and 1410 cm^{-1} for $Eu(DBM)_3(L2)$, indicating that coordination of the ligands L1 and L2 to the europium ion has taken place. Two strong C–H out-of–plane bending vibrations appearing at 741 and 812 cm^{-1} for L1, and 748 and 827 cm^{-1} for L2 were obscured by following dominant absorption contributed by the $Eu(DBM)_3$ moiety: out-of-plane bending vibration π(C–H) at 784 cm^{-1}, phenyl ring out-of-plane bending C–H vibration $\phi\pi$(C–H) at 690 and 721 cm^{-1}. A ν(C=O) stretching vibration was observed at 1594 cm^{-1} for $Eu(DBM)_3(L1)$ and at 1595 cm^{-1} for $Eu(DBM)_3(L2)$, and a ν(C=N) stretching vibration was observed at 1610 cm^{-1} for $Eu(DBM)_3(L1)$ and at 1611 cm^{-1} for $Eu(DBM)_3(L2)$. However, the ν(C=O) and ν(C=N) stretching vibrations for the two complexes were merely subjected to minor red- or blue-shift compared to their counterparts, $Eu(DBM)_3{\cdot}2H_2O$, L1 and L2.

3.4. Thermal analysis

Thermogravimetric and differential thermal analyses (TG–DTA) provide important information on vacuum-deposition behaviors of the materials. TG–DTA curves showed the complex $Eu(DBM)_3(L1)$ is chemically stable from the room temperature to 360 °C and no endothermic peak was observed on the corresponding differential thermal curve, indicating that there exist no melting point prior to decomposition. Over 360 °C the complex underwent a four-stage decomposition–oxidation process. Similarly, complex $Eu(DBM)_3(L2)$ also exhibited a four-stage decomposition–oxidation process without melting. However, $Eu(DBM)_3(L2)$ is thermodynamically less stable than $Eu(DBM)_3(L1)$ and has a lower decomposition temperature of 256 °C.

3.5. Luminescence spectra at room temperature

As shown in Fig. 3, powder of the free ligand L1 gave a broad band emission at $\lambda_{max} = 515$ nm with a shoulder at about 500 nm upon excitation at 370 nm, while that of L2 showed an emission band centered at about 432 nm upon excitation at 374 nm. It is noteworthy that the ligand emission characteristics totally vanished in the emission spectra of $Eu(DBM)_3(L1)$ and $Eu(DBM)_3(L2)$, showing that efficient energy transfer from the ligands L1 and L2 to Eu(III) has occurred. The emission spectra of the complexes, excited at 386 nm for $Eu(DBM)_3(L1)$ and 400 nm for $Eu(DBM)_3(L2)$, do not show any significant difference and both exhibit characteristic emissions of Eu(III) ions. As shown in Fig. 4, five narrow emission peaks centered at 580, 592, 612, 652 and 703 nm, assigned to $^5D_0 \rightarrow {}^7F_0$, $^5D_0 \rightarrow {}^7F_1$, $^5D_0 \rightarrow {}^7F_2$, $^5D_0 \rightarrow {}^7F_3$ and $^5D_0 \rightarrow {}^7F_4$ transitions, respectively, were obtained for the two complexes. Among the peaks, the emission at 612 nm from the $^5D_0 \rightarrow {}^7F_2$ electronic dipole transition is the strongest, suggesting low symmetry around the Eu(III) ion [17]. Because the forbidden $^5D_0 \rightarrow {}^7F_2$ electronic dipole transition is sensitive to the coordination environment of the Eu(III) ion, the asymmetric microenvironment causes the polarization of the Eu(III) ion under the influence of the electric field of the surrounding ligands and thus increases the probability for the electronic dipole transition. More interesting is that the luminescence intensity of Eu-

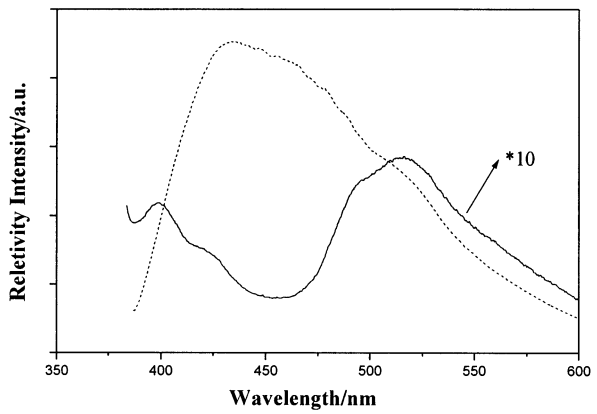

Fig. 3. The emission spectra of the ligands (solid line—L1, dashed line—L2).

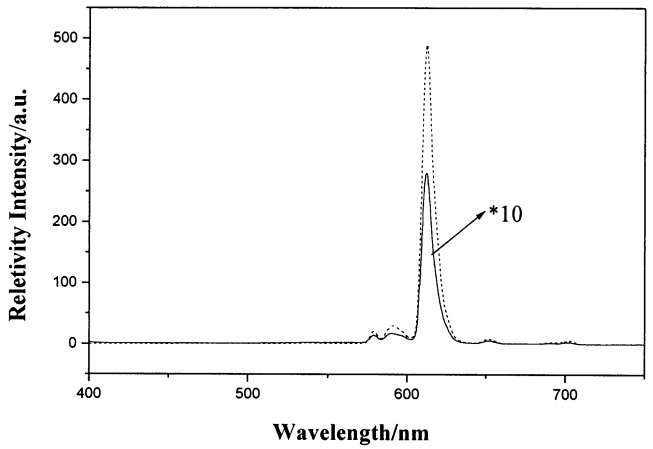

Fig. 4. The emission spectra of the complexes (solid line—Eu(-DBM)$_3$L1, dashed line—$Eu(DBM)_3L2$).

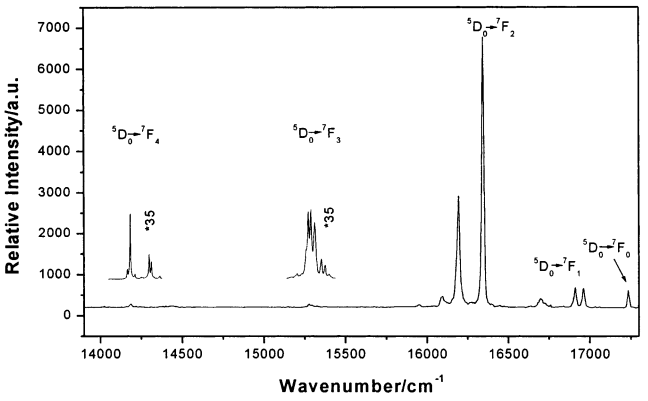

Fig. 5. The highly resolved emission spectrum of $Eu(DBM)_3L1$, $\lambda_{exc} = 335$ nm, 77 K.

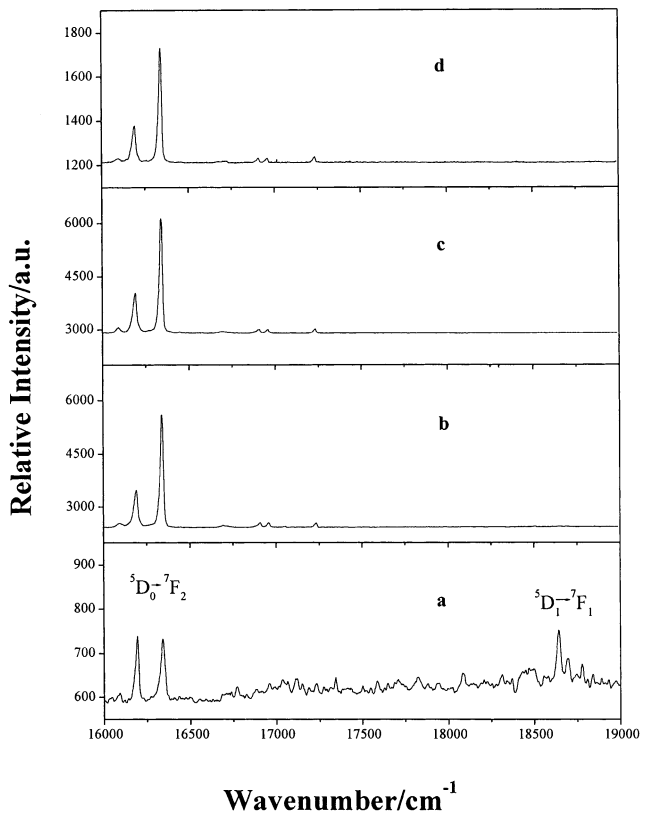

Fig. 6. The time resolved spectra of $Eu(DBM)_3L1$, $\lambda_{exc} = 335$ nm, 77 K. Delay time (a) 2 s; (b) 30 s; (c) 100 s; (d) 500 s.

$(DBM)_3(L2)$ is 18 times that of $Eu(DBM)_3(L1)$. Two reasons may account for the improved luminescence intensity observed. One is that the quenching effect of the luminescence by the non-radiative dissipation of energy on the high-energy N–H vibrations was removed after ethyl group substituted the hydrogen atom bonding with the nitrogen atom on the imidazole ring in $Eu(DBM)_3(L1)$. The other reason is that the energy transfer to Eu(III) from ligand L2 is more efficient than from ligand L1 on account of energy level and absorption factors.

3.6. Highly resolved luminescence spectra at 77 K and time-resolved luminescence spectra

In order to get information regarding the energy transfer mechanism and Eu(III) site symmetry in the crystal, time-resolved luminescence spectra and highly resolved luminescence spectra at 77 K were measured for $Eu(DBM)_3(L1)$ and $Eu(DBM)_3(L2)$. Unfortunately, irreproducible luminescence spectra were detected for $Eu(DBM)_3(L2)$ due to chemical unstability of $Eu(DBM)_3(L2)$ under the laser irradiation. Therefore, only highly resolved luminescence spectra (Fig. 5) and time–resolved luminescence spectra (Fig. 6) for $Eu(DBM)_3(L1)$ are reported here. The degeneracy of J manifolds of a Eu(III) ion can be split into the maximum $2J+1$ non-degenerate energy levels. One can determine through group theory whether a particular transition will be symmetry allowed or forbidden [18]. This has been well documented for Eu(III) compounds with different site symmetry [19]. It can be seen from Fig. 5 that no splitting of the singlet $^5D_0 \rightarrow {}^7F_0$ transition implies a single Eu^{3+} ion crystallographic site symmetry. Additionally, three peaks for the $^5D_0 \rightarrow {}^7F_1$ transition, four peaks for the $^5D_0 \rightarrow {}^7F_2$ transition, 5 peaks for the $^5D_0 \rightarrow {}^7F_3$ transition and seven peaks for the $^5D_0 \rightarrow {}^7F_4$ transitions with reasonable intensity were observed, corresponding to a C_{2v} site symmetry in a rhombic crystal system of eight-coordinated Eu(III) compounds. This is in agreement with the result of crystal structural determination.

The time-resolved photoluminescence spectra of $Eu(DBM)_3(L1)$ obtained using 355 nm excitation at 77 K are shown in Fig. 6. Emission lines of $^5D_1 \rightarrow {}^7F_1$ transition were observed when the delay time was 2 μs, but $^5D_1 \rightarrow {}^7F_1$ emission bands disappeared after 30 μs. However, the emission band intensity of $^5D_0 \rightarrow {}^7F_J$ transitions increases. This reveals that the lowest triplet state of the ligands is higher than the emission level $^5D_1$ of the Eu^{3+} ion and energy mostly transfers from the triplet state of the ligands DBM and L1 to the $^5D_1$ level of the Eu^{3+} ion followed by the $^5D_0$ emission level although it is not exclusive that energy directly transfers from the triplet state of the ligands to the lowest emission level $^5D_0$ of the Eu^{3+} ion, and then a $^5D_0 \rightarrow {}^7F_J$ transition occurs. This also indicates that the $^5D_1$ state of the Eu^{3+} ion is deactivated within 30 μs and the lifetime of the $^5D_1$ state is much shorter than that of the $^5D_0$ level of the Eu^{3+} ion in the complex. The lifetime of the $^5D_0$ level of the Eu^{3+} ion in the complex obtained from the delayed curve is 1.24 ms.

4. Conclusion

Two novel imidazo[4,5-f]1,10-phenanthroline-containing Eu(III)-dibenzoyl-methanate mixed ligand com-

plexes were designed and synthesized. Alkylation at the imidazo ring of the Eu(III) complex resulted in greatly enhanced emission. The work on electroluminescent devices based on vacuum deposited films of these two Eu(III) complexes is in progress.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Centre, CCDC Nos. 153376 and 173284 for compounds $Eu(DBM)_3$(L1) and L2, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 22 August 2001; accepted 8 November 2001

Abstract

Complex formation equilibria of the aminomethane-1,1-diphosphonic acids with Zn^{II}, Mg^{II} and Ca^{II} have been studied by potentiometric pH titrations and by means of NMR spectroscopy. The ligands exhibit a strong tendency to form protonated species over a wide range of pH. The most efficient binding mode in all the studied systems is the formation of the six-membered chelate ring involving oxygens of both phosphonate groups. An evident preference for the formation of multinuclear complexes is noted in the case of zinc(II). Magnesium demonstrates preference for mononuclear complexes, whereas calcium(II) tends to form insoluble species with most of the studied ligands. The structures of the main complex species are discussed with respect to the priorities in the hydrogen-bond network organization in solid state. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

Osteoporosis is the most common metabolic bone disease which affects 40–50% of the elderly female and 10–15% elderly male population. The disease involves the gradual loss of bone mass as a result of an imbalance between the bone resorption activity of osteoclasts and the bone formation activity of osteoblasts. Analogues of the inorganic pyrophosphate with non-hydrolysable P–C–P structure, commonly known as bisphosphonates, strongly inhibit bone resorption. For more than 20 years, they have been used successfully for the treatment of bone disorders such as Paget's disease, cancer-related hypercalcemia and post-menopausal osteoporosis, presently comprising nearly US$ 1 billion of the global pharmaceutical market [1–4]. Some of bisphosphonates have also been shown to act as inhibitors of matrix metalloproteases, thus additionally blocking the initiating step in the bone resorption process, i.e. degradation of connective tissues associated with peridontal diseases [5]. Surprisingly very little is known about the molecular mechanism of action of these compounds which are believed to act as complexing agents of bone calcium ions or affect enzyme essential metal ions. Quite unexpectedly the same bisphosphonates may form a basis for a new generation of anti-malarial compounds not only being active against *Plasmodium faciparum*, a causative agent for malaria, but also killing trypanosomes, *Leishmania* and *Toxoplasma gondii* [6]. Together these parasites infect over 500 million people annually worldwide, mostly in tropics.

The aminomethane-1,1-diphosphonic acids constitute an interesting class of bisphosphonates that exert herbicidal activity. However, similarly as in the case of bone disorder treatment, the molecular basis of their action still awaits elucidation. The available data suggest that they should be considered as an heterogenous group of compounds with various modes of action [7]. Their activity is most likely a result of their simultaneous action on several enzymes that are metal-dependent. The preliminary calculations of their interaction with

farnesyl pyrophosphate synthase, glutamine synthetase and 3-deoxy-D-*arabino*-heptulosonate-7-phosphate synthase, suggested as molecular targets, have shown that their action most strongly depends on the complexation of the metal ion present in the active centre of the enzyme [8]. Thus, the understanding the complex-forming abilities of these compounds seems to be crucial for the proper interpretation of their physiological properties.

The most important structural feature that accounts for the complexation properties of the aminomethane-1,1-diphosphonic acids is an attachment of two phosphonate groups to the central $CH(P_2)$ carbon atom. It predisposes the ligands to exhibit greater diversity in coordination modes, when compared to the iminodimethylenediphosphonic acids [9]. X-ray data demonstrate that the *gem*-diphosphonate groups can either coordinate through as few as two oxygen donors to bidentately chelate metal ions [10–14] or can perform the multidentate bridging functions using a higher number (up to six) oxygen donors [15–25]. A peculiar coordination mode for this class of compounds is a 'doubly bidentate' chelation with one metal ion bound on the one side of the P–C–P plane and another on the opposite side of this plane [20–25].

This work is aimed at aqueous solution studies of the stability and coordination modes of the complexes of Zn^{II}, Mg^{II} and Ca^{II} with a series of aminomethane-1,1-

diphosphonic acids having amino group substituted by various functional groups (Table 1). Our final goal is to shed some light on the general relations between the complexation mechanism in solution and the molecular organization in the solid state.

2. Experimental

2.1. Materials

The aminomethane-1,1-diphosphonic acids were obtained according to the previously described procedures [27–33]. Their identity and purity were confirmed with the use of ES-MS spectrometry (Table 1) and by the NMR method. The exact concentrations of the solutions of the ligands used for potentiometric studies were determined by the Gran method [34]. The concentrations of the zinc(II) and the alkaline-earth metal(II) chloride stock solutions were standardized by complexometric ethylenedinitrilotetraacetate (EDTA) titration. Carbonate-free potassium hydroxide (the titrant) was prepared and standardized against a standard potassium hydrogenphthalate solution.

2.2. Methods

2.2.1. Potentiometric measurements

The stability constants of the proton and metal(II) complexes were determined by pH-metric titration of 2 cm^3 samples except for the Zn^{II}–**2** and Zn^{II}–**4** systems for which the sample volumes were 5 and 3 cm^3, respectively. The ligand (L) concentration for the Zn^{II} systems was varied between 1×10^{-3} and 3×10^{-3} mol dm^{-3} and for Mg^{II} or Ca^{II} between 3.5×10^{-3} and 5×10^{-3} mol dm^{-3} (because of precipitation the ligand concentration for the zinc(II) system with **1** was 5×10^{-4} mol dm^{-3}). The metal-to-ligand molar ratios were 1: 1.5, 1: 2 and 1: 2.5 and the ionic strength was adjusted to 0.2 mol dm^{-3} with KCl in each case. The pH-metric titrations were performed with a carbonate-free KOH solution. For the Zn^{II} and Mg^{II} systems the measurements were made from pH 3 to $\sim$11. The exception were Zn^{II}–**7** and Mg^{II}–**7** measured from pH 4 to $\sim$11 due to a poor solubility of the ligand in acidic pH. For the majority of the Ca^{II} systems immediate precipitation of insoluble species, even in the case of the highest ligand excess, precluded the reliable titration curves at pH > 4.5 (ligands **1**–**3**) and pH > 6 (ligands **6**, **7**) being obtained. Only the Ca^{II}–**4** and Ca^{II}–**5** systems were titrated throughout the whole range pH 3–11. All titration solutions were thermostatted at 25 ± 0.1 °C using a constant-temperature water-bath.

The pH was measured with a MOLSPIN automatic titration system using a micro combination pH electrode (Mettler-Toledo, Type 2). Small amounts ($\Delta v =$ 0.001 cm^3) of titrant were added (total volume 0.1 or 0.2 cm^3). The electrode system was calibrated by periodic titrations of HCl solution (7.5×10^{-3} mol dm^{-3} in KCl) against standard KOH solution. The resulting titration data were used to calculate the standard electrode potentials, $E°$, and the dissociation constant for water ($pK_w = 13.74$). These values were then used to calculate the hydrogen ion concentration $[H^+]$ from emf readings [35]. The titrations were performed in triplicate and calculations were carried out using the SUPERQUAD computer program [36] with three titration curves for each system. The χ^2 values never exceeded the range 5–12. The standard deviations (σ values) quoted were computed by the program and refer to random errors only. They are, however, a good indication of the importance of the particular species in the equilibrium.

In the calculations of the equilibrium models hydrolysis was considered. The values of the hydrolysis constants for the most possible hydroxo complexes were taken from the literature [37].

The charges of the complexes have been omitted in the text and tables. However, for clarity, it should be mentioned that the fully deprotonated forms of **1**–**5** and **7** have negative charges L^{4-} and of **6** L^{5-}.

2.2.2. Mass spectrometry

Mass spectra were recorded in a positive-ion mode on a Finnigan Mat TSQ 700 triple quadrupole mass spectrometer operating with an ESI source. The spray voltage was 4.5 kV and the heated capillary temperature was maintained at 473 K.

2.2.3. NMR measurements

NMR spectra were recorded on a Bruker DRX spectrometer operating at 121.50 MHz for ^{31}P, 300.13 MHz for ^{1}H and 75.46 MHz for ^{13}C, at 300 K (unless otherwise noted), and are given in relation to 85% H_3PO_4 (^{31}P) and $SiMe_4$. The Bruker standard program was used to acquire [^{31}P–^{31}P] 2D spectra. All downfield shifts are denoted as positive.

Samples for NMR studies were prepared in deuteriated water with a metal(II) concentration of 1×10^{-2} mol dm^{-3} and M^{II} to ligand molar ratios of 1:1 and 1:2. Nitrate salts of Zn^{II}, Mg^{II} and Ca^{II} (Aldrich) were used as a source of the metal ions. The measurements were performed only for freshly prepared samples.

The pH of the samples was measured using a Radiometer pHM83 instrument equipped with a 2401 C combined electrode and given as meter readings without correction for p*D*.

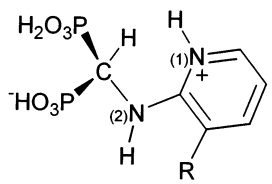
3. Results and discussion

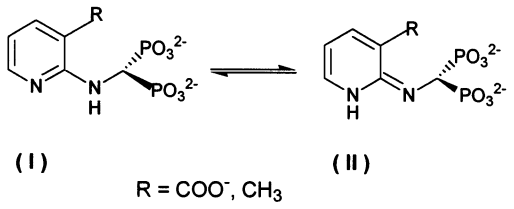
3.1. Solution properties of compounds 1–7



The fully protonated ligand forms contain five dissociable protons (H_5L^+) for **1**–**5** and **7** and six protons (H_6L^+) for **6** (because of the additional proton on the carboxylic group). The amino and imino nitrogen is protonated in compounds **1**–**4** and **5**, respectively. In compounds **6** and **7** the protonation of $N_{pyridine}$ instead of the amino group occurs [26]. On the other side, as shown in Table 2, the studied ligands in the measurable pH range release only three protons: two protons from the PO_3H^- groups and one proton from NRH_2^+ (**1**–**4**), $NH^+_{pyrrolidine}$ (**5**) or $NH^+_{pyridine}$ (**6**, **7**). An additional proton from COOH dissociates in **6**. This is due to the fact that the characteristic pK values for dissociation of one proton from each of the PO_3H_2 groups lie in the range 1.5–2.

The protonation constants for both phosphonic functions of **1**–**5** correspond well with those reported for the aminoethane-1,1-diphosphonic and *N*,*N*-dimethylaminomethane-1,1-diphosphonic acids [39–41]. Generally, the positively charged NH_2^+ (**1**–**4**) or NH^+ (**5**) nitrogen atom bound to the central $CH(P_2)$ carbon lowers the pK values of each PO_3H^- group by approximately 1–2 log units when compared to alkane-1,1-diphosphonic acids [42–44] and to compounds **6** and **7** (Table 2).

The ^{31}P NMR spectra of **1**–**7** exhibit the single resonance lines over the whole pH range studied except for compounds **3** and **4** that both represent chiral molecules used as racemate forms (Table 1). In these cases the spectra consist of two signals of close chemical shifts and 1:1 intensity ratio that are interpreted as belonging to the non-equivalent phosphonate groups. The two-bond coupling between the phosphorus nuclei confirmed by the ^{31}P–^{31}P correlation spectra is reflected as a slight broadening of the ^{31}P resonances of compound **3**. In the spectra of **4** the $^2J_{P-P}$ coupling constants of 1.2–2.1 Hz are detected in a narrow pH range 7–8.



The solution behaviour of **1**–**5**, reflected in their ^{31}P NMR titration curves, does not depart significantly from that of the iminodimethylenediphosphonic acids [9]. The evident similarity, i.e. relatively small changes in the chemical shifts upon deprotonation of the PO_3H^- groups and a large ($\Delta\delta \sim 7$ ppm), commonly observed [9,45,46] downfield shifting upon deprotonation of NH_2^+, is detected for **4** bearing the most electronegative methylenetetrahydrofuryl moiety. Since as compared to **4**, the basicities of NH_2^+ in **1**–**3** and NH^+ in **5** are higher (Table 2) the appropriate ^{31}P NMR titration curves reflect the lower abundance of the completely deprotonated ligand form even under the pH titration limit (pH $\sim$13.5). Accordingly, in the ^{1}H NMR spectra of compounds **1**–**5** the methine proton resonance, appearing as a triplet, shifts gradually upfield upon increase of pH.

A number of distinct features is observed in the case of **6** and **7**. Both compounds crystallize in the solid state as *E* isomers (Fig. 1) and are also proved to preserve their configuration in solution [26]. In **6**, the internal molecular configuration is stabilised with the intramolecular hydrogen bonds involving amino N(2) hydrogen as a donor and two oxygens, one from the carboxylate and one from the phosphonate group, as the proton acceptors. In **7**, the same conformation of

6 R = COOH
7 R = CH_3

Scheme 1.

the pyridyl moiety is constrained through a N(2)H···O(phosphonate) hydrogen bond and a N(2)H···CH_3 short contact.

The proton transfer toward the pyridine instead of to the amino nitrogen in the zwitterionic form (Fig. 1) is dictated by the tendency of these compounds to delocalise the lone pair on the amino nitrogen onto the electron deficient pyridyl ring π system. This is a general property of all 2-aminopyridine derivatives, conveniently described in terms of resonance between the mesomeric structures [48]. Due to the conjugation, the N(2)–C(2) bond bears partial double bond character. Consequently, the 2-aminopyridine portions of **6** and **7** are almost planar in any state of protonation.

In addition, in alkaline conditions at pH higher than 8–9 both **6** and **7**, contrary to the 5- or 6-pyridine substituted *N*-(2-pyridyl)aminomethane-1,1-diphosphonic acids, presumably exist as an equilibrium mixture of the amino (**I**) and imino (**II**) tautomers [26] (Scheme 1).

3.2. Complexation of zinc(II), magnesium(II) and calcium(II) with aminomethane-1,1-diphosphonic acids

The chemical models for the studied systems were considered taking into account on one side the potential ability of the ligands to form multinuclear complexes and on the other, revealed by the ^{31}P NMR titration curves, the strong preference to form exclusively protonated species over a wide range of pH. The best-fit models based on the potentiometric data calculations are given in Tables 3–5.

3.2.1. Zinc(II) complexes

The pH-metric titrations indicate that the extent of complex formation in the Zn^{II}–ligand systems is quite similar (Table 3). Each sample with a 1:2 metal to ligand molar ratio could be titrated without precipitation up to pH 11. However, functionalization of the ligands by structural modification of the amino moiety decides the peculiarity in their coordination capabilities.

The metal complex speciations derived from the potentiometric calculations carried out for compounds **1**–**5** do not differ considerably. Generally, the Zn^{II}–**1** system presented in Figs. 2 and 3 exhibits approximately the same distribution curves as those observed for **2**–**5**. Therefore, it can be considered as a representative for all the mentioned systems. The pH dependence of the ^{31}P chemical shifts (Fig. 3(b)) fits well the species distribution pattern, thus confirming a predominance of the protonated species up to pH of about

9–10. This is reflected in the relatively small chemical shift changes in the spectra of the ligand solutions upon addition of Zn^{II}, that indicate that formation of these complexes involves the ligand forms with the protonated nitrogen atom.

In the presented systems $[Zn(H_2L)]$ complexes are formed as the minor ones. The $pK_{[Zn(H_2L)]}$ values characteristic for the first deprotonation step for the $[Zn(H_2L)]$ complexes are of the same order of magnitude and are lower than the corresponding dissociation constants of the 'free' ligands (Table 2). Thus, they can be assigned to deprotonation of the phosphonic group promoted by the zinc(II) binding. In [Zn(HL)] the protonated ligand coordinates to zinc(II) in a bidentate

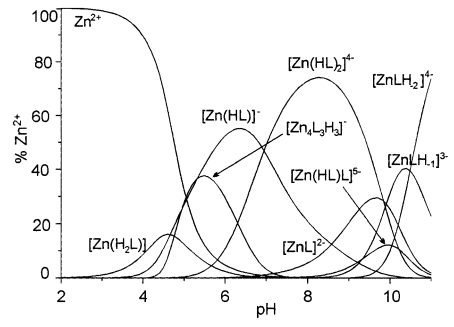

Fig. 2. Species distribution curves for the Zn^{II}–**1** system as a function of pH for the measurement conditions; $c_M = 2.5 \times 10^{-4}$, $c_L = 5 \times 10^{-4}$ mol dm^{-3}.

Fig. 3. manner using one oxygen atom of each suitably positioned phosphonate group to form the six-membered chelate ring. The preference for such coordination is well documented in the literature [10–14]. The $\log K_{[Zn(HL)]} = \log \beta_{[Zn(HL)]} - pK_{(NH_2^+)}$ constants provide further evidence indicating increase in stability of the [Zn(HL)] complexes by about two to three orders of magnitude when compared to those formed by the iminodimethylenediphosphonic acids [9]. The latter compounds use phosphonate group(s) to bind zinc(II) monodentately or to form disadvantageous eight-membered chelate rings [49].

The striking feature of the Zn^{II} systems with ligands **1**–**5** is the formation of the protonated multinuclear species, which is strongly dependent upon the metal to ligand stoichiometry and the solution concentration (Figs. 2 and 3(a)). The ^{31}P NMR experiments clearly support this indication. A pronounced formation of the $[Zn_4L_3H_3]$ (or $[Zn_3L_2H_2]$) complexes demonstrated on the speciation diagrams (see Fig. 3(a) as example) is always accompanied with an exceptional broadening of the corresponding resonance line ($\nu_{1/2} \sim 200$–400 Hz). This feature is not observed when mononuclear protonated complexes predominate in solution ($\nu_{1/2} \sim 20$–25 Hz). A possible explanation can be the relatively slow, on the NMR time scale, exchange of the ligand between the multinuclear complex species. In the relevant ^{1}H NMR experiments the methine $CH(P_2)$ resonances are broad and shifted downfield with $\Delta\delta$ being about 0.1 ppm with respect to the HL species. According to our observations serious broadening of $CH(P_2)$ (one broad line with $\nu_{1/2} \sim 10$–40 Hz) appears to serve as a direct estimation of the incorporation of the *gem*-diphosphonate groups in the six-membered chelate ring.

The second deprotonation step, having $pK_{[Zn(HL)]}$ values much lower than $pK_{NH_2^+}$ (**1**–**4**) and pK_{NH^+} (**5**) of the 'free' ligands (Tables 2 and 3) may be attributed to Zn^{II}-promoted nitrogen deprotonation. This corresponds to our recent finding [9,45,46] that involvement of a nitrogen atom in zinc(II) chelation moves the pH region indicating a gradual downfield shifting of the ^{31}P resonances towards the acidic side by about 2–3 log units, when compared to 'free' ligand (Fig. 3(b)). Accordingly, the respective ^{1}H NMR spectra demonstrate an upfield shifting for the protons adjacent to the nitrogen donor. This allows anticipation that the [ZnL] complexes are very likely tridentate with both phosphonates and the nitrogen donor complexed to Zn^{II}. A tridentate binding mode is also reflected in the $\log K_{[ZnL]}$ values that are generally 3–4 log units higher than the $\log K_{[Zn(HL)]}$ values. In the particular case of **4** a tetrahydrofuryl moiety is also involved in coordination. This is seen from the comparison of the basicity-adjusted constant $\log K_{[ZnL]} - \Sigma pK$ for **4** (-13.77) with those for ligands **1**–**3** (-14.89, -15.14, -15.03, respectively). An increase in stability of about 1–1.4 log units can be explained by the presence of an additional chelate ring in the complex.

In addition, a comparison of the basicity-adjusted constants for **2** and **4** (see above) with the values found for their iminodimethylenediphosphonic acid counterparts which differ structurally but have the same functionalities, namely **8a** and **8b** (-14.01 and -11.53, respectively) [9] (Scheme 2), demonstrates that due to a higher rigidity imposed by the chelate rings the tridentate [ZnL] complexes formed by the aminomethane-1,1-diphosphonic acids are less stable than those formed by the iminodimethylenediphosphonic acids [9].

The two further deprotonation processes of [ZnL] can also be detected by potentiometry. At around pH 10–10.5 coordinated water molecules lose protons to yield $[ZnLH_{-1}]$ and $[ZnLH_{-2}]$. On the other side, at pH 9–13 the ^{1}H NMR spectra of the equimolar Zn^{II}–ligand solutions demonstrate different behaviour for

the protons placed on the opposite sides of the nitrogen donor. Specifically, the protons of the substituent which are placed in the neighbouring α position, namely CH_2 (**1**, **2**, **4**, **5**) or CH (**3**), appear as broad lines. Quite oppositely, $CH(P_2)$ of the methane-1,1-diphosphonate portion undergoes apparent narrowing upon increase of pH. Accordingly, the ^{31}P NMR spectra reveal the single, rather broad resonance lines except for the Zn^{II}–**3** system, which demonstrates two broad signals ($\delta_P =$ 20.28 ppm, $\delta_P = 11.77$ ppm, pH 12.48) coalescing at 320–330 K. These facts may indicate that one phosphonate group leaves the coordination sphere of the zinc(II) ion before a final release of the ligand, usually observed at pH ≥ 13.5.

The protonated bis complexes are also formed in the studied systems (Figs. 2 and 3(a)). Their formation does not lead to any distinct variation in the ^{31}P chemical shifts when compared to the equimolar solutions (Fig. 3(b)). Therefore, one can presume no variation in the coordination modes of ligand molecules in $[Zn(HL)_2]$ with respect to [Zn(HL)]. The deprotonation constants, $pK_{[Zn(HL)_2]}$, of the corresponding equilibrium: $[Zn(HL)_2] \rightleftharpoons [Zn(HL)L] + H^+$ for the systems with ligands **1**–**3** (10.22, 10.72 and 10.53, respectively) are considerably lower than are deprotonation constants of the amino nitrogen of the 'free' ligands. Thus, the most likely binding mode for [Zn(HL)L] is the mixed bidentate/tridenate chelation with the fully deprotonated ligand (L) providing both phosphonate oxygens and the nitrogen donor to coordinate zinc(II).

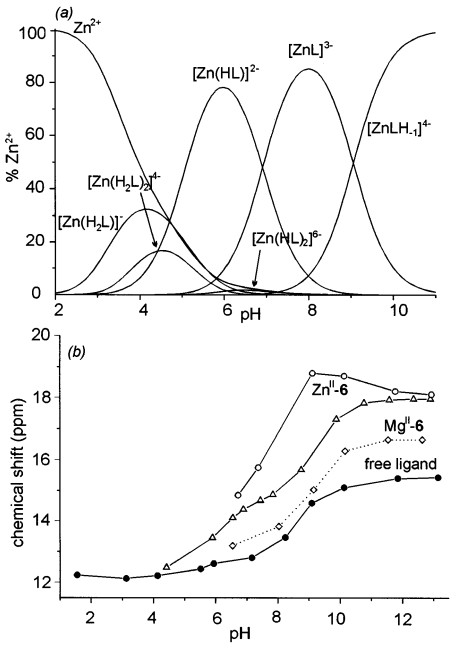

Fig. 4. (a) Species distribution curves for the Zn^{II}–**6** system as a function of pH simulated for conditions used in NMR studies; $c_M = c_L = 1 \times 10^{-2}$ mol dm^{-3}. (b) ^{31}P NMR chemical shifts as a function of pH for compound **6** (●) and for Zn^{II}–**6** 1:1 (○) and 1:2 (△) solutions; $c_M = 1 \times 10^{-2}$ mol dm^{-3}. For comparison, see the analogous NMR titration curve for the Mg^{II}–**6** 1:1 solution (dotted line).

Generally, the formation of the $[ZnL_2]$ complexes is disfavoured due to a strong inter-phosphonate electrostatic repulsion of highly charged phosphonate groups. In fact, the two fully deprotonated ligands would bring together a high negative charge density, 8-, around Zn^{II}. It is the reason why only **4** is capable of forming $[ZnL_2]$ (Table 3). In this case, an additional stabilisation induced by a coordination of the tetrahydrofuryl moiety may partly compensate the unfavourable effect of the electrostatic repulsion. The ratio of the stepwise stability constants $\log(K_{[ZnL]}/K_{[ZnL_2]})$ of 6.52 indicates, however, that the binding of the second ligand molecule is strongly hindered.

The most essential feature that preponderates the complex-forming properties of both **6** and **7** is a propensity of the amino nitrogen to delocalise the lone pair onto the pyridyl ring resulting in its sp^2-hybridization both in the solid [26,47] and in the solution state [26]. The consequent roughly planar 2-aminopyridine portion of the ligand as well as an inability of the amino nitrogen to coordinate metal ion are further substantiated in the chemical models for the Zn^{II}–**6** and Zn^{II}–**7** systems.

As shown on the species distribution diagram of the representative Zn^{II}–**6** system (Fig. 4(a)) the ligands form exclusively mononuclear complexes. The sets of complex species calculated from the potentiometric titrations are in both cases essentially identical (Table 3). Likewise, 1:1 and 1:2 molar ratio complexes are detected. The $[ZnL_2]$ species, as has been discussed above, are strongly disfavoured owing to the repulsion between the negatively charged phosphonate groups. The unfavourable conditions for their formation are expressed with high $\log(K_{[ZnL]}/K_{[ZnL_2]})$ values; 5.70 for Zn^{II}–**6** and 6.34 for Zn^{II}–**7**.

The stability constants of $[Zn(H_2L)]$ and [Zn(HL)] are lower than those of the analogous species formed by compounds **1**–**5** due to the lower $\log \beta_3^H$ values (Table 2). However, from the comparison of the values $\log K_{[Zn(HL)]} = \log \beta_{[Zn(HL)]} - pK_{(PO_2H^-)}$ for ligands **6** and **7** with the values $\log K_{[Zn(HL)]} = \log \beta_{[Zn(HL)]} - pK_{(NH_2^+)}$ for ligands **1**–**5**, which are of the same order of magnitude (Table 3), one can conclude that coordination in [Zn(HL)] is similar for all the studied ligands. Thus, in [Zn(HL)] the proton is most likely bound to the phosphonate group. Consequently, the deprotonation constant of [ZnL] can be assigned to the ionisation of a bound water molecule.

In contrast to the rest of the studied systems the ^{31}P spectra of either 1:1 or 1:2 Zn^{II}–ligand solutions exhibit relatively sharp resonance lines over the whole pH range. The chemical shift profiles for the representative Zn^{II}–**6** system are depicted alongside with the species

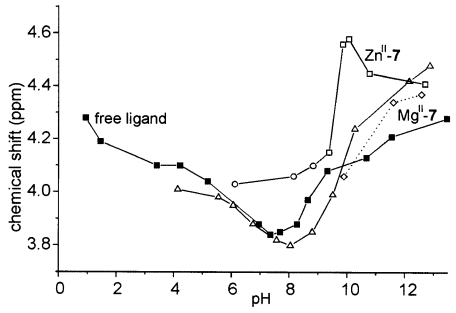

Fig. 5. ^{1}H NMR chemical shifts of $CH(P_2)$ as a function of pH for compound **7** (■) and for Zn^{II}–**7** 1:2 (△) and 1:1 (○, $T = 300$ K; □, $T = 330$ K, see text) solutions; $c_M = 1 \times 10^{-2}$ mol dm^{-3}. For comparison, see the analogous NMR titration curve for the Mg^{II}–**7** 1:1 solution (dotted line).

distribution diagram (Fig. 4(b)). The changes in δ_P observed for the 'free' ligand solutions reflect the deprotonation sequence determined by potentiometry (Table 2), indicating that the loss of the proton from the pyridyl nitrogen ($pK_{NH^+\,pyr} = 5.30$) has greater impact on the phosphorus chemical shift than the deprotonations of the PO_3H^- groups. Since the unfavourable position of pyridyl moiety (Fig. 1) precludes simultaneous coordination of both the pyridine nitrogen and the phosphonate groups the changes in chemical shifts upon complexation can be considered as resulting from the formation of only 'pure' phosphonate bonded complexes. Interestingly, this effect is larger from that produced upon formation of the phosphonate-bonded species by compounds **1**–**5** (Fig. 3(b)).

As we discussed already [26] the position of the methine $CH(P_2)$ resonance in the ^{1}H NMR spectrum can serve as a defining 'fingerprint' of the configurational preferences of *N*-(2-pyridyl)aminomethane-1,1-diphosphonic acids. The δ_P dependence on pH for **7** (*E* geometrical isomer) is depicted in Fig. 5. The extraordinary downfield shifts of the $CH(P_2)$ proton signal upon increase of pH to above 7 can be considered as resulting from a combination of two effects: the deshielding contributed by the electron lone pair of the deprotonated nitrogen in the proximate pyridine ring and the deshielding caused by the pyridine ring current (Fig. 1). The driving force that aligns the methine proton co-planar with respect to the pyridine ring is the enhancement of repulsion resulting from the additional negative charges on the deprotonated phosphonate groups. Quite oppositely, in the *Z* isomer of *N*-2-pyridylaminomethane-1,1-diphosphonic acid the $CH(P_2)$ proton is too distant to be affected by the pyridine nitrogen. Thus, under analogous conditions the proton will be affected exclusively by the deprotonation(s) of the functional group(s) and $CH(P_2)$ resonance will shift upfield, similarly as in the case of compounds **1**–**5**.

We studied carefully the behaviour of the $CH(P_2)$ resonance in the ^{1}H NMR spectra of the ligand solutions upon addition of zinc(II). Interestingly, at pH above 10 the line is too broad to be detected at 300 K. As shown for the Zn^{II}–**7** system (Fig. 5), the increase of the temperature to 320–340 K allows the separation of the signal located in close proximity to the position of the water resonance. This, in the context of the earlier discussion, demonstrates that the configuration of the ligand remains likely unchanged upon complexation of zinc(II). Analogous conclusions can also be drawn for the Zn^{II}–**6** system, which behaves similarly to Zn^{II}–**7**.

In addition, we presumed [26] that the splitting of the C-2 resonance in the ^{13}C NMR spectra ($\Delta\delta \sim 7$ ppm (**6**) and ~ 10 ppm (**7**)), observed when pH is higher than 8–9, might be an indication of the presence of both amino (upfield C-2 signal) and imino (downfield C-2 signal) tautomeric forms of the ligand (Scheme 1). An analogous pattern of the C-2 resonance signals is detected in the ^{13}C NMR spectra of either 1:1 or 1:2 Zn^{II}–ligand alkaline solutions with compounds **6** and **7** (see for example: Zn^{II}–**6**: 165.41 and 155.89 ppm, pH 10.72, 1:1 ratio; Zn^{II}–**7**: 166.70 and 157.69 ppm, pH 11.19, 1:1 ratio). This suggests that the tautomeric equilibrium is not induced by zinc(II) complexation and both amino and imino tautomeric forms (Scheme 1) may bind zinc(II) in a similar manner.

On the other hand, the positions of the carbon resonances do not differ markedly from those detected for the non-protonated 'free' ligand samples, confirming that only phosphonate oxygens participate in the complexation of zinc(II).

3.2.2. Magnesium(II) and calcium(II) complexes

The refined formation constants obtained from the best fit model data for the magnesium(II) systems with compounds **1**–**7** are presented in Table 4. The following species: $[Mg(H_2L)]$, $[Mg(HL)]$ and $[Mg(HL)_2]$ are found in all the systems studied. The formation of others species such as $[Mg_3L_2H_2]$, $[MgL]$, $[Mg(HL)L]$ and $[MgL_2]$ is dependent on the steric requirements and the coordination capabilities of each individual ligand. As an illustration the species distribution curves and the ^{31}P chemical shifts dependence on pH for the Mg^{II}–**4** system are presented in Fig. 6. Generally, a lesser tendency to form multinuclear complexes is noted as compared to zinc(II). $[Mg_3L_2H_2]$ is detected exclusively as the minor species throughout the pH range 4–7 in the solutions of Mg^{II}–**1** and Mg^{II}–**2**.

In the case of **1**–**5** the deprotonation of $[Mg(H_2L)]$ leading to $[Mg(HL)]$ can be assigned to the proton dissociation at the phosphonic group. A further deprotonation, giving $[MgL]$, corresponds to the proton dissociation at the amino group. The latter species is not formed in the Mg^{II}–**5** system at all. On the other hand, only **4** and **5** show a propensity to form $[Mg(HL)L]$, whereas $[MgL_2]$ is detected exclusively in the case of **4**. The increase in log $K_{[Mg(HL)]}$ values with respect to those

of the iminodimethylenediphosphonic acids [9] in the order of approximately 2.5 log units indicates that magnesium(II), similarly to zinc(II), prefers bidentate chelation. The relatively small changes in the ^{31}P NMR chemical shifts upon formation of the protonated species clearly confirm the binding mode(s) based on oxygen complexation. A comparison of the stability constants $\log K_{[MgL]}$ for **1**–**4** with equilibrium constants $\log \beta_{[Mg(HL)]} - pK_{(NH_2^+)}$ reveals increase in stability of approximately 1.3 log units in the case of **1**–**3** and 2.1 for **4**. This fact may indicate that in the [ML] complex the ligand coordinates by the phosphonate groups possibly involving also the amino nitrogen. The comparison of the basicity adjusted stability constants $\log K_{[MgL]} - \Sigma pK$ for **4** (-17.57) with those for **1**–**3** (-19.01, -19.17 and -19.07, respectively) reveals an increase in stability of about 1.5 log units which suggests some stabilising interaction between the magnesium(II) and the teterahydrofuryl oxygen. Accordingly, the metal ion promoted nitrogen deprotonation is accompanied by the downfield shifts of the ^{31}P NMR resonance lines in agreement with an increasing abundance of [ML], [ML(HL)] or [ML_2], in the species distribution diagrams. A slow chemical exchange similar to that of the Zn^{II}–**3** system is detected for the alkaline solutions of Mg^{II}–**3** and Mg^{II}–**4**.

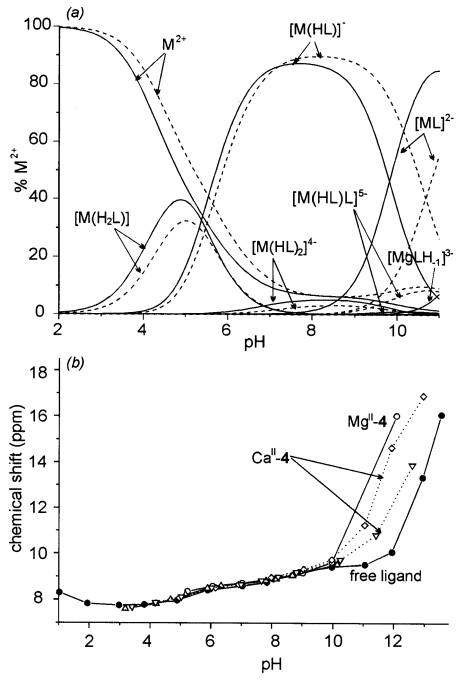

Fig. 6. (a) Species distribution curves for the M^{II}–**4** systems (Mg^{II}, solid line; Ca^{II}, dashed line) as a function of pH simulated for conditions used in NMR studies; $c_M = c_L = 1 \times 10^{-2}$ mol dm^{-3}. (b) Averaged ^{31}P NMR chemical shifts as a function of pH for compound **4** (●) and for Mg^{II}–**4** 1:1 (○) and 1:2 (△) solutions; $c_M = 1 \times 10^{-2}$ mol dm^{-3} (solid lines). For comparison, see the analogous NMR titration curves for the Ca^{II}–**4** 1:1 (◇) and 1:2 (▽) solutions (dotted lines).

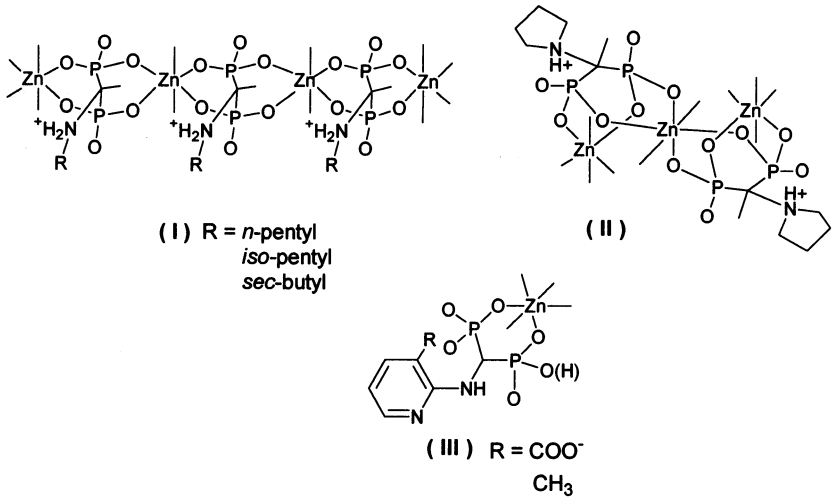

The coordination of Mg^{II} to **6** and **7** is similar to that discussed for the Zn^{II} systems (Tables 3 and 4). The changes in the ^{31}P chemical shifts upon complexation support no variation in the coordination modes for both protonated and non-protonated complexes with respect to those of zinc(II) (Fig. 4(b)). Similarly, magnesium(II) complexation does not tend to induce either a change in the configurational geometry of the ligand (Fig. 5) or the tautomeric equilibrium.

Calcium(II) behaves differently compared to magnesium(II). Among the studied ligands only Ca^{II}–**4** and Ca^{II}–**5** can be titrated over the whole pH range. Owing to the precipitation the pH-metric titrations of the rest of the Ca^{II} systems are confined to the acidic region of pH (see Section 2) that allows detecting only 1:1 protonated complexes (Table 5). No attempt was made to identify the precipitates. We can only speculate that several features that differentiate magnesium and calcium chemistry may have a critical impact on their formation. Calcium(II) is a bigger and a more flexible ion compared to magnesium(II) and prefers higher coordination numbers such as 7, 8. In addition, it forms more ionic, weaker M–L bonds [50,51]. These properties, combined with the peculiar steric requirements of the *gem*-diphosphonate groups allow the binding of several calcium ions to the same molecule [20,52] and enable formation of aggregate polynuclear complexes that deposit as solid materials under conditions when charge balance is achieved.

Functionalization of the aminomethane-1,1-diphosphonic core with either methylenetetrahydrofuryl (**4**) or pyrrolidine directly attached to the $CH(P_2)$ carbon (**5**) allows the formation of mononuclear complexes that are soluble. This can be primarily due to a dominance of steric factors imposed by the substituents. In addition, in **4,** a tetrahydrofuryl moiety decreases the basicity of the ligand and provides a potential coordination site for Ca^{II}. Both the potentiometric and NMR data indicate that coordination of Ca^{II} to **4** is very similar to that observed for the Mg^{II}–**4** system (Fig. 6). In the case of Ca^{II}–**5**, only the protonated, oxygen-bonded species are found from the calculations of the potentiometric titration data and based on NMR data. In general, Ca^{II} forms less stable complexes than Mg^{II} (Tables 4 and 5) even in the particular case of **4**. This is in contrast to the calcium(II) and magnesium(II) systems with compound **8b** where [CaL] has been demonstrated to be more stable than [MgL] [9].

4. Conclusion

There is a full consistency between the pH-metric and NMR spectroscopic studies indicating that the aminomethane-1,1-diphosphonic acids prefer formation of the protonated species over a wide range of pH. The

Scheme 3.

most efficient binding of Zn^{II}, Mg^{II} or Ca^{II} ions, dictated by the structural arrangement of the *gem*-diphosphonate groups, is the formation of the six-membered chelate ring involving oxygens of both phosphonate groups. Such a coordination is preferred in the protonated species of **1**–**5,** as well as in [M(HL)] and [ML] complexes of **6** and **7**. The role of the amino group in compounds **1**–**5** is to decrease the $pK_{PO_3H^-}$ of the phosphonate groups, thus enabling the formation of the [HL] ligand forms efficiently chelating metal ions.

The formation of the nitrogen bonded [ML] complexes by **1**–**5** is generally of lesser importance. They are detected at relatively high pH values and, contrary to the [M(HL)] species, are less stable than those formed by the iminodimethylenediphosphonic acids [9]. In the case of **4** the complexation of a sterically accessible tetrahydrofuryl oxygen promotes the nitrogen binding that results in a tetradentate coordination not only in [ZnL] and [MgL] but also in the [CaL] complex.

Some ligands demonstrate an evident preference for the formation of protonated, multinuclear complexes, that are soluble. This tendency is strongly dependent upon the metal to ligand stoichiometry and the concentration (Figs. 1 and 2) and is especially well expressed in the case of zinc(II). We already suggested [26] that it is also dependent upon the structural organization of the ligands and especially upon the strong capacity of the phosphonic (PO_3H_2) and/or phosphonate (PO_3H^-) groups to form intermolecular hydrogen bonds. On the other hand, the priorities in the hydrogen bond network organization are influenced by the structural peculiarities of each particular amino moiety.

Accordingly, the solid state ribbon aggregation via phosphonic–phosphonic and phosphonate–phosphonate interactions in compound **1** allows for the formation of multinuclear complexes of $[M_4L_3H_3]$ type in solution. The complex of $[M_3L_2H_2]$ type is detected for **5**, where due to phosphonic–phosphonate and phosphonate–phosphonate intermolecular interactions multimeric aggregates composed of two different dimeric units are formed. In the case of **7**, where only mixed phosphonic–phosphonate intermolecular hydrogen-bonding exist in the solid state, any metal ion coordination as well as deprotonation destroys the basic hydrogen-bonded network. Consequently, mononuclear complexes are explicitly formed which is proved by both potentiometry and NMR methods.

In the light of the above discussion it seems to be evident that prior crystal structural studies of the ligands themselves might be valuable in predicting the most likely binding modes. Three examples are presented in Scheme 3.

Structure **I** is presumed based on the molecular ribbon formed by **1**, provided that in all *N*-alkyl substituted aminomethane-1,1-diphosphonic acids the intermolecular hydrogen bond networks are similar. Structure **II** is based on the dimeric units that constitute the multimeric aggregates of ligand **5**. Structure **III** represents the mononuclear complex(es) formed preferentially with compounds **6** and **7**.

Magnesium(II) is worst as a template organizing the multinuclear complex forms. The $[M_3L_2H_2]$ species formed exclusively with **1** and **2** may be assumed, by analogy, as short forms of structure **I**.

Zinc(II), forming the strongest M–O bonds among all of the studied cations, prefers formation of multinuclear complexes, whilst Mg^{II} and Ca^{II} behave quite differently. Magnesium(II) demonstrates a preference for mononuclear species whereas calcium(II) tends to form insoluble complexes with most of the studied ligands.

Abstract

A simple synthetic procedure for the mono- or di-functionalization of tri- and tetra-azamacrocycles with electron rich arenes has been developed. Specifically, 1,4,7-triazacyclononane (tacn), 1,4,7,10-tetraazacyclododecane (cyclen) and 1,4,8,11-tetraazacyclotetradecane (cyclam) react with 2,4,6-trimethylstyrene in the presence of *n*-butyllithium to give, respectively *N*-(mesitylethyl)-1,4,7-triazacyclononane ($\mathbf{L}_1$), *N*-(mesitylethyl)-1,4,7,10-tetraazacyclododecane ($\mathbf{L}_4$), and *N*-(mesitylethyl)-1,4,8,11-tetraazacyclotetradecane ($\mathbf{L}_5$). In contrast, when styrene itself or *p*-vinylanisole are used as the Michael acceptor with 1,4,7-triazacyclononane, the *N′*,*N″* product is formed, respectively *N′*,*N″*-*bis*(phenylethyl)-1,4,7-triazacyclononane ($\mathbf{L}_2$) and *N′*,*N″*-*bis*(*p*-methoxyphenylethyl)-1,4,7-triazacyclononane ($\mathbf{L}_3$). Using conventional mono-functionalization techniques, the phenyl derivatives *N*-(4-hydroxymethylbenzyl)-1,4,7-triazacyclononane ($\mathbf{L}_6$) and *N*-(4-benzylcarboxylic acid)-1,4,7-triazacyclononane ($\mathbf{L}_7$) have also been synthesised. A series of transition metal complexes of $\mathbf{L}_1$ to $\mathbf{L}_7$ with Ni(II), Cu(II), Zn(II) and Co(II) have been prepared. The X-ray crystal structures of $[Cu(\mathbf{L}_1)_2](PF_6)_2$, $[(\mathbf{L}_1)CuCl_2]$, $[Cu(\mathbf{L}_6)(NO_3)_2]$ and $[Cu_2(\mathbf{L}_7\text{–H})_2(OH_2)_2](PF_6)_2\cdot 3H_2O$ are described. In all of these complexes, coordination to the metal takes place through the macrocycle nitrogens. The crystal structure of $[Cu_2(\mathbf{L}_7\text{–H})_2(OH_2)_2](PF_6)_2\cdot 3H_2O$ reveals that it is a coordinate-polymeric material. Attempts to coordinate the pendent arenes to Rh(I) are discussed. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

The chemistry of triazamacrocycles, *N*-functionalized with hard ligators, e.g. carboxylic acids [1], alcohols [2], amines [3], sulfates [4], phosphates [5], imidazoles [6] and pyridine [7] is now well established. More recently the chemistry has been extended to include more classic soft donors such as sulfides [8], alkenes [9], phosphines [10] and alkynes [11]. As part of our own research effort we have been exploring the possibility of introducing aromatic groups onto the macrocycle (Scheme 1), which are either electron rich so as to generate organometallic clusters, or have oxygen binding sites for further molecular recognition [12]. As a result we

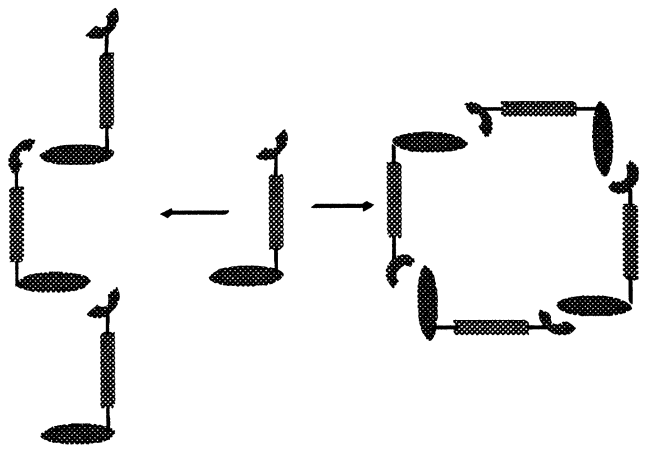

Scheme 1. List and numbering scheme of the macrocycles discussed in the text.

now present some of our work towards these goals. In particular, a high yielding procedure is reported for the monofunctionalization of tacn with the electron rich arene derived from 2,4,6-trimethylstyrene.

Syntheses of single pendent arm macrocycles are comparatively rare, and are often not straightforward, requiring chromatographic separation of the products. We have found that direct reaction of an excess of 2,4,6-trimethylstyrene with either of the macrocycles, tacn, cyclen or cyclam in the presence of *n*-butyllithium leads to good yields of the monosubstituted products without further separation. Under the same experimental conditions, the vinylaromatics styrene or *p*-vinylanisole give the *N′*,*N″* disubstituted products, in a similarly pure state.

Complexes of $\mathbf{L}_1$ with the metals, Cu(II), Ni(II), Co(II) and Zn(II) were synthesised and the X-ray crystal structures of $[Cu(\mathbf{L}_1)_2](PF_6)_2$ and $[(\mathbf{L}_1)CuCl_2]$ are described. It was anticipated that the pendent 'activated' arene of the coordinated ligand would react with soft metal centres, but no reaction was observed with Rh(I) [13] or Mo(0) [14] despite the use of forcing conditions. Complexes of $\mathbf{L}_6$ with the metals, Cu(II), Ni(II), Co(II) and $\mathbf{L}_7$ with Cu(II) were also prepared. In these two cases it was expected that the hydroxyl or carboxyl unit would play host to intermolecular bonding, and hence the construction of self-assembled molecular aggregates (e.g. polymers, boxes) as illustrated in Scheme 2.

Scheme 2. Pictorial representation of potential products from the self-assembly of an 'L' type motif.

2. Experimental

All chemicals unless otherwise stated were purchased from Aldrich and used as received. 1,4,7,10-Tetraazacyclododecane (cyclen) was purchased from Strem Chemicals. Solvents where necessary were dried by reported methods [15]. 1,4,7-Triazacyclononane (tacn) [16], 1,4,8,11-tetraazacyclotetradecane (cyclam) [17], 1,4,7-triazacyclo[5.2.1.^{04,10}]decane [18] and $[Rh(\mu\text{-}Cl)(COD)]_2$ [19] were synthesised according to literature procedures. ^{1}H and ^{13}C NMR spectra were recorded using a Bruker AM360 360 MHz spectrometer. UV–Vis spectra were recorded using a Shimadzu UV-3101 PC spectrophotometer. Mass spectra were obtained using a JEOL JMS 700 (The MStation) mass spectrometer. Combustion analysis was performed using in-house facilities.

2.1. Synthesis of *N*-(mesitylethyl)-1,4,7-triazacyclononane ($\mathbf{L}_1$)

^{n}BuLi (4 ml of a 2.5 M solution in hexanes, 10 mmol) was added dropwise to a solution of tacn (1.0 g, 7.8 mmol) dissolved in THF (20 ml). The reaction mix was stirred for 5 min, followed by the dropwise addition of 2,4,6-trimethylstyrene (3.4 g, 23.2 mmol) in THF (10 ml) and the solution stirred at 60 °C for 16 h. Water (1 ml) was added and the reaction mix stirred for 5 min. All volatiles were removed in vacuo. The residue was extracted into CH_2Cl_2 and the solution extracted with 2 M HCl (2 × 40 ml). The aq. phase was basified with NaOH (1 M) solution and the free ligand extracted into $CHCl_3$ (3 × 40 ml). The combined organic phases were dried over $MgSO_4$, filtered and the solvents removed in vacuo to leave a clear oil which slowly solidified. Yield: 1.1 g, 3.9 mmol, 50%. ^{1}H NMR ($CDCl_3$): $\delta = 6.80$ (s, 2H, $C_6H_2Me_3$), 2.98–2.60 (m, 18H, CH_2NH), 2.27 (s, 6H, *o*-$C_6H_2(CH_3)_2$), 2.21 (s, 3H, *p*-$C_6H_2CH_3$). ^{13}C NMR ($CDCl_3$): $\delta = 136.0$, 135.3, 133.3, 128.9 (phenyl–*C*), 55.6 (N–CH_2–CH_2–$C_6H_2Me_3$), 52.3, 46.7, 46.4 (N–CH_2–CH_2–N), 27.2 (N–CH_2–CH_2–$C_6H_2Me_3$), 20.8 (*p*-$C_6H_2CH_3$), 19.8 (*o*-$C_6H_2(CH_3)_2$). EI MS: $m/z = 273$ $[M-2H]^+$, 154 $[M-C_6H_2Me_3]^+$.

2.2. Synthesis of N-(mesitylethyl)-1,4,7,10-tetraazacyclododecane (L_4)

^{n}BuLi (1.6 ml of a 2.5 M solution in hexanes, 4.0 mmol) was added dropwise to a solution of cyclen (0.50 g, 3.0 mmol) in THF (20 ml). The reaction mixture was stirred for 5 min, followed by the addition of 2,4,6-trimethylstyrene (1.3 g, 9 mmol) in THF (10 ml) and the reaction mixture was stirred at 60 °C for 16 h. Water (5 ml) was added and the reaction mixture stirred for 5 min. All volatiles were removed in vacuo. The residue was dissolved in CH_2Cl_2 and the solution extracted into 2 M HCl (2×40 ml). The aq. phase was basified with NaOH (1 M) solution and the free ligand extracted into $CHCl_3$ (3×40 ml). The combined organic phases were dried over $MgSO_4$, filtered and the solvents removed in vacuo to leave a clear, yellow oil. Yield: 0.58 g, 1.8 mmol, 60%. ^{1}H NMR ($CDCl_3$): $\delta = 6.80$ (s, 2H, $C_6H_2Me_3$), 2.82–2.50 (m, 23H, CH_2,NH), 2.27 (s, 6H, o-$C_6H_2(CH_3)_2$), 2.21 (s, 3H, p-$C_6H_2CH_3$). ^{13}C NMR ($CDCl_3$): $\delta = 135.9$, 135.0, 133.2, 129.7 (phenyl–C), 53.0 (N–CH_2–CH_2–$C_6H_2Me_3$), 51.0, 46.9, 45.7, 45.3 (N–CH_2–CH_2–N), 26.8 (N–CH_2–CH_2–$C_6H_2Me_3$), 20.6 (p-$C_6H_2CH_3$), 19.5 (o-C_6H_2-$(CH_3)_2$). EI MS: $m/z = 185$ $[M - (CH_2)_2C_6$-$H_2Me_3]^+$, 147 $[(CH_2)_2C_6H_2Me_3]^+$, 133 $[CH_2C_6H_2Me_3]^+$.

2.3. Synthesis of N-(mesitylethyl)-1,4,8,11-tetraazacyclotetradecane (L_5)

Prepared similarly to $\mathbf{L}_1$ from cyclam (0.40 g, 2.0 mmol), ^{n}BuLi (1.1 ml of a 2.5 M solution in hexanes, 2.8 mmol) and 2,4,6-trimethylstyrene (1.2 g, 8.0 mmol). Yield: 0.30 g, 0.88 mmol, 44%. ^{1}H NMR ($CDCl_3$): $\delta = 6.73$ (s, 2H, $C_6H_2Me_3$), 2.72–2.51 (m, 23H, NH, N–CH_2–CH_2–N,N–CH_2–CH_2–CH_2–N), 2.23 (s, 6H, o-$C_6H_2(CH_3)_2$), 2.15 (s, 3H, p-$C_6H_2CH_3$), 1.67 (m, 4H, N–CH_2–CH_2–$C_6H_2Me_3$). ^{13}C NMR ($CDCl_3$): $\delta = 135.9$, 134.8, 133.4, 128.7 (phenyl–C), 54.0, 52.3, 50.9, 50.7, 50.5, 49.3, 49.1, 49.0, 48.9, 47.9, 28.9, 28.6, 26.3, 24.5 (CH_2), 20.7 (p-$C_6H_2CH_3$), 19.8 (o-$C_6H_2(CH_3)_2$). EI MS: $m/z = 213$ $[M - CH_2(C_6H_2Me_3]^+$, 147 $[(CH_2)_2C_6$-$H_2Me_3]^+$.

2.4. Synthesis of N′,N″-bis(phenylethyl)-1,4,7-triazacyclononane (L_2)

Prepared similarly to $\mathbf{L}_1$ from tacn (0.20 g, 1.58 mmol), ^{n}BuLi (1.0 ml of a 2.5 M solution in hexanes, 2.1 mmol) and styrene (0.50 g, 4.8 mmol). Yield: 0.24 g, 0.72 mmol, 45%. ^{1}H NMR ($CDCl_3$): $\delta = 7.29$–7.18 (m, 10H, C_6H_5), 2.79–2.62 (21H, CH_2 NH). ^{13}C NMR ($CDCl_3$): $\delta = 140.6$, 128.6, 128.3, 125.9 (phenyl–C), 59.1 (NH–CH_2–CH_2–C_6H_5), 53.0, 53.5, 46.7 (NH–CH_2–CH_2–NH), 34.1 (NH–CH_2–CH_2–C_6H_5). EI MS: $m/z = 335$ $[M]^+$, 246 $[M - CH_2C_6H_5]^+$, 105 $[C_6H_5(CH_2)_2]^+$.

2.5. Synthesis of N′,N″-bis(p-methoxyphenylethyl)-1,4,7-triazacyclononane (L_3)

Prepared similarly to $\mathbf{L}_1$ from tacn (0.21 g, 1.58 mmol), ^{n}BuLi (1.0 ml of a 2.5 M solution in hexanes, 2.1 mmol), and p-vinylanisole (0.64 g, 4.8 mmol). Yield: 0.28 g, 0.71 mmol, 45%. ^{1}H NMR ($CDCl_3$): $\delta = 7.09$ (d, 4H, C_6H_4, $J = 8.64$ Hz), 6.81 (d, 4H, C_6H_4, $J = 8.68$ Hz), 3.74 (s, 6H, CH_3), 2.71–2.58 (m, 21H, CH_2, NH). ^{13}C NMR ($CDCl_3$): 157.8, 132.2, 129.6, 113.7 (phenyl–C), 59.0 (N–CH_2–CH_2–C_6H_4OMe), 55.1 (CH_3), 52.3, 50.1, 45.8 (N–CH_2–CH_2–N), 33.0 (N–CH_2–CH_2–C_6H_4OMe). EI MS: $m/z = 396$ $[M]^+$, 276 $[M - CH_2C_6H_4OMe]^+$, 135 $[CH_2CH_2C_6H_4OMe]^+$.

2.5.1. Synthesis of A

To a one-necked flask flushed with dinitrogen and charged with 1,4,7-triazacyclo[5.2.1.^{04,10}]decane (0.69 g, 4.96 mmol) in dry THF (30 ml), was slowly added 4-bromomethylbenzyl alcohol (1 g, 4.98 mmol) in dry THF (20 ml). The reaction mixture was stirred overnight and the resultant white precipitate filtered washed with THF and dried. Yield: 1.03 g, 3.02 mmol, 61%. ^{1}H NMR (C_3H_6O-d_6): $\delta = 7.73$–7.72 (d, 2H, C_6H_4, $J = 7.9$ Hz), 7.54–7.52 (d, 2H, C6H_4, $J = 7.9$ Hz), 5.97 (s, 1H, N–CH), 4.75 (s, 2H, Ar–CH_2), 4.71 (s, 2H, ArCH_2), 4.04–3.98 (m, 2H, NCH_2), 3.81–3.70 (m, 4H, NCH_2), 3.50–3.42 (m, 2H, N–CH_2), 3.33–3.25 (m, 4H, N–CH_2).

2.6. Synthesis of N-(4-hydroxymethylbenzyl)-1,4,7-triazacyclononane (L_6)

Compound **A** (1.31 g, 3.85 mmol) was refluxed in water (40 ml) for 4 h followed by the addition of NaOH (0.54 g, 10 mmol). The resulting basic solution was refluxed for 24 h and the water removed with $C_6H_5CH_3$ using a Dean–Stark apparatus. Removal of the $C_6H_5CH_3$ afforded an oil which was sufficiently pure enough for metal ion complexation. Yield: 0.65 g, 2.6 mmol, 68%. ^{1}H NMR ($CDCl_3$): $\delta = 7.26$ (s, 4H, C_6H_4), 4.53 (s, 2H, N–CH_2–OH), 3.62 (s, 2H, CH_2–N), 2.65 (m, 4H, N–CH_2), 2.54 (m, 8H, N–CH_2). EI MS: $m/z =$ 250 $[M$H$]^+$.

2.6.1. Synthesis of B

This compound was prepared in a similar manner to that reported for compound **A**, using methyl-4-(bromomethyl)benzoate (1 g, 4.37 mmol) and 1,4,7-triazacyclo[5.2.1.^{04,10}]decane (0.69 g, 4.96 mmol). Yield: 1.1 g, 2.98 mmol, 68%. ^{1}H NMR (C_3H_6O-d_6): $\delta = 8.11$–8.09 (d, 2H, C_6H_4, $J = 8.1$ Hz), 7.91–7.88 (d, 2H, C_6H_4,

$J = 8.2$ Hz), 6.02 (s, 1H, NC*H*), 4.79 (s, 2H, Ar–CH_2), 3.98–3.93 (m, 2H, NCH_2), 3.90 (s, 3H, OCH_3), 3.82–3.75 (m, 4H, N–CH_2), 3.45–3.32 (m, 2H, NCH_2), 3.26–3.31 (q, 4H, NCH_2, $J = 6.7$ Hz).

2.7. Synthesis of N-(4-benzylcarboxylic acid)-1,4,7-triazacyclononane (L_7)

Compound **B** (1 g, 2.8 mmol) was dissolved in water (50 ml) and refluxed for 2 h followed by addition of NaOH (0.2 g, 5 mmol) and further refluxing for 4 h. The solution was cooled to room temperature and extracted with CH_2Cl_2 to remove organic impurities. The solution was made acidic with concd. HBr and the solvent removed on a rotary evaporator. The remaining solid was extracted with EtOH (3×50 cm^3) and the combined EtOH fractions removes on a rotary evaporator to afford a yellow solid, which was recrystallized from MeOH–Et_2O (1:5). Yield: 0.44 g, 1.7 mmol, 60%. ^{1}H NMR (DMSO-d_6): $\delta = 7.91$–7.88 (d, 2H, C_6H_4, $J = 8.0$ Hz), 7.57–7.54 (d, 2H, C_6H_4, $J = 8.1$ Hz), 4.42 (s, 2H, Ar–CH_2), 3.88 (m, 4H, N–CH_2), 3.13 (m, 4H, N–CH_2), 2.87 (m, 4H, N–CH_2). EI MS: $m/z = 264$ $[M\text{H}]^+$, 247 $[M - \text{OH}]^+$, 219 $[M - \text{CO}_2\text{H}]^+$.

2.8. Metal complexes

2.8.1. $[Cu(L_1)_2](PF_6)_2 \cdot 1/2CH_3CN$ (1)

The ligand $\mathbf{L}_1$ (150 mg, 0.55 mmol) in EtOH (2 ml) was added to $CuCl_2 \cdot 2H_2O$ (48 mg, 0.28 mmol) in EtOH (10 ml), containing NH_4PF_6 (230 mg). Stirring was continued for approximately 16 h. A blue precipitate was filtered off, washed with EtOH and ether, and air-dried. The compound was recrystallized from MeCN. Yield: 138 mg (50%). IR (cm^{-1}): 3142 $\nu_{(\text{N–H})}$, 843 $\nu_{(\text{P–F})}$. CHN Found (Calc.): C, 45.80 (45.45); H, 6.55 (6.48); N, 9.46 (9.84)%.

2.8.2. $[Co(L_1)_2](PF_6)_2$ (2)

The ligand $\mathbf{L}_1$ (256 mg, 0.93 mmol) in EtOH (5 ml) was added to $CoCl_2 \cdot 6H_2O$ (88 mg, 0.37 mmol) in degassed EtOH (20 ml), containing NH_4PF_6 (300 mg). The reaction mixture was stirred for approximately 16 h under nitrogen. A pink precipitate was filtered off, washed repeatedly with EtOH and dried in vacuo. Yield: 200 mg (60%). IR (cm^{-1}): 3200 $\nu_{(\text{N–H})}$, 845 $\nu_{(\text{P–F})}$. CHN Found (Calc.): C, 45.30 (45.39); H, 6.57 (6.50); N, 9.18 (9.34)%.

2.8.3. $[Zn(L_1)_2](PF_6)_2$ (3)

The ligand $\mathbf{L}_1$ (200 mg, 0.72 mmol) in EtOH (2 ml) was added to $ZnCl_2$ (48 mg, 0.36 mmol) in EtOH (20 ml) containing NH_4PF_6 (300 mg). The mixture was stirred for 2 h. A white precipitate was then filtered off, washed with EtOH and dried in vacuo. Yield: 183 mg (56%). IR (cm^{-1}): 3214 $\nu_{(\text{N–H})}$, 843 $\nu_{(\text{P–F})}$. CHN Found (Calc.): C, 44.9 (45.06); H, 6.52 (6.45); N, 9.23 (9.27)%. ^{1}H NMR (CD_3CN): $\delta = 6.87$ (s, 4H, phenyl–*H*), 3.31 (s, 4H, N*H*), 2.96–2.64 (m, 32H, CH_2), 2.25 (s, 12H, *o*-$C_6H_2(CH_3)_2$), 2.23 (s, 6H, *p*-$C_6H_2CH_3$). ^{13}C NMR (CD_3CN): 136.8, 131.6, 129.5, 117.8 (phenyl–*C*), 55.8, 49.1, 44.0, 43.2 (N–*C*H$_2$), 22.5 (*C*H$_2$-mesityl), 20.3 (*p*-$C_6H_2CH_3$), 19.5 (*o*-$C_6H_2(CH_3)_2$).

2.8.4. $[Ni(L_1)_2](PF_6)_2$ (4)

The ligand $\mathbf{L}_1$ (150 mg, 0.55 mmol) in EtOH (5 ml) was added to $NiCl_2 \cdot 6H_2O$ (60 mg, 0.25 mmol) in EtOH (20 ml), containing NH_4PF_6 (200 mg). The mixture was stirred for 4 h. A purple precipitate was filtered off and air-dried. Yield: 100 mg (44%). IR (cm^{-1}): 3270 $\nu_{(\text{N–H})}$, 841 $\nu_{(\text{P–F})}$. CHN Found (Calc.): C, 44.9 (45.4); H, 6.71 (6.50); N, 8.88 (9.34)%.

2.8.5. $[Cu(L_4)](ClO_4)_2 \cdot 1/2EtOH$ (5)

The ligand $\mathbf{L}_4$ (140 mg, 0.44 mmol) in EtOH (5 ml) was added to $Cu(ClO_4)_2 \cdot 6H_2O$ (130 mg, 0.35 mmol) in EtOH (20 ml). The solution was stirred for 24 h. A purple precipitate was filtered off, washed with EtOH and dried in vacuo. Yield: 114 mg (54%). IR (cm^{-1}): 3280 $\nu_{(\text{N–H})}$, 1100 $\nu_{(\text{Cl–O})}$. CHN Found (Calc.): C, 40.0 (39.77); H, 5.78 (6.17); N, 8.95 (9.28)%. UV–Vis (CH_3NO_2): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 579 (334).

2.8.6. $[Zn(L_4)Cl](ClO_4)_2$ (6)

The ligand $\mathbf{L}_4$ (202 mg, 0.64 mmol) in EtOH (3 ml) was added to $ZnCl_2$ (69 mg, 0.51 mmol) in EtOH (20 ml) containing $LiClO_4$ (300 mg). Stirring was continued for approximately 24 h. The white precipitate was filtered off, washed with EtOH and ether and dried in vacuo. Yield: 120 mg (45%). ^{1}H NMR (CD_3CN): $\delta =$ 6.84 (s, 2H, phenyl–*H*), 3.11–2.69 (m, 23H, CH_2 N*H*), 2.27 (s, 6H, *o*-$C_6H_2(CH_3)_2$), 2.20 (s, 3H, *p*-$C_6H_2CH_3$). ^{13}C NMR (CD_3CN): 137.2, 132.8, 130.0, 118.3 (phenyl–*C*), 53.0 (N–*C*H$_2$–CH$_2$–mes), 50.2, 45.5, 44.6, 43.6 (N–*C*H$_2$–*C*H$_2$–N), 22.5 (*C*H$_2$–mes), 20.9 (*p*-$C_6H_2CH_3$), 19.9 (*o*-$C_6H_2(CH_3)_2$). IR (cm^{-1}): 3280 $\nu_{(\text{N–H})}$, 1090 $\nu_{(\text{Cl–O})}$. CHN Found (Calc.): C, 44.1 (44.6); H, 6.74 (6.71); N, 10.2 (10.9)%.

2.8.7. $[Ni(L_4)](ClO_4)_2 \cdot 1/2Et_2O$ (7)

The ligand $\mathbf{L}_4$ (301 mg, 0.94 mmol) in butan-1-ol (10 ml) was added to $Ni(ClO_4)_2 \cdot 6H_2O$ (278 mg, 0.76 mmol) in hot butan-1-ol (30 ml). The reaction mixture was stirred for 24 h. A green precipitate was filtered off, washed with butan-1-ol and dried in vacuo. Yield: 142 mg. The blue liquor was concentrated in vacuo to dryness to leave a yellow solid. This was washed repeatedly with ether and dried in vacuo. Yield: 280 mg (64%). IR (cm^{-1}): 3260 $\nu_{(\text{N–H})}$, 1100 $\nu_{(\text{Cl–O})}$. CHN Found (Calc.): C, 40.60 (41.14); H, 6.19 (6.41); N, 8.54 (9.14)%. UV–Vis (CH_3NO_2): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 418 (40), 454 (26.1), 878 (27.9).

*2.8.8. [Cu(**L**$_5$)](ClO$_4$)$_2$·H$_2$O (**8**)*

The ligand **L**$_5$ (120 mg, 0.34 mmol) in EtOH (2 ml) was added to Cu(ClO$_4$)$_2$·6H$_2$O (100 mg, 0.27 mmol) in EtOH (10 ml). The reaction mixture was stirred for approximately 16 h. A purple precipitate was filtered off, washed with EtOH and ether, and dried in vacuo. Yield: 105 mg (63%). IR (cm^{-1}): 3230 $\nu_{(N-H)}$, 1100 $\nu_{(Cl-O)}$. CHN Found (Calc.): C, 40.7 (40.23); H, 6.38 (6.43); N, 9.33 (8.94)%. UV–Vis (MeOH): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 516 (135).

*2.8.9. [Ni(**L**$_5$)](ClO$_4$)$_2$ (**9**)*

The ligand **L**$_5$ (150 mg, 0.43 mmol) in EtOH (5 ml) was added to Ni(ClO$_4$)$_2$·6H$_2$O (124 mg, 0.34 mmol) in EtOH (20 ml). The reaction mixture was stirred for approximately 16 h. A red precipitate was filtered off, washed with EtOH and ether, and dried in vacuo. Yield: 98 mg (50%). IR (cm^{-1}): 3210 $\nu_{(N-H)}$, 1100 $\nu_{(Cl-O)}$. CHN Found (Calc.): C, 41.3 (41.7); H, 6.24 (6.35); N, 9.28 (9.28)%. UV–Vis (MeOH): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 463.5 (79).

*2.8.10. [Ni(**L**$_5$)Cl$_2$] (**10**)*

(a) The ligand **L**$_5$ (150 mg, 0.43 mmol) in EtOH (5 ml) was added to NiCl$_2$·6H$_2$O (93 mg, 0.39 mmol) in warm EtOH (20 ml). The reaction mixture was stirred for approximately 16 h. Diethyl ether was added and a mauve precipitate was filtered off, washed with ether and dried in vacuo. Yield: 23 mg (12%).

(b) LiCl (108 mg, 2.55 mmol) in C$_3$H$_6$O (10 ml) was added to **9** (150 mg, 0.207 mmol) in C$_3$H$_6$O (10 ml) with stirring. A mauve precipitate was filtered off, washed with C$_3$H$_6$O, and dried in vacuo. Yield: 23 mg (15%). IR (cm^{-1}): 3190 $\nu_{(N-H)}$. CHN Found (Calc.): C, 52.9 (53.0); H, 7.99 (8.06); N, 11.57 (11.77)%. UV–Vis (MeOH): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 463 (90).

*2.8.11. Reaction of **L**$_1$ with [Rh(COD)]$^+$(PF$_6$)$^-$*

AgPF$_6$ (101 mg, 0.40 mmol) in MeCN (5 ml) was added under nitrogen to [Rh(μ-Cl)(COD)]$_2$ (100 mg, 0.20 mmol) in MeCN (10 ml). The yellow solution was separated from precipitated AgCl and added to **6** (362 mg, 0.40 mmol) in MeCN (10 ml). No reaction was observed by ^{1}H or ^{13}C NMR spectroscopy after prolonged heating and stirring. When **6** was substituted by free **L**$_1$, no reaction of the pendent arene group was observed.

*2.8.12. [Ni(**L**$_6$)$_2$](PF$_6$)$_2$ (**12**)*

The ligand **L**$_6$ (200 mg, 0.8 mmol) in EtOH (5 ml) was added to a solution of Ni(NO$_3$)$_2$·6H$_2$O (0.23 g, 0.79 mmol) in H$_2$O (5 ml) and stirred for 5 min. A saturated NH$_4$PF$_6$ solution was added and the product extracted with CH$_3$NO$_2$ (2 × 5 ml). The organic layer was separated and removed to give oil, which was recrystallized from CH$_3$CN–Et$_2$O (1:3). Yield: 100 mg (30%). IR (cm^{-1}): 3424 $\nu_{(N-H)}$, 2927 $\nu_{(C-H)}$, 843 $\nu_{(P-F)}$. FAB MS: $m/z = 701$ [Ni(**L**$_6$)$_2$](PF$_6$)$^+$, 555 [Ni(**L**$_6$)$_2$]$^+$. UV–Vis (CH$_3$CN): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 885 (18), 533 (10), 316 (63).

*2.8.13. [Co(**L**$_6$)(NO$_3$)$_2$(OH$_2$)]·H$_2$O (**13**)*

The ligand **L**$_6$ (100 mg, 0.4 mmol) in EtOH (5 ml) was added to a solution of Co(NO$_3$)$_2$·6H$_2$O (116 mg, 0.4 mmol) in H$_2$O (5 ml) and stirred for 5 min. The solution was left to slowly evaporate until a precipitate formed, which was filtered off and purified by passing down a Sephadex column eluting with CH$_3$CN. Yield: 69 mg (40%). IR (cm^{-1}): 3527 ν_{OH}, 3272 ν_{NH}, 1480, 1318 ν_{NO_2}. FAB MS: $m/z = 370$ [Co(**L**$_6$)NO$_3$]$^+$. CHN Found (Calc.): C, 37.10 (37.34); H, 5.85 (5.60); N, 15.08 (15.55)%. UV–Vis (CH$_3$CN): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 539 (119).

*2.8.14. [Cu(**L**$_6$)(NO$_3$)$_2$] (**14**)*

The ligand **L**$_6$ (97 mg, 0.39 mmol) in EtOH (5 ml) was added to a solution of Cu(NO$_3$)$_2$·3H$_2$O (94 mg, 0.39 mmol) in H$_2$O (5 ml) and stirred for 5 min. The solution was left to slowly evaporate until a precipitate was formed, which was filtered off and purified as described above. Yield: 85 mg (50%). IR (cm^{-1}): 3527 ν_{OH}, 3272 ν_{NH}, 1480, 1318 ν_{NO_2}. FAB MS: $m/z = 374$ [Cu(**L**$_6$)NO$_3$]$^+$. CHN Found (Calc.): C, 38.68 (38.48); H, 5.36 (5.31); N, 15.87 (16.03)%. UV–Vis (CH$_3$CN): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 647 (59).

*2.8.15. [Cu(**L**$_7$)(Br$_2$)]·2H$_2$O (**15**)*

The ligand **L**$_7$·HBr (158 mg, 0.46 mmol) in H$_2$O (5 ml) was added to a solution of Cu(NO$_3$)$_2$·3H$_2$O (111 mg, 0.46 mmol) in H$_2$O (5 ml) and stirred for 5 min. The solution was left to slowly evaporate until a precipitate formed, which was filtered off and dried under vacuum. Yield: 89 mg (37%). IR (cm^{-1}): 3430 ν_{OH}, 3288 ν_{NH}, 2920 ν_{CH}, 1695 ν_{CO}. FAB MS: $m/z =$ 485 [Cu(**L**$_7$)Br$_2$]$^+$, 407 [Cu(**L**$_7$)Br]$^+$, 326 [Cu(**L**$_7$)]$^+$. CHN Found (Calc.): C, 31.79 (32.16); H, 4.12 (4.82); N, 8.55 (8.04)%. UV–Vis (H$_2$O): λ_{max} (nm) (ε_{max}, mol^{-1} l cm^{-1}): 650 (39).

*2.8.16. [Cu$_2$(**L**$_7$–H)$_2$(OH$_2$)$_2$](PF$_6$)$_2$·6H$_2$O (**16**)*

A saturated aq. solution of KPF$_6$ was added to a solution of [Cu(**L**$_7$)(Br$_2$)]·2H$_2$O (40 mg, 0.076 mmol) in H$_2$O (5 ml). The water was allowed to slowly evaporate until a blue crystalline solid precipitated, which was filtered off and dried under vacuum. Yield: 37 mg (95%). IR (cm^{-1}): 3430 ν_{OH}, 2925 ν_{CH}, 1609 ν_{CO}, 838 ν_{PF}. CHN Found (Calc.): C, 30.36 (30.96); H, 4.03 (4.79); N, 7.33 (7.74)%. FAB MS: $m/z = 326$ [Cu(**L**$_7$)]$^+$.

2.9. Crystallography

Details of the data collection and analysis of **1**, **14** and **16** are collected in Table 1. Single crystals were attached to a glass fibre using acrylic resin, and mounted on a goniometer head in a general position. Data were collected using an Enraf–Nonius CAD4 diffractometer (compound **1**) or a Bruker–Nonius Kappa CCD diffractometer (compounds **14** and **16**) using graphite-monochromated X-radiation ($\lambda =$ 0.71073 Å). The structures were solved by direct methods (SIR-92) [20]. All non-H atoms were allowed anisotropic thermal motion. Aliphatic CH hydrogen atoms were included at calculated positions with C–H = 0.96 Å. Refinement (SHELXL-97) [21] was by full-matrix least-squares on F^2. All crystals of **16**, which were examined proved to be twins. The crystal chosen was twinned according to a rotation of 180° about 010. Many reflections from both lattices are overlapped. Despite these problems, the overall identity of compound **16** was satisfactorily determined by the X-ray analysis. Neutral atom scattering factors, coefficients and anomalous dispersion and absorption coefficients were obtained from [22].

3. Results and discussion

3.1. Synthesis of the ligands

The ligands $\mathbf{L}_1$–$\mathbf{L}_5$ were synthesised according to a Michael type reaction [23]. An excess of the 'activated' vinylaromatic was added to a THF solution of the free macrocycle to which an excess of ^{n}BuLi had been added. After removal of solvents, the residue was converted to the hydrochloride salt, extracted into water then basified to liberate the free amine. In the case of those reactions involving 2,4,6-trimethylstyrene, the single pendent arm product was the only one isolated. When the Michael acceptor was styrene or *p*-vinylanisole, the *N*′,*N*″ disubstituted product was the only one isolated after work up. This variation is curious and no explanation is apparent. The ligands $\mathbf{L}_6$–$\mathbf{L}_7$ were prepared by the conventional mono-functionalization technique of reacting the appropriate arylalkyl halide with 1,4,7-triazacyclo[5.2.1.$^{04.10}$]decane followed by base hydrolysis (Scheme 3).

3.2. Synthesis of the complexes

The complexes were prepared by addition of the free ligand to ethanolic or water solutions of the appropriate metal salts. The solid complexes could be obtained as precipitates by addition of a suitable counter ion ($(PF_6)^-$ or $(ClO_4)^-$). In the case of the neutral complex **1**, the product was precipitated from ethanolic solution by the addition of diethyl ether. Crystals suitable for X-ray crystallography were obtained for complexes **1**, **14** and **16**.

3.3. Description of the crystal structures

The structure of the two different cations found in the unit cell of complex **1** are illustrated in Fig. 1. In the first case the Cu(II) metal ion is coordinated to the three nitrogens of the macrocycle with the two other sites occupied by chloride ions. The Cu–N bond lengths

are consistent with a complex that is Jahn–Teller distorted, affording the cation a square-based pyramidal geometry. The pendant mesitylene is non-coordinated which is compatible with the 'soft' nature of the ligand. The second cation is a six coordinate centrosymmetric copper complex containing two macrocycles. Again the complex is Jahn–Teller distorted with two long bonds, the Cu–N (axial) bond length significantly greater than that found in the five coordinate complex. The pendant mesitylene group is well separated from the copper centre suggesting that steric hindrance is not a major factor in rationalising the lack of any reaction of the group with organometallic reagents (see later).

For complexes containing the ligands $\mathbf{L}_6$ and $\mathbf{L}_7$, the alcohol and carboxyl groups, respectively are, in contrast to most pendant arm macrocyclic ligands, not available for binding to the same metal ion centre. For complexes of the two ligands intermolecular bonding is however feasible, and hence affords a way to create well-defined supramolecular structures. Illustrated in Fig. 2 is the structure of the complex $[Cu(\mathbf{L}_6)(NO_3)_2]$, and collected is a list of selected bond lengths and angles. The complex is five-coordinate and, as observed for the previously discussed copper systems, has a Jahn–Teller distorted square-based pyramidal structure. The two nitrate ions act as monodentate ligands and the pendant aromatic group is well separated from the copper–tacn core. The oxygen of the benzylalcohol segment is disordered over two sites consistent with a lack of intermolecular bonding to an adjacent unit. Indeed, no weak forces such as H-bonding to the nitrate ions are evident in the crystal-packing diagram.

In contrast to the previous complex the structure of the Cu(II) system containing the ligand $\mathbf{L}_7$ displays a more interesting recognition phenomenon as depicted in Fig. 3. As before the three nitrogens of the macrocycle are all coordinated and the pendant aromatic is well separated from the Jahn–Teller distorted Cu(II) centre. Unlike the copper complex of $\mathbf{L}_6$ the carboxyl oxygen from a neighbouring unit coordinates to the copper so that the asymmetric unit contains a basic $[Cu_2(\mathbf{L}_7\text{–H})_2]^{2+}$ repeat unit. As a result, a one-dimensional coordination polymer is produced as illustrated in the packing diagram of Fig. 4. A water molecule completes the fifth coordination sphere of each copper and it is noted that these water molecules point in the same direction but do not hydrogen bond to the layer above. The 'L' motif of the complex has dimensions of approximately 9.5×11 Å^2, which leads to speculation that further self-assembly using an appropriate template could generate a tetracopper molecular box (Scheme 2). Such control of molecular self-assembly is currently of great interest but as of yet has not utilised triazamacrocycles containing pendant arms. Further coordination studies of ligands based on $\mathbf{L}_7$ are underway and will be reported at a later date.

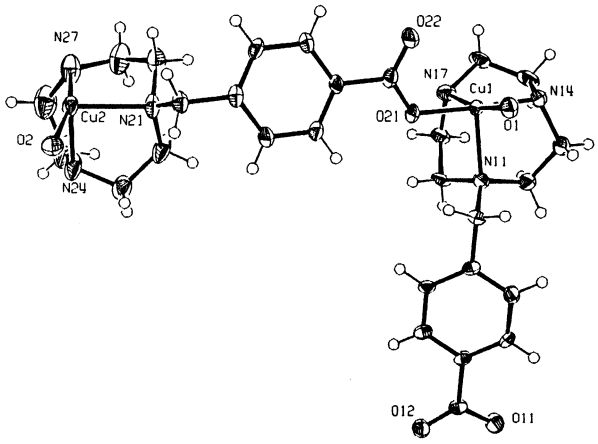

Fig. 3. ORTEP for Windows [30] plot of $[Cu_2(\mathbf{L}_7\text{–H})_2(H_2O)_2]^{2+}$ (thermal ellipsoids are shown at 50% probability and hexafluorophosphate anions and extraneous water molecules are omitted or clarity); selected bond lengths (Å) and angles (°): Cu1–N11, 2.235(6); Cu1–N14, 2.021(7); Cu1–N17, 2.035(7); Cu1–O1, 1.981(6); Cu1–O21, 1.946(6); Cu2–N21, 2.246(7); Cu2–N24, 2.024(8); Cu2–N27, 2.035(9); Cu2–O2, 1.978(7); Cu2–O11, 1.932(6); O21–Cu1–O1, 92.4(3); O21–Cu1–N14, 175.3(3); O1–Cu1–N14, 91.6(3); O21–Cu1–N17, 90.2(3); O1–Cu1–N17, 168.1(3); N14–Cu1–N17, 85.4(3); O21–Cu1–N11, 97.6(2); O1–Cu1–N11, 107.4(2); N14–Cu1–N11, 83.4(3); N17–Cu1–N11, 83.7(3); O11–Cu2–O2, 93.2(3); O11–Cu2–N24, 175.0(4); O2–Cu2–N24, 91.5(4); O11–Cu2–N27, 89.0(4); O2–Cu2–N27, 166.6(3); N24–Cu2–N27, 86.0(4); O11–Cu2–N21, 96.0(3); O2–Cu2–N21, 109.6(3); N24–Cu2–N21, 83.9(3); N27–Cu2–N21, 83.2(3).

3.4. Description of the metal complexes

3.4.1. L_1 complexes

The $\mathbf{L}_1$ complexes are all typical octahedral *bis* ligand species as expected for the metal ions concerned. As is described above, a second form of **1** is observed in the crystal, namely a neutral 1:1 dichloro-complex. This five coordinate species is analogous to the copper complex of *N*-(5-pent-2-yne)-1,4,7-triazacyclononane described elsewhere [11]. Solutions of the pale pink cobalt complex rapidly darken in air suggesting oxidation to Co(III), though no single species could be obtained from the dark solutions.

The 'hard' Lewis acidic metal centres in these complexes do not interact with the pendent arm arene groups, and coordination takes place exclusively through the ring nitrogens. For example, the ^{13}C NMR of the zinc complex **3** shows the signals due to the arene moiety to be essentially unshifted from those of the free ligand.

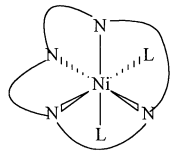

Fig. 5. Proposed folding of the cyclen macrocycle to generate a *cis*-complex.

3.4.2. L_4 complexes

The copper complex **5** is, as isolated in the solid state, a 1:1 species containing a four coordinate Cu(II) centre [24], though it may well become five coordinate in solution. When $\mathbf{L}_2$ in butan-1-ol is added to $Ni(ClO_4)_2{\cdot}6H_2O$ in hot butan-1-ol, a green solid precipitates from solution. This species shows three visible bands in nitromethane solution at 882, 586 and 443 nm, respectively. On this basis, we postulate a five- or six-coordinate nickel species. The size of the macrocyclic cavity in the 12 membered cyclen ring is such that square coplanar coordination of the metal is unlikely. The ligand rather is wrapped around the metal forming a *cis* complex [25], with the remaining coordination sites occupied by water (Fig. 5).

The blue liquor from the reaction yields, on removal of the solvent, a yellow solid. This dissolves in nitromethane or acetonitrile to give blue solutions. The yellow colour of the solid suggests a four-coordinate square coplanar environment for the nickel atom. This behaviour is well documented and Lincoln and coworkers [24] have described such a high spin-low spin equilibrium for the nickel complex of 1,4,7,10-tetramethyl-1,4,7,10-tetraazacyclododecane (tmc) (Eq. (1)).

1,4,7,10-tetraazacyclododecane (tmc) (equation 1).

$$[Ni(tmc)]^{2+} + H_2O \leftrightarrow [Ni(tmc)H_2O]^{2+} \quad (1)$$

low spin high spin

In addition, Fabbrizzi [26] has noted that in aqueous solutions of the nickel complex of cyclen, the normal blue colour of the octahedral high spin species becomes yellow on addition of 6 M $LiClO_4$ when heated, and the electronic spectrum, showing a new band at 23 000

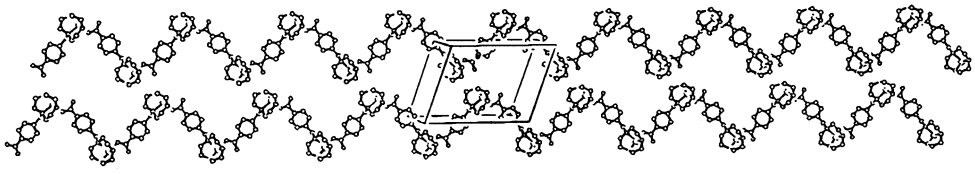

Fig. 4. ORTEP for Windows [30] view down the *a*-axis of the coordination polymer generated by the repeating $[Cu_2(\mathbf{L}_7\text{–H})_2(H_2O)_2]^{2+}$ moiety.

cm^{-1} becomes more typical of a low spin square planar species. Unfortunately, electronic spectra of the yellow form of **7** were not available in solution, as any solvent which led to dissolution, regenerated the octahedral form.

3.4.3. L_5 complexes

The macrocyclic cavity of the larger 14-membered ring is large enough to accommodate the metal ions Cu(II) and Ni(II) in square coplanar coordination. The UV–Vis spectrum of $[Ni(\mathbf{L}_5)](ClO_4)_2$ (**9**) in methanol ($\lambda = 463$ nm, $\varepsilon_{max} = 79\ mol^{-1}\ l\ cm^{-1}$) is consistent with a four coordinate complex. On addition of an excess of LiCl, a mauve solid separates from an acetone solution, which may be identified as $[Ni(\mathbf{L}_5)Cl_2]$ (**10**). This complex may also be prepared by addition of free ligand to $NiCl_2{\cdot}6H_2O$ in ethanol [27]. The UV–Vis spectrum of **10** in methanol is identical to that of **9** indicating the ionisation of the two chlorides in methanolic solution.

3.4.4. L_6 complexes

The complexation of $\mathbf{L}_6$ with Ni(II) produced a pale pink solid which exhibited three bands in the UV–Vis region at 885, 533 nm and a shoulder at 316 nm, respectively. The mass spectrum of the complex revealed a prominent ion at $m/z = 701$ which is assigned to the $[Ni(\mathbf{L}_6)_2](PF_6)^+$ ion. Interestingly a weaker peak as also observed in the mass spectrum at $m/z = 1547$ which can be attributed to a dimeric $[Ni(\mathbf{L}_6)_2]_2(PF_6)_3^+$ ion. It is possible that weak intermolecular H-bonds between the hydroxyl groups are responsible for the self-aggregation (Fig. 6).

The cobalt complex of $\mathbf{L}_6$ is dark claret in colour and displays one band at 539 nm in the UV–Vis region. The mass spectrum of the complex reveals a prominent ion at $m/z = 370$ which is compatible with the $[Co(\mathbf{L}_6)NO_3]^+$ ion. The IR and elemental analysis supports the existence of coordinated water so that as in the nickel case the complex is six-coordinate. Unlike the cobalt complex of $\mathbf{L}_1$ a solution of **13** exhibits no observable change in air suggesting that oxidation to Co(III) is slow.

3.5. Attempts to coordinate the pendent arene arm

Electron rich arenes such as mesitylene (1,3,5-trimethylbenzene) are excellent π acceptor ligands towards 'softer' transition metals. Such metal species as $[Rh(COD)]^+$, generated in situ from $[Rh(\mu\text{-}Cl)(COD)]_2$ (COD = 1,5-cyclooctadiene) and $AgPF_6$ react smoothly with arenes at room temperature to give η^6 arene complexes [28,29]. However, in our hands, reaction of either $\mathbf{L}_1$ or the zinc complex **3** with $[Rh(COD)](PF_6)$ in refluxing THF showed no reaction of the arene ring after 24 h. In the former case, ^1H NMR spectroscopy indicated reaction of the rhodium centre with the macrocycle ring nitrogens, but addition of further $[Rh(COD)](PF_6)$ did not lead to the formation of an η^6 complex. Clearly, the presence of the ring nitrogens must have a considerable deactivating effect on the arene moiety.

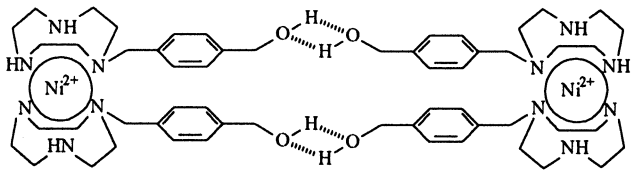

Fig. 6. Proposed dimerization of $[Ni(\mathbf{L}_6)_2]^{2+}$ by H-bonding of the alcohol groups.

4. Conclusions

A number of aromatic functionalized azamacrocycles have been prepared along with their metal complexes. Electron rich aromatics can be selectively incorporated into tri- and tetra-azamacrocycles in good yields using Michael-type chemistry. Complexation via the macrocycle nitrogens to hard metal ions is facile but unfortunately the π-rich aromatics do not react with soft metal ions to create mixed metal systems.

The Cu(II) complex of a single pendant arm benzylcarboxylic acid funtionalized 1,4,7-triazacyclononane macrocycle displays interesting self-assembly properties. This recognition phenomenon has the potential to be exploited in the creation of large superstructures with interesting magneto properties, and hence the generation of novel inorganic materials.

5. Supplementary data

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 166329 ,166330, 166331 for compounds **1**, **14** and **16**. Copies of the data may be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Pt(II) and Pt(IV) chloride complexes with 1,2,4-triazolo-[1,5α]-pyrimidines: *trans*-$[Pt(tp)_2Cl_2]$, *trans*-$[Pt(dmtp)_2Cl_2]$, *trans*-$[Pt(tp)_2Cl_4]$ and *trans*-$[Pt(dmtp)_2Cl_4]$ where tp = 1,2,4-triazolo-[1,5α]-pyrimidine and dmtp = 5,7-dimethyl-1,2,4-triazolo-[1,5α]-pyrimidine were synthesised and studied by ^1H, ^{13}C, ^{15}N, ^{195}Pt NMR and IR spectroscopies. Significant ^{15}N NMR upfield coordination shifts (92–96 ppm) were observed for the N(3) atom indicating that this nitrogen is the metallation site. The X-ray structure of an ionic pair $(dmtpH)_2[PtCl_6]$ {bis(5,7-dimethyl-1,2,4-triazolo-[1,5α]-pyrimidinium) hexachloroplatinate(IV)} was determined, exhibiting the presence of unique $(dmtpH)_2^{2+}$ dimeric cations, protonated at N(3), N(3′) atoms and linked by hydrogen bonding. © 2002 Elsevier Science Ltd. Keywords: Platinum chloride complexes; X-ray structures; N-donor ligands; ^{15}N NMR; 1,2,4-Triazolo-[1,5α]-pyrimidines

1. Introduction

1,2,4-triazolo-[1,5α]-pyrimidines are heterocycles isomeric to purines, their fused ring system differing in having the pyrimidine nitrogen atom in a bridge-head position (Fig. 1) [1,2]. The transition metal complexes with this class of N-donor ligands have been studied intensively, the researches concerned mainly with 1,2,4-triazolo-[1,5α]-pyrimidine (tp), 5,7-dimethyl-1,2,4-triazolo-[1,5α]-pyrimidine (dmtp) and 4,7-H-5-methyl-7-oxo-1,2,4-triazolo-[1,5α]-pyrimidine (HmtpO) [3]. Among them, a few coordination compounds with platinide metals have been also described: $[Pt^{II}(dmtp{-}N^3)_4][Pt^{IV}(SCN)_6]$, *trans*-$[Pd^{II}(dmtp{-}N^3)_2Br_2]\cdot CH_3OH$, *cis*-$[Pt^{II}(Hmtpo{-}N^3)_2Cl_2]\cdot 2H_2O$, *cis*-$[Pt^{II}(HmtpO{-}N^3)_2(NH_3)_2](NO_3)_2\cdot 2H_2O$, *mer*-$[Ru^{III}(dmtp{-}N^3)_2Cl_3(H_2O)]\cdot H_2O$ and *mer*-$[Ru^{III}(2\text{-amino-dmtp}{-}N^3)_2Cl_3(H_2O)]\cdot H_2O$ [4–9]. Recently we have characterised a series of *cis*-dichlorocomplexes of Pd(II) with tp, dmtp, 5,7-diphenyl-1,2,4-triazolo-[1,5α]-pyrimidine (dptp) and 5,7-di-*tert*-butyl-1,2,4-triazolo-[1,5α]-pyrimidine (dbtp), their general formula being *cis*-$[Pd^{II}L_2Cl_2]\cdot xH_2O$ where L = tp, dmtp, dptp, dbtp ($x = 0$, 1) [10]. The ^{15}N NMR measurements have shown that the coordination site in

PII: S0277-5387(01)01000-2

all triazolopyrimidine ligands has been N(3). We have reported also the X-ray structure of *cis*-[Pd^{II}(dbtp–N^3)$_2Cl_2$]·0.5C_2H_5OH that has been isostructural with the former compounds [10].

Strong N(3) coordination tendency of 1,2,4-triazolo-[1,5α]-pyrimidines, noted for the majority of their complexes with transition metals [3], is in favour of their usage as model ligands for metal–purine interactions. These heterocycles, however, differ in the strength of metal–nitrogen bonds, depending on the presence of substituents in the five and seven positions. In this paper we study four new Pt(II) and Pt(IV) coordination compounds with unsubstituted tp and its 5,7-dimethyl derivative dmtp: *trans*-[Pt^{II}(tp)$_2Cl_2$] (**1**), *trans*-[Pt^{II}(dmtp)$_2Cl_2$] (**2**), *trans*-[Pt^{IV}(tp)$_2Cl_4$] (**3**) and *trans*-[Pt^{IV}(dmtp)$_2Cl_4$] (**4**). It is the first report on Pt(IV) complexes with this class of heterocycles.

The present work is also a continuation of our ^{15}N NMR studies of the chloride complexes of diamagnetic transition metal ions with 1,2,4-triazolo-[1,5α]-pyrimidines. In our earlier reports we have described the correlation between the ^{15}N NMR coordination shifts and the type of a metal ion, the former researches concerning Zn(II) and Pd(II) compounds [10–12].

During the present studies we have solved the crystal and molecular structure of (dmtpH)$_2$[$PtCl_6$] (**5**). The molecule of this ionic pair seems to be interesting as there is a unique dimerization of the two N(3)-protonated dmtpH^+ cations resulting in the formation of a divalent $(dmtpH)_2^{2+}$ ion. Such a phenomenon has never been observed for 1,2,4-triazolo-[1,5α]-pyrimidines. In the only described X-ray structure with a protonated form of dmtp, (dmtpH)$_2$[$CdBr_4$]·2H_2O, the dmtpH^+ cations have not been dimerized [13].

2. Experimental

2.1. Materials

Pt of 99.9% purity was purchased from the Polish State Mint whereas tp and dmtp were from Aldrich. A water solution of H_2PtCl_6 was prepared using a standard procedure by the dissolution of Pt in aqua regia. K_2PtCl_4 was obtained by the reduction of H_2PtCl_6 with hydrazine to H_2PtCl_4 and neutralization by KOH.

2.2. Methods

The content of C, H, N in **1**–**4** was determined by elemental semi-microanalysis, whereas Pt was determined gravimetrically [14]. IR spectra were measured with a Perkin–Elmer spectrum 2000 FT IR spectrometer, using KBr (400–4000 cm^{-1}) and polyethylene discs (100–4000 cm^{-1}). ^1H, ^{13}C, ^{15}N, ^{195}Pt NMR spectra were performed on a Varian INOVA 500 spectrometer equipped with inverse Nalorac Z gradient shielded probe. ^{15}N NMR was detected by 2D ^1H–^{15}N gradient selected heteronuclear multiple quantum correlation (HMQC) in the absolute value mode. ^{195}Pt NMR of Pt(II) species was measured by a 1D technique optimised for fast relaxing nuclei (acquisition time 10 ms, relaxation delay 10 ms, flip angle 20°, spectral width 100 kHz) whereas that of Pt(IV) compounds was measured by phase-sensitive 2D ^1H–^{195}Pt HMQC. The solvent was dmf-d_7, the concentration of samples 0.05 M and the temperature 303 K. The reference standard was TMS for ^1H and ^{13}C; CH_3NO_2 for ^{15}N and K_2PtCl_6 for ^{195}Pt.

The X-ray data for **5** was collected for an $0.08 \times 0.10 \times 0.10$ mm orange crystal with a Kuma KM-4 diffractometer using Mo Kα radiation, $\lambda = 0.71069$ Å at 100(1) K, by 2θ method. The structure was solved with the Patterson method using SHELXS-86 [15] and refined with SHELXL-93 [16] giving $R = 0.038$, $wR_2 = 0.1009$ and goodness-of-fit on $F^2 = 1.046$ [$I > 2\sigma(I)$]. The atomic scattering factors were taken from the International Tables for Crystallography [17]. The geometry of **5** was compared to other compounds using the Cambridge Structural Database [18].

2.3. Synthesis

2.3.1. Complexes *1*–*4*

K_2PtCl_4 (1 mmol, for **1** and **2**) or H_2PtCl_6 (1 mmol, 30% water solution, for **3** and **4**) was dissolved in 10 ml of water and added to: (a) 2 mmol of tp in 20 ml of water (for **1** and **3**); (b) 2 mmol of dmtp in 20 ml of ethanol (for **2** and **4**). The mixture was stirred and left for 24 h at room temperature (r.t.). The obtained yellow precipitate was filtered, washed with ethanol and dried in air. The elemental analysis of **1** corresponded to Pt(tp)$_2Cl_2$ formula (%; calc. for $PtC_{10}H_8N_8Cl_2$/found): Pt (38.5/38.1), C (23.7/23.2), H (1.6/1.3), N (22.1/21.6); that of **2** to Pt(dmtp)$_2Cl_2$ (%; calc. for $PtC_{14}H_{16}N_8Cl_2$/found): Pt (34.7/34.4), C (29.9/29.8), H (2.9/3.1), N (19.9/19.8); that of **3** to Pt(tp)$_2Cl_4$ (%; calc. for $PtC_{10}H_8N_8Cl_4$/found): Pt (33.8/34.0), C (20.8/21.0), H (1.4/1.5), N (19.4/19.1); that of **4** to Pt(dmtp)$_2Cl_4$ (%; calc. for $PtC_{14}H_{16}N_8Cl_4$/found): Pt(30.8/31.0), C (26.6/27.0), H (2.5/2.7), N(17.7/17.3).

2.3.2. The ionic pair *5*

H_2PtCl_6 (1 mmol) and 2 mmol of dmtp were mixed in a strongly acidic (5 M HCl) water–ethanol (1:1) solution. The obtained (after 24 h) orange crystals were filtered, washed with 1 M HCl and ethanol, then dried over P_2O_5.

3. Results and discussion

3.1. The crystal structure of 5

The crystal structure data of **5** are listed in Table 1 and the selected bond lengths and angles are in Table 2. The perspective view of the molecule with its numbering scheme is shown in Fig. 2.

Complex **5** is an ionic pair consisting of two N(3)-monoprotonated dmtpH$^+$ cations and one $[PtCl_6]^{2-}$ anion. The unit cell, marked by eight Pt atoms, contains two triazolopyrimidinium ions related by the centre of symmetry $[-x, -y, -z]$. Each of those dmtpH$^+$ species is linked by hydrogen bonding {N(3)–H···N(4′) and N(4)···H–N(3′)} with an analogous ion, positioned in an adjacent unit cell and related by the centre of symmetry $[-x+1, -y+1, -z]$. Thus, in the crystal lattice there are unique dimeric and divalent $(dmtpH)_2^{2+}$ cations. It is interesting that the repulsion forces of the two positively charged triazolopyrimidinium ions are weaker than their attraction by hydrogen bonds.

i, imidazole ring; p, pyrimidine ring.

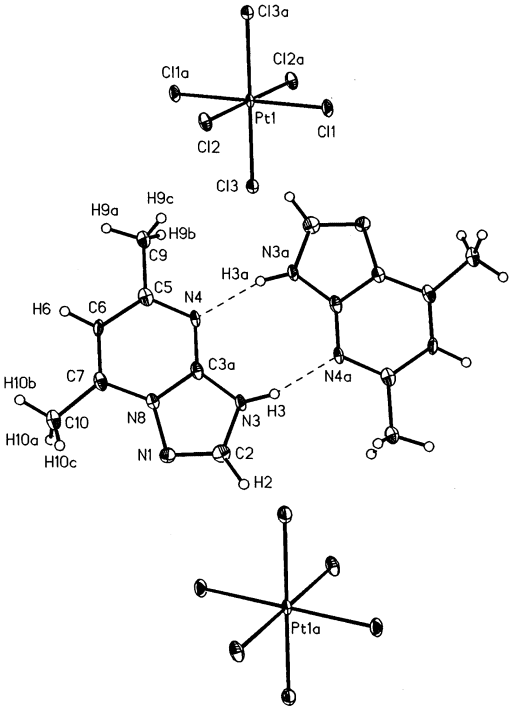

Fig. 2. ORTEP drawing of the $(dmtpH)_2[PtCl_6]$ (**5**) molecule.

In a single dmtpH$^+$ cation the triazolopyrimidine rings are planar, the rms. deviation from the best plane for the N(1)···N(8) moiety being 0.020 Å. The comparison of their geometry with that of solvated dmtp in the compound $[Pd(thiourea)_4]\cdot 2\ dmtp\cdot 2H_2O$ [19] shows that the protonation at N(3) results in an increase of the C(2)–N(3)–C(3a) angle {from 102.2(3)° to 106.5(5)°} and a decrease of adjacent angles N(1)–C(2)–N(3) {from 117.6(4)° to 113.0(6)°} and N(3)–C(3a)–N(8) {from 109.5(3)° to 106.5(6)°}. The N(3)–C(2) and N(3)–C(3a) bonds have been elongated upon protonation, from 1.333(5) to 1.369(9) Å and from 1.313(4) to 1.340(9) Å, respectively. Similar effects were described for another ionic pair, $(dmtpH)_2[CdBr_4]\cdot 2H_2O$ [13]. The formation of N(3)–H···N(4′) and N(4)···H–N(3′) hydrogen bonding has not affected the geometry of the pyrimidine ring, the C(3a)–N(4)–C(5) angle in **5** being the same as in solvated dmtp [19] (115.4(6)° compared to 115.6(3)°). The parameters of the H–bonds are as follows: N(3)–H(3) 0.86 Å, H(3)···N(4′) 1.98 Å, N(3)–H(3)···N(4′) 161.4°.

The $[PtCl_6]^{2-}$ anions are nearly octahedral, although some deviations from the ideal geometry occur. The lengths of Pt–Cl bonds vary from 2.317(2) to 2.324(2) Å and the Cl–Pt–Cl angles from 88.5(1)° to 91.5(1)°. Such a phenomenon is not unusual and has been described for $[N(CH_3)_4]_2[PtCl_6]$ [20], $[N(C_2H_5)_4]_2[PtCl_6]$ [21], $[NH_2(CH_3)_2]_2[PtCl_6]$ [22] and $(9\text{-MeGuH})_2[PtCl_6]$ [23] (9-MeGuH = 9-methylguaninium cation).

3.2. IR spectroscopy

For **1**–**4** the coordination of tp or dmtp molecules by Pt(II) or Pt(IV) ions results in very slight shifts of the absorption bands in the region 400–1700 cm^{-1}. The two most characteristic ones, assigned previously by us as the whole triazolopyrimidine ring skeletal vibration ($\nu_{tp} = 1621$ cm^{-1} for tp, 1637 cm^{-1} for dmtp) and the pyrimidine ring skeletal vibration ($\nu_{py} = 1525$ cm^{-1} for tp, 1550 cm^{-1} for dmtp) [12] are shifted by a maximum of 11 cm^{-1} (Table 3). There are no significant differences between the respective Pt(II) and Pt(IV) complexes.

In the case of **5** the observed shifts of those bands are much larger, approximately 10–20 cm^{-1} towards higher wave numbers. This phenomenon can be the result of both N(3) protonation and the formation of N(3)–H···N(4′) hydrogen bonding. In the IR spectrum of **5** there is also an intensive band of rich structure in the 2500–2700 cm^{-1} range, characteristic for the $(N–H)^+$ stretching vibration in the salts of tertiary ammines [24]. Its presence is in full agreement with the X-ray data revealing the protonated $dmtpH^+$ species in the solid phase of **5**.

Far-IR spectroscopy of **1**–**4** has exhibited one new absorption band of large intensity in a narrow range 338–347 cm^{-1} (Table 3). Its energy is similar to that found for some chloride complexes of Pt(II) and Pt(IV) with ammonia, pyridine (py) or imidazole (imH) {365 cm^{-1} for *trans*-$Pt(NH_3)_2Cl_2$, 345 and 331 cm^{-1} for *cis*-$Pt(NH_3)_2Cl_2$, 352 cm^{-1} for *trans*-$Pt(NH_3)_2Cl_4$, 353, 344 and 330 cm^{-1} for *cis*-$Pt(NH_3)_2Cl_4$ [25]; 342 cm^{-1} for *trans*-$Pt(py)_2Cl_2$, 343 and 329 cm^{-1} for *cis*-$Pt(py)_2Cl_2$ [26]; 350 cm^{-1} for *trans*-$Pt(imH)_2Cl_2$, 329 and 322 cm^{-1} for *cis*-$Pt(imH)_2Cl_2$ [27]}. Thus it derives, most likely, from a Pt–Cl stretching vibration. As only one band is active in the IR spectra, we can assume that **1**–**4** are *trans* isomers of symmetry C_{2h} (square-planar in **1** and **2**) or D_{4h} (pseudooctahedral in **3** and **4**) [28]. The Pt–N stretching vibrations, expected in the range 200–300 cm^{-1}, have not been detected, most probably due to overlapping with ligand internal modes, observed at 237 cm^{-1} (tp) or 286, 276, 236 cm^{-1} (dmtp).

In the far-IR spectrum of **5** one could expect two absorption bands analogous to those found at 342 and 183 cm^{-1} for K_2PtCl_6 [29]. In reality we have observed a group of heavily overlapped bands in the range 150–330 cm^{-1}.

Table 3
Selected IR bands (cm^{-1}) for **1**–**5** (coordination shifts, $\Delta\nu_{coord} = \nu_{compl} - \nu_{lig}$, in parentheses)

Compound	ν_{tp} (cm^{-1})	ν_{py} (cm^{-1})	ν(Pt–Cl) (cm^{-1})
1	1623 (+2)	1536 (+11)	338
2	1631 (−6)	1554 (+4)	343
3	1622 (+1)	1531(+6)	347
4	1630 (−7)	1554 (+4)	345
5	1649 (+12)	1571 (+21)	150–330

3.3. NMR spectroscopy

The ^1H and ^{13}C NMR spectra of tp and dmtp have been reported by many authors, however, the data concerned $CDCl_3$ or dmso-d_6 solutions [30–35]. Recently, we have completely assigned ^{15}N NMR signals of tp and dmtp in dmso-d_6 using heteronuclear correlation (HETCOR) methods [10–12]. During this work we had to perform all NMR measurements in dmf-d_7, due to insolubility or decomposition of the complexes in $CDCl_3$ and dmso-d_6. The assignment of the signals for tp, dmtp and **1**–**5** was based on analogous HETCOR techniques.

3.3.1. ^{15}N NMR

The ^{15}N NMR chemical shifts for tp, dmtp and **1**–**5** are listed in Table 4.

In the case of **1**–**4** the Pt(II) or Pt(IV) coordination most significantly affects the N(3) signal, shifting it upfield 92.6–92.9 or 94.7–95.4 ppm, respectively. Such a diamagnetic shift unambiguously indicates that the complexation occurs via N(3). The absolute values of the coordination shifts are larger than for analogous Pd(II) complexes (78–90 ppm) [10] which is consistent with the known fact that the shielding of nitrogen increases down a group of coordinating transition metals in the periodic table [36]. The increased shielding of the Pt(II)- or Pt(IV)-coordinated nitrogen nucleus is, most likely, the result of the decrease of the absolute value of the paramagnetic term in its ^{15}N NMR shielding constant. It is evident that this effect increases with the oxidation number of platinum.

For **5** the observed upfield shift of N(3) signal is only 10 ppm whereas the other resonances are nearly not

Table 4
^{15}N NMR chemical shifts for tp, dmtp and **1**–**5** in dmf-d_7 (coordination shifts, $\Delta\delta_{coord} = \delta_{compl} - \delta_{lig}$, in parentheses)

shifted. It is discussable if so moderated shielding can be regarded as a result of protonation as the common range for azoloazines is 80–150 ppm [37]. However, if to assume that the dmtpH$^+$ cations are dimerised also in dmf-d_7 solution, it is possible that the formation of N(3)–H···N(4′) hydrogen bonding results in an additional deshielding of N(3), this effect being opposite to that of protonation.

3.3.2. ^1H and ^{13}C NMR

The selected ^{1}H and ^{13}C NMR chemical shifts for tp, dmtp and **1**–**5** are listed in Table 5.

For **1**–**4** the chemical shifts changes pattern is very clear. The protons in heteroaromatic rings are generally deshielded, this effect being much more pronounced for H(2) (0.47–0.64 ppm) than for H(6) (0.06–0.19 ppm). The carbons adjacent to the N(3) metallation site, i.e. C(2) and C(3a), are shielded (0.7–4.6 ppm) whereas the others are deshielded (1.6–3.4 ppm). Those coordination shifts also increase with the oxidation number of platinum. Analogous results but of a smaller magnitude were described by us for Pd(II) complexes [10].

In the ^{1}H NMR spectrum of **5** an additional broad singlet occurs at 11 ppm. It disappears when D_2O is added which proves that it derives from the N(3)–H$^+$ protonated group. This observation reveals that in dmf-d_7 solution the dmtp molecules of **5** are also protonated (as it was in the solid state) although it is not clear if they appear as monomeric dmtpH$^+$ or in the dimerised $(dmtpH)_2^{2+}$ form.

3.3.3. ^{195}Pt NMR

The ^{195}Pt signals of **1** and **2** are observed at -2061 and -2058 ppm whereas those of **3** and **4** at -17 and -30 ppm. Such values of ^{195}Pt chemical shifts are typical for Pt(II) and Pt(IV) complexes in N-donor heteroaromatic compounds [38–42]. A characteristic 'oxidation shift' of approximately 2040 ppm (downfield, when comparing Pt(IV) with Pt(II) species) is very close to that described in literature (e.g. for Pt(bipy)Cl$_2$ and Pt(bipy)Cl$_4$ the $\delta(^{195}Pt)$ value increases from -2315 to -311 ppm) [43].

The ^{195}Pt signals of Pt(II) complexes (**1** and **2**) have been detected as broad singlets, their half-line widths being approximately 650–750 Hz. Such values are relatively high, comparing to those found for $[PtCl_4]^{2-}$ ions (ca. 110 Hz) [44], which can be explained, most likely, by the quadrupolar ^{195}Pt–^{14}N interactions between the Pt and N(3) nuclei.

In the case of Pt(IV) complexes (**3** and **4**) the ^{195}Pt–^{1}H spin–spin interactions have been observed in HMQC spectra between the Pt and H(2) nuclei. The measured values of $^3J_{Pt-H}$, approximately 11 Hz, are rather small comparing to those found for Pt(IV) complexes with ethylenediamine (26–28 Hz) [45].

The ^{195}Pt signal of **5**, observed at $+353.5$ ppm (half–line width 10–15 Hz) exhibits a characteristic shape with ^{35}Cl/^{37}Cl isotopic lines typical for the $[PtCl_6]^{2-}$ anion [46], which proves that this ion is present also in dmf-d_7 solution.

4. Conclusions

In the direct reactions of $[PtCl_4]^{2-}$ or $[PtCl_6]^{2-}$ with tp or dmtp the formation of *trans*-isomers is favoured in water–ethanol solutions, contrary to the case of $[PdCl_4]^{2-}$ where *cis*-forms have been obtained. ^{15}N NMR spectroscopy proves that the Pt(II) or Pt(IV) coordination by 1,2,4-triazolo-[1,5α]-pyrimidines occurs via N(3). Such a complexation mode can be regarded as representative for this class of heterocycles and analogous to the N(9) coordination of purines. The formation of Pt–N(3) bonding results in the increased shielding of this nitrogen nucleus as well as of the adjacent carbon atoms. The observed upfield shifts of N(3) signals are larger than for analogous Pd(II) complexes and increase with the oxidation number of platinum. The X-ray study of the ionic pair $(dmtpH)_2[PtCl_6]$ shows that in the solid state the dmtp molecules are protonated at N(3) and the formed dmtpH$^+$ cations are linked by N(3)–H···N(4′) hydrogen bonding into unique dimeric and divalent species $(dmtpH)_2^{2+}$. The ^{1}H and ^{195}Pt NMR measurements

Table 5
^{1}H and ^{13}C NMR chemical shifts for tp, dmtp and **1**–**5** in dmf-d_7 (coordination shifts, $\Delta\delta_{coord} = \delta_{compl} - \delta_{lig}$, in parentheses)

Compound	H(2)	H(6)	C(2)	C(3a)	C(5)	C(6)	C(7)

Preparation and crystal structures of new phenoxide derivatives of tungsten(VI) oxytetrachloride

Ari Lehtonen *, Reijo Sillanpää

Department of Chemistry, University of Turku, Fin-20014 Turku, Finland

Received 25 September 2001; accepted 22 November 2001

Abstract

Two oxotungsten(VI) complexes of the type $[WOCl_2(OAr)_2]$ (OAr = OC_6H_3–^{t}Bu-2-Me-6 or OC_6H_2–^{t}Bu-2-Br-4-Me-6) were prepared by the reaction of $WOCl_4$ with 2 equiv. of phenolic ligand precursors in a refluxing toluene solution. Both compounds form monomeric units, in which the tungsten ion has adopted a square pyramidal coordination geometry with the oxo ligand in the apical position and phenoxide groups bound in a *trans* orientation. © 2002 Elsevier Science Ltd. Keywords: Chloride ligands; Oxo ligands; Phenolates; Tungsten

1. Introduction

Aryloxide derivatives of oxotungsten(VI) are used commonly in production of unsaturated polymers using ROMP chemistry, as well as in the syntheses of cyclic compounds by the use of ring closing metathesis [1]. The general benefit of aryloxide ligands in these complexes is that altering the substituents on the aromatic ring can easily vary their electron-withdrawing properties and also modify steric effects in the close neighbourhood to the metal. The hard donor character of phenoxide ligand also stabilises the high oxidation state of tungsten ion. A standard procedure for the preparation of these complexes is the reaction of $WOCl_4$ (**1**) with a phenolic compound [2], which may also result in a mixture of species with varying numbers of aryloxide substituents [3,4]. Sometimes the use of lithium aryloxides is necessary to complete the reaction [5]. Although oxotungsten derivatives of type $[WOCl_2(OAr)_2]$ are frequently prepared and used as catalyst precursors, only few compounds have been structurally fully characterised [5–7]. In the context of a broader program aimed at developing transition metal catalysts for olefin metathesis, our laboratory has recently become interested in the chemical manipulation of tungsten aryloxide complexes [8]. To have more detailed knowledge about this chemistry, we are at present studying monomeric oxotungsten(VI) chloride phenoxides. In this paper, we report syntheses and X-ray crystal structures of two new potential catalyst precursors.

2. Experimental

$WOCl_4$ and 2-*tert*-butyl-4-bromo-6-methylphenol were prepared according to literature procedures [9,10]. 2-*tert*-Butyl-6-methylphenol was used as received from Aldrich. Solvents were distilled over sodium benzophenone ketyl prior to use. Syntheses and manipulations were performed using standard inert atmosphere techniques [11].

2.1. Syntheses

A suspension of **1** (340 mg, 1.0 mmol) in toluene (25 ml) was treated with 2 equiv. of phenol **2a** (330 mg) or **2b** (490 mg), respectively. These reaction mixtures were stirred at reflux temperature for 4 h to obtain intense red solutions. Evaporation of solvents afforded red microcrystalline solids, which were practically pure (according to ^{1}H NMR analyses) compounds **3a** and **3b**, respectively. These solids were extracted by C_6H_{14}, con-

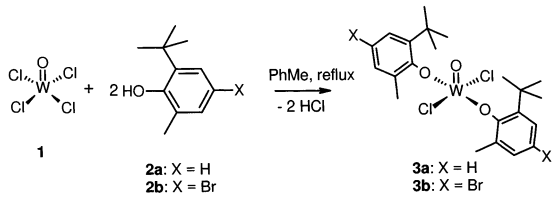
centrated and stored at −20 °C to obtain purple, moderate air-stable crystals. For **3a**: yield 370 mg (62%). NMR: δ_H ($CDCl_3$, standard $SiMe_4$): 7.35 (d, 2H, ArH), 7.20 (d, 2H, ArH), 6.97 (t, 2H, ArH), 2.55 (6H, ArCH_3), 1.58 (18H, C(CH_3)$_3$). IR: 1181 (vs, C–O), 997 (s, W=O) cm^{-1}. *Anal.* Found: C, 44.0; H, 5.0. $C_{22}H_{30}Cl_2O_3W$. Calc. for C, 44.2; H, 5.1%. For **3b**: yield 545 mg (72%). NMR: δ_H ($CDCl_3$, standard $SiMe_4$): 7.47 (2H, ArH), 7.34 (2H, ArH), 2.49 (6H, ArCH_3), 1.55 (18H, C(CH_3)$_3$). IR: 1196 (vs, C–O), 995 (s, W=O) cm^{-1}. *Anal.* Found: C, 35.2; H, 4.1. $C_{22}H_{28}Br_2Cl_2O_3W$. Calc. for C, 35.0; H, 3.7%.

2.2. Crystal structure determination



Single-crystal data collections were performed at ambient temperature on a Rigaku AFC5S diffractometer using graphite monochromatised Mo Kα radiation ($\lambda = 0.71069$ Å). The unit cell parameters were determined by least-squares refinement of 22 and 25 carefully centred reflections for **3a** and **3b**, respectively. Data reduction and subsequent calculations were performed with TEXSAN for Windows [12]. The data was corrected for Lorenz and polarisation effects, for absorption (PSI-scans [13]) and for decay. Crystal data for compounds **3a**–**3b** along with other experimental details, are summarised in Table 1.

Scheme 1.

The structures were solved by direct methods using the SIR-92 program [14] and full-matrix least-squares refinements on F^2 were performed using the SHELXL-97 program [15]. For both compounds all heavy atoms were refined anisotropically. The CH hydrogen atoms were included at the fixed distances with fixed displacement parameters from their host atoms. Figures were drawn with ORTEP-3 for Windows [16].

3. Results and discussion

3.1. Preparations and spectral characterisation

Studied compounds were prepared by known halide displacement reaction of $WOCl_4$ (**1**) [2]. A suspension of tungsten precursor **1** in toluene was reacted with 2 equiv. of 2-*tert*-butyl-6-methylphenol (**2a**) or 2-*tert*-butyl-6-4-bromo-methylphenol (**2b**) at reflux temperature for 4 h to obtain intense red solutions (Scheme 1). Evaporation of solvent and HCl coproduct afforded red solids, which were extracted by hexane, concentrated and stored at −20 °C to obtain purple, prismatic crystals. Complex **3b** crystallised nicely overnight, but the crystallisation of **3a** was unexpectedly slow, and about a week is needed to attain an acceptable recovery (> 50%) of compound. Both compounds **3** are very soluble in non-coordinating solvents, e.g. hexane, toluene and dichloromethane. They are soluble also in coordinating solvents, e.g. pyridine, acetone, thf and acetonitrile, but decompose quickly to form white deposit. Even small amounts of coordinating molecules in hexane solution can destroy these complexes, hence our attempts to prepare six-coordinated adducts $WOCl_2(OAr)_2L$ failed. Crystals of **3** are stable in air for a few hours, but can be stored for weeks under an inert atmosphere.

The ^{1}H NMR spectra of compounds showed typical resonances for aromatic and aliphatic protons. In principal, the unsymmetrical phenolato ligands could adopt different rotational isomers (two *syn*- and one *anti*-isomer). However, the ^{1}H NMR spectra of compounds **3** in $CDCl_3$ at room temperature contain only individual singlet resonances for the ^{t}Bu and Me substituents on the phenoxide group. Thus, on the NMR time-scale in solution at room temperature phenoxide groups are time-averaged and yield only one signal. X-ray structure determinations verified that these asymmetric phenolato ligands adopted a *syn* conformation in the solid state (see Section 3.2). The IR spectra of compounds **3a** and **3b** show strong absorption bands at 997 and 995, respectively, which were assigned as metal–oxygen stretching modes of terminal oxo ligands [17].

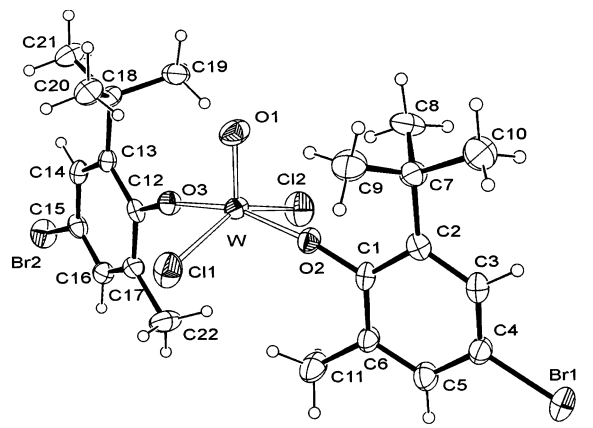

Fig. 2. Molecular structure of $[WOCl_2(OPh\text{-}2\text{-}^tBu\text{-}4\text{-}Br\text{-}6\text{-}Me)_2]$ (**3b**). Thermal ellipsoids have been drawn by 30% probability.

3.2. Structures

Nugent et al. [6] and Wagener and coworkers [7] have published some structures of oxotungsten derivatives of type $[WOCl_2(OAr)_2]$ bearing substituted 2,6-dibromophenoxide ligands. In these structures one bromine atom from phenoxide ligand has some interaction with the tungsten centre, which also makes these two phenoxide groups inequivalent. Thus the coordination sphere around W(VI) is virtually a distorted octahedron. X-ray crystallographic studies of **3** reveal that both compounds form monomeric units, in which the tungsten(VI) cation has adopted a square pyramidal coordination geometry with the oxo ligand in the apical position and phenoxide groups in a *trans* orientation, as shown in Figs. 1 and 2. In solid state, the both studied compounds have adopted similar conformation. The aryloxide ligands with *tert*-butyl and methyl groups are almost parallel in **3a** as the dihedral angle between the phenyl rings is 3.0(2)°, while in **3b** this dihedral angle is 27.4(4)°. This large difference can be related to the fact that in **3a** there is no π-stacking of the phenyl rings, but in **3b** one phenyl ring (C1, …, C6) is stacked with a phenyl ring ($C1^i$, …, $C6^i$) (symmetry code $i = 1-x, -y, 1-z$) at a distance of about 4.2 Å. Orientation of *tert*-butyl and methyl groups indicate the formation of only the *syn* isomer in both compounds. The possible reasons for the formation of this isomer are ($C^{t\text{-}}$Bu)H···O=W and (C^{Me})H···Cl hydrogen bonds, e.g. in **3a** the four shortest ($C^{t\text{-}Bu}$)H···O1 distances are from 2.760 to 2.894 Å and in **3b** from 2.592 to 2.959 Å (H atoms are in calculated positions). Relevant C···O distances vary from 3.669 to 3.778 Å in **3a** and in **3b** from 3.464 to 3.620 Å, respectively. For comparison, in organic molecules the weak C–H···O is observed if the appropriate C···O distances lie in the range of 3.00–4.00 Å [18]. The four shortest C–H···Cl distances are from 2.950 to 3.367 Å in **3a** (relevant C···Cl distances are from 3.844 to 3.952 Å) and from 2.965 to 3.286 Å in **3b** (C···Cl distances are 3.464–3.620 Å). Thus the intramolecular H-bonds seem to freeze molecules to the *syn* isomer. Consequently the structures above resemble the structure of the corresponding complex bearing two 2,6-diisopropylphenoxide ligands [5].

In the high-valent transition metal aryloxides the M–O distances are generally shorter than the values expected solely on the basis of σ-bonding. This indicates that π-bonding (electron donation from the p-orbital of oxygen to the d-orbitals of metal) is present. As a result, the relationship between the M–O bond distances and the degree of π-bonding for the terminal phenoxides has been widely discussed [19,20]. The value of the M–O–C angle can also, in theory, reflect the degree of π-donation to the metal, but it has been shown to be an extremely flexible parameter and primarily controlled by steric properties [20,21]. In the compounds studied now (see Table 2) the W–O–C angles vary from 161.6(5)° to 165.4(5)°. The relevant W–O bond lengths vary from 1.861(5) to 1.849(5) Å. However, no evident correlation between W–O distance and W–O–C angle can be seen, thus crystal-packing forces seem to have strong effects to the bending of these bonds.

4. Supplementary data

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre CCDC No. 170998–170999 for compounds **3a** and **3b**, respectively. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Monolacunary Wells-Dawson 16-tungsto-molybdo-phosphate $[P_2MoW_{16}O_{61}]^{10-}$ reacts with $[Ti(H_2O)_6]^{4+}$ in aqueous solution to give the $[Ti(H_2O)P_2MoW_{16}O_{61}]^{6-}$ complex, isolated as the potassium salt. Optimal synthesis conditions were established by spectrophotometric and conductometric studies. The molecular formula of the complex was determined by elemental analysis, thermogravimetric analysis and basicity titration. The Ti(IV) complex was further characterized by UV, FTIR, Raman and ^{31}P NMR spectroscopies as well as cyclic voltammetry. Powder X-ray diffraction was used to obtain the lattice parameters for both ligand and complex. A modified Wells-Dawson structure for the new Ti(IV) polyoxometalate complex was inferred from the results. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Polyoxometalates; Heteropolyanions; Ti(IV) complex; Wells-Dawson structure

1. Introduction

Polyoxometalates are a broad class of complexes of considerable interest from both theoretical and practical points of view [1]. Recently, the chemistry of Ti(IV) polyoxometalates became an attractive research field not only for fundamental reasons, due to the newly synthesized complexes [2–8], but also for the potential applications of these compounds as catalysts in oxidation reactions [9–13], or as antiviral agents [14–18].

According to the basic principles of polyoxometalate formation (ionic radius, ionic charge and availability of vacant 'd' orbitals to form π oxygen–metal bonds), Ti(IV) polyoxometalates can be classified as isopolytitanates or heteropolytitanates [19,20]. In isopolytitanates the structure consists only of TiO_6 octahedra, but in heteropolytitanates the Ti(IV) atom can act as the central heteroatom with tetrahedral geometry [21,22] or as an addendum with octahedral geometry [2,3]. In the last case, enhanced reactivity and very interesting properties are usually observed due to the presence of Ti(IV) as an addendum [11,17]. For that reason in the present study the synthesis and characterization of a new polyoxometalate complex formed by introducing one Ti(IV) atom into the monolacunary 16-tungsto-molybdo-2-phosphate polyoxoanion $[P_2MoW_{16}O_{61}]^{10-}$ is described.

2. Experimental

2.1. Physical measurements

Elemental analysis was performed upon decomposition of the complex in aq. alkaline solution at pH ~ 12. Ti(IV) was photocolorimetrically determined using H_2O_2 in the presence of H_2SO_4 [23]. A Baird I.C.P. 2070 optical emission spectrometer was used for phosphorus, tungsten and molybdenum determinations. Water content was determined thermogravimetrically

by means of a Paulik Erdely OD-102 type derivatograph, at a temperature range of 20–800 °C and a heating rate of 5 °C min^{-1}. Conductometric studies were performed with a Radelkis OK-102 type conductometer in an acetate buffer solution, pH 5.6, using Ti:P_2MoW_{16} molar ratios ranging from 0.2:1 up to 2.5:1. Conductometric titration of 10^{-3} M Ti(IV) derivative with 4.9×10^{-2} M thalium acetate established the basicity of the complex [24].

UV–Vis spectra were recorded on a Specord or a Unicam spectrophotometer. The absorbances of 1.2×10^{-5} M mixtures of Ti(IV) and $[P_2MoW_{16}O_{61}]^{10-}$ (in 1:1 molar ratio) at 33 800 and 40 800 cm^{-1} were measured in different reaction conditions. The pH of the solutions were adjusted between 4 and 7.5 using 5% KOH and 1 M HCl. IR spectra were recorded using KBr pellets on a FTIR–JASCO 610 spectrophotometer. Raman experiments were performed on solid powders at room temperature (r.t.), using a DILOR OMARS 89 Raman spectroscope equipped with a microscope, CCD detection and a 632.8 nm He–Ne laser (1–5 mW). ^{31}P (121.5 MHz) NMR spectra were recorded at r.t. on a Bruker AC-300 MHz spectrometer, using saturated solutions. Chemical shifts were referenced to 85% H_3PO_4. The main parameters used were: 32 K data domain size, 62 500 Hz spectral width, 2 s relaxation delay and 100 scans. X-ray diffraction (XRD) experiments were performed on a Philips Analytical X-ray PW 1050 Diffractometer using Cu Kα radiation.

Cyclic voltammetry measurements were made using a Vinci Technologies P/G STAT Z1 potentiostat, operating in conjunction with a 33120 A Hewlett Packard function/arbitrary waveform generator and with a Linseis LY 18100 X-Y recorder. A conventional (single-compartment) three electrode electrochemical cell was used, with a Metrohm planar platinum counter electrode and a Metrohm saturated calomel ($Hg–Hg_2Cl_2$) reference electrode (SCE). Pyrolytic graphite (Union Carbide, $\Phi \sim 3$ mm) was used as a working electrode (WE), which was polished with emery paper 4000 and cleaned in ultrasons prior to use. The WE was polarized in a 10^{-3} M solution of the complex in acetate buffer (pH 4.0–5.6) with a scan rate between 10 and 200 mV s^{-1}. The experiments were performed in deoxygenated solutions by passing purified Ar gas (99.9%) through the solutions. During the experiment the Ar was passed over the solution surface.

2.2. Materials

All chemicals were commercially available, of reagent grade quality and used as received. In all syntheses and studies distilled water was used. $K_{10}[P_2MoW_{16}O_{61}]\cdot 21H_2O$ was prepared according to the literature [25].

2.2.1. Preparation of $K_{10}[P_2MoW_{16}O_{61}]\cdot 21H_2O$

$K_6[P_2MoW_{17}O_{62}]\cdot 14H_2O$ (40 g, 8.4 mmol), prepared as described by Contant and Ciabrini [26], was dissolved in 142 ml of water and treated with 124 ml 1 M $KHCO_3$. When the solution became blue in color, the precipitate was filtered, washed with cold 1 M KCl, followed by MeOH and then air dried. The yield was 33 g (86%).

IR (cm^{-1}, KBr pellets, polyoxometalate region): 1083, 1049, 1018, 939, 916, 886, 805, 730, 600, 566, 525. Raman (cm^{-1}): 1016, 974, 964, 953, 939, 890, 586, 541, 520, 368, 332, 264, 229, 163, 126. ^{31}P NMR (D_2O) δ −6.12 (s), −13.28 (s).

2.2.2. Preparation of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]\cdot 17H_2O$

$TiCl_4$ (15.24 ml, 0.139 mol) was added dropwise to a solution of 0.1 M HCl (100 ml) under vigorous stirring while keeping cool at 5 °C (solution A). $K_{10}[P_2MoW_{16}O_{61}]\cdot 21H_2O$ (18 g, 3.71 mmol) was dissolved in 100 ml water and heated to 65–75 °C (solution B). Solution A (2.66 ml) was then added dropwise under vigorous stirring. A KOH solution (5%) was used to maintain the pH between 4 and 6. After addition of $[Ti(H_2O)_6]^{4+}$, the reaction mixture was kept at 65–75 °C for 20 min and then brought to boiling. The slight turbid solution was filtered while hot. After several days at r.t., white crystals were obtained from the filtrate which were further purified by recrystallization from distilled water. The yield was 3.48 g (20%).

Anal. Calc. for $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]\cdot 17H_2O$: P, 1.32; Ti, 1.02; Mo, 2.04; W, 62.82; H_2O, 6.86. Found: P, 1.32; Ti, 1.05; Mo, 1.92; W, 62.45; H_2O, 6.99% (TGA). IR (cm^{-1}, KBr pellets, polyoxometalate region): 1086, 1015, 949, 917, 778, 598, 566, 527. Raman (cm^{-1}): 1021, 982, 967, 925, 901, 855, 784, 666, 539, 495, 463, 419, 378, 325, 305, 231, 205, 160, 121. ^{31}P NMR (D_2O) δ −9.26 (s), −12.87 (s).

3. Results and discussion

Conductometric titration of the ligand $[P_2MoW_{16}O_{61}]^{10-}$ with $[Ti(H_2O)_6]^{4+}$ was performed in order to establish the complex composition in solution. The titration curve presents a clear break point at 1 equiv. of Ti(IV) per equivalent of the ligand. Then the best synthesis conditions were spectrophotometrically determined by successively varying the reaction parameters (pH, temperature). The solution pH was adjusted between 4 and 7.5 and the absorbances of Ti(IV) and $[P_2MoW_{16}O_{61}]^{10-}$ mixtures (stoichiometric ratios of 1:1) at 33 800 and 40 800 cm^{-1} were measured under different reaction conditions. The optimum pH range for the complex formation was between 4 and 6 and the maximum absorption was observed for samples brought up to boiling.

The study of the polyoxometalate complex thermal behavior depicts four main processes, two endothermal and two exothermal, (see Supporting Information). In the DTA curve, the endothermal processes at 120 and 205 °C were assigned to water loss. The second process was faster than the first, as shown by the DTG curve. The first exothermal process, with a maximum at 590 °C on the DTA curve, was assigned to decomposition of the polyoxometalate while the second, with a maximum at 620 °C, may be assigned to the polymorph transformations of the oxides that resulted from the decomposition of polyoxometalate [27]. Based on the thermogravimetric study, it can be concluded that the polyoxometalate is thermally stable up to 500 °C and has a water content of 6.99%.

The elemental analysis found (P, 1.32; Ti, 1.05; Mo, 1.92; W, 62.45) is in excellent agreement with the calculated composition of the complex (P, 1.32; Ti, 1.02; Mo, 2.04; W, 62.82). Moreover, the basicity determination performed by thalium acetate titration, resulted in a 6^- charge for the polyoxometalate species in solution. Thus, taking into account the formation studies, elemental analyses, basicity determination and thermal behavior of the synthesized compound, the following reaction sequence is suggested:

$$[P_2MoW_{16}O_{61}]^{10-} + [Ti(H_2O)_6]^{4+} \rightarrow [Ti(H_2O)P_2MoW_{16}O_{61}]^{6-} + 5H_2O \quad (1)$$

The UV electronic spectra of the $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex and the $K_{10}[P_2MoW_{16}O_{61}]$ ligand are similar in shape and number of bands (see Section 5: Supporting Information). The band at ~ 200 nm is assigned to $p_\pi - d_\pi$ transitions in $M-O_t$ bonds. The two shoulders at ~ 250 and ~ 290 nm are assigned to the electron transitions between the energy levels of $M-O_b-M$ (M = W, Mo) tricentric bonds [28]. In the spectrum of the complex, both bands are red shifted when compared to the corresponding bands of the monolacunary polyoxometalate, but the energy levels are higher than in the isocharge $K_6[P_2MoW_{17}O_{62}]$ polyoxometalate. This is due to distorsions introduced by the weaker Ti(IV) ion onto its neighbouring MO_6 octahedra (M = W, Mo).

It is important to notice that the IR spectrum of the $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ polyoxometalate complex shows a frequency shift of the stretching vibrations towards higher wavelengths compared to that of the ligand. This is consistent with an increase of the anion cohesion by coordination of the Ti(IV) in the polyoxometalate framework [29]. Moreover, owing to the structural modifications, the band patterns of the bridge regions (950–700 cm^{-1}) are considerably changed. In the 1100–1000 cm^{-1} range, where the asymmetric stretch vibration of the P–O bond appears, a band splitting is seen, similar to the splitting normally observed in α-Dawson structures [30]. This is characteristic of lower symmetry for modified or lacunary polyoxometalate structures. The value of the band splitting can be considered as a measure of the deviation from the saturated structure symmetry [29]. The ν_{as}P–O (asymmetric stretching) band splitting of the ligand is diminished upon Ti(IV) coordination, implying an increase of the PO_4 tetrahedron symmetry as a result of vacancy completion. In the range 1000–700 cm^{-1} three other characteristic bands were observed and assigned to the asymmetric stretching vibrations of the bridges ($M-O_b-M$) and the terminal bonds ($M-O_t$) [29,30]. The bands appearing in the 600–500 cm^{-1} region assigned to the deformations δ P–O and stretching vibrations of the internal bonds ($M-O_i-M$) are not significantly influenced by the coordination of Ti(IV) (Figs. 1 and 2).

In a similar way, in the Raman investigation the main vibrations of the polyoxometalate complex are shifted towards higher energies suggesting an increase of the polyoxometalate stability [31]. The Raman spectrum of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ shows characteristic strong vibration bands at 982, 967 and 231 cm^{-1}, assigned to $\nu_s(M-O_t)$, $\nu_{as}(M-O_t)$ and $\nu_s(M-O_i)$, respectively. O_i represents the bridging oxygen between the

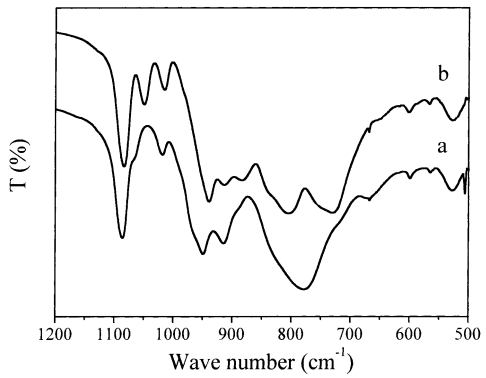

Fig. 1. FTIR spectra of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex (a) and $K_{10}[P_2MoW_{16}O_{61}]$ ligand (b).

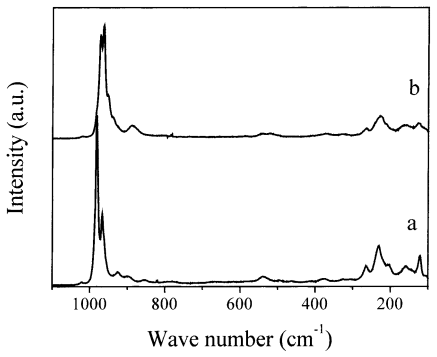

Fig. 2. Raman spectra of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex (a) and $K_{10}[P_2MoW_{16}O_{61}]$ ligand (b).

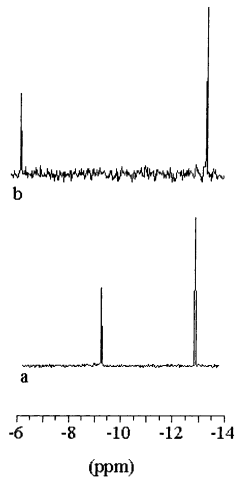

Fig. 3. ^{31}P NMR spectrum of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex (a) and $K_{10}[P_2MoW_{16}O_{61}]$ ligand (b) recorded in D_2O.

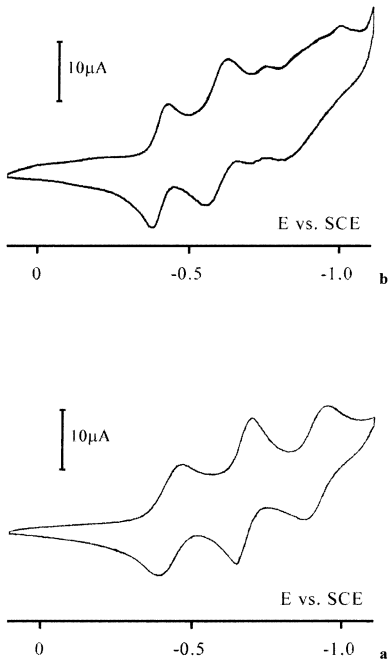

Fig. 4. Cyclic voltammograms of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex (a) and $K_{10}[P_2MoW_{16}O_{61}]$ ligand (b) recorded in acetate buffer solutions (pH 5.2), sweep rate 20 mV s^{-1}.

internal P heteroatom and external addenda (Mo, W or Ti). Other weak Raman lines appearing at 1021, 950, 924, 901 and 855 cm^{-1} can be assigned to $\nu_s(P–O_i)$, $\nu_{as}(P–O_i)$ and $\nu_{as}(M–O_b)$ [31].

The ^{31}P NMR spectrum in D_2O solution of $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ consists of two sharp singlets at P(1) δ −9.26 and P(2) δ −12.87 indicative of two inequivalent phosphorus centers (Fig. 3). P(1) is the phosphorus atom closest to the substitution site while P(2) is further away. These resonances are different from the lacunary $K_{10}[P_2MoW_{16}O_{61}]$ (P(1) δ −6.12 and P(2) δ −13.28) and are close to $K_6[\alpha_2$-$P_2MoW_{17}O_{62}]$ species (P(1) δ −11.9 and P(2) δ −12.6) [32], suggesting the presence of Ti(IV) in a polar site.

To establish the electrochemical behavior of $K_{10}[P_2MoW_{16}O_{61}]$ and of the $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ derivative, cyclic voltammogram experiments were performed in aqueous solutions and the results are reported on Fig. 4.

Three well defined oxidation–reduction pairs of waves were obtained for the Ti(IV) complex. A linear dependence between the peak current logarithm ($\log I_{pc}$) and the sweep rate logarithm ($\log v$) confirmed the reversibility of the three electron transfer processes (see Supporting Information). Such a behavior is not unusual. In fact, previous studies on a V(IV) complex with $K_{10}[P_2MoW_{16}O_{61}]$ [33], showed that the polyoxometalate anion in the negative potential range presented only three peaks instead of the four observed in the ligand. On the other hand, from literature data [34,35], the presence of both molybdenum and tungsten cations in the same polyoxometalate structure, first leads to electrochemical reduction of molybdenum (Mo^{VI}) and then to that of tungsten (W^{VI}). As a result, in the case of the $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$ complex, the first wave at $\sim$0.4 V was assigned to the Mo^{VI}–Mo^{V} redox reaction, while the other two waves were attributed to the W^{VI}–W^{V} redox processes. The formal potential $\varepsilon^{0\prime}$ (estimated as the average value of anodic and cathodic peak potentials) showed a negative shift with increasing values of pH (see Supporting Information). For all three peaks, the $\varepsilon^{0\prime}$ versus pH dependences are linear, with slopes of 38.70, 62.66 and 52.41 mV/ΔpH. The anodic to cathodic peak separation values (ΔE) and the described pH dependence are probably consistent with the fact that both a single electron and one proton are involved in parallel in each redox reaction [36].

Attempts to obtain single crystals of the complex were unsuccessful. However, powder XRD was used to obtain the lattice parameters for both the monolacunary $K_{10}[P_2MoW_{16}O_{61}]$ ligand and the Ti(IV) derivative (see Supporting Information). The lattice constants obtained ($K_{10}[P_2MoW_{16}O_{61}]$: $a = 14.25$, $b = 14.70$, $c = 18.76$ Å, $\alpha = \beta = 90$, $\gamma = 104°$, $Z = 2$; $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]$: $a = 14.12$, $b = 14.744$, $c = 18.44$ Å, $\alpha = \beta = 90°$, $\gamma = 103.75°$, $Z = 2$), were characteristic of a monoclinic structural modification for both the ligand and the Ti(IV) complex.

4. Conclusion

A $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]\cdot 17H_2O$ complex was prepared by reaction of $[Ti(H_2O)_6]^{4+}$ with $K_{10}[P_2MoW_{16}O_{61}]\cdot 21H_2O$ monolacunary polyoxometalate after establishing optimal synthesis conditions. Spectroscopic studies show that the structure of the

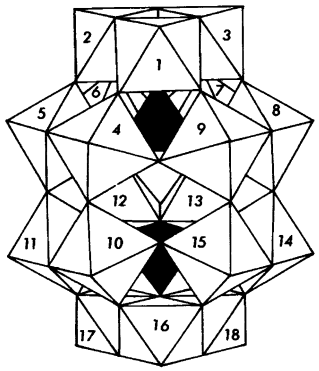

Fig. 5. The structure of the $K_6[Ti(H_2O)P_2MoW_{16}O_{61}]\cdot 17H_2O$ polyoxometalate (white octahedra represent MO_6 site. Black tetrahedra represent PO_4 sites).

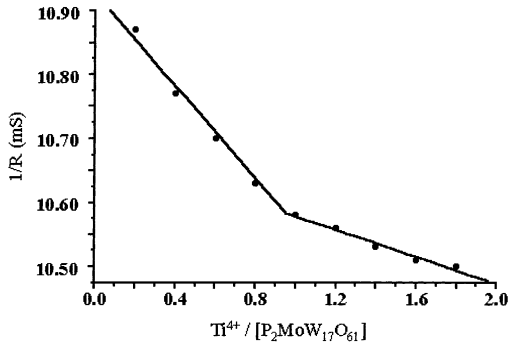

ligand is stabilized upon addition of the Ti(IV) atom. Cyclic voltammetry experiments clearly showed three single electron reversible reduction processes instead of four as obtained for the ligand. The complex belongs to the monoclinic system and adopts a modified Wells-Dawson structure as found by ^{31}P NMR and XRD data (Fig. 5), in which the Ti atom occupies a polar position (1, 2, 3, 16, 17 or 18) and the Mo atom is located on a belt site (4) [25].

Abstract

Six oxamido-bridged binuclear Cu(II)–M(II) (M = Cu, Ni and Mn) complexes containing macrocyclic oxamido ligands have been synthesized and characterized by IR, ESR and electronic spectra. They are of the formula $[Cu(L^2)M(L)_n](ClO_4)_2$, where H_2L^2 = 2,3-dioxo-5,6:13,14-dibenzo-7,12-bis(ethoxycarbonyl)-1,4,8,11-tetraazacyclotetradeca-7,11-diene, L = 2,2′-bipyridine and 1,10-phenanthroline (phen), $n = 1$ for M = Cu and $n = 2$ for M = Ni and Mn. The magnetic properties of the complexes with L = phen have been investigated and quantitatively interpreted using the Hamiltonian $\hat{H} = -2J\hat{S}_1 \cdot \hat{S}_2$, suggesting antiferromagnetic interactions through the oxamido bridge with $J = -210.2$, -53.9 and -14.1 cm^{-1} for the Cu_2, CuNi and CuMn complexes, respectively. Finally, the magnitudes of the Cu(II)–M(II) interactions with M = Cu, Ni and Mn have been compared and qualitatively justified. © 2002 Published by Elsevier Science Ltd.

1. Introduction

The design and magnetism of polynuclear complexes are of interest for designing new magnetic materials and for investigating the structure and the role of the polymetallic active sites in biological systems [1,2]. One of the best strategies to design polynuclear species is the 'complex as ligand' approach [3,4]. This approach has been widely employed to prepare oxamido-bridged bi- and polynuclear complexes, by using mononuclear *N*,*N*′-disubstituted oxamidocopper(II) complexes as ligands [5–13]. Recently, we have synthesized several copper(II) complexes of macrocyclic oxamides (Fig. 1, $[Cu(L^i)]$, $i = 1–4$) [14,15]. The mononuclear complexes contain unbridged oxamido groups so that they are potential bidentate chelating 'ligands'. Non-cyclic oxamides may adopt a *cis* or *trans* conformation on coordination, and this flexibility allows less control over the type of the complex formed [6–8], while the exclusive *cis* conformation of the macrocyclic oxamides allows us to synthesize polynuclear systems in a more controlled fashion. Along this line, we have reported some heterotetranuclear species of $[(CuL^i)_3M]$ type [M = Mn(II), Fe(III), Ni(II)] [15–17] and heterobinuclear species of $[(CuL^i)Ni(N_4)]$ type (N_4 = tetradentate terminal ligands [18] or a tridentate ligand plus NCS^- [19]). Robertson and co-workers have reported a trinuclear complex of $[(CuL^5)_2Cu]$ type (see also Fig. 1 for $[Cu(L^5)]$) [20].

As an extension of the investigation, here we report the synthesis, characterization and magnetism of new binuclear Cu(II)–M(II) (M = Cu, Ni and Mn) complexes derived from $[Cu(L^2)]$. They are of formulas $[Cu(L^2)Cu(L)](ClO_4)_2$ [L = 1,10-phenanthroline (phen)

(**1**) and 2,2′-bipyridine (bpy) (**2**)] and $[Cu(L^2)M(L)_2](ClO_4)_2$ [M = Ni, L = phen (**3**) and bpy (**4**); M = Mn, L = phen (**5**) and bpy (**6**).

2. Experimental

2.1. Materials and syntheses

All chemicals were of A. R. grade and used as received. The mononuclear precursor, $[Cu(L^2)]$, was prepared as described elsewhere [15]. All attempts to grow single crystals of the binuclear complexes were unfortunately unsuccessful.

2.1.1. Caution

Although we have not encountered any problems, it should be kept in mind that perchlorate salts of metal complexes are potentially explosive and should be handled with care.

2.1.2. $[Cu(L^2)Cu(phen)](ClO_4)_2$ (*1*)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.3 mmol) in EtOH (6 ml) was added to a suspension of $[Cu(L^2)]$ (0.3 mmol) in EtOH (8 ml). The mixture was stirred for 10 min until it became a brownish red solution and then a solution of 1,10-phenanthroline (0.3 mmol) in the same solvent (6 ml) was added. The mixture was stirred at room temperature (r.t.) for 4 h and the resulting brownish yellow precipitate was filtered off, washed successively with EtOH and Et_2O, and then dried in vacuo over P_2O_5. Yield: 75%. *Anal.* Found: C, 44.4; H, 3.3; N, 8.5. Calc. for $C_{36}H_{30}Cl_2Cu_2N_6O_{14}$: C, 44.6; H, 3.1; N, 8.7%. IR (KBr, cm^{-1}): 1720s, 1620sh, 1593s, 1570s, 1550s, 1512w, 1478w, 1440sh, 1425m, 1345m, 1324m, 1270m, 1205s, 1172w, 1140sh, 1100s, 1075sh, 1035s, 1015sh, 915m, 848m, 770w, 750m, 720m. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 225.

2.1.3. $[Cu(L^2)Cu(bpy)](ClO_4)_2$ (*2*)

The complex was synthesized by a similar procedure, using 2,2′-bipyridine instead of 1,10-phenanthroline. Yellow powder. Yield: 83%. *Anal.* Found: C, 43.5; H, 3.0; N, 9.1. Calc. for $C_{34}H_{30}Cl_2Cu_2N_6O_{14}$: C, 43.2; H, 3.2; N, 8.9%. IR (KBr, cm^{-1}): 1735s, 1620sh, 1600s, 1570s, 1553s, 1475m, 1440s, 1350m, 1320m, 1270m, 1200s, 1170w, 1140sh, 1080s (br), 1035sh, 1010sh, 913w, 845w, 760m, 740sh, 725w. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 254.

2.1.4. $[Cu(L^2)Ni(phen)_2](ClO_4)_2$ (*3*)

This complex was synthesized by the following procedure: a solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.2 mmol) in EtOH (5 ml) was added to a suspension of $[Cu(L^2)]$ (0.2 mmol) in EtOH (5 ml). The mixture was stirred for 10 min until it became a brownish red solution and then a solution of 1,10-phenanthroline (0.4 mmol) in the same solvent (5 ml) was added. The mixture was stirred at r.t. for 4 h and the resulting yellow brown precipitate was filtered off, washed successively with EtOH and Et_2O, and then dried in vacuo over P_2O_5. Yield: 81%. *Anal.* Found: C, 50.0; H, 3.4; Cu, 6.0; N, 10.0; Ni, 5.3. Calc. for $C_{48}H_{38}Cl_2CuN_8NiO_{14}$: C, 50.4; H, 3.4; Cu, 5.6; N, 9.8; Ni, 5.1%. IR (KBr, cm^{-1}): 1728s, 1625s, 1598s, 1575s, 1550s, 1515m, 1480m, 1440m, 1425s, 1345s, 1326m, 1272m, 1202s, 1170w, 1142m, 1080s (br), 1040sh, 1015w, 920w, 845m, 770w, 748m, 725s. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 228.

The other complexes were synthesized from $[Cu(L^2)]$, the appropriate hydrated metal perchlorate and terminal bidentate ligands by procedures similar to that for **3**.

2.1.5. $[Cu(L^2)Ni(bpy)_2](ClO_4)_2$ (*4*)

Brownish yellow powder. Yield: 78%. *Anal.* Found: C, 48.6; H, 3.5; Cu, 5.6; N, 10.3; Ni, 5.7. Calc. for $C_{44}H_{38}Cl_2CuN_8NiO_{14}$: C, 48.2; H, 3.5; Cu, 5.8; N, 10.2; Ni, 5.4%. IR (KBr, cm^{-1}): 1725s, 1625s, 1595s, 1572s, 1550s, 1478m, 1440s, 1345s, 1324m, 1270m, 1202s, 1170w, 1075s (br), 1040sh, 1005m, 920w, 863w, 808w, 760s, 745m, 730w. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 234.

2.1.6. $[Cu(L^2)Mn(phen)_2](ClO_4)_2$ (*5*)

Brownish yellow powder. Yield: 68%. *Anal.* Found: C, 50.2; H, 3.3; N, 10.1. Calc. for $C_{48}H_{38}Cl_2CuMnN_8O_{14}$: C, 50.6; H, 3.4; N, 9.8%. IR (KBr, cm^{-1}): 1735s, 1620sh, 1600s, 1575s, 1550m 1515m, 1475w, 1440m, 1425m, 1347m, 1326sh, 1265w, 1205s, 1170w, 1140w, 1080s (br), 1040sh, 1010w, 920w, 845m, 770w, 748m, 726m. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 249.

2.1.7. $[Cu(L^2)Mn(bpy)_2](ClO_4)_2$ (*6*)

Brownish orange powder. Yield: 74%. *Anal.* Found: C, 48.3; H, 3.4; N, 10.4. Calc. for $C_{44}H_{38}Cl_2CuMnN_8O_{14}$: C, 48.4; H, 3.5; N, 10.3%. IR (KBr, cm^{-1}): 1734s, 1624s, 1595s, 1570s, 1548s, 1474m, 1436s, 1340s, 1265m, 1200s, 1168m, 1135w, 1075s (br), 1040sh, 1010m, 920m, 855w, 810w, 765m, 745m, 730w. Molar conductance (MeCN, Ω^{-1} cm^2 mol^{-1}): 220.

2.1.8. Physical measurements

Elemental analysis (C, H, N) were performed on a Perkin–Elmer 240 analyzer. Conductivities of the complexes in MeCN were measured using a DDS-11A conductometer. IR spectra were recorded on a Shimadzu IR-408 spectrometer as KBr pellets, electronic spectra on Shimadzu UV-240 and Hitachi UV-330 recording spectrophotometers in MeCN, and solid-state X-band ESR spectra on a Bruker ER 200 D-SRC ESR spectrometer. Variable-temperature magnetic suscepti-

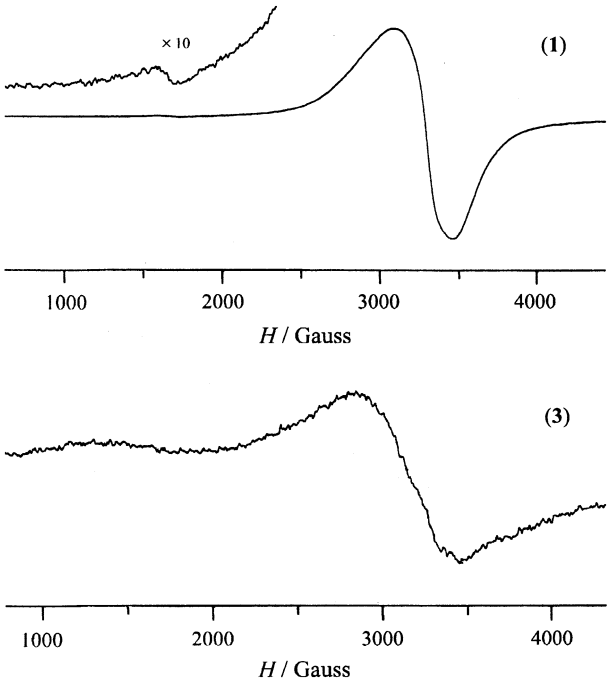

Fig. 2. Polycrystalline X-band ESR spectra of complexes **1** and **3** at room temperature.

bilities were measured on a Quantum Design MPMS-7 SQUID magnetometer. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms [21].

3. Results and discussion

Elemental analysis confirmed that the complexes are of formula $[Cu(L^2)M(L)_n](ClO_4)_2$ ($n = 1$ for M = Cu; $n = 2$ for M = Ni and Mn). Their molar conductance values fall within the range expected for 1:2 electrolytes [22], indicating that the perchlorate ion is non-coordinated in acetonitrile solutions.

3.1. IR spectra

The IR spectra of the six complexes are quite similar. It would be informative to compare the spectra of the present binuclear complexes with those of the mononuclear $[Cu(L^2)]$ precursors [15] and the tetranuclear $[(CuL^2)_3M](ClO_4)_2$ (M = Ni, Mn) complexes [15,17]. The bands attributable to the ν(C=O) (ester carbonyl) and ν(C=N) vibrations appear at approximately 1730 and 1620 cm^{-1}, respectively, and show no significant shift in comparison with the mononuclear precursor. However, the ν(C=O) (oxamido carbonyl) band observed at 1650 cm^{-1} for the mononuclear precursor is significantly shifted to approximately 1575 cm^{-1}. The significant red shift suggests the coordination of the $[Cu(L^2)]$ precursor to M(II) through the oxamido carbonyl oxygen atoms and reflects the decrease in the C=O bond strength upon coordination. All binuclear complexes show a broad strong band at approximately 1080 cm^{-1}, indicating the presence of the perchlorate ion. Nearly all bands of the tetranuclear complexes can be found in the spectra of the binuclear complexes, with no significant shift. Complexes **1**, **3** and **5** exhibit several medium or strong bands at $\sim$1515, 1425, 845 and 725 cm^{-1}, which were not observed for the mono- and tetranuclear complexes. They are attributable to the phen ligand. Complexes **2**, **4** and **6** show two weak bands at $\sim$810 and 730 cm^{-1}, attributable to the bpy ligand. The other absorptions of bpy may be obscured by the bands of the $[Cu(L^2)]$ moiety and cannot be easily distinguished.

3.2. Electronic spectra

The electronic spectra of the binuclear complexes in acetonitrile exhibit an intense maximum absorption at approximately 355 ($\varepsilon > 10^4$ M^{-1} cm^{-1}) and two shoulders at approximately 410 nm ($\varepsilon \sim 5000$ M^{-1} cm^{-1}) and 530 nm ($\varepsilon = 200$–300 M^{-1} cm^{-1}). According to the intensities and positions, the first two bands should be due to intraligand or charge-transfer transitions, and the last band is attributable to the envelope of the d–d transitions of the Cu(II) ions. No other d–d transition absorptions were observed for the Cu(II)Mn(II) complexes, consistent with the spin-forbidden nature of the d–d transitions of the Mn(II) ion. The Cu(II)Ni(II) complexes **3** and **4** show a weak broad near-infrared absorption at 850–890 nm ($\varepsilon \sim 50$ M^{-1} cm^{-1}), assignable to the $^3A_{2g} \rightarrow {}^3T_{2g}$ transition of the Ni(II) ion in an octahedral environment. The other two spin-allowed transitions of the Ni(II) chromophore may be obscured by the d–d and charge-transfer bands of the Cu(II) ion.

3.3. ESR spectra

The X-band powder ESR spectra of complexes **1** and **3** at room temperature are shown in Fig. 2. Complex **1** presents an intense quasi-isotropic feature around 3280 G ($g = 2.06$) and a weak half-field signal at 1650 G ($g = 4.10$). These features are characteristic of magnetically coupled dicopper(II) pairs: the two signals arise from the $\Delta M_S = \pm 1(|0\rangle \leftrightarrow |\pm 1\rangle)$ and $\pm 2(|+1\rangle \leftrightarrow |-1\rangle)$ transitions, respectively, within the $S = 1$ excited state.

Complex **3** exhibits a broad intense band around $g = 2.14$ (3160 G) and a weak broad signal at $g = 4.98$ (1365 G), quite similar to the oxamido- and oxamato-bridged binuclear Cu(II)–Ni(II) complexes reported elsewhere [18,19], indicating the presence of magnetically coupled Cu(II)–Ni(II) pairs. The spectrum can be explained by the allowed $|S, +1/2\rangle \leftrightarrow |S, -1/2\rangle$ tran-

sitions within the doublet ground state ($S = 1/2$) and the quartet excited state ($S = 3/2$) [9,18].

The room temperature spectrum of **5** was also measured and was found to exhibit only a broad isotropic signal centered at $g = 2.01$, indicating the presence of magnetic exchange between Cu(II) and Mn(II).

According to the above discussion, together with magnetic studies (Section 3.4), the present complexes are proposed to have the molecular structure schematized in Fig. 3, in which Cu(II) and M(II) ions are bridged by an oxamido group.

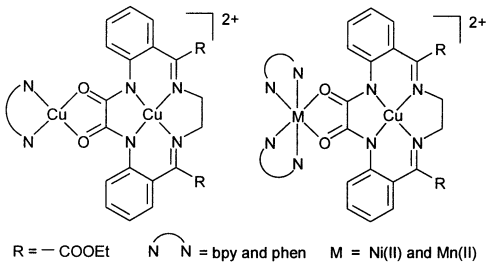

Fig. 3. The proposed molecular structure for the complexes.

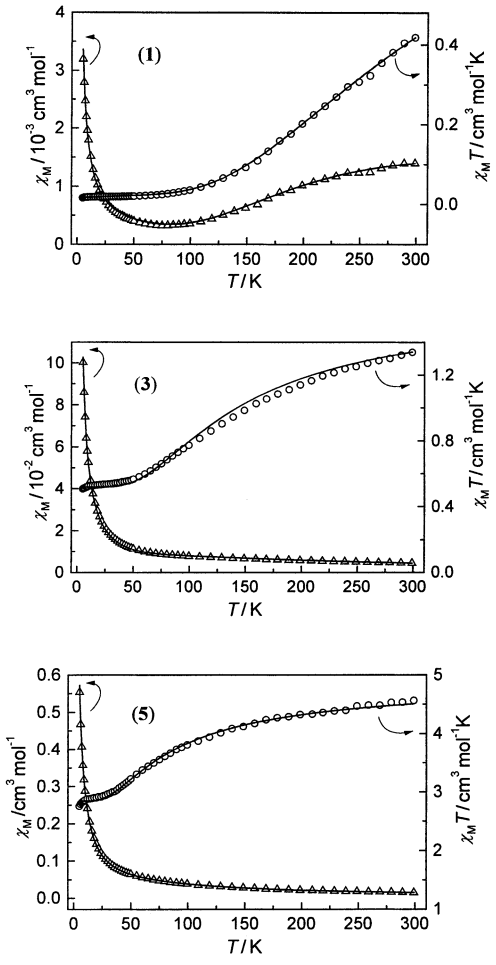

Fig. 4. χ_M versus T and $\chi_M T$ versus T plots for complexes **1**, **3** and **5**.

3.4. Magnetic properties

The temperature dependence of the molar magnetic susceptibility (χ_M) and its product with temperature ($\chi_M T$) for **1**, **3** and **5** are shown in Fig. 4.

The $\chi_M T$ product of **1** at room temperature is approximately 0.40 cm^3 mol^{-1} K, well below the spin-only value (0.75 cm^3 mol^{-1} K, assuming $g = 2.0$) expected for an uncoupled dicopper(II) system. Both χ_M and $\chi_M T$ decrease as the temperature is lowered from room temperature to approximately 75 K. This behavior is typical of discrete dicopper(II) pairs with a rather strong antiferromagnetic intramolecular interaction [23]. The increase of χ_M upon cooling further below 75 K indicates the presence of paramagnetic impurity. The impurity accounts for the plateau value of the $\chi_M T$ product in the low temperature region.

The $\chi_M T$ product of **3** at room temperature is approximately 1.33 cm^3 mol^{-1} K, less than the spin-only value (1.38 cm^3 mol^{-1} K) expected for an uncoupled Cu(II)–Ni(II) pair. The product decreases upon cooling and finally reaches a plateau below approximately 40 K with $\chi_M T = 0.52$ cm^3 mol^{-1} K. These features are quite typical of isolated Cu(II)–Ni(II) pairs with antiferromagnetic intramolecular interaction [9,18,19]. The plateaus below 30 K indicate that only the doublet ground state is thermally populated at low temperature.

The $\chi_M T$ product of **5** at room temperature is approximately 4.56 cm^3 mol^{-1} K, decreases as the temperature is lowered, reaches an approximate plateau between 25 and 10 K with $\chi_M T = 2.9$ cm^3 mol^{-1} K and finally decreases rapidly upon cooling further. This behavior indicates an antiferromagnetic interaction between the Cu(II) and Mn(II) ions. The plateaus indicate that only the quintet ground state is thermally populated below 25 K and the rapid decrease below 10 K may be due to secondary effects such as an antiferromagnetic intermolecular interaction and/or the zero-field splitting effect, which are operative only at very low temperature.

The magnetic data were fitted on the basis of the isotropic Heisenberg model $\hat{H} = -2J\hat{S}_1 \cdot \hat{S}_2$, where J is the interaction parameter between two spin carriers. The molar magnetic susceptibility for dicopper(II) complexes is expressed as

$$\chi_M = \frac{2N\beta^2 g^2}{kT}\left[\frac{1}{3+\exp(-2J/kT)}\right](1-\rho) + \frac{N\beta^2 g^2}{2kT}\rho + N\alpha$$

where ρ is the proportion of the paramagnetic impurity (presumably non-coupled monomeric copper(II) complex), $N\alpha$ is the temperature-independent paramagnetism (120×10^{-6} cm^3 mol^{-1}) and the other symbols

have their usual meaning. The simulation of the experimental data of **1** leads to $J = -210.2\ cm^{-1}$, $g = 2.29$ and $\rho = 0.016$. The agreement factor R defined as $R = \Sigma(\chi_{obsd} - \chi_{cacld})^2/\Sigma\chi^2_{obsd}$ is 1.1×10^{-3}. These large J values suggest that a very strong antiferromagnetic interaction between the two Cu(II) ions is mediated through the oxamido group.

For Cu(II)–Ni(II) complexes, the theoretical expression of the magnetic susceptibility is:

$$\chi_M = \frac{N\beta^2}{4kT}\left[\frac{g_{1/2}^2 + 10g_{3/2}^2\exp(3J/kT)}{1 + 2\exp(3J/kT)}\right]$$

where the g_S ($S = 1/2, 3/2$) factors are related to local g factors by $g_{1/2} = (4g_{Ni} - g_{Cu})/3$, and $g_{3/2} = (2g_{Ni} + g_{Cu})/3$. The simulations of the experimental data of **3** leads to $J = -53.9\ cm^{-1}$, $g_{Ni} = 2.27$, $g_{Cu} = 2.01$ with $R = 3.6 \times 10^{-4}$.

For Cu(II)–Mn(II) complexes,

$$\chi_M = \frac{2N\beta^2}{kT}\left[\frac{5g_2^2 + 14g_3^2\exp(6J/kT)}{5 + 7\exp(6J/kT)}\right]$$

where the g_S ($S = 2, 3$) factors are related to local g factors by $g_2 = (7g_{Mn} - g_{Cu})/6$, and $g_3 = (5g_{Mn} + g_{Cu})/6$. The simulations of the experimental data of **5** leads to $J = -14.1\ cm^{-1}$, $g_{Mn} = 1.99$, $g_{Cu} = 2.22$, with $R = 3.5 \times 10^{-4}$.

The antiferromagnetic interaction between Cu(II) and M(II) (M = Cu, Ni and Mn) can be easily understood in term of the non-zero overlap between the magnetic orbitals around Cu(II) and M(II) [24]. It has been demonstrated that, for oxalato-, oxamido- or oxamato-bridged copper(II) complexes, the magnitude of the magnetic interaction can be tuned by the coordination geometry around the metal ions [23,25–28]. Therefore, one can derive important structural information from the J parameter. The very strong antiferromagnetic interaction in the present dicopper complexes strongly suggest that the coordination planes of both Cu(II) ions are approximately coplanar with the oxamido bridge, as illustrated in Fig. 3. With such a geometry, the magnetic orbitals of both Cu(II) ions are favorably oriented and delocalized towards the bridging network to give a very large overlap, thus resulting in a very strong antiferromagnetic interaction. A similar structure has been determined for [Cu(oxpn)-Cu(bpy)]$(ClO_4)_2$ [oxpn = *N*,*N*′-bis(3-aminopropyl)-oxamido] [23], for which the J value ($-219.8\ cm^{-1}$) is comparable to the value reported here.

It should be worthwhile to compare the magnitude of the interaction in this series of binuclear Cu(II)–M(II) species containing the same bridging and terminal ligands but different M(II) ions. For the present series, we have $J_{CuCu} \approx 4J_{NiCu} \approx 15J_{MnCu}$. According to Kahn [24], the J_{CuM} parameter can be related to contributions from pairs of magnetic orbitals by $J_{CuM} = (\Sigma_\mu J_{\mu b_1})/n_M$, where n_M is the number of the magnetic orbitals (or unpaired electrons) around M, the index b_1 stands for the symmetry of the unique magnetic orbital ($d_{x^2-y^2}$) around Cu, and μ for the symmetry of the magnetic orbital around M, assuming a C_{2v} local symmetry for the Cu($C_2O_2N_2$)M bridging network. According to this relation, we have $J_{CuCu} = J_{b_1b_1}$, $J_{NiCu} = (J_{b_1b_1} + J_{a_1b_1})/2$ and $J_{MnCu} = (J_{b_1b_1} + J_{a_1b_1} + J_{a_1b_1} + J_{a_2b_1} + J_{b_2b_1})/5$. $J_{b_1b_1}$ involves the magnetic orbitals located in the plane of the bridging network and makes a predominant antiferromagnetic contribution. All other $J_{\mu b_1}$'s involve orthogonal magnetic orbitals and make small ferromagnetic contributions. Assuming that $J_{b_1b_1}$ is independent of M, it can be derived that $5|J_{MnCu}| < 2|J_{NiCu}| < |J_{CuCu}|$, where the $<$ signs are used to include the ferromagnetic contributions. This order is in agreement with the J_{MCu} values deduced from experimental magnetic data. Similar justification has been made for the MCu(obp)$(H_2O)_n$ [obp = oxamidobis(*N*,*N*′-propionato), M = Mn(II), Co(II) and Ni(II)] series [29]. However, the differences between the $n_M|J_{MCu}|$ values are so large that they cannot be only due to ferromagnetic contributions that are usually very small. It is difficult to estimate the ferromagnetic contributions in systems where the antiferromagnetic contribution predominates, but we can get some information from some similar Cu(II)Cr(III) systems where there are only ferromagnetic contributions [$J_{CrCu} = (J_{a_1b_1} + J_{a_2b_1} + J_{b_2b_1})/3 > 0$]. The J_{CrCu} values for several oxalato-bridged binuclear complexes and two oxamido-bridged Cu_3Cr species have been evaluated and are less than $7\ cm^{-1}$ [30–32]. The other origin of the differences between the $n_M|J_{MCu}|$ values lies in the antiferromagnetic contribution $J_{b_1b_1}$ itself, which is actually dependent on M. The dependence of $J_{b_1b_1}$ on M may be related to the following facts: (i) the 3d-orbital energy decreases in the order Mn > Ni > Cu due to the increased nuclear charge. A lower 3d energy means a smaller energy gap between the single-occupied 3d-orbital of M and the symmetry-adapted orbital of the bridging ligand; (ii) the M–O distance decreases in the same order. Both a smaller energy gap and a shorter M–O distance result in a stronger interaction between the metal and the ligand orbitals, and thus yield a magnetic orbital (the antibonding orbital) with enhanced ligand character, i.e. the delocalization of the magnetic orbital from M towards the bridge increases in the order Mn < Ni < Cu. It then follows that the overlap between the b_1-type magnetic orbitals of Cu and M and the resulting antiferromagnetic contribution $J_{b_1b_1}$ increase in the same order.

Abstract

New copper(II) pyridinecarboxylate compounds of the composition $[CuX_2(Et_2nia)_2(H_2O)_2]$ (where X = 2-methylthionicotinate (2-MeSnic), 2-chloronicotinate (2-Clnic), 2,6-dichloronicotinate (2,6-Cl_2nic), isonicotinate (isonic) and Et_2nia = *N*,*N*-diethylnicotinamide) have been prepared. All the $[CuX_2(Et_2nia)_2(H_2O)_2]$ compounds seem to possess octahedral copper(II) stereochemistry with differing tetragonal distortions. An X-ray analysis of $[Cu(2\text{-}Clnic)_2(Et_2nia)_2(H_2O)_2]$ was carried out and it featured a tetragonal-bipyramidal geometry around the copper(II) atom. The tetragonal plane is created by 2-chloronicotinate anions bonded to the copper(II) atom via the unidentate carboxylate oxygen atoms [Cu–O1 = 1.965(2) Å] and the pyridine ring nitrogen atoms of the neutral ligand *N*,*N*-diethylnicotinamide [Cu–N1 = 2.015(2) Å], whilst in axial positions are water molecules [Cu–O1w = 2.503(2) Å]. © 2002 Elsevier Science Ltd. 1. Introduction

The interaction of the Cu(II) atom, which plays a vital role in a number of a quite different biological processes [1], with therapeutically administered drugs is a subject of considerable interest. Pyridinecarboxylic acid and its derivatives constitute an important group of antihelmintics and vitamins. It is known that the same drugs act via chelation [2] or via the inhibition of metalloenzymes [3], but little is known about modification of the activities of most drugs that are potential ligands.

Synthesis and spectral properties of various complexes $CuX_2{\cdot}nH_2O$ (where X = nicotinate (nic), isonicotinate (isonic), 2-methylthionicotinate (2-MeSnic), 2-chloronicotinate (2-Clnic) or 2,6-dichloronicotinate (2,6-Cl_2nic); $n = 0$–4) have been reported [4–9]. For complexes $Cu(nic)_2$ [8], $Cu(nic)_2{\cdot}4H_2O$ [9], $Cu(isonic)_2{\cdot}4H_2O$ [9] and $Cu(2\text{-}Clnic)_2{\cdot}H_2O$ [5] monomeric, dimeric and polymeric structures have been determined by X-ray analysis.

Some complexes of copper(II) carboxylates with *N*,*N*-diethylnicotinamide were also studied by X-ray. Structures of these complexes are dimeric [10] (similarly as for copper(II) acetate monohydrate [11]), polymeric [12] or monomeric [13–16], where carboxylate anions are bonded in an unidentate [13–15] or bidentate [16] manner, and *N*,*N*-diethylnicotinamide in all examples is a monodentate nitrogen donor ligand.

In order to better understand some aspects of copper(II) interactions with pyridine-carboxylates, we have studied the complexation of pyridine-4-carboxylate (isonicotinate) and 2-substituted derivatives of pyridine-3-carboxylate in the presence of *N*,*N*-diethylnicotinamide (Et_2nia). In the present paper, compounds of

general composition, $[CuX_2(Et_2nia)_2(H_2O)_2]$ (where X = isonicotinate (isonic), 2-methylthionicotinate (2-MeSnic), 2-chloronicotinate (2-Clnic) or 2,6-dichloronicotinate (2,6-Cl_2nic)) are characterized by spectral methods. Moreover, the crystal structure of one of the complexes $[Cu(2\text{-Clnic})_2(Et_2nia)_2(H_2O)_2]$ has been studied by X-ray analysis. Based on the molecular structure the electronic, infrared and EPR spectra are discussed.

2. Experimental

2.1. Chemical reagents, analysis and spectral studies

All the chemicals used were of analytical grade (Aldrich or Sigma) and were used without further purification.

Copper was determined by electrolysis after mineralization of the complexes; carbon, hydrogen, nitrogen and sulfur were determined by microanalytical methods (Carlo Erba Instruments EA 1108). Besides the elemental analysis, the water content in hydrates was determined from thermogravimetrical curves.

Electronic spectra of the powdered samples in Nujol mulls were recorded at room temperature on a Specord M40 and Specord 200. IR spectra were recorded on a Magna 750 spectrophotometer at room temperature. Spectra of solid samples were obtained in nujol mulls, KBr and polyethylene pellets at a resolution of 1 cm^{-1}. EPR spectra of powdered samples were measured on a Bruker 200D SRC X-band (9.4 GHz) at room temperature.

2.2. X-ray crystallographic study

Data collection and cell refinement were carried out using Kuma CCD diffractometer and software [17]. Intensity data were corrected for Lorentz and polarization factors using KM4CCD software package [17]. The structure was solved by the heavy atom method with SHELXS-86 [18], and subsequent Fourier syntheses using SHELXL-93 [19], anisotropic thermal parameters were refined for all non-hydrogen atoms. Geometrical analysis was performed using SHELXL-93 [19]. The structure was drawn using ORTEP-3 [20]. The carbonyl oxygen atom of the carboxylic group is disordered occupying two statistical positions, represented by O2a and O2b with site occupancy factors of 0.44(7) and 0.56(7), respectively. The final parameters after refinement are summarized in Table 1. Selected interatomic distances and bond angles are given in Table 2.

2.3. Preparation of complexes $[Cu(2\text{-MeSnic})_2(Et_2nia)_2(H_2O)_2]$ (**1**), $[Cu(2\text{-Clnic})_2(Et_2nia)_2(H_2O)_2]$ (**2**), $[Cu(2,6\text{-}Cl_2nic)_2(Et_2nia)_2(H_2O)_2]$ (**3**) and $[Cu(isonic)_2(Et_2nia)_2(H_2O)_2]$ (**4**)

To the aqueous solutions (40 cm^3) of copper(II) sulfate (2 mmol), the aqueous solutions of the appropriate nicotinic acid (2-MeSnicH, 2-ClnicH or 2,6-Cl_2nicH) and equimolar quantities of sodium hydroxide (4 mmol) were slowly added and refluxed for 15 min. These reaction mixtures were left to stand at room temperature (r.t.) and the green $[CuX_2(H_2O)]_2$ (X = 2-MeSnic and 2-Clnic) or blue $[Cu(2,6\text{-}Cl_2nic)_2(H_2O)_2]$ products were isolated [4,5].

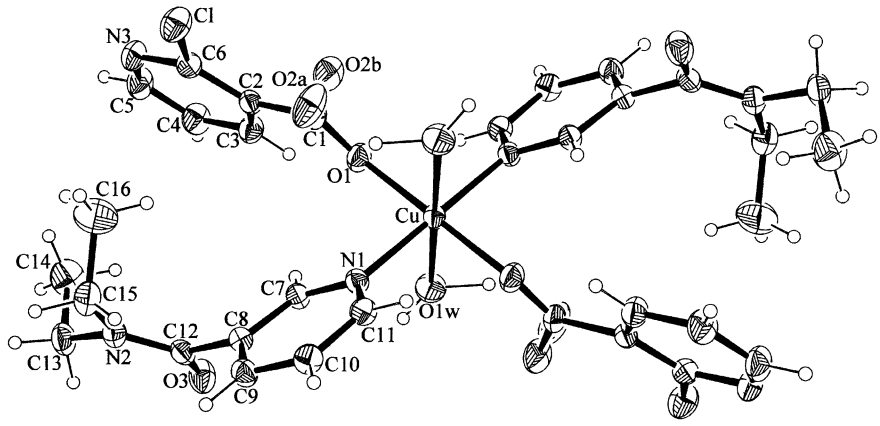

Fig. 1. Perspective view of the complex $[Cu(2\cdot Clnic)_2(Et_2nia)_2(H_2O)_2]$ (**2**), with atom numbering scheme. Thermal ellipsoids are drawn at the 30% probability level.

Compounds of the composition $[CuX_2(Et_2nia)_2(H_2O)_2]$ (**1**–**3**) were prepared by adding Et_2nia (5 cm^3) in excess to methanol solutions (20 cm^3) of appropriate $CuX_2\cdot nH_2O$ (1,25 mmol). The fine blue microcrystals produced on standing were separated, washed and dried in vacuo. Well-shaped single crystals of $[Cu(2\text{-}Clnic)_2(Et_2nia)_2(H_2O)_2]$ suitable for structure determination were obtained by recrystallizing in methanol. *Anal.* Calc. for $C_{34}H_{44}CuN_6O_8S_2$ (**1**): C, 51.5; H, 5.6; N, 10.6; S, 8.1; Cu, 8.0. Found: C, 51.9; H, 5.8; N, 10.9; S, 8.3; Cu, 8.2%. *Anal.* Calc. for $C_{32}H_{38}CuN_6O_8Cl_2$ (2): C, 50.0; H, 5.0; N, 10.9; Cu, 8.3. Found: C, 50.4; H, 5.0; N, 11.1; Cu, 8.0%. *Anal.* Calc. for $C_{32}H_{36}CuN_6O_8Cl_4$ (3): C, 45.9; H, 4.3; N, 10.0; Cu, 7.6. Found: C, 45.7; H, 4.4; N, 9.8; Cu, 7.4%.

Complex **4** was prepared only by adding Et_2nia (5 cm^3) in excess to the solid complex $[Cu(isonic)_2(H_2O)_4]$ (which was prepared as described earlier [7]). The resulting suspension was left to stand at r.t. After standing the suspension for 1 week, acetone (20 cm^3) was added to the resulting oil and blue crystals of complex **4** were collected by filtration, washed with ethanol and dried in vacuo. The analogous reaction of anhydrous $[Cu(nic)_2]$ [6] with Et_2nia under the same experimental conditions leads only to separation of unchanged starting complex. *Anal.* Calc. for $C_{32}H_{40}CuN_6O_8$ (4): C, 54.9; H, 5.8; N, 12.0; Cu, 9.1. Found: C, 55.3; H, 5.4; N, 12.2; Cu, 8.9%.

3. Results and discussion

3.1. Crystal structure description of complex (2)

The principal structural features of $[Cu(2\text{-}Clnic)_2(Et_2nia)_2(H_2O)_2]$ (**2**) are illustrated in Fig. 1. Selected bond lengths and angles of **2** are tabulated in Table 2. The coordination environment of the copper(II) atom is elongated tetragonal bipyramidal. The tetragonal plane is built up by a pair of unidentate 2-Clnic anions using carboxylate oxygen atoms (Cu–O1 = 1.965(2) Å) and by a pair of neutral *N*,*N*-diethylnicotinamide molecules using pyridine ring nitrogen atoms (Cu–N1 = 2.015(2) Å) in *trans* positions. The axial positions are occupied by water molecules (Cu–O1w = 2.503(2) Å). Intramolecular hydrogen bonding interactions involving an axial coordinated water molecule and disordered carboxylic oxygen atoms [O1w–H17···O2a, or O1w–H17···O2b, with O···O distances 2.652(10). and 2.736(8) Å, respectively] stabilize the molecular structure. The packing diagram of $[Cu(2\text{–}Clnic)_2(Et_2nia)_2(H_2O)_2]$ (**2**) perpendicular to the *bc* plane is shown in Fig. 2. All pyridine rings of *N*,*N*-diethylnicotinamide molecules coordinating to copper(II) ions are involved in offset face-to-face p–p stacking interactions by themselves (face-to-face distance 3.43 Å $[-x, -y+1, -z]$) [21], leading to supramolecular 1D chains propagating along the *b* axis. Supramolecular 1D chains are connected by intermolecular hydrogen bonds O1w–H18···O3 $[-x+1, -y+1, -z]$ with O···O distance 2.850(3) Å in the *ab* plane.

Table 3 shows selected bond distances of complex **2** and other complexes $[Cu(ArCO_2)_2L_2(H_2O)_2]$ (Ar = aryl; L = Et_2nia or nicotinamide (nia)), which have a similar centrosymetric molecular structure [13–16,22]. All five compounds have the same *trans*-$Cu^{II}O_2N_2\cdots O_2$ chromophore with a tetragonal bipyramidal geometry, axially elongated as predicted by the Jahn–Teller theorem. The values of the *T* parameter ($T = R_S/R_L$) [23], indicating the degree of tetragonal distortion about the copper(II) centers [23], decrease for the complexes in the sequence: 0.809 $[Cu(flu)_2(Et_2nia)_2(H_2O)_2] > 0.800$ $[Cu(4\text{-}O_2Nbz)_2(Et_2nia)_2(H_2O)_2] > 0.795$ $[Cu(2\text{-}Clnic)_2(Et_2nia)_2(H_2O)_2] > 0.775$ $[Cu(mef)_2(Et_2nia)_2(H_2O)_2] > 0.770$ $[Cu(4\text{-}HObz)_2(nia)_2(H_2O)_2]$, which follows the trend of the observed distortions. On the other hand, complex $[Cu(salicylate)_2(nia)_2(H_2O)_2]$ crystallizes in the non-centrosymmetric space group $P2_1$.

The geometrical environment around the copper(II) centre is asymmetric tetragonal bipyramidal, with significantly different axial bond distances Cu–Ow = 2.373(3) and 2.894(4) Å [24].

3.2. IR spectra

The IR spectra of all complexes under study show one or two strong absorption bands in the region from 3300 to 3500 cm^{-1}. These bands correspond to the antisymmetric and symmetric OH stretch and confirm the presence of water in the compounds. Moreover, the IR spectra exhibit characteristic bands at approximately 870 and 550 cm^{-1} assigned to rocking and wagging modes of the coordinate water molecule [25].

Extensive infrared studies have been made on metal complexes of carboxylic acids [25]. Each compound showed the carboxylate stretching frequencies

4	$[Cu(isonic)_2(Et_2nic)_2(H_2O)_2]$	15700br	1.989	2.217	2.049	

[a] br, broad.
[b] $G = (g_\parallel - 2)/(g_\perp - 2)$.

$\nu_{as}(COO^-)$ and $\nu_s(COO^-)$. The broad bands at about 1620 cm^{-1} (assigned to the antisymmetric stretch $\nu_{as}(COO^-)$) are overlaped with the stretching vibrations of ν(C=O) (amide I) of *N*,*N*-diethylnicotinamide. The differences between the antisymmetric stretch $\nu_{as}(COO^-)$ and symmetric stretch $\nu_s(COO^-)$ (Δ) give information on the carboxylate bonding mode for the complexes after comparison with Δ values of complexes with ionic carboxylic groups. Paris et al. [26] have studied the IR spectra of pyridinecarboxylic acid and its sodium and potassium salts. For sodium nicotinate the Δ value is approximately 220 cm^{-1}. The greater Δ values for all complexes under study containing 2-substituted nicotinates or isonicotinate (from 253 to 275 cm^{-1}) are rather typical for unidentately bonded carboxylic groups.

The non-coordination of the pyridinecarboxylate ring of X^- in all $[CuX_2(Et_2nia)_2(H_2O)_2]$ complexes is in agreement with the positions of the absorption bands at about 400 cm^{-1}, which are due to out-of-plane deformation of the uncoordinated pyridine rings [25]. On the other hand, the positions of bands which correspond to pyridine ring deformation of *N*,*N*-diethylnicotinamide (the band due to out-of-plane pyridine ring deformation at 400 cm^{-1} for free Et_2nia are shifted to higher wavenumbers at about 430cm^{-1}) show that it is coordinated only through the nitrogen atom of the pyridine ring. The coordination of the pyridine ring is also indicated from the IR spectra by other typical shifts of bands of the pyridine ring which are characteristic for its coordination. Moreover, the absorption bands in the region of 270–283 cm^{-1} (assigned to ν(Cu–N)) confirm the coordination of the nitrogen atom of pyridine ring of *N*,*N*-diethylnicotinamide to the Cu(II) atom.

3.3. Electronic spectra

The solid state electronic spectra of all copper(II) complexes **1**–**4** exhibit a broad ligand field band with a maximum in the range of 15700–15100 cm^{-1} (Table 4). This type of spectrum is typical for tetragonal arrangement around copper(II) atoms corresponding to electron transfer from the one-electron orbital state $d_{x^2-y^2}$ [27]. Moreover, the suggested stereochemistry of the above complexes has also been confirmed by structure analysis in complex **2**. Maxima of the bands are consistent with the assignments for other copper(II) carboxylates with a *trans*-$Cu^{II}N_2O_2\cdots O_2$ chromophore [28].

3.4. EPR spectra

The EPR data for complexes **1**–**4** at ambient temperature are given in Table 4. The X-band spectra for complexes **1**–**4** are typical for axial type complexes. They exhibit two g values at room temperature with $g_\parallel > g_\perp$, suggesting a $d_{x^2-y^2}$ ground state which is consistent with the observed elongated octahedral stereochemistry [29]. The calculated G values [$G = (g_\parallel - 2)/(g_\perp - 2)$] show that the two g-value spectra with the lowest g-value (> 2.0) of complexes **1** and **3** are outside the range 3.5–5.0 and exchange coupling invalidates the observed g-values [30]. The spectral parameters are comparable to those of adducts of copper(II) carboxylates with *trans*-$Cu^{II}O_2N_2\cdots O_2$ chromophores [28]. The calculated G value of $[Cu(2\text{-}Clnic)_2(Et_2nia)_2(H_2O)_2]$ (**2**) indicates little resolution due to dipol–dipol interactions between copper atoms of neighboring molecules. It is in agreement with the X-ray results which reveal a mononuclear structure with a Cu···Cu distance of 7.174(4) Å, which is in the range, up to 11 Å [31], for which a magnetic exchange has been observed [32,33]. A similar magnetic exchange has been observed in the bis copper(II) carboxylate adducts with *trans*-$Cu^{II}O_2N_2\cdots O_2$ chromophores [Cu(acetylsalicylato-O,O′)$_2$(pyridine)$_2$] [34] with a Cu···Cu distance of 6.598(4) Å.

4. Supplementary material

Supplementary material including all atomic coordinates ($\times 10^4$), anisotropic displacement parameters for non-hydrogen atoms and all interatomic distances and bond angles have been deposited with the Cambridge Crystallographic Centre, CCDC No. 145984 for the

compound [Cu(2-Clnic)$_2$(Et$_2$nia)$_2$(H$_2$O)$_2$]. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The aim of this paper is to look for a better knowledge of the behaviour of bent tantalocenes that bear hydrides, phosphorus PR_2X (R = Me, Ph; X = H, lone pair) and cyclopentadienyl ($Cp = C_5H_5$, $Cp' = C_5H_2^tBu(Me)_2$, $Cp^* = C_5Me_5$) ligands. An orbital control of regioselectivity of insertion of the PR_2 phosphide fragment of chlorophosphines PR_2Cl into the central Ta–H bond of trihydrides Cp_2TaH_3 leading to the formation of metallophosphonium cations is discussed. Neutralisation of cationic complexes with strong bases leads either to the Ta(V)–phosphide or to the Ta(III)–phosphine species depending on the nature of the cyclopentadienyl ligand; good electron donor Cp′ and Cp* rings favour the formation of Ta(V)–phosphide species, while C_5H_5 orients neutralisation towards Ta(III)–phosphine ones. These trends are roughly confirmed by DFT calculations. The X-ray structure of the first tantalocene phosphonium ionic compound $[CpCp'TaH_2(PMe_2H)]PF_6$ ($Cp' = C_5H_2^tBu(Me)_2$) as well as that of the bimetallic complex $Cp_2Ta(H)(\mu\text{-}PPh_2,H)Fe(CO)_3$ are also reported. © 2002 Elsevier Science Ltd. 1. Introduction

The search for binuclear complexes containing two different transition metals still attracts great interest [1]. In particular, the chemistry of heterobimetallic compounds stabilised by bridging phosphido groups has been widely studied [2]. Our group is involved in this field and we have developed synthetic strategies starting from metalloligands. These metallophosphines are obtained by reacting d^2 monohydrides $Cp_2M(L)H$ (M = Nb, Ta; L = two electron donor) [3] or d^0 dihydrides Cp_2MH_2 (M = Mo, W) [4] with chlorophosphines PR_2Cl. In keeping with our interest in phosphido derivatives, we turned our attention to the trihydrides Cp_2MH_3 (M = Nb, Ta; d^0) which are good precursors of highly reactive unsaturated intermediates $[Cp_2MH]$ and are therefore able to undergo coordination or insertion reactions with phosphines. Boni and coworkers [5] and Nikonov et al. [6] have shown that trihydrides Cp_2MH_3 give clean reactions with chlorophosphines PR_2Cl. In this paper we report on the syntheses and properties of some new mononuclear and dinuclear complexes with Ta–P bonds.

2. Results and discussion

2.1. Cationic complexes

It is experimentally established that chlorophosphines PR_2Cl react with tantalocene (and niobocene) trihydrides (**1**) leading to the formal insertion of the PR_2 unit into the central Ta–H bond with formation of

symmetrical metallophosphonium cations $[Cp_2TaH_2(PR_2H)]^+$ (**2**) ($Cp_2 = (C_5H_5)_2$ (**2**,**2**), $(C_5H_5)(C_5H_2'Bu(Me)_2)$ (**2**,**2′**), $(C_5H_5)(C_5Me_5)$ (**2**,**2***) and $(C_5Me_5)_2$ (**2***,**2***); R = Me, Ph) bearing both residual hydrides in lateral positions (Scheme 1).

Nikonov proposed recently a plausible general mechanism of an insertion process based on carbenoid behaviour of halophosphines [6c]. This model involves the HOMO and the LUMO of PR_2Cl molecules which represent, respectively, the canonical lone pair of phosphorus (LP), and the σ*(p) antibonding P–Cl molecular orbital. We calculated the shapes of these orbitals for PMe_2Cl with a semi-empirical PM3 method [7] and depicted them on Fig. 1. Their lobes of chemical interest have a high contribution of phosphorus and form an angle close to 60°.

The first step of this mechanism consists of an interaction between one of the three M–H bonds of the complex with the LUMO of the PR_2Cl reagent (hydride nucleophilic attack on the P atom of chlorophosphine). However, the regiochemistry of this interaction is not clear, because both the central and the lateral M–H bonds of Cp_2MH_3 may formally operate. Nikonov assumed that it is the central M–H_a bond that attacks the σ*(p)P–Cl orbital, because he knows the result of this action. The simplified energy diagrams of tantalocene trihydrides (Fig. 2), calculated at the DFT/

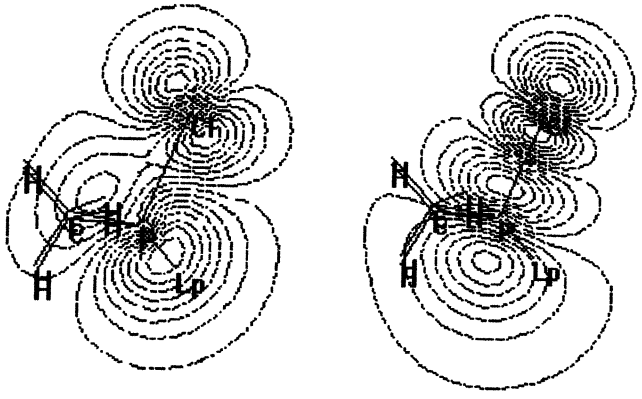

Fig. 1. Shapes of the HOMO (left) and the LUMO (right) for PMe_2Cl.

B3LYP level with Lanl2DZ basis[8], do not distinguish clearly which Ta–H bond ($2a_1$ or b_2) is preferentially responsible for the initial interaction with the σ*(p)P–Cl orbital. The $2a_1$ occupied molecular orbital of trihydride is mainly built of the Ta–H central bond, while the filled b_2 orbital contains contributions from the lateral ones. The HOMO for (**1**,**1**) is $2a_1$, thus indicating the reactivity of the central bond, but it lies only 0.25 eV over b_2. With a good electron donor permethylated ligands (**1***,**1***) the b_2 orbital builds the HOMO, thus suggesting a lateral interaction. However, the energy difference HOMO–HOMO-1 here is still smaller (0.15 eV) than for (**1**,**1**), and consequently, this electronic argument for lateral interaction may be contoured by steric hindrances in the transition state of insertion. If we consider the interaction of the $2a_1$ molecular orbital (central Ta–H bond of the trihydride) with the LUMO of PR_2Cl, we should assume that the HOMO of PR_2Cl (P lone pair) must be placed in the *xz* molecular plane defined by the Ta atom and the centres of the cyclopentadienyl rings (because of repulsions between the phosphorus lone pair and Ta–H bonds) and, consequently, should overlap with the b_1 empty metallic orbital (d_{xz}) located in this plane. On the other hand, if the lateral Ta–H bond (b_2) is implied in the interaction with the LUMO of PR_2Cl, the lone pair of this reagent should now interact with the metallic a_2 (d_{xy}) orbital. The d_{xz}–LP(P) ligand interaction consists of a direct metal–ligand overlap ('strong' interaction), whereas that involving d_{xy} is of lateral nature ('weak' interaction). Such an analysis of bonding favours a central coordination of the chlorophosphine. Moreover, the lateral interaction can lead to steric hindrances consisting of geometrical conflicts between R substituents of PR_2Cl and cyclopentadienyl rings. Thus, the participation of the b_1 metallic orbital (in the building of the transition state) may explain the observed regiochemistry of the insertion process.

It is worth noting that the tantalocene cationic species bearing the phosphine (PMe_2Ph) or the phosphite ($P(OMe)_3$) [9] in lateral sites, obtained by protonation of Ta(III) (d^2) $Cp_2Ta(L)H$ derivatives, are known and stable. However, the ligands in these last derivatives already occupy the lateral positions allowing the attack of the proton on the central lobe of the non-bonding HOMO in the d^2 system [10].

In order to confirm the stereochemistry of the insertion process we have carried out the experiments with a centrally deuteriated complex $(C_5H_5)(C_5H_2'Bu(Me)_2)TaH_2D$ [11]. Reaction of this freshly prepared complex in toluene with PMe_2Cl at low temperature (−78 °C) gives almost exclusively (90%) the phosphorus deuteriated salt $[(C_5H_5)(C_5H_2'Bu(Me)_2)TaH_2(PMe_2D)]Cl$ together with a small fraction of the metal deuteriated isotopomer $[(C_5H_5)(C_5H_2'Bu(Me)_2)TaHD(PMe_2H)]Cl$ (10%) (the ratios estimated from ^1H NMR data). The

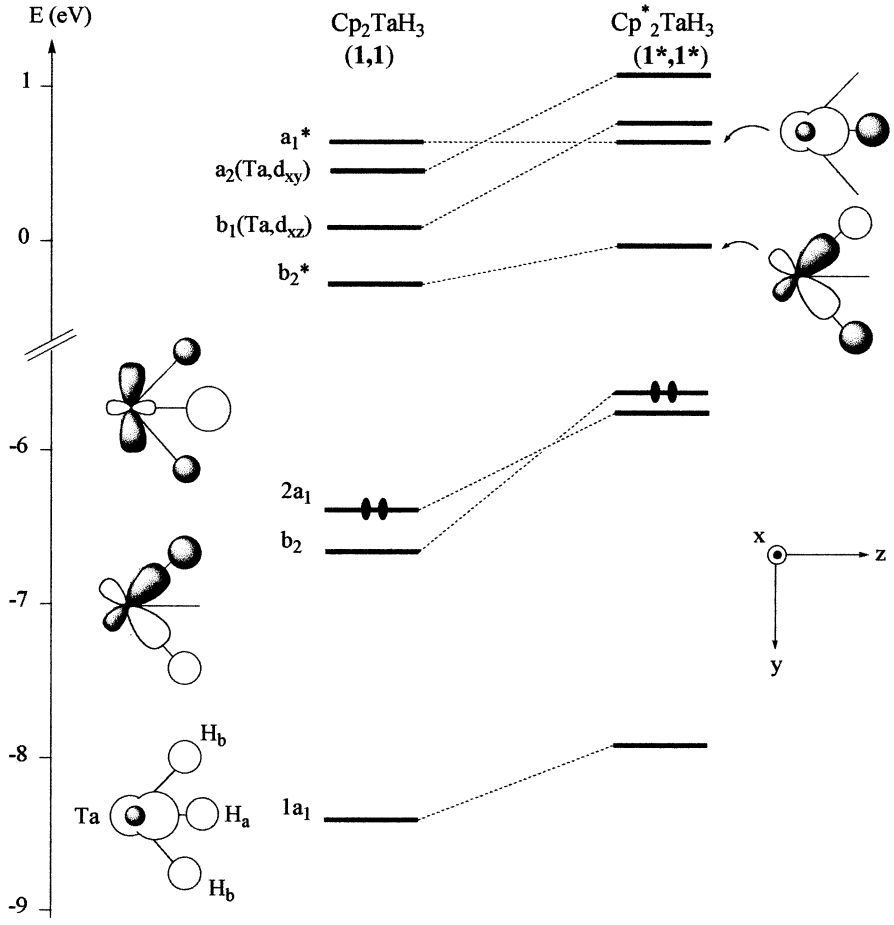

Fig. 2. Simplified energy diagram of the frontier molecular orbitals for C_5H_5 (**1**,**1**) and C_5Me_5 (**1***,**1***) trihydrides.

complex $[C_5H_5)(C_5H_2^tBu(Me)_2)TaH_2(PMe_2D)]Cl$ is stable in toluene solution under argon for several days with neither detectable H/D exchange nor the formation of isomers with the phosphine in the lateral position.

The use of the new ($C_5H_2^tBu(Me)_2$) ligand [12] allowed us to grow for the first time X-ray quality crystals of a Group 5 cationic metallocene bearing a secondary phosphine ligand (**2**,**2**′,**Me**). The crystal structure of (**2**,**2**′,**Me**) is built of organometallic cations and PF_6 anions. The cation has a structure similar to that reported for the neutral complex $Cp_2TaH_2PPh_2$ with a terminal phosphido ligand [6b]. The geometry of the cation may be regarded as a highly distorted trigonal bipyramid or as a tetrahedron one with one edge (H–H) capped with a phosphorus ligand (Fig. 3).

The Ta–P(PMe_2H) bond length of 2.533(1) Å in (**2**,**2**′,**Me**) is significantly shorter than that reported by Nikonov for the Ta(V) neutral complex with a terminal PPh_2 ligand $Cp_2Ta(H)_2PPh_2$ (2.595(3) Å) [6b]. Although, the substituents on the P atom (Me vs. Ph) are different it seems reasonable to assume that the presence of a diffused phosphorus lone electron pair in the neutral complex, instead of the hydrogen atom in

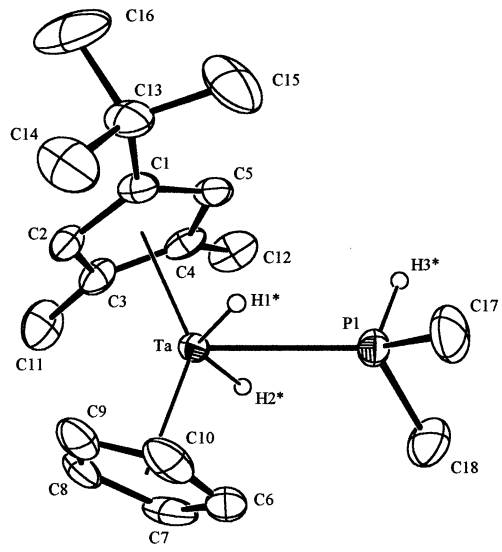

Fig. 3. ORTEP plotting (50% probability level) of the cation in (**2**,**2**′,**Me**). Selected bond lengths (Å) and angles (°): Ta–P1 2.533(1); Ta–H1 1.69(4); Ta–H2 1.73(6); Ta–CP′ 2.063; Ta–CP 2.059; H1–Ta–H2 135(2); H1–Ta–P1 70(1); H2–Ta–P1 66(2); CP′–Ta–CP 138.8.

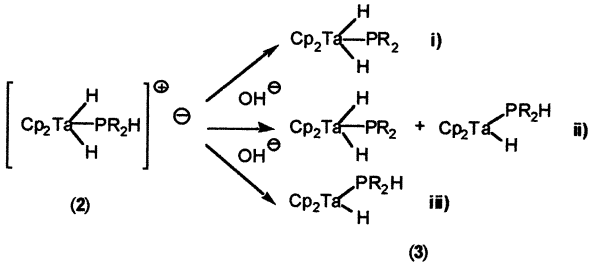

(**2**,**2′**,**Me**), is responsible for the long Ta–P bond observed in the neutral complex. The pure so called 'transition metal gauche effect' [3d,13] cannot be applied to the observed lengthening in the neutral complex because there is no non-bonding tantalum filled orbital in a formal (Ta(V), d^0) structure. However, the repulsions between the P lone pair and Ta–H bonds may easily operate therein.

2.2. Neutral complexes

It has been observed that the cationic metallophosphonium compounds of type **2** (Group 5 and 6 metallocenes) are easily deprotonated by strong bases [3–6,14,15]. In the case of Group 5 metals, like Ta(V) complexes, the neutralisation may lead either to the Ta(III)–phosphine or to the Ta(V)–phosphide species (complexes **3**, Scheme 2).

A similar phosphine (M–PPh_2H) versus phosphide (M–PPh_2) isomerism due to the nature of the second versus third row transition metal has been observed by Baker et al. [16] for Mo/W monocyclopentadienyl $Cp^*Mo(PMe_3)(PPh_2)(PPh_2H)$/$Cp^*W(PMe_3)(PPh_2)_2H$ and by Nikonov [6a,6b] for the Nb/Ta metallocene $Cp_2Nb(PPh_2H)(H)$/$Cp_2Ta(H)_2(PPh_2)$ series. This has been assigned to the stronger metal–hydrogen bonds for third row metals as compared to those from the second row [17]. We have also observed such an isomerism after deprotonation of molybdenocene phosphonium cations $[Cp_2Mo(H)(PR_2H)]^+$ (R = Me, Ph) which gives either the Mo^{II} $Cp_2Mo(PMe_2H)$ or the Mo^{IV} $Cp_2Mo(H)(PPh_2)$ neutral species; a process clearly depending on the nature of the coordinated secondary phosphine [15]. A similar behaviour is also observed for tantalocenes (**2**,**2**) (pathways (i) and (iii) in Scheme 2). Thus, the type of neutral complex (M, d^2-phosphine) or (M, d^0-phosphide) depends on the nature of M and on that of R.

The isomerism observed in the case of new neutralised 'tantalocene–PMe_2X (X = H or LP)' systems depends on a third factor: the nature of the substituted

i) $Cp_2 = (C_5H_5)_2$, R = Ph, (**3**,**3**,**Ph**) ; $Cp_2 = (C_5H_5)(C_5Me_5)$, R = Me, (**3**,**3***,**Me**)
ii) $Cp_2 = (C_5H_5)(C_5H_2Me_2{}^tBu)$, R = Me, (**3**,**3′**,**Me**)
iii) $Cp_2 = (C_5H_5)_2$, R = Me, (**3**,**3**,**Me**)

Scheme 2.

cyclopentadienyl ligands. Strong electron donor Cp ligands e.g. alkyl substituted cyclopentadienyl rings, ($C_5H_2'Bu(Me)_2$) and (C_5Me_5) versus non-substituted C_5H_5 favour the formation of Ta(V)–phosphide complexes when R = Me. Both isomers are formed with mixed Cp/Cp′ ligands (**3**,**3′Me**), but a sole Ta(V)–phosphide isomer is found for the mixed Cp/Cp* complex (**3**,**3***Me**). Note, however, that neutralisation of permethylated cations (**2***,**2***) (expected formation of Ta(V)–phosphide isomer) does not give the isolable defined product of the type (**3***,**3***Me**). This may be due to a very electron rich nature of the expected complex.

Because all neutral complexes (**3**), whatever their phosphine (Ta(III)) or phosphide (Ta(V)) nature, react with Group 6 and 8 metal carbonyls giving μ-phosphido bimetallics [14], we focussed our attention on the relative stabilities of different Ta(V) and Ta(III) neutral species ((**3**,**3**) and (**3**,**3***)). They have been estimated from total energies calculated for optimised geometries of extreme Ta(V) and Ta(III) cases with the DFT/B3LYP method with Lanl2DZ basis. The results are shown on Fig. 4.

The calculations indicate that for non-substituted (**3**,**3**) isomers (part *a*) on Fig. 4) the Ta(V)–phosphide structure should be more stable than that of Ta(III)–phosphine, but only by 0.35 eV (some 34 kJ mol^{-1}). Note, that the last one (Ta(III)–phosphine) is experimentally observed upon neutralisation of (**2**,**2**). In the (**3**,**3***) series (part *b*) on Fig. 4), the lowest energy Ta(V)–phosphide structure is more stable than that of Ta(III)–phosphine by 0.52 eV (50 kJ mol^{-1}). It agrees with experimental observation. Thus, one may conclude that the calculated trends roughly correspond to the experimental ones: the presence of a good electron donor Cp ligand stabilizes the Ta(V) isomer more than the Ta(III) isomer. The Me groups of the phosphide ligand in a stable geometry of the (**3**,**3***) system are found, with respect to the TaH_2P plane, on the side of the non-substituted Cp ligand (structure *x*). We also looked at what happens when the Me groups are placed on the other side of this plane (rotation by 180°), in the space of the Cp* ligand (structure *y*). A local minimum of energy has been effectively observed for this conformation (*y*), lying only 0.2 eV higher with respect to the structure (*x*). The Ta–P distances in optimised structures (**3**,**3**) and (**3**,**3***) remain roughly unchanged. However, one observes an increase of the Ta–P–Me angle in the (*y*) conformer (113.6°, Cp*–Me repulsions) with respect to the value (109.8°) calculated for (*x*). Thus, the P lone pair is pushed towards the unsubstituted Cp ring in (**3**,**3***). Such a tendency may lead to an energetically (and geometrically) unfavourable structure in the presence of two permethylated Cp* ligands and, consequently, may explain the experimental difficulties encountered upon neutralisation of (**2***,**2***) cations attempted for the isolation of (**3***,**3***) metallophos-

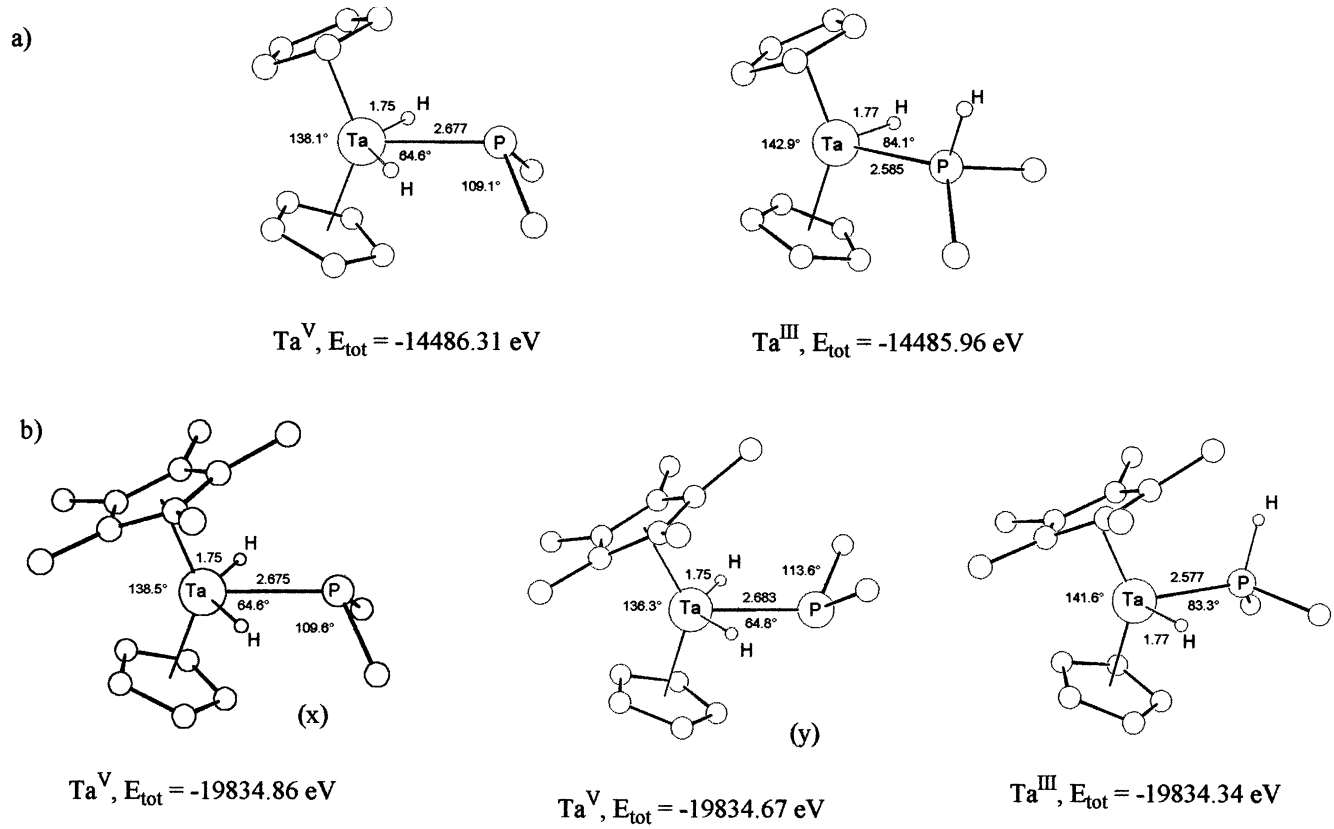

Fig. 4. Optimised geometries and total energies for Ta(V)–phosphide and Ta(III)–phosphine complexes. (a) $(C_5H_5)(C_5H_5)$, (b) $(C_5H_5)(C_5Me_5)$ series.

phides. For this last case, there are some indications on the ^{1}H NMR spectrum of the crude material that (**3***,**3***) is formed, but we were not able to isolate it. It is worth noting that the attempts of optimisation of permethylated metallocene Ta(V) or Ta(III) structures (**3***,**3***) failed with our standard computational DFT method. Another interesting observation arising from this study concerns the Ta–P bond lengths. The Ta–P optimised distances are shorter for Ta–PMe_2H bonds (2.58 Å) than for Ta–PMe_2 ones (2.68 Å), confirming the trends observed in crystal structures of (**2**,**2′**,**Me**) (phosphine, 2.53 Å) and of $Cp_2TaH_2PPh_2$ (phosphide, 2.59 Å) [6b].

2.3. Bimetallic phosphido bridged complexes

The neutral complexes (**3**) easily react with metal–carbonyls of Group 6 M′$(CO)_6$ (M′ = Cr, Mo, W) giving rise to the monobridged Ta(μ-PR_2)M′ (**4**) and the dibridged Ta (μ-PR_2, H) M′ (**5**) isolated species, while with $Fe(CO)_5$, $Fe_2(CO)_9$ or (BDA)$Fe(CO)_3$ the dibridged structures (**5**) are directly formed [14]. However, no crystal structure in the series of monobridged compounds $M^V(H)_2$(μ-PR_2)M′ has been reported to date, probably because they easily transform to the dibridged structures during crystallisation.

In the series of bimetallic dibridged complexes (μ-PR_2,H) we have already reported two crystal structures of Group 5 (d^0) metallocenes $Cp_2Ta(H)$(μ-PMe_2,H)Cr-$(CO)_4$ [5b] and $Cp_2Nb(H)$(μ-PPh_2,H)$W(CO)_4$ [18], and describe here the third member in this series, the Ta–Fe complex $Cp_2Ta(H)$(μ-PPh_2,H)$Fe(CO)_3$ (**5**,**5Fe**). There is one dinuclear organometallic and one solvent (acetone) molecule in the asymmetric unit of $P2_1/n$ space group. The metallic fragments have their usual pentacoordinated (Ta) and trigonal bipyramidal (Fe) geometries (Fig. 5). The Ta, H1, H2, P, Fe, C3 and O3 atoms roughly lie in the plane bisecting that of the Cp rings. The apical Fe–C3 (CO trans to H) distance of 1.71(2) Å in the iron polyhedron is apparently, but not significantly, shorter than the equatorial ones (1.75(2) Å). It may suggest, however, that a slight compression of iron bipyramide is due to the donor *trans* effect of the hydride [19]. These distances fall in a lower part of the range of Fe–CO bond lengths observed in $Fe(CO)_n$ units (1.73–1.81 Å; $n = 3$–5) [20] indicating a rather high electron density (due to the π-back bonding) retained on the $Fe(CO)_3$ fragment in (**5**,**5Fe**). Note, that the mean Fe–CO bond length reported for the structurally related electron rich discrete [*cis*-$HFe(CO)_3$-$P(OPh)_3]^-$ anion (1.73(1) Å) [20a] is essentially the same. The electron density on the $Fe(CO)_3$ fragment

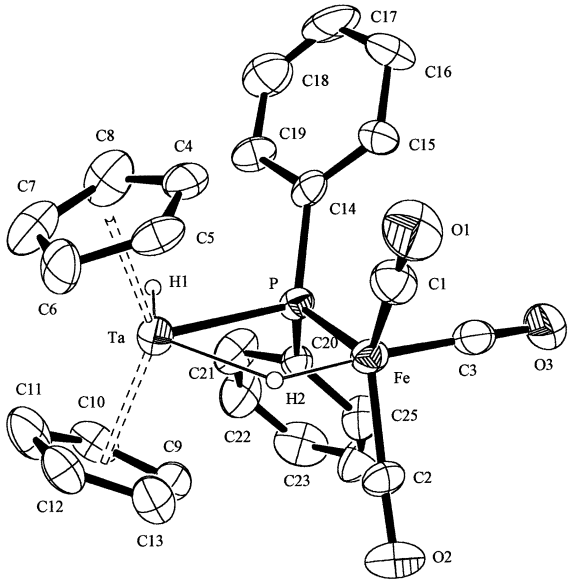

Fig. 5. ORTEP drawing of (**5**,**5Fe**) (30% probability level). Selected bond lengths (Å) and angles (°): Ta–Fe 3.111(2); Ta–P 2.548(3); Ta–H1 1.82(13); Ta–H2 2.01(12); Fe–P 2.168(4); Fe–H2 1.49(12); Fe–C1 1.740(17); Fe–C2 1.757(14); Fe–C3 1.708(16); Ta–CP1 2.059; Ta–CP2 2.068; H1–Ta–H2 124(5); H1–Ta–P 58(4); H2–Ta–P 67(3); Ta–P–Fe 82.1(1); Ta–H2–Fe 125(3); CP1–Ta–CP2 135.2.

is still higher in (**5**,**5*Fe**) as indicated by its ν(CO) IR data (see Section 4). All these observations argue for no (or little) direct electron density exchange between the metals. Effectively, the Ta–Fe separation in (**5**,**5Fe**) of 3.111(2) Å is longer than in $Cp_2Nb(\mu\text{-}PPh_2,CO)Fe(CO)_3$ for which a direct Nb–Fe bond (2.884(2) Å) has been postulated and confirmed by EHMO calculations [3c]. Thus, the electron density exchange (bonding) between the $Cp_2Ta(H)(\mu\text{-}PPh_2,H)$ and $Fe(CO)_3$ fragments in (**5**,**5Fe**) operates via the bridging atoms and not through a direct Ta–Fe bond. Such a difference may be rationalised in a frame of singular properties of 's' (bridging hydride) and 'p' (bridging carbon (CO)) atomic orbitals which are able to orient the phases (lobes) of metal atomic orbitals in these bimetallic systems either towards the 'in phase' (bonding M–M′) interaction (as in the case of $M(\mu\text{-}PR_2,CO)M'$) or towards the opposite phases (antibonding M–M′) as in the case of the hydride bridge in the $M(\mu\text{-}PR_2,H)M'$ system.

3. Conclusion

In this contribution we attempted to clarify the crucial points of tantalocene–hydride–phosphorus chemical systems: the regiochemistry of insertion of PR_2 (from PR_2Cl) into the central Ta–H bond of trihydrides Cp_2TaH_3 (formation of symmetrical metallophosphonium cations) and the influence of substitution on the cyclopentadienyl ring on the site (Ta–H or P–H) of neutralisation in these organometallic cations with strong bases. The proposed pathways for these reactions have been confirmed by DFT calculations. Good electron donor cyclopentadienyl ligands (Cp′ and Cp*) favour the formation of Ta(V)–phosphide structures when R is also a donor (Me). A supposition that the metal–phosphide (PR_2) bonds are longer than the metal–secondary phosphine (PR_2H) ones, because of a more diffuse nature of the phosphorus lone pair than that of the P–H bond, is also confirmed by DFT calculations.

4. Experimental

Nuclear magnetic resonance spectra were recorded on a Bruker AC 200 instrument at 200 MHz for ^1H and 81 MHz for ^{31}P. The chemical shifts are reported in ppm relative to $SiMe_4$ (^1H) and external H_3PO_4 (^{31}P–$\{^1H\}$). Infrared spectra were obtained with a Nicolet 250 spectrometer, with the sample in solution in thf. Elemental analyses were performed on a EA 1108 CHNS-O FISONS Instruments apparatus.

All manipulations were performed under a dry nitrogen atmosphere by standard techniques. Solvents were dried and deoxygenated by using conventional procedures. $Cp_2TaH_2(PPh_2)$ [5a,6b], $CpCp'TaH_3$ [12], $CpCp^*TaH_3$, $Cp^*_2TaH_3$ [21] and $Fe(CO)_3$(BDA) [22] were prepared according to literature methods.

4.1. Preparation of [CpCp*TaH$_2$(PMe$_2$H)]Cl (2,2*,Me)

To a $C_6H_5CH_3$ solution (30 ml) of Cp^*CpTaH_3 (0.19 g, 0.5 mmol) was added 1 equiv. of PMe_2Cl. After 15 min of stirring, a white precipitate was filtered, washed with $C_6H_5CH_3$ and C_5H_{12} and dried under vacuum (yield 0.22 g, 92%). ^1H NMR (200 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = 5.69$ (s, Cp), 5.29 (dh, $^1J(H, P) = 348.4$ Hz, $^3J(H, H) = 6.5$ Hz, PH), 2.19 (s, Cp*), 1.76 (dd, $^2J(H, P) = 10.7$ Hz, $^3J(H, H) = 6.5$ Hz, Me), -0.58 (d, $^2J(H, P) = 75.1$ Hz, TaH). $^{31}P\{^1H\}$ NMR (81 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = -43.1$ (s, PMe_2H).

4.2. Preparation of CpCp*TaH$_2$(PMe$_2$) (3,3*,Me)

A saturated aq. solution of KOH (10 ml) was added to the dried salt $[Cp^*CpTaH_2(PMe_2H)]Cl$ (0.24 g, 0.5 mmol). The mixture was stirred for 30 min. The product was extracted with $C_6H_5CH_3$ (2×15 ml) and the organic layer was evaporated under vacuum (yield 0.2 g, 90%). ^1H NMR (200 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = 4.99$ (s, Cp), 2.02 (s, Cp*), 1.27 (d, $^2J(H, P) = 2.9$ Hz, Me), -0.67 (d, $^2J(H, P) = 56.1$ Hz, TaH). $^{31}P\{^1H\}$ NMR (81 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = -81.3$ (s, PMe_2).

4.3. Preparation of $[Cp^*_2TaH_2(PMe_2H)]PF_6$ (**2***,**2***,**Me**)

To a $C_6H_5CH_3$ solution (30 ml) of $Cp^*_2TaH_3$ (0.23 g, 0.5 mmol) was added 1 equiv. of PMe_2Cl. After 15 min of stirring, a white precipitate was filtered, washed with $C_6H_5CH_3$ and C_5H_{12} and dried under vacuum. The resulting white powder was dissolved in water (10 ml). One equiv. of a water solution of NH_4PF_6 was added. A white precipitate was instantaneously formed which was filtered washed with water a dried under vacuum (yield 0.25 g 75%). ^{1}H NMR (200 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = 5.15$ (dh, ^1J(H, P) = 344.0 Hz, ^3J(H, H) = 7.1 Hz, PH), 2.06 (s, Cp*), 1.67 (dd, ^2J(H, P) = 9.3 Hz, ^3J(H, H) = 7.3 Hz, Me), 0.00 (d, ^2J(H, P) = 77.1 Hz, TaH). ^{31}P{^{1}H} NMR (81MHz, CD_3COCD_3, 25 °C, TMS): $\delta = -50.2$ (s, PMe_2H), -146.3 (h, ^1J(P, F) = 703.2 Hz, PF_6).

4.4. Preparation of $[Cp^*_2TaH_2(PPh_2H)]PF_6$ (**2***,**2***,**Ph**)

The procedure was the same as above starting from $Cp^*_2TaH_3$ (0.23 g, 0.5 mmol) and 1 equiv. of PPh_2Cl (yield 0.27 g, 80%). ^{1}H NMR (200 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 7.66$–7.30 (m, Ph), 6.86 (d, ^1J(H, P) = 356.2 Hz, PH), 1.97 (s, Cp*), 0.67 (d, ^2J(H, P) = 73.7 Hz, TaH). ^{31}P{^{1}H} NMR (200 MHz, $CDCl_3$, 25 °C, TMS): $\delta = 2.3$ (s, PPh_2H), -146.3 (h, ^1J(P, F) = 703.2 Hz, PF_6).

4.5. Preparation of $[CpCp'TaH_2(PMe_2H)]PF_6$ (**2**,**2′**,**Me**)

To a $C_6H_5CH_3$ solution (30 ml) of $Cp'CpTaH_3$ (0.2 g, 0.5 mmol) was added 1 equiv. of PMe_2Cl. After 15 min of stirring, a white precipitate was filtered, washed with $C_6H_5CH_3$ and C_5H_{12} and dried under vacuum. To a water solution (20 ml) of this salt was added 1 equiv. of NH_4PF_6. A white precipitate was instantaneously formed. After 10 min of stirring, it was filtered, washed with cold water and dried under vacuum (yield 0.22 g, 72%). Recrystallization from thf gave colourless crystals. *Anal.* Calc. for $C_{18}H_{31}F_6P_2Ta$: C, 35.81; H, 5.23. Found: C, 35.74; H, 5.16%. ^{1}H NMR (200 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = 5.75$ (s, Cp), 5.21 (d, ^3J(H, P) = 3.5 Hz, CH), 5.54 (dh, ^1J(H, P) = 360 Hz, ^3J(H, H) = 6 Hz, PH), 2.33 (s, CH_3), 1.79 (dd, ^2J(H, P) = 9.7 Hz, ^3J(H, H) = 6 Hz, PMe), 1.27 (s, ^{t}Bu), -0.82 (d, ^2J(H, P) = 74 Hz, TaH). ^{31}P NMR (81 MHz, CD_3COCD_3, 25 °C, TMS): $\delta = -54.0$ (d, ^1J(H, P) = 360 Hz, PMe_2H), -141.0 (h, ^1J(P, F) = 708 Hz, PF_6).

4.6. Preparation of $CpCp'TaH(PMe_2H)$ and $CpCp'TaH_2(PMe_2)$ (**3**,**3′**,**Me**)

The procedure was the same as for (**3**,**3***,**Me**), starting from (**2**,**2′**,**Me**) (0.1 g, 0.2 mmol). The two complexes have not been separated from the mixture. The NMR data of each complex are given from the spectra of the mixture.

4.7. $Cp'CpTaH(PMe_2H)$ (60%)

^{1}H NMR (200 MHz, C_6D_6, 25 °C, TMS): $\delta = 5.10$ (dh, ^1J(P, H) = 309 Hz, ^3J(H, H) = 6 Hz, PH), 4.30 (d, J(P, H) = 2 Hz, Cp), 3.82 (dd, J(P,H) = 5Hz, J(H, H) = 3.3 Hz, CH) 3.41 (dd, J(P, H) = 3 Hz, J(H, H) = 3.3 Hz, CH), 1.96 (s, Me), 1.95 (s, Me), 1.28 (s, ^{t}Bu), 1.23 (dd, ^2J(P, H) = 7Hz, ^3J(H, H) = 6 Hz, PMe_2), 1.05 (dd, ^2J(P, H) = 6 Hz, ^3J(H, H) = 6Hz, PMe_2), -8.82 (d, ^2J(P, H) = 22 Hz, TaH). ^{31}P NMR (81 MHz, C_6D_6, 25 °C, TMS): $\delta = -46.8$ (d, ^1J(P, H) = 309 Hz, PMe_2H).

4.8. $Cp'CpTaH_2(PMe_2)$ (40%)

^{1}H NMR (200 MHz, C_6D_6, 25 °C, TMS): $\delta = 4.70$ (s, Cp), masked (CH), 2.08 (s, Me), 1.77 (d, ^2J(P, H) = 3.7 Hz, PMe_2), 1.27 (s, ^{t}Bu), -0.51 (d, ^2J(P, H) = 53 Hz, TaH). ^{31}P NMR (81 MHz, C_6D_6, 25 °C, TMS): $\delta = -113.7$ (d, ^2J(P, H) = 53 Hz, PMe_2).

4.9. Preparation of $Cp_2TaH(\mu\text{-}H)(\mu\text{-}PPh_2)Fe(CO)_3$ (**5**,**5**,**Fe**)

To a thf solution (30 ml) of $Cp_2TaH_2(PPh_2)$ (0.50 g, 1 mmol) was added 1 equiv. of $Fe(CO)_3$(BDA). The mixture was stirred for 2 h at room temperature (the reaction was monitored by IR spectroscopy). The solvent was removed under vacuum and the crude reaction product was chromatographed on silica gel with $C_6H_5CH_3$ as eluent affording a red bimetallic complex (72% yield). *Anal.* Calc. for $C_{25}H_{22}FeO_3PTa$: C, 47.05; H, 3.47. Found: C, 47.25; H, 3.32%. IR (thf): ν_{CO}, 1989, 1940, 1916 cm^{-1}. ^{1}H NMR (200 MHz, C_6D_6, 25 °C, TMS): $\delta = 8.16$–7.89 (m, Ph), 7.21–6.89 (m, Ph), 4.43 (s, Cp), -1.36 (dd, ^2J(H, H) = 8.9 Hz, ^2J(H, P) = 46.2 Hz, H), -10.11 (dd, ^2J(H, H) = 8.9 Hz, ^2J(H, P) = 43.3 Hz, H). ^{31}P{^{1}H} NMR (81MHz, C_6D_6, 25 °C, TMS): $\delta = 177.2$ (s, PPh_2). Crystals for X-ray analysis have been grown from acetone solution.

4.10. Preparation of $CpCp^*TaH(\mu\text{-}H)(\mu\text{-}PMe_2)Fe(CO)_3$ (**5**,**5***,**Fe**)

The procedure was the same as above starting from $Cp^*CpTaH_2(PMe_2)$. *Anal.* Calc. for $C_{20}H_{28}FeO_3PTa$: C, 41.12; H, 4.83. Found: C, 41.04; H, 4.81%. 4.11. X-ray crystallography

All measurements have been carried out at 296 K on an Enraf–Nonius CAD4 diffractometer. The pertinent crystallographic data are given in Table 1. The unit cells have been determined from 25 randomly selected reflections (CAD4-Express) [23]. Intensity data have been reduced with PROCESS contained in MolEN package [24] with neutral–atom scattering factors. Both structures were solved by direct methods (SHELXS-97) [25] and refined by using the SHELXL-97 library [26]. All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrides in both structures and the hydrogen atom bound to phosphorus in (**2**,**2′**,**Me**) were found from difference Fourier synthesis and refined isotropically. All other hydrogen atoms were placed in calculated positions and included in refinements in a riding model with isotropic U(H) = 1.3 U_{eq}(C). The acetone molecule in (**5**,**5**,**Fe**) was refined isotropically.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with CCDC (12 Union Road, Cambridge CB2 1EZ, UK) and are available on request quoting the deposition numbers CCDC No. 147080 and 147081 for compounds **2**,**2′Me** and **5**,**5Fe**, respectively (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction of $[Os_3(CO)_{10}(\mu\text{-}dppm)]$ (**1**) with H_2S at 110 °C leads to the known compound $[(\mu\text{-}H)_2Os_3(CO)_7(\mu_3\text{-}S)(\mu\text{-}dppm)]$ (**2**) (11%) and the new compound $[Os_3(CO)_7(\mu_3\text{-}CO)(\mu_3\text{-}S)(\mu\text{-}dppm)]$ (**3**) (65%). Treatment of **1** with thiourea at 110 °C gives **2** (70%). The analogous reaction of **1** with tetramethylthiourea at 110 °C yielded two 50 electron stereoisomeric compounds **4a** and **4b** with stoichiometry $[Os_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-}dppm)]$ in 16 and 64% yields, respectively. The new compounds **3**, **4a** and **4b** were characterized by spectroscopic data and X-ray diffraction studies. Compound **3** reacts with tetramethylthiourea at 110 °C to give **4a** and **4b**. Hydrogenation of **3** at 1 atmosphere pressure at 151 °C gives **2**. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Triosmium cluster; Tetramethylthiourea; Desulfurization; Sulfido; X-ray structures

1. Introduction

There is considerable interest in the synthesis, structure and reactivity of sulfido triosmium carbonyl clusters. The most important simple sulfido triosmium clusters are $[Os_3(\mu_3\text{-}CO)(CO)_9(\mu_3\text{-}S)]$ (**5**) and $[Os_3(CO)_9(\mu_3\text{-}S)_2]$ (**6**) together with their corresponding dihydrides $[(\mu\text{-}H)_2Os_3(CO)_9(\mu_3\text{-}S)]$ (**7**) and $[(\mu\text{-}H)_2Os_3(CO)_8(\mu_3\text{-}S)_2]$ (**8**) [1,2]. The synthesis of sulfido triosmium clusters has been tackled from a number different routes including the cleavage of carbon–sulfur bond of the coordinated organosulfur ligands, direct reaction of $[Os_3(CO)_{12}]$ with elemental sulfur, with hydrogen sulfide or with carbon disulphide. For example, the cluster **5** along with **6** and various other Os_4 and Os_6 sulfido clusters have been synthesized by desulfurization of the coordinated thiolato ligand in $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}SPh)]$ (**9**) [3]. The distribution of the products can be controlled by performing the reaction under a pressure of CO and at 120 atm it is possible to obtain just **6**, $[Os(CO)_5]$ and C_6H_6 [4]. However, the UV decomposition of **9** under CO is more useful and gives **5** in moderate yield [5]. The reaction mixture is purged with H_2 during photolysis to give **7** while treatment with COS gives **6** [5]. Another good route to the simple clusters is from *cyclo*-SCH_2CH_2, which reacts with $[Os_3(CO)_{12}]$ to give **5** and **6** [6]. Hydrogen sulfide (H_2S) reacts with $[Os_3(CO)_{12}]$ at 128 °C to give **7** in almost quantitative yields [7]. Elemental sulfur reacts with $[Os_3(CO)_{12}]$ at 128 °C to yield **6**, **8** and $[(\mu\text{-}H)_2Os_4(CO)_{12}(\mu_3\text{-}S)_2]$ [8]. Carbon disulfide (CS_2) reacts with $[Os_3(CO)_{12}]$ to form $[Os_3(CO)_8(\mu_3\text{-}S)_2(CS)]$ [9] and with the lightly-stabilized cluster $[(\mu\text{-}H)_2Os_3(CO)_8(\mu_3\text{-}S)(NCMe)]$ it yields $[(\mu\text{-}H)_2Os_3(CO)_8(\mu_3\text{-}S)_2(CS)]$ [10]. Sulfurdimide, $Me_3SiN{=}S{=}NSiMe_3$, reacts with $[Os_3(CO)_{12}]$ at 128 °C to give $[Os_3(CO)_9(\mu_3\text{-}S)(\mu_3\text{-}NSiMe_3)]$ [11]. Recently, it has been reported that *N*-(*p*-methoxybenzoyl)-*S*-benzoylsulphenamide reacts with $[Os_3(CO)_{10}(MeCN)_2]$ at room temperature to yield **5** and $[Os_6(CO)_{20}(\mu_4\text{-}S)(MeCN]$ [12] (Fig. 1).

The reactivity of thioureas with $Ru_3(CO)_{12}$ has extensively been studied by Süss-Fink and coworkers [13–20]. These reactions are associated with the cleavage of C–S, C–N, N–H and/or C–H bonds of the alkyl substituted derivatives, and they depend markedly on the substituent groups and also on the reaction conditions. For example, thiourea and its dimethyl derivative react with $[Ru_3(CO)_{12}]$ to give the N–H activated product $[(\mu\text{-}H)Ru_3(CO)_9(\mu_3\text{-}\eta^2\text{-}NRCSNHR)]$ (R = H or Me) [13] whereas the analogous reaction with di-*tert*-butylthiourea yields $[(\mu\text{-}H)Ru_3(CO)_8(\mu_3\text{-}S)(\eta^2\text{-}CH_2\text{-}CMe_2NHCNHBu^t)]$ and $[(\mu\text{-}H)Ru_3(CO)_9\{\mu_3\text{-}SRu(CO)_3\text{-}(\eta^2\text{-}CH_2CMe_2NHCNHBu^t)\}]$ in which both C=S and C–H bonds of the ligand have been cleaved [18]. In comparison to the extensive ruthenium carbonyl cluster chemistry of thiourea ligands, only a few examples concerning the reactivity of these ligands with triosmium carbonyl clusters are known [21–23]. For example, Azam et al. [22] and others [21] have reported that thiourea and its diphenyl analogue react with the lightly stabilized cluster $[Os_3(CO)_{10}(MeCN)_2]$ to give the edge and triply bridging clusters $[(\mu\text{-}H)Os_3(CO)_{10}(\mu\text{-}NRC\text{-}SNHR)]$ and $[(\mu\text{-}H)Os_3(CO)_9(\mu_3\text{-}\eta^2\text{-}NRCSNHR)]$ (R=H or Ph). We also reported that tetramethylthiourea reacts with $[Os_3(CO)_{12}]$ in presence of a methanolic solution of Me_3NO and H_2O at 80 °C to give $[Os_3(CO)_{11}\text{-}\{\eta^1\text{-}SC(NMe_2)_2\}]$, $[Os_3(CO)_9(\mu\text{-}OH)(\mu\text{-}OMeCO)\{\eta^1\text{-}SC(NMe_2)_2\}]$ and $[(\mu\text{-}H)Os_3(CO)_8(\mu_3\text{-}S)(\mu\text{-}OMeCO)\{\eta^1\text{-}SC(NMe_2)_2\}]$ [23]. As part of a study of the reactivity of thiourea ligands with trimetallic clusters, we have investigated the reactions of $[Os_3(CO)_{10}(\mu\text{-}dppm)]$ with thiourea, tetramethylthiourea and H_2S, and report here the synthesis, structures and reactivity of the sulphido triosmium clusters $[Os_3(CO)_7(\mu_3\text{-}CO)(\mu_3\text{-}S)(\mu\text{-}dppm)]$ and the two isomers of $[Os_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-}dppm)]$.

2. Results and discussion

The reaction of $[Os_3(CO)_{10}(\mu\text{-}dppm)]$ (**1**) with H_2S at 110 °C yielded $[(\mu\text{-}H)_2Os_3(\mu_3\text{-}S)(CO)_7(\mu\text{-}dppm)]$ (**2**) and $[Os_3(\mu_3\text{-}CO)(\mu_3\text{-}S)(CO)_7(\mu\text{-}dppm)]$ (**3**) (Scheme 1). Compound **2** was previously reported from the reaction of $[(\mu\text{-}H)_2Os_3(CO)_9(\mu_3\text{-}S)]$ with dppm and structurally characterized [24]. Compound **3** is now characterized by spectroscopic methods together with a crystal structure determination. In the crystals of **3**, there are two independent molecules in an asymmetric unit, one of which is shown in Fig. 2. Selected bond distances and angles in the two molecules are compared in Table 1. The structures of the two molecules are very similar with only minor differences in the orientations of the phenyl rings on the phosphorus atoms. For the sake of brevity, the bond lengths and angles in molecule 1 are quoted in the following discussion. The structure of **3**

[a] Average value.

consists of an Os_3 triangle with three osmium–osmium bonds containing seven terminal and one triply bridging carbonyl ligands, a μ_3-sulphido ligand and a bridging dppm ligand. Two of the metal–metal bonds, Os(1)–Os(3) = 2.8378(11) Å and Os(2)–Os(3) = 2.8323(11) Å, are equal and only marginally longer than the third bond, Os(1)–Os(2) = 2.8245(10) Å. There are no significant differences between the bridged and unbridged edges. This is in contrast with the structure of **2**, where the unbridged Os–Os edge is significantly shorter than the two bridged Os–Os edges [2.7658(6) vs 2.8981(4) and 2.9212(6) Å] [24]. All three bonds in **3** are significantly shorter than those found in $[Os_3(CO)_{12}]$ {2.877(3) Å} [25]. The triply bridging carbonyl and the sulfido ligands lie on opposite sides of the Os_3 triangle resulting in a trigonal bipyramidal geometry for the $Os_3(S)(CO)$ core. The μ_3-S is bound to the Os_3 triangle in a symmetrically, with the Os–S distances lying in the narrow range, 2.385(4)–2.400(4) Å and the average value {2.393(4) Å} is comparable with those found for the triply bridging sulfido ligands in **5** {2.378(3) Å} [5], $[Os_4(CO)_{12}(\mu_3\text{-S})]$ {2.381(3) Å} [26] and $[(\mu\text{-H})_2Os_3(CO)_7(\mu_3\text{-S})(\mu\text{-dppm})]$ {2.389(2) Å} [24]. In contrast, the μ_3-CO group is bonded asymmetrically to the Os_3 triangle. Two of these distances Os(3)–C(1) = 2.151(14) Å and Os(2)–C(1) = 2.16(2) Å are equal, and the third Os(1)–C(1) = 2.270 (14) Å is significantly longer. These values are close to those involving the μ_3-CO ligand in **5**, which range from 2.157(12) to 2.188(12) Å [5]. As expected, the Os–C distances involving the terminal CO groups are considerably shorter {average value = 1.91(2) Å}. The Os–P bond distances in **3** {Os(2)–P(1) = 2.339 (4) and {Os(3)–P(2) = 2.345(4) Å} are comparable to those found in **1** {2.332(3) and 2.312(3) Å} [27]. Overall, the structure of **3** is similar to that of **5** [5] if one considers that an equatorial carbonyl group on each of the two osmium atoms is replaced by the Ph_2P groups of the dppm ligand. The complex contains 48 valence electrons and is electron precise with three metal–metal bonds.

The spectroscopic properties of **3** are consistent with the solid state structure being maintained in solution. The infrared spectrum shows, in addition to absorptions due to terminal carbonyls, a weak absorption at 1820 cm^{-1} indicating the presence of a triply bridging carbonyl ligand. In the ^1H NMR spectrum, the multiplets centered at δ 3.67 and 4.83 are assigned to the methylene protons while that at δ 7.31 is due to the phenyl protons of dppm ligand. The $^{31}P\text{-}\{^1H\}$ spectrum contains a singlet at δ 20.4 indicating equivalent ^{31}P nuclei. The mass spectrum displays the molecular ion peak at m/z 1210 and fragmentation peaks corresponding to the loss of up to eight carbonyl ligands. Compound **3** reacts with molecular hydrogen at 1 atmosphere pressure at 151 °C to give **2** in 50% yield. However, attempts to convert **2** into **3** by prolong thermolysis at 110 °C were not successful.

The reaction of **1** with thiourea at 110 °C gave **2** resulting from the oxidative cleavage of N–H and C=S bonds of thiourea. In order to explore the effect of alkyl substituent groups of thiourea ligands on their reactivity with **1**, we investigated the reaction of **1** with tetramethylthiourea. The reaction of **1** with tetramethylthiourea at 110 °C yielded two isomeric compounds **4a** and **4b** with stoichiometry $[Os_3(CO)_7(\mu_3\text{-S})_2(\mu\text{-dppm})]$, that were characterized by spectroscopic and crystallographic methods. The structure of **4a** (Fig. 3; Table 2) consists of an open cluster of three osmium atoms with two metal–metal bonds, Os(1)–Os(3) = 2.8620(2), Os(2)–Os(3) = 2.8251(8) Å, a bridging dppm ligand and two triply bridging sulfido ligands. The Os(1)···Os(2) distance at 3.6196(14) Å is clearly nonbonding and shorter than that observed in **6**

{3.662(1) Å} [28]. Two of the osmium atoms Os(1) and Os(2) are six-coordinate, whilst the third Os(3) is seven-coordinate. The Os–S distances to the seven-coordinated osmium atom in **4a** {Os(3)–S(1) = 2.430(3), Os(3)–S(2) = 2.432(3) Å} are slightly longer than those to the six-coordinate osmium atoms {2.392(3)–2.407(3) Å} and also than the corresponding values in **3**. The dppm ligand bridges the two basal osmium atoms in the axial positions and the Os–P bond distances {Os(1)–P(1) = 2.286(3) Å, Os(2)–P(2) = 2.302(3)} are slightly shorter than those found in **1** [27] and **3**. Overall, compound **4a** has a square pyramidal structure with the two bridged Os atoms and two sulfur atoms alternating in the basal plane and the third osmium atom at the apex of the pyramid.

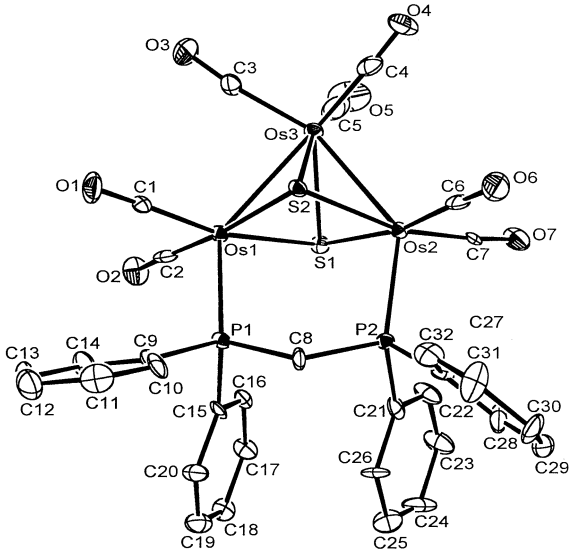

Fig. 3. Molecular structure of $[Os_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-dppm})]$ **4a** showing the atom labelling scheme. Thermal ellipsoids are drawn at 50% probability level. The hydrogen atoms are omitted for clarity.

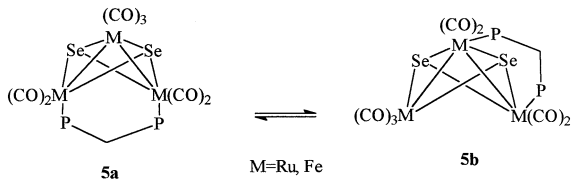
P(1)–Os(2)–S(2)	85.41(14)	P(2)–Os(3)–S(1)	128.64(14)
P(2)–Os(3)–S(2)	95.8(2)		

The structure of **4b** (Fig. 4; Table 3) consists of an Os_3 triangle involving two metal–metal bonds {Os(2)–Os(3) = 2.8412(12), Os(1)–Os(3) = 2.7910(11) Å} and a nonbonding osmium–osmium separation {Os(1)···Os(2) = 3.6760(14) Å}. In contrast to **4a**, the dppm ligand in **4b** bridges one of the bonded pair of osmium atoms Os(2) and Os(3) and the two Os–P distances are significantly different. The shorter Os(3)–P(2) distance {2.316(4) Å, axial position, *transoid* to Os} is comparable to those observed in **4a** where the dppm bridges the basal osmium atoms in the axial positions {Os–P = 2.286(3) and 2.302(3) Å}. In comparison, the Os(2)–P(1) distance {2.362(4) Å, equatorial, *transoid* to S} is significantly longer. This is consistent with the suggestion that the Os–P interaction in the Ru_3S_2 *indo* clusters suffers a short of *trans* effect [29]. The dppm substitution on Os(2)–Os(3) edge causes



an important deformation in the cluster core, and the two Os–Os bond distances are significantly shorter than those in **4a**. The Os–S distances to the triply bridging sulfido ligands {Os(1)/Os(2)/Os(3)–S(1) = 2.386(4)/2.363(4)/2.432(4) and Os(1)/Os(2)/Os(3)–S(2) = 2.411(4)/2.428(4)/2.466(4) Å} are similar to those in **4a** and **6** [28], and as observed in **4a** the bonds with S(1) are slightly longer than those with the corresponding bonds to S(2).

The spectroscopic data of **4a** and **4b** are in accord with their solid state-structures. In the ^{31}P NMR spectra, as is expected, the minor isomer **4a** exhibits a singlet at δ 13.8 indicating equivalent ^{31}P nuclei while the major isomer **4b** shows two doublets at δ 9.5 and -20.3 indicating nonequivalence of the ^{31}P nuclei. In the ^{1}H NMR, in addition to the phenyl resonances, the isomer **4a** shows a triplet at δ 3.23 while the isomer **4b** shows two pseudo-quartets (dt, $J_{H-H} = 14.1$, $J_{H-P} = 10.5$ Hz) centered at δ 3.81 and 5.10. The pattern of ^{31}P NMR and ^{1}H NMR spectra of **4a** and **4b** is similar to that of $[Ru_3(CO)_7(\mu_3\text{-}Se)_2(\mu\text{-dppm})]$ which exists as an equilibrium mixture of two isomers in solution [30]. The mass spectrum of each isomer shows the molecular ion peak at m/z 1215 and fragment ions formed by the sequential loss of seven carbonyl groups. Compound **3** reacts with tetramethylthiourea at 110 °C affording **4a** and **4b**, which demonstrates that **3** is an earlier intermediate of **4a** and **4b** (Scheme 2).

In summary the reaction of the tetramethylthiourea with **1** provides a simple, one step route to the two isomers (**4a** and **4b**) of the open-triangular-nido cluster $[Os_3(CO)_7(\mu_3\text{-}S)_2(\mu\text{-dppm})]$ through oxidative transfer of the sulfur atoms to the low-valent osmium centres. The corresponding ruthenium and iron analogues $[M_3(CO)_7(\mu_3\text{-}Se)_2(\mu\text{-dppm})]$ have recently been reported

Scheme 2.

Scheme 3.

from the reaction of $[M_3(CO)_{12}]$ (M = Fe or Ru) with $dppmSe_2$ [31,32]. It was also suggested [29] that these compounds exist as a mixture of two isomers in solution because of the reversible migration of a metal–metal bond from one side of the open triangle to the basal plane resulting in the linking of the two metal atoms (Scheme 3). In the present work, we have successfully isolated the isomers **4a** and **4b** by careful chromatographic separation and characterized them structurally. It is also suggested that intramolecular fluxional processes are faster for ruthenium and iron compounds than for osmium. Another interesting aspect of the present study is the synthesis of **3** from the reaction of **1** with H_2S which reacts with tetramethylthiourea to give **4a** and **4b** and this shows that **3** is an earlier intermediate to **4a** and **4b**.

3. Experimental

All manipulations were carried out under N_2 atmosphere by employing standard Schlenk techniques. The solvents were of reagent grade and distilled from appropriate drying agents. The infrared spectra were recorded on a Shimadzu 8101 spectrophotometer. $^{31}P\{^{1}H\}$- and ^{1}H NMR spectra were obtained by use of a Bruker AC 200 spectrometer. Chemical shifts are referenced to internal TMS $\{^{1}H\}$ and to external 85% H_3PO_4 $\{^{31}P\}$. Mass spectra were recorded on a Varian Mat 312 mass spectrometer. Elemental analyses were carred out at the microanalytical Laboratory of the Institut für Anorganische and Analytical Chemie, Universität Freiburg, Germany. The cluster $[Os_3(CO)_{10}(\mu\text{-dppm})]$ was prepared according to the published procedure [33]. Tetramethylthiourea and thiourea were purchased from Aldrich and used as received.

3.1. Reaction of $[Os_3(CO)_{10}(dppm)]$ (1) with H_2S

Hydrogen sulphide gas was bubbled through a refluxing $C_6H_5CH_3$ solution (50 cm^3) of **1** (0.105 g, 0.085 mmol) for 2 h. The solvent was removed under vacuum and the residue chromatographed by TLC on silica gel. Elution with C_6H_{14}–CH_2Cl_2 (2:1, v/v) developed three bands. The first moving band gave unconsumed **1** (0.005 g), the second band gave $[(\mu\text{-}H)_2Os_7(CO)_7(\mu_3\text{-}S)(dppm)]$ (**2**) (0.011 g, 11%) and the third band yielded $[Os_3(\mu_3\text{-}CO)(CO)_7(\mu_3\text{-}S)(dppm)]$ (**3**) (0.067 g, 65%) as yellow crystals after recrystallization from C_6H_{14}–CH_2Cl_2 at room temperature (r.t.) by slow evaporation of the solvents. Spectroscopic and analytical data for **3**: (*Anal.* Calc. for $C_{33}H_{22}O_8Os_3P_2S$: C, 32.72; H, 1.83. Found: C, 32.81; H, 1.93%). IR (νCO, CH_2Cl_2): 2073s, 2017vs, 1995s, 1962m cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 3.67 (m, 1H), 4.83 (m, 1H), 7.31 (m, 20H); $^{31}P\{^{1}H\}$ NMR: δ 20.4 (s); mass spectrum: m/z 1210.

[a] Details in common: fast area detector, Mo Kα, $\lambda = 0.71069$ Å, 150 K, triclinic, space group $P\bar{1}$ full-matrix least-squares on F^2 (SHELXL-96).
[b] Number of data with [$I>2\sigma(I)$]:6881 (**3**), 4062 (**4a**), and 3652 (**4b**).

3.2. Reaction of **1** with thiourea

A $C_6H_5CH_3$ solution (25 cm^3) of **1** (0.110 g, 0.089 mmol) and thiourea (0.014 g, 0.184 mmol) was heated to reflux for 4 h. A similar chromatographic separation to that above afforded **2** (0.074 g, 70%).

3.3. Reaction of **1** with tetramethylthiourea

To a $C_6H_5CH_3$ solution (30 cm^3) of **1** (0.200 g, 0.162 mmol) was added tetramethylthiourea (0.107 g, 0.809 mmol) and the reaction mixture was heated to reflux for 6 h. Chromatographic separation as above gave two bands which afforded two isomeric compounds **4a** (0.031 g, 16%) and **4b** (0.126 g, 64%) as yellow crystals. Spectroscopic and analytical data for **4a**: *Anal*. Calc. for $C_{32}H_{22}O_7Os_3P_2S_2$: C, 31.63; H, 1.82. Found: C, 31.85; H, 1.93%. IR (νCO, CH_2Cl_2): 2072s, 2057m, 2002vs, 1985w, 1942m cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 3.23 (t, 2H), 6.81–7.85 (m, 20H); ^{31}P{^{1}H}: δ 13.8 (s), mass spectrum: m/z 1215. Spectroscopic and analytical data for **4b**: *Anal*. Calc. for $C_{32}H_{22}O_7Os_3P_2S_2$: C, 31.63; H, 1.82. Found: C, 31.72; H, 1.90%. IR(νCO, CH_2Cl_2): 2071s, 2055m, 2002vs, 1987m, 1945m cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 3.81 (dt, $J_{H-H} = 14.1$, $J_{H-P} = 10.5$ Hz, 1H), 5.10 (m, 1H), 6.81–7.85 (m, 20H); ^{31}P{^{1}H}: δ 9.5 (d, $J = 37.5$ Hz), -20.3 (d, $J = 37.5$ Hz); mass spectrum: m/z 1215.

3.4. Reaction of **3** with H_2

Hydrogen gas was bubbled through a refluxing $C_6H_5CH_3$ solution (20 cm^3) of **3** (0.025 g, 0.021 mmol) for 2 h. The solvent was removed under vacuum and the residue was chromatographed as above to give **2** (0.012 g, 50%).

3.5. Reaction of **3** with tetramethylthiourea

To a $C_6H_5CH_3$ solution (25 cm^3) of **3** (0.045 g, 0.037 mmol) was added tetramethylthiourea (0.024 g, 0.181 mmol) and the reaction mixture refluxed for 4 h. The solvent was removed under vacuum and the residue chromatographed to give **4a** (0.007 g, 19%) and **4b** (0.028 g, 76%).

3.6. X-ray crystallography

Crystallographic measurements for **3**, **4a** and **4b** were made at 150 K on a FAST TV area-detector diffractometer positioned at the window of a rotating anode generator, using Mo Kα radiation ($\lambda = 0.71069$ Å) in a manner described previously [34]. In all cases the unit-cell parameters were obtained by least-squares refinement of the diffractometer angles for 250 reflections. The crystallographic data and the data collection and refinement details are presented in Table 4. All data sets were corrected for absorption using DIFABS [35]. The structures were solved by direct methods (SHELXS-86)

[36], developed via difference syntheses, and refined on F^2 by full-matrix-least squares (SHELXL-96) [37] using all unique data with intensities greater than zero. In all cases, the phenyl rings were treated as idealized hexagon (C–C = 1.390 Å, C–C–C = 120.0°), the nonhydrogen atoms were anisotropic, and the hydrogen atoms included in calculated positions (Riding model).

4. Supplementary material

Crystallographic data for the compounds have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 169489 (**3**), 169490 (**4a**) and 169491 (**4b**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-3360333 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The reaction of alkali–metal diperoxovanadate with vanadyl sulphate in the presence of EDTA afforded the dinuclear heteroligand peroxovanadates(V), $A_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$, A = Na (**1**) or K (**2**). The compounds were characterised by elemental analysis, magnetic susceptibility and spectral studies. The two vanadium(V) centres in the complex ion are bridged by an oxo group and a hexadentate EDTA ligand. One of the vanadium(V) centres of the dinuclear species contains a bidentate peroxide, whereas the other vanadium centre is bonded to a unidentate sulphate and water leading to hepta-co-ordination around each vanadium(V). Oxygen release reactions and molar conductance measurements revealed that the compounds were stable in solution. The compounds were resistant to catalase and were unable to oxidise NADH or bromide. It is proposed that this dinuclear complex species corresponds to the complex formed in solution responsible for EDTA induced inhibition of oxidation of NADH and bromide by a mixture of diperoxovanadate and vanadyl. © 2002 Published by Elsevier Science Ltd.

Keywords: Diperoxovanadate; Vanadyl; EDTA inhibition; EDTA bridged heteroligand peroxovanadates; Catalase resistance; Oxo-bridged peroxovanadates containing sulphate

1. Introduction

Diperoxovanadate is receiving importance as a biologically active vanadium compound. It mimicks insulin action [1] and was found to have antineoplastic activity [2,3]. An intermediate derived from diperoxovanadate was shown to stimulate oxidation of NADH [4]. It has been reported earlier by others [4–7] that diperoxovanadate (DPV) gains oxidant activity by complexing with vanadyl (V^{IV}) to form a highly reactive peroxo-bridged intermediate, $[OVOOVO(O_2)]^+$, which could act as oxidant species of NADH [4] and bromide [5], as well as inactivate glucose oxidase [6] or release oxygen as gas in the absence of any substrate [7]. Our studies on synthetic compounds with a 'VOOV' bridge of the type, $[V_2O_2(O_2)_3L_2]$ (L = amino acid or peptide) lent further support for such an intermediate as the powerful bromide oxidant at physiological pH [8,9].

One interesting finding of such studies was the inhibitory effect of certain organic ligating agents viz. EDTA, histidine, imidazole etc. on the above redox processes [4–9]. Such inhibition was found to be maximum in the presence of EDTA. EDTA induced inhibition was also reported to occur in the oxygen release reaction involving H_2O_2 and $VOSO_4$ [10]. The basis for such potent inhibition appeared to be the inactivation of the reactive peroxo intermediates by the ligands through complexation with V(V) and V(IV) centres. However, there has been a paucity of evidence on the exact identity of the actual species responsible for such an inhibitory effect [4–8].

We therefore, considered it worthwhile to investigate the reaction of DPV and VO^{2+} in presence of EDTA with an aim to ascertain the nature of the above inhibitory complex by attempting to isolate such species in the solid state. Moreover, it has been realised that any information related to the interaction of vanadate or vanadyl with ligands like EDTA may be relevant in addressing the role of vanadium in vanadate mediated inhibition or activation of enzymes [11,12]. In view of the continued search for stable peroxovanadate com-

PII: S0277-5387(01)01005-1

pounds suitable for therapeutic use [13–15], an additional goal of the present study was also to explore the possibility of gaining an access to newer heteroligand peroxovanadate compounds stable at physiological conditions.

We report here, an account of the reaction of alkali diperoxovanadate (ADPV) with $VOSO_4$ in presence of EDTA which led to the synthesis of novel dimeric peroxovanadates of the type $A_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$ thought to correspond to the inhibitor complex in the above redox processes. The compounds have been subjected to dissolution and reactivity studies in order to determine their nature and stability in solution.

2. Experimental

The chemicals used were all reagent grade products. Catalase and NADH were obtained from Sigma–Aldrich Chemical Company. The water used for solution preparations was deionised and distilled.

2.1. Preparation of alkali metal diperoxovanadate, $A[VO(O_2)_2(H_2O)]$ (A = Na or K)

Alkali metal diperoxovanadate (ADPV) was prepared by adding an equal volume of H_2O_2 solution (40 mM) to a vanadate solution (20 mM) maintaining the pH at 7.0 by adding dilute alkali hydroxide solution. On addition of pre-cooled EtOH to this solution, a yellow microcrystalline product precipitated out which was separated by centrifugation, washed with EtOH and finally dried over conc. H_2SO_4. Analysis of the content of vanadium and peroxide agreed with the formula $A[VO(O_2)_2(H_2O)]$ (A = Na or K).

2.2. Reaction of $A[VO(O_2)_2(H_2O)]$ (A = Na or K) with $VOSO_4$ in presence of EDTA. Synthesis of $A_4[V_2O_3(O_2)\ (EDTA)\ (SO_4)\ (H_2O)]\cdot 2H_2O$

In a typical reaction the disodium or dipotassium salt of EDTA (2.5 mmol) was dissolved in approximately 5 ml of water by warming. To this $VOSO_4\cdot 5H_2O$ (0.42 g, 1.66 mmol) was added with constant stirring. The reaction mixture was stirred for approximately 5 min in an ice-bath. Alkali hydroxide pellets were added to this solution to raise the pH to 7. Solid $A[VO(O_2)_2(H_2O)]$ complex (2.5 mmol) was then added in one portion to the reaction mixture with constant stirring. The pH of the solution was ultimately raised to 8.5 by the further addition of AOH. The initial blue colour of the solution changed to green on addition of yellow ADPV and ultimately a deep red coloured clear solution was obtained within approximately 4 min. On addition of pre-cooled C_3H_6O in portions (approximately 5 ml) to the reaction solution under vigorous stirring, a red coloured pasty mass separated. The supernatant liquid was decanted off, and the oily residue was treated repeatedly with C_3H_6O under scratching until it became a microcrystalline solid. The product was separated by centrifugation, washed with EtOH and dried in vacuo over conc. H_2SO_4.

Anal. Calc. for $Na_4[V_2O_3(O_2)_3(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$: C, 16.85; H, 2.52; N, 3.93; Na, 12.92; O_2^{2-}, 4.49; SO_4^{2-}, 13.48; V, 14.32. Found: C, 16.78; H, 2.58; N, 3.87; Na, 13.11; O_2^{2-}, 4.44; SO_4^{2-}, 13.41; V, 14.27%. Yield: approximately 55%.

Anal. Calc. for $K_4[V_2O_3\ (O_2)_3(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$: C, 15.46; H, 2.31; K, 20.10; N, 3.60; O_2^{2-}, 4.12; SO_4^{2-}, 12.37; V, 13.14. Found: C, 15.41; H, 2.35; K, 20.13; N, 3.62; O_2^{2-}, 3.98; SO_4^{2-}, 12.30; V, 13.16%. Yield: approximately 30%.

The complexes in the solid state were found to be stable for several weeks stored dry at a temperature < 20 °C, but tended to be hygroscopic and decompose in a few days at a temperature ≥ 30 °C. The compounds were soluble in water.

2.3. Elemental analysis

The compounds were analysed for C, H, N, Na and K at the Regional Sophisticated Instruments Centre, North-Eastern Hill University, Shillong, India. Vanadium and peroxide were estimated by methods mentioned in earlier papers [16,17].

2.4. Physical and spectroscopic measurements

Spectra in the UV–Vis region were recorded on a Hitachi model 2001 recording spectrophotometer in 1 cm quartz cuvettes. The absorbance values are denoted as, e.g. A_{592}, A_{340}, at the wavelengths indicated. The infrared (IR) spectra were recorded with samples as KBr pellets in a Nicolet model 410 FTIR spectrophotometer and also in a Perkin–Elmer Model 983 spectrophotometer. The ^1H NMR spectra were recorded in deuterium oxide using a Varian EM-390 90 MHz spectrophotometer. Sodium salt of 3-(trimethylsilyl)-1-propane sulphonic acid was used as the internal standard. Magnetic susceptibilities were measured by the Gouy Method, using $Hg[Co(NCS)_4]$ as the calibrant.

2.5. Measurement of catalase-dependent oxygen release

A Gilson 5/6 H oxygraph fitted with a Clark oxygen electrode was used for measuring changes in dissolved oxygen (0.224 mM at 30 °C) in the medium and the changes were recorded in units of μM of dissolved oxygen. The rate and total amount of oxygen released from a 0.2 mM solution of the compound in phosphate

buffer (50 mM, pH 7.0) on adding catalase (0.08 mg protein ml^{-1}) were measured. The recorder pen was set in the middle of the chart paper for measuring the release of oxygen into the medium. The machine was standardised by the increases in dissolved oxygen obtained on adding catalase to buffered solutions containing known amounts of H_2O_2.

The effect of catalase on complexes was also studied by estimating the peroxide content of the compound **1** at different time intervals in a solution containing catalase. The reaction solution contained phosphate buffer (50 mM, pH 7.0), catalase (20 mg) and the compound **1** (50 mg). The volume of the reaction solution was kept at 25 ml. The solution was incubated at 30 °C. Aliquots of 5 ml were pipetted out and titrated for peroxide content at time 5, 10. 20, 30 and 40 min from starting the reaction.

2.6. Measurement of bromination activity

The method of de Boer et al. [18] of introducing four bromine atoms into the molecule of C_6H_5OH red ($\varepsilon^{433} = 19.7$ mm) to form the product, bromophenol blue ($\varepsilon^{592} = 67.4$ mm) was used to measure bromination activity. Phenol red acts as an efficient trap of active bromine species without influencing the rate of reaction until it is exhausted. The reaction mixture contained phosphate buffer (50 mM, pH 5.5), KBr (2 M) and C_6H_5OH red (20 μM). The redox activity was tested by adding the solid compounds and by monitoring the possible change in absorbance at 592 nm at 30 °C. The volume of the reaction mixture was kept at 25 ml in experiments where weighed amounts of solid peroxovanadate samples were added. Aliquots were transferred to the spectrophotometer immediately after mixing.

2.7. Measurement of oxidation of NADH

The absorbance at 340–380 nm by high concentrations of peroxovanadates had to be balanced by adding equivalent amounts in the blank and experimental cuvettes. Weighed samples of compound (20 mg/10 ml) were added to phosphate buffer (50 mM, pH 7.0). Only the experimental sample contained NADH (0.2 mM). Immediately after mixing, the sample was transferred to a cuvette and A_{340} was noted. No effect was observed on A_{340}.

3. Results and discussion

Based on their detailed investigations on V^{IV}–DPV reactions [4–8] and taking into account the redox chemistry of vanadyl, vanadate and peroxovanadates described earlier by Brooks and Sicilio [10] and Jaswal and Tracey [19], it was proposed by Ramasarma and co-workers that a short lived [$OVOOV(O_2)$] species is the intermediate shared by the processes: oxidation of NADH [4], formation of oxidised bromine species [5], inactivation of glucose oxidase [6] and release of oxygen [7]. Evidence was shown earlier for the participation of the peroxo-bridged divanadate compound in oxidising bromide ion at physiological pH [5,8,9]. Observing the inhibitory effect of EDTA and other organic ligands on each of the above-mentioned redox processes [4–7], we realised the distinct possibility of stabilising and isolating the proposed peroxo-bridged intermediate through complexation. Using this as a synthetic strategy, the reactions of alkali diperoxovanadate, EDTA and $VOSO_4$ were carried out at varying pH, ranging from 7 to 9. The success of obtaining the solid dinuclear heteroligand peroxovanadates containing SO_4^{2-} and EDTA as heteroligands, as sodium or potassium salts depended on the following essential components: maintenance of the molar ratio of DPV:VO^{2+}:EDTA at 1:0.75:1, order of addition of the reactants, pH of 8.5, maintenance of required reaction time as well as temperature at ≤ 4 °C. A solid product isolated at pH 7–8 was found to be EDTA peroxovanadate, which rendered inconsistent analysis.

The elemental analysis data provided crucial information regarding composition of the compounds. A ratio of 2:1 was ascertained for V:peroxide, V:EDTA, as well as for V:SO_4^{2-}. This suggested a dimeric nature of the complex species. The elemental analysis results and the molar conductance values obtained from measurement at ambient temperatures (510–522 Ω^{-1} cm^2 mol^{-1}) were in complete agreement with the formulation of the complexes as $A_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$ (A = Na or K).

The electronic spectra of the complexes **1** and **2** displayed a broad band at 390–400 nm ($\varepsilon \approx 600$ mm) which has been assigned to the peroxo (LMCT) transition. According to previous studies [7], the absorbance at 780 nm of a blue coloured aqueous solution of $VOSO_4$ decreases progressively on adding batches of DPV to the solution. The complete absence of the 780 nm band in the spectra of the newly synthesised complexes indicated the oxidative loss of V^{IV} during complex formation. Occurrence of vanadium in the complexes **1** and **2** in its +5 oxidation state was further evident from their being diamagnetic at room temperature and ESR silent. The 8-band spectrum (hyperfine splitting **a** = 115 G) characteristic of V^{IV} of an aqueous solution of $VOSO_4$ was not observed in case of the complexes suggesting oxidation of V^{IV} to V^{V} during the course of the reaction.

The IR spectra of the complexes **1** and **2** displayed a rich but sufficiently well resolved spectral pattern significant features of which are summarised in Table 1. The bands observed for peroxo groups were in the

range characteristic of a triangularly bonded peroxide [15–17,20]. For the binuclear V–O–V unit the antisymmetric and symmetric stretchings were expected in the 700 and 500 cm^{-1} region [20]. Accordingly, a medium intensity band observed at approximately 712 cm^{-1} was assigned to a $\nu_{as}(V_2O)$ mode. The strong absorption at approximately 950 cm^{-1} was consistent with the presence of a terminally bonded V=O group in the complexes. This band was observed to be rather broad in the spectra probably owing to the presence of bridging oxo groups as well as co-ordinated sulphate in the complexes. The IR spectra of the complexes displayed a strong broad band with a maximum at approximately 1625 cm^{-1}, typical of co-ordinated carboxylato groups of EDTA [21a]. The broadening of the band was possibly caused by the additional OH deformation modes of the water molecules present in the complexes. No other band was observed in the vicinity of 1700 cm^{-1} which indicated the absence of free carboxylate groups, thereby suggesting the co-ordination of EDTA as a hexadentate ligand in the complexes. The corresponding $\nu_s(COO^-)$ band of EDTA was observed at approximately 1399 cm^{-1} which was shifted from the free ligand value (1412 cm^{-1}) as expected for unidentate carboxylate groups [21a]. The presence of water in the complexes was evident from the broad absorption at 3500–3400 cm^{-1}, due to ν(O–H). A band at approximately 755 cm^{-1}, assigned to the rocking mode of water, suggested the occurrence of co-ordinated water. The existence of co-ordinated sulphate in the complexes was evident from their IR spectra. The well-resolved splitting of the ν_3 and ν_4 modes of SO_4^{2-} into two bands each (Table 1) and appearance of a medium intensity ν_2 mode at approximately 465 cm^{-1} conclusively proved that the sulphate ligand binds the vanadium centre in an unidentate (C_{3v}) fashion [21b]. The ν_1 mode of an unidentately bonded SO_4^{2-} expected in the vicinity of 970 cm^{-1} could not be assigned decisively due to its possible mixing with the V=O stretching of terminal oxo groups. Significantly, the IR spectral pattern originating from co-ordinated sulphate in the complexes was observed to be very similar to that of vanadyl sulphate, $VO(SO_4)\cdot 5H_2O$. This observation led us to infer that the sulphate–vanadium co-ordination in $VOSO_4$ remained unaltered during its reaction with DPV in the presence of EDTA, being affected neither by the oxidation of V^{IV} to V^{V} nor by the complexation with EDTA leading to the formation of the newly synthesised complexes.

Table 1
Structurally significant IR bands of $A_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$ (A = Na or K)

Compound	IR bands (cm^{-1})	Assignment
$Na_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$	3434m	ν(O–H)
	1624s	ν_{as}(COO)
	1404s	ν_s(COO)
	1136s, 1103s	ν(S–O)(ν_3)
	641m, 614m, 464m	ν(S–O)(ν_4), ν(S–O)(ν_2)

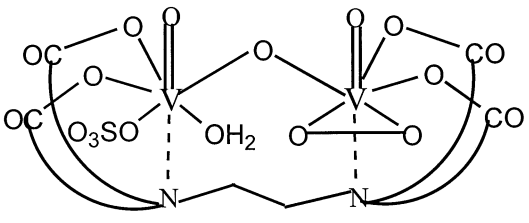

Fig. 1. Proposed structure of dinuclear heteroligand peroxovanadate(V) compounds, $A_4[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]\cdot 2H_2O$ (A = Na, K).

The ^{1}H NMR spectra of the complexes **1** and **2** exhibited a singlet at δ 2.71 and an AB quartet at δ 3.03 of intensity ratio 2:1. On the basis of previous studies on EDTA complexes, the AB quartet was assigned to the eight acetate protons and the singlet to the four ethylenic protons of the EDTA ligand [22]. The close analogy between the NMR spectra of the complexes **1** and **2** and that of a previously reported Mo–EDTA complex [22] containing bridging EDTA suggested the occurrence of the ligand in these complexes as a bridging one, as anticipated by us.

Based on the above observations a structure of the type shown in Fig. 1 has been envisaged for the complex species. An hexadentate EDTA ligand occupying three co-ordination positions around each of the oxo-bridged hepta co-ordinated vanadium(V) centres probably enhances the stability of the dinuclear complexes.

To us it appears that EDTA, which is known to undergo a facile condensation reaction with DPV [11,12] and also forms a stable complex with VO^{2+}, binds simultaneously to V^{V} and V^{IV} centres of the

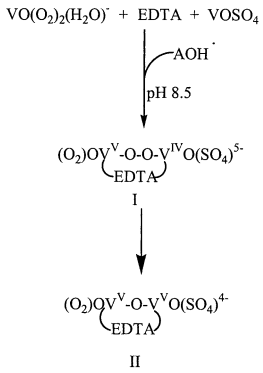

Fig. 2. Schematic representation of the formation of the dinuclear heteroligand peroxovanadate(V) complex, $[V_2O_3(O_2)(EDTA)(SO_4)(H_2O)]^{4-}$ from the reaction of diperoxovanadate with $VOSO_4$ in presence of EDTA. Hexa co-ordination of EDTA is not shown for simplicity. No attempt is made to show exact stoichiometry of reactions.

μ-peroxovanadate intermediate proposed to be formed in a solution of DPV and vanadyl (Fig. 2, complex I). This species then undergoes internal redox involving the reductive cleavage of the bridging peroxo group at the expense of oxidation of V^{IV} to V^{V} leading to formation of the stable dinuclear EDTA and oxo bridged complex (Fig. 2, complex II).

The stability of the complexes in solution has been studied by testing the possible oxygen release from a freshly prepared solution of the dinuclear peroxovandate **1** with the help of an oxygraph. However, no oxygen was found to be released on dissolution of the complex in water. Moreover, the single broad band observed in the 390–400 nm region in the electronic spectra of the complexes showed no change in its position or absorbance over a 2 h period. From these observations in combination with molar conductance values the stability of the complexes in water was implicit.

Having achieved the synthesis of these compounds we were interested in studying their activity in terms of their ability in bromide and NADH oxidation and action with the enzyme, catalase. On incubation with catalase DPV was found to be degraded releasing half the molecular equivalent of oxygen [23] at the rate of 36.0 μM min^{-1} from a solution of 0.2 mM. EDTA selectively inhibited this reaction of diperoxovandate with catalase [23]. For complexes **1** and **2**, a maximum of 0.5 O_2 per mole of the compound is expected to be released due to the presence of one peroxide group per molecule. However, no oxygen release took place from the solution of the complexes **1** and **2** in phosphate buffer (pH 7.0) on treatment with catalase and incubating at 30 °C for up to 30 min, confirming the resistance of the compounds to the enzyme. After 30 min, oxygen was found to be released from the solution at an extremely slow rate. The exceptional stability of the compounds to resist the catalase action is evidently owing to the extra stability imparted to the complex species by chelation, which probably interferes with the redox changes in the molecule necessary for catalase action.

The complexes were unable to bring about NADH oxidation as expected. Under the conditions given above, NADH was rapidly oxidised by a mixture of DPV and $VOSO_4$ [4]. We now find that addition of the solid compound **1** to solutions of NADH (0.2 mM) failed to oxidise it even at high concentration. There was no instant oxidation and A_{340} decreased at a negligible rate (results not shown).

Unlike our earlier experience with peroxo bridged dimeric compounds, $[V_2O_2(O_2)_3L_2]$ (L = amino acid or peptide) which led to the instant bromination of phenol red into its 592-absorbing brominated product, bromophenol blue, at physiological pH [8,9], with the complexes **1** and **2** no such activity was observed.

The above observations suggest that the factors such as absence of a μ-peroxo group in the complexes as well as their high stability due to chelation by EDTA are probably responsible for their lack of participation in the above redox processes thus resembling the inhibitor complex formed in solution.

In summary, with the examples of the newly synthesised compounds, the present investigation has established that it is possible to isolate the species formed in a solution of diperoxovanadate and VO^{2+} in presence of EDTA which is considered to be responsible for inhibiting the NADH and bromide oxidation and oxygen release reaction by a combination of DPV and VO^{2+}. Formation of the complex proceeds through steps where EDTA co-ordinates simultaneously to the V^{V} and V^{IV} centres of the proposed $[(O_2)OV^{V}OOV^{IV}O]^{+}$ intermediate. The peroxo bridged species then undergoes internal redox to produce the oxo and EDTA bridged dinuclear peroxovanadate(V) complex (Fig. 2, species II), which is resistant to further degradative loss of peroxide and can be isolated in the solid state as its Na^{+} or K^{+} salts. It is of interest to note that although SO_4^{2-} is not directly co-ordinated to the peroxovanadate centre, these complexes are probably the only known peroxovanadate compounds containing co-ordinated sulphate. The reaction may serve as a paradigm for the synthesis of stable dinuclear heteroligand peroxovanadates if carried out in the presence of suitable organic ligands in lieu of EDTA.

A significant finding in the present study is the high stability of the synthesised complexes at physiological pH and their resistance to catalase action. This may be relevant in the cellular milieu where H_2O_2 has little chance to survive abundant catalase and glutathione peroxidase. By forming peroxo complexes of the above type vanadate may provide a way of preserving cellular H_2O_2 in presence of abundant catalase and make it available for its functions.

Synthesis and structural studies of the dien complexes of metal saccharinates, $[M(dien)_2]\cdot 2(sac)\cdot H_2O$ [M(II) = Ni(II), Cu(II) and Zn(II); dien = diethylenetriamine, $C_4H_{13}N_3$; sac = saccharinate, $C_7H_4NO_3S^-$], and $[Cd(dien)_2]\cdot 2(sac)$

Abstract

The synthesis and structural characterisation of a series of metal–saccrarinate complexes of formula $[M(dien)_2]\cdot 2(sac)\cdot H_2O$ [M(II) = Ni(II), Cu(II), Zn(II); dien = diethylenetriamine, $C_4H_{13}N_3$, sac = saccharinate, $C_7H_4NO_3S^-$] and $[Cd(dien)_2]\cdot 2(sac)$ are described. The Ni, Cu and Zn complexes are isostructural and belong to the monoclinic space group *Ia*, whilst the Cd complex crystallizes in the triclinic space group $P\bar{1}$. In each case, two tridentate dien ligands are bonded with the metal in a distorted octahedral arrangement, and the saccharinate anions remain outside the coordination sphere but participate in extensive hydrogen bonding network. The Ni, Cu and Zn complexes have a meridonal distribution of the dien ligands, whilst the Cd complex shows a facial configuration. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Nickel; Copper; Zinc; Cadmium; Saccharinate; X-ray structures

1. Introduction

Chemistry of metal–saccharin complexes is an interesting area of research because of the potential biological significance of such compounds [1–3]. The saccharin molecule ($C_7H_5NO_3S$) contains an imino hydrogen which is acidic in nature and can easily be lost producing the anion $(C_7H_4NO_3S)^-$. This anion has several potential donor atoms, i.e. the imino nitrogen, one carbonyl and two sulphonyl oxygens, which can be utilised in forming coordination bonds with different metals ions. We and others have shown that all the divalent transition metal ions in the 1st transition series form an isostructural series of complexes with stoichiometry $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ [sac = $(C_7H_5NO_3S)^-$] in which the sac anions are directly bonded to the metals through the nitrogen atom in a *trans* octahedral geometry [4–9]. There are also examples where one sac anion is bonded to the metal whereas the other anion remains outside the coordination sphere [10–12]. In a recent paper, we have shown that in some bipyridine derivatives belonging to this category, the whole complex can be taken as examples of the formation of 'cation–anion' pair [13]. Salt-like compounds where both the sac anions remain in the lattice are relatively few, but this type of situation appears to be preferred when the secondary ligand has got strong chelating properties [14]. In the present paper, we describe the synthesis, properties and structural characterisation of the Ni, Cu, Zn and Cd complexes of diethylenetriamine (dien) with saccharinate anions, and show that they form salt-like structures stabilised by extensive hydrogen bonded networks.

2. Experimental

2.1. General

Analar grade chemicals (BDH or E. Merck) were used as received. CHN analyses were done using an automatic microanalyser. The metal contents were de-

termined by atomic absorption spectroscopy using a Shimadzu atomic absorption/flame emission spectrophotometer, model AA-680, and also by standard gravimetric (dimethylglyoximate) as well as complexometric (Na_2EDTA) methods. Melting point was measured on a heating device MEL-TEMP (II) with a FLUKE 51 thermometer. IR spectrum (KBr pillet) was recorded on a Shimadzu IR spectrophotometer, Model IR-470, range 4000–400 cm^{-1}.The UV–Vis spectrum was recorded on a Shimadzu UV–Vis spectrophotometer, range 200–100 nm. The magnetic susceptibility was measured at room temperature using a Curie–Chenevean magnetic balance.

2.2. Synthesis of the complexes

The complexes described in this work were all synthesised from the reactions of $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ (M = Ni, Cu, Zn, Cd) with dien. The detailed procedure is described below for the nickel complex (**1**) and this was also adopted in other cases. The starting purely saccharinate complexes were prepared by following known methods [1,15].

$[Ni(sac)_2(H_2O)_4]\cdot 2H_2O$ (2.6558 g, 5 mmol) was dissolved in 150 ml of methanol and dien (1.08 ml, 10 mmol) was added. The color changed from light green to violet. The resulting solution was filtered, and the filtrate heated gently to about 50 °C on a water bath for 30 min and allowed to stand overnight at room temperature. Violet crystals of $[Ni(C_4H_{13}N_3)_2]\cdot 2(C_7N_4NO_3S)\cdot H_2O$ (**1**) were formed, which were collected by filtration, washed with methanol and dried over silica gel. Yield 84.3%, m.p. 236.8 °C. *Anal*. Calc. for $C_{22}H_{32}NiN_{16}O_7S_2\cdot H_2O$: C, 40.53, H, 5.55; N, 17.42; Ni, 8.99. Found. C, 40.82; H, 5.61; N, 17.31; Ni, 9.07%. I.R. (KBr disc), ν cm^{-1}, 3455 (s), 3408 (s), 3360 (vs), 3330 (vs), 3280 (vs), 3185 (s), 2920 (s), 2880 (s), 1638 (vs), 1615 (vs), 1579 (vs), 1490 (sh), 1484 (sh), 1449 (m), 1333 (vs), 1272 (sh), 1252 (vvs), 1160 (sh), 1146 (vs), 1118 (sh), 1073 (m), 1062 (sh), 1040 (m), 1037 (m), 1013 (s), 972 (s), 958 (vs), 912 (vw), 891 (m), 864 (vw), 831 (vw), 798 (m), 788 (sh), 761 (vs), 703 (m), 680 (vs), 632 (s), 604 (vs), 540 (s), 531 (s), 505 (sh), 453 (w), 409 (vw). UV–Vis (λ_{max})/nm: 242 (π–π*), 295 (n–π*).

2.3. X-ray crystallography

Crystallographic measurements for the complexes **1**–**4** were made at 293 K on a CAD4 diffractometer using graphite monochromatised Mo Kα radiation, $\lambda =$ 0.71069 Å, and ω–2θ scan technique. The structures were solved by direct methods (SHELXS-86) [16] and refined by full-matrix least-squares on F (SHELX-80) [17] using the observed data [$F_o > 3\sigma(F_o)$]. The weighting scheme applied was of the form $w = 1/[\sigma^2(F_o) + g(F_o^2)]$ and the coefficients 'g' were chosen to five flat analyses of variance with $\sin\theta/\lambda$. For **1**–**3**, the hydrogen atoms belonging to the H_2O molecules were experimentally located but not refined; those on the saccharinate and dien ligands were included in calculated positions. For **4**, one of the carbon atoms [C(47)] in a CH_2CH_2 bridge was disordered between two positions, which were refined with partial occupancies of 0.70 and 0.30. In this structure, the hydrogen atoms on the disordered carbon were ignored, and others included in calculated positions. Anisotropic displacement coefficients were refined for all non-hydrogen atoms. Final difference maps did not show any residual electron density of stereochemical significance. The correct absolute structure for **1**–**3** was chosen on the basis of the fact that the this model gave slightly lower R/R_w values compared

with the corresponding inverted structure. The crystal data and refinement details are summarised in Table 1, and selected bond lengths and angles involving the metal atoms are collected together in Table 2. Dimensions of the hydrogen bonds and some significant short contacts are listed in Table 3. ORTEP drawings of the structures of **1** and **4** are shown in Figs. 1 and 2, respectively.

3. Results and discussion

The new complexes **1**–**4** were obtained as air-stable violet (Ni), blue (Cu) or colorless (Zn and Cd) crystals from the reaction of the respective metal saccharinates $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ with diethylenetriamine (dien) in aqueous medium. All the complexes are soluble in water, alcohol, acetone and DMSO. The analytical and spectroscopic data are consistent with the proposed formulation of the complexes, and are confirmed by an X-ray study. The relatively low melting points of the complexes suggest that they are monomeric species. The magnetic data indicate the presence of two unpaired electrons on Ni(II) (high-spin, d^8 configuration) in **1** and one unpaired electron on Cu(II) (d^9 configuration) in **2**.

3.1. Spectral study of *1*–*4*

Some of the important peaks in the IR spectra of the complexes were assigned by comparing with related compounds [2]. There are several close peaks in the region 3465–3200 cm^{-1} which may be attributed to the ν(O–H) vibrations of the H_2O molecules and N–H vibrations of the dien NH_2 groups. Splitting and broadening of these peaks suggest that the H_2O molecules/NH_2 groups are coordinated and/or hydrogen bonded. Two close peaks at $\sim$2925–2880 cm^{-1} are due to the ring ν(C–H) vibrations. The ν(CO) peaks appears at 1640, 1644, 1637 and 1638 cm^{-1} with corresponding shoulders at 1616, 1615, 1619 and 1615 $cm^{-1}$for **1**–**4**, respectively. The peaks with medium intensity at 1579–1578 cm^{-1} may be attributed to the ring ν(CC) vibrations. The peaks at $\sim$1333–1328 cm^{-1} are due to the ν(CN) ring vibrations. The $\nu_{as}(SO_2)$ peaks appear as strong peaks at 1263–1252 cm^{-1} and also as shoulders at $\sim$1274–1272 cm^{-1} whilst the $\nu_{sy}(SO_2)$ bands appear as strong peaks at 1144–1146 cm^{-1}. The ring ν(CC) absorption band overlaps with the $\nu_{as}(SO_2)$ peak at 1267 cm^{-1}. The weak bands at 456–453 cm^{-1} may be assigned to the M–N (dien) vibrations. There are also other peaks in the spectra that are difficult to assign

unambiguously. It should be noted, however, that the IR spectra of the four complexes are strikingly similar in relative positions and intensities of the peaks, which suggests a close structural relationship among the compounds.

3.2. Crystal structural studies

X-ray crystal structural studies show that the Ni(II) (**1**), Cu(II) (**2**) and Zn(II) (**3**) complexes have the same stoichiometry $[M(dien)_2]\cdot 2(sac)\cdot H_2O$ and are isostructural (monoclinic, comparable cell dimensions, same space group, similar atom coordinates). The crystal structures consist of $[M(dien)_2]^+$ cations, $(sac)^-$ anions and H_2O molecules (1:2:1) held together by several hydrogen bonds and van der Waals' interactions. The coordination sphere around M(II) consists of two tridentate dien ligands with a meridonal configuration. The two sacchrinate anions and the H_2O molecule remain outside the coordination sphere, but these are linked with each other and also with the cation through several strong hydrogen bonds (Table 3). This is illustrated in Fig. 1, which shows the structure of the Ni complex **1** and represents the above isostructural series of three compounds. The H_2O molecule forms an acceptor hydrogen bond with the central amine group [N(32)–H(32)] of one of the dien ligands, and two donor bonds with the carbonyl oxygen atoms [O(11)] of two symmetry related saccharinate anions. Relatively short donor–acceptor distances (2.80–2.93 Å) and very favourable donor–hydrogen–acceptor angles (155–160°) indicate that these hydrogen bonds are quite strong and play crucial roles in the stabilisation of the crystal structural framework. Further stabilisation is achieved through additional hydrogen bonds involving the amine groups on the dien ligands and the nitrogen and sulfonyl oxygens of the saccharinate anions. In the Cd complex **4**, there is no water molecule to form any O–H···O hydrogen bond as observed in the other three complexes, but in this case there are several N–H···O hydrogn bonds involving the amine groups and the carbonyl/sulphonyl oxygen atoms of the saccharinate anions to hold the crystal structure together (Fig. 2 and Table 3). Further, the two tridentate dien ligands in this complex are arranged differently, i.e. in a facial mode, in contrast with the meridonal mode in the other complexes. The reasons for this different behaviour of the Cd complex are not clear, but a relatively larger size of Cd compared with Ni, Cu and Zn [18] could be a contributing factor.

The coordination polyhedron in each case shows large distortions from ideal octahedral geometry. The M–N (dien) bond distances vary from 2.065(5) to 2.192(6), 1.995(14) to 2.634(14), 2.106(5) to 2.286(6) and 2.327(5) to 2.431(4) Å in **1**–**4** respectively. Similar values and variations in the M–N(dien) distances have also been observed in other complexes, i.e. 2.083–2.166 in $[Ni(dien)_2]\cdot 2Cl\cdot H_2O$ [19], 2.096–2.133 in $[Ni(dien)_2]\cdot 2(CNS)$ [20], 2.027–2.459 in $[Cu(dien)_2]\cdot 2Br\cdot H_2O$ [21], 2.001–2.265 in $[Cu(dien)_2]\cdot 2(NO_3)$ [21], 2.126–2.283 in $[Zn(dien)_2]\cdot 2Br\cdot H_2O$ [22], 2.155–2.245 in $2[Zn(dien)_2]\cdot[Fe(CN)_6]\cdot 4H_2O$ [23], and 2.340–2.425 in the polymeric cluster $[Cd(dien)_2]\cdot[Cd(dien)_2]\cdot 3(CN)\cdot[Cd_8(CN)_{19}]\cdot 3H_2O$ [24]. In the present Ni, Zn and Cd complexes, one of the dien ligands has two short and one long, and the other one short and two long M–N bonds, but in the Cu complex there are four short Cu–N bonds in the coordination plane and two long bonds along the normal to the plane. The long bonds in this case are associated with the two terminal NH_2 groups of the same dien, but in other cases, each dien has both long and short M–N bonds. It is noticed that the shortest M–N bond involves the central –NH– group in each case.

The distortions in the coordination polyhdra are also evident from the N–M–N angles. Thus the mutually cis and mutually trans angles, respectively, range from 80.6(2)° to 103.9(3)° and 161.9(2)° to 175.3(2)° in **1**, 74.6(5)° to 107.9(5)° and 154.8(5)° to 177.4(5)° in **2**, 78.4(2)° to 107.0(2)° and 157.9(1)° to 173.2(1)° in **3**, and 72.6(2)° to 112.4(2)° and 150.5(1)° to 163.5(2)° in **4**. As expected the N–M–N bite angles in each complex are all acute due to the steric constraints imposed by the ethylene bridge, and those in the Cd complex are narrowest due to longer Cd–N bonds. Similarly, the narrowing down of the trans angles from ideal value of

Abstract

A heterocycle, previously untested as a polydentate ligand, 2,5-bis(2-pyridyl)-1,3,4-thiadiazole, namely bptd, has been found to form the monomeric complexes, $Co(bptd)_2(H_2O)_2(NO_3)_2$ (**I**), $Ni(bptd)_2(H_2O)_2(ClO_4)_2$ (**II**), $Co(bptd)_2(H_2O)_2(ClO_4)_2$ (**III**), and $Cu(bptd)_2(NO_3)_2$ (**IV**) with Co(II), Ni(II) and Cu(II) in the presence of nitrate or perchlorate anions. Despite similar syntheses, nitrate serves as a ligand to Cu(II) in **IV** whereas, it is seen as a free ion in the cell of $Co(bptd)_2(H_2O)_2(NO_3)_2$ (**I**).

1. Introduction

The associative magnetic properties of transition metal complexes in the solid state are influenced by the presence of close metal–metal distances, by the presence of bridging atoms or pathways and by the overall geometry of metals, bridging atoms and coordinated ligands. Thus there is interest in designing ligands capable of enforcing close metal contacts during the process of assembly or crystallization to form the solid state. Four heteroatom derivatives of 1,2-diazoles with *o*-pyridine substitution at the 3 and 5 positions have been of interest for such applications (Scheme 1A and B).

The use of (1,3,4)-oxadiadiazoles with such substitution [2,5-bis(2-pyridyl)-1,3,4-oxadiazole] (1C) abbreviated as (bpo) however, has normally led to the crystallization of monomeric complexes without metal–metal interaction [1–3]. The only reported example of a multimetal complex with bpo is the polymeric species $[Cu(bpo)Cl_2]_\infty$ in which successive metal centers are indeed bridged by the tetradentate ligand. In this case the ligands show a large deviation from coplanarity, resulting in a large intermetal distance and EPR measurements show the copper atoms to have no interaction [3].

(1,2,4-Triazoles) with *o*-pyridine substitution at the 3 and 5 positions [3,5-bis(2-pyridyl)-4H-1,2,4-triazole] (bpt) may be used as ligands in neutral (1A) or anionic form (1B). When one of the three nitrogen atoms of the aromatic triazole ring bears a substituent, the ligand is neutral. When this substituent is absent, the ligand is in the anionic form. With one exception, the reported solid state complexes involving the neutral ligand and divalent transition metals are monomeric [4–8]. An exception to this generalization is the nickel dimer formed with 4-amino-1,2,4-triazole, water and chloride molecules. This neutral ligand forms a dimeric face to face complex with close Ni–Ni interactions [9].

Anionic forms of the ligand, on the other hand, are normally seen to bridge two metal atoms. When the pyridyl nitrogen atoms face in the same direction as the N1 and diazole rings, the four nitrogen atoms bond to two metal atoms and metal–metal distances of about 4 Å are seen [10]. However, one pyridine ring may rotate 180° to bond to a metal atom along with the nitrogen atom in the 4 position. A second metal is found on the opposite side of the ligand, bound to the nitrogen atom of the remaining pyridine ring and to the near nitrogen of the triazole ring [11].

There are no reports in the literature of the complexed form of the 2,5-bis(2-pyridyl)-thia derivative (**1D**). We begun exploration of the properties of the 1-thia-3,4-diazole species with ortho pyridine rings substituted at the 2 and 5 positions [2,5-bis(2-pyridyl)-1,3,4-thiadiazole (bptd)] as a molecular architect with transition metals. We report here the single crystal structures of several complexes formed by bptd with divalent Co (structures **I** and **III**), Ni (structure **II**) and Cu (structure **IV**).

Table 1

III	1634	1603	1560	1100	
IV	1649	1603	1560	1384	1323

2. Experimental

2,5-Bis(2-pyridyl)-1,3,4-thiadiazole was synthesized as described previously [12,13]. $Co(NO_3)\cdot 6H_2O$ (1.5 mmol, 0.44 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand dissolved in 8 ml of EtOH. The solution was filtered and after 24 h the orange compound (**I**) crystallized at room temperature (r.t.). Crystals (**I**) were washed with water and dried under vacuum.

$Ni(ClO_4)\cdot 6H_2O$ (1.5 mmol, 0.55 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand dissolved in 8 ml of EtOH. The solution was filtered and after 24 h the colorless compound (**II**) crystallized at r.t. Crystals were washed with water and dried under vacuum.

$Co(ClO_4)\cdot 6H_2O$ (1.5 mmol, 0.55 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand dissolved in 8 ml of EtOH. The solution was filtered and after 24 h the colorless compound crystallized at r.t. Crystals of (**III**) were washed with water and dried under vacuum.

$Cu(NO_3)\cdot 2.5H_2O$ (1.5 mmol, 0.35 g) in 8 ml of water was added to (0.42 mmol, 0.1 g) of ligand dissolved in 8 ml of EtOH. The solution was filtered and after 24 h the blue compound (**IV**) crystallized at r.t. Crystals were washed with water and dried under vacuum.

Infrared spectra were recorded on a Nicolet FT Impact 400 D double-beam spectrometer. Solid samples were examined in the form of KBr pellets.

Intensity data were collected on a Bruker AXS SMART three-circle diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å), equipped with a CCD two dimensional detector [14]. Crystal data are given in Table 2. All non-hydrogen atom positions were determined by direct methods [15]. Positional parameters and a scaling factor were refined to convergence [16] using first isotropic thermal parameters and then anisotropic displacement factors. Hydrogen atoms on the pyridyl rings were placed in idealized positions whereas those on the water molecules were identified from a difference Fourier synthesis. For (**II**) and (**III**), the perchlorate anion was found to be disordered over two principal orientations. Occupancy factors for these two positions were refined. Bond angles and distances are given in Table 3.

3. Discussion

The bonding mode of the ligands and anions can be deduced from the IR spectra of the complexes, see Table 1. The indicators for the ligand are the two intensive bands of the pyridine ring vibrations near

1580 cm^{-1}. Upon pyridine coordination to a metal the higher one of these bands is shifted by about +20 cm^{-1} [17]. In all cases there are two IR bands in the 1600–1650 cm^{-1} range which can be assigned to one coordinated and one uncoordinated pyridine ring. This means that in these 2:1 complexes each thiadiazole ligand uses one pyridine nitrogen and probably one thiadiazole nitrogen for chelate binding, as was confirmed by the structure determination of complexes (see below). With respect to anion binding, the positions of the two nitrate stretching bands of (**IV**) point to unidentate nitrate coordination in this complex. The nitrate in (**I**) and perchlorate in (**II**) and (**III**) are free anions [18,19].

(**I**), (**II**), (**III**) and (**IV**) crystallize with the monomeric metal atom situated on a center of symmetry and with coordination to four nitrogen atoms plus the oxygen atoms of two water molecules [(**I**), (**II**) and (**III**)] or of two nitrate moieties (**IV**) (Figs. 1–4). In each structure, M [(**I**) and (**III**), M = Co, (**II**), M = Ni, (**IV**) M = Cu] is seen in a distorted octahedral geometry with the N3 and N7 atoms of each of two ligand molecules forming an equatorial plane on which the metal atom is found. The three rings forming the ligand are each individually planar within experimental limits. Ring, C6, N7, C8, C9, C10, C11, is close to coplanarity with ring S1, C2, N3, N4, C5; S.D. (**I**) 0.021, (**II**) 0.026, (**III**) 0.027, (**IV**) 0.022. In (**I**), ring C12, N13, C14, C15, C16, C17 subtends an angle of 2.0° with the plane of the other two rings. In (**II**), this angle is 18.0°, in (**III**), 19.0° and in (**IV**), 7.0°. This rotation may be attributed to packing influences, as there are no obvious hydrogen bonding or other influences seen.

Metal nitrogen distances average 2.125(3) Å (**I**), 2.076(4) Å (**II**), 2.107(3) Å (**III**), 2.035(4) Å (**IV**) and are normal for these metals.

Axial positions in (**I**), (**II**) and (**III**) are occupied by water molecules with M–O distances of 2.101(3) Å (**I**),

$i = -x, -y, -z$.

2.083(4) Å (**II**) and 2.087(4) Å (**III**). In (**IV**), the axial positions are occupied by monodentate nitrate oxygen atoms, Cu–O(nitrate) 2.323(4) Å. M bonds to the oxygen atoms are close to perpendicular as seen in the ranges of O–M–N angles which deviate only slightly from the theoretical value of 90°; (**I**) 89.37(12)–90.63(12), (**II**) 88.84(16)–91.16(16), (**III**) 88.52(15)–91.48(15), (**IV**) 87.0(2)–93.0(2)°.

Hydrogen bonding is seen between hydrogen atoms of the water molecule and in (**I**) H11b is 2.33 Å from O21 $(x, 1+y, -1+z)$ and 2.30 Å from O23 $(x, 1+y, -1+z)$ whereas H11c is 1.96 Å from O21 $(-1-x, -1-y, 1-z)$. In (**II**), bonding is seen to oxygen atoms of the perchlorate anion: H11b is 2.14 Å from O2$(0.5-x, -0.5+y, 0.5-z)$ and H11c is 1.92 Å from O3 $(x, -1+y, z)$. H11b of (**III**) is 2.114 Å from the perchlorate oxygen atom, O2 $(1/2-x, -1/2+y, 1/2-z)$ and H11c is 1.947 Å from O3 $(x, -1+y, z)$. Bonding details within nitrate and perchlorate ions are normal.

Both (**I**) and (**IV**) were prepared from the appropriate metal nitrate salts and ligand dissolved in water and ethanol, respectively and then mixed. Stoichiometry and crystallization conditions were equivalent, yet cobalt is seen with water molecules as axial ligands and two nitrate ions as a distant counter ions whereas copper has two nitrate ions as axial ligands and no solvent water molecules are found in the cell. This behavior is normal for Co(II). In 62 published structures in which Co(II), NO_3^- and H_2O are present in the cell, cobalt is ligated to neither Lewis base in 26 cases and only to water in 33 examples. A review of the 110 published Cu(II) crystal structures with both nitrate and water molecules present in the cell shows only the water molecule complexed in 56 structures and neither water nor nitrate complexed to Cu(II) in 21 other structures. There are 20 reported examples of Cu(II) coordination to both, but only seven in which copper is coordinated to two nitrate anions and not to water. Thus, structure (**III**), in which copper(II) is axially coordinated to two nitrate ions, is unusual. It remains

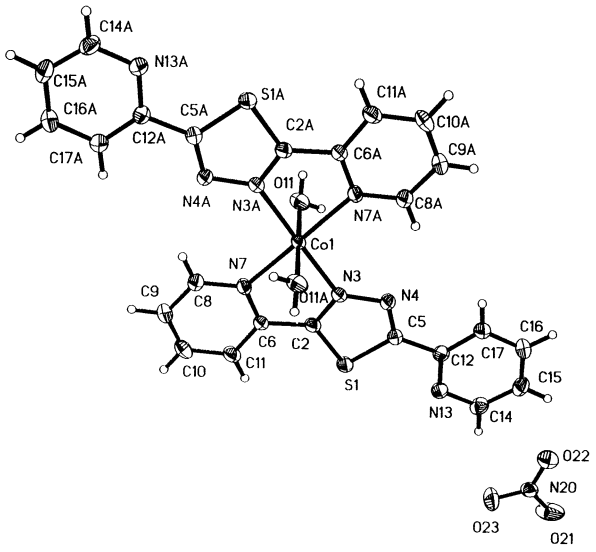

Fig. 1. Projection view of $Co(bptd)_2(H_2O)_2(NO_3)_2$ (**I**) (thermal ellipsoids are shown at the 50% probability level).

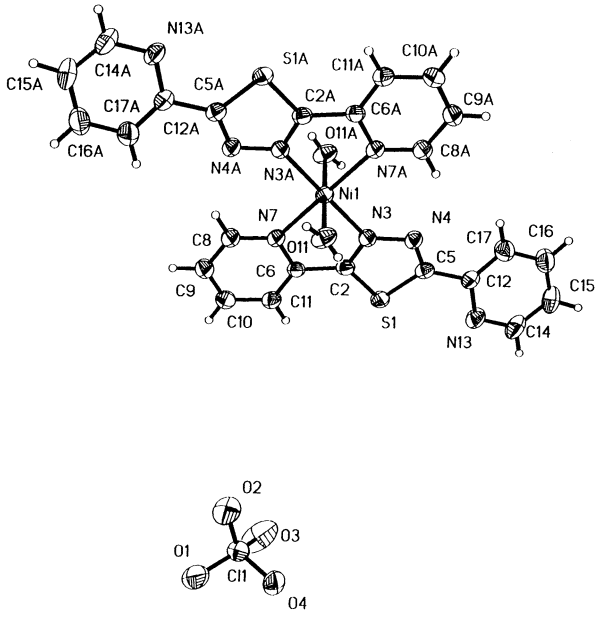

Fig. 2. Projection view of $Ni(bptd)_2(H_2O)_2(ClO_4)_2$ (**II**) showing one of two ClO_4^- molecules disordered about the Cl site (thermal ellipsoids are shown at the 50% probability level).

to be seen if copper complexation to nitrate has been influenced by some electronic or geometric influence of the bptd ligand.

In structures (**I**), (**II**), (**III**) and (**IV**), metal complexation under the synthetic conditions used and with the perchlorate and nitrate counter ions, follows the pattern of formation of monomeric complexes expected for neutral ligands of the bis(2-pyridyl) substituted oxadiazole and triazole family.

Abstract

Condensation of aminoguanidine with 2-formylpyridine, 2-benzoylpyridine and 2,6-diacetylpyridine results in the aminoguanidones, HFogu, HBzgu and $H_2$2,6Acgu$_2$, respectively. Reaction of the heterocyclic aminoguanidone in a mixture of hydrochloric acid–ethanol with copper(II) chloride produces the following mixed salts: [H_3Fogu][$CuCl_4$], (**1**), [H_3Bzgu]$_2$[$CuCl_4$]Cl_2·H_2O, (**2**), and [$H_5$2,6Acgu$_2$][$CuCl_4$]Cl·H_2O, (**3**). Their crystal structures, as well as their ESR and UV spectra, have been obtained. The influence on the geometry of the $[CuCl_4]^{2-}$ of the N–H···Cl–Cu hydrogen bonds, in the context of charged compensation hypothesis, has been evaluated. © 2002 Elsevier Science Ltd. Keywords: Aminoguanidonium; Copper(II) halides; Crystal structures; Tetrachlorocuprate(II)

1. Introduction

There has been a continuous interest in the chemistry of copper(II) halides due to their stereochemical complexity and the magnetic and optical properties many of them display. The structural chemistry of more than 60 salts containing tetrachlorocuprate(II) ions were summarized a few years ago [1], and many others have been reported more recently [2]. The copper(II) halides reported show a wide variety of geometric complexity. Compounds with coordination numbers 4, 5 and 6 with several geometries for each coordination number have been reported. The bridging ability of the halides complicates even more the structural chemistry of these compounds. In addition to the simple mononuclear species, it is possible to obtain oligomeric units ranging from 2 to 14 Cu(II) ions, and infinite one- two- or three-dimensional polimeric species. Willett proposed that it is possible to have some reasonable rationalization for many of these structures through the application of some simple electrostatic arguments which he called 'charged compensation' [3]. According to this idea the observed structure of copper(II) halides salts can be visualized as a balance between crystal field stabilization effects and an electrostatic ligand–ligand repulsion effect. In four-coordinate compounds, the former favors a square-planar, and the latter a tetrahedral geometry. As long as hydrogen bonds tend to remove charge from the Cl atoms they will promote the $[CuCl_4]^{2-}$ ion to move toward a square-planar geometry.

In this paper we present the crystal and molecular structure as well as spectroscopic properties of chlorocuprate(II) salts with cations of heterocyclic derivatives of aminoguanidine with 2-formylpyridine, 2-benzoylpyridine and 2,6-diacetylpyridine, Scheme 1. The cations of these compounds have several N–H hydrogen bonding atoms, and therefore, we expect to have

multiple N–H···Cl–Cu hydrogen bonds, which will allow us to evaluate the charged compensation hypothesis in systems with multiple hydrogen bonds.

2. Experimental

The aminoguanidones were prepared by reaction of a one molar equivalent of aminoguanidine bicarbonate per carbonyl functionality of the desired ketone or aldehyde. Prior to mixing with the aldehyde–ketone, an ethanolic solution of aminoguanidine bicarbonate was neutralized by the dropwise addition of concentrated H_2SO_4 until the evolution of CO_2 ceased. Representative of the preparations is the preparation of 2-benzoylpyridine aminoguanidone: 0.008 moles (1.46 g) of 2-benzoylpyridine was added to 30 ml of EtOH in a 100 ml round-bottom flask and stirred until dissolution occurred. To this solution, 0.008 mol (1.09 g) of neutralized aminoguanidine was added, followed by 2–3 drops of H_2SO_4 to catalyze the reaction. The mixture was refluxed for 5 h, slowly evaporated at approximately 35 °C and white HBzgu (m.p. = 206–208 °C) was isolated by suction filtration. HFogu (m.p. = 190–192 °C) is yellow and $H_2$2,6Acgu$_2$ (m.p. = 249–251 °C) is white. Their IR, ^{1}H and ^{13}C NMR, and mass spectra confirmed the identification of the aminoguanidones.

The chlorocuprate(II) salts were prepared by dissolving an aminoguanidone in approximately 50 ml of a 3:1 EtOH–HCl by volume, adding an equimolar amount of $CuCl_2$, and refluxing for 1 h. The resultant solution was decanted into a beaker, and left until crystals formed. The aldehyde–ketones and the aminoguanidine bicarbonate were purchased from Aldrich and used as received; other reagents were of the highest quality available.

IR spectra were recorded as nujol mulls between CsI plates using Nicolet 5SCX FT (4000–400 cm^{-1}) and Magna 850 (600–100 cm^{-1}) spectrometers. Solid state (i.e. nujol mulls on strips of filter paper) and solution (DMSO solutions in 1 cm cells) electronic spectra were recorded with a Cary 5E spectrometer. ESR spectra of the copper(II) complexes were recorded as solids at 298 and 3 mm Pyrex tubes on a Brucker EMX spectrometer.

2.1. X-ray data collection, structure solution and refinement

Crystals of the chlorocuprate(II) salts were mounted in a random orientation on glass fibers. Crystal data were collected at 293(2) K using a Siemens P4/PC four-circle diffractometer with graphite monochrometer Mo Kα ($\lambda = 0.71073$ Å) radiation. Crystal stability was monitored by measuring standard reflections every 97 reflections. Cell parameters were obtained from 35 accurately centered reflections. Data were collected using a ω–2θ scanning technique. Three reflections were chosen as intensity standards, being re-measured every 97 reflections, there were no significant variation in the intensity of these standards. Lorentz and polarization corrections were applied. The structures were solved by direct methods, and the non-hydrogen atoms were found by successive full-matrix least-squares refinement on F^2 and refined with anisotropic thermal parameters. Hydrogen atom positions were located from difference Fourier maps: and a riding model with fixed thermal parameters ($U_{iso} = 1.2\ U_{eq}$ for the atom to which they are bonded) was used for subsequent refinements. The weighting function applied was $w^{-1} = (\sigma^2(F_o^2) + (gP)^2)$ where $P = (F_o^2 + 2F_c^2)/3$. Scattering factors were taken from the International Tables for Crystallography (1974, vol. IV). The SHELXTL-97 package was used for data reduction and structure solution and refinement. Table 1 contains a summary of the crystallographic data for the three salts.

3. Results

Three aminoguanidones were synthesized from the condensation of aminoguanidine with 2-formylpyridine, HFogu; 2-benzoylpyridine, HBzgu; and 2,6-diacetylpyridine, $H_2$2,6Acgu$_2$, using one molar equivalent of aminoguanidine per carbonyl functionality. The compounds are stable to air and moisture, and melt without decomposition. Under acid conditions the first two compounds form dications and $H_2$2,6Acgu$_2$ a trication by protonation of the pyridyl and guanyl nitrogens, see Scheme 1. Their corresponding aminoguanidonium chlorocuprate(II) salts were prepared by the reaction of equimolar amounts of the aminoguanidone and $CuCl_2$ in EtOH–HCl: [H_3Fogu][$CuCl_4$] (**1**); [H_3Bzgu]$_2$[$CuCl_4$]$Cl_2\cdot H_2O$ (**2**), and [$H_5$2,6Acgu$_2$][$CuCl_4$]$Cl\cdot H_2O$ (**3**).

Details of data collections and structural refinements for **1**, **2** and **3** are given in Table 1. The molecular geometries, thermal ellipsoids (30%) and numbering schemes are shown in Figs. 1–3. Selected bond dis-

tances and angles are in Table 2 and intra- and intermolecular hydrogen bonds are in Table 3. The solid state electronic spectral bands and their assignments are shown in Table 4.

The asymmetric unit of **1** consist of a $[CuCl_4]^{2-}$ anion and a H_3Fogu^{2+} cation. The H_3Fogu^{2+} is protonated at the pyridyl nitrogen and the guanyl nitrogen (N3). Two intra-molecular H-bonds, N1–H···N2 and N5–H···N2, give planarity to the cation, the angle between the pyridine ring and the aminoguanidone moiety (N2–N3–C8–N4–N5) is 2.0(2). The copper(II) center has a coordination geometry intermediate between tetrahedral and square-planar with *trans* angles of 132.46(5)° and 124.94(4)° and the Cu–Cl bond distance ranges from 2.216(1) to 2.288(1) Å. Due to several N–H···Cl–Cu hydrogen bonds, pair wise ribbons are present in the crystal structure. The ESR spectra of **1** shows only a broad isotropic spectrum with $g_{iso}=2.205$ indicating considerable interaction between copper(II) centers.

The asymmetric unit of **2** contains two non-equivalent H_3Bzgu^{2+} ions, which are balanced by a $[CuCl_4]^{2-}$, two Cl^- ions and a hydrate water molecule. HBzgu is protonated in the pyridyl nitrogen and the guanyl nitrogen. The two H_3Bzgu^{2+} ions present in the asymmetric unit of **2** have significantly different distances in the 'equivalent' moieties. For example, the bond distances for N2–N3 and N22–N23 are 1.384(7) and 1.351(7) Å, and the related N2–C7–C2 and N22–C27–C22 bond angles, 112.6(5)° and 115.0(5)° respectively, Table 2. These differences likely result from the different hydrogen bonding interactions of the two ions; N5–H5B and N1–H1 hydrogen bond to O1W of the water molecule and O1W–H1W hydrogen bonds to N2, but the 'equivalent' N25–H25B and N21–H21

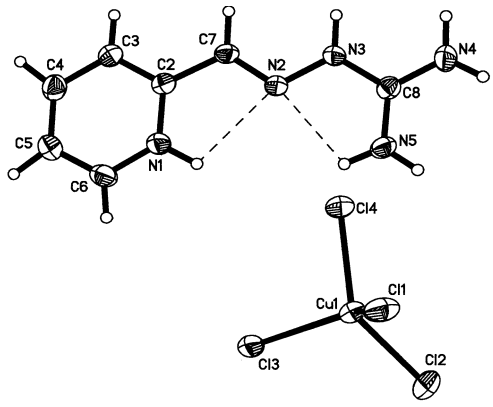

Fig. 1. Labeling scheme and thermal ellipsoid (30%) for **1**. Intramolecular hydrogen bonds are shown with dotted lines.

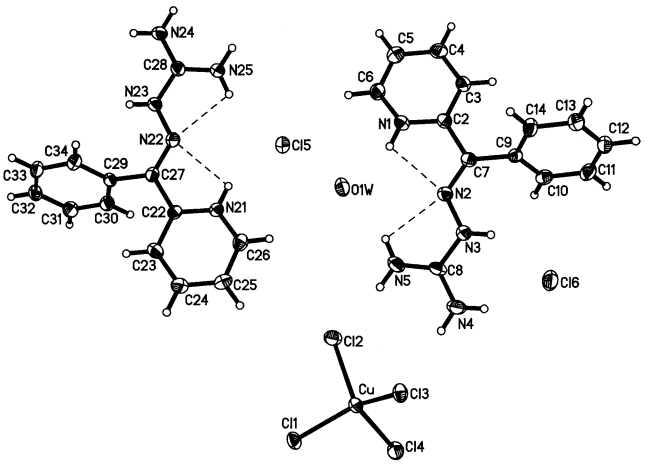

Fig. 2. Labeling scheme and thermal ellipsoid (30%) for **2**. Intramolecular hydrogen bonds are shown with dotted lines.

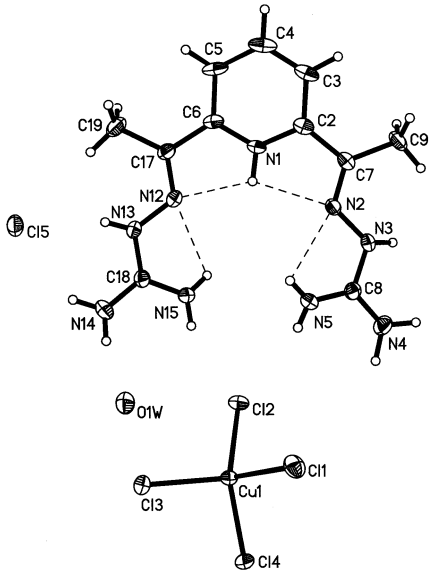

Fig. 3. Labeling scheme and thermal ellipsoid (30%) for **3**. Intramolecular hydrogen bonds are shown with dotted lines.

hydrogen bond to the chloride ion, Cl5. There are two intramolecular H-bond in each non-equivalent molecule, N1–H···N2, N5–H···N2 and N21–H···N22, N25–H···N22. The angle between the phenyl and pyridyl rings in the two forms, are 12.0(3)° and 8.9(3)° and may also be explained by the different modes of hydrogen bonding. The copper(II) center has a coordination geometry intermediate between tetrahedral and square-planar the *trans* angles are 135.44(7)° and 130.50(7)° and the Cu–Cl bond distances range from 2.232(2) to 2.269(2) Å. The ESR spectra of **2** has an axial signal having $g_{\|} = 2.336$, $g_{\perp} = 2.079$ and $g_{av} = 2.165$ indicating minimal distortion from a regular stereochemistry. Calculation of Racah covalency parameters for **2** gives $k_{\|} = k_{\perp} = 0.72$, which is significantly higher than found for aminopyridinium tetrachlorocuprate(II) salts [4] and indicates that there is minimal π-bonding in the anions.

The asymmetric unit of **3** contains one tetrachlorocuprate(II), a chloride ion, a hydrate water molecule and $H_5$2,6Acgu$_2^{3+}$, the latter resulting from protonation of the pyridyl nitrogen and the two guanyl nitrogens, Fig. 3. There are four intramolecular hydrogen bonds in the trication, N1–H···N2, N5–H···N2, N11–H···N12 and N15–H···N12. The angle between the pyridine ring and the aminoguanidone moieties, N2–N3–C8–N4–N5 and N12–N13–C18–N14–N15, are 23.6(2)° and 15.9(1)°, respectively. The copper(II) center has a coordination geometry intermediate between tetrahedral and square-planar, the *trans* angles are 138.86(8)° and 137.73(7)° and the Cu–Cl bond distance ranges from 2.211(1) to 2.265(2) Å.

The ESR spectra of **3** has a rhombic spectrum with $g_1 = 2.239$, $g_2 = 2.159$ and $g_3 = 2.092$ resulting in a $g_{av} = 2.163$, which is consistent with the two long and two short Cu–Cl bonds found by crystal structure determination.

4. Discussion

4.1. Structure of the aminoguanidonium cations

The heterocyclic aminoguanidonium ions have the same pattern of protonation in the three salts; the pyridyl nitrogen and guanyl nitrogen, N3 (or the equivalent N13 or N23). Protonation at the guanyl nitrogen results in two NH_2 groups being attached to the guanidine moiety's carbon atom, C8 (C18 or C28), and a formal double bond is present between this carbon atom and N3 (N13 or N23) resulting in a formal positive charge on N3 (N13 or N23), as found in previous studies [5,6]. However, the C–N bond distances to the two NH_2 groups, C8–N4 (C18–N14 or C28–N24) and C8–N5 (C18–N15 or C28–N25), are shorter than the C8–N3 'double' bond in the three salts indicating considerable π-character in the former bonds and suggesting that the formal bonding picture described above is very approximate.

The imine bond, C2–N7 (C12–N17 or C22–N27), in the three cations is the shortest carbon–nitrogen bond of these guanidonium moieties, and its distance is similar to the analogous bond of neutral thiosemicarbazones prepared from 2-formyl- [7], 2-benzoyl- [7] and 2,6-diacetylpyridine [8]. This suggests that protonation of both the pyridine ring and aminoguanidone moiety in these cations has little effect on the imine bond distance. This is consistent with the small distance changes of the imine bond on coordination except to the hardest metal ions [9].

Bond distances and angles within the guanidonium moieties are similar among the three salts, as well as the

two unique ions of H_3Bzgu^{2+} and the two moieties of $H_52,6Acgu_2^{3+}$. The N2–C7–C2 angle of H_3Fogu^{2+} is significantly larger than in the other cations, which was not observed for neutral heterocyclic thiosemicarbazones [7,8], but each of these angles is in the same range as found for the thiosemicarbazones. Also, the N2–N3 (N12–N13, N22–N23) bond distances are essentially the same in the present cations as they are in the neutral thiosemicarbazones [7,8].

4.2. Structure of the tetrachlorocuprate(II) ions

According to the charge compensation hypothesis, the hydrogen bonds tend to remove charge from the Cl atoms, and promote $[CuCl_4]^{2-}$ to have a more square-planar geometry [3]. In the present compounds the presence of multiple hydrogen bonds in the three structures, as well as chloride anions and hydrate water molecules in **2** and **3**, allow us to test this simple hypothesis in complex situations. Considering the short and intermediate intermolecular N–H···Cl–Cu contacts, Table 3, **1** has more contacts than **2** and **3** (**3** > **2**) and according to the above mentioned hypothesis a geometry more near to square-planar will be expected for **1**. Based on the *trans* angles the three compounds have distorted D_{2d} symmetry, but **1** is the nearest to tetrahedral symmetry, the opposite to the expected result. This indicate that other crystal forces, not considered in this simple model, have a substantial effect upon the geometries of the metal ions in this compounds [9].

4.3. Spectroscopic characterization

Bands above 40,000 cm^{-1} are assigned to $\pi \rightarrow \pi^*$ transitions of the pyridine ring and imine function. Since the pyridyl nitrogen is protonated in all three salts, the two bands in the 30,000 cm^{-1} region are assigned to the $n \rightarrow \pi^*$ transitions of the guanidonium moiety. 2-Acetylpyridine N(4)–dialkyl- or azacyclothiosemicarbazones exist in a bifurcated hydrogen bonding form, which results in conjugation in an analogous manner to the guanidonium moiety [10]. Conjugation of the thiosemicarbazone moiety results in strong bands in the 25,000 and 30,000 cm^{-1} range with the band at 25,000 cm^{-1} being assigned to the thioamide part of the thiosemicarbazone. Conjugation of the aminoquanidone moiety would be expected to produce a band at higher energy as assigned above. Although, there are five assignable Cl → Cu(II) charge transfer bands for tetrachlorocuprate(II) ions having D_{2d} sym-

metry [11], most are obscured by the higher energy bands of the cations in the salts of this study. These bands are very broad, but there are no resolvable shoulders present. However, the lowest energy Cl→Cu(II) bands in the 25,000 cm^{-1} range are present in the spectra of all three salts and, there is some resolution of this band for **3**.

While most studies of the various $[CuCl_4]^{2-}$ ions having D_{2d} symmetry have reported two bands for the d→d transitions in the spectral ranges 5800–6400 and 8900–9500 cm^{-1} ranges [4,12,13], D_{2d} symmetry allows for three or even four bands (i.e. when the excited ^2E level is split). We have been able to assign either three or four bands in the NIR region for these three salts although narrow bands due to various ν(NH) combination bands complicate the spectra. The assignments for the $^2B_2 \rightarrow {}^2A_1, \rightarrow {}^2B_1$ and $\rightarrow {}^2E$ transitions in D_{2d} symmetry are included in Table 4.

$Cl \rightarrow Cu(II)$	23,930	24,600	26,700, 25,530, 22,830
$^2B_2 \rightarrow {}^2A_1$	10,470	11,170	11,500
$^2B_2 \rightarrow {}^2B_1$	8670	10,170	10,300
$^2B_2 \rightarrow {}^2E$	5160	6100, 5680	7,600, 6,570
$g_{\|}$ or g_1		2.336	2.239
g_2			2.159
g_1 or g_3		2.079	2.092
g_{av} or g_{iso}	2.205	2.165	2.163

The nature of the powder ESR spectra of the three salts is different. These spectra correlate well with the ESR found for tetrachlorocuprate salts of 2-aminopyridinium ion, $g_{av} = 2.189$; 2-amino-5-picolinium ion, $g_{av} = 2.152$; and 2-amino-4,6-picolinium ion, $g_{av} = 2.164$ [13]. The higher energy $d \rightarrow d$ bands and g_{av} values at the lower end of the range found for related tetrachlorocuprate(II) salts [4] are in agreement that these salts having stronger hydrogen bonding interactions resulting in a greater $[CuCl_4]^{2-}$ planarity, particularly for **2** and **3**.

5. Conclusions

The C–N bond distances to the two NH_2 groups are shorter than the C8=N3 'double' bond in the three salts indicating considerable π-character in the former bonds. This indicates that the formal bonding picture, which considers a single bond between the C–NH_2 and a double bond between C8=N3, is very approximate.

As expected the crystal structure of the compounds present extended hydrogen bonding networks. Unfortunately, the presence of water molecules and Cl^- in two of these structures prevent an analysis of reproducible N–H···Cl–Cu hydrogen bonding patterns.

Due to the complicated hydrogen bond networks and crystal forces present in these compounds the charge compensation hypothesis fail to predict the geometry of the $[CuCl_4]^{2-}$ ions.

6. Supplementary material

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 157431 for **1**, 157432 for **2** and 157433 for **3**. Copies of the information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, (fax: +44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 8 March 2001; accepted 26 November 2001

Abstract

The synthesis of four new di-*n*-butylhydroxytin(IV) derivatives obtained from 1,3-diketone malonates **2a**–**2d** is reported. All compounds were characterized by ^{1}H, ^{13}C, ^{119}Sn NMR, infrared spectroscopy and mass spectrometry (FAB). The ^{119}Sn NMR spectra at room temperature showed that in $CDCl_3$ solution the tin atom is hexacoordinated. Moreover, the ^{119}Sn NMR spectra of compound **2a** at low temperature exhibits two signals in the range of hexacoordinated compounds, suggesting the existence of additional species in higher states of aggregation. © 2002 Elsevier Science Ltd. Keywords: Tin enolates; Diorganohydroxytin; Diorganotin; Sn(IV) complexes; Malonates; Di-*n*-butylhydroxytin(IV)

1. Introduction

Organotin reagents have been extensively studied in the context of carbon–carbon bond formation [1]. Organotin(IV)enolates in particular have been the subject of studies with electrophiles such as carbonyl compounds [2–4] and organic halides [5–9]. These reagents usually exist as mixture of *C*-stannyl ketone and *O*-stannylenolate, the ratio being dependent on structural factors [10–12]. NMR studies have indicated that tin(IV)enolates exhibit high-coordinated *O*-stannyl enolates in the presence of HMPA, which may be responsible for the selectivity observed in the reactions of α-haloketones [13]. Tin(IV)enolates have been prepared by transmetallation of lithium enolates, transesterification of enolates and hydrostannation of conjugate carbonyls [1]. In spite of the fact that tin(IV)enolates are relativity more stable than their lithium and silicium analogous there are few reports concerning their structures [14]. Our current interest in the synthesis of organotin(IV) compounds [15–17] prompted us to extend our investigations in the synthesis of new organotin(IV) enolates, which could have biological properties [18]. This paper describes the synthesis of new di-*n*-butylhydroxytin(IV) enolates **2a**–**2d** derived from 1,3-diketone malonates **1a**–**1d**, where the latter exist as enolates [19,20], (Fig. 1). All compounds were characterized by ^{1}H, ^{13}C, ^{119}Sn NMR, infrared spectroscopy and mass spectrometry (FAB).

2. Results and discussion

The reaction of 1,3-diketone malonates **1a**–**1d** with di-*n*-butyltin(IV) oxide led to di-*n*-butylhydroxytin(IV) enolates **2a**–**2d** (Fig. 1). The compounds were

obtained as yellow oils. The ^{1}H and ^{119}Sn NMR data of **2a**–**2d** are summarized in Table 1. An analysis of the ^{1}H NMR spectra showed that both the $(n\text{-Bu})_2Sn$ protons and those due to the ligands are in a 1:1 ratio. This requires that a OH group be bonded to the tin atom, although it is not observed, probably due to the formation of hydrogen bond or to the overlap with other signals. The CH_2CO and C=CH vinyl protons appear as broad signals (0.04 and 0.2 ppm) at higher field with respect to the free ligands, (**1a**–**1d**), which appear as triplet and singlet signals, respectively. This constitutes evidence for the formation of a Sn–O bond between the enolate moiety and C=O→Sn coordination bond, respectively. Their ^{119}Sn chemical shifts in chloroform are within the range of di-*n*-butyltin(IV) hexacoordinated compounds [21–25], suggesting the existance of additional aggregates in chloroformic solution (Fig. 2).

In order to obtain more information about the structure of these compounds, a variable-temperature NMR ^{119}Sn study of **2a** was undertaken. Thus the ^{119}Sn spectra in chloroform at 293 and 283 K showed only one peak at δ −383.75 and −383.97, respectively. However, upon lowering the temperature to 273 and 263 K the signal became broad at δ −384.67 and −384.06, respectively and the spectrum at 253 K exhibited two equally intense resonances at δ −383.94 and −385.16. The same result was observed at 240, 233 and 223 K. The temperature-dependent changes observed in the spectra are fully reversible, and the data could be indicative of a fast dynamic equilibrium, on the NMR time scale, between the aggregates shown in Fig. 2 and an additional species in a higher state of aggregation, where the tin atom is also hexacoordinated.

Table 2 shows the ^{13}C NMR data spectra for compounds **2a**–**2b**. The signals assigned to the C_5 (enolate)

δ: (ppm); in $CDCl_3$.
[a] The quaternary carbons and methy I group of the *t*-Bu group appear at δ 35.38 and 31.56, respectively.

Table 3
IR data for compounds **2a**–**2d**

Compound	C–H_{arom}	C–H_{aliph}	C=O	C=C–C–O	Sn–O
2a	3100	2956 2866	1736	1542	432–318
2b	3110	2958 2866	1736	1551	444–314
2c	3089	2960 2928	1734	1558	438–302
2d	3107	2956 2928	1734	1558	442–316

v(cm^{-1}), $CHCl_3$.

and C_7 (carbonyl) appear broad and small, indicating again the formation of the Sn–OC bond of the enolate moiety and C=O→Sn coordination bond, respectively. While the C_{11} (carbonyl ester) exhibits a sharp signal, which indicates that this carbonyl group does not interact with tin atom. Characteristic IR bands of the investigated compounds are summarized in Table 3. Compounds **2a**–**2d** show the band due to the carbonyl function located between 1736 and 1734 cm^{-1}, a band due to the enolate group in the range of 1558–1541 cm^{-1} and broad bands due to the Sn–O group between 444–432 and 318–302 cm^{-1}.

The FAB mass spectra for **2a**, **2c** and **2d** exhibit a molecular ion corresponding to a dimeric structure and for all compounds other fragment ions are associated with an spiroostannolane ion, (Fig. 3). They also exhibit the fragment ion $[RC_6H_4CO]^+$ at $m/z = 105$ (13%), 161 (26%), 150 (7%) and 139 (15%), respectively.

3. Conclusions

The new diorganotin(IV) compounds **2a**–**2d** were obtained as enolate derivatives, according to their spectroscopic data they are aggregates in solution. The ^{119}Sn variable-temperature NMR study for compound **2a** indicated the existence of a dynamic equilibrium between aggregates, where the tin atoms are hexacoordinated. Their FAB mass spectra exhibit the molecular ion corresponding to a dimer structure, which supports the existence of a additional specie aggregated.

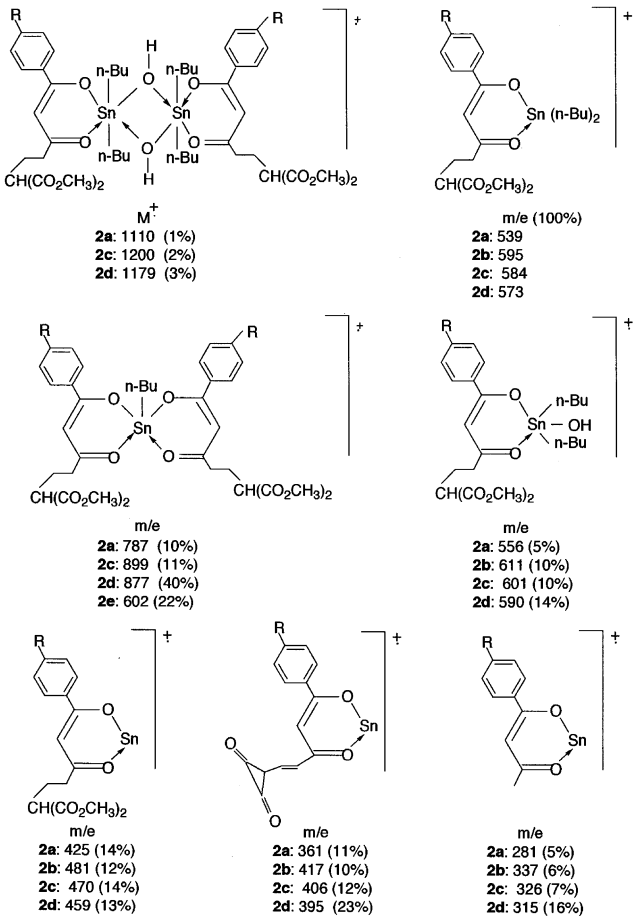

Fig. 3. Mass spectral data of compounds **2a**–**2d**.

4. Experimental

4.1. General procedure and measurements

Reagents were purchased from Aldrich Co. 1,3-Diketone malonates **1a**–**1d** were prepared according to the literature [18]. ^{1}H, ^{13}C and ^{119}Sn NMR spectra were recorded on Jeol GLX-270 JEOL Eclipse-400 and Bruker Avance 300-DPX spectrometers. All ^{1}H and ^{13}C resonances are reported relative to TMS in $CDCl_3$ being used as solvent. High resolution mass spectra (FAB) were obtained with a Jeol JMS-AX 505 mass spectrometer, and infrared spectra were recorded on a Perkin–Elmer 16F PC FT-IR spectrometer.

4.2. Preparation of compounds *2a*–*2d*

The procedure outlined in the following paragraph is general for the preparation of compounds **2a**–**2d**.

4.2.1. Synthesis of di-n-butylhydroxy[dimethyl 2-(3-oxo-5-phenylpenten-5-ato)malonate]tin(IV) (*2a*)

A solution of 0.10 g (0.33 mmol) of **1a**, in 100 ml of a 80/20 $C_6H_5CH_3$–EtOH mixture was placed in a flask equipped with a magnetic stirrer and a Dean-stark trap and 0.08 g (0.33 mmol) of di-*n*-butyltin(IV) oxide were added. The suspension was refluxed during 9 h and after cooling to room temperature (r.t.), the solvents were evaporated under vacuum and the residue was treated with $CHCl_3$. The solution was filtered and the solvent was evaporated under vacuum to yield 0.85 g (45%) of **2a** as a yellow oil.

4.2.2. Synthesis of di-n-butylhydroxy[dimethyl 2-{5-(4-tertbutylphenyl)-3-oxopenten-5-ato}malonate]-tin(IV) (*2b*)

A 0.07 g (0.28 mmol) amount of compound **1b** gave 0.70 g of compound **2b** (57%) as a yellow oil.

4.2.3. Synthesis of di-n-butylhydroxy[dimethyl 2-{5-(4-nitrophenyl)-3-oxopenten-5-ato}malonate]-tin(IV) (*2c*)

A 0.10 g (0.28 mmol) amount of compound **1c** gave 0.70 g of compound **2c** (54%) as a yellow sticky solid.

4.2.4. Synthesis of di-n-butylhydroxy[dimethyl 2-{5-(4-chlorophenyl)-3-oxopenten-5-ato}malonate]-tin(IV) (*2d*)

A 0.09 g (0.28 mmol) amount of compound **1d** gave 0.10 g of compound **2d** (59%) as a yellow oil.

Abstract

The complexes [Ni(SCH_2CH_2S)(dppen)], dppen = $PPh_2CH{=}CHPPh_2$ (**1**) and [Ni($SCH_2CH_2CH_2S$)(dppen)] (**2**), have been prepared by reacting dried $NiCl_2$, the phosphine and the appropriate dithiolate compound, in a 1:1:1 molar ratio. For both complexes the ^{31}P NMR spectra confirmed that a chelate ring was formed around the metal, as the single resonance showed a downfield shift compared to the free phosphine. A less shielding effect was observed for the five-member ring formed in complex **1**. In the ^{13}C NMR could be observed a pseudo triplet for the resonance of the methylene carbons as a result of a different coupling to the phosphorus atoms. The crystal structure of complex **1** was determined by X-ray diffraction. Two molecules were found in the unit cell with square planar geometries, with one of them more distorted than the other. © 2002 Elsevier Science Ltd. All rights reserved.

1. Introduction

Sulfoxides are chiral compounds and complexes that have them as ligands can be used to induce chirality in other compounds in asymmetric synthesis [1]. One way to obtain sulfoxides is from thiolates by oxidation [2]. Accordingly we decided to obtain nickel complexes containing thiolate ligands, to be used as precursors to sulfoxides. As has been observed by others, monomeric homoleptic thiolate complexes of nickel and platinum are not formed. In general what is obtained is a polymeric, insoluble, material [3]. In order to avoid this problem, we decided to use as an ancillary ligand, *cis*-1,2-bis(diphenylphosphine)ethene, dppen, as a strong chelating ligand is necessary to form monomers in this type of reaction. In this paper we wish to describe the synthesis of two nickel thiolate complexes, their characterization by spectroscopic methods and elemental analysis, as well as the solution of the X-ray structure of complex **1**.

2. Experimental

2.1. Methods and materials

All solvents were used without purification. $NiCl_2{\cdot}6H_2O$, ethanedithiol, from Aldrich and *cis*-1,2-bis(diphenylphosphine)ethene, dppen, from Strem, were used as received. Elemental analyses (C, H, N) were performed on a Perkin–Elmer model PE-2400 CHN instrument. IR spectra were recorded on a Perkin–Elmer 283B instrument. ^1H (200 MHz) and ^{13}C (50 MHz) NMR spectra were recorded on a Bruker Advance DPX200, using Me_4Si as an internal reference and ^{31}P NMR (161.97 MHz) on a Bruker Advance DPX400, using H_3PO_4 as internal reference and operating at room temperature (r.t.).

2.2. Syntheses

2.2.1. cis-1,2-Bis(diphenylphosphino)-etheneethanedithiolatenickel(II) (1)

This complex was prepared according to the procedure described in the literature, with small modifications [3]. Previously dried $NiCl_2 \cdot 6H_2O$ (0.150 g, 1.16 mmol) was dissolved in 3 ml of water, filtered and diluted with 40 ml of EtOH (95%). Dppen (0.459 g, 1.16 mmol) was added and the mixture was left under reflux for 20 min. On addition of 0.109 g (1.16 mmol) of ethanedithiol the solution darkened, and 0.50 ml of Et_3N was added. The mixture was left under stirring at r.t. for 12 h. A violet precipitate settled at the bottom of the flask after this time. The mixture was filtered and the solid was dissolved in CH_2Cl_2 followed by extraction with a saturated aq. solution of NaCl. The CH_2Cl_2 solution was separated and dried over $MgSO_4$. The solvent was removed under reduced pressure, giving complex **1** in 58% yield. *Anal.* Calc. for $C_{28}H_{26}NiP_2S_2 \cdot 1/2CH_2Cl_2$: C, 59.00; H, 4.74. Found: C, 58.25; H, 4.55%. Atomic absorption for Ni: 10.00. Found: 11.38. ^{1}H NMR (δ, $CDCl_3$): 7.94–7.44 (m, $4C_6H_5$), 7.03–6.70 (dd, 2H, CH=CH), 2.78 (s, CH_2CH_2); $^{13}C\{^1H\}$ NMR (δ, $CDCl_3$): 146.82 (t, CH=CH, $J_{C-P} = 36.7$ Hz), 133.19–125.83 (m, C_6H_5), 40.61 (t, CH_2CH_2). ^{31}P NMR (δ, $CDCl_3$): 67.34 (s). IR (CsI, cm^{-1}): $\nu_{Ni-S} = 295$ and 320, $\nu_{Ni-P} = 420$ and 440.

2.2.2. cis-1,2-Bis(diphenylphosphino)-etheneethanedithiolatenickel(II) (2)

This complex was prepared in a similar manner as described above for complex **1**. Complex **2** was obtained in 46% yield. *Anal.* Calc. for $C_{29}H_{28}NiP_2S_2 \cdot 1/2CH_2Cl_2$: C, 59.62; H, 4.96. Found: C, 59.33; H, 5.12%. Atomic absorption for Ni: 9.77. Found: 10.94. ^{1}H NMR (δ, $CDCl_3$): 7.79–7.35 (m, $4C_6H_5$, dd, 2H), 2.44 (q, $CH_2CH_2CH_2$), 2.0 (m, $CH_2CH_2CH_2$); $^{13}C\{^1H\}$ NMR (δ, $CDCl_3$): 146.82 (t, CH=CH, $J_{C-P} = 36.7$ Hz), 133.46–125.83 (m, C_6H_5), 30.97 (t, $CH_2CH_2CH_2$). ^{31}P NMR (δ, $CDCl_3$): 59.67 (s). IR (CsI, cm^{-1}): $\nu_{Ni-S} = 280$ and 325, $\nu_{Ni-P} = 420$ and 435.

2.3. X-ray crystal structure elucidation of complex 1

General operating procedures and listings of programs have been given previously [4]. Data were collected using a standard moving crystal, moving detector technique with fixed background counts at each extreme of the scan. All data were corrected for Lp, and equivalent data were then averaged to yield a unique set of intensities. The sample consisted of transparent green needles of various morphologies and sizes up to several mm. A small, nearly equidimensional fragment was cleaved from one of the larger crystals and was affixed to a glass fiber. The crystal was then transferred to the goniostat where it was cooled to 100 K for characterization and data collection. A systematic search of reciprocal space located a set of diffraction maxima with no obvious symmetry or systematic absences. Subsequent solution and refinement confirmed a non-centrosymmetric triclinic space group $P\bar{1}$. Data were collected using a standard $\theta/2-\theta$ scan with fixed backgrounds at each extreme of the scan. The structure was solved using MULTAN-78 and Fourier techniques. Two independent molecules were present in the asymmetric cell. A difference Fourier located most of the hydrogen atoms. In the final cycles of refinement, all hydrogens were included as fixed isotropic contributors. No absorption correction was attempted. The absolute structure was confirmed by refinement of the two possible configurations. Details of crystallographic data collection, structure refinement and crystal data are given in Table 1. Complex **1** crystallizes in the space group $P\bar{1}$. Cell constants were obtained from the refinement of 16 reflections. A total of 9114 reflections were collected of which 8992 were independent and 6938 were flagged as observed ($F > 2.33\sigma(F)$).

3. Results and discussion

The compounds studied in the present work are shown in Fig. 1. The first step in the syntheses of the complexes consists on the formation of [Ni(Cl)$_2$(dppen)], in situ, that can contaminate the final products, if appropriate care is not taken to ensure complete reaction, as shown for the preparation of complex **1**.

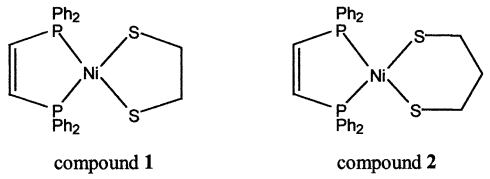

Fig. 1. Compounds studied in the present work.

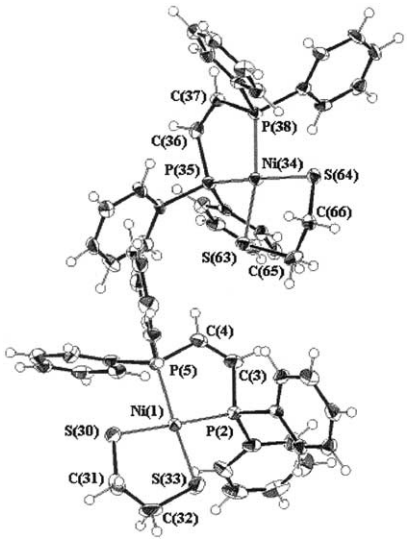

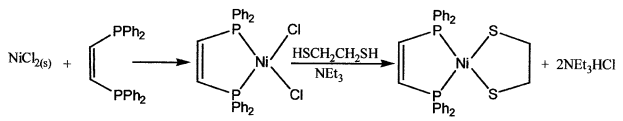

Fig. 2. ORTEP for complex **1** with ellipsoids at 30% probability.

The complexes were obtained as powdered red–maroon solids, stable in air, and soluble in common organic solvents. In both syntheses a small amount of CH_2Cl_2 was found in the products, as in the IR and ^1H NMR spectra could be found absorptions due to it, and this was confirmed by the elemental analyses. However, no solvent molecules were found upon resolution of the structure of complex **1**. In the ^{13}C NMR spectra of both complexes could be observed a pseudo triplet for the resonance of the methylene carbons, as a result of a different coupling to the phosphorus atoms. The compounds exhibit a single chemical shift in the ^{31}P NMR spectrum. The ^{31}P chemical shift values of δ 64.70 and 59.67 for complexes **1** and **2**, respectively, are characteristic of compounds that have chelating phosphines, as they are less shielded as compared to the free phosphine, δ −22.36. Also, the ^{31}P shift of the five membered chelate ring, in compound **1**, is less shielded than the six membered chelate ring in compound **2**, as observed previously for diphosphine complexes [5–9].

Crystals of good quality for a X-ray diffraction analysis were obtained from an ethanolic solution that was left under room temperature for several days. The structure consists of two crystallographically independent molecules (Fig. 2).

Each nickel atom is four coordinated by two sulfur atoms and two phosphorus atoms in a square-planar arrangement. In Table 1 are given crystallographic data and structure refinement details.

In one of the molecules the nickel atom and its four neighbors deviate from a plane through the following atoms: Ni(34), 0.0064; S(64), −0.2429; S(63), 0.2432; P(38), 0.2565 and P(35), −0.2631. As a consequence the square-planar geometry of the nickel atom shows a larger distortion than in the other molecule, leading to S–Ni–P angles of 166.07(6)° and 166.62(6)°, Table 2.

The Ni, P and the carbons atoms that forms the double bond are almost coplanar: deviations are Ni(34), −0.0097; P(35), 0.0054; P(38), 0.0133; C(37), −0.0135; C(36), 0.0045. The angle between these two planes is 4.28°. Larger deviations are found in the ring formed by Ni, S and the methylene carbons: Ni(34), 0.0294; S(64), −0.1734; S(63), 0.1080, C(65), −0.3086; C(66), 0.3446. The Ni–P and Ni–S bond distances are nearly identical, 2.131(17), 2.130(16) and 2.184(16), 2.176(16) Å, respectively, Table 2. These values are shorter than the corresponding bond distances in the complex $[Ni(dipdtc)(PPh_3)_2]ClO_4{\cdot}CHCl_3$ [10]. The C=C bond distance in this molecule is 1.315(7) Å. In the other molecule, a least-squares planes through Ni, S and P gave the following results: Ni(1), −0.0018; S(33), 0.0294, S(30), −0.0284, P(2), −0.0299. The angles around the nickel atoms were more close to the ideal ones for a square-planar geometry. The Ni, P and C atoms that form the double bond were almost coplanar, but more disordered than the previous molecule: Ni(1), −0.0254; C(3), 0.0124; C(4), −0.0366; P(2), 0.0141; P(5), 0.0355. The angle between these two

planes is only 1.95°. As before, larger deviations were found in the plane formed by Ni, S and the methylene carbons: Ni(1), −0.0268; S(33), 0.0927; S(30), −0.0372, C(32), −0.1591; C(31), 0.1305. The Ni–P bond distances were Ni(1)–P(2) = 2.138(18), Ni(1)–P(5) = 2.148(17) Å, longer than the previous ones and the Ni–S bond distances were smaller: Ni(1)–S(30) = 2.146(19) and Ni(1)–S(33) = 2.173(18) Å. The C=C bond distance was 1.300(7) Å. Similar to complex **1**, double bond distance values of 1.316(5), 1.280(2) and 1.315(5) Å were found in complexes $[Ni(Cl)_2$(*cis*-dppen)] [8], $[Pt(Cl)_2$(*cis*-dppen)] [6] and $[Pt($*cis*-dppen$)_2[BPh_4]_2$ [8]. The Ni–P and Ni–S bond distances are relatively short as compared to the distances reported for $[Ni(dipdtc)(PPh_3)_2]ClO_4 \cdot CHCl_3$ [10] and $[Ni(S_2CO)$-(dippe)] [11].

In one of the molecules there is better coplanarity in the plane formed by Ni, P and C's of the double bond (rms deviation of 0.010) but less coplanarity in the plane formed by Ni, and the ethanedithiolate unit; the Ni–P bond distance is smaller, and the Ni–S and C=C bond distances are longer, Table 2. In the other molecule, where there is more distortion on the plane formed by Ni, P and C's of the double bond (rms deviation of 0.0268) but more coplanarity in the plane formed by Ni and the ethanedithiolate unit, the Ni–P bond distance is longer and the other ones are smaller.

It is known that crystal packing effects can lead to structural differences and variations in bond distances and angles parameters, for molecules belonging to the same unit cell as well for different crystalline forms of the same molecule. Recently, a study that compared geometric data for crystal structures, for which more than one molecule of complex is present per crystallographic asymmetric unit, was performed. This study allowed a quantification of the crystal packing effect on molecular structures. The determined metal–ligand bond distance deviations were found to be in the range 0.01–0.02 Å and for the bond angles the range was 1–2° (or 3°). Also, this study showed that there exists a flexibility of metal complexes in crystals [12].

In the present work the Ni–P and Ni–S bond distance differences (mean values) within the two molecules are 0.013 and 0.011 Å, respectively, and the P–Ni–P and S–Ni–S bond angle differences (mean values) are 1.29° and 0.96°, respectively, and according to the previously mentioned work these differences are due to crystal packing effects. However, the reduction of the double bond distance below the ideal value of 1.337(6) Å and an almost coplanarity in the plane formed by the metal, P and C=C atoms, is an indication, for some authors, of a π bonding interaction throughout the atoms [6–9].

4. Conclusion

Compounds **1** and **2** are described for the first time. Both the Ni–P and Ni–S bond distances of compound **1** are shorter as compared to related bond distances for similar compounds described in the literature [10,11]. Also, there is a reduction of the C=C bond distance below the ideal value, and the planes formed by the metal and the two rings showed small deviations from coplanarity. This data can indicate that for this complex a π backbonding is occurring for both phosphorus and sulfur, Ni ⇒ P and Ni ⇒ S. The unsaturated nature of the diphosphine can lead to an enhancement of this interaction.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center under deposition number 163995 for complex **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Lanthanide(III) complexes of six-nitrogen-donor macrocyclic ligands carrying a benzyl-type group, $–CH_2–C_6H_4–X$ (X = –H, –OH, or $–NH_2$), at each di-imine side chain were synthesized by the metal-templated, cyclic Schiff-base condensation of 2,6-diacetylpyridine with substituted *S*- or *R*,*S*-1,2-diaminopropanes. The complexes were obtained as mixtures of constitutional isomers and stereoisomers, which were identified by ^{1}H NMR spectra and separated by fractional crystallization. The molecular structure of the 11-coordinate complex $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)(H_2O)$ was established by X-ray crystallography. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Lanthanide(III) complexes; Macrocyclic ligands; 2,6-Diacetylpyridine; 3-Substituted-1,2-diaminopropanes

1. Introduction

The potential usefulness of the lanthanide(III) ions as markers for histochemical techniques and immunoassays has focused attention on the complexes of these elements with macrocyclic ligands having functionalized peripheral substituents suitable for attachment to biosubstrates [1–5]. The symmetrically di-substituted complexes of this class (Fig. 1), synthesized by the metal-templated cyclic Schiff-base condensation of 2,6-diacetylpyridine with carbon-substituted 1,2-diaminopropanes, can exist as stereoisomers as well as constitutional isomers, depending on the chirality of the substituent-bearing carbon-3 of the parent diamine and on the relative positions of the R substituents at the di-imine side chains, $=N–CH_2–CH(R)–N=$, of the macrocycle moiety [6–8]. Previous studies on the simplest members of this series—the complexes in which the R substituents are methyl groups—have shown that, when a lanthanum(III) salt is used as template in the synthesis of the di-substituted macrocycles, constitutional isomers are indeed formed and can be distinguished on the basis of their different ^{1}H NMR spectra [6]. It was found that lanthanum(III) acetate provides high yields of macrocyclic complexes with useful solubilities, and that the temperature at which the synthesis

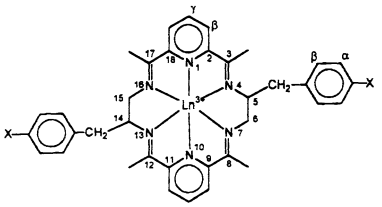

Fig. 1. Schematic formula of one of the two constitutional isomers of the cationic entity {LnL}, where Ln is a lanthanide(III) ion and L is a neutral six-nitrogen-donor macrocyclic ligand with identical substituents at the di-imine side chains. X = –H for L_A, –OH for L_B and $–NH_2$ for L_C. According to the conventional numbering scheme of the macrocycle cavity, this formula represents the 5,14 isomer. The absolute configurations of the 5 and 14 stereocenters are not specified.

PII: S0277-5387(01)01008-7

is carried out offers some degree of isomer selectivity. At room temperature, products obtained from *S*-1,2-diaminopropane were greatly enriched in the 5,14 isomer, whereas products obtained from the *R*,*S*-diamine consisted primarily of the (*R*,*S*)-5,15 isomer. It was also noted that in each case the more abundant isomer had the side-chain $-CH_3$ groups in the same hemisphere relative to the macrocycle [6].

The preceding results provided a general guideline for the synthesis and study of a series of lanthanide(III) complexes of macrocyclic ligands with benzyl-type substituents carrying hydroxo, amino, and isothiocyanato functionalities that offer the opportunity for covalent coupling to a variety of substrates. Examples of their applications have been reported [2–4]. The related complexes with non-functionalized benzyl substituents were also investigated as models, and the crystal structure of a La(III) derivative is reported as characteristic of this class.

2. Experimental

2.1. Materials and instrumental procedures

Metal salts (Aldrich Chem. Co.), *S*-phenylalanine amide, *S*-tyrosine amide, *S*- and *R*,*S*-(4-aminophenyl)alanine (all from Sigma Chem. Co.) were used as received. Solvents were of reagent or analytical grade and anhydrous. NMR spectra were obtained with a GE QE-300 spectrometer at ambient temperature (24–26 °C). Chemical shifts for ^1H spectra are reported as δ (ppm); coupling constants, *J*, are given in Hz; spectra were referenced to tetramethylsilane (TMS, 0.00) or to the residual proton signal of the solvent: $CHCl_3$, 7.26(1); CD_3OD, 3.30(5); deutero-dimethylsulfoxide, DMSO-d_6, 2.49(5). Abbreviations: s = singlet, d = doublet, dd = doublet of doublets, m = multiplet, br = broad, v = very. Infrared spectra were obtained on a Perkin–Elmer Model 1600 FT instrument (4000–500 cm^{-1}). Samples were examined as KBr pellets. Absorption frequencies are reported in cm^{-1}; abbreviations: s = strong, m = medium, w = weak, br = broad, v = very; asterisk indicates absorption only partly resolved from adjacent stronger peak. Microanalyses (C, H, N) were performed by Atlantic Microlab, Atlanta, GA; compounds had analyses corresponding to the given formulas.[1] Solvent content was confirmed by thermogravimetric analysis using a Perkin–Elmer TGS-2 instrument with helium flow. The complexes lost solvent completely between 50 and 110 °C; they decomposed without melting at 160–180 °C. Dried samples reabsorbed moisture when exposed to the atmosphere.

[1] Tables of analytical data, carbon-13 NMR spectra, and details of synthetic procedures are available upon request from the corresponding author.

2.2. Syntheses of amine precursors

The hydrochlorides of *S*-1,2-diamino-3-phenylpropane [9] and *S*-1,2-diamino-3-(4-hydroxyphenyl)-propane [10] were obtained from the commercially available amides by reduction with BH_3/thf [10]. The *S*- and *R*,*S*-1,2-diamino-3-(4-aminophenyl)propane were obtained from the corresponding *S*- and *R*,*S*-aminoacids according to the scheme:

$$NH_2–C_6H_4–CH(NH_2)–COOH$$
$$\rightarrow (NH_3^+Cl^-)–C_6H_4–CH(NH_3^+Cl^-)–COOCH_3$$
$$\rightarrow (NH_3^+Cl^-)–C_6H_4–CH(NH_3^+Cl^-)–CONH_2$$
$$\rightarrow NH_2–C_6H_4–CH(NH_2)–CONH_2$$
$$\rightarrow (NH_3^+Cl^-)–C_6H_4CH(NH_3^+Cl^-)–CH_2–NH_3^+Cl^-.$$

The first three steps were carried out by standard procedures; the amide was converted to the amine trihydrochloride as reported for the 4-hydroxyphenyl-analog [10].

2.2.1. S- and R,S-(4-aminophenyl)alanine methyl ester dihydrochloride

Colorless crystals. Diagnostic IR: 3424 m*, 2900 vs, br* and 2590* s, ν(OH) water and $\nu(NH_3^+)$; 1743 vs, ν(C=O) ester. ^1H NMR (DMSO-d_6/TMS): 3.12 dd, 1H and 3.20 dd, 1H (ABX pattern, $J_{AB} = 14.1$, $J_{AX} = 7.2$, $J_{BX} = 5.7$, $CH_{(A)}H_{(B)}$, with coupling to vicinal $CH_{(X)}$); 4.26 br, 1H (CH); 7.32 m, 4H (phenyl); 8.75 s 2H and 10.4 vbr, 2H (NH_3^+, deprotonated in DMSO).

2.2.2. S- and R,S-(4-aminophenyl)alanine amide hydrochloride

Colorless crystals. Diagnostic IR: 3500–2500 vs vbr, with partly resolved peaks, ν(OH) water and $\nu(NH_3^+)$; 1690 vs, ν(C=O) amide. ^1H NMR (D_2O/DSS): 3.07 dd, 1H and 3.15 dd, 1H (ABX pattern, $J_{AB} = 14.4$, $J_{AX} = 7.5$, $J_{BX} = 6.6$, $CH_{(A)}H_{(B)}$, with coupling to vicinal $CH_{(X)}$); 4.19 dd, 1H (CH); 6.85 d, 2H and 7.14 d, 2H ($J = 8.1$, phenyl); $CONH_2$ exchanged in D_2O, in DMSO-d_6: 8.08 s, 1H and 8.56 s, 1H; NH_3^+ exchanged in D_2O, in DMSO-d_6: 8.3 vbr, 3H.

2.2.3. S- and R,S-(4-aminophenyl)alanine amide

Cream-colored hygroscopic powder. Diagnostic IR: 3401 vs (sharp) and 3318 vs (sharp), $\nu(NH_2)$; 1675–1638 s, ν(C=O) amide. ^1H NMR (DMSO-d_6/TMS): 2.69 dd, 1H and 2.73 dd, 1H (ABX pattern, $J_{AB} = 13.4$, $J_{AX} = 8.3$, $J_{BX} = 5.0$, $CH_{(A)}H_{(B)}$, with coupling to vicinal $CH_{(X)}$); 3.19 dd, 1H (CH); 6.45 d, 2H and 6.83 d, 2H ($J = 8.1$, phenyl); 6.91 s, 1H and 7.24 s, 1H, $CONH_2$); 4.85 s, 4H (NH_2).

2.2.4. S- and R,S-1,2-diamino-3(4-aminophenyl)-propane trihydrochlorides

Colorless, hygroscopic microcrystals. IR: 3406 m–s, br, 2876 vs, br, and 2590 m–s, br, $\nu(NH_3^+)$; 1980 w br; 1579 m–w; 1511 vs; 1411 w; 1389 vvw; 1291 vw; 1245 m–s; 1190 w; 1121 w; 1054 w; 988 vvw; 934 vvw; 897 vvw; 860 w; 816 w; 642 vw; 549 vw; 495 w. ^{1}H NMR (DMSO-d_6/TMS): 2.9–3.1 two overlapping dd, 4H (CH_2–phenyl and CH_2–NH_3^+); 3.58 m, 1H (CH); 7.32 d, 2H and 7.41 d, 2H ($J = 8.4$, phenyl); 8.68 s br, 2H, 8.58 s, br, 2H and 10.3 s, br, 2H (NH_3^+, deprotonated in DMSO).

2.3. Macrocyclic complexes from metal-templated syntheses

The complexes were obtained from 2,6-diacetylpyridine, the appropriate diamine, and lanthanide(III) acetate (2:2:1 mole ratio), following the procedure described for the dimethyl-substituted analogs [6]. The products were washed with Et_2O and dissolved in $CHCl_3$ (for the dibenzyl-complexes) or in 9:1 $CHCl_3$–MeOH (for the dihydroxybenzyl- and diaminobenzyl-complex), discarding the undissolved inorganic salts. The solutions were diluted with Et_2O, and the solids that formed were isolated and dried in vacuo over Drierite. The IR spectra of the La(III), Eu(III) and Gd(III) complexes of each macrocyclic ligand were nearly identical, except for the intensity of the ν(OH) absorption of water; for the di-(4-aminophenyl)-macrocycles, no difference was observed between the IR spectra of complexes obtained from the *S*- and *R*,*S*-diamine. The ^{1}H NMR spectra of the products served to establish the original isomer composition.

2.3.1. (S,S)-{LaL_A}$(CH_3COO)_{2.5}Cl_{0.5}\cdot 6.5(H_2O)$, (S,S)-{$EuL_A$}$(CH_3COO)_2Cl\cdot 1.5(H_2O)$, and (S,S)-{$GdL_A$}$(CH_3COO)_2Cl\cdot 2.5(H_2O)$

Pale yellow powders, very soluble in $CHCl_3$, MeOH, EtOH, Me_2SO and DMF; moderately soluble in water; insoluble in Et_2O and hydrocarbons. Bulk recrystallization from MeOH–(charcoal)–Et_2O gave colorless microcrystals; IR: 3400 s vbr, ν(OH) water; 3060 vw; 3027 vw; 2926 vw; 1636 m, ν(C=N) imine; 1587 m, ν(C=N) pyridine; 1542 vs, ν_{asymm}(COO); 1496 w; 1435 vs ν_{symm}(COO); 1378 m–w; 1291 vw; 1248 m; 1199 m; 1152 w; 1130 vvw; 1082 w; 1004 m; 926 w; 817 m; 746 m; 706 m–w; 665 m, δ(COO); 636 w; 615 vw; 563 vw; 492 vw (the last several peaks overlaid on the broad absorption of lattice water at 650 cm^{-1}). The ^{1}H NMR ($CDCl_3$) spectrum of the bulk-purified La(III) complex showed the presence of two isomers: (*S*,*S*)-5,14 60% and (*S*,*S*)-5,15 40%. Repeated fractional crystallization from MeOH–Et_2O gave isomer-enriched fractions but complete separation was not achieved. ^{1}H NMR spectra: Table 1.

2.3.2. (S,S)-{LaL_B}$(CH_3COO)_{2.25}Cl_{0.25}\cdot 2.75(H_2O)$ and (S,S)-{EuL_B}$(CH_3COO)_2Cl\cdot 3(H_2O)$

Pale yellow powders, very soluble in MeOH, EtOH, Me_2SO and DMF; moderately soluble in water; insoluble in $CHCl_3$, Et_2O and hydrocarbons. Bulk recrystallization from 1:9 MeOH–$CHCl_3$(charcoal)–Et_2O gave colorless microcrystals. IR: 3409–2900 s, vbr (with shoulders and ill-resolved splitting), ν(OH) and ν(C–H); 1637 m, ν(C=N) imine; 1589 m, ν(C=N) pyridine; 1543 vs, ν_{asymm}(COO); 1516 s; 1435 vs. ν_{symm}(COO); 1378 m; 1248 m; 1187 m; 1066 w; 933 w; 813 m; 742 m; 669 m, δ(COO); 635 w; 617 w; 568 w. The ^{1}H NMR ($CDCl_3$) spectrum of the bulk-purified La(III) complex showed the presence of two isomers: (*S*,*S*)-5,14 60% and (*S*,*S*)-5,15 40%. Repeated fractional crystallization from MeOH–Et_2O gave isomer-enriched fractions but complete separation was not achieved. ^{1}H NMR spectra: Table 1.

2.3.3. (S,S)-{LaL_C}$(CH_3COO)_3\cdot 3.0(H_2O)$, (R,S)-{$LaL_C$}$(CH_3COO)_3\cdot 4.0(H_2O)$, (R,S)-{$EuL_C$}–$(CH_3COO)_3\cdot 3.5(H_2O)\cdot 1.5(CH_3OH)$, and (R,S)-{$GdL_C$}$(CH_3COO)_3\cdot 3.25(H_2O)$

Orange–brown glassy solids, moderately soluble in $CHCl_3$; very soluble in MeOH, EtOH, Me_2SO and DMF; insoluble in Et_2O, hydrocarbons and water. Bulk recrystallization from 9:1 $CHCl_3$–MeOH(charcoal)–Et_2O gave pale mustard–yellow powders, much less soluble in $CHCl_3$ than the original products. IR: 3420–3300 vs, vbr, ν(OH) water; 3220 m*, $\nu(NH_2)$; 3063 w; 3006 w; 2925 w; 2910 w; 1632 s, ν(C=N) imine; 1585 s, ν(C=N) pyridine; 1538 vs, ν_{asymm}(COO); 1515 vs; 1432 vs, ν_{symm}(COO); 1373 m–w; 1290 w; 1248 m–s; 1196 m–s; 1153 vw; 1125 vw; 1080 vw; 1004 m; 927 vw; 809 m; 739 w; 666 m–s. δ(COO); 635 w; 616 vw; 563 vw. The ^{1}H NMR ($CDCl_3$–CD_3OD 9:1) spectrum of the La(III) complex from the *S*-diamine showed the presence of two isomers, (*S*,*S*)-5,14 60% and (*S*,*S*)-5,15 40%. For the La(III) complex obtained from the *R*,*S*-diamine, the ^{1}H NMR spectrum ($CDCl_3$–CD_3OD 9:1) showed four isomers, of which three were identified: (*R*,*S*)-5,15 43%, (*S*,*S*)-5,14 18% and (*S*,*S*)-5,15 17%. A fourth set of signals in the –CH_3 (macrocycle) region was tentatively identified as arising from the (*R*,*S*)-5,14 isomer (22%), but the spectrum was not fully assigned. Repeated fractional crystallization from MeOH–Et_2O produced fractions enriched in the major isomer but complete separation was not achieved. ^{1}H NMR spectra: Table 1.

2.4. Macrocyclic complexes from anion metathesis

These were obtained by procedures similar to those described for the di-methyl-substituted analogs [6].

Table 1
Proton NMR spectra of lanthanum(III) complexes of di(benzyl)-, di(4-hydroxybenzyl)- and di(4-aminobenzyl)-substituted macrocyclic ligands [a]

Group	Complex, isomer, solvent

CH_3 acetate			1.67 s 9H	1.67 s 9H	1.74 s 9H	1.74 s 9H	1.65 s 6H

[a] Minor variations in chemical shifts were observed for samples with different moisture contents.
[b] Pure isomer.
[c] Enriched isomer mixture. The signal of the (phenyl)–OH group was not detected in $CDCl_3$–CD_3OD solution; in DMSO-d_6, the signal appeared as a broad singlet (2H) at approximately 9.3 ppm.
[d] Enriched isomer mixture. The signal of the (phenyl)–NH_2 group was not detected in $CDCl_3$ or $CDCl_3$–CD_3OH solution; in DMSO-d_6, the signal appeared as a broad singlet (4H) at 5.0 ppm.
[e] ABX spin pattern. Each component of the pattern was broadened with ill-resolved splitting (coupling to CH_2 of macrocycle, $J < 1.5$ Hz).
[f] Broad with ill-resolved splitting.
[g] Coupling to vicinal CH; each component of the doublet was broad with ill-resolved splitting (coupling to CH_2 of macrocycle).
[h] Coupling to vicinal CH. The higher-field component of the doublet was broad with ill-resolved splitting (coupling to CH_2 of macrocycle).
[i] AB spin pattern. Each component of the pattern was broadened with ill-defined splitting (coupling to vicinal CH and CH_2 of benzyl).
[j] Partly obscured by strong signal at 4.25 ppm (water of hydration in complex).
[k] With ill-resolved splitting (coupling to vicinal CH and CH_2 of benzyl).
[l] With ill-resolved splitting.
[m] Signals of isomers overlapped.
[n] With ill-resolved splitting (coupling to CH_2 of macrocycle and CH_2 of benzyl). Signals of isomers overlapped. AB spin pattern.
[o] Distorted toward AB spin pattern.
[p] ABC spin pattern.
[q] A_2B spin pattern.

2.4.1. $\{LaL_A\}Cl_3\cdot n(H_2O)$, (S,S)-5,14 and (S,S)-5,15 pure isomers

Fractional crystallization of the (*S*,*S*)-5,14/(*S*,*S*)-5,15 isomer mixture from MeOH–Et_2O gave small amounts of the pure isomers, having virtually identical IR spectra but different and structurally diagnostic ^{1}H NMR spectra. Colorless microcrystals, very soluble in polar organic solvents; slightly soluble in water; insoluble in Et_2O and hydrocarbons. IR: 3400 s, br, ν(OH) water; 3060 vw; 3025 vw; 2927 vw; 1638 s, ν(C=N) imine; 1590 s, ν(C=N) pyridine; 1449 m; 1372 m; 1254 m; 1199 m; 1153 vw; 1084 vw; 1004 m–w; 932 vw; 815 m–w; 745 m; 706 m; 671 m–s; 637 vw; 614 vw; 568 vw; 519 vw. ^{1}H NMR spectra: Table 1.

2.4.2. R,S-$\{LaL_C\}(NCS)_2(CH_3COO)\cdot CH_3OH$

Rosettes of opaque red–brown needles, slightly soluble in Me_2SO and DMF; insoluble or nearly insoluble in other common organic solvent. IR: 3423 m–s*, 3335 m–s* and 3290*m $\nu(NH_2)$; 3078 w; 3013 w; 2919 w; 2043 vvs, ν(C≡N) of SCN^-; 1628 s, ν(C=N) imine; 1587 s, ν(C=N) pyridine, 1538 m* ν_{asymm}(COO), 1515 s; 1438 m, ν_{symm}(COO); 1373 m; 1248 m; 1192 m; 1152 w; 1126 w; 1004 m–w;, 954 vw; 866 vw; 812 m–s, ν(C–S) of SCN^-; 738 w; 635 w; 553 vw; 511 w. The ^{1}H NMR spectrum (poorly resolved, DMSO-d_6) showed the presence of several isomers. Separation of the isomers by fractional crystallization was not attempted for lack of solubility in useful solvents.

2.4.3. R,S-$\{EuL_C\}(NCS)_3\cdot 0.25(H_2O)$

Dark red ill-formed prisms, nearly insoluble in most organic solvents and water. IR: 3423 m*, 3337 m* and 3216 m–s* $\nu(NH_2)$; 3013 w; 3007 w; 2924 w; 2017 w; 2048 vvs, ν(C≡N) of SCN^-; 1626 s, ν(C=N) imine; 1590 s, ν(C=N) pyridine, 1542 vw; 1517 s; 1439 m; 1376 m–w; 1360 m–w; 1290 m; 1260 m; 1243 m*; 1195 m; 1154 w; 958 w; 812 m, ν(C–S) of SCN^-; 739 m; 650 w; 600 vw; 553 vw; 513 vw.

2.4.4. $\{LaL_A\}(NO_3)_3\cdot 2(H_2O)$

A MeOH solution of $\{LaL_A\}$ acetate chloride (90% (*S*,*S*)-5,14-isomer) and lithium nitrate, filtered on a 0.45 μm pore-size syringe filter and refrigerated at 4 °C, gave crystals suitable for X-ray analysis (see later section).

2.5. Investigation of the inertness of the lanthanide-macrocycle moieties

2.5.1. ^{1}H NMR study of the interaction of $\{LaL_C\}(CH_3COO)_3$ with 2,4-pentanedione

The complex *R*,*S*-$\{LaL_C\}(CH_3COO)_3\cdot 4(H_2O)$ was dissolved in 9:1 $CDCl_3$–CD_3OD and a threefold molar amount of 2,4-pentanedione (acetylacetone) was added. The ^{1}H NMR spectrum of the solution gave the typical pattern of the *R*,*S*-$\{LaL_C\}$ macrocycle, together with the signals of acetate and acetylacetone–acetylacetonate, showing that no decomposition of the lanthanum-macrocycle moiety had occurred. The spectrum remained unchanged over time.

2.5.2. Attempted transmetallation between the $\{LaL_C\}$ macrocycle and 'free' Eu(III) ion

The complex *R*,*S*-$\{LaL_C\}(CH_3COO)_3\cdot 4(H_2O)$ was dissolved in CD_3OD and a twofold molar amount of Eu(III) acetate was added. The ^{1}H NMR spectrum of the resulting solution showed the typical pattern of the $\{LaL_C\}$macrocycle, with no change over time. In contrast, the presence of the paramagnetic Eu(III) ion caused the signal of the acetate $-CH_3$ to shift in a manner dependent on concentration, as previously observed for the unsubstituted macrocyclic complex [11].

2.6. Reactions of peripheral functional groups

2.6.1. Esterification of the hydroxo-phenyl groups with acetic anhydride

The reaction was carried out under dry nitrogen flow. The finely ground $\{LaL_B\}$ acetate–chloride complex (5.0 mmol, *S*,*S* isomer mixture) was dehydrated at 90 °C for 30 min in a dry nitrogen flow, dissolved in 5 ml of anhydrous DMF, and treated with acetic anhydride (5.0 ml, approximately 50 mmol) and 4-dimethylaminopyridine (0.40 ml, approximately 2.5 mmol). The mixture was refluxed for 12 h. Diethyl ether was added to the cooled solution and the solid that formed was isolated and taken up in $CHCl_3$. The undissolved residue was discarded and the solution was evaporated to dryness under reduced pressure. The residue was crystallized from MeOH–Et_2O. Cream-colored powder (yield, 40%) of composition $C_{46}H_{58}N_6O_{13.5}La$=La-$\{C_{22}H_{24}N_6(CH_2C_6H_4OCOCH_3)_2\}(CH_3COO)_3\cdot 3.5(H_2O)$. IR: 3425 s, ν(OH) water; 2919 w; 1755 s, ν(C=O) ester; 1637 s, ν(C=N) imine; 1587 s, br, ν(C=N) pyridine and ν_{asymm}(COO); 1559 w; 1542 s; 1508 s; 1436 s, ν_{symm}(COO); 1372 s; 1244 m; 1218 m; 1195 s; 1167 m; 1014 w; 1005 w; 913 w; 812 m; 741 w; 666w; 638 m, δ(COO); 556 w. ^{1}H NMR (DMSO-d_6/TMS): 1.48 s, 6H (CH_3 acetate); 2.18 s and 2.20 s, 6H total (CH_3 ester); 2.01 s, 2.06 s, 2.45 s, 2.48 s, 12H total (CH_3 macrocycle); 2.80–3.10 m, 4H (CH_2 benzyl); 3.75–4.15 m, 4H (CH_2 macrocycle); 4.60 br, 2H (CH); 6.93–7.05 m, 8H (phenyl); 8.09–8.33 m, 6H (pyridine).

2.6.2. Reaction of the amino-phenyl groups with thiophosgene

The reaction was carried out at room temperature, avoiding contact with atmospheric moisture. The $\{EuL_C\}$ triacetate complex (0.50 g, bulk-product from *R*,*S*-amine) was allowed to react for 24 h with thiophosgene (2.00 ml) and calcium carbonate (0.50 g) in $CHCl_3$ (250 ml). The resulting mixture was filtered,

Table 2
Selected bond lengths (Å) and angles (°) for $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)(H_2O)$

Bond lengths

2.6.3. Crystal data for $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)(H_2O)$

Mr = 915.7 monoclinic, space group $P2_1$, a = 10.123(2), b = 16.943(3), c = 11.748(3) Å, β = 107.64(3)°, V = 1920.2(8) Å^3, Z = 2, Dx = 1.58 Mg m^{-3}, λ(Mo Kα) = 0.71069 Å, μ (Mo Kα) = 11.8 cm^{-1}, T = 293 K.

A prismatic white transparent crystal of dimensions 0.14 × 0.20 × 0.28 mm was centered on a four-circle Philips PW1100 (Febo System) [12] diffractometer operating in θ–2θ scan mode with graphite-monochromated Mo Kα radiation, following standard procedures. There were no significant fluctuations of intensities other than those expected from Poisson statistics. The intensity data were corrected for Lorentz-Polarization effects and for absorption, as described by North et al. [13]. No correction was made for extinction.

The structure was solved by heavy atom method. Refinement was carried out by full-matrix least-squares; the function minimized was $\Sigma w(F_o^2 - F_c^2)^2$, with weighting scheme $w = 1/[2(F_o^2) + 6.54P]$, where $P = \max(F_o^2 + 2F_c^2)/3$. All non-hydrogen atoms were refined with anisotropic thermal parameters. The H-atoms were placed in calculated positions with fixed, isotropic thermal parameters (1.2 Uequiv of the parent carbon atom). For a total of 519 parameters, $wR' = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{1/2} = 0.086$, $S = 1.131$, and conventional $R = 0.037$, based on the F values of 3272 reflections having $F_o^2 \geq 2.5\ \sigma(F_o^2)$.

The absolute configuration of the space group was assigned on the basis of Flack parameter [14]. Structure refinement and final geometrical calculations were carried out with SHELXL-93 [15] and PARST [16] programs, drawings were produced using ORTEP II [17]. Selected geometric parameters are reported in Table 2.

3. Results and discussion

3.1. Synthesis and characterization of the complexes

Complexes of La(III), Eu(III), and Gd(III) with the macrocyclic ligands $L_A = C_{22}H_{24}N_6(CH_2C_6H_5)_2$, $L_B = C_{22}H_{24}N_6(CH_2C_6H_4–OH)_2$ and $L_C = C_{22}H_{24}N_6$-$(CH_2C_6H_4–NH_2)_2$, in which the two benzyl-type substituents are attached to opposite di-imine side chains (Fig. 1), were synthesized by the condensation of 2,6-diacetylpyridine with the appropriate *S*- or *R*,*S*-diamine in the presence of a lanthanide acetate. The complexes from the (*S*)-diamines had general formula $\{LaL\}$-$(CH_3COO)_2Cl\cdot n(H_2O)$, where Ln = La(III), Eu(III), or Gd (III); L = L_A, L_B, or L_C; and n = 0.25–2.75; they were obtained as mixtures of the two possible isomers, containing, respectively the (*S*,*S*)-5,14- and (*S*,*S*)-5,15-di-substituted metal-macrocycle moieties. The complexes from (*R*,*S*)-(4-aminophenyl)-1,2-diaminopropane had formula $\{LnL_C\}(CH_3COO)_3\cdot nH_2O$, with Ln = La(III), Eu(III), Gd,(III) and n = 1.5–4.0; they were obtained as a mixture of species, three of which were identified as the (*R*,*R*/*S*,*S*)-5,14, (*R*,*R*/*S*,*S*)-5,15, and (*R*,*S*)-5,15 isomers. The L_A and L_B complexes formed colorless, crystalline solids, soluble in highly polar organic solvents, insoluble in diethyl ether, hydrocarbons and water; the L_A complexes were also soluble in chloroform and dichloromethane. The L_C complexes were obtained as yellow-tan amorphous solids, very soluble in highly polar organic solvents, moderately soluble in chloroform, insoluble in diethyl ether, hydrocarbons and water. In their thermal behavior, as in

other properties, all complexes resembled those of the corresponding non-substituted analogues [18–22]. In particular, the La-macrocycles moieties were found to be inert to decomposition by hydrogen chloride, metal exchange with competing metal ions, and metal release in the presence of strongly complexing ligands such as β-diketones [22]. The coordinated anions, however, were labile; complexes of formula $\{EuL_B\}(NCS)_2Cl\cdot 0.25(H_2O)$, $\{LaL_C\}(NCS)_2(CH_3COO)\cdot 3.5(H_2O)$, $\{LaL_C\}(NCS)_3\cdot 0.25(H_2O)$ and $\{LaL_A\}(NO_3)_3\cdot 2(H_2O)$ were easily obtained from the triacetates or acetate chlorides by exchange with sodium thiocyanate or lithium nitrate.

The infrared spectra of all complexes showed the characteristic macrocycle absorptions arising from the imine and pyridine C=N stretching modes at 1640–1637 and 1588–1584 cm^{-1}, respectively. The absorptions of the counterion-ligands appeared in their usual ranges and were structurally informative. The isothiocyanates had a very strong ν(C≡N) absorption at 2045–2030 cm^{-1}, consistent with the presence of *N*-coordinated SCN^- ligands [23,24]. The triacetates and diacetate chlorides had two strong ν(COO) absorptions at approximately 1540 and 1430 cm^{-1}, identical in each case to those of the non-substituted europium(III) analogues, $[Eu(CH_3COO)_2(C_{22}H_{26}N_6)]$–$(CH_3COO)\cdot 9H_2O$ [20] and $[Eu(CH_3COO)_2(C_{22}H_{26}N_6)]Cl\cdot 4H_2O$ [19], and suggesting similar structures with bidentate chelating carboxylate groups.

The nuclear magnetic resonance spectra of the La(III) complexes, examples of which are given in Table 1, showed that the signals of the protons belonging to the macrocycle moiety retain the typical pattern previously observed for the dimethyl-macrocycles [6]. Specifically, the $-CH_3$ groups of each isomer gave rise to two equal-intensity singlets, one for the two $-CH_3$ groups neighboring the benzyl-type substituents and one for the other two. Thus, the $-CH_3$ region of the spectrum (2.00–2.70 ppm) provided information on the number of isomers present in a sample as well as on their relative abundance. The macrocycle CH, CH_2 and pyridine signals also followed the patterns of the dimethyl-analogs, with the pyridine signals (8.0–8.5 ppm) sensitive to isomer structure. In the (*R*,*R*/*S*,*S*)-5,14 isomers, where the two pyridine moieties are identical and non-symmetrical, their signals appeared as a single ABC spin pattern. In contrast, both the (*R*,*R*/*S*,*S*)-5,15 and the (*R*,*S*)-5,15 isomers, in which the pyridine moieties are symmetrical but different from one another, produced two equal intensity A_2B patterns. Thus the pyridine sections of the spectra, which correlate univocally with the structures established by X-ray crystallography for the dimethyl-macrocycles [6] and for the dibenzyl-macrocycle $\{LaL_A\}(NO_3)_3\cdot 2(H_2O)$ described in the following section, provide a convenient general tool for the identification of constitutional isomers in macrocyclic complexes of this type. On the basis of these considerations, it was established that all complexes obtained from the (*S*)-diamines consist of two non-interconvertible species—the two possible constitutional isomers, (*S*,*S*)-5,14 and (*S*,*S*)-5,15—in the approximate ratio 6:4. In the products from the (*R*,*S*)-diamine, only three of the four possible isomers—the (*S*,*S*)-5,14, (*S*,*S*)-5,15 and (*R*,*S*)-5,15 species—were unambiguously identified, with the (*R*,*S*)-5,15 isomer being by far the most abundant.

3.2. Crystal structure of $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)(H_2O)$

The complex consists of a mono-positive coordination entity associated with an ionic nitrate. In the cationic entity, the La(III) ion is linked to the six N-donor atoms of the uncharged macrocyclic ligand, to two bidentate chelating nitrates situated on opposite sides of the macrocycle, and to a water molecules on the convex side. An additional water molecule per complex unit is clathrated in the crystal lattice. An ORTEP view of the cationic coordination entity, with the atom numbering scheme, is shown in Fig. 2.

In the macrocyclic ligand, the two benzyl substituents are in *cis* position to each other with respect to the macrocycle and are attached to the ethylenic chain at the 5 and 14 positions (see Fig. 1 for conventional numbering of the cavity atoms). The complex is thereby identified as the 5*S*,14*S* isomer, according to the CIP rules [25]. A comparison of the structural features of this complex with those of related La(III) complexes containing the same six-nitrogen-donor macrocyclic moiety but less bulky methyl substituents reveals both

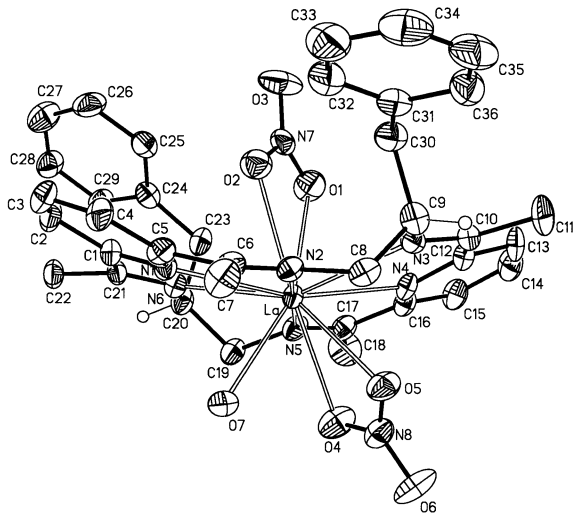

Fig. 2. ORTEP drawing of the cationic moiety $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)]^+$ containing the (*S*,*S*)-5,14-dibenzyl-substituted macrocyclic ligand. Note that atoms C20 and C9 of the ORTEP drawing correspond to positions 5 and 14, respectively, of the macrocycle cavity shown in Fig. 1.

similarities and differences. In the dibenzyl-macrocycle, the conformation of the ethylenic side chains is characterized by the torsion angles, N(5)–C(19)–C(20)–N(6) $-61.1(9)°$ and N(2)–C(8)–C(9)–N(3) $-58.9(9)°$, that determine a rather puckered conformation for the entire macrocycle. The total puckering amplitude of the six-nitrogen ring is 0.742(9) Å, considerably greater than the value of 0.493(6) Å found in the 5*R*,15*S* (or 5*S*,15*R*) isomer of the dimethyl-substituted complex $[La(Me_2Mac)(NCS)_3(H_2O)]$, [6]. The interplanar angle between the two pyridine-containing section of the dibenzyl-macrocycle, 35.0(1)°, is also greater than the interplanar angle, 14.4(1)°, of the (5*R*,15*S*)-$[La(Me_2Mac)(NCS)_3(H_2O)]$ complex, but approaches the value of 38.3(3)° found in the nine-coordinated isomer (5*S*,15*S*)-$[La(Me_2Mac)(NCS)_3]$ [7]. In each case, the flexibility of the ethylenic side-chains allows the macrocycle moiety to assume the conformation that best accommodates the steric requirements of both the metal ion and the exocyclic anionic or neutral ligands.

The La–nitrogen bond distances in the dibenzyl-macrocycle are rather irregular. The $La–N_{(imine)}$ bonds range from 2.659(9) to 2.776(7) Å, while the two $La–N_{(pyridine)}$ are 2.738(6) and 2.775(6) Å, respectively. The two La–O bond distances of the chelated nitrate on the concave part of the macrocycle are fairly similar to one another (2.654(7) and 2.691(9) Å), but they differ significantly in the nitrate on the convex side (2.642(7) and 2.74(1) Å). The coordinated water molecule is more loosely bound in the dibenzyl-complex, with a La–O(7) distance of 2.607(6) Å, than in the dimethyl-complex $[La(Me_2Mac)(NCS)_3(H_2O)]$, [6] where the La–Ow distance is 2.536(6) Å. Since in both complexes the coordinated water molecule occupies the same hemisphere as one of the counterion ligands, the difference in La–water bond lengths is most likely due to the greater steric hindrance of the bidentate chelating nitrate relative to the monodentate and linear thiocyanate. The coordinated water molecule of the dibenzyl-complex is involved in hydrogen bonding with the clathrated water molecule ($O(11)_{water}\cdots O(7)'$ 2.76(1) Å) (′ at $1-x, 0.5+y, -z$); the latter is also hydrogen bonded to the 'free' nitrate ($O(11)_{water}\cdots O(8)$ 2.82(1) Å), contributing to the crystal packing (see Fig. 3).

The structure of the tri-nitrate dibenzyl-macrocycle complex reported here leads to another meaningful comparison. In the related tri-nitrate complex $[LaL(NO)_3]$ [26], where $L = C_{22}H_{26}N_6$ is the prototype six-nitrogen-donor macrocyclic ligand with unsubstituted ethylene side-chains, the three nitrates are all chelated to the La(III) ion, resulting in an uncharged coordination entity. In contrast, when the macrocyclic ligand contains two bulky benzyl substituents in the conformation observed here, one of the three nitrates remains ionic and is substituted within the coordination sphere by a less sterically demanding water molecule.

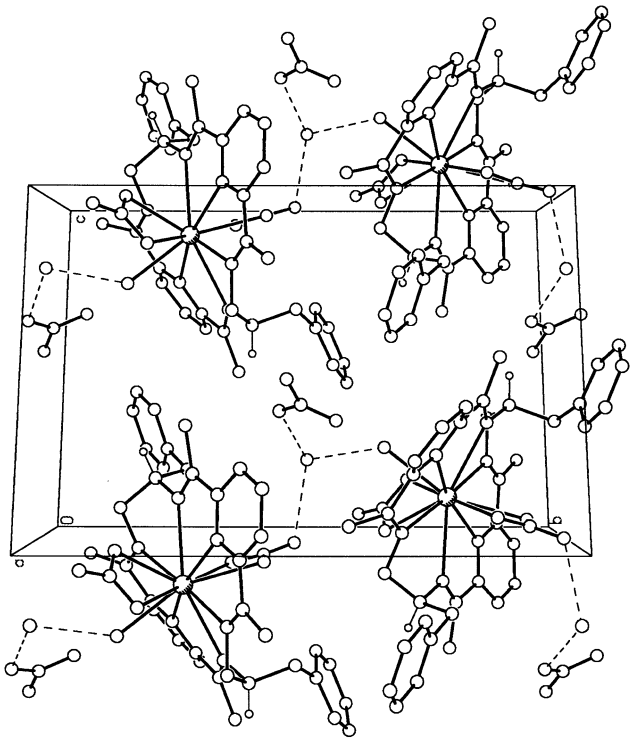

Fig. 3. Crystal packing of the $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)(H_2O)$ complex, showing the hydrogen bonding interactions of the cationic moiety with the ionic nitrate and the clathrated water molecule.

These observations, as well as those previously reported for the dimethyl-substituted complexes, suggest that changing the substituents at the ethylenic chains of the macrocycle and/or the anions may allow to modulate the formation of neutral or cationic complexes with different coordinations and geometries.

4. Conclusions

A facile route has been developed for the synthesis of complexes of the lanthanide(III) ions with six-nitrogen-donor macrocyclic ligands containing peripheral hydroxo-benzyl or amino-benzyl groups. These complexes combine the characteristic properties of this type of lanthanide-macrocycles with the reactivities typical of the peripheral –OH and $–NH_2$ functionalities. Specifically, the lanthanide-macrocycle moieties are inert to metal release or exchange in the presence of competing ligands or competing metal ions, whereas the exocyclic anionic ligands are labile and can be easily exchanged. The hydroxo-benzyl group forms esters by reaction with acid anhydrides, and the primary amino-benzyl group reacts with thiophosgene to produce the corresponding isothiocyanate, which in turn combines with primary amines via a thiourea linkage [1,2]. These complexes are therefore suitable for coupling to a vari-

ety of substrates—biomolecules, polymers, functionalized glass surfaces—and the unique inertness of the lanthanide-macrocycle moieties ensures that the characteristic properties of the lanthanide ion, such as luminescence and paramagnetism, will remain incorporated in the substrate under conditions that would cause rapid degradation of complexes of the same metal ion with other ligands.

As a structural model, complexes with non-functionalized benzyl substituents were also synthesized. The characterization of $[La(NO_3)_2(H_2O)(C_{36}H_{38}N_6)](NO_3)\cdot(H_2O)$ by X-ray crystallography established unambiguously the S configuration of both stereocenters in the macrocycle, proving that no racemization or isomerization had occurred during the series of reactions by which the complex had been obtained from the *S*-phenylalanine amide as precusor. A similar retention of conformation was observed in the synthesis of dimethyl-substituted macrocycle complexes of La(III) [6,7].

For all complexes obtained in this work, the metal-templated synthesis presented the same isomer preferences previously observed for complexes containing the less sterically demanding methyl groups: in each case the more abundant isomer was that with the side-chain benzyl groups in '*cis*' positions relative to the metal macrocycle moiety. This preference may be related to the general tendency of the trivalent lanthanide ions to remain in contact with three mononegative anionic partners, two of which can be accommodated on one side of the macrocycle if the peripheral substituents are on the other side, still affording sufficient space for the third anion.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 146221. Copies of the data can be obtained free of charge, on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Conformation of adenosine-5′-triphosphate in the presence of Mg^{2+} at different pH

Ling Jiang, Xi-An Mao *

Laboratory of Magnetic Resonance and Atomic Molecular Physics, Wuhan Institute of Physics and Mathematics, The Chinese Academy of Sciences, P.O. Box 71010, Wuhan 430071, China

Received 7 August 2001; accepted 26 November 2001

Abstract

NOESY experiments have been performed on adenosine-5′-triphosphate (ATP) in the presence of 1:1 Mg^{2+} ($MgCl_2$) at different pH. The results show that H8–H1′ and H8–H2′ interproton NOE intensities change with pH, with nearly equal intensity at low pH (pH 1.9) and with H8–H2′ signal stronger than the H8–H1′ signal at higher pH (between 3.7 and 8.5). The H8–H1′ and H8–H2′ distances and the C4–N9–C1′–O4′ torsion angle (χ) have been measured from random structures of adenosine and ATP. It is concluded that the lower pH allows the formation of a P_γ–O–Mg^{2+}–N1 bridge and the torsion angle takes a *cis* conformation accordingly. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Adenosine-5′-triphosphate (ATP); Mg(II); NOESY; Torsion angle (χ)

1. Introduction

It is well known that nucleic acid structures are strongly dependent on the conformation of individual nucleotide residues. A-form DNA differs from B-form DNA by different sugar puckering (C2′ endo for B-form DNA and C3′ endo for A-form DNA). In Z-form DNA, the glycosidic bond of guanosine takes a *syn* conformation, in contrast to the *anti* conformations in normal B- and A- form DNA [1]. Because the biological effects of nucleotides have a strong relation to their conformations, the conformational study of nucleotides, particularly in solutions, has attracted much attention. X-ray crystallography, NMR spectroscopy and CD (circular dichroism) have been widely used for this purpose [2–4]. The conformation of a nucleotide also influences the binding site when it binds to metal ions. It is believed that the glycosidic bond of most guanosines and adenosines takes the *anti* conformation and they bind to metal ions with N7 in the purine ring [5–7]. However, recent reports suggest that when pH is low, ATP (adenosine-5′-triphosphate) binds to metal ions with N1 and this would require the glycosidic bond to be in the *syn* conformation [8–10].

In order to see if the *syn* conformation of the glycosidic bond in ATP is natural, we performed NMR NOESY experiments on 1:1 ATP–Mg^{2+} solutions with varied pH. The results are reported in this paper and they show a rotation range from 20 to $-150°$ for the torsion angle C4–N9–C1′–O4′ (χ). This torsion angle range covers part of the *syn* conformation (defined by $\chi = 0 \pm 90°$ [11]) and part of the *anti* conformation ($\chi = 180 \pm 90°$). At very low pH (pH 1.9), the H8–H1′ and the H8–H2′ NOE cross peaks have nearly equal intensities, while at higher pH (pH $\geq$ 3.7), the H8–H2′ peak become stronger than the H8–H1′ peak. A quantitative relationship between the interproton distance and the base-to-sugar torsion angle is established with the help of molecular modelling, which shows that, in the presence of Mg^{2+}, at lower pH ATP takes a *syn* conformation, while at higher pH *anti* conformations predominate.

Conformations of nucleotides that are affected by pH have been well documented. Some new conformations of Pt complexes with nucleotides have been discovered in variable pH experiments [12–14]. Although the mechanism of the pH dependent conformation of nucleotides is not yet fully understood, the phenomenon

has been suggested to be very important in biological activity of the nucleotides [15]. Since the ATP–Mg^{2+} complex is of great importance in biology, the pH dependent conformation of ATP in the presence of Mg^{2+} reported in this paper would provide some insight to the pH dependent binding site of Mg^{2+} on ATP.

2. Experimental

The Na salt of ATP was used in this study, which was purchased from Boehringer Mannheim, GmbH, Germany and used directly without further purification. Other chemicals ($MgCl_2 \cdot 6H_2O$, NaOH and HCl) were of analytic purity from Shanghai Chemical Company, China. The pH values were determined by a Cole–Parmer pH meter equipped with a Cole–Parmer glass-body combination pH electrode (Chicago). Buffers of pH 4.01, 6.86 and 9.18 were used to calibrate the pH meter.

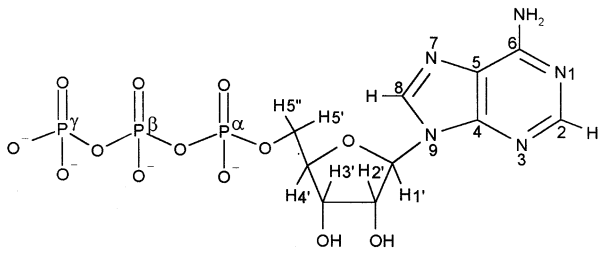

Fig. 1. The schematic structure of ATP.

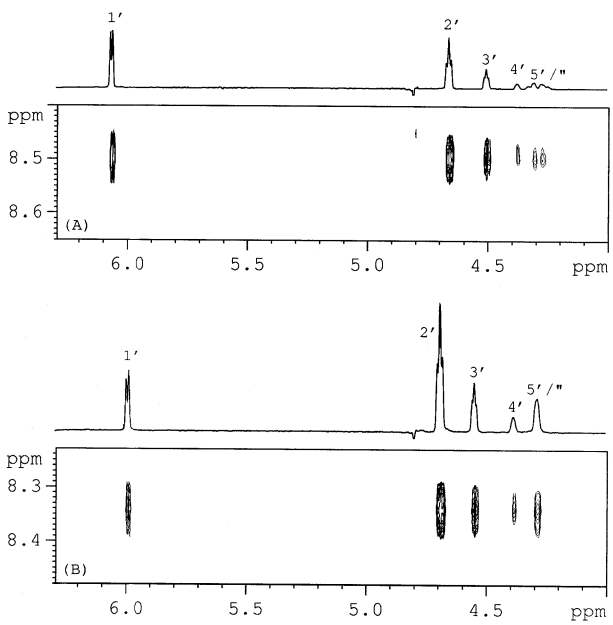

Fig. 2. Regional NOE spectrum of ATP in the presence of equimolar $MgCl_2$ at pH 1.9 (A) and pH 8.5 (B), showing the NOE correlation between H8 (8.51 ppm at pH 1.9 and 8.35 ppm at pH 8.5) and the sugar protons. The slices are shown at the top as projections.

ATP solutions, with and without equimolar $MgCl_2$, were prepared by quantitatively dissolving the chemical(s) in H_2O with 10% D_2O for field lock purpose. The pH values were adjusted by adding tiny drops of NaOH and HCl. The concentrations of ATP and $MgCl_2$ were all kept at 0.2 mol l^{-1}.

NMR experiments were performed on both ATP and ATP–Mg^{2+} samples on a Bruker ARX-500 spectrometer at 298.2 K. Two-dimensional phase-sensitive NOESY spectra were recorded with $2048(\omega 2) \times 256(\omega 1)$ data points and 16 scans per FID. The mixing time was set to 500 ms for all experiments. Water suppression was accomplished by low power, continuous wave presaturation. All 2D FID were apodized in both dimensions with a $\pi/2$ shifted, squared sine-bell function and zero filled to give a 2048×512 matrix before Fourier transformation. The water signal serves as the reference (4.8 ppm).

Molecular modelling was performed on a silica graphics workstation with the CNS version 1.0 (Crystallography and NMR System, http://cns.csb.yale.edu) software package. InsightII module was used for molecule display. In CNS, a single stranded DNA consisting of 63 adenine residues was generated. The 63 residues had random conformations, and their interproton distances and torsion angles were measured. In the meantime, molecular dynamics were performed on an ATP molecule using simulation annealing protocol. Sixty dynamics structures were sampled.

3. Results and discussion

For clarity we present the ATP structure in Fig. 1, with the atoms numbered. We have measured NOESY spectra of ATP in the presence of equimolar Mg^{2+} at four pH values (pH 1.9, 3.7, 5.0 and 8.5). Fig. 2 shows the H8 slices of the NOESY spectra for the ATP–Mg^{2+} system at pH 1.9 and 8.5, where H8 correlates mainly with H1′ (6.06 ppm at pH 1.9 and 5.99 ppm at pH 8.5) and H2′ (4.66 ppm at pH 1.9 and 4.69 ppm at pH 8.5). Since the other protons (H3′, 4.50–4.55 ppm; H4′, 4.38 ppm; H5′ and H5″, 4.26–4.32 ppm) are also in the proximity of H8 with the distance under 0.5 nm, the NOE peaks correlating with those protons also appear, partly due to a spin diffusion effect or a multiple-step NOE transfer effect during the long mixing time (500 ms). However, the nearly equal intensity of the H8–H1′ and H8–H2′ cross peaks implies that H8 has nearly equal distances to H1′ and to H2′. The cross peak intensities relative to the diagonal peak of H8 are listed in Table 1. For comparison, the NOE data for ATP solutions free of Mg^{2+} are also presented. The data in Table 1 suggest that the interproton distances are dependent on pH.

Table 1
Integration volumes of the H8–H1′ and H8–H2′ NOE peaks of ATP at different pH, referenced to the H8 diagonal peak in each spectrum

pH	With Mg^{2+}		Without Mg^{2+}	
	H8–H1′	H8–H2′	H8–H1′	H8–H2′
1.9	0.075	0.073	−0.003	−0.043
3.7	0.148	0.278	−0.000	−0.050
5.0	0.116	0.279	−0.010	−0.069
8.5	0.073	0.190	−0.014	−0.064

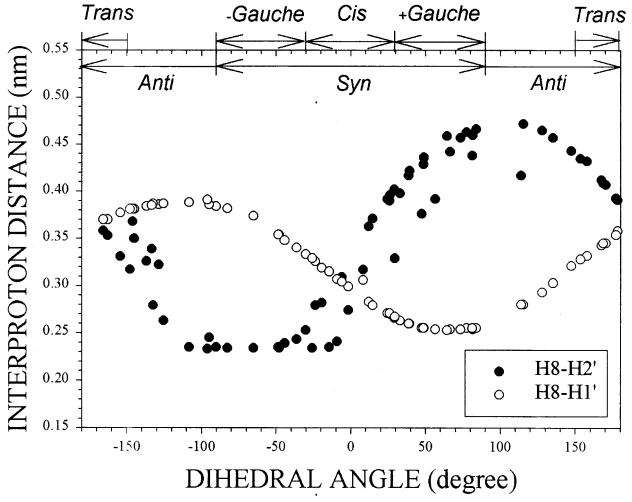

Fig. 3. Plot of H8–H1′ and H8–H2′ distances versus the torsion angle χ for adenine.

The relative intensities of the NOE peaks should be an indication of the relative distances of the involved spins. It is true that the mixing time in our experiments is rather long (500 ms), compared to those used in macrobiomolecules. But since ATP is a small molecule, the spin diffusion effect should not be too serious and stronger NOE peaks should correspond to shorter distances, although the spin diffusion effect probably has broken the r^{-6} rule for quantitative analysis. In solutions, the ATP molecule can take all possible conformations, but at a given pH, the molecule should have a certain average conformation, and this average conformation can be pH dependent, because pH can change the charge distribution of the molecule. As a result, the H8–H2′ and H8–H1′ distances are also pH dependent.

The curves presented in Fig. 3 are helpful to our understanding of the conformation-dependent interproton distances, where the H8–H1′ (open circles) and H8–H2′ distances (filled circles) are plotted versus the torsion angle χ, i.e. the dihedral angle C4–N9–C1′–O4′. The data were taken from 63 random CNS structures for adenosine. Similar curves have also been obtained from DISCOVER structures of ATP sampled in molecular dynamics calculations. The H8–H1′ curve is a perfect sine function, but the H8–H2′ curve is not so smooth as the H8–H1′ curve. In generating the CNS structures and in the molecular dynamics calculation, the ribose sugar can take random conformations or puckers (C3′ endo, C2′ endo, etc.). Since the H8–H1′ distance, or r(H8–H1′), is not affected by the sugar pucker, the curve is smooth, which shows a sine function of the torsion angle in a full rotation cycle (from -180 to 180°). As a contrast, the H8–H2′ distance, or r(H8–H2′), is strongly dependent on the sugar pucker, so at a given χ angle, the H8–H2′ distance can have two or more values. Even so, the H8–H2′ curve can still be approximated by a sine function. In biochemistry, a full rotation of the glycosidic bond can be described by *anti* and *syn* conformations which are defined by $\chi = 0 \pm 90°$ and $\chi = 180 \pm 90°$, respectively. In the meantime, another set of notations are also in current use: *cis* ($\chi = 0 \pm 30°$), *trans* ($\chi = 180 \pm 30°$), *+gauche* ($\chi = 60 \pm 30°$) and *−gauche* ($\chi = 300 \pm 30°$, or $\chi = -60 \pm 30°$) [11], but in this set of notations names are not given to $\chi = 120 \pm 30°$ and $\chi = 240 \pm 30°$ ($-120 \pm 30°$). For clarity, the two sets of notations are indicated in Fig. 3. When χ is close either to 0° (*cis* conformation) or to $\pm 180°$ (*trans* conformation), the two distances do not differ much. Their differences reach maxima when χ is close to $\pm 90°$. Fig. 3 indicates that when χ falls in the range from 0 to $-180°$, the r(H8–H1′) distance is longer, while when χ is between 0 and 180°, r(H8–H2′) is longer. Thus, NOE experiments can indicate, at least qualitatively, the conformation of the glycosidic bond in ATP.

The data in Table 1 show that at pH 1.9, the H8–H1′ and H8–H2′ NOE peaks have nearly equal intensities, with the implication that the torsion angle is around 0 or 180°. As pH is increased, the H8–H2′ signal becomes stronger than the H8–H1′ signal, corresponding mainly to the *−guache* conformation. We have shown that for solutions where ATP interacts with Mg^{2+}, Zn^{2+} and Fe^{3+}, N1 binds with the metal ions [8–10,15]. Therefore, it is reasonable to propose that, in the pH range we are studying in this paper, the torsion angle of ATP is in the range from 20 to $-150°$. The conformation of the ATP molecule changes from *cis* to *trans* through *−guache*, as the pH of the solution is increased. At lower pH, the ATP molecule are more likely to take the *cis* conformation, while at higher pH, the *trans* conformation is more stable, in full agreement with the ^{1}H–^{15}N HMBC experiments reported recently [15].

The data for the pure ATP solutions show a much narrower rotation range for the glycosidic bond, most probably in the *−gauche* conformation. The negative sign in the intensities for pure ATP shown in Table 1 is the indication of the fast motion limit. The much wider conformation range for ATP in the presence of Mg^{2+} than in the absence of Mg^{2-} suggests that the ATP–metal interaction is easily affected by pH. At lower pH, there is a binding competition between metal ion and

H^+. Since the charge of the metal ions (Mg^{2+}, Zn^{2+} and Fe^{3+}, etc.) is stronger than H^+, the metal ions usually win the competition. In the meantime, the γ-phosphate can become negatively charged even when pH is very low. A P_γ–O–M–N1 bridge is likely to form in the solution, where M denotes the metal ion. In this case the ATP molecule can easily take the *cis* conformation. When pH is increased from 1.9 to 5, the binding ability of the metal ion should be reduced, since the hydrated metal ion could form hydroxo species. As a result, N1 loses connection with the metal ion, leading to $-$*gauche* conformations, which are the most common structure for ATP and adenosine in DNA. In the absence of the metal ions, the hydrogen cannot build a bridge between P_γ and N1. So only the $-$*gauche* conformation can be found.

Our NMR experiments do not show any evidence for the existence of the $+$*gauche* conformation either in the presence or in the absence of the Mg^{2+} ion, although the CNS-generated structures can have all conformations. Intuitively, $+$*gauche* conformations have higher tension than $-$*gauche* conformations, since in $+$*gauche* conformations the six-member ring of the adenine is directly on the top of the sugar. It should be pointed out that not all *anti* conformations have the lowest energy; the torsion angle range between 30 and 90° (i.e. $+$*gauche* conformation) which is just in the *anti* conformation range, has not been found in our experiments, probably due to the very high tension. But since the structures generated by CNS and sampled in molecular simulation represent molecules in vacuum rather than in solutions, all structures have similar energy. In vacuum, the dissociation (or association) of the phosphate protons and the protonation (or deprotonation) of N1, N7 and the amine nitrogen (N6) are hardly taken into account.

From Fig. 3 it can be seen that both $r(\mathrm{H8–H2}') > r(\mathrm{H8–H1}')$ and $r(\mathrm{H8–H2}') < r(\mathrm{H8–H1}')$ can happen in *syn* conformation range as well as in *anti* conformations. Thus, it is better to use the *cis*, *trans* and $\pm$*gauche* notations to describe the conformation of ATP and adenosine when NOE intensity is involved, although the notations are not complete.

4. Conclusion

The change of the relative NOE intensities with pH, as has been observed in 1:1 ATP–Mg^{2+} solutions, suggests that, as the pH increased, the conformation of the torsion angle χ of ATP changes from *cis* to *trans* over $-$*gauche*. The *cis* conformation is probably due to a bridge between P_γ and N1 built by a Mg^{2+} ion. At higher pH such a bridge is broken, because hydration of metal ions is strengthened and $-$*gauche* conformations predominate.

Received 15 August 2001; accepted 26 November 2001

Abstract

The *fac*-$MnBr(CO)_3$(3,3′-R-2,2′-biquinoline) (R = CH_3 and CH_3; H and H; $–CH_2–CH_2–$ or $–CH_2–CH_2–CH_2–$) compounds were synthesized and characterized. The *fac*-conformation for the carbonyl complexes was established by IR spectroscopy. Conformational effects were investigated by means of ^1H NMR and UV–Vis spectroscopical and electrochemical properties and these properties were compared with related rhenium compounds. © 2002 Published by Elsevier Science Ltd.

Keywords: Metallic carbonyl complexes; Manganese; Heterocyclic nitrogen ligands

1. Introduction

The ability of bidentate nitrogen donor ligands to modify chemical, catalytic and photochemical properties of Os(II), Ir(III), Re(I), Ru(II), and Mn(I) transition metal complexes has prompted numerous studies [1]. The goal of these studies has been to learn more about the chemistry of these systems and to apply such knowledge to develop better catalysts for reactions of practical interest [2]. Some of these compounds have been used as sensitizers in conversions from solar to chemical energy, as models of natural and artificial photosynthesis, in the preparation of molecular-level devices and in the manufacturing of drugs for medical applications [1]. Their applicability has recently been extended to potential antitumor agents [3].

The desirable properties of the complexes could be controlled by judicious steric and electronic modifications of the pyridine ligand. In addition, studies of photochemical and photophysical properties of these complexes provide information about the relation between the ligand structure, the energy gap and the properties of the ground and the excited states nonradiative decay [4]. Consequently, we have studied how changes in the π electronic density and in the structural conformation of the polypyridine ligands affect the properties of the tricarbonylrhenium complexes [5].

In the present paper, we report the synthesis of new complexes of the type $BrMn(CO)_3(L)$, where L corresponds to ligands derived from the annelated or substituted 2,2′-biquinoline in 3,3′ positions (Fig. 1). The preparation, as well as the spectroscopic and redox

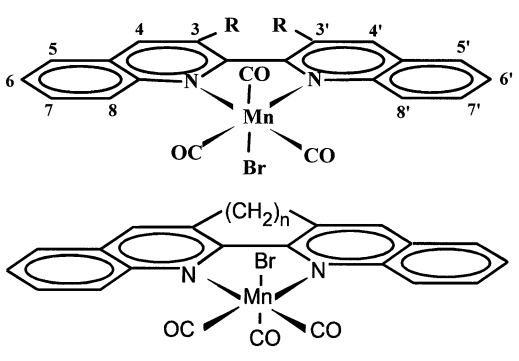

Fig. 1. Structure of *fac*-$BrMn(CO)_3(L)$ complexes with L being the biquinoline ligand derivatives used in this study.

properties are described. The electronic effects provided by the aromatic rings and the steric and conformational effects caused by the annelation or the 3,3′-substitution of the ligand are investigated by comparison of our results with those found for analogous rhenium complexes.

2. Experimental

2.1. Physical measurements

IR spectra were measured on a Bruker IFS-66 V FTIR spectrophotometer in the solid state (KBr cell of 0.2 mm length) and $CHCl_3$ solution. Proton NMR spectra were recorded on a 250 MHz Bruker spectrometer. Absorption spectra were measured on a Shimadzu UV-160 spectrophotometer. Molar extinction coefficients were calculated from a least-square linear regression of absorbance data at different concentrations. Microanalyses were performed at the Departamento de Química Orgánica, Facultad de Química y Farmacia, Universidad de Chile. Molar conductivities were determined in $CHCl_3$ at 25 °C using a conductivity meter Cole-Parmer 01481. The X-ray fluorescence spectra were recorded on a Phillip EDAD PV-9500 (energy dispersion type) at 20 kV and 150 μA. Electrochemical data were acquired by cyclic voltammetry following the procedure already reported [1d]. Potentials were reported as $E_{1/2}$ values versus SCE and were determined from the following relationship: $E_{1/2} = 1/2(Ep_a + Ep_c)$, where Ep_a and Ep_c are the anodic and cathodic peak potentials, respectively. Ferrocene was used as an internal standard ($E_{1/2} = +0.418$ V in dimethylformamide vs. SCE). The cyclic voltammograms were recorded at a sweep rate of 200 mV s^{-1} for all the scans, at room temperature (r.t.) and in a nitrogen atmosphere. Coulometric measurements were carried out using a reticulated vitreous carbon (ERG) and a saturated calomel as working and reference electrodes, respectively. The platinum spiral wire counter electrode was separated by means of a salting bridge.

2.2. Chemicals

Solvents were purified, distilled from the appropriate drying agents and stored under dry N_2 over 3 Å molecular sieves [6]. 2,2′-Biquinoline (0,2N), 1,2-cyclohexanedione, 3,4-hexanedione, 1,2-nitrobenzaldehyde, and $BrMn(CO)_5$ were commercially available and used without further purification. The ligands 3,3′-dimethyl-2,2′-biquinoline, (Me,2N), 3,3′-dimethylene-2,2′-biquinoline, (2,2N), and 3,3′-trimethylene-2,2′-biquinoline, (3,2N), were prepared according to literature procedures [7].

2.3. General synthesis procedure for the complexes

The complexes were prepared by replacement of two carbonyl groups in $BrMn(CO)_5$ by the corresponding bidentate heterocyclic ligand. A stochiometric amount of heterocyclic nitrogen ligand in $C_6H_5CH_3$ was added to a solution of $BrMn(CO)_5$ in the same solvent. The mixture was refluxed in a dry N_2 atmosphere until formation of a red precipitate. The solid was collected by filtration, washed with $C_6H_5CH_3$ under dry N_2 and then it was dried under vacuum. Yields for all complexes were equal to or higher than 80%.

3. Results and discussion

The complexes are sparingly soluble in most common organic solvents, e.g. methylenechloride, acetone, ethyl alcohol. Solutions of these complexes decompose in air after 20 min and a dark brown solid is formed. IR and UV–Vis spectra of the resulting solution were similar to those containing only the uncoordinated ligand. However, solutions kept under nitrogen were stable for periods equal to or longer than 15 days. The low

solubility of the complexes limited the spectroscopic studies to a smaller range of solvents. The proposed $BrMn(CO)_3(L)$ formulation for the products is supported by the elemental analysis, conductivity measurements and X-ray fluorescence (that confirms the bromine and manganese presence). The spectroscopic studies are in accord with the proposed structures.

The solid state or solution infrared spectra of the manganese complexes do not show the effect of the metal–nitrogen coordination on the characteristic bands of the ligand. The ν_{CO} pattern of three equal intense bands for the complexes in solution is consistent with a facial arrangement of the carbonyl groups in a C_s molecular symmetry [8]. A similar ν_{CO} pattern is observed in the solid IR spectrum for both $MnBr(CO)_3$(Me,2N) and $MnBr(CO)_3$(0,2N) complexes. For the other complexes the presence of only two bands in the solid IR spectra can be due to the overlapping of the two smaller energy bands.

These complexes exhibited similar ν_{CO} frequency values in the IR spectra. It appears, therefore, that structure modifications on the biquinoline ligand were small enough to produce only negligible changes in the electronic density of the metal. The two smaller frequency bands appear to higher energies in the manganese compounds than those found for similar rhenium compounds already prepared [5g]. This experimental observation suggests a stronger interaction between the Mn and a π-orbital of the nitrogen than in homologous rhenium complexes [8c].

Proton NMR data for the manganese complexes are shown in Table 1. The low solubility of the complexes only allowed partial assignment of the resonances. Although it is impossible to make an accurate estimation of the coupling constants, the basic signal pattern of the polypyridine ligand is in good agreement with previously published NMR spectra of related rhenium complexes [5a,5b,5e] (Fig. 2). The spectra of the analogous Re compounds were used for the signal assignments of the Mn complexes.

Nearly all aromatic proton signals for the biquinoline ligand in the complex are shifted to lower field. This deshielding effect is a characteristic feature of quinoline coordinated to the metal. The shift to lower field of the $H_{8,8'}$ proton in the free ligand was assigned for a *peri* interaction with the nitrogen. The increasing shift of this proton should be the consequence of a great steric hinderance and the paramagnetic effect of the carbonyls in a facial configuration of the Mn complexes. The *syn* conformation of the 0,2N ligand affords a more protected environment around the $H_{3,3'}$ proton and explains well the observed shielding.

The double signal pattern observed in the spectrum of $MnBr(CO)_3$(Me,2N) (Table 1) is due to the presence of two conformers in solution. It is possible that the slow exchange rate between both mirror image isomers caused by the great distortion of the 3,3′-dimethyl 2,2′-biquinoline ligand in the complexes is responsible for the presence of these two conformers. Such a distortion was observed in the X-ray diffraction structure of the related $ReBr(CO)_3$(Me,2N) compound [9].

UV–Vis spectra of the $MnBr(CO)_3L$ complexes (Table 2) show most intense bands to highest energy corresponding to intraligand transitions ($\pi \rightarrow \pi^*$ biquinoline). The lowest energy band found around 400 nm is assigned to a metal to ligand charge transfer transition (MLCT $t_{2g} \rightarrow \pi^*$). This assignment is based on the band intensity, spectral response to solvent polarity and assignments previously reported for related complexes [4,5a]. The energy for the MLCT band

increases in the order of (0,2N) > (2,2N) > (3,2N) > (Me,2N) showing a slight dependence of the MLTC absorption maximum with the deviation of the quinoline halves from planarity in the coordinated biquinoline ligand. The related rhenium complexes with these ligands exhibit a similar trend.

Potentials obtained from cyclic voltammograms for $BrMn(CO)_3(L)$ complexes in DMF are shown in Table 3. The potentials quoted are relative to SCE. Measurements in acetonitrile were not possible due to the fast chemical decomposition observed in the system.

Two successive reductions and one oxidation were the only observed waves with fresh solutions of the complexes (Fig. 3).

Two electrochemical reductions on the first scan occur in the $E_{1/2} = -0.82$ to -1.04 V range and $E_{1/2} = -1.27$ to -2.2 V range versus SCE for the complexes series. The first reduction is a quasi-reversible one-electron transfer process determined by using the method of comparative waves with the Fc^+–Fc couple under identical conditions. Coulometric measurements yield result supporting a one-electron process. Literature re-

Table 3

ports on related polypyridine manganese(I) complexes do not provide reduction potentials [10]. In analogous rhenium(I) complexes, these waves correspond to quasi-reversible one-electron transfer processes, assigned to the reduction of the heterocyclic nitrogen ligand.

On the other hand, the electrochemistry in dichloromethane for identically formulated manganese(I) complexes containing a bidentate phosphine ligand has shown that the reduction is a two-electron process that releases the halogen atom to form the corresponding $Mn(CO)_3(dpm)$ species, (dpm = $Ph_2PCH_2PPh_2$). The $Mn(CO)_3(dpm)$ decomposes after a short time [10]. In our case, the observation of one-electron processes suggests that the reduction is located mainly on the biquinoline ligands similarly to those of the rhenium(I) complex, which is quite different from the reduction processes found in the manganese–phosphine complexes.

The first oxidation wave is irreversible and it is found in the +1.06–1.13 V range. This one-electron oxidation process can be assigned to the Mn(II)/Mn(I) pair in accord with the one observed with $MnX(CO)_3L$ (L = phosphines) and $[MnX(CO)_3L]^+$ complexes by Bond et al. [10]. The second irreversible oxidation wave is observed in the potential 1.33–1.38 V range and it is commonly observed with this type of compound. An additional one-electron oxidation is likely followed by decomposition of the product [10]. The irreversibility in both processes can be correlated with the chemical instability of these complexes.

An additional wave near to +0.75 V was observed during the second scan (Fig. 3b). This wave is related to the first oxidation process. Bond et al. have established that it is due to the oxidation of *mer*-$MnBr(CO)_3L$, i.e. a product of isomerization of the oxidized facial complex [10].

It was possible to establish a correlation between the position of the lower energy MLCT band and $E_{1/2}$ potentials of the first reduction wave (Fig. 4). This correlation assumes that reduction in those orbitals involved in the MLCT are the same involved in the oxidation and reduction processes [5,11]. The linear correlation:

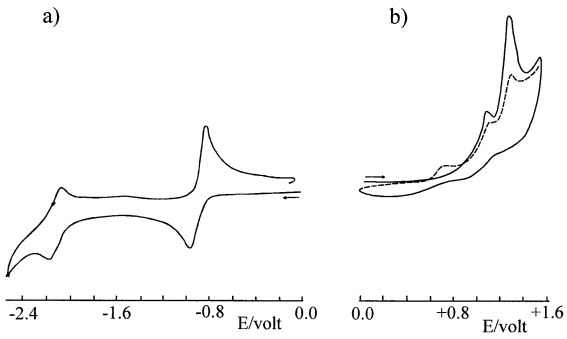

Fig. 3. Cyclic voltammogram of $BrMn(CO)_3(2,2N)$ complex.

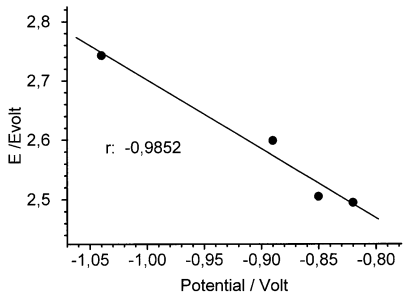

Fig. 4. MLCT energy versus $E_{1/2}$ reduction potential plot.

$$E_{abs} = -1.377E_{1/2}\,\text{red} + 0.537$$

with $r = 0.99$, supports the assignment of the process as a reduction centered on the biquinoline ligand.

4. Conclusions

The X-ray studies for rhenium complexes with the same biquinoline ligands revealed that the structure of the complexes deviate in various degrees from a perfect octahedron [5a,9b,9c]. Spectroscopic and electrochemical results already discussed are in accord with such deviations. Indeed, these deviations can be related to a decrease in the electronic repulsion between the d-metal orbital and the π-biquinoline orbitals when quinoline halves are removed from a perfect plane. Destabilization of the LUMO and stabilization of the HOMO will usually result from such increasing distortion.

Yttrium halide complexes of phosphine- and arsine oxides: synthesis, multinuclear NMR and structural studies

Nicholas J. Hill, William Levason *, Michael C. Popham, Gillian Reid, Michael Webster

Department of Chemistry, University of Southampton, Southampton SO17 1BJ, UK

Received 12 November 2001; accepted 30 November 2001

Abstract

The reactions of $YCl_3{\cdot}6H_2O$, $YBr_3{\cdot}6H_2O$ and $YI_3{\cdot}8H_2O$ with Ph_3PO, Ph_3AsO, Ph_2MePO, Me_3PO, Me_3AsO, o-$C_6H_4\{P(O)Ph_2\}_2$ (ppO_2) and $Ph_2P(O)CH_2P(O)Ph_2$ ($dppmO_2$) have been examined in EtOH or Me_2CO solution. Complexes isolated in the solid state include $[YX_2(Ph_3PO)_4]Z$ (X = Cl, Br or I; Z = X or PF_6), $[YX_3(Ph_2MePO)_3]$, $[YCl_2(Ph_2MePO)_4]PF_6$, $[YCl(Ph_3PO)_5][SbCl_6]_2$, $[Y(Me_3PO)_6]X_3$, $[YX_2(Ph_3AsO)_4]X$, $[Y(Me_3AsO)_6]Cl_3$ and $[YCl_2(L{-}L)_2]Cl$ (L–L = ppO_2 or $dppmO_2$) which were characterised by analysis, IR and multinuclear (^1H, $^{31}P\{^1H\}$ and ^{89}Y) NMR spectroscopy and conductance measurements. The X-ray crystal structures of $[YCl_2(Ph_3PO)_4]Cl{\cdot}2.5EtOH{\cdot}H_2O$, $[YBr_2(Ph_3PO)_4]PF_6{\cdot}Et_2O$ and $[Y(Me_3PO)_6]Br_3$ are reported and discussed. The solution speciation (in CH_2Cl_2) in the various systems was examined by variable temperature multinuclear NMR spectroscopy. The ^{89}Y NMR chemical shifts show systematic trends with donor set which are described. No reaction between these ligands and $YF_3{\cdot}1/2H_2O$ was observed. © 2002 Elsevier Science Ltd. Keywords: Yttrium; Phosphine oxide; Arsine oxide; X-ray structures

1. Introduction

The chemistry of yttrium is the least studied of any 4d element, although interest has increased in recent years with applications in oxide materials [1], ethene and α-olefin polymerisation and ROMP catalysis [2–4], whilst complexes of the radioisotope ^{90}Y are used in radiotherapy [5]. The only oxidation state achieved in aqueous solution, Y(III) $[Kr]4d^05s^0$, is diamagnetic and colourless, and the high lability of many yttrium complexes, has seriously hindered studies. Potentially ^{89}Y NMR (^{89}Y = 100%, I = 1/2) spectroscopy could provide a valuable probe [6], but its poor sensitivity D_c (receptivity relative to ^{13}C) of 0.67, low resonance frequency Ξ = 4.92 MHz, and very long T_1's have restricted studies. We have recently reported [7,8] detailed studies of $Y(NO_3)_3$ complexes with R_3PO and R_3AsO ligands which exhibit a range of stoichiometries including nine-coordinate $[Y(R_3PO)_3(NO_3)_3]$, eight-coordinate $[Y(R_3PO)_4(NO_3)_2]^+$ and six-coordinate $[Y(Me_3AsO)_6]^{3+}$. Curiously little has been reported about yttrium halide complexes. Reviews [9,10] indicate that the lanthanides and yttrium form $M(Ph_3PO)_xCl_3$ complexes (x = 4 or 3), claimed as non-conductors in solution, indicating seven- and six-coordination, respectively. However, consultation of the original references often reveals incomplete studies of a few lanthanide examples which are taken as characteristic of the whole series (including Y) [11–13]. Specific information on yttrium compounds is sparse [14,15] and none have been structurally characterised or their solution behaviour explored. Here we report detailed studies of complexes of these ligands with yttrium halides $YX_3{\cdot}nH_2O$ (X = F, Cl, Br or I).

2. Results and discussion

2.1. Synthesis

Reactions of the hydrated yttrium halides (excluding fluoride) with Ph_3PO, Ph_3AsO, Ph_2MePO, Me_3PO and

Me_3AsO in ethanol, acetone or CH_2Cl_2 were carried out using a variety of molar ratios and reaction conditions (see Section 2.2). Isolated complexes were identified by a combination of analysis, IR, $^{31}P\{^1H\}$ and ^{89}Y NMR spectroscopy. X-ray structures were determined for three examples. The insoluble $YF_3 \cdot 1/2H_2O$ did not react with Ph_3PO or Me_3PO in refluxing ethanol or acetone even with extended reaction times.

2.2. $[Y(Me_3PO)_6]X_3$ (X = Cl, Br or I) and $[Y(Me_3AsO)_6]Cl_3$

The reaction of $YX_3 \cdot nH_2O$ with Me_3PO with a YX_3:Me_3PO ratio of 1:6 produced $[Y(Me_3PO)_6]X_3$. These complexes are insoluble in acetone, CH_2Cl_2 or cold ethanol, slightly soluble in $MeNO_2$, and decomposed by DMF or DMSO. The IR spectra of these complexes are superimposable, with a strong broad feature at 1110 cm^{-1} assigned as ν(PO), which compares with 1161 cm^{-1} in the 'free' ligand. In nitromethane solution all have conductivities in the range typical of 3:1 electrolytes, and the ^1H NMR spectra (d^3-$MeNO_2$) each show a doublet with $^2J(^{31}P–^1H) = 13$ Hz. The $^{31}P\{^1H\}$ NMR spectra in $MeNO_2$ at 295 K are singlets at $\delta \sim 55$, which on cooling to 248 K show doublet coupling to ^{89}Y of ~ 8 Hz. The poor solubility in $MeNO_2$ and the relatively high m.p. (244 K) made obtaining ^{89}Y NMR data very difficult. No ^{89}Y resonances were observed at ambient temperatures, but from $[Y(Me_3PO)_6]Cl_3$ in $MeNO_2$ at 245 K after very long accumulations, a weak multiplet pattern consistent with the central five lines of a binomial septet $^2J(^{89}Y–^{31}P)$ approximately 8 Hz, was observed at δ 133. The bromide and iodide salts were less soluble than the chloride and no ^{89}Y spectra were obtained from these. Confirmation of the composition was obtained from the X-ray crystal structure of $[Y(Me_3PO)_6]Br_3$ which shows the six trimethylphosphine oxide ligands octahedrally coordinating to the yttrium (Fig. 1). The yttrium is located on a centre of symmetry with the O–Y–O angles close to the idealized values (Table 1). There is little change in geometry among the three crystallographically independant phosphine oxides with the largest variation being in the Y–O–P angle (142°–159°). As noted before [7], these angles are smaller than those in complexes of the triphenyl derivative (see later).

The $[Y(Me_3AsO)_6]Cl_3$ was obtained from hydrated YCl_3 and Me_3AsO in ethanol, and has similar properties to those of $[Y(Me_3PO)_6]Cl_3$, including a broad ν(AsO) at 877 cm^{-1}, the conductance of a 3:1 electrolyte in 10^{-3} mol dm^{-3} $MeNO_2$, δ(Me) at 2.0(s) in the ^1H NMR spectrum and an ^{89}Y NMR resonance (in $EtNO_2$ at 185 K) at δ 135. The $[Y(Me_3AsO)_6](NO_3)_3$ previously characterised by an X-ray study [8], has ν(AsO) = 877 cm^{-1} and $\delta(^{89}Y)$ 133, and the presence of the same octahedral YO_6 cation in the present complex is therefore clear. It is notable that in the nitrate systems, $[Y(Me_3PO)_3(\eta^2\text{-}NO_3)_3]$ and $[Y(Me_3PO)_4(\eta^2\text{-}NO_3)_2]NO_3$ form, but not $[Y(Me_3PO)_6](NO_3)_3$, showing that the preference of the oxophilic Y(III) for nitrate is stronger than for halides. In the halide systems, reactions using a Y:Me_3PO ratio of $1: < 6$ resulted only in precipitation of $[Y(Me_3PO)_6]X_3$, albeit in poor yield.

2.3. $[YX_2(Ph_3PO)_4]Z$ (X = Cl, Br or I; Z = X or PF_6)

The reaction of $YCl_3 \cdot 6H_2O$, $YBr_3 \cdot 6H_2O$ or $YI_3 \cdot 8H_2O$ with Ph_3PO in ethanol in a 1:3–4 mol ratio produced white $[YX_2(Ph_3PO)_4]X$ (X = Cl or Br) or pale yellow $[YI_2(Ph_3PO)_4]I$. If the reactions are conducted in the

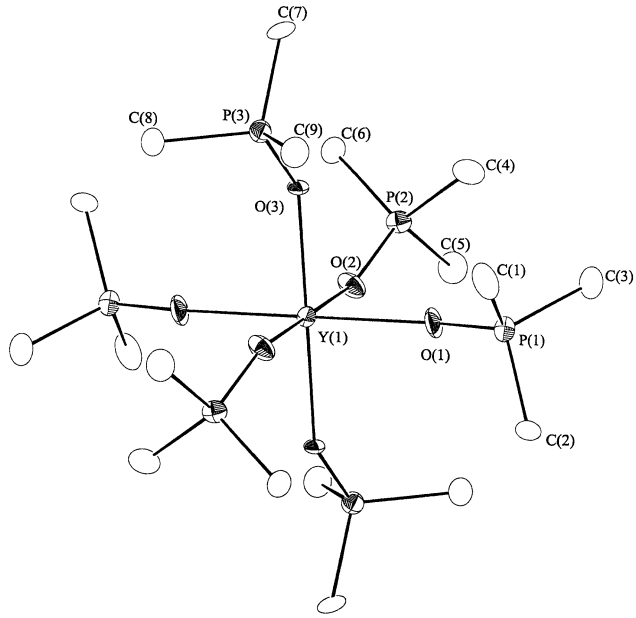

Fig. 1. Structure of the cation in $[Y(Me_3PO)_6]Br_3$ showing the atom numbering scheme. Thermal ellipsoids are drawn at the 40% probability level and H atoms omitted for clarity. The yttrium is located on a centre of symmetry.

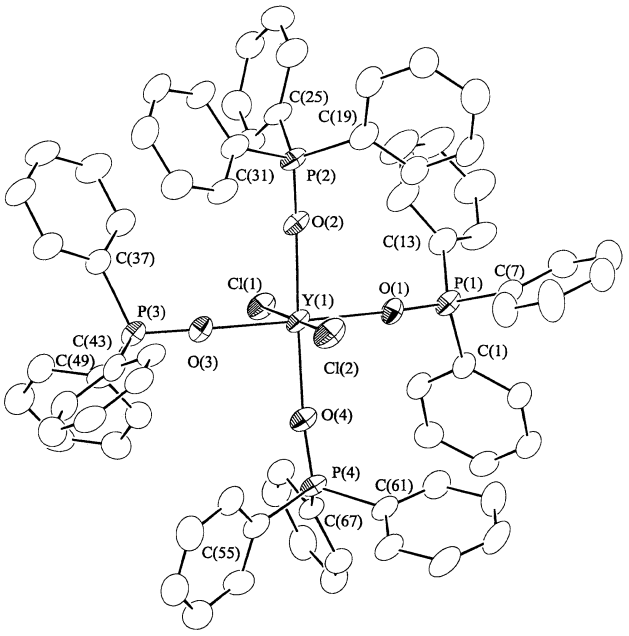

Fig. 2. Structure of the cation in $[YCl_2(Ph_3PO)_4]Cl{\cdot}2.5EtOH{\cdot}H_2O$ showing the atom numbering scheme. Thermal ellipsoids are drawn at the 40% probability level and H atoms omitted for clarity.

presence of NH_4PF_6, the products are $[YX_2(Ph_3PO)_4]$-PF_6, which apart from features due to PF_6^- anions are spectroscopically identical to the X^- salts. The isolated chloro- and bromo-complexes are air and moisture stable, the iodocomplexes darken slowly in the solid state and turn brown in a few hours in solution in chlorocarbon solvents due to liberation of diiodine, and this is accompanied by the appearance of new phosphine oxide resonances in the ^{31}P NMR spectra. The latter reaction does not occur in the absence of oxygen, and would appear to involve yttrium-promoted oxidation of the coordinated iodide ligands by oxygen.

The X-ray structures of $[YCl_2(Ph_3PO)_4]Cl{\cdot}2.5EtOH{\cdot}H_2O$ and $[YBr_2(Ph_3PO)_4]PF_6{\cdot}Et_2O$ (Figs. 2 and 3) reveal *trans*-octahedral cations with angles at Y close to the idealized values. The Y–O distances (Tables 2 and 3) are all very similar (approximately 2.2 Å) to the values found in the hexakis-trimethylphosphine oxide structure (Table 1). The difference in the Y–halogen distance closely reflects the difference in the ionic radii of the two halogens (0.14 Å). The complexed phosphine oxide geometry is unexceptional and shows Y–O–P angles of 167–174° (Cl) and 156–172° (Br) which are in general larger than the trimethyl derivative (Table 1). The IR spectra of the complexes each exhibit a very strong broad feature in the range 1150–1130 cm^{-1} assignable to ν(PO), which move to high frequency along the series $I \rightarrow Br \rightarrow Cl$. Uncomplexed Ph_3PO exhibits ν(PO) at 1195 cm^{-1} [7]. In CH_2Cl_2 solution the complexes are 1:1 electrolytes [7], and show $^{31}P\{^1H\}$ NMR resonances at room temperature which are doublets due to coupling to ^{89}Y with $^2J(^{89}Y–^{31}P)$ 10–12 Hz. The resonances shift to high frequency along the series $Cl \rightarrow Br \rightarrow I$, and are unchanged on cooling to 200 K. Dilute solutions of $[YX_2(Ph_3PO)_4]X$ (X = Cl, Br or I) show weak resonances ($\leq 5\%$ of the tetrakis signal) approximately 1 ppm to low frequency of the main peak, which on cooling the solutions show doublet ^{89}Y couplings. These resonances disappear on adding Ph_3PO to the solutions and are attributed to some dissociation into the tris $[YX_3(Ph_3PO)_3]$ complexes. A CH_2Cl_2 solution of $[YCl_2(Ph_3PO)_4]Cl$ boiled with $YCl_3{\cdot}6H_2O$ showed three ^{31}P NMR resonances with δ 36.0 (tetrakis), 27.0 (Ph_3PO) and 34.5 which is probably due to $[YCl_3(Ph_3PO)_3]$. The ^{89}Y NMR spectrum obtained from this solution showed two multiplets at δ 192 ($[YCl_2(Ph_3PO)_4]Cl$ below) and 242(quartet), the latter consistent with $[YCl_3(Ph_3PO)_3]$, although at-

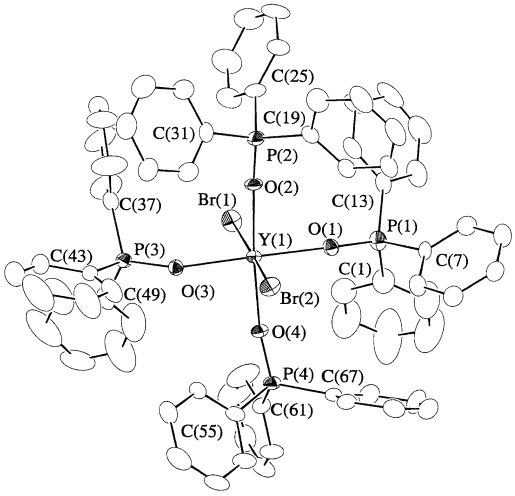

Fig. 3. Structure of the cation in $[YBr_2(Ph_3PO)_4]PF_6{\cdot}Et_2O$ showing the atom numbering scheme. Thermal ellipsoids are drawn at the 40% probability level and H atoms omitted for clarity.

tempts to isolate $[YCl_3(Ph_3PO)_3]$ as a solid have been unsuccessful. Solutions of $[YX_2(Ph_3PO)_4]PF_6$ containing 2 equiv. of Ph_3PO show weak features at δ 37.5 and 40.0 (X = Cl) or δ 37.0 and 38.0 (X = Br), which by comparison with data for $[YCl(Ph_3PO)_5][SbCl_6]_2$ may be identified as due to $[YX(Ph_3PO)_5]^{2+}$, suggesting a competitive equilibrium between X^- and Ph_3PO for the Y centre. In these cases insufficient of the second species was formed to permit its identification via ^{89}Y NMR. The iodide complexes differ in that mixtures of $[YI_2(Ph_3PO)_4]^+$ and 5 equiv. of Ph_3PO in CH_2Cl_2 at ambient temperatures show markedly broadened resonances indicating the onset of intermolecular exchange. At 180 K this solution shows strong resonances due to Ph_3PO, $[YI_2(Ph_3PO)_4]^+$, intense doublets at δ 37.5 and 38.0 (integral 4:1) attributable to formation of $[YI(Ph_3PO)_5]^{2+}$, and some weaker unassigned features. The greater proportion of $[YX(Ph_3PO)_5]^{2+}$ formed when X = I is consistent with easier displacement of the soft iodide from the oxophilic yttrium. Solutions of $[YX_2(Ph_3PO)_4]^+$ fail to exhibit ^{89}Y resonances at 300 K, but on cooling to 200 K a single resonance is present in each complex, which under high resolution appear as binomial quintets due to coupling to four equivalent R_3PO ligands (Table 4, Fig. 4).

2.4. $[YCl(Ph_3PO)_5][SbCl_6]_2$

The reaction of $[YCl_2(Ph_3PO)_4]^+$ with Ph_3PO in dry CH_2Cl_2 in the presence of 2 equiv. of the strong Lewis acid $SbCl_5$ results in chloride abstraction to form $[YCl(Ph_3PO)_5][SbCl_6]_2$. Excess $SbCl_5$ causes decomposition to form (among other products) $[SbCl_5(Ph_3PO)]$ [16] (δ (^{31}P) = 47) while $[Y(Ph_3PO)_6][SbCl_6]_3$ does not appear to form. The $[YCl(Ph_3PO)_5][SbCl_6]_2$ shows a $^{31}P\{^1H\}$ NMR spectrum containing two doublets at δ 37.5 and 40.0 (integral 4:1). The corresponding ^{89}Y NMR resonance is at δ 179 and approximates to a sextet pattern, although the outer lines were ill-defined. This is attributed to the very similar ^{89}Y–^{31}P couplings to the axial and equatorial phosphine oxides (10, 11 Hz). The ν(PO) frequency occurs at 1141 cm^{-1} for the dication, some 10 cm^{-1} lower than in $[YCl_2(Ph_3PO)_4]^+$ showing the effect of the increased positive charge. The presence of $[SbCl_6]^-$ is shown by a strong band at 347 cm^{-1} [17].

2.5. $[YX_2(Ph_3AsO)_4]X$

The corresponding reactions to those in Section 2.3, but replacing Ph_3PO with Ph_3AsO, produced $[YX_2(Ph_3AsO)_4]X$. The iodide systems are again sensitive to air and, as described in the Section 3, the polyiodide $[YI_2(Ph_3AsO)_4](I_5)$ has been characterised. Spectroscopically these complexes are very similar to their phosphine oxide analogues: 1:1 electrolytes in solution and showing a single broad ν(AsO) at approximately 890 cm^{-1}. The ^{89}Y NMR spectra from CH_2Cl_2 solutions at 200 K contain single sharp resonances (Table 4) attributable to the $[YX_2(Ph_3AsO)_4]^+$ cations, the resonances being slightly (≤ 10 ppm) to high frequency of those in $[YX_2(Ph_3PO)_4]X$ for constant X. An acetone solution of $[YCl_2(Ph_3AsO)_4]Cl$ containing 1 equiv. of YCl_3 showed (at 200 K) only a singlet ^{89}Y NMR resonance at δ 200 attributable to the tetrakis complex, with no evidence for formation of $[YCl_3(Ph_3AsO)_3]$ for which $\delta(^{89}Y)$ would be expected approximately δ 250–260. The poor sensitivity of ^{89}Y NMR means that minor species could easily escape detection, but this shows that the $[YCl_3(Ph_3AsO)_3]$ is not formed in substantial amounts.

2.6. $[YX_3(Ph_2MePO)_3]$

In marked contrast to the Ph_3PO systems, reaction of $YX_3 \cdot 6H_2O$ (X = Cl or Br) with Ph_2MePO in ethanol or acetone irrespective of the ratio gave solid $[YX_3(Ph_2MePO)_3]$ complexes. The complexes are non-conductors in solution, and the IR spectra show a very strong feature in the range 1150–1140 cm^{-1} attributable to ν(PO) (cf. 'free' Ph_2MePO 1172 cm^{-1} [7]). In solution each complex shows a single $^{31}P\{^1H\}$ NMR resonance which appear as singlets at ambient temperature, but show ill-defined doublet couplings to ^{89}Y on cooling. The ^{89}Y resonances are only observed at 200 K, and under high resolution are binomial quartets showing coupling to 3 equiv. phosphorus atoms, consistent with a *fac* geometry (Table 4, Fig. 4). On addition of Ph_2MePO to the solutions very broad ^{31}P NMR resonances δ approximately 29 and 40 were present at room temperature, showing intermolecular exchange is occurring. On cooling the resonances sharpen, but in addition to those of $[YX_3(Ph_2MePO)_3]$ and Ph_2MePO, a new feature is present δ approximately 41. In the

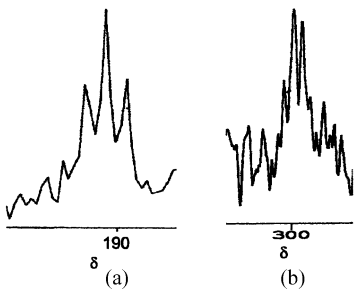
[a] The ^2J couplings are often not evident at higher temperatures, possibly due to exchange, although in some cases they are probably lost in the line widths.
[b] The PF_6^- resonances at approximately −145 (septet) are not listed; ^{31}P NMR shifts at 300 K are given in Section 3.
[c] Couplings not resolved or ill-defined.
[d] Data from Ref. [7].
[e] Data from Ref. [8].

presence of a large excess of ligand, ^{89}Y NMR spectra (200 K) showed quintet patterns near δ 190 (Cl) or 220 (Br) which by comparison with the Ph_3PO analogues can be attributed to the formation of $[YX_2(Ph_2MePO)_4]^+$, although only $[YX_3(Ph_2MePO)_3]$ were isolated from these solutions as solids. However, the reaction of $YCl_3{\cdot}6H_2O$, Ph_2MePO and NH_4PF_6 in ethanol in a 1:4:1 ratio produced white $[YCl_2(Ph_2MePO)_4]PF_6$, which showed a quintet ^{89}Y NMR resonance at δ 192 and $\delta(^{31}P)$ at 40.5. Low



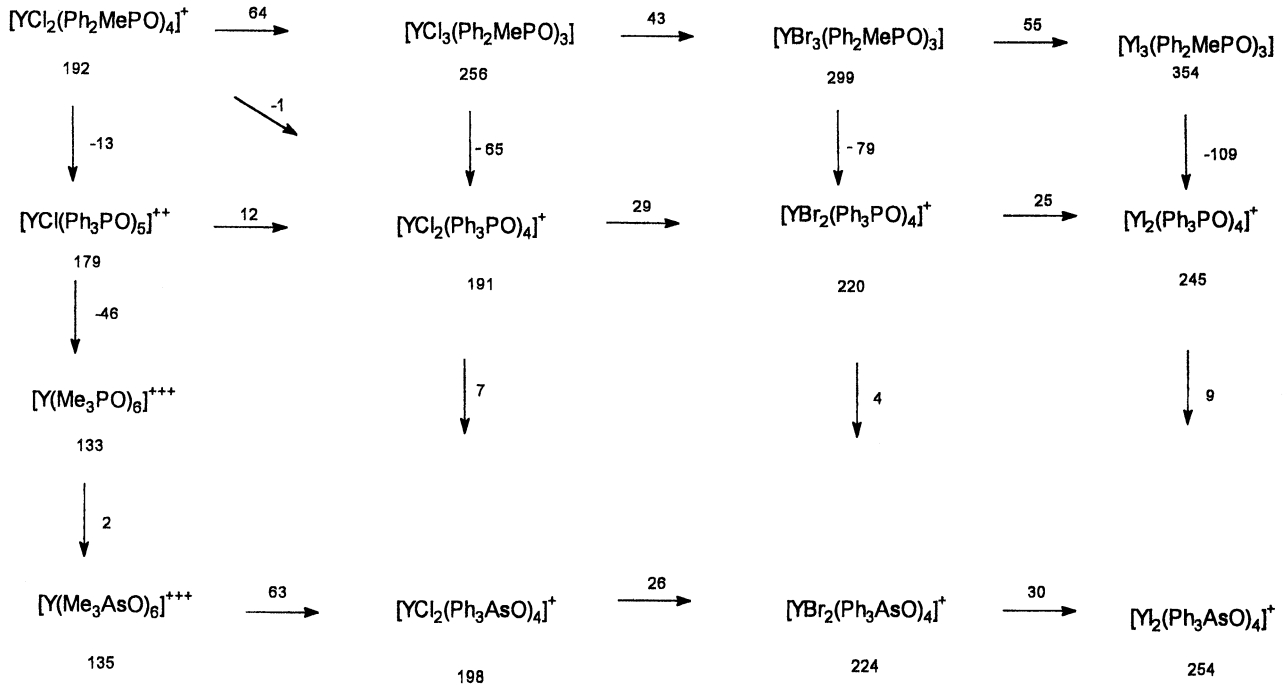


Fig. 4. ^{89}Y NMR spectra of: (a) $[YCl_2(Ph_3PO)_4]^+$; (b) $[YBr_3(Ph_2MePO)_3]$ in $CH_2Cl_2/CDCl_3$ at 200 K.

temperature ^{31}P NMR studies reveal the presence of some Ph_2MePO and $[YCl_3(Ph_2MePO)_3]$ in CH_2Cl_2 solutions of $[YCl_2(Ph_2MePO)_4]PF_6$, showing an equilibrium is present. The $[YBr_2(Ph_2MePO)_4]PF_6$ was not prepared.

The $YI_3{\cdot}8H_2O$–Ph_2MePO system is more labile and isolation of pure complexes proved difficult. A pale yellow $[YI_3(Ph_2MePO)_3]$ was isolated from ethanol solution containing a YI_3:Ph_2MePO of 1:2. At 180 K in CH_2Cl_2 solution this shows a rather broad ^{89}Y resonance at δ 354 which seems reasonable for an I_3O_3 donor set (see Table 4), but the coupling was not clearly resolved. The ^{31}P NMR spectrum has a very broad feature at δ 41.5 at 300 K which on cooling sharpens and at 190 K shows a doublet at 41.5 ($^2J(^{89}Y–^{31}P) = 14$ Hz) and some other weak features to higher frequency. In the $[YI_3(Ph_2MePO)_3]$ with excess Ph_2MePO, ligand exchange is fast on the ^{31}P NMR time scale down to low temperatures, and even at 190 K the lines are still broad, although separate resonances at 29.0 (Ph_2MePO), 41.5 (d) ($[YI_3(Ph_2MePO)_3]$) and 42.0 (d) ($[YI_2(Ph_2MePO)_4]^+$?) are resolved. The corresponding $YI_3/Ph_2MePO/PF_6^-$ system is complex and appears to

Scheme 1. ^{89}Y NMR chemical shifts of various yttrium complexes. Values below formulae represent chemical shifts and values alongside the arrows are the differences in chemical shift. For practical reasons (see text) the $[Y(Me_3EO)_6]^{3+}$ were recorded in $MeNO_2$ or $EtNO_2$, and the others in CH_2Cl_2. Although small solvent and temperature shifts may be present in the data, they are unlikely to alter the pattern of characteristic shifts with X, R_3EO, and X:R_3EO ratio, which are clear.

contain at least three yttrium species, but attempts to isolate pure solid complexes from this system failed.

2.7. Diphosphine dioxide complexes

The reaction of $YCl_3{\cdot}6H_2O$ with $Ph_2P(O)CH_2P(O)Ph_2$ (dppmO_2) or o-$C_6H_4\{P(O)Ph_2\}_2$ (ppO_2) in ethanol gave white $[YCl_2(L–L)_2]Cl$, which appear to be the first reported diphosphine dioxide complexes of yttrium. Both are 1:1 electrolytes in CH_2Cl_2 solution. The $[YCl_2(ppO_2)_2]Cl$ exhibits a single broad $^{31}P\{^1H\}$ NMR resonance at ambient temperatures and no ^{89}Y resonance is evident. However, at 200 K the ^{89}Y NMR spectrum shows a clearly resolved quintet at δ 210 ($^2J(^{89}Y–^{31}P) = 7$ Hz) showing it is the *trans* cation with a Cl_2O_4 donor set. The $[YCl_2(dppmO_2)_2]Cl$ is generally similar although its solubility in CH_2Cl_2 is poor.

2.8. ^{89}Y NMR studies

The identification of solution species as discussed in previous sections relied in most cases on the $^{31}P–^{89}Y$ coupling patterns. Here we compare chemical shifts in an attempt to correlate these with donor set. Data from our previous studies of the nitrate systems are also included. Scheme 1 shows the systematic changes observed as the nature and number of X and R_3EO ligands are varied. As expected the effect on the ^{89}Y chemical shift of changing R groups on the ligand is small, and changing R_3PO to R_3AsO produces a high frequency shift of ≤ 10 ppm. The homoleptic $[Y(Me_3EO)_6]^{3+}$ (E = P or As) have $\delta(^{89}Y)$ 133–135. Incorporating Cl in the coordination sphere in $[YCl(Ph_3PO)_5]^{2+}$, $[YCl_2(Ph_3PO)_4]^+$ and $[YCl_3(Ph_2MePO)_3]$ causes a stepwise high frequency shift. Similarly exchanging Cl for Br and then I causes progressive high frequency shifts (Scheme 1). Comparison with data on the nitrate systems (Table 4) shows that replacement of NO_3 by R_3EO results in a high frequency shift, although the trends are less regular, probably due to the varying coordination numbers in the nitrate systems. The $^{31}P\{^1H\}$ chemical shifts are much less useful in identifying complexes since they differ by approximately 1–2 ppm between $[YX_2(R_3PO)_4]^+$ and $[YX_3(R_3PO)_3]$.

3. Experimental

Multinuclear NMR spectra were obtained on a Bruker DPX400 at 161.9 MHz ($^{31}P\{^1H\}$) and referenced to external 85% H_3PO_4 or 19.60 MHz (^{89}Y) using a 2–4 s pulse delay and TEMPO as a relaxation agent and referenced to 1 mol dm^{-3} YCl_3 in water. Other physical measurements were made as before [7]. Ph_3PO, Ph_2MePO, Ph_3AsO, $YCl_3{\cdot}6H_2O$ (Aldrich) and Me_3PO (Alfa) were used as received. Me_3AsO was made by H_2O_2 oxidation of Me_3As in Et_2O and purified by

sublimation in vacuo [8]. $YF_3 \cdot 1/2H_2O$ was made by precipitation from aq. solutions of $Y(NO_3)_3$ and NaF, washed with H_2O and dried in vacuo. $YBr_3 \cdot 6H_2O$ was prepared by evaporating Y_2O_3 with 48% HBr, and recrystallising the product from H_2O. *Anal*. Found: Br, 54.8. Calc. for $YBr_3 \cdot 6H_2O$: Br, 54.9%. $YI_3 \cdot 8H_2O$ was made by metathesis of aq. solutions of yttrium sulfate and barium iodide, removal of the precipitated $BaSO_4$, and evaporation to dryness in vacuo. The fawn hygroscopic solid was stored in a desiccator. Yield: 92%. *Anal*. Found: I, 61.9. Calc. for $YI_3 \cdot 8H_2O$: I, 62.0%. Several attempts to prepare this compound from Y_2O_3 and aq. HI gave materials containing excess diiodine, which could not be removed.

3.1. $[YCl_2(Ph_3PO)_4]Cl$

$YCl_3 \cdot 6H_2O$ (0.20 g, 0.66 mmol) and Ph_3PO (1.11 g, 4.0 mmol) were dissolved separately in cold EtOH (2×5 cm^3) and the solutions mixed. Refrigeration overnight resulted in colourless crystals, which were filtered off and dried in vacuo. Yield: 0.56 g, 60%. *Anal*. Found: C, 65.7; H, 4.5. Calc. for $C_{72}H_{60}Cl_3O_4P_4Y$: C, 66.1; H, 4.6%. IR (cm^{-1}) (Nujol mull): 1310m, 1188w, 1150vs (PO), 1119s, 1087s, 1074m, 997w, 975w, 749s, 692s, 543s, 420w, 398w, 353w, 310m, 260m. ^{1}H NMR (300 K, $CDCl_3$): 7.1–7.9 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 35.0 (d) $^2J(^{31}P–^{89}Y) = 12$ Hz. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 30 Ω^{-1} cm^2 mol^{-1}.

3.2. $[YCl_2(Ph_3PO)_4]PF_6$

To a solution of $YCl_3 \cdot 6H_2O$ (0.30 g, 1.0 mmol) in warm EtOH (10 cm^3) were added sequentially $[NH_4][PF_6]$ (0.16 g, 1.0 mmol) and Ph_3PO (1.1 g, 4.0 mmol) dissolved in EtOH (10 cm^3), resulting in a fine white precipitate. The solution was stirred for 1 h, the precipitate filtered off and dried in vacuo. Yield: 1.09 g, 75%. *Anal*. Found: C, 61.1; H, 4.4. Calc. for $C_{72}H_{60}Cl_2F_6O_4P_5Y$: C, 61.0; H, 4.3%. IR (cm^{-1}) (CsI disc): 3061w, 1439m, 1318m, 1192w, 1150vs (PO), 1122s, 1092s, 1028m, 999m, 839s, 750m, 725s, 693s, 559s, 543s, 459m, 446m, 421m, 305m, 267s. ^{1}H NMR (300 K, $CDCl_3$): 7.1–7.9 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 35.0 (d) $^2J(^{31}P–^{89}Y) = 13$ Hz, -145(septet) PF_6^-. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 21 Ω^{-1} cm^2 mol^{-1}.

3.3. $[YBr_2(Ph_3PO)_4]Br$

Prepared similarly to $[YCl_2(Ph_3PO)_4]Cl$. Yield: 52%. *Anal*. Found: C, 59.6; H, 4.2. Calc. for $C_{72}H_{60}Br_3O_4P_4Y$: C, 59.9; H, 4.2%. IR (cm^{-1}) (CsI disc): 1307m, 1188w, 1140vs (PO), 1119s, 1087s, 1084m, 998w, 973w, 763m, 693s, 543s, 449m, 417w, 305m, 262m. ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.9 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 36.0 (d) $^2J(^{31}P–^{89}Y) = 11$ Hz. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 20 Ω^{-1} cm^2 mol^{-1}.

3.4. $[YBr_2(Ph_3PO)_4]PF_6$

Prepared similarly to $[YCl_2(Ph_3PO)_4]PF_6$. Yield: 90%. *Anal*. Found: C, 57.9; H, 4.2. Calc. for $C_{72}H_{60}Br_2F_6O_4P_5Y$: C, 57.4; H, 4.2%. IR (cm^{-1}) (CsI disc): 3061w, 1439m, 1359w, 1191w, 1147vs (PO), 1123s, 1089s, 1029m, 1000m, 839vs, 750m, 726s, 693s, 559sh, 543s, 449m, 417m, 305m, 250w. ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.9 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 36.0 (d) $^2J(^{31}P–^{89}Y) = 11$ Hz, -145(septet) PF_6^-. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 19 Ω^{-1} cm^2 mol^{-1}.

3.5. $[YI_2(Ph_3PO)_4]I$

Prepared similarly to $[YCl_2(Ph_3PO)_4]Cl$ as a pale yellow solid. Yield: 38%. *Anal*. Found: C, 54.2; H, 3.8. Calc. for $C_{72}H_{60}I_3O_4P_4Y$: C, 54.6; H, 3.8%. IR (cm^{-1}) (CsI disc): 1485w, 1438m, 1359m, 1188w, 1136vs (PO), 1121s, 1083s, 1027w, 1000w, 749m, 725s, 696s, 543s, 460m, 449m, 421w, 299m. ^{1}H NMR (300 K, $CDCl_3$): 7.1–7.6 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 37.2 (d) $^2J(^{31}P–^{89}Y) = 11$ Hz. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 25 Ω^{-1} cm^2 mol^{-1}.

3.6. $[YI_2(Ph_3PO)_4]PF_6$

Prepared similarly to $[YCl_2(Ph_3PO)_4]PF_6$ as pale yellow powder. Yield: 39%. *Anal*. Found: C, 53.8; H, 3.7. Calc. for $C_{72}H_{60}F_6I_2O_4P_5Y$: C, 54.0; H, 3.8%. IR (cm^{-1}) (CsI disc): 1486w, 1439m, 1359w, 1183w, 1144vs (PO), 1122s, 1087s, 1029w, 999m, 842vs, 753m, 725s, 696s, 559sh, 542s, 460m, 445m, 424m, 304m. ^{1}H NMR (300 K, $CDCl_3$): 7.4–7.8 (m). $^{31}P\{^1H\}$ NMR (300 K, $CH_2Cl_2/CDCl_3$): 37.5 (d) $^2J(^{31}P–^{89}Y) = 11$ Hz, -145(septet) PF_6^-. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 23 Ω^{-1} cm^2 mol^{-1}.

3.7. $[YCl(Ph_3PO)_5][SbCl_6]_2$

Under a nitrogen atmosphere antimony pentachloride (0.05 g, 0.17 mmol) was added dropwise to a solution of $[YCl_2(Ph_3PO)_4]Cl$ (0.11 g, 0.08 mmol) in anhydrous CH_2Cl_2 (5 cm^3). A solution of Ph_3PO (0.02 g, 0.08 mmol) in CH_2Cl_2 (5 cm^3) was added, resulting in a milky suspension. The solution was concentrated to 5 cm^3, the white powder filtered off and dried in vacuo. Yield: 0.12 g, 56%. *Anal*. Found: C, 49.6; H, 3.3. Calc. for $C_{90}H_{75}Cl_{13}O_5P_5Sb_2Y$: C, 49.4; H, 3.5%. IR (cm^{-1}) (CsI disc): 2975w, 1484w, 1437m, 1357m, 1191w, 1141s (PO), 1121s, 1090m, 1027w, 995m, 745s, 692s, 543s, 347s($SbCl_6^-$). ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.7 (m).

Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 42 Ω^{-1} cm^2 mol^{-1}.

3.8. $[YCl_2(Ph_3AsO)_4]Cl$

$YCl_3 \cdot 6H_2O$ (0.30 g, 1.0 mmol) and Ph_3AsO (1.28 g, 4.0 mmol) were dissolved in boiling EtOH (10 cm^3). Cooling to room temperature (r.t.) followed by refrigeration overnight resulted in white crystals, which were filtered off and dried in vacuo. Yield: 0.32 g, 20%. *Anal.* Found: C, 57.7; H, 3.9. Calc. for $C_{72}H_{60}As_4Cl_3O_4Y$: C, 58.3; H, 4.1%. IR (cm^{-1}) (CsI disc): 1440m, 1359m, 1186w, 1089m, 1071w, 1026w, 999w, 894vs (AsO), 744s, 693s, 553w, 481s, 376m, 365s, 273m, 260s. ^{1}H NMR (300 K, $CDCl_3$): 7.3–7.8. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 31 Ω^{-1} cm^2 mol^{-1}.

3.9. $[YBr_2(Ph_3AsO)_4]Br$

Made similarly to the above. Yield: 55%. *Anal.* Found: C, 53.0; H, 3.8. Calc. for $C_{72}H_{60}As_4Br_3O_4Y$: C, 53.4; H, 3.7%. IR (cm^{-1}) (CsI disc): 1440m, 1359m, 1089m, 1071w, 1025w, 999w, 893vs (AsO), 744s, 691s, 478s, 368s, 338sh, 272m, 243m. ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.8. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 23 Ω^{-1} cm^2 mol^{-1}.

3.10. $[YI_2(Ph_3AsO)_4]I_5$

Made similarly as dark brown crystals. Yield: 25%. *Anal.* Found: C, 38.2; H, 2.9. Calc. for $C_{72}H_{60}As_4I_7O_4Y$: C, 38.1; H, 2.7%. IR (cm^{-1}) (CsI disc): 1484m, 1440m, 1360w, 1186w, 1088s, 1025w, 999m, 893vs (AsO), 740s, 691s, 477s, 457m, 367m, 356m, 273w, 244w. ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.8. Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 41 Ω^{-1} cm^2 mol^{-1}.

3.11. $[Y(Me_3PO)_6]Cl_3$

An ethanolic solution (10 cm^3) of $YCl_3 \cdot 6H_2O$ (0.15 g, 0.5 mmol) was added to Me_3PO (0.28 g, 3.0 mmol) in EtOH (10 cm^3) and the solutions stirred for 1 h. Refrigeration gave a white precipitate. Yield: 0.34 g, 90%. *Anal.* Found: C, 28.9; H, 7.6. Calc. for $C_{18}H_{54}Cl_3O_6P_6Y$: C, 28.9; H, 7.2%. IR (cm^{-1}) (CsI disc): 2960w, 1423w, 1358w, 1299w, 1111vs, br (PO), 960m, 872m, 762m, 396m, 364w, 332m. ^{1}H NMR (300 K, d^3-$MeNO_2$): 1.60 (d) $^2J(^{31}P–^1H)$ = 14 Hz. Λ_M (10^{-3} mol dm^{-3} $MeNO_2$) = 225 Ω^{-1} cm^2 mol^{-1}.

3.12. $[Y(Me_3PO)_6]Br_3$

Boiling EtOH solutions (2 × 10 cm^3) of $YBr_3 \cdot 6H_2O$ (0.44 g, 1.0 mmol) and Me_3PO (0.37 g, 4.0 mmol) were mixed, resulting in a white suspension, which redissolved on shaking. Refrigeration of the resulting solution overnight deposited white needles. Yield: 0.39 g, 66%. *Anal.* Found: C, 24.2; H, 6.2. Calc. for $C_{18}H_{54}Br_3O_6P_6Y$: C, 24.5; H, 6.1%. IR (cm^{-1}) (CsI disc): 2962w, 2896w, 1358m, 1299m, 1111s,br (PO), 959s, 872m, 761m, 395s, 364m, 330m. ^{1}H NMR (300 K, d^3-$MeNO_2$): 1.69 (d) $^2J(^{31}P–^1H)$ = 13 Hz. Λ_M (10^{-3} mol dm^{-3} $MeNO_2$) = 207 Ω^{-1} cm^2 mol^{-1}.

3.13. $[Y(Me_3PO)_6]I_3$

A boiling EtOH solution (10 cm^3) of $YI_3 \cdot 8H_2O$ (0.31 g, 0.5 mmol) was added to a solution of Me_3PO (0.18 g, 2.0 mmol) resulting in a yellow suspension. The mixture was refrigerated overnight, the solid filtered off and dried in vacuo. Yield: 0.21 g, 50%. *Anal.* Found: C, 20.9; H, 5.4. Calc. for $C_{18}H_{54}I_3O_6P_6Y$: C, 21.2; H, 5.3%. IR (cm^{-1}) (CsI disc): 2964w, 2897w, 1421w, 1358m, 1299m, 1110s, br (PO), 957s, 871m, 761m, 396s, 364m, 331m. ^{1}H NMR (300 K, d^3-$MeNO_2$): 1.73 (d) $^2J(^{31}P–^1H)$ = 13 Hz. Λ_M (10^{-3} mol dm^{-3} $MeNO_2$) = 228 Ω^{-1} cm^2 mol^{-1}.

3.14. $[YCl_3(Ph_2MePO)_3]$

A solution of $YCl_3 \cdot 6H_2O$ (0.30 g, 1.0 mmol) in boiling EtOH (10 cm^3) was added to a solution of Ph_2MePO (0.22 g, 1.0 mmol) in EtOH (5 cm^3) and the mixture stirred for 1 h, then concentrated to approximately 5 cm^3 and refrigerated overnight. The white solid was filtered off and dried in vacuo. Yield: 0.28 g, 88%. *Anal.* Found: C, 54.5; H, 4.1. Calc. for $C_{39}H_{39}Cl_3O_3P_3Y$: C, 55.5; H, 4.7%. IR (cm^{-1}) (CsI disc): 1709w, 1641m, 1439m, 1363w, 1225w, 1148vs (PO), 1127m, 1101m, 999w, 896m, 783w, 752m, 696m, 614m, 515s, 306w, 254s. ^{1}H NMR (300 K, $CDCl_3$): 2.29 (br), 7.4–7.7 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 2 Ω^{-1} cm^2 mol^{-1}.

3.15. $[YBr_3(Ph_2MePO)_3]$

Made similarly to the above from a 1:3 molar ratio of $YBr_3 \cdot 6H_2O$: Ph_2MePO. Yield: 46%. *Anal.* Found: C, 48.2; H, 4.1. Calc. for $C_{39}H_{39}Br_3O_3P_3Y$: C, 47.9; H, 4.0%. IR (cm^{-1}) (CsI disc): 1591w, 1439m, 1358w, 1178sh, 1144vs (PO), 1127sh, 1098s, 998m, 894s, 782w, 750s, 720m, 694m, 515s, 503sh, 392w, 312w. ^{1}H NMR (300 K, $CDCl_3$): 2.18 (br), 7.3–7.7 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 7 Ω^{-1} cm^2 mol^{-1}.

3.16. $[YI_3(Ph_2MePO)_3]$

Prepared similarly using $YI_3 \cdot 8H_2O$ and Ph_2MePO in a 1:2 molar ratio, as a yellow powder. Yield: 28%. *Anal.* Found: C, 42.5; H, 3.7. Calc. for $C_{39}H_{39}I_3O_3P_3Y$: C, 41.9; H, 3.5%. IR (cm^{-1}) (CsI disc): 2896w, 1592w, 1439m, 1359w, 1178sh, 1140vs (PO), 1125s, 1093s,

1071m, 1029m, 996m, 895s, 786w, 749s, 720m, 696m, 519s, 478m, 421m, 383w. ^{1}H NMR (300 K, $CDCl_3$): 2.0 (d), 7.2–7.7 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 5 Ω^{-1} cm^2 mol^{-1}.

3.17. $[YCl_2(Ph_2MePO)_4]PF_6$

To a solution of $YCl_3{\cdot}6H_2O$ (0.15 g, 0.5 mmol) in boiling EtOH (10 cm^3) was added solid NH_4PF_6 (0.082 g, 0.5 mmol), and the mixture allowed to cool to r.t. A solution of Ph_2MePO (0.43 g, 2.0 mmol) in EtOH (5 cm^3) was added resulting in an immediate precipitate. After some hours this was filtered off, and dried in vacuo. Yield: 0.28 g, 43%. *Anal*. Found: C, 53.0; H, 4.4. Calc. for $C_{52}H_{52}Cl_2F_6O_4P_5Y$: C, 53.4; H, 4.5%. IR (cm^{-1}) (CsI disc): 1591w, 1486w, 1440m, 1305w, 1165sh, 1151s (PO), 1126m, 1101w, 1075w, 1031w, 1000m, 903s, 840s, 782s, 756s, 748s, 720m, 698s, 559s, 511s, 498s, 455m, 418m, 387w, 312m, 264s. ^{1}H NMR (300 K, $CDCl_3$): 1.92 (br), 7.2–7.7 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 20 Ω^{-1} cm^2 mol^{-1}.

3.18. $[Y(Me_3AsO)_6]Cl_3$

$YCl_3{\cdot}6H_2O$ (0.15 g, 0.5 mmol) was dissolved in boiling EtOH (10 cm^3) and a solution of Me_3AsO (0.41 g, 3.0 mmol) in EtOH (10 cm^3) added. The solvent was removed in vacuo, the oil remaining dissolved in cold C_3H_6O which on standing produced a colourless powder. Yield: 0.22 g, 43%. *Anal*. Found: C, 21.0; H, 5.2. Calc. for $C_{18}H_{54}As_6Cl_3O_6Y$: C, 21.3; H, 5.4%. IR (cm^{-1}) (CsI disc): 2896w, 1418m, 1359s, 1269m, 1097w, 925w, 877s, 648s, 344s, 285m. ^{1}H NMR (300 K, $CDCl_3$): 2.0(s). Λ_M (10^{-3} mol dm^{-3} $MeNO_2$) = 224 Ω^{-1} cm^2 mol^{-1}.

3.19. $[YCl_2(dppmO_2)_2]Cl$

To a solution of $YCl_3{\cdot}6H_2O$ (0.076 g, 0.25 mmol) in boiling EtOH (5 cm^3) an ethanolic solution (10 cm^3) of $dppmO_2$ (0.10 g, 0.25 mmol) was added, resulting in an immediate white precipitate. The mixture was left to stand for 1 h, the precipitate filtered off and dried in vacuo. Yield: 0.06 g, 47%. *Anal*. Found: C, 57.9; H, 4.4. Calc. for $C_{50}H_{44}Cl_3P_4O_4Y$: C, 58.4; H, 4.3%. IR (cm^{-1}) (CsI disc): 3042w, 1437m, 1410s, 1368m, 1167s (PO), 1120m, 1071w, 997w, 843s, 790s, 742m, 692m, 572w. ^{1}H NMR (300 K, $CDCl_3$): 2.2 (s), 7.2–7.8 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 21 Ω^{-1} cm^2 mol^{-1}.

3.20. $[YCl_2(ppO_2)_2]Cl$

Was made similarly to the above. Yield: 55%. *Anal*. Found: C, 62.9; H, 4.3. Calc. for $C_{60}H_{48}Cl_3P_4O_4Y$: C, 62.6; H, 4.2%. IR (cm^{-1}) (CsI disc): 2960w, 1439m, 1410s, 1359m, 1171br, s (PO), 1121m, 1073w, 1005w, 844m, 750s, 730s, 694s, 562s, 549s, 534m. ^{1}H NMR (300 K, $CDCl_3$): 7.2–7.8 (m). Λ_M (10^{-3} mol dm^{-3} CH_2Cl_2) = 19 Ω^{-1} cm^2 mol^{-1}.

3.21. Crystallography

Crystals of the Ph_3PO complexes were obtained by vapour diffusion from CH_2Cl_2/Et_2O in a refrigerator. $[Y(Me_3PO)_6]Br_3$ was obtained directly from the synthesis. Crystallographic details are shown in Table 5; data were collected on a Nonius–Kappa CCD diffractometer fitted with Mo Kα radiation and graphite monochromator and the cell dimensions were taken from the diffractometer software recognizing that the e.s.d. values are unreasonably small [18]. Structure solution and refinement were routine [19–21] and data processing used the SORTAV absorption correction [22]. Phenyl and methyl H atoms were introduced in calculated positions. During the structure solution for two of the compounds, solvent molecules appeared in the difference electron density maps and these were modelled. One EtOH molecule was given a reduced s.o.f. (0.5) in order to obtain adp's similar to the other EtOH molecules.

4. Conclusions

This study has shown that yttrium halides (X = Cl, Br or I) form complexes with phosphine oxides in ratios varying from 1:6 through 1:3 (although not all types form with each ligand), and there are similar complexes with R_3AsO. Only certain of these complexes have been isolated in the solid state. Solution studies have shown that often a mixture of species is present in equilibrium, the relative amounts being easily varied by addition of R_3EO. In spite of this, it is usually possible to crystallise a single pure species from these solutions. Contrary to the literature reports [9–11,14] and in contrast to the nitrate systems [7,8] all the halide complexes contain six-coordinate *pseudo*-octahedral yttrium. Fluxionality in solution was observed in the nitrate systems [7], but the NMR spectra of $[YX(Ph_3PO)_5]^{2+}$ cations show these are not fluxional. Fluxionality is relatively rare in six-coordinate species (except metal hydrides) and although the symmetry is too high in the cases of the other complexes to provide evidence one way or the other, it seems likely that all the halide complexes are stereochemically rigid in solution.

5. Supplementary material

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data

Abstract

The adducts of $M(OAc)_2{\cdot}nH_2O$ (M = Cu, Co, Ni, Zn) with 2-anilinopyridine, $M(OAc)_2(PhNHpy)$, have been synthesized and characterized. The X-ray crystal structure of $Cu_2(\mu\text{-}OAc)_4(PhNHpy)_2$ shows the dimer structure of $Cu_2(\mu\text{-}OAc)_4(H_2O)_2$ with the PhNHpy ligand in the axial positions of the water molecules. It is antiferromagnetic ($2J = -286\ cm^{-1}$). Signals of the triplet state are observed in its EPR spectrum and the zero field splitting parameter ($D = 0.33\ cm^{-1}$) has been calculated. The electronic spectra and the strong antiferromagnetism of the cobalt ($2J = -324\ cm^{-1}$) and nickel ($2J = -382\ cm^{-1}$) compounds allow to propose also a dimeric structure for them. By excess of ligand, in the anionic form, the Cu(I) compound Cu(PhNpy) was obtained for which a dinuclear structure with a lineal coordination in Cu(I) is proposed. © 2002 Elsevier Science Ltd. Keywords: 2-Anilinopyridine; Crystal structures; Antiferromagnetic dimers; Dinuclear acetates; Copper(I)

1. Introduction

The dinuclear copper(II) acetate dihydrate $[Cu_2(\mu\text{-}OAc)_4(H_2O)_2]$, with four bridging acetate groups and the water molecules in the axial positions, is one of the most studied dinuclear compounds of Cu(II) in the structural and magnetic aspects [1,2]. Also the adducts $[Cu_2(\mu\text{-}OAc)_4L_2]$ and $[Cu_2(\mu\text{-}O_2CR)_4L_2]$ with different ligands in the axial positions [3–6].

The hydrated acetates of cobalt(II) and nickel(II), $M(OAc)_2{\cdot}4H_2O$, are monomers and isostructurals [7]. The acetate groups are monodentate and two of them are coordinated to each metal atom. The octahedral coordination is completed by four water molecules. Intermolecular hydrogen bonds between non-coordinated oxygen atoms of the acetate groups and hydrogen atoms of water are involved in a tridimensional net. They have normal magnetic moments at room temperature. Among the carboxylate complexes of Co(II) and Ni(II) the dimer structures as that of $[Cu_2(\mu\text{-}OAc)_4L_2]$ are infrequent. The X-ray diffraction has confirmed this structure in $[M_2(\mu\text{-}O_2CPh)_4(quin)_2]$, for quin = quinoline and M = Co(II) [8] and Ni(II) [9]. These complexes are antiferromagnetic, unlike other compounds with the same components but different structure, as $[Co_3(O_2CPh)_6(quin)_2]$ [10].

In $Zn(OAc)_2{\cdot}2H_2O$ two bidentate acetate anions and two water molecules are coordinated to the zinc atom [11]. The hydrogen bonds are established in a bidimensional net.

The 2-anilinopyridine, (*N*-phenyl-2-pyridinamine, PhNHpy), is an asymmetrical ligand, with two nitrogen atoms in the 1,3 positions, which can coordinate as monodentate or bidentate. As monodentate ligand the coordination is established through the pyridinic nitrogen and as anionic bidentate through both nitrogen atoms [12,13]. In previous papers we reported the reaction between $[Cu_2(NN)_2(\mu\text{-}OH)_2]X_2{\cdot}nH_2O$, where *NN* = 2,2′-bipyridyl or 1,10-phenanthroline and X^- =

PF_6^- or CLO_4^-, and PhNHpy. For $X^- = PF_6^-$ [14] each PhNHpy molecule is coordinated to a copper atom through the pyridinic nitrogen and the hydrogen bonded to the anilinic nitrogen is involved in an hydrogen bond with the oxygen atom of a bridging OH group. When $X^- = ClO_4^-$ [15] the ligand interacts with the medium (methanol) and a methylene group is inserted between the anilinic nitrogen atom and the bridging oxygen. The corresponding magneto–structural correlations were established for the resulting dinuclear complexes.

In this paper we describe the interaction between PhNHpy and the $M(OAc)_2{\cdot}nH_2O$ acetates (M = Cu, Co, Ni, Zn). The scope of substitution of AcO^- by the anionic ligand $PhNpy^-$ was unsuccessful and the Cu(I) compound CuPhNpy was obtained. The other adducts of PhNHpy, $M(OAc)_2$(PhNHpy) were obtained. Crystal structure of Cu(II) compound has been determined. Electronic spectra and magnetic and EPR results are also described and allow to make a structural proposition.

2. Experimental

2.1. Synthesis

The anionic form of PhNHpy was prepared, in situ. The ligand was dissolved in the minimal volume of absolute EtOH and metallic Na, in stoichiometric proportion, was added. The mixture was allowed to stand 15 min before using it [16].

2.1.1. Cu(PhNpy) (**1**)

A solution of anionic PhNHpy (5 mmol) in absolute EtOH (10 ml) was added to a solution of $Cu(OAc)_2{\cdot}H_2O$ (1 mmol) in MeOH (30 ml). The mixture was refluxed for 3 h and cooled at room temperature (r.t.). A yellow precipitate was formed. It was filtered off, washed with MeOH and dried by air suction.

Yield: 83%. m.p. (dec.) 262 °C. *Anal.* Found: C, 56.6; H, 3.9; Cu, 27.6; N, 11.9. Calc. for $C_{11}H_9CuN_2$: C, 56.8; H, 3.9; Cu, 27.3; N, 12.0%. Soluble in C_6H_6 and CH_2Cl_2 under nitrogen and slightly soluble in dimethylformamide.

2.1.2. Cu(OAc)$_2$(PhNHpy) (**2**)

A solution of PhNHpy (0.34 g, 2 mmol) in THF (10 ml) was added to $Cu(OAc)_2{\cdot}H_2O$ (0.20 g, 1 mmol) in THF (40 ml). The solution was stirred during 2 h and a precipitate was formed. The blue green precipitate was filtered off, washed with THF and dried in vacuo over $CaCO_3$.

Yield: 80%. m.p. (dec.) 262 °C. *Anal.* Found: C, 51.7; H, 4.5; Cu, 17.9; N, 7.7. Calc. for $C_{15}H_{16}CuN_2O_4$: C, 51.2; H, 4.6; Cu, 18.0; N, 8.0%. Soluble in dimethylformamide, $C_6H_5NO_2$, nitromethane and partially soluble in $CHCl_3$ and MeOH.

2.1.3. M(OAc)$_2$(PhNHpy), M = Co (**3**), Ni (**4**), Zn (**5**)

These complexes were synthesized according to the method described by Brookes and Martin [17] for the reaction of NiOAc with azaindole. A solution of PhNHpy (0.68 g, 4 mmol) in MeOH (10 ml) was added to a solution of $M(OAc)_2{\cdot}nH_2O$ (2 mmol) in MeOH (40 ml). The solution was stirred during 5 min and was concentrated to dryness in the rotavapor. The product was of colour garnet for Co, green for Ni and white for Zn. It was dissolved in $C_6H_5CH_3$ and heated at 100 °C during 45 min (30 min for the Zn compound). The precipitate formed was filtered off, washed with $C_6H_5CH_3$ and dried by air suction.

Compound ***3****:* Dark green powder. Yield: 79%. m.p. (dec.) 215 °C. *Anal.* Found: C, 51.8; H, 4.4; N, 8.5. Calc. for $C_{15}H_{16}CoN_2O_4$: C, 51.9; H, 4.6; N, 8.1%. Soluble in $C_6H_5NO_2$. Soluble in dimethylformamide, MeOH, EtOH and C_3H_6O with colour change from green to garnet. Partially soluble in $CHCl_3$.

Compound ***4****:* Light green powder. Yield: 60%. m.p. (dec.) 209 °C. *Anal.* Found: C, 51.2; H, 4.5; N, 78.3; Ni, 17.3. Calc. for $C_{15}H_{16}N_2NiO_4$: C, 51.9; H, 4.6; N, 8.1; Ni, 16.7%. Soluble in dimethylformamide and $C_6H_5NO_2$ and partially soluble in MeOH, EtOH and $CHCl_3$.

Compound ***5****:* White powder. Yield: 87%. m.p. (dec.) 172 °C. *Anal.* Found: C, 50.5; H, 4.4; N, 7.6; Zn, 18.7. Calc. for $C_{15}H_{16}N_2O_4Zn$: C, 50.9; H, 4.6; N, 7.9; Zn, 18.4%. Soluble in dimethylformamide, $C_6H_5NO_2$, MeOH and $CHCl_3$ (partially).

2.2. Measurements

C, H and N were analysed in a Perkin–Elmer 240C Elemental Analyser. Copper, Ni and Zn were measured with an Atomic Absorption Spectrophotometer Perkin–Elmer 2380, $\lambda = 324.8$, 232.0 and 213.9 nm, respectively. Melting points were measured on an Electrothermal 9300. Conductivity measurements were made using a Metrhom E518 conductometer. IR spectra were recorded on a Nicolet FT-IR 510 spectrometer in the range 4000–400 cm^{-1} using KBr pellets and on a Nicolet 740 in 650–50 cm^{-1} range using nujol on a polyethylene film. Mass spectrum was obtained on an VG Autospec instrument with the liquid secondary ion mass spectra technique (LSISM), using nitrobenzyl alcohol as matrix with the addition of trifluoroacetic acid. Cs^+ cations at 30 Kv were used. Electronic spectra were recorded on a Shimadzu UV-265 FW spectrophotometer.

Magnetic measurements were carried out with a magnetometer Manics DSM-8 or a SQUID MPMSXL of

Quantum Design. Diamagnetic corrections have been applied [2]. The EPR spectra were recorded on a Bruker ESP 300 spectrometer with a Bruker ER 035 M gaussmeter, and HP 5325B frequency counter.

2.3. Crystal structure determination

Prismatic single crystals of $C_{30}H_{32}Cu_2N_4O_8$ (**2**) were grown by layering MeOH solution of copper(II) acetate dihydrate, MeOH and ether solution of 2-anilinopyridine. The X-ray diffraction data were collected, at 296 K, on a Bruker Smart CCD diffractometer, with graphite-monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å), operating in the ω and φ scanning mode. A summary of the crystallographic data, conditions used for the data collection and some refinement data are listed in Table 1.

Data were collected over and hemisphere of the reciprocal space by combination of the three exposure sets. Each exposure of 20 s covered 0.3 in ω. The first 50 frames were collected at the end of the data collection to monitor crystal decay. No appreciable drop in the intensities of standard reflections was observed.

The structure was solved by Patterson (Cu atoms) and conventional Fourier techniques and refined by full-matrix least-squares on F^2 [18]. All atoms were refined anisotropically. Hydrogen atoms were included in calculated positions and refined riding on the respective carbon atoms, with some exceptions. H(2) has been located in a Fourier synthesis, included and riding on a N bonded atom.

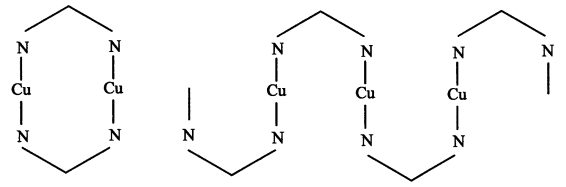
3. Results and discussion



3.1. Characterization

The molar conductivity values for **1** in dimethylformamide and for **2**–**5** in methanol correspond to non-ionic compounds. The most significant band in the IR spectra is that assigned to the stretching ν(N–H) at approximately 3300 cm^{-1}. In compound **1** this band is not observed. This result confirms the presence of the anion $PhNpy^-$. In compounds **2**–**5** this band appears between 3274 and 3312 cm^{-1}, indicating the neutral form of the ligand.

In Table 2 are registered the mass spectra results for the Cu(I) compound. They agree with the dimeric structure of **1**. The most intense signals are those of LH + 1, CuL + 1 and CuLLH + 1, which can be generated in the matrix, from the dimer Cu_2L_2. The spectrum exhibits some signals for a mass higher than that of the dimer, but of very low intensity (< 1%). The corresponding cations can be due to molecular associations.

The electronic spectrum of **1** shows the ligand band at 280 nm and no d → d transition bands. The yellow colour is due to charge transfer. The compound is diamagnetic.

According to the coordination possibilities of the ligand and the ligand–metal ratio, the compound **1** may present a dimeric or a linear chain structure (Scheme 1). In both cases the Cu(I) cation adopts a linear coordination and the ligand, in the anionic form, acts as bridging bidentate through pyridine and aniline nitrogen atoms. The dimeric structure has been found in [$Cu_2(dab)_2$] (dab = diazoaminobenzene) [19], [$Cu_2(form)_2$] (form = *N*,*N*′-di-*p*-tolylformamidinato) [20] and [$Cu_2(hpp)_2$] (hppp = 1,3,4,6,7,8-hexahydro-2H-

Scheme 1. Dimer and linear chain disposition for Cu(PhNpy) (**1**).

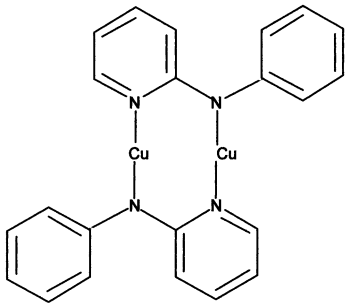


Fig. 1. Proposed structure for Cu(PhNpy) (**1**).

pyrimido[1,2-a]pyrimidinate) [21a]. In all three cases an eight members ring is formed, with a short Cu···Cu distance (2.45–2.50 Å) attributed to a combination of strong Cu–N bonding (1.86–1.94 Å) and very short bite distance for the ligands. In the ligand $PhNpy^-$ the relative position of the coordinating nitrogen atoms is the same that in the reported complexes and a similar dimeric structure is proposed (Fig. 1). The chain structure will be hindered by the steric effects between pyridine and phenyl groups of neighbouring ligands. The same dimeric structure has been proposed for $[Cu_2(MeNpy)_2]$ [21b].

3.2. Crystal structure of $[Cu_2(\mu\text{-}OOCCH_3)_4(PhNHpy)_2]$ (2)

Compound **2** consists of centrosymmetric dinuclear units, similar to other copper acetate derivates, in which four acetate groups are bridging the two copper atoms and a PhNHpy neutral ligand occupies the axial position of each copper atom, coordinated to them through the pyridine nitrogen atom. Fig. 2 shows an ORTEP view of the dimer geometry with 35% probability ellipsoids that includes the atom labelling. The hydrogen atoms have been omitted for clarity, only H(2) involved in an hydrogen bond is included. Selected interatomic distances and angles are listed in Table 3.

Each copper atom has a distorted square-planar pyramidal coordination, with four oxygen atoms in a plane, at an average distance of 1.971(3) Å; the fifth coordination position is occupied by the pyridine nitrogen, N(1), of a ligand molecule at 2.186(3) Å. The copper atom rises from the basal plane to the apical N(1) atom by 0.209(0.001) Å. The Cu···Cu separation is 2.6479(9) Å. The hydrogen atom, H(2), bonded to the anilinic nitrogen, N(2), is involved in an hydrogen bond to the oxygen, O(1), of an acetate group. Only two of the four acetate groups are involved in hydrogen bond.

The results are similar to those found for $[Cu_2(\mu\text{-}OAc)_4(H_2O)_2]$ [2] and other complexes, as the polymeric adduct of copper(II) acetate with 2-amonipyrimidine [22]. Hydrogen bonds of PhNHpy have been before described [12,14].

3.3. Electronic spectra

The dimethylformamide solution and diffuse reflectance spectral data are summarized in Table 4. The $\pi \rightarrow \pi^*$ band on the ligand, at 274 nm, which in the reflectance spectra presents a broad absorption in the 360–190 nm range, is reproduced in all the complexes.

For $[Cu_2(\mu\text{-}OAc)_4(PhNHpy)_2]$ in solution, the three expected bands are observed: (a) 700 nm for the $d \rightarrow d$ transitions; (b) 360 nm, characteristic of copper acetate dimer structure and which is not observed in analogue monomers; and (c) 300 nm for charge transfer [23,24].

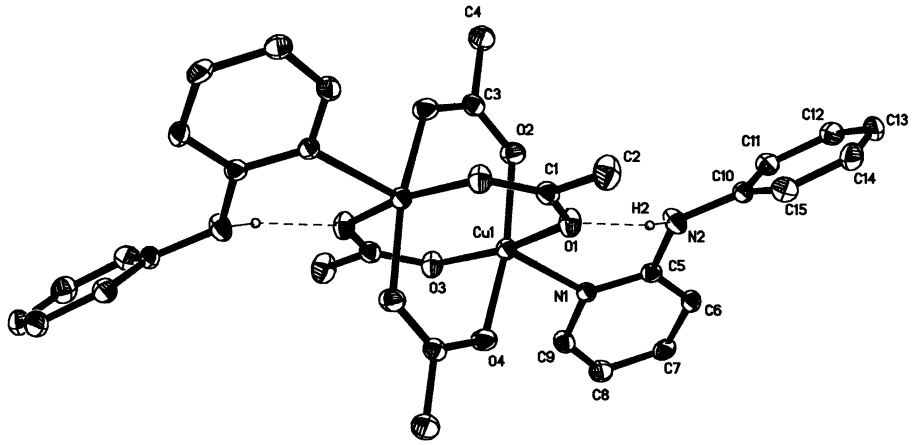

Fig. 2. ORTEP view of $[Cu_2(\mu\text{-}OAc)_4(PhNHpy)_2]$ (**2**).

Symmetry transformations used to generate equivalent atoms: *, $-x+2, -y+2, -z$.

The cobalt compound **3** changes colour from green (solid) to pink (solution). The solution spectrum may be explained in basis to an octahedral coordination. The absorption at 540 nm is assigned to the $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition. Of the three possible transitions for a d^7 high spin state: $^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)$, $^4T_{1g}(F) \rightarrow {}^4A_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$, the first is of low energy and can be not observed and the second is a transition of two electrons (Scheme 2).

The diffuse reflectance spectrum corresponds to a d^7 high spin ion in a square-pyramidal (C_{4v}) environment [25]. The spectrum is similar to those described for the dimer $[Co_2(\mu\text{-}O_2CPh)_4(quin)_2]$ [10]. The transition $^4A_2 \rightarrow {}^4E$ ($^4T_{2g}$) can be of lower energy than the limit of the spectrophotometer (900 nm). The bands at 730, 585 and 440 nm are assigned to the transition to $^4B_1$, ^4E ($^4T_{1g}$) and $^4A_2$ ($^4T_{1g}$), respectively. The shoulders at 530 and 370 nm may be due to transitions to levels of the ^2G and ^2F free ion terms, respectively.

The reflectance spectrum of the nickel compound **4** is similar to those of $[Ni_2(\mu\text{-}O_2CPh)_4(quin)_2]$ [9]. Scheme 3 shows the splitting of the $T(O_h)$ levels for a d^8 ion, in a square-pyramidal symmetry (C_{4v}). The transitions to $^3E[^3T_{2g}(F)]$, $^3B_2[^3T_{2g}(F)]$, and $^3A_2[^3T_{1g}(F)]$ are of low energy. The band at 690 nm is assigned to the $^3B_1 \rightarrow {}^3E[^3T_{1g}(F)]$ transition and the band at 410 nm to the non-resolved transitions to $^3A_2$ and ^3E levels of $^3T_{1g}(P)$. The solution spectrum is similar. The shoulder at 740 nm can be assigned to the spin forbidden $^3A_{2g} \rightarrow {}^1E_g$ transition, which frequently is observed near the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transition when Dq/B is close to one. In this case, the assumption of 687 and 400 nm as the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transitions, respectively, allows to estimate the values $Dq = 830\ cm^{-1}$ and $B = 850\ cm^{-1}$ ($Dq/B = 0.98$). The absorption at 300 nm is assigned to charge transfer between metal and acetates.

For the zinc compound **5** only the ligand band and the charge transfer between metal and acetates are observed.

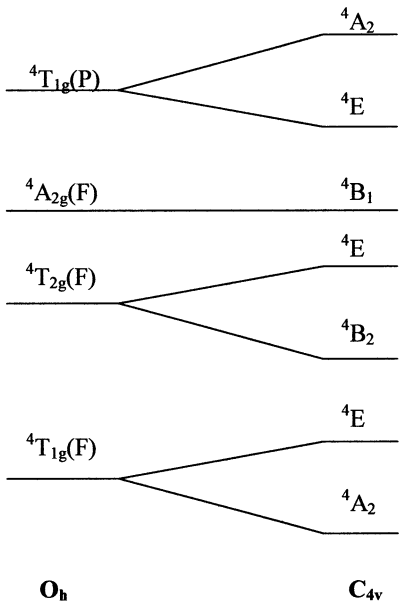
3.4. Magnetic results

Compounds of Cu(I), (**1**), and Zn(II), (**5**), are diamagnetic. Other three compounds **2**, **3** and **4** are antiferromagnetic.

The plots of $\chi_M T$ versus temperature (T) for compound **2** are shown in Fig. 3. The data, between 14 and 300 K, were fitted to the Bleaney–Bowers equation for a dimer with $S_1 = S_2 = 1/2$, modified by the inclusion of the fraction of monomeric impurity [26]:

$$\chi_M = [Ce^x(1-\rho)/(1+3e^x)] + C\rho/4 + N\alpha$$

where $C = Ng^2\beta^2/kT$, $x = 2J/kT$, ρ is the fraction of monomeric impurity and $N\alpha$ is the temperature independent paramagnetism (TIP). The results of the best fit for $g = 2.16$ (EPR result) and $N\alpha = 60 \times 10^{-6}\ cm^3\ mol^{-1}$ are collected in Table 5. The $2J$ value, indicating a significant antiferromagnetic intradimer interaction, is similar to the values found in other adducts of copper acetate [27,28].



For Co(II) (**3**) and Ni(II) (**4**) complexes, a strong antiferromagnetic effect is observed. The magnetic moment decreases with decreasing temperature, from 3.03 (287 K) to 0.75 MB (4 K) for **3** and from 2.16 (293 K) to 1.24 MB (14 K) for **4**. This effect is still stronger than the found in other dimeric carboxylate complexes

Table 4
Electronic spectral data

Compound	λ_{max} (nm), in dimethylformamide	ε_{max} (l mol^{-1} cm^{-1})	λ (nm), diffuse reflectance
PhNHpy	274	25 900	360–190
2	700	193	725

sh, shoulder.

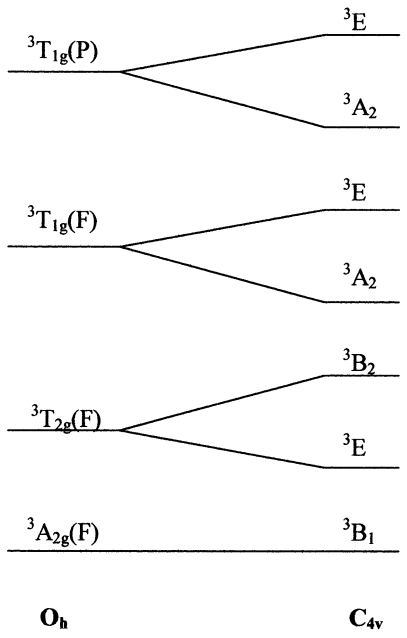
of Co(II) and Ni(II) [9,10,29]. These results are interpreted in basis to a dimeric structure, with an intramolecular interaction between the cations through the bridging acetate groups. The plots of $\chi_M T$ versus T (Fig. 4) have been fitted using the application of the Van Vleck equation to each case [30]. These are, with

Scheme 2. Level splitting for d^7, high spin configuration, in C_{4v} symmetry.

$C = Ng^2\beta^2/kT$, $x = 2J/kT$ and $\rho =$ fraction of monomeric impurity, for cobalt(II) dimer ($S_1 = S_2 = 3/2$):

$$\chi_M = C[e^x + 5e^{3x} + 14e^{6x}](1-\rho)/[1 + 3e^x + 5e^{3x} + 7e^{6x}] + 5C\rho/4 + N\alpha$$

for nickel(II) dimer ($S_1 = S_2 = 1$):



$$\chi_M = C[e^x + 5e^{3x}](1-\rho)/[1 + 3e^x + 5e^{3x}] + 2C\rho/3 + N\alpha$$

The results of these fittings in the range 50–300 K, with $N\alpha = 60 \times 10^{-6}$ and 100×10^{-6}, for **3** and **4**, respectively, are summarized in Table 5.

The magnetic behaviour below 50 K may be complicated by zero field splitting effects, especially in nickel compound, and other possible intermolecular interactions. The lack of knowledge of the crystal structure prevents us to make a more accurate interpretation. The conjunction of electronic spectra and magnetic results lets suppose a dimeric structure for the compounds **3** and **4**, $[M_2(\mu\text{-}OAc)_4(PhNHpy)_2]$, similar to one of Cu(II) compound.

3.5. EPR spectra

The powder EPR spectra of **2** in Q band, at room temperature, shows the typical signals of the triplet state ($S = 1$) for $D \neq 0$ and $E \approx 0$ (Fig. 5). The spectra were interpreted according to the Wasserman, Snyder and Yager equations [31,32], based on the Hamiltonian

Scheme 3. Level splitting for d^8 configuration in C_{4v} symmetry.

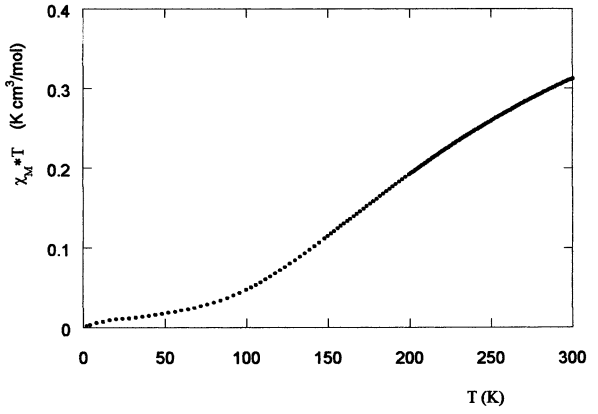


Fig. 3. Plot of χT versus T for **2**.

Table 5
Magnetic results

Compound	g	$2J$ (cm^{-1})	ρ	R^a
2	2.12	−286 [b]	0.0083	7.85×10^{-5}
3	4.27	−324 [c]	0.020	2.46×10^{-4}
4	2.78	−382 [d]	0.119	4.45×10^{-4}

[a] $R=\Sigma(\chi T_{iexp}-\chi T_{ical})^2/\Sigma(\chi T_{iexp})^2$.
[b] Calculated from $\chi_M=[Ce^x(1-\rho)/(1+3e^x)]+C\rho/4+N\alpha$.
[c] Calculated from $\chi_M=C[e^x+5e^{3x}+14e^{6x}]\ (1-\rho)/[1+3e^x+5e^{3x}+7e^{6x}]+5C\rho/4+N\alpha$.
[d] Calculated from $\chi_M=C[e^x+5e^{3x}]\ (1-\rho)/[1+3e^x+5e^{3x}]+2C\rho/3+N\alpha$.

$\mathcal{H}=gHS\beta+D[S_z^2-2/3]+E[S_x^2-S_y^2]$, with $D\neq0$ y $E=0$. For $\Delta M=\pm1$:

$$H_{\parallel}=(g_e/g_{\parallel})(H_o-D')$$

$$H_{\perp1}=(g_e/g_{\perp})[H_o(H_o-D')]^{1/2}$$

$$H_{\perp2}=(g_e/g_{\perp})[H_o(H_o+D')]^{1/2}$$

For $\Delta M=\pm2$:

$$H_{min}=(g_e/g_{min})[(H_o^2/4)-(D'^2/3)]^{1/2}$$
$$H_{dq}=(g_e/g_{av})[H_o^2-D'^2/3]^{1/2}$$

$$H_o=h\nu/g_e\beta;\ D'=D/g_e\beta$$

From the experimental values: $H_{min}=4896$; $H_{\parallel}=7262$; $H_{\perp1}=9755$; $H_{\perp2}=13\,317$ and $H_{dq}=11\,035$ G, the following parameters have been calculated: $g_{\parallel}=2.33$; $g_{\perp}=2.07$; $g_{av}=2.16$ and $D=0.33$ cm^{-1}. These results agree with the results found for analogue compounds [23,28].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 167019 for compound **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road,

Foreword

Polyhedron Symposia-in-Print, number 24
Subvalent and multiply bonded compounds of the p-block elements

Two of the more interesting areas of development in the chemistry of the p-block elements over recent years have been concerned with their subvalent and multiply bonded complexes. In particular, much emphasis has been given to the heavier elements due to the existence of the so-called 'classical double bond rule' which states that compounds featuring (p–p)π-bonds between the heavier main-group elements would not be stable, in contrast to the numerous examples that are known for the lighter elements, carbon, nitrogen and oxygen. Synthetic chemists have, however, faced the challenge presented by the 'classical double bond rule' and have been successful in isolating many novel species that exhibit multiple bonding between the heavier elements. Likewise, theoretical chemists have addressed the nature of the bonding in such complexes. The latter is an area that is not without controversy, clearly emphasizing the current interest in the topic. Subvalent complexes have a close relationship to multiply bonded derivatives in that they are frequently the synthetic precursors to multiply bonded complexes. The present Symposium-in-Print serves to provide a forum for discussing various aspects of the chemistry of these interesting subvalent and multiply bonded complexes and related derivatives metal–metal bonds.

Multiple bonds to silicon: 20 years later

Robert West *

Organosilicon Research Center, Department of Chemistry, University of Wisconsin, Madison, WI 53706 USA

Received 15 May 2001; accepted 7 December 2001

Abstract

The discovery of stable compounds containing Si=C and Si=Si bonds in 1981 led to the overturning of the 'double bond rule', and paved the way for the recent explosive growth in multiple bond chemistry of the heavier elements. This paper traces the events leading up to the 1981 discoveries, summarizes some of the developments in multiply-bonded silicon chemistry since that date, and outlines challenges for further research in this area. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Disilenes; Silenes; Silanones; Matrix isolation; Photolysis

1. Introduction

Silicon is the immediate congener to carbon, which forms multiple bonds in profusion. The search for multiply-bonded silicon therefore attracted the attention of chemists throughout the twentieth century. The pioneer organosilicon chemist, F.S. Kipping of the University of Nottingham, carried out extensive attempts to make compounds with Si=C, Si=O and Si=Si bonds. At one point, he believed he had synthesized a disilene, Ph(Et)Si=Si(Et)Ph [1]. However, later physical and chemical studies showed that not only this, but all of the compounds obtained in his studies were singly-bonded oligomers or polymers and not the sought for multiply-bonded compounds. Kipping eventually concluded that multiple bonds to silicon were not possible [2,3].

Similar negative results were obtained by other workers who attempted to make multiply-bonded compounds of elements outside the first row of the periodic table, including phosphorus, arsenic, antimony, and germanium [4]. Early theoretical papers by Pitzer [5] and Mulliken [6] rationalized these results, showing that π bonds between heavier elements should be weak. The combined experimental and theoretical results led to the consensus embodied in the 'double bond rule', which stated that elements with a principal quantum number greater than 2 do not form multiple bonds with themselves or with other elements [7]. This was the view expressed in most chemistry textbooks until the 1980s.

A major breakthrough came in 1981. At the 15th Organosilicon Symposium in Durham, NC, companion papers announcing stable compounds containing Si=C [8] and Si=Si [9] bonds were presented; and shortly thereafter Yoshifuji and coworkers reported the synthesis of a stable diphosphene, Mes*P=PMes* [10]. These findings led to decisive overturning of the double bond rule. The resulting paradigm shift paved the way for the remarkable flowering of multiple bond chemistry of the heavier elements which continues to the present day.

The first sections of this paper describe retrospectively the events leading up to the syntheses of stable silenes (Si=C) and disilenes (Si=Si). In later sections, some of the developments since 1981 in the multiple bond chemistry of silicon are recounted, and challenges for future researchers are presented.

Many useful reviews on multiply-bonded silicon compounds are available [11,12]. The early history is covered in some detail in a 1979 review by Gusel'nikov and Nametkin [12a].

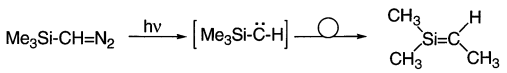
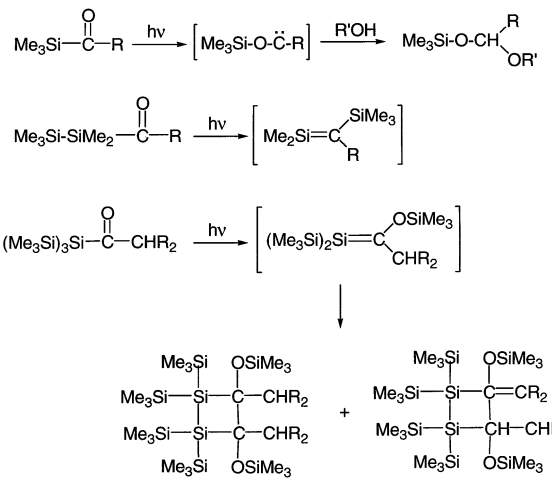
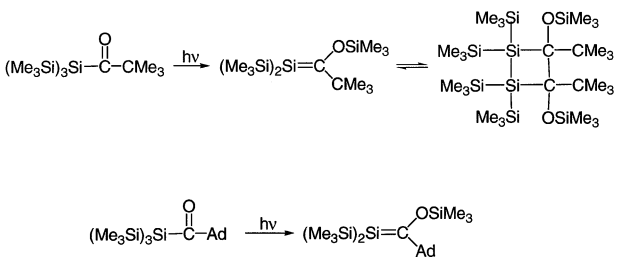
2. The discovery of a stable silene



The synthesis of molecules with novel types of chemical bonding often follows a common progression. First, evidence is presented for the species as a transient intermediate in chemical reactions. Next, it may be isolated at very low temperatures, in a matrix, for example. Finally, with appropriate steric or electronic stabilization, a molecule stable at room temperature may be synthesized. Just such a sequence was followed in the discovery of stable silenes.



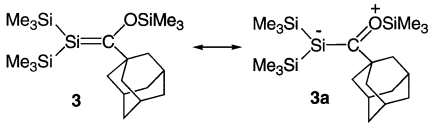
Scheme 1.



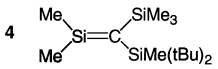
Scheme 2.

Scheme 3.

Scheme 4.



Scheme 5.

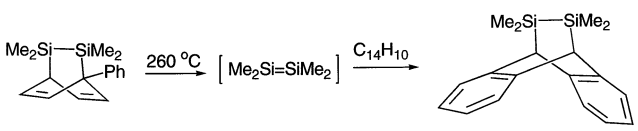


The first convincing evidence for silenes as reaction intermediates came in 1966 from studies of the gas-phase thermolysis of 1,1-dimethyl-1-silacyclobutane (**1**) by Gusel'nikov and coworkers [13]. At 700–1000 K and low pressures, **1** fragments cleanly. The products are ethane and 1,1,3,3-tetramethyl-1,3-disilacyclobutane (**2**), the latter arising from the dimerization of the intermediate silene (Scheme 1). The kinetics of the reaction are strikingly similar to those for the gas-phase thermolysis of dialkylcyclobutanes into alkenes [14]. Furthermore the intermediate silene could be intercepted by various trapping agents. For instance, as shown in Scheme 1, addition of alcohols to the pyrolysis stream produced the corresponding alkoxysilanes. Later, Boudjouk and Sommer showed that photolytic fragmentation of cyclobutanes could also produce transient silenes (Scheme 2) [15].

The next development was the isolation of unstable silylenes in an argon matrix, at 10–20 K. This was accomplished almost simultaneously by three different groups. Mal'tsev and coworkers employed the thermolysis of **1**, trapping the products by condensation in argon [16]. The two other groups both used the photolysis of trimethylsilyldiazomethane to generate a silyl carbene, which rearranged to the silene (Scheme 3) [17,18]. These experiments allowed the infrared spectrum of silenes to be determined, and a band near 1000 cm^{-1} was identified as the C=Si stretching mode.

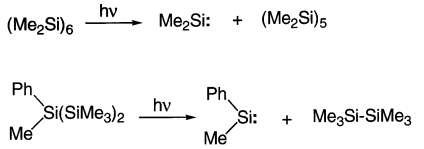
We proceed now to the final step: the actual isolation of a stable silene. During the 1960s and 1970s, photolysis of acylsilanes (organosilyl ketones) was under investigation in Adrian Brook's laboratories at the University of Toronto. The usual reaction involved rapid reversible rearrangement of silicon from carbon to oxygen, producing a siloxycarbene, which could be intercepted by various trapping agents (Scheme 4) [19]. The question then arose: What would happen in the case of an acyldisilane? A 1,2 rearrangement would produce a disiloxycarbene, but a 1,3 rearrangement would lead to a silene, as shown in Scheme 4.

Experiments showed that the 1,3 rearrangement is favored. The next step was to carry out the photolysis with acylpolysilanes, $(Me_3Si)_3Si–CO–R$. When R is small, methyl, phenyl etc., the product observed is a linear or cyclic, head-to-head dimer of the silene [20]. When R is *t*-butyl, photolysis produced an equilibrium mixture of silene and cyclic dimer [21]. Finally, with R = 1-adamantyl, the stable, crystalline silene **3** is produced [22] (Scheme 5).



The X-ray crystal structure of **3** gave a value of 176.4 pm for the Si=C bond length, somewhat longer than the theoretically predicted value of ~170 pm. The bond lengthening arises from ylidic electron donation from the siloxy oxygen into the Si–C π bond, as illustrated by the resonance form **3a**. Subsequently the non-ylidic silene **4** was synthesized by Wiberg and his group, by a route involving lithium fluoride elimination, and shown to have a normal Si=C bond length of 170.2 ppm [23].

3. A stable disilene



The pathway which actually led to the discovery of stable disilenes involved only the first antecedent step, the identification of disilenes as transient intermediates. A classic, convincing study was carried out by Peddle and Roark in 1972 [24]. Pyrolysis of a 7,8-disilabicycloocta-2,5-diene led to retrodiene fragmentation to give tetramethyldisilene, which could be trapped by naphthalene, anthracene or 1,4-diphenyl-1,3-butadiene. The reaction with anthracene is illustrated in Scheme 6.

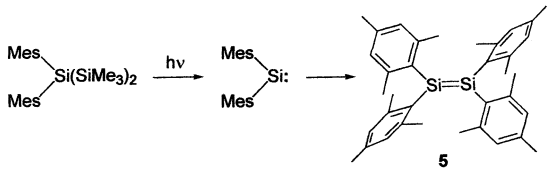
Investigations in this area by our group at the University of Wisconsin began in a collaboration with Josef Michl, then at the University of Utah [25]. We thought of combining our experience with organosilicon compounds with his expertise in matrix isolation of unstable species, to obtain matrix-isolated disilenes. A graduate student, Tim Drahnak, traveled from Madison to Utah with the plan to solve this problem by isolating tetramethyldisilene, produced through metal-induced, flow dehalogenation of 1,2-dihalodisilanes, $Me_2SiX–SiXMe_2$. However, attempts to do this were dismally unsuccessful. If the desired disilene ever formed, it did not survive long enough to be captured on the cold surface.

Since this investigation gave no useful results, we turned our attention to diorganosilylenes, R_2Si:. Previously, Kumada and Ishikawa had shown that transient

Scheme 6.

Scheme 7.

silylenes were formed in the photolysis of cyclic or linear polysilanes, as shown in Scheme 7 [26], although they had not been detected. Drahnak carried out the photolysis of $(Me_2Si)_6$ in argon at ~10 K, which was immediately successful and provided the first direct observation of the important intermediate, Me_2Si:. This allowed studies of its electronic and IR spectra to be carried out [27].

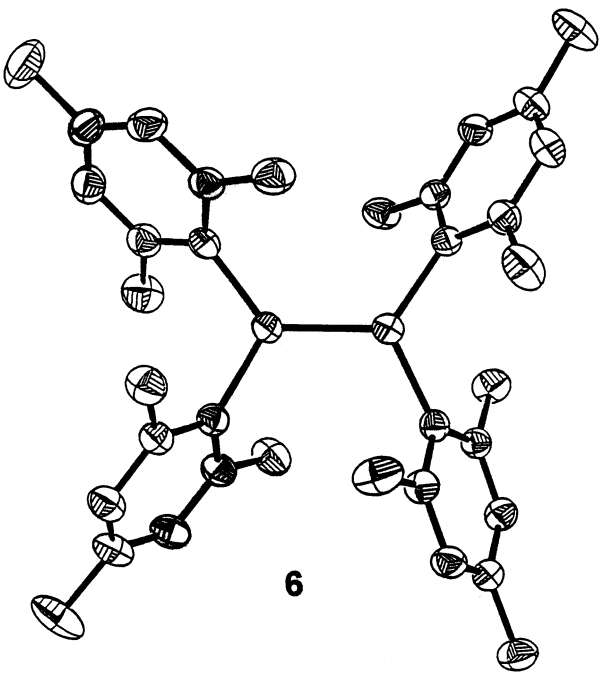


Eventually at Wisconsin silylenes were shown to be stable not only in inert gas matrices, but also in hydrocarbon glass (3-methylpentane) at liquid nitrogen temperature. This made investigations of silylenes much simpler, since a liquid helium cryostat was not required. We then began a study of substituent effects on the electronic spectra of silylenes, generated either from cyclic polysilanes or from aryltrisilanes, $Ar(R)Si(SiMe_3)_2$ (in the trisilanes, an aryl group proved necessary for absorption of UV light). Phenyl groups gave some side reactions, but with mesityl as the aryl group the results were clean.

Silylenes have strong visible absorption bands, resulting from an s–p electronic transition. Some of the silylenes made during these experiments and their absorption wavelengths are listed in Table 1 [28]. The electronic spectra are strongly influenced by the substituents. Either increasing the size of the R groups or substituting an aryl group leads to bathochromic shifts. These effects combine in the hindered species dimesitylsilylene, which is blue with absorption at 610 nm.

In some cases, as the 3-methylpentane matrix was melted, the color of the silylene gave way to a yellow solution, which persisted through part of the warm-up process. This, we now know, was due to disilenes, which had been formed by dimerization of the silylenes.

Table 1
Electronic absorption of silylenes in 3-methylpentane matrix



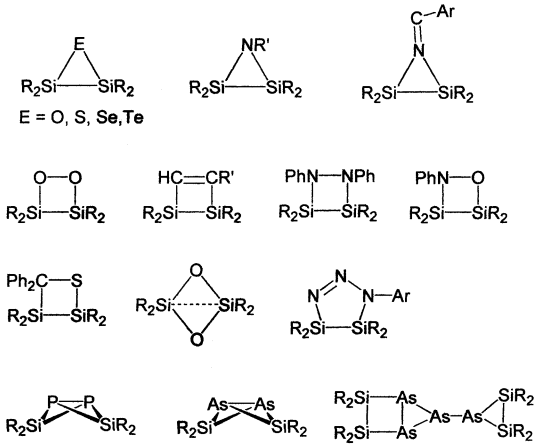
Silylene	λ_{max} (nm)	Color
Me_2Si	453	yellow
Et_2Si	460	yellow
$t\text{-}Bu_2Si$	480	orange
Ph(Me)Si	490	red
Ph_2Si	495	red
Mes(Me)Si	496	red
Mes(Ph)Si	530	purple
Mes_2Si	577	blue

Scheme 8.

With dimesitylsilylene, the yellow color was still present even after the solution was warmed to room temperature. Mark Fink carried out the crucial experiment in 1981, by evaporating the solvent, to yield bright yellow crystals of tetramesityldisilene (**5**) (Scheme 8) [29].

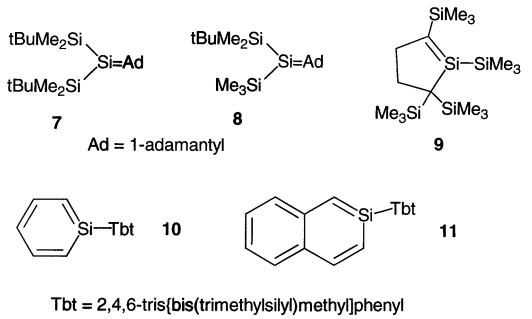
Complete characterization of **5**, including an X-ray crystal structure, was soon obtained. This prototypical compound, the best studied of disilenes, exhibits surprisingly complex behavior in the solid state. No less than four different conformational isomers have been isolated [30]. The structure of one form is shown as **6**.

4. Multiple bonds to silicon: 1981–2001



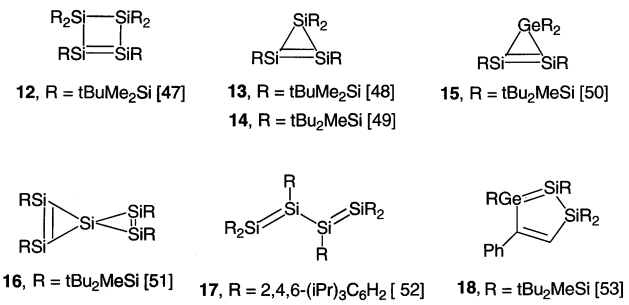
The 1981 discoveries opened the way for the synthesis of many new classes of multiply-bonded compounds of the heavier elements. The key proved to be steric protection of the multiple bond to provide kinetic stability, as employed in all three of the 1981 syntheses. The types of multiply-bonded silicon compounds isolated as stable compounds to date are listed in Table 2. In addition, many other kinds of stable multiply-bonded compounds have now been made, involving the elements Ge, Sn, Pb, As, Sb, Bi, B, Al, and Ga.

The chemistry of disilenes has evolved remarkably over the past 20 years. Only one tetraalkyldisilene, $[(Me_3Si)_2CH]_2Si{=}Si[CH(SiMe_3)_2]$, has been reported [41], but many tetraaryl and alkyl–aryl disilenes have been made, and tetra(organosilyl)disilenes have been synthesized and carefully studied by Kira and coworkers [42]. A 1996 review lists 38 different stable disilenes, including Z and E isomers [11], and perhaps a dozen more have been reported since. Reactions of stable disilenes, and of silenes, have led to the synthesis of a host of new structural types not available by other means. Some examples from disilene reactions are shown in Scheme 9 [11].



Significant developments have also taken place in the chemistry of silenes. Many reactions are now known for **3**, from studies in Brook's group [12e]. Important recent advances in Si=C double bond chemistry include the new synthesis of stable silenes **7** and **8** by Apeloig and coworkers via a sila-Peterson type reaction [43], and the synthesis of cyclic silene **9**, obtained by rearrangement of a silylene [44]. In addition, the first stable silaaromatic compounds, **10** and **11**, have been reported by Okazaki [45,46].

Table 2
The synthesis of stable multiply-bonded silicon compounds



Bond	Year	Reference	Bond	Year	Reference
Si=C	1981	[22]	$[P\cdots Si\cdots P]^-$	1989	[35]
Si=Si	1981	[29]	$[N\cdots Si\cdots N]^-$	1990	[36]
Si=P	1984	[31]	Si=C=C	1993	[37]

Si=As	1992	[33]	Si=S	1994	[39]
Si=Ge	1992	[34]	Si=Se	1999	[40]
			Si=Te	1999	[40]

Scheme 9.

Several stable compounds containing Si=Si double bonds and having new and beautiful structures have recently been synthesized [47–51,53]. Examples are shown in structures **12**–**18**.

5. Future possibilities

In spite of the great progress in the chemistry of multiply-bonded silicon, a number of significant synthetic challenges remain. Silanones, $R_2Si{=}O$, are unknown as isolable compounds, although they have been identified in matrix and there is plenty of evidence that they are important reaction intermediates. The problem to be overcome is the very great energy of the Si–O single bond, which gives silanones a strong tendency to oligomerize to siloxanes [12i]. Yet it seems likely that this barrier will be overcome, allowing stable silanones to be isolated.

No stable triply-bonded silicon compound yet exists, although there is evidence for $CH_3Si{\equiv}SiCH_3$ [54] and PhSi≡N [55] as reaction intermediates, both HSi≡N [56] and PhSi≡N [57] have been trapped in low-temperature matrices, and HC≡SiF and HC≡SiCl have recently been identified in the gas phase by neutralization–reionization mass spectrometry [58]. Calculations suggest that highly hindered aryl ligands should stabilize the Si–Si triple bond against dimerization [59], but an attempt to synthesize a compound of this type led to insertion of the silicon atoms into C–C bonds [60]. In the future we can expect to see additional attempts, which may eventually be successful, to make stable compounds with Si≡Si, Si≡C, Si≡N and Si≡P triple bonds.

Although the synthesis of the first conjugated tetrasilabutadiene by Weidenbruch and coworkers represents a significant advance [52], a major challenge is to extend this π delocalization by synthesizing conjugated polymers, **19** and **20**, which may be expected to have highly unusual electronic properties.

Now that many reactions of silenes and disilenes are known, studies of reaction mechanisms are needed. Early results indicate that the reaction mechanisms for disilenes may be quite different from those for alkenes, and may involve unique pathways. Examples include the reaction of disilenes with dioxygen [61], and the addition of alcohols [62] and haloalkanes [63] to disilenes, all of which involve novel, unexpected reaction routes. Additional careful studies of silene and disilene reaction mechanisms will undoubtedly appear.

Abstract

Two aspects of Group 13 metal chemistry are surveyed in the light of recent matrix-isolation and quantum chemical studies. The first concerns derivatives of the metals Al, Ga and In (M) in formal oxidation states less than +3: these include the M^0 derivatives ML_n, where L = CO, N_2, NH_3 or PH_3, and $n = 1$ or 2; the M^I derivatives MX, where X = H, CH_3 or NH_2, and M_2H_2; and the M^{II} derivatives HMX, where X = H, CH_3, NH_2 or PH_2. The second concerns derivatives in which there is the opportunity for the metal to engage in multiple bonding, as exemplified by the cases of M_2H_2 and H_2MNH_2. Experimental studies have involved thermally or photolytically excited reactions between M atoms, or sometimes M_2 molecules, and an appropriate substrate, e.g. H_2, CO, N_2, CH_4, NH_3 or PH_3. The reagents have been trapped in solid noble gas matrices, the IR spectra of which have been exploited to deduce the course of events and identities of the products. Confirmation of the identity and geometry of each of the products have been achieved primarily on the basis (i) of isotopic effects and (ii) of comparison of the measured spectrum with that anticipated by quantum chemical calculations. This liaison of experiments with theory has led to the characterisation not only of numerous simple molecules that are short-lived under normal conditions, but also of some of the reaction channels open to them, typically through photolytic activation. The structure, energies and reactivities of the compounds are reviewed. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Low valent; Multiply bonded derivatives; Group 13 metals; Matrix isolation

1. Introduction

For anyone filled, like the elephant's child, with 'satiable curiosity' [1], aluminium, gallium and indium have given good hunting in the past decade [2]. Surprising discoveries have emerged mainly through the search for new materials, or new ways of making known materials, with specific electrical, optical, thermal or chemical properties—ranging from films or nanocrystals through microporous or layered solids to discrete complexes having applications in nuclear medicine. At the same time, curiosity-led research has resulted in the synthesis and characterisation of two types of compound, which had hitherto attracted rather little attention. One type features the metal in a formal oxidation state less than +3, e.g. $[Et_3N{\cdot}AlBr]_4$, $Ga_5Cl_7(OEt_2)_5$, and $[GaSi(SiMe_3)_3]_4$ [2–5], the other invites the engagement of the metal in multiple bonding, e.g. $Na_2[Ar^*GaGaAr^*]$ [$Ar^* = 2,6\text{-}(2,4,6\text{-}Pr^i_3C_6H_2)_2C_6H_3$] and Me_2AlNH_2 [2,6]. This is molecular, rather than macromolecular territory, although compounds such as $[Ga_{84}\{N(SiMe_3)_2\}_{20}][Li(thf)_4]_2[Li_2Br(thf)_6]_2{\cdot}2$ toluene [7]

and $[Al_{77}\{N(SiMe_3)_2\}_{20}][Li_2I(OEt_2)_5]_2 \cdot 2$ toluene [8] appear to prefigure the transition from molecular cluster to bulk metal. These are but two of some of the remarkable structures that have come to light, stimulating a lively debate about questions of bonding [2,6], while at the same time holding out tantalising prospects of new properties. It is with low-valent and would be multiply bonded hydride derivatives of the Group 13 metals that this article is concerned.

Simple subvalent molecules of the types MH and MH_2, where M = Al, Ga or In, are highly endoergic with respect to both decomposition to the elements in their standard states and to disproportionation into M atoms and MH_3 molecules. A degree of stabilisation can be achieved through aggregation to give oligomers, viz. $[MH]_n$ and $[MH_2]_n$, respectively, but not so as to produce a compound that is lastingly stable under normal conditions. The molecules AlH, GaH, InH and AlH_2 have each been sighted and characterised in some detail by high-resolution spectroscopic studies of discharges including H_2 and the appropriate metal atoms [3,9]. The lifetimes of such molecules can be extended up to a point by operating at low pressures and low temperatures, achieved for example by seeding a supersonic jet [10], but more or less indefinitely by matrix isolation, i.e. by entrapment at high dilution in a solid inert matrix at low temperatures [10,11]. Otherwise stabilisation of subvalent derivatives of the Group 13 metals other than thallium requires the replacement of hydrogen by a much bulkier substituent, e.g. C_5Me_5, $CH(SiMe_3)_2$, $Si(SiMe_3)_3$, or 2,6-(2,4,6-$Pr^i_3C_6H_2)_2C_6H_3$ [4,5,12]. Even then, aggregation takes place under normal conditions to give products with cores composed of two or more metal atoms. As a result M^{II} derivatives are isolated, for example, not as paramagnetic monomers but as diamagnetic M–M bonded dimers, e.g. $[(Me_3Si)_2(H)C]_2MM[C(H)(SiMe_3)_2]_2$ (M = Al, Ga or In) [4]. Electron delocalisation in some of these aggregates may then admit the possibility of partial oxidation or reduction so that the metal atoms take on other, fractional oxidation states, as in $[Al_6Bu^t_6]^{\bullet -}$ [5], or a mixture of different oxidation states, as in $Ga_5Cl_7(OEt)_5$ or the Al_{77} [8] and Ga_{84} [7] cluster compounds. While ligand bulk is undoubtedly the dominant influence, bonding electronic interactions between metal and ligand cannot be discounted, and stabilisation may also depend to a significant degree on coordination by a neutral base and, where the metal fragment is charged, on coulombic factors as well.

In the same vein, simple hydride species such as $[HMMH]^{2-}$, $[H_2MMH_2]^{2-}$, and H_2MNH_2, which afford the Group 13 metal atom M the opportunity for multiple bonding, may be fertile ground for the theoretician [2,6,13,14], but quite barren ground for the experimentalist working under normal conditions. Once again, aggregation or decomposition gains the upper hand to deny a sight of molecular units simple enough to be intelligible to both experiment and theory. Instead, lasting stability of what may be multiply bonded MM or MN units requires the mediation of highly encumbered ligands like 2,4,6-$Bu^t_3C_6H_2$ and 2,6-(2,4,6-$Pr^i_3C_6H_2)_2C_6H_3$ [2,6,12], but at the expense of theoretical tractability.

Here, we describe the results of studies carried out for the most part in our separate laboratories and in which attempts have been made to reconcile theory with experiment by investigating simple molecules of the type ML (L = CO, N_2, NH_3 or PH_3), MH, M_2H_2, HMX (X = H, CH_3, NH_2 or PH_2), and H_2MNH_2, where M = Al, Ga or In. All of these are amenable to detailed quantum chemical calculations at various levels of theory; they have been made experimental reality by carrying out thermally or photolytically induced reactions of the metal atoms, or sometimes their dimers M_2, with the appropriate reagent molecules, and trapping the products at high dilution in a solid noble gas matrix at temperatures of 4–20 K. Here the new molecules have been detected and interrogated by their IR spectra, their identities, geometries and vibrational properties being underwritten by the effects of isotopic change, and also by comparison with the vibrational properties forecast by theory. The resulting synergy between experiment and theory helps us to establish with confidence some physical and chemical characteristics of these low valent and/or would-be multiply bonded molecules. While the molecules remain high-energy species with no more than a fleeting existence outside a matrix at normal temperatures, they still hold important lessons for Group 13 metal chemistry at large.

2. Matrix isolation as a vehicle for chemical exploration

The general principles of matrix isolation are now familiar enough [10,11]. The trapped molecule is at once isolated and effectively immobilised in a rigid, inert matrix such as solid argon which is transparent to broad regions of electromagnetic radiation. Spectroscopic measurements can then be made at leisure and therefore in detail, and several different methods can be applied to the interrogation of a particular sample. In practice, IR spectroscopy has been the principal agent of detection, identification and characterisation. Critical features of such a matrix experiment are as follows [15].

- The structure of a molecule is unaffected by trapping, provided that there is no direct reaction with the solid matrix.
- The matrix environment provides for efficient quenching of any surplus energy the trapped molecule may possess as a result of the means of its

formation; excited electronic states do not enjoy lifetimes significantly different from those in the gas phase.

- Dynamic processes leading to the interconversion of different isomers or conformers are halted; at a matrix temperature of 10 K ($kT = 0.08$ kJ mol^{-1}) a barrier of only 5 kJ mol^{-1} cannot be overcome by thermal means.
- The rigidity of the matrix produces a marked *cage effect*. Only very small molecules or atoms are able to diffuse, and only the very smallest molecules, e.g. NH_3 or H_2O, to rotate in the matrix. As a result of this cage effect, photo-induced unimolecular reactions are arrested immediately after decomposition or rearrangement of the molecular precursor, and may even be reversed. The inability of the products to migrate from the matrix site at which they are formed contrasts with the freedom they enjoy in the fluid phases where they are often lost to facile reactions with other molecules. Just as atom–molecule or molecule–molecule pairs are entrained as the products of photodissociation, so similar pairs play an essential role as *precursors* to *bimolecular* changes, whether thermally or photolytically activated.
- The quenching of rotational motion combines with the relatively isotropic, weakly interacting matrix environment and low temperatures to produce sharp IR absorptions the positions of which can meaningfully be measured to ± 0.1 cm^{-1} in many cases. The linelike character of the vibrational transitions has a crucial part to play when it comes to investigating subtle isotopic effects.

Identification of an unfamiliar captive molecule on the basis of its IR spectrum is then typically achieved in the following steps.

- First, the number of distinct species present in the matrix has to be established on the evidence of a detailed investigation of how the spectrum responds to changes in the experimental conditions, e.g. concentrations, annealing, photolysis time and wavelength, etc.
- It is then necessary to assess the number, wavenmubers and relative intensities of all the absorptions associated with a given molecule before seeking to formulate its likely identity by drawing on the testimony of what may be distinctive features signalling the presence of specific groups, analogies with known compounds, or the vibrational selection rules expected to operate.
- Annealing or photolysis of the matrix may be instructive, particularly if it results in the conversion of the unknown molecule into a clearly identifiable product.
- Most revealing of all in purely experimental terms is likely to be the response of the spectrum to changes in the isotopic composition of the molecule. Hence it is possible, in principle, to establish the stoicheiometry, to test whether particular atoms are equivalent or inequivalent, and to assess the most plausible geometry for the molecule.
- In parallel with the experiments, quantum chemical calculations are carried out to determine possible equilibrium structures corresponding to a particular atomic composition, and to simulate their IR spectra. The final decision on the identity and geometry of the trapped molecule then rests on how closely theory matches experiment. There are few reporters more sensitive to the precise geometry and bonding of a molecule than its IR spectrum, and even small changes of bond distance or interbond angle are likely to translate into substantial changes of vibrational wavenumber and/or IR intensity. Accordingly, the ability to reproduce by calculation the wavenumber and intensity patterns of the observed spectrum constitutes an exacting test of molecular identity. Provided only that there are sufficient experimental data, the conclusions are quite compelling.

Fig. 1 illustrates schematically the matrix apparatus used in the experiments carried out at Oxford [16]. The metal is evaporated from a resistively heated Knudsen cell and the vapour codeposited with an excess of the matrix gas (usually argon) doped with the reagent on a CsI window cooled to approximately 12 K. The IR spectrum of the resulting deposit is then measured in transmission. The assemblies at both Karlsruhe [17] and Paris [18] differ only in matters of detail, for example, in that the matrix is condensed on a highly polished copper block, so that the IR spectrum can be measured in reflectance, thereby giving some advantage in sensitivity. In all cases the outer shroud of the apparatus carries a quartz window that enables the matrix deposit to be irradiated with light spanning an appropriate range of wavelengths. Only simple addition reactions of the precursor species opposed by little or no activation barrier are likely to occur spontaneously given the low thermal energy available under the conditions of the experiment. By contrast, a much higher price in activation will usually have to be paid for changes that involve bond dissociation, insertion into a bond, or isomerisation. Photons are then the only currency available to matrix-isolated species.

Quantum chemical calculations have been performed with the aid of the GAUSSIAN-98 [19] or Amsterdam Density Functional (ADF) [20] program systems. In most cases, these have involved the use of density functional theory (DFT) methods, but the scope of some calculations has been extended by drawing also on ab initio (MP2) methods. The B3LYP hybrid methodology has found the most general application, this having been shown previously to give satisfactory results for small aluminium and gallium compounds [21]. A 6-311g(d) basis set was chosen for Al and Ga, a

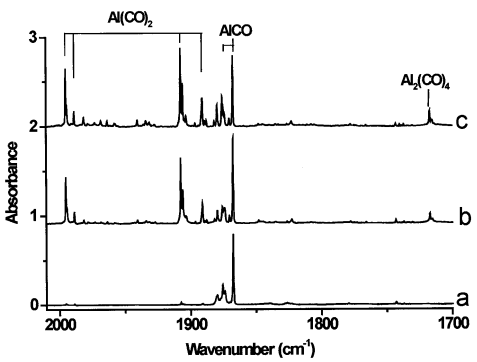
LANL2DZ basis set with additional d-polarisation functions (exponent 0.5) for In.

3. Oxidation state 0: metal atom complexes

3.1. Metal carbonyls

Main Group metals, unlike d-block metals, do not form lastingly stable derivatives with neutral molecules like CO, PF_3 or C_6H_6, so that the bulk metals are effectively the sole representatives of the oxidation state 0. The first sign that the Group 13 metal atoms are in fact capable of binding CO came in 1972 with the report [22] that the matrix formed by co-condensing Al atoms with an excess of krypton doped with CO at approximately 20 K displays new bands in the ν(CO) region of the IR spectrum that are red-shifted by approximately 150 cm^{-1} with respect to the corresponding band of free CO. These could be attributed to an aluminium dicarbonyl, $Al_x(CO)_2$. Subsequent studies involving different matrices and EPR [23] as well as IR [24,25] measurements have confirmed this first sighting and shown that $x = 1$. The most recent and detailed IR study, carried out in Paris [25], has explored systematically the effects of varying the metal and CO concentrations, and of annealing the resulting argon matrices, as well as extending the range of IR analysis down to 200 cm^{-1}. Typical results are illustrated in Fig. 2. Hence it has become clear that more than one product is formed, and examination of how the intensities of the different IR bands vary with the metal or CO concentrations has led, in addition, to the identification of AlCO and also the bimetallic species Al_2CO and $Al_2(CO)_4$. For example, the intensities of bands due to species containing more than one Al atom or CO molecule are found to increase more or less quadratically as a function of the concentration of that particular reagent.

In experimental terms, $Al(CO)_2$ is the most fully characterised of these products with no less than six IR bands attributable to vibrational fundamentals having been observed in the range 2000–200 cm^{-1}. Its signature includes two IR-active ν(CO) modes near 1995 and 1908 cm^{-1}, although the picture is complicated somewhat by the occupancy of more than one type of matrix site (see Fig. 2). Perhaps the clearest indication of stoicheiometry comes from experiments with an equimolar mixture of ^{12}CO and ^{13}CO which reveal 1:2:1 triplet patterns for each of the ν(CO) bands corresponding to the three distinct isotopomers $Al(^{12}CO)_2$, $Al(^{12}CO)(^{13}CO)$, and $Al(^{13}CO)_2$, respectively. The observation of two bands corresponding to the in-phase



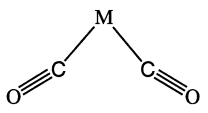


Fig. 2. IR spectrum of a solid Ar matrix showing the formation of AlCO and $Al(CO)_2$: (a) after deposition at 10 K; (b) after annealing at 32 K; and (c) after annealing at 38 K [25].

Table 1
Calculated and observed properties for mono- and dicarbonyls of the Group 13 metals [27]

Compound	Calculated structure		ν(CO) (cm^{-1})		Calculated energy (kJ mol^{-1})
	Distances [a]	Angles [a]	Calculated	Observed [b]	
AlCO	r(M–C) 2.146, r(C–O) 1.167	∠M–C–O 168	1890	1867.7 [c]	−81 [d]

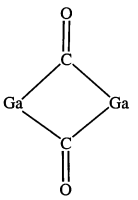
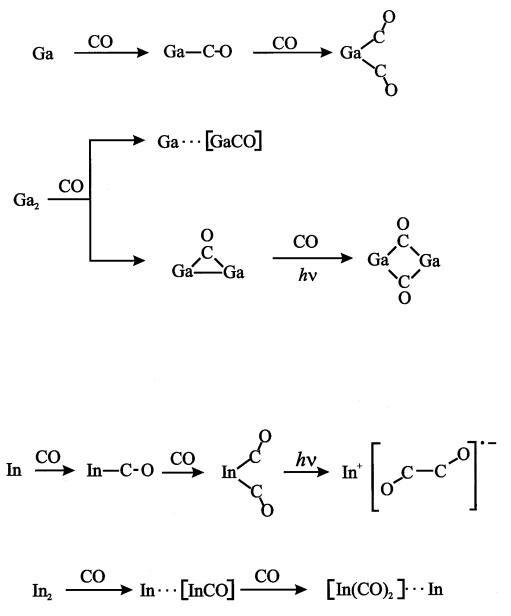
and out-of-phase ν(CO) fundamentals then implies an angular skeleton. If the simplifying assumption is made that the bond moments can be added vectorially, it follows that the angle θ subtended by the two CO oscillators is given by the ratio of the intensities I_{sym}: $I_{asym} = \cot^2(\theta/2)$, whence a value of $\theta = 110° \pm 5°$ has been estimated. Ab initio and DFT calculations [26,27] suggest a value near 102° but, more strikingly, a tight C–Al–C angle of about 74°, so that the Al–C–O arms are bent slightly but significantly outwards (**1**) with the two carbon atoms appearing to be drawn towards each other. This may reflect simply the achievement of optimum overlap between the vacant np valence orbital of Al coincident with the twofold axis of the molecule and the π-orbitals of the CO ligands, but there are at least three alternative explanations, viz. (i) repulsive interaction between the metal ns^2 electrons and the 5σ donor pair on CO; (ii) the establishment of a C···C interaction between the two CO groups made admissible to the bonding scheme, say, through an O=C=C=O contribution to the ground-state wave function [25]; or (iii) coulombic repulsion between the O atoms which carry a small but significant negative charge and are otherwise brought unusually close together by the narrow C–Al–C angle.



1

Similar experiments with gallium or indium in place of aluminium have revealed that the following molecules are formed on deposition: GaCO, InCO, Ga·GaCO, In·InCO, Ga(μ-CO)Ga, $Ga(CO)_2$, $In(CO)_2$ and $In(CO)_2$·In, the proportions of which vary markedly with the metal and CO concentrations [27]. The identification of binuclear products, both here and in the earlier experiments with aluminium [25], suggests that addition of CO occurs to the metal dimers M_2 (M = Al, Ga or In) which are also trapped when the metal vapours are co-condensed with an excess of a noble gas [28]. That these dimers have a chemistry of their own and do not merely shadow the parent atoms will soon be apparent when we come to consider the reactions with H_2 (see Section 5). The presence of products like Al(μ-CO)Al and Ga(μ-CO)Ga is signalled by the appreciably lower wavenumbers of the IR bands associated with the ν(CO) modes (1737 and 1828 cm^{-1}, respectively). DFT studies find that all three metals behave in a similar fashion in their response to coordination by CO. What is striking, though, is the magnitude of the estimated binding energies, ranging from 81 to 43 kJ mol^{-1} for AlCO, GaCO, and InCO, and from 176 to 85 kJ mol^{-1} for $Al(CO)_2$, $Ga(CO)_2$, and $In(CO)_2$ (see Table 1 for example). These, in common with the wavenumbers of the ν(CO) modes, signify M–CO bonds at least as strong as those formed by a late transition metal like Ni [27]. This must surely challenge conventional wisdom regarding the ability of CO to bind to a Main Group metal.

The known photolability of transition metal carbonyls [11,29] has prompted an investigation of the action of UV light on the matrix-isolated gallium and indium carbonyls [27]. Hence it is found that Ga(μ-CO)Ga can be induced to take up an additional CO molecule to produce the symmetrical $Ga(\mu\text{-}CO)_2Ga$ molecule, **2**, which is characterised by a ν(CO) IR band at 1774 cm^{-1}. DFT calculations suggest a potential minimum corresponding to a singlet planar structure with D_{2h} symmetry, with the following dimensions (distances in Å, angles in °): Ga···Ga 3.188; Ga–C 2.155; C–O 1.178; < Ga–C–Ga 95.4. The compound suffers



decomposition under the action of visible radiation. UV irradiation causes the decay of all the indium carbonyls formed on deposition but no new product is evident until the matrix is exposed to broad-band UV–Vis radiation. Then it appears that photoactivation of $In(CO)_2$ results in metal-to-ligand charge transfer with the coupling of the two CO molecules to produce the ion-pair $In^+[OCCO]^{\bullet -}$. Calculations show an increased electron density between the two carbon atoms in the first excited state of $In(CO)_2$, and so hint at the mechanism of this photoisomerisation. Scheme 1 contrasts the reaction pathways taken by Ga atoms and Ga_2 molecules in the presence of CO with those taken by In atoms and In_2 molecules under similar (matrix) conditions.

2

3.2. Other adducts of the metal atoms

Experiments along the same lines have also been carried out with Al, Ga or In atoms isolated in argon matrices doped with H_2 [30], N_2 [31], CH_4 [16], NH_3 [32] or PH_3 [33]. In the cases of H_2 and CH_4 it has not been possible to detect in the IR spectra of the deposits any new bands that can be ascribed to $M{\cdot}H_2$ or $M{\cdot}CH_4$ adducts, although the presence, at the very least, of contact pairs is implicit in the photochemical changes which can be induced in these matrices [16,30]. There are, however, signs that N_2 forms very loosely bound $M{\cdot}N_2$ pairs in that IR absorptions in the ν(NN) region are detectable, being red-shifted by approximately 16 cm^{-1} with respect to ν(NN) of free N_2 [31].

Scheme 1. Pathways for the thermally and photolytically activated matrix reactions of Ga, Ga_2, In and In_2 with CO [27].

Stronger interactions are apparent in the $M{\cdot}NH_3$ adducts formed on isolation of the metal atoms in argon matrices doped with 0.3–2% NH_3 [32]. The IR spectra recorded after deposition of these matrices include new bands identifiable with ν(N–H), $\delta_{asym}(NH_3)$ and $\delta_{sym}(NH_3)$ modes of a perturbed NH_3 molecule. Correlating with these features is a new band at approximately 440 nm in the visible spectrum. That the intensities of both the IR and visible absorptions should vary roughly in *direct* proportion to the matrix concentration of NH_3 argues strongly, moreover, for the formulation of each of these species as monoammines, viz. $M{\cdot}NH_3$. The IR properties of the adducts are then notable for the *blue* shifts of 108–157 cm^{-1} suffered by the $\delta_{sym}(NH_3)$ mode as compared with the corresponding mode of free NH_3. The implication of ligand-to-metal charge transfer is confirmed by DFT calculations which find a global minimum for an $M{\cdot}NH_3$ molecule with the geometry **3** deviating slightly from regular C_{3v} symmetry as a result of Jahn–Teller distortion [14,32,34,35]. The calculations reproduce well the general patterns presented by the IR spectra, with isotopic responses (D for H and ^{15}N for ^{14}N) wholly in line with those observed, and the direction of charge transfer, with a small negative charge on the metal, is also consistent with the results of very recent EPR studies [36] involving the $Al–NH_3$ system. Similar 1:1 metal ammines have been described previously in experiments involving severally the alkali metals [37], Fe [38], Ni [38], and Cu [38].

3 **4**

Experiments with PH_3-doped matrices give superficially similar results [33,34]. With each of the metals Al, Ga and In, new IR bands associated with the ν(P–H), $\delta_{asym}(PH_3)$ and $\delta_{sym}(PH_3)$ fundamentals of a perturbed PH_3 molecule can be discerned more or less clearly. Indeed, two families of bands can typically be recognised and distinguished by their dependence on the PH_3 concentration as arising from complexes of the types $M{\cdot}PH_3$ and $M(PH_3)_2$, respectively. Intriguingly, though, the most intense feature in each family, which corresponds to the $\delta_{sym}(PH_3)$ transition is not blue-shifted

Table 2
Calculated binding energies for neutral Group 13 metal atom complexes of the types M·L and M·L_2 [33,34]

Ligand, L	Metal atom, M	Binding energy (kJ mol^{-1}) [a]	
		M·L	M·L_2
N_2	Al	16.4	26.4
	Ga	8.4	17.1
	In	7.0	14.6
PH_3	Al	21.8	48.9
	Ga	22.1	45.0
	In	17.0	34.1
NH_3	Al	60.2	103.0
	Ga	51.8	86.1
	In	48.5	79.8
CO	Al	81	176
	Ga	61	125
	In	43	85

[a] Energy with respect to L and each M atom in its ^2P ground state.

but *red*-shifted by 20–30 cm^{-1} with respect to uncoordinated PH_3. It appears, therefore, not only that the degree of charge transfer is smaller than in the M–NH_3 adducts, but also that the transfer proceeds in the *opposite* sense to produce a slight positive charge on the metal atom, as indicated by recent independent theoretical studies on Al·PH_3 [39]. The vibrational properties are thus comparable with those displayed by PH_3 in the transition metal complexes $Cu(PH_3)_n$ ($n = 1–3$) [40a], $Ni(PH_3)_4$ [40a,b], and $H_3P{\cdot}TiCl_4$ [40c]. They are also replicated pleasingly well by DFT calculations [33,34], the 1:1 complexes resembling geometrically their ammonia counterparts and the 1:2 complexes conforming to C_{2v} symmetry, **4**, with P–M–P angles in the order of 80° and M···P distances about 0.06–0.08 Å shorter than in their 1:1 counterparts.

The calculated binding energies of the various neutral complexes of Al, Ga, and In atoms are listed in Table 2. Hence it emerges (i) that ligand–metal interactions increase in the orders In < Ga < Al and $N_2 < PH_3 < NH_3 < CO$, and (ii) that, with the exception of $Al(N_2)_2$, the 1:2 complexes each have a total binding energy similar to, or slightly greater than, twice the value associated with the corresponding 1:1 complex. The maximum bond energies thus range from 16 kJ mol^{-1} (for Al·N_2), through 24 and 60 kJ mol^{-1} [for $Al(PH_3)_2$ and Al·NH_3, respectively], to a remarkable 88 kJ mol^{-1} [for $Al(CO)_2$].

4. Oxidation state +2: metal hydrides of the type HMX (X = H, CH_3, NH_2 or PH_2)

Somewhat perversely, it might seem, we move next to the formal oxidation state +2, where paramagnetic behaviour is to be expected, at least in a mononuclear derivative of the Group 13 metal. As noted previously, compounds like AlH_2 are normally prey to rapid decomposition or disproportionation. It turns out, however, that they are also the *first* stage in the train of reactions typically induced by photoexcitation of the metal atom in a solid noble gas matrix that also includes as a prospective reagent H_2, CH_4, SiH_4, NH_3 or PH_3.

4.1. The hydrides MH_2

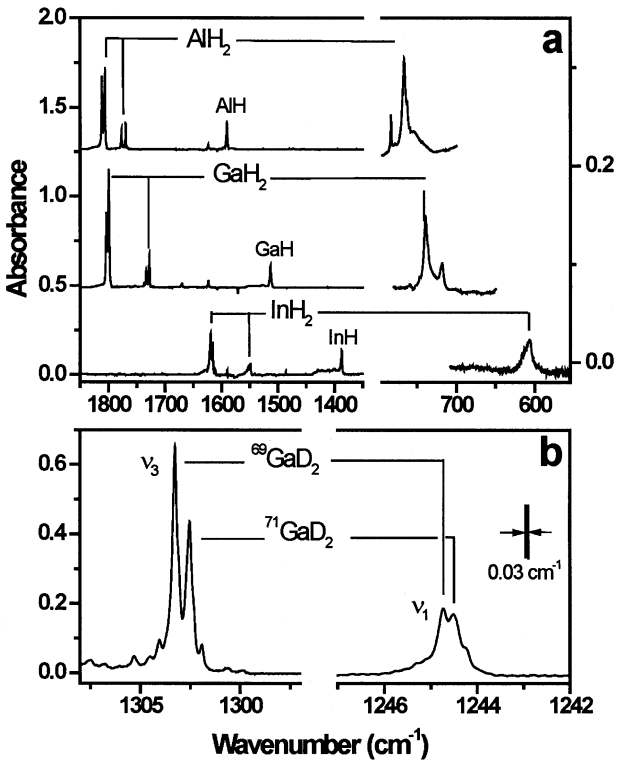
The earliest report of AlH_2, made by Herzberg [41], identified the molecule in a hydrogen discharge on the evidence of its emission spectrum. Matrix methods have been exploited subsequently to characterise the molecule by its IR [42] and EPR [43] spectra following its formation (i) by the reaction of photo-excited or laser-ablated Al atoms with H_2 [42]; or (ii) by a secondary reaction triggered by the photolysis of another divalent aluminium compound, HAlOH [43]. GaH_2 has been described as one of several photoproducts formed on broad-band photolysis of solid argon matrices including Ga atoms and H_2 [44]. However, the most detailed investigation of the dihydrides formed by all three metals Al, Ga, and In has been that carried out in Paris and published in 1994 [45]. Not only did this confirm how the molecules come to be formed from the metal atoms and H_2, it also made clear their photolytic fates.

When the Group 13 metal atoms (M) are condensed with H_2 molecules in solid argon, the IR spectrum observed directly after deposition displays no absorption attributable to M·H_2 or any other product. It requires irradiation of the matrix to induce any reaction, but only when the photolysing radiation coincides with the $^2S \leftarrow {}^2P$ or $^2D \leftarrow {}^2P$ transition of the M atoms (occurring in the wavelength range 290–340 nm) does the IR spectrum witness the appearance of new bands in the region 1500–1820 cm^{-1} suggestive of the formation of a metal hydride [45]. As illustrated in Fig. 3(a), each of the metals then gives a primary product characterised by three IR bands, two in the ν(M–H) region and one at 600–770 cm^{-1}. That this product is the angular triatomic molecule MH_2 is confirmed by experiments with D_2 and HD. In the case of the gallium compound, each of the two IR features attributable to stretching modes displays splitting due to the ^{69}Ga and ^{71}Ga isotopes present in natural abundance; this is best observed with GaD_2, where there is greater motion of the metal, with isotopic shifts of 0.75 and 0.22 cm^{-1} (see Fig. 3(b)). An interbond angle close to 120° is thus implied. Knowledge of the vibrational wavenumbers of the three isotopomers MH_2, MHD and MD_2 is sufficiently detailed to admit force field calculations which yield the following M–H stretching force constants (in

N m^{-1}): AlH_2 183, GaH_2 182, and InH_2 147. These trends, as well as the other spectroscopic characteristics, are exactly reproduced in the properties calculated by ab initio DFT and coupled cluster (CCSD) methods: the Al–H and Ga–H internuclear distances are thus estimated to be almost identical (1.609 and 1.615 Å, respectively) and approximately 0.2 Å shorter than the In–H distance [45].

In the past there have of course been numerous false starts with compounds professing by their formulae to be M^{II} derivatives [3], the most celebrated cases being those of $GaCl_2$ and Me_4NGaCl_3 which are in reality a mixed valence compound $Ga^{I}[Ga^{III}Cl_4]$ and metal–metal bonded compound $[Me_4N]_2[Cl_3GaGaCl_3]$, respectively. Another false impression is created by the paramagnetic compounds $M(dbab)_2$, where M = Al or Ga and dbab = $Bu^tNCHCHNBu^t$, but which actually contain the trivalent metal bound to one singly and one doubly reduced dbab ligand [3]. Any doubts about the credentials of the matrix-isolated MH_2 molecules have been set aside, however, by the EPR spectra displayed by AlH_2 [43] and GaH_2 [46].

Once formed, the MH_2 molecules themselves prove to be photolabile. Moving the photolysing radiation to shorter wavelengths (250–290 nm) results in the decay of the IR bands due to MH_2 with the simultaneous growth of a single new band at 1380–1600 cm^{-1} corresponding to the MH diatomic which has been well characterised previously in the gas phase [9]. This implies the existence of an excited electronic state of the MH_2 molecule about 4.5 eV above the ground state which is dissociative towards MH + H. Consistent with such a view are the findings of an ab initio study of the excited states of AlH_2 in that the first Rydberg state is calculated to have a linear geometry and a term value close to 4.75 eV [47]. Nor is this the end of the tale for the AlH photoproduct observed in the matrix experiments. Changing the character of the photolysing radiation yet again—and moving this time to longer wavelength (ca. 400 nm)—causes the AlH absorption to decay with the simultaneous growth of three new bands at 1883, 784, and 698 cm^{-1} identifiable, on the basis of deuteration experiments and of the results of parallel matrix studies [42b,48,49], with the planar AlH_3 molecule. The amount of AlH actually disappearing is found to be proportional to the H_2 concentration in the matrix, and it is evident, therefore, that both AlH and H_2 are needed to form AlH_3 in what must then be, overall, a three-photon process (Eq. (1)). The efficient wavelength range (365–410 nm) is indeed close to the first electronic transition ($A\ ^1\Pi \leftarrow X\ ^1\Sigma^+$) of AlH for which ν_{00} = 23470.93 cm^{-1} according to gas-phase studies [50]. This insertion into the H–H bond of electronically excited AlH does not appear to be matched by similar reactions on the part of GaH and InH, although analogous reactions *can* be engineered with photoexcited MCl molecules to give H_2MCl (M = Ga [51a] or In [51b]). To access GaH_3 and InH_3 it is necessary to introduce H atoms to the metal atoms; the IR spectra of the resulting matrices recorded immediately after deposition then attest the formation of all three hydrides MH, MH_2 and MH_3 for M = Al, Ga or In [49]. Although photostable, all the trihydride molecules are rapidly lost to either aggregation or decomposition under normal conditions. The vapour over solid gallane, $[GaH_3]_n$, at low temperatures (180–215 K) does contain in addition to the dimer $H_2Ga(\mu\text{-}H)_2GaH_2$ much lower partial pressures of GaH_3, so further matrix studies



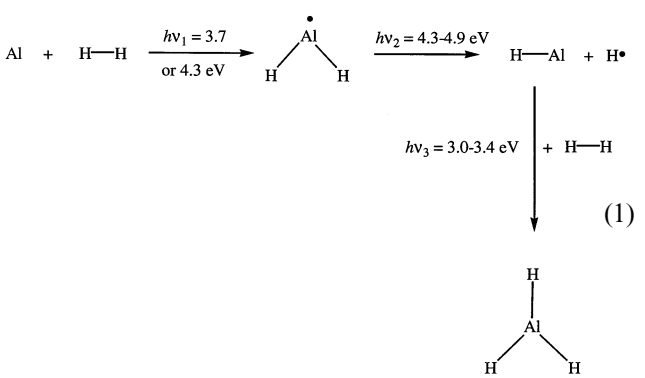


Fig. 3. (a) IR difference spectra showing the formation of simple Group 13 metal hydrides in solid Ar matrices at 10 K after irradiation at λ = approximately 334 nm (Ga) or 289 nm (Al and In). Other bands are due to traces of AlH_3 (top spectrum) and HMOH (M = Ga or In). (b) IR spectrum of $^{69}GaD_2$ and $^{71}GaD_2$ in the antisymmetric and symmetric ν(Ga–D) regions [45].

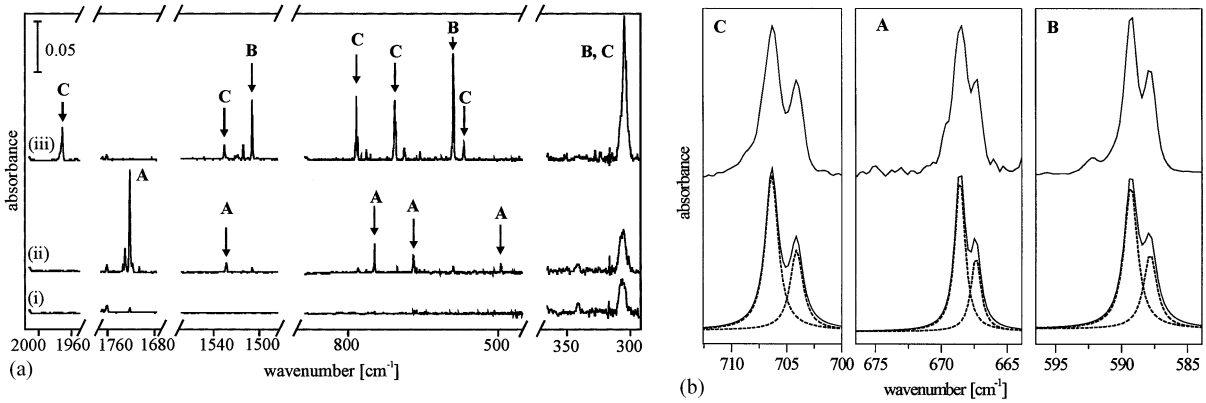

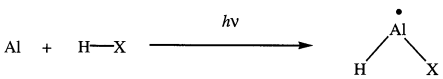

Fig. 4. IR spectra of an Ar matrix containing Ga and NH_3: (a) (i) following deposition; (ii) following UV photolysis ($\lambda = 200$–400 nm); and (iii) following broad-band UV–Vis photolysis ($\lambda = 200$–800 nm); (b) bands near 700 (**C**), 670 (**A**), and 590 cm^{-1} (**B**) showing $^{69}Ga/^{71}Ga$ splitting. **A** = $HGaNH_2$, **B** = $GaNH_2$, and **C** = H_2GaNH_2 [32].

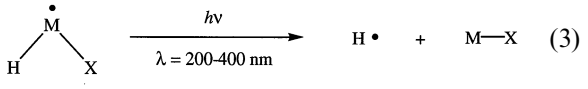
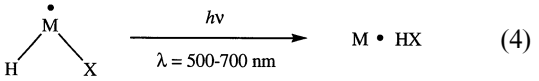
suggest [52]. Otherwise we must depend largely on theory for our knowledge of MH_3 molecules.

4.2. Other hydrides of the type HMX



Insertion into the H–H bond is by no means the limit to the reactivity of a Group 13 metal atom once excited to its ^2S or ^2D electronic state. Indeed, replacement of H_2 by CH_4, SiH_4, NH_3 or PH_3 as a partner to the excited metal atom has been found under matrix conditions to give rise to a primary reaction analogous to the first stage of Eq. (1); breaching of a C–H, Si–H, N–H or P–H bond occurs with the formation of an angular hydride molecule of the type HMX, where X = CH_3 [16,53], SiH_3 [54], NH_2 [32] or PH_2 [33], respectively (Eq. (2)). The photolysis conditions vary somewhat according to the initial degree of interaction between M in its electronic ground state and the prospective reagent. Where there is little or no specific interaction—as with CH_4, for example—optimum conversion is achieved with radiation having wavelengths close to that of the $^2S \leftarrow {}^2P$ transition of the matrix-isolated M atom (ca. 340 nm or $h\nu = 3.7$ eV). Where specific interaction yields a recognisable adduct, however, there is a move to longer wavelengths. For example, the visible absorption near 440 nm ($h\nu$ = ca. 2.8 eV) associated with the formation of an M·NH_3 complex in an argon matrix is the ideal target for the photolysing radiation needed to promote insertion and so give what may be regarded as a tautomer of the original complex. Although it has not been possible to locate all the IR-active fundamentals, the effects of isotopic change and the ability of DFT calculations to match the observed spectra put beyond question the identities and structures of the HMX products. To judge by the EPR spectra recorded for CH_3AlH [53], CH_3GaH [46], and $HAlNH_2$ [36], moreover, we need be in no doubt that these too are authentic M^{II} derivatives. Only in the case of the M–PH_3 system does it appear that the M^{II} product $HMPH_2$ is accompanied by an M^{III} isomer, H_2MPH, where the unpaired electron is localised on the P rather than the M atom [33].

(2)



The HMX molecules share the photolability of the parent dihydrides, and indeed feature quite a rich photochemistry. The response of the dihydrides to UV photolysis is echoed by CH_3MH and $HMNH_2$; under the action of broad-band UV–Vis light, these suffer photodissociation of the M–H bond with the formation of the univalent products CH_3M [16] and MNH_2 [32], respectively (Eq. (3)). Given the unselective nature of the photolysis, it is not possible to decide whether the primary photochemical act is truly selective or whether both the M–H and the M–CH_3 or M–NH_2 bonds are ruptured and the matrix cage then filters the products by admitting the escape of the small, mobile $H^\bullet$ atoms while denying that of the larger $^\bullet CH_3$ or $^\bullet NH_2$ radicals [55]. In the case of the M–NH_3 system, broad-band photolysis also results in a significant yield of a secondary product, namely the M^{III} compound H_2MNH_2, so that the M^{II} precursor appears to have disproportionated into MNH_2 and H_2MNH_2 (see Fig. 4). A fuller discussion of this last product is deferred, however, to Section 6. But this is by no means the end of the photochemical channels that can be accessed by HMX molecules, for there is evidence—direct in some cases, less direct in others—that some at least are characterised by visible absorption in the range 500–700 nm. For example, $HAlPH_2$ displays an absorption near 550 nm. Irradiation at these wavelengths then opens up the possibility of a reversal of reaction 2, with the regeneration of the M·HX contact-pair or complex (Eq. (4)). This is certainly the case with HX = SiH_4 [54b] and with HX = PH_3, although there is competition in the second case from alternative decomposition channels

that afford, among other products, PH (when M = Ga or In) [33]. Earlier experiments suggest that matrix-isolated CH_3AlH and CH_3GaH are likewise susceptible to reversion to $CH_4{\cdot}M$ when exposed to light at wavelengths >450 nm [53].

(3)

$X = CH_3$ or NH_2

(4)

5. Oxidation state +1: mononuclear derivatives MX (X = H, CH_3 or NH_2) and dinuclear derivatives M_2H_2

5.1. Mononuclear derivatives

As noted in the preceding section, irradiation of matrix-formed HMX molecules with light at wavelengths in the range 200–400 nm affords a source of monomeric univalent MX molecules, where X = H [45], CH_3 [16], or NH_2 [32] (Eq. (3)). The monohydrides and CH_3Al have been detected in the gas phase, for example by their rotational spectra [3,9,56], but most of the knowledge about simple molecules of this type available hitherto has come from theoretical inquiries. With the new experimental results it is possible not only to check the fidelity of quantum chemical calculations, but also to compare the bonding in molecules of the type MX with that in HMX, MX_3 and H_2MNH_2 molecules, where X = H, CH_3 or NH_2. Bond distances, r(MX) (mostly estimated by theoretical methods) and stretching force constants, k(MX) (all determined by experiment), are set out in Table 3. For a given metal M, it is thus evident that the steady decrease in r(MX) in the order $M^I > M^{II} > M^{III}$ is matched by a steady *increase* in k(MX) as the M–X bond becomes less polar and the curvature at the foot of the potential well correspondingly steeper. There is also an intriguing change in the pattern of r(MX) and k(MX) as a function of the

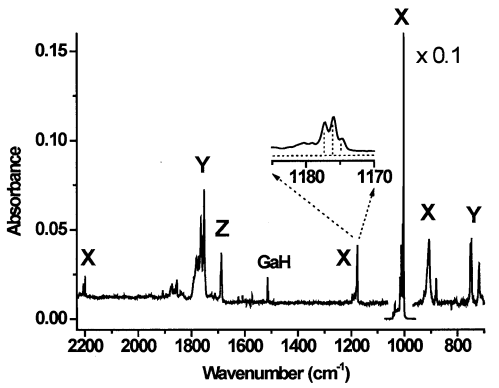

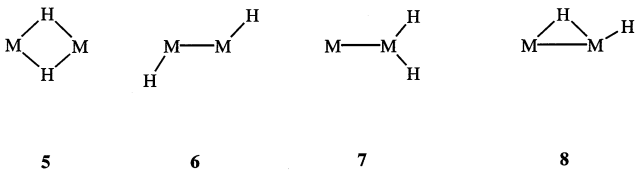

Fig. 5. IR spectrum in the region 2300–700 cm^{-1} for Ga vapour codeposited with H_2 in an excess of Ar ($Ga/H_2/Ar = 0.6/1/100$) at 14 K. The absorbance scale in the 1100–950 cm^{-1} region is divided by 10 for the sake of presentation. **X** = Ga(μ-H)$_2$Ga, **Y** = $GaGaH_2$, and **Z** = HGaGaH [30]. The inset presents an enlarged view of the $a_g + b_{1u}$ combination transition with a stick spectrum symbolising the intensity pattern expected for the natural isotopic composition of a symmetrical digallium species.

valence state of M according to whether M = Al, Ga or In. Univalent derivatives consistently comply with the sequence Al > Ga > In for k(MX) [with the reverse order for r(MX)], whereas the corresponding sequence for trivalent derivatives is Al ~ Ga > In in keeping with the extra stability of the 4s valence shell in Ga.

5.2. Binuclear derivatives M_2H_2

Subhydrides of the Group 13 metals of the type M_2H_2 have attracted the attention of theorists despite a dearth of hard experimental fact. Part of the concern has arisen from the question of what part multiple bonding between the M atoms might play. Diborene, B_2H_2, has been identified by its EPR and IR spectra in matrix-isolation experiments and the consensus of experiment and theory is that it has a linear triplet ground state with little or no B–B double-bonding [2,9,57,58]. By contrast, a bis(μ-hydrido) structure **5** with D_{2h} symmetry is calculated to be the most stable form for all the other Group 13 elements [2,9,58,59]. Instead of the linear form which is now only a transition state, a *trans*-bent isomer **6** (C_{2h}) appears as a second minimum on the PE surface, and there are two other possible isomers, namely the asymmetric M–MH_2, **7** (C_{2v}), and mono-H-bridged HM(μ-H)M, **8** (C_s), also giving minima at energies not far above the global minimum. None of these molecules offers the opportunity for significant M–M multiple bonding. Only with the addition of two extra electrons to give a species isoelectronic at the valence level with C_2H_2 does such bonding seem feasible, the lowest energy form assuming not a linear but a *trans*-bent configuration akin to **6** [2,13]. No simple hydride derivative of this sort has yet been sighted, but replacement of hydrogen by a very bulky ligand Ar* = 2,6-(2,4,6-$Pr^i_3C_6H_2$)$_2C_6H_3$ has led to the isolation of the deeply coloured compound Na_2[Ar*GaGaAr*] featuring a relatively short Ga–Ga bond and a non-linear C–Ga–Ga–C skeleton with C_{2h} symmetry [13,60].

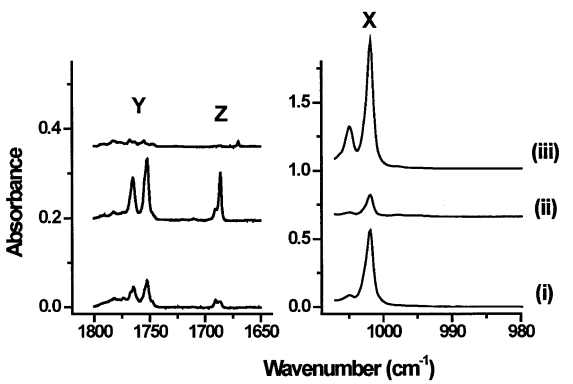
5 **6** **7** **8**

The first experimental evidence of a neutral hydride of the type M_2H_2 came in 1993 when it was reported by Xiao et al. [44] that co-condensation of gallium vapour, produced by thermal evaporation, with H_2 in a noble gas matrix results in the formation of a molecule believed to be Ga(μ-H)$_2$Ga, i.e. with the structure **5**. Since it is known that a small proportion of the gallium is trapped as Ga_2 and larger clusters [28], the obvious inference is that the product is formed *spontaneously* by the reaction of Ga_2 with H_2. Furthermore, the IR spectra of argon matrices formed by condensing laser-ablated Al atoms with H_2 are found to include absorptions attributable on the evidence of their wavenumbers and isotopic responses and theoretical modelling to Al(μ-H)$_2$Al, **5**, and, more tentatively, to HAl(μ-H)Al, **8** [42b,61]. However, the high energy of the atoms produced in this way, including some that are in electronically excited states, and the potential for photolysis by the hard radiation emanating from the focussed laser plume at the metal target make it difficult to judge how these particular products come to be formed.

More recent studies carried out in Paris [30] confirm that a new product is indeed formed by the spontaneous reaction of Ga_2 with H_2 in solid argon matrices at approximately 12 K. Five bands traceable to the product occur at 2200, 1176, 1002, 906.5, and 880 cm^{-1}, with the third of these being the most intense by an order of magnitude (see Fig. 5). Particularly striking is the triplet pattern displayed by the weak band at 1176 cm^{-1}; the intensity pattern of the closely spaced components tallies closely with that expected (2.3:3:1) for naturally occurring ^{69}Ga and ^{71}Ga with the freedom to occupy two equivalent sites. On these grounds alone, models **7** and **8** would appear to be excluded. Arguing against model **6**, moreover, is the failure to find any bands in the region associated with the stretching of *terminal* Ga–H bonds (1500–2050 cm^{-1}) [9]. The most plausible interpretation of the results is that the compound is indeed the dihydrido-bridged molecule Ga(μ-H)$_2$Ga with the structure **5**. For a planar molecule of this sort with D_{2h} symmetry only three vibrational fundamentals are expected to be active in IR absorption and calculations in the optimised geometry anticipate that one of these, corresponding to the

ring-puckering mode, will occur at a wavenumber (ca. 200 cm^{-1}) and with an intensity (ca. 1% that of the strongest absorption) which will make it hard to locate in practice. On the other hand, the same calculations find no difficulty in identifying the intense band at 1002 cm^{-1} with the b_{1u} ring-stretching mode and its weaker neighbour at 906.5 cm^{-1} with the corresponding b_{2u} mode. The weak band at 880 cm^{-1} can then be ascribed to the b_{3g} ring-stretching mode made active by the reduced symmetry (C_{2v}) of the $^{69}Ga^{71}GaH_2$ isotopomer making up 48% of the product. With the aid of the vibrational properties calculated for the optimum geometry, the remaining bands can be attributed to combination tones each involving an IR-silent (a_g) fundamental. The net result is that all but one (b_{3u}) of the six fundamentals of the molecule ($2a_g + b_{3g} + b_{1u} + b_{2u} + b_{3u}$) have been located more or less certainly, the assignments being underwritten by the effects of isotopic change ($^{69}Ga/^{71}Ga$ and D for H) and by the properties forecast by theory. Experiments with mixtures of H_2 and D_2 give no hint of absorptions due to the mixed isotopomer Ga(μ-H)(μ-D)Ga (formed from HD) and so confirm the bimolecular nature of the reaction between Ga_2 and H_2. Intriguingly, though, the reaction shows a marked kinetic isotope effect, being much slower with D_2 than with H_2 or HD at 10–12 K, although it can be accelerated by exposure of the matrix to additional IR radiation.

In similar studies carried out partly in Oxford but mainly in Karlsruhe [30], replacement of gallium by indium gives matrices that tell a rather different tale. In this case, the IR spectra of the initial deposits give no sign of any reaction between In_2 and H_2. On the other hand, such a reaction can be induced by irradiation of the matrix with light having wavelengths near 365 nm. Hence the corresponding indium hydride In(μ-H)$_2$In is formed. The parallel with the gallium compound is at once announced by the IR spectrum which is dominated by an intense absorption at 955 cm^{-1}, accompanied by much weaker ones at 2021, 1079, 848 and 800 cm^{-1}. The interpretation of the spectrum follows closely that of the gallium compound, allowing five of the six fundamentals to be identified, with conclusions again endorsed both by the effects of deuteration and by the results of calculations at different levels of theory.



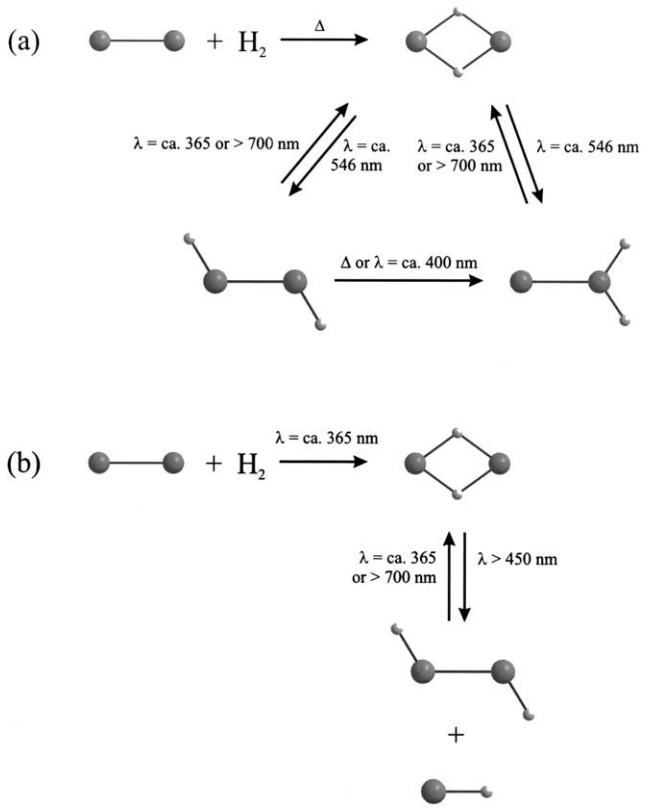


Fig. 6. IR spectrum of an Ar matrix containing Ga vapour and H_2 in the regions 1800–1650 and 1100–980 cm^{-1} (i) after deposition, (ii) after irradiation at λ = approximately 546 nm, and (iii) after irradiation at $\lambda = 600–800$ nm [30].

The contrasting reactivities of Ga_2 and In_2 in these reactions pose a teasing problem to which there is no obvious solution. It is generally agreed that the electronic ground state of each of the dimers is a *triplet*, although the first singlet state lies only approximately 50 kJ mol^{-1} higher in energy. The M(μ-H)$_2$M molecule, on the other hand, almost certainly possesses a *singlet* ground state. Calculations then suggest that the reaction of triplet ($^3\Pi_u$) M_2 molecules with H_2 to form singlet M(μ-H)$_2$M is mildly endothermic, whereas the corresponding reaction of singlet ($^1\Sigma_g^+$) M_2 molecules is strongly exothermic. A possible explanation is then that a fraction of the M_2 molecules entering the matrix populates the excited singlet state, and that the difference in reactivity depends on the lifetime of this state.

But that is by no means the end of the tale. For both Ga(μ-H)$_2$Ga and In(μ-H)$_2$In prove to be photolabile under visible light ($\lambda > 450$ nm) [30]. Exposure of the gallium compound to green light (λ = ca. 546 nm) results in its conversion to two distinct products **X** and **Y**, the first being marked by IR bands at 1765, 1752 and 752 cm^{-1}, the second by just one sharp band near 1686 cm^{-1} (see Fig. 6). **Y** can be distinguished from **X** and indeed converted into it by annealing the matrix at temperatures up to 30 K or by irradiation with near-UV light. Comparison with the spectra of other gallium hydrides and with the spectra simulated for different Ga_2H_2 isomers with the geometries **6**–**8**, allied to the response to deuteration, suggests that **X** is $GaGaH_2$ (**7**) and **Y**, HGaGaH (**6**). By contrast, irradiation of In(μ-H)$_2$In with visible light ($\lambda > 450$ nm) gives rise to only a single isomer, HInInH, together with InH. The isomerisation can be reversed by UV photolysis (λ = ca. 365 nm) of HMMH (M = Ga or In) and $GaGaH_2$, or by near-IR photolysis ($\lambda > 700$ nm) of HGaGaH and $GaGaH_2$. Of isomers of the type HM(μ-H)M, **8**, however, there is as yet no trace. Scheme 2 summarises the reactions variously activated by thermal or photolytic means and which have thus been charted by experiment.

All of this must be seen as a major triumph for the theoretical studies that foreshadowed subhydrides of the type M_2H_2 [58,59]. Yet experiment does more than vindicate theory, for 'nothing ever becomes real till it is experienced'.

Scheme 2. Pathways for the matrix reactions of Ga_2 and In_2 molecules with H_2 [30].

6. Trivalent metal hydrides with the potential for multiple bonding

There is no question but that π-type bonding to the heavier p-block elements is relatively weak and that compounds containing such bonds are ready prey to aggregation or electrophilic attack. On the other hand, the increase in coordination number at the p-block element in the transition state and often in the product means that this vulnerability can be countered by steric congestion. Accordingly, it has been found that encumbering the heavier elements of Groups 14 and 15 with sufficiently bulky ligands affords isolable mononuclear compounds featuring more or less well authenticated multiple bonding [62]. The same strategy has also been tried with more limited success with the Group 13 metals, but the bonding status of even the most promising products, e.g. Na_2[Ar*GaGaAr*], is still the subject of considerable debate [2,13,60]. As noted in the preceding section, neither quantum chemical calculations nor experiment find evidence for a stable M_2H_2 molecule that involves significant M–M π-type interactions. Here we consider not the wider issue but the special case of the heavier homologues of H_2BNH_2, viz. H_2MNH_2, where M = Al, Ga or In. Once again, matrix isolation brings practical substance to theoretical speculation.

Amido derivatives of Group 13 metals are normally oligomeric or polymeric, with a coordination number of 4 or greater at the metal [3]. Only with the introduction of bulky substituents at the metal and nitrogen centres can monomeric compounds with three-coordinated M and N atoms be sustained under normal conditions [63]. Despite the planar structures favoured by the skeletons of such compounds, however, it is difficult to assess the contributions made to the overall properties by bonding and non-bonding interactions associated with the ligands. The difficulty is minimised in a simple monomeric compound like H_2GaNH_2, but this aggregates under normal conditions as the trimer $[H_2GaNH_2]_3$, which decomposes on heating not to regenerate the monomer but to eliminate H_2 and form GaN [64]. Quantum chemical calculations on molecules of the type H_2MNH_2 [14,32,34,35] certainly indicate a planar, ethene-like structure **9** with C_{2v} symmetry for the equilibrium geometry. In this respect there is no difference from the structure deduced previously by both experiment and theory for the corresponding boron compound H_2BNH_2 [65].

9 **10**

The IR spectra of argon matrices containing initially M atoms and NH_3 signal that the first photoproduct $HMNH_2$ decomposes on exposure to broad-band UV–Vis light to give both the M^I derivatives MNH_2 and the M^{III} derivative H_2MNH_2 as the photostable end-products [32]. For example, photolysis of $HGaNH_2$ results, particularly in the later stages, in the growth of no less than nine bands which can be attributed to the formation of H_2GaNH_2 (see Fig. 4). There are several immediate clues to this identity: (i) absorptions at 1970.8 and 779.6 cm^{-1} are strongly suggestive of a terminal GaH_2 unit in a *trivalent* gallane derivative [cf. GaH_3 1923.2 and 758.7 cm^{-1} [49], and H_2GaCl 1978.1/1964.6 and 731.4 cm^{-1} [51a]; (ii) absorptions at 3510.7, 3413.4, 1530.4, 782.8, and 567.7 cm^{-1} bear all the hallmarks of an NH_2 group; and (iii) the doublet pattern of an absorption at 706.2/704.1 cm^{-1} implies $^{69}Ga/^{71}Ga$ splitting arising from the motion of a single Ga atom, most likely in a ν(Ga–N) vibration. Confirmation is provided both by the response of the IR signature to isotopic enrichment of the molecule in D or ^{15}N, and by the strikingly close agreement of the measured spectra with those simulated for the different isotopomers of the H_2GaNH_2 molecule by DFT calculations. The corresponding aluminium and indium compounds have been detected and characterised in a similar manner.

How well the calculations are able to reproduce the measured spectra is demonstrated by rms deviations of no more than 3.3 and 5.8% for the wavenumbers of the different isotopomers of H_2AlNH_2 and H_2GaNH_2, respectively. No less impressive are the ^{15}N shifts (all negative and in cm^{-1}) presented in parentheses in the order experimental/calculated for the following bands of H_2GaNH_2 (with wavenumbers also in cm^{-1}): 3510.7 (10.0/10.8), 3413.4 (7.5/4.9), 1970.8 (0.1/0.1), 1530.4 (6.1/5.4), 782.8 (4.5/4.7), 779.6 (4.4/3.5), 706.2/704.1 (14.0/13.1), 567.7 (0.3/0.0), and 304.9 (2.1/2.4). In addition, the observed $^{69}Ga/^{71}Ga$ splitting of 2.1 cm^{-1} characterising the band near 705 cm^{-1} matches admirably the calculated value of 1.9 cm^{-1} for what approximates demonstrably to the ν(Ga–N) mode.

How these products come to be formed is not immediately obvious. The knowledge that H_2 molecules undergo photoactivated addition to matrix-isolated GaCl [51a] or InCl [51b] to give the trivalent product H_2MCl (M = Ga or In) suggests one mechanism in which a similar reaction is induced between the univalent metal amide MNH_2 and H_2 (formed by recombination of the H atoms released on photodissociation of the M^{II} molecule $HMNH_2$ (Eq. (3)). There is another possibility, however, namely the direct addition of the H atoms released to the subvalent metal compounds MNH_2 and $HMNH_2$. Telling evidence that this is indeed the principal—possibly sole—means of access to H_2MNH_2 comes from experiments in which a matrix containing Ga atoms and NH_3 is additionally doped with D_2 [32,34]. Were D_2 addition the primary reaction, the main product would then be D_2GaNH_2 readily recognisable by strong IR absorptions near 1400 cm^{-1} due to its ν(Ga–D) modes. In the event, only weak absorptions are observed to build up hereabouts, whereas relatively strong bands develop near 1970 cm^{-1} [due to ν(Ga–H) modes]. It is also apparent that the yield of H_2GaNH_2 decreases almost to vanishing point when the matrix concentration of NH_3 is reduced by a factor of 10. There seems to be little doubt, then, that H atoms are the main precursors to the formation of H_2MNH_2 in a reaction sequence that plainly requires the activation of more than one NH_3 molecule.

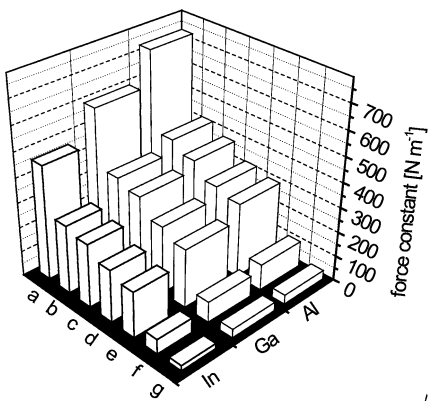

Fig. 7. Plot of the force constants k(MN) of compounds with the general formula H_mMNH_n (M = Al, Ga or In; m, $n = 0$–3): (a) HMNH; (b) H_2MNH_2; (c) $HMNH_2$; (d) MNH_2; (e) MN; (f) $H_3M{\cdot}NH_3$; (g) $M{\cdot}NH_3$ [34].

The calculated M–N distances in the H_2MNH_2 molecules—1.779, 1.821, and 1.970 Å for M = Al, Ga and In, respectively—are indeed short, being near or below the lower limits for the observed distances in three-coordinated amido derivatives of the relevant metal (Al 1.78 Å, Ga 1.818 Å, and In 2.049 Å) [34]. As shown in Fig. 7, the M–N stretching force constants determined by experiment are also larger than those of any other compound of the type H_mMNH_n (m, $n = 0$–3), with the sole exception of the hypothetical, high-energy species HMNH which has so far eluded the experimentalist. The planar geometry calculated for the H_2MNH_2 molecule contrasts with the *trans*-C_{2h} geometry of H_2SiSiH_2 [63a,66] and while it must imply some π-bonding, the barrier to inversion of NH_3 and its derivatives is so small that planarity is of itself no guarantor of a strong π-interaction.

To explore further the nature of the M–N bond, DFT methods have been used to optimise each H_2MNH_2 molecule in the conformation where the H_2M and NH_2 planes are orthogonal to each other [34]. The resulting twisted conformation is a transition state with two imaginary frequencies, one for the torsion back to the planar molecule and the other for pyramidalisation of the M–NH_2 unit. Calculation of the energy of the transition state relative to the equilibrium ground state of the molecule then gives an estimate of the barrier to rotation about the M–N bond, ΔE. Hence it has been estimated [34], in agreement with results reported elsewhere [14,67], that $\Delta E = 161.9$, 50.6, 65.7, and 51.5 kJ mol^{-1} for M = B, Al, Ga, and In, respectively. If ΔE is taken to be a lower limit to the π-bond strength, there are then just two conclusions to be drawn. Firstly, only in H_2BNH_2 does π-bonding add significantly to the strength of the M–N bond. Secondly, such bonding varies in strength in the order $B \gg Al < Ga > In$; that gallium should again be out of line with its neighbours is noteworthy but scarcely destined to stem the tide running against π-bonding as a major influence.

Of phosphorus analogues of H_2MNH_2 there is no obvious glimpse when matrix-isolated $HMPH_2$ molecules are similarly irradiated with broad-band UV–Vis light. DFT calculations lead us to expect that the hypothetical H_2MPH_2 molecules will assume non-planar geometries, **10**, with C_s symmetry and incorporating sharply pyramidal MPH_2 fragments [34]. Very similar results have been reported previously for H_2AlPH_2 and H_2GaPH_2 on the basis of SCF calculations which nevertheless encourage the belief that the non-planar skeletons are not necessarily incompatible with some M–P double-bond character [68]. In fact, the

different structures of H_2MNH_2 and H_2MPH_2 have more to do with the grossly different inversion barriers of the parent molecules NH_3 and PH_3 (24 vs. 148 kJ mol^{-1} according to one estimate [34]) than with π-bonding ability. Interestingly, the inversion barriers of H_2MPH_2 molecules are estimated to be 39–53 kJ mol^{-1}, i.e. only about one-third the values for free PH_3, suggesting that there is appreciable stabilisation of the planar transition state [34]. What is more, the barrier to rotation around the M–P bond of this state has been calculated to be 65.9, 80.1, and 65.3 kJ mol^{-1} for M = Al, Ga, and In, respectively [34]. M–P π-bonding is somewhat stronger than M–N π-bonding, so theory proposes: how real or significant this may be has yet to be tested by experiment.

Abstract

Metastable Aluminum(I) halide solutions proved to have a high potential for the synthesis of novel subvalent Al compounds, such as Al_nX_m species (X = Cl, Br, I; $n < m$, average oxidation state of Al below $+3$ or $n > m$, average oxidation state of Al below $+1$) or Al_nR_m species (R = bulky ligand; $n > m$). There are two principal reaction types, which are essential for the formation of the compounds discussed herein. The disproportionation, which finally results in Al(III) halides and Al metal and the metathesis which leads to a substitution of X atoms against R groups. By this way the *metalloid* cluster compounds $[Al_7\{N(SiMe_3)_2\}_6]^-$, $[Al_{12}\{N(SiMe_3)_2\}_8]^{-\bullet}$, $[Al_{14}I_6\{N(SiMe_3)_2\}_6]^{2-}$, $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$, and $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-\bullet}$ could be isolated. The characteristic feature of these *metalloid* Al clusters is the number of Al–Al contacts being larger than the number of Al–ligand bonds, i.e. there are more 'naked' than ligand-bonded Al atoms. Furthermore, the topology of the closest packing in Al metal is already pre-formed in these compounds. © 2002 Elsevier Science Ltd. All rights reserved.

Keywords: Aluminum(I) halides; Metalloid clusters; Nanosized clusters; Intermediates; Metal lattice; X-ray structural analysis

1. Introduction

Recently we introduced the term of *metalloid* cluster [1] in order to limit the very broad definition of Cotton's *metal atom* cluster [2]. The fact that the core of a *metal atom* cluster can also contain non-metal atoms leads to the logical consequence of describing the large selenide and sulfide clusters—e.g. $Cu_{146}Se_{73}$ synthesized by Fenske and co-workers [3]—as *metal atom* clusters as well. In contrast, the definition *metalloid* was originally limited to the macroscopic properties of elements (e.g. germanium) and shall now also include the topology of atoms, i.e. *metalloid* clusters exhibit a similar topology of the atoms as in the metal itself. The suffix *-oid* from the Greek term ειδος means idea, prototype: i.e. the topology of a *metalloid* cluster contains the idea of the formation of metals. For elements occurring in various modifications (e.g. gallium) the term *elementoid* would be more comprehensive.

However, *metalloid* clusters do not necessarily have to be *metallic* clusters, as these—apart from the topology of atoms—should also possess other properties attributed to metals (e.g. electrical conductivity). However, *metallic* clusters of this type ought to be obtained only with far larger sized metal frames than the *metalloid* aluminum clusters described below. For instance, within the $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ cluster compound [4] there is a core of 57 'naked', no ligand-bearing metal atoms surrounded by 20 ligand bound metal atoms which results in the number of metal–ligand bonds being smaller than the number of metal–metal contacts.

Metalloid clusters might well be formed as intermediates during the reduction of metal compounds on the way to the metal, i.e. the oxidation state approximates 0. *Metalloid* precious metal clusters were firstly in the center of interest, as these precious metals which represent the final steps during the reduction process are known to be stable even under drastic chemical conditions (e.g. acid). In the last decades, a considerable number of results concerning such *metalloid* clusters, e.g. of gold, palladium and platinum, have been obtained and discussed in numerous monographs [5,6].

However, until recently only a few precious metal clusters with a larger number of 'naked' metal atoms were known and could be characterized unambiguously by X-ray structural analysis. For example, the $[Ni_{38}Pt_6(CO)_{48}H_{6-n}]^{n-}$ cluster [7] synthesized in 1985 contains only six 'naked' metal atoms, and the $Pd_{59}(CO)_{32}(PMe_3)_{21}$ cluster molecule [8] published in 1999 carries 11 of them. The most astonishing cluster compound of this type is a $Pd_{145}(CO)_{60}(PEt_3)_{30}$ cluster [9] with 55 'naked' Pd atoms. Therefore, the publication describing the $[Al_{77}R_{20}]^{2-}$ cluster in 1997 [4] came as a surprise in many respects:

1. It was the first molecular *metalloid* cluster of a non-precious metal to be structurally analyzed. The crystals of the $[Al_{77}R_{20}]^{2-}$ compound showed to be reactive, partly pyrophoric.
2. It was the largest *metalloid* cluster (57 'naked' Al atoms) ever to be structurally analyzed [10].

How unexpected the formation of such a cluster of non-precious metals had been can be seen in the fact that only 8 years before the first molecular compound with one Al–Al bond had been published [11].

For a better insight of the formation of *metalloid* Al clusters we start with a short survey of the historical development of their synthesis principle. This cluster chemistry of nanosized species has its origin in the spectroscopical characterization of biatomic high-temperature molecules AlX (X = Cl, Br, I), whose reactivity was examined by means of matrix isolation techniques in our group several years ago. For instance, in solid argon, molecular AlF was found to react with O atoms to give O=AlF, the first compound with an Al=O double bond [12]; another example is the reaction between HCl and AlCl in solid argon leading to the extraordinary $HAlCl_2$ molecule [13]. Evidently, the roots of *metalloid* clusters are to be found in the area of pure basic research of smallest molecules. Subsequently, we transferred the synthesis of AlX from matrix conditions (μg- to mg-scale) to the preparative scale (g-scale) [14–16] and thus obtained metastable AlX solutions, which are unstable towards disproportionation to give AlX_3 and solid aluminum. This behavior is plausible due to the high temperature equilibrium (Scheme 1):

Under mild conditions (in the range of -78 to $+50$ °C) this disproportionation reaction can be controlled in a way that intermediates, such as Al_2X_4 species, can be trapped on the way to AlX_3 and *metalloid* Al clusters on the way to metal (Al_nX_m with $n > m$, resp. Al_nR_m upon substituting the halogenide by larger ligands R). In this review we will show that by simple variation of the reaction conditions the number of Al atoms in these *metalloid* clusters can be altered and that actually the topology of the Al metal with closed packing of Al atoms is already pre-formed in small molecular units. If, however, a variation from the close packing of Al atoms is observed, these clusters may give an indication for hypothetical new modifications of Al (cf. Chapter 3b).

$$3\ AlX_{(g)} \rightleftharpoons 2\ Al_{(s)} + AlX_{3\,(g)}$$

Scheme 1.

$$2\ Al_{(l)} + AlX_{3\,(g)} \rightleftharpoons 3AlX_{(g)}$$

Scheme 2.

2. Technique for the synthesis of metastable AlX solutions

The synthesis of *metalloid* AlX solutions (X = Cl, Br, I) is based on the primary generation of molecular AlX, which unlike the disproportionation to solid Al and AlX_3 will be thermodynamically stable only at a temperature of about 1000 °C and a pressure of 10^{-3} mbar, i.e. in principle AlX is synthesized by comproportionation (Scheme 2).

AlX is generated by passing gaseous AlX_3 over liquid Al. Lower temperatures such as 500 °C or higher pressures will move the equilibrium to the $Al + AlX_3$ side. Due to the difficulties in handling of AlX_3 HX proved to be more suitable for our synthesis technique. Passing HX over liquid aluminum contained in a graphite oven [15,16] leads to the formation of either AlX_3 at lower temperatures (Scheme 3) or immediately to the formation of AlX in the hot zone (Scheme 4).

The AlX molecules emitted from the graphite oven are frozen on a surface which is cooled to -196 °C under high vacuum conditions (10^{-5} mbar) before any disproportionation can occur. Simultaneously a mixture of solvents such as toluene/ether is condensed, so that the AlX molecules are embedded in a solid matrix of the solvent. The solvent has to fulfil the following criteria:

1. it has to be vaporizable easily at room temperature,
2. it should have good solving properties with a melting point as low as possible (e.g. toluene at $T = -83$ °C),
3. it should contain a donor component such as Et_2O or NEt_3, which can contribute to stabilize the AlX molecules.

$$Al_{(l)} + 3\ HX_{(g)} \xrightarrow{500\ °C} AlX_{3\,(g)} + 3/2\ H_{2\,(g)}$$

Scheme 3.

$$Al_{(l)} + HX_{(g)} \xrightarrow{1000\ °C} AlX_{(g)} + 1/2\ H_{2\,(g)}$$

Scheme 4.

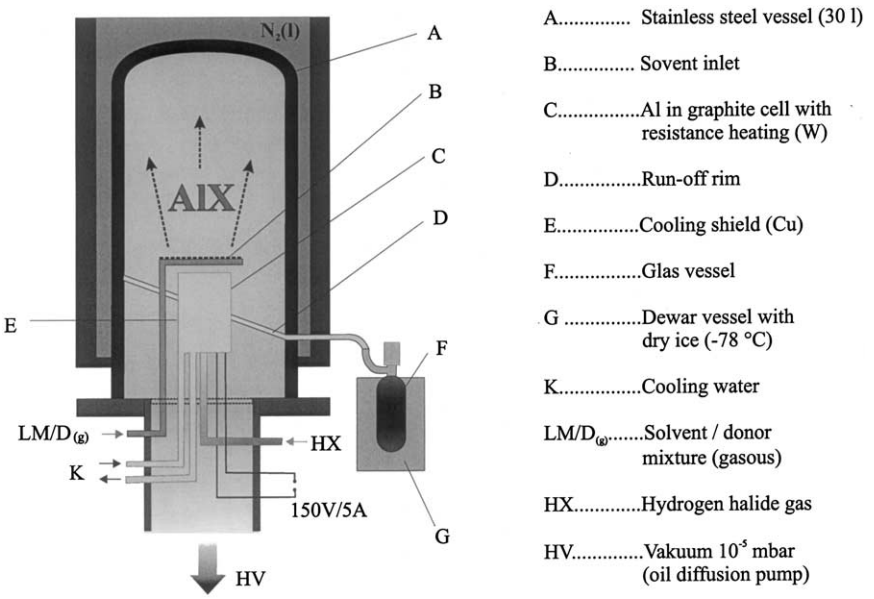

Fig. 1. Schematic illustration of the cocondensation apparatus for the generation of gaseous AlX high-temperature species.

For obvious reasons, H-acide solvents such as alcohol are omitted ($AlX + HOR \rightarrow HAlXOR$). Fig. 1 shows a sketch of the apparatus we used for this experiment. Upon removing the coolant a metastable AlX solution is obtained at a temperature of approximately -100 °C which is collected in a Schlenk vessel attached to the apparatus. This solution can be kept in a freezer (e.g. at -30 °C) without signs of disproportionation. These AlX solutions will be discussed with regard to the following questions.

1. Which species Al_nX_n are contained in the primary solution?
2. Which metathesis reactions to $(AlR)_n$ oligomers have been carried out?
3. Which Al_nX_m $(n > m)$ clusters are developed in the primary solution?
4. Which *metalloid* clusters will arise if both reactions—disproportionation and metathesis reaction—go off simultaneously?

For comprehensible reasons, we herein mainly focus on those *metalloid* clusters, which are listed under Section 3.4.

3. Subvalent Al compounds from AlX solutions

3.1. Al_nX_n species in the primary AlX solution

First of all, our special interest was focussed on the nature of the species existing in the primary AlX solutions. The detection and characterization of the dissolved species in AlX solutions proved to be difficult due to the lack of suitable analytical methods [17]. Thus, only crystalline products can be definitely characterized by X-ray structural analysis. We succeeded in synthesizing several crystalline $(AlX)_4$ tetramers which consist of a planar 4-membered ring of Al atoms stabilized by donor molecules: $Al_4X_4{\cdot}4D$ (X = Br, I; D = MeOPh, NEt_3, PEt_3) [18,19]. The molecular structure of $Al_4Br_4{\cdot}4NEt_3$ shown in Fig. 2 is representative for all these species.

As these compounds—in contrast to most other subvalent Al species—are soluble in toluene, they could be used as starting materials in substitution reactions with bulky ligands such as $Si(SiMe_3)_3$ or $N(SiMe_3)_2$ (cf. next chapters).

3.2. Metathesis reaction

An established strategy for the synthesis of subvalent aluminum compounds is the substitution of the halide by a ligand with great steric demand according to the metathesis in Scheme 5.

The driving force for the metathesis reaction is the formation of solid MX salt. So far, no monomeric AlR products [20], but several $(AlR)_4$ tetramers [21] are structurally characterized which implies that the metathesis of AlX species is accompanied by the forma-

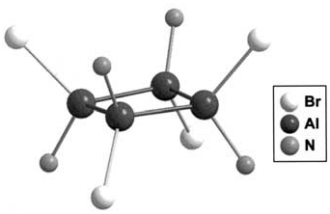

Fig. 2. Molecular structure of $Al_4Br_4{\cdot}4NEt_3$ (ethyl groups are omitted). The Al–Al bond length amounts to 2.653 Å.

$$AlX + MR \longrightarrow AlR + MX$$

(X = Cl, Br, I; M = Li, Na;

R = nonmetallic ligand, e.g. Cp = C_5H_5, Cp* = C_5Me_5)

Scheme 5.

tion of new Al–Al bonds. The ligand R must be able to (i) compensate partially the electron deficiency of the aluminum atoms, (ii) shield the 'metallic' skeleton from the insertion of further Al(I) species, and (iii) prevent reactions of O_2, e.g. via the formation of heterocuban-like $Al_4O_4R_4$ species [22].

3.2.1. $Al_4Cp^*_4$ (1)

Arenes with 6π electrons such as the substituted cyclopentadienyde anion $Cp^* = C_5Me_5$ are because of their sterical demand and their capability to act as electron donor well suited for stabilizing metals in low oxidation states. In 1986 Jutzi et al. synthesized the first monomeric Si(II) compound with a Cp* ligand. The analogous Al(I) compound, $Al_4Cp^*_4$ (**1**) (Fig. 3), prepared in our group 10 years ago [23], was the first example of a crystallographically characterized stable Al(I) compound at 300 K [24].

Compound **1** was prepared via a metathesis reaction between dissolved AlCl and $MgCp^*_2$ according to Scheme 6 [23,25].

The characteristic structural feature of **1** is the central Al_4 tetrahedron. The average Al–Al bond length amounts to 2.767 Å [23,26].

3.2.2. Al_4R_4

Other tetrameric Al(I) compounds could be stabilized by the ligands $R = Si^tBu_3$ (*supersilyl*), [22,27], $Si(SiMe_3)_3$ (*hypersilyl*) [26,28], $C(SiMe)_3$ (*trisyl*) [29]. The *supersilyl* and *hypersilyl* compounds exhibiting T_d symmetry are products of metathesis reactions of AlCl with LiR, the $Al_4\{C(SiMe)_3\}_4$ tetraedral species was synthesized by H.W. Roesky and co-workers by reductive elimination: $AlCl_2C(SiMe)_3$ is reduced by potassium while heating up to 100 °C [29]. Furthermore a new tetrahedral Al_4 species with two different substituents is known: $Al_4Cp^*_3N(SiMe_3)_2$ [30].

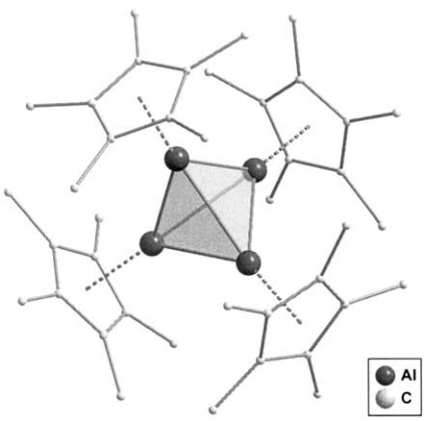

Fig. 3. Molecular structure of **1** (H atoms are excluded).

$$4\,AlCl + 4\,MgCp^*_2 \longrightarrow 2\,(MgCp^*Cl)_2 + Al_4Cp^*_4$$

Scheme 6.

3.3. Disproportionation

The disproportionation of Al^IX species finally results in the formation of Al(III) halides and aluminum metal. Upon warming a metastable AlX solution the disproportionation process is initiated which leads to intermediates Al_nX_m ($n > m$) with average oxidation states of the aluminum atoms between +1 and 0—in addition to species with oxidation states between +1 and +3 ($n < m$). Starting from Al^IX solutions we were able to trap the first aluminum subhalides with $n > m$ (oxidation state of Al below +1) and $n < m$ (oxidation state of Al below +3). In contrast to the other elements of the 13th Group, aluminum subhalides were not known before. Even M_2X_4 species, well-known for gallium (e.g. Ga_2Br_4 [31]) and boron (e.g. B_2Cl_4 [32]), have been obtained for the first time via the condensation technique described here: Al_2Br_4·2anisol which is shown in Fig. 4 [33].

3.3.1. Al_5Br_7·5THF (2)

By concentrating an AlBr·THF solution to half the volume at room temperature the solvent excess is removed. From this solution the mixed-valent compound $[Al_5Br_6{\cdot}6THF]^+[Al_5Br_8{\cdot}4THF]^-$ (**2a** and **2b**, respectively; Fig. 5 [34]) crystallized which represents the first salt-like subvalent Al species. The average oxidation state of the aluminum atoms is 1.4. Therefore, the disproportionation of AlBr has been stopped on the way to Al_2Br_4 and finally $AlBr_3$. Both ions consist of a central Al atom, which is tetrahedrally surrounded by four Al atoms. While the anion is coordinated by four $AlBr_2$·THF groups, in the cation two $AlBr_2$·THF and two AlBr·2THF units are arranged around the central Al atom.

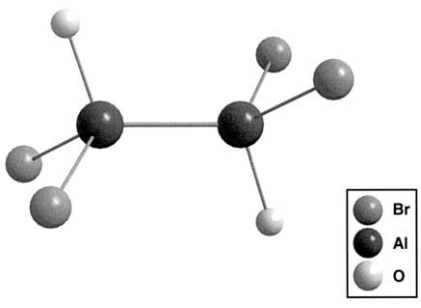

Fig. 4. Molecular structure of Al_2Br_4·2anisol.

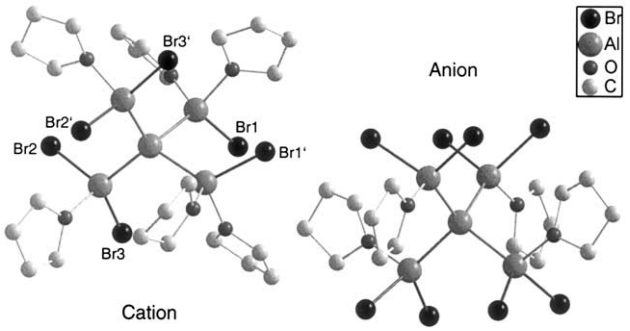

Fig. 5. Molecular structure of $[Al_5Br_6{\cdot}6THF]^+$ (**2a**; left) and $[Al_5Br_8{\cdot}4THF]^-$ (**2b**; right); without H atoms. Average bond lengths (Å): Al–Al: 2.532, Al–Br: 2.346, Al–Br2/Br2′: 2.380, Al–O: 1.884.

Starting from $GaCl{\cdot}Et_2O$ the analogous neutral compound, $Ga_5Cl_7{\cdot}5Et_2O$, with only one $GaCl{\cdot}2Et_2O$ unit and three $GaCl_2{\cdot}Et_2O$ units surrounding a central Ga atom can be synthesized [35].

A hypothetical mechanism for the formation of $E_5X_7{\cdot}5D$ (E = Al, Ga; X = Cl, Br; D = THF, Et_2O) species proceeds as follows. Starting from $E^{III}X_3{\cdot}D$ the comproportionation products $E_2X_4{\cdot}2D$ [36], $E_3X_5{\cdot}3D$ [37] and finally $E_5X_7{\cdot}5D$ can be formed by successive insertion of $E^{I}X{\cdot}D$ units [34].

3.3.2. $Al_{22}X_{20}{\cdot}12D$ [X = Br, D = THF (3a); X = Cl, D = THF (3b); X = Cl, D = THP (3c)]

Simultaneously with the synthesis of the halogen-rich oxidation product $Al_5Br_7{\cdot}5THF$ (**2**) we were able to isolate the halogen-deficient species $Al_{22}Br_{20}{\cdot}12THF$ (**3a**) as a product of a reduction [38]. From AlCl·D (D = THF, THP) solution the species $Al_{22}Cl_{20}{\cdot}12THF$ (**3b**) resp. $Al_{22}Br_{20}{\cdot}12THP$ (**3c**) could be isolated [39]. The $Al_{22}X_{20}{\cdot}12D$ molecules are the first polyhedral subvalent Al species with a novel type of structure in the chemistry of the 13th Group and, to the best of our knowledge, in the entire field of chemistry. Even for boron such types of molecule are not known, though solid boron exhibits B_{12} icosahedra that can be connected to further boron atoms. The result of the X-ray structural analysis of **3a** is shown in Fig. 6.

The common feature of **3** is a compressed icosahedral Al_{12} framework coordinated via Al–Al bonds by 10 $AlX_2{\cdot}D$ groups and two donor molecules for the stabilization of the 'naked' Al atoms at the top and the bottom. Therefore, the formula $Al_{12}[AlX_2{\cdot}L]_{10}{\cdot}2L$ is a more appropriate description for these compounds. The aluminum atoms' average oxidation state amounts to 0.91. The formal oxidation state of the 12 Al atoms of the icosahedral unit is 0, whereas the 10 halide bearing Al atoms have the oxidation state +2. Thus, the $Al_{22}X_{20}$ molecules can be considered as products of an *internal* disproportionation of 24 AlX units with formal elimination of Al_2Br_4.

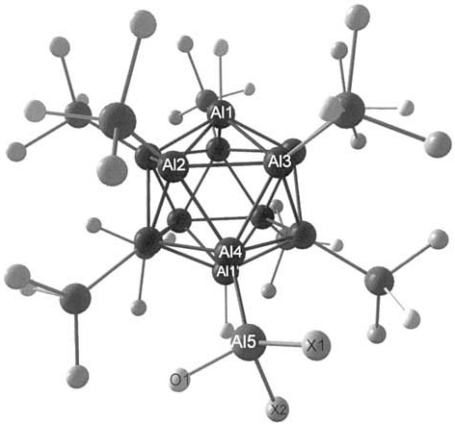

Fig. 6. Molecular structure of $Al_{22}Br_{20}{\cdot}12THF$ (**3a**). Only the O atoms of the donor molecules are illustrated. Selected Al–Al distances (Å): Al1–Al2: 2.650, Al2–Al3: 2.762, Al3–Al4: 2.692, Al4–Al5: 2.526.

The bonding situation can be described according to the Wade's rules: The 2 *para*-positioned Al atoms of the inner icosahedron can each contribute three electrons to the polyhedral framework, whereas the remaining 10 Al atoms, which bear AlX_2 groups, can only each provide two electrons. This 26 electron framework ($2n + 2$ with $n = 12$) corresponds to a *closo*-type molecule (icosahedron).

If we consider the icosahedral Al_{12} core as an intermediate on the way to the metal formation, the polyhedral coordination with the lack of a central atom doesn't fit with the *fcc* structure of aluminum metal. This arises the question if there might exist a second Al modification (β-Al) consisting of icosahedral Al_{12} entities—in contrast to the anticuboctahedral coordination pattern of *fcc* Al metal (α-Al). By means of ab inito full-potential calculations [39] we compared the *fcc* type and the hypothetical new modification which would be analogous to the β-rhombohedral boron. In order to minimize computing time we calculated the hypothetical β-Al type with the structure of α-B where B_{12} icosahedra are arranged as in a cubic close packing of spheres. The results principally show, that β-Al as the less compact allotrope (in comparison to *fcc* α-Al) is indeed energetically between **3** and Al metal (α-Al). By means of quantum chemical calculations it has been demonstrated that starting from AlCl about 80% of the disproportionation energy is gained by the formation of **3**. During the remaining energy drop the hypothetical β-Al, at first, and finally $AlCl_3$ and Al metal is formed as the bottom of the thermodynamical ladder. Thus, in principle it may be possible to reach this new Al allotrope via species like **3**.

In order to get a better insight in this novel type of clusters we performed some spectroscopic investigations.

In addition to the X-ray structural analysis, the different types of Al atoms in $Al_{22}Br_{20}{\cdot}12THF$ were validated by ^{27}Al MQMAS (Multiple Quantum Magic

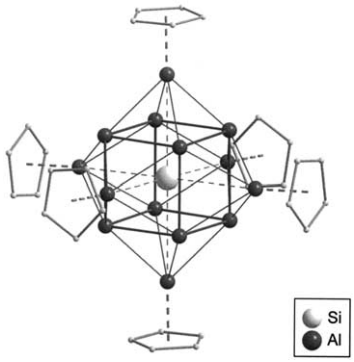

Fig. 7. Molecular structure of $SiAl_{14}Cp^*_6$ (**4**); methyl groups are excluded. Selected distances (Å): Al–Si: 2.49…2.51, Al_{cube}–Al_{cube}: 2.90, Al_{cube}–Al_{Cp^*} : 2.79…2.81.

Angle Spinning) spectroscopy and XPS. The three types of Al atoms—the exterior Al atoms which bear the AlX_2·THF groups, the 'naked' Al atoms and the THF coordinated—were found in the expected ratio of 10:10:2. The results of ^{27}Al MQMAS spectroscopy and XPS for **3a** and **3b** indicate that the 'quasi-naked' Al atoms, which are only coordinated by THF molecules are relatively close to those obtained for elemental aluminum. In contrast, the Al atoms in **3a** and **3b** which are neighbored to halide bearing Al atoms, in spite of their oxidation state of 0, behave differently. However, the two spectroscopic methods can distinguish between the Al atoms in their different chemical environments. Ab initio calculations lend further support for the experimental results. It was firstly demonstrated that XPS has the capacity to identify subvalent Al atoms by the measurement of the Al(I) compound $Al_4Cp^*_4$ [39].

Following the detailed quantum chemical calculations for **3** we tried to find a simple, general scheme to classify bonding in Al resp. Ga subhalides and partially substituted subhalides. We found, that in E_nX_{n+y} species there are $n-1/2y$ bonding MOs for E–E bonds [39,40]. Only for $y \leq 0$ there exist $2e^-$–2c bonds—e.g. Al_4X_4 [18,19]: four Al–Al bonds, Al_5X_7 [34]: four Al–Al bonds, $Al_5Cp^*_3I_6$ [41]: three Al–Al bonds, Al_2X_4 [33]: one Al–Al bond, AlX_3: no Al–Al bonds—while multiple center bonding is observed for $y < 0$ like in the species E_nX_{n-2}, e.g. $Al_{22}X_{20}$ [38,39]; E_nX_{n-4} ($\triangleq E_nX^{2-}_{n-2}$), e.g. $Al_{14}R_6I^{2-}_6$ [42] (cf. Chapter 4c); E_nX_{n-5}, e.g. $Al_{12}R_8^-$ [43] (cf. Chapter 4b). That means, a decreasing number of X ligands in comparison with the number of E atoms leads to an increasing quantity of multiple center bonds.

3.3.3. $SiAl_{14}Cp^*_6$ (4)

In this chapter the compound $SiAl_{14}Cp^*_6$ (**4**) is discussed together with the disproportionation products of halides because a precursor of **4** is (i) the $SiAl_4Cl_8$ halide [44] where a Si atom is tetrahedrally surrounded by four Al atoms and (ii) besides **4** Cl-containing species, e.g. $SiAl_{14}Cl_2Cp^*_6$, are generated [45] (cf. below). The species **4** is synthesized via two routs: (i) the reaction between $SiCp^*_2$ and AlCl and (ii) the reaction of $SiCl_4$ with AlCp*. The molecular structure of **4** is shown in Fig. 7.

$$Si(AlCl_2)_4 + 6\,AlCl \longrightarrow SiAl_8Cl_8 + 2\,AlCl_3$$

Scheme 7.

The main structural unit of **4** is a body-centered Al_8 cube with a Si atom in the center. The six faces of the cube are capped by six AlCp* groups.

Besides the X-ray characterization, the composition of the $SiAl_{14}$ cluster was validated by laser desorption mass spectroscopy. The existence of the molecular peak of **4** (M^+: 1217 m/e) in the mass spectrum demonstrated that **4** exhibits a relatively stable species which can be vaporized without decomposition [45].

Counting the electrons gave another hint of the stability of **4**. If the central Si atom contributes four electrons to the cluster core, each of the eight Al atoms of the $SiAl_8$ cube adds three electrons and the outer six Al atoms each contribute two electrons, then 40 electrons result for the whole cluster entity. Metal clusters with 40 electrons correspond to a stable *Jellium* state [46].

However, the X-ray structural determination indicated that besides **4** there exist a $SiAl_{14}Cl_2Cp^*_6$ (**4a**) species in the same crystal. Species like **4a** are plausible, since the above mentioned $SiAl_4Cl_8$ compound [44] may react with AlCl to generate $SiAl_8Cl_8$ which contains a cube of Al atoms in the first step (Scheme 7).

In a second step, the eight Cl atoms are removed by reacting with AlCl or AlCp* and the six AlCp* units are added to complete the formation of **4**. Thus, **4a** is an intermediate on this way to **4** [45] (Scheme 8) as shown by a DFT calculation.

The formula $SiAl_8(AlCp^*_6)$ emphasizes the different types of Al atoms: the six exohedral Al atoms have each a formal oxidation state of +1, i.e. **4** is formed via a disproportionation of Al(I) halides and, finally, a substitution with the help of the reductive capacity of AlCp*. In contrast, as the result of a disproportionation reaction, the oxidation state of the inner eight Al atoms is 0.

The structure of the inner $SiAl_8$ cube of **4** represents a cut-off from a *bcc* metal lattice—instead of the *fcc* lattice of metallic aluminum. In view of the Si atom in the center the $SiAl_8$ framework of **4** could be regarded

$$AlCp^* + SiAl_{14}Cl_2Cp^*_6\,(\mathbf{4a}) \longrightarrow SiAl_8(AlCp^*)_6\ (\mathbf{4}) + AlCp^*Cl_2$$

Scheme 8.

as a molecular Si–Al alloy. It seems to be promising if it would be possible to prepare more of similar clusters as molecular alloys perhaps even in the gas phase [47].

3.4. Metathesis and disproportionation reaction

The formation of the species discussed above is determined by one reaction type, i.e. metathesis ($AlX + MR \rightarrow AlR + MX$) [48] or disproportionation ($3AlX \rightarrow 2Al + AlX_3$) [49]. In this chapter we will describe the simultaneous process of both reactions. While the disproportionation reaction is controlling the growth of the cluster framework [50], the metathesis reaction is responsible for the structure of the ligand shell. When the ligand shell is completed, the cluster core is completely protected and, therefore, no further reaction can occur. Hence, disproportionation and metathesis reaction are competing and it depends on various parameters—like temperature, concentration of Al(I), AlX/MR ratio, solubility of the ligand compound MR, etc.—which one is finally predominant.

3.4.1. $[Al_7\{N(SiMe_3)_2\}_6]^-$ (5)

A mixture of $AlCl{\cdot}OEt_2$ solution and $LiN(SiMe_3)_2$ reacts to $[Al_7\{N(SiMe_3)_2\}_6]^-{\cdot}[Li(OEt_2)_3]^+$ [51] which precipitates while warming from -78 to 25 °C. Fig. 8a illustrates the molecular structure of **5**. The coordination of the central Al atom of **5** is similar to the cuboctahedral coordination of the Al atoms in the metallic *fcc* lattice (Fig. 8b).

The central 'naked' Al atom is quasi-octahedral coordinated by six AlR groups. The coordination may also be described as two Al_4R_3 tetrahedra which are vertices-bridged via the central Al atom, i.e. the *metalloid* cluster species **5** is an unique example for an element E to form E_4R_3 tetrahedra coordinated via a 'naked' E atom.

We performed SCF calculations on the ^{27}Al NMR shift of the Al atoms in **5**. The result for the central Al atom ($\delta^{27}Al = +652$) shows that the bonding situation is 'on the way' to the Al atoms in metallic aluminum ($\delta^{27}Al = +1640$). A description as a central Al^{3+} 'ion' sandwiched by two $Al_3R_3^{2-}$ [52] ligands could be excluded since such a central Al^{3+} species should exhibit a ^{27}Al NMR high field shift like $[AlCp^*_2]^+$ ($\delta^{27}Al = -84$) [53].

3.4.2. $[Al_{12}\{N(SiMe_3)_2\}_8]^{-\bullet}$ (6)

If a solution with the same starting materials employed for the synthesis of **5**, i.e. $AlCl{\cdot}OEt_2$ and $LiN(SiMe_3)_2$, is heated to 60 °C for 1 h, black crystals result which were identified by X-ray diffraction to be $[Al_{12}\{N(SiMe_3)_2\}_8]^-{\cdot}[Li(OEt_2)_3]^+$ (**6**; Fig. 9a) [43]. The coordination in this *metalloid* cluster—as in the case of **5**—is comparable with the topology of the Al atoms in metallic aluminum (Fig. 9b).

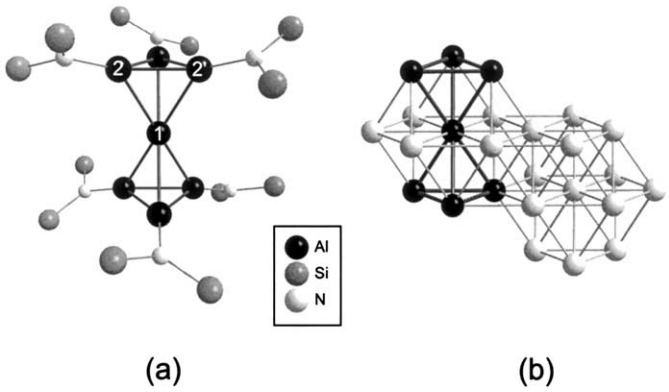

Fig. 8. (a) Molecular structure of $[Al_7\{N(SiMe_3)_2\}_6]^-$ (**5**); methyl groups are excluded. (b) Section of the cubic close packing of Al metal. The Al_7 unit is marked. Characteristic Al–Al distances (Å): Al1–Al2: 2.737, Al2–Al2′: 2.540.

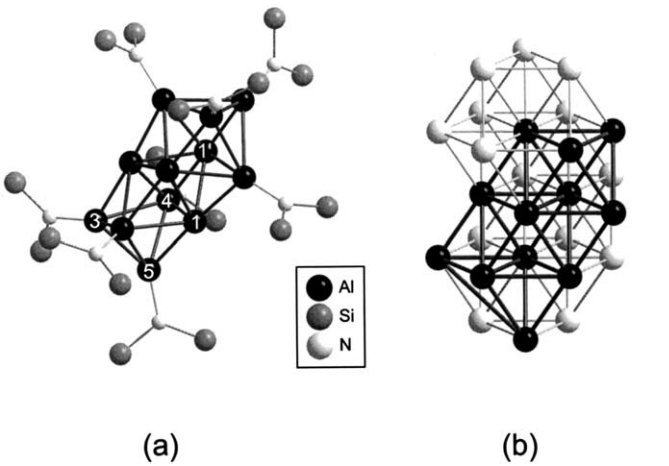

Fig. 9. (a) Molecular structure of $[Al_{12}\{N(SiMe_3)_2\}_8]^{-\bullet}$ (**6**); methyl groups are excluded. (b) Section of the cubic close packing of Al metal (the Al_{12} unit in black). Characteristic Al–Al distances (Å): Al1–Al5: 2.598, Al1–Al4: 2.788, Al3–Al5: 2.542, Al4–Al5: 2.818, Al1–Al1′: 2.629.

The odd number of electrons ($12 \times 3 + 1 = 37$) was confirmed by an ESR measurement.

Wiberg et al. synthesized a neutral $In_{12}R_8$ (**6a**; R = $Si'Bu_3$) cluster which contains a structurally identical metal framework like **6**, but the ligand sphere in **6a** is built up by the larger $Si'Bu_3$ instead of the $N(SiMe_3)_2$ ligand in **6** [54]. This result seems not to be unexpected, as the larger metal cluster framework of In_{12} can only be completely protected by ligands with a greater steric demand, i.e. the $Si'Bu_3$ group. In contrast, a similar Ga_{12} species has not been obtained so far. However, a $Ga_{12}R_{10}^{2-}$ species (R = $C_{13}H_9$, *fluorenyl*; $Ga_{12}R_8 + 2R^-$) formed an icosahedral framework [55]. This different behavior seems to be plausible since contrary to the metals aluminum and indium for gallium no *fcc*-like allotrope has been detected so far [56].

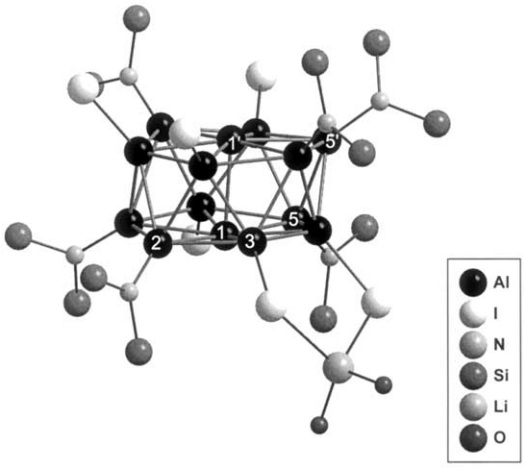

Fig. 10. Molecular structure of $[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ (**7**); methyl groups are excluded. Selected Al–Al distances (Å): Al1–Al3: 2.662, Al1–Al2: 2.690, Al1–Al1′: 2.728, Al1–Al3: 2.662, Al3–Al4: 2.597, Al5–Al5′: 2.910.

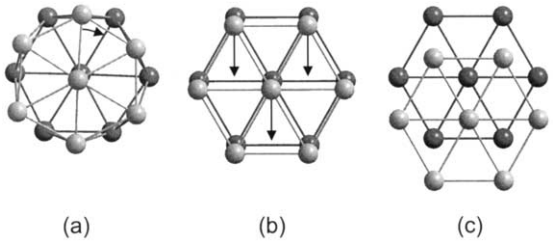

Fig. 11. Transformation of the arrangement of the Al atoms in **7** to that in the closest packing in Al metal: Rotation of the upper ring (a) by 30° leads to a structure (b) which can easily be transformed into a section of the closest packing of Al metal (c) by shifting in the layer of the page by (1/4, 1/4, 0).

3.4.3. $[Al_{14}I_6\{N(SiMe_3)_2\}_6]^{2-}$ (7)

If we use a mixture of Al(I) iodide instead of the Al(I) chloride with the same ligand and heat this solution several times shortly to 60 °C, black crystals grow after a few days at 7 °C. The X-ray structural analysis showed the compound to be $[Al_{14}\{N(SiMe_3)_2\}_6I_6Li(OEt_2)_2]^-\cdot[Li(OEt_2)_4]^+\cdot$toluene (**7**; Fig. 10) [42].

The main structural element of **7** is a twice capped hexagonal prism of Al atoms with a distorted D_{6h} symmetry, which resembles to the geometry of a wheel. There are two 'naked' Al atoms in the center of each Al_6 ring. The topology of the Al atoms in **7** may be regarded as a partially preformed metal structure. If we perform a rotation by 30° and a subsequent translation (Fig. 11), the closest packing of the Al metal structure results.

So far, the reactions of Al^IX with LiR ($R = N(SiMe_3)_2$) were characterized by a total substitution of the halide X against the $N(SiMe_3)_2$ group—cf. the products $[Al_7R_6]^-$ (**5**), $[Al_{12}R_8]^-$ (**6**) as well as $[Al_{69}R_{18}]^{3-}$ (**8**) and $[Al_{77}R_{20}]^{2-}$ (**9**) which will be presented in the following chapter. In contrast, $[Al_{14}I_6R_6]^{2-}$ (**7**) represents the first partially substituted *metalloid* aluminum halide cluster. Its formation seems to be plausible, as exclusively the less reactive AlI reacts in the way described above, while starting with AlCl a complete substitution results.

In **7** and **5** the average oxidation state of the Al atoms has the value of 0.71, i.e the disproportionation process of the primary monovalent Al species to aluminum metal is on the same stage for both compounds. Possibly, there could exist a common precursor like $Al_7R_3X_3^-$ that is quickly substituted for X = Cl to give the 'monomer' $Al_7R_6^-$ (**5**). For X = I the dimerization to $[Al_{14}I_6R_6]^{2-}$ (**7**) is obviously kinetically preferred.

In order to understand the bonding situation in **7**, we carried out DFT calculations on the model compounds $Al_7R_6^-$ (**5a**; $R = NH_2$), $Al_{14}R_{12}^{2-}$ (**7a**; $R = NH_2$) and an polyhedral isomer $Al_{14}R_{12}^{2-}$ (**7b**; $R = NH_2$), that arises by elongating the central Al atoms from the Al–Al distance 269.3 (**7a**) up to 490.3 pm (**7b**). According to these calculations the dimerization reaction **5a** → **7a** is exothermic (-275 kJ mol^{-1}). The species **7b** is calculated to be clearly destabilized with respect to **7a** ($+123$ kJ mol^{-1}). According to the Wade's rules, one expect a *precloso* or *nido* structure for $Al_{14}R_{12}^{2-}$. This doesn't match with **7a**, where neither a *precloso* nor a *nido* structure is realized. The higher stability of **7a** is accountable to the additional Al–Al bond between the central Al atoms.

In contrast, calculations on the similar $Ga_{14}R_{12}^{2-}$ compound [57] show that in this case a polyhedral species is energetically preferred compared with the 'wheel' structure of **7** [58]. This result demonstrates that for every element that structure among the *metalloid* clusters is preferred which exhibits similarities to the structure of the element and its possible allotropes. This is even true for elements with the same number of valence electrons since for *metalloid* clusters of B, Al and Ga containing the same number of metal atoms and ligands different structures of the metal core are obtained (cf. 3b: Al_{12} and In_{12} clusters).

3.4.4. $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ (8) and $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-\bullet}$ (9)

By suitable variation of the reaction parameters in the system $AlX\cdot OEt_2$ (X = Cl, I)/LiR ($R = N(SiMe_3)_2$)/toluene we succeeded in synthesizing nanosized *metalloid* Al clusters with an oxidation state of the Al atoms close to that of the metal.

From the reaction of $LiN(SiMe_3)_2$ with $AlCl\cdot OEt_2$ the *metalloid* cluster compound $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}\cdot[Li(OEt_2)_3]_3^+\cdot$6toluene (**8**; Fig. 12a) [59] was isolated, and, 5 years ago, using the same starting materials—with the exception that iodide instead of chloride was used—the largest *metalloid* Al cluster, $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-\bullet}\cdot[Li_2I(OEt_2)_5]_2\cdot$2toluene (**9**; Fig.

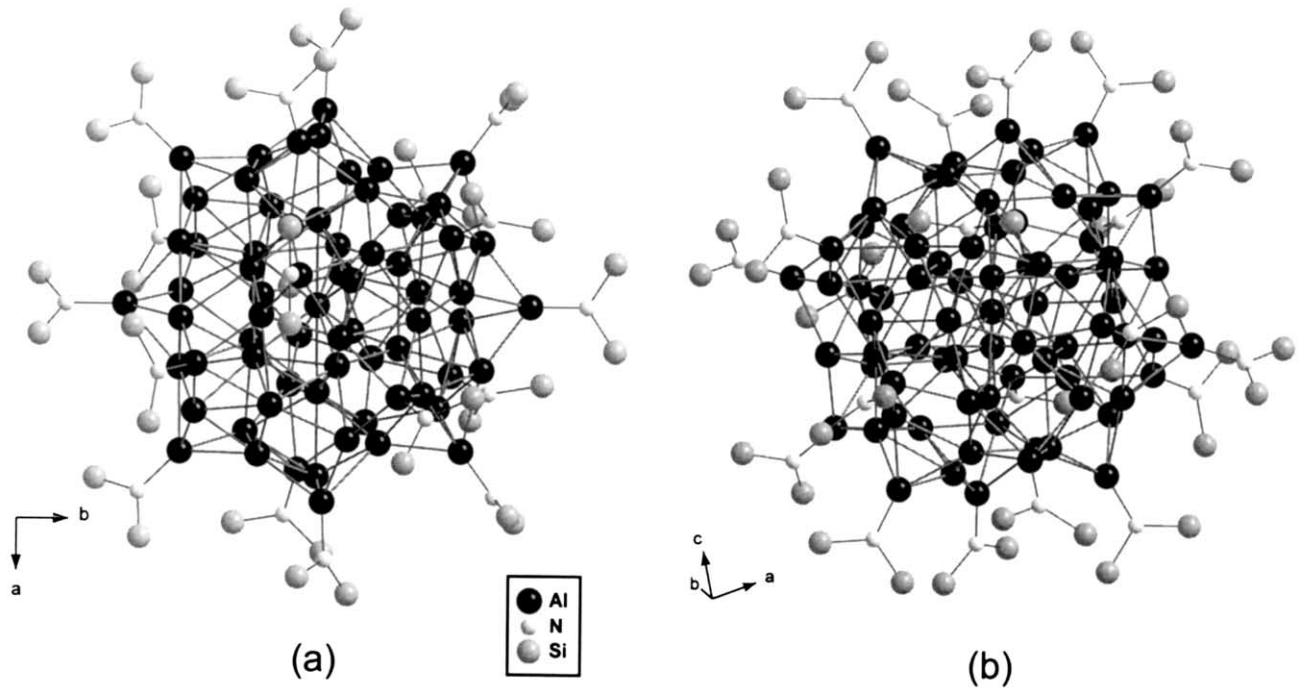

Fig. 12. Molecular structure of (a) $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ (**8**) and (b) $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-\bullet}$ (**9**); methyl groups are excluded.

12b) [4] was formed. The synthesis of **8** and **9** proceeded under similar preparative conditions: The reaction mixture was heated for 1 h to 60 °C and subsequently cooled either to +25 or to +7 °C. After a few days black crystals precipitated.

The lack of an ESR signal is in agreement to the even electron number of the $Al_{69}R_{18}^{3-}$ cluster core ($51 \times 3 + 18 \times 2 + 3 = 192$). In contrast, we proved the $Al_{77}R_{20}^{2-}$ cluster anion (electron number: $57 \times 3 + 20 \times 2 + 2 = 213$) to be a radical species. After numerous runs of the cluster synthesis we collected enough crystalline material of **9** to perform a measurement of the magnetic moment (and with it the susceptibility) with a SQUID magnetometer (Superconduction Quantum Interference Device) which demonstrated the paramagnetic character of **9** [57].

The common characteristic of **8** and **9** is a 3-shell framework of Al atoms with the 3rd shell consisting of $AlN(SiMe_3)_2$ units, which are arranged so that a complete protection of the cluster core is achieved. To emphasize the number of 'naked' Al atoms, which have exclusively Al–Al contacts, we write the modified formula $[Al_{51}(AlR)_{18}]^{3-}$ (**8**) resp. $[Al_{57}(AlR)_{20}]^{2-}$ (**9**). Fig. 13 illustrates the shell-like structure of the Al frame of **8** and **9**.

The *metalloid* aluminum cluster anions **8** and **9** represent intermediate stages of the disproportionation of Al(I) compounds to aluminum metal and Al(III) compounds. Although **8** and **9** show similarities in the shell-like structure, the Al/R ratio (**8**: 3.83, **9**: 3.85) and, consequently, the oxidation state (**8**: +0.217, **9**: +0.234), there are significant differences in the particular topology as well as in the bonding relations.

The geometries of both clusters differ already in the inner shell: In each cluster the central Al atom is coordinated by 12 Al atoms. The first shell of **8** exhibits a distorted D_{5h} symmetry, while the inner shell of **9** can be described as a polyhedral icosahedron, which is distorted in direction of a cuboctahedron. The second shell of **8** consists of 38 Al atoms, that of **9** is built up by 44 Al atoms. The outer shell contains 18 Al atoms (**8**) resp. 20 Al atoms (**9**).

In Table 1 the average Al–Al distances for **8** within and between the shells are summarized, the analogous values of **9** are given in Table 2.

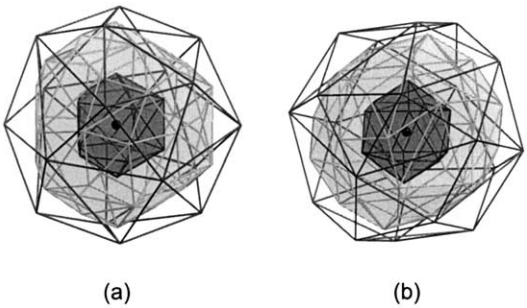

Fig. 13. (a) Al frame of **8** (from central atom to exterior); 1st shell: 12 Al atoms, 2nd shell: 38 Al atoms, 3rd shell: 18 Al atoms. (b) Al frame of **9** (from central atom to exterior): 1st shell: 12 Al atoms, 2nd shell: 44 Al atoms, 3rd shell: 20 Al atoms. Each illustration with the same orientation as in the corresponding comprehensive view (**8**: Fig. 12a, **9**: Fig. 12b) The Al–Al bonds between the shells are omitted for a better visualization of the shell-like structure.

Table 1
Al–Al distances within and between (e.g. 1 → 2) the Al_{69} cluster shells

Shell	Center	1	1 → 2	2	2 → 3	3
Atoms	1	12		38		18
c.n. [a]	12	9 [b]	4	7 [c]	2	(4) [d]
$d_{average}$ (Å)	2.783	2.782	2.783	2.797	2.683	(5.103)

[a] c.n., coordination number. Number of the next atoms surrounding the central atom and forming the 1st shell ('Center'; column 2), coordination of each of the atoms in the 1st shell by the atoms in the 2nd shell ('1 → 2'; column 4) etc. For the coordination within the 1st resp. 3rd shell (column 3 resp. 5) a total c.n. is given. All numbers represent average values (except for column 2).

[b] The total c.n. of an atom in the 1st resp. 2nd shell is the sum of the next atoms within the same shell and the next atoms of the neighboring shells. Total $c.n. = c.n._{1.shell \rightarrow central\ atom} + c.n._{1.shell} + c.n._{1 \rightarrow 2.\ shell} = 1+4+4 = 9$.

[c] Total $c.n. = c.n._{2 \rightarrow 1.shell} + c.n._{2.\ shell} + c.n._{2 \rightarrow 3.shell} = 1.5+3.5+2 = 7$.

[d] There is no significant bonding between the pairs of Al atoms within the 3rd shell.

Only atoms with a distance ranging from 2.5 to 3.0 Å from a particular atom were included and considered for the coordination number.

Table 2
Al–Al distances within and between (e.g. 1 → 2) the Al_{77} cluster shells

Shell	Center	1	1 → 2	2	2 → 3	3
Atoms	1	12		44		20
c.n.	12	9 [a]	4	7 [b]	2	(4) [c]
$d_{average}$ (Å)	2.762	2.795	2.818	2.756	2.688	(5.019)

[a] Total $c.n. = c.n._{1.shell \rightarrow central\ atom} + c.n._{1.shell} + c.n._{1 \rightarrow 2.shell} = 1+4+4 = 9$.

[b] Total $c.n. = c.n._{2 \rightarrow 1.shell} + c.n._{2.shell} + c.n._{2 \rightarrow 3.shell} = 1+4+2 = 7$.

[c] There is no significant bonding between the pairs of Al atoms within the 3rd shell.

Only atoms with a distance ranging from 2.5 to 3.0 Å from a particular atom were included and considered for the coordination number.

The distances within the 2nd shell (i.e. including the center and the 1st shell) are almost identical in **8**, but not in **9** where the distances slightly increase in the direction from the center to the 2nd shell. Both clusters have their shortest Al–Al bonds between the 2nd and the 3rd shell, which means that in the outer sphere the bonding situation becomes more similar to that of molecular bonded Al(I) compounds where the average oxidation number of the Al atoms is closer to +1 [60].

The most obvious difference between **8** and **9** can be found in the second shell (38 resp. 44 Al atoms). In the space-filling model (Fig. 14) two significant gaps in the second shell of **8** stand out, so that a closer look on the first shell is possible; in **9** the second shell encloses completely the inner 12-membered shell.

While according to the MACKAY closed-shell model an icosahedron is surrounded by a 42-membered regular shell this could not be expected to be the case for **8** and **9**, as their inner shells possess no I_h symmetry. The 1st shells may be described as a decahedron (**8**) or a distorted icosahedron (**9**). These significant changes of details within the topology of **8** and **9** could only be extracted from the X-ray structural analysis, since other methods normally used in nano-technology like AFM would not be able to give this information, which may be essential for the interpretation of other physical properties. The measurement of these properties (e.g. electrical conductivity) might be the next step in order to understand the intermediate character of bonding in **8** and **9**. However, handling of *metalloid* clusters like **8** and **9** is by far not trivial since they have pyrophoric properties in the presence of oxygen.

In order to get a feeling for the topology of the *metalloid* clusters **8** and **9** with respect to the final

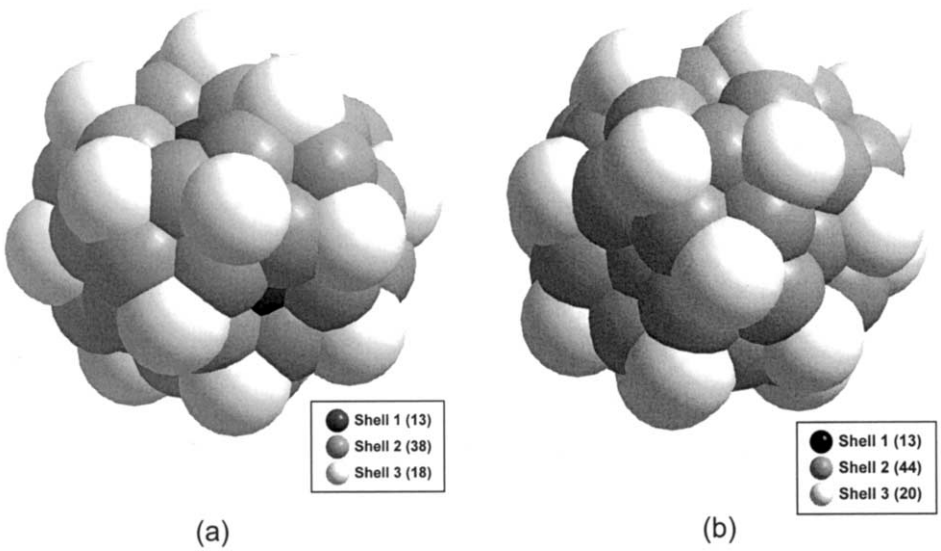

Fig. 14. Space-filling model of **8** (a) and **9** (b). Only Al atoms are shown.

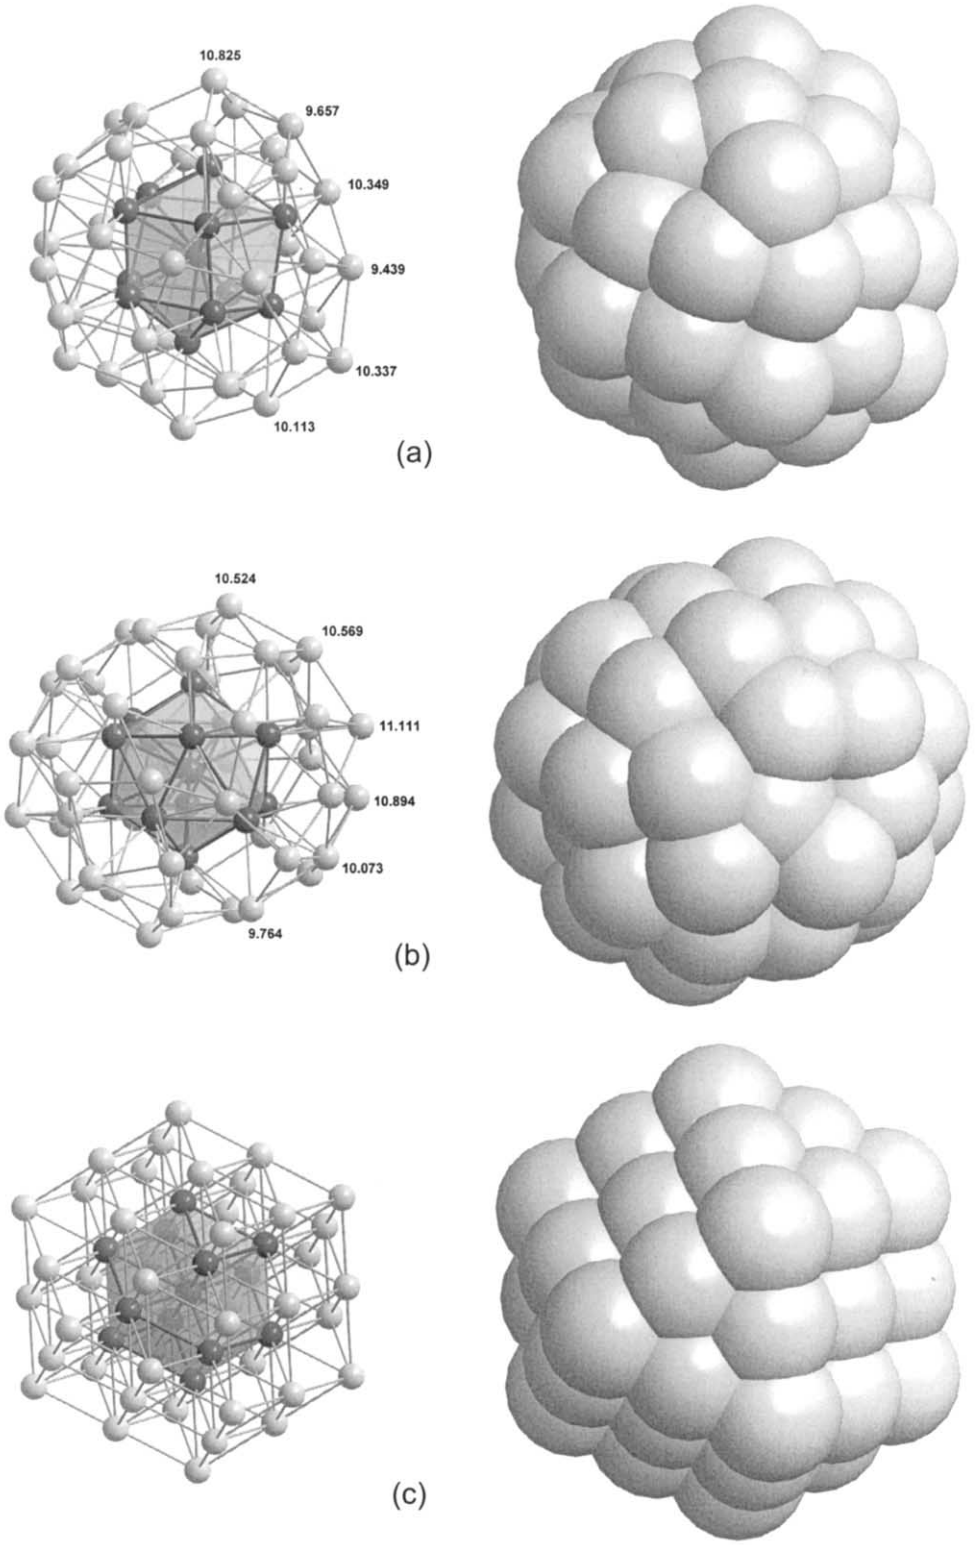

Fig. 15. Ball-and-stick models and space-filling models of the Al_n clusters. (a) shells $1 + 2$ of **8a**: Al_{51} ($1 + 12 + 38$ Al atoms); (b) shells $1 + 2$ of **9a**: Al_{57} ($1 + 12 + 44$ Al atoms); (c) hypothetical Al_{55} cluster section (**10**) from the *fcc* lattice of Al metal ($1 + 12 + 42$ Al atoms). For Al_{51} and Al_{57} the different diameters are shown in the illustration.

product Al metal, which is formed in every experiment, we calculated the atomic volume of the 'naked' Al atoms in **8** and **9** and compared it with the volume of a hypothetical molecular section of the *fcc* Al metal lattice [59]. For a better comparison the same charge of -3 was assumed for the 'naked' Al_{51} (**8a**; $1 + 12 + 38$

Al atoms from **8**; Fig. 15a) and Al_{57} (**9a**; 1 + 12 + 44 Al atoms from **9**; Fig. 15b) species and for a Al_{55} species (**10**; 1 + 12 + 42 Al from α-Al; Fig. 15c).

For **8a** and **9a** the topology within the experimentally determined structure of **8** and **9** was the basis for a singe point SCF calculation and for **10** the coordinates of Al metal. As a result, the atomic volume decreases in the order **8a** (29.61 Å), **9a** (29.51 Å^3) and **10** (29.21 Å^3). That means the driving force for the formation of the bulk metal is the energy gained by the most compact arrangement with the highest possible c.n. of 12 even if the distances are large. The intermediates **8a** and **9a** are less compact with smaller, more molecular distances and lower c.n. (cf. Tables 1 and 2).

4. Conclusions and outlook

On the way from metastable AlX solutions to the bulk metal only a small variation of the reaction parameters (e.g. temperature, concentration of the Al(I) species etc.) in the system $AlX{\cdot}OEt_2$ (X = Cl, I)/LiR (R = $N(SiMe_3)_2$)/toluene leads to the different crystalline *metalloid* aluminum clusters **5**, **6**, **7**, **8**, and **9** which all are protected by the $N(SiMe_3)_2$ ligand. Further examples with other ligands are necessary to understand the influence of the ligand type on the cluster size. Besides the topology of these *metalloid* clusters their physical properties (e.g. conductivity, UV–Vis spectra) will be important to understand the intermediate character on the way to the metal. Additional support comes from theoretical calculations, e.g. by means of band structure calculations, which recently have been performed for **9** [61]. Within further experimental and theoretical investigations there may be expected surprises such as the superconductivity of the $Ga_{84}R_{20}^{4-}$ compound [10,62] as the largest structurally characterized *metalloid* cluster with respect to the 'naked' metal atoms. Thus, studies starting with pure fundamental chemistry have opened a novel field in cluster chemistry, which may give essential impulses to applied science, e.g. in nano-technology.

Understanding the electron counts of aluminum metalloid clusters

Wai Han Lam, Zhenyang Lin *

Department of Chemistry, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong

Received 10 July 2001; accepted 27 November 2001

Abstract

The structures and bonding of several Al metalloid clusters have been analyzed with the aid of density functional theory calculations. These clusters include $[Al_7\{N(SiMe_3)_2\}_6]^-$ (**1**), $[Al_{12}\{N(SiMe_3)_2\}_8]^-$ (**2**), $[Al_{22}Br_{20}\cdot 12THF]$ (**3**) $[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ (**4**), $Al_{14}(\mu_8\text{-Si})Cp^*_6$ (**5**), $[(AlEt)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-H})]$ (**6**), $[(AlMe)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}C{\equiv}CPh)]$ (**7**) and $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-H})_2]$ (**8**). In this paper, an attempt has been made to illustrate the relationship between the observed geometry and electron counts for these metalloid clusters. © 2002 Elsevier Science Ltd. Keywords: Electron counts; Aluminum; Metalloid clusters

1. Introduction

In recent years, the chemistry of the heavier group 13 elements has made rapid progress. Through the excellent work of Schnöckel, Uhl and their coworkers over the last decade, numerous high nuclearity aluminum and gallium clusters have been synthesized and structurally characterized [1–13]. Amazing examples include the most recently reported $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ [6], $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ [7] and $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$ [10]. These high nuclearity clusters are classified as metalloid clusters in which the number of metal–metal contacts far exceeds the number of metal–ligand interactions. Unlike the boron clusters, the majority of these group 13 metalloid clusters, which show much more versatile structural varieties, do not follow Wade's electron counting rules [14].

In view of the abundant knowledge on the synthetic routes to these clusters and structural data available [15], we still lack the understanding of their electronic structures. A general understanding of their electronic structures has not emerged although several theoretical calculations have been done [1–5,9a]. In an effort to establish relationships between the observed geometries and electron counts for these metalloid clusters, we attempt to analyze several recently reported high nuclearity aluminum clusters in this paper. These clusters include $[Al_7\{N(SiMe_3)_2\}_6]^-$ **(1)** [3], $[Al_{12}\{N(SiMe_3)_2\}_8]^-$ **(2)** [5], $[Al_{22}Br_{20}\cdot 12THF]$ **(3)** [4], $[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ **(4)** [2], $Al_{14}(\mu_8\text{-Si})Cp^*_6$ **(5)** [1], $[(AlEt)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-H})]$ **(6)** [9a], $[(AlMe)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}C{\equiv}CPh)]$ **(7)** [9a] and $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-H})_2]$ **(8)** [9a] (see Fig. 1). With the aid of molecular orbital calculations, our approach is to analyze the electronic structures of these clusters one by one in terms of concepts of orbital interactions [16] and the knowledge we have had on the cluster bonding [17]. We hope that the discussion below will provide a better insight into our understanding of these clusters in a simple and understandable manner. We also hope that the analyses provided here will be used as a starting point to further understand the even more complicated and versatile clusters of the analogous gallium element. Because of their structural versatility and complicated electronic behavior, electron counts of gallium clusters can be very different when compared to these of aluminum clusters. Therefore, in this paper we limit our discussion to the clusters of aluminum except in Section 3.5 where some comments are given to $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$.

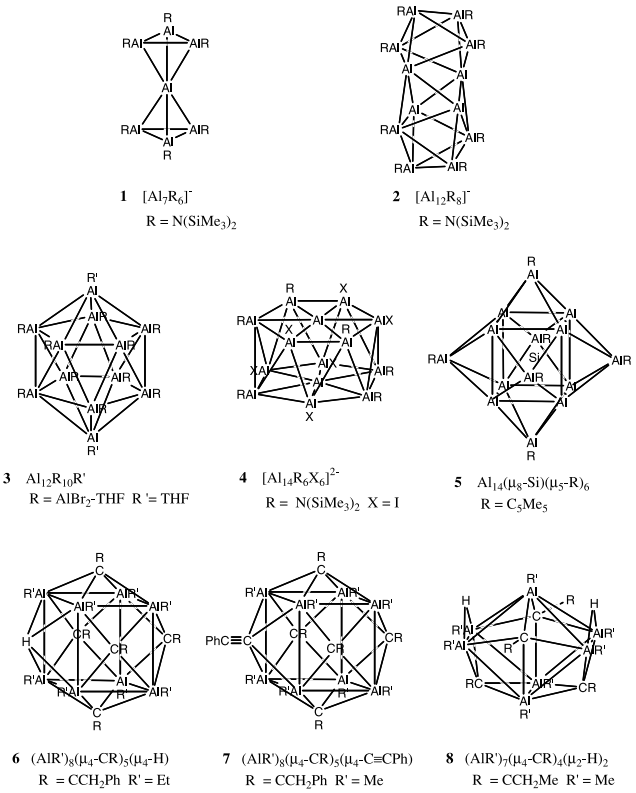

Fig. 1. Structures of various Al metalloid clusters.

2. Molecular orbital calculations

Density functional theory calculations at the Becke3LYP (B3LYP) level [18] have been performed to study the detailed electronic structures of various aluminum clusters. Geometry optimizations have been done for the following model clusters $[Al_7(N(H_2)_6]^-$ (**1a**), $[Al_{12}(NH_2)_8]^-$ (**2a**), $[Al_{14}(NH_2)_6I_6]^{2-}$ (**4a**), $Al_{14}(\mu_8\text{-Si})Cp_6$ (**5a**), $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-H})]$ (**6a**), $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-C}\equiv\text{CH})]$ (**7a**) and $[(AlMe)_7(\mu_4\text{-}CCH_3)_4(\mu_2\text{-H})_2]$ (**8a**). The effective core potentials (ECPs) of Hay and Wadt with double-ξ valence basis set (LanL2DZ) [19] were used to describe main group atoms of period three with polarization functions for Al ($\xi_d(Al) = 0.198$) and Si ($\xi_d(Si) = 0.262$) atoms [20], while the standard 6-31G basis set [21] was used for all other atoms. For model complex $Al_{14}(\mu_8\text{-Si})Cp_6$ (**5a**), the STO-3G basis [22] set was used for C and H of the Cp ligands. The size of the cluster together with the limited computational resource prevents us from using a better basis set. The use of the smaller basis set for **5a** does not affect our qualitative discussion in the text, which will be seen below.

All calculations were performed with the use of GAUSSIAN 98 [23] on Silicon Graphics Indigo^2 workstations and PC Pentium III computers. The electron density analysis was carried out with MOPLOT 2.4 [24] and the natural bond orbital (NBO) analysis was performed by using the NBO program [25] associated with the GAUSSIAN 98 package. The molecular orbitals obtained from the B3LYP calculations were plotted using the MOLDEN 3.7 program [26].

3. Results and discussion

3.1. $[Al_7\{N(SiMe_3)_2\}_6]^-$

In $[Al_7\{N(SiMe_3)_2\}_6]^-$ (**1**), the seven Al atoms form a vertex-shared bitetrahedral structure and the six $-N(SiMe_3)_2$ groups are bonded to the six non-shared Als (see Fig. 1). The bonding of this cluster has been described as follows [3]. An Al^{3+} center binds two $[Al_3\{N(SiMe_3)_2\}_3]^{2-}$ units in a ferrocene-type fashion. The approximately planar $[Al_3\{N(SiMe_3)_2\}_3]^{2-}$ structural unit conforms to the aromatic electronic structure having two π electrons in addition to three Al–Al σ bonds. Geometry optimization on the model complex $[Al_7(NH_2)_6]^-$ (**1a**) gives the Al–Al bond distances consistent with the experimental data (see Table 1). Fig. 2 shows the spatial plots of the molecular orbitals accommodating the eight pairs of metal electrons. These eight Al–Al bonding molecular orbitals correspond to the in-phase and out-of-phase combinations of orbitals derived from the two $[Al_3(NH_2)_3]^{2-}$ fragments. Each fragment contributes four orbitals, i.e. three Al–Al σ bonds and one delocalized π bond. The role of the central aluminum is to use its s and p orbitals to stabilize some of the eight Al–Al bonding molecular

Table 1
The calculated Al–Al bond distances and Wiberg bond indices for various model complexes

Model clusters		Al–Al bond distances (Å)	Wiberg bond indices (WBI)
$[Al_7(NH_2)_6]^-$	**1a**	2.554–2.806 (2.540–2.737)	0.59–0.89
$[Al_{12}(NH_2)_8]^-$	**2a**	2.532–2.785 (2.542–2.818)	0.37–0.76
$[Al_{14}(NH_2)_6I_6]^{2-}$	**4a**	2.671–2.818 (2.570–2.910)	0.37–0.60
$Al_{14}(\mu_8\text{-Si})(\mu_5\text{-Cp})_6$	**5a**	2.869–2.906 (2.786–2.912)	0.32–0.42
$(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-H})$	**6a**	2.606–2.845 (2.585–2.858)	0.08–0.09
$(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-C}\equiv\text{CH})$	**7a**	2.582–2.849 (2.603–2.913)	0.06–0.08
$(AlMe)_7(\mu_4\text{-}CCH_3)_4(\mu_2\text{-H})_2$	**8a**	2.608–2.881 (2.569–2.816)	0.07–0.11

For comparison, the corresponding experimental Al–Al bond distances are given in parentheses.

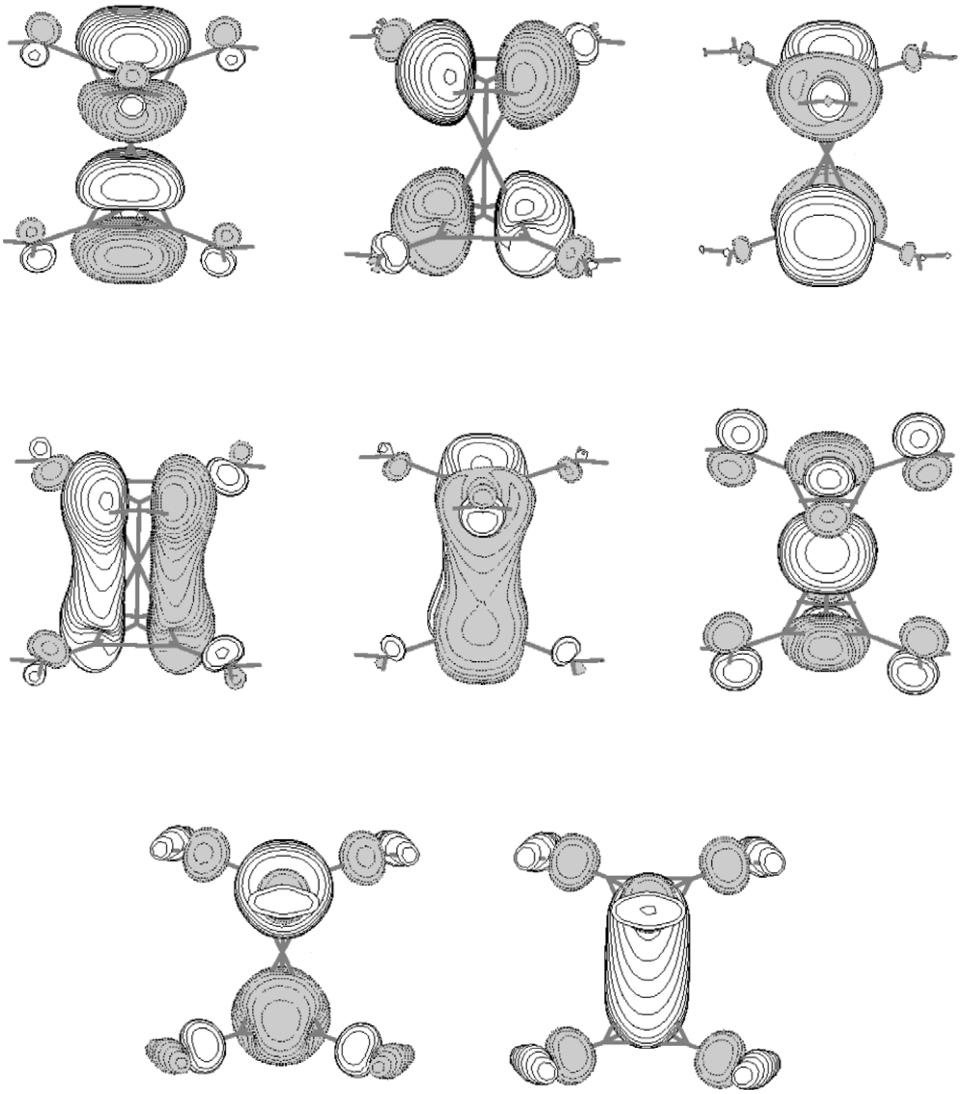

Fig. 2. Spatial plots of the eight skeletal Al–Al bonding molecular orbitals for model complex $[Al_7(NH_2)_6]^-$. The highest occupied molecular orbital is on the top of the left hand side. The orbital energies decrease from left to right and from top to bottom.

orbitals. These results support the qualitative bonding description given by Schnöckel and his coworkers [3].

3.2. $[Al_{12}\{N(SiMe_3)_2\}_8]^-$

Similar to $In_{12}(SiBu^t_3)_8$ [27], $[Al_{12}\{N(SiMe_3)_2\}_8]^-$ (**2**) [5] adopts a stretched ellipsoid structural shape among the 12 Al atoms. The structure can also be described as linking two distorted octahedral $Al_6\{N(SiMe_3)_2\}_4$ fragments in a staggered fashion (see Fig. 1). Each distorted octahedral fragment breaks an Al–Al bond. Geometry optimization was performed for the model cluster $[Al_{12}(NH_2)_8]^-$ (**2a**). Consistent with an early calculation [5], the calculated Al–Al distance together with the experimental data are shown in Table 1 and the calculated geometry reproduces its experimental structure quite well. To better understand the metal–metal interactions, it is more convenient if we consider the metal–metal molecular orbitals in terms of the two distorted octahedral fragments. Because of the mixing of N's p orbitals into the $[Al_{12}(NH_2)_8]^-$ skeletal molecular orbitals, we employ a simpler model $[Al_{12}H_8]^-$ here to illustrate the orbital interactions between the two distorted octahedral fragments. Fig. 3 shows such a qualitative orbital interaction diagram. The left and right columns in the figure give the fragment orbitals for the two distorted octahedral units arranged in a staggered fashion. Each fragment has nine orbitals shown in the figure. These nine fragment orbitals correspond to seven skeletal orbitals, commonly found for an octahedral cluster (e.g. $[B_6H_6]^{2-}$) [28], and two out-pointing orbitals based on the two Al atoms which do not have terminal H atoms. The central column represents the resulting MOs. In the central column of Fig. 3, the bottom ten MOs are simply the results of addition from the two fragments. The top eight MOs form the impor-

tant part derived from the orbital interactions between the two fragments. Among the top eight MOs, four are bonding and four antibonding. One can envisage the situation as follows. Each fragment uses the two out-pointing fragments' orbitals to interact/stabilize the two high-energy skeletal fragment orbitals from the other fragment. These mutual orbital stabilizing interactions between the two fragments give rise to four bonding and four antibonding MOs. The total number of the skeletal electrons is 28 for $Al_{12}H_8$ [or $[Al_{12}\{N(SiMe_3)_2\}_8]$ or $In_{12}(SiBu^t_3)_8$]. The electron count of 14 skeletal electron pairs represents the simple addition of electron counts from two octahedral clusters. In order to achieve this simple addition, the four metal atoms in the middle part of the cluster do not have a terminal R group. $[Al_{12}\{N(SiMe_3)_2\}_8]^-$ (**2**) represents a case when the lowest of the four antibonding orbitals is singly occupied. That there is no In analog anionic species implies the higher electronegativity of Al in comparison to In.

3.3. $[Al_{22}Br_{20}\cdot 12THF]$, $[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ and $Al_{14}(\mu_8\text{-}Si)Cp^*_6$

According to Schnöckel and his coworkers, $[Al_{22}Br_{20}\cdot 12THF]$ (**3**) (see Fig. 1) can be reformulated as $Al_{12}\{AlBr_2(THF)\}_{10}(THF)_2$ [4]. The central Al_{12} unit can be described as an icosahedral. The cluster is isoelectronic to $[Al_{12}Bu^i_{12}]^{2-}$ [29] and conforms to Wade's $n+1$ rule if the ten $AlBr_2(THF)$ moieties and the two THF solvent molecules are considered as ligands forming single bonds with the central Al_{12} structural unit. Each $AlBr_2(THF)$ moiety contributes one electron and each THF donates two electrons to the electron count of the cluster. The total electron count of 50 $(=10+4+3\times 12)$ can be derived, giving the $4n+2$ (here $n=12$) electrons. Therefore, the bonding of this cluster can be easily understood.

$[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ **4** has been described as two staggered, approximately Al-centered Al_6 rings (see Fig.

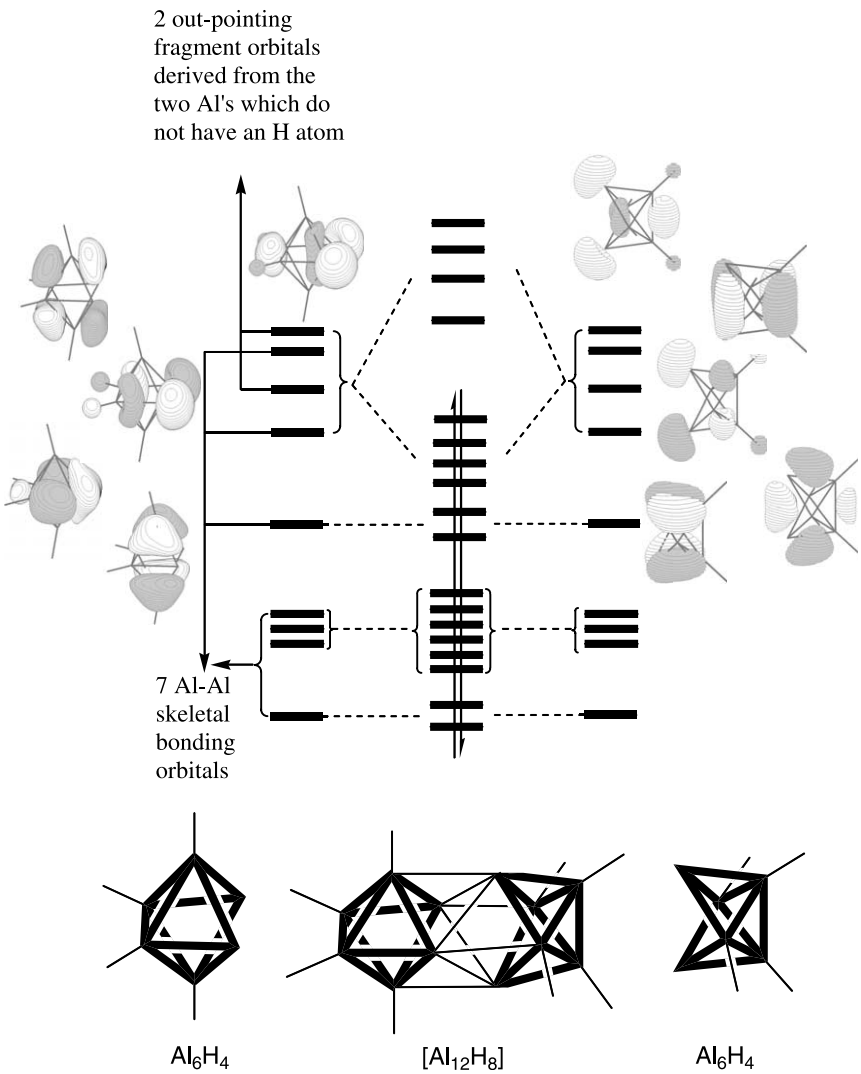

Fig. 3. A schematic diagram showing the orbital interactions between two perpendicular distorted octahedral Al_6H_4 fragments for $[Al_{12}H_8]$.

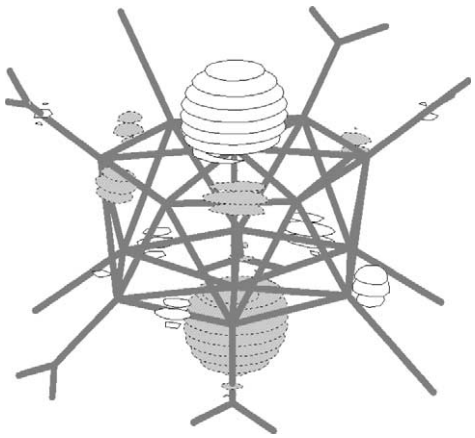

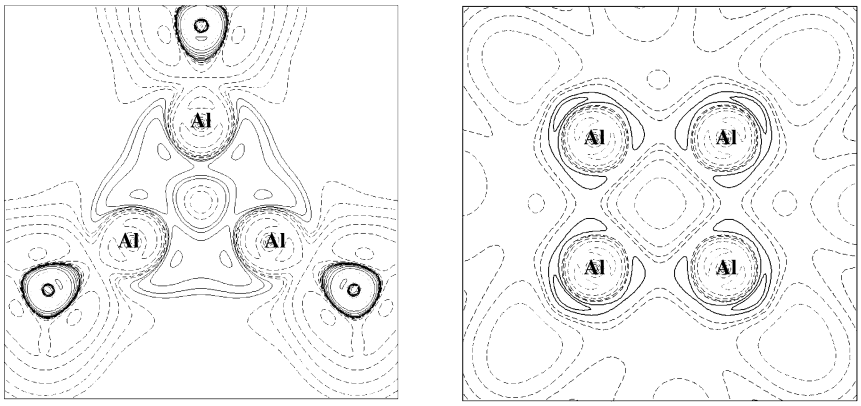

Fig. 4. Spatial plot of the lowest unoccupied molecular orbital (LUMO) for model complex $[Al(NH_2)_6I_6]^{2-}$.

1). The central Al atoms do not have ligands associated with them, while each of the remaining Al atoms is coordinated by either iodide or $N(SiMe_3)_2$ ligands. Geometry optimization on the model complex $[Al_{14}(NH_2)_6I_6]^{2-}$ (**4a**) gives the Al–Al bond distances consistent with the experimental data (see Table 1). The total electron count of the cluster is 56 ($=3\times14+6+6+2$). Instead of conforming to the $4n+2$ rule, the cluster has an electron count of $4n$. In the structural studies of neutral silicon clusters, it has been concluded that the spherical (deltahedral) geometries exhibited by boranes, characterized by $4n+2$ electrons, are not stable for Si_n which have $4n$ electrons. In order to achieve a stable electron configuration with a substantial HOMO–LUMO gap for these $4n$-electron clusters, two mechanisms have been proposed. One is oblate distortion from the spherical polyhedron to remove one axially antibonding orbital from the bonding region and the other is capping of a suitable spherical polyhedron [30]. Clearly, cluster $[Al_{14}\{N(SiMe_3)_2\}_6I_6]^{2-}$ (**4**) adopts the former mechanism by forming an oblate structure derived from a bicapped hexagonal antiprism. Due to the closer contact of two apical Al atoms in oblate structure, the out-of-phase combination MO from the two apical Al atoms in the bonding region will be pushed up. Indeed, this MO can be found in the LUMO region in model cluster $[Al_{14}\{NH_2)_6I_6]^{2-}$ (**4a**) (see Fig. 4). One may ask why a spherical polyhedron cannot be formed by adding two electrons or two R groups to the cluster framework. In order to form a spherical polyhedron, the two apical Al atoms have to move away from each other. Therefore, unfavorable Al–Al interactions would arise between the apical atoms and the hexagonal Als because of the long Al(apical)–Al(hexagonal) distances. The long distances are the result of moving the apical atom away from the center of a hexagon.

$Al_{14}(\mu_8\text{-Si})Cp^*_6$ **5** can be reformulated as $Al_8((\mu_8\text{-Si})(\mu_4\text{-AlCp})_6$ and described as a Si-centered Al_8 cube capped by six AlCp fragments. Based on the detailed analysis of the DFT molecular orbital calculations, Schnöckel and his coworkers [1] nicely invoked the simple Jellium model [31] to account for the 40 metal valence cluster electrons in the clusters by having a closed-shell electron configuration of $1s^21p^61d^{10}2s^21f^{14}2p^6$ (here 1s, 1p, … are the Jellium orbitals). Alternatively, the cluster can also be considered as having a regular electron count for a cubic structure. A cubic C_8R_8 molecule is actually having 40 valence electrons. Many analogous cubic $M_8(\mu_4\text{-E})_6L_8$ (M = Ni; E = S, Se, or PPh; L = phosphine or CO) transition metal clusters which have 120 cluster valence electrons can be found in the literature [32]. When M is a main group atom, the type of clusters should have 40 cluster valence electrons because the d orbitals of a main group atom normally do not play a role in increasing the number of bonding/non-bonding orbitals. In this alternative description, the cluster **5** formally has 12 metal–metal bonds and each Al atom in the cubic structural unit is expected to have an electron pair which shows out-pointing. These out-pointing orbitals accommodating the Al electron pairs also have significant contribution from the capping AlCp fragments. The capping AlCp fragments play important roles in stabilizing these electrons.

3.4. $[(AlEt)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}H)]$, $[(AlMe)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}C{\equiv}CPh)]$ and $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-}H)_2]$

In $[(AlEt)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}H)]$ (**6**) and $[(AlMe)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}C{\equiv}CPh)]$ (**7**) (see Fig. 1), the eight Al atoms of each cluster form a cubic arrangement in which each Al has a terminal R ligand. The structures can be also described as a hexa-capped cube. These two clusters are actually isoelectronic, each having an electron count of 48 [$=(3+1)\times8+5\times3+1$]. Unlike the cubic cluster $Al_{14}(\mu_8\text{-Si})Cp^*_6$ discussed above, these two clusters does not have the regular electron count of 40. Based on the quantum chemical calculations, Uhl and his coworkers [9a] concluded a delocalized multicenter bonding situation with only weak direct Al–Al interactions for these clusters. Interestingly, one can formally assign +3 to each Al center in these clusters including $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-}H)_2]$ (**8**) (see Fig. 1). In other words, one can envisage the bonding in these clusters as follows. The Al atoms in these clusters provide all their valence electrons to make sure that all bonded carbon atoms satisfy the octet rule and hydrogen atoms the 2-electron closed-shell electronic requirement. The multicenter bonding situation is realized through the bridging units. The electronic structures and bonding picture for these clusters are thus quite simple from such a

(a) (b)

Fig. 5. Laplacian plots of the electron density for model cluster $[Al_7(NH_2)_6]^-$ on a triangle plane formed by three non-shared Al atom (a) and for model cluster $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-}C \equiv CH)]$ on the plane of the square face opposite to square face capped by the μ_4-acetylenyl ligand (b). Solid lines represent local electron density concentration, and dashed lines represent local density depletion.

traditional view. Based on such a simple bonding picture, it is not difficult to understand that the direct Al–Al interactions are weak in these clusters. Geometry optimization were performed for the model cluster $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-}H)$ (**6a**), $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-}C{\equiv}CH)]$ (**7a**) and $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-}H)_2]$ (**8a**). The calculated geometries are in good agreement with the corresponding experimental complexes $[(AlEt)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}H)]$ (**6**), $[(AlMe)_8(\mu_4\text{-}CCH_2Ph)_5(\mu_4\text{-}C{\equiv}CPh)]$ (**7**) and $[(AlMe)_7(\mu_4\text{-}CCH_2Me)_4(\mu_2\text{-}H)_2]$ (**8**). The Wiberg bond indices (WBI) of model clusters **6a**, **7a** and **8a** have been shown in Table 1. Consistent with the qualitative analyses above, these model clusters have relatively smaller WBI when compared with other types of Al clusters. Fig. 5 showed the Laplacian plots of model clusters $[(AlMe)_8(\mu_4\text{-}CCH_3)_5(\mu_4\text{-}C{\equiv}CH)]$ (**7a**) and $[Al_7(NH_2)_6]^-$ (**1a**). Significant electron density concentrations can be found along the Al–Al bonding path in **1a**, but not in **7a**. These results suggest that there is considerable Al–Al bonding in other types of Al clusters except **6**, **7** and **8** in which Al^{3+} can be formally assigned to each aluminum center of the clusters.

3.5. Comments on $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ and $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$

Recently, three remarkably large clusters, $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ [6], $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ [7] and $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$ [10], have been successfully synthesized and structurally characterized. All three clusters have a shell-like structural arrangement. For $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$, successive shells contain 1, 12, 44 and 20 Al atoms while for $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ they are 1, 12, 38 and 18 Al atoms. For $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$, the successive shells have 2, 20, 42 and 20 Ga atoms. Detailed structural descriptions have been given by Schnöckel and his coworkers [6,7,10]. Apparently, there is no simple rule which can be used to appreciate the electron counts of these three large clusters. $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$ has a total number of 192 metal electrons, having the $3n-15$ electron count for Al–Al bonding. $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ has a total number of 213 metal electrons, giving the $3n-18$ electron count for Al–Al bonding. $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$ has a total number of 236 metal electrons, leading to the $3n-16$ electron count for Ga–Ga bonding. $3n$ metal electrons are associated with metallic aluminum and gallium. Clearly, the electron counts given here for the three large clusters indicate that they are approaching the metallic character in terms of metal–metal interactions. A better understanding of their bonding requires further studies. It is only when more and more of these types of metalloid clusters become known that one will be in a position to establish the structure–electron count relationship.

4. Summary

The aluminum metalloid clusters provide much more versatile structural varieties which differ markedly from those of their lighter congener. Although these clusters do not simply follow Wade's electron counting rules, through the bonding analyses given in this paper, we demonstrate that the existing bonding knowledge on other types of clusters, e.g. boranes, hydrocarbons and metal–carbonyl clusters can still be used to understand the electron counts for the majority of these aluminum metalloid clusters. $[Al_{69}\{N(SiMe_3)_2\}_{18}]^{3-}$, $[Al_{77}\{N(SiMe_3)_2\}_{20}]^{2-}$ and $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$ are believed to possess more metallic characters.

Abstract

Treatment of the digallane(4) derivative $R_2Ga–GaR_2$ (**1**) [$R = CH(SiMe_3)_2$] with the dicarboxylic acid muconic acid or with squaric acid yielded macrocyclic compounds (**4** and **5**, respectively) by retention of the Ga–Ga single bonds and release of 2 equiv. of bis(trimethylsilyl)methane per formula unit of **1**. Both products contain four Ga–Ga single bonds connected by four dicarboxylato or diolato ligands. Large heterocycles resulted which contain 36 (**4**) and 20 atoms (**5**), respectively. The cavity of the macrocycle of **5** is filled by two *n*-pentane molecules. In contrast, two pentane molecules are located in hollows on the surface of the macrocycle of **4** in a supramolecular arrangement. They influence the molecular conformation significantly. The reaction with squaric acid gave a by-product (**6**) which also has eight gallium atoms in a heterocycle, but one Ga–Ga bond was cleaved by oxidation and probably by the release of elemental hydrogen. © 2002 Elsevier Science Ltd. Keywords: Gallium–gallium bonds; Macrocycles; Supramolecular chemistry

1. Introduction

The first known and well-characterized organoelement compounds containing Al–Al, Ga–Ga and In–In single bonds were obtained in our group about 10 years ago [1–3]. Their syntheses succeeded by reduction of the corresponding dialkylelement halides or by treatment of subhalides still containing element–element single bonds with alkyllithium derivatives. They need bulky substituents in order to prevent the thermodynamically favored disproportionation reaction and the formation of elemental aluminum, gallium or indium. We employed bis(trimethylsilyl)methyl groups for the stabilization of compounds of the type $R_2E–ER_2$ (E = Al, Ga, In). Later on, many further derivatives were published bearing bulky aryl [4] or silyl [5] substituents. These compounds showed a remarkable chemical reactivity and six different types of reaction were observed such as insertion reactions or the formation of radical anions possessing 1e–E–E π-bonds [6]. Substituent exchange by retention of the E–E bonds is another particularly important reaction. It succeeds only with the digallium derivative $R_2Ga–GaR_2$ (**1**) [$R = CH(SiMe_3)_2$] [2] and requires treatment of **1** with protic reagents containing chelating residues [7–10]. In contrast, the originally expected cleavage of the element–element single bonds by oxidation of the bivalent elements and the release of elemental hydrogen was observed in all cases when we employed the aluminum or indium derivatives under similar conditions [11]. Substituent exchange products derived from **1** were isolated in almost quantitative yield when we treated **1** with carboxylic acids such as acetic acid or benzoic acid (**2**, Scheme 1) [7], while a decrease of the acidic strength gave side reactions with the formation of mixtures of products and at least partial cleavage of Ga–Ga bonds [10]. Much more interesting are reactions with bifunctional dicarboxylic acids, because owing to the bridging capability of their residues they open the route to the synthesis of polymeric or macrocyclic organoelement compounds. Dimeric products, in which two Ga–Ga units were bridged by two dicarboxylato ligands, were obtained with those dicarboxylic acids which have a more flexible backbone such as phenylene diacetic acid (**3**, Scheme 1) [8]. In contrast, the rigid backbone of

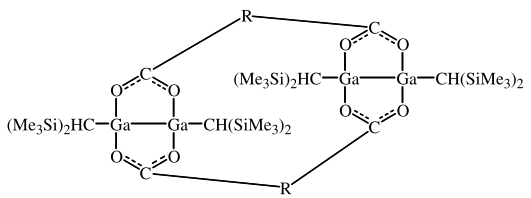
ferrocene dicarboxylic acid prevented the formation of a dimer, and a tetramer was formed with four Ga–Ga bonds and four dicarboxylato bridges [9]. We report here on further investigations into the syntheses of macrocyclic polygallium compounds by the treatment of **1** with bifunctional acidic reagents. One aspect of this chemistry is the approach to supramolecular interactions with the inclusion of solvent molecules into the cavity of the macrocycles, for instance.

2. Experimental

All procedures were carried out under purified argon. *n*-Pentane was dried over $LiAlH_4$; THF over Na/benzophenone; acetonitrile over P_4O_{10}. $Ga_2[CH(SiMe_3)_2]_4$ (**1**) was obtained according to a literature procedure [2]. Commercially available muconic acid (*trans–trans*-2,4-hexadienedioic acid, Aldrich) and squaric acid (3,4-dihydroxy-3-cyclobuten-1,2-dione, Merck) were employed without purification.



2.1. Synthesis of compound *4*

A cooled (0 °C) solution of 0.278 g (0.358 mmol) of **1** in 40 ml of THF was treated with solid *trans–trans*-muconic acid (0.051 g, 0.358 mmol). The mixture was warmed to room temperature and stirred for 22 h. The solvent was removed in vacuum, and the thoroughly evacuated residue was treated with *n*-pentane. After filtration and concentration, the product (**4**) crystallized upon cooling to − 30 °C. Yield: 0.133 g (62%), bright yellow crystals. Dec. (argon, sealed capillary): above 180 °C (see text). ^{1}H NMR (C_6D_6, 300 MHz): $\delta = 7.20$ (2 H, part of a AA′ spectrum, distances between the inner and outer lines 8 and 14 Hz, respectively, C=CH), 5.91 (2 H, second part of the AA′XX′ spectrum, distances between the inner and outer lines 8 and 14 Hz, respectively, C=C–H), 0.31 (36 H, s, $SiMe_3$), − 0.15 (2 H, s, GaCH). ^{13}C NMR (C_6D_6, 75.5 MHz): $\delta = 176.3$ (CO_2), 142.2 and 123.0 (C=C), 4.4 (GaC), 2.9 ($SiMe_3$). IR (CsBr plates, paraffin, cm^{-1}): 1615 w, 1532 m $\nu(CO_2)$; 1461 vs, 1378 vs paraffin; 1291 w, 1248 m δCH_3; 1013 w, 1003 w δCH; 968 sh, 943 w, 864 m, 844 s, 759 w, 723 w ρCH_3(Si); 675 vw ν_{as}(SiC); 629 vw ν_s(SiC); 601 vw, 514 vw, 466 vw ν(GaC), ν(GaO). UV–Vis (*n*-hexane): λ_{max} (nm) (log ε) = 210 (4.3), 270 (4.5), 280 (4.5), 290 (4.3), 330 (3.1).

2.2. Synthesis of compound *5*

A mixture of the digallium compound **1** (0.119 g, 0.153 mmol) and squaric acid (0.0175 g, 0.153 mmol) was treated with 25 ml of acetonitrile. The suspension was refluxed for 1 h. A clear solution resulted in the heat. After cooling to room temperature the solvent was removed in vacuum, and the residue was treated with *n*-pentane and filtered. The colorless product precipitated upon cooling of the solution to − 70 °C. Yield: 0.026 g (30%). Dec. (argon, sealed capillary): 284 °C. ^{1}H NMR (C_6D_6, 200 MHz): $\delta = 0.26$ (36 H, s, $SiMe_3$), − 0.13 (2 H, s, GaCH). ^{13}C NMR (C_6D_6, 75 MHz): $\delta = 196.6$ (CO), 10.4 (GaC), 3.6 ($SiMe_3$). IR (CsBr plates, paraffin, cm^{-1}): 1590 sh, 1539 vs, 1515 vs ν(CO), ν(CC); 1463 vs, 1377 vs paraffin; 1302 w, 1252 sh, 1248 s δCH_3; 1111 w, 1095 m ν(CC) (pentane); 1013 w δCH; 964 m, 851 sh, 843 s, 777 m, 759 m, 724 m ρCH_3(Si); 673 m ν_{as}(SiC); 625 w ν_s(SiC); 610 vw, 507 w, 447 w, 419 m ν(GaC), ν(GaO). UV–Vis (*n*-hexane): λ_{max} (nm) (log ε) = 210 (1.5), 270 (4.0).

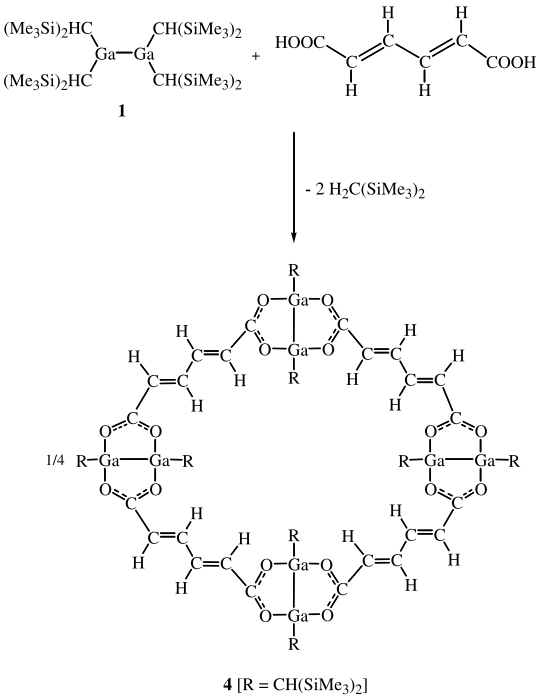
2.3. Crystal structure determination of *4*

Single crystals of **4** by slow concentration of a solution in *n*-pentane at room temperature over several days; crystals grew above the surface of the solvent; they included two molecules of pentane per formula unit of **4**; $C_{90}H_{192}O_{16}Si_{16}Ga_8$, crystal size 0.60 × 0.12 × 0.07, STOE IPDS diffractometer, temperature 193 K, monoclinic, $P2_1/c$ (no. 14 [12]), $a = 1247.34(3)$, $b = 2712.1(1)$, $c = 2142.13(7)$ pm, $\beta = 105.179(3)°$, $V = 6993.7(4) \times 10^{-30}$ m^3, $D_{calc} = 1.205$ g cm^{-3}, $Z = 2$ (**4**) and 4 (*n*-pentane), μ(Mo Kα) = 1.70 mm^{-1}, numerical absorption correction, 2θ range $3.9 \leq 2\Theta \leq 52°$, index ranges $-13 \leq h \leq 13$, $-33 \leq k \leq 33$, $-26 \leq l \leq 25$, number of unique reflections 12 841, number of parameters 596, structure solution by direct methods,

programs SHELXTL-PLUS and SHELXL-97 [13], refinement by the full-matrix least-squares method based on F^2, R_1 (6891 reflections $I > 2\sigma(I)) = 0.041$, wR_2 (all data) = 0.128, max/min residual electron density = $0.678/-0.404 \times 10^{30}$ e m^{-3}. The molecules reside on crystallographic inversion centers. One $CH(SiMe_3)_2$ group (C3/Si5/Si6) was disordered, the carbon atoms of its methyl groups were refined isotropically on split positions.

2.4. Crystal structure determination of **5**

Single crystals of **5** by slow concentration of a solution in *n*-pentane at room temperature over several days; the crystals included two molecules of pentane per formula unit of **5**; $C_{82}H_{176}O_{16}Si_{16}Ga_8$, crystal size $0.36 \times 0.36 \times 0.09$, STOE IPDS diffractometer, temperature 193 K, triclinic, $P\bar{1}$ (no. 2 [12]), $a = 1868.25(9)$, $b = 1957.63(9)$, $c = 2191.6(1)$ pm, $\alpha = 95.494(6)$, $\beta = 107.960(6)$, $\gamma = 118.481(5)°$, $V = 6413.3(5) \times 10^{-30}$ m^3, $D_{calc} = 1.256$ g cm^{-3}, $Z = 2$, μ(Mo Kα) = 1.85 mm^{-1}, numerical absorption correction, 2θ range $3.8 \leq 2\Theta \leq 52°$, index ranges $-22 \leq h \leq 22$, $-23 \leq k \leq 23$, $-26 \leq l \leq 26$, number of unique reflections 23 273, number of parameters 1101, structure solution by direct methods, programs SHELXTL-PLUS and SHELXL-97 [13], refinement by the full-matrix least-squares method based on F^2, R_1 (16 425 reflections $I > 2\sigma(I)) = 0.043$, wR_2 (all data) = 0.117, max/min residual electron density = $1.293/-1.028 \times 10^{30}$ e m^{-3}; the molecules reside on crystallographic inversion centers, and two half molecules were found in each asymmetric unit.



2.5. Crystal structure determination of **6**

Single crystals of **6** by slow concentration of a solution of an impure reaction product (see text) in *n*-pentane at room temperature over several days; $C_{86}H_{190}O_{16}Si_{20}Ga_8$, crystal size $0.24 \times 0.18 \times 0.15$, STOE IPDS diffractometer, temperature 193 K, triclinic, $P\bar{1}$ (no. 2 [12]), $a = 1654.5(1)$, $b = 1886.0(1)$, $c = 2476.9(2)$ pm, $\alpha = 72.542(6)$, $\beta = 86.456(6)$, $\gamma = 75.193(5)°$, $V = 7127.1(8) \times 10^{-30}$ m^3, $D_{calc} = 1.212$ g cm^{-3}, $Z = 2$, μ(Mo Kα) = 1.70 mm^{-1}, numerical absorption correction, 2θ range $2.5 \leq 2\Theta \leq 50.7°$, index ranges $-19 \leq h \leq 19$, $-22 \leq k \leq 22$, $-29 \leq l \leq 29$, number of unique reflections 25 896, number of parameters 1232, structure solution by direct methods, programs SHELXTL-PLUS and SHELXL-97,[13] refinement by the full-matrix least-squares method based on F^2, R_1 (12 911 reflections $I > 2\sigma(I)) = 0.045$, wR_2 (all data) = 0.116, max/min residual electron density = $1.607/-0.624 \times 10^{30}$ e m^{-3}.

3. Results and discussion

3.1. Reactions of **1** with muconic acid and squaric acid

A bright yellow solution was obtained upon treatment of digallane(4) **1** with muconic acid. A small quantity of a colorless solid precipitated, the constitution of which is unknown. Possibly a polymer had formed as a by-product which would be of particular interest in the context of this research project. Investigations concerning its composition are in progress. After filtration, evaporation and recrystallization, yellow crystals of the product **4** were isolated in 62% yield (Eq. (1)). Crystalline **4** was thermally stable up to 180 °C. Above that temperature it adopted an orange color and became black at about 305 °C. The ^{1}H and ^{13}C NMR resonances of the central hydrogen and carbon atoms of the bis(trimethylsilyl)methyl groups neighboring gallium are strongly shifted to a higher field compared to those of the starting compound **1** (**1**: $\delta = 1.11$ (^{1}H) and 25.9 (^{13}C); **4**: $\delta = -0.15$ and 4.4, respectively), which is characteristic of an enhancement of the coordination numbers of the gallium atoms from three in **1** to four in **4** [14]. An absorption at 1532 cm^{-1} was observed in the IR spectrum for the bridging carboxylato groups, which is in the very narrow range of related compounds (**2** and **3**, Scheme 1) [7–9].

(1)

Reaction of **1** with squaric acid in pentane afforded a mixture of compounds as was detected by several broad lines in the ^{1}H NMR spectrum of the crude product. One of these compounds could be isolated in a pure form in trace amounts; its crystal structure is discussed

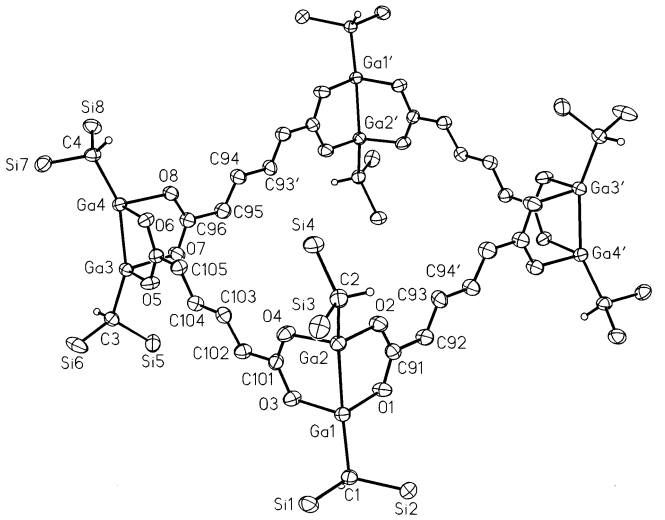


Fig. 1. Molecular structure of **4**. The thermal ellipsoids are drawn at the 40% probability level. Methyl groups and hydrogen atoms of the bridging ligands are omitted for clarity.

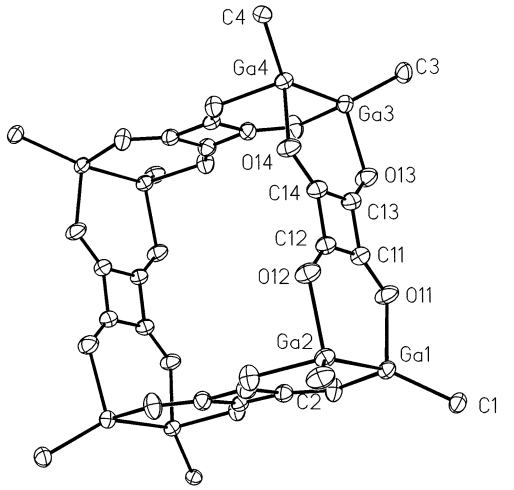

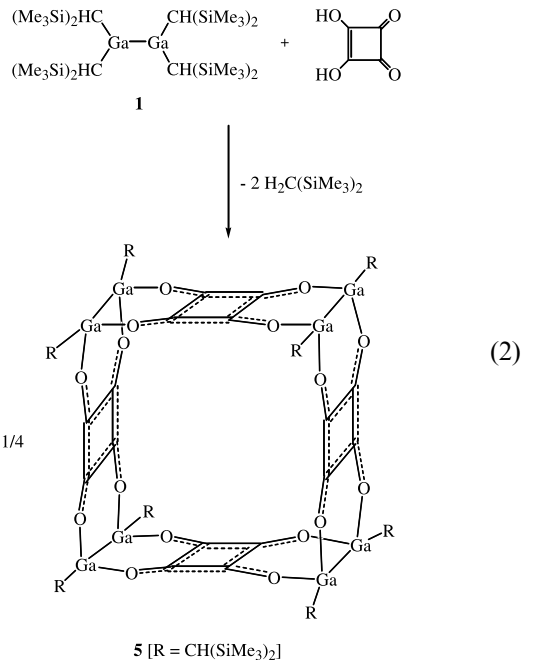

Fig. 2. Molecular structure of **5**. Only one of the two independent molecules is shown. The thermal ellipsoids are drawn at the 40% probability level. Trimethylsilyl groups and hydrogen atoms are omitted for clarity.

below. The spectra of the crude products became clearer when we employed solvents with increasing polarity, and finally an almost pure compound (**5**) with only one singlet of $SiMe_3$ groups was obtained in acetonitrile. Colorless crystals of **5** (Eq. (2)) were isolated after recrystallization from *n*-pentane. Similar to **4**, the inner hydrogen and carbon atoms of the bis(trimethylsilyl)methyl groups were shifted to a higher field ($\delta = -0.13$ and 10.4, respectively) compared to the starting compound **1**. Three absorptions (1590, 1539 and 1515 cm^{-1}) were observed in the IR spectrum for the C–C and C–O bonds of the C_4O_4 bridging ligand possessing a delocalized π-bonding system. Compound **5** is thermally quite stable and does not decompose before 284 °C.

(2)

3.2. Crystal structures

The molecular structure of **4** as determined by X-ray diffraction is depicted in Fig. 1, and a schematic drawing is given in Eq. (1). Compound **4** contains four Ga–Ga single bonds bridged by four dicarboxylato ligands. A large organometallic macrocycle results, consisting of 36 gallium, oxygen and carbon atoms. Each Ga–Ga bond is bridged by two carboxylato groups similar to all dicarboxylatodigallium derivatives reported before [7–9]. Each gallium atom is coordinated by two oxygen atoms of different chelating ligands, by a carbon atom of a bis(trimethylsilyl)methyl group and by the second gallium atom of the Ga–Ga bond. A similar structure was observed for the squaric acid derivative **5** (Fig. 2), which has two 20-membered heterocycles connected by four Ga–Ga and eight C–C bonds. Similar macrocyclic compounds, which contain four pairs of transition metal atoms bridged by four dicarboxylato groups, were published only recently [15].

Owing to the smaller bite of the bridging carboxylato group, the Ga–Ga bond lengths of **4** (238.3 pm on average, Table 1) are shorter than those of **5** (245.5 pm, Table 2). A similar lengthening compared to carboxylatodigallium compounds was observed for the five-atomic imidotetraphenyldiphosphinato ligand [16]. All distances are shorter than the Ga–Ga bond of the unsupported tetraalkyl compound **1** (254.0 pm) [2]. The bridging ligands of each Ga–Ga bond are almost ideally perpendicular to one another (angles O–Ga–O = 92.1° (**4**) and 91.0° (**5**) on average), and the Ga–Ga–C groups approach linearity (156.8°) for the carboxylato derivative **4** (139.7° for the less stressed squaric acid

derivative **5**). The particular bonding situation resulting from these structural parameters has been discussed extensively before [7]. The bond lengths and angles of the bridging anionic organic ligands are similar to those observed in other derivatives [17] and do not need a more detailed discussion. They verify alternating C–C single and double bonds (145.2 and 132.1 pm) in the case of *trans*,*trans*-muconic acid and a completely delocalized π-electronic system in the case of squaric acid (C–C 145.8 pm; C–O 125.6 pm).

The crystals of compound **5** enclose two molecules of *n*-pentane per formula unit. These solvent molecules approach the molecular center from both sides of the macrocycle and occupy its cavity in a supramolecular arrangement [18]. They are almost completely covered by the organic substituents of the octagallium compound. Both independent molecules of **5** differ with respect to the depth of penetration of the solvent molecules, which is most effective for that molecule containing the atoms Ga5–Ga8 (Fig. 3(b)). Here, the pentane molecules approach a narrow distance between their nearest terminal carbon atoms of only 341.7 pm, which is shorter than the intramolecular contact distances observed in crystalline alkanes (about 360 pm) [19]. These pentane molecules deviate only slightly from the ideal perpendicular position to the average plane of the gallium atoms (78.9°). They are more tilted for the second macrocycle comprising the atoms Ga1–Ga4 (angle between the average plane of the macrocycle and the pentane molecule = 63.3°) (Fig. 3(a)). In this case, the pentane molecules penetrate the cavity to a lesser extent, and the distance between the terminal carbon atoms is enlarged by more than 100 pm to 452.5 pm. Thus, interestingly, the pentane molecules stand more upright the more they approach the center of the macrocycle. Short contact distances are observed between the terminal carbon atoms of the pentane molecules and atoms of the squaric acid residue (372.6 pm to C51′, 374.0 pm to C52, 376.0 pm to C62, 378.4 pm to C44, 382.6 pm to C42; second molecule 357.7 pm to O13′, 365.4 pm to C13′). Also, the crystals of **4** enclose two solvent molecules per formula unit, but these do not reside in the cavity of the macrocycle. Instead, they are localized in opposite exocyclic positions between the bulky organoelement substituents of two Ga–Ga bonds and are parallel to two butadiene backbones of the muconic acid residues (Fig. 4). Several short intermolecular contact distances between carbon atoms of the pentane molecules and oxygen or carbon atoms of the macrocycle and trimethylsilyl groups of >385 pm indicate weak van der Waals interactions as expected for crystal solvents. However, these pentane molecules cause a distortion of the macrocycle so that those butadienyl bridges which are not covered by the solvent molecules (C92–C95′) form a concave line, while those neighboring pentane (C102–

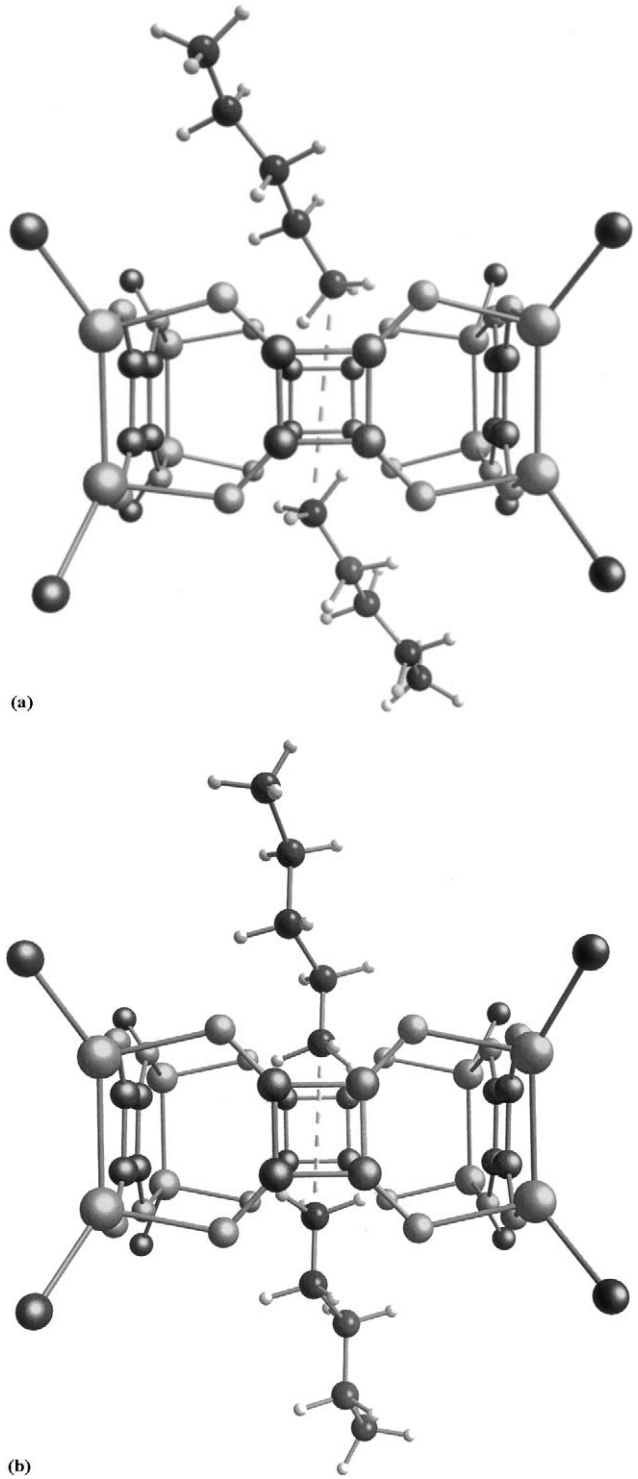

Fig. 3. Arrangement of *n*-pentane molecules in the molecular center of **5**. Only the inner carbon atoms of the bis(trimethylsilyl)methyl groups are shown, its hydrogen atoms and $SiMe_3$ groups are omitted. The pentane molecules are almost completely covered by the organic substituents.

C105) have a convex orientation. The shortest transannular distances between the inner carbon atoms of the opposite concave muconic acid residues (C93, C94) are 1021 pm on average compared to 1249 pm between C102 and C103 of the remaining bridging ligands. This particular conformation causes the tilting of the Ga_2R_2 groups. The hollows for the deposit of the pentane molecules become larger, and the contacts between butadienyl and pentane carbon atoms are closer. Thus, we observe a remarkable supramolecular influence on the structure of the macrocycle. The distances between two gallium atoms along the edges of the macrocycle of **4** are 1088–1186 pm and in a narrower range compared to the transannular C–C distances. The macrocycle of **5** is smaller. The Ga–Ga distances along the edges are 708.1–710.2 pm, and the transannular C–C contacts are only slightly lengthened (709–735 pm), indicating a weak deviation from an ideal planar arrangement of the atoms at one face of the molecule.

The reaction of **1** with squaric acid in non-polar solvents gave mixtures of products. In one case we isolated a few single crystals of one of these products (**6**) by very slow concentration of a solution in *n*-pentane under reduced pressure at room temperature over several days. Its molecular structure is depicted in Fig. 5, and Scheme 2 gives a schematic drawing. It is quite similar to compound **5**, but has three intact Ga–Ga bonds only. One bond was opened by oxidation of its two gallium atoms (Ga1, Ga2) from $+2$ to $+3$. These atoms are bridged by two squaric acid residues and

Scheme 2.

have a distorted tetrahedral coordination sphere, in which each gallium atom is coordinated by two oxygen atoms of squaric acid and two carbon atoms of two bis(trimethylsilyl)methyl substituents. The largest deviation from the ideal tetrahedral angle is observed between the bulky organoelement groups (130.2° and 136.5°, Table 3). The enhanced oxidation state of the gallium atoms has only a minor influence on the Ga–C or Ga–O bond lengths, and quite similar values are observed within the molecule (Ga–C = 195.9 pm for Ga1 and Ga2, 195.2 pm for the remaining gallium atoms; Ga–O = 198.8 pm and 200.1 pm, respectively). The Ga–Ga bond lengths (245.2 pm on average) correspond to those of compound **5**. As expected, the Ga1–Ga2 distance of the opened Ga–Ga bond (583.5 pm) is far outside the range of significant bonding interaction (sum of the van der Waals radii of Ga 380 pm [20]). The remaining structural parameters are quite similar to those of **5**. The squaric acid residues bridging one Ga–Ga bond are almost ideally perpendicular to one another, and even at the trivalent gallium atoms (Ga1, Ga2) the O–Ga–O angles approach 90°. The opening of Ga–Ga bonds was observed in our group several times before when we treated **1** with very weak protonic acids such as diphenyltriazene [10]. Also in the case of squaric acid, the acidic strength does not seem to be high enough to ensure the selective substitution reaction, and partial or complete opening of Ga–Ga bonds resulted. Thus, the mixture obtained by the reaction in non-polar solvents may comprise the whole series of products expected by the successive opening of Ga–Ga bonds including compound **5**, which was detected by NMR spectroscopy as a main component in all crude products. No further compound was obtained in a pure form, and **6** was isolated only in trace amounts so that with the exception of **5**, spectroscopic findings could not unambiguously be assigned to particular derivatives.
