The ∠ O–M–N angles are used to depict the geometry within the metal–ligand plane. The M–N and M–O distances are presented as a measure of the change in the ligand to metal bond nature. The torsion angles associated with the region adjacent to the two imine moieties and aromatic planes are used to show how the ligand contorts to accommodate the desired geometry of the metal centre.

is the simplest homologue of a series of polymers, i.e. $[Zn(Salpr)]_n$, $n = 2$, which has been preferentially extracted from the bulk material. The structure of Zn(Salpr) displayed here contrasts markedly with the two other reported Zn(Salpr) species namely [(ZnSalpr)HOMe]$ZnCl_2$ [17] and {[(ZnSalpr)$_2$](OAc)$_2$Zn} [18] which are bi and tri metallic (c.f. Zn(Salbu) below). The contrast between these two motifs again [1] indicates that structural divergence occurs at this juncture i.e. where the alkyl chain between the two imine moieties contains three or more methylene units.

3.3. ZnSalbu

Unfortunately the structural progression was interrupted at Salbu as no simple complex could be structurally characterised. However, from the mixture it was possible to isolate crystals of an important minor component, {[Zn(Salbu)]$_2$(OAc)$_2$Zn}, which could be prepared by a more rational route. Intriguingly, this species follows the reported structures of ({[ZnSalpr]$_2$[OAc]$_2$Zn}) [18] and ({[Ni(Salbu)DMF]$_2$[OAc]$_2$Ni}) [1] in that we obtain a trimetallic complex (Fig. 5). The motif in the vicinity of the Salbu ligand is a typical five coordinate zinc environment with a slight saddle shape in the 'plane' defined by the Schiff's base donors (Table 2) and the zinc atom. The increased size of the chelate ring demands that the ligand alters certain characteristics to accommodate the additional ring methylene unit. Thus we observe an large increase (c.f. {[ZnSalpr]$_2$[OAc]$_2$Zn}; 3.5°) in the torsion angles associated with the aromatic planes (32.1°) and imine regions (39.8°) and a divergence of the M–N and M–O bond distances to values greater and smaller than the respective Salpr complex (Table 2). The effect of the buckling in the Salbu ligand also affects the geometry at the apical acetate ligand (∠ OAc–Zn–N, 96.1° and 117.0°; ∠ OAc–Zn–O, 90.5° and 106.7°) which moves away from the more regular pyramidal values observed for the ZnSalpr complex [18] (∠ OAc–Zn–N, 102.9° and 104.9°; ∠ OAc–Zn–O 101.2° and 103.7°).

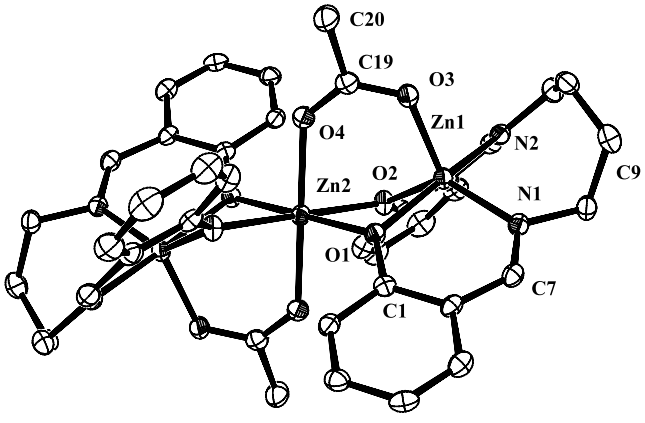

Fig. 5. The structure of {[Zn(Salbu)]$_2$(OAc)$_2$Zn}. The key bond lengths within the Zn(Salbu) unit are given in Table 2. The central zinc sits in an octahedral position. Although the *trans* ∠ O–Zn2–O angles are 180° the *cis* ∠ O–Zn–O angles are more variable with the somewhat tighter internal ∠ O1–Zn1–O2 angle (76.9°) being compensated by the more obtuse cross Salbu ∠ O1–Zn2–O1 angle (103.1°).

3.4. Structural homology

The structural homology of zinc Schiff's base complexes has been unclear for many years. Our ability to crystallise additional representative species offers us an opportunity to identify and clarify certain key patterns available to zinc. It has been known for some time that the simple Salen complexes of zinc can have two interchangeable forms, a five coordinate motif (viz. Zn(Salen)L, L = Pyridine, H_2O) and an anhydrous form. In the absence of any substantive structural data Bately resorted to spectroscopic measurements to suggest a structure for the anhydrous forms of Zn(Salen) and Zn(Salpr). Notably the motif isolated for Zn(Salpr) is not vastly different to that suggested and consequently it is proposed that this motif is representative of Zn(Salen) also. Batley formed the opinion that since Zn(Salbu) would not form a pyridine adduct that it must be four coordinate. However, their supporting IR infrared evidence (phenolic νC–O at 1530 cm^{-1}) is at odds with current band assignments. Furthermore, we now know that five coordinate complexes do form when suitable ligands such as acetate are involved (Fig. 5). Thus with the realisation that Salbu affords greater flexibility and thus less strain and that with suitable ligands and environments five coordinate species are highly favoured, we believe that Zn(Salbu) structurally follows Salpr and Salen and is an oxygen bridged polymer in its simplest form.

Although ZnSalen is content to adopt a five coordinate environment as yet no complexes have been clearly identified which include a second metal complexed to the oxygen donor atoms (c.f. Salen complexes of nickel [3] and copper [25]). In contrast to Salen, zinc complexes of Salpr and Salbu would seem to readily accept a second guest metal cation thus forming bi and tri metallic complexes. This behaviour is a common feature for Salpr and Salbu complexes of late transition metals [1] (Tables 2 and 3). The contrast between the ligand sets here is marked. However, there is little evidence to suggest that Salpr and Salbu have more favourable donor characteristics than Salen. The propensity of these complexes to accept a guest metal in this manner most probably arises from the greater degree of flexibility afforded to the Salpr and Salbu ligands, allowing them to cantilever into a more accommodating orientation for complexation. Indeed a narrowing of the

Table 3
The key bond lengths and bond angles for the established structures of Cu(Salen) [8–10], Cu(Salpr) [4,11] and Cu(Salbu) [12] complexes

Compound	$-(CH_2)-$ units between the imines	N_2O_2 plane angles (°)	M–N distance	M–O distance	Aromatic planes (°)	∠ CN–NC torsion angle
Cu(Salen) [8]	2	176.5	192.8	190.5	2.9	18.0
		174.5	190.3	188.5		
Cu(Salen) [9]	2	176.5	196.6	192.5	11	16.7
		174.8	193.8	190.4		
Cu(Salen) [10]	2	167.4	194.4	188.9	22.8	23.9
		164.5	191.8	189.1		
Cu(Salpr) [11]	3	164.1	199.4	191.0	7.7	7.1
		172.7	200.0	193.3		
Cu(Salpr) [4]	3	174.1	193.8	187.8	32.0	20.3
		159.9	195.8	185.7		
Cu(Salbu) [18]	4	153.3	200.0	189.7	56.6	49.4
		143.9	194.0	190.3		

The ∠ O–M–N angles are used to depict the geometry within the metal–ligand plane. The M–N and M–O distances are presented as a measure of the change in the ligand to metal bond nature. The torsion angles associated with the region adjacent to the two imine moieties and aromatic planes are used to show how the ligand contorts to accommodate the desired geometry of the metal centre.

internal ∠ O–Zn–O angle is observed between Zn(Salen)NC_5H_5 (93.3°) and {$[Zn(Salbu)]_2(OAc)_2Zn$} (79.9°).

3.5. Comparative analysis

The isolation of the three zinc complexes above completes the matrix of motifs, which can be constructed between Salen, Salpr and Salbut with nickel [1], copper [4,8–11,18] (Table 3) and zinc. By combining the data above with the existing data it is possible to demonstrate clearly the structural geometry available to these ligands [1] (Tables 2 and 3) with these metals. Unsurprisingly the Salen ligand remains conformationally restricted to planar and square-pyramid geometries at the metal centre. Within these planar geometries any strain would seem to be transmitted into the alkyl chain between the two imine moieties where –CN–NC torsion angles of 20° are commonly observed. By virtue of the stability of the chair conformation six membered rings, Salpr also demonstrate a preference for a meridial arrangement (e.g. planar and pyrimidal geometry). However, in contrast to Salen, Salpr also supports *mer*-octahedral configurations. Unlike Salen the increased freedom afforded by the extra methylene unit would seem to be able to offset the torsional strain in the di-imine region with angles falling to negligible values (Table 2). At this juncture the incorporation of additional metals at the phenolic oxygen's becomes highly favoured and we observed a trend towards bi and tri metallic systems.

The greatest geometric variation is found for the Salbu ligand which can be seen to support five different geometries; namely distorted tetrahedral (CuSalbu) [18], planar (NiSalbu) [7], square based pyramid (Zn(Salbu), *mer*-Oh (NiSalbu) [1] and *fac*-Oh (NiSalbu) [1]. In all examples of Salbu complexes the formation of the seven membered ring creates some strain in the backbone. The M–O and M–N distances are in general longer [1] (Tables 2 and 3). This strain is sufficient to facilitate the adoption of a *fac*-octahedral geometries with nickel. In the structural chemistry of copper (Table 2) it manifests itself as clear shift from a planar to a heavily distorted tetrahedral motif. Our inability to isolate a regular tetrahedral motif with this ligand set probably stems simply from the geometric preferences of the metal cations studied (e.g. Ni(II) and Cu(II)) each of which will prefer either a planar or a more distorted conformation. Studies currently being conducted clearly show that a butanediamine based ligand system coupled to copper(I) can move to a tetrahedral motif once the electronic factors are accommodated.

Overall the Salbu ligand offers the widest possible conformational flexibility (Fig. 2) which suggests that a generic system could be designed which could support metal cations during chemistry which operate at the extremes of conformational change. The preponderance of the complexes themselves to act as ligands via the formation of bridging oxygen's could be considered as both an advantage or disadvantage and will need great consideration during any refinement of this concept.

4. Supplementary material

Scheme 1.

line acids Zn^{II}, Cu^{II} and Ni^{II} [14–16] to softer Cd^{II} [17]. Both donor sets (O,O) and (N,N) of α-alaninehydroxamic acid form, when co-ordinated, very stable five-membered chelate rings, β-alaninehydroxamic acid forms less stable six-membered chelate ring when co-ordinated via N_{amino}, $N_{hydroxamate}$ donor atoms.

The aim of the study in this paper was to obtain information on preferred sets of donor atoms of α- and β-alaninehydroxamic acids in mixed-ligand complexes, as well as to collect information about their spectroscopic data. The co-ordination tendencies of studied ligands towards zinc(II) ions in aqueous solution were studied by potentiometry and NMR spectroscopy.

2. Experimental

2.1. Materials

α- and β-Alaha were prepared by us via the methyl ester of the respective amino acid as described in [18]. Dien and trien were from Aldrich (Germany) used without further purification and its purity was greater than 99%.

The exact concentrations of the stock solutions of the hydroxamic acids and polyamines were determined by Gran's method [19]. Zinc(II) chloride solution was purchased from Titrisol ampoule (Merck). Zinc(II) nitrate (Aldrich) was used as a source of Zn^{II} in the NMR studies.

2.2. Methods

2.2.1. Potentiometric measurements

The potentiometric measurements were carried out at 25.0±0.1 °C. A summary of the experimental details is given in Table 1.

The data for the Zn^{II}–α-Alaha and Zn^{II}–β-Alaha binary systems can be found in our early papers [14,20] and some of them are included in Table 2. Data for the Zn^{II}–dien binary system can be found in the literature [21], but for a comparison we had to determine stability constants under identical conditions to those of the ternary systems, i.e. at 25.0 °C and ionic strength of 0.2 M (KCl). For the binary system 1:1, 1:2 and 1:4 metal to ligand ratios were used. For the determination of the stability constants of the mixed ligand complexes the concentration ratios of metal–dien/trien–α-Alaha/β-Alaha were 1:1:1, 1:1:2, 1:2:1 and 1:2:2. All the pH-metric titrations were carried out with carbonate-free KOH solution of known concentration (ca. 0.2 M). Titration emf data were used to calculate the hydrogen ion concentration, $[H^+]$. Stability constants $\beta_{pqrs} = [M_pA_qL_rH_s]/[M]^p[A]^q[L]^r[H]^s$ were calculated with the aid of the SUPERQUAD computer program [22].

Table 1
Summary of experimental parameters for the potentiometric measurements

Systems	Binary:dien, trien, α-Alaha or β-Alaha with H^+ or Zn^{II} in water solution; ternary–dien/trien and α-Alaha/β-Alaha with Zn^{II} in water solution
Solution composition	[dien], [trien], [α-Alaha] and [β-Alaha] range—0.002–0.004 M, $[Zn^{II}]$ range—0.001–0.004 M; ionic strength—0.200 M; electrolyte KCl
Experimental method	pH-metric titration of 5 cm^3 samples in the range of pH 2–11; $pK_w = 13.73$
Instruments	Microburette ABU-80 (Radiometer), Radelkis OP-208/1 pH-meter, micro combination pH electrode (Mettler-Toledo, Type 2)
Calibration	By periodic titrations of a HCl solution (5×10^{-2} M KCl) against standard KOH soution
T (°C)	25.0±0.1
n_{tot} [a]	50–70
n_{tit} [b]	6–8
Method of calculation	SUPERQUAD [22]

[a] Number fo titration points per titration.
[b] Number of titration per metal–ligand (or metal–ligand A–ligand L) systems.

For clarity, the charges of the complexes have been omitted in the tables. It has to be mentioned, however, that the fully deprotonated forms of aminohydroxamic acids are negative (L^-) while the polyamines are neutral (A).

2.2.2. NMR spectra

NMR spectra were recorded on a Bruker DRX spectrometer operating at 300.13 MHz for ^1H and 75.46 MHz for ^{13}C at 300 K, unless otherwise noted. The chemical shifts are given in relation to $SiMe_4$. All downfield shifts are denoted as positive.

The assignments for carbon atoms of dien and trien (Scheme 1) follow those presented in ref. [23]. In order to correlate the ^1H and ^{13}C chemical shift assignments for the studied ligands inverse detected [^1H–^{13}C] HMQC NMR experiments were performed using STANDARD BRUKER program.

The samples for NMR studies were prepared in deuteriated water. The measurements were performed only for freshly prepared solutions. In the Zn^{II}–hydroxamate binary systems the metal to ligand molar ratios were 1:1 and 1:2, the ligand concentration was 2×10^{-2} M. The binary Zn^{II}–polyamine and ternary Zn^{II}–

polyamine–hydroxamate systems were prepared with a zinc(II) concentration of 1×10^{-1} M at the 1:1 or 1:1:1 metal to ligand A to ligand L molar ratios, respectively.

The pH of the samples was measured using a Radiometer pHM83 instrument equipped with a 2401c combined electrode and given as meter readings without correction for pD.

3. Results and discussion

3.1. Solution equilibria

The acid dissociation constants of the studied ligands are given in Table 2, together with the values previously published by us for dien, trien, α- and β-Alaha. The values of the stability constants obtained for the complexes in the studied systems are listed in the same Table 2.

The general four-component equilibria can be written as:

$$pZn + qA + rL + sH \rightleftharpoons Zn_pA_qL_rH_s$$

where p, q, r and s are the stoichiometric coefficients corresponding to the zinc(II) metal ion, A = dien or trien, L = α-Alaha or β-Alaha, and H, respectively; charges are omitted for simplicity.

The overall formation constants are defined as:

$$\beta_{pqrs} = [Zn_pA_qL_rH_s]/[Zn]^p[A]^q[L]^r[H]^s$$

The β_{pqrs} constant expresses the stability of the $[ZnAL]^+$ mixed-ligand species.

3.1.1. Zn^{II}–dien–α-Alaha/β-Alaha systems

The equilibrium constant, K_{ZnAL}, evaluated from the computed values of the related β_{pqrs} values according to equation: $\log K_{ZnAL} = \log \beta_{ZnAL} - \log \beta_{ZnA}$, shows how tightly L (aminohydroxamic anion) is bound to the simple $[ZnA]^{2+}$ complex.

The log $K_{Zn(dien)L}$ values are 4.65 and 5.09 for L = α-Alaha or β-Alaha, respectively. These values should be compared with log β_{ZnL}. For L = β-Alaha this comparison cannot be done, since the complex with 1:1 ratio is not formed in measurable concentrations in the Zn^{II}–β-Alaha system. The log β_{ZnL} value describing the reaction Zn^{2+} + α-Alaha ⇌ $[Zn(\alpha\text{-Alaha})]^+$ gives 5.29. The difference of these two values (4.65 − 5.29), $\Delta \log K$, describes the difference between the affinities of α-Alaha to Zn^{II} and to $[Zn(dien)]^{2+}$. Since it is similar to that expected on a statistical basis [24,25], it indicates that α-Alaha binds to the $[Zn(dien)]^{2+}$ complex as easily as to Zn^{II}.

Sigel's log $X_{Zn(dien)L}$ value (the constant due to the equilibrium $[Zn(dien)_2]^{2+} + [ZnL_2] \rightleftharpoons 2[Zn(dien)L]^+$) for L = α- or β-Alaha are 3.92 and 3.22, respectively, and are abnormally high (expected on a statistical basis is 0.6

Table 3
Overall stability constants (log β), deprotonation constants (pK) and characteristic parameters for Zn^{II} complexes formed with diethylenetriamine–triethylenetetramine (A) and α-Alaha/β-Alaha (L) in ternary systems at 25 °C and $I = 0.2$ M (KCl) in wayter solutions (the ion charges are omitted)

No	Assignment	A = dien		A = trien

15	σ	2.86	2.92	5.08	6.41

[24,25]), which means that the formation of the mixed complexes is strongly favoured in these systems (Table 3) and there are some special causes to stabilise them. It is notable that the denticity of the amines is certainly different in the ternary and binary systems. This is clearly demonstrated by the derived equilibrium constant, representing the binding ability of dien to their 1:1 complex and to the 1:1 complex of α-Alaha:

$$Zn(dien) + dien \rightleftharpoons Zn(dien)_2 \quad \log K = 5.02$$

$$Zn(\alpha\text{-Alaha}) + dien \rightleftharpoons Zn(\alpha\text{-Alaha})(dien) \quad \log K = 8.31$$

In the second case, the derived equilibrium constant is significantly higher, indicating that dien has a higher denticity in the ternary complex, than in the binary one.

From Table 3, it can be seen that for the Zn^{II}–dien–α-Alaha system the speciation model contains six simple species an two mixed-ligand ones: [Zn(dien)(α-Alaha)]$^+$ and [Zn(dien)(α-Alaha)H$_{-1}$]. For this system concentration distribution curves are presented in Fig. 1.

The Zn^{II}–dien 1:1 and 1:2 complexes are formed at high concentrations at zinc(II)–dien–α-Alaha ratio of 1:2:2. Under these conditions the mixed-ligand complexes are of approximately 30% of the total zinc content, but at 1:1:2 ratio the mixed-ligand complex reaches of approximately 90% (Fig. 1(c)). Additionally, Fig. 1(c) shows that the presence of dien suppresses the formation of polymeric [Zn$_2$(α-Alaha)$_3$]$^+$ species in the ternary system.

The calculated concentrations of these eight zinc(II) complex species, as a function of pH (shown in Fig. 1(c)) indicate that under these conditions the [Zn(dien)(H–dien)]$^{3+}$, [Zn(α-Alaha)$_2$], [Zn(dien)$_2$]$^{2+}$ species are the minor ones, so can be regarded as negligible. The first mixed-ligand species, [Zn(dien)(α-Alaha)]$^+$, is seen above pH 7 whereas above pH 9.5 [Zn(dien)(α-Alaha)H$_{-1}$] appears.

In the Zn^{II}–dien–β-Alaha system, the titration data fit satisfactorily to the assumption of the presence of the four simple species: [Zn(dien)]$^+$, [Zn(H–β-Alaha)$_2$]$^+$, [Zn(dien)$_2$]$^{2+}$, [Zn(dien)(H–dien)]$^{3+}$, and two mixed-ligand ones: [Zn(dien)(H–β-Alaha)]$^{2+}$ and [Zn(dien)(β-Alaha)]$^+$. The stability constants obtained for the complexes in the binary and ternary systems are given in Tables 2 and 3, together with the values for the simple complexes taken from the previous studies [14].

Concentration distribution curves are presented in Fig. 2.

The calculated concentrations of these six zinc(II) complex species, as a function of pH, for Zn^{II}–dien–β-Alaha 1:1:2 ratio system (shown in Fig. 2(c)) indicate that under these conditions the first mixed-ligand species, [Zn(dien)(H–β-Alaha)]$^{2+}$, appears above pH 6 and reaches a maximum concentration of approximately 65% at pH 8. The next mixed-ligand species [Zn(dien)(β-Alaha)]$^+$, is a major one (ca. 100% at pH 11). The [Zn(dien)$_2$]$^{2+}$ and [Zn(dien)(H–dien)]$^{3+}$ species were found in the ternary system with a very low ($<4\%$) concentrations. However, when these species were not included in the model the goodness of fit tests was much worse.

The deprotonation process of [Zn(dien)(H–β-Alaha)]$^{2+}$ leading to the formation of [Zn(dien)(β-Alaha)]$^+$ above pH 7 corresponds to the liberation of the proton from the $-NH_3^+$ group of β-Alaha, which is hardly likely, since the p$K_{Zn(dien)(H-\beta\text{-Alaha})}$ value equal to 8.73 (Table 3 number 8) is characteristic for the pK_{β}-

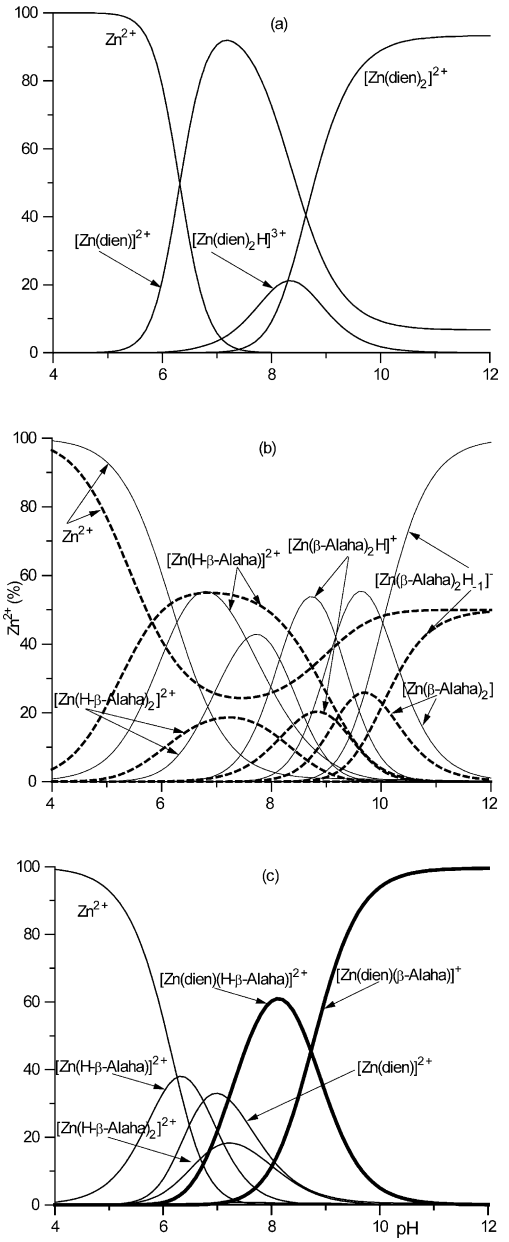

Fig. 2. Species distribution patterns of Zn^{II} complexes in the binary and ternary systems: (a) Zn^{II}–dien at 1:2 molar ratio; $c_{Zn^{II}} = 4 \times 10^{-3}$ M; (b) Zn^{II}–β-Alaha at 1:2 molar ratio; $c_{Zn^{II}} = 4 \times 10^{-3}$ M (solid lines) and Zn^{II}–β-Alaha at 1:1 molar ratio; $c_{Zn^{II}} = 2 \times 10^{-2}$ M (dashed lines; simulated for conditions used in NMR studies); (c) Zn^{II}–dien–β-Alaha at 1:1:2 molar ratio; $c_{Zn^{II}} = 4 \times 10^{-3}$ M.

$_{Alaha}{}^{micro}$ (NH_3^+) microconstant (8.85) (see Table 2). Taking into account these protonation constants, hydroxamate type (O,O) co-ordination of H–β-Alaha can be supposed for the $[Zn(dien)(H\text{–}\beta\text{-Alaha})]^{2+}$ species.

Comparing both Zn^{II}–dien–L ternary systems, it can be seen that α-Alaha is the same effective chelating ligand as β-Alaha. This is reflected in almost identical basicity-adjusted stability constants, $\log K_{Zn(dien)(\alpha\text{-Alaha})/(\beta\text{-Alaha})} - pK^{micro}_{\beta\text{-Alaha}}$. These values are −3.25 and −3.38 for $[Zn(dien)(\alpha\text{-Alaha})]^+$ and $[Zn(dien)(\beta\text{-Alaha})]^+$, respectively (Table 4). Taking into account these basicity-adjusted stability constants, hydroxamate type (O,O) co-ordination of α-Alaha and β-Alaha can be supposed for these species.

Owing to the larger space requirement and neutral charge of dien (the fully deprotonated hydroxamate group has a charge of −1), the chelating ability of this ligand to the $[Zn(dien)]^{2+}$ species is lower than that of the hydroxamate anion. So, the mixed-ligand species are more stable than the simple, $[Zn(dien)_2]^{2+}$.

Table 4
Overall stability constants (log β), stepwise formation constants (log K) and basicity-adjusted stability constants for Zn^{II} mixed-ligand complexes formed with amines (A) and α-alaninehydorxamic acid–β-alaninehydroxamic acid (L) at 25 °C and $I = 0.2$ M (KCl) in water solutions (the ion charges are omitted)

3.1.2. Zn^{II}–trien–α-Alaha/β-Alaha systems

For the determination of the stability constants of the mixed complexes formed in the Zn^{II}–trien–α-Alaha/β-Alaha systems (presented in Table 3), potentiometric measurements were carried out with at least twofold excess of the total amount of moles of aminohydroxamic ligands relative to the number of moles of trien and the metal ion. Within the whole studied pH range (i.e. from ca. 5 to 11) no precipitate was observed. The mixed complexes start to be formed from pH of about 5 and above pH 6.5 only mixed-ligand species exist in both systems (Fig. 3(b and c)).

The $[Zn(H–α\text{-Alaha})]^{2+}$ and $[Zn(α\text{-Alaha})]^{+}$ species are minor ones, so may be regarded as negligible (Fig. 3(b)).

The deprotonation process of $[Zn(trien)(H–α\text{-Alaha})]^{2+}$ leading to the formation of $[Zn(trien)(α\text{-Alaha})]^{+}$ above pH 6.5 corresponds to the liberation of the proton from the $–NH_3^+$ group of α-Alaha, the $pK_{Zn(trien)(H–α\text{-Alaha})}$ value equal to 7.56 (Table 3 number 8) is characteristic for the $pK^{micro}_{β\text{-Alaha}}$ (NH_3^+) microconstant (7.48) (see Table 2). Thus, hydroxamate type (O,O) co-ordination of H–α-Alaha ligand can be supposed for the $[Zn(trien)(H–α\text{-Alaha})]^{2+}$ species.

The final deprotonation of $[Zn(trien)(α\text{-Alaha})]^{+}$ leading to the $[Zn(trien)(α\text{-Alaha})H_{-1}]$ species at pH ≈ 9 corresponds to the ionisation of a metal-bound water molecule.

In the Zn^{II}–trien–β-Alaha system all pH-metric titration curves were consistent with the formation of $[Zn(trien)(H–β\text{-Alaha})]^{2+}$ and $[Zn(trien)(β\text{-Alaha})]^{+}$ as main complexes (ca. 98%). Optimisation using the SUPERQUAD software necessitated the introduction of $[Zn(H–trien)]^{3+}$, $[Zn(H–β\text{-Alaha})]^{2+}$ and $[Zn(H–trien)(H–β\text{-Alaha})]^{3+}$ as the additional complex species in the complexation set. The stability constants obtained for the complexes in the binary and ternary systems are given in Tables 2 and 3. Concentration distribution curves are presented in Fig. 3(c).

The deprotonation process of $[Zn(trien)(H–β\text{-Alaha})]^{2+}$ leading to the formation of $[Zn(trien)(β\text{-Alaha})]^{+}$ above pH 8 may correspond to the liberation of the proton from the $–NH_3^+$ group of β-Alaha, as it was in the system with α-Alaha, but it is not univocal (see deprotonation constants of trien in Table 2). However, the basicity-adjusted stability constants, $\log \beta_{Zn(trien)(H–α\text{-Alaha})/(H–β\text{-Alaha})} - pK^{micro}_{NH_3^+}$, are almost identical with $\log \beta_{Zn(trien)(α\text{-Alaha})/(β\text{-Alaha})}$ (Table 3). Therefore, we suggest that the amino group of either α-Alaha or β-Alaha is out of the co-ordination sphere in the ternary systems.

Sigel's log $X_{Zn(trien)L}$ value (the constant due to the equilibrium $[Zn(trien)_2]^{2+} + [ZnL_2] \rightleftharpoons 2[Zn(trien)L]^{+}$) for L = α-Alaha or β-Alaha are 8.31 and 7.30, respectively, and are abnormally high. This means that the formation of mixed complexes is even more strongly favoured in these systems (Table 3) than in those discussed in Section 3.1.1. So, the statistical effects are more important in the systems with trien than with dien. The larger space requirement for trien, compared with dien, is the reason that the chelating ability of trien to the $[Zn(trien)]^{2+}$ species is lower than of dien to $[Zn(dien)]^{2+}$ and the hydroxamate anion (which is smaller from both polyamines) is preferred as a secondary ligand in these systems.

In the Zn^{II}–trien–L ternary systems α-Alaha is as effective chelating ligand as is β-Alaha. This is reflected in almost identical basicity-adjusted stability constants, $\log \beta_{Zn(trien)(α\text{-Alaha})/(β\text{-Alaha})} - pK^{micro}_{NHOH}$ (the same situation was observed in the systems with dien). These values are 9.42 and 9.28 for $[Zn(trien)(α\text{-Alaha})]^{+}$ and $[Zn(trien)(β\text{-Alaha})]^{+}$, respectively (Table 3). Taking into account these basicity-adjusted stability constants, hydroxamate type (O,O) co-ordination of α- and β-Alaha ligand can be supposed for these species.

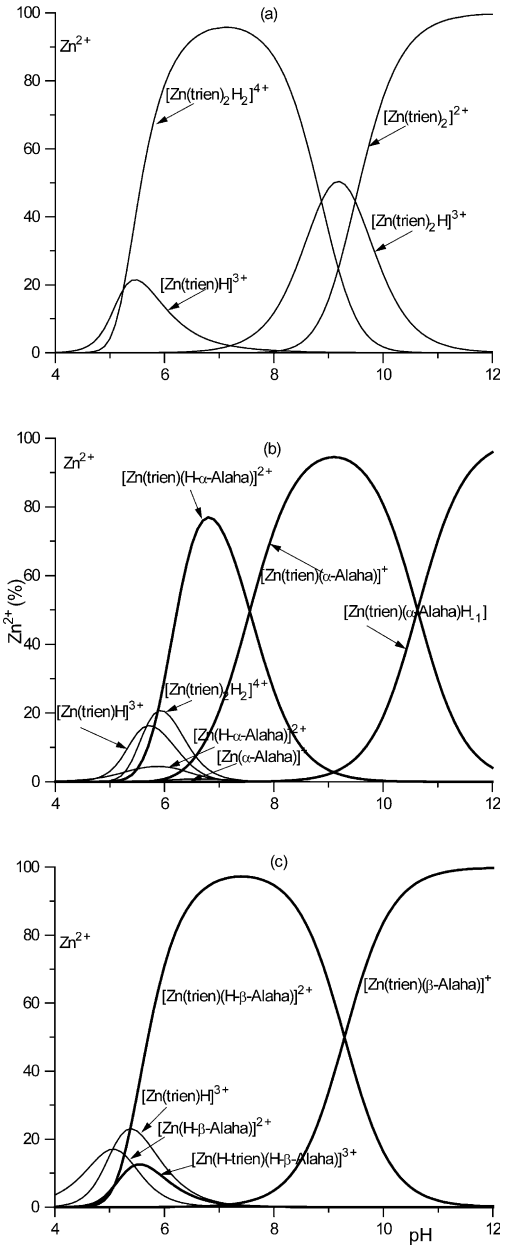

Fig. 3. Species distribution patterns of Zn^{II} complexes of trien: (a) at 1:2 molar ratio and trien–α-Alaha (b) and trien–β-Alaha (c) at 1:1:2 molar ratio; $c_{Zn^{II}} = 4 \times 10^{-3}$ M.

3.2. NMR studies

In order to obtain supporting evidence for the interpretation of the potentiometric data and to get some structural information of the species in solution, we undertook the ^{1}H and ^{13}C NMR studies. The spectra were measured as a function of pH and compared with those obtained for free ligand alone and for the respective Zn^{II}–hydroxamate and Zn^{II}–polyamine binary systems. Finally, we compared the NMR titration

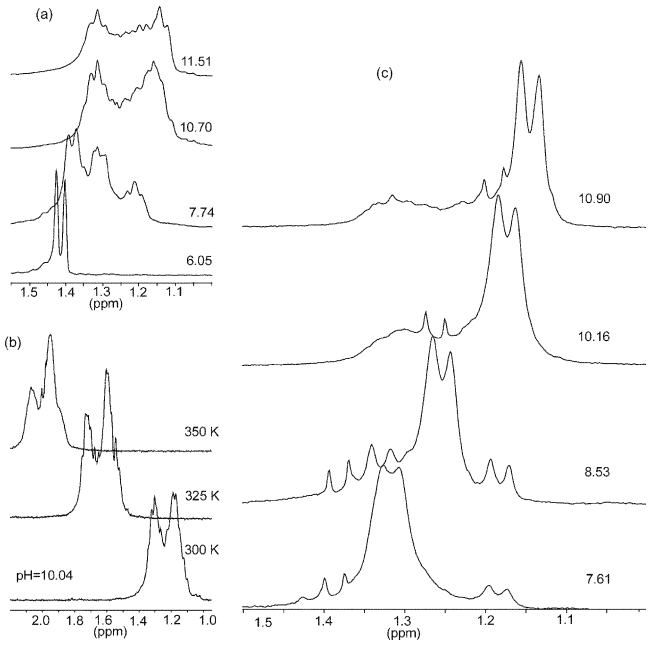

Fig. 4. ^{1}H MNR spectra (CH_3 region) for the Zn^{II}–α-Alaha binary systems at different molar ratios and pH values: (a), (b) 1:1 solutions, (c) 1:2 solutions; $c_{\alpha\text{-Alaha}} = 2 \times 10^{-2}$ M.

data with the species distribution curves recalculated for the conditions used in NMR experiments.

3.2.1. Zn^{II}–α-Alaha and Zn^{II}–β-Alaha binary systems

There are significant differences between the spectra of the Zn^{II}–α-Alaha solutions depending on the metal to ligand stoichiometric ratio. Specifically, the zinc(II) equimolar mixture exhibits rather complex pattern of the resonances in the pH range ~7–12. As an illustration, the number of doublets for the CH_3 group in the proton spectra is presented in Fig. 4(a).

As seen, most of the peaks are almost intact versus pH, whereas their intensities change when pH is varied. The spectra are temperature sensitive. The signals move gradually downfield with increasing temperature and some coalescence above 330 K. Finally, at 350 K two broad features are observed (Fig. 4(b)). Interesting is, that under the same conditions the spectra of the 1:2 molar ratio system are significantly simplified. The intensities of the most resonances roughly decrease with resultant one set of signals predominating in an evident manner in the studied range of pH (Fig. 4(c)). Accordingly, the zinc(II) system with sarcosine hydroxamic acid (not discussed here) exhibits similar behaviour, whereas comparative study with harder magnesium(II) ion revealed only one set of resonances in the whole range of pH. All these facts demonstrate that aminohydroxamic acids are capable of binding zinc(II) not only through the (O,O) hydroxamate function but also through the *N*-amino donor, which, in turn, can enhance the (N,N) chelate binding mode

involving N_{amino} and $N_{hydroxamate}$ donor set. The evidences for facilitating such co-ordination in the case, when the amino group is in adjacent (α or β) position in relation to the nitrogen of the hydroxamate group are provided from both X-ray and solution studies for Cu^{II}, Ni^{II} and Mo^{VI} [15,26–30].

Unfortunately, the character of the spectra precludes the detailed assignments. We can only speculate that the observed phenomena are due to a slow on the NMR time scale equilibria for complexation reactions. A noteworthy feature of the 1:1 molar ratio system is that all ligand is consumed to form $[Zn_2(\alpha\text{-Alaha})_3]^+$ and $[Zn(\alpha\text{-Alaha})H_{-1}]$ as the two major species at $pH > 7$. In the former complex, the only way of co-ordination is that one molecule serves as a bridge between the two zinc(II) ions, involving both pairs of available donor sets, (O,O) and (N,N), whereas the two others bind to the dinuclear core in the chelate modes ((O,O) or (N,N)). Such co-ordination enables the formation of four different co-ordination isomers of this complex that could give rise to the separate set of signals in the NMR spectra. In the latter complex, the most likely co-ordination mode is via the *N*-amino and *N*-hydroxamic functions. Therefore, a kinetic inertness of both complexes may be either due to a strained structure of $[Zn_2(\alpha\text{-Alaha})_3]^+$ imposed by the planar disposed hydroxamate (O,O) and N-donors or due to inert, long-lived in respect of the NMR time scale, zinc(II)–nitrogen bonds. Consequently, the behaviour of the 1:2 molar ratio system may be associated with the metal-free ligand, proved from the potentiometric data to remain in solution over the whole range of pH. In particular, $[Zn_2(\alpha\text{-Alaha})_3]^+$ and free ligand are the major species contributing the spectrum at pH 8.53, whereas $[Zn(\alpha\text{-Alaha})H_{-1}]$ and free ligand, appearing in nearly the same concentrations, contribute the spectrum at pH 10.90 (Fig. 4(b)). Both these complexes are shown to be capable of a slow on the NMR time-scale complex-formation kinetics. Therefore, may be considered as exchanging slow with the ligand present in the system.

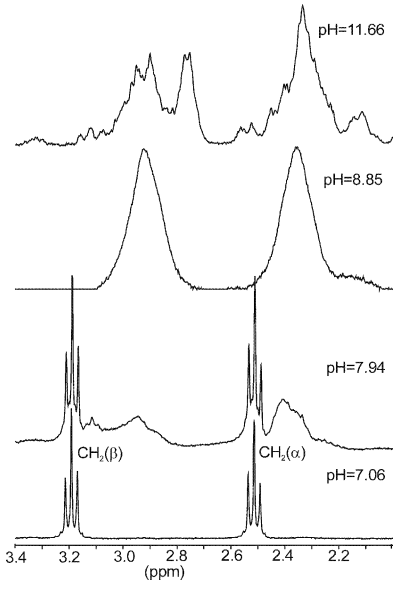

Fig. 5. ^1H NMR spectra for the Zn^{II}–β-Alaha 1:1 solutions at different pH values, $c_{\beta\text{-Alaha}} = 2 \times 10^{-2}$ M.

The comparative studies with β-Alaha having reversed, with respect to α-Alaha, acidity sequence for the $-NH_3^+$ and –CONHOH groups (Table 2) reveal differences between both Zn^{II}–β-Alaha and Zn^{II}–α-Alaha systems. One most important is the lack of the dinuclear complex, besides 1:2 molar ratio complexes are formed. In addition, due to increased basicity of the $-NH_3^+$ group the protonated complexes dominate over a wider range of pH (up to ~8.5) (Fig. 2(b)). As long as the amino group remains protonated, the ligand is capable of co-ordinating via the oxygens of the hydroxamate group. Accordingly, the only effects of co-ordination are little changes in chemical shifts of the major CH_2 signals, with respect to the metal-free ligand (Fig. 5).

However, the spectra show that the relatively inert (N,N) bonded species may also be formed under

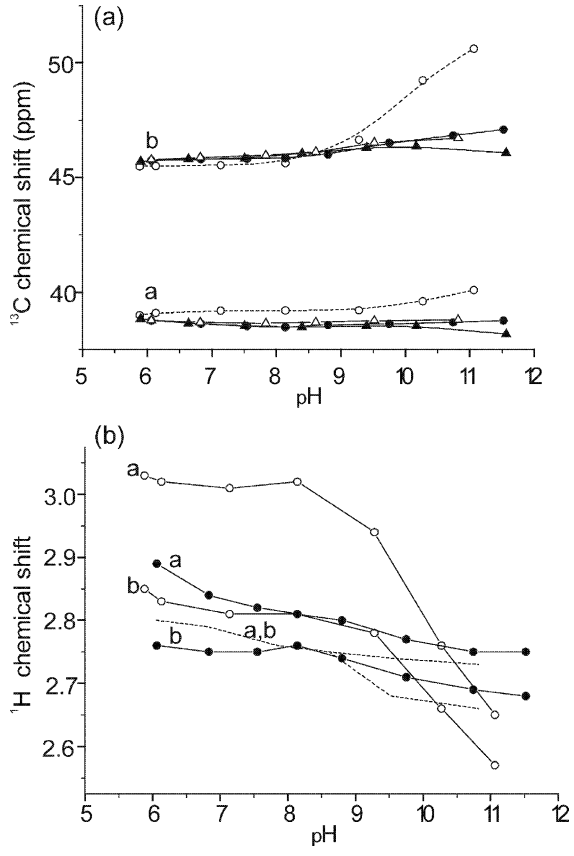

Fig. 6. ^{13}C and ^1H chemical shifts for C carbons (a) and CH_2 protons (b) of dien as a function of pH:free dien (○); Zn^{II}–dien 1:1 (Δ, …); Zn^{II}–dien–α-Alaha 1:1:1 (●) and Zn^{II}–dien–β-Alaha 1:1:1 (▲) ternary solutions. The assignments for C and CH_2 are consistent with those in Scheme 1.

conditions where the amino nitrogen is capable of competing with the hydroxamate oxygens for co-ordination. This is accompanied with a significant broadening of the resonance signals and their upfield shifts with respect to free β-Alaha. Thus, we suggest that formation of [Zn(β-Alaha)$_2$] and further [Zn(β-Alaha)$_2$H$_{-1}$]$^-$ is somehow accompanied with a change in the co-ordination modes from (O,O) towards the (N,N).

3.3. Ternary systems

The set of pH profiles of the ^{13}C chemical shifts for metal-free dien, dien in 1:1 molar ratio solutions with zinc(II) and of equimolar mixtures of zinc(II) and dien with α- or β-Alaha in the 1:1:1 molar ratio is presented in Fig. 6(a).

It is generally accepted for aliphatic polyamines that the change in chemical shift for a particular C atom on forming a zinc(II) chelate is typically about half that seen on fully protonating free ligand (A) [30–32]. The chemical shifts for both C_a and C_b in the Zn^{II}–dien system are nearly constant at pH > 6 and fulfill the above requirement. Thus, clearly show that dien apparently acts as a tridentate ligand involving all available nitrogen donors. The same is confirmed if consider the methylene protons of dien in the ^{1}H NMR spectra (Fig. 6(b)). Taking into account that under conditions studied the chemical shifts for the corresponding C and CH_2 of dien in the Zn^{II}–dien–α-Alaha/β-Alaha ternary systems are almost unchanged with respect to those of Zn^{II}–dien at pH > 6 (Fig. 6(a and b)) it is clear that, the arrangement adopted by amine in the [Zn(dien)]$^{2+}$ complex is retained on formation of the mixed-ligand species with either α- or β-Alaha. A similar conclusion holds in the case of the ternary systems with trien. (Fig. 7(a and b)).

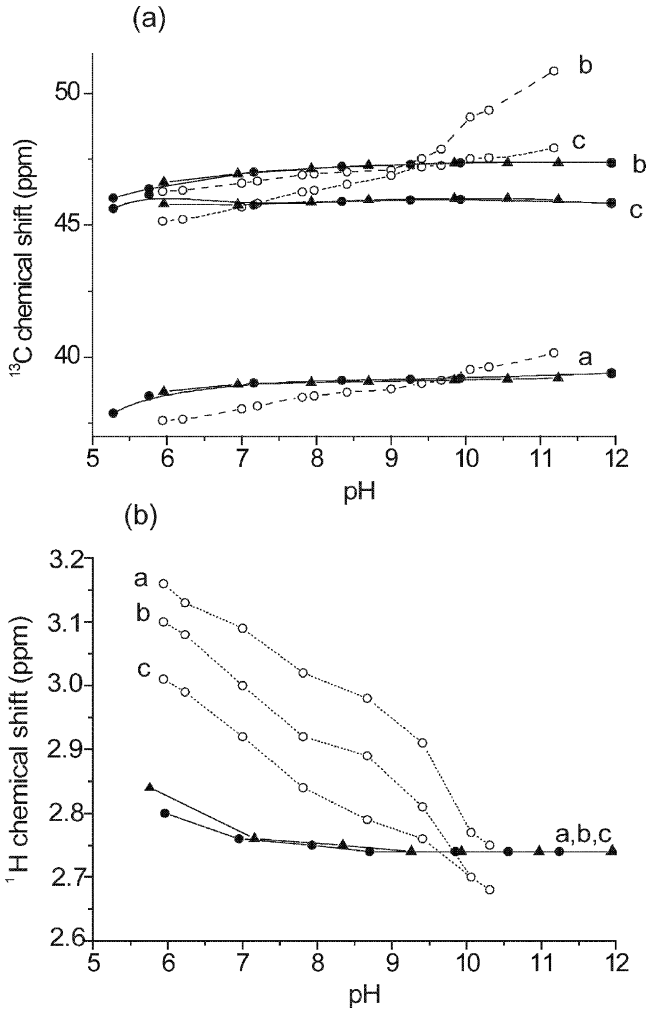

Fig. 7. ^{13}C and ^{1}H chemical shifts for C carbons (a) and CH_2 protons (b) of trien as a function of pH: free trien (○); Zn^{II}–trien–α-Alaha 1:1:1 (●) and Zn^{II}–trien–β-Alaha 1:1:1 (▲) ternary solutions. The assignments for C and CH_2 are consistent with those in Scheme 1.

The general invariance of the chemical shifts on pH in the appropriate ^{1}H and ^{13}C NMR spectra above pH 7 shows that a tetradentate co-ordination of trien is a common feature of either [Zn(trien)(α-Alaha)]$^+$ and [Zn(trien)(α-Alaha)H$_{-1}$] or [Zn(trien)(H–β-Alaha)]$^{2+}$ and [Zn(trien)(β-Alaha)]$^+$, respectively.

Interestingly, co-ordination exerts relatively small effect on the chemical shifts of bound α- and β-Alaha (Fig. 8).

Moreover, in contrast to the binary Zn^{II}–α-Alaha and Zn^{II}–β-Alaha systems both ^{1}H and ^{13}C NMR spectra comprise a single set of sharp signals indicating that exchange of hydroxamate between complex species is fast throughout. Under conditions where the mixed-ligand complexes emerge as the major species the resonance attributed to $C_\alpha H$ of α-Alaha in the ^{1}H spectra shifts downfield ($\Delta\delta \sim 0.15$ ppm) with respect to the fully deprotonated free ligand form (L^-) (Fig. 8(a)). A comparative study with β-Alaha reveal little differences in the ^{1}H NMR behaviour between both acids (Fig. 8(b)). All these facts demonstrate that there is no binding to the amino group in the mixed-ligand species, thus confirm, that in principal complexes ([ZnAL]$^+$ with α-Alaha and [ZnA(LH)]$^{2+}$ with β-Alaha) hydroxamic acids coordinate zinc(II) exclusively through the (O,O) hydroxamate donor set. The same evidence is provided from the ^{13}C NMR experiments where upfield shifts due to zinc(II) complexation are detected for either $C_\alpha H$ of α-Alaha or $C_\alpha H_2$ of β-Alaha (Fig. 8(c and d)).

The above results are fully consistent with the previous studies on zinc(II) mixed-ligand complexes of aliphatic polyamines with a range of small potentially bidentate O- and N-binding ligands (L) [30–32]. The noteworthy feature of all these complexes is a little transmission of inductive effects from ligand L to the polyamine moiety through the zinc(II) ion resulting in apparent similarities of the chemical shifts for respective

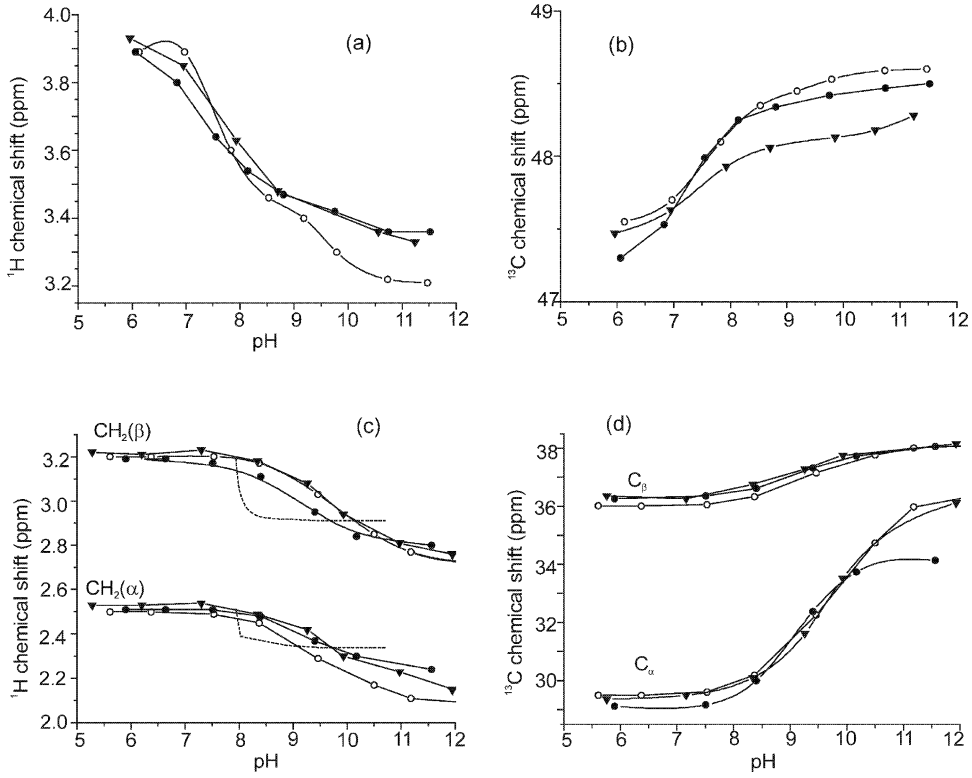

Fig. 8. ^{1}H and ^{13}C chemical shifts for $C_\alpha H$ (a) C_α (b) of α-Alaha and $CH_2(\alpha)$, $CH_2(\beta)$ (c), C_α, C_β (d) of β-Alaha as a function of pH:free ligand (○) and Zn^{II}–dien-hydroximate 1:1:1 (●), Zn^{II}–trien-hydroxamate 1:1:1 (▼) ternary solutions. The assignments for C, CH and CH_2 are consistent with those in Scheme 1. For comparison the ^{1}H NMR titration curves for the major peaks of the Zn^{II}–β-Alaha 1:1 solutions, $c_L = 2 \times 10^{-2}$ M (dashed lines).

carbons of polyamines between the simple Zn^{II}–polyamine and mixed-ligand complexes (Figs. 9–11).

4. Conclusion

A comparison of the stability constants of the mixed-ligand complexes obtained from the studied ternary systems: Zn^{II}–en–α-Alaha/β-Alaha [33,34], Zn^{II}–dien–α-Alaha/β-Alaha and Zn^{II}–trien–α-Alaha/β-Alaha reveals that the stability constants of mixed-ligand species

with α-Alaha are lower than those with β-Alaha. This can probably be explained by the higher basicity of the hydroxamic oxygen of β-Alaha. There is a strong evidence from our pH-metric and NMR results that two oxygen donors of the aminohydroxamic anion are involved in the zinc(II) co-ordination sphere. Besides, we found a linear correlation between stability constants of the mixed-ligand complexes. Plot of log $\beta_{[ZnA(\beta\text{-Alaha})]}$ as a function of log $\beta_{[ZnA(\alpha\text{-Alaha})]}$ (A = en, dien or trien) is presented in Fig. 9. Taking into account that 'A' represents polyamine that forms a very stable complex and aminohydroxamic anions are compounds of the same type this plot, to a first approximation, can be interpreted as reflecting the same type of co-ordination in these complexes.

Plotting log β of the mixed-ligand species as a function of the number of nitrogen donors in polyamine (Fig. 10) we found that the correlation between these two parameters is a function of the number of the co-ordinated nitrogens in the mixed-ligand species. As the log K values of [ZnA_2] and [ZnAL] are very close, one can conclude that sterical hindrance is the major factor, which determinates a formation of the mixed-ligand complexes. Accordingly, the smaller α- or β-Alaha are bound preferentially over second dien or trien to form the mixed-ligand [ZnAL] species. Plot of log X as a function of a number of nitrogen donors in polyamines (Fig. 11) shows that the formation of mixed complexes is more favoured if polyamine has more nitrogen donors.

vides the first example of a dien-bridged dinuclear complex.

2. Experimental

2.1. Materials and physical measurements

All the chemicals were purchased from Aldrich and used without further purification. Microanalyses were performed by Perkin–Elmer 2400II elemental analyzer and CE instruments. IR spectra (4000–400 cm^{-1}) were recorded from KBr disks with a Nicolet Magna-IR spectrophotometer (Series II), UV–Vis spectra on a Shimadzu UV-160A spectrophotometer, ^1H NMR and ^{13}C NMR spectra by a Bruker DPX200 spectrometer. FAB mass spectra (3-nitrobenzyl alcohol as a matrix in DMF as solvent) were carried out on a VG Autospec M-250 instrument. Cyclic voltammetry was performed at a planar EG&G PARC G0229 glassy carbon milli electrode using EG&G PARC electrochemical analysis system (model 250/5/0) in purified and anhydrous DMF under dry nitrogen atmosphere in conventional three electrode configurations. Under the experimental conditions employed here and scan rate of 50 mV s^{-1}, the reference ferrocene–ferrocenium couple appears at 0.468 V versus SCE with ΔE_p of 114 mV.

2.2. Preparations

2.2.1. $[Hg_2(dien)_3](ClO_4)_4$ (1)

Pulverized $Hg(CH_3COO)_2$ (0.320 g, 1 mmol) was dissolved in 50 ml of 80% ethanol. To this solution 0.11 ml (1 mmol) of dien was added drop-wise with constant stirring. The colorless reaction mixture was stirred at room temperature (r.t.) for 1 h, after which it was filtered. To the filtrate, 0.146 g (1.2 mmol) of sodium perchlorate dissolved in 5 ml of water was added drop-wise with constant stirring. This reaction mixture was left in the air for 3 days. Colorless crystals suitable for X-ray analysis were deposited. Then, they were filtered, washed with few drops of 80% ethanol and dried in air. Yield: 0.185 g, 33%. ^1H NMR (200 MHz, $(CD_3)_2SO$, TMS): δ_H: 2.64 (d, methylene protons). ^{13}C NMR (200 MHz, $(CD_3)_2SO$, TMS): δ 47.8. Main IR bands (KBr, ν, cm^{-1}): 3323(vs), 3255(s), 2930(m), 2880(m), 1570(s), 1490(s), 1435(m), 1147(vs), 1114(vs), 1090(vs), 627(s, split). *Anal.* Found: C, 12.83; H, 3.64; N, 11.32. Calc. for $C_{12}H_{39}N_9O_{16}Cl_4Hg_2$: C, 12.99; H, 3.55; N, 11.37%.

2.2.2. $[Hg(dien)(H_2O)](PF_6)_2$ (2)

This compound was prepared by a procedure exactly the same as used for **1**, by reacting 0.320 g (1 mmol) of pulverized $Hg(CH_3COO)_2$ and 0.11 ml (1 mmol) of dien in 50 ml of 80% ethanol, and then adding 5 ml water solution of 0.200 g (1.2 mmol) of sodium hexafluorophosphate. Colorless crystals suitable for X-ray analysis were obtained by keeping the reaction mixture in air for 4 days. They were filtered out, washed with few drops of 80% ethanol and dried in air. Yield: 0.330 g, 54%. ^1H NMR (200 MHz, $(CD_3)_2SO$, TMS): δ_H: 2.66 (d, methylene protons). ^{13}C NMR (200 MHz, $(CD_3)_2SO$, TMS): δ 46.7. Main IR bands (KBr, ν, cm^{-1}): 3323(vs), 3256(vs), 3145 (w), 2927(m), 2880(m), 1579 (vs), 1434(s, split), 1129(s), 1060(s), 835(vs), 561(vs). *Anal*. Found: C, 7.96; H, 3.38; N, 6.82. Calc. for $C_4H_{15}N_3OP_2F_{12}Hg$: C, 7.85; H, 2.47; N, 6.87%.

Caution! Perchlorate salts with organic ligands are potentially explosive and mercury salts are expected to be toxic. These materials should be handled with the necessary precautions.

2.3. Crystallography

The X-ray diffraction measurements were carried out at approximately 110 K on a Nonius KappaCCD diffractometer, using Mo Kα ($\lambda = 0.7107$ Å) radiation and 1.0° ϕ scans. The intensity data were integrated and scaled by the programs DENZO-SMN and SCALEPACK [14]. The analyzed crystals were coated with a layer of hydrocarbon oil (in order to avoid deterioration) and mounted on a glass fiber. The intensity data were corrected empirically for absorption effects. The structures were solved by Patterson and Fourier methods (DIRDIF-96, [15]), and refined by full-matrix least-squares based on F^2 for all reflections (SHELXL-97, [16]). All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were located in calculated positions to correspond to standard bond lengths and angles, and were included in the refinement with isotropic displacement parameters using a riding model. The crystal and experimental data are summarized in Table 1. The two compounds crystallized in non-centrosymmetric space groups (as confirmed by the corresponding intensity statistics and structure solution) as racemic twins. Furthermore, in structure **2** there are two mirror-related $[Hg(H_2O)(dien)]$ molecules in the asymmetric unit. One of the perchlorates in **1** is rotationally disordered.

3. Results and discussion

3.1. Syntheses and spectral characterization

The nuclearity of the product (P) in reaction (1) between $Hg(CH_3COO)_2$ and dien in the presence of NaX ($X^- = ClO_4^-$ and PF_6^-) in 80% of EtOH, appears to depend on the nature of the anion. When X^- is ClO_4^-, the product is a dimer, bridged by one dien, while when X^- is PF_6^- the product is only a monomer

[a] $R_1 = \Sigma\ ||F_o|-|F_c||/\Sigma\ |F_o|$. $wR_2 = \{\Sigma[w(F_o^2-F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$.

(comfirmed by elemental analysis, FAB mass spectra and X-ray crystal structure). In both cases the acetate residues are excluded from the resulting complexes. This phenomena is an example of 'unproliferating effect' exerted by larger non-coordinating anion [17,3i]. The volumes of ClO_4^- and PF_6^- are 51.3 and 69.7 Å^3, respectively [17]. When the anion is smaller the product is a dimer, but when the anion is larger, the product is only a monomer.

$$Hg(CH_3COO)_2 + Dien + NaX \xrightarrow[80\%\ \ EtOH]{1:1:1.2} Product\ (P) \quad (1)$$

The solution behavior of complexes **1** and **2** was analyzed by fast atom bombardment mass spectrometry (FAB MS) and cyclic voltammetry. From FAB MS of **1**, it is clear that the dimeric structure of **1** is preserved in solution too. Its FAB MS is little bit complicated but still informative, indicating successive loss of ClO_4^- and dien fragment. The peaks at $m/z = 1009.0$, 909.5, 810, 710.5 and 607.5 could be assigned as (**1**–ClO_4), (**1**–$2ClO_4$), (**1**–$3ClO_4$), (**1**–$4ClO_4$) and [**1**–($4ClO_4$ + $C_4H_{13}N_3$)], respectively. FAB MS of **2** displays three characteristic peaks at $m/z = 467.0$ (**2**–PF_6), 322.1 (**2**–$2PF_6$) and 304.1 [**2**–($2PF_6 + H_2O$)], respectively. The complexes **1** and **2** do not show any absorption in their electronic spectra in the 900–200 nm region.

In the NMR spectra of **1**, $(CD_3)_2SO$, all the methylene protons appear at, 2.64 ppm, and all the methylene carbons are also characterized by the same chemical shift of 47.8 ppm. In **2**, these protons appear at 2.66 ppm, and the carbon atoms at 46.7 ppm. The NH protons of the two compounds could not be observed.

There are only slight differences between the IR spectra of **1** and **2**, when the characteristic bands due to the anions are not taken into account. In the IR spectra of **1**, the peaks at 3323 and 3255 cm^{-1} may be attributed to ν(N–H) vibrations. Then, the sharp peak at 1570 cm^{-1} is due the $\delta(NH_2)$ bending vibration [13], two close peaks at 2930 and 2880 cm^{-1} are due to the ν(C–H) vibrations [18], and three very well resolved and strong bands at 1147, 1114 and 1090 cm^{-1} along with a very strong doublet at 627 cm^{-1} were assigned to the non-coordinated $\nu(ClO_4^-)$ vibrations in a distorted geometry [19]. For the complex **2**, the ν(N–H) vibrations appear at 3323 and 3256 cm^{-1}, the ν(C–H) vibrations appear at 2927 and 2880 cm^{-1}, and $\delta(NH_2)$ bending vibration appears at 1579 cm^{-1}. The non-coordinated $\nu(PF_6^-)$ vibrations appear at 1060, 835 and 561 cm^{-1} [20].

3.2. Cyclic voltammetry

The electrochemical behavior of the complexes **1** and **2** has been examined by cyclic voltammetry in DMF (0.1 M tetraethyl ammonium perchlorate as supporting electrolyte) under dry N_2 atmosphere at a glassy carbon electrode in the voltage range −0.5 to 0.7 V versus SCE. For both complexes, somewhat irreversible cyclic responses are obtained. Complexes **1** and **2** show Hg(II)–Hg(III) couple with half-wave potential ($E_{1/2}$) of 0.030 and 0.026 V versus SCE with ΔE_p, 0.400 and 0.410 V at a scan rate of 50 mV s^{-1} (Fig. 1).

3.3. Structural description

The molecular structures of **1** and **2** are illustrated in Figs. 2 and 3, respectively. Selected structural parameters are summarized in Table 2. All the nitrogen coordinate to the Hg ions (within Hg–N = 2.2–2.4 Å) in the two structures. The N–Hg–N angles of five-membered chelate ring formed by the tridentate dien ligand are less than 90° due to the inherent geometric constraints in this ligand. All the N–C–C–N conformations are gauche to facilitate of the N-sites to the metal

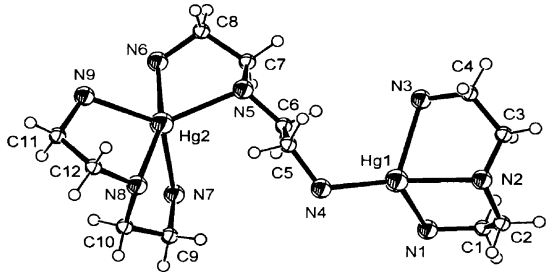

Fig. 2. Perspective view of the molecular structure of oligomer **1**, in which one of the dien species coordinates to two different mercury ions, showing the atom labeling scheme. Hydrogen atoms on N and the perchlorate anions are omitted for clarity.

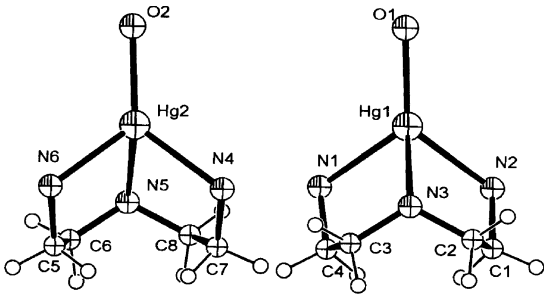

Fig. 3. The two crystallographically independent [Hg(dien)(H_2O)] complexes in structure **2**, showing the atom labeling scheme. Hydrogen atoms on N and O and the PF_6 anions are omitted for clarity.

ions, with the exception of the N4–C5–C6–N5 torsion angle in the conformationally stretched bridging ligand in **1**, which is anti (Table 2). Noteworthy also is the unusual penta Hg–N coordination around Hg2 in **1**, as opposed to the more common tetrahedral coordination environment in other parts of the two structures. The perchlorate and hexa-fluorophosphate anions are not bonded to the Hg atoms.

trans configuration with respect to terminal bonds, an argument that seems to be based on the fact that individual *trans*-to-*oxo* bonds in polyanions are considerably weaker than *cis*-to-*oxo* (bridging) bonds.

In a recent comparative investigation of W complexes and polyanions containing tri-*oxo* groups [32], we have found that the fact that these species are rarely observed does not appear to be a direct consequence of the individually weak *trans*-to-*oxo* bonds. Valency and bonding-energy analyses have indicated that the bonding capacity of the high-coordinate bridging centres can be similar to that of the unshared terminal sites. This article is focused on the chemical bonding in the isolated $[W_4O_{16}]^{8-}$ anions, and contains a detailed description of the electronic structures of the T_d and C_{2h} forms, which reveals that closed-loop orbital interactions are possible in these polyanions.

2. Computational approach

All density–functional calculations reported in this work were performed with the ADF (2000.02) [33–37] program. Functionals based on the Vosko–Wilk–Nusair (VWN) [38] form of the local density approximation (LDA) [39], and on a combination (labelled BP86) of Becke's 1988 exchange [40] and Perdew's 1986 correlation [41] corrections to the LDA were employed. Slater-type-orbital (STO) basis sets of triple-zeta quality incorporating frozen cores and the ZORA relativistic approach (ADF O.1s and W.4f type IV) [37] were utilised.

The functional and basis-set choices were based on the results of tests performed on several $[MO_4]$ and $[M_2O_7]$ species [42,43]. Geometry optimisations were carried out using LDA methods, whereas data on thermochemistry and energetics were extracted from single-point BP86 calculations. Graphics of molecular orbitals were generated with the MOLEKEL [44] program.

3. Results and discussion

Structural and atom-labelling schemes for the $[W_4O_{16}]^{8-}$ isomers are shown in Fig. 1. In the T_d form there are two types of oxygen sites, terminal (O_t) and three-coordinate bridging (O_b) atoms. The C_{2h} form contains a mixture of *cis* di-*oxo* (W2–O_t) and tri-*oxo* (W3–O_t) terminal moieties, and two classes of bridging sites, the two-coordinate O2 and the three-coordinate O3 atoms. A detailed report of calculated structural and bonding parameters for the T_d and C_{2h} isomers, and a comparison with experimental results have been presented in a previous publications [32]. A summary of computational W–O distances and bond orders is given in Table 1.

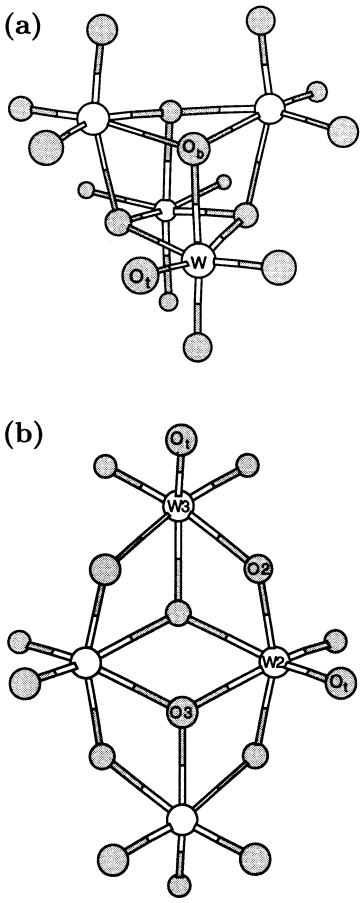

Fig. 1. Structural and atom-labelling schemes for (a) T_d and (b) C_{2h} isomers of $[W_4O_{16}]^{8-}$.

Table 1
Calculated W–O distances (in pm) and bond orders for the $[W_4O_{16}]^{8-}$ anions

Isomer	Parameter	Bond distance	Bond order
T_d	W–O_t	185	1.44
	W–O_b	223	0.47
C_{2h}	W2–O_t	185	1.43
	W3–O_t	188	1.38
	W2–O2	195	0.92
	W3–O2	214	0.52
	W2–O3	227	0.43
	W3–O3	219	0.52

3.1. Molecular-orbital description

Qualitative molecular-orbital schemes showing predominant metal and oxygen contributions to the valence levels of the T_d and C_{2h} isomers are given in Fig. 2. These diagrams are entirely qualitative in the sense that no accurate quantitative correlation exists amongst the

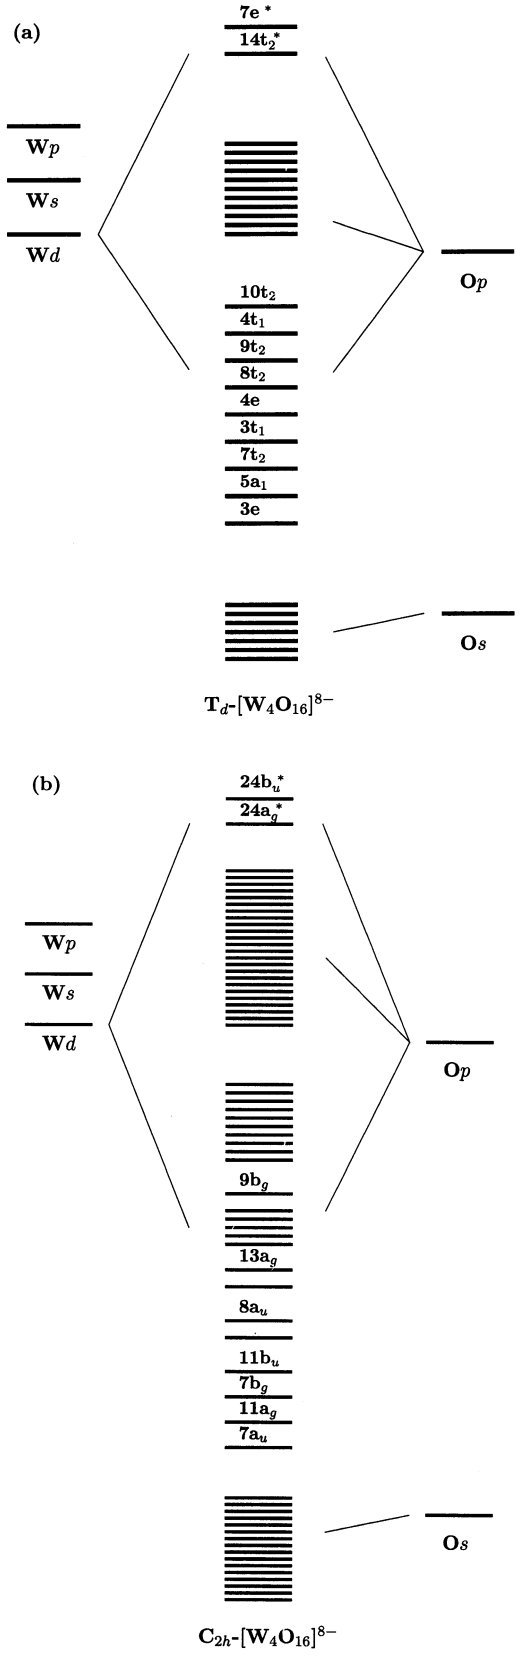

Fig. 2. Qualitative molecular-orbital schemes showing predominant W and O contributions to the valence levels of (a) T_d and (b) C_{2h} isomers of $[W_4O_{16}]^{8-}$.

positions of the atomic and molecular energy levels. They are intended to summarise the most general and representative characteristics of the electronic structure of the polyanions by highlighting the major atomic contributions to the molecular orbitals.

The schemes in Fig. 2 are characterised by the presence of two distinct sets of molecular energy levels, separated by a gap of approximately 10 eV. The low-lying orbitals comprise a predominantly nonbonding Os band. The high-lying set can be further divided into two bands. The higher-energy levels ('Op band') correspond to nonbonding combinations of Op-type functions, whereas the lower-energy levels ('Wd–Op band') are composed of orbitals that incorporate significant contributions from both the metal and oxygen atoms, and represent W–O bonding interactions of largely Wd–Op character.

All W–O bonding orbitals in the T_d form have been identified with their symmetry labels in the diagram of Fig. 2. The four lowest (3e, $5a_1$, $7t_2$, $3t_1$) levels incorporate both W–O_b and W–O_t interactions, but the remaining (higher) levels involve, primarily, W–O_t bonds. A similar pattern is observed in the C_{2h} form. All W–O bonding orbitals possess W–O_t character, but only the lower-lying levels incorporate substantial contributions from the various W–O2 and W–O3 interactions. Some of the highest-lying levels involve the relatively short W2–O2 bonds (in addition to W–O_t bonds).

It has been mentioned that Nomiya and Miwa have concluded that there are no closed loops in the T_d-$[W_4O_{16}]^{8-}$ anion. This is not supported by the present calculations. In this isomer, although all bridging-oxygen atoms occupy *trans*-to-*oxo* sites, they participate in the formation of delocalised bonds along $[W_2O_2]$ rings (representing the faces of the central $[WO_b]$ cube) that possess both σ and π character. Spatial plots (for the 3e orbitals) describing these multicentred bonding modes are shown in Fig. 3.

In C_{2h}-$[W_4O_{16}]^{8-}$, the bridging sites are in partial or total *trans* configuration with respect to the terminal bonds and, as in the T_d form, these oxygen atoms are involved in closed loops. An example of a $[W_2O_2]$ ring is given in Fig. 4, where the spatial plots of the σ and π components ($7b_g$ and $11b_u$ orbitals, respectively) of a four-membered loop comprising the W2 and O3 atoms are displayed.

In addition to $[W_2O_2]$ loops, eight-membered $[W_4O_4]$ rings are also found in the C_{2h} isomer. Spatial representations of σ and π interactions involving the W2 and W3 sites and all four O2 atoms are given in Fig. 5. These plots correspond to the $7a_u$, and $9b_g$ orbitals (and similar closed loops occur in the $11a_g$, $13a_g$, and $8a_u$, orbitals).

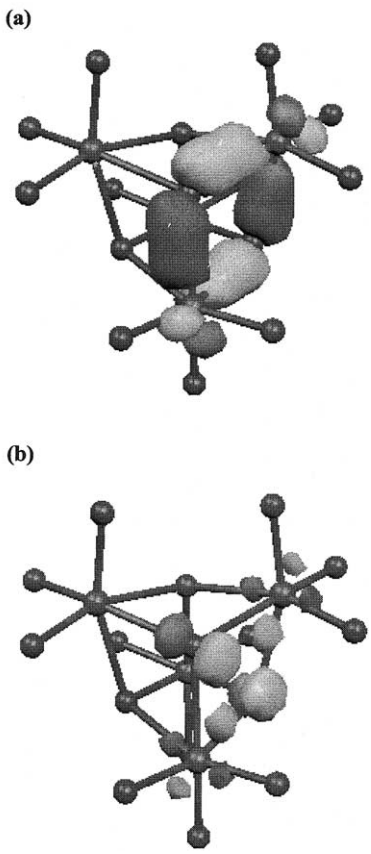

Fig. 3. Spatial molecular-orbital representation of (a) σ and (b) π $[W_2O_2]$ closed loops in the T_d-$[W_4O_{16}]^{8-}$ anion.

3.2. Bonding energetics

The molecular bonding energy (E_B) can be decomposed as:

$$E_B = E_O + E_P + E_E \quad (1)$$

where E_O, E_P, and E_E are, respectively, orbital-mixing, Pauli-repulsion, and electrostatic-interaction terms. Descriptions of the physical significance of these properties have been given by Landrum, Goldberg, and Hoffmann [45], and by Baerends and coworkers [37,46]. Both E_O and E_P represent orbital-interaction effects, but the former is stabilising whereas the latter is destabilising. The E_E contribution is primarily dominated by the nucleus-electron attractions and, therefore, has a stabilising influence.

Calculations on the $[W_4O_{16}]^{8-}$ anions, performed at the BP86 level of theory, indicate that the C_{2h} form is more stable than the T_d form by 223 kJ mol^{-1} (2.31 eV). Table 2 provides a summary of the contributions (to the individual bonding energies) associated with orbital-mixing, Pauli-repulsion, and electrostatic effects.

The orbital-mixing and electrostatic interactions are more favourable in the C_{2h} isomer, whereas Pauli repulsion is somewhat less destabilising in the T_d isomer. These results correlate with the W–O distances and

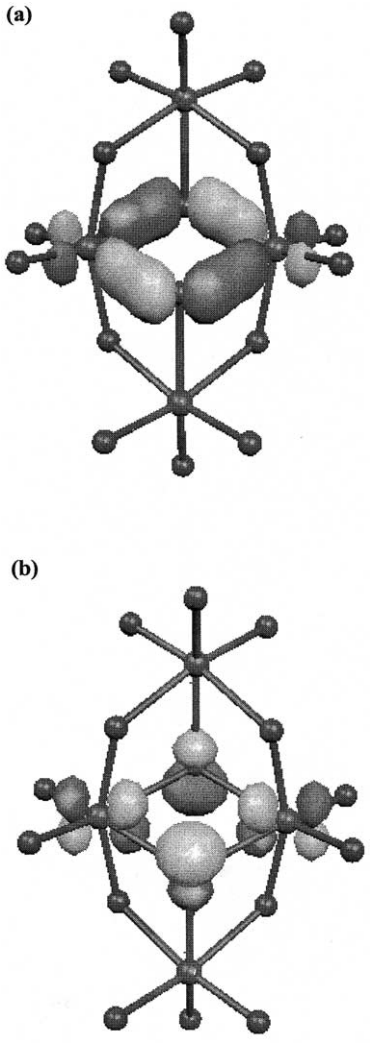

Fig. 4. Spatial molecular-orbital representation of (a) σ and (b) π $[W_2O_2]$ closed loops in the C_{2h}-$[W_4O_{16}]^{8-}$ anion.

indexes observed in the two $[W_4O_{16}]^{8-}$ anions. The terminal bonds show largely similar parameters, but the average bond lengths and orders of the bridging bonds suggest that, these are stronger in the C_{2h} (with respect to the T_d) form. The shorter distances and higher indexes of the W–O bridging interactions in C_{2h} $[W_4O_{16}]^{8-}$ should be associated with greater orbital and charge-distribution overlap, which can be related with the larger E_O, E_E, and E_P values obtained for this isomer [46].

The results of the present calculations are in agreement with some of the original ideas presented by Nomiya and Miwa [23], in the sense that the stabilising effects of orbital mixing are involved in making the C_{2h} isomer more stable than the T_d isomer. This is, however, not a general result. In the case of the α and β isomers of $[Mo_8O_{26}]^{4-}$ [47], the latter has a larger orbital-mixing contribution but a smaller total bonding energy than the former.

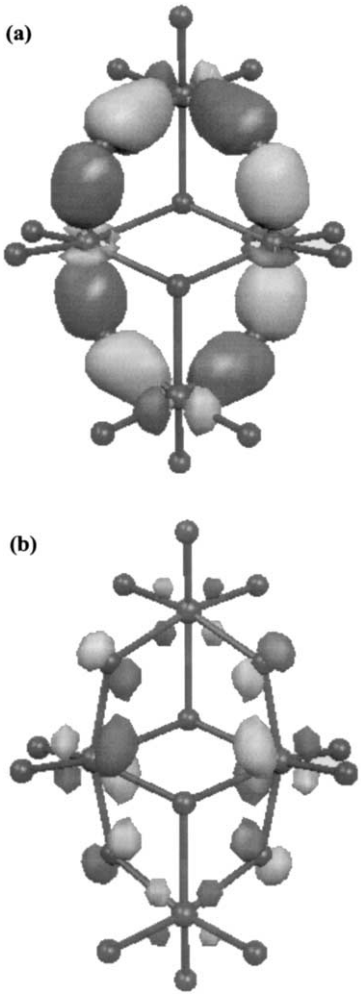

Fig. 5. Spatial molecular-orbital representation of (a) σ and (b) π $[W_4O_4]$ closed loops in the C_{2h}-$[W_4O_{16}]^{8-}$ anion.

Table 2
Orbital (E_O), Pauli (E_P), and electrostatic (E_E) contributions (in eV) to the bonding energy (E_B) of the T_d and C_{2h} isomers of $[W_4O_{16}]^{8-}$

Term	Isomer	
	T_d	C_{2h}
E_O	−273.98	−277.78
E_P	+297.49	+299.56
E_E	−110.61	−111.19
E_B	−87.10	−89.41

A fragment approach to the molecular structures of the polyanions can provide further insight into the relative effects of terminal and bridging W–O interactions on the bonding stability. In the present work, we have utilised the following decomposition scheme:

$$[W_4O_{15}]^{(6-)} + [O]^{(2-)} = [W_4O_{16}]^{(8-)} \quad (2)$$

for a comparison of all types of oxygen atoms in each $[W_4O_{16}]^{8-}$ isomer. The total molecular bonding energy relative to the fragments—described by Eq. (2)—is given by:

$$\Delta E_B = \Delta E_O + \Delta E_P + \Delta E_E \quad (3)$$

The results of the application of Eqs. (2) and (3) are shown in Table 3. It is observed that the orbital-mixing contributions from the various oxygen atoms are comparable despite the individual coordination environments and W–O interactions of the terminal and bridging sites being rather different. The *trans*-to-*oxo* configuration of the latter does not appear to lead to weaker overall bonding, neither does their participation in closed-loop delocalised interactions seem to generate a distinctively stronger contribution. The structural stability derived from the orbital interactions in the polyanions appears to be the result of the combined effect of all bonding modes involving the various oxygen types.

The molecular-orbital analysis has indicated that bonding to the metal atoms in the $[W_4O_{16}]^{8-}$ isomers is predominantly realised through participation of W d-type functions, the contributions from W s and p orbitals being minor or not significant. This phenomenon can be quantitatively characterised if the polyanions are described as:

$$4[W]^{(6+)} + 16[O]^{(2-)} = [W_4O_{16}]^{(8-)} \quad (4)$$

and calculations are carried out both with and without metal s and p valence orbitals. The relative effect of removing these orbitals can be measured as:

$$\delta(\Delta E_{B/O}) = \frac{\Delta E_{B/O}(d) - \Delta E_{B/O}(dsp)}{\Delta E_{B/O}(dsp)} \quad (5)$$

The results are summarised in Table 4 and support the general description of the W–O bonds as predominantly Wd–Op in character. The contributions from metal s and p orbitals are less that 1% if the total bonding energy is considered, and approximately 3% in the case of the orbital-mixing term.

4. Conclusion

The electronic structures of the T_d and C_{2h} isomers of $[W_4O_{16}]^{8-}$ have been calculated using density–

Table 3
Fragment analysis (ΔE_O in eV) for the isomers of $[W_4O_{16}]^{8-}$

Isomer	Atom	ΔE_O
T_d	O_t	−13.73
	O_b	−12.67
C_{2h}	O_t	−13.13
	O2	−13.72
	O3	−12.66

Results are based on Eq. (2).

Table 4
Changes (percentage) to the bonding (ΔE_B) and orbital-mixing (ΔE_O) energies caused by removal of metal s and p valence functions

Isomer	$\delta(\Delta E_B)$	$\delta(\Delta E_O)$
T_d	−0.5	−2.6
C_{2h}	−0.5	−2.5

Results are based on Eqs. (4) and (5).

functional methods, and analysed on the basis of molecular-orbital theory and bonding-energy approaches. In both anions, the W–O bonds have been found to be of predominantly Wd–Op character, and the greater stability (as isolated species) of the C_{2h} (with respect to the T_d) form has been observed to be, primarily, the consequence of somewhat stronger W–O orbital interactions.

As in the case of larger polyanions, some molecular orbitals are delocalised along closed loops, with $[W_2O_2]$ (T_d and C_{2h}) or $[W_4O_4]$ (C_{2h}) structures, which can involve all bridging sites. The results obtained from orbital and fragment analyses have suggested that these multicentred interactions are an important bonding mode and that bonding to the bridging-oxygen atoms should make a significant contribution to the stability of the $[W_4O_{16}]^{8-}$ clusters.

It should be noted that in the $[W_4O_{16}]^{8-}$ polyanions, as in the larger clusters, the presence of closed loops is not exclusively a consequence of the relatively high symmetry of these species. The calculations suggest that the (extensively) delocalised orbital interactions along the structural rings are possible due to the significant covalent character of metal–oxygen bridging bonds.

2. Experimental

2.1. Synthesis

Bis(triphenylarsine oxide)hydrogen(I) tetrachloroaurate(III), $[(Ph_3AsO)_2H][AuCl_4]$, and bis(pyridine *N*-oxide)hydrogen(I) tetrachloroaurate(III), $[(PyO)_2H][AuCl_4]$, were prepared by the slow evaporation of a solution containing the respective oxo-ligand and $HAuCl_4$ in a 2:1 molar ratio, according to [6,2], respectively. $DAuCl_4$ was obtained by dissolving Au_2O_3 in a DCl solution in D_2O and was used for the preparation of deuterated compounds. The extent of deuteration was not determined for the partially deuterated compounds except for $[(PyO)_2D][AuCl_4]$. In the following, we tentatively use the chemical formula with deuterium for the sake of convenience to distinguish the partially deuterated compound from the normal compound. $[Ph_3AsOD][AuCl_4]$ and $[PyOD][AuCl_4]$ were obtained accidentally using the oxo ligand and $DAuCl_4$ in a 2:1 molar ratio. For the synthesis of $[(PyO)_2D][AuCl_4]$ a large excess (ca. 2.5 equiv.) of the ligand was employed. A single crystal suitable for X-ray analysis was obtained by the slow evaporation of the solution of PyO and $DAuCl_4$ in a 5:1 molar ratio. $[PyOH][AuCl_4]$ was prepared from the solution of PyO and $HAuCl_4$ in a 1:2 molar ratio. This ratio was selected since $[(PyO)_{1.5}H][AuCl_4]$ had been obtained from the 1:1 solution.

$[(Ph_3AsO)_2H][AuCl_4]$ and $[(PyO)_2H][AuCl_4]$ were identified by comparing X-ray powder diffraction patterns with the expected ones from the reported crystal data [2,3]. Elemental analysis was made by Center for Organic Elemental Microanalysis, Kyoto University for the following compounds. *Anal*. Calc. for $[(Ph_3AsO)_2H][AuCl_4]$: C, 43.9; H, 3.2; Cl, 14.4. Found: C, 44.1; H, 3.4; Cl, 14.4%. Calc. for $[Ph_3AsOD][AuCl_4]$: C, 32.6; H/D, 2.6; Cl, 21.4. Found: C, 32.7; H/D, 2.6; Cl, 21.4%. Calc. for $[PyOH][AuCl_4]$: C, 13.8; H, 1.4; Cl, 32.6. Found: C, 13.8; H, 1.4; Cl, 32.4%. Calc. for $[(PyO)_2D][AuCl_4]$: C, 22.6; H/D, 2.3; Cl, 26.7; N, 5.3; O, 6.0. Found: C, 23.0; H/D, 2.3; Cl, 26.8; N, 5.3; O, 6.2%. Calc. for $[PyOD][AuCl_4]$: C, 13.8; H/D, 1.6; Cl, 32.5; N, 3.2; O, 3.7. Found: C, 13.7; H/D, 1.4; Cl, 32.3; N, 3.0; O, 3.5%. Calc. for $[(PyO)_{1.5}H][AuCl_4]$: C, 18.7; H, 1.8; Cl, 29.4. Found: C, 18.8; H, 1.7; Cl, 29.1%.

2.2. Physical measurements

A pulsed spectrometer based on the Matec gated amplifier 515A was used for the nuclear quadrupole resonance (NQR) measurements. The sample temperature was controlled using an electronic controller LakeShore 331 and measured with an accuracy of ± 0.5 K by use of gold +0.07% iron versus chromel thermocouple.

Powder diffraction experiments were performed using a Rigaku RINT 2100S diffractometer with Cu Kα radiation. Silicon powder was used as an internal standard of the diffraction angle.

IR spectra in the region 4000–400 cm^{-1} were recorded on a Bio-Rad FTS-7 FT IR spectrometer using KBr pellets.

For the ^2H NMR measurements of the solution, a JEOL JNM-EX270 NMR spectrometer was employed.

The density of the crystal at room temperature (r.t.) was determined by a floating method by using a mixture of *o*-xylene and bromoform.

2.3. Crystal structure determination of $[(PyO)_2D][AuCl_4]$

A SMART 1000/CCD diffractometer (Bruker) was employed for the diffraction measurements using graphite monochromated Mo Kα radiations (2θ range 3.2°–55.0°). Data collections were carried out at 289 K. Crystal data and the details of the experiments and refinements are given in Table 1.

Table 1
Crystal data and details of the experiments and refinements

Formula	$C_{10}H_{10}N_2O_2DAuCl_4$
Formula weight	530.97
X-ray radiation	Mo Kα
Wavelength (Å)	0.71073
Crystal system	Orthorhombic
Space group	*Pbca*
a (Å)	7.139(1)
b (Å)	15.631(2)
c (Å)	27.888(4)
Cell volume (Å^3)	3112.2(7)
Z	8
D_{calc} (g cm^{-3})	2.262
D_m (g cm^{-3})	2.27(1)
μ(Mo Kα) (mm^{-1})	10.138
F(000)	1984
Temperature (K)	289
Crystal color	Orange
Crystal size (mm)	0.17 × 0.07 × 0.04
Theta range (°)	2.61–27.50
Index range	$-6 \le h \le 9;\ -20 \le k \le 20;\ -32 \le l \le 33$
Reflections collected	16498
Reflections unique	3270
R_{int}	0.1010
Reflections ($I > 2\sigma(I)$)	1638
$R_1(F)$ ($I > 2\sigma(I)$)	0.0446
$wR_2(F^2)$ for all reflection	0.0860
Number of parameters	175
Goodness-of-fit for all reflections (F^2)	0.839
Weighting scheme	$w^{-1} = [\sigma^2(F_2^2) + (0.0293p)^2 + 0.00p]$, $p = (F_o^2 + 2F_o^2)/3$
Maximum shift/e.s.d.	0.001
ρ_{max} (e Å^{-3})	2.173
ρ_{min}(e Å^{-3})	−0.859

The structure was solved by the direct method and refined by full-matrix least-squares calculations based on F_o^2 with absorption correction (SADABS) using SHELXL-97 [7]. Non-hydrogen atoms were included in the least-squares calculations with anisotropic displacement parameters. The positions of the hydrogen atoms on the six-membered rings were calculated and they were included in the refinement under constraints with isotropic displacement parameters. To account for the H (or D) atom attached to the O atom, we applied two models. In the first one, a hydrogen atom (H(11)) was fixed at the midpoint between the two oxygen atoms of the $(PyO)_2$ group (final R values: $R_1 = 0.0447$ and $wR_2 = 0.0862$). In the second model, starting from the first one, the positional parameters were included in the refinement. The hydrogen atom converged to a point apart from the O(1) and O(2) by 1.36(10) and 1.35(10) Å, respectively (final R values: $R_1 = 0.0446$ and $wR_2 = 0.0860$). In each model, the maximum residual electron density (peak) was approximately 2.2 e $Å^{-3}$ on the final difference Fourier map. The position of the peak is too close to Cl(4) (ca. 1.68 Å) to assign any atom to it. The observed density of the crystal (2.27 ± 0.01 g cm^{-3}) was in good agreement with the calculated one (2.262 g cm^{-3}). The IR spectrum indicated that the crystal was free of the water of crystallization.

3. Results and discussion

3.1. Isotope dependent synthetic feature and new phases of the complexes between pyridine N-oxide and tetrachloroauric acid

Yuqiu and Shihua [6] reported for the compound with Ph_3AsO that the 2:1 compound of $[(Ph_3AsO)_2H][AuCl_4]$ crystallized even from the aqueous solution of Ph_3AsO–$HAuCl_4 = 1{:}1$, and the 1:1 compound was obtained only by the extraction method using 1,2-dichloroethane as an extraction solvent. These results suggest the stability of the diadduct of proton in the non-deuterated aqueous system. Similarly, for the complexes between PyO and tetrachloroauric acid, the stability of the diadduct of proton was suggested by the following observations in the present work. (1) The 2:1 compound of $[(PyO)_2H][AuCl_4]$ was obtained from the aqueous solution of PyO–$HAuCl_4 = 5{:}1$ as well as 2:1. (2) The 3:2 compound of $[(PyO)_{1.5}H][AuCl_4]$ and the 1:1 compound of $[PyOH][AuCl_4]$ were obtained from the solution of PyO–$HAuCl_4 = 1{:}1$ and 1:2, respectively.

In the course of the present study, on the other hand, we have found the tendency that the dimeric cation was less stable in the deuterated solvent system as compared with that in the non-deuterated one. To prepare the compound with the base-to-acid molar ratio of 2:1 in the deuterated system, we had to employ the solution with the much higher ratio of the base. In other words, the monoadduct of deuteron, instead of the diadduct, seems to be more stable in the deuterated system.

$[PyOH][AuCl_4]$ and $[(PyO)_{1.5}H][AuCl_4]$ are new compounds reported here for the first time. The X-ray powder diffraction of the latter was completely different from the superposition of those of $[(PyO)_2H][AuCl_4]$ and $[PyOH][AuCl_4]$, indicating the presence of a 3:2 compound as an independent crystalline phase.

3.2. ^{35}Cl NQR spectrum

In accordance with the reported crystal structure, two ^{35}Cl NQR frequencies were observed at 29.056 and 28.863 MHz at 77 K in $[(Ph_3AsO)_2H][AuCl_4]$, and at 28.295 and 27.799 MHz at 77 K in $[(PyO)_2H][AuCl_4]$. The temperature dependences of the resonance frequencies are shown in Fig. 1. The temperature dependence curves are smooth in the whole temperature range studied indicating no structural phase transition takes place down to 4.2 K. This means the symmetric hydrogen bond is retained even at 4.2 K presumably due to a tunneling motion of hydrogen atom in these compounds.

At 77 K, ^{35}Cl NQR frequencies were observed at 28.822 and 28.600 MHz in $[Ph_3AsOD][AuCl_4]$ and at 29.164, 28.727, 28.625, 28.272 and 27.618 MHz in $[PyOD][AuCl_4]$. As for $[PyOH][AuCl_4]$, $[(PyO)_2D][AuCl_4]$ and $[(PyO)_{1.5}H][AuCl_4]$, NQR measurements have not been undertaken since we have not yet obtained enough crystals for the measurements.

3.3. Infrared spectrum and ^2H NMR

In $[Ph_3AsOD][AuCl_4]$ and $[PyOD][AuCl_4]$, an IR band which can be assigned to the O–D stretching

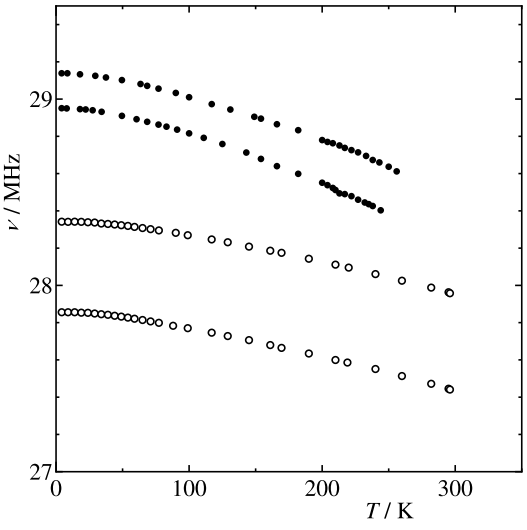

Fig. 1. Temperature dependence of ^{35}Cl NQR frequencies of $[(Ph_3AsO)_2H][AuCl_4]$ (●) and $[(PyO)_2H][AuCl_4]$ (○).

vibration was clearly observed at 2470 and 2378 cm^{-1}, respectively, without overlapping with the other bands. However, the bands observed at 3316 and 3179 cm^{-1} in $[Ph_3AsOD][AuCl_4]$ and [PyOD][$AuCl_4$], respectively, suggest an occurrence of isotope exchange with a proton. The strong broad IR bands which are assignable to vibrations corresponding to a symmetric O···H···O hydrogen bond were observed in the region 1500–400 cm^{-1} [8,9] in $[(RO)_2H][AuCl_4]$ type compounds. Similar broad bands were observed also in $[(RO)_{1.5}H][AuCl_4]$, although weakened, suggesting the presence of a symmetric O···H···O hydrogen bond. The IR spectra of $[(PyO)_2D][AuCl_4]$ also showed broad bands in the same region. Therefore, the partial isotope exchange with proton is suggested. The extent of the deuteration of $[(PyO)_2D][AuCl_4]$ has been estimated to be H/D = approximately 30/70 by use of ^2H NMR measurements of the aqueous solution.

3.4. Characterization of $[(PyO)_nH/D][AuCl_4]$ ($n = 1, 2$) by X-ray powder diffraction

The effect of hydrogen isotope substitution on the crystal structure was investigated both on the 2:1 and 1:1 compounds of PyO by use of X-ray powder diffraction measurements. The crystal structures of the 1:1 compounds, i.e. [PyOH][$AuCl_4$] and [PyOD][$AuCl_4$], are considered to be independent of the hydrogen isotope substitution, because they gave diffraction patterns similar to each other. In the case of the 2:1 compound, on the other hand, the diffraction patterns of $[(PyO)_2H][AuCl_4]$ and $[(PyO)_2D][AuCl_4]$ were found to exhibit a drastic difference as can be seen in Fig. 2. The unit cell parameters obtained by the single crystal X-ray study (Table 1) completely reproduced the positions of the peaks in the powder X-ray diffraction pattern of $[(PyO)_2D][AuCl_4]$. Thus the crystal structure of $[(PyO)_2D][AuCl_4]$ was expected to be remarkably different from that of $[(PyO)_2H][AuCl_4]$. Since the solution from which the $[(PyO)_2D][AuCl_4]$ crystal was obtained had not the same composition as that used in the preparation of the non-deuterated compound, one may propose the difference of the condition of the preparation as a cause of the structural change. Then, we have prepared $[(PyO)_2H][AuCl_4]$ repeatedly from a solution of PyO–$HAuCl_4$ = 5:1, the composition of which is the same as that used for $[(PyO)_2D][AuCl_4]$ preparation. By powder X-ray measurements, we have found a case in which the reflection peaks characteristic of 'the $[(PyO)_2D][AuCl_4]$ type crystal' are coexisting together with the peaks of the normal $[(PyO)_2H][AuCl_4]$ crystal. Therefore, the present phenomenon will be recognized as a polymorphism depending on the isotope concentration of the solvent used for crystallization. The phenomenon was interesting enough to lead to the single crystal X-ray study on the deuterate, the results of which will be discussed in the next section.

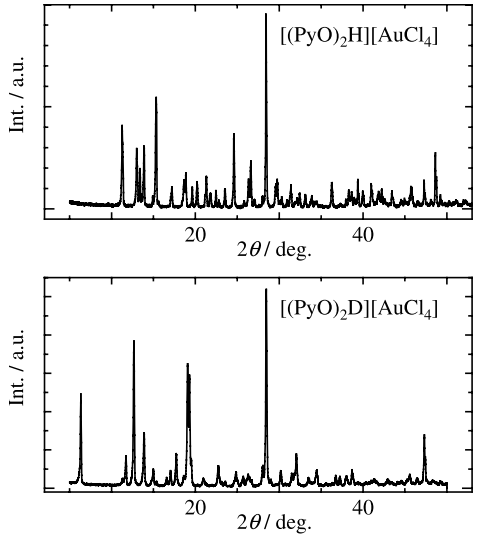

Fig. 2. X-ray powder diffraction patterns of $[(PyO)_2H][AuCl_4]$ and $[(PyO)_2D][AuCl_4]$. Strong diffraction at 28.46° and 47.34° are from silicon powder used as an internal standard. The pattern of $[(PyO)_2H][AuCl_4]$ can be explained by the reported crystal data in ref. [2]: $P\bar{1}$, $a = 7.276$, $b = 8.631$, $c = 6.799$ Å, $\alpha = 105.4$, $\beta = 96.4$, $\gamma = 67.9°$.

3.5. Crystal structure of $[(PyO)_2D][AuCl_4]$

The structures of the anion and cation in $[(PyO)_2D][AuCl_4]$ (D-salt) are shown in Fig. 3. For the sake of convenience, the corresponding structures of

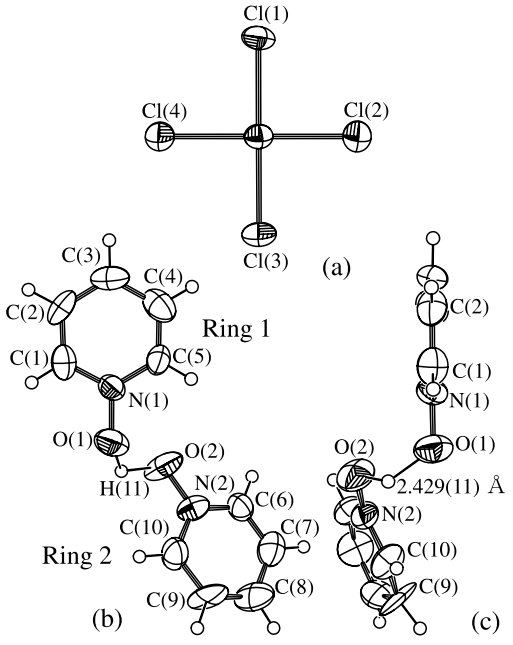

Fig. 3. Structure of the anion and cation in the D-salt with atom labelling. (a) the anion; (b) and (c) the cation viewed perpendicular and parallel to the pyridine ring having N1 (Ring 1), respectively. The distance 2.429(11) Å given in (c) is the O(1)···O(2) distance.

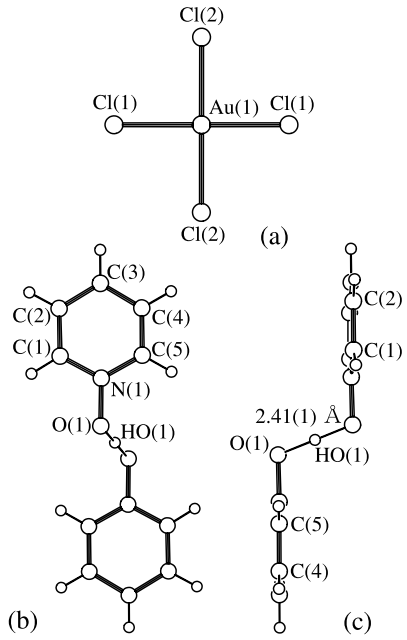

Fig. 4. Structure of the anion and cation in the H-salt with atom labelling. (a) the anion; (b) and (c) the cation viewed perpendicular and parallel to the pyridine ring, respectively. The distance 2.41(1) Å given in (c) is the O···O distance.

$[(PyO)_2H][AuCl_4]$ (H-salt) [2] are given in Fig. 4. The relevant bond lengths and angles are summarized in Table 2. We will tentatively describe the $(PyO)_2H$ group in the D-salt as $[PyO–D–PyO]^+$. The anion in the D-salt is almost planar: the maximum deviation from the mean plane of the anion is 0.024 Å for Cl(2). The average of the Au–Cl bond lengths of the D-salt is only by approximately 0.01 Å longer than that of the H-salt. The structure of the PyO moiety also agrees between the two salts (see Table 2). Thus, one can conclude that the structures of the $[AuCl_4]$ unit and the PyO moiety of the two salts are very close to each other except for the slight reduction in the C(8)–C(9) bond length of the D-salt, for which a certain thermal motion would be responsible.

Contrary to the case of the PyO moiety, the three-dimensional structure of $[PyO–H–PyO]^+$ in the H-salt is completely different from that of $[PyO–D–PyO]^+$ in the D-salt (Fig. 3 (b and c) and Fig. 4 (b and c)). As can be seen in Fig. 4 (b and c), the former cation has center of symmetry. In the case of the latter, however, the magnitude of the torsion angle χ around the O···O axis is 142.8° and the two pyridine planes make an angle of approximately 29.2°. Thus, the cation in the D-salt is asymmetric (C_1 point symmetry). The $[(PyO)_2H]$ cation is able to have another symmetry in a different crystal: i.e. it has twofold symmetry in the crystal of $[(PyO)_2H][ClO_4]$ [9]. The observation that the structure of the cation differs from compound to compound is considered to be a consequence of the fact that its three-

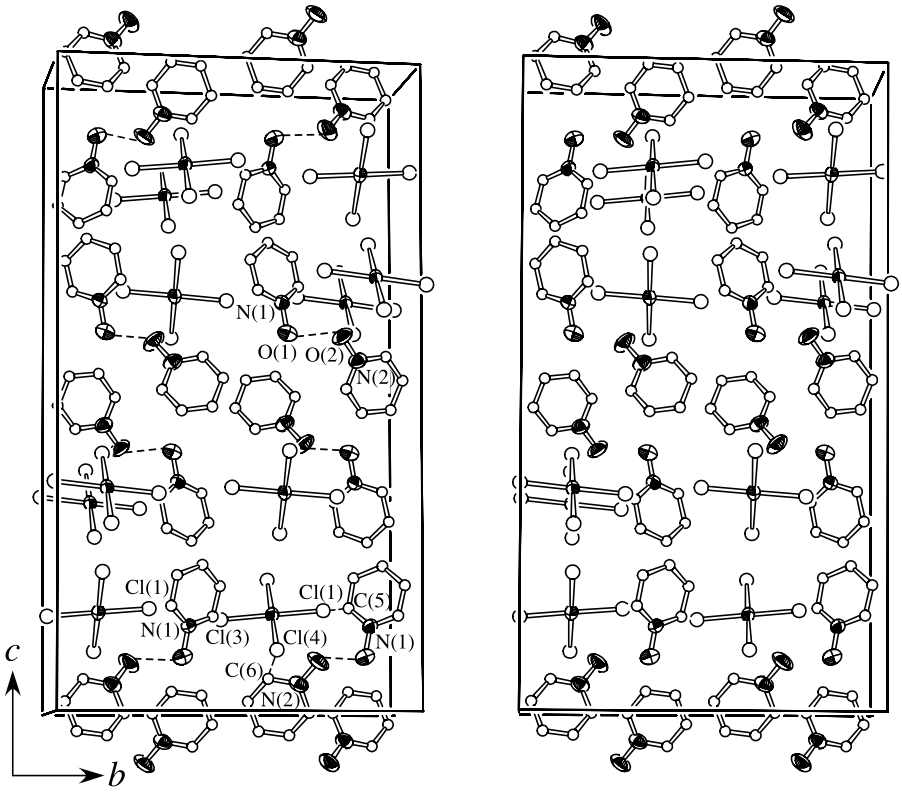

Fig. 5. Stereo drawing of the crystal structure of the D-salt viewed along the *a*-axis. Light broken lines indicate short Cl···C contacts (Cl(4)···C(6) and Cl(1)···C(5): 3.448(11) and 3.476(11) Å, respectively).

dimensional structure is flexible owing to the possibility of the two kinds internal rotations around the O···O and N–O axes.

Besides the fact that the overall structure of the cation in the D-salt is asymmetric, it should be noted that the two N–O bond lengths in the D-salt are not equivalent: N(1)–O(1) and N(2)–O(2) are 1.354(9) and 1.314(9) Å, respectively, the former value being closer to the N–O distances in the H-salt (1.362(8) Å) and that in $[(PyO)_2H][ClO_4]$ (1.353(3) Å). The O···O distance in the D-salt (2.429(11) Å) would differ from that of the H-salt (2.41(1) Å). These observations suggest the difference in the nature of the hydrogen bond between H- and D-salts. The position of the D atom in $[(PyO)_2D]^+$ may deviate from the mid-point between the two O atoms to result in a hydrogen bond with an asymmetric potential well.

The crystal structures of the D- and the H-salts are shown in Figs. 5 and 6, respectively. In the H-salt, the anion and the cation pack alternately parallel to the (100) plane to result in a layer structure. In the D-salt, however, there exists no such simple layer structure. As can be seen from a comparison of the figures, the D-salt adopts a crystal structure completely different from that of the H-salt. This phenomenon is interesting, but not necessarily unusual because the structure of the cation is also totally different in the two salts as mentioned above.

The isotope effect on the crystal structure is a rather rare phenomenon, but it has been observed, for instance, in the following compounds. The fully deuterated oxalic acid dihydrate has been reported to crystallize with a structure (β-form) different from that of the non-deuterated one (α-form) [10–12]. Since the fully deuterated crystal with an α-form was also obtained [13,14], these forms are regarded as crystalline polymorphs. For trifluoroacetic acid tetrahydrate, a change from an ionic to a molecular structure on deuteration has been reported [15]. As to the structural change of $Rb_3H(SeO_4)_2$ due to deuteration, the symmetry-breaking of the symmetric hydrogen bond or the reduction of tunneling motion has been proposed as the possible cause [4].

The structural difference between the D- and H-salts presented in this paper may be explained as a result of polymorphism. But, the present phenomenon is not a usual one, where the structure of the component is expected to be identical in the polymorphs.

A slight difference in the intermolecular interaction due to the isotope difference will determine which structure is more stable as in the case of $Rb_3H(SeO_4)_2$. It should be mentioned, however, that the effect of hydrogen isotope substitution in the present case might include not only a pure isotope effect, but also an effect of the condition of the preparation, because it was different between the preparations of the normal and

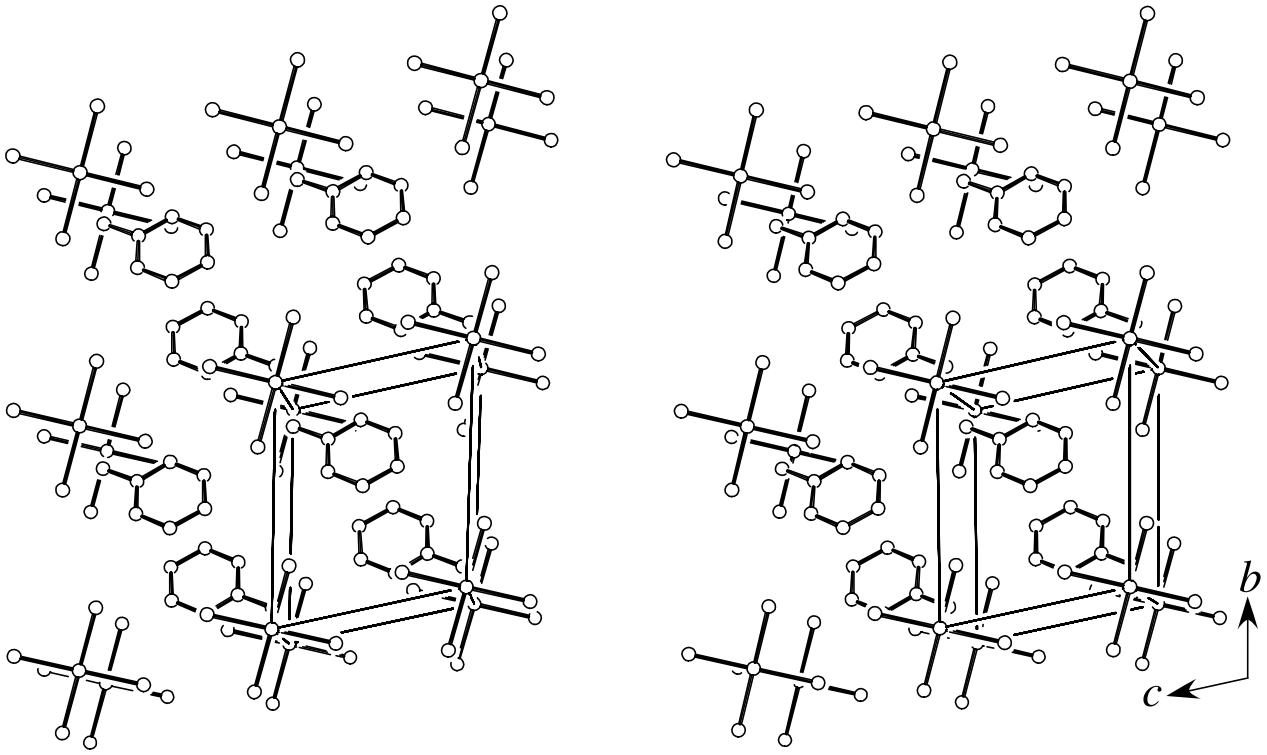

Fig. 6. Stereo drawing of the crystal structure of the H-salt viewed along the *a*-axis.

deuterated compounds as described in the earlier section. It is ambiguous, therefore, that the change in the structure of the cation and hence that of the crystal can be ascribed to mere isotope effect.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 184567. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

position, and examination of the ^{1}H NMR signals of this complex in the aromatic region should provide evidence on orientations of the two phenanthrolines with respect to the sugar. The conformation of crystalline sucrose [11] is such that complexation at an octahedral center does not markedly distort the sugar residue [10].

The ^{1}H NMR signals of the sucrose moiety showed that the face of one phenanthroline is sufficiently close to the glucose residue to allow observation of a nuclear overhauser effect (NOE) between H-2(g) and one phenanthroline hydrogen, and there was a second NOE involving OH-1(f) of the fructose residue and a hydrogen of the other phenanthroline ligand. Both aromatic hydrogens are at positions adjacent to nitrogens, and the phenanthrolines are in different environments relative to the sugar [10b], but there was no information on the other ^{1}H NMR signals. These conclusions were consistent with structural optimization of the Δ-complex with semi-empirical PM3(tm) parameters [12,13], which gives the structure shown in Fig. 1. This structure was obtained by a slightly different optimization procedure from that used earlier [10b], and it is described later. Structures from the two procedures are superimposable. We designate phenanthroline A as *trans*- to O-2(g), phenanthroline B as *trans*- to HO-1(f) [10b], and phenanthroline positions are numbered 1–10 with N-1(A) and N-1(B) in a trans-relationship. The linkage of the fructose residue to Co(III) through a hydroxymethyl group ensures that the fructose ring is not in close contact with a phenanthroline group, but the linkage through O-2(g) brings the glucose residue very close to phenanthroline B.

The ^{1}H NMR signals of the mixed sucrose complex in the aromatic region and other spectral evidence showed that this complex is sufficiently stable in solution to allow examination of all the ^{1}H signals of the two

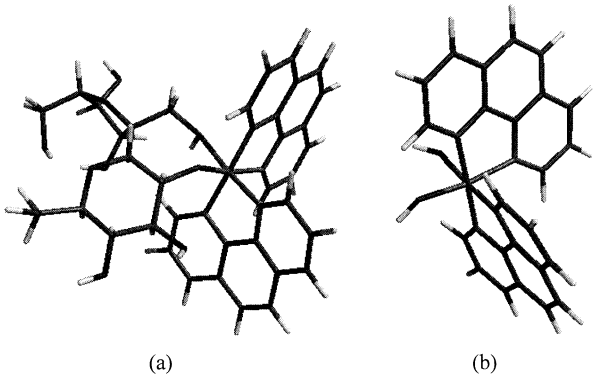

Fig. 1. Reoptimized geometry of the Δ-complex. Phenanthroline ring A is attached to the upper coordination site of Co(III) with the sucrose residue on the left and ligated glucose at the front, B is attached to the lower site of Co(III): (a) complex; (b) with sucrose ligand removed for clarity.

phenanthroline ligands and their interactions with the sugar residue, which had not been feasible with monosaccharide complexes [3,8,10]. Ito et al. had assigned the aromatic ^{1}H signals in a mixed complex of Co(phen)$_2$ with ethylenediamine, where the phenanthrolines are identical [14]. They showed that hydrogens in one part of a phenanthroline are close to the face of the other phenanthroline with consequent π-shielding and chemical shifts at position 9 are lower than at position 2 by approximately 2 ppm.

The ^{1}H signals of OH groups of the sugar residue had been examined in DMSO, where there was less overlap of the aromatic ^{1}H NMR signals than in D_2O, which simplifies assignment. Aliphatic ^{1}H signals were similar in the two solvents, and we assumed that the structure did not change, but we planned to confirm that assumption by comparing the CD spectra in H_2O and DMSO [10b]. We were also interested in comparison of the absorption and CD spectra of the sucrose complex and other mixed monosaccharide complexes, because positions of the CD extrema seemed to be insensitive to monosaccharide structure [3,8]. We have been unable as yet to obtain crystals of these mixed complexes suitable for X-ray crystallography and, therefore, rely on evidence from CD and NMR spectroscopy [6,8,10], and use semi-empirical treatments to predict overall structures consistent with spectral and other data.

2. Results and discussion

2.1. NMR spectroscopy

The ^{1}H NMR spectrum in the aromatic region in either D_2O or DMSO-d_6 shows signals of 16 hydrogens, with some overlap (Table 1). Signals of H-2 (A) and H-2(B), which had been assigned [10b], have the highest chemical shifts [14], and their $H_{2,3}$ coupling constants (Table 1) show that they are adjacent to phenanthroline nitrogens [15]. Following the Rules of Ito et al. [14] we conclude that signals with the lowest chemical shifts are of H-9 (A, B), consistent with their coupling constants [14,15], but these observations do not distinguish between signals of phenanthrolines A or B.

Hydrogens 3(A) and 4(A), and 3(B) and 4(B), are assigned from the COSY spectrum and decoupling in both DMSO-d_6 and D_2O. We applied a similar approach to hydrogens at positions 7, 8 and 9 in each phenanthroline, but to assign them to phenanthroline A or B we had to establish connectivities through positions 5 and 6 for each phenanthroline.

Signals in DMSO-d_6 are sufficiently separated that we could use NOE to establish connectivities within each phenanthroline. We irradiated one H-5, which could be in either ring, and saw an NOE in one, but not the other, H-4 signal, and then irradiated the other H-5 and saw

[a] At 500 MHz, referred to DMSO or TSP in D_2O.

the NOE in the other H-4 signal, thus assigning H-5 (A and B). Connectivities between H-5 and -6 (A and B) where then assigned by the COSY spectrum and decoupling. Connectivities between H-6 and -7 of rings A or B were similarly established by observing the appropriate NOE after irradiating H-7 of either ring A or B. This procedure gives assignments of all the ^{1}H phenanthroline signals and chemical shifts, coupling constants and T_1 values are in Table 1.

Assignments of the ^{1}H NMR signals in D_2O are based on the COSY spectrum, values of coupling constants [15], and decoupling at positions 2–4, 5–6, 7–9, the rules given by Ito et al. [14], and the assumption that sequences of chemical shifts will be the same in DMSO-d_6 and D_2O (Table 1). We saw long-range coupling for some phenanthroline signals in D_2O, but not in DMSO-d_6, probably because its higher viscosity broadens signals sufficiently to obscure weak coupling.

For a given phenanthroline ^{1}H chemical shifts vary qualitatively as predicted [14], and differences between values in rings A and B (Table 1) are governed by mutual interactions between the phenanthrolines and those with the glucose and fructose residues of the sugar. Differences in the ^{1}H NMR chemical shifts for a given phenanthroline, and between hydrogens at similar positions in the two rings, are largest for H-2 and -3 which are nearest to the sugar residues but are in different environments (Fig. 1 and Table 1).

2.2. Absorption and CD spectra

Spectra of the Δ-complex in the UV and visible regions are in Table 2. Positions of the CD extrema and shoulders are similar in H_2O and DMSO, although solvent absorbance by DMSO limits the low wavelength range. Positions and signs of the CD signals are similar to those of Δ-complexes of $Co(phen)_2$ with α-D-galactose and β-D-arabinose [8], where the sugar is bonded to Co(III) in a five-membered ring as compared with the eight-membered ring in the sucrose complex, i.e. they depend on the atoms bound to Co(III) rather than on the ring size. Following classical work on the electronic spectra of mixed complexes with $Co(phen)_2$ [9], as applied to the galactose and arabinose complexes [8], assignments in water are: λ, (nm), and ν, (cm^{-1}) in parentheses: phenanthroline transitions: 229, 241 (4.37×10^4, 4.15×10^4); β; 267, 281 (3.75×10^4, 3.56×10^4), p; 297 (3.37×10^4), α. Co(III), d–d transitions: 323, 363 (3.01×10^4, 2.75×10^4), ^1T_2g; 413, 513 (2.42×10^4, 1.95×10^4), ^1T_1g; approximately 610 (1.64×10^4), ^3T_2g. Assignments in DMSO are as in H_2O, within the wavelength range that can be examined, and there is a positive CD signal at < 260 nm (Table 2), although we cannot specify its location. In both solvents excitonic effects confirm that two phenanthrolines are bound to Co(III) and the sign sequence establishes the Δ-configuration [6,8]. The CD signals at 332 and 363 nm assigned to the ^1T_2g state represent forbidden transitions for a complex with strict octahedral symmetry, but in these mixed complexes there is distortion of the octahedral Co(III).

The CD signals in the UV are at similar wavelengths in H_2O and DMSO, confirming that there is no solvent effect on configuration, but those in the visible are red-shifted in DMSO, and apparently solvent effects upon energies associated with the d–d transitions are larger than those with the phenanthrolines. There is a shoulder at 413–436 nm in the absorption spectrum in DMSO, which was not seen in H_2O [10b].

[a] From ref. [10b].

The quantitative treatment applied to electronic transitions of mixed complexes of Co(phen)$_2$ with α-galactose or β-arabinose [8] applies to spectra of the sucrose complex in terms of similar energy levels on the basis of similar wavelengths of extrema and shoulders in the CD spectra.

2.3. Geometrical optimization

The structure of the Δ-sucrose complex had been treated by using semi-empirical PM3(tm) parameters (PC Spartan Plus 2.0, Wavefunction) [13] which had been parameterized for transition metal ions, including Co(III), but only the geometry of the sucrose-Co(III) residue had been discussed [10b]. The predicted O-2(g)–Co–O-1(f) bond angle of 92.8° was higher than in a strictly octahedral complex. We, therefore, repeated the optimization with this angle constrained to 90°, which gave a less favorable heat of formation by approximately 10 kcal mol^{-1}, but removal of the constraint and re-optimization gave the structure (Fig. 1) which is indistinguishable from the original and has the original bond angle at Co(III) indicating that the optimized structure was not in a false minimum. The heat of formation, rounded off to the fourth significant figure, is −1684 kcal mol^{-1} as found earlier [10b].

Predicted bond lengths and angles at Co(III) are given in Table 3 and [10b] for the Δ- and the hypothetical Λ-complex, which was not detected and whose formation is predicted to be disfavored, relative to the Δ- complex, by approximately 9 kcal mol^{-1} [10b].

2.4. Factors that control structure of the complex

The ^{1}H NMR and CD spectra of Δ-Co(phen)$_2$(sucrose) identify the configuration at Co(III) and the ligating groups of the sugar. The NMR spectra show

Table 3
Predicted bond lengths and angles of the Δ-complex

Bond distances (Å)	
O^--2(g)–Co	1.89 (1.85)
HO-1(f)–Co	2.03 (2.03)
N-1(A)–Co	1.93 (1.93)
N-10(A)–Co	1.96 (1.96)
N-1(B)–Co	1.93 (1.93)
N–10(B)–Co	1.90 (1.90)
Bond angles (°)	
O^--2(g)–Co–HO-1(f)	92.8 (82.2)
HO-1(f)–Co–N-1(A)	84.4 (97.4)
N-1(A)–Co–N-10(A)	89.9 (90.0)
N-10(A)–Co–N-10(B)	91.9 (92.3)
N-10(B)–Co–N-1(B)	89.7 (90.5)
N-1(B)–Co–O^-2(g)	99.4 (80.9)

Values for a hypothetical Λ-complex are in parentheses.

that the phenanthrolines are in different environments [10b] and we need to rationalize these observations.

Predicted values of the torsional angles ϕ (O-5(g)–C-1(g)–O-1(g) –C-2(f)) of 114.5° and Ψ (C-1(g)–O-1(g)–C-2(f)–O-5(f)) of −51.2° are not very different from those of crystalline sucrose, 107.8° and −44.8°, respectively, indicating that ligation does not markedly perturb the conformation of sucrose [10b,11]. However, it forces the glucose moiety into close proximity with phenanthroline B, as shown by the strong upfield shift of O*H*-3(g) (by ca. 1.4 ppm) [10b]. There is not room for H_2O to hydrogen-bond to OH-3 (g), but there may be hydrogen bonding to the π-system [16]. We note that geometrical optimization orients OH-3 (g) away from the face of phenanthroline B (Fig. 1), which does not agree with the NMR evidence [10b]. It appears that the semi-empirical PM3(tm) treatment does not take into account O–H–π hydrogen bonding. In a Λ-complex the sucrose conformation would be perturbed relative to

that of the free sugar [11], with $\phi = 131.1$ and $\psi = -22.5°$, consistent with the relatively low stability of this hypothetical complex [10b].

The multiplicity of the ^{1}H NMR signal of H-3 (g) in the Δ-complex confirms that HO-3 (g) is oriented towards the face of phenanthroline B [10]b and the computed distance from O-3(g) to the phenanthroline face is approximately 2.7 Å. Accomodation of the glucose moiety with respect to phenanthroline B affects bond angles at Co(III) and optimization indicates that the N-1(A)–Co–N-1(B) axis is approximately linear, but not strictly orthogonal to the O^--2(g)–Co–HO-1(f) plane. This deviation from octahedral symmetry is consistent with the large predicted N-1(B)–Co–O^--2(g) angle, which reflects congestion between the glucose moiety and phenanthroline B, and the correspondingly smaller HO-1(f)–Co–N-1(A) angle (Table 2). In the optimized structure the fructose ring is not close to phenanthroline A because ligation is through the hydroxymethyl group, HO-1(f), whereas for the glucose residue it involves O^--2(g) [10b].

Deviations from strict octahedral symmetry place the phenanthrolines in different environments with respect to both the sugar residue and themselves, in accord with their different NMR signals (Table 1). These interactions may bow the phenanthroline rings. In a Co(III) bis-phenanthroline complex each phenanthroline rear face is close to H-9 of the other phenanthroline [14] consistent with variations in the ^{1}H chemical shifts (Table 1). In the Δ-sucrose complex H-9(B) is predicted to be approximately 2.7 Å from positions 1(A) and 2(A), and H-9(A) is a similar distance from positions 1(B) and 2(B). However, H-9(A) and H-9(B) are further from other positions of phenanthrolines B and A, respectively. These interactions between the phenanthrolines are, in general, opposed by those with the third bidentate ligand, e.g. sucrose, whose glucose moiety is very close to the front face of phenanthroline B [10b]. These opposing interactions can cause a phenanthroline to bow towards, or away from, sucrose and tilt in either direction. The magnitude of the bowing, or curvature, is indicated by the absolute sum of the torsional angles indicated by the heavy lines in Fig. 2(a). The tilt, with respect to the O–Co–O plane, is given by the absolute mean of the torsional angles indicated by the heavy lines in Fig. 2(b). The magnitude and direction of these distortions in a given phenanthroline depend on the balance between opposing effects of interactions with the sugar ligand and the second phenanthroline. Therefore, in the Δ-complex, where phenanthroline B is very close to the glucose moiety, predicted curvature is towards the sugar by 19°, and phenanthroline A, which is distant from the fructose ring, is curved away from the sugar by 15°, and is tilted modestly towards the sugar by approximately 6°, while ring B is tilted away by a similar extent. Thus phenanthroline A presents a convex, and B

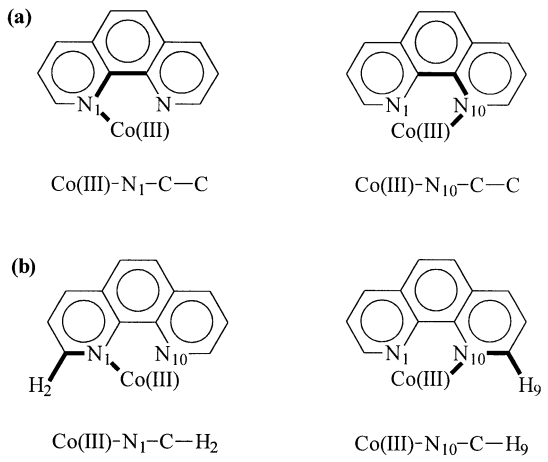

Fig. 2. Illustrations of estimated distortions of the phenanthroline group, c.f. Fig. 1. (a) Curvature of a group, the heavy lines indicate the noncoplanarities of Co(III)–N_1–C–C and Co(III)–N_{10}–C–C. (b) Tilt of a group, indicated by the torsional angles of Co(III)–N_1–C–H_2 and Co(III)–N_{10}–C–H_9.

a concave face towards sucrose, representing the balance between the interactions. Congestion between the glucose moiety and phenanthroline B more than offsets interactions from the rear with phenanthroline A. Predicted distortions for a hypothetical Λ-complex are similar in magnitude to those given above, except that curvatures are in the opposite sense.

These predicted deviations from planarity are responsible for differences between ^{1}H chemical shifts in the two phenanthroline rings (Table 1), even for hydrogens, which are distant from the sucrose moiety or the other phenanthroline (Fig. 1). These differences are more evident in DMSO-d_6 than in D_2O. The structure around Co(III) is very congested, as shown by examination of space-filling models, data not shown. Several distances between non-bonded atoms are within, or close to, the sum of the van der Waals radii.

So far as we are aware there is little information on structures of mixed bis-phenanthrolineCo(III) complexes from X-ray crystallography. There is distortion of octahedral symmetry in the carbonato complex [17] where the O–Co–O bond angle is low (ca. 69°), and Niederhoffer et al. report only modest bowing of the phenanthrolines, although Hennig et al. report deviations from planarity [18].

3. Experimental

Preparation and isolation of the mixed completes with Cl^- or I_3^- as counterion have been described, but the I_3^- salt was not used in the present work [10]. The ^{1}H NMR spectra were monitored on a Bruker DRX instrument, (300 MHz for ^{1}H) at 25 °C, or on a Varian Unity instrument (500 MHz for ^{1}H) at 21 or 25 °C for

the COSY spectrum and are referred to TSP (sodium 3-(trimethylsilyl)propanesulfonate) in D_2O ($\delta = 0$ ppm), or to DMSO ($\delta = 2.50$ ppm). Signals of the sucrose residue had been assigned [10]. There are uncertainties in chemical shifts of some of the phenanthroline signals in D_2O due to overlap (Table 1) but they do not affect the sequence of the chemical shifts.

The CD and absorption spectra in water are from [10], and those in DMSO were monitored at 25 °C on a Jobin–Yvon CD6 spectrometer, or, for the absorption spectrum, on a Unicam UV3 spectrometer, with freshly prepared solutions. With some monosaccharides the less stable diastereomer is formed initially and is gradually converted into the thermodynamically preferred complex [7,8], but only the Δ-complex was detected with sucrose.

4. Conclusions

The CD spectrum of $[Co(III)(phen)_2(sucrose)]Cl_2$ shows that it has the Δ-configuration in H_2O and DMSO and allows assignment of the electronic transitions. Differences in the ^1H NMR signals in the aromatic region show that the nonequivalent phenanthrolines differ in their non-bonding interactions with the sucrose moiety. The glucose residue is very close to one phenanthroline and structural optimization with the semi-empirical PM3 (tm) parameters indicates that there should be deviations from strict octahedral symmetry and planarity of the phenanthrolines consistent with differences in the ^1H NMR signals.

reflections were performed with the HKL Denzo–Scalepack system of programs [8]. Absorption corrections were carried out using the integration method [9] for compound **I** and multi-scan method [10] for **II**.

The structures were solved by direct methods with SHELXS-97 [11]. The model was refined by full-matrix least-squares on F^2 by means of SHELXL-97 [12]. All the hydrogen atoms were stereochemically positioned and refined with the riding model [12]. All H atoms were located on stereochemical grounds. Hydrogen atoms of the aromatic rings and CH_2 were set isotropic with a thermal parameter 20% greater than the equivalent isotropic displacement parameter of the atom to which each one is bonded; this percentage was set to 50% for the hydrogen atoms of the methyl groups.

Data collection and experimental details for complexes **I** and **II** are summarized in Table 1. Relevant interatomic bond lengths and angles are listed in Table 4.

2.2. Measurements

The infrared spectra of the complexes were measured from powder samples diluted in CsI on a FTIR Bomem–Michelson 102 spectrometer in the 4000–200 cm^{-1} region. Cyclic voltammetry (CV) experiments were carried out at room temperature (r.t.) in CH_2Cl_2 containing 0.10 M $Bu_4N^+ClO_4^-$ (TBAP) (Fluka Purum) using a BAS-100B/W Bioanalytical Systems Instrument; the working and auxiliary electrodes were stationary Pt foils, and the reference electrode was Ag/AgCl, 0.10 M TBAP in CH_2Cl_2, a medium in which ferrocene is oxidized at 0.43 V (Fc^+/Fc).

All the NMR experiments were running in a Bruker, DRX400 9.4 Tesla equipment, in a BBO 5 mm probe at 298 K. For the compounds **I** and **II** CH_2Cl_2 was used as solvent while for the compound **III** $CDCl_3$ was utilized. TMS and H_3PO_4 85% were used for internal and external reference for ^1H, ^{13}C and ^{31}P, respectively.

For complex **III** the completely ^1H, ^{13}C and ^{31}P attribution were done using 1D $^1H\{^{31}P\}$, $^{31}P\{^1H\}$ and 2D g^1H-^1H COSY45, $^1H-^{13}C$ gHMQC, $^1H-^{13}C$ gHMBC, $^{31}P-^1H$ HETCORR NMR experiments.

2.3. Material and methods

All manipulations involving solutions of the complexes were performed under argon. Solvents were purified by standard methods. All chemicals used were of reagent grade or comparable purity. The $RuCl_3 \cdot 3H_2O$ was purchased from Degussa and the ligands dppb and diop were purchased from Aldrich. The $RuCl_3(NO)$, *mer*-[$RuCl_3$(diop)H_2O] and *mer*-[$RuCl_3$-(NO)(dppb)] were prepared according to the literature [6,13] Yields are based on the metal. Microanalyses were performed by Microanalytical Laboratory of Universidade Federal de São Carlos, São Carlos (SP) or by Universidade de São Paulo, São Paulo (SP).

2.4. Preparation of compounds

2.4.1. *fac*-Trichloronitrosyl-1,4-bis-(diphenylphosphino)butaneruthenium(II) (*I*)

A methanol solution of *mer*-[$RuCl_3$(NO)(dppb)] (0.15 g, 0.226 mmol) was refluxed for 4 h under Ar. The yellow precipitate was collected, washed with ether and methanol, and dried under vacuum. Re-crystallization from dichloromethane–ether yielded orange crystals. Yield: 0.14 g (95%). *Anal*. Calc. for $C_{28}H_{28}Cl_3NORuP_2$: C, 50.7; H, 4.2; N 2.1. Found: C, 51.3; H, 4.4; N, 2.2%. Selected IR (cm^{-1}): 1868 (NO), 310, 289 (Ru–Cl). $^{31}P\{^1H\}$ NMR: 22.8 ppm.

2.4.2. *mer*-Trichloronitrosyl-2S,3S-O-isopropylidene-2,3-dihydroxy-1,4-bis(diphenylphosphino)-butaneruthenium(II) (*II*)

mer-[$RuCl_3NO$(diop)] was synthesized by bubbling NO [generated by reaction of dilute nitric acid (ca. 33%) over copper metal and dried passing it through a column containing anhydrous $CaCl_2$] in a dichloromethane solution of the *mer*-[$RuCl_3$(diop)(H_2O)] (0.07 g, 0.0967 mmol) for 1 h. After this time the red solution initially formed gradually changed to yellow. The dichloromethane was removed by evaporation and CCl_4 was added (10 cm^3). A small amount of green solid was separated from the yellow solution. After removing the

green solid by filtration, the yellow filtrate was reduced in volume to approximately 5 cm^3 and hexane (15 cm^3) added. The yellow precipitate formed was filtered off, and dried under vacuum. Re-crystallization from dichloromethane yielded yellow crystals. Yield: 0.05 g (70%). *Anal*. Calc. for $C_{31}H_{32}Cl_3NO_3RuP_2$: C, 50.6; H, 4.4; N, 1.9. Found: C, 50.9; H, 4.3; N, 1.9%. Selected IR (cm^{-1}): 1879 (NO), 339, 292 (Ru–Cl). $^{31}P\{^1H\}$ NMR: −2.1(d) and 5.5(d) ppm, $^2J(P–P) = 40.0$ Hz.

3. Results and discussion

In both complexes studied in this work, the NO stretching band (νNO) in the infrared spectra were close to 1870 cm^{-1} corresponding to the $\{Ru^{II}–NO^+\}$ type [14,15]. The $^{31}P\{^1H\}$ NMR spectra obtained for **I** and **II** indicate different geometries for these complexes. The *fac* isomer of the dppb species **I** presents a singlet signal (22.8 ppm) while the diop complex **II** shows two doublets (5.5 and −2.1 ppm, $^2J(P–P) = 40.0$ Hz) that can be assigned to the *mer* configuration. It is interesting to mention that the isomerization process from the *fac* to the *mer*-[$RuCl_3$(NO)(dppb)] was observed through $^{31}P\{^1H\}$ NMR experiments. This was noticed by the appearance of two doublets ($\delta = 13.65$(d) and 10.10(d) ppm, $^2J(P–P) = 36.6$ Hz) and also by the lower intensity of the singlet at 22.8 ppm of a solution maintained at room temperature. After 3 h of the compound solubilization the doublets can be identified and after 24 h approximately 50% of the *fac*-isomer was converted to the *mer*-isomer. Under longer periods of time the conversion was not completed. From this observation and from our previous report [5] it follows that these two isomers are likely to coexist in a CH_2Cl_2 solution at room temperature but at high one (temperature of boiling methanol) the *fac* isomer is the only species present in the solution. Complex **II** does not isomerize at room temperature, as indicated by the fact that its $^{31}P\{^1H\}$ NMR spectrum in dichloromethane solution remains unchanged over several days. A suggestion for this lack of isomerization in the diop complex could be the steric effect or rigidity caused by the additional ring in this ligand compared with dppb. The difference in the structures of these two ligands probably is also responsible by the better solubility of the *mer*-[$RuCl_3$(NO)(diop)] complex in common organic solvents when compared with its similar isomer with dppb, the same behavior is observed in the precursors *mer*-[$RuCl_3$(dppb)(H_2O)] and *mer*-[$RuCl_3$(diop)(H_2O)]. This can be advantageous in using this diop complex in catalytic processes.

In the $^{31}P\{^1H\}$ NMR spectrum of the *mer*-[$RuCl_3$(NO)(dppb)] complex **III**, two doublets are observed (Table 2) and we assume that the more shielded phosphorous is *trans* positioned to NO group (P_d), because the competitive effect between two strong acceptors ligands (P and NO group). In Table 3 there is the complete assignment of carbon and hydrogen signals of the coordinated diphosphine for the *mer*-isomer **III**. This assignment was based on two-dimension $^{31}P–^1H$ HETCORR spectrum, COSY $^1H–^1H$ spectrum and an HMQC $^1H–^{13}C$ experiment. The HMBC $^1H–^{13}C$ spectrum, was used to correct the attribution of the quaternary aromatic carbon.

The numbering scheme of the hydrogen and carbon atoms in compound **III** is shown in Fig. 1.

The limited solubility of the *fac* isomer **I** in most of the usual solvents do not permitted the realization of NMR experiments for the attribution of ^1H and ^{13}C signals.

The proposed structures for complexes **I** and **II** based upon $^{31}P\{^1H\}$ NMR data have been confirmed by X-ray structure measurements. The molecular structures of **I** and **II** are shown in Fig. 2(a) and (b), respectively, together with the numbering scheme of the atoms.

In the *fac*-[$RuCl_3$(NO)(dppb)] isomer **I** the NO is essentially linear with the ruthenium atom [Ru–N–O = 171.8(8)°] and the Ru–Cl [2.418(2), 2.434(3) and 2.355(3) Å, for Cl(1), Cl(2) and Cl(3), respectively]. Ru–N (1.731(8) Å) and Ru–P (2.405(2) and 2.420(2) Å) bond lengths in this nitrosyl complex are comparable to those found for the similar complex *fac*-[$RuCl_3$(NO)(dppm)] [6]. It is interesting to point out

Table 4
Selected bond distances (Å) and selected bond angles (°) for *fac*-[$RuCl_3$(NO)(dppb)] (**I**) and *mer*-[$RuCl_3$(NO)(diop)] (**II**)

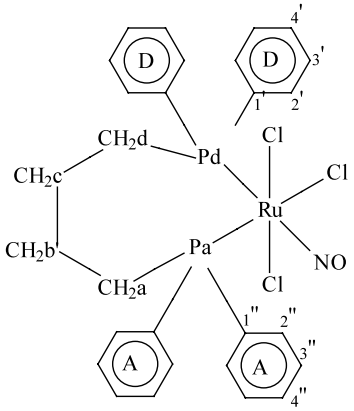

Fig. 1. Scheme of *mer*-[$RuCl_3$(NO)(dppb)], showing proton and carbon numbering.

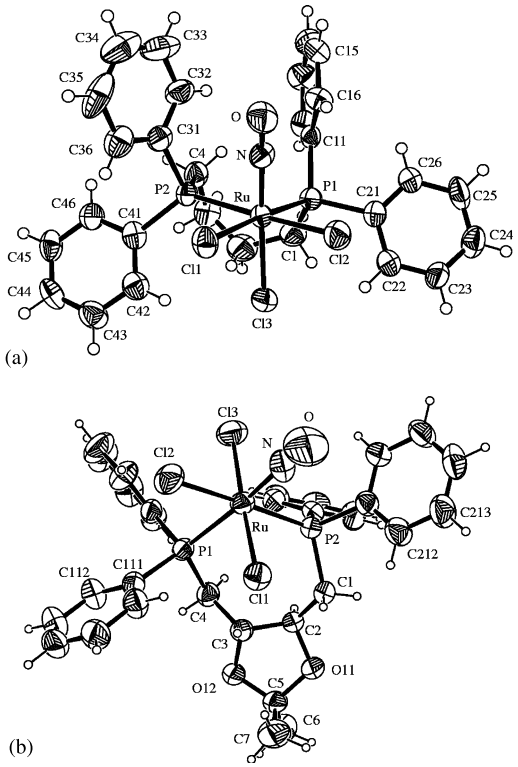

Fig. 2. ORTEP [16] view of *fac*-[$RuCl_3NO$(dppb)] (a) and *mer*-[$RuCl_3NO$(diop)] (b) with 50% probability thermal ellipsoids.

that the distance Ru–Cl(3), the chloride *trans* to NO, is shorter than the distances Ru–Cl(1) and Ru–Cl(2). Here, like in our *fac*-[$RuCl_3$(NO)(dppm)] complex [6] the *trans* influence of the NO group is observed. In the *mer*-[$RuCl_3$(NO)(diop)] isomer **II** the NO is also linear with the ruthenium atom [Ru–N–O = 176.0(6)°] and the Ru–Cl [2.3810(11), 2.4159(12) and 2.3700(13) Å, for Cl(1), Cl(2) and Cl(3), respectively]. Ru–N [1.816(5) Å) and Ru–P (2.5124(11) and 2.3887(11) Å] bond lengths are also comparable to those found for the similar complex *mer*-[$RuCl_3$(NO)(dppp)] [5]. The distance Ru–P(1), P(1) *trans* to the NO in the *mer*-[$RuCl_3$(NO)-(diop)], is much longer than the Ru–P(2) in the same complex. This observation can be ascribed as a consequence to the competition between two good coordinating species (NO group and phosphorus atom) for the electrons of the ruthenium atom. This same situation is found in the *ttt*-[$RuCl_2(CO)_2(PPh_3)_2$] isomer where the CO's *trans* to each other show a longer Ru–C separation than the corresponding separation when the CO is *trans* to the chlorine [17,18]. The NO bond length for complex **I** [1.124(10) Å] is a little longer than the distance 1.06 Å of the free NO^+ group [19] and practically the same NO distance [(1.151(9) Å] was found for the complex *mer*-[$RuCl_3(NO)(AsPh_3)_2$] [5].

The observed Ru–N–O bond angle for the *fac*-[$RuCl_3$(NO)(dppb)] isomer [171.8(8)°] is bigger than the angle of approximately 160.0° for the *mer*-

[$RuCl_3(NO)(dppb)$] isomer [6]. This probably happens because in the *fac* complex the axial NO group is symmetrically surrounded by the phenyl rings and two chloride ligands present in the equatorial plane, such a way the NO group tends to assume an almost linear configuration. In contrast, in the *mer* complex, three chloride ligands and the phenyl rings of the dppb ligand asymmetrically surround the NO ligand. This asymmetry, coupled with the big repulsion between the extensive molecular orbital of NO and the phenyl rings of the dppb ligand, tends to distort the NO group away from the phenyl groups. The bond lengths and bond angles for *mer*-[$RuCl_3(NO)(dppb)$] and for the *mer*-[$RuCl_3(NO)(diop)$] complex are essentially the same except only for the Ru–NO angles. This difference is probably due to the different rigidities of the chains in the dppb and diop ligands since the lengths between the two phosphorus atoms in these biphosphines are practically the same.

In a previous paper [6], we suggested that the faster isomerization process in the *mer*-[$RuCl_3(NO)(dppp)$] compared with the *mer*-[$RuCl_3(NO)(dppb)$] is due to the stronger strain caused by the shorter carbon chain between the phosphorus atoms in the dppp ligand when compared with the dppb molecule. Here we could suggest that the rigidity introduced by the ring present in diop ligand is the principal cause of the absence of the isomerization process in the *mer*-[$RuCl_3(NO)(diop)$], a process that is present in both *fac*- and *mer*-[$RuCl_3(NO)(dppb)$] isomers [6]. The silent EPR of the *fac*-[$RuCl_3(NO)(dppb)$] and the *mer*-[$RuCl_3(NO)(diop)$] complexes confirm the diamagnetic character of them, and consequently the presence of the $\{Ru^{II}–NO^{+}\}$ unit.

Both **I** and **II** complexes exhibit irreversible electrochemical processes. The cathodic waves at -900 and -650 mV, respectively, for the complex **I** and **II** are attributed to the $Ru–NO^{+} \rightarrow Ru–NO^{\circ}$ reduction. No waves corresponding to the metal centers were observed until $+1.4$ V what is consequency of the high stabilization of Ru(II) by the nitrosyl group.

4. Conclusions

The *fac* and *mer*-[$RuCl_3(NO)(dppb)$] isomers coexist in a CH_2Cl_2 solution at room temperature while in refluxing methanol only the *fac* isomer is present. The *mer*-[$RuCl_3(NO)(diop)$] complex does not isomerize at room temperature in CH_2Cl_2. The grater rigidity of the diop ligand, as compared with that of dppb, is probably the principal cause for the absence of the isomerization process of the *mer*-[$RuCl_3(NO)(diop)$] isomer and its high solubility in common organic solvents.

5. Supplementary data

Crystallographic data for structural analysis have been deposited with Cambridge Crystallographic Centre, CCDC No. 171904 for complex **I** and 171905 for complex **II**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambidge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://ccdc.cam.ac.uk).

2. Experimental

2.1. General comments

All operations were carried out under nitrogen using Schlenk and vacuum techniques. Nitrogen was dried over molecular sieves. Hexane, tetrahydrofuran and $C_6H_5CH_3$ were distilled over sodium/benzophenone. Acetonitrile was distilled over phosphorus pentoxide. All the solvents were used immediately after distillation or stored under nitrogen over molecular sieves. Ethane-1,2-dithiol ($EDTH_2$), propane-1,3-dithiol ($PDTH_2$) from Aldrich and [$NbCl_2Cp_2$] from Fluka, were used as supplied. Infrared spectra in the 4000–200 cm^{-1} region were recorded on a Perkin–Elmer 283 spectrometer, as a Nujol mull, in CsI plates. C, H, N elemental analyses were performed using a Perkin–Elmer PE-2400 CHN microanalyser. Cyclic voltammetry studies were performed on a Bioanalytical Systems 200 A voltamograph. The potentials were referred to a Ag^0/AgCl electrode with Pt metal as the working electrode. The auxiliary electrode was Pt wire. Solutions were 1 mM in solute and 0.1 M in supporting electrolyte [Bu_4N][PF_6]. The niobium samples and the supporting electrolyte were weighed inside the glovebox. Purified solvents were syringed into the cell containing the supporting electrolyte under a flow of N_2 at the electrochemical instrument bench. Fast atom bombardment mass spectra were recorded on a VG analytical 70-S mass spectrometer. ESR spectra were recorded on a spectrometer built at the Physics Department of Federal University of Minas Gerais, Brazil, utilizing a Varian magneton, a Hewlett-Packard microwave source, a Bruker resonance cavity and as locking EG&G.

2.2. Syntheses

2.2.1. Dithiolate salts

These were prepared by reacting 2 mol of CH_3ONa with 1 mol of the appropriate dithiolate compound ($EDTH_2$, $PDTH_2$) in THF, at room temperature for 2 h. After this time a precipitate was obtained that was separated from the solution and dried in vacuum. The salts (Na_2EDT, Na_2PDT) were characterized as described before [3].

2.2.2. [$NbCp_2PDT$] (**1**)

In a Schlenk flask were loaded 0.13 g (0.85 mmol) of Na_2PDT and 0.25 g (0.85 mmol) of [$NbCl_2Cp_2$], together with 50 ml of $C_6H_5CH_3$. The reaction mixture was left under reflux for 2 h, after which a violet solution was obtained. This was let to cool to room temperature and filtered over neutral alumina and then over celite. Upon addition of C_6H_{14} [$NbCp_2PDT$] was obtained in 71% yield. IR (cm^{-1}, Nujol): $\nu_{Nb-S} = 330$. ^1H NMR (δ, C_3H_6O-d_6): 6.22 (s, C_5H_5), 2.11 and 2.00 (t, 4H, $SCH_2CH_2CH_2S$), 1.59 (m, $SCH_2CH_2CH_2S$). ^{13}C NMR (δ, C_3H_6O-d_6): 112.04 (C_5H_5), 28.37 ($SCH_2CH_2CH_2S$), 18.48 ($SCH_2CH_2CH_2S$). EPR: $\langle A\rangle iso = 90.5$ G, $g = 1.948$, 10 lines. *Anal*. Calc. for $C_{13}H_{16}NbS_2$ (Found): C, 47.41 (47.44); H, (4.85) 4.89%. FAB mass spectrum: $m/z = 328.9$ (100%) [M^+, $C_{13}H_{16}NbS_2$].

2.3. Crystallographic studies

Dark violet crystals of [$NbCp_2PDT$] were mounted at room temperature, in mineral oil, on a glass fiber, and quickly cooled to −95 °C. Preliminary examination and data collection were performed on a Siemens P4 diffractometer using Mo Kα ($\lambda = 0.71073$ Å) radiation, a graphite crystal monochromator, employing ω–2θ scanning techniques with a variable scan rate (2.27°–25.00° min^{-1}). Details of the crystallographic data collection and refinement are summarized in Table 1. The molecular structure was solved by direct methods and was refined employing the SHELXS-97 [6] and SHELXL-97 programs, respectively [7]. Complex **1** crystallizes in space group $P2(1)/n$. A total of 2439 reflections were collected of which 2267 were independent and 1994 were flagged as observed. Cell constants were obtained from the refinement of 146 reflections. The structure was refined on F^2, against all reflections, by full-matrix least-square calculations. The weighted R-factors wR and GOF are based on F^2 and conventional R-factors are based on F, with F set to zero for negative F^2.

Table 1

Parameters refined	146
Goodness-of-fit	1.184

2.4. Computational details

All quantum chemistry calculations were performed at Hartree-Fock level employing an effective core potentials (ECP) [8] to describe the average eletrostatic potential, due to the core electrons of C, S, and Nb atoms. The GAMESS [9] program, working in a direct SCF mode [10] was used for all computations. The need for using ECPs comes from, on one hand, the large computational demands for an all electron evaluation of the electronic charge density and the corresponding molecular geometry optimization thereof for the size of molecules reported in this work and, on the other hand, for an effective inclusion of some relativistic correction on the total electronic energy required by the heavy niobium atom [8a]. The SBKJ effective core potentials [8a] were used throughout for C, S and Nb atoms, and the respective atomic basis set were taken as the ECP/SBK(d) sp(4-21G+)d(3-1G+) splitted valence plus diffuse basis for niobium [8b] and sp(4G) plus d polarization function for sulphur ($\alpha d(\mathrm{S}) = 0.65$) and carbon ($\alpha d(\mathrm{C}) = 0.8$) atoms. For the hydrogens a 3-1G* set of Pople [11] plus polarization was used.

A doublet spin ground state electronic configuration is expected for both [$NbCp_2EDT$] and [$NbCp_2PDT$], due the odd number of electrons and the +4 formal oxidation state of the niobium metallic center. Stable molecular conformations were sought using restricted open shell Hartree-Fock (ROHF) [12a] energies and wave functions, analytic molecular gradients and numeric hessians.

The ROHF method was chosen because it warrants the correct spectroscopic doublet state of the molecules for all stationary and distorted molecular geometries, although an unrestricted Hartree-Fock (UHF) [12b] spin polarized electronic density will give a lower electronic energy for this doublet electronic state and might induce some change on the optimized ROF geometries. However, based on the considerations and results presented in what follows, keeping the calculations at an uncorrelated Hartree-Fock level, the ROF/ECP appears to be a safer method for computing the electronic structure and molecular equilibrium geometries obtained thereof, since this wave function displays the expected correct qualitative valence orbital space structure, including there the SOMO (single occupied molecular orbital) molecular orbital, for the present class of cyclopentadienyl dithiolate bent metallocenes. For bent metallocenes compounds it has been shown [13] that the occupation of the metal d_{xy} SOMO drives the extent of the L–M–L′ bond angle: the ionized (or oxidized) HOMO$\{-1\}$ molecular state is expected to tight the L–M–L′ bond angle to values close to 80° [13], a reduction of about 10°–20° as compared with the parent neutral (or non-oxidized) species. Any resulting ROHF/UHF change on the metal d_{xy} SOMO orbital electronic occupation may then produce slightly different molecular equilibrium geometries, if this effect is not fully or partially compensated by equivalent changes on other key occupied molecular orbitals. In order to access possible resulting changes induced on the issued optimized ROHF stable molecular structure, induced by relaxing the electronic orbital doubly occupation restriction, we have computed their UHF energies, charge and spin densities, at their respective found stable ROHF molecular conformations. The net spin densities may qualitatively be used to estimate the atomic metallic and non-metallic center contribution. The results showed a ROHF/ECP SOMO orbital displaying the expected correct qualitative feature of a major content of Nb d_{xy} atomic orbital whereas within the UHF/ECP SOMO, unexpectedly, a large amount of the ligand atomic sulfur p_x and p_y has been built in. Actually, the UHF/ECP solution moves the molecular orbital which has the largest Nb d_{xy} contribution downward in energy leaving it as a doubly occupied molecular orbital instead. It should be noticed that, in spite of this qualitative contradicting results, quantitatively, the UHF SOMO Koopmans ionization potential is found to be much better in agreement with the experimental result than the ROHF SOMO Koopmans ionization potential (vide infra). These results point out the need of inclusion of some correction for the correlation energy, a point which has not been further pursuit in this work [14]. Here, the role of the electronic correlation energy was only partially accounted for through a simple restricted and unrestricted open-shell MP2 [15] energies and natural orbitals analysis, obtained at the ROHF stable molecular geometries.

Stable geometric unconstrained optimization searches were performed for molecular structures; a C_1 symmetry point group symmetry was used throughout. The starting geometries were guessed for a distorted tetrahedron environment around the Nb atom bounded to the two dithiolate ligands and two Cp rings. These were initially disposed in a more symmetric C_s or C_2 arrangement. After locating the equilibrium geometries, the potential energy profile along the relative internal Cp–Cp ring rotation were evaluated for fixed Nb–EDT/PDT metallocene stable ring fragment in order to ascertain that no other minimum energy molecular structure along this path could be found. Indeed, no such structure could be found (Fig. 8), a result that indicates that the final optimized geometries most certainly were not propensitly caused by the initial guess. The [$NbCp_2EDT$] five member ring was refined for a starting twisted conformation, whereas the chair, boat and twisted [$NbCp_2PDT$] six member ring conformations were initially guessed and optimized. A tight gradient geometry convergency criterion of 10^{-7} was requested, and all stable conformations were confirmed as being true relative minima at the respective electronic

potential energy hypersurfaces, by their vibrational normal mode analysis. The vibrational frequencies for all found structures were computed as real numbers.

3. Results and discussion

The complexes that were studied in the present work are shown in Fig. 1.

The solution EPR spectrum of complex **1**, at room temperature, showed the expected ten lines for a niobium paramagnetic species, $I = 9/2$, with $g_{iso} = 1.9483$ and $A_{iso} = 90.5$ G (Fig. 2). The spectrum that was taken at 14 K (Fig. 3), has a much more intense central line than the other ones. A solid solution of a Nb(IV) paramagnetic ion, d^1 configuration, is formed, and the spectrum becomes the sum of several EPR resonances, due to the various directions of the anisotropic spin magnetic momentum, having different $g_\perp$ and $g_\parallel$ factor components. This behavior has been observed before, for instance for complexes [Nb(O_2C-NEt)$_4$] [16], [Nb(hfacac)$_4$] [16] and [YTc_2Cl_8]·$9H_2O$ [17].

In Table 2 are listed some related complexes to **1** with the g_{iso} and A_{iso} values, obtained from the EPR spectra. As can be observed the g_{iso} values for complex **1** is smaller than the other ones. Smaller values of g are related to the unpaired electron be more tightly bound to the metal [19]. In the other complexes the electron is expected to be more delocalized over the ligands. For example, if one compares complexes **1** and [$NbCp_2(SPh)_2$] [4], it is expected for the first a g value lager then the former as the PDT^{2-} ligand is a better electron donor than SPh. Indeed, this is the observed tendency.

3.1. X-ray diffraction analysis

Crystals of complex **1** suitable for X-ray analysis were obtained from a dichloromethane/ether 3:1 solution, at 5 °C. In Fig. 4 is shown a ZORTEP for **1**, in the chair form, and in Table 3 is shown selected bond angles and distances.

The geometry around niobium is tetrahedral with minor distortions, S–Nb–Cp(1) = 104.2° (mean value) and S–Nb–Cp(2) = 108.85° (mean value). The bond angle Cp(1)–Nb–Cp(2) = 133.5° is in the range normally observed for related niobium bent metallocenes [4,20,21]. The S(1)–Nb–S(2) bond angle of 87.86° is within the range of S–M–S angles for related d^1 complexes, that is, bigger than 80° [13,21–23], and is close to the one found in complex [VCp_2PDT], 86.91° [24]. The Nb–S bond distances were determined to be 2.487 and 2.478 Å, and are smaller than the values found for niobium metallocenes complexes containing non-chelating ligands [21,22]. The same was observed for the [VCp_2PDT] complex and was attributed to the greater basicity of the chelating ligand.

3.2. ECP quantum results

Theoretical calculations were performed in order to determine an equilibrium molecular geometry for the hypothetical complex **2** and for complex **1**, to allow a comparison of the data for these two complexes according to this technique, and with the experimental data obtained from the X-ray investigation, for the latter. Also, theoretical calculations were performed for the hypothetical cationic analog of **2**, complex $\mathbf{2}^+$. This was done in order to verify the variation of the S–Nb–S angle in these complexes. According to theoretical calculations and as observed experimentally for a number of complexes, the X–M–X angle opens up, as a result of less electronic repulsion, on going from a d^1 to a d^0 complex [13]. In Table 4 are shown the data obtained and in Fig. 5 the optimized geometry of **2**.

At the end of the optimization process, whereby no other symmetry constraints but C_1 has been required, the minimal energy molecular structure was found to have a C_2 symmetry, with the symmetry axis lying along the line connecting the niobium atom and midway of the C–C bond. The L1–Nb–L2 bond angles average to 107.8° for L1 = S and L2 = Ctr(Cp) (Ctr is the Cp's

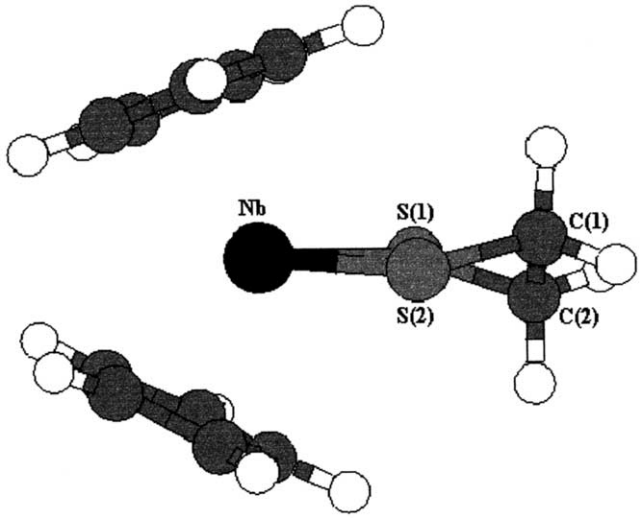

Fig. 5. Proposed molecular structure for complex **2** according to theoretical calculations.

centroid), and for L1 = L2 = S it was found to be 82.1°, according to the smaller size of the chelate ring. The Ctr(Cp)–Nb–Ctr(Cp) bond angle of 132.0° is in the range normally observed for related niobium bent metallocene complexes [4,20,21]. The calculated Nb–S and Nb–Ctr(Cp) equilibrium bond distances are 2.55 and 2.17 Å, figures that are in the range observed for other compounds [4,20,21]. The metal ethanedithiol five member ring adopts a twisted conformation, with the two carbon atoms lying out the S–Nb–S plane by ± 12.5°, respectively, and typical values are obtained for the included interatomic distances, 1.83 (S–C), 1.53 (C–C) and 1.09 Å (C–H). Actually, a pair of interconverting stable twisted conformations are possible, λ and Δ [25]. Fig. 5 represents the λ conformation. These two minima are separated by a ROHF/ECP barrier of 2997 cm^{-1}, as can be seen in Fig. 6.

This value should be taken as an upper limit for the correct inversion barrier energy since it has been evaluated for fixed Cps ligands spatial arrangement: as λ/Δ interconverting pseudo-rotation angle, θ, was swept, a semi-empirical (PM3 hamiltonian) re-optimization for the bond and torsion angles at the Nb(SCH_2CH_2S) ring was allowed. Besides, a differential contribution from the correlation energy may reduce the quoted interconvertion energy barrier by about 10%. The harmonic vibrational distortion mode around the λ or Δ equilibrium geometry has a ROHF/ECP frequency of 280 cm^{-1}. Combined, these data thus indicate a fairly slow interconversion rate between the two conformers at room temperature; the thermal energy KT is about 190 cm^{-1}. There are two rigid Cp pseudo-rotation modes with respect to a frozen Nb(SCH_2CH_2S) equilibrium

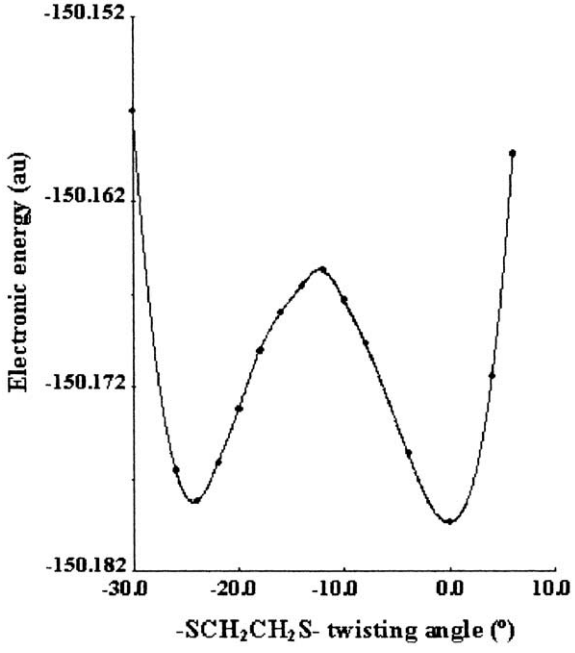

Fig. 6. Complex **2** ROHF/ECP ring puckering energy.

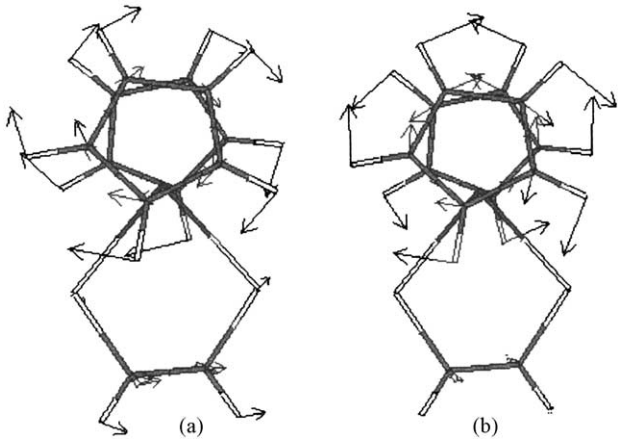

Fig. 7. Cp pseudo-rotation modes: (a) in phase clockwise rotation; (b) out of phase clockwise rotation.

conformation. The first corresponds to an in phase clockwise rotation mode with an harmonic frequency as low as 30 cm^{-1} (Fig. 7(a)), whereas the second corresponds to an out-of-phase clockwise-counter rotation with a harmonic frequency of 32 cm^{-1} (Fig. 7(b)).

The in-phase Cp–Cp pseudo-rotation leads to a breakdown of the overall C_2 molecular symmetry. The ROHF/ECP energy barrier along the out-of-phase Cp–Cp pseudo-rotation was computed to be only 1049 cm^{-1} (Fig. 8).

The maximum in Fig. 8 corresponds to the [$NbCp_2(SCH_2CH_2S)$] conformation with the two Cp–Cp rings aligning each other such that each sulphur atom is surrounded by only two equidistant Cp's

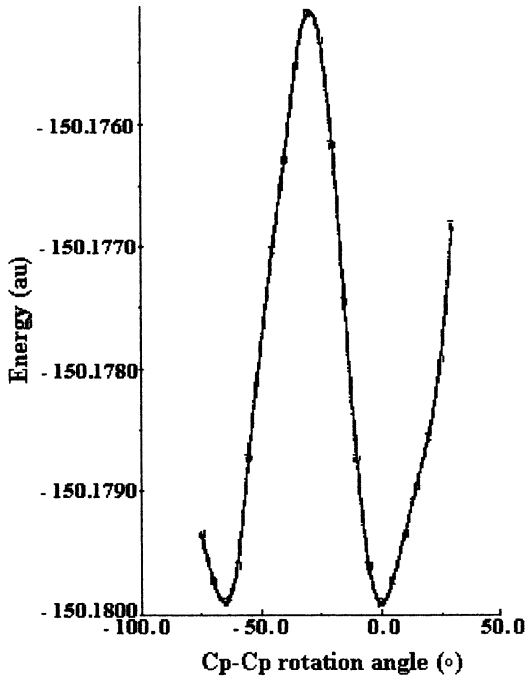

Fig. 8. Complex **2** ROHF/ECP electronic energy along a Cp–Cp pseudo-rotation motion.

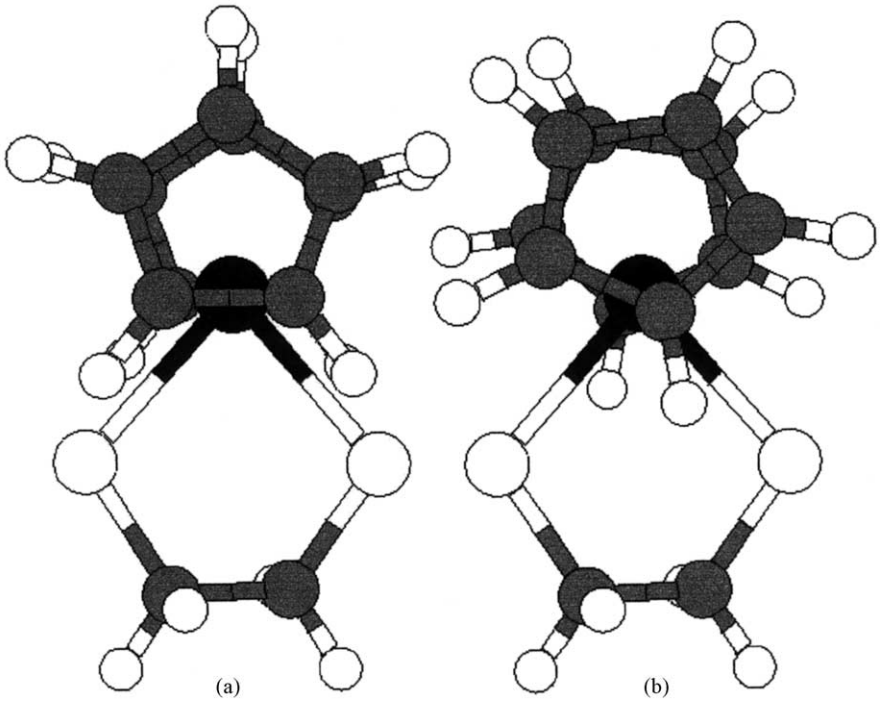

Fig. 9. (a) Conformation adopted by complex **2** at the maximum Cp–Cp rotation angle shown in Fig. 8; (b) 180° Cp–Cp ring in phase rotation of the structure shown in Fig. 8.

hydrogen atoms (Fig. 9(a)). The 180° Cp–Cp ring in phase rotation of the previous molecular structure (Fig. 9(b)), corresponds to the +10° pseudo-rotation angle in Fig. 8, and the asymmetry of the potential energy curve seen at about 20°, would correspond to the mirror [$NbCp_2(SCH_2CH_2S)$] equilibrium structure except for the restriction that the Nb(SCH_2CH_2S) five member rings has been kept frozen.

A molecular dipole moment of 4.94 D is calculated for [$NbCp_2(SCH_2CH_2S)$], where the partial negative charge is distributed over the Cp rings. The outermost single occupied molecular orbital (SOMO) has a restricted Hartree-Fock orbital energy of -3140 cm^{-1} whereas the spin polarized unrestricted solution sum up $-62\,370$ cm^{-1}. This gives a fairly large 4.2 eV of spin correlation energy for the UHF result. The adiabatic ΛSCF first ionization potential energy of [$NbCp_2(SCH_2CH_2S)$] is computed as being 6.4 eV which favours the UHF Koopmans ionization energy of 7.7 eV, as above. Despite of the bad performance of the ROHF calculation for describing the SOMO energy orbital, the UHF spin contamination is only 0.034 ($\langle S^2\rangle$UHF) = 0.784 to be compared with the spectroscopic ($\langle S^2\rangle$ROHF = 0.7) of an electronic doublet state), an indication that the total ROHF and UHF wave functions have about the same quality. The Mulliken atomic net spin population over niobium is +0.95 and +1.45 for the ROHF and UHF wave functions, respectively, where an electronic density withdrawing, mostly from the sulphur atoms, is responsible by the large UHF spin density.

The ECP/Hartree-Fock 50–4000 cm^{-1} calculated infrared spectrum for complex **2**, showed two groups of strong bands at 925 and 3230 cm^{-1} and a few groups of medium intensity bands. The two bands that are seen lying around 273 and 370 cm^{-1} that are formed by individual vibrational excitations on mainly six normal modes that contain, each, Cp ring tilting, ethylenic HCH wagging, the five member Nb(SCH_2CH_2S) ring deformation and distortion due to S–Nb–S symmetric (351 cm^{-1}) and antisymmetric (267, 283 cm^{-1}) stretching and in-plane S–Nb–S bending (270, 318 cm^{-1}) modes. At 366 cm^{-1} a vibrational transition occurs that can be assigned to an antisymmetric stretching mode for pseudo-triatomic Cp–Nb–Cp. The strong band around 925 cm^{-1} is composed of four peaks due to Cp's CCH out-of-plane angular deformation. The weak band about 1120 cm^{-1} contains excitations on Cp's in-plane CHH bending, rocking and HCCH scissoring modes. At 1443 cm^{-1} a week band is seen for the HCH ethylenic wagging mode, at 1590 cm^{-1}, a weak one, for the ethylenic HCH in-plane bending modes and at 1600 cm^{-1} Cp's C=C stretching and HCC. At higher energy, the CH stretching modes can be found: the ethylenic CH vibration modes gives the strong and medium intense bands lying between 3204 and 3287 cm^{-1} and the weak band around 3427 and 3478 cm^{-1} corresponds to Cp's CH stretching modes. For the [$NbCp_2$PDT] complex the following bands were observed: $\nu_{Nb-S} = 330$ cm^{-1}; $\delta_{C-H} = 1010$ cm^{-1} (in plane); $\delta_{C-H} = 870$ and 735 cm^{-1} (out of plane); $\nu_{C=C} = 1430$ cm^{-1}; $\nu_{C-H} = 3080$

cm^{-1}. It can be observed that there is a good agreement between the experimental IR data for complex **1** with the theoretical ones for complex **2**.

The determined geometry around niobium in complex **1** was in good agreement with the results obtained from the X-ray experiment. As can be observed, the bond distances and angles determined by this technique differed only slightly from the values obtained from the X-ray diffraction studies (Table 4). A comparison of the data for complexes **1** and **2**, according to the theoretical calculations, showed that, as expected, the S–Nb–S angle decreased from 89.1° to 82.1°, due to the smaller size of the chelate ligand. However, the bond distances did not differ at all.

For complex $\mathbf{2}^{+}$, the geometry is more distorted from the tetrahedral as the angles S(22)–Nb–Cp(2) and S(23)–Nb–Cp(1) were found to be 102.8° and 102.7°, respectively. The S–Nb–S angle was found to be bigger, 85.6°, than in **2**, as predicted [22], and the bond distances, smaller.

3.3. Cyclic voltammetric studies

The voltammogram for complex **1** showed two reversible waves with defined anodic and cathodic peaks with $E_{1/2} = -0.29$ and $E_{1/2} = -1.48$ V that were attributed to the redox process shown below:

$$Cp_2Nb(SCH_2CH_2CH_2S)^{+}_{d^0} \overset{-0.29\ V}{\rightleftharpoons} Cp_2Nb(SCH_2CH_2CH_2S)_{d^1} \overset{-1.48\ V}{\rightleftharpoons} Cp_2Nb(SCH_2CH_2CH_2S)^{-}_{d^2}$$

The potential of −1.48 V for the process Nb(IV)⇔Nb(III) is much higher than the values described in the literature for other bismetallocene complexes such as $[NbCp_2(SPh)_2]$ [4], $[NbCp_2dmit]$ [17] and $[NbCp_2ddt]$ [18]. This difference can be ascribed to the fact that in complex **1** the electron is more tightly bound to the metal, in agreement with the results obtained from the EPR data.

4. Conclusions

The six member niobium metallacycle complex $[NbCp_2PDT]$ is reported for the first time and although we have tried to obtain the five member analog, $[NbCp_2EDT]$, we were unsuccessful, as it was always obtained as a mixture together with the alkoxide complex. Semi-empirical calculations for **2** showed that the five member ring adopts a twisted conformation, with the carbon atoms lying above and below the S–Nb–S plane by ±12.5°, leading to the conformers λ and Δ, that are separated by an energy potential barrier of 8.6 kcal mol^{-1}. According to the g values obtained from the EPR spectra and confirmed by the results obtained from cyclic voltammetric studies, in niobium (IV) complexes, paramagnetic species, that have good electron donors as ligands, the unpaired electron is more tightly bound to the metal. As observed by others [18] and confirmed by this work, niobium complexes that have aliphatic thiolate ligands are very susceptible to hydrolysis originating the alkoxo analog complex very easily, being very difficult to handle and to be obtained in a pure form.

5. Supplementary material

A table of complete crystallographic data, tables of fractional atomic coordinates for all atoms, complete list of bond distances and angles and tables of anisotropic displacement parameters, have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 150217 for complex **1**. Copies of this information are available, free of charge, from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk). Table of complete theoretical calculations data for complexes **1**, **2** and $\mathbf{2}^{+}$ can be obtained from the authors upon request.

2. Experimental

2.1. Physical measurements and materials

Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyser. Infrared spectrum was recorded on a Perkin–Elmer 883-Infrared spectrophotometer in the range 4000–200 cm^{-1} as KBr pellets. $Ca(NO_3)_2 \cdot 2H_2O$ (Lancaster), 1,10-phenanthroline and $K_3[Fe(CN)_6]$ (Loba Chemie. India) were obtained commercially and used as received.

2.2. Synthesis of $[(Phen)_2(H_2O)_2CaNC(NC)_4FeCN\text{-}Ca(OH_2)(Phen)_2NO_3] \cdot H_2O$

An aqueous solution (10 ml) of $K_3[Fe(CN)_6]$ (0.33 gm, 1 mmol) was added to a stirred mixture of 10 ml aqueous solution of $Ca(NO_3)_2 \cdot 2H_2O$ (0.40 gm, 2 mmol) and 15 ml methanolic solution of 1,10-phenanthroline (0.79 gm, 4 mmol). On slow evaporation of the solution, at r.t., the orange crystals appeared. The crystals were washed with water and dried in air and used for X-ray analysis. *Anal.* Found: C, 56.39; H, 3.32; N, 18.11.Calc. for $C_{54}H_{40}Ca_2FeN_{15}O_7$: C, 56.54; H, 3.51; N, 18.30%.

2.3. X-ray crystallography

Intensity data for an orange block ($0.29 \times 0.32 \times 0.36$ mm) were collected at 173 K on a Rigaku AFC7R diffractometer employing Mo Kα radiation (λ 0.71073 Å) and the ω–2θ scan technique such that θ_{max} was 27.5°. Corrections were made for Lorentz and polarisation effects [22], and for absorption [23]. Of the 12 241 reflections measured, 11 705 were unique and of these, 8157 satisfied $I > 2.0\sigma(I)$ criterion of observability. Crystal data and refinement details are given in Table 1.

R_w (all data)	0.112
Maximum residual e.d.p (e $Å^{-3}$)	1.23

The structure was solved by heavy-atom methods [24] and refined by a full-matrix least-squares procedure based on F^2 [25]. Non-hydrogen atoms were refined employing anisotropic displacement parameters, carbon-bound hydrogen atoms were included in the model at their calculated positions and the O–H atoms were located from a difference map. The nitrate anion was found to be disordered over two positions. From refinement these were assigned 0.52% and 0.48% site occupancy factors. A weighting scheme of the form $w = 1/[\sigma^2 (F_o^2) + (0.0467P)^2 + 1.5976P]$ where $P = (F_o^2 + 2F_c^2)/3$ was employed and at convergence, final $R = 0.036$ (obs. data) and $R_w = 0.112$ (all data). The maximum residual electron density peak (1.23 e $Å^{-3}$) was located in the vicinity of the disordered nitrate anion. Fig. 1, showing the crystallographic numbering scheme, was drawn with ORTEP at the 50% probability level [26].

3. Results and discussion

3.1. IR spectra

The IR spectrum of the complex is consistent with the structural data presented in this paper. The broad absorption band for ν(O–H) appeared in the region 3316 cm^{-1}, indicating the presence of water molecules in the crystal. For ν(C≡N) mode of $[Fe(CN)_6]^{3-}$ two main band systems of comparable intensity are observed. The band at 2118 cm^{-1} is assigned to the intermetallic C≡N stretching, and the band appeared at 2055 cm^{-1} due to the terminal C≡N stretching mode [19]. The bands at 1538, 1140, 1099, 718 cm^{-1} are the characteristic absorptions of 1,10-phenanthroline [27].

3.2. Description of structure

The molecular structure of **1** is illustrated in Fig. 1 and selected geometric parameters are collected in Table 2. The structure features a central $[Fe(CN)_6]^{3-}$ unit that links a $[Ca(phen)_2(OH_2)_2]^{2+}$ dication and a $[Ca(phen)_2(OH_2)(NO_3)]^{+}$ cation via two *trans*-cyanide bridges. The asymmetric unit is completed by a solvent water molecule of crystallisation, which is associated with the anion, and there is no molecular symmetry owing to the presence of different calcium coordination geometries. The coordination geometry about iron is almost regular octahedral with the greatest deviation from the ideal being found in the C50–Fe–C53 angle of 84.42(9)°. There is evidence that the Fe–C distances fall into two classes with the longer distances, i.e. involving C49, C50 and C52, participating in links to calcium or water. By

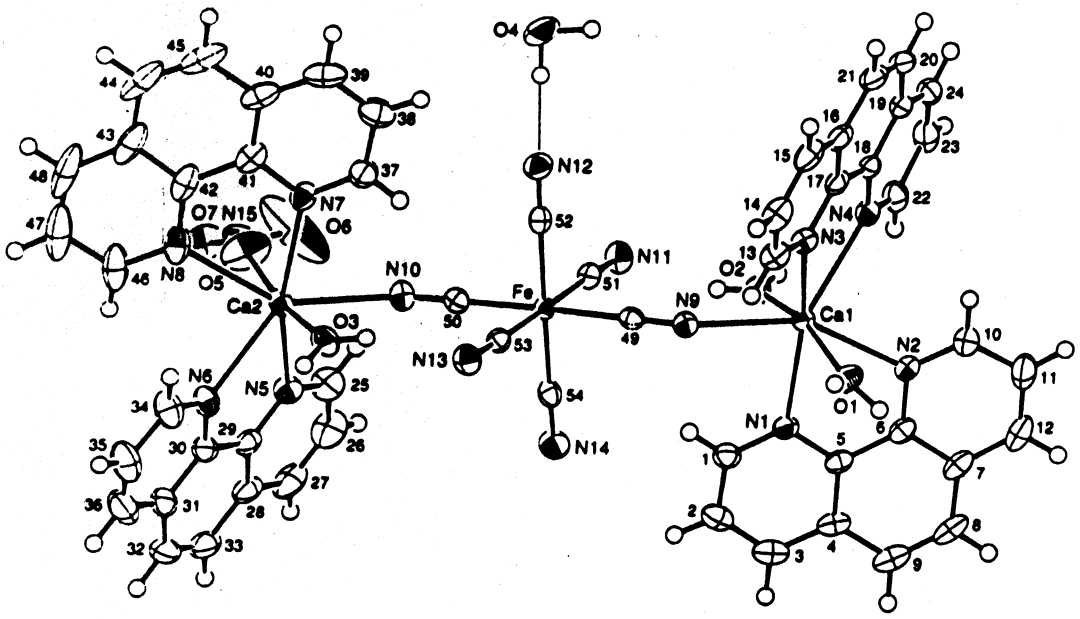

Fig. 1. Molecular structure and crystallographic numbering scheme for **1**. Atoms otherwise not indicated are carbons. Only one component of the disordered nitrate anion in the monodentate orientation is shown.

contrast to the regular geometry found for iron, the geometries about calcium are irregular. The Ca1 atom exists within a N_5O_2 donor set with the water molecules subtending an angle of 163.56(6)° at Ca1. If the five nitrogen atoms defined an approximate plane, the geometry might be described as being based on a pentagonal bipyramidal arrangement. However, the dihedral angle between the two effectively planar five-membered CaN_2C_2 chelate rings (respective mean deviations: 0.056 and 0.006 Å) is large at 53.4° suggesting that this is not an appropriate description. An examination of the Ca–N bond distances revealed that the Ca–N4 bond length is significantly longer than the others and that Ca–N2, N3 are longer than Ca–N1, N9. A capped octahedral geometry for Ca1 may be thus envisaged where the two octahedral faces are defined by O1, N1 and N9; N2, N3 and O2 with a dihedral angle of 9.8° between them. The N4 atom may be thought to protrude through the later face, thereby elongating the Ca1–N2, N3 bonds. However, it is noted that (i) there is no significant difference between the Ca1–O bonds and, (ii) that the Ca1 atom lies 1.4 Å from the first face and 0.7 Å from the larger octahedral face in this decription. The situation is even more complicated for the Ca2 atom as the nitrate is disordered so that approximately 50% of the time it functions as a unidentate ligand and 50% of the time it is bidentate, (see Section 2 for details). On the basis that the Ca2–O chelating distances are longer than the Ca2–O monodentate distance and the O8–Ca2–O9 chelate angle is very acute (Table 2), this ligand is assumed to occupy a single position in the coordination geometry about the Ca2 atom. The average Ca2–O chelating distance of 2.672 Å is slightly longer than the values given in the literature [28,29] whereas the Ca2–O monodentate distance of 2.236(5) Å is slightly shorter than that of the reported complexes [29,30]. The Ca2 atom also exists in a seven coordinate geometry defined by a N_5O_2 donor set as for the Ca1 centre and the description of the coordination geometry follows that given above for Ca1. Seven coordination is very uncommon [31,32], whereas the eight coordination is very common [28–30,33] for Ca complexes. There are significant distortions away from a pentagonal bipyramidal geometry in that while the O–Ca2–O axial angle is 170.9(2)°, the dihedral angle between the two CaN_2C_2 five-membered chelates (respective mean deviations of 0.025 and 0.057 Å) is 48.4°. In the capped octahedral description, the dihedral angle between the smaller O5, N7 and N10 and larger O3, N5 and N8 octahedral faces is 14.2° with the Ca2 atom 1.4 and 0.7 Å from these faces, respectively. The N6 atom caps the larger face and the trends in the interatomic parameters match those seen for Ca1. The Ca–O_{water} bond distances [2.379(2)–2.382(2) Å] are comparable with the other seven co-ordinated calciun complexes [31,32,34]. The Ca–N–C angle is 147.74(17)° for Ca1 and 151.01(17)° for Ca2, which give the arrangement of a slightly asymmetric 'bowed' disposition [20] rather than an exclusively linear arrangement.

As can be seen from Fig. 1, the O4 water molecule forms a hydrogen bond with a coordinated cyanide group. Indeed, the structure is stabilised by a complicated network of hydrogen bonds as well as π···π and O–H···π interactions. Table 3 summarises key hydrogen bonding contacts for **1**. The coordinated water molecule, O1, forms a bifurcated interaction with two

[a] Atoms indicated with a superscript i have a site occupancy factor (sof) = 0.52 and those with ii have sof = 0.48.

non-coordinating oxygen atoms of the nitrate coordinating in the monodentate mode and forms a donor interaction to the water molecule of solvation, i.e. O4. The O2 water molecule forms two donor interactions and bridges two cyanide nitrogen atoms, one intramolecularly to N11 and another intermolecularly to N11 that results in the formation of a centrosymmetric eight-membered $(H–O–H\cdots N\cdots)_2$ ring. The O3 water molecule behaves in the same way, forming a similar eight-membered ring but involving two N13 atoms. The interaction between the solvent water molecule and the iron-bound cyanide ligand has already been mentioned. The second hydrogen atom of the O4 water forms an interaction of the type O–H···π so that the H···ring centroid of the N4–C22 ring is 2.55 Å and the angle subtended at H is 151° (symmetry operation: $-x$, $-y$, $-z$). The most significant π···π interaction occurs between a centrosymmetrically related pair of C28–C33 rings such that the separation between the centroids is 3.51 Å (symmetry operation: $1-x$, $-y$, $-z$). In terms of the overall crystal structure, the hydrogen bonding interactions described above involving the coordinated O1, O2 and O3 water molecules leads to the formation of a two-dimensional (layer) structure. This arises as the water molecules concerned along with the key N11 and N13 acceptor atoms are, to a first approximation, coplanar. Successive layers are linked via the O–H···π and π···π interactions resulting in the formation of a cohesive three-dimensional network.

4. Supplementary material

Crystallographic data has been deposited at the Cambridge Crystallographic Data Centre with deposition number 166280. Copies of the information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Table 3
Key hydrogen bonding contacts (Å, °) in **1** [a]

AHB	A–H	H···B	A···B	A–H···B	Symmetry operation

$[Ni(NO_2)(R'NHCS_2)(PR_3)]$ or $[NiBr(R'NHCS_2)(PR_3)]$ with Lewis bases such as $(CH_3)_3N$ and NH_3 [12]. However, their structures were not determined by X-ray diffraction techniques.

Herein we investigate the three new bis(triphenylphosphine)*N*-R-sulfonyldithio-carbimatenickel(II) complexes (R = 2-$CH_3C_6H_4$, 4-$CH_3C_6H_4$, 4-BrC_6H_4) that were obtained in the crystalline form by the reaction of $NiCl_2 \cdot 6H_2O$ with triphenylphosphine and dithiocarbimate anions derived from sulfonamides. These complexes were characterized by UV–Vis, IR, ^1H, ^{13}C and ^{31}P NMR, elemental analyses for C, H, N, Ni and by single crystal X-ray diffraction techniques.

2. Experimental

2.1. Methods and materials

The solvents were purchased from Merck and used without further purification. The sulfonamides, 4-bromophenylsulphonyl chloride, nickel(II) chloride hexahydrate and triphenylphosphine were purchased from Aldrich. Carbon disulfide and potassium hydroxide were purchased from Vetec. The 4-bromobenzenesulphonamide was prepared from the 4-bromobenzenesulphonyl chloride as described elsewhere [13]. The *N*-R-sulfonyldithiocarbimate potassium salts dihydrate were prepared in dimethylformamide from sulfonamides analogously as described in the literature [14,15]. These salts, which are soluble in water and insoluble in most of the organic solvents, were re-crystallized from hot ethanol–water. Melting points (m.p.) were determined with a Mettler FP5 equipment. Microanalyses for C, H and N were obtained from a Perkin–Elmer 2400 CHN. Nickel was analyzed by atomic absorption with a Hitachi Z-8200 Atomic Absorption Spectrophotometer. The IR spectra were recorded with a Perkin–Elmer 283 B infrared spectrophotometer using CsI pellets. The UV–Vis spectra were recorded with a Beckman DU 640 spectrometer using nujol mull suspension. The ^1H (400 MHz), ^{13}C (100 MHz) and ^{31}P (162 MHz) NMR spectra of the complexes were recorded on a Bruker Advance RX-400 spectrophotometer in $CDCl_3$ with TMS (H_3PO_4 for ^{31}P NMR spectra) as internal standard.

2.2. Syntheses

The syntheses of the nickel(II) complexes were performed according to the Scheme 1. A solution of *N*-R-sulfonyldithiocarbimate dihydrate (1.0 mmol) in water (10 ml) was added to a solution of triphenylphosphine (2.0 mmol) in ethanol (40 ml). Nickel(II) chloride hexahydrate (1.0 mmol) was added to the suspension and the reaction mixture was stirred for 6 h at room temperature (r.t.). The color of the suspension changed from green to pink/red. The solid product of the reaction was filtered, washed with distilled water and ethanol, and dried under reduced pressure for 1 day yielding $[Ni(PPh_3)_2(RSO_2N{=}CS_2)]$ (ca. 70%). Suitable crystals for X-ray structure analysis were obtained after slow evaporation of solutions of the compounds in dichloromethane–methanol and few drops of water.

$$RSO_2N{=}CS_2K_2.2H_2O \xrightarrow[-8H_2O,\ -2KCl]{NiCl_2.6H_2O,\ 2PPh_3,\ EtOH/H_2O} [Ni(PPh_3)_2(RSO_2N{=}CS_2)]$$

2.2.1. Bis(triphenylphosphine)2-methylphenyldithiocarbimatenickel(II) (*1*)

Elemental analysis: Found (Calc.): C, 63.39 (63.78); H, 4.37 (4.50); N, 1.70 (1.69); Ni, 7.01 (7.08)%. M.p. (°C): 165.5–166.0. UV–Vis (nm): 197; 236; 320; 426 and 557. IR (most intense bands) (cm^{-1}): 1440 ν(C=N); 1300 $\nu_{ass}(SO_2)$; 1120 $\nu_{sym}(SO_2)$; 920 $\nu_{ass}(CS_2)$ and 345 ν(NiS). ^1H NMR (δ): 7.88–7.79 (m, 1H, H2′ (R group)); 7.42–7.05 (m, 33H, H3′, H4′, H5′, R group and triphenylphosphine signals) and 2.63 (s, 3H, CH_3). $^{13}C\{^1H\}$ NMR (δ): 197.35 (N=CS_2); 140.77 (C1′); 137.98 (C2′); 131.49 (C3′); 129.02 (C5′); 127.94 (C6′); 125.09 (C4′) and 20.84 (CH_3). Triphenylphosphine signals: 134.39 (t, $J = 7$, C2″ and C6″); 130.89 (s, C4″); 129.35 (d, $J = 31$, C1″); 128.45 (t, $J = 7$, C3″ and C5″). ^{31}P NMR (δ): 31.69 (s).

2.2.2. Bis(triphenylphosphine)4-methylphenyldithiocarbimatenickel(II) (*2*)

Elemental analysis: Found (Calc.): C, 63.91 (63.78); H, 4.39 (4.50) N, 1.72 (1.69); Ni, 7.11 (7.08)%. M.p. (°C): 166.5–167.0. UV–Vis (nm): 197; 234; 320; 429 and 557. IR (most intense bands) (cm^{-1}): 1445 ν(C=N); 1300 $\nu_{ass}(SO_2)$; 1135 $\nu_{sym}(SO_2)$; 910 $\nu_{ass}(CS_2)$ and 344 ν(NiS). ^1H NMR (δ): 7.69–7.57 (m, 2H, H2′ and H6′ (R group)); 7.44–7.20 (m, 30H triphenylphosphine signals); 7.17–7.15 (m, 2H, H3′ and H5′ (R group)) and 2.39 (s, 3H, CH3). $^{13}C\{^1H\}$ NMR (δ): 197.37 (N=CS2); 142.58 (C1′); 139.42 (C4′); 128.94 (C3′ and C5′); 127.49 (C2′ and C6′); 21.78 (CH_3). Triphenylphosphine signals: 134.29 (t, $J = 6$, C2″ and C6″); 130.64 (s, C4″); 129.25 (d, $J = 46$, C1″); 128.27 (t, $J = 5$, C3″ and C5″). ^{31}P NMR (δ): 30.47 (s).

2.2.3. Bis(triphenylphosphine)4-bromophenyldithiocarbimatenickel(II) (*3*)

Found (Calc.): C, 57.29 (57.80); H, 3.79 (3.84); N, 1.60 (1.57); Ni, 6.61 (6.57)%. M.p. (°C): 169.0–170.5. UV–Vis (nm): 193; 247; 308; 426 and 557. IR (most intense bands) (cm^{-1}): 1435 ν(C=N); 1310 $\nu_{ass}(SO_2)$; 1135 $\nu_{sym}(SO_2)$; 915 $\nu_{ass}(CS_2)$ and 335 ν(NiS). ^1H NMR (δ): 7.68–7.65 (m, 2H, H2′ and H6′ (R group)); 7.45–

7.19 (m, 32H, H3′, H5′ R group and triphenylphosphine signals). $^{13}C\{^1H\}$ NMR (δ): 145.00 (C1′); 131.93 (C3′ and C5′); 128.88 (C2′ and C6′); 127.50 (C4′). Triphenylphosphine signals: 134.29 (t, $J = 6$, C2″ and C6″); 130.75 (s, C4″); 129.33 (d, $J = 54$, C1″); 128.33 (t, $J = 5$, C3″ and C5″). ^{31}P NMR (δ): 31.75 (s).

2.3. X-ray crystallography

X-ray intensity data for all crystals were collected using graphite monochromatic Mo Kα radiation on a four circle KUMA KM-4 diffractometer with a two-dimensional area CCD detector. The ω-scan technique with $\Delta\omega = 0.75^\circ$ for each image was used for data collection. The 960 images for six different runs covered over 90% of the Ewald sphere were performed. Initially the lattice parameters were refined on about 200 reflections obtained from 40 images for eight runs with different orientation in the reciprocal space. Finally the lattice parameters were refined by least-squares method based on the all reflection with $I > 4\sigma(F^2)$. One image was used as standard for monitoring the data collection after every 40 images, and no correction on the relative intensity variation was necessary. Integration of the intensities, correction for Lorenz and polarization effects were performed using a KUMA KM-4 CCD program system [16]. Total of 18 419 (9819 independent, $R_{int} = 0.0294$), 27 613 (10 354 independent, $R_{int} = 0.0750$) and 55 811 (9891 independent, $R_{int} = 0.0773$) reflections were collected for the complexes **1**–**3**, respectively. The face-indexed analytical absorption was calculated using the SHELXTL program [17].

The structures were solved by a Patterson heavy-atom method using the SHELXL-97 program [18]. The Patterson map revealed the positions of the nickel, sulfur, bromide (**3**) and some of the P and C atoms. The remaining non-hydrogen atoms were located from difference Fourier synthesis. The structures were refined with anisotropic thermal parameters. Difference Fourier maps gave electron density concentrations approximately located for all hydrogen atom positions; these positions were idealized (HFIX 43 for all hydrogen atoms of the phenyl rings with isotropic thermal parameters of 1.2 U_{eq} of the carbon atoms joined directly to the hydrogen atoms, and HFIX 137 for the CH_3 group in the complexes **1** and **2** with isotropic thermal parameters of 1.5 U_{eq} of the methyl carbon atom). Final differences Fourier maps showed no peaks of chemically significance. Details of data collection parameters and final agreement factors are collected in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

The compounds are quite stables at the ambient conditions. In contrast to the dithiocarbamate Ni-complexes with the general formula of $[Ni(PR_3)_2(RN{=}CS_2)]$ which are soluble in THF, benzene and dichloromethane [12], these *N*-R-sulfonyldithiocarbimate Ni-complexes characterized in this paper are insoluble in most organic solvents and are slightly soluble in chloroform and dichloromethane. These complexes are stable up to the melting point without decomposition. Attempted to prepare the monotriphenylphosphine Ni-complexes like $K[NiCl(PPh_3)(N\text{-}RSO_2N{=}CS_2)]$ in the same conditions described above, with 1 equiv. of triphenylphosphine was unsuccessful.

The electronic spectra of the complexes show two shoulders (ca. 426 and 557) that are typical for square-planar nickel complexes and are assigned to d–d transitions [9]. The 190–300 nm region in the spectra of the complexes is dominated by three very intense bands of the triphenylphosphine and the dithiocarbimate ligands.

There are no strong or medium bands in the 1400–1600 cm^{-1} region in the IR spectra of the potassium dithiocarbimates related to the complexes **1**–**3**, the ν(CN) band being observed around 1260 cm^{-1} [14,19]. This low value indicates a great contribution of the canonical forms (a) and (b) for the resonance hybrid (Fig. 1). A strong band observed around 1455 cm^{-1} in the spectra of the complexes was assigned to the ν(CN). In the spectrum of the complex $[Ni(PPh_3)_2(4\text{-}CH_3C_6H_4N{=}CS_2)]$ that has no SO_2 group linked to the nitrogen atom, this band is located at 1500 cm^{-1} [12]. In the case of the complex $[Ni(4\text{-}CH_3C_6H_4SO_2N{=}CS_2)_2]^{2-}$ this band is observed around 1345 cm^{-1} [20]. This fact is probably due to a major negative charge on the Ni atom in this anionic complex in comparison to the complexes here synthesized. The substitution of one dithiocarbimate ion by two triphenylphosphine molecules is expected to result in a greater drift of electrons from the remainder dithiocarbimate ion to the metal. This effect is also observed, for example when the spectrum of the complex $[Ni(dtc)_2]$ (dtc = *N*,*N*-diethyldithiocarbamate) (ν(CN) band is observed in 1518 cm^{-1}) is compared with the spectrum of $[Ni(dtc)(PPh_3)_2]^+$ (ν(CN) band is observed in 1530 cm^{-1}) [8]. The $\nu_{ass}(CS_2)$ were observed at higher frequency in the spectra of the potassium salts of dithiocarbimates (ca. 955 cm^{-1}) [19] than that in the spectra of the complexes here studied (ca. 915 cm^{-1}). The shifts observed in the ν_{ass}(CS2) and ν(CN) in the spectra of the complexes when compared with the spectra of the ligands, are consistent with the increased importance of the canonical form (c) after complexation (Fig. 1). The spectra of the complexes also show the expected medium band in the 300–400 cm^{-1} range

[a]Function minimized: $\Sigma\, w(|F_o|-|F_c|)^2$, where $w = 4F_o^2/\sigma^2(F_o^2)$; $[\Sigma\, w(|F_o|-|F_c|)^2/(N_o-N_v)]^{1/2}$, where N_o, number of observations, N_v, number of variables. The final discrepancy factors: $R = \Sigma||F_o|-|F_c||/\Sigma|F_o|$ and $R_w = [\Sigma\, w(|F_o|-|F_c|)^2/\Sigma\, wF_o^2]^{1/2}$.

assigned to the NiS vibrations [21]. The ν(NiP) band was not observed above 200 cm^{-1}.

The NMR spectra of **1**–**3** were typical for diamagnetic species. The ^{1}H NMR spectra of the complexes showed the signals for the hydrogen atoms of the triphenylphosphine. The remaining signals could be assigned to the CH_3 group of the aromatic moiety and the other aromatic hydrogen atoms. The integration curves on the ^{1}H NMR spectra were consistent with a 2:1 proportion between the triphenylphosphine ligands and the dithiocarbimate anion. The signals in the spectra of the free dithiocarbimates [19] and in the complexes show approximate the same chemical shifts. The chemical shifts of the aromatic carbon atoms of the dithiocarbimate anions in the complexes are similar to those of the corresponding sulfonamides [22]. The N=CS_2 (C1) signal is shifted in the spectra of the complexes to higher field if compared with the spectra of the ligands (this signal is too weak and was not observed for **3**). Although the solvents are, necessarily different, this shift is expected. If the canonical form (c) (Fig. 1) is more important for the complexes than for the ligands, then the C1 carbon atom is expected to be more shielded in the complexes. The C1 signal for the complex **2** is also shifted to higher field when compared with the spectrum of the correspondent anionic complex $[Ni(4\text{-}CH_3C_6H_4SO_2N{=}CS_2)_2]^{2-}$ [20]. Most of the triphenylphosphine signals in the ^{13}C NMR spectra appeared as pseudo triplets or doublets. This is consistent with square-planar geometry for the complexes. Doublets or pseudo triplets are commonly observed in the ^{13}C NMR spectra of bis-phosphine transition metal *cis*-complexes [23]. As expected, the ^{31}P NMR spectra exhibited only one signal (ca. 30 δ) indicating that all phosphorus atoms in the molecules are magnetically equivalent.

The X-ray molecular structures of the **1**–**3** complexes are illustrated in Fig. 2(a–c), respectively. In all complexes, the nickel cation is coordinated by two triphenylphosphine ligands and chelated by two sulfur atoms of the *N*-R-sulfonyldithiocarbimate anion into a similarly distorted square-planar configuration. The P(1)–Ni(1)–S(1) and P(2)–Ni(1)–S(2) angles are less distorted from 90° than the P(1)–Ni(1)–P(2) and S(1)–Ni(1)–S(2) angles. The P(1)–Ni(1)–P(2) angle is significantly greater than 90° in all complexes due to the steric effect of the large triphenylphosphine ligands and the S(1)–Ni(1)–S(2) angle is smaller than 90° due to the chelation of the *N*-R-sulfonyldithiocarbimate ligand. The *N*-R-sulfonyldithiocarbimate anion $(RSO_2N{=}CS_2)^{2-}$ as an asymmetric didentate ligand forms a stable four membered ring by chelation through the two sulfur atoms (NiS_2C). The Ni(1)–S(1) bond lengths of 2.190(1) in **1**, 2.179(1) in **2** and 2.178(1) in **3** Å are shorter than the Ni(1)–S(2) [2.220(1), 2.219(1) and 2.224(1) Å in **1**, **2** and **3**, respectively]. These deviations are more obvious than those found in the $[Ni(CH_3SO_2N{=}CS_2)_2]^{2-}$ [24]. This fact may be ex-

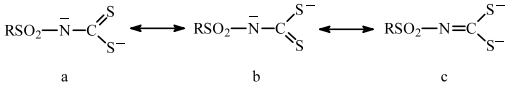

Fig. 1. Some possible canonical forms for the *N*-R-sulfonildithiocarbimate anion.

plained by the stereochemistry affecting the phenyl ring of the *N*-R-sulfonyldithiocarbimate ligand, which is located in *cis* position to the S1 atom. The C1–N1 bond lengths of 1.279(3), 1.288(3) and 1.296(4) in **1**–**3**, respectively, are shorter than the normal single C(sp^2)–N(sp^2) bond length (ca. 1.35 Å), and similar to that of the double bond C=N (1.275–1.295 Å) [25,26]. The C(1)–S(1) and C(1)–S(2) averaged bond lengths (1.745 Å) are slightly shorter than the typical C–S single bond length (ca. 1.81 Å) due to partial π-delocalization in the S–C–S group. The S(1)–C(1)–N(1) angles of 132.0(2)°,

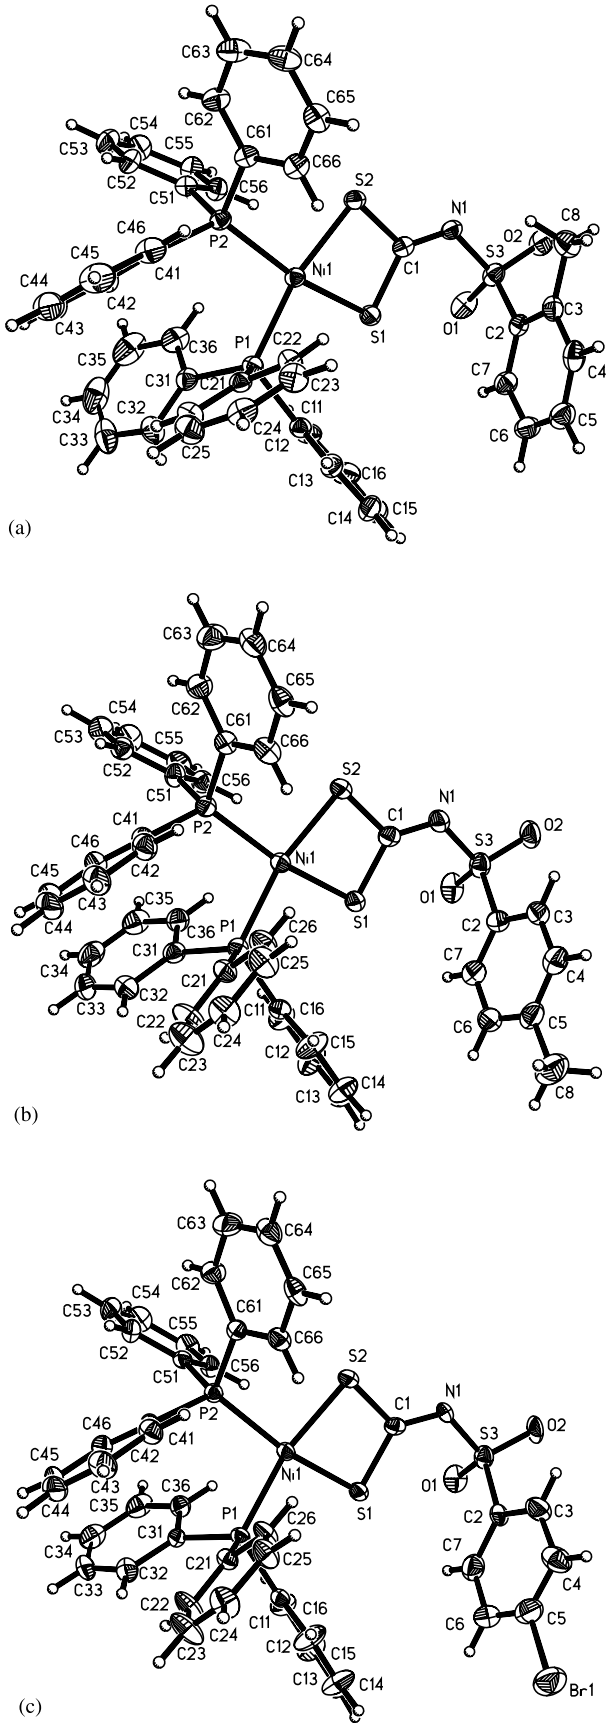

Fig. 2. View of the molecular structure of the complexes **1** (a), **2** (b) and **3** (c).

132.2(3)° and 131.0(3)° in the complexes **1**–**3**, respectively, are significantly greater than S(2)–C(1)–N(1) [122.9(2) in **1**, 122.1(3)° in **2** and 123.6(3)° in **3**] due to the interaction between the SO_2R group and the S(1) atom, which are joined in *cis* position in relation to the C(1)–N(1) bond. The steric effect of the R-sulfonyl group is greater than the effect of the lone-pair of electron at the N(1) atom, since the C(1)–N(1)–S(3) angle is greater than 120° in all complexes. If R is a small group such as $-SO_2CH_3$ [24] or –C≡N [27] the repulsive interaction predicted by the valence-shell electron pair repulsion theory (VSEPR) [28] between the lone-pair of electron at the N(1) atom and the S(2) atom is greater than the steric effect and the angle S(2)–C(1)–N(1) is greater than the angle S(1)–C(1)–N(1). In other dithiocarbimate complexes with larger R groups, the steric effect between S(1) and R group is more important and similarly as in the **1**–**3** complexes the angle S(1)–C(1)–N(1) is greater than S(2)–C(1)–N(1) [29].

The C(1)–N(1)–S(3) fragment of the *N*-R-sulfonyldithiocarbimate ligand (Fig. 2(a–c)) is coplanar with the NiS_2P_2 fragment, thus the P(1)P(2)Ni(1)S(1)S(2)C(1)-N(1)S(3) atoms lie in plane. The phenyl ring of the *N*-R-sulfonyldithiocarbimate ligand is inclined by about

Table 3
Comparison between selected crystallographic and spectroscopic data for the CN bond in compound **2** and related compounds

Parameters	**2**	$[Ni(4\text{-}CH_3C_6H_4SO_2N{=}CS_2)]^{2-}$ [b]	$(4\text{-}CH_3C_6H_4SO_2N{=}CS_2)^{2-}$ [a]
CN length (Å)	1.288(5)	1.35(2)	
ν(CN) (cm^{-1})	1445	1390	1260
^{13}C chemical shift (NCS_2) (ppm)	197.37	210.07	225.19

[a] Ref. [19].
[b] Ref. [20].

88.6(2)° in the complex **1**, and 78.1(2)° and 79.1(2)° in the isostructural crystals of the **2** and **3** complexes, respectively. The torsion angle of C(1)–N(1)–S(3)–C(2) describing the conformation of the ligand along the N(1)–S(3) bond is more similar in the complexes **1** and **2** [−65.2(2)° and −65.0(1)°], since both have a methyl group in the phenyl ring, than in **3** [−61.4(2)°], containing a Br-substituted aromatic ring. The S(3) atom has an expected slightly distorted tetrahedral geometry. The S(3)–O(1) and S(3)–O(2) bond lengths indicate their double bond character (S=O); a typical distance of the double S=O bond ranging from 1.431 to 1.442 Å [27]. The S(3)–C(2) bond with a distance ranging from 1.767(4) to 1.783(3) Å is well correlated with the C_{Ar}–S bond length in the related complexes which comprise the C_{Ar}–SO_2–N fragment [26]. The S(3)–N(1) bond length with a value ranging from 1.626(3) to 1.655(3) Å indicates a single bond nature; the typical value of the N(sp^2)–S bond distance is 1.623–1.659 Å [26]. Both P atoms of the triphenylphosphine ligands have similar tetragonal geometry. The phenyl ring C(21)–C(26) of the P(1) triphenylphosphine is almost parallel to the phenyl ring C(41)–C(46) of the P(2) triphenylphosphine, the dihedral angle being equal to 9.3(2)° in the complex **1**, and 15.2(2)° and 15.8(2)° in isostructural **2** and **3** complexes. Although the crystal of the complex **1**, is not isostructural with the crystals of **2** and **3** the structure analysis clearly shows that the geometry of the molecules of the compound **1** is quite similar to that of **2** and **3**. The differences between the **1** and **2** and/or **3** may be found in the molecular arrangement and the crystal packing. The complexes **1** and **2** differ only in the position of the methyl group substituted in the aromatic ring of the *N*-R-sulfonyldithiocarbimate ligands (**1** in *ortho* and **2** in *para* position). The crystal of the isomer **2** is more compacted since the molecules interact more effectively than in compound **1**. The arrangement of molecules in both **2** and **3** crystals is quite similar since both have *para*-substituents. These structures are slightly stabilized by weak C–H···O intermolecular hydrogen interactions of neighbouring molecules to form a polymeric structure. The C–H···O interactions with C···O of approximately 3.37 and 3.36 Å distances in **2** and **3** compounds, respectively, lead to the formation of the pseudo mono-dimensional columns aligned along the *a*-axis in the crystal (Fig. 3(b–c)). Although the intermolecular C–H···O are weak, we suppose that they are important for the crystal packing, since this can be the reason for the more compacted arrangement of the molecules in **2** and in **3** in relation to the crystal of **1**, in which the C–H···O interactions were not observed.

4. Conclusion

Three novel bis(triphenylphosphine)*N*-R-sulfonyldithiocarbimatenickel(II) complexes were prepared and characterized by UV–Vis, IR, ^1H, ^{13}C and ^{31}P NMR, elemental analyses for C, H, N, Ni and by single crystal X-ray diffraction techniques.

The spectroscopic and X-ray data for the complex $[Ni(4\text{-}CH_3C_6H_4SO_2]^{2-}$ [20] show an interesting relation with the data obtained for compound **2** (Table 3). The C(1)–N(1) bond length in **2** is shorter than in $[Ni(4\text{-}CH_3C_6H_4SO_2N{=}CS_2)_2]^{2-}$ [20]. The wavenumber for the ν(CN) in the IR spectrum of **2** is greater than that in the spectrum of the related anionic complex and this band is observed in smaller wavenumber in the spectrum of the parent dithiocarbimate ligand [19]. The NMR spectra show that the carbon atom of the dithiocarbimate group of **2** is more shielded than that of the anionic complex and in the parent ligand. These facts are in accord with an increase of the contribution of the (c) canonical form (Fig. 1) to the resonance hybrid from the ligands to the complexes, with a consequent increase of the CN double bond character.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 181695, 181696 and 181697 for the compounds **1**–**3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

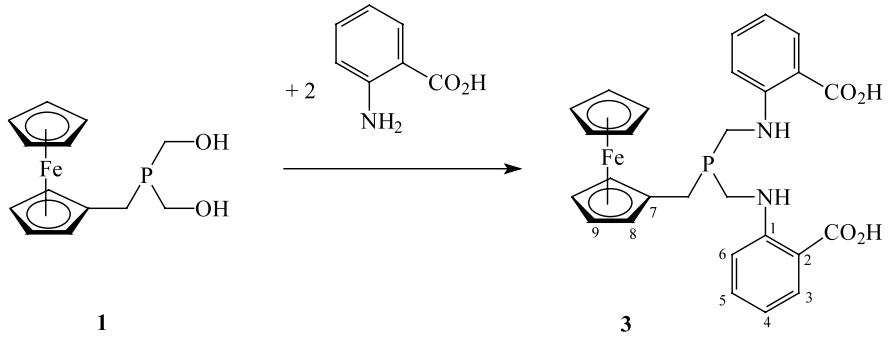
anes [14]. Reaction of bis(hydroxymethyl)(ferrocenylmethyl)phosphine (**1**) [3] with 2 equiv. of glycine in the presence of 2 equiv. of KOH and 1 equiv. of paraformaldehyde gives the corresponding 1,3-diaza-5-phosphacyclohexane **2** (Eq. (1)).



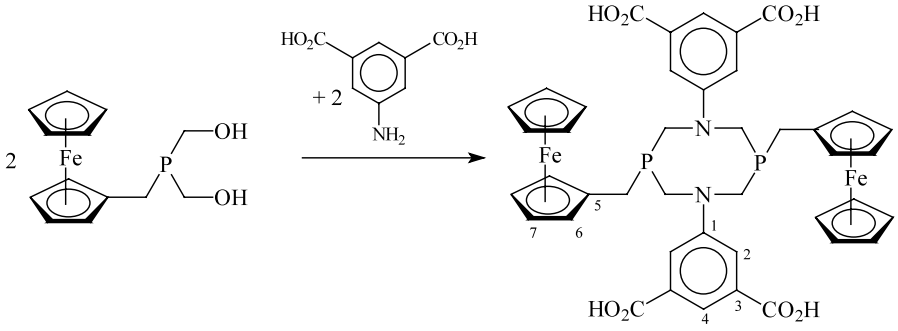
(1)

Although the ^{31}P chemical shift of **2** (in CD_3OD) is to lower field than expected for diazaphosphacyclohexanes [14], the presence of this type of heterocycle was established on the basis of the ^{1}H and ^{13}C NMR spectra. Well-identified signals of the protons and the carbon atom of the N–CH_2–N fragment and signals for all other groups confirmed the structure of **2**.

In the ^{31}P NMR spectrum in 10% aqueous solution of NaOH only a very broad signal at about −55 ppm was observed together with sharp, intense signals at 35.6 and 1.7 ppm, which probably correspond to products of hydrolysis of the C–N bond and oxidation, and thus indicate some instability of **2** in water.

Oxidation in the course of a Mannich-type reaction of **1** was observed earlier with dimethylamine [3] and by us with optically active (*S*)-α-phenylglycine and (*S*)-1-methylbenzylamine. In the ^{31}P NMR spectra of the reaction mixtures and products isolated as powders the signals of the desired products were accompanied by those of the phosphine oxides.

The stability of aminobenzoic acid derivatives is usually higher than that of α-amino acids [14–16]. It was recently established that the type of amino acid used in the condensation reaction with primary phosphines and formaldehyde determines the type of phosphino amino acid that is formed regardless of the stoichiometry of the reagents, i.e. primary phosphine, formaldehyde and amino acid [15,16]. For example, for *o*-aminobenzoic acid bis(*o*-carboxyphenylaminomethyl)phosphines are the predominant products, even when an excess of formaldehyde is employed in the reaction [9,10,15]. Thus, the reaction of **1** with 2 equiv. of *o*-aminobenzoic acid leads as expected to the open-chain product **3**, even when an excess of CH_2O is employed in the formation of **1** from (ferrocenylmethyl)phosphine (Eq. (2)).



(2)

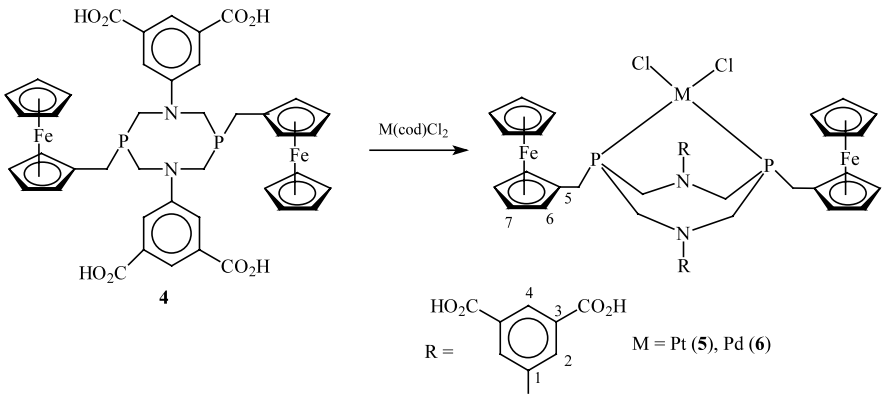
Compound **3** was isolated as a yellow microcrystalline solid. The ^{31}P NMR chemical shifts of **3** in methanol and DMF are similar and comparable to those of previously reported bis(arylaminomethyl)phenylphosphines [9,15]. The ^{1}H and ^{13}C NMR spectra of **3** are in accordance with the open-chain structure. The

protons of the P–CH_2–N and P–CH_2–Fc fragments give rise to broad singlets, in contrast to the P–CH_2–N groups of the previously obtained analogues, for which two doublets of doublets were observed due to inequivalence of the two prochiral hydrogen atoms [15].

In the presence of at least 2 equiv. of potassium or sodium hydroxide, **3** is soluble in water (up to 1 M). The ^{31}P NMR signal of the salt solution is broadened and slightly shifted upfield relative to neutral **3** in DMF solution. ^{1}H NMR signals in D_2O/NaOD are also broad, but are generally similar to those in DMF solution.

It was shown previously that bis(hydroxymethyl)-phosphines react with primary aryl- and benzylamines (2:2) with the formation of crystalline, air- and moisture-stable 1,5-diaza-3,7-diphosphacyclooctanes [17–19], which can be used as bidentate chelate diphosphine ligands for various transition metals [20–22]. However, water-soluble derivatives were obtained only with *p*-aminobenzoic acid as primary amine and oxymethyl derivatives of *o*-phosphinophenols [15]. Therefore, a more hydrophilic amine should be used to obtain water-soluble 3,7-bis(ferrocenylmethyl)-1,5-diaza-3,7-diphosphacyclooctane ligands. Heating of **1** with 5-aminoisophthalic acid in boiling ethanol resulted in the formation of yellow, microcrystalline, air-stable 1,5-bis(*meta*-dicarboxyphenyl)-3,7-bis(ferrocenylmethyl)-1,5-diaza-3,7-diphosphacyclooctane (**4**) (Eq. (3)).

1 **4** (3)



The IR spectrum of **4** exhibits strong absorptions for the carboxyl groups (1596, 1698, and 3440 cm^{-1}). In the ^{31}P NMR spectrum only one signal is observed in the characteristic region for 1,5-diaza-3,7-diphosphacyclooctanes [15,17–19]. The ^{13}C and ^{1}H NMR spectra of **4** are consistent with the heterocyclic phosphine structure [15,17–19]. The ^{13}C NMR spectrum shows signals for the P–CH_2–N and P–CH_2–Fc methylene groups, one signal for the cyclopentadienyl rings, three signals for the substituted cyclopentadienyl rings, four signals for the aryl carbon atoms and a singlet for the carboxyl groups. ^{1}H NMR data provide additional information about the conformational behavior of heterocyclic phosphines. The protons of the P–CH_2–N methylene group form an ABX spin system (two doublets of doublets) with a notable difference in the values of the P–H coupling constants ($^{2}J(PH^{A})$ approximately 5 Hz, $^{2}J(PH^{B})$ approximately 9 Hz). This pattern is typical of diazadiphosphacyclooctanes in a crown conformation with diaxial orientation of the phosphorus lone pairs [17–19], that is, the ferrocenylmethyl substituents on the phosphorus atoms and the *meta*-dicarboxyphenyl groups on the nitrogen atoms do not change the conformational behavior of diazadiphosphacyclooctanes.

The NMR data of **4** in 10% aqueous solutions of NaOH are quite similar to those of **4** in DMF. Deprotonation of the carboxyl groups results in a high-field shift of the aryl and P–CH_2–N signals in the ^{1}H NMR spectrum. No evidence of oxidation or hydrolysis was observed in aqueous solutions.

When **4** is treated with [MCl_2(cod)] (M = Pt, Pd; cod = cyclooctadiene) in DMF, the ^{31}P NMR spectrum of the reaction mixture shows a signal downfield relative to **4** ($\Delta\delta = 44.1$ (M = Pt) and 61.1 ppm (M = Pd)) with satellites due to coupling with ^{195}Pt nuclei. The Pt–P coupling constant of 3064 Hz indicates the formation of the *cis*-*P*,*P* chelate trinuclear complexes **5** and **6** [22] (Eq. (4)).

The IR spectra of **5** and **6** exhibit strong absorptions for carboxyl groups (1590–1720 and 3430 cm^{-1}) and also absorption bands of the backbone vibrations of heterocycles.

The ^{13}C and ^{1}H NMR spectra are consistent with the structure and are in general similar to that of **4**. In the ^{1}H NMR spectra only the signal of the P–CH_2–Fc

4

(4)

methylene groups of **5** and **6** change dramatically. These signals are shifted downfield ($\Delta\delta \sim 1.2$–1.5 ppm) and overlap with those of the P–CH_2–N fragment. Due to this overlap it is impossible to establish the conformation of **5** and **6** in solution. In the ^{13}C NMR spectra, the signal of the P–CH_2–Fc methylene group is situated in the usual region.

The trinuclear complexes **5** and **6** are readily soluble in water in the presence of at least 4 equiv. of base (NaOH). The deprotonation and change of solvent cause a high-field shift of the ^{13}P NMR signal ($\Delta\delta = -6.2$ ppm) and a decrease in the Pt–P coupling constant for **5** ($\Delta = 85$ Hz). High-field shifts in aqueous solution were previously observed for tertiary phosphino amino acids [15], including **4**. The ^1H NMR signals of the P–CH_2–N methylene groups are slightly shifted to low-field relative to **4**.

Studies on the coordination chemistry of **2**, **3** and **4** are in progress.

3. Conclusions

A number of water-soluble open-chain and cyclic phosphino amino acids containing ferrocenylmethyl moieties was obtained via a Mannich-type condensation reaction of bis(hydroxymethyl)ferrocenylmethylphosphine with potassium glycinate, *o*-aminobenzoic acid and 5-aminoisophthalic acid. The water-soluble trinuclear Fe_2Pt and Fe_2Pd complexes were synthesized and characterized spectroscopically.

4. Experimental

4.1. General considerations

All manipulations were carried out with standard high-vacuum and dry-nitrogen techniques. NMR spectra: Avance DRX 400 (Bruker), standards: ^1H NMR (400 MHz): internal solvent; ^{13}C NMR (100.6 MHz): internal solvent; ^{31}P NMR (162 MHz): external 85% H_3PO_4. The IR spectra were recorded as KBr mulls on a Perkin–Elmer FT-IR spectrometer System 2000 in the range 350–4000 cm^{-1}. The m.p. were determined in sealed capillaries and are uncorrected.

Bis(hydroxymethyl)(ferrocenylmethyl)phosphine (**1**) was obtained according to a literature procedure [3].

4.1.1. 1,3-Bis(carboxymethyl)-5-(ferrocenylmethyl)-1,3-diaza-5-phosphacyclohexane (**2**)

To a suspension of **1** (0.75 g, 2.6 mmol) were added glycine (0.39 g, 5.2 mmol) and paraformaldehyde (0.08 g, 2.7 mmol) in 3 ml of MeOH and 2.8 ml of 10% KOH (5.3 mmol) in MeOH, and the reaction mixture was stirred for 24 h. The yellow microcrystalline solid which formed was filtered off, washed with MeOH and dried under vacuum. Yield: 0.62 g (38%); m.p. >250 °C (dec.). *Anal*. Calc. for $C_{18}H_{25}FeK_2N_2O_6P$ [530.42]: C, 40.8; H, 4.8; N, 5.3; P, 5.9. Found: C, 40.3; H, 4.5; N, 5.4; P, 6.1%.

^1H NMR (MeOH-d_4): δ 2.99 (s, br, 2H, P–CH_2–Fc), 3.28–3.30 (m, 4H, P–CH_2–N), 3.41 (s, 4H, N–CH_2–CO_2), 4.05 (d, $J_{HH} = 12.0$ Hz, 1H, N–CH_2^B–N), 4.06 (s, br, 2H, C_5H_4–H3 (for numbering scheme see Eq. (1))), 4.12 (s, 5H, C_5H_5), 4.16 (d, $J_{HH} = 12.0$ Hz, 1H, N–CH_2^A–N), 4.19 (s, 2H, C_5H_4–H2), 4.83 (s, 4H, H_2O). $^{13}C\{^1H\}$ NMR (MeOH-d_4): δ 18.7 (s, br, P–CH_2–Fc), 60.7 (s, br, P–CH_2–N), 68.8 (s, C_5H_4–C3), 69.9 (s, C_5H_5), 70.0 (s, C_5H_4–C2), 76.4 (s, N–CH_2–N), 84.7 (s, br, C_5H_4–C1), 174.1 (s, CO_2H). $^{31}P\{^1H\}$ NMR (MeOH-d_4): δ -50.0; $^{31}P\{^1H\}$ NMR (10% NaOH in D_2O): δ -55 (s, br). IR ($\tilde{\nu}/cm^{-1}$, KBr): 1599, 1630 (CO + H_2O), 3424 (HO).

4.1.2. Bis(o-carboxyphenylaminomethyl)-ferrocenylmethylphosphine (3)

A solution of **1** (0.77 g, 2.6 mmol) and anthranilic acid (0.72 g, 5.2 mmol) in 15 ml of MeOH was stirred for 24 h. The solvent was removed under vacuum, and the yellow powder was washed with Et_2O, collected by filtration and dried under vacuum. Yield: 1.00 g (72%); m.p. >250 °C (dec.). *Anal*. Calc. for $C_{27}H_{27}FeN_2O_4P$ [530.34]: C, 61.1; H, 5.1; N, 5.3; P, 5.8. Found: C, 60.9; H, 5.3; N, 5.1; P, 5.6%.

^{1}H NMR (DMF-d_7): δ 3.04 (s, br, 2H, P–CH_2–Fc), 3.71 (s, br, 4H, P–CH_2–N), 4.24 (s, br, 2H, C_5H_4–H9 (for numbering scheme see Eq. (2))), 4.29 (s, 5H, C_5H_5), 4.34 (s, br, 2H, C_5H_4–H8), 6.76 (dd, $^3J_{HH}=7.8$, $^3J_{HH}=7.3$ Hz, 2H, C_6H_4–H4) 7.04 (d, $^2J_{HH}=8.3$ Hz, 2H, C_6H_4–H6), 7.52 (m, $^3J_{HH}=8.3$, $^3J_{HH}=7.3$ Hz, 2H, C_6H_4–H5), 8.07 (d, $^3J_{HH}=7.83$ Hz, 2H, C_6H_4–H3), 13.0 (s, br, 2H, CO_2H). ^{13}C{^{1}H} NMR (DMF-d_7): 24.8 (d, $^1J_{PC}=16.5$ Hz, P–CH_2–Fc), 39.6 (d, $^1J_{PC}=14.5$ Hz, P–CH_2–N), 68.1 (s, C_5H_4–C9), 69.4 (s, $C_5H_5+C_5H_4$–C8), 84.4 (s, br, C_5H_4–C7), 111.4 (s, C_6H_4–C6), 112.5 (s, C_6H_4–C2), 115.2 (s, C_6H_4–C4), 132.5 (s, C_6H_4–C3), 135.0 (s, C_6H_4–C5), 152.1 (s, br, C_6H_4–C1), 171.1 (s, CO_2H). ^{31}P{^{1}H} NMR (DMF-d_7): δ −30.0 (s); ^{31}P{^{1}H} NMR (10% NaOH in D_2O): δ −35.4 (s, br). IR ($\tilde{\nu}$/cm^{-1}, KBr): 1590–1720 (CO+aryl), 3500 (HO, NH).

4.1.3. 1,5-Bis(meta-dicarboxyphenyl)-3,7-bis(ferrocenylmethyl)-1,5-diaza-3,7-diphosphacyclooctane (4)

A solution of **1** (1.42 g, 5 mmol) and 5-aminoisophthalic acid (0.88 g, 5 mmol) in 40 ml of EtOH was refluxed for 6 h. The resulting yellow crystals were collected by filtration, washed with EtOH, and dried under vacuum. Yield: 1.21 g (57%); m.p. >250 °C (dec.). *Anal*. Calc. for $C_{42}H_{40}Fe_2N_2O_8P_2$ [874.43]: C, 57.7; H, 4.6; N, 3.2; P, 7.1. Found: C, 56.9; H, 4.4; N, 3.4; P, 7.4%.

^{1}H NMR (DMF-d_7): δ 2.81 (s, 4H, P–CH_2–Fc), 3.96 (dd, $^2J_{HH}=14$, $^2J_{PH}=6.0$ Hz, 4H, P–CH_2^A–N), 4.14 (s, 4H, C_5H_4–H7 (for numbering scheme see Eq. (3))), 4.15 (s, 4H, C_5H_4–H6), 4.19 (s, 10H, C_5H_5), 4.27 (dd, $^2J_{HH}=14.0$, $^2J_{PH}=13.0$ Hz, 4H, P–CH_2^B–N), 7.54 (s, 4H, C_6H_3–H2), 7.89 (s, 2H, C_6H_3–H4), 13.3 (s, br, 4H, CO_2H); ^{1}H NMR (10% NaOH in D_2O): 2.78 (s, 4H, P–CH_2–Fc), 3.6 (dd, $^2J_{HH}=12.0$, $^2J_{PH}=12.0$ Hz, 4H, P–CH_2^A–N), 3.8 (dd, $^2J_{HH}=12.0$, $^2J_{PH}=2.0$ Hz, 4H, P–CH_2^B–N), 4.01 (s, 4H, C_5H_4–H7), 4.03 (s, 10H, C_5H_5), 4.07 (s, 4H, C_5H_4–H6), 7.12 (s, 4H, C_6H_5–H2), 7.48 (s, 2H, C_6H_5–H4). ^{13}C{^{1}H} NMR (DMF-d_7): δ 25.7 (s, br, P–CH_2–Fc), 56.2 (d, $^1J_{PC}=18.3$ Hz, P–CH_2–N), 68.1 (s, C_5H_4–C7), 69.4 (s, C_5H_5), 69.5 (s, C_5H_4–C6), 84.4 (s, br, C_5H_4–C5), 117.6 (s, C_6H_3–C2), 118.0 (s, C_6H_3–C4), 132.4 (s, C_6H_3–C3), 146.6 (s, C_6H_3–C1), 168.0 (s, CO_2H). ^{31}P{^{1}H} NMR (DMF-d_7): δ −53.9 (s); ^{31}P{^{1}H} NMR (10% NaOH in D_2O): δ −54.6 (s). IR ($\tilde{\nu}$/cm^{-1}, KBr): 1596, 1698 (CO+aryl), 3440 (HO).

4.1.4. cis-{P,P-1,5-Bis(meta-dicarboxyphenyl)-3,7-bis(ferrocenylmethyl)-1,5-diaza-3,7-diphosphacyclooctane}dichloroplatinum(II) (5)

[$PtCl_2$(cod)] (0.18 g, 0.5 mmol) was added to a solution of **4** (0.41 g, 0.5 mmol) in 15 ml of DMF, and the reaction mixture was stirred for 24 h. The solvent was removed in vacuum, and the yellow microcrystalline solid was washed with Et_2O, collected by filtration and dried under vacuum. Yield: 0.30 g (52%); m.p. >250 °C (dec.). *Anal*. Calc. for $C_{42}H_{40}Cl_2Fe_2N_2O_8P_2Pt$ [1140.42]: C, 44.2; H, 3.5; N, 2.4; P, 5.4. Found: C, 43.8; H, 3.8; N, 2.3; P, 5.2%.

^{1}H NMR (DMF-d_7): δ 3.99–4.04 (m, 8H, P–CH_2–Fc+P–CH_2^A–N), 4.17 (d, $^2J_{HH}=15.6$ Hz, 4H, P–CH_2^B–N) 4.23 (s, 10H, C_5H_5), 4.26 (s, 4H, C_5H_4–H7 (for numbering scheme see Eq. (4))), 4.68 (s, 4H, C_5H_4–H6), 7.74 (s, 4H, C_6H_3–H2), 8.17 (s, 2H, C_6H_3–H4), 13.5 (s, br, 4H, CO_2H); ^{1}H NMR (10% NaOH in D_2O): δ 2.04 (s, 4H, P–CH_2–Fc), 3.31 (m, 4H, P–CH_2^A–N), 3.64 (d, $^2J_{HH}=14.4$, 4H, P–CH_2^B–N), 3.88 (s, 4H, C_5H_4–H7), 4.06 (s, 10H, C_5H_5), 4.19 (s, 4H, C_5H_4–H6), 7.18 (s, 4H, C_6H_5–H2), 7.66 (s, 2H, C_6H_5–H4). ^{13}C{^{1}H} NMR (DMF-d_7): δ 22.5 (d, $^1J_{PC}=24.8$ Hz, P–CH_2–Fc), 46.7 (d, $^1J_{PC}=36.0$ Hz, P–CH_2–N), 69.4 (s, C_5H_4–C7), 69.7 (s, C_5H_5), 70.2 (s, C_5H_4–C6), 80.2 (s, br, C_5H_4–C5), 122.1 (s, C_6H_3–C2), 122.7 (s, C_6H_3–C4), 133.1 (s, C_6H_3–C3), 150.9 (s, C_6H_3–C1), 167.4 (s, CO_2H). ^{31}P{^{1}H} NMR (DMF-d_7): δ −9.8 (s with Pt satellites, $^1J_{PPt}=3064$ Hz); ^{31}P{^{1}H} NMR (10% NaOH in D_2O): δ −16.0 ($^1J_{PPt}=2979$ Hz). and angles are listed in Table 2. The stereochemistry of the copper(II) ion can be described as a distorted square-pyramid with a geometrical factor $\tau = 0.06$ (where $\tau = (\beta - \alpha)/60$; β is the greatest of the basal angles and α the second in magnitude) [9]. The basal plane is formed by two oxalato oxygen, the pyridine N(1) and the oxadiazole N(2) nitrogen atoms, with bond lengths of 1.929(2), 1.931(2), 2.023(2) and 2.012(2) Å, respectively. A water oxygen is placed in the apical position [Cu–O(1S) 2.414(2) Å]. The metal ion sits at 0.141 Å above the basal plane.

The oxadiazole ligand may be considered as quasi-planar. The maximum deviation from the pyridine plane corresponds to the C(8) atom, 0.167(4) Å.

The structure of **1** can be viewed as an alternating sequence of monomeric units (up-and-down with respect to the coordinated water molecule) forming double sheets parallel to the (1,−1,1) plane (Fig. 2). The crystallization water molecules reside between these sheets, but their arrangement is better described as planes parallel to (1,−1,2). The $[Cu(L)(oxalato)(H_2O)]$ entities are interconnected by strong hydrogen bonds in which the oxalato and water oxygen atoms play an important role (see Table 2).

It is worth mentioning that the shortest C···C distance between the pyridine and oxadiazole from different monomers is 3.22 Å. This fact suggests the existence of π–π stacking interactions between the aromatic rings. The stacking does not necessarily exhibits a perfect face-to-face alignment of the atoms as shown in Fig. 3, but can be described as a slipped packing [10]. These types of interactions have been evaluated [11,12], and the results are shown in Table 3. The coordination of a metal ion to the nitrogen

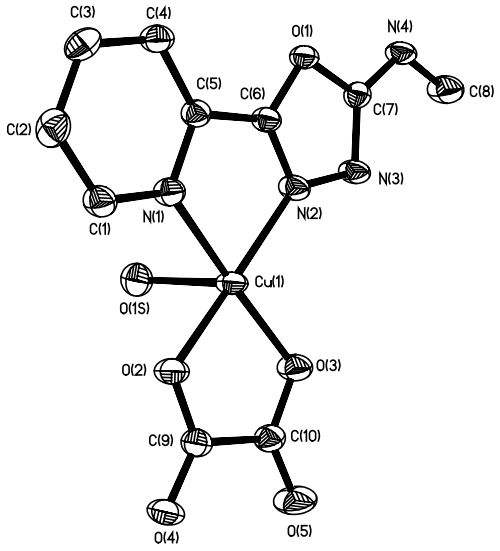

Fig. 1. Molecular structure of the [Cu(L)(oxalato)(H_2O)] entity with thermal ellipsoids at 30% probability level.

heteroatom from pyridines and other heterocycles enhances the electron-withdrawing effect through its positive charge, so that the stability of the π–π interaction increases [13,14]. In our case, the existence of further π–π interactions between the oxadiazole rings and the carboxylato groups with a shortest C(7)···C(10) distance of 3.27 Å cannot be excluded.

The crystal structure of complex **2** consists of $[Cu(L)_2(H_2O)_2]^{2+}$ cationic discrete entities and nitrate groups acting as counterions. A perspective view of the molecular structure of the centrosymmetric cationic entity is shown in Fig. 4. Selected interatomic dimensions are given in Table 4. The metal ion exhibits an elongated *trans*-octahedral geometry. It is coordinated by four nitrogen atoms at the equatorial plane: the pyridine N(1) and the oxadiazole N(2) atoms belonging to each ligand, at distances 2.033(3) and 2.040(3) Å, respectively. The axial positions are occupied by the oxygen atoms from both water molecules [Cu–O(2) 2.319(3) Å].

The oxadiazole ligand exhibits high planarity, the maximum deviation from the pyridine plane corresponding to the C(8) atom (0.163(6) Å).

Several hydrogen bonds are established in the lattice in which the nitrate ions, the water molecules, the amino N(4) and the oxadiazole N(3) nitrogen atoms and some of the pyridine carbon atoms are involved (Table 4). It is interesting to note the existence of an intramolecular hydrogen bond between the C(1) and N(3) atoms from the two different ligands.

The shortest interplanar atom···atom distance is 3.42 Å. The results of the structural analysis shown in Table 3 are in good agreement with the presence of π–π stacking interactions in compound **2**.

To evaluate some geometrical features in this 1,3,4-oxadiazole system, a comparative study on complexes containing the L ligand has been carried out. The ligand in compounds **1** and **2** shows a *syn* conformation with respect to both the C(5)–C(6) and C(7)–N(4) bonds, as in the free L molecule [8]. However, in the case of the $[\{Cu(L)(H_2O)_2(SO_4)\}_2]\cdot 2H_2O$ dimeric compound [8], the C(8) and N(3) atoms are anti with respect to the C(7)–N(4) bond. This conformational change can be attributed to the presence of a steric hindrance between the methyl and sulfato groups in the dimer. There is not

Symmetry transformations used to generate equivalent atoms: i, $x, y-1, z-1$; ii, $-x+1, -y+2, -z+2$; iii, $-x+2, -y+3, -z+2$; iv, $x, y+1, z$.

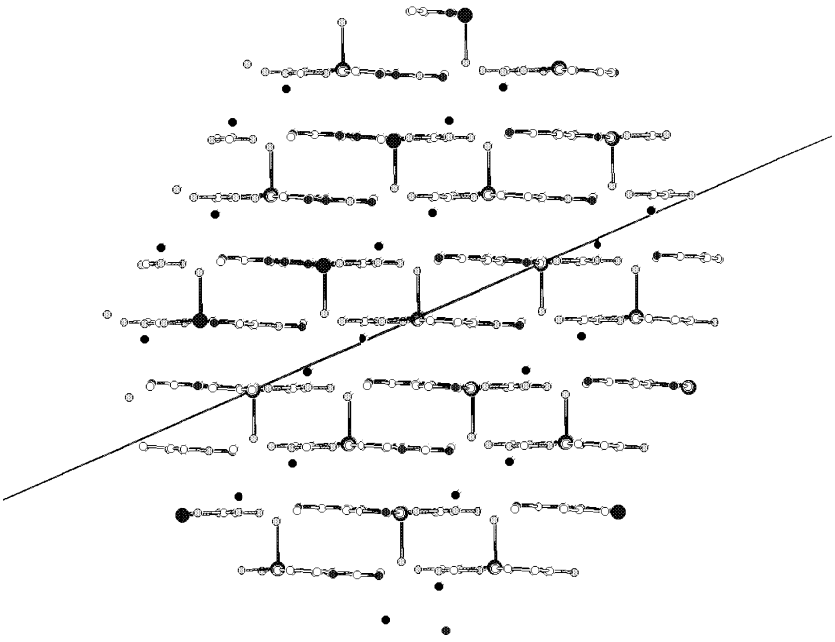

Fig. 2. View of the planar arrangement in **1**. The line in the drawing represents the (1, −1, 2) plane.

a significant variation in the bond lengths of L with complexation to the copper(II) ions. The main divergences for some selected parameters are given in Table 5. As can be seen, the value of the N(1)–C(5)–C(6)–N(2) dihedral angle between the pyridine and the oxadiazole rings decreases for the coordinated ligand. The C(5)–C(6)–N(2) angle also decreases with complexation. Complexes **1** and **2** exhibit the smallest values for both mentioned angles. This fact correlates well with the increase of the N(1)–Cu–N(2) bite angle for the monomer compounds, indicating that (i) the metal ion induces a higher planarity in the ligand, and (ii) the monomeric systems are less stressed than the dimer one.

The existence of different infrared absorption corresponding to the methylamino substituent, the pyridine and the oxadiazole rings, together with the electron delocalization along the whole oxadiazole molecule, make the unambiguous assignation of the bands difficult in these compounds. Moreover, the infrared spectra of 2-methylamino-5-pyridin-2-yl-1,3,4-oxadiazolecopper(II) derivatives show many important differences with respect to that of the free ligand. The intense band observed at 1653 cm^{-1} in the free ligand can be attributed to the $\nu(C{=}N)_{oxadiazolic}$, $\nu(C{=}N)_{pyridinic}$ and $\delta(NH)$ modes. This absorption shows a slight shift to

1656 and 1658 cm^{-1} for compounds **1** and **2**, respectively.

The absorptions at 1683 (vs), 1411 (s), 1273 (m) and 810 cm^{-1} in complex **1** have been attributed to the $\nu_a(C{=}O)$, $[\nu_s(C{=}O)+\nu(CC)]$, $[\nu_s(CO)+\delta(O{-}C{=}O)]$ and $[\nu(MO)+\delta(O{-}C{=}O)]$ modes of the oxalato ligand, respectively. Nevertheless, some of these absorptions are overlapped with those corresponding to the oxadiazole ligand. The spectrum of compound **2** shows a strong absorption at 1385 cm^{-1} and a weak band at 826 cm^{-1}, which can be assigned to the free nitrate groups, in good agreement with the structural results.

The reflectance spectra show bands in the 225–275, 345–405 and 650–1040 nm regions (see Table 6). They are attributed to intraligand, LMCT N/O → d and d → d transitions, respectively.

In order to make a good assignment of these bands a study in solution for the free ligand and compound **2** was carried out. Complex **1** is practically insoluble in all common solvents. The absorption at 226 nm in the reflectance spectrum of **2** is shifted towards higher energies in solution, and its maximum is only observed in the spectrum recorded on a methanolic solution. The strong band at 272 nm in the solid UV–Vis spectrum of **2** shows a shift to 297–304 nm in solution (see Table 6). A very small dependence of this band with respect to the polarity of the solvents is detected. These absorptions correspond to those observed in the free ligand at 204 and 298–300 nm, respectively, corroborating the intraligand character in both complexes. These bands have been assigned to the $(\pi\rightarrow\pi^*)_{pyridine/oxadiazole}$ and $(n\rightarrow\pi^*)_{pyridine/oxadiazole}$ transitions, respectively [15].

The shoulders observed at 345–405 nm in the reflectance spectra are attributed to the N→Cu(II) and O→Cu(II) charge transfer transitions. Unfortunately, these bands do not appear in the solution spectra because they are obscured by the tail of the intense intraligand absorption. A shoulder at around 328 nm was only observed for compound **2** in methanol, which does not appear in the spectrum of the free ligand. This fact is consistent with a decrease in the intensity of the intraligand band at around 300 nm observed in the methanol solution of **2** with respect to other solutions of this complex (see Table 6). These results suggest that the charge transfer bands shift to higher energies in solution overlapping with the intraligand absorption.

The reflectance spectrum of **1** shows a band at 654 nm characteristic of d→d transitions for compounds exhibiting a square-pyramidal geometry with a $d_{x^2-y^2}$ ground state. Compound **2** shows a broad band at 670 nm and a less intense absorption at around 1037 nm. This spectrum is typical of octahedral tetragonally distorted copper(II) complexes. These bands could be assigned to the $^2E_g \leftarrow {}^2B_{1g}$ and $^2A_{1g} \leftarrow {}^2B_{1g}$ transitions, respectively, in good agreement with the results reported for analogous triazole systems [16]. The band at 670 nm is shifted to lower energies in solution suggesting the replacement of the axially coordinated aquo ligands by the solvent molecules.

The X-band EPR spectrum of compound **1** at r.t. exhibits axial symmetry with $g_{\parallel}=2.269$ and $g_{\perp}=2.063$. These g-values are typical of complexes containing copper(II) ions in distorted square-pyramidal topologies with $d_{x^2-y^2}$ ground state. The value of $G=(g_{\parallel}-2)/(g_{\perp}-2)=4.3$, suggests that exchange coupling interactions are negligible in this complex [17]. This fact allows us to calculate the mixing coefficient c between the $d_{x^2-y^2}$ and d_{z^2} orbitals using the vibrational model proposed by Reinen and Atanasov [18]. The obtained c value is 0.577, which corresponds to a perfect square-pyramidal geometry, in good agreement with the structural results.

In the case of compound **2**, the EPR spectrum at r.t. shows an axial signal with $g_{\parallel}=2.235$ and $g_{\perp}=2.080$. These values are characteristic of octahedral copper(II) complexes with $d_{x^2-y^2}$ ground state.

It is worth mentioning that the title complexes are stable for months at r.t., while the free oxadiazole ligand decomposes with time. The addition of ferrocyanide removes easily the copper(II) ions from the ligand [8]. In this sense, the coordination represents a good route to stabilise and store the free ligand, in particular as the biscomplex **2**.

On the other hand, the presence of uncoordinated potential chelating centers in compounds **1** and **2**, as the oxadiazole N(3) and the oxalato O(4) and O(5) atoms, and/or a further substitution of the water molecules by ligands acting as bridges between the metal ions suggest that these compounds can be used as precursors of systems with a higher dimensionality (polynuclear complexes, chains, sheets, ...). In this sense, a simple preparative protocol as that reported in this work could be of importance to synthesize biologically active molecules, as well as active site models, which are bridged by histidine moieties.

3. Experimental

3.1. Preparation of the complexes

Potassium oxalato and copper(II) nitrate were purchased from Fluka. 2-Methylamino-5-pyridin-2-yl-1,3,4-oxadiazole (L) and $[\{Cu(L)(H_2O)_2(SO_4)\}_2]\cdot 2H_2O$ were synthesized following a published method [8].

3.2. Synthesis of $[Cu(L)(oxalato)(H_2O)]\cdot H_2O$ (1)

An aqueous solution of potassium oxalato (0.024 g, 0.13 mmol) was added dropwise to a solution of $[\{Cu(L)(H_2O)_2(SO_4)\}_2]\cdot 2H_2O$ (0.051 g, 0.06 mmol) in 40 ml of water. The mixture was stirred at room temperature (r.t.) overnight. The resulting precipitate was filtered off and washed with water. The yield was 48%. *Anal.* Calc.: C, 33.02; H, 3.32; N, 15.40; Found: C, 32.75; H, 3.44; N, 15.25%. Turquoise-blue crystals suitable for X-ray studies were grown by slow evaporation of the mother liquor at r.t. The compound is insoluble in water, methanol, ethanol, dimethylformamide, dimethylsulfoxide and acetone.

3.3. Synthesis of $[Cu(L)_2(H_2O)_2](NO_3)_2$ (2)

Copper(II) nitrate dissolved in 20 ml of water was allowed to react with solid, crystalline L (0.070 g, 0.3 mmol) suspended in 10 ml of water to give a green

solution. The yield was 43%. *Anal*. Calc.: C, 33.36; H, 3.50; N, 24.32; Found: C, 33.18; H, 3.33; N, 24.07%. Bright green crystals of **2** suitable for X-ray analysis were separated from the mother liquor by slow evaporation at r.t. This complex could also be synthesized starting from **1**: an aqueous solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.070 g, 0.3 mmol) was added to a suspension of $[Cu(L)(oxalato)(H_2O)] \cdot H_2O$ (0.054 g, 0.15 mmol) in water. The compound is soluble in water, methanol, dimethylformamide and dimethylsulfoxide, slightly soluble in ethanol and not soluble in acetone. Molar conductivity of 5×10^{-4} M solutions in water (dimethylformamide) at 25 °C: $\Lambda_M = 281$ (139) Ω^{-1} cm^2 mol^{-1}.

3.4. Physical measurements

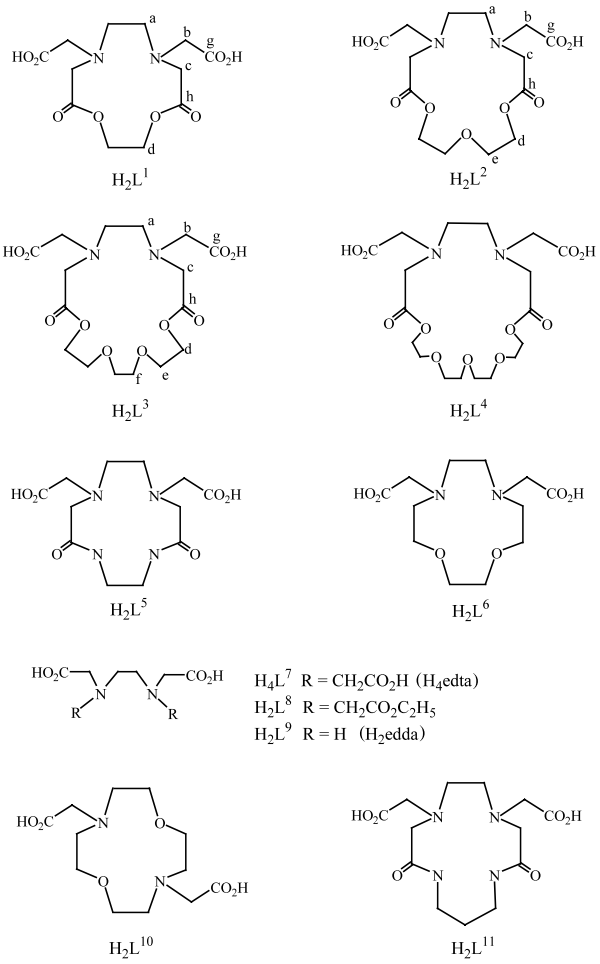
Microanalyses were performed with a LECO CHNS-932 analyzer. Conductivity measurements were made by a CRISON-522 conductimeter. Infrared spectra were obtained with samples prepared as KBr pellets in the 400–4000 region on a Nicolett Impact 410 FTIR spectrophotometer. Reflectance spectra were carried out on a Cary 2415 spectrometer in the range 5000–50 000 cm^{-1}. For UV–Vis solution measurements, a Varian UV–Vis–NIR spectrophotometer was employed. X-band EPR spectra were recorded on a Bruker EMX spectrometer, equipped with a standard Oxford continuous flow cryostat.

3.5. X-ray crystallographic studies

Crystal data collections were carried out on an Bruker Smart CCD area detector equipped single crystal diffractometer. Absorption corrections were made using the SADABS program [19]. Direct methods (SHELXS-97) [20] were employed to solve the structures and then they were refined by a full-matrix least-squares method, using the SHELXL-97 computer program [21]. All non-hydrogen atoms were assigned anisotropic thermal parameters. Hydrogen positions were determined by difference Fourier syntheses and introduced in calculations with a riding model. The scattering factors and anomalous dispersion coefficients were taken from International Tables of X-ray Crystallography [22]. Refinements were made on F_o^2 for all reflections.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center. The deposition numbers are CCDC-182346, and -182347 for compounds **1** and **2**, respectively. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).



Acknowledgements

We thank Dr. J.J. Delgado (SCAI, Universidad de Burgos, Spain) for the elemental analysis and Professor R. Olazcuaga and Dr. F. Guillen (CNRS, Pessac, France) for the reflectance measurements. This work has been carried out with the financial support of the Basque Government (PI99/53). P.G.-S. thanks to the Universidad de Burgos for her Doctoral Fellowship.

received much attention [27–32]. The cyclic diamides as well as the corresponding cyclic diesters derived from edta dianhydride cannot be useful for applications such as those mentioned above, because of the low stability constants of their metal complexes [13,14,28,30]. However, the diester macrocyclic compounds combine two moieties of contrasting metal complexes preferences. The edta-moiety, which contains two amines, two ester functions incorporated into the macrocyclic backbone and two appended *N*-acetate groups, and the crown-ether moiety, consisting of an increasing number of ether oxygen atoms. The length of the crown-ether pocket can be tuned for the selective complexation of an alkali or an alkaline-earth metal ion, while the edta-moiety is more appropriate for the co-ordination of transition or post-transition metal ions. Thus the latter metal ion complexes formed in the edta moiety can behave as a molecular sensor for the recognition of alkali or alkaline-earth metal ions. With this in mind, we synthesised a series of macrocyclic compounds of the diester type derived of edta, H_2L^1–H_2L^4, as shown in Scheme 1. The protonation reactions of the ligands and their thermodynamic stability constants with a series of divalent metal ions were undertaken. However, the easy hydrolysis of those ligands and especially of some of their metal complexes, with the consequent rupture of the macrocyclic backbone, never mentioned before [27–31], restricts their possible applications. The hydrolysis reaction observed was studied with the objective of understanding the metal catalysis involved in the procedure.

Scheme 1.

2. Results and discussion

2.1. Synthesis of compounds

Reaction of the ethylenediamine tetracetic dianhydride with polyethyleneglycols $HO(CH_2CH_2O)_nH$ ($n = 1$–4) leads to the macrocyclic diesters H_2L^1–H_2L^4 [27]. The original procedure and published modifications [28] led to materials, which still contained edta. We, therefore, modified the reaction conditions and the work up to obtain products free from this impurity, albeit in lower yield. The compound H_2L^2 was obtained in such small amount that only NMR and EPR spectroscopic studies could be performed. The ^1H and ^{13}C spectra in D_2O and d_6-DMSO for all compounds and some of their zinc(II) and lead(II) complexes are summarised in Table 1. We also checked the published assignment [29,30] of the ^1H and ^{13}C b and c resonances, of the $-NCH_2COO^-$ groups, as well as the ^{13}C g and h signals, of the $-NCH_2COO^-$ groups, see NMR studies.

2.2. Acid-base behaviour of H_2L^1–H_2L^4

The protonation constants of H_2L^1–H_2L^4 are collected in Table 2. For each compound only two values were determined, the other two are very low to be obtained by the technique used. Both values for all compounds have similar magnitude, although slightly smaller ones for the 12-membered macrocycle H_2L^1. The latter and the corresponding diamide compound, H_2L^5, present practically the same values, indicating that it is the presence of the carbonyl function that matters. In agreement with this, both protonation constant values are higher for H_4edta [33], and for H_2L^6 [34], while the diester derivative of edta, H_2L^8 [28], has values similar to those of the cyclic derivatives (see Table 2). This is due to the greater electron-withdrawing ability of the carbonyl over that of the carboxylate group. Thus the introduction of the carbonyl group in the cyclic backbone of H_2L^1–H_2L^4 leads to a significant decrease of the overall basicity of these compounds when compared with H_4edta or H_2L^6 (of about 5–6 log units), which will have important implications upon its metal complexing behaviour.

On the other hand, although no doubts exist about the site where the first protonation occurs, which is in

[a] When the pD is not quoted, the compound was dissolved in pure solvent without any additional pD adjustment.

the amine nitrogen, the same cannot be said about the second protonation, that can be attributed to the second amine or to a carboxylate group. If it occurs in the other amine, which is at short distance from that already protonated, a net decrease of basicity would be observed due to the strong repulsion of positive charged ammonium ions formed, as happens in H_4edta [33] and in H_2L^6 [34]. The value obtained for the second protonation is also in agreement with the protonation of an *N*-acetate group appended to a non-protonated amine, as found for many *N*-polyacetate polyaza-macrocycles [34–36]. A titration followed by NMR spectroscopy can elucidate this problem [34–36]. In fact, the observed deshielding of the methylene hydrogen atoms due to the protonation of basic centres of the ligands located in their vicinity can be correlated with the percentage of protonation of the amine and carboxylate groups [34–36]. The ^1H NMR obtained at three distinguishable pD values of H_2L^2 in D_2O, corresponding to the formation of H_2L, HL^- and L^{2-} species, gave the following results, see Table 1: at $pD \geq 7$ the main species in solution is completely deprotonated corresponding to a high shielding of the protons. A single protonation can be achieved by lowering the pH to 4.4, which is accompanied by a deshielding of the protons of the CH_2 groups attached to nitrogen (for compound H_2L^2: $\Delta\delta$ (a) = 0.36 ppm, $\Delta\delta$ (b) = $\Delta\delta$ (c) = 0.31 ppm, see Scheme 1 for labelling of compounds). This suggests that the first protonation occurs at the nitrogen atoms, which will be 50% protonated. Further lowering of the

pD to 2.4, results in a second protonation. At this pD value only the b signal shifts downfield ($\Delta\delta$ (b) = 0.18 ppm), all the other resonances remain basically unchanged, implying the assignment of protons b to the methylene group of CH_2COOH and testifying that the second protonation occurs in a carboxylate group. The lower shift observed for protons b by the protonation of the nearby carboxylate when compared with the shift caused by the protonation of amine centres is due to the lower shielding constant of the carboxylate compared with that of an amine [35].

2.3. Stability constants of some complexes and metal-catalysed hydrolysis of the ligands

The stability constants of H_2L^1, H_2L^3 and H_2L^4 with alkaline-earth metal ions, Cu^{2+}, Ni^{2+}, Cd^{2+} and Pb^{2+} are collected in Table 3, together with the corresponding constants for complexes of other ligands taken from the literature for comparison. Only mononuclear complexes, ML and MHL, were found in solution for all the compounds with the studied metal ions. Hydroxocomplexes, $ML(OH)_i$, could not be determined due to decomposition of the complexes in aqueous solution at higher pH values, as explained below. Dinuclear or other species, such as M_2L, M_2HL, M_3L_2 or ML_2, were expected to form with the larger membered rings, but were either not accepted by the HYPERQUAD program [37] or accepted with worse statistical parameters.

Aqueous solutions of the ligands decompose slowly with time, especially at pH $\geq$ 7. Minor increases of the rate of decomposition were observed in presence of alkaline-earth metal ions, while for the other complexes studied the decomposition rate depends of the metal ion following the order: Cu(II) > Pb(II) > Cd(II) > Zn(II) for H_2L^1 and Pb(II) $\gg$ Cd(II) > Cu(II) > Zn(II) for H_2L^2–H_2L^4. Even so, it was possible to determine the equilibrium constants by dissolution of the ligand immediately before starting the titration. It was observed that the rate of the decomposition reaction is lower than that of the formation of the complex, and in all the studied cases the equilibrium was attained in a pH range sufficient for calculations. Some of the constants were determined with few data points, due to the critical compromise between equilibration and decomposition rates, although with larger standard deviations.

The solutions resulting from complete decomposition of ligands, or of their complexes, needed 1 equiv. more of strong base for total neutralisation. The reason for this is obviously hydrolysis of the ester bonds, which liberates a carboxylic acid that is neutralised by the strong base. The 18- and 21-membered macrocycles are more stable in water, probably because of less strained conformations. On the other hand, the edta- or dtpa-derived diamides studied by Q. Fernando et al. [7,9–26] and C.A. Chang et al. [8] are also stable due to the greater stability of amide bonds compared with ester ones.

Table 3
Stability constants (log units) for metal complexes of H_2L^1, H_2L^3, and H_2L^4 and other similar ligands with several divalent metal ions

Ion	Equilibrium quotient	H_2L^1	H_2L^3	H_2L^4	H_2L^5	H_2L^6 [d]	H_2L^7 [e] (H_4edta)

Surprisingly, the metal-catalysed hydrolysis of H_2L^1–H_2L^4 has only mentioned before by us [32]. One can understand that the alkali metal ions should be the least efficient catalysts, however, lanthanides should even be more effective than the cations studied by us, but the authors did not mention it [28,30].

The self-destruction of the studied macrocycles by hydrolysis reactions excludes their use as analytical reagents, namely as molecular sensors or as catalysts for other reactions.

The thermodynamic stability of the alkaline-earth metal complexes of H_2L^1, H_2L^3 and H_2L^4 decreases from Ca^{2+} to Sr^{2+} but slightly increases from Sr^{2+} to Ba^{2+}. For each metal ion, the complexes of the 12-membered ligand present the lower values and a plateau of stability is observed for the 18- and 21-membered ligands. Thus, the charge density on the metal mainly govern the complexation, as the Ca^{2+} complexes of all ligands are the most stable (except for the Mg^{2+} complexes due to it small size), and that the complexes of all ligands present the same stability trend independently of its cavity size. These conclusions allow to infer that (1) the complexation with the rigid 12-membered macrocyclic compound is only possible with severe steric strain, and (2) the co-ordination sphere should be the same for all the complexes, implying that the ether oxygen atoms do not directly co-ordinate to these metal ions. In other words, all the studied metal ions are co-ordinated to the edta-moiety of the ligands.

For the complexes formed with the other metal ions studied, Cu^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+}, roughly the same conclusions are applied, in spite of the more covalent character of their interactions with ligands, and the strict stereochemical demands of co-ordination geometry and the limited co-ordination number of the Cu^{2+} complexes. The highest thermodynamic stability values of the Pb^{2+} complexes worth to be emphasised, and once more the size of this metal ion is the important factor. Also, the stability constants of the complexes with the 12-membered ligand are lower than with the 18- and 21-membered ligands, H_2L^3 and H_2L^4, the values for the latter ligands being practically identical.

The comparison of stability constants of complexes of the three 12-membered ligands (H_2L^1, H_2L^5 and H_2L^6) compiled in Table 3 for all the metal ions allows to conclude that: (1) the values for the diester (H_2L^1) and the diamide (H_2L^5) macrocycles are practically identical indicating the same co-ordination sphere for the complexes of both ligands (see below) and (2) the differences of values between complexes of H_2L^1 and the corresponding complexes with the compound without ester bonds (H_2L^6) are mainly due to differences on overall basicity of both ligands, as indicated by pM values determined at pH 7 (not shown).

The comparison of linear ligands, such as H_4edta (unfortunately values for H_2L^8, which would be more adequate for comparison, were not found), with H_2L^1 is not straightforward because besides the large differences in the overall basicity of both ligands, differences in entropic changes and of solvating effect of complexes with both ligands should also be taken into account as H_4edta has two additional carboxylate groups with their respective negative charges.

2.4. Structural studies in solution

2.4.1. NMR spectroscopic data

^1H and ^{13}C spectra of all the compounds were studied before [28–32]. We agree with the assignment of the resonances made by those authors except for b and c of the ^1H NMR and g and h in the ^{13}C NMR spectra of all compounds (for labelling see Scheme 1). In fact as mentioned in the acid-base discussion, only resonance b and also g (in the ^{13}C NMR spectra) shift to lower field when the pD is decreased from 4.4 to 2.4, as at this pD range only the acetate group is being protonated the assignment is unambiguous. For the cyclic amides derivatives of edta, Q. Fernando et al. [14] reached the same conclusion in another way. These authors consider that the internal fluctuation of the CH_2 protons close to the carbonyl in the macrocyclic backbone is significantly slower than that of the CH_2 protons in the acetate arm, thus the taller signal of the spectra is assigned to b (acetate arm) and the shorter to protons c in the ring, due to the rigid macrocyclic ring resulting from the planarity of the $CH_2NHCOCH_2$ moiety (confirmed by X-ray crystal analysis) [14]. This argument is also valid for the assignment of g and h resonances of the ^{13}C NMR spectra, the taller signal was assigned to g (carboxylate of the arm). In Table 1 we compiled the ^1H and ^{13}C NMR resonances for H_2L^1–H_2L^3 and also for their Zn^{2+} and Pb^{2+} complexes. The spectra of the free ligands were performed in D_2O and in d_6-DMSO, but most of the complexes were studied only in d_6-DMSO due to their decomposition in the first solvent.

Compound H_2L^1 shows only singlet resonances in the ^1H NMR spectrum due to its symmetric structure. The signals d and e of the $-CO-OCH_2CH_2O-$ units in compounds H_2L^2 and H_2L^3 in d_6-DMSO appear as broad singlets where one might expect triplets for a symmetric compound. This points to conformational equilibria in the macrocycles with coalescence about room temperature. In D_2O, each of the corresponding signals consists of a superposition of two multiplets of the AA′XX′ type, indicating a single conformation with slightly different environments for the two protons of each CH_2 group.

^1H NMR resonances corresponding to the edta-derived part (protons a, b and c) of the Zn^{2+} and Pb^{2+} complexes of H_2L^1 and H_2L^3 shift considerably ($\Delta\delta$ 0.3–0.57 ppm) but the shifts are negligible for the glycol-derived part ($\Delta\delta < 0.09$ ppm for the resonance d

of H_2L^1 complexes and for d, e and f of H_2L^3 complexes), see Table 1. This means that the oxygen atoms of the ether units do not participate in the metal complexation. The same was observed for the corresponding alkali [31] and Y^{3+} complexes [30]. However, the ^1H NMR data of Y^{3+} complexes indicate that the acetate protons (a) and the methylene ester protons (c) become indistinguishable upon metal co-ordination, both exhibiting an AB splitting pattern indicative of long-lived metal–nitrogen bonds, and short-lived metal–oxygen bonds as also found in $[Y(edta)]^-$ [30,38]. In the case of our complexes the edta-derived part exhibit only singlets indicating short lifetimes for both the metal–oxygen (of acetate or ester) and the metal–nitrogen bonds [38].

The 15-membered ligand, which we obtained in minute amount, was used to study the ligand as well as its Pb^{2+} complex in D_2O, the latter at low pD value. Even at that pD value the complex is completely formed, as the signals of the free ligand are not present on the NMR spectra. After complexation all ^1H resonances shift to upfield except b, see Fig. 1. This

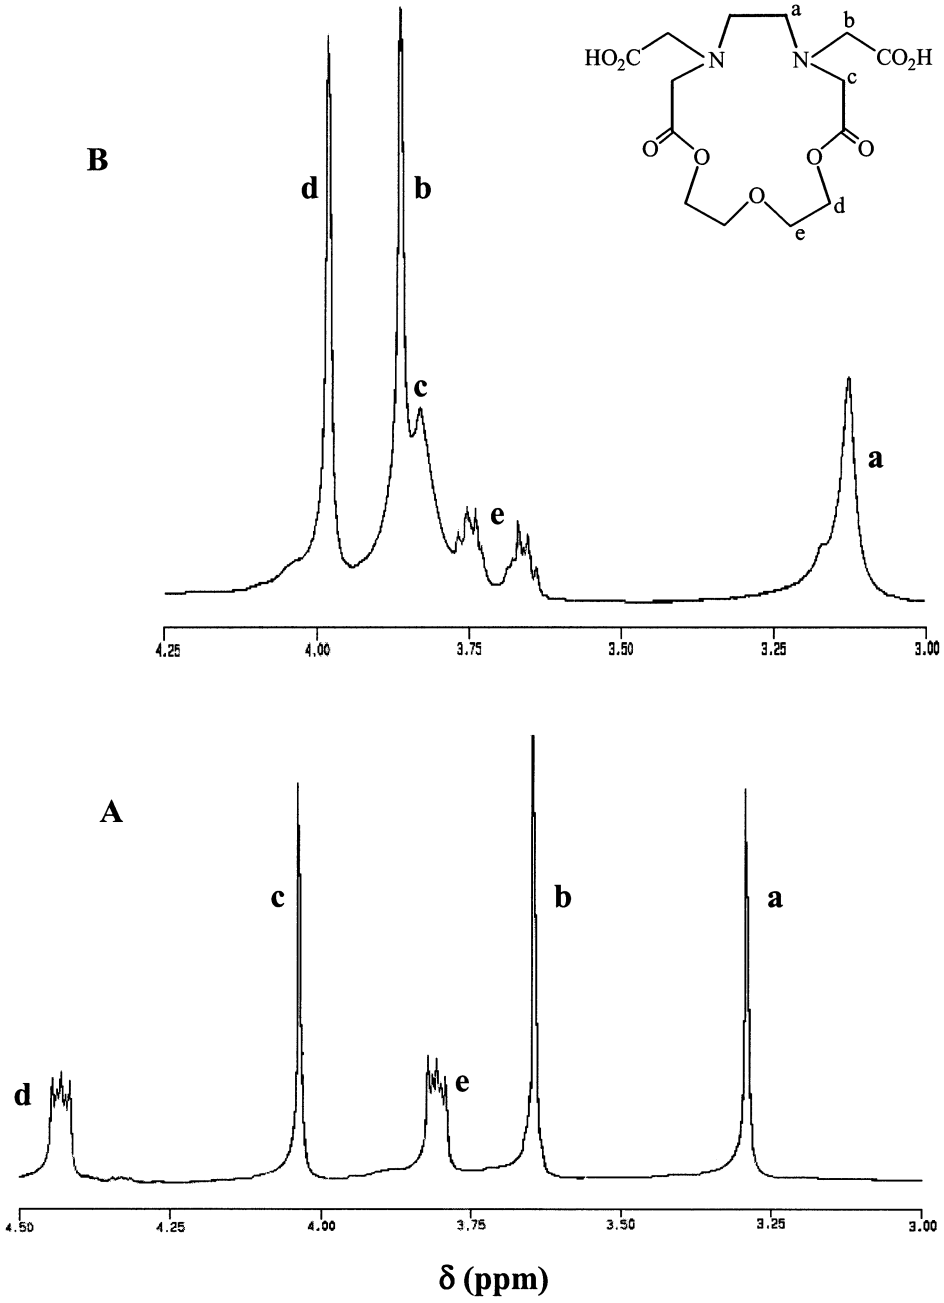

Fig. 1. ^1H NMR spectra of H_2L^2 at pD 4.4 (A) and of its Pb^{2+} complex at pD 1.6 (B) in D_2O (δ ppm vs. 3-(trimethylsilyl)-propanoic acid-d_4-sodium salt) at probe temperature and assignments of resonances.

apparent contradiction is due to the lower pH value of the solution after complexation and to the fact that at this pH range only the b protons shift downfield by acid addition, thus for a correct comparison a spectrum of the free ligand at pD 1.6 would be necessary. The ^{1}H NMR spectrum exhibits three singlets assigned to a, b and c, a broad signal corresponding to d and a ABX_2 pattern assigned to protons e. Nuclear Overhauser effect (NOE) experiments point to close proximity of d and a protons. The spectra and the NOE experiments clearly show that, in this case, the oxygen atom of the ether moiety is involved on the direct co-ordination to Pb^{2+}, as protons and carbon d and e significantly shift after complexation (see Table 1). CPK models also show that the folding of the macrocycle approaches the ether oxygen at a co-ordinated distance to a metal such as Pb^{2+}. The large size of the Pb^{2+} and its no strict stereochemical demands strongly contribute to the folding of the ligand.

On the other hand, the ^{13}C NMR spectra of the Y^{3+} complexes of H_2L^1–H_2L^4 exhibited only one resonance for g and h carbon atoms of the carboxylate and ester groups, at about 180 ppm, pointing to similar chemical environments of both oxygen atoms on complexation [30]. Otherwise, the ^{13}C NMR spectra of the Zn^{2+} and Pb^{2+} complexes of H_2L^1–H_2L^3 exhibit two downfield resonances, in the range 170–182 ppm, which indicate a dissimilar environment for the carboxylate and ester moieties upon co-ordination or different co-ordination of both oxygen of the ester groups or of the carboxylate groups. The last hypotheses seem more likely according to the behaviour of similar bisamide derivatives. Indeed, in spite of the unsymmetrical molecules formed, the simple ^{1}H NMR spectra obtained can be interpreted by an alternately co-ordination of the two ester oxygen atoms, or of the two carboxylate oxygen, or both, to the metal in an exchange rate higher than the NMR frequency, which indicate a high degree of lability of the of the metal carbonyl bonds. Similarly the ^{1}H NMR of the Ca^{2+} complexes of the 12- and 13-membered macrocycles of the amide derivatives of edta (H_2L^5 and H_2L^{11}, respectively) showed only four and five resonances, respectively, indicative of symmetrical molecules, but the X-ray crystal structure of the Ca^{2+} complex of H_2L^{11} revealed that a dimer was formed $[Ca_2(L^{11})_2(H_2O)_4]$, where each calcium atom is co-ordinated to only one amide oxygen and both oxygen atoms of the acetate groups of one molecule but also to one carboxylate oxygen of the neighbouring molecule, besides two nitrogen atoms, and two oxygen atoms from water molecules. This means that eight donor atoms form a distorted square antiprism around each calcium atom, one carboxylate oxygen of each molecule being simultaneously co-ordinated to two calcium atoms forming a binuclear structure with a double bridge of carboxylate oxygen atoms [16].

No X-ray crystal structures exist of the studied macrocycles or their metal complexes [39], because its hydrolysis prevents the slow evaporation of solutions to obtain good crystals. However, some crystal structures of several divalent metal complexes of 12- to 14-membered macrocycles of cyclic amides derived of edta [7,11,13,16,21], Ca^{2+}, Mn^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+} complexes, have shown that most of them co-ordinate to all the donor atoms of the ligands but only one amide oxygen, plus one water molecule. Dinuclear complexes of the type M_2L_2 are also frequent [13,16]. Only one complex is known where both amide oxygen atoms are directly co-ordinated to the metal; it is the case of $[Pb(L^{11})(H_2O)]\cdot 2H_2O$, thus in this complex all the donor atoms of the ligand are co-ordinated to the metal [11]. This means that the 12-membered ring, being too rigid and small, force the metal out of the plane formed by the donor atoms of the macrocycle, preferring to co-ordinate one water molecule rather than leading to the fold of the macrocycle, to achieve the most stable conformation. The arms of this molecule, with additional donor atoms, are not passive agents and also contribute to the final adopted configuration. Similar structures should be adopted by $[ZnL^1]$ and $[PbL^1]$ to explain our NMR spectra, in particular the two downfield resonances of the ^{13}C NMR spectra.

The cavity size of the 18-membered macrocycle, H_2L^3, is too large for the co-ordination of the studied metal ions, and, also, it prefers to accommodate the metal ion in one side of the molecule (the edta moiety) than to fold to co-ordinate both ether oxygen atoms. As shown by the NMR spectra, the protons and carbons of the ethylene groups of the ether moiety (d, e and f) remain unchanged upon co-ordination to zinc(II) and lead(II). The two signals at lower field of the ^{13}C spectra point also to one co-ordinated and the other uncoordinated ester oxygen atoms similar to what happens with the 12-membered complexes. These observations are indicative that the configurational energy necessary to fold the macrocycle is too much to compensate the gain with the ether oxygen interactions.

2.4.2. *UV–Vis and EPR spectra of the copper(II) complexes*

The copper(II) complexes of H_2L^1–H_2L^4 exhibit a broad band in the visible region with the maximum centred about 740 nm, but 667 nm for $[CuL^2]$, see Table 4. The X-band EPR spectra of the four complexes, in 1:1 rates and low concentrations ($\approx 4\times10^{-3}$ mol dm^{-3}) in water glasses at 165 K are shown in Fig. 2 and the simulated parameters [40] compiled in the Table 4, together with some of other complexes from the literature for comparison. All the studied complexes present the same g_i parameters and hyperfine coupling constants (A_i) and the presence of two species although in different proportions for each complex, as can be seen

Table 4
Spectroscopic X-band EPR data for the Cu^{2+} complexes of H_2L^1–H_2L^4, and other similar complexes

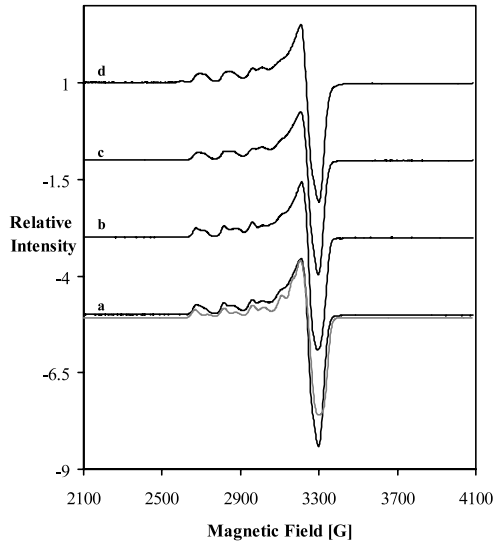

Fig. 2. EPR X-band spectra of the Cu^{2+} complexes of H_2L^1–H_2L^4 in 1:1 ratio at pH 3.0 in 1.0 M $NaClO_4$ (black lines) and the simulated spectrum of the first one (grey line): (a) [CuL^1], 3.93×10^{-3} mol dm^{-3}; (b) [CuL^2], 3.70×10^{-3} mol dm^{-3} (c) [CuL^3], 5.91×10^{-3} mol dm^{-3}, and (d) [CuL^4], 3.55×10^{-3} mol dm^{-3}, recorded at 165 K, microwave power of 2.4 mW, modulation amplitude of 1.0 mT. The frequency (ν) were of 9.405, 9.408, 9.404 and 9.409 GHz for a, b, c and d, respectively. All the spectra show the presence of two species in different proportions.

by the splitting of the bands at low field. As our potentiometric studies, in the same solvent, have not revealed the presence of protonated or other complexes, the two species formed in glass water are probably different isomers. Both species exhibit three well resolved lines of the four expected at low field, due to the interaction of the unpaired electron spin with the copper nucleus, and no superhyperfine splitting due to the coupling with the two nitrogen atoms of the macrocycle has been observed. The fourth copper line is completely overlapped by the much stronger and not resolved band of the high field part of the spectra. The simulation of the spectra indicated three different g values, showing that the Cu^{2+} ion is in a rhombically-distorted ligand field. Both species show $g_z > (g_x + g_y)/2$ and the lowest $g \geq 2.04$, which is characteristic of mononuclear copper(II) complexes having rhombic symmetry with elongation of the axial bonds and a $d_{x^2-y^2}$ ground state. Trigonal–bipyramidal or tetragonal geometries involving compression of axial bonds are not compatible with those data [41].

All the complexes reported in Table 4 have g_z and A_z parameters consistent with N_2O_2 donor atoms closelying the metal [42]. The differences between them can be visualised in the diagram g_z versus A_z of the Fig. 3, and rationalised in terms of different axial field of each complex. Indeed, the g_i and A_i values are related to the electronic transitions by the factors derived from the ligand field theory [47,48]: the g_i values increase and the A_i values decrease as the axial ligand field becomes stronger and this occurs with the simultaneous red-shift of the d–d absorption bands in the electronic spectra [48–50]. Thus, the position of each complex in the diagram of Fig. 3 can be analysed in this way. The complex of H_2edda([CuL^9]) fits to a square plane structure formed by two amine nitrogen and two carboxylate oxygen atoms [42]. According to the structures of [CuL^{10}] [51] and [$Cu(L^7)$]$^{2-}$ [52] both complexes are octahedral having the equatorial plane identical to that of the edda complex and the axial positions occupied by the two ether oxygen atoms of the macro-

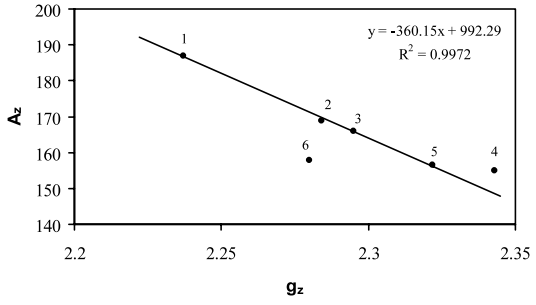

Fig. 3. Diagram of the EPR parameters A_z vs. g_z for a series of copper(II) complexes in 1:1 ratio, the ligands being, respectively: (1) H_2L^9 (edda); (2) H_2L^{10}; (3) H_4L^7 (edta); (4) H_4L^7 (edta), diprotonated complex; (5) H_2L^1–H_2L^4, first isomer; (6) H_2L^1–H_2L^4, second isomer.

cycle of H_2L^{10} and the other oxygen of the remaining two acetate groups of H_4edta, respectively. The parameters of the first isomer of the copper(II) complexes of H_2L^1–H_2L^4 fall in the straight-line g_z versus A_z (Fig. 3) pointing to stronger axial field, as indicated by larger g_z and smaller A_z values and a slight red shift. On the other hand, two complexes exhibit parameters which do not fit into the mentioned straight line: the protonated complex of edta, $[Cu(H_2L^7)\cdot(H_2O)]$, and the second isomer of the complexes studied in this work, H_2L^1–H_2L^4. The first one, has EPR parameters in agreement to the crystal structure [53], the stronger axial field derived from the co-ordination of one amine nitrogen and one carboxylate oxygen in axial positions. The equatorial plane is formed by the other nitrogen, two other carboxylate oxygens and one oxygen from a water molecule, and the last carboxylate group protonated and not co-ordinated to the copper. The second isomer of the complexes studied in this work, although having g_z higher than that of $[CuL^9]$, have lower A_z values when compared with those of edta, $[CuL^7]^{2-}$, and a noticeable anisotropy of the $g_\perp$ values, all these factors giving a clear indication of a geometrical distortion from the planar to tetrahedral geometry in the case of our complexes [54].

The increase of the concentrations of copper(II) complexes of H_2L^1–H_2L^4 to $\approx 3.5 \times 10^{-2}$ mol dm^{-3} in the 1:1 ratio or the amount of copper(II) to the ratio 1.8:1 lead to spectra with the typical features of a triplet-state dinuclear copper(II) species, see Fig. 4, a well-defined hyperfine structure consisting of seven peaks observed in the $\Delta M_s = 1$ transition and the signal in

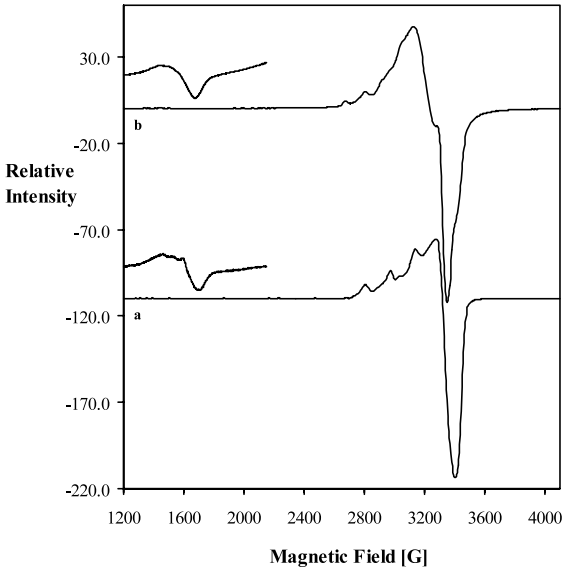

Fig. 4. EPR X-band spectra of the Cu^{2+} complexes of H_2L^4 in 1.0 M $NaClO_4$ recorded at 5 K: (a) at 1:1 ratio, concentration 3.41×10^{-2} mol dm^{-3} and at pH 3.95, and (b) at 1.8:1 ratio, concentration 2.00×10^{-2} mol dm^{-3} and at pH 3.50. Microwave power of 2.4 mW, modulation amplitude of 1.0 mT, and frequency (ν) 9.642 GHz.

$\Delta M_s = 2$ transition suggesting the proximity of two copper atoms. The spectra for all complexes are similar, but the solutions at 1.8:1 ratio show slightly different spectra. The $\Delta M_s = 2$ signal, which lies in the 1620 G range ($g = 4.3$) reveals a spin exchange interaction between the two copper atoms. However, the singlet-triplet transition could not be observed, presumably is obscured by the $\Delta M_s = 1$ absorption. If assumed that two unpaired electrons, each located on a Cu^{2+}, are exchanged with an energy larger than the hyperfine coupling energy, each unpaired electron ($S = 1/2$) couples with two copper nuclei ($I_{Cu} = 3/2$) in an equivalent manner, the hyperfine structure consists of seven lines. In our spectra the seven hyperfine lines can be observed in the $\Delta M_s = 1$ region with an average hyperfine spacing of 90.4 G and $g_\parallel = 2.26$ and $g_\perp = 2.07$. The hyperfine constant is approximately half the value found in mononuclear copper(II) complexes having the same donor atoms and geometry. In the $\Delta M_s = 2$ region the signal is very broad but even so some hyperfine lines can be observed, but it is impossible to confirm the hyperfine spacing. In practice, $\Delta M_s = 2$ transitions are expected mainly for dinuclear complexes with Cu–Cu distances between ~ 3 and 5 Å, because when the Cu–Cu distance is small the $\Delta M_s = 2$ signal is not observed due to the overlap zero-field split components of the $\Delta M_s = 1$ and $\Delta M_s = 2$ transitions. When the Cu–Cu distance is large the zero-field parameter D (dipolar term which depends on d^{-3}, d being the distance between the two copper atoms) and the intensity of the $\Delta M_s = 2$ signal is very low [55–57].

3. Conclusions

Compounds H_2L^1–H_2L^4 were prepared by one step synthetic way although with low yield. The critical point of them and their complexes is the hydrolysis of the ester bonds, which is metal-catalysed.

However, in spite of the low yield of the synthesis of these compounds and of the hydrolysis reaction that prevented a complete study of them, it was possible to achieve some interesting conclusions. (1) In the complexes formed with these ligands the metal atom is accommodated close to the edta-moiety of the ligand. This conclusion was supported by our potentiometric studies of alkaline-earth, Cu^{2+}, Zn^{2+}, Cd^{2+} and Pb^{2+} complexes of H_2L^1, H_2L^3 and H_2L^4, by the ^1H and ^{13}C NMR spectroscopic studies of the Zn^{2+} and Pb^{2+} complexes of H_2L^1 and H_2L^3 and the EPR spectroscopic studies of the copper(II) complexes of all ligands. (2) In most complexes the metal prefer to co-ordinate to one water molecule and only one ester oxygen then to both ester oxygen atoms of the molecule, as shown by the NMR studies. (3) The ether oxygen atoms seems to be involved directly on the co-ordination to the metal in

only one complex, among all studied by us, which was the case of the Pb^{2+} complex of the 15-membered macrocycle, H_2L^2. Unhappily, we had not enough compound for the determination of stability constants of metal complexes, as a peak of stability for the Pb^{2+} and Ba^{2+} complexes of this ligand and a normal trend for metals such as Cu^{2+} and Zn^{2+} will be expected. Indeed the EPR spectroscopy of the copper(II) complex of H_2L^2 did not show any particular difference from the others in agreement to the last prediction. (4) EPR studies of the copper(II) complexes revealed the presence of dinuclear species with the two copper atoms at short distance (between 3 and 5 Å). The fact that these species were not observed by the NMR experiments point to the formation of dinuclear complexes involving donors of the edta-moiety and only one amide oxygen atom, similarly to $[Ca_2(L^{11})_2(H_2O)_4]$, where the distance Ca–Ca is 4.019 Å [16]. This type of dinuclear structure, which can dissociate in solution to form two mononuclear molecules, are also in agreement with our potentiometric studies, as M_2L_2 complexes cannot be distinguished from the ML species in the solution studies.

4. Experimental

4.1. Materials

Dioxane was dried with sodium–benzophenone, distilled and stored under nitrogen. Ethyleneglycols were dried by storage over molecular sieves. All the other chemicals were of reagent grade and used as supplied.

4.2. Equipment for ligands and metal complexes characterisation

^1H and ^{13}C NMR spectra were recorded with a Bruker AMX-300 spectrometer at probe temperature in D_2O and d_6-DMSO, using 3-(trimethylsilyl)-propanoic acid-d_4-sodium salt as standard. Solutions of the ligands and respective complexes for the measurements (≈ 0.01 mol dm^{-3}) in D_2O were made up and the pD was adjusted by addition of DCl or CO_2-free KOD with an Orion 420A instrument fitted with a combined Ingold 405M3 microelectrode. The $-\log[D^+]$ was measured directly in the NMR tube, after the calibration of the microelectrode with buffered aqueous solutions. The final pD was calculated from $pD = pH^* + 0.40$ [58]. The value of pH* corresponds to the reading of the pH meter previously calibrated with two standard aqueous buffers at pH 4 and 7 [58]. Electronic spectra were measured with a UNICAM UV4 spectrophotometer using aqueous solutions of the complexes. EPR spectroscopic measurements of the Cu^{2+} complexes were recorded with a Bruker ESP 380 spectrometer equipped with continuous-flow cryostats for liquid helium or for liquid nitrogen, operating at X-band. The complexes were prepared at $(3.6–5.91) \times 10^{-3}$ mol dm^{-3} and $(2.0–3.8) \times 10^{-2}$ mol dm^{-3} in 1.0 mol dm^{-3} $NaClO_4$ at pH ≈ 3 and were recorded at 165 K (lower concentrations) and 5 K (higher concentrations). C, H, and N analysis were performed by the Analytical Laboratory at ITQB (Oeiras, Portugal).

4.3. Synthesis of ligands (H_2L^1–H_2L^4)

The ligands were prepared by the reaction between ethylenediamine tetracetic dianhydride and the corresponding mono- or polyethyleneglycol $[HO(CH_2CH_2O)_nH$, $n = 1$, 2, 3 and 4] as described before [27–30]. A typical procedure is as following: ethylenediamine tetracetic dianhydride (1.00 g, 3.90 mmol) was added to dioxane (300 cm^{-3}) under nitrogen and the temperature adjusted to 90–95 °C. When the entire solid had dissolved, a solution of the corresponding polyethyleneglycol (39.2 mmol for mono- and diethyleneglycol, 19.5 mmol for tri- and tetraethyleneglycol) in dioxane (150 cm^{-3} for the monoethyleneglycol and 100 cm^{-3} for the others) was added during 6 h at the same temperature. The mixture was heated to reflux for 24 h (for the monoethyleneglycol) and 40 h (for the others). After cooling to 0 °C, the product precipitated within a few minutes and was filtered off, washed with acetone (3×5 cm^{-3}) and dried under vacuum.

H_2L^1: yield. 9%, m.p. 182–4 °C. Found: C, 44.3; H, 5.9; N, 8.6. Calc. for $C_{12}H_{18}N_2O_8 \cdot 5H_2O$: C, 44.6; H, 6.1; N, 8.4%. For NMR data, see Table 1.

H_2L^2: 40 mg (3%), m.p. 161–2 °C. Found: C, 45.3; H, 6.2; N, 7.5. Calc. for $C_{14}H_{22}N_2O_9 \cdot 0.5H_2O$: C, 45.4; H, 6.5; N, 7.2%. For NMR data, see Table 1.

H_2L^3: 12%, m.p. 155–6 °C. Found: C, 45.3; H, 6.7; N, 6.6. Calc. for $C_{16}H_{26}N_2O_{10}.H_2O$: C, 45.6; H, 6.7; N, 6.3%. For NMR data see Table 1.

H_2L^4: 17%, m.p. 136–8 °C. Found: C, 47.9; H, 6.6; N, 6.0. Calc. for $C_{18}H_{30}N_2O_{11}$, 48.0; H, 6.7; N, 6.2%. NMR in D_2O δ (ppm), ^1H: 3.19 (s, 4H, NCH_2CH_2), 3.55 (s, 8H, OCH_2CH_2O), 3.66 (br, 4H, $COOCH_2CH_2O$), 3.70 (s, 4H, NCH_2COOH)), 3.91 (s, 4H, NCH_2COOCH_2), 4.27 (m, 4H, $COOCH_2CH_2$). ^{13}C: 53.8, 57.0, 58.5, 67.3, 70.7, 72.2, 172.3, 174.9.

4.4. Potentiometric measurements

4.4.1. Reagents and solutions

Metal ion solutions were prepared at about 0.025 mol dm^{-3} from the nitrate salts of the metals, of analytical grade with demineralised water obtained by a Millipore/Milli-Q system, and were standardised as described [57]. Carbonate-free solutions of the titrant, tetramethylammonium hydroxide, were prepared by reaction of a

tetramethylammonium iodide solution with Ag_2O, maintained and discarded as described [57].

4.4.2. Equipment

For the potentiometric measurements an Orion 720A instrument was used together with a 91-01 glass electrode, 90-05 Ag/AgCl reference electrode and a Wilhelm-type salt bridge containing a 0.10 mol dm^{-3} NMe_4NO_3 solution; a glass-jacketed titration cell (50 cm^3) completely sealed from the atmosphere was used and the temperature was controlled by a Grant W6 thermostat coupled with a cryostat by circulation of thermostatted water through the jacketed cell; and the standard base (or acid) was added through a capillary tip at the surface of the solution by a Metrohom Dosimat 665 burette.

4.4.3. Work conditions

The temperature was kept at 298.0 ± 0.1 K; atmospheric CO_2 was excluded from the cell during the titration by passing purified argon across the top of the experimental solution in the reaction cell. The ionic strength of the solutions was kept at 0.10 mol dm^{-3} with NMe_4NO_3.

4.4.4. Measurements

The $[H^+]$ of the solutions was determined by the measurement of the electromotive force of the cell, $E = E'^0 + Q \log[H^+] + E_j$. E'^0, Q, E_j and $K_w = ([H^+][OH])$ were obtained as described previously [57]. The term pH is defined as $-\log [H^+]$. The value of K_w was found equal to $10^{-13.80}$ mol^2 dm^{-6}.

The potentiometric equilibrium measurements were made on 20.00 cm^3 of $\cong 2.50 \times 10^{-3}$ mol dm^{-3} ligand solutions diluted to a final volume of 30.00 cm^3, in the absence of metal ions and in the presence of each metal ion for which the C_M:C_L ratios were 1:1 and 2:1. A minimum of two replicates was made.

4.4.5. Calculation of equilibrium constants

Protonation constants ($K_i^H = [H_iL]/([H_{i-1}L] \times [H^+])$) were calculated by fitting the potentiometric data obtained for the free ligand to the HYPERQUAD program and listed in Table 2 [37]. Stability constants of the various species formed in solution were obtained from the experimental data corresponding to the titration of solutions of different metal ions to ligand ratios, also using the HYPERQUAD program. The initial computations were obtained in the form of overall stability constants, $\beta_{M_mH_hL_l}$ values,

$$\beta_{M_mH_hL_l} = M_mH_hL_l/([M]^m \times [H]^h \times [L]^l)$$

Only mononuclear species, ML and MHL were found. Differences, in log units, between the values β_{MHL} and β_{ML} provide the stepwise protonation reaction constants, shown in Table 3. The errors quoted are the standard deviations of the overall stability constants given directly by the program for the input data, which include all the experimental points of all titration curves. The standard deviations of the stepwise constants were determined by the normal propagation rules.

5. Supplementary material

The data on the ^1H NMR spectrum of H_2L^2at pD 2.4 in D_2O at probe temperature and assignments of resonances (δ ppm vs. 3-(trimethylsilyl)-propanoic acid-d_4-sodium salt) is available on request from the authors.

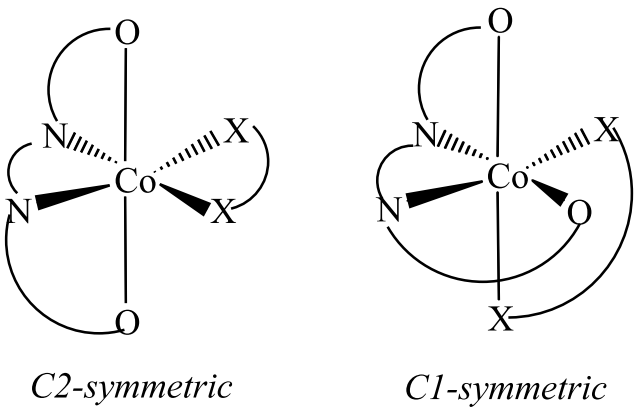

Fig. 1. Possible geometric isomers of the $[Co(eddp)XX]^+$ complexes, $XX = R_2eddp$.

2. Experimental

Reagents were obtained commercially and used without further purification.

Infrared spectra were recorded on a Perkin–Elmer FTIR 31725-X spectrophotometer using the KBr pellet technique. Electronic absorption spectra were recorded on a Varian GBC 911A spectrophotometer. Aqueous 1×10^{-3} molar solutions of the complexes were used for these measurements. ^1H and ^{13}C NMR spectra were recorded on a Varian Gemini-200 NMR spectrometer using DSS [sodium salt of 3-(trimethylsilyl)propanesulfonic acid] as internal reference in D_2O. Elemental analyses for C, H and N were performed by standard methods.

2.1. Preparation of ethylenediamine-N,N′-di-3-propanoic acid dihydrochloride ($H_2eddp \cdot 2HCl$)

This substance was prepared by the reported method [10].

2.2. Preparation of ethylenediamine-N,N′-di-3-propanoate dimethyl ester dihydrochloride (dmeddp·2HCl)

This substance was prepared by the modificated method reported from Haydock and Mulholland [11]. Thionyl chloride (1.95 cm^3; 26.9 mmol) was added dropwise to ice-cold absolute MeOH (30.00 cm^3). The acid (2.500 g; 9.0 mmol) was then added and the suspension was refluxed for 16 h. The resulting suspension was filtered off from the $H_2eddp \cdot 2HCl$, and left to crystallize. The product was recrystallized from boiling MeOH. M.p. 208 °C.

2.3. Preparation of ethylenediamine-N,N′-di-3-propanoate diethyl ester dihydrochloride (deeddp·2HCl)

This was prepared by the same method as that used to prepare the dmeddp·2HCl using an equal volume of absolute EtOH in place of absolute MeOH. The crude products were recrystallized from boiling EtOH. M.p. 209 °C. Yield: 2.52 g (75.5%). *Anal.* Found: C, 42.95; H, 7.97; N, 8.39. Calc. for $C_{12}H_{26}Cl_2N_2O_4$: C, 43.25; H, 7.86; N, 8.40%.

2.4. Preparation of ethylenediamine-N,N′-di-3-propanoate dipropyl ester dihydrochloride (dpeddp·2HCl)

This was prepared by the same method as that used to prepare the dmeddp·2HCl using an equal volume of absolute C_3H_7OH in place of absolute MeOH. M.p. 200 °C. Yield: 2.30 g (63.7%). *Anal.* Found: C, 46.39; H, 8.82; N, 7.88. Calc. for $C_{14}H_{30}Cl_2N_2O_4$: C, 46.54; H, 8.37; N, 7.75%.

2.5. Preparation of ethylenediamine-N,N′-di-3-propanoate dibutyl ester dihydrochloride (dbeddp·2HCl)

This was prepared by the same method as that used to prepare the dmeddp·2HCl using an equal volume of absolute C_4H_9OH in place of absolute MeOH. M.p. 185 °C. Yield: 2.34 g (60.1%). *Anal.* Found: C, 49.07; H, 8.58; N, 7.49. Calc. for $C_{16}H_{34}Cl_2N_2O_4$: C, 49.35; H, 8.80; N, 7.19%.

2.6. Preparation of ethylenediamine-N,N′-di-3-propanoate dipentyl ester dihydrochloride (dveddp·2HCl)

This was prepared by the same method as that used to prepare the dmeddp·2HCl using an equal volume of absolute pentanol in place of absolute MeOH. M.p. 176 °C. Yield: 1.80 g (43.1%). *Anal.* Found: C, 51.64; H, 8.82; N, 6.85. Calc. for $C_{18}H_{38}Cl_2N_2O_4$: C, 51.79; H, 9.17; N, 6.71%.

2.7. Preparation of C_1-symmetric-(ethylenediamine-N,N′-di-3-propanoato)(O,O-dimethyl-ethylenediamine-N,N′-di-3-propanoate)cobalt(III)chloride, C_1-symmetric-[Co(eddp)dmeddp]Cl

To a solution of $CoCl_2 \cdot 6H_2O$ (0.048 g; 0.2 mmol) in 10.0 cm^3 of water, dmeddp·2HCl (0.152 g; 0.5 mmol) and charcoal (0.01 g) were added. The pH of the solution was adjusted to 8.5 with KOH (0.1 mol dm^{-3}) and was accompanied by oxidation of Co(II) to Co(III) with atmospheric oxygen during 4 h. The solution was filtered, then concentrated to 5.0 cm^3 and placed onto a 2.5×30 cm column containing Sephadex G-10. The violet eluate was then poured onto a 2.5×32

cm column containing SP-Sephadex C-25. The column was washed with water to remove the non-adsorbed by-product and then eluted with 0.2 molar KCl. The adsorbed complex was violet. The violet eluate was concentrated under reduced pressure, then MeOH was added in order to remove KCl. From the desalted solution the C_1-symmetric-[Co(eddp)dmeddp]Cl complex was obtained. Yield: 0.046 g (42.59%). *Anal.* Found: C, 40.28; H, 6.05; N, 10.16. Calc. for $CoC_{18}H_{34}ClN_4O_8 \cdot 0.5H_2O$: C, 40.19; H, 6.55; N, 10.41%.

2.8. Preparation of C_1-symmetric-(ethylenediamine-*N,N′*-di-3-propanoato)(*O,O*-diethyl-ethylenediamine-*N,N′*-di-3-propanoate)cobalt(III)chloride, C_1-symmetric-[Co(eddp)deeddp]Cl

This was prepared by the same method as that used to prepare C_1-symmetric-[Co(eddp)dmeddp]Cl, using deeddp·2HCl (0.167 g; 0.5 mmol) in place of dmeddp·2HCl. Yield: 0.050 g (40.65%). *Anal.* Found: C, 39.36; H, 6.72; N, 9.23. Calc. for $CoC_{20}H_{38}ClN_4O_8 \cdot 3H_2O$: C, 39.31; H, 7.26; N, 9.17%.

2.9. Preparation of C_1-symmetric-(ethylenediamine-*N,N′*-di-3-propanoato)(*O,O*-dipropyl-ethylenediamine-*N,N′*-di-3-propanoate)cobalt(III)chloride, C_1-symmetric-[Co(eddp)dpeddp]Cl

This was prepared by the same method as that used to prepare C_1-symmetric-[Co(eddp)dmeddp]Cl, using dpeddp·2HCl (0.181 g; 0.5 mmol) in place of dmeddp·2HCl. Yield: 0.048 g (38.88%). *Anal.* Found: C, 43.26; H, 7.84; N, 9.82. Calc. for $CoC_{22}H_{42}ClN_4O_8 \cdot 1.5H_2O$: C, 43.17; H, 7.41; N, 9.16%.

2.10. Preparation of C_1-symmetric-(ethylenediamine-*N,N′*-di-3-propanoato)(*O,O*-dibutyl-ethylenediamine-*N,N′*-di-3-propanoate)cobalt(III)chloride, C_1-symmetric-[Co(eddp)dbeddp]Cl

This was prepared by the same method as that used to prepare C_1-symmetric-[Co(eddp)dmeddp]Cl, using dbeddp·2HCl (0.195 g; 0.5 mmol) in place of dmeddp·2HCl. Yield: 0.055 g (38.73%). *Anal*. Found: C, 40.62; H, 8.02; N, 8.37. Calc. for $CoC_{24}H_{46}ClN_4O_8 \cdot 5H_2O$: C, 40.99; H, 8.03; N, 8.07%.

2.11. Preparation of C_1-symmetric-(ethylenediamine-*N,N′*-di-3-propanoato)(*O,O*-dipentyl-ethylenediamine-*N,N′*-di-3-propanoate)cobalt(III)chloride, C_1-symmetric-[Co(eddp)dveddp]Cl

This was prepared by the same method as that used to prepare C_1-symmetric-[Co(eddp)dmeddp]Cl, using dveddp·2HCl (0.209 g; 0.5 mmol) in place of dmeddp·2HCl. Yield: 0.051 g (36.37%). *Anal.* Found: C, 44.80; H, 8.10; N, 7.72. Calc. for $CoC_{26}H_{50}ClN_4O_8 \cdot 3H_2O$: C, 44.91; H, 8.11; N, 8.06%.

3. Results and discussion

The *O,O*-dialkyl-ethylenediamine-*N,N′*-di-3-propanoate, R_2eddp·2HCl, ligands have been obtained from the reaction between H_2eddp·2HCl, the corresponding absolute alcohol and thionyl chloride. All the ligands show a strong band for the ester group around 1730 cm^{-1} in their IR spectra. The ^{1}H NMR spectra of the ligands show the methylene protons between two nitrogen donor atoms, and between the carbonyl group and nitrogen donor atom, at around 2.9 ppm, as a triplet, and 3.4 ppm, as a triplet, respectively. All ligands show in the ^{13}C NMR spectra resonances at around 33 ppm for the carbons from ethylenediamine, 46 ppm for the carbons between the ester group and nitrogen donor atom, and 174 ppm for the ester carbon. The isolated esters crystallized as thin and flimsy crystals, and because of that we were unable to obtain a single crystal.

The reaction of $CoCl_2$ with ester in aqueous solutions using an air oxidation method has yielded only one isomer. During the preparation of these complexes, one part of the ester coordinated as a bidentate ligand and the other part hydrolyzed and coordinated as a tetradentate ONNO ligand. The isolated complexes are very hygroscopic and because of that we were unable to obtain single crystals. Each of the IR spectra of these complexes shows an antisymmetric CO_2 vibration at around 1600 cm^{-1}, which is of lower energy than that of H_2eddp·2HCl, indicating bond formation between the metal and the ligand carboxylate oxygen donor atoms [12]. C_1- and C_2-symmetric isomers can differ in the shape of the carboxylate region. The presence of one broad shape or two shapes is characteristic for C_1-symmetric and a strait shape for the C_2-symmetric isomers [8,9]. IR spectra of isolated complexes showed a broad shape in this region, from which we assigned the configuration as C_1-symmetric. All of the complexes show an antisymmetric CO_2 absorption at around 1730 cm^{-1}, like the free ligand ester, which indicate that ester groups are present in the complexes. The symmetric stretching bands of the coordinated carboxylate groups lie in the expected region (about 1400 cm^{-1}). The stretching bands of the amino groups are also summarized in Table 1.

The electronic absorption spectra of [Co(eddp)-R_2eddp]$^+$ (Fig. 2) are related to those of [Co(edda)X_2] species [13–15], a *symmetric*-CoN_4O_2 system [1,8], and suggest that these complexes prepared in this work have the *symmetric* configuration. Since the C_1-symmetric isomer has a bigger $^1T_{tg}$ splitting than the C_2-symmetric isomer, the electronic absorption spectra of the C_1-

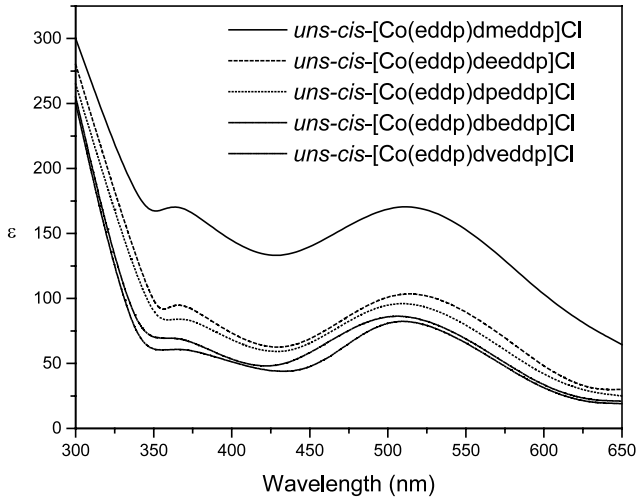

Fig. 2. Electronic absorption spectra of C_1-symmetric-[Co(eddp)R_2eddp]Cl.

symmetric isomer may have a very broad and non-symmetrical absorption band, while the C_2-symmetric isomer have a more Gaussian shape [1,13,16,17]. The C_1-symmetric geometry of [Co(eddp)en]Cl assigned by crystal structure [7] was investigated with an electronic absorption spectrum [8]. From the absorption spectrum (Fig. 2, Table 2) of [Co(eddp)R_2eddp]$^+$ very broad bands are found at $\lambda_{max} \approx 505$ nm, like C_1-symmetric-[Co(eddp)en]Cl, which suggests the compounds are the C_1-symmetric isomers. The second bands at $\lambda_{max} \approx 360$ nm, are assigned to the transition $^1A_{1g}$ to $^1B_{2g}+{}^1E_g$ [1,16].

^{1}H NMR has been used extensively in the characterization of metal chelates containing aminocarboxylate ligands [8,15,18,19]. The $C1$- and C_2-symmetric geometry of [Co(eddp)en]Cl assigned by crystal structures [7] was investigated with ^{1}H NMR spectra [8]. Consistent

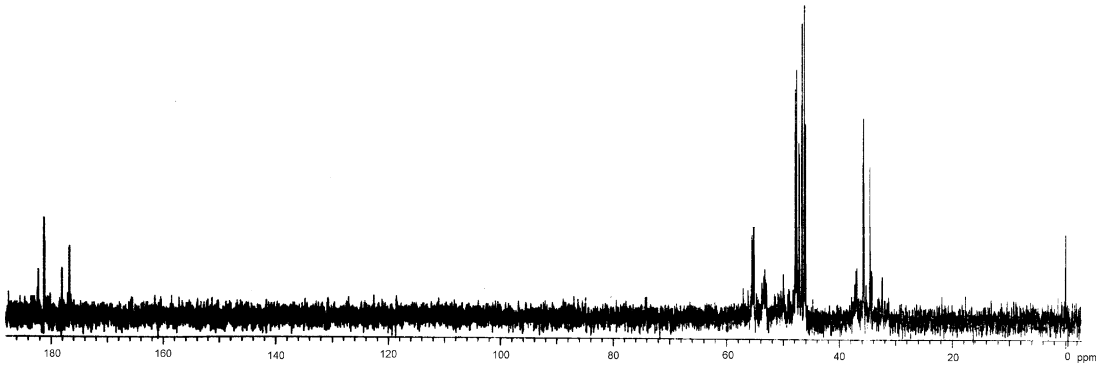

Fig. 4. ^{13}C NMR spectrum of the C_1-symmetric-[Co(eddp)dmeddp]Cl complex.

with above papers, our complex (Fig. 3) showed an AA′BB′ pattern at δ 3.0–3.4 due to the protons of the β-alaninato ring of eddp ligand. Protons associated with the N–CH_2–CH_2–N ring of both eddp and esters are found between δ 2.5 and 3.0. These protons exhibit an AA′BB′ pattern owing to the different chemical shifts of axial and equatorial protons. Because of the highly collapsed nature and overlap of the patterns, a complete analysis is very difficult. The C_1-symmetric isomers exhibit complex spectra in asymmetry introduced by changing one of the R β-alaninato rings [20] (oxygen above the plane containing Co and eddp nitrogens) to a G ring (oxygen in Co-eddp nitrogen plane) which should result in two different patterns observed at δ 2.75 and 3.22. Similarities of ^1H NMR spectra of the isolated complexes with the C_1-symmetric-[Co(eddp)en]Cl complex suggest C_1-symmetric geometry of our compounds. While the proton spectra of these complexes have had definite usefulness in the study of molecular geometry of these complexes, collapsed nature and overlapping of peaks have placed limits upon their utility.

The ^{13}C NMR spectra of the [Co(eddp)dmeddp]$^+$ complex (Fig. 4) exhibits shifts at 183 and 181 ppm, which correspond with shifts from the carbon atoms of coordinated carboxyl groups. Shifts found at 178 and 177 ppm are assigned to the ester carbons [21]. All methylene resonances occur within the range 50–32 ppm, and the methyl carbons resonate at 55.5 and 55.3 ppm. For the other complexes methyl carbons resonate from 16.0 to 12.2 ppm, α-methylene (ester) carbons resonate from 70.7 to 65.0 ppm, carboxyl carbons resonate from 183 to 181 ppm and ester carbons resonate from 178 to 177 ppm. As expected these spectra exhibit twice as many peaks in the methylene and carboxyl regions as are observed for the free ligand. Finally, as expected from electronic absorption, infra red and ^1H NMR spectra, differences in shifts indicate that these are C_1-symmetric isomers. Selected ^1H and ^{13}C NMR shifts for esters and the corresponding complexes are given in Table 3.

Table 3
Characteristic ^1H and ^{13}C NMR shifts of R_2eddp·2HCl and the C_1-symmetric-[Co(eddp)R_2eddp]Cl complexes

Compound	^1H		^{13}C	
	CH_3	COO^-	COO–R	CH_3
dmeddp·2HCl	3.75s[a]	–	175.3	55.5

amine to give the conjugate amido species [Pt(bpmaH$_{-1}$)Cl]. Following on these observations and considering the paucity of kinetic data on amine deprotonation of Pt(II) systems and the effect of amine deprotonation on associatively activated substitution reactions, we thought of interest to carry out a kinetic study on the base hydrolysis of $[Pt(bpma)Cl]^+$. An investigation on the acid–base behaviour of the aqua species $[Pt(bpma)(OH_2)]^{2+}$ has also been performed in order to elucidate the nature and the distribution of the species formed in solution.

The crystal structures of $[Pt(bpma)Cl]Cl\cdot H_2O$ and $[Pt(bpma)(OH_2)](ClO_4)_2\cdot 2H_2O$ are also included.

2. Experimental

2.1. Materials

Pure reagent grade NaBr, $LiClO_4$, $NaCH_3SO_3$, $AgClO_4$ and $AgCF_3SO_3$ (Fluka and Aldrich) were dried over P_2O_5 in a vacuum desiccator and used without further purification. Deuterated solvents were furnished by Euriso-top. Bis(2-pyridylmethyl)amine was prepared according to a published method [8] and its identity confirmed by ^{1}H NMR.

2.2. Instruments

Infrared spectra (4000–250 cm^{-1}, KBr discs and Nujol mulls; 400–150 cm^{-1}, polyethylene pellets) were recorded on a Nicolet Magna FT IR 750 spectrometer. Electronic spectra and kinetics measurements were obtained on a Perkin–Elmer Lambda 15 spectrophotometer. Proton NMR spectra were taken on a Bruker AC 200 F spectrometer. pH measurements were obtained using an Amel combined glass electrode on an Amel 334-B instrument. Conductivity measurements were carried out with a CDM 83 Radiometer Copenhagen conductivity meter and a CDC 334 immersion cell. Elemental analyses were performed by the Microanalytical Laboratory of the University of Padua.

2.3. Preparation of complexes

2.3.1. Chloro[bis(2-pyridylmethyl)amine]platinum(II)-chloride monohydrate, [Pt(bpma)Cl]Cl·H$_2$O (1)

It was prepared as previously reported [7]. Crystals suitable for X-ray structure determination was grown from a hot concentrated aqueous solution of the compound by slow cooling.

2.3.2. Aqua[bis(2-pyridylmethyl)amine]platinum(II)-trifluoromethanesulfonate, [Pt(bpma)(OH$_2$)](CF$_3$SO$_3$)$_2$ (2)

Silver trifluoromethanesulfonate (0.257 g, 1 mmol) was added to a warm solution (70 °C) of $[Pt(bpma)Cl]Cl\cdot H_2O$ (0.241 g, 0.5 mmol) in water (20 cm^3) and the mixture stirred in the dark for 15 min. The AgCl formed was filtered off and the solution evaporated to dryness. The title compound was obtained as a white powder in almost quantitative yield. (*Anal*. Found: C, 23.6; H, 1.96; N, 5.95. $C_{14}H_{15}F_6N_3O_7PtS_2$ requires: C, 23.7; H, 2.13; N, 5.91%). Λ_M (dmf = dimethylformamide) = 139 Ω^{-1} cm^2 mol^{-1}; λ_{max}/nm (water) 267, 274 (sh) (ε/dm^3 mol^{-1} cm^{-1} = 14 100); δ_H (200 MHz; solvent D_2O; protonated signals of the solvent downfield from $SiMe_4$ as reference) 8.20 [2H, d, J = 5.3 Hz, J(Pt–H) = 28 Hz, H_6], 7.99 (2H, t, J = 7.8 Hz, H_4), 7.45 (2H, d, J = 7.7 Hz, H_3), 7.38 (2H, t, J = 7.5, 5.3 Hz, H_5), 4.45 (4H, m, 2CH_2, partially masked by solvent peak).

2.3.3. Aqua[bis(2-pyridylmethyl)amine]platinum(II)-perchlorate dihydrate, [Pt(bpma)(OH$_2$)](ClO$_4$)$_2$·2H$_2$O

The complex was obtained by dissolving **2** (50 mg) in hot water (80 °C, 10 cm^3) containing an excess of $LiClO_4$ (100 mg). Slow cooling of the solution at room temperature resulted in the formation of colourless crystals, which were filtered off, washed with cold water (2–3 cm^3) and dried in vacuo. Yield: > 80%.

2.4. Kinetics

The reactions were followed spectrophotometrically by measuring the changing absorbance at a suitable wavelength (296 nm) as a function of time. They were initiated by adding 2–20 μl of a 0.015 mol dm^{-3} water solution of the substrate, $[Pt(bpma)Cl]Cl\cdot H_2O$, to 3 cm^3 of the required NaOH or NaBr solution previously brought to the reaction temperature (25 °C) in a thermostated cell in the spectrophotometer. The ionic strength was kept constant at 0.2 mol dm^{-3} with $NaCH_3SO_3$. Pseudo first-order rate constants (k_{obs}/s^{-1}) were obtained either from the gradients of plots of $\log(D_t - D_\infty)$ versus time or from a non-linear least-squares fit of experimental data to the equation $D_t = D_\infty + (D_o - D_\infty)\exp(-k_{obs}t)$, where D_o, D_∞ and k_{obs} are the parameters to be optimized (D_o, absorbance after mixing of reactants; D_∞, absorbance at completion of reaction).

2.5. Determination of the pK$_a$'s values of the complex [Pt(bpma)(OH$_2$)](CF$_3$SO$_3$)$_2$

Aliquots of a 0.01 mol dm^{-3} aq. solution of $[Pt(bpma)(OH_2)](CF_3SO_3)_2$ (I = 0.2 mol dm^{-3},

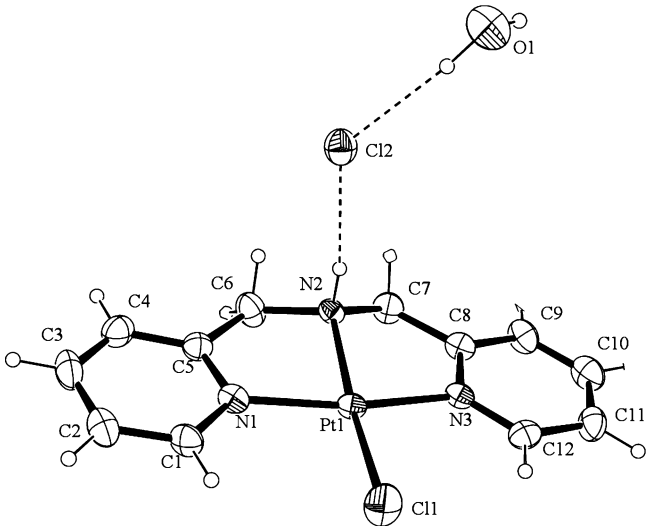

Fig. 1. ORTEP view and atom numbering of the asymmetric unit of **1** showing the thermal ellipsoids at 30% probability level.

$NaCH_3SO_3$) thermostated at 25 °C were titrated with standard CO_2-free 0.1 mol dm^{-3} NaOH solution (I = 0.2 mol dm^{-3}, $NaCH_3SO_3$). The electrode was calibrated with buffer solutions of the same ionic strength prepared according to Ref. [9]. The ionization constants pK_1 and pK_2 have been computed by a non-linear regression of the titration data by means of the Marquardt algorithm.

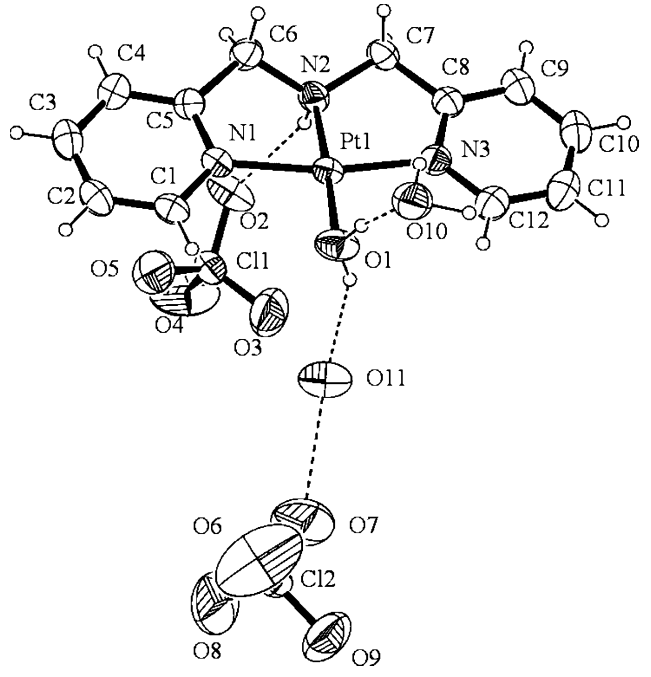

Fig. 2. ORTEP view and atom numbering of the asymmetric unit of **2** showing the thermal ellipsoids at 30% probability level.

2.6. X-ray crystallography

The data for both structures **1** and **2** were collected on a Nonius Kappa CCD area detector diffractometer using graphite monochromated Mo Kα radiation (λ = 0.7107 Å). The reflections were corrected for Lp and absorption [10] effects. The crystal parameters and other experimental details of the data collections are summarized in Table 3. The structures were solved by direct and Fourier methods. Full-matrix least-squares refinement was performed with all non-hydrogen atoms anisotropic and hydrogens in calculated positions. For structure **1**, the positions of both hydrogens belonging to the water molecule were found in the difference-Fourier map and kept fixed during the refinement. The N2 atom of the secondary amine group was found to be disordered over two positions with occupancy factors of 0.62(4) and 0.38(4), respectively. For structure **2**, the hydrogens belonging to the water molecules O1 and O10 were found in the difference-Fourier map and refined isotropically, while the positions of those linked to the water oxygen O11 were not determined. Programs used and sources of scattering factor data are given in Ref. [11].

3. Results and discussion

3.1. Structures of $[Pt(bpma)Cl]Cl\cdot H_2O$ and $[Pt(bpma)(OH_2)](ClO_4)_2\cdot 2H_2O$

ORTEP [12] views of the asymmetric units of **1** and **2** are shown in Figs. 1 and 2, respectively. Selected bond distances and angles are reported in Table 4.

The asymmetric unit of compound **1** consists of a square-planar $[Pt(bpma)Cl]^+$ cation, a Cl^- anion and a water molecule. The bpma molecule binds the central metal with its three N atoms; the coordination around Pt is completed by a Cl atom in *trans* position with respect to N2 atom, which is found to be disordered over two positions, N2 and N2′, below and above the mean coordination plane with deviations of −0.45(2) and +0.34(5) Å, respectively. Pt–N and Pt–Cl distances (Table 4) compare well with the mean values of 2.01 [4] and 2.29 [1] Å, respectively, obtained from a systematic analysis of several $PtCl_2L_2$ complexes (L = N-donor ligand) [13]. Due to the strain induced by the small bite of the chelate ligand both the N–Pt–N(*cis*) angles have a value of 83.3°, rather smaller than 90°.

The Cl^- counterion acts as a bridge between the cation and the water molecule being involved in two hydrogen bonds with O1 and N2 atoms (Table 5). The square-planar cations are assembled in dimeric units, through a crystallographic centre of symmetry, by means of Pt···Pt interactions of 3.7467(4) Å and N2–H···Cl1 hydrogen bonds. This arrangement is shown in Fig. 3 and the intra- and intermolecular H-bonds are listed in Table 5. Intermolecular short contacts between Pt atoms are not infrequent in crystals. Taken as reference-value the van der Waals radius given by Bondi [14] for Pt atom of 1.80 Å, a search has been made on the Cambridge Crystallographic Database [15] of all structures of Pt(II) complexes containing at least a pyridine ligand, where the Pt metal is involved in Pt···Pt contacts less than 4.0 Å. Thirty-eight structures have been retrieved, giving a mean Pt–Pt distance of 3.5 Å [2]. A list of CSD refcodes and Pt···Pt distances is available in Section 4. The mutual orientation of the complexes joined by means of Pt···Pt contacts has been evaluated by calculating the angle ϕ formed by the least-squares coordination plane and the line connecting the two central metal. The shortest Pt···Pt distances of 3.235, 3.237 and 3.244 Å [16] are associated with angles of 85.2°, 80.6° and 85.7°, very close to 90°, while longer distances, similar to that found in the present compound, of 3.755, 3.787 and 3.852 Å [17] are associated with smaller angles of 64.0°, 67.0° and 61.7°, respectively. In the present compound the ϕ angle is 73.0(1)°. It can be concluded that the Pt···Pt interaction is as stronger as the ϕ angle is closer to 90°, in agreement with the presence of an interaction between two filled d_z^2 and two empty p_z orbitals of the two adjacent Pt atoms [18].

The asymmetric unit of compound **2** is built up by a square-planar $[Pt(bpma)H_2O]^{2+}$ cation, two ClO_4^- anions and two water molecules. Pt1, the three N coordinated atoms and O1 lie almost perfectly on a plane; the deviations from the best plane are as follows: Pt1, 0.024(1); N1, −0.001(6); N2, −0.011(6); N3, −0.002(6); O1, −0.011(6) Å. Pt1–N (pyridine) distances of 2.010(5) and 2.014(6) are in agreement with those observed in compound **1**, in $[Pt(bpma)pyridine]^{2+}$ [7] and in other Pt(II) square-planar complexes [13,19]. Pt–N2(sp^3) distance of 1.952(7) Å, however, is remarkably shorter than those found both in [Pt(II)bpma] complexes [2.009(12) in **1**, 2.008(5) [7], 2.11(2) [19] Å] and in square-planar Pt(II) complexes where an N(sp^3) atom is in *trans* position to a water molecule [Pt–N in the range 2.01–2.02 Å] [20]. From a search on CSD files [15], a number of structures containing a water molecule directly co-ordinated to Pt(II) has been retrieved. From these structural data it is possible to determine the *trans* influence exerted by different atoms on the water oxygens. For instance, in structures where the water molecule is in *trans* position with respect to a nitrogen atoms [Pt–OH_2 distances from 2.05 to 2.10 Å [20], in

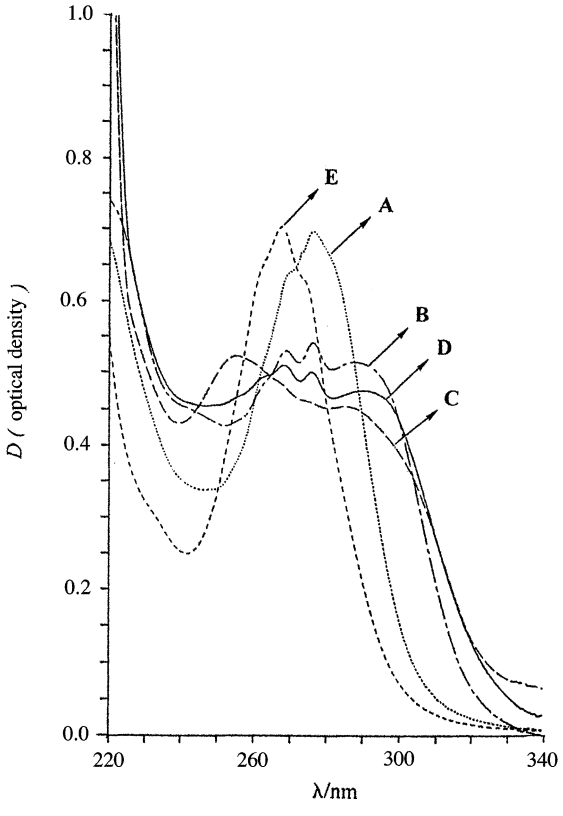

Fig. 4. Absorption spectra of 5×10^{-5} mol dm^{-3} $[Pt(bpma)Cl]^+$ (25 °C, $I = 0.2$ mol dm^{-3}): in water solution (A); aged with $[OH^-] = 5\times10^{-4}$ mol dm^{-3} (B); immediately after dissolution in the presence of $[OH^-] = 10^{-1}$ mol dm^{-3} (C); aged in the presence of $[OH^-] = 10^{-1}$ mol dm^{-3} (D). Absorption spectrum of 5×10^{-5} mol dm^{-3} $[Pt(bpma)(OH_2)](CF_3SO3)_2$ (25 °C, $I = 0.2$ mol dm^{-3}) at pH 4 ($HClO_4$) (E).

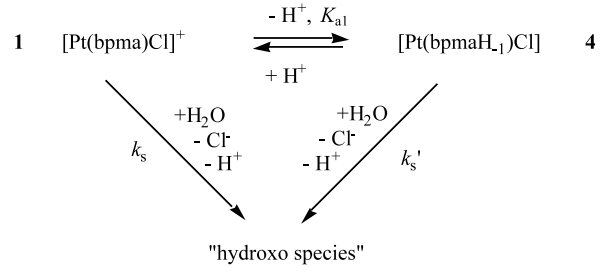

agreement with the value of 2.048(7) Å reported for the present structure], the *trans* influence exerted by the nitrogen can be evaluated by comparing these distances with those of 2.015 Å observed in a *trans*-diaqua Pt(II) complex [21] where the *trans* influences on Pt–O bonds are mutually balanced. The maximum lengthening is observed in Pt(II) complexes where the water molecule is in *trans* position to a carbon atom [22] [Pt–O distances from 2.17 to 2.27 Å] while similar effects to that observed for nitrogen are found for P–Pt(II)–OH_2 [23] and Cl–Pt(II)–OH_2 [24] systems where Pt–O lengths are in the range 2.08–2.12 Å.

The analysis of the crystal packing of complex **2** shows that all the water molecules, the perchlorate anions and the N2–H amine group are involved in the formation of a complex network of hydrogen bonds listed in Table 3, and that no Pt···Pt contacts less than 7.5 Å are present in the crystal.

3.2. Solution chemistry

The UV–Vis spectrum of an aqueous solution of [Pt(bpma)Cl]Cl (curve A in Fig. 4) does not change appreciably even after a long period of time. Addition of NaOH to this solution leads to an immediate change in the spectrum. The new spectrum depends to some extent on $[OH^-]$, but for $[OH^-] \geq 0.16$ mol dm^{-3} it becomes pH independent (curve C). Immediate reacidification of the basic solutions leads to a spectrum which is identical with that of the starting chloro species. Without reacidification, subsequent slow spectral changes are observed which is pH dependent. The final spectra for $[OH^-] = 5 \times 10^{-4}$ and 0.1 mol dm^{-3} are shown as curves B and D, respectively. Addition of NaCl up to 0.1 mol dm^{-3} has no effect on these spectra.

The above observations can be accounted for by the reactions shown in Scheme 1. The amino species **1** undergoes reversible deprotonation of the secondary amino group to give the conjugate amido species **4**. This rapid process (spectral changes from A to C) is followed by slow solvolysis of **1** and **4** to give the corresponding aqua complexes which, under our experimental conditions, are fully converted to hydroxo species which are known to be inert toward nucleophilic substitution [25].

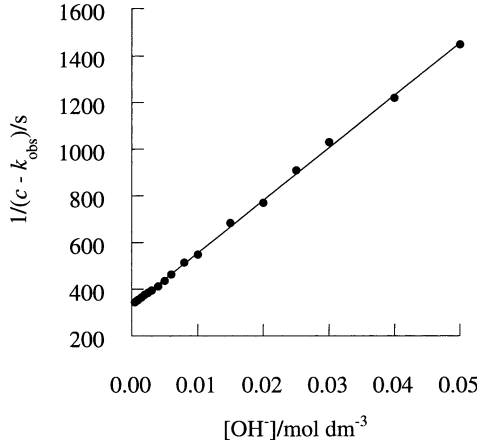

Fig. 5. Plot of $1/(c - k_{obs})$ against $[OH^-]$ for the base hydrolysis of $[Pt(bpma)Cl]^+$.

3.3. Kinetics of the base hydrolysis

The kinetics of the base hydrolysis were carried out in presence of at least 10-fold excess of sodium hydroxide ($5 \times 10^{-4} \leq [OH^-] \leq 0.2$ mol dm^{-3}) with respect to the concentration of the substrate. The individual runs gave

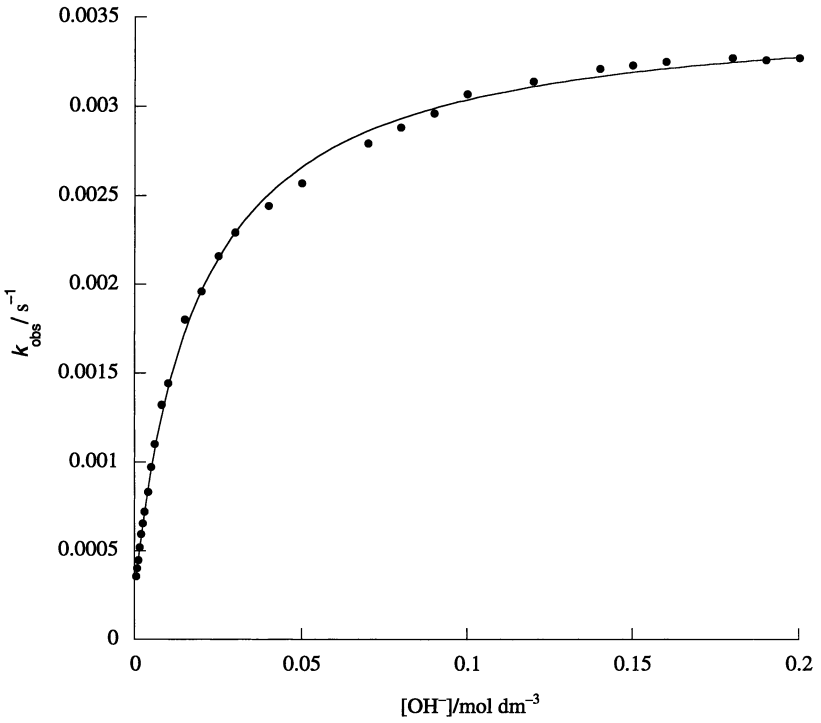

Fig. 6. Plot of pseudo first-order rate constants k_{obs} against $[OH^-]$ for the base hydrolysis of $[Pt(bpma)Cl]^+$.

first-order plots. The pseudo first-order rate constants, k_{obs}, has been reported in Table 1.

k_{obs} increases with increasing $[OH^-]$, but for $[OH^-] \geq 0.16$ mol dm^{-3} it is independent of $[OH^-]$, the mean value of four determinations being $c = (3.26 \pm 0.01) \times 10^{-3}$ s^{-1}. A plot of $1/(c - k_{obs})$ against $[OH^-]$ is linear up to $[OH^-] = 0.05$ mol dm^{-3} (Fig. 5), with finite intercept $a = (330 \pm 3)$ s and slope $b = (2.26 \pm 0.02) \times 10^4$ s mol^{-1} dm^3 according to Eq. (1)

$$1/(c - k_{obs}) = a + b[OH^-] \quad (1)$$

Eq. (1) can be rearranged to Eq. (2) to give the explicit dependance of k_{obs} from $[OH^-]$

$$k_{obs} = (c - 1/a + [OH^-]bc/a)/(1 + [OH^-]b/a) \quad (2)$$

From reaction Scheme 1, assuming the preequilibrium condition between **1** and **4**, and for $[OH^-] \gg$ [substrate], the following expression for k_{obs} is derived

$$k_{obs} = (k_s + [OH^-]k_s'K_{a1}/K_w)/(1 + [OH^-]K_{a1}/K_w) \quad (3)$$

where k_s and k_s' are the rate constants for the solvolysis of **1** and **4**, respectively, K_{a1} the protolysis constant of **1**, and $K_w = [H^+][OH^-]$. Eq. (3) is in complete agreement with the observed kinetics, the equilibrium and kinetic constants being related to those extracted from the empirical rate law (2) through the expressions $c = k_s'$, $a = 1/(k_s' - k_s)$, and $b/a = K_{a1}/K_w$. From a non-linear best fit of all the experimental data to Eq. (3) with k_s, k_s' and K_{a1} the parameters to be optimized ($K_w = 10^{-14}$ mol^2 dm^{-6}) the values $k_s = (2.8 \pm 0.2) \times 10^{-4}$ s^{-1}, $k_s' = (3.28 \pm 0.02) \times 10^{-3}$ s^{-1}, $pK_{a1} = 12.3$ have been computed (Fig. 6). An independent determination of the solvolytic rate constant k_s has been achieved by carrying out the kinetics of the reaction $[Pt(bpma)Cl]^+ + Br^- \rightarrow [Pt(bpma)Br]^+ + Cl^-$ in water solution at 25 °C and $I = 0.2$ mol dm^{-3} under pseudo first-order conditions. The two terms rate law $k_{obs} = k_s + k_{Br}[Br^-]$, usually found in nucleophilic substitution in square-planar complexes [25], is obeyed (Fig. 7) with $k_{Br} = (4.1 \pm 0.1) \times 10^{-2}$ s^{-1} mol^{-1} dm^3 and $k_s = (2.6 \pm 0.3) \times 10^{-4}$ s^{-1}, in close agreement with the value obtained from the kinetics of the base hydrolysis. The pseudo first-order rate constants, k_{obs}, has been reported in Table 2.

The higher reactivity of the amido species **4** with respect to the amino species **1** ($k_s'/k_s = 11.7$) is in

keeping with the results found by Romeo et al. [5] in the study of the system $[Pt(enH_{-1})(dmso)_2]^+$/$[Pt(en)(dmso)_2]^{2+}$ ($k_s'/k_s \simeq 10$). If one assumes that the different charge on the substrates has no a significative effect on the rate of hydrolysis, as found by Martin and coworkers [26] for a number of Pt(II) chloroammine complexes, the difference in reactivity could be ascribed to the greater *trans* effect of the amido group. Unfortunately, no study has been performed on other comparable systems and a comparison with data relative to substitution reactions with anionic nucleophiles in other amino–amido systems [2,5], for which a reversal of behaviour with the conjugate base becoming less labile than the amine species was observed, cannot be properly done as charge neutralization, absent in the hydrolysis reactions, could overcome the effect of the deprotonation. Therefore, further investigations are necessary before any reasonable conclusion can be drawn.

The nature and the distribution of the species formed in solution have been elucidated on investigating the acid–base behaviour of the aqua species $[Pt(bpma)(OH_2)]^{2+}$.

In Fig. 4, the UV spectrum of the aqua-complex $[Pt(bpma)(OH_2)](CF_3SO_3)_2$ (**2**) in perchloric acid solution (pH 4) is shown as curve E. When titrated with NaOH, **2** behaves as a dibasic acid and two acid

Scheme 2.

dissociation constants, $pK_1 = 5.4 \pm 0.1$ and $pK_2 = 11.5 \pm 0.1$, are obtained which can be discussed on considering the acid–base equilibria occurring in solution, as depicted in Scheme 2.

Not all of the microscopic equilibrium constants in Scheme 2 can be derived from the two experimentally determined K_1 and K_2 constants unless at least one piece of additional information is available. Literature data on similar systems indicate that the dissociation constant of a –NH– group ($K_{2,5}$ in the present case) is always some six order of magnitude smaller than the acid dissociation constant of a coordinated water molecule ($K_{2,3}$ in the present case). For instance, the pK_a values for the deprotonation of the secondary amino group in the cationic species $[Pt(dien)(Me_2SO)]^{2+}$ [5] and $[PtMe(dpa)(Me_2SO)]^{+}$ [6] are 11.94 ± 0.02 and 12.1 ± 0.2, respectively, while a $pK_a = 6.13$ for the protolysis of co-ordinated water in the aquo-cation $[Pt(dien)(OH_2)]^{2+}$ has been reported [27].

It is therefore reasonable to assume $K_{2,3} \gg K_{2,5}$ and since [28] $K_1 = K_{2,3} + K_{2,5}$ and $K_2 = (K_{3,6} \times K_{5,6})/(K_{3,6} + K_{5,6})$, it follows that $K_1 \cong K_{2,3}$ and $K_2 \cong K_{3,6}$. Consequently, it can be concluded that the reaction products formed in the base hydrolysis of **1** are the hydroxo species **3** and **6**, the anpholite **5** being completely dismutated. Up to $[OH^-] \cong 3 \times 10^{-4}$ mol dm^{-3}, the prevailing product is the amino-hydroxo species **3**, whose spectrum is shown as curve B in Fig. 4.

4. Supplementary material

Crystallographic data of the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 168846–168847 for the compounds $[Pt(bpma)Cl]Cl \cdot H_2O$ and $[Pt(bpma)(OH_2)](ClO_4)_2 \cdot 2H_2O$. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Scheme 1.

$[Cd_2(ibn)(SeCN)_4]_n$ **(1)** (ibn = 1, 2-diamino-2-methyl propane) and $[Cd(pyz)(SeCN)_2]_n$ **(2)** (pyz = pyrazine). Compound **1** shows the unique symbiotic phenomena [25] with alternating octahedral (CdN_6) and tetrahedral ($CdSe_4$) centre.

2. Experimental

2.1. Reagents

High purity (98%) 1,2-diamino-2-methylpropane, pyrazine and potassium selenocyanate were purchased from Aldrich Chemical Company Inc. and used as received. All other chemicals used were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyser and cadmium(II) content was estimated gravimetrically [26]. Infrared spectra (4000–400 cm^{-1}) were taken using Nicolet Magna-IR 750 spectrometer series-II where KBr was used as medium.

2.3. Synthesis of complexes

Complex $[Cd_2(ibn)(SeCN)_4]_n$ (**1**): an aqueous solution (5 cm^3) of potassium selenocyanate (2 mmol, 0.288 g) was added to an aqueous solution (10 cm^3) of cadmium perchlorate hexahydrate (1 mmol, 0.419 g) with constant stirring. After 10 min 1,2-diamino-2-methylpropane (ibn) (1 mmol, 0.088 g) was added slowly to the reaction mixture and stirred for 30 min. The resulting solution was filtered and the filtrate was kept in a $CaCl_2$ desiccator. After a few days shiny crystals suitable for X-ray determination were obtained. Yield: 80%. *Anal.* Found: C, 13.15; H, 1.66; N, 11.47; Cd, 30.41. Calc. for $C_8H_{12}Cd_2N_6Se_4$: C, 13.10; H, 1.63; N, 11.46; Cd, 30.67%.

Complex $[Cd(pyz)(SeCN)_2]_n$ (**2**): An aqueous solution (5 cm^3) of potassium selenocyanate (2 mmol, 0.288 g) was added to an aqueous solution (10 cm^3) of cadmium nitrate tetrahydrate (1 mmol, 0.308 g) with vigorous stirring for about 10 min. A methanolic solution (5 cm^3) of pyrazine was (1 mmol, 0.080 g) added to it very slowly with constant stirring. The resulting mixture was filtered and the filtrate was kept in a $CaCl_2$ desiccator. After a few days shiny single crystals suitable for X-ray structural analysis were obtained. Yield: 75%. *Anal.* Found: C, 17.83; H, 0.98; N, 13.87; Cd, 27.87. Calc. for $C_6H_4CdN_4Se_2$: C, 17.80; H, 0.99; N, 13.85; Cd, 27.79%.

2.4. X-ray data collection and structure determination

Suitable single crystals of complex **1** was mounted on a Siemens SMART CCD diffractometer whereas complex **2** was mounted on Rigaku/AFC 7S diffractometer equipped with a graphite monochromated Mo Kα (λ = 0.71069 Å) radiation. The intensity data were corrected for Lp [27] and an empirical absorption corrections were also employed using SAINT program [28] for complex **1** and using ψ scan for complex **2**. For **1** a total of 3329 reflections were measured and 2775 were assumed observed applying the condition $I > 2\sigma(I)$, and 471 reflections were measured and 418 were assumed observed applying the condition $I > 2\sigma(I)$ for complex **2**. Both the structures were solved by Patterson syntheses and followed by successive Fourier and difference Fourier syntheses. Full matrix least-squares refinements on F^2 were carried out using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were constrained to ride on the respective carbon or nitrogen atoms with an isotropic displacement parameter equal to 1.2 times the equivalent isotropic displacement parameter of their parent atom. The refinement converged to residual indices R = 0.0352 and 0.0197; wR_2 = 0.0953 and 0.0550 with $I > 2\sigma(I)$ for complexes **1** and **2**, respectively. Complex neutral atomic scattering factors [29] were used throughout. The final difference Fourier map showed the minimum and maximum peak heights of −1.55 and 0.95 e $Å^{-3}$ for complex **1** and −0.45 and 0.53 e $Å^{-3}$ for complex **2**. All calculations were carried out using SHELXS-97 [30], SHELXL-97 [31], PLATON-99 [32] and ORTEP-3 [33] programs. All crystallographic data for complexes **1** and **2** are summarized in Table 1. Selected bond lengths and angles are given in Table 2 and H-bonding parameters in Table 3 for complex **1**. For complex **2** the selected bond lengths and angles are displayed in Table 4.

3. Results and discussion

3.1. IR spectra

The complex **1** shows several split strong bands in the range 3270–3356 cm^{-1}, which can be assigned to the ν(NH) stretching frequency of the corresponding diamine ligand. Several bands in the range 2869–2950 cm^{-1} are assigned to the aliphatic ν(CH) stretching vibrations for complex **1**. The free SeCN ligand shows one sharp band corresponding to ν(CN) at 2070 cm^{-1}. The most intense split band is observed assigned to ν(CN) at 2113, 2134 cm^{-1} for complex **1** and only one sharp band at 2133 cm^{-1} for complex **2**. The higher frequency correlates that all the selenocyanato groups in both the complexes are involved in bridging with same environment [34]. All other bands appear at their usual positions.

3.2. Description of structure $[Cd_2(ibn)(SeCN)_4]_n$ (**1**)

An ORTEP drawing with atom numbering scheme of complex **1** is shown in Fig. 1. X-ray structure determination reveals that it is a neutral infinite molecular ladder in which selenocyanate anions function both as support and rung. According to Fig. 1, two adjacent racemic chains are interlinked by selenocyanate anions to form a one-dimensional ladder like chain. Every chain running parallel to b-axis comprises of alternating octahedral and tetrahedral cadmium(II) centres bridging through selenocyanate anions. Tetrahedral and octahedral centres possess the chromophores $CdSe_4$ and CdN_6, respectively. The supports are alternatively singly and doubly bridged evident from the extended structure shown in Fig. 2. Although there was only one observation of alternating tetrahedral and octahedral array in cadmium(II) system [18], it is to be remembered that no

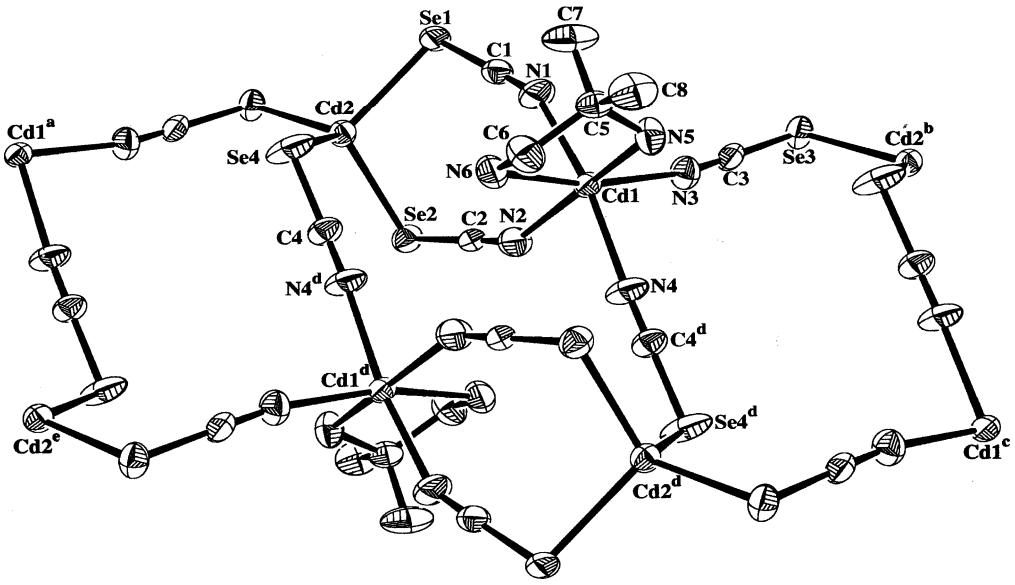

Fig. 1. ORTEP diagram of $[Cd_2(ibn)(SeCN)_4]_n$, **1** with atom numbering scheme. Ellipsoids are drawn at 50% probability. (Symmetry code: a = x, $1+y$, z; b = x, $-1+y$, z; c = $-x$, $2-y$, $1-z$; d = $-x$, $2-y$, $1-z$; e = $-x$, $3-y$, $1+z$.)

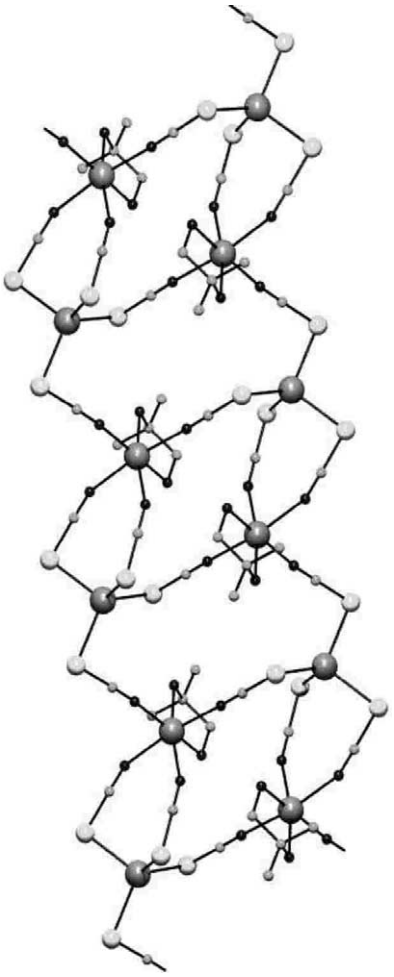

Fig. 2. Extended ladder like view of complex **1** having alternatively octahedral and tetrahedral cadmium(II) centres with singly and doubly bridged SeCN ligand.

analogous ladder structure has yet been reported previously in the cadmium(II)–selenocyanate system.

The Cd1 atom exists in a distorted octahedral environment. The nitrogen atoms, N3 and N6 (Cd1–N3, 2.258(6); Cd1–N6, 2.334(6) Å) of the diamine ligand (ibn) and two nitrogen atoms, N2 and N5, (Cd1–N2, 2.355(6); Cd1–N5, 2.336(6) Å) from two different bridging as well as supporting selenocyanate anions describe the equatorial plane around Cd1 atom. The axial positions are occupied by N4 atom (Cd1–N4, 2.375(6) Å) of the rung selenocyanate anion and N1 atom (Cd1–N1, 2.374(6) Å) of another bridging as well as support selenocyanate anion. The deviation of Cd1 from the mean plane formed by the four equatorial nitrogen atoms is 0.025(1) Å and the maximum deviation of N5 atom from plane among all the equatorial nitrogen atoms is 0.156(7) Å. The Cd2 atom is in distorted tetrahedral environment, being coordinated by four selenocyanato Se donors (Cd2–Se1, 2.6646(9); Cd2–Se2, 2.6756(10); Cd2–Se3, 2.6110(10); Cd2–Se4, 2.6378(11) Å). The degrees of distortion from an ideal octahedral geometry are reflected in the cisoid [74.9(2)°–102.8(2)°] and transoid angles [165.9(2)°–169.1(2)°]. It is interesting to note that only nitrogen atoms surround the octahedral centres (Cd1) whereas only selenium atoms surround the tetrahedral centers (Cd2). The nitrogen atoms of the diamine ligand 'harden' Cd1, so the selenocyanate anions are bonded to it preferentially through N atoms. Conversely the soft ends (Se atoms) of the selenocyanate anions are coordinated to tetrahedral Cd2 making it 'soft'. Thus all the selenium atoms of selenocyanate ligand are clubbed together around Cd2. The bridging Cd1–N–C and Cd2–Se–C are in the range 148.5(5)°–172.7(6)° and 93.3(2)°–99.8(2)°, respec-

tively. The selenocyanate ligands are quasi linear [range 175.8(7)°–178(6)°]. The bond distances and angles are comparable to other similar selenocyanato bridging systems [18,23c]. The linkage forming the rungs of the ladder has a Cd1···Cd2 distance of 6.523 Å and the bridges forming the side of the ladder have Cd1···Cd2 distances of 5.468 Å for double selenocyanate bridge and of 6.035 Å for single selenocyanate bridge. It is worth noting that there are two types of hydrogen bonding due to N6 donor of diamine ligand forming an intra-ladder hydrogen bonds with N2 atom of a selenocyanate (H6B···N2, 2.5706; N6···N2, 3.369(8) Å; <N6–H6B···N2, 148.15°) and due to N5 atom of diamine ligand forming one hydrogen bond with Se1 atom of adjacent ladder (H5B···Se1, 2.9014; N5–Se1, 3.791(7) Å; <N5–H5B···Se1, 169.78°). As shown in Fig. 3, this arrangement results in a supramolecular 2D sheet in *bc*-plane.

3.3. Description of structure $[Cd(pyz)(SeCN)_2]_n$ (2)

Complex **2** is made up of a 2D neutral rectangular-grid layer (Fig. 4). The pyrazine ligand is in μ-mode and forms [Cd(μ-pyrazine)]$_n$ chain running along parallel to *b*-axis. The SeCN anion is also in μ-mode and bridges two Cd atoms in adjacent chains, resulting in a rectangular-grid coordination layer in *bc*-plane. The principal structural features of the present complex with atom labelling scheme are shown in Fig. 4. The structure determination reveals that the cadmium atom, Cd, occupies 2/*m* site [1/2, 1/2, 1/2]. Se, C and N atoms of selenocyanate ligand are located on a mirror plane [*x*, 1/2, *z*] and N1 atom of pyrazine ligand lies on a twofold axis [1/2, *y*, 1/2]. The geometry around Cd atom is a distorted octahedron. The two nitrogens (N^a and N^i, a = *x*, *y*, −1+*z*; i = 1−*x*, *y*, 2−*z*) of the selenocyanate anion are in the equatorial plane [Cd–N^a/N^i 2.296(5) Å] together with two nitrogens (N1 and $N1^h$, h = 1−*x*, 1−*y*, 1−*z*) of pyrazine ligand [Cd–N1/$N1^h$

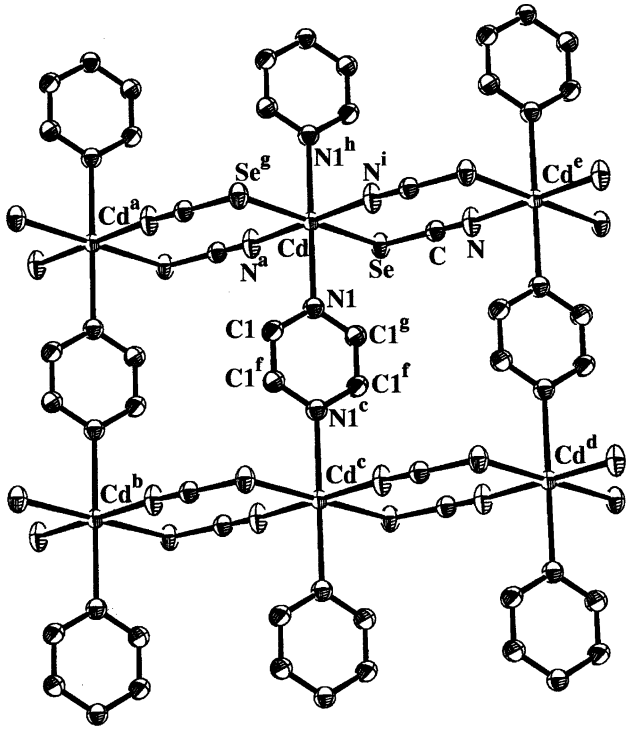

Fig. 4. ORTEP diagram of $[Cd(pyz)(SeCN)_2]_n$, **2** with atom numbering scheme showing the rectangular grid like structure. Ellipsoids are drawn at 50% probability. (Symmetry code: a = *x*, *y*, −1+*z*; b = *x*, −*y*, −1+*z*; c = *x*, −*y*, *z*; d = *x*, −*y*, 1+*z*; e = *x*, *y*, 1+*z*; f = 1−*x*, −*y*, 1−*z*; g = 1−*x*, *y*, 1−*z*.)

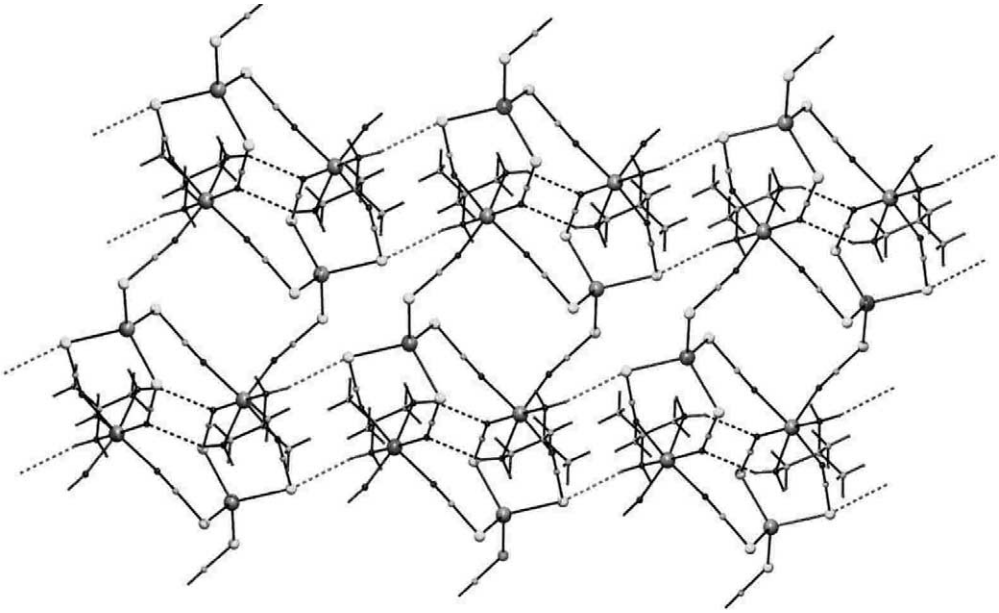

Fig. 3. 2D supramolecular sheet of complex **1** lying on the *bc*-plane.

2.429(5) Å]. The Se atoms (Se and Se^{g}, g = 1 − *x*, *y*, 1 − *z*) of selenocyanate anion occupy *trans*-axial sites [Cd–Se/Se^{g} 2.7987(9) Å]. The axial distance is larger than the Cd–Se distances of complex **1**. The cisoid angles are in the range 86.11(11)°–93.83(11)° and the transoid angles are 180°. The equatorial plane is essentially planar with Cd atom. The bridging Cd–Se–C angles [96.23(18)°] and Cd–N–C (SeCN) [169.1(4)°] are comparable with those found in other similar complexes [18,23c]. The pyrazine moieties of alternate layers are found to shift towards the SeCN moieties (Fig. 5). The Cd···Cd distance of pyrazine linkage is 7.647 Å and that of SeCN linkage is 6.007 Å. The distance between the two adjacent layers is 5.485 Å.

4. Conclusions

Two new coordination polymers of selenocynato-bridged cadmium(II) complexes are synthesized in combination of two organic (ibn and pyz) ligands. Single crystal X-ray diffractions are carried out to determine the structures of complexes. In complex **1**, reaction of cadmium selenocyanate with ibn results in two 1D parallel chains of cadmium(II), each having alternate tetrahedral ($CdSe_4$) and octahedral (CdN_6) centres bridged through selenocyanate exhibiting symbiotic phenomena, whereas in complex **2**, reaction of cadmium selenocyanate with pyrazine generates a 2D network in which doubly selenocyanato bridged 1D coordination polymeric chains are linked through the pyrazine ligand forming rectangular grid in *bc* plane. In our recent work [18], $[Cd(medien)(SeCN)_2]_n$ **1a** is 1D polymeric chain with CdN_4Se_2 octahedra and $[Cd(iprdien)(SeCN)_2]_n$ **1b** is 2D network with alternating CdN_6 octahedra and $CdSe_4$ tetrahedra. In the synthesis of the compounds **1**, **1a** of **1b** we have taken three different amines keeping other reagents and synthetic procedure the same. The complex **1a** showed usual structural features that each cadmium atom was coordinated by both N and Se atoms, but the generation of two types of Cd environments in complexes **1** and **1b** are rather unique. The 'ibn' (contains two methyl group at one C atom) and 'iprdien' (contains one isopropyl group at one end of primary N-atom) are asymmetric ligands in comparison to 'medien' (contains one methyl group at central N-atom) and exert greater steric forces which may be the responsible for the formation of the alternating octahedral (CdN_6) and tetrahedral ($CdSe_4$) centres as tetrahedral geometry occupies less space than the octahedral geometry. On the other hand, tetrahedral cadmium centres have sp^3 hybridization and the octahedral centres have sp^3d^2 hybridization leading to tetrahedral centre more electronegative than the octahedral centre. Thus, according to the Jørgenson symbiotic theory, [25] the hard species will tend to increase the hardness of the atom to which they are bound and thus increase its tendency to attract more hard species, i.e. 'ibn' and 'iprdien' ligands increase the hardness of octahedral cadmium(II) which preferably bind the N-atoms of the ambidentate SeCN ligand. And in case of thiocyanate ligand we reported the symbiotic phenomena between two octahedral cadmium centres (CdN_6 and CdS_6) [17]. The occurrence of such phenomenon in between octahedral and tetrahedral cadmium(II) centres in title complex **1** is probably due to the large size of Se (more soft) in comparison to small size S atom (less soft). For complex **2** the molar ratio of metal–selenocyanate–pyz (1:1:1) is very much important and the use 'organic-rod' pyrazine enhances the formation of grid-like structure. The above facts indicate the utility and reliability of the selenocyanate moiety as spacer in forming coordination polymer and also reveal that the variation of organic spacer profoundly influences the packing of the polymeric complexes.

2. Experimental

2.1. General procedures

All the reagents used in this research were purchased from commercial sources and used as they were required. The starting materials used in this research namely, $[MI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ (M = Mo or W) [30], $[MoX(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_4R)]$ (X = Cl, R = H or Me; X = Br, R = H) [31] and $[FeI(CO)_2(Cp \text{ or } Cp')]$ (Cp = C_5H_5; Cp′ = C_5H_5Me) [32] were prepared by published procedures.

Elemental analyses (C, H and N) were determined using a Carlo Erba Elemental Analyser MOD 1108 (using helium as the carrier gas). IR spectra were obtained using a Perkin–Elmer 1600 series FT IR spectrophotometer. ^1H and $^{31}P\{^1H\}$ spectra were recorded on a Bruker AC250 MHz NMR spectrometer; ^1H NMR spectra were referenced to $SiMe_4$, $^{31}P\{^1H\}$ NMR spectra were referenced to 85% H_3PO_4. Molecular weight measurements were made using Rast's method [33], using camphor as the standard.

2.2. $[\{Mo(\mu\text{-}Cl)(CO)_2(L^{Mo})(\eta^3\text{-}C_3H_5)\}_2]$ (1)

To a stirred solution of $[MoCl(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_5)]$ (0.08 g, 0.32 mmol) in CH_2Cl_2 (25 cm^3) was added $[MoI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}](L^{Mo})$ (0.3 g, 0.26 mmol). Filtration and removal of solvent in vacuo after 24 h, gave the green crystalline powder $[\{Mo(\mu\text{-}Cl)(CO)_2(L^{Mo})(\eta^3\text{-}C_3H_5)\}_2]$ (**1**), which was recrystallized from CH_2Cl_2–Et_2O at −17 °C. Yield of pure product = 0.22 g (54%).

Similar reactions of $[MoX(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_4R)]$ (X = Cl and Br) with 1 equiv. of L^{Mo} or L^W {L^{Mo} or $L^W = [MI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ in CH_2Cl_2 at room temperature (r.t.) gave the complexes $[\{Mo(\mu\text{-}X)(CO)_2(L^{Mo} \text{ or } L^W)(\eta^3\text{-}C_3H_4R)\}_2]$ {X = Cl, R = H, L^W (**2**); R = Me, L^{Mo} (**3**); L^W (**4**)}; {X = Br, R = H, L^{Mo} (**5**), L^W (**6**)}. For physical and analytical data see Table 1.

2.3. $[MoCl(CO)_2(L^{Mo})_2(\eta^3\text{-}C_3H_5)]$ (7)

To a stirred solution of $[MoCl(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_5)]$ (0.05 g, 0.16 mmol) in CH_2Cl_2 (25 cm^3) was added $[MoI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ (0.34 g, 0.32 mmol). Filtration and removal of solvent in vacuo after 24 h, gave the green crystalline powder $[MoCl(CO)_2(L^{Mo})_2(\eta^3\text{-}C_3H_5)]$ (**7**), which was recrystallized from CH_2Cl_2–Et_2O at −17 °C. Yield of pure product = 0.24 g (64%).

Similar reactions of $[MoX(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_4R)]$ (X = Cl and Br) with 2 equiv. of L^{Mo} or L^W {L^{Mo} or $L^W = [MI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$} in CH_2Cl_2 at r.t. gave the complexes, $[MoX(CO)_2$ (L^{Mo} or $L^W)_2(\eta^3\text{-}C_3H_4R)]$ {X = Cl, R = H, L^W (**8**); R = Me, L^{Mo} (**9**); L^W (**10**)}; {X = Br, R = H, L^{Mo} (**11**), L^W (**12**)}. For physical and analytical data see Table 1.

19	$[Fe(CO)_2(L^W)Cp][BPh_4]$	35	54.3 (54.8)	5.7 (3.9)

[a] All complexes **1** to **19** are green.
[b] Calculated values in parenthesis.

2.4. $[Fe(CO)_4(L^{Mo})]$ (13)

To a stirred solution of $[Fe_2(CO)_9]$ (0.05 g, 0.13 mmol) in CH_2Cl_2 (25 cm^3) was added $[MoI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ (0.3 g, 0.28 mmol). Filtration and removal of solvent in vacuo after 24 h, gave the green powder $[Fe(CO)_4(L^{Mo})]$ (**13**), which was recrystallized from CH_2Cl_2–Et_2O at −17°C. Yield of pure product = 0.08 g (45%).

A similar reaction of $[Fe_2(CO)_9]$ with 2 equiv. of L^W in CH_2Cl_2 at r.t. gave the complex, $[Fe(CO)_4(L^W)]$ (**14**). For physical and analytical data see Table 1.

2.5. $[Fe(CO)_2(L^{Mo})(Cp]I$ (15)

To a stirred solution of $[FeI(CO)_2(\eta^5\text{-}C_5H_5)]$ (0.05 g, 0.16 mmol) in warm CH_2Cl_2 (25 cm^3) was added $[MoI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ (0.17 g, 0.16 mmol). Filtration and removal of solvent in vacuo after 2 h gave $[Fe(CO)_2(L^{Mo})(\eta^5\text{-}C_5H_5)]I$ (**15**), which was recrystallized from CH_2Cl_2–Et_2O. Yield of pure product = 0.07 g (32%).

A similar reaction of $[FeI(CO)_2(\eta^5\text{-}C_5H_4R)]$ (R = H or Me) with 1 equiv. of L {L = $[MI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ (M = Mo or W)} in warm CH_2Cl_2 at r.t. gave the complexes $[Fe(CO)_2(L^{Mo} \text{ or } L^W)(\eta^5\text{-}C_5H_4R)]I$, {R = H, L^W (**16**); R = Me, L^{Mo} (**17**), L^W (**18**)}. For physical and analytical data see Table 1.

2.6. [Fe(CO)$_2$(L^W)(η^5-C$_5$H$_5$)][BPh$_4$] (19)

To a stirred solution of [Fe(CO)$_2$(L^W)(η^5-C$_5$H$_5$)]I (0.05 g, 0.43 mmol) in CH_2Cl_2 (25 cm^3) was added Na[BPh$_4$] (0.012 g, 0.42 mmol). Filtration and removal of solvent in vacuo after 24 h, gave the green complex, [Fe(CO)$_2$(L^W)(η^5-C$_5$H$_5$)][BPh$_4$] (**19**), which was recrystallized from CH_2Cl_2–Et_2O at −17 °C. Yield of pure product = 0.02 g (35%).

3. Results and discussion

3.1. Preparation and characterization of the tetrametallic complexes [{Mo(μ-X)(CO)$_2$(L^{Mo} or L^W)(η^3-C$_3$H$_4$R)}$_2$] (1–6)

The starting materials used in this research, [MI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}] (M = Mo or W) were prepared by reacting the bis(acetonitrile) complexes [MI$_2$(CO)$_3$(NCMe)$_2$] [24], with 1 equiv. of tripodal triphos, MeC(CH$_2$PPh$_2$)$_3$, in CH_2Cl_2 for 15 min at room temperature [30]. Equimolar amounts of [MoX(CO)$_2$(NCMe)$_2$(η^3-C$_3$H$_4$R)] (X = Cl, R = H or Me; X = Br, R = H) and [MI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}] (M = Mo, L^{Mo}; M = W, L^W) react in CH_2Cl_2 at room temperature to eventually give the halo-bridged and tripodal triphos-bridged tetrametallic complexes, [{Mo(μ-X)(CO)$_2$(L^{Mo} or L^W)(η^3-C$_3$H$_4$R)}$_2$] (**1**–**6**) in moderate yield, via displacement of both of the acetonitrile ligands. All the complexes **1**–**6** were characterised by elemental analysis (C, H and N) (Table 1), IR (Table 2), ^{1}H and ^{31}P{^{1}H} NMR spectroscopy (Tables 3 and 4). Molecular weight measurements of selected complexes were determined using Rast's method [33]. These measurements confirmed the tetrametallic nature of these complexes. Complex **1** (X = Cl, R = H, L^{Mo}) was confirmed as a CH_2Cl_2 solvate by repeated elemental analyses and ^{1}H NMR spectroscopy. The new complexes **1**–**6** are moderately stable in the solid-state when stored under dinitrogen, but they all readily decompose in solution when exposed to air. Complexes **1**–**6** are soluble in $CHCl_3$ and CH_2Cl_2, but only slightly soluble in diethyl ether.

The IR spectra of complexes **1**–**6** (Table 2) as expected all show a number of carbonyl bands due to both the [MI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}] unit, and the π-allyl molybdenum fragment. For example, complex **1** showed bands at 2015, 1941, 1933 and 1842 cm^{-1}. It is highly likely that the bands at 1933 and 1842 cm^{-1} are due to the *cis*-carbonyl groups on the π-allyl molybdenum part of the molecule. {The complex, [MoCl(CO)$_2$(NCMe)$_2$(η^3-C$_3$H$_5$)] has carbonyl bands at ν(CO)($CHCl_3$) = 1955 and 1848 cm^{-1} [31].} The broad band at 1933 cm^{-1}, together with the bands at 2015 and 1941 cm^{-1} are very likely to be due to the [MoI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}] part of the molecule. The complex [MoI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}] [30], has ν(CO)($CHCl_3$) = 2041, 1938 and 1917 cm^{-1}. The molecular structures of several π-allyl complexes of the type [MoX(CO)$_2$L$_2$(η^3-allyl)] (L$_2$ = nitrogen donor ligands) have been crystallographically determined [34–43], and all show a *cis*-carbonyl geometry in an equivalent plane with the nitrogen donor ligands. The axial sites have the halide and π-allyl groups. However, the only monodentate bis(phosphorus) donor ligand π-allyl complex of this type to be crystallographically characterised is [MoCl(CO)$_2${P(OMe)$_3$}$_2$(η^3-C$_3$H$_5$)] [44]. This complex has a distorted pentagonal bipyramidal geometry, with a carbonyl ligand and a chloride group in axial positions, and the π-allyl group occupying two adjacent sites. In view of the IR carbonyl pattern for the complexes **1**–**6**, it is likely the *pseudo*-octahedral geometry will be described for the mono(phosphine) complexes **1**–**6**, rather than the pentagonal bipyramidal geometry shown for [MoCl(CO)$_2${P(OMe)$_3$}$_2$(η^3-C$_3$H$_5$)] [44]. The two halides of the halo-bridged dimers are identical, as only two *cis*-carbonyl groups were observed.

The ^{31}P{^{1}H} NMR spectra (Table 4) show resonances for the 2 equiv. phosphorus atoms attached to the molybdenum and tungsten centres in the units, [MI$_2$(CO)$_3${MeC(CH$_2$PPh$_2$)$_3$-*P*,*P*′}]. Tungsten satellites were not observed, due to the poor solubility of the complexes in a range of NMR solvents. For example, the ^{31}P{^{1}H} NMR spectrum of **2** has a resonance at δ = −17.7 ppm (due to the fluxional seven-coordinate L^W fragment), and δ = 27.3 ppm due to the phosphorus

[a] Spectra recorded in $CDCl_3$ (+25 °C) and referenced to 85% H_3PO_4.

atoms attached to the π-allyl fragment in an approximately 2:1 intensity ratio. The assignments of resonances in the $^{31}P\{^{1}H\}$ NMR spectra were due to the expected resonances of the phosphine ligands, $[MI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ [30], and the generally lower field and less intense resonance due to the phosphorus atom attached to the π-allyl molybdenum moiety. The geometry of one isomer of complexes **1**–**6** is shown in Fig. 1, which shows that the L^{Mo} or L^{W} are coordinated in a *trans* configuration to each other, with a bulky phosphine group and π-allyl group *trans* to the other one.

Complexes **1**–**6** are most likely to be obtained from the bimetallic complexes, $[MoX(CO)_2(NCMe)(L^{Mo}$ or $L^{W})(\eta^3\text{-}C_3H_4R)]$, which could not be isolated even with short reaction times, and the tetrametallic nature of the products was confirmed by the lack of nitrogen in the elemental analysis results and no acetonitrile resonances observed in the ^{1}H NMR spectra. Also molecular weight studies using Rast's method [33] confirmed the tetrametallic nature of **1**–**6**. Several unsuccessful attempts were made to obtain FAB mass spectra of the complexes, although fragment peaks were obtained the parent ions could not be observed for these complexes.

3.2. Synthesis and characterization of the trimetallic complexes, $[MoX(CO)_2(L^{Mo}$ or $L^{W})_2(\eta^3\text{-}C_3H_4R)]$ (7–12)

Reaction of $[MoX(CO)_2(NCMe)_2(\eta^3\text{-}C_3H_4R)]$ (X = Cl, R = H or Me; X = Br, R = H) with 2 equiv. of L^{Mo} or L^{W} in CH_2Cl_2 at room temperature affords the trimetallic, tripodal triphos-bridged complexes, $[MoX(CO)_2(L^{Mo}$ or $L^{W})_2(\eta^3\text{-}C_3H_4R)]$ (**7**–**12**) in moderate yield, by displacement of both of the acetonitrile ligands. The complexes **7**–**12** have been fully characterised by elemental analysis (C and H), (Table 1), IR (Table 2), ^{1}H and $^{31}P\{^{1}H\}$ NMR spectroscopy. The complex $[MoBr(CO)_2(L^{Mo})_2(\eta^3\text{-}C_3H_5)]\cdot Et_2O$ (**11**) was confirmed as a diethyl ether solvate by repeated

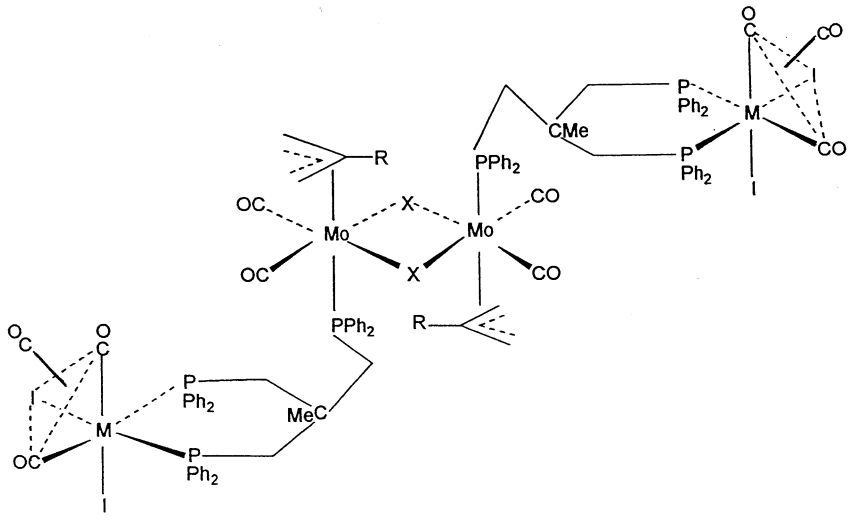

Fig. 1. Proposed structure of [{Mo(μ-X)(CO)$_2$(L^{Mo} or L^{W})(η^3-C$_3$H$_4$R)}$_2$] (M = Mo or W) (**1**–**6**).

elemental analyses and ^{1}H NMR spectroscopy. FAB mass spectra were attempted without success, as no parent ions were observed. However, molecular weight studies by Rast's method [33] suggest the trimetallic nature of these complexes (see Table 5). Generally, complexes **7**–**12** are more stable and less soluble than the tetrametallic complexes **1**–**6** described earlier. Complexes **7**–**12** have to be stored under dinitrogen in the solid-state.

The IR spectra of the trimetallic complexes, **7**–**12** are all relatively simple and show the expected bands for the π-allyl molybdenum *cis*-dicarbonyl unit, and the diiodo tricarbonyl molybdenum and tungsten moieties. For example, complex **7** has bands at ν(CO) = 2041, 1959, 1939 and 1846 cm^{-1}. It is very likely the bands at 1939 and 1846 cm^{-1} are due to the *cis*-dicarbonyl π-allyl unit, and the bands at 2041, 1959 and 1939 cm^{-1} (and probably a masked band due to MI$_2$(CO)$_3$ unit), are due to the L^{Mo} part of the molecule. The room temperature ^{31}P{^{1}H} NMR spectrum for complex **7** shows a resonance due to the equivalent phosphine atoms attached to the fluxional [MoI$_2$(CO)$_3${MeC(CH$_2$-PPh$_2$)$_3$-*P*,*P*′}] units at δ = 17.6 ppm. The resonance at δ = 32.9 ppm is due to the 2 equiv. phosphorus atoms attached to the molybdenum π-allyl unit. The intensity ratio of the resonances at δ = 17.6 and 32.9 ppm is approximately 2:1, which was expected. Although the only crystal structure of a bis(monodentate) phosphorus donor complex [MoCl(CO)$_2${P(OMe)$_3$}$_2$(η^3-C$_3$H$_5$)] [44], has a distorted pentagonal bipyramidal structure with carbonyl and a chloro group in the axial position, the two phosphite ligands are in different environments in the equatorial plane. In view of the IR and ^{31}P{^{1}H} NMR spectral data (Tables 2 and 4), it is more likely the structure of **7**–**12** has distorted pentagonal bipyramidal arrangement with the two organometallic phosphine units *trans* to each other, with the carbonyl groups, chloro group and π-allyl unit occupying the five equatorial sites, (the π-allyl group occupying two sites). The proposed structure for **7**–**12** is shown in Fig. 2. The structure of the seven-coordinate halocarbonyl part of the molecule most likely has a distorted capped octahedral structure as many structures of [MX$_2$(CO)$_3$L$_2$] have distorted capped octahedral geometries [25,26,45–47].

[a] Camphor was used as the solvent in these measurements.

3.3. Synthesis and characterization of the bimetallic complexes, [Fe(CO)$_4$(L^{Mo} or L^{W})] (**13** and **14**)

Reaction of [Fe$_2$(CO)$_9$] with 2 equiv. of L^{Mo} or L^{W} in CH$_2$Cl$_2$ at room temperature affords the bimetallic, tripodal triphos-bridged complexes, [Fe(CO)$_4$(L^{Mo} or L^{W})] (**13** and **14**) in moderate yield. Complexes **13** and **14** have been characterised by elemental analysis (Table 1), IR (Table 2) and ^{1}H and ^{31}P{^{1}H} NMR spectroscopy (Tables 3 and 4). Molecular weight studies by Rast's method [46] on both complexes (Table 5), confirmed the bimetallic nature of these complexes.

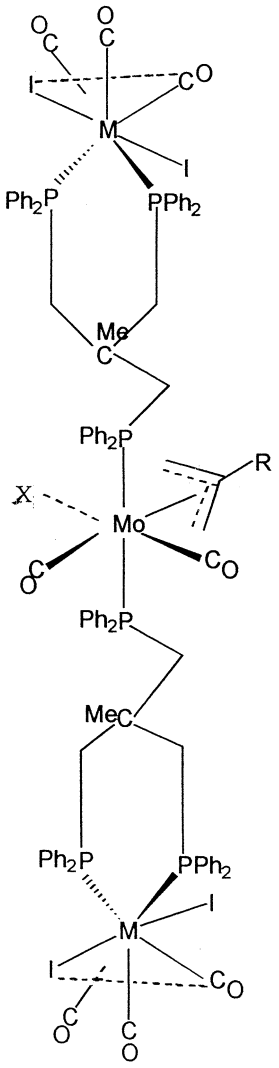

Fig. 2. Proposed structure of $[MoX(CO)_2(L^{Mo}$ or $L^{W})_2(\eta^3\text{-}C_3H_4R)]$ (M = Mo or W) (**7**–**12**).

Complexes **13** and **14** are soluble in CH_2Cl_2, less soluble in $CHCl_3$, and only sparingly soluble in diethyl ether and hydrocarbon solvents. The complexes are air-sensitive in solution, but can be stored in the solid-state under an inert atmosphere.

The IR spectra of **13** and **14** have as expected a number of carbonyl bands, there are four carbonyl ligands on the iron centre and three carbonyl groups on the molybdenum or tungsten centres. For example, complex **14** has carbonyl bands ($CHCl_3$) at 2030, 1955, 1928, 1912 and 1901 cm^{-1}. It is likely the bands at 2030, 1955 and 1901 cm^{-1} are due to the $[WI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ fragment [30], but for the $[Fe(CO)_4]$ part of complex **14**, may have three carbonyl bands at 2030, 1928 and 1912 cm^{-1}. It should be noted that the tungsten phosphine ligand, $[WI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ has bands at $\nu(CO)(CHCl_3) = 2036$, 1958 and 1904 cm^{-1} [30], and a related simple monodentate phosphine complex, $[Fe(CO)_4\{P(o\text{-tolyl})_3\}]$ has carbonyl bands at $\nu(CO)(Hexane) = 2043$, 1975 and 1947 cm^{-1} [48]. Hence, the bands are similar for the two complexes, which agrees with the broad overlapping carbonyl region of the IR spectra of **13** and **14**.

The $^{31}P\{^1H\}$ NMR spectra of **14** shows one signal due to the fluxional $[WI_2(CO)_3\{MeC(CH_2PPh_2)_3\text{-}P,P'\}]$ unit at $\delta = -16.4$ ppm, and another signal at $\delta = 39.3$ ppm due to the phosphorus atom which is coordinated to the iron centre, in an approximately 2:1 intensity ratio. The X-ray crystal structures of the complexes $[Fe(CO)_4L]$ {L = P(*p*-tolyl)$_3$ [48] and PPh_3 [49]} have been reported, and both have a very similar trigonal bipyramidal geometry, with the phosphine ligand in the axial position. In view of these studies, and the IR and $^{31}P\{^1H\}$ NMR spectral data of complexes **13** and **14**, the most likely structure for **13** and **14** is shown in Fig. 3.

3.4. Synthesis and characterization of the cationic bimetallic complexes, $[Fe(CO)_2(L^{Mo}$ or $L^{W})(Cp$ or $Cp')]X$ (15–19)

Equimolar quantities of $[FeI(CO)_2(Cp$ or $Cp')]$ and L^{Mo} or L^{W} react in warm CH_2Cl_2 to give the cationic iodide displaced bimetallic complexes $[Fe(CO)_2(L^{Mo}$ or $L^{W})(Cp$ or $Cp')]I$ (**15**–**18**) in moderate yield. The cationic nature of these complexes was confirmed by an iodide exchange reaction with $Na[BPh_4]$. Reaction of $[Fe(CO)_2(L^{W})Cp]I$ (**16**) with 1 equiv. of $Na[BPh_4]$ in CH_2Cl_2 at room temperature furnished the iodide-exchanged complex, $[Fe(CO)_2(L^{W})Cp][BPh_4]$ (**19**) in 35% yield. The cationic complexes **15**–**19** were characterised in the normal manner (Tables 1–5). Complexes **15**–**19** are soluble in polar solvents such as CH_2Cl_2, $CHCl_3$ and acetone, but as expected completely insoluble in diethyl ether and hydrocarbon solvents. The complexes are stable in the solid-state if stored under an

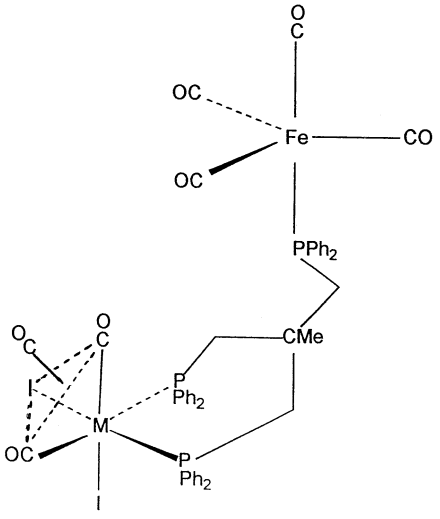

Fig. 3. Proposed structure of $[Fe(CO)_4(L^{Mo}$ or $L^{W})]$ (M = Mo or W) (**13** and **14**).

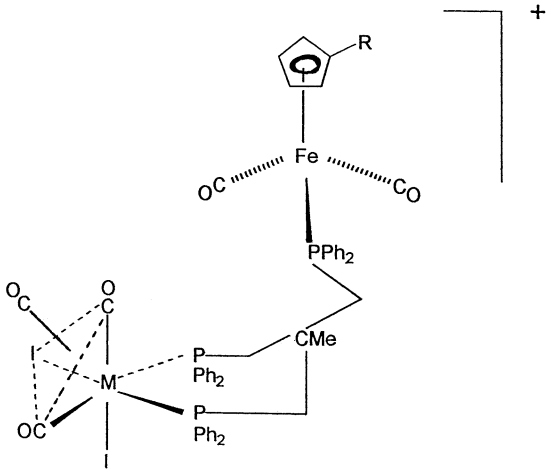

Fig. 4. Proposed structure of the cationic complexes, $[Fe(CO)_2(L^{Mo}$ or $L^{W})(Cp$ or $Cp')]X$ (M = Mo or W) (**15**–**19**).

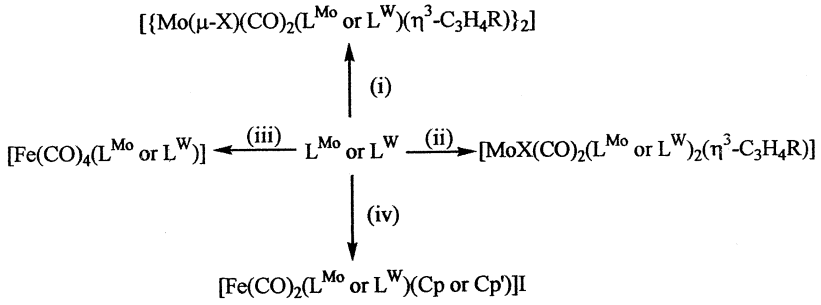
inert atmosphere, but decompose in solution when exposed to air.



The IR spectra of **15**–**19** show the overlapping carbonyl bands expected for the *cis*-$Fe(CO)_2$-units, and the $[MI_2(CO)_3]$ unit. For example, the IR spectrum for $[Fe(CO)_2(L^{Mo})Cp]I$ (**15**) has bands at $\nu(CO) = 2043$, 2019, 1998, 1938 and 1906 cm^{-1}. The two bands at 2043 and 1998 cm^{-1} are similar to the closely related monodentate phosphine complex, $[Fe(CO)_2(PPh_3)Cp]I$, which has carbonyl stretching bands at $\nu(CO) = 2045$ and 1995 cm^{-1} [50]. The bands at 2019, 1938 and 1906 cm^{-1} are due to L^{Mo} [30]. The $^{31}P\{^1H\}$ NMR spectra of complexes **15**–**19** show two resonances, and suggest a single isomer for the complexes in solution. For example, complex **15** has a single resonance at $\delta = 52.7$ ppm due to $[Ph_2P–Fe]$ unit and at $\delta = 17.6$ ppm for L^{Mo} in an approximately 1:2 intensity ratio. The likely structure of complexes **15**–**19** is as shown in Fig. 4. A number of unsuccessful attempts were made to grow suitable single crystals for X-ray crystallography of complexes **15**–**19** is as shown in Fig. 4.

4. Conclusions

In conclusion, the preparation and characterization of a range of new multimetallic complexes (nineteen) containing bridging-tripodal triphos, attached with two phosphorus atoms on $[MI_2(CO)_3\{MeC(CH_2PPh_2)_3$-$P,P'\}]$, and one phosphorus atom attached to a molybdenum(II) π-allyl unit, an iron(0) unit or an iron(II) moiety. These results are summarised in Scheme 1.

Acknowledgements

M. Al-Jahdali thanks the Saudi Arabian government for supporting him on a PhD studentship.

$L^{Mo} = [MoI_2(CO)_3\{MeC(CH_2PPh_2)_3$-$P,P'\}]$

$L^{W} = [WI_2(CO)_3\{MeC(CH_2PPh_2)_3$-$P,P'\}]$

Reagents:-

(i) One equivalent of $[MoX(CO)_2(NCMe)_2(\eta^3$-$C_3H_4R)]$ (X = Cl, R = H or Me; X = Br, R = H) in CH_2Cl_2

(ii) Half an equivalent of $[MoX(CO)_2(NCMe)_2(\eta^3$-$C_3H_4R)]$

(iii) Half an equivalent of $[Fe_2(CO)_9]$

(iv) One equivalent of $[FeI(CO)_2(Cp$ or $Cp')]$

Scheme 1. Reactions of L^{Mo} and L^{W} with $[MoX(CO)_2(NCMe)_2(\eta^3$-$C_3H_4R)]$, $[Fe_2(CO)_9]$ or $[FeI(CO)_2(Cp$ or $Cp')]$.

metallated phenyl ring. In the present paper, we report the synthesis and characterization of new examples of mono- and polynuclear cyclometallated compounds of palladium(II) derived from terephthalbenzylidenimines with diphosphine ligands.

2. Experimental

2.1. Materials and instrumentation

All solvents were distilled prior to use from appropriate drying agents [15]. Chemicals were used as supplied from commercial sources. Elemental analyses (C, H, N) were carried out in a Carlo-Erba 1108 elemental analyser. IR spectra were recorded as KBr pellets or Nujol mulls on a Perkin–Elmer 1330 spectrophotometer. NMR spectra were obtained as $CDCl_3$ solutions and referenced to $SiMe_4$ (^1H, $^{13}C-\{^1H\}$) or 85% H_3PO_4 ($^{31}P-\{^1H\}$), and were recorded on a Bruker AC-200F spectrometer (200.0 MHz for ^1H, 50.3 MHz for $^{13}C-\{^1H\}$, 81.0 MHz for $^{31}P-\{^1H\}$). Mass spectra were obtained in a QUATRO mass spectrometer with Cs ion-gun and 3-NBA matrix. Conductivity measurements were made on a Crison GLP 32 conductivimeter using 10^{-3} M solutions in dry acetonitrile at room temperature (r.t., 298 K). The synthesis of [Pd{4-(COH)C_6H_3C(H)=N(Cy)-*C2,N*}(μ-Cl)]$_2$ (**1**) was reported in a recent paper from this laboratory [13].

2.2. Synthesis of the complexes

2.2.1. Syntheses of [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2$(μ-$Ph_2PCH_2PPh_2$)] (**2**)

To a solution of **1** (25.00 mg, 0.035 mmol) in acetone (ca. 10 cm^3), $Ph_2PCH_2PPh_2$ (dppm, 12.13 mg, 0.032 mmol) was added. The mixture was stirred for 12 h at r.t., after which the precipitate formed was filtered off, dried in vacuo, and recrystallized from chloroform/*n*-hexane to yield the desired product as pale yellow microcrystals. Yield: 42% (14.68 mg). *Anal.* Found: C, 57.9; H, 4.9; N, 2.7. $C_{53}H_{54}Cl_2N_2O_2P_2Pd_2$ requires: C, 58.0; H, 5.0; N, 2.6%. IR: ν(C=O): 1692s, ν(C=N): 1621m. FAB Mass: 1061 $[M-Cl]^+$, 1033 $[M-Cl-COH]^+$, 704, $[LPd(PP)]^+$, 676 $[LPdCl]^+$. NMR ^1H: 9.07 (s, Ha), 7.38 (dd, H5, ^3J(H5H6) = 7.9 Hz, ^4J(H3H5) = 1.2 Hz), 6.88 (dd, H3, ^4J(PH3) = 4.9 Hz), 5.03 (t, CH_2P, ^{2}J(PH) = 13.4 Hz). NMR $^{31}P-\{^1H\}$: 30.90 (s).

Compounds **3**–**8** were prepared similarly, using the corresponding diphosphine ligand as appropriate.

2.2.1.1. [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2$(μ-$Ph_2PCH_2CH_2PPh_2$)] (**3**).

Yield: 85%. *Anal.* Found: C, 58.7; H, 4.8; N, 2.4. $C_{54}H_{56}Cl_2N_2O_2P_2Pd_2$ requires: C, 58.4; H, 5.1; N, 2.5%. IR: ν(C=O): 1692s, ν(C=N): 1622m. FAB Mass: 1075 $[M-Cl]^+$, 718 $[LPd(PP)]^+$. NMR ^1H: 9.20 (s, Ha), 4.51 (t, CH_2P, ^2J(PH) = 10.8 Hz). NMR $^{31}P-\{^1H\}$: 36.98 (s).

2.2.1.2. [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2${μ-$Ph_2P(CH_2)_4PPh_2$}] (**4**).

Yield: 91%. *Anal.* Found: C, 58.3; H, 5.0; N, 2.3. $C_{56}H_{60}Cl_2N_2O_2P_2Pd_2\cdot(CHCl_3)_{0.15}$ requires: C, 58.3; H, 5.2; N, 2.4%. IR: ν(C=O): 1695s, ν(C=N): 1622m. FAB Mass: 1103 $[M-Cl]^+$, 746 $[LPd(PP)]^+$, 718 $[(L-COH)Pd(PP)]^+$. NMR ^1H: 9.20 (s, Ha), 8.14 (dd, Hi, ^4J(PHi) = 8.3 Hz, ^5J(HiH7) = 1.0 Hz), 6.79 (dd, H3, ^4J(PH3) = 5.6 Hz, ^4J(H3H5) = 1.2 Hz), 4.52 (m, CH_2P). NMR $^{31}P-\{^1H\}$: 33.78 (s). NMR $^{13}C-\{^1H\}$: 192.2 (s, COH), 170.0 (d, C=N, ^4J(PC) = 4.3 Hz), 157.9 (s, C1), 154.4 (s, C2), 135.7 (d, C4, ^4J(PC) = 5.0 Hz), 135.3 (d, C3, ^3J(PC) = 9.9 Hz), 133.9 (d, C_o, ^2J(PC) = 11.4 Hz), 130.0 (d, C_i, ^1J(PC) = 46.1 Hz), 128.6 (d, C_m, ^3J(PC) = 10.6 Hz), 127.4 (s, C5), 124.3 (s, C6), 62.8 (s, C7), 33.5 (s, C8, C12), 29.7 (d, *C*H_2P, ^1J(PC) = 33.4 Hz), 26.4 (d, *C*H_2CH_2P, ^2J(PC) = 17.8 Hz), 25.8 (s, C10), 25.4 (s, C9, C11).

2.2.1.3. [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2${μ-$Ph_2P(CH_2)_6PPh_2$}] (**5**).

Yield: 64%. *Anal.* Found: C, 60.5; H, 5.0; N, 1.2. $C_{58}H_{64}Cl_2N_2O_2P_2Pd_2\cdot(Me_2CO)_{0.15}$ requires: C, 60.4; H, 5.6; N, 1.2%. IR: ν(C=O): 1687s, ν(C=N): 1622m. FAB Mass: 1166 $[M]^+$, 1130 $[M-Cl]^+$, 774 $[LPd(PP)]^+$. NMR ^1H: 9.22 (s, Ha), 8.15 (dd, Hi, ^4J(PHi) = 8.3 Hz, ^5J(HiH7) = 1.0 Hz), 6.83 (dd, H3, ^4J(PH3) = 5.2 Hz, ^4J(H3H5) = 1.5 Hz), 4.50 (m, CH_2P). NMR $^{31}P-\{^1H\}$: 33.69(s).

2.2.1.4. [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2${μ-($Ph_2PC_5H_4$)$_2$Fe}] (**6**).

Yield: 58%. *Anal.* Found: C, 50.2; H, 4.3; N, 1.9. $C_{62}H_{58}Cl_2FeN_2O_2P_2Pd_2\cdot(CHCl_3)_{2.75}$ requires: C, 50.6; H, 4.0; N, 1.8%. IR: ν(C=O): 1698s, ν(C=N): 1622m. FAB Mass: 1229 $[M-Cl]^+$, 874 $[LPd(PP)]^+$, 845 $[(L-COH)Pd(PP)]^+$. NMR ^1H: 9.12 (s, Ha), 8.17 (dd, Hi, ^4J(PHi) = 8.8 Hz, ^5J(HiH7) = 1.0 Hz), 6.59 (dd, H3, ^4J(PH3) = 5.9 Hz, ^4J(H3H5) = 1.0 Hz), 5.00, 4.60 (m, $H_{ferrocene}$). NMR $^{31}P-\{^1H\}$: 31.40 (s).

2.2.1.5. [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-C2,N](Cl)}$_2${μ-trans(Ph_2PCH=$CHPPh_2$)}] (**7**).

Yield: 20%. *Anal.* Found: C, 54.2; H, 4.7; N, 2.6. $C_{54}H_{54}Cl_2N_2O_2P_2Pd_2\cdot(Me_2CO)_{0.85}$ requires: C, 54.4; H, 4.6; N, 2.3%. IR: ν(C=O): 1697m, ν(C=N): 1619m. FAB Mass: 1073 $[M-Cl]^+$, 1045 $[M-Cl-COH]^+$, 716 $[LPd(PP)]^+$, 687[(L-COH)Pd(PP)]$^+$. NMR ^1H: 9.20 (s, Ha), 8.18 (dd, Hi, ^4J(PHi) = 8.3 Hz, ^5J(HiH7) = 1.0 Hz), 7.00 (at, CH=C*H*, *N* = 39.5 Hz), 6.81 (dd, H3, ^4J(PH3) = 4.8 Hz, ^4J(H3H5) = 1.0 Hz). NMR $^{31}P-\{^1H\}$: 34.59 (s).

*2.2.1.6. [{Pd[4-(COH)C$_6$H$_3$C(H)=N(Cy)-C2,N](Cl)}$_2$(μ-Ph$_2$PCCPPh$_2$)] (**8**).* Yield: 50%. *Anal.* Found: C, 58.7; H, 4.6; N, 2.4. $C_{54}H_{52}Cl_2N_2O_2P_2Pd_2$ requires: C, 58.6; H, 4.7; N, 2.5%. IR: ν(C=O): 1698s, ν(C=N): 1626m. FAB Mass: 1106 $[M]^+$, 714 $[LPd(PP)]^+$. NMR ^{1}H: 9.24 (s, Ha), 8.12 (dd, Hi, $^4J(PHi) = 8.9$ Hz, $^5J(HiH7) = 1.0$ Hz), 6.92 (dd, H3, $^4J(PH3) = 7.3$ Hz, $^4J(H3H5) = 1.0$ Hz). NMR ^{31}P–{^{1}H}: 14.46(s).

*2.2.2. Syntheses of [Pd{4-(COH)C$_6$H$_3$C(H)=N(Cy)-C2,N}(Ph$_2$PCH$_2$PPh$_2$-P,P)][PF$_6$] (**9**)*

To a solution of **1** (20.00 mg, 0.028 mmol) in acetone (ca. 15 cm^3), dppm (21.56 mg, 0.056 mmol) was added. The mixture was stirred for 2 h at r.t., after which ammonium hexafluorophosphate (13.69 mg, 0.084 mmol) was added, the resultant solution was stirred for a further 1 h, water (ca. 40 cm^3) was added dropwise and the resulting mixture stirred for 2 h. The precipitate formed was filtered off, washed with water (2×5 cm^3) and dried in vacuo. The desired complex was recrystallized from chloroform/*n*-hexane as pale yellow microcrystals. Yield: 92% (43.72 mg). *Anal.* Found: C, 56.3; H, 3.7; N, 1.4. $C_{39}H_{38}F_6NOP_3Pd\cdot(Me_2CO)_2$ requires: C, 56.0; H, 5.2; N, 1.5%. IR: ν(C=O): 1689s, ν(C=N): 1620m. FAB Mass: 704 $[M]^+$, 676 $[M-COH]^+$. NMR ^{1}H: 9.51 (s, Ha), 8.41 (d, Hi, $^4J(P_\alpha Hi) = 7.3$ Hz), 7.09 (m, H3, $^4J(P_\beta H3) = 9.5$ Hz, $^4J(P_\alpha H3) = 7.3$ Hz, $^4J(H3H5) = 1.2$ Hz), 4.31 (dd, CH_2P, $^2J(PH) = 11.8$, 11.2 Hz). NMR ^{31}P–{^{1}H}: −4.98 (d, P$_\alpha$, $^2J(PP) = 65.7$ Hz), −28.16 (d, P$_\beta$). NMR ^{13}C–{^{1}H}: 191.6 (s, COH), 175.4 (m, C=N), 161.6 (dd, C2, $^2J(P_\beta C) = 127.8$ Hz, $^2J(P_\alpha C) = 9.4$ Hz), 154.0 (d, C1, $^3J(P_\beta C) = 2.1$ Hz), 137.0 (dd, C4, $^4J(P_\beta C) = 8.5$ Hz, $^4J(P_\alpha C) = 6.3$ Hz), 136.6 (dd, C3, $^3J(P_\beta C) = 12.7$ Hz, $^3J(P_\alpha C) = 3.5$ Hz), 133.9 (d, C$_o$, $^2J(PC) = 13.5$ Hz), 133.5 (d, C$_o$, $^2J(PC) = 12.8$ Hz), 133.0 (d, C$_p$, $^4J(PC) = 2.8$ Hz), 132.3 (d, C$_p$, $^4J(PC) = 2.8$ Hz),129.8 (d, C$_m$, $^3J(PC) = 12.1$ Hz), 129.5 (s, C5), 128.8 (d, C$_m$, $^3J(PC) = 10.6$ Hz), 128.3 (b, C6), 70.0 (s, C7), 127.5 (dd, C$_i$, $^1J(PC) = 31.6$ Hz, $^2J(PC) = 4.9$ Hz), 124.8 (dd, C$_i$, $^1J(PC) = 50.3$ Hz, $^2J(PC) = 4.9$ Hz), 41.4 (dd, CH_2P, $^1J(P_\alpha C) = 27.7$ Hz, $^1J(P_\beta C) = 20.4$ Hz), 33.2 (s, C8, C12), 24.9 (s, C10), 24.7 (s, C9, C11).

Compounds **10**–**16** were prepared similarly, but using the corresponding diphosphine ligand as appropriate, in a **1**/diphosphine 1:2 molar ratio.

*2.2.2.1. [Pd{4-(COH)C$_6$H$_3$C(H)=N(Cy)-C2,N}{Ph$_2$P(CH$_2$)$_2$PPh$_2$-P,P}][PF$_6$] (**10**).* Yield: 56%. *Anal.* Found: C, 55.7; H, 4.8; N, 1.5. $C_{40}H_{40}F_6NOP_3Pd\cdot(Me_2CO)$ requires: C, 55.9; H, 4.9; N, 1.5%. 2.3. X-ray crystallographic study

Three-dimensional, room temperature X-ray data were collected on a Siemens SMART CCD diffractometer by the omega scan method. Reflections were measured from a hemisphere of data collected of frames each covering 0.3 degrees in omega. Of the 18879 reflections measured, all of which were corrected from Lorentz and polarisation effects and for absorption by semi-empirical methods based on symmetry-equivalent and repeated reflections (max./min. transmissions; 0.87,0.80), 3263 independent reflections exceeded the significance level $|F|/\sigma|F| > 4.0$. The structure was solved by direct methods and refined by full matrix least squares on F^2. Hydrogen atoms were included in calculated positions and refined in riding mode. Refinement converged at a final $R = 0.0588$ ($wR_2 = 0.1310$, for all 7131 unique data; 285 parameters, mean and maximum δ/σ 0.000, 0.000), with allowance for the thermal anisotropy of all non-hydrogen atoms. Minimum and maximum final electron density -0.458 and 1.440 e A^{-3} The structure solution and refinement were carried out using the program package SHELX-97 [16].

3. Results and discussion

For the convenience of the reader the compounds and reactions are shown in Scheme 1. The compounds

Scheme 1.

described in this paper were characterized by elemental analysis (C, H, N), mass spectrometry, and by IR and ^1H, $^{31}P-\{^1H\}$ and (in part) $^{13}C-\{^1H\}$ NMR spectroscopy (data in Section 2).

Reaction of [Pd{4-(COH)C_6H_3C(H)=N(Cy)-*C2*,*N*}-(μ-Cl)]$_2$ (**1**) [13] with bis(diphenylphosphino)methane (dppm), 1,2-bis(diphenylphosphino)ethane (dppe), 1,4-bis(diphenylphosphino)butane (dppb), 1,6-bis(diphenylphosphino)hexane (dpph), 1,1′-bis(diphenylphosphino)ferrocene (dppf), *trans*-bis(diphenylphosphino)-ethene (*trans*-dppe), or bis(diphenylphosphino)acetylene (dppac) in a 1:1 molar ratio, in acetone at room temperature afforded the polinuclear complexes [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-*C2*,*N*](Cl)}$_2$(μ-Ph_2PRPPh_2)] (R: CH_2, **2**; CH_2CH_2, **3**; $(CH_2)_4$, **4**; $(CH_2)_6$, **5**; Fe$(C_5H_4)_2$, **6**; *trans*-CH=CH, **7**; C≡C, **8**) in which the diphosphine is acting as a bridging ligand. The new compounds were air-stable and soluble in the more common solvents, such as toluene, chloroform, acetone or ethanol, and gave satisfactory elemental analysis (see Experimental section). The MS FAB spectra showed similar fragmentation patterns, containing peaks assigned to, among others, $[M]^+$, $[M-Cl]^+$, $[M-Cl-COH]^+$ and $[LPd(PP)]^+$, after consideration of the palladium isotopes [17], thereby confirming the dinuclear (**2**–**5**, **7**, **8**) and trinuclear (**6**) nature of these complexes. The IR spectra showed the shift of the C=N stretch towards lower wavenumbers, as compared to the free Schiff base ligand (1638 vs. ca. 1620 cm^{-1}), indicating N-coordination of the C=N group [18]. A ν(C=O) band in the range 1698–1687 cm^{-1} was assigned to the free formyl group [19]. The $^{31}P-\{^1H\}$ NMR spectra showed a singlet in the range δ 38–30, shifted to higher frequency from the spectrum of the free phosphine, in agreement with phosphorus coordination to the metal center and indicated that the two phosphorus nuclei are equivalent [20].

In the ^1H NMR spectrum for complexes **3**–**8** the COH group gave rise to a singlet ca. δ 9.20, shifted to lower field from the starting product, ca. 0.8 ppm, due to the shielding effect of the phosphine phenyl rings, in agreement with a phosphorus *trans* to nitrogen arrangement [21]. The HC=N resonance ca. δ 8.10 appeared as a doublet of doublets due to coupling to the ^{31}P nucleus [^4J(PHi) ca. 8.5 Hz] and with the NC*H* proton atom of the cyclohexyl ring [$^5J(HiH7) = 1.0$ Hz]. The H6 and H5 proton resonances were overlapped and could not be adequately assigned, but in compound **2** the latter could be clearly distinguished as a doublet of doublets at δ 7.38 by coupling to H3 and H4. A doublet of doublets at δ 6.92–6.59 was assigned to H3, with coupling to the phosphorus nucleus [$^4J(PH3) = 4.8$–7.3 Hz]. This resonance was shifted to lower field from the starting product ca. 1.2 ppm, due to the shielding effect of the phosphine phenyl rings. The non-phenyl proton resonances of the diphosphine ligands could be unambigu-

ously assigned: the CH_2P resonances appeared as a triplet at δ 5.03 and δ 4.51 in compounds **2** and **3**, respectively [^2J(PH) = 13.4, 10.8 Hz, also respectively], and as a multiplet ca. δ 4.50 in compounds **4** and **5**. For complex **6** two multiplets at δ 5.00 and δ 4.60 were assigned to the ferrocene protons, and in complex **7** the AA′XX′ spin system of the PCH=C*H*P group gave rise to an apparent triplet at δ 7.00 [N = 39.5 Hz].

The ^{13}C–{^{1}H} NMR spectrum of compound **4** showed a doublet at δ 170.0 and two singlets at δ 157.9 and δ 154.4 assignable to the HC=N, C1 and C2 carbons, respectively, downfield shifted from the spectrum of the free ligand (ca. 12, 20 and 26 ppm, also respectively) [22], thereby confirming that cyclometallation was maintained [13,23]. The C3 and C4 resonances appeared as doublets at δ 135.7 and δ 135.3, respectively, by coupling to the phosphorus nuclei [^3J(PC3) = 9.9 Hz, ^4J(PC4) = 5.0 Hz]. Two doublets at δ 29.7 and δ 26.4 were assigned to the *C*H$_2$P and *C*H$_2$CH$_2$P carbon atoms, respectively [^1J(PC) = 33.4 Hz, ^2J(PC) = 17.8 Hz, respectively]. The X-ray crystal structure determination of compound **2** (see below) confirmed the spectroscopic data.

Treatment of the chloro-bridged complex **1** with dppm, dppe, dppb, dpph, dppf, *cis*-dppe, 1,2-bis(diphenylphosphino)benzene (1,2-dppb) or bis(diphenylphosphine)amine (dppa) in a 1:2 molar ratio in the presence of NH_4PF_6 yielded the cyclometallated compounds [Pd{4-(COH)C$_6$H$_3$C(H)=N(Cy)-*C2*,*N*}(Ph$_2$PRPPh$_2$-*P*,*P*)][PF$_6$] (R: CH$_2$, **9**; CH$_2$CH$_2$, **10**; (CH$_2$)$_4$, **11**; (CH$_2$)$_6$, **12**; Fe(C$_5$H$_4$)$_2$, **13**; 1,2-C$_6$H$_4$, **14**; *cis*-CH=CH, **15**; NH, **16**). The new compounds were air-stable and soluble in the more common solvents. The conductivity data (125–150 Ω^{-1} cm^2 mol^{-1} in 10^{-3} mol dm^{-3} solutions in dry acetonitrile) showed them to be 1:1 electrolytes [24]. The MS FAB spectra showed, among others, the corresponding peaks assigned to $[M]^+$, $[M-\mathrm{COH}]^+$ and/or $[M-\mathrm{Cy}]^+$ (see Section 2). In the IR spectrum a broad and strong band at 850 cm^{-1} arising from the PF_6^- counterion [19] was observed.

The ^{31}P–{^{1}H} NMR spectra showed two doublets, suggesting the two phosphorus atoms to be non-equivalent. The assignment of the doublets was made on the assumption that a ligand of greater *trans* influence shifts the resonance of the phosphorus atoms *trans* to it to lower frequency [20]. The ^{31}P chemical shifts were clearly influenced by ring size [25], and the corresponding data for compounds **10**–**16** are summarized in Table 1. The four-membered ring compound **9** gave a negative Δ_R, as well as the larger ring compounds **11** and **12**. The five-membered ring compounds **10**, **14** and **15** gave a positive Δ_R. In the case of compounds **13** and **16** the effect of the ferrocene moiety and the heteroatom in the phosphine backbone gave a slightly positive Δ_R.

Table 1
^{31}P NMR parameters

	$\delta(P_\alpha)$	Δ_R [a]
9	−4.98	−44.28
10	61.24	+21.94
11	32.19	−7.11
12	33.12	−6.18
13	39.93	+0.63
14	55.89	+16.69
15	63.85	+24.55
16	44.40	+5.10

[a] Difference respect to an equivalent phosphorus in a non-chelated analogue, [(C–N)Pd(PPh$_3$)(Cl)] (PPh$_3$ *trans* to nitrogen, δ 39.30 ppm), Ref. [13].

The singlet signal of the CO*H* resonance was shifted to lower field from the starting product by 0.3–0.7 ppm due to the shielding effect of the P*Ph*$_2$ groups *cis* to carbon. This was most noteworthy in compounds **11**–**13**, due to larger chelate ring size. The HC=N resonance in the ^{1}H NMR spectra ca. 8.40 ppm appeared as a doublet due to coupling with the ^{31}P nucleus *trans* to nitrogen. The H6 resonance was overlapped and could not be assigned, but the H5 and H3 resonances were clearly distinguished in some complexes (see Section 2). Thus, a doublet of doublets at δ 7.85 (**10**) and δ 7.74(**14**) was assigned to the H5 proton, and a multiplet at δ 7.15–6.14 was assigned to H3, coupled to both phosphorus nuclei. Selective decoupling experiments allowed the correct assignment of the corresponding coupling constants, e.g. for compound **9**, *trans*-^4J(PH3) = 9.5 Hz, *cis*-^4J(PH3) = 7.3 Hz.

For complexes **9** and **16** the ^{13}C–{^{1}H} NMR data were consistent with the proposed structure (see Section 2). A multiplet, a doublet of doublets and a doublet ca. δ 175, δ 161 and δ 154 were assigned to the C=N, C2 and C1 carbon atoms, respectively, coupled to phosphorus. These resonances were shifted downfield from the starting product ca. 17, 33 and 16 ppm, also respectively. In the case of the C2 resonance, a large coupling constant to the phosphorus nucleus *trans* to carbon was observed ($^3J(P_\beta C)$ = 127.8 Hz). The diphosphine phenyl carbon resonances, as well as those of the cyclohexyl ring, could also be unambiguously assigned (see Experimental Section).

4. Molecular structure of complex 2

Suitable crystals of the title compound were grown by slowly evaporating a chloroform/*n*-hexane solution. The labeling scheme for the compound is shown in Fig. 1. The crystals consist of discrete molecules, separated by normal van der Waals distances. Crystallographic data and selected interatomic distances and angles are listed in Tables 2 and 3.

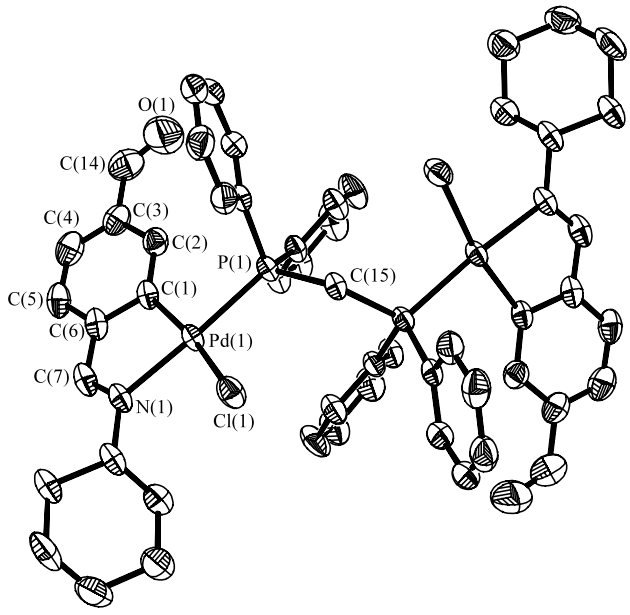

Fig. 1. Molecular structure of [{Pd[4-(COH)C_6H_3C(H)=N(Cy)-*C2,N*](Cl)}$_2$(μ-$Ph_2PCH_2PPh_2$)] (**2**), with labeling scheme. Hydrogen atoms have been omitted for clarity.

The crystal structure of **2** comprises a half molecule per asymmetric unit, and exhibits C_2 symmetry about the central methylene PCH_2P group. The four-coordinated palladium(II) is bonded to an adjacent *ortho*-carbon atom and to the nitrogen atom of the imine group of the deprotonated Schiff base ligand and to a chlorine atom (*trans* to C2). A phosphorus atom from the diphosphine ligand which bridges the two metal centers, completes the metal coordination sphere. The sum of angles about palladium is 360.26°, with the distortion most noticeable in the somewhat reduced 'bite' angle of the cyclometallated moiety consequent upon chelation. The requirements of the five-membered ring forces the bond angle N(1)–Pd(1)–C(1) to 80.43(17)°. The geometry around the palladium atom is slightly distorted square-planar, the mean deviation from the least squares plane (plane 1: Pd1, C1, N1, P1, Cl1) is 0.0916 Å.

Table 3
Selected bond lengths (A) and bond angles (°) for complex **2**

Bond lengths			
Pd(1)–C(1)	2.014(5)	C(6)–C(7)	1.431(7)
Pd(1)–N(1)	2.111(3)	N(1)–C(7)	1.271(6)
Pd(1)–P(1)	2.268(1)	O(1)–C(14)	1.166(8)
Pd(1)–Cl(1)	2.393(1)	P(1)–C(15)	1.844(3)
C(1)–C(6)	1.414(6)		
Bond angles			
C(1)–Pd(1)–N(1)	80.43(17)	N(1)–C(7)–C(6)	119.3(4)
C(1)–Pd(1)–P(1)	93.52(13)	C(1)–C(6)–C(7)	115.3(5)
P(1)–Pd(1)–Cl(1)	93.35(4)	C(6)–C(1)–Pd(1)	112.4(4)
N(1)–Pd(1)–Cl(1)	92.96(12)	C(15)–P(1)–Pd(1)	115.63(6)
C(7)–N(1)–Pd(1)	112.5(3)	P(1)–C(15)–P(1)#1	121.6(3)

The palladium–nitrogen bond length in the metallacycle, 2.111(3) Å, is longer than the predicted single bond value of 2.011 Å, based on the sum of covalent radii for nitrogen(sp^2) and palladium, 0.701 and 1.31 Å, respectively [26], and reflects the *trans* influence of the phosphorus atom [27]. The palladium–carbon bond length, 2.014(5) Å, is within the expected value of 2.081 Å (based on the sum of the covalent radii for carbon(sp^2) and palladium, 0.771 and 1.31 Å, respectively), but longer than those found in related complexes where partial multiple-bond character of the Pd–C bond was proposed [11,28]. The Pd–P bond distance, 2.268(1) Å, is shorter than the sum of the single bond radii for palladium and phosphorus (2.41 Å), suggesting partial double bond character similar to others reported earlier [29,30]. The Pd–Cl bond length, 2.393(1) Å, is consistent with Pd–Cl distances found in related species [30,31] but longer than the sum of the covalent radii (2.30 Å) as a consequence of the *trans* influence of the C(phenyl) carbon.

The mean deviations from the least squares planes determined for the metallacycle (plane 2: Pd1, C1, C6, C7, N1) and the metallated phenyl ring (plane 3: C1, C2, C3, C4, C5, C6) are 0.0122 and 0.0027 Å, respectively. The angle between these planes is 5.3°. The angles between plane 1 and the previous planes are: plane 1/plane 2: 6.2°, and plane 1/plane 3: 11.4°.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic

Data Centre, CCDC No. 185113 for compound **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: mailto: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

sium methoxide with subsequent distillation. Toluene (Merck, *p.a.*) was distilled after refluxing with $LiAlH_4$.

IR spectra of Nujol mulls were obtained with a Perkin–Elmer FT-IR 1720 X spectrometer. Metal ratio in the samples was determined at the Arrhenius Laboratory, Stockholm University using a JEOL JSM-820 scanning microscope (SEM), supplied with a Link AN-10000 energy dispersive spectrometer (EDS). Mass spectra (electron beam ionization, direct probe introduction) were recorded using JEOL JMS-SX/SX-102A mass-spectrometer. The determination of carbon and hydrogen contents was carried out by Mikrokemi AB, Uppsala, Sweden, using the conventional organic microanalysis technique.

The alkoxides, $Nb_2(OMe)_{10}$ and $Ta_2(OMe)_{10}$, used in this work as starting materials for the synthesis of bimetallic complexes, were prepared by anodic oxidation of the corresponding metals in methanol and purified according to conventional techniques [9]. Rhenium(VII) oxide (99.9+%) was purchased from Aldrich.

2.1. Synthesis of $(Nb,Ta)_2(OMe)_8(ReO_4)_2$ (*I*)

Solutions of $Nb(OMe)_5$ (0.131 g, 0.529 mmol) in 3.5 ml of $C_6H_5CH_3$ and $Ta(OMe)_5$ (0.182, 0.543 mmol) in 2.5 ml of $C_6H_5CH_3$ were mixed. Re_2O_7 (0.273 g, 0.564 mmol) was added to the obtained solution upon stirring. No color changes at the initial stage were observed. Slow dissolution of Re_2O_7 occurred and the solution gradually became brownish-pink. Slight brownish coloration of Re_2O_7 particles and the formation of a small amount of nearly colorless crystals were observed. At the end of the process, after dissolution of almost all the Re_2O_7 (40 min), the mixture was heated to 60 °C for 10 min. The solution was cooled to room temperature (r.t.), then to −30 °C for crystallization. After 3 days the solution was decanted and the crystalline product (light pink prismatic platelets) was dried in vacuum. Yield: 0.411 g (76%). IR, cm^{-1}: 1138 s br, 998 m, 945 sh, 935 s (ν-Re=O), 896 sh, 818 s br (ν-Re=O···Nb(Ta), compare [6,8]), 723 w, 618 w, 569 m, 514 s. MS, *m/z* (I,%), interpretation: 641(1.0), $Ta_2(OMe)_9^+$, 595(1.0), $Ta_2O(OMe)_7^+$, 553(1.0), $TaNb(OMe)_9^+$, 522(0.5), $TaNb(OMe)_8^+$, 507(1.1), $TaNbO(OMe)_7^+$, 476(0.5), $TaNbO(OMe)_6^+$, 461(0.6), $TaNbO_2(OMe)_5^+$, 305(19.3), $Ta(OMe)_4^+$, 281(1.7), $ReO_2(OMe)_2^+$, 274(3.6), $Ta(OMe)_3^+$, 266(61.4), $ReO_3(OMe)^+$, 265(51.5), $ReO_3(OCH_2)^+$, 251(2.7), ReO_4^+, 249(2.1), $Re(OMe)_2^+$, 248(1.6), $Re(OCH_2)(OMe)^+$ and $Nb(OMe)_5^+$, 247(1.8), $Nb(OMe)_4(OCH_2)^+$, 238(6.5), $Re(OH)_3^+$, 237(7.5), $ReO(OH)_2^+$, 236(100), $ReO_2(OH)^+$, 235(32.9), ReO_3^+, 234(59.3), $ReO(OMe)^+$, 233(17.3), $ReO(OCH_2)^+$, 231(1.9), $TaO(OH)_2^+$, 220(17.0), $ReO(OH)^+$, 219(61.6), ReO_2^+, 217(50.8), $Nb(OMe)_4^+$, 204(4.8), $Re(OH)^+$, 203(22.0), ReO^+ and $Nb(OMe)_3(OH)^+$, 187(10.5), Re^+, 186(1.8), $Nb(OMe)_3^+$, 172(10.1), $Nb(OMe)_2(OH)^+$, 171(8.4), $NbO(OMe)_2^+$, 157(2.9), $NbO(OH)(OMe)^+$, 155(2.4), $Nb(OMe)_2^+$, 141(1.8), $Nb(OMe)(OH)^+$, 140(1.5), $NbO(OMe)^+$, 139(2.5), $NbO(OCH_2)^+$, 125(2.6), NbO_2^+.

2.2. Synthesis of $(Nb,Ta)_4O_2(OMe)_{14}(ReO_4)_2$ (*II*)

Solutions of $Nb(OMe)_5$ (0.140 g, 0.565 mmol) in 3.5 ml of $C_6H_5CH_3$ and $Ta(OMe)_5$ (0.194, 0.577 mmol) in 2.5 ml of $C_6H_5CH_3$ were mixed. Re_2O_7 (0.276 g, 0.570 mmol) was added to the obtained solution upon stirring. No color changes at the initial stage were observed. Upon slow dissolution of Re_2O_7, the solution became light pink. After 10 min of stirring, the mixture was heated. The solution became reddish-brown and Re_2O_7 changed color to black. The mixture was refluxed for 15 min. The formation of a black non-crystalline residue as a by-product was observed (EDS analysis showed the by-product to comprise of Re as the major component, and Nb and Ta in minor quantities, 5–7% atom). The solution was cooled to r.t., then to −30 °C for crystallization. After 3 days the solution was decanted and a crystalline product (thick needle shaped crystals brownish-pink in color) was dried in vacuum. Yield: 0.306 g (71% on $M(OMe)_5$ and 35% on Re_2O_7). IR, cm^{-1}: 1124 s br, 998 m w, 978 w, 931 s (ν-Re=O), 893 w, 808 s (ν-Re=O···Nb(Ta), compare [5]), 735 sh, 722 m, 569 m, 512 s. 2.3. Alternative technique for the synthesis of $(Nb,Ta)_4O_2(OMe)_{14}(ReO_4)_2$ (II)

Solutions of $Nb(OMe)_5$ (0.132 g, 0.532 mmol) in 3.5 ml of $C_6H_5CH_3$ and $Ta(OMe)_5$ (0.178, 0.531 mmol) in 2.5 ml of $C_6H_5CH_3$ were mixed. Re_2O_7 (0.139 g, 0.288 mmol) was added to the obtained solution upon stirring. No color changes at the initial stage were observed. Upon slow dissolution of Re_2O_7, a brownish-violet color of the latter and precipitation of a small amount of lightly colored pink fine crystals were observed. After approximately 20 min of stirring, the solution was light pink in color. After 40 min of stirring most of the Re_2O_7 was dissolved and further formation of fine crystalline precipitate occurred. After 70 min the color of the solution was light orange–pink and almost all of the Re_2O_7 was dissolved. After 80 min the mixture was heated and the solution became brownish–pink. The mixture was refluxed for 15 min. In the course of the heating the dissolution of the initially formed crystals occurred. At the end of refluxing the solution became dark reddish-brown. The solution was cooled to r.t., then to −30 °C for crystallization. After 3 days the solution was decanted and the crystalline product (thick needle shaped crystals brownish-pink in color) was dried in vacuum. Yield: 0.258 g (64%). IR and MS data were identical to those reported above.

2.4. Crystallography

The crystal data and experimental conditions are shown in Table 1. The data were collected using a SMART CCD 1K diffractometer at 22 °C. All calculations were performed on an IBM PC using the SHELXTL-NT [10] program package. The absorption correction has been introduced for both experiments using Bruker SADABS program. Both structures were solved by direct methods. The positions of metal atoms were obtained from the initial solution and refined first in isotropic and then anisotropic approximation. The occupancy factors for all the metal atom positions in the structures of compounds **I** and **II** were refined in supposition that they can be occupied with equal opportunity by both niobium and tantalum atoms; the total occupancy for each position being 1.0. The values obtained are within experimental errors in agreement with those obtained by EDS-analysis. The positions of all other non-hydrogen atoms were obtained from difference Fourier syntheses and refined first in isotropic and then anisotropic approximation. The positions of hydrogen atoms were calculated geometrically and included into the final refinement in isotropic approximation; the thermal parameters for H-atoms were taken as $U_{iso} = 1.50U_{eq}(C)$, where $U_{eq}(C)$ is the equivalent parameter for the carbon atom to which the hydrogen atom is attached.

3. Results and discussion

3.1. Reaction pathways

The reaction of the alkoxylation of rhenium heptoxide, Re_2O_7, has recently been proved to provide a facile access to bimetallic oxoalkoxide derivatives of rhenium [5,6] and it appeared attractive to investigate its potential for the preparation of trimetallic compounds, applying a bimetallic alkoxide as reactant. We have chosen in this purpose the bimetallic methoxide of niobium and tantalum formed easily on mixing the two homometallic species in hydrocarbon media [7] and existing due to the extraordinary likeness of the coordination geometries of the two metals, which permits to consider it as a product of isomorphous substitution of one metal in the structure with the other.

Carrying out of this reaction at ambient temperature was found to lead practically exclusively to compound **I**, independently of the ratio of the reactants:

$$Re_2O_7 + NbTa(OMe)_{10} \rightarrow (Nb,Ta)_2(OMe)_8(ReO_4)_2\ (\mathbf{I}) + \ldots$$

It may be supposed that the reaction pathway includes in this case, first, some partial oxidation of the methoxide ligands producing water that leads to formation of perrhenic acid, which produces compound **I** via the chemical modification of the bimetallic alkoxide:

$$Re_2O_7 + H_2O \rightarrow 2HReO_4$$

$$2HReO_4 + NbTa(OMe)_{10} \rightarrow (Nb,Ta)_2(OMe)_8(ReO_4)_2 + 2MeOH$$

In favor of this pathway speaks the quite high, but far not quantitative, yield of compound **I**, and the absence of the intensive coloration, indicating otherwise the formation of low-valent rhenium alkoxides in the course of the alkoxylation [5,6].

The processes occurring on heating follow evidently the mechanism proposed earlier [5,6] for the alkoxylation of rhenium heptoxide, but the elevated temperature leads to deeper condensation of the products resulting in formation of a more oxo-substituted tetranuclear core of compound **II**. It is to be noted also that compound **I** formed in the reaction mixture at low temperature can on further heating undergo an almost quantitative thermal condensation in solution with an excess of $NbTa(OMe)_{10}$ and provide **II** with a significantly increased yield in relation to Re_2O_7. The condensation occurs supposedly via partial oxidation of the methoxide ligand by the perrhenate ligand present, which provides the water necessary for this process.

It is important to note that the metal atom content in the product corresponds perfectly to that in the reaction media and the Nb:Ta = 1:1 ratio is conserved in the trimetallic products obtained opening the prospect of the application of these precursors in the preparation of trimetallic oxide and alloy materials.

3.2. Molecular structures

Unfortunately, both **I** and **II** are almost insoluble in common organic solvents at room temperature. On heating, they remain unchanged in hydrocarbons (toluene, hexane), while in methanol the crystals turn slowly dark, supposedly because of the reduction of rhenium(VII) by the alcohol, but still no transfer into solution of the metal-containing species could be observed. This precluded the application of NMR for the estimation of the possible molecular structures in solution (*in statu nascendi*) and those discussed below are the solid state ones obtained by the X-ray single crystal studies.

The structure of **I** (Fig. 1) turned out to be very close to the structures of its bimetallic analogues, $M_2(OMe)_8(ReO_4)_2$, M = Nb, Ta [6]. Its centrosymmetric molecules are pairs of octahedra sharing a common (μ-OR)$_2$ edge, the perrhenate substituents being situated in the axial positions. The oxo-bridging bond to the rhenium atom is as long M(1)–O(2) 2.12(2) Å as that in the structure of the tantalum-only derivative (Ta(1)–O(5) 2.115(16) Å) and has evidently also a decreased multiplicity. The terminal alkoxide ligand situated in the *trans*-position to it has quite logically a significantly shortened M(1)–O(7) 1.78(3) distance (compared to (Ta(1)–O(4) 1.814(19) Å in the tantalum-only analogue) with the multiplicity increased due to the p_π–d_π interaction. The bridging M–O distances are noticeably asymmetric and significantly longer than the terminal

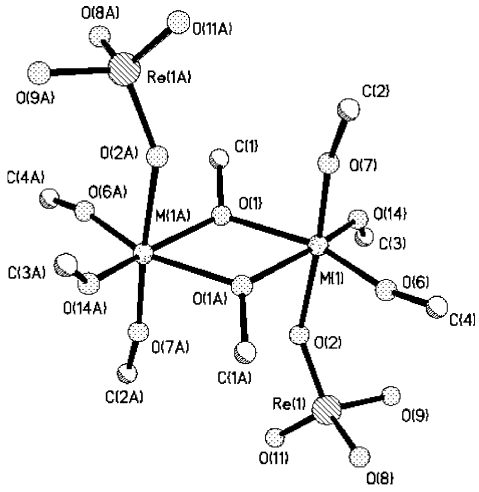

Fig. 1. Molecular structure of $(Nb,Ta)_2(OMe)_8(ReO_4)_2$ (**I**).

M–O bonds (M(1)–O(1) 2.13(2), M(1)–O(1)# 2.02(2) Å in **I** compared to Ta(1)–O(1) 2.08(2), Ta(1)–O(1)# 2.10(2) Å in $Ta_2(OMe)_8(ReO_4)_2$ [6]. The structure of **I** contains only one symmetrically independent position for the quinquevalent metal present, and its unit occupancy is achieved by 50% of niobium and by 50% by tantalum atoms within the standard deviations for this determination (Tables 2 and 3).

The structure of compound **II** (see Fig. 2) is built up of centrosymmetric molecules that contain a planar tetranuclear $M_4(\mu\text{-}O)_2(\mu\text{-}OMe)_4$ core, where M = Nb or Ta, coordinating 10 methoxo and 2 perrhenate ligands. The M–O(Me) distances fall into the range usually observed and are very close to those observed in the structures of the bimetallic analogues based on niobium- or tantalum-only cores [5]. The most interesting feature of this structure is the non-uniform distribution of niobium and tantalum between the two symmetrically

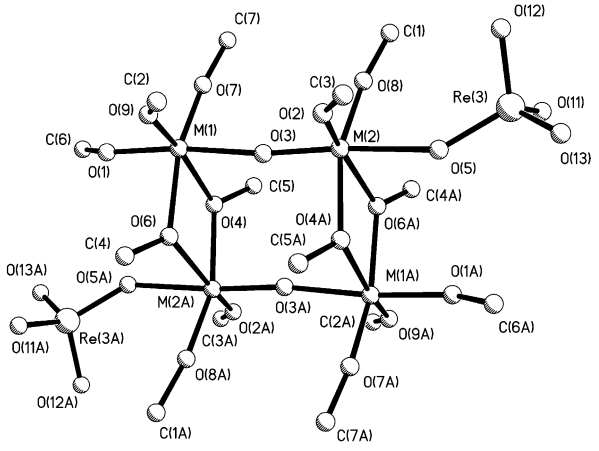

Fig. 2. Molecular structure of $(Nb,Ta)_4O_2(OMe)_{14}(ReO_4)_2$ (**II**).

independent positions: the M(1) position, surrounded by five alkoxide and one bridging oxoligand, turns out to be occupied by tantalum to 70% and niobium by 30% within the accuracy of the experiment, while the M(2) one, connected to four alkoxide, one bridging oxo- and one terminal perrhenate ligand, is in contrast richer in niobium (70%) and poorer in tantalum (30%). This difference can be explained by the difference in the chemical bonding for the atoms occupying these positions: the metal atom in M(1) is involved in the bonding of predominantly σ-character—even the bond to the oxoligand is a strongly elongated one (M(1)–O(3) 2.043(11) Å), which is thermodynamically preferential for the heavier tantalum atom. The metal atom in the M(2) position has a very much shorter distance to the bridging oxo-ligand (M(2)–O(3) 1.791(11) Å), which indicates a considerable π-input in its nature that can easier be made by a light niobium atom.

The difference in composition and molecular structures between compounds **I** and **II** is reflected also in the differences between their mass-spectra. Both compounds undergo a complete decomposition on evaporation. The preparative investigation of the thermal properties of **I** and **II** in vacuum showed the deposition of two different products on the cool parts of the glass vessel at the initial stage (135 °C, 10^{-2} mm Hg) of the sublimation process, namely the white film of a less volatile product and the reddish purple one of a more volatile product. The latter became dark on further heating and resembled the sublimation product of the $Re_4O_6(OMe)_{12}$ [5]. The formation of two different sublimation products should have occurred through the separation of rhenium- and niobium and tantalum-containing volatile methoxide species upon the decomposition of the complex compound. The mass-spectral investigation confirmed this observation as no heterometallic species containing rhenium together with niobium or tantalum could be observed in the spectra. The 'volatility' (total of intensities of different ions in the spectra) appears generally to be higher for **II**, containing a smaller number of oxidizing perrhenate ligands. It is also to be noted that the intensity of the tantalum-containing ions is relatively slightly but noticeably higher for **II** compared to **I**, reflecting thus the placement of predominantly tantalum atoms in the position not connected directly to the perrhenate ligands hindering volatility.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 185852 and 185853 for compounds **I** and **II**, respectively. Copies of this information may be obtained free of charge from The Director, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

2. Experimental

2.1. Material and procedures

Experimental work was carried out under an atmosphere of dry nitrogen. All manipulations were conducted using Schlenk techniques, employing a vacuum/nitrogen line or using a glove box under an atmosphere of nitrogen. Solvents were distilled from K or Na suspension and kept in Schlenk flasks with K or Na mirror or else dry molecular sieves. NMR spectra were recorded at 100.62 MHz (^{13}C) and 148.97 MHz (^{119}Sn) using a Bruker DPX-400 spectrometer equipped with an 89 mm wide-bore magnet. ^{13}C shifts are reported relative to $SiMe_4$ and ^{119}Sn shifts relative to $SnMe_4$. ^{119}Sn Mössbauer spectra were collected with samples kept at 77 K using a $CaSnO_3$ source kept at room temperature. All spectra were fitted by means of Lorentzian line shapes. The infrared spectra were recorded with samples pressed as CsI pellets on a Perkin–Elmer 283B spectrometer in the 4.000–200 cm^{-1} range. Carbon, nitrogen and hydrogen analyses were performed on a Perkin–Elmer PE-2400 CHN-analyses using tin sample-tubes. Chlorine and bromine analyses were performed by means of X-ray fluorescence in Rigaku-Geigerflex spectrophotometer with samples pressed as borax plates. Tin analysis was carried out using a Hitachi Z-8200 atomic absorption spectrophotometer (Sn lamp, $\lambda_{max} = 224.6$ nm, N_2O/acetylene flame).

2.2. X-ray structure determination of **1**, **2**, **3** and **6**

The data were collected using a Siemens P4 diffractometer equipped with a SMART CCD area detector; graphite-monochromated Mo Kα. The structures were solved by direct methods with SHELXTL version 5.0 [10] and the refinements were carried out using SHELXTL96 software [11]. Further details are given in Table 1. Tables of atom positions and thermal parameters have been deposited with the CCDC. All non-H atoms were anisotropic. Methyl groups were fixed at idealised geometry but with the torsion angle defining the H atom positions refined and U_{iso}(H) equal to $1.5U_{eq}$(C). The ORTEP drawing shows the non-H atoms as 50% thermal vibration ellipsoids.

2.3. Synthesis of [Ru(η-C_5H_5)(PPh_3)$_2N_3$]

To a Schlenk flask containing [Ru(η-C_5H_5)(PPh_3)$_2$Cl] (0.5 g, 0.69 mmol), under an atmosphere of dry N_2, dissolved in 100 ml of ethanol, was added at once NaN_3 (0.67 g, 10.33 mmol). The resultant mixture was stirred and refluxed for 6 h. Thus, the solvent was partially removed under vacuum to 40 ml and an orange precipitate was obtained. After filtration the solid was washed with *n*-hexane and re-crystallised in a mixture of dichloromethane and *n*-hexane. Yield 85%. M.p. (dec.) 118–120. ^{1}H NMR ($CDCl_3$, 400.13 MHz), δ 4.2 (s, C_5H_5), 6.7–7.4 (m, C_6H_5); ^{13}C{^{1}H} NMR ($CDCl_3$, 100.61 MHz), δ 81.3 (s, C_5H_5), 127.6–131.2 (m, C_6H_5); ^{31}P{^{1}H} ($CDCl_3$, 161,98 MHz), δ 42.4 (s, PPh_3). IR (CsI) ν(N_3) 2005, δ(N_3) 675 ν(Ru–N) 390 cm^{-1}. Elemental analysis for $C_{41}H_{35}N_3P_2Ru$, calc. (found): C, 66.18 (67.20); H, 4.65 (4.81); N, 5.77 (5.73)%.

2.4. Synthesis of [Ru(η-C_5H_5)(dppe)N_3]

To a solution of [Ru(η-C_5H_5)(dppe)Cl] (0.25 g, 0.42 mmol) and 50 ml of ethanol in a Schlenk flask, under an atmosphere of dry N_2, was added at once NaN_3 (0.25 g, 2.5 mmol). After 6 h of stirring and reflux the solvent was partially removed under vacuum to 20 ml and an orange precipitate was obtained. Following filtration, the solid was washed with *n*-hexane and recrystallised in a mixture of CH_2Cl_2 and *n*-hexane. Yield 92%. M.p. (dec.) 245–255. ^{1}H NMR ($CDCl_3$, 400.13 MHz), δ 2.2 (m, CH_2), 4.5 (s, C_5H_5), 7,4–7.8 (m, C_6H_5); ^{13}C{^{1}H} NMR ($CDCl_3$, 100.61 MHz), δ 31.0 (m, CH_2), 81.9 (s, C_5H_5), 127.8–135.8 (m, C_6H_5); ^{31}P{^{1}H} ($CDCl_3$, 161.98 MHz), δ 81.5 (s, dppe). IR (CsI) ν(N_3) 2000, δ(N_3) 680 ν(Ru–N) 393 cm^{-1}. Elemental analysis for $C_{31}H_{29}N_3P_2Ru$, calc. (found): C, 59.62 (61.28); H, 4.10 (4.18); N, 6.59 (6.62)%.

2.5. Synthesis of [Ru(η-C_5H_5)(PPh_3)$_2SnF_3$]

To a Schlenk flask containing [Ru(η-C_5H_5)-(PPh_3)$_2N_3$] (0.47 g, 0.64 mmol), under an atmosphere of dry N_2, dissolved in 100 ml of ethanol, was added at once SnF_2 (0.20 g, 1.28 mmol). The resultant mixture was stirred and refluxed for 6 h. Thus, a yellow solution was separated by filtration from a colourless solid. Then the yellow solid was washed with *n*-hexane and recrystallised in a mixture of CH_2Cl_2 and *n*-hexane. Yield 70%. M.p. 199–202. ^{1}H NMR ($CDCl_3$, 400.13 MHz), δ 4.5 (s, C_5H_5), 7.1–7.4 (m, C_6H_5); ^{13}C{^{1}H} NMR ($CDCl_3$, 100.61 MHz), δ 81.3 (s, C_5H_5), 128.2–138.5 (m, C_6H_5); ^{31}P{^{1}H} ($CDCl_3$, 161.98 MHz), δ 48 (s, PPh_3) {$^2J_{(^{31}P-^{117}Sn)} = 480$ Hz, $^2J_{(^{31}P-^{119}Sn)} = 500$ Hz}, ^{119}Sn{^{1}H} ($CDCl_3$, 149.21 MHz), δ −357 (qt, SnF_3) {$^1J_{(^{19}F-^{119}Sn)} = 3714$ Hz, $^2J_{(^{31}P-^{119}Sn)} = 500$ Hz}. ^{119}Sn Mössbauer: isomer shift (IS) 1.53 mm s^{-1}, QS 2.17 mm s^{-1}. IR (CsI): ν(Sn–F) 490 cm^{-1}. Elemental analysis for $C_{41}H_{35}F_3P_2RuSn$, calc. (found): C, 54.22 (54.86); H, 3.44 (3.57); Sn, 13.18 (13.70)%.

2.6. Synthesis of [Ru(η-C_5H_5)(PPh_3)$_2SnCl_3$]

Was similarly prepared employing [Ru(η-C_5H_5)-(PPh_3)$_2$Cl] (0.35 g, 0.52 mmol) and $SnCl_2$ (0.09 g, 0.52

IR (CsI): ν(Sn–Cl) 276 and 291 cm^{-1}. Elemental analysis for $C_{31}H_{29}Cl_3P_2RuSn$, calc. (found): C, 47.15 (46.39); H, 3.70 (3.65); Cl, 13.46 (13.38); Sn, 15.03 (15.15)%.

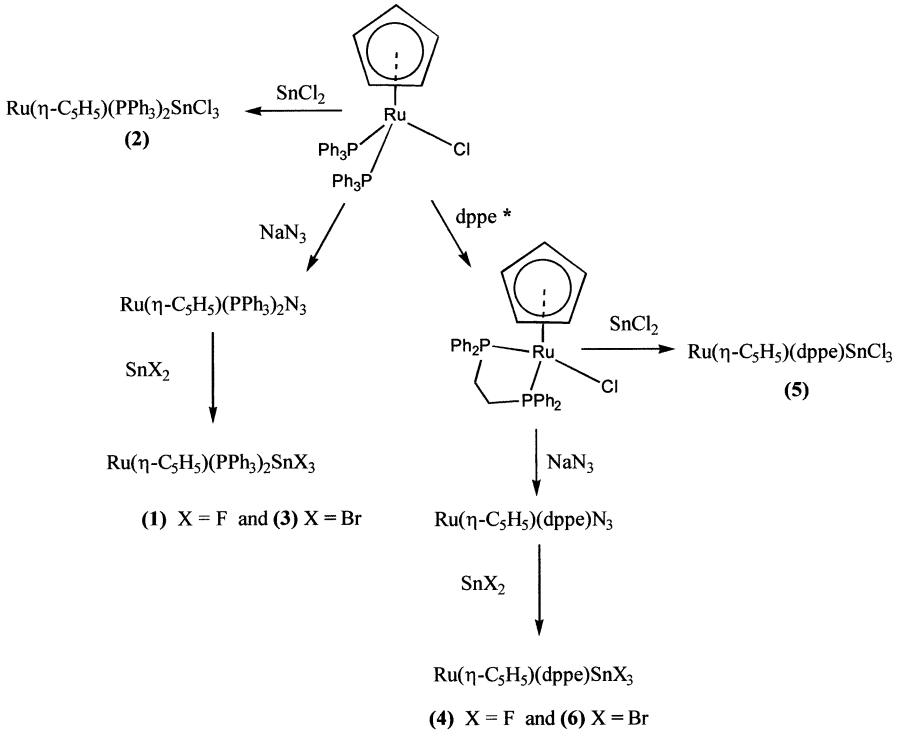
2.10. Synthesis of [Ru(η-C_5H_5)(dppe)$SnBr_3$]

Synthesised in a similar way using [Ru(η-C_5H_5)(dppe)N_3] (0.22 g, 0.36 mmol) and $SnBr_2$ (0.20 g, 0,72 mmol). Yield 82%. M.p. 253–255. ^{1}H NMR ($CDCl_3$, 400.13 MHz), δ 2.2–3.3 (m, CH_2), 4.9 (s, C_5H_5), 7.2–7.8 (m, C_6H_5); $^{13}C\{^1H\}$ NMR ($CDCl_3$, 100.61 MHz), δ 28.1 (s, CH_2), 81.1 (s, C_5H_5), 128.4–133.2 (m, C_6H_5); $^{31}P\{^1H\}$ ($CDCl_3$, 161.98 MHz), δ 77.4 (s, PPh_3) $\{^2J_{(^{31}P-^{117}Sn)} = 355$ Hz, $^2J_{(^{31}P-^{119}Sn)} = 370$ Hz$\}$, $^{119}Sn\{^1H\}$ ($CDCl_3$, 149.21 MHz), δ −110.8 (t, $SnCl_3$) $\{^2J_{(^{119}Sn-^{31}P)} = 373$ Hz$\}$. ^{119}Sn Mössbauer: IS 2.05 mm s^{-1}, QS 1.80 mm s^{-1}. IR (CsI): ν(Sn–Cl) 256 and 263 cm^{-1}. Elemental analysis for $C_{31}H_{29}Cl_3P_2RuSn$, calc. (found): C, 40.30 (41.10); H, 3.17 (3.05); Br, 26.00 (25.02); Sn, 12.86 (12.85)%.

3. Results and discussion

The starting material [Ru(η-C_5H_5)$(PPh_3)_2$Cl] was prepared as follows (Eq. (1)):

$$RuCl_3 \cdot xH_2O + C_5H_6 + 2PPh_3 \xrightarrow{EtOH} [Ru(\eta\text{-}C_5H_5)(PPh_3)_2Cl] + \text{other products} \quad (1)$$



The authentication was carried out by experiments of multinuclear NMR, which showed the expected resonances for ^{1}H at δ 4.1 (C_5H_5) and 6.7–7.5 (C_6H_5); for $^{13}C\{^1H\}$ at δ 81 (C_5H_5) and 127–139 (C_6H_5); and $^{31}P\{^1H\}$ at δ 39.6. Its identity was confirmed by infrared spectroscopic studies as well as by melting point and carbon and hydrogen elemental analysis.

The insertion of SnX_2 into the Ru–X bond was conducted by reacting [Ru(η-C_5H_5)$(PPh_3)_2$Cl] or [Ru(η-C_5H_5)(dppe)Cl] with NaN_3 and following equimolar addition of SnX_2 (Scheme 1).

In all experiments the starting materials were refluxed with SnX_2 {X = F, Cl, Br} in EtOH for 6 h. After removing part of the solvent a precipitate was isolated and filtrated.

3.1. Reactions of [Ru(η-C_5H_5)$(PPh_3)_2N_3$] with SnX_2 (X = F, Cl and Br)

The reaction of [Ru(η-C_5H_5)$(PPh_3)_2$Cl] with NaN_3 yielded [Ru(η-C_5H_5)$(PPh_3)_2N_3$] which was treated with

Scheme 1. Reactions of [Ru(η-C_5H_5)$(PPh_3)_2$X] where X = F, Cl and Br. * The exchanging reaction of PPh_3 by dppe also yielded the boat and chair conformer of [{Ru(η-C_5H_5)Cl}$_2$(μ-dppe)$_2$]. However, for the insertion of $SnCl_2$ or the reaction with NaN_3 only the major product [Ru(η-C_5H_5)(dppe)Cl] was employed [12,13].

equimolar amounts of SnX_2. [Ru(η-C_5H_5)(PPh_3)$_2SnF_3$] (**1**), [Ru(η-C_5H_5)(PPh_3)$_2SnCl_3$] (**2**) and [Ru(η-C_5H_5)(PPh_3)$_2SnBr_3$] (**3**) were isolated as mixture-free derivatives. They were obtained as air- and moisture-stable orange crystalline solids, readily soluble in polar organic solvents. After recrystallisation from a mixture of CH_2Cl_2/*n*-hexane compounds **1**, **2** and **3** showed acceptable melting points at 199–202, 188–189 and 181–182 °C, respectively, as well as satisfactory elemental analysis.

All three compounds were studied by X-ray crystallography (Table 1). Apart from the Ru–Sn and Sn–X distances, the other structural results revealed similar angles and bond lengths for all three compounds. The X-ray study of **1** showed the presence of two unique molecules in the unit cell, not related one to another by symmetry but linked by an intermolecular F···H bond, 2.43 Å at the Cp ring. Such interactions are observed only in the solid state since no splitting of the hydrogen atoms or coupling with the fluorine was observed in the solution-state ^{1}H NMR spectrum (Figs. 1 and 2).

The $RuCp(PPh_3)_2$ fragment remains almost unchanged when the Cl is replaced by the SnX_3^- anion. The geometry at the Sn(II) centre is pyramidal trigonal with the Sn–X bond of 1.956 Å (av.), X = F, 2.394 Å (av.), X = Cl and 2.549 Å (av.) X = Br. The Ru–Sn distance, 2.5375 (av.) Å in the fluorine compound is a bit shorter than in the other two derivatives, implying a stronger interaction of the Ru fragment with the Sn moiety. The Sn–Cl bond in **2** is comparable with other known results and lies in the range of bond lengths which should be expected for such complexes [8,9]. All the molecules present a quasi-symmetry plane through Sn, Ru and the centroid of the Cp ring (Table 2).

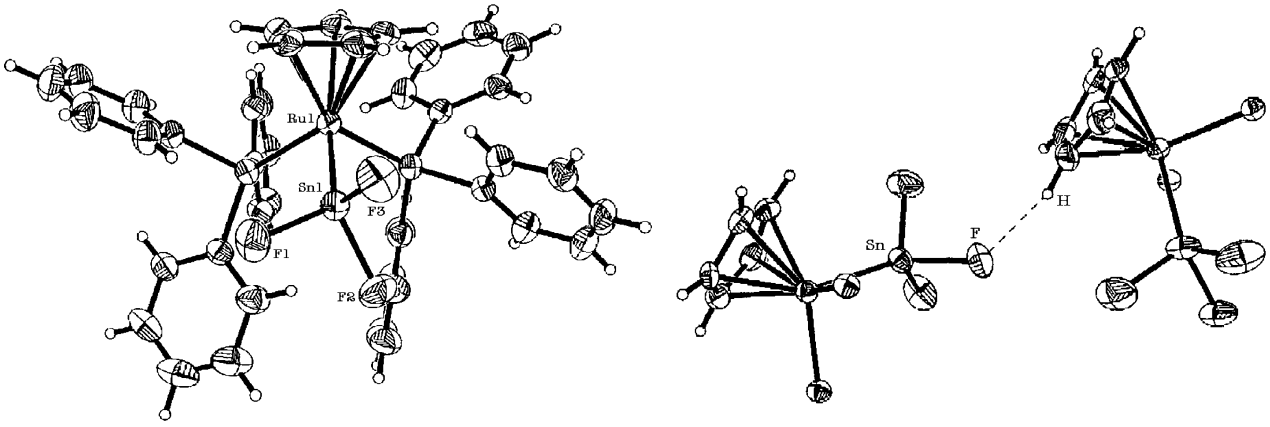


Fig. 1. The molecular structure of **1** and atom numbering scheme. For clarity the hydrogen atoms have been omitted in (A) and in (B) also the phenyl groups.

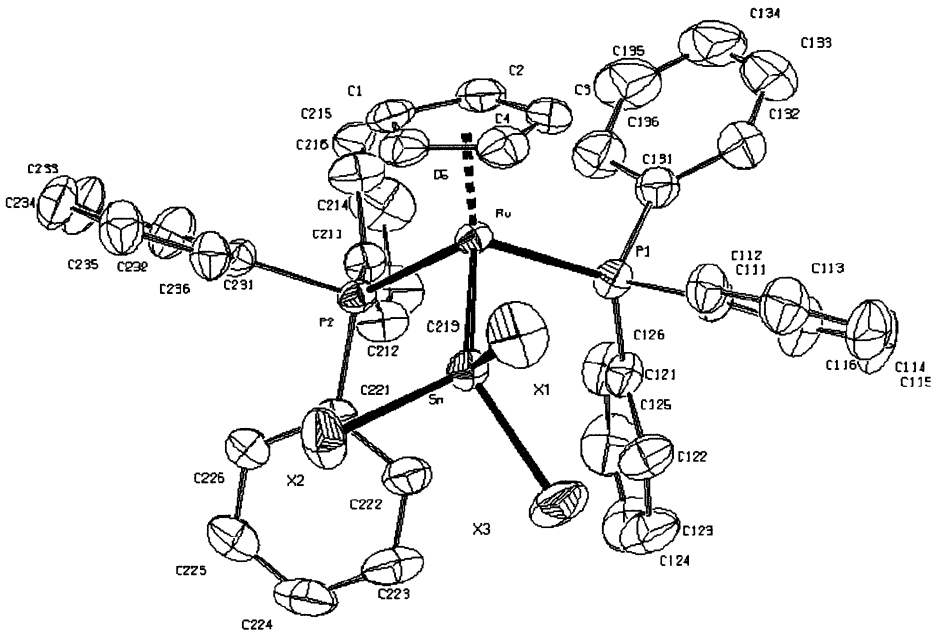

Fig. 2. The molecular structure of **2**, X = Cl, and **3**, X = Br, and atom numbering scheme. Hydrogen atoms have been omitted for clarity.

The results of ^{1}H, ^{13}C and ^{31}P NMR spectroscopy were unexceptional since no great differences were observed in the chemical shifts comparing with other reported results [5,6]. On the other hand, the ^{119}Sn NMR chemical shifts revealed interesting aspects of the bonding scheme in the compounds described here.

It was expected, the greater the halogen electronegativity, the lesser the shielding effect at the Sn centre. For the Cl and Br containing derivatives the chemical shifts, δ −68 (t) for **2** and −139 (t) for **3** are in accordance with the deshielding effect caused for the electronegativity of the halogens. However, compound **1** shows an abnormal value for the ^{119}Sn resonance, δ −357. In our opinion the ^{119}Sn chemical shift in this compound is heavily affected by an anomalous π contribution in the bonding scheme at the Sn(II) centre. In order to counterbalance the strong electronic withdraw inductive effect of the fluorine atom, the Sn centre forms a π-back bond with the Ru atom, stronger than in the other derivatives, which increases the shielding effect on the ^{119}Sn nucleus. Another indication for this is the higher $^{2}J_{(^{31}P-^{119}Sn)}$ coupling constant, 500 Hz, which indicates a closer approach of Sn and P in **1** in the P–Ru–Sn system. In fact the Ru–Sn bond is a bit shorter in **1** compared to the others.

Concerning the infrared spectroscopic studies, the most important signals observed in the spectra were the $\nu_{(Sn-X)}$, 490 cm^{-1} {X = F}, 290 and 272 cm^{-1} {X = Cl} and 265 and 260 cm^{-1} {X = Br}.

In contrast to the ^{119}Sn NMR chemical shifts, the IS obtained from studies of ^{119}Sn Mössbauer spectroscopy revealed an increasing in the IS values with the decreasing of the halogen electronegativity, 1.53 mm s^{-1} (**1**), 1.98 mm s^{-1} (**2**) and 2.10 mm s^{-1}(**3**). The Mössbauer experiments revealed that the π-bond contribution to the bonding scheme does not cause a great change in the Mössbauer spectroscopic data, as expected, since the IS parameters depends only of the *s*-electrons density. The second set of data, QS 2.17 mm s^{-1} (**1**), 1.93 mm s^{-1} (**2**) and 1.79 mm s^{-1} (**3**) showed differences in the symmetry of charge distribution.

3.2. Reactions of $[Ru(\eta\text{-}C_5H_5)(dppe)N_3]$ with SnX_2 (X = F, Cl and Br)

The compound $[Ru(\eta\text{-}C_5H_5)(dppe)N_3]$ was prepared by reacting $[Ru(\eta\text{-}C_5H_5)(dppe)Cl]$ [12] with NaN_3 [13].

Similar reactions with equimolar amounts of SnX_2 {X = F, Cl, Br} afforded $[Ru(\eta\text{-}C_5H_5)(dppe)SnF_3]$ (**4**), $[Ru(\eta\text{-}C_5H_5)(dppe)SnCl_3]$ (**5**) and $[Ru(\eta\text{-}C_5H_5)(dppe)SnBr_3]$ (**6**). These compounds were also isolated as air- and moisture-stable crystalline solids and gave satisfactory elemental analysis and melting points 270–272, 255–257 and 252–254 °C.

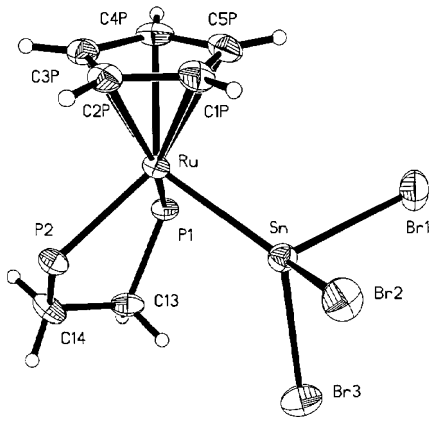

Fig. 3. The molecular structure of **6** and atom numbering scheme. Phenyl rings have been omitted for clarity.

The X-ray crystallographic determination of compound **6** served to compare structural features of compounds **6** with **3** (Fig. 3).

Compound **6** displays shorter Ru–P and Ru–Sn bonds, 2.2889 (av.) and 2.5649(4) Å versus 2.3519 (av.) 2.5854(7) observed for **3**, respectively. Also a smaller P–Ru–P angle, 82.91(4)°, is revealed for **6** compared to the same angle in **3**, 102.00(4)°. It is tentatively explained considering that the two phenyl groups bonded to the phosphorous and the bidentate nature of dppe renders it a less hindered ligand than PPh_3. It causes smaller P–Ru–P angles in **6**, as pointed to by the structural determination. The decrease in the steric effect permits a closer approach of the groups effecting shorter Ru–P and Ru–Sn bonds.

The ^{119}Sn NMR results show that in all the dppe containing derivatives the ^{119}Sn chemical shifts, (**4**) δ −345 (q), (**5**) δ −22 (t) and (**6**) δ −111 (t), locates in higher frequency indicating a decrease in the electronic density at the Sn atom. It is also reflected in the smaller $^{119}Sn-^{31}P$ coupling constants, 444, 390 and 373 Hz, respectively.

The Sn(II) chemical shift in **1**–**6** is not far from the signal exhibited by other Ru–Sn based compounds, such as $[Ru(SnCl_3)_6]^{4-}$, δ −34.6 [14], $[Ru(SnCl_3)_5Cl]^{4-}$, δ −167.9 (equatorial), −149.2 (axial), $[Ru(SnCl_3)_5(MeCN)]^{3-}$, δ −70.6 (equatorial), −103.9 (axial) [15] and *cis*-$[Ru(CO)_4(SnMe_3)_2]$, δ −207.

The changing of ligands caused no differences in the infrared data since in each compound the signals corresponding to $\nu_{(Sn-X)}$, were observed at 493 cm^{-1} {X = F}, 291 and 276 cm^{-1} {X = Cl} and 256 and 257 cm^{-1} {X = Br}, which are coincident with the previous results.

Also no great changes were observed in the ^{119}Sn Mössbauer spectroscopic data. The IS values, 1.59, 1.98 and 2.05 mm s^{-1} and QS data, 2.19, 1.94, 1.80 mm s^{-1} obtained for the dppe derivatives are very close to the

Table 3
Methanol conversion into methyl acetate catalysed by compounds **1**–**6**

[Catalyst] (10^{-3} mol l^{-1})	Rate of methyl acetate formation (10^{-4} mol l^{-1} h^{-1})					
	1	**2**	**3**	**4**	**5**	**6**

0.10	0.6	1.7	0.6	1.3	0.6	0.6

PPh_3 derivatives, indicating little change in the *s*-electronic density at the Sn centre.

3.3. Catalysis reactions

Compounds **1**–**6** showed to be active in the catalytic process of obtaining acetic acid from methanol. The catalytic cycle described here can be more interesting than Monsanto's because it needs only methanol as starting material and uses less expensive material (Ru + Sn vs. Rh) without a corrosive iodide promoter [16]. The only product observed was acetic acid detected as methyl acetate. Neither formaldehyde, which is supposed to be the intermediate in methanol conversion to acetic acid [14], nor methyl formate, possible product of formaldehyde dimerisation, was detected in all cases. We believe that the nature of the phosphorus-containing ligand, the nature of the halogen as well as the presence of the Ru–Sn bond exerts a strong influence on the catalytic activity of complexes (Table 3).

The order of catalytic activity of the complexes follows the halogen electronegativity, the SnF_3 bearing derivatives being far more efficient than the others. It seems to be related to the more efficient π-back donation from the Ru fragment to the Sn centre in the SnF_3^- containing products. It is possible that such a bonding scheme generates an extra positive density of charge in the Ru atom, which could facilitate a coordination to the oxygen atom of the methanol.

4. Supplementary material

Tables of atom positions and thermal parameters have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 166690, 166691, 166692 and 166693 for compounds **1**, **2**, **3** and **6**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

the carboxylic acid [HORc = HO_2CH, HO_2CCH_3, HO_2CCHMe_2, HO_2CCMe_3 (HOBc), $HO_2CCH_2CMe_3$(HONc)], control over the final structures of these ORc-modified $Ti(OR)_4$ complexes was realized. A demonstration of this synthetic control was illustrated through the reaction of HOBc and [Ti(μ-ONep)(ONep)$_3$]$_2$ which, due to steric constraints, yielded the first simple-metathesis, unesterified species, [Ti(μ-OBc)(μ-ONep)(ONep)$_2$]$_2$. One general trend that was noted from this study, and has been shown for other metal systems [10,14–20], was that the ONep ligated species yielded alternative arrangements that were typically lower in nuclearity in comparison to other OR derivatives.

Group 5 $M(OR)_5$ (M = Nb, Ta) are also widely used to prepare a variety of materials; however, little work has been presented concerning the products of HORc-modified Group V compounds. One exception is the report by Hubert-Pfalzgraf and co-workers [21] which detailed the formation of [Nb$_2$(μ-O)$_2$(OMc)$_2$(OCHMe$_2$)$_4$]$_2$, where OMc = $O_2CCMeCH_2$, from the reaction of $Nb(OCHMe_2)_5$ and HOMc (higher yields were realized through the stoichiometric addition of water). In the same report, the acetate (OAc) derivative, [Nb$_2$(μ-O)$_2$(OAc)$_2$(OCHMe$_2$)$_4$]$_2$ was formed from a mixture of $Nb(OCHMe_2)_5$ and $La(OAc)_3\cdot 2HOAc$. Fig. 1 shows the schematic representation of the central core of these compounds.

We were interested in the effects that could be induced using the ONep ligand and sterically hindered ORc with Group 5 cations. Therefore, we investigated the reactions between [M(μ-OEt)(ONep)$_4$]$_2$ (M = Nb (**1**) [15] and Ta (**2**) [17] (see Fig. 2), and HORc where ORc = OBc, ONc to determine the esterification products that were formed (Eq. (1)). The products isolated from the room temperature reactions (Eqs. (2)–(5)) were characterized as [Nb(μ-OBc)(ONep)$_3$]$_2$(μ-O) (**3**), [Nb(μ-O)(μ-ONc)(ONep)$_2$]$_4$ (**4**), [Ta(μ-OBc)(ONep)$_3$]$_2$(μ-O) (**5**), and [Ta(μ-ONc)(ONep)$_4$]$_2$ (**6**). Upon heating of identical reaction mixtures (Eqs. (6) and (7)), only the Ta system yielded additional structural species: [Ta(μ-O)(OBc)(ONep)$_4$]$_2$, (**7**), [Ta(μ-ONc)(ONep)$_3$]$_2$(μ-O) (**8**), and [Ta(μ-O)(μ-ONc)(ONep)$_2$]$_4$ (**9**). Collectively, these compounds lend structural insights into the esterification pathway of Group V alkoxides (see Scheme 1). This work presents the details of the syntheses, characterizations, solid and solution state behaviors of **3**–**8** and a comparison to other HORc modified Group V compounds available in the literature.

2. Experimental

All compounds described below were handled with rigorous exclusion of air and water using standard Schlenk line and glove box techniques. All solvents were freshly distilled from the appropriate drying agents immediately prior to use [22]. The following chemicals were used as received: $Nb(OEt)_5$, $Ta(OEt)_5$, HONep, HOBc, and HONc. The [M(μ-OEt)(ONep)$_4$]$_2$ (M = Nb (**1**) [15] and Ta (**2**) [17]) compounds were synthesized according to literature reports.

FT-IR data were obtained on a Bruker Vector 22 Instrument using KBr pellets under an atmosphere of flowing nitrogen. Elemental analysis was performed on a Perkin–Elmer 2400 CHN-S/O Elemental Analyzer. All NMR samples were prepared from dried crystalline materials that were handled and stored under an argon

Scheme 1. Schematic representation of the structurally verified (numbered compounds shown in bold bock) esterification pathway of HORc-modified Group V compounds.

atmosphere. All $^{13}C\{^{1}H\}$ solid-state NMR spectra were obtained on a Bruker AMX400 spectrometer, at a frequency of 100.63 MHz using a 4 mm broadband magic angle spinning (MAS) probe spinning at 4 kHz. For all of the $^{13}C\{^{1}H\}$ cross-polarized (CP) MAS spectra acquired, a standard CP sequence with high power ^{1}H decoupling, and a 1 ms contact time and 64-256 scans were utilized. For solution spectra, each sample was redissolved in toluene-d_8 at saturated solution concentrations. All solution spectra were obtained on a Bruker DMX400 spectrometer at 399.87 and 100.54 MHz for ^{1}H and ^{13}C experiments, respectively. A 5 mm broadband probe was used for all experiments. ^{1}H NMR spectra were obtained using a direct single pulse excitation, with a 10 s recycle delay and 8 scan average. The $^{13}C\{^{1}H\}$ NMR spectra were obtained using a WALTZ-16 composite pulse ^{1}H decoupling, a 5 s recycle delay and a $\pi/4$ pulse excitation.

2.1. General synthesis

Due to the similarity of synthetic procedures, a general description is presented for the unheated and heated reaction conditions.

2.1.1. Unheated. Compounds 3–6

$[M(\mu\text{-OEt})(ONep)_4]_2$ (**1** or **2**) was dissolved in toluene followed by addition, via pipette, of the appropriate HORc in toluene at glovebox temperatures. After 12 h, the reaction mixture was allowed to sit at glove box temperature with slow evaporation of any volatile material until crystals formed. If after an extended period of time no crystals were formed, additional volatile materials were removed by rotary evaporation. The reaction mixture was then allowed to again sit at glovebox temperatures or placed at −40 °C until crystals formed.

2.1.2. Heated. Compounds 3–4, 7–8

An identical setup as above was used. After mixing the two reagents, the reaction mixture was heated at reflux temperatures for 12 h and then allowed to cool to room temperature. Crystals were grown as described above.

2.1.3. $[Nb(\mu\text{-OBc})(ONep)_3]_2(\mu\text{-O})$ (3)

Used (unheated): **1** (0.622 g, 1.28 mmol) and HOBc (0.136 g, 1.33 mmol). Crystalline yield: 0.808 g (68.1%). Used (heated): **1** (0.602 g, 1.24 mmol) and HOBc (0.152 g, 1.49 mmol). Crystalline yield: 0.652 g (56.8%). FT-IR (KBr pellet, cm^{-1}) 2952(s), 2906(m), 2866(m), 2687(w),

1573(s), 1540(sh, s), 1480(s), 1420(s), 1361(s), 1235(w), 1089(br, s), 1029(sh, m), 937(w), 904(w), 777(s), 672(s), 480(m), 460(m). ^{1}H NMR (400 MHz, tol-d_8) δ 4.27, 4.26 (2.0H, s, OCH_2CMe$_3$), 4.23 (1.0H, s, OCH_2CMe$_3$), 1.29 (3.8H, s, O$_2$CCMe_3), 1.09, 1.02 (11.2H, s, OCH$_2$CMe_3). ^{13}C{^{1}H} (100 MHz, tol-d_8) δ 182.2 (O$_2C$CMe$_3$) 82.0, 77.3 (OCH$_2$CMe$_3$), 36.1 (O$_2$CCMe$_3$) 29.6, 29.1 (OCH$_2C$Me$_3$), 23.7 (O$_2$CCMe_3), 23.0, 22.2 (OCH$_2$CMe_3). 2.1.7. [Ta(μ-O)(μ-OBc)(ONep)$_2$]$_4$ (7)

Used (heated): **2** (0.588 g, 1.02 mmol) and HOBc (0.106 g, 1.04 mmol). Crystalline yield 1.28 g (66.3%). FT-IR (KBr pellet, cm^{-1}) 2952(s), 2893(m), 2860(m), 1587(s), 1481(m), 1428(m), 1354(w), 1262(w), 1229(w), 1162(br, s), 1109(br, s), 1029(sh, m), 824(s), 804(s), 645(s). ^{1}H NMR (400 MHz, tol-d_8) δ 4.32 (1H, dd, OCH_2CMe$_3$), 4.24 (1H, s, OCH_2CMe$_3$), 1.28 (3.3H, s, O$_2$CCMe_3), 1.10 (3.2H, s, O$_2$CCMe_3), 1.02 (H, s, OCH$_2$CMe_3). ^{13}C{^{1}H} (100 MHz, tol-d_8) δ 187.1 (O$_2C$CMe$_3$), 87.0, 82.3 (OCH$_2$CMe$_3$), 41.0 (O$_2$CCMe$_3$), 34.5, 34.1 (OCH$_2C$Me$_3$), 28.6, 28.4 (O$_2$CCMe_3), 27.1 (OCH$_2$CMe_3). Elemental *Anal*. for $C_{15}H_{31}O_5Ta$: Calc. C, 38.14; H, 6.61. Found: C, 40.78; H, 6.53%.

2.1.8. [Ta(μ-ONc)(ONep)$_3$]$_2$(μ-O) (8)

Used (heated): **2** (0.622 g, 1.08 mmol) and HONc (0.130 g, 1.12 mmol). Crystalline yield: 0.789 g (37.4%). FT-IR (KBr pellet, cm^{-1}) 2959(s), 2899(m), 2853(m), 2700(w), 1580(s), 1474(m), 1414(m), 1387(m), 1354(m), 1255(w), 1096(br, s), 1029(sh, m), 785(br, s), 652(br, s). ^{1}H NMR (400 MHz, tol-d_8) δ 4.33 (2.0H, dd, OCH_2CMe$_3$), 4.20 (0.98H, s, OCH_2CMe$_3$), 2.30 (1.0H, s, O$_2$CCH_2CMe$_3$), 1.11 (5.4H, s, O$_2$CCH$_2$CMe_3), 1.07 (5.4H, s, O$_2$CCH$_2$CMe_3), 1.05 (10.7 H, s, OCH$_2$CMe_3). ^{13}C{^{1}H} (100 MHz, tol-d_8) δ 181.9 (O$_2C$CH$_2$CMe$_3$), 84.6, 80.9 (OCH$_2$CMe$_3$), 51.7 (O$_2$CCH$_2$CMe$_3$), 34.3, 34.1 (O$_2$CCH$_2C$Me$_3$), 31.0, 30.2 (OCH$_2C$Me$_3$), 27.5, 26.7, 26.5, 25.7 (O$_2$CCH$_2C$Me$_3$, OCH$_2$CMe_3). Elemental *Anal*. for $C_{42}H_{88}O_{11}Ta_2$: Calc. C, 44.60; H, 7.84. Found: C, 44.39; H, 7.46%.

2.2. General X-ray crystal structure information [23]

Each crystal was mounted onto a thin glass fiber from a pool of Fluorolube™ and immediately placed under a liquid N_2 stream on a Bruker AXS diffractometer. The radiation used was graphite monochromatized Mo Kα radiation ($\lambda = 0.7107$ Å). The lattice parameters were optimized from a least-squares calculation on carefully centered reflections. Lattice determination and data collection were carried out using SMART Version 5.054 software. Data reduction was performed using SAINT Version 6.01 software. The structure refinement was performed using XSHELL 3.0 software. The data were corrected for absorption using the SADABS program within the SAINT software package.

Each structure was solved using direct methods. This procedure yielded the heavy atoms, along with a number of the C atoms. Subsequent Fourier synthesis yielded

the remaining C atom positions. The hydrogen atoms were fixed in positions of ideal geometry and refined within the XSHELL software. These idealized hydrogen atoms had their isotropic temperature factors fixed at 1.2 or 1.5 times the equivalent isotropic U of the C atoms for which they were bonded. The final refinement of each compound included anisotropic thermal parameters on all non-hydrogen atoms. Additional information concerning the data collection and final structural solutions of **3**–**9** can be found in the supplemental information. Data collection parameters for **3**–**9** are given in Table 1.

2.2.1. $Nb_2(O)(OBc)_2(ONep)_6$ (**3**)

Many of the methyl carbon atoms of the ONep and OBc ligands appeared to be disordered over several sites. These included the methyl carbon positions C(4), C(5), C(10), C(19), C(20), C(23), C(25), and C(30) which were refined as two one-half occupancy sites. The anisotropic refinement of several of the one-half occupancy methyl sites was problematic, which necessitated their subsequent isotropic refinement. Additionally, attempts to model the disorder in the methylene carbon atoms C(16) and C(26) were not successful, and these atom positions were refined isotropically. Finally, C(29) also displayed unrealistic atom positions when attempts were made to split the density over two sites. This carbon was also refined as isotropic. Hydrogen atoms were not refined on split-site carbons, however, the proper number of hydrogens was entered into the formula upon refinement to obtain correct structural parameters.

2.2.2. $[Nb(O)(ONc)(ONep)_2]_4$ (**4**) [23]

A colorless, irregular shaped crystal was attached to a glass fiber using silicone grease and was mounted from a matrix of mineral oil. The crystal was immediately placed on a Bruker P4/CCD/PC diffractometer, and cooled to 203 K using a Bruker LT-2 temperature device. The data were collected using a sealed, graphite monochromatized Mo Kα X-ray source. A hemisphere of data was collected using a combination of φ and ω scans, with 30 s frame exposures and 0.3° frame widths. Data collection and initial indexing and cell refinement were handled using SMART 4.210 software. Frame integration and final cell parameter calculation were carried out using SAINT V 4.05 software. The data were corrected for absorption using the DIFABS program. Decay of reflection intensity was not observed. The structure was solved in space group $C2/c$ using direct methods and difference Fourier techniques. The initial solution revealed the niobium–oxygen framework atomic positions. Subsequent Fourier synthesis revealed the carbon atom positions, including a disordered toluene solvent molecule. Attempts to model the lattice toluene were largely unsuccessful, and the program PLATON/SQUEEZE was used to remove the corresponding solvent electron density. (The solvent volume modeled was 1053 Å^3, and 144 electrons per unit cell were removed. The solvent void was centered at 0, 0.213, 0.25 in the unit cell.) The hydrogen atom positions were fixed (C–H = 0.96 Å for methyl, and 0.97 Å for methylene). The hydrogen atoms were refined using the riding model, with isotropic temperature factors fixed to 1.2 (methylene) or 1.5 (methyl) times the

[a] $R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o| \times 100$.
[b] $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma(w|F_o|^2)^2]^{1/2} \times 100$.

equivalent isotropic U of the carbon atom they were bound to. Three of the *t*-Bu groups were severely disordered and were modeled using a rigid-body refinement. The final refinement included anisotropic temperature factors on all non-hydrogen atoms. Structure solution, refinement, graphics, and preparation of publication materials were performed using SHELXTL V. 5.10.

2.2.3. $Ta_2(O)(OBc)_2(ONep)_6$ (**5**)

Significant disordering of the O(4) ONep group was observed which resulted in large anisotropic thermal parameters for the methylene carbon C(11) and the methyl carbons C(13), C(14), and C(15). Attempts to refine these carbon atoms anisotropically as shared occupancy resulted in non-positive definite thermal parameters for one or both of the sites. Therefore, after all attempts to model the disordered ONep failed, carbons C(11), C(13), C(14) and C(15) were refined with only isotropic temperature factors. The refinement also indicated racemic twinning. This was accommodated by adding the twin law $(-h, -k, -l)$ to the refinement.

2.2.4. $Ta_2(ONc)_2(ONep)_8$ (**6**)

The ONep groups that displayed significant positional disordering were modeled with partially occupied C sites, namely the ONep ligands off of the O(3), O(9), and O(11) atoms. The disordered carbon sites did not have hydrogen atoms added, however, the correct number of hydrogens were added to the overall composition in the final refinement cycle to obtain accurate calculated structural parameters.

2.2.5. $[Ta(O)(OBc)(ONep)_2]_4\cdot(toluene)$ (**7**)

A disordered toluene solvent molecule was located within the lattice and was modeled using the PLATON/SQUEEZE program (Ver. 01-11-99). (The solvent volume modeled was 1053 $Å^3$, and 218 electrons per unit cell. The solvent void was centered at 0.5, 0.228, 0.25 in the unit cell.) Four toluene molecules were added to the contents of the unit cell during the final refinement series so that the proper structural parameters could be calculated. Many of the methyl carbon atoms appeared to be disordered over two sites, including C(8), C(9), C(10), C(19), C(20), C(29), and C(30). Subsequent refinements of these split sites yielded reasonable positions for rotational disordering of ONep and OBc ligands. Additionally, the bridging O(2) atom was difficult to refine as anisotropic (displayed very elongated ellipsoids) and was fixed as isotropic during refinement.

2.2.6. $[Ta(ONc)(ONep)_3]_2(O)$ (**8**)

Due to difficulty refining some oxygen and carbon atom positions (resulting from disorder of ONep ligands) all carbon and oxygen atoms were refined with a single isotropic temperature factor. Significant bond length restraints were required to achieve convergence of the model. All like bonds within the structure were restrained to be equivalent ($\sigma = 0.04$ Å) resulting in a total of 95 bond length restraints. Due to the poor quality of the high-angle data and structural disorder, the overall refinement was substandard. However, it was possible to discern the central core connectivity of the molecule from the observed data.

2.2.7. $Ta_4(O)_4(ONc)_4(ONep)_8\cdot(THF)$ (**9**)

A disordered THF solvent molecule was observed and modeled using the PLATON/SQUEEZE program (Ver. 01-11-99). The SQUEEZE program located the solvent center to be at (1/2, 0.203, 1/4), with a potential volume of 1040.6 $Å^3$ and electron count of 168 electrons/cell, consistent with four THF molecules/unit cell. Four THF molecules were added to the contents of the unit cell during the final refinement series so that the proper structural parameters could be calculated. Due to difficulty refining some of the carbon atom positions (resulting from disorder of ONep ligands) 12 of the carbon atoms were refined with a single isotropic temperature factor as follows: methylene carbon atoms C(18) and C(23); methyl carbons C(4), C(5), C(15), C(16), C(17), C(20), C(21), C(25, C(26), and C(27). Attempts made to model the disorder by splitting the site occupancy over two sites were largely unsuccessful, hence these carbons were refined isotropically. Additionally, O(5) and O(9) were also fixed as isotropic during refinement. A few bond length restraints were employed to achieve convergence of the model. The quaternary-methyl bonds for the O(8) ONep ligand were restrained to be equivalent ($\sigma = 0.04$ Å). Additionally, the Ta–O bond lengths for the bridging oxygens O(1) and O(9) were also restrained to be equivalent ($\sigma = 0.04$ Å). This resulted in a total of 6 bond length restraints for the refinement.

3. Results and discussion

Previously, the crystallographically characterized ORc-modified Group V metal alkoxides were all found to adopt the general structure $[Nb_2(\mu\text{-}O)_2(ORc)_2(OCHMe_2)_4]_2$ (ORc = OAc, OMc) [21]. Due to the unique structures characterized for the ORc-modified $Ti(OR)_4$ family using the ONep ligand [9], we decided to investigate the reaction between **1** [15] or **2** [17] and HORc (ORc = OBc or ONc). The larger ORc ligands were chosen since it was observed in the titanium system that the OBc ligand yielded species without esterification (i.e., simple exchange) and the ONc ligand formed structures similar to the OAc products [9]. The final products of Eqs. (2)–(7) were characterized in both the

solid and solution state. A schematic representation of the structural variations noted in this study showing the progression of the esterification process for Group V alkoxides is presented in Scheme 1.

3.1. Synthesis

The room temperature reaction between the appropriate Group V metal alkoxides (**1**-or **2**, Fig. 2) and HORc in toluene (Eq. (1)) yielded **3**–**6** which are shown in Figs. 3–6 and Eqs. (2)–(5), respectively. Identical reaction mixtures were also heated at reflux temperatures overnight, to investigate the degree of esterification that could be wrought from these compounds. The concentration of the reactions was held relatively at the same level but was not rigorously controlled. For the Nb system, there was no change in the structures isolated; however, for the Ta system **7**–**8** were isolated upon heating (Eqs. (6) and (7)). Compound **9** was isolated in small yield in an identical synthesis noted for **8** except that the solution was substantially more concentrated which may have played a large role in dictating the structure of the final species obtained. Plots of **7**–**9** are shown in Figs. 7–9, respectively. Interestingly, it appears that the OEt are preferentially reacted for all scenarios and are most likely the main source of the oxide ligands; however, as noted by Hubert-Pfalzgraf [21], the carboxylic acids may also contribute to oxide formation.

3.2. Solid-state

3.2.1. Structure

Plots of **3**–**9** are shown in Figs. 3–9, respectively. Table 1 lists the data collection parameters for **3**–**9**. Tables 2 and 3 are the tabulation of the metrical data for **3**–**4** and **5**–**7** and **9**, respectively. The quality of the crystal structure isolated for **8** precludes discussion of

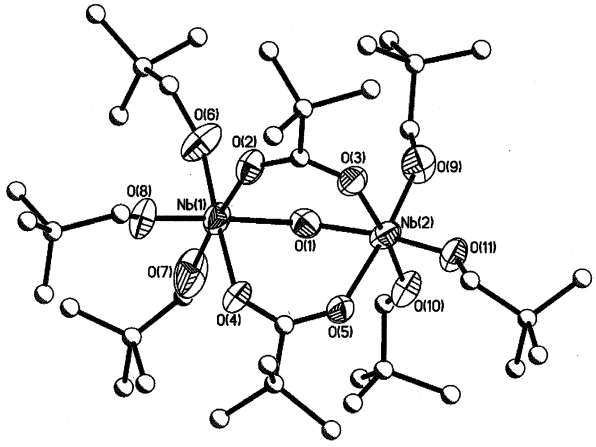

Fig. 3. Thermal ellipsoid plot of **3**. Ellipsoids are drawn at the 30% level.

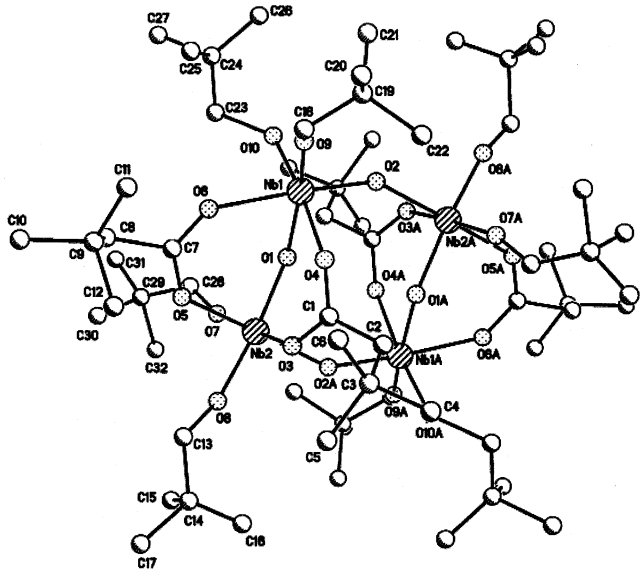

Fig. 4. Ball and stick plot of **4**. Ellipsoids are drawn at the 30% level.

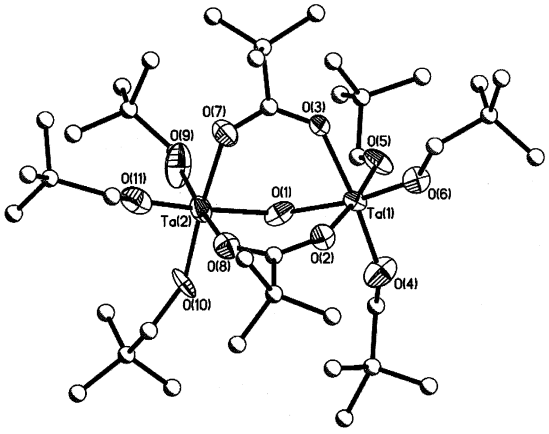

Fig. 5. Thermal ellipsoid plot of **5**. Ellipsoids are drawn at the 30% level.

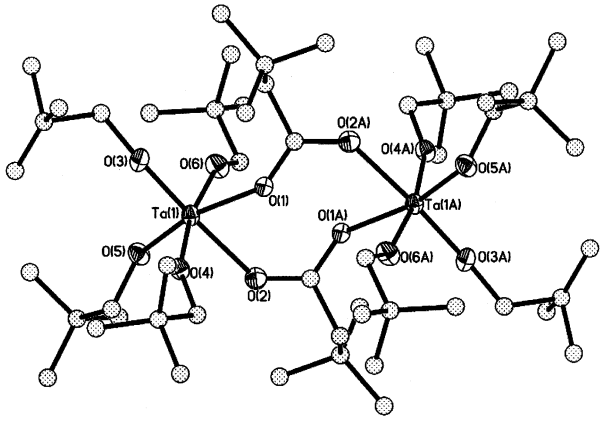

Fig. 6. Thermal ellipsoid plot of **6**. Ellipsoids are drawn at the 30% level.

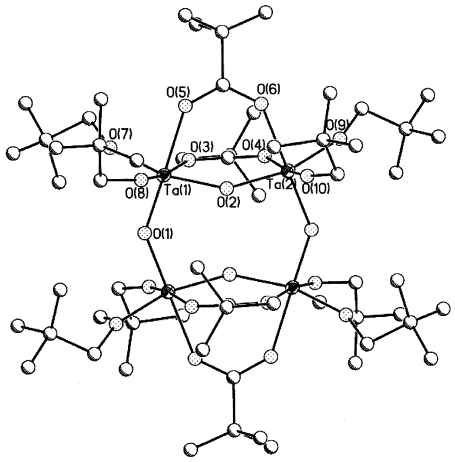

Fig. 7. Thermal ellipsoid plot of **7**. Ellipsoids are drawn at the 30% level.

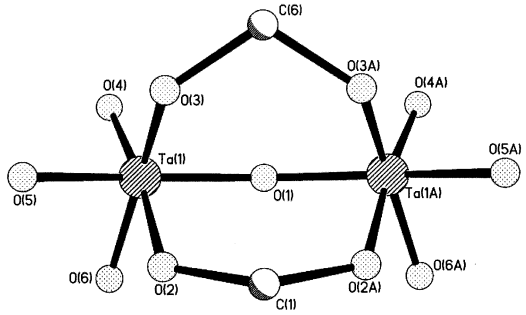

Fig. 8. Ball and stick plot of **8**. Ellipsoids are drawn at the 30% level.

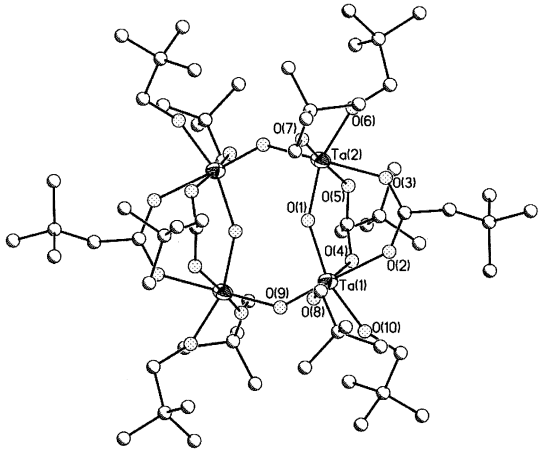

Fig. 9. Ball and stick plot of **9**. Ellipsoids are drawn at the 30% level.

the metrical data for this compound; however, the connectivity of the molecule's central core was unequivocally observed. Additional information pertaining to the full crystal structure can be found in the supplementary information. Notably, the μ-OEt ligands were absent from the final structures, indicating these ligands are preferentially esterified during the syntheses of **3**–**9**.

Compounds **3**, **5**, **6**, and **8** were dinuclear with octahedral (Oh) metal centers. For **3**, **5**, and **8** an oxo atom and two ORc ligands bridge the metal centers with three ONep ligands filling the remainder of the coordination sphere (the metrical data for **8** is omitted from the following discussions). In contrast, compound **6** is the first example of the simple exchange Group V species, surprisingly void of esterification-generated oxo ligands. The Oh coordination spheres of the Ta metal centers are formed by the two bridging ONc ligands and four terminal ONep ligands. The metrical data for **3**, **5**, and **6** are self-consistent and are in agreement with observed literature values [21]. The Nb–O and Ta–O distances aggrandize with increased bonding and reduced electron density (ONep < μ-O < ORc). The Nb···Nb distances for **3** were 3.62 Å and are similar to the Ta···Ta distance of 3.64 Å noted for **5**. For **6**, due to the absence of an oxo ligand, the Ta···Ta distance is substantially longer at av. 5.13 Å. The ORc ligands possess bite angles that range from 122 to 127° for **3**, **5**, and **6**.

Compounds **4**, **7**, and **9** were isolated in the same general centrosymmetric structural arrangement that consists of two "$M_2(\mu\text{-}O)_2(\mu\text{-}ORc)_2(ONep)_4$" moieties which are linked by μ-O ligands. This results in the formation of an eight-member ring of $[M–O]_4$ as the central core. The acetate ligands do not bridge between moieties but instead each pair of metals is bridged by two ORc ligands, independent of the steric bulk of the pendant hydrocarbon chain. This is the same structure as was noted for the ORc/$OCHMe_2$ (ORc = OAc or OMc, Fig. 1) system and the metrical data are in agreement [21]. The shortest M···M distances were av. 3.66 Å wherein substantially longer distances were noted for the diagonally located M···M distances (av. 5.18 Å).

Compounds **1**–**9** structurally reveal the step-wise esterification pathway (see Scheme 1) that Group V species undergo. Initially, the HORc reagent exchanges with the weakest bound and most sterically accessible OR (in this system the OEt) to generate dinuclear bridged species (**6**). Once generated, one of the free HOR (HOEt) reacts with HORc to generate the ester and H_2O. The H_2O reacts with the terminal OR (HONep) to generate an oxo species; however, due to the bite angle of the ORc ligands, linking to the other molecules is unlikely and therefore binding to the second metal in the molecule occurs (**3**, **5**, and **8**). The next step would be to repeat this hydrolysis, however, now the steric hindrance around the metal centers of the molecule prevents further oxo linkages within the molecule and M–O–M bonds are formed externally to form the fully hydrolyzed species (**4**, **7**, and **9**).

While detailed computational investigations are required to fully understand the structures that were preferentially formed, some general trends can be stated for this family of compounds. In the titanium system [9],

the size and shape of the pendant hydrocarbon chain of the HORc ligands played a vital role in determining nuclearity and shape of the molecules isolated. For the Nb species (**3**, **4**) the ORc ligands also appear to dictate the nuclearity of the product isolated wherein the more sterically hindering OBc ligand led to the smaller, dinuclear species **3**, in comparison to the tetranuclear ONc-ligated species **4**. These are the most kinetically and thermodynamically stable species since the same structures were isolated, independent of the temperature of the reaction. In contrast, the Ta species follow the reverse trend concerning the ORc ligands (the smaller the steric bulk of the carboxylate the less esterification observed). Further, the Ta species appear to be less susceptible to hydrolysis than the Nb complexes as evidenced by the isolation of less condensed species for the former system under identical conditions. Since the ionic radii of Nb^{5+} or Ta^{5+} are the same (0.78 Å [24]) and identically ligated precursors and modifiers were used, the stabilization of the Ta intermediates over the Nb species must be based on the subtle electronic variations between these congeners.

3.2.2. Elemental analysis

Elemental analyses of the bulk powders for the Nb system were consistent with the solved solid-state structures. For the Ta systems, **5** and **8** were found to be consistent with their respective solid-state structures. For **6**, the analyses obtained were in agreement with the oxo species (**8**), which may be due to the rapidity that **6** undergoes hydrolysis under the conditions used for analyses. For **7**, the analyses were consistently higher

than the calculated values which may be a reflection of residual solvent or incomplete esterification. Due to the limited amount of **9** isolated and the similarity to **4** and **7**, full characterization was not undertaken.

3.2.3. FT-IR spectroscopy

Due to the similarity in ligand constructs of **3**–**8**, it is not surprising that the FT-IR spectra of dried crystalline powders are comparable. Standard aliphatic stretches and corresponding methyl bends for the ONep ligands were observed in each spectrum with no stretches present for OH in any of the spectra. The C=O stretches of the precursor acids, HOBc and HONc, are both located at 1706 cm^{-1}. The $\sim$200 cm^{-1} shift of the C=O stretch was observed when reacted (1573, **3**; 1586, **4**; 1578, **5**; 1583, **6**; 1577, **7**; 1583 cm^{-1}, **8**) indicating the acids are bound to a metal in a chelating manner. These changes are in agreement with the OMc derivative [21].

Table 4
Solid state MAS ^{13}C NMR data for **3**–**8**

Compound	δ ppm (assignment)	Compound	δ ppm (assignment)
3	29.0, 28.1, 27.8, 27.0 (OCH_2CMe_3, O_2CCMe_3)	**6**	27.0 (OCH_2CMe_3)

	85.7, 82.6 (OCH_2CMe_3)		83.9, 80.0 (OCH_2CMe)
	181.8 ($O_2CCH_2CMe_3$)		187.3 (O_2CCMe_3)
5	27.1 (OCH_2CMe_3)	**8**	26.9 (OCH_2CMe_3)
	28.6 ($O_2CCH_2CMe_3$)		30.3 ($O_2CCH_2CMe_3$)
	33.6 (OCH_2CMe_3)		34.0 (OCH_2CMe_3)
	40.1 (O_2CCMe_3)		51.5 ($O_2CCH_2CMe_3$)
	83.7, 80.3 (OCH_2CMe_3)		84.2, 80.4 (OCH_2CMe_3)
	187.8 (O_2CCMe_3)		181.3 ($O_2CCH_2CMe_3$)

The M–O–M stretches for the OMc derivative were assigned at 998 and 733 cm^{-1}; however, a shoulder at 605 was also reported. The $[Nb_2(\mu\text{-}O)(OEt)_3(BHMP)]_2$ complex reportedly had an M–O–M stretch at 700 cm^{-1} [15]. For all of the oxo containing species in this study, the two peaks were observed around 650 and 675 cm^{-1}. Only the 650 cm^{-1} peak was noted for the non-oxo species **6**. For every sample, a stretch was noted around 1000 cm^{-1}. Therefore, the stretch around 675 cm^{-1} was assigned to the Nb–O–Nb moieties with the remaining stretches due to the Nb–O of the various ligands.

3.2.4. ^{13}C MAS NMR spectroscopy

To further characterize the bulk powder of these reactions, ^{13}C CP-MAS NMR data were collected on samples that were packed and handled under an argon atmosphere. Compounds **3**, **5**, and **6** are symmetric molecules and it is expected that one type of ORc and one type of terminal ONep resonance would be observed. The centrosymmetric nature of **4**, **7**, and **8** should also generate one type of ONep and one ORc resonances. The collected data were tabulated in Table 4.

The spectra for **3**, **5**, and **8** are very similar and show one set of resonances for the ORc ligands and two sets of resonances for the ONep ligands in what appears to be a 2:1 ratio. This is in agreement with the symmetry of the molecule in the solid-state crystal structure. For **6**, one set of resonances for the ONc and ONep ligands were observed but the observed peaks were broad and fine splitting may be observed on some of these resonances. The spectrum for **7** has one set of OBc resonances and two sets of ONep resonances. Again, packing inequivalencies can be postulated to explain the numerous ONep resonances that were unexpectantly observed. The spectrum of **4** is nearly identical and as was noted for **7**, two ONep and one ONc resonance set were observed; however, the quaternary carbons were not observed. For these compounds, it appears that the solid-state spectra are in agreement with the crystal structures.

3.3. Solution state NMR

Dried crystals of **3**–**8** were redissolved in toluene-d_8 and then sealed in an NMR tube to determine if the solid-state structures were retained in solution. The chemical shifts of the ORc ligands and lack of OH peak in the ^1H NMR spectra are indicative of the bidentate nature of the ORc ligands. Since a number of structural similarities exist between metal and ligand sets, the compounds of identical central cores are discussed collectively. Variable temperature NMR data were collected on selected species (**4**, **5**, **6** were chosen since they represent all of the various structure types observed) to further investigate any dynamic behavior. While there was sharpening of several peaks for the samples studied, there were no significant variations in the NMR spectra observed from -30 to $+60\,^{\circ}C$, demonstrating that there was no ligand exchange that could be observed at this temperature.

The solution state ^1H and ^{13}C NMR spectra of **3**, **5**, and **8** display two ONep resonances in a 2:1 ratio and one ORc methyl resonance. The larger ONep resonance displays multiple J_{H-H} splittings consistent with locked out methylene protons of two ONep ligands. These ONep ligands are most likely hindered from rotating by

the OBc ligands and the *t*-butyl groups of the other ONep ligands. The other methyl is located adjacent to the oxo ligand and is free to rotate. Based on these data, it is apparent that the solid-state structure is maintained in solution for these compounds.

For the unesterified complex **6**, two types of ONep in a 2:1 ratio and one ONc ligand were noted in the ^{1}H NMR toluene-d_8. One of the methylene resonances was present as a multiplet. The ^{13}C NMR spectrum has peaks similar to that observed in the ^{13}C MAS NMR solid-state but hyperfine splitting revealed two complete ONc and two ONep resonance sets. It appears that the solid-state structure is maintained in solution but the fine splitting was observed.

Based on the symmetry of the solid-state structures and assuming averaging of the ligands of **4** and **7** there should be one set of resonances noted for the ONep and ORc ligands. For **7**, two ONep resonances in a 1:2 ratio are observed with only one ORc resonance. Again as noted previously, hindered rotation about one of the ONep ligands and free rotation of the others would explain the observed spectrum.

4. Summary and conclusion

We have successfully isolated and characterized several carboxylic acid derivatives of the Group V congeners (**3**–**9**). The resulting products range from simple exchange through partially hydrolyzed to fully hydrolyzed species, which were found to be dependent *not* only on the pendant hydrocarbon chain of the carboxylic acid, but also on the reactivity of the metal center. Three interesting phenomena were noted for this family of compounds which may be exploitable in controlling the amount of esterification that occurs in a sol–gel system. First, the OEt ligands are completely absent in all of the structures observed indicating preferential substitution/hydrolysis of these ligands over the ONep ligands. Second, the Nb species appear to be more susceptible to the esterification process than the Ta system as evidenced by the increased oxolation in the isolated products. Third, for the Ta system, the ONc ligated species appear to offer more stabilization (protection) against esterification in comparison to the OBc ligated species, again based on the degree of oxolation observed. Combined, these structures lend insight into the esterification pathway which begins with an exchange of an acetate for an alkoxide ligand (**6**). This is then followed by formation of an oxo bond between the metal centers (**3**, **5**, and **8**). Further induced esterification by heating leads to a coupling of these partially hydrolyzed species to yield what appears to be the favored $M_4(O)_4(ORc)_4(ONep)_8$ (**4**, **7**, and **9**). The solution state NMR indicates that these compounds are stable in solution.

5. Supplementary material

X-ray crystallographic files in CIF format for the structures **3**–**9** have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 179216–179221. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccd.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

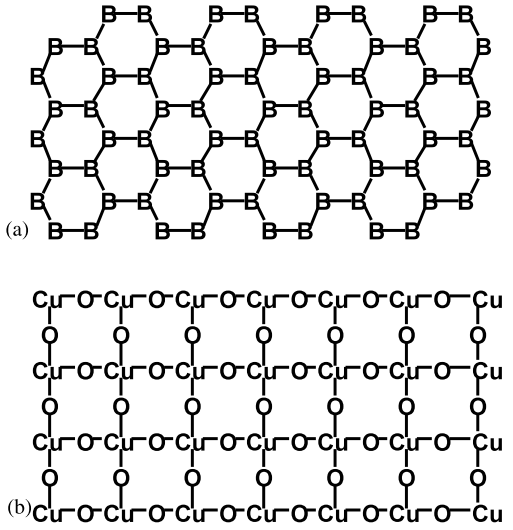

Fig. 1. (a) Part of a hexagonal boron layer in MgB_2; (b) part of a square Cu–O layer in the superconducting cuprate structures.

conductivity in MgB_2 analogous to similar models for the superconducting cuprates. The possible role of the magnesium counterions in doping the conducting boron skeleton of MgB_2 is then examined by comparison of MgB_2 with other inorganic solid state structures in which the magnesium counterions appear to be subvalent, i.e. have an effective formal oxidation state below +2. Such solid state structures include certain ternary magnesium transition metal hydrides [13]. Of particular significance is the observation that the magnesium counterions in some solid state hydrides, such as Mg_2RuH_4, Mg_3RuH_3, and Mg_4IrH_5, appear not to function as simple monomeric Mg^{2+} units expected from the position of magnesium in the periodic table as an alkaline earth. Instead when the solid state geometry forces the magnesium atoms to be relatively close together (i.e. ~3.0 Å or less), the magnesium ions can couple to form Mg_2^{2+} leading to a lower negative charge on the anionic portion of the solid state structure than would be expected with Mg^{2+} counterions. A similar coupling of the magnesium ions in MgB_2 leading to incomplete oxidation to Mg^{2+} provides a mechanism for generating the experimentally observed hole superconductivity [14].

2. Subvalent magnesium in solid state structures: examples in ternary magnesium transition metal hydrides

The prototypical form of subvalent magnesium is the dimeric ion Mg_2^{2+} with an Mg–Mg bond analogous to the well-known mercurous ion, Hg_2^{2+} and a formal magnesium oxidation state of +1. Density functional calculations indicate an Mg–Mg bond distance of 2.928 Å [15,16] in the hypothetical isolated ion Mg_2^{2+} (Table 1). A Mg–Mg bond distance (2.930 Å) similar to that

Table 1
Some Mg–Mg distances

Compound	Formulation	Mg–Mg (Å) [a]	Ref.
Mg_4IrH_5	$[Mg_2^{2+}]_2[Ir^{I}H_3^{2-}][H^-]_2$	2.754	[21]
Mg_2^{2+}	from DFT calculations	2.928	[15,16]
Mg_2RuH_4	$[Mg_2^{2+}][Ru^{II}H_4^{2-}]$ or $[Mg^{2+}]_2[Ru^0H_4^{4-}]$	2.930	[17]
Mg_3RuH_3	$[Mg_2^{2+}]_3[Ru^0H_3^{3-}]_2$	3.034	[20]
MgB_2	$[Mg^{2+}]_\infty[B^-]_{2\infty}$	3.083	[22]
Mg_2CoH_5	$[Mg^{2+}]_2[Co^{I}H_5^{4-}]$		[23]
Mg_2FeD_6	$[Mg^{2+}]_2[Fe^{II}D_6^{4-}]$	3.216	[24]
Mg_2NiD_4	$[Mg^{2+}]_2[Ni^0H_4^{4-}]$	3.254	[25]

[a] For compounds with more than one type of Mg atom, only the smallest Mg–Mg distance is listed.

calculated for Mg_2^{2+} is found in Mg_2RuH_4 [17]. This suggests formulation of Mg_2RuH_4 as $[Mg_2^{2+}][Ru^{II}H_4^{2-}]$ with Ru(II) rather than $[Mg^{2+}]_2[Ru^0H_4^{4-}]$ with Ru(0) [18]. In the former formulation the $Ru^{II}H_4^{2-}$ anion is isoelectronic with the $Rh^{III}H_4^-$ anion found in Li_3RhH_4 [19]. Similarly the Mg–Mg bond distances in Mg_3RuH_3 [20] and Mg_4IrH_5 [21] are also rather short (Table 1). Considering the magnesium counterions as the subvalent Mg_2^{2+} in these ternary hydrides leads to the formulations $[Mg_2^{2+}]_3[RuH_3^{3-}]_2$ and $[Mg_2^{2+}]_2[IrH_3^{2-}][H^-]_2$, respectively, with the central metal atoms in the fairly typical low, but reasonable oxidation states Ru(0) and Ir(I). The special role of magnesium in Mg_2RuH_4, Mg_3RuH_3, and Mg_4IrH_5, possibly through functioning as Mg_2^{2+} rather than the more usual Mg^{2+}, is also suggested by the observations that analogous ternary hydrides are unknown with electropositive metals other than magnesium as counterions. For comparison Table 1 also shows some Mg–Mg distances in other ternary magnesium transition metal hydrides (or the corresponding deuterides) not believed to contain subvalent magnesium such as Mg_2NiD_4, Mg_2CoH_5, and Mg_2FeD_6. These latter three compounds, which all have minimum Mg···Mg distances greater than 3.15 Å, can be formulated with fully oxidized Mg^{2+} cations and NiD_4^{4-}, CoH_5^{4-}, and FeD_6^{4-} anions, respectively. All three of these anions have the favored 18-electron rare gas configurations and are isoelectronic with known cyanometalates and/or metal carbonyls.

Further details of the structure and bonding in the hydrometallate anions in these solid state materials are discussed elsewhere [13,16]. The important point in the context of this paper is that the relatively short Mg–Mg distances in Mg_2RuH_4, Mg_3RuH_3, and Mg_4IrH_5 all provide evidence for subvalent magnesium in these structures. If the subvalent magnesium in these ternary magnesium transition metal hydrides is assumed to be Mg_2^{2+}, then the corresponding hydrometallate counter-

anions have reasonable metal oxidation states, electron counts, and chemical bonding models.

3. A comparison of the chemical bonding topology of magnesium diboride with that of the cuprate superconductors

All of the cuprate superconductors [26–28] appear to consist of layers of two-dimensional Cu–O conducting skeletons separated by layers of positive counterions. The following points are of interest concerning the chemical bonding topology of the cuprate superconductors [3,29]:

1) The conducting skeleton consists of Cu–O layers constructed from Cu–O–Cu bonds rather than direct Cu–Cu bonds (Fig. 1(b)). The much higher ionic character and thus much lower polarizability of metal–oxygen bonds relative to direct metal–metal bonds has been related to the persistence of superconductivity in cuprates to much higher temperatures than that in metals and metal clusters with direct metal–metal bonds.
2) The required metal–metal interactions are antiferromagnetic interactions between the single unpaired electrons in suitable d-orbitals of two d^9Cu(II) ions separated by an oxygen bridge similar to antiferromagnetic Cu(II)–Cu(II) interactions [30,31] in discrete binuclear complexes (the resonating valence bond model of Anderson and co-workers [32,33]).
3) The positive counterions in the cuprate superconductors control the negative charge in the Cu–O layers and thus the oxidation states of the copper atoms.
4) Partial oxidation of some of the Cu(II) to Cu(III) in the cuprate superconductors generates the holes in the valence band required for conductivity in accord with Hall effect measurements [34].

A model for the chemical bonding topology of MgB_2 can be developed which is closely related to that of the cuprates discussed above. In this connection note that the Mg–Mg distance in MgB_2 is 3.083 Å, which is comparable to that in some of the ternary magnesium transition metal hydrides discussed above (Table 1). This suggests the presence of subvalent magnesium of some type in MgB_2 leading to the following chemical bonding topology:

1) The conducting skeleton of MgB_2 consists of the hexagonal boron layers (Fig. 1(a)).
2) Electron transport occurs through the boron–boron σ bonds in the boron layers [6,8].
3) Electron transfer from the magnesium counterions to the boron layers controls the negative charge on the boron layers. If the magnesium ionizes fully to Mg^{2+}, then the boron layers are isoelectronic with graphite.
4) Partial reduction of some of the Mg^{2+} to Mg_2^{2+} (i.e. the formation of subvalent magnesium) generates the holes in the valence band required for conductivity in accord with the positive Hall effect measurements [14].

In this model the magnesium counterions in MgB_2 play an active role in controlling electron transport in the hexagonal boron layers (Fig. 1(a)) thereby affecting conducting and superconducting properties. It is therefore not surprising that substitution of other bivalent metals for MgB_2 leads to materials without comparable superconducting properties.

2. Experimental

2.1. Instrumental

IR spectra were recorded on a BOMEM FT-IR model BM 100 spectrometer. ^{1}H NMR spectra were measured on a BRUKER AC250 instrument with TMS as internal standard. Elemental analyses (CHN) were determined with a FISONS EA-1108 equipment. Enraf–Nonius CAD4 diffractometers were used for the diffraction measurements. Routine FAB$^-$ mass spectra have been recorded on a TSQ spectrometer (Finnigan) with nitrobenzylalcohol as matrix.

2.2. Preparation of the boron complexes

The hydroximatoborates were prepared as described previously [14], with slight modifications. Solvents and commercially available chemicals (H_3BO_3, benzohydroxamic acid, di-*n*-butylamine, dicyclohexylamine, tetra-*n*-butylammonium bromide, tetra-*n*-propylammonium bromide and silver oxide) were used as purchased.

2.2.1. Dicyclohexylammonium bis(benzohydroximato)borate (*1*)

A mixture of 0.068 g H_3BO_3 (1.10 mmol), 0.302 g benzohydroxamic acid (2.20 mmol) and 0.200 g dicyclohexylamine (1.1 mmol) in 25 ml C_6H_6 was heated under reflux for 8 h, using a Dean-Stark trap for azeotropic elimination of water. After evaporation of the C_6H_6, the solid residue was dissolved in 15 ml CH_2Cl_2, 15 ml *n*-C_6H_{14} was added and the mixture was kept at −15 °C. After 48 h the crystals were filtered off and washed with *n*-C_6H_{14} yielding 0.474 g of **1** (yield: 91%). M.p. 226–229 °C. *Anal*. Found: C, 67.12; H, 6.93; N, 9.12. Calc. for $C_{26}H_{34}BN_3O_4$: C, 67.39; H, 7.40; N, 9.07%. NMR (25 °C): ^{1}H (250 MHz, $CDCl_3$): δ 1.02 (m, 6H, CH_2), 1.47 (m, 4H, CH_2), 1.56 (m, 6H, CH_2), 1.95 (m, 4H, CH_2), 3.10 (m, 2H, CH), 7.26 (m, 6H, C_6H_5), 7.78 (m, 4H, C_6H_5). FTIR (KBr): 3035m (ν NH), 2934s (ν CH_2), 2856s (ν CH_2), 1597ms (C_6H_5), 1562ms (C_6H_5), 1499m, 1447m (δ CH_2), 1388vs (ν OCN), 1125s (ν_{as} $^{10}BO_4$), 1085vs (ν_{as} $^{11}BO_4$), 987s, 942m (δ_{as} BO_4), 792m (ν ONC), 742m (ν ONC), 691m (C_6H_5) (IR data: vs, very strong; s, strong; ms, medium strong; m, medium).

2.2.2. Di-n-butylammonium bis(benzohydroximato)borate (*2*)

Compound **2** was prepared from 0.080 g H_3BO_3 (1.30 mmol), 0.357 g benzohydroxamic acid (2.60 mmol) and 0.170 g di-*n*-butylamine (1.31 mmol) as described above. Yield: 0.450 g (84%). M.p. 113–114 °C. *Anal*. Found: C, 64.06; H, 6.45; N, 10.28. Calc. for $C_{22}H_{30}BN_3O_4$: C, 64.24; H, 7.35; N, 10.22%. NMR (25 °C): ^{1}H (250 MHz, $CDCl_3$): δ 0.80 (t, 6H, CH_3), 1.3 (m, 4H, CH_2–CH_3), 1.79 (m, 4H, CH_2–CH_2–CH_2), 3.10 (t, 4H, N–CH_2) 7.49 (m, 6H, C_6H_5), 7.91 (m, 4H, C_6H_5). FTIR (KBr): 3122m (ν NH), 2956ms (ν CH_2/CH_3), 1594ms (C_6H_5), 1563s (C_6H_5), 1498m, 1470m, 1446m (δ CH_2), 1380s (ν OCN), 1124s (ν_{as} $^{10}BO_4$), 1086vs (ν_{as} $^{11}BO_4$), 993s, 942m (δ_{as} BO_4), 773m (ν ONC), 738m (ν ONC), 703m (C_6H_5), 690m (C_6H_5).

2.2.3. Tetra-n-propylammonium bis(benzohydroximato)borate (*3*)

A mixture of 0.031 g H_3BO_3 (0.50 mmol), 0.058 g Ag_2O (0.25 mmol), 0.137 g benzohydroxamic acid (1.00 mmol), 0.133 g tetra-*n*-propylammonium bromide (0.50 mmol) in 25 ml C_6H_6 was heated to reflux for 8 h as described above. The solid was filtered off and extracted with 15 ml CH_2Cl_2. After vacuum evaporation 0.201 g of **3** (yield 86%) were obtained as colorless crystals (m.p. 136 °C). *Anal*. Found: C, 66.41; H, 8.10; N, 8.88. Calc. for $C_{26}H_{38}BN_3O_4$: C, 66.81; H, 8.19; N, 8.99%. NMR (25 °C): ^{1}H (250 MHz, $CDCl_3$): δ 0.84 (t, 12H, CH_3), 1.50 (m, 8H, CH_2–CH_3), 3.03 (t, 8H, CH_2–N), 7.32 (m, 6H, C_6H_5), 7.86 (m, 4H, C_6H_5). FTIR (KBr): 2975ms (ν CH_2/CH_3), 2945m (ν CH_2/CH_3), 1592ms (C_6H_5), 1558ms (C_6H_5), 1488ms, 1461m, 1447m (δ CH_2), 1377vs (ν OCN/δ CH_3), 1114s (ν_{as} $^{10}BO_4$), 1078s (ν_{as} $^{11}BO_4$), 981s, 944m (δ_{as} BO_4), 780m (ν ONC), 736m (ν ONC), 701ms (C_6H_5), 674m. FAB$^-$ MS; *m*/*z*: 281.2, 162.1.

2.2.4. Tetra-n-butylammonium bis(benzohydroximato)borate (*4*)

Compound **4** has been prepared from 0.062 g H_3BO_3 (1.00 mmol), 0.274 g benzohydroxamic acid (2.00 mmol), 0.240 g tetra-*n*-butylammonium bromide (1.00 mmol) and 0.116 g Ag_2O (0.50 mmol) as described for **3**, yielding 0.470 g (90%). M.p. 165 °C. *Anal*. Found: C, 67.64; H, 8.79; N, 8.07. Calc. for $C_{30}H_{46}BN_3O_4$: C, 68.83; H, 8.86; N, 8.03%. NMR (25 °C): ^{1}H (250 MHz, $CDCl_3$): δ 0.84 (t, 12H, CH_3), 1.40 (m, 16H, CH_2–CH_3), 3.14 (t, 8H, N–CH_2), 7.32 (m, 6H, C_6H_5), 7.86 (m, 4H, C_6H_5). FTIR (KBr): 2966ms (ν CH_2/CH_3), 2929m (ν CH_2/CH_3), 1594m (C_6H_5), 1558m (C_6H_5), 1490m, 1382vs (ν OCN), 1118s (ν_{as} $^{10}BO_4$), 1083vs (ν_{as} $^{11}BO_4$), 981 s, 944m (δ_{as} BO_4), 770m (ν ONC), 737m (ν ONC), 695s (C_6H_5), 670m (C_6H_5).

2.3. X-ray crystal structure determinations

Crystals of the chloroform solvate **1**·$CHCl_3$ and of **3** suitable for structure analysis were obtained from $CHCl_3$–*n*-C_6H_{14} solutions (1:1) of the complexes. The cell constants were calculated from 25 reflexes with a wide range of 2θ. The program HELENA [16] was used for the data reduction. Both complexes crystallize monoclinic. The space groups were assigned using the criterion of choosing the setting which corresponds to the lowest monoclinic β angle. The structures were solved by direct methods with SHELXS-97 [17] and

refined with SHELXL-97 [18]. A ψ-scans [16] absorption correction was performed and all non-hydrogen atoms were refined with anisotropic displacement parameters in both structures. The hydrogen atoms were found in the Fourier-map in **1**·$CHCl_3$ and calculated at idealized positions and refined using the riding model in **3**. Crystal data and more detailed information about the structure determinations are given in Table 1. Labeled diagrams of the structures of **1**·$CHCl_3$ and **3** are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. Synthesis of the bis(benzohydroximato)borates

Bis(benzohydroximato)borates were obtained in high yield in simple one-step reactions according to:

$$H_3BO_3 + 2C_6H_5CONHOH + R_2NH \rightarrow [R_2NH_2][B(C_6H_5CONO)_2] + 3H_2O$$

for **1** and **2**, or:

$$2H_3BO_3 + 4C_6H_5CONHOH + 2[R_4N]Br + Ag_2O \rightarrow 2[R_4N][B(C_6H_5CONO)_2] + 2AgBr + 7H_2O$$

for **3** and **4**.

The use of silver oxide and a quaternary ammonium bromide, which resulted in the formation of insoluble silver bromide and easily removable water as byproducts, proved to be a favorable synthetic route for tetraalkylammonium bis(benzohydroximato)borates.

These quaternary ammonium cations acted efficiently, as expected due to their favorable size, as counter ions for the crystallographic study also in absence of the N–H···O and N–H···N hydrogen bonds between the anionic complex and the counter ion, normally present in the lower alkylammonium salts, as in **1**·$CHCl_3$. Good quality crystals of **3**, additionally

without solvent of crystallization, could be obtained for this purpose.

3.2. Spectroscopic characterization

The infrared spectra of the presented compounds (KBr pellets) exhibit the expected characteristic features of the bis(hydroximato)borate moiety [14]. The strongest absorption at about 1080 cm^{-1} corresponds to ν_{as} $^{11}BO_4$, showing the component for ν_{as} $^{10}BO_4$ at about 1120 cm^{-1}. Another strong absorption band at approximately 985 cm^{-1} can be attributed to a deformation mode δ_{as} BO_4. The strong absorption band at about 1380 cm^{-1} most probably involves a stretching vibration of the OCN group (ν OCN) within the hydroximato chelate. The N–H stretching vibration of the dialkylammonium salts **1** and **2** appears as multicomponent absorption pattern in the range 3050–2400 cm^{-1}, characteristic for strong hydrogen bonds.

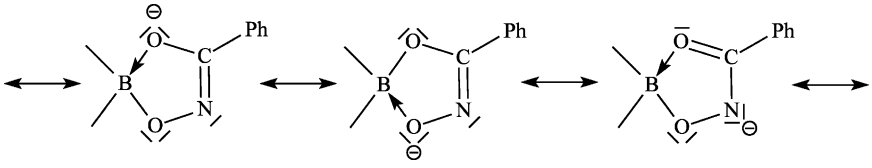
[a] Values for two non equivalent chelate rings, respectively.
[b] Symmetry operation: $-x+1$, $y+1/2$, $-z+1/2$.

The ^1H NMR spectra of the described hydroximatoborates in $CDCl_3$ show the expected patterns.

The FAB^- MS-Spectrum of **3** (nitrobenzylalcohol matrix) shows m/z peaks at 281.2 and 162.1, corresponding to $[B(C_6H_5CONO)_2]^-$ (281) and $[OB(C_6H_5CONO)]^-$ (162), respectively.

3.3. Crystal structures



The crystal structures show the expected spirochelate structure of the bis(benzohydroximato)borate anions with slightly distorted tetahedral BO_4 coordination. The B–O distances (mean value 147.0 pm) are in good agreement with the mean value of 146.8 pm for compounds containing the BO_4^- moiety [19]. The endocyclic O–B–O-angles lie between 101.6° and 102.7°, the exocyclic O–B–O-angles (112.5°–113.9°) are slightly larger compared to the ideal tetrahedral angle. The C–N bond lengths (126.5–128.9 pm) are

close to the standard value of a double bond. The C–O bonds (132.6–133.6 pm) are considerably shortened with respect to a single bond [19]. The N–O bond lengths (141.6–144.6 pm) correspond to a single bond and are longer compared to the mean N–O distance of 139.4 pm in oximes [19].

The chelate rings are essentially planar with maximum atomic displacements from the mean plane between 0.80 and 6.1 pm. The phenyl groups are slightly distorted with respect to the adjacent chelate rings, showing torsion angles from 4.80° to 27.18°.

Bond lengths and angles of the BONCO heterocyles in **1** and **3** show only slight variations and are in fairly good agreement with those observed in difluoro-*N*-methylacetohydroxamatoboron (**5**) [1]. The B–O distances in **1** and **3** (mean value 147.0 pm) are slightly shorter compared to **5** (mean value 148.3 pm) while the N–O bonds are considerably longer (mean value 142.7 for **1** and **3**, and 134.2 pm for **5**).

The structural data indicate a considerable delocalization of π electrons in the boron chelates **1** and **3**, as well as in the hydroxamatoboron complexes [1,2]. We propose the following resonance structures having major contribution to the bonding hybrid in the benzohydroximatoborates:

Strong hydrogen bonds between the dicyclohexylammonium nitrogen N(3) and the atoms N(1) and O(4), from different complex molecules, occur in **1**·$CHCl_3$, forming a chain like arrangement, as shown in Fig. 1. The distances N(3)–H(31)···N(1) = 286.7(6) and N(3)–H(31)···O(4b) = 283.6(4) pm are considerably shorter compared to the mean values for these types of H-bond, 307 and 293 pm [20], respectively. The corresponding bond angles are N(3)–H(31)–N(1) = 178(6)° and N(3)–H(31)–O(4b) = 175(5)°.

4. Conclusions

The comparison of crystallographic data shows that the bond lengths among the chelate ring in hydroximate(2−)- and in N-substituted hydroxamate(1−) boron complexes do not differ significantly, suggesting that the presence of an additional negative charge in the hydroximate anion does not change substantially the electron density distribution in the chelate ring, as it could be expected. Thus, the bonds among the rings are not affected due to the presence of the lone electron pair at the hydroximate's nitrogen atom in the bis(benzohydroximato)borate complex. Also the involvement of chelate's atoms in strong hydrogen bonds between the complex and the counter ion do not promote any substantial changes in the ring's bonds in **1**·$CHCl_3$, in comparison with the values found in **3**.

5. Supplementary material

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 178861 and 178862 for compounds **1**·$CHCl_3$ and **3**. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2, 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

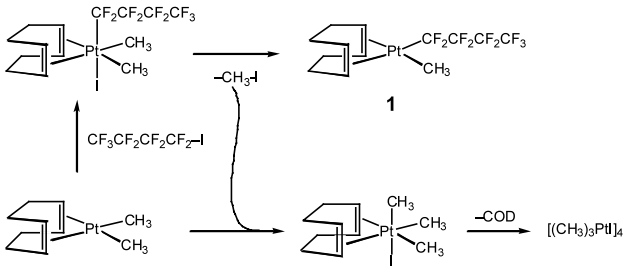
could not be isolated in the cases of larger primary and secondary perfluoroalkyl iodides. We have now reinvestigated the reaction of $(COD)PtMe_2$ with a higher fluoroalkyl iodide, $^nC_4F_9I$, and find that selective formation of a single fluoroalkyl product can be achieved under suitable reaction conditions.



2. Results and discussion

Modifications to the originally described procedures were made. Both previous reports describe syntheses using an excess of CF_3I, making the production of a mixture of compounds understandable. In contrast, we found that when a hexane suspension of $(COD)PtMe_2$ was allowed to react with only one molar equivalent of $^nC_4F_9I$, the ^{19}F NMR spectrum of the crude product indicated that only one fluorinated species was formed. However, the ^1H NMR spectrum showed the presence of two Pt species by virtue of two singlets corresponding to CH_3 groups with Pt satellites at δ 1.73 ($J = 77.1$ Hz) and 1.18 ($J = 79.2$ Hz), though there were only peaks arising from the presence of a single diolefin ligand. The two compounds were easily separated using hexane extraction.

The fluorinated organometallic complex was determined to be $(COD)PtMe(C_4F_9)$ (**1**). The ^{19}F NMR spectrum showed large Pt–F couplings for the α and β CF_2 groups (404, 102 Hz, respectively). The compound exhibited air and moisture stability and was soluble in all common organic solvents. Compound **1** is presumably formed by oxidative addition of the fluoroalkyl iodide to $(COD)PtMe_2$, followed by reductive elimination of CH_3I.

Indeed, the second platinum product giving rise to the ^1H NMR singlet at δ 1.73 was determined to be $[PtMe_3I]_4$, as previously observed [11]. Formation of this product is clearly the result of the oxidative addition of CH_3I (formed in the reductive elimination step that affords **1**) to the starting material $(COD)PtMe_2$, followed by loss of the diolefin from the putative Pt(IV) intermediate $(COD)PtMe_3I$, as shown in Scheme 1.

No bis(perfluoroalkyl) platinum species were formed using these conditions, even though there must be a slight excess of iodoperfluorocarbon due to the consumption of some $(COD)PtMe_2$ that instead reacts with

Scheme 1.

MeI. Presumably the absence of a large excess of iodoperfluorocarbon precludes subsequent oxidative addition reaction with **1** followed by a second elimination of CH_3I. However, we have not attempted to assess the role of the solvent. Previous reports used dichloromethane, and solvent effects have been shown to be important in such oxidative addition/reductive elimination reactions at platinum centers [13,14].

During the course of this work, we were fortuitously able to obtain single crystals of the starting material $(COD)PtMe_2$, the molecular structure of which has not been reported. As this compound would be a benchmark structure for other (COD)Pt compounds, we determined its solid state structure by means of a single crystal X-ray diffraction experiment. An ORTEP diagram is shown in Fig. 1. The Pt–C distances to the diolefin ligand fall in a narrow range [2.204(11)–2.255(12) Å, $\Delta = 0.051$ Å] as do the two Pt–CH_3 distances (2.040(11), 2.072(11) Å). These distances compare favorably with other bond lengths in similar bis(alkyl) or bis(aryl) COD complexes. There is a slightly larger range for the Pt–C bond distances involving the diene than in those observed in $(COD)Pt(Ph)_2$ which range from 2.249(5) to 2.278(6) Å ($\Delta = 0.029$ Å) [15], but they mirror those in $(COD)Pt(CH_2SiMe_3)_2$ where the range is 2.212(8)–2.268(9) Å ($\Delta = 0.056$ Å) [16]. Likewise, the Pt–CH_3 distances correspond well to those in $(COD)Pt(CH_2SiMe_3)_2$ (2.069(7), 2.070(8) Å) whereas the higher s-character in the carbon orbital of the phenyl groups in $(COD)Pt(Ph)_2$ understandably results in shorter Pt–C distances of 2.013(5) and 2.022(5) Å (Table 2).

In conclusion, we have described a controlled synthesis of a perfluoroalkyl platinum compound by the oxidative addition of C_4F_9I to the convenient starting material $(COD)PtMe_2$. By employing only one molar equivalent of iodoperfluorocarbon and using hexanes as the reaction solvent, the selective formation of only one fluorinated species could be achieved. The known Pt(IV) compound $[PtMe_3I]_4$ was isolated as well. An X-ray

[a] Quantity minimized $= R(wF^2) = [\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[(wF_o^2)^2]]^{1/2}$; $R(F) = \Sigma\Delta/\Sigma(F_o)$, $\Delta = |(F_o - F_c)|$.

crystallographic study of (COD)PtMe(C_4F_9) established the bond connectivity within the molecule, though detailed bond distances and angles could not be determined due to poorly diffracting crystals. In addition, we have determined the solid state structure of (COD)$PtMe_2$, which serves as a benchmark structure for COD containing Pt compounds. Future work will focus on the oxidative addition of other perfluoroalkyl iodides to Pt(II) species containing different ligand sets to control the electronic environment at the metal center as well as investigating the effect of solvent in such reactions.

3. Experimental

3.1. General considerations

All reactions were performed in oven-dried glassware, using standard Schlenk techniques, under an atmosphere of dinitrogen that had been deoxygenated over BASF catalyst and dried over Aquasorb®. Hexanes were distilled from sodium immediately before use. NMR spectra were recorded on a Varian Unity Plus 300 FT spectrometer. ^{1}H NMR spectra are referenced as ppm downfield from TMS. ^{19}F NMR spectra were referenced to $CFCl_3$ (0.00 ppm). Microanalyses were performed by Schwarzkopf Microanalytical Laboratory, Woodside, NY. $I(CF_2)_3CF_3$ (Aldrich) was purified by washing with a solution of sodium thiosulfate to remove iodine, followed by washing with water and then drying over magnesium sulfate and deoxygenation by several cycles of freeze–evacuate–thaw.

3.2. Reaction of (COD)$PtMe_2$ and n-C_4F_9I

(COD)$PtMe_2$ (0.10 g, 0.30 mmol) was suspended in hexanes (25 ml) in a 125 ml Schlenk flask and stirred vigorously. Neat n-C_4F_9I (78 μl) was added and the resulting mixture was allowed to stir for 12 h. The resultant yellow solid was filtered and washed twice with hexanes (10 ml). The combined filtrate and washings were evaporated under vacuum to give pale yellow (COD)PtMe(C_4F_9) (0.086 g, 0.16 mmol) in 53% yield. ^{1}H NMR (C_6D_6): δ 5.14 (br s, CH, $J_{PtH} = 34$ Hz); 4.44 (br s, CH, $J_{PtH} = 46$ Hz); 1.53 (br m, CH_2); 1.18 (s, CH_3, $J_{PtH} = 79$ Hz). ^{19}F NMR (C_6D_6): δ −81.2 (s, CF_3); −94.3 (br s, α-CF_2, $J_{PtF} = 404$ Hz); −115.3 (br s, β-CF_2, $J_{PtF} = 102$ Hz); −125.5 (br s, γ-CF_2). ^{19}F NMR (acetone-d_6): δ −82.2 (s, CF_3); −95.5 (br s, α-CF_2, $J_{PtF} = 404$ Hz); −116.4 (br s, β-CF_2, $J_{PtF} = 102$ Hz); −126.4 (br s, γ-CF_2). *Anal*. Calc. for $C_{13}H_{15}F_9Pt$: C, 29.06; H, 2.81. Found: C, 29.65; H, 2.70%.

The hexane-insoluble material was determined to be $[PtMe_3I]_4$ (0.044 g, 0.12 mmol) in 40% yield by comparison of its ^{1}H NMR spectrum to that previously obtained [17,18].

3.3. Crystallographic structural determination

Crystal, data collection, and refinement parameters are given in Table 1. The systematic absences in the diffraction data are uniquely consistent for the reported space group. The structure was solved using direct

methods, completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures. Empirical DIFABS [19] absorption corrections were applied to the data set. All non-hydrogen atoms were refined with anisotropic displacement coefficients and hydrogen atoms were treated as idealized contributions.

All software and sources of the scattering factors are contained in the SHELXTL (5.10) program library.

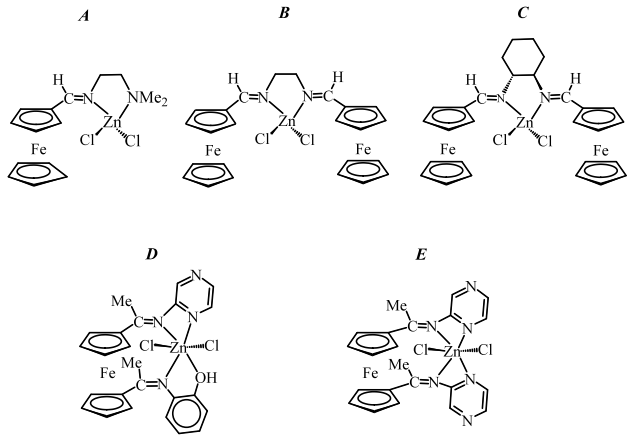

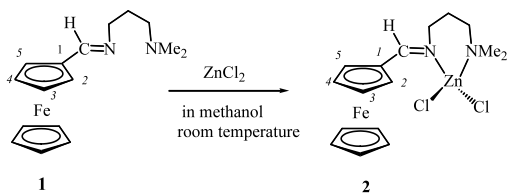

Fig. 1. Schematic view of some Zn(II) compounds containing ferrocenyl Schiff bases described so far.

preparation of several Pd(II) and Pt(II) complexes [11]. On this basis it seemed interesting to test its reactivity towards Zn(II) salts. In this manuscript we describe the synthesis and characterisation of *cis*-[Zn{(η^5-C_5H_5)Fe{(η^5-C_5H_4)–CH=N–$(CH_2)_3$–NMe_2}Cl_2] (**2**) as well as its behaviour in solution.

2. Results and discussion

When ligand **1** was treated with the equimolar amount of $ZnCl_2$ in methanol at room temperature, an orange solid was obtained (Scheme 1). Its elemental analyses (see Section 3) agreed with those expected for [Zn{(η^5-C_5H_5)Fe[(η^5-C_5H_4)–CH=N–$(CH_2)_3$–NMe_2]}Cl_2] (**2**), which arises from the binding of the two nitrogen atoms of the ligand to the '$ZnCl_2$' unit. The band due to the asymmetric stretching of the functional >C=N– group appeared at lower energies ($\nu = 1629$ cm^{-1}) than for the free ligand ($\nu = 1640$ cm^{-1}) [11]. This finding suggests, according to the literature [12], that the ligand binds to the Zn(II) through the imine nitrogen. Compound **2** has also been characterised by X-ray diffraction. Its molecular structure together with the atom numbering scheme is presented in Fig. 2, and a selection of bond lengths and angles are summarised in Table 1.

The structure consists of discrete molecules of [Zn{(η^5-C_5H_5)Fe[(η^5-C_5H_4)–CH=N–$(CH_2)_3$–NMe_2]}Cl_2], separated by van der Waals contacts. The

Standard deviation parameters are given in parenthesis.
[a] Average value for the ferrocenyl moiety.

zinc atom is tetracoordinated, bound to two chlorines {Cl(1) and Cl(2)} and the two nitrogen atoms of the ferrocenyl Schiff base {N(1) and N(2)} in a slightly distorted tetrahedral environment.

The variations observed in the Zn–Cl(1) and Zn–Cl(2) bond lengths may be attributed to the different *trans*-influence of the two nitrogen atoms {N(imine) vs. N(amine)} [13]. The N(1)–Zn–N(2) angle [93.60(9)°] is drastically reduced from the ideal tetrahedral value and the opposite Cl(1)–Zn–Cl(2) angle is 114.93(4)°.

The six-membered chelate ring has a chair-conformation in which the atoms N(1) and C(14) are out of the main plane defined by the Zn, N(2), C(12) and C(13) atoms.

The >C=N– bond length [1.286(3) Å] is similar to the values reported for related Schiff bases of general formula [(η^5-C_5H_5)Fe{(η^5-C_5H_4)–C(R)=N–R′}], derived from formyl-, acetyl- or benzoylferrocene [14]. The substituents at the imine group: C_5H_4 and the '–$(CH_2)_3$–NMe_2' moiety are in a *trans*-arrangement [the torsion angle defined by: C(10)–C(11)–N(1)–C(12) is 179.5°] thus confirming the *anti*-conformation of the ligand. This arrangement is consistent with the results

obtained from X-ray studies for a wide variety of Schiff bases containing ferrocenyl fragments [14,15].

The distance between the Cl(1) ligand and the H(6) atom is clearly smaller [2.60 Å] than the sum of the van der Waals radii of Cl (1.75 Å) and H (1.20 Å) [16], thus suggesting a weak C(6)···H(6)···Cl(1) intramolecular interaction. Similar types of interactions have also been recently described for a wide variety of transition metal complexes containing N-donor ferrocenyl groups [17].

The Fe–C and C–C bond lengths as well as bond angles of the ferrocenyl unit are similar to those reported for related complexes [18]. The two pentagonal rings are planar, nearly parallel [*tilt angle*: 2.54(19)°] and they deviate by approximately 0.42° from the ideal staggered conformation. The separation between the two metals {Fe and Zn} is 5.0218 Å, which implies that there is no direct interaction.

2.1. Solution studies

Despite the simplicity of the molecular structure of **2**, ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra of **2** in acetone-d_6 or in $CDCl_3$ registered at room temperature (25 °C) were more complex than expected. In all cases, two superimposed sets of signals of relative intensities 1:0.6 in acetone-d_6, (Fig. 3) and in $CDCl_3$ were observed in the ^{1}H NMR spectra (Table 2), thus, suggesting that at least two species coexisted in solution. Besides that, the comparison of the ^{1}H NMR spectra of freshly prepared solutions of **2** and after 24 h of storage at room temperature revealed that neither the positions of the signals or their relative intensities changed with time. The similarity between the molar ratios of the two species in $CDCl_3$ and acetone-d_6, suggested that the relative abundance was not dependent of the solvent.

All these observations are in contrast with the NMR studies reported for related Zn(II) complexes containing a five-membered chelate ring and a ferrocenyl- or a bis(ferrocenyl) Schiff base, such as $[Zn\{(\eta^5\text{-}C_5H_5)Fe[(\eta^5\text{-}C_5H_4)\text{–}CH\text{=}N\text{–}(CH_2)_2NMe_2]\}Cl_2]$ (**3**) [8] and $[Zn\{(\eta^5\text{-}C_5H_5)Fe[(\eta^5\text{-}C_5H_4)\text{–}CH\text{=}N\text{–}CH_2\text{–}]\}_2Cl_2]$ [6], for which only one set of signals was detected in the NMR spectra.

Molar conductivity measurements of 10^{-3} M solutions of **2** in acetone or in $CHCl_3$ (see Section 3) suggested a non-electrolyte nature [19] of the two species present in solution. Variable temperature ^{1}H NMR experiments of **2** in acetone-d_6 were also carried out in the range 220–320 K; however, coalescence was not observed.

The two-dimensional $\{^{1}H\text{–}^{1}H\}$ NMR experiments (NOESY and 2D-phase sensitive ROESY experiments) suggested that the two species did not interchange in solution. For the two species present in solution the signal due to the imine proton showed a cross-peak with that due to the H^5 proton (Fig. 4). Thus suggesting that these two protons are proximal in the two species. In addition, for the major component, the presence of an additional cross-peak between the imine proton and that belonging to the '–N–CH_2–' fragment was also observed (Fig. 4). This is only possible if the ligand adopts the *E*(*anti*-) form. These results suggested that the two species present in solution may differ in the conformation of the ligand *E*(*anti*-) or *Z*(*syn*-) (Fig. 5).

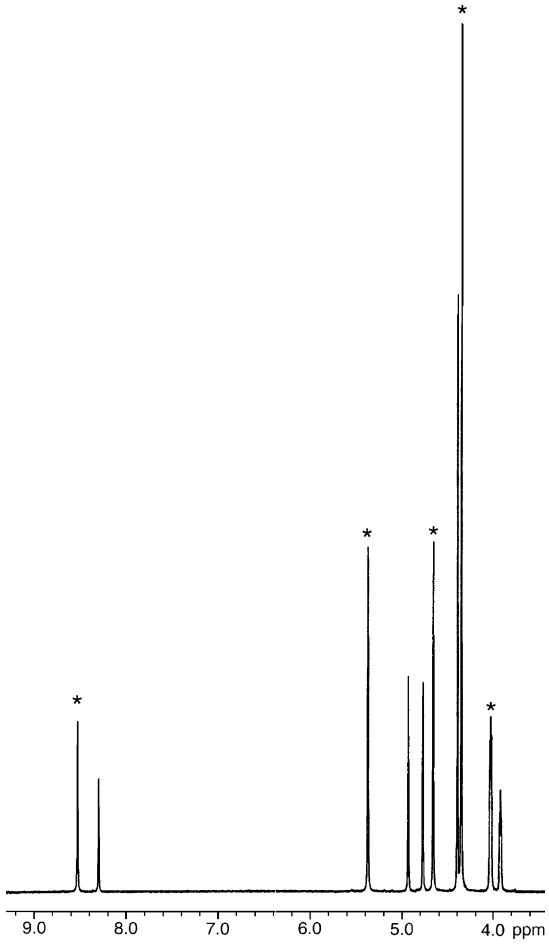

Fig. 3. Partial view of the ^{1}H NMR spectrum (500 MHz) of **2** in acetone-d_6 at room temperature (20 °C), in the range 3.70–9.30 ppm. The signals marked with an asterisk correspond to the major species present in the solution.

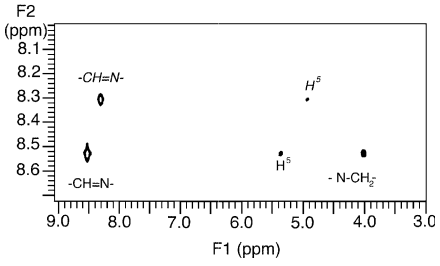

Fig. 4. Partial view of the $\{^{1}H\text{–}^{1}H\}$ NOESY spectrum of **2** in acetone-d_6 at 20 °C. Labels in italics correspond to the protons of the minor component.

[a] Labelling of the atoms refers to that shown in Scheme 1 (see text). The chemical shifts presented in the upper row correspond to the major component, and data given in the second row to the minor component.
[b] Partially overlapped by the signal due to the water present in the commercial acetone-d_6.
[c] Partially masked by the signal due to the solvent used in the experiment.
[d] Partially overlapped by the signal at $\delta = 1.90$ ppm due to the protons of the –N–CH_2– fragment of the major component.
[e] The signal due to the *ipso* carbon atom of the C_5H_4 ring (C^1), appeared at 74.9 ppm for the major component and at 74.0 ppm for the other component, in acetone-d_6 and at 72.1 ppm for the major component present in the $CDCl_3$ solution of **2**.
[f] The resonance due to the C^1 carbon of the minor component of the mixture was not observed.

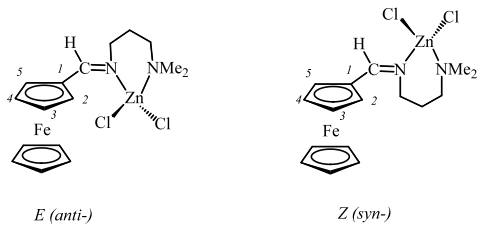

Fig. 5. Schematic view of the two isomeric forms of compound **2** which differ in the conformation of the ligand: *E*(*anti*-) and *Z*(*syn*-).

In order to ascertain if the duplicity of peaks observed in the NMR spectra could be ascribed to the existence in solution of a mixture of these two isomers, a theoretical study was undertaken based in DFT methodology. In a first step, the geometries of both isomers were fully optimised. The comparison of the corresponding energies reveals that the *E*(*anti*-) isomer is 2.78 kcal mol^{-1} more stable than the *Z*(*syn*-) isomer. The results agree with the fact that the *E*(*anti*-) isomer is more abundant in solution. However, the difference in energy is small enough as to allow the co-existence of the two isomers. In a second stage, and in order to perform a thermochemical analyses, a frequency calculation was carried out. In this case the difference in free energies (calculated at 298.15 K) was 2.97 kcal mol^{-1}, again being the *E*(*anti*-) isomer the most stable. Also the values of the corresponding entropies {168.6 cal K^{-1} mol^{-1} for the *Z*(*syn*-) isomer and 168.1 cal K^{-1} mol^{-1} for the *E*(*anti*-) isomer} are very similar. These results suggest that the difference in free energies between both isomers should change very little upon varying the temperature, thus supporting the results obtained from variable temperature ^1H NMR experiments.

Finally, in order to take into account the effects due to the solvent, calculations for the two isomers in chloroform have been performed using the Polarised Continuum Model [20]. The comparison of energies corresponding to the optimised geometries shows that also in this case the *E*(*anti*-) isomer is more stable, although the energy difference is (2.16 kcal mol^{-1}) slightly smaller than in the gas phase calculations.

In conclusion, the results presented here show how tiny changes on the backbone of the ligand such as the incorporation of a –CH_2– group could be important in determining the relative proportion of the two isomeric forms of compounds $[Zn\{(\eta^5\text{-}C_5H_5)Fe[(\eta^5\text{-}C_5H_4)\text{–}CH\text{=}N\text{–}(CH_2)_n\text{–}NMe_2]\}Cl_2]$ with $n = 2$ or 3.

3. Experimental

Elemental analyses (C, H and N) were carried out at the *Serveis Cientifico-Tècnics* de la *Universitat de Barcelona*. The IR spectrum was obtained with a Nicolet 520-FTIR spectrophotometer using KBr pellets. Routine ^1H and $^{13}C\{^1H\}$ NMR spectra were registered with a Gemini-200 MHz instrument at room temperature (r.t.). High resolution ^1H NMR spectra and the two-dimensional NMR experiments {heteronuclear single quantum coherence (HSQC) and heteronuclear multiple bond coherence (HMBC), NOESY and ROESY} were obtained with either a Bruker-DMX 500 MHz or a Varian-500 spectrophotometer using

C_3H_6O-d_6 (99.9%) or $CDCl_3$ (99.9%) as solvents and $SiMe_4$ as internal reference. The $\{^1H-^1H\}$ NOESY spectra of **2** were recorded at 20 °C using different mixing times (t) and the best results were obtained for $t = 0.65$ s. Variable temperature NMR experiments (in the range 220–320 K) were performed with a Bruker-DMX 500 MHz instrument using C_3H_6O-d_6 as solvent. Molar conductivity of 10^{-3} M solutions of **2** in C_3H_6O or $CHCl_3$ were measured at r.t. (25 °C) using a Crison-Micro-MC 2200 conductivity-meter.

3.1. Materials and synthesis

The ligand **1**, was prepared as described previously and $ZnCl_2$ was obtained from standard sources and used as received. The MeOH used for the preparation of **2** was HPLC grade [21], and the remaining solvents were dried and distilled before use.

3.1.1. Preparation of $[Zn\{(\eta^5\text{-}C_5H_5)Fe[(\eta^5\text{-}C_5H_4)\text{–}CH{=}N\text{–}(CH_2)_3\text{–}NMe_2]\}Cl_2]$ (2)

The ferrocenyl Schiff base **1**, (0.261 g, 9.5×10^{-4} mol) was dissolved in the minimum amount of MeOH (approximately 2 ml) [21]. Then a solution formed by 0.130 g (9.5×10^{-4} mol) of $ZnCl_2$ and 5 ml of MeOH was added. The reaction mixture was stirred at r.t. approximately 20 °C for 1 h. The orange solid formed was collected by filtration air-dried and then dried in vacuum for 2 days. (Yield: 0.338 g, 82%.) Good quality X-ray crystals were obtained by slow evaporation of a $CHCl_3$ solution of **2** at 20 °C. *Anal*. % Calc. for $C_{16}H_{22}Cl_2FeN_2Zn$ (Found): C, 44.23 (44.05); H, 5.10 (5.20); N, 6.45 (6.35). IR: $\nu(>C{=}N-) = 1629$ cm^{-1}. $\Lambda_M = 13$ (in C_3H_6O) and 8 (in $CHCl_3$) Ω^{-1} cm^2 M^{-1}.

3.2. Crystallography

3.2.1. Crystal data for 2

$C_{16}H_{22}Cl_2FeN_2Zn$, $M = 434.48$; monoclinic, space group: $P2_1/c$, $a = 10.3650(10)$, $b = 14.5620(10)$, $c = 12.7400(10)$ Å, $\alpha = \gamma = 90$ and $\beta = 111.7130(10)°$; $U = 1786.5(3)$ Å^3; $Z = 4$; $D_{calc} = 1.615$ mg m^{-3}; $\lambda = 0.71069$ Å, μ(Mo Kα) = 2.450 mm^{-1}; $F(000) = 888$, crystal dimensions: $0.1 \times 0.1 \times 0.2$ mm and $T = 293(2)$ K.

3.2.2. Data collection and refinement

A prismatic red crystal of compound **2** was selected and mounted on a MAR345 diffractometer with a image plate detector. Unit cell parameters were determined from automatic centring of 9359 reflections in the range $3 < \Theta < 31°$ and refined by least-squares method. Intensities were collected with a graphite monochromatized Mo Kα radiation. The number of reflections measured was 11 619, of which 5091 were non-equivalent by symmetry {R_{int} (on I) = 0.026} and 4210 reflections were assumed as observed applying the condition $I > 2\sigma(I)$. Lp and absorption corrections were performed. The structure was solved by direct methods, using SHELXS computer program [22] and refined by full-matrix least-squares method using SHELX-97 computer program [23] using 5091 reflections (very negative intensities were not assumed). The function minimized was $\Sigma\, w||F_o|^2 - |F_c|^2|^2$, where $w = [\sigma(I) + (0.0607P)^2 + 1.6746P]^{-1}$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. f, f' and f'' were taken from the literature [24]. All hydrogen atoms were located from a difference synthesis and refined with an overall isotropic temperature factor. The final R (on F) factor was 0.040, wR (on $F^2 = 0.108$) and the goodness-of-fit was 1.099 for all observed reflections. Final R indices were $R_1 = 0.0405$, $wR_2 = 0.1080$ for [$I > 2\sigma(I)$]; and $R_1 = 0.0503$, $wR_2 = 0.1165$ for all data.

3.3. Computational details

DFT calculations were performed using the GAUSSIAN-98 software [25], using B3LYP functional [26]. The basis set has been chosen as follows: 6-31G [27] for hydrogen, 6-31G with polarisation [28] for carbon and nitrogen and LANL2DZ [29] for Fe, Zn and Cl. In the later case, polarisation functions [30] have been added. PCM calculations have been carried out using the polarisable conductor calculation model [20b]. In all cases, geometries have been optimised without imposing any symmetry restriction.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 180588 for compound **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

[21] The use of high quality methanol (HPLC) is strongly recommended for the synthesis of **2**. The success of the preparation of **2** is strongly dependent on the quality of the methanol used since the presence of small amounts of water, reduces considerably the yield of the synthesis and produces the formation of large

amounts of ferrocenecarboxaldehyde due to the hydrolysis of the ligand.

carrier ligands (such as cisplatin and carboplatin) [15]. Oxaliplatin and JM216 are in clinical trials and show promise for the treatment of cisplatin-resistant tumors. Another platinum-based drug called L-NDDP (liposome-entrapped *cis*-bis(neodecanoato)(*trans*-diaminocyclohexane)platinum(II), which was developed in our laboratory, is also currently in clinical trials [16].

In our continuing efforts to develop new platinum-based antitumor agents, we have reported platinum(II) and platinum(IV) complexes with various isomers of 1,2-diaminocyclohexane (1,2-DACH) [17–21] and *cis*-1,4-DACH [22–26] as carrier ligands. Here we report the synthesis and characterization of a series of platinum complexes containing heptamethyleneimine as a non-leaving ligand and dicarboxylate as leaving group. We also report the X-ray crystal structure of *cis*-[Pt(heptamethyleneimine)$_2$(malonate)]·H_2O.

2. Experimental

2.1. Chemicals

K_2PtCl_4 was purchased from Johnson Mathey (Seabrook, NH). Heptamethyleneimine, 1,1-cyclobutanedicarboxylic acid, malonic acid, methylmalonic acid, dimethylmalonic acid, ethylmalonic acid, and diethylmalonic acid were obtained from Aldrich Chemical Co. (Milwaukee, WI). Silver nitrate, sodium hydroxide, sodium oxalate, sodium chloride, and potassium iodide were purchased from Fisher Scientific Co. (Houston, TX).

2.2. Physical measurements

Elemental analyses of the complexes were performed by Robertson Microlit Laboratories, Inc. (Madison, NJ). IR spectra in the range of 600–4000 and 100–600 cm^{-1} were recorded for complexes in KBr and polyethylene pellets, respectively, using a Perkin–Elmer 2000 spectrophotometer. ^{195}Pt NMR spectra were recorded at 43.055 MHz in D_2O using a Bruker Advance 300 spectrometer. The chemical shifts were referenced to an external standard of 2.2 M Na_2PtCl_6 in D_2O, which was set to 0.0 ppm.

2.3. Synthesis of platinum complexes

2.3.1. [$Pt^{II}(L)_2(CBDCA)$] (complex **1**)

The desired compound was synthesized using a slight modification of a previously described procedure [23,24]. K_2PtCl_4 (10.00 g, 24.09 mmol) was dissolved in 30 ml of deionized water and filtered. KI (31.99 g, 192.72 mmol) was dissolved in 150 ml of water and added to this solution. The reaction mixture was stirred for 15 min after which a solution of heptamethyleneimine (**L**) (5.46 g, 48.23 mmol) in 30 ml of methanol was added dropwise to the reaction mixture with stirring. After 2 h, a brown precipitate was obtained. The compound was separated by filtration and redissolved in DMF. This solution was filtered, evaporated to 10 ml under reduced pressure, and finally the product was precipitated with water to obtain a yellow crystalline compound, [$Pt(L)_2I_2$]. The solid was isolated by filtration and dried in vacuo. A solution of silver nitrate (0.245 g, 1.44 mmol) in 80 ml water was treated with [$Pt(L)_2I_2$] (0.500 g, 0.74 mmol) in the dark at room temperature. The reaction was allowed to proceed for 24 h before the precipitate of AgI was removed by filtration. The filtrate was reacted with an aqueous solution of the sodium salt of CBDCA (0.123 g, 0.74 mmol). The mixture was stirred for 24 h and concentrated to 15 ml under reduced pressure, then cooled to 6 °C for 24 h to afford a white crystalline precipitate. The product was collected by filtration, washed with small amount of cold water, and dried in vacuo (yield 72%).

Complexes **2**–**8** were prepared using a method similar to that described for preparing complex **1**, except that corresponding sodium salts of dicarboxylic acids were used.

2.4. Single crystal X-ray crystallographic study

The experimental details of the X-ray data collection, the structure solution, and refinement of the title compound are compiled in Table 1. A single crystal of [Pt(heptamethyleneimine)$_2$(malonate)]·H_2O was coated with a thin layer of epoxy cement and glued to the end of a glass fiber mounted on the goniometer of a Bruker SMART 1K diffractometer equipped with a CCD area detector. The data was corrected for Lorentz and polarization effects. Absorption correction was applied using the program SADABS [27]. No appreciable decay of the crystal was detected during data collection.

The structure was solved using direct methods with the SHELXTL software package [27]. Scattering factors were taken from the literature [28]. Heavy atoms were located initially in structure solution. All other atoms were located by successive Fourier maps and were refined using the full-matrix least-squares method on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions ($d_{C-H} = 0.96$ Å, $d_{N-H} = 0.90$ Å) and allowed to ride on the adjacent carbon atom. Toward the end of the structure solution, it became apparent that one of the heptamethyleneimine ligands was disordered over two positions in the crystal lattice. The disorder was modeled by allowing for partial occupancy of each of the potential atomic locations. Refinement of positional and anisotropic parameters of the resulting model, led to convergence.

Table 1
Crystal data and structure refinement for [Pt(heptamethyleneimine)$_2$(malonate)]·H_2O

Empirical formula	$C_{17}H_{32}N_2O_4Pt \cdot H_2O$
Formula weight	541.54
Temperature (K)	293(2)
Wavelength (Å)	0.71073

Largest difference peak and hole (e Å^{-3})	0.892 and −1.055

3. Results and discussion

3.1. Synthesis of platinum complexes

The procedure used in the synthesis of complexes is shown in Scheme 1. The desired compound was synthesized using a slight modification of previously described work [23,24]. K_2PtI_4 was prepared in situ according to Dhara's method through the reaction of K_2PtCl_4 with an excess of KI [29]. Addition of 2 equiv. of heptamethyleneimine (**L**) resulted in the precipitation of $[Pt(L)_2I_2]$. Reaction of $[Pt(L)_2I_2]$ with $AgNO_3$ produced $[Pt(L)_2(H_2O)_2](NO_3)_2$ in solution, which was directly reacted with 1 equiv. of the disodium salts of a dicarboxylic acids or an oxalate molecule (Na_2X) to form the white crystalline compound $[Pt(L)_2(X)]$.

$$K_2PtCl_4 + 8KI \longrightarrow K_2PtI_4 + 4KI + 4KCl$$
$$K_2PtI_4 + 2L \longrightarrow [Pt(L)_2I_2] + 2KI$$
$$[Pt(L)_2I_2] + 2AgNO_3 + 2H_2O \longrightarrow [Pt(L)_2(H_2O)_2](NO_3)_2 + 2AgI$$
$$[Pt(L)_2(H_2O)_2](NO_3)_2 + Na_2X \longrightarrow [Pt(L)_2(X)] + 2NaNO_3$$

Scheme 1.

3.2. Characterization of platinum complexes

The complexes were characterized by elemental analysis and IR, ^{13}C and ^{195}Pt NMR spectroscopy. The composition of each complex as determined by elemental analysis showed good agreement between the theoretical and actual values. The analytical results are summarized in Table 2. The results of characterization by IR and ^{195}Pt spectroscopy are shown in Table 3. In the IR spectra of all complexes, prominent changes were observed [30]. Broad absorption between 3120 and 3189 cm^{-1} in the IR spectra of all the complexes was attributed to the coordinated N–H bond of ligand L. The carboxyl groups in all the complexes displayed a band in the range of 1600–1674 cm^{-1} corresponding to the ν(C=O) band. The ν(C–O) band appeared in the range of 1347–1384 cm^{-1}. The Pt–N and Pt–O stretching frequencies in all the complexes showed peaks in the range of 549–609 and 457–483 cm^{-1}, respectively.

The proton-decoupled ^{13}C NMR spectra showed a signal in the range of 175–190 ppm for the carbonyl carbon of coordinated carboxylate ligands. This suggests that the two carboxylate carbons are magnetically equivalent in these complexes. These values are also close to the values for carboxylate carbons reported for other platinum carboxylate complexes [17,31,32]. In all

Table 2
Elemental analysis of platinum(II) complexes

Complex	Complex name	Observed (calculated)		
		C (%)	H (%)	N (%)
1	[Pt(L)$_2$(CBDCA)]·2.5H_2O	42.51 (42.63)	6.53 (6.39)	5.18 (4.97)

4	3120	1673	1381	553	477	180	−1996
5	3168	1612	1381	609	457	182	−1943
6	3189	1600	1384	553	472	184	−1976
7	3135	1623	1376	577	478	182	−1932

[a] NMR data were recorded in D_2O.

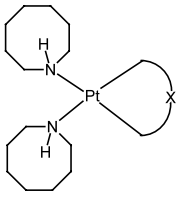

Fig. 1. Chemical structure of [Pt(heptamethyleneimine)$_2$(X)], where X = CBDCA, oxalate, malonate, methylmalonate, dimethylmalonate, ethylmalonate, or diethylmalonate.

cases, the ^{13}C NMR shifts of the free acids and platinum complexes ($\Delta C = \delta$[complex] − δ[ligand]) fell between 1.6 and 2.2 ppm.

In the ^{195}Pt NMR spectra, the singlet observed in the range of −1932 to −2041 ppm was assignable to the PtN_2O_2 system and this value was close to the related square-planar platinum(II) complexes having two nitrogen and two oxygen atoms as donor ligands [33–35], (Fig. 1).

3.3. Crystal structure

The complex [Pt(heptamethyleneimine)$_2$(malonate)] gave crystals suitable for single crystal X-ray diffraction studies. The crystals were obtained by slow evaporation in air of a concentrated aqueous solution of the complex. A representative view of [Pt(heptamethyleneimine)$_2$(malonate)]·H_2O including the numbering scheme employed in this work is provided in Fig. 2. Selected bond lengths and bond angles of the molecule are given in Table 4.

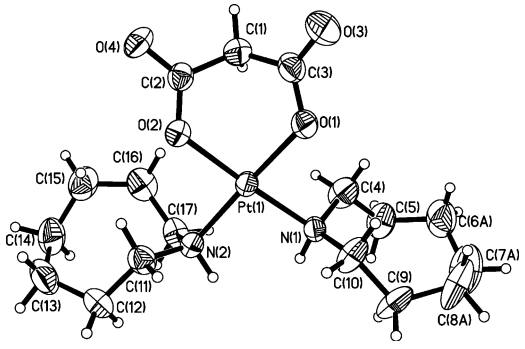

Fig. 2. ORTEP representation of the structure of [Pt(heptamethyleneimine)$_2$(malonate)]. Thermal ellipsoids are drawn at the 50% probability level. Only one orientation of the disordered ligand is shown.

Table 4
Selected bond lengths (Å) and angles (°) for [Pt^{II}(heptamethyleneimine)$_2$ (malonate)]·H_2O

Bond lengths	
Pt(1)–O(1)	2.026(3)
Pt(1)–O(2)	2.036(3)
Pt(1)–N(1)	2.048(3)
Pt(1)–N(2)	2.056(3)
Bond angles	
O(1)–Pt(1)–O(2)	89.27(12)
O(1)–Pt(1)–N(1)	88.46(12)
O(2)–Pt(1)–N(1)	177.35(11)
C(10)–N(1)–Pt(1)	110.6(3)
C(4)–N(1)–Pt(1)	108.6(3)
C(17)–N(2)–Pt(1)	114.2(3)
O(1)–Pt(1)–N(2)	175.92(13)
O(2)–Pt(1)–N(2)	91.39(12)
N(1)–Pt(1)–N(2)	90.96(12)
C(11)–N(2)–Pt(1)	111.6(3)
C(3)–O(1)–Pt(1)	120.3(3)
C(2)–O(2)–Pt(1)	119.9(3)

The platinum center exists in a slightly distorted square-planar coordination environment. The Pt–O bond distances are 2.026(3) and 2.036(3) Å, while the Pt–N bond distances are 2.048(3) and 2.056(3) Å. These distances are in agreement with similar complexes (Pt–N and Pt–O bond distances in compound $Pt(NH_3)_2$(CBDCA) are 2.017 and 2.031 Å) [17,36–40]. An eight-membered cyclic amine acts as a monodentate ligand coordinated with platinum atoms in the *cis* positions. The remaining positions in the metal coordination sphere are occupied by two oxygen atoms of the malonate ligand. The bond angles of O(1)–Pt–O(2) and O(1)–Pt–N(1) are 89.27(12)° and 88.46(12)°, respectively, for the *cis* coordination, where as O(2)–Pt–N(1) and O(1)–Pt–N(2) are 177.35(11)° and 175.92(13)°, respectively, for the *trans* coordination. The Pt–N–C

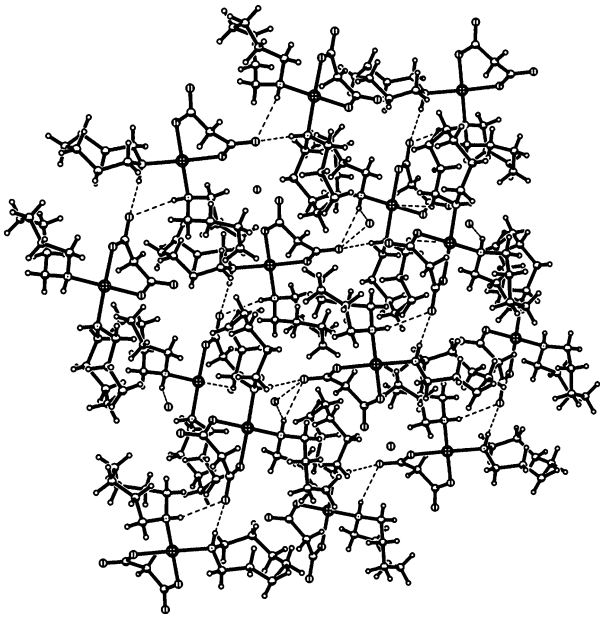

Fig. 3. Packing diagram of [Pt(heptamethyleneimine)$_2$(malonate)]·H_2O. Hydrogen bonds are indicated by dashed lines.

angles are comparable (108.6(3)°, 110.6(3)° and 111.6(3)°, 114.2(3)°), with tetrahedral value as observed in other Pt–amine compounds. The Pt–O–C angles are comparable with (120.3(3)° and 119.9(3)°) $Pt(NH_3)_2$(CBDCA) (Pt–O–C angles are 121.3(3)°) [36,37].

The title complex was found to cocrystallize with a molecule of water in the solid-state. Analysis of the single crystal X-ray diffraction data revealed that there were hydrogen bonds present between the heptamethyleneimine ligand and the malonate ligand ($d_{O\cdots N}$ = ~2.97 Å) and between the solvent water and the malonate ligand ($d_{O\cdots O}$ = ~2.87 Å). A packing diagram including a representation of the hydrogen bonding network is presented in Fig. 3.

In conclusion, we have synthesized and characterized a series of new cisplatin analogs containing heptamethyleneimine as nonleaving ligand and oxalate, malonate, methylmalonate, ethylmalonate, dimethylmalonate, diethylmalonate, or CBDCA as leaving ligand. The structure of *cis*-[Pt(L)$_2$(malonate)]·H_2O was determined by X-ray crystallography.

(I) cetonic form (II) enolic form

the knowledge of some spectroscopic, thermal and conductimetric properties, a report of the experiments and results obtained with DPKBH and DPKBH/Ni(II) complex is to follow.

2. Experimental

2.1. Reagents and solutions

All reagents and solvents were of analytical-reagent grade. The synthesis of DPKBH was performed as previously reported by Garcia-Vargas et al. [8]. The ligand was obtained from the reaction of stoichiometric amounts of di-2-pyridyl ketone and benzoylhydrazide mixed in EtOH, when few drops of concd. HCl were added. The mixture was refluxed for 1 h, and after cooling, distilled water was added to a 1:3 volume ratio (EtOH–water). Several drops of NaOH solution were added to the refluxed solution to increase the pH to approximately 5. The resulting precipitate was collected on a Büchner funnel and recrystallized twice from an EtOH–water solution. After synthesis, the m.p. of the product was verified to be (137 ± 1) °C and it is in excellent agreement with the literature [8]. DPKBH solutions were prepared by dissolving the reagent in EtOH; $NiSO_4 \cdot 6H_2O$ was dissolved in water and the respective concentration was determined with standard EDTA solution titration.

The complex was prepared by reaction between the corresponding Ni hydrated salt and the ligand (molar ratio 1:2) in EtOH. This molar ratio was achieved by mixing 30 ml of each solution: 2×10^{-2} mol l^{-1} Ni(II) and 4×10^{-2} mol l^{-1} DPKBH. After a slow evaporation of the solvent, the complex was dried under vacuum over anhydrous $CaCl_2$ and purple crystals were obtained.

The experimental data necessary to apply the continuous variations [13–17] or Job's method are the absorbances relatives to solutions with different ligand molar fraction, varying both from the concentrations (Ni(II) and DPKBH) but maintaining constant the sum of the ligand and metal ion concentrations, 5×10^{-5} mol l^{-1}. These solutions are obtained with complementary volumes of equimolar solutions when the total volume is constant. The stoichiometry of the Ni(II)/DPKBH complexes was determined using a series of solutions having a constant sum of the DPKBH and Ni(II) concentrations, in 50% EtOH–water and pH 6 adjusted with 3.2×10^{-2} mol l^{-1} CH_3COONH_4. The molar ratio was varied from 0 to 1 and the absorbances values were measured at $\lambda = 390$ nm, using pathlength of 1.0 cm.

2.2. Apparatus

The UV–Vis spectra were registered on an Hewlett-Packard (HP) 8452A diode-array spectrophotometer using 1.00 cm quartz cells. The pH measurements were performed with a Metrohm 654 pHmeter equipped with a Metrohm glass electrode of which the Ag/AgCl reference was filled with 3 mol l^{-1} NaCl. FTIR spectra (4000–500 cm^{-1}; KBr pellets) were recorded on a Perkin–Elmer 1750 Series FTIR spectrophotometer. The mass spectra were obtained with a Mat-90 of the Finnigan-Mat. A CHN Elemental Analyzer instrument from Perkin–Elmer model 2400 was used to determine the C, H and N percentages both in DPKBH and Ni(II)/DPKBH complex. The percentage of oxygen in the ligand was calculated by difference and the Ni(II) percentage present in the complex was obtained from TG experiments. The conductance measurements were obtained on a Micronal conductometer model B 330 and using the Analyzer 7A04 conductivity cell. TG/DTG curves were obtained on a Model TGA50 thermogravimetric Analyzer (Shimadzu) in the range of 25–900 °C with 10 °C min^{-1} heating rate, under dynamic nitrogen atmosphere (approximately 50 ml min^{-1}) and samples weighing between 3.5 and 4.3 mg, in Pt crucible. DSC curves were registered on a model DSC50 (Shimadzu) in the temperature range of 25–600 °C, with a heating rate of 10 °C min^{-1}, under dynamic nitrogen atmosphere (approximately 50 ml min^{-1}) with sample masses in the range of 1–2.3 mg, in aluminum crucibles. DSC system was calibrated with indium (m.p. = 156.6 °C; $\Delta H_{fus} = 28.54$ J g^{-1}) and Zn (m.p. = 419.6 °C).

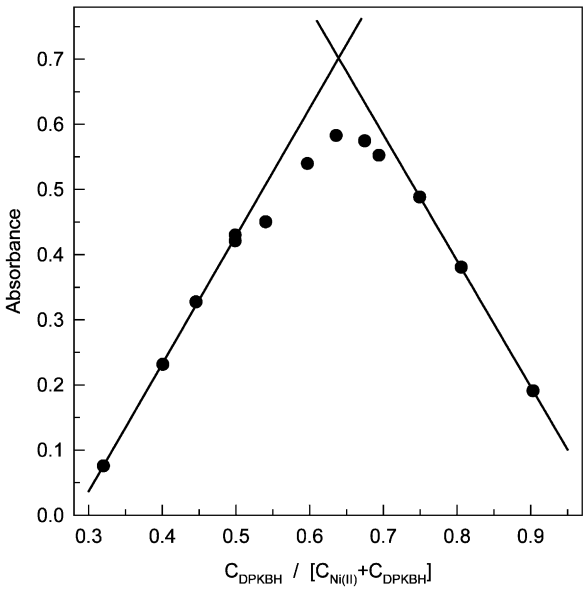

Fig. 1. Values of absorbance vs. molar fraction of the ligand, $C_{DPKBH}/(C_{Ni(II)}+C_{DPKBH})$. Pathlength = 1 cm, $\lambda = 390$ nm, pH 6. $C_{DPKBH}+C_{Ni(II)} = 5.00 \times 10^{-5}$ mol l^{-1} in ethanol/water 50% (v/v).

3. Results and discussion

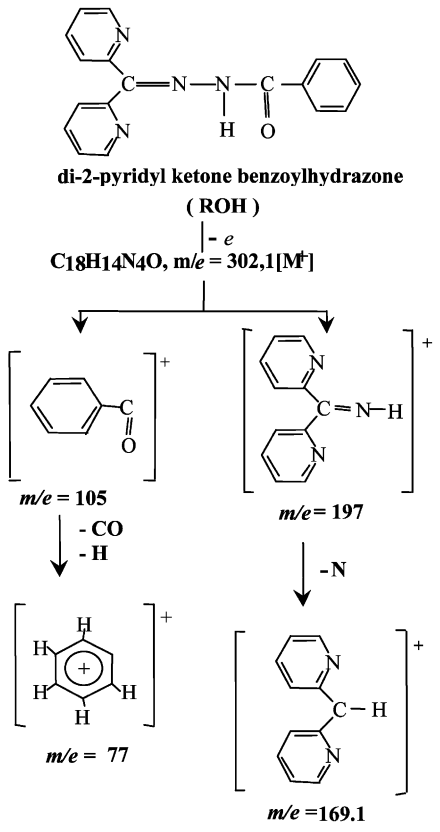
The molar ratio relative to the maximum of the Job's curve [17] corresponds to the more favorable species present in the equilibrium and it is obtained from the intersection between the tangents of the curves. Fig. 1 shows the absorbances at $\lambda = 390$ nm for several solutions with different molar (DPKBH: [Ni(II)+DPKBH]) ratios. The maximum absorbance was found at a molar ratio equal to 0.64 which corresponds to a 1:2 metal–ligand molar ratio or the coordination of two molecules of DPKBH to Ni(II).

In aqueous–ethanolic–acid solutions, DPKBH exhibits an acid equilibrium between the neutral and the protonated forms. Considering the protonation of a pyridine nitrogen atom, the extension of this equilibrium is given by the respective ionization constant ($pK_1 = 3.362$) [18]. The dissociation of a proton from the neutral DPKBH molecule (from COH group) is not favorable under the conditions of our experiments (pH 6) but, the interaction between DPKBH and the metal cation promotes an enhancement in the ligand acidity and it can change to an anionic form. In order to check this assumption, molar conductances were followed during the complexation of Ni(II) by DPKBH in a titration mode. The very low initial conductance of a DPKBH/ethanol/water solution varied significantly when a solution of Ni(II) was added. The known acidity of the Ni(II) stock solution necessary to avoid its hydrolysis was considered in the calculations.

Molar conductances were determined in a titration of 1.00×10^{-3} mol l^{-1} DPKBH solution with 9.90×10^{-3} mol l^{-1} $Ni(SO_4)\cdot 6H_2O$ (pH 3.1), both of them in ethanol/water 50% (v/v). The conductance values plotted versus Ni(II) volumes showed two linear segments with very different slopes with an intersection that corresponds to 1:2 molar ratio for Ni(II)–DPKBH. The first linear segment, which is in a range of concentration of DPKBH higher than the Ni(II) one, has a slope higher than the second segment showing that the coordination of DPKBH to Ni(II) is via an anionic form with H^+ releasing.

The opposite titration, i.e. 9.90×10^{-4} mol l^{-1} Ni(II) solution (pH 3.1) with 1.00×10^{-2} mol l^{-1} DPKBH showed a similar behavior for the conductance measurements as a function of the DPKBH volume. The intersection between the segments was observed on a 1:2 ratio of Ni(II)–DPKBH, in an excellent agreement with the first titration. The first segment showed a high slope and in the second part the conductance was almost constant due to the presence of excess of ligand, DPKBH, which is a very weak acid.

Mass spectra of the ligand and the complex Ni(II)/DPKBH were recorded in a range of *m/e* ratio between 0 and 800. For the Ni(II)/DPKBH complexes, the more intensive peak or the base peak was found at *m/e* = 169.1. The molecular peak ion was observed at *m/e* = 662.6; corresponding to the formula weight of the complex, $[Ni(DPKBH)_2]$. The base peak for the ligand



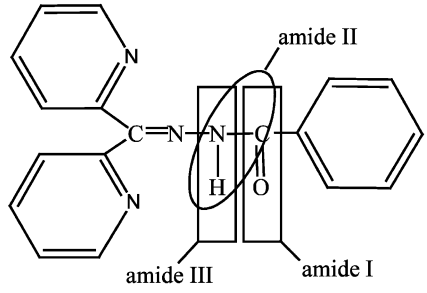


Fig. 2. Main DPKBH fragments relatives to the main peaks registered in the mass spectra.

Table 1
Important IR frequencies (cm^{-1}) of DPKBH and Ni(II)/DPKBH complex and their assignments [a]

Ni(II)/DPKBH λ (cm^{-1})	DPKBH λ (cm^{-1})	Assignment
3055 w	3063 w	=C–H phenolic, N–H
	1686 vs	amide I (C=O)
1587 m	1581 m	(C–C and C–N) phenolic
	1533 m	(CN, δ NH) amide II

1465 m	1464 s	C–C and C–N pyridyn
1357 s		phenolic
1320 s	1322 m	phenolic
1290 s	1265 m	amide III (δ NH)
1087 s	1081 m	C–H phenolic
746 w	746 m	C–H phenolic
714 m	706 s	δ (OH) out-of-plane

[a] s, strong; m, medium; w, weak; and vs, very strong.

was found also at $m/e = 169.1$ and the molecular ion peak at $m/e = 302.1$ which corresponds to the formula weight of the ligand. The peaks lower than 200 (77.0, 105.0, 169.1 and 197.0) were the same for the ligand and the complex. The main fragments found for the DPKBH are indicated in Fig. 2.

Table 1 presents the main IR data for the ligand and the complex. Since DPKBH exhibits a keto-enol tautomerism [8], the IR spectra were used to determine which forms predominate in the nickel complex formation. IR spectrum of the complex differs significantly from that of the free ligand. The ν(N–H) band almost disappears in the 3000 cm^{-1} region, as a consequence of the deprotonation of the CONH system [19]. The high intensity band due to the C=O stretch [19–21] in 1686 cm^{-1} observed for the ligand is also suppressed in the spectrum of the complex. The shift of the carbonyl stretching mode to lower frequencies is in accordance with coordination through oxygen [20]. The bands due to phenolic group C–O in 1322 and 1265 cm^{-1} are shifted to a higher frequency [22] in the complex, to 1357 and 1290 cm^{-1}, respectively, with a higher intensity.

All these observations suggest that, in the complex, DPKBH exists in the enol form and exhibits a tridentate behavior. This result confirms the conductance data that indicated a coordination of DPKBH via an anionic form.

Table 2 shows the elemental analysis data for DPKBH and its complex with Ni(II). These results are in an excellent agreement with the calculated C, H and N percentages for the ligand and the respective complex of Ni(II) considering a 1:2 stoichiometry: $[Ni(DPKBH)_2]$. The calculated oxygen percentage and the complement of (C+H+N) experimental percentage are 5.29 and 5.06, respectively, showing also a good agreement. The calculation was realized considering the formula weight of the DPKBH equal to 302.34 g mol^{-1}.

The thermal behavior of the compounds under investigation was studied using the thermogravimetry/derivative thermogravimetry (TG/DTG) and the DSC techniques. Fig. 3 shows TG/DTG curves for the ligand and the Ni(II) complex. Thermal decomposition of DPKBH occurs abruptly in a single step, with a DTG peak at 315 °C. Several thermal events for the Ni(II)/DPKBH complex appear between 359 and 900 °C. The first and fastest mass loss observed between 359 and 375 °C, with a DTG peak at 365 °C and $\Delta m = 45.4\%$ corresponds to the elimination of one molecule of DPKBH (calculated value = 45.7%). At higher temperatures (375–730 °C), a gradual mass loss totalizes 43.1%. The total mass loss was found to be 88.5% and the color of the residue was green. This evidence led to consider that nickel oxide is the final product of the thermal decomposition.

Considering the total decomposition of the $[Ni(DPKBH)_2]$ complex and NiO as the residue at

Table 2
Elementary analysis of the DPKBH ligand and Ni(II)/DPKBH complex

%	DPKBH (MM = 302.34 Da)			$[Ni(DPKBH)_2]$ (MM = 661.36 Da)		
	Calculated	Experimental	Error (%)	Calculated	Experimental	Error (%)
C	71.51	71.51	0	65.38	65.23	0.2
H	4.67	4.73	1.3	3.96	4.11	−3.8
N	18.53	18.70	−0.92	16.94	16.74	1.2
Ni(II)				8.87	9.04 [a]	−1.9

[a] Calculated from TG/DTG.

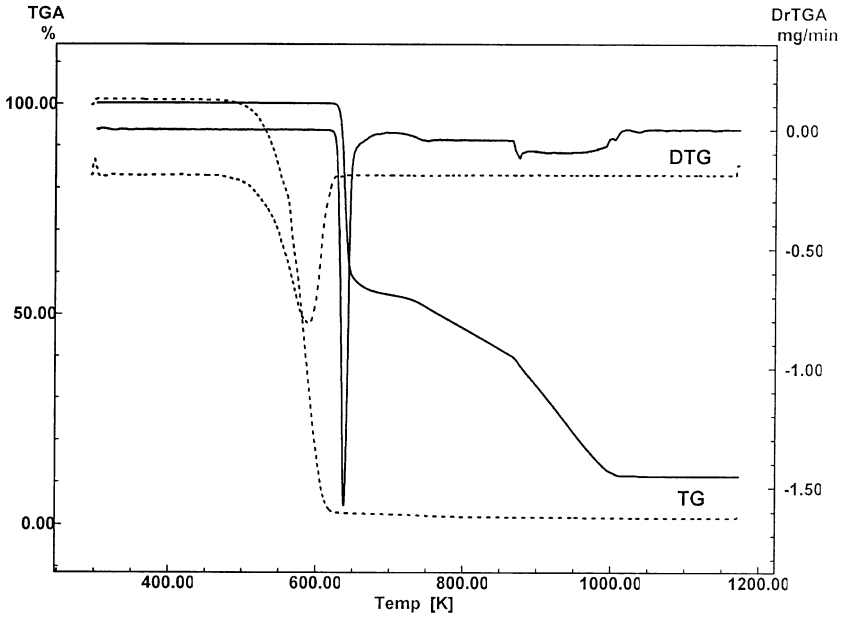

Fig. 3. TG/DTG curves: for (---) DPKBH ($m = 3.577$ mg) and (—) [Ni(DPKBH)$_2$] ($m = 4.285$ mg). Both of the curves were obtained in dynamic nitrogen atmosphere (approximately 50.0 ml min^{-1}) and heating rate of 10 °C min^{-1}.

730 °C, the experimental value (11.5%) is in accordance with the calculated percentage (11.3%) of the residue. This good agreement is another evidence about the coordination of two molecules of DPKBH to Ni(II) cations and confirms the proposed stoichiometry for this complex.

A comparison between TG/DTG curves of the ligand and the complex shows a higher thermal stability for this last because the mass losses begin at 359 and 246 °C for the complex and the ligand, respectively. This higher stability of the ligand when it is coordinated to Ni(II) is owing to the ligand–metal interaction.

DSC curves of DPKBH and [Ni(DPKBH)$_2$] are shown in Fig. 4. DSC curve profiles are quite different for the ligand and the complex. The ligand shows an intense sharp endothermic peak between 137 and 147 °C and, $\Delta H = 122.5$ kJ mol^{-1} that corresponds to the melting of DPKBH; TG/DTG curves do not present mass loss in that temperature range. The onset temperature, 137.9 °C, is in an excellent agreement with the

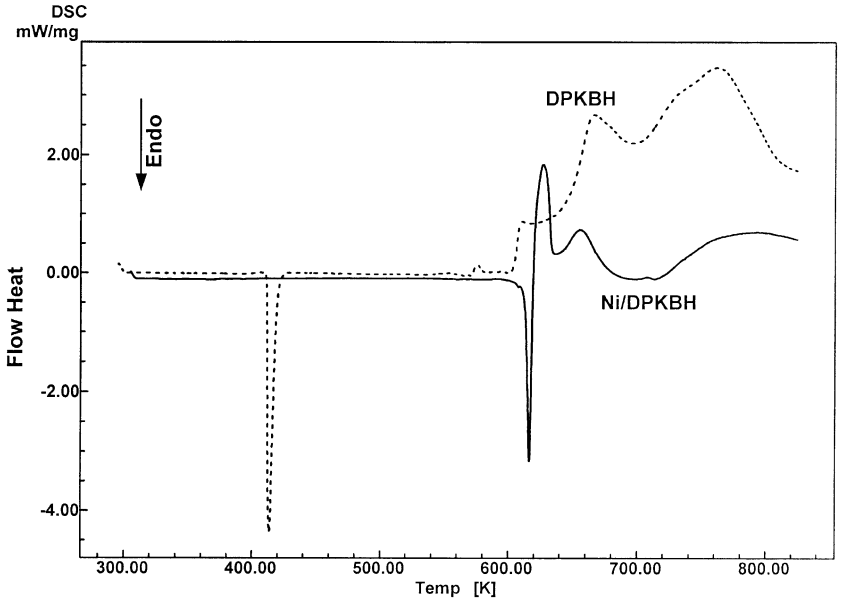

Fig. 4. DSC curves of the ligand and [Ni(DPKBH)$_2$] obtained in dynamic nitrogen atmosphere (approximately 50.0 ml min^{-1}) and heating rate of 10 °C min^{-1}, respectively, with mass 2.305 and 1.128 mg.

temperature range of melting indicated in Section 2. Above 300 °C, several exothermic peaks can be seen and they are related to thermal decomposition processes. DSC curve of the complex shows a sharp endothermic peak which characterizes the melting process at 343 °C with $\Delta H = 72$ kJ mol^{-1}. After the complex melting, a fast thermal decomposition indicated by exothermic peaks is observed and such peaks are associated with a gradual mass loss process.

After 2 days violet–grey crystals were obtained. The CMANa compound was prepared by a published method [9].

Anal. Calc. for: $C_{36}O_{10}N_6H_{34}Cu$: C, 55.85; H, 4.43; N, 10.85; Cu 8.21. Found: C, 55.12; H, 4.65; N, 10.46; Cu, 8.45%.

2.2. Physical measurements

The solid state spectrum of a powdered sample was measured in the diffuse reflectance mode on a Carry 500 Scan (Varian) UV–Vis–NIR spectrophotometer. Variable temperature magnetic susceptibility data were measured using a Cahn RH electrobalance by the Faraday method. The magnetic field applied was 4.28 kOe, and the temperature range was 4.2–300 K.

The EPR spectrum was recorded on a Bruker ESP 300E (Bruker, Germany) spectrometer operating at X-band and equipped with a Bruker NMR gaussmeter ER 035M and a Hewlett–Packard microwave frequency counter HP 5350B. EPR parameters were calculated by computer simulation of the experimental spectrum using Bruker WIN–EPR SIMFONIA Software Version 1.25.

IR spectra were recorded as KBr pellets or nujol mulls by using Perkin–Elmer 1600 and Perkin–Elmer 180 spectrophotometers. The Raman spectrum of the solid sample was recorded on a Magna (Nicolet) instrument with 1064 nm excitation.

2.3. Crystal data

The crystal was mounted on a glass fiber and then flash-frozen to 100 K (Oxford Cryosystem-Cryostream Cooler). Preliminary examination and intensity data collections were carried out on a Kuma KM4 CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. Crystals were positioned at 65 mm from the KM4CCD camera. Six hundred and twelve frames were measured at 0.75° intervals with a counting time of 25 s. The data were corrected for Lorentz and polarization effects. An absorption correction was also applied. Data reduction and analysis were carried out with the Kuma Diffraction (Wrocław) programs. The structure was solved by direct methods [13] (program SHELXS-97) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 [14] programs. All hydrogen atoms were found by Fourier synthesis. Crystal data and the details of data collection and the refinement procedure are given in Table 1.

3. Results and discussion

The direct reaction of Him, CMANa and $CuCl_2$ in water or ethanol solution yields the violet–grey crystals of the title compound. The structure of the molecule of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ is shown in Fig. 1, the packing of the complex in the crystal along with the hydrogen bond system is shown in Fig. 2. Selected bond distances and angles are listed in the Table 2.

Table 1

Z	2
μ (mm^{-1})	0.728
Number of reflections measured	10 714
Number of independent reflections	3095
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0341$ [a], $wR_2 = 0.0859$ [b]
R indices (all data)	$R_1 = 0.0494$ [a], $wR_2 = 0.0895$ [b]

[a] $R_1 = \Sigma||F_o|-|F_c||/\Sigma|F_o|$.
[b] $wR_2 = \{\Sigma[w(F_o^2-F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$.

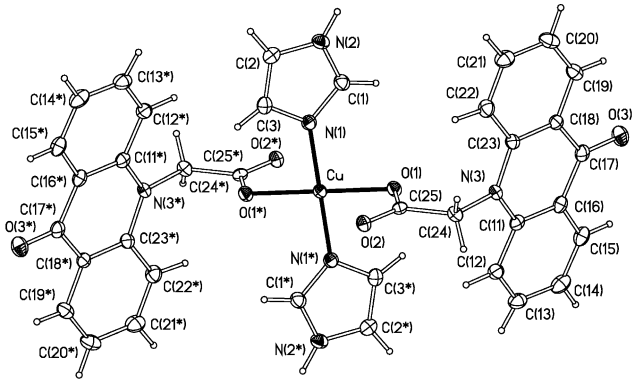

Fig. 1. ORTEP drawing for the $Cu(CMA)_2(Him)_2$ molecule. Ellipsoids at 50% probability level. Symmetry transformations used to generate equivalent atoms: *, $-x$, $-y+1$, $-z$.

The crystal of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ consists of neutral monomers of the complex and water molecules. The copper ion, located in the center of symmetry, is coordinated via two imidazole nitrogen atoms (N1) and two carboxylic oxygen atoms (O1) from the CMA^- ligands. Moreover, short non-bonding Cu–O contacts are observed, the length of Cu–O(2) is 2.790(1) Å. Therefore, the title compound can be regarded as a pseudo-six-coordinated complex. This geometry around the copper is typical of ternary complexes of Cu(II) with carboxylates and aromatic amines or imidazole [4,15–24]. The length of Cu–O(1) bond equals 1.977(2) Å and is in the normal range for a carboxylate group monodentately coordinated to copper, whereas the Cu–N(1)

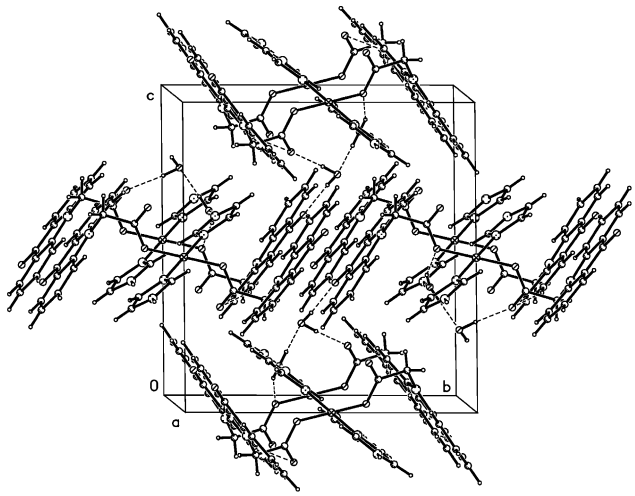

Fig. 2. The crystal packing of $Cu(CMA)_2(Him)_2\cdot 4H_2O$. Hydrogen bonds are indicated by dashed lines.

Table 2
Selected bond lengths (Å) and angles (°) for $Cu(CMA)_2(Him)_2\cdot 4H_2O$

O(1)–Cu–O(1*)	180.00(7)

Symmetry transformations used to generate equivalent atoms: *, $-x$, $-y+1$, $-z$.

distance of 1.953(2) Å is very short as compared with those observed for imidazole coordinated to copper(II) [2–4,7,8,15–17,24,25,27]. The distance between the copper ion and O(2) oxygen atom is very long and corresponds well with those found in similar copper-carboxylate-imidazole systems [2,4,15–17,24,25]. The mean $Cu–O_{axial}$ distance estimated for 136 monomeric hexacoordinate copper(II) compounds with the O_4N_2 chromophore equals 2.56 Å [26]. The group of 15 copper(II) complexes with carboxylate and imidazole or aromatic amine ligands ([4–8,16–25] and this work), shows the largest elongation of the coordination octahedron (tetragonal distortion) among all CuO_4N_2 compounds [26] and the mean value of the $Cu–O_{axial}$ bond length found for this group reaches 2.74(1) Å.

The geometry of carboxylate group of the CMA^- ligand is characteristic of a monodentate bonding mode [28]. The bond distances and angles of the acridine part of 9,10-dihydro-9-oxo-10-acridineacetate ion are in good agreement with those of other CMA^- complexes [10–12] and CMAH [29], differences between average and individual values are insignificant. The geometrical parameters of imidazole correspond to those reported for the neutral ligand in other complexes [27]. The dihedral angle between the imidazole plane and the equatorial plane of the complex equals 88.8(1)°. The acridine ring systems in the molecule are almost parallel, the interplane angle is 0.5(1)°, whereas the imidazole ring is twisted by 16.7(1)° with respect to the acridine plane. The crystal is further stabilized by O–H···O and N–H···O hydrogen bonds involving water and imidazole molecules (Table 3). There are five independent hard hydrogen bonds in the structure, four O–H···O and one N–H···O. Each water molecule acts as a double donor in O–H···O hydrogen bonds and as a single acceptor. The imidazole N(2) atom acts as a single donor in the hydrogen bond network. In addition to hydrogen bonds of the classical type, a weak C–H···O interaction is also observed. The intermolecular C(20)–H(20)···O(2) distances: C···O of 3.326(3) Å and H···O of 2.50(3) Å, and the C–H···O angle of 151(2)° satisfy the criteria for hydrogen bonds of this type [30]. Moreover, stacking interaction is observed between CMA^- ligands. The angle between the interacting rings is 0.52(1)° and the shortest distance equals 3.216(3) Å.

The magnetic moment calculated from the susceptibility data for $\Theta = -9.8$o K equals 1.96 μ_B, which gives the average g value 2.26, and is in the range expected for similarly distorted octahedral complexes of copper (II) [31–33].

The EPR spectrum of finely ground polycrystalline $Cu(CMA)_2(Him)_2\cdot 4H_2O$ complex exhibits axial character with well resolved copper hyperfine splitting of parallel orientation. The spectrum with $g_{zz} = g_{\|} \gg g_{xx} \approx g_{yy} = g_{\perp} > 2.0023$ and $A_{zz} = A_{\|} \gg A_{xx} \approx A_{yy} = A_{\perp}$ is typical of a tetragonal geometry of the Cu(II) environment indicating that the ground state is essentially $d_{x^2-y^2}$. The values of the EPR parameters ($A_{\|} = 180 \times 10^{-4}$ cm^{-1} and $g_{\perp} = 2.058$, $g_{\|} = 2.260$) correspond to the N_2O_2 donor set in Cu(II) coordination plane determined by the crystal structure analysis, although $A_{\|}$ is apparently higher and $g_{\|}$ smaller than usually observed for Cu(II) complexes with two imidazole and two water molecules [34]. This effect should be assigned to stronger donor properties of the negatively

O(12)–H(122)···O(1)$^{(v)}$	0.81(3)	2.08(3)	2.836(3)	156(3)
C(20)–H(20)···O(2)$^{(vi)}$	0.91(2)	2.50(3)	3.326(3)	151(2)

Symmetry transformations used to generate equivalent atoms (ii) $-x+1$, $y-1/2$, $-z+1/2$ (iii) $-x$, $y+1/2$, $-z+1/2$ (iv) $-x+1$, $-y+1$, $-z+1$ (v) x, $-y-1/2$, $z-3/2$ (vi) $x-1$, y, z.

charged carboxylate oxygen than those associated with water oxygen. On the other hand, the differences displayed by $g_{\|}$ as compared with that found for solid 2-methyl-vinylimidazoles and two nitrato ligands ($g_{\|} = 2.325$) [34] is most likely consistent with stronger in-plane interactions in the $Cu(CMA)_2(Him)_2\cdot 4H_2O$ complex due to a longer axial Cu–O(carboxy) (2.79 Å) than in the case of the Cu–O(nitrato) (2.42 Å) bond. The same tendency to decrease $g_{\|}$ (to 2.249) and increase $A_{\|}$ (to 189×10^{-4} cm^{-1}) as a result of very weak interactions with two carboxylic oxygens at axial positions was found for bis(*N*-tosylglicinato)bis(*N*-methylimidazole) copper(II) [16] where square-planar coordination is realized in the same way by two carboxylic and two imidazole groups.

The diffuse reflectance spectrum of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ exhibits a maximum at 18.2 kK ($d_{xz(yz)} \rightarrow d_{x^2-y^2}$) with a well discernible shoulder at 15.0 kK ($d_{xy} \rightarrow d_{x^2-y^2}$), and is consistent with the presence of a strongly elongated tetragonal ligand field around the copper(II) ion [31]. The position of the former band fits the correlation between the d–d band maximum and $Cu\cdots O_{axial}$ distance for several copper(II)-carboxylate-imidazole systems, proposed by Battaglia [16], (Table 4).

The assignment of the electronic spectra may be correlated with the EPR data. Assuming the ground state as almost pure $d_{x^2-y^2}$ orbital, one can calculate the principal values of the g tensor [35]:

$$g_x = 2.0023 + 2k_x^2\zeta/(E_{GS} - E_{yz}) \quad (1)$$

$$g_y = 2.0023 + 2k_y^2\zeta/(E_{GS} - E_{xz}) \quad (2)$$

$$g_z = 2.0023 + 8k_z^2\zeta/(E_{GS} - E_{xy}) \quad (3)$$

where k is the orbital reduction factor, ζ, the spin-orbit coupling constant (830 cm^{-1}) and E_{GS} is the ground state energy. The EPR and electronic spectra do not show a considerable separation of d_{xz} and d_{yz} orbitals.

Table 4
Correlation between the d–d band maximum and the $Cu\cdots O_{axial}$ distance for copper(II)–carboxylate–imidazole systems

Compound	d–d Band maximum (10^{-3} cm^{-1})	$Cu\cdots O_{axial}$ distance (Å) [a]
$Cu(Ac\text{-}\alpha\text{-}ala)_2(N\text{-}MeIm)_2\cdot H_2O$ [32]	18.2	2.907(4)
$Cu(CMA)_2(Him)_2$ this work	18.2	2.790(2)
$Cu(TsglyH)_2(N\text{-}MeIm)_2$ [16]	17.9	2.758(4)
$Cu(Zala)_2(N\text{-}MeIm)_2$E-tOH [15]	17.6	2.731(4)
$Cu(Hippu)_2(Him)_2$ [4]	17.5	2.736(4)

Hippu, hippurato; Him, imidazole; Zala, *N*-benzyloxycarbonyl-alanilato; *N*-MeIm, *N*-methylimidazole; TsglyH, *N*-tosylglicinato; Ac-α-ala, *N*-acetyl-α-alanilato.

[a] Oxygen atom from carboxylate group.

Therefore, it is reasonable to assume $g_x \approx g_y = g_{\perp}$, $g_z = g_{\|}$ and from (1)–(3) we obtain $k_x \approx k_y = 0.78$ and $k_z = 0.76$. The orbital reduction factors are comparable in magnitude to the k-values of other tetragonal copper(II) complexes [36].

The ν_{as}(COO) and ν_s(COO) bands of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ are found at 1608 and 1381 cm^{-1} in the IR spectrum and at 1609 and 1386 cm^{-1} in the Raman spectrum. The values of $\Delta = \nu_{as}(COO) - \nu_s(COO)$ equal 227 cm^{-1} (IR) and 223 cm^{-1} (R), and correspond well to those estimated for bis(*N*-tosylglycinato)bis(*N*-methylimidazole)copper(II) [16] and are characteristic for a monodentate mode of carboxylate coordination [28]. On the basis of the detailed comparison of the low frequency IR and Raman spectra of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ and $Cu(CMA)_2\cdot 2H_2O$ [10] and other literature data [37,38], the frequencies of stretching vibrations of coordination bonds are assigned as follows: 337 cm^{-1} for ν_{as}(Cu–O), 300 cm^{-1} for ν_s(Cu–O), 269 cm^{-1} for ν_{as}(Cu–N) and 244 cm^{-1} for ν_s(Cu–N). In spite of the very high complexity of the studied compound several characteristic bands of imidazole are very distinctly observed in the IR and Raman spectra. Their wavenumbers are very similar to those assigned in the spectra of the free ligand [39] and of neutral imidazole complexes [40]. In the spectra of $Cu(CMA)_2(Him)_2\cdot 4H_2O$ the $\nu(C\text{–}H)_{im}$ vibrations give rise to the weak bands located at 3138, 3100 cm^{-1} (IR) and at 3162, 3141 cm^{-1} (R). Also the out of plane deformations of $(C\text{–}H)_{im}$ groups are observed as the strong bands in the IR spectrum at 938 and 843 cm^{-1}, and as a weak band at 935 cm^{-1} in the Raman spectrum. Vibrations of the N–H group are assigned to the following bands: ν(N–H) at 3233 cm^{-1} (IR), δ(N–H) at 1314 cm^{-1} (IR, R) and γ(N–H) at 1074 cm^{-1} (IR), 1071 cm^{-1} (R). Imidazole ring stretching and deformation modes generate strong IR and weak Raman bands located at the frequencies: IR—1546, 1450, 1331, 1150, 915, 673, 644 cm^{-1}. Raman, 1331, 643 cm^{-1}.

The results of our work show a preference for monomer formation over dimer formation in copper(II)–carboxylate–imidazole systems and are consistent with other studies. Although the electronic effects play the more important role in adoption of the structure of these compounds than the steric effect, the results of our study demonstrates that steric demand of the CMA^- ligand and strong interligand interactions affect the composition and structure of $Cu(CMA)_2(Him)_2\cdot 4H_2O$. The single crystal X-ray study shows that the structure of the presented compound is very similar to those of known antitumor complexes $Co(O_2CMe)_2(Him)_2$ [6] and $Cu(O_2CMe)_2$(1-methyl-4,5-diphenyloimidazole)$_2$ [7]. The solid state far IR, FT Raman, UV–Vis, EPR and magnetic susceptibility data are consistent with the structure of the complex.

4. Supplementary material

Supplementary data on $Cu(CMA)_2(Him)_2 \cdot 4H_2O$ are available from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number 176220.

2. Experimental

The starting materials used in the present investigations were prepared by literature methods: Ph_3SbBr_2 [23], and internally functionalized oximes HON=C(R)Ar (R = H, CH_3; Ar = C_5H_4N-2, C_4H_3S-2, C_4H_3O-2 [24,25]). All the preparative reactions were performed under anhydrous conditions. IR spectra were recorded as Nujol mulls using a Perkin–Elmer 577 spectrophotometer. ^1H (in $CDCl_3$) and $^{13}C\{^1H\}$ (in $CHCl_3$ using D_2O lock) NMR spectra were obtained on a JEOL FX 90Q spectrometer using TMS as an internal reference.

2.1. Preparation of $[Ph_3Sb\{ON{=}C(Me)C_5H_4N\text{-}2\}_2]$

To a methanolic solution of sodium salt of 2-acetylpyridyl oxime [prepared in situ from sodium metal (109 mg, 4.74 mmol) dissolved in methanol (15 ml) and 2-acetylpyridine oxime (648 mg, 4.75 mmol)], a benzene solution (20 ml) of Ph_3SbBr_2 (1.218 g, 2.37 mmol) was added with constant stirring. The reactants were refluxed for 4 h. The solvent was evaporated under vacuum and the residue was extracted with benzene (2 × 15 ml) and filtered and dried under vacuum to give light pink solid which was recyrstallized from benzene–hexane mixture at −10 °C as colorless crystals (yield 1.29 g, 87%). All other complexes of the type $[Ph_3Sb\{ON{=}C(R)Ar\}_2]$ were prepared in a similar manner and the corresponding data are summarized in Table 1.

2.2. Preparation of $[Ph_3Sb(Br)\{ON{=}C(H)C_5H_4N\text{-}2\}]$

To a stirred benzene solution (15 ml) of $[Ph_3Sb\{ON{=}C(H)C_5H_4N\text{-}2\}_2]$ (484 mg, 0.81 mmol), a solution of Ph_3SbBr_2 in benzene (410 mg, 0.80 mmol) was added and then mixture was stirred for 30 min. The solvent was stripped off in vacuo to give the title compound in quantitative yield (876 mg, 98%). Similarly $[Ph_3Sb(Br)\{ON{=}C(Me)C_5H_4N\text{-}2\}]$ was prepared from $[Ph_3Sb\{ON{=}C(Me)C_5H_4N\text{-}2\}_2]$ and Ph_3SbBr_2.

2.3. Controlled hydrolysis of $[Ph_3Sb\{ON{=}C(H)C_5H_4N\text{-}2\}_2]$

A methanolic solution (5 ml) of sodium methoxide [prepared from sodium metal (17 mg, 0.76 mmol) in methanol] was added to a benzene solution (15 ml) of $[Ph_3Sb\{ON{=}C(H)C_5H_4N\text{-}2\}_2]$ (451 mg, 0.76 mmol), and refluxed for 2 h. After cooling to room temperature, 0.2 ml of distilled water was added and stirred for 30 min. The solvents were evaporated in vacuo and the residue was extracted with benzene and filtered. The filtrate was concentrated and recrystallized from hexane at −10 °C to give colorless crystals of $[Ph_3Sb(OH)\{ON{=}C(H)C_5H_4N\text{-}2\}]$ (328 mg, 88%).

2.4. X-ray structure determination

Crystals of $[Ph_3Sb\{ON{=}C(Me)C_5H_4N\text{-}2\}_2]$ (**1**) were colorless blocks. A suitable specimen was mounted on a glass fibre and cell dimensions and intensity data were recorded on an Enraf Nonius KCCD diffractometer with ϕ scans and ω scans chosen to give a complete asymmetric unit. Data collection and cell refinement [26] gave cell constants corresponding to a monoclinic cell whose dimensions are given in Table 2 along with other experimental parameters. An absorption correction was applied [27], which resulted in transmission factors ranging from 0.0497 to 0.0263.

The structure was solved by direct methods [28], and the structure was refined using the WINGX version [29] of SHELX-97 [30]. All of the non-hydrogen atoms were treated anisotropically. All hydrogen atoms were included in idealized positions with C–H set at 0.95 Å and with isotropic thermal parameters set at 1.2 times that of the carbon atom to which they were attached. The final cycle of full-matrix least-square refinement [30] was based on 3297 observed reflections (2537 for $F^2 > 4\sigma F^2$))

Table 1
Physical and analytical data of triphenylantimony(V) complexes

and 237 variable parameters and converged (largest parameter shift was 0.001 times its e.s.d.). Selected bond distances and angles are given in Table 3 and the molecule is displayed in the ORTEP diagram in Fig. 1.

3. Results and discussion

3.1. Preparation

All the preparative reactions were performed under anhydrous conditions and are summarized in Scheme 1. The reaction of Ph_3SbBr_2 with the sodium salt of internally functionalized oximes in 1:2 stoichiometry in refluxing anhydrous benzene afforded $[Ph_3Sb\{ON{=}C(R)Ar\}_2]$ [R = CH_3, Ar = C_5H_4N-2(**1**), C_4H_3S-2(**2**) C_4H_3O-2(**3**); R = H, Ar = C_5H_4N-2(**4**), C_4H_3S-2(**5**) and C_4H_3O-2(**6**)]. Further the reaction of (**1**) and (**4**) with 1 equiv. of Ph_3SbBr_2, yielded the redistribution products $[Ph_3Sb(Br)\{ON{=}C(R)C_5H_4N\text{-}2\}]$ [R = CH_3(**7**), H(**8**)]. The reaction was instantaneous and completed at room temperature. $[Ph_3Sb(OH)\{ON{=}C(R)C_5H_4N\text{-}2\}]$ were prepared by partial hydrolysis of $[Ph_3Sb\{ON{=}C(R)C_5H_4N\text{-}2\}_2]$. All these complexes are pinkish to white solids and are soluble in common organic solvents.

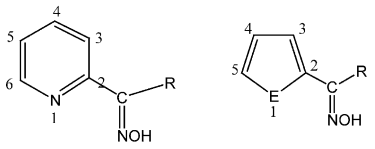
3.2. IR spectra

The IR spectra of these complexes were interpreted by comparing these with those of the free oximes and other related complexes [12–14,31]. Broad stretching vibra-

Scheme 1.

tions at ~3300 cm^{-1} due to –OH group of the free oximes disappeared in the IR spectra of (**1**)–(**6**), suggesting the deprotonation of –OH group and formation of Sb–O bond. The formation of Sb–O bond is further supported by the appearance to a weak to medium intensity band in the region 410–460 cm^{-1} and is assigned to ν Sb–O [32]. The ν C=N and ν N–O stretching vibrations appear at lower wavenumbers (~45 cm^{-1}) than those of the free ligands [33].

3.3. NMR spectra



The ^{1}H and $^{13}C\{^{1}H\}$ NMR spectra of these complexes showed characteristic peaks and peak multiplicities for Ph–Sb. The data are summarized in Table 4. The Ph–Sb carbon resonances of complexes are slightly shielded on substituting bromine with oximate in Ph_3SbBr_2. The shielding of these resonances increases in the order: $Ph_3SbBr_2 < Ph_3SbBrL < Ph_3SbL_2$ and are

[a] Antimony–phenyl (Ph–Sb) carbon values are given in the order C(p), C(o), C(m) and C(i), respectively.

unaffected by the nature of oxime. No significant changes in chemical shifts have been observed for the ligand proton resonances on complexation, except for the methyl and CH signals which, in general, appear at higher field than that for the corresponding free oxime.

(R=H, CH_3; E=O,S)

In the ^{13}C NMR spectra of triphenylantimony(V) complexes C-2 and C=N, in general, are deshielded as compared with their positions with the corresponding free oximes. The carbon signals of the heterocyclic ring of the functionalized oximes were observed at their expected positions and do not show any appreciable shifts indicating that the heteroatom of the aryl group is not coordinated to antimony. This is further substantiated by the X-ray structure of (**1**).

3.4. Crystal and molecular structure of $[Ph_3Sb\{ON=C(Me)C_5H_4N\text{-}2\}_2]$ (*1*)

Important bond distances and angles for $[Ph_3Sb\{ON=C(Me)C_5H_4N\text{-}2\}_2]$ (**1**) are listed in Table 3 and the molecular structure is displayed as an ORTEP diagram in Fig. 1. The structure consists of discrete monomeric $[Ph_3Sb\{ON=C(Me)C_5H_4N\text{-}2\}_2]$ units with both 2-acetylpyridineoxime ligands bound to the antimony atom through oxygen [Sb(1)–O(1) 2.0680(14) Å]. The molecule sites a twofold axis and the coordination environment around the antimony can be described as slightly distorted trigonal bipyramidal with equatorial Sb–C bonds and axial oxygen atoms [O(1)–Sb(1)–O(1)′ angles of 172.78(7)°]. The SbC_3 unit is planer (the sum of the C–Sb–C angle is 359.99°) and O–Sb–C angles lie in the range 85.91°–93.61°. The average Sb–O bond of 2.068(14) Å is approximately equal to the sum of the covalent radii of Sb and O (2.07 Å), while the average Sb–C bond of 2.098(2) Å is slightly shorter than the sum of the covalent radii of Sb and C (2.18 Å), as expected for the axial and equatorial positions of a trigonal bipyramid. The interatomic distances from antimony to the nitrogen [Sb(1)–N(2) 2.817 (1) Å] of the 2-NC_5H_4 moiety is well outside the sum of the van der Waals radii of Sb and N (2.11 Å), thus confirming unidentate linkage of the oximate ligand to antimony.

4. Supplementary material

The crystal code for $[Ph_3Sb\{ON=C(Me)C_5H_4N\text{-}2\}_2]$ is CCDC 181239. Supplementary data are available from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number 181239. Additional material available from the Cambridge Crystallographic Data Centre comprises the final atomic coordinates for all atoms, thermal parameters, and a complete listing of bond distances and angles.

Acknowledgements

Two of the authors (A.G. and R.K.S.) are grateful to DAE, Mumbai for the award of a Senior Research Fellowship and a Research Associateship to them through a BRNS project No. 98/37/33. M.B.H. thanks the UK Engineering and Physical Sciences Research Council for support of the X-ray facilities at Southampton and J.E.D. the Natural Sciences and Engineering Research Council of Canada for financial support. We are also thankful to Mr. Suman Kumar Gupta (Sr. Tech. FT-NMR) for recording the NMR spectra and kind cooperation.

nol)bis(saccharinato)cobalt(II), nickel(II), copper(II) and mercury(II) complexes are also reported.

2. Experimental

2.1. Materials and instrumentation

2-Pyridylmethanol (also named 2-pyridinemethanol, 2-hydroxymethylpyridyl or 2-pyridylcarbinol), sodium saccharinate dihydrate, and all metal salts were purchased from Merck. All other analytical grade chemicals and solvents were purchased commercially and used as received.

IR spectra were recorded on a Mattson FTIR spectrophotometer as KBr pellets. Room temperature (r.t.) magnetic susceptibility measurements were carried out using a Sherwood Scientific MXI model Evans magnetic balance. The elemental analyses (C, H and N contents) were carried out at the TUBITAK Marmara Research Centre, using a Carlo Erba 1106 microanalyser. Thermal analysis curves (TG, DTA and DTG) were obtained using a Rigaku TG8110 thermal analyser in a static air atmosphere. A sample size of 5–10 mg and a heating rate of 10 °C min^{-1} were used.

2.2. Synthesis of the metal complexes

The starting metal complexes of sac, $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ (M = Mn, Fe, Co, Ni, Cu, Zn, Cd and Hg), were prepared by literature methods [4,6].

$[Mn(sac)_2(mpy)_2]$ (**1**): the mpy ligand (0.218 g, 2.0 mmol) dissolved in MeOH (15 cm^3) was added dropwise to a solution of the tetraaquabis(saccharinato)manganese(II) dihydrate (0.527 g, 1 mmol) dissolved in a MeOH–isopropanol mixture (v:v, 1:1) (30 cm^3) with continuous stirring at r.t. The complex **1** precipitated as a white polycrystalline solid, which was filtered off, washed with C_3H_6O and dried in air. Yield: 80%. *Anal.* Calc. for $C_{26}H_{22}MnN_4O_8S_2$: C, 49.0; H, 3.5; N, 8.8. Found: C, 48.7; H, 3.2; N, 8.7%. Main IR features (cm^{-1}, KBr pellet): 3500–3300sbr for ν(OH); 2812w, 2933w for ν(CH); 1620vs for ν(C=O); 1286vs for $\nu_{asym}(SO_2)$; 1158vs for $\nu_{sym}(SO_2)$. $\mu_{eff} = 5.59$ BM.

The preparation of $[Fe(sac)_2(mpy)_2]$ (**2**) is analogous to that described for **1**. Yellow polycrystalline powder of **2** was obtained within 1 day. Yield: 85%. *Anal.* Calc. for $C_{26}H_{22}FeN_4O_8S_2$: C, 48.9; H, 3.5; N, 8.8. Found: C, 48.5; H, 3.2; N, 8.7%. Main IR features (cm^{-1}, KBr pellet): 3500–3100sbr for ν(OH); 2804w, 2963w for ν(CH); 1621vs for ν(C=O); 1304vs for $\nu_{asym}(SO_2)$; 1161vs for $\nu_{sym}(SO_2)$. $\mu_{eff} = 4.74$ BM.

The preparation of $[Co(sac)_2(mpy)_2]$ (**3**) is analogous to that described for **1**, but the starting tetraaquabis(saccharinato)cobalt(II) dihydrate (0.531 g, 1 mmol) was dissolved in MeOH and mixed with a solution of mpy ligand (0.218 g, 2.0 mmol) dissolved in MeOH (15 cm^3) with stirring. The resulting solution was left to stand at r.t. and allowed to evaporate slowly over a night for crystallization. Well-formed plate purple crystals of **3** were collected by suction filtration, washed with C_3H_6O and dried in air. Yield: 94%. *Anal.* Calc. for $C_{26}H_{22}CoN_4O_8S_2$: C, 48.7; H, 3.5; N, 8.7. Found: C, 48.5; H, 3.4; N, 8.3%. Main IR features (cm^{-1}, KBr pellet): 3500–3200sbr for ν(OH); 2963w, 2816w for ν(CH); 1621vs for ν(C=O); 1301vs for $\nu_{asym}(SO_2)$; 1162vs for $\nu_{sym}(SO_2)$. $\mu_{eff} = 4.52$ BM.

The preparation method used for $[Ni(sac)_2(mpy)_2]$ (**4**) was the same as that for **1**, using 0531 g (1 mmol) of tetraaquabis(saccharinato)nickel(II) dihydrate and 0.218 g (2 mmol) of mpy. Pale blue-plate crystals of compound **4** were obtained after 2 days. Yield: 94%. *Anal.* Calc. for $C_{26}H_{22}N_4NiO_8S_2$: C, 48.7; H, 3.5; N, 8.7. Found: C, 48.7; H, 3.5; N, 8.3%. Main IR features (cm^{-1}, KBr pellet): 3550–3200sbr for ν(OH); 2828w, 2963w for ν(CH); 1621vs for ν(C=O); 1301vs for $\nu_{asym}(SO_2)$; 1162vs for $\nu_{sym}(SO_2)$. $\mu_{eff} = 2.85$ BM.

Single crystals of $[Cu(sac)_2(mpy)_2]$ (**5**) were prepared by the same procedure as that used for **4**. Well-shaped blue crystals were obtained after 1 day. Yield: 93%. *Anal.* Calc. for $C_{26}H_{22}CuN_4O_8S_2$: C, 48.3; H, 3.4; N, 8.7. Found: C, 48.0; H, 3.4; N, 8.4%. Main IR features (cm^{-1}, KBr pellet): 3550–3300sbr for ν(OH); 2928w, 2806w for ν(CH); 1621vs for ν(C=O); 1307vs for $\nu_{asym}(SO_2)$; 1172vs for $\nu_{sym}(SO_2)$. $\mu_{eff} = 1.64$ BM.

$[Zn(sac)_2(mpy)_2]$ (**6**) was prepared by following an analogous procedure to that for **4** and obtained as a white polycrystalline solid. Yield: 95%. *Anal.* Calc. for $C_{26}H_{22}N_4O_8S_2Zn$: C, 48.2; H, 3.4; N, 8.6. Found: C, 48.1; H, 3.3; N, 8.4%. Main IR features (cm^{-1}, KBr pellet): 3550–3200sbr for ν(OH); 2938w, 2825w for ν(CH); 1636vs for ν(C=O); 1301vs for $\nu_{asym}(SO_2)$; 1162vs for $\nu_{sym}(SO_2)$.

Single crystals of $[Cd(sac)_2(mpy)_2]$ (**7**) is analogous to that described for **4**. The solid was collected as a polycrystalline solid. Yield: 95%. *Anal*. Calc. for $C_{26}H_{22}CdN_4O_8S_2$: C, 44.9; H, 3.2; N, 8.1. Found: C, 45.0; H, 3.3; N, 7.8%. Main IR features (cm^{-1}, KBr pellet): 3400–3200sbr for ν(OH); 2900w, 2962w for ν(CH); 1626vs for ν(C=O); 1256vs for $\nu_{asym}(SO_2)$; 1151vs for $\nu_{sym}(SO_2)$.

Single crystals of $[Hg(sac)_4(mpy)_2]$ (**8**) were prepared by the same procedure as that used for **4**. Colourless crystals of **8** were obtained after 2 days. Yield: 90%. *Anal.* Calc. for $C_{20}H_{15}HgN_3O_7S_2$: C, 35.5; H, 2.2; N, 6.2. Found: C, 35.5; H, 2.3; N, 6.2%. Main IR features (cm^{-1}, KBr pellet): 3500–3200sbr for ν(OH); 2825w, 2962w for ν(CH); 1635vs for ν(C=O); 1254vs for $\nu_{asym}(SO_2)$; 1152vs for $\nu_{sym}(SO_2)$.

2.3. X-ray crystallography

Suitable crystals of the complexes **3**, **4**, **5** and **8** were glued to a thin glass fibre and mounted on a BRUKER SMART 1000 CCD area detector diffractometer with Mo Kα radiation, $\lambda = 0.71073$ Å. The intensity data were collected at $T = 298 \pm 2$ K and processed with the aid of the SMART, SAINT and SADABS software packages [13]. Absorption corrections were made with SADABS [13]. The structures were solved by direct methods using SIR-97 [14] and refined by a full-matrix least-squares procedure (SHELXL-97) [15]. Molecular drawings were obtained using ORTEP-III [16]. Hydroxyl hydrogen atoms of the complexes **3** and **5** were found in difference maps and refined with geometric restraints [d(O–H) = 0.82 Å)]. All hydrogen atoms of the complexes **4** and **8**, and other H atoms of the phases **3** and **5** were positioned geometrically and refined by riding on their appropriate carbon atoms [d(O–H) = 0.82 Å for the hydroxyl hydrogens and d(C–H) = 0.93 and 0.96 Å for phenyl and methylene hydrogens, respectively]. The details of data collection, refinement and crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

The aim of the work is to prepare new mixed-ligand sac complexes with mpy as a co-ligand, since the mpy ligand offers two different donor atoms to metal centres, namely N and O (hydroxyl). For the synthesis of mixed-ligand metal complexes of sac it became a common practice to apply $[M(sac)_2(H_2O)_4]\cdot 2H_2O$ as synthetic precursors, since the aqua ligands in these metal

complexes are labile and readily displaced by neutral ligands. The new complexes were simply prepared by the direct reaction of mpy with the respective tetraaquabis(saccharinato)M(II) dihydrate in solution. The addition of the mpy ligand to the solutions of the aqua complexes resulted in the substitution of all the four aqua ligands, and the formation of the air-stable complexes of $[M(sac)_2(mpy)_2]$ where M is manganese(II), iron(II), cobalt(II), nickel(II), copper(II), zinc(II), cadmium(II). The complexes **1**, **2**, **6** and **7** were precipitated as polycrystalline solids, while all the other complexes were crystallized from the reaction solutions. All the complexes, except **8** complex are monomeric with a M:mpy molar ratio of 1:2 and show an octahedral coordination geometry around the metal ions, whereas the complex **8** is a coordination polymer. All the complexes do not exhibit melting points, but decompose at the temperatures given in Table 5. All the complexes were obtained in good yields (over 80%) and the analytical data are consistent with the proposed formulation of the complexes, and also confirmed by X-ray crystallography as reported in this paper. All the complexes are soluble in methanol and DMSO, and all the complexes, except the mercury(II) complex are also soluble in warm water and ethanol.

3.2. Spectral and magnetic properties

The most significant frequencies in the IR spectra of the metal complexes are given in Table 3. The IR spectra of all the complexes are resemble each other indicating a similar structural relationship. The strong and broad absorption bands in the range 3200–3500 cm^{-1} are attributed to the ν(OH) vibrations of mpy. The relatively weak two close bands at 2800–2900 cm^{-1} are due to the ν(CH) vibrations. The stretching vibration of C=N of the py ring at approximately 1600 cm^{-1} was not clearly observed because of the overlap of the ν(C=O) vibration of the sac ions. However, the N-coordination of the mpy ligand is confirmed by the absorption bands at around 680 cm^{-1} due to γ(py) [17]. The bands for the carbonyl group appear characteristically at approximately 1620 cm^{-1} as very strong bands for all complexes, while the stretching vibrations of $\nu_{asym.}(SO_2)$ and $\nu_{sym.}(SO_2)$ occur at approximately 1300 and 1160 cm^{-1}, respectively. The asymmetric stretching vibrations of the sulfonyl group in the IR spectra of **8** significantly shift to the low frequency region due to involving in coordination with mercury(II) ion. Furthermore, the carbonyl vibration frequencies of the carbonyl O-bonded sac ligands in the corresponding sac complexes with mpy shifted to the low frequency region by 10–55 cm^{-1} compared to the starting complexes with only N-bonded sac ligands, indicating the coordination of the carbonyl group of sac. The shift value for the copper(II) complex was zero. Additional peaks at approximately 1360 and 960 cm^{-1} may be assigned to the symmetric and asymmetric stretchings of the CNS moiety of the sac ligands, respectively as proposed previously [8,9]. The medium peaks at around 1555 and 1450 cm^{-1} correspond to the ring ν(C–C) vibrations. The weak bands below 500 cm^{-1} may be attributed to both M–N and M–O vibrations.

The room temperature magnetic moments indicate that the metal complexes exhibit high-spin configuration. The effective magnetic moments are consistent with the calculated values of the spin-only magnetic moments of the octahedral coordination geometry around the metal ions.

3.3. Description of the crystal structures

3.3.1. $[M(sac)_2(mpy)_2]$ ($M = Co$ (**3**) and Ni (**4**))

Compounds **3** and **4** are isomorphous and crystallize in the triclinic space group $P\bar{1}$. Molecular structures of the both complexes are given in Figs. 1 and 2, while the selected geometrical data and hydrogen bonding geometry are presented in Table 2. The crystal structures consist of neutral molecules of $[M(sac)_2(mpy)_2]$. Each metal ion is octahedrally coordinated by two mpy and two sac ligands forming a MN_3O_3 core. The mpy ligand acts as a bidentate donor through the amine nitrogen and the methanol oxygen atoms forming a five-membered chelate ring. The nitrogen atoms of the two mpy ligands are placed at *trans* positions, while the hydroxyl oxygen atoms occupy the *cis* positions of the coordination octahedron in **3** and **4**.

Sac usually interacts with transition metal ions through its deprotonated nitrogen atom, whereas O-bonding occurs in the case of alkaline, alkaline earth and p-block metals [20–23]. The coordination of sac to the transition metal ions using the donor groups other than the amine nitrogen atom is unusual and the only examples of O-coordination reported previously in mononuclear complexes are in $[V(sac)_2(py)_4]\cdot 2py$ [6], $[Ni(sac)_2(py)_4]\cdot 2py$ [9], $[Cu(sac)_2(dipyr)_2]$ [24] (py and dipyr are pyridine and dipyridylamine, respectively), $[Cu(sac)(PPh_3)_2]$ [25] and $[Cu(sac)(PPh_3)]_2$ [25] as reported recently. Therefore, the most interesting aspect of the complexes **3** and **4** is the coordination of the sac ligands, which occur in two distinct manners. Both sac ligands behaves as an ambidentate ligand: one of them is N-bonded, while the other one is O-coordinated. The $Ni–O_{sac}$ bond distance of 2.066(6) is significantly longer than 2.070(3) Å found in $[Ni(sac)_2(py)_4]\cdot 2Py$ [9]. Large distortions in the coordination polyhedra from ideal octahedral geometry are also clearly evident from the N–M–N, N–M–O and O–M–O interbond angles. The *cis* and *trans* angles, respectively, range from 76.96(5) to 101.87(5)° and 158.43(5)° to 175.10(5)° in the compound **3**, and 79.3(2)° to 98.5(3)° and 163.2(2)° to 175.9(2)° in

the compound **4**. As a result, these complexes may be regarded as having a distorted octahedral structure.

The sac ligands present in the two complexes are essentially planar with an r.m.s. deviation of approximately 0.02 Å. The py rings of the mpy ligands are also planar and both hydroxyl O and methylene C atoms slightly deviate from the py planes by approximately 0.14(4) Å in the compounds **3** and **4**. The mpy ligands in **3** and **4** are almost perpendicular to each other with the dihedral angles of 82.32(5)° and 79.9(2)°, respectively. The hydrogen atoms of the hydroxyl groups of the mpy ligands form strong intramolecular hydrogen bonds with the carbonyl O and the negatively charged N atoms of the sac ligands (Table 2). The methylene and phenyl hydrogen atoms are involved in weak intermolecular C–H···O interactions with the hydroxyl and sulfonyl O atoms in **3** and **4**. The molecules are held together by the weak hydrogen bonds and van der Waals' interactions by forming a 3D lattice.

3.3.2. *[Cu(sac)$_2$(mpy)$_2$] (**5**)*

The compound **5** crystallizes in orthorhombic system with a space group of *Pbca*. Table 3 presents selected distances and angles about the metal centre together with the hydrogen bonding geometry, while the molecular view of **5** is shown in Fig. 3. The copper(II) ion lies on a centre of symmetry and is coordinated by two neutral mpy and two anionic sac ligands. The sac ligands occupy the *trans* positions, while the two bidentate mpy ligands form the equatorial plane of the coordination octahedron around the copper(II) ion. The Cu–N_{mpy} and Cu–O_{mpy} bond distances are 1.9667(13) and 2.1394(13) Å, respectively and similar to the corresponding values found in [Cu(sal)$_2$(mpy)$_2$] [26] where sal is salicylate. In contrast to complexes **3** and **4**, both sac ligands in **5** are N-coordinated. The Cu–N_{sac} bond distance of 2.3345(15) Å is significantly longer than those reported for [Cu(sac)$_2$(H$_2$O)(py)$_2$] [19], [Cu(sac)$_2$(dipyr)$_2$]·0.5H$_2$O [24], [Cu(sac)$_2$(dea)$_2$] [27], [Cu$_2$(μ-dea)$_2$(sac)$_2$] [28], [Cu(sal)$_2$(NH$_3$)$_4$] [29] and [Cu$_2$(μ-tea)$_2$(sac)$_2$]·2CH$_3$OH [30] (dea and tea = di- and triethanolamine, respectively). The larger deviations from regular octahedral geometry for the complex **5** are characteristic of the Jahn–Teller effect. The Cu–N_{sac} bonds occupying the axial positions are much longer than the Cu–N_{mpy} and Cu–O_{mpy} bonds forming the

equatorial plane of the CuN_4O_2 chromophore, resulting in an usual elongated tetragonal octahedron around the copper(II) ion. The *cis* bond angles in the complex **5** are in the range 80.66(5)°–92.65(5)°. The individual molecules of **5** are connected by the strong O–H···$O_{carbonyl}$ and weak C–H···$O_{carbonyl\ and\ sulfonyl}$ hydrogen bonds, which stabilize the crystal structure creating a 3D network.

3.3.3. $[Hg_2(sac)_4(mpy)_2]$ (**8**)

The coordination around the mercury atom and a fragment of the polymeric structure of this complex together with the atom-numbering scheme is shown in Fig. 4, while selected bond distances and angles are tabulated in Table 4. The structure consists mainly of the dimeric $[Hg_2(sac)_4(mpy)_2]$ units in which the mercury atoms have a HgN_3O_2 environment by three nitrogen atoms, two from the sac ligands and the other from the mpy ligand, and two oxygen atoms of the neutral mpy ligands. Two methanol oxygen atoms of two mpy ligands bridge two mercury atoms and each methanol oxygen atom serves as a bifurcate bridge between the mercury centers. The dimeric units are sequentially linked by the sulfonyl oxygens of the sac ligands of the adjacent units forming a 1D polymeric chain as shown in Fig. 4. Consequently, the mercury atoms in the coordination polymer are six-coordinate. The most significant difference between the other structures reported in this paper is the bidentate coordination behavior of the sac ligands in **8**.

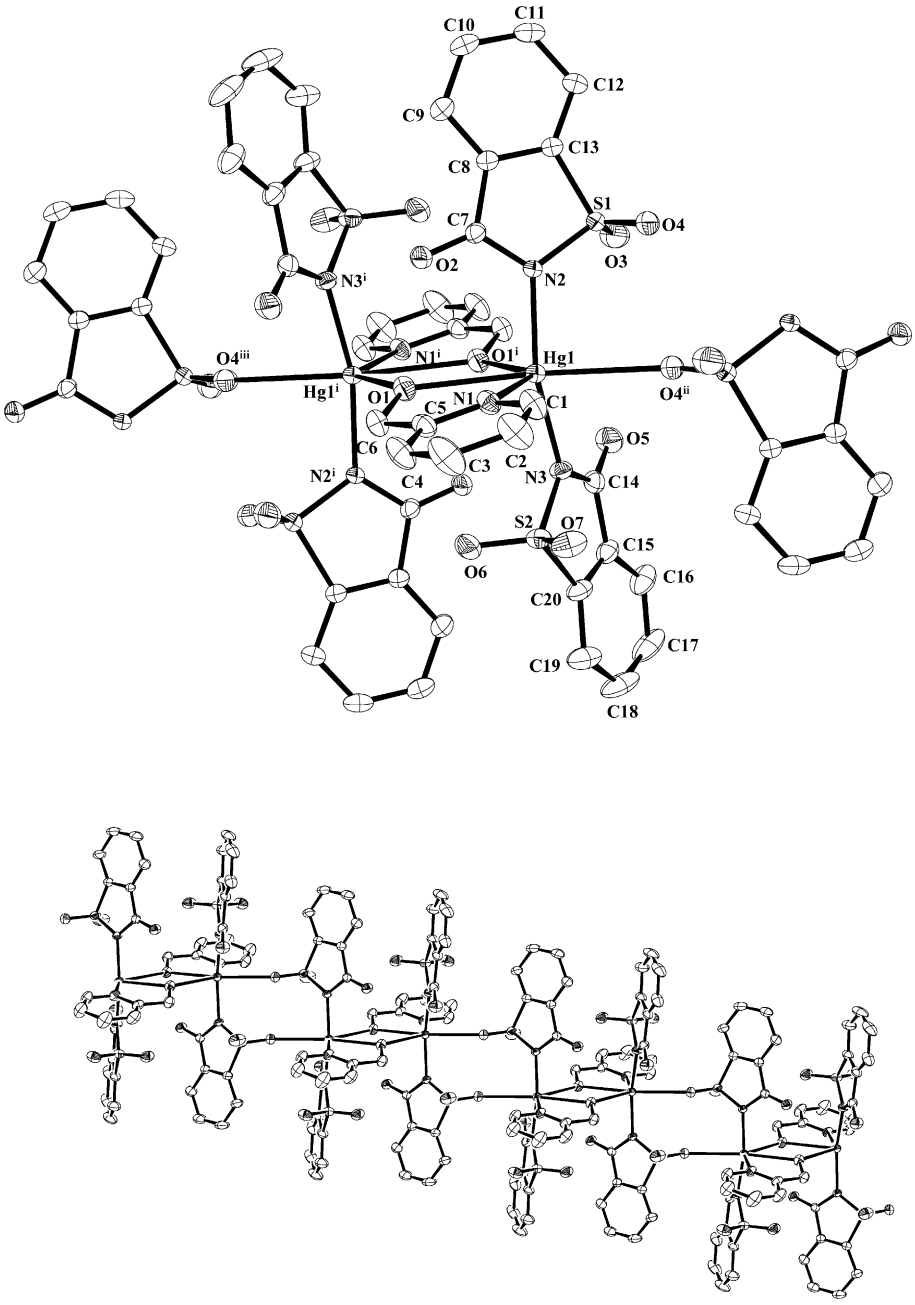

Fig. 4. Coordinartion environment of the mercury atom (30% thermal ellipsoids) and a view of a fragment of the chain in **8**. Hydrogen atoms were omitted for clarity.

The Hg···Hg separation is 4.4927(3) Å. The –Hg–O–Hg–O– bridging group is planar and the bridging angles Hg–O1–Hg(a) and O1–Hg–O1(a) are 112.21(7)° and 67.78(6)°, respectively. Both sac and mpy ligands are essentially planar and dihedral angles between the best planes of sac and mpy ligands are 76.32(6)° and 88.88(7)°. The hydroxyl oxygen atom (O(1)) of the bridging mpy ligand form a very strong intramolecular hydrogen bond with the carbonyl oxygen atom (O(2)) of the sac ligand. The polymeric chains are held together by weak C–H···$O_{sulfonyl}$ interactions. Additionally, some of the phenyl hydrogens (C(9)–H(9) and C(10)–H(10)) of the sac ligands are involved in H···π type interactions with the aromatic rings of the sac and mpy ligands, respectively.

3.4. Thermal analysis

Thermoanalytical data (decomposition stages, temperature ranges, peak maxima and mass losses) for the metal complexes are summarised in Table 5. From the thermal decomposition behaviour of the complexes in the air atmosphere the following general features can be recognized:

Table 5
Thermoanalytical data for the metal complexes

Complex	Stage	Temperature range (°C)	DTG_{max} (°C) [a]	Mass loss (%) [b]	Solid residue
1	1	178–360	204(−), 250(+)	33.7 (34.1)	$[Mn(sac)_2]$
	2	395–775	413(+), 532(−), 546(−)	57.3 (57.2)	MnO

	2	348–585	397(+), 573(−)	52.5 (52.6)	CdO
8	1	168–220	200(+)	16.6 (16.2)	$[Hg(sac)_2]$
	2	220–550	273(+), 508(−)	– [c]	– [c]

[a] (+) and (−) donate endothermic and exothermic processes, respectively.
[b] Required values are given in parentheses.
[c] Sublimation above 550 °C.

The complexes exhibit a continuous mass loss in the temperature range 160–715 °C. The low initial decomposition temperatures of the complexes suggest that they are monomeric species. The first decomposition stages correspond to the elimination of the two mpy ligands. This stage are observed as a single peak in the DTA and DTG curves of **2**–**4** and **8**, while **1** and **5**–**7** lose their mpy ligands in two steps, which are associated with the degradation of the mpy ligand. A similar behaviour was observed for the metal complexes of sac with ligands containing ethanol groups [18]. The experimental mass losses are in agreement with the calculated values (Table 5). The removal of the mpy ligand results in the formation of the respective metal saccharinates as stable intermediates, which were identified by the characteristic IR absorption bands of the sac ligand. The metal saccharinates decompose exothermically at higher temperatures to give the corresponding metal oxides, similar to the tetraaquabis(saccharinato)M(II) complexes [19], although the Hg(II) complex sublimes at approximately 550 °C leaving an empty crucible.

4. Conclusions

The results in this paper clearly show that the sac ligand exhibits different modes of coordination in the presence of mpy. Although the conditions for the synthesis and crystallization of the metal complexes are almost the same, the reasons for the occurrence of the different coordination modes are not readily understandable and need further research. However, it may be suggested that some factors such as the electron density or steric effects of the ligands, intermolecular forces and the most favourable crystallization kinetics may determine the coordination type of sac.

5. Supplementary data

Crystallographic data for the structures reported in the paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 174133, 174134, 174135, 183285 for complexes **3**, **4**, **5** and **8**. Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

were prepared in similar fashion and the pertinent data is given in Table 1.

2.2. Synthesis of $[UO_2(TTA)_2 \cdot p\text{-}NO_2\text{–}C_5H_4NO]$

This compound was synthesized according to the reported method [4a] and the crystals suitable for X-ray analyses were obtained from $CHCl_3$–$C_6H_5CH_3$ mixture.

2.3. Physical methods

^{1}H NMR spectra of free ligands and compounds were recorded in Varian-300 NMR instrument operating at 300 MHz. The chemical shifts are relative to the internal $CHCl_3$ peak (7.21 ppm).

2.4. X-ray crystallography

The X-ray diffraction data for the compound $[UO_2(TTA)_2 \cdot p\text{-}NO_2\text{–}C_5H_4NO]$ was collected on a Siemens SMART CCD diffractometer fitted with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 213(2) K with a detector distance of 4 cm and swing angle of $-35°$. A hemisphere of reciprocal space covered by a combination of three sets of exposures; each set had a different ϕ angle (0°, 88°, 180°) and each exposure of 30 s covered 0.3° in ω. Data collection, indexing and initial cell refinement were handled using SMART software [6a]. Frame integration and final cell refinement were carried out using SAINT software [6b]. The SADABS software [6c] package was used to perform the absorption corrections. The atomic scattering factors are from the International Tables for Crystallography [6d]. The summary of crystallographic data, structural parameters and refinement details is given in Table 2.

2.5. Solution and refinement of the structure

The structure was solved by direct methods, completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures on F^2 using SHELXTL [7] version 5.1. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms were refined with geometrical constraints with ideal bond lengths and angles were treated as riding atoms. All

computation was carried out on a PC using the SHELXTL-PC program package.

3. Results and discussion

The reaction of $[UO_2(OO)_2\cdot 2H_2O]$ (OO = TTA, DBM, BTA or BA) with 1 equiv. of nitrone in benzene yielded yellow or orange colored products of the type $[UO_2(OO)_2\cdot L]$ (where L = nitrone). IR spectra of all compounds show (Table 3) that the broad peak observed for the H_2O molecules ($\nu_{OH} = 3200–3500$ cm^{-1}) of starting compound $[UO_2(OO)\cdot 2H_2O]$ has been completely disappeared. It indicates clearly that the water molecules from the starting compound $[UO_2(OO)\cdot 2H_2O]$ have been replaced completely by the nitrone ligand. The spectra further show that the ν_{N-O} in compounds has been shifted to lower frequencies compared to the free ligand, indicating the coordination of nitroxyl oxygen atom of nitrone to the uranyl group. The observed frequency differences $\Delta\nu_{(N-O)}$ ($\nu_{free} - \nu_{complex}$) (20–30 cm^{-1}) agree well with the earlier

reported [bis(β-diketonato)uranium(VI)] N-oxide adduct compounds [4a]. The observed frequencies $\nu_{(C=O\cdots M)}$ and $\nu_{(C-O\cdots M)}$ show that the β-diketonates act as bidentate chelating ligand [5].

The ^{1}H NMR spectra of all the compounds show (Table 3) the expected peaks and multiplicities. The –CH=N(O) and $H_{2,6}$ protons of nitrone ligands are deshielded by about approximately 0.3–0.5 ppm with respect to free ligands, supporting the coordination of nitroxyl oxygen atom of nitrone with uranyl group. The –CH– proton of the β-diketonate part gave only one resonance for all compounds, indicating that the compounds are existing exclusively in one isomeric form [5c]. The ^{19}F NMR spectrum supports this observation by showing only one resonance for the CF_3 group of TTA and BTA ligands. We could not get suitable crystals for all nitrone compounds to carry out single crystal X-ray diffraction studies to support our spectral observations similar to one that is reported in literature [8] viz: [Cu(TTA)$_2$·NIT*p*Py], in which the TTA acts as bidentate chelate ligand and the NIT*p*Py coordinates through its nitroxyl oxygen to copper atom.

In order to confirm our observation the spectral data of all nitrone compounds were compared [4a] with the analogous pyridine N-oxide compounds and which have shown similar spectral results [$\Delta\nu_{N-O} = 25–35$ cm^{-1}; H_a and H_b protons of pyridine N-oxides are deshielded about approximately 0.4–0.8 ppm with respect to the free ligands]. It indicates clearly that the nitrone and pyridine N-oxide ligands have similar type of bonding with uranyl bis(β-diketonates). The structure of the compound [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO] was determined by using single crystal X-ray diffraction methods and which is confirming our spectroscopic observations.

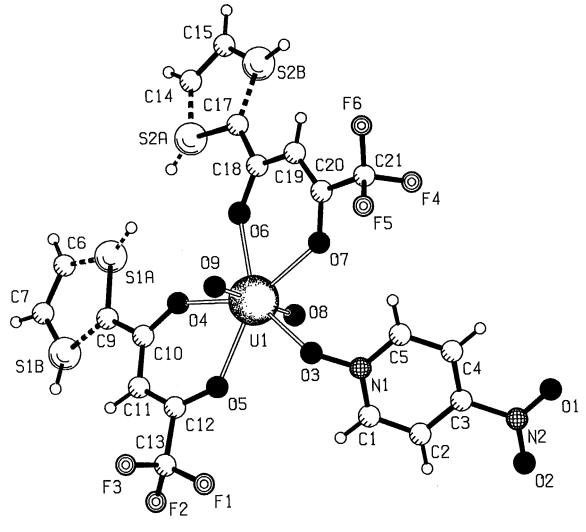

Fig. 2. The molecular structure of [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO].

Table 4
Selected interatomic bond distances (Å) and angles (°) for the compound [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO]

Bond distances			
U1–O3	2.361(4)	U1–O4	2.358(4)
U1–O5	2.372(4)	U1–O6	2.361(4)
U1–O7	2.377(4)	U1–O8	1.762(4)
U1–O9	1.757(4)	N1–O3	1.330(6)
Bond angles

3.1. Structure of [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO]

The molecular structure of the compound [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO] with numbering scheme is given in Fig. 2. The inter atomic bond distances and angles are given in Table 4. The structure of the molecule shows that the uranium atom is surrounded by seven oxygen atoms in a distorted pentagonal bi-pyramidal geometry. Four oxygen atoms of the TTA and one oxygen atom of N-oxide forms a planar pentagon and two uranyl oxygen atoms occupy the apices. The average U–$O_{(uranyl)}$ (1.759(5) Å) and U–$O_{(TTA)}$ (2.367(4) Å) [5a–h] distances are within the accepted values. The U–O(N) N-oxide distance (2.361(4) Å) is comparable with the earlier reported uranyl bis(β-diketonates) neutral ligand adduct compounds [5a–h]. The overall bond lengths and angles show that the uranium atom has a distorted pentagonal bi-pyramidal geometry. The whole molecule is stabilized in solid state by the intermolecular hydrogen bonding interactions to give a polymeric arrangement [C15–H15···O9; 3.241(10) Å, 164.56°]. There is a disorder seen in the thiophene ring and this disorder is due to the 180° rotation of this ring about C17–C18 and C9–C10 bonds. A hybrid scattering factor consisting of 66% sulfur and 34% carbon was used to model this disorder.

4. Conclusion

The IR and ^{1}H NMR spectral studies show that the nitrone forms adduct compounds with the uranyl bis(β-diketonates) and coordinates through its nitrosyl oxygen atom to the uranyl group. The structure of the compound [$UO_2(TTA)_2$·*p*-NO_2–C_5H_4NO] confirms our spectroscopic observations.

5. Supplementary material

Crystallographic data for structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 180472. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit @ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

S.K wish to thank V. Venugopal, Head, Fuel Chemistry Division, BARC for his support, Professor S. Sivasubramanian, School of Chemistry, Madurai Kamaraj University, Madurai for the donation of ligands L_1 and L_2, the Head, Analytical Chemistry Division, BARC, for carbon, hydrogen and nitrogen analysis and the Head, RSIC, IIT, Mumbai for NMR spectra. H.K.F would like to thank the Malaysian Government and Universiti Sains Malaysia for research grant R&D No. 305/pfizik/610961. A.U. thanks the Universiti Sains Malaysia for a visiting Post-Doctoral Fellowship.

Scheme 1.

highly colored impurity were present. Complex **1** was thermally stable, decomposing slowly in toluene at 105 °C over several days to give unidentified products [8].

Addition of 2 equiv. of $PMes_2H$ to $PdCl_2$ in acidic ethanol gave *trans*-PdL_2Cl_2 (**2**) [9]. This complex could also be prepared by addition of 2 equiv. of $PMes_2H$ to either $Pd(cod)Cl_2$ (cod = 1,5-cyclooctadiene) or $Pd(NCPh)_2Cl_2$ (Scheme 1). The *trans* stereochemistry of **2** and its Pt analogue **3** (see below) was established by NMR. Analysis of the $PMes_2H$ AA′XX′ patterns in the ^1H and ^{31}P NMR spectra [7] and simulation using gNMR [10] gave the coupling constants shown in Table 2. The large J_{PP} values (598 and 523 Hz, respectively) are consistent with the *trans* geometry [11].

Interestingly, treatment of **2** with 2 equiv. of MeLi gave partial conversion to the dimethyl complex **1** (Scheme 1). The steric bulk of $PMes_2H$ would seem to contraindicate the observed *trans*–*cis* isomerization, but similar results have been observed previously. For example, *trans*-$Pd(PPh_3)_2Me_2$ isomerizes on heating in DMSO to the *cis* complex [8a]. Electronic arguments based on the strong *trans* influence of the methyl group

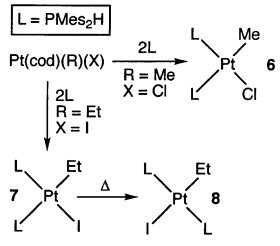
[b] 80 °C.
[c] Additional $^{31}P\{^1H\}$ NMR data for **8** (CD_2Cl_2, −70 °C): Four isomers (A–D) with approximate ratio 4.8:2.7:1:1 were observed; δ −39.4 (J_{Pt-P} = 3069, A), −29.0 (J_{Pt-P} = 3153, B), −37.3 (J_{Pt-P} = 3006, C), −26.7 (J_{Pt-P} = 3153, D). See the text and Section 4 for additional discussion of these and related low-temperature ^1H NMR spectra.
[d] Apparent d, J = 384, J_{Pt-H} = 26, perhaps the most intense two peaks of an AA′XX′ pattern.

have been advanced to explain this behavior (''anti-symbiotic effect'' [12], ''transphobia'' [13]).

Reaction of 2 equiv. of L with three different platinum sources [K_2PtCl_4, $PtCl_2$, and $PtCl_2(NCPh)_2$] yielded *trans*-$Pt(PMes_2H)_2Cl_2$ (**3**) as a yellow powder (Scheme 1, Table 2). In contrast, treatment of $Pt(cod)Cl_2$ with L gave *cis*-$Pt(PMes_2H)_2Cl_2$ (**4**) as shown in Scheme 2. Its room temperature NMR spectra contain very broad peaks, attributed to restricted rotation about the P–C and/or Pt–P bonds (see below). At high temperature (100 °C, C_6D_5Cl) a sharp average spectrum consistent with the *cis* geometry is observed (Table 1).

The reactivity of **4** was briefly examined (Scheme 2). Irradiation of a CD_2Cl_2 solution of **4** with a mercury lamp caused slow conversion to the *trans* isomer **3**, consistent with literature reports of related photochemical *cis*–*trans* isomerizations in PtL_2X_2 complexes (L = PPh_3, pyridine, isoquinoline, X = Cl, Br) [9,14]. Treatment of $Pt(cod)Cl_2$ with 3 equiv. of $PMes_2H$ gave a mixture of **4** and $PMes_2H$, which did not undergo exchange on the NMR time scale, while 1 equiv. of $PMes_2H$ gave a mixture of **4** and unreacted $Pt(cod)Cl_2$, as shown by the ^1H NMR spectrum. Addition of more phosphine completed the conversion to **4**. $PMes_2H$ was readily displaced from **4** by 2 equiv. of dppe (dppe = $Ph_2PCH_2CH_2PPh_2$) to yield $[Pt(dppe)_2][Cl]_2$ [15]. Heating **4** at 45 °C in CH_2Cl_2 with 2 equiv. of PPh_3 gave *cis*-$Pt(PMes_2H)(PPh_3)Cl_2$ (**5**). Consistent with the stoichiometry, ^{31}P NMR monitoring of the reaction mixture showed formation of $PMes_2H$ and the presence of unreacted PPh_3. Recrystallization from CH_2Cl_2/petroleum ether gave white crystals, identified by NMR as the *cis* isomer (J_{PP} = 14 Hz, Table 1).



Scheme 2.

Reaction of Pt(cod)(Me)(Cl) with 2 equiv. of L yielded *cis*-$Pt(PMes_2H)_2(Me)(Cl)$ (**6**, Scheme 3). The *cis* geometry was established by ^{31}P NMR (see Table 1) and by the Pt–Me ^{13}C NMR signal (δ 3.5, dd, J = 96, 6 Hz, CD_2Cl_2). Similarly, treatment of Pt(cod)(Et)(I) with 2 equiv. of L gave white *cis*-$Pt(PMes_2H)_2(Et)(I)$ (**7**, Table 1), which readily isomerized on standing or gentle heating to the yellow *trans* isomer (**8**, Scheme 3). The room temperature NMR spectra of complex **8** were very broad, indicative of a dynamic process (see Section 2.2), but at 80 °C in C_6D_5Cl, it showed the expected AA′XX′ ^{31}P NMR spectrum (Table 2).

2.1. Solid-state structures

The X-ray crystal structures of *trans*-PdL_2Cl_2 (**2**·$2CH_2Cl_2$), *cis*-PtL_2Cl_2 (**4**·CH_2Cl_2), *cis*-$PtL(PPh_3)Cl_2$ (**5**·$2CH_2Cl_2$), *cis*-$PtL_2(Me)(Cl)$ (**6**) and the phosphine–borane L-BH_3 (**9**, see Section 4) were determined to investigate the effect of the bulky phosphine on the structures of its simple coordination complexes. For thermal ellipsoid plots, see Figs. 1–5; crystal data is summarized in Table 3, and additional details are included in Sections 4 and 5. See the figure captions and Tables 4 and 5 for selected bond lengths and angles.

The structure of **2** shows a minor distortion from ideal square planar geometry, and Pd–P and Pd–Cl bond

Scheme 3.

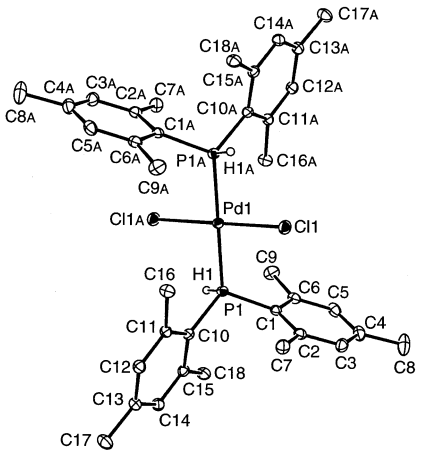


Fig. 1. ORTEP diagram of *trans*-$Pd(PMes_2H)_2Cl_2$ (**2**·$2CH_2Cl_2$), with thermal ellipsoids at 30% probability. The solvent molecules and hydrogen atoms, except those on P, have been removed for clarity. Selected bond lengths (Å) and angles (°): Pd–Cl(1) 2.3028(7), Pd–Cl(1A) 2.3028(7), Pd–P(1) 2.3057(7), Pd–P(1A) 2.3057(7), P(1)–C(10) 1.819(3), P(1)–C(1) 1.822(3), Cl(1)–Pd–Cl(1A) 180.0, Cl(1)–Pd–P(1) 93.91(2), Cl(1A)–Pd–P(1) 86.09(2), Cl(1)–Pd–P(1A) 86.09(2), Cl(1)–Pd–P(1) 93.91(2), P(1)–Pd–P(1A) 180.0, C(10)–P(1A)–C(1) 110.45(12).

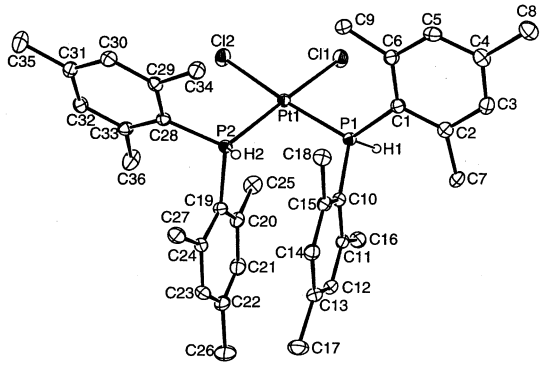

Fig. 2. ORTEP diagram of *cis*-$Pt(PMes_2H)_2Cl_2$ (**4**·CH_2Cl_2), with thermal ellipsoids at 30% probability. The solvent molecule and hydrogen atoms, except those on P, have been removed for clarity.

lengths typical of those in square planar phosphine complexes [16]. The *cis*-Pt complexes **4**–**6** (see Table 4) all show slight distortions from square planar geometry. As might be expected, the P–Pt–P bond angles, which range from 95.65(7)° to 97.07(7)° are larger than the ideal value, presumably due to steric hindrance between the bulky phosphines, as previously observed in *cis*-$Pt(PPh_3)_2Cl_2$ (Table 4) and related structures [17]. The close similarity between the structures of **4**, **5** and *cis*-$Pt(PPh_3)_2Cl_2$ suggests that L and PPh_3 have comparable steric and electronic properties. This is consistent with the similar J_{Pt-P} values found for these phosphines in **5** (3538 Hz for L, 3589 Hz for PPh_3, $CDCl_3$). As expected from *trans* influence trends, the Pt–P bond *trans* to the methyl group in **6** is longer [2.3311(17) Å] than the one *trans* to chloride [2.214(2) Å] [18].

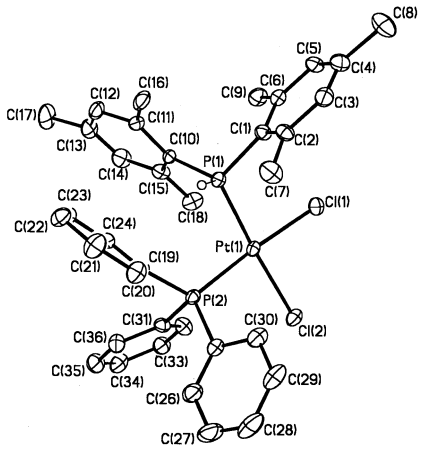

Fig. 3. Thermal ellipsoid plot (25% probability) of *cis*-$Pt(PMes_2H)(PPh_3)Cl_2$ (**5**·$2CH_2Cl_2$). The solvent molecule and hydrogen atoms, except the one on P, have been removed for clarity.

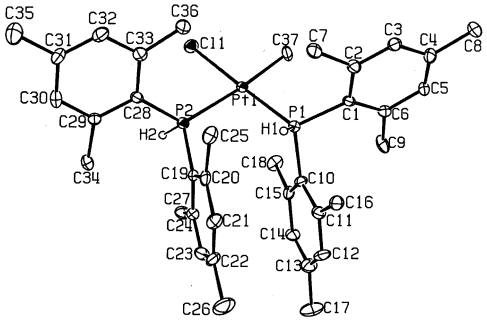

Fig. 4. ORTEP diagram of *cis*-$Pt(PMes_2H)_2(Me)(Cl)$ (**6**), with thermal ellipsoids at 30% probability. The hydrogen atoms, except those on P, have been removed for clarity.

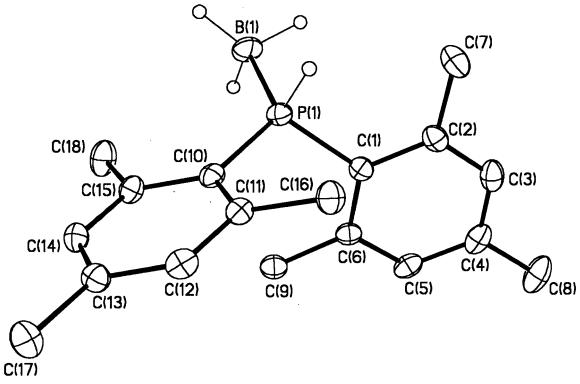

Fig. 5. Thermal ellipsoid plot (25% probability) of $PMes_2H{\cdot}BH_3$ (**9**). Hydrogen atoms, except those on P and B, have been removed for clarity. Selected bond lengths (Å) and angles (°): P–H(1) 1.35(3), P–C(1) 1.824(3), P–C(10) 1.829(3), P–B(1) 1.938(4), H(1)–P–C(10) 97.3(11), H(1)–P–C(1) 104.0(11), H(1)–P–B(1) 108.3(12), C(10)–P–C(1) 110.71(12), C(10)–P–B(1) 124.41(15), C(1)–P–B(1) 109.62(15).

In the structure of phosphine–borane **9**, the PH and BH_3 hydrogens were found and refined freely. The geometry around phosphorus is tetrahedral as expected, though the C(10)–P–B bond angle is somewhat larger

[a] Quantity minimized = $R(wF^2) = [\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]]^{1/2}$; $R = \Sigma\Delta/\Sigma(F_o)$, $\Delta = I|(F_o - F_c)|I$.

than the ideal angle at 124.41(15)°. The P–B bond length (1.938(4) Å) is typical of those in phosphine–boranes, for which a recently reported range is 1.832–1.983 Å [19]. Comparison to the structure of $PMes_2H$ [20] (Table 5) shows that borane complexation has little effect on the structure of the phosphine. The P–C bonds become slightly shorter and the C(1)–P–C(10) bond angle is increased.

The program STERIC [21] was used to determine the cone angle of L from the crystal structure data, setting a P–B distance of 2.28 Å in the case of **9** [22]. Although this is longer than the experimental distance, this choice allows comparison to the results for the metal complexes. As shown in Table 6, the cone angle falls in a narrow range in this series of complexes, although significant differences can be seen even within a single compound containing two phosphines, such as **4**. The average cone angle is approximately 149°. Consistent with the discussion above, the crystallographically determined cone angles for L and PPh_3 in **5** are similar;

compare to Tolman's reported cone angle of 145° for PPh_3 [22].

2.2. Solution structures: fluxional processes

Conformational isomerism due to restricted rotation has often been observed in metal complexes of bulky secondary phosphines. For example, Shaw reported that room-temperature solutions of *trans*-$Pt[P(t\text{-}Bu)_2H]_2Cl_2$ contained two conformational isomers; this complex has recently been studied in more detail by Mastrorilli et al. [23]. Similarly, Bushweller's detailed investigation of *trans*-$Rh[P(t\text{-}Bu)_2H]_2(CO)(X)$ (X = halide) revealed several conformations as a result of restricted rotation about the Rh–P bonds [24], and analogous behavior was observed for $Ir[P(t\text{-}Bu)_2H]_3(Cl)$ [2c]. We observed similar phenomena in Pt dimesitylphosphine complexes **4**–**8** by low-temperature NMR spectroscopy.

Although the room-temperature ^{31}P NMR spectrum of *cis*-PtL_2Cl_2 (**4**) was very broad, three different signals in about a 1:1:0.15 ratio were observed at −70 °C in CD_2Cl_2 (Table 1). We assign these to two major isomers (A and B) and one minor one (C), although we cannot rule out the possibility that the A and B signals are in fact due to a single conformer which contains two inequivalent dimesitylphosphine ligands [24].

Low-temperature ^1H NMR studies (−70 °C, CD_2Cl_2) provided additional information on the dynamic processes in **4**. As detailed in Section 4, 12 aryl proton signals (8 from the major and 4 from the minor isomers) and 18 methyl signals (12 major, 6 minor) were observed. These observations can be explained if, in the two major isomers, rotation about the P–C and Pt–P bonds is slow on the NMR time scale. If rotation about the P–C bond is slow, the *o*-Me and *m*-aryl protons are inequivalent in a given Mes group; if rotation about the Pt–P bond is slow, then there are two types of mesityl groups in a given $PMes_2H$. The crystal structure (Fig. 2), if maintained in solution at low temperature, would be consistent with these observations. The two major isomers might then be *syn* and *anti* conformers, as reported for *trans*-$Pt[P(t\text{-}Bu)_2H]_2Cl_2$ [23].

Four P–H resonances were also observed (Table 1). Three of these are easily assigned, one each to the major and minor isomers, from matching the P–H couplings in the low temperature ^1H NMR spectrum with those obtained in the low temperature ^{31}P NMR spectrum, but the origin of the fourth signal is not clear. These P–H resonances are expected to show an AA′XX′ pattern, but either simple doublets or doublet of doublets patterns were observed. If the $^2J_{PP}$ and $^3J_{PH}$ couplings are small, then the signals would appear as a doublet. The doublet of doublets patterns could arise if $^2J_{PP}$ is small. Alternatively, the observed resonances could be due to the inner lines of an AA′XX′ pattern, if the low intensity outer peaks are not observed [7].

Similarly, at −20 °C in CD_2Cl_2, the rotation about the P–C and Pt–P bonds in **5** is slow on the NMR time scale, so each of the Mes *m*-aryl protons and *o*-Me groups is inequivalent, consistent with the conformation found in the crystal structure (Fig. 3). Thus, four sharp peaks for the Mes *m*-aryl protons were observed from 6.92 to 6.63 ppm, and four *o*-Me signals appeared at δ 3.38, 2.50, 1.85, and 1.20. Because the two Mes groups are inequivalent, two separate *p*-Me resonances were observed at δ 2.25 and 2.23.

The related complexes **6** and **7** showed similar fluxional behavior, again ascribed to restricted rotation about the Pt–P and P–C bonds, giving rise to four different isomers in each case at low temperature. This could be observed most clearly by ^{31}P NMR (Table 1). Five and six of the expected eight P–H resonances could also be observed by low-temperature ^1H NMR for **6** and **7**, respectively (see Section 4 for details).

trans-$PtL_2(Et)(I)$ (**8**) also showed broad peaks in the room temperature NMR spectra. As for the *cis* isomer **7**, four isomers were observed by low-temperature ^{31}P NMR (Table 2). However, the lines in the expected AA′XX′ patterns could not all be resolved because of weak, overlapping signals. Similarly, the ^1H NMR spectrum (CD_2Cl_2, −70 °C) revealed the most intense

signals of the four expected PH AA′XX′ patterns; however, two of these peaks were obscured by Mes resonances (see Table 2 and Section 4).

3. Conclusion

We prepared several simple coordination complexes of the bulky secondary phosphine $PMes_2H$. Its crystallographically determined cone angle of approximately 149° is comparable to that of PPh_3, and comparison of the structures of *cis*-PtL_2Cl_2 (**4**), *cis*-$PtL(PPh_3)Cl_2$ (**5**), and *cis*-$Pt(PPh_3)_2Cl_2$ shows these ligands to have similar steric and electronic properties. The bulk of dimesitylphosphine is reflected in the dynamic properties of its complexes in solution at low temperature, where restricted rotation about Pt–P and P–C(Mes) bonds was frequently observed.

4. Experimental

4.1. General

Unless otherwise noted, all reactions and manipulations were performed in dry glassware under a nitrogen atmosphere at 20 °C in a dry box or using standard Schlenk techniques. Petroleum ether (b.p. 38–53 °C), ether, THF, CH_2Cl_2 and toluene were dried and degassed using columns with activated alumina [25].

NMR spectra were recorded (at 21 °C unless otherwise noted) with Varian 300 or 500 MHz spectrometers; the latter was used for variable temperature studies. ^1H or ^{13}C NMR chemical shifts are reported versus Me_4Si and were determined by reference to the residual ^1H or ^{13}C solvent peaks. ^{31}P NMR chemical shifts are reported versus H_3PO_4 (85%) used as an external reference. Coupling constants are reported in Hz, as absolute values unless noted otherwise. Unless indicated, peaks in NMR spectra are singlets. Infrared spectra were recorded using KBr pellets on a Perkin Elmer 1600 series FTIR machine and are reported in cm^{-1}. Elemental analyses were provided by Schwarzkopf Microanalytical Laboratory. Low resolution FAB Mass Spectroscopy was performed on a VG ZAB-SE instrument at the University of Illinois.

Unless otherwise noted, reagents were from commercial suppliers. The following compounds were made by the literature methods: $Pd(tmeda)Me_2$ [6], $PMes_2H$ [20], $Pd(cod)Cl_2$ [26], $Pd(NCPh)_2Cl_2$ [27], $Pt(NCPh)_2Cl_2$ [27], $Pt(cod)Cl_2$ [28], Pt(cod)(Me)(Cl) [29], and Pt(cod)(Et)(I) [30].

4.2. *cis*-$Pd(PMes_2H)_2Me_2$ (**1**). Method 1

$Pd(tmeda)Me_2$ (80 mg, 0.32 mmol) and $PMes_2H$ (165 mg, 0.610 mmol) were dissolved in 10 ml of THF to give a pink–red solution. The THF was removed under vacuum to give a brownish white solid, which was washed with petroleum ether (4 ml). The resulting blood-red solution was removed using a pipet to give a pink solid, which was dried under vacuum to yield 189 mg (88%) of the product.

Anal. Calc. for $C_{44}H_{52}P_2Pd$: C, 67.40; H, 7.74. Found: C, 67.23; H, 7.32%. ^1H NMR (C_6D_6): δ 6.55 (8H, Mes), 5.97 (d, $J_{PH} = 339$, 2H, PH), 2.33 (broad, 24H, *o*-Me), 2.01 (12H, *p*-Me), 1.00 (m, 6H, Pd–Me). $^{13}C\{^1H\}$ NMR (C_6D_6): δ 142.7 (Mes), 139.1 (Mes), 130.2 (t, $J = 3$, Mes), 126.3 (d, $J = 26$, Mes), 23.7 (Me), 21.2 (Me), 5.0 (dd, $J = 105$, 10, Pd–Me). IR: 3433, 2922, 2388, 1727, 1600, 1450, 1377, 1133, 1027, 844, 694, 616, 550.

4.3. Method 2

A pale yellow solution of *trans*-$Pd(PMes_2H)_2Cl_2$ (26 mg, 3.6×10^{-2} mmol, **2**, see below) in 10 ml of THF was cooled to −78 °C and treated with methyllithium (106 μl of 1.4 M solution in ether, 0.15 mmol). The resulting golden solution was stirred for 1 h at −78 °C, then quenched by the addition of one drop of water, which turned the solution orange. The solution was concentrated under vacuum and transferred to a NMR tube. The ^{31}P NMR spectrum showed partial conversion (73%) of the dichloro complex **2** to the dimethyl complex **1**. ^{31}P NMR (THF/ether): δ −34.8 (AA′XX′, **2**), −48.3 (d, $J = 339$, **1**).

4.4. *trans*-$Pd(PMes_2H)_2Cl_2$ (**2**). Method 1

$PdCl_2$ (57 mg, 0.32 mmol) was treated with concentrated HCl (4 ml) and the brown solution was stirred for 10 min. After addition of 8 ml of absolute ethanol, the solution was stirred for an additional 5 min. A solution of $PMes_2H$ (174 mg, 0.643 mmol) in 4 ml of ether was added, causing a yellow precipitate to form immediately. The mixture was allowed to stir for another 5 min, and then filtered on a frit. The solid was washed with water (1×10 ml) and ether (2×20 ml) and dried on the frit to give 230 mg, 99%. The yellow solid was recrystallized from methylene chloride/petroleum ether to give yellow crystals of a methylene chloride solvate, as quantified by ^1H NMR integration.

Anal. Calc. for $C_{36}H_{46}Cl_2P_2Pd \cdot 0.6CH_2Cl_2$: C, 57.17; H, 6.19. Found: C, 57.06; H, 6.12%. ^1H NMR ($CDCl_3$): δ 6.85 (8H, Mes), 6.52 (m, $J_{PP} = 598$, $J_{PH} = 386$, $J_{PH'} = -2$, 2H, P–H, AA′XX′), 2.52 (24H, *o*-Me), 2.25 (12H, *p*-Me). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 21 °C): δ 142.5 (t, $J = 5$, Mes), 140.9 (Mes), 130.1 (t, $J = 4$, Mes), 122.1 (t, $J = 24$,

Mes), 23.7 (t, $J = 4$, *o*-Me), 21.3 (*p*-Me). IR: 2956, 2922, 2400, 1600, 1556, 1449, 1405, 1374, 1264, 1029, 837.

4.5. Method 2

A yellow solution of $Pd(cod)Cl_2$ (22 mg, 0.11 mmol) in methylene chloride was treated with $PMes_2H$ (86 mg, 0.32 mmol), causing the solution to turn orange. ^{31}P NMR (CH_2Cl_2): δ −41.0 (AA′XX′, $J_{PP} = 597$, $J_{PH} = 386$, $J_{PH'} = -0.07$). Recrystallization from methylene chloride and petroleum ether gave yellow crystals of compound **2**.

4.6. Method 3

A brown slurry of $Pd(NCPh)_2Cl_2$ (22 mg, 5.7×10^{-2} mmol) in 10 ml of CH_2Cl_2 was treated with $PMes_2H$ (46.5 mg, 0.173 mmol), which gave a homogeneous yellow solution. $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ −41.0.

4.7. *trans*-$Pt(PMes_2H)_2Cl_2$ (**3**). Method 1

$PMes_2H$ (50 mg, 0.19 mmol) was dissolved in 10 ml of ethanol with gentle heating, then cooled to room temperature. A red–orange solution of K_2PtCl_4 (38 mg, 9.1×10^{-2} mmol) in 14 ml of water was added to the phosphine solution, and a fine white precipitate immediately formed. The mixture was filtered through a fine frit, and the solid was air dried to give 38 mg (51%) of the product as a very fine white powder. Recrystallization from methylene chloride/petroleum ether gave yellow crystals of a methylene chloride solvate. These crystals desolvated under vacuum to give an analytically pure sample.

Anal. Calc. for $C_{36}H_{46}Cl_2P_2Pt$: C, 53.60; H, 5.75. Found: C, 53.58; H, 5.91%. ^1H NMR ($CDCl_3$): δ 6.85 (8H, Mes), 6.66 (m, $J_{PP} = 523$, $J_{PH} = 396$, $J_{P'H} = -2$, 2H, P-H, AA′XX′), 2.53 (24H, *o*-Me), 2.25 (12H, *p*-Me). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 142.6 (t, $J = 6$, Mes), 140.7 (Mes), 130.2 (t, $J = 4$, Mes), 121.5 (t, $J = 28$, Mes), 23.5 (t, $J = 4$, *o*-Me), 21.3 (*p*-Me). IR: 2956, 2731, 2404, 1599, 1559, 1446, 1407, 1373, 1289, 1243, 1029, 962, 933, 905, 849, 708, 623, 550, 420.

4.8. Method 2

A CH_2Cl_2 solution of $PtCl_2(NCPh)_2$ (10 mg, 2.2×10^{-2} mmol) was treated with $PMes_2H$ (15 mg, 4.2×10^{-2} mmol). The $^{31}P\{^1H\}$ NMR spectrum of the reaction mixture showed that **3** had formed: δ −37.9 ($J_{Pt-P} = 2506$).

4.9. Method 3

A NMR tube containing a clear solution of *cis*-$PtCl_2(PMes_2H)_2$ (**4**) (20 mg, 2.5×10^{-2} mmol, **4**, see below) in 1 ml of CH_2Cl_2 was suspended about 3 cm from an Ace-Hanovia Photochemical Lamp with a mercury bulb. The tube was irradiated and monitored by $^{31}P\{^1H\}$ NMR. After 9 h the solution was pale yellow and the ^{31}P NMR spectrum showed about 10% conversion of **4** to **3**.

4.10. *cis*-$PtCl_2(PMes_2H)_2$ (**4**)

A solution of $Pt(cod)Cl_2$ (100 mg, 0.267 mmol) in CH_2Cl_2 (4 ml) was treated with $PMes_2H$ (145 mg, 0.535 mmol). Petroleum ether (10 ml) was layered on the methylene chloride and the clear solution was cooled to −20 °C, yielding white crystals after several days. The mother liquor was removed and the crystals dried under vacuum to give 151 mg (70%) of product. ^1H NMR integration and elemental analysis showed that these crystals contained CH_2Cl_2.

Anal. Calc. for $C_{36}H_{46}Cl_2P_2Pt \cdot 0.8CH_2Cl_2$: C, 50.54; H, 5.49. Found: C, 50.12; H, 5.25%. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 21 °C): δ −47.5 (very broad, $J_{Pt-P} = 3508$). ^1H NMR (CD_2Cl_2, 21 °C): δ 6.78 (broad), 2.39 (very broad), 2.26 (broad). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 21 °C): δ 142.5 (broad), 141.7, 130.6, 23.7 (broad), 21.1. ^1H NMR (CD_2Cl_2, −70 °C): Three isomers A–C were observed; unless otherwise noted, the ^1H NMR signals are assigned to A and B, with specific assignments given where possible. δ 7.02 (C), 6.98 (d, $J = 3$, 2H, Mes), 6.94 (2H, Mes), 6.91 (C), 6.89 (d, $J = 428$, PH, C), 6.88 (d, $J = 3$, 2H, Mes), 6.86 (C), 6.82 (2H, Mes), 6.78 (C), 6.77 (d, $J = 430$, 2H, PH, B), 6.73 (2H, Mes), 6.68 (2H, Mes), 6.52 (2H, Mes), 6.48 (C), 6.11 (2H, Mes), 5.55 (apparent dd, $J = 408$, 10, 2H, PH, A), 5.16 (apparent dd, $J = 414$, 10, PH, C), 3.41 (6H), 3.37 (6H), 3.33 (C), 3.20 (C), 2.65 (6H), 2.42 (C), 2.26 (6H), 2.23 (6H), 2.22 (6H), 2.08 (6H), 2.07 (6H), 2.03 (C), 1.99 (6H), 1.98 (6H), 1.89 (6H), 1.39 (6H), 1.20 (C), 0.90 (C). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, −60 °C): δ 143.9 (d, $J = 15$), 143.4 (d, $J = 14$), 143.0 (d, $J = 8$), 142.0 (m), 141.5 (m), 141.3 (d, $J = 6$), 141.1 (m), 140.9 (m), 139.9 (m), 139.7 (m), 139.4 (m), 131.0–130.8 (m), 130.3 (d, $J = 10$), 129.7 (m), 129.4 (d, $J = 8$), 129.2 (m), 121.7, 121.2, 118.2, 118.0, 117.9, 117.4, 117.1, 116.7 (m), 27.1 (d, $J = 9$), 26.4 (d, $J = 10$), 22.6–22.2 (m), 21.7 (m), 20.9–20.5 (m).

^1H NMR (C_6D_5Cl, 21 °C): δ 6.53 (broad, Mes), 2.31 (broad, *o*-Me), 2.05 (*p*-Me). ^1H NMR (C_6D_5Cl, 100 °C): δ 6.57 (8H, Mes), 6.34 (d, $J = 414$, 2H, PH), 2.38 (24H, *o*-Me), 2.06 (12H, *p*-Me). $^{31}P\{^1H\}$ NMR (C_6D_5Cl, 21 °C): δ −48.7 (very broad).

4.11. *cis*-Pt(PMes$_2$H)(PPh$_3$)Cl$_2$ (**5**)

PPh_3 (49 mg, 0.19 mmol) was dissolved in methylene chloride (6 ml) to give a clear solution. *cis*-$PtCl_2(PMes_2H)_2$ (100 mg, 0.124 mmol) was added. No color change occurred, and the solid did not dissolve completely. The solution was filtered through Celite to give a yellow filtrate. After the solution was left standing at room temperature overnight, it turned clear. The solution was heated to 45 °C for 5 h using a water bath. The solvent was then removed under vacuum to give white crystals, which were recrystallized from methylene chloride/petroleum ether to give 51 mg (52%) of white solid which was a CH_2Cl_2 solvate, according to the ^{1}H NMR spectrum in $CDCl_3$. Recrystallization from THF/ether gave analytically pure material.

Anal. Calc. for $C_{36}H_{38}Cl_2P_2Pt$: C, 54.14; H, 4.80. Found: C, 54.45; H, 4.60%. ^{1}H NMR (CD_2Cl_2, 21 °C): δ 7.66–7.62 (m, 6H, Ph), 7.47 (m, 3H, Ph), 7.36–7.32 (m, 6H, Ph), 6.89–6.62 (broad, 4H, Mes), 4.89 (dd, J = 409, 12, 1H, PH), 3.42 (broad, 3H, *o*-Me), 2.54 (broad, 3H, *o*-Me), 2.26 (6H, *p*-Me), 1.87 (broad, 3H, *o*-Me), 1.26 (broad, 3H, *o*-Me). ^{1}H NMR (CD_2Cl_2, −20 °C): δ 7.61 (broad, 6H, Ph), 7.48–7.46 (m, 3H, Ph), 7.35–7.32 (m, 6H, Ph), 6.92 (1H, Mes), 6.86 (1H, Mes), 6.75 (1H, Mes), 6.63 (1H, Mes), 4.82 (dd, J = 414, 13, 1H, PH), 3.38 (3H, *o*-Me), 2.50 (3H, *o*-Me), 2.25 (3H, *p*-Me), 2.23 (3H, *p*-Me), 1.85 (3H, *o*-Me), 1.20 (3H, *o*-Me). The PH signals were not observed. ^{31}P{^{1}H} NMR (CD_2Cl_2, 21 °C): δ −39.9 (very broad, $J_{Pt-P} \approx 4500$) −43.5 (very broad, $J_{Pt-P} \approx 1310$).

^{1}H NMR (CD_2Cl_2, −60 °C): Six different PH groups were observed, confirmed by ^{1}H{^{31}P} NMR: δ 6.82 (obscured by Mes, d, J = 353, 1H, PH), 6.75 (obscured by Mes, d, J = 324, 1H, PH), 5.86 (apparent dd, J = 395, 16, 1H, PH), 5.41 (apparent dd, J = 400, 17, 1H, PH), 5.18 (apparent dd, J = 354, 6, 1H, PH), 4.71 (apparent dd, J = 361, 8, 1H, PH). Additional signals: δ 6.95–6.88 (m, Mes), 6.81–6.79 (m, Mes), 6.69–6.67 (m, Mes), 6.57 (Mes), 6.46 (Mes), 6.35–6.32 (m, Mes), 6.02–5.99 (m, Mes), 3.18–3.17 (m, Me), 3.12–3.11 (m, Me), 3.01 (Me), 2.89 (Me), 2.64 (Me), 2.59 (Me), 2.54 (Me), 2.50 (Me), 2.32–2.27 (m, Me), 2.23–2.18 (broad m, Me), 2.08–2.01 (broad m, Me), 1.99 (Me), 1.91 (Me), 1.88 (Me), 1.85 (Me), 1.80 (Me), 1.76 (Me), 1.66 (Me), 1.50–1.48 (m, Me), 1.33–1.26 (m, Me), 1.16–1.12 (m, Me), 0.94 (Me), 0.83 (Me), 0.71–0.66 (m, Pt–Et), 0.59–0.54 (m, Pt–Et).

4.14. *trans*-Pt(PMes$_2$H)$_2$(Et)(I) (**8**)

cis-PtL_2(Et)(I) (91 mg, 0.10 mmol) was dissolved in approximately 1 ml of $CDCl_3$ to give a yellow solution, which was heated for 4 days at 40 °C and monitored by ^{1}H NMR. When the isomerization to the *trans* compound was complete, the contents of the NMR tube were poured into a vial and petroleum ether was layered

on top. After 3 days, 72 mg (80%) of a bright yellow precipitate formed. Recrystallization from CH_2Cl_2/ether gave analytically pure light yellow crystals.

Anal. Calc. for $C_{38}H_{51}IP_2Pt$: C, 51.18; H, 5.76. Found: C, 50.81; H, 5.80. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ −39.5 (broad, J_{Pt-P} = ca. 3350). ^1H NMR ($CDCl_3$): δ 6.88 (8H, Mes), 2.48 (broad, Me), 2.30 (broad, Me), 1.10 (q, $J_{H-H}=7$, $J_{Pt-H}=114$, 2H, CH_2CH_3), 0.68 (t, $J_{H-H}=7$, $J_{Pt-H}=70$, 3H, CH_2CH_3). The PH peaks were not observed. $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ 143.1 (Mes), 140.9 (Mes), 130.6 (Mes), 124.1 (broad, Mes), 23.8 (broad, *o*-Me), 21.5 (*p*-Me), 17.6 (CH_2CH_3), 6.0 ($J_{Pt-C}=671$, CH_2CH_3). IR: 3440, 2953, 2906, 2846, 2728, 2395, 1604, 1556, 1443, 1408, 1378, 1289, 1259, 1200, 1063, 1028, 850, 802, 612, 553, 422.

^1H NMR (CD_2Cl_2, 21 °C): δ 6.96 (8H, Mes), 2.51 (24H, *o*-Mes), 2.42 (12H, *p*-Mes), 1.16 (q, $J_{H-H}=7$, $J_{Pt-H}=83$, CH_2CH_3), 0.73 (t, $J_{H-H}=7$, $J_{Pt-H}=70$, CH_2CH_3). $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 21 °C): δ −39.0 ($J_{Pt-P}=3099$). ^1H NMR (CD_2Cl_2, −70 °C): The four expected PH signals were observed by ^1H and $^1H\{^{31}P\}$ NMR, but their low intensity and the presence of Mes signals precluded detailed analysis of the AA′XX′ patterns. Instead we report the separation between the two most intense lines of these patterns for a given resonance. δ 7.35 (apparent d, J = ca. 400), 7.1 (obscured by Mes), 6.8 (apparent d, $J=355$), 6.15 (apparent d, $J=375$). Additional signals: δ 7.15–6.70 (broad m, Mes), 3.23 (Me), 3.22 (Me), 3.17 (Me), 3.03 (Me), 2.62 (Me), 2.34 (Me), 2.29 (Me), 2.27 (Me), 2.08 (Me), 2.04 (Me), 1.87 (Me), 1.75 (Me), 1.67 (Me), 1.51 (Me), 1.50 (Me), 1.16–1.11 (m, Me), 0.89–0.87 (m, Me), 0.80–0.60 (broad m, Me), 0.45 (m, Pt–Et), 0.29 (m, Pt–Et).

^1H NMR (C_6D_5Cl, 21 °C): δ 6.72 (Mes), 2.52 (*o*-Me), 2.07 (p-Me), 1.35 (m, Pt–Et), 0.84 (m, Pt–Et). The PH resonances were not observed. $^{31}P\{^1H\}$ NMR (C_6D_5Cl, 21 °C): δ −36.8 (very broad, J_{Pt-P} = ca. 3300). ^1H NMR (C_6D_5Cl, 80 °C): δ 7.24 (apparent d, $J=384$, $J_{Pt-H}=26$, perhaps the most intense two peaks of an AA′XX′ pattern), 6.72 (Mes), 2.51 (*o*-Me), 2.08 (*p*-Me), 1.33 (q, $J_{HH}=8$, $J_{Pt-H}=84$, CH_2CH_3), 0.84 (t, $J_{HH}=8$, $J_{Pt-H}=72$, CH_2CH_3).

4.15. $PMes_2H\cdot BH_3$ (**9**)

A clear solution of $PMes_2H$ (300 mg, 1.11 mmol) in THF (6 ml) was cooled to 0 °C and treated with 834 μl of $BH_3\cdot SMe_2$ (1.67 mmol). The solution was warmed to room temperature with stirring. The solvent was removed under vacuum to give a white solid, which was recrystallized from petroleum ether at 0 °C to give large white crystals (297 mg, 95%, in four crops). *Anal.* Calc. for $C_{18}H_{26}BP$: C, 76.08; H, 9.22. Found: C, 75.73; H, 9.37%. $^{31}P\{^1H\}$ NMR (C_6D_6): δ −27.3 (broad). ^{31}P NMR (C_6D_6): δ −27.3 (broad d, $J_{PH}=383$). ^1H NMR (C_6D_6): δ 6.53 (d, $J=3$, 4H, Mes), 6.42 (dq, $J=382$, 8, PH), 2.29 (12H, *o*-Me), 1.96 (6H, *p*-Me). The BH_3 protons were not observed. $^{13}C\{^1H\}$ NMR (C_6D_6): δ 143.0 (d, $J=9$, Mes), 141.1 (d, $J=2$, Mes), 130.8 (d, $J=8$, Mes), 123.4 (d, $J=50$, Mes), 22.3 (d, $J=6$, *o*-Me), 21.2 (*p*-Me). IR: 3445, 3026, 2952, 2732, 2406, 2376, 2338, 2255, 2115, 1725, 1633, 1602, 1446, 1384, 1135, 1061, 1030, 967, 943, 893, 849, 756, 694, 626, 545.

4.16. Crystallographic structural determination

Crystal, data collection, and refinement parameters are given in Table 3. A Siemens P4 diffractometer equipped with a CCD detector was used. The structures were solved using direct methods, completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures. All non-hydrogen atoms were refined anisotropically. The P–H hydrogens were located from the electron difference map and allowed to refine isotropically. All software and sources of the scattering factors are contained in the SHELXTL (5.10) program library (G. Sheldrick, Siemens XRD, Madison, WI). The figures were prepared using either SHELXTL or ORTEP-3 for Windows [31].

4.17. Cone angle calculations

Cone angles were calculated using the program STERIC [21], as previously reported [32]. Hydrogen atoms, as placed in the crystallographic determination, were fixed at a C–H distance of 1.1 Å, and a P–H distance of 1.42 Å [33]. Calculations on **5**·$2CH_2Cl_2$ showed that changing the P–H distance from 1.22 to 1.50 Å had minimal effect (change from 147° to 149°) on the cone angle. The M–P bond distances were fixed at 2.28 Å [22]. The CPK van der Waals radii set was used for all cone angle calculations.

5. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 181084–181086 and 181088–181089. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

We thank the NSF Career Program, DuPont, and Union Carbide (Innovation Recognition Award) for support, and the Department of Education for a GAANN fellowship for M.A.Z. The University of

Delaware acknowledges the NSF (Grant CHE-9628768) for their support of the purchase of the CCD-based diffractometer.

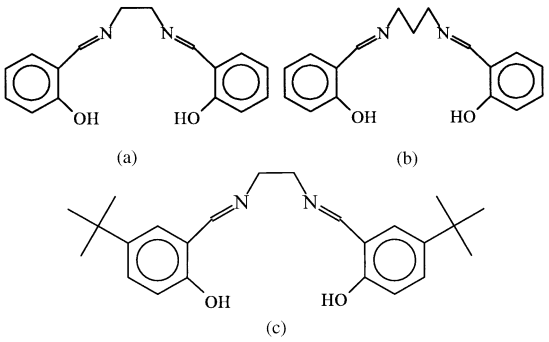

Fig. 1. The ligands: (a) salen; (b) salpn; and (c) *t*-butylsalen.

this steric freedom that makes them an ideal class of ligands for both transition metals and the *f*-block elements. Ligand field effects in most *d*-transition elements favour an arrangement where the equatorial ligands are arranged in an approximately square-planar geometry, whereas the much smaller ligand field effects in the *f*-block elements in combination with a much larger ionic size results in a significantly different coordination geometry for lanthanoid and actinoid elements [6,7,20]. This is further enhanced by the presence of the particularly strong, *trans* O–U–O apical bonds. Hence the ability of the salen type ligands to 'flex' and accommodate both types of geometric requirements impart a degree of stabilization to these systems [21].

Only a limited amount of work has been performed in this area. Early studies investigated the co-crystallisation of UO_2Cl_2 or $UO_2(NO_3)_2$ from methanol in the presence of the salen ligand, and the ethanol adduct of the more sterically rigid [*N*,*N*′-*o*-phenylenebis(salicylideneimine)](phenylsalen) (Fig. 2) [21].

The uranyl ion can also be used as a template ion, and the two constituents of salen (salicylaldehyde and ethylendiamine) were combined in the presence of the metal salt, with the metal facilitating the Schiff base reaction. This yielded complexes of the formula $[UO_2(salen)(X)]$, (where X = ethanol or methanol). The general structural motif involves the salen ligand bound in a tetradentate fashion surrounding the equatorial axis of the uranyl coordination sphere, while a solvent molecule occupies a fifth equatorial position, resulting in distorted pentagonal bipyramidal geometry. This conformation was observed for both the basic salen ligand and the phenyl derivative [14]. Studies involving the more sterically flexible salpn ligand have not revealed any recorded uranyl complexes [22–25].

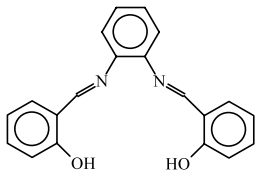

Fig. 2. The phenylsalen ligand, containing the aromatic linker group rather than the ethylene or propylene group.

These studies were undertaken some time ago, hence they were unable to make a detailed study of the crystal packing of the molecule. Modern advancements in X-ray diffraction technology have enabled a more detailed characterization to be undertaken in an effort to elucidate how incorporated solvent molecules may affect the molecular geometry and crystal packing as a whole. We report here-in the synthesis and X-ray crystal characterization of $[UO_2(salen)H_2O]$ (**1**), $[UO_2(salen)EtOH]$ (**2**), $[UO_2(salen)DMSO]$ (**3**), $[UO_2(t\text{-butylsalen})py]$ (**4**), $[UO_2(salpn)MeOH]$ (**5**), $[UO_2(salpn)EtOH]$ (**6**), $[UO_2(salpn)py]$ (**7**), and $[UO_2(NO_3)_2(salpn)]$ (**8**).

2. Experimental

$UO_2(NO_3)_2\cdot 6H_2O$, was purchased from Aldrich and used without purification. Salen and salpn were all synthesised according to literature methods [19,26]. Dimethyl sulfoxide, Py, EtOH and MeOH were purchased from Aldrich and freshly distilled prior to use. IR spectra were recorded in the range of 4000–400 cm^{-1} on KBr plates as Nujol mulls on a Nicolet Nexus FTIR spectrophotometer. Microanalyses were carried out at James Cook University on a Carlo Erba EA 1109 C, H, N by Brian Foster.

2.1. $[UO_2(salen)H_2O]$ (1)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of water, then added to an equimolar solution (0.027 g, 0.1007 mmol) of salen in water (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which yellow X-ray quality crystals formed after several days. *Anal*. Calc. for $C_{16}H_{16}N_2O_5U$: H, 2.91; C, 34.67; N, 5.05. Found: H, 2.40; C, 33.89; N, 5.39%; IR (Nujol): 1625(m), 1594(m), 1305(w), 1035(w), 904(m), 427(s) cm^{-1}.

2.2. $[UO_2(salen)EtOH]$ (2)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of water, then added to an equimolar solution (0.027 g, 0.1007 mmol) of salen in EtOH (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which deep yellow, X-ray quality crystals formed after several days. Complex analysed similar to the values reported in the literature [27]. IR (Nujol): 1622(s), 1604(w), 1308(s), 1274(m), 911(s), 663(m) cm^{-1}.

2.3. [UO_2(salen)DMSO] (**3**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of DMSO, then added to an equimolar solution (0.027 g, 0.1007 mmol) of salen in DMSO (5–10 cm^3). Vigorous heating was used to affect dissolution. The solution was left open to the atmosphere at ambient conditions, upon which deep orange X-ray quality crystals formed after several weeks. *Anal*. Calc. for $C_{18}H_{20}N_2O_5SU$: H, 3.28; C, 35.19; N, 4.56. Found: H, 3.48; C, 35.65, N, 4.43%; IR (Nujol): 1598(w), 1300(m), 1185(m), 891(s), 743(w) cm^{-1}.

2.4. [UO_2(*t*-butylsalen)py] (**4**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of Py, then added to an equimolar solution of *t*-butyl(salen) (0.03625 g, 0.0857 mmol) in Py (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which blood red X-ray quality crystals formed after several days. *Anal*. Calc. for $C_{29}H_{35}N_3O_4U_1$: H, 4.85; C, 47.87; N, 5.77. Found: H, 4.92; C, 47.84; N, 5.82%; IR (Nujol): 1625(s), 1547(w), 1299(m), 894(s), 751(w) cm^{-1}.

2.5. [UO_2(salpn)MeOH] (**5**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of MeOH, then added to an equimolar solution of (salpn) (0.02808 g, 0.0996 mmol) in MeOH (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which deep yellow X-ray quality crystals formed after several days. *Anal*. Calc. for $C_{18}H_{20}N_2O_5U$: H, 3.46; C, 37.12; N, 4.81. Found: H, 3.45; C, 36.65; N, 5.05%; IR (Nujol): 1650(s), 1605(s), 1308(m), 1272(m), 1022(s), 918(s), 722(m) cm^{-1}.

2.6. [UO_2(salpn)EtOH] (**6**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of EtOH, then added to an equimolar solution of (salpn) (0.028 g, 0.0993 mmol) in EtOH (10–20 cm^3). Vigorous heating was needed to effect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which yellow X-ray quality crystals formed after several days. *Anal*. Calc. for $C_{19}H_{22}N_2O_5U$: H, 3.72; C, 38.26; N, 4.70. Found: H, 3.47; C, 38.55; N, 4.85%; IR (Nujol): 1654(s), 1605(s), 1280(m), 1049(s), 902(m), 762(m) cm^{-1}.

2.7. [UO_2(salpn)py] (**7**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of Py, then added to an equimolar solution of (salpn) (0.02808 g, 0.0996 mmol) in Py (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which dark orange X-ray quality crystals formed after several days. Repeated attempts to obtain meaningful microanalysis were prevented due to the apparent loss of solvent from the crystalline material. IR (Nujol): 1625(s), 1598(s), 894(s), 662(m), 743(m), 529(s) cm^{-1}.

2.8. [$UO_2(NO_3)_2$(salpn)] (**8**)

Uranyl nitrate (0.05 g, 0.0996 mmol), was dissolved in a minimum of water, then added to an equimolar solution of (salpn) (0.02808 g, 0.0996 mmol) in water (10–20 cm^3). Vigorous heating was used to affect dissolution. The solution was filtered and left open to the atmosphere at ambient conditions, upon which dark red X-ray quality crystals formed after several days. *Anal*. Calc. for $C_{17}H_{18}N_4O_{10}U$: H, 2.10; C, 30.37; N, 8.33. Found: H, 2.46; C, 30.80; N, 9.77%; IR (Nujol): 3385(m), 1650(s), 1605(s), 1308(m), 1274(m), 1022(s), 918(s), 863(w), 757(m) cm^{-1}.

2.9. X-ray determinations

For compounds **1**–**8** hemispheres of data were collected (capillary sealed specimens) at room temperature on a Bruker SMART CCD diffractometer using the omega scan mode with total reflections and unique data listed below. Data sets were corrected for absorption using the program SADABS [28]. The structures were solved using the Patterson method for heavy atoms and refined on F^2 using SHELXL-97-2 [29] with X-SEED as the graphic interface [30]. All non-hydrogen atoms were located and were refined with anisotropic thermal parameters. Hydrogen atoms were placed in calculated positions (riding model) and were not refined. Crystal data and a summary of data collection appear below, while selected bond distances and angles appear in Tables 1–3; hydrogen bonding tables for compounds **1**, **2**, **5** and **6** are found in Table 4.

2.10. [UO_2(salen)H_2O] (**1**)

$C_{16}H_{16}N_2O_5U$, $M = 554.34$, triclinic, space group $P\bar{1}$ (No. 2), $a = 8.237(3)$, $b = 9.335(4)$, $c = 11.562(5)$ Å, $\alpha = 77.830(7)^\circ$, $\beta = 75.638(6)^\circ$, $\gamma = 75.964(6)^\circ$, $V = 824.7(6)$ $Å^3$, $Z = 2$, $D_{calc} = 2.232$ g cm^{-3}, yellow prismatic, $0.20 \times 0.20 \times 0.18$ mm, $F(000) = 516$, $2\theta_{max} = 46.5^\circ$, 3695 reflections collected, 2330 unique ($R_{int} = 0.0536$). Final goodness-of-fit = 1.023, $R_1 = 0.0330$, $wR_2 =$

3. Results and discussion

This study was undertaken in an effort to establish what effect the supporting solvent exerts upon the modes of crystallisation of uranyl Schiff base complexes. The synthesis of these complexes involved the mixing of uranyl nitrate and the salen species in the appropriate solvent. In most cases, these ligands displayed only partial solubility, hence vigorous heating was generally required to affect dissolution. The resulting solutions were then filtered and left to crystallise by gradual evaporation. The crystals were intensely coloured, either red or yellow, as would be expected from the highly conjugated nature of these ligands. The IR spectra all contained (C=N) stretches at approximately 1625 and 1594 cm^{-1}.

All the complexes adopt a similar morphology about the uranium centre, in which the Schiff base ligands are tetradentate and adopt a stepped conformation when viewed along the equatorial plane. This is very similar to the [UO_2(salen)MeOH] adduct obtained in a previous study [14]. The angle between the planes of the two aromatic rings deviates slightly from coplanar for the salen ligands, however they are close-to-coplanar for the salpn ligands. In all solvent adducts, pentagonal bipyramidal geometry about U is observed, with four of the equatorial sites about the uranium centre occupied by the Schiff base ligand, while the remaining available area is occupied by a solvent molecule. Oxo ligands occupy the axial sites and the uranyl nitrate species (**8**) contains no solvent molecules, and the salpn ligand acts in a bidentate fashion, with the remainder of the coordination sphere occupied by the bidentate nitrate ions. These compounds exist as monomers unless the coordinated solvent molecules contain hydrogen bond donors, in which case dimers are formed through hydrogen bonding.

3.1. Salen complexes

The eight uranyl complexes will be grouped together according to the salen type involved in the complex, and discussed together so a comparison can be made between these similar complexes. The four salen complexes all crystallise in different space groups, but possess similar asymmetric units. The water adduct [UO_2(salen)H_2O] (**1**) (Fig. 3 crystallises in the centrosymmetric space group $P\bar{1}$, while the ethanol adduct [UO_2(salen)EtOH] (**2**) (Fig. 4) crystallises in $P2_1/c$.

In both these complexes, the coordinated solvent molecules possess hydrogen bonding donor species, and this results in the formation of a hydrogen bonded dimer about an inversion centre through a $O_{(solvent)}$–H···$O_{(salen)}$ interaction (Figs. 3 and 4). These hydrogen

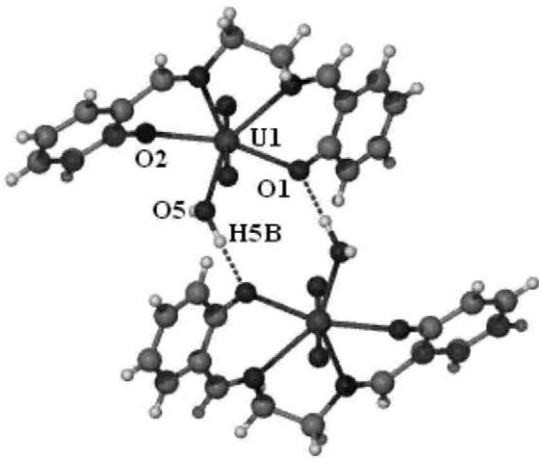

Fig. 3. X-ray crystal structure of the hydrogen-bonded dimer [UO_2(salen)H_2O] (**1**).

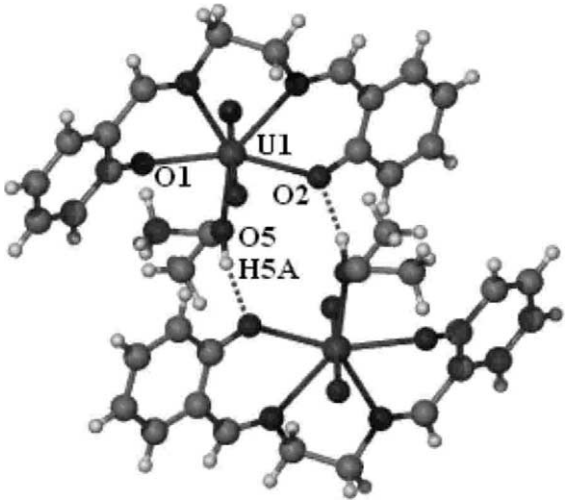

Fig. 4. X-ray crystal structure of the hydrogen-bonded dimer [UO_2(salen)EtOH] (**2**). The methyl group of ethanol molecule is disordered over two sites.

bonding interactions result in the complex packing in rows of zigzagging, polymeric chains where each molecule is linked to an adjacent molecule via the solvent ligand.

In contrast, the DMSO adduct [UO_2(salen)DMSO] (**3**) (Fig. 5) crystallises in the acentric space group $P2_12_12_1$, while the pyridine adduct [UO_2(*t*-butylsalen)py] (**4**) (Fig. 6) crystallises in the space group R-3. Neither of these two latter species contain hydrogen bonding, hence they both crystallise as discrete monomeric units, and are less ordered in terms of crystal packing.

The equatorial geometry surrounding the uranyl centres for all four compounds is distorted pentagonal bipyramidal. The average lengths of the apical uranyl oxygen bonds U1–O3 and U1–O4 (both average 1.76 Å) are in close agreement with other uranyl complexes of this type (average 1.77 Å) [14,21], illustrating how the coordination environment surrounding the uranyl cation has very little effect on the apical bond lengths. The

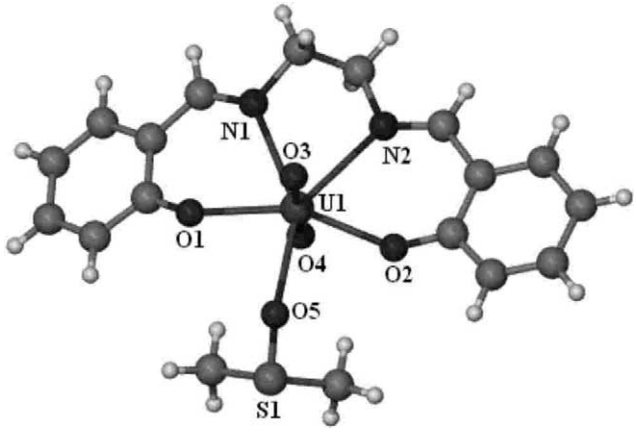

Fig. 5. X-ray crystal structure of monomeric [UO_2(salen)DMSO] (**3**).

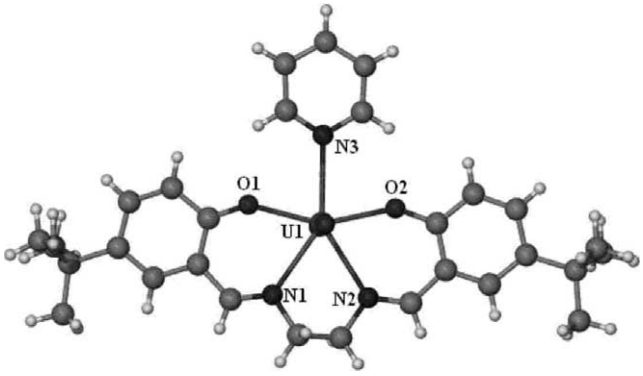

Fig. 6. X-ray crystal structure of monomeric [UO_2(*t*-butylsalen)py] (**4**).

imino–uranium bonds are asymmetric, and the bond lengths of U1–N1 (range of 2.545(9)–2.560(7) Å), U1–N2 (range of 2.563(6)–2.584(8) Å) all fall within the range expected for these types of compounds [14,21].

Previous work by Bandoli et al. investigated both the salen methanol and ethanol adducts, as well as the ethanol adduct of the more sterically rigid [*N*,*N*′-*o*-phenylenebis(salicylideneiminato)UO_2] (phenylsalen) [14,21] and found that all three species crystallised in the dimeric form and contained distorted pentagonal bipyramidal geometry around the uranium metal centre, and the U–$O_{(salen)}$ (range of 2.245(14)–2.330(32) Å) and U–N (range of 2.542(47)–2.572(24) Å) bond lengths were very similar to those reported here. In the case of the ethanol adduct, we discovered disorder in the coordinated ethanol molecule of the salen adduct which was overlooked in the previous study, but they did have extraordinarily large thermal parameters on these C-atoms. This has been included in this study.

The salen ligand has an advantage over cyclic ligands of a polydentate nature in that free rotation between the aromatic planes allow the ligand freedom to orientate the two donor oxygens for favourable U–$O_{(salen)}$ interactions, hence alleviating excess steric repulsions around the uranyl centre. This steric freedom can be influenced by the solvent ligand, illustrated by comparing the plane of the salen phenol rings between the four different compounds.

For **1** and **2**, there is a distinct difference between the planes of opposing phenol rings whereas the corresponding angle deviations for **3** and **4** are far less pronounced. This difference in conformation may be attributed to the hydrogen bonding of the dimeric species anchoring the two monomers together, slightly decreasing the steric freedom. As a result the angles between the apical uranyl–oxygen bond and the five equatorial atoms of **1** and **2** (83.0(2)°–97.2(2)°) show a greater deviation from perpendicular than those of **3** and **4** (87.6(3)°–92.1(3)°), in which hydrogen bonding is absent. The torsion angle between the two nitrogen donor atoms is also narrower for complexes **1** and **2**

(50.06(85)° and 56.62(93)°, respectively), than **3** and **4** (61.41(120)° and 58.95(100)°, respectively) suggesting that the latter are less sterically strained. This is further exemplified by the position of the pyridine ligand in **4**, the plane of which resides almost parallel to the aromatic planes of the phenols. The presence of any significant steric repulsions between the salen ligand the solvent molecule would result in rotation of the pyridine around the $C_{(salen)}$–$N_{(pyridine)}$ bond and this is not observed.

Closer examination of **1** and **2** show the *trans* phenol rings of opposing uranyl units in both dimers align in the same plane, that extends throughout the entire crystal lattice, suggesting π–π stacking may be influencing the crystal packing, however the degree of separation of the aromatic groups precludes this, hence is probably a result of the separation of molecules enforced by the uranyl oxygens. Therefore, the alignment of the aromatic groups must simply be a result of the crystal packing at close to van der Waal separations.

For complexes **3** and **4**, the lack of hydrogen bonding results in the packing of the crystal lattice being solely dependent on the geometry of the uranyl molecule. This is especially true for the DMSO species and demonstrates how the DMSO molecule causes this species to crystallise in repeating helical rows containing a 2_1 screw that extends through the lattice. The resulting crystal displays chirality as a whole, even though the monomeric unit does not.

Even though the aromatic planes of adjacent molecules are coplanar, the distance between aromatic moieties is too great for any significant π–π interactions within the crystal lattice. This coplanarity must therefore again simply be a result of the crystal packing.

Solvent effects again dominate the crystal packing of **4**, although in a significantly different way. This species is a trigonal crystal system, containing a threefold rotational axis. The large steric bulk of the pyridine ligand, along with the presence of the *t*-butyl groups imposes steric limitations on the packing of this molecule. As such there appears to be no significant interactions between rows, rather they are arranged such as steric limitations allow.

There is surprisingly little difference in the U–$O_{(solvent)}$ bond lengths in all three X-ray crystal structures (2.430(5), 2.420(6) and 2.414(6) Å in compounds **1**, **2** and **3**, respectively). Considering the difference in donor strength between these ligands, these distances do not vary significantly and may be dominated by the macrocyclic ligand. The U–$O_{(pyridyl)}$ bond length in **4** (2.640(6) Å) is significantly longer, as expected, than the U–O lengths above.

These four cases demonstrate clearly how, even though the geometry of several closely related uranyl species do not appear to be significantly different, the coordinated solvent can impart a great influence on the overall morphology of the crystal.

3.2. Salpn complexes

The solvent adducts of the uranyl–salpn complexes possess similar geometry directly adjacent to the uranyl centre, however the extended propyl carbon bridge linking the amino units allows them greater steric freedom to orientate favourably around the uranyl moiety and reduce steric interference.

These solvent adducts adopt an asymmetric unit consisting of a single uranyl cation surrounded by a single doubly deprotonated salpn ligand and a single coordinated solvent molecule. The methanol adduct $[UO_2(salpn)MeOH]$ (**5**) (Fig. 7) and the ethanol adduct $[UO_2(salpn)EtOH]$ (**6**) (Fig. 8) crystallise in the monoclinic space group $P2_1/n$ and are structurally very similar to **1** and **2**, again forming a hydrogen bonded dimeric unit. The pyridine adduct $[UO_2(salpn)py]$ (**7**) crystallises in the orthorhombic space group *Pbca*, exists as the discrete monomer and contains no hydrogen bonding (Fig. 9).

The nitrate analogue **8**, however, contains a completely separate morphology in that no solvent is incorporated into the coordination sphere of the uranyl cation, hence the two *bidentate* nitrate anions occupy the four additional coordination sites. This restricts the available coordination sites for the ligand and distorts the salpn ligand into a bidentate, cupped U-shape, illustrating clearly the conformational freedom this ligand possesses (Fig. 10). This has ramifications when considering the packing of the crystal lattice (see below). However, the reason that the nitrates remain coordinated in this case,

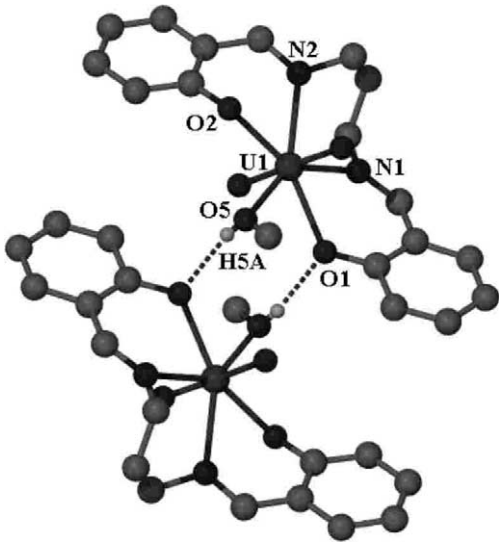

Fig. 7. X-ray crystal structure of the hydrogen-bonded dimer $[UO_2(salpn)MeOH]$ (**5**). Hydrogen atoms except those on the solvent have been omitted for clarity.

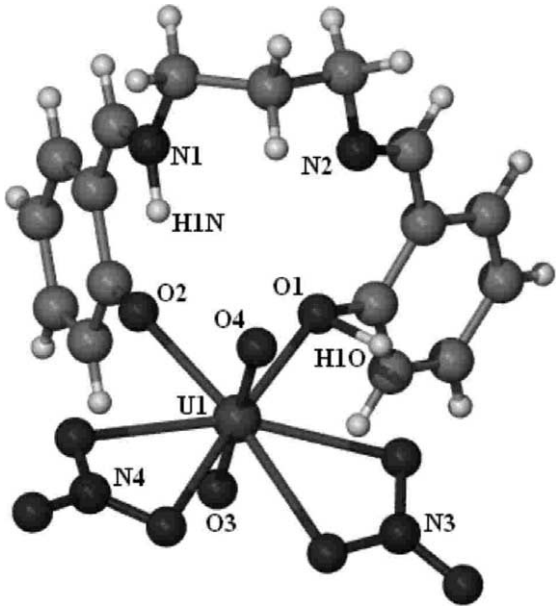

Fig. 10. The X-ray crystal structure of $[UO_2(NO_3)_2(salpn)]$ (**8**).

even though the complex was synthesised in water remains unclear but presumably arose from pH dependency.

The geometry surrounding the uranyl centre for the solvent adducts is again distorted pentagonal bipyramidal, and the U1–O1 and U1–O2 bond lengths of the uranyl cation are in close agreement with those reported [14,21,27], as are U1–N1 (range of 2.556(15)–2.588(4) Å), U1–N2, (range of 2.565(4)–2.661(116) Å), U1–O3 (range of 1.76(8)–1.782(4) Å) and U1–O4 (range of 1.756(11)–1.781(7) Å).

The geometry of unsolvated compound **8** is distorted hexagonal bipyramidal, or octahedral if the nitrate anions are considered as one coordination site, with the plane of the two nitrate ions deviating from coplanar as a result of the steric repulsions of the ligand. The U–$O_{(salpn)}$ bonds are asymmetric since one of the donor oxygens remains protonated, as does one of the imino groups, resulting in a Zwitterion and increasing the distortion of the geometry around the uranyl moiety. This unusual bidentate salpn coordination results in a 13-membered chelate ring, and has not been observed previously for any other metal system. The protonation of the imino group and the retention of a phenolic proton imparts a neutral overall charge on the ligand, allowing the nitrate anions to remain coordinated to the uranyl cation without disturbing the charge balance.

The major conformational differences between the salen complexes and those involving salpn are that the salpn adopts a more 'twisted' conformation in relation to the uranyl cation, with the difference between the planes of the aromatic phenols in the asymmetric unit being very small. The relief of steric repulsions in this exaggerated 'chair' orientation allows can be illustrated by examining the geometry of the five equatorial bonds relative to the apical oxygens. For the dimeric salpn compounds, the deviation of these angles from perpendicular is small (87.97(15)°–93.63(15)°), even in the presence of hydrogen bonding distortions, contrasting with the analogous salen species, in which the deviations from perpendicular are relatively large (83.0(2)°–95.7(2)°).

The geometry of the pyridine analogue deviates slightly from this, however, with the O1–U1–N3 angle distorted up to 6° from perpendicular. Slight rotation is also observed around the U1–$N_{(pyridine)}$ bond, and these two effects probably indicate the greater 'bite diameter' of the salpn is pushing the aromatic rings in closer proximity to the pyridine, hence increasing the repulsions about the pyridine molecule.

Another example of how the salpn ligand encompasses the uranyl coordination sphere more efficiently than salen is illustrated by comparing the respective N1–U1–N2 angles of the complexes **1**–**7**. The N1–U1–N2 angle for compounds **1**–**4** (64.84(18)°–67.1(2)°) is markedly less than that of the salpn complexes which all

display a N1–U1–N2 angle in the range of 70.14(12)°–70.3(5)°.

As stated above, **5** and **6** are structurally similar, and so pack in an identical fashion as alternating rows of dimeric units. In contrast, the crystal packing of the monomeric pyridine adduct (**7**) is relatively simple and consists of rows in which each consecutive monomer is rotated on its horizontal axis by 180°.

The crystal packing in **8** is influenced mainly by the folded orientation of the two aromatic groups in respect to the equatorial plane, and consists of repeating rows of interlocking monomeric units. The planes of opposing aromatic units on each partnered molecule are coplanar, however the degree of separation of these molecules prevents π–π stacking. This particular geometry illustrates clearly how the salpn ligand easily conforms to fill the unique coordination environment of the parent metal ion.

As in the salen complexes above, there is little difference in the $U–O_{(solvent)}$ bond lengths in the salpn structures (2.463(4) and 2.475(15) for **5** and **6**, respectively). These U–O lengths are perhaps surpisingly slightly longer than the salen complexes above given the greater steric freedom associated with the salpn ligand. The $U–O_{(pyridyl)}$ bond length in **7** (2.632(11) Å) is significantly longer, as expected, than the U–O lengths but very similar to that in the salen complex **4**.

4. Conclusions

This study involved the synthesis of a range of solvent adducts of uranyl nitrate with both the salen and salpn ligands, and illustrated how the solvent used in the synthesis of uranyl-salen and uranyl-salpn complexes can influence the morphology of the resulting crystal structures. The geometry immediately surrounding the uranyl cation is quite similar in all cases, with only slight differences observed in the bond lengths and angles of the uranyl salen bonds. These subtle differences, however, are sufficient to drastically alter the packing of each crystal and produce a unique lattice.

The water adduct (**1**) and the ethanol adduct (**2**) exist as hydrogen bonded dimers linked via the two solvent molecules. This hydrogen bonding extends axially from each ligand, resulting in one-dimensional rows extending throughout the lattice. The DMSO adduct (**3**) and the pyridine adduct (**4**) both contain more complicated lattice packing, and lack hydrogen bonding.

The salpn compounds display somewhat more similarity between adducts, with the methanol (**5**) and ethanol (**6**) adducts crystallizing as hydrogen bonded dimers, while the pyridine adduct crystallises as a distinct monomeric unit.

Compound **8** differs from these solvent adducts in that it contains the original uranyl nitrate salt bound to a neutral salpn ligand. The hexagonal bipyramidal geometry surrounding the uranyl centre differs significantly from that of the previous examples, and this is the first example of a structurally characterised complex containing a mononuclear, bidentate salpn ligand with any metal. The 13-membered chelate ring produced by this mode of binding is also unique. The presence of the nitrate anions severely restricts the number of available coordination sites around the uranyl centre, resulting in bidentate coordination. This has the effect of 'folding' the two aromatic units together like the pages of a book, giving a 'cupped' appearance. This added steric freedom of the salpn ligand that results from the elongated propyl linkage causes a slightly larger separation of the aromatic planes, thus preventing the possibility of π–π stacking.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 184610, 184611, 184612, 184613, 184614, 184860, 184615, 184616 for compounds **1**–**8**, respectively. We have been exploring the possibility of using copper(I) complexes of tertiary aryl phosphines to design systems suitable for sensing anions [8]. While most transition metal ions form rather rigid complexes due to crystal field stabilization effects, closed shell systems like Cu(I) have a plastic coordination sphere [9]. This allows for considerable deviations from the ideal geometry required for stability in partly filled d orbitals. The Cu(I) complex of diphenylphosphinohexane (dpph) reported by Kitagawa et al. [10] hosts oxoanions of different shapes and sizes between two copper centers bridged by the ligand. Our recent studies have demonstrated the efficiency of non-covalent interactions with anions in modulating the conformation of phenyl rings on the ligand such as bis diphenylphosphinomethane (dppm) [8b]. The nuclearity of the Cu(I) dppm complexes is controlled by the nature of anions. Oxoanions form dimers having short contacts or weak interactions between the anion and aromatic hydrogen atoms. However, halides, hydroxide and pseudohalides lead to very strong interactions of the anion with copper and result in the formation of trinuclear copper clusters bridged on the edges by dppm [8a]. Strong interactions are a limitation when sensor applications are envisaged due to possible deactivation on binding. Hence, alternative aryl phoshpines are being explored in our laboratory. Here we report our studies on 1,2-bis(diphenylphosphino)ethane (dppe).

Dppe is one of the most versatile phosphine ligands, capable of stabilizing copper in its +1 state [11]. Unlike dppm, this ligand can chelate as well as bridge copper centers. We have earlier demonstrated the possibility of obtaining both coordination modes upon altering the ratio of the phosphine with respect to the amount of Cu(I) [12]. A survey of Cu(I) dppe complexes indicates repeated occurrence of a family of complexes with the general stoichiometry $Cu_2(dppe)_3X_2$ (X = various mono anions/guest) [13]. In all these structurally characterized complexes, two Cu centers are bridged by a dppe ligand and each metal center possesses one chelating dppe, with the fourth coordination site available for the anion/guest (X). It is found that $[Cu_2(dppe)_3]^{2+}$ forms a cavity capable of accommodating a wide variety of anions of different shapes and sizes. X ranges from chloride to bulky thiolates. In one system, a neutral ligand acetonitrile, is present in the place of X [14]. This prompted us to prepare and study three new complexes with potentially bidentate/bridging anions [15], CN^-, SCN^- and NO_3^-. The complexes have been structurally characterized and their solution behavior examined. A critical examination of the cavity to accommodate guests with diverse steric demands has been made. Surprisingly, copper complexes of phosphines with cyanide or thiocyanate in the monodentate mode are very few and the complexes we have synthesized represent some of the first examples with the anions in this environment. Encapsulation of these anions in a hydrophobic sheath prevents bidentate interactions and introduces new solution behavior.

2. Results

2.1. Molecular composition and characterization

The composition of Cu(I) phosphine complexes is not always determined by the stoichiometry of the reactants. In several cases, it has been shown that halides and phosphines form complexes with very different formulae from those dictated by the reaction stoichiometry [13g,13h]. In the current study, we found that starting with ratios of dppe/Cu equal to 1.5 always gave copper complexes with the same stoichiometry. Single crystal X-ray crystallographic analysis confirmed the structures proposed on the basis of spectroscopic data. The complexes chosen for crystallographic examination have anions that are potentially bidentate and are predominantly found in bridging environments [15]. These compounds join the group of rare examples of Cu(I) complexes where cyanide and thiocyanate anions are found in a monodentate binding mode [16].

2.2. General description of the structures

X-ray diffraction studies of single crystals of the compounds made in this study confirm the formation of molecular structures expected in this series [13,14]. Selected bond angles and lengths are given in Table 1. A representative structure showing the molecular structure of **2** is given in Fig. 1. There are two types of dppe

Table 1
Selected bond lengths and bond angles for **1**, **2** and **3**.

	Bond lengths (Å)		Bond angles (°)	
1	Cu(1)–C(3)	1.964(4)	C(3)–Cu(1)–P(1)	107.05(9)
	Cu(1)–P(1)	2.2808(8)	P(1)–Cu(1)–P(2)	112.76(3)
	Cu(1)–P(2)	2.3040(9)	P(1)–Cu(1)–P(3)	115.16(3)
	Cu(1)–P(3)	2.3276(8)	C(3)–Cu(1)–P(2)	120.73(9)
			C(3)–Cu(1)-P(3)	111.43(8)
			P(2)–Cu(1)-P(3)	89.22(3)
2	Cu(1)–N(1)	1.985(3)	N(1)–Cu(1)–P(1)	108.79(9)
	Cu(1)–P(1)	2.2707(9)	P(1)–Cu(1)–P(3)	115.24(3)
	Cu(1)–P(3)	2.2998(9)	P(1)–Cu(1)–P(2)	117.01(3)
	Cu(1)–P(2)	2.3058(10)	N(1)–Cu(1)–P(3)	113.75(9)
			N(1)–Cu(1)-P(2)	111.44(9)
			P(3)–Cu(1)-P(2)	89.72(4)

	Cu(1)–P(1)	2.2684(10)	P(1)–Cu(1)–P(3)	112.79(4)
	Cu(1)–P(3)	2.3285(10)	O(3)–Cu(1)–P(2)	116.25(8)
			O(3)–Cu(1)-P(3)	104.01(9)
			P(2)–Cu(1)-P(3)	89.84(4)

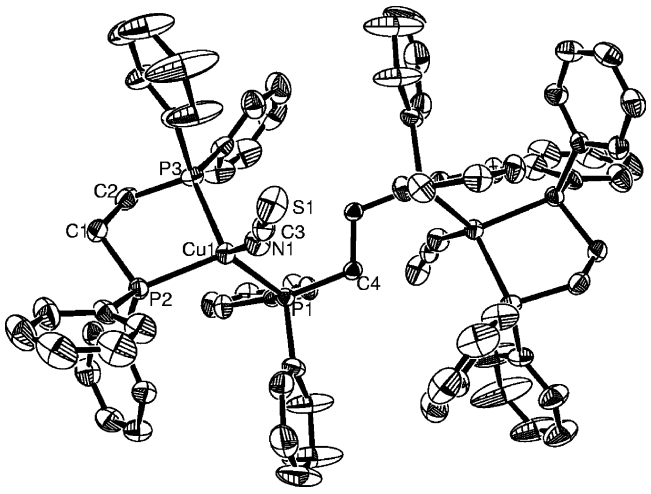

Fig. 1. The molecular structure of **2** at the 30% probability level. (Hydrogen atoms and labels for phenyl rings are omitted for clarity. Structure for **1** and **3** are given in supporting information.)

ligands in each of the three molecules. A bridging dppe holds two metal centers together and both metal centers posses a second chelating dppe. All are centrosymmetric molecules and the center of symmetry is located between the methylene carbons of the bridging dppe. Thus both metal centers are crystallographically equivalent. In all these complexes, the copper atom adopts a distorted tetrahedral geometry due to the constraint imposed by a chelating dppe. The bite angles of the chelating dppe are comparable to what has been observed in other structures [13,14]. They are remarkably constant (89.2°, 89.7°, 89.8° for anions CN^-, SCN^-, NO_3^-, respectively) and hence an invariant feature of the complex. The Cu–P distances range from 2.27 to 2.33 Å. The fourth coordination site is occupied by the anion. In the case of complex **1** the C of CN^- coordinated to the copper makes an angle of 107.05° with respect to the P1 atom of the bridging dppe and 120.71°, 111.44°, respectively to the P2 and P3 atoms of the chelating dppe. Similarly, the N1 atom of the thiocyanate complex **2** and the O3 atom in the nitrate complex **3** coordinate to the copper in a near tetrahedral environment. In the case of the cyanide complex, the Cu–C distance (1.96 Å) is comparable to the value found in a similar complex [16] (1.95 Å, $(PPh_2N(H)PPh_2)Cu(PPh_3)CN$). The Cu–N (1.98 Å) bond distance observed in the thiocyanate structure is in good agreement with the typical length of a Cu–N bond [17]. In the structure containing nitrate, the Cu–O bond distance is 2.07 Å and slightly shorter than other copper complexes where nitrate is coordinated to Cu (2.174(2) Å for $[Cu(PPh_3)_3NO_3]$ [18] and 2.206 Å for $[Cu(PPh_2Me)_3NO_3]$ [19]. Thus no unusual features are observed in these systems other than the slightly shorter bond length in the case of the nitrate ion. The predominantly bridging character of these anions is inhibited as they are encapsulated within the $[Cu_2(dppe)_3]^{2+}$ core.

It is interesting to note that there is a significant relationship between the bending of the anion at the coordinating atom and the dihedral angle of the bridging dppe. The Cu–CN bond is almost linear with the angle of 174.3°, where as the angle of Cu–N–C in the case of thiocyanate, and Cu–O–N bond of the nitrate are 167° and 121.7°, respectively. Similarly, the torsion angles about C–C in chelating dppe is almost similar in these three cases (CN^- 55°, SCN^- 56°, NO_3^- 57°), but the torsion angles of Cu–P–C–C (bridging dppe) vary significantly for the anions CN^- (56.3°), SCN^- (54.9°), and NO_3^- (64.8°). The relevance of these differences to the steric requirements of the anion will be evaluated later after discussing the solution state behavior.

2.3. Spectroscopic characterization

2.3.1. IR spectroscopy

In the solid state, the IR spectra of all these complexes show characteristic bands for the host framework and the guest anions. The preferences of the host for different anions are reflected in the lability of the complexes in solution. A comparison of the solid state spectra with the solution IR spectra offers useful information in this regard. The stretching frequency $\nu_{(C\equiv N)}$ of the cyanide ion in complex **1** occurs at 2100 cm^{-1} in the solid state and at 2105 cm^{-1} in chloroform solution. Compared to the value of the ionic or uncomplexed cyanide [20] (which occurs at 2076 cm^{-1}), the complexed form shows an increase of 30 cm^{-1}. Similarly in complex **2**, the $\nu_{(C\equiv N)}$ mode of the thiocyanate group is very intense and offers information about the nature of anion binding. The thiocyanate group can bind to the metal through sulfur (M–SCN), or nitrogen (M–NCS), or bridge through N and S (M–NCS–M). The mode of coordination can be distinguished from the vibrational frequencies of the SCN group. Although the exact frequency is dependent on the metal center, its oxidation state, and the ancillary ligands [20], the S-bound or bridging thiocyanate groups exhibit $\nu_{(C\equiv N)}$ at higher frequencies than the N-bound thiocyanate [21]. In the structurally characterized complex **2**, the SCN group binds through nitrogen. As expected, in the solid state the value of $\nu_{(C\equiv N)}$ stretch in the present complex is observed at 2070 cm^{-1}. This is lower in energy in comparison with other Cu(I) phosphine complexes possessing a bridging SCN [17] group. This value is also higher than the stretching frequency of the uncomplexed SCN^- ion (which occurs at 2053 cm^{-1}). In chloroform solution, the same complex exhibits a band at 2080 cm^{-1} and free thiocyanate group is not detected (Fig. 2). Significant differences between **1**, **2** and **3** (vide infra) prompted us to examine

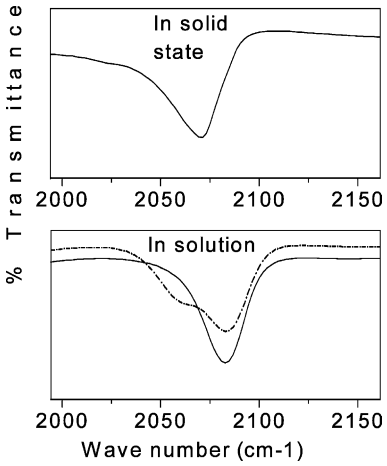

Fig. 2. The IR of complex **2** showing the $\nu_{(C\equiv N)}$ vibrations. The broken trace (in the bottom spectrum) indicates the effect of added dppe ligand. Other IR spectra are given in supporting information.

the analogous complex with azide $Cu_2(dppe)_3(N_3)_2$ (**4**). The IR spectrum of complex **4** indicates a characteristic band at 2033 cm^{-1} in the solid state indicative of the azide ion. In chloroform solution the band shifts to 2041 cm^{-1}. As in the case of the thiocyanate complex, no band corresponding to the presence of free azide anion could be seen.

The behavior of complex **3** is distinctly different from that of complexes, **1**, **2**, and **4**. In the solid state, the nitrate group in complex **3** shows a band at 1287 cm^{-1} close to the value reported for a monodentate nitrate ion [20,21]. Other bands corresponding to this ion could not be observed as they are obscured by bands of the phosphine ligand in the same region. In chloroform solution, however, the nitrate ion remains uncoordinated. In solution, a stretching frequency of 1378 cm^{-1} is observed for this complex very close to that of free nitrate ions. This dissociation in solution is quite surprising since the nitrate–Cu bond should be quite strong if the short Cu–O bond, shorter than other comparable complexes, is any indication of bond strength.

The ability of the host $[Cu_2(dppe)_3]^{2+}$ to retain the anion in its cavity is reflected by its reaction with dppe. This was probed using IR spectroscopy. Excess dppe (2.2 equiv.) was added to a chloroform solution of the respective complex and the solution IR spectrum was recorded. In the case of complex **1** the C≡N stretch remains unaffected and no band corresponding to ionic CN^- ion was observed. In contrast, solutions of **2** and **4** indicate observable dissociation to give the free anion when excess dppe is added. The C≡N stretch of free thiocyanate (Fig. 2), and N≡N stretch of the free azide ions are observed in addition to those of the complexed species. Since the nitrate is uncomplexed in solution in the absence of added dppe, one expects no change on addition of dppe. Indeed this is exactly what is observed.

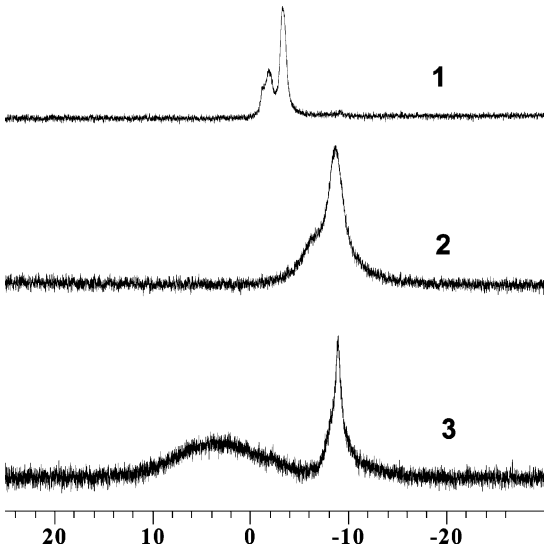

Fig. 3. ^{31}P NMR of complexes: (1) **1**; (2) **2**; and (3) **3** in $CDCl_3$ at 293 K. Other NMR spectra are given in Section 6.

2.4. ^{31}P NMR spectroscopy

The compounds prepared in this study differ only in their counterions and so one would not have expected the ^{31}P NMR of these complexes to be very different. The solution ^{31}P NMR of complex **3** (with NO_3^-), in $CDCl_3$ at room temperature consists of two sets of peaks; a broad resonance at 5.0 ppm and a relatively sharp peak at −9.6 ppm (Fig. 3(3)). At 223 K the broad peak becomes narrower and the peak at −9.6 ppm splits further. The observation of a temperature dependent broad peak is consistent with the presence of a bis chelated intermediate ($[Cu(dppe)_2]^+$) which has been previously observed in the family of $Cu_2(dppe)_3X_2$ complexes, as well as in some other Cu(I) dppe complexes [13a,13f,14].

However, the room temperature ^{31}P NMR of compound **1** in $CDCl_3$ consists of two broad signals at −1.5 and −3.5 ppm (Fig. 3(1)). Surprisingly, there is no peak between 0 and 10 ppm, indicating the absence of the bis chelated form. On lowering the temperature to 223 K, the intensity of the peak at −1.5 ppm increases at the expense of the other peak at −3.5 ppm. Addition of excess dppe (2.5 equiv.) at room temperature results in a new set of peaks with a major peak at −3.4 ppm and a smaller peak at −0.5 ppm. Interestingly, the intensity changes are reversed when the sample is cooled to 223 K and only the peak at −0.5 ppm is observed. The free dppe signal at 223 K undergoes an upfield shift similar to what was observed for dpph by Kitagawa et al. [10].

The room temperature ^{31}P NMR in $CDCl_3$ of thiocyanate (Fig. 3(2)), and azide compounds show two broad signals merged together in each case, at −9.0 and −6.5 ppm for the thiocyanate complex and −9.0, −5.7 ppm for the azide complex. Lowering the

temperature to 223 K does not produce any new peaks in both cases and only increases the separation between the peaks present. The addition of excess dppe (2.5 equiv.) changes the solution equilibrium as indicated by new broad signals, which are barely distinguishable from the base line at room temperature. While at room temperature these new signals appear at −6 ppm for thiocyanate and at −2 ppm for the azide complex, lowering the temperature to 223 K shifts these broad signals downfield with well-defined peak positions. At the low temperature limit, with excess dppe, the SCN complex shows a clear peak at 6.6 ppm and the azide complex at 7.5 ppm indicative of the formation of the bis chelated complex in rapid equilibrium with the non-chelated form.

2.5. ^1H NMR spectroscopy

All the compounds prepared in this study indicate temperature dependent chemical shifts in the ^1H NMR spectra. The room temperature NMR spectrum of complex **1** indicates two broad resonances at 2.3 and 2.0 ppm for methylene protons. A broad multiplet is observed for aromatic protons in the range 6.6–7.8 ppm. Upon lowering the temperature, the methylene signals start splitting, and at 223 K two clear signals are obtained centered at 2.0 and 1.8 ppm. Likewise, the aromatic protons also exhibit temperature dependence, and at 223 K they show a complex multiplet in the range 6.4–8.0 ppm.

Complexes **2** and **4** show nearly identical temperature dependence and differ slightly from complex **1**. At room temperature, the methylene protons show two broad peaks, 2.2 and 2.1 ppm for the thiocyanate complex and for the azide complex they are 2.3 and 2.1 ppm. Gradual lowering of the temperature splits the methylene resonances into three clear signals at the low temperature limit (2.2, 2.0, and 1.8 ppm for thiocyanate complex and for azide complex they are 2.2, 2.1, and 1.9 ppm). Similarly, the aromatic signals observed in the range 7.3–6.8 for both complexes **2** and **4** undergo further splitting at 223 K in the range 7.7–6.6 ppm. Although complex **3** shows changes with temperature, the changes are distinctly different. Both methylene (2.4, 2.1 ppm) and aromatic protons (7.3–7.1 ppm) do not show fine structure but do show slight changes in their chemical shift on lowering the temperature.

3. Discussion

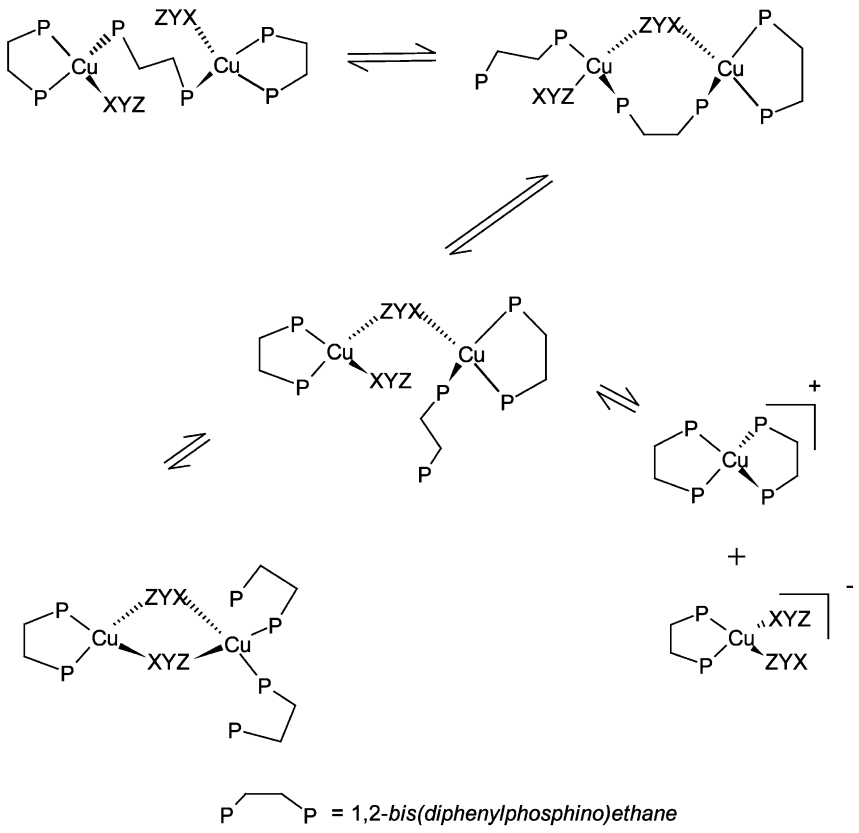
3.1. Solution behavior

The solution behavior of complexes **1**, **2**, and **4** are significantly different from **3** and those studied earlier with counterions, Cl^-, ClO_4^-, or I^-. The elegant work of Sadler and coworkers [13f] has shown that a bis chelated form $[Cu(dppe)_2]^+$ is the major species with a ^{31}P resonance at 10.0 ppm when Cl^- is the counter anion. In the presence of excess dppe the intensity of this peak increased. The temperature dependent ^1H NMR studies were also consistent with the observation of dissociative equilibria with the 2.42 ppm peak assignable to $[Cu(dppe)_2]^+$, present over the entire range of temperature and more predominant at lower temperatures. A similar temperature dependent behavior has been observed in two other complexes. In solutions of $[Cu_2(dppe)_3(CH_3CN)_2]^{2+}$, Vijayashree et al. [14] have noted a similar equilibrium. More recently, Comba et al. [13a] have studied the iodo complex $Cu_2(dppe)_3I_2$ in solution and reached the same conclusion. The observed low temperature ^{31}P NMR signals of the reported complexes and those of the present study are collected in Table 2.

Based on the ^{31}P, ^1H NMR and IR spectra, the three complexes **1**, **2** and **4** appear to be unique in not forming the bis chelated complex of Cu(I) at any temperature. Further, complex **1** is different from **2** and **4**. Even the deliberate addition of excess dppe aimed to produce $[Cu(dppe)_2]CN$ species (in analogy with the chloride complex), was not successful. These results suggest that the binding of the cyanide group to the metal is quite strong and the anion is retained in the cavity even in the presence of excess dppe. The formation of a species with an ionic cyanide such as $[Cu(dppe)_2]CN$ is not favored. The solution behavior can thus be described by a fluxional processes involving breaking and closing of the chelate ring and retention of the bridging coordination in the ^{31}P NMR time scale. Chelation is normally a stable coordination mode for five member rings, but the angle subtended at the metal center (90°), is much smaller than what is required for an ideal tetrahedron. This would cause bond weakening in this family of complexes. Since there are two chelate rings, solution equilibrium will naturally involve a number of species. As a result of rapid equilibrium, only two sets of phosphorous resonances are observed. A signal at −3.5 ppm could be assigned to the P atoms of bridging dppe. The other peak at −1.5 ppm could be assigned to the P atoms present in the partially broken chelating ligand that undergoes exchange with the coordinated arm. The broad nature of this signal is probably due to many magnetically inequivalent P atoms in equilibrium. On decreasing the temperature, a slowing down of the exchange process leads to reduced line broadening and increased intensity of the signals. The tenacious nature of CN^- is revealed by the absence of $[Cu(dppe)_2]^+$ even at the low temperature limit.

Likewise, the ^{31}P NMR of complexes **2** and **4** do not indicate the presence of the $[Cu(dppe)_2]^+$cation in significant concentrations. The IR spectra are also very clear that the free anions are not involved in

Table 2
Summary of low temperature ^{31}P NMR data for copper dppe complexes



Complex	T (K)	$[Cu(dppe)_2]^{2+}$ form (ppm)	Various forms of monodentate dppe (ppm)				References
$Cu(dppe)_2BF_4$ in CD_2Cl_2	198	+7.5					[13a]

3 in $CDCl_3$	223	+5.0				−9.0, −9.7	this work

significant concentrations as in the case of complex **1**. But in the presence of added dppe there are differences in the IR spectrum and the ^{31}P NMR pattern. This suggests a different kind of solution processes from what is observed for **1**. The solution ^{31}P NMR indicates a very broad singlet in both cases (a major difference from the cyano complex), at room temperature. These anions are long enough for bridging the metal centers. This might result in a breaking of the bridging/chelated dppe. Rapid equilibration through the intermediacy of anion bridged structures in solution could result in a single broad peak. In other words, the dissociation in the case of the thiocyanate and azide complexes could be promoted by the extra bridging ability of the anion. First the anion attacks the metal center resulting in a partially bonded chelated/bridging dppe unit. These processes lead to the formation of a weakly bound intermediate (S bound SCN complex for example), which dissociates to give $[Cu(dppe)_2]^+$. As a result, in the presence of excess dppe, the equilibrium is shifted towards the bis chelated complex. In this series, the nitrate complex **3** alone, behaves similar to the chloride complex. The anion is not held firmly in the cavity or coordinated to the copper in solution. However, in the solid state, there is no difference between the three complexes. Given the choice between ambidentate anions and dppe, the latter is preferred for bridging the metal centers.

These results including the ^1H NMR spectra are best understood on the basis of varying degree of lability exhibited by these anions. They point out that the cyanide complex **1** represents one extreme where the anion remains completely coordinated to the copper. Even in the presence of excess dppe, there is no hint of formation of the bis chelated complex. The nitrate complex **3** is the other extreme, typical of most complexes in this series. Complexes **2** and **4** are intermediate cases and represent unique examples where additional anion bridged structures exist. The formation of $[Cu(dppe)_2]^+$ species only in the presence of added dppe indicates that the SCN^- or N_3^- is less labile than the complexes studied earlier but more labile compared to the cyanide. The predominance of the bis chelated form at low temperatures is similar to what is observed in the chloride complex and is a reflection of the thermodynamic stability of this form. The solution equilibrium unique to **2** and **4** is shown in Scheme 1.

On the basis of these results it is clear that the solid state structure is not retained in solution in these complexes except in the case of the cyanide. The cyanide remains coordinated to the copper while most anions are labile. The π accepting and soft nature of the cyanide favors an inert complex. However, if these were the only factors, one is hard put to explain the structure of the nitrate and thiocyanate complexes. Binding with the nitrate anion appears to be quite strong judging from the distance between Cu and O, a hard donor. The ambidentate SCN anion prefers to have nitrogen coordination rather than sulfur, despite Cu(I) being soft and thiophillic [22]. However, all these results are consisent with the tendency of Cu(I) to balance the number of soft donors and hard donors in its coordination sphere [23]. This tendency, along with favorable short contacts (vide infra) with anions might be responsible for the coordination of hard donors like N and O to Cu in the solid state. The $Cu–ONO_2$ bond in complex **3** is expected to be strong (on the basis of solid state results), it succumbs to competition from the soft centers in solution and is not coordinated to Cu(I) in their presence leading to the formation of $Cu(dppe)_2^+$.

What makes the $[Cu_2(dppe)_3]^{2+}$ core capable of accepting large anions? The steric demands of aryl phosphines and their relationship to the stability of their metal complexes are quite well known. Usually the cone angles of phosphines are the best criteria to assess the steric demands of phosphines. The cone angles of PPh_2Me, and PPh_3 are 136°, and 145°, respectively. Since the dppe ligand is structurally very similar to PPh_2Me (differs only in the methyl group) one would have expected a similar cone angle at the P center. However, covalent tying of methylene units results in significant reduction of cone angle and the cone angle of dppe has been estimated to be 125° [11]. This significant

Scheme 1. Equilibria unique to complexes **2** and **4**.

reduction of steric demand around phosphorus atoms upon chelation to the metal offers sufficient space for a fourth coordination site involving rather bulky ligands.

3.2. Analysis of the solid state structures

We now discuss why this framework is flexible making it an universal host for anions. Using the programs PREQUEST and VISTA available in CSD [24] we have analyzed the bond distances, angles and torsion angles associated with this framework in the present and reported structures. It is clear that the torsion angles about the C–C bond (t_1) (see Fig. 4) of the chelating dppe are not very different for different anions. This is in accord with the theoretical studies on five member chelates. It was shown that the energy of the chelate critically depends on the torsion angles about the C–C bond rather than any other conformational change within the chelate ring [25]. Accordingly, the torsion angles t_1 are found to be invariant in all the structures of the $Cu_2(dppe)_3$ series.

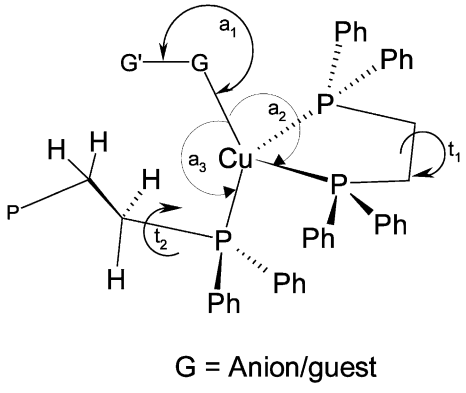

Fig. 4. The flexible torsion and bond angles of the host frame work.

The conformation associated with the bridging dppe varies significantly. The torsion angles associated with the bridging dppe (involving small anions) are listed in Table 3. Gaughan et al. have found the torsion angle (t_2) of the bridging dppe (Cu–P–C–C) as a key parameter for describing the overall conformation of the molecule [13i]. An increase in t_2 (rotation about the P–C bond) is expected to minimize intramolecular bumping. In the case of small anions, an increase is observed in the torsion angles of the bridging dppe (Cu–P–C–C) on increasing the size requirements of the anion. It is interesting to note that the changes in this torsion angle correlates with the coordination angle a_1 rather than the size indicated by the thermochemical radii. If one considers the solid angle swept away by the anion rather than the volume occupied by the anion, the coordination angle at the metal is a critical factor. The solid angle

Table 3
Steric and conformational parameters in $[Cu_2(dppe)_3X_2]$ complexes

Anions X	Thermochemical radius (pm)	Torsion angle (°) t_2 (Cu–P–C–C_{br})	a_1 (°)	a_3 (°)	a_2 (°)
NO_3^-	165	64.8	121.7	109.86	116.25
Cl^-	167	51.3		102.23	115.65
CN^-	177	56.3	174.3	107.05	111.43
N_3^-	181	61.9	134.4	99.87	117.48
SCN^-	199	54.9	161.7	108.78	111.45
I^-	206	61.2		109.80	113.9

spanned by a bent anion is more. Hence the steric requirement of the anions are dictated by the coordination angles rather than the thermochemical radii. In addition to this, the angles a_2 and a_3, which involve the anion and the host frame work, show an inverse correlation.

The steric demands of bulkier anions are more difficult to interpret since a major portion of the anion is outside the cavity formed by dppe ligands. Unlike small anions, factors other than the coordination angles influence the bridging dppe angles. This is understandable as there are aromatic rings in these anions which are capable of interacting with the aromatic rings of dppe. The deviation of the torsion angles in the case of bulkier guests were attributed by Gaughan et al. to several non-bonded interactions [13i].

Further modulation of cavity size can be achieved by changing the spatial arrangement of the six phenyl rings surrounding each metal center. Four hydrogens on these phenyl rings roughly demarcate the cavity size. Some of the aromatic hydrogen atoms are found to interact with the anion through C–H π interactions. A list of short contacts with explanatory figures is given in the supporting material. These short contacts were also noticed by Albano et al. in the case of $Cu_2(dppe)_3Cl_2$ [13h]. It is the N and/or O atom of the anions that exhibit weak interactions with the aromatic hydrogen atoms. Thus the short contacts observed in the case of the thiocyanate are between the N of SCN^- and the aromatic hydrogen atoms. The bent coordination geometry of the thiocyanate localizes the charge on the more electronegative nitrogen end of the ligand resulting in a lone pair being available for short contacts. It also causes a deviation from the correlation between the coordination angle with the torsion angle t_2 in the solid state.

4. Conclusion

In the present study, direct reactions between dppe and Cu(I) salts with different bidentate anions have been explored. The resulting complexes have very similar solid state structures and conform to the structural motif that has been characterized for this stoichiometry. The variation in the size of the cavity produced by the three PPh_2 units coordinated to the Cu^+ to accommodate anions is a result of several factors. The flexibility associated with the rotation of phenyl rings, the torsion angles associated with the bridging dppe and the possibility of different coordination angles around Cu(I) lead to a fairly flexible host for anions. The bond distances around copper and the metrical parameters associated with the chelating dppe remain constant. The IR, and NMR spectra of these compounds in solution suggest a complex solution behavior very much dependant on the anion. A new process involving a bridging anion rather than one bridged through dppe is suggested to explain the behavior of azide and thiocyanate complexes. A bis chelated dppe complex is observed only in the presence of added dppe in these systems. However, the cyanide ion is distinctly different and is the only one, which is kinetically inert. The $[Cu_2(dppe)_3]^{2+}$ core is indeed unique in accommodating a variety of anions of different shapes and sizes making it an ideal universal host for anions.

5. Experimental

5.1. General remarks

Dichloromethane, petroleum ether (b.p. 60°–80°), and MeCN were purified and dried by conventional methods. They were distilled under N_2 and deoxygenated before use. All manipulations were carried out under an atmosphere of purified N_2 Standard Schlenk techniques were used. CuCN was obtained locally and CuSCN, was freshly prepared before use [27]. Cupric nitrate was obtained from Ranbaxy, India. The complex $Cu_2(dppe)_3(N_3)_2$ (**4**) was synthesized using the reported procedure [13j]. ^1H NMR spectra were recorded on a Bruker ACF 200 MHz or on a Bruker AMX 400 MHz spectrometer with TMS as the internal reference. $^{31}P\{^1H\}$ NMR spectra were recorded on a Bruker AMX 400 MHz spectrometer operating at 162 MHz. IR spectra were recorded either in solid state as KBr pellets or as $CHCl_3$ solution on a Bruker spectrometer.

Table 4
Summary of crystallographic information for compounds **1**–**3**

5.2. Syntheses of complexes

5.2.1. $Cu_2(dppe)_3(CN)_2$ (**1**)

To a slurry of CuCN (0.02 g, 0.2 mmol) in CH_2Cl_2 (10 ml), 1.5 equiv. of dppe (0.133 g) was added and stirred for 1 h. After complete dissolution of CuCN, the solvent was removed under vacuum. The residue was then washed with Et_2O and dried in vacuum to give complex **1** in quantitative yield. *Anal*. Calc. for $[Cu_2(C_{26}H_{24}P_2)_3(CN)_2]\cdot CH_2Cl_2$: C, 66.66; H, 5.07; N, 1.92. Found: C, 66.91; H, 5.19; N, 2.11%. Suitable crystals for X-ray diffraction were grown from CH_2Cl_2 on layering with petroleum ether.

5.2.2. $Cu_2(dppe)_3(SCN)_2$ (**2**)

A similar procedure was adopted with 0.03 g of CuSCN and 0.15 g (1.5 equiv.) of dppe and the yields were quantitative. *Anal*. Calc. for $[Cu_2(C_{26}H_{24}P_2)_3(SCN)_2]\cdot 0.5CH_2Cl_2$: C, 65.29; H 4.93; N, 1.89. Found: C, 64.81; H, 4.95; N, 1.91%. Suitable crystals for X-ray diffraction were grown from CH_2Cl_2 on layering with petroleum ether.

5.2.3. $Cu_2(dppe)_3(NO_3)_2$ (**3**)

To a solution of $Cu(NO_3)_2$ (0.03 g) in distilled MeCN (15 ml), few strips of Cu foil were added and stirred. After complete reduction of $Cu(NO_3)_2$ (as indicated by the disappearance of blue color), 0.15 g of dppe was added to the same solution and stirred for 20 min. After filtration, the solvent was removed under vacuum. The white residue was washed with ether, and dried in vacuum to get **3** in quantitative yield. *Anal*. Calc. for $[Cu_2(C_{26}H_{24}P_2)_3(NO_3)_2]\cdot 0.5CH_2Cl_2$: C, 63.32; H, 4.90; N, 1.88. Found: C, 63.70; H, 4.95; N, 1.95%. Suitable crystals for X-ray diffraction studies were grown from CH_2Cl_2 on layering with petroleum ether.

5.3. X-ray crystallographic study

Crystals were mounted along the largest dimension and used for data collection. The intensity data were collected on a Siemens P4 single crystal diffractometer equipped with Mo source ($\lambda = 0.71073$ Å) and highly oriented graphite monochromator. The lattice parameters and standard deviations were obtained by least-squares fit to 40 reflections. The data were collected by $2\theta-\theta$ scan mode with a variable scan speed ranging from 2.0° to a maximum of 60.0° min^{-1}. Three reflections were used to monitor the stability and orientation of the crystal and were re-measured after every 97 reflections. Their intensities did not change significantly during the data collection. The data were corrected for LP factors and an empirical absorption correction based on ψ scan method was also applied.

The structure was solved by direct methods using SHELX-97 package [28] and also refined using the same. All the non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included in the ideal positions with fixed isotropic U values and were riding with their respective non-hydrogen atoms. The hydro-

gen atoms of the water molecule were located from the difference Fourier and included as such in the refinement and were riding with water oxygen. A summary of the details of structure determination is given in Table 4.

6. Supplementary material

Crystallographic data for the crystal structures have been deposited with the Cambridge Crystallographic Data Centre, CCDC NOS. 183692–183694 for compounds **1**, **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: (internet) +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk/conts/retrieving.html).

Acknowledgements

We wish to thank CSIR, New Delhi for financial assistance and the Chairman, Bioinformatics Center, and Sophisticated Instrumentation Facility, Indian Institute of Science, Bangalore, India for the data from CSD and the NMR spectrometer, respectively.

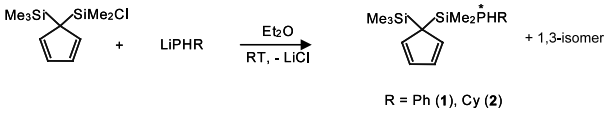
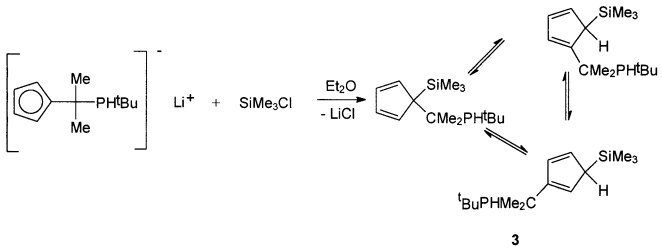
C_6H_2) [13] have been structurally characterised. Such compounds should be useful precursors for dianionic bifunctional ligands in transition metal chemistry. In addition, the presence of a P-containing group is advantageous for reactivity studies by ^{31}P NMR spectroscopy.



We have previously reported the synthesis of the PH-functionalised ferrocene derivatives *rac*-[Fe{(η^5-C_5H_4)CMe_2PHR}$_2$] (R = Ph, Mes) [14] and the metallocene derivatives [{(η^5-C_5H_4)CMe_2PHR}$_2ZrCl_2$] and [{(η^5-C_5H_4)CMe_2PHR}$_2$TiCl] (R = Ph, ^{t}Bu). The latter slowly decompose on recrystallisation from THF, Et_2O or toluene with formation of [{(η^5-C_5H_4)$_2CMe_2$}MCl_2] (M = Zr, Ti) and $(PR)_n$ (R = Ph, n = 4–6; R = ^{t}Bu, n = 4) and PH_2R [15].

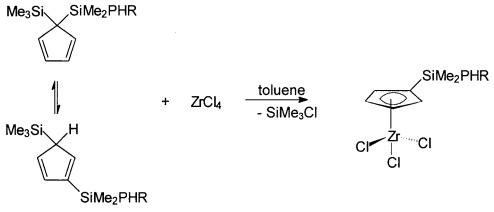
We now report the synthesis of the first stable monosubstituted PH-functionalised phosphanylalkyl- and phosphanylsilylcyclopentadienyl complexes of Group 4 metals, namely, [{(η^5-C_5H_4)$SiMe_2PHR$}$ZrCl_3$] [R = Ph (**4**), Cy (**5**)] and [{(η^5-C_5H_4)CMe_2PH^tBu}MCl_3] [M = Ti (**6**), Zr (**7**)] and their activity in the polymerisation of ethene and propene. Recently, Erker et al. reported the synthesis and catalytic properties in the polymerisation of olefins of the constrained-geometry catalysts [{(η^5-C_5H_4)CMe_2PCy}$M(NR_2)_2$] (M = Ti, R = Me; M = Zr, R = Et) [16]. Hou et al. reported the synthesis of [{(η^5-C_5Me_4)$SiMe_2PMes^*$}$Ln(L)_n$] (Ln = Sm: L = THF, n = 1 or 3; L = $MeOCH_2CH_2OMe$, n = 2; L = $PO(NMe_2)_3$, n = 2; Ln = Yb, L = THF, n = 3) and the polymerisation of ethene, ε-caprolactone and 1,3-butadiene with the Sm^{II}–mono-THF complex [13].



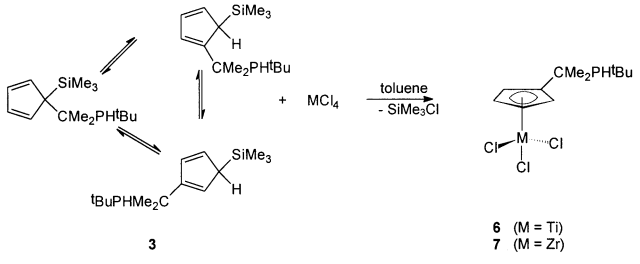
2. Results and discussion

2.1. Synthesis

The general synthetic method for the preparation of a monocyclopentadienyl metal trichloride complex of Group 4 metals is the elimination of $SiMe_3Cl$ [17]. Occasionally, this method can also be employed for the synthesis of metallocene derivatives. We therefore prepared the silylated phosphanylsilyl- and phosphanylalkylcyclopentadienes 1- and 3-$SiMe_3$–1-$SiMe_2PHRC_5H_4$ [R = Ph (**1**), Cy (**2**)] and 1-, 2- and 3-CMe_2PH^tBu–1-$SiMe_3C_5H_4$ (**3**) from LiPHR and 1-$SiMe_3$–1-$SiMe_2ClC_5H_4$ [18] (Eq. (1)) and Li[1-$PH^tBuCMe_2C_5H_4$] and $SiMe_3Cl$ (Eq. (2)), respectively.



(1)



(2)

Work-up yielded **1**–**3** as colourless (**1**, **2**) or yellow (**3**) oil. The different constitutional isomers could not be separated by distillation [19]. Compounds **1**–**3** were characterised by NMR (^1H, ^{31}P) and IR spectroscopy and mass spectrometry. In the MS, molecular-ion peaks were observed, and the peak of 100% intensity was due to $m/z = M^+ - PHR$ (R = Ph, Cy, ^{t}Bu).

Compounds **1** and **2** react with $ZrCl_4$ in toluene to give [{(η^5-C_5H_4)$SiMe_2PHR$}$ZrCl_3$] [R = Ph (**4**), Cy (**5**); Eq. (3)], and **3** reacts with MCl_4 with formation of [{(η^5-C_5H_4)CMe_2PH^tBu}MCl_3] [M = Ti (**6**), Zr (**7**); Eq. (4)]. As $SiMe_3Cl$ is eliminated, the mixture of constitutional isomers (see Eqs. (1) and (2)) can be employed in these reactions. Compounds **4**–**7** can be recrystallised from dichloromethane or THF; the complexes are almost insoluble in non-coordinating and non-polar solvents, and this indicates association in the solid state (presumably by chloro bridges, cf. [{(η^5-C_5H_4)$_2CH_2CH_2PPh_2$}$ZrCl_3$] [20]) and adduct formation in THF (cf. [{(η^5-C_5Me_4)$_2CH_2CH_2PPh_2$}$ZrCl_3$(THF)] [21]). Compounds **4**–**7** are obtained as yellow (**4**), white (**5**, **6**) or red (**7**) microcrystalline powders in good to moderate yields (45–80%). Compounds **4** and **5** are only moderately air sensitive, while **6** and **7** are more so, and all complexes decompose with formation of phosphine

(3)

(4)

(PH_2R).

Compounds **4**–**7** were characterised by NMR (^1H, ^{13}C, ^{31}P) and IR spectroscopy and mass spectrometry. Compounds **4**, **5** and **7** [**4**: −117.1 ($^1J_{P-H} = 200.9$ Hz); **5**: −121.6 ($^1J_{P-H} = 201.0$ Hz); **7**: 36.7 ppm ($^1J_{P-H} = 213.4$ Hz)] exhibit a doublet in the ^{31}P NMR spectrum (in [D_8]THF), which is shifted to low field by approximately 1–12 ppm relative to the starting materials **1**–**3** [**1**: −121.6 ($^1J_{P-H} = 201.0$ Hz) and −122.3 ppm ($^1J_{P-H} = 204.1$ Hz); **2**: −124.9 ($^1J_{P-H} = 191.2$ Hz) and −127.6 ppm ($^1J_{P-H} = 189.5$ Hz); **3**: 25.2 (d of dec, $^1J_{P-H} = 196.7$ Hz, $^3J_{P-H} = 12.1$ Hz), 19.2 (d, $^1J_{P-H} = 198.4$ Hz) and 13.1 ppm (d of dec, $^1J_{P-H} = 199.5$ Hz, $^3J_{P-H} = 12.2$ Hz)]. This indicates that there is no interaction between the phosphanyl group and the transition metal. In contrast, **6** [−6.8 ppm ($^1J_{P-H} = 282.5$ Hz)] exhibits a doublet in the ^{31}P NMR spectrum (in [D_8]THF) which is shifted to high field relative to the starting material **3**, and the coupling constant increased by approximately 85 Hz.

For **4**–**7**, only peaks for the monomeric complexes were observed in the mass spectra. While the formation of monomeric molecules is rather unlikely, this suggests that readily cleavable dimers are probably present rather than oligomers.

3. Polymerisation studies

The complexes **4**–**7** were studied in the catalytic polymerisation of ethene, propene and styrene with activation by MAO (1000-fold excess, in toluene) as cocatalyst. No reaction was observed with styrene, which was rather unexpected as related side-chain-functionalised monocyclopentadienyl complexes of Ti exhibit good catalytic properties [22]. Presumably, complexes **4**–**7** are destroyed by MAO (attack at the P–Si or P–C bond with concomitant decomposition of the complexes) at the elevated temperatures employed (60 °C). However, ethene and propene are readily polymerised with formation of high-density polyethylene and polypropylene (Table 1); the elastomeric properties of the latter indicate a P–M interaction during the polymerisation process. Similar behaviour was already observed for related constrained-geometry catalysts with *N*-functionalised side-chains [6e].

Table 1
Activity of **4**–**7** in the polymerisation of propene

Complex	Ratio MAO:cat.	Activity for polypropylene (g mol^{-1} h^{-1})
4	300	0.86×10^3
5	300	2.61×10^3
6	300	0.84×10^3
7	300	8.20×10^3

The activities of complexes **4** and **7** are slightly higher than those of the constrained-geometry complexes and on the same order of magnitude as those of the Cp/phosphanido Group 4 complexes [14]. Regarding propene, the activity attained by complexes **4**–**7** is far lower than that observed with metallocene complexes [2,6e].

4. Experimental

All experiments were carried out under purified dry Ar. Solvents were dried and freshly distilled under Ar. The NMR spectra were recorded at 25 °C in C_6D_6 or [D_8]THF with an AVANCE DRX 400 spectrometer (Bruker): ^1H NMR: internal standard solvent (C_6H_6 or THF), external standard $SiMe_4$; ^{13}C NMR: external standard $SiMe_4$, internal standard solvent; ^{31}P NMR: external standard 85% H_3PO_4. The IR spectra were recorded on a Perkin–Elmer System 2000 FT-IR spectrometer in the range 350–4000 cm^{-1}. The mass spectra were recorded with an MAT-212 (Finnigan), EI MS, 70 eV. The m.p. were determined in sealed capillaries under Ar and are uncorrected.

LiPHPh [23], LiPHCy [24], Li[1-PH^{t}BuCMe$_2$C$_5$H$_4$] [15], and 1-SiMe$_3$–1-SiMe$_2$ClC$_5$H$_4$ [18] were prepared according to literature procedures.

4.1. 1- and 3-SiMe$_3$–1-SiMe$_2$PHPhC$_5$H$_4$ (1)

LiPHPh (4.10 g, 35 mmol) was suspended in *n*-C_6H_{14} (150 ml) and cooled to −20 °C. Then 1-SiMe$_3$–1-SiMe$_2$ClC$_5$H$_4$ (8.10 g, 35 mmol) was added, and the reaction mixture warmed to ambient temperature. The mixture was stirred for 1 day, filtered, the solvent evaporated in vacuo and the resulting yellow oil distilled under reduced pressure (65–75 °C, 2×10^{-2} Torr) to give 6.5 g (61%) of **1** as a colourless oil.

^1H NMR (C_6D_6): $\delta = -0.05$ (s, 18H, C*H*$_3$ in SiMe$_3$, 2 isomers), 0.01 (d, 6H, C*H*$_3$ in SiMe$_2$, $^3J_{P-H} = 2.4$, 2 isomers), 0.02 (d, 6H, C*H*$_3$ in SiMe$_2$, $^3J_{P-H} = 2.8$ Hz, 2 isomers), 3.10 (br s, 1H, C*H* in C_5H_4, 1 isomer), 3.20 (d, 2H, P*H*, $^1J_{P-H} = 192.6$ Hz, 2 isomers), 6.44 (m, 2H, C*H* in C_5H_4, 2 isomers), 6.48 (m, 1H, C*H* in C_5H_4, 1 isomer), 6.75 (m, 4H, C*H* in C_5H_4, 2 isomers), 7.01 (m, 6H, *o*- and *p*-C*H* in Ph, 2 isomers), 7.26 (t, 4H, *m*-C*H* in Ph, $^3J_{H-H} = 5.4$ Hz, 2 isomers).—^{31}P NMR (C_6D_6): $\delta = -121.6$, d, $^1J_{P-H} = 201$ Hz; −122.3, d, $^1J_{P-H} = 204$ Hz.—EI MS: *m*/*z* 304 (45%, [M^+]), 195 (100%, [M^+ − PHPh]), 73 (65%, $SiMe_3$), and fragmentation products thereof.—IR (KBr): $\tilde{\nu}$ (cm^{-1}): 2352 st (νPH), 1622 m, 1484 m (νC=C).—*Anal*. Calc. for $C_{16}H_{25}PSi_2$ (304.51): C 63.1, H 8.3, P 10.2; Found: C 56.8 (due to silicon carbide formation), H 8.1, P 9.3%.

4.2. 1- and 3-$SiMe_3$–1-$SiMe_2PHCy$–C_5H_4 (**2**)

LiPHCy (3.80 g, 31 mmol) was suspended in n-C_6H_{14} (150 ml) and cooled to −50 °C. Then 1-$SiMe_3$–1-$SiMe_2ClC_5H_4$ (8.00 g, 34 mmol) was added, and the reaction mixture warmed to ambient temperature. The mixture was stirred for 1 day, filtered, the solvent evaporated in vacuo and the resulting yellow oil distilled under reduced pressure (50–55 °C, 1×10^{-2} Torr) to give 4.1 g (43%) of **2** as a colourless oil.

^{1}H NMR (C_6D_6): $\delta = -0.01$ (s, 18H, CH_3 in $SiMe_3$, 2 isomers), 0.03 (d, 6H, CH_3 in $SiMe_2$, $^3J_{P-H} = 3.0$ Hz, 2 isomers), 0.04 (d, 6H, CH_3 in $SiMe_2$, $^3J_{P-H} = 3.3$ Hz, 2 isomers), 1.2–2.1 (m, 22H, Cy, 2 isomers), 2.60 (d of d, 2H, PH, $^1J_{P-H} = 191.0$, $^3J_{P-H} = 6.4$ Hz, 2 isomers), 2.91 (br s, 1H, CH in C_5H_4, 1 isomer), 6.50 (m, 3H, CH in C_5H_4, 2 isomers), 6.62 (m, 4H, CH in C_5H_4, 2 isomers).—^{31}P NMR (C_6D_6): $\delta = -124.9$, d, $^1J_{P-H} =$ 191.2 Hz; −127.6, d, $^1J_{P-H} = 189.5$ Hz.—EI MS: m/z 360 (27%, [M^+]), 209 (100%, [$M^+ -$PHCy]), 73 (100%, $SiMe_3$) and fragmentation products thereof.—IR (KBr): $\bar{\nu}$ (cm^{-1}): 2327 st (νPH), 1635 m, 1625 m (νC=C).—*Anal*. Calc. for $C_{20}H_{33}PSi_2$ (360.62): C 61.9, H 10.1, P 10.0; Found: C 56.9 (due to silicon carbide formation), H 9.5, P 8.9%.

4.3. 1-, 2- and 3-CMe_2PH^tBu–1-$SiMe_3C_5H_4$ (**3**)

Li[1-$PH^tBuCMe_2C_5H_4$] (1.00 g, 4.5 mmol) was dissolved in Et_2O (25 ml), $SiMe_3Cl$ (0.6 ml, 5 mmol) was added and the reaction mixture stirred for 12 h. LiCl was filtered off, the solvent evaporated in vacuo and the resulting yellow oil distilled under reduced pressure (55 °C, 3×10^{-3} Torr) to give 1.1 g (91%) of **3** as a yellow oil.

^{1}H NMR (C_6D_6): $\delta = -0.09$ (br s, 27H, CH_3 in $SiMe_3$, 3 isomers), 0.98 (d, 9H, CH_3 in ^{t}Bu, $^3J_{P-H} = 8.5$ Hz, 1 isomer), 1.07 (d, 9H, CH_3 in ^{t}Bu, $^3J_{P-H} = 8.7$ Hz, 1 isomer), 1.10 (d, 9H, CH_3 in ^{t}Bu, $^3J_{P-H} = 13.2$ Hz, 1 isomer), 1.34 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 16.6$ Hz, 1 isomer), 1.36 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 16.6$ Hz, 1 isomer), 1.43 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 13.6$ Hz, 1 isomer), 1.45 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 10.1$ Hz, 1 isomer), 1.48 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 12.3$ Hz, 1 isomer), 1.56 (d, 3H, CH_3 in CMe_2, $^3J_{P-H} = 7.6$ Hz, 1 isomer), 3.08 (br s, 2H, CH in C_5H_4, 2 isomers), 3.31 (d, 2H, PH, $^1J_{P-H} = 197.4$ Hz, 2 isomers), 3.49 (d, 1H, PH, $^1J_{P-H} = 199.5$ Hz, 1 isomer), 5.98 (s, 2H, CH in C_5H_4, 1 isomer), 6.05 (s, 1H, CH in C_5H_4, 1 isomer), 6.15 (s, 1H, CH in C_5H_4, 1 isomer), 6.36 (s, 2H, CH in C_5H_4, 1 isomer), 6.63 (s, 1H, CH in C_5H_4, 1 isomer), 6.65 (s, 1H, CH in C_5H_4, 1 isomer), 6.80 (s, 1H, CH in C_5H_4, 1 isomer), 6.81 (s, 1H, CH in C_5H_4, 1 isomer).—^{31}P NMR (C_6D_6): $\delta = 25.2$, d of dec, $^1J_{P-H} = 196.7$ Hz, $^3J_{P-H} = 12.1$ Hz; 19.2, d, $^1J_{P-H} = 198.4$ Hz; 13.1, d of dec, $^1J_{P-H} = 199.5$ Hz, $^3J_{P-H} = 12.2$ Hz.—EI MS: m/z 268 (25%, [M^+]), 179 (100%, [$M^+ -$PH^{t}Bu]), 73 (100%, $SiMe_3$), and fragmentation products thereof.—IR (KBr): $\bar{\nu}$ (cm^{-1}): 2345 m (νPH), 1625 m, 1503 m (νC=C).—*Anal*. Calc. for $C_{15}H_{29}PSi$ (268.45): C 67.1, H 10.9, P 11.5; Found: C 65.9, H 9.9, P 10.9%.

4.4. [{(η^5-C_5H_4)$SiMe_2PHPh$}$ZrCl_3$] (**4**)

$ZrCl_4$ (1.33 g, 5.7 mmol) was suspended in $C_6H_5CH_3$ (30 ml), and a solution of **1** (1.75 g, 5.8 mmol) in $C_6H_5CH_3$ (20 ml) was added dropwise. The reaction mixture was stirred for 1 day, then the solvent was evaporated in vacuo and the resulting residue washed with n-C_5H_{12} (30 ml) and extracted with THF to give 2.0 g (80%) of **4** as a yellow microcrystalline solid. M.p.: 150–155 °C. ^{1}H NMR ([D$_8$]THF): $\delta = 0.54$ (d, 3H, CH_3 in $SiMe_2$, $^3J_{P-H} = 4.9$ Hz), 0.55 (d, 3H, CH_3 in $SiMe_2$, $^3J_{P-H} = 3.9$ Hz), 2.62 (d, 1H, PH, $^1J_{P-H} = 200.9$ Hz), 6.52 (m, 1H, CH in C_5H_4), 6.55 (m, 1H, CH in C_5H_4), 6.58 (m, 1H, CH in C_5H_4), 6.61 (m, 1H, CH in C_5H_4), 7.10 (m, 3H, CH in Ph), 7.11 (m, 2H, CH in Ph).—^{13}C NMR ([D$_8$]THF): $\delta = -1.09$ (d, 1C, CH_3Si, $^2J_{P-C} = 2.9$ Hz), −1.00 (d, 1C, CH_3Si, $^2J_{P-C} = 5.5$), 119.34 (s, 2C, C in C_5H_4), 121.95 (d, 2C, C in C_5H_4, $^3J_{P-C} = 6.2$ Hz), 126.32 (d, 1C, *ipso*-C in Ph, $^1J_{P-C} =$ 22.0 Hz), 126.70 (d, 1C, C1 in C_5H_4, $^2J_{P-C} = 12.8$ Hz), 127.00 (s, 1C, *p*-C in Ph), 128.66 (d, 2C, *m*-C in Ph, $^3J_{P-C} = 5.8$ Hz), 134.45 (d, 2C, *o*-C in Ph, $^2J_{P-C} = 14.4$ Hz).—^{31}P NMR ([D$_8$]THF): $\delta = -117.1$, d, $^1J_{P-H} =$ 200.9 Hz.—EI MS: m/z 428 (2%, [M^+]), 319 (32%, [$M^+ -$PHPh]), 122 (100%, $C_5H_4SiMe_2^+$), 109 (52%, $PHPh^+$), and fragmentation products thereof.—IR (KBr): $\bar{\nu}$ (cm^{-1}): 2351 s (νPH).—*Anal*. Calc. for $C_{13}H_{16}Cl_3PSiZr$ (428.9): C 36.4, H 3.8, P 7.2; Found: C 26.4 (due to silicon carbide formation), H 4.0, P 7.1%.

4.5. [{(η^5-C_5H_4)$SiMe_2PHCy$}$ZrCl_3$] (**5**)

$ZrCl_4$ (1.80 g, 7.7 mmol) was suspended in $C_6H_5CH_3$ (50 ml), and a solution of **2** (2.79 g, 7.8 mmol) in $C_6H_5CH_3$ (50 ml) was added dropwise. The reaction mixture was stirred for 1 day, then the solvent was evaporated in vacuo and the resulting residue washed with n-C_5H_{12} (30 ml) and extracted with THF to give 2.0 g (58%) of **5** as white microcrystalline solid. M.p.: 145 °C. ^{1}H NMR ([D$_8$]THF): $\delta = 0.63$ (d, 3H, CH_3 in $SiMe_2$, $^3J_{P-H} = 4.3$ Hz), 0.64 (d, 3H, CH_3 in $SiMe_2$, $^3J_{P-H} = 6.1$ Hz), 1.18–1.85 (m, 11H, Cy), 2.59 (d, 1H, PH, $^1J_{P-H} = 191.1$ Hz), 6.57 (m, 2H, CH in C_5H_4), 6.64 (m, 2H, CH in C_5H_4).—^{31}P NMR ([D$_8$]THF): $\delta =$ −121.6, d, $^1J_{P-H} = 201.0$ Hz.—EI MS: m/z 434 (7%, [M^+]), 319 (45%, [$M^+ -$PHCy]), 122 (100%, $C_5H_4SiMe_2^+$), 115 (82%, $PHCy^+$), and fragmentation products thereof.—IR (KBr): $\bar{\nu}$ (cm^{-1}): 2403 m (νPH).—*Anal*. Calc. for $C_{13}H_{22}Cl_3PSiZr$ (434.95): C

35.9, H 5.1, P 7.1; Found: C 27.3 (due to silicon carbide formation), H 4.9, P 6.5%.

4.6. [{(η^5-C_5H_4)CMe_2PH^tBu}$ZrCl_3$] (6)

$ZrCl_4$ (1.00 g, 4.3 mmol) was suspended in $C_6H_5CH_3$ (50 ml), and a solution of **3** (1.15 g, 4.3 mmol) in $C_6H_5CH_3$ (10 ml) was added dropwise. The reaction mixture was stirred for 12 h, then the solvent was evaporated in vacuo and the resulting residue washed with n-C_5H_{12} (30 ml) and extracted with THF to give 0.76 g (45%) of **6** as white microcrystalline solid. M.p.: 105 °C. ^{1}H NMR ([D$_8$]THF): $\delta = 1.03$ (d, 9H, CH_3 in ^{t}Bu, $^3J_{H-H} = 13.2$ Hz), 1.46 (d, 3H, CH_3C, $^3J_{P-H} = 8.1$ Hz), 1.54 (d, 3H, CH_3C, $^3J_{P-H} = 11.2$ Hz), 3.54 (d, 1H, PH, $^1J_{P-H} = 294.9$ Hz), 6.31 (m, 1H, CH in C_5H_4), 6.53 (m, 1H, CH in C_5H_4), 6.55 (m, 1H, CH in C_5H_4), 6.63 (m, 1H, CH in C_5H_4).—^{13}C NMR ([D$_8$]THF): $\delta =$ 30.04 (d, 3C, CH$_3$ in ^{t}Bu, $^2J_{P-C} = 5.5$ Hz), 33.02 (d, 1C, $C(CH_3)_2$, $^1J_{P-C} = 8.1$ Hz), 33.20 (d, 1C, $C(CH_3)_3$, $^1J_{P-C} = 11.9$ Hz), 33.64 (d, CH$_3$C, $^2J_{P-C} = 4.3$ Hz), 34.30 (d, CH$_3$C, $^2J_{P-C} = 5.8$ Hz), 115.39 (s, 1C, C in C_5H_4), 119.01 (s, 1C, C in C_5H_4), 119.78 (s, 1C, C in C_5H_4), 119.82 (s, 1C, C in C_5H_4), 129.71 (d, 1C, C1 in C_5H_4, $^2J_{P-C} = 10.2$ Hz).—^{31}P NMR (d$_8$-THF): $\delta = -$ 6.8, d, $^1J_{P-H} = 282.5$ Hz.—EI MS: m/z 392 (3%, [M^+]), 303 (11%, [$M^+ - PH^tBu$]), 107 (80%, $C_5H_4CMe_2^+$), and fragmentation products thereof.—IR (KBr): $\tilde{\nu}$ (cm^{-1}): 2379 m (νPH).—*Anal*. Calc. for $C_{12}H_{20}Cl_3PZr$ (392.84): C 36.7, H 5.1, P 7.9; Found: C 34.3, H 4.9, P 7.5%.

4.7. [{(η^5-C_5H_4)CMe_2PH^tBu}$TiCl_3$] (7)

$TiCl_4$ (1.50 g, 7.9 mmol) was suspended in $C_6H_5CH_3$ (50 ml), and a solution of **3** (2.11 g, 7.9 mmol) in $C_6H_5CH_3$ (20 ml) was added dropwise. The reaction mixture was stirred for 12 h, then the solvent was evaporated in vacuo and the resulting residue washed with n-C_5H_{12} (30 ml) and extracted with $C_6H_5CH_3$ to give 1.85 g (67%) of **7** as a red microcrystalline solid. M.p.: 82–86 °C. ^{1}H NMR ([D$_8$]THF): $\delta = 0.92$ (d, 9H, CH_3 in ^{t}Bu, $^3J_{H-H} = 12.0$ Hz), 1.69 (m, 6H, CH_3C), 3.50 (d, 1H, PH, $^1J_{P-H} = 212.6$ Hz), 6.26 (m, 2H, CH in C_5H_4), 6.93 (m, 2H, CH in C_5H_4).—^{13}C NMR ([D$_8$]THF): $\delta = 31.07$ (d, 3C, CH$_3$ in ^{t}Bu, $^2J_{P-C} = 12.8$ Hz), 31.45 (d, 1C, $C(CH_3)_2$, $^1J_{P-C} = 19.2$ Hz), 33.12 (d, 1C, $C(CH_3)_3$, $^1J_{P-C} = 10.1$ Hz), 35.37 (s, CH$_3$C), 37.20 (s, CH$_3$C), 121.09 (s, 2C, C in C_5H_4), 122.64 (d, 1C, C1 in C_5H_4, $^2J_{P-C} = 27.7$ Hz), 130.88 (s, 2C, C in C_5H_4).—^{31}P NMR ([D$_8$]THF): $\delta = 36.7$, d, $^1J_{P-H} =$ 213.4 Hz.—EI MS: m/z 348 (5%, [M^+]), 224 (26%, [$M^+ - Cl-PH^tBu$]), 107 (20%, $C_5H_4CMe_2^+$), and fragmentation products thereof.—IR (KBr): $\tilde{\nu}$ (cm^{-1}): 2324 m (νPH).—*Anal*. Calc. for $C_{12}H_{20}Cl_3PTi$ (349.5): C 41.2, H 5.8, P 8.9; Found: C 39.8, H 5.5, P 8.4%.

4.8. Polymerisation experiments

All manipulations of air-sensitive materials were performed with the rigorous exclusion of oxygen and moisture in flamed Schlenk-type glassware on a dual-manifold Schlenk line, or interfaced to a high vacuum (10^{-5} Torr) line, or in a nitrogen-filled Vacuum Atmospheres glove box with a medium-capacity recirculator (1–2 ppm O_2). Argon, ethene, propene and nitrogen gases were purified by passage through a MnO oxygen-removal column and a Davison 4 Å molecular sieve column. Styrene (Spectrum) was freshly distilled under vacuum from CaO. All solvents for vacuum-line manipulations were stored in vacuo over Na/K alloy in resealable bulbs.

The polymerisation experiments were conducted in a 100 ml flamed heavy-wall glass round-bottom reaction flask attached to a high-vacuum line. In a typical experiment, 10 mg of **4**–**7** and the corresponding amount of MAO (MAO:cat. = 1:300) were charged to the flask containing a magnetic stir bar. The reaction vessel was connected to a high-vacuum line, pumped down and back-filled three times with Ar. Then the flask was re-evacuated, and a measured quantity of $C_6H_5CH_3$ (5 ml) was vacuum transferred into the reaction flask from Na/K. Then gaseous ethene or propene was condensed into the vessel through a gas-purification column. The flask was warmed to room temperature, and the pressure was continuously measured by means of a manometer. Rapid stirring of the solution was initiated, and after a measured time interval (2 h), the polymerisation was quenched by releasing the excess pressure of ethene or propene and immediately injecting a methanol/HCl mixture. The polymer product was collected by filtration, washed with C_6H_{14} and C_3H_6O and dried under vacuum for several hours.

to heavier alkali metal compounds. In this work "[Li(PyNSiMe$_3$)(15C5)]", which could only be isolated as a viscous red oil, was employed. Despite numerous attempts, no crystalline material could be isolated; this implies an ill-defined complex, reflecting the poor host–guest fit of lithium with 15C5. Metathesis of "[Li(PyNSiMe$_3$)(15C5)]" with potassium *tert*-butoxide or rubidium 2-ethylhexoxide affords **3** and **4**, respectively, as red oils, in essentially quantitative yields (Eq. (1)). Recrystallisation of these oils from solutions of methylcyclohexane containing THF yields crystals of **3** and **4** suitable for X-ray crystallographic study.

$$\text{"[Li(PyNSiMe}_3\text{)15C5)]"} + \text{MOR} \rightarrow 1/2[\{\text{M(PyNSiMe}_3\text{)(15C5)}\}_2] + \text{LiOR}$$

$$\text{M} = \text{K};\ \text{R} = \text{Bu}^t$$

$$\text{M} = \text{Rb};\ \text{R} = \text{CH}_3(\text{CH}_2)_3\text{CH}(\text{CH}_2\text{CH}_3)\text{CH}_2 \qquad (1)$$

The ^{1}H and ^{13}C NMR spectra of **3** and **4** exhibit the expected signals in accord with the solid state structures (see below). The ^{29}Si NMR spectra exhibit signals at −19.03 and −18.97 ppm, respectively, reflecting the similarity of potassium and rubidium in terms of Pauling electronegativities, and are commensurate with the soft polarisable nature of higher alkali metals leading to increased shielding at the amido centre.

An X-ray crystallographic study reveals that **3** crystallises as a 'slipped' dimer with no significant intermolecular interactions (Fig. 1). Selected bond lengths and angles are given in Table 1. The coordination sphere of each potassium ion is dominated by the 15C5, which bridges via one oxygen centre to the other potassium centre, forming a $(KO)_2$ ring that lies on a crystallographic inversion centre. This bridging nature of crown ethers with alkali metals is rare, but some examples have been reported with lithium [10,11], sodium [12] and potassium [13–15]. The coordination

[b] Symmetry operations for equivalent atoms (A): $-x+1, -y+1, -z+1$.

sphere of each potassium cation is completed by the amide, which is relegated to a terminal chelating role. This bonding mode illustrates the strength of the macrocyclic effect; clearly the potassium cation is not large enough to accommodate bridging amide with a capping 15C5 molecule as with the previously reported dimer **1** [9], so the dimer 'slips'.

The five terminal K–O bond lengths span the narrow range 2.776(2)–2.875(2) Å, a smaller range than observed in **1**, reflecting the better host–guest fit of 15C5 than 12C4 with potassium. This range also compares well with other previously reported examples of K(15C5) complexes [16,17]. Thus, each potassium resides 1.558 Å from the mean plane of the oxygen atoms of the crown, a smaller deviation than in **1**. The bridging K–O bond length of 2.951(2) Å is longer, as would be expected for a bridging oxygen centre. The K–N(2) bond length of 2.880(2) Å is somewhat longer than the K–N(1) bond length of 2.793(2) Å. It might be expected that the amido N(2) centre would have the shorter bond length. However, inspection of a space-filling plot reveals that the amido centre is pushed away to relieve steric strain by the bulky trimethylsilyl group. Nevertheless, the observed K–N bond lengths fall within ranges previously reported [9,18]. The ligand bite angle of 48.87(3)° is substantially smaller than those observed

in the compound [{Na(12C4)$_2$}{Na(PyNSiMe$_3$)$_2$(THF)}] [9], reflecting the larger ionic radius of potassium compared to sodium (effective ionic radii for coordination number 6 are given as 1.02, 1.38, and 1.52 Å for Na^+, K^+, and Rb^+, respectively [19]). The amides exhibit a hinge angle of 157.8°, defined as the dihedral angle between the mean plane of the pyridyl ring and amido N(2), and the KN_2 plane; this would be 180° if the potassium ion lay exactly in the plane of the ligand. This hinge angle results in a deviation from planarity at N(2) [sum of bond angles = 356.83(9)°]. The trimethylsilyl groups are staggered with respect to the pyridyl ring to minimise steric strain.

The molecular structure of **4** is illustrated in Fig. 2 and selected bond lengths and angles are given in Table 1. The complex crystallises as a contact ion pair dimer constructed around a transoid $(RbN)_2$ ring involving the amido nitrogen centres, with additional coordination by bridging pyridyl groups, and capped on each end by a molecule of 15C5. The molecule is centrosymmetric, the $(RbN)_2$ ring lying on a crystallographic inversion centre. The larger ionic radius of rubidium compared to potassium is demonstrated by the retention of the bridged amide dimer core observed in **1** and **2**, instead of 'slipping' to the dimer architecture observed in **3**. The Rb–O bond lengths span the range 2.970(2)–3.177(2) Å, reflecting the increased ionic radius of rubidium compared to potassium and agreeing well with previous examples [20,21]. Consequently the rubidium cation resides 1.943 Å above the oxygen mean plane of the crown, reflecting not only the larger ionic radius of rubidium, but also the more congested coordination sphere of the metal. For the amido ligand, the Rb–N bond lengths span the ranges 2.979(2)–3.174(2) Å (amide) and 3.036(2)–3.143(2) Å (pyridyl). Whilst the lower value for the Rb–N(amide) is in good agreement with bond lengths observed in **2**, the other three bond lengths are at the higher end of bond lengths associated with tertiary amines coordinated to rubidium. For example, Rb–N bond lengths in the ranges 3.022–3.099 and 3.092–3.131 Å have been observed in the complexes [{Rb(fluorenyl)(PMDETA)}$_8$] [22] and [{RbC(H)(SiMe$_3$)$_2$(PMDETA)}$_2$] [23] (PMDETA = *N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine), respectively. This is, perhaps, an indication of the crowding in this dimer as a result of increasing the size of the crown. Whereas potassium cannot accommodate the complete coordination environment and gives a 'slipped' dimer, rubidium is just large enough, but at the expense of a long Rb–N bond as the macrocyclic effect dominates. The trimethylsilyl groups are again staggered with respect to the pyridyl rings minimising steric strain. The pyridyl rings are tilted from the normal of the Rb(1)···Rb(1A) vector. The N(1) pyridyl ring tilts towards Rb(1A) (hinge angles of 143.9° to the plane of N(1)/N(2)/Rb(1) and 134.7° to the plane of N(1)/N(2)/Rb(1A)). This is a smaller degree of tilt than observed in **1** or **2**, reflecting the increased coordination number of rubidium, and hence a diminished requirement of electron density from the π system of the pyridyl ring.

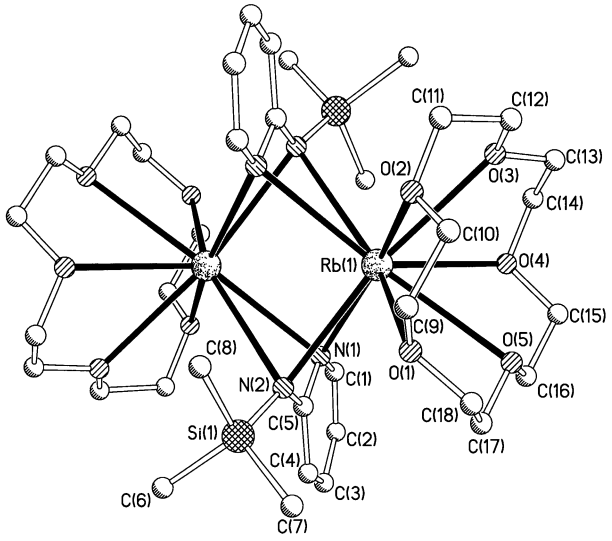

Fig. 2. The molecular structure of **4**, without H atoms.

3. Conclusion

The new potassium and rubidium amides are readily prepared by a metathesis protocol in excellent yields. The structures adopted in the solid state are cation dictated; in **3** a slipped dimer is formed by bridging crowns, giving a $(KO)_2$ ring with terminal chelating amides, whereas for **4** a dimer with a $(RbN)_2$ ring is formed, with additional coordination by bridging pyridyl groups and capping crowns, as a consequence of the larger size of rubidium compared to potassium.

4. Experimental

4.1. General comments

All manipulations were carried out using standard Schlenk techniques under an atmosphere of dry nitrogen. Methylcyclohexane and THF were distilled from sodium–benzophenone ketyl radical under an atmosphere of dry nitrogen and stored over activated 4A molecular sieves. 15-Crown-5 ether was dried by, and stored over activated 4A molecular sieves. 2-Trimethylsilylaminopyridine was prepared as described previously [9]. Butyllithium was purchased from Aldrich as a 2.5 M solution in hexanes. Potassium *tert*-butoxide was purchased from Aldrich and was baked at 100 °C (10^{-2} mmHg) and stored under an atmosphere of dry nitrogen prior to use. Rubidium-2-ethylhexoxide was prepared by

a literature method [24]. Deuteriated solvents were distilled from a potassium mirror, deoxygenated by three freeze–pump–thaw cycles, and stored over activated 4A molecular sieves.

The ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AC200 spectrometer and ^{29}Si spectra on a Bruker WM300 operating at 200.1, 50.3 and 59.6 MHz, respectively, and chemical shifts are quoted in ppm relative to tetramethylsilane. Elemental analyses were obtained by Elemental Microanalysis Ltd., Okehampton, UK.

4.2. Preparation of [{K(PyNSiMe$_3$)(μ-15C5)}$_2$] (3)

Bu^{n}Li (1.28 ml, 3.19 mmol) was added dropwise to a solution of 2-trimethylsilylaminopyridine (0.53 g, 3.19 mmol) and 15-crown-5 (0.63 ml, 3.19 mmol) in THF (40 ml) and stirred for 1 h to afford a yellow solution. Dropwise addition of this solution to Bu^{t}OK (0.36 g, 3.19 mmol) gave a dark orange solution. Removal of volatiles in vacuo yielded a viscous red oil; recrystallisation from methylcyclohexane/THF solution at 5 °C gave crystals of **3** suitable for X-ray crystallography (0.98 g, 72.3%). Microanalysis for **3**: C, 50.68; H, 8.21; N, 6.31. $C_{36}H_{66}K_2N_4O_{10}Si_2$ requires C, 50.91; H, 7.83; N, 6.60%. Spectroscopic data for **3**: δ_H ([^{2}H]$_8$ THF) 0.10 (18H, s, SiMe$_3$), 3.67 (40H, s, 15C5), 5.68 (2H, t, β-H-Py), 6.05 (2H, d, β′-H-Py), 6.78 (2H, t, γ-H-Py) and 7.68 (2H, d, α-H-Py). δ_C ([^{2}H]$_8$ THF) 2.79 (SiMe$_3$), 69.64 (15C5), 103.01 (β-C-Py), 115.27 (β′-C-Py), 134.66 (γ-C-Py), 149.53 (α-C-Py) and 170.47 (α′-C-Py). δ_{Si} ([^{2}H]$_8$ THF) −19.03 (s, SiMe$_3$).

4.3. Preparation of [{Rb(μ-PyNSiMe$_3$)(15C5)}$_2$] (4)

Bu^{n}Li (1.35 ml, 3.37 mmol) was added dropwise to a solution of 2-trimethylsilylaminopyridine (0.56 g, 3.37 mmol) and 15-crown-5 (0.67 ml, 3.37 mmol) in THF (40 ml) and stirred for 1 h to afford a yellow solution. Addition of this solution to rubidium-2-ethylhexoxide (0.72 g, 3.37 mmol) gave a dark orange solution. Removal of volatiles in vacuo yielded a viscous red oil; recrystallisation from a methylcyclohexane/THF solution at 5 °C gave crystals of **4** suitable for X-ray crystallography (1.15 g, 72.4%). Microanalysis for **4**: C, 46.25; H, 7.40; N, 5.65. $C_{36}H_{66}N_4O_{10}Rb_2Si_2$ requires C, 45.90; H, 7.06; N, 5.95%. Spectroscopic data for **4**: δ_H ([^{2}H]$_8$ THF) 0.10 (18H, s, SiMe$_3$), 3.62 (40H, s, 15C5), 5.72 (2H, t, β-H-Py), 6.04 (2H, d, β′-H-Py), 6.79 (2H, t, γ-H-Py) and 7.73 (2H, d, α-H-Py). δ_C ([^{2}H]$_8$ THF) 2.77 (SiMe$_3$), 69.90 (15C5), 103.11 (β-C-Py), 115.60 (β′-C-Py), 134.75 (γ-C-Py), 149.65 (α-C-Py) and 170.16 (α′-C-Py). δ_{Si} ([^{2}H]$_8$ THF) −18.97 (s, SiMe$_3$).

4.4. X-ray crystallography

Crystal data for complexes **3** and **4** are listed in Table 2. Crystals were examined on a Bruker AXS SMART CCD area detector with graphite-monochromated Mo Kα radiation ($\lambda = 0.70173$ Å) at 160 K with an Oxford Cryostream low-temperature device. Cell parameters were refined from positions of all strong reflections in each data set. Intensities were corrected semi-empirically for absorption, based on symmetry-equivalent and repeated reflections. The structures were solved by direct methods and refined on F^2 values for all unique data. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in geometrically calculated positions and constrained with a riding model; U(H) was set at 1.2 (1.5 for methyl groups) times U_{eq} for the parent atom. Programs were Bruker AXS SMART (control) and SAINT (integration) [25], and SHELXTL for structure solution, refinement and molecular graphics [26].

Table 2
Crystal data and structure refinement parameters for **3** and **4**

Compound	**3**	**4**
Formula	$C_{36}H_{66}K_2N_4O_{10}Si_2$	$C_{36}H_{66}N_4O_{10}Rb_2Si_2$
Formula weight	849.3	942.1
Temperature (K)	160	160
Crystal system	monoclinic	triclinic
Space group	$P2_1/c$	$P\bar{1}$
Unit cell dimensions		
a (Å)	12.7950(6)	10.6890(7)
b (Å)	9.4632(4)	11.2629(7)
c (Å)	18.5977(8)	11.7875(8)
α (°)		103.220(2)
β (°)	92.661(2)	112.535(2)
γ (°)		108.048(2)
V (Å^3)	2249.41(17)	1144.57(13)
Z	2	1
Absorption coefficient (mm^{-1})	0.32	2.24
Crystal size (mm)	0.76 × 0.48 × 0.36	0.80 × 0.80 × 0.38
θ_{max} (°)	28.6	28.6
Reflections measured	18968	9981
Unique reflections	5377	5226
Reflections with $F^2 > 2\sigma(F^2)$	4410	3813
Transmission factors	0.754–0.881	0.176–0.361
R_{int}	0.0185	0.0396
Number of parameters	247	248
R [a] [$F^2 > 2\sigma(F^2)$]	0.0318	0.0358
R_w [b] (all data)	0.0922	0.0840
Goodness-of-fit [c] (S)	1.084	0.851
Largest difference peak and hole (e Å^{-3})	0.65 and −0.26	1.06 and −0.86

[a] Conventional $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ for 'observed' reflections having $F^2 > 2\sigma(F^2)$.

[b] $R_w = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{1/2}$ for all data.

[c] $S = [\Sigma w(F_o^2 - F_c^2)^2/(\text{no. of unique reflections} - \text{no. of parameters})]^{1/2}$.

5. Supplementary information

Crystallographic data for the structural analysis of compounds **3** and **4** have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 179632 and 179631 for compounds **3** and **4**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

2.2. Synthesis of ligand

The pentadentate ligand was made adopting a modified procedure of similar type of ligand as reported [6]. Diethylene triamine (0.515 g, 5 mmol) and 2-benzoyl pyridine (1.83 g, 10 mmol) was refluxed in 15 cm^3 dehydrated alcohol for 4 h. The pentadentate ligand was isolated after evaporating the solvent and purified from alcohol. The product was isolated as a brown semisolid mass after dried in vacuum over P_4O_{10}: yield 1.86 g ($\sim$86%). *Anal*. Found: C, 77.4; H, 6.2; N, 15.9. Calc. for $C_{28}H_{27}N_5$: C, 77.6; H, 6.3; N, 16.2%.

L

2.3. Preparation of $[Ni_2L_2(NCS)_2](ClO_4)_2$ (1)

The MeCN solution (10 cm^3) of the ligand (L) (0.217 g, 0.5 mmol) was added to an MeCN solution (5 cm^3) of $Ni(ClO_4)_2\cdot 6H_2O$ (0.183 g, 0.5 mmol). To the resulting brown–red solution, an aqueous solution (0.038 g, 0.5 mmol, 2 cm^3 H_2O) of ammonium thiocyanate was added slowly with constant stirring. The clear red solution was left for slow evaporation and after 3–4 days deep red needle crystals of **1** were obtained (0.142 g, 44%). *Anal*. Found: C, 53.9; H, 4.0; N, 12.8; Ni, 9.0. Calc. for $C_{58}H_{54}Cl_2N_{12}Ni_2O_8S_2$: C, 53.6; H, 4.2; N, 12.9, Ni, 9.0%.

2.4. Preparation of $[Ni_2L_2(NCO)_2](ClO_4)_2$ (2)

This compound was synthesized following the same procedure as illustrated above for **1** except that ammonuim thiocyanate was replaced with equimolar quantity of sodium cyanate. Red crystals of composition $[Ni_2L_2(NCO)_2](ClO_4)_2\cdot 4CH_3CN$ suitable for X-ray study was isolated after about 5 days (yield of the dried product was 0.085 g, 27%). *Anal*. Found: C, 54.9; H, 4.1; N, 13.2; Ni, 9.1. Calc. for $C_{58}H_{54}Cl_2N_{12}Ni_2O_{10}$ (without MeCN solvent of crystallization): C, 55.0; H, 4.3; N, 13.3; Ni, 9.3%.

Caution: Perchlorate complexes are potentially explosive especially in presence of organic ligands. Therefore, preparation and handling of these compounds deserve special attention.

2.5. Physical measurements

Elemental analysis for carbon, hydrogen and nitrogen were performed using a Perkin–Elmer 2400II elemental analyzer. Nickel contents was determined by atomic absorption spectrophotometric measurements (A GBC Model-Avanta was used). Variable temperature magnetic susceptibility data were obtained with a Quantum Design MPMS5 SQUID spectrophotometer. Pascal's constants were utilized to estimate diamagnetic correction, this value was subtracted from the experimental susceptibility data to give molar magnetic susceptibility (χ_M). IR spectra (4000–400 cm^{-1}) were taken at 298 K using JASCO FT/IR-420 spectrometer.

2.6. Crystal structures determination and refinement

Single crystals suitable for X-ray crystallographic analysis were selected following examination under a microscope. Crystals of $[Ni_2L_2(NCO)_2](ClO_4)_2\cdot 4CH_3CN$ were not stable outside mother liquor and were quickly coated with an inert oil to prevent solvent loss before collecting the relevant data at 200 K. Single crystal X-ray diffraction data for the compounds were collected on a Bruker-AXS SMART APEX/CCD diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å) in an $\omega-2\theta$ scan mode. Diffracted data were corrected for Lp effects [7] and for absorption using the SADABS program. The structures were solved by direct methods and the structure solution and refinement was based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic U values 1.2 times that of the atom to which they are bonded. Hydrogen atoms bonded to heteroatoms were located in the Fourier map and their coordinates fixed to ride on the bonded atom with isotropic U values 1.2 times that of the atom to which they are bonded. All crystallographic calculations were conducted with the SHELXTL program package. The crystal data and data collection details are collected in Table 1.

3. Results and discussion

3.1. Synthesis

The ligand was synthesized by refluxing diethylene triamine and 2-benzoyl pyridine in 1:2 mol ratio in dehydrated alcohol. It reacted with nickel(II) perchlorate hexahydrate and ammonium thiocyanate/sodium cyanate using a ratio of $L–Ni^{II}–NCS^-/NCO^- = 1:1:1$ in aqueous acetonitrile medium affording red crystalline products suitable of X-ray crystallographic work having composition $[Ni_2L_2(NCS)_2](ClO_4)_2$ (**1**) and $[Ni_2L_2(NCO)_2](ClO_4)_2\cdot 4CH_3CN$ (**2**), respectively. It is also interesting to note that by changing ratio of $L–Ni^{II}–NCS^-/NCO^- = 1:1:0.5$, which is usual ratio to make binuclear compound of the usual type $[Ni_2L_2(X)]^{3+}$ (where $X^- = NCS^-$ or NCO^-) lead to the same

of three nitrogen atoms from one, two nitrogen atoms from another pentadentate ligand and the last one from terminal ion. In these molecules each flexible ligand shows a very unusual [5] type of binding mode and distributed its coordination potential to two different nickel(II) centers thereby forms the dimer. Usually bivalent nickel reacts with a linear pentadentate or macrocyclic ligand (L) to form complexes of the type $[Ni^{II}L(X)]^{n+}$ (where X = neutral or anionic donor) or $[Ni_2^{II}(L)_2(Y)]^{3+}$ (where Y = monoanionic bridging ligand) [5], but in the present case the linear pentadentate ligand itself act like a bridge between two nickel ions forming the complexes $[Ni_2L_2(NCS)_2]^{2+}$ (**1**) and $[Ni_2L_2(NCO)_2]^{2+}$ (**2**) with thiocyanate and cyanate as terminal ligands. The Ni–N distances are ranging from 2.021(3) to 2.150(3) Å for **1** and 2.0313(17) to 2.1604(17) Å for **2**. These Ni–N distances are consistent with corresponding values of analogous NiN_6 chromophores [2,9]. The Ni1···Ni1a distances for **1** and **2** are, respectively 5.809(1) and 5.695(1) Å. The *cis* and *trans* angles are varied from 77.97(12)° to 101.81(12)° and 158.88(13)° to 177.61(11)° for **1** and 78.08(7)° to 101.80(6)° and 159.21(6)° to 176.72(7)° for **2**, respectively, indicating the nature of distortion in the coordination sphere. The crystals of compound **1** contains no solvent of crystallization, but there are four acetonitrile solvent of crystallization in the molecule **2**, the loss of which explains the deterioration of these crystals outside mother liquor. Both compounds **1** and **2** consist of isolated binuclear unit in the crystal lattice and is consistent with their magnetic properties (vide infra).

3.4. Magnetic properties

A variable temperature magnetic susceptibility study was performed on polycrystalline sample of **1** and **2**. The magnetic susceptibilities (χ_M) of these two compounds were examined in a 10.0 kG field in the temperature range 2.0–300.0 K. The $\chi_M T$ versus T plot indicates a very weak intramolecular interaction between two nickel atoms. Inspite of our best effort we were unable to get good fit for magnetic data to determine exchange parameters. The plausible reason is that the nickel centers are so far apart (Ni1···Ni1a distances are 5.809(1) and 5.695(1) Å for compounds **1** and **2**, respectively) and bridged by a ligand that involves a long pathway for exchange interaction and also containing saturated $-CH_2-CH_2-$ links that are further weakening the magnetic interaction [10]. As a result intermolecular interactions and zero-field splittings become just as important as the intramolecular interactions, and thereby fitting becomes in applicable. So, although we have described here a very unusual coordination behavior of a flexible pentadentate ligand to produce a binuclear nickel complex, but to achieve reasonably good interactions between two metal atoms we have to modify the ligand pathways as well as suitable linkages (such as unsaturated linkages instead of saturated one) that are able to propagate magnetic exchange interactions in a better way.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 183183 and 183182 for compounds **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: 44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

The project was financially supported by the Council of Scientific and Industrial Research and University Grants Commission (under DSA program), New Delhi, India. One of the authors (S.D.) is thankful for the fellowship provided by The University of Burdwan. We are also grateful to Professor A.K. Das and B.C. Mondal of our department for help regarding atomic absorption data. The authors are indebted to Professor George Christou and M. Soler for the magnetic results.

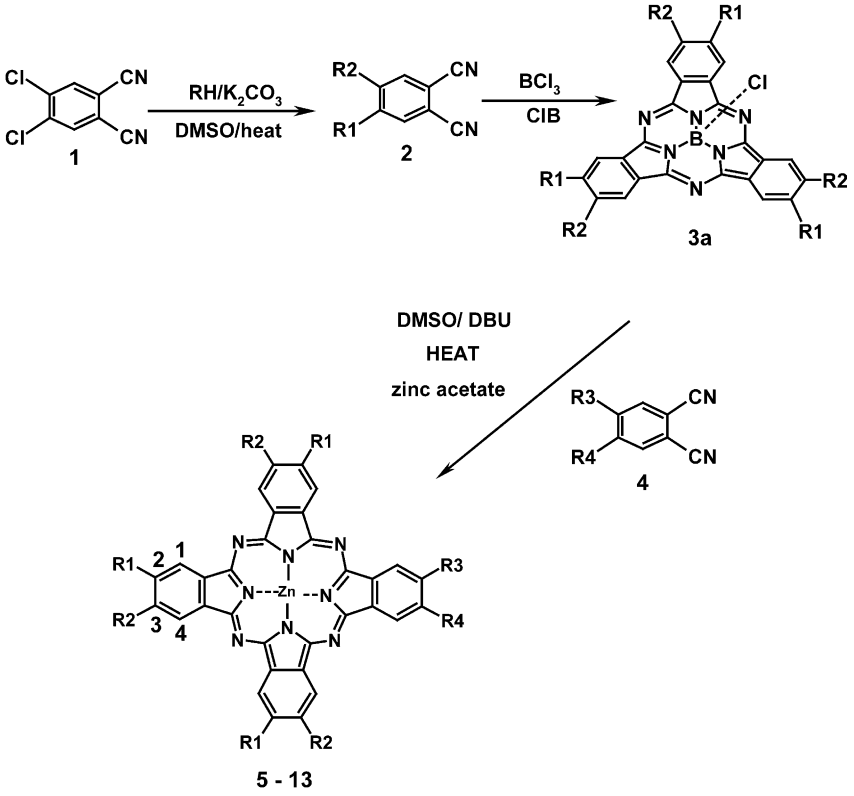
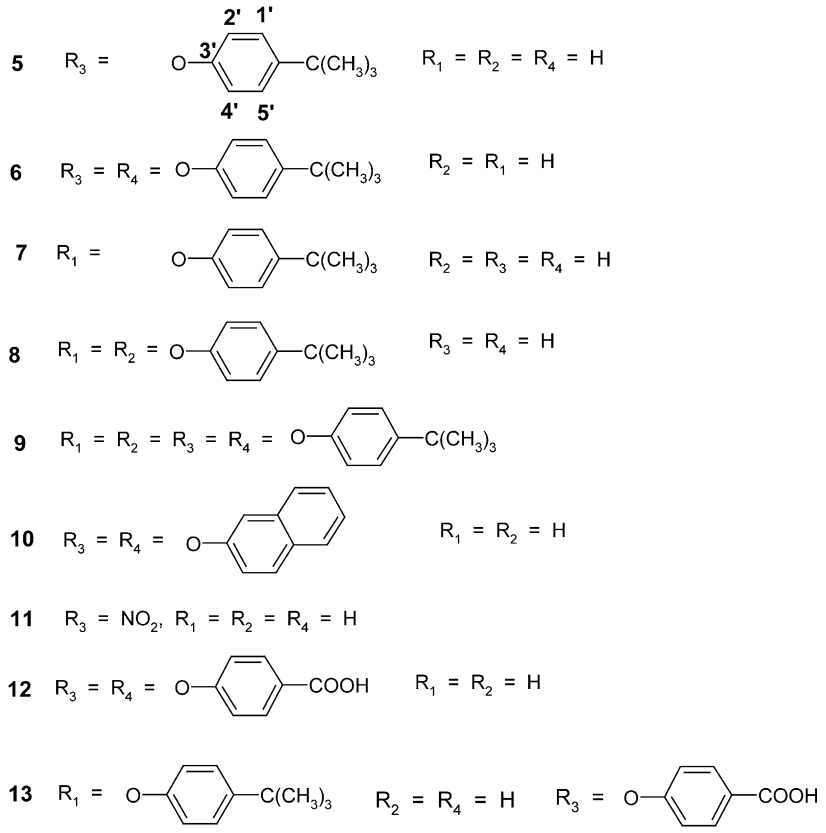
(photobleaching) of the phthalocyanines are also important for determining the stability of the MPc complexes during PDT action. We report on the singlet oxygen quantum yields and the photobleaching studies of a series of unsymmetrically and symmetrically substituted zinc phthalocyanines (Scheme 1).

2. Experimental



2.1. Materials

N,*N*′-dimethylformamide (DMF) used for electrochemical studies was freshly distilled. Dimethylsulfoxide (DMSO) was dried over alumina before use. Thionyl chloride, potassium carbonate, nitrophthalimide, dichlorophthalic anhydride, dicarboxynaphthalene, 2-naphthol, 4-*tert*-butylphenol, 4-hydroxybenzoic acid, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), diazabicyclooctane (DABCO), 1,3-diphenylisobenzofuran (DPBF) and chlorobenzene (ClB) were purchased either from Aldrich or Merck and were used as received. Tetrabutylammonium perchlorate (TBAP) was recrystallized from ethanol and used as an electrolyte for electrochemical studies.



2.2. Synthesis

2.2.1. Substituted dicyanobenzene (*2* and *4*)

4,5-Dichlorodicyanobenzene (**1**) was synthesized from dichlorophthalic anhydride according to a reported procedure [21]. The disubstituted dicyanobenzenes ($\mathbf{R_1} = \mathbf{R_2}$ (for **2**) or $\mathbf{R_3} = \mathbf{R_4}$ for **4**) were then synthesized from 4,5-dichlorodicyanobenzene using the general procedure reported before [21] as follows: dry potassium carbonate (0.64 g, 0.0046 mol) was suspended in DMSO under nitrogen. To this suspension, 4,5-dichlorodicyanobenzene and the appropriate amount of the respective phenoxy substituent (2-naphthol, 4-*tert*-butylphenol or 4-hydroxybenzoic acid) were added. See Table 1 for the amounts of reagents used. Further aliquots of potassium carbonate were added after 4 h, and 24 h of stirring at room temperature (r.t.), giving total amounts shown in Table 1. The mixture was further stirred at r.t. and under nitrogen atmosphere for the total time shown in Table 1. The product was purified following literature methods [21]. Monosubstituted dicyanobenzenes ($\mathbf{R_2} = \mathbf{H}$ (for **2**) or $\mathbf{R_3} = \mathbf{H}$ (for **4**)) were synthesized by the procedure outlined above for the disubstituted derivatives using nitrophthalonitrile instead of dichlorodicyanobenzene. The amounts for the synthesis are shown in Table 1. 4-Nitrophthalonitrile was synthesized from 4-nitrophthalimide using reported procedures [22].

Scheme 1.

Scheme 1 (*continued*).

Dicyanonaphthalonitrile was synthesized from dicarboxynaphthalene following reported procedures [21].

2.2.2. Sub-phthalocyanines(*3a*)

The unsubstituted, tri- or hexa-substituted subphthalocyanines were synthesized by following reported procedures [15,16] as follows. The respective dichlorocyanobenzene (**1**), di- or mono-substituted dicyanobenzene (**2**, 0.4 g, 0.003 mol), was suspended in 1-chloronaphthalene (6 ml), stirred at r.t. in an atmosphere of nitrogen and in the presence of 0.001 mol (0.12 g) BCl_3. The reaction mixture was heated to 220 °C for 0.5 h. The products were purified according to reference [16], and characterized by UV–Vis, infrared and ^1H NMR spectroscopies.

2.2.3. Sub-naphthalocyanine (Sub-NPc, *3b*)

Sub-naphthalocyanine was synthesized from dicyanonaphthalonitrile following the procedure outlined above for Sub-Pc, by replacing **2** with dicyanonaphthalonitrile.

2.2.4. Symmetrically (*9*) and unsymmetrically (*5–8, 10–14*) substituted zincphthalocyanines (Scheme 1)

These complexes were synthesized according to literature methods [23] by dissolving (0.25 g, 0.00092 mol) the unsubstituted or substituted dicyanobenzene (**4**) to

Table 1
Amounts of reagents used for synthesis of substituted dicyanobenzenes

Substituent	Amount of substituent added (g, mol)	4,5-Dichloro-dicyanobenzene (g, mol)	Total K_2CO_3 added (g, mol)	Total stirring time
Di-substituted				
4-Hydroxy benzoic acid	0.21, 0.00021	0.36, 0.0021	1.92, 0.0138	28 h
4-*tert*-Butylphenol	2.2, 0.015	1.0, 0.005	4.1, 0.12	28 h
2-Naphthol	8.6, 0.06	2.0, 0.0095	8.2, 0.24	28 h
Mono-substituted				
4-Dihydroxy benzoic acid	0.43, 0.0031	0.36, 0.0021	1.92, 0.0138	5 days
4-*tert*-Butylphenol	4.4, 0.03	3.4, 0.02	16.5, 0.12	48 h
2-Naphthol	1.3, 0.009	1.0, 0.0059	5.4, 0.039	5 days

be used for ring expansion in a mixture of freshly distilled DMSO–1-chloronaphthalane (4/2 ml) in the presence of DBU (0.1 g, 0.00065 mol). The reaction mixture was heated to 130 °C, then a suspension of the appropriate unsubstituted or substituted Sub-Pc (**3a**) or the sub-naphthacyanine (**3b**) (0.2 g, 0.00046 mol) and zinc(II) acetate dihydrate (0.11 g, 0.0005 mol) in the DMSO–1-chloronaphthalene solvent mixture was added drop-wise to the heated mixture over a period of 1 h. After cooling, glacial acetic acid (0.04 g, 0.65 mol) was added and the solvents evaporated. For complex **9**, there was no need for ring expansion of Sub-Pc, hence the complex was synthesized by reacting dicyanobenzene disubstituted with *tert*-butylphenol directly with zinc (II) acetate dihydrate. For all complexes, methanol was added and the product was separated by centrifugation. The product was further purified by thin layer chromatography (TLC), using ethyl acetate and toluene for elution.

2.2.5. 2-Mono(tert-butylphenoxy) phthalocyanato zinc (**5**)

Yield 35%. *Anal.* Calc. for $C_{42}H_{28}N_8O_1Zn\cdot 6(C_4H_8O_2)$: C, 63.16; H, 6.06; N, 8.93. Found: C, 63.99; H, 6.24; N, 8.14%.

IR (KBr), ν (cm^{-1}). 3962, 3056, 1715, 1602, 1558, 1507 (C–H); 1471, 1394, 1363, 1336, 1262 (C–O–C); 1235, 1174, 1091, 1046, 946, 803. ^{1}H NMR (*d*-DMSO, 400 Hz): 8.90 (s, 8H, 1,4-Pc); 8.85 (s, 7H, 2,3-Pc); 8.10 (d, 2H, 1′,5′-H); 7.40 (d, 2H, 2′,4′-H); 1.30 (s, 9H, CH_3). λ_{max} (nm) (log ε) in DMF: 675 (5.09), 609 (3.71), 348 (3.96).

2.2.6. 2,3-Bis(tert-butylphenoxy) phthalocyanato zinc (**6**)

Yield 40%. *Anal.* Calc. for $C_{52}H_{40}N_8O_2Zn\cdot 6H_2O$: C, 63.58; H, 5.30; N, 11.41. Found: C, 61.54; H, 3.54; N, 13.41%. IR (KBr), ν (cm^{-1}): 3403, 2964 (C–H); 1601, 1508 (C–H); 1392, 1247, 1106, 994, 895 (C–O–C); 831, 745, 726, 477. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.20 (s, 6H, 1,4-Pc); 8.50 (s, 2H, 1,4-Pc); 8.17 (s, 6H, 2,3-Pc); 8.00 (d, 4H, 1′,5′-H); 7.93 (d, 4H, 2′,4′-H); 1.45 (s, 18H, CH_3). λ_{max} (nm) (log ε) in DMF: 678 (4.47), 611 (3.74), 359 (4.00).

2.2.7. 2,9,16-Tri(tert-butylphenoxy) phthalocyanato zinc (**7**)

Yield 43%. IR (KBr), ν (cm^{-1}): 3385, 2931 (C–H); 1709, 1625, 1485, 1331, 1250 (C–O–C); 1185, 1092, 887, 776, 751, 725, 467. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.48 (s, 8H, 1,4-Pc); 8.54 (m, 2H, 2,3-Pc); 8.10 (m, 3H, 2,3-Pc); 7.60 (d, 6H, 1′, 5′-H); 7.30 (d, 6H, 2′, 4′-H); 1.3 (s, 27H, CH_3). λ_{max} (nm) (log ε) in DMF: 669 (4.57), 604 (3.82), 335 (4.24).

2.2.8. 2,3,9,10,16,17-Hexa(tert-butylphenoxy) phthalocyanato zinc (**8**)

Yield 30%. IR (KBr), ν (cm^{-1}): 2946 (C–H); 1699, 1486, 1409, 1332, 1273 (C–O–C); 1091, 889, 774, 752, 467. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.80 (s, 8H, 1,4-Pc); 8.75 (s, 2H, 2,3-Pc); 8.00 (d, 12H, 1′,5′-H); 7.70 (d, 12H, 2′,4′-H); 1.3 (s, 54H, CH_3). λ_{max} (nm) (log ε) in DMF: 670 (4.75), 605 (3.91), 342 (4.09).

2.2.9. 2,3,9,10,16,17,23,24-Octa(tert-butylphenoxy) phthalocyanato zinc (**9**)

Yield 38%. IR (KBr), ν (cm^{-1}): 3056, 2959 (C–H); 2622, 2550, 2433, 1954, 1719, 1607, 1506, 1484, 1456, 1407, 1331, 1283 (C–O–C); 1244, 1209, 1164, 1114, 1092, 1059, 950, 886, 829, 794, 774, 751, 728, 634, 570, 499, 435. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.5 (s, 8H, 1,4-Pc); 7.5 (d, 16H, 1′,5′-H); 7.0 (d, 16H, 2′,4′-H); 1.2 (s, 72H, CH_3). λ_{max} (nm) (log ε) in DMF: 670 (4.73), 605 (4.20), 335 (4.48).

2.2.10. 2,3-Bis(naphthoxy) phthalocyanato zinc(II) (**10**)

Yield 20%. *Anal.* Calc. for $C_{42}H_{28}N_8O_1Zn\cdot 2(H_2O)$: C, 69.60; H, 3.57; N, 12.50. Found: C, 68.78; H, 2.70; N, 14.17%. IR (KBr), ν (cm^{-1}): 3053, 2930 (C–H); 2859, 2625, 2547, 1957, 1713, 1600, 1484, 1408, 1334, 1285 (C–O–C); 1210, 1165, 1059, 962, 913, 887, 809, 771, 752, 721, 634, 571, 500, 471, 433. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.25 (s, 8H, 1,4-Pc); 8.25 (s, 6H, 2,3-Pc); 8.8–7.5 (m, 14H, naphthoxy). λ_{max} (nm) (log ε) in DMF: 670 (4.97), 605(4.24), 335 (4.69).

2.2.11. 2-Mono-nitro phthalocyanato zinc(II) (**11**)

Yield 41%. *Anal.* Calc. for $C_{32}H_{15}N_9O_2Zn\cdot 2(C_4H_8O_2)$: C, 60.15; H, 3.88; N, 15.79. Found: C, 59.67; H, 3.18; N, 16.28%. IR (KBr), ν (cm^{-1}): 3931, 3332, 1950, 1702, 1652, 1458, 1322 (NO_2); 1162, 1055, 885, 724, 632, 567, 495, 433. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.70 (s, 8H, 1,4-Pc); 8.60 (s, 6H, 2,3-H). λ_{max} (nm) (log ε) in DMF: 670 (4.00), 605 (3.50), 343 (4.10).

2.2.12. 2,3-Bis(carboxyphenoxy) phthalocyanato zinc(II) (**12**)

Yield 48%. *Anal.* Calc. for $C_{46}H_{24}N_8O_6Zn\cdot 5H_2O$: C, 57.68; H, 3.76; N, 11.70. Found: C, 59.76; H, 3.58; N, 11.85%. IR (KBr), ν (cm^{-1}): 3437, 3050 (OH); 1602, 1502, 1403, 1271 (C–O–C); 1213, 1165, 1013, 951, 889, 858, 782, 745, 699, 618, 495, 433. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.4–9.6 (s, 8H, 1,4-Pc); 8.35 (d, 6H, 2,3-Pc); 7.95 (d, 4H, 1′,5′-H); 7.50 (d, 4H, 2′,4′-H); 2H from COOH are not seen as their peak is too weak compared with that of the Pc ring and the phenoxy ring. λ_{max} (nm) (log ε) in DMF: 671 (6.05), 606 (4.32), 357 (3.71), 284 (4.57).

*2.2.13. 2,9,16-Tri(tert-butylphenoxy)-23-mono(carboxyphenoxy) phthalocyanato zinc(II) (**13**)*

Yield 20%. *Anal.* Calc. for $C_{42}H_{28}N_8O_1Zn\cdot 2(H_2O)$: C, 66.19; H, 4.20; N, 14.71. Found: C, 66.57; H, 4.21; N, 16.36%. IR (KBr), ν (cm^{-1}): 3056, 2946 (C–H); 1716, 1658, 1597, 1499, 1453, 1270 (C–O–C); 1218, 1162, 1107, 1015, 883, 759, 690, 619, 486. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.40 (s, 8H, 1,4-Pc); 9.00 (s, 4H, 2,3-Pc); 7.55 (d, 8H, 2′,4′-H); 7.42 (d, 8H, 1′,5′,-H); 1.28 (t, 27H, CH_3). λ_{max} (nm) (log ε) in DMF: 682 (4.97), 614 (4.24), 346 (4.69).

*2.2.14. 2,3-Tribenzo phthalocyanato zinc(II) (**14**)*

Yield 38%. *Anal.* Calc. for $C_{44}H_{22}N_8Zn\cdot 8H_2O$: C, 60.45; H, 4.35; N, 12.82. Found: C, 60.77; H, 5.67; N, 14.71%. IR (KBr), ν (cm^{-1}): 3389, 3180, 3056 (C–H); 1720, 1440, 1255, 1009, 797, 752, 615, 468. ^{1}H NMR (*d*-DMSO, 400 Hz): 9.45 (d, 8H, 1,4-Pc); 8.30 (d, 6H, 6,7-H); 7.90 (d, 6H, 5,8-H). λ_{max} (nm) (log ε) in DMF: 672 (4.76), 607 (4.07), 344 (4.69).

2.3. Electrochemical methods

Electrochemical data were collected with the BioAnalytical Systems (BAS) model 100 B/W electrochemical workstation. For cyclic and square wave voltammetries, a platinum disk (3.0 mm diameter) was used as a working electrode. Platinum wire auxiliary and Ag wire pseudo-reference electrodes were employed for all electrochemical experiments. DMF containing $\sim$0.5 mol dm^{-3} TBAP was employed as an electrolyte. Nitrogen gas was bubbled through the solutions prior to recording cyclic voltammograms, and a nitrogen atmosphere was maintained throughout the cyclic voltammogram scans. The ferrocinium–ferrocene (Fc^+–Fc) couple was employed as an internal standard, and potentials were referenced versus saturated calomel electrode (SCE) using the reported [24] potential of 0.46 V (vs. SCE) for the Fc^+–Fc couple in DMF. The cathodic to anodic peak separation was found to be 80 mV for the Fc^+–Fc couple. Prior to cyclic voltammetry (CV) scans, the platinum working electrode was polished with alumina (<10 μm) on a Buehler felt pad, followed by washing with deionized water and rinsing with methanol and DMF. For cyclic and square wave voltammetry studies concentrations were of the order of 10^{-4} mol dm^{-3}.

2.4. Photodegradation and determination of singlet oxygen studies

Photodegradation and singlet oxygen quantum yield determinations were carried out using experimental setup which has been described in detail somewhere else [19,25]. Experiments were performed in air. Typically a 2 ml DMSO solution of the complex (about 1×10^{-5} mol l^{-1}) was introduced to a 1 cm pathlength UV–Vis cell and photolyzed in the Q band region with a General Electric Quartz line lamp (300 W). For singlet oxygen quantum yield studies, photolysis was performed in the presence of DPBF as a singlet oxygen quencher. To avoid chain reactions induced by DPBF in the presence of singlet oxygen [26] the concentration of DPBF was lowered to $\sim3\times10^{-5}$ mol l^{-1}. The DPBF decay at 417 nm was monitored. A 600 nm glass cut off filter (Schott) and a water filter were used to filter off ultraviolet and far infrared radiation. And an interference filter (Intor, 670 nm with a bandwidth of 20 nm) was placed in the light path before the sample. The light intensity at 670 nm was measured with a power meter (Lasermate) and was found to be 5×10^{16} photons s^{-1} cm^{-2}.

Quantum yields of singlet oxygen (Φ_Δ) photogeneration were determined using the relative method with unsubstituted zinc phthalocyanine (ZnPc) as reference, using the following relationship Eq. (1).

$$\Phi_\Delta = \Phi_\Delta^{PcZn}\frac{W\times I_{abs}^{PcZn}}{W^{PcZn}\times I_{abs}} \quad (1)$$

where, Φ_Δ^{PcZn} is the singlet oxygen quantum yield in the presence of unsubstituted ZnPc as a standard. For ZnPc standard, Φ_Δ^{PcZn} in DMSO is 0.67 [27]. W and W^{ZnPc} are the DPBF photobleaching rates in the presence of substituted ZnPc derivatives under investigation and unsubstituted ZnPc standard, respectively. I_{abs} and I_{abs}^{ZnPc} are the rates of light absorption by the substituted ZnPc derivatives and ZnPc standard, respectively. The initial DPBF concentrations were kept the same for both the ZnPc reference and the samples. No significant changes in the absorbance of the substituted ZnPc derivatives was observed during the singlet oxygen studies. All the experiments were carried out at r.t.

The quantum yields for photobleaching were determined using Eq. (2).

$$\Phi = -\frac{(C_t - C_0)\times V\times N_A}{I_{abs}\times S\times t} \quad (2)$$

where C_t and C_0 in mole l^{-1} are the concentrations of the substituted ZnPc derivatives after and prior to irradiation, respectively, the changes in concentration of the dyes was about 15% for these studies. Values of C_t and C_0 were obtained in DMF using the Q band extinction coefficient given in the Section 2. V is the reaction volume, S the irradiated area of the cell, t the irradiation time, N_A is the Avogadro's number and I_{abs} the overlap integral of the radiation source light intensity and the absorption of the substituted ZnPc derivatives (the action spectrum) in the region of the interference filter transmittance and is defined by Eq. (3).

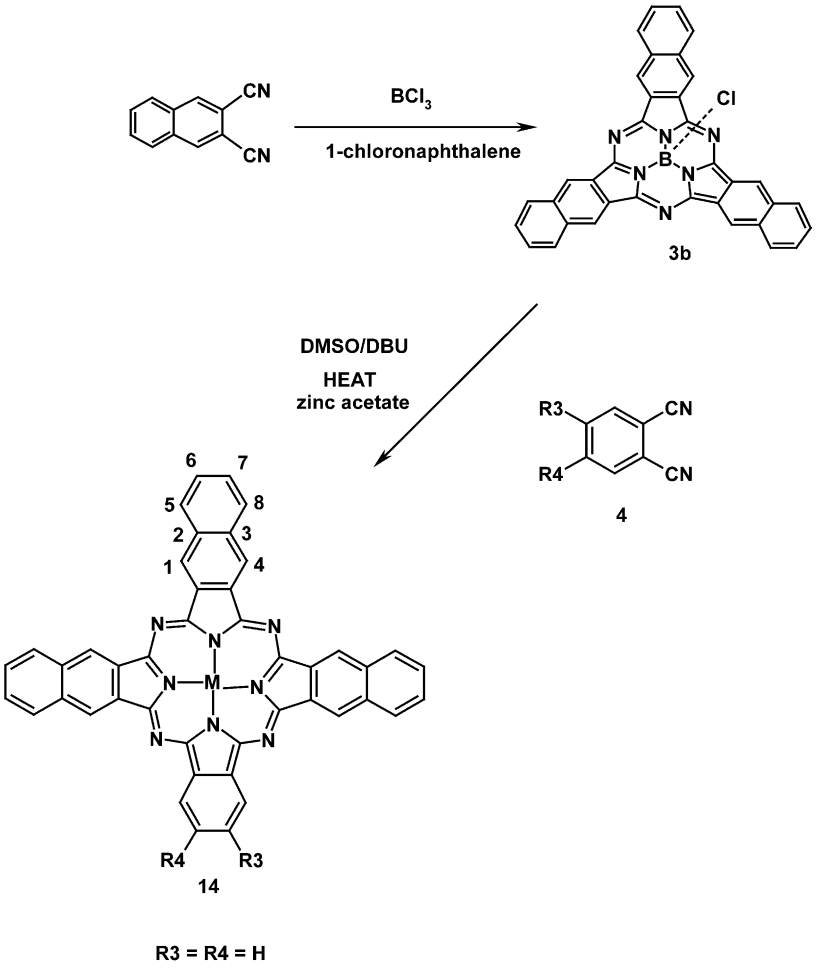
$$I_{abs} = \int (1 - 10^{A_\lambda}) I_\lambda d\lambda \quad (3)$$

where I_λ is the intensity of light and A_λ is the absorbance of the ZnPc derivative at wavelength, λ. Experiments were performed also whereby the solutions were deaerated with N_2 gas or saturated with O_2 in order to study the role of oxygen in the photodegradation process.

Triplet state life times were determined for complexes **5**, **7** and **8** using a flash photolysis system. The excitation pulse was provided by a Nd-Yag (in frequency-doubled mode, providing 160 mJ, 8 ns pulses of laser light at 0–10 Hz), pumping a Lambda-Physik FL2002 dye laser. Single laser pulse energies used ranged from 0.001 to 2 mJ. A 75 W xenon arc lamp provided the analyzing light. Triplet state quantum yields (ϕ_T) were calculated by a comparative method using zinc phthalocyanine as a standard (ϕ_T ZnPc = 0.25 [28]).

UV–Vis spectra were recorded on a Varian 500 UV–Vis–NIR spectrophotometer. IR spectra (KBr pellets) were recorded on a Perkin–Elmer Spectrum 2000 FTIR spectrometer. ^{1}H nuclear magnetic resonance (NMR, 400 MHz) spectra were obtained in $CDCl_3$ and d_6-DMSO using the Bruker EMX 400 NMR spectrometer.

3. Results and discussion



3.1. Synthesis and characterization

Synthesis of unsubstituted and substituted Sub-Pcs has been reported by several researchers [15,16,29–31]. The Sub-Pc complexes have been employed as starting materials for the formation of unsymetrically substituted MPc complexes by ring expansion using substituted or unsubstituted phthalonitriles. The use of Sub-Pcs as intermediates for the synthesis of unsymmtrically substituted phthalocyanines has gained popularity over using statistical condensation of two differently substituted phthalonitrile derivatives. The later results in a complex mixture of products. However, using the reaction mixture containing phthalonitriles and boron trihalide, gives ring-halogenated Sub-Pc, in addition to the desired products. The halogenated Sub-Pcs is difficult to separate. The Sub-Pc complexes were used to prepare the unsymmetrically substituted zinc phthalocyanines according to Schemes 1 and 2. The product mixture will inevitably contain halogenated Pc derivatives and the desired products were separated using preparative TLC.

The ZnPc derivatives (**5**, **6**, **10**–**12**) were synthesized using unsubstituted Sub-Pc and ring expanding using dicyanobenzene which was mono-substituted with *tert*-butylphenol (**5**) or nitro (**11**); and dicyanobenzene disubstituted with *tert*-butylphenol (**6**), naphthol (**10**) or hydroxybenzoic acid (**12**). Complexes **7**, and **13** were synthesized using Sub-Pc substituted with three *tert*-butylphenol groups and ring expanding with unsubstituted dicyanobenzene (**7**) or hydroxybenzoic acid (**13**). Complex **8** was synthesized using Sub-Pc substituted with six *tert*-butylphenol groups and ring expanding with unsubstituted dicyanobenzene (**8**). Complex **9** was sythesized from dicyanobenzene disubstituted with *tert*-butylphenol. Complex **14** was synthesized from subnaphthalocyanine (Sub-NPc, **3b**, Scheme 2) and ring expanding with dicyanobenzene (**4**). In all cases an excess of the dicyanobenzene (over the Sub-Pc or Sub-NPc) was employed. The complexes gave satisfactory spectroscopic analyses, confirming the absence of chlorinated derivatives. The formation of the ZnPc derivatives was monitored using UV–Vis spectroscopy, Fig. 1. An expected decrease in the absorption band of the Sub-Pc in the 570 nm region and the simultaneous formation of the Q and B bands of the phthalocyanine was observed. The reaction was complete within 1–4 h depending on the complex. Complex **5** required only 1 h, while the rest of the complexes needed 2–4 h. Reaction times much longer than these have been reported for these types of reactions [29]. The lack of clear isosbestic points in Fig. 1, could be due to the presence of differently ring substituted isomers.

Yields of the ZnPc derivatives were comparable or higher than those reported in the literature [29] for synthesis of Pcs from Sub-Pcs. The complexes were soluble in DMF or DMSO to a varying degree. Complexes containing *tert*-butylphenol substituents or hydroxybenzoic acid were found to be more soluble. Complexes **1**–**9**, **12** and **13** were soluble in chloroform. Elemental analysis was not obtained for some of the complexes because of the difficulty in obtaining reliable results due to the presence of differently ring substituted isomers.

In general the spectra of the complexes was typical of non-aggregated species at concentrations lower than 1×10^{-5} mol dm^{-3}, as judged the fact that Beer's law was obeyed, Fig. 2. The Q band wavelengths of complexes under discussion ranged from 669 (complex **7**) to 682 nm (complex **13**) in DMF, Table 2. The Q band maximum for complex **13** is shifted to longer wavelengths compared with the rest of the complexes. This complex contains two different type of substituents: *tert*-butylphenol and hydroxybenzoic acid on the phthalocyanine ring, while the rest of the complexes contain one type of substituent. It is well known [30] that the Q band shifts to longer wavelengths with enlargement of π-conjugated system and that the shifts became less, the larger the molecules. On going from complex **5**–**9**, the bulkiness of the molecule increases as the number of *tert*-butylphenol groups is increased from 1 (**5**) to 8 (for **9**). For these complexes, the wavelength of the Q band increases as follows: **6** (678) > **5** (675) > **8** (670) = **9**

Scheme 2.

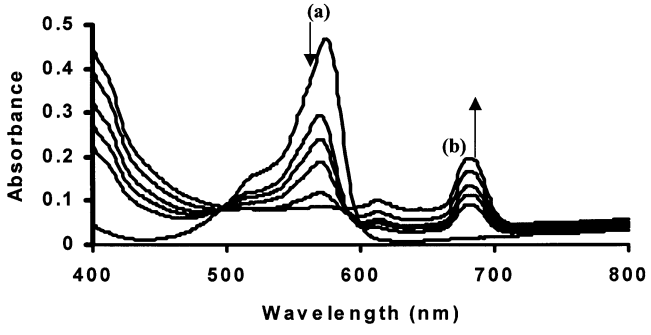


Fig. 1. Changes in UV–Vis spectra during the formation of ZnPc derivatives from Sub-Pc. Spectra at the start (a), and at the end (b), of the reaction. Solvent, DMF.

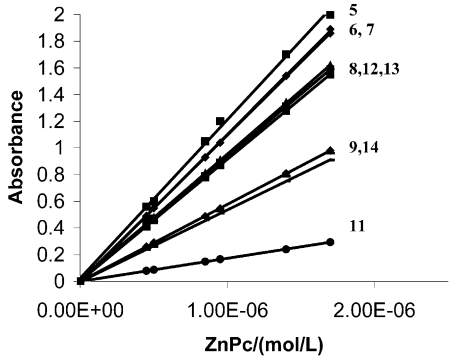

Fig. 2. Beer's law dependence of the ZnPc derivatives in DMF.

(670) ~ **7** (669 nm). Thus the Q band wavelength is shorter for the more bulky molecules (complexes **7**, **8** and **9**) and longer for less bulky molecules (complexes **5** and **6**), in agreement with the literature [30]. The shift to longer wavelength could be due to either the destabilization of the highest occupied molecular orbital (HOMO) or the stabilization of the lowest unoccupied molecular orbital (LUMO). It has been observed that the shifting of the Q band observed on increasing the π-system, is due mainly to the destabilization of the HOMO. Lack of symmetry in phthalocyanines results in the splitting in the Q band [29]. Fig. 3 shows a representative spectra of the complexes, and no split in the Q band was observed showing that the complexes still have some symmetry.

Infrared spectra observed for the phthalocyanine complexes are all very similar. All the compounds with the exception of **11** and **14**, show a band at ~1200 cm^{-1} (C–O–C vibration) which is characteristic of a phenyl ether functionality.

Table 2
Quantum yields for singlet oxygen and photobleaching for the ZnPc derivatives in DMSO

Complex	$\lambda_{Q\ band}$ (nm)	Φ_{Δ} [a]	$10^5\ \Phi_{photobleaching}$
5	675	0.68 (114)	3.9
6	678	0.49	4.1
7	669	0.57 (240)	5.8
8	670	0.51 (129)	6.5
9	670	0.52	3.3
10	670	0.43	4.1
11	670	0.49	3.8
12	671	0.40	3.7
13	682	0.22	3.3
14	672	0.32	3.0

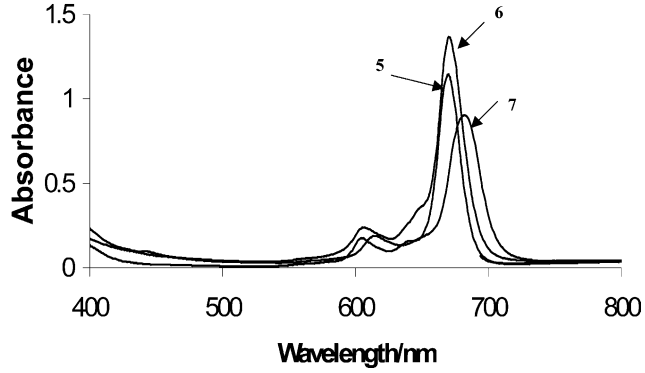

Fig. 3. Electronic absorption spectra of selected complexes (**5**–**7**) in DMF. Concentration = 5×10^{-6} mol dm^{-3}.

^{1}H NMR spectra of the complexes was recorded in *d*-DMSO. Characteristic resonances due to the peripheral (1,4 positions, see Schemes 1 and 2 for numbering) protons of the phthalocyanes were observed as mainly singlets between 8.5 and 9.8 ppm, integrating for a total of eight protons. A doublet was observed for these protons for complex **14**. In addition, 2,3 protons for the phthalocyanine ring were observed at resonances ranging from 8.0 to 9.0. For mono-substituted ZnPc derivatives (**5** and **11**) a singlet integrating for a total of seven protons (2,3 protons) was observed for each complex. For di-substituted ZnPc derivatives (**6**, **10** and **12**), singlets or doublets integrating for six protons was observed for each complex. Tri-substituted complex (**7**) gave a multiplets integrating for a total of five protons, and for the hexasubstituted complex (**8**), a singlet integrating for two protons was observed as expected. Tetrasubstituted complex **13** gave a singlet for the 2,3 protons of the phthalocyanine ring, integrating for a total of four protons, Complex **9** is octasubstituted hence contained no 2,3 protons.

The substituents on the phthalocyanine ring showed resonances due to the aromatic rings and these integrated correctly. In the Section 2, the ring protons of the substituents are denoted as 2′,4′-H or 1′,5′-H, and the numbering is shown for complex **5** in Scheme 1.

3.2. Voltammetric studies

The redox properties of the ZnPc derivatives were studied using both CV and Osteryoung square wave voltammetry (OSWV) in DMF containing TBAP. Figs. 4 and 5 show the cyclic voltammogram and square wave voltammograms for complexes **8** and **5**, respectively. Two reduction couples labeled **II** and **III** was observed, and oxidation couple(s) (labeled as **I** or **Ia** and **Ib**) were also observed. The cyclic voltammograms for the first scan were similar to those of the second and subsequent scans, suggesting that no complicated reactions occurs following oxidation or reduction. For all couples, the cathodic to anodic peak currents (ip_c/ip_a) were near unity, and cathodic to anodic peak separation ranged from 80 to 150 mV, suggesting reversible to quasi-reversible behavior. The cathodic to anodic peak separation was found to be 80 mV for the Fc^+–Fc couple. The peak currents increased linearly with the square root of scan rates, for scan rates ranging from 5 to 800 mV s^{-1}, indicating that the electrode reactions are purely diffusion-controlled. The broadness of some of the redox couples could be a result of the presence of isomers.

All processes are ring based since the central Zn metal is electroinactive [32]. Using controlled potential coulometry, couples **II** and **III** are assigned to ring reduction in ZnPc derivatives and the formation of Pc^{-3}–Pc^{-2} and Pc^{-4}–Pc^{-3}, respectively. The separation between the first and second ring reductions was found to range between 0.4 and 0.5 V in agreement with the separation reported [32] for ring based reductions in non-transition metal phthalocyanines. For complex **5**, Fig. 5, two closely spaced couples (**Ia** and **Ib**) were observed for the oxidation process. For complex **8**, the splitting was more easily observed in the SWV, Fig. 4. The splitting

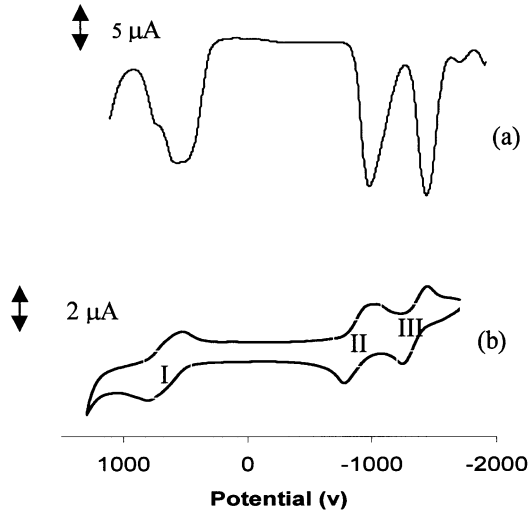

Fig. 4. Osteryoung square wave voltammogram (a) and cyclic voltammogram (b) of 1×10^{-4} mol dm^{-3} of complex **8** in DMF containing 0.1 mol dm^{-3} TBAP. Scan rate = 100 mV s^{-1}.

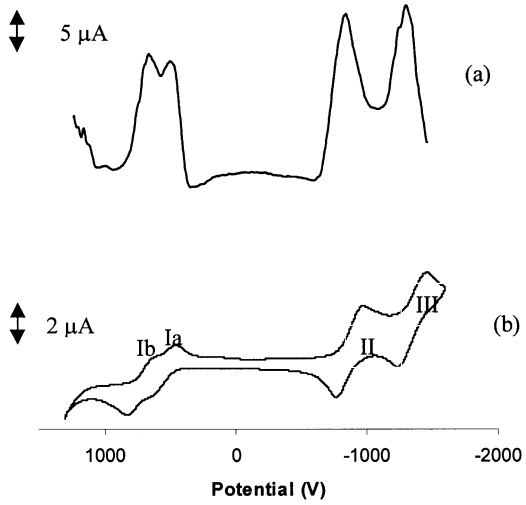

Fig. 5. Osteryoung square wave voltammogram (a) and cyclic voltammogram (b) of 1×10^{-4} mol dm^{-3} of complex **5** in DMF containing 0.1 mol dm^{-3} TBAP. Scan rate = 100 mV s^{-1}.

was observed to varying extents for the ZnPc derivatives. The observation of two closely spaced oxidation peaks has been attributed to the presence of both the aggregated and unaggregated substituted ZnPc complexes in solution [32]. At the concentrations employed for voltammetric studies in this work ($\sim 10^{-4}$ mol dm^{-3}), aggregation of the ZnPc derivatives is expected and was confirmed by the broadening of the spectra at these concentrations. The observation of two closely spaced oxidation peaks could also be a result of the presence of isomers. Thus the two couples observed for the oxidation process in Fig. 5, are attributed to the ring oxidation of the aggregated and non-aggregated species. Table 3 compares the half-wave potentials ($E_{1/2}$) for complexes **5**, **7**, **8** and **9** containing increasing number of *tert*-butyl phenol substituents. The Pc ring becomes easier to reduce and more difficult to oxidize as the number of *tert*-butyl phenol substituents increase from 1 (complex **5**) to 8 (complex **9**), Table 3. The presence of electron donating methyl groups is expected to make the ring more difficult to reduce and easier to oxidize. Thus it is expected that as the number of *tert*-butyl phenol substituents increases, the ring should be more difficult to reduce and easier to oxidize. The reverse is observed in Table 3.

3.3. Photobleaching and singlet oxygen studies

Photobleaching of complexes is characterised by complete disappearance of the spectra due to the degradation of the phthalocyanine ring. Photobleaching studies were undertaken in order to determine the effects of the different substituents on the stability of the ZnPc derivatives in the presence of light.

Photobleaching studies were performed in DMSO and the quantum yields for photobleaching are listed in Table 2. Photobleaching quantum yields were of the order of 10^{-5} for all the complexes. Photodecomposition of phthalocyanine complexes usually occurs through oxidative cleavage [33]. Comparing complexes which contain an increasing number of the *tert*-butyl phenol substituents (**5**–**9**), we observe a low photobleaching quantum yield (hence higher stability) for complex **9** which was shown to be more difficult to oxidize by electrochemical methods, hence confirming that oxidative degradation occurs for these complexes. Complex **5** was easier to oxidize electrochemically, but is relatively stable, suggesting that it is not only the oxidative mechanism which plays a part in the degradation of the ring in these ZnPc derivatives. It is normally accepted [33] that during photodegradation of MPc complexes O_2 ($^1\Delta_g$) is generated which attacks the phthalocyanine ring. However, the attack of O_2 ($^1\Delta_g$) on the Pc ring may also be affected by the shielding effects of the ring substituents [34]. It has been shown [33,34] that the singlet oxygen interacts with the phthalocyanine, resulting in the macrocycle destruction and formation of phthalimide as the product of photodegradation.

Quantum yields of photobleaching increased when oxygen was bubbled to solutions, confirming that oxidative degradation occurs. Inhibition of the photobleaching process in the presence of the singlet oxygen quencher, DABCO, Fig. 6 is in agreement with the involvement of singlet oxygen in the degradation of the phthalocyanine macrocycle.

Quantum yields of singlet oxygen photogeneration (Φ_Δ) of compounds **5**–**14** are listed in Table 2. These values range from 0.22 to 0.68. No photobleaching of the complexes was observed during the determination of singlet oxygen quantum yields, since these processes

Table 3
Comparison of redox potentials for complexes **5**, **7**, **8** and **9** substituted with varying numbers of *tert*-butyl phenol substituents

Complex	Number of *tert*-butyl phenol substituents	$E_{1/2}$ (V vs. SCE)		
		I Pc^{-1}–Pc^{-2}	**II** Pc^{-2}/Pc^{-3}	**III** Pc^{-3}–Pc^{-4}
5	1	0.35, 0.55	−1.08	−1.56
7	3	0.75	−0.82	−1.32
8	6	0.70	−0.84	−1.32
9	8	0.97	−0.68	−1.12

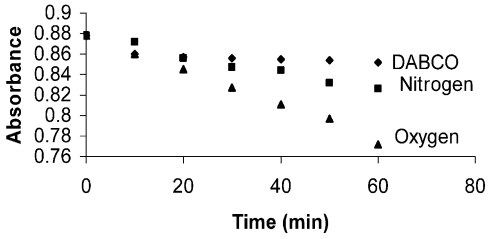

Fig. 6. Kinetic curves for the photobleaching of complex **5** in DMSO saturated with oxygen and nitrogen, and containing DABCO (2×10^{-3} mol dm^{-3}).

occur much slower than singlet oxygen production. It is well known that aggregation of the phthalocyanine complexes results in decreased photochemical activity due to enhanced probability of radiationless decay of excited states. The concentration employed for Φ_Δ and photobleaching studies was 1×10^{-6} mol dm^{-3}, hence no aggregation is expected according to Fig. 2. Comparing complexes which, contain an increasing number of the *tert*-butyl phenol substituents (**5**–**9**), complex **5** with one substituent gave the largest value for Φ_Δ. Triplet life times (τ_T) were determined for complexes **5**, **7** and **8** and are listed in Table 3. Of the three complexes, the largest τ_T value was observed for complex **7** and the lowest for **5** even though the later has the highest Φ_Δ value. A direct correlation between Φ_Δ, and τ_T or Φ_Δ was also not evident for substituted MPc complexes reported in the literature [3]. The lowest Φ_Δ value was observed for complex **14** containing naphthalene units.

In conclusion voltammetric behavior of the substituted ZnPc derivatives under discussion show that as the number of *tert*-butyl substituents increase, the complexes become more difficult to oxidize and easier to reduce. The complexes are relatively stable to photodegradation with quantum yields of photobleaching of the order of 10^{-5}. The majority of the complexes have singlet oxygen quantum yields in the 0.4 and 0.5 region, hence show promise as candidates for PDT.

2.2. X-ray crystallography

2.2.1. Crystal data

$C_{20}H_{20}CuN_4O_5$, $M_r = 459.94$, monoclinic, space group $C2/c$, $a = 14.6748(7)$, $b = 18.0138(9)$, $c = 8.3678(4)$ Å, $\beta = 115.946(5)^\circ$, $V = 1989.1(2)$ Å^3, $Z = 4$ (cell parameters from 7810 reflections).

2.2.2. Data collection

A blue, prismatic crystal of dimensions $0.4 \times 0.3 \times 0.2$ mm was used for data collection at 293 K on a Kuma KM4CCD diffractometer [7] with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) using ω scans, $3.73^\circ < \theta < 27.50^\circ$, $-19 \le h \le 18$, $-23 \le k \le 23$, $-9 \le l \le 10$, 11 174 measured reflections, 2272 independent reflections, 2228 reflections with $I > 2\sigma(I)$, $R_{int} = 0.0177$. Extinction coefficient 0.0020(3). No significant decay. Numerical absorption correction, min./max. transmission 0.598/0.701 [8,9].

2.2.3. Structure analysis and refinement

The title structures were solved by the conventional Patterson method and refined by full-matrix least-squares calculations on F^2 using programs SHELXS-97 and SHELXL-97 [10,11]. The large displacement factors of two central C atoms of the dicarboxylate ion indicated disordered localization of the aliphatic chain. Two different positions (a and b) of C12 were established with occupancy factors of 0.725 and 0.275, respectively. All non-H atoms were refined anisotropically. A weighting scheme of the form $w = 1/[\sigma^2(F_o^2) + (0.0223P)^2 + 2.3576P]$, where $P = (F_o^2 + 2F_c^2)/3$ was applied. The H atom connected to the C12b atom was included in a calculated position with C–H = 0.93 Å and refined using a riding model, with a fixed isotropic displacement factor taken as $1.2U_{eq}$ of the bonded C12b atom. All other H atoms were located from a difference synthesis and refined isotropically. The largest difference peak was 0.293 e Å^{-3}, largest hole −0.287 e Å^{-3}. The final data: parameter ratio was 12.0:1, goodness-of-fit = 1.097, $R[F^2 > 2\sigma(F^2)] = 0.0248$, $wR(F^2) = 0.0596$.

2.3. Magnetism

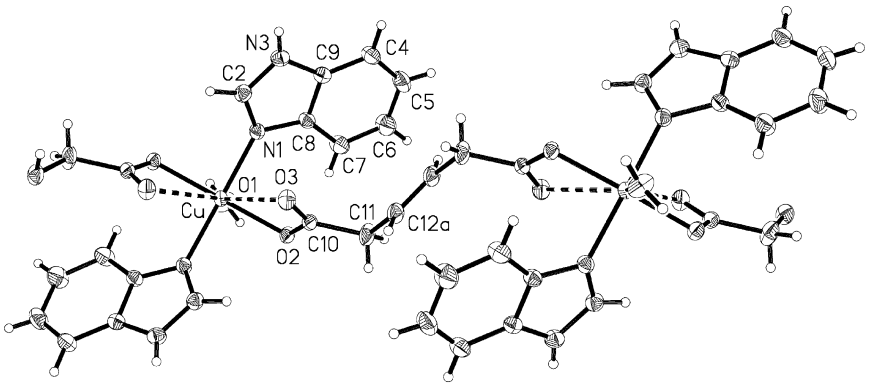
Magnetic susceptibility measurements in the temperature range 1.7–300 K were carried out on powdered samples of the complexes, at a magnetic field of 5 kG using a Quantum Design SQUID magnetometer (type MPMS-5). Powdered samples used for magnetic measurements were prepared from the single crystals. They were measured twice from different samples using the Faraday method and SQUID, the results were the same in each case. This is the confirmation of the magnetic purity of the samples. Corrections for diamagnetism of the constituent atoms were calculated using Pascal constants [12].

The value 60×10^{-6} cm^3 mol^{-1} was used as the temperature-independent paramagnetism of the Cu(II) ion. The effective magnetic moment was calculated per Cu atom from the equation $\mu = 2.83\sqrt{\chi_M T}$ B.M., where χ_M is the molar magnetic susceptibility corrected for diamagnetism of the constituent atoms.

EPR spectra were recorded at room temperature and 77 K on a Bruker ESP 300 spectrometer operating at X-band equipped with an ER 035M Bruker NMR gaussmeter and a HP 5350B Hewlett–Packard microwave frequency counter.

Reflectance d–d spectra of undiluted compounds were measured on a Beckmann UV5240 spectrophotometer in the 250–2000 nm range.

3. Results and discussion



3.1. Crystal structure

A fragment of the polymeric structure of the title compound **I** is shown in Fig. 1(a). It is isostructural with μ-adipato complex **II** [2]. The Cu atom and H_2O molecule are located on the twofold axis. The Cu atoms are connected by bridging tetradentate *trans*-2-butene-

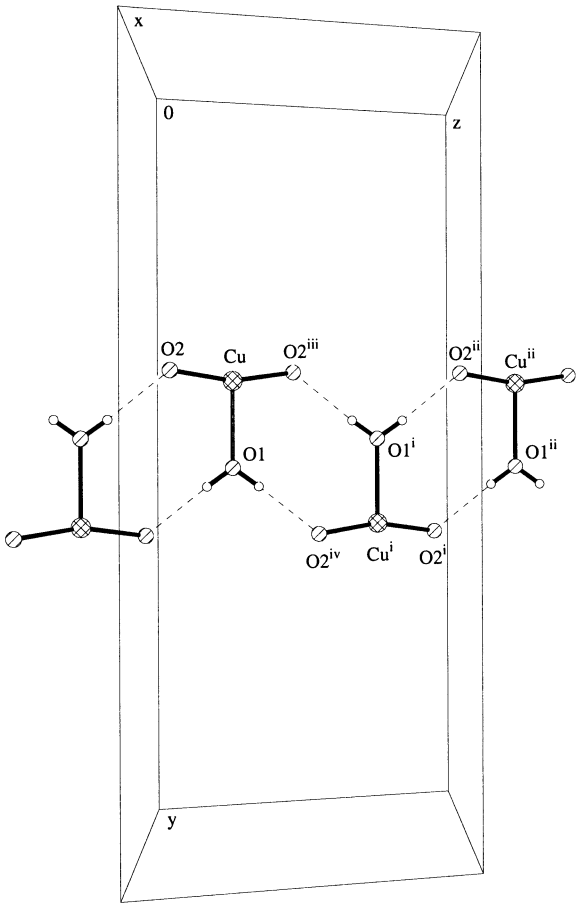

Fig. 1. (a) A fragment of the polymeric structure of **I**. Displacement ellipsoids are drawn at the 30% probability level. (b) The arrangement of the polymeric chains, the hydrogen bonds and Cu···Cu contacts. H atoms not involved in the hydrogen bonding and Cu···O3 semicoordinate bonds are omitted for clarity.

1,4-dicarboxylate ions to form polymeric chains, which are extended in a zigzag form along [10$\bar{1}$]. Fig. 1(b) shows the arrangement of the polymeric chains, interchain hydrogen bonds and Cu···Cu contacts. Selected bond lengths and angles are given in Table 1.

Two N1 atoms (one from each benzimidazole group) and two O2 atoms (one from each carboxylate group) form Cu–N1 and Cu–O2 bonds of lengths 2.0065(13) and 2.0152(10) Å, respectively. The Cu–H_2O bond of 2.230(2) Å completes the coordination to an elongated pyramid, which is completed to a pyramid with a double-capped base by two long, semicoordinate Cu–O3 bonds of 2.9078(11) Å.

The bidentate carboxylic group is not in the ideal coplanar position with the Cu atom, giving a Cu–O2–C10–O3 torsion angle of 17.6(2)°, distinctly more than the value of 10.2(2)° in the adipato complex **II**.

The neighbouring $[Cu(H_2O)(C_7H_6N_2)_2(C_6H_6O_4)]_\infty$ chains are connected by a hydrogen bond system formed by O–H···O, O···H–N and O···H–C contacts (Table

symmetry codes: ^{i} *-x, -y+1, -z+1;* ^{ii} *x, y, z+1;* ^{iii} *-x, y, -z+1/2;* ^{iv} *x, -y+1, z+1/2*

Fig. 2. The ribbon of condensed centrosymmetric rings formed by the O2···H–O1–H···O2 hydrogen bonds between the shortest separated Cu atoms in the structures **I** and **II**.

2, Figs. 1(b) and 2). In **I** the O1–H1···O2 and C4–H4···O3 bonds are shorter than in **II**. The distances O1···O2 and C4···O3 are 2.860(1) and 3.413(2) Å in **I** and 2.917(3) and 3.460(3) Å in **II**, respectively.

In **I** and **II** the Cu···Cu spacing between neighbouring atoms in the polymeric chains are 11.2383(6) and 10.926(1) Å, respectively. The shorter Cu···Cu distances (5.5896(3) Å in **I** and 5.6109(8) Å in **II**) are observed between the interchain Cu atoms located on the $x = 0$ plane of the unit cell. As it is shown on Fig. 2, they are closed by two hydrogen bonds in eight-membered centrosymmetric condensed rings, which form a continuous nearly planar ribbon extended along the z axis. In the continuous –Cu–O2···H1–O1–H1···O2–Cu– chain along the translation vector c, Cu···Cu distances are 8.3678(4) and 8.535(1) Å in **I** and **II**, respectively.

The N3–H3···O3 and C4–H4···O3 hydrogen bonds (see Fig. 1(b)) are formed between the Cu-semicoordinated O3 atoms and a benzimidazole molecule of the neighbouring polymeric chain. The interchain Cu···Cu separations are of 8.5190(5) and 8.494(1) Å in **I** and **II**, respectively. In the 12-membered rings the H3···O3 distances of 1.93(2) and 2.03(3) Å in **I** and **II**, respectively, are comparatively short.

To compare the relative importance of Cu–N and Cu–O bonds of Cu(II) polyhedra in **I** and **II** and to check the assumed Cu(II) coordination numbers, the

Table 3
Valence sums around the Cu atoms in **I** and **II**

Cu–j	**I**		**II**	
	d_{Cu-j} (Å)	v_{Cu-j} (v.u.)	d_{Cu-j} (Å)	v_{Cu-j} (v.u.)
Cu–N1	2.005(2)	0.454 [a]	2.007(2)	0.452 [a]
Cu–O1	2.229(2)	0.226	2.245(4)	0.217
Cu–O2	2.013(1)	0.405 [a]	2.010(2)	0.409 [a]
Cu–O3	2.907(1)	0.036 [a]	2.930(2)	0.034 [a]
V_{Cu}	2.016		2.007	

d_{Cu-j} are the observed bond lengths between Cu and j atoms, v_{Cu-j} is the computed bond valence (v.u.) and $V_{Cu} = \Sigma\ v_{Cu-j}$.
[a] Occurs twice around the Cu atom.

valences of Cu bonds (v_{Cu-j}) and of Cu atoms (V_{Cu}) were computed (Table 3). The bond valences were computed according to Brown [13,14] and O'Keeffe and Brese [15], as $v_{Cu-j} = \exp[(R_{Cu-j} - d_{Cu-j})/0.37]$, where R_{Cu-j} are the bond valence parameters (in the formal sense R_{Cu-j} is the bond length between Cu and j atoms for $v_{Cu-j} = 1$); d_{Cu-j} are the Cu–j bond lengths. R_{Cu-N} was determined by us from the Cambridge Structural Database [16] as 1.713 Å [5]. R_{Cu-O}, according to Brese and O'Keeffe [17], was taken as 1.679 Å. In both structures the valences of the Cu atoms are consistent with the valence-sum rule ($V_i = \Sigma\ v_{ij}$), which gives $V_{Cu} = 2.016$ and 2.007 v.u. (v.u., valence unit) for **I** and **II**, respectively.

In the Cu(II) polyhedra, the Cu–N bonds are stronger than the short Cu–O2 bonds (average $v_{Cu-N} = 0.453$ v.u. and average $v_{Cu-O2} = 0.407$ v.u.). The average valence of the longer axial Cu–O1 bond is 0.221 v.u., distinctly greater than usually observed in Cu(II) square-pyramidal complexes. The average valences of the two very long Cu–O3 bonds are only 0.035 v.u., but neglect of these bonds disturbs the valence sum rule.

3.2. Magnetism

Both complexes present quantitatively similar magnetic properties. The results of susceptibility measurements are illustrated in Figs. 3 and 4 in the form $\chi_{Cu}T$ versus T (χ_{Cu} being the corrected molar magnetic susceptibility per Cu(II) and T the absolute temperature).

The room temperature $\chi_{Cu}T$ values (0.429 and 0.418 $cm^3\ K\ mol^{-1}$ for **I** and **II**, respectively) correspond well to that expected for isolated, magnetic Cu(II) centres. The $\chi_{Cu}T$ value is constant up to 10 K and then with lowering temperature decreases rapidly and reaches values 0.304 $cm^3\ K\ mol^{-1}$ in **I** and 0.318 $cm^3\ K\ mol^{-1}$ in complex **II** at 1.72 K. It suggests a weak antiferromagnetic interaction between the Cu(II) centres in the crystal lattice.

The crystal structure in both cases is composed of polymeric chains where Cu centres are connected by bridging of tetradentate 2-butane-l,4-dicarboxylate ions in **I** and tetradentate μ-adipate ligands in **II**. An interesting feature of these structures is three-dimensional hydrogen bond system (Fig. 1(b), Fig. 2).

It is well known that a bridging moiety is most effective in supporting an antiferromagnetic exchange interaction between two transition magnetic ions if the bridge has available molecular orbitals that can interact with the bonding combination of two metal d orbitals [18,19]. It was shown earlier that the adipate bridging unit will not propagate any interaction due to the small and incomplete effective overlap at the chain C–C

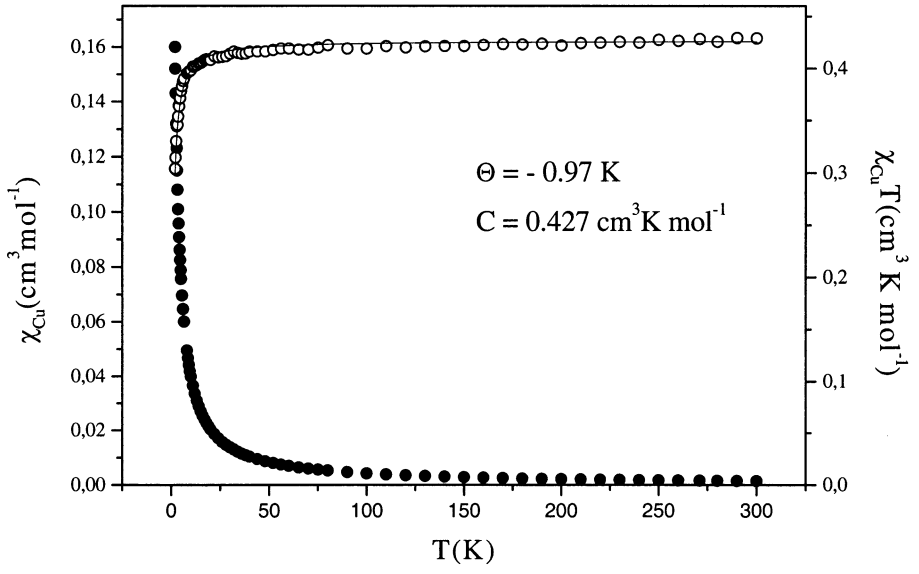

Fig. 4. Plots of χ_{Cu} and $\chi_{Cu}T$ vs. T for **II**. Solid line: theoretical fit of the data with the parameters listed in the text.

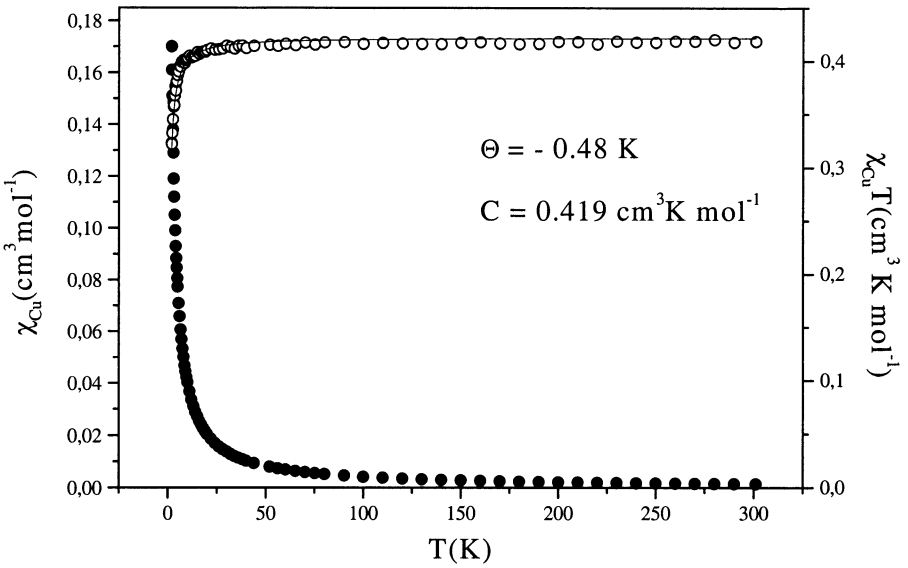

Fig. 3. Plots of χ_{Cu} and $\chi_{Cu}T$ vs. T for **I**. Solid line: theoretical fit of the data with the parameters listed in the text.

interactions [20,21]. Nevertheless, the capability of both hydrogen bonds and carboxylate groups will be examined.

Magnetic data were analyzed using the Ising expression:

$$\chi_M = \frac{Ng^2\beta^2}{4kT}\exp\left(-\frac{J}{kT}\right)$$

for infinite chains of Cu ions [19], the J value characterizes intrachain interactions, the spin Hamiltonian is defined as $H = -J\,\Sigma\, S_iS_{i+1}$.

A molecular field term was added to describe interchain interactions:

$$\chi_M^{mf} = \frac{\chi_M}{1 - \dfrac{2zJ' - \chi_M}{Ng^2\beta^2}}$$

where χ_M is the molar susceptibility given by Ising's

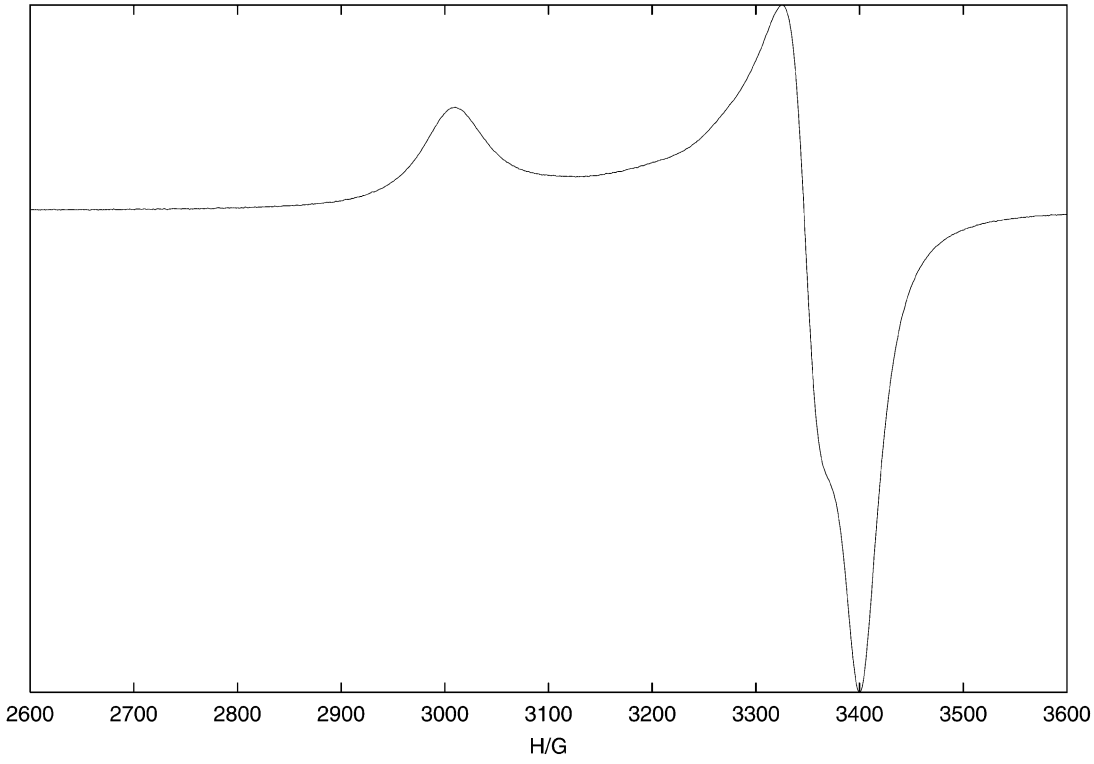

Fig. 5. Polycrystalline powder EPR spectrum of **I**, at 77 K. Compound **II** presents the same type of spectrum, parameters are listed in the text.

expression, J' characterizes interchain interaction between z Cu(II) neighbours.

A least-squares fit of the data leads to the values of $J = -0.58$ cm^{-1}, $zJ' = +0.38$ cm^{-1}, $g = 2.13$ and $R = 1.8 \times 10^{-5}$ for **I** and $J = -0.63$ cm^{-1}, $zJ' = +0.80$ cm^{-1}, $g = 2.12$ and $R = 1.8 \times 10^{-5}$ for **II**. R is the agreement factor defined as $R = \Sigma_i [(\chi_{Cu}T)_{obs}(i) - (\chi_{Cu}T)_{calc}(i)]^2/\Sigma_i [(\chi_{Cu}T)_{obs}(i)]^2$. Intrachain antiferromagnetic interaction, although weak, compensates ferromagnetic interchain contribution and is dominant in both complexes.

The temperature dependence of χ_{Cu}^{-1} is represented by a Curie–Weiss law with $\theta = -0.97$ K and $C = 0.427$ cm^3 K mol^{-1} for **I** and $\theta = -0.48$ K and $C = 0.419$ cm^3 K mol^{-1} for complex **II**, and confirms weak antiferromagnetic interaction between Cu(II) centres in the crystal lattice.

Average spectroscopic splitting parameters obtained from the EPR spectra and from the fitting process are in good agreement. The EPR spectra of the polycrystalline samples of both complexes **I** and **II** are temperature independent and show a pseudorhombic pattern (Fig. 5), consisting of three g values: **I**, 2.32_4, 2.08_8, 2.05_7 ($g_{av} = 2.15_3$) and **II**, 2.31_7, 2.08_8, 2.05_3 ($g_{av} = 2.15_2$). It is a result of the existence of partial mixing of the d_{z^2} orbital into the $d_{x^2-y^2}$ magnetic orbital [22]. This EPR aspect is in fairly good agreement with the Cu geometries obtained from the crystal structures.

The d–d spectra of complexes **I** and **II** consist of broad bands, centered at 655 nm in **I** and at 705 nm in **II**. The shift toward lower energy can be related to a lower ligand field in complex **II** with the adipate anion.

4. Supplementary material

Further details of the crystal structure investigation are available from the Cambridge Crystallographic Data Centre, CCDC no. 172444 (compound catena-((μ2-*trans*-2-butene-1,4-dicarboxylato-O,O′:O″,O‴)-aquabis-(benzimidazole-N^3)copper(II)). As compared to the bridged dinuclear ruthenium(II) complexes, studies made with the diosmium(II) analogues are less numerous; still less studies have been reported for heterodinuclear $Os^{II}Ru^{II}$ complexes. In two previous publications [14,15] we have reported the structures, spectroscopic properties and proton-coupled electron transfer reactions of diastereoisomerically pure diruthenium(II) polypyridal complexes involving pyrazole-3,5-bis(benzimidazole) [H_3pzbzim] and pyrazole-3,5-bis(benzothiazole) [Hpzbzth] as the bridging ligands. To extend this study for the homo- and heterodinuclear osmium(II) complexes, we report here the synthesis and compare the properties of the mononuclear osmium(II) complexes of H_3pzbzim with the ruthenium(II) analogues.

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and used as received. Pyrazole-3,5-bis(benzimidazole) [15] and $[Os(bpy)_2Cl_2]$ [16] were prepared by the literature methods. Robinson–Britton [17] buffer solutions of pH range 2–12 were used. The supporting electrolyte tetraethylammonium perchlorate (TEAP) was prepared according to the reported method [18] and recrystallized thrice from hot water.

2.2. Preparation of the complexes

2.2.1. $[(bpy)_2Os(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (1)

A mixture of $[Os(bpy)_2Cl_2]$ (0.29 g, 0.5 mmol) and H_3pzbzim (0.30 g, 1.2 mmol) in 50 cm^3 of EtOH–water (1:1) mixture was heated under reflux in nitrogen atmosphere with constant stirring for 60 h. After removal of the unreacted ligand, the dark red filtrate was rotary evaporated to approximately 20 cm^3 and to it was then added an aqueous solution (5 cm^3) of $NaClO_4$ (1 g). A dark microcrystalline product that separated was filtered and recrystallized from MeOH–water (1:1) containing a few drops of $HClO_4$ (1 mmol dm^{-3}). Yield: 0.21 g, 40%. *Anal.* Found: C, 42.7; H, 3.15; N, 13.6. $C_{37}H_{32}Cl_2N_{10}O_{10}Os$ requires: C, 42.8; H, 3.1; N, 13.5%. IR (KBr): 3400br, 1640s, 1600s, 1485m, 1470s, 1430m, 1390w, 1290m, 1270w, 1240w, 1100s, br, 785s, 760s, 740m, 675m, 650w, 630s, 600w cm^{-1}.

2.2.2. $[(bpy)_2Os(Hpzbzim)]\cdot 2H_2O$ (2)

To a stirred MeOH solution (20 cm^3) of (**1**) (0.12 g) was added a piece of freshly cut sodium metal (approximately 0.05 g). In a few minutes, a dark red microcrystalline product deposited. This was collected by filtration and thoroughly washed with MeOH. Yield: 0.08 g, almost quantitative. *Anal.* Found: C, 53.25; H, 3.5; N, 16.65. $C_{37}H_{30}N_{10}O_2Os$ requires: C, 53.1; H, 3.6; N, 16.75%. IR (KBr): 3400br, 1610m, 1575w, 1470s, 1460s, 1420m, 1380w, 1320w, 1280m, 1220w, 1050w, 1010m, 750s, 735w, 680m cm^{-1}.

$[(bpy)_2Ru(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (**3**) and $[(bpy)_2Ru(Hpzbzim)]\cdot 2H_2O$ (**4**) were prepared according to the earlier reported procedures [15].

CAUTION! The perchlorate salts reported in this study are potentially explosive and therefore should be handled with care.

2.3. Physical measurements

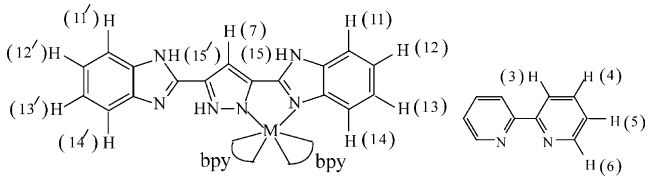
The C, H and N analyses were performed on a Perkin–Elmer 2400II elemental analyzer. Infrared spectra were recorded on a Perkin–Elmer 783 spectrophotometer using KBr discs. ^1H and $\{^1H$–$^1H\}$COSY NMR spectra were recorded on a Bruker Avance DPX 300 spectrometer using $(CD_3)_2SO$ solutions.

The electrochemical measurements were carried out with a BAS 100B electrochemistry system. A three-electrode assembly comprising a Pt or glassy carbon working electrode, Pt auxiliary electrode, and an aqueous Ag/AgCl reference electrode were used. The cyclic voltammetric (CV) and differential pulse voltammetric (DPV) measurements were carried out at 25 °C in MeCN solution of the complexes (approximately 1 mmol dm^{-3}) with TEAP (0.1 mol dm^{-3}) as the supporting electrolyte. The electrochemical measurements were carried out with oxygen-free solutions made by purging with purified nitrogen. The reference electrode was separated from the bulk electrolyte by a salt bridge containing TEAP (0.1 mol dm^{-3}) in MeCN–water (1:1). The potentials measured were compensated for the *iR* drop in the cell. Under the experimental condition used the reversible oxidation of the ferrocene/ferrocenium ion was observed at 0.36 V.

For variable-pH electrochemical measurements, MeCN–aqueous (3:2) solutions of the complexes were used. The pH measurements were made with a Beckman Research Model pH meter. The pH meter responded reproducibly to the variation of hydrogen ion concentration and as such, the pH meter readings were referred to as pH. The $E_{1/2}$ value of the ferrocene/ferrocenium couple in the above solvent mixture at approximately pH 7 is 0.26 V.

Electronic spectra were recorded on a Shimadzu UV-2100 spectrophotometer. To determine the pK_a values of the complexes spectrophotometric titrations were carried out with a series of MeCN–aqueous buffer (3:2) solutions containing the same amount (10^{-5} mol dm^{-3}) of complex and pH adjusted in the range 2–12. The oxidative titrations were also followed spectrophotometrically by incremental addition of a solution of ceric(IV) ammonium nitrate in MeCN–water (3:2) to a solution of the complex in the same solvent mixture. Emission

spectra were recorded on a Hitachi F-4500 fluorescence spectrophotometer using MeOH–EtOH (1:4) solution of the complex (at 300 K) and glass (at 77 K).



3. Results and discussion

The reaction between one equivalent each of *cis*-$[(bpy)_2OsCl_2]$ and pyrazole-3,5-bis(benzimidazole) [H_3pzbzim] leading to the substitution of the two chloride ions by the two imine nitrogen donors of the incoming ligand is kinetically slow. The product was isolated as $[(bpy)_2Os(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (**1**) (in 40% yield) after 60 h reaction. Complex (**1**) is asymmetric because only one part of the bridging ligand H_3pzbzim is involved in metal binding, while the other part remains free. As will be seen, consequent to complexation, the NH groups in closer proximity to the metal centre in (**1**) become considerably more acidic relative to those in the free ligand. In particular, the pyrazole NH gets partially deprotonated in solution, thus, requiring recrystallization of (**1**) to be carried out in mildly acidic solution. Complex (**1**) gets deprotonated to $[(bpy)_2Os(Hpzbzim)]\cdot 2H_2O$ (**2**) on treatment with sodium alkoxide or triethylamine. As reported earlier [15], compared to (**1**), the formation of $[(bpy)_2Ru(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (**3**) takes place more readily.

3.1. ^1H NMR spectra

The ^1H and $\{^1H–^1H\}$COSY NMR spectra for complexes $[(bpy)_2Os(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (**1**), $[(bpy)_2Os(Hpzbzim)]\cdot 2H_2O$ (**2**), $[(bpy)_2Ru(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (**3**) and $[(bpy)_2Ru(Hpzbzim)]\cdot 2H_2O$ (**4**) have been recorded in $(CD_3)_2SO$ solutions at room temperature. The numbering scheme used to assign the observed resonances is given in Scheme 1.

The ^1H NMR spectra for complexes (**1**)–(**4**) are shown in Figs. 1–4, respectively. The asymmetric nature of the complexes are evident from the occurrence of fairly large number of resonances, many of which, especially in (**1**), are overlapped with each other. The COSY spectra have been particularly useful to locate spin couplings in the aromatic protons of the benzimidazole moiety bound to the metal as against the uncoordinated one. The assignments of the bipyridine protons were facilitated by taking into consideration of

Scheme 1.

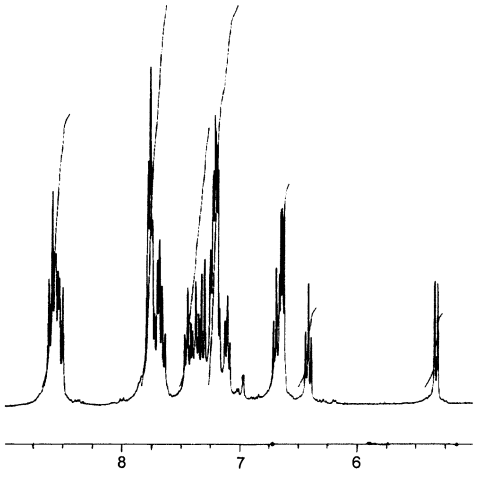

Fig. 2. ^1H NMR spectrum of $[(bpy)_2Os(Hpzbzim)]$ (**2**) in $(CD_3)_2SO$.

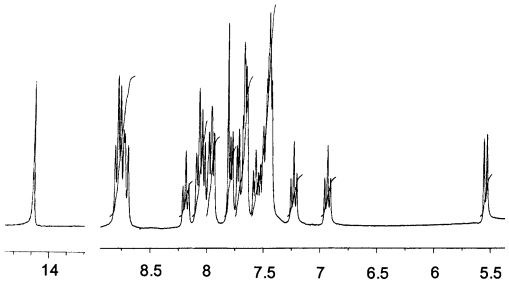

Fig. 3. ^1H NMR spectrum of $[(bpy)_2Ru(H_3pzbzim)]^{2+}$ ($\mathbf{3}^{2+}$) in $(CD_3)_2SO$.

the following facts [19]. The usual decreased order of chemical shifts is H(3) > H(4) ≥ H(5) > H(6); $J_{3,4}/J_{4,5} \approx 8$ Hz, $J_{5,6} \approx 5$ Hz and $J_{3,5}/J_{4,6} \approx 1.2$ Hz; the protons H(3) and H(6) are normally observed as doublets, while H(4) and H(5) appear either as triplet or doublet of doublet.

As may be seen in Figs. 1–4, for each of the complexes all the resonances, barring two, occur in the range 6.4–8.8 ppm. Of the two disparate signals, the one which is most shielded amongst all appears as a doublet between 5.3 and 5.5 ppm. The doublet accounts for a single proton and is clearly due to H(14) (see Scheme 1 for proton labelling) since this proton experiences maximum diamagnetic shielding by the anisotropic

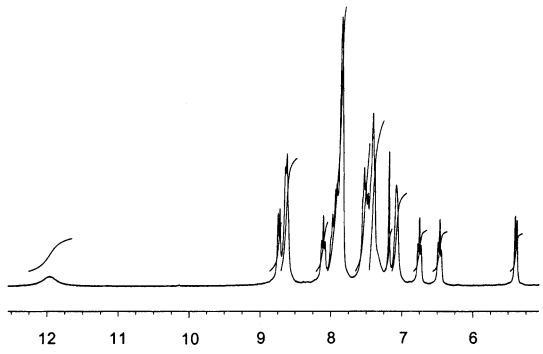

Fig. 4. ^{1}H NMR spectrum of $[(bpy)_2Ru(Hpzbzim)]$ (**4**) in $(CD_3)_2SO$.

ring current of the adjacent bipyridine rings. The second distinct signal, which is most downfield-shifted, is observed either as a sharp singlet at 14.2 ppm for (**1**) and (**3**) or as a broad feature at approximately 12.0 ppm for (**2**) and (**4**). The singlet observed for (**1**) and (**3**) is due to the two benzimidazole NH protons (H(15) and H(15′)), while the broad signal observed in (**2**) and (**4**) is due to the single NH group (H(15′)) in these compounds. The relative higher field shift of this signal in (**2**)/(**4**) with respect to (**1**)/(**3**) is consistent with the augmentation of electronic charge in (**2**)/(**4**).

Table 1 summarizes spectral assignments made for complexes (**1**)–(**4**). It would be of interest to compare the chemical shifts of some of the pertinent resonances in the osmium(II) complexes with their ruthenium(II) analogues and also to examine the influence of deprotonation on chemical shifts. It may be noted that, the chemical shift due to H(14) proton of the osmium(II) complex (**1**) (5.57 ppm) is almost identical to that of the ruthenium(II) complex (**3**) (5.55 ppm). The same is more or less true for the other phenyl ring protons of the two compounds. Interestingly, the singlet due to pyrazole H(7) is observed at 7.85 ppm for (**1**) as against 7.82 ppm for (**3**). Similarly, the singlet due to the NH protons occurs almost at the same place for (**1**) (14.21 ppm) and (**3**) (14.23 ppm). When the two deprotonated complexes (**2**) and (**4**) are compared, again a similar trend is observed.

On deprotonation of the NH groups belonging to the pyrazole and one of the benzimidazole moieties of (**1**) and (**3**), significant upfield shifts occur for the aromatic protons H(11)–H(14), which are in the vicinity of the deprotonated sites. Specifically, H(7) pyrazolate ring proton of (**2**) and (**4**) gets more shielded relative to (**1**) and (**3**) by 0.64 ppm.

3.2. Redox properties

The redox activities of complexes (**1**)–(**4**) have been studied in acetonitrile solution and the relevant electrochemical data are given in Table 2. In all the cases metal-centred oxidation (M^{II}/M^{III}) take place reversibly as borne out by their strict adherence to the usual criteria of reversibility. Fig. 5 shows the cyclic voltammograms of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) and $[(bpy)_2Ru(H_3pzbzim)]^{2+}$ ($\mathbf{3}^{2+}$) over the potential range +1.2– −2.2 V (vs. Ag/AgCl). It may be noted that the redox

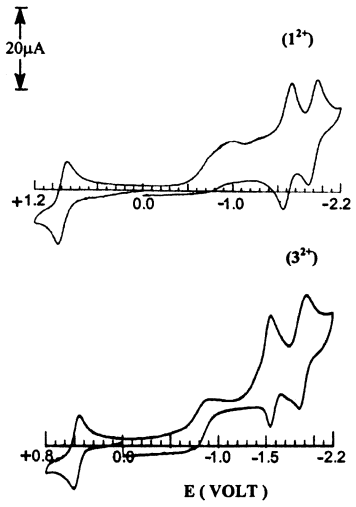

Fig. 5. Cyclic voltammograms of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) and $[(bpy)_2Ru(H_3pzbzim)]^{2+}$ ($\mathbf{3}^{2+}$) in acetonitrile.

potential of the Os^{II}/Os^{III} couple in (**1**) ($E^{ox}_{1/2} = 0.48$ V) is 0.41 V less positive as compared to the Ru^{II}/Ru^{III} couple in (**3**) ($E^{ox}_{1/2} = 0.89$ V). In the deprotonated state, the removal of an electron from the metal centre becomes more facile. Thus, the $E^{ox}_{1/2}$ values of (**2**) and (**4**) 0.14 and 0.60 V, respectively, are appreciably less relative to those of (**1**) and (**3**). On the other hand, the electrochemical responses for all the four complexes are similar in the negative potential regime upto −2.2 V, where electrons are added to the unoccupied acceptor orbitals of bipyridine. As may be seen in Fig. 5, both for ($\mathbf{1}^{2+}$) and ($\mathbf{3}^{2+}$), two reversible one electron reduction processes occur at about −1.65 and −1.90 V. Interestingly, Fig. 5 also shows the presence of a broad irreversible feature around −1 V for both ($\mathbf{1}^{2+}$) and ($\mathbf{3}^{2+}$). The origin of this reduction process is not clear at this stage. However, it could be due to the reduction of an acidic ligand proton $H^+ + e^- \rightarrow 0.5H_2$.

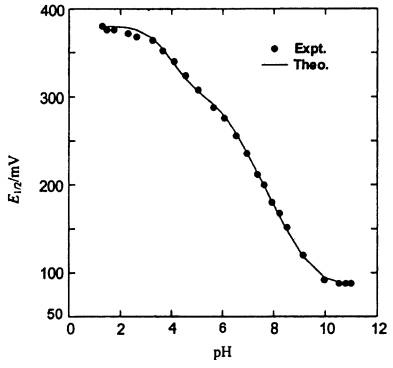
3.3. Equilibrium constants involving electroprotic reactions

The coupled electron and proton transfer reactions of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) in acetonitrile–water (3:2) have been studied over the pH range 1–12 in the same way as reported earlier [14] for $[(bpy)_2Ru(H_3pzbzim)]^{2+}$ ($\mathbf{3}^{2+}$). It should be noted that while in pure acetonitrile the $E_{1/2}$ value for the ferrocene/ferrocenium couple was found to be 0.36 V, in acetonitrile–water (3:2) it is 0.26 V. Thus, while comparing the $E_{1/2}$ values in the two solvent media the normalizing factor 0.10 V should be applied.

The variation of $E_{1/2}$ as a function of pH for ($\mathbf{1}^{2+}$) is shown in Fig. 6. It may be noted that in strongly acidic medium (pH < 2) as well as in strongly basic medium (pH > 10), the $E_{1/2}$ values remain pH independent, indicating that in these two regions the electron transfer is not accompanied by proton transfer. In the intermediate range, 2 < pH < 10, steady decrease of $E_{1/2}$ with the increase of pH occurs in two steps. The slopes of the $E_{1/2}$ versus pH plots in these two regions are close to −60 mV/pH, indicating that both the steps are associated with one-electron–one-proton transfer reactions. The observed electro-protic reactions are illustrated in Scheme 2.

Further dissociation of the benzimidazole proton away from the metal site does not occur even at pH 12. It should be noted that the dissociation constants K_1 and K_2 refer to the species involving osmium(II), while K_3 and K_4 refer to osmium(III) containing species.

As the electron transfer reactions occur reversibly, the observed $E_{1/2}$ can be related to the acid dissociation



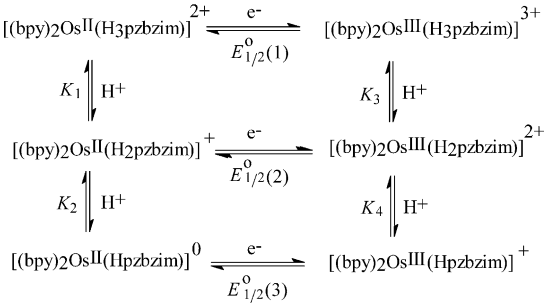


Fig. 6. Variation of $E_{1/2}$ for the Os^{II}/Os^{III} couple in $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) as a function of pH in acetonitrile–water (3:2).

Scheme 2.

constants of the complexes by Eq. (1)

$$E_{1/2} = E^{\circ}_{1/2} + 0.059 \log \frac{[H^+]^2 + K_1[H^+] + K_1K_2}{[H^+]^2 + K_3[H^+] + K_3K_4} \qquad (1)$$

where $E^{\circ}_{1/2}$ is the standard redox potential of the Os^{II}/Os^{III} couple at pH 0 and at 25 °C. As shown in Fig. 6, nonlinear least-squares analysis of the 25 experimental data points has provided the best fit curve with the following pK values: $pK_1 = 4.7$, $pK_2 = 9.5$, $pK_3 = 3.3$ and $pK_4 = 5.9$. These values may be compared with those of the corresponding ruthenium species for which $pK_1 = 5.4$, $pK_2 = 10.0$, $pK_3 = 3.0$ and $pK_4 = 6.3$ [14]. The results indicate: (i) as compared to the ruthenium species, the azole protons are more acidic in the osmium species. (ii) The acid dissociation constant for a given ligand site is considerably greater when the metal ion is in +3 state relative to that in +2 state. For the metal-free H_3pzbzim, the pK value of the pyrazolyl proton is 10.5, while for the benzimidazolyl protons these are well above 12.

The $E^{\circ}_{1/2}$ values of all the protonated and deprotonated redox couples for the osmium and ruthenium complex species in acetonitrile–water (3:2) are given below for comparision

$E^{\circ}_{1/2}(1) = 0.38$ V(Os), 0.78 V(Ru)

$E^{\circ}_{1/2}(2) = 0.33$ V(Os), 0.66 V(Ru)

$E^{\circ}_{1/2}(3) = 0.09$ V(Os), 0.44 V(Ru)

These results show the expected trend of progressive shifts of the redox potentials to less positive values. The extent of shift in potentials on passing from the fully protonated state to the fully deprotonated state, that is $E^{\circ}_{1/2}(1) - E^{\circ}_{1/2}(3)$, is 0.29 V for osmium and 0.34 V for ruthenium. On the other hand, at every state of protonation the osmium species get more easily oxidized relative to the corresponding ruthenium species by a margin of 0.33–0.40 V.

A comparison of the redox potentials for complexes (**1**)–(**4**) in acetonitrile, as given in Table 2, vis-à-vis those in acetonitrile–water (3:2) show some differences even by taking into account the shift of the $E_{1/2}$ value for the ferrocene/ferrocenium couple from 0.36 V in acetonitrile to 0.26 V in acetonitrile–water (3:2). For instance, $E^{\circ}_{1/2}(3)$ for Os at 0.09 V in acetonitrile–water is somewhat more positively shifted relative to the Os^{II}/Os^{III} couple of (**2**) observed at 0.14 V. Further, the difference between $E^{\circ}_{1/2}(1)$ and $E^{\circ}_{1/2}(3)$ is 0.29 V for Os and 0.34 V for Ru, while the corresponding differences in redox potentials given in Table 2 for the protonated and deprotonated species are 0.34 and 0.29 V, respectively. We attribute these deviations to non-specific solvent effects.

3.4. Absorption spectral studies of proton and electron transfer reactions

The absorption spectrum of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) in acetonitrile recorded over the range 300–900 nm exhibit three bands at 345 (29 400), 515 (11 600) and 685 nm (2800) with their molar absorptivities (ε/dm^3 mol^{-1} cm^{-1}) given in parentheses. The band at 345 nm seems to be due to intraligand (H_3pzbzim) π–π^* transition, while the other two bands are due to $Os(d\pi) \rightarrow bpy(\pi^*)$ charge transfer transitions. In the deprotonated complex $[(bpy)_2Os(Hpzbzim)]$ (**2**), substantial red shift of the MLCT bands take place with their peaks occurring at 560 (11 100) and 780 nm (2900). On the other hand, the band due to intraligand transition is nominally shifted to 340 nm (28 300).

The influence of pH on the absorption spectral behavior of ($\mathbf{1}^{2+}$) in acetonitrile–water (3:2) over the pH range 2–12 is shown in Fig. 7. As may be noted, with the increase of pH, the two MLCT bands in the successive absorption curves undergo redshifts during which they pass through four isosbestic points at 457, 525, 628 and 700 nm. These observations along with the analysis of the spectrophotometric titration data by a graphical method [20] suggest the occurrence of the

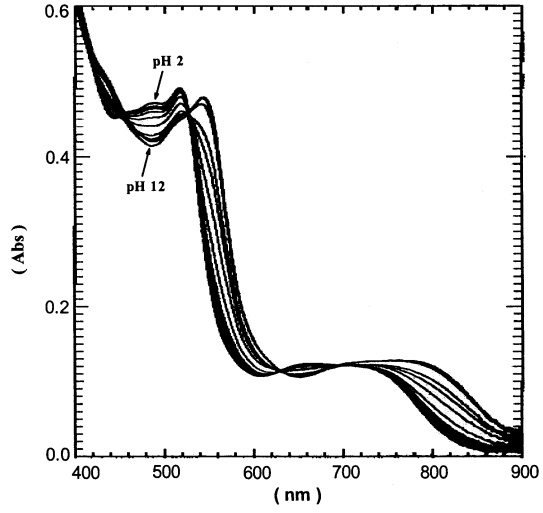

Fig. 7. Changes in the absorption spectrum of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) with the variation of pH in acetonitrile–water (3:2).

following acid–base equilibria.

$$[(bpy)_2Os(H_3pzbzim)]^{2+} \overset{K_1}{\rightleftharpoons} [(bpy)_2Os(H_2pzbzim)]^{+} + H^{+} \quad (2)$$

$$[(bpy)_2Os(H_2pzbzim)]^{+} \overset{K_2}{\rightleftharpoons} [(bpy)_2Os(Hpzbzim)] + H^{+} \quad (3)$$

The pK_I values have been evaluated from the absorption data pertaining to the pH ranges 2–7 and 7–12 of Fig. 7 using Eq. (4)

$$pH = pK_1 - \log\frac{A - A_o}{A_f - A} \quad (4)$$

where A_o, A_f and A refer to the absorbances at the initial, final and intermediate pH values at a given wavelength. The results thus obtained, $pK_1 = 4.75(5)$ and $pK_2 = 9.40(5)$, are in good agreement with those obtained by the electrochemical method ($pK_1 = 4.7$ and $pK_2 = 9.5$).

The redox equilibrium involving the generation of the osmium(III) species by the chemical oxidation of ($\mathbf{1}^{2+}$) with cerium(IV) ammonium nitrate in acetonitrile–water (3:2) has also been studied spectrophotometrically. The spectral changes that occur during the redox titration is shown in Fig. 8. It may be noted that the more intense MLCT band of ($\mathbf{1}^{2+}$) at 515 nm gradually gets depleted and undergoes red shift till the oxidation is complete, when the MLCT band is replaced by the LMCT ($H_3pzbzim \rightarrow Os^{III}$) band with its peak at 530 nm ($\varepsilon = 4100$ dm^3 mol^{-1} cm^{-1}). Further, the second MLCT band at 680 nm gradually disappears during oxidation.

Fig. 8 shows that the one-electron chemical oxidation reaction takes place smoothly and quantitatively as the successive absorption curves pass through two isosbestic points at 365 and 795 nm.

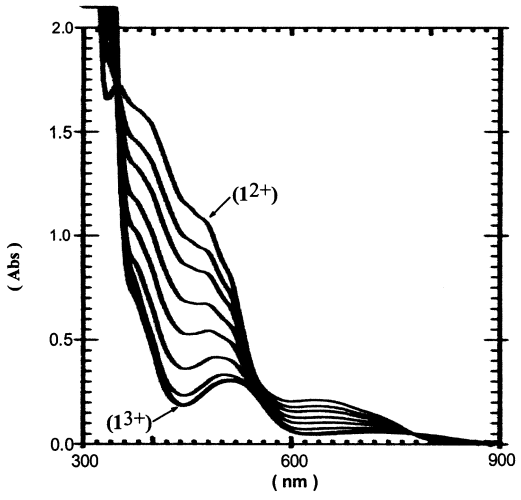

Fig. 8. Changes in the absorption spectrum of $[(bpy)_2Os(H_3pzbzim)]^{2+}$ ($\mathbf{1}^{2+}$) on oxidation with cerium(IV) in acetonitrile–water (3:2).

3.5. Luminiscence spectra

The emission spectral behavior of complexes (**1**) and (**2**) have been studied at 300 and 77 K in methanol–ethanol (1:4) solutions and glass, respectively. The osmium complex (**1**) does not luminescent at room temperature in solution. However, in frozen glass at 77 K a very weak and broad luminiscence with its peak around 760 nm. In contrast, the ruthenium(II) complex (**3**) exhibits fairly strong luminiscence both at 300 and 77 K with quantum yield 3.5×10^{-3} and 7.2×10^{-2}, respectively. It should be noted that for a given ligand, ^{3}MLCT energy decreases for osmium(II) relative to that of ruthenium(II). Consequently, quenching to the ground state takes place more efficiently for a osmium(II) compound [21]. In the case of the deprotonated osmium(II) compound (**2**) further lowering of ^{3}MLCT energy occurs and as a result (**2**) does not luminescent even at 77 K.

special interest as certain ferric cytochromes having a FeS_6 moiety are associated with electron transport in biological systems and these are involved in spin equilibrium suggesting that spin state conversion is coupled to electron transport [11].

Thermal decomposition studies of iron(III) dithiocarbamates and related compounds have also attracted the attention of several workers [12,13]. Thermogravimetric studies of $[Fe(S_2CNEt_2)_3]$ by D'Ascenzo and Wendlendt [14] have shown this to be completely volatile, whereas Lanjewar and Garg [15] have reported volatile, non-volatile and partially volatile natures depending on symmetrical and unsymmetrical substituents. Earlier we had reported Mössbauer spectral, magnetic moment and thermal decomposition studies of some tris(*N*,*N*′-dialkyldithiocarbamato) iron(III) complexes wherein $Fe(SCN)_3$ was formed as an intermediate product [16].

In this paper we have reported the synthesis, IR spectral, variable temperature magnetic moment, Mössbauer spectral and thermal decomposition studies of the four unsymmetrically substituted complexes $[(OHCH_2CH_2)RNCS_2]_3Fe$ with R = CH_3, C_2H_5, *n*-C_3H_7 and *n*-C_4H_9. Also from the TGA plots, the kinetic and thermodynamic parameters were calculated using a Freeman and Carroll method [17].

2. Experimental

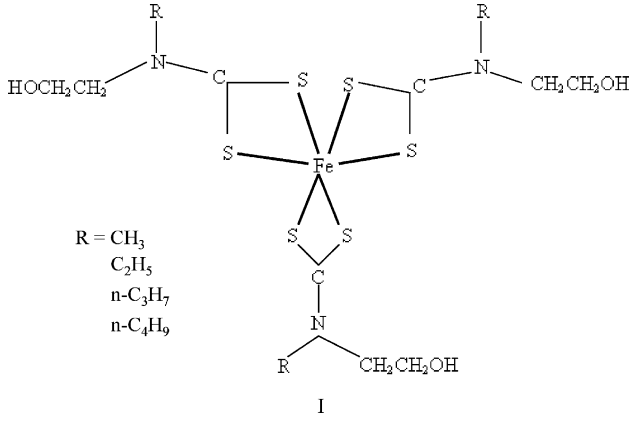
All the chemicals used were of analytical/guaranteed or high purity grade.

2.1. Preparation of the complexes

First the dithiocarbamate ligands were prepared as sodium salts by the reaction of the respective secondary amine in tetrahydrofuran with CS_2 and adding sodium hydroxide solution in equal mole ratio with vigorous stirring for 5–6 h at room temperature [16]. The crude product was recrystallized from methanol. The purity of ligands was checked by determining m.p. which matched well with the literature values. 4 g of ferric nitrate was dissolved in a minimum amount of absolute ethanol and then a calculated amount of sodium *N*-alkyl,*N*′-hydroxyethyldithiocarbamate was added with thorough stirring for 1–2 h at room temperature as described earlier [16]. In all cases a black coloured complex was formed. These were washed with water and dried diethyl ether and then dried over fused calcium chloride in a vacuum desiccator overnight. Elemental analysis of the complexes is given in Table 1.

2.2. Physical measurements

Mössbauer spectra were recorded using a constant acceleration transducer driven Mössbauer spectrometer (ECIL, Hyderabad) in conjunction with 1024 MCA (Canberra). A 25 mCi $^{57}Co(Rh)$ source procured from Amersham, UK was used. The spectrometer was calibrated using a natural iron foil as well as recrystallized sodium nitroprusside dihydrate (SNP) as standards at 295 K. The spectral data were least-square fitted. Magnetic moments were measured at room temperature (295 K) using a Vibrating Sample Magnetometer (VSM Model 155, Princeton Applied Research, USA). Thermograms were recorded on a thermogravimetric analyser system, STA-780 series (Stanton Redcroft, UK) at a heating rate of 10 °C min^{-1}. All the measurements were carried out in static air atmosphere using Al_2O_3 as reference material. IR spectra in the range 4000–400 cm^{-1} were recorded in KBr medium on a Perkin–Elmer 1600, FT-IR Spectrophotometer. Further spectra were also recorded down to 50 cm^{-1} at the RSIC, IIT-Madras.



3. Results and discussion

All the four complexes were black solids, which are stable under normal atmospheric conditions. Typical Mössbauer spectra of the (*N*-methyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complex from room temperature (295 K) down to liquid nitrogen temperature (77 K) are shown in Fig. 1. Mössbauer parameters derived from these spectra after fitting are listed in Table 2. Variation of magnetic moment with temperature in the 77–295 K range for all the complexes, are shown in Fig. 2. Typical thermograms (TG, DTG and DTA) of the complexes, $[(HOCH_2CH_2)RNCS_2]_3Fe$ having R = CH_3 and C_2H_5 are shown in Fig. 3. Thermogravimetric data and the kinetic and thermodynamic parameters for all the complexes are listed in Table 3.

Tris(*N*,*N*′-dialkyldithiocarbamato) iron(III) complexes have trigonally distorted octahedral geometry with six sulfur donor atoms surrounding the central iron(III) in D_3 symmetry with a twist angle φ varying from about 33° to 40°, depending on the nature of the alkyl group [18]. Earlier we had studied the crystal structure of the tris(*N*,*N*′-diallyl dithiocarbamato) iron(III) complex and confirmed that the crystals are monoclinic with space group $C2/c$ where $a = 18.737(5)$ Å, $b = 10.229(3)$ Å and $c = 15.571(3)$ Å and the angles $\alpha = 90°$, $\beta = 106.13°$ and $\gamma = 90°$. The bond lengths of Fe–S were found to be 2.3262, 2.3657 and 2.3488 Å and bond angles S–Fe–S were 74.25°, 90.48°, 94.58°, 97.99°, 98.93° and 160.09° [19]. Since the basic nature of the ligands remains the same, the molecular structure of the presently studied unsymmetrically substituted complexes is likely to remain similar and the possible structure may be represented as I.

I

3.1. Magnetic moment

Magnetic moment studies of dialkyldithiocarbamato iron(III) complexes have been reported by several workers [3–6]. On the basis of the room temperature magnetic moments, all the complexes are in a mixed spin state though these are predominantly in high spin state ($^6A_{1g}$). This suggests that the complexes exhibit high spin(HS)⇌low spin(LS) equilibria at room temperature. As the temperature is lowered it is converted more and more towards the low spin state ($^2T_{2g}$). This is quite evident from the plots of variation of magnetic moment with temperature as shown in Fig. 2. Also an interesting relationship seems to exist between the nature of alkyl group and the magnetic moment. Evidently as the carbon chain length increases from methyl to *n*-butyl, it tends to shift more towards a high spin state and the same trend is observed at all temperatures. Apparently this is due to an increase in the electron density on the Fe atom due to the positive inductive effect of the alkyl group.

3.2. IR spectra

The metal–ligand stretching band appearing in the far IR region provides information about the strength of the metal–ligand bond and the spin state of the system [20,21]. Ewald et al. [3] proposed the 300–400 cm^{-1} region for both the high and low spin states of the Fe–S stretching band. Butcher et al. [20] examined the far IR spectra of $Fe(R_2dtc)_3$ complexes using isotopic substitution, and assigned the high spin ν_{Fe-S} at a lower energy than that for the low spin mode, keeping both in the 300–400 cm^{-1} region. In a further investigation of far IR spectra of tris(*N*,*N*′-dialkyldithiocarbamato) iron(III) complexes using ^{54}Fe and ^{57}Fe isotopes, Hutchinson et al. [21] showed that high spin ν_{Fe-S} appears at 205–250 cm^{-1}, the low spin at 305–350 cm^{-1} and the intermediate spin ν_{Fe-S} in both regions. Various assignments for the IR stretching bands are listed in Table 1. On the basis of literature reports the ν_{Fe-S} stretching band in the 226–233 cm^{-1} region corresponds to the high spin state and another strong band in the 332–353 cm^{-1} region is attributed to the low spin state. Interestingly, intensities of the two bands corresponding to high and low spin states also vary depending on their contributions in the equilibrium mixture.

Besides ν_{Fe-S}, IR spectral assignments of other bands are also reported. Chatt et al. [22] suggested resonance structures on the basis of an intense band in the region 1550–1480 cm^{-1} due to a C···N stretching vibration. Bradley and Gitlitz [23] studied IR bands in several metal *N*,*N*′-dialkyldithiocarbamates and reported the thioureide (N···C) band near 1500 cm^{-1} as a characteristic of the ligand indicating considerable double bond character in the $(S_2)C\cdots N(R_2)$ bond. We have observed $\nu_{(N\cdots C)}$ in the 1492–1496 cm^{-1} region, which matches well with the literature value. Another strong band in the 1165–1190 cm^{-1} region may be attributed to $N-C_2$

for all the complexes. Strong bands at 981–992 cm^{-1} and 1224–1327 cm^{-1} due to $\nu_{(C_S)}$ are suggestive of the chelating character of the dithiocarbamate ligand in all cases [24].

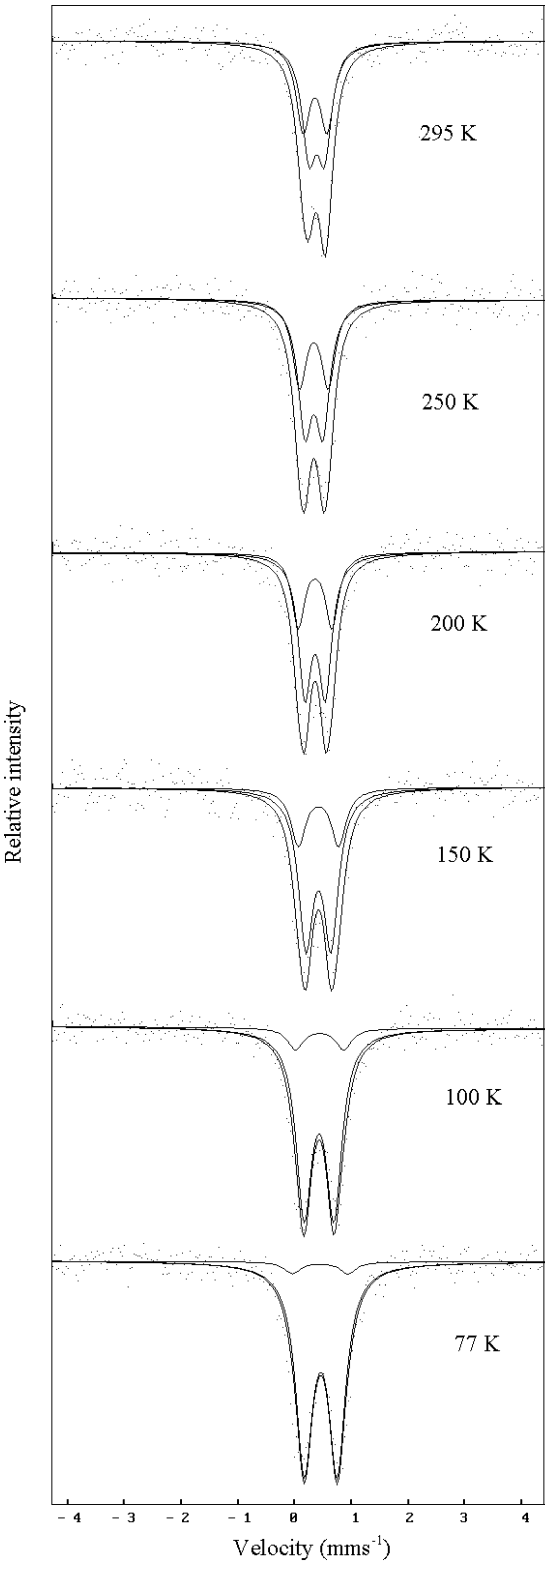

Fig. 1. Mössbauer spectra of the tris(*N*-methyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complex at different temperatures.

An electronic spectrum of the complexes in acetone exhibits a strong band at 28 600 cm^{-1} which corresponds to charge transfer ($^2T_2 \rightarrow {}^4T_1$). Another weak band at 19 600 cm^{-1} is due to a spin forbidden *d*–*d* transition ($^2T_2 \rightarrow {}^2T_1$). These observations are in accordance with the literature [3].

3.3. Mössbauer spectra

Mössbauer spectra for all the complexes at 295 K exhibit an asymmetric doublet, which can be resolved into two doublets corresponding to low and high spin states. However, at temperatures ≤ 250 K the spectra become increasingly symmetric with large line widths. Typical Mössbauer spectra of tris(*N*-methyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complex at various temperatures in Fig. 1 indicate two doublets corresponding to high and low spin states in equilibrium at 295 K and then the contribution of the HS state continuously decreases with the lowering of temperature. The isomer shift (δ) values for both spin states do not vary significantly. However, the quadrupole splitting (ΔE_Q) values for the low spin state are somewhat lower (0.27–0.44 mm s^{-1}) compared to that for the high spin state (0.42–0.59 mm s^{-1}). In general, the ΔE_Q value increases with decreasing temperature and on increasing the number of carbon atoms in the alkyl group attached to the N-atom of the ligand. Pandeya et al. [7] have claimed the largest ever reported $\Delta E_Q = 0.716$ mm s^{-1} at 300 K in the complex tris[bis(hydroxyethyl)dithiocarbamato)]iron(III) suggesting a large asymmetry of the ligand field. In the present study, since one of the hydroxyethyl groups has been replaced by alkyl groups, still larger asymmetry was expected. However, in Table 2 the largest value of ΔE_Q is 0.59 mm s^{-1} for tris(*N*-butyl,*N*′-hydroxyethyldithiocarbamato) iron(III) at 295 K which increases to 1.28 mm s^{-1} at 77 K. It seems asymmetric substitution at N-atoms does not necessarily mean more asymmetry at the central Fe atom.

In order to find out the correlation, ΔE_Q was plotted with the molecular weight of the alkyl group and it shows a linear increase in Fig. 4. Surprisingly ΔE_Q for both the spin states increases linearly with temperature. It is well known that by increasing the carbon chain length, the positive inductive effect of the alkyl group increases. This will result in an increase in *s*-electron density at the Fe nucleus by way of donation. On going down to 77 K all the complexes exhibit increasing tendency towards low spin state ($^2T_{2g}$). In fact Mössbauer spectral results confirm our observation of increasing contribution of the HS state with increasing carbon chain length. However, an opposite trend is observed for the LS state. Magnetic moments were also calculated on the basis of estimated percent contribu-

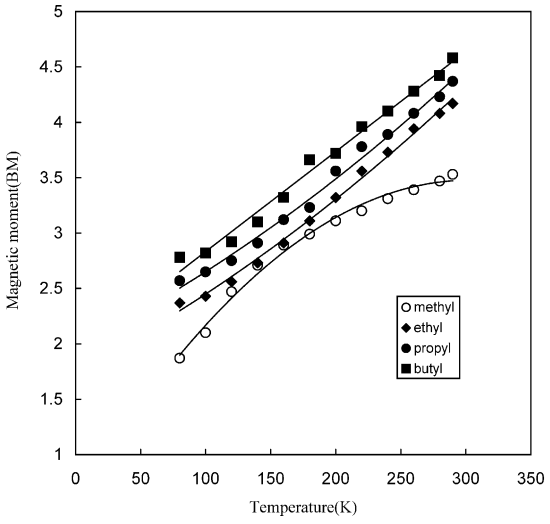

Fig. 2. Variation of magnetic moment with temperature for tris(*N*-alkyl,*N*′-hydroxyethyl-dithiocarbamato) iron(III) complexes.

tions of high and low spin states. The magnetic moments so calculated compare well with the experimentally determined values showing good agreement between Mössbauer spectral and magnetic moment data (Table 2).

3.4. Thermogravimetric studies

Thermogravimetric studies suggest that all the complexes, are stable up to ~140 °C, after which decomposition starts and the whole process is completed at ~650 °C in two stages. In all cases the first step is very fast, corresponding to 65–70% weight loss and it is completed up to ~350 °C, as can be seen in Fig. 3.

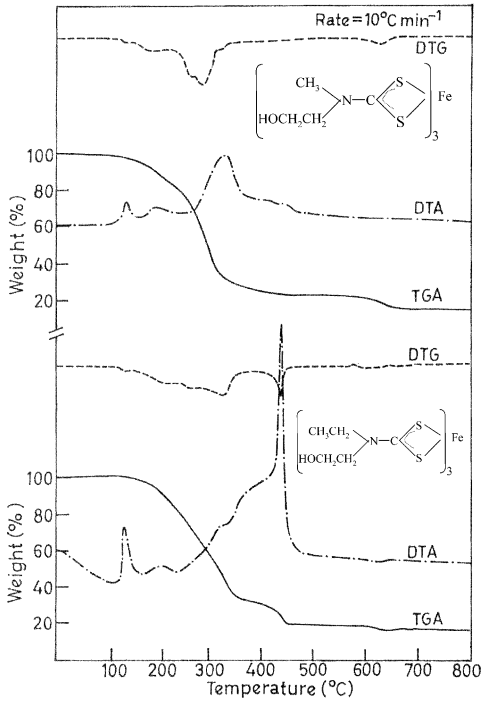

Fig. 3. TGA (—), DTG (-----) and DTA (- · · · -) plots for some typical iron(III) complexes.

Further decomposition takes place at ~550 °C and a constant weight is obtained at 610–650 °C (Table 3). In all the complexes, the final weight matches well with the expected weight of Fe_2O_3 and hence all the complexes can be grouped as non-volatile. In earlier reports there have been speculations about the formation of Fe_2S_3 [13,14] or a partially non-volatile group of complexes yielding 70–80% residual weight at 900 °C [15]. In the present studies no Fe_2S_3 is formed. Incidentally melting

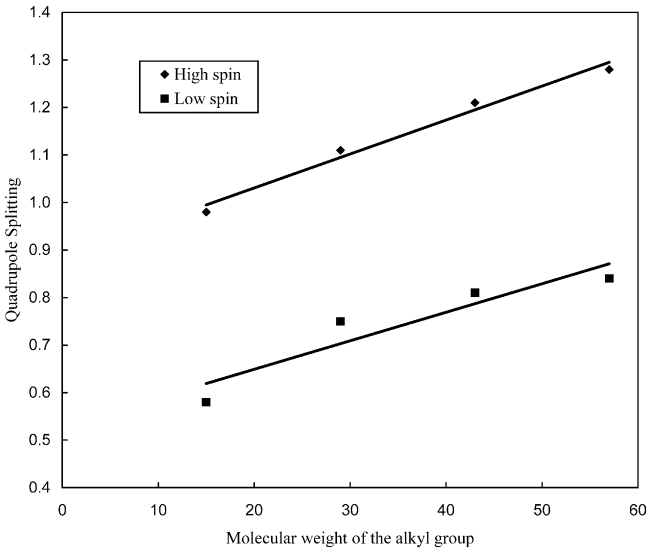

Fig. 4. Variation of quadrupole splitting with molecular weight of alkyl group for tris(*N*-alkyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complexes.

points of all the complexes were observed in the range 170–240 °C whereas the first exothermic DTA peak is also observed in this temperature range only (Fig. 3). It suggests that the first stage of decomposition involves melting of the complex. In addition, another broad exotherm is observed at ~350 °C. Kaushik et al. [25] have attributed this to the conversion of iron sulfate to iron oxide. However, we could not identify the formation of iron sulfate as an intermediate though we had earlier confirmed the formation of $Fe(SCN)_3$ in some dithiocarbamates [16].

In order to identify the intermediate and final products, Mössbauer spectra were recorded after heating the complexes at 500 and 700 °C. Typical Mössbauer spectra for the tris(*N*-ethyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complex after heating at these temperatures in Fig. 5 show that α-Fe_2O_3 starts forming at 500 °C as indicated by the appearance of a sextet with $H_{eff} = 517$ kOe and $\delta = 0.37$ mm s^{-1}. A centrally located doublet is also observed having $\delta = 0.39$ mm s^{-1} and $\Delta E_Q = 0.51$ mm s^{-1}. It suggests primarily an undecomposed compound in a high spin state. After further heating up to 700 °C the centrally located doublet disappears and a pure sextet is observed with $H_{eff} = 514$ kOe and $\delta = 0.39$ mm s^{-1}. These parameters correspond to that for α-Fe_2O_3 [26]. Therefore, no evidence was found for the formation of Fe_2S_3. Undoubtedly the decomposition of unsymmetrically substituted tris(*N*-alkyl,*N*′-hydroxyethyldithiocarbamato)iron(III) complexes is affected by the nature of alkyl substituents. However, intermediate products seem to be different although we had earlier confirmed it to be $Fe(SCN)_3$ [16]. Finally α-Fe_2O_3 is formed in all cases.

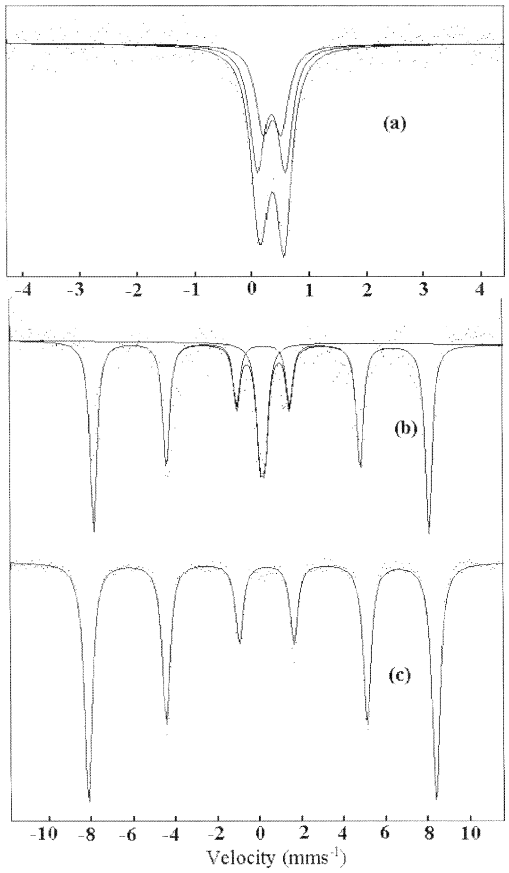

Fig. 5. Mössbauer spectra of the tris(*N*-ethyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complex at r.t., after heating at (b) 500 °C and (c) 700 °C for 1 h.

From the thermograms of the complexes various kinetic and thermodynamic parameters were calculated using the Freeman and Carroll [17] method and these are given in Table 3. From the linear plots of [$\Delta\log(dw/dt)/\Delta\log w_r$] vs. $\Delta(1/T)/\Delta\log w_r$, the activation energy (E_a) and order of the reaction were calculated. The

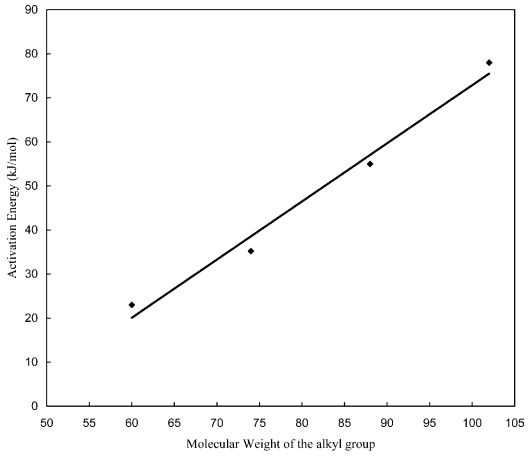

Fig. 6. Variation of the activation energy with molecular weight of alkyl group for tris(*N*-alkyl,*N*′-hydroxyethyldithiocarbamato) iron(III) complexes.

frequency factor ($\ln A$) was calculated from the intercept using the relationship:

$$\ln \frac{d\alpha/dt}{(1-\alpha)^n} = \ln A - \frac{E_a}{RT}$$

and then the rate constant was calculated. It is observed that all these parameters vary with the nature of the alkyl substituent suggesting strong dependence on the nature of the substituent. A perusal of data in Table 3 shows that the activation energy varies in a wide range of 22.98–78.50 kJ $mol^{-1}$and a linear correlation is observed between E_a and the molecular weight of the alkyl group as shown in Fig. 6. Incidentally these do not correlate with the spin state of the complexes. The order of the reaction of the complexes is in the range 0.28–1.48, well within unity suggesting intramolecular rearrangement. Similarly the rate of the reaction decreases as the molecular weight is increased as shown in Table 3. As the number of carbon atoms in the alkyl group is increased the electron density at the iron atom increases so that more energy is required to break the bond and the reaction becomes slower. Possibly this is due to positive inductive effect of the alkyl group causing increased polarity in the molecule. In other words as we move from CH_3 to the bulkier n-C_4H_9 group, the ionic character increases so that the Fe–S bond becomes stronger.

The activation thermodynamic parameters, namely enthalpy (ΔH), entropy (ΔS) and free energy (ΔG), were also evaluated (Table 3). The values of ΔS in all cases were found in the range -155.1 to -266.7 J K^{-1} mol^{-1}. This suggests that the decomposition process involves molecular rearrangement whereby a significant restriction is exerted on the vibrational degrees of freedom. However, during these processes an intermediate is likely to be formed which ultimately decomposes into α-Fe_2O_3 at ~ 700 °C in air atmosphere.

which are also used to build selective sensors [15]. In addition, many examples of alkali metal ion complexation by calix[4]arenes bearing complexing arms on the lower rim (particularly carbonyl derivatives) are known [16] as well as complexes uniting transition metal and alkali metal ions [17] and complexes with *p*-sulfonato derivatives of calix[4,5]arenes [18] and calix[6]arenes [19]. Considering the relative scarcity of simple calix[4]arenes (unsubstituted on the lower rim) used for the structural characterization of such complexes, these being reduced to *p-tert*-butylcalix[4]arene, *p-tert*-butyldihomooxacalix[4]arene and *p-tert*-butyltetrathiacalix[4]arene, we decided to investigate the complexes formed by the simplest member of this family, calix[4]arene, denoted LH_4 hereafter, in its anionic state and we report herein the synthesis and crystal structures of one sodium and two caesium ion complexes obtained in the course of this work. In the case of caesium, novel arrangements result from the absence of *para* substituents in the ligand.

2. Experimental

2.1. Synthesis

Calix[4]arene was synthesized as previously published [20].

2.1.1. $\{Na_2(LH_3)_2[(CH_3)_2CO]_3\}\cdot 2CHCl_3\cdot 2H_2O$ (**1**)

Calix[4]arene (500 mg, 1.18 mmol) was dissolved in a mixture of $CHCl_3$ (120 ml) and aq. NaOH 6 M (120 ml). After stirring for half an hour at room temperature (r.t.) a sevenfold excess of $NaNO_3$ (700 mg, 8.24 mmol) was added and the resulting mixture stirred for 2 h. The organic phase was then separated, evaporated to dryness and the product recrystallized from hot acetone, resulting in colourless crystals suitable for X-ray crystallography.

2.1.2. $[Cs(LH_3)(py)]$ (**2**)

Calix[4]arene (100 mg, 0.24 mmol) was dissolved in CH_3CN (100 ml) in the presence of a large excess of NaOH (1.5 g). The solution became light pink on refluxing. Cs_2CO_3 in excess (200 mg, 0.61 mmol) was then added and the resulting pink solution was further stirred for 1 h at r.t., then filtered. The solution was evaporated to dryness and recrystallized from pyridine, giving colourless single crystals suitable for X-ray crystallography on slow evaporation.

2.1.3. $[Cs_2(LH_3)_2(H_2O)]\cdot CH_3CN$ (**3**)

Calix[4]arene (110 mg, 0.26 mmol) was dissolved in $CHCl_3$ (50 ml) with a large excess of NEt_3 (4 ml). Cs_2CO_3 in excess (330 mg, 1.01 mmol) was then added and the resulting cloudy whitish solution was stirred for 1 h at r.t., then filtered. The solution was evaporated to dryness and recrystallized from CH_3CN, giving colourless single crystals suitable for X-ray crystallography on slow evaporation.

2.2. Crystallography

The data were collected on a Nonius Kappa-CCD area detector diffractometer [21] using graphite-monochromated Mo Kα radiation (0.71073 Å). The crystals were introduced in Lindemann glass capillaries with a protecting 'Paratone' oil (Exxon Chemical Ltd.) coating. The unit cell parameters were determined from the reflections collected on 10 frames and were then refined on all data. The data were processed with DENZO-SMN [22]. The structures were solved by direct methods with SHELXS-97 [23] and subsequent Fourier-difference synthesis and refined by full-matrix (compounds **2** and **3**) or blocked full-matrix (compound **1**) least-squares on F^2 with SHELXL-97 [24]. Absorption effects were empirically corrected with the program DELABS from PLATON [25]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Special details for each compound are as follows.

2.2.1. Compound *1*

Some constraints have been applied, particularly on the badly resolved chloroform molecules. Phenolic and water protons were not found, nor introduced. All other protons were introduced at calculated positions as riding atoms, with an isotropic displacement parameter equal to 1.2 (CH, CH_2) or 1.5 (CH_3) times that of the parent atom.

2.2.2. Compound *2*

Constraints on displacement parameters have been applied for some atoms behaving badly on refinement. The phenolic protons were not found, nor introduced. All other protons were introduced at calculated positions as riding atoms, with an isotropic displacement parameter equal to 1.2 times that of the parent atom.

2.2.3. Compound *3*

The protons bound to the phenolic oxygen atoms have been found on the Fourier-difference map and introduced as riding atoms with an isotropic displacement parameter equal to 1.2 times that of the parent atom. All other protons (except those of the water molecule) were introduced at calculated positions as riding atoms, with an isotropic displacement parameter equal to 1.2 (CH, CH_2) or 1.5 (CH_3) times that of the parent atom.

Crystal data and refinement details are reported in Table 1. The molecular plots were drawn with SHELXTL [26]. All calculations were performed on a Silicon Graphics R5000 workstation.

3. Discussion

The asymmetric unit in $\{Na_2(LH_3)_2[(CH_3)_2CO]_3\}\cdot 2CHCl_3\cdot 2H_2O$ (**1**) corresponds to two independent and nearly identical dimeric complexes, with calixarene molecules denoted A–B and C–D in the two dimers, respectively. As represented in Fig. 1 in the case of the A–B dimer, two mono-anionic calixarenes in *cone* conformation are bridged by two sodium ions, the coordination sphere of the latter being completed by three acetone molecules located in the median plane, two of them monodentate and one bridging. Each calixarene acts as a bidentate ligand towards one sodium ion and monodentate towards the other, the situation respective to each cation being reversed in the two calixarenes. In each molecule, the phenolic atom O3 is not bound to the cation, which results in the two calixarenes not being parallel to each other. The plane defined by the four oxygen atoms being taken as a reference plane the dihedral angles between these two planes in each dimer are 50.1(2) and 48.9(2)°, respectively, the distance between the two planes being the largest where they are separated by the bridging acetone molecule. The protons were not located in this rather large structure due to the limited data quality and it cannot be ascertained where the phenoxides are located. The Na–$O_{calixarene}$ distances, reported in Table 2, do not provide any clear-cut clue in this respect, being in the range 2.280(5)–2.518(6) [mean value 2.34(7)] Å, in agreement with published values. The O···O separations between adjacent phenolic groups are in the range 2.472(8)–2.905(8) Å, with however a difference between the O···O separations relative to the oxygen atoms coordinated to the same cation (O1 and O2 in molecules A and C, O1 and O4 in B and D) and all the other distances. The former are significantly larger, with a range 2.849(8)–2.905(8) Å and a mean value of 2.87(3) Å, than the latter, which are in the range 2.472(8)–2.684(8) [mean value 2.56(6)] Å. When taking in consideration the corresponding distances in complex **3**, in which the protons were located (vide infra), it can be concluded that the two atoms corresponding to the largest separation are both protonated and involved in strong hydrogen bonds with their other two neighbours, the phenoxide atom among the latter being probably the coordinated one. The dihedral angles between the reference O_4 planes and the mean planes defined by the aromatic rings are in the range 43.1(2)–72.4(2)°. The largest values, associated to the more 'vertical' aromatic rings, correspond in the four calixarenes to coordinated groups, and particularly to those bound to the same cation, while the lowest values, in all but one case, correspond to the uncoordinated group. It may be that the latter adopts a more 'horizontal' position due to the vicinity of the bridging acetone molecule. The three acetone molecules are located so that the three donating

[b] Symmetry code: $x+0.5, 2.5-y, z+0.5$.

oxygen atoms are roughly located in a plane bisecting the two calixarene mean planes, with Na–O distances larger for the bridging species [mean value 2.39(4) Å] than for the other ones [mean value 2.27(6) Å]. The coordination geometry of the cation can be described as distorted trigonal bipyramidal, with, in the case of Na1 for instance, O1, O3 and O1A defining the equatorial plane and O2A and O2B the axial positions, with an O2A–Na1–O2B angle of 169.3(2)° (Fig. 1). The location of the solvent molecules is unremarkable, the water molecules being hydrogen bonded to each other, but not to the calixarene phenol/phenoxide oxygen atoms.

It is worth comparing this structure to those of sodium complexes of simple, parent calix[4]arenes and tetrathiacalix[4]arenes previously reported. In the presence of sodium hydride [4] or triethylamine [12] as deprotonating agent, mono-deprotonation of these ligands is always observed in the case of sodium complexation (the dianion has however been reported in the case of the 1,3-dimethyl ether derivative of *p-tert*-butylcalix[4]arene in the presence of sodium hydride [6]). All other conditions being equal, LiH leads to twofold deprotonation of *p-tert*-butylcalix[4]arene and NaH to mono-deprotonation [4]. This observation has been discussed on the basis of structural arguments [4] (see also Ref. [12]). The present result, with concentrated NaOH as a deprotonating agent, does not differ from the previous cases in this respect. It is however possible to generate higher deprotonation degrees, up to three and fourfold ones, in the presence of lithium amide [5] and butyl-lithium [7,8], respectively. The sodium cation/calixarene system appears to give very different complexes depending on the calixarene and conditions used. Central coordination by all four oxygen atoms is observed with the tetramethyl ether derivative of *p-tert*-butylcalix[4]arene [3] and *exo* coordination to two oxygen atoms with the parent *p-tert*-butylcalix[4]arene [4] and *p-tert*-butyltetrathiacalix[4]arene [12], with additional loose coordination to sulfur in the latter. Complex **1** is closer to the sodium-fused calixarene systems obtained with the 1,3-dimethyl ether derivative of *p-tert*-butylcalix[4]arene [6] or some mixed transition metal ion/sodium ion complexes of *p-tert*-butylcalix[4]arene [17]. The closest relative to **1** is however to be found in the potassium ion complex of *p-tert*-butyltetrathiacalix[4]arene [12], which is also a $M_2(LH_3)_2$ binuclear 'sandwich', with one singly coordinating, two chelating and one uncomplexed oxygen atoms in each calixarene and two coordinated diethylether and one bridging water molecules near the bisecting plane. Similar arrangements are thus obtained with either the smallest or the largest cation/calixarene pair (tetrathiacalix[4]arene being significantly more spacious than its methylene-linked counterpart), with however the difference of a higher coordination number in the case of K^+ ensured by bonding to sulfur.

The isolation of the complex [Cs(LH$_3$)(py)] **2** from a solution highly concentrated in sodium ions evidences a selectivity for caesium which has been demonstrated in the related case of *p-tert*-butylcalix[4]arene [2]. Compound **2** crystallizes with only one complex molecule in the asymmetric unit, but it appears to be a polymeric compound, as represented in Fig. 2. As in complex **1**, the calixarene in **2** is a mono-anion. As a common feature with the caesium complex of *p-tert*-butylcalix[4]arene, in which caesium π-bonding by a calixarene was structurally evidenced for the first time and in which the calixarene is also mono-anionic [10], the cation in **2** is complexed in an *endo* fashion, with likely π-bonding to the aromatic rings, but the absence of bulky *para* substituents results in novel features and overall arrangement. Whereas Cs^+ was located on the fourfold symmetry axis of *p-tert*-butylcalix[4]arene, it is located off-centre in **2**, the interactions with the four aromatic rings being quite dissymetric, with mean Cs···C distances of 4.3(4), 3.6(1), 4.0(4) and 3.6(1) Å and Cs···centroid distances of 4.14, 3.30, 3.79 and 3.35 Å for the four rings, respectively. The shortest Cs···C contacts for each ring are 3.78(2), 3.42(2), 3.55(2) and 3.45(2) Å, respectively, and they involve the carbon atoms bound to oxygen in rings 1 and 3 and either *ortho* or *meta* carbon atoms in rings 2 and 4. On the basis of these distances, the interactions with rings 2 and 4 at least can be considered as strong π-bonds (in the possible range of interactions from η_1 to η_6, these are closer to the latter). For comparison, the Cs···C distances were 3.545(3)–4.121(4) and 3.53(1)–4.17(1) Å and the Cs···centroid distances 3.57 and 3.61 Å in the complexes of *p-tert*-butylcalix[4]arene and *p-tert*-butyldihomooxacalix[4]arene, respectively (two aromatic rings only being involved in the latter). The cation in **2** is also bound to one phenolic (or phenoxide) oxygen atom of the calixarene in which it is included, with a Cs–O3 distance of 3.704(16) Å, larger than that observed for bonding to two oxygen atoms in the *p-tert*-butyldihomooxacalix[4]arene complex [3.422(7) Å], which may be due to the smaller cavity size and less shallow conformation of calix[4]arene preventing the cation from going deeper in the cavity, i.e. closer to the coordinated oxygen atom. However, a peculiar feature of complex **2** is that the cation is bound to one phenolic (or phenoxide) oxygen atom of the neighbouring molecule along the *a* axis, with a shorter Cs–O1′ distance of 3.169(12) Å. The cation coordination sphere is completed by a pyridine molecule located between the calixarene moieties. By contrast with the observation that solvents with high cation solvating ability, such as acetone or acetonitrile, are likely to withdraw Cs^+ from the calixarene cavity [11], acetonitrile has been used as the reaction solvent in the present case and pyridine, used for recrystallization, completes the coordination sphere, which suggests that **2** is a highly stable species. The resulting structure consists of polymeric chains directed along the *a* axis, the calixarenes being tilted with respect to this axis. The O···O separations, as in complex **1**, seem to indicate that O1 and O4 are both protonated, the phenoxide group corresponding either to O2 or O3, both involved in strong hydrogen bonds with all their neighbours. The dihedral angles between the four mean planes defined by the aromatic rings and the reference O_4 plane are 46.5(5), 58.4(5), 42.3(7) and 76.2(5)°, the two rings more strongly involved in π-bonding being more 'vertical' than the other ones. These dihedral angles are 57.4(1)° in the *p-tert*-butylcalix[4]arene complex and 25.4(3) (O-coordinated rings) and 68.7(3)° (polyhapto-coordinated rings) in the *p-tert*-butyldihomooxacalix[4]arene one.

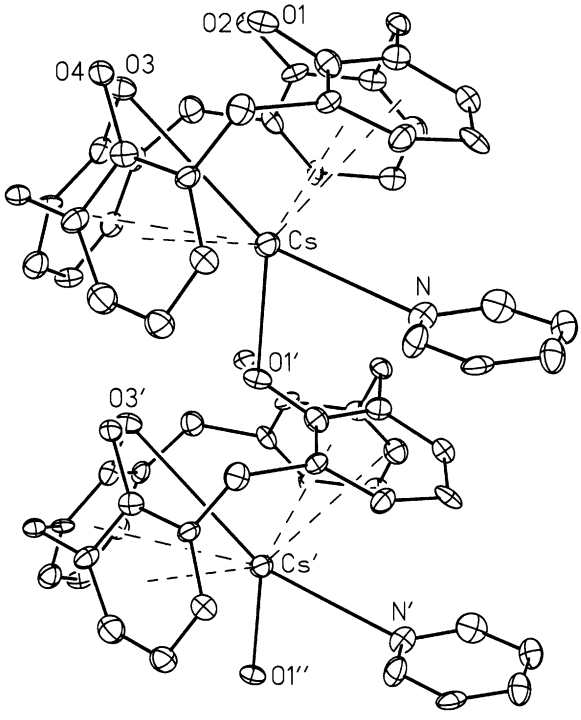

Fig. 2. Partial view of the columnar arrangement in complex **2**, *a* axis vertical. π-Bonding is indicated by dashed lines joining the cation and the aromatic ring centroids. Hydrogen atoms have been omitted for clarity. Thermal ellipsoids are drawn at the 10% probability level. Symmetry codes: $' = x-1, y, z$; $'' = x-2, y, z$.

Comparison of complex **2** with the two other caesium complexes of simple and small calixarenes, *p-tert*-butylcalix[4]arene and *p-tert*-butyldihomooxacalix[4]arene, evidences some interesting features (*p-tert*-butyltetrathiacalix[4]arene does not provide a relevant comparison since it complexes Cs^+ in an *exo* fashion, the soft sulfur donors being prefered to π-electrons). The distance between the cation and the O_4 reference plane can be taken as a measure of the depth of cation inclusion. This value is virtually identical in calix[4]arene and its *p-tert*-butyl derivative (3.56 and 3.57 Å, respectively) and it is significantly shorter in the homo-

oxacalixarene (3.06 Å), allowing for a stronger intramolecular O-coordination in the latter. Slight differences in conformation probably account for O-coordination by calix[4]arene and its absence in the *p*-*tert*-butyl derivative. O-coordination to a neighbouring calixarene in **2**, which can be seen as 'intermolecular' O-coordination for the sake of clarity, notwithstanding the ambiguity of this term in the present case, is very likely related to the absence of *p*-*tert*-butyl substituents, which enables a closer approach of the second anion. In the *p*-*tert*-butyl derivative, an acetonitrile molecule is located on the main axis of the calixarene, near its upper rim, and is coordinated to Cs^+. The distance between the cation and the mean plane defining (approximately) the border of the upper rim (aromatic carbon atoms in *para* position in **2**, terminal *tert*-butyl carbon atoms in the other complexes) is a parameter which gives some information on the accessibility of the cation towards *'intermolecular'* coordination. This parameter amounts to 0.23 Å in **2**, to be compared to 2.29 and 1.83 Å in the other two compounds. The cation is thus far more accessible in the former case, with approximately a free half-coordination sphere.

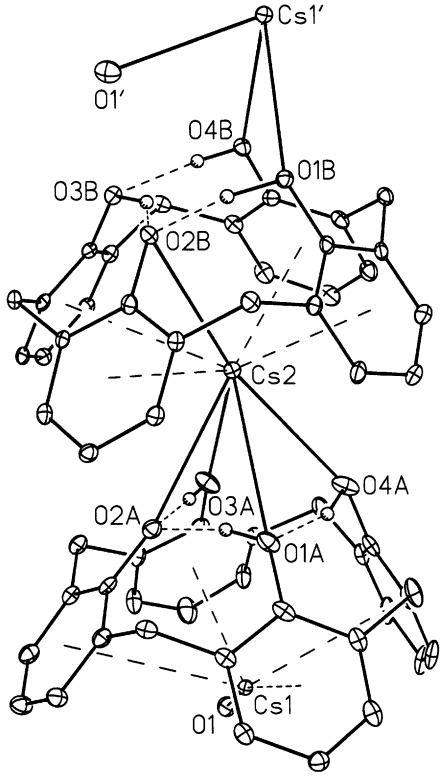

Fig. 3. Partial view of the columnar arrangement parallel to the (101) direction in complex **3**. π-Bonding is indicated by dashed lines joining the cation and the aromatic ring centroids. Hydrogen bonds are represented as dashed lines and phenolic protons as small spheres of arbitrary radii. Other hydrogen atoms and solvent molecules are omitted for clarity. Thermal ellipsoids are drawn at the 10% probability level. Symmetry code: $' = x-0.5, 2.5-y, z-0.5$.

A similar situation arises in $[Cs_2(LH_3)_2(H_2O)]\cdot CH_3CN$ (**3**). This complex, obtained with triethylamine as a deprotonating agent, crystallizes with two independent caesium ions and two calixarene mono-anions, denoted A and B, in the repeat unit (it may be noted that in its triethylammonium ion complexes, calix[4]arene is also mono-deprotonated [27]). As shown in Fig. 3, the overall shape, with formation of polymeric chains parallel to the (101) direction from units related by the glide plane perpendicular to the *b* axis, is roughly analogous to that of complex **2**, but the details are quite different. The two caesium ions are not equivalent in what concerns their environment. Both of them are located in the cavity of a calixarene moiety and are involved in polyhapto bonding. The mean Cs···C distances are 3.9(3), 4.0(3), 3.9(2) and 3.7(4) Å in the case of Cs1 and the four aromatic rings of calixarene A, with the corresponding shortest contacts of 3.530(7), 3.540(7), 3.652(7) and 3.637(8) Å and Cs···centroid distances of 3.61, 3.73, 3.69 and 3.41 Å. In the case of Cs2 and the four aromatic rings of calixarene B, the mean distances are 3.74(9), 4.1(4), 4.0(3) and 3.71(8) Å, the shortest contacts 3.639(7), 3.518(7), 3.558(6) and 3.596(7) Å and the Cs···centroid distances 3.47, 3.89, 3.71 and 3.44 Å. π-Bonding is obvious in both cases, the four rings being differently involved, as in compound **2**. Cs1 is further bound to two phenolic oxygen atoms of a neighbouring calixarene, with a mean Cs–O distance of 3.07(1) Å, slightly shorter than its counterpart in complex **2** and it is also bound to a water molecule (O1) located in a similar manner as the pyridine molecule in **2**. No bond between Cs1 and the oxygen atoms of the calixarene in which it is included is observed, at variance with the previous complex. By contrast, Cs2 is bound to one such oxygen atom, with a bond length of 3.673(5) Å comparable to its equivalent in **2**, and it is also bound to the four oxygen atoms of the neighbouring calixarene, with a much larger mean Cs–O bond length of 3.9(3) Å. The distances between caesium ions and the mean planes defining the borders of the lower and upper rims (O_4 in the first case) are 3.559(3) and 0.144(5) Å for Cs1 and calixarene A and 3.520(3) and 0.145(4) Å for Cs2 and calixarene B, i.e. in both cases the cation is even closer to the upper rim than in complex **2**. The dihedral angles between the aromatic rings and the reference O_4 plane are 52.9(2), 44.3(3), 58.8(3) and 73.7(2)° in calixarene A and 68.2(2), 37.4(3), 48.1(2) and 70.8(2)° in calixarene B, both sets of values indicating a distorsion of the *cone* conformation analogous to that in complex **2**. The dihedral angle between the two reference O_4 planes is 13.0(4)°, indicating a slight deviation of the calixarene units with respect to parallelism. By contrast with the structures of complexes **1** and **2**, the phenolic protons can be located in that of **3**. In both molecules A and B, the phenoxide oxygen atom is O2, which is involved in strong hydrogen bonds with

its two neighbours (Table 2). A possible hydrogen bond links the water molecule and O3B of the neighbouring calixarene.

Apart from the differences between complexes **2** and **3** with regards to O-coordination, the same polymeric structure is found, with a stacking of alternate cations and anions, the latter all pointing towards the same direction. To the best of our knowledge, this peculiar arrangement has never been observed in alkali metal ion complexes of *p*-*R*-calix[4]arene and its derivatives. The lack of *p*-alkyl substituents in the present cases enables the cation enclosed in the calixarene cavity to be easily complexed through the upper rim aperture by a bulky species such as a second calixarene moiety. Although stacking of uncomplexed calixarenes in columns held by feeble interactions is known, the present results show that novel tightly linked polymeric chain assemblages can be obtained from alkali-metal ions and one of the simplest calixarenes.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 187709–187711 for compounds **1**, **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

products but others are also formed in variable amounts, as was shown by IR and NMR investigation of the reaction mixture. From this mixture one new compound was isolated in crystalline form. This prompted us to conduct a structural examination of this novel norbornadiene complex, [Mo(μ-Cl)($SnCl_3$)$(CO)_2$(η^4-C_7H_8)(NCMe)] (**3**). To the best of our knowledge, up to now only three molybdenum(II) compounds containing norbornadiene ligands, [$MoBr_2$(CO)(η^4-C_7H_8)(bpy)] [9], [MoBr(CO)(η^4-C_7H_8)(terpy)]SbF_6 [10] and [Mo(μ-Cl)($SnCl_3$)$(CO)_3$(η^4-C_7H_8)] (**2**) [7], have been analysed by X-ray diffraction studies.

Additionally, we were especially intrigued by the possibility that the seven-coordinate molybdenum(II) and tungsten(II) compounds containing norbornadiene ligands could initiate ROMP of cyclic olefins and the rearrangement mechanism of the coordinated alkene to the alkylidene species initiating the catalytic reaction.

2. Experimental

2.1. General data

All reactions were carried out under nitrogen by standard Schlenk line techniques. The solvents and reagents applied were dried, distilled and stored in air-tight solvent bulbs with Teflon closures. Solution IR spectra were obtained using KBr or NaCl plates whereas solid samples were recorded using KBr pellets on a Nicolet model-400 FT-IR instrument. ^{1}H, ^{13}C, ^{13}C{^{1}H} and two-dimensional correlation ^{1}H–^{1}H, and ^{1}H–^{13}C NMR spectra were recorded on an AMX 300 and 500 MHz Brucker spectrometer. All chemical shifts are referenced to solvent signals. In ^{1}H NMR spectra $\delta_H = 1.98$ for CD_3CN, $\delta_H = 5.32$ for CD_2Cl_2 and $\delta_H = 7.24$ for $CDCl_3$. In ^{13}C NMR spectra $\delta_C = 118.00$ for CD_3CN, $\delta_C = 54.00$ for CD_2Cl_2 and $\delta_C = 77.00$ for $CDCl_3$.

2.2. Synthesis of [Mo(μ-Cl)($SnCl_3$)$(CO)_2$(η^4-C_7H_8)(NCMe)] (3)

A solution of the complex [Mo(μ-Cl)($SnCl_3$)$(CO)_3$($NCMe)_2$] (**1**) [11] (0.25 g, 0.48 mmol) and NBD (0.1 cm^3, 0.9 mmol) in CH_2Cl_2 (50 cm^3) was stirred under an atmosphere of nitrogen at room temperature (r.t.) for 96 h. The orange–yellow solution was layered with $C_6H_5CH_3$ (2 cm^3) and n-C_7H_{16} (12 cm^3) and put into a refrigerator. After 2 weeks orange crystals of [Mo(μ-Cl)($SnCl_3$)$(CO)_2$(η^4-C_7H_8)(NCMe)] (**3**) were obtained (0.16 g, 60%). The solution was removed and the crystals were washed several times with n-C_7H_{16} to separate a greenish–yellow powder of other molybdenum compound.

Anal. Calc. for $C_{11}H_{11}Cl_4MoNO_2Sn$: C, 24.21; H, 2.03; N, 2.57%. Found: C, 24.18; H, 2.10; N, 2.50%. IR (cm^{-1}, KBr disc): 2291 (vw) ν(CN), 2012 (s), 1963 (s) ν(CO); ^{1}H NMR (δ_H, ppm, CD_2Cl_2, 293 K): 5.43 (t, $J_{HH} = 3.7$ Hz, $^1J_{CH} = 182$ Hz, =C*H*), 4.84 (t, $J_{HH} = 4.0$ Hz, $^1J_{CH} = 182$ Hz, =C*H*), 4.00 (t, $J_{HH} = 4.5$ Hz, $^1J_{CH} = 180$ Hz, =C*H*), 3.91 (t, $J_{HH} = 4.6$ Hz, =C*H*), 3.81 (broad s, C*H*), 3.76 (broad s, C*H*), 2.46 (CH_3CN), 1.77 (m, CH_2); ^{13}C{^{1}H} NMR (δ_C, ppm, CD_2Cl_2, 293 K): 219.67, 214.17 (*C*O), 128.45 (CH_3*C*N), 96.00, 94.07, 53.86, 52.31 (=*C*H), 62.09 (*C*H_2), 45.67, 45.42 (*C*H), 4.83 (*C*H_3CN).

2.3. Synthesis of [Mo($SnCl_3$)$_2$(CO)(η^4-C_7H_8)($NCMe)_2$] (4)

A solution of complex **1** (0.20 g, 0.38 mmol) and NBD (0.1 cm^3, 0.9 mmol) in CH_2Cl_2 (25 cm^3) was stirred under an atmosphere of nitrogen at r.t. for 1 week. During that time a greenish–yellow precipitate was settled out. It was separated by filtration, washed with CH_2Cl_2 and dried. After crystallisation from MeCN, the compound was identified as [Mo($SnCl_3$)$_2$(CO)(η^4-C_7H_8)($NCMe)_2$] (**4**) (0.1 g, 35%). *Anal*. Calc. for $C_{12}H_{14}Cl_6MoN_2OSn_2$ C, 19.26; H, 1.89; N, 3.74. Found: C, 18.94; H, 2.05; N, 4.07%. IR (cm^{-1}, KBr disc): 2320 (w), 2291 (w), ν(CN), 1961 (s) ν(CO); ^{1}H NMR (δ_H, ppm, CD_3CN, 293 K): 4.43 (t, $J_{HH} = 4.3$ Hz, =C*H*), 4.04 (t, $J_{HH} = 4.3$ Hz, =C*H*), 3.72 (broad s, C*H*), 3.65 (broad s, C*H*), 2.45, 2.42 (CH_3CN), 1.67 (CH_2); ^{13}C NMR (δ_C, ppm, CD_3CN, 293 K): 215.23 (*C*O), 129.45, 126.39 (CH_3*C*N), 70.31 (dt, $^1J_{CH} = 186$ Hz, $^3J_{CH} = 6$ Hz, =*C*H), 68.31 (dt, $^1J_{CH} = 185$ Hz, $^3J_{CH} = 6$ Hz, =*C*H), 60.29 (t, $^1J_{CH} = 135$ Hz, *C*H_2), 43.52 (d, $^1J_{CH} = 155$ Hz, *C*H), 42.73 (d, $^1J_{CH} = 155$ Hz, *C*H), 4.74 (*C*H_3CN).

2.4. Crystal and refinement data for compound 3

Crystal data and relevant refinement details are presented in Table 1. The orange–yellow crystals of **3** were grown from a CH_2Cl_2–$C_6H_5CH_3$–n-C_7H_{16} (5:0.2:1.2) solution. The crystals were stable enough when handled in an inert atmosphere or coated with a light-hydrocarbon oil to protect them from the atmosphere.

Crystal data for **3** were collected on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation, μ(Mo Kα) = 2.848 mm^{-1}. The data were corrected for Lp effects. After refinement with isotropic displacement parameters for all atoms, an absorption correction based on the least-squares filled against $|F_c| - |F_o|$ differences was also applied [12]. Minimum and maximum value of the absorption correction factors ranging between 0.7875 and 1.1842. Data reduction and analysis were carried out with

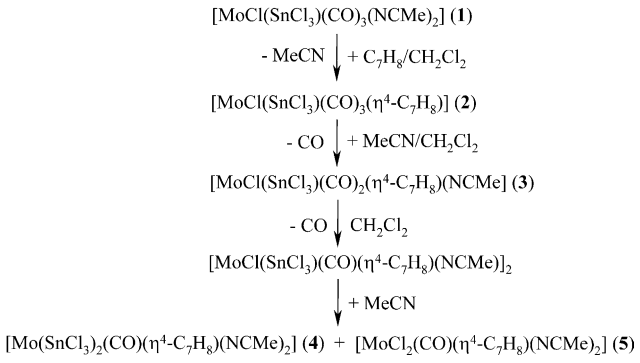
KUMA DIFFRACTION (Wrocław) programs. The structure was solved by heavy-atom methods using the SHELXS-97 program [13] and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 program [14] to $R_1 = 0.0613$, $wR_2 = 0.0704$. Hydrogen atoms were included from geometry of molecules. During the refinement they were treated as rigid groups with fixed interatomic distances.

2.5. Reactions in NMR tubes

2.5.1. Decomposition of compound 3 in $CDCl_3$

The solution of compound **3** (0.01 g, 0.018 mmol) in $CDCl_3$ (0.5 cm^3) was periodically analysed by ^{1}H NMR spectroscopy over a period of several days at r.t. The decay of signals due to compound **3** and the formation of an amorphous greenish–yellow precipitate were observed. The ^{1}H NMR spectrum of this solid in CD_3CN solution shows signals due to compound **4** (see Section 2.3) and other proton signals at $\delta_H = 4.12$, 3.79 (t, $J_{HH} = 4.4$ Hz, =C*H*), 3.63, 3.56 (broad s, C*H*), 1.62 (CH_2) assigned to the compound [$MoCl_2$(CO)(η^4-C_7H_8)(NCMe)$_2$] (**5**). In the ^{13}C{^{1}H} NMR spectrum, carbon signals at 68.31, 43.00 (=*C*H), 59.21 (*C*H$_2$), 42.80, 41.88 (*C*H) due to compound **5** were detected. The proper assignment of these resonances was possible due to the correlation of ^{1}H–^{1}H and ^{1}H–^{13}C NMR spectra.



2.5.2. Reaction of compound 3 with NBD in CD_2Cl_2

To the NMR tube containing the solution of compound **3** (0.04 g, 0.073 mmol) in CD_2Cl_2 (0.5 cm^3) were added 10 equiv. of NBD (0.06 cm^3, 0.73 mmol) by means of a syringe and a sample was periodically analysed by ^{1}H NMR spectroscopy at r.t. A decrease in the intensity of proton signals due to **3** and increase in the intensity of proton signals due to polynorbornadiene (poly-NBD) at $\delta_H = 5.60$, 5.57, 5.37, 5.20 (=C*H*), 3.64, 3.24 (C*H*), 2.33 and 1.23 (CH_2) was parallel with the appearance of signals at $\delta_H = 10.49$ (broad s), 6.21 (dd, $J_{HH} = 5.6$ and 3.0 Hz), 5.99 (dd, $J_{HH} = 5.6$ and 3.0 Hz), 2.94 (broad s) and 2.86 (broad s), which can be assigned to an alkylidene ligand deriving from the transformation of an NBD ligand.

3. Results and discussion

3.1. Reaction of [Mo(μ-Cl)($SnCl_3$)(CO)$_3$(NCMe)$_2$] (1) with NBD

In reaction of [Mo(μ-Cl)($SnCl_3$)(CO)$_3$(NCMe)$_2$] (**1**) with NBD monitored by IR spectra in dichloromethane solution, the formation of [Mo(μ-Cl)($SnCl_3$)(CO)$_3$(η^4-C_7H_8)] (**2**) is observed due to a characteristic weak ν(CO) band at approximately 2090 cm^{-1} [7] from the beginning of the reaction. After prolonged reaction time this band decays and other ν(CO) bands appear at lower frequencies and increase. During a slow crystallisation process the compound [Mo(μ-Cl)($SnCl_3$)(CO)$_2$(η^4-C_7H_8)(NCMe)] (**3**) is separated from the reaction mixture in a pure crystalline form. In the IR spectrum of **3** two equal-intensity ν(CO) bands at 2012 and 1963 cm^{-1} are observed, indicating the *cis* arrangement of the two CO ligands. Compound **3** is the first example of a Group 6 metal(II), a norbornadiene complex, in which such an arrangement of two CO groups is observed. Up to now only compounds with two mutually *trans* CO groups, such as [WBr_2(CO)$_2$(η^4-C_7H_8)] [15], [WBr(SC_6F_5)(CO)$_2$(η^4-C_7H_8)] [16] and [WBr_2(CO)$_2$(η^4-C_7H_8)(PMePh_2)] [17], have been characterised by X-ray diffraction studies. In the IR spectra of these and other bis(carbonyl) compounds one weak and one strong ν(CO) band has been observed [9,15–17]. However, compound **3** is unstable in CH_2Cl_2 solution and decomposes losing the CO ligand. This process is accompanied by the decay of the ν(CO) bands characteristic for **3** and an increase in one strong band at about 1970 cm^{-1} in CH_2Cl_2 solution. Simultaneously, a greenish–yellow precipitate is formed. It is soluble only in coordinating solvents such as acetonitrile. After recrystallisation from MeCN, a new compound was

Scheme 1.

isolated with one characteristic ν(CO) band at 1961 cm^{-1} (KBr) and elemental analysis for C, H and N indicating the presence of $[Mo(SnCl_3)_2(CO)(\eta^4\text{-}C_7H_8)(NCMe)_2]$ (**4**). The reaction course and the pathway leading to the formation of compound **4** are proposed in Scheme 1. This involves the CO loss in CH_2Cl_2 solution and the formation of a dimeric compound containing chloride bridges. In acetonitrile solution the redistribution of anionic ligands between two molybdenum atoms occurs to give bis(stannyl) and bis(chloride) complexes **4** and **5**. Such a process were observed earlier during the preparation of $[Mo(SnCl_3)_2(CO)_2(NCMe)_3]$ from compound **1** [11].

3.2. NMR identification of new compounds containing NBD ligand

The ^{1}H NMR spectrum of **3** shows seven well-separated signals due to the protons of the norbornadiene ligand. Four peaks at $\delta_H = 5.43$, 4.84, 4.00 and 3.91, which appear as pseudo-triplets with approximately $J_{HH} = 4$ Hz, are due to protons attached to the double C=C bonds, while the broad peaks at $\delta_H = 3.81$ and 3.76 are due to protons attached to the bridgehead methine carbons. The signal at $\delta_H = 1.77$ appears as a pseudo-quartet, i.e. two doublets with second-order distortion, and can be assigned to two protons of the bridge methylene group. Four resonances of the olefin protons of **3** are at a higher field than that of the free NBD by 1.22–2.74 ppm. Thus, the ^{1}H NMR data for **3** suggest that the NBD ligand coordinates unsymmetrically to the metal centre.

For the previously investigated compound **2**, with a more symmetrically coordinated NBD ligand, only two olefinic proton signals at $\delta_H = 5.27$ and 4.02 were observed in the ^{1}H NMR spectrum [7]. The lower-field norbornadiene signal of **2** was assigned to the protons of the HC=CH unit in *trans* position to the CO group and the signal at a higher field to the protons of the double bond *trans* to the chlorine ligand. By analogy, for **3**, two lower-field resonances can be assigned to protons of the olefinic bond *trans* to CO and two higher-field resonances to protons of the olefinic bond *trans* to an anionic ligand. However, in dichloromethane solution compound **3** slowly decomposes to give the complex $[MoCl(SnCl_3)(CO)(\eta^4\text{-}C_7H_8)(NCMe)]_2$, insoluble in this solution and most probably dimeric. The latter compound in acetonitrile solution gives two different monomeric compounds, **4** and **5** (Scheme 1), both characterised by five proton signals in the integration ratio 2:2:1:1:2 in ^{1}H NMR spectra. Only two olefinic proton signals at δ_H 4.43 and 4.04 are observed in the ^{1}H NMR spectrum of compound **4**. However, from the ^{1}H–^{1}H NMR correlation spectrum it can be seen that each of them is coupled with different bridgehead methine protons ($\delta_H = 3.65$ and 3.72, respectively), thus both signals are due to protons belonging to the same olefinic unit. The high value of the coordination shift ($\Delta\delta_H$) of these signals ($\Delta\delta_H = 2.22$ and 2.61) suggests that both olefinic units are in *trans* position to the same, most probably anionic ligands. A similar set of NBD resonances as for **4** has been reported by Daniel et al. for $[MoBr_2(CO)(\eta^4\text{-}C_7H_8)(bpy)]$ ($\delta_H = 4.48$, 3.92 (=C*H*), 3.96, 3.65 (C*H*) and 1.76 (CH_2) [9]). Proton signals due to $[MoCl_2(CO)(\eta^4\text{-}C_7H_8)(NCMe)_2]$ (**5**), which is formed alongside compound **4** in the CH_3CN solution of the decarbonylation product of compound **3** (Scheme 1), were observed at $\delta_H = 4.12$, 3.79 (=C*H*), 3.63, 3.56 (C*H*) and 1.62 (CH_2). Such a ^{1}H NMR spectrum was always observed immediately after the dissolution in CD_3CN of the precipitate formed in CH_2Cl_2 solution of compound **3** (Scheme 1). Compound **5** is more labile than **4** and decays during the isolation process.

The $^{13}C\{^1H\}$ NMR spectrum of **3** shows four olefinic carbon resonances. The detection of two higher-field signals in CD_2Cl_2 solution was possible due to the measurement of two-dimensional heteronuclear correlation spectra (^{1}H–^{13}C NMR). The chemical shifts of the olefinic carbon signals for compound **4** are at a higher field than for **2** [7] and **3**. The greater coordination shift of the olefinic protons and the olefinic carbon signals for **4** indicate a stronger interaction of the NBD ligand with the Mo centre in the latter complex than in **2** or **3**. The carbon resonances for the norbornadiene ligand in compound **5** are at higher field, than for the other molybdenum compounds **2**–**4**. The higher-field shifts of the olefinic proton and the carbon signals suggest a stronger interaction of the NBD ligand with the molybdenum centre for **5** than for **2**, **3** and **4**. This correlates with π acidity of the ligands in *trans* position to the olefinic bonds, which decreases in the order $CO > SnCl_3^- > Cl^-$.

3.3. Solid state structure of 3

The results of an X-ray investigation of compound **3** are shown in Figs. 1 and 2 and Tables 1 and 2. The

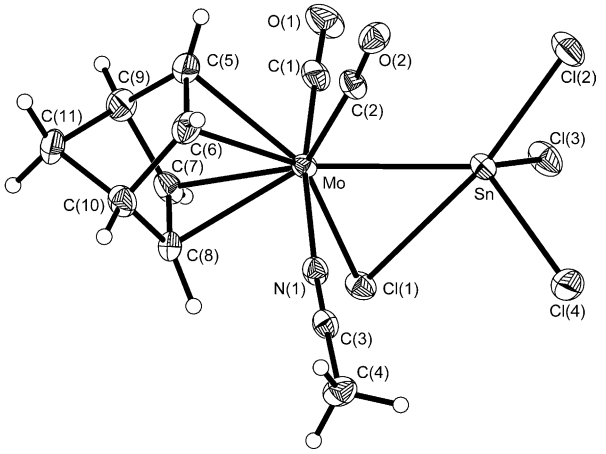


Fig. 1. Molecular structure of $[Mo(\mu\text{-}Cl)(SnCl_3)(CO)_2(\eta^4\text{-}C_7H_8)(NCMe)]$ (**3**).

molecule $[Mo(\mu\text{-}Cl)(SnCl_3)(CO)_2(\eta^4\text{-}C_7H_8)(NCMe)]$ (**3**), is shown in Fig. 1 together with the atomic numbering scheme. Table 2 contains selected bond distances and angles. The molybdenum atom is seven-coordinate and the tin atom is five-coordinate, with one chlorine atom occupying a bridging position between the two metal atoms. The environment of the molybdenum atom in **3** is a distorted pentagonal bipyramid (Fig. 2). In the pentagonal plane there are two olefinic bonds of the NBD ligand, carbonyl, $SnCl_3^-$ and chloride ligands. The Mo–Sn bond of 2.739(1) Å is supported by a chlorine bridge.

The angles subtended at the molybdenum atom by the five atoms determining the pentagonal plane are in the 63.1°–82.1° range (Fig. 2). The greatest distortions from the regularity of the pentagonal bipyramid appear to be associated with the presence of the chelating NBD ligand. The angles between the two alkene bonds are approximately 63° while those between the alkene bonds and the neighbouring ligands are approximately 80°.

The two axial sites are occupied by CO and acetonitrile ligands with a C(1)–Mo–N(1) angle of 170.2(2)°. The CO group *trans* to the nitrile ligand is a shorter distance from the Mo atom, at 1.989(7) Å, than the CO group *trans* to the olefinic ligand, at 2.010(6) Å.

The most significant feature of complex **3** is the fact that the arrangement of the coordination of the norbornadiene ligand is of two types. One of the olefinic bonds is approximately *trans* to CO and the other *trans* to Cl. This gives rise to a slight difference between the Mo–C distances; such that Mo–C(5) = 2.288(7) and Mo–C(6) = 2.338(7) Å are almost 0.12 Å shorter than Mo–C(8) = 2.403(6) and Mo–C(7) = 2.455(6) Å, whereas the difference between the shortest and the longest Mo–C(olefinic) bond is 0.167 Å. The above bond lengths are in excellent agreement with the degree of electron back-donation from the dπ-orbitals of molybdenum to the ligands whose π acidity is taken into account. As CO is a better π acid than the olefinic bond, back-donation to CO is much preferred. For the C=C and its *trans* Cl ligand, the electron density due to back-donation is almost completely accepted by C=C, resulting in shortened Mo–C(5) and Mo–C(6) and in lengthened C(5)–C(6) distances compared to Mo–C(7) and Mo–C(8) and C(7)–C(8) distances. Thus the

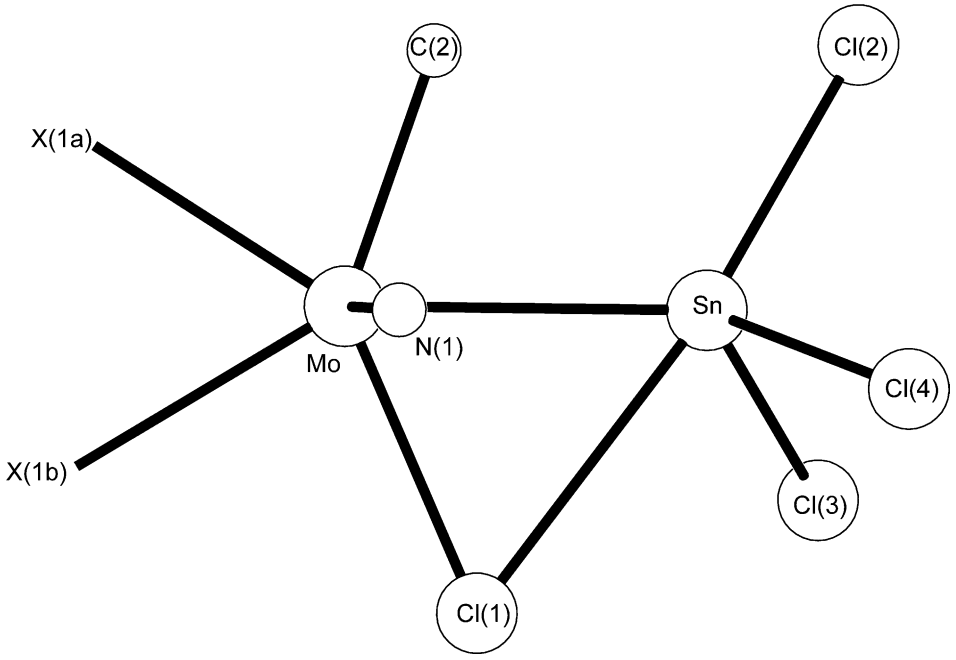

Fig. 2. Projection of the coordination sphere of Mo on the pentagonal plane illustrating the pentagonal bipyramid geometry of **3**. X(1a) and X(1b) represents the midpoint of the C=C linkage.

structure of **3** provides a good model for comparing the effect of the relative position of alkene and CO ligands on the Mo–C bond distance. Regarding the mutual position of the olefinic carbons and the two ligands (CO and NCMe) in an axial position to the pentagonal plane, it should be noted that the olefinic carbon which is closer to the CO ligand is more strongly coordinated to the metal, with the Mo–C distance 0.05 Å shorter than that closer to the nitrile group (Fig. 2).

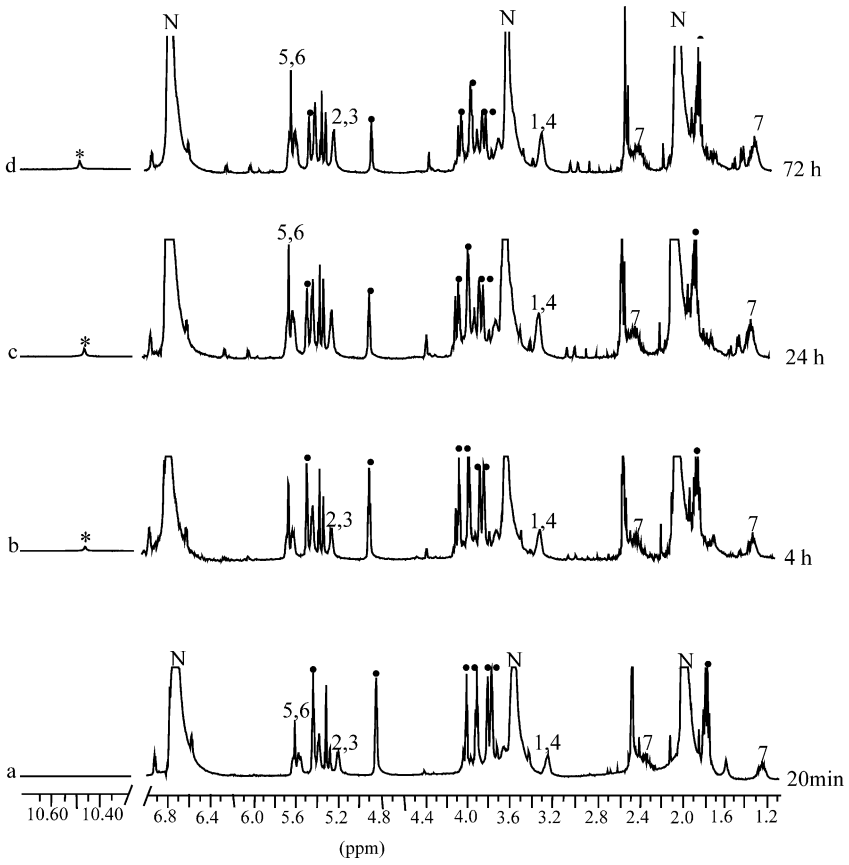
The tin atom is five-coordinate in **3** with a geometry that is best described as distorted trigonal bipyramid with the two chlorine atoms occupying the axial sites. In the trigonal plane there are two chlorine atoms and the Mo atom. The tin-to-bridging-chlorine distance is 2.897(2) Å, being considerably longer than the Sn–Cl distances in the trigonal plane (av. 2.35 Å). The molybdenum-to-bridging-chlorine distance is 2.484(1) Å and indicates that the bridging chlorine forms a stronger bond with the molybdenum whereas the Sn–Cl bond is weakened.

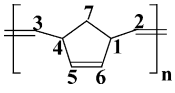
3.4. Searching for the catalytically active species

The reaction between **3** and an excess of NBD was followed by ^{1}H NMR spectroscopy, which confirmed the formation of polynorbornadiene with characteristic signals of the olefinic protons above 5 ppm (Fig. 3). The ROMP of NBD starts immediately after reagents are mixed. At the beginning of a reaction the olefinic proton signals of the coordinated NBD in **3** decrease in intensity. Simultaneously the signal of an alkylidene species at $\delta_H = 10.49$ appears and grows. Parallel with the latter signal, other, very low-intensity signals appear at $\delta_H = 6.21$, 5.99, 2.99 and 2.91. These can be assigned to protons of a cyclopentadienyl moiety formed after the rearrangement of the NBD ligand (Scheme 2). The coupling between protons observed at $\delta_H = 6.21$ and 5.99 was confirmed by two-dimensional correlation ^{1}H–^{1}H NMR spectra. After a prolonged reaction time (7 days), signals due to **3** decrease in intensity by approximately 60% and the intensity of signals due to poly-NBD increases considerably. However, only a small part of compound **3** rearranges to species initiating the polymerisation reaction. The intensity of the signal due to the proton of the alkylidene ligand at $\delta_H =$ 10.49 reaches a value of 0.5–5% of the intensity of the signal due to the starting compound **3** at $\delta_H = 4.84$ (Fig. 3a–d). Although the polymerisation reaction is stopped due to a gelation process, at least 10 molecules of NBD were polymerised by one molecule of compound **3**.

In the observed ^{13}C{^{1}H} NMR spectrum (Fig. 4) of the above reaction mixture the microstructure of the poly-NBD formed can be analysed [18]. From the intensity ratio of the signal due to methine carbons denoted 1,4 at $\delta_C = 48.38$ (*trans* double bond) and 43.65 (*cis* double bond), the value of the *cis* double bond content was calculated to be approximately 42%. This spectrum was measured during a reaction in the NMR tube, so carbon signals due to free NBD and the NBD ligand in the residual compound **3** could still be observed.

Although the mechanism of the transformation of compound **3** to the alkylidene species initiating the ROMP is not clear at present, three possible ways of norbornadiene ligand rearrangement can be considered. One of the possible reaction routes may involve first, the formation of metallacyclobutane species (due to the valence isomerisation and the creation of the cyclopropane ring) and next alkylidene containing a cyclopentadienyl fragment as the end group (Scheme 2A). The rearrangement of two norbornadiene molecules to a





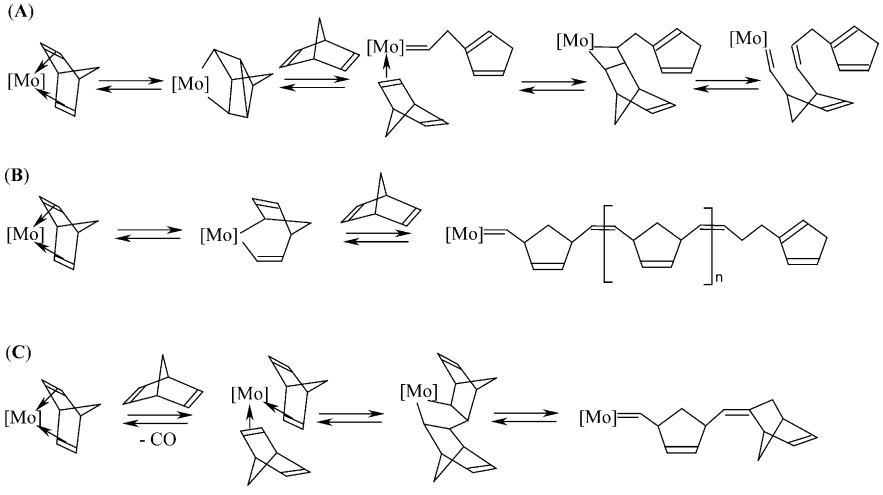


Fig. 3. The olefinic proton region of the ^{1}H NMR spectra recorded at 500 MHz during reaction of **3** and NBD (N) at 293 K in CD_2Cl_2 after (a) 20 min, (b) 4 h, (c) 24 h, (d) 72 h. The resonances denoted by (●) are due to protons of the NBD ligand in **3**. Signals assigned to an alkylidene signal at $\delta_H = 10.49$, 6.21, 5.98, 2.96 and 2.89 are marked with an asterisk (*). Proton signals in the poly-NBD are labelled as follows:

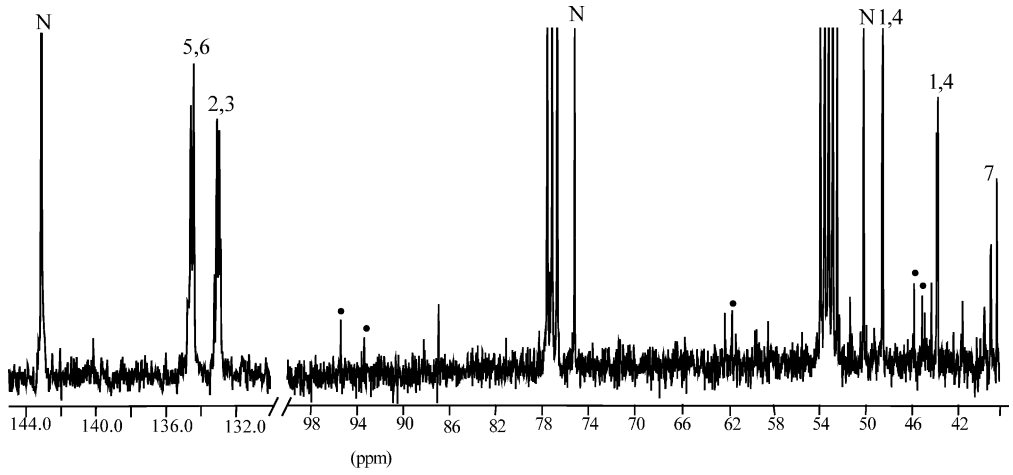
nortricyclyl–norbornenyl group was first observed by Itoh et al. [19], in reduction reaction of $[RuCl_2(C_7H_8)]_n$ by means of zinc powder in the presence of NBD. Other pathway for the conversion of coordinated NBD in **3** is

Scheme 2.



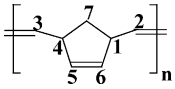


Fig. 4. $^{13}C\{^{1}H\}$ NMR spectrum recorded at 300 MHz in CD_2Cl_2–$CDCl_3$ = 5:2, after reaction of **3** (●) and NBD (N) at 293 K. Carbon signals in the poly-NBD are labelled as follows:

the cleavage of C–C bond and the formation of vinylcyclopantadiene species (Scheme 2B). This type of transformation was observed in reaction of several ruthenium complexes containing norbornadiene ligand [20–25]. Such a transformation can result first from the asymmetry shown by the NBD ligand and a very weak interaction of one of the olefinic bond with the metal centre. Another reason for the high reactivity of compound **3** towards NBD is that the carbonyl ligand in *trans* position to the olefinic bond is very labile. Thus, in the presence of an excess of NBD, the weakly coordinating alkene bond or CO ligand in **3** can be substituted by the olefinic bond of the NBD molecule leading to the formation of a metallacyclopentane (Scheme 2C). Such intermediates were considered by Grubbs and Miyashita [26], Schrock and coworkers [27] and Rooney [28,29]. However, our results have only shown the formation of an alkylidene ligand from the olefin coordinated to molybdenum(II). Hopefully further DFT calculation on the transformation of the model compounds **2** and **3** to the alkylidene complex could established this mechanistic proposal.

4. Conclusions

In this work the reactivity and catalytic application of a heterobimetallic Mo–Sn complex **1** in metathesis polymerisation of norbornadiene have been studied. It is shown that the labile nitrile ligands in **1** can be substituted under mild conditions by norbornadiene to give $[Mo(\mu\text{-}Cl)(SnCl_3)(CO)_3(\eta^4\text{-}C_7H_8)]$ (**2**). Next, the CO ligand in complex **2** very easily undergoes substitution by nitrile to give $[Mo(\mu\text{-}Cl)(SnCl_3)(CO)_2(\eta^4\text{-}C_7H_8)(NCMe)]$ (**3**).

The results presented here conclusively establish the existence of a very unsymmetrically coordinated norbornadiene ligand in **3**. We also outline how these structural features relate to the alkylidene ligand formation observed in the presence of an excess of norbornadiene, and the initiation of norbornadiene polymerisation.

To the best of our knowledge this paper presents the first study that has simultaneously detected the alkylidene ligand formation from olefin coordinated to metal and the initiation of ROMP by this catalytically active species.

Studies aiming at a better understanding of the formation mechanism as well as further applications of this new compound in catalysis will be continued.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 182154 for compound **3**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

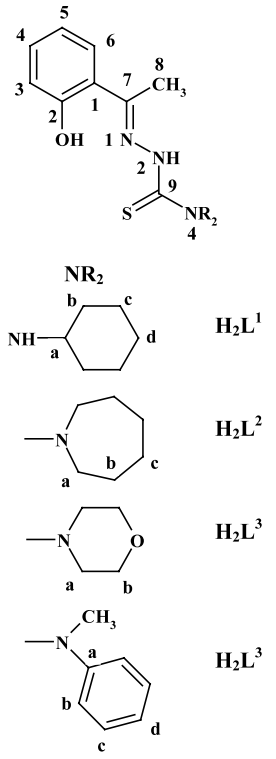

Fig. 1. Structures of thiosemicarbazones.

2. Results and discussion

2.1. Synthesis of complexes

It has been found that the Co(II) ion undergoes oxidation in the presence of methanol or chloroform unlike in ethanol [15]. All the complexes are found to be brown in colour but the crystalline nature may vary depending on their mode of formation. Complexes of H_2L^4 were found to give fine crystals on keeping while compounds of H_2L^1 and H_2L^2 were found to give the products more readily.

The elemental analysis data (Table 1) of all compounds suggests a formulation of [$MLBN_3$]. This along with the conductance data indicates that the azide ion is coordinated to the metal. However, for the compound **1** the elemental data matches with a stochiometry containing 0.5 molecule of water of crystallization/lattice water. The compounds **2** and **4** each contain one molecule of uncoordinated water and compound **6** contains three molecules of water. Compound **8** is obtained in two different colours, viz. brown (**8a**) and green (**8b**). The elemental data indicate that **8a** is having one molecule of water, while the later **8b** is devoid of it. The elemental data of compound **8b** is reported here. Both give similar IR and UV spectra. The slight variations found in the elemental data for some of the compounds are due to the presence of non-stochiometric amount of water of crystallization present. All the complexes are found to be diamagnetic confirming that the cobalt is in the +3 oxidation state and hence corresponds to d^6 ion in strong field.

The thermal analysis of the compounds **1**, **2**, **4** and **6** showed that the non-stochiometric water of crystallization begins to leave in the 220–260 °C range. The loss is gradual in **1**, **4** and in **5** but a sharp change at 250 °C is found in the case of compound **2**. All the complexes started decomposing at 310 °C and the changes are sharp at 330 °C.

The FAB mass spectrum of the compound **6** gives a molecular ion [M^+] peak at m/z 613 (15) corresponding to trihydrated formulation. The next major peak at m/z 558 (20) corresponds to the non-hydrated formulation. The next lower but major fraction appears at m/z 516 (78) corresponding to a fraction stripped off its azido group.

2.2. Crystal structure of CoL^4bipyN_3

Dark brown X-ray quality single crystals of compound **7** (CoL^4bipyN_3) were grown by slow diffusion of ethanol into a solution of the compound in chloroform. The compound crystallized into a monoclinic lattice with space group symmetry $P2_1/a$ with one molecule per asymmetric unit. The molecular structure of the compound was found to be distorted octahedral. The

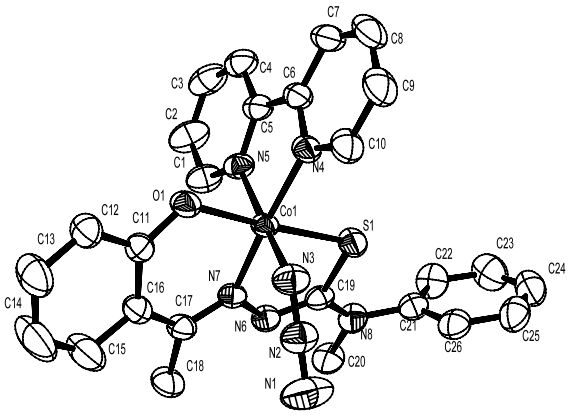

Fig. 2. ORTEP diagram for compound **7** (CoL^4bipyN_3), displacement ellipsoids are drawn at the 54% probability level and hydrogen atoms are omitted for clarity.

perspective view of the complex CoL^4bipyN_3 (Fig. 2) shows that the thiosemicarbazone is functioning as an ONS donor ligand and it is coordinated in a meridonal arrangement along with bipy and a terminal azido group. The selected bond lengths and angles are presented in Table 2. As observed the thiosemicarbazone moiety is in the same plane of the Co atom indicated by the bond angles O1–Co1–N3 (89.51°) and N7–Co1–O1 (94.9°). The apical positions of the octahedron are occupied by one of the nitrogen N3 of the azido group and N5 of the bipy with bond lengths 1.946 Å (Co–N3) and 1.963 Å (Co–N5). The bond angles N3–Co1–N5 (172.3°) and N5–Co1–N4 (82°) are quiet far from a perfect octahedron indicating distortion in the geometry. Coordination lengthens the thiosemicarbazone moiety's C19–S1 bond from 1.699 to 1.743 Å [12] and shortens C19–N6 bond from 1.358 to 1.294 Å, which is consistent with the C19–S1 acquiring a partial single bond and C19–N6 a partial double bond. Short bond length of Co–N4 (1.948 Å) compared to Co–N5 (1.963 Å) indicates strong bonding due to equatorial bipy nitrogen. Strong coordination of azomethine nitrogen is indicated by much shorter Co–N7 (1.900 Å) bond length. The N(4) methyl group (C20) is on the same side of the thiosemicarbazone moiety as the methyl group C18 of the azomethine function (i.e. *trans* to the sulfur and *Z* isomer). The Co–N3–N2 bond angle is 121.36° and shows the azido coordination is bent but N3–N2–N1 (177.2°) is nearly linear.

2.3. Electronic and IR spectra

The electronic spectra (Table 3) of Co(III) complexes have four d–d bands: $^1A_{1g}\rightarrow{}^1T_{1g}$; $^1A_{1g}\rightarrow{}^1T_{2g}$; $^1A_{1g}\rightarrow{}^3T_{1g}$ and $^1A_{1g}\rightarrow{}^3T_{2g}$ [16,17]. We have assigned $^1A_{1g}\rightarrow{}^1T_{1g}$ approximately 20 620 cm^{-1}, $^1A_{1g}\rightarrow{}^1T_{2g}$ approximately 25 000 cm^{-1}, and $^1A_{1g}\rightarrow{}^3T_{2g}$ approximately 16 870 cm^{-1}. Assignment of the two high energy bands is complicated by overlap of inter ligand and charge transfer transitions. $^1A_{1g}\rightarrow{}^3T_{2g}$ was most difficult to assign because this weak spin forbidden band is always at the onset of other high-energy intense bands. The CT band is rather too broad and is explained as a combination of two bands resulting from the S→Co(III) and O→Co(III) LMCT transitions. Compounds **8a** and **8b** dissolve to give a reddish brown solution in CH_2Cl_2 and give similar IR and UV spectra.

Compounds **1**, **4**, **5** and **6** show broad IR bands (Table 4) approximately 3400 cm^{-1}, which is due to the O–H stretching modes of the uncoordinated water molecules. The IR spectrum of the complexes show peaks approximately 1595 cm^{-1} due to the newly formed $^2N{=}^9C$ bond indicating that the coordination of the thiosemicarbazone takes place in the form of thiol rather than as thione. The lowering of the band approximately 1602 cm^{-1} ($^7C{=}^1N$) by 30–50 cm^{-1} is an explicit evidence for the coordination of the thiosemicarbazone through the azomethine nitrogen. The spectra of the complexes exhibit a systematic shift in the position of the bands in the region 1600–1350 cm^{-1} due to ν(C=C) and ν(C=N) vibrational modes, and their mixing patterns are different from those present in the ligand spectrum. Coordination of the bases is indicated by the presence of weak bands in the 410–485 cm^{-1} region due to Co–N stretching vibration. Weak bands in the region 510–565 cm^{-1} indicate the presence of Co–O bond resulting from coordination of phenolic oxygen. Besides the shifting of the band due to Ar–O group to lower

[a] ε is expressed in (l mol^{-1} cm^{-1}).

frequencies indicates the weakening of the Ar–O bond due to coordination. The presence of the azide group in the coordination sphere is evidenced from the very strong and sharp absorption peak approximately 2022 cm^{-1}. The azido group is bound to cobalt as terminal indicated by a strong absorption at 2030 cm^{-1} characteristic of a terminal azido group [18]. The slight lowering in values is assumed to the result of its coordination to the metal [19]. The coordination via the thiolate sulfur is evidenced from the lowering of band due to the C–S stretching vibration approximately 1365 cm^{-1}, and C–S bending vibration approximately 864 cm^{-1}. The two very intense bands at 1495 and 1465 cm^{-1} show presence of different delocalised ligand molecules linked to the metal through the imine nitrogen.

2.4. ^1H NMR spectra

^1H NMR spectral measurements (Table 5) show disappearance of the peaks corresponding to the phenolic and proton attached to the ^2N of the thiosemicarbazone moiety. This supports the evidence from IR spectra that the thiosemicarbazone coordinate as dibasic tridentate ligand existing in the thiol form. The signals corresponding to the phenoxy group are shifted up field by 0.2–0.6 ppm in the complex. This is due to the electron withdrawal from the aromatic ring due to coordination with the metal. The protons corresponding to the heterocyclic base show separate signals, which indicate loss of symmetry for the base on coordination due to imposition of rigid geometry around the metal ion. This suggests that the complexes indicate signals corresponding to the heterocyclic bases and the thiosemicarbazone moiety. The resonance absorptions of some of the protons near to the coordinated nitrogens are shifted downfield. This unusual position of the signal viz. δ 9.4 of the aromatic system of the bipyridine can be attributed to the proximity to the azide group that cause polar interaction. The coordinated phenoxy oxygen is weekly bound to the closely lying bipyridine/phenanthroline proton via intramolecular hydrogen

bonding. Fig. 3 shows the atom labeling and approximate ^{1}H NMR assignments for compound **4**.

3. Experimental

3.1. Synthesis of ligands

The thiosemicarbazones were obtained as per reported procedure of Scovill et al. [1b] from 2-hydroxyacetophenone and N(4)-substituted thiosemicarbazide (1:1 molar ratio) in MeCN or MeOH. The mixture was refluxed for 20–40 min and then cooled, filtered and recrystallised. All analytical and spectroscopic data are in good agreement with the expected values. Sodium azide (Merck) and heterocyclic bases, viz. bipyridine and phenanthroline were of reagent grade (Merck), and were used as supplied. Cobalt acetate tetrahydrate (BDH) was purified by recrystallisation before complexation.

3.2. Synthesis of complexes

The thiosemicarbazone (0.5 mmol) was dissolved in 20 ml of EtOH, to which was added 0.5 mmol of the heterocyclic base in the solid form. The mixture was slightly warmed to ensure complete dissolution of the ligands. To the above mixture was added about 10 ml of methanolic solution of cobalt(II) acetate tetrahydrate (0.5 mmol), with stirring. When a deep brown solution resulted, solid sodium azide (0.75 mmol) was added. Stirring was continued for about an hour. The solution was kept aside overnight for crystallization to occur. The compound was filtered washed with EtOH, water, and ether, respectively. It was then dried over P_4O_{10} in vacuo.

3.3. Physical measurements

Elemental analyses were carried out using a Heraeus Elemental Analyzer at CDRI, Lucknow, India. Cobalt was estimated on a Perkin–Elmer AAnalyst 700 spectrophotometer, after decomposing the compounds by standard methods. FAB mass spectrum was recorded on a JEOL SX-102 FAB mass spectrometer. IR spectra were recorded on a Shimadzu DR 8001 series FTIR instrument as KBr pellets and electronic spectra were recorded on Shimadzu 160A UV–Vis Spectrophotometer from a solution in CH_2Cl_2/DMF. ^{1}H NMR spectra were recorded in an AMX 400 MHz FT NMR Spectrometer using $CDCl_3$ as a solvent and TMS and an internal standard at Sophisticated Instrumental Facility, IISc, Bangalore, India.

Table 6
Crystal data and structure refinement for $CoL^4(N_3)$bipy (compound **7**)

Empirical formula	$C_{26}H_{23}CoN_8OS$
Formula weight (M)	554.51
Temperature (T) K	293(2)
Wavelength (Mo Kα) (Å)	0.70930 Å
Crystal system	monoclinic
Space group	$P2_1/a$
Unit cell dimensions	
a (Å)	13.625(2)
b (Å)	10.610(14)
c (Å)	17.8410(19)
α (°)	90.000(10)
β (°)	107.355(10)
γ (°)	90.000(10)
Volume (V) (Å^3)	2461.9(6)
Z	4
Calculated density (ρ) (mg m^{-3})	1.496
Absorption coefficient (μ) (mm^{-1})	0.820
$F(000)$	1144
Crystal size (mm)	0.4 × 0.4 × 0.4
θ Range for data collection (°)	1.19–24.92
Limiting indices	$0 \le h \le 16$, $0 \le k \le 12$, $-21 \le l \le 20$
Reflections collected	4069
Unique reflections	4069 [$R_{int} = 0.000$]
Completeness to θ	24.92 (88.7%)
Max. and min. transmission	1.000 and 0.952
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	4069/0/426
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0347$, $wR_2 = 0.0962$
R indices (all data)	$R_1 = 0.0380$, $wR_2 = 0.0996$
Goodness-of-fit on F^2	1.102
Largest difference peak and hole (e Å^{-3})	0.494 and −0.342

3.4. X-ray crystallography

A dark brown monoclinic crystal of the CoL^4bipyN_3 (**7**) having approximate dimensions 0.4 × 0.4 × 0.4 mm was sealed in a glass capillary, and intensity data were measured at room temperature (293 K) on an Nonius MACH3 diffractometer equipped with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The crystallographic data along with details of structure solution refinements are given in Table 6. Unit cell dimensions were obtained using 25 centered reflections in the θ range 5.53°–12.15°. The intensity data were collected by ω-scan mode within $1.190° < \theta < 24.92°$ for hkl ($0 \le h \le 16$, $0 \le k \le 12$, $-21 \le l \le 20$) in monoclinic system. The trial structure was obtained by direct methods using SHELXS-97 [20] and refined by full-matrix least-squares on F^2 (SHELXL-97) [21]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All the hydrogen atoms were geometrically fixed and allowed to refine using a riding model. Absorption corrections were employed using ψ-scan ($T_{max} = 1.000$ and $T_{min} = 0.952$).

4. Supplementary material

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Center, CCDC No. 182200 for compound CoL^4-bipyN_3. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

R.P.J. thanks the Council of Scientific and Industrial Research (CSIR), Government of India for the award of research fellowship. The authors are also thankful to RSIC, CDRI, Lucknow for the elemental analysis, SIF, IISc Bangalore for NMR measurements, National Single Crystal X-ray Diffraction Facility, IIT Bombay for the X-ray crystallographic data.

2.1. Carbonylation products of $(Et_4N)_2[(Cl_4\text{-}cat)Mo(MeCN)Fe_3S_4Cl_3]$ (**I**) in the presence of $Fe(PEt_3)_2Cl_2$

The $(Et_4N)_2[(Cl_4\text{-cat})Mo(MeCN)Fe_3S_4Cl_3]$ cluster (**I**) (2.5 g, 2.39 mmol) and 3 equiv. of $Fe(PEt_3)_2Cl_2$ (2.6 g, 7.16 mmol) were dissolved in MeCN (50 ml) and the solution was put into the high pressure reactor. CO gas (500 psi) was introduced and the reaction mixture was stirred under CO pressure for 2 days. The CO was vented by releasing pressure and the solvent was removed by purging with nitrogen. The residue was subjected to flash column chromatography using *n*-pentane, hexanes and CH_2Cl_2 eluents on TLC silica gel. The reaction products from each fraction have been crystallized and identified by FT-IR spectroscopy.

2.1.1. $(Cl_4\text{-cat})Mo(CO)_2(PEt_3)_2$ (**II**)

$(Cl_4\text{-cat})Mo(CO)_2(PEt_3)_2$ (**II**) was eluted with *n*-pentane. Slow evaporation of the pentane solution produced a dark purple crystalline material (130 mg, 0.2 mmol, 8.36% yield). FAB (positive, NBA), (*m*/*z*, relative intensity) 633.9($[M]^+$, 44.9), 577.9 ($[M-2(CO)]^+$, 69.3), 460.2($[M-\{2(CO)+(PEt_3)\}]^+$, base peak); FT-IR (KBr, cm^{-1}) 2969(w), 2937(w), 2875(w), 1928(s), 1843(vs), 1421(s), 1266(m), 1032(m), 985(m), 809(w), 788(w), 770(w), 759(w), 622(w), 567(w).

2.1.2. $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**)

$(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**) was eluted using 25–50% of CH_2Cl_2–hexanes. Black crystalline material (500 mg, 0.458 mmol) was isolated, after standing for 5–7 days in 19% yield. *Anal*. Calc. for $MoFe_3Cl_5S_6P_3O_2C_{24}H_{45}$ (MW 1091.67): C, 26.41; H, 4.15. Found: C, 27.05; H, 4.15%. FT-IR (KBr, cm^{-1}) 2971, 2935, 2903, 2878, 1432(s), 1251(m), 1037, 976(m), 773(m), 537. UV–Vis (CH_2Cl_2, nm) 314(sh), 470. EPR (CH_2Cl_2, 17 K) $g = 5.46$, 5.15, 4.38, 2.12, 2.06, 1.99. Mössbauer (125 K, mm s^{-1}) $\delta = 0.420$, 0.441, 0.370. $\Delta E_Q = 0.659$, 0.934, 1.144.

2.2. Carbonylation products of $(Et_4N)_2[(Cl_4\text{-}cat)Mo(MeCN)Fe_3S_4Cl_3]$ (**I**) in the presence of PEt_3–$NaBPh_4$

$(Et_4N)_2[(Cl_4\text{-cat})(MeCN)MoFe_3S_4Cl_3]$ (1.0 g, 0.96 mmol) (**I**) was dissolved in 60 ml of MeCN in the high pressure reactor vessel and 4.3 equiv. of PEt_3(0.6 ml, 4.11 mmol) and 3 equiv. of $NaBPh_4$ (1.0 g, 2.92 mmol) were added into the solution. The reactor was charged with CO at a pressure of 500 psi. After 3 days, the reaction mixture was transferred to a Schlenk flask to reduce the volume. The concentrated solution was loaded on the preparative silica gel TLC and developed using a 1:1 mixture of hexanes and CH_2Cl_2. The major product, isolated from the dark red band on the preparative TLC, was the known $(Cl_4\text{-cat})Mo(O)Fe_3S_3(PEt_3)_3(CO)_5$ cluster (200 mg, 0.179 mmol, 19% yield) [4b].

2.3. $(Cl_4\text{-cat})_2MoFe_2S_2(CO)_4(PEt_3)_2$ (**IV**)

Elution of the bright red band with CH_2Cl_2 and slow evaporation of this solution produced 20 mg (18 μmol, 1.9% yield) of purple rhombic crystals of **IV**. FT-IR (KBr, cm^{-1}) 2963(w), 2952(w), 2925(w), 2883(w), 2022(s), 1999(vs), 1970(s), 1965(s), 1960(s), 1455(s), 1274(s), 1033(m), 1001(m), 990(m), 813(m), 791(m), 569(m), 478(m), 449(s), 414(s), 377(s), 362(m). Microprobe. Calculated for $C_{28}H_{30}Cl_8Fe_2MoO_8P_2S_2$ (MW 1111.86): Mo, 8.63; Fe, 10.05; Cl, 25.51; S, 5.77; P, 5.57. Found: Mo, 9.92(19); Fe, 10.31(14); Cl, 25.86(36); S, 6.36(76); P, 5.23(42)%.

2.4. X-ray crystallography

The crystals isolated from the chromatographic fractions were attached to glass fibers and diffraction data were collected at 158(2) K using a Siemens SMART area diffractometer. The empirical absorption correction SADABS has been applied to the data. The crystal data and structural parameters for the compound **II**, **III** and **IV** are listed in Table 1. The structures were determined by direct methods to locate heavy atoms. The non-hydrogen atoms were located through subsequent difference Fourier syntheses. Structural refinements were carried out by full-matrix least-squares on F^2. Hydrogen atoms were assigned idealized positions. All non-hydrogen atoms were refined with anisotropic thermal parameters and all hydrogen atoms were refined isotropically. All calculations were performed using SHELXTL-NT V. 5.1 software.

3. Results and discussion

In previous reports we have described the reactivity of cluster-bound R_3P ligands cluster manifested in the concomitant formation of $P_3P{=}S$ and depletion of μ_3 sulfido ligands. Thus, under a pressure of CO the $(Cl_4\text{-cat})_2Mo_2Fe_6S_8(PR_3)_6$ [R = Et [10], ^{n}Pr [3]] fused-cubane clusters afford new, reduced, FeMoS clusters that contain CO and R_3P terminal ligands and the rare, sulfur-voided $[MoFe_3S_3]^{2+,4+}$ cores. In these reactions, non-polar solvent soluble, alkali metal salts of non-coordinating anions such as BPh_4^- or PF_6^-. were used to remove the halide ligands. The latter readily precipitate as insoluble alkali metal chloride salts.

The cluster reduction, and removal of terminal halide and bridging sulfide ligands also can be achieved using the $Fe(PR_3)_2Cl_2$ (R = alkyl) 'reagent'. The latter both provides PR_3 and removes halide ligands to form

[Fe(PEt_3)Cl_2X]$^-$ or [$FeCl_2X_2$]$^{2-}$ [3]. The reaction of the Fe(PR_3)$_2Cl_2$ reagent with **I** affords the mononuclear(Cl_4-cat)Mo(CO)$_2$(PEt_3)$_2$, (**II**) and the neutral cubane (Cl_4-cat)Mo(PEt_3)Fe_3S_4(SPEt_3)$_2$Cl (**III**). In the latter the generated P_3P=S byproduct serves as a terminal ligand to the Fe atoms.

The reaction of **I** with CO in the presence of R_3P and $NaBPh_4$ in CH_3CN solution also proceeds with the removal of Cl^- ligands as NaCl and formation of P_3P=S. However, the products isolated by this route are the known (Cl_4-cat)Mo(O)Fe_3S_3(PEt_3)$_3$(CO)$_5$ cluster and the trinuclear cluster (Cl_4-cat)$_2$MoFe_2S_2(CO)$_4$(PEt_3)$_2$ (**IV**).

3.1. Structures

3.1.1. (Cl_4-cat)Mo(PEt_3)$_2$(CO)$_2$ (II)

The monomeric, **II**, is a six-coordinate 16-electron Mo(II) complex (Fig. 1) with a distorted trigonal prismatic coordination geometry. In the coordination sphere of the Mo atom, the triangular, coordination polyhedron faces, P(1)–C(7)–O(2) and P(2)–C(8)–O(1) are rotated approximately 25° from being trigonal prismatic and they are roughly parallel to each other. There are a few structurally characterized six-coordinate 16-electron MoX_2(PR_3)$_2$(CO)$_2$ [X = halide] complexes [11] and several seven-coordinate 18-electron complexes [12], such as Mo(O_2CR')$_2$(PR_3)$_2$(CO)$_2$ and MoX(O_2CR')(PR_3)$_2$(CO)$_2$ [R, R′ = H, Me, Et, Ph]. All of these compounds have the (PR_3)$_2$(CO)$_2$ ligand unit in common with **II**. A comparison of selected bond distances in **II** with other Mo(II) complex is available in Table 2. The Mo–C distances of 1.951(2) and 1.961(2) Å in **II** are similar to those found in (O_2CH)$_2$Mo(PEt_3)$_2$(CO)$_2$ (1.951(3) and 1.954(3) Å). The latter [12c] is an 18-electron complex adopting a 3:4 'piano stool' configuration. The three oxygen atoms of the two formato ligands, with the forth free oxygen atom, occupy the triangular cap. The CO and PEt_3 ligands form the rectangular base of the molecule. The ν(C≡O)'s also are similar at 1928 and 1843 cm^{-1} and at 1929 and 1833 cm^{-1} for **II** and (O_2CH)$_2$Mo(PEt_3)$_2$(CO)$_2$), respectively.

The 18-electron, (acac)MoI(PEt_3)$_2$(CO)$_2$ [12a], shows relatively different bond length distributions where two Mo–C bonds have different distances (1.950(10) and 1.994(11) Å) and the Mo–P bonds (2.541(2) and 2.543(3) Å) are longer than those of the 16-electron complexes. This probably is due to the bulky iodide ligand in the Mo(II) coordination sphere. It should be

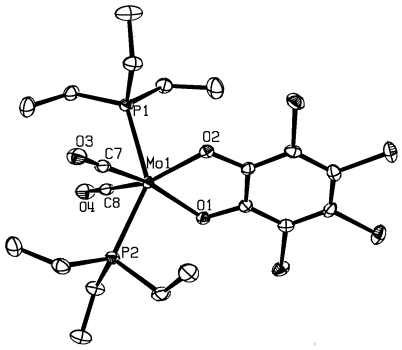

Fig. 1. The crystallographic structure of the $(Cl_4\text{-cat})Mo(PEt_3)_2(CO)_2$ (**II**) compound.

noted that compound **II** could also be described as an 18-electron complex if the Cl_4-cat (tetrachlorocatecholate) ligand is internally oxidized to a tetrachloroquinone ligand (and the Mo atom is now Mo(0)). The assignment of the ligand as $Cl_4\text{-cat}^{2-}$ is based on the low energy ν(C=O) in the IR spectrum at 1421 cm^{-1} and the rather long C–O bonds of 1.331(3) and 1.325(3) Å. Generally, distances of C–O for benzoquinones, semiquinonates and catecholates are 1.23, 1.29, and 1.35 Å, respectively [13].

3.1.2. $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (*III*)

The new $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ cluster (**III**) is the first example of a site-differentiated $MoFe_3S_3$ cluster with a $[MoFe_3S_4]^{3+}$ core and two different terminal ligands on the Fe atoms (Fig. 2). The structure of **III** shows a core geometry similar to that in **I**, but has shorter M–M distances (Table 3). There is a crystallographic mirror plane within the molecule that contains P(1), Mo(1), Fe(2), S(3), S(1), and Cl(3). The Mo(1) atom has distorted octahedral coordination geometry and the crystllographically independent P(1), O(1), S(2), and S(3) atoms are found at distances of 2.5918(15),

Table 2
Selected bond distances (Å) of the $(Cl_4\text{-cat})Mo(PEt_3)_2(CO)_2$ (**II**), the $(O_2CH)_2Mo(PEt_3)_2(CO)_2$, and the $(acac)MoI(PEt_3)_2(CO)_2$ compounds

Compound	**II**	$(O_2CH)_2Mo(PEt_3)_2(CO)_2$	$(acac)MoI(Pet_3)_2(CO)_2$

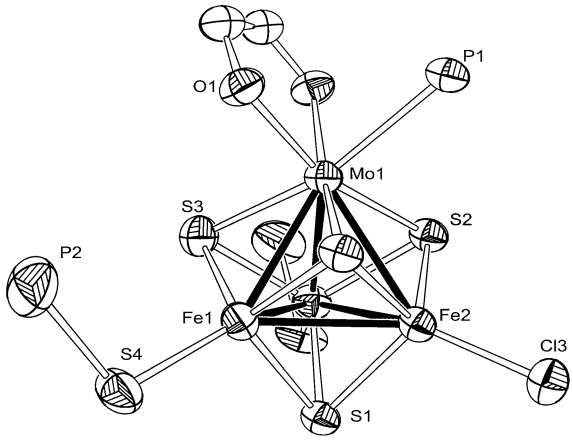

Fig. 2. The crystallographic structure of the $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**) cluster.

2.076(3), 2.3565(10), and 2.4006(17) Å, respectively. The Mo(1)–P(1) distance of 2.5918(15) Å in **III** is slightly shorter than that in the $(Cl_4\text{-cat})_2Mo_2Fe_6S_8(PEt_3)_6$ cluster at 2.602(3) Å. The latter has a reduced $[MoFe_3S_4]^{2+}$ core. The Mo(1)–P(1) bond in **III** also is within the range found for the Mo–P bonds in the $(Cl_4\text{-cat})_2Mo_2Fe_6S_8(PR_3)_6$ [R = Et, ^{n}Pr, ^{n}Bu] clusters (2.602(3)–2.575(2) Å) [3]. The only $[MoFe_3S_4]^{3+}$ (oxidized) cluster with a phophine ligand bound to the Mo atom is $(Et_4N)[Mo(dmpe)Fe_3S_4Cl_4]$ [14]. The two P atoms in the latter are found at distances of 2.562(3) and 2.545(3) Å from the Mo atom.

The tetrahedrally coordinated Fe(1) atom has four ligands, S(1), S(2), S(3) and S(4) at distances of 2.2787(13), 2.2543(11), 2.2543(14), and 2.3020(13) Å, respectively. The ligands of the tetrahedrally coordinated Fe(2) atom, S(1), S(2), S(2)#, and Cl(3), are found at 2.2776(15), 2.2730(17), 2.2730(17), and 2.2030(17) Å, respectively. As shown in Table 3, the average Mo–Fe distance in **III** at 2.71(2) Å is shorter than that of **I** [15] at 2.754(5) Å, and slightly longer than those in other $[MoFe_3S_4]^{2+}$ clusters. The Mo(1)–Fe(2) distance of 2.7512(10) Å in **III** is significantly longer than the other Mo(1)–Fe(1) distance of 2.6894(8) Å. A recent report [16] on the reduced $[MoFe_3S_4]^{2+}$ clusters shows average Mo–Fe and Fe–Fe distances that range from 2.67(1) to 2.71(1) and 2.62(1) to 2.693(3) Å, respectively. The average Fe–Fe distance in **III** (2.692(9) Å) is shorter than that in **I** (2.733(5) Å) and is the shortest among $[MoFe_3S_4]^{3+}$ clusters [17]. Indeed, the Mo–Fe and Fe–Fe distance comparison shows **III** with metric details closer to the reduced $[MoFe_3S_4]^{2+}$ clusters. The average Mo–S distance of 2.371(15) Å in **III** is slightly longer than that of 2.354(9) Å in **I** and the average Fe–S distance of 2.266(4) Å in **III** also is the shortest among $[MoFe_3S_4]^{3+}$ clusters.

At present the origin of the shorter distances intracluster M–M and M–S distances in **III** is difficult to ascertain. It may be due to the σ/π donor (reducing)

Table 3
Selected bond distances (Å) of the $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**), the $(Et_4N)_2[(Cl_4\text{-cat})Mo(MeCN)Fe_3S_4Cl_3]$ (**I**), the $(Cl_4\text{-cat})_2Mo_2Fe_6S_8(Pet_3)_6$, and the $(Cl_4\text{-cat})Mo(MeCN)Fe_3S_4(P^iPr_3)_3$ clusters

[b] Ref. [14].

properties of the $SPEt_3$ ligands but also it could be due to the neutral nature of the cluster. In general, charged clusters may have longer bonds than the neutral ones because of net intra-molecular repulsions among the atoms. It is reasonable to assume that both electronic and charge effects contribute to the short M–M and M–L distances in **III**.

The Mössbauer spectrum [18] of **III** can be fit by three Fe sites with isomer shifts of $\delta = 0.420$, 0.441, 0.370 and quadrupole splittings of $\Delta E_Q = 0.659$, 0.934, 1.144, respectively (Fig. 3). As the Fe centers in **III** has non-thiolate ligands, the empirical equation ($\delta = 1.44–0.43$ s) between isomer shift and mean oxidation state [19] is not applicable. Generally, the average isomer shifts of $[MoFe_3S_4]^{3+}$ clusters [20] are found between 0.29–0.40 mm s^{-1} and those of the $[MoFe_3S_4]^{2+}$ clusters [21] are found between 0.41 and 0.52 mm s^{-1}. The average isomer shift of **III** at $\delta = 0.41$mm s^{-1} which is close to a $Fe^{+2.33}$ formal mean oxidation state for a $[MoFe_3S_4]^{2+}$ cluster. By Mössbauer spectroscopic criteria, the electronic structure of the core in **III** is closer to that in the $[MoFe_3S_4]^{2+}$ clusters. The Mössbauer spectroscopy and structural results suggest that the oxidation states of the metal atoms in **III** could best be assigned as Mo(IV)Fe(II)$_2$Fe(III).

3.1.3. $(Cl_4\text{-cat})_2MoFe_2S_2(PEt_3)_2(CO)_4$ (**IV**)

There are several known organometallic clusters [22] with the $[MFe_2E_2]$ cores, [M = Pt, Pd, Mo, Co, Ni, Ti, Fe, Sn, Ge, and E = S, Se, Te]. They are mainly synthesized from the reaction of (μ-dithio)bis(tricarbonyliron) with coordinatively unsaturated low-valent transition metal compounds. Among them, only a few have been structurally characterized [23]. Their syntheses require the reduced $[Fe_2S_2(CO)_6]^{2-}$ unit and a Mo(II) reagent. These compounds, which contain the $MoFe_2S_2$ moiety as a subunit., include: The $Fe_3S_4(PEt_3)_3MoFe_2S_2(CO)_6$ cluster [24], clusters that contain the $[Mo_2O_2(\mu\text{-}E)_2]^{2+}$ (E = O or S) cores bound by $[Fe_2S_2(CO)_6]^{2-}$ units [25], a compound with two $[Fe_2S_2(CO)_6]$ units bound to a central $[(O)Mo(\mu\text{-}S)_2Fe]$

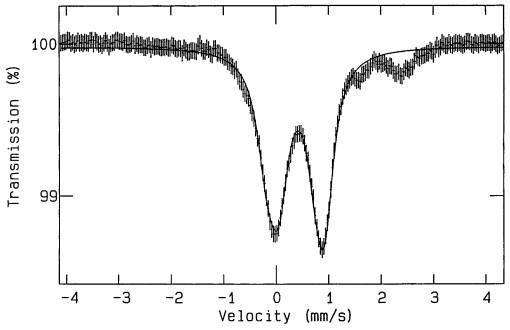

Fig. 3. ^{57}Fe Mössbauer spectrum of the $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**) cluster measured at 125 K in zero applied magnetic field. The source was ^{57}Co in a Rh matrix and the isomer shift was reported vs. Fe metal at room temperature. The solid lines show the fitted spectra as described in the text.

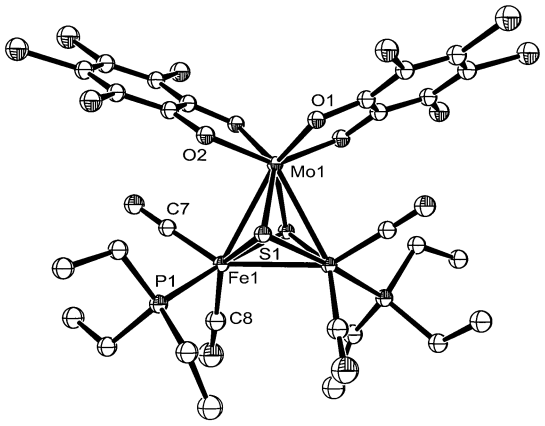
core [26] and a compound with three $[Fe_2S_2(CO)_6]$ units bound to central Mo atom [27].

The isolation of products, **II**, **III**, and **IV** from the reaction of **I** with CO can be rationalized in terms of the pathway shown in Scheme 1. Addition of CO ligands on the Fe atoms of **I** (probably following μ_3-S^{2-} abstraction by trialkylphosphine) initiates the oxidative cleavage of the $[MoFe_3S_4]$ core [28] into $[Fe_2S_2(PEt_3)_2(CO)_4]$ and $[(Cl_4\text{-cat})Mo(PEt_3)FeS_2L_n]$ units. Further cleavage of the $[(Cl_4\text{-cat})Mo(PEt_3)FeS_2L_n]$ unit in the presence of CO may produce **II** and $S{=}PEt_3$. The latter substitutes for the PEt_3 ligands on the Fe atoms of $[(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(PEt_3)_2Cl]$ cluster to produce **III**. The addition of **II** to the $[Fe_2S_2(PEt_3)_2(CO)_4]$ unit with dissociation of CO ligands results in the $[(Cl_4\text{-cat})Mo(PEt_3)_2Fe_2S_2(PEt_3)_2(CO)_4]$ cluster which is further oxidized to **IV** while the PEt_3 ligand on the Mo atom is substituted by $Cl_4\text{-cat}^{2-}$.

The compound **IV** has been structurally characterized (Table 1) [29] and the structure has a crystallographic C_2 axis. The rotation axis contains the Mo(1) atom and passes through the center of the Fe–Fe# bond (Fig. 4). The Fe(1)–Fe(1#) distance of 2.6642(10) Å is short and indicative of M–M bonding. The Mo(1) shows weaker M–M interactions with the two Fe atoms (Mo(1)–Fe(1); 2.8515(7) Å). The Mo(1) atom's coordination geometry can be defined as trigonal prismatic brought about by four O atoms and two S atoms (Mo(1)–O(1); 1.995(2) Å, Mo(1)–O(2); 2.042(2) Å, Mo(1)–S(1); 2.3351(9) Å). The Fe(1) atom has a trigonal bipyramidal coordination geometry with axial S(1) (2.2216(10) Å) and P(1) (2.2649(10) Å) ligands and equatorial S(2) (2.2172(10) Å), C(7) (1.775(4) Å) and C(8) (1.798(4) Å) ligands. The S atoms on the equatorial position have shorter Fe–S distances compared with those on the axial position.



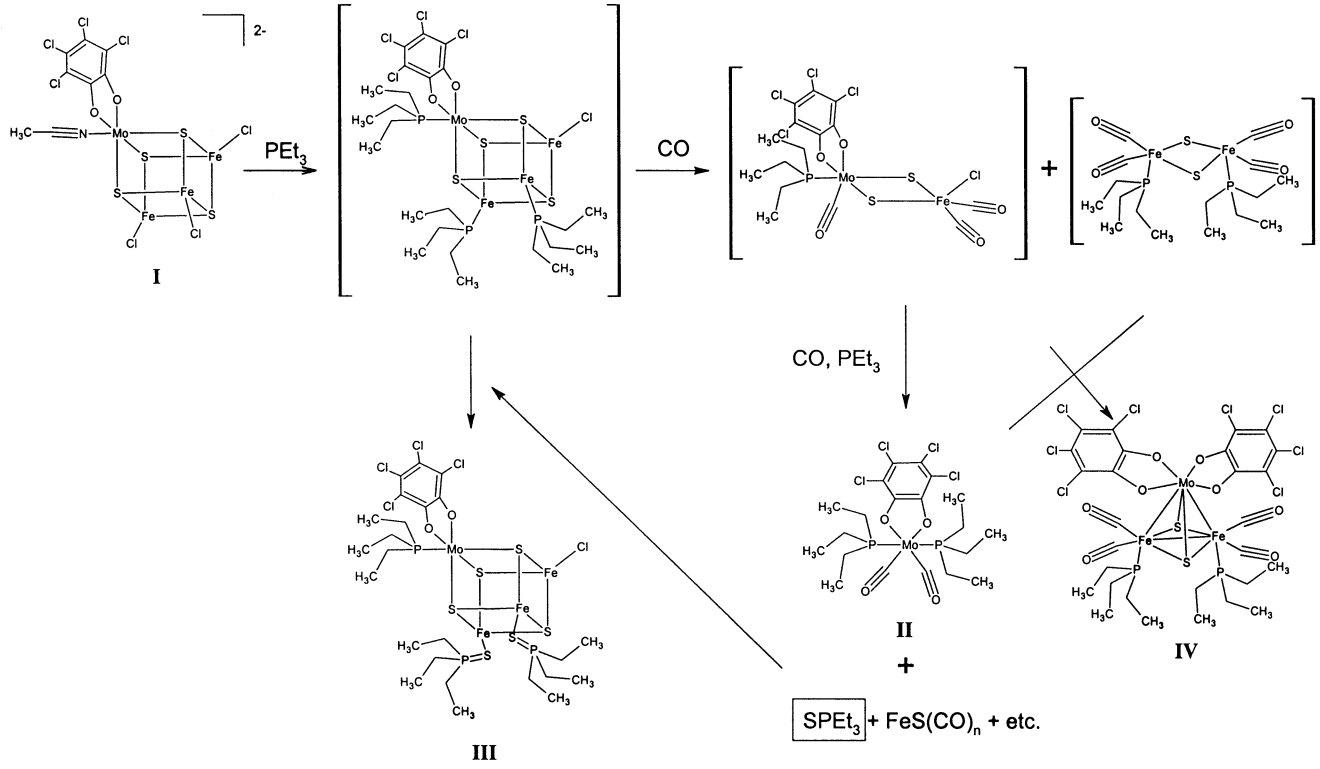


Fig. 4. The crystallographic structure of the $(Cl_4\text{-cat})_2MoFe_2S_2(PEt_3)_2(CO)_4$ (**IV**) cluster. Selected distances (Å) and angles (°): Mo1–Fe1, 2.8515(7); Fe1–Fe1#, 2.6642(10); Mo1–S1, 23351(9); Fe1–S1, 2.2172(10); Fe1–S1#, 2.2216(10); Fe1–P1, 22649(10); Fe1–C7,1.775(4); Fe1–C8, 1.798(4). S1–Mo1–S1# 85.33(5); Fe1–Mo1–Fe1#, 55.70(2); S1–Fe1–S1#, 90.97(4); Fel–Sl–Fel#, 73.77(3).

Scheme 1. Proposed reaction pathways for the $(Cl_4\text{-cat})Mo(PEt_3)_2(CO)_2$ (**II**), the $(Cl_4\text{-cat})Mo(PEt_3)Fe_3S_4(SPEt_3)_2Cl$ (**III**), and the $(Cl_4\text{-cat})_2MoFe_2S_2(PEt_3)_2(CO)_4$ (**IV**) clusters from the $(Et_4N)_2[(Cl_4\text{-cat})Mo(MeCN)Fe_3S_4Cl_3]$ (**I**) cluster.

The $(Cl_4\text{-cat})_2MoFe_2S_2(PEt_3)_2(CO)_4$ (**IV**) cluster contains the $[MoFe_2]^{8+}$ core and is a 46-electron cluster. The oxidation states of the metal atoms in **IV** can be assigned as Mo(IV) and 2Fe(II). The Mo(IV) atom is considered as a 14-electron center with two $Cl_4\text{-cat}^{2-}$ and two μ_3-S ligands. The two Fe(II) atoms are considered as 16-electron centers coordinated by two CO, a PEt_3 and two μ_3-S ligands. The addition of three M–M bonds between the Mo and Fe atoms results in a 16-electron Mo center and two 18-electron Fe centers.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 168354 for compound **II**, CCDC No. 168353 for compound **III**, and CCDC No. 168352 for compound **IV**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336066; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

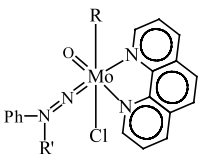
[28] Such a reductive cleavage of the $[MoFe_3S_4]$ cuboidal core has been reported by us in reference [5].
[29] Compound **IV** was also crystallized with a CH_2Cl_2 molecule in the orthorhombic cell system. Space group was *Pcnb* and $R_1 = 0.0577$ (for $I > 2\sigma(I)$).



zido-molybdenum complexes [*trans*-$R_2MoO(NNPhR')(o\text{-phen})$], R = R′ = Me (**1**), R = Me, R′ = Ph (**2**), R = Ph, R′ = Me (**3**), R = R′ = Ph (**4**) toward (i) neutral hydrazines: $R'PhNNH_2$ and (ii) organohydrazine hydrochlorides: $R'PhNNH_2 \cdot HCl$, R′ = Me, Ph. These studies provide a convenient access to the synthesis of new coordination complexes containing the *trans*-[RMoCl] fragments (R = Me, Ph). The new coordination compounds, formulated as [*trans*-$RClMoO(NNPhR')(o\text{-phen})$], R = R′ = Me (**5**), R = Me, R′ = Ph (**6**), R = Ph, R′ = Me, (**7**)·MeCN, R = R′ = Ph, (**8**)·MeCN, and [*trans*-$Cl_2MoO(NNPhR')(o\text{-phen})$], R′ = Me (**9**), Ph (**10**), were characterised by IR, UV–Vis and ^{1}H NMR spectroscopies and, in the case of complex **6**, by X-ray diffraction analysis.

2. Results and discussion

2.1. Synthesis and spectroscopic characterisation

The organometallic compounds previously described by us [17] as [*trans*-$Me_2MoO(NNPhR)(o\text{-phen})$], R = Me (**1**), Ph (**2**) and [*trans*-$Ph_2MoO(NNPhR)(o\text{-phen})$], R = Me (**3**), Ph (**4**), were synthesised in two steps: firstly, the mono-functionalisation of complex [$MoO_2Br_2(o\text{-phen})$] with neutral 1,1-disubstituted hydrazines and then alkylation or arylation of the resultant mono-functionalised complexes [$MoO(NNPhR')Br_2(o\text{-phen})$] with an excess of the appropriate Grignard reagents. In order to study the functionalisation of the residual oxo group in complexes **1**–**4**, we examined their reactivity toward (i) an excess of neutral 1,1-disubstituted hydrazines, $RPhNNH_2$, R = Me, Ph, and (ii) 1,1-disubstituted hydrazine hydrochlorides, $RPhNNH_2 \cdot HCl$, R = Me, Ph, at room temperature and using acetonitrile as a solvent.

In the first experimental case, the complexes **1**–**4** were inert toward the neutral 1,1-disubstituted hydrazines whatever the experimental conditions used (reflux, excess of hydrazine, time of reaction, etc.). On the other hand, in the second case, the reactions of precursors **1**–**4** with the 1,1-disubstituted hydrazine hydrochlorides, in a 1:1 molar ratio, did not afford the expected bis(organohydrazido) complexes [$R_2Mo(NNPhR')_2(o\text{-phen})$] but they afforded *trans*-MeCl–molybdenum complexes **5** and **6**, and *trans*-PhCl–molybdenum complexes **7**·MeCN and **8**·MeCN (Scheme 1). Finally, when the precursors **1**–**4** were reacted with 1,1-disubstituted hydrazine hydrochlorides in MeCN using a 1:2 molar ratio, the known dichloro-complexes of formula [*trans*-$Cl_2MoO(NNPhMe)(o\text{-phen})$] (**9**) and [*trans*-$Cl_2MoO(NNPh_2)(o\text{-phen})$] (**10**) were obtained [14].

Scheme 1.

The reactions can be rationalised considering an acid–base reaction between the organohydrazinium acid, $RPhNNH_3^+$, and the basic methyl- and phenyl-transition metal complexes [18]. Although the mechanism is unknown, one can reasonably put a proton on the metal centre followed by a reductive elimination of the methyl or phenyl ligands as methane or benzene, respectively, and by a coordination of the chloride ion. Nevertheless, these reactions are a useful synthetic route to the *trans*-MeCl–molybdenum complexes **5**–**6**, and *trans*-PhCl–molybdenum complexes (**7**–**8**)·MeCN. To produce compounds **9** and **10**, this process must operate with twice the amount of 1,1-disubstituted hydrazine hydrochlorides.

The four new organometallic complexes **5**–**6** and (**7**–**8**)·MeCN were obtained as red–orange air stable microcrystalline solids in yields ranging from 21 to 70%, and were characterised by elemental analyses, ^{1}H NMR, IR and UV–Vis spectroscopy (see Section 4). The crystalline and molecular structure of **6** was determined by single crystal X-ray diffraction analysis (vide infra).

For all the compounds, the ^{1}H NMR spectra showed a complex resonance pattern in the 8.00–10.20 ppm range, assigned to the eight non-equivalent protons of the *o*-phenanthroline ligand. The phenyl proton resonances also exhibited a complicated pattern at the upper field in the 6.60–8.00 ppm range. Moreover, the spectra of the compounds (**7**–**8**)·MeCN are more complex than those of **5** and **6** due to the overlapping of the proton resonances of the phenyl ligands bonded to the molybdenum centre. The spectra of the compounds **5** and **7**·MeCN also showed methyl proton resonances attributable to the NNMePh ligand at 4.23 and 4.31 ppm, respectively. In addition to this, the compounds **5** and **6** exhibited methyl proton resonances at 0.56 and 0.63 ppm which is a characteristic of methyl ligands bonded to the molybdenum centre. These signals shifted downfield compared to the signals of the methyl groups in the starting complexes **1** and **2** ($\delta = 0.17$ and 0.19, respectively), which is indicative of a less electron-rich metal centre in **5** and **6**. Both spectra of compounds **7**·MeCN and **8**·MeCN, which crystallise with a CH_3CN solvent molecule, exhibit a methyl proton resonance at 2.50 ppm. The IR spectra of these organometallic compounds show a characteristic medium intensity band in the 1586–1592 cm^{-1} range, which was attributed to the ν(NN) vibration [19] and a strong band in the 880–900 cm^{-1} region corresponding to the ν(MoO) mode [20]. Finally, the electronic spectra of compounds **5**–**6** and (**7**–**8**)·MeCN, recorded in CH_2Cl_2, exhibit three absorp-

tion bands in the 260–520 nm region. The bands observed in the 260–300 and 300–390 nm regions were attributed to the *cis*-MoO(NNPhR) chromophore [21] while the band observed above 400 nm could be assigned to a L–Mo charge transition [22].

2.2. Structural study

A single crystal X-ray diffraction study was undertaken on a selected good quality block-shaped crystal of [*trans*-MeClMoO(NNPh$_2$)(*o*-phen)] (**6**), and its crystal structure was determined as outlined in Section 4. The ORTEP view of [*trans*-MeClMoO(NNPh$_2$)(*o*-phen)] is presented in Fig. 1. The molybdenum centre displays a distorted octahedral geometry, with the methyl and chloro ligands occupying *trans* positions, and with the equatorial plane which is defined by the oxo group, the N(1) atom of the diphenylhydrazido ligand and the N(3) and N(4) atoms of the *o*-phenanthroline. The geometric parameters observed in the *cis*-[MoO(NNPh$_2$)]$^{2+}$ core of this complex (Table 1) are similar to those reported in the literature for other (organohydrazido)oxomolybdenum complexes [13,23]. An extensive delocalisation of the electron density throughout the Mo(NNPh$_2$) unit is supported by (i) the short Mo–N(1) and N(1)–N(2) bond lengths of 1.787(9) and 1.30(1) Å, (ii) the Mo–N(1)–N(2) bond angle of 172.5(8)° which is practically linear and (iii) the Mo–N(1)–N(2)C(1)C(7) moiety, which is almost planar, being the sum of the bond angles around the N(2) atom 360°. Similar to what is observed with its precursor **2** [17], the *trans* influence exerted by the oxo group is clearly far more important than that exerted by the organohydrazido ligand, e.g. Mo–N(3) = 2.346(9) Å versus Mo–N(4) = 2.30(1) Å.

One of the most remarkable features of the structure of this compound is the preferential inclination of the methyl and the chloro ligands toward the N(3) atom of the *o*-phenanthroline ligand; thus, the C(25)–Mo–N(3) and Cl–Mo–N(3) bond angles are 78.5(4)° and 79.1(3)°, respectively, while the C(25)–Mo–N(4) and Cl–Mo–N(4) bond angles are 84.7(4)° and 84.2(3)°, respectively.

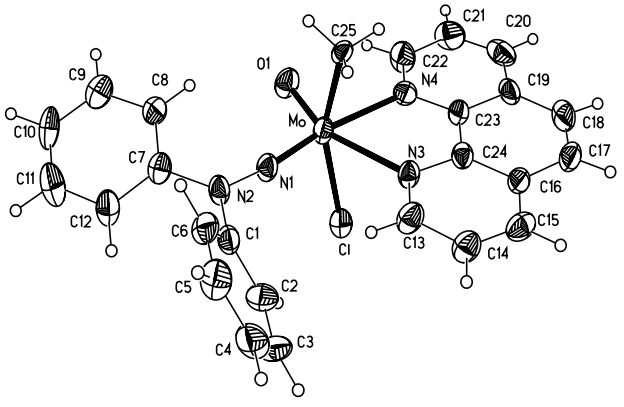


Fig. 1. ORTEP view of complex **6** with the atom-labelling scheme.

Table 1
Selected bond lengths (Å) and angles (°) of complex **6**

Bond distances			
Mo–O(1)	1.712(8)	Mo–Cl	2.472(4)
Mo–N(1)	1.787(9)	N(1)–N(2)	1.30(1)
Mo–N(4)	2.30(1)	N(2)–C(7)	1.44(2)
Mo–C(25)	2.29(1)	N(2)–C(1)	1.46(2)
Mo–N(3)	2.346(9)		
Bond angles			
O(1)–Mo–N(1)	105.1(4)	Cl–Mo–N(1)	95.5(3)
N(1)–Mo–N(3)	98.8(4)	Cl–Mo–N(3)	79.1(3)
N(3)–Mo–N(4)	69.7(3)	Cl–Mo–N(4)	84.2(3)
N(4)–Mo–O(1)	86.2(4)	C(25)–Mo–Cl	157.2(3)
N(1)–Mo–C(25)	91.5(4)	O(1)–Mo–N(3)	155.8(4)
C(25)–Mo–O(1)	97.1(4)	N(1)–Mo–N(4)	168.4(4)
C(25)–Mo–N(1)	91.5(4)	Mo–N(1)–N(2)	172.5(8)
C(25)–Mo–N(3)	78.5(4)	N(1)–N(2)–C(1)	117.0(1)
C(25)–Mo–N(4)	84.7(4)	N(1)–N(2)–C(7)	120.0(1)
Cl–Mo–O(1)	101.9(3)		

These differences can be mainly ascribed, as it has been observed in the parent compound, [*trans*-Me$_2$MoO(NNPh$_2$)(*o*-phen)] [17], to repulsions between the methyl and chloro ligands and the oxo group. As a further consequence of these repulsions, the C(25)–Mo–Cl bond angle is 157.2°, approximately 7.3° greater than that of the precursor [17].

3. Conclusion

The present study provides a convenient access to the preparation of organometallic molybdenum compounds containing the *trans*-[RMoCl] fragment (R = Me, Ph) which could be further functionalised with a variety of monodentate ligands via Mo–Cl substitution reaction. The new organometallic compounds **5**–**6** and (**7**–**8**)·MeCN cannot be directly synthesised by a reaction of [*trans*-X$_2$MoO(NNPhR)(*o*-phen)], X = Cl, Br, with an equimolar amount of Grignard reagents.

4. Experimental

All manipulations were carried out under inert atmosphere using standard vacuum/dinitrogen line (Schlenk) techniques. Organometallic molybdenum compounds, [*trans*-Me$_2$MoO(NNPhR)(*o*-phen)], R = Me (**1**), Ph (**2**) and [*trans*-Ph$_2$MoO(NNPhR)(*o*-phen)], R = Me (**3**), Ph (**4**) were synthesised as was previously described [17]. 1,1-Diphenylhydrazine hydrochloride, Ph$_2$NNH$_2$·HCl, was obtained from commercial sources and used without further purification. 1-Methyl-1-phenylhydrazine hydrochloride, MePhNNH$_2$·HCl was prepared as described in Ref. [14c]. Solvents were dried and distilled under dinitrogen by standard methods prior to use. Electronic spectra were recorded in a CH$_2$Cl$_2$ solution

on a Hewlett–Packard 8452A spectrophotometer. IR spectra were obtained as KBr disks on a Perkin–Elmer model 1600 FT-IR spectrophotometer. ^{1}H NMR spectra were recorded in $CDCl_3$ or DMSO-d_6 on a Bruker FT AC/200P spectrometer; chemical shifts were reported in ppm related to tetramethylsilane, with the residual solvent proton resonance as internal standards. Microanalytical data were obtained on a Perkin–Elmer model 2400 elemental analyser. Melting points were determined by using a Kofler apparatus.

4.1. Preparation of complexes 5–8

4.1.1. [trans-MeClMoO(NNPhMe)(o-phen)] (5)

51.0 mg (0.322 mmol) of $MePhNNH_2 \cdot HCl$ dissolved in 10 ml of dry MeCN were added dropwise to 142 mg (0.322 mmol) of **1** dissolved in 30 ml of dry MeCN under dinitrogen at room temperature. The solution was vigorously stirred for 1 day at room temperature giving an orange solid. Then, the suspension was filtered and washed with MeCN and recrystallised from Me_2CO. Yield: 122 mg (38%). M.p.: 125 °C dec. *Anal*. Calc. for $C_{20}H_{19}ClMoN_4O$: C, 51.91; H, 4.14. Found: C, 51.62; H, 4.06%. UV–Vis [(CH_2Cl_2), λ_{max}, nm (log ε)]: 270 (6.25); 282 (6.27); 292 (6.29); 332 (6.34); 382 (6.41); 472 (6.50). IR (cm^{-1}, KBr): 3074 (w), ν(CH); 2961 (m), ν(CH); 2899 (w), ν(CH); 1624 (m), 1592(m), ν(NN); 897(s), ν(Mo=O). ^{1}H NMR ($CDCl_3$), δ (ppm), TMS. *o*-Phen resonances: 10.14 (d, 1H, $J = 4.8$ Hz); 9.17 (d, 1H, $J = 5.0$ Hz); 8.61 (d, 1H, $J = 6.7$ Hz); 8.47 (d, 1H, $J = 8.3$ Hz); 8.09–8.01 (m, 4H). Phenyl resonances: 7.80–7.68 (m, 3H); 7.47 (pseudo-t, 2H). Methyl resonances: 4.23 (3H, NCH_3); 0.56 (s, 3H, MoCH_3).

4.1.2. [trans-MeClMoO(NNPh$_2$)(o-phen)] (6)

The procedure adopted was similar to that described for the preparation of **5**, using in this case 72.4 mg (0.328 mmol) of $Ph_2NNH_2 \cdot HCl$ and 165 mg (0.328 mmol) of **2**. The product was obtained as a red orange solid. Yield: 239 mg (70%). M.p.: 113 °C dec. *Anal*. Calc. for $C_{25}H_{21}ClMoN_4O$: C, 57.21; H, 4.03. Found: C, 57.02; H, 3.98%. UV–Vis [(CH_2Cl_2), λ_{max}, nm (log ε)]: 278 (6.24); 296 (6.27); 388 (6.38); 514 (6.51). IR (cm^{-1}, KBr): 3063 (m), ν(CH); 2899 (w), ν(CH); 2834 (w), ν(CH); 2684 (w), ν(C=N); 1627 (m), ν(C=N); 1587 (m), ν(NN); 900 (s), ν(Mo=O). ^{1}H NMR ($CDCl_3$), δ (ppm), TMS. *o*-Phen resonances: 10.18 (dd, 1H, $J = 5.0$; 1.5 Hz); 8.58 (dd, 1H, $J = 8.2$;1.5 Hz); 8.30 (dd, 1H, $J = 8.2$; 1.4 Hz); 8.08–7.89 (m, 5H). Phenyl resonances: 7.73 (pseudo-t, 4H); 7.53 (t, 4H, $J = 7.4$ Hz); 7.42–7.29 (m, 2H). Methyl resonance: 0.63 (s, 3H, MoCH_3). Suitable single crystals for X-ray diffraction studies were obtained from acetone.

4.1.3. [trans-PhClMoO(NNPhMe)(o-phen)]·MeCN (7·MeCN)

53.3 mg (0.340 mmol) of $MePhNNH_2 \cdot HCl$ dissolved in 10 ml of dry MeCN were added dropwise to 190 mg (0.335 mmol) of **3** dissolved in 35 ml of dry MeCN under nitrogen. The solution was vigorously stirred for 1 day at room temperature giving a dark red solid. Then, the suspension was filtered and washed with MeCN and recrystallised from Me_2CO. Yield: 133 mg (40%). M.p.: 218 °C dec. *Anal*. Calc. for $C_{27}H_{24}ClMoN_5O$: C, 57.30; H, 4.27. Found: C, 57.02; H, 4.12%. UV–Vis [(CH_2Cl_2), λ_{max}, nm (log ε)]: 268 (6.17); 298 (6.22); 334 (6.27); 390 (6.33); 478 (6.42). IR (cm^{-1}, KBr): 3041 (w), ν(CH); 2954 (m), ν(CH); 1627 (m), ν(C=N);1586 (w), ν(NN); 899 (s), ν(Mo=O). ^{1}H NMR ($CDCl_3$), δ (ppm), TMS. *o*-Phen resonances: 10.12 (d, 1H, $J = 4.0$ Hz); 9.38 (d, 1H, $J = 4.5$ Hz); 8.98 (d, 1H, $J = 7.8$ Hz); 8.79 (d, 1H, $J = 7.8$ Hz); 8.35–8.04 (m, 4H). Phenyl resonances: 7.89 (d, 2H, $J = 6.9$ Hz); 7.47 (t, 2H, $J = 7.8$ Hz); 7.19–7.15 (m, 3H); 6.62 (pseudo-d, 3H). Methyl resonances: 4.31 (s, 3H, NCH_3); 2.50 (s, 3H, CH_3CN).

4.1.4. [trans-PhClMoO(NNPh$_2$)(o-phen)]·MeCN (8·MeCN)

The procedure adopted was similar to that described for the preparation of **7**, using in this case 25.0 mg (0.117 mmol) of $Ph_2NNH_2 \cdot HCl$ and 71.5 mg (0.114 mmol) of **4**. The product was obtained as an orange solid. Yield: 24 mg (21%). M.p.: 158 °C dec. *Anal*. Calc. for $C_{32}H_{26}ClMoN_5O$: C, 61.20; H, 4.17. Found: C, 60.96; H, 4.14%. UV–Vis [(CH_2Cl_2), λ_{max}, nm (log ε)]: 278 (6.36); 294 (6.39); 300 (6.40); 366 (6.48); 500 (6.62). IR (cm^{-1}, KBr): 3052(m), ν(CH); 2899 (s), ν(CH); 2848(s), ν(CH); 2673(s), ν(C=N); 1624 (m), ν(C=N); 1587(s), ν(NN); 901(m), ν(Mo=O). ^{1}H NMR (DMSO-d_6), δ (ppm), TMS. *o*-Phen resonances: 10.14 (d, 1H, $J = 3.8$ Hz); 9.00 (d, 1H, $J = 7.2$ Hz); 8.66 (d, 1H, $J = 8.1$ Hz); 8.38–8.12 (m, 4H); 8.02 (d, 1H, $J = 4.0$ Hz). Phenyl resonances: 7.92–7.50 (m, 9H); 7.20–7.16 (m, 3H); 7.03–6.65 (pseudo-d, 3H). Methyl resonance: 2.50 (s, 3H, CH_3CN).

4.1.5. [trans-Cl$_2$MoO(NNPhR′)(o-phen)], R = Me (9), Ph (10)

Similar reactions to those described for the preparation of complexes **5** and **6** were studied in MeCN using $MePhNNH_2 \cdot HCl$ with **1**, and $Ph_2NNH_2 \cdot HCl$ with **4**, in a 2:1 molar ratio. Complexes formulated as [*trans*-$Cl_2MoO(NNPhMe)(o\text{-phen})$] (**9**), and [*trans*-$Cl_2MoO(NNPh_2)(o\text{-phen})$]·MeCN (**10**), were authenticated by comparing their IR and ^{1}H NMR data with those presented in Ref. [14h].

4.2. X-ray structure determination of **6**

4.2.1. Data collection

$C_{25}H_{21}ClMoN_4O$, $M_r = 524.85$ g mol^{-1}, unit cell dimensions: $a = 8.733(6)$, $b = 9.013(7)$, $c = 16.368(9)$ Å, $\alpha = 101.04(6)$, $\beta = 92.10(5)$, $\gamma = 111.98(6)^\circ$, $V = 1164(1)$ Å^3, triclinic, $P\bar{1}$, $Z = 2$, $D_{calc} = 1.494$ g cm^{-3}, μ(Mo Kα) = 0.702 mm^{-1}, $F(000) = 530$, crystal size (mm): $0.16 \times 0.14 \times 0.04$. Siemens R3m/V four circle diffractometer; Mo Kα radiation ($\lambda = 0.71073$, graphite monochromator), 2θ range 5.00°–50.10° at 298 K, scan type $\theta-2\theta$, reflections collected 4133, observed reflections 2214 [$F_o^2 > 2\sigma(F_o^2)$]. Convergence at $R_1 = 0.081$, $wR_2 = 0.136$. Cell parameters were determined from least-squares fits of 25 reflections with $5.00^\circ \leq 2\theta \leq 50.10^\circ$. Two standard reflections, monitored every 98 reflections, showed no significant variation of intensity during data collection. Intensities were corrected for Lorentz and polarisation effects, and semiempirical corrections based on ψ scans were applied for absorption.

4.2.2. Structure refinement

The structure was solved by direct methods and refined on F by full-matrix least-squares calculations. The function minimised was $\Sigma w(F_o - F_c)^2$. All non-hydrogen atoms were refined anisotropically. A riding model was applied to H atoms, which were placed at calculated positions with C–H = 0.96 Å, with the equivalent isotropic thermal parameters of their parent C atoms. All calculations were performed with the Siemens SHELXTL-PLUS system of programs [24].

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure of **6** reported in this paper were deposited with the Cambridge Crystallographic Data Centre, CCDC No. 178505. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk)].

Photochromic properties of these compounds are closely related to the reduction potential of the polyoxoanion and to the donor properties of the organic molecules. Structural factors can also be important although no correlations have been found, so far, between the electronic or photochromic properties and the structure of charge transfer compounds based on Keggin anions [20,22–27,29,31,33,35–38]. For application in technological devices reversible photocromism is desirable [15]. Many photochromic polyoxoanion salts are reported in literature, but they generally do not meet the above condition, showing irreversible photo-redox processes [15,39].

Charge transfer salts based on polyoxometalates have also been studied on account of their non-linear optical properties. A few compounds combining Keggin-type anions with organic molecules of high dipole moments, leading to second-order harmonic generation (SHG), have been reported [26,30]. The highest SHG was obtained with the compound $(4\text{-DMSP})_4(NH_2Me_2)_2[HSiFeMo_{11}O_{40}]\cdot 3H_2O$, 4-DMSP = 4-[(*p*-(dimethylamino)styril]pyridine, with an efficiency 1.2 times that of KH_2PO_4 under the same conditions [30]. Until now, the second-order non-linear optical responses of those compounds are not comparable to those of some organic molecules, but the chemical and thermal instability or the weak mechanical resistance that are a drawback to the application of the organic crystals in non-linear optical devices [40,41] can possibly be overcome with the polyoxometalates. Polyoxometalate compounds with third-order non-linear optical properties were described as well [26,28,32].

Our interest has been focused on the preparation of charge transfer salts by co-crystallization of electron-rich heterocyclic aromatic amines like 2,2′-bipiridine, 1,10-phenantroline, or 2,2′-biquinoline with the Keggin anions $\alpha\text{-}[XM_{12}O_{40}]^{m-}$ (**1**), X = P, Si, M = Mo, W (abbreviated as XM_{12}. The α-isomers were used in all studies and the prefix α- will be omitted subsequently). Of the prepared compounds, only those obtained from 2,2′-biquinoline (**2**) showed significant charge transfer properties. Their synthesis and characterization in the solid state and in solution will be presented here, with special attention to the electronic properties. Studies of the photochromic properties of some of the prepared compounds under visible radiation will be presented. Second-order non-linear optical properties were studied, but significant SHG of 1064 nm radiation was only found for one compound.

2. Experimental

2.1. Synthesis

2.1.1. $(Hbiqui)_3[PM_{12}O_{40}]$ and $(Hbiqui)_4[SiM_{12}O_{40}]\cdot nH_2O$, M = W, Mo

A solution of 2,2′-biquinoline (0.234 g, 0.91 mmol) in 30 cm^3 of boiling acetonitrile was added, with vigorous stirring, to a solution of $H_3[PW_{12}O_{40}]\cdot 23H_2O$ (1.00 g, 0.30 mmol) in 5 cm^3 of water, at the same temperature. A yellow precipitate was formed immediately. The solid was filtered, washed with warm acetonitrile and dried in an evacuated desiccator. The same procedure was applied for the synthesis of the other compounds, starting with the acids $H_3[PMo_{12}O_{40}]\cdot nH_2O$ and $H_4[SiM_{12}O_{40}]\cdot nH_2O$, M = Mo, W. In all cases a molar proportion of organic base/Keggin anion equal to the polyanion charge was used. The compounds with Mo must be protected from light during preparation as they are photosensitive.

$(HC_{18}N_2H_{12})_3[PW_{12}O_{40}]$ *Anal*. (%). Found (Calc.): C, 17.31 (17.77); N, 2.23 (2.30); H, 1.01 (1.08). IR (cm^{-1}): ν_{as}(P–O_a) 1080 (vs), ν_{as}(W–O_d) 978 (vs), ν_{as}(W–O_b–W) 897 (s), ν_{as}(W–O_c–W) 810 (vs).

$(HC_{18}N_2H_{12})_4[SiMo_{12}O_{40}]\cdot 3dmf$ *Anal.* (%). Found (Calc.): C, 31.37 (31.71); N, 5.26 (5.02); H, 2.25 (2.40); dmf, 6.7 (7.1). IR (cm^{-1}): ν_{as}(Mo–O$_d$) 944 (s), ν_{as}(Si–O$_a$) 901 (vs), ν_{as}(Mo–O$_b$–Mo) 865 (m), ν_{as}(Mo–O$_c$–Mo) 796 (vs).

^{1}H NMR spectra in dmso-d_6 showed, besides the spectra of 2,2′-biquinoline, three additional singlets at 2.73, 2.89 and 7.95 ppm, of relative intensities 3:3:1, assigned to the CH_3 and CH protons of the dmf molecules. Integration of the signals corresponding to the methyl protons and to the aromatic protons of 2,2′-biquinoline confirms the number of dmf molecules in the formula determined by thermogravimetric analyses.

2.2. Reagents and methods

All chemicals were used as received from suppliers. Elemental analyses (C, H, N) were performed on a Leco CHNS-932. Thermogravimetric analyses were carried out in air between 30 and 700 °C at a heating rate of 5 °C min^{-1}, on a Mettler M3 thermobalance equipped with a TC 10A microprocessor.

Electronic absorption spectra (visible/UV) were recorded on a JASCO V-560 spectrophotometer using solutions approximately 0.005 mol dm^{-3}. Diffuse reflectance spectra (UV/visible/near infrared) were registered on a Shimadzu 3100 spectrophotometer, using MgO as reference. Infrared absorption spectra were recorded on a Mattson 7000 FTIR spectrometer, using KBr pellets.

^{1}H and ^{31}P NMR spectra (in dmso-d_6) were carried out in 5 mm tubes on a Bruker AMX 300 spectrometer. ^{31}P spectra were recorded using 85% aqueous H_3PO_4 as external reference.

Powder EPR spectra were recorded with a Bruker ESP 300E spectrometer at 120 K. Typical experimental conditions used: microwave frequency, 9.53 GHz; modulation frequency, 100 KHz, modulation amplitude, 0.1–0.5 mT, microwave power, 5 mW.

Powder XRD at room temperature data were collected on a X'Pert MPD Philips diffractometer (Cu Kα X-radiation) with a curved graphite monochromator, a fix incident area of 10 mm^2, and a flat plate sample holder, in a Bragg–Brentano para-focusing optics configuration. Intensity data were collected by the step counting method (step 0.02° and time 5 s) in the range $2\theta = 5°–50°$.

Second-order non-linear optical properties were estimated by the following procedure. Powder samples of determined average grain sizes were prepared with the aid of standard sieves and were used to fill round glass cells of 16 mm diameter. The fundamental beam of a Nd:YAG laser (1064 nm), pulse duration of 7 ns and a 10 Hz-repetition rate, was weakly focused on the sample. The second harmonic was separated from the incident fundamental beam using dichroic mirrors and then sent into a monochromator. The signal was detected using a photomultiplier tube (type 1P28 at 900 V bias) and read using a fast digital oscilloscope (Tektronix TDS 520 with a bandwidth of 500 MHz). Averages over 100 laser shots were acquired in order to reduce the influence of the shot-to-shot variations in laser power.

Photochromism experiences were performed as follows: samples of each compound (100 mg, finely ground) were exposed to sunlight or placed under a tungsten lamp (40W Osram Concentra R80), for the chosen period of time. Those powders that evidenced photosensitivity were, after irradiation, placed in the dark for a determined period of time or introduced in an autoclave and kept under O_2 (5 atm) for 24 h. Changes were monitored by reflectance and EPR spectroscopy.

3. Results and discussion

3.1. Synthesis and characterization of new compounds

Solids with cations formed by protonation of the organic base 2,2′-biquinoline (**2**) and Keggin polyoxoanions (**1**) were easily obtained by addition of a solution of the former in acetonitrile to an aqueous solution of the heteropolyacid of interest. The chemical formula of all obtained compounds presented the molar proportion organic cation/Keggin anion equal to the polyanion charge. Re-crystallization of the prepared solids in *N*,*N*-

dimethylformamide yielded new dmf solvated compounds.

The infrared spectra of all compounds presented the characteristic peaks corresponding to the Keggin anions in the 790–1100 cm^{-1} region, at frequencies near to those of tetra-*n*-butylammonium salts of XM_{12} [42]. Bands corresponding to the organic molecules were observed at frequencies higher than 1100 cm^{-1}.

All compounds were soluble in dimethylsulfoxide (dmso) and these solutions were used to obtain ^{31}P and ^{1}H NMR spectra. One peak was observed at −14.5 ppm in the ^{31}P NMR spectra of compounds with PW_{12} and at −2.95 ppm for those with PMo_{12} (chemical shifts identical to the observed for $H_3[PW_{12}O_{40}]$ and $H_3[PMo_{12}O_{40}]$ in the same solvent, respectively), indicating that the $[PM_{12}O_{40}]^{3-}$ anions are present in solution. The ^{1}H NMR spectrum of 2,2′-biquinoline in dmso showed several signals that were assigned to the protons of the molecule by comparison with published studies [43,44]. The proton spectra of the prepared compounds showed the peaks corresponding to the organic base with a slight change (0.02–0.05 ppm) in chemical shifts (except H3) to higher frequencies and almost no variation on coupling constants. The largest differences were observed for protons H4 and H8. Additionally, signals corresponding to dmf were observed in the spectra of dmf-solvated compounds.

The methods of preparation used and the molecular formula obtained suggested that the 2,2′-biquinoline molecules should be protonated in the solids. However, extensive dissociation must take place in solution, and no evidence could be found in the ^{1}H NMR spectra to corroborate that fact. The slight chemical shift variation observed in the spectra of the prepared compounds in comparison with that of free base was reproduced by addition of adequate stoichiometric quantities of trifluoroacetic acid to the dmso-d_6 solutions of 2,2′-biquinoline. Larger differences could only be observed when a much larger excess of acid was added to the solutions.

By means of thermogravimetric analyses, it was found that the crystallization solvent (when present) was lost below 100 °C (water) or in a narrow range around 150–160 °C (dmf). The decomposition of 2,2′-biquinolinium (after loss of solvent, when present) started at temperatures around 280–330 °C, with the exception of compounds with PW_{12}, in which it was stable up to 410 °C (Table 1).

Single crystals were developed for the compounds solvated with dmf, but single crystal X-ray diffraction measurements could only be made for the $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3dmf$ compound. However, the analyses of X-ray data revealed disordered Keggin anions and disordered 2,2′-biquinoline molecules and the structure could not be resolved with adequate refinement. Nevertheless, there is no evidence of a close contact (that would indicate covalent interaction) between the organic base molecules and the SiW_{12} anions [45]. This means that the charge transfer properties observed by electronic spectroscopy and described below are not associated with direct interactions but may result from induced-dipole effects as it has been reported for analogous charge transfer compounds [24,26].

Table 1
Temperature (°C) interval of decomposition of 2,2′-biquinolinium in the prepared compounds

Anion	Anhydrous or hydrated compounds [a]	dmf-solvated compounds [a]
PW_{12}	410–620	412–624
SiW_{12}	331–624	311–553
PMo_{12}	318–528	318–451
$SiMo_{12}$	286–522	309–509

[a] Values obtained by thermogravimetric analysis: first value, beginning of weight loss due to decomposition of 2,2′-biquinolinium; second value: end of thermal decomposition of the compound.

Samples of other compounds but $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3dmf$ had, generally, low crystallinity, as shown by X-ray powder diffraction. By comparison of the diffraction patterns of the various compounds it was apparent that some pairs of compounds, like $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$ and $(Hbiqui)_3[PW_{12}O_{40}]\cdot 3dmf$ or $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$ and $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$, were isomorphous and that compounds with formula that differ only on solvation, like $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$ and $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3dmf$ or $(Hbiqui)_3[PW_{12}O_{40}]$ and $(Hbiqui)_3[PW_{12}O_{40}]\cdot 3dmf$, had different crystal structures.

3.2. Electronic spectra and charge transfer properties

Diffuse reflectance spectra of the prepared compounds were compared with those of 2,2′-biquinoline and of the heteropolyacids used as starting materials. Two maxima were observed in the spectrum of 2,2′-biquinoline at 248 and 350 nm (Fig. 1). $H_3[PW_{12}O_{40}]\cdot nH_2O$ and $H_4[SiW_{12}O_{40}]\cdot nH_2O$ absorbed in the same region (PW_{12}: 259 and 331 nm; SiW_{12}: 259 and 341 nm). The reflectance spectra of $(Hbiqui)_3[PW_{12}O_{40}]$ and $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$ presented in Fig. 1(A and B) also have two bands with maxima at about 250 and 350 nm, mainly due to the presence of 2,2′-biquinoline (as a consequence of compounds stoichiometry). However, an additional band at about 410–420 nm, with intensity close to that of the UV bands, was observed in each spectrum. This band is characteristic of the synthesized compounds and is responsible for their yellow colour. It is not observed in the spectra of 2,2′-biquinoline, $H_3[PW_{12}O_{40}]$ or $H_4[SiW_{12}O_{40}]$ (all white)

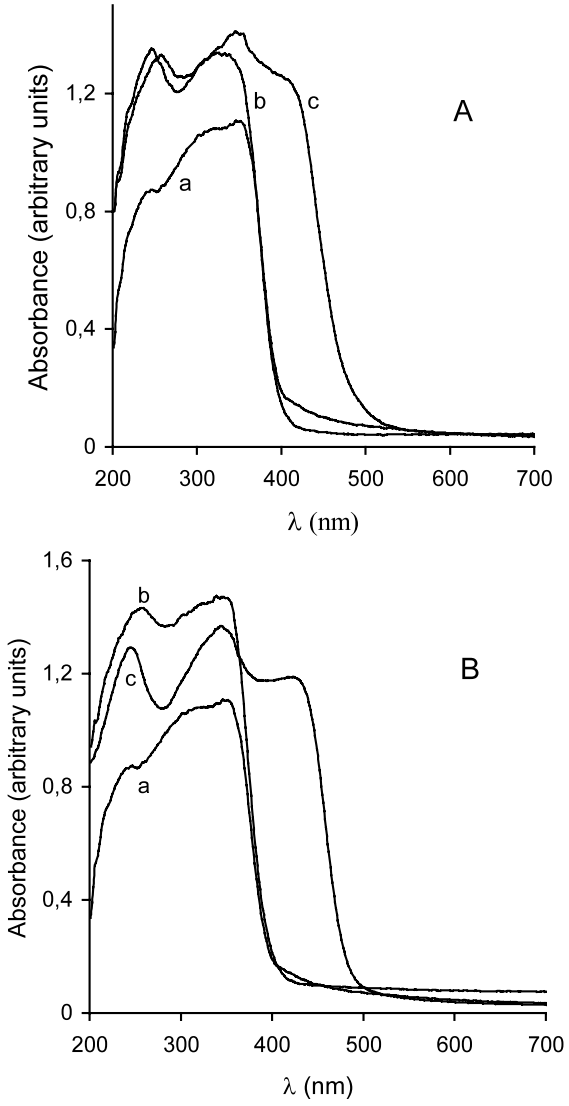

Fig. 1. (A) Diffuse reflectance spectra of 2,2′-biquinoline (a), $H_3[PW_{12}O_{40}]\cdot nH_2O$ (b), $(Hbiqui)_3[PW_{12}O_{40}]$ (c). (B) Diffuse reflectance spectra of 2,2′-biquinoline (a), $H_4[SiW_{12}O_{40}]\cdot nH_2O$ (b), $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 4H_2O$ (c).

and was assigned to charge transfer between the organic base and the Keggin anions [26,27].

Similar spectra were obtained for other prepared compounds, often with the absorption around 410 nm being observed as a shoulder. These results gave evidence of strong intermolecular electronic interactions between the organic moiety and any of the Keggin anions in the solids. In the case of $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$, the spectrum showed also a large band with low intensity centred around 750 nm, which was attributed to an electronic transition $Mo^{V}\rightarrow Mo^{VI}$ in the Keggin anion [1]. This implies the occurrence of reduction of the Keggin anion (Section 3.3) and could, possibly, be due to the difficulty of keeping compounds in the dark during synthesis and manipulation.

Electronic absorption spectra in dmso (0.005 mol dm^{-3}) were registered for $\lambda > 350$ nm, with the purpose of finding if the electronic interaction exhibited in the solids was retained in solution. This solvent is not possibly the most convenient for this type of studies, as it is known to be involved in electronic interaction with Keggin anions [25], but the choice of solvent was limited by the solubility of the different compounds. The organic base (in dmso) does not absorb in this range of λ and the spectra of the prepared compounds were, thus, compared with those of the corresponding heteropolyacid in the same solvent. Changes in the electronic spectra were more pronounced for compounds with the polyanion SiW_{12} (Fig. 2). In this case the tail of the lowest energy absorption band moved to significantly higher wavelengths (red shift of about 40 nm) in comparison with the spectra of the corresponding heteropolyacid. Changes were less obvious in the case of compounds with PW_{12} and negligible for other anions (Fig. 2). Spectra of the dmf-solvated compounds were identical to those of the non-solvated or hydrated compounds.

These results indicate that there is a strong electronic interaction between the 2,2′-biquinoline and $[SiW_{12}O_{40}]^{4-}$, in the studied solutions. This result is quite unusual. For other charge transfer compounds with Keggin polyanions reported in literature, it has always been shown that the electronic interactions observed in the solid are insignificant or weak in solution, unless there is a large excess of the organic base relative to the Keggin anion [23–27,29,35,36].

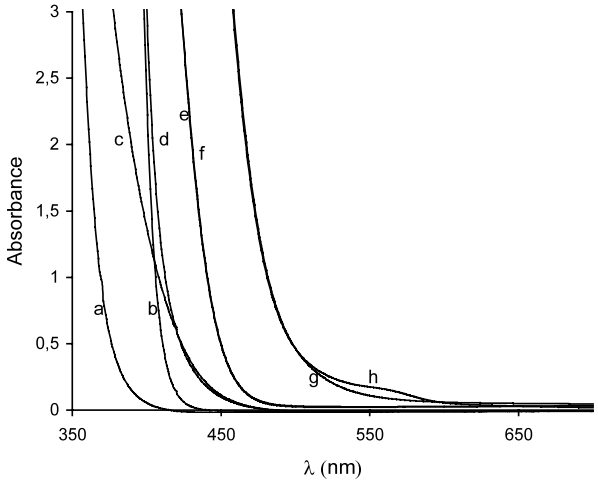

Fig. 2. Electronic absorption spectra of compounds in dimethylsulfoxide solutions (0.005 mol dm^{-3}): (a) $H_4[SiW_{12}O_{40}]\cdot nH_2O$; (b) $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$; (c) $H_3[PW_{12}O_{40}]\cdot nH_2O$; (d) $(Hbiqui)_3[PW_{12}O_{40}]$; (e) $H_4[SiMo_{12}O_{40}]\cdot nH_2O$; (f) $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$; (g) $H_3[PMo_{12}O_{40}]\cdot nH_2O$; (h) $(Hbiqui)_3[PMo_{12}O_{40}]$.

3.3. Photochromism of molybdenum compounds under sunlight or visible radiation

Studies concerning photochemistry of charge transfer compounds based on Keggin polyoxoanions have been, in most of cases, performed in solution [23,25,46]. Photosensitivity of solid compounds to radiation from UV sources [26,27,29] or sunlight [36–38] has been referred, but no detailed studies were presented. In this work we report studies on the photochromism of solid compounds under exposure to sunlight or under irradiation of a tungsten lamp (visible region).

Compounds with the XMo_{12} anions showed significant alterations in colour and in the spectroscopic properties (diffuse reflectance and EPR spectra) after irradiation with sunlight or with the tungsten lamp. The former were more pronounced and will be described below. The experiences conducted under the W lamp provided comparable results but only after longer periods of time (more than 48 h to reach the largest change in colour, compared with 2–10 h under sunlight, depending upon the compound).

Under sunlight, the compounds $(Hbiqui)_3[PMo_{12}O_{40}]$ and $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$ changed from yellow or yellow–green to green and the corresponding solvates with dmf changed from yellow–green to dark green or green, respectively (Fig. 3). The corresponding reflectance spectra showed an electronic band around 750 nm that, for each compound, increased up to a limit, with irradiation time (Table 2). EPR spectra of the irradiated solids had one isotropic signal at $g = 1.95$ (Fig. 4). These facts indicate the presence of Mo(V) in the Keggin anion [1,22,28,31,33] and suggest that the exposure to sunlight has induced the reduction of $[XMo_{12}^{VI}O_{40}]^{m-}$ to $[XMo_{11}^{VI}Mo^{V}O_{40}]^{(m+1)-}$, possibly as a result of charge transfer between 2,2′-biquinolinium and the anions. No decomposition was detected by spectroscopic techniques

Table 2
Intensities of selected bands in the diffuse reflectance spectra of compounds

Compound	Conditions	A_{750} [a]	A_{350} [b]	A_{750}/A_{350}
$(Hbiqui)_3[PMo_{12}O_{40}]$	[c]	0.501	1.602	0.313
$(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$	[d]	0.167	1.660	0.101
$(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$	[c]	1.149	1.687	0.681
$(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$	[c]	0.452	1.647	0.274
$(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$	[e]	0.280	1.640	0.171
$(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$	[c]	0.762	1.737	0.438
$(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$	[f]	0.291	1.675	0.174

[a] Absorbance (in arbitrary units) of the maximum near 750 nm. This band is not present in the spectra of non-irradiated compounds, except for $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$.
[b] Absorbance (in arbitrary units) of the maximum near 350 nm.
[c] After exposure to sunlight for 10 h.
[d] Without irradiation.
[e] After 1 month in the dark after previous exposure.
[f] After 3 months in the dark after previous exposure.

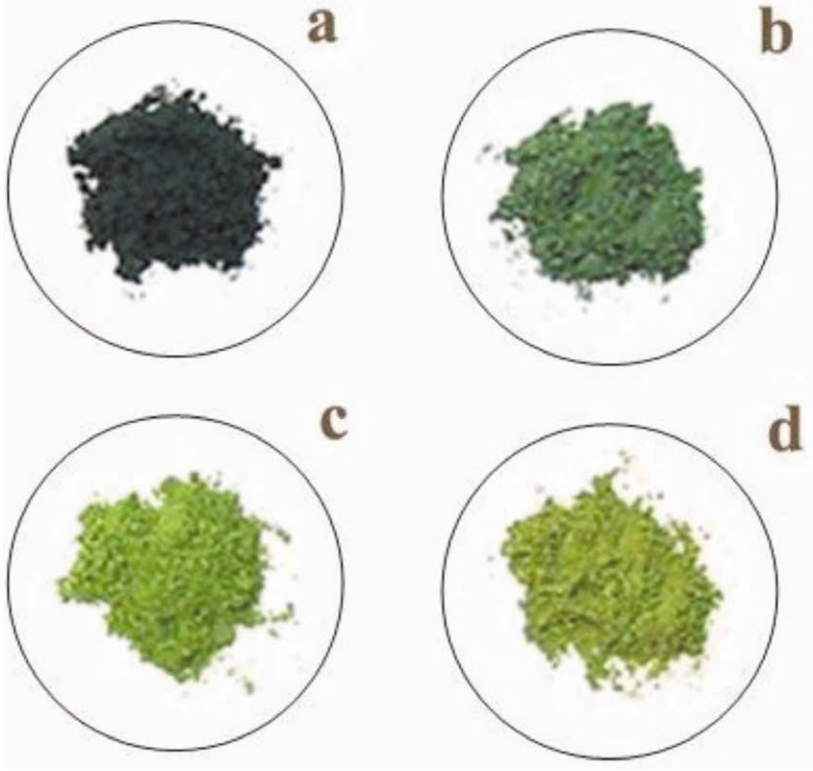

Fig. 3. Samples irradiated with sunlight for 10 h: (a) $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$; (b) $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$; (c) $(Hbiqui)_3[PMo_{12}O_{40}]$; (d) $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$.

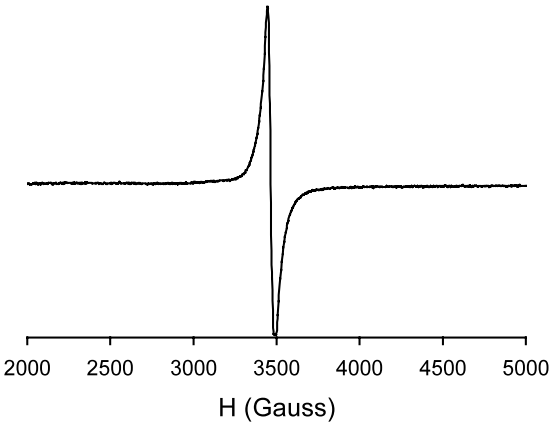

Fig. 4. Powder EPR spectrum ($T = 120$ K) of $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$ after exposure to sunlight for 10 h.

of the protonated organic base or of the Keggin anions on the solid compounds after exposure to light.

When similar experiments were performed with the XW_{12} compounds, no significative alterations in colour or in the spectra were observed. This is not unexpected, since the respective anions have lower reduction potentials than the molybdenum counterparts [1,47–49].

It was possible to make a semi-quantitative evaluation of the extension of reduction of the Keggin anions in the photosensitive compounds by comparing the intensities of the maxima in the reflectance spectra near 750 nm (a band corresponding to the reduced Keggin anion, A_{750}) and 350 nm (mainly an absorption band of 2,2′-biquinolinium, A_{350}). Based on the values of the ratio A_{750}/A_{350}, after irradiation for 10 h (Table 2), the following order of photosensitivity was found (that corresponds to the colour changes of Fig. 3): $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf > (Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf > (Hbiqui)_3[PMo_{12}O_{40}] > (Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$. The variation of A_{750}/A_{350} with irradiation time (Fig. 5) showed that the compounds with $SiMo_{12}$ reached faster a state for which no further alteration was observed (less than 2 h for the hydrated salt). For compounds with PMo_{12} very little evolution could be detected after irradiation for more than 10 h.

The two compounds of XMo_{12} crystallizing with dmf molecules were found to be more photosensitive than any of the others studied, for any time of irradiation considered. This means that the dmf molecules also play a role in the charge transfer that leads to the reduction of the anions. The existence of charge transfer between amides and Keggin anions is known [23–26,46] and the compound $[(dma)_2H]_3[PMo_{12}O_{40}]\cdot CH_3CN\cdot 0.5H_2O$ (dma = *N*,*N*-dimethylacetamide) was reported to be light sensitive [24]. For comparison, $[(dmf)_2H]_3[PMo_{12}O_{40}]$ was isolated using a similar procedure [24] and was found to be photosensitive in the conditions used in this work [50]. This does not prove that dmf is directly involved as an electron donor, but there is no

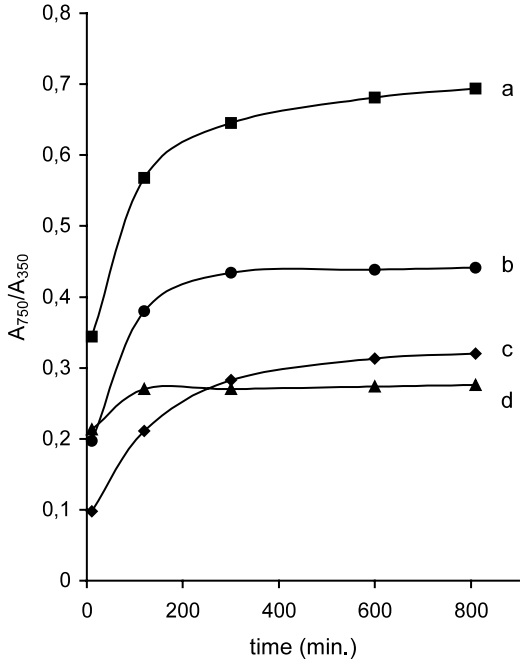

Fig. 5. Time dependence of A_{750}/A_{350}: (a) $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$; (b) $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$; (c) $(Hbiqui)_3[PMo_{12}O_{40}]$; (d) $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 4H_2O$.

doubt that the compounds $(Hbiqui)_3[PMo_{12}O_{40}]\cdot 3dmf$ and $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$ were more photosensitive than those that have only 2,2′-biquinolinium or dmf. The simultaneous combination of these organic molecules with the molybdenum Keggin anions leads to an enhancement of the response to sunlight or W-lamp visible light. Other dmf-solvated charge transfer compounds with Keggin anions have been reported [29,31,35], but the influence of this solvent in the photosensitivity has not been considered.

Some of the studied photosensitive compounds recovered partially the original colours (and reflectance spectra) when left in the dark, at room temperature, under aerobic conditions, during a comparatively long period of time after previous exposure to light (Table 2, Fig. 6). Only $(Hbiqui)_3[PMo_{12}O_{40}]$ did not show any degree of recovering. In the spectra of compounds with $SiMo_{12}$, the visible band around 750 nm decreased 50–70% after about 1–3 months in the dark (Fig. 6). Attempts to accelerate the recovery by the use of O_2 (5 atm, 24 h) did not yield different results. To use these compounds as photochromic materials the recovery of the original colours, after removal of the light source, should occur faster. Until now, truly reversible photochromism has been well established for a few alkylammonium salts of isopolymolybdates [39,51]. Concerning charge transfer compounds with Keggin anions, reversible photochromic properties have only been briefly mentioned for some solids with the $[(CH_2OH)_3CNH_3]^+$ cation [36].

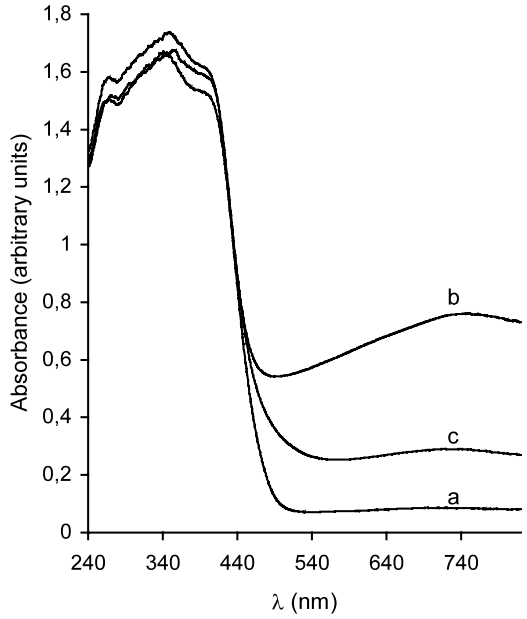

Fig. 6. Diffuse reflectance spectra of $(Hbiqui)_4[SiMo_{12}O_{40}]\cdot 3dmf$: (a) without irradiation; (b) after irradiation with sunlight (5 h); (c) after 3 months in the dark following previous light exposure.

3.4. Non-linear optical properties

The Kurtz powder test set-up [52] was used to characterize the intensity of the optical second harmonic signal. Several samples were prepared, each consisting of crystal grains with an average size of 30, 50, 65, 90 and 100 μm measured on standard sieves. Upon irradiation with Nd:YAG laser light ($\lambda = 1064$ nm), the intensity of the green light from the powder samples was measured in $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$ and urea under the same conditions and its values compared. It was found that the SHG signal intensity was about 15% that of urea. This value is comparable to that obtained with the compound $(hmpaH)_4[SiW_{12}O_{40}]\cdot 2H_2O$, hmpa = hexamethylphosphoramide [26]. Preliminary tests on the other prepared compounds have provided negligible responses. Future work on the design of polyoxometalate-based materials in order to obtain more intense SHG is required. The study of third-order non-linear properties is in progress and will be presented elsewhere.

3.5. Concluding remarks

Reaction of the electron donor 2,2′-biquinoline with heteropolyacids originated novel compounds of general formula $(Hbiqui)_m[XM_{12}O_{40}]\cdot n$solv, X = P ($m = 3$), Si ($m = 4$); M = Mo, W. These were coloured yellow or yellow–green due to charge transfer between protonated 2,2′-biquinoline and the anions. Electronic spectroscopy corroborated this fact. The salt $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3H_2O$ is particularly interesting, since it exhibited intense charge transfer in the solid state, intermolecular electronic interaction in solution and second-order non-linear optical properties. Some of the prepared compounds are potential candidates for third-order non-linear optics.

Compounds with molybdenum proved to be photochromic under sunlight and, to a smaller extent, under visible light from a tungsten lamp. Change in colour accompanied reduction of the Keggin anions. Solids crystallized with dmf were more photosensitive than others. None of the studied compounds exhibited a truly reversible photochromism, but for some of them partial recovery of the initial colours and spectra were observed.

[45] Crystal structure analysis on $(Hbiqui)_4[SiW_{12}O_{40}]\cdot 3dmf$: orthorhombic, space group *Fddd*, $a = 1796.9(2)$, $b = 2124.1(2)$, $c = 5275.4(2)$ pm, $V = 20135(4) \times 10^6$ pm^3, $Z = 8$. Preliminary examination and data collection were carried out on a Nonius κ-CCD device attached to a rotating anode (NONIUS FR591) and graphite monochromator Mo Kα radiation. Data collection was performed at 143 K. A total of 19 778 reflections were collected. After merging ($R_{int} = 0.093$), 4203 independent reflections remained and were used for all calculations. Data were corrected for Lorentz and polarization effects. The structure was solved by a combination of direct methods and difference-Fourier syntheses. Due to the presence of highly disordered 2,2′-biquinoline molecules and $[SiW_{12}O_{40}]^{4-}$ anions the *dmf* molecules could not be resolved and we decided to stop the calculations at $R_1 = 0.1177$. Nevertheless these results are exact enough for the statements given in Section 3.

[50] $[(dmf)_2H]_3[PMo_{12}O_{40}]$ was obtained by adding dmf to a concentrated aqueous solution of $H_3[PMo_{12}O_{40}]$ (molar ratio of 6:1). A yellow solid was collected and dried in vacuum. Its characterization by thermogravimetric analyses, infrared and NMR (^{31}P and ^{1}H) spectroscopy was consistent with the chemical formula indicated above. Exposure to sunlight changed the colour of this compound to green. The reduction of $[PMo_{12}O_{40}]^{3-}$ was evidenced by EPR and diffuse reflectance spectroscopy.

intriguing observation that the pharmacological activity has been found to be highly dependent on the identity of the metal and the donor sequence of the ligands with different ligands showing widely different biological properties although they may vary only slightly in their molecular structure [20,24]. However, no pattern has emerged to enable the activity to be predicted on the basis of the structure of this type of compound, their substituents or their metal complexes [27]. Apart from their biological activity, nitrogen–sulfur donor ligands of thiosemicarbazides and thiosemicarbazones and their metal complexes generate intriguing stereochemical, electrochemical and electronic properties. Current research is probing into the electron-transfer behaviors of these complexes as well [28–30].

We continue our work in this area to supplement available information and thus contribute to the effort to elucidate the selectivity pattern of these Schiff base ligands. Our recent observations have shown that antimony and cobalt complexes with NNS donor sequence Schiff bases exhibited very low CD_{50} values of 0.35–1.6 μg cm^{-3} [31] while a number of transition metal complexes of methyl-3-[1-(2-pyridyl)ethylidene]carbodithioate have been reported to have antitumor activity [2] and palladium(II) complexes containing the dithiocarbazate moiety showed positive in vitro antiamoebic activity against *E. histolytica* [32]. Encouraged by these results, we have extended our study to new bidentate NS Schiff bases derived from the condensation of SBDTC with 5-methyl-2-furyldehyde (NS) and 2-furyl-methylketone (NS′). In addition, we report herein the bioactivity of a previously reported tridentate NNS Schiff base (SBD1) [33] derived from SBDTC with pyrrole-2-carboxaldehyde and its nickel(II) and copper(II) complexes.

2. Experimental

All the chemicals and solvents were of reagent grade, and were used as received.

2.1. Preparation of S-benzyldithiocarbazate and its Schiff bases

SBDTC was prepared as previously reported [3]. The yield was 35 g (85%), m.p. 124 °C (Lit. 125 °C). All the Schiff bases were prepared by adding a solution of SBDTC (0.1 mol) in absolute EtOH (40 cm^3) to an equimolar solution of aldehyde or ketone in 50 cm^3 of the same solvent. The mixture was heated on a steam bath for 10 min and then cooled to 0 °C in an ice bath until the Schiff base precipitated. After being filtered, washed with cold EtOH and dried in vacuo over silica gel, the yield of each product was measured and its m.p. was recorded.

2.2. General method for the preparation of metal complexes

Schiff base (0.0076 mol) prepared as outlined in Section 2.1 was dissolved in EtOH (50 cm^3) in the presence of an equimolar amount of KOH (0.4 g). The clear solution was treated with a solution containing a stoichiometric amount of metal salt in the same solvent (approximately 50 cm^3). The mixture was heated to 100 °C for 5 min and then kept in an ice-salt bath. The product was isolated, washed with EtOH and dried in a vacuum desiccator over P_2O_5. The metal salts used were $Cu(NO_3)_2 \cdot 2.5H_2O$, $NiCl_2 \cdot 6H_2O$, $Cd(CH_3COO)_2 \cdot 2H_2O$ and $ZnCl_2$.

2.3. Physical measurements

The analyses for carbon, hydrogen and nitrogen were carried out at *Mikroanalytisches Labor Pascher*, Remagen-Bandorf, Germany. The IR spectra in KBr pellets were recorded (4000–400 cm^{-1}) using a Perkin–Elmer FTIR 1750X spectrophotometer. The molar conductance of a 10^{-3} M solution of each metal complex in DMSO was measured at 29 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinised electrode. M.p. were determined using an Electrothermal digital m.p. apparatus while the UV–Vis spectra were recorded on a Shimadzu UV-2501 PC spectrophotometer (800–200 nm).

2.4. X-ray structure determination of [Cd(NS)$_2$]

A selected crystal of the recrystallized Cd(II) complex was mounted on a SMART CCD diffractometer. Reflection data were measured at 20 °C using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation with a detector distance of 4 cm and swing angle of −35°. The collected data were reduced using the program SAINT [34] and an empirical absorption correction was carried out using SADABS [35]. The structure was solved by direct methods and refined using the full-matrix least-squares method on F^2_{obs} using the SHELXTL [36] software package. All non-H atoms were anisotropically refined. The hydrogen atoms were located by different syntheses and refined isotropically, using SHELXTL created the molecular graphics. Atomic scattering factors and anomalous dispersions corrections were taken from the International Table for X-ray crystallography [37].

2.5. Target microorganisms

Eight pathogenic microbes were used to test the biological potentials of the ligands and their complexes. They were *Methicillin resistant sthaphylococcus* (MRSA), *Bacillus subtilis* wild type (B29), *Subtilis*

mutant (mutant defective DNA repair-B28), *Pseudomonas aeruginosa* (60690), *Candida albicans* (C.A.), *Aspergillus ochraceous* (398), *Saccaromyces ceciricaee* (20341) and *Candida lypolytica* (2075).

2.5.1. Qualitative antimicrobial assay

Antimicrobial activity of each sample was qualitatively determined by a modified disc diffusion method as previously reported [31,38].

2.5.2. Quantitative antimicrobial assay

Compounds that showed positive antimicrobial activities with the modified disc diffusion assay were subjected to the broth dilution method for the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [39]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg cm^{-3}). Streptomycin and nystatin were used as positive controls for bacteria and fungi, respectively.

2.5.3. Cytotoxic assay

CEM-SS (Human T-lymphoblastic leukemia cell line) obtained from the National Cancer Institute, USA and HT-29 (Human colon adenocarcinoma cell line) obtained from American Type Culture Collection were used. The cells were cultured in RPMI-1640 medium supplemented with 10% fetal calf serum. Cytotoxicity was determined using the microtitration of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay (MTT) (Sigma, USA) as reported by Mosmann [40]. The solutions of compounds of different concentrations were prepared from the stock solutions (10 mg cm^{-3}) by serial dilution in RPMI-1640 to give a volume of 0.1 cm^3 in each well of a microtiter plate as described previously [19]. Each well was filled with 0.1 cm^3 of cell suspension in complete growth medium (CGM) at 1–2×10^5 cells cm^{-3}. Controls that contained only cells were included for each sample. Doxorubicin and tamoxifen were used as control cytotoxins.

3. Results and discussion

The condensation of SBDTC with 5-methyl-2-furfural and 2-furyl-methylketone yielded the isomeric Schiff bases, **1** and **2**, respectively. The CHNS elemental analyses results are in full agreement with the calculated values (Table 1). The Schiff bases **1** and **2** have protons adjacent to the thione groups. The thione groups are relatively unstable in the monomeric forms and tend to turn to the more stable thiol forms by enethiolization in solution [3] (Figs. 1a,b and 2a,b). The absence of ν(SH) modes at approximately 2570 cm^{-1}, in the solid state, indicates that thione (**1a**) and (**2a**) was the major tautomer in each case. However, in the presence of KOH, the Schiff bases can quickly form the thiolate anions in solution [3]. This enhances the nucleophilicity of the ligand thus affording bidentate uninegative chelation with metal ions. The results of elemental analyses, the melting points, UV–Vis spectra, IR spectra and molar conductance values are given in Tables 1 and 2. The IR spectra of the Schiff bases **1** and **2** display strong bands at approximately 1000 cm^{-1} which can be assigned to the asymmetric stretching mode of CSS. Upon coordination, these bands were found either to split or to give well-defined shoulders, indicating the presence of unidentate sulfur coordination [41]. The ν(C=S) modes of **1** and **2**, at approximately 1100 cm^{-1}, were lost in all the metal complexes (Table 2), confirming that the Schiff bases were coordinated through the thiolo sulfur. The ν(C=N) modes of **1** and **2** observed at 1620 and 1599 cm^{-1}, respectively, were shifted to lower (approximately 50 cm^{-1}) frequencies (Table 2) in the complexes, indicating coordination by the azomethine nitrogen. The ν(N–N) modes of all the free ligands were shifted to higher wave numbers on complexation as a result of a reduction in the repulsion between the lone pairs of electrons on the nitrogen atoms due to coordination through the azomethine nitrogen atom [42]. The disappearances of the ν(NH) modes of the free Schiff bases **1** and **2**, at 3200 and 3210 cm^{-1}, upon complexation (Table 2), evidences coordination through

Table 1
Analytical data and physical properties of the Schiff bases and their complexes

Compound	Color	M.p (°C)	Found (Calc.) (%)			Molar conductance (Ω^{-1} cm^2 mol^{-1})
			C	H	N	
NS (**1**)	orange	134.4

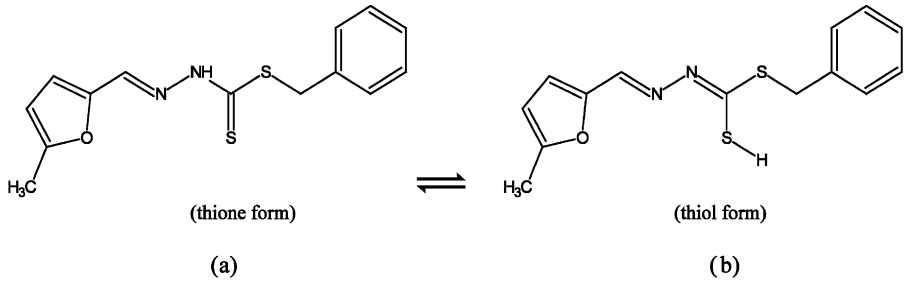

Fig. 1. The Schiff base **1**, thione form turning to thiol form.

the thiolate anions generated as a result of enethiolization.

The zinc complex, **5**, has a molar conductance of 33 Ω^{-1} cm^2 mol^{-1}, in DMSO, characteristic of 1:1 electrolytes [43]. Other metal complexes have molar conductance values <25.0 Ω^{-1} cm^2 mol^{-1} indicating covalent bonding in each case.

The band maxima in the UV–Vis spectra of the dark orange nickel complex, **3** at 485, 420, 357 nm and its dark green nickel complex, **6**, at 510, 420, 315 nm were characteristic of a square-planar Ni(II) configuration [3]. The bands may be attributed to the $^1A_1g \rightarrow {}^1A_2g$, $^1A_1g \rightarrow {}^1B_1g$ and $^1A_1g \rightarrow {}^1Eg$ transitions, respectively [44]. The UV–Vis spectra for the copper(II) complex, **4**, displays two bands corresponding to $^2B_1g \rightarrow {}^2A_1g$ (380–375 nm) and $^2B_1g \rightarrow {}^2E_1g$ (350–345 nm) transitions, presumably arising from a square-planar Cu(II) [3]. The very low solubility of the yellow zinc(II) complex, **5**, in most organic solvents indicates a polymeric structure. A bridged dimeric square-planar structure is very unlikely since zinc(II) ion generally forms tetrahedral complexes because of its d^{10} electronic configuration. The absorption maxima at 360, 340 and 300 nm can be attributed to intra-ligand transitions only [44].

3.1. X-ray crystal and molecular structure study of [Cd(NS)$_2$]

Recrystallization of [Cd(NS)$_2$] from DMF gave beautiful dark yellow transparent crystals after a week. Fig. 3 shows the perspective view and the atomic numbering scheme of the complex. The summary of crystallographic data, as well as the solution and refinement information for the complex are given in Table 6. Selected bond lengths and angles are listed in Table 7. The complex, of composition [$CdC_{28}H_{26}N_4S_4O_2$], is composed of discrete molecules (Fig. 3). The central cadmium atom of the complex molecule adopts a distorted tetrahedral geometry with N–Cd–N, N–Cd–S and S–Cd–S angles between 79.07(8)° and 130.15(8)°. The C–N bond distances of the bi-chelated ligands of 1.279(5)–1.293(5) Å are typical for double bond Schiff base compounds [45,46]. The C–S bond distances of 1.741(4)–1.798(5) Å indicate single bond character which supports the suggestion that the complex formation involves the ligand in its thiol form. Both the Cd–N (2.267(3) and 2.286(4) Å) and Cd–S (2.4807(11) and 2.4819(11) Å) bond lengths are slightly shorter than those found in complexes of octahedral symmetry where Cd–N bond lengths of between 2.349(3) and 2.578(4) Å [28] and Cd–S bond length of 2.640(1) Å in the Cd(II) complex containing 1,4,7,10-tetrakis(pyrazol-1-ylmethyl)-1,4,7,10-tetraazacyclododecane ligand [25,47] have been reported. The methylfurylmethylenedithiocarbazate moieties C7/S2/C8/N1/N2/S1/C9/C10/C11/C12/C13/C14/O1/Cd and C21/S4/C22/N3/N4/S3/C23/C24/C25/C26/C27/C28/O2/Cd are essentially planar but almost perpendicular to each other about the central Cd atom with a dihedral angle of 75.76(3)°. The phenyl rings, C1/C2/C3/C4/C5/C6 and C15/C16/C17/C18/C19, are out of plane with their respective methylfurylmethylenedithiocarbazate groups with dihedral angles of 73.0(1)° and 76.4(1)°, respectively. A weak intramole-

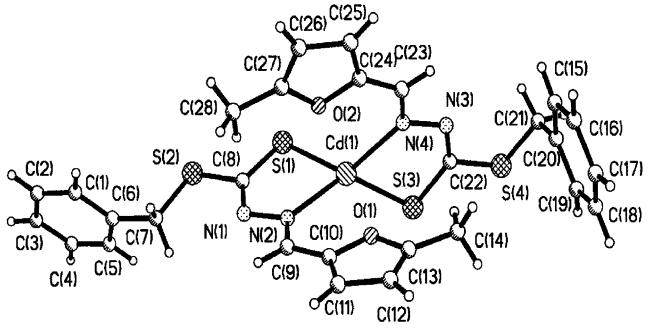

Fig. 3. Molecular structure of $[Cd(NS)_2]$ with 50% probability displacement ellipsoids.

cular interaction involving C28–H28···N1 is present in the molecule with H28···N1 bond length of 2.555 Å and C28–H28···N1 bond angle of 169.9°.

3.2. Cytotoxic activity

Compounds having CD_{50} values of less than 5 μg cm^{-3} are considered highly active, 5–10 μg cm^{-3}, moderately active, 10–20 μg cm^{-3}, weak and more than 20 μg cm^{-3}, inactive [19]. Screening results against CEM-SS (Human T-lymphoblastic leukemia cell line) cells are shown in Table 3. The NNS Schiff base, SBD1, reported by Ali et al. [33] and the new NS Schiff base, **1**, were highly active with the same CD_{50} values of 3.10 μg cm^{-3}, while **2** showed weak activity with a CD_{50} value of 12.00 μg cm^{-3}. The complexes, SBD1·Cu, **5** and **6**, were active against CEM-SS cells. Compound **5** showed strong activity with a CD_{50} value of 2.0 μg cm^{-3} while the CD_{50} value for **6** was 3.4 μg cm^{-3}. $[Cd(NS)_2]$ was also strongly active against CEM-SS with a CD_{50} value of 4.95 μg cm^{-3}. This cadmium complex was also tested against HELA (Cervical Cancer Cells) and was found to be very active with a CD_{50} value of 4.0 μg cm^{-3}. Epoxide was used as standard in the screening against HELA. The previously reported complex, SBD1·Cu [33], showed weak activity against CEM-SS cells (CD_{50} value of 19.5 μg cm^{-3}). All Schiff bases reported herein were inactive towards HT-29 while the complexes, SBD1·Cu and **5** showed weak activities against HT-29 with CD_{50} values of 12.0 and 13.0 μg cm^{-3}, respectively. Cytotoxicity of the simple metal salts is included in Table 3 for comparison. The selectivity of the Schiff bases and their complexes is of particular interest and is undoubtedly related to the mode of interaction between them and the target organisms. A study on the mechanism of chelation/binding has therefore been initiated.

3.3. Qualitative and quantitative antimicrobial assay results

Qualitative results for antimicrobial assays are given in Table 4. The SBD1 Schiff base showed a clear inhibition zone of 15 mm and above with all fungi,

n.a., not available; –, inactive.

while **1** showed clear inhibition of 15 mm and above with *A. ochraceous* (398) and *C. lypolytica* (2075). Compound **5** showed clear inhibition (> 15 mm) against all bacteria and *A. ochraceous* (398), while **6**, showed a clear inhibition zone against all fungi and *S. mutant* (mutant defective DNA repair-B28). $[Cd(NS)_2]$ complex was active against all bacteria and fungi used in our qualitative screening.

The quantitative antimicrobial results (Table 5) showed that the Schiff base, SBD1 was very effective against *S. ceciricaee* (20341) with a MIC value of 2500 μg cm^{-3}, while the MIC values for SBD1 against *C. lypolytica* (2075) were comparable to the antifungal control (Table 5).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 163829 for the compound $[Cd(NS)_2]$. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

the present paper, we want to show the nature of adducts formed between thallium(I) nitrate and 3-nitrophenoxide, 2,4-dinitrophenoxide and 4-nitrobenzoate ligands.

2. Experimental

2.1. Physical measurements

IR spectra were recorded as Nujol mulls using Perkin–Elmer 597 and Nicolet 510P spectrophotometers. Microanalyses were carried out using a Heraeus CHN-O-Rapid analyzer.

2.2. Preparation of Tl(3-np)

The complex Tl(3-np) was prepared by dissolving 0.266 g (1 mmol) thallium(I) nitrate in distilled water and adding a mixture of 3-nitrophenol (0.139 g, 1 mmol) and potassium hydroxide (0.057 g, 1 mmol) in ethanol (10 ml). The resulting solution was stirred for 1 h at room temperature, then it was allowed to stand for 2–3 days in a refrigerator. Yellow crystals of the desired product precipitated, were filtered off, washed with acetone and ether and air dried (0.239 g, yield 70%), m.p. 190 °C.

Anal. Found: C, 19.65; H, 1.29; N, 4.31. Calc. for $C_{12}H_8N_2O_6Tl_2$: C, 21.05; H, 1.17; N, 4.05%.

IR (cm^{-1}) selected bands: 720(s), 850(s), 1380(vs), 1590(s), 1612(s), 2980(w), 3140(w).

2.3. Preparation of Tl(2,4-dnp)

An ethanolic solution of 2,4-dinitrophenol (0.368 g, 2 mmol) and potassium hydroxide (0.114 g, 2 mmol) was added to a solution of thallium(I) nitrate (0.532 g, 2 mmol) in water. The resulting solution was concentrated on a water bath at 80 °C and cooled to room temperature (~ 25 °C), when a red microcrystalline compound was separated. The compound was filtered off, washed with cold ethanol and dried over silica gel (0.387 g, yield 50%). The red single crystals were isolated by the following branch tube method. The complex (0.3 g) was placed in one arm of the branched tube. Methanol was carefully added to fill both arms, then the tube was sealed and the complex-containing arm immersed in a bath at 60 °C while the other was at ambient temperature. After 10 days, red crystals (m.p. 240 °C) had deposited in the cooler arm. *Anal*. Found: C, 18.3; H, 0.9; N, 7.3. Calc. for $C_6H_3N_2O_5Tl$: C, 18.59; H, 0.77; N, 7.23%.

IR(cm^{-1}) selected bands: 720(w), 850(w), 1180(s), 1350(vs), 1385(vs), 1560(s), 1590(s), 1640(vs), 3030(w).

2.4. Preparation of Tl(4-nb)

The complex Tl(4-nb) was prepared by dissolving 0.266 g (1 mmol) thallium(I) nitrate in distilled water and adding an ethanolic solution of 3-nitrobenzoic acid (0.167 g, 1 mmol) and potassium hydroxide (0.057 g, 1 mmol). The resulting solution was stirred for 2 h at room temperature, and then it was allowed to stand for 3–4 days in a refrigerator. A white powder of the desired product precipitated, which was filtered off, washed with acetone and ether and air dried (0.230 g, yield 55%), m.p. 208 °C.

Anal. Found: C, 22.15; H, 1.13; N, 3.82. Calc. for $C_7H_4NO_4Tl$: C, 22.67; H, 1.08; N, 3.78%.

IR(cm^{-1}) selected bands: 717(vs), 817(s), 1331(vs), 1375(vs), 1507(vs), 1544(s), 2980(w), 3045(w).

2.5. Crystallography

2.5.1. Crystal data and refinement details

[Tl(3-np)]. $C_{12}H_8N_2O_6Tl_2$, M 684.94, triclinic, space group $P\bar{1}$, $a = 3.7649(15)$, $b = 9.400(4)$, $c = 10.068(4)$ Å, $\alpha = 85.159(8)^\circ$, $\beta = 86.133(8)^\circ$, $\gamma = 78.749(7)^\circ$, $V = 347.8(2)$ Å^3, D_{calc} ($Z = 1$ f.u.) 3.271 Mg m^{-3}, $F(000)$ 304. Specimen: $0.10 \times 0.1 \times 0.20$ mm; $T_{max,min}$ 0.761, 0.265, N 2891, N_0 1359, R 0.0468, R_w 0.0835.

Tl(2,4-dnp)]. $C_6H_3N_2O_5Tl$, M 387.47, monoclinic, space group $P2(1)/c$, $a = 5.7649(15)$, $b = 19.261(11)$, $c = 7.636(4)$ Å, $\alpha = 90^\circ$, $\beta = 91.857(11)^\circ$, $\gamma = 90^\circ$, $V = 802.4(8)$ Å^3, D_{calc} ($Z = 4$ f.u.) 3.208 Mg m^{-3}, $F(000)$ 696. Specimen: $0.05 \times 0.2 \times 0.30$ mm; $T_{max,min}$ 0.1553, 0.0294, N 9196, N_0 2339, R 0.0500, R_w 0.1046.

2.5.2. Determination of the structures

Crystallographic measurements were made at 140(2) K for [Tl(3-np)] and 120(2) K for [Tl(2,4-dnp)] using a Siemens R3m/V diffractometer. The intensity data were collected within the range $2.03^\circ \le \theta \le 27.03^\circ$ for [Tl(3-np)] and $3.41^\circ \le \theta \le 30.06^\circ$ for [Tl(2,4-dnp)] using graphite monochromated Mo Kα radiation ($\lambda =$ 0.71073 Å). Accurate unit cell parameters and an orientation matrix for data collection were obtained from least-squares refinement. Intensities of 2891 and 9196 unique reflections were measured, from which 1359 and 2339 with $I > 2\sigma(I)$ were used in the refinement for [Tl(3-np)] and [Tl(2,4-dnp)], respectively. The structures have been solved by direct methods and refined by full-matrix least-squares techniques on F^2.

The positions of hydrogen atoms were idealized and included in the calculations of the structure factors as fixed contributions. Each hydrogen atom was assigned an isotropic thermal parameter. R, R_w, with goodness-of-fit on F^2 0.897 and 0.754 are 0.0468, 0.0835 and 00.0385, 0.0962 for [Tl(3-np)] and [Tl(2,4-dnp)], respectively. The final difference density map showed a maximum peak and hole of 1.992, −1.495 e Å^{-3} for

[Tl(3-np)] and 2.507, −2.103 e Å^{-3} for [Tl(2,4-dnp)]. Corrections for Lorentz and polarization effects as well as the empirical correction for absorption using the SADABS programs were applied. All structural calculations were carried out with a PDP−11/23+ computer using the SDP-PLUS program package [17,18].

Crystal data and structure refinement are given in Tables 1 and 2. Selected bond lengths and angles are given in Tables 3 and 4. Anisotropic thermal parameters, observed and calculated structure factors, full lists of bond distances, bond angles and torsion angles are given in the supplementary material. ORTEP diagrams and a perspective view of the packing in the unit cells are shown in Figs. 1–4.

3. Discussion

3.1. Synthesis

Reaction between 3-nitrophenoxide, 4-nitrobenzoate and 2,4-dinitrophenoxide ligands provided powdered

Table 1
Crystal data and structure refinement for Tl(3-$NO_2C_6H_4O$)

Identification code	Tl(3-$NO_2C_6H_4O$)
Empirical formula	$C_{12}H_8N_2O_6T_{12}$
Formula weight	684.94

materials analyzing as [Tl(3-np)], [Tl(4-nb)] and [Tl(2,4-dnp)], respectively. Attempts to isolate suitable single crystals for X-ray crystallography for [Tl(4-nb)] were not successful and each time the powdered compound was isolated.

3.2. Crystal structure of [Tl(3-np)]

Determination of the structure of [Tl(3-np] by X-ray crystallography (Table 1) showed the complex in the solid state (Fig. 2) to be a polymeric species with various similarities to the polymeric structures of [Tl(2-np)] and [Tl(4-np)], and it is really a novel one-dimensional polymer. The thallium atoms are linked within a classical 'stair-polymer' array by phenoxide oxygen atoms, each Tl(μ-O)$_2$Tl unit having an inversion point at its center, and a pair of them making up the unit b component of the polymer.

Thus, each thallium atom can be considered to be three-coordinate with an O_3 donor atom array (three

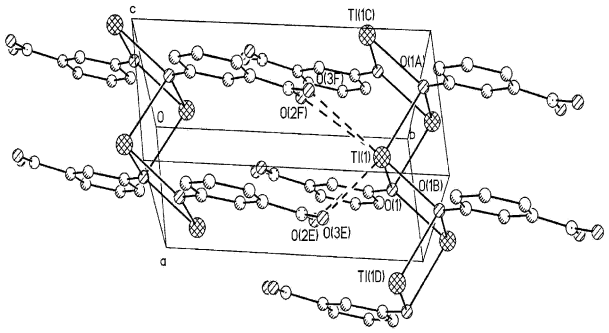

Fig. 2. A view perpendicular to a polymeric strand of the solid showing the chelating and bridging functions of the 3-nitrophenoxide ligand and the full donor atom environment of the Tl atoms in Tl(3-np).

oxygen atoms of the 3-nitrophenoxide ligand with Tl–O distances of Tl1···O1 = 2.499, Tl1···O1 $(-x+1, -y+2, -z)$ = 2.562 and Tl1···O $(-x, -y+2, -z)$ = 2.717 Å), and the weak interaction of thallium(I) with oxygen atoms of an adjacent molecule produces polymer units in the solid state. In fact each Tl atom in this structure alone with three normal bonds forms four "weak" Tl···O bonds and the exact distances are Tl1···O2 $(-x+1, -y+1, -z)$ = 3.005, Tl1···O3 $(-x, -y+1, -z)$ = 3.396 Å, Tl1···O3 $(-x+1, -y+1, -z)$ = 3.515 and Tl1···O2 $(-x, -y+1, -z)$ = 3.554 Å (Table 3). The presence of a lone pair of electron on the thallium atom is apparently the reason that the bridging interactions cannot come closer together. If the stereochemically active lone pair was not present, it might create more interaction between the bridging atoms of thallium(I) with the neighboring oxygen atoms

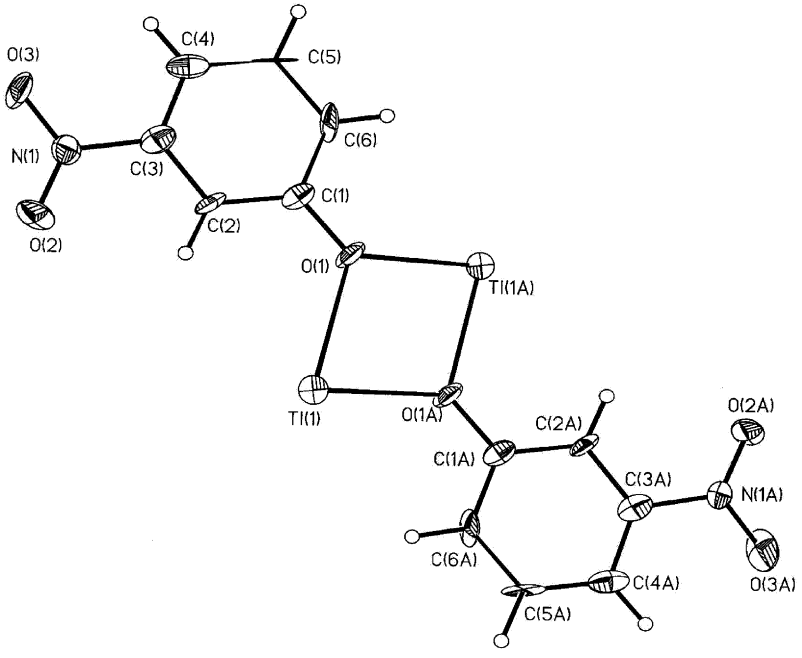

Fig. 1. The ORTEP diagram of the Tl_2O_2 rhomb forming the basic link of the polymeric structure of [Tl(3-np)]$_2$.

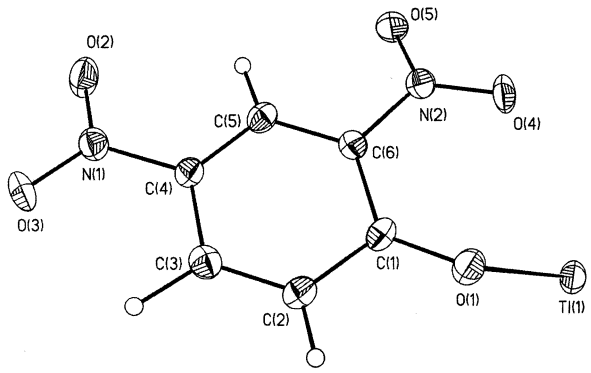

Fig. 3. The ORTEP diagram of Tl(2,4-dnp).

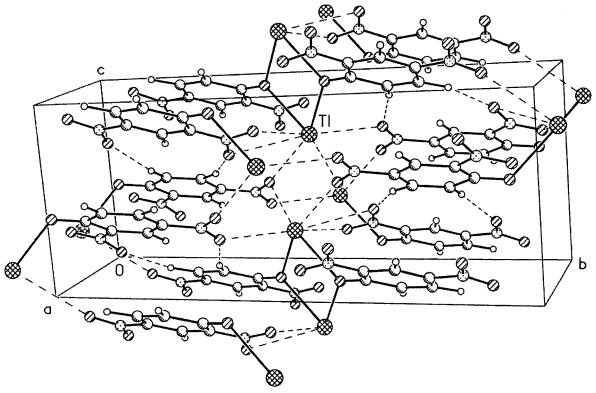

Fig. 4. A view perpendicular to a polymeric strand of the solid showing the chelating and bridging functions of the 2,4-dinitrophenoxide ligand and the full donor atom environment of the Tl atoms in Tl(2,4-dnp).

of nitrophenoxide. Consequently, this phenomenon could lead to more symmetry.

The arrangement of the oxygen atoms of nitrophenoxide suggest a gap or hole in the coordination geometry around the metal ion, occupied possibly by a stereoactive lone pair of electrons on thallium(I). The observed shortening of the Tl–O bond on the side of the Tl(I) ion opposite to the putative lone pair (2.499 compared with 2.717 Å adjacent to the lone pair) supports the presence of this feature. There are some "weak" Tl···Tl bonds in the polymeric state and the exact distances are Tl1···Tl1 $(-x, -y+2, -z) =$ 3.9308 Å, Tl1···Tl1 $(-x+1, -y+2, -z) = 4.0696$ Å, Tl1···Tl1 $(x+1, y, z) = 3.7649$ Å and Tl1···Tl1 $(x-1, y, z) = 3.7649$ Å (Table 3). The Tl···Tl across the rhomb (3.7649 Å) is appreciably shorter than the normal of approximately 4.0696 Å proposed as typical of Tl···Tl in Tl(μ-O_2)Tl rhomb. The nakedness of the resulting thallium environment possibly suggests a stereochemically active lone pair.

3.3. Crystal structure of [Tl(2,4-dnp)]

Determination of the structure of [Tl(2,4-dnp] by X-ray crystallography (Table 2) showed the complex in the solid state (Fig. 4) to be a polymeric species with various similarities to the polymeric structures of [Tl(2-np)], [Tl(4-dnp)] and [Tl(3-dnp)], and it is really a novel three-dimensional polymer. The thallium atoms are linked within a classical 'stair-polymer' array by phenoxide oxygen atoms. Each thallium atom can be considered to be two-coordinate with an O_2 donor atom array (two oxygen atoms of the 2,4-nitrophenoxide ligand) with Tl–O distances of Tl1···O1 = 2.601, and Tl1···O1 $(-x+1, -y+2, -z+2) = 2.626$, and the weak interaction of thallium(I) with oxygen atoms of the nitro group of an adjacent molecule produces polymer units in the solid state (Table 4). There are "weak" Tl···Tl bonds in the polymeric state and the exact distances are Tl1···Tl1 $(-x+1, -y+1, -z+1) = 3.740$ Å (Table 4). The presence of a lone pair of electrons on the thallium atom is apparently the reason that the bridging interactions cannot come closer together. The arrangement of oxygen atoms of nitrophenoxide suggest a gap or hole in the coordination geometry around the metal ion, occupied possibly by a stereoactive lone pair of electrons on thallium(I). If the stereochemically active lone pair was not present, it might create more interaction between the bridging atoms of thallium(I) with the neighboring oxygen atoms of nitrophenoxide. Consequently, this phenomenon could lead to more symmetry.

The strikingly similar feature of the $[Tl(3\text{-np})]_n$ complex with the $[Tl(2,4\text{-dnp})]_n$ complex is that there is a π–π stacking [19,20] interaction between the parallel aromatic rings belonging to adjacent chains in the two compounds. The question is, does the π–π stacking between the parallel aromatic rings help to increase the "gap" in coordination geometry around the metal ion or does the 'gap' arise from the "stereochemical activity" of valence shell lone electron pairs that then help to form π–π stacking.

The strikingly different feature of the $[Tl(3\text{-np})]_n$ complex with the $[Tl(2,4\text{-dnp})]_n$ complex is that the $[Tl(3\text{-np})]_n$ complex is a one-dimensional polymer whereas the $[Tl(2,4\text{-dnp})]_n$ complex is a three-dimensional polymer. This point must relate to the additional nitro group in the nitrophenoxide ligand. The $[Tl(2\text{-np})]_n$ and $[Tl(4\text{-np})]_n$ complexes [8] are one-dimensional polymers and support the presence of this feature.

Crystallographic data, selected bond lengths and angles are given in Tables 1–4. Atomic coordinates, anisotropic thermal parameters, observed and calculated structure factors, full lists of bond distances, bond angles and torsion angles are given in the supplementary material. A perspective view of the ORTEP diagram and the packing in the unit cell are shown in Figs. 1–4.

4. Supplementary material

Complete bond lengths and angles, co-ordinates and displacement parameters have been deposited with the Cambridge Crystallography Data Centre, CCDC Nos. 174597 for [Tl(3-np)] and 183434 for [Tl(2,4-dnp)]. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@cdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

tetrachlorocuprate(II) monohydrate is thermochromic and the crystal structure of its hydrated green phase was reported [11]. For a clear understanding of the mechanism of thermochromism one needs the crystal structure analysis of both the phases.

In this paper, we report the synthesis and crystal structure of the anhydrous yellow phase; the role of the water molecule in the thermochromism is also explored.

2. Experimental

2.1. Materials and measurements

High purity (98%) benzimidazole and copper(II) chloride, dihydrate were purchased from Emerck Germany and used as received. Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer and the Cu contents in all the complexes were estimated spectrophotometrically [12]. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Electronic spectra of mulls (1200–350 nm) were recorded with a Hitachi U-3501 spectrophotometer where Nujol was used as a medium as well as a reference. The effective magnetic moments were calculated from magnetic susceptibility measurements with an EG&G PAR vibrating sample magnetometer model 155 at room temperature (r.t.) and diamagnetic corrections were made using Pascal's constants [13]. The thermal analyses (TG–DTA) were carried out on a Metler Toledo TGA/SDTA 851 thermal analyzer in a dynamic atmosphere of dinitrogen (flow rate: 30 cm^3 min^{-1}). The sample was heated in an alumina crucible at a rate of 5 °C min^{-1}. The X-ray powder diffraction experiments were carried out using a Philips PW 3710 diffractometer with a Cu tube anode.

2.2. Preparations

2.2.1. $(HBz)_2CuCl_4$ (yellow) (1)

$CuCl_2 \cdot 2H_2O$ (5 mmol) was dissolved in a minimum volume of water. To this solution was mixed benzimidazole (10 mmol) dissolved in 5 ml of 10 (M) HCl. The resulting solution was concentrated in a water bath to approximately 3 ml and kept in a desiccator. After a few days yellow crystals suitable for X-ray diffraction were obtained. *Anal*. Found (Calc.): C, 38.0 (37.9); H, 3.8 (3.6); Cu, 14.5 (14.3); N, 12.5 (12.6)%. μ_{eff} 1.73 BM at 278 K. λ_{max} 22 222, 8734 cm^{-1}.

2.2.2. $(HBz)_2[CuCl_4] \cdot H_2O$ (green) (2)

The green crystals of the compound were prepared according to the reported method [11]. *Anal*. Found (Calc.): C, 36.2 (36.4); H, 4.2 (3.9); Cu, 13.6 (13.8); N, 12.3 (12.1)%. μ_{eff} 1.80 BM at 278 K. λ_{max} 24 155 (sh), 12 500 cm^{-1}.

The concentration of HCl in the reaction medium plays an important role in the synthesis of compound **1** or **2**. The green needle shaped crystals of **2** are readily obtained if the acidity of the reaction mixture is less than 6 M, whereas yellow crystals of **1** is the only product when the acidity is 9–12 M. Both the green and yellow compounds can be isolated from the 6 to 9 M acid solutions depending upon the experimental conditions. For instances, **2** is always resulted on cooling (10–12 °C) of a dilute solution (10 mmol benzimidazole, 5 mmol $CuCl_2 \cdot 2H_2O$ in 10 ml of 6–9 M HCl). If the solution is more concentrated (approximately 5 ml) and the temperature is higher (approximately 25 °C), yellow crystals of **1** are obtained on keeping the solution overnight without stirring. On stirring, however, **2** crystallizes immediately. It is very interesting to observe that the seeding of green or yellow crystals in this solution produce solely the respective crystals at r.t.

2.3. X-ray crystallography

A suitable single crystal of the complex **1** was mounted on a Bruker AXS CCD area detector system for data collection. The crystal data of the complex was collected at 293(2) K. Intensity data were collected in the

ω–2θ scan mode using graphite monochromated Mo Kα radiation (0.71073 Å). The empirical absorption corrections were based on ψ scans. The structure was solved by direct method using SIR-97 [14]. The derived atomic coordinates were put through the full-matrix least-squares method of refinement by the SHELXL-97 [15] program. The structure was first refined isotropically varying the positional parameters and isotropic thermal parameters of the non-hydrogen atoms together with the overall scale factor. Further least-square refinements of the coordinates of non-hydrogen atoms were done using anisotropic temperature factors. The hydrogen atoms were placed geometrically and refined in the 'riding' model with isotropic thermal parameters 1.2 times U_{eq} of the atom to which they were attached and were treated as fixed contributors to the final structure factor calculations. Complex neutral atom scattering factors were used throughout the refinement. All calculations were carried out using SHELX-97 [15], PLATON-99 [16] and ORTEP [17] programs. Selected crystallographic data for compound **1** are displayed in Table 1 while selected bond lengths and angles of the compound are presented in Table 2. The H- and non-bonding contacts of **1** are listed in Table 3.

3. Results and discussion

3.1. Description of the structure

An ORTEP view of compound **1** with the atom numbering scheme is shown in Fig. 1. The crystal structure of $(HBz)_2[CuCl_4]$ (Bz = benzimidazole) consists of a discrete tetrachlorocuprate anion and two benzimidazolium cations. The Cu atom, Cu1, occupies the special position on the twofold axis of the *C*2/*c* space group. The $CuCl_4^{2-}$ anion assumes a distorted tetrahedral geometry of D_{2d} symmetry, consistent with the anticipated distortions predicted by the Jahn–Teller effect. These distortions are typically measured by the value of the *trans* Cl–Cu–Cl angle, which is 132.89° [8] in the present compound. The observed yellow colour of compound **1** is also consistent with the value of the *trans* angle [9]. In the organic cation, both the benzene and imidazole rings are almost planar with deviations ranging between −0.0071 and 0.0073 Å and are fused to lie in the same plane. Here, both the hydrogen atoms H1 and H3 attached to nitrogen atoms N1 and N3, respectively play an important role in forming the extended molecular association through hydrogen bonding where only one Cl atom, Cl1, acts as an acceptor of these N–H···Cl hydrogen bonds (Fig. 2). It is interesting to note that the other Cl atom, Cl2, is not participating in the hydrogen bonding network. The

Symmetry equivalents: (1) $x-1/2, y+1/2, z$.

Cu–Cl distances differ appreciably (0.109 Å) with the longer Cu–Cl distance associated with the Cl atom, Cl1, which is engaged in hydrogen bonding and is consistent with those found in other chlorocuprates [2]. Molecular packing and stacking interaction plays the major role in structural association. Cohesion of the crystal occurs due to van der Waals' interaction. An intermolecular stacking is observed between the planes containing the fused aromatic rings. The imidazole ring of one cationic moiety is stacked with the benzene ring of two other cationic moieties ($1/2-x$, $1/2-y$, $-z$; $-x$, $1-y$, $-z$) where the perpendicular distances between the stacked rings are 3.429 and 3.166 Å, respectively. The benzene ring of the same cationic moiety was found to be stacked with the imidazole rings of two other likewise symmetry-related cations with the same intervals. Thus one cationic moiety forms antiparallel stacking with both the symmetry related cations. The shortest C–H···Cl distance is more than 3.75 Å, which excludes any C–H···Cl interactions [10].

Since compound **1** can be obtained by solid state transformation of **2**, a structural comparison between them is relevant. The crystal structure of compound **2** consists of alternating polymeric $[CuCl_4^{2-}]_\infty$ and $[CuCl_2(H_2O)_2]_\infty$ chains along the y-axis [11]. The structure of both chains may be described as elongated square bipyramids with four very short Cu–Cl(H_2O) bonds and two very long Cu–Cl bonds of 3.154(1) and 3.330(1) Å. The four cationic columns surrounding each polymeric chain form an extensive net of hydrogen bonds. Unlike the yellow phase, here all the Cl atoms of the $CuCl_4^{2-}$ units as well as the coordinated water molecules participate in the hydrogen bonding. The H atom of the imidazole carbon (C_2) is also involved significantly in the hydrogen bonding network in addition to both the hydrogens attached to the N atoms. The extensive hydrogen bonding stabilises the square bipyramid geometry and makes the aromatic ring much more puckered compared to that of **1**. Bezimidazolium cations are stacked in parallel one upon another (compared to the antiparallel stacking in the yellow phase) along the y-axis. The colour of the square bipyramidal tetrachlorocuprate is also found to be green in other similar types of complexes [9].

3.2. Thermal analysis and mechanism of thermochromism

The simultaneous TG–DTA curves of compound **2** (Fig. 3) show that it loses the coordinated water molecule in two steps. The first step starts rather abruptly at approximately 43 °C and continues up to approximately 60 °C (obs. loss = 1.4 ± 0.1%). The remaining portion of water is lost gradually up to approximately 145 °C (obs. loss = 2.5 ± 0.1%). The observed total loss in the two steps (3.9 ± 0.1%) corresponds to the calculated loss of one molecule of water (4.06%). The colour of **2**, however, changes from green to yellow at approximately 43 °C. This yellow compound (and compound **1** also) on keeping in open atmosphere at room temperature for several hours absorbs exactly one molecule of water and transforms to the green compound. The X-ray powder diffraction pattern and the thermal profile of this transformed species are found to be identical to those of **2**.

In the hydrated green phase (**2**), an extended copper halide network exists along with the extensive hydrogen bonding network. In such a structure, usually, there is a competition between the hydrogen bonding interaction and the bridging Cu–Cl–Cu interaction. At higher temperature, the increased thermal vibration of the water molecules and organic cations weaken the hydrogen bonding which in turn increases the electrostatic repulsion between the chloride ions [8]. Consequently, the Cl–Cu–Cl angles which are close to 90° in the square bipyramid structure tend to increase causing changes in the coordination number and geometry around Cu(II). The results of thermal analysis suggest that the sequence of events starts at 43 °C with the loss of one water molecule per Cu in the hydrated chain (leaving the chain intact), followed by slow break up of the hydrated chain at higher temperature corroborating the gradual loss of water molecule until 145 °C. Alternatively, both the water molecules of the hydrated chlorocuprate chain may be thrown out of the coordination sphere at 43 °C leading to the formation of discrete $CuCl_4^{2-}$. For water molecules, the temperature 43 °C is too low to be evaporated instantly. Moreover, at least part of the water molecules should remain in the crystal lattice by forming hydrogen bonds with the $CuCl_4^{2-}$. As a result, in the TG curve a partial weight loss, approximately 1.4% is recorded at 43–60 °C and

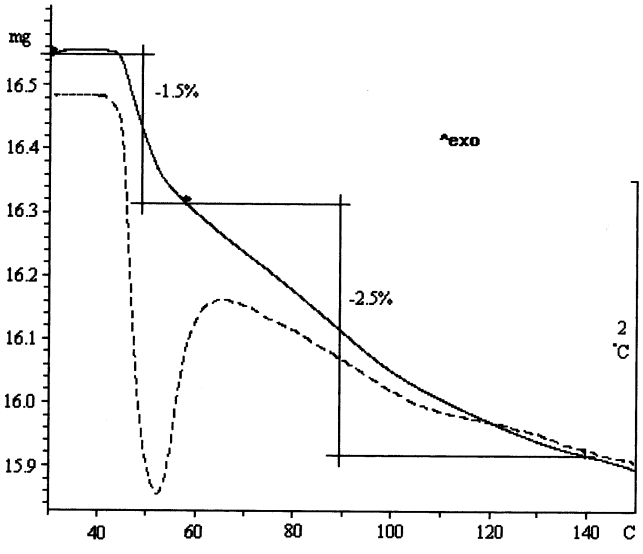

Fig. 3. The simultaneous TG (—) and DTA (----) curves for compound **2** (sample mass 16.4 mg).

the rest water is lost slowly upon heating. The different structural parameters of the green and yellow phases suggest that a phase transition should be accompanied with the colour change as in related systems [4]. The endothermic peak, found in the DTA curve at approximately 51 °C, is probably a combined effect of phase transition and loss of water. This is further supported by the fact that the compound **2** turns completely yellow at approximately 43 °C, the temperature where the loss of water just begins. The loss of water molecule is therefore not the cause of the colour change, rather it is the effect of some thermochromic phase transitions at this temperature. On the other hand, compound **2** on keeping in a desiccator at room temperature turns slowly into yellow. The complete transformation takes place over several days in a P_2O_5 desiccator. The proportion of yellow phase increases gradually with the loss of water from compound **2** at this temperature indicating that the bridging copper chloride framework is stabilized only in the presence of coordinated water molecule. The loss of water molecule is therefore the cause of the green to yellow transformation at any temperature below 43 °C. The mechanism of the reversal of the yellow to green phase is also very interesting. One discrete tetrachlorocuprate of compound **1** absorbs two molecules of water and selectively forms a one dimensional polymeric $[CuCl_2(H_2O)_2]_\infty$ chain with the similarly hydrated species. As a requirement of the crystal lattice of compound **2**, another chloro bridged chain of anhydrous tetrachlorocuprates, $[CuCl_4^{2-}]_\infty$, should also be formed simultaneously. In thermochromic chlorocuprates, thermally induced change of coordination number and consequent changes in the connectivity of the extended copper halide framework is known [1]. To our knowledge, to date the present system is the only example of thermochromic tetrachlorocuprates containing cations of organic base where deaquation–aquation is connected with monomeric⇋polymeric transformation associated with thermochromism.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 181606 ($C_{14}H_{14}Cl_4CuN_4$). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

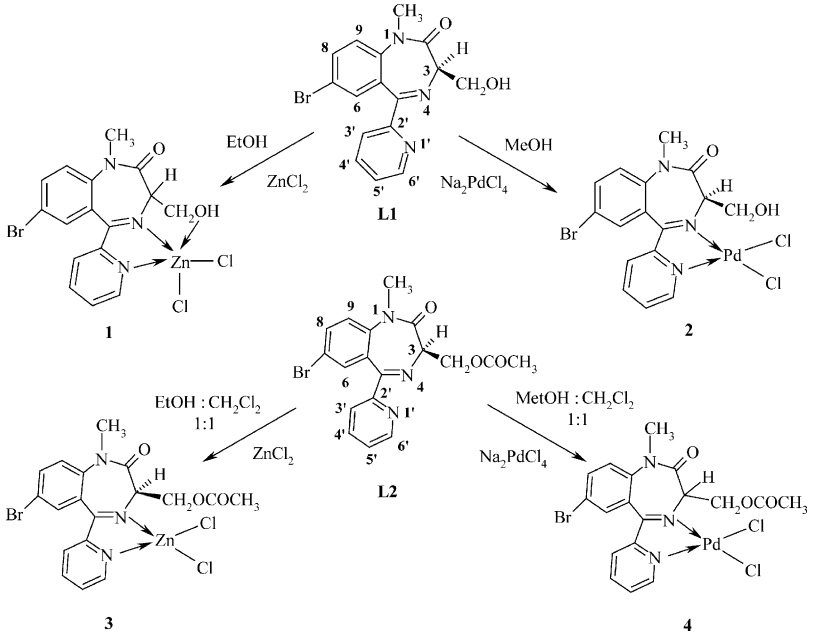
catalytic oxygenation and the ring contraction of 3-substituted 5-(2′-pyridyl)-1,4-benzodiazepin-2-one derivatives [19]. Here we report on the preparation and structural characterisation of the Zn^{II} and Pd^{II} complexes with ligands (+)-**L1** and (±)-**L2** (Scheme 1) as well as on biological properties of free benzodiazepine ligands and their complexes. To our knowledge, compounds Zn**L1**Cl_2 (**1**) and Zn**L2**Cl_2 (**3**) are the first Zn^{II} complexes of benzodiazepines reported so far.

2. Experimental

2.1. Materials and instrumentation



(+)-7-Bromo-1,3-dihydro-3-hydroxymethyl-1-methyl-5-(2′-pyridyl)-2*H*-1,4-benzodiazepin-2-one ((+)-**L1**) was prepared by lipase catalysed kinetic resolution [15] whereas *rac*-3-acetoxymethyl-7-bromo-2,3-dihydro-1-methyl-5-(2′-pyridyl)-2*H*-1,4-benzodiazepin-2-one ((±)-**L2**) was prepared according to the reported method [11]. All other reagents and solvents were analytical grade products and were used without further purification. FTIR spectra were recorded on a Perkin–Elmer 2000 spectrophotometer using KBr (4000–400 cm^{-1}) and polyethylene (400–200 cm^{-1}) pellets. ^1H NMR spectra were performed with a Varian broadband Gemini 300 spectrometer in $CDCl_3$ and DMSO-d_6 containing Me_4Si as an internal standard. Two-dimensional experiments were performed by standard pulse sequences, using Gemini Data System software Version 6.3. Elemental analyses were performed with a Perkin–Elmer Elemental Analyser E-2400 Series 2 (CHN) and thermogravimetric analyses with a Cahn RG electromicrobalance in an air atmosphere.

2.2. Zn[*L1*]Cl_2 (*1*)

A solution of (+)-**L1** (0.072 g, 0.20 mmol) in absolute EtOH (1.0 ml) was added dropwise to a stirred solution of $ZnCl_2 \cdot 2H_2O$ (0.035 g, 0.20 mmol) in absolute EtOH (2.0 ml). The reaction mixture was stirred for 1 h at room temperature (r.t.), the yellow hygroscopic precipitate formed was separated, washed with absolute cold EtOH and stored overnight in vacuum. Yield: 0.031 g (30%). Crystals for X-ray analysis were obtained from absolute EtOH by slow evaporation in a desiccator over silica gel. *Anal*. Calc. for $C_{16}H_{14}BrCl_2N_3O_2Zn \cdot 2H_2O$ (532.53): C, 36.09; H, 3.41; N, 7.89. Found: C, 36.29; H, 3.28; N, 7.32%. IR (cm^{-1} KBr disc): 3369 w br [ν(OH], 1677 vs br [ν(C=O)], 1625 m, 1592 s and 1560 w [δ(OH), ν(C=N), ν(C=C)], 1496 s, 1485 s, 1444 m, 1403 m, 1337 s, 1300 sh, 1265 sh, 1253 m, 1190 w, 1125 m-s, 1102 m, 1050 w, 1020 m, 978 w, 889 w, 834 m-s, 801 m-s, 756 w, 724 w, 678 m and 642 w-m; IR (cm^{-1}, polyethylene): 314 m-s br.

2.3. Pd[*L1*]Cl_2 (*2*)

A solution of (+)-**L1** (0.053 g, 0.15 mmol) in MeOH (1.0 ml) was added dropwise to a stirred solution of $Na_2PdCl_4 \cdot 3H_2O$ (0.055 g, 0.15 mmol) in MeOH (3.0 ml). The reaction mixture was stirred for 2 h at r.t., the yellow precipitate formed was filtered off, washed with cold MeOH and dried in vacuum over P_2O_5. Yield: 0.070 g (87%). Single crystals were obtained from DMF.

Scheme 1. Chemical diagrams of ligands and complexes.

Anal. Calc. for $C_{16}H_{14}BrCl_2N_3O_2Pd$ (537.73): C, 35.80; H, 2.44; N, 7.87. Found: C, 36.17; H, 2.75; N, 7.61%. IR (cm^{-1} KBr disc): 3427 m-s [ν(OH)], 1669 vs [ν(C=O)], 1590 s, 1561 m and 1541 w [δ(OH), ν(C=N), ν(C=C)], 1489 s, 1479 s, 1442 m, 1443 w, 1400 m, 1352 m, 1321 m-s, 1255 m-s, 1187 w, 1140 w-m, 1125 w, 1068 m, 1034 m-s, 97 w, 924 w, 889 w, 826 s, 791 m, 751 w-m, 745 w-m, 677 w-m and 659 w; IR (cm^{-1}, polyethylene): 373 w, 345 w, 328 w-m and 299 w.

2.4. *Zn[**L2**]Cl$_2$ (**3**)*

A solution of **L2** (0.100 g, 0.25 mmol) in a 1:1 mixture of absolute EtOH and CH_2Cl_2 (2 ml) was added dropwise to a stirred solution of $ZnCl_2 \cdot 2H_2O$ (0.050 g, 0.29 mmol) in the same mixture of solvents (2 ml). After complete addition, the reaction mixture was continuously stirred for 24 h at ambient temperature and left at 277 K for another 48 h. Yellow crystals were obtained (yield: 0.070 g, 52%). *Anal.* Calc. for $C_{18}H_{16}BrCl_2N_3O_3Zn \cdot H_2O$ (556.77): C, 38.82; H 3.26; N 7.58. Found: C, 39.28; H, 3.12; N, 7.15%. IR (cm^{-1} KBr disc): 3508 w br [ν(OH)], 1742 vs [ν(C=O) acetate], 1691 vs br [ν(C=O) lactam, ν_{as}(COO)], 1599 m, 1589 s, 1568 m and 1556 s [δ(OH),ν(C=N), ν(C=C)], 1480 s, 1470 s, 1439 s, 1427 m, 1395 m-s, 1364 m-s, 1334 s, 1301 m, 1261 s, 1221 vs br, 1186 m, 1125 m, 1120 m, 1102 s, 1054 m, 1023 s, 973 w, 932 w-m, 920 w-m, 892 w, 830 s, 802 s, 745 m-s, 720 w-m, 710 w, 678 s, 643 m and 619 w; IR (cm^{-1}, polyethylene): 335 s br, 313 m-s and 326 w br.

2.5. *Pd[**L2**]Cl$_2$ (**4**)*

A mixture of **L2** (0.100 g, 0.25 mmol) and $Na_2[PdCl_4] \cdot 3H_2O$ (0.084 g, 0.25 mmol) in a 1:1 mixture of MeOH and CH_2Cl_2 (3.0 ml) was stirred for 3 h at ambient temperature. The yellow precipitate formed was filtered off, washed with cold MeOH and CH_2Cl_2, and dried in vacuum over P_2O_5. Yield: 0.120 g (80%). *Anal*. Calc. for $C_{18}H_{16}BrCl_2N_3O_3Pd$ (579.77): C, 37.28; H, 2.78; N, 7.28. Found: C, 36.81; H, 3.00; N, 6.71%; IR (cm^{-1} KBr disc): 1742 s [ν(C=O) acetate], 1683 vs and 1668 vs [ν(C=O) lactam, ν_{as}(COO)], 1593 m, 1564 w and 1539 w [ν(C=N), ν(C=C)], 1489 m, 1472 m, 1441 w, 1403 w, 1368 w-m, 1340 m, 1257 s, 1247 m-s, 1214 s, 1190 w, 1126 w, 1105 w-m, 1040 sh, 1034 m-s, 980 w, 920 w, 874 w, 842 w, 822 w, 798 w, 760 w, 709 w, 679 w, 642 w and 616 w-m; IR (cm^{-1}, polyethylene): 353 m-s, 343 m, 328 m, 313 m and 280 w-m.

2.6. *X-ray structure analysis*

Suitable single crystals were obtained by a slow evaporation from different solvents listed in Table 1, which also summarises crystal data, experimental details of data collection and refinement. Data were collected on an Enraf–Nonius CAD4 diffractometer for complex **3**, and on a Nonius Kappa CCD 2000 diffractometer for **1** and **2**. Data were corrected for Lp effects [20]. Structures of **1** and **3** were solved using the package SIR-97 [21], whereas the structure of **2** was solved with SHELXS-86 [22]. Complex **2** was refined with a racemic twin model. The occupation of the component with opposite chirality from that shown in Fig. 2 refined to 0.007(9), indicating that the crystal is enantiopure and has strong inversion distinguishing power [23]. All data were refined using the package SHELXL-97 [24]. Molecular geometry calculations and illustrations were prepared with PLATON [25]. Atomic scattering factors were those included in SHELXL-97. The H-atom coordinates were calculated geometrically and refined using the SHELXL-97 riding model.

2.7. *In vitro cytostatic assays*

The cytostatic activity of the free benzodiazepine ligands and their metal complexes was assayed in vitro on the murine leukemia L1210/0 cell line as well as on the human T-lymphoblast Molt4/C8 and CEM/0 cell lines, according to previously described methods [26,27]. The activity was expressed as the concentration (in μg ml^{-1}) of the compound at which tumour cell growth showed 50% inhibition (IC_{50}).

2.8. *In vitro antiviral assays*

The antiviral and cytotoxicity assays of compounds were carried out in either Vero, HEL or HeLa cell cultures, following previously established procedures [28]. The inhibitory effects of the test compounds on the replication of parainfluenza-3 virus, reovirus type 1, Sindbis virus, Coxsackie virus B4 and Punta Toro virus was evaluated in Vero cells, on herpes simplex virus type 1 (KOS), herpes simplex virus type 2(G), vaccinia virus, vesicular stomatitis virus and herpes simplex virus type 1 (TK^- KOS ACV) in HEL cells, and on vesicular stomatitis, Coxsackie virus B4 and respiratory syncytial virus in HeLa cells. The antiviral activity was expressed as concentration of the compound required to reduce virus-induced cytopathogenicity by 50%.

3. Results and discussion

3.1. *Preparation of the complexes*

The reaction of benzodiazepine ligands **L1** and **L2** with the appropriate zinc and palladium salt yielded dichloro adducts as depicted in Scheme 1. The enantiomerically pure (+)-**L1** gave with $ZnCl_2$ in absolute ethanol the pale yellow complex dichloro-[7-bromo-1,3-dihydro-3-hydroxymethyl-1-methyl-5-(2′-pyridyl)-2*H*-

1,4-benzodiazepin-2-one-*N*,*N*,*O*]zinc(II) (**1**). The reaction of 60% enantiomerically pure **L2** [19] and $ZnCl_2$ in a 1:1 mixture of ethanol and dichloromethane yielded the enantiomerically pure complex dichloro-[3-acetoxymethyl-7-bromo-1,3-dihydro-1-methyl-5-(2′-pyridyl)-2*H*-1,4-benzodiazepin-2-one-*N*,*N*]zinc(II) (**3**), which reversibly changes its colour from pale-yellow to pink. In the mother liquor, crystals are yellow-coloured, whereas exposed to air they quickly change their colour to pink. Hygroscopic properties of the compound might be related to this effect. The reaction of benzodiazepine ligands with Na_2PdCl_4 in methanol (**L1**) and in a mixture of methanol and dichloromethane 1:1 (**L2**), yielded the yellow square-planar complex *cis*-dichloro-[7-bromo-1,3-dihydro-3-hydroxymethyl-1-methyl-5-(2′-pyridyl)-2*H*-1,4-benzodiazepin-2-one-*N*,*N*]palladium(II) (**2**) and *cis*-dichloro-[7-bromo-1,3-dihydro-3-acetoxymethyl-1-methyl-5-(2′-pyridyl)-2*H*-1,4-benzodiazepin-2-one-*N*,*N*]palladium(II) (**4**), respectively. No racemisation was observed during the formation of the Pd^{II} complexes.

3.2. The crystal structures

ORTEP [29] drawings of **1** and **2** are given in Figs. 1 and 2, respectively. A PLUTON drawing of the molecular structure of **3** is given in Fig. 3. The crystal structure of **2** is depicted in Fig. 4. The selected geometry for all structures is summarised in Tables 2 and 3. Hydrogen bonds are listed in Table 4.

In the molecular structure of **1**, Zn^{II} is five-coordinated. **L1** acts as a tridentate ligand, through two azomethine nitrogens, N4 and N15, and hydroxy oxygen O13 (Fig. 1). Fivefold coordination of Zn^{II} is completed with two chlorine atoms. Bond distances Zn–O and Zn–N (Table 3) are in accordance with the previously reported values for five-coordinated Zn^{II} complexes found in the *CSD* [30]. The molecule of **1** displays a strongly distorted trigonal bipyramidal coordination, with Cl1, Cl2 and N4 in an equatorial plane, whereas the Zn atom is slightly above it [0.045(2) Å]. The distortion from the regular trigonal bipyramidal coordination has been introduced by the angle N15–Zn–O13 of 145.8(5)° (that differs considerably from the required 180°). Molecular structure of **1** exhibits the usual *boat* conformation [31]. There are no significant differences in values of geometrical parameters inside the diazepin ring of complex **1** (Table 2) and its Cu^{II} analogue described in our previous paper [19]. Thus, the metal coordination has a minor influence on the conformation of the diazepine ring. In **2**, Pd^{II} is, as expected, in a fourfold square-planar coordination

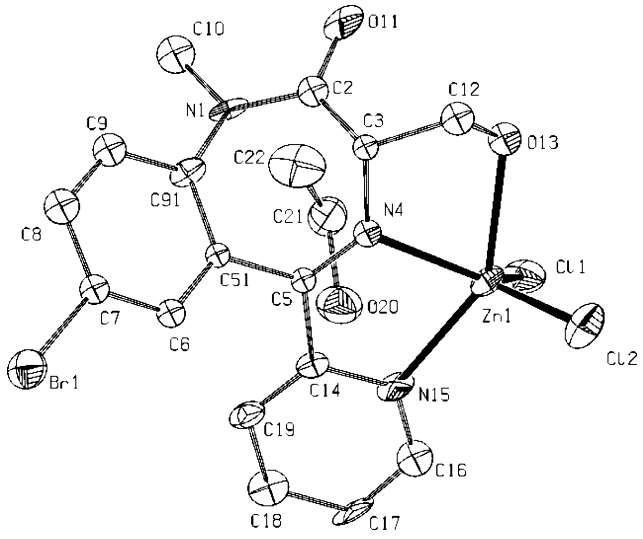

Fig. 1. ORTEP drawing of complex **1** with atom numbering. Thermal ellipsoids are scaled at the 30% probability level. Hydrogen atoms are omitted for clarity.

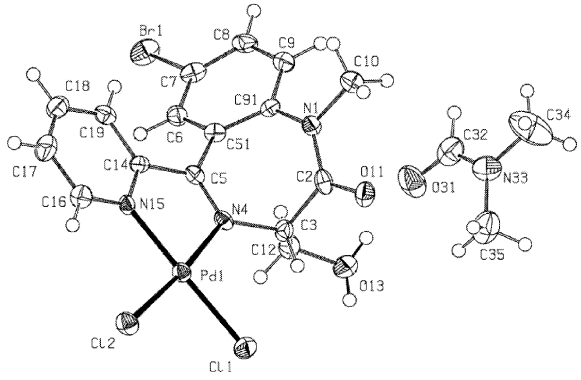

Fig. 2. ORTEP drawing of complex **2** with atom numbering. Thermal ellipsoids are scaled at the 50% probability level.

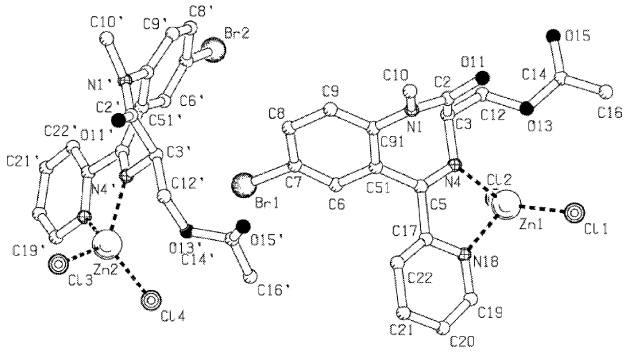

Fig. 3. PLUTON drawing of complex **3**. Hydrogen atoms are omitted for clarity.

[deviations from the least-squares plane ranging from −0.038(4) Å for N15 to 0.0300(14) Å for Cl2] (Fig. 2). In this complex, **L1** acts as a bidentate ligand to Pd^{II} through the pyridine and diazepine nitrogens. The fourfold coordination is completed by two chlorine

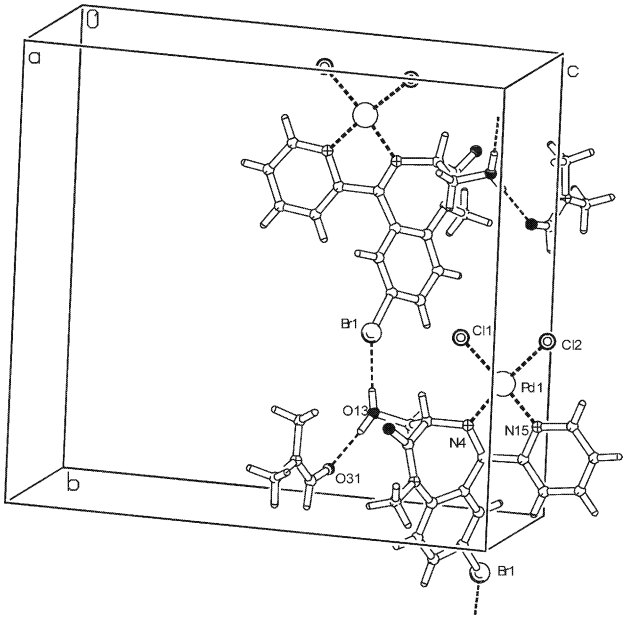

Fig. 4. Crystal packing of the complex **2**. The complex molecules are connected via an O13–H···Br interaction. This interaction has half site occupancy, the other half being occupied by an O13–H···O31 hydrogen bond which connects the complex molecule with a solvent.

atoms. X-ray structure analysis has revealed *S*-configuration at the C3 stereogenic centre. Significant conformational changes in the ligand upon coordination were not observed; hence the *boat* conformation of the seven-membered diazepine ring is retained. In **3**, **L2** acts as an *N*,*N*-bidentate ligand chelating Zn^{II} through diazepine and pyridyl nitrogen atoms (Fig. 3). The fourfold coordination is completed by two chlorine atoms. Severely distorted tetrahedra were observed; bond angles involving Zn^{II} ranged from 79.1(7)° to 125.3(5)° in molecule **A**, and from 76.5(8)° to 119.9(6)° in molecule **B** (Table 3). Unlike in **1**, hydroxy oxygen O13 is not coordinated to Zn^{II}. Complex **3** crystallises in the non-centrosymmetric space group $P2_12_12_1$ with two independent molecules in an asymmetric unit. The *R*-absolute configuration at the stereogenic centres C3 and C3′ was determined by X-ray structure analysis. Comparison of the coordination details in Cu^{II} complexes of **L1** and **L2**, and in their Zn^{II} analogues, reveals significant differences, related to their electronic configuration [32]. Both Cu^{II} and Zn^{II} form with **L1** five-coordinated complexes, and **L1** acts as an *N*,*N*,*O*-tridentate ligand. In **L2**, instead of an hydroxymethyl group at C3, there is a bulky acetoxymethyl group, and for steric reasons O13 is not involved in the metal coordination. Therefore, copper forms five-coordinated species using lactame oxygen from the neighbouring molecule to complete the fivefold coordination in the shape of square-planar pyramide with a long apical Cu^{II}–O bond, whereas Zn^{II} retains the fourfold coordination sphere [22]. However, in the active sites of zinc-

[a] N2′ is a pyridyl nitrogen (N15 in **1** and **2**, N18 in **3**).

containing enzymes, Zn^{II} is mostly four-coordinated [33].

The crystal structure of **1** is characterised by the hydrogen bond O13–H···O20 which connects the complex with ethanol as the solvent molecule. In the crystal structure of **2**, two equally populated positions of the hydrogen atom at O13 were observed. As a consequence of this structural disorder, O13 is (as a donor) involved in two different hydrogen bonds; with the carbonyl oxygen of the solvent molecule and with the bromine from a neighbouring molecule (Table 4, Fig. 4). In the crystal structure of **3** only weak van der Waals interactions were observed.

3.3. Infrared spectra

The IR spectra of the free benzodiazepine ligands and their complexes are complicated with significant vibrational coupling and overlapping of absorption bands. Upon metal coordination, the marked changes of ligand bands may be noticed between 1700 and 1500 cm^{-1} where the azomethine and pyridine C=N, lactam and acetate C=O, and aromatic C=C stretching vibrations are found [19,34]. In the spectra of complexes with *N*,*N*-chelatation (complexes **2**, **3** and **4**), most of these bands are shifted to lower frequencies, while in Zn^{II} complex **1** in which **L1** acts as a *N*,*N*,*O*-tridentate ligand, they are

Table 4
Hydrogen bonds in complexes **1** and **2**

	D–H···*A* (Å)	D–H (Å)	H···*A* (Å)	D–H···*A* (°)	Symmetry operation on *A*
1					
O13–H···O20	2.71	1.12	1.63	162	$-x, y-0.5, 0.5-z$

O13–H···Br	3.060	0.80	2.30	160	$-x, 0.5+y, 0.5-z$

shifted slightly to the higher frequency region. The similar spectral pattern was observed in the Cu^{II} complex of this ligand with the similar fivefold metal–ligand coordination [19].

The far-IR spectra (400–200 cm^{-1}) of complexes give insight into the metal–ligand vibrations. In complex **1**, a very broad band of weak to medium intensity between 350 and 240 cm^{-1} covers the whole region expected for stretching modes of the zinc–oxygen/halogen/nitrogen vibrations for this kind of complex [35,36]. The absence of highly characterised zinc-specific vibrations may be ascribed to low symmetry of this complex and to the presence of a mixture of conformers. A complicated spectral pattern was found also in **3** and **4**, where the internal deformation modes of the acetate ligand are superimposed on the metal–ligand vibrations. The spectrum of **2** shows four rather sharp bands in this frequency region, as expected for the *N*,*N*-bonded dichloro *cis*-square-planar Pd^{II} complexes [22].

3.4. ^1H NMR spectra

The ^1H NMR data of the free ligands **L1** and **L2**, their Zn^{II} complexes in $CDCl_3$ and Pd^{II} complexes in DMSO-d_6, are summarised in Table 5 according to the numbering scheme shown in Scheme 1. The spectral studies have shown that Pd^{II} complexes retain their integrity in DMSO solution, while this solvent with strong complexing ability initiates dissociation of Zn^{II} complexes by displacing the benzodiazepine ligands. This is in accordance with the assumption that zinc complexes generally show low stability [37].

The NMR spectral patterns of the aromatic region of free ligands **L1** and **L2** are in general similar to those obtained for various benzodiazepine derivatives [25,38–41]. The 3-H proton of the heterocyclic diazepine ring in both ligands appears as a triplet, while absorptions of the 3-CH_2 and OH protons are solvent-dependent. In **L1** two non-equivalent diastereotopic methylene protons in DMSO-d_6 give two separated multiplets due to geminal coupling and couplings with H-3 and OH protons, while two broad singlets (partly split) could be observed in chloroform solution. In **L2** these protons in $CDCl_3$ resonate as two distinctive doublet of doublets, while in DMSO-d_6 signals are overlapped giving a multiplet pattern. The OH signal in **L1** appears as a triplet (DMSO-d_6) or as a broad singlet ($CDCl_3$). The assignment of proton resonances was ascertained by connectivities in COSY spectra. The *N*,*N*-metal bonding in all the complexes through the azomethine and pyridine nitrogens brings about similar spectral changes for the aromatic protons. The pyridine protons, apart from H-3′, show a downfield shift (0.30–0.70 ppm), which may be related to the deshielding effect of the metal atom due to its magnetic anisotropy and to the lowering in the electron density in this aromatic ring following the electron-withdrawing effect of complexation. The upfield shift of H-3′ comes from two opposite phenomena, a downfield shift produced by the metal inductive effect and a prevalent upfield shift produced by the disappearance of the N-4 paramagnetic effect upon complexation [27,29]. The same two effects may also be expected to influence the H-6′ signal, but due to closer proximity of this proton to the metal, the latter effect is predominant. This situation could be explained by the fact that free ligands are characterised by *anti* orientation of the nitrogen atoms N-1′ and N-4, as two centres of high electron density, while in complexes the α-diimine system is in the *syn* orientation due to *N*,*N*-bidentate ligand coordination. For this reason, great changes could also be observed in absorptions of the H-3 and 3-CH_2 protons (Fig. 5). In complex **1**, a downfield shift of OH ($\sim$1 ppm) and 3-CH_2 ($\sim$3 ppm) signals supports the ligand coordination also through the hydroxy oxygen (Fig. 1). The absorption of the H-3 proton with a downfield shift ($\sim$0.40 ppm) and that of OH with an upfield shift ($\sim$0.70 ppm) are overlapped in complex **2**, giving a very broad signal at about 4 ppm. Not visible is the coupling with the adjacent 3-CH_2 protons, which appeared as two separate singlets with downfield shifts of approximately 1.35 ppm with respect to the free ligand. The second set of signals observed for the pyridine H-3′ and H-6′ protons (in a ratio $\sim$1:8) may be ascribed to the presence of two isomeric forms caused by restricted rotation within the Pd^{II} coordination sphere. In complexes **3** and **4**, the H-3 proton shows a downfield shift of 0.32 and 2.14 ppm, respectively. There are also differences in the 3-CH_2 resonances. In **4**, signals of diastereotopic methylene protons show upfield shifts of 0.78 and 0.98 ppm, while in **3** one of them

[m] Overlapped with H-6 and H-9. Tentative value obtained from a COSY experiment.

shows a slight downfield shift and the second one a slight upfield shift. In both complexes the separation between the two sets of signals becomes larger (up to 0.30 ppm) than in free ligand **L2**. This variation in spectral patterns of methylene protons indicates their different proximity to the metal centre. The proton chemical shifts of the remote $N–CH_3$ and $COCH_3$ groups, as well as of H-8 and H-9 of the second aromatic ring, are practically unchanged in comparison to the free ligands. The H-6 proton shows a downfield shift of 0.25–0.47 ppm.

3.5. In vitro cytostatic activity

The cytostatic activity of the free benzodiazepine ligands **L1** and **L2** and their Zn^{II}, Pd^{II} and Cu^{II} complexes was determined in vitro against the murine leukemia L1210/0 cell line as well as the human T-lymphoblast Molt4/C8 and CEM/0 cell lines. The data, expressed as concentration of the compound required to inhibit tumour cell growth by 50% (IC_{50}), are summarised in Table 6. None of the examined compounds were found to exhibit cytostatic activity at therapeutically meaningful concentrations (1–10 μg ml^{-1}). Their activity varied widely from 40 to >500 μg ml^{-1}, and the most active is the Pd^{II} complex **2** with IC_{50} values within 40–60 μg ml^{-1}. There were no significant differences in response between the three cell lines used.

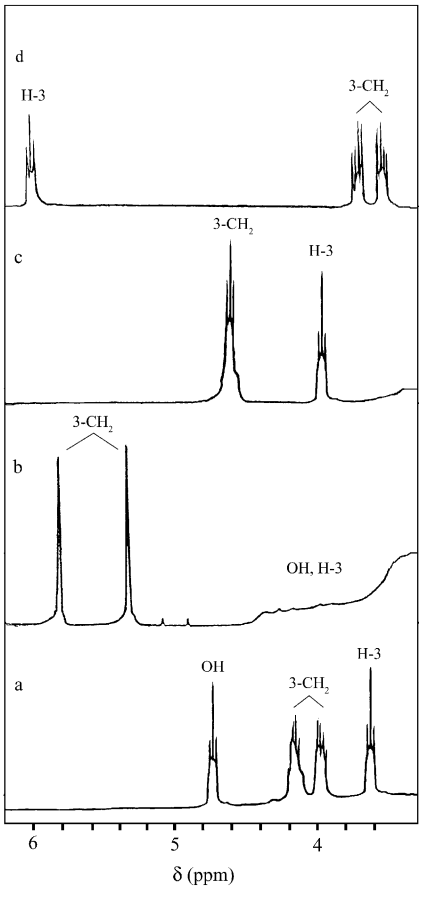

Fig. 5. Selected portions of ^1H NMR spectra of **L1** (a), **2** (b), **L2** (c) and **4** (d).

Table 6
In vitro cytostatic activity of **L1** and **L2** and their Zn^{II}, Pd^{II} and Cu^{II} complexes

Compound	IC_{50} (μg l^{-1}) [a]

3.6. In vitro antiviral activity

The antiviral assays of free benzodiazepine ligands and their complexes were based on an inhibition of virus-induced cytopathogenicity in Vero, HEL or HeLa cell cultures against a variety of DNA and RNA viruses. The antiviral activity expressed as concentration of the compound required to reduce virus-induced cytopathogenicity by 50% as well as their cytotoxicity expressed as a concentration of the compound required to cause a microscopically detectable alteration of normal cell morphology, obtained in Vero cell cultures are summarised in Table 7, together with bromovinyldeoxyuridine (BVDU), (*S*)-9-(2,3-dihydroxypropyl)adenine [(*S*)-DHPA] and ribavirin as the control test compounds. The results obtained in HEL and HeLa cells are given as Supplementary Material available from the authors upon request. The compounds showed no or only marginal antiviral activity. No antiviral effects were noted for any of the compounds against any of the viruses evaluated at concentrations that were at least fivefold below the cytotoxic concentrations. The latter ranged from 40 to 200 μg ml^{-1}.

4. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 177526–177528 for compounds **1**, **3**, **2**. Copies of the data may be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2

to deal with these other cases. Thus, we have tried to provide IR and NMR spectroscopic data leading to general observations that may be useful for the characterization of other phosphazene polymers with organometallic complexes.

2. Experimental

2.1. General considerations

All the reactions were carried out under dry nitrogen. K_2CO_3 and Cs_2CO_3 were dried at 140 °C prior to use. The C_3H_6O used as solvent was predistilled from $KMnO_4$, and distilled twice from anhydrous $CaSO_4$. The MeOH was distilled from CaH_2. The THF was treated with KOH and distilled twice from Na in the presence of benzophenone. Petroleum ether refers to that fraction with boiling point in the range 60–65 °C. The hexachlorocyclotriphosphazene $[N_3P_3Cl_6]$ (Fluka) was purified from hot petroleum ether and dried in vacuum. The cyclic $[N_3P_3(O_2C_{12}H_8)_2Cl_2]$ [11], and $[N_3P_3(O_2C_{12}H_8)_2(OC_6H_4PPh_2)]$ [8], were prepared as described elsewhere. The polymer $[NPCl_2]_n$ was prepared by heating the $[N_3P_3Cl_6]$ in solution as described by Magill and coworkers [26]. The phosphine $[PPh_2(C_6H_4–OH)]$ was prepared as described in the experimental part (a slight modified version of the reported in Ref. [8]).

The IR spectra were recorded with a Perkin–Elmer FT Paragon 1000 spectrometer. NMR spectra were recorded on Bruker AC-200, AC-300 and DPX 300 instruments, using $CDCl_3$ as solvent. ^1H and $^{13}C\{^1H\}$ NMR are given in δ relative to TMS. $^{31}P\{^1H\}$ NMR are given in δ relative to external 85% aqueous H_3PO_4. Coupling constants are in Hz. C, H, N analyses were performed with a Perkin–Elmer 2400 microanalyzer. The chlorine, Mn and P elemental analyses were performed by Galbraith laboratories. GPC were measured with a Perkin–Elmer equipment with a model LC 250 pump, a model LC 290 UV, and a model LC 30 refractive index detector. The samples were eluted with a 0.1% by weight solution of tetra-*n*-butylammonium bromide in THF through Perkin–Elmer PLGel (Guard, 10^5, 10^4 and 10^3 Å) at 30 °C. Approximate molecular weight calibration were obtained using narrow molecular weight distribution polystyrene standards. T_g values were measured with a Mettler DSC 300 differential scanning calorimeter equipped with a TA 1100 computer, at 10 °C min^{-1}. Thermal gravimetric analyses were performed on a Mettler TA 4000 instrument. The polymer samples were heated at a rate of 10 °C min^{-1} from ambient temperature to 800 °C under constant flow of nitrogen.

2.2. Preparation of $PPh_2(C_6H_4–OH)$

A mixture of *p*-bromophenol (12.5 g, 72.2 mmol), 2-methoxypropene (13.8 ml, 144.5 mmol) and a drop of $POCl_3$ was stirred in the absence of light for 1 h. Four drops of Et_3N were added and the volatiles were evaporated in vacuo. The resulting pale yellow oil (very light sensitive) was dissolved in petroleum ether (80 ml). To this solution was added dropwise and with stirring a solution of LiBu 2.5 M (31.8 ml, 79.42 mmol) in petroleum ether (30 ml). The stirring was continued for 4 h to give a white precipitate that was filtered and dried in vacuo. The resulting solid was dissolved at −70 °C in THF (70 ml) and to the solution was added dropwise a solution of $PClPPh_2$ (8.4 ml, 47.04 mmol) in THF (30 ml). The mixture was allowed to reach room temperature (r.t.) and stirred overnight. Then, 20% aqueous HCl (36 mL) was added and, after stirring for 3 h, the mixture was extracted with Et_2O (4 × 50 ml). The extracts were stirred with an excess of solid Na_2CO_3, washed with water (3 × 50 ml), dried over Na_2SO_4, and filtered. The solvent was evaporated in vacuo to give an orange oily residue that was dissolved in CH_2Cl_2, filtered through silica-gel, concentrated by evaporation in vacuo, and mixed with petroleum ether to obtain two layers. This mixture was then kept into a freezer until crystallization and then the white microcrystals were dried in vacuo. Yield: 6 g (46%).

Anal. Found: C, 77.3; H, 5.5. Calc.: C, 77.7; H, 5.4%.

^1H NMR ($CDCl_3$): 7.4–6.7 (m.br., 14H, aromatic rings); 5.3 (s.br., 1H, OH). ^{31}P NMR ($CDCl_3$): −6.6. ^{13}C NMR ($CDCl_3$): 157.4 s, 136.5 {d, J ($^{31}P–^{13}C$) = 21.6}, 128.5 {d, J ($^{31}P–^{13}C$) = 8}, 116.4 {d, J ($^{31}P–^{13}C$) = 8.3}, [P–C_6H_4]; 138.2 {d, J ($^{31}P–^{13}C$) = 9.2}, 134.1 {d, J ($^{31}P–^{13}C$) = 19.3}, 129.1 {d, J ($^{31}P–^{13}C$) = 10.6}, 129.0 [PPh_2].

2.3. Preparation of $\{Mn(CO)_2(\eta^5\text{-}C_5H_4Me)[PPh_2(C_6H_4–OH)]\}$ (1)

To a solution of $PPh_2(C_6H_4–OH)$ (1.85 g, 6.65 mmol) in THF (40 ml) cooled at −30 °C was added the complex $[Mn(THF)(CO)_2(\eta^5\text{-}C_5H_4Me)]$, obtained by irradiating with UV light a solution of $[Mn(CO)_3(\eta^5\text{-}C_5H_4Me)]$ (1.88 g, 8.62 mmol) in THF (45 ml) at −30 °C until the carbonyl band at 2018 cm^{-1} could not longer be observed (approximately 3.5 h). The mixture was stirred at r.t. overnight and the volatiles were removed in vacuo. The residue was chromatographed in silica–gel eluting first with petroleum ether and then with CH_2Cl_2. The CH_2Cl_2 fraction was evaporated to give $\{Mn(CO)_2(\eta^5\text{-}C_5H_4Me)[PPh_2\text{-}(C_6H_4–OH)]\}$ as a brown solid. Yield: 2.2 g, 71%.

Anal. Found: C, 66.6; H, 4.6. Calc.: C, 66.7; H, 4.7%.

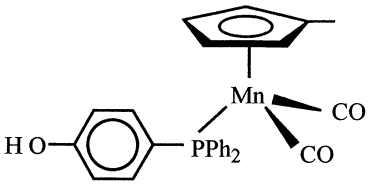
CH_3). ^{31}P NMR ($CDCl_3$): 92.9 (s., PPh_2), 25.7 [d, $P(O_2C_{12}H_8)$] 9.7 [dd, $P(OC_6H_4PP_2)_2$]{M_2X spin system, J (P–P) = 93}. ^{13}C NMR ($CDCl_3$): 233.5 {d, J (^{31}P–^{13}C) = 24, CO}; 152.1m, 138.9 {d, J (^{31}P–^{13}C) = 40.5}, 136.5 {d, J (^{31}P–^{13}C) = 40.5}, 135.1 (d, J (^{31}P–^{13}C) = 11.5}, 133.4 (d, J (^{31}P–^{13}C) = 10.5), 130.1, 128.8 (d, J (^{31}P–^{13}C) = 9), 121.4m, ($OC_6H_4PPh_2$); 148.6, 130.4, 130.3, 129.3, 126.8, 122.5 ($OC_{12}H_8$); 99.7, 83.8, 82.5 (C_5H_4Me); 14.5 (Me).



2.5.2. Method b

A mixture of [$N_3P_3(O_2C_{12}H_8)_2Cl_2$] (0.2 g, 0.35 mmol) and [$Mn(CO)_2(\eta^5$-$C_5H_4Me)$[$PPh_2(C_6H_4$–OH)]} (0.35 g, 0.75 mmol) and Cs_2CO_3 (0.46 g, 1.4 mmol) in THF (25 ml) was refluxed for 2 h. The solvent was removed in vacuo and the residue was extracted with CH_2Cl_2 (5 × 20 ml). The solution was filtered and evaporated to dryness to give **6** as a yellow solid that was washed with methanol (2 × 40 ml) and dried in vacuo. Yield: 0.45 g, 90%.

Anal. Found: C, 62.9; H, 4.2; N, 2.7. Calc.: C, 63.5; H,4.1; N, 2.9%.

2.6. Preparation of [{$NP(O_2C_{12}H_8)$}$_{0.6}${NP[OC_6H_4P-Ph_2–$Mn(CO)_2(\eta^5$-$C_5H_4Me]_2$}$_{0.4}$·$0.5(OC_4H_8)$]$_n$ (**4**)

A mixture of [$NPCl_2$]$_n$ (1.0 g, 8.63 mmol), 2,2′-HO–C_6H_4–C_6H_4–OH (0.965 g, 5.18 mmol) and K_2CO_3 (2.86 g, 20.69 mmol) in THF (130 ml) was refluxed with mechanical stirring for 10 h. Then, the complex {[$Mn(CO)_2(\eta^5$-$C_5H_4Me)$][$PPh_2(C_6H_4$–OH)]} (4.85 g, 10.35 mmol) and Cs_2CO_3 (3.37 g, 10.34 mmol) were added, and the reaction was continued for another 131

1

Chart 1.

h. The resulting mixture was poured into water (1.5 l) to give a precipitate that was washed twice with water (1 l) and dissolved in THF (200 ml). The solution was filtered and concentrated until a viscous liquid was formed that was precipitated slowly into water (1.5 l). The reprecipitation procedure was repeated in the same way from THF/isopropyl alcohol, and THF/petroleum ether to give a yellow solid that was dried in vacuo at r.t. for a week. Yield: 3.3 g, 68%.

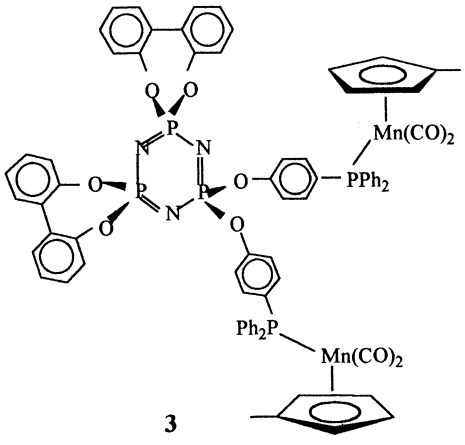
3. Results and discussion



Following a method previously described by us for other phosphazene phosphine complexes [8], the hexachlorocyclotriphosphazene [$N_3P_3Cl_6$] was reacted with 6 equiv. of the phenolic phosphine complex {$Mn(CO)_2(\eta^5$-$C_5H_4Me)[PPh_2(C_6H_4$–$OH)]$} (**1**) (Chart 1) in acetone in the presence of Cs_2CO_3 to give the hexametallic phosphazene complex {$N_3P_3[OC_6H_4PPh_2$–$Mn(CO)_2(\eta^5$-$C_5H_4Me)]_6$} (**2**) in good yield and analytically pure (Chart 2).

This result is interesting, because it has been reported [12] that the direct substitution reaction of the cyclophosphazene–hexaphosphine {$N_3P_3[OC_6H_4PPh_2]_6$} with the precursor [$Mn(THF)(CO)_2(\eta^5$-$C_5H_5)$] in THF gives a mixture of complexes with $OC_6H_4PPh_2$–$Mn(CO)_2(\eta^5$-$C_5H_5)$ units, and the saturation of all the PPh_2 sites required the presence of an important excess of the organometallic manganese precursor. Thus, the synthesis of the pure totally substituted complex analogous to (**2**) was not reported.

In a similar manner, the cyclic chorophosphazene [$N_3P_3(O_2C_{12}H_8)_2Cl_2$] where ($O_2C_{12}H_8$ = 2,2′-dioxybiphenyl) was reacted with (**1**) to give the bimetallic cyclic

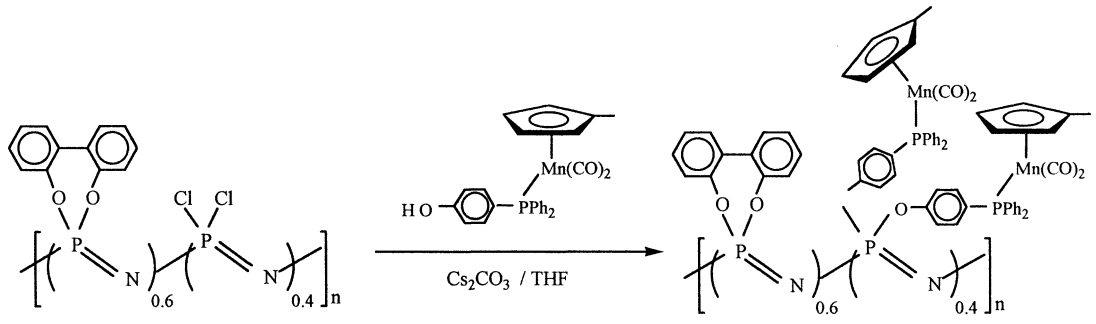
2

3

Chart 2.

phosphazene complex $\{N_3P_3(O_2C_{12}H_8)_2[OC_6H_4PPh_2–Mn(CO)_2(\eta^5\text{-}C_5H_4Me)]_2\}$ (**3**), also in good yield. We observed that, in this case, the same complex **3** could be also prepared by ligand replacement reaction from the diphosphine $\{N_3P_3(O_2C_{12}H_8)_2[OC_6H_4PPh_2]_2\}$ [8] and $[Mn(THF)(CO)_2(\eta^5\text{-}C_5H_4Me)]$ in THF.

The reactions of the phenolic complex **1** with the cyclic models could be successfully extended to the partially substituted phosphazene copolymer $\{[NP(O_2C_{12}H_8)]_{0.6}[NPCl_2]_{0.4}\}_n$, which is a polymeric counterpart of the cyclic bis-spirophosphazene $[N_3P_3(O_2C_{12}H_8)_2Cl_2]$. Thus, the reaction of this latter with **1** in THF in the presence of Cs_2CO_3 gave the high molecular weight polymeric complex $[\{NP(O_2C_{12}H_8)\}_{0.6}\{NP[OC_6H_4PPh_2–Mn(CO)_2(\eta^5\text{-}C_5H_4Me)]_2\}_{0.4}\cdot 0.5(OC_4H_8)]_n$ (**4**) (Scheme 1). The yield (68%) was good and much higher than for the analogous polymer with $W(CO)_5$ fragments [8], and the effectiveness of the substitution reaction was very high, as shown by the very low residual chorine content in the isolated polymer (0.03% in weight). This shows that the method in Scheme 1 may be of wide application provided that the necessary phenolic complex OH–C_6H_4–L–MLn is stable under refluxing THF for several hours.



The polymer **4** was very stable and could be stored in the solid state for years unaltered. The M_w (by GPC) was 1,100,000 (polydispersity index = 4). Taking into account that the weight of the chain units is 529.4, the weight-averaged degree of polymerization is approximately 2000 units per chain, a value which is only slightly low for that type of phosphazene random copolymer [11]. The presence of some polytetrahydrofuran (PTHF) in this copolymer, that is expected when using THF as solvent in the substitution reaction from $[NPCl_2]_n$ [11,13], was detected and measured as described below. The PTHF, that can be minimized if necessary [13], represents approximately 6% in weight of the isolated material and does not alter the efficacy of the synthesis of **4**.

The successful preparation of polymer **4** from $\{[NP(O_2C_{12}H_8)]_{0.6}[NPCl_2]_{0.4}\}_n$ is valuable considering that it could not be prepared by the ligand substitution reaction from the precursor $[Mn(THF)(CO)_2(\eta^5\text{-}C_5H_4Me)]$, using the known phosphine containing polymer $[\{NP(O_2C_{12}H_8)\}_{0.6}\{NP[OC_6H_4PPh_2]_2\}_{0.4}]_n$ [8,14]. Thus, even using a large excess of the organometallic precursor the product isolated by this method had only 50% of the available PPh_2 ligands coordinated to $Mn(CO)_2(\eta^5\text{-}C_5H_4Me)$ fragments (as measured by ^{31}P NMR), and the elemental analysis showed a Mn content of 9.6%, much larger than the expected (4.4%), indicating the presence of uncharacterized contaminating Mn species. Considering the stability of **4**, this shows that the difficulty in completing the coordination of the PPh_2 groups in the $[\{NP(O_2C_{12}H_8)\}_{0.6}\{NP[OC_6H_4PPh_2]_2\}_{0.4}]_n$ by the THF substitution of $[Mn(THF)(CO)_2(\eta^5\text{-}C_5H_4Me)]$ is mainly due to the large steric effects imposed to the entering $Mn(CO)_2(\eta^5\text{-}C_5H_4Me)$ fragments by those already present in the polymeric chain.

All the spectroscopic data (see Section 2) were in accord with the structure proposed for the new compounds and provided further useful experimental evidences to characterize polymeric complexes of the transition metals.

The IR spectra (cm^{-1}) in CH_2Cl_2 or THF solutions of **1** to **4** (Section 2) showed the expected two strong stretching carbonyl absorptions of the $Mn(CO)_2(C_5H_4CH_3)$ groups at 1927, 1860. The solid state spectra (KBr pellets) showed several helpful features. In Section 2 are quoted all the signals observed with appreciable intensity. However, the assignments given (see the discussion below) correspond only to those more relevant absorptions, and in the region 800–600, where various significant frequencies appear among other from the vibrations of the aromatic rings, they have been quoted under a general assignment.

The IR of the cyclic phosphazene models **2** and **3**, showed the presence of the organometallic fragment by the two carbonyl absortions and also by two of the expected bands of the Mn–$C_5H_4CH_3$ ring [15], that were clearly distinguished at 2922w (ν-CH, CH_3) and 1376vw

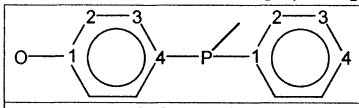
4

Scheme 1.

(δ-CH_3), and by three conspicuous bands at 662m, 618m and 596m, that are related to δ-MnCO modes [15]. All those bands were absent in the spectra of the uncoordinated phosphazene phosphines $\{N_3P_3[OC_6H_4PPh_2]_6\}$ and $\{N_3P_3(O_2C_{12}H_8)_2[OC_6H_4PPh_2]_2\}$. However, in the region from 1600 to 680, that could be potentially useful to study P-aryl compounds [16], the IR spectra of **2** and **3** (Section 2) appear almost identical to those of the corresponding free ligands. Thus, except for the commented weak band at 1376, the only significant difference was observed in a pair of very closed but well resolved peaks at 950–940, because, in the case of the metal complexes, the later, that is assignable to δ-POC modes [17], is much stronger than the former. As this feature is also observed for the analogous $W(CO)_5$ complexes, it suggests a decrease intensity of the band at 950 after the complexation of a MLn fragment to the PPh_2 group that could be useful to denote it. However, although all the differences commented between the spectra of the cyclic phosphazene phosphines and its complexes were also found in the spectra of the polymeric complex **4** and its corresponding free ligand $[\{NP(O_2C_{12}H_8)\}_{0.6}\{NP[OC_6H_4PPh_2]_2\}_{0.4}]_n$, in this case, the 950–940 band was too broad to unambiguously show the coordination of a metallic fragment.

A couple of bands at 2927w, 2857w in the IR of the polymer **4**, evidenced the presence of the PTHF, that was expected in this synthesis [13].

Finally, the broad band near 525 cm^{-1}, that is observed in the spectra of **2**, **3** and **4**, may be attributed to the aryloxyphosphazene scheleton (δ-NPO modes) [17], but similar bands are also present in the spectra of the phosphine **1**, therefore is was not assigned in Section 2.



The ^{31}P NMR spectra was specially significant showing the very large deshielding of the phosphorus of the PPh_2 coordinated to the manganese dicarbonyl fragment as compared with those of the free phosphines. Thus, in the free phenolic phosphine $HOC_6H_4PPh_2$, in the cyclic phosphazene hexaphosphine $\{N_3P_3[OC_6H_4PPh_2]_6\}$, and in the spyro-phosphazene bis-phosphine $\{N_3P_3(O_2C_{12}H_8)_2[OC_6H_4PPh_2]_2\}$, the chemical shift is circa -6 ppm, while in their $Mn(CO)_2(C_5H_4{-}CH_3)$ complexes **1**, **2** and **3**, the value is near 93 ppm. Consistently, the ^{31}P NMR of the polymer **4** showed three peaks at 92.1(PPh_2), −6.4 [$NP(O_2C_{12}H_8)$] and −23.6 [$P(OC_6H_4PPh_2Mn(CO)_2(C_5H_4{-}CH_3)$], and the intensity of the latter two were in accord with the ratio of the units present in the proposed formula. By comparing the chemical shift of the phosphorus of the phosphazene rings in $\{N_3P_3[OC_6H_4PPh_2]_6\}$ (8.8 ppm) $\{N_3P_3(O_2C_{12}H_8)_2\ [OC_6H_4PPh_2]_2\}$ (25.8 for the $NP(O_2C_{12}H_8)$, and 10.0 for the $NP[OC_6H_4PPh_2]_2$) [8], with those in **2** (8.0) and **3** (25.7 and 9.7, respectively), it can be noticed how they are sensitive to the presence of the coordinated metallic fragment. This has been repeatedly observed in cyclic and polymeric phosphazenes having pendant complexes with other ligands, such as $OC_6H_4{-}CN$ [18], or OC_5H_4N [9,19,20]. This effect is also noted in the chemical shifts of the phosphorus atoms baring the groups $OC_6H_4PPh_2{-}Mn(CO)_2(\eta^5\text{-}C_5H_4Me)$ in polymer **4**, that are 1.6 ppm lower than in the free phosphine polymer $[\{NP(O_2C_{12}H_8)\}_{0.6}\{NP[OC_6H_4PPh_2]_2\}_{0.4}$ [8].

The ^1H NMR of all the Mn complexes showed the ($C_5H_4CH_3$) ring as two multiplets at 4.2 and 4.0, and a singlet at 1.9 (CH_3). In the case of the polymer **4**, those peaks appeared at slightly lower frequencies (3.9, 3.7 and 1.8 ppm). This is usually observed by comparing the NMR signals of different groups when free and when pendant from long spyro-phosphazene copolymeric chains [9]. On the other hand, the relative intensities of those signals with those of the aromatic protons (broad signals between 7.5 and 6.7 ppm) gave a ratio of 0.62/0.38 for the two phosphazene units in the copolymer, very close to the idealized value given in the proposed formula. The ^1H spectra of polymer **4** also showed the presence of PTHF (peaks at 3.4 and 1.6) the intensity of which corresponded to an amount of 0.5 OC_4H_8 units per NP unit, representing 6.4% in weight.

The ^{13}C NMR of the models **2** and **3** and the polymer **4**, showed the two carbonyls $Mn(CO)_2$ as a doublet at 234 ppm with a coupling constant $^{13}C{-}^{31}P$ of 24 Hz, and the ($C_5H_4CH_3$) ring as four singlets at nearly 100, 84, 82 and 14 (CH_3) ppm. Other peaks in the ^{13}C NMR spectra corresponded to the $O_2C_{12}H_8$ rings (148.6, 130.4, 130.3, 129.3, 126.8, 122.5) [11], and to the $OC_6H_4{-}PPh_3$ units (in Table 1 are given the assignments, that may be useful for the characterization of similar phosphazenes with transition metal phosphine complexes). As can be noticed, some peaks of the two types of aromatic rings may interfere, as happens in the polymer **4**, where some assignments may be ambiguous, specially those near the 130 ppm region. However, the data in Table 1 clearly show that, in agreement with a general rule noted by us [21], when the phenol $HOC_6H_4{-}PPh_2Mn(CO)_2(C_5H_4CH_3)$ is transformed into $NP{-}OC_6H_4{-}PPh_2Mn(CO)_2(C_5H_4CH_3)$ groups pendant from cyclic or polymeric phosphazene units, the chemical shift of the C1 carbon of the $OC_6H_4{-}$ ring is shifted approximately 5 ppm to lower frequencies, that of the C4 increases by nearly the same amount, that of C2 also increases, and that of the C3 remains almost unaffected. On the other hand, the carbons of the $P(C_6H_5)_2$ rings shift very little upon the coordination of a metallic fragment to the phosphorus atom, although a large increase in the $^{13}C{-}^{31}P$ coupling constant (from 10 to 40 Hz) is clearly observed.

In the case of polymer **4**, the spectrum was rather broad, and the peaks at 130–129 corresponding to the C6, C4 and C1 carbons of the $O_2C_{12}H_8$ rings are hidden

[a] δ in ppm, J in Hz, $CDCl_3$ as solvent.

under the intense signals of the C3 and C4 of the $P(C_6H_5)_2$ groups (see Table 1). The ^{13}C NMR spectra of polymer **4** also confirmed the presence of PTHF (71.3, 27.2 ppm).

The thermal stability of the polymeric complex **4**, as measured by TGA at a heating rate of 10 °C min^{-1}, was only moderate. Surprisingly, the initial loss of weigh below 150[a]C expected for the depolymerization of PTHF (6%) and evaporation of the resulting THF, was reduced to 1.25% between 0 and 250 °C. A first important loss (22%) was centered at 350 °C, followed by another one of 36% at 450 °C. At 800 °C the residue was of the order of 41%. The loss of 350 °C is probably due to the volatilisation of organic molecules arising from the organometallic ligands, while the loss at higher temperature correspond to the formation of volatiles after the decomposition of the aryloxypolyphosphazene units to give a crosslinked pyrolitic residue [22].

The DSC curve for **4**, scanned from −50 to 250 °C, showed a clear heat capacity jump corresponding to a glass transition with $T_g = 128$ °C ($\Delta C_p = 0.16$ J g^{-1} K^{-1}). This T_g is higher than that of the free phosphine polymer [{NP($O_2C_{12}H_8$)}$_{0.6}${NP[$OC_6H_4PPh_2$]$_2$}$_{0.4}$·0.7[OC_4H_8]$_n$ ($M_w = 800.000$, $T_g = 96$ °C), made by the same method [14], a difference due to the presence of voluminous transition metal-ligand fragments in **4** [23–25] (for the similar phosphine polymer with higher M_w the value is 115 °C, and for its $W(CO)_5$ complex is 127 °C [8]).

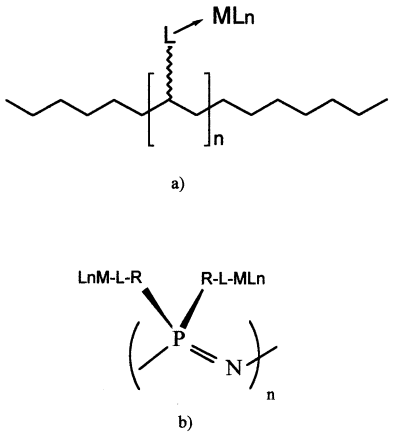

Chart 1.

The 2,2′-dihydroxybiphenyl, HO–C_6H_4–C_6H_4–OH, the 4-hydroxypyridine HOC_5H_4N and the *N*-methyl-piyrrolidinone (NMP) were used as purchased (Aldrich). The hexachlorocyclotriphosphazene $[N_3P_3Cl_6]$ (Fluka) was purified from hot petroleum ether and dried in vacuum. The starting polymer $[NPCl_2]_n$ was prepared as described by Magill and coworkers [11]. The complex $[W(HOMe)(CO)_5]$ was prepared as described in the literature [12]. All the reactions were carried out under dry nitrogen.

The IR spectra were recorded with a Perkin–Elmer Paragon 1000 spectrometer. wavenumbers are in cm^{-1}. NMR spectra were recorded on Bruker AC-200, AC-300 and DPX-300 instruments. ^1H and $^{13}C\{^1H\}$ NMR are given in δ relative to TMS. $^{31}P\{^1H\}$ NMR are given in δ relative to external 85% aqueous H_3PO_4. Coupling constants are in Hz. C, H, N analyses were performed with a Perkin–Elmer 240 microanalyzer. Cl analyses were performed by Galbraith Laboratories. GPC were measured with a Perkin–Elmer equipment with a model LC 250 pump, a model LC 290 UV, and a model LC 30 refractive index detector. The samples were eluted with a 0.1% by weight solution of tetra-*n*-butylammonium bromide in THF through Perkin–Elmer PLGel (Guard, 10^5, 10^4 and 10^3 Å) at 30 °C. Approximate molecular weight calibration was obtained using narrow molecular weight distribution polystyrene standards. T_g values were measured with a Mettler DSC 300 differential scanning calorimeter equipped with a TA 1100 computer. Thermal gravimetric analysis were performed on a Mettler TA 4000 instrument. The polymer samples were heated at a rate of 10 °C min^{-1} from ambient temperature to 800 °C under constant flow of nitrogen.

2.2. Synthesis of $\{[NP(O_2C_{12}H_8)]_{0.7}[NP(OC_5H_4N)_2]_{0.3}\}_n$ (**2**)

To a solution of $[NPCl_2]_n$ (3.2 g, 27.6 mmol) in THF (95 ml), HO–C_6H_4–C_6H_4–OH (3.43 g, 18.4 mmol), K_2CO_3 (15.26 g, 110.6 mmol) and more THF (150 ml) were added and the mixture was refluxed and mechanically stirred for 12 h. The ^{31}P NMR of the mixture showed two groups of signals, one at −6.2 ppm ($[NP(O_2C_{12}H_8)]$, approximately 73%), and other at −23.3 ($NPCl_2$, approximately 27%). To the mixture, HOC_5H_4N (1.77 g, 18.6 mmol) and more THF (50 ml) was added, and the refluxing with stirring was continued for another 74 h. The mixture was poured into water (1.5 l) and the precipitate was washed with more water and dissolved in THF (300 ml). The resulting solution was concentrated until viscous and poured dropwise into water (1.5 l) with stirring. The precipitated product was purified twice by dissolving it in THF, concentrating the solution, and precipitating dropwise first into isopropanol, and finally into petroleum ether. The resulting lentil-shaped white powder was dried at 70 °C in the vacuum for 7 days. Yield: 3.7 g (58.1%).

TGA: −2% beginning at 75 °C (evaporation of the THF), fast loss centred at 450 °C to give a residue at 800 °C of 42%. Continuing the heating at 800 °C for 20 min gave a final residue of 35.7%.

DSC: $T_g = 174$ °C ($\Delta C_p = 0.10$ J g^{-1} K^{-1}).

2.3. Synthesis of $\{[NP(O_2C_{12}H_8)]_{0.7}[NP(OC_5H_4N-W(CO)_5)_2]_{0.3}\}_n$ (**4**)

A solution of $[W(CO)_6]$ (0.65 g, 1.86 mmol) in MeOH (75 ml) was stirred under UV irradiation until the disappearance of the 1977 cm^{-1} IR absorption (approximately 1 h), to give an orange solution of $[W(HOMe)(CO)_5]$ (IR: 2075w, 1932s, 1887m.,br.). To this solution, another solution of the polymer **2** (0.65 g, 2.83 mmol = 1.7 mmol OC_5H_4N) in CH_2Cl_2 (250 ml)

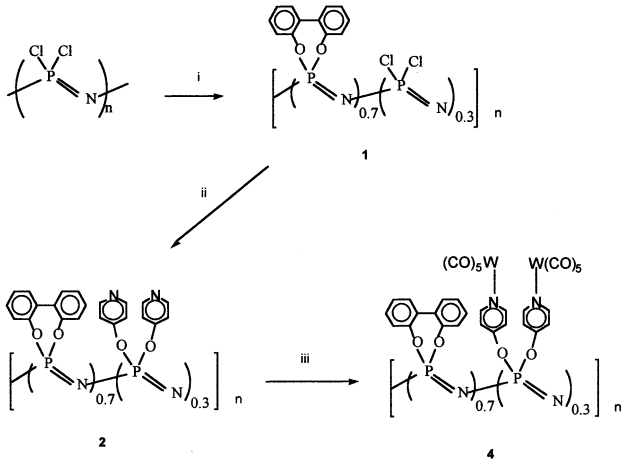
was added and the mixture was stirred at room temperature for 2.5. The volatiles were evaporated and the resulting solid was washed with C_6H_{14} (4 × 50 ml) and CH_2Cl_2, and dried in vacuum for 24 h to give complex **4** as a yellow solid. Yield: 0.86 g (72%).

$(C_{14.4}H_8N_{1.6}O_5PW_{0.6})_n$ $(424.59)_n$: *Anal.* Calc.: C, 40.7; H, 1.90; N, 5.28. Found: C, 39.5; H, 1.98; N 5.25%.

IR (KBr): 3067 (m, br, νCH, OC_5H_4N, $O_2C_{12}H_8$), 2071w, 1977m, 1925s,br [ν(CO)], 1636m, 1605m, 1500s (νCC, νCN, OC_5H_4N), 1477s (νCC, $O_2C_{12}H_8$); 1246vs, 1193vs (νPN), 1096s (νP–OC), 927vs,br. (δPOC), 785s, 751s, 716m (δCH, $O_2C_{12}H_8$ and δPNP). IR (NMP, solnt.): 2069w, 1973m, 1927s, 1887m.

$^{31}P\{^1H\}$ NMR (NMP/D_2O): $\delta = -3.8$ br [$NP(O_2C_{12}H_8]$, −25.3 vbr [$NP(OC_5H_4N)_2$].

^1H NMR (NMP/D_2O): $\delta = 8.8$–8.4 (m, vbr, *o*-H, OC_5H_4N), 7.5–7.3–6.9 (m, br, $O_2C_{12}H_8$).



^{13}C $\{^1H\}$ NMR (NMP/D_2O): $\delta = 199.7$, 192.9 [$W(CO)_5$], 149br (C2), 130 vbr (C1,C6,C4), 127br (C5), 123br (C3) [$O_2C_{12}H_8$], 159br (C4), 149br (C2), 118br (C3) [OC_5H_4N], 70.5, 26.4 [OC_4H_8]$_n$.

TGA: continuous loss beginning at 75 °C to give a residue at 800 °C of 72.2% that decreased to 71% after 20 min at this temperature.

DSC: No glass transition detected below 250 °C.

3. Results and discussion

Using a method earlier described by us [13], the reaction of the parent polydichoro–phosphazene $[NPCl_2]_n$ with 0.7 equiv. of the bifunctional biphenol 2,2′-dihydroxybiphenyl (HO–C_6H_4–C_6H_4–OH) and K_2CO_3 in (THF) gave a solution of the uncrosslinked linear polymer $\{[NP(O_2C_{12}H_8)]_{0.7}[NPCl_2]_{0.3}\}_n$ (**1**) ((i) in Scheme 1). The addition of 4-hydroxypyridine to complete the substitution of the chlorine atoms gave the stable phosphazene copolymer $\{[NP(O_2C_{12}H_8)]_{0.7}$-$[NP(OC_5H_4N)_2]_{0.3}\}_n$ (**2**), that carries pyridine ligands as side groups ((ii) in Scheme 1).

Scheme 1. (i) HO–C_6H_4–C_6H_4–OH/K_2CO_3/THF; (ii) HOC_5H_4N/K_2CO_3/THF; (iii) [W(HOMe)$(CO)_5$].

The average M_w, as measured by GPC was 560.000 (polydispersity ratio of 7.0), which is smaller that those found for other analogous polyspirophosphazene copolymers [13] suggesting some degree of chain degradation during the substitution step with the hydroxypyridine.

All the analytical and spectroscopic data for (**2**) were in accord with its formulation. First of all, the IR spectrum (cm^{-1}) in KBr (Fig. 1 and Section 2) showed, the signals for the CH stretching vibrations at 3060m ($O_2C_{12}H_8$ groups) and 3029m (OC_5H_4N ring). Other CH stretching at 2940w, 2862w revealed the presence of some polytetrahydrofuran (PTHF) [14], a product that can be anticipated in some polyphosphazenes obtained from $[NPCl_2]_n$ dissolved in THF [13,14]. The CC and CN stretching frequencies corresponding to the aromatic rings appeared at 1635m, 1582vs and 1500s (OC_5H_4N) and 1477s ($O_2C_{12}H_8$, the other absorption predicted at 1500 is hidden by the strong one of the pyridinoxy group). The expected bands for the poly-p(aryloxy)phosphazene skeleton [15] appeared at 1244vs, 1190vs (νPN), 1267sh (νC–OP), 1095s (νP–OC), 923vs,br (δPOC). The spectrum shows other peaks at 785s, 751s and 716m, that may be assigned to the deformation PNP modes, and also to the expected CH deformation modes for the $O_2C_{12}H_8$ rings [15].

The ^{31}P NMR showed two broad signals, one at −4.32 ppm, corresponding to the cyclic $[NP(O_2C_{12}H_8]$ units, and other at −24.12 ppm, corresponding to the $[NP(OC_5H_4N)_2]$ units. Another weak single peak at −19.18 ppm indicated the presence of a small fraction of $[NPCl(OC_5H_4N)]$ units. The relative intensities showed that the actual formula of the polymer was $\{[NP(O_2C_{12}H_8)]_{0.68}[NP(OC_5H_4N)_2]_{0.3}$ $[NPCl(OC_5H_4N)]_{0.02}\}_n$, which is in accord with the residual chlorine content found (less than 0.5% in weight).

The ^1H NMR spectrum showed the complex pattern expected for the presence of $[NP(O_2C_{12}H_8)]$ and $[NP(OC_5H_4N)]$ groups. Thus, only the doublet (not resolved) of the *ortho*-hydrogens of the AB spin system of the oxypyridines was observed separately (7.9 ppm), the other one (expected at 6.9 ppm) being masked by one of the signals of the dioxy-biphenyl groups. It is interesting to note that the *ortho*-hydrogens of the oxypyridine appear 0.75 ppm to lower field than in the model spyrocyclic compound $[N_3P_3(O_2C_{12}H_8)_2$-$(OC_5H_4N)_2]$ (**3**), previously reported by us [8]. This may be attributed to the fact that the oxypyridines are present in a long polymeric chain. Again the relative intensities of the signals were in accord with the proposed chemical formula.

The ^1H NMR spectrum also showed two multiplets at 3.42 and 1.63 ppm, showing the presence of a small amount of PTHF. Their integration gave a ratio of 0.06

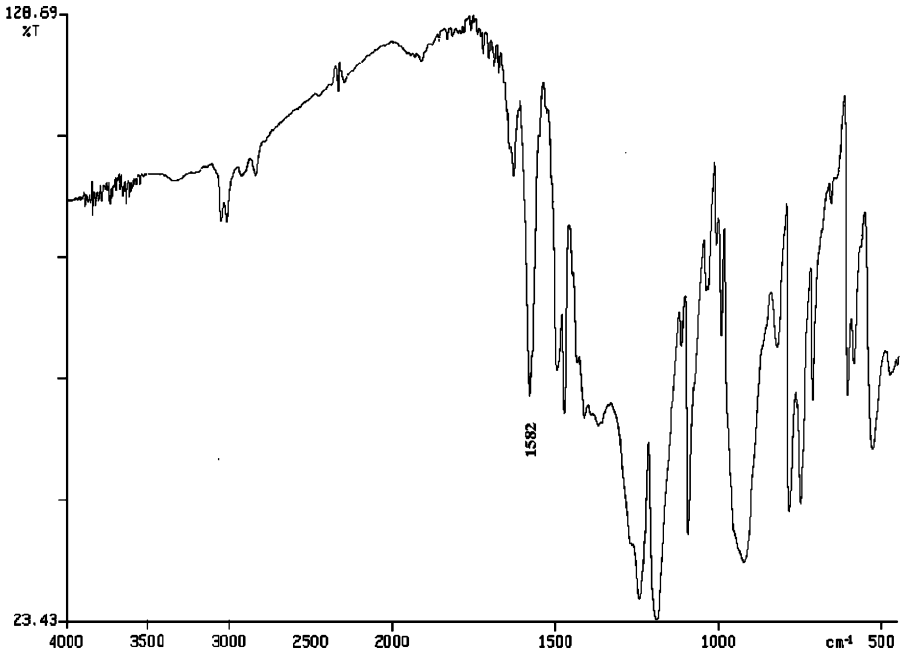


Fig. 1. 4000–500 cm^{-1} IR spectrum of polymer **2** in KBr pellets.

(OC_4H_8) units per formula unit of the polymer (a PTHF content of 1.85% in weight), which is low, as observed in other polyspirophosphazene copolymers prepared by the same experimental procedure [13]. Therefore, the composition of the product (**2**) can be adjusted, without significant error, to the proposed ideal formula $\{[NP(O_2C_{12}H_8)]_{0.7}[NP(OC_5H_4N)_2]_{0.3}\}_n$.

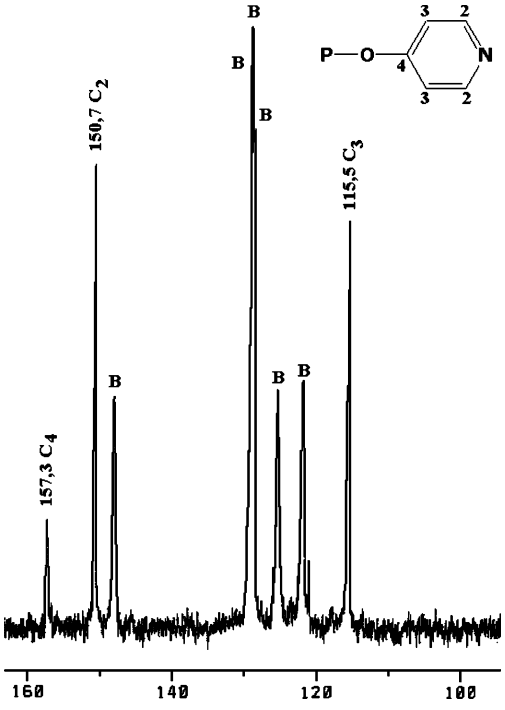

Fig. 2. 200 MHz ^{31}C NMR spectrum ($CDCl_3$ solution) of polymer **2**. B = peaks corresponding to the diphenoxybiphenyl rings (see text).

The ^{13}C NMR of (**2**) (Fig. 2) further confirmed its structure, showing the expected peaks for the dioxybiphenyl rings carbons at 148.1 (C2), 129.1, 129.0, 128.8 (C1,C6,C4), 125.4 (C5) and 121.8 (C3), and those of the OC_5H_4N ring at 157.3 (C4), 150.7 (C2), and 115.5 (C3) ppm (for the free HOC_5H_4N, the peaks appear at 180.0, 139.0 and 117.5 in $CHCl_3$). Other peaks at 70.5 and 26.4 corresponded to the PTHF carbons.

The values observed for the pyridinoxy rings in **2** are consistent with those found for the cyclic triphosphazene $[N_3P_3(OC_5H_4N)_6]$ (157.1, 152.6 and 116.4) [7] and show that the shielding of the C4 carbon of the hydroxypiridine HOC_5H_4N following its transformation into a $NP–OC_5H_4N$ group is rather large (22.7 ppm).

The thermal stability of the polymer was estimated by the TGA curve, that showed a first mass loss of approximately 2% beginning at 75 °C, due to the depolymerization of the PTHF and evaporation of the resulting THF, followed by a fast loss centred at 450 °C. After reaching 800 °C the residue was 42%, but it was further decreased (to 35.7%) after 20 min of heating at 800 °C. The final residue corresponds to the crosslinked pyrolitic material, that, similarly to other polyaryloxyphosphazenes [16], is formed in the decomposition.

The thermal stability allowed an study of the DSC curves from −50 to 250 °C, which showed a well defined glass transition with a $T_g = 174$ °C and a $\Delta C_p = 0.1$ J g^{-1} K^{-1}. This T_g is very high for a polyphosphazene and is consistent with the contribution of the rigid $[NP(O_2C_{12}H_8)]$ units. However, as the value for the homopolymer $[NP(O_2C_{12}H_8)]_n$ is 160 °C [13], it is apparent that the presence of the $[NP(OC_5H_4N)_2]$

units makes a positive contribution to the T_g. This is important in order to design high glass transition temperature polymers, useful in NLO [17].

The presence of the pyridine side groups in (**2**) suggested the possibility of using it as a ligand to coordinate transition metal complexes. In fact, we have previously shown that the model compound (**3**) is able to coordinate $W(CO)_5$ fragments [8].

Therefore, we reacted a CH_2Cl_2 solution of polymer (**2**) with a solution of [W(HOMe)$(CO)_5$] in methanol [ν(CO) absorptions at 2075w, 1932s, 1887m,br] to give the complex $\{[NP(O_2C_{12}H_8)]_{0.7}[NP(OC_5H_4N–W(CO)_5)_2]_{0.3}\}_n$ (**4**) as a yellow solid, that was only sparingly soluble in THF (Scheme 1).

The IR spectrum of the solid in KBr (Fig. 3) clearly evidenced the coordination of the $W(CO)_5$ fragment to the pendant pyridines. Thus, apart from the ν(CO) pentacarbonyl absorptions [8] at 2071vw, 1978m, 1918 vs, br, it was evident the absence of the strong oxypyridine band at 1582 cm^{-1} and the appearance of a new weak band at 1604 cm^{-1}, a fact also noted in the IR spectra of the cyclic model (**3**) and its bis-$W(CO)_5$ complex [8]. We believed that this observation could be very useful in the detection of this coordination in pyridine complexes.

Although the product (**4**) was almost insoluble in THF and CH_2Cl_2, it was very soluble in NMP, to give a deep yellow solution, the IR spectrum of which showed four carbonyl absorptions for the $W(CO)_5$ fragment [18] at 2069vw (A1), 1973w (B2), 1927s,br (E), and 1887m (A1). The ^1H and ^{31}P NMR spectra (see Section 2), and the comparison with those of the parent polymer **2** in the same solvent, are consistent with the coordination of the $W(CO)_5$ fragments to the N atoms of the pendant $–OC_5H_4N$ ligands. Of special significance was the effect on the chemical shift of the *o*-H of the pyridinoxy groups that increased from 8.15 in **2** to 8.8–8.5 in **4**. The broadness of this latter signal is due to the polymeric nature of the complex **4**. This fact is totally consistent with the ^1H NMR spectra of the cyclic model (**3**) and their $W(CO)_5$ complexes. The ^{13}C NMR of **4**, taken in NMP overnight, showed very broad unresolved peaks but also indicated the presence of the $W(CO)_5$ fragments. A signal assigned to the four CO ligands cis to the pyridine appeared at δ 199.7 whereas the CO trans to the pyridine (and trans location making it more sensitive to the heteroligand) gave a signal at δ 193. No ^{183}W satellites could be unambiguously measured.

The solutions of **4** are only moderately stable. Thus, although the polymeric complex can be recovered almost unaffected by dropwise reprecipitation into water of a freshly prepared solution, the metallic content decreases slowly on standing, which is consistent with the behaviour of the analogous cyclic models [8]. In fact, heating for several hours a suspension of **4** in THF in the presence of NCMe or pyridine, and precipitating it into water gave a derivative having much less content of $W(CO)_5$ fragments.

The thermal stability of **4** was low as compared with that of the free polymeric ligand (**2**), decomposing from 75 °C. However, the final residue above 800 °C was very high (70.8%), due to the contribution of the metal (26.0%) that may be involved in the ultimate cross-linking degradation process to form a pyrolitic material. No glass transition could be identified in the DSC curves in the range −50 to 250 °C (a larger interval would be

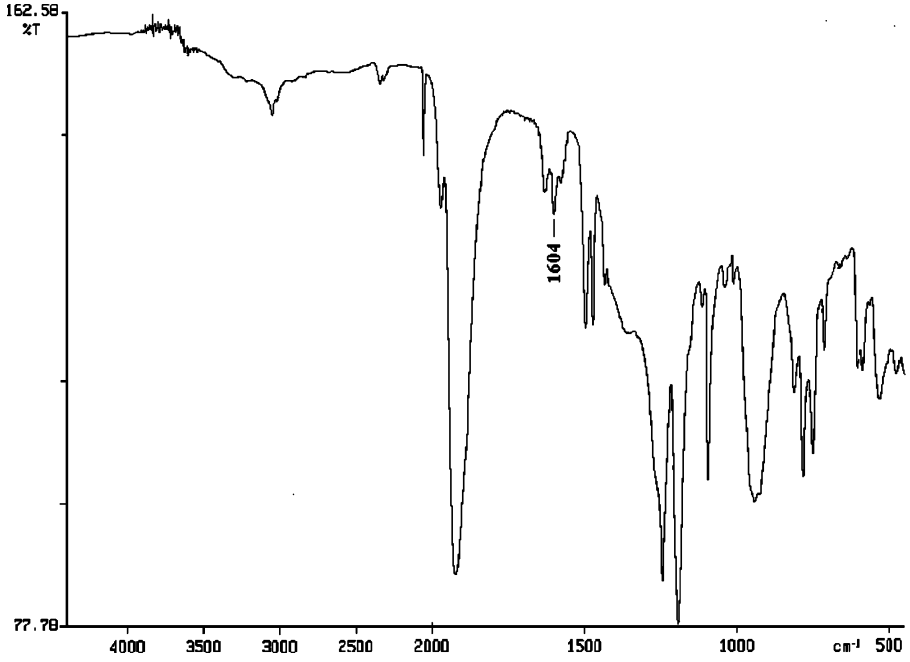

Fig. 3. 4000–500 cm^{-1} IR spectrum of polymer **4** in KBr pellets.

influenced by the decomposition of the copolymer), which could indicate a T_g higher that 250 °C, as expected by the presence of a transition metal [19–21].

2.1. Synthesis of compounds

The ligand was obtained from *N*-methylisatin and thiosemicarbazide (1:1 molar ratio) in EtOH–water as previously reported for other thiosemicarbazones [6]. M.p. 257 °C. *Anal.* Found: C, 51.3; H, 4.1; N, 23.3; S, 13.4. Calc. for $C_{10}H_{10}N_4OS$: C, 51.3; H, 4.3; N, 23.9; S, 13.7%. Mass spectrum (*m*/*z*, 235 (M^+, 50%), 218 (M^+-NH_2, 30), 176 (M^+-NH_2-CS, 35), 79 (C_4NO, 100). ν_{max}/cm^{-1} (KBr): 3426s, 3247m,br, 3150m (NH_2+NH); 1676s (C=O); 1607s,br (C=N); 832m (C=S). NMR data (see Fig. 1 for numbering scheme): ^1H: δ[N(2)H] 12.39 s(1); δ[N(1)H_2] 9.05 s(1), 8.70 s(1); δ[C(4)H] 7.68d(1); δ[C(5)H] 7.44 t(1); δ[C(6,7)H] 7.15 m(2); δ[C(10)H_3] 3.21 s(3); ^{13}C: δ[C(1)] 178.7, δ[C(9)] 160.7, δ[C(8)] 143.6, δ[C(2)] 131.2, δ[C(6)] 130.9, δ[C(5)] 122.9, δ[C(4)] 120.6, δ[C(3)] 119.3, δ[C(7)] 109.8, δ[C(10)] 25.7 ppm.

All complexes were prepared by the following general procedure: a hot EtOH solution of the ligand was added to the chlorides (1:1 molar ratio) or acetates (1:2 molar ratio) of Cu(II), Ni(II), Co(II) dissolved in EtOH. The solution was refluxed for 3–6 h and after cooling a solid was formed that was isolated and dried under vacuum.

2.1.1. $CuL_2\cdot 2H_2O$

Anal. Found for green solid: C, 41.7; H, 3.4; N, 18.7; S, 11.9. $C_{20}H_{22}CuN_8O_3S_2$ requires: C, 42.4; H, 3.9; N, 19.7; S, 11.3%, m.p. 202 °C. ν_{max}/cm^{-1} (KBr): 3418m,vbr, 3287m,vbr, 3165w,br (NH_2+NH); 1688m (C=O); 1655m,br, 1608s,br (C=N); 779m (C=S).

2.1.2. CuClL

Anal. Found: C, 36.2; H, 2.6; N, 15.7; S, 9.7. $C_{10}H_9ClCuN_4OS$ requires: C, 36.1; H, 2.7; N, 16.9; S, 9.6%, m.p. 187 °C. ν_{max}/cm^{-1} (KBr): 3398m,br, 3289m, 3167w (NH_2+NH); 1658m (C=O); 1627w, 1604s (C=N); 778m (C=S).

In the mother liquor brown crystals suitable for X-ray studies were isolated and the structural analysis revealed that the complex shows a polymeric nature corresponding to the formula $[CuClL]_n$ (**1**).

2.1.3. NiL_2

Anal. Found: C, 45.3; H, 3.3; N, 20.6; S, 12.5. Calc. for $C_{20}H_{18}N_8NiO_2S_2$: C, 45.7; H, 3.4; N, 21.3; S, 12.2%, m.p. >300 °C. ν_{max}/cm^{-1} (KBr): 3428w, 3320m,br, 3171vw (NH_2+NH); 1654m (C=O); 1609s (C=N); 772m (C=S).

The same complex was obtained as a garnet powder both starting from the chloride and from the acetate. When the garnet solid was dissolved in *N*,*N*′-dimethylformamide, after several days, a crystalline product of formula $[NiL_2]$ (**2**) was isolated.

2.1.4. CoL_2

Anal. Found for garnet solid: C, 45.3; H, 3.3; N, 20.4; S, 12.8. Calc. for $C_{20}H_{20}CoN_8O_2S_2$: C, 45.7; H, 3.4; N, 21.3; S, 12.2%, m.p. >300 °C. ν_{max}/cm^{-1} (KBr): 3432m, 3264m,vbr, 3167w (NH_2+NH); 1658sh(C=O); 1643s, 1607s,br (C=N); 781m (C=S).

2.1.5. $CoClL\cdot 0.5H_2O$

Anal. Found for garnet solid: C, 36.4; H, 3.3; N, 17.0; S, 10.1. Calc. for $C_{10}H_{10}ClCoN_4O_{1.5}S$: C, 35.7; H, 3.0; N, 16.6; S, 9.5%, m.p. 248 °C. ν_{max}/cm^{-1} (KBr): 3363m,vbr, 3270m, 3057w (NH_2+NH); 1639s (C=O); 1605sh, 1590s (C=N); 774m (C=S). When the mother liquor was slowly evaporated in the air, it afforded few red crystals that were suitable for X-ray diffraction studies and later identified as $[CoL_2]_2[CoCl_4]\cdot 2EtOH$ (**3**).

2.2. X-ray crystallography

The crystal and instrumental parameters used in the unit-cell determination and data collection for all three compounds are summarized in Table 1. The intensity data were collected with a Siemens AED, on a Philips and with a CAD4 single-crystal diffractometer for compounds **1**, **2** and **3**, respectively using the $\theta-2\theta$ scan technique. Data were corrected for Lp, but no correction for absorption was applied. The structures of **1** and **2** were solved using SIR-92 [7a] and structure of **3** using SIR-97 [7b]. Refinements were carried out by full-matrix least-squares using the SHELXL-97 [8] program. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms, located on a difference map, were refined isotropically only for complex **2**. In complex **1** and **3**, the poor data quality has limited the accuracy of the refinement. Several crystals were used in the attempt to improve the accuracy of the results, but all sets of data suffered from the same problems. The hydrogen atoms were placed in calculated positions 'riding' on their C atoms; in **1** only the aminic nitrogen hydrogens were located on a difference map. All atomic scattering factors were taken from Ref. [9]. All calculations were performed on an ENCORE 91 computer at the Centro di Studio per la Strutturistica Diffrattometrica del CNR (Parma). Molecular geometry calculations were carried out by using the computer program PARST [10] and the structure drawings by using the ORTEP [11] and PLUTO [12] programs.

3. Results and discussion

The coordinating properties of 1-methylisatin 3-thiosemicarbazone (HL) have been investigated towards cobalt, nickel and copper ions in presence of chloride or acetate anions. All the complexes were isolated as solid products and with high yield, performing the reaction at

[a] The data were corrected for absorption following Sheldrick's method [8].

room temperature; they are soluble in dmso and dmf, but insoluble in water and common organic solvents, except for CuClL and CoClL, which are soluble in EtOH. The analytical data show different stoichiometries, mainly influenced by the nature of the inorganic anion. In fact all the metal acetates give complexes of formula ML_2 in spite of the molar ratio M:L, while using the metal chlorides, with the exception of the nickel derivative, the formula $MClL \cdot xH_2O$ is found.

3.1. Description of the structures

The molecular structure of complex $[CuClL]_n$ (**1**) is shown in Fig. 1. The copper atom presents a penta-coordination (square-pyramidal). The SNO terdentate ligand and a chlorine atom constitute the square base, while a sulphur atom belonging to a molecule in the $1/2-x, y-1/2, 1/2-z$ position occupies the axial site, Cu–S′ = 2.825(8) Å. In this way sulphur-bridged polymeric chains are formed along the y axis (Fig. 2), joined through longer interactions [Cu···C6 $(-x, 1-y, -z) = 3.26$ Å] and these generate sheets of polyhedra parallel to the (1 0 −1) planes. This last weak contact completes the copper coordination to a very elongated square-bipyramid. The pyramid basal plane shows a slight tetrahedral distortion and the copper atom lies 0.18 Å out of the same plane towards the S′ atom. The angles formed by Cu–S′ and Cu–C6 lines and the normal to the coordination plane are 12.3° and 0.85°, respectively. In the basal plane the Cu–S, Cu–N and Cu–Cl bond distances (Table 2) agree well with those found in other copper(II) complexes with thiosemicarbazones; the Cu–O(carbonyl) [2.21(1) Å] is longer than Cu–O (carboxylate) [13] or Cu–O (phenol) [14] where a negative charge is present which probably determines the observed bond shortening. In comparison with other Cu–O (carbonyl) distances reported in literature [15] this fairly long distance is probably mainly imposed by the rigidity of the ligand backbone which affects the geometry of the chelation ring. The endocyclic angle C9–C2–N3 in the five-membered chelation ring Cu–

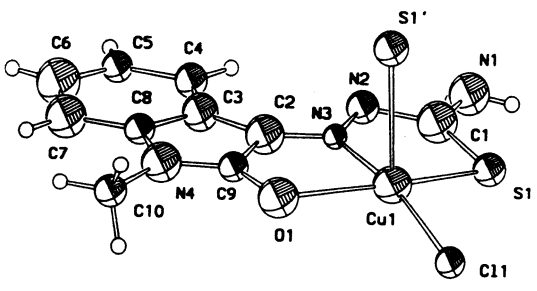

Fig. 1. Perspective view of the copper complex [CuClL] in **1**.

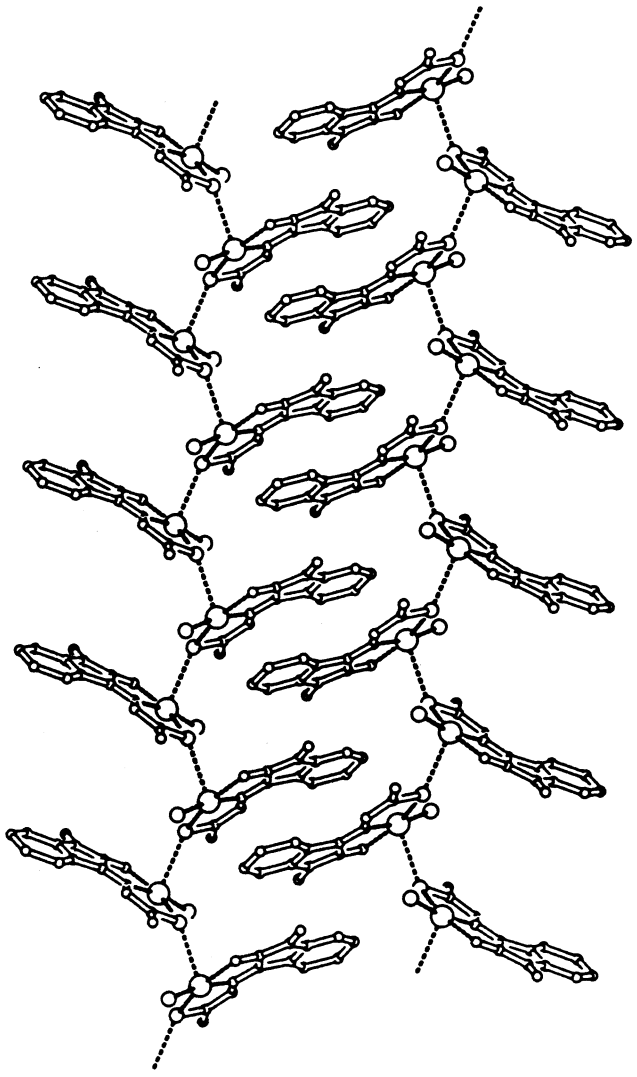

Fig. 2. Polymeric chains of sulfur bridged complexes along the y-axis in compound **1**.

N3–C2–C9–O1 is 119(2)°, while in uncoordinated isatin thiosemicarbazones the corresponding value is larger [128.3(4)°, 127.2(4)°, 127.6(4)° in Ref. [16] and 127.1(4)° in Ref. [17]. The two five-membered chelate rings are nearly planar and the dihedral angle between the mean planes is 7.0(3)°.

In the packing hydrogen bonds N1···Cl ($1/2-x$, $1/2+y$, $1/2-z$) = 3.33(2) Å and N1···Cl ($x-1$, y, z) = 3.43(2) Å link the layers of polyhedra. Weak charge transfer interactions are present between the aromatic rings (C4···C9 ($-x$, $1-y$, $-z$) = 3.36(3) Å, C3···C3 ($-x$, $1-y$, $-z$) = 3.53(3) Å).

The crystal structure of compound [NiL_2] (**2**) is shown in Fig. 3. The nickel atom lies on a crystallographic twofold axis and the two ligands, symmetrically related, are coordinated by the metal via the sulphur, the nitrogen from the hydrazine chain and the carbonyl oxygen of the isatin moiety in a distorted octahedral

isatin and acenaphthenequinone thiosemicarbazones [2,18]. Also in this complex the Ni–O bond is particularly long in comparison with the sum of the Pauling covalent radii, 2.05 Å. This lengthening is probably caused by the rigidity of the methylisatin moiety which affects the geometry of the chelation ring. In the five-membered chelation ring Ni–N3–C2–C9–O1 the endocyclic angle C9–C2–N3 is 115.6(5)°, similar to that found in Ref. [2].

The pair of five-membered chelate rings are only approximately planar (maximum dev. 0.07 Å), the dihedral angle between them being 3.5(1)°. The Ni–O1–C9–C2–N3 ring assumes an *envelope* conformation (puckering parameters: $q_2 = 0.109(4)$ Å, $\phi_2 = -179(3)°$), while the Ni–N3–N2–C1–S1 one shows a *twist* conformation with a twofold axis passing through the Ni atom [$q_2 = 0.057(4)$ Å, $\phi_2 = -17(5)°$] [19]. The packing is determined by hydrogen bonds involving the aminic nitrogen N1, N1···O1 ($x-1/2$, $y-1/2$, z) = 3.029(8) and N1···N2 ($-x-1/2$, $y-1/2$, $1/2-z$) = 3.197(7) Å.

In the crystals of (**3**) the asymmetric unit contains three cobalt atoms lying on binary axes, and therefore with site occupation factors of 0.5; in two of them the metal atom results to be surrounded by two ligands chelating in a SNO fashion and giving the metal a octahedral coordination (Fig. 4) while the third cobalt is part of a tetrachlorocobaltate(II) anion. The compound is an ionic complex, of formula $[CoL_2]_2[CoCl_4]\cdot 2C_2H_5OH$, formed by $[CoL_2]^+$ cations, $[CoCl_4]^{2-}$ anions and ethanol as crystallization solvent (Fig. 5). As the ligands can undergo a single deprotonation the only combination of oxidation states that can justify the stoichiometry is that the two complexes, that have the 1-methylisatin 3-thiosemicarbazone as a ligand, contain Co(III), while the $[CoCl_4]^{2-}$ unit contains a Co(II). This assignment is corroborated by typical bond lengths Co–S, Co–N and Co–O reported in the literature [15] for Co(III) that differ significantly from those present in analogous compounds of Co(II) (Table 4). The packing (Fig. 5) is determined by a complex network of hydrogen bonds involving the terminal amino groups of both cobalt complexes in the asymmetric unit, two of the chlorides belonging to the $[CoCl_4]^{2-}$ unit and the hydroxyl groups of the ethanol molecules.

In all three complexes the deprotonated 1-methylisatin 3-thiosemicarbazone moiety adopts the *Z* conformation with respect to the C1–N2 bond to facilitate the coordination to the metal, as already found in other isatin 3-thiosemicarbazone complexes [2,17,20]. An *E* conformation about this bond was instead present in the free ligand isatin 3-thiosemicarbazone [17] and in N(4)-substituted isatin 3-thiosemicarbazones [16].

In nickel complex **2** the bond distances and angles in the thiosemicarbazone and 1-methylisatin moieties (Table 3) are similar to that found in nickel complexes with the not methylated ligand [2], while the greatest difference in comparison with the free isatin-3-thiosemicarbazone [17] can be noticed in C1–S1 bond [1.719(7) vs. 1.663(4) Å] and in N2–N3 bond [1.332(7) vs. 1.356(5) Å]. For the copper and cobalt complexes **1** and **3** as a consequence of the poor data quality we are unable to discuss the ligand bonds in detail. The dihedral angles between the methylisatin and the thiosemicarbazide moieties are 10.1(6)° and 11.2(1)° in complexes **1** and **2**, respectively and 4.6(4)°, 10.0(5)° in the two Co1 and Co2 cation complexes of compound **3**. The six- and five-membered rings of methylisatin moiety are nearly coplanar in all three compounds. The dihedral angles between the mean planes are only 1.7(1)° in **1**, 1.3(2)° in **2** and 1.1(5)°, 0.2(5)° in **3**.

3.2. IR spectra

The infrared spectra of the ligand and the metal complexes are mainly characterized by the vibrational modes of the NH_2, NH, C=O and C=S groups.

The IR spectrum of HL shows three bands at 3426s, 3247m, 3150m cm^{-1} attributed to $\nu(NH_2)$ and $\nu(NH)$; while in the spectra of the complexes the monodeprotonated nature of the ligand justifies the presence of only two absorption bands.

The coordination of the carbonyl oxygen of the isatin moiety is related to the value of the $\nu(CO)$ band in the 1700–1650 cm^{-1} range; the $\nu(CO)$ values in the spectra of $CuL_2{\cdot}2H_2O$ (1688 cm^{-1}) agree well with an uncoordinated carbonyl oxygen; on the contrary the negative shift observed in the spectra of CoL_2 (1658 cm^{-1}), NiL_2 (1654 cm^{-1}), CuClL (1658 cm^{-1}) is consistent with a participation of the carbonyl oxygen in the coordination to the metal. A stronger metal–oxygen interaction seems to be present in the $CoClL{\cdot}0.5H_2O$ complex, since a more negative shift (1639 cm^{-1}) is observed in the spectrum. The attribution of the thioamide band, which has a substantial contribution from the $\nu(C{=}S)$ is at 832 cm^{-1} in the spectrum of the free ligand and shifts to lower energies in the spectra of all the complexes (see Section 2) [5a].

Taking into account the assignments of the vibrational absorptions, the following considerations on the ligand behaviour in the metal complexes can be made:

i) a N, S bidentate ligand behaviour can be proposed in the $CuL_2{\cdot}2H_2O$ with a probable tetracoordination around the metal atom;
ii) an O, N, S tridentate ligand behaviour is suggested in the other complexes.

4. Supplementary data

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 179029 (**1**), 179030 (**2**) and 179031 (**3**). Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

crystal structures of three new organic–inorganic hybrid polyoxovanadates: $[Ni(1,10'\text{-phen})_3]_2[V_{10}O_{26}]$ (**1**), containing an unusual empty ellipsoidal mixed-valent polyoxoanion $[V_{10}O_{26}]^{4-}$ 'host' cage; $[Zn(2,2'\text{-bipy})_3]_3[V_{15}O_{36}Cl]\cdot 3H_2O$ (**2**) and $[Co(2,2'\text{-bipy})_3]_3\ [V_{15}O_{36}Cl]\cdot 3H_2O$ (**3**), both containing a spherical mixed-valent oxovanadate cluster $[V_{15}O_{36}]$ 'host' shell with a Cl^- 'guest' encapsulated. To our knowledge, the organic–inorganic hybrid polyoxovanadate **1** has been isolated for the first time from aqueous solution with the help of a hydrothermal technique. The polyoxoanions of **2** and **3**, cocrystallized with transitional metal coordination complex cations, are also isolated for the first time. The role of organic templates (1,10′-phen and 2,2′-bipy) on the structures of polyoxoanions is discussed.

2. Experimental

2.1. Materials and measurements

All chemicals purchased were of reagent grade and used without further purification. Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 CHN Elemental Analyzer. V, Co, Ni, Zn were determined by a Leeman inductively coupled plasma (ICP) spectrometer. Cl was determined by a DX-300 ion chromatograph (IC) equipped with a conductivity detector and an AS4A-SC anion column. IR spectra were recorded in the range 400–4000 cm^{-1} on an Alpha Centaurt FT/IR Spectrometer using KBr pellets. EPR spectra were obtained on a Japanese JES-FE3AX spectrometer at 293 K. TG analyses were performed on a Perkin–Elmer TGA7 instrument in flowing N_2 with a heating rate of 10 °C min^{-1}.

2.2. Hydrothermal syntheses

2.2.1. Synthesis of $[Ni(1,10'\text{-phen})_3]_2[V_{10}O_{26}]$ (1)

A mixture of NH_4VO_3, $NiCl_2\cdot 6H_2O$, 1,10′-phenanthroline and H_2O in the mole ratio 1:1:2:444 was sealed in a 20 ml Teflon-lined autoclave, adjusted by 1 mol l^{-1} HCl to pH 5.0 and heated to 155 °C for 3 days. After cooling to room temperature (r.t.), dark-red column crystals of **1** were obtained. The compound was filtered, washed with distilled water and dried in air (65% yield based on V). *Anal*. Found: C, 40.63; H, 2.32; N, 7.84; V, 23.87; Ni, 5.44. Calc. for $C_{72}H_{48}N_{12}Ni_2O_{26}V_{10}$: C, 40.71; H, 2.28; N, 7.92; V, 23.98; Ni, 5.53%.

2.2.2. Synthesis of $[Zn(2,2'\text{-bipy})_3]_3[V_{15}O_{36}Cl]\cdot 3H_2O$ (2)

A mixture of NH_4VO_3, $ZnCl_2$, 2,2′-bipyridine and H_2O in the mole ratio 1:1:2:444 was sealed in a 20 ml Teflon-lined autoclave, adjusted by 1 mol l^{-1} HCl to pH 5.0 and heated to 155 °C for 4 days. After cooling to r.t., deep-red block crystals of **2** were obtained. The product was filtered, washed with distilled water and dried in air (70% yield based on V). *Anal*. Found: C, 36.59; H, 2.64; N, 8.45; Cl, 1.25; V, 25.34; Zn, 6.39. Calc. for $C_{90}H_{78}ClN_{18}O_{39}V_{15}Zn_3$: C, 35.66; H, 2.59; N, 8.32; Cl, 1.17; V, 25.21; Zn, 6.47%.

2.2.3. Synthesis of $[Co(2,2'\text{-bipy})_3]_3[V_{15}O_{36}Cl]\cdot 3H_2O$ (3)

When $ZnCl_2$ was substituted by $CoCl_2\cdot 6H_2O$ while the other reaction conditions remained the same, dark-brown block crystals of **3** were obtained (60% yield based on V). *Anal*. Found: C, 36.28; H, 2.62; N, 8.87; Cl, 1.27; Co, 5.78; V, 25.74. Calc. for $C_{90}H_{78}ClCo_3N_{18}O_{39}V_{15}$: C, 35.89; H, 2.61; N, 8.37; Cl, 1.18; Co, 5.87; V, 25.37%.

When $ZnCl_2$ was substituted by $NiCl_2\cdot 6H_2O$ with the same synthetic conditions, dark green crystals of **4** were obtained. The IR spectrum of **4** exhibits the similar characteristic peaks as **2** and **3**. However, owing to the poor quality of the crystals, no precise structure was determined by single crystal X-ray diffraction.

2.3. X-ray crystallography

Data for **1** were collected on a Siemens P4 four-circle diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K using the ω-scan technique. Empirical absorption correction (ψ scan) was applied. Data for compound **2** were collected at 293 K on a Bruker CCD diffractometer employing graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Empirical absorption correction was applied. Data for **3** were collected at 293 K on a *R*-axis RAPID diffractometer with the IP technique. Empirical absorption correction was applied.

All structures were solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXL-97 software [21]. All of the non-hydrogen atoms were refined anisotropically. All the hydrogen atoms were located from difference Fourier maps. Atomic coordinates, bond lengths and angles, and anisotropic displacement parameters of **1**, **2** and **3** are available in the supplementary crystallographic data. A summary of crystal data and structure refinement for compounds **1**, **2** and **3** is provided in Table 1. Selected bond lengths and angles of **1**, **2** and **3** are listed in Tables 2 and 3.

3. Results and discussion

3.1. Hydrothermal syntheses of 1–3

The isolation of **1**–**3** relies on hydrothermal techniques. Hydrothermal synthesis has recently been proved a useful technique in preparation of organic–inorganic hybrid materials [2,11–15,18–20]. In the hydrothermal

[a] M = Zn (in **1**) or Co (in **2**).

environment, the reduced viscosity of the solvent results in enhanced rates of solvent extraction of solids and crystal growth from solution. Furthermore, since different solubility problems are minimized, a variety of simple organic and/or inorganic templating agents can be introduced. [14,15,22,23]. However, hydrothermal synthesis is still a relatively complex process because many factors can effect the reaction, such as initial reactants, concentration, pH and crystallization temperature.

To investigate the influence of ligands on the formation of cage-like polyoxovanadates, we selected two bidentate N-containing ligands (1,10-phen and 2,2′-bipy) and kept the other synthetic conditions the same. It is noteworthy that the introduction of different organic structure-directing agents leads to two kinds of polyoxovanadate structures during the preparations of **1**–**3**. The geometry of organic templating agents in this case may be one of the important factors that influence the self-assembly of the oxovanadate clusters. Further-

more, the prolonged reaction time is probably another factor, which leads to higher polymerization of polyoxovanadate clusters.

3.2. Crystal structures of *1–3*

Single crystal X-ray analysis reveals that **1** consists of an unusual oblate spherical mixed-valent polyoxoanion $[V_{10}O_{26}]^{4-}$ and two $[Ni(1,10\text{-phen})_3]^{2+}$ cations. The polyoxoanion of **1** (Fig. 1(a)) exhibits two independent vanadium coordination environments, that is, the distorted $\{VO_4\}$ tetrahedron and the distorted $\{VO_5\}$ square pyramid (Fig. 1(b)). In the $\{VO_4\}$ tetrahedron, the vanadium center is coordinated with three bridging oxygen (O_b) atoms and one terminal oxygen (O_t) atom with V–O_b distances in the range of 1.662(4)–1.800(3) Å and V–O_t distances 1.586(3)–1.617(3) Å. The bond angles at V atoms range from 105.50(12)° to 110.95(16)°. In the $\{VO_5\}$ square pyramid, the vanadium center is connected with four O_b atoms and one O_t atom with V–O_b lengths in the range 1.933(3)–1.949(4) Å and V–O_t lengths 1.582(4)–1.585(4) Å. The bond angles at V atoms vary from 83.75(13)° to 151.0(2)°.

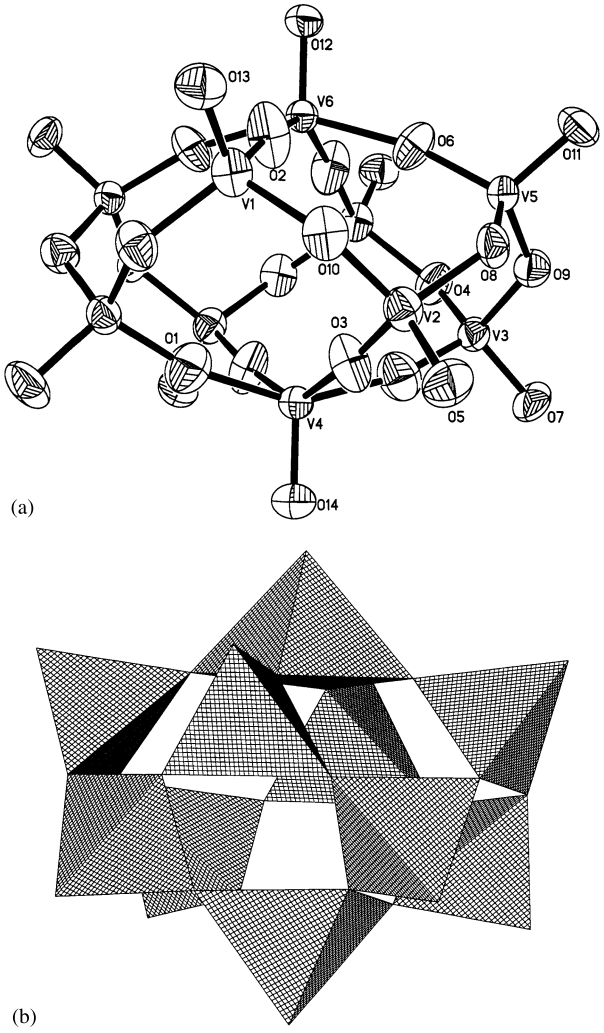

Fig. 1. (a) The structure of $[V_2^{IV}\ V_8^{V}\ O_{26}]^{4-}$ in **1**; (b) The polyhedron representative of $[V_2^{IV}\ V_8^{V}\ O_{26}]^{4-}$ in **1**.

It is interesting that eight $\{VO_4\}$ tetrahedra are connected with one another via the corner-sharing mode to form a puckered 16-member ring with an average diameter of 6.68 Å. Two $\{VO_5\}$ units are capped on both sides of the ring to form an empty ellipsoidal 'host' cage. The distance between two $\{VO_5\}$ moieties is 4.69 Å.

Valence sum calculations [24] (see Table 4) show that the eight vanadium centers in $\{VO_4\}$ tetrahedral environments are in the 5+ oxidation state, while the other two vanadium centers in the $\{VO_5\}$ units are in the 4+ oxidation state. Therefore, the detailed formula of the cluster can formally be described as $[V_2^{IV}\ V_8^{V}\ O_{26}]^{4-}$.

In compound **1**, two coordination complexes $[Ni(1,10'\text{-phen})_3]^{2+}$ act as counter cations. The Ni^{2+} ion is coordinated with six N atoms in three phen groups to form a chiral cationic unit with an average Ni–N length of 2.078 Å. In the unit cell of **1**, weak π–π interactions (with an average distance 3.42 Å) exist between the $[Ni(1,10\text{-phen})_3]^{2+}$ cations, while the $[V_{10}O_{26}]^{4-}$ anions are connected with these cations via electrostatic attraction. The packing arrangement of **1** along the *b* axis is shown in Fig. 2.

Compound **2** consists of a spherical mixed-valent polyoxoanion $[V_{15}O_{36}Cl]^{6-}$ (see Fig. 3(a)), three $[Zn(2,2'\text{-bipy})_3]^{2+}$ cations and three lattice water molecules. The polyoxoanion $[V_{15}O_{36}Cl]^{6-}$ can be described as a nearly spherical oxo-vanadium cluster formed by 15 $\{VO_5\}$ square pyramids via the cornering-sharing mode as shown in Fig. 3(b). A 'guest' Cl^- ion was encapsulated in the $[V_{15}O_{36}]$ 'host' shell. In the distorted $\{VO_5\}$ square pyramid, V–O_b lengths are in the range of 1.810(3)–1.992(5) Å, V–O_t lengths 1.596(7)–1.604(5) Å, and the bond angles of O–V–O vary from 90.27(7)° to 144.1(2)°. The average radius (the distance from V atom to Cl^- ion) of the cage is 3.41 Å.

The $[V_{15}O_{36}Cl]^{6-}$ cluster is closely related to those found in alkali–vanadium oxide–halide systems described by Müller et al. [4,5]. Valence sum calculations (see Table 4) of **2** give an average value of 4.51 for calculated oxidation states of V. The calculations show

Table 4
Sums of the bond valences [a] for the V atoms of **1**, **2** and **3**

	1	2	3
V(1)	4.91	4.79	4.79
V(2)	4.94	4.77	4.76
V(3)	5.00	3.98	4.15
V(4)	4.31		
V(6)	4.35		

[a] The results refer to the equation $V_i = \Sigma_j \exp((r_0 - r_{ij})/B)$ (Ref. [24]).

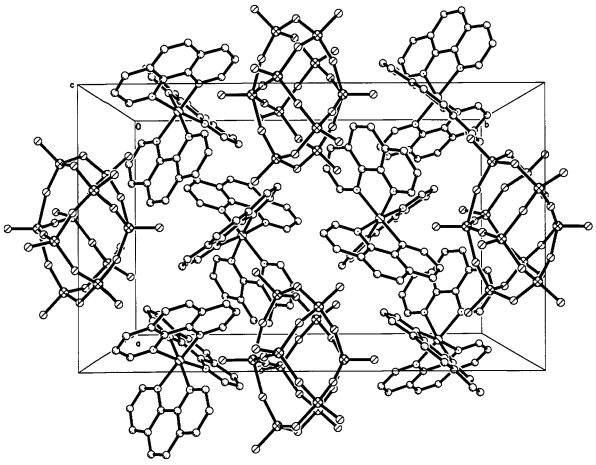

Fig. 2. Packing arrangement of compound **1** along the *c* axis.

that eight vanadium centers are in the 4+ oxidation state, while the other seven vanadium centers are in the 5+ oxidation state, which confirms the molecular formula of **2** and is consistent with the previous reports [4,5,25]. Therefore, the detailed formula of the polyoxoanion can be described as $[V_8^{IV}\ V_7^{V}\ O_{36}Cl]^{6-}$.

In compound **2**, three coordination complexes $[Zn(2,2'\text{-bipy})_3]^{2+}$ act as counter cations. The Zn^{2+} ion is coordinated with six N atoms in three 2,2′-bipy groups to form a chiral cationic unit with an average Zn–N distance of 2.162 Å. Every four $[Zn(2,2'\text{-bipy})_3]^{2+}$ groups in **2** lie in the same plane. The polyoxoanions are located above and below this plane and are connected with the $[Zn(2,2'\text{-bipy})_3]^{2+}$ groups via electrostatic attraction. The packing arrangement of **1** along the *b* axis is shown in Fig. 4.

Compound **3** is isostructural with **2** and needs no further discussion.

3.3. IR and EPR spectra

In the IR spectrum of **1** (see Fig. 5), the strong bands at 965, 888, 844, 721 and 665 cm^{-1} are due to the ν(V=O) or ν(V–O–V) vibrations. Bands in the 1626–1099 cm^{-1} regions are attributed to extending vibrations of the 1,10′-phen groups. The IR spectra of compounds **2**, **3** and **4** exhibit similar characteristic peaks**.** The strong bands at 981, 769, 732 and 660 cm^{-1} are ascribed to the ν(V=O) or ν(V–O–V) vibrations. Bands in the range of 1632–1017 cm^{-1} are characteristic of C=C and/or C–N bonds of the 2,2′-bipy groups.

The EPR spectrum of **1** (Fig. 6(a)) at room temperature shows a V^{4+} signal with $g = 1.9884$. No fine signals were recorded for **1** owing to the high concentrations of vanadium. The EPR spectrum of **2** (Fig. 6(b)) at room temperature shows fine V^{4+} signals with $g_{\perp} = 1.997$, $g_{\parallel} = 1.934$, $A_{\perp} = 1.875$, and $A_{\parallel} = 1.668$. All these results are in accordance with the valence sum calculations,

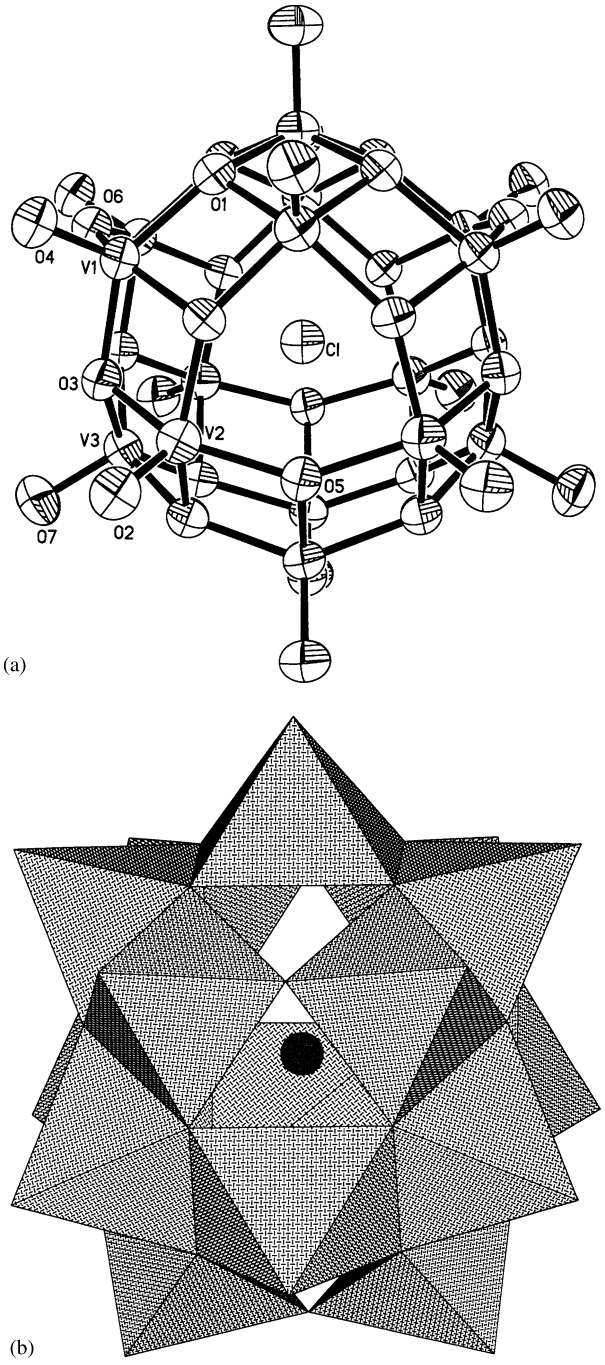

Fig. 3. (a) The structure of $[V_8^{IV}\ V_7^{V}\ O_{36}Cl]^{6-}$ in **2**; (b) The polyhedron representative of $[V_8^{IV}\ V_7^{V}\ O_{36}Cl]^{6-}$ in **2**.

further confirming that compounds **1**–**3** all possess mixed V^{4+}/V^{5+} oxidation states.

3.4. Thermal analyses of *1*–*3*

The TG curve of compound **1** (Fig. 7(a)) is divided into three continuous stages. The first weight loss is 5.49% in the temperature range 498–518 °C. The second weight loss is 27.32% from 530 to 650 °C and the third is 15.61% in the range 655–755 °C. These

three continuous weight losses are ascribed to the release of the 1,10′-phen groups. The whole weight loss (48.41%) is in good agreement with the calculated value (50.84%). The sample does not lose weight at temperatures higher than 760 °C.

The TG curve of compound **2** (Fig. 7(b)) exhibits four steps of weight losses. The first weight loss is 2.91% in the temperature range 25–120 °C, corresponding to the release of crystal water. The second weight loss is 5.59% from 195 to 345 °C, the third is 31.50% in the range 345–485 °C, and the fourth is 7.01% in 485–570 °C, all assigned to the release of 2,2′-bipy groups. The whole weight loss (47.01%) is consistent with the calculated value (48.10%). The sample does not lose weight at temperatures higher than 570 °C.

The TG curve of compound **3** (see Fig. 7(c)) exhibits similar weight loss stages compared with **2**. The first weight loss is 2.03% in the temperature range 25–180 °C, corresponding to the release of crystal water. The remaining three weight losses amount to 44.45% from 180 to 570 °C, and are ascribed to the release of 2,2′-bipy groups. The whole weight loss (46.48%) agrees well with the calculated value (48.41%).

4. Conclusions

In this paper, three new organic–inorganic hybrid materials based on the spherical mixed-valent polyoxovanadates have been hydrothermally synthesized. Under similar synthetic conditions, the introduction of different organic N-containing ligands leads to various self-assembly of polyoxovanadate clusters. The geometry of these organic templating agents may be one of the important factors that influence the growth and self-assembly of the oxovanadate clusters. Studies are going on in order to provide more structural information of such organic–inorganic hybrid complexes and reveal structural relationships between N-containing ligands and the polyoxoanions.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 182191–182193 for compounds **1**, **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

nones), has been recently proposed a special role on the increase of the bone uptake of ^{67}Ga, thus, conferring to carboxyl–hydroxypyridonate derivatives a potential interest in bone tumour radiodiagnosis [11,12]. On the other hand, there is a large number of biological active MMP enzyme inhibitors which have a hydroxamate chelating group, as well as a carboxylate extra-functional group [13]. Some hydroxypyridinones, such as mimosine (β-*N*-(3-hydroxy-4-pyridone)-α-aminopropionic acid, herein named as H_2L^4), which has been also implicated in the inhibitory activity of various M(II)-containing enzymes (M = Cu, Zn) and other biological systems, possess also a 'free' carboxylate group [2].

Accordingly, this new ligand could be thought as a candidate for potential radiopharmaceutical, in relation to its chelation either with $^{64,67}Cu$, to be used in PET analysis [14], or with other M^{2+} metal ions, for metalloenzyme inhibition.

In this paper, we report the study of a tetradentate bifunctional ligand, *cis*,*cis*-1,3-di-[1′-(3″-carboxyaminopropyl)-3′-hydroxy-2′-methyl-4′-pyridinone-yl]-5-carboxyl-1,3,5-trimethylcyclohexane, hereafter named as KEMP(NPrHP)$_2$ or H_3L^1 (Scheme 1). It is a bis(3-hydroxy-4-pyridinonate)-monocarboxylate ligand and so, herein, sometimes it is referred as a 'bis-chelator', in comparison with the corresponding 'mono-chelator' pendant unit, 1-(3′-methylcarboxyaminopropyl)-3-hydroxy-2-methyl-4-pyridinone), hereafter named AcNPrHP or HL^2, which was also studied. Each 3,4-HP unit is linked to an aminoalkylic chain, which acts both as a spacer and also a way of attachment to the cyclic backbone via its carboxylate groups. Besides the preparation and characterization of the ligands (acid–base and lipo-hydrophilic properties), their complexation ability towards the first transition series of divalent metal ions [Cu(II), Zn(II) and Ni(II)] as well as the corresponding speciation are described and discussed herein. The equilibrium studies were carried out in aqueous media and were based on potentiometric and spectrophotometric measurements. A brief molecular mechanics simulation was also carried out to get an insight on the ability of this new 'bis-chelator' to wrap this type of metal ions.

KEMP(NPrHP)$_2$, H_3L^1 AcNPrHP, HL^2

2. Results and discussion

2.1. Synthesis

The synthesis of this bis(hydroxypyridinonate)-carboxylate ligand involved a preliminary protection of one of the carboxylic functions of the starting material, the *cis*–*cis*-1,3,5-trimethylcyclohexane-1,3,5-tricarboxilic acid (KEMP acid), by its convertion into the intermediate cyclic anhydride [5-(chloroformyl)-*cis*,*cis*-1,3,5-trimethylcyclohexane-1,3-dicarboxilic anhydride], by standard methods [15]. This reaction takes advantage of the proximity between the carboxylic groups in the starting material and so it was performed with high yield. This intermediate was then coupled to 1-(3′-propylamine)-3-benzyloxy-4-pyridinone, to give the *O*-benzyl protected bis-hydroxypyridinone-mono-carboxylic acid derivative. To afford the final product, H_3L^1, the deprotection of the hydroxypyridinonate hydroxyl groups was performed by standard methods of hydrogenolysis [11]. The synthesis of the 'mono-chelator' compound, HL^2, involved a condensation of 1-(3′-propylamine)-3-benzyloxy-4-pyridinone with acethyl chloride.

2.2. Acid–base properties of the ligands

The bis- and the mono-hydroxypyridonate ligands, in their neutral form (H_3L^1 and HL^2), have only three and one labile protons, respectively, due to the carboxylic/phenolic groups, whereas, in their fully protonated form, they have the extra dissociable pyridinium protons. From the fitting analysis of potentiometric titration curves of the ligands (Fig. 1) with the SUPERQUAD program [16], five and two protonation constants were determined, respectively. Table 1 shows the calculated stepwise protonation constants together with the corresponding values for some representative 3-hydroxy-4-pyridinone analogues, such as 1,2-dimethyl-3-hydroxy-2-methyl-4-pyridinone (HL^3) [17] and mimosine (H_2L^4) [2]. Based on chemical evidences, the first two protonation constants of H_3L^1 ($\log K_a = 10.17$; 9.43) and the first one of HL^2 ($\log K_{a1} = 9.61$) are undoubtedly attributed to the phenolic groups. The three remaining $\log K_a$ values (4.70; 3.64; 2.96) of H_3L^1 are attributed to the carboxylic group and to the pyridinium groups. Although these three processes overlap each other, comparison between these stepwise protonation constants and the corresponding values for the pyridinium group of HL^2 (3.37) and other analogous compounds

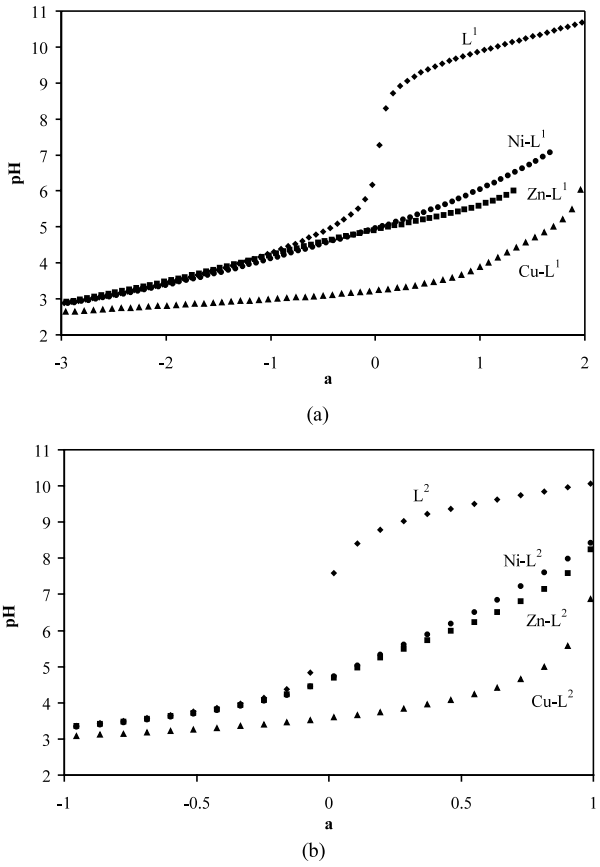

Fig. 1. Potentiometric titration curves for the ligands alone and in the presence of each M(II) metal ion (M = Cu, Ni, Zn): H_3L^1, at 1:1 metal to ligand molar ratio ($C_L = 2.9 \times 10^{-3}$ M, $I = 0.2$ M (KCl)) (a); HL^2, at 1:2 metal to ligand molar ratio. ($C_L = 1.6 \times 10^{-3}$ M, $I = 0.1$ M (KNO_3)) (b). $T = 25.0 \pm 0.1$ °C; a = mols of base added per mol of ligand.

(see Table 1) suggests that the two lower values (3.64; 2.96) should be mainly attributed to the pyridinium groups. Besides, the higher value (4.70), attributed to the carboxylic group, is comparable to the log K_a values of other tertiary carboxylic groups (ex. 2,2-dimethylpropanoic acid, log $K_a = 4.8$) [18]. Analysis of the speciation plots related to the calculated log K_a values shows that the mono-anion $[H_2L^1]^-$ dominates over the pH range 5.5–8.5. Thus, this tetradentate ligand is expected to have a considerably higher hydrophilic character at the physiological conditions than the neutral bidentate derivative (HL^2).

2.3. Complexation studies

Complexation behaviour of these di- and mono-hydroxypyridinonate ligands ($H_3L^1$and HL^2) with the first transition series of metal ions [Cu(II), Ni(II) and Zn(II)] was studied by potentiometry and the interpretation of these results was aided by UV–Vis spectrophotometry. Precipitation was not observed in the samples containing some ligand excess but appeared at 1:1 ratio or at metal ion excess. The titrations were finished if precipitation occurred. Representative titration curves of these two ligands in the presence of each of those metal ions studied are shown in Fig. 1(a) (H_3L^1) and (b) (HL^2), for the 1:1 and in 2:1 ligand to metal molar ratios, respectively. Some species distribution diagrams for the complexation with the di-hydroxypyridonate ligand (H_3L^1) are presented in Fig. 2.

Analysis of the titration curves indicates that the metal complexation of both the ligands starts at a quite lower pH (approximately 2.5) with copper(II) than with nickel(II) and zinc(II) (approximately pH 4), thus, indicating a stronger interaction with copper(II). The experimental data presented good fittings for the complexation models having 1:1 and 1:2 stoichiometry for H_3L^1 and HL^2, respectively, with different protonation degrees. Comparison between the formation constants calculated for the complexes with H_3L^1 (Table 1) shows that log β_{ML} is higher for Cu(II) than for Zn(II) and Ni(II) by a factor of 5.6 and 7.0 logarithmic units, respectively. Identical difference was found between the log $\beta_{ML_2^1}$ of the complexes of these metal ions with the monomeric derivatives, HL^2 and HL^3 (deferiprone) [17] (see Table 1).

Comparative analysis of the chelating abilities of H_3L^1 and the other analogues has to be made with care, mainly due to differences in the acid–base properties of the ligands and the stoichiometry of the complexes. Therefore, the pM values ($pM = -\log[M^{2+}]$) were also calculated for the different metal ions, at the physiological conditions (pH 7.4, Table 1) and for Cu(II), along a large range of pH (Fig. 3). A brief comparison of the complexing behaviour of the di-hydroxypyridinone and the mono-analogue suggests that the same binding sites (the 3-hydroxy-4-pyridinone portions) should be involved in the co-ordination of the ligands to each metal ion. In fact, for each metal ion, the profiles of the titration curves are very similar. The overall formation constants (log β_{ML}) calculated for the (1:1) complexes of this di-hydroxypyridinonate ligand with copper(II), nickel(II) and zinc(II) (17.42, 10.41, 11.78) are close to, albeit slightly lower than, the values (log β_{ML_2}) for the corresponding (1:2) complexes with the mono-hydroxypyridinonate ligands: HL^2, (18.99, 12.38, 13.70) and HL^3, (19.61, 12.13, 13.53) [17]. However, at conditions of 10-fold excess of the ligand and mM or μM concentrations, the pM values are higher for the dihydroxypyridinone, H_3L^1, (ex.: for $C_{Cu} = 10^{-4}$ M, pCu = 13.5; for $C_{Cu} = 10^{-6}$ M, pCu = 13.6) then the monohydroxypyridinone, HL^2, (ex.: for $C_{Cu} = 10^{-4}$ M, pCu = 12.4; for $C_{Cu} = 10^{-6}$ M, pCu = 10.4). Fig. 3 presents a graphical illustration of the higher copper binding ability of the bischelator KEMP(NPrHP)$_2$ (H_3L^1) over the monochelators (HL^2 and HL^3), along a range of pH above 4.

[a] $I = 0.1$ M, KNO_3.
[b] According to Ref. [17].
[c] According to Ref. [2].

The stability constants of the di-hydroxypyridone (H_3L^1) complexes with this set of bivalent metal ions seem to follow the proposed Irving–Williams order Ni < Cu > Zn [19], as it happens with hydroxamate complexes [20].

Regarding the type of binding modes in MHL^1 species, two different possibilities can be admitted. As a first possibility, two hydroxypyridinonate groups could be involved in the co-ordination to the metal ion, leaving the dissociable proton in the carboxylic group. Such a co-ordination mode could be favourable if the complex species was formed when the carboxylic moiety is protonated (below pH 4, as happens with the copper complexes, see Figs. 1 and 2(a)). As a second possibility, one of the hydroxypyridinonate groups is in the co-ordinated form while the other one is in protonated form; this complex would be favoured in the pH-range where the carboxylic moiety is already deprotonated (above pH 4, as happens for the nickel and zinc complexes, see Figs. 1 and 2(b)).

In order to get some insight into the co-ordination modes involved in the copper(II) complexes with the di-hydroxypyridonate ligand, UV–Vis absorption spectra of solutions containing this metal ion in the presence of H_3L^1 or HL^2 were registered at different pH (Fig. 4), for comparison purpose. Analysis of Fig. 4 confirms that, in both the systems, complexation has already started at approximately pH 2.5, in accordance with the species distribution diagram (Fig. 2(a)). At pH 3.5, the samples containing the copper(II)–H_3L^1complexes exhibit a *d*–*d* transition band centred at 680 nm ($\varepsilon = 43$ M^{-1} cm^{-1}) and a charge transfer transition ($\lambda_{max} = 377$ nm, $\varepsilon = 250$ M^{-1} cm^{-1}). From the species distribution diagram, it can be mostly assigned to the CuL^1H species. The similarity between the *d*–*d* transition band of this complex and the corresponding bands for the 1:2 complexes with HL^2 ($\lambda_{max} = 675$ nm, $\varepsilon = 59$ M^{-1} cm^{-1}, at pH 5.56), HL^3 ($\lambda_{max} = 692$ nm, $\varepsilon = 31$ M^{-1} cm^{-1}) [17] and H_2L^4 ($\lambda_{max} = 690$ nm, $\varepsilon = 33$ M^{-1} cm^{-1}) [2] gives support to the assumption made on the binding mode through the hydroxypyridinonate moieties. For higher pH values ($3.5 < pH < 5.3$), there is a small blue shift of λ_{max} to 665 nm ($\varepsilon = 51$ M^{-1} cm^{-1}) which may be associated with some formation of the CuL^1 species and some strengthening of metal–ligand bond in these species.

Above pH 5.3, more than 80% of the copper complex is in the neutral form (CuL^1) (see Fig. 2(b)) and precipitation starts in our experimental conditions.

Concerning the nickel(II) complexes, at pH 6.7, the UV–Vis spectra presented a charge transfer transition ($\lambda_{max} = 392$ nm, $\varepsilon = 66$ M^{-1} cm^{-1}) and a very week band in the *d*–*d* region ($\lambda_{max} = 673$ nm, $\varepsilon = 15$ M^{-1} cm^{-1}). This should correspond to the neutral bis-chelated species (NiL, approximately 50%) which started to precipitate with increasing concentration (at pH ≥ 7). According to the spectra, octahedral or pseudo-octahedral geometry around the metal ion is suggested. Since only four coordination sites are occupied by two hydroxypyridinonate moieties, probably

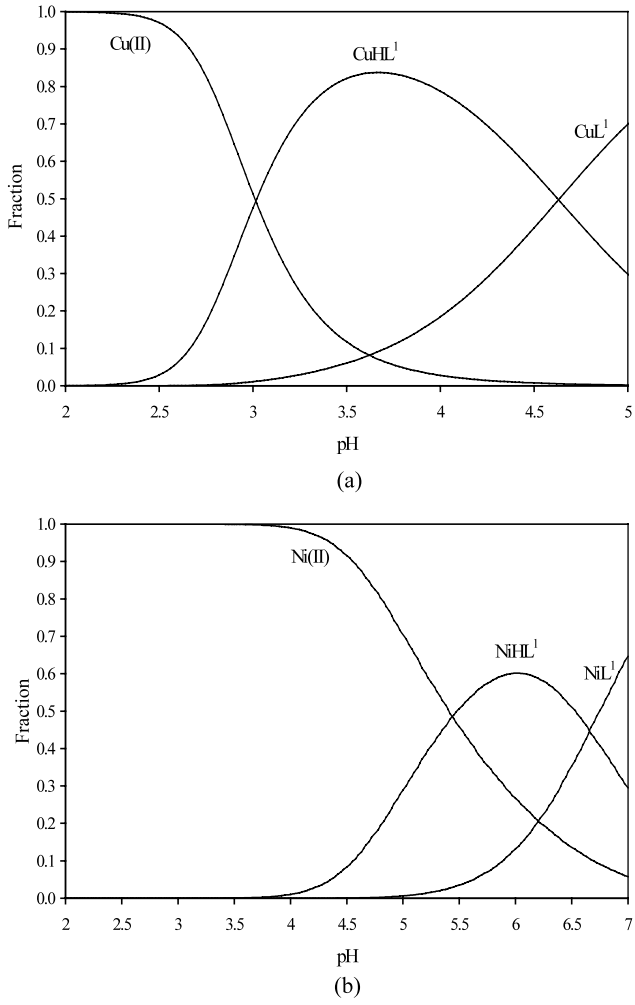

Fig. 2. Concentration distribution curves calculated for the Cu–H_3L^1 complexes (a) and Ni–H_3L^1 complexes (b), at 1:1 metal to ligand ratio and $C_L = 2.9 \times 10^{-3}$ M.

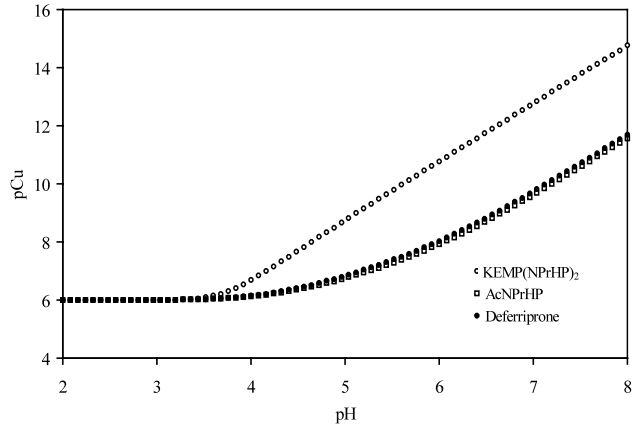

Fig. 3. Copper complexation strength for H_3L^1 ($KEMP(NPrHP)_2$), HL^2 (AcNPrHP) and HL^3 (Deferiprone), reported as pCu vs. pH ($pCu = -\log[Cu^{2+}]$ with $C_L/C_{Cu} = 10$ and $C_{Cu} = 10^{-6}$ M).

two water molecules are also involved to complete the co-ordination around the metal centre. The involvement

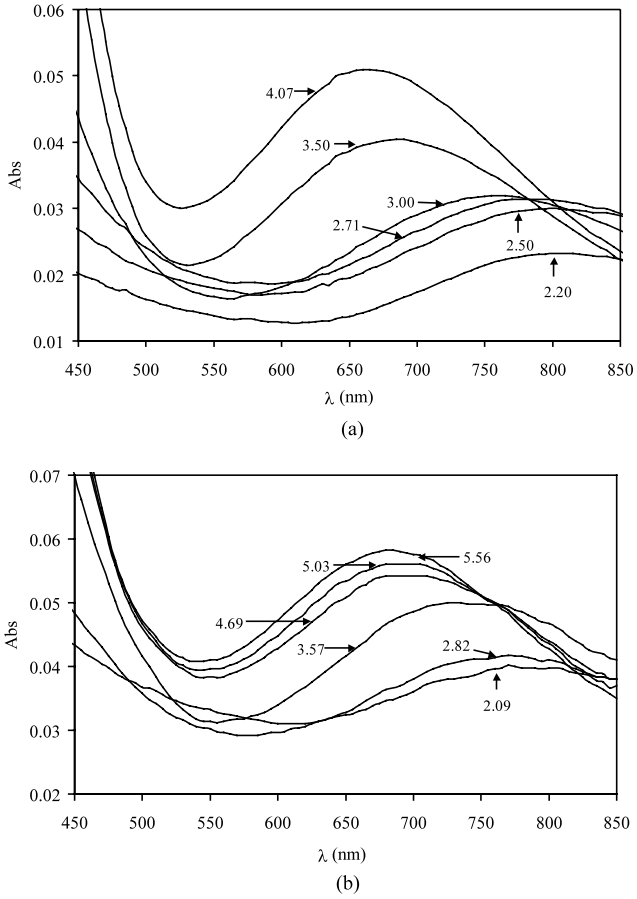

Fig. 4. Absorption spectra registered at various pH values for: the Cu(II)–H_3L^1 system ($C_L = 1.5 \times 10^{-3}$ M, $C_L/C_M = 1.5$) (a); the Cu(II)–HL^2 system ($C_L = 2.0 \times 10^{-3}$ M, $C_L/C_M = 2$).

of the carboxylate group in the coordination can hardly be assumed, due to steric demands.

Regarding the zinc(II) complexes, a brief comparative analysis of the ^1H NMR spectra was performed for complex and ligand solutions in the pH range 4–6. These results showed that the highest deviations in the chemical shifts, $\Delta\delta = -(0.2–0.4)$ ppm, were observed for the two hydroxypyridinone ring protons, thus suggesting the involvement of the hydroxypyridinonate moieties in the co-ordination to the metal centre.

Furthermore, as stated above, the hydroxypyridonate coordination in the metal complexes is also supported by the similarity between the potentiometric titration profiles and also between the overall formation constants obtained for the 1:1 complexes and the 1:2 complexes with H_3L^1 and HL^2, respectively.

Finaly, aimed at giving some contribution to the interpretation of the complexation behaviour of the dihydroxypyridonate ligand, a brief molecular modelling calculation was performed for this ligand (using MOPAC program included in the INSIGHT package [21]) and the Cu–L^1 complex (using molecular mechanics, with the CERIUS2 [22] program and the default force

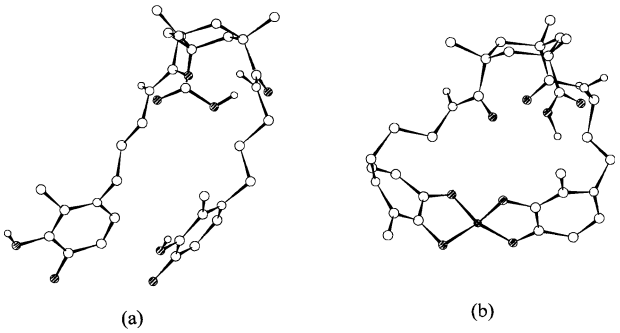

Fig. 5. Structure diagrams calculated for: the ligand H_3L^1, KEMP(NPrHP)$_2$, (a) and the CuL^1 complex (b). The metal ions are doubly hatched; the oxygen atoms are hatched; hydrogen atoms bonded to carbon atoms are omitted.

fields [23]). The simulated structure of the ligand (Fig. 5(a)) suggested a *chair* conformation for the cyclohexane backbone with the alkylamide-hydroxypyridinonate and the carboxylate pendant arms in axial position, thus, pre-orientated to wrap the metal ion. That conformation is apparently supported by some hydrogen-bond interaction between the neighbouring pendant arms. Concerning the Cu–L^1 complex, a distorted square-planar coordination geometry seems probable, with no significant interaction between the carboxylate group and the metal ion, due to steric demands. The coordination of the ligand towards the Cu(II) ion requires the disruption of the hydrogen-bond network found in the ligand, although the *chair* conformation was kept in the minimum energy conformer (Fig. 5(b)).

2.4. Distribution coefficient

The distribution coefficient of the free ligand between the aqueous phase (buffered at pH 7.4 with Tris) and octanol showed that, at physiological pH, the 'dimeric' ligand ($\log D = -1.96 \pm 0.02$) is much more hydrophilic than the corresponding monomeric species ($\log D = -1.04 \pm 0.02$). This is due to the fact that, at this pH, the 'dimeric' ligand is mono-charged $[H_2L^1]^-$ as a result of the dissociation of the carboxylic proton. Even so, it is much less hydrophilic than other (carboxyalkyl)hydroxypyridinones [$\log D = -(2.8–2.9)$] [12] due to some hydrophobicity induced by the higher ratio between the number of hydroxypyridinonate and carboxylate groups (2:1 instead of 1:1).

3. Conclusions

This new heteropodant bis-hydroxypyridonate ligand forms quite stable 1:1 complexes with the bivalent metal ions of the first transition series. The metal co-ordination environment is dominated by the hydroxypyridinonate moieties, thus leaving the extra carboxylic group for further eventual interaction with biological ligands (e.g. proteins). It has proved a good lipo-hydrophilic balance. So, important biological roles may be admitted for this ligand, probably as an enzymatic inhibitor, related to its affinity for Ni(II) and Zn(II), or as a good chelating agent for radio-diagnosis (PET) due to its high affinity for ^{64,67}Cu(II).

4. Experimental

4.1. Chemicals

Analytical grade reagents were used as supplied. Whenever necessary, solvents were dried according to standard methods [24]. All the chemical reactions were TLC controlled.

4.1.1. Synthesis of the ligand, H_3L^1 (or KEMP(NPrHP)$_2$) (**1**)

*4.1.1.1. 1-(3′-Aminopropyl)-3-benzyloxy-2-methyl-4-pyridinone (**3**).* 3-Benzyloxy-2-methyl-4-pyrone (2.3 g, 10.7 mmol), obtained according to previously described [11], and 1,3-diaminopropane (1.1 ml, 13.2 mmol) were left refluxing in water (30 ml) for 6 h. Evaporation of water and excess of 1,3-diaminopropane in vacuum gave an oil which was then dissolved in MeOH. Acidification of that solution until pH 2 with HCl saturated MeOH gave a white precipitate which was recrystallized from dry MeOH–MeCN to give the pure product ($\eta = 40\%$). M.p. 186–189 °C; IR (cm^{-1}, KBr) 1630 ($\nu_{C=O}$). ^{1}H NMR ($CDCl_3$) 8.14 (1H, d, 6-HPy), 7.42 (5H, s, Ph), 7.11 (1H, d, 5-HPy), 5.13 (2H, s, CH_2Ph), 4.31 (2H, t, CH_2N–Pyr), 3.03 (2H, t, CH_2N), 2.36 (2H, t, CH_2CH_2-CH_2), 2.12 (3H, s, Me). *m/z* (FAB) 273 ($M+1$).

*4.1.1.2. 5-(Ch1oroformyl)-cis,cis-1,3,5-trimethylcyclohexane-1,3-dicarboxilic anhydride (**4**).* To a solution of 1,3,5-trimethyl-1,3,5-cyclohexane-tricarboxylic acid (1.95 g, 7.4 mmol) in dry CH_2Cl_2 (50 ml), oxalyl chloride (0.8 ml) was added as well as one drop of dry dimethylformamide (DMF). The mixture was left refluxing under dry nitrogen atmosphere for 4 h. Excess of oxalyl chloride was removed by rota-evaporation. Two 10 ml batches of dry $CHCl_3$ were subsequently added to the residue and then removed by vacuum distillation, giving a white solid. Recrystallisation from dry toluene gave the pure product ($\eta = 85\%$). M.p. 254–258 °C (255–260 °C) [15]. IR (KBr): 1790 cm^{-1} ($\nu_{C=O}$). ^{1}H NMR (C_6D_6) δ: 0.11, 0.77 (2H, 2 × d, $J =$ 14.1 Hz, CH_2Cy); 0.32, 2.33 (4H, 2 × d, $J = 14.1$ Hz, CH_2Cy); 0.86 (6H, s, CH_3), 0.59 (3H, s, CH_3). *m/z* (FAB): 260 ($M+1$).

4.1.1.3. Cis,cis-1,3-di-(1′-(3″-carboxyaminopropyl)-3′-benzyloxy-2′-methyl-4′-pyridinone-yl)-5-carboxyl-1,3,5-

*trimethyl-cyclohexane (**5**)*. To a solution of **3** (1.7 g; 6.25 mmol) and Et_3N (2.6 ml, 18.8 mmol) in dry CH_2Cl_2 (50 ml), under a nitrogen atmosphere and in ice-water bath, a freshly prepared solution of **4** (0.572 g, 2.21 mmol) in dry CH_2Cl_2 (15 ml) was drop-wise added. The reaction mixture was then stirred at room temperature (r.t.) for 6 h. The solvent was removed under reduced pressure and the solid residue was purified by column chromatography on silica gel with CH_2Cl_2–MeOH (30/8) as the eluent. The isolated product was recrystallized from dry MeOH–MeCN ($\eta = 48\%$). M.p. 189–191 °C. IR (cm^{-1}, KBr): 2374 (ν_{NH+}); 1626, 1558 ($\nu_{C=O}$). ^1H NMR (CD_3OD) δ: 7.74 (2H, d, 6-HPy), 7.30 (10H, s, Ph), 6.31 (2H, d, 5-HPy), 5.01 (4H, s, CH_2Ph), 3.96 (4H, t, CH_2NPy); 3.07, 2.82 (4H, 2 × m, CH_2NCO), 2.72 (4H, d, CH_2Cy), 2.12 (6H, s, Me–Py), 1.72 (4H, t, $CH_2CH_2CH_2$), 1.17 (3H, s, CH_3), 1.08 (6H, s, CH_3Cy), 0.85 (2H, d, CH_2Cy). *m/z* (FAB): 767 ($M+1$).

*4.1.1.4. cis,cis-1,3-Di-(1′-(3″-carboxyaminopropyl)-3′-hydroxy-2′-methyl-4′-pyridinonyl)-5-carboxyl-1,3,5-trimethyl-cyclohexane, H_3L^1 (**1**)*. To a solution of **5** (0.2 g, 0.26 mmol) in dry MeOH (50 ml) was added 10% Pd/C (0.05 g) and the mixture was stirred under H_2 (1 atm) for 5 h at r.t. After filtration of the solid residue, the solvent was evaporated under reduced pressure and the product was obtained as a white powder, which was then recrystallized from MeOH–MeCN ($\eta = 80\%$). M.p. 180–182 °C. IR (cm^{-1}, KBr): 3285 (ν_{OH}), 2361 (ν_{NH+}); 1629, 1568 ($\nu_{C=O}$). ^1H NMR (MeOD) δ: 7.65 (2H, d, 6-HPy), 6.31 (2H, d, 5-HPy), 3.95 (4H, t, CH_2NPy), 3.04, 2.86 (2 × 2H, 2 × m, CH_2NCO), 2.72 (4H, d, CH_2Cy), 2.343 (6H, s, Me–Py), 1.77 (4H, t, $CH_2CH_2CH_2$), 1.17 (3H, s, CH_3Cy), 1.08 (6H, s, CH_3Cy), 0.85 (2H, d, CH_2Cy). *m/z* (FAB): 587 ($M+1$). *Anal.* Calc. for $C_{30}N_4H_{42}O_8 \cdot 3H_2O$: C, 56.27; H, 7.50; N, 8.75. Found: C, 56.6; H, 7.58; N, 8.42%.

*4.1.2. Synthesis of the ligand HL^2 (or AcNPrHP) (**2**)*

*4.1.2.1. 1-(3′-Methylcarboxyaminopropyl)-3-benzyloxy-2-methyl-4-pyridinone (**6**)*. To a solution of 1-(3′-aminopropyl)-3-benzyloxy-2-methyl-4-pyridinone (0.46 g; 1.69 mmol) and *N*-methylmorpholine (0.17 g; 1.69 mmol) in dry MeOH (15 ml), cooled in a ice-water bath, was dropwise added a solution of acethylchloride (0.17 g; 2.20 mmol) in dry THF (10 ml). After the addition, the reactional mixture was left under stirring at r.t. for 3 h. The *N*-methylmorpholinium salt, formed during the reaction, was filtered off and the solvents were removed under reduced pressure. The obtained product was than purified by flash column chromatography on silicagel with CH_2Cl_2–MeOH (30:7) as the eluent. The pure product was isolated as a pale oil ($\eta =$ 47%). ^1H NMR (CD_3OD) δ: 7.63 (1H, d, 6-HPy), 7.26 (5H, s, Ph), 6.39 (1H, d, 5-HPy), 5.00 (2H, s, CH_2Bz), 3.90 (2H, t, CH_2NPy), 3.10 (2H, t, CH_2NH), 2.09 (3H, s, CH_3Py), 1.86 (3H, s, $CH_3C{=}O$), 1.76 (2H, q, $CH_2CH_2CH_2$). *m/z* (FAB): 315 ($M+1$).

*4.1.2.2. 1-(3′-Methylcarboxyaminopropyl)-3-hydroxy-2-methyl-4-pyridinone, HL^2 (**2**)*. To a solution of **6** (0.25 g; 0.80 mmol) in dry MeOH (10 ml) was added 10% Pd/C (0.08 g) and the mixture was stirred under H_2 (1.4 atm) for 4 h at r.t. After the solid residue filtration, the solvent was evaporated under reduced pressure and product was obtained as a pale solid. Recrystallization from dry MeOH–MeCN afforded the pure product as pale crystals ($\eta = 84\%$). M.p. = 135–136 °C. ^1H NMR (CD_3OD) δ: 7.53 (1H, d, 6-HPy), 6.30 (1H, d, 5-HPy), 3.98 (2H, t, CH_2NPy), 3.14 (2H, t, CH_2NH), 2.34 (3H, s, CH_3Py), 1.85 (3H, s, $CH_3C{=}O$), 1.79 (2H, q, $CH_2CH_2CH_2$). *m/z* (FAB): 225 ($M+1$). *Anal.* Calc. for $C_{11}N_2H_{16}O_3 \cdot 1.3H_2O$: C, 53.34; H, 7.57; N, 11.31. Found: C, 53.59; H, 7.69; N, 10.82%.

4.2. Potentiometric measurements

The potentiometric measurements were performed at 25 ± 0.1 °C with a MOLSPIN pH-Meter equipped with a Metrohm combined electrode and Mol-ACS microburette controlled by computer. The electrode system was calibrated by the method of Irving et al. [25], so that the pH-meter readings could be converted into hydrogen ion concentrations. Atmospheric CO_2 was excluded from the system with a purging stream of argon gas. The ligand concentration in the sample was 2.9×10^{-3} M (H_3L^1) and 1.6×10^{-3} M (HL^2) with ionic strength of 0.2 M (KCl) and 0.1 M (KNO_3), respectively. The concentration of the ligand stock solutions together with the protonation constants was determined from the potentiometric data by the use of the SUPERQUAD computer program [16].

The complexation studies were performed for each metal ion by potentiometric titrations, with 1:1 and 1:2 metal-ion:ligand ratios. The metal ions were provided from metal-ion stock solutions of the corresponding chloride or nitrate salts. The stability constants were determined using the computer program PSEQUAD [26].

The selection of the equilibrium models was based on the critical analysis of the weighted residuals and the statistical parameters (χ^2 and σ for the SUPERQUAD [27] and the fitting parameter for the PSEQUAD) as well as on graphical comparisons between the experimental and simulated potentiometric curves.. The fitting parameters obtained for the equilibrium models of each ligand–metal ion system were less than 2×10^{-3}.

4.3. Spectrophotometric measurements

All spectra were measured on a HP 8453 and a Lambda 9 Perkin–Elmer spectrophotometer at 25 °C

and at constant ionic strengths. Solutions of the metal complexes were generated in situ by addition of a standard metal ion solution to the ligand solution. The pH measurements were carried out using a 420A Orion pH-meter, equipped with an Orion 91-03 glass calomel combination electrode.

4.4. Partition coefficients

Octanol–water partition coefficients of the ligands were determined at physiological pH, at approximately 25 °C, as described previously [11]. Equal volumes (3 ml) of 2×10^{-4} M ligand solutions in octanol and water (2×10^{-3} M tris buffered solution, pH 7.4) were placed in a 20 ml screw-cap vial. The mixture was stirred for 18 h, allowed to stand for 3 h and then poured into an extraction funnel to separate the two phases. After adequate dilution of the samples, the species concentration was evaluated by UV spectrophotometry (using the 285–295 nm λ_{max} bands). The partition coefficients, D (or $\log D$), were obtained as the ratio of the ligand concentrations in the organic phase to that in the aqueous phase. Both the solvents used in all determinations (octanol and buffered water solution) were previously saturated in each other, by stirring the mixture for 18 h.

4.5. Other measurements

The ^{1}H NMR spectra were recorded on a Varian Unity 300 spectrometer at 25 °C. Chemical shifts are reported in ppm (δ) from internal reference tetramethylsilane (TMS) in organic solvents and sodium 3-(trimethylsilyl)-[2,2,3,3-$^2H_4$]propionate in D_2O solutions (DSS). The following abbreviations are used: d, duplet; s, singlet; t, triplet. Melting temperatures were measured with a Leica Galen III hot stage apparatus and are uncorrected. Elemental analysis was performed on a Fisons EA1108 CHNF/O instrument. Mass spectra were recorded on a VG TRIO-2000 GC/MS instrument.

Now we are extending our studies to the reactivity of the compounds $[ReOX_3(AsPh_3)_2]$ (X = Cl, Br) towards NO and here we present our results of the synthesis, spectroscopic and structural characterisation of the following complexes: $[ReBr_3(NO)(OAsPh_3)_2]$ (**1**), $[ReCl_3(NO)(OAsPh_3)_2]$ (**2**), $[ReCl_3(NO)(AsPh_3)_2]$-$[ReCl_4(AsPh_3)_2]$ (**3**) and $[ReCl_4(OAsPh_3)_2]$ (**4**).

We have also carried out the reactions of $[NBu_4]_2$-$[ReX_5(NO)]$ (X = Cl, Br) with an excess of triphenylarsine, which lead to $[ReCl_3(NO)(AsPh_3)_2][ReCl_4$-$(AsPh_3)_2]$ (**3**) and $[ReBr_3(NO)(AsPh_3)_2]$ (**5**), respectively.

Considering that $AsPh_3$ and $OAsPh_3$ molecules are replaced more readily than P- and N-donor ligands, these complexes are predicted to be very useful starting material in the synthesis of new rhenium nitrosyls [17–22].

2. Experimental

Triphenylarsine and NH_4ReO_4 were purchased from Aldrich Chemical Co. and used without further purification. The $[ReOX_3(AsPh_3)_2]$ and $[NBu_4]_2[ReX_5(NO)]$ (X = Cl, Br) complexes were synthesised according to the literature methods [23,24]. Gaseous NO, obtained in the reaction: $2NaNO_2 + 3H_2SO_4 + 2FeSO_4 \rightarrow 2NO + 2NaHSO_4 + Fe_2(SO_4)_3 + 2H_2O$, was purified by passing through washers with concentrated KOH solution and over solid NaOH. Solvents were dried and deoxygenated prior to use in the usual way. The reaction, all preparations and the recrystallisation were performed under argon atmosphere.

2.1. Synthesis of *1*

NO was passed through a vigorously stirred and refluxing solution of $[ReOBr_3(AsPh_3)_2]$ (1.05 g, 1 mmol) in CH_2Cl_2, tetrahydrofurane or C_6H_6 (40 cm^3).

The reaction was carried out for 4–5 h. The colour changed gradually from bright green to dark green. Then the resulting solution was evaporated to the volume of 10 cm^3. The green precipitate was formed by an addition of 40 cm^3 of EtOH and after 15 min it was filtered off. The product was washed with cold ether and dried in vacuo. The yield of **1** does not depend on sort of solution and it equals to 0.88 g (0.80 mmol).

Anal. Calc. for $C_{36}H_{30}As_2Br_3O_3NRe$ (**1**): C, 39.29; H, 2.75; N, 1.27. Found: C, 39.24; H, 2.72; N, 1.29%.

2.2. Synthesis of *2, 3 and 4*

The reaction of gaseous NO with $[ReOCl_3(AsPh_3)_2]$ (0.92 g, 1 mmol) in a CH_2Cl_2, tetrahydrofurane or C_6H_6 solution (40 cm^3) was carried out in the same manner as for **1**, but a mixture of the three products was isolated and the complexes **2**, **3** and **4** were separated by recrystallisation. At room temperature complex **3** does not dissolve in MeCN but **2** and **4** compounds dissolve in CH_3CN readily and **4** precipitates from the solution first. Compound **3** was recrystallised from CH_2Cl_2. The yield of **2**, **3** and **4** depends on the kind of the reaction solution; in CH_2Cl_2 and tetrahydrofurane—**2** (75%), **3** and **4** (3%); in C_6H_6—**2** (70%), **3** and **4** (5%).

Anal. Calc. for $C_{36}H_{30}As_2Cl_3O_3NRe$ (**2**): C, 44.71; H, 3.13; N, 1.45. Found: C, 44.64; H, 3.16; N, 1.41%. Calc. for $C_{72}H_{60}As_4Cl_7ONRe_2$ (**3**): C, 46.11; H, 3.22; N, 0.75. Found: C, 46.24; H, 3.25; N, 0.87%. Calc. for $C_{36}H_{30}$-$As_2Cl_4O_2Re$ (**4**): C, 44.46; H, 3.11. Found: C, 44.57; H, 3.15%.

2.3. Synthesis of *3*

A mixture of $[NBu_4]_2[Re(NO)Cl_5]$ (1 g, 1.14 mmol) and $AsPh_3$ (5 g, 0.016 mol) in EtOH (30 cm^3) was refluxed for 6 h. The formed dark red precipitate was filtered and washed with ether. Yield: 65%.

2.4. Synthesis of *5*

A mixture of $[NBu_4]_2[Re(NO)Br_5]$ (1 g, 0.91 mmol) and $AsPh_3$ (5 g, 0.016 mol) in EtOH (30 cm^3) was refluxed for 6 h. The formed dark red precipitate was filtered and washed with ether. Yield: 70%.

Anal. Calc. for $C_{36}H_{30}As_2Br_3ONRe$ (**5**): C, 40.47; H, 2.83; N, 1.31. Found: C, 40.41; H, 2.87; N, 1.34%.

2.5. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of potassium bromide pellets. Electronic spectra were measured on a Beckman 5240 spectrophotometer in the range 800–220 nm in deoxygenated CH_2Cl_2 solution.

EPR spectra in the X-band ($\nu \approx 9.5$ GHz) at $T = 295$ K have been recorded for CH_2Cl_2 solutions of complexes **1** and **5** and for **5** in the solid state, using a Bruker EMX spectrometer. About 10^{-3} M solutions of **1** and **5** in CH_2Cl_2 were used.

Magnetic susceptibilities were measured at 296 K by the Faraday method.

Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.6. Crystal structure determination and refinement

The crystals of **1**, **3**–**5** suitable for X-ray structure determination were obtained by slow evaporation from MeCN solutions. The X-ray intensity data were collected on a Kuma KM-4 diffractometer (compounds **3** and **5**) with ω–2θ scan mode and on a KM-4-CCD automatic diffractometer equipped with CCD detector

(compounds **1** and **4**), with ω scan mode, 30 s exposure time was used and a half of the Ewald sphere was collected. The unit cell parameters were determined from least-squares refinement of the setting angles from a number of the strongest reflections. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization, empirical absorption corrections (compounds **3** and **5**) and numerical absorption corrections [25] (compounds **1** and **4**) were applied. The structures were solved by means of the Patterson and direct methods and subsequently completed by difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms of the phenyl rings were treated as 'riding' on their parent carbon atoms [d(C–H) = 0.96 Å] and assigned isotropic temperature factors equal to 1.2 times the value of the equivalent temperature factor of the parent carbon atom. SHELXS-97 [26a], SHELXL-97 [26b] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

3. Results and discussion

It is known that reactions of high oxidation state metal halides with gaseous nitric oxide usually lead to low-valent nitrosyl complexes and it is accompanied with the elimination of nitrosyl halides [28,29].

The reaction of $[ReOCl_3(AsPh_3)_2]$ with NO leads to the complex **2** (the main product) and two by-products (**3** and **4**), whereas only one compound (complex **1**) was isolated in the reaction of the bromine oxocomplex with nitric oxide.

The difference in the course of the reactions $[ReOX_3(AsPh_3)_2]$ (X = Cl, Br) with NO depending on the kind of halogen in the starting oxocomplex can be explained considering that NOX are relatively unstable

gaseous compounds under normal conditions and that NOBr is much less stable than NOCl.

The suggested course of the main (**2**) and minor (**3** and **4**) product formation is given in the following scheme:

$$[ReOCl_3(AsPh_3)_2] + 3NO \rightarrow [ReCl_3(NO)(OAsPh_3)_2] + N_2O \quad (1)$$

$$[ReOCl_3(AsPh_3)_2] + 4NO \rightarrow [ReCl_2(NO)_2(AsPh_3)_2] + NOCl + NO_2 \quad (2)$$

$$[ReCl_2(NO)_2(AsPh_3)_2] + 2NOCl \rightarrow [ReCl_4(OAsPh_3)_2] + 2N_2O \quad (3)$$

$$2[ReOCl_3(AsPh_3)_2] + NOCl \rightarrow [ReCl_3(NO)(AsPh_3)_2] \; [ReCl_4(AsPh_3)_2] + O_2 \quad (4)$$

The $[ReCl_2(NO)_2(AsPh_3)_2]$ compound has not been isolated, but the analogous dinitrosyl $[ReCl_2(NO)_2(PPh_3)_2]$, obtained in the reaction of $[ReOCl_3(PPh_3)_2]$ with nitric oxide, has been characterised [7].

The proposed above mechanism of the reaction of $[ReOCl_3(AsPh_3)_2]$ with NO can be confirmed by the higher yields of by-products in benzene solution than in CH_2Cl_2 or THF. Due to the formation of the $ClNO \cdot C_6H_6$ complex, the concentration of nitrosyl chloride in benzene is much higher than in dichloromethane or tetrahydrofurane, where $ClNO \cdot CH_2Cl_2$ and $ClNO \cdot THF$ are not formed [30,31].

As in the reaction of $[ReOBr_3(AsPh_3)_2]$ with NO only one product has been isolated—$[ReBr_3(NO)(OAsPh_3)_2]$ (**1**)—it can be assumed that the unstable NOBr is not formed and the reactions similar to Eqs. (2)–(4) do not occur.

The reaction equation explains the formation of complex **5**:

$$[NBu_4]_2[ReBr_5(NO)] + 2AsPh_3 \rightarrow [ReBr_3(NO)(AsPh_3)_2] + 2[NBu_4]Br$$

whereas the reaction of $[NBu_4]_2[ReCl_5(NO)]$ with triphenylarsine goes as follows:

$$2[NBu_4]_2[ReCl_5(NO)] + 4AsPh_3 \rightarrow [ReCl_3(NO)(AsPh_3)_2] \; [ReCl_4(AsPh_3)_2] + NOCl + 2[NBu_4]Cl$$

The yield of the product in the reactions of $[NBu_4]_2$-$[ReX_5(NO)]$ with $AsPh_3$ depends on:

- mass ratio of $[NBu_4]_2[ReX_5(NO)]$ to triphenylarsine and it is the highest when it is equal to 1:5.
- reaction time; the yield drops considerably when the reaction is carried out for a time shorter than 6 h.

The complex **1** crystallises in the monoclinic space group $P2_1/n$ and its structure consists of discrete and well-separated monomers. Fig. 1 shows the molecular structure of this compound. The rhenium atom is in a distorted octahedral environment with a linear N–O group *trans* to one of the $OAsPh_3$ ligands, two mutually

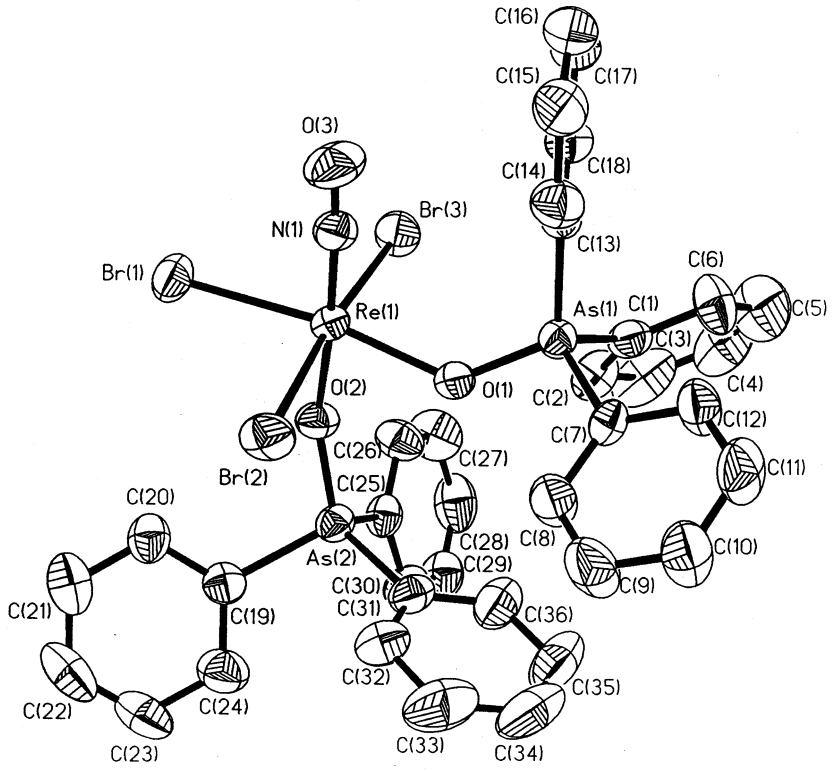

Fig. 1. The molecular structure of **1**. The thermal ellipsoids are drawn at the 50% probability level.

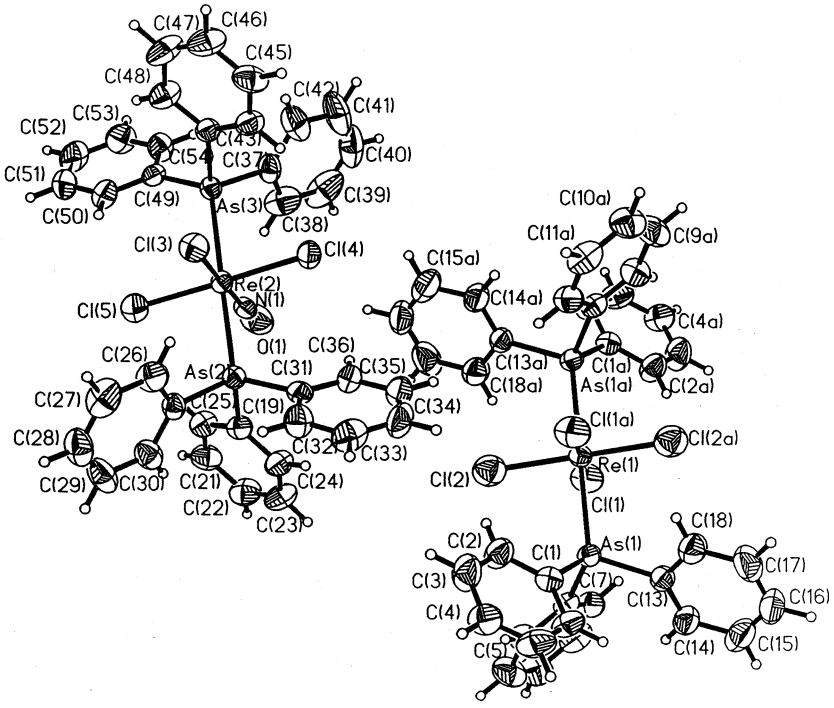

Fig. 2. The molecular structure of **3**.

cis $OAsPh_3$ molecules and three bromine ligands in *meridional* geometry. The major distortion in the geometry, which is an increase in the N(1)–Re(1)–O(1) angle, is caused by the presence of a multiply bonding ligand (Re–NO) and sizeable steric interactions of two mutually *cis* $OAsPh_3$ molecules.

The asymmetric unit of **3**, which crystallises in the triclinic space group $P\bar{1}$, consists of one molecule—$[ReCl_3(NO)(AsPh_3)_2]$—with all atoms in general positions and half the $[ReCl_4(AsPh_3)_2]$ molecule with the rhenium atom on a centre of symmetry. Due to the requirements of the symmetry, the atoms Re(1), Cl(1), Cl(2) and the symmetry equivalents of the two chlorine atoms of the $[ReCl_4(AsPh_3)_2]$ complex lie in one plane and the coordination around the central atom is a square bipyramid extended along the Re–As bonds. Three mutually meridional chlorine atoms, two $AsPh_3$ ligands *trans* to each other and the linear nitrosyl group octahedrally surround the rhenium atom in the $[ReCl_3(NO)(AsPh_3)_2]$ complex. The departure from the ideal octahedron—the angles between *cis*-ligands vary between 85.31° and 95.38°, and the *trans*-angles are between 175.17° and 178.31°—appears to be due to the electronic factors and steric interactions with the NO ligand and it is commonly observed in octahedral complexes containing a multiply bonding ligand [32–34]. The relative orientation of the $[ReCl_4(AsPh_3)_2]$ and $[ReCl_3(NO)(AsPh_3)_2]$ molecules is depicted in Fig. 2.

The complex **4** belongs to the *C*2/*c* space group and the molecular structure of **4** is shown in Fig. 3. The rhenium atom in **4** occupies a special position *e* of the space group *C*2/*c* with multiplicity 4 and site symmetry 2. Atom O(1) shows signs of disorder with a particularly high value of one of the displacement parameters, but all attempts to model the disorder failed. It can be suggested that the disorder is dynamical in character. The atom Cl(2) shows multipositional disorder, but invoking this model did not improve the quality of refinement, therefore the model was not applied. The chlorine atoms Cl(2) and its symmetry equivalent Cl(2A) and two *cis*-oxo atoms of OAsPh3 molecules, O(1) and O(1A) hold the equatorial positions. The Cl(1) and its symmetry equivalent Cl(1A) ions occupy the apical positions. The deviations from an ideal octahedron (the angles between *cis*-ligands vary between 84.1° and 95.06°, and the *trans*-angles are between 171.33° and 178.4°) are caused by steric interactions of two mutually *cis* $OAsPh_3$ molecules.

The structure of **5** consists of discrete and well-separated monomers. The numbering scheme of **5** is shown in Fig. 4. The complex has pseudooctahedral geometry with *trans* arsine ligands, *meridional* bromo ligands and a linear nitrosyl group. The rhenium, NO and bromine species are sited on a crystallographic twofold axis, therefore only half of the molecule is independently located in the asymmetric unit. The three mutually perpendicular coordination planes are well defined and there are no significant intermolecular contacts. The angles between *cis*-ligands vary between 87.83° and 92.14° (Table 2), and the *trans*-angles are between 177.88° and 180°.

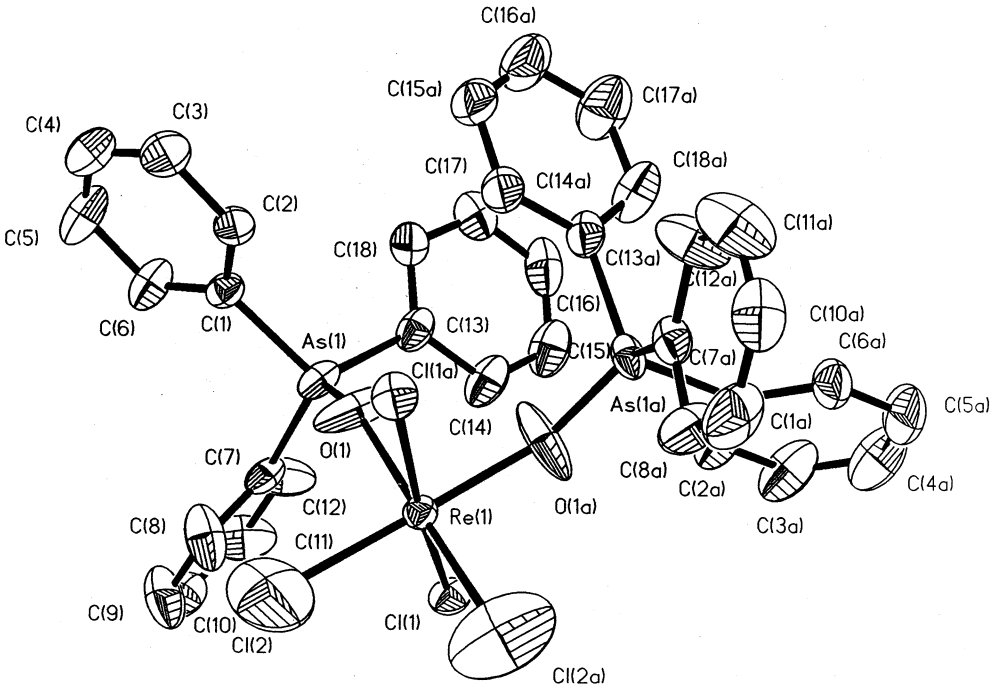

Fig. 3. The molecular structure of **4**.

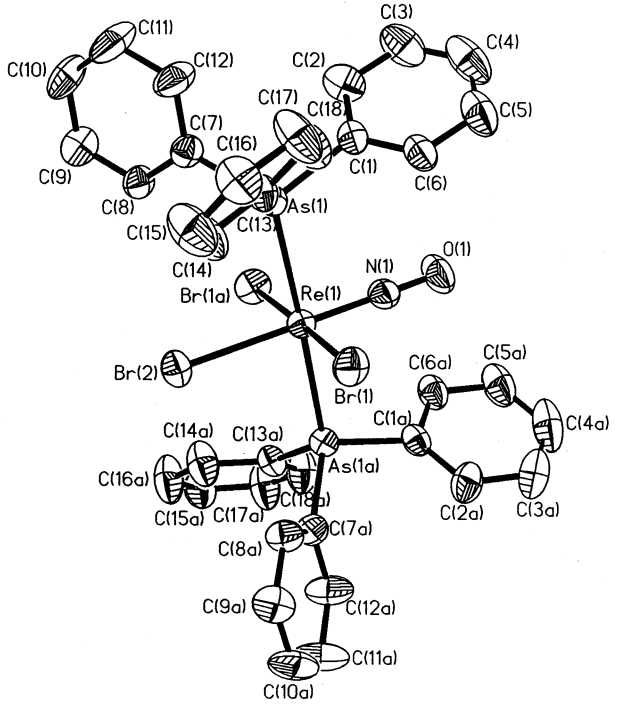

Fig. 4. The molecular structure of **5**.

The complex **5** is isomorphous with $[ReX_3(NO)(PPh_3)_2]$ (X = Cl and Br) [14,16], $[ReOCl_3(PPh_3)_2]$ [35] and several similar ruthenium nitrosyl compounds [36,37]. The packing of the two bulky triphenylarsine or triphenylphosphine ligands, which are *trans* to each other, seems to govern the solid-state structure of these complexes. In fact, the *C*2/*c* space group with four formula units per unit cell is the preferred one for such neutral pseudooctahedral bis(triphenylphosphine) or bis(triphenylarsine) complexes when the co-ordination plane perpendicular to the P–P or As–As vector contains three or four ligands of low steric bulk, which will not cause unusual intermolecular interactions.

The *trans*-arrangement of the two bulky triphenylarsine molecules in **3** and **5** complexes, connected with sterically demanding nature of the arsine ligands, causes the *cis*-location of the nitrosyl group, with respect to the $AsPh_3$ molecules (π-acid ligands). This is also supported by the electronic influence of the multiply bonded ligand, which forces the metal nonbonding d electrons to lie in the plane perpendicular to the M–NO bond axis. This general rule appears to hold for isonitrile, carbonyl, olefin, acetylene, thioether and often phosphine ligands [38–40].

Table 1 presents crystal data and structural refinement for compounds **1**, **3**, **4** and **5**. The most important bond lengths and angles for compounds **1**, **3**, **4** and **5** are reported in Table 2. The Re–NO and N–O bond lengths and the values of Re–N–O angles for complexes **1**, **3** and **5**, summarised in Table 3, confirm the linear coordination of the nitrosyl group and are comparable with values previously found by others (Table 3). For nitrosyl complexes containing two *trans* triphenylarsine molecules, elongation of the Re–halogen bond *trans* to the linear nitrosyl group is observed: the Re–Br(2) bond length at 2.5578(19) Å in **5** is longer than Re–Br(1) by about 0.05 Å and in $[ReCl_3(NO)(AsPh_3)_2]$ the Re–Cl(3)

837	850		840		ν(As=O)
739	739	741	740	737	δ(C–C out of the plane)
688	689	692	690	691	δ(C–C in the plane)
628	625				δ(C–C in the plane)
480	481	471		474	ν(Re–N)

bond length at 2.376(2) Å is longer than Re–Cl(4) and Re–Cl(5) by about 0.04 Å. A similar trend is observed in $[ReX_3(NO)(PPh_3)_2]$ (X = Cl, Br) complexes [14,16].

The Re–As distances 2.6023(10) Å in $[ReCl_4(AsPh_3)_2]$, 2.6060(11) and 2.6186(11) Å in $[ReCl_3(NO)(AsPh_3)_2]$ and 2.5946(9) Å in **5** are considerable longer than those found in the rhenium complexes with a *cis* arrangement of arsine ligands: 2.557(2) and 2.541(2)Å in $[ReO_2(dadpe)_2]^+$ and 2.532(1), 2.552(1), 2.541(1) and 2.546(1) Å in $[ReN(dpae)_2Cl]^+$ [43].

The Re–$OAsPh_3$ and the As–O bond lengths in complexes **1** and **4** (Table 2) are in good agreement with values found for $[ReOBr_3(AsPh_3)(OAsPh_3)]$ (Re–O = 2.010(7), As–O = 1.675(7) Å) and $[ReOCl_3(AsPh_3)(OAsPh_3)]$ (Re–O = 2.019(8), As–O = 1.643(9) Å [44]). In complex **4**, the Re–Cl(2) distance at 2.292(7) Å is shorter than Re–Cl(1) by about 0.08 Å as a result of its *trans* position to the $OAsPh_3$ molecule.

The bond valences were computed as $v_{ij} = \exp[(R_{ij} - d_{ij})/0.37]$ [47–49], where R_{ij} is the bond-valence parameter (in the formal sense R_{ij} is the single-bond length between *i* and *j* atoms) [50]. The R_{Re-O}, R_{Re-N}, R_{Re-Br}, R_{Re-Cl} values were taken as 1.97, 2.06, 2.45 and 2.23 [47], respectively. The computed bond valences of rhenium in compound **1** are $v_{Re-O} = 0.79$, 0.80, $v_{Re-Br} = 0.80$, 0.81, 0.85; $v_{Re-N} = 2.32$ v.u. (valence units), in compound **3** are $v_{Re-As} = 0.81$, 0.84, $v_{Re-Cl} =$ 0.67, 0.71, 0.75, 0.74, 0.76, 0.81, 0.85; $v_{Re-N} = 1.93$ v.u., in compound **4** are $v_{Re-O} = 0.92$, $v_{Re-Cl} = 0.68$, 1.04 v.u. and in compound **5** are $v_{Re-As} = 0.86$, $v_{Re-Br} = 0.74$, 0.86; $v_{Re-N} = 2.37$ v.u. The weakest bonds are Re–Cl bonds in compound **3** and the strongest are Re–N bonds (formally these bonds can be considered as double bonds).

The molecules of **1** are linked to form dimers via C(10)–H(10A)···Br(2#$-x$, $-y+2$, $-z+1$) intermolecular weak hydrogen bonds [51] (D···A distance equals 3.603(8) Å and D–H···A angle 137.4°). One more C(26)–H(26A)···O(2) weak intramolecular hydrogen bond (D···A distance equals 2.992(8) Å and D–H···A angle 112.9°) exists in the molecule, which provides additional conformational stabilisation. The conformations of molecules of compound **3** are stabilised by six C–H···Cl weak intramolecular hydrogen bonds (D···A distances vary from 3.31(1) to 3.67(1) Å and D–H···A angles vary from 112.9° to 149.9°) and one C(38)–H(38A)···N(1) weak intramolecular hydrogen bond (D···A distance equals 3.34(1) Å and D–H···A angle 127.2°). The molecules of **4** are assembled via C(11)–H(11A)···Cl($1-x+1/2$, $-y+1/2$, $-z+1$) weak intermolecular hydrogen bonds (D···A distance equal to 3.59(1) Å and D–H···A angle 145.9°) to give an infinite hydrogen bonded chain created by perpendicular rings in a spiro arrangement. Only one weak intramolecular hydrogen bond, C(8)–H(8A)···Br($1-x$, y, $-z+1/2$) with a D···A distance equal to 3.507(9) Å and D–H···A angle 133.1°, can be found in compound **5**, providing slight stabilisation to the molecule.

Table 4 contains assignments of characteristic bands in the IR range for **1**–**5** compounds.

For $[ReX_3(NO)L_2]$ complexes with an identical ligand L, the NO stretching frequency of the chloro-compounds is lower than that of the corresponding bromo-complexes, which is in accordance with the greater π-acceptor character of the bromo ion than the chloro one. A neutral group, L, also causes a variation in the NO stretching frequency. The higher frequencies are found for complexes containing $AsPh_3$ than $OAsPh_3$. The difference between ν_{NO} of bromo- and chloronitrosyl is much higher for complexes containing arsines (**3** and **5**) than for complexes containing arsine oxides (**1** and **2**), which results from the different ligands' arrangement around the rhenium atom in these complexes. The presence of two strong bands at about 890 and 840 cm^{-1} in the IR spectra of complexes **1**, **2** and **4** confirms the *cis* geometry of the two coordinated $OAsPh_3$ molecules.

Complexes **1**, **2**, **4** and **5** are paramagnetic compounds with a magnetic moment corresponding to one unpaired electron.

ε = molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$).
[a] Covered by $\pi^b_{Re-Cl} \rightarrow d_{xz}$ transition.

Table 6
Values of ligand field parameters for **1**, **2**, **4** and **5**

Complex	Ligand field parameter		
	Dq (cm^{-1})	Ds (cm^{-1})	Dt (cm^{-1})
$[ReBr_3(NO)(OAsPh_3)_2]$	3690	−3741	−449
$[ReCl_3(NO)(OAsPh_3)_2]$	3690	−5104	−111
$[ReCl_4(OAsPh_3)_2]$	3400	−5272	−143
$[ReBr_3(NO)(AsPh_3)_2]$	3521	−5952	1

The positions and molar absorption coefficients of electronic bands for complexes **1**–**5** and the electronic transitions assigned to the bands are shown in Table 5. Based on the data of Table 5, the values of the ligand field parameters Dq, Ds and Dt have been defined and the energies of molecular orbitals for the complexes have been estimated. The values of ligand field parameters are listed in Table 6, and simplified MO diagrams for complexes **1**, **2**, **4** and **5** are presented in Fig. 5.

Intensities of $\pi^{b}_{C6H5} \rightarrow 4d_{As}$ transitions in complexes containing arsine oxides are significantly higher in

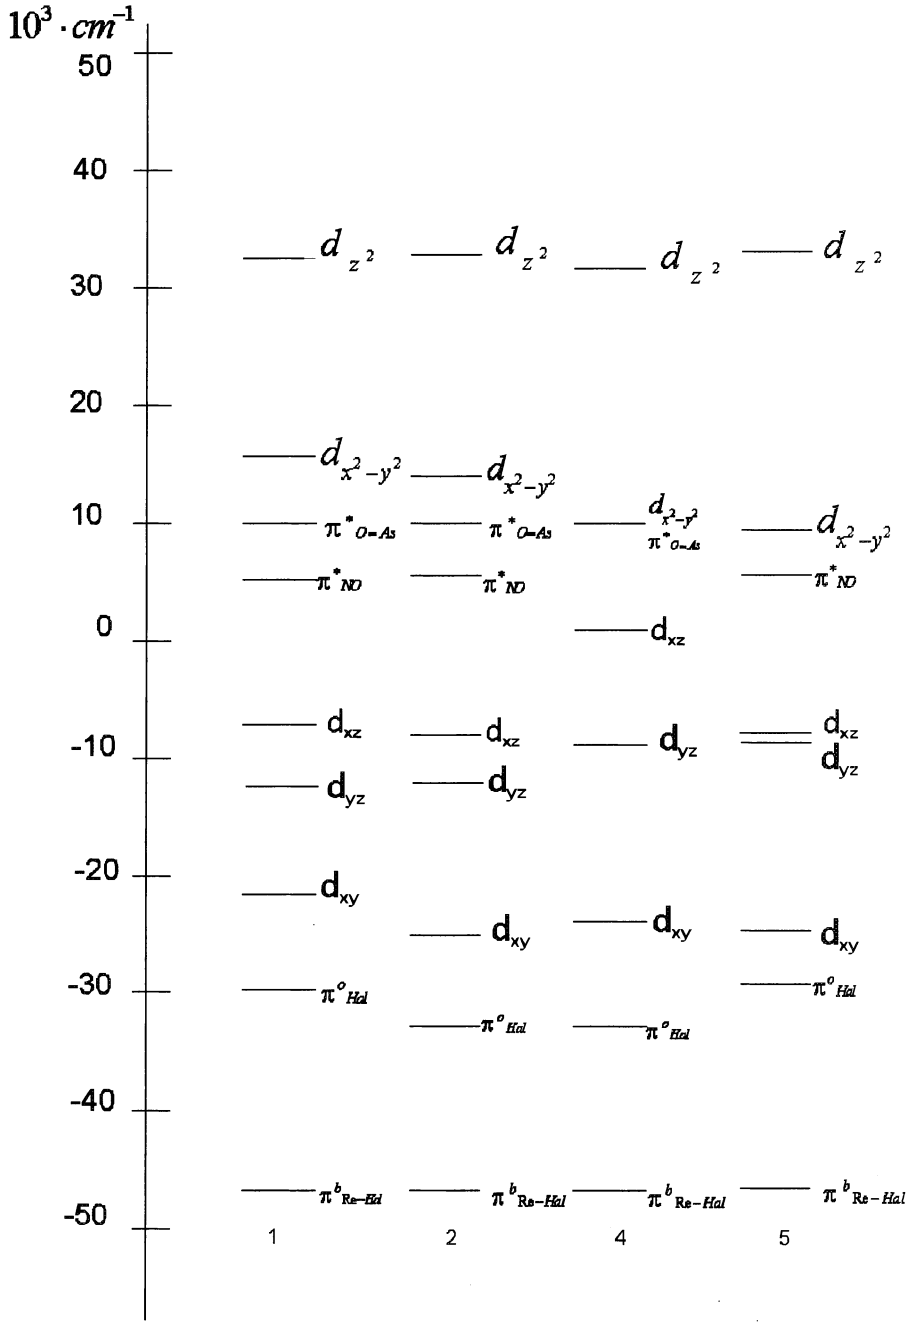

Fig. 5. The simplified molecular orbitals diagrams for **1**, **2**, **4** and **5**.

comparison with complexes containing arsines, which is connected to:

- As⇒O electron density transfer,
- lack of a Re→As transition, which leads to an increase in As acceptor ability towards π_{C6H5} electrons.

Significant intensities of bands:

- at 23 900, 27 740, 36 900 and 37 900 cm^{-1} in **1**,
- at 36 900 cm^{-1} in **2**
- at 36 100 cm^{-1} in **3**
- at 34 000 cm^{-1} in **4**

result from a superposition of charge transfer transitions and d→d transitions.

The lower intensity of the $d_{xy} \rightarrow \pi^*_{NO}$ transition in complexes containing arsine oxides in comparison with complexes containing arsines results from the presence of an O=As acceptor group in the *xy* plane, which is competitive towards NO. That is why in complexes containing an O=As group, the N–O bond is shorter and the Re–N bond is longer than in complexes containing $AsPh_3$. High electron density on oxygen atoms from the O–As group also results in an effective σ_{Re-O} bonding and simultaneously an increase in electron density on the Re^{II} ion. The last fact increases its π-donor ability towards Br(1), resulting in a shortening of the Re–Br(1) bond in comparison with the Re–Br(3) bond.

The comparatively high intensity of the bands attributed to the $d_{xy} \rightarrow \pi^*_{NO}$ transition proves the linear NO coordination (lack of electron density in π^*_{NO}). The low intensity of the $d_{yz} \rightarrow \pi^*_{NO}$ and $d_{xz} \rightarrow \pi^*_{NO}$ transition is caused by the symmetry of these orbitals and NO to each other. Based on the presented simplified MO diagrams and absorption band analysis, one can conclude that complexes **1**, **2** and **5** have electron configurations $(d_{xy})^2(d_{yz})^2(d_{xz})^1$, and complex **4**—$(d_{xy})^2(d_{yz})^1$. In **3** both these configurations exist simultaneously.

The Dq parameter for the $[ReBr_3(NO)(AsPh_3)_2]$ complex is slightly higher (by 2638 cm^{-1}) than Dq for the $[ReBr_3(NO)(PPh_3)_2]$ complex. This increase in its value is connected with the increase in the degree of covalency of the Re–As bonds (higher π-acceptor ability of As compared to P) and Re–N bonds. The higher π-acceptor ability of As manifests also in an increase in molar extinction coefficient of the band resulting from $\pi^b_{C_6H_5} \rightarrow 4d_{As}$ and in consequence in an elongation of C–C bonds in $AsPh_3$ compared to PPh_3. The small elongation of the Re–As bond (by only 0.054 Å) compared to the Re–P bond, in spite of the fact that $r_{As^{-3}}$ is longer (by 0.1 Å) also proves the higher acceptor ability of As in comparison to P. The decrease in electron density at the rhenium atom, connected with $5d_{xz,yz} \rightarrow 4d_{As}$ electron transitions, increases the probability of charge transfer from Br^- to $5d_{Re}$ (the band at 21 598 cm^{-1}; other authors observed the $Br^- \rightarrow Re$ transition at 23 830 cm^{-1}) [45,46]. Therefore, it leads to an increase in the probability of the $d_{xy} \rightarrow \pi^*_{NO}$ electron transition and causes an abridgement of the Re–N bond (by 0.015 Å) and an elongation of the N–O bond (by 0.057 Å) in the $[ReBr_3(NO)(AsPh_3)_2]$ complex compared to the $[ReBr_3(NO)(PPh_3)_2]$ complex. Replacing PPh_3 with $AsPh_3$ in nitrosyl Re(II) complexes causes a change in charge distribution in complex molecules.

Spectroscopic data confirm EPR signals in the solid phase of **5** and in methylene chloride solutions of **1** and **5** (Figs. 6–8). The solid phase signal clearly confirms the axial symmetry of complex **5**, characterised by $g_{\|} =$

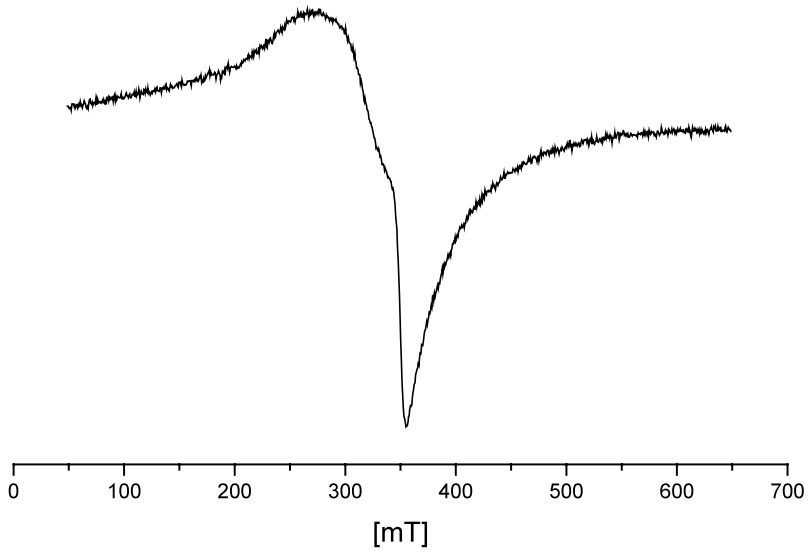

Fig. 6. Experimental X-band EPR spectrum of **5** in the solid phase at $T = 295$ K.

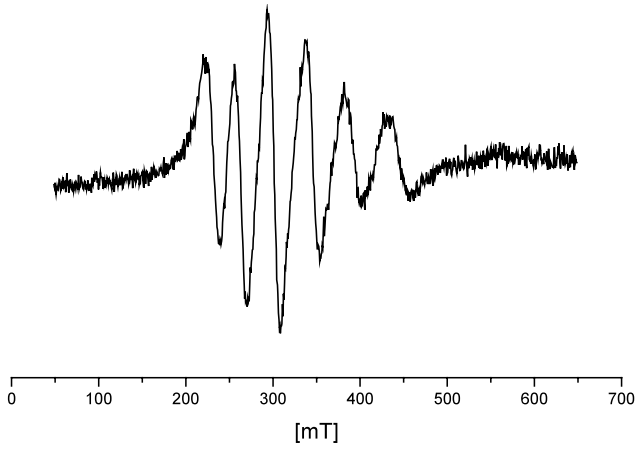

Fig. 7. Experimental X-band EPR spectrum of **3** in CH_2Cl_2 at $T = 295$ K.

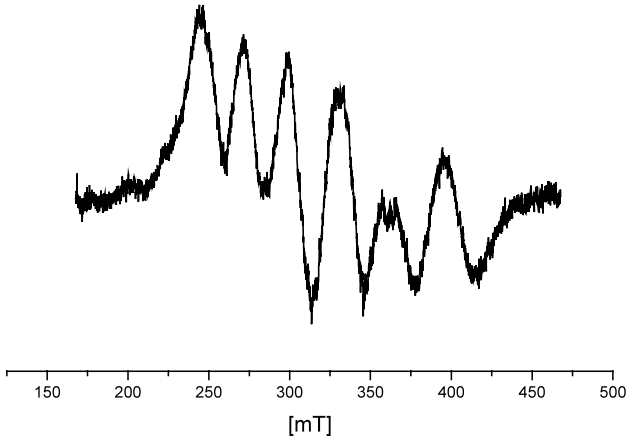

Fig. 8. Experimental X-band EPR spectrum of **5** in CH_2Cl_2 at $T = 295$ K.

2.4057, $g_{\perp} = 2.0412$ and $g_{av} = 2.1624$ values. EPR signals of methylene chloride solutions of **1** and **5** also have axial symmetry. Complex **5** is characterised by $g_{av} = 2.1942$ and $A_{av} = 31.3$ mT values, and complex **1**—by $g_{av} = 2.2192$ and $A_{av} = 26.7$ mT values. These facts confirm an interaction of an unpaired electron $(d_{xz})^1$ with the axial ligands. If the unpaired electron was on the d_{xy} orbital, the values of g_{av} in complexes **1** and **5** would be in reverse relation. The higher g_{av} value in **1** results from a higher spin-orbital contribution of axial Br^- ligands ($\lambda_{Br^-} = 2460\ cm^{-1}$) into $g_{||}$, compared to $AsPh_3$ ligands with significantly lower λ_{As} value. The lower A_{av} value of complex **1** results from covalency of the Re–Br bond, confirmed by $r_{Re-Br} = 0.251$ nm. The Re–Br distance is shorter than the sum of the ion radii $r_{Re}^{2+} + r_{Br^-}$ by 0.041 nm.

The sextet signal of complexes **1** and **5**, resulting from an interaction of the unpaired electron with the nuclear spins of ^{185}Re and ^{187}Re, indicates a small delocalisation of this electron towards the ligands. Quadruple moments of ^{14}N, ^{75}As, ^{79}Br, ^{81}Br, ^{185}Re and ^{187}Re, broadening the signals, cause superposition of hyperfine structure components.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 188153–56 for compounds $[ReBr_3(NO)(AsPh_3)_2]$, $[ReCl_3(NO)(AsPh_3)_2]$-$[ReCl_4(AsPh_3)_2]$, $[ReCl_4(OAsPh_3)_2]$, $[ReBr_3(NO)$-$(OAsPh_3)_2]$. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Acknowledgements

We wish to express our thanks to Danuta Kwapulińska for recording EPR spectra. X-ray crystallography of compounds **1** and **4** was financed by statutory funds allocated by the State Committee for Scientific Research to the Institute of General and Ecological Chemistry, Technical University of Łódź.

We have employed as starting material the nickel binuclear compound $[\{Ni(dien)(H_2O)\}_2(\mu\text{-ox})](PF_6)_2\cdot 2H_2O$ owing to the lability of their water molecules, which may be replaced by a plethora of ligands, such as the pseudohalide ligands: N_3^-, NCO^-, NCS^-, and, due to the attractiveness of polymers comprised of M–CN–M′ units, CN^- and the cyanocomplexes $[M(CN)_n]^{y-}$, M: Ni, Pd, Pt, Cu, and Au. In this paper we report the synthesis, crystal structure, magnetic properties and DFT calculations of the molecular complexes of type $[\{Ni(dien)\}_2(\mu\text{-ox})\{(\mu\text{-}M(CN)_4)\}]$ where M = Ni(II) [7a], Pd(II) and Pt(II).

2. Experimental

Microanalyses of carbon, nitrogen and hydrogen were performed on a LECO CHNS-932 analyser. IR spectra were recorded on a Nicolet 740 FTIR spectrometer using KBr pellets. All reagents were commercial grade chemicals and were used without further purification. The $[\{Ni(dien)(H_2O)\}_2(\mu\text{-ox})](PF_6)_2\cdot 2H_2O$ complex was synthesised according to the literature method [7g].

2.1. Synthesis

A general procedure was followed in the synthesis of the three compounds: two aqueous solutions of $K_2[M(CN)_4]$ (0.06 mmol) and $[\{Ni(dien)(H_2O)\}_2(\mu\text{-ox})](PF_6)_2\cdot 2H_2O$ (0.06 mmol) were mixed. The initially formed pink precipitate was removed by filtration, and the concentrated solution was allowed to cool slowly to room temperature to obtain blue single crystals of the corresponding compounds, yield 15% for **1**, 25% for **2** and 40% for **3**.

2.1.1. $[\{Ni(dien)\}_2(\mu\text{-ox})\{(\mu\text{-}Pd(CN)_4)\}]$ (**2**)

FTIR (KBr disk, cm^{-1}): ν(C≡N) 2132m, 2159w. *Anal*. Found C, 26.9; H, 4.0; N, 22.3. Calc. for $C_{14}H_{26}N_{10}Ni_2O_4Pd$: C, 27.02; H, 4.21; N, 22.51%.

2.1.2. $[\{Ni(dien)\}_2(\mu\text{-ox})\{(\mu\text{-}Pt(CN)_4)\}]$ (**3**)

FTIR (KBr disk, cm^{-1}): ν(C≡N) 2132m, 2163w, 2173w. *Anal*. Found C, 23.4; H, 3.5; N, 19.2. Calc. for $C_{14}H_{26}N_{10}Ni_2O_4Pt$: C, 23.65; H, 3.69; N, 19.70%.

2.2. X-ray crystallography

Data collection for prismatic blue single crystals of **2** and **3** were performed on a STOE IPDS diffractometer, equipped with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Indexes and unit-cell refinement were based on all observed reflections from 10 frames collected with an oscillation range of 1°/frame and exposure time of 3 min/frame. Experimental details and crystal data for both compounds are listed in Table 1. The atomic scattering factors were taken from the International Tables for X-ray Crystallography [8]. The data were processed and corrected for Lp effects. Analytical absorption corrections were applied. Both structures were solved by direct methods (DIRDIF-96) [9] and refined by full-matrix least-squares refinement of F^2 [10]. All non-hydrogen atoms were anisotropically refined except cyanide atoms in compound **3**. Hydrogen atoms were placed in calculated positions and refined with a riding model. The calculations were performed using the WINGX crystallographic software package [11].

[a] Relevant data from Ref. [7a] for compound **1**: space group *I2/a*, $a = 13.133(1)$, $b = 11.644(1)$, $c = 14.154(1)$ Å, $\beta = 97.13(1)°$, $V = 2147.7(5)$ Å^3.

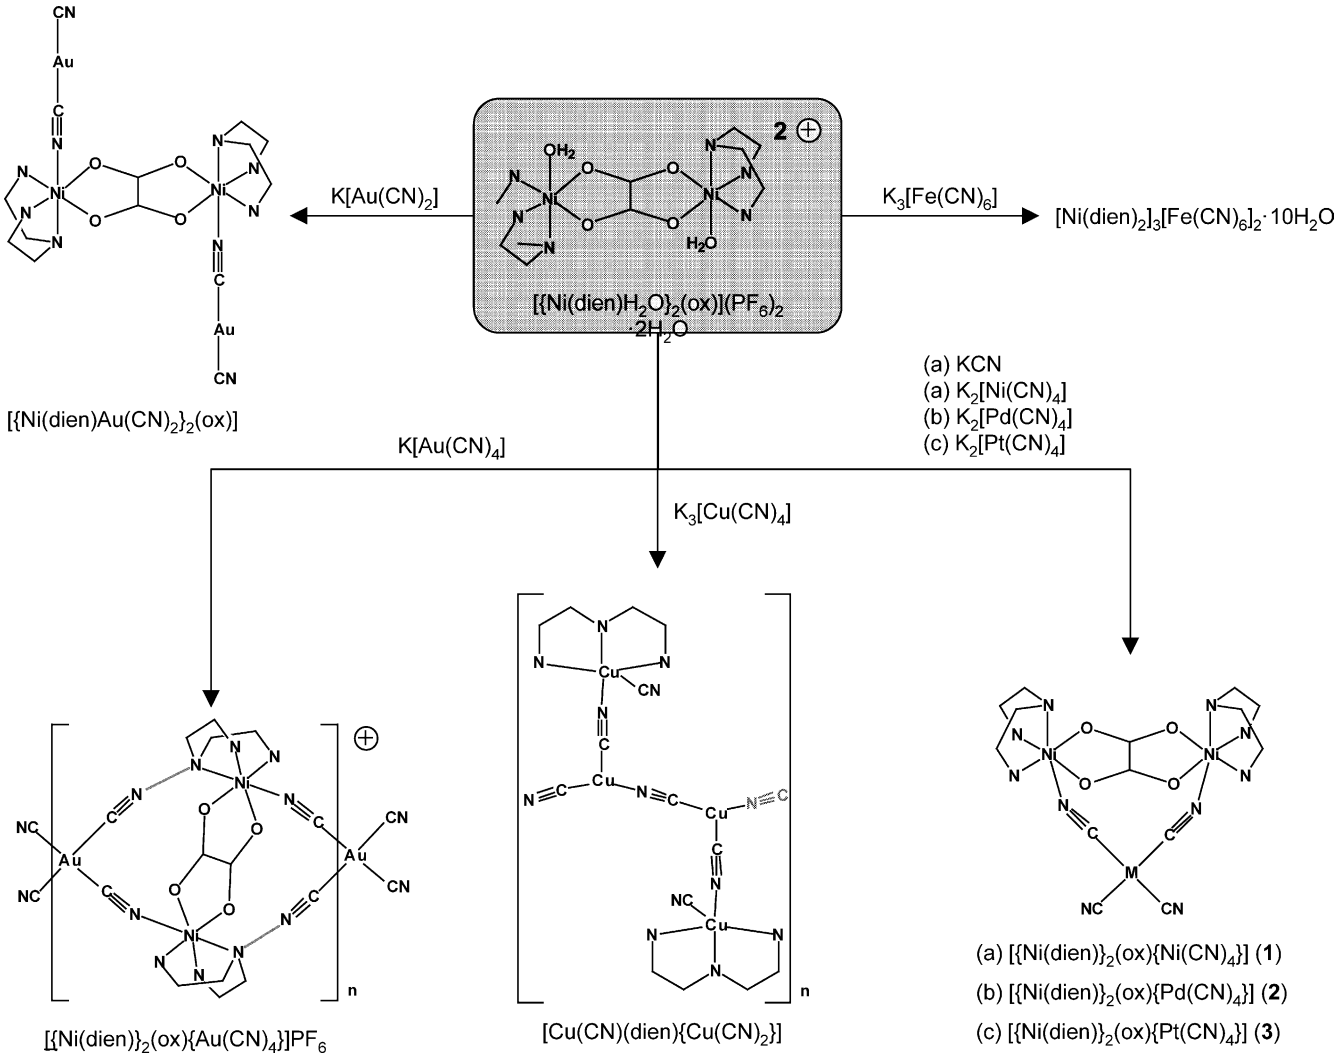
2.3. Magnetic susceptibility measurements

Magnetic susceptibility measurements were carried out on polycrystalline samples in the temperature range 4.2–300 K, with a pendulum type susceptometer/magnetometer (Manicsd DSM8) equipped with a helium continuous flow cryostat. The diamagnetic contribution was calculated from Pascal's constants.

2.4. Computational details

Single point energy calculation at the experimental geometry for compound **1** in C_2 symmetry was performed at the B3PW91 level of theory [12]. The Los Alamos effective core potential combined with a DZ basis (LANL2DZ) [13] was chosen for the transition metals, as a compromise between accuracy and computational power available. For the remaining atoms, the

D95V [14] basis was used. All calculations were performed using the GAUSSIAN-98W program [15]. The MO figures were done with MOLEKEL 4.2 [16].



3. Results and discussion

3.1. Synthesis

In the synthesis of the three compounds, the binuclear complex $[\{Ni(dien)(H_2O)\}_2(\mu\text{-}ox)]^{2+}$ was used as precursor owing to the lability of their water molecules which may be substituted by a plethora of ligands. As can be seen in Scheme 1, reaction of the precursor with different cyanometallates gives complexes with a high structural diversity. Thus, when tetracyanocuprate(I) or tetracyanoaurate(III) is employed polynuclear complexes are obtained. In the case of tetracyanometallates of Group 10 trinuclear species are obtained, where dien ligands are *cis* respect to the oxalate plane. Water substitution in the precursor occurs when dicyanoaurate(I) is used.

3.2. Crystal structure of compounds [{Ni(dien)}$_2$(μ-ox){(μ-M(CN)$_4$)}], M = Ni (1), Pd (2) and Pt (3)

The three compounds crystallise in the same monoclinic space group *I2/a* and are isostructural. Single crystal structure analyses reveals the presence of a neutral trinuclear complex with C_2 crystallographic symmetry. The twofold axis passes through the tetracoordinated metal atom and the middle point of the C1–C1′ bond of the oxalate ligand, which is coordinated in a bis (bidentate) fashion to the twofold related Ni1 atoms. The distorted octahedral environment of each Ni1 atom is completed by three nitrogen atoms from a diethylenetriamine ligand in *fac* arrangement and one nitrogen atom from a bridging cyanide ligand, which belongs to the square-plane coordination M atom (Fig. 1). Thus, the $M(CN)_4^{2-}$ group act as a *cis*

bidentate-bridging unit between both octahedrically coordinated nickel atoms. The bridging *cis* coordination of the tetracyanometallate anion is very unusual. The *cis* disposition implies the substitution and rupture, during the synthesis process, of the starting binuclear complex in which the two water molecules were in *trans* disposition with respect to the oxalate plane. Bond lengths and angles involving non-hydrogen atoms are listed in Table 2. The *cis* coordination of $M(CN)_4^{2-}$ group also induces a significant distortion around octahedral Ni centres, forcing the Ni–oxalato–Ni fragment to adopt a boat conformation which produces a shortening in the Ni1···Ni1 distance. The dihedral angle between the oxalate plane and the equatorial coordination Ni1 plane is around 10.5° for the three compounds.

The crystal structure of these compounds has a pronounced two-dimensional character and can be viewed as a succession along the [1 0 −1] direction of antiparallel layers of molecular complexes. Inside the layers each trinuclear complex is linked to its neighbours through hydrogen bonds of type N–H···N≡C (Fig. 2). The amino groups of *dien* as donors and oxygen atoms of the oxalate as acceptors are involved in the connection between layers (Table 2).

Abbreviations used: dien = diethylenetriamine. J in cm^{-1}, Ni–O$_{ox}$: distance Ni–O(oxalato); Ni–N$_{eq}$: distance Ni–N(dien-equatorial); Ni–N$_{ap}$: distance Ni–N(dien-apical); Ni–N′$_{ap}$: distance Ni–N(cyanide); d(Ni···Ni): nickel–nickel separation across the oxalato ligand; O–Ni–O: bite angle; h(Ni): metal height from the oxalate mean plane.

3.3. Magnetic properties

The substantially flat square-planar coordination of the $M(CN)_4^{2-}$ diamagnetic units permits that, from a magnetic point of view, the compounds can be treated as a dimeric complexes in which the two octahedrically coordinated Ni(II) ions are linked by two different bridging ligands. The magnetic coupling between the two nickel atoms might propagate through both bridges, but the length of the exchange pathway through the bidentate tetracyanometallate(II) ligand is large enough to predict that the magnetic interaction may take place mainly through the oxalate ligand, which is known to be very effective in mediating antiferromagnetic coupling between first-row transition metal ions separated by around 5.5 Å in homo- [17] and heteropolynuclear compounds [18]. The thermal dependence of the molar magnetic susceptibility, χ_M, of the complexes is characteristic of an antiferromagnetic interaction between the two single ion triplet states (Fig. 3). The susceptibility curve for these complexes increases when the compound is cooled until a maximum is reached, T_{max} 46 (**1**), 49 (**2**) and 49 K (**3**), and then decreases very quickly. The ground state of a nickel(II) ion in an

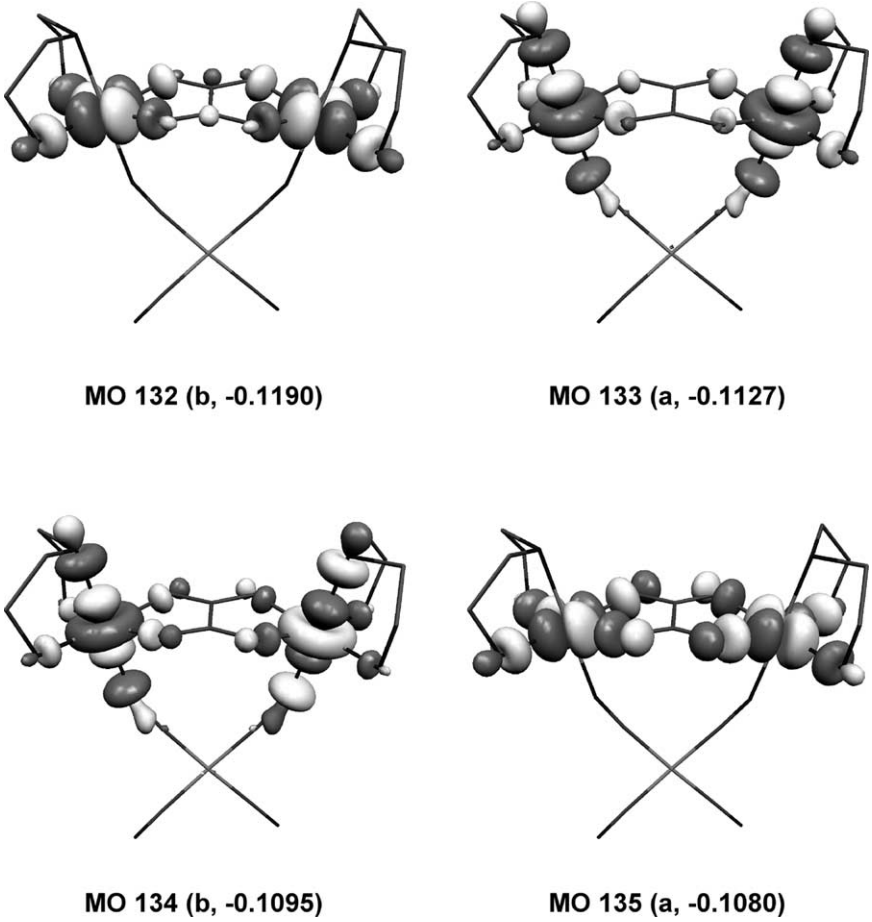

Fig. 4. Magnetic orbitals for compound **1** (symmetry, energy).

octahedral environment is orbitally non-degenerate, and as such, it is possible to represent the intradimer magnetic interaction, J, with the isotropic spin Hamiltonian $H = -JS_A \cdot S_B$. The molar magnetic susceptibility for a nickel(II) dimer (local spins $S_A = S_B = 1$) may be expressed by Eq. (1):

$$\chi_M = \frac{2N\beta^2 g^2}{kT} \times \frac{\exp(J/kT) + 5\exp(3J/kT)}{1 + 3\exp(J/kT) + 5\exp(3J/kT)} \quad (1)$$

Previously reported J values for compounds containing the $[\{Ni(dien)(H_2O)\}_2(\mu\text{-ox})]^{2+}$ building block are close to those of compounds **1**–**3**. This information is summarised in Table 3 for Ni^{II}-oxalate systems in NiO_2N_4 environments containing cyanometal complexes as axial ligands. It is well-known that structural distortions (distance Ni–O_{ox}, bite angle O–Ni–O, deviation from the planarity of the nickel ion respect to mean plane of the oxalate bridging ligand) can play a key role on the fine tuning of exchange coupling.

A graphical representation of the four DFT magnetic orbitals, obtained with restricted open formalism (RODFT) for the high spin state ($S = 2$), of compound **1** are given in Fig. 4, with those for compound **2** and **3** being very similar. As expected for the case of octahedral nickel centres, the unpaired electrons are mainly located in the d_{z^2} and d_{xy} orbitals, with a noticeable contribution to the d_{z^2} magnetic orbital of the nitrogen lone pairs which belong to the bridging cyanide ligands.

4. Supplementary material

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 188643–188644 for compounds **2** and **3**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

2. Experimental

2.1. General

Unless otherwise stated, all reactions were carried out under an oxygen-free nitrogen atmosphere using standard Schlenk techniques. Diethyl ether and thf were purified by reflux over sodium-benzophenone and distillation under nitrogen. Dichloromethane and MeCN were heated to reflux over CaH_2 and distilled under nitrogen. ClP^iPr_2 was from Aldrich. 2-(Diphenylphosphino)ethylamine [11] and 3-(diphenylphosphino)-1-propylamine [12], $MCl_2(PhCN)_2$ (M = Pt, Pd) [13] and PtMeX(cod) (X = Me, Cl) [14] were prepared according to literature methods. IR spectra were recorded as either KBr discs or solutions in the range 4000–200 cm^{-1} on a Perkin–Elmer 2000 FT spectrometer. NMR spectra were recorded on a Gemini 2000 spectrometer (operating at 121.4 MHz for ^{31}P and 300 MHz for ^{1}H). Microanalyses were performed by the St. Andrews University service and EI/FAB mass spectra by the Swansea Mass Spectrometer Service.

2.1.1. $Ph_2PCH_2CH_2NHPPr^i_2$ (1)

Chlorodiisopropyl phosphine (1.04 cm^3, 0.998 g, 6.54 mmol) was added dropwise over a period of 20 min to a stirred solution of $Ph_2PCH_2CH_2NH_2$ (1.5 g, 6.54 mmol) and Et_3N (1.09 cm^3, 0.794 g, 7.85 mmol) in Et_2O (50 cm^3). The mixture was stirred at room temperature (r.t.) for 1 h. The white precipitate (triethylamine hydrogen chloride) was filtered off and the solvent removed in vacuo to produce a clear, viscous liquid. Yield: 2.03 g, 90%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ −20.2(s) ppm; $\delta(P_X)$ 66.0(s) ppm. ^{1}H NMR ($CDCl_3$): δ 7.56–7.45 (m, 10H, aromatics), 3.23 (m, 2H, CH_2), 2.41 (m, 2H, CH_2), 1.30 (m, 1H, NH), 1.34 (m, 2H, CH), 1.15 (m, 12H, CH_3) ppm. MS: m/z 345 [M^+].

2.1.2. $Ph_2PCH_2CH_2CH_2NHPPr^i$ (2)

Chlorodiisopropyl phosphine (1.01 cm^3, 0.971 g, 6.37 mmol) was added dropwise over a period of 20 min to a stirred solution of $Ph_2PCH_2CH_2CH_3NH_2$ (1.548 g, 6.36 mmol) and Et_3N (1.01 cm^3, 0.773 g, 7.59 mmol) in Et_2O (50 cm^3). The mixture was stirred at r.t. for 1 h. The white precipitate (triethylamine hydrogen chloride) was filtered off and the solvent removed in vacuo to produce a white solid. Yield: 1.359 g, 60%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ −14.7(s) ppm; $\delta(P_X)$ 66.9(s) ppm. ^{1}H NMR ($CDCl_3$): δ 7.52–7.43 (m, 10H, aromatics), 3.13 (m, 2H, CH_2), 2.17 (m, 2H, CH_2), 1.67 (m, 2H, CH_2), 1.10 (m, 12H, CH_3) ppm.

2.1.3. $PdCl_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (3)

$Ph_2PCH_2CH_2NH_2$ (1) (0.113 g, 0.327 mmol) and $PdCl_2(PhCN)_2$ (0.125 g, 0.327 mmol) were stirred in CH_2Cl_2 (10 cm^3) for 20 min. A cream precipitate started to form. The solvent was removed in vacuo until about 2 cm^3 remained. Diethyl ether was added dropwise to fully precipitate the cream solid which was collected by suction filtration. Yield: 0.093 g, 54%. *Anal*. Found (Calc. for $C_{20}H_{29}Cl_2NP_2Pd$): C, 45.67 (45.95); H, 5.51 (5.59); N, 2.65 (2.68)%. $^{31}P\{H\}$NMR ($CDCl_3$): $\delta(P_A)$ 20.9(d) ppm; $\delta(P_X)$ 90.3(d) ppm, $^{2}J(^{31}P-^{31}P) = 7$ Hz. MS: m/z 545 [$M+Na$]$^+$, 487 [$M-Cl$]$^+$. IR (KBr): 3244s (νNH), 3072w, 1638w, 287m, 217s cm^{-1}.

2.1.4. $PtCl_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (4)

$Ph_2PCH_2CH_2NHPPr^i_2$ (1) (0.079 g, 0.22 mmol) and $PtCl_2(PhCN)_2$ (0.108 g, 0.22 mmol) were stirred in CH_2Cl_2 (10 cm^3) for 20 min. The solvent was removed in vacuo until product just started to precipitate; ether (10 cm^3) was added dropwise to aid precipitation. The cream solid was collected by suction filtration. Yield: 0.105 g, 75%. *Anal*. Found (Calc. for $C_{20}H_{29}Cl_2NP_2Pt$): C, 39.60 (39.29); H, 4.53 (4.78); N, 2.25 (2.29)%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ −1.4(d) ppm, $^{1}J(^{195}Pt-^{31}P_A) =$ 3584 Hz; $\delta(P_X)$ 57.8(d) ppm, $^{1}J(^{195}Pt-^{31}P) = 3595$ Hz, $^{2}J(^{31}P_A-^{31}P_X) = 17$ Hz. MS: m/z 576 [$M-Cl$]$^+$. IR (KBr): 3273s (νNH), 3027w, 303w, 278w cm^{-1}.

2.1.5. $PtMe_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (5)

$Ph_2PCH_2CH_2NH_2$ (1) (0.117 g, 0.34 mmol) and $PtMe_2$(cod) (0.113 g, 0.34 mmol) were stirred in CH_2Cl_2 (10 cm^3) for 20 min. The solvent was removed in vacuo until a white solid started to precipitate; then Et_2O was added dropwise to aid precipitation. The solid was collected by suction filtration. Yield: 0.061 g, 32%. *Anal*. Found (Calc. for $C_{22}H_{35}NP_2Pt$): C, 46.06 (46.36); H, 6.03 (6.18); N, 2.30 (2.45)%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 7.1(d) ppm, $^{1}J(^{195}Pt-^{31}P_A) = 1849$ Hz; $\delta(P_X)$ 68.3(d) ppm, $^{1}J(^{195}Pt-^{31}P_X) = 1990$ Hz, $^{2}J(^{31}P_A-^{31}P_X) = 22$ Hz. ^{1}H NMR ($CDCl_3$): δ 7.69–7.39 (m, 10H, aromatics), 3.20 (m, 2H, CH_2), 2.35 (m, 2H, CH_2), 2.19 (m, 2H, CH_2), 1.29–1.03 (m, 12H, CH_3), 0.78–0.67 (m, 6H, CH_3) ppm. MS: m/z 555 [$M-Me$]$^+$. IR (KBr): 3384s (νNH), 3070w, 2959s, 2864s, 1589w, 1098s cm^{-1}.

2.1.6. $PtClMe(Ph_2PCH_2CH_2NHPPr^i_2)$ (6)

$Ph_2PCH_2CH_2NH_2$ (1) (0.113 g, 0.33 mmol) and PtClMe(cod) (0.116 g, 0.33 mmol) were stirred in CH_2Cl_2 (10 cm^3) for 20 min. The solvent was removed in vacuo until a white solid started to precipitate. Diethyl ether was added dropwise to aid precipitation. The solid was collected by suction filtration. Yield: 0.141 g, 73%. *Anal*. Found (Calc. for $C_{21}H_{32}ClNP_2Pt$): C, 42.31 (42.68); H, 5.53 (5.46); N, 2.09 (2.37)%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 6.4(d) ppm, $^{1}J(^{195}Pt-^{31}P_A) =$ 1879 Hz; $\delta(P_X)$ 63.8(d) ppm, $^{1}J(^{195}Pt-^{31}P_X) = 4626$ Hz, $^{2}J(^{31}P_A-^{31}P_X) = 18$ Hz. ^{1}H NMR ($CDCl_3$): δ 7.85–7.38 (m, 10H, aromatics), 3.45 (m, 2H, CH_2), 2.25 (m, 2H, CH_2), 1.38 (m, 2H, CH), 1.2 (m, 12H,

CH_3), 0.76 (m, 3H, CH_3) ppm. MS: *m/z* 555 $[M-Cl]^+$. IR (KBr): 3277s (*v*NH), 3052w, 2962s, 2867s, 1435s, 1100s, 274w cm^{-1}.

2.1.7. $Fe(CO)(\eta^5\text{-}C_5H_5)(Ph_2PCH_2CH_2NHPPr^i_2)I$ (7)

$Ph_2PCH_2CH_2NHPr_2$ (**1**) (0.114 g, 0.33 mmol), $Fe(CO)_2(\eta^5\text{-}C_5H_5)I$ (0.091 g, 0.30 mmol) and catalyst $Fe(CO)_2(\eta^5\text{-}C_5H_5)$ (0.010 g, 0.057 mmol) were refluxed in MeCN (15 cm^3). Reaction followed by IR to completion. The reaction mixture was allowed to cool to r.t., before the solvent was removed in vacuo, producing a green precipitate. The precipitate was re-dissolved in CH_2Cl_2 and precipitated with 60–80 pet ether. The solid was collected by suction filtration. Yield: 0.107 g, 57%. *Anal*. Found (Calc. for $C_{26}H_{34}FeINOP_2$): C, 50.59 (50.27); H, 5.65 (5.52); N, 2.30 (2.25)%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 53.0(d) ppm; $\delta(P_X)$ 119.8(d) ppm, $^2J(^{31}P_A-^{31}P_X) = 67$ Hz. ^1H NMR ($CDCl_3$): δ 7.96–7.37 (m, 10H, aromatics), 4.99 (m, 5H, Cp), 3.57 (m, 2H, CH_2), 2.73 (m, 2H, CH_2), 2.27 (m, 2H, CH), 1.50–1.21 (m, 12H, CH_3) ppm. MS: *m/z* 494 $[M^+]$. IR (KBr): 3179m (*v*NH), 3048m, 1954s.

2.1.8. $NiCl_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (8)

$Ph_2PCH_2CH_2NHPr_2$ (**1**) (0.273 g, 0.79 mmol) and $NiCl_2\cdot 6H_2O$ (0.188 g, 0.79 mmol) were stirred in thf (10 cm^3) at r.t. for 20 min. A dark orange solid started to precipitate. The solvent was removed in vacuo and Et_2O added dropwise to aid precipitation. The orange solid was collected by suction filtration. Yield: 0.263 g, 70%. *Anal*. Found (Calc. for $C_{20}H_{29}Cl_2NNiP_2$): C, 50.22 (50.57); H, 6.65 (6.15); N, 2.94 (2.95)%. IR (KBr): 3263s (*v*NH), 326m, 287m.

2.1.9. $PdCl_2[Ph_2P(CH_2)_3NHPPr^i_2]$ (9)

$Ph_2P(CH_2)_3NHPPr^i_2$ (**2**) (0.125 g, 0.45 mmol) and $PdCl_2(PhCN)_2$ (0.133 g, 0.45 mmol) were stirred at r.t. in CH_2Cl_2 (10 cm^3) for 20 min. Cream solid started to precipitate. Solvent was removed in vacuo until approximately 2 cm^3 remained. Diethyl ether was added dropwise to fully precipitate solid. The solid was collected by suction filtration. Yield: 0.159 g, 85%. *Anal*. Found (Calc. for $C_{21}H_{31}Cl_2NP_2Pd$): C, 47.03 (47.14); H, 5.61 (5.84); N, 2.78 (2.62)%. No NMR as very insoluble. MS: *m/z* 500 $[M-Cl]^+$, 463 $[M-2Cl]^{2+}$. IR (KBr): 3262s (*v*NH), 3052w, 1435s, 297m, 282m cm^{-1}.

2.1.10. $PtCl_2[Ph_2P(CH_2)_3NHPPr^i_2]$ (10)

$Ph_2P(CH_2)_3NHPPr^i_2$ (**2**) (0.248 g, 0.69 mmol) and $PtCl_2(PhCN)_2$ (0.326 g, 0.69 mmol) were stirred at r.t. in CH_2Cl_2 (10 cm^3) for 20 min. The solvent was removed in vacuo until a white solid started to precipitate. Diethyl ether was added dropwise to precipitate the white solid. The solid was collected by suction filtration. Yield: 0.356 g, 92%. *Anal*. Found (Calc. for $C_{21}H_{31}Cl_2NP_2Pt$): C, 40.24 (40.41); H, 4.42 (5.01); N, 2.58 (2.24)%. MS: *m/z* 590 $[M-Cl]^+$, 552 $[M-2Cl]^+$. IR (KBr): 3330s (*v*NH), 3053w, 1700w, 1653w, 304m, 297, 282 *v*(M–Cl) cm^{-1}.

2.1.11. $PtMe_2[Ph_2P(CH_2)_3NHPPr^i_2]$ (11)

$Ph_2P(CH_2)_3NHPPr^i_2$ (**2**) (0.105 g, 0.29 mmol) and $PtMe_2$(cod) (0.097 g, 0.29 mmol) were stirred at r.t. in CH_2Cl_2 (10 cm^3) for 60 min. Solvent was removed in vacuo until precipitate started to form. Diethyl ether was added to aid precipitation. White solid was collected by suction filtration. Yield: 0.122 g, 71%. *Anal*. Found (Calc. for $C_{23}H_{37}NP_2Pt$): C, 47.05 (47.29); H, 6.12 (6.38); N, 2.48 (2.4)%. $^{31}P\{H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 7.3 ppm, $^1J(^{195}Pt-^{31}P_A) = 1823$ Hz; $\delta(P_X)$ 94.4 ppm, $^1J(^{195}Pt-^{31}P_X) = 2164$ Hz, $^2J(^{31}P_A-^{31}P_X) = 15$ Hz. ^1H NMR ($CDCl_3$): δ 7.83–7.46 (m, 10H, aromatics), 3.31–3.22 (m, 2H, CH_2), 2.88–2.75 (m, 2H, CH_2), 2.41–2.26 (m, 2H, CH_2), 1.65–1.52 (m, 2H, CH), 1.35–1.24 (m, 12H, CH_3), 0.77–0.48 (m, 3H, CH_3), 0.37–0.08 (m, 3H, CH_3) ppm. MS: *m/z* 584 $[M]^+$, 569 $[M-Me]^+$, 554 $[M-2Me]^+$. IR (KBr): 3377s (*v*NH), 3073w, 1434s.

2.1.12. $PtMeCl[Ph_2P(CH_2)_3NHPPr^i_2]$ (12)

$Ph_2P(CH_2)_3NHPPr^i_2$ (**2**) (0.126 g, 0.49 mmol) and PtMeCl(cod) (0.124 g, 0.49 mmol) were stirred at r.t. in CH_2Cl_2 (10 cm^3) for 60 min. Solvent was removed in vacuo until a precipitate started to form. Diethyl ether was added dropwise to fully precipitate solid. The white solid was collected by suction filtration. Yield: 0.155 g, 73%. *Anal*. Found (Calc. for $C_{22}H_{34}ClNP_2Pt$): C, 43.75 (43.74); H, 5.51 (5.67); N, 2.41 (2.32)%. $^{31}P\{H\}$ NMR ($CDCl_3$): δ 8.8 ppm, $^1J(^{195}Pt-^{31}P) = 1655$ Hz, $^2J(^{31}P-^{31}P) = 12$ Hz; δ 23.2 ppm, $^1J(^{195}Pt-^{31}P) = 3042$ Hz; δ 67.5 ppm, $^1J(^{195}Pt-^{31}P) = 2945$ Hz; δ 82.2 ppm, $^1J(^{195}Pt-^{31}P) = 4575$ Hz, $^2J(^{31}P-^{31}P) = 13$ Hz. MS: *m/z* 604 $[M]^+$, 569 $[M-Cl]^+$. IR (KBr): 3280s (*v*NH), 3052m, 1588w, 279w cm^{-1}.

2.2. Crystallography

X-ray diffraction studies were performed at 293 K using a Rigaku Mercury CCD for **8** and a Bruker SMART diffractometer for **11** with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods, non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms bound to carbon were idealised and fixed (C–H 0.95 Å), the NH protons were located by ΔF map. Structural refinements were by the full-matrix least-squares method on F^2 using SHELXTL [15]. Compound **8** was only obtained as poorly diffracting very thin plates.

*2.2.1. $NiCl_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (**8**)*

$C_{20}H_{29}Cl_2N_1Ni_1P_2$, $M = 474.99$, monoclinic, space group $P2_1/n$, $a = 8.979(3)$, $b = 15.115(6)$, $c = 16.688(6)$ Å, $\beta = 91.903(5)^\circ$, $U = 2264(1)$ Å^3, $Z = 4$, $D_{calc} = 1.394$ Mg m^{-3}, $\mu = 1.239$ mm^{-1}, $F(000) = 992$, crystal size = $0.23 \times 0.10 \times 0.02$ mm. Of 14 456 measured data, 4774 were unique ($R_{int} = 0.0517$) and observed to give R_1 [$I > 2\sigma(I)$] = 0.1153.

*2.2.2. $PtMe_2[Ph_2P(CH_2)_3NHPPr^i_2]$ (**11**)*

$C_{23}H_{37}N_1P_2Pt$, $M = 584.57$, monoclinic, space group $P2_1/c$, $a = 9.4476(2)$, $b = 15.5972(3)$, $c = 16.1970(1)$ Å, $\beta = 91.161(1)^\circ$, $U = 2386(1)$ Å^3, $Z = 4$, $D_{calc} = 1.627$ Mg m^{-3}, $\mu = 6.022$ mm^{-1}, $F(000) = 1160$, crystal size = $0.10 \times 0.10 \times 0.13$ mm. Of 10 219 measured data, 2965 were unique ($R_{int} = 0.0192$) and observed to give R_1 [$I > 2\sigma(I)$] = 0.0159.

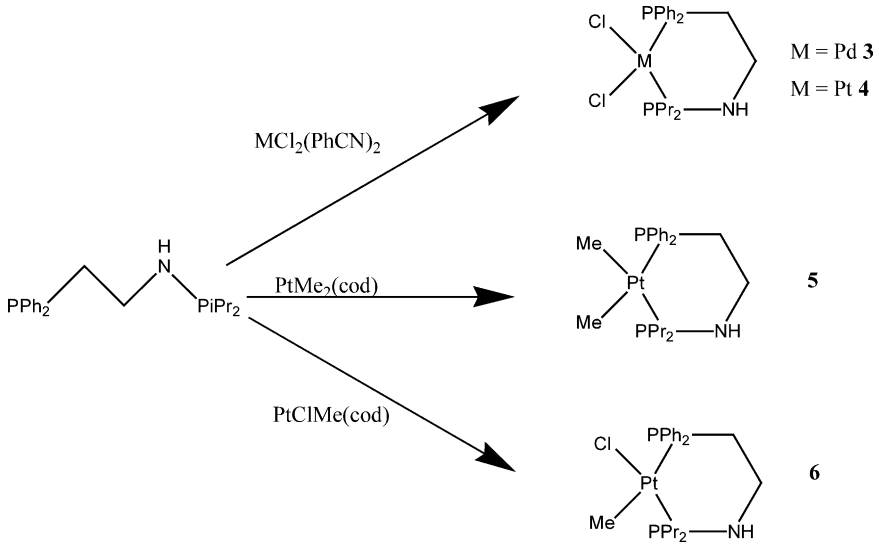
3. Results and discussion

Surprisingly, there are relatively few examples of unsymmetrical diphosphines in which the two phosphorus atoms have different substituents. One limiting factor in the synthesis has been the inconvenient routes involving highly air sensitive intermediates. Grim et al. [15–18] have synthesised a number of diphosphines of the types $RPhP(CH_2)_nPPh_2$ ($n = 1$–3, R = Me, Et, Pr, Pr^i, Bu^t, Bu) and $R_2P(CH_2)_nPPh_2$ ($n = 1$, R = Me, Pr^i, $n = 3$, R = Me), but their route is experimentally difficult. Briggs and coworkers [19] reported an easier synthesis of diphosphines of the type $RPhP(CH_2)_nPPh_2$ ($n = 3$–6, R = Me, Et, c-C_6H_{11}) via the stepwise formation of the mono- and di-phosphonium salts, using a non-polar solvent in the first stage and a polar solvent for the second stage, and on the loss of phenyl in preference to alkyl at the hydrolysis stage. More recently a one-pot synthesis to unsymmetrical 1,2-bis(phosphanyl)ethanes has been developed [20]. We have been interested in the use of P–N bond forming reactions for phosphine synthesis and have developed strategies for the synthesis of unsymmetrical aryl backbone phosphines from amines [21–26]. Here we have extended our methods to alkyl backbone systems. Thus $Ph_2PCH_2CH_2NHPPr^i_2$ (**1**) and $Ph_2P(CH_2)_3NHPPr^i_2$ (**2**), were obtained by direct reaction of the appropriate amine, and chlorodiisopropylphosphine. The presence of slightly more than 1 M equivalent of triethylamine ensures complete removal of the hydrogen chloride by-product (Eq. (1)).

$$Ph_2P(CH_2)_nNH_2 + {}^iPr_2PCl + Et_3N \rightarrow Ph_2P(CH_2)_nNHP^iPr_2 + NEt_3HCl \quad (1)$$

$n = 2$ (**1**); 3 (**2**)

The structure of **1** was confirmed by mass spectrometry and $^{31}P\{H\}$ and ^1H NMR. MS gave a M^+ peak at 345. $^{31}P\{H\}$ NMR revealed the predicted AX spectrum. The peak at $\delta(P_A)$ −20.2 ppm was assigned to the diphenyl phosphorus, as the peak in the starting material was at −20.5 ppm and $\delta(P_X)$ 65.9 ppm was assigned to the di-isopropyl phosphorus. There is no observable coupling between the 2 inequivalent. phosphorus nuclei. Compound **2** is a white solid whilst **1** is a clear, viscous liquid. In **2** the P_A peak corresponding to the diphenyl phosphorus is at −14 ppm [similar to the starting material at −14.6 ppm]; the $\delta(P_X)$ peak assigned to the di-isopropyl phosphorus, like that of **1**, occurs at $\delta(P)$ 67 ppm.



Further evidence for the above assignment is that **1** reacts with 1 equiv. of elemental selenium at the most basic and therefore most reactive phosphorus atom, the di-isopropyl phosphorus atom since $\delta(P_A)$ −20 ppm remains in the same place, whilst $\delta(P_X)$ 65.9 ppm in **1** shifts to 89 ppm in $Ph_2PCH_2CH_2NHP(Se)Pr^i_2$.

We examined some simple coordination chemistry of **1** and **2**. Complexation reactions were straightforward, with coordination to platinum, palladium and nickel all being carried out at room temperature. Coordination to iron required refluxing in acetonitrile in the presence of a catalyst. All complexes were formed as fine powders. The spectroscopic data for the complexes are readily interpreted and consistent with chelate monomeric systems though we noted some weak high value m/z peaks in some of the mass spectra which could suggest dimer formation in the mass spectrometer at least.

The palladium dichloride complex **3** was formed by direct reaction of **1** with $PdCl_2(PhCN)_2$. Mass spectroscopy gave the $M+Na^+$ peak at 545, corresponding to a monomeric complex and microanalysis was in good agreement with the proposed structure. In its $^{31}P\{^1H\}$ NMR the diphenyl phosphorus group is observed at $\delta(P_A)$ 20.9 ppm whilst $\delta(P_X)$ 90.3 ppm, the coupling constant, $^2J(P_X–P_A) = 7$ Hz, is very small. The two peaks in the IR spectrum assigned as ν(M−Cl) 297, 282 cm^{-1} suggest the ligand coordinates in a *cis*-geometry and therefore the complex has a six-membered PdP_2NC_2 chelate ring. The dichloro-, dimethyl- and chloromethylplatinum complexes were all formed by similar ligand substitution reactions (Scheme 1).

The geometry of complexes **4**–**6** was confirmed by examination of the Pt–P coupling constants in their $^{31}P\{H\}$ NMR summarised below (Table 1). The mass spectrum of **4** has a major peak at 576 corresponding to $[M-Cl]^+$. The $^{31}P\{H\}$ NMR of complex **6** has $\delta(P_A)$ 6.4 ppm, $^1J(Pt–P_A) = 1879$ Hz and $\delta(P_X)$ 63.8 ppm, $^1J(Pt–P_X) = 4626$ Hz. The $\delta(P_A)$ peak is assigned to the diphenyl phosphorus group *trans* to methyl with the PPr^i_2 group is *trans* to chloride.

Coville et al. [27] found $[(\eta^5\text{-}C_5H_5)Fe(CO)_2I]$ reacts with diphosphines (L–L) in the presence of $[(\eta^5\text{-}C_5H_5)Fe(CO)_2]_2$ catalyst to produce $[(\eta^5\text{-}C_5H_5)Fe(CO)(L–$

Scheme 1. Formation of palladium and platinum complexes of **1**.

L)]I. The reaction for each of the diphosphines, L–L = $Ph_2P(CH_2)_nPPh_2$ ($n = 1$–4), was followed by IR and in each case $[(\eta^5\text{-}C_5H_5)Fe(CO)_2(L\text{–}L)]I$ was readily identified by the characteristic ν(CO) at 2050, 2000 cm^{-1}. We have found that reaction of **1** under the same conditions as above gives $[(\eta^5\text{-}C_5H_5)Fe(CO)(Ph_2PCH_2CH_2NHPPr^i_2)]I$ (**7**) identified by ν(CO) 1954 cm^{-1}, microanalysis and mass spectrometry. The ^{31}P NMR of **7** contains the expected AX spectrum, with a large change in chemical shift on coordination to the iron ($\delta(P_A)$ 53.0 ppm, $\delta(P_X)$ 119.8 ppm) compared to the free ligand values of $\delta(P_A)$ −20.2 ppm and $\delta(P_X)$ 66.0 ppm. The spectrum also shows a large P–P coupling, $^2J(P_X\text{–}P_A) = 67$ Hz. In a separate experiment in which no catalyst was used, the intermediate $[(\eta^5\text{-}C_5H_5)Fe(CO)_2(Ph_2PCH_2CH_2NHPPr^i_2)]I$ was observed after 16 h [ν(CO) 2951, 2006 cm^{-1}] which is consistent with Coville's work [27].

$NiCl_2\cdot 6H_2O$ reacts with **1** to give $NiCl_2(Ph_2PCH_2CH_2NHPPr^i_2)$ (**8**). Microanalyses are consistent with this formulation and its IR spectrum contains peaks at 287 and 326 cm^{-1}, confirming the presence of *cis* Ni–Cl bonds. We were unable to obtain a satisfactory NMR spectrum of **8** since it is poorly soluble and appears to be paramagnetic in solution which suggests at least some tetrahedral character in solution. X-ray crystallography reveals the solid state structure of **8** (Fig. 1) with the nickel in an approximate square planar geometry and the two phosphorus atoms coordinating in a *cis* fashion. The diphosphine ligand forms a six-membered metallacycle, which can best be described as having a half-boat conformation, $NiP_2NC(13)$ are approximately coplanar with C(14) at the prow of the boat. Hydrogen bonding between the amine proton N(2) and Cl(2) of the adjacent complex [Cl···H 2.40, Cl···N 3.37 Å, N–H···Cl 170°) results in an infinite chain motif (Fig. 2).

As with **1** complexation of $Ph_2P(CH_2)_3NHPPr^i_2$ (**2**) involves straight forward ligand substitution reactions, we established coordination to platinum and palladium for illustrative purposes. All complexes were produced as fine powders. In the ^{31}P NMR of **11** the spectrum is again the expected AX type, with satellites due to coupling to platinum. $\delta(P_A)$ 7.3 ppm is assigned to

Selected bond lengths (Å) and angles (°) Pt–P(1) 2.285(1), Pt–P(2) 2.285(1), Pt–C(27) 2.124(3), Pt–C(28) 2.110(3), P(1)–C–(!3) 1.844(3), C(13)–C(14) 1.524(5), C(14)–C(15) 1.508(5), C(15)–N(2) 1.455(4), N(2)–P(2) 1.684(3); P(1)–Pt–P(2) 100.0(1), C(27)–Pt–C(28) 82.8(1), N(2)–P(2)–Pt 115.5(1), C(15)–N(6)–P(2) 123.8(2).

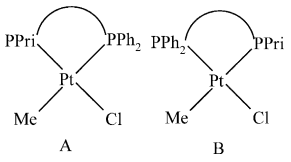

Fig. 4. Different isomers of **12**.

PPh_2 and $\delta(P_X)$ 94.4 ppm is assigned to PPr^i_2. The proton NMR clearly shows the different environments of the two methyl groups on the platinum, both methyl groups are coupled to the phosphorus to give an apparent quartet $J(^1H–^{31}P) = 7.7$ Hz with satellite peaks either side due to coupling to the platinum. Crystallography confirmed the structure of **11** (Fig. 3) to be monomeric with the diphosphine ligand coordinating as a chelate. The geometry around the platinum is distorted square planar, [P(1)–Pt(1)–P(2) 100.0(1)° and C(28)–Pt(1)–C(27) 82.8(1)°] with the ligand displaying a significantly larger bite angle than **1** in **8** as a consequence of the extra methylene group in the backbone here and since the *trans* methyl groups are less sterically demanding than the chlorides in **8**. The conformation of the ring is a distorted 'chaise longue'.

Complex **12** was formed by reaction of ligand **2** with PtMeCl(cod). ^{31}P NMR (Table 1) shows the presence of equal proportions of two isomers (Fig. 4). If $\delta(P_A)$ is assigned to PPh_2 and $\delta(P_X)$ is assigned to PPr^i_2 then in isomer A the PPh_2 moiety is *trans* to methyl and has a small coupling constant to platinum, $^1J(^{31}P_A–^{195}Pt) =$ 1665 Hz, and the PPr^i_2 moiety is *trans* to chloride and therefore has a large coupling constant with platinum, $^1J(^{31}P_X–^{195}Pt) = 4575$ Hz.

This work clearly illustrates the ease of formation of unsymmetrical phosphines and should allow the effect of variation of the two phosphorus centres on a range of catalytic processes to be studied.

4. Supplementary material

Full lists of structure refinement data, atomic coordinates, bond lengths and angles, anisotropic displacement parameters and hydrogen atom parameters have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 188819 (**8**), 188820 (**11**). preconcentration [12], and stationary phases for chromatography [13], and as well as in the use of these new materials to immobilize agrochemical compounds in order to anchor pesticides [14].

The present investigation is focused on the silylant agent 3-glycidoxypropyltrimethoxysilane (GPTS), taking into account its ability to react by considering epoxide group opening, in the presence of nucleophiles. This enhanced reactivity leads to ring opening allowing facile introduction of nucleophiles like amines, as represented here by the bifunctional molecule, propane-1,3-diamimine.

2. Experimental

2.1. Chemicals

Reagent grade solvents were purified and distilled just before use. Silica gel, with particle size in the range 70–230 mesh, average pore diameter 60 Å and pore volume 0.75 $cm^3\ g^{-1}$, was treated and activated as before [7,8]. The silylant agent GPTS was used without further purification; propane-1,3-diamine and triethylamine were distilled under reduced pressure.

2.2. Heterogeneous process

The heterogeneous route consisted in suspending 20.0 g of activated silica gel in 100.0 cm^3 of dry toluene, followed by addition of 20.0 cm^3 (91.0 mmol) of GPTS. The mixture was mechanically stirred under reflux of the solvent in an inert dry nitrogen atmosphere for 72 h [7,8]. The mixture was filtered and the solid was washed with toluene and methanol. The white product (SiG) was dried in vacuo for 24 h at 323 K. In sequence, 5.0 g of this modified silica was suspended in 100.0 cm^3 of toluene. This suspension was heated to solvent reflux with mechanical stirring when 8.5 cm^3 (102.0 mmol) of propane-1,3-diamine was added, under a dry atmosphere, and maintained at reflux for another 48 h. After cooling, the solid was filtered, washed and dried as described before, obtaining the product, SiHT [7,8].

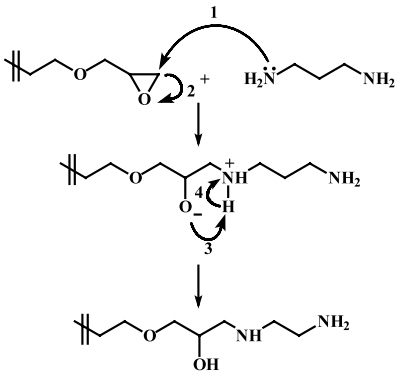
2.3. Homogeneous process

This method comprised in reacting 5.0 cm^3 (23.0 mmol) of GPTS with 1.9 cm^3 (23.0 mmol) of the diamine in 100 cm^3 of dry methanol. The mixture was refluxed under a dry atmosphere of nitrogen for 48 h. The solution was concentrated to approximately 40 cm^3 and added to 5.0 g of silica suspended in 100.0 cm^3 of dry toluene. After refluxing for 72 h under a dry nitrogen atmosphere, the solid was filtered, washed with toluene and methanol and dried as described for the heterogeneous route, to obtain the product, SiHM [14,15].

2.4. Characterization

The anchored surfaces, SiG, SiHT and SiHM, had their elemental compositions analyzed with a Perkin–Elmer 2400 Series II microelemental analyzer. The values obtained reflect the degree of organofunctionalization of both kinds of these matrices.

The surface area of the silicas was obtained by using the BET equation, through nitrogen adsorption isotherms at 77 K, by means of a Flowsorb 2300 analyzer. Before starting the analysis, the samples were dried at 373 K and each surface was purged in a stream of dry nitrogen [7,8].



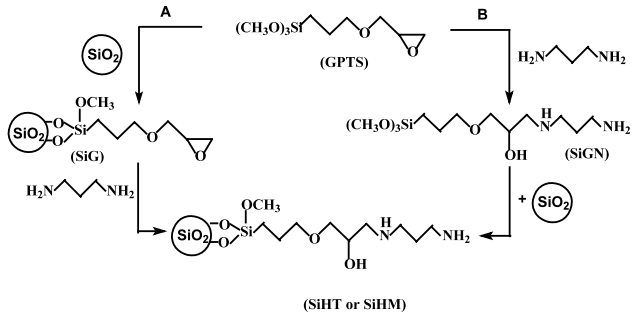
The mass loss determinations were performed on a DuPont instrument, Model 951, using 8.0–12.0 mg of the sample under nitrogen at a heating rate of 0.17 K s^{-1}. Infrared spectra of the compounds were obtained in the 4000–400 cm^{-1} region with a resolution of 4 cm^{-1}, by accumulating 32 scans using a MB-Bomem FTIR spectrophotometer; KBr pellets were used for solid samples and NaCl windows for liquid samples [7,8].

Nuclear magnetic resonance spectra of the solid samples were obtained on an AC 300/P Bruker spectrometer at room temperature. For each run, approximately 1 g of each modified silica was compacted into a 7 mm zirconium oxide rotor. The measurements were obtained for carbon and silicon with frequencies at 75.47 and 59.61 MHz, respectively, with a magic-angle spinning speed of 4 Hz. In order to increase the signal to noise ratio of the solid-state spectra, the CP/MAS technique was used for ^{13}C and ^{29}Si nuclei. The spectra were obtained with pulse repetitions of 1 and 3 s and contact times were 1 and 3 ms, with number of the scans 19 000 and 22 000 for carbon and silicon, respectively [7,8].

3. Results and discussion

The reaction between the epoxy moiety attached to the silylant agent GPTS, with a diamine molecule is based on a typical nucleophilic attack of the basic nitrogen atom on the strained acidic carbon atom of the ring [16], as represented in Scheme 1 when the propane-1,3-diamine is involved.

The non-bonded electron pair on the nitrogen of propane-1,3-diamine interacts initially with the acidic carbon atom of the epoxy ring (1); consequently the electrons of the bond between the carbon and oxygen of the epoxy ring are transferred to oxygen, opening the ring as represented in step (2). The excess of charge on the oxygen atom attracts the nearby hydrogen atom,



Scheme 1. Proposed mechanism of the reaction between the epoxy moiety of the silylant agent and propane-1,3-diamine.

once bonded to nitrogen, to form an oxygen–hydrogen bond (3), permitting electronic rearrangement (4) and producing the final, neutral product.

Taking this into account, epoxy ring reactivity in the presence of an amine molecule causes the incorporation of propane-1,3-diamine onto the silylant agent chain, to give a new silylant agent, which can be immobilized in two distinct ways, that is, by homogeneous and heterogeneous processes, as represented in Scheme 2.

The heterogeneous route was based on the prior immobilization of the silylant agent GPTS onto silica gel to form a SiG surface. This reaction is followed by incorporation of propane-1,3-diamine to give the final product, SiHT. When the silylant agent GPTS reacted with the diamine, a new silylant agent, SiGN, is formed, which was then anchored onto silica gel to yield the SiHM surface.

The contents of carbon, nitrogen and hydrogen for the anchored surfaces are listed in Table 1. These elemental analysis data are in agreement with propane-1,3-diamine molecule incorporation into GTPS and its immobilization onto the silica gel surface, as proposed. Taking into account the percentages of these elements, it is easy to conclude that the amount of the propane-1,3-diamine immobilized onto the silica gel surface by the homogeneous route is much higher than the amount immobilized by the heterogeneous route. Thus, based on

Scheme 2. Incorporation of the propane-1,3-diamine molecule into the epoxy moiety by using heterogeneous (A) and homogeneous (B) processes.

Table 1
Percentages of carbon (C), hydrogen (H) and nitrogen (N) and the anchored amount (n) of groups per gram of silica

Surface	C (%)	H (%)	N (%)	n (mmol g^{-1})
SiG	8.62±0.01	1.75±0.01		1.03±0.01
SiHT	11.59±0.02	2.46±0.04	2.22±0.01	0.80±0.01
SiHM	20.76±0.53	4.39±0.08	4.28±0.24	1.53±0.09

the nitrogen content, the values of 0.80 and 1.53 mmol of pendant groups were calculated, respectively.

The surface areas for SiHT and SiHM silicas were determined through the BET equation and the results obtained were 154.8±12.2 and 133.2±1.4 m^2 g^{-1}, respectively, values which differ from that of the original silica, 420.8±3.4 m^2 g^{-1}. This decrease in the surface area after functionalization is due to the presence of pendant groups, which partially block the adsorption of nitrogen molecules on the surface.

The infrared spectra of liquid samples obtained for reagents propane-1,3-diamine and GPTS, and the liquid silylant agent, SiGN, corroborate the nucleophilic reaction between the amine and the epoxy groups. Evidence of the progress of reaction involving SiGN is its spectrum, that showed the disappearance of a peak at a 1254 cm^{-1}, which is characteristic of the presence of the epoxy group. This fact confirms that the epoxy ring is opened to form the GPTS silylant agent, after reacting with the amine group of the propane-1,3-diamine compound. In the SiGN spectrum, another important band is related to nitrogen–hydrogen stretching of an aliphatic amine at 3360 cm^{-1}, whose appearance denotes the immobilization [17]. These spectra are shown in Fig. 1.

The infrared spectra obtained for solid samples are presented in Fig. 2. The main features of all silica spectra are related to the similarity of bands associated with the inorganic backbone such as (i) a large broad

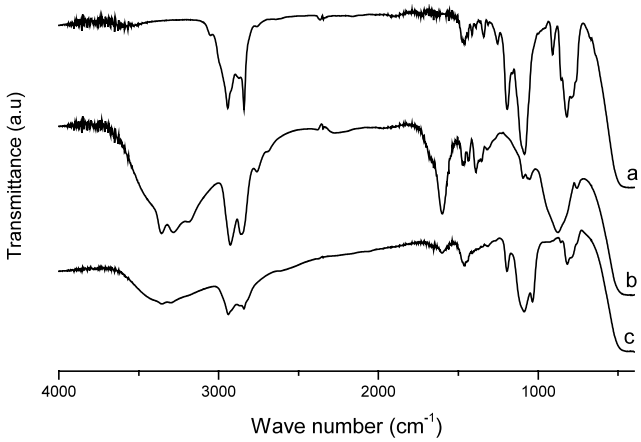


Fig. 1. Infrared spectra of liquid samples: GPTS (a), propane-1,3-diamine (b), and the new synthesized silylant agent, SiGN (c).

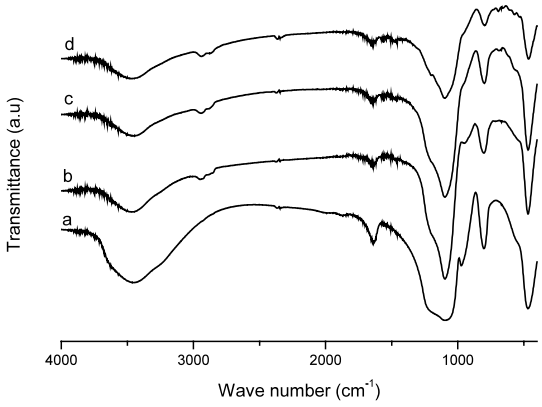

Fig. 2. Infrared spectra of solid samples: silica gel (a), SiG (b), SiHT (c) and SiHM (d).

band between 3400 and 3200 cm^{-1}, which is attributed to the presence of the O–H stretching frequency of silanol groups and also to the remaining adsorbed water, (ii) the intense band related to siloxane stretching of these groups at 1100 cm^{-1}, (iii) a band assigned to Si–O stretching frequency for silanol groups at 900 cm^{-1} and (iv) the band around 1650 cm^{-1}, assigned to angular vibration of water molecules. Moreover, SiG, SiHT and SiHM spectra showed the characteristic peak assigned to tetrahedron carbon at 2950 cm^{-1}, which confirms the presence of the organic groups immobilized onto the silica gel surface [7,8].

The thermogravimetric curves for crude and immobilized silicas are shown in Fig. 3. The profiles indicate that the anchored silicas have similar thermal stability, with distinct mass losses, as a consequence of the quantity of the pendant groups covalently bonded to the inorganic backbone.

Physically adsorbed water initially bonded on silica was lost at a low temperature in a first step. An increase in temperature caused condensation of surface silanol groups that gives a second mass loss step. The functionalized surfaces showed a mass loss due to the physically adsorbed water in the first step, near the same range as observed for the original silica. An abrupt loss in mass was detected in the second step, which included loss of the anchored molecules and also loss of water from the condensing surface silanol groups. In examining the degree of mass loss, which reflects the amount of silylant agent anchored onto the silica gel surface, it is clearly observed that the curve of SiHM presented a mass loss twice as high as that found for SiHT or SiG surfaces, indicating that the homogeneous route encourages the anchoring process.

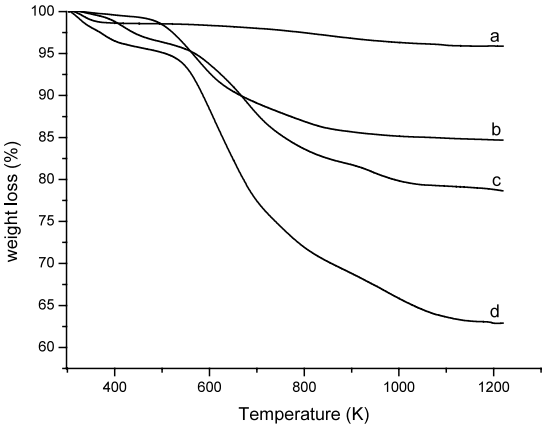

Fig. 3. Thermogravimetric curves for silica gel (a), SiG (b), SiHT (c) and SiHM (d) surfaces.

Important features related to the information about the attachment of the pendant group on the inorganic structure of the hybrid formed can be obtained through ^{13}C NMR spectra in solid state. Thus, spectra for hybrids SiG, SiHT and SiHM are shown in Fig. 4. For the SiG spectrum, four well-formed peaks, at 4, 32, 51 and 75 ppm, are observed. A similar sequence of four peaks is also observed for SiHT and SiHM. The first surface presented peaks at 4, 37, 50, 73 ppm and the second one at 4, 27, 43, 50, 73 ppm. These peaks are assigned to carbons of the pendant groups that conform to the numbers on the structure shown on the spectrum. These peaks show that both materials were obtained as expected, due to the fact that the sequence of peaks are related to the carbon of the pendant groups of the organic part of these synthesized hybrids and confirm the success of the preparation of these materials [18,19].

These silicas were easily synthesized, based on the nucleophilic attack of a compound having an amine group on an epoxy group and showed that this kind of reaction yields new silylant agents, available to graft to a

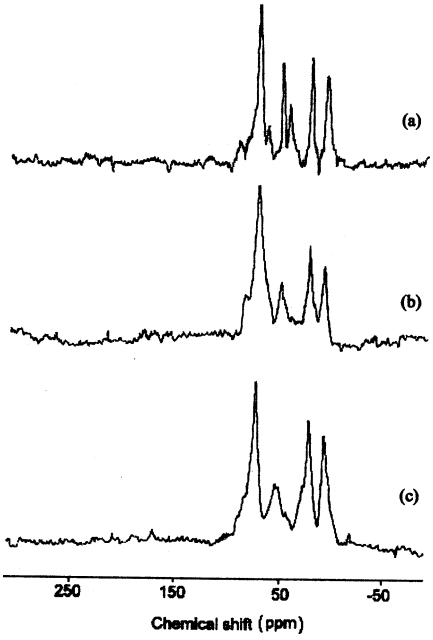

Fig. 4. ^{13}C NMR spectra of anchored SiG (A); SiHT (B) and SiHM (C).

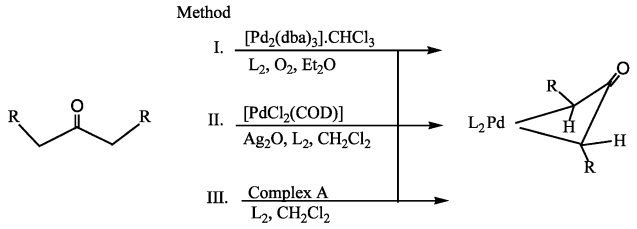
silica surface having basic centers. Such reaction systems should be further explored, due to this rapid and quantitative reaction for the opening of an epoxy ring. The known ability of these attached basic centers in removing and preconcentrating cations and other contaminants from water and other solvents merits further investigations [20].

4. Conclusions



Incorporation of propane-1,3-diamine molecules on free or anchored silylant agent, GPTS, through homogeneous or heterogeneous routes, enabled the production of the same kind of immobilized surface. However, the efficiency in covalently attaching the desired pendant groups manifested with the homogeneous route is nearly twice that for the heterogeneous route. This fact suggests a better applicability of such a surface in extracting cations from solution, through the basic center atoms bonded on the pendant groups.

Scheme 1. Complex A: $[Pd(\eta^3\text{-}CH\{CO_2Me\}COCH\{CO_2Me\})(L')_2]$ ($L' = PPh_3$ or $AsPh_3$).

The room temperature ^1H NMR spectra of complexes, $[Pd(\eta^3\text{-}CH\{CO_2Me\}COCH\{CO_2Me\})L_2]$ (**3**), showed the expected features, with a singlet resonance at low frequency for methyl protons of the CO_2Me groups and one doublet for the CH protons of the oxodimethylenemethane ligand. The ^1H NMR spectra of the palladium complex $[Pd(\eta^3\text{-}CH\{CO_2Et\}COCH\{CO_2Et\})(dppe)]$ (**4a**), exhibited a triplet resonance at low frequency for the methyl protons, a quartet for the methylene protons of the CO_2Et groups, and one doublet for the CH protons of the oxodimethylenemethane ligand.

The room temperature $^{31}P\{^1H\}$ NMR spectra for all the bidentate phosphorus complexes of oxodimethylenemethane consist of two sets of resonances, in a 5:1 or 4:1 ratio. This is thought to be due to the presence of both the equatorial–equatorial and more favourable axial–equatorial isomers. In order to identify the presence of both isomers, various low temperature ^1H NMR experiments were performed. The ^1H NMR spectrum of **3a** measured at −86 °C at 300 MHz, showed the expected features for the axial–equatorial static structure, with two signals for the methyl protons of the CO_2Me groups on the oxodimethylenemethane, and two signals for the CH protons. The two signals for the CH protons can be assigned on the basis of previous work [6]. The equatorial hydrogen, the lower frequency signal, couples to both the *cis*-phosphorus and *trans*-phosphorus, and appears as a broad signal. The higher frequency signal is assigned to the axial hydrogen, showing no discernible coupling to its *cis*-phosphorus ligand and appears as a doublet ($^3J(PH) = 8.53$ Hz) due to *trans*-phosphorus coupling only. In addition to these signals there is a methyl resonance at δ 2.84 ppm and a doublet at δ 3.20 ppm due to the CH protons of a small amount of the equatorial–equatorial isomer, which is also present.

Previous studies on oxodimethylenemethane metal complexes have shown that the complexes undergo ring inversion in solution at room temperature and that the complexes exhibited temperature dependent ^1H NMR spectra. Activation energies for ring inversion have been determined. Examination of the ^1H NMR spectra of **3a** showed that the CH protons of the palladium complex appeared as a doublet (δ 4.34) at room temperature which split into a doublet at δ 4.68 and a broad singlet at δ 3.97 ppm. These signals are assigned to the axial and equatorial protons of **3a**, respectively, by analogy with related systems [6]. The coalescence temperature for the complex **3a**, was found to be −48 °C and application of the Gutowsky–Holm equations [12] gave a value for barrier to ring inversion of 43.1 kJ mol^{-1}. This value is very similar to those observed for the reported palladacyclobutan-3-ones [6]. A coalescence temperature for the methyl resonances in **3a** could not be observed.

The CH protons of the palladium complex **3d** appeared as a doublet (δ 4.34) at room temperature which collapsed to a broad signal at −34 °C. At lower temperature the complex began to crystallise from the solution.

The IR spectra of the oxodimethylenemethane metal complexes normally exhibit five maxima in the 1705–1550 cm^{-1} region. For the complexes with methyl ester groups, two bands are observed in the region 1705–1660 cm^{-1} and are assigned to ν(CO) of the ester carbonyls. The carbonyl of the oxodimethylenemethane ligand gives a band in the region of 1595–1580 cm^{-1}. The observed frequencies for the ring carbonyl are lower than that found for the analogous platinum complexes which occurs in the region of 1625–1635 cm^{-1} [2,11]. The lower values for the ring carbonyls of palladium complexes suggest that the metal–CO interactions in palladium complexes are stronger than those in platinum complexes.

The FAB MS spectra indicate the presence of parent ions and fragmentation patterns due to loss of the dialkyl ester and the donor ligand.

3. Experimental

Microanalytical results, melting points (m.p.), IR, mass spectral and NMR data are presented for the new complexes. Microanalysis were carried out by Butterworth Laboratories Ltd., 54-56 Waldegrave Rd., Teddington, Middlessex, TW11 8LG. M.p. were measured on a Gallenkamp apparatus and are uncorrected. The FAB MS spectrum of the solid complexes were obtained on a Kratos Concept Double Focusing Sector Mass Spectrometer. The ^{1}H NMR spectra were recorded at room temperature in [$^2H_1$]chloroform on a Bruker AM300 spectrometer operating at 300.13 MHz or on a Bruker ARX 250 spectrometer at 250.13 MHz with $SiMe_4$ (0.0 ppm) as internal reference. Coupling constants J are in Hz. The $^{31}P\{^1H\}$ NMR spectra were recorded at room temperature in dichloromethane on a JEOL JNM-FX90 spectrometer operating at 36.2 MHz, with $[P(OH)_4]^+$ in [$^2H_2$]water (0.0 ppm) as external reference. The IR spectra were recorded on a Perkin–Elmer 580B spectrophotometer in Nujol mulls between NaCl plates in the range 2000–1400 cm^{-1}.

All reactions were performed under a dry, oxygen-free, nitrogen atmosphere unless otherwise stated, using solvents which were dried and distilled under nitrogen just prior to use. The following drying agents were used: dichloromethane (calcium hydride) and diethyl ether (sodium–benzophenone). Light petroleum refers to the fraction that boils in the 40–60 °C range. The compounds triphenylphosphine (Lancaster), silver(I) oxide, 1,3-dimethylacetonedicarboxylate, triphenylarsine, 1,3-diethylacetone-dicarboxylate 1,2-bis(diphenylphosphino)ethane, 1,3-bis(diphenylphosphino)propane, 1,4-bis(diphenylphosphino)butane, 1,1′-bis(diphenylphosphino)-ferrocene (Aldrich) were used as supplied by commercial sources. The complexes $[Pd_2(dba)_3]\cdot CHCl_3$ [13], $[PdCl_2(COD)]$ [14], and $[Pd\{\eta^3\text{-}CH(CO_2Me)CO\text{-}CH(CO_2Me)\}(L')_2]$ ($L' = PPh_3$ or $AsPh_3$) [6] were all prepared as described in the literature. Precious metal salts were obtained on loan from Johnson Matthey plc.

3.1. Method I

An excess of the appropriate diphosphine was added to a stirred suspension of $[Pd_2(dba)_3]\cdot CHCl_3$ (0.5 g, 0.48 mmol) in diethyl ether (50 cm^3) containing the required 3-oxopentanedioic acid dialkyl ester (1 cm^3) under oxygen for 24–96 h. The resulting pale yellow solid was collected, recrystallised from dichloromethane–diethyl ether and dried in vacuo.

3.1.1. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppe)] (**3a**)

A mixture of $[Pd_2(dba)_3]\cdot CHCl_3$, dppe (0.4 g, 1 mmol) and 3-oxopentanedioic acid dimethyl ester was stirred for 24 h. Recrystallisation from dichloromethane–diethyl ether gave a pale yellow solid, **3a** (0.250 g, 38%). Found: C, 59.0; H, 5.0; P, 8.9. $C_{33}H_{32}O_5P_2Pd$ requires C, 58.6; H, 4.7; P, 9.2%. M.p. 180–182 °C (dec.); IR: 1705, 1668, 1595 ν(CO) cm^{-1}. ^{1}H NMR (250 MHz, [$^2H_1$]chloroform), $\delta = 7.85$–7.32 (20H, m, Ph), 4.34 [2H, d, CH, $|^3J(PH)_{trans} + {}^3J(PH)_{cis}|$ 8.53], 2.94 (6H, s, CH_3), 2.50–2.20 (4H, m, CH_2); ^{1}H NMR (300 MHz, [$^2H_1$] dichloromethane, −86 °C), $\delta = 7.80$–7.18 (20H, m, Ph), 4.68 [1H, d, CH, ^3J(PH) 10.8], 3.97 (1H, bs, CH), 2.68 (3H, s, CH_3), 2.65 (3H, s, CH_3), 2.13–2.0 (4H, m, CH_2CH_2) ppm. $^{31}P\{^1H\}$ NMR (24 MHz, CD_2Cl_2), $\delta = 49.8$ ppm (s), 48.3 ppm (s) (5:1 ratio). Mass spectrum (FAB), $[MH]^+$ 677.

3.1.2. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppp)] (**3b**)

A mixture of $[Pd_2(dba)_3]\cdot CHCl_3$, dppp (1 g, 2.4 mmol) and 3-oxopentanedioic acid dimethyl ester was stirred for 72 h. Recrystallisation from dichloromethane–diethyl ether gave a pale yellow solid, **3b** (0.5 g, 75%). Found: C, 59.3; H, 5.2; P, 8.3. $C_{34}H_{34}O_5P_2Pd$ requires C, 59.1; H, 5.0; P, 9.0%. IR: 1705, 1665, 1592 ν(CO), cm^{-1}. ^{1}H NMR (250 MHz, [$^2H_1$]chloroform), $\delta = 7.70$–7.22 (20H, m, Ph), 3.6 (2H, m, CH), 2.78 (6H, s, CH_3), 2.35–1.92(6H, m, CH_2CH_2) ppm. $^{31}P\{^1H\}$ NMR (24 MHz, CH_2Cl_2), $\delta = 6.7$ ppm (s), 5.5 ppm (5:1 ratio). Mass spectrum (FAB), $[MH]^+$ 691.

3.1.3. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppb)] (**3c**)

A mixture of $[Pd_2(dba)_3]\cdot CHCl_3$, dppb (0.93 g, 2 mmol) and 3-oxopentanedioic acid dimethyl ester was stirred for 96 h. Recrystallisation from dichloromethane–diethyl ether gave a pale yellow solid, **3c** (0.7 g, 90%). Found: C, 59.2; H, 5.6; P, 8.5. $C_{35}H_{36}O_5P_2Pd$ requires C, 59.6; H, 5.1; P, 8.8%. M.p. 220–222 °C (dec.). IR: 1705, 1670, 1556 ν(CO), cm^{-1}. ^{1}H NMR (250 MHz, [$^2H_1$]chloroform), $\delta = 7.8$–7.24 (20H, m, Ph), 4.2 (2H, br, CH), 3.0 (3H, s, CH_3), 2.9 (3H, s, CH_3), 2.50–2.20 (8H, m, CH_2CH_2) ppm. $^{31}P\{^1H\}$ NMR (24 MHz, $CDCl_3$), $\delta = 19.5$ ppm (s). Mass spectrum (FAB), $[MH]^+$ 705.

3.1.4. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppf)] (**3d**)

A mixture of $[Pd_2(dba)_3]\cdot CHCl_3$ (0.3 g, 0.3 mmol), dppf (0.28 g, 0.5 mmol) and 3-oxopentanedioic acid dimethyl ester was stirred for 48 h. Recrystallisation from dichloromethane–diethyl ether gave a solid, **3d** (0.420 g, 84%). Found: C, 59.5; H, 4.2; P, 7.9. $C_{41}H_{36}FeO_5P_2Pd$ requires C, 59.1; H, 4.4; P, 7.4%. M.p. 178–180 °C (dec.). IR: 1690, 1660, 1590 ν(CO), cm^{-1}. ^{1}H NMR (300 MHz, [$^2H_1$]chloroform), $\delta = 7.74$–7.08 (20H, m, Ph), 4.34 [2H, d, CH, $|^3J(PH)_{trans} + {}^3J(PH)_{cis}|$ | 10.6], 4.63–3.83 (8H, m, Cp), 2.98 (6H, s, CH_3) ppm.

$^{31}P\{^{1}H\}$ NMR (24 MHz, $CDCl_3$), $\delta = 28.2$ (s) and 24.4 ppm (s) (1:4 ratio). Mass spectrum (FAB), $[MH]^+$ 833.

3.2. Method II

An excess of ligand was added to a stirred solution of [$PdCl_2$(COD)] (0.5 g, 1.75 mmol) in dichloromethane (25 cm^3) containing the required 1,3-dialkylacetone dicarboxylate (1 cm^3) and an excess of silver(I) oxide (0.7 g) under nitrogen and was refluxed for 5 h. Filtration to remove silver salts afforded a pale yellow solution which was evaporated to dryness under reduced pressure and redissolved in dichloromethane (5 cm^3) followed by the addition of diethyl ether or petroleum ether to give a pale yellow solid. Removing the solid by filtration afforded the complex which was dried in vacuo.

3.2.1. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppe)] (**3a**)

A mixture of [$PdCl_2$(COD)], dppe (0.7 g, 1.75 mmol), 1,3-dimethylacetone dicarboxylate and an excess of silver(I) oxide in dichloromethane gave a pale yellow solid which was identified as **3a** (0.210 g, 18%) by comparison of its IR and ^1H NMR spectra with an authentic sample.

3.2.2. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppp)] (**3b**)

A mixture of [$PdCl_2$(COD)] (0.2 g, 0.7 mmol), dppp (0.43 g, 1 mmol), 1,3-dimethylacetone dicarboxylate and an excess of silver(I) oxide in dichloromethane gave an oily residue of **3b** which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.2.3. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppb)] (**3c**)

A mixture of [$PdCl_2$(COD)] (0.2 g, 0.7 mmol), dppb (0.45 g, 1.1 mmol), 1,3-dimethylacetone dicarboxylate and an excess of silver(I) oxide in dichloromethane gave a pale yellow solid of **3c** (0.325 g, 66%) which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.2.4. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppf)] (**3d**)

A mixture of [$PdCl_2$(COD)], dppf (0.195 g, 0.35 mmol), 1,3-dimethylacetone dicarboxylate and an excess of silver(I) oxide in dichloromethane gave a solid of **3d** (0.280 g, 96%) which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.2.5. Preparation of [Pd{η^3-CH(CO_2Et)COCH(CO_2Et)}(dppe)] (**4a**)

A mixture of [$PdCl_2$(COD)] (0.2 g, 0.7 mmol), dppe (0.3 g, 0.75 mmol), 1,3-diethylacetone dicarboxylate and an excess of silver(I) oxide in dichloromethane gave a pale yellow solid, **4a** (0.25 g, 50%). Found: C, 59.5; H, 4.7; P, 9.0. $C_{33}H_{32}O_5P_2Pd$ requires C, 59.7; H, 5.1; P, 8.8%. M.p. 170–172 °C (dec.). IR: 1730, 1700, 1668, 1580, ν(CO), cm^{-1}. ^1H NMR (250 MHz, [$^2H_1$]chloroform), $\delta = 7.98$–7.54 (20H, m, Ph), 4.74 (2H, d, CH), 3.85 (4H, q, CH_2CH_3), 2.48 (4H, m, CH_2CH_2), 1.0 (6H, t, CH_2CH_3) ppm. $^{31}P\{^1H\}$ NMR (24 MHz, CH_2Cl_2), $\delta = 49.2$ ppm (s), 48.8 ppm (s) (5:1 ratio). Mass spectrum (FAB), $[MH]^+$ 705.

3.3. Method III

A mixture of [Pd(η^3-CH{CO_2Me}COCH{CO_2Me})(L′)$_2$], (L′ = PPh_3 (**2a**) or $AsPh_3$ (**2b**)) and the appropriate ligand was refluxed in dichloromethane for several hours. The resulting mixture was evaporated to 1–2 cm^3 volume under reduced pressure and addition of diethyl ether afforded a pale yellow solid which was filtered and washed with diethyl ether and then dried in vacuo.

3.3.1. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppe)] (**3a**)

A mixture of **2a** (0.085 g, 0.1 mmol) and dppe (0.06 g, 1.5 mmol) in dichloromethane gave a pale yellow solid, **3a** (0.070 g, 98%) which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.3.2. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppp)] (**3b**)

A mixture of **2a** (0.1 g, 0.125 mmol) and dppp (0.1 g, 0.24 mmol) in dichloromethane gave a pale yellow solid, **3b** (0.04 g, 50%) which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.3.3. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppe)] (**3a**)

A mixture of **2b** (0.2 g, 0.225 mmol) and dppe (0.1 g, 0.25 mmol) in dichloromethane gave a pale yellow solid, **3a** (0.140 g, 92%) which was identified by comparison of its IR, ^1H and $^{31}P\{^1H\}$ NMR spectra with that of an authentic sample.

3.3.4. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppp)] (**3b**)

A mixture of **2b** (0.1 g, 0.11 mmol) and dppp (0.7 g, 1.7 mmol) in dichloromethane gave pale yellow solid, **3b** (0.025 g, 33%) which was identified by comparison of its

IR, ^{1}H and $^{31}P\{^{1}H\}$ NMR spectra with that of an authentic sample.

3.3.5. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppb)] (**3c**)

A mixture of **2b** (0.1 g, 0.11 mmol) and dppb (0.1 g, 0.24 mmol) in dichloromethane gave a pale yellow solid of **3c** (0.021 g, 26%) which was identified by comparison of its IR, ^{1}H and $^{31}P\{^{1}H\}$ NMR spectra with that of an authentic sample.

3.3.6. Preparation of [Pd{η^3-CH(CO_2Me)COCH(CO_2Me)}(dppf)] (**3d**)

A mixture of **2b** (0.17 g, 0.18 mmol) and dppf (0.1 g, 0.19 mmol) in dichloromethane gave a pale yellow solid, **3d** (0.090 g, 60%) which was identified by comparison of its IR, ^{1}H and $^{31}P\{^{1}H\}$ NMR spectra with that of an authentic sample.

Acknowledgements

The Zonguldak Karaelmas University, Turkey, is thanked for financial support, the University of Leicester, UK, for laboratory facilities, and Johnson Matthey plc. for the supply of palladium metal salts.

bend toward the major groove and a widening and flattening of the minor groove. Studies showing significant differences in the effectiveness of EN–Pt (EN = 1,2-ethylenediamine) and DACH–Pt (DACH = 1,2-diaminocyclohexane) adducts in inhibiting transformation efficiency in a repair-deficient strain of *Escherichia coli* suggest that some carrier ligand effects on resistant cell lines arise from differences in the ability of certain Pt–DNA adducts to inhibit other processes like replication or transcription [5,6,12–14]. These structural distortions and differences in carrier ligand effects in turn likely affect the ability of the platinum drugs to block DNA replication and transcription [15,16].

A series of compounds with 1,2-DACH, 1,4-DACH and homopiperazine as carrier ligands have been synthesized in our laboratory [17,18]. Here at the M.D. Anderson Cancer Center, DACH–acetate–Pt(IV) complexes have been identified as circumventing cisplatin resistance [19]. This led us to design and synthesize platinum complexes of a monodentate seven-member hexamethyleneimine (HMI) ligand as a stable amine with different leaving groups. We wish to report here the synthesis, and characterization of new platinum complexes and the crystal structure of [Pt^{II}(hexamethyleneimmine)$_2$(cyclobutanedicarboxylato)]·H_2O complex.

2. Experimental

2.1. Chemicals

K_2PtCl_4 and silver sulfate were purchased from Johnson Matthey, Seabrook, NH. HMI, 1,1-cyclobutanedicarboxylic acid (CBDCA), sodium oxalate, malonic acid disodium salt, and acetic anhydride were purchased from Aldrich Chemical Co., Milwaukee, WI. Silver nitrate and HCl were obtained from Fisher Scientific Co., Houston, TX. All chemicals obtained from commercial sources were used as supplied.

2.2. Physical measurements

Elemental analyses of the complexes were performed by Robertson Laboratory Inc., Madison, NJ. Infrared (IR) spectra in the range of 600–4000 cm^{-1} and far-IR spectra in the range of 150–600 cm^{-1} were recorded in KBr and polyethylene pellets, respectively, on a Perkin–Elmer 2000 spectrophotometer. ^{13}C and ^{195}Pt NMR spectra in methanol were recorded using a Bruker Advance 300 spectrometer. ^{13}C spectra were recorded with a 5 mm tunable probe at 75.13 MHz, ^{195}Pt spectra were recorded at 43.055 MHz, and the shifts were measured relative to an external standard of 2.2 M Na_2PtCl_6 in D_2O at 0.00 ppm.

2.3. Synthesis

2.3.1. Preparation of [Pt(HMI)$_2$Cl$_2$] (complex 1)

K_2PtCl_4 (20.00 g, 48.19 mmol) was dissolved in 300 ml of deionized water and filtered. A solution of KI (63.99 g, 385.54 mol) in 150 ml of water was added to it, and the reaction mixture was stirred for 10 min. Next, HMI (9.55 g, 96.38 mmol) was added dropwise to the mixture while stirring to obtain a yellow precipitate of [Pt(HMI)$_2$I$_2$] (**1a**). The stirring was continued for a further 30 min, and the precipitate was then collected by filtration. This compound was stirred in 100 ml of dimethylformamide, filtered, washed with water, ethanol, and acetone, and dried under vacuum (yield, 95%). [Pt(HMI)$_2$I$_2$] (13.00 g, 20.08 mmol) was suspended in an aqueous solution of silver nitrate (6.87 g, 40.16 mmol) in 400 ml of water. The reaction mixture was stirred for 24 h at room temperature (r.t.) in the dark. The AgI precipitate was filtered off, and a solution of 1:1 concentrated HCl was added to the filtrate with constant stirring until a yellow precipitate of **1** formed. It was filtered washed with water and acetone and dried under vacuum. Complex **1** was used as a precursor for Pt(IV) complexes **7**–**9** (see below).

2.3.2. [Pt^{II}(HMI)$_2$(OSO_3)H_2O] (complex 2)

To a suspension of **1a** (3.1 g, 4.79 mmol) in 250 ml of water Ag_2SO_4 (1.49, 4.79 mmol) was added. The reaction mixture was then stirred in the dark at r.t. for 24 h. The dark yellow precipitate was filtered off, and the filtrate was evaporated to dryness under reduced pressure at 35 °C. A pale yellow solid was obtained. The product was recrystallized from water, to yield a white compound. Complex **2** was used as a precursor for Pt(II) complexes **3**–**6** (see below).

2.3.3. [Pt^{II}(HMI)$_2$(CBDCA)]·H_2O (complex 3)

Complex **2** (0.40 g, 0.84 mmol) was dissolved in 50 ml of water and then added to 50 ml of sodium salt of CBDCA (0.067 g, 1.68 mmol) prepared in situ. The reaction mixture was stirred for 24 h, filtered, and evaporated to 10 ml under reduced pressure. It was cooled at 0 °C for 24 h in a refrigerator. A white precipitate of **3** was obtained. The final product was filtered, washed with cold water, and dried in vacuum. Recrystallization of **3** was achieved by dissolving 0.025 g of the compound in 100 ml of methanol, after which the volume of the solution was reduced to 50 ml and filtered. The filtrate was allowed to evaporate slowly at r.t. Within 2 weeks, colorless needle-shaped crystals were separated from the solution and used for single-crystal X-ray diffraction.

Complexes **4**–**6** were prepared by the same procedure as described for the complex **3**.

2.3.4. [$Pt^{IV}(HMI)_2$trans-$(OH)_2Cl_2$] (complex 7)

To a suspension of **1** (2.00 g, 4.30 mmol) in 200 ml of water was added 30 ml of 30% H_2O_2. The reaction mixture was then stirred for 3 h at 70 °C and thereafter continuously stirred for 24 h at r.t. It was filtered and evaporated to dryness and precipitated with acetone. A pale yellow precipitate of **7** formed and was filtered, washed with acetone, and dried in vacuo.

2.3.5. [$Pt^{IV}(HMI)_2$trans-(acetato)$_2Cl_2$] (complex **8**)

Complex **7** (1.00 g, 2.00 mmol) was suspended in 25 ml of acetic anhydride and stirred at r.t. for 24 h. Methanol (25 ml) was added to the reaction mixture and stirred. A clear solution formed, which was filtered and evaporated to dryness. The crude product was dissolved in acetone, supplemented with activated carbon, and filtered. The resulting solution was then evaporated to dryness. A pale yellow compound was obtained and dried in vacuo.

2.3.6. [$Pt^{IV}(HMI)_2Cl_4$] (complex **9**)

Complex **7** (1.00 g, 2.20 mmol) was suspended in 20 ml of water supplemented with 15 ml of concentrated HCl. A clear solution was obtained. The stirring was continued for 4 days at r.t. to obtain a yellow crystalline compound. This was filtered and washed with water. The solid was recrystallized from acetone and dried in vacuo.

2.4. Single-crystal X-ray crystallographic study

The experimental details of the X-ray data collection, the structure solution, and refinement of the title compound are compiled in Table 1. A single-crystal of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$ was coated with a thin layer of epoxy cement and mounted on the goniometer of a Bruker SMART 1K diffractometer equipped with a CCD area detector. The data was corrected for Lorentz and polarization effects. An empirical absorption correction was applied using the program SADABS [20]. No appreciable decay of the crystal was detected during data collection.

The structure was solved using direct methods with the SHELXTL software package [20]. Scattering factors were taken from the literature [21]. Heavy atoms were located initially to set the correct phases for the model. All other atoms were located by successive Fourier maps and were refined using the full-matrix least-squares method on F^2. Two complete molecules were found to occupy the asymmetric unit of the crystal lattice. Attempts to transform the crystallographic data to a space group that possessed higher symmetry and would presumably only contain a single molecule in the asymmetric unit, did not result in successful solution of the data. The choice of the space group *Pc* was confirmed through symmetry software in the PLATON crystallographic package [22]. Hydrogen atoms were placed in calculated positions and allowed to ride on the adjacent atom. Toward the end of the refinement it was discovered that one of the amine ligands on each platinum atom was disordered over two positions. The disorder was modeled and the structure was refined accordingly. Carbon–carbon bonds in the disordered ligands were constrained to the same distances. Disordered atoms were allowed to refine isotropically. All other non-hydrogen atoms were refined anisotropically. Refinement of positional and anisotropic parameters led to convergence.

Table 1
Crystal data and structure refinement for $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$

Empirical formula	$C_{18}H_{32}N_2O_4Pt\cdot H_2O$
Formula weight	552.54

Max/min transmission	1.000000, 0.603765
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	5697/53/438
Goodness-of-fit on F^2	1.040
Final *R* indices [$I > 2\sigma(I)$]	$R_1 = 0.0348$, $wR_2 = 0.0916$
R indices (all data)	$R_1 = 0.0367$, $wR_2 = 0.0927$
Absolute structure parameter	0.017(13)
Largest difference peak and hole (e Å^{-3})	1.480 and −1.411

3. Results and discussion

3.1. Synthesis of platinum complexes

The steps involved in the synthesis of platinum(II) and platinum(IV) complexes are shown in Schemes 1 and 2. Compound **1** was prepared according to the method described by Dhara [23], which was adopted because it is rapid and easy and provides a much higher yield than when K_2PtCl_4 is treated directly with HMI.

Pt^{II} Complexes

$K_2PtCl_4 + 8KI \longrightarrow K_2PtI_4 + 4KI + 4KCl$ (A)

$K_2PtI_4 + 2(HMI) \longrightarrow [Pt^{II}(HMI)_2I_2] + 2KI$ (B)

$[Pt^{II}(HMI)_2I_2] + 2AgNO_3 \longrightarrow [Pt^{II}(HMI)_2(H_2O)_2](NO_3)_2 + 2AgI$ (C)

$[Pt^{II}(HMI)_2(H_2O)_2](NO_3)_2 + 2HCl \longrightarrow [Pt^{II}(HMI)_2Cl_2] + 2HNO_3 + 2H_2O$ (D)

$[Pt^{II}(HMI)_2Cl_2] + 2AgSO_4 \longrightarrow [Pt^{II}(HMI)_2(OSO_3)H_2O] + 2AgCl$ (E)

$[Pt^{II}(HMI)_2(OSO_3)H_2O] + Na_2X \longrightarrow [Pt^{II}(HMI)_2X] + Na_2SO_4$ (F)

Scheme 1. Where HMI = hexamethyleneimine; X = 1,1-cyclobutyldicarboxylato (CBDCA), methylmalonato, oxalato, or tartronato; Y = chloro or acetato.

Pt^{IV} Complexes

$[Pt^{II}(HMI)_2Cl_2] \xrightarrow{30\%\ H_2O_2} [Pt^{IV}(HMI)_2trans\text{-}(OH)_2Cl_2]$ (G)

$[Pt^{IV}(HMI)_2trans\text{-}(OH)_2Cl_2] \xrightarrow{\text{acetic anhydride}} [Pt^{IV}(HMI)_2trans\text{-}(Y)_2Cl_2]$ (H)

$[Pt^{IV}(HMI)_2trans\text{-}(OH)_2Cl_2] \xrightarrow{\text{conc. HCl}} [Pt^{IV}(HMI)_2trans\text{-}(Y)_2Cl_2]$ (I)

Scheme 2. Where HMI = hexamethyleneimine; X = 1,1-cyclobutyldicarboxylato (CBDCA), methylmalonato, oxalato, or tartronato; Y = chloro or acetato.

Complexes **1** and **2** were used as precursors for both $[Pt^{II}(HMI)_2X]$- and $[Pt^{IV}(HMI)_2trans\text{-}(Y)_2Cl_2]$-type complexes.

In Scheme 1, K_2PtCl_4 mixed with an excess of KI produced K_2PtI_4 in solution. K_2PtI_4 was then treated with 2 equiv. of HMI to precipitate $[Pt^{II}(HMI)_2I_2]$. The reaction of $[Pt^{II}(HMI)_2I_2]$ with $AgNO_3$ led to the formation of $[Pt^{II}(HMI)_2(H_2O)_2](NO_3)_2$ in solution, which was further converted to $[Pt^{II}(HMI)_2Cl_2]$ by treating it with a concentrated 1:1 HCl solution. The reaction of $[Pt^{II}(HMI)_2Cl_2]$ with Ag_2SO_4 formed $[Pt^{II}(HMI)_2(OSO_3)H_2O]$. The reaction of $[Pt^{II}(HMI)_2(OSO_3)H_2O]$ with 1 equiv. of corresponding sodium salt of dicarboxylic acids in methanol produced $[Pt^{II}(HMI)_2X]$ type complexes (complexes **3**–**6**).

In Scheme 2, Pt(II) complexes of the type $[Pt^{II}(HMI)_2X]$ were oxidized with 30% H_2O_2 to form corresponding axial dihydroxyplatinum(IV) complex **7** $[Pt^{IV}(HMI)_2trans\text{-}(OH)_2Cl_2]$. By substitution of the hydroxo group with acetate using acetic anhydride, complex **8** $[Pt^{IV}(HMI)_2trans\text{-}(acetato)_2Cl_2]$ was produced. Hydroxide was substituted with chloride by reacting *trans*-hydroxy complex with conc. HCl to form complex **9** $[Pt^{IV}(HMI)_2Cl_4]$.

3.2. Characterization of platinum complexes

The complexes were characterized by elemental analysis and IR, ^{13}C NMR, and ^{195}Pt NMR spectroscopy. The composition of each complex as determined by elemental analysis showed good agreement between the theoretical and actual values. The analytical results are summarized in Table 2. The results of characterization by IR, ^{13}C NMR, and ^{195}Pt NMR are shown in Table 3. These values are close to the values reported for similar types of platinum complexes [18,24–27].

The IR spectra of the complexes in general showed a broad absorption between 3204 and 3009 cm^{-1}, which was due to the ν_{N-H} stretching vibrations of coordinated HMI. The carboxyl groups in complexes **3**–**6** displayed a band in the range of 1580–1610 cm^{-1} corresponding to the $\nu_{as}(COO^-)$ band. The $\nu_s(COO^-)$ band appeared in the range of 1360–1390 cm^{-1}. Two intense bands at 620 and 1130 cm^{-1} in complex **2** indicated the presence of an SO_4 group in the complex. The Pt–N, Pt–Cl, and Pt–O stretching frequencies showed peaks in the range of 520–525, 325–360, and 420–430 cm^{-1}, respectively.

The proton-decoupled ^{13}C NMR spectra showed a signal in the range of 180–190 ppm for magnetically equivalent carbonyl carbons in complexes **3**–**7**. The values of the free acids and platinum complexes are shown in the Table 3. Complexation shifts ($\Delta C = \delta$[complex] $- \delta$[ligand]) fell between 1.8 and 2.5 ppm.

The ^{195}Pt NMR data shown in Table 3 further confirmed the structures of these platinum complexes. $[Pt^{II}(HMI)_2Cl_2]$ showed a signal at −2210 ppm, which is characteristic of the square planar platinum(II) complex in which the two adjacent corners are occupied by two nitrogen and the other two positions by two chlorides. Two peaks were observed at −1623 and −1666 ppm in the spectrum of complex **2**. Complexes **3**–**7** showed signals in the range of −1802 through −1821 ppm. Such chemical shifts are characteristic of square planar platinum(II) complexes having two nitrogens and two oxygen atoms as donor ligands. As oxidation of platinum(II) to platinum(IV) leads to a large shift, complex **7** showed a singlet at 1069 ppm and complex **8** a singlet at 1150 ppm. These values are close to those of the related platinum(IV) complexes having two nitrogen atoms, two oxygen atoms, and two chloride ions as donor ligands. In these complexes (**7** and **8**), the chloride ions occupied the equatorial positions. Complex **9** showed a signal at −150 ppm, consistent with the values of platinum(IV) complexes having two nitrogen atoms and four chloride ions as donor ligands. Figs. 1 and 2 show the general structure of the complexes.

3.3. Crystal structure

Fig. 3 shows a view of the crystal structure of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$. Selected bond lengths and bond angles are given in Table 4. In this molecule, the coordination environment around the platinum atom is a slightly distorted square plane, with the angles ranging from 88.0(4)° to 92.9(4)°. The distortion is caused by limitation in the bite distances of the chelating ligand.

Table 2
Elemental analysis of platinum complexes

Complex	Complex name	Observed (calculated)				Yield (%)
		C	H	N	Cl	
1	$[Pt^{II}(HMI)_2Cl_2]$	31.62 (32.77)	5.70 (5.46)	6.00 (5.88)	14.88 (14.91)	61.53
2	$[Pt^{II}(HMI)_2(OSO_3)H_2O]$	27.50 (28.04)	5.47 (5.52)	5.41 (5.52)		90.90

[a] See Figs. 1 and 2 for structures.
[b] Recorded in *N*,*N*-dimethylformamide.
[c] Recorded in methanol.
[d] Recorded in acetone; $\Delta C = \delta$[complex] $- \delta$[ligand].

The platinum coordination environment contains two adjacent corners occupied by the two nitrogen atoms of the HMI ligand, whereas the remaining two *cis* positions are coordinated with two of the oxygen atoms of the CBDCA. All Pt–N and Pt–O bond lengths are in the range normally observed for platinum(II) complexes. The average Pt–N bond length of 2.06(9) Å is consistent with the length of those found in other monodentate and bidentate amine ligand-containing complexes. For instance, this length is 1.99(2) Å in $[Pt^{II}$(1-methylhomopiperazine)(methylmalonato)]$\cdot 2H_2O$ [18], 2.02(10) Å in $[Pt^{II}$(hpip)(pentadecanoato)$_2]$ [25], 2.038(8) Å in $[Pt^{II}$(3-methylpiperidine)(malonato)]$\cdot H_2O$ [28], 2.03 Å in [Pt(*trans*-*l*-1,2-DACH)(CBDCA)]$\cdot H_2O$ [29], 2.043(2) Å in [Pt(*cis*-1,4-DACH)(CBDCA)] [30], and 2.02 Å in [Pt(*cis*-1,4-DACH)(malonato)] [31].

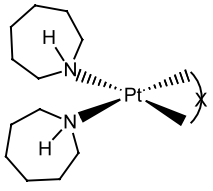

Fig. 1. Structure of $[Pt^{II}(HMI)_2X]$; HMI = hexamethyleneimine; X = dichloro in complex **1**; sulfato in complex **2**; CBDCA, methylmalonato, oxalato, or tatronato in complexes **3**–**6**, respectively.

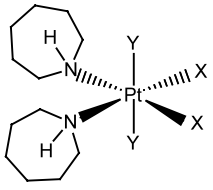

Fig. 2. Structure of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$; X = chloro in complexes **7**–**9**; Y = OH in complex **7**, acetato in complex **8**, and chloro in complex **9**.

The average Pt–O bond length of 2.02 Å is normal as compared with the values observed in other Pt(II) carboxylate complexes, e.g. 2.01(9) Å in [Pt(*trans*-*l*-1,2-DACH)(CBDCA)]$\cdot H_2O$ [29], 2.02(2) Å in $[Pt^{II}$(1-methylhomopiperazine)(methylmalonato)]$\cdot 2H_2O$ [18], 2.014(7) Å in [Pt(3-methylpiperidine)$_2$(malonato)]$\cdot H_2O$ [28], and 2.038(10) Å in $[Pt^{II}$(hpip)(pentadecanoato)$_2]$ [25].

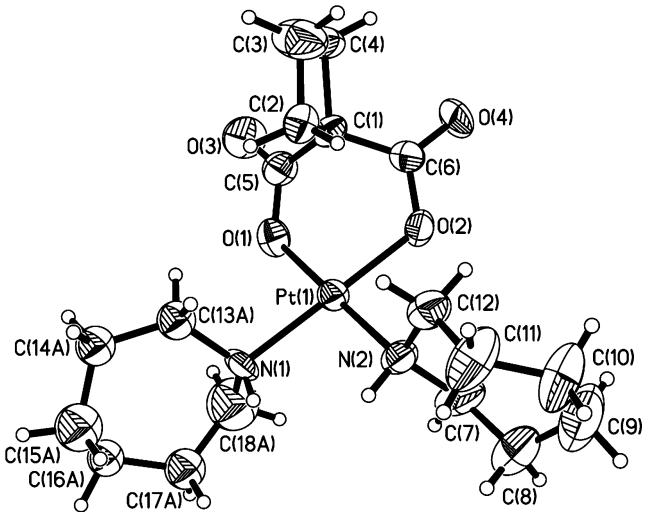

Fig. 3. ORTEP representation of the structure of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$ with atom numbering scheme.

Table 4
Selected bond lengths (Å) and angles (°) for $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$

Bond lengths

C(25)–O(21)–Pt(2)	119.3(7)
C(26)–O(22)-Pt(2)	121.5(8)
C(38)–N(22A)–Pt(2)	109.7(8)
C(33A)–N(22A)–Pt(2)	109.5(8)

The coordination structure of the platinum complex with two ring nitrogens of HMI is considerably strained. The N(2)–Pt(1)–N(1) bond angle is expanded to an average value of 93.0° due to geometric constraints imposed by the ligand. These angles are close to the 98.8(4)° reported for [Pt(*cis*-1,4-DACH)(CBDCA)] [30] and the 100.0(2)° reported for [Pt(*cis*-1,4-DACH)(malonato)] [31]. The bond between HMI and the metal ion are also considerably strained as evidenced by the average C–N–Pt angle of 109.1(8)°. These angles are 112.1(9)°, 114.2(7)°, and 122.3(7)° in [Pt(*trans*-*l*-1,2-DACH)(CBDCA)] [29], [Pt(3-methylpiperidine)$_2$(malonato)]·H_2O [28], and [Pt(*cis*-1,4-DACH)(CBDCA)] [30], respectively. The expansion of the N(2)–Pt(1)–N(1) bond angle was compensated for by the contraction of the O(1)–Pt(1)–O(2) angle to 89.9(3)° and the O(21)–Pt(2)–O(22) angle to 88.3(3)°. The molecules in the crystal show a system of N–H···O hydrogen bonds (Fig. 4). The hydrogen bond interactions were examined using the program CRYSTALS [32]. The hydrogen bond lengths were found to range from 2.039 to 2.413 Å, with the average N–H···O interaction being 2.207 Å in length and possessing a bond angle of approximately 158.3°.

In summary, we have synthesized and characterized a series of new platinum(II) and (IV) complexes containing HMI as nonleaving amine ligands and different groups as leaving ligands. The crystal structure of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$ was determined by X-ray crystallography.

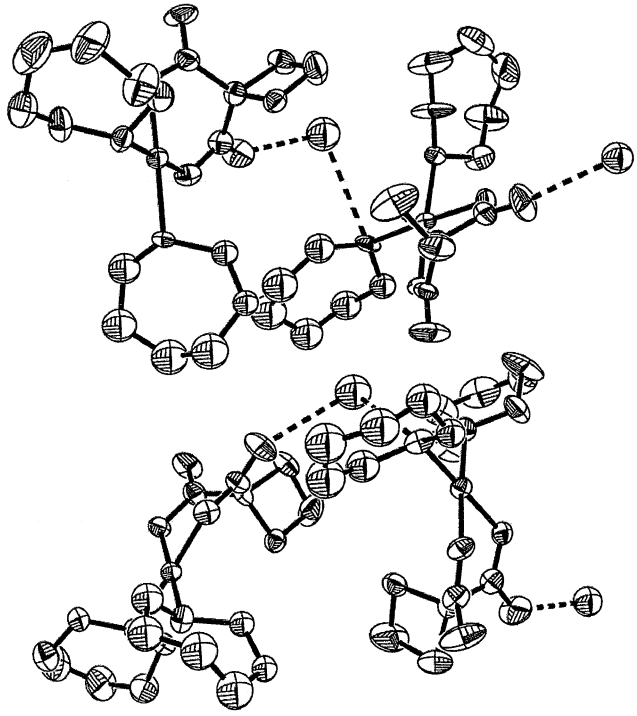

Fig. 4. Packing diagram of $[Pt^{II}(HMI)_2(CBDCA)]\cdot H_2O$ Hydrogen bonds are shown by dashed lines.

4. Supplementary material

Full lists of bond lengths and bond angles, atomic coordinates and equivalent isotropic displacement parameters, anisotropic displacement parameters, and hydrogen coordinates have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Supporting information is available from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition number 181721. Any request to the CCDC for this material should quote the full literature citation.

ences in the bond lengths (M–N and M–O), ring strain and the ligand configuration [1–5,8–19,21–29].

The edta-like ligands [diamine-*N*,*N*′-diacetate-*N*,*N*′-di-3-propionate ions (eddadp or 1,3-pddadp)], differing only in the length of the diamine chain, can form a maximum of three geometrical isomers on hexadentate coordination: *trans*(O_5) (I), *trans*(O_5O_6) (II) and *trans*(O_6) (III) (Fig. 1) (O_5 and O_6 refer to the five- and six-membered N–O rings, respectively). The six-membered β-alaninate rings serve better for the formation of less-strained G rings favoring the *trans*(O_5) isomers of $[M(eddadp)]^{n-}$ complexes [6–15]. Only one of two *trans*(O5) isomers was also prepared with the optically active *SS*-edds ligand (*SS*-ethylenediamine-*N*,*N*′-disuccinate ion) which produces metal complexes stereospecifically with the Λ configuration [6,7,15–18]. Contrary to this, all possible isomers of $[M(1,3\text{-pddadp})]^{n-}$ have been reported for Cr(III) [19], but only two isomers (*trans*(O_5O_6) and *trans*(O_6) for Co(III) [20,21] and *trans*(O_5) and *trans*(O_5O_6) for Rh(III) [22]) have been isolated and characterized. In addition, only one dominant isomer of the same complex *trans*(O_6) of Cu(II) [23] has been established.

This paper deals with the preparation and characterization of the two geometrical isomers (*trans*(O_5) (**1**) and *trans*(O_5O_6) (**2**)) of the $[Ni(1,3\text{-pddadp})]^{2-}$ complex. The X-ray data are reported for the binuclear complex *trans*(O_5)-$[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (**1**). Structural parameters and strain analysis data of this complex and the other related complexes are compared and discussed in relation to the structure of the ligand, geometry of complexes and their octahedral distortion. The results presented for isomers **1** and **2**, based upon IR (carboxylate region) and electronic absorption spectroscopy, are compared with earlier results obtained for related complexes.

2. Experimental

All commercially obtained reagent-grade chemicals were used as supplied. The 1,3-propanediamine-*N*,*N*′-diacetic-*N*,*N*′-di-3-propionic acid ($H_4$1,3-pddadp) was prepared using a previously described procedure [20].

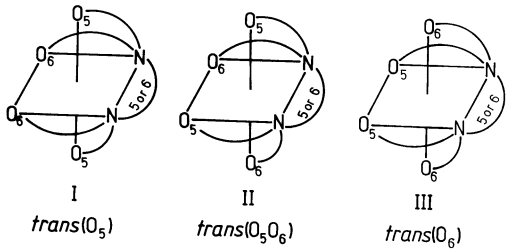

Fig. 1. Three possible geometrical isomers of hexadentate $[M(eddadp)]^{n-}$ and $[M(1,3\text{-pddadp})]^{n-}$ complexes.

2.1. Preparation and separation of complexes: *trans*(O_5) geometrical isomer of sodium (1,3-propanediamine-*N*,*N*′-diacetato-*N*,*N*′-di-3-propionato)nickelate(II) dihydrate, *trans*(O_5)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 2H_2O$ (**1**) and *trans*(O_5O_6) geometrical isomer of sodium (1,3-propanediamine-*N*,*N*′-diacetato-*N*,*N*′-di-3-propionato)nickelate(II) trihydrate, *trans*(O_5O_6)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 3H_2O$ (**2**)

A solution of nickel(II) chloride hexahydrate, $NiCl_2\cdot 6H_2O$ (2.38 g, 0.0100 mol in 25 cm^3 of water) was added to solution of $H_4$1,3-pddadp (3.34 g, 0.0100 mol) and $NaHCO_3$ (1.68 g, 0.0200 mol) in 25 cm^3 of water with heating (65 °C) and stirring. Heating with stirring at the same temperature was continued for 1 h. After the pH of the mixture was adjusted to approximately 7 by gradual addition of $NaHCO_3$, the blue solution was then heated (80 °C) with stirring for a further 2 h (the volume of the solution was maintained by periodic addition of hot water). The solution was then reduced to approximately 15 cm^3 and desalted by passing it through a G-10 Sephadex column, eluting with distilled water. The obtained eluate was introduced into a 5 × 60 cm column containing Dowex 1-X8 (200–400 mesh) anion-exchange resin in the Cl^- form. After the column was washed with water, the charged complexes were eluted with a 0.1 M NaCl solution at a rate of 0.3 $cm^3\ min^{-1}$. Two bands appeared on the column. The obtained eluate of each band was reduced to a small volume and then desalted. The eluate of the first band (*trans*(O_5) isomer (**1**)) was reduced to a volume of 4 cm^3 and stored in a desiccator over methanol for several days. The light blue crystals of *trans*(O_5)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 2H_2O$ (**1**) were collected, washed with methanol and then ether, and air-dried (2.5 g). The second eluate (*trans*(O_5O_6) isomer (**2**)) was reduced to 2 cm^3 and stored in a desiccator over $CaCl_2$ for several days. The light blue crystal powder of *trans*(O_5O_6)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 3H_2O$ (**2**) was collected (0.2 g). Found: Ni, 12.40; C, 32.82; H, 4.76; N, 5.85; H_2O, 8.02%. Calc. for *trans*(O_5)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 2H_2O$ (**1**), $Na_2NiC_{13}H_{22}N_2O_{10}$ (FW = 471.00): Ni, 12.46; C, 33.15; H, 4.71; N, 5.95; H_2O, 7.65%. Found: Ni, 12.20; C, 31.84; H, 4.96; N, 5.70; H_2O, 11.32%. Calc. for *trans*(O_5O_6)-$Na_2[Ni(1,3\text{-pddadp})]\cdot 3H_2O$ (**2**), $Na_2NiC_{13}H_{24}N_2O_{11}$ (FW = 489.01): Ni, 12.00; C, 31.93; H, 4.95; N, 5.73; H_2O, 11.05%.

Complex **1** in the form of the nickel(II) salt was obtained using the ion-exchange column technique. The eluate was reduced to a small volume and allowed to stand at room temperature (r.t.) to crystallize the complex $[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (**1**). Found: Ni, 19.74; C, 26.50; H, 5.74; N, 4.80%. Calc. for $[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (**1**), $Ni_2C_{13}H_{34}N_2O_{16}$ (FW = 591.80): Ni, 19.83; C, 26.38; H, 5.79; N, 4.73%.

The suitable crystal for X-ray analysis of this complex was obtained from an aqueous solution.

2.2. Physical measurements

2.2.1. $[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (**1**)

A pale blue crystal with approximate dimensions of $0.39 \times 0.47 \times 0.54$ mm was used for X-ray data collection. Intensity measurements were made on a Siemens AED single-crystal diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K.

Crystal data: $Ni_2C_{13}H_{34}N_2O_{16}$ (FW = 591.80), triclinic, space group $P\bar{1}$, $a = 14.065(4)$, $b = 10.070(2)$, $c = 9.408(1)$ Å, $\alpha = 63.21(6)^\circ$, $\beta = 74.11(5)^\circ$, $\gamma = 79.41(4)^\circ$, $V = 1141.2(8)$ Å^3, $Z = 2$, $D_c = 1.722$ g cm^{-3}, $D_m = 1.68$ g cm^{-3}, $F(000) = 620$, μ(Mo Kα) = 17.30 cm^{-1}.

The unit-cell dimensions were obtained from the setting angles of 28 accurately measured reflections with $14.7^\circ < \theta < 19.9^\circ$. No decay in the intensity of the standard reflection was noticed over the course of data collections. The intensity data were corrected for Lorentz and polarization effects but not for absorption. The structure was solved by direct methods using SIR-92 [30] and refined by full-matrix least-squares techniques based on F^2. The refinement converged to $R = 0.0521$ ($wR(F^2) = 0.1725$) for 5210 reflections ($F_o > 2\sigma(F_o)$) of 6629 collected in the range $6^\circ < 2\theta < 60^\circ$. Anisotropic thermal parameters were employed for non-hydrogen atoms, the hydrogen atoms being put in calculated positions and refined isotropically. Neutral scattering factors [31] were employed and the anomalous dispersion terms for all atoms were included in F_c. All calculations were performed on an ENCORE-91 computer using the programs SHELXL-93 [32], PARST [33] and ORTEP [34].

IR spectra were recorded on a Perkin–Elmer FT-IR 1725X spectrophotometer using KBr pellets. Aqueous solution spectra were obtained in D_2O.

Electronic absorption spectra were recorded on a Varian Cary 17D spectro-photometer. For these measurements, about 8×10^{-2} M aqueous solutions were used.

Elemental microanalyses for carbon, hydrogen, nitrogen and nickel were performed by the Microanalytical Laboratory, Faculty of Chemistry, University of Belgrade (Serbia, YU).

3. Results and discussion

The geometrical isomers of the complex $[M(1,3\text{-pddadp})]^{n-}$ have been chromatographically separated following the order: *trans*(O_5) (first), *trans*(O_5O_6) (second) and *trans*(O_6) (third) (Fig. 1). This order was established for the corresponding three isomers of Cr(III) [19], two isomers of Co(III) [20,21] and the two isomers of Rh(III) [22]. The two isomers of the $[Ni(1,3\text{-pddadp})]^{2-}$ complex [*trans*(O_5) (**1**) (C_2 molecular symmetry) and *trans*(O_5O_6) (**2**) (C_1 molecular symmetry)] have been prepared at pH ∼ 7 and all carboxylate groups are expected to be coordinated. The *trans*(O_5) configuration was verified in the molecular structure of (**1**) presented here. Following the order of elution, the complex (**2**) (second band) is expected to represent the *trans*(O_5O_6) isomer of the same complex. Spectral data reported for **1** and **2** are in agreement with the geometry of the complexes.

3.1. Description of the molecular structure of *trans*(O_5)-$[Ni_2(1,3\text{-pddadp})\text{-}(H_2O)_4]\cdot 4H_2O$ (**1**)

An ORTEP drawing of the *trans*(O_5)-$[Ni_2(1,3\text{-pddadp})(H_2O)_4]\cdot 4H_2O$ (**1**) is shown in Fig. 2, where the numbering scheme adopted for the respective atoms is also given. The bond lengths and selected bond angles are listed in Table 1.

The crystals of **1** are built up from binuclear homometallic complexes. The structural unit consists of $[Ni(1,3\text{-pddadp})]^{2-}$ and $[Ni(H_2O)_4(O_G\text{-carbox.})_2]^{2+}$ octahedra and four water solvent molecules (Fig. 2). In the complex anion, the Ni1 atom is surrounded by all of the donating atoms (2N and 4O) of the 1,3-pddadp ligand acting in a hexadentate. The complex anion represents a *trans*(O_5) isomer with the two glycinate (R_1 and R_2) rings in the *trans* positions and the two β-alaninate (G_1 and G_2) rings coordinated in the equatorial position forming a 6–6–6 ring system in the G-plane. The Ni2 atom is coordinated to four water molecules and two bridging carboxylate oxygen atoms, O(1) and O(3) of the G_1 and G_2 β-alaninate rings, respectively, resulting

in a four terms ring and making a discrete binuclear unit (Fig. 2). Both octahedra formed around the central atoms are irregular in shape and their octahedral *cis* angles (Table 1) range from 78.2(1)° to 98.1(1)° (for Ni1) and from 78.3(1)° to 95.5(1)° (for Ni2) while the *trans* ones in the complex anion are 179.3(1)°, 168.2(1)° and 169.1(1)°.

The conformations of the chelate rings in the complex anion (Fig. 2) are those usually expected for these kinds of chelates. The two five-membered glycinate rings show a relatively small puckering (R_1 in a twist conformation with puckering parameters of $q_2 = 0.081(4)$ Å and $\varphi_2 = 88(2)°$ and R_2 in an envelope conformation with puckering parameters of $q_2 = 0.105(4)$ Å and $\varphi_2 = 71(2)°$). The six-membered diamine (T) ring adopts a twist-boat conformation (λ, as expected for the complex anion presented in Fig. 2 having Δ configuration) with puckering parameters of QT = 0.781(4) Å and $\theta_2 = 90.5(3)°$. Two β-alaninate (G) rings adopting an envelope-like conformation show a similar degree of puckering (puckering parameters: QT = 0.566(4) Å, $\theta_2 = 63.7(4)°$ for G_1 ring and QT = 0.544(4) Å, $\theta_2 = 59.1(3)°$ for G_2 ring). The binuclear unit is stabilized by the two coordination bonds (Ni2–O(1), 2.073(3) Å; Ni2–O(3), 2.083(2) Å) and also by an extended hydrogen bonding network involving prevalently the oxygen atoms of the carboxylic groups and the hydrogen atoms of the coordinated and crystal water molecules.

3.2. Structural parameters of edta-type chelates and their octahedral distortion in relation to the structure of the ligand and geometry of the complex

The mean Ni–L bond distances and some bond angles of binuclear complex **1** and the corresponding values of some other Ni(II) complexes containing various edta-type ligands eddadp (**3**) [13], edds (**4**) [16–18], 1,3-pdta (1,3-propane-diaminetetraacetate ion) (**5**) [24] and edta (**6**) [3–5]) are given in Table 2. The presence of the two carboxylic atoms (O(1) and O(3)) bridging the two metal centers and the resulting four terms ring (Fig. 2) is responsible for both the lengthening of the Ni–O(G) distances compared with the Ni–O(R) distances (mean: 2.082 vs. 2.060 Å) and the narrowing of the corresponding O(1)–Ni–O(3) angle (78.2(1)° for Ni1 and 78.3(1)° for Ni2) (Tables 1 and 2). These two values are limited in a series of complexes listed in Table 2. The values for complexes **4** [16–18] and **6** [3–5] (Table 2) are not significantly changed by variation of counter ions.

As was expected [8,13–15,24–26], the mean Ni–O(R) distances are on average shorter than the mean Ni–O(G) distances (Table 2), with an exception for **4** and **5**, where the equatorial Ni–O(G) bonds are shorter than the Ni–O(R) bonds. However, the mean Ni–O distances of complexes listed are shorter than the mean Ni–N distances. The values given (Table 2) indicate that the mean Ni–O distances (mean Ni–O range, 2.044–2.071 Å) and the mean Ni–N distances (mean Ni–N range, 2.058–2.105 Å) are less sensitive to the structure of the ligand than was the case for the corresponding distances of M(III) complexes [8,13,22,25,26]. The complexes considered (Table 2) attain octahedral symmetry with varying degrees of distortion, reflecting the structure of the ligand and geometry of the complex. Octahedral distortion of these complexes slightly decreases with an increasing number of six-membered rings in the G-plane. Among the complexes listed (Table 2) the greatest deviation of the O(G_1)–Ni–O(G_2) angle was realized for **1**, **5** and **6** and vice versa for the O(R_1)–Ni–O(R_2) and N(1)–Ni–N(2) angles. For complexes **3** and **4**, having a 6–5–6 ring system in the G-plane, these angles are closer to the ideal values and these complexes attain higher octahedral symmetry. We observe that an increase in number of six-membered rings in the G-plane, going from **6** to **1**, causes a steady decrease in the

[a] For complexes **1**, **3** and **4** the values are given for *trans*(O_5) isomer.

$O(G_1)$–Ni–$O(G_2)$ *cis* angle. This angle for the group of Ni(II) complexes decreases in the order: 112.0(1)°-115.3(3)° (**6**) > 99.4(3)° (**5**) > 93.0(3)°-95.5(3)° (**4**) > 92.8(2)° (**3**) > 78.2(1)° (**1**). The same trend is observed for the N(1)–Ni–N(2) bond angle, although, it fits better for a series of complexes forming the diamine (T) or the diamine (E) ring only. For both *cis* angles similar trend was recently observed for a series of Rh(III) and Co(III) edta-type complexes [22].

Strain analysis data are available for the *trans*(O_6)-$[M(1,3\text{-}pddadp)]^{n-}$ complexes (M=Co(III) [14,25], Cr(III) [14,26] or Cu(II) [23]). The corresponding data are reported here for the two isomers (the *trans*(O_5) and *trans*(O_5O_6)) of Rh(III) [22] and the *trans*(O_5) isomer of the investigated Ni(II) complex (complexes **1** and **7**–**11**, Table 3). The total deviation of the octahedral angles of these complexes varies reflecting their large ionic radii [35] and the geometry of the complex (the ring system in the G-plane). These values vary from 38° for **7** [14,25] to 43° for **9** [23] (*trans*(O_6) isomers) and from 42° for **11** (*trans*(O_5O_6) isomer) to 55° for **10** and 60° for **1** (*trans*(O_5) isomers). The values are less for complexes **7**–**9** (5–6–5 ring system) and the complex **11** (5–6–6 ring system) and these complexes attain higher octahedral symmetry. The Rh(III) complex **11** (C_1 molecular symmetry) with respect to **10** (having 6–6–6 ring system in the G-plane and C_2 molecular symmetry) attains higher octahedral symmetry ($\Sigma\Delta(O_h)$, 42° vs. 55°, Table 3). For metal ions of the size comparable with Rh(III), as was reported [22], the best combination of the rings that can span the girdle plane seems to be the 5–6–6 system (**11**) which allows the diamine ring to adopt the energetically favored twist conformation and brings the $O(G_1)$–Rh–$O(G_2)$ *cis* angle close to 90°. The total deviation of the octahedral angles sums 60° for **1** indicating a greater octahedral distortion with respect to the size of the ionic radii [35] than among the other complexes listed. This value is expected because of the structure of the binuclear complex unit (**1**) (the presence of the two oxygen atoms (O(1) and O(3)) bridging the two metal centers by forming a four-membered ring) (Fig. 2). The six octahedral angles of **1** show very large deviations (Table 1).

The bond angle chelate-ring sums for the R, G, and diamine (T) rings are as expected for these kinds of chelates [13–15,23–26] (Table 3). The bond angle chelate-ring sums for the R glycinate rings are closer to the ideal values (538.5°). The total deviations are 0° for **1** and +1° for **11**, but unusually a large negative deviation (of −6°) was observed for **10** [22]. The bond angle chelatering sums for the G glycinate rings, as expected, are less than the ideal values (the negative total deviation varies from −10° to −11°). The larger deviations are positive for all six-membered rings (Table 3). The diamine (T) rings are in a twist-boat conformation and show positive total deviation (from +26° for **8**

[a] Ionic radius for C.N. = 6 [35].
[b] $\Sigma\Delta(O_h)$ is the sum of the absolute values of the deviations from 90° of the L–M–L' bite angles. All values rounded off to the nearest degree.
[c] $\Delta\Sigma$(ring) is the deviation from the ideal of the corresponding chelate rings' bond angle sum. A mean value of the two rings (R or G) is reported for complexes having in approx. C_2 molecular symmetry.
[d] Δ(M–O–C) (ring) is the mean value of the deviation of the corresponding rings' M–O–C bond angle from 109.5°.
[e] ΣΔ(N) is the sum of the absolute values of the deviations from 109.5° of the six bond angles made by the nitrogen atoms. A mean value for the two nitrogens is reported.
[f] For this complex having C_1 molecular symmetry the two values are reported. The values in parentheses are given for six-membered rings.

to +37° for **10**). The total deviations of the β-alaninate rings vary from +14° to +33° (for the R rings) and from +27° to +41° (for the G rings). An extremely large deviation of the G ring for **11** (+41°, ca. 6.8° per angle) is comparable with those observed for some related M(III) complexes [14,25,26]. All complexes considered (Table 3) show positive deviation of the M–O–C(R,G) bond angles (except for tetragonally elongated complex **9**, Cu–O–C(R) = 109.0 [23]). These deviations, as expected [13,14,25,26], are less for the glycinate rings (from +5° to +7° and from +4° to +5° for the R and G rings, respectively) than for the β-alaninate rings (from +14° to +19° for the R rings (except for **9** [23]) and from +14° to +21° for the G rings, Table 3).

When each of the deviations for the six angles made by the nitrogen atoms is summed, the total deviations (absolute values) for each complex were obtained (Table 3). Total deviation about the chelating N atoms sums to roughly 16° (for **7**) [14,25], 15° (for **8**) [14,26], 17° (for **9**) [23], 17° (for **10**), 13° (for **11**) and 8° (for **1**). These complexes, having N atoms connecting mixed (one acetate and one β-alaninate) rings, with respect to those containing N atoms connecting two acetate or two β-alaninate rings [25,26], show less total deviations about the N atoms. Among the complexes listed, the least deviation was observed for complex **1** (8°). This complex, compared with those of **7**–**11**, contains N atoms with less strained bonds.

3.3. Spectral characteristics of complexes

In the expected IR carboxylate region [6,7,13,23–25] the complexes **1** and **2** show absorption in agreement with their molecular symmetries (C_2 for **1** and C_1 for **2**). Infrared spectra for these complexes were taken both in the solid state and in D_2O (to eliminate interference from OH) and data obtained support fully coordinated carboxylates in both states. Complex **1** (having two pairs of equivalent rings, R and G) exhibits two very strong bands [at 1640sh cm^{-1} (1600 cm^{-1} in D_2O) and at 1591 cm^{-1} (1580 cm^{-1} in D_2O)] assigned to the asymmetric stretch of five-membered carboxylate moieties at higher energy (R rings) and six-membered carboxylate moieties at lower energy (G rings). In the same region, complex **2** having four non-equivalent rings, instead of four, exhibits three absorption bands [at 1635sh and 1610 cm^{-1} (1606 and 1590 cm^{-1} in D_2O) at higher energy and at 1588 cm^{-1} (1570 cm^{-1} in D_2O) at lower energy]. These data are in agreement with its C_1 molecular symmetry and the two bands appearing at higher energy correspond to the asymmetric stretch of coordinated carboxylates contained in a glycinate residue (R and G rings) and the one at lower energy was assigned to the moieties of the six-membered carboxylate arms. The bands appearing in the symmetric frequency region (at 1409 and 1337 cm^{-1} for **1** and at 1393, 1366 and 1330 cm^{-1} for **2**) can be assigned tentatively to the symmetric

stretching vibrations of the corresponding carboxylate groups.

The ligand field absorption spectra for complexes **1** and **2** and the spectrum of complex [Ni(1,3-pdta)]$^{2-}$ (**5**) of known structure [24], taken for comparison, are given in Fig. 3 (Table 4). All of these complexes forming diamine (T) rings, with respect to those of related complexes forming diamine (E) rings [13], show broadening of the first absorption band (lower energy side, Fig. 3) due to the influence of tetragonality on the spectrochemical behavior of these complexes (D_{4h} model). Apparently, if the equatorial N_2O_2 ligand field is smaller than the one imposed by two axially coordinated oxygen atoms, the D_{4h} model is consistent with the pattern, the lower energy peak being $^3B_{1g} \rightarrow {}^3B_{2g}$ (D_{4h}) and the higher energy peak being $^3B_{1g} \rightarrow {}^3E_g$ (D_{4h}), both of which are derived from the same $^3T_{2g}(O_h)$ state [36]. However, the noncubic field components are small compared with the approximately cubic field and spectra of these complexes, as established for edta-type [13,24] and most other Ni(II) complexes [37–40], can best be interpreted by using an octahedral model: $^3A_{2g} \rightarrow {}^3T_{2g}(F)$ (band I); $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ (band III) and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ (band IV) (Table 4). In each of the spectra a shoulder at approximately 13 000 cm^{-1} (band II, Table 4) occurs on the higher-energy side of the spin-allowed band. This band probably arises from a spin-forbiden triplet to singlet transition.

The spectrochemical behavior of Ni(II) complexes often reflects the average coordination geometry. That such is the case for complexes **1** and **2** is demonstrated by the calculation of the energies of the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transitions from the $^3A_{2g} \rightarrow {}^3T_{2g}(F)$ transition which has an energy of $10Dq$ [39]. The close agreement (within 2%) between the observed and calculated values (Table 4) gives strong support for the expected octahedral geometry of these complexes. The absorption maxima of **1** and **2** (bands I and III) are located at lower energies than those found for complex **5** [24]. The ligand field strength (LFS) for these complexes (Fig. 3, Table 4) increases in the order: **1** < **2** < **5** with the decreasing number of six-membered rings in the G-plane.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 182490 for compound **1**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Academy of Sciences. IR spectra were recorded on a Nicolet AVATAR-360IR spectrophotometer in KBr pellets. Electronic spectra were recorded on a Shimadzu UV 240 spectrometer in CH_2Cl_2. X-ray photoelectron spectral (XPS) data were measured on a Perkin–Elmer PHI 5000C ESCA System, calibrated by carbon (C1s = 284.6 eV).

2.2. Synthesis of $(NH_4)_2WO_2Se_2$ and $(NH_4)_2WOSe_3$

Activated $WO_3 \cdot H_2O$ was synthesized as described in the literature [5]. The vessels used in the reaction were flushed with dinitrogen beforehand. The reaction mixture was prepared under nitrogen atmosphere by dissolving 5 g of activated $WO_3 \cdot H_2O$ in 25 ml of concentrated NH_3 aqueous solution and then stirred under 0 °C. H_2Se was generated by hydrolysis of Al_2Se_3 in dilute hydrochloric acid and was introduced to the reaction mixture by a stream of N_2. The reaction was monitored via the electronic spectrum of the reaction mixture. H_2Se addition was halted when the characteristic band of $(NH_4)_2WO_2Se_2$ reached a maximum but before the appearance of that of $(NH_4)_2WOSe_3$ [6]. An equal volume of cold absolute ethanol was slowly added to the stirred reaction mixture and the same volume of ether was then added. An orange–red solid was precipitated and separated by a glass frit, washed with a small amount of ethyl ether, and dried in vacuum. Solid (2.1 g) were obtained with about 25% yield. It was confirmed as $(NH_4)_2WO_2Se_2$ by its electronic and IR spectra. It can be used for synthesis purposes without further purification.

When excess H_2Se was introduced into the reaction mixture of 5 g of activated $WO_3 \cdot H_2O$ and 25 ml of concentrated NH_3 aqueous solution, after the maximum absorption band of $(NH_4)_2WOSe_3$ was observed, cold absolute ethanol and ether were added successively as described above. After filtering off the formed $(NH_4)_2WO_2Se_2$, the filtrate was allowed to stand overnight. A red crystalline solid settled down in the filtrate. The solid (2.9 g) was separated by a glass frit and washed with a small amount of ethyl ether, dried in vacuum, yield 31%. It was confirmed by its electronic and IR spectra as $(NH_4)_2WOSe_3$. It also can be used for synthesis purposes without further purification.

Both dried $(NH_4)_2WO_2Se_2$ and $(NH_4)_2WOSe_3$ are stable in the desiccator.

2.3. Synthesis of $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$ (**1**)

$(NH_4)_2WO_2Se_2$ (0.266 g, 0.646 mmol), CuCl (0.126 g, 1.29 mmol) and $(C_4H_9)_4NBr$ (0.422 g, 1.31 mmol) were mixed and well grounded under N_2 atmosphere and then sealed in a glass tube filled with N_2. The glass tube was heated to about 95 °C for 10 h. The reaction mixture was extracted with 2×8 ml of methylene chloride. The extracting solvent was combined and 8 ml of isopropanol was added under stirring. The mixed solution was filtered through celite. 0.35 g of violet red crystals were obtained from the solution under ventilation. Yield 42%. *Anal.* Found: C, 30.32; H, 5.70; N, 2.41%. Calc. for $C_{32}H_{72}N_2WOSe_3Cu_3Br_{1.67}Cl_{1.33}$ C, 29.73; H, 5.61; N, 2.17%. UV–Vis λ_{max} (nm) (CH_2Cl_2): 445 (ε dm^3 mol^{-1} 1.75×10^3), 365 (4.80×10^3), 286 (8.45×10^3), 255 (1.39×10^4), 229 (1.77×10^4). IR (KBr pellet), ν_{max} cm^{-1} 910 (W=O), 540 (W–Se), 440 (W–Se). Raman ν_{max} cm^{-1} 910 (W=O), 276 (Cu–Se)vs, 153 $\delta(WSe_2)$vs. Single crystals suitable for X-ray analysis were obtained from the methylene chloride extractant by layering isopropanol on the top and storing in a refrigerator for several weeks.

2.4. Synthesis of $[(C_4H_9)_4N]_3[WSe_4Cu_3Br_2Cl_2]$ (**2**)

The synthesis method is similar to that described for $[(C_4H_9)_4N]_2[WOSe_3Cu_3BrCl_2]$. $(NH_4)_2WOSe_3$ was used as starting material instead of $(NH_4)_2WO_2Se_2$. The crystalline product was a mixture of **1** and **2**, which could be identified from the feature and color of the crystals. Brick red crystals of **2** were separated and a single crystal suitable for X-ray analysis was selected.

Other cluster compounds of the type $[(C_4H_9)_4N]_2[MOS_3Cu_3X_3]$ (M = Mo, W; X = Cl, Br) were similarly synthesized by the above procedure. For example $[(C_4H_9)_4N]_2[MoOS_3Cu_3Cl_3]$ was synthesized with $(NH_4)_2MoO_2S_2$, CuCl and $(C_4H_9)_4NCl$, and

The positions of Cl(1) and Cl(2) are statistically occupied by Br(1) and Br(2) atoms with a 50% occupancy factor. C(12), C(17) and C(22) shown two possible positions due to their high thermal vibrational effect.

The structures of the clusters were solved by direct methods and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically with full-matrix least-squares. Hydrogen atoms were not included in the refinement. The crystal data and structure refinement parameters are given in Tables 4 and 5.

2.6. Optical limiting measurements

The optical limiting properties of these clusters were measured with 8 ns and 35 ps duration laser pulses at 532 nm in methylene chloride solution. The nanosecond laser pulses were generated from a Q-switched, frequency-doubled Nd-YAG laser and the picosecond laser pulses were generated from a mode-locked and frequency-doubled Nd-YAG laser. In our experiments, the 35 ps pulsed laser was operated at 10 Hz repetition rate, but the 8 ns pulsed laser was maintained at a low repeatability of 2 Hz in order to reduce the influence of thermal effects. The laser beams were focused by a 13 cm focal length lens into the methylene chloride solution of the clusters placed in a 5 mm thick quartz cuvette. The laser power was adjusted by neutral attenuators. The incident and transmitted pulse energies were measured simultaneously by two 5×5 mm^2 Si photoelectric diode detectors. The signals were averaged by a Boxcar and then recorded by a PC computer.

3. Results and discussion

3.1. Synthesis

Traditionally, Cu–Mo(W)–S clusters were synthesized via reactions in solution [7]. However, a versatile method has been devised to synthesize the Cu–Mo–S clusters by heating a solid mixture of $(NH_4)_2MO_2S_2$, CuX and a suitable cation such as $(C_4H_9)_4NX$ (M = Mo, W; X = halogen or pseudohalogen such as CN) under dinitrogen. Due to the strong coordination ability of sulfur atoms, cage or nest-shaped clusters can be synthesized starting from a $MO_2S_2^{2-}$ anion with CuX and $(C_4H_9)_4NX$ (X can be halogen or pseudohalogen) in different molecular ratios. The Cu atom can be replaced by Ag and Mo can be replaced by W or both. In our study, compounds $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$, $[(C_4H_9)_4N]_2[MoOS_3Cu_3Br_3]$ and $[(C_4H_9)_4N]_2[MoOS_3Cu_3Cl_3]$ were all synthesized by this method. Their similar structure can be deduced from their electronic spectra, which was attributed to the common chromophore $MoOS_3^{2-}$. The products maintained similar structure when Mo was replaced by W and S was replaced by Se. But if all the skeleton atoms were replaced by heavier atoms, that is Mo, S, Cu by W, Se, Ag, respectively, the product obtained was not the expected compound $[(C_4H_9)_4N]_2[WOSe_3Ag_3X_3]$. For example, $(NH_4)_2WO_2Se_2$, AgBr and $(C_4H_9)_4NBr$ were mixed and well grounded under N_2 atmosphere and then heated to about 95 °C for 10 h under N_2. The product obtained from the methylene chloride extractant showed a very different electronic spectrum (λ_{max} at 227 and 279 nm). Its IR (KBr pellet) gave peaks at 2962s, 2874s, 974s, 814s, 668s, 578m and 447s cm^{-1}, also indicating a different skeleton with $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$ (**1**). The Ag-containing product decomposed slowly in solution but remained stable in the solid state for several days.

In the synthesis process, rearrangement of the terminal M–S bond of $(NH_4)_2MO_2S_2$ must have occurred during heating because the nest shape product contains a MOS_3 molecular fragment. In the case of $(NH_4)_2MO_2Se_2$, the Se atom should be more labile than the S atom on heating. However, it seems that only one of the terminal oxygen atoms can be replaced by the Se atom to form $WOSe_3^{2-}$, which is found as a molecular fragment in cluster compound **1**. It was reported recently that MSe_4^{2-} as a synthesis precursor remained as a building block in its products [8]. In our synthesis, some MSe_4^{2-} might form. One of the labile terminal Se atoms in MSe_4^{2-} was replaced by Br or Cl, forming a W–Br or W–Cl bond as in cluster **2**.

3.2. Description of structures

The cluster structure of molecule $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$ (**1**) is shown in Fig. 1. Selected bond lengths and bond angles are collected in Table 6. The skeleton of the cluster anion, $[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]^{2-}$, consisting of one W atom, three μ_3-Se atoms and three Cu atoms, is in a nest shape, similar to that of its analogue compound $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$ [9]. The W atom has an ideal tetrahedral geometry, being

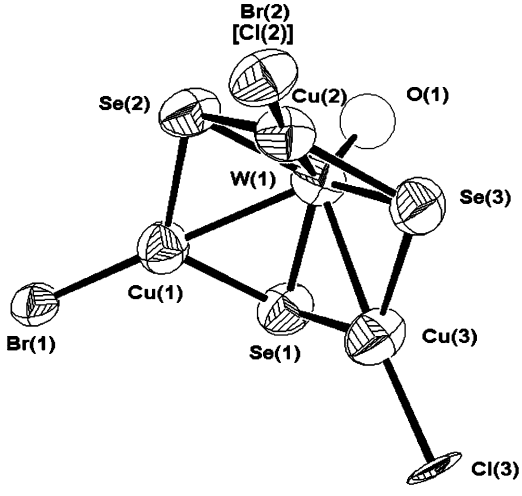

Fig. 1. ORTEP diagram of the cluster anion of $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$.

[a] Numbers in parentheses are e.s.d. in the least significant digits.

surrounded by three bridging Se atoms and one terminal O atom with Se–W–Se angles of 109.5° and O–W–Se angles of 109.4°, respectively. In its Mo–S analogue anion $[MoOS_3Cu_3BrCl_2]^{2-}$, the Mo atom has a distorted tetrahedral geometry in which the corresponding bond angles S–Mo–S and O–Mo–S are 107.5° and 112.0°, respectively. In its W–S analogue anion $[WOS_3Cu_3Cl_3]^{2-}$, the average S–W–S bond angle is 108.1° [9]. The larger Se–W–Se angle in cluster **1** is evidently due to the larger volume and weaker electronegativity of Se atoms comparing to S atoms in the anion skeleton. As a result, cluster **1** has a larger opening in its nest shaped structure of the anion than that of $[MoOS_3Cu_3BrCl_2]^{2-}$ and $[WOS_3Cu_3Cl_3]^{2-}$. The three W–Se bond distances in the cluster **1**, ranging from 2.382(2) to 2.403(2) Å, are in the range of single bonds. The W–O bond length of 1.721(9) Å is typical for a double bond. All three Cu atoms in the cluster **1** adopt trigonal planar coordination geometry. The Cu atoms are linked to W through symmetrical $Cu(Se)_2$ bridges with all Cu–Se distances in a range from 2.335(3) to 2.364(3) Å. All three W–Cu–X (X = Cl, Br) bond angles range from 174.7° to 178.3°; this allows formation of stronger π-bonding over the $W(Se)_2Cu$ ring. In its Mo–S analogue, the Mo–Cu–Cl bond angles are 167.3° and 166.9° and only the Mo–Cu–Br bond angle is close to linearity. In **1**, the terminal ligand site of Cu–X was statistically occupied by a Br atom with five-ninths occupancy factor and by a Cl atom with four-ninths occupancy factor.

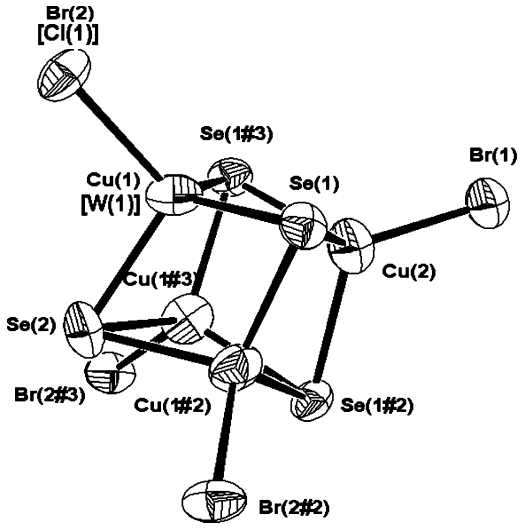

Fig. 2. An ORTEP diagram of the cluster anion of $[(C_4H_9)_4N]_3[WSe_4Cu_3Br_2Cl_2]$. The W(1) atom statistically occupies the position of the Cu(1) atom and has one third of the occupancy factor. The Cl(1) atom statistically occupies the position of the Br(2) atom and has two third of the occupancy factor.

Se(1)–W(1)–Se(1)#2	106.6(1)	Se(1)#1–Cu(2)–Se(1)	100.1(2)

[a] Numbers in parentheses are e.s.d. in the least significant digits. Symmetry transformations used to generate equivalent atoms; #1 $-y+1, x-y-1, z$; #2 $-x+y+2, -x+1, z$.

The cluster structure of compound $[(C_4H_9)_4N]_3[WSe_4Cu_3Br_2Cl_2]$ (**2**) is shown in Fig. 2. Selected bond lengths and bond angles are collected in Table 7. The anion of cluster **2** has a distorted cubane structure with trigonal symmetry. Four Se atoms and four Cu (or W) atoms

alternatively compose the vertexes of the closed cage. Atoms Br(1), Cu(2) and Se(2) are aligned on a threefold axis. Different from cluster **1**, all the Cu atoms in cluster **2** are in tetrahedral geometry. The coordination environment of Cu(2) atom contains three Se atoms and one Br atom. The three metal positions off the threefold axis are statistically occupied by Cu atom with two-thirds occupancy factor and W atom with one-third occupancy factor. The terminal M–X bonds are statistically occupied by Br atom with one-third occupancy factor and by Cl atom with two-thirds occupancy factor. The cage has an obtuse vertex at Cu(2) with a Se(1)–Cu(2)–Se(1, #2) angle of 100.09° and an acute vertex at Se(2) with a Cu(1)-Se(2)-Cu(1, #2) angle of 69.52°. In its analogue compound $[MAg_3Se_3I(PPh_3)_3Se]$ (M = W, Mo) and $[MoCu_3Se_3Cl(PPh_3)_3Se]$ [8], all have distorted cage shaped cubane structures. The former analogue cubane structure has an obtuse vertex angle of about 107.3° and an acute vertex at the I atom of about 68.7°, and the later has an obtuse vertex angle of about 108.6° and an acute vertex at the Cl atom of about 74.6°. The statistical arrangement of Cu–W and Cl–Br in cluster **2** is supported by the X-ray photoelectron spectrum data and the composition also agrees with the X-ray photoelectron spectrum measurement (Table 8).

3.3. Electronic spectrum

Fig. 3 gives the linear absorption spectrum of cluster **1**, showing characteristic absorption bands similar to that of $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$. There is no absorbency above 550 nm until near the IR region. Its absorption maxima at 445, 365 and 290 nm, showing clearly blue shift in the visible region compared with the values of 488, 400 and 280 nm found in the spectrum of $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$ under the same conditions, are comparable to the values found in the spectrum of $WOSe_3^{2-}$, which are 452, 385 and 293 nm, respectively [10].

The dominant features of the electronic spectra of $[(C_4H_9)_4N]_2[MoOS_3Cu_3Br_3]$ and $[(C_4H_9)_4N]_2[MoOS_3Cu_3Cl_3]$ is that they are more like $[(C_4H_9)_4N]_2[WOSe_3Cu_3BrCl_2]$ than their analogue $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$. From the data listed in Table 2, it is noticed that all compounds have relatively low linear absorptivity at 532 nm [11].

Table 8
Binding energies (eV) of elements in the anion of cluster **2**

$[WSe_4Cu_3Br_2Cl_2]^{3-}$	W	Se	Cu	Cl	Br

Relative ratio	0.47	1.3	1	0.86	0.75

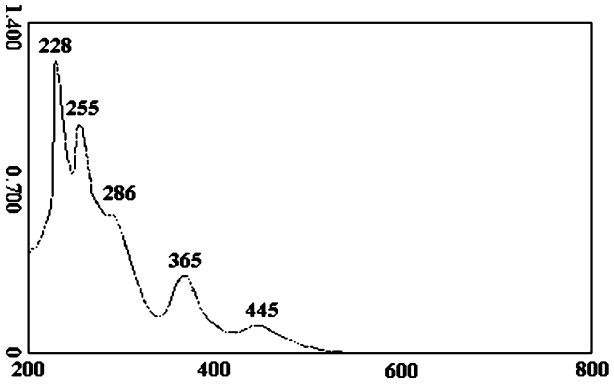

Fig. 3. The electronic spectrum of $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$ in CH_2Cl_2 with a concentration of 5.90×10^{-5} M. The optical path is 1 cm.

3.4. Optical limiting properties

A common problem with many inorganic semiconductors is their large linear absorption (α_o) and hence small optical limiting figure of merit $\chi^{(3)}/\alpha_o$ in the visible region (especially the blue–green region) of the spectrum. There has been considerable interest in clusters that exhibit strong reverse saturable absorption (RSA) in the visible spectral region. The skeletal atoms of these clusters are believed to be critical to their nonlinear optical properties [12].

Experimental results obtained in acetonitrile solution with a 7 ns pulsed laser at 532 nm show that cage shaped clusters $[MS_4M'_3BrX_3]^{3-}$ (M = Mo W; M′ = Cu, Ag; X = Cl, Br, I) exhibit strong NLO absorption and weak light self-focusing effects [13], whereas nest-shaped clusters $[MoOS_3(CuNCS)_3]^{4-}$ $[MoOS_3(CuCl)_2(CuBr)]^{4-}$ and $[Mo_2O_2S_2(CuI)_4(CuBr)_2]^{4-}$ exhibit both strong NLO absorption and strong self-defocusing effects [14].

The nanosecond and picosecond optical limiting effects of the nest-shaped cluster **1** and $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$ are depicted in Fig. 4. At very low light fluence they respond linearly to the incident light in accordance with Beer's law. The output energy deviates from the linear response when the incident laser pulse energy exceeds 30 μJ. The materials become increasingly less transparent as the light fluence rises. It is interesting to note that under the same transmitting conditions, cluster **1** shows a poorer optical limiting property than $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$ under 35 ps laser pulses. However, under 8 ns laser pulses, cluster **1** shows a better optical limiting property than $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$. The heavy atoms effect cannot adequately explain the different optical limiting properties of $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$ and $[(C_4H_9)_4N]_2[WOSe_3Cu_3BrCl_2]$ under different durations of the laser pulses. It was noticed that two structural differences of the clusters might be related to their different response to the duration of the laser pulses.

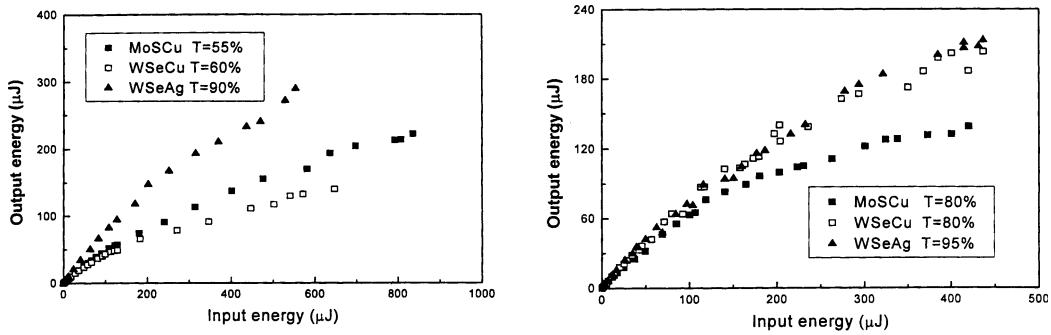

Fig. 4. Optical limiting properties of different nest-shaped clusters in nanoseconds (a) and picosecond (b). MoSCu, $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$; WSeCu, cluster **1** and WSeAg, silver containing compound.

One of the structural differences is the heavier atoms of W (molecular weight 184) and Se (79) compared with Mo (96) and S (32) in the skeleton of the two clusters. It is believed that heavier atoms in the skeleton of the clusters may introduce large numbers of excited states positioned close to the ground state, which, therefore, will help to enhance the singlet–triplet intersystem crossing under excitation. The contribution of the excited triplet states to optical limiting properties towards a nanosecond pulsed laser may then be enhanced. The other structural difference is the larger opening of the nest-shaped structure of cluster **1** compared with $[(C_4H_9)_4N]_2[MoOS_3Cu_3BrCl_2]$. We are not sure whether the shape of the skeleton may play any important role in optical limiting behavior. Although the Ag-containing product shows some optical limiting property, its solubility in methylene chloride solution is too low and it decomposed in solution slowly.

In W–Se–Cu and Mo–S–Cu clusters, the influence of the peripheral ligands on the optical limiting properties is trivial. However, we found that a larger peripheral ligand (Br) showed better optical limiting properties compared with the smaller ligand (Cl) in W–Se–Ag complexes.

4. Supplementary data

Crystallographic data have been deposited with the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) and are available on request quoting the deposition number 162956 for $[(C_4H_9)_4N]_2[WOSe_3Cu_3Br_{1.67}Cl_{1.33}]$ (**1**) and 162683 for $[(C_4H_9)_4N]_3[WSe_4Cu_3Br_2Cl_2]$ (**2**).

interesting series of ligands whose properties can be greatly modified by introducing organic substitutents thereby inducing different stereochemistries in the resultant metal complexes. Some of the metal complexes may be expected to be biologically active. Indeed, carcinostatic activities have already been found for some metal complexes of dithiocarbazic acid and some Schiff bases derived from its *S*-methyl ester [20]. The synthesis of these complexes continues to be of interest in order to evaluate their coordination chemistry and their potential as anti-microbial and anti-cancer agents.

2. Experimental

2.1. Physical measurements

Carbon, hydrogen, nitrogen and sulfur analyses were carried out at Mikroanalytisches Labor Pascher, Remagen-Bandorf, Germany or at the Department of Chemistry, University Putra Malaysia. The IR spectra were recorded as KBr pellets, in the 4000–400 cm^{-1} region, on a Perkin–Elmer 1750X FTIR spectrometer. Metal determinations were carried out using a Perkin–Elmer Plasma 1000 Emission Spectrometer. ^1H NMR spectra were recorded on an Hitachi R1200 (60 MHz) NMR spectrometer. The molar conductance of 10^{-3} M solutions of the metal complexes in DMSO was measured at 30 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinized electrode. The UV–Vis spectra were run on a Shimadzu UV-2501 PC spectrophotometer (900–200 nm). Melting points (m.p.) were determined using an electrothermal digital m.p. apparatus. Magnetic susceptibility measurements were carried out using a Sherwood Auto MSB at 298 K. All susceptibilities were corrected for the diamagnetic contribution using Pascal's constant. All measurements were carried out at the Department of Chemistry, University Putra Malaysia unless otherwise mentioned.

2.2. Preparation of S-methyldithiocarbazate (SMDTC)

SMDTC was prepared as previously reported [21].

Potassium hydroxide (22.8 g, 0.4 mol) was dissolved completely in 90% ethanol (114 ml) and the mixture was cooled in ice. To the mixture, hydrazine hydrate (20 g, 0.4 mol) was added slowly with stirring. Carbon disulfide (30.4 g, 0.4 mol) was then added dropwise with vigorous stirring. The temperature of the reaction mixture was not allowed to rise above 6 °C during the period of addition of carbon disulfide. The resulting yellow oil was separated by means of a separatory funnel and dissolved in 40% ethanol (40 ml) and the solution was cooled in ice. Methyl iodide (58 g, 0.4 mol) was added slowly with vigorous stirring. The white product was separated by filtration, washed with water and dried in air. The crude product was recrystallized from ethanol; yield, 20 g (40%); the m.p. was 81 °C (Lit. 81–82 °C) [21].

2.3. General method for preparation of the Schiff bases

SMDTC (2.44 g, 0.02 mol) dissolved in hot absolute ethanol (30–40 ml) was added to the solution of an equimolar amount of carbonyl compound in hot absolute ethanol (20 ml). The mixture was heated for 10 min and then cooled to 0 °C in an ice-bath. The products were filtered, washed with absolute ethanol, recrystallized from absolute ethanol, and then dried over silica gel. The carbonyl compounds used were 2-furylmethylketone and 5-methyl-2-furaldehyde. The yield and m.p. were recorded for each product.

2.4. General method for preparation of the metal complexes

To 0.1 mol of metal salt dissolved in absolute ethanol (40 ml) was added Schiff base (0.2 mol) in 40 ml of absolute ethanol. The mixture was heated while being stirred. The precipitate was filtered, washed with ice-cold ethanol and dried over silica gel. The yield and m.p. were recorded for each product. The metal salts used for synthesis were copper(II) acetate, nickel(II) acetate tetrahydrate and zinc(II) acetate dihydrate.

2.5. X-ray structure determination

The selected crystal of the Zn(II) complex was mounted on a SMART CCD diffractometer. Reflection data were measured at 20 °C using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation with a detector distance of 4 cm and a swing angle of $-35°$. The data collected were reduced using the program SAINT [22] and an empirical absorption correction was carried out using SADABS [23]. The structure was solved using direct methods and refined using the full-matrix least-square method on F_{obs}^2 using the SHELTXL [24] software package. All non-H atoms were anisotropically refined. The hydrogen atoms were located by difference syntheses and refined isotropically. The molecular graphics were created using SHELXTL. Atomic scattering factors and anomalous dispersion correction were taken from the International Table for X-Ray Crystallography [25].

2.6. Bioactivity

Antimicrobial and cytotoxic activities were evaluated at the Animal Cell and Tissue Culture Laboratory, Department of Biotechnology, University Putra Malaysia.

2.6.1. Qualitative antimicrobial assay

Eight pathogenic microbials were used to test the biological potential of the compounds: (i) Methicillin resistant *Staphylococcus* (MRSA), (ii) *Bacillus subtilis* wild type (B29), (iii) *Bacillus subtilis* mutant defective DNA repair (B28), (iv) *Pseudomonas aeruginosa* (60690), (v) *Candida albicans*, (vi) *Aspergillus ochraceous* (398), (vii) *Saccharomyces cereviceae* (20341) and (viii) *Candida lypolytica* (2075). The sources of microbes and culture maintenance were as previously described [26]. The antimicrobial activity of the extracts was qualitatively determined by a modified disc diffusion method [27]. A lawn of microorganisms was prepared by pipetting and evenly spreading inoculum (10^{-4} cm^3, adjusted turbidometrically to 10^5–10^6 cfu cm^3 (cfu, colony forming units) on to agar set in petri dishes, using nutrient agar (NA) for the bacteria and potato dextrose agar (PDA) for fungi. Whatman No. 1 filter paper discs of 6 mm diameter were impregnated with stock solution of the compound (100 mg cm^{-3}) and dried under sterile conditions. The dried discs were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 30 °C for bacteria and 37 °C for fungi. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs. Commercially available streptomycin was used for antibacterial control while nystatin was used as antifungal control.

2.6.2. Quantitative antimicrobial assay

Substances showing positive antimicrobial activity via the disc diffusion assay were subjected to the broth dilution method for the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [28]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg cm^{-3}). Streptomycin and nystatin (Sigma, USA) were used as positive controls for bacteria and fungi, respectively.

2.6.3. Cytotoxic assay

Three types of cell lines were used, CEM-SS (human cell T-lymphoblastic leukemia), HT-29 (human colon andenocarcinoma cells) and HELA (cervical cancer cells). The CEM-SS and HELA cell lines were obtained from the National Cancer Institute, USA while the HT-29 cell line was obtained from American Type Culture Collection (ATCC). The cells were cultured in RPMI-1640 (Sigma) medium supplemented with 10% fetal calf serum. Cytotoxicity was determined using the MTT (3-[4,5-dimethylthiozol-2-yl]-2,5-diphenyltetrazolium bromide) assay following Mosmann's report [26]. Solutions of compounds of different concentrations were prepared from the stock solutions (10 mg cm^{-3}) by serial dilution in RPMI-1640. About 10^{-4} cm^3 was placed in each well of a microtiter plate as described before by Ali et al. [11]. Each well was filled with 10^{-4} cm^3 of cell suspension in complete growth medium (CGM) at $(1–2) \times 10^5$ cells cm^{-3}. Controls that contained only cells were included for each sample.

The assay for each concentration of extract was performed in triplicate. The culture plates were kept at 37 °C under 5% (v/v) CO_2 for 3 days. After 72 h of incubation, 10^{-4} cm^3 of the medium was removed from each well. Subsequently, 20×10^{-3} cm^3 of 50% w/v MTT dissolved in phosphate buffered saline solution was added to each well and incubated for a further 4 h. All supernatants were then carefully discarded from each well of the microtiter plate and 10^{-4} cm^3 of pure spectral grade DMSO was added to each well and vigorously mixed to dissolve the formazan crystals. Absorbance values were measured with a microplate reader (Bio Tek EL 340, USA) at 550 nm. Cytotoxicity was expressed as CD_{50}, i.e. the concentration, which reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin and tamoxifen were used as cytotoxic standards.

3. Results and discussion

In a neutral medium, condensation of SMDTC with 2-furyl-methylketone and 5-methyl-2-furaldehyde gave the isomeric Schiff bases **1** and **2**, in high yield. The Schiff bases exist in tautomeric forms through the loss of thiolo protons as shown in Fig. 1. Both Schiff bases behaved as uninegatively charged bidentate ligands by coordinating through the thiolo sulfur and the azo-

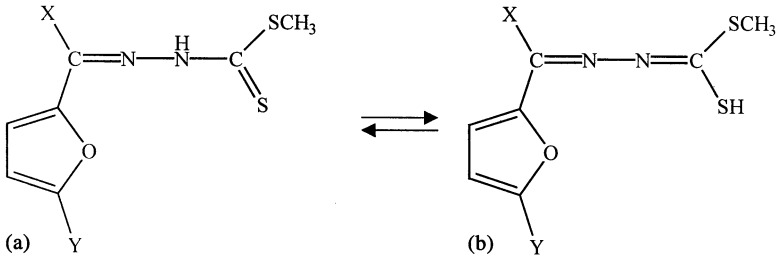

Fig. 1. Tautomeric forms. (a) Thione form. (b) Thiolo form. NS′: X = CH_3, Y = H; NS″: X = H, Y = CH_3.

7		1588		1008
8		1568		1026

methine nitrogen. The melting point, elemental analyses and percentage yield for each are given in Table 1.

The ^{1}H NMR data for the Schiff bases are given in Table 2. The assignments shown are based on those for closely similar Schiff bases [29]. The ^{1}H NMR spectra of the Schiff bases do not show any peak at approximately δ 4.0 ppm attributable to the S–H proton [30], indicating that they exist in the thioketo tautomeric form in solution. The **1** and **2** Schiff bases containing a methyl group on the aliphatic carbon atom and furanic ring, respectively, showed a peak at approximately δ 2.3–2.5 ppm attributed to the methyl hydrogen while the peak at approximately (3.33 ppm may be assigned to the methyl groups attached to a sulfur atom. Meanwhile, **1** Schiff base does not has methine (C–H) group on the aliphatic carbon atom while the signal at 8.542 ppm is attributed to the N–H group. However, the signals at 3.512 and 8.835 ppm are attributed to the methine (C–H) and N–H group, respectively. The aromatic groups are observed in the range approximately δ 6.2–7.1 ppm.

The IR spectra (Table 3) of the **1** and **2** Schiff bases showed strong bands at 3210 and 3114 cm^{-1}, respectively. These are attributed to the secondary amine ν(N–H) mode of the free ligands. The thione groups are relatively unstable in the monomeric form and tend to turn to the more stable thiolo forms by enethiolization in solution [3] (Fig. 1). The absence of ν(S–H) absorbance at approximately 2570 cm^{-1}, indicates that in the solid state, the bases exist primarily in the thione form. The disappearance of ν(N–H) bands the IR spectra of the metal complexes suggests deprotonation and consequent coordination through the thiolate anions. The **1** and **2** Schiff bases also showed strong bands at 1572 and 1618 cm^{-1}, respectively. These are assigned to the ν(C=N) modes for the free ligands. In the metal complexes, this stretching band shifted to lower frequencies, due to the lowering of the C=N bond order as a result of the metal–nitrogen bond formation. The **1** and **2** Schiff bases also showed ν(C=S) modes at 1064 and 1098 cm^{-1}, respectively. The ν(C=S) mode observed in the free ligand disappeared in the complexes, thus supporting the above contention of thiolate bonding with metal ions. Consequently the ν(C–S) mode is observed in the spectra of the complexes confirming that complexation occurred.

The molar conductance data (Table 4) indicated that all complexes were non-electrolytes, suggesting that the two molecules of Schiff bases were covalently bonded with the metal ions. The magnetic susceptibility measurements (Table 4) show that the **3** and **4** complexes were paramagnetic at room temperature. The magnetic moments of 1.75 and 1.79 B.M. for **3** and **4** are consistent with a square-planar structure [31]. The remaining complexes **5**, **6**, **7** and **8** were diamagnetic.

Table 4
The physical properties of the metal complexes

Compound	UV–Vis spectra (λ_{max} (nm)) [a]	Molar conductance (Ω^{-1} cm^2 mol^{-1})	μ_{eff} (B.M.)
3	308 (4.3), 370 (3.2)	2.35	1.75
4	298 (3.3), 374 (2.3)	3.69	1.79
5	312 (4.2), 355 (3.4), 412 (2.5)	1.60	diamagnetic
6	320 (3.3), 357 (2.3), 421 (1.2)	4.32	diamagnetic
7	312 (2.3), 359 (1.4)	2.78	diamagnetic
8	369(3.4)	3.56	diamagnetic

[a] log ε (cm^{-1} mol^{-1} l) are given in parentheses.

For the electronic spectra, the diamagnetic nature of complexes **5** and **6** (Table 4) indicate a singlet ground state term characteristic of square-planar Ni(II). Three bands corresponding to the transitions $^1A_{1g} \rightarrow {}^1A_{2g}$ (312–320 nm), $^1A_{1g} \rightarrow {}^1B_{1g}$ (355–357 nm), and $^1A_{1g} \rightarrow {}^1E_g$ (412–421 nm) are observed in the electronic spectra of such square-planar nickel(II) complexes as expected [27]. The **3** and **4** complexes display two bands corresponding to $^2B_{1g} \rightarrow {}^2A_{1g}$ (298–308 nm) and $^2B_{1g} \rightarrow {}^2E_{1g}$ (370–374 nm) transitions, presumably arising from a square-planar copper(II) configuration. The **7** and **8** complexes gave only bands in the electronic spectra region, which are attributed to charge transfer.

3.1. Description of the structure

The crystal system of bis[*S*-methyl-β-*N*-(2-furylmethyl)methylenedithiocarbazato]zinc(II) is monoclinic with space group of *C*2/*c*, $a = 13.2778(2)$ Å, $b = 12.0398(2)$ Å, $c = 27.1919(3)$ Å, $\alpha = 90°$, $\beta = 99.1186(11)°$ and $\gamma = 90°$. The crystal data and structure refinement parameters are shown in Table 5. The ORTEP diagram of the molecule with the atomic numbering scheme is shown in Fig. 2 and the selected bond lengths and bond angles are listed in Table 6. The two bidentate ligands are coordinated to the zinc atom through an azomethine nitrogen and thiolo sulfur in a distorted tetrahedral environment around zinc atom with S–Zn–N angles between 85.98(13)° and 126.16(16)°. The coordinated sulfur and nitrogen atoms in the two ligands are in opposite positions The C1–N2, N1–C5, C11–N3 and N4–C3 bond distances of 1.274(7), 1.300(5), 1.299(6) and 1.307(7) Å, respectively, indicate a strong electron delocalization in the conjugation of the C–N–N–C moiety compared with the tridentate complex of zinc with *S*-benzyl-β-*N*-(2-pyridyl)methylenedithiocarbazate, $[Zn(C_{14}H_{22}N_3S_2)_2]$ [32]. The coordinated Zn–S and Zn–N bond lengths of 2.30(16) and 2.0(4) Å are also shorter than similar bonds in the tridentate complex (2.34(1) and 2.45(1) Å, respectively). The Zn1S1C1N2N1 and Zn1S3C3N4N3 planes are essentially planar but bisect each other by 86.96(16)°. The furyl O1C6C7C8C9 and O2C12C13C14C15 planes are also planar with the angle between the planes of 61.1(4)°. The dihedral angle between the furyl ring O1C6C7C8C9 and the five-membered ring Zn1S1C1N2N1 of 11.79(19)° is smaller than the dihedral angle between O2C12C13C14C15 and Zn1S3C3N4N3 of 30.4(3)°.

3.2. Biological activities

3.2.1. Antimicrobial activity

All the Schiff bases and metal complexes were tested for antimicrobial activity. The disc diffusion technique was employed [33]. Only the **3** complex showed clear inhibition of the bacteria, *B. subtilis* mutant-defective DNA repair (B28), while both Schiff bases **1** and **2** showed strong activity against all fungi. Complexes **3** and **5** showed clear inhibition of *C. albicans* and *S. cereviceae* (20341), respectively. Qualitative antimicrobial results are shown in Table 7. Quantitative measurements (Table 8) were done to determine the MIC values. The Schiff bases and complexes showed antifungal activity comparable to the standard drug, nystatin, but, the compounds **2** and **5** showed MIC values higher than that of nystatin (MIC = 25 000–50 000 μg cm^{-3}) for *S. cereviceae* (20341). Only **3** showed a MIC value higher than that of streptomycin.

3.2.2. Cytotoxic activity

The **3**, **5** and **7** complexes showed very good activity against the leukemic cell (CEM-SS) line with CD_{50} values of 1.6, 2.1 and 3.0 μg ml^{-1}, respectively. The remainder of the Schiff bases and complexes were inactive towards CEM-SS cells. None of the compounds showed any activity towards colon cancer cells (HT-29). Only complexes **3** and **7** were highly active against cervical cancer cells (HELA cells) with CD_{50} values of 1.5 and 2.1 μg ml^{-1}, respectively, while complex **5** was weakly active against these cells (HELA cells) with a CD_{50} value of 23.0 μg ml^{-1}. The compounds mentioned were more active than their uncomplexed metal salts. The results of cytotoxic assays are shown in Table 9.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 184218. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk. or www: http://www.ccdc.cam.ac.uk.

Acknowledgements

We thank the Department of Chemistry and the Department of Biotechnology, at UPM, for the provision of laboratory facilities. We also wish to thank the Ministry of Science, Technology and Environment, Malaysia, for funding this research under the Intensification of Research in Priority Areas scheme (IRPA grant No. 09-02-04-0296).

study on ligands derived from *S*-benzyldithiocarbazate (SBDTC), we report herein the synthesis, characterization and bioactivity of some transition metal (Fe^{2+} and Co^{2+}) and non-transition metal (Cd^{2+}, Pb^{2+} and Sn^{2+}) complexes of isomeric nitrogen–sulfur donor ligands formed between SBDTC with 5-methyl-2-furaldehyde (NS), (Fig. 1) and 2-furaldehyde (NS′), (Fig. 2). The structures of *S*-benzyl-β-*N*-(5-methyl-2-furyl methylene)dithiocarbazate, NS, free ligand and bis[*S*-benzyl-β-*N*-(2-furylmethylketone) dithiocarbazato] cadmium(II), $[Cd(NS')_2]$, as determined by X-ray analysis of single crystals are also given.

2. Experimental

All chemicals and solvents were of analytical grade and were used as received.

2.1. Preparation of S-benzyldithiocarbazate (SBDTC)

SBDTC was prepared as previously reported [9].

2.2. General method for synthesizing Schiff bases

A solution of SBDTC (1.98 g, 0.1 mol) in absolute ethanol (40 cm^3) was added to an equimolar solution of 5-methyl-2-furyladehyde or 2-furylmethylketone in 50 cm^3 of the same solvent. The mixture was heated on a steam bath for 10 min and then cooled to 0 °C in an ice bath. Precipitated Schiff bases were filtered, washed with cold ethanol and dried in vacuo over silica gel. The yield and melting point were recorded for each product.

2.3. General method for synthesis of metal complexes

Schiff base (0.0076 mol) prepared as outlined in Section 2.2 was dissolved in ethanol (50 cm^3) in the presence of an equimolar amount of potassium hydroxide (0.4 g). The clear solution was treated with a solution containing a stoichiometric amount of metal salt in the same solvent ($\sim$50 cm^3). The mixture was heated at 90 °C for 5 min and subsequently cooled in an ice–salt bath. The product was isolated and washed with ethanol. It was dried in a vacuum desiccator over P_2O_5. The metal salts used were $SnCl_2$, $FeCl_3$, $CoCl_2$, $Pb(CH_3COO)_2\cdot 3H_2O$ and $Cd(CH_3COO)_2\cdot 2H_2O$.

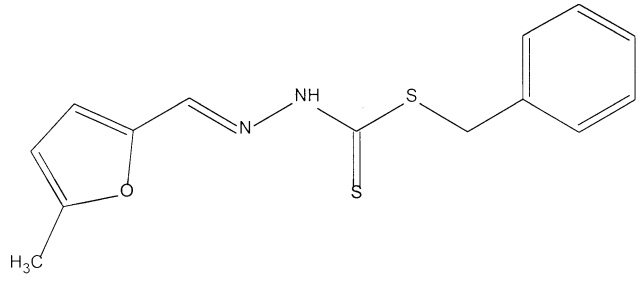

Fig. 1. Chemical structure of *S*-benzyl-β-*N*-(5-methyl-2-furylmethylene) dithiocarbazate.

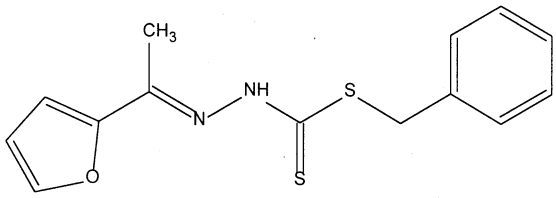

Fig. 2. Chemical structure of *S*-benzyl-β-*N*-(2-furylmethylketone) dithiocarbazate.

2.4. Physical measurements

The analyses for carbon, hydrogen, nitrogen and sulfur were carried out using a LECO CHNS-932 instrument. The IR spectra in KBr pellets were recorded using a Perkin–Elmer FT IR 1750X spectrophotometer (4000–400 cm^{-1}). The molar conductance of 10^{-3} M solutions of the metal complexes in dimethyl sulfoxide (DMSO) were measured at 29 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinized electrode. Magnetic susceptibilities at room temperature were measured using a Sherwood Scientific MSB-AUTO magnetic susceptibility balance. The UV–Vis spectra were run on a Shimadzu UV-2501 PC Recording Spectrophotometer (900–200 nm). All these measurements were done at the Chemistry Department, UPM.

2.5. X-ray structure determination of NS and $[Cd(NS')_2]$

Beautiful dark-yellow crystals of the NS ligand and $[Cd(NS')_2]$ complex were formed after the DMF solutions were allowed to slowly evaporate for a few weeks. A selected crystal was mounted on a SMART CCD diffractometer in each case. Reflection data were measured at 20 °C using graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation with a detector distance of 4 cm and swing angle of $-35°$. The collected data were reduced using the program SAINT [10] and an empirical absorption correction was carried out using SADABS [11]. The structure was solved by direct methods and refined by using the full-matrix least-squares method on F^2_{obs} using the SHELXTL [12] software package. All non-H atoms were anisotropically refined. The hydrogen atoms were located by difference syntheses and refined isotropically. The molecular graphics were created using SHELXTL. Atomic scattering factors and anomalous dispersion correction were taken from the International Table for X-ray Crystallography [13].

2.6. Target microorganisms

Eight pathogenic microbials were used to test the biological potential of the ligands and their complexes. They were *Methicillin resistant sthaphylococcus* (MRSA), *Bacillus subtilis wild type* (B29), *Subtilis mutant* (mutant defective DNA repair-B28), *Pseudomonas aeruginosa* (60690), *Candida albicans* (C.A.), *Aspergillus ochraceous* (398), *Saccaromyces ceciricaee* (20341) and *Candida lypolytica* (2075).

2.6.1. Qualitative antimicrobial assay

Antimicrobial activity of each sample was qualitatively determined by a modified disc diffusion method as previously reported [14]. Antimicrobial activity was indicated by the presence of clear inhibition zones around the discs. Commercially available streptomysin (Sigma, USA) was used for antibacterial control while nystatin (Sigma, USA) was used as antifungal control.

2.6.2. Quantitative antimicrobial assay

Compounds that showed positive (>15 mm) antimicrobial activities with the disc diffusion assay were subjected to the broth dilution method for the quantitative measurement of microbiostatic (inhibitory) activity as described by Hufford and Clark [15]. The lowest concentration that completely inhibited visible microbial growth was recorded as the minimum inhibitory concentration (MIC, μg cm^{-3}). Both streptomycin and nystatin were used as positive controls for bacteria and fungi, respectively.

2.6.3. Cytotoxic assay

The CEM-SS (Human T-lymphoblastic leukemia) cell line was obtained from the National Cancer Institute, USA. The cells were cultured in RPMI-1640 medium supplemented with 10% fetal calf serum. Cytotoxicity was determined using the microtitration of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay (Sigma, USA) as reported by Mosmann [16]. Controls that contained only cells were included for each sample.

Cytotoxicity was expressed as CD_{50}, i.e. the concentration that reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin and tamoxifen were used as control cytotoxins.

3. Results and discussion

The physical and analytical data for the metal complexes are given in Table 1. All the analytical data obtained are in agreement with the proposed empirical formulae. The characterized ligands are soluble in all organic solvents tested and all compounds are stable in air. For both the NS and NS′ free ligands, the physical and analytical data have been reported earlier [17].

3.1. Infrared spectra

Major vibration bands of the free ligands and metal complexes are given in Table 2. For complexation to occur, the free ligand must exibit thiol–thione tautomers which is brought about by the presence of thioamide –NH–C=S functional group [18,19]. The ν(C=S) band at 1096 cm^{-1} and the ν(NH) band at approximately 3150 cm^{-1} were present, indicating that the free ligands remain as the thione tautomer in the solid state. The ν(NH) band present in the free ligand was not observed in any metal complex, indicating deprotonation of the ligand in situ to form the thiol tautomers for the formation of metal complexes to take place.

The ν(C=S) bands at 1096 and 1026 cm^{-1} for NS and NS′ free ligand were also not observed in the metal complexes, thus supporting the suggestion of coordination through the thione sulfur. Sharp bands observed in the spectrum of the free ligand at approximately 1600 cm^{-1} are assigned to ν(C=N) [20]. In the metal complexes this absorption was shifted to lower frequencies indicating coordination of the azomethine nitrogen to the central metal atoms [21,22]. The lowering in frequency of the ν(N–N) band in all the metal complexes is another clear indication that the coordination involves azomethine nitrogen. There was no

Table 1

$[Pb(NS')_2]$		1584		990	1230	22	
$[Cd(NS')_2]$		1590		998	1230	20	

significant displacement of the frequency of the ring breathing and ν(C–O–C) vibrations at 1230 cm^{-1} [7] and no presence of metal oxygen bond stretching observed at 440–450 cm^{-1} [8] in any complex. This shows that there was no coordination by the furanic oxygen. Indeed there is no indication of oxygen bonding to the central metal atom in the crystal structure of the $[Cd(NS)_2]$ complex.

3.2. Magnetic and conductivity data and electronic spectra

At room temperature, magnetic susceptibility (Table 3) measurements show that all the complexes are diamagnetic and low spin except for $[Fe(NS)_2]Cl_2\cdot H_2O$ which has paramagnetic properties with μ_{eff} of 1.77 B.M., characteristic of a square planar structure. All the diamagnetic complexes are four-coordinated and expected to be distorted tetrahedral, as proved for our cadmium complex by its crystal structure. For the iron(II) ion which has a $3d^6$ electron configuration, the magnetic moment (1.77 B.M.) suggests that the iron(II) ion is in a low-spin iron(II) state.

The complexes $[Sn(NS)_2]Cl_2\cdot H_2O$ and $[Fe(NS)_2]Cl_2\cdot H_2O$ exhibit molar conductance values corresponding to 2:1 electrolytes in DMSO. The conductivity presumably arises from solvation according to the following scheme:

$$[Sn(NS)_2]Cl_2\cdot H_2O + DMSO \rightarrow [Sn(NS)_2](DMSO)_2\cdot H_2O + 2Cl^-$$

and

$$[Fe(NS)_2]Cl_2\cdot H_2O + DMSO \rightarrow [Fe(NS)_2](DMSO)_2\cdot H_2O + 2Cl^-$$

The electronic spectrum of the $[Co(NS)_2]$ complex displays two diagnostic absorptions at 393 and 339 nm corresponding to $^1A_{1g}\rightarrow{}^1T_{1g}$ and $^1A_{1g}\rightarrow{}^1T_{2g}$ transitions. The remaining compounds showed bands that are caused by charge transfer.

3.3. Crystal structure studies

3.3.1. Crystal structure of NS (see Table 6)

A perspective view of the ligand with the numbering scheme is shown in Fig. 3. The relevant bond distances and bond angles are given in Table 7. The asymmetric unit consists of two independent *S*-benzyl-β-*N*(5-methyl-2-furylmethylene)dithiocarbazate molecules. The methylfurylmethylenedithiocarbazate moiety of the two molecules are not exactly planar. The methylfuryl plane of (O1–C10–C11–C12–C13–C9) is planar with C14 atom deviated by only −0.030(3) Å. This plane makes a dihedral angle of 11.33(9)° with the S1–S2–N1–N2–C7–C8 plane. Similarly, in the second molecule the methylfuryl O2–C24–C25–C26–C27–C28 is planar with maximum deviation of 0.04(2) Å at the C28

Table 3
UV–Vis spectral of band maxima (λ, nm (log ε)) and magnetic susceptibility of metal complexes

Compound	λ_{max} (nm)	μ_{eff} (B.M.) [a]
$[Pb(NS)_2]\cdot H_2O$	355.5(4.817), 588.0(4.738)	diamagnetic
$[Sn(NS)_2]Cl_2\cdot 2H_2O$	357.5(4.821), 295.5(4.056), 585.0(1.523)	diamagnetic
$[Fe(NS)_2]Cl_2\cdot H_2O$	354.5(6.045), 418.0(5.574), 587.0(5.097)	1.77
$[Co(NS)_2]\cdot Cl$	339.0(4.402), 393.0(4.385)	diamagnetic
$[Pb(NS')_2]$	303.5(4.434), 347.5(4.569)	diamagnetic
$[Cd(NS')_2]$	307.5(4.320), 359.5(4.420)	diamagnetic

Beer's law: $A = \varepsilon bc$ where A, absorption, $b = 1$ cm and c, concentration (M), log ε (cm^{-1} mol^{-1} l) are given in parentheses.
[a] Tetrahedral complex, 1.94–2.00 B.M.; distorted square-planar, 1.90–1.93 B.M.; square-planar, 1.85–1.89 B.M.

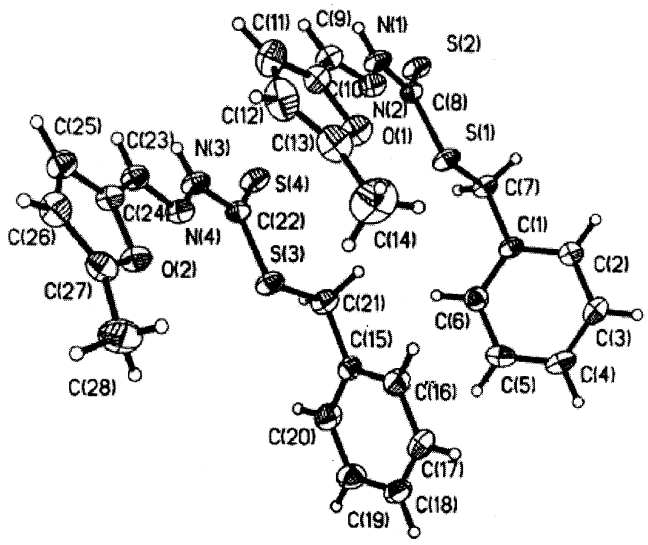

Fig. 3. Molecular structure and atom numbering scheme of (NS).

atom. However, the S3–S4–N3–N4–C4–C5–C6–C7 plane showed large deviation from the planar S3–N3–C21–C22 group at the S4 and N4 atoms of 0.126(1) and −0.119(1) Å, respectively. The dihedral angle between the methylfurfuryl O2–C24–C25–C26–C27–C28 plane and S3–N3–C21–C22 is 6.41(16)° which is smaller than in the first molecule. The phenyl ring C1–C2–C3–C4–C5–C6–C7 is nearly perpendicular to the methylene-dithiocarbazate S1–S2–N1–N2–C7–C8 of 80.21(6)°. In the second molecule, the phenyl ring C15–C16–C17–C18–C19–C20 makes a dihedral angle of 74.12(9)° with the S3–N3–C21–C22 plane.

The C8–S2 and C22–S4 bond lengths in the two molecules of 1.6669(15) and 1.6667(15) Å, respectively, are intermediate between 1.82 Å for C–S single bond and 1.56 Å for C=S double bond [23] and is in agreement with the reported value in SBDTC [24]. Thus, the compound exits as a thioketo tautomeric form. The furylmethylene and benzyl groups are *trans* and *cis* with respect to the ion about the the C–N and C–S bonds, respectively. A similar configuration was also reported for SBDTC [24]. The N1–N2 and N3–N4

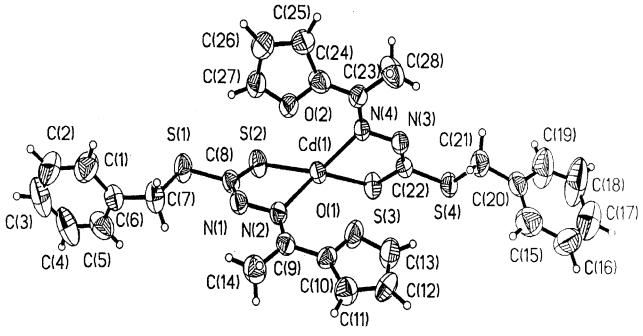

Fig. 4. Molecular structure and atom numbering scheme of $[Cd(NS')_2]$.

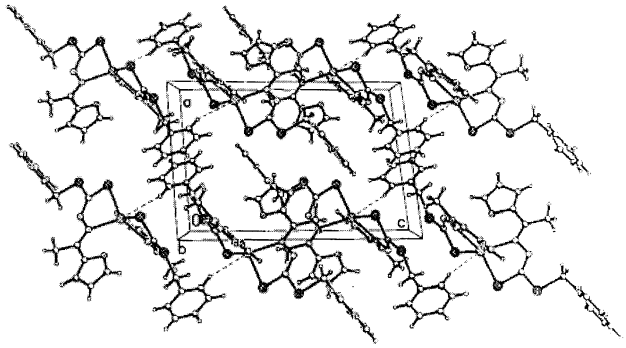

Fig. 5. Packing arrangement of $[Cd(NS')_2]$.

bond distances of 1.3820(16) and 1.3824(17) Å are slightly shorter than the corresponding bond lengths in unsubstituted SBDTC (1.406(3) Å) [24] due to the delocalised electrons of the furan ring. The two molecules are connected by hydrogen bondings, N1–H1A···S4 (H1A···S4 2.578 Å) and N3–H3A···S2 (H3A···S2 2.589 Å), and therefore, are arranged as dimers parallel to the *b* and *c* axes in the lattice.

3.3.2. Crystal structure of the $[Cd(NS')_2]$ complex

The molecular structure of the $[Cd(NS')_2]$ complex is shown in Fig. 4, while Fig. 5 shows the packing arrangement of the molecules on the ac plane. The central cadmium atom is bis-chelated by the uninegatively charged bidentate ligand through the azomethine nitrogen atoms, N2 and N4, and the thiolate sulfur atoms, S2 and S3. Both nitrogen atoms (N2, N4) and sulfur atoms (S2 and S3) from the two ligands are coordinated at opposite positions. The formation of this complex gives a distorted tetrahedral geometry about the central cadmium atom with angles of 78.89(10)°–137.72(11)°. The bond lengths of the complex are comparable to the analogous complex bis[*S*-benzyl-β-*N*(5-methyl-2-furylmethylene)dithiocarbazato]cadmium(II) reported earlier [17]. Both complexes show non-participation of the furanic oxygen in the coordination to the central cadmium atom. This observation, however, is in contrast to the one proposed by Jouad et al. [25]. There is slight variation in corresponding bond lengths in the C9–N2–N1–C8–S1–C17 and C23–N4–N3–C22–S4–C21 moieties in the complex. The largest variation is shown by the C9–C10 and C23–C24 of 1.466(6) and 1.419(7) Å, respectively. The C8–N1 and C22–N3 bond lengths of 1.257(6) and 1.300(7) Å clearly indicate the complexation involves deprotonation at N1 and N3 atoms of the ligand. The conjugation system of the moieties is influenced by the coordination with the metal as shown by the slight bond lengthenings compared with the uncomplexed ligand. The N1–N2 and N3–N4 distances of of 1.424(5) and 1.417(5) Å are slightly longer than the normal values of about 1.36–1.38 Å [22,26]. The corresponding bond lengths in

octahedral tridentate bis[*S*-benzyl-β-*N*(2-pyridylmethylene)dithiocarbazato]zinc(II) are 1.379(4) and 1.374(4) Å, respectively [1]. The cadmium atom makes a linear plane with the furyl groups Cd1–O1–N1–N2–C9–C10–C11–C12–C13–C14, with maximum deviation of 0.048(4) Å at C11, and Cd1–O2–N3–N4–C23–C24–C25–C26–C27 with maximum deviation of 0.032(7) Å at N4, respectively. The cadmium-bidentate rings are less planar. The Cd1–S2–N1–N2–C8 has a minimum deviation of 0.085(5) Å at the N1 atom and maximum deviation of 0.181(4) Å at the S4 atom. For the Cd1–S3–N3–N4–C22 plane the minimum deviation is 0.096(5) Å at the N3 atom and the maximum deviation is 0.219(9) Å at the N4 atom. The dihedral angles between the planar benzyl planes C1–C2–C3–C4–C5–C6–C7 and C15–C16–C17–C18–C19–C20–C21 with their corresponding furyl planes O1–C10–C11–C12–C13–C14 (maximum deviation at C9, 0.021(5) Å) and O2–C32–C24–C25–C26–C27 (maximum deviation at C24, 0.047(6) Å) are quite different with values of 83.9(4)° and 67.7(4)°, respectively. The intramolecular interaction of C14–H14A···N1 (H14A···N1, 2.259 Å) and C28–H28A···N3 (H28A···N3, 2.248 Å) result in the formation of six-membered rings in the ligand moieties and may contribute to the planarity of the furyl-Schiff base group of the complex.

3.4. Biological activity

3.4.1. Cytotoxic activity

$PbNO_3$ salt is inactive, but chelation by the NS is active, but chelation by Nsfree ligand gives $[Pb(NS)_2]\cdot H_2O$ complex of high cytoxicity against CEM-SS with a CD_{50} of 3.25 μg cm^{-1}. Most of our recent research on cadmium(II) complexes [17] showed high cytotoxic activity on all of the cell lines, but the activity of the $[Cd(NS')_2]$ complex was greatly reduced and was even much lower than the simple cadmium(II) salt. The remainder of the complexes investigated do not possess any significant activity against CEM-SS, with the exception of $[Sn(NS)_2]Cl_2\cdot 2H_2O$ and $[Pb(NS')_2]$ complexes which are toxic at higher concentrations. Detailed results against CEM-SS cell lines are shown in Table 4.

Table 4
Results of screening against leukemic cells (CEM-SS)

Compound	CD_{50} (μg cm^{-3}) [a] CEM-SS
$[Fe(NS)_2]Cl_2\cdot H_2O$	–
$[Sn(NS)_2]Cl_2\cdot 2H_2O$	29

–, inactive.
[a] CD_{50} (μg cm^{-3}), cytotoxic dose at 50%, i.e. the concentration to reduce growth of cancer cells by 50%.

3.4.2. Antimicrobial assay

Preliminary screening for antimicrobial activity was done on all compounds. All the compounds showed clear inhibition zones of 10 mm and above against *A. ochraceous* except the $[Cd(NS')_2]$ complex. $[Fe(NS)_2]Cl_2\cdot H_2O$ was active against *A. ochraceous* with a clear inhibition zone of 21 mm. The qualitative screening results are shown in Table 5.

Only $[Fe(NS)_2]Cl_2\cdot H_2O$ was used for quantitative measurement of MIC. Its MIC value of 100 000 μg cm^{-3} towards *A. ochraceous* is higher than that for the standard drug nystatin (3125 μg cm^{-3}).

Table 5
Qualitative antimicrobial assay results [a] (diameter in mm)

Compound	MRSA	B29	B28	60690	C.A.	398	20341	2075

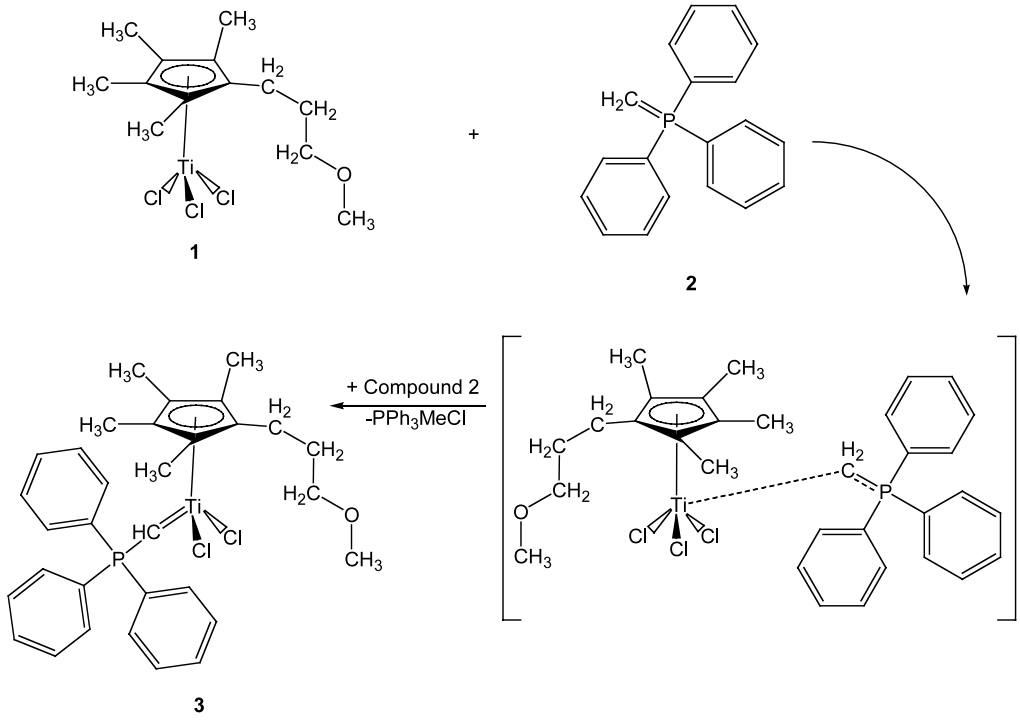

Fig. 1. First step in the two-step synthesis of the title complex.

energy than the dissociated singlet carbene and neutral phosphine [8,9].

From a structural point of view, in a phosporonium ylid the phosphorous atom is in a pseudo-tetrahedral environment, while the carbon atom has a pseudo-trigonal planar geometry. In addition, one of the H–P–C angles is slightly larger than the other two; the respective H–P bond length is also longer [6]. These features are characteristics of phosphorous ylids.

In a phosphorus ylid, the formally cationic phosphorus group has very stable unoccupied molecular orbitals (UMOs), including phosphorus 3d and P–H σ^* orbitals. The anionic carbon's highest occupied molecular orbital (HOMO) is of very high energy and can donate electron density into the UMOs on the phosphorus in a back-bonding manner. This back-bonding results in two strongly polarized τ (banana) bonds between phosphorous and carbon. Repulsion between the τ bonds and the P–H σ bond is responsible for the larger C–P–H bond angle and corresponding P–H bond length [7].

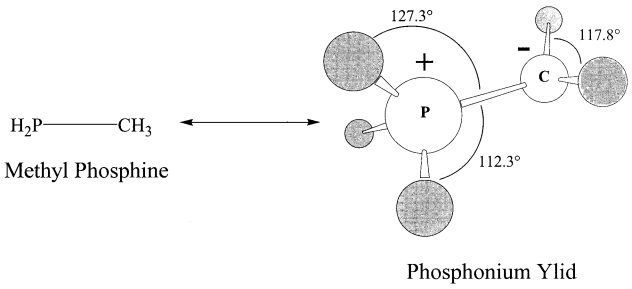

Fig. 3. Structural characteristics of the simplest phosphorus ylid [6].

Phosphorus ylids are Brønsted bases with phosphonium salts as conjugate acids. This basicity permits

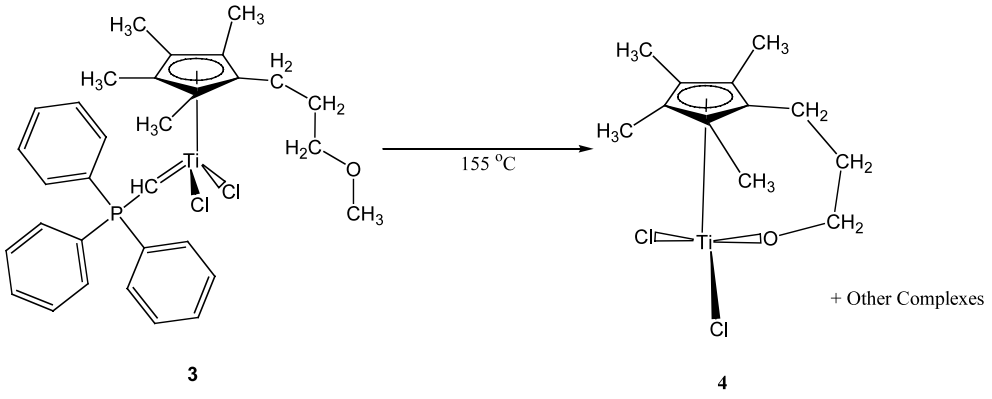

Fig. 2. Second step in the two-step synthesis of the title complex.

strong acid phosphonium salts and strong base phosphorus ylids to undergo transylidation reactions, such as the one shown in Fig. 1 [10]. As a ligand, the ylid can be either neutral or anionic which in turn leads to a plethora of ylid-metal coordination modes. A few of these modes, relevant to this work, are depicted in Fig. 4. The coordination modes illustrate the utility of ylids in forming metal carbon bonds. Another advantage ylids maintain is the presence of a β onium group that stays in the product after attachment to the metal center(s).

2. Details of the calculations

The structure of complex **4** was obtained by optimizing [12] crystal structure parameters for this molecule [1]. The optimized structure of **4** was then used to construct the initial coordinates in the optimization of all compounds via the Gaussian 98^{TM} [11] geometry optimization algorithm [12]. The Gaussian 98^{TM} [11] suite of programs were employed to solve Schrödinger's equation using the Hartree–Fock–Roothaan Self-Consistent-Field method [13]. The triple zeta basis set, 6-311G, successfully represents titanium but lacks the required polarization functions for carbon and phosphorus [7]. Therefore, all reported values were calculated from restricted Hartree–Fock optimized structures using the 6-311G(d) basis set provided in Gaussian [14–21].

In order to increase the speed of the calculations and simplify the analysis of the results, the methyl groups on the substituted cyclopentadienyl ligand (Cp*) were replaced by hydrogen atoms (Cp). The results shown in Table 1 indicate that the substitution had negligible effects on the results of the calculations.

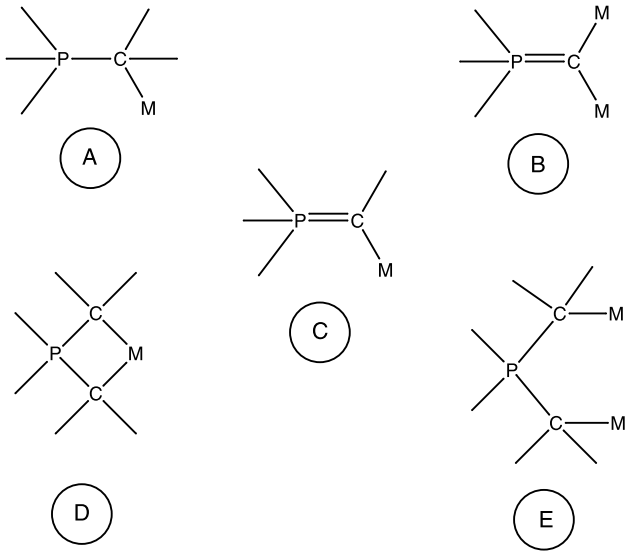

Fig. 4. A sample of possible coordination modes between the phosphorus ylid ligand and transition metals [10].

Table 1
A comparison of the energy (in hartrees) of selected molecular orbitals of complex **4**

Molecular orbital	Complex **4** with Cp	Complex **4** with Cp*
LUMO	0.0507	0.0726
HOMO	−0.3708	−0.3457
SHOMO	−0.3748	−0.3472
HOMO–LUMO gap	0.3201	0.2731

Gaussian 98^{TM} was executed on either a Gateway^{TM} E-5200 computer or the National Computational Science Alliance's HP-Convex Exemplar X-Class Scalable Supercomputer located at the University of Kentucky.

3. Results and discussion

Discussion of the data begins with an analysis of the role of the phosphorus ylid in the two-step synthesis. We turn first to the phosphonium ylid: this molecule is known to have one larger H–P–C bond angle and one longer H–P bond length. It also displays pseudo-tetrahedral geometry at the phosphorus center and pseudo-trigonal planar geometry at the carbon. Table 2 shows that **2**, the free ylid in the synthesis, diplays these structural characteristics. This is also evident in Fig. 3.

When bonded in complex **3**, methylenetriphenylphosphorane, **2** exhibits structural characteristics similar to those of the free ylid, except that the unique bond angle and length are smaller than their counterparts in the free ylid. The longer P–X bond lengths are expected, due to the increased steric requirement of the phenyl substituents. The C–H bond length remains almost exactly the same as in the free ylid, while the C–P bond length increases to accommodate the larger Ti group on the ylidic carbon. Zwitterionic character persists between the carbon and phosphorus atoms in **3**, as evident in Table 2. As expected the phosphorus ylid structural trends reappear in methylated **2**, one of the side products of the second synthetic reaction.

Titanium-ylid bonding in **3** can be described by the two resonance structures in Fig. 5. Teuben and associates reported form B as the major contributor [1], but this implies a partial negative charge on the titanium atom, which does not agree with the results of the calculations. These indicate that form A is the major contributor, as specified by the partially positive titanium atom and partially negative ylidic carbon in Table 3.

The site of attack in Reaction 2 is now considered, where an intramolecular nucleophilic attack was proposed as the probable mechanism [1]. Intramolecular

Table 2
Selected ylid structural characteristics

	Phosphonium ylid	Compound **2** [22]	Complex **3**	Methylated compound **2**

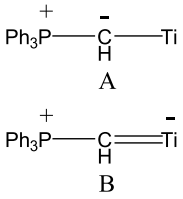

Fig. 5. The two resonance structures representing titanium–ylid bonding in complex **3**.

nucleophilic attacks can be orbital or charge controlled. If the attack is orbital controlled, the nucleophilic site is expected to be at the HOMO of complex **3**, while its LUMO would be localized at the electrophilic site. In this reaction, the HOMO should be on the ylidic carbon and the LUMO on the methoxy group. From Figs. 6 and 7 we discern that this is not the case. Although **3**'s HOMO does exhibit electron density at the ylidic carbon there is a complete absence of the LUMO on the methoxy group.

On the other hand, a charge-controlled reaction is one in which the nucleophilic site carries the largest negative charge and the electrophilic site carries the largest positive charge. For **3** we would expect the ylidic carbon to carry a partial negative charge and the methoxy carbon to carry a partial positive charge. Reaction 2 does appear to be charge controlled as portrayed by Table 3 data. We now turn to the bonding characteristics of **4**.

When investigating bonding in an organometallic complex containing a Cp ring, hapticity can not be

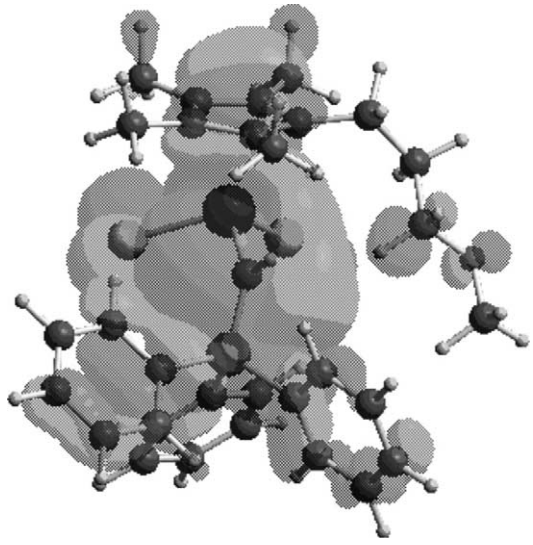

Fig. 6. The HOMO of complex **3**.

ignored. Cp rings commonly display η^5 hapticity but have been known to exhibit η^1 or η^3 bonding [23]. The Mulliken overlap population analysis of **4** contained in Table 4, indicates that the amount of electron density between the titanium atom and each of the cyclopentadienyl carbons is not exactly equal, as predicted for true η^5-type bonding. The Cp ring exhibits ring slippage as expected due to the constraining propoxy chain as seen in Fig. 8.

Another bond of interest in **4** is the titanium–oxygen bond. We know the titanium–chlorine bond in **4** is a

C(24)–C(14)	0.2313
Ti–C(14)	0.0297
Ti–C(12)	0.0419
Ti–C(9)	0.0559
Ti–C(8)	0.0617
Ti–C(5)	0.0461

single bond with an overlap density of about 0.20 electrons. **4**'s titanium–oxygen bond exhibits an overlap of 0.13 electrons and can, therefore, also be considered a single bond.

4. Conclusion

The bonding and reactivity of Complex **3** and **4** in Reactions 1 and 2 were investigated via ab initio Hartree–Fock calculations at the 6-311G(d) basis set level. Results of the calculations indicate that methylenetriphenylphosphorane continues to exhibit structural and electronic properties characteristic of ylids when bonded to the titanium center in **3**. In addition, the Ti–O bond in **4** is a single bond, while the cyclopentadienyl ring exhibits a slight degree of ring slippage, due to constraints imposed by the linking propoxy arm. The titanium–ylid bonding in **4** can be described by two resonance structures. Of these two structures, the predominant form has a partial positive charge on the phosphorus atom, a partial negative charge on the ylidic carbon, and a single bond between the ylidic carbon atom and the titanium center.

The intramolecular nucleophilic attack occurring in the second step of the synthesis is charge controlled. In this step, **3**'s partially negative ylidic carbon attacks the partially positive carbon of the dangling methoxy group.

2.2. Starting material

The complexes $Zn(NO_3)_2\cdot 6H_2O$ and $CoCl_2\cdot 6H_2O$ were used as obtained from commercial sources without further purification. The reagent PPz hexahydrate (PPz = piperazine) was purchased from Aldrich.

2.3. $[Zn(NCS)_2(PPz)]_n$ (1)

Compound **1** was obtained upon carefully laying a solution of $Zn(NO_3)_2\cdot 4H_2O$ (0.19 g, 1 mmol) and NH_4SCN (0.15 mg, 2 mmol) in methanol (5 ml) onto a solution of PPz (0.19 mg, 1 mmol) in methanol (5 ml). Large pale crystals formed and were collected by filtration to give a yield of 0.17 g (65%). *Anal*. Calc. for $C_{10}H_{20}N_6S_2Zn$ C, 26.89; H, 3.74; N, 20.92. Found: C, 26.79; H, 3.72; N, 21.27%. IR (KBr disk): 3218(m), 3127(m), 2987(s), 2928(s), 2858(s), 2077(m), 1426(m), 1319(m), 1265(s), 1190(s), 1141(s), 1103(m), 1077(s), 1017(m), 990(m), 872(m), 667(s), 625(s), 474(m).

2.4. $[CoCl_2(PPz)]_n$ (2)

Compound **2** was obtained upon carefully laying a solution of $CoCl_2\cdot 4H_2O$ (0.24 g, 1 mmol) in methanol (5 ml) onto a solution of PPz (0.19 g, 1mmol) in methanol (5 ml). Large blue crystals formed and were collected by filtration to give a yield of 0.11 g (52%). *Anal*. Calc. for $C_4H_{10}N_2Cl_2Co$ C, 26.89; H, 4.63; N, 20.92. Found: C, 26.61; H, 4.53; N, 20.13%. IR (KBr disk): 3203(br), 2976(m), 2949(s), 2825(s), 2373(m), 1658(s), 1572(s), 1464(s), 1421(s), 1125(s), 1098(m), 1071(s), 883(m), 641(s), 528(s).

3. X-ray crystallography

The diffraction data of each compound was collected on a Siemens P4 diffractometer using graphite-monochromated Mo Kα ($\lambda_\alpha = 0.71073$ Å) radiation. Data reduction was carried out by standard methods [12].

The positions of the heavy atoms, including zinc atoms, were located by the direct method. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [13]. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1, selected bond distances and angles are listed in Table 2 for **1** and Table 3 for **2**.

4. Results and discussion

4.1. Syntheses and spectroscopic studies

The reaction pathways are shown in Scheme 1. The IR spectrum of the complex **1** clearly shows the existence of PPz and thiocyanate molecules. The absorption bands at 2077, 872 and 474 cm^{-1} correspond to ν(C≡N), ν(C–S) and δ(N≡C–S), respectively, consistent with terminally nitrogen-bonded NCS^- group [14]. The complexes **1**–**2** contain characteristic C–N and C–C vibrational frequencies of the ligand PPz. There is a shift of approximately 15 cm^{-1} of the absorption bands to higher frequencies as compared with those of the free PPz molecule.

4.2. Structure

The complex of **1** belongs to type a in Fig. 1 and forms a 1-D zigzag Zn–PPz–Zn chain. Fig. 2(a) shows the local coordination of the zinc center, and Fig. 2(b) shows an infinite one-dimensional chain. The distorted tetrahedral Zn(II) metal center is achieved by means of a single bridging PPz ligands and two terminal N-bonded NCS^- anions. There are one long Zn–N(PPz) bond (2.039(2) Å) and two short Zn–N (NCS) bonds (1.940(3) and 1.953(3) Å), again consistent with corresponding bond length in, for $[Zn(NCS)_2(PPz)]$ [15] molecules. The NCS^- groups are almost linear with an N–C–S angle of 178.7(3) Å. The connection between Zn atoms and NCS^- groups are bent with a C(1)–N(1)–Zn(1) angle of 162.1(3)°. The $[Zn(NCS)_2(PPz)]_n$ structures are linked into three-dimensional structure through NCS···H–N (S···H = 2.58(3) and 2.68(3)) interactions, which are formed between adjacent chains

Scheme 1. Reaction pathways for $[Zn(NCS)_2(PPz)]_n$ and $[CoCl_2(PPz)]_n$.

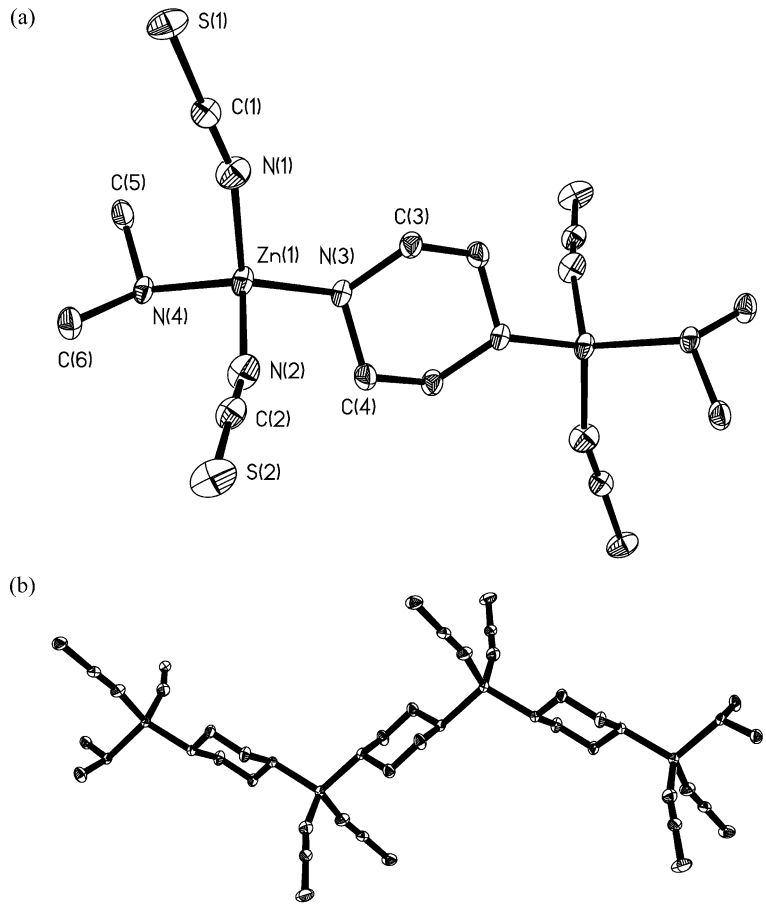

Fig. 2. (a) ORTEP drawing of the local coordination of Zn in **1**. (b) An infinite one-dimensional chain.

through the sulfur atoms and the amine hydrogen atoms of PPz molecules (Fig. 3).

In the structure of **2**, the Co center is coordinated to one PPz ligands and two Cl anions. Fig. 4(a) shows the

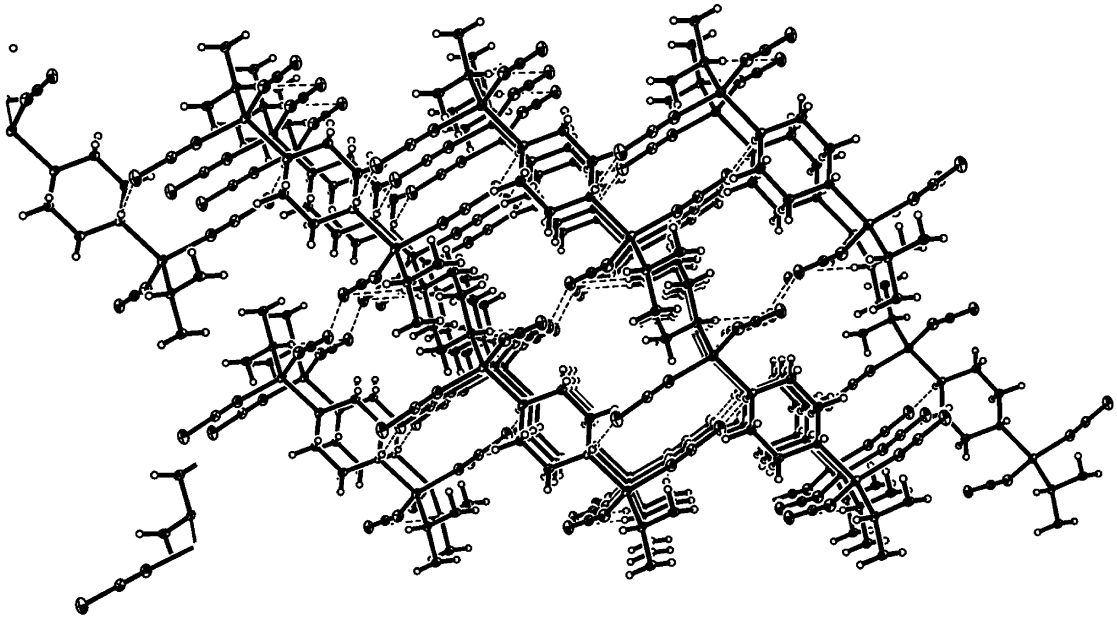

Fig. 3. Packing diagram of **1**, showing the crystal structures are linked via NCS···H–N interactions.

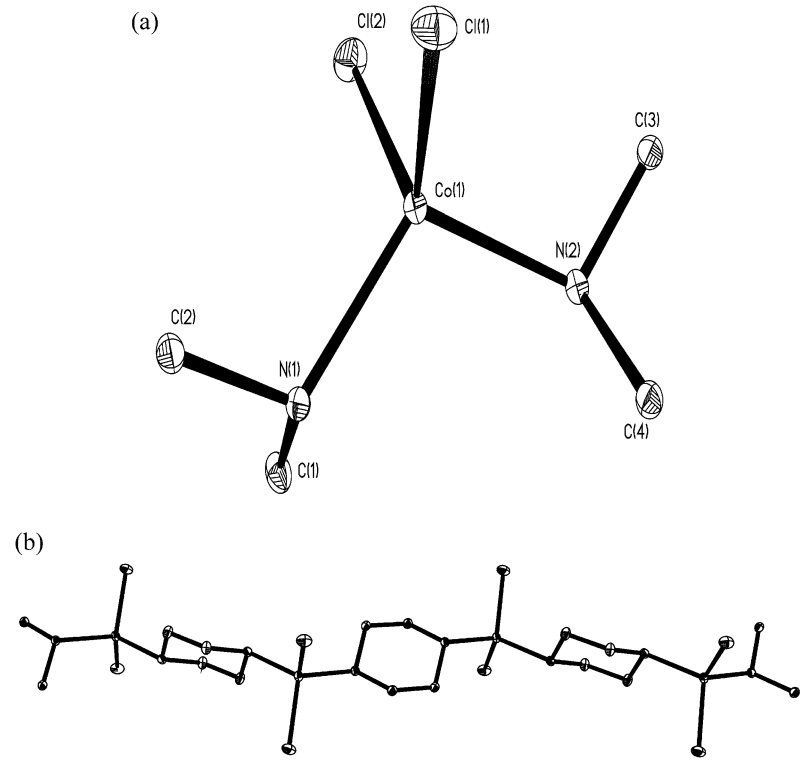

Fig. 4. (a) ORTEP drawing of the local coordination of Co in **2**. (b) An infinite one-dimensional chain.

local coordination of the zinc center, and Fig. 4(b) shows an infinite one-dimensional chain. The Co–Cl distances, which are 2.2467(8) and 2.2470(8) Å, respectively, are significantly shorter than those of molecular $Co_4Cl_8(C_4H_8O)_6$ (av. Co–(μ_2-Cl) = 2.400 Å) [16], $Co_3Cl_8(C_4H_8O)_2$ (av. Co–(μ_2-Cl) = 2.403 Å) [17] and polymeric $[CoCl_2(H_2O)_2][HN(CH_3)_3Cl]$ (av. Co–(μ_2-Cl) = 2.480 Å) [18], $CoCl_2(DMSO)_2$(4,4-bipy) (Co–Cl = 2.4707(5)) [19] and $CoCl_2(Pyz)_2$ [20]. The Cl–Co–Cl angle is 105.18(3)° and the N(2)–Co–N(1) angle is 108.86(9)°.

The ability of metal chloride complexes to act as hydrogen bond acceptors has been investigated and designed structures have been successfully prepared [21]. The existence and structural importance of weak C–H···X hydrogen-bonding interaction are now well

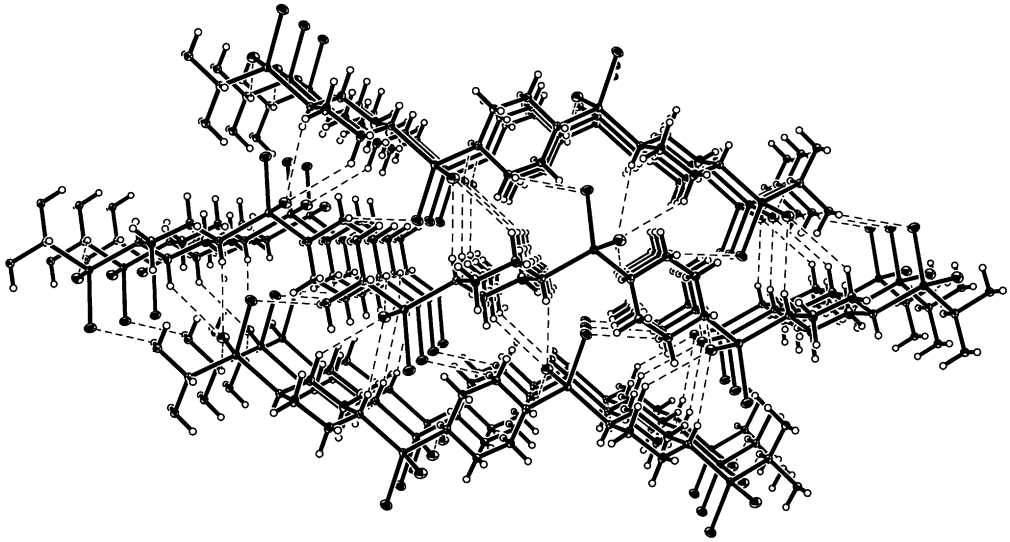

Fig. 5. Packing diagram of **2**, showing the crystal structures are linked via N–H···Cl–M and C–H···Cl–M interactions.

established [22] and are observed in many compounds, such as the N···H–C interaction in 1,3,5-tricyanobenzene-hexamethylbenzene [23], the O···H–C interaction in $(C_{14}H_{12}N_2)[Cu(opba)]\cdot 3H_2O$ and $Na_2C_{12}H_{12}N_2[Cu(opba)]_2\cdot 4H_2O$ (opba = *o*-phenylenebis(oxamate)) [24], and the Cl···H–C interaction in CuCl(Pyz) [25], $CdCl_2$(Pyz) [26] and Cu_2Cl_2(Pyz) [27]. In complex **2**, linkage into a three-dimensional structure is achieved through three N–H···Cl–M (H···Cl = 2.75(2), 2.83(3) and 2.87(2) Å ∠ N–H···Cl = 57(2)°, 142(2)° and 152(1)°) and one C–H···Cl–M (H···Cl = 2.82(2) Å, ∠ C–H···Cl = 72.2(4)°) hydrogen bonds (Fig. 5).

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper has been deposited with the Cambridge Crystallographic Data Center as CCDC Nos. 187495 and 187496. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

by an unusual conformation of the puckered chelate ring where the methyl group will occupy an axial position. The structure of analogous coordination compounds can be understood or predicted on this basis. X-ray structure of Cu(II) complexes with Schiff base derived from propanediamine and salicylaldehyde [8] reveals that Cu(II) is five-coordinated with water molecule in axial position, but others [9,10] found Cu(II) in the complex with the same Schiff base in six-coordination. However, there is an evidence of the essentially four-coordinated nearly planar copper(II) in the discussed type of Schiff bases complexes [11,12]. The diversity of structures and properties of the Cu(II) complexes with Schiff bases derived from acetylacetone or salicylaldehyde depends on the donors field strength and thus to view that the p- and π*-orbitals of the ligand are important but there is also a stereochemical impact on the geometry of Cu(II) coordination sphere.

The structure of Schiff base coordination compounds derived from substituted 1,2-cyclohexanediamines and 2-hydroxy-3- and 2-hydroxy-5-methylbenzaldehyde have not been studied and it is presently not possible to predict how the ligands orient themselves around the metal ion. The electronic structure of a benzylaldimine is less suited for stereochemical studies, by means of CD, because of the low effective symmetry so that the internal $\pi \rightarrow \pi^*$ transition moments are found to have directions far from the N–O line or its perpendicular order in the plane of the molecule. Thus an earlier study on such salicylaldimine copper(II) compounds has not tried to relate CD to electronic or geometric structure. In a series of the studied metal complexes containing π–π conjugated ligand the reactivity of the complexes and the redox potential of the central metal are sensitive to the nature of the substituents on the chelate ring [13]. CD spectra of transition metal complexes have been extensively studied in recent years as their interpretation can yield valuable information concerning the origin of absorption bands in the electronic spectra of complexes [14–17]. The sensitivity of CD on a molecular structure makes the technique valuable for investigation of the chelate ring conformation and configuration and these will be discussed in the present work.

2. Experimental

2.1. Materials

$Cu(AcO)_2 \cdot H_2O$, $Co(AcO)_2 \cdot 4H_2O$, $Ni(AcO)_2 \cdot 4H_2O$ (analytical grade) were purchased from POCh (Gliwice, Poland); 2-hydroxy-3-methylbenzaldehyde (98%), 2-hydroxy-5-methylbenzaldehyde (99%) were purchased from Aldrich. *trans*-(1*R*,2*R*)-(−)-1,2-cyclohexanediammonium $(+)_D$-tartrate [(−)-chxn(+)tart], was prepared according to Galsbol et al. [18] and employed to obtain (1*R*,2*R*)-*trans*-(−)-cyclohexanediamine (−)-chxn, which was used in situ or isolated for Schiff bases synthesis.

2.2. Instrumentation

UV–Vis absorption spectra were recorded on a Milton Roy Spectronic 1201 in CH_3CN (1×10^{-5} M) solution and with a Specord M-40 (Carl Zeiss Jena) spectrophotometer as Nujol mulls. IR spectra were performed on a Spectrum 2000 Perkin–Elmer FT IR using KBr pellets in the range 400–4000 cm^{-1} and PE discs in 400–200 cm^{-1}. ^1H NMR spectra were collected with a Varian Gem. 1200 MHz in $CDCl_3$ for diamagnetic and paramagnetic complexes. Paramagnetic complexes spectra were measured in 0.003 M solution, data block size 8K, acquisition time 0.256 s and relaxation delay (RD) 0 s at 295 K. CD spectra were measured with a JASCO 715 spectropolarimeter in 800–180 nm range for the same solution as for UV–Vis.

2.3. Synthesis

2.3.1. Syntheses of Schiff bases

(−)-Chxn 1.82 g (16 mmol) and 2-hydroxy-5-methylbenzaldehyde 4.35 g (32 mmol) or 2-hydroxy-3-methylbenzaldehyde (32 mmol) in EtOH solutions were stirred under reflux for 2 h. The yellow solution of the Schiff base was evaporated to the dryness on a rotary evaporator and recrystallized from ethanol. Schiff bases were characterized with ^1H NMR (−)-chxn-(3-methylbaH)$_2$: 1.4–1.9 (m-8H), 3.29, 3.31, 3.34 (t-2H) 8.24 (s-4H), 2.24 (s-6H), 13.6 (s-2H), 6.67–7.14 (m-8H), (−)-chxn-(5-methylbaH)$_2$ 1.25–1.96 (m-8H), 3.27, 3.29, 3.31 (t-2H), 8.19 (s-2H), 2.21 (s-6H), 13.05 (s-2H), 6.77–7.07 (m-8H) ppm. IR (−)-chxn-(3-methylbaH)$_2$: 1624 cm^{-1} ν(CN), 3437 cm^{-1} ν(OH), (−)-chxn-(5-methylbaH)$_2$: 1628 cm^{-1} ν(CN), 3433 cm^{-1} ν(OH).

2.3.2. Syntheses of complexes

Cobalt(II), copper(II) and nickel(II) complexes were obtained as follows: $Co(AcO)_2 \cdot H_2O$ 1.95 g (10 mmol) was dissolved in hot MeOH and added to the stirred deoxygenated ligand 3.5 g (10 mmol) solution in *n*-PrOH, under argon. The precipitate appeared immediately and the reaction mixture was stirred and heated under reflux for 30 min, to complete the reaction. The complex was filtered, washed and dried on a vacuum line. $Ni(AcO)_2 \cdot 4H_2O$ (2.5 g–10 mmols) or $Cu(AcO)_2 \cdot H_2O$ (2 g–10 mmols) were dissolved in ethanol and stirred under reflux for 10 min, followed by the addition of the Schiff base 3.5 g (10 mmol) in ethanol and reaction mixtures were stirred upon heating for 1 h. Obtained precipitates were filtered, washed with methanol and dried in the air. Besides many attempts (chloromethane–benzene, dichloromethane–benzene,

acetonitrile–benzene) we were unable to obtain crystals suitable for X-ray analysis. Results of elemental analyses: [(Co(−)-chxn-(3-methylba)$_2$] (**1**) (Calc./Found) C (64.9/65.2); H (5.94/6.14); Co (14.5/14.7); N (6.9/6.53)%. [(Co(−)-chxn-(5-methylba)$_2$] (**2**) (Calc./Found) C (64.9/64.5); H (5.94/5.4); Co (14.5/14.2); N (6.9/6.4)%. [(Cu(−)-chxn-(3-methylba)$_2$] (**3**) (Calc./Found) C (64.2/64.5); H (5.9/5.5); Cu (15.4/15.1); N (6.8/6.2)%. [(Cu(−)-chxn-(5-methylba)$_2$] (**4**) (Calc./Found) C (64.2/64.5); H (5.9/6.0); Cu (15.4/15.6); N (6.8/6.7)%. [(Ni(−)-chxn-(3-methylba)$_2$] (**5**) (Calc./Found) C (64.9/65.1); H (5.9/6.3); N (6.9/6.7); Ni (14.4/14.6)%. [(Ni(−)-chxn-(5-methylba)$_2$] (**6**) (Calc./Found) C (64.9/65.3); H (5.9/5.8); N (6.9/6.3); Ni (14.4/14.3)%.

3. Results and discussion

3.1. CD and UV–Vis absorption spectra

The free ligand absorption spectra in acetonitrile revealed bands at 222 and 255 nm for (−)-chxn-(5-methylbaH)$_2$ and at 217 and 255 nm for (−)-chxn-(3-methylba)$_2$, which can be assigned to π–π* type transitions of the benzene ring. These bands in the spectra of **1**–**6** were detected in 220–230 and 242–270 nm ranges. The band from π–π* transition, which involves molecular orbital of C=N chromophore was detected for (−)-chxn-(5-methylbaH)$_2$ at 325 nm, whereas for (−)-chxn-(3-methylbaH)$_2$ at 321 nm [19–21]. Upon coordination the latter ones, in the spectra of **3**, **4** are shifted towards lower energies (372 nm), whereas for **1**, **2**, **5**, **6** in the range 320–410 nm several coinciding bands were observed.

CD spectra of [Co(−)-chxn-(3-methylba)$_2$] (**1**) and [Co(−)-chxn-(5-methylba)$_2$] (**2**) revealed bands at 578 (+0.33), 485.5 nm (−0.11), 463 nm (+0.10), and 415.5 (−2.89) nm for **1** and at 565.5 nm (+0.47), 412.5 nm (−1.63) for **2**, which derived from d–d transitions from xz, yz or z^2 to x^2-y^2 (Fig. 1). The higher energy CD components at 355.5 nm (−1.33) and 294 nm (+0.2), for **1**, and at 336.5 nm (−0.76) and 289.5 nm (+0.07) for **2** are all assigned to π→π* and ligand to metal charge transfer transitions. Bands from the π–π* transition of the benzene ring are localized at 244 nm (−4.66) and 217.5 nm (+2.01) for **1** and at 251 nm (−2.09) and 219 nm (+1.36) for **2** and the dominating sign of these bands is negative (Fig. 1). The Cotton effects observed as a minimum CD at 251 nm and a maximum CD at 219 nm come out from the exciton coupled π–π* type transitions [14]. The wing shape of the CD components was typical for the exciton-coupled transitions. The two CD constituents of the π→π* transitions in (−)-chxn-(salH)$_2$ system have approximately the same rotational strength and can, therefore, be considered to represent a relatively pure exciton couplet. The above results can be concluded, that in (1*R*,2*R*)-(−)-cyclohexanediamine Schiff base Co(II) chelates, the cyclohexane ring is transfused to the central chelate ring, forming a rigid structure in which the metalated ring is locked stereospecifically in the λ-conformation similar to the observed previously [1,7,14–17].

In CD spectra of **3** and **4** the band from π→π* transition is split into 360.5 nm (**3** +2.42), 361.5 nm (**4** +2.56) and 399.5 nm (**3** −4.21), and 400 nm (**4** −3.94) components (Fig. 1). The exciton interaction can be related to the molecular geometry of the complex, where two azomethene groups are not planar but produce the tetrahedral distortion. CD bands observed for **3** at 478 nm (+0.50); 595 nm (−0.11) and for **4** at 480 nm (+0.44) can be assigned to d–d transitions from xz, yz, zx to x^2-y^2 [17].

The CD spectrum of [Ni(−)-chxn-(5-methylba)$_2$] exhibited an absorption in the range 400–700 nm with components at 413 nm (−0.99), whereas for [(Ni(−)-chxn-(3-methylba)$_2$] at 415.5 (−0.80) (Fig. 1). These transitions give rise to the CD bands, which most probably are from the non-bonding, the π-antibonding and the weakly σ antibonding 3d-orbitals to strongly σ antibonding 3d-orbitals (x^2-y^2, when O, N, N, O are placed at the x- and y-axes). The π→d transitions obtain an electric transition moment, **P**, which is defined from the atomic arrangement in the mean coordination plane. The magnetic transition moment, **M**, associated with the same transition is mainly from the tetrahedral out of plane distortion as a charge rotation during the transition. To produce a negative rotational strength $\mathbf{R} = \mathbf{P} \times \mathbf{M}$ the distortion has to take the shape shown in Fig. 2, and not its mirror image [7]. The higher energy bands at 348.5 (−0.67) nm in the spectrum of [(Ni(−)-chxn-(3-methylba)$_2$] and 346 nm (−0.89) in [(Ni(−)-chxn-(5-methylba)$_2$] are all considered to be ligand metal charge transfer (LMCT) bands [14]. Observed transitions can be rationalized as a result of the λ-conformation of bridging cyclohexylene carbons. Similar observations were noted for [Ni(−)chxn-(sal)$_2$] and [Ni(−)-chxn-(hacphen)$_2$] [7,14], where the slight distortion from planarity was detected both in the solid state (X-ray structures) and solution.

3.2. NMR studies of diamagnetic Ni(II) and paramagnetic Co(II) complexes

The ^{1}H NMR spectra of [Ni(−)-chxn-(3-methylba)$_2$] and [(Ni(−)-chxn-(5-methylba)$_2$] revealed signals from methyl group at C-3′ and C-5′ at 2.20 ppm (singlet), phenyl hydrogens in the region from 6.8 to 7.1 ppm, a singlet centered at 3.09 ppm from methine hydrogens in cyclohexyl ring and 7.25 ppm from C-4 hydrogen (Fig. 3). The largest coordination shift $\Delta = \delta_{comp} - \delta_{lig}$ (0.9 ppm) was observed for azomethine hydrogen, which is

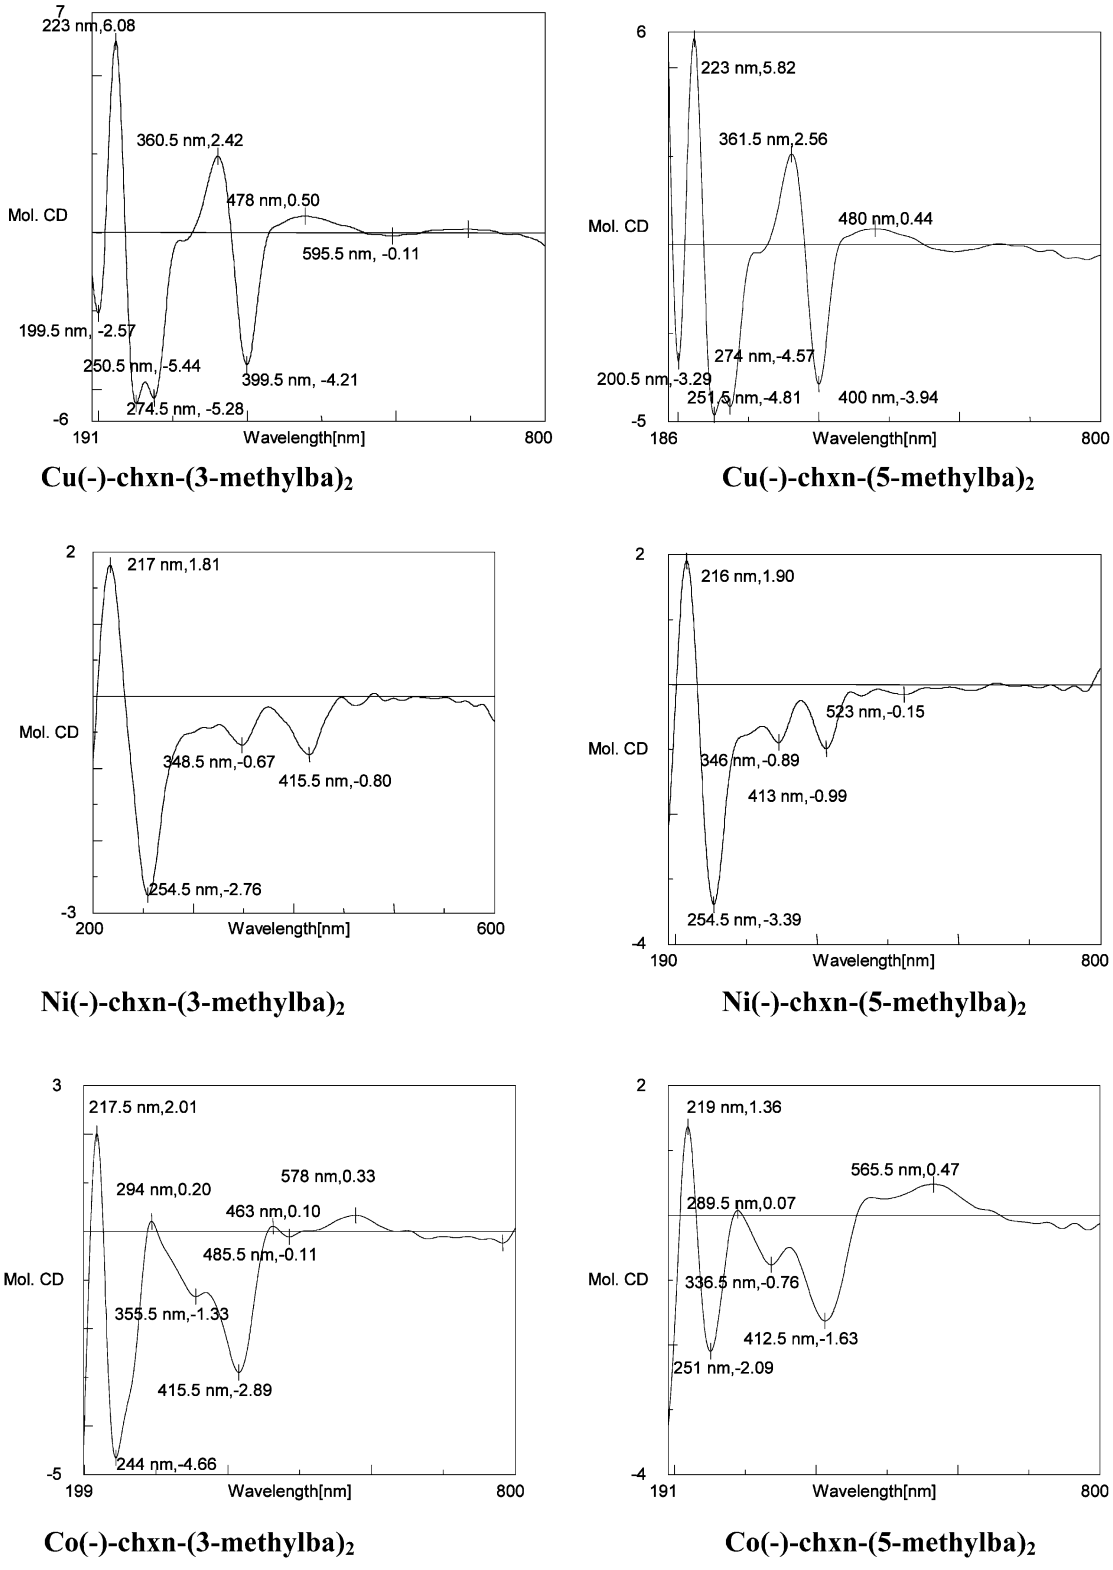

Fig. 1. CD spectra of the complexes.

close to coordination center. In the latter complex the interactions via space between methyl and C-4 hydrogens were indicative and the same distortion can be postulated for the complexes studied for imine and methine hydrogens [14]. Due to the lack of the X-ray structure we cannot suggest the umbrella form but rather tetrahedral distortion as it was found in X-ray structure of [Ni(−)-chxn-(salal)$_2$] [14]. Unfortunately

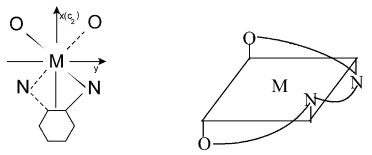

Fig. 2. A schematic structure of [M(−)-chxn-(3-methylba)$_2$] and [M(−)-chxn-(5-methylba)$_2$] complexes and tetrahedral distortion of coordination plane.

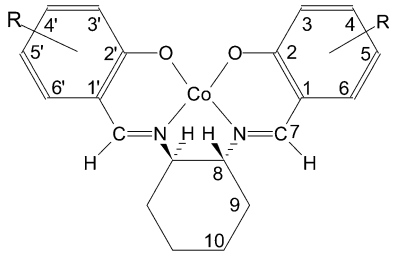

Fig. 3. Ni(II), Cu(II) and Co(II) complexes with Schiff bases derived from (1*R*,2*R*)-(−)-1,2-cyclohexylenediamine and 2-hydroxy-3-methylbenzaldehyde or 2-hydroxy-5-methylbenzaldehyde.

due to the poor solubility of complexes we were unable to obtain ^{13}C NMR spectra where these effects could be observed.

^{1}H NMR spectroscopy has not been applied extensively to Co(II) coordination complexes because of their paramagnetism, which complicates spectra acquisition and interpretation. Chemical shift assignments were made for ligand hydrogens detected outside what is typically considered as the diamagnetic region (0–14 ppm), through systematic substitution of the aromatic hydrogens [C(3′) and C(5′) phenyl ring] in **1** and **2**. It has been shown that the ligand geometry markedly affected the chemical shift pattern of hydrogens. The ^{1}H NMR paramagnetic spectra of [Co(−)-chxn-(5-methylba)$_2$] and [Co(−)-chxn-(3-methylba)$_2$] (Fig. 4), were measured in the range from +250 to −250 ppm. The most upfield shifted resonance at −60 ppm, which is extremely broad and weak, can be assigned to the hydrogen in –CH=N– group. This signal was registered after more than 1000 scans, that is the fivefold longer acquisition time as compared with the remainder of the spectrum. Similarly large upfield shift ($\sim$400 ppm) was observed for azomethine proton for Mn(III) complexes [22,23]. On the other hand for [Co(−)-chxn-(salen)$_2$] complexes this signal was registered in the 'diamagnetic' part of the spectrum. In order to show that CH=N gives rise to the most upfield resonance, selectively deuterated compounds should be used in NMR experiments. The broad signal detected at −28 ppm for [Co(−)-chxn-(3-methylba)$_2$] can be assigned to the hydrogen atom in position 5′ of phenyl ring, because for the [Co(−)-chxn-(5-methylba)$_2$], in which hydrogen atom is replaced by –CH$_3$ group and there is no other signal between −50 and 0 ppm. In the spectrum of [Co(−)-chxn-(3-methylba)$_2$], a pair of signals was observed at 21.58 and 23.83 ppm, which can be assigned to the cyclohexane methine bridge hydrogens (at CH–CH). These resonances are from the hydrogens, which are in the closest proximity to the paramagnetic center. For [Co(−)-chxn-(5-methylba)$_2$] the same hydrogen atoms give rise to signals at 20.94 and 24.7 ppm. The resonances of these hydrogens most probably are affected by the distortion in the N_2O_2 coordination plane that results in their magnetic unequivalency and detected different chemical shifts and relaxation times. The assignment of all signals, which appeared in the paramagnetic part of the spectrum, is impossible due to the lack of the subsequently substituted Schiff bases. Presented analysis of the paramagnetic spectra of Co(II) complexes confirms the influence of the steric distortions in the coordination sphere on the chemical shift of hydrogens in the closest distance to Co(II), similar to the observed for [Co(−)-chxn-(sal)$_2$] [24–28]. The paramagnetic and diamagnetic spectra of Co(II) and Ni(II) revealed the most significant changes in the resonances of the CH–CH and CH=N hydrogens which are in the nearest neighborhood to the coordination center and can be moved outside the coordination plane due to the pseudotetrahedral distortion from the planarity.

3.3. Infrared studies

Upon complexation characteristic C=N stretching absorption band in 1620–1640 cm^{-1} range for Schiff bases, is shifted towards lower energies (1601–1634 cm^{-1}). Another absorption band which is sensitive on ligand coordination origins from (Ph)C–O vibrations (1270–1300 cm^{-1} in Schiff base) is also shifted upon coordination towards higher energies (ca. 50 cm^{-1}). Assuming C_{2v} symmetry for the nearest surrounding of the central ion (N_2O_2), one can expect two M–O (A_1+B_1) and two M–N (A_1+B_1) stretching vibrations active in IR [29]. Literature data revealed that M–O vibrations should appear between 270 and 330 cm^{-1}, whereas M–N in 410–450 cm^{-1} range [30–33]. In the spectra of **1** and **2** bands noted at 313 cm^{-1} (B_1) and 279 cm^{-1} (A_1) can be assigned to ν(Co–O), whereas at 422 cm^{-1} (A_1) and 444 cm^{-1} (B_1) to ν(Co–N) stretching vibrations. In the case of **3**–**6** metal–ligand vibrations appeared at the following frequencies: Ni–N: 441 cm^{-1} (B_1), 403 cm^{-1} (A_1), Cu–N: 416 cm^{-1} (A_1), 441 cm^{-1} (B_1), Ni–O: 323 cm^{-1} (B_1), 294 cm^{-1} (A_1) and Cu–O: 316 cm^{-1} (B_1), 275 cm^{-1} (A_1). Hence the IR data are in favor of the chelating mode of Schiff bases and four-coordinated central ions (N_2O_2 chromophore).

4. Conclusions

Spectroscopic results (CD) confirmed the square planar tetrahedrally distorted geometry of the coordina-

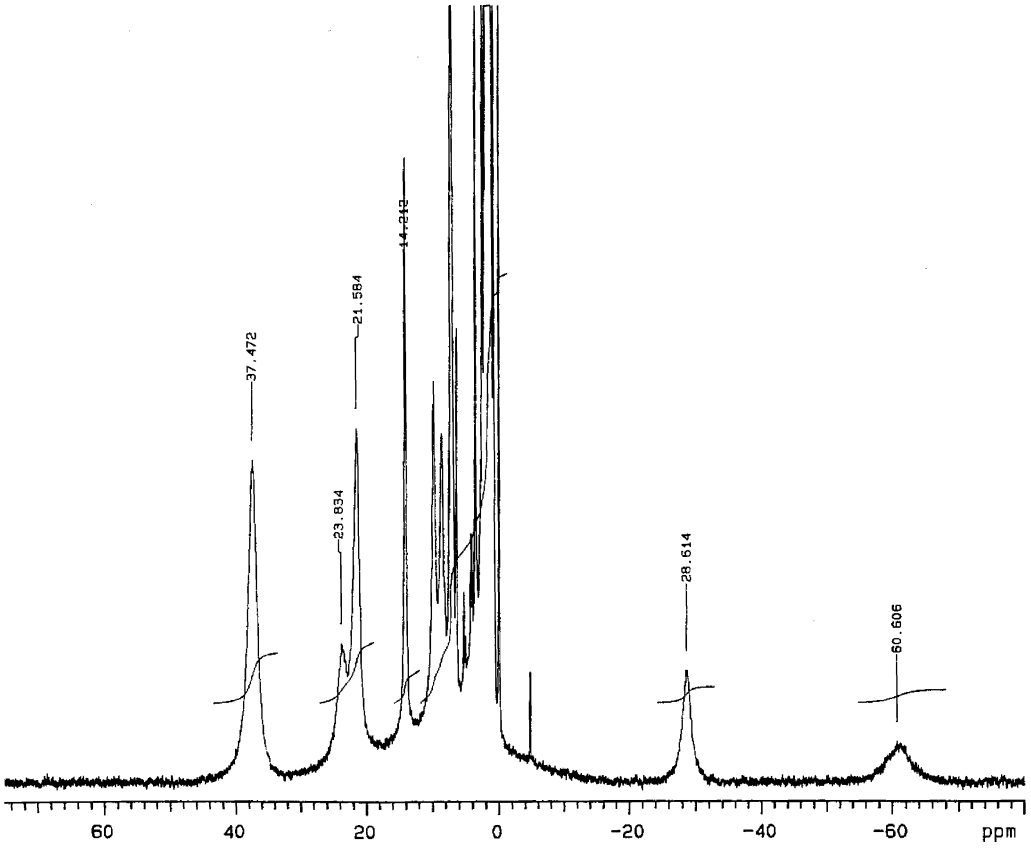

Fig. 4. ^{1}H NMR spectrum of [Co(−)-chxn-(3-methylba)$_2$].

tion center. Distortion has further evidence in Ni(II) diamagnetic and paramagnetic ^{1}H NMR spectra of Co(II) complexes, which revealed significant coordination shifts of the hydrogen atoms in the closest proximity to the coordination center. Hydrogen atoms of the imine carbon are shifted upfields, whereas those from C-1 are split upon coordination that suggests unequivalency of these atoms coming out from the ligand coordination to the metal center.

Cu(II)–Ida ratio, the Cu(II) exhibits either distorted square pyramidal coordination (type 4+1) or an octahedral coordination (type 4+2 or 4+1+1) or, more rarely, a square planar one (type 4). The Ida or Ida-like ligand acts as a tridentate ligand exhibiting a *trans*-conformation (forming two nearly coplanar five-membered chelate rings) or a *cis*-conformation (forming two nearly perpendicular chelate rings):

cis- *trans-*

In the absence of additional ligands, with the exception of water molecules, the structurally characterized Cu(II) complexes with Ida have a polymeric chain structure and a *cis*-conformation [9–11]. On the other hand, in all known Cu(II) complexes with the *N*-aryliminodiacetates a *trans*-conformation has been observed [12–19], most of them having a monomeric structure. Only in the [Cu(*p*-Cl–Phida)] and [Cu(*p*-OH–Phida)H_2O] complexes (*p*-Cl–Phida = *N*-(*p*-chlorophenyl)iminodiacetate, *p*-OH–Phida = *N*-(*p*-hydroxyphenyl)iminodiacetate) does the Ida-group act as a bridge between two metal centers via carboxylate binding [17,18]. In the presence of an *ortho*-substituent, the dihedral angle between the benzene plane and the mean equatorial plane around the Cu atom is nearly perpendicular [12–15], otherwise it is close to 109.5° (sp^3-hybridization of the N atom) [16–19].

There are many structural data about the conformations of glycinate chelate rings. However, information about β-alaninate A-rings is relatively scarce and only a few Cu(II) complexes containing A-rings without peptide bonds are known [20–33]. According to Ilyukhin et al. [34], A-rings can be divided into two groups due to the magnitudes of the dihedral angle O–Cu–N–C(3) (ϕ). In the case of $\phi < 40°$, a plane CuNC(2)C(1) is observed. If ϕ is higher than 40°, the base plane is OCuC(3)C(2):

In the present work, the Cu(II) complex of *p*-Tdp was synthesized and characterized by XRD, IR and UV–Vis spectroscopy with the purpose of studying the selectivity of arylamino-di-3-propionates towards copper(II) ions. It seems to be the first structurally characterized complex with an Idp-like ligand.

2. Experimental

2.1. Preparation of the complex $[Cu(p\text{-}Tdp)(H_2O)_2]\cdot 2H_2O$

H_2(*p*-Tdp) was prepared as follows: 17 ml (0.25 mol) of acrylic acid (Aldrich 14,723-0) was added to a solution of 10.7 g (0.10 mol) *p*-toluidine (Fluka 89632) in 40 ml of 1,2-dichloroethane. The mixture was heated at boiling temperature for 7 h. After 2 h H_2(*p*-Tdp) precipitated as a polycrystalline powder. Then H_2(*p*-Tdp) was filtered, washed and recrystallized three times from 1,2-dichloroethane. Yield after recrystallization was 14.5 g (57.7 %). The purity of the acid H_2(*p*-Tdp) ($\geq$99.5%) was checked by pH-titration with a standard carbonate-free solution of KOH. *Anal*. Calc. for $C_{13}H_{17}NO_4$: C, 62.14; H, 6.82; N, 5.57. Found: C, 62.27; H, 6.79; N, 5.57%. ^{1}H NMR (δ, ppm): 2.17 (s; 3H; $-CH_3$), 2.42 (t; 4H; $-CH_2-COOH$; $J = 7.2$ Hz), 3.51 (t; 4H; $=N-CH_2-$; $J = 7.2$ Hz), 6.60 (d; 2H; H_{Ph} 3.5; $J = 8.4$ Hz), 6.99 (d; 2H; H_{Ph} 2.6; $J = 8.4$ Hz), 12.22 (sbr; 2H; –COOH).

The Cu(II) complex of *N*,*N*-di(2-carboxyethyl)-*p*-toluidine was prepared by mixing a hot saturated aq. solution of H_2(*p*-Tdp) with $(CuOH)_2CO_3$ until CO_2 is removed. After filtration, crystals suitable for X-ray crystallography were obtained by slow evaporation at room temperature (r.t.) over a few days. *Anal*. Calc. for $C_{13}H_{23}CuNO_8$: C, 40.57; H, 6.02; N, 3.64; Cu, 16.51. Found: C, 40.47; H, 6.25; N, 3.68; Cu, 16.49%.

2.2. X-ray structure analysis

The experimental data for a deep-blue crystal with dimensions 0.76 × 0.70 × 0.34 mm was measured using a CAD4 diffractometer (λ (Mo Kα) = 0.71073 Å, graphite monochromator, $T = 293(2)$ K).

Crystal data: $C_{13}H_{23}CuNO_8$ (FW 384.86), triclinic, space group $P\bar{1}$, $a = 11.522(1)$, $b = 12.563(2)$, $c = 19.304(2)$ Å, $\alpha = 95.982(9)°$, $\beta = 106.789(7)°$, $\gamma = 99.526(8)°$, $V = 2603.9(5)$ Å^3, $Z = 6$, $D_{calc} = 1.473$ g cm^{-3}, $\mu = 1.296$ mm^{-1}.

The $\theta/2\theta$ scan technique was employed to measure the intensities for 6133 reflections in the range $1.85° < \theta < 22.50°$. The structure was solved by direct methods and refined by the full-matrix least-squares method in an anisotropic approximation for all non-hydrogen atoms and isotropically for H atoms with positions located on a difference electron density map. The final *R* indices are $R_1 = 0.0431$ and $wR_2 = 0.1127$ for 5724 non-zero unique I_{hkl} (899 parameters) with ($I > 2\sigma$); goodness-of-fit = 0.992. All calculations were performed with the SHELX-97 program package.

2.3. Spectral measurements

IR spectra were recorded in the 4000–400 cm^{-1} range on a Specord 75IR spectrophotometer (Carl Zeiss, Germany) as KBr pellets. Electronic absorption spectra were recorded on a SF-46 spectrophotometer (LOMO, Russia) at r.t. An electronic reflectance spectrum was run on a Shimadzu UV-3101PC spectrophotometer. The ^1H NMR spectrum was realized on an Avance 400 spectrometer from Brucker in DMSO-d_6 at a frequency of 400 MHz, the internal standard was TMS.

2.4. pH measurements

Potentiometric titrations were carried out with a PC-controlled system assembled with a Crison MicropH 2002 pH meter, a Crison MicroBU 2030 micro burette, an Orion 90-02-00 (double junction AgCl/Ag) reference electrode and a Russel SWL/S7 glass electrode. The titrations were conducted under an atmosphere of CO_2 and O_2-free nitrogen at 25.0(1) °C in a Metrohm EA880T double wall glass cell with a Metrohm E649 stirrer. The control program was written in QuickBasic (Microsoft Corporation, version 7.0) to control the titration system, via an RS232C interface. The glass electrode was calibrated in terms of hydrogen ion concentration with buffers: 0.01 M borax, phosphate (0.025 M KH_2PO_4 and 0.025 M Na_2HPO_4) and 0.05 M potassium hydrogen phthalate with ionic strength adjusted to 0.1 M with potassium nitrate in a procedure recommended by Vasconcelos and Machado [35].

A *p*-Tdp concentration range of 1–10 mM was studied, varying the concentration of Cu(II) ($Cu(NO_3)_2$ 0.1000 M Orion standard solution no. 942906) in the ligand–metal ratios 1:1, 1:2, 2:1. CO_2-free KOH 0.1 M was used as a titrant. All acid–base and metal–ligand complexation parameters were calculated and refined with the SUPERQUAD program [36].

3. Results and discussion

3.1. Crystal structure

The crystal structure of [Cu(*p*-Tdp)(H_2O)$_2$]·2H_2O consists of neutral [Cu(*p*-Tdp)(H_2O)$_2$] complexes and water molecules. Three crystallographically independent [Cu(*p*-Tdp)(H_2O)$_2$] complex molecules have a similar structure. A generalized numbering system is shown in Fig. 1, while selected bond lengths and angles are given in Table 1.

The coordination polyhedron of each Cu atom is a square pyramid (type 4+1) with a slight trigonal bipyramidal distortion, and is formed by the donor atoms of the tridentate *p*-Tdp ligand, the O atom of the water molecule in the base plane and by another water molecule in the apex of the pyramid. The percentage of trigonal distortion from the idealized square pyramidal coordination, $\tau = 100(\beta - \alpha)/60$ (where β is the largest *trans* angle and α is the second one [37]), is 12.92%, 13.28% and 0.9% for each of three crystallographically independent molecules. The Cu–O2 apical bonds (2.216–2.297 Å) are longer than the bond lengths in the plane, but significantly shorter than usually obtained for square pyramidal Cu(II) complexes. The *ortho*-H atom in benzene ring blocks up the sixth coordination position in the Cu polyhedron (Cu–H distances are 2.54–2.57 Å). The basal planes are tetrahedrally dis-

N–Cu–O2	102.49(4)	105.05(5)	104.52(4)

torted (0.105, 0.120 and 0.034 Å). The Cu atoms are located out of the mean planes of the four basal atoms (0.20–0.30 Å) toward the O2 atoms.

The tridentate function of the *p*-Tdp ligand is realized by the formation of two β-alaninate rings (A1 and A2, Fig. 1), which are located practically in one plane, dihedral angles between A1/A2 mean planes are 9.87°, 6.13° and 6.82°. Thus, the ligand in the complex has a *trans*-conformation in contrast with the *cis*-conformation of Ida [9–11]. The benzene ring is arranged almost perpendicularly to the base plane of the copper pyramid (82.2°–87.1°), opposite to Cu(II) complexes with *meta*- or/and *para*-substituted *N*-phenyliminodiacetates [16–19], in which the equatorial plane of the coordinating polyhedron is placed with an angle of about 109.5°.

The crystal structure of $[Cu(p\text{-Tdp})(H_2O)_2]\cdot 2H_2O$ exhibits six non-equivalent A-rings. Puckering parameters of the A-rings are given in Table 2. The dihedral angle ϕ varies in a wide range from 28.3° to 45.8° that gives the possibility of tracking the chelate ring conformation changes as a function of ϕ magnitude. In four A-rings with $\phi < 40°$, a plane defined by CuNC(2)C(1) is observed, the plane in the two others being OCuC(3)C(2). The lowest $\phi = 28.3°$ is observed in the A1(**1**)-ring, in which the conformation of a strongly plane boat B_{25} at the oxygen atom is implemented. The oxygen atom is deviated only 0.076 Å from the average plane defined by CuNC(2)C(1). Therefore, the most approximate conformation may be considered as the sofa S_5 (half-boat, envelope). With the following increase of ϕ, A1(**3**)-ring would have an intermediate form between the sofa S_5 and the half-chair H_{56}, then A1(**2**), A2(**2**), A2(**3**)-rings ($\phi = 36.8°$–$42.7°$) adopt a shape close to the half-chair H_{56}, and finally A2(**1**)-ring ($\phi = 45.8°$) has the intermediate form between the half-chair H_{56} and the sofa S_6. The reason for such a large deviation of ϕ resides in the significant dependence of the coordinated oxygen atom O_c position in the crystal packing.

For evaluation of the ring stress level capacity, the deviation of the sum of the internal angles from the 'ideal' value $648 = 120 + (109.5 \times 4) + 90$ was applied [38]. One can see from Table 5 that all A-rings present a positive deviation and have a stress resulting in the flattering (decreasing of goffering). The greatest deviation was observed for Cu–O–C (+21.2°–24.5°) and O–C–C (+7.6°–11.2°) angles.

The bond lengths and angles in the coordination polyhedra (Table 1) are comparable with the corresponding values of Cu(II) complexes containing A-rings [20–33]. In all A-rings internal angles N–Cu–O are higher than 90° in contrast with glycinate rings [9–19]. The sum of internal angles is higher than the ideal magnitude of 20°–40°. The distinction in the C–N bond lengths towards the benzene ring (1.465–1.474 Å) and side branches (1.497–1.512 Å) is induced by a negative mesomeric effect of the benzene ring.

Complex molecules and non-coordinated water molecules are joined in a three-dimensional framework by H-bonds with O···O distances ranging from 2.692 to 2.913 Å.

3.2. IR spectra

The IR spectrum shows a zwitterionic structure of $H_2(p\text{-Tdp})$ that is confirmed by the existence of a N^+–H band and carboxylate group bands. The 'ammonium' stretching band $\nu(N^+–H) = 2700–2400\ cm^{-1}$ has a characteristic position for the $R_3N^+–H$ group [39] and it is observed as a group of weak bands. The existence of $\nu(C{=}O) = 1705$ and $\delta(O–H) = 1290\ cm^{-1}$ bands that are specific for a carboxyl group as well as carboxylate bands $\nu_s(COO^-) = 1385$ and $\nu_{as}(COO^-) = 1605\ cm^{-1}$ points out for the zwitterionic structure of $H_2(p\text{-Tdp})$.

The IR spectrum of $[Cu(p\text{-Tdp})(H_2O)_2]\cdot 2H_2O$ differs significantly from the $H_2(p\text{-Tdp})$ spectrum. The absence of absorption bands corresponding to the carboxyl group $\nu(C{=}O)$ and $\delta(OH)$ and to the ammonium group

Table 2
Sum of internal angles, dihedral angles ϕ and Cremer–Pople parameters of β-alaninate chelate rings in $[Cu(p\text{-Tdp})(H_2O)_2]\cdot 2H_2O$

Ring	Sum of internal angles (°)	ϕ (°)	Cremer–Pople parameters [a]			Conformation [b]
			Q (Å)	θ (°)	φ (°)	
A1(**1**)	682.7	28.31(7)	0.560	57.4	244.6	S_5
A1(**2**)	684.5	36.78(9)	0.555	54.3	262.9	H_{56}
A1(**3**)	686.2	33.80(8)	0.533	53.1	257.2	S_5/H_{56}
A2(**1**)	684.0	45.79(8)	0.569	46.6	281.0	H_{56}/S_6
A2(**2**)	683.7	38.46(9)	0.572	56.0	268.5	H_{56}
A2(**3**)	682.5	42.8(1)	0.564	46.9	273.6	H_{56}

[a] Ref. [34].

[b] According to Ref. [35]. *B*, boat; *S*, sofa; *H*, half-chair. The subscripts show the numbers of atoms responsible for conformation: in *B*, they are atoms in the *trans* position deviating in the same direction; in *H* adjacent atoms deviating in opposite directions. The numeration order is Cu–O–C–C–C–N.

$\nu(N^+–H)$ must be mentioned. These variations were caused by the participation of the carboxylate and amino groups in the coordination with the Cu(II) cation. In the range of stretching bands ν(O–H) of water molecules 3390 and 3250 cm^{-1} bands were registered that corresponds to the non-coordinated and coordinated water molecules, respectively. For crystal water molecules, the absorption band δ(O–H) at 1630–1600 cm^{-1} is equally typical [40], however it is overlapped with a $\nu_{as}(COO^-)$ band giving a multiplet in the range 1595–1555 cm^{-1}. Absorption band $\nu_s(COO^-)$ is located at 1380 cm^{-1} (Fig. 2).

3.3. Electronic spectra

The electronic absorption spectra of aqueous solutions of *p*-Tdp versus pH value confirmed the assumption about the existence of two groups that absorb light species: one group contains all the protonated forms having a betaine-like structure {H_3(*p*-Tdp)$^+$, H_2(*p*-Tdp) and H(*p*-Tdp)$^-$—Fig. 3, curve *1*}, whereas the other contains only the deprotonated form {(*p*-Tdp)$^{2-}$, Fig. 3, curve *2*}. The corresponding numeric data for these spectra are summarized in Table 3. The absorption bands were assigned by comparing the spectra of benzene, aniline, and the anilinium cation [41].

The electronic absorption spectra of aqueous solutions of the Cu(*p*-Tdp) complex in the pH range 1–8 have been studied. In more alkaline solutions, precipitation is observed. The spectrum of the complex at the optimal pH range is displayed in Fig. 3 (curves *3* and *4*).

In the visible spectrum, one wide asymmetric absorption band (Fig. 3, curve *4*) is observed. This band is interpreted as an envelope of the three bands caused by electron transitions $E_1(z^2 \rightarrow x^2-y^2)$, $E_2(xy \rightarrow x^2-y^2)$, $E_3(xz, yz \rightarrow x^2-y^2)$ [42]. The complex compound formation is developed in hypsochromic shift ($\lambda = 740$ nm)

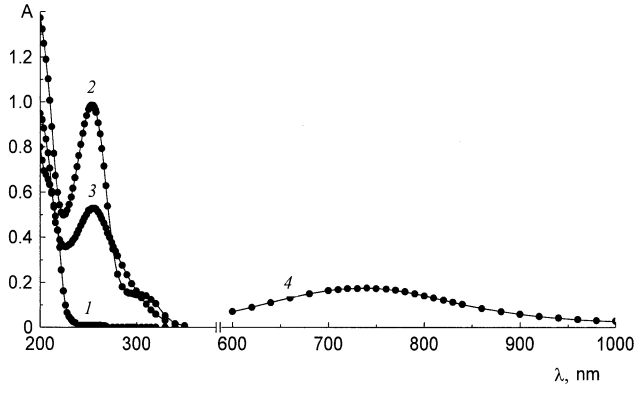

Fig. 2. Electronic absorption spectra of the aqueous solutions of *p*-Tdp and Cu(*p*-Tdp): (1) pH 1.88, $c(p\text{-Tdp}) = 1.10 \times 10^{-4}$ mol l^{-1} (protonated form); (2) pH 9.50, $c(p\text{-Tdp}) = 1.10 \times 10^{-4}$ mol l^{-1} (deprotonated form); (3) pH 7.0, $c(p\text{-Tdp}) = c(CuSO_4) = 1.10 \times 10^{-4}$ mol l^{-1}; (4) pH 7.0, $c(p\text{-Tdp}) = c(CuSO_4) = 2.00 \times 10^{-3}$ mol l^{-1}.

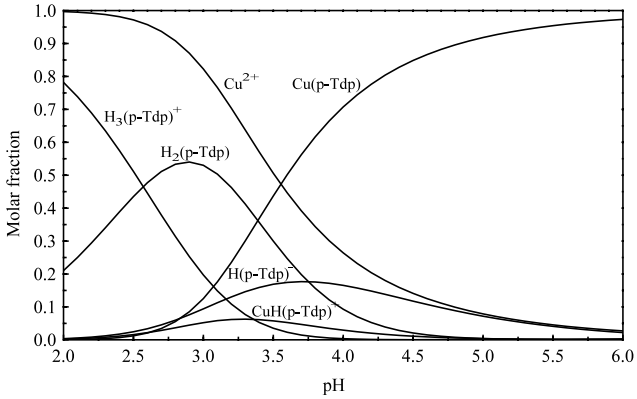

Fig. 3. Species distribution diagram as a function of pH for the Cu(II)–(*p*-Tdp) system, $c(Cu^{2+}) = c(p\text{-Tdp}) = 5.0 \times 10^{-3}$ mol l^{-1} ($I = 0.1$ M KNO_3, 25 °C).

Table 3
Electronic spectra of aqueous solutions of *N*,*N*-di(2-carboxyethyl)-*p*-toluidine

Band	ν (cm^{-1})	ε (l mol^{-1} cm^{-1})	$\nu_{1/2}$ (cm^{-1})
H_3(p-Tdp)$^+$, H_2(p-Tdp), H(p-Tdp)$^-$			
$^1B_{1u}$	> 50 000	–	–
$^1B_{2u}$	39 280(80)	220(5)	1650(90)
(p-Tdp)$^{2-}$			
$^1B_{1u}$	39 570(60)	9160(90)	230(80)
$^1B_{2u}$	32 540(230)	1300(150)	1530(280)

and hyperchromy ($\varepsilon = 98$ l mol^{-1} cm^{-1}) of the absorption band in comparison with the spectrum of the hexaaquacation $[Cu(H_2O)_6]^{2+}$.

Studies applying the method of continuous variation (Job's method) showed that the maximum deviation from absorbance additivity is observed at the 1:1 molar ratio. Similar results were obtained by a molar-ratio method for the variable concentration of one of the components.

The similarity of the reflectance spectra of the crystal $[Cu(p\text{-Tdp})(H_2O)_2]\cdot 2H_2O$ ($\lambda = 262$, 735 nm) and those taken from the solution shows that the complex has the same square pyramidal geometry in both states.

3.4. Protonation and stability constants

The protonation constants of *p*-Tdp and stability constants of its Cu(II) complex were determined in our previous work [2,6] at room temperature 20(1) °C and $I = 0.1$ M KCl with calibration of a glass electrode in terms of proton activity. Therefore, the mixed constants were obtained. In this work, these constants were determined using more accurate procedures and both types of glass electrode calibration (Table 4).

The mixed protonation constants of *p*-Tdp are in good agreement (Table 4) in spite of the different

Table 4
Protonation constants of *p*-Tdp and stability constants of its Cu(II) complexes

Log *K*					*I* (M)	*T* (°C)	Type of constants [a]	Reference
$H(p\text{-Tdp})^-$	$H_2(p\text{-Tdp})$	$H_3(p\text{-Tdp})^+$	$CuH(p\text{-Tdp})^+$	$Cu(p\text{-Tdp})$				
6.96(6)	3.93(6)	2.99(5)	–	6.75(7)	0.1 KCl	20(1)	*m*	[2,6]
6.96(2)	3.87(2)	2.90(2)	2.20(5)	6.36(3)	0.1 KNO_3	25.0(1)	*m*	this work
6.87(2)	3.75(2)	2.57(2)	2.13(5)	6.38(3)	0.1 KNO_3	25.0(1)	*c*	this work

[a] *m*, mixed; or *c*, concentration constants.

temperature and media used. Hence, the difference between mixed and concentration protonation constants mainly depends on the type of calibration.

The model of complex formation that best fits the experimental results consists as $CuH(p\text{-Tdp})^+$ and $Cu(p\text{-Tdp})$ complexes. The stability constants slightly depend on the type of glass electrode calibration but are sparingly compared, as they were determined in different conditions (Table 4). The species distribution diagram (Fig. 3) was calculated taking into account the values of the protonation constants of the ligand and stability constants of the complexes. The diagram indicates that the protonated complex $CuH(p\text{-Tdp})$ has an important contribution in the pH range 2.5–4.5.

4. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 143764. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

[a] Nomenclature S(i), $i = 1, 2, 3, 4$, is chosen with the Zn–S bond length increasing.
[b] C(1) and C(2) are the C–N carbon atoms in the pyridine molecule which lies between S(1) and S(3), and between S(2) and S(4) atoms, respectively, when projected parallel to the Zn–N bond.
[c] Measured from data on compound 103200 deposited at the Cambridge Crystallographic Data Center.
[d] This work.

tate of **1** was collected, filtered off, washed with water, dried in vacuo over phosphorus pentoxide and recrystallized two times from toluene. The adduct, $[Zn(Py)(S_2CNEt_2)_2]$ (**2**) (see Fig. 1), was prepared by dissolving equimolar quantities of pyridine and the initial zinc(II) complex in a minute volume of toluene and isolated by means of slow evaporation of the solvent. In contrast, O'Brien et al. have prepared $[Zn(Py)(S_2CNEt_2)_2]$, by the reaction of 2,4,6-$C_6H_2Me_3SZnS_2CNEt_2$ with an excess of pyridine. The mixture was heated to obtain a clear solution, concentrated under vacuum, and left in the fridge to crystallize [2]. Recently, we also reported the formation of the solvated form of the discussed adduct with the outer-sphere Py molecule, $[Zn(Py)(S_2CNEt_2)_2]\cdot Py$ (compound **3** in Fig. 1), from the initial complex **1**, which is either recrystallized from pure pyridine or if Py is absorbed by **1** in the molar ratio 2:1, respectively [5]. Clathrated adduct, $[Zn(Py)(S_2CNEt_2)_2]\cdot Py$ (**3**), crystallizes in the same monoclinic space group, $P2_1$ [5], as $[Zn(Py)(S_2CNEt_2)_2]$ reported by O'Brien et al. One pyridine molecule of **3** has a covalent bond, N–Zn, in adduct molecules while the other pyridine molecule is the outer-sphere one and only held by van der Waals forces

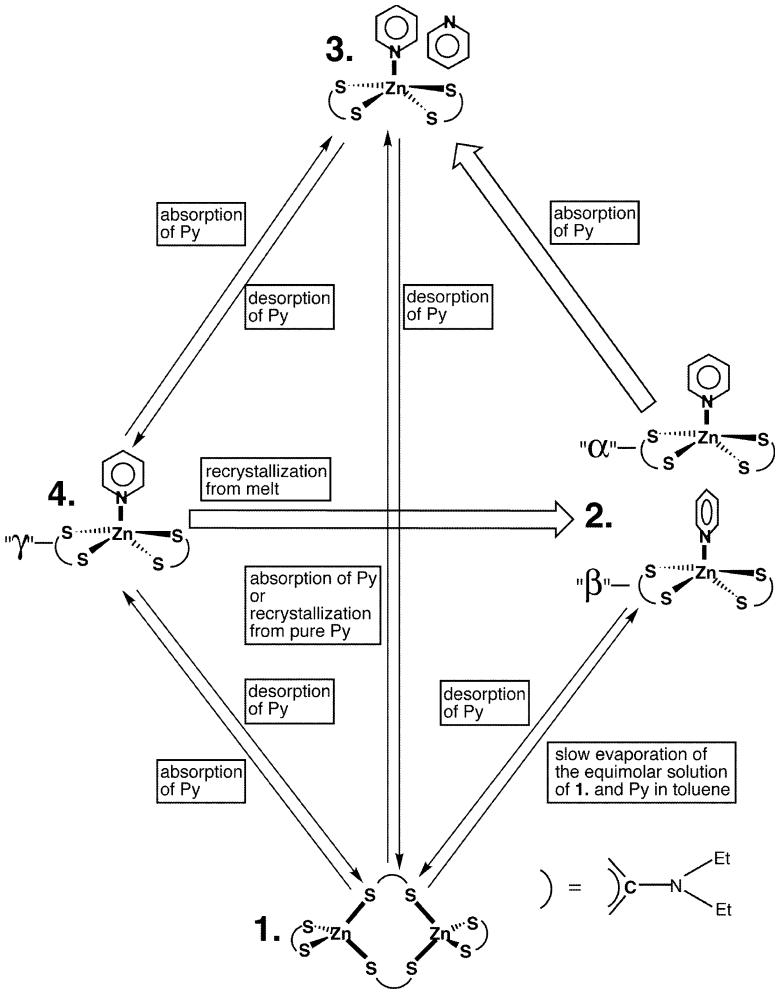

Fig. 1. Chemical pathways for bis(diethyldithiocarbamato)zinc(II), **1**; its adduct with pyridine, $[Zn_2(Py)(S_2CNEt_2)_2]$ (**2**), (α- and β- are two isomorphs of **2**); the solvated form of the adduct with guest molecules of pyridine, $[Zn_2(Py)(S_2CNEt_2)_2]\cdot Py$ (**3**); and the metastable state of the adduct, γ-$[Zn_2(Py)(S_2CNEt_2)_2]$ (**4**).

in the system of channels formed by $[Zn(Py)(S_2CNEt_2)_2]$ molecules [5]. The solvated form **3** is not very stable and slow desorption of guest Py molecules cannot be avoided at room temperature, if crystals of the clathrate are not protected by a thin film of glue during X-ray data collection. The single crystal structure of **3** has been resolved from X-ray measurements at 170(1) K with crystals protected by films of an epoxy glue [5]. On the contrary, O'Brien et al. performed their X-ray measurements at 293(2) K without any particular protection of the crystals [2]. We suggest that $[Zn(Py)(S_2CNEt_2)_2]$ reported by this group is, in fact, a special structural state of the adduct formed from the clathrate **3**, which has lost either a large part of or all of its guest pyridine molecules. The symmetry of the single crystal, and most of the unit cell dimensions of **3**, are retained after desorption of guest Py molecules (see Table 1). Here we abbreviate this state of the adduct as γ-$[Zn(Py)(S_2CNEt_2)_2]$ (**4**) (see Fig. 1).

In order to check this hypothesis, we used natural abundance solid-state ^{15}N cross-polarization/magic-angle-spinning NMR spectroscopy with high-power ^{1}H-decoupling [6]. Recently, we pointed out that the ^{15}N chemical shifts of nitrogen sites have extremely high sensitivity to structural variations in polycrystalline thioorgano-metallic compounds, such as dithiocarbamate complexes of Ni and Zn [7], dithiocarbamatezinc adducts with nitrogen bases, [1,8–11] and solvated forms of these adducts with pyridine [5], morpholine [9–12], benzene [8–11,13], and various chlorcarbohydrates [14–17].

Owing to the low natural abundance of the ^{15}N isotope (0.365%) and a low resonance frequency of 36.48 MHz at the magnetic field of 8.46 T (Chemagnetics CMX-360 NMR spectrometer), large quantities of samples were needed for obtaining a reasonable signal-to-noise ratio during 24–72 h of total accumulation time with a pulse delay of 2 s. Polycrystalline samples of approximately 300–400 mg were packed in 7.5 mm Chemagnetics ZnO_2 rotors and spun at either 6 or 5.5 kHz. Generally, from 15 000 to 75 000 signal acquisitions were sufficient to obtain signal intensities with

signal-to-noise ratio (S/N) > 5 for all resonances. The cross-polarization contact time was varied from 1.2 to 3.5 ms for different samples in order to achieve a maximum cross-polarization efficiency for the weakest resonance line in the spectrum (usually nitrogen sites of pyridine molecules). The proton π/2 pulse duration was either 3.2 or 5 μs. The dipole-dipole $^{1}H-^{15}N$ interactions, which broaden resonance lines in the solid state, were suppressed by high power ^{1}H-continuous-wave-decoupling at the proton resonance frequency with a nutation frequency of the rf-field from 48.8 to 85 kHz for different samples. The isotropic ^{15}N chemical shifts (ppm) were referenced to external crystalline NH_4Cl (0 ppm; −341 ppm on the absolute scale [18,19]). No special B_0-field stabilization was used, since the magnetic-field drift for the ^{15}N nuclei was only 0.016 Hz h^{-1}.

Fig. 2 shows ^{15}N CP/MAS NMR spectra of the polycrystalline zinc(II) diethyldithiocarbamate complex, its adducts and the clathrated form with pyridine. Fig. 2(a) represents the spectrum of the initial polycrystalline

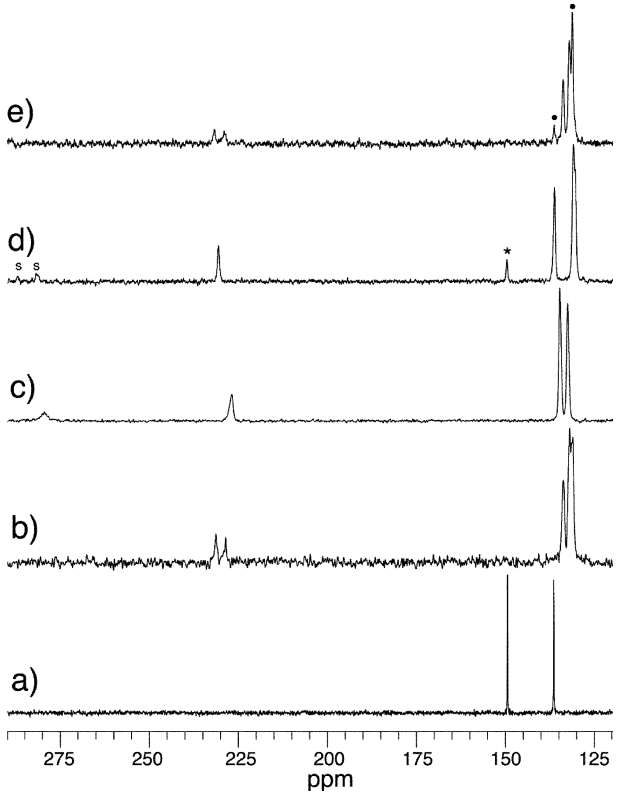

Fig. 2. ^{15}N CP/MAS NMR (36.46 MHz) spectra of powder samples of **1** (a), **2** (b), **3** (c), **3** after a partial desorption of pyridine (d) and following recrystallization from the melt (e). The MAS frequency was 6.0 kHz in (a), (b), (c) and (e) or 5.5 kHz in (d). The number of transients and cross-polarization times were, respectively: (3740, 1.25 ms) (a); (17 600, 3.5 ms) (b); (25 000, 3.5 ms) (c); (77 702, 1.2 ms) (d); and a sum of two spectra with (50 000, 1.2 ms) and (25 000, 2.4 ms) (e). An admixture of the initial complex **1** in (d) and the adduct **4** in (e) are labeled as (*) and (●), respectively. 's' in (d) denotes spinning sidebands.

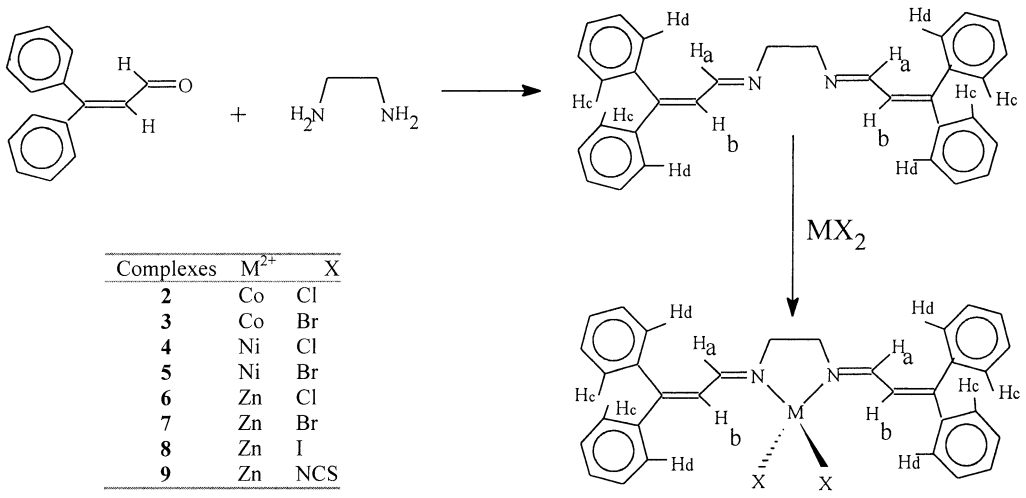
dinuclear diethyldithiocarbamate zinc(II) complex, $[Zn_2(S_2CNEt_2)_4]$. Two resonances have been assigned previously to two pairs of magnetically equivalent nitrogen sites in bridging (149.6 ppm) and terminal (136.6 ppm) diethyldithiocarbamate ligands [7]. The adduct **2**, $[Zn(Py)(S_2CNEt_2)_2]$, recrystallized from toluene has only terminal ligands (131.3, 132.2 and 133.9 ppm) and two distinct resonances of the adduct pyridine molecules (231.7 and 228.9 ppm), which correspond to two different isomers of **2** in the asymmetric unit cell (see Fig. 2(b)) [1]. The latter resonances are weaker than those of nitrogen sites in dithiocarbamate ligands because of differences in both cross-polarization efficiency and in $T_{1\rho}$ relaxation times. After further adsorption of pyridine molecules by **2** (or by recrystallization of **1** from pure pyridine), up to a molar ratio of $Zn(S_2CNEt_2)_2$: Py equal to 1:2, the solvated species of the adduct, $[Zn(Py)(S_2CNEt_2)_2]\cdot Py$ (**3**), is formed. Fig. 2(c) shows the spectrum of **3** with four well resolved nitrogen resonances at 132.7, 134.9 ppm (nitrogen sites in the two terminal diethyldithiocarbamate groups which are structurally slightly different), 227.1 ppm (coordinated pyridine molecules) and at 279.7 ppm (solvating Py molecules held by van der Waals forces in the system of channels formed by adduct molecules) [5]. X-ray diffraction analysis revealed only one adduct molecule in the unit cell that faithfully correlates with the ^{15}N CP/MAS NMR spectrum of **3** (a single resonance for the coordinated Py molecule) [5]. Fig. 2(d) depicts the spectrum of a sample of **3** after partial desorption of Py, which was achieved by gentle heating of the sample. The resonance of solvating pyridine molecules at 279.7 ppm has disappeared, and the resonance line of the other (coordinated by Zn) pyridine molecule is shifted from 227.1 to 230.8 ppm. The latter is close to the mean value of chemical shifts of nitrogen sites in Py of the two isomers of the adduct **2** (compare with Fig. 2(b) and Table 1). Furthermore, the chemical shifts of nitrogen sites in diethyldithiocarbamate groups after the desorption of Py are substantially different from those for both the adduct **2** and the clathrated form **3**. It can be also seen that, in a part of the sample, the desorption of Py proceeded even further to the initial complex **1** (a small peak labeled (*) at 149.6 ppm and a part of the resonance at 136.4 ppm). We suggest that the spectrum shown in Fig. 2(d) corresponds to the adduct **4**, γ-$[Zn(Py)(S_2CNEt_2)_2]$, with the X-ray diffraction structure reported earlier by O'Brien and co-workers [2]. The presence of a single nitrogen resonance of adduct Py in this ^{15}N NMR spectrum suggests a single rotation isomer of $[Zn(Py)(S_2CNEt_2)_2]$ in the unit cell [2], with a slightly different structure from the other two, so called α- and β-isomers of this adduct **2** discussed in [1] (see Table 1). It is noteworthy that, an almost identical ^{15}N NMR spectrum (as in Fig. 2(d)) is produced by a sample of **1** after equimolar absorption

of pyridine from the gas phase, suggesting that the same compound **4** is formed (spectrum not shown). That the state of the adduct **4** is a meta-stable one can be proved by a simple recrystallization of **4** from the melt. This procedure gives rise to a more stable state of the adduct, i.e. **2**, with the two isomers discussed above, as can be seen in Fig. 2(e). This spectrum is very similar to that of the adduct **2** (compare with Fig. 2(b)) apart from a small admixture of the residual adduct form **4** (marked with (●)).

These results can be summarized in the diagram shown in Fig. 1. The metastable state of the adduct, **4**, is formed by either absorption of Py by the initial complex **1** or by desorption of guest molecules of pyridine from the solvated form **3**. In contrast, the other state of the adduct, **2**, can be prepared by either slow evaporation of an equimolar solution of **1** and pyridine from toluene or by the recrystallization of **4** from the melt. The latter process, **4**→**2** (as well as **2**→**3**) is not directly reversible, since **4** can be obtained from **2** only through the clathrated form **3** (or through the initial complex **1**). This points to chemical hysteresis in the adduct formation of $[Zn(Py)(S_2CNEt_2)_2]$.



In conclusion, this work illustrates the chemical hysteresis in which the structure of an adduct depends on the pathway of physico-chemical conditions during the preparation of metastable compounds, such as adducts or clathrates of alkyldithiocarbamates of transition metals. We anticipate that similar types of polymorphism of adducts of other thio- and selenocarbamate complexes reported earlier by O'Brien et al. [2] can occur. Therefore, special precautions are needed during the synthesis, preparation and analysis of these compounds.

Acknowledgements

One of the authors (A.V.I.) acknowledges the financial support from Luleå University of Technology. The CMX-360 spectrometer was purchased with a grant from the Swedish Council for Planning and Coordination of Research (FRN). We express our gratitude to Dr. M. Kritikos for loading and recalculating data on **4** from the CCDC and to Dr. D. Baxter for comments on the manuscript.

reactions were purified and dried by conventional methods [18].

2.1. Physical measurements

NMR spectra were obtained on a BRUKER AVANCE DRX500 (500 MHz) spectrometer. Proton chemical shifts δ are reported in part per million (ppm) relative to an internal standard of Me_4Si, and the J values are reported in Hertz. The UV–Vis spectra were recorded on a Perkin–Elmer Lambda 9 spectrophotometer with quartz cells (1 cm path length). Elemental analyses were performed by using Heraeus CHN-O-RAPID elemental analyzer. IR spectra were recorded as KBr pellets on a Shimadzu 435 spectrophotometer.

2.2. Synthesis

2.2.1. *N,N′-bis(β-phenylcinnamaldehyde)-1,2-diiminoethane, Phca$_2$en (**1**)*

To a solution of 2.08 g (10 mmol) β-phenylcinnamaldehyde in 25 ml ethanol, cooled in an ice bath, was added dropwise 300 mg (5 mmol) of ethylenediamine. The mixture was then stirred for an additional 2 h. *N*,*N*′-bis(β-phenylcinnamaldehyde)-1,2-diiminoethane (Phca$_2$en) was obtained as a white microcrystalline precipitate. The precipitate was filtered off, washed with 5 ml cold absolute ethanol. Yield: 3.960 g (90%). *Anal*. Calc. for $C_{32}H_{28}N_2$: C, 87.28; H, 6.36; N, 6.36. Found: C, 87.30; H, 6.35; N, 6.38%. IR (KBr, cm^{-1}): ν_{max} 1614 (s, C=N). ^{1}H NMR: δ 3.68 (s, 4H, –C*H*$_2$–C*H*$_2$–), 6.82 (d, 2H, Ph_2C=C*H*–), 7.31 (m, 20H, Ar*H*), 7.85 (d, 2H, –C*H*=N–). ^{13}C NMR: δ 61.52 (=N^{13}CH$_2^{13}$CH$_2$N=), 126.72, 127.87, 128.15, 128.23, 128.35, 128.72, 130.31, 140.95, 151.73 (Ph^{13}CH–), 163.01 (–^{13}C=N–).

2.2.2. *[Co(Phca$_2$en)Cl$_2$] (**2**)*

To a solution of Phca$_2$en (440 mg, 1 mmol) in 10 ml CH_2Cl_2 was added 130 mg (1 mmol) of anhydrous $CoCl_2$, and stirred at room temperature (r.t.) for 3 h under nitrogen atmosphere. The reaction mixture was filtered off. The volume of the solvent was reduced under vacuum to about 1 ml. The diffusion of diethyl ether vapor into the concentrated solution gave needle like blue crystals suitable for X-ray studies. The crystals were filtered off and washed with a mixture of diethyl ether–dichloromethane (9:1 v/v), and dried in vacuo. Yield: 456 mg (80%). *Anal*. Calc. for $C_{32}H_{28}N_2Cl_2Co$: C, 67.41; H, 4.91; N, 4.91. Found: C, 67.42; H, 4.93; N, 4.90%. IR (KBr, cm^{-1}): ν_{max} 1603 (s, C=N).

2.2.3. *[Co(Phca$_2$en)Br$_2$] (**3**)*

This complex was prepared in a similar manner to **2** using $CoBr_2$ (218 mg, 1 mmol). Deep green crystals were collected by filtration and dried in vacuo. Yield: 514 mg (82%). *Anal.* Calc. for $C_{32}H_{28}N_2Br_2Co$: C, 58.31; H, 4.25; N, 4.25. Found: C, 58.33; H, 4.27; N, 4.26%. IR (KBr, cm^{-1}): ν_{max} 1600 (s, C=N).

2.2.4. *[Ni(Phca$_2$en)Cl$_2$] (**4**)*

To a stirring solution of 129 mg (1 mmol) of anhydrous $NiCl_2$ in 20 ml acetonitrile was added dropwise a solution of 440 mg (1 mmol) Phca$_2$en in 10 ml acetonitrile, and refluxed for 30 min. The solvent was evaporated on a rotatory evaporator at 40 °C under reduced pressure. The solid residue was dissolved in 20 ml acetonitrile and filtered off. The filtrate was left overnight under diffusion of diethyl ether to give pink–red crystals. Yield: 415 mg (73%). *Anal.* Calc. for $C_{32}H_{28}N_2Cl_2Ni$: C, 67.43; H, 4.91; N, 4.91. Found: C, 67.49; H, 4.90; N, 4.95%. IR (KBr, cm^{-1}): ν_{max} 1603 (s, C=N).

2.2.5. [Ni(Phca$_2$en)Br$_2$] (5)

This complex was prepared in a similar manner to **4** using $NiBr_2$ (218 mg, 1 mmol). Deep pink crystals were collected by filtration and dried in vacuo. Yield: 501 mg (76%). *Anal*. Calc. for $C_{32}H_{28}N_2Br_2Ni$: C, 58.34; H, 4.25; N, 4.25. Found: C, 58.37; H, 4.27; N, 4.26%. IR (KBr, cm^{-1}): ν_{max} 1604(s, C=N).

2.2.6. [Zn(Phca$_2$en)Cl$_2$] (6)

To a solution of 136 mg (1 mmol) $ZnCl_2$ in 10 ml methanol was added a solution of 440 mg (1 mmol) Phca$_2$en in 5 ml methanol and stirred at r.t. for 3 h. The product precipitated as a white microcrystalline powder and collected by filtration. The crude product was recrystallized from acetone to give white needle-shape crystals. The crystals were collected by filtration and dried in vacou. Yield: 529 mg (92%). *Anal*. Calc. for $C_{32}H_{28}N_2Cl_2Zn$: C, 66.65; H, 4.85; N, 4.85. Found: C, 66.68; H, 4.86; N, 4.86%. IR (KBr, cm^{-1}): ν_{max} 1616(s, C=N). ^{1}H NMR: δ 3.72 (s, 4H, $-CH_2-CH_2-$), 7.35 (m, 22H, $Ph_2C{=}CH-$, Ar*H*), 8.0 (d, 2H, $J_{HH} = 9.78$ Hz, $-CH{=}N-$). ^{13}C NMR: δ 58.72 ($=N^{13}CH_2^{13}CH_2N=$), 124.45, 129.75, 129.86, 130.14, 130.47, 131.52, 131.72, 138.39,140.45, 161.48 ($Ph^{13}CH-$), 168.91 ($-^{13}C{=}N-$).

2.2.7. [Zn(Phca$_2$en)Br$_2$] (7)

This complex was prepared in a similar manner to **6** using $ZnBr_2$ (225 mg, 1 mmol). Yield: 578 mg (87%). *Anal.* Calc. for $C_{32}H_{28}N_2Br_2Zn$: C, 57.75; H, 4.21; N, 4.21. Found: C, 57.77; H, 4.20; N, 4.21%. IR (KBr, cm^{-1}): ν_{max} 1615 (s, C=N). ^{1}H NMR: δ 3.72 (s, 4H, $-CH_2-CH_2-$), 7.36 (m, 22H, $Ph_2C{=}CH-$, Ar*H*), 8.01(d, 2H, $J_{HH} = 9.82$ Hz, $-CH{=}N-$). ^{13}C NMR: δ 58.65 ($=N^{13}CH_2^{13}CH_2N=$), 124.37, 129.75, 129.89, 130.19, 130.48, 131.54, 131.75, 138.38, 140.48, 161.53 ($Ph^{13}CH-$), 168.80 ($-^{13}C{=}N-$).

2.2.8. [Zn(Phca$_2$en)I$_2$] (8)

This complex was prepared in a similar manner to **6** using ZnI_2 (319 mg, 1 mmol). Yield: 637 mg (84%). *Anal*. Calc. for $C_{32}H_{28}N_2I_2Zn$: C, 50.60; H, 3.69; N, 6.39. Found: C, 50.48; H, 6.37; N, 6.37%. IR (KBr, cm^{-1}): ν_{max} 1614 (s, C=N). ^{1}H NMR: δ 3.72 (s, 4H, $-CH_2-CH_2-$), 7.37 (m, 20H, Ar*H*), 7.57 (d, 2H, $J_{HH} = 9.83$ Hz, $Ph_2C{=}CH-$), 8.02 (d, 2H, $J_{HH} = 9.83$ Hz, $-CH{=}N-$). ^{13}C NMR: δ 58.49 ($=N^{13}CH_2^{13}CH_2N=$), 124.28, 129.77, 129.93, 130.29, 130.53, 131.55, 131.78, 138.35, 140.60, 161.39 ($Ph^{13}CH-$), 168.51 ($-^{13}C{=}N-$).

2.2.9. [Zn(Phca$_2$en)(NCS)$_2$] (9)

To a solution of 261 mg (1 mmol) $Zn(NO_3)_2$ in 10 ml ethanol was added a solution of 194 mg (2 mmol) of KSCN in 5 ml ethanol and stirred for 20 min. The resulting white KNO_3 salt was filtered off and a solution of 440 mg (1 mmol) of Phca$_2$en in 5 ml methanol was added to the filtrate and stirred for 30 min. The product was precipitated as a white microcrystalline powder and collected by filtration and dried in air. Yield: 528 mg (85%). *Anal*. Calc. for $C_{34}H_{28}N_4S_2Zn$: C, 61.80; H, 4.50; N, 4.50. Found: C, 61.85; H, 4.52; N, 4.51%. IR (KBr, cm^{-1}): ν_{max} 1603 (s, C=N), 2055 (s, NCS). ^{1}H NMR: δ 3.67 (s, 4H, $-CH_2-CH_2-$), 6.99 (d, 2H, $J_{HH} = 9.80$ Hz, $Ph_2C{=}CH-$) 7.36 (m, 20H, Ar*H*), 8.02 (d, 2H, $J_{HH} = 9.80$ Hz, $-CH{=}N-$). ^{13}C NMR: δ 58.75 ($=N^{13}CH_2^{13}CH_2N=$), 123.47, 129.88, 130.00, 130.12, 130.44, 130.95, 131.65, 132.26, 138.12, 140.15, 163.75 ($Ph^{13}CH-$), 170.07 ($-^{13}C{=}N-$).

2.3. X-ray crystallography

Suitable single crystals of [Co(Phca$_2$en)Cl$_2$] (**2**), [Ni(Phca$_2$en)Br$_2$] (**5**), and [Zn(Phca$_2$en)Cl$_2$] (**6**), were obtained by diffusion of diethyl ether vapor into the dichloromethane solution of **2** and acetonitrile solution of **5** or by slow evaporation of an acetone solution of **6** at r.t. Data were collected on a Siemens SMART CCD diffractometer using graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. For each crystals, a full sphere of reciprocal lattice was scanned by 0.3° steps in ω with a crystal-to-detector distance of 3.97 cm. Preliminary orientation matrices were obtained from the first frames using SMART [19]. The data were empirically corrected for absorption and other effects using SADABS [20]. The structures were solved by direct methods and refined by the full-matrix least-squares method on F^2 data using the SHELXTL [21]. All non-H atoms were refined anisotropically. The H atoms were constrained to idealized geometries and refined isotropically.

3. Results and discussion

3.1. Synthesis

Phca$_2$en was prepared by the condensation of β-Phenylcinnamaldhyde with ethylenediamine. The product, as a white solid material, was characterized by IR, UV–Vis and ^{1}H, ^{13}C NMR spectroscopy.

The cobalt complexes were prepared by reacting equimolar quantities of the anhydrous cobalt halides salts and Phca$_2$en in dichloromethane. These complexes are stable in air in the solid state. The stability of cobalt complexes in solution depends on the solvent used. The compounds are stable in dichloromethane for at least 24 h, while they are much less stable in methanol. A methanolic solution in open air slowly turns brown in 6 h. To avoid any oxidation of the cobalt complexes, the synthesis of **2** and **3** were carried out under nitrogen atmosphere.

The nickel complexes were prepared by reacting equimolar quantities of the anhydrous nickel halides salts and Phca$_2$en in boiling acetonitrile. The zinc

complexes were prepared by reacting equimolar quantities of anhydrous zinc salts and $Phca_2en$ in dichloromethane. The zinc complexes are colorless solids dissolving in chloroform, methanol, ethanol and acetone and they are stable at ambient conditions.

3.2. Spectral studies

All complexes show similar IR spectral features, exhibiting a strong band between 1600 and 1616 cm^{-1} corresponding to ν(C=N). This band is shifted to the lower frequencies by 6–20 cm^{-1} relative to the free ligand upon the coordination of the nitrogen atoms. The observation of a strong band at 2065 cm^{-1} in the IR spectrum of complex **9** indicates that the NCS ligand in this complex is most probably N-bonded [22].

The ^{1}H NMR data of the $Phca_2en$ suggest that the ligand has a symmetrical structure with H_a and H_b protons (Scheme 1) in *trans* positions ($J = 9.5$ Hz). The four methylene protons appear as a singlet at 3.68 ppm. The two vinyl C*H* protons (H_b) are observed as a doublet centered at 6.82 ppm, and the multiplet centered at 7.31 ppm is assigned to the phenyl protons. The two *H*–C=N protons (H_b) appear as a doublet at 7.85 ppm.

In the ^{1}H NMR spectra of compounds **6**–**9**, the hydrogen of the imine C*H* groups (H_a) exhibits a downfield shift relative to the free ligand and shows no significant difference by changing the anion. Nevertheless, the signals due to H_b protons appear at 7.35, 7.36, 7.57 and 6.99 ppm for $ZnLCl_2$, $ZnLBr_2$, $ZnLI_2$ and $ZnL(NCS)_2$, respectively (Fig. 1). In search for an explanation for this behavior, we have found no interaction between H_b and the chloride atoms in $ZnLCl_2$. However, the observed variation in the H_b chemical shifts could be attributed to an intramolecular interaction with metal atom in the form of C–H···Zn weak hydrogen bonds (see more details in the crystal structures). Such interactions have also been reported by others [23,24]. The extent of interaction depends on the steric restrictions imposed by the coordinated anion and the electron density of metal atom. The shielding effect resulting from this intramolecular interaction is strongest for Cl followed by Br and I and to a greater extent for NCS coordinated to the metal atom.

The ^{13}C NMR spectrum of the free ligand exhibits 12 signals due to the fact that the two phenyl rings (*exo* and *endo*) are in different position relative to the ethylenic protons (*trans* and *cis*), and each phenyl ring has the its own characteristic signals. In the ^{13}C NMR spectra of the complexes **6**–**9**, the carbon atoms adjacent to the donor nitrogen atoms show downfield shift in their positions as compared with the free ligand, clearly indicating the coordination of the ligand and retention of the structure in the chloroform solutions.

The UV–Vis spectral data of $M(Phca_2en)X_2$ complexes are presented in Table 1. The $Co(Phca_2en)Cl_2$ show three closely spaced weak bands in the visible region and a very intense band in the UV region. In the regular tetrahedral and near-tetrahedral Co(II) complexes only one d–d transition [$^4A_2(F) \rightarrow {}^4T_1(P)$, assigned as υ_3] is observed in the visible region. This transition has been reported for the tetrahedral $[Co(NCS)_4]^{2-}$ at 615 nm and for the pseudotetrahedral $[Co(morpholine)_2(NCS)_2]$ at 616 nm [25]. The three

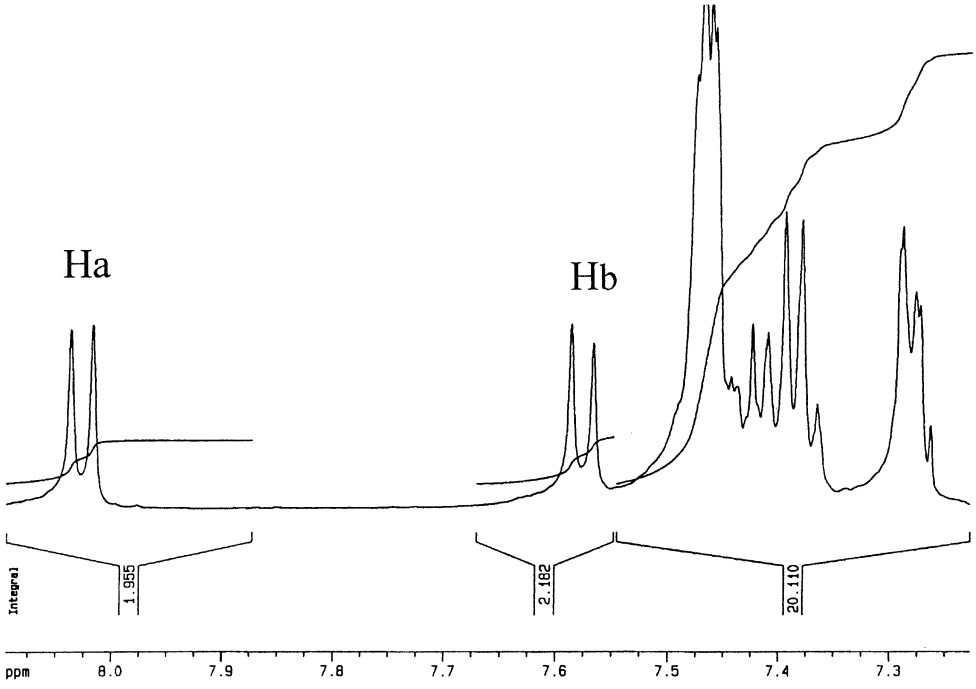

Fig. 1. ^{1}H NMR spectrum of $[Zn(Phca_2en)I_2]$ (**8**).

Table 1
UV–Vis spectral data of M(Phca$_2$en)X$_2$ complexes

Compound	Solvent	UV–Vis λ_{max} (nm) (log ε (M^{-1} cm^{-1}))
Phca$_2$en (**1**)	chloroform	330(4.73)
Co(Phca$_2$en)Cl$_2$ (**2**)	chloroform	651(2.77), 633(2.79), 580(3.08), 342(4.59)
Co(Phca$_2$en)Br$_2$ (**3**)	chloroform	649(3.00), 602(3.00), 578(2.67), 350(4.57)
Ni(Phca$_2$en)Cl$_2$ (**4**)	chloroform	499(2.20), 320(4.65)
Ni(Phca$_2$en)Br$_2$ (**5**)	chloroform	514(2.29), 330(4.68)
Zn(Phca$_2$en)Cl$_2$ (**6**)	chloroform	329.5(4.75)
Zn(Phca$_2$en)Br$_2$ (**7**)	chloroform	331(4.71)
Zn(Phca$_2$en)I$_2$ (**8**)	chloroform	332(4.72)
Zn(Phca$_2$en)(NCS)$_2$ (**9**)	chloroform	335(4.70)

closely spaced transitions in the spectrum of Co(Phca$_2$en)X$_2$ complexes arise from the distortion in the tetrahedral symmetry around the metal center. This splitting originates from the reduction of the orbital degeneracy due to the difference in the ligand field strength of imine and halides donor atoms and the restricted bite angle of the N(1)–M–N(2) chelating ligand [25,26]. The intensity of the UV-band is consistent with its being a ligand-centered $\pi \rightarrow \pi^*$ transition or/and a charge-transfer transition.

The $^3T_1(F) \rightarrow {}^3T_1(P)$ transition [27] in Ni(Phca$_2$en)X$_2$ complexes (**4**, **5**), appears as a low intensity band at 514 nm which is similar to that reported for Ni(Me$_4$propylenediamine)$_2$Cl$_2$ (512 nm) [25]. A strong band at 330 nm is assigned to a ligand-centered $\pi \rightarrow \pi^*$ transition or/and a charge-transfer transition. The electronic spectral data conform with the structures determined by X-ray crystallography for cobalt and nickel complexes.

The electronic absorption spectra of the Zn(Phca$_2$en)X$_2$ complexes (**6**–**9**) in chloroform, are dominated by the broad band in the region 320 nm corresponding to the intra-ligand transition of Phca$_2$en or/and a charge-transfer transition. No d–d transition are expected for d^{10} Zn(II) complexes.

3.3. Crystal and molecular structure of *2*, *5* and *6*

The crystallographic and refinement data are summarized in Table 2 and the selected bond distances and angles are given in Table 3. The molecular structures of **2**, **5** and **6** are illustrated in Figs. 2 and 3, respectively, where metal atoms are coordinated by the bidentate Schiff base ligand and two halogen atoms. Our results show that **2** and **6** are isomorph and isostructure. While a tetrahedral geometry might be expected for a four-coordinated M(II) center, the geometry about M(II) in **2**, **5** and **6** is distorted by the restricting bite of chelating ligand. Considering a low structural preference energy for other geometries of d^7 and d^{10} ions, a distorted tetrahedral structure can be inferred for other Co(Phca$_2$en)X$_2$ and Zn(Phca$_2$en)X$_2$ complexes and most probably for Ni(Phca$_2$en)X$_2$ complexes as well.

For **2** (see Fig. 2), the N(1)–Co–N(2) angle is only 84.07(15)° being in the range of 82°–89° found for ethylenediamine chelated complexes [28–30]. This angle is fixed by the bite size of the ligand (N(1)···N(2) = 2.737(1) Å). The Cl(1)–Co–Cl(2) angle is 110.17(6)° but the Cl(1)–Co–N(2) angle, 117.27(12)°, is larger than the tetrahedral values. The average Co–Cl bond length of 2.22 Å agrees well with the same distance in other tetrahedral cobalt complexes: Co(ethylenedimorpholine)Cl$_2$, 2.23 Å; Co(*p*-toluidine)$_2$Cl$_2$, 2.26 Å; Co(bdmpab)Cl$_2$, 2.23 Å. The Co–N$_{av}$ of 2.0483 Å is being normal [29–33]. The Co(II) complexes with bidentate Schiff bases showing a distorted tetrahedral structure, are common both in solid state and in solution (of non-coordinating solvents) [34–36] and the observed pseudotetrahedral structure for Co(Phca$_2$en)Cl$_2$ (**2**) is in accordance with this expectation.

The compound Ni(Phca$_2$en)Br$_2$ crystallizes with two molecules per asymmetric unit (molecule A and B) showing some conformational differences (see Fig. 3). Nickel complexes with bidentate chelating ligands including Schiff-bases often prefer tetragonal geometries [29,30]. However, the steric effects from Phca$_2$en distort the geometry at Ni(II) in Ni(Phca$_2$en)Br$_2$, (**5**), to pseudotetrahedral (Fig. 4). The angles N(1)–Ni–N(2), 84.63(9)° (A) and 85.08(9)° (B), and Br(1)–Ni–Br(2), 122.645(18)° (A) and 125.729(18)° (B), are indicative of a large deviation from idealized tetrahedral symmetry that is similar to those found in Ni($C_{20}H_{24}N_2$)Br$_2$ [23] and Ni(biq)Br$_2$ [37].

The Ni–Br average bond length of 2.34 Å agrees with those reported for other tetrahedral nickel complexes: [Ni(PPh$_3$)$_2$Br$_2$], 2.34 Å [38,39]; [(*n*-C_4H_9)$_4$N]-[Ni(C_9H_7N)Br$_3$], 2.38 Å [25] and Ni(biq)$_2$Br$_2$, 2.34 Å [37]. The average Ni–N distances of 1.99 Å are similar to those found in the pseudotetrahedral bis(*N*-isopropylsalicylaldiminato)nickel(II), 1.97 Å [40,41] and Ni(II) imine complexes, (Ni(biq)$_2$Br$_2$ 1.99 Å [37] and [Ni(TC-6,6)] 1.95 Å), [42], but they are approximately 0.07 Å longer than those for tetragonal Ni(II) analogues [43,44]. In the tetragonal case, the dx^2-y^2 orbital is vacant, allowing ligands to approach to the metal along the *x* and *y* axes.

The Zn(II) in **6** adopts a pseudotetrahedral coordination (see Fig. 2), where the tetrahedron is somewhat distorted by a small N(1)–Zn–N(2) angle being 83.45(16)°. The Cl(1)–Zn–Cl(2) angle has opened up to 112.02(6)°. The average Cl–Zn–N angle of 114.67° is also larger than the tetrahedral value. The Zn–N distance ranging from 2.078(4) to 2.066(4) Å are considered normal and comparable for those for **2** and **5**. The average Zn–Cl distance of 2.22 Å agree well with normal Zn–Cl bond distances [24].

The ligand adopts a Z,Z configuration in these complexes. The mean value for dihedral angles N=C–C=C is about 177.5° indicating the planarity of this moiety for the complexes studied here. However, the N=C–C=C moieties in each complex are not coplanar, but showing parallel configuration. The single bond distance C(2)–C(3) in **2**, **5**, and **6** (1.42, 1.43–1.44 and 1.42 Å, respectively) being slightly shorter than C(4)–C(5) in **2**, **5** and **6** (1.518, 1.523–1.528 and 1.524 Å, respectively) indicating an extended electron delocalization in these complexes. Torsion angles in the chelating ring and the stiryl moieties are listed in Table 4. In comparison to the *exo*-phenyl rings, the planes of the *endo*-phenyl rings are more parallel to the planes defined by the C–C=N groups. This result demonstrates that π delocalization in the stiryl moiety is solely between the *endo*-phenyl rings and the chain connecting the rings to the coordinated nitrogen atoms.

Despite the fact that the donor nitrogen atoms are sp^2 hybridized, the chelate ring is significantly puckered in all three complexes and some strain in the chelate ring is suggested by the deviation from 120° angle about the nitrogen, Co–N(1)–C(3) (134.7(3)°) and Co–N(1)–C(4) (107.8(3)°) in **2**; Ni–N(1)–C(3) (132.53(19)°, 130.44(19)°) and Ni–N(1)–C(4) (107.90(16)°, 109.51(16)°) in **5**; Zn–N(1)–C(3) (135.0 (4)°) and Zn–N(1)–C(4) (107.6(3)°) in **6**. The dihedral angles N(1)–C(4)–C(5)–N(2) are −56.8(5)° in **2**, −51.9(3)° and 50.1(3)° in **5** and −56.3(5)° in **6** that is typical for diamine chelate [30,45,46].

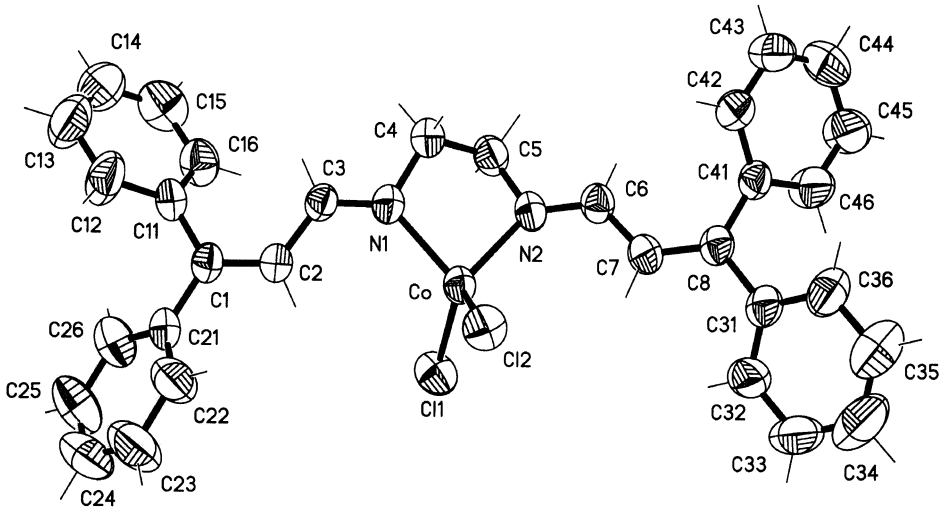

Fig. 2. Representation of molecular structure of **2** with atom-labeling scheme. Atomic displacement parameters are shown at 50% probability level. The crystal structure of $[ZnCl_2(Phca_2en)]$ (**6**) is visually indistinguishable from that of the cobalt compound and uses an identical atom numbering scheme, but with 'Co' replaced by 'Zn'.

The geometry of hydrogen bonds are given in Table 5. Complexes **2** and **6** exhibit similar hydrogen bonding patterns built up from the C–H···Cl hydrogen bonds. Chains of $MLCl_2$ molecules arranged along *a* axis are linked together via C–H···Cl hydrogen bonds to form three-dimensional networks (Fig. 4(a and b)). The H···Cl contacts range from 2.63 to 2.83 Å with the C–H···Cl angles of 134°–167°. For complex **5**, the C–H···Br hydrogen bonds have minor impact on crystal packing, though a three-dimensional hydrogen bonding network exists. The H···Br contacts are as large as 3.01 Å and the mean C–H···Br angle being 139° reflecting the weakness of such intermolecular interactions in the solid state.

Due to the geometrical restrictions in **2**, **5** and **6**, the H_b atoms, i.e. H(2) and H(7), lie in the vicinity of the metal atoms making intramolecular interactions possible in the form of weak C–H···M hydrogen bonds. This type of interaction is somewhat similar to the agostic interactions found in many organometallic complexes [47,48], although a $C-H^{\delta+}\cdots M^{\delta-}$ charge-assisted hydrogen bonding could be encountered here. As a matter of fact, the involvement of the metal centers in hydrogen bonding is now well established and known as non-traditional hydrogen bonds [49,50]. A recent survey by Desiraju and Steiner [51], gives the range 2.5–3.2 Å for the weak (C–)H···M hydrogen bonds. Our structural data reveals that the (C–)H···M interactions ranging from 2.9 to 3.13 Å in **2**, **5** and **6** would meet the above criteria and can be regarded as intramolecular weak hydrogen bonds. Consequently, the H_b atoms are influenced by the change in the electron density on the central metal atom and this can be followed easily by ^1H NMR spectroscopy. Our results from ^1H NMR study of $Zn(Phca_2en)X_2$ complexes, in which X = Cl, Br, I and NCS, clearly give further evidence to the existence of

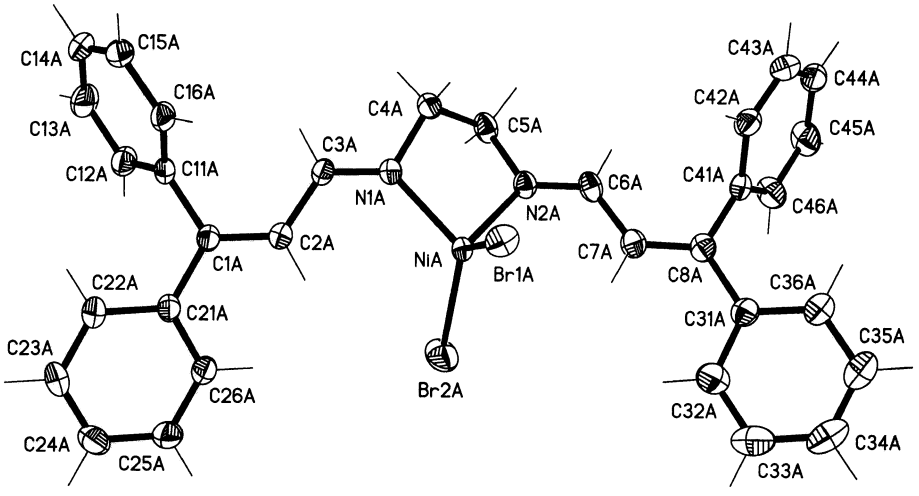

Fig. 3. Representation of molecular structure of **5** with atom-labeling scheme. Atomic displacement parameters are shown at 50% probability level.

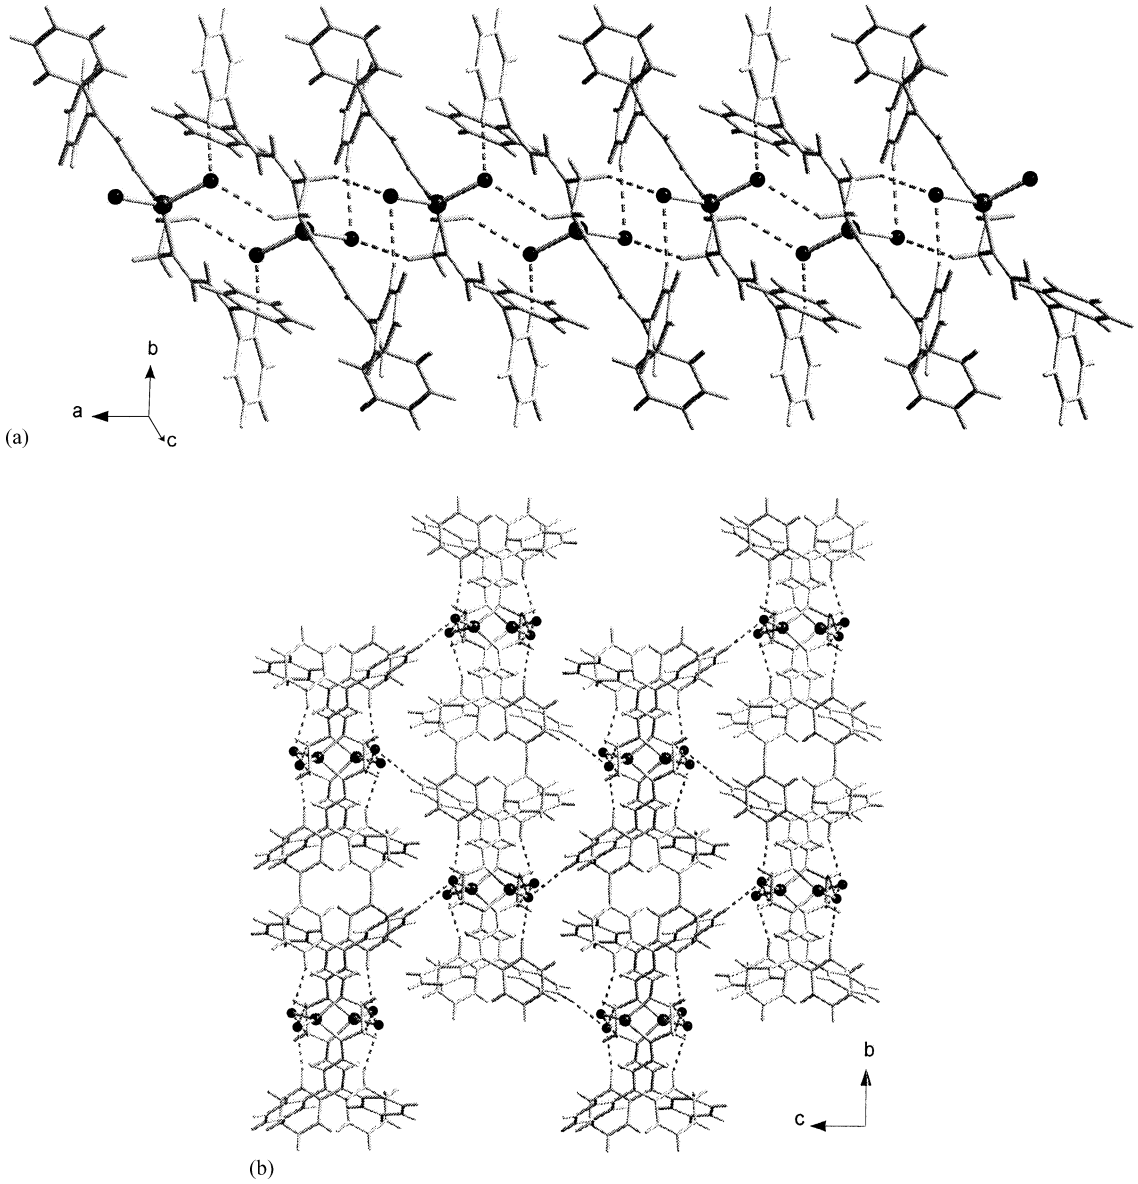

Fig. 4. The C–H···Cl hydrogen bonds are forming chains (a) of $CoLCl_2$ (or $ZnLCl_2$) molecules along *a* axis in the crystal structure of **2** (or **6**) and a three-dimensional network (b) is built up from linking chains.

NMR spectroscopy was successfully used as an analytical and structural method for those high-spin cobalt(II) complexes from the early beginning [11–17].

In case of homo- or heteroscorpionate tris(pyrazolyl)borate ligands of low or medium steric hindrance both bis-ligand Tp'_2M or mono-ligand Tp′MX complexes are formed depending on the method of synthesis (X, an anion disregarded as a ligand in this case). Here we report on the synthesis and structures of mono- and bis-ligand complexes with tris(pyrazolyl)borates obtained from 3(5)-phenyl,5(3)-methylpyrazole and 3,5-dimethylpyrazole. We also describe the unexpected reactivity of hydrobis(3-phenyl,5-methylpyrazolyl)(3,5-dimethylpyrazolyl)boratocobalt(II)(L) complexes, where L = $[OOCCH(OH)CH_3]^-$ (Lac), $[OOCC(O)CH_3]^-$ (Pyr), and $[OOCCH(OH)CH_2CH_3]^-$ (Hbu).

2. Experimental

2.1. Syntheses

2.1.1. General synthetic and analytical procedures

Sodium hydrotris(3-phenyl,5-methylpyrazolyl)borate (Na[HB(3-Ph,5-Mepz)$_3$]) and sodium hydrobis(3-phenyl,5-methylpyrazolyl)(3-methyl,5-phenylpyrazolyl)borate (Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]) as well as hydrobis(3-phenyl,5-methylpyrazolyl)(3,5-dimethylpyrazolyl)borate (Na[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]) and its high-spin cobalt(II) complex-[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) have been synthesized before [7,12]. Here we have described the optimized protocols of synthesis of heteroscorpionate Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz) in which the homoscorpionate Na[HB(3-Ph,5-Mepz)$_3$] is obtained as side-product and that for Na[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)].

The general procedure of synthesis of Tp′CoX complexes (X = thiocyanate or carboxylate anion) used here was based on addition of solution of NaTp′ in tetrahydrofuran (THF) to an excess of the metal ion salt (0.1 M) and additional excess of potassium thiocyanate or sodium carboxylate (0.5 M, unless otherwise stated) in water, and subsequent extraction of the product(s) into methylene dichloride. In some cases a mixture of NaTp′ salts was used and separation of ligands as Tp′Co(NCS) complexes was applied. The composition of mixtures of Tp′Co(NCS) at every step of both the synthesis and separation was controlled by means of ^{1}H NMR spectroscopy.

2.1.2. Optimized protocol for the synthesis of Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)] and Na[HB(3-Ph,5-Mepz)$_3$]

The synthesis of the sodium salts of ligands and Tp′Co(NCS) complexes have been described before [7]. An optimized large-scale protocol of the synthesis of Na[HB(3-Ph,5-Mepz)$_3$] and Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)] is given as follows: 1.1368 g $NaBH_4$ (30 mmol) was heated with 3(5)-phenyl,5(3)-methylpyrazole (14.2378 g, 90 mmol) in octadecane (40 cm^3). The temperature of the mixture was gradually increased up to boiling point of the solvent and the reaction mixture was heated until hydrogen evolution ceased (2.3 dm^3 were collected within a period of 20 min). Heptane (100 cm^3) was added to the pre-cooled mixture, which was then slowly cooled down with continuous stirring for next 12 h. The solid residue was filtered off, washed with petroleum ether and dried under high vacuum. White solid (13.7 g) was isolated. The precipitate was heated three times in boiling heptane (100 cm^3, 20 min) and filtered off while hot. Then the heating was repeated with 500 cm^3 heptane. Finally, 9.56 g of pure Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)] was isolated as a heptane-insoluble compound (18.9 mmol, 62.9% yield). From the first three combined filtrates 0.81 g of pure Na[HB(3-Ph,5-Mepz)$_3$] was isolated as colorless crystals (1.6 mmol, 5.3% yield).

2.1.3. Optimized protocol for the synthesis of Na[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)] and [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS)

Syntheses of Na[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)] and [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) have been described previously [12].

In the optimized protocol the sodium salt of [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]$^-$ was obtained by condensation of $NaBH_4$ (0.7684 g, 20.3 mmol) with 3,5-dimethylpyrazole (2.1189 g, 22.0 mmol) and 3(5)-phenyl,5(3)-methylpyrazole (6.0116 g, 38.0 mmol) in heptadecane (40 cm^3) gradually heated up to boiling point; 1430 cm^3 of hydrogen evolved. The reaction mixture was cooled to approximately 100 °C and 50 cm^3 of heptane was added. After storage at room temperature for 12 h the white precipitate formed, which was filtered off, washed with approximately 100 cm^3 of petroleum ether and dried under reduced pressure. Yield of crude product (calculated for the desired compound): 6.29 g (69.7%).

Further purification has been done by heating the crude product under refluxing heptane (150 cm^3) twice for 20 min and separation of the insoluble product by filtration. Finally, 2.6 g of solid sodium salt was isolated (28.8% yield).

The [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) complex was obtained by the described procedure [12], i.e. typically by dropwise addition of 1.0 g of NaTp′ in THF (35 cm^3) into 0.1 M $Co(NO_3)_2$ and 0.5 M KNCS water solution (200 cm^3). The product was extracted into dichloromethane (300 cm^3), the organic phase was washed twice with 300 cm^3 water, and dichloromethane was removed on a rotary evaporator keeping the temperature of bath at 30 °C. Formation of a white precipitate was observed (about 0.15 g), which was later

identified as a mixture of bis-ligand Tp′CoTp″ complexes (vide infra). These were insoluble in cold THF. Thus, the violet [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) was easily separated by dissolving in THF.

The solvent was removed under high vacuum and the complex was found to be pure as analyzed by its ^{1}H NMR spectrum. However, it has been found that prolonged storage of the complex in polar solvents like methanol or tetrahydrofuran was accompanied by formation of a white precipitate. When [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) was heated to the boiling point of the solvents, vast side reactions took place.

2.1.4. Pyruvato hydrotris(3-phenyl,5-methylpyrazolyl)boratocobalt(II) ($Tp^{Ph,Me}Co(Pyr)$, (**1**))

The $NaTp^{Ph,Me}$ and $Tp^{Ph,Me}Co(NCS)$ complexes were prepared as described before [7]. The $Tp^{Ph,Me}Co(Pyr)$ complex was obtained by metathesis of $Tp^{Ph,Me}$-Co(NCS)(THF) (100 mg, 0.149 mmol). The starting compound was dissolved in 100 cm^3 dichloromethane and vigorously stirred three times with 0.5 M water solution of sodium pyruvate for 2 h. After separation of the organic phase, the dichloromethane was stripped out on a rotary evaporator and the solid residue was recrystallized twice from tetrahydrofuran–hexane mixture to give pink needles of $Tp^{Ph,Me}Co(Pyr)$ (20 mg, 21.3% yield). One of the collected crystals was analyzed crystallographically (Table 1).

2.1.4.1. Analytical data for **1**.

Elemental analysis: Calc. for $C_{33}H_{31}N_6O_3BCo$ (M.W. 629.38): C, 62.97; H, 4.96; N, 13.35. Found: C, 63.15; H, 4.86; N, 13.28%.

^{1}H NMR ($CDCl_3$, 298K); δ (intensity, assignment): −10.1 (3H, CH_3(Pyr)); 4.4 (6H, broad, *o*-H(3-Ph)); 7.1 (4H, *p*-H(3-Ph)); 8.9 (6H, *m*-H(3-Ph)); 12.6 (1H, B-*H*); 18.9 (9H, 5-CH_3); 64.5 (3H, 4-H).

(CD_3OD, 298K); δ (intensity, assignment): −21.4 (6H, *o*-H(3-Ph)); 9.4 (3H, CH_3(Pyr)); 27.5 (9H, 5-CH_3); 40.0 (1H, B-*H*); 57.8 (3H, 4-H). IR (KBr) $\nu_{(BH)}$ 2561 cm^{-1}.

2.1.5. Bis[hydrobis(3-phenyl,5-methylpyrazolyl)(3-methyl,5-phenylpyrazolyl)borato]cobalt(II) ([HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Co(II) (**2**))

Cobalt(II) nitrate (3.8 cm^3, 0.05 M, 0.19 mmol) was added dropwise to a vigorously stirred THF solution (30 cm^3) containing 200 mg Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)] (0.39 mmols). A yellow precipitate formed, which dissolved upon addition of chloroform (100 cm^3). The organic phase was separated and washed twice with water (100 cm^3), solvents were removed on a rotary evaporator and the solid residue was dried under high vacuum. The product was recrystallized from THF–hexane mixture to give 193 mg of yellow crystals of [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Co(II) (0.17 mmol, 97% yield). One of the crystals was analyzed crystallographically.

2.1.5.1. Analytical data for **2**.

Elemental analysis: Calc. for $C_{60}H_{56}N_{12}B_2Co$ (M.W. 1025.72): C, 70.26; H, 5.50; N, 16.39. Found: C, 69.95; H, 5.69; N, 16.52%.

^{1}H NMR (two rotational isomers were observed). Temperature dependent spectra were taken in toluene-d_8. (see Section 3).

IR (KBr) $\nu_{(BH)}$ 2555 cm^{-1}.

Mass spectrum (ESI, positive polarization) *m*/*e*: (**2**)$^+$ 1025.7 (3%); (**1**-$C_{10}N_2H_9$, corresponding to 3(5)-Me,5(3)-PhpzH) 868.8 (100%).

2.1.6. Bis[hydrotris(3-phenyl,5-methylpyrazolyl)borato]cobalt(II) ($Tp_2^{Ph,Me}Co(II)$ (**3**))

Cobalt(II) nitrate (3.8 cm^3, 0.05 M, 0.19 mmol) was added dropwise to a vigorously stirred THF solution (30 cm^3) containing 204 mg $NaTp^{Ph,Me}$ (0.40 mmol). A pink precipitate formed, which dissolved upon addition of chloroform (100 cm^3). The organic phase was washed twice with water (100 cm^3), solvents were removed on rotary evaporator and the solid residue was dried under high vacuum. The product was recrystallized from THF–hexane.

After 1 week of co-diffusion of solvents 162 mg of pink crystals of **3** were obtained (0.158 mmol, 83% yield). One of the crystals was analyzed crystallographically (Table 1).

2.1.6.1. Analytical data for **3**.

Elemental analysis: Calc. for $C_{60}H_{56}N_{12}B_2Co$ (M.W. 1025.72): C, 70.26; H, 5.50; N, 16.39. Found: C, 70.15; H, 5.63; N, 16.56%.

^{1}H NMR ($CDCl_3$, 298K); δ (intensity, assignment): −39.5 (12H, *o*-H(3-Ph)); 0.5 (6H, *p*-H(3-Ph)); 0.8 (12H, *m*-H(3-Ph)); 36.1 (18H, 5-CH_3); 50.2 (6H, 4-H); 87.9 (2H, B–H).

IR (KBr): $\nu_{(BH)}$ 2547 cm^{-1}.

2.1.7. Bis[hydrobis(3-phenyl,5-methylpyrazolyl)(3-methyl,5-phenylpyrazolyl)borato]copper(II) ([HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Cu(II) (**4**))

Na[HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)] (200 mg, 0.39 mmols) dissolved in 5 cm^3 THF was added dropwise to a vigorously stirred 0.14 M water solution of cobalt(II) nitrate and 1.5 M sodium pyruvate (30 cm^3). A yellow precipitate formed, which dissolved upon addition of chloroform (80 cm^3). The organic phase was separated and washed twice with water (100 cm^3), the solvents were removed on a rotary evaporator and the solid residue was dried under high vacuum. The product was recrystallized from THF–hexane to give 120 mg of **4** as reddish–amber crystals (0.116 mmol, 59.7% yield). One

*2.1.7.1. Analytical data for **4**.* Elemental analysis: Calc. for $C_{60}H_{56}N_{12}B_2Cu$ (M.W. 1030.33): C, 69.94; H, 5.48; N, 16.31. Found: C, 69.80; H, 5.29; N, 16.20%.

IR (KBr): $\nu_{(BH)}$ 2559 cm^{-1}.

2.1.8. Conversion of [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(X) upon addition of sodium carboxylates (X = thiocyanate, lactate, pyruvate and 2-hydroxybutyrate)

In an attempted synthesis of [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(Lac), which was previously obtained in situ by addition of sodium lactate to [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) [12], Na[HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)] (100 mg, 0.225 mmol) dissolved in 5 cm^3 THF was added dropwise to 50 cm^3 0.1 M cobalt(II) nitrate and 2M sodium lactate with vigorous stirring. The reddish-pink product was extracted with 100 cm^3 of dichloromethane. The organic layer was washed twice with 100 cm^3 water. Formation of a white precipitate, which was insoluble in cold THF, accompanied evaporation of organic solvents. The reddish product(s) was dissolved in THF and left for crystallization from THF–heptane. Again, the formation of a white precipitate upon standing in co-diffusing solvents was observed. Totally, 65 mg of white products were collected by filtration and analyzed by ^{1}H NMR spectroscopy and mass spectra. The isolated solid products turned out to be a mixture of bis-ligand homo- and heteroleptic complexes:

[HB(Ph,Mepz)$_2$(Me$_2$pz)]Co[HB(Ph,Mepz)$_3$] (*m/e* 964.2, 1%) [HB(Ph,Mepz)$_2$(Me$_2$pz)]$_2$Co (and/or [HB(Ph,Mepz)(Me$_2$pz)$_2$]Co[HB(3-Ph,5-Mepz)$_3$]) (*m/e* 901.2, 20%); [HB(Ph,Mepz)$_2$(Me$_2$pz)]Co[HB(Ph,Mepz)-(Me$_2$pz)$_2$] (*m/e* 839.0, 100%); [HB(Ph,Mepz)-(Me$_2$pz)$_2$]$_2$Co (and/or [HB(Ph,Mepz)$_2$(Me$_2$pz)]Co[HB-(Me$_2$pz)$_3$) (*m/e* 777.1, 45%); [HB(Ph,Mepz)(Me$_2$pz)$_2$]-Co[HB(Me$_2$pz)$_3$] (*m/e* 715.2, 2%); [HB(Me$_2$pz)$_3$]$_2$Co (*m/e* 653.4, 18%).

The solvents were removed from the filtrate in a stream of nitrogen and the solid residue was examined by ^{1}H NMR spectroscopy in CD$_3$OD solution. The identified products were: [HB(3-Ph,5-Mepz)$_2$(3,5-di-Mepz)]Co(Lac),Tp^{Ph,Me}Co(Lac), and [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]Co(Lac) [12,7].

Metathesis of thiocyanate into carboxylate anions were performed by stirring a THF and/or methanol solution of [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) (at ca. 0.16 mmol scale) with aqueous sodium lactate (1 M), sodium pyruvate (1 M) or sodium 2-hydroxybutyrate (0.2 M), followed by extraction of the product into CH$_2$Cl$_2$. The procedure was repeated three times.

The products were crystallized from THF–hexane or THF–heptane. The formation of bis-ligand complexes as white precipitates was observed in every case. The white compounds were analyzed as before by MS and ^{1}H NMR spectroscopy giving analogous results as those described above.

2.2. Methods and instruments

^{1}H NMR spectra were obtained with a Bruker AMX300 spectrometer operating in the quadrature mode at 300 MHz. The residual peaks of deuterated solvents were used as internal standards. The FT IR spectra were recorded on a Perkin–Elmer 1725X instrument.

Mass spectra were obtained on a Finnigan MAT TSQ 700 spectrometer by the ESI method at 4.5 kV ionization potential and 250 °C capillary temperature in chloroform.

Crystal data are given in Table 1, together with refinement details. All measurements of crystals **1**–**4** were performed at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. Crystals were positioned at 65 mm from the CCD camera. 612 frames were measured at 0.75° intervals with a counting time of 10–15 s. Accurate cell parameters were determined and refined by a least-squares fit of 1800 for **3** to 6200 for **1** strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. Z o.o. (formerly Kuma Diffraction Wroclaw, Poland) programs. Structures were solved by direct methods (program SHELXS-97 [18]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 [19] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps. They were refined with isotropic displacement parameters for **1** and **4**, and fixed for **2** and **3**.

3. Results and discussion

The unsubstituted Tp ligand forms bis-ligand Tp_2M complexes (M = Fe(II), Co(II), Ni(II), Cu(II), Zn(II)) even in the presence of excess of metal ion [20]. In the case of Tp′ ligands of medium steric demands (bearing for instance *i*Pr, *neo* Pent, Ph substituents attached to C-3), the protocol for synthesis of Tp′CoX complexes (where $X = NCS^-$, Cl^-, NCO^-, N_3^- and others) requires the use of metal ion in excess and sometimes additional excess of X^-. The series of homo- and heteroscorpionate Tp″CoX complexes have been prepared previously according to this method [2,3,7–9,11–15].

3.1. Synthesis and structure of hydrotris(3-phenyl,5-methylpyrazolylborate)cobalt(II) pyruvate ($Tp^{Ph,Me}Co(Pyr)$ (**1**))

The $Tp^{Ph,Me}Co(Pyr)$ complex was obtained by metathesis of the anion achieved in a two-phase system: methylene dichloride (containing starting $Tp^{Ph,Me}$-Co(NCS)) and water (saturated with sodium pyruvate). The conversion was completed after threefold extraction and the resulting product was obtained without substantial loss of $Tp^{Ph,Me}Co$(II). The **1** was recrystallized from THF–hexane mixture and subjected to X-ray crystallographic analysis. Two crystallographically independent molecules were found in the solid state. The details of the molecular structure are presented in Table 2 and Fig. 1. The pyruvate anion is coordinated to the central metal ion via two atoms: the oxygen from the carboxylate group and the second one from the carbonyl group. Thus, a five-membered chelate ring is formed and the molecule is stable enough to be isolated. Relatively large bite angles of $Tp^{Ph,Me}$ ligands in **1** (boron-centered bite angles, 75.1° and 74.9°; cobalt-centered bite angles, 135.4° and 135.0°) renders the cobalt(II) central ion available for two oxygen donors from the pyruvate ligand. In comparison, when nitrogen from thiocyanate and oxygen from tetrahydrofuran complete the coordination sphere of pentacoordinate $Tp^{Ph,Me}$-Co(NCS)(THF) the boron-centered and cobalt-centered bite angles are 76.5° and 140.3°, respectively [12]. Although carboxylate $Tp^{Ph}Co(X)$ complexes were synthesized before (where X = OAc, OBz, OBz-4-NO_2, OBz-4-F and OBz-2-NH_2; OBz = benzoate) structural data were not available due to difficulties in crystallization of complexes [21]. It has been found for example that attempted crystallization of $Tp^{Ph}Co$(anthranilate) from THF led to dismutation of the starting complex into insoluble Co(anthranilate)$_2$ and $(Tp^{Ph})_2Co$ [21]. The only complex of $Tp^{Ph,Me}$ and a carboxylate ancillary ligand that was characterized structurally was pentacoordinate $Tp^{Ph,Me}Cu$(OBz)(3-Ph,5-MepzH) [22].

3.2. Properties of thiocyanato hydrobis(3-phenyl, 5-methylpyrazolyl)(3,5-dimethylpyrazolyl)boratocobalt(II) ([HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS)) in presence of sodium carboxylates

Previously we have demonstrated that the heteroscorpionate ligand in [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) is stable enough to survive the demanding procedure of thermal conversion to form [HB(3-Ph,5-Mepz)(3-Me,5-Phpz)(3,5-diMepz)]Co(NCS) with approximately 30% yield accompanied with for-

[a] Both nitrogens from the same Tp′ ligand.

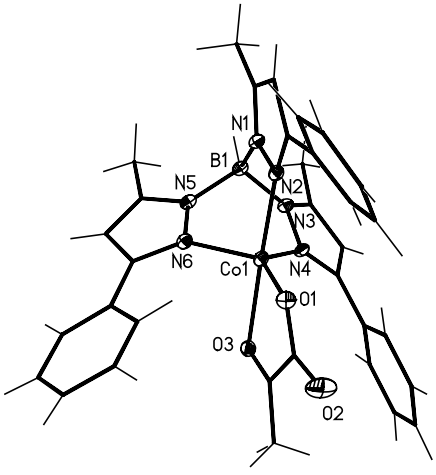

Fig. 1. View of one of two independent molecules of **1**.

mation of a not-identified side-product with about 10% yield [12]. On the other hand, the [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) undergoes slow conversion into not identified bis-ligand complexes, when stored in polar solvents like methanol or tetrahydrofuran. The heteroscorpionate [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(NCS) was also demonstrated to convert into [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(Lac) in situ upon addition of sodium lactate in methanol-d_4 solution. Encouraged with those results we have attempted to obtain [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(Lac) by large scale metathesis with excess sodium lactate. Surprisingly, we have isolated a colorless precipitate, which was a mixture of bis-ligand complexes. Reproducible mass spectral data have demonstrated that mixture composes of:

$[HB(Ph,Mepz)_2(Me_2pz)]Co[HB(Ph,Mepz)(Me_2pz)_2]$, $[HB(Ph,Mepz)(Me_2pz)_2]_2Co$, $[HB(Ph,Mepz)(Me_2pz)_2]$-$Co[HB(Me_2pz)_3]$ and $[HB(Me_2pz)_3]_2Co$, whereas the filtrate indicated the presence of mostly $[HB(3\text{-}Ph,5\text{-}Mepz)_3]Co(Lac)$, easily identified by its ^1H NMR spectrum [7]. In order to answer the question whether the conversion results from alkyl (methyl of lactate) versus aryl (3-phenyl of pyrazolyl moiety) cross-transfer, we have performed an additional experiment using sodium α-hydroxybutyrate instead of sodium lactate. The mass spectrum taken for bis-ligand cobalt(II) complexes was identical with that obtained previously. The same result was obtained with sodium pyruvate. Thus, we have concluded that cross-exchange of pyrazolyl moieties between two molecules of Tp′Co(L) complexes took place. Two questions desired answering, (i) is the formation of bis-ligand complexes (heteroleptic Tp′CoTp″ ones, containing sterically non-demanding $[HB(Ph,Mepz)(Me_2pz)_2]^-$ and $[HB(Me_2pz)_3]^-$ anions) a driving force for the observed conversions; and (ii) does the cross-exchange of other pyrazoles, able to form less sterically demanding Tp′ ligands, occur in a similar fashion.

Several attempts to prepare the crystals of mono-ligand Tp′M(carboxylate) complexes both by a preparative way, starting from M(II) carboxylates (M(II) = Co(II) or Cu(II)) and by metathesis of the corresponding Tp′Co(NCS) failed and the products isolated were bis-ligand complexes containing unconverted Tp′ ligands (Tp′ = $[HB(3\text{-}Ph,5\text{-}Mepz)_2(3\text{-}Me,5\text{-}Phpz)]^-$ and $[HB(3\text{-}Ph,5\text{-}Mepz)_3]^-$). The only example of a carboxylate complex of the Tp′Co(carboxylate) type isolated by crystallization from concentrate solution was **1** (vide supra).

3.3. Structure of bis-ligand homoleptic complexes: $[HB(3\text{-}Ph,5\text{-}Mepz)_2(3\text{-}Me,5\text{-}Phpz)]_2Co$ (**2**), $Tp_2^{Ph,Me}Co$ (**3**), and $[HB(3\text{-}Ph,5\text{-}Mepz)_2(3\text{-}Me,5\text{-}Phpz)]_2Cu$ (**4**)

Bis-ligand homoleptic Co(II) and Cu(II) complexes with Tp′ ligands composed of 3(5)-phenyl-5(3)-methylpyrazoles form spontaneously from the corresponding Tp′Co(carboxylate) counterparts via dismutation. In order to establish if the ligands bound in the bis-ligand complexes undergo interconversion we have synthesized **2** and **3** by a deliberate synthetic pathway using an excess of the sodium salt of the corresponding homo- and heteroscorpionates and cobalt(II) nitrate. The compounds were isolated with good yields and their structures have been elucidated crystallographically. Both complexes were stable both in solution when heated in refluxing toluene-d_8 and in the solid state. However, they were unstable in conditions used for mass spectral examination. Only **2** gave reliable results although the relative intensity of the peak of the molecular cation was low in comparison to the fragment **1**-3(5)-Me,5(3)-PhpzH. For other complexes studied here further fragementation took place.

In the case of **3** the Tp^{PhMe} ligands are bound to cobalt(II) central ion less tightly than heteroscorpionate Tp′ ligands in **2** and probably even in the solid state some percentage of the molecules of **3** contain Tp′ ligands bound in a $\eta^3\eta^2$ manner resulting in a lower value of R_f. The tight packing of two ligands in **3** causes a 2.7° deviation of the B···Co···B angle from linearity. Consistently, the $\nu_{(BH)}$ stretching vibration is less shifted towards higher wavenumbers in **3** in comparison with that in **2**.

The molecular structures of **2** and **3** are presented in Figs. 2 and 3. Selected bond lengths and angles are collected in Table 2. The Tp′ ligands are η^3 coordinated via three pyrazolyl nitrogen atoms. Thus, the cobalt central metal ions are hexacoordinate in both complexes. There are two slightly different molecules of **2**, with boron-centered (α) and cobalt-centered angles (β) of 85.5°; 85.9° and 154.7°; 154.5°, respectively (entry 1 in Table 3). However, both molecules have only slightly distorted octahedral environments around metal ion; all N_t–Co–N_t angles are ideally 180° (where N_t are *trans*-nitrogen donors). Also the B···Co···B axes are collinear ($\gamma = 180°$, column 6 in Table 3). The cobalt(II) ion in **3** is more distorted from the octahedral environment; N_t–Co–N_t angles are equal to 169.0°, 169.0°, and 171.5° resulting from considerably smaller bite angles of the homoscorpionate ligand (entry 2 in Table 3). Consequently, as one can see from Table 3, γ is smaller than 180° in **3**, which is a general trend observed for Tp′ ligands with α lower than 83°, with only a few exceptions.

The heteroscorpionate bis-ligand complex $[HB(3\text{-}Ph,5\text{-}Mepz)_2(3\text{-}Me,5\text{-}Phpz)]_2Cu$ (**4**) was obtained during the attempted synthesis of a mono-ligand copper(II)

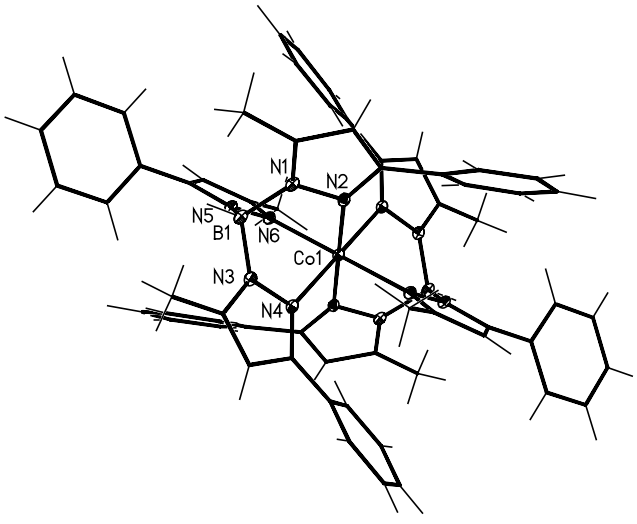

Fig. 2. View of one of two independent molecules of **2**.

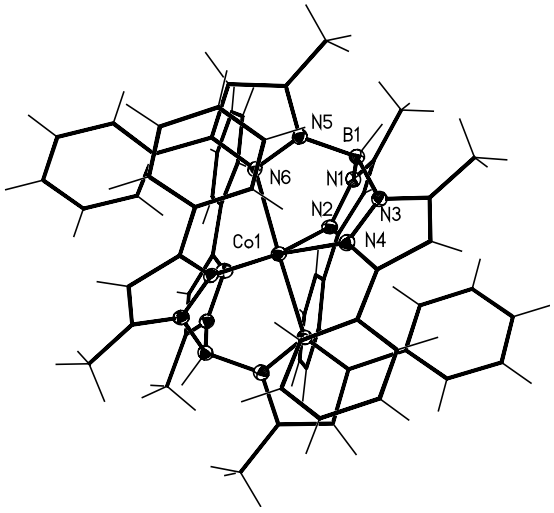

Fig. 3. View of **3**.

complex with a lactate auxiliary ligand. The molecular structure in **4** is presented in Fig. 4. Relevant bond lengths and angles are collected in Table 2. Both ligands are η^3 coordinated via three pyrazolyl nitrogen atoms. The boron-centered and copper-centered bite angles in two crystallographically different centrosymmetric molecules are, 86.0°; 87.3° and 155.0°; 154.8°, respectively, which are slightly larger than the corresponding ones in the cobalt(II) analogue (see entries 15 and 1 in Table 3). Generally, the Tp′ ligands are less tightly bound to Cu(II) in comparison with Co(II) Tp′MTp″ analogues; bite angles are larger and B–B distances are also slightly longer in the case of copper analogues (see entries 3 vs. 16, 6 vs. 21 and 1 vs. 15). Undoubtedly it results from the Jahn–Teller effect in octahedral Cu(II) complexes, which is clearly pronounced for almost all considered Tp′CuTp″ complexes (entries 16–21). As one can see, for smaller bite angles (larger steric hindrance of Tp′), smaller Jahn–Teller distortion is observed. Thus, the effect is almost negligible in **4**.

3.4. The ^{1}H NMR studies of [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Co

The temperature dependent ^{1}H NMR spectra of [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Co have shown that two rotational isomers are present in solution (Fig. 5).

It is reasonable to assume that population of anti-periplanar isomer (*I*) in solution is higher than that of any of two enantiomeric synclinal isomers (*II*(*S*) and *II*(*R*)).

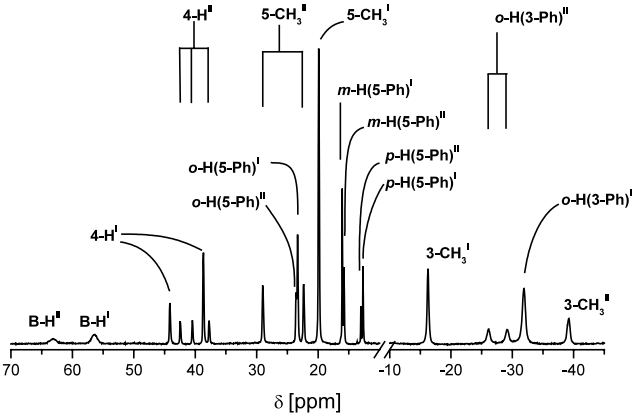

Fig. 5. ^{1}H NMR spectrum of **2** in toluene-d_8 at 350K. The corresponding resonances of isomer *I* and isomer *I* are labelled with $^{I,\ II}$ superscripts, respectively. The −10–10 ppm region was omitted for the sake of clarity.

Isomer *I* was found to be the only one existing at 100 K in the solid state by crystallographic measurement. It has a the plane of symmetry passing through the 3-methyl,5-phenylpyrazolyl rings (the donor atom is depicted as N_a in rotational isomer *I*) and a center of inversion at the metal ion. Thus, both 3-CH_3 groups and *o*-H(5-Ph) hydrogens give one resonance each, shifted upfield (−16 ppm) and downfield (23 ppm), respectively (Fig. 5). Also both 3-phenyl,5-methylpyrazolyl entities are equivalent resulting in presence of one *o*-H(3-Ph) and one 5-CH_3 resonances at −32 and 20 ppm, respectively. The pyrazolyl 4-H resonances of 4:2 intensity ratio are downfield shifted to about 40–45 ppm at 350 K. The spectrum of isomer *II* is much more complicated, though absolutely clear; the diastereotopic Tp′ ligands give three pyrazolyl 4-H, and pairs of both of *o*-H(3-Ph) and 5-CH_3 signals, as shown at Fig. 5. The spectrum presented in Fig. 5 was recorded at 350 K; at this temperature the resonances from *II* have relatively high intensity. Furthermore, no overlapping of resonances is observed. From integral intensity of the corresponding resonances of isomers *I* and *II* in the ^{1}H NMR variable temperature spectra the concentration ratio of *I* and *II*, and thus the equilibrium constant were estimated. The van't Hoff plot revealed considerable curvature, suggesting the involvement of additional species, undistinguishable by ^{1}H NMR spectroscopy. One of the possible explanations may be the presence of Tp′η^3Coη^2CoTp″ species being in fast equilibrium with *I* and *II*. Also the Curie plots for both isomers reveal a substantial curvature (Fig. 6). It has been evidenced that the hyperfine shift for hexacoordinate Tp$_2$Co complexes is dominated by a dipolar shift [16]. Thus, rather the involvement of the above mentioned Tp′η^3Coη^2Tp″ species in the averaged spectral picture should be considered instead of a large contribution of contact shift into isotropic shift [33]. Indeed, even in the solid state a medium sterically hindered Tp^{Ph} ligand produces a stable Tp$^{Ph}\eta^3$Coη^2Tp^{Ph} complex [21].

4. Conclusions

Carboxylate anions (OOCR = lactate, pyruvate and 2-hydroxybutyrate) induce conversion of [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]Co(OOCR) and [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]Cu(OOCR) into [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Co and [HB(3-Ph,5-Mepz)$_2$(3-Me,5-Phpz)]$_2$Cu. In the case of [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]Co(OOCR) the scrambling of pyrazoles takes place accompanied by formation of bis-ligand complexes of the Tp′CoTp″ type with Tp′ (Tp″) ligands of lower steric hindrance. This property of the [HB(3-Ph,5-Mepz)$_2$(3,5-diMepz)]$^-$ heteroscorpionate is rather unique; other two Tp′ ligands; the more hindered

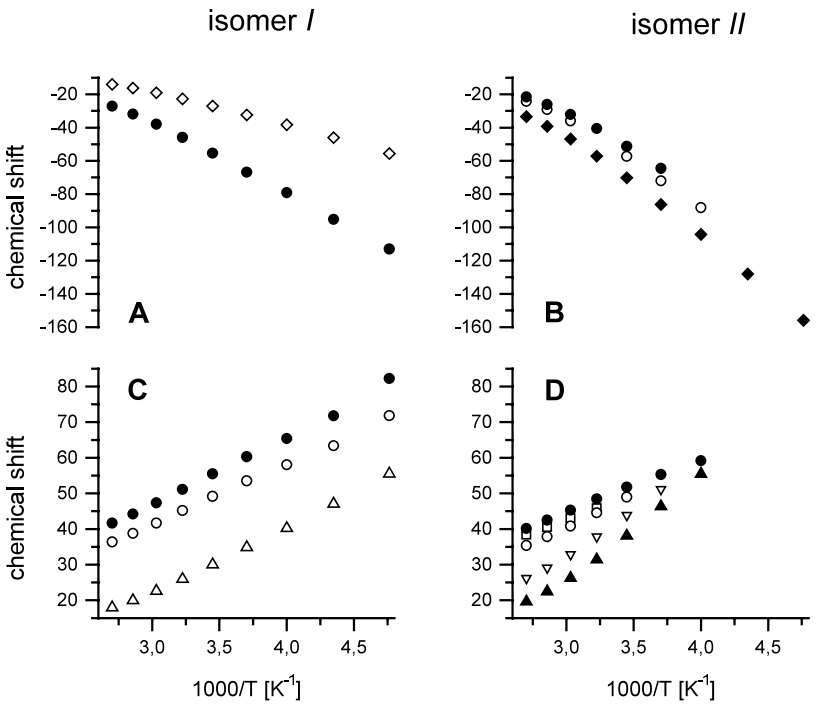

Fig. 6. Curie plots for isomers *I* and *II* of **2**. The *o*-H(Ph) and 3-CH_3 resonances are denoted as circles and diamonds, respectively, at traces A and B. The 4-H(pz) and 5-CH_3 resonances are denoted as circles and triangles, respectively, at traces C and D.

$[HB(3\text{-}Ph,5\text{-}Mepz)_2(3\text{-}Me,5\text{-}Phpz)]^-$ and $[HB(3\text{-}Ph,5\text{-}Mepz)_3]^-$ do not interconvert into their Tp'_2Co complexes. The only stable Tp′Co(carboxylate) complex was $Tp^{Ph,Me}Co(OOCC(O)CH_3)$ whose molecular structure was determined crystallographically.

5. Supplementary data

Crystallographic data for the structures reported in this paper (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 182947 for compound **1**, CCDC no. 182945 for **2**, CCDC no. 182946 for **3** and CCDC no. 182947 for **4**. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Unity Inova-400 spectrometer (400 MHz for ^{1}H and 161.92 MHz for ^{31}P). Chemical shifts are relative to TMS (^{1}H), or external 85% H_3PO_4 (^{31}P), with downfield values reported as positive. Coupling constants J are given in Hertz.

2.2. Preparation of the complexes

2.2.1. Preparation of $UO_2Br_2 \cdot xH_2O$

Uranyl acetate was quantitatively transformed to uranyl bromide as follows: $UO_2(CH_3CO_2)_2 \cdot 2H_2O$ (0.5 g, 1.18 mmol) was dissolved in a mixture of methanol (5 ml) and 47% hydrobromic acid (2 ml). The solution was concentrated to dryness in a bath at approx. 100 °C leading to an orange residue of composition $UO_2Br_2 \cdot xH_2O$ ($2 < x < 3$).

2.2.2. Preparation of $[UO_2L_4](Br_3)_2$ ($L = HMPA$, $OPPh_3$, $OAsPh_3$)

The orange residue above obtained (ca. 1.15 mmol of $UO_2Br_2 \cdot xH_2O$) was dissolved in methanol (2 ml) and 0.5 g (3.13 mmol) of Br_2 was added with stirring. Then a solution of L (6.27 mmol) in methanol (15 ml) was added. After stirring the resulting mixture for 10 min at room temperature (r.t.), the orange microcrystalline precipitate was filtered, washed with diethyl ether (3 × 2 ml), and dried under vacuum.

2.2.2.1. $[UO_2(HMPA)_4](Br_3)_2$. Yield 1.477 g (85.5%). IR (cm^{-1}): ν(U=O) 917; ν(P=O) 1068. *Anal*. Found: C, 19.47; H, 4.70; N, 11.65; U, 16.01. Calc. for $C_{24}H_{72}Br_6N_{12}O_6P_4U$: C, 19.66; H, 4.95; N, 11.46; U, 16.23%.

2.2.2.2. $[UO_2(OPPh_3)_4](Br_3)_2$. Yield 1.623 g (75.8%). IR (cm^{-1}): ν(U=O) 925; ν(P=O) 1050. *Anal*. Found: C, 44.05; H, 3.15; U, 12.55. Calc. for $C_{72}H_{60}Br_6O_6P_4U$: C, 46.43; H, 3.25; U, 12.78%.

2.2.2.3. $[UO_2(OAsPh_3)_4](Br_3)_2$. Yield 2.27 g (94.4%). IR (cm^{-1}): ν(U=O) 901; ν(As=O) 840, 858. *Anal*. Found: C, 41.62; H, 2.94; U, 11.81. Calc. for $C_{72}H_{60}As_4Br_6O_6U$: C, 42.43; H, 2.97; U, 11.68%.

2.2.3. Preparation of a solution of UO_2I_2 in acetonitrile

Uranyl acetate was quantitatively transformed to $UO_2Cl_2 \cdot xH_2O$ by heating to dryness a solution of $UO_2(CH_3CO_2)_2 \cdot 2H_2O$ (0.5 g, 1.18 mmol) in a mixture of methanol (5 ml) and 35% hydrochloric acid (2 ml). The resulting $UO_2Cl_2 \cdot xH_2O$ was dissolved in acetonitrile (2 ml) and then a solution of 1.4 g (6.6 mmol) of NaI in acetonitrile (6 ml) was added. After stirring the mixture for 10 min the NaCl precipitated was filtered and washed with acetonitrile (2 × 1 ml). The clear red filtrate, consisting of a solution of UO_2I_2 and NaI in acetonitrile with some residual water, was used to prepare the polyiodides.

2.2.4. Preparation of $[UO_2L_4](I_3)_2$ ($L = HMPA$, $OPPh_3$, $OAsPh_3$)

The solution above prepared, containing about 1.15 mmol of UO_2I_2 in 10 ml of acetonitrile was treated with 1.21 g (4.76 mmol) of I_2 dissolved in 15 ml of acetonitrile. Then, 5 mmol of L in acetonitrile (15 ml) was added. After stirring the resulting mixture for 10 min the brown microcrystalline precipitate was filtered, washed with diethyl ether (3 × 2 ml) and dried under vacuum.

2.2.4.1. $[UO_2(HMPA)_4](I_3)_2$. Yield 1.858 g (90.06%). IR (cm^{-1}): ν(U=O) 917; ν(P=O) 1072. *Anal*. Found: C, 16.31; H, 4.02; N, 9.71; U, 13.39. Calc. for $C_{24}H_{72}I_6N_{12}O_6P_4U$: C, 16.49; H, 4.15; N, 9.61; U, 13.62%.

2.2.4.2. $[UO_2(OPPh_3)_4](I_3)_2$. Yield 1.75 g (69.14%). IR (cm^{-1}): ν(U=O) 920; ν(P=O) 1065. *Anal*. Found: C, 39.95; H, 2.83; U, 11.22. Calc. for $C_{72}H_{60}I_6O_6P_4U$: C, 40.32; H, 2.82; U, 11.10%.

2.2.4.3. $[UO_2(OAsPh_3)_4](I_3)_2$. Yield 2.588 g (93.42%). IR (cm^{-1}): ν(U=O) 890; ν(As=O) 850. *Anal*. Found: C, 36.76; H, 2.59; U, 10.08. Calc. for $C_{72}H_{60}As_4I_6O_6U$: C, 37.27; H, 2.61; U, 10.26%.

2.2.5. Preparation of $[UO_2L_4](I_7)_2$ ($L = HMPA$, $OPPh_3$, $OAsPh_3$)

A solution of UO_2I_2 in acetonitrile containing about 1.15 mmol of UO_2I_2 was treated successively with 16 g (18.9 mmol) of I_2 in acetonitrile (20 ml) and 5 mmol of L in acetonitrile (15 ml) at r.t. After stirring the resulting mixture for 10 min, the microcrystalline precipitate was filtered and dried under vacuum.

2.2.5.1. $[UO_2(HMPA)_4](I_7)_2$. Yield 2.941 g (90.19%). Blue black. IR (cm^{-1}): ν(U=O) 922; ν(P=O) 1065. *Anal*. Found: C, 10.96; H, 2.85; N, 6.72; U, 8.57. Calc. for $C_{24}H_{72}I_{14}N_{12}O_6P_4U$: C, 10.43; H, 2.63; N, 6.08; U, 8.61%.

2.2.5.2. $[UO_2(OPPh_3)_4](I_7)_2$. Yield 3.178 g (85.22%). Blue black. IR (cm^{-1}): ν(U=O) 918; ν(P=O) 1054. *Anal*. Found: C, 27.19; H, 1.87; U, 7.66. Calc. for $C_{72}H_{60}I_{14}O_6P_4U$: C, 27.37; H, 1.91; U, 7.53%.

2.2.5.3. $[UO_2(OAsPh_3)_4](I_7)_2$. Yield 3.784 g (96.138%). Brown black. IR (cm^{-1}): ν(U=O) 898; ν(As=O) 850, 858. *Anal*. Found: C, 39.38; H, 2.85; U, 7.07. Calc. for $C_{72}H_{60}As_4I_{14}O_6U$: C, 25.93; H, 1.81; U, 7.14%.

2.3. Crystal-structure determinations

Suitable single crystals were grown at r.t. by slow evaporation of saturated solutions in acetonitrile. Crystal data for $[UO_2(OAsPh_3)_4](Br_3)_2$: monoclinic, $P2_1/n$, $a = 9.383(1)$, $b = 15.150(1)$, $c = 26.358(1)$ Å, $\alpha = 90°$, $\beta = 94.668(1)°$, $\gamma = 90°$, $V = 3734.8(1)$ Å^3, $Z = 2$. Crystal data for $[UO_2(OPPh_3)_4](I_3)_2$: monoclinic, $P2_1/n$, $a = 9.407(1)$, $b = 15.739(1)$, $c = 26.189(1)$ Å, $\alpha = 90°$, $\beta = 98.366(1)°$, $\gamma = 90°$, $V = 3836.4(1)$ Å^3, $Z = 2$.

Crystals of $[UO_2(OAsPh_3)_4](Br_3)_2$ (block, orange, dimensions $0.50 \times 0.15 \times 0.10$ mm) and for $[UO_2(OPPh_3)_4](I_3)$ (block, orange, dimensions $0.20 \times 0.10 \times 0.05$ mm) were used for the structure determination. X-ray data were collected using a Bruker SMART CCD area detector single-crystal diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) by the phi-omega scan method. A total of 1271 frames of intensity data were collected for each compound. The first 50 frames were recollected at the end of data collection to monitor for decay. The integration processes yield a total 25 322 for $[UO_2(OAsPh_3)_4](Br_3)_2$ and 20 468 for $[UO_2(OPPh_3)_4](I_3)$, of which 9182 and 6782, respectively, were independent. Absorption corrections were applied using SADABS program (maximum and minimum transmission coefficients 0.5334 and 0.1235 for $[UO_2(OAsPh_3)_4](Br_3)_2$; and 0.8004 and 0.4559 for $[UO_2(OPPh_3)_4](I_3)$). The structures were solved using the Bruker SHELXTL-PC software by direct methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were included in calculated positions and refined in the riding mode. For $[UO_2(OAsPh_3)_4](Br_3)_2$ convergence was reached at a final $R_1 = 0.0440$ [for $I > 2\sigma(I)$], $wR_2 = 0.0910$ (for all data), 403 parameters, with allowance for the thermal anisotropy for all non-hydrogen atoms. Residual electron densities extremes were 1.253 and -0.919 e Å^{-3} and the goodness-of-fit on F^2 was 1.047 for all observed reflections. For $[UO_2(OPPh_3)_4](I_3)$ convergence was reached at a final $R_1 = 0.0553$ [for $I > 2\sigma(I)$], $wR_2 = 0.1204$ (for all data), 403 parameters, with allowance for the thermal anisotropy for all non-hydrogen atoms. Residual electron densities extremes were 1.476 and -1.622 e Å^{-3} and the goodness-of-fit on F^2 was 1.031 for all observed reflections. Crystal data and details on the data collection and refinement are given in the supplementary material.

3. Results and discussion

3.1. Synthesis and characterization of the complexes

The first evidence of the facile formation of uranyl tribromide complexes was obtained during the preparation of addition compounds of UO_2Br_2 (**4**). Thus, when 30% H_2O_2 was added to a solution consisting of UO_2Br_2, HBr, CH_3OH and $AsPh_3$ a product consistent with the formulation $[UO_2(OAsPh_3)_4](Br_3)_2$ was obtained. This was attributed to the simultaneous formation of $OAsPh_3$ and Br_2, and the subsequent rearrangement of the species in solution to form the tribromide complex. Following a more rational procedure—treatment of a solution of $UO_2Br_2 \cdot x H_2O$ in CH_3OH with Br_2 and then with $OAsPh_3$—we were able to prepare the same product in good yield. The tribromides containing $OPPh_3$ and HMPA were similarly isolated. The addition of bromine to the solution of uranyl bromide prior to the organic ligand is advisable. This way the precipitation of neutral $UO_2Br_2L_2$ adducts is avoided. However, to minimize side reactions of bromine with the organic ligands these should be added soon after the addition of bromine is completed.

In a similar manner a number of polyiodides can be easily isolated. The ability of iodide ions to form triiodides but also higher polyiodides allowed the isolation of a variety of compounds with the same uranyl cation and variable amount of iodine. Among them only the triiodides and 'heptaiodides' could be prepared in an accurate and reproducible manner. The triiodides could be obtained even with a significant excess of iodine above the stoichiometric. In this regard it is to note that the starting UO_2I_2 solution is rich in NaI so that a considerable excess of iodine is required to form species beyond I_3^-; and also that neither NaI nor NaI_n lead to precipitation with the organic ligands in these conditions. The 'heptaiodides' are formed with a large excess of iodine and likely they are authentic heptaiodides having in mind that the anion I_7^- is well known in many compounds [11]; however, at present we have been unable to obtain crystals of quality for the structural characterization.

All compounds are insoluble in water and diethyl ether, somewhat soluble in acetone and methanol, and very soluble in dimethyl formamide and dimethyl sulfoxide. Care should be exercised in the washing of the precipitates with diethyl ether, and in drying by pumping, as the halogen is easily removed from the polyhalide ions. They decompose before melting with liberation of the halogen.

The IR spectra of the compounds in the region 4000–400 cm^{-1} characterize by a strong band around 900 cm^{-1} characteristic for $\nu_{as}(UO_2)$ along with several bands attributable to the organic ligand. It is to note that $\nu_{as}(UO_2)$ shifts slight but regularly to lower energies, for each set of compounds with the same anion, in the sequence $OPPh_3 > HMPA > OAsPh_3$. This suggests that the basicity of the ligands [12] plays same role (*cis*-effect) on the strength of the U–O multiple bond, the more basic the ligand ($OAsPh_3$) the lower $\nu_{as}(UO_2)$. However, the nature of the anion also affects the position of this band as for compounds with the

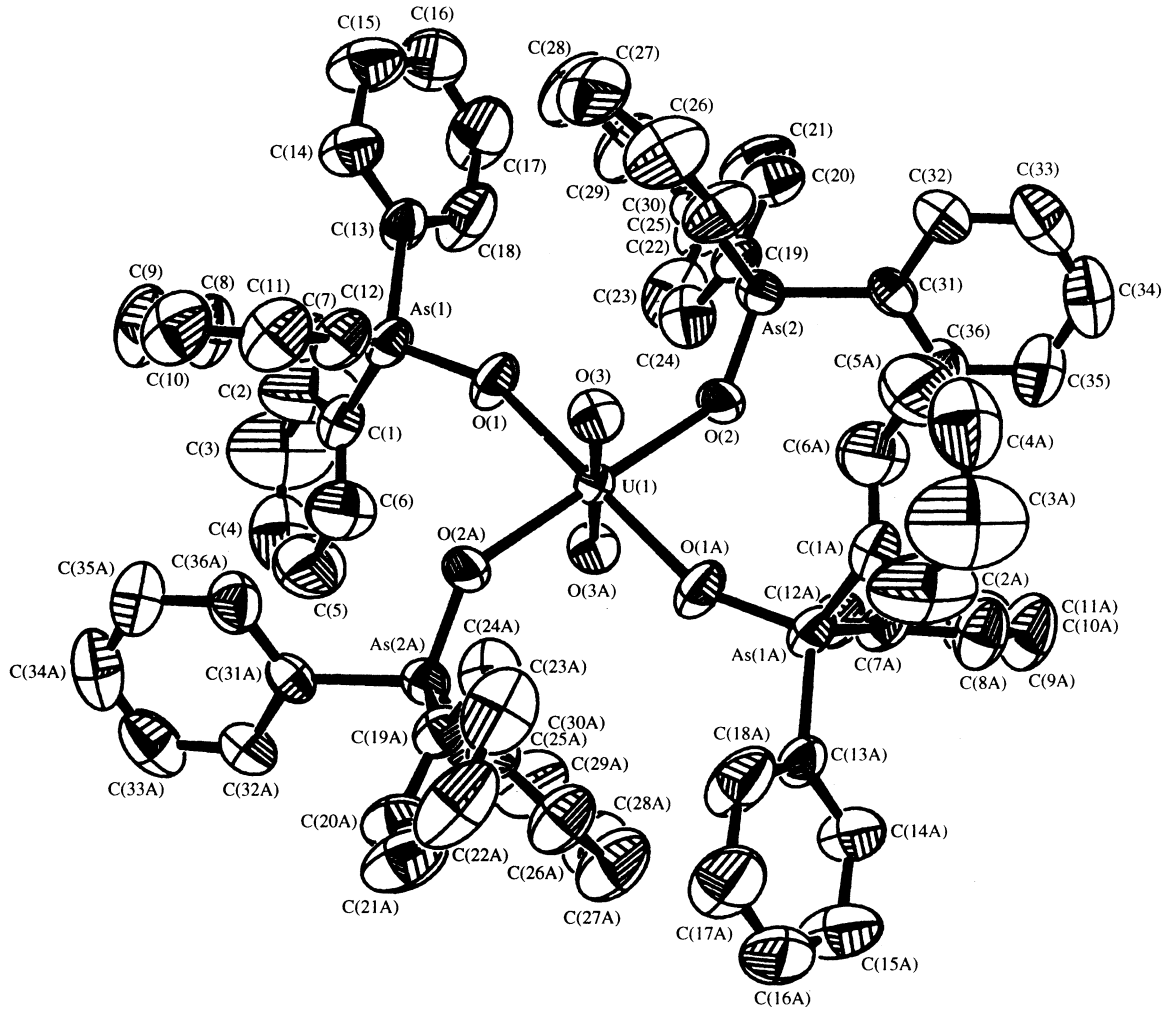

Fig. 1. Molecular structure and atom-labeling scheme for $[UO_2(OAsPh_3)_4](Br_3)_2$, (50% probability ellipsoids); hydrogen atoms are omitted.

same cation $\nu_{as}(UO_2)$ are only occasionally coincident. The bands assigned to ν(O=P) and ν(O=As) occur at lower frequencies in the complexes than in the free ligands as expected [13]. In this regard, it is worth noting that we have obtained products of composition $[UO_2(OAsPh_3)_4](Br_3)_2$ with three slightly different IR spectra (data reported in the experimental part belong to the product structurally characterized). This suggests the existence of conformational isomers for the cation, what can be extended to the other cations having in mind the steric requirements of these ligands and the precedent for all *trans*-$[UO_2Cl_2(OPPh_3)_2]$ [14].

Full characterization of the complexes through NMR is difficult. ^{31}P NMR spectra show that in solvents in which they are more soluble, DMF and DMSO, the ligands $OPPh_3$ and HMPA are totally displaced from the coordination sphere of uranium. The same occurs in methanol, despite the tribromides are prepared in this solvent. In acetone-d_6, at 20 °C, the ^{1}H NMR spectrum of $[UO_2(HMPA)_4](Br_3)_2$ shows two signals at $\delta = 2.92$ and 2.78 ppm (d, $J_{P-H} = 9.8$ Hz, intensity ratio = 5/6) that shift at $\delta = 2.88$ and 2.66 ppm (d, $J_{P-H} = 9.8$ Hz, intensity ratio = 3/2) at −70 °C. The ^{31}P NMR spectrum shows a broad signal at $\delta = 35.6$ ppm at 20 °C, and two signals at $\delta = 35.5$ and 29.7 ppm at −70 °C, far from the position for the free ligand ($\delta = 25.1$ ppm at 20 °C). Similar superior complexity was observed in the NMR of the other HMPA and $OPPh_3$ compounds. These findings are also consistent with the existence of conformational isomers for the cations in solution. However, this assumption should be regarded with caution as the polyhalide ions react with the solvent, and the reaction by-products may react with the cationic complexes.

3.2. Molecular structures

The molecular structures for the cations in $[UO_2(OAsPh_3)_4](Br_3)_2$ (**1**) and $[UO_2(OPPh_3)_4](I_3)_2$ (**2**) are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles are listed in Table 1.

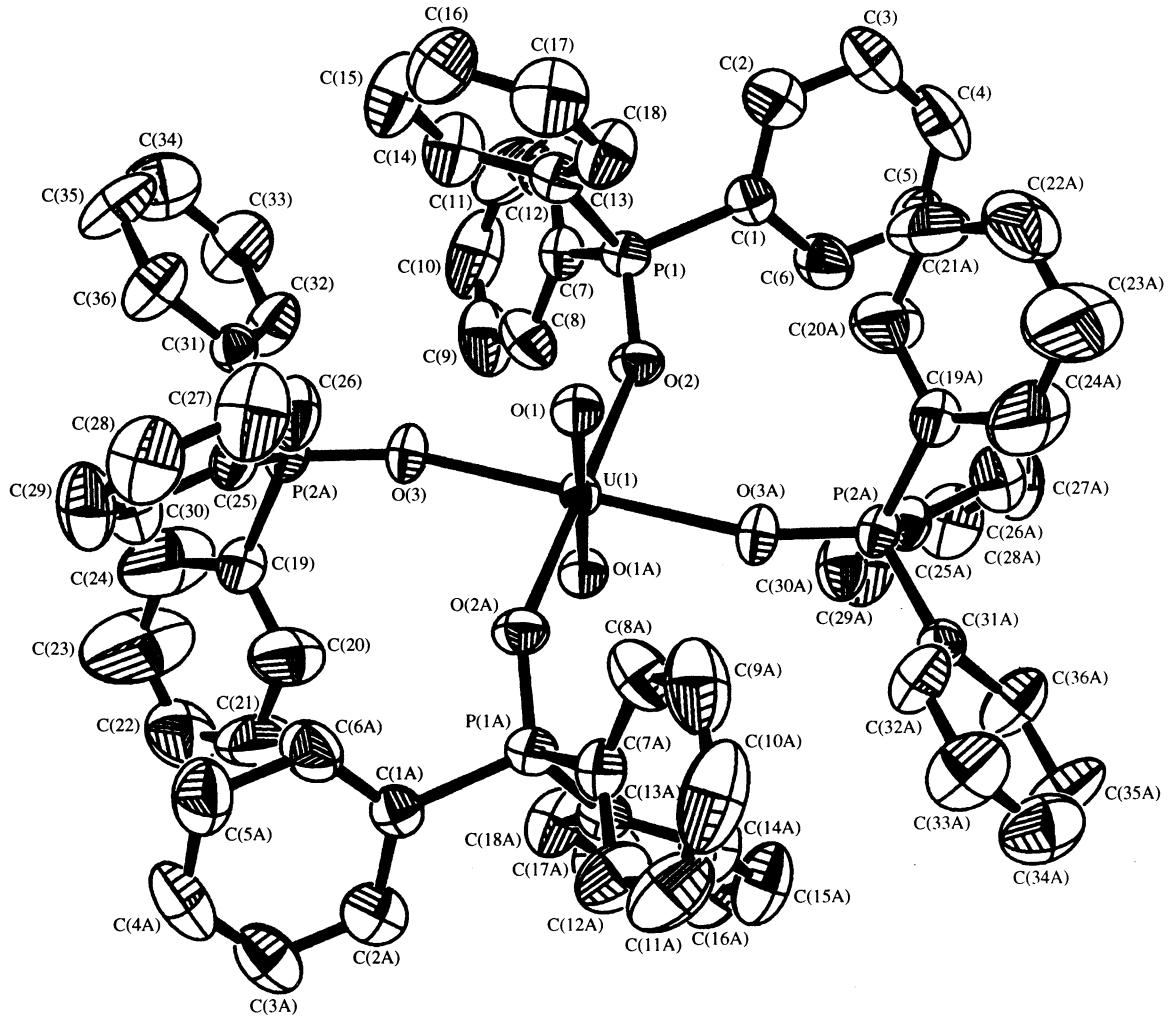

Fig. 2. Molecular structure and atom-labeling scheme for $[UO_2(OPPh_3)_4](I_3)_2$, (50% probability ellipsoids); hydrogen atoms are omitted.

Table 1
Selected bond lengths (Å) and angles (°) for $[UO_2(OAsPh_3)_4](Br_3)_2$ and $[UO_2(OPPh_3)_4](I_3)_2$

$[UO_2(OAsPh_3)_4](Br_3)_2$ (**1**)		$[UO_2(OPPh_3)_4](I_3)_2$ (**2**)	
Bond lengths			
U(1)–O(3)	1.772(3)	U(1)–O(1)	1.753(5)
U(1)–O(1)	2.265(3)	U(1)–O(2)	2.302(6)

As(2)–O(2)–U(1)	140.4(2)	U(1)–O(2)–P(1)	146.9(4)
Br(3)–Br(2)–Br(1)	179.06(6)	I(3)–I(2)–I(1)	179.75(5)

As expected, the uranium is coordinated in a pseudo-octahedral fashion by two *trans*-oxo and four O-donor ligands in the equatorial plane. Comparison with related complexes is difficult, as these are the unique uranyl tribromides structurally identified, and only one uranyl triiodide has been fully characterized [8]. In **1** there are three couples of identical U-ligand distances associated to each pair of *trans*-ligands. In **2** the four U–O distances in the equatorial plane are virtually identical. The trihalide ions in **1** and **2** are almost linear and symmetrical, with distances and angles in the range of other trihalides [11].

The distances U–O(oxo) in **1** (1.772) and **2** (1.753) are typical for uranyl compounds [15]. The somewhat larger distance in **1** might be derived from the superior basicity of $OAsPh_3$ respect to $OPPh_3$. This may cause reduction in π-donation from the oxo ligands to the uranium with concomitant decreasing in the strength of the bonds within the uranyl entity. Consistent with this assumption are the distances U–O(P,As), shorter in **1** than in **2**, and the position of $\nu_{as}(UO_2)$ before commented. The ex-

istence of two pairs of slightly different distances in **1** may be due only to packing forces. Indeed, several uranyl complexes of composition UO_2L_4 as for example $[UO_2Br_4]^{2-}$ in $(NMe_4)_2[UO_2Br_4]$ [16] and $[UO_2(HMPA)_4]^{2+}$ in $[UO_2(HMPA)_4](ClO_4)_2$ [10] display two and four different U–L distances, respectively, despite the counterions possess high symmetry. It is to note that the mean U–O(P) distance in **2**, 2.305, is slightly superior to that in the closely related $[UO_2(HMPA)_4](I_3)_2$, 2.292 [8], as expected from the lower basicity of $OPPh_3$ with regard to HMPA.

The angles O(oxo)–U–O(oxo), O(oxo)–U–O(P,As) and O(P,As)–U–O(P,As) are close to 180°, 90° and 90°, respectively, in both cations. In **1** the angles U–O–As, 154.2° and 140.4°, are identical for each pair of *trans*-ligands, both within the wide range of values found in UO_2–$OAsPh_3$ complexes [4,17–19]. The same is applicable to the angles U–O–P in **2**, 146.0° and 159.2°, also in the range of other UO_2–$OPPh_3$ complexes (for example in $[UO_2(NCS)_2(OPPh_3)_2(Me_2CO)]$ the angles are 143.3° and 163.3° [20]).

Finally, the orientation of the equatorial ligands is similar in both complexes. The cations are centrosymmetric with regard to the $UO_2(OX)_4$ (X = P, As) group. Two of opposite X atoms are oriented toward the bisection of adjacent O(oxo)–U–O(X) angles while the other two X atoms lye close to the equatorial plane (dihedral angles for As(2)–O(2)–U(1)–O(3) = 42.92°, for As(1)–O(1)–U(1)–O(2) = 5.57°, for P(1)–O(2)–U(1)–O(1) = 43.13°, for P(2)–O(3)–U(1)–O(2) = 7.29°). We believe there are several possible conformations of similar energy for the group $U(OX)_4$ (square planar UO_4, non-linear U–O–X). The adoption of a particular conformation is likely determined by packing forces. However, the steric demand of these ligands may lead to restraints in free rotation and consequently to the existence of stable conformers for these cations no only as solid salts but also in solution. Studies to get further insight on this possibility are in progress with salts involving anions more stable than polyhalides.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 186697 and 186698 for $[UO_2(OAsPh_3)_4][Br_3]_2$ and $[UO_2(OPPh_3)_4][I_3]_2$, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

MeCN, 0.1 M TEAP) was done at a platinum electrode under nitrogen atmosphere on a PAR model 370-4 electrochemistry system [10]. EPR measurements were made at X-band using Varian E-109C spectrometer fitted with a quartz dewar. The relevant parameters are: microwave frequency, 9.1–9.2 GHz; modulation, 100 kHz; power 30 dB; sweep center 3300 G; sweep width 250 G; sweep time, 240 s. Microanalyses (C, H, N) were done by using a Perkin–Elmer 2400C Series II elemental analyzer. Magnetic moments were measured by using a PAR-155 vibrating sample magnetometer.

2.2. Synthesis of chlorocarbonyl(3,5-ditertiarybutyl-o-benzosemiquinone)bis (triphenylphosphine)ruthenium(II), [Ru(dbsq)(Cl)(CO)(PPh$_3$)$_2$] (**5**)

A solution of dbq (89 mg, 0.40 mmol) in ethanol (20 ml) was purged with N_2 for 15 min. To it was added [Ru(H)(Cl)(CO)(PPh3)3] (100 mg, 0.10 mmol) and the reaction mixture was heated to reflux under nitrogen for 2 h. The resulting greenish blue solution was allowed to cool to room temperature (r.t.) affording a dark solid which was filtered off and washed with a little *n*-hexane and then dried in air. The solid was recrystallized from ethanol and then from dichloromethane–hexane solution. Yield: (51 mg, 53%). *Anal*. Calc. for $C_{51}H_{50}ClO_3P_2Ru$: C, 67.36; H, 5.54. Found: C, 67.52; H, 5.42%. UV–Vis [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 238(28 890), 256(23 590), 502(1985), 642(2390), 878(820), 1002(sh)(615). IR (KBr, cm^{-1}): 1939 (CO), 1410 (sq).

2.3. Synthesis of chlorocarbonyl(tetrachloro-o-benzosemiquinone)bis(triphenylphosphine)-ruthenium(II), [Ru(tcsq)(Cl)(CO)(PPh$_3$)$_2$] (**6**)

The quinone tcq (99 mg, 0.40 mmol) was dissolved in dry benzene (20 ml) and purged with nitrogen for 15 min. To this solution was added [Ru(H)(Cl)(CO)(PPh$_3$)$_3$] (100 mg, 0.10 mmol) and the mixture was heated to reflux under nitrogen for 4 h. The initial bluish green colour changed to dark blue. The solution was then cooled to r.t. and filtered to remove unreacted starting materials. The solvent was stripped from the filtrate under reduced pressure. The residue thus obtained was extracted with hexane. The extract was subjected to chromatography on silica gel. The [Ru(tcsq)(Cl)(CO)(PPh$_3$)$_2$] complex moved as a blue band with benzene. The solid obtained by stripping benzene was recrystallized from dichloromethane–hexane to yield the blue complex in pure form. Yield: (52 mg, 53%). *Anal*. Calc. for $C_{43}H_{30}Cl_5O_3P_2Ru$: C, 55.24; H, 3.23. Found: C, 55.57; H, 3.60%. UV–Vis [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 230(45 030), 370(3630), 502(sh)(1240), 608(2150), 674(2120), 744(2425), 934(940), 1058(940). IR (KBr, cm^{-1}): 1959 (CO), 1422 (sq).

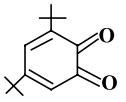
2.4. Synthesis of carbonyl(tetrachloro-o-benzosemiquinone)hydridobis(triphenylphosphine)-ruthenium(II), [Ru(tcsq)(H)(CO)(PPh$_3$)$_2$] (7)

The quinone tcq (107 mg, 0.44 mmol) was dissolved in dry benzene (20 ml) and purged with nitrogen for 15 min. To this solution was added [Ru(H)$_2$(CO)(PPh$_3$)$_3$] (100 mg, 0.11 mmol) and the mixture was heated to reflux under nitrogen for 2 h. The reaction mixture was then cooled to r.t. and the solvent removed under reduced pressure. The residue was extracted with dichloromethane and subjected to chromatography on silica gel followed by further recrystallization in the same manner as in the case of (**6**). Yield: (56 mg, 57%). *Anal*. Calc. for $C_{43}H_{31}Cl_4O_3P_2Ru$: C, 57.35; H, 3.47. Found: C, 56.81; H, 3.38%. UV–Vis [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 230(49 020), 272(23 455), 336(4190), 368(3830), 496(sh)(1135), 610(2180), 754(2790), 1060(1260). IR (KBr, cm^{-1}): 1961(CO), 1421(sq), 2050 (hydride).

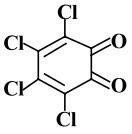
2.5. X-ray crystallography

Single crystals of compound [Ru(dbsq)(Cl)(CO)-(PPh$_3$)$_2$] were grown by slow diffusion of hexane into dichloromethane solution of the complex. Cell parameters were determined by the least-squares fit of 30 machine-centered reflections ($14^\circ \le 2\theta \le 28^\circ$). Data were collected by the ω-scan technique on a Siemens R3m/V four circle diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at 25 °C in the range $3^\circ \le 2\theta \le 48^\circ$. Two check reflections measured after every 198 reflections showed no significant intensity reduction. All data were corrected for Lorentz-polarization effects, an empirical absorption correction was done on the basis of azimuthal scan of six reflections [11]. The metal atom was located from a Patterson map and the rest of the non-hydrogen atoms emerged from successive Fourier synthesis. The structure was refined by full-matrix least-squares procedure on F^2. All non-hydrogen atoms were refined anisotropically and hydrogen atoms added at calculated positions. All calculations for data reduction and structure solution and refinement were done by using the SHELXTL V5.03 [12] Program package. Significant crystal data are listed in Table 1.

3. Results and discussion



3.1. Synthesis



The starting materials for synthesis are quinones and hydridic carbonyl ruthenium(II) species. Specific items and the isolated semiquinone radical species are listed and numbered in Scheme 1. The semiquinone complexes [Ru(dbsq)(Cl)(CO)(PPh$_3$)$_2$] and [Ru(tcsq)(Cl)(CO)-(PPh$_3$)$_2$] were synthesized by reacting [Ru(H)(Cl)(CO)-

Table 1

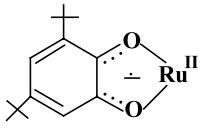
(PPh$_3$)$_3$] with fourfold excess of quinones in dry solvents under an inert atmosphere. The dihydride [Ru(H)$_2$(CO)(PPh$_3$)$_3$] similarly afforded the semiquinone complex [Ru(tcsq)(H)(CO)(PPh$_3$)$_2$] which is unusual in having hydride as a coligand. The basic synthetic reaction is stated in Eq. (2). The



$$\text{Ru–H} + \text{q} \rightarrow \text{Ru(sq)} + 1/2\text{H}_2 \qquad (2)$$

semiquinone chelates occur as dark colored solids which afford blue solutions in organic solvents. The present work adds a notable dimension in Ru^{II}(sq) chemistry [13] in terms of the new synthetic method and in terms of realization of model semiquinone binding, vide infra. The reported methods for the synthesis of ruthenium semiquinonates include chelation of preformed semiquinone salts [14], oxidation of preformed catecholate complexes [15–17], oxidative addition of quinones [18–20] and reductive addition of catechols [18]. Structurally characterized semiquinone species include two monochelates viz. [Ru^{II}(dbsq)(bpy)$_2$]$^+$ and [Ru^{III}(dbsq)(PPh$_3$)$_2$Cl$_2$] and a few bis-chelates having the Ru(sq)$_2$ fragment [18,20–23].

3.2. Structure

The chelate [Ru(dbsq)(Cl)(CO)(PPh$_3$)$_2$] (**5**) afforded good single crystals and a molecular view in shown in Fig. 1. Selected bond parameters are listed in Table 2. In the pseudooctahedral RuCClO$_2$P$_2$ coordination sphere the *trans* RuP$_2$ fragment defines a nearly linear axis (P(2)–Ru–P(1) ~ 177.81(5)°). The metal and the donors O1, O2, C51 and Cl make a satisfactory equatorial plane of mean deviation 0.04 Å. The Ru(dbsq) fragment minus the *t*-butyl groups is approximately planar (mean deviation of 0.04 Å) and it makes a dihedral angle of 7.2° with the virtually perfect Ru(CO)(Cl) plane.

In the Ru(dbsq) fragment, the two C–O lengths, 1.291(6) and 1.296(6) Å, are equal within experimental error. The C37–C38, C39–C40, C40–C41 and C37–C42 distances are significantly longer (average, 1.43 Å) than the C39–C40 and C41–C42 distances (average, 1.36 Å). These bond length trends are diagnostic of model semiquinonoid binding as in **8** [13,24]. To our knowledge the only other structurally characterized semiquinone monochelate of bivalent ruthenium is [Ru^{II}(dbsq)(bpy)$_2$]$^+$ wherein the bonding is complicated by two unequal C–O distances [25].

8

It is instructive to compare metal–ligand bond distances of **5** with that of the trivalent complex [Ru^{III}(dbsq)(PPh$_3$)$_2$Cl$_2$] (**9**) [18] which is formally related to **5** via substitution of the carbon monoxide ligand by a chloride ligand with concomitant increase of the metal oxidation level by one unit. Since the Ru–O and Ru–Cl bonds are primarily σ in character, their average lengths in **5** are larger than those in **9** by ~0.05 Å reflecting the logical σ-radius trend Ru^{II} > Ru^{III}. On the other hand, the average Ru–P length in **5** is shorter than that in **9** by 0.02 Å. This is attributed to Ru^{II}–P back bonding in **5**. The bonding is evidently strong enough to more than offset the above noted σ-trend. Trivalent ruthenium (as in **9**) can at best be a very weak π-base [26,27].

3.3. Magnetism and spectra

The semiquinone chelates are paramagnetic ($s = 1/2$), (Table 3) and in the microcrystalline state display an EPR line at $g \sim 2.00$. In fluid solution a three-line

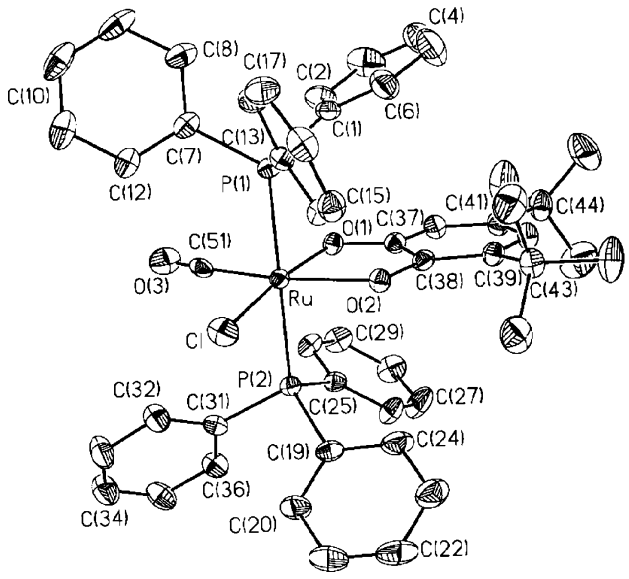


Fig. 1. ORTEP plot (30% probability ellipsoids) and atom labelling scheme for $[Ru(dbsq)(Cl)(CO)(PPh_3)_2]$ (**5**).

superhyperfine structure ($A_{iso} \sim 17$ G) due to coupling with two *trans*-^{31}P atoms is resolved [28]. EPR spectral parameters are listed in Table 3 and a representative spectrum is shown in Fig. 2. IR and electronic spectral data are listed in the Section 2. In IR a semiquinone CO stretch [17] occurs in the region 1410–1425 cm^{-1}. In $[Ru(tcsq)(H)(CO)(PPh_3)_2]$, the Ru–H stretch is clearly observed as a weak but sharp band at 2050 cm^{-1}. The stretching frequency of the carbon monoxide ligand increases from 1939 to 1959 cm^{-1} in going from $[Ru(dbsq)(Cl)(CO)(PPh_3)_2]$ to $[Ru(tcsq)(Cl)(CO)(PPh_3)_2]$, consistent with electron withdrawal by chloro substituents in tcsq. All the semiquinone complexes display a few bands of moderate intensity in the region 500–1100 nm presumably due to CT transitions from split t_2 components of the metal to sq π*-orbitals [17,29].

3.4. Electrochemistry

Two one-electron cyclic responses are observed for each complex in acetonitrile solution. The responses at higher and lower potentials are, respectively, assigned to the coordinated q–sq and sq–cat couples (cat is catechloate). Reduction potential data are given in Table 4 and representative voltammograms are shown

Table 3
Bulk magnetic moments and EPR g values at 298 K

Compound	Polycrystalline		Solution	
	μ_{eff} (μ_B)	g (ΔH_{pp} [a](G))	g_{iso}	A_{iso}
$[Ru(dbsq)(Cl)(CO)(PPh_3)_2]$	1.90	2.003(25)	2.002	17
$[Ru(tcsq)(Cl)(CO)(PPh_3)_2]$	1.84	2.002(30)	2.004	16.5

Table 4
Cyclic voltammetric data in acetonitrile solution (0.1 M TEAP) [a]

Compound	$E_{1/2}$ (V) (ΔE_P (mV))	
	q/sq	sq/cat
$[Ru(dbsq)(Cl)(CO)(PPh_3)_2]$	0.42 (80)	−0.55 (140)
$[Ru(tcsq)(Cl)(CO)(PPh_3)_2]$	0.87 (60)	+0.05 (60)
$[Ru(tcsq)(H)(CO)(PPh_3)_2]$	1.00 (60)	+0.15 (80)

[a] Conditions: working electrode, platinum; reference electrode, SCE; scan rate 50 mV s^{-1}. $E_{1/2} = 1/2(E_{pa} + E_{pc})$, where E_{pa} and E_{pc} are the anodic and cathodic peak potentials, respectively; $\Delta E_p = E_{pa} - E_{pc}$.

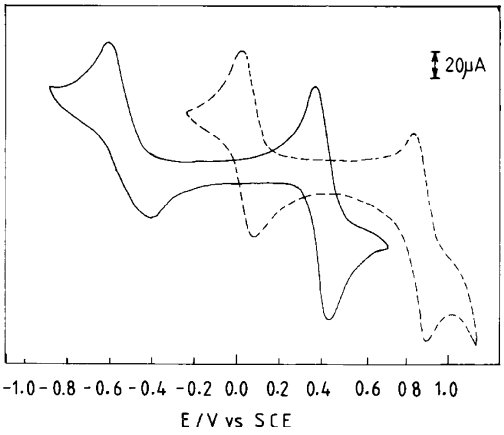

Fig. 3. Cyclic voltammograms of [Ru(dbsq)(Cl)(CO)(PPh_3)$_2$] (**5**) (—) and [Ru(tcsq)(Cl)(CO)(PPh_3)$_2$] (**6**) (– – –) in acetonitrile solution.

in Fig. 3. The $E_{1/2}$ values undergo a shift of $\sim$500 mV to higher potentials in going from **5** to **6** consistent with effects of substituents (*t*-Bu vs. Cl) [30]. Upon replacement of the chloride ligand by hydride (**6**→**7**), the $E_{1/2}$ values move further to higher potentials by $\sim$100 mV due to weaker *trans*-metal electron donation by hydride compared with chloride.

4. Conclusion

It is demonstrated that homolytic cleavage of an Ru–H bond by *o*-quinones constitute an excellent method for synthesis of semiquinone monochelates of carbonylruthenium(II) (**5**–**7**). Structure determination of **5** has revealed model semiquinone character of the chelating ligand which has four long and two short ring C–C bonds and two equal C–O bonds.

Solution EPR spectra of **5**–**7** are characterized by the presence of superhyperfine coupling of the radical anion electron with ^{31}P atoms. The q/sq and sq/cat $E_{1/2}$ values are more positive in [Ru(tcsq)(Cl)(CO)(PPh_3)$_2$], and [Ru(tcsq)(H)(CO)(PPh_3)$_2$] than in [Ru(dbsq)(Cl)(CO)-(PPh_3)$_2$]. Correspondingly, the carbon monoxide stretching frequency is lower in **5**.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 169368 for compound **5**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

using FX-80-Q Fourier transform NMR spectrometer. Electronic spectra were recorded on a Hewlett–Packard 8452 A spectrophotometer in the range 250–820 nm. The IR spectra were recorded on a Hitachi 270-50 spectrophotometer in the range 400–4000 cm^{-1}. The cyclic voltammograms were obtained on an apparatus comprising a PAR model 173 potentiostat/galvanostat, 175 universal programmer, 176 current follower and 179 coulometer. Conductivity measurements of the complexes were determined on an Elico model SX80 conductivity bridge using freshly prepared solutions of the complexes in DMF. For cyclic voltammetry three electrode systems were used in which the counter and working electrodes were platinum foils (1 cm^2) and the reference electrode was Ag/AgCl. Ferrocene/ferrocenium(1+) couple was used as an internal standard. All potentials are reported relative to the Ag/AgCl reference electrode. The $E_{1/2}$ of the ferrocenium/ferrocene (Fc^+/Fc) couple under the experimental condition is 470 mV in DMF and ΔE_p for Fc^+/Fc is 70 mV. IR compensation was not applied. All electrochemical measurements were carried out in solutions purged with analor nitrogen gas for 30 min prior to each experiment. Variable-temperature magnetic studies were performed on a PAR model 155 vibrating-sample magnetometer in the temperature range 77–300 K, and the instrument was calibrated using metallic nickel. Room temperature magnetic moments of the complexes were determined using a Guoy balance. $Hg[Co(SCN)_4]$ was used as the reference. X-band EPR spectra were recorded on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference.

2.2. Materials

5-Methylsalicylaldehyde and 6,6′-piperazine-1,4-diyl-dimethylenebis(4-methyl-2-formyl-phenol) (P.C-I) was prepared by following the literature method [11]. Tetrabutylammoniumperchlorate (TBAP) was obtained from Fluka and recrystallized from methanol. (**Caution**! All perchlorate salts are explosive and hence care should be taken while handling). DMF (HPLC) was obtained from Qualigens and used as such. All other chemicals and solvents were of reagent grade and used as received.

2.3. Synthesis of complexes

All the oxime binuclear complexes were prepared [12] by a stepwise synthesis. Reaction of P.C-I with M(II) (M = Ni or Cu) acetate led to the isolation of mononuclear complex. Further reaction with 1 equiv. of the appropriate divalent metal ion, hydroxylamine hydrochloride and triethylamine gave the binuclear complex Scheme 1.

2.4. Synthesis of mononuclear complexes

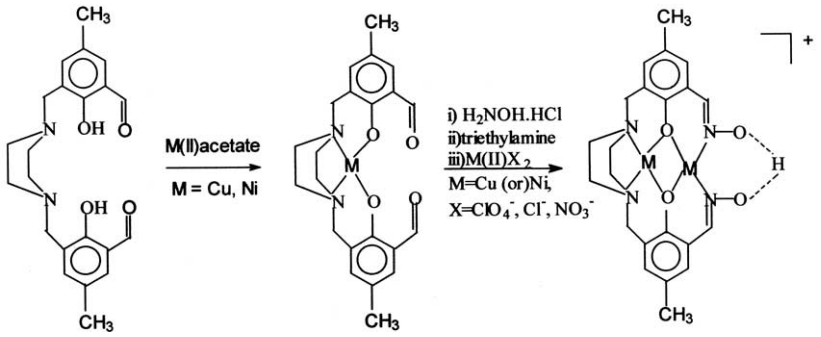
2.4.1. [NiL]

Nickel(II) acetate (2.48 g, 10 mmol) dissolved in methanol (25 ml) was added to P.C-I (3.82 g, 10 mmol) dissolved in $CHCl_3$–MeOH(40 ml, 1:1) under boiling condition and refluxed for 1 h. The orange coloured precipitate formed was collected by filtration, washed with $CHCl_3$ followed by MeOH and dried. *Anal*. for $C_{22}H_{24}N_2O_4Ni$: Found: C, 60.12; H, 5.39; N, 6.54; Ni, 13.25. Calc. C, 60.17; H, 5.47; N, 6.39; Ni, 13.37%. Selected IR data (ν cm^{-1} using KBr): 3320(br), 1670(s) cm^{-1} (br, broad, str, strong, s, sharp, m, medium).

2.4.2. [CuL]

Copper(II) acetate (1.99 g, 10 mmol) dissolved in methanol (25 ml) was added to P.C-I (3.82 g, 10 mmol) dissolved in $CHCl_3$–MeOH (40 ml, 1:1) under boiling condition and refluxed for 1 h. The orange coloured precipitate formed was collected by filtration, washed with $CHCl_3$ followed by MeOH and dried. *Anal*. for $C_{22}H_{24}N_2O_4Cu$: Found: C, 60.01; Cu, 14.64; H, 5.21; N, 6.41. Calc. C, 59.52; Cu, 14.32; H, 5.41; N, 6.31%. Selected IR data (ν cm^{-1} using KBr): 3310(br), 1665(s) cm^{-1}.

2.5. Synthesis of binuclear complexes



2.5.1. $[Ni_2L](ClO_4)\cdot CH_3OH$ (1)

$Ni(ClO_4)_2\cdot 6H_2O$ (0.91 g, 2 mmol) in methanol (30 ml) was added to a suspension of [NiL] (0.87 g, 2 mmol) in MeOH (30 ml) and hydroxyl amine hydrochloride (0.14 g, 2 mmol) in the presence of triethylamine (2 mmol) with stirring. The resulting orange colored product was obtained by evaporation of the solvent and collected by filtration, washed with methanol and recrystallized from DMF–MeOH. *Anal*. for $C_{22}H_{25}N_4O_4Ni_2(ClO_4)\cdot CH_3OH$: Found: C, 41.39; H, 4.14; N, 8.62; Ni, 17.80. Calc. C, 41.95; H, 4.40; N, 8.51; Ni, 17.84%. Selected IR (KBr disc, ν cm^{-1}): 3320(br), 2350(str), 1630(str), 1586, 1112, 1070(s), 620(s). UV–Vis [λ_{max} nm (ε M^{-1} cm^{-1})] in DMF: 670(250), 417(sh), 302(6190), 270(8880). Molar conductance [Λ_M S (cm^2 Ω^{-1} mol^{-1})] in DMF: 78.

The above procedure was used for the following oxime complexes by varying the metal(II) salt (salt = chloride, nitrate, perchlorate).

2.5.2. $[Ni_2L(Cl)]H_2O$ (2)

Orange colored solid. *Anal*. for $C_{22}H_{25}N_4O_4Ni_2(Cl)\cdot H_2O$: Found: C, 45.72; H, 4.45; N, 9.52; Ni, 20.12. Calc. C, 45.53; H, 4.65; N, 9.65; Ni, 20.24%. Selected IR (KBr disc, ν cm^{-1}): 3450(br), 2360(m), 1625(str), 1556, 1152(s), 1112(s) 762. UV–Vis [λ_{max} nm (ε M^{-1} cm^{-1})] in DMF: 740(sh), 620(206), 328(5910),

Scheme 1.

270(10 000). Molar conductance [Λ_M S (cm^2 Ω^{-1} mol^{-1})] in DMF: 84.

2.5.3. $[Cu_2L](ClO_4)\cdot CH_3OH$ (3)

Dark green colored solid. *Anal*. for $C_{22}H_{25}N_4O_4Cu_2(ClO_4)\cdot CH_3OH$: Found: C, 41.13; Cu, 19.12; H, 4.24; N, 8.65. Calc. C, 41.37; Cu, 19.04; H, 4.34; N, 8.39%. Selected IR (ν cm^{-1} using KBr): 3423(br), 2374(m), 1630(str), 1593, 1096(s), 620. UV–Vis [λ_{max} nm (ε M^{-1} cm^{-1})] in DMF: 600(286), 326(3760), 268(8070). Molar conductance [Λ_M S (cm^2 Ω^{-1} mol^{-1})] in DMF: 71.

2.5.4. $[Cu_2L(Cl)]H_2O$ (4)

Green colored solid. *Anal*. for $C_{22}H_{25}N_4O_4Cu_2Cl\cdot H_2O$: Found: C, 44.73; Cu, 21.28; H, 4.52; N, 8.98. Calc. C, 44.78; Cu, 21.54; H, 4.58; N, 9.50%. Selected IR (ν cm^{-1} using KBr): 3410(br), 2335(m), 1625(str), 1556, 1124(s), 1020(s) 762. UV–Vis [λ_{max} nm (ε M^{-1} cm^{-1})] in DMF: 680(sh), 614(304), 324(2780), 266(7870). Molar conductance [Λ_M S (cm^2 Ω^{-1} mol^{-1})] in DMF: 86.

2.5.5. $[Cu_2L(NO_3)]\cdot H_2O$ (5)

Green colored solid. *Anal*. for $C_{22}H_{25}N_4O_4Cu_2(NO_3)\cdot H_2O$: Found: C, 42.68; Cu, 20.35; H, 4.58; N, 11.61. Calc. C, 42.85; Cu, 20.61; H, 4.38; N, 11.36%. Selected IR (ν cm^{-1} using KBr): 3250(br), 2362(m), 1625(str), 1745, 1703(s), 1158, 1124(s). UV–Vis [λ_{max} nm (ε M^{-1} cm^{-1})] in DMF: 720(sh), 620(206), 384(5980), 307(8460). Molar conductance [Λ_M S (cm^2 Ω^{-1} mol^{-1})] in DMF: 75.

3. Results and discussion

All the oxime complexes were prepared by stepwise synthetic method. The IR spectral data of the mononuclear complexes M(II) (M = Ni or Cu) show a peak around 1670 cm^{-1} due to –CHO group. This peak disappears and a new peak due to ν(C=N) [13,14] appears around 1625 cm^{-1} for binuclear complexes. Binuclear complexes show a peak observed around 2350 cm^{-1} attributed to O···H···O hydrogen-bond fragment. A peak due to N–O bond [15,16] is observed around 1112–1280 cm^{-1}.

The complexes $[Ni_2L](ClO_4)$ (**1**) and $[Cu_2L](ClO_4)$ (**3**) show a broad peak due to uncoordinated perchlorate ion [17] around 1090 and 620 cm^{-1}. For $[Cu_2L(NO_3)]$ (**5**) two peaks have been observed at 1703 and 1745 cm^{-1} due to coordinated nitrate ion [18,19].

The electronic spectra were recorded in DMF solvent in the region 260–820 nm. The nickel complexes $[Ni_2L](ClO_4)$ complex shows a single weak d–d band at 670 nm ($\varepsilon = 250$ M^{-1} cm^{-1}) due to $^1A_1g \rightarrow {}^1A_2g$ transition [20,21] associated with square planar geometry. The two compartments in the binuclear complexes have N_2O_2 coordinating sites in the equatorial position. So, the d–d transition of the two Ni(II) ions in square planar geometry absorbs more or less same region. The two peaks are very close to each other and give rise to a single broad spectrum. The complex $[Cu_2L](ClO_4)$ shows a single weak d–d transition [600 nm ($\varepsilon = 486$ M^{-1} cm^{-1})] associated with square planar geometry. The complex $[Cu_2L(Cl)]$, $[Cu_2L(NO_3)]$, $[Ni_2L(Cl)]$ shows two d–d transition. This shows the coordination of counter ion to one of the copper(II) ion and has square pyramidal geometry. Moderately intense band observed in the region 320–400 nm ($\varepsilon = 1580$–5910 M^{-1} cm^{-1}) is associated with ligand to metal charge transfer transition while intense transition observed around 290 nm ($\varepsilon = 7860$–$10\,000$ M^{-1} cm^{-1}) is due to ligand to ligand charge transfer transition.

3.1. Electrochemistry of the complexes

The electrochemical properties of the binuclear complexes were studied by using cyclic voltammetry in DMF solution containing TBAP as supporting electrolyte in the potential range +1.3 to −1.3 V. The electrochemical data are given in Tables 1 and 2. The cyclic voltammogram of the complexes is shown in Figs. 1 and 2.

Generally the electrochemical properties of the complexes depend on a number of factors such as chelate ring/size [22,23] axial ligation [24,25], degree and distribution of unsaturation [26] and substitution pattern [27] in the chelate ring.

Table 1

5	$[Cu_2L(NO_3)]\cdot H_2O$	−0.18	−0.08	100	−0.13	−1.18	−0.95	230	−1.06

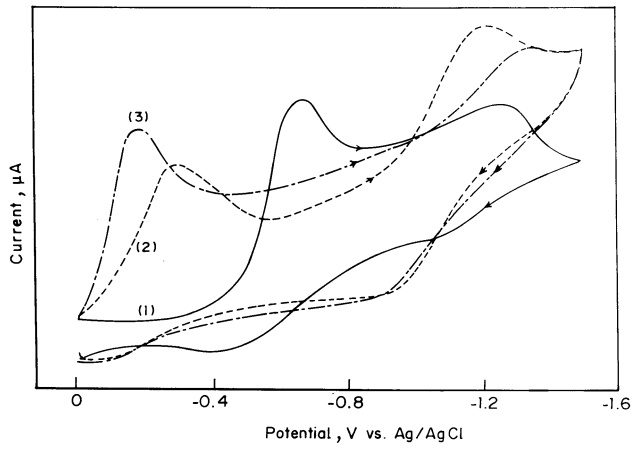

Fig. 1. Cyclic voltammograms of the copper complexes: $[Cu_2L](ClO_4)$ (**3**), $[Cu_2L(Cl)]$ (**4**), $[Cu_2L(NO_3)]$ (**5**) in dmf, scan rate 50 mV s^{-1}. Potential are given in V vs. Ag/AgCl; platinum working and Ag/AgCl reference electrodes; supporting electrolyte TBAP; concentration of complex 1×10^{-3} M, concentration of TBAP 1×10^{-1} M.

3.1.1. Reduction process

All the complexes show a quasi-reversible two step single electron transfer process as it is evidenced from the criteria: the $E_{1/2}$ values are independent of scan rate; the ΔE_p increases with increasing scan rate and is always greater than 60 mV. The peak currents i_{pc} and i_{pa} are not equal. Controlled potential electrolysis carried out at 100 mV more negative than the first reduction wave confirms the consumption of one electron per molecule ($n = 0.95$). Controlled potential electrolysis conducted at 100 mV more negative than second reduction wave confirmed the consumption of two electrons per molecule.

$[Cu_2L(Cl)]$ ($E_{pc} = -0.28$ V) and $[Cu_2L(NO_3)]$ ($E_{pc} = -0.18$ V) reduces at less negative potential compared with $[Cu_2L](ClO_4)$ ($E_{pc} = -0.62$ V) (Fig. 1). Similarly, $[Ni_2L(Cl)]$ (**2**) ($E_{pc} = -0.40$ V) reduces at less negative potential compared with $[Ni_2L](ClO_4)$ ($E_{pc} = -0.63$ V). This may be due to distortion [28–30] in geometry that arises due to axial coordination of the anions (chloride and nitrate) to the copper and nickel ion. $E_{1/2}$ value for $[Cu_2L](ClO_4)$ is −0.55, $[Cu_2L(Cl)]$ is −0.19 and $[Cu_2L(NO_3)]$ is −0.13. For nickel complexes also the change in redox potential observed with change in geometry. $E_{1/2}$ value for $[Ni_2L](ClO_4)$ is −0.56, $[Ni_2L(Cl)]$ is −0.32. The coordination site influence is less than geometrical distortion effect in the redox potential of the complexes. Since the difference in $E_{1/2}$ value between chloro complex and nitrato complex is less when compared with these two $E_{1/2}$ values with respect to perchlorato complex.

3.1.2. Oxidation process

The cyclic voltammogram of nickel complexes at positive potential show two step single electron transfer

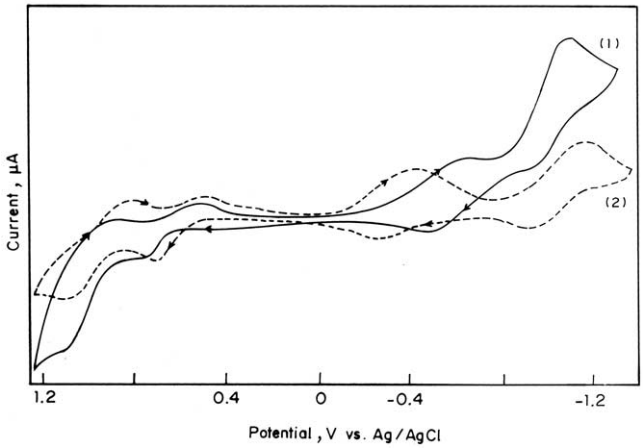

Fig. 2. Cyclic voltammograms of the nickel complexes $[Ni_2L](ClO_4)$ (**1**), $[Ni_2L(Cl)]$ (**2**) in dmf, scan rate 50 mV s^{-1}. Potential are given in V vs. Ag/AgCl; platinum working and Ag/AgCl reference electrodes; supporting electrolyte TBAP; concentration of complex 1×10^{-3} M, concentration of TBAP 1×10^{-1} M.

Table 2
Electrochemical data of the nickel(II) oxime complexes (oxidation at anodic potential)

Number	Complex	E^{1}_{pa} (V)	E^{1}_{pc} (V)	ΔE^{1}_{p} (mV)	$E^{1}_{1/2}$ (V)	E^{2}_{pa} (V)	E^{2}_{pc} (V)	ΔE^{2}_{p} (mV)	$E^{2}_{1/2}$ (V)
1	$[Ni_2L](ClO_4)\cdot CH_3OH$	0.78	0.55	230	0.66	1.13	0.93	200	1.03
2	$[Ni_2L(Cl)]\cdot H_2O$	0.75	0.52	230	0.63	1.10	0.88	220	0.99

Table 3
ESR spectral data of the copper(II) oxime complexes

Number	Complex	$g_{\|}$	$g_{\perp}$	$-2J$, cm^{-1}	ρ	μ_{eff} (B.M) (RT)
3	$[Cu_2L](ClO_4)\cdot CH_3OH$	2.18	2.04	172	0.001	1.59
4	$[Cu_2L(Cl)]\cdot H_2O$	2.11	2.03			1.55
5	$[Cu_2L(NO_3)]\cdot H_2O$	2.21	2.09			1.49

processes in the potential range 0–1.15 V. The electrochemical data for the complexes at positive potential region is given in Table 2. The cyclic voltammogram of the nickel complexes in cathodic and anodic potential region is given in Fig. 2. The redox process is quasi-reversible in nature. The $E_{1/2}$ values for nickel complex $[Ni_2L](ClO_4)$ is $E_{1/2} = +0.66$ V and for the complex $[Ni_2L(Cl)]$ is $E_{1/2} = +0.63$ V. This shows that the chloride complex oxidised easily than the perchlorate complex, but the difference in $E_{1/2}$ value is very small (0.03 V).

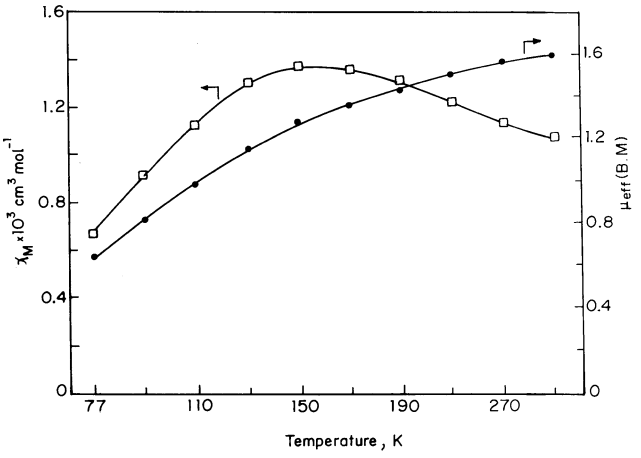

Fig. 3. Temperature dependence of magnetic susceptibility (χ_{cu}) and effective magnetic moment (μ_{eff}) for complex $[Cu_2L](ClO_4)$.

3.2. Magnetic properties of the complex

The nickel complexes are EPR inactive, which evinces that the nickel complexes are diamagnetic and have square planar geometry. The EPR spectra of the mononuclear copper complexes show four line with hyperfine splitting and binuclear complexes show a broad signal at $g = 2.1$ and room temperature (at 298 K) magnetic moment studies of the complex $[Cu_2L](ClO_4)$ show μ_{eff} value of 1.59 B.M, which is less than the spin only value of single copper(II) ion. These indicate that the presence of coupling between two copper(II) centers. So, to evaluate the singlet–triplet energy separation ($-2J$), variable temperature magnetic susceptibility measurement (77–300 K) was carried out for complex $[Cu_2L](ClO_4)$. The magnetic susceptibility measurement data for the complex $[Cu_2L](ClO_4)$ was fitted to the modified form of Bleaney–Bowers equation.

$$\chi_{cu} = (Ng^2\beta^2)/(kT)[3 + \exp(-2J/kT)]^{-1}(1-\rho) + N_{\alpha}$$

where χ_{cu} is the paramagnetic susceptibility per metal atom after the correction for the diamagnetism, N is Avagadro number, β Boltzman constant, g is the

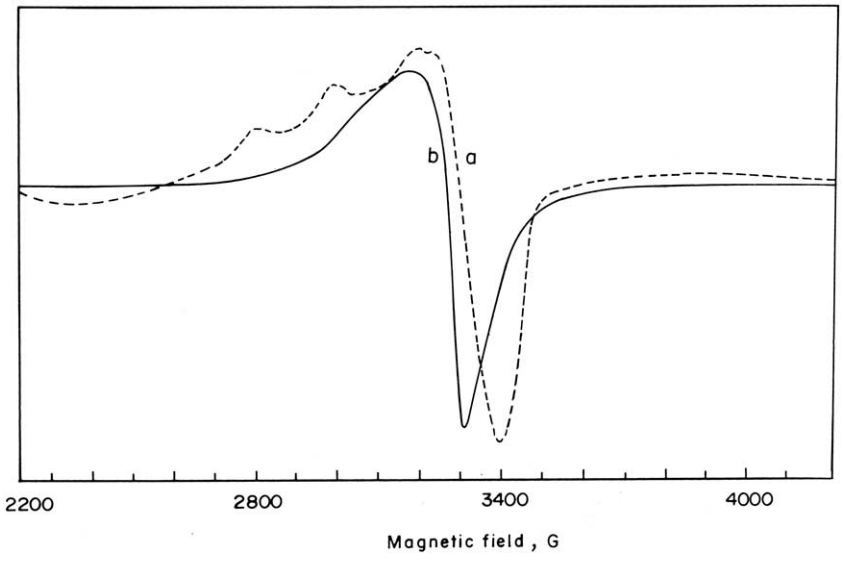

Fig. 4. ESR spectra of the complexes: (a) [CuL]; (b) $[Cu_2L](ClO_4)$.

average gyromagnetic ratio and ρ is the fraction of the monomeric copper(II) impurities, $-J$ the singlet–triplet separation, N_α is the temperature independent paramagnetism (60×10^{-6} cgs units) per copper(II) complexes. A nonlinear least-square fitting programme was employed to calculate $-J$, g and ρ. The best fit parameters are tabulated in Table 3. Temperature dependence of the magnetic properties for complexes $[Cu_2L](ClO_4)$ is given in Figs. 3 and 4. The antiferromagnetic exchange interaction ($-2J = 172$ cm^{-1}) observed for the complex $[Cu_2L]ClO_4$ is similar to that of analogous unsymmetrical macrocyclic complex ($-2J = 170$ cm^{-1}) reported by Kandaswamy et al. [28]. This is in agreement with the results reported by Busch et al. [12] for unsymmetrical schiff base oxime complexes and analogous unsymmetrical macrocyclic complexes.

4. Summary

The binuclear unsymmetrical compartmental oxime ligands and their mono, binuclear nickel(II) and copper(II) complexes have been synthesized and characterized. The electrochemical and magnetic properties of the complexes are discussed.

Thus, besides the great number of investigations, the challenge to find the 'ideal antenna molecule' still remains.

The choice of ruthenium metal is of particular interest because of its octahedral geometry since one can introduce specific ligands in a controlled manner [4]. More specifically, by introducing different donor/acceptor/functional groups it is possible to 'fine tune' the spectral properties of the complex. In the family of Ru(II) polypyridine complexes few molecules with terpy derivatives are known. The complexes with the bdmpp ligand exhibit significantly different electronic properties from their terpy analogs [5]. Very recently it has been demonstrated that they can also be used for the sensitization process [6]. The topic of this work is to present the synthesis and characterization of a new Ru(II) dye molecule, [Ru(II)(dcbpyH_2)(bdmpp)NCS](PF_6) (**1**), and evaluate the performance of the corresponding dye-sensitized solar cell. The complex is of theoretical interest because it contains two chromophore units (bpy and bdmpp). The first ligand (dcbpyH_2 = 2,2′-bipyridine-4,4′-dicarboxylic acid) bears a carboxylic acid functional moiety, which serves as interlocking agent. The second ligand [bdmpp = 2,6-bis(3,5-dimethyl-*N*-pyrazoyl)pyridine] can be considered as a terpyridine derivative, exhibiting significantly different electronic properties. The complex is also endowed with a monodentate thiocyanato ligand, –N=C=S. The role of this ligand is to tune the metal t_{2g}-orbitals of Ru(II) and possibly to stabilize the hole that is being generated on the metal, after having injected an electron into the TiO_2 conduction band [7].

2. Experimental

2.1. Materials

$RuCl_3 \cdot 3H_2O$, 2,2′-bipyridine-4,4′-dicarboxylic acid (dcbpyH_2), sodium thiocyanate (NaSCN) were purchased from Riedel-de Haën, Fluka and Carlo Erba, respectively, and were used as received without additional purification. The bdmpp ligand was prepared by Prof. V.J. Catalano. Ammonium hexafluorophosphate (NH_4PF_6) and tetrabutyl ammonium hexafluorophosphate (Bu_4PF_6) were purchased from Aldrich. The solvents ethanol, toluene, acetonitrile and diethyl ether were from Riedel-de Haën, Panreac and Merck, respectively. MeOH-d_4 was from Riedel-de Haën.

2.2. Methods

2.2.1. Analytical measurements

The mass spectra were obtained on a TSQ 7000 Finnigan Mat spectrometer using the ESI (electrospray) technique. All the m/z values are based on ^{102}Ru, which is the most abundant isotope. UV–Vis spectra were recorded using a Perkin–Elmer Lambda 19 spectrometer using Teflon-stoppered quartz cells having a path length of 1 cm. ^{1}H and ^{13}C NMR spectra 1D and 2D were measured in CD_3OD solution with a Bruker Avance 500 MHz spectrometer. The reported chemical shifts were against TMS. The IR spectra were measured using a Nicolet 550 Magna-IR^{TM} spectrometer. The spectra are the average of 16 accumulated scans.

Cyclic voltammetry measurements were performed in a 5×10^{-4} M solution of the complex in acetonitrile (CH_3CN) in the presence of 0.1 M $TBAPF_6$ supporting electrolyte, using a Vinci Technologies P/G STAT Z1 potentiostat, operating in conjunction with a 33120 A Hewlett–Packard function/arbitrary waveform generator with a Linseis LY 18100 X-Y recorder. A three-electrode electrochemical cell was used, with a Metrohm dot platinum working electrode (WE), a Metrohm planar platinum counter electrode (CE) and a Metrohm 6.0726.100 Ag/AgCl reference electrode containing 0.1 M Bu_4NCl in CH_3CN as the inner electrolyte and the outer electrolyte. The experiments were performed in deoxygenated solutions by passing purified Ar gas (99.9%) through the solutions. During the experiment the Ar was passed over the solution surface. Under these conditions the ferrocenium/ferrocene couple has an $E_{1/2}$ of 0.343 V versus AgCl with $E_{pa} - E_{pc} = 111$ mV.

2.3. Synthesis of [Ru(dcbpyH_2)(bdmpp)NCS](PF_6)

To prepare the Ru(bdmpp)Cl_3 precursor, $RuCl_3 \cdot 3H_2O$ (260 mg, 1.26 mmol) and bdmpp (267 mg, 1.0 mmol) were dissolved in absolute ethanol and the mixture was refluxed for 3 h under stirring. The solution was then cooled at room temperature (r.t.), filtered and the resulting brown powder was washed with absolute ethanol and ether and air-dried, Fig. 1, reaction (1). The precursor [Ru(bdmpp)Cl_3] thus prepared (without any purification) and the dcbpyH_2 ligand (1/1 molar ratio) were refluxed for 8 h in EtOH–H_2O (3/1:v/v) containing LiCl and triethylamine as a reductant. The hot solution was filtered through celite and evaporated to dryness. After dissolving the crude product in EtOH, a saturated methanol solution of NH_4PF_6 ($\sim$10 ml) was added (Fig. 1, reaction (2)). The solution was left at 0 °C for a

$$RuCl_3 \cdot H_2O + bdmpp \xrightarrow{EtOH,reflux} Ru(bdmpp)Cl_3 \quad (1)$$

$$Ru(bdmpp)Cl_3 + dcbpyH_2 \xrightarrow{NEt_3,EtOH/H_2O,reflux} [Ru(bdmpp)(dcbpyH_2)Cl]^+ \quad (2)$$

$$[Ru(bdmpp)(dcbpyH_2)Cl]^+ \xrightarrow{NaNCS,EtOH/H_2O,reflux} [Ru(bdmpp)(dcbpyH_2)NCS]^+ \quad (3)$$

Fig. 1. Schematic diagram of the synthesis of [Ru(dcbpyH_2)(bdmpp)(NCS)](PF_6) complex.

day. The resulting deep brown precipitate corresponding to [Ru(dcbpyH$_2$)(bdmpp)Cl](PF$_6$) [6,8] was collected on a sintered glass funnel and washed with cold water then with ether (yields 76.2 mg, 24%). The complex is soluble in EtOH, MeOH, AcCN, aceton, moderably soluble in $CHCl_3$.

A suspension of [Ru(dcbpyH$_2$)(bdmpp)Cl](PF$_6$) (60 mg, 0.076 mmol) and NaNCS (25.4 mg, 0.31 mmol) in (10 ml) of ethanol–water (1:1) mixture was refluxed under Ar for 4 h in the dark. After cooling, a saturated aqueous solution of ammonium hexafluorophosphate (12 ml) was added dropwise to the reaction mixture. The black precipitate formed was filtered and washed successively with water (2×5 ml), toluene (2×5 ml) and ether (2×12 ml) to yield the title compound **1** as a dark powder (59 mg, 95%), Fig. 1, reaction (3). The complex is soluble in carbon tetrachloride, toluene, ethanol, methanol and acetonitrile. It is insoluble in cyclohexane. Melting point (m.p.): above 250 °C.

3. Results and discussion

3.1. FT-IR spectroscopy

The most direct evidence for the presence of N-coordinated NCS comes from the FT-IR spectrum of complex **1**, recorded in a KBr pellet in the 4000–400 cm^{-1} region (see supplementary information Fig. 8). The strong absorption band at 2109 cm^{-1} is assigned as to the N-bonded NCS^- ligand ν(C=N) stretching vibration. The presence of band at 771 cm^{-1} is assigned to the ν(C=S) stretching vibration. For the complex **1** at 2856–2927 cm^{-1} (w) there are the C–H stretch vibrations for the CH_3 groups. The 1713 cm^{-1} (m) vibration is characteristic of the C=O bond stretching on the carboxylate group. Ring stretching vibrations occur in the region between 1613 and 1317 cm^{-1} (m). The C–O stretch occurs at 1262–1232 cm^{-1} (w). At 846 cm^{-1} (s) appears the characteristic band of multinuclear aromatics from the C–H out of plane bend. The C–H stretch vibrations of the heteroaromatic pyridines expected about 3100 cm^{-1} are weak because of a very strong moisture background.

3.2. Mass spectrometry

The identity of complex **1** was ascertained by mass spectrometry (ESI), Fig. 2. Both parent ion peaks and expected fragments of the complex were detected. In fact, in the case of the +Q1MS mode (positive region), a strong peak at $m/z = 671.2$ was observed and was attributed to the $(Ru(dcbpy)(bdmpp)NCS)^+$ cation. In −Q1MS mode (see supplementary information Fig. 9), a peak at $m/z = 144.8$ characteristic of the (PF_6^-) anion was obtained. The m/z value is based on ^{102}Ru, which is the most abundant isotope.

3.3. Molecular confuguration and ^{1}H NMR spectroscopy

On the basis of the IR analysis, the electrospray MS data and taking into account that the presence of the

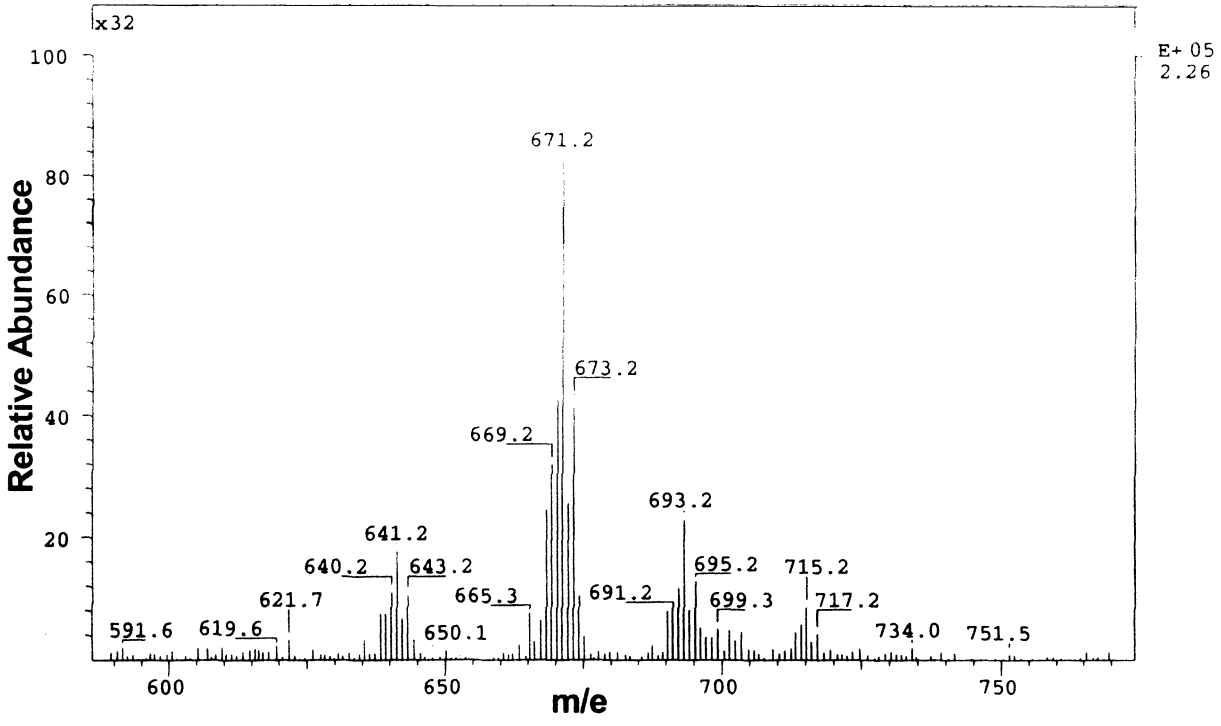

Fig. 2. Ionization electrospray ESI MS spectra of complex **1**: +Q1MS.

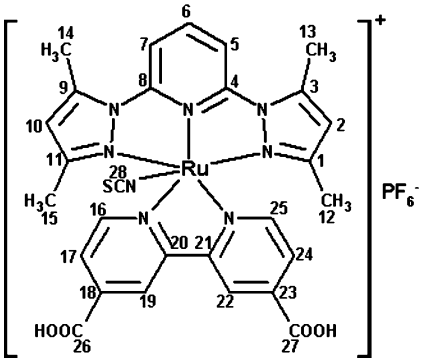

Fig. 3. Proposed molecular configuration for the [Ru(II)(dcbpyH$_2$)(bdmpp)NCS](PF$_6$) complex.

carboxylic acid moieties on the bipyridine ligand can not essentially modify the structure of the obtained species, a molecular configuration similar to that obtained for the [Ru-(bdmpp-bpy)Cl]$^+$ complex [6] can be proposed, Fig. 3.

The NMR data (the 1D and 2D NMR spectra) strongly support the above molecular configuration for the [Ru(dcbpy)(bdmpp)NCS)](PF$_6$) (**1**). In complex **1**, the proton assignments of the bdmpp and the 2,2′-bipyridine-4,4′-dicarboxylic acid ligands were made on the basis of peak integration, coupling constants and ^{1}H–^{1}H COSY and NOESY experiments (see supplementary information, Fig. 10). The chemical shift data and corresponding assignments are presented on Table 1.

3.4. ^{13}C NMR spectroscopy

The 1D ^{13}C NMR spectrum of complex (**1**) in CD_3OD, Fig. 4(a)), shows 19 resonance signals in the

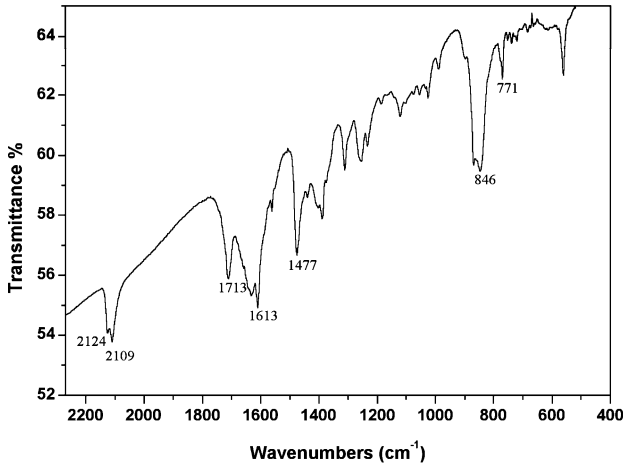

Fig. 8. FT-IR spectrum of [Ru(II)(dcbpyH$_2$)(bdmpp)NCS](PF$_6$) (1) in a KBr pellet.

aromatic region (δ 109–161 ppm) corresponding to 2,2′-bipyridine-4,4′-dicarboxylic acid, bdmpp and NCS^-. The assignment of the peaks (listed in Table 1) is based on the 2D HSQC spectrum, Fig. 4(b) as well as on chemical reasoning.

The two resonance peaks in the aliphatic region, at δ 14.69 and 12.13 ppm, correspond to 2 nonequiv. methyl carbon atom groups of the coordinated bdmpp ligand. The downfield resonance at 160.61 ppm is assigned to the carboxylate carbons of the 2,2′-bipyridine-4,4′-dicarboxylic acid ligand. The peak at 159.09 ppm is assigned to quaternary C4 and C8 carbons, which are near to two electron withdrawing nitrogens of the coordinated bdmpp ligand. The more intense peak at 158.16 ppm is due to quaternary C3, C9 carbons which are near to one electron withdrawing nitrogen but also are near to the electron withdrawing nitrogen of the central coordinated pyridine. More upfield there is an intense peak at 152.23 ppm, which is assigned to quaternary C1, C11 carbons. The C20, C21 carbons are observed at 140.89 and 140.12 ppm, respectively. The peaks at 139.35 and 136.99 are due to quaternary C18 and C23 carbons. The peak at 147.69 ppm is assigned to the carbon of the NCS^- ligand [9]. The most likely reason for such a downfield shift could be that this carbon is *trans* to one ring of the bidentate ligand dcbpyH$_2$ [8].

3.5. Electronic spectra

The electronic absorption spectra of **1** (10^{-4} M in MeOH), Fig. 5, is typical of Ru(II) diimine systems. The complex presents an intense and composite broad band in the visible attributed to a MLCT process. The band consists of three absorption maxima of very high intensity appearing at 383 nm ($\varepsilon = 21\,274$ M^{-1} cm^{-1}), 432 nm ($\varepsilon = 22\,353$ M^{-1} cm^{-1}) and 475 nm ($\varepsilon = 23\,397$ M^{-1} cm^{-1}), respectively (Table 2). The visible absorption spectrum of the new complex shows that it absorbs over the most of the visible, with a significant degree of

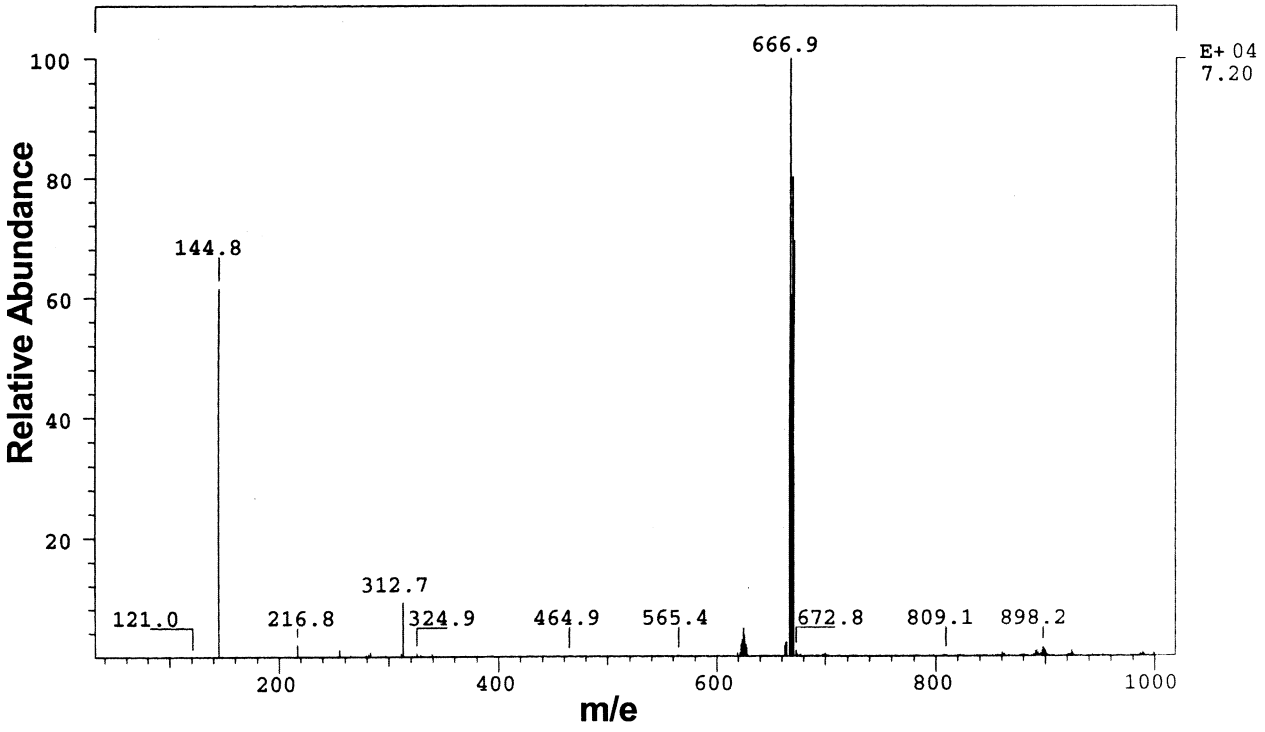

Fig. 9. Ionization electrospray ESI MS spectra of complex **1**: −Q1MS.

absorption into the low energy region greater than 525 nm. It is worth mentioning the presence of an absorption hump at 569 nm (5481 M^{-1} cm^{-1}) and the fact that even at 620 nm, the extinction coefficient is still high ($\varepsilon = 3768$ M^{-1} cm^{-1}). This is very important point for the photosensitization purpose [10].

3.6. Electrochemistry

The cyclic voltammogram of the complex was similar with those of other typical dyes containing bipyridine, phenanthroline and terpyridine ligands which have been used as sensitizers in regenerative photoelectrochemical cells. It was obtained in CH_3CN containing 0.1 M TBAH at a sweep rate of 100 mV s^{-1}, Fig. 6, and shows a well defined reversible oxidation–reduction wave attributed to the Ru(II)/Ru(III) redox couple, with a half-wave potential ($E_{1/2}$) of +0.795 V versus Ag/AgCl and $E_{pa} - E_{pc} = 120$ mV; the peak observed at −0.612 V can be assigned to the first ligand centred reduction.

3.7. Sensitizing ability

Rough, high surface area nanostructured TiO_2 thin film electrodes prepared using the doctor-blade technique on TEC 15 conductive glass substrates [11] developed a deep yellow–brown color following overnight immersion in a 10^{-4} ethanolic solution of the complex. The complex is chemically adsorbed on TiO_2 via an ester-like linkage formed between the carboxylic acid functional groups (–COOH) of the bipyridine ligand and the hydroxyl moieties (–OH) present on the semiconductor surface [12]. To check the sensitizing ability of the complex, the derivatized electrodes (active surface size 0.4 cm^2) were then incorporated in a solid-state dye-sensitized solar cell using a composite electrolyte consisting of polyethylene oxide (PEO) with an

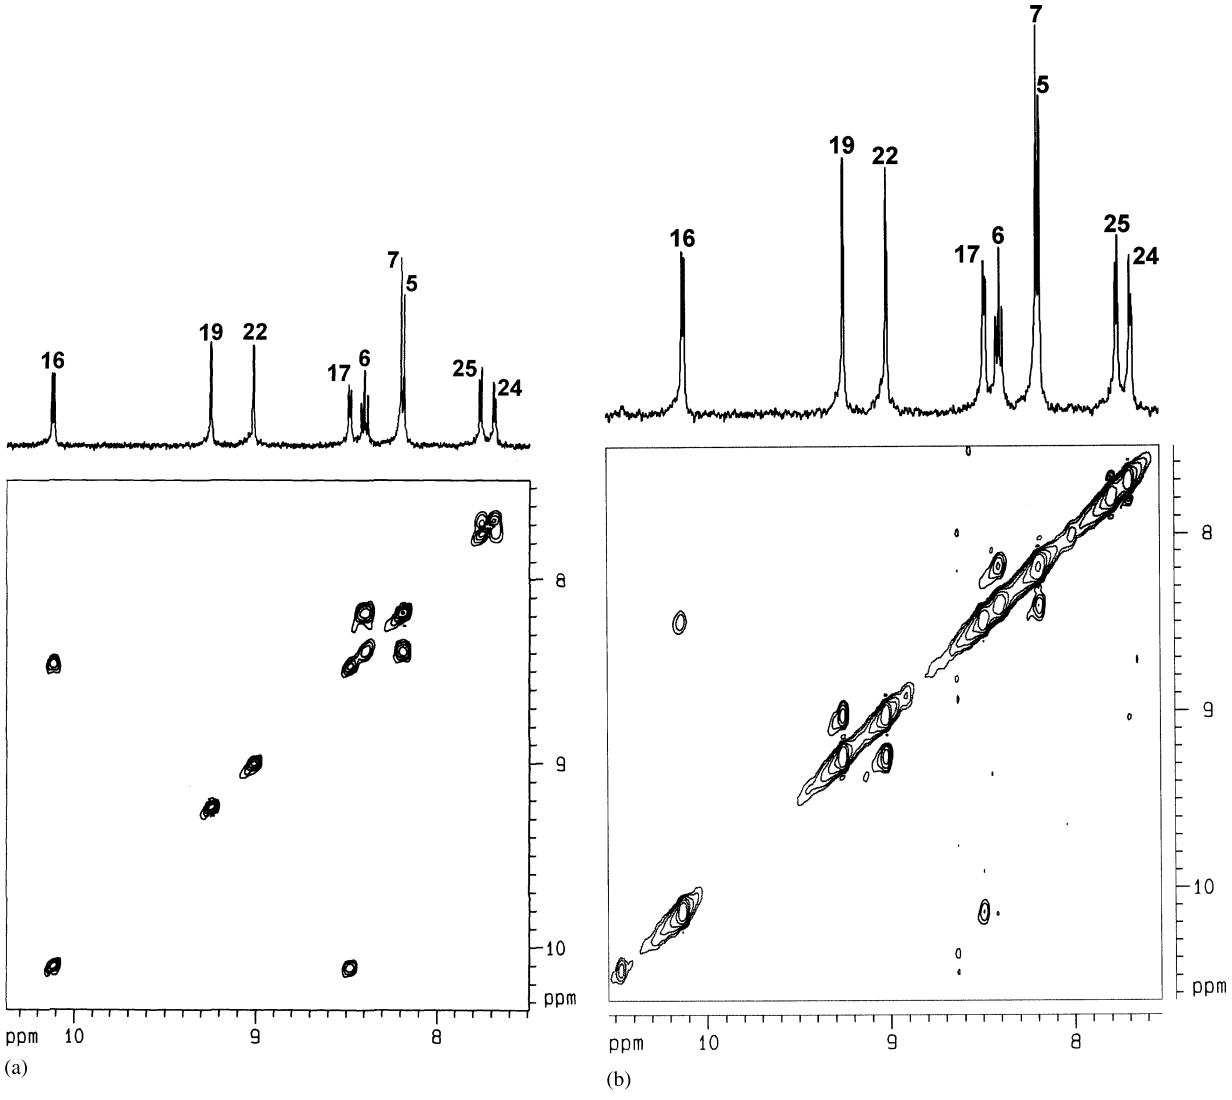

Fig. 10. Two-dimensional ^1H–^1H NMR spectra of complex **1**: COSY (a); NOESY aromatic region (b); NOESY aromatic vs. aliphatic region (c).

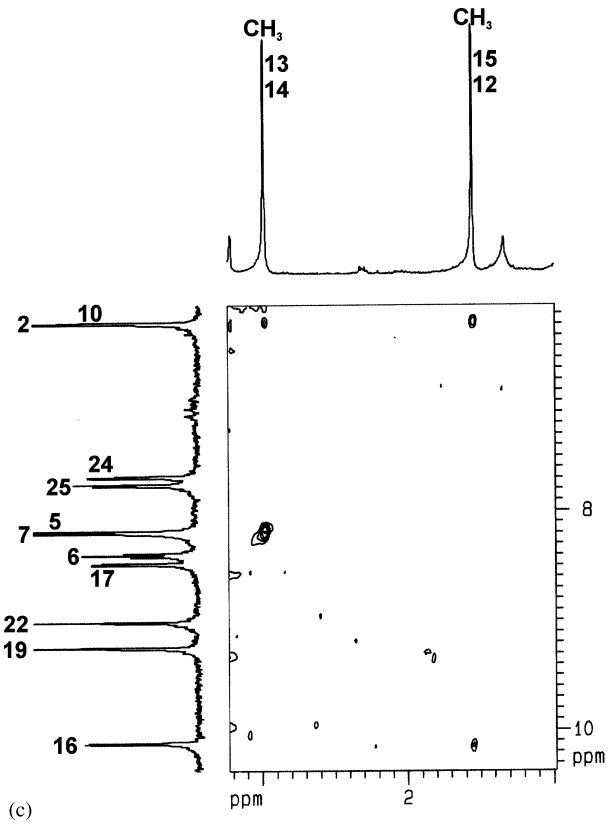

Fig. 10 (*Continued*)

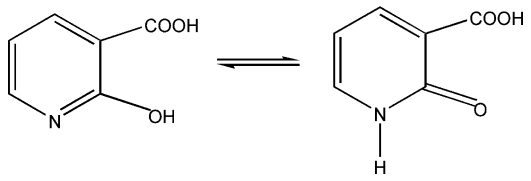
inorganic oxide (TiO_2 Degussa P25) as the filler, in the presence of the I^-/I_3^- redox couple [13,14]. The electrolyte was sandwiched between the photoelectrode and a TEC 8 transparent conductive glass on which very small platinum layer was deposited. An adhesive tape was placed between the photoelectrode and the CE to avoid short-circuiting. This solid-state dye-sensitized solar cell gave high incident monochromatic photon-to-current conversion efficiency (IPCE) values. Under short circuit conditions, in the wavelength region between 400 and 500 nm, the IPCE values (number of electrons generated, divided by the number of incident photons) exceed 30%, Fig. 7. At higher wavelengths, significantly lower IPCE values were obtained and this is attributed to a low light harvesting ability, as the absorption spectrum indicates.

Under direct sunlight illumination (solar irradiance was 600 W m^{-2}), the cell produced a continuous photocurrent as high as 4.3 mA cm^{-2}, and a photovoltage of 600 mV. The corresponding overall energy conversion efficiency (electric power produced to incident solar irradiance ratio) was as high as 1.7%. This sounds particularly optimistic, especially when one takes into account the solid-state nature of the cell. It is well known that dye-sensitized solar cells using a liquid electrolyte present expressively higher conversion efficiencies (at least three times) that the corresponding solid-state modules using room temperature molten salts, inorganic p-type semiconductors, ionic conducting polymers or organic hole transport materials [2,15,16].

The idea that bdmpp is potentially useful in complexes capable of solar energy conversion has been recently reported [6]. However, the incorporation of the monodentate thiocyanato (NCS^-) ligand (replacing the Cl^- moiety) into the complex aims at generating a new dye with superior properties to those of the Cl-complex. Moreover, the coexistence of bdmpp, bpy and NCS^- ligands is believed to affect the ability of the complex to function as a charge transfer sensitizer for solar energy conversion. In fact, the corresponding solid-state solar cell using the $[Ru(bdmpp)(dcbpy)Cl]^+$ complex shows clearly lower performance (IPCE values of about 23% and overall energy conversion efficiency of 0.5%). Such a difference can be attributed to NCS^- ligand, which is able to better stabilize the oxidized complex form following electron injection [7].

4. Conclusions

We have succeeded in developing a new sensitizer based on a ruthenium(II) complex having two chromophore groups, 2,6-bis(3,5-dimethyl-*N*-pyrazoyl)pyridine, and 2,2′-bipyridine-4,4′-dicarboxylic acid as well



as one thiocyanate group as ligands. The synthesis of the $[Ru(dcbpyH_2)(bdmpp)NCS](PF_6)$ complex (*trans*-isothiocyanate species with respect to one ring of the bidentate ligand $dcbpyH_2$) was performed by reaction of the $[Ru(dcbpyH_2)(bdmpp)Cl](PF_6)$ precursor with the monodentate ligand NCS^- in ethanol–water (1:1) mixture. The complex was characterized and identified by IR, ES MS and NMR and its molecular configuration is proposed on the basis of the spectroscopic data. The electronic spectrum is consistent with very interesting light harvesting properties. The effectiveness of the complex in sensitizing the titanium dioxide was evaluated in a solid-state dye-sensitized solar cell, thus confirming its molecular antenna character.

Acknowledgements

Thanks must be addressed to Professor V.J. Catalano for providing the bdmpp ligand, to Degussa AG Frankfurt-Germany/Dellis AE-Greece for generously providing the TiO_2 Degussa P25 and to I.M. Arabatzis and G. Katsaros for their precious help and assistance. Financial support from NCSR 'Demokritos' (Dimoerevna 598 project) and General Secretariat for Research and Technology of Greece (EPET II, 98AΔ86 project) is also greatly acknowledged.

Scheme 1.

through the nitrogen atom only. Spectroscopic results are in agreement with the crystallographic data, showing preferential coordination of the $HnicO^-$ ligand through the nitrogen atom of the pyridine ring, and in the case of rhenium, molybdenum and tungsten, a possible *N*,*O*-chelation with the adjacent oxygen atom.

2. Results and discussion

2.1. Preparations

Suspensions of *trans*-$[Pd(PPh_3)_2Cl_2]$ or *cis*-$[Pt(PPh_3)_2Cl_2]$ and H_2nicO in an ethanol–methanol mixture were stirred for several days in the presence of triethylamine to give the complexes *trans*-$[PdCl(HnicO)(PPh_3)_2]\cdot 0.75CH_3OH$ (**1**) and *cis*-$[PtCl(HnicO)(PPh_3)_2]\cdot 0.75CH_3OH\cdot 0.5H_2O$ (**4**). When $K_2[PdCl_4]$ was used as starting material, the compound obtained was $K[PdCl(HnicO)_2]\cdot H_2O$ (**2**). The reaction of the 2,2′-bipyridine (bipy) complexes $[M(bipy)Cl_2]$ (M = Pd, Pt) with H_2nicO gave the complexes $[Pd(HnicO)_2(bipy)]$ (**3**) and $[PtCl(HnicO)(bipy)]$ (**5**). The complex *cis*-$[ReOI_2(HnicO)(PPh_3)]$ (**6**) was synthesised by refluxing *trans*-$[ReOI_2(OEt)(PPh_3)_2]$ with H_2nicO in acetone. The reaction of $Na_2[MO_4]\cdot 2H_2O$ (M = Mo or W) and H_2nicO in water, under reflux, produced the complexes $Na_2[M_2O_6(HnicO)_2]\cdot 5H_2O$ (M = Mo **7** or W **9**) and $Na_2[Mo_4O_{12}(HnicO)_2]\cdot 2H_2O$ (**8**). Suitable crystals of complexes **1** and **4** for X-ray diffraction studies were obtained by vapour diffusion of diethyl ether into acetonitrile solutions of the complexes.

2.2. Crystal structures

The crystals structures of *trans*-$[PdCl(HnicO)(PPh_3)_2]\cdot 0.75CH_3OH$ (**1**) and *cis*-$[PtCl(HnicO)(PPh_3)_2]\cdot 0.75CH_3OH\cdot 0.5H_2O$ (**4**) were determined by single crystal X-ray diffraction. ORTEP diagrams of the complexes **1** and **4** with the labeling scheme adopted are shown in Figs. 1 and 2, respectively. Selected bond lengths and angles are listed in Table 2 and indicate that both metal centers display distorted square coordination spheres composed of two phosphorus from two PPh_3 ligands, one chlorine and one nitrogen from the $HnicO^-$ ligand. However, the ligands adopt different spacial dispositions in these two complexes. In **4** the two PPh_3 ligands provide a *trans* geometric arrangement with a P(1)–Pt–P(2) angle of 172.2(1)° and in **1** they are mutually *cis* with a P(1)–Pd–P(2) angle of 97.2(1)°. In addition, in **4** the $HnicO^-$ ligand is almost perpendicular to the equatorial coordination plane intersecting at 88.3(1)° while in **1** that ligand is sandwiched between two phenyl rings of the PPh_3 ligands and intersecting the equatorial P_2NCl coordination plane at 77.2(1)°.

In both complexes the coordination of the $HnicO^-$ ligand, through the nitrogen donor, forces the phenol group to be directed towards the metal centre, leading to similar Pd···O and Pt···O distances of 3.009 and 3.047 Å, respectively. This structural feature was also found in the related complexes [1] $[PdCl(picOH)(PPh_3)_2]$ (HpicOH = 3-hydroxypicolinic acid) and $[PtCl(picOH)(PPh_3)_2]$ in which the ligands display a NP_2Cl coordination sphere with identical disposition of the ligands to the corresponding complexes reported here. However, in those $picOH^-$ complexes, the oxygen that is directed towards the metal centre belongs to a carboxylate group rather than a phenol group giving Pd···O and Pt···O distances of 2.773(5) and 2.734(4) Å, respectively, which are substantially shorter than those found for **1** and **4**. On the other hand the dimensions of bonds and angles subtended at the metal centres in **1** and **4** are similar to those found for the respective $picOH^-$ complexes. In the latter two complexes, the $picOH^-$ ligand is also nearly perpendicular to the N_4Cl_2 coordination plane, intersecting at angles of 88.8° and 84.2° for the Pd and Pt complexes, respectively. Therefore, this comparison suggests that the specific orientation of the aromatic ligand is determined in each structure by the minimisation of the steric interactions between the bulky PPh_3 ligands and the $HnicO^-$ anion. As would be expected in the *cis* complex **4** a slight *trans* differential effect is apparent from the M–P bond lengths. Thus, the length of the Pt–P(1) bond [2.266(3) Å] *trans* to the Pt–Cl bond [2.353(4) Å] is slightly shorter than that of the Pt–P(2) bond [2.293(4) Å], which is *trans* to the Pt–N bond [2.104(10) Å].

2.3. Vibrational spectra

Infrared and Raman data for H_2nicO and its complexes are shown in Table 3. Tentative assignments are based on those found in the literature for complexes of 3-hydroxypicolinc acid, [1,2] salicylic acid [13] and 2-hydroxypyridines [14,15]. Only the bands more sensitive to metal coordination are reported.

In both infrared and Raman spectra of the free ligand, the bands corresponding to the hydroxyl group vibrations seem to be absent, namely, the ν(O–H) stretch (missing at ca. 3400 cm^{-1}) [16] and the in-plane $\beta(C_2$–OH) bend (missing at ca. 1280 cm^{-1}); [14] also, the strong band around 1023 cm^{-1}, indicative of the pyridine structrure, [14] is not seen in the vibrational

spectra. These features suggest that the ligand is possibly in the ketone rather than the hydroxy form. Furthermore, the presence of the stretching vibrations ν(C2=O) at 1740 cm^{-1} and ν(N–H) at 3229 cm^{-1}, the in-plane β(NH) bend at 1608 cm^{-1} and the out-of-plane π(NH) bend at 538 cm^{-1}, in the IR and Raman spectra of free ligand, suggest that the ketone form predominates in the solid state [14].

The C=O stretch of the carboxylic group, $\nu(C{=}O)_c$, in the IR and Raman spectra of the free ligand, is seen at 1630 and 1628 cm^{-1}, respectively. These bands shift to higher wavenumbers (in the range 1640–1702 cm^{-1}) in the spectra of complexes **1**, **2**, **4**, **5** and **7**–**9**. These shifts are possibly due to the destruction of the hydrogen bond between the COOH and C=O groups on coordination, with the carboxyl group not bound to the metals [17]. The C–O stretch of the carboxyl group, $\nu(C{-}O)_c$, shows small shifts in the complexes spectra.

The ν(C2=O) band shifts to lower wavenumbers on coordination; the smallest shifts are possibly observed in the spectra of the complexes where the HnicO$^-$ ligand coordinates only through the nitrogen atom, as can be suggested for complexes **1**–**5** (and according to the crystal structures of **1** and **4**). For complexes **6**–**9**, the shifts in the ν(C2=O) bands are the highest, up to 80 cm^{-1}, and the coordination to metals through the oxygen atom also (in a orto position to the ring nitrogen) can be suggested.

In the spectra of the Mo(VI) and W(VI) complexes the MoO_2 stretches, $\nu_s(MoO_2)$ and $\nu_{as}(MoO_2)$, provide two strong bands at approximately 930 and 880 cm^{-1}, respectively. In the IR spectrum of the rhenium complex a very strong band characteristic of the Re=O stretch is observed at 989 cm^{-1}. In addition PPh_3 and bipy bands were observed in all the applicable spectra.

The proposed formula for complexes **2**, **3** and **5**–**9** are based on elemental analysis and spectroscopic data, considering analogous complexes that have been reported [1,2,4,17] for similar bidentate ligands. In complex **2**, two HnicO$^-$ ligands are coordinated to palladium together with a chlorine ligand, as shown in the infrared and Raman spectra by the presence of a band assigned to the ν(Pd–Cl) stretch; a similar compound was reported with 3-hydroxypicolinc acid (picOH$^-$ ligand) [1]. For the palladium and platinum complexes containing 2,2′-bipyridine, two HnicO$^-$ ligands are coordinated to palladium in **3** while only one is coordinated to platinum in **5**; the latter complex keeps one chlorine ligand from the starting [Pt(bipy)Cl_2] compound, as shown in the infrared and Raman spectra by the presence of a band assigned to the Pt–Cl stretching vibration. Complex **6** is analogous to a reported rhenium complex with the picOH$^-$ ligand [1]. Compounds **7**–**9** are analogous to the polynuclear molybdenum and tungsten complexes of HpicOH previously reported, [2] having possibly similar structures, though with a four membered *N*,*O*-chelate ring in the HnicO$^-$ ligand (instead of the six-membered *N*,*O*-chelate ring that is formed with the picOH$^-$ ligand).

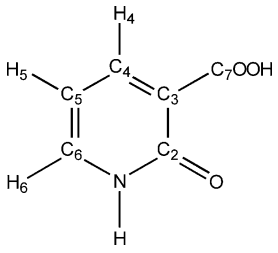

Plate 1.

7 in solution are given in Tables 4 and 5. Complexes **2**, **3**, **5**, **8** and **9** were not sufficiently soluble in the common NMR solvents for ^{13}C NMR measurements; for **8** and **9** ^{1}H NMR measurements were also not possible. CP-MAS ^{13}C NMR spectra of the free ligand and of some of the solid complexes were recorded (Table 5). Tentative assignments of the NMR spectra are based on those found in the literature for complexes of mercaptonicotinic acid, [4,18,19] 3-hydroxypyridin-2-one, [20] 1,2-dimetil-3-hydroxypyridin-2-one [20] and salicylic acid [13].

The ^{1}H NMR spectrum of the ligand in dmso-d_6 shows a triplet at 6.69 ppm assigned to the H_5 proton, a doublet–doublet at 7.96 ppm assigned to the H_4 proton and another doublet–doublet at 8.39 ppm assigned to the H_6 proton. The NH proton gives rise to a broad signal at about 13.4 ppm and another broad signal at 14.79 ppm is assigned to the COOH proton. In all complexes, only one signal is present in the range 17.5–13.4 ppm assigned to the latter proton. In general, the resonance of the ring protons of the coordinated ligand shifts upfield in all complexes. The chemical shift of C2 in the free ligand (164.66 ppm in dmso-d_6 solution and 166.10 ppm in solid state) is consistent with the ketonic form of H_2nicO [1,20]. The major downfield chemical shifts are observed in the ^{13}C NMR spectra of the complexes where the $HnicO^-$ ligand coordinates via monodentate-*N*, for the C2 and C6 carbon atoms. In the complexes where the ligand coordinates via bidentate-*N*,*O*, there is an upfield shift in the chemical shift of C2 due to the reduction of the bonding order from double to single [21]. Small shifts are observed for the other carbons. In the spectra of complexes **1** and **4**, two signals are observed for each carbon. In the CP-MAS ^{13}C NMR spectra of **2**, **8** and **10**, the major downfield chemical shifts (4–6 ppm) are observed for C2 and C6 as was also observed in the solution spectra of the other complexes.

2.5. FAB mass spectra

Positive-ion FAB mass spectra were recorded for complexes **1**, **4** and **6** in the appropriate solvents and in a *p*-nitrobenzyl alcohol matrix. In all cases, a molecular ion [MH^+] peak confirms the molecular structure of the complexes. In the positive-ion FAB mass spectra of **1** the [MH^+] peak was observed at *m*/*z* 806. Other peaks resulting from the fragmentation of **1** are observed at *m*/*z* 768, 665 and 506, assigned to $[Pd(HnicO)(PPh_3)_2]^+$, $[PdCl(PPh_3)_2]^+$ and $[Pd(HnicO)(PPh_3)]^+$, respectively. Similar peaks are found in the ion-positive FAB mass spectra of **4**, the molecular ion being observed at *m*/*z* 894, with peaks at *m*/*z* 858 and 754 assigned to $[Pt(HnicO)(PPh_3)_2]^+$ and $[PtCl(PPh_3)_2]^+$, respectively. In the mass spectra of **6** the molecular ion appears at *m*/*z* 858 and peaks at *m*/*z* 730 and 719 are assigned to $[ReOI(HnicO)(PPh_3)]^+$ following loss of I^- and $[ReOI_2(PPh_3)]^+$ following subsequent loss of $HnicO^-$.

3. Experimental

3.1. Preparation of complexes

All chemicals were of at least reagent grade and used as supplied by Aldrich. The starting complexes, *trans*-

[$PdCl_2$(PPh_3)$_2$], [16] *cis*-[$PtCl_2$(PPh_3)$_2$], [22] [MCl_2(bipy)] [20] (M = Pd, Pt) and *trans*-[$ReOI_2$(EtO)(PPh_3)$_2$] [23] were prepared by the relevant literature procedures.

3.1.1. *trans*-[PdCl(HnicO)(PPh_3)$_2$]·0.75CH_3CN (**1**)

To a stirred suspension of *trans*-[$PdCl_2$(PPh_3)$_2$] (0.35 g, 0.5 mmol) in ethanol (10 cm^3) was added a methanolic suspension (4 cm^3) of 2-hydroxynicotinic acid (0.14 g, 1 mmol) and triethylamine (0.28 cm^3, 2 mmol) giving a beige suspension. This suspension was stirred during 1 week and then centrifuged and a yellow solid isolated. It was washed with ethanol and dried over silica gel. Yield: 0.38 g, 0.47 mmol, 94%. Yellow X-ray quality crystals of **1** were obtained by vapour diffusion of diethyl ether into a solution of the compound in CH_3CN.

3.1.2. K[PdCl(HnicO)$_2$]·H_2O (**2**)

A suspension of 2-hydroxynicotinic (0.14 g, 1 mmol) in methanol (4 cm^3) was added to an aqueous solution (5 cm^3) of K_2[$PdCl_4$] (0.14 g, 0.5 mmol). The resulting suspension was stirred for 1 day. It was centrifuged and a pale yellow solid was isolated, washed with ethanol and dried over silica gel. Yield: 0.13 g, 0.27 mmol, 54%.

3.1.3. [Pd(HnicO)$_2$(bipy)] (**3**)

To a stirred suspension of [Pd(bipy)Cl_2] (0.05 g, 0.15 mmol) in ethanol (5 cm^3) was added a methanolic suspension (5 cm^3) of 2-hydroxynicotinic acid (0.04 g, 0.3 mmol) and triethylamine (0.08 cm^3, 0.6 mmol). The resulting orange suspension was stirred for 1 day. It was centrifuged and an off white solid was isolated, washed with ethanol and dried over silica gel. Yield: 0.08 g, 0.148 mmol, 99%.

3.1.4. *cis*-[PtCl(HnicO)(PPh_3)$_2$]·0.75CH_3OH·0.5H_2O (**4**)

To a stirred suspension of *cis*-[$PtCl_2$(PPh_3)$_2$] (0.40 g, 0.5 mmol) in ethanol (10 cm^3) was added a methanolic suspension (4 cm^3) of 2-hydroxynicotinic acid (0.14 g, 0.5 mmol) and triethylamine (0.28 cm^3, 2 mmol). The resulting off white suspension was stirred during 2 weeks. It was centrifuged and an off white solid was isolated, washed with ethanol and dried over silica gel. Yield: 0.29 g, 0.32 mmol, 64%. Off-white X-ray quality crystals of **4** were obtained by vapour diffusion of diethyl ether into a solution of the compound in CH_3CN.

3.1.5. [PtCl(HnicO)(bipy)] (**5**)

To a stirred suspension of [Pt(bipy)Cl_2] (0.06 g, 0.15 mmol) in ethanol (5 cm^3) was added a methanolic suspension (5 cm^3) of 2-hydroxynicotinic acid (0.04 g, 0.3 mmol) and triethylamine (0.08 cm^3, 0.6 mmol). The resulting suspension was stirred for 2 weeks. It was centrifuged and a yellow solid was isolated, washed with ethanol and dried over silica gel. Yield: 0.07 g, 0.13 mmol, 87%.

3.1.6. *cis*-[$ReOI_2$(HnicO)(PPh_3)] (**6**)

To a suspension in acetone (20 cm^3) of *trans*-[$ReOI_2$(EtO)(PPh_3)$_2$] (0.31 g, 0.3 mmol) was added 2-hydroxynicotinic acid (0.08 g, 0.6 mmol). The suspension was refluxed by 5 h. Some of the solvent was evaporated until a solid formed. To the dark solution obtained was added ether and a dark suspension was obtained. It was centrifuged and a dark green solid was isolated, washed with ether and dried over silica gel. Yield: 0.05 g, 0.064 mmol, 21%.

3.1.7. $Na_2[Mo_2O_6(HnicO)_2]\cdot 5H_2O$ (7)

2-Hydroxynicotinic acid (1.39 g, 10 mmol) was added to an aqueous solution (20 cm^3) of $Na_2MoO_4\cdot 2H_2O$ (1.21 g, 5 mmol). The resulting suspension was refluxed for 6 h and then filtered off. A white solid was isolated, washed with water and dried over silica gel. Yield: 1.59 g, 2.3 mmol, 91%.

3.1.8. $Na_2[Mo_4O_{12}(HnicO)_2]\cdot 2H_2O$ (8)

A suspension of 2-hydroxynicotinic acid (0.28 g, 2 mmol) was added to an aqueous solution (5 cm^3) of $Na_2MoO_4\cdot 2H_2O$ (0.24 g, 1 mmol). The resulting suspension was refluxed for 3 h and then filtered off. The white solid was washed with hot CH_3CN and dried over silica gel. Yield: 0.20 g, 0.21 mmol, 84%.

3.1.9. $Na_2[W_2O_6(HnicO)_2]\cdot 5H_2O$ (9)

2-Hydroxynicotinic acid (1.39 g, 10 mmol) was added to an aqueous solution (20 cm^3) of $Na_2WO_4\cdot 2H_2O$ (1.65 g, 5 mmol). The resulting suspension was refluxed for 7 h and then filtered off. Some solvent was evaporated and a white solid was formed. It was isolated, washed with water and dried over silica gel. Yield: 0.8 g, 0.91 mmol, 37%.

3.2. Crystallography

The crystal data of the complexes **1** and **2** are given in Table 1, together with refinement details. The X-ray data for all three complexes were collected on a MAR research plate system using graphite Mo Kα radiation at Reading University. The crystals were positioned at 70 mm from the image plate. 95 frames were measured at 2° intervals using an adequate counting time between 2 and 5 min. Data analysis was carried out with the XDS program [24].

The structures were solved by direct methods with the SHELXS program. All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were introduced in the refinement at the geometric idealised positions and given isotropic thermal parameters equal 1.2 times those of the carbon atom they were attached. An empirical absorption correction was applied to intensities of both complexes using version of the DIFABS program modified for image plate geometry [25]. The two structures were then refined by full-matrix least-squares on F^2 until convergence with the SHELXL [26]. ORTEP plots were drawn with the PLATON graphical interface [27].

3.3. Instrumentation

Infrared spectra were measured as KBr pellets on a Mattson 7000 FT instrument. Raman spectra were measured on a Bruker RFS100/S FT instrument (Nd:YAG laser, 1064 nm excitation). ^1H and ^{13}C NMR spectra were recorded on a Bruker AMX300 spectrometer (^1H, 300 MHz; ^{13}C, 75.4 MHz) referenced to $SiMe_4$ or to the solvent. CPMAS ^{13}C NMR spectra were recorded on a Bruker MSL 400P spectrometer at 100.6 MHz with a 4.5 μs 90° pulse, contact time of 2 ms. Mass spectra were recorded on a VG Autospec spectrometer (Micromass, Manchester). Microanalyses (C, H and N) were measured at the Department of Chemistry, University of Aveiro.

4. Supplementary material

Supplementary data are available from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers 188751 and 188752.

Acknowledgements

The authors would like to acknowledge Fundação para a Ciência e a Tecnologia (FCT) for financial support. S.M.O. Quintal thanks the FCT for a postgraduate grant. We also thank EPSRC (UK) and the University of Reading (UK) for funds for the Image Plate System and A.W. Johans for his assistance with the crystallography.

have been studied. We report spectroscopic and electrochemical studies on the complexes with phosphine and phosphine oxide coordination, along with structural characterization of the dppeo complex. The solvent and anion dependent lability of P=O coordination in solution has also been studied.

2. Experimental

All the reactions were carried out under an atmosphere of purified nitrogen, and the solvent chloroform was dried with P_2O_5 and distilled prior to the reaction. Diethyl ether and petroleum ether were distilled before use. The ligands were synthesized according to the reported procedure [9].

2.1. Physical measurements

^{1}H NMR spectra were recorded on a Bruker ACF 200 MHz spectrometer with tetramethylsilane as the internal reference. ^{31}P $\{^1$H$\}$ NMR spectra were recorded on a Bruker AMX 400 MHz spectrometer operating at 162 MHz. H_3PO_4 was used as external reference. FT-IR spectra were recorded in the solid state dispersed in KBr pellets on a Bruker (EQUINOX 55) spectrometer. The MALDI mass spectra were recorded on a Kratos PCKompact spectrometer using an α-cyanocinnamic acid matrix prepared from methanol solutions of the complexes with a laser power of 120. A CH Instruments 600A potentiostat was used for the electrochemical measurements. Elemental analyses were performed on a Carlo–Erba elemental analyzer model 1106.

2.2. Preparation of the complexes

2.2.1. $Cu(dppeo)_2ClO_4$ (1)

About 0.02 g of $[Cu(CH_3CN)_4]ClO_4$ was mixed with 0.05 g (2 equiv.) of the ligand in chloroform (5 ml) and stirred for 20 min. Completion of reaction was ascertained by the absence of free ligand using TLC (eluant: diethyl ether: chloroform, 50:50). During this time, a white turbidity appeared in the reaction mixture. Addition of excess of diethyl ether precipitated complex **1** as a white powder in 83% yield. *Anal*. Calc. for $C_{52}H_{48}P_4O_6ClCu\cdot CHCl_3$ C 57.22, H 4.41. Found: C, 57.8; H, 4.62%. ^{1}H NMR (δ, $CDC1_3$, 293 K): 7.26–7.72 (40H, m), 2.59 (8H, br). ^{31}P NMR (δ, $CDC1_3$, 293 K): −9 (br), +42 (br) ppm. MS (MALDI): *m/z* 893.0 (100) ($[C_{52}H_{48}P_4O_2Cu]^+$, Calc. 891.2.

2.2.2. $Cu(dppmo)_2ClO_4$ (2)

Synthesis of complex **2** was carried out following the procedure used for complex **1**. After 2 h of stirring, the reaction was complete and the complex was precipitated with diethyl ether in 69% yield. *Anal*. Calc. for $C_{50}H_{44}P_4O_6ClCu\cdot 0.5CHC1_3$: C, 59.24; H, 4.35. Found: C, 58.44; H, 4.41%. ^{1}H NMR (δ, $CDC1_3$, 293 K): 7.20–7.75 (40H, m), 3.52 (4H, d, $J_{HH} = 6$). ^{31}P NMR (δ, $CDC1_3$, 293 K): −21 (br), +38 (br) ppm. MS (MALDI): *m/z* 864.7 (100) ($[C_{50}H_{44}P_4O_2Cu]^+$, Calc. 863.15.

2.3. Crystallographic structure determinations

Single crystals were grown from a dichloromethane solution of complex **1** by layering with diethyl ether. Although most of them were opaque, a moderately formed single crystal ($0.3 \times 0.2 \times 0.3$ mm) was sealed in a Lindemann capillary along with the mother liquor and used for data collection. The intensity data were collected on an Enraf–Nonius CAD4 single crystal diffractometer equipped with graphite-monochromatized Mo Kα radiation. The lattice parameters and standard deviations were obtained by least-squares refinements of 25 well orientated reflections in the range $12^\circ \leq 2\theta \leq 24^\circ$. Three reflections were used to monitor the stability and orientation of the crystal during the time of data collection. All computations were performed using the WINGX [12a] package. Data collected at 25 °C were corrected for Lorentz, polarization and absorption effects using DIFABS [12b]. The positions of the heavy atoms were determined by SHELS-86 [12c,12d]. The remaining atoms were located from difference Fourier analysis using SHELXL-97 [12c,12d]. Hydrogen atoms were included in the final stage of the refinement on calculated positions bonded on their carrier atoms.

3. Results and discussion

Copper(I) complexes were made by mixing the BPMO ligand with $[Cu(CH_3CN)_4]ClO_4$ in the appropriate ratio. Since this source of copper(I) has labile acetonitrile ligands, it has been used effectively for the preparation of several complexes with less volatile ligands [1]. In this case, completion of reaction could be confirmed by the absence of free ligand. Once complexation of the ligand was complete, the reaction mixture was treated with a solvent in which the complex was less soluble such as diethyl ether or petroleum ether. In the case of complex **1**, single crystals suitable for X-ray diffraction studies could be obtained. A brief summary of the crystal structure determination is given in Table 1.

3.1. Molecular structure of *1*

The molecular structure of $Cu(dppeo)_2ClO_4$ consists of a cation containing Cu(I) coordinated to two ligands and a non-coordinating perchlorate anion. Fig. 2 shows the cationic part of the molecular structure, and the selected bond distances and angles are given in Table 2.

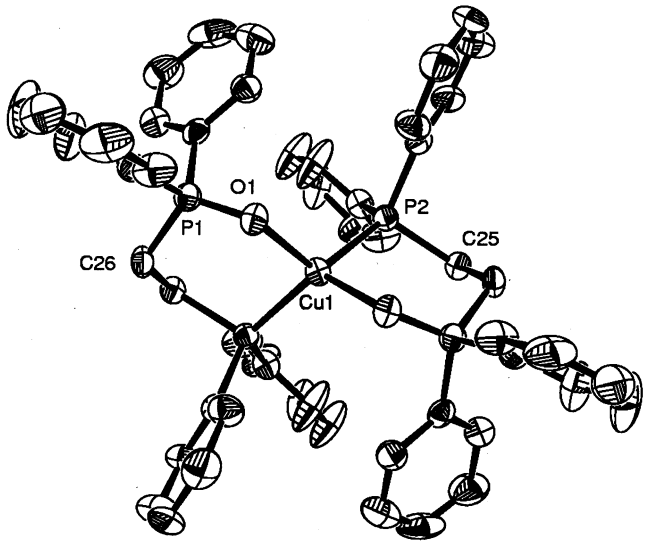

Fig. 2. ORTEP diagram of complex **1** at the 30% probability level. The hydrogen atoms and the disordered counter anion are omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) for complex **1**

Bond lengths (Å)	
Cu(1)–O(1)	2.117(6)
Cu(1)–P(2)	2.225(3)
P(1)–O(1)	1.495(6)
Bond angles (°)	
O(1)–Cu(1)–P(2)	120.32(19)
O(1)#1–Cu(1)–O(1)	98.3(4)
O(1)–Cu(1)–P(2)#1	99.03(18)
P(2)#1–Cu(1)–P(2)	119.19(16)

Two dppeo ligands are in chelating mode. The central copper atom adopts a severely distorted tetrahedral geometry with two P atoms and two O atoms coordinating to it, thus confirming phosphine oxide coordination. The Cu–P distances (2.225 Å) and Cu–O distances (2.117 Å) are in the usual ranges expected for Cu(I) complexes. Chelation produces two six-membered rings which are present in a chair conformation very similar to the reported six-membered chelate structure found in $Cu(dppp)_2ClO_4$, where dppp is bis(diphenylphosphino)propane [13]. The molecule possesses a twofold axis passing through the central metal ion. The angles involving O–Cu–P atoms are symmetry related. The chelate angles O–Cu–P are each 99.0° and the non-chelating O–Cu–P angles are 120.3°. The other angles comprising of O–Cu–O and P–Cu–P are 98.3° and 119.2°, respectively. In the case of copper(II) complexes with PPh_3O, the P=O–Cu (II) [6] unit has an angle of 180° whereas in the present case an angle of 119.9° is observed.

A perchlorate anion, and a solvent molecule were also located in the structure. The perchlorate group remains non-coordinating. As observed in other systems [14], the non-bonded anion is disordered with the chloride atom in a special position, and oxygen atoms exhibiting positional disorder with huge thermal parameters. Modeling the perchlorate ion as two intermeshed tetrahedra with partial occupancies did not improve the fit. The error observed in bond lengths, and angles might be due to the poor quality of the crystal examined.

3.2. IR spectroscopy

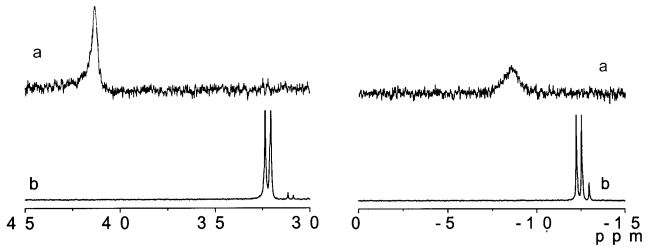
In the absence of a crystal structure for complex **2**, IR spectroscopy appears suitable for characterization of the compound. The coordination of aromatic phosphine oxides to metal complexes is identified by a shift in the $\nu_{(P=O)}$ stretch. This characteristic band is moderately intense and occurs around 1180, and 1183 cm^{-1} in the free ligands, dppeo and dppmo, respectively. IR spectroscopy thus offers the quickest means of proving oxygen atom coordination to Cu. Bonding to Cu(I) results in a significant shift of the P=O stretching frequency to

lower values in complexes **1**, and **2**. Structurally characterized phosphine oxide complexes show broadening of the $\nu_{(P=O)}$ vibration in some cases. Cotton et al. [15], have explained the line broadening to the coupling of two P=O vibrations via the metal atom. In complex **1** no broadening of the P=O stretching frequency could be observed, although, complex **2** exhibited a slight broadening. The bands due to perchlorate anions present in complex **1** and **2** are similar and occur at 1090 cm^{-1} as expected for a non-coordinating perchlorate anion [16].

3.3. ^{31}P NMR studies

The lability of copper(I) complexes in solution is well known [17]. In order to examine the solution behavior of these complexes, the ^{31}P NMR spectra were recorded for the complexes and the free ligand. The free dppeo ligand is soluble in chloroform and slightly soluble in acetone, whereas the complex is sparingly soluble in chloroform and freely soluble in acetone. As a result spectroscopic studies on the free ligand were carried out in acetone-d_6 or when greater concentrations were required, as in ^{31}P NMR, in a mixture of acetone-d_6 and $CDCl_3$. No significant solvent effect was found for the ^{31}P NMR chemical shifts on increasing $CDCl_3$ content. The spectrum exhibits a signal at -12 ppm for the P(III) center, and another peak at $+33$ ppm for the phosphine oxide group (Fig. 3). Similarly, for dppmo, the signals are at -28 ppm for the P(III) center and at $+28$ ppm for the phosphine oxide center. These signals are doublets due to P–P coupling with the values of 53 and 55 Hz for dppmo and dppeo, respectively [9].

An acetone-d_6 solution of complex **1** displays a broad peak at -9 ppm, $\Delta\delta = 3$ ppm, (δ complex$-\delta$ ligand), attributable to coordinated phosphine and a relatively more intense peak at 42 ppm ($\Delta\delta = 9$ ppm) for the phosphine oxide group. A noteworthy feature of the ^{31}P NMR of complex **1** is the disappearance of the doublet pattern observable in the free ligand (Fig. 3). The solution ^{31}P NMR of complex **1** illustrates that the solid state structure is predominantly retained in solution. However, Cu–P coupling is not observed and only broad signals are observable at RT suggesting, an exchange process involving breaking of Cu–P and Cu–O bonds. The peaks are significantly narrower at low temperature. The solution NMR of Cu(dppmo)$_2$$ClO_4$ obtained in $CDCl_3$ and in acetone-d_6, is similar to that of **1** in terms of upfield shifts of the signals ($\Delta\delta_{P=O} = 10$ ppm, $\Delta\delta_P = 7$ ppm) and the line broadening due to an exchange process involving an equilibria where chelation is lost.



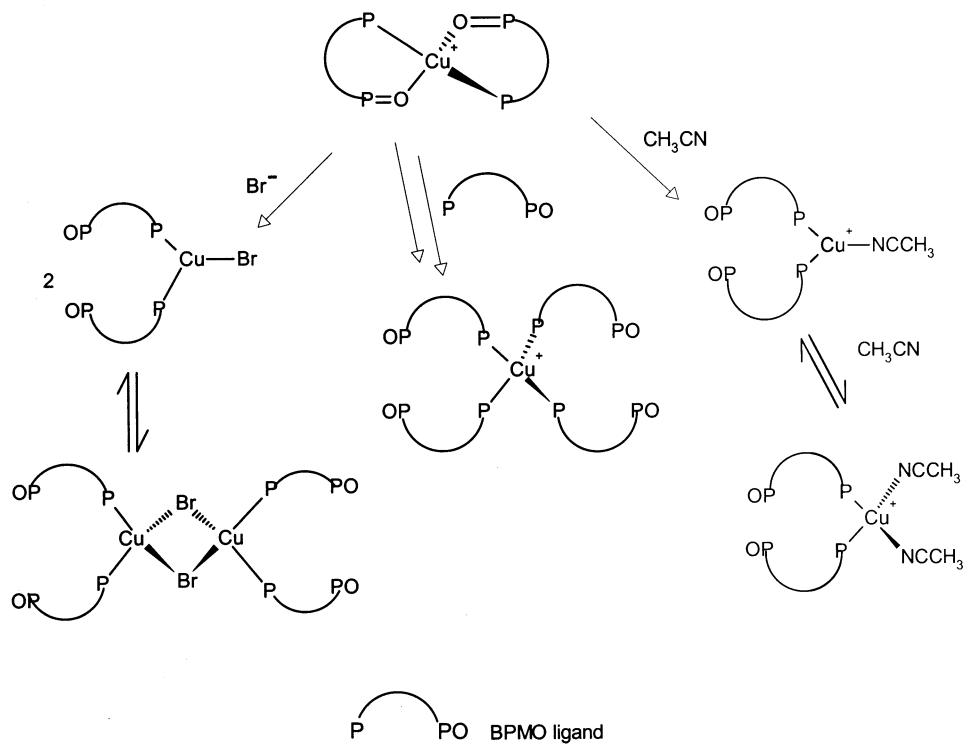


Fig. 3. The ^{31}P NMR of (a) complex **1**, and (b) dppeo.

The two different methylene protons of the dppeo framework are degenerate in ^1H NMR and appear as a broad singlet in the free ligand. The accidental degeneracy is almost removed in the ^1H NMR of **1** and a slight upfield shift (0.31 ppm) of the peaks is observed. Hence it is certain that **1** and **2** possess the expected phosphine oxide coordination in non-coordinating solvents like aetone-d_6 and $CDCl_3$. Based on these evidences we suggest similar solution and solid state structures for **1** and **2** in which only equilibria with non-chelated forms is occurring.

Since rapid equilibria with the non-coordinated forms are involved, it is of interest to examine the relative strengths of the Cu–O/Cu–P bonds through competition experiments. The ability of the P=O group relative to acetonitrile to coordinate to copper(I), which is a moderate π-acceptor was examined by recording the NMR spectrum of complex **1** in CD_3CN as the solvent. The influence of solvent is quite pronounced on the signal for the phosphine oxide group. The P=O group now resonates at $+33$ ppm very close to that of free phosphine oxide group. Interestingly, the signal appears as a doublet and resembles the signal for free P=O present in the ligand. On the contrary, the signal due to phosphine group shows little difference in CD_3CN and retains the position ($\delta = 8.8$ ppm) and line shape observed in acetone-d_6. The spectrum of complex **2** in CD_3CN produces similar results as well. The phosphine moiety shows binding ($\Delta\delta_P = 8$ ppm), while the phosphine oxide signal occurs close to the free ligand with a doublet pattern, ($\Delta\delta_{P=O} = 1$ ppm). These results are in accord with the preference of copper(I) for acetonitrile, a moderate π-acceptor rather than the oxygen of P=O when the former is present in excess.

In another experiment, 4 equiv. of the ligand were added to [Cu(CH_3CN)$_4$]ClO_4 in $CDCl_3$. The presence of 4 equiv. of the dppeo ligand with respect to the copper(I) source, leads to a competition between the chelated structure (CuP_2O_2) and a complex with all four phosphine centers coordinated to Cu(I), with uncoordinated P=O centers. The spectrum indicates the presence of free P=O group and bound phosphine moiety with signals at $+33$ and -9 ppm, respectively. The reappearance of the doublet near the free ligand value for the P(V) center is clearly due to loss of Cu–O bonding. The NMR results indicate that the intermolecular P(III) center is more acceptable to the Cu(I) center than intramolecular interaction from P(V) (see Scheme 1). Thus the CuP_2O_2 unit is stable only in the absence of competitive interactions from soft donors.

Scheme 1.

In a separate experiment, tetrabutylammonium bromide was added to the complex **1** in 1:1 ratio. Addition of bromide increases the solubility of 1 in $CDCl_3$, the phosphine signal in ^{31}P NMR is shifted downfield, where as the P=O signal is close to the free ligand value. The shifts in the ^{31}P NMR spectrum illustrate that the bromide ion retards the coordination of P=O moiety. The accidental degeneracy of the ^{1}H NMR signal in the free ligand is lifted on coordination. Two sets of broad peaks are observed in the ^{1}H NMR spectrum (2.34 and 2.58 ppm) and thus different from what is observed for complex **1**. The $\nu_{(P=O)}$ stretch of the product in this reaction, also occurs close to the free ligand and the IR studies are consistent with what is expected on the basis of NMR studies. When 2 equiv. of the ligand dppeo are mixed with CuBr in $CDCl_3$, similar observations were made in ^{31}P NMR and ^{1}H NMR spectra.

An attempt was made to isolate the complex $(CuBr)(dppeo)_2$ formed in the reaction of CuBr with dppeo following the procedure used for making **1** and **2**. The IR spectral changes for the complex generated in this fashion closely resembles the free ligand spectrum in the $\nu_{(P=O)}$ region. It is to be noted that the ^{31}P resonance of the P=O moiety occurs close to the δ value for free P=O and is different from that in the perchlorate complex, and the resulting NMR matches that observed in the in situ generation of the complex. In addition, the doublet pattern reappears for the P=O signal as in the case of non-coordinating phosphine oxides. However, the white complex isolated in this reaction was relatively unstable and became colored precluding complete characterization.

3.4. Electrochemical studies

Electrochemical studies were performed in chloroform solution using Pt as working electrode and Ag/AgCl as the reference electrode. Tetrabutylammonium perchlorate was used as the supporting electrolyte (0.08 M). All the complexes examined had an electrochemical event in the potential window of 1.4–0 V where the Cu(I)/Cu(II) redox couple is usually observed for copper(I) phosphine complexes [18]. A clean background was ascertained in each experiment prior to the addition of the complex. The results from cyclic voltammograms at 50 mV S^{-1} are reproduced in Fig. 4 and the details of cyclic voltammograms at other scan speeds are summarized in Table 3.

The cyclic voltammogram of $Cu(dppeo)_2ClO_4$ (0.1 mM solution in chloroform) displays well-defined anodic and cathodic peaks (Fig. 4(a)). However, the process is only quasi reversible, as indicated by ΔE_P values and I_p^a/I_p^c, at different scan rates. The electrochemical behavior of complex **2**, $Cu(dppmo)_2ClO_4$ was also examined under identical conditions. Although the $E_{1/2}$ values at different scan rates are comparable to that of **1**, the cathodic process in complex **2** is suppressed and

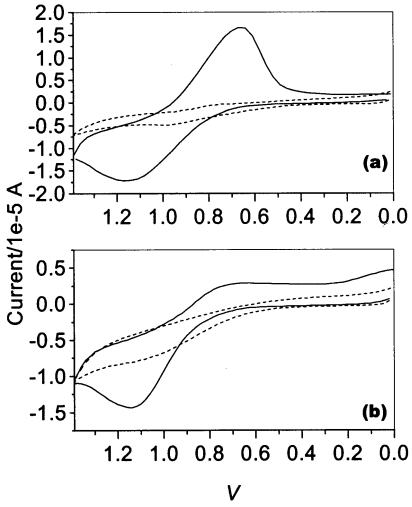

Fig. 4. Cyclic voltammogram of (a) complex **1**, and (b) complex **2**. The broken line traces are for the respective free ligands (scan rate: 50 mV S^{-1}).

I_p^a/I_p^c values at different scan rates are quite large (Fig. 4(b)). The electrochemical behavior of the BPMO derived complexes are dependent on the chain length. The influence of chain length on electrochemical processes in chelate complexes has been noted quite often [19]. The I_p^a/I_p^c values indicate that complex **1** with dppeo shuttles between two oxidation states more readily than complex **2**.

The complex $Cu(dppe)_2ClO_4$ with all soft phosphorus centers in the coordination sphere was also studied for comparison. Unlike complexes **1** and **2**, the $Cu(dppe)_2ClO_4$ shows a broad oxidation wave, while the reduction wave is well-defined and occurs at more positive potentials than for BPMO complexes. The broad anodic peak precludes accurate measurement of an E_{pa} value, and was calculated from the derivative of the cyclic voltammogram. The electrochemical behavior of the relevant ligands was also probed in order to confirm the origin of electrochemical processes. In the potential window studied, the ligands are inactive and the complexes are clearly distinguishable from the ligands due to the presence of the Cu(I)/Cu(II) couple.

The results of the electrochemical studies on BPMO complexes with a mixed coordination sphere are compared with the results from studies on the dppe complex, which possesses only soft ligands in the coordination sphere. The reduction potential values are well-defined in all three complexes, and indicate that the phosphine complex is more easy to reduce (more positive potential), than complex **1** and **2**. Similarly the broad anodic wave of the dppe complex illustrates a less favorable, slower oxidation processes than the BPMO analogues. This trend is also supported by the observation that the addition of excess dppeo (2 equiv.) to the complex **1** shifts the redox processes anodically by 50 mV and approaches the behavior of the CuP_4 complex. The addition of bromide to the complex to generate the bromide complex, complicates the oxidation event with multiple processes presumably due to the presence of an equilibrium in solution as illustrated in the Scheme 1. However, at least one of the processes requires a more positive potential than the CuP_2O_2 system. This can be reasonably attributed to the dimeric species, while the other wave might originate from the three-coordinated monomer. As expected, the reduction potential of the bromide complex is more positive than the BPMO complexes.

Hence the electrochemical results are suggestive of the fact that the CuP_2O_2 system is relatively easier to oxidize to the copper(II) complex. Whereas, a complex with an all soft coordination environment, is more difficult to oxidize. Complexes with the P_2O_2 ligand set are readily synthesized and stable enough for isolation when copper(I) is not given a choice to coordinate to soft ligands.

4. Summary

The present study indicates that bis(phosphine) monooxides are suitable ligands for Cu(I) and form stable copper(I) complexes. It is also clear that the Cu–O bond and Cu–P bonds are quite labile. Unlike the Cu–P bond the Cu–O bond requires a non-coordinat-

Table 3
Cyclic voltammetry data

Complex	Scan rate mV S^{-1}	E_{pa}	E_{pc}	$E_{1/2}$	I_p^a/I_p^c
$Cu(dppeo)_2ClO_4$	20	1.19	0.70	0.94	0.6
	50	1.17	0.67	0.92	0.6
	100	1.30	0.48	0.89	
$Cu(dppmo)_2ClO_4$	20	1.06	0.68	0.87	4
	50	1.14	0.65	0.89	3.8
	100	1.20	0.56	0.88	
$Cu(dppe)_2ClO_4$	50	1.25	0.80	1.02	
$Cu(dppeO)_2ClO_4$+2 equiv. of dppeo	50	1.24	0.73	0.98	
$CuBr(dppeo)_2$	50	1.25, 1.08	0.78		

ing counter anion or solvent to remain in the coordination sphere of copper(I). Spectroscopic studies show that copper(I) would favor soft donors to O, a hard donor in its coordination sphere. In a situation where 4 equiv. of the BPMO ligand are made available for copper(I), the coordination of four P atoms to Cu is favored. Even entropy driven stabilization of the CuP_2O_2 coordination fails to win over the CuP_4 coordination. The electrochemical behavior of the complexes illustrates that the mismatched coordination environment leads to a copper(I) center that is more easily oxidized. Thus the four phosphine-coordinated complex is more difficult to oxidize than the complex with two O and two P atoms. The greater stability Cu(I) complexes with a complement of soft ligands is evident from these competition experiments.

5. Supplementary material

Crystallographic data for the crystal structure of **1** has been deposited at the Cambridge Crystallographic Data center as CCDC-175552. These data can be obtained free of charge at www: http://www.ccdc.cam.ac.uk/conts/retrieving.html or from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk.

metal ion binding sites as well as conformational changes that occur on the ligand by chelation. In a first time, the complexation mechanism with Al(III) of 3-hydroxyflavone, 5-hydroxyflavone and 3′4′-dihydroxyflavone have been studied by spectroscopy and quantum chemical calculations [17–19], these molecules possess only one chelating site. In a second time, the quercetin molecule, that presents three potential sites for the coordination of Al(III), has been investigated in order to compare the chelating power of the different sites in competition [20]. As a continuation of this work, we report, in this paper, the study of the complexation of Al(III) by isoquercitrin (2-(3,4-dihydroxyphenyl)-3-(β-D-glucofuranosyloxy)-5,7-dihydroxy-4H-1-benzopyran-4-one). Isoquercitrin (Fig. 1) presents two chelating sites: the 5-hydroxy-4-keto and the 3′,4′dihydroxyl (catechol) groups in competition towards aluminium ion. The aim of this study is to determine the first site implicated in the complex formation with Al(III), the stoichiometry and formation constants of complexes. Due to the very low solubility of isoquercitrin in water, study in methanol solution was performed. The pH influence upon the complexation has been investigated by adding sodium acetate or methanoate to the solution. The molecular geometry of the free ligand and of the formed complexes has been optimized by semiempirical molecular orbital calculations (AM1 method) in order to observe the conformational changes engendered by the chelation. Recent advances both in computational chemistry and in rapidity of computers make it possible to optimize structures of medium-size molecules by density functional theory (DFT). So, from geometrical parameters obtained by the AM1 method, the structures have been re-optimized by DFT. Electronic and vibrational spectroscopies were used to confirm the theoretical models.

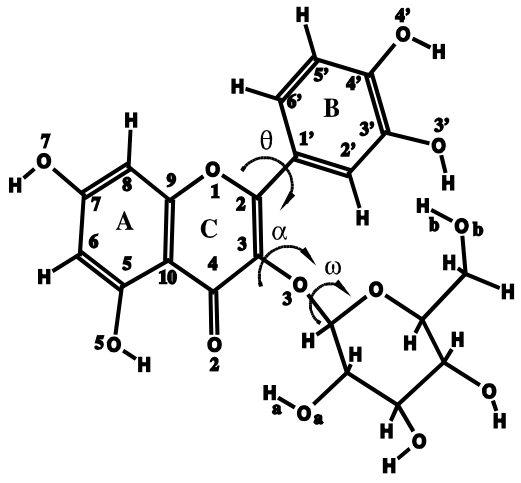

Fig. 1. Scheme and atomic numbering of isoquercitrin.

2. Experimental

2.1. Solution preparation for spectrophotometric methods

Isoquercitrin was obtained commercially from Extrasynthèse (France). Anhydrous aluminium chloride, hydrochloric acid, sodium acetate, sodium methanoate and spectroscopic grade methanol were used without purification.

The molar ratio method, introduced by Yoe and Jones [21] permits to deduce the composition of complexes in solution from spectrophotometric spectra. For this method, solutions containing a constant concentration (4×10^{-5} M) of isoquercitrin in methanol and variable concentration of $AlCl_3$ (from 4×10^{-7} to 4×10^{-2} M) were prepared. In order to verify the results of the first method, the complex stoichiometry has also been determined by the method of continuous variation (Job's method). For the study in alkaline solution, isoquercitrin solutions were successively prepared in methanol containing sodium acetate 10^{-1} M, and in methanol with 5×10^{-3} M of sodium methanoate. The molar ratio method was used for the determination of complex stoichiometry. In acidic medium, the solutions consist in a mixture of 90% methanol–10% water where the ionic strength has been adjusted to 0.1 with sodium chloride. The aqueous solution contains hydrochloric acid 3.2×10^{-2} M (apparent pH 2.5).

2.2. Instrumentation

The UV–Vis spectra were recorded on a Cary-1 (Varian) spectrophotometer with cells of 1 cm path length. FT-Raman spectra of isoquercitrin (10^{-2} M) and of its complexes with Al(III) were recorded with a Bruker IFS 88W spectrometer connected to a Raman module (Bruker, FRA-106). Radiation of 1064 nm from an Nd:Yag laser was used for excitation with a laser power of 300 mW. An excitation in the near-infrared range allows the collection of fluorescence-free spectra.

2.3. Calculations

The formation constants of the complexes of isoquercitrin were estimated by using a multivariate data analysis program for modelling and fitting equilibrium titration 3D data sets obtained from the spectrophotometric measurements. The UV–Vis spectra were refined using the SPECFIT software (version 3.0) [22]. The set of spectra obtained at variable Al(III) concentration were treated by evolving factor analysis (EFA) [23] in order to determine the number of absorbing species in the system and the pure electronic spectrum of each complex. The SPECFIT software has also been used to estimate the stability constants (β) of the complexes and the standard deviation (σ) of each value. In order to obtain

the best fit between the complexation model and the experimental data, several models of complexes with different stoichiometries and with different initial constant values have been envisaged for the refinement of the stability constants.

The free isoquercitrin molecule was previously studied by us [24] using the Austin Model 1 (AM1) quantum mechanical semiempirical method [25] with the HYPERCHEM program [26]. Three stable conformers (noted Ia, Ib and Ic) with equivalent energy have been found for the molecule. Their molecular structures only differ by the torsional angle of the B ring and by the glucose orientation. These three conformers are stabilized by seven or eight intramolecular hydrogen bonds involving both aglycon and sugar moities. In this study, only the conformer Ib, with a θ angle value of -14.3° has been considered for DFT calculations.

The DFT calculations with the hybrid functional method (B3LYP) [27,28] were carried out by using the GAUSSIAN 98 program package [29] implemented on a IBM RS/6000 SP computer. We performed full structural optimizations of the free isoquercitrin and of the more predominant complexed forms starting from geometrical data first obtained by the quantum semiempirical treatment. Due to the size of the molecular system, the 6-31G* basis set was used for all the calculations. In order to reduce the computational time, the SCF convergence criterion has been set to 10^{-6}. For the complexes, water molecules have been added to aluminium atoms to obtain an octahedral environment of this ion and thus to respect its valence. Previous studies indicated that the substitution of water by methanol has only little influence on the calculated structure of aglycon.

The wavelengths of electronic transitions observed in the UV–Vis spectra of isoquercitrin and of its complexes have been calculated with HYPERCHEM program using a configuration interaction treatment. This calculation only takes into account the contribution of the singly excited configurations involving the 11 highest occupied and the 11 lowest unoccupied molecular orbitals.

3. Results and discussion

3.1. Stoichiometry and formation constants of complexes in neutral methanol

The electronic spectrum of free isoquercitrin in methanoic solution is mainly characterised by an important absorption band (band I) at 359 nm. The addition of anhydrous $AlCl_3$ to an isoquercitrin solution in methanol results in important modifications of the UV–Vis spectrum of the flavonoid, with the appearance of a new band centred on 406 nm for $[AlCl_3]$–[Iso] ratios comprised between 0 and 0.5. For these ratios, an isobestic point is observed at 380 nm, indicating an equilibrium between the free molecule and a first complexed form (complex I). For ratios $0.5 < [AlCl_3]$–$[Iso] < 1$, bathochromic shifts of the band at 406 nm are observed with the increase of added $AlCl_3$ amount, no isobestic point is then observed, and let presume the presence of at least three different absorbing species in solution. For ratios superior to 1, a new isobestic point appears at 409 nm, indicating a novel equilibrium between two complexed forms of isoquercitrin and the absorption maximum of the second complex is centered on 436 nm. The fact that a certain number of spectra do not cross at one of the two possible isobestic points provides evidence that the second complex formation begins before a complete chelation of the first site of free isoquercitrin. So, for ratios $0.5 < [AlCl_3]$–$[Iso] < 1$, one can simultaneously observed the formation of the two complexes. The UV–Vis spectra on Fig. 2 illustrate the different steps occurring in the chelation process of isoquercitrin with Al(III) according to the $[AlCl_3]$–[Iso] ratio.

The molar ratio method was used to determine the stoichiometry of the complexes of isoquercitrin with aluminium(III). In this method ideally two straight lines are obtained when the absorbance at one wavelength is plotted versus the Al(III) to flavonoid ratio, and the point of intersection of these two lines corresponds to the stoichiometric ratio upon interpolation to the molar ratio axis. The molar ratio plots at 406 nm (λ_{max} of the first complex: complex I) and at 436 nm (λ_{max} of the second complex: complex II) are presented on Fig. 3(b), respectively. The curve of absorbance versus $[AlCl_3]$–[Iso] molar ratio plotted at 406 nm (Fig. 3(a)) clearly shows a stoichiometry of 1:1 for complex I. The presence of more than one complexed forms in the

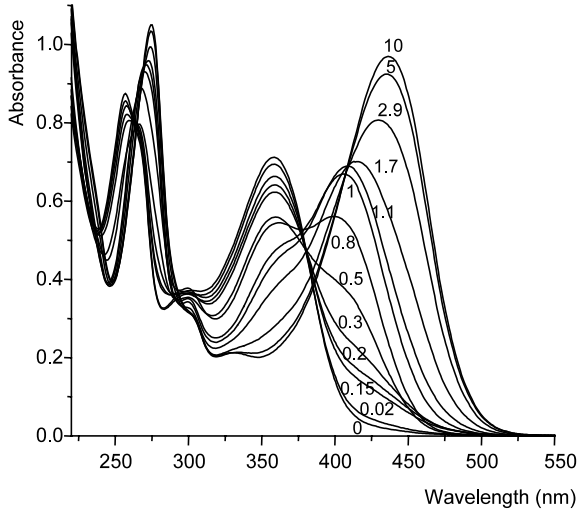

Fig. 2. Evolution of UV–Vis spectra of isoquercitrin in neutral methanol in presence of $AlCl_3$. The molar ratio [Al(III)]–[Iso] is indicated on each spectrum.

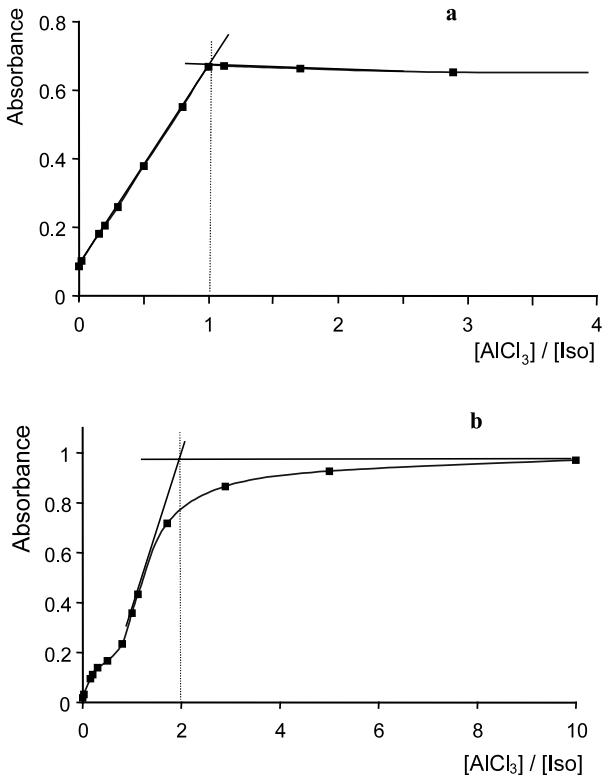

Fig. 3. Absorbance vs. $[AlCl_3]$–[Iso] molar ratio plots at 406 nm (a) and 436 nm (b).

system simultaneously, is reflected on the shape of the curve shown in Fig. 3(b). For the second complex, one can deduce from this curve that two aluminium ions are coordinated to the ligand, and so a Al(III)–Iso = 2:1 stoichiometry. However, one can notice that a tenfold excess of aluminium(III) is necessary to obtain a complete complexation of isoquercitrin. The stoichiometries of the two complexed species have been confirmed by the Job's method or continual variations method (results not shown). Similar results were obtained by Porter et al. concerning rutin (3,5,7,3′,4′-pentahydroxy-flavone-3-*O*-rutinoside), a parent of isoquercitrin, where the sugar at position 3 is not a glucose but a rutinose [30]. These authors have found, in neutral methanol solution, the formation of two complexes of stoichiometry Al(III)–rutin = 1:1 and 2:1.

In order to know the potential site involves in formation of the first complex, pH conditions were changed by adding concentrate HCl to the complex II solution. The acid addition has led to a complete vanishing of the electronic absorption band relative to complex II, whereas the absorption band of complex I was not modified. Our previous works, concerning notably the complexation of 3′4′-dihydroxy-flavone and quercetin, have shown that *ortho*-dihydroxyl group does not complex aluminium(III) in very acidic medium. This fact allows to conclude that the catechol group is only involved in the second step of the complexation of isoquercetin, and consequently it could be predicted that, in complex I, the coordination of isoquercitrin with Al(III) in neutral methanol solution takes place through the carbonyl and hydroxyl group in position 5 of the molecule. So, for low concentration of aluminium in methanol, Al ion coordinates with the 5-hydroxychromone group to lead to the formation of $Al(Iso)^{2+}$ complex, and for larger amount of aluminium ($[AlCl_3]$–[Iso] > 0.5) a second atom of Al(III) coordinates to the catechol group to give the complex II $(Al_2Iso)^{3+}$. In pure methanol, only hydroxyls involving in chelate are deprotonated.

From electronic spectra obtained by varying the $[AlCl_3]$–[Iso] molar ratio, the determination of the number of spectroscopically distinct species was estimated by the EFA method. Three principal components were found corresponding, respectively, to spectra of free ligand, $Al(Iso)^{2+}$ and $Al_2(Iso)^{3+}$ complexes. A fourth component can be also detected only in the first spectra and with a very low contribution. However, it is worth noting that the electronic spectrum of a specie only existing in very minor concentration is poorly defined. Further, spectral changes due to the coordination of one, two or three ligands on the Al(III) atom are rather similar insofar as the same chelating site is implicated, and thus difficult to differentiate. In order to estimate the formation constants and with regard to our previous observations, a numerical treatment of the electronic spectra has been carried out starting from a simple model containing species with stoichiometry 0:1, 1:1 and 2:1 (metal–ligand). The relatively large deviation of this model from the experimental data, reflected by the σ values, led us to introduce new species. Several ratios and initial formation constants were tested, introducing the model or the species that yield more reasonable fittings. The model which provides the best fit to the experimental spectra is composed of the complexes of stoichiometry (metal:ligand) 1:1 ($\log \beta = 6.49 \pm 0.16$), 1:2 ($\log \beta = 10.50 \pm 0.19$) and 2:1 ($\log \beta = 11.24 \pm 0.17$). This result comes from the following reaction equation:

$$a\mathrm{Al} + b\mathrm{Iso} \Leftrightarrow \mathrm{Al}_a\mathrm{Iso}_b$$

with the corresponding stability constant:

$$\beta = \frac{[\mathrm{Al}_a\mathrm{Iso}_b]}{[\mathrm{Al}]^a[\mathrm{Iso}]^b}$$

The deprotonation of the oxygen atoms at the level of the chelating site has not been taking into account in the constant calculation insofar as the pH notion has no much sense in methanoic medium. Moreover, no deprotonated form of the ligand exits in this medium. The minor participation of the complex $Al(Iso)_2^{+}$ is illustrated on Fig. 4 which shows the concentration variations of the different species versus the added

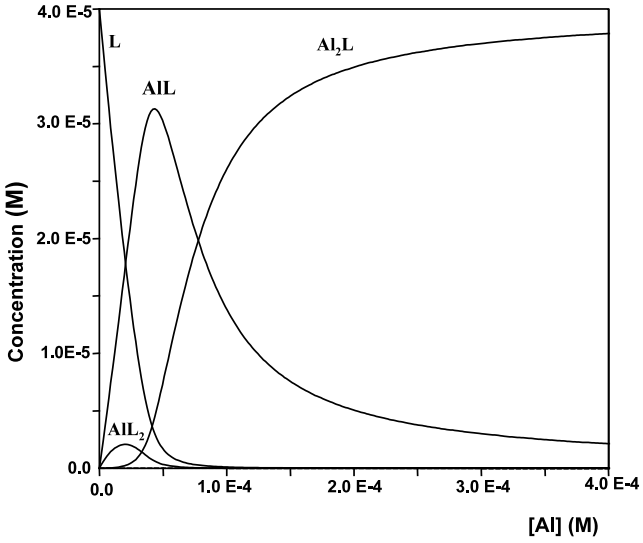

Fig. 4. Distribution curves of the aluminium complexes with isoquercitrin in methanol as a function of Al(III) concentration.

quantity of aluminium. These curves well confirm that the chelation of the second site (catechol), with the formation of $Al_2(Iso)^{3+}$, occurs before a complete formation of the first complex $Al(Iso)^{2+}$. For purpose of comparison, the complexation of Al(III) by quercetin shows that two consecutively steps occur. The chelation at the level of the catechol group only starts when the totality of ligands is already involved in the first complex implicating the 3-hydroxychromone group.

3.2. Conformational analysis of complexes

The most relevant structure parameters of isoquercitrin, complex I $Al(Iso)(H_2O)_4^{2+}$ and complex II $Al_2(Iso)(H_2O)_8^{3+}$ determined with both the semiempirical AM1 and B3LYP/6-31G* DFT methods are given in Tables 1–3. Only bond lengths and valence angles of the aglycon have been reported, and the main torsion angles have been selected. Concerning the free ligand, the bond lengths and valence angles of the γ-pyrone ring calculated with DFT are slightly different than those obtained from AM1 calculations, whereas the valence bonds and angles of both A and B rings show minor differences. The comparison of the torsional angle values obtained with the two methods reveals small discrepancy in the sugar orientation (α and ω angles), while the position and the orientation of the B ring are similarly calculated. The C–O distances relative to the hydroxyl groups calculated at the DFT level are a little bit smaller than those obtained by the AM1 method.

With regard to isoquercitrin, the geometrical parameters of complexes I and II, vary in the same way and commonly with the same magnitude for both methods of calculations. By coordination of Al(III) on the 5-hydroxy-4-keto site, the structure of the ligand is profoundly modified as well for bond lengths as for valence angles. The γ-pyrone ring is the most affected part of the molecule. A clear decrease of the values of C(3)C(4), C(4)C(10) and of the inter-ring bond C(2)C(1′) is observed associated to an increase of the C(2)C(3) bond length that takes a single bond character. The B ring geometry is also modified, the C(1′)C(2′), C(3′)C(4′), C(4′)C(5′) and C(6′)C(1′) bond lengths increase whereas C(2′)C(3′) and C(5′)C(6′) are calculated shorter than in the free ligand. These observations let assume a preponderant participation of a mesomeric cynnamoyl form (Fig. 5(a)). This is confirmed by the shortening of 0.02 Å of the C(4′)O(4′) bond that is more influenced than the C(3′)O(3′) one. The participation of a benzoyle mesomeric form (Fig. 5(b)) to the resonance of the system is manifested by the reduction of the C(5)C(6), C(8)C(9) and C(7)O(7) and the augmentation of the C(10)C(5), C(6)C(7), C(7)C(8) and C(9)C(10) bond lengths. In spite of the increase of the electronic conjugation over the chromone part and the B ring, through the inter-ring bond, the aglycon is not planar and the θ value is very weakly reduced. The strong intra-molecular hydrogen bonds established between the glucose and the B ring should certainly prevent its rotation. At the level of the chelating site, the six-membered ring obtained with the coordination of Al(III) is slightly puckered with the metallic ion out of plane. For purpose of comparison, the chelation of the quercetin molecule with aluminium on the 3-hydroxyl-4-keto site led to a structure mainly stabilised by a pyronium mesomeric form [20].

The chelation of the entity $Al(H_2O)_4^{3+}$ on the catechol group, to form the complex II, leads to an important steric hindrance with the sugar moiety. The consequence is a rotation of the B-ring that adopts a θ value of 27° (−13° for the free ligand) and a reorientation of the glucose with a modification of α and ω angle values. The electronic delocalisation between the B ring and the γ-pyrone is reduced and then the inter-ring bond length increases with respect to complex I. In this second complex, the contribution of the benzoyle form to the stabilisation of the aglycon structure is reinforced, whereas the cynnamoyl form becomes insignificant.

3.3. Model validation by FT-Raman and UV–Vis spectroscopies

Changes in the vibrational spectra caused by the coordination of a Al(III) ion to isoquercitrin have been used to confirm that the first site implied in the complexation mechanism is the 5-hydroxyl-4-keto group. A complexation at the level of the 3-hydroxyl-4-keto group must result in a considerable modification of the carbonyl vibration band. The FT-Raman spectrum of isoquercitrin in methanol solution exhibits lines at 1657 and 1617 cm^{-1} (shoulder) which can be,

respectively, assigned to C(4)=O(2) and C(2)=C(3) stretching modes. However, ours previous studies have shown that for such flavonoids, the carbonyl stretching is partially coupled with the C(2)=C(3) stretching vibration. Thus, the frequency generally assigned to the carbonyl function involves a participation of the C(2)=C(3) vibrator, and consequently the vibrational normal mode attributed to C(2)=C(3) stretching also implicates the carbonyl vibration. The addition of aluminium to the isoquercitrin solution (with [Al(III)]–[Iso] ratio < 1) significantly modifies the spectrum both in wavenumbers and intensity, notably in the spectral range 1200–1700 cm^{-1}. The Raman line previously assigned to the carbonyl vibration disappears, whereas the C(2)=C(3) stretching mode shifts to 1635 cm^{-1}. The high frequency shift observed for the C(2)=C(3) vibration might seem incoherent with an increase of the C(2)=C(3) bond length in complex I with respect to isoquercitrin and a displacement to lower frequencies of this mode would be expected. This fact can be easily explained by the mechanical coupling between the C(4)=O(2) and C(2)=C(3) vibration modes in isoquercitrin. This coupling increases the carbonyl frequency and decreases the C=C frequency, whereas in complex I, the line at 1635 cm^{-1} corresponds to a pure C(2)=C(3) stretching vibration. Two new intense bands located at 1548 and 1426 cm^{-1} appear in the Raman spectrum of complex I. These lines can be, respectively, assigned to the anti-symmetric and symmetric C–O stretching modes involving the C(4)–O(2) and C(3)–O(3) bonds. In the same time, the line at 1501 cm^{-1} attributed to the C(3)–O(3) stretching mode in the isoquercitrin Raman spectrum, has totally vanished of the complex spectrum. All these observations validate the hypothesis that chelation between Al(III) and isoquercitrin firstly occurs with the 5-hydroxyl-4-keto site. Nevertheless, the complex FT-Raman spectrum does not allow to observe and to differentiate the two forms: $Al(Iso)^{2+}$ and $Al(Iso)_2^{+}$, certainly because of the low concentration of this last one.

In order to obtain additional arguments for the structural modifications of the ligand engendered by the complexation with Al(III) and to certain of the presence of the $Al(Iso)_2^{+}$ complex, the electronic spectra of the different forms have been calculated and compared with the experimental ones. Due to the size of studied systems (more than hundred atoms for $Al(Iso)_2^{+}$), only semiempirical calculations could be envisaged. From optimised structures, the electronic spectra of isoquercitrin and of its three complexed forms

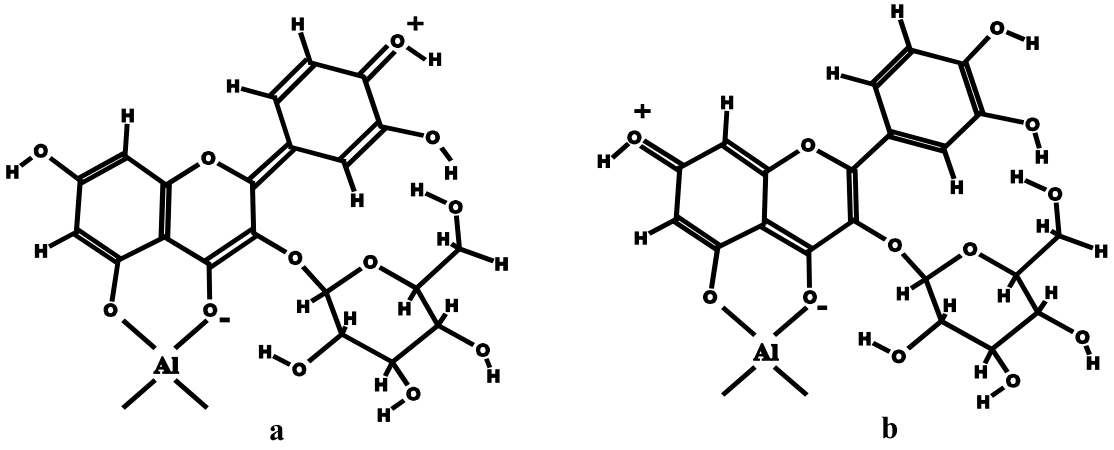

Fig. 5. Cinnamoyl (a) and benzoyle (b) mesomeric forms participating in the resonance of $Al(Iso)(H_2O)_4^{2+}$. Water molecules have been omitted.

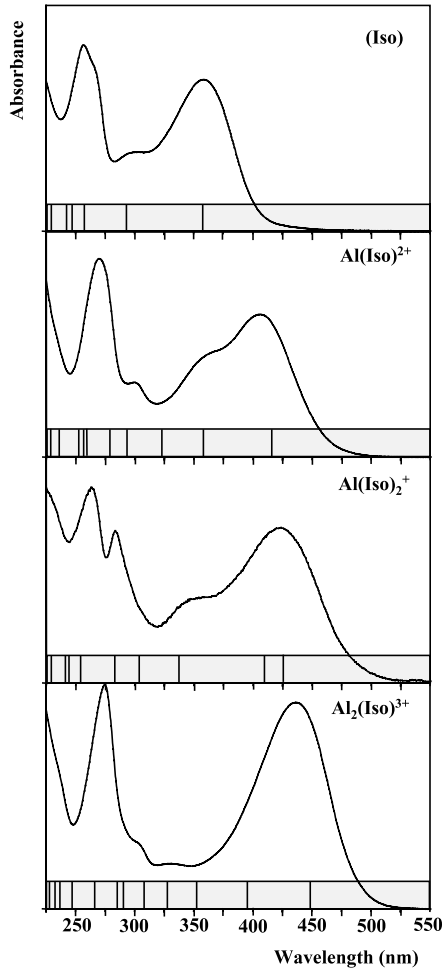

Fig. 6. UV–Vis spectra of isoquercitrin and its complexes with aluminium(III) in methanol. Vertical lines correspond to allowed calculated transitions.

isoquercitrin with a [Al(III)]–[Iso] ratio of 10, whereas the UV–Vis spectra of $Al(Iso)^{2+}$ and $Al(Iso)_2^{+}$ have been extracted using the SPECTFIT program. For all the compounds, a rather good accord is observed between the experimental spectra and the calculated allowed electronic transitions. Notably, excellent agreement of the experimental and calculated longest-wavelength band positions is obtained. This transition mainly involves the HOMO→LUMO contribution and presents a $\pi \rightarrow \pi^*$ character. Moreover, the bathochromic shift of the band I observed by addition of Al(III) to isoquercitrin is well reproduced by the CI calculations. The calculated electronic spectrum of complex $Al(Iso)_2^{+}$ is consistent with the extracted spectrum by SPECTFIT program and proves the existence of this form despite its low contribution. The accuracy found in the electronic spectra of isoquercitrin and of its complexes validates the geometries of these different forms obtained by the quantum chemical calculations.

3.4. Influence of the deprotonation state of isoquercitrin upon complexation

As previously explained, the *ortho*-dihydroxyl group cannot be involved in a complex with Al(III) in acidic medium. The voltammetric studies of Downard et al. [31] concerning the catechol–Al(III) system have shown that no complex is formed for pH below 4, whereas chelates of high stoichiometry particularly dominate in alkaline solution. We have studied the complexation of isoquercitrin in a mixture methanol (90%)–water (10%), in presence of HCl (3.2×10^{-2} M). The addition of $AlCl_3$ to the isoquercitrin solution leads to the formation of a complex of stoichiometry 1:1 involving the 5-hydroxyl-4-keto site, this complexed form is the same as this obtained in neutral methanol.

The complexation of isoquercitrin has also been investigated in alkaline medium, by adding to the methanol solution either sodium acetate (10^{-1} M) or sodium methanoate (5×10^{-3}). Generally, the flavonols are decomposed in alkaline medium. Dechene has shown that the unprotrected hydroxyl on position 3 contributes to the instability of flavonols, and conse-

quently the glycosilation on position 3 increases the stability of these compounds [32]. Thus, isoquercitrin is stable in presence of MeO^-, whereas the quercetin molecule is decomposed. The presence of sodium acetate or methanoate ionizes only the most acidic hydroxyl group in flavonoids and these ions compete with the potential sites of the molecule for complexing the metal ion. In flavonoids, the weakest acidic hydroxyl groups are generally in position 3, 7 and 4′ [33], in the case of isoquercitrin, only 7-hydroxyl and 4′-hydroxyl groups are susceptible to be deprotonated. The protonation constants of rutin have been spectroscopically determined by Escalar et al. [34], they estimated the two first pK_a at 7.1 and 8.3 but these last values have not be assigned to particular hydroxyl groups. As rutin only differs from isoquercitrin by the nature of the sugar, it is reasonable to think that the pK_a values of isoquercitrin are very close to those of rutin. The works of Jurd et al. [35] suggest that the hydroxyl function on position 7 of flavones and flavonols is more acidic than the other hydroxyls present in compounds, and that the presence of a free 7-hydroxyl group is observed by a bathochromic shift of the low wavelength band in alcoholic sodium acetate medium. On the other hand, for quercetin, Sauerwald et al. [36] propose pK_a values of 7.0 for the 3′ or 4′ positions and 9.1 for the hydroxyl on position 7, implicating that the 4′-hydroxyl is more acidic than the 7-hydroxyl. Nevertheless, these values are dubious and in complete disagreement with earlier studies concerning this kind of flavonoids such as morin (3,5,7,2′,4′-pentahydroxyflavone) [34,37]. Finally, the quercetin monoanion may be a mixture of tautomer species formed upon deprotonation of the most acidic 4′-hydroxyl and 7-hydroxyl group [38,39].

The UV–Vis spectrum of isoquercitrin in presence of acetate (Fig. 7(b)) exhibits a bathochromic shift of both the two absorption bands (band I: $\lambda_{max} = 378$ nm) with respect to the isoquercitrin in pure methanol spectrum (band I: $\lambda_{max} = 359$ nm) (Fig. 7(a)). This spectrum could be mainly assigned to the mono-deprotonated molecule involving two forms with deprotonation of the 4′-OH and 7-OH groups. Whereas the spectrum of isoquercitrin in presence of methanoate (band I: $\lambda_{max} = 407$ nm; Fig. 7(c)) could be attributed to a bi-deprotonated form with deprotonation both in 4′ and 7 positions. The addition of aluminium to the solution in presence of AcO^- leads to the formation of a first complex of stoichiometry 1:1. The spectrum (Fig. 7(d)) (band I: $\lambda_{max} = 425$ nm) of this chelate totally differs of the spectrum of complex 1:1 obtained in pure methanol. Therefore, the site implicates in this chelate is the catechol group and the formed complex is $Al(Iso)^+$. In a same way, the catechol group is involved in the complex obtained with isoquercitrin in presence of MeO^- (Fig. 7(e)) but with a stoichiometry Al(III):Iso = 1:2. Both with AcO^- or MeO^-, a large amount of added $AlCl_3$, with $[AlCl_3]$–[Iso] > 1 leads to the formation of a same complex (band I: $\lambda_{max} = 436$ nm) of stoichiometry Al(III)–Iso = 2:1, where the two potential sites are involved.

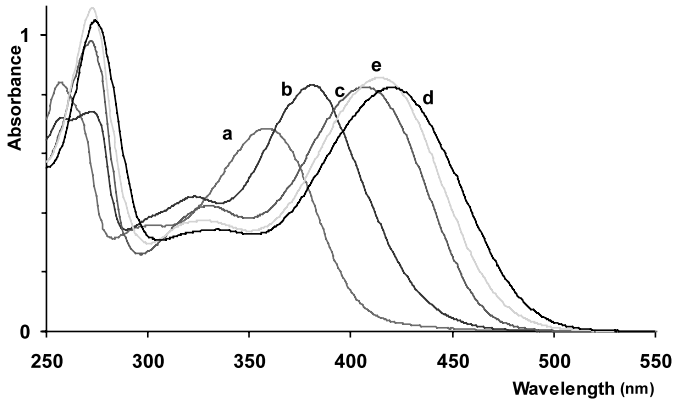

Fig. 7. UV–Vis spectra of: (a) isoquercitrin in pure methanol, (b) in pure methanol in presence of acetate, (c) in methanol in presence of methanoate, (d) of the complex in methanol in presence of acetate, (e) of the complex in methanol in presence of methanoate.

4. Conclusion

UV–Vis and Raman spectroscopies have permitted to determine the composition and the involved chelating sites of complexes of Al(III) with isoquercitrin molecule. Table 4 resumes the complexed species observed in different media and the chelating group involved in each form. It is worth noting that the formation of complexes simultaneously involving the two potential chelating sites necessitate a great amount of aluminium, and reasonably only the first formed specie present an interest. In acidic and in neutral conditions, the 5-hydroxy-4-keto group has a chelating power superior to the catechol group, whereas the complexation in alkaline medium occurs in the reverse order.

Table 4
Complex composition of Al(III) with isoquercitrin in different media

Medium	Complex	Chelating site
Neutral methanol	$Al(Iso)^{2+}$	5OH
	$Al(Iso)_2{}^+$	5OH
	$Al_2(Iso)^{3+}$	5OH + cat
Methanol + H_2O + HCl	$Al(Iso)^{2+}$	5OH
Methanol + AcO^-	$Al(Iso)^+$	cat
	$Al_2(Iso)^{3+}$	5OH + cat
Methanol + MeO^-	$Al(Iso)_2{}^-$	cat
	$Al_2(Iso)^{3+}$	5OH + cat

The last column present the group(s) involved in each complex. 5OH is relative to 5-hydroxy-4-keto group and cat to the catechol group.

attempt to recrystallize **3** from CH_3CN, afforded single crystals of a compound of formula [Cu(HMANO)-(bipy)$_2$](HMANO)·H_2MANO·CH_3CN (**3a**).

In the 3000–3500 cm^{-1} region, the IR spectra of **1**–**3** show two bands, generally of medium intensity, corresponding to OH stretching vibrations. The strong band around 1590 cm^{-1} is attributable to ν_{asym}(OCO), and the band between 1330 and 1390 cm^{-1} to ν_{sym}(OCO). The values of $\Delta\nu = \nu_{asym}(OCO) - \nu_{sym}(OCO)$, 209–258 cm^{-1}, are typical of monodentate carboxylato groups [8] and very similar to those found in copper(II)/α-hydroxycarboxylato/1,10-phenanthroline systems [9]. The bands around 1490 and 1450 cm^{-1} are due to the C=C and C=N stretching modes of the coordinated 2,2′-bipyridine molecules. A weak band around 400 cm^{-1} is assignable to ν(CuO), and the band between 250 and 300 cm^{-1} is tentatively identified as due to ν(CuN) [10].

The three compounds have similar diffuse reflectance spectra (Table 2). They consist of an intense charge transfer band between 26600 and 28600 cm^{-1} together with a broad d–d band centred at wavenumbers typical of octahedral copper(II) complexes with tetragonal distortion, 14200–12800 cm^{-1} [11].

Table 2
UV–Vis spectra, EPR and magnetic moment data for complexes **1**–**3**

Complex	UV–Vis (cm^{-1})	$G_{\|\|}$	$g_\perp$	$g_{av.}$	μ_{eff} (BM)
1	26 600, 14 200	2.29		2.06	1.47
2	27 030, 12 850	2.30	2.04	2.08	1.67
3	28 570, 12 800	2.25	2.03	2.09	1.56

The magnetic moments of **1** and **3** fall as temperatures rises. At room temperature μ_{eff} is only 1.47 BM for **1**, 1.67 BM for **2** and 1.56 BM for **3**. Such low values suggest the possibility of antiferromagnetic coupling between metal centres [12,13], although low magnetic moments are also displayed by mixed complexes of Cu^{II} with 1,10-phenanthroline and glycolic or mandelic acid in which there is no antiferromagnetic coupling [9]. At low temperatures (79–200 K for **1** and 79–250 K for **3**), the magnetic moments are within the range reported for copper(II) complexes lacking Cu–Cu interaction, 1.7–2.2 BM [14].

The room temperature EPR spectrum of polycrystalline **1** (Table 2) is typical of axially symmetric coordination, with $g_{||} > g_{\perp}$. The symmetry of the copper atom is thus approximately C_{4v}, and the unpaired electron occupies a $3d x^2-y^2$ orbital. The value of 2.29 for g suggests octahedral coordination with a tetragonal distortion [12,15]. Similar spectra are displayed by complexes of copper(II) with α-hydroxycarboxylato ligands and 1,10-phenanthroline [9]. The EPR spectra of **2** and **3** (Table 2) are typical of rhombic systems with g values consistent with compressed rhombic-octahedral or *cis*-distorted octahedral stereochemystries [15].

The thermogravimetric behaviour of compounds **1** and **3** (Table 3) is similar to that of mixed complexes containing 1,10-phenanthroline and α-hydroxycarboxylato ligands [9]. Weakly bound lattice water is largely lost during stabilization of the balance. Decomposition of the ligands begins at 200 °C and in the case of **3** continues up to 400 °C. In **1**, ligand decomposition over the range 200–250 °C, is followed by a stable region up to 400 °C and by further weight loss between 400 and 450 °C. For **2**, one water molecule is lost between 75 and 150 °C, and the ligands decompose over the range 150–225 °C. No further weight loss was suffered by any of the compounds. The ratios of final to initial weights (19.48% for **1**, 16.41% for **2** and 17.77% for **3**) approximated the values expected for CuO (20.51% for **1**, 17.91% for **2** and 15.24% for **3**).

Table 3
Thermogravimetric analyses for the complexes **1**–**3**

Compound	Temperature range (°C)	% Weight loss	Corresponding to
1	RT–200	stable	
	200–250	76.22	bipy + HLACO
	250–400	stable	
	400–450	4.25

3. Structural analysis

Selected interatomic distances and angles are listed in Table 4, and the main hydrogen bonds in Table 5. Figs. 1–3 show drawings of the structures of compounds **1**, **2** and **3a**, respectively, together with the atom-numbering schemes used.

The structure of **1** and **3a** are essentially the same at −65 °C (**1**) or −50 °C (**3a**) as at 20 °C, the only marginally significant differences being that at room temperature the unit cell volume is slightly greater and the axes slightly longer (Table 1). In what follows, the bond lenghts and angles cited (Table 4) are the values measured at low temperature.

The crystals of **1** and **2** are based on neutral complexes of the form $[Cu(HL)_2(2,2'\text{-bipy})]\cdot n H_2O$, where HL is a monoanionic O,O′-bidentate α-hydroxycarboxylato li-

Table 4

gand (lactato in **1**, 2-methyllactato in **2**). The copper ions are six-coordinate, being bound to the nitrogen atoms of the 2,2′-bipyridine molecule and to one carboxy and one hydroxyl oxygen of each of two α-hydroxycarboxylato anions. There are thus three five-membered chelate rings. In both **1** and **2** the copper atom has elongated octahedral coordination geometry with the two nitrogen atoms and the mutually *cis* $O_{carboxy}$ atoms equatorial and the two α-hydroxyl oxygen atoms axial, the difference between the average equatorial and axial bond lengths being 0.356 Å in **1** and 0.301 Å in **2**. This elongation of the coordination polyhedron, due to a Jahn–Teller effect, is also observed in polymeric complexes containing lactato or 2-methyllactato ligands and 4,4′-bipyridine [16]. Additional deviation from ideal octahedral geometry is shown by the chelating angles ranging from 74.92° to 80.80° in **1** and from 75.90° to 81.01° in **2** (Table 4) and by some of the *trans* angles, such as $O_{hydroxyl}$–Cu–$O_{hydroxyl}$ in **1** [159.21(8)°] and $O_{carboxy}$–Cu–N in **2** [166.69(18)° and 166.48(18)°]. The Cu–$O_{carboxy}$ distances fall within the range usually observed in similar copper(II) complexes (1.90–1.97 Å) [16–19], as do the Cu–$O_{hydroxyl}$ distances [16], and as in other complexes with a CuN_2O_4 core [16,17,20] the values of the latter depend on their involvement in hydrogen bonds, the hydroxyl oxygens with the shorter Cu–$O_{hydroxyl}$ bonds having the shorter hydrogen bond (Table 5). The Cu–N distances, 1.995–2.015 Å, are within the normal range for complexes with N,N-chelating ligands [17,18] but are slightly shorter

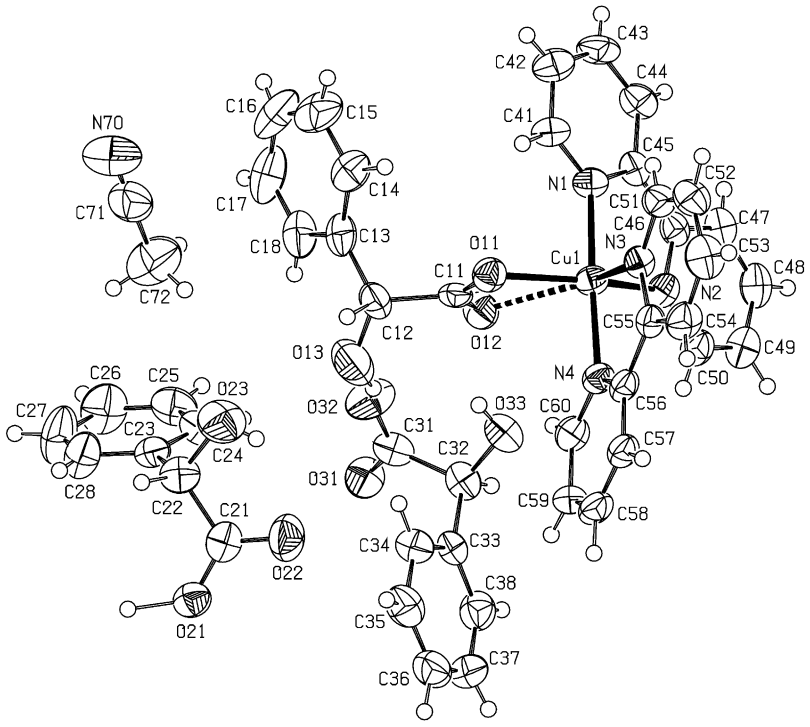

Fig. 3. Structure of $[Cu(HMANO)(bipy)_2](HMANO)(H_2MANO)\cdot CH_3CN$ (**3a**).

than in polymeric copper(II) complexes containing 4,4′-bipyridine [16].

In compound **3a** the asymmetric unit is composed of the cationic complex $[Cu(HMANO)(bipy)_2]^+$ and, in the outer coordination sphere, an $HMANO^-$ counterion, a nondeprotonated neutral H_2MANO molecule, and a solvating acetonitrile molecule. α-Hydroxycarboxylic acids have been reported to show similarly diverse behaviour in mixed complexes containing other diamines [9,21,22], without there apparently being any relation between this behaviour and the bulk of the α-hydroxycarboxylic acid. The copper atom in **3a** is five-coordinated to the four 2,2′-bipyridine nitrogens and to one of the carboxylato oxygens of the monodentate, monodeprotonated mandelic acid; the second carboxylato oxygen, O12, is too far from the metal [2.673(3) Å] for coordination. The Cu–N and Cu–O distances are within the usual ranges for this kind of copper(II) complex [9,13,23]. The coordination polyhedron cannot be described as either a square pyramid or a trigonal bipyramid, having a trigonality index $\tau = 0.49$ ($\tau = (\beta - \alpha)/60°$, where β and α are the largest angles in the coordination sphere [24]; its value is zero for a perfect square pyramid and unit for a perfect trigonal bipyramid).

The C–O distances of the coordinated α-hydroxycarboxylato oxygen atoms are similar in the three complexes (between 1.256 and 1.267 Å) and only slightly longer than those of the uncoordinated oxygen atoms (1.226–1.246 Å). The O–C–O angles are also very similar, 122.5°–125.1°. As expected, the individual pyridine rings of the bipy ligands are all planar. The bipy ligand as a whole is also planar in **1**, but in **2** and **3a** there are dihedral angles between the pyridyl rings of each bipy: 7.2(2)° in **2**, and 2.3(3)° and 8.0(3)° in **3a**. Twisting around the 2-2′ bond is normal in coordinated bipy [25].

All three compounds have both intra- and intermolecular hydrogen bonds (Table 5). In **1** the two solvating water molecules play a key role in the formation of a 2D network, bridging between neighbouring molecules of **1** (Fig. 4). Each water molecule accepts the hydroxyl

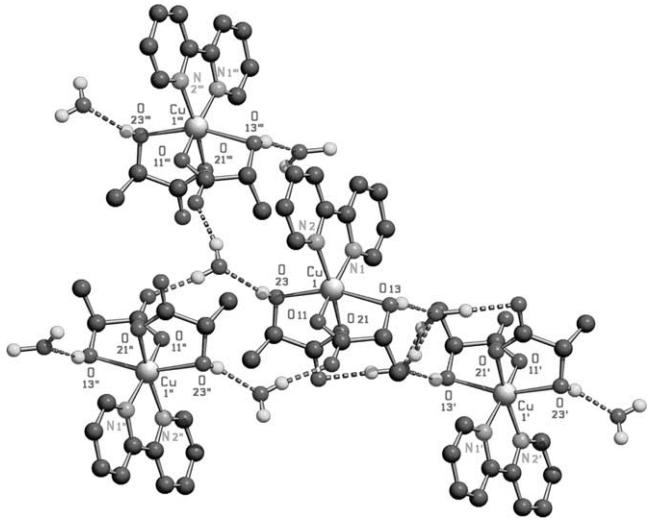

Fig. 4. View of the hydrogen bonding linkage in **1**.

hydrogen of one of the α-hydroxycarboxylato ions of its 'own' molecule, and donates hydrogens to the uncoordinated O atoms of neighbouring molecules (and, in the case of H_2O (**2**), to another O2 oxygen). The O···O hydrogen bond distances and angles are in the ranges 2.643(3)–2.993(4) Å and 160.5°–178.2°, respectively. In **2** the salient feature of the crystal packing is the three-dimensional supramolecular arrangement of the molecules around a fourfold screw axis, which is stabilized by hydrogen bonds between the hydroxyl groups and the uncoordinated carboxylato O atoms (Table 5 and Fig. 5). The channels so generated run through the crystal in the direction of the c axis with the water molecules inside them. The O···O hydrogen bond distances are in the range 2.657(6)–2.958(8) Å.

In all three complexes there are also C–H···O interactions, mainly involving bipy carbons and $O_{carboxy}$ atoms (Table 5). In **3a**, in which these hydrogen bonds play a decisive role in the crystal packing (Fig. 6), there are also C–H···O interactions between the mandelic acid and the mandelato anion of the outer sphere. The C···O distances and C–H···O angles of these bonds have values indicating significant interactions [26], 3.023–3.338 Å and 113.7°–173.2°, respectively (Table 5), the strongest of these bonds being intramolecular.

The shortest centroid-to-centroid distances between pyridyl rings belonging to different bipy ligands are 3.655 Å in **1** and **3a** and 3.913 Å in **2** [27]. The latter distance is too large for a π stacking interaction [28], but both are similar to those observed in copper(II) complexes of 1,10-phenanthroline [9,29]

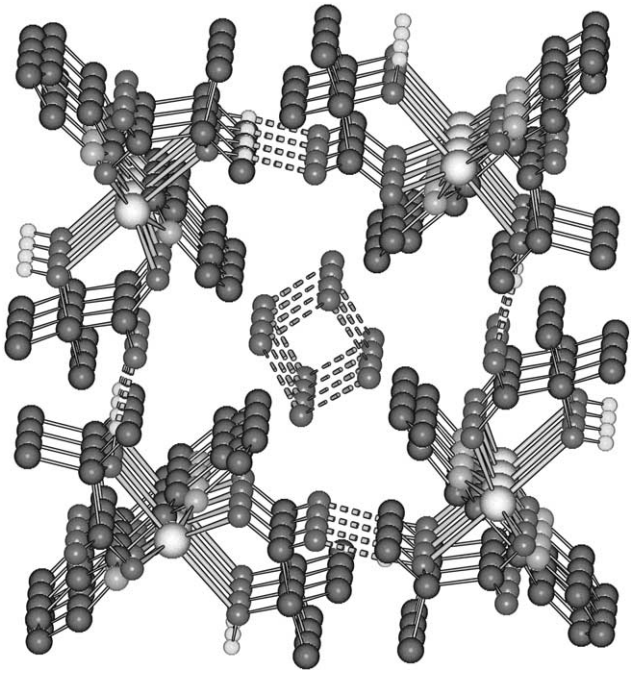

Fig. 5. View of the packing in **2**, showing the channel formation along *c* with the water molecules inside them.

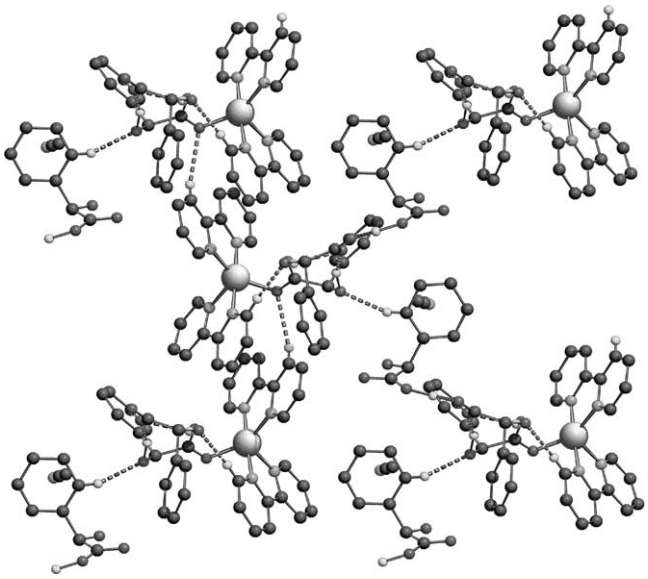

Fig. 6. View of the hydrogen bonding linkage in **3a**.

4. Experimental

4.1. Materials and instruments

Chemicals were purchased from commercial sources and used without further purification. Elemental analyses (C, H, N) were performed in a Carlo Erba 1108 microanalyser. Melting points were measured in a Büchi melting point apparatus and are uncorrected. The IR spectra of samples incorporated in KBr discs (4000–400 cm^{-1}) or polyethylene-sandwiched Nujol mulls (500–100 cm^{-1}) were recorded on a Bruker IFS66v spectrophotometer. A Shimadzu UV-3101PC spectrophotometer was used to obtain electronic spectra in the region 900–350 nm. Magnetic susceptibility measurements were made at room temperature using a Johnson Matthey magnetic susceptibility balance (for **2**) or at variable temperature with a DSM-10 magnetometer (for **1** and **3**). X-band (9300 MHz) EPR spectra were obtained at room temperature with a Bruker ESP 300E spectrometer. Thermogravimetric analyses were performed on a Shimadzu TGA-DGT-50H instrument coupled to a Nicolet Magma 550 FT-IR spectrophotometer.

4.2. Preparation of the complexes

A mixture of $CuCO_3 \cdot Cu(OH)_2$ (2.26 mmol) and the appropriate α-hydroxycarboxylic acid (9.10 mmol) in 35 mL of ethanol was refluxed for 4 h at 75 °C. 2,2′-Bipyridine (4.52 mmol) was added, and refluxing was continued for 2 h, after which the mixture was stirred for several days. The blue solids formed were filtered out, washed with ethanol and dried over $CaCl_2$.

4.3. [Cu(HLACO)$_2$(bipy)]·2H$_2$O (1)

Yield: 55%. M.p.: 206 °C. *Anal.* Found: C, 44.5; H, 5.2; N, 6.6. Calc. for $C_{16}H_{22}N_2O_8Cu$ (433.9): C, 44.3; H, 5.1; N, 6.5%. IR (ν cm^{-1}): 3407, 3115, ν(OH); 1607, ν(CC); 1595, ν_{asym}(OCO); 1386, ν_{sym}(OCO); 1497, 1450, ν(CC, CN); 1084, ν(CO); 1049, ring breathing; 733, γ(CH); 396, ν(CuO); 310, ν(CuN).

Single crystals of **1** were obtained by slow concentration of the mother liquor at room temperature (r.t.).

4.4. [Cu(HMLACO)$_2$(bipy)]·H$_2$O (2)

Yield: 65%. M.p.: 190 °C. *Anal.* Found: C, 47.9; H, 5.6; N, 6.2. Calc. for $C_{18}H_{24}N_2O_7Cu$ (443.9): C, 48.7; H, 5.4; N, 6.3%. IR (ν cm^{-1}): 3442, 3205, ν(OH); 1642, ν(CC); 1593, ν_{asym}(OCO); 1359, ν_{sym}(OCO); 1492, 1459, ν(CC, CN); 1176, ν(CO); 1059, ring breathing; 734, γ(CH); 393, ν(CuO); 296, ν(CuN).

Crystals of **2** were grown at room temperature by slow diffusion of *n*-hexane into a solution of the compound in acetone.

4.5. [Cu(HMANO)$_2$(bipy)]·4H$_2$O (3)

Yield: 75%. M.p.: 199 °C. *Anal.* Found: C, 52.3; H, 4.2; N, 4.7. Calc. for $C_{26}H_{30}N_2O_{10}Cu$ (594.0): C, 52.6; H, 5.1; N, 4.7%. IR (ν cm^{-1}): 3410, 3110, ν(OH); 1607, ν(CC); 1597, ν_{asym}(OCO); 1339, ν_{sym}(OCO); 1490, 1445, ν(CC, CN); 1082, ν(CO); 1058, ring breathing; 731, γ(CH); 406, ν(CuO); 272, ν(CuN).

Slow concentration of the mother liquor yielded a blue oil that upon attempted recrystallization from CH_3CN afforded blue single crystals of formula [Cu(HMANO)(bipy)$_2$](HMANO)(H$_2$MANO)·CH_3CN (**3a**).

4.6. X-ray crystallography

Data collection and refinement parameters are listed in Table 1. The diffraction data were collected on an Enraf–Nonius CAD4 (complex **1** at −65 °C and complex **3a** at 20 °C), on a Bruker SMART CCD (complexes **1** and **2** at r.t.) and on a STOE-IPDS diffractometer (complex **3a** at −50 °C). Graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) or Cu Kα radiation ($\lambda = 1.54184$ Å) were used and the data were corrected for Lorentz and polarization effects for absorption [30,31]. The structures were solved by direct methods and subsequent Fourier difference techniques (SHELXS [32]), and were refined on F^2 using SHELXL [33]. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters, except for those hydroxyl and water H atoms that it was possible to locate from a Fourier difference map, which were refined isotropically. Complex **3a** crystallizes in the chiral space group *Cc*, and the analysis unambiguously established its absolute stereochemistry [Flack parameter 0.000(14)]. Neutral atom scattering factors and anomalous dispersion corrections were taken from International Tables for X-ray Crystallography [34]. Geometrical calculations and illustrations were performed or generated with the SHELXL-97 [33], SCHAKAL-97 [35] and PLATON [27] packages.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 182331 for **1** (20 °C), 182332 for **1** (−65 °C), 182333 for **2**, 182334 for **3a** (−50 °C) and 194598 for **3a** (20 °C). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

were washed with methanol and dried on air. (Found: C, 32.23; H, 3.61; N, 15.04; $C_{10}H_{13}N_4O_5ClZn$ Calc. C, 32.46; H, 3.54; N, 15.14%; melting point (m.p.) 172 °C).

2.2. Instrumental

IR spectra were recorded on Perkin–Elmer FTIR 1600 spectrometer using standard KBr pellet technique. Raman data were collected on a Bruker RFS100 spectrometer equipped with Nd laser excitation. The UV–Vis reflectance spectrum was obtained on a CARY 500 UV–Vis NIR instrument, however, the complex spectrum was very similar to that of the ligand sodium salt and will not be discussed here.

2.3. Crystal structure determination

Crystal data together with refinement details are given in Table 1. All measurements on the crystal were performed on a KUMA KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation. The data were corrected for Lorentz and polarisation effects. No absorption correction was applied. The structure was solved by direct methods (program SHELXS-97 [11]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 [12] program. Non-hydrogen atoms were refined with anisotropic thermal parameters; hydrogen atoms were included from the $\Delta\rho$ maps and refined with isotropic thermal parameters. Crystal structures were drawn with help of the ORTEP [13].

Table 1
Crystallographic details

Empirical formula	$C_{10}H_{13}N_4O_5ClZn$
Formula weight	370.06
Temperature (K)	293(2)
Wavelength (Å)	1.54180
Crystal system	triclinic
Space group	$P\bar{1}$
Unit cell dimensions

$F(000)$	376
Crystal size (mm)	0.10 × 0.12 × 0.15
θ Range for data collection (°)	3.90–80.21
Index ranges	$-9 \le h \le 9$, $-10 \le k \le 10$, $-14 \le l \le 14$
Reflections collected/unique	6074/2764 [$R_{int} = 0.0398$]
Refinement method	full-matrix least-squares on F^2
Data [$I > 2\sigma(I)$]/parameters	2302/242
Goodness-of-fit on F^2	1.088
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0375$, $wR_2 = 0.0853$
R indices (all data)	$R_1 = 0.0517$, $wR_2 = 0.1000$
Largest difference peak and hole (e Å^{-3})	0.368 and −1.304

2.4. Density functional calculations

The theoretical studies presented in this work were performed using the GAUSSIAN-98 package [14] and applying the density functional theory (DFT) [15] methods. The DFT approach utilised the Becke's three-parameter hybrid functional (B3LYP) [16] and the LanL2DZ [17,18] basis set. The vibrational analyses were carried out on the optimised structures and applying the harmonic oscillator approximation.

3. Results and discussion

3.1. Description of the structure

The imidazole-4-acetic acid is a complexing agent offering several co-ordination centres as both imidazole ring nitrogen and carboxylate oxygen atoms (Fig. 1) Taking into account the stability of the chelate complexes, the anionic form **IV** seems to by the most suitable for metal binding. This chelating ability has been postulated in equilibrium analysis [19,20] and has been found in the X-ray studies [21,22] where copper(II) ions were chelated by one of the carboxylate oxygen atoms and N_3 atom of the imidazole ring.

Quite different co-ordination mode of imidazole-4-acetic acid is observed in the present work, where two ligand forms are engaged in complex formation. One half of the ligand acts as bidentate, but not chelating agent. Prior to complexation, the 'chelating' form **IV** is converted into tautomeric form **V** by translating the N_1 proton to the N_3 atom. Thus, the zinc(II) ions are bonded via carboxylate oxygen and N_1 nitrogen atoms leading to the one-dimensional polymeric structure of the complex (Fig. 2). The polymeric pattern extends along the b axis of the crystal unit cell. The metal co-ordination sphere is completed by one chloride anion and carboxylate oxygen of second, neutral ligand molecule being in form **III**. This 'zwitterion' form is

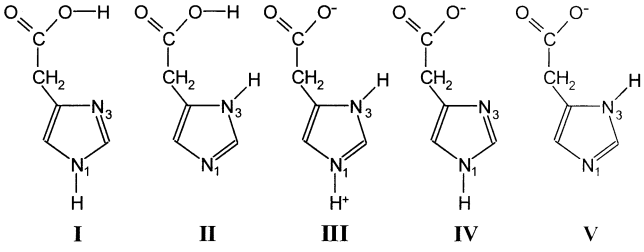

Fig. 1. Neutral and ionic forms of the ligand.

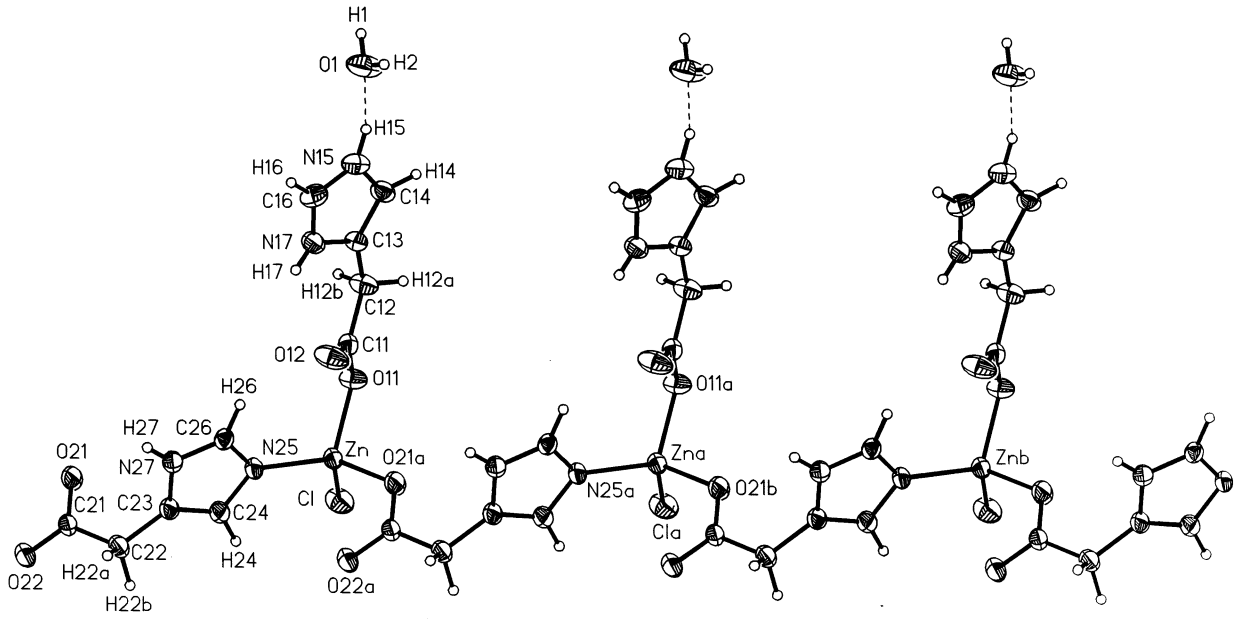

Fig. 2. View of [ZnCl(ia)(Hia)]·H_2O polymer with atom numbering scheme and 50% probability thermal ellipsoids.

typical for pure ligand in solid state, as has been found in the crystal structure of the imidazole-4-acetic acid monohydrate [23]. The same investigation revealed that imidazole ring and adjacent carbon atom of methylene group are planar. Such planarity is also preserved in the studied complex, for both forms of the ligand. The difference between free and co-ordinating ligand was found for the orientation of the carboxylate group with respect to the imidazole ring. In the Hia·H_2O structure [23], these subunits are nearly perpendicular. In the present complex structure, the carboxylate group is less twisted forming with the imidazole plane an angle 77.2(3)° found for bridging form **V** and 31.6(3)° for side ligand described as tautomer **III**. In the ligand form **V**, one of the imidazole ring nitrogen atoms is involved in metal bonding, whereas in the form **III** is not. It is interesting to check how much the imidazole skeleton is altered by Zn–N bond formation. The comparison of the respective structural data (Table 2) shows that co-ordination effects are relatively small: only one, C26–N27 bond is 0.036 Å longer when imidazole ring is co-ordinating. The differences in the remaining bond lengths of the imidazole moiety are comparable with their standard deviations. Also the 'in-plane' imidazole ring angles are altered less than 3°.

The metal surrounding is quasi-tetrahedral. The maximum deviation from the ideal tetrahedron angles is observed for the N25–Zn–O21a angle equal to 119.2(1)°. Metal–nitrogen and metal–oxygen bond lengths are very similar (1.987(2) and 1.981(2), 1.979(2) Å, respectively), whereas the metal–chlorine bond, being 2.258(1) Å, is markedly longer. The two Zn–O bond distances are comparable with those frequently

Atom numbering is given in Fig. 2. Symmetry transformation used to generate equivalent atoms; a: $x, y-1, z$.

observed for carboxylato complexes [24,25]. The distances between pendant carboxylic oxygen atoms and the zinc(II) ion are much longer (2.929(3) and 3.013(2) Å), indicating the monodentate configuration of the carboxylato groups. The length of co-ordination bond between zinc and imidazole N_1 (N25) atom is similar to these found in tetrahedral zinc complexes of neutral imidazole as co-ligand [26], but slightly shorter than those of the imidazole derivatives [25,27].

The zinc(II) environment can partially be compared with the active site of the native carboxypeptidase A, where the metal is bonded to two imidazole rings (His69 and His196) and carboxylic oxygen (Glu72) [28,29]. The metal–nitrogen distance found here is almost the same as the Zn–His69 (1.98 Å) and 0.1 Å shorter than the Zn–His196 (2.08 Å) [29]. The metal–oxygen bond lengths in carboxypeptidase A are longer being 2.17 Å [28] and 2.24 Å [29].

The complex polymer chains are linked in a three-dimensional manner by hydrogen bonds. The side, monodentate ligand subunits of parallel chains are intercalated (Fig. 3), which provides many ineratomic contacts suitable for hydrogen bonding. In these interactions the water molecules are fully engaged, joining three polymer chains via N15–H15···O1, O1–H1···O22e and O1–H2···O12f bonds (equivalent oxygen atoms are generated by symmetry transformations e: $x-1$, $y-1$, $z+1$; f: $-x-1$, $-y$, $-z+1$). The respective donor–acceptor distances are 2.663(5), 2.780(4) and 2.818(5) Å indicating the strong H-bonding and the significant role of the water molecules in the stabilisation of the crystal structure. Additional hydrogen bonds are formed by remaining N–H groups. The monodentate ligand shows an intramolecular N17–H17···O12 interaction with N17···O12 distance equal 2.805(4) Å. In the bidentate ligand moiety, similar distance N27···O22 is much longer being 4.458(4) Å, as a result of much more twisted orientation of the carboxylate group with respect to the imidazole ring. However, an interchain bonding is observed between N27–H27 group and O22d (d: $-x$, $-y+2$, $-z$) atom with 2.884(4) Å donor–acceptor distance. In addition, the weak interaction of the mentioned N17–H17 group and chlorine atom has also be considered since the respective N17···Clc distance is 3.239(3) Å (c: $x-1$, y, z).

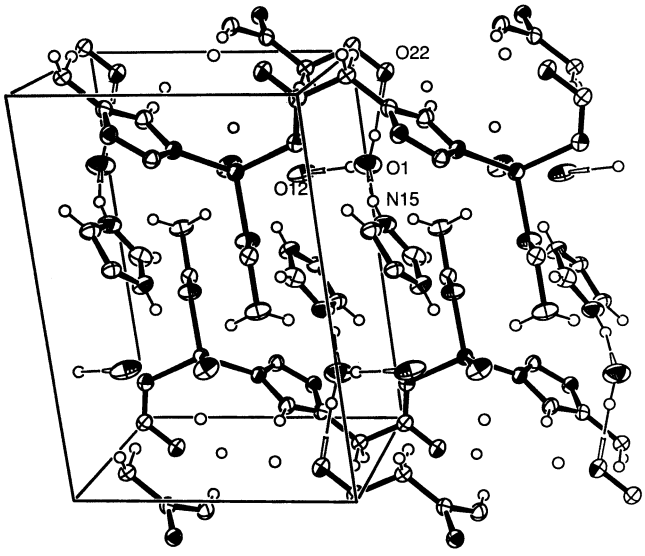

Fig. 3. View of the unit cell content demonstrating the intercalation of polymer chains and H-bonding of water molecule. In order to complete the polymeric pattern, atoms in the range $0 \le a \le 1$, $0 \le b \le 2$, $-0.9 \le c \le 1.1$ are presented.

3.2. Vibrational spectra

Since two different forms of the ligand are present in the complex, it is interesting how this phenomenon is reflected in the vibrational spectra. First evidence is the higher number of bands observed for the complex in the middle-infrared region in comparison with the spectra of copper(II) imidazole-4-acetate complexes where only one, chelating form of the ligand is present [21,22]. However, this number of bands is not twice higher, which suggests that only some ligand vibrations of mono- and bidentate ligand forms have significantly different frequencies. The main difference between these forms is the co-ordination Zn–N bond instead of the N–H bond. Thus, the differences between respective vibrations of imidazole rings are expected to be the most significant. As results from the X-ray data, the geometry of imidazole rings is almost the same, which means that the electron density and respective force constants are of similar values. Considering also the H–Zn mass effect, it is difficult to predict simply the vibrational effects caused by imidazole–zinc(II) bond formation. In order to solve this problem, the vibrations of two subunits (Fig. 4), representing both ligand forms were predicted from density functional calculations.

In such theoretical attempts there is always a problem of model simplification, necessary in case of polymeric

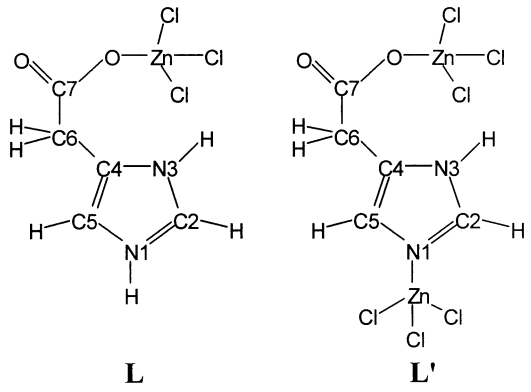

Fig. 4. Models of the mono- and bidentate ligand forms.

compounds. In present work, the calculations were carried out for two molecular ions shown in Fig. 4. The quasi-tetrahedral surrounding of the zinc(II) ions was mimic by additional chloride ions, which produced additional vibrations but of low frequencies and not interfering with the imidazole ring or carboxylate group modes. The attempts to use only zinc(II) ions as terminal ones gave the optimised geometry too much differing from that found in the X-ray investigation. For applied models, the geometry of the imidazole ring was

very well reproduced. All calculated bond lengths were slightly overestimated, but no more than 4%. For ring angles the agreement was excellent, the maximum deviation was 0.9° (0.8%).

Normal vibrations, calculated by GAUSSIAN-98 program in Cartesian co-ordinates, were converted into internal co-ordinates defined as recommended by Pulay et al. [30]. Using these co-ordinates, a potential energy distribution (PED) has been calculated for all normal modes of natural and N-deuterated species.

Table 3 lists the wavenumbers of selected normal vibrations characterised by predominant PED terms contributing more than 10% to the vibrational energies. Observed IR and Raman bands were correlated with calculated modes on the basis of similar frequencies, relative intensities and deuteration effects. Comparing both ligand subunits, one may expect that imidazole stretching vibrations of the N1–C2 and N1–C5 bonds (Fig. 4) should be the most affected by zinc(II) co-ordination. The performed calculations do not support such assumption. The vibrations of predominant ν(N1–C5) character are observed at close frequencies (1110 and 1095 cm^{-1}) for both ligand forms. The ν(N1–C2) vibration is strongly coupled with other modes and cannot be similarly compared. It contributes, together with the ν(C2–N3) vibration, to two normal modes observed for **L** at 1538 and 1149 cm^{-1} and for **L′** at 1495 and 1364 cm^{-1}. In addition, the ν(N1–C2) vibration is involved in the 1445 cm^{-1} mode, predominantly due to δ(N1–H) vibration of monodentate form **L**. The last vibration is not present in **L′** and in consequence the ν(N1–C2) vibration additionally appears in the 1110 cm^{-1} mode. Different distribution of the ν(N1–C2) vibration causes changes in the ν(C2–N3) contributions and further, in the PEDs and frequencies of most imidazole 'in plane' vibrations, being strongly coupled. For example, the ν(C4–C5) vibration contributes mainly to the normal modes observed for **L** at 1628 cm^{-1} and at much lower wavenumber (1550 cm^{-1}) for **L′**. The stretching of the fifth imidazole bond, namely ν(N3–C4) vibration, dominates in only one normal mode observed for **L′** at 1387 cm^{-1}, and it is coupled with imidazole bending modes δ1(im), δ2(im) which also have considerably different frequencies 989 and 937 cm^{-1} for **L** and **L′** subunits, respectively.

The aforementioned coupling between imidazole ring vibrations is partially extended on side, acetic chain vibrations, causing the differences in their frequencies as it is noted for ν(CC) and ν(CO) vibrations. According to PED, the ν(C6–C7) vibration has a dominating contribution to 887 and 852 cm^{-1} modes related to **L′** and **L** ligands. The ν(C4–C6) vibration is strongly mixed with imidazole ring vibrations and cannot be definitely attributed to any of observed bands. The asymmetric ν(CO) vibrations, calculated for **L′** and **L** at 1626 and 1607 cm^{-1}, were attributed to local maxima of an intense band centred in the IR spectrum at about 1600 cm^{-1}. The symmetric counterparts were localised at about 1300 cm^{-1}, giving approximately 300 cm^{-1} separation from the asymmetric modes, which confirms the monodentate co-ordination of the carboxylate groups.

The above results suggest the conclusion that the discussed differences between **L** and **L′** vibrations are rather due to the detachment of the N1 proton than the imidazole–zinc(II) bond formation. As has been predicted by calculations, the wavenumbers of many corresponding vibrational modes of **L** and **L′** are different enough to be observed as separate bands or shoulders. This also explains the higher number of observed IR and Raman transitions, mentioned at the beginning of the present section.

4. Conclusions

The chelating ability of the imidazole-4-acetic acid has been previously documented. In the presence study, we have unambiguously demonstrated for the first time that this compound in its deprotonated form is also capable of acting as bridging ligand. Such co-ordination mode leads to the 1D polymeric structure of the metal complex. Moreover, at each metal centre we have found another, neutral ligand molecule co-ordinating the zinc(II) ion via carboxylate oxygen atom. The use of the carboxylate group for metal co-ordination, instead of imidazole ring nitrogen atoms may be explained by general tendency of the imidazole-4-acetic acid to adopt the 'zwitterionic' structure, as has been observed in its crystalline state [23]. This tautomer preference is also confirmed by the respective values of the acidity constants equal $pK_{COOH} = 3.188(2)$ for the carboxylic group and $pK_{im} = 7.336(1)$ for the NH group [19].

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 189497. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033); e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk.

2.2. Preparations

2.2.1. Preparation of 1-bromo-2,6-bis(bromomethyl)benzene

To a stirred solution of 2-bromometaxylene (24.95 g, 0.135 mol) in CCl_4 (150 ml) were added 2 equiv. of *N*-bromosuccinimide (NBS) (48.01 g, 0.270 mol) and a catalytic amount of 2,2′-azobis-(2-methylpropionitrile) (AIBN). The reaction mixture was heated to reflux and stirred for 6 h. The succinimide formed was then filtered off and the orange filtrate evaporated to dryness. A solid was obtained and recrystallized in hexane (150 ml) affording white needles. Yield: 21.11 g (46%). M.p.: 95 °C (literature: 97–98 °C [3a]); ^{1}H NMR ($CDCl_3$, 250.1 MHz, δ ppm): 4.65 (s, 4H, CH_2), 7.29 (t, $^3J_{H/H}$ = 6.7 Hz, 1H, 4-aryl-H), 7.42 (d, $^3J_{H/H}$ = 6.7 Hz, 2H, 3,5-aryl-H); ^{13}C NMR ($CDCl_3$, 50.3 MHz, δ ppm): 33.92 (CH_2Br), 126.69 (1-aryl-C), 128.08 (4-aryl-C), 131.45 (3,5-aryl-C), 138.52 (2,6-aryl-C). EI MS (70 eV, *m*/*z* %): 342 (M^+, 11); 263 ($M^+ - Br$, 100), 182 ($M^+ - Br_2$, 35), 103 ($M^+ - Br_3$, 32).

2.2.2. Preparation of 1-bromo-2,6-bis[(diethylamino)methyl]benzene

To a stirred solution of 1-bromo-2,6-bis(bromomethyl)benzene (21.11 g, 0.062 mol) dissolved in 150 ml of toluene was added dropwise a solution of diethylamine (21.67 g, 0.296 mol, 31 ml) in 50 ml of toluene for 1 h. After 10 min a white precipitate of diethylammonium bromide was formed. The reaction mixture was stirred for 18 h and the solid filtered off. The filtrate was evaporated to dryness to lead to a yellow oil, which was purified by distillation affording a colorless oil (132 °C/0.25 mmHg (literature: 150 °C/0.5 mmHg [4b]b)). Yield: 12.95 g (64%). ^{1}H NMR ($CDCl_3$, 80.1 MHz, δ ppm): 1.07 (t, $^3J_{H/H}$ = 7.0 Hz, 12H, CH_3(Et)), 2.61 (q, $^3J_{H/H}$ = 7.0 Hz, 8H, CH_2(Et)), 3.69 (s, 4H, CH_2N); 7.16–7.52 (m, 3H, 3,4,5-aryl-H); ^{13}C NMR ($CDCl_3$, 50.3 MHz, δ ppm): 12.07 (CH_3(Et)), 47.30 (CH_2(Et)), 57.90 (CH_2N), 125.92 (1-aryl-C), 126.66 (4-aryl-C), 128.66 (3,5-aryl-C), 139.71 (2,6-aryl-C); EI MS (70 eV, *m*/*z* %): 326 (M^+, 19), 311 (M^+ − Me, 100), 254 ($M^+ - NEt_2$, 29), 240 ($M^+ - CH_2NEt_2$, 28).

Anal. Found: C, 58.84; H, 8.42. Calc. for $C_{16}H_{27}N_2Br$: C, 58.71; H, 8.31%.

2.2.3. Preparation of 1-bromo-2,6-bis[(diisopropylamino)methyl]benzene

A solution of diisopropylamine (29.98 g, 0.296 mol, 42 ml) and 1-bromo-2,6-bis(bromomethyl)benzene (21.11 g, 0.062 mol) in toluene (250 ml) was heated to reflux for 48 h. The white diisopropylamine bromide solid was then removed by filtration; the filtrate was concentrated in vacuum and the crude product recrystallized from pentane at −20 °C affording white crystals. Yield: 22.70 g, 96%. M.p.: 76 °C. ^{1}H NMR (C_6D_6, 250.1 MHz, δ ppm): 0.95 (d, $^3J_{H/H}$ = 6.5 Hz, 24H, CH_3(*i*-Pr)), 2.95 (sept, $^3J_{H/H}$ = 6.5 Hz, 4H, CH(*i*-Pr)), 3.88 (s, 4H, CH_2N), 7.28 (t, $^3J_{H/H}$ = 7.6 Hz, 1H, 4-aryl-H), 7.77 (d, $^3J_{H/H}$ = 7.6 Hz, 2H, 3,5-aryl-H); ^{13}C NMR (C_6D_6, 50.3 MHz, δ ppm): 20.91 (CH_3(*i*-Pr)), 49.00 (CH(*i*-Pr)), 50.17 (CH_2N), 124.80 (1-aryl-C), 126.96 (4-aryl-C), 128.59 (3,5-aryl-C), 142.12 (2,6-aryl-C); EI MS (70 eV, *m*/*z* %): 382 (M^+, 18), 367 (M^+ − Me, 100), 282 ($M^+ - N$*i*-Pr_2, 26), 182 ($M^+ - 2(N$*i*-$Pr_2)$, 56).

2.2.4. Preparation of chloro[2,6-bis[(diethylamino)methyl]phenyl]germylene (**1**)

A solution of 1-bromo-2,6-bis[(diethylamino)methyl]benzene (2.0 g, 6.1 mmol) in Et_2O (15 ml) was treated by a stoichiometric amount of *n*-butyllithium (4.2 ml, 1.6 M in hexane) at 0 °C, and the mixture was stirred for 30 min. After removal of the solvents in vacuum, 15 ml of THF was added. The 1-lithio-2,6-bis[(diethylamino)methyl])benzene was then added dropwise to a solution of $GeCl_2$·dioxane (1.41 g, 6.1 mmol) in THF (15 ml) at −78 °C. The solution was allowed to warm to room temperature (r.t.) and stirred for 30 min. Volatile materials were removed in vacuum and the residue was treated in pentane. The mixture was filtered to remove LiCl and concentrated under reduced pressure. After several hours in pentane at r.t., X-ray quality crystals of **1** were obtained. Yield: 1.84 g, 85%. M.p.: 70 °C. ^{1}H NMR (C_7D_8, 400.1 MHz, δ ppm): 1.18 (t, $^3J_{H/H}$ = 7.1 Hz, 12H, CH_3(Et)), 2.85, 2.86 (2q, $^3J_{H/H}$ = 7.1 Hz, 8H, CH_2(Et)), 3.62, 3.91 (AB system, $^2J_{H/H}$ = 14.3 Hz, 4H, CH_2N), 7.25–7.46 (m, 3H, 3,4,5-aryl-H); ^{13}C NMR (C_7D_8, 100.6 MHz, δ ppm): 9.72 (CH_3(Et)), 44.94 (CH_2(Et)), 58.68 (CH_2N), 123.93 (3,5-aryl-C), 127.60 (4-aryl-C), 145.04 (2,6-aryl-C), 157.48 (1-aryl-C); EI MS (70 eV, *m*/*z* %):356 (M^+, 24), 327 (M^+ − Et, 22), 291 (M^+ − 2Me − Cl, 18), 217 (Ar − 2Me, 100).

Anal. Found: C, 54.19; H, 7.76. Calc. for $C_{16}H_{27}N_2GeCl$: C, 54.07; H, 7.66%.

2.2.5. Preparation of chloro[2,6-bis[(diisopropylamino)methyl]phenyl]germylene (**2**)

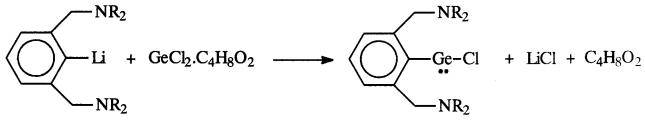
A solution of 1-bromo-2,6-bis[(diisopropylamino)methyl]benzene (1.30 g, 3.4 mmol) in THF (15 ml) was treated with a stoichiometric amount of *n*-butyllithium (2.3 ml, 1.6 M in hexane) at −78 °C. The mixture was stirred for 20 min at −78 °C and slowly added to a solution of $GeCl_2$·dioxane (0.79 g, 3.4 mmol) in THF (15 ml) at the same temperature. The solution was then allowed to warm up to r.t. and stirred for 30 min. Solvents were evaporated in vacuum and the residue was treated with pentane. The mixture was filtered to remove LiCl and a yellow solid was obtained after evaporation to dryness. Yield: 1.26 g, 90%. M.p. (dec.): 77 °C. ^{1}H NMR (C_6D_6, 250.1 MHz, δ ppm): 1.03

(d, $^3J_{H/H} = 6.7$ Hz, 12H, CH_3(*i*-Pr)), 1.08 (d, $^3J_{H/H} = 6.7$ Hz, 12H, CH_3(*i*-Pr)), 3.42 (sept, $^3J_{H/H} = 6.7$ Hz, 4H, CH(*i*-Pr)), 3.70, 3.99 (AB system, $^2J_{H/H} = 15.0$ Hz, 4H, CH_2N), 6.96 (d, $^3J_{H/H} = 7.4$ Hz, 2H, 3,5-aryl-H), 7.15 (t, $^3J_{H/H} = 7.4$ Hz, 1H, 4-aryl-H); ^{13}C NMR (C_6D_6, 50.3 MHz, δ ppm): 20.33, 21.00 (CH_3(*i*-Pr)), 51.25 (CH(*i*-Pr)), 53.64 (CH_2N), 123.15 (3,5-aryl-C), 128.19 (4-aryl-C), 147.70 (2,6-aryl-C), 158.86 (1-aryl-C); IE MS (70 eV, *m*/*z* %): 412 (M^+, 26), 377 ($M^+ - Cl$, 26), 369 ($M^+ - i$-Pr, 100).

Anal. Found: C, 58.51; H, 8.69. Calc. for $C_{16}H_{27}N_2GeCl$: C, 58.37; H, 8.57%.

2.2.6. Preparation of chlorobis[2,4,6-tris(trifluoromethyl)phenyl]germane Ar'_2GeHCl

A diethyl ether solution of [2,4,6-tris(trifluoromethyl)phenyl]lithium [5] (2.14 mmol) was added dropwise to a 0 °C diethyl ether solution of $GeCl_2$·dioxane (196 mg, 0.85 mmol). The mixture was allowed to warm to r.t. and stirred for 2 h. All volatiles were removed in vacuum, 10 ml of pentane was added to filter the insoluble salts. A yellow powder precipitated after 24 h at −20 °C in pentane. Yield: 0.11 g, 8%. M.p. (dec.): 160 °C. ^{1}H NMR (C_6D_6, 250.1 MHz, δ ppm): 7.16 (13 peaks, $^5J_{H/F} = 4.5$ Hz, 1H, Ge–H), 7.75 (s, 4H, 3,5-aryl-H); ^{13}C NMR (C_6D_6, 62.9 MHz, δ ppm): 122.48 (q, $^1J_{C/F} = 273.7$ Hz, *p*-CF_3), 123.27 (q, $^1J_{C/F} = 275.7$ Hz, *o*-CF_3), 127.32 (s, 3,5-aryl-C), 133.57 (q, $^2J_{C/F} = 34.8$ Hz, 2,6-aryl-C), 136.87 (q, $^1J_{C/F} = 34.1$ Hz, 4-aryl-C), 165.41 (s, 1-aryl-C); ^{19}F NMR (C_6D_6, 188.3 MHz, δ ppm): 11.96 (s, 6F, *p*-CF_3), 20.15 (s, 12F, *o*-CF_3); IE MS (70 eV, *m*/*z* %): 671 ($M^+ - H^+$, 1), 653 ($M^+ - F$, 2), 637 ($M^+ - Cl$, 2), 391 ($M^+ - Ar$, 100), 355 (ArGe, 5); IR (C_6D_6, cm^{-1}): 2187.0 (ν(GeH)).



2.2.7. Preparation of chlorobis[2,6-bis(trifluoromethyl)phenyl]germane Ar''_2GeHCl

A solution of [2,6-bis(trifluoromethyl)phenyl]lithium [6] (50.61 mmol) in THF (100 ml) was added dropwise to a solution of $GeCl_2$·dioxane (2.34 g, 10.11 mmol) in THF (100 ml) at −78 °C during a period of 1 h. The mixture was allowed to warm up to r.t. and stirred for 8 h. All volatiles were removed in vacuum, 100 ml of pentane was added to filter the insoluble salts. A orange powder precipitated at −20 °C in pentane. Yield: 0.54 g, 10%. M.p.: 132 °C. ^{1}H NMR (C_6D_6, 250.1 MHz, δ ppm): 6.64 (t, $^3J_{H/H} = 7.9$ Hz, 2H, 4-aryl-H), 7.27 (d, $^3J_{H/H} = 7.9$ Hz, 2H, 3,5-aryl-H), 7.38 (13 peaks, $^5J_{H/F} = 4.2$ Hz, 1H, Ge–H). ^{13}C NMR (C_6D_6, 62.9 MHz, δ ppm): 124.33 (q, $^1J_{C/F} = 274.9$ Hz, *o*-CF_3), 130.50 (s, 4-aryl-C), 130.73 (s, 3,5-aryl-C), 135.51 (q, $^2J_{C/F} = 33.1$ Hz, 2,6-aryl-C), 169.02 (s, 1-aryl-C); ^{19}F NMR (C_6D_6, 188.3 MHz, δ ppm): 20.54 (s); IE MS (70 eV, *m*/*z* %): 535 ($M^+ - H^+$, 3), 501 ($M^+ - Cl$, 7), 323 ($M^+ - Ar$, 100); IR (C_6D_6, cm^{-1}): 2167.9 (ν(GeH)).

3. Results and discussion

3.1. The arylchlorogermylenes 1 and 2

The reaction of ArLi with $GeCl_2$·dioxane in THF in 1:1 molar ratio at −78 °C affords germylenes ArGeCl in good yield (Eq. (1)). Single crystals of **1**, suitable for an X-ray structure determination were grown from pentane at room temperature. The structure determination and refinement [7] show a monomeric structure in the solid state (Fig. 1). Significant bond lengths and angles are presented in Table 1.

1: R = Et, **2**: R = *i*Pr

(1)

In this complex, the Ar ligand is tridentate to germanium: σ-bonded through *ipso*-carbon C(1) and also bis-orthochelated by intramolecular N→Ge coordinations. In solid state, the observed Ge–N distances are quite different, 2.337(11) Å for the coordinated bond N(2)→Ge and 2.570(10) Å for the other distance Ge–N(1). This latter is the longest coordination bond of all known chlorogermylenes with substituents bearing nitrogen donors in a side-chain. At the opposite, the Ge–Cl bond (2.309(4) Å), oriented almost orthogonal to the plane of the aryl ligand, lies in the range of chlorogermylenes coordinated by a side-chain nitrogen atom (see Table 2). The geometry at the germanium center may show us that the degree of hybridization of the metal is quite low. Indeed, the angles (Table 1) C(1)–Ge(1)–Cl(1), C(1)–Ge(1)–N(2), N(2)–Ge(1)–Cl(1), C(1)–Ge(1)–N(1) are in the range of 90° (74.2(4)°–97.2(4)°). This seems indicate that the bonds to the ligands are involving p-orbitals at the germanium atom. So, the nitrogen atoms of the side-chains can interact easily with the vacant p-orbital on the germanium; the lone pair is

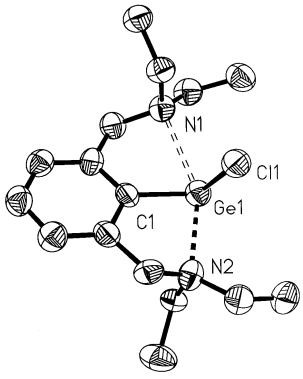


Fig. 1. Thermal ellipsoid plot (30%) of **1**. Hydrogen atoms are not shown. Important structural data are given in Table 1.

Table 1
Selected bond length (Å) and angles (°) for **1**

Bond lengths			
Ge(1)–N(2)	2.337(11)	Ge(1)–N(1)	2.570(10)
Ge(1)–Cl(1)	2.309(4)	Ge(1)–C(1)	1.941(11)
Bond angles			
C(1)–Ge(1)–Cl(1)	97.2(4)	N(2)–Ge(1)–Cl(1)	89.2(3)
C(1)–Ge(1)–N(2)	76.9(4)	C(1)–Ge(1)–N(1)	74.2(4)

localized in an orbital with high s character. On the other hand, **1** exhibits a surprisingly short Ge–C(1) bond length (1.941(11) Å) appreciably shorter than in the other halogermylenes (1.989(5)–2.402(3) Å) (Table 2). This value seems to indicate a back bonding donation  of the germanium to the *ipso*-carbon arising from consequent electronic effects of the two side-chain ligands: donation N→Ge and withdrawing inductive effect of the two *ortho* CH_2NEt_2 moieties, increasing the electrophilic character of the *ipso*-carbon. Removal of the back bonding by complexation of the germanium atom, for example in the recently described complex $ArGeOH{\cdot}W(CO)_5$, leads as expected to a lengthening of the Ge–C(1) bond (1.975(3) Å) [8]. This explanation can also be supported regarding the ^{13}C NMR chemical shift of the *ipso*-carbons C(1). Indeed, in the above complex, the C(1) appears at 153.44 ppm [8], much more shielded than in **1** (157.48 ppm) or in **2** (158.86 ppm). The ^1H NMR spectra (80 MHz) of **1** and **2** at room temperature show that, in solution, the chelate side-chains are equivalent due to a rapid exchange of the coordination sites. The signal of the two inequivalent benzyl hydrogen atoms appears as an AB pattern; moreover, in the case of **1**, we can also observe two resonances for the methylenic protons of the ethyl groups due to the chirality of the germanium atom and for **2**, two resonances for the methyl protons of the isopropyl groups.

3.2. Comparison of *1* and *2* with reviewed halogermylenes

Fruitful comments can be made from a study of known stable and isolated halogermylenes (Table 2). Non hindered halogermylenes such as ethylchlorogermylene EtGeCl and phenylchlorogermylene PhGeCl were the first representatives of halogermylenes [9,10]. These chlorogermylenes are 'associated' by intermolecular germanium–chlorine bonds but without Ge–Ge bonds. All phenylhalogermylenes PhGeX (X = F, Cl, Br, I) have been synthesized [11]. Later, were described the most interesting halogermylenes stabilized as monomeric species by hindered substituents or by donor ligands. Chlorogermylenes RGeCl are the most numerous owing to the easy available and most often used dichlorogermylene $GeCl_2{\cdot}C_4H_8O_2$ complex precursor. Known so far stable and isolated halogermylenes are chronologically reported in Table 2. We can distinguish alkyl or arylhalogermylenes with C–Ge–X linkage (compounds **1**–**2**, **9**–**11**, **13**, **16**–**19**, **23**, **25**–**26**, **35**) and heterohalogermylenes with Y–Ge–X (Y = N, O, P) moieties (compounds **3**–**8**, **12**, **14**–**15**, **20**–**22**, **24**, **27**–**34**). As expected, a comparison of different coordinated and non coordinated derivatives shows that intramolecular coordination of the amino functionality in the side-chain makes longer and so weakens drastically the Ge–Cl bond. Accordingly, such derivatives are suitable synthons for easy nucleophilic substitutions at the divalent metal to access to many heteroleptic germylenes. In our group, a recent example showed that diazogermylenes $RGeC(N_2)R'$, precursors of germynes RGe≡CR′, have been obtained from correspondent chlorogermylenes **1** or **2** and a lithiodiazo compound [12].

If many halogermylenes are stabilized by donor ligands (cf. Table 2), none monohalogermylene bearing strong electron-withdrawing effect substituent is known yet. In this area, only the symmetric diarylgermylene Ar'_2Ge: [Ar′ = 2,4,6-tris(trifluoromethyl)phenyl] has been described [13]. In order to have suitable synthons to access to electron poor low coordinated species of germanium, we attempted to synthesize the two chlorogermylenes Ar′GeCl and Ar″GeCl (Ar″ = 2,6-bis(trifluoromethyl)phenyl).

3.3. New chlorodiarylgermanes

Surprisingly, the classic reaction using stoichiometric amounts of lithio-derivatives Ar′Li [5] or Ar″Li [6] with complex $GeCl_2{\cdot}$dioxane, did not lead to the expected chlorogermylenes but beside unidentified products to chlorodiarylgermanes Ar'_2GeHCl and Ar''_2GeHCl in low yields. In these compounds, the hydrogen atom bonded to germanium exhibits an exceptional acidic character because of the strong withdrawing effects of two aryl groups 14 and of the chlorine atom. Thus, in the ^1H NMR spectra, the deshielded Ge–H signal appears at 7.16 ppm for Ar'_2GeHCl and at 7.38 ppm for Ar''_2GeHCl and in the Infra-Red spectra, we can observe characteristic ν_{Ge-H} at 2187.0 cm^{-1} for Ar'_2GeHCl and at 2167.9 cm^{-1} for Ar''_2GeHCl. These results evidenced the instability of these chlorogermylenes in our experimental conditions. Formation of chlorodiarylgermanes remains difficult to explain; we can postulate that creation of a Ge–H linkage probably arises from a radical process. Is this result in relation with a triplet structure of germylenes bearing strong electron-withdrawing groups such as Ar′ or Ar″ and Cl? This question is now in study.

plexes, Five-coordinate complexes, EPR spectra, Vis spectra, 295
Aminohydroxamic acids
Zinc(II) complexes, Mixed-ligand complexes, Polyamines, NMR spectra, Potentiometry, 2183
α-Aminoisobutyryl-α-aminoisobutyric acid (H–Aib–Aib–OH)
Copper(II) peptide complexes, Spectroscopic characterization, X-ray crystal structures, 229
Aminomethane-1,1-diphosphonic acids
Zinc(II) complexes, Magnesium(II) complexes, Calcium(II) complexes, Potentiometry, NMR, 321
2-(Aminomethyl)pyridine
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
2-Aminophenol
Cd(II) and Hg(II) complexes, Spectroscopic properties, Normal coordinate, Force constant, 2-Phenylenediamine, 987
8-Aminoquinoline
Nickel complexes, Sulfonamide complexes, X-ray crystal structures, 1229
Aminotroponimine
Azide, Germanium, Tin, Silver, Tris(pyrazolyl)borate, 611
β-Aminovinylimines
Trinuclear metal chelates, Chemical and electrochemical synthesis, 2081
Analogous multiple bonded systems
Electronic states, Linear disilaketenylidene (SiSiO), Renner effect, 599
Ancillary functions
Ruthenium monoterpyridine complexes, Crystal structures, 2033
2-Anilinopyridine
Crystal structures, Antiferromagnetic dimers, Dinuclear acetates, Copper(I), 457
Anion controlled assembly
Lanthanide contraction, Crystal structures, Magnetic properties, 1097
Anions
Copper(I), Dppe, Coordination mode, Solid state structures, 2433
Antibacterial activity
Binuclear, Ruthenium(II) complexes, Thiobis(β-diketone), Syntheses, Catalytic oxidation, 1721
Antibacterial activity
Ruthenium(II), Binuclear, Bis(β-diketone), Triphenylarsine, Syntheses, Catalytic study, 219
Antiferromagnetic
Copper, Formato, Dinuclear complexes, EPR, 1057
Antiferromagnetic coupling
Density functional theory, Face-shared dimers, Metal–metal bonding, High spin/low spin crossover, Electron delocalization, Broken-symmetry, 1969
Antiferromagnetic coupling
Tetranuclear copper(II) complexes, Crystal structures, Magnetism, Molecular orbital calculation, 1539
Antiferromagnetic dimers
2-Anilinopyridine, Crystal structures, Dinuclear acetates, Copper(I), 457
Antimony(III)
1,3-Dithiole-2-thione-4,5-dithiolates, 1,3-Dithiole-2-one-4,5-dithiolates, Crystal structures, 2107
APCVD
Tin phosphide, Thin film, 1943
Apparent molar enthalpies of
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-heptylbenzoate, Potassium *p*-*n*-octylbenzoate, Partial molar enthalpies of, Micellization enthalpy, Methylene group contribution, 1497
Aqueous solution
Acidity parameter, Hydroxy groups, Glycine-conjugated bile acids, 1421
Aqueous solutions
Uranyl oxalates, Oxalic acid, UV–Vis spectrophotometry, Speciation, Stability constants, 1411
Arene ruthenium
Absolute configuration, Crystal structures, CH–π interaction, 2D NMR, 1929
Aromatic pendant arms
Azamacrocycles, Coordination compounds, Metallic polymer, 333
Aromatic π,π-staking interactions
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
Arsenic
B3LYP, CCSD(T), Germanium, 579
Arsenic
Heteropolyoxometalate, Tungstate, Lacunary, Synthesis, Redox chemistry, 959
Arsine oxide
Scandium, Phosphine oxide, X-ray structures, ^{45}Sc NMR, 1579
Arsine oxide
Yttrium, Phosphine oxide, X-ray structures, 445
Artificial neural networks
Experimental design, Stability constants, Metal complexes, Ion selective electrodes, Metal–ligand equilibria, 1375
Arylazopyrimidines
Osmium(II) complexes, Geometrical isomers, X-ray structures, MLCT transitions, Redox property, 753
Arylmetal complexes
Mercury(II), Boron, The 2,6-bis(dimethylamino)phenyl ligand, 635
Aryloxide
Gallium, Hydrogen bonding, Hydrolysis, 1877
Aryloxide
Yttrium, Salen, Amide, Organometallic, 1683
Aspartate
Cadmium(II), Structures, ^{111}Cd NMR, 935
Assembly chemistry
Silver(I), Nicotinamide, Nicotinic acid, Sulfonate, Hydrogen bond, Ag–Ag interaction, 689
Association constants
Zinc(II)tetrasulfophthalocyanine, Sulfur dioxide, Fluorescence quenching, 951
Asymmetric catalysis
Nickel, Malic acid, Malate, Coordination polymer, Crystal structures, Electroplating, 787
Asymmetric 14-π nickel(II) tetraazaannulene
Synthesis and electrochemistry, Hammett plot, Electrocatalysis, 917
Asymmetric unit
Acyclic, Binuclear, Pyrazole bridged, Pentagonal bipyramidal, 925
Autoxidation
Copper(I) complexes, Kinetic data, Catalytic activity, 181
Azamacrocycles
Aromatic pendant arms, Coordination compounds, Metallic polymer, 333
Aza-Wittig reaction
Iminophosphorane, Cycloaddition, Four-membered ring compounds, Thermolysis, X-ray analysis, 657
Azide
Germanium, Tin, Silver, Tris(pyrazolyl)borate, Aminotroponimine, 611
Azide
Organotin, Crystal structures, Halides, *N*-Thiocyanate, Acetate, 1667

Backscatter Mössbauer spectroscopy
Iron(II) phthalocyanine, Gas sensing, 115
Base hydrolysis kinetics
Equilibria, Crystal and molecular structures, 2283
bdmpp
Ru(II) complexes, dcbpy, Thiocyanato ligands, Sensitizing ability, 2773
Benzimidazoles
Copper(II), Alkoxo-bridged, Magnetism, Crystal structures, 141
Benzimidazolium
Thermochromism, Crystal structures, Tetrachlorocuprate, 2561
Benzoate ligands
Cobalt(II) complexes, Di-2-pyridyl ketone complexes, End-on azide ligands, Magnetic properties, 2027
Benzohydroximate anion
Boron complexes, Synthesis, Crystal structures, 2351
Benzotriazole
Ruthenium-ammine, Polynuclear complexes, Mixed-valence, Electron transfer, Molecular wires, 2089
Benzyl 8-quinolyl sulfide
Palladium(II) complexes, Phenethyl 8-qui-

nolyl, Crystal structures, 843
BF_2^+-capped complexes
Nickel(II) complexes, Heterotrinuclear complexes, Dioxadithiadiazamacrobicycle, Template effect, *vic*-Dioxime, 1865
Bidentate ligands
Cobalt(III) complexes, Tetradentate ligands, Eddp, 2277
Bidentate nitrogen ligands
Palladium, Nickel, Chirality, Crystal structures, 27
Bifunctional ligand
Hydroxypyridinones, Hydroxypyridinonate complexes, Chelating agents, 2609
Bimetallics
Tantalum, Metallocenes, Hydrides, Metallophosphines, X-ray structures, 371
Binuclear
Acyclic, Pyrazole bridged, Asymmetric unit, Pentagonal bipyramidal, 925
Binuclear complexes
Lanthanide(III) chelate, Cobalt(III) chelate, Inner-sphere coordination, Outer-sphere coordination, Stability constant, 805
Binuclear complexes
Macrocyclic compound, Magnetic properties, 359
Binuclear complexes
Synthesis, Equilibria, Polyamines, 1351
Binuclear nickel(II) complexes
Crystal structures, Magnetic properties, Terminal thiocyanato ion complexes, Terminal cyanato ion complexes, Pentadentate ligands, 2457
Binuclear
Ruthenium(II), Bis(β-diketone), Triphenylarsine, Syntheses, Antibacterial activity, Catalytic study, 219
Binuclear
Ruthenium(II) complexes, Thiobis(β-diketone), Syntheses, Catalytic oxidation, Antibacterial activity, 1721
Binucleating ligand
Copper(II) complexes, Nickel(II) complexes, Electrochemistry, Magnetic properties, 2767
Bioactivity of metal complexes
Metal complexes, *S*-Benzyldithiocarbazate, Bioactivity of Schiff bases, Crystal structure of Cd(II) complexes, 2547
Bioactivity of Schiff bases
Metal complexes, *S*-Benzyldithiocarbazate, Bioactivity of metal complexes, Crystal structure of Cd(II) complexes, 2547
Bioactivity
Schiff base ligands, Cadmium(II) complexes, Crystal structures, Dithiocarbazate Schiff base crystal structures, Metal complexes, 2691
Bioligands
Palladium(II) complexes, Glycine methyl ester hydrolysis, 167
2,2′-Bipyridine complexes
Mixed-ligand complexes, Copper(II) complexes, Lactic acid, 2-Methyllactic acid, Mandelic acid, Crystal structures, 2811
4,4′-bipyridine
Hydrogen-bonding, Silanol, Amine, Adducts, Acridine, Phenylpyridine, 1689
Bis(β-diketone)
Ruthenium(II), Binuclear, Triphenylarsine, Syntheses, Antibacterial activity, Catalytic study, 219
bis(diphenylthiophosphinyl)ethane
Phosphine chalcogenide, Seven-membered, Palladium(II), Mercury(II), Metallacyclic rings, 205
Bis-ligand and anion-bound copper(II) complexes
2-(3,5-Dimethylpyrazol-1-ylmethyl)pyridine, X-ray structure, Absorption and EPR spectra, Cyclic voltammetry, 1245
Bismuth
Polycations, Cluster compounds, Crystal structures, Iridium, Rhodium, 651
Bis(phosphine) monoxides
Cu(I), Chelates, NMR, Electrochemistry, Hard–soft acids and bases, 2793
Bis(pyrazol-1-yl)alkane
Organotin(IV), X-ray structures, 873
Bis-sulfamide
Tantalum(V), Diamide, Crystal structures, 1051
Bithiophene
Polyamine, Coordination, Cu(II)-electrochemical pattern, Potentiometry, 1523
B3LYP
CCSD(T), Germanium, Arsenic, 579
Bond dissociation energy
Digermene, Germylene, X-ray crystallographic analysis, Dissociation, Equilibrium, Dioxadigermetane, Terminal tungsten complexes, 563
Boron
Arylmetal complexes, Mercury(II), The 2,6-bis(dimethylamino)phenyl ligand, 635
Boron complexes
Benzohydroximate anion, Synthesis, Crystal structures, 2351
Boron
Lithium, Imido, Complexes, X-ray, 549
Boron monochloride
Halogen exchange, Polyboron halides, 543
BPTI
Capillary electrophoresis, Hydrophobic interaction chromatography, Heterologous protein, *Saccharomyces cerevisiae*, 1405
Broken-symmetry
Density functional theory, Face-shared dimers, Metal–metal bonding, High spin/low spin crossover, Electron delocalization, Antiferromagnetic coupling, 1969
BTZ ligands
X-ray crystallography, Pb(II) salts, π–π stacking interaction, 197
Bubble extraction
Urinary trypsin inhibitors, Affinity chromatography, RP-HPLC, 1475
Buffer capacity
Partition function, Equilibria in solution, Cooperativity, Site affinity, Heat capacity, 1439
Bulky ligands
β-Diketiminate, Low valent indium, Metal–metal bonds, 525

Cadmium complexes
Dca ligand, Double end-to-end, Zigzag chain, π–π interaction, 893
Cadmium(II)
Aspartate, Structures, ^{111}Cd NMR, 935
Cadmium(II) complexes
Coordination polymers, Crystal structures, Symbiosis, 2293
Cadmium(II) complexes
Cyanometalate, Coordination polymers, Crystal structures, 721
Cadmium(II) complexes
Polyamines, X-ray structures, 739
Cadmium(II) complexes
Schiff base ligands, Crystal structures, Dithiocarbazate Schiff base crystal structures, Metal complexes, Bioactivity, 2691
Cadmium(II)
2-Pyridineformamide, Thiosemicarbazone, Nickel(II), Zinc(II), Crystal structures, 729
Cadmium(II)
Tris(pyrazolyl)borate and 2,6-pyridyl-diimine ligands, Thiocyanate, Lead(II), 1795
Cadmium
Macrocycles, Polyamines, Dipyridine, Phenanthroline, 1329
Cadmium
Nickel, Copper, Zinc, Saccharinate, X-ray structures, 395
Cadmium
Pyrazineformamide, Thiosemicarbazone, Zinc, Crystal structures, Electrochemical synthesis, 1553
Caesium ion
Alkali metal ions, Sodium ion, Calix[4]arene, Crystal structures, 2497
Caffeic acid complexes
Vanadium complexes, IR spectra, UV–Vis spectra, Potentiometric titrations, Catecholate-like ligand, 1979
Cage-like structure
Polyoxovanadates, Organic–inorganic hybrid, Mixed-valence, Hydrothermal synthesis, 2601
Calcium(II) complexes
Aminomethane-1,1-diphosphonic acids, Zinc(II) complexes, Magnesium(II) complexes, Potentiometry, NMR, 321
Calix[4]arene
Alkali metal ions, Sodium ion, Caesium ion, Crystal structures, 2497
Calixarenes
Uranyl ion, Homooxacalixarenes, Supramolecular assembly, Crystal structures, 1125
Calorimetry
Zinc adducts, Emprirical correlations, Infrared spectroscopy, 1677
^{13}C and ^{15}N NMR spectroscopy
Synthesis, Cyano(selenone)gold(I) complexes, 2099
Capillary electrophoresis

Hydrophobic interaction chromatography, Heterologous protein, BPTI, *Saccharomyces cerevisiae*, 1405
Carbacylamidophosphates
Cobalt(II), Cubane complexes, X-ray data, 963
Carba metallaboranes
Carboranes, Dicarbollides, Cyclic voltammetry, Liquid–liquid extraction, Lanthanide and actinide extaction, 975
Carbohydrates
Cobalt complexes, Circular dichroism, Sucrose complexes, ^{1}H NMR, Semi-empirical calculations, 2215
Carbonyl
Rhenium(I), Aminoalcohol, Cytotoxicity, Oxidative-alkoxylation, Hydrogen-bonding, 1991
Carbonyls
Cyclophosphazenes, Polyphosphazenes, Phenolic phosphine, Macromolecular complexes, Spectroscopic characterization, 2579
Carboranes
Carba metallaboranes, Dicarbollides, Cyclic voltammetry, Liquid–liquid extraction, Lanthanide and actinide extaction, 975
Carboxylate
Trinuclear complexes, Single crystal structures, Copper(II), Silver(I), Thioether, 33
Carnosine
Oxovanadium(IV) complexes, Potentiometric and spectrophotometric studies, Stability constants, 1513
Catalase resistance
Diperoxovanadate, Vanadyl, EDTA inhibition, EDTA bridged heteroligand peroxovanadates, Oxo-bridged peroxovanadates containing sulphate, 389
Catalysis
Organometallics, Heterobimetallics, Organoruthenium, Mössbauer, NMR, 2323
Catalysis
Silver, Hydroxylamine, Kinetics, Mechanism, Redox, 1893
Catalysis
Triflates, Triphenylphosphine oxide complexes, Single crystal X-ray diffraction, Scandium and lanthanide, 287
Catalytic activity
Copper(I) complexes, Autoxidation, Kinetic data, 181
Catalytic disproportionation
Manganese(II) complexes, 2-Pyrazine carboxylic acid, 2,6-Pyridinedicarboxylic acid, Chelidamic acid, Crystal structures, Hydrogen peroxide, 1063
Catalytic oxidation
Binuclear, Ruthenium(II) complexes, Thiobis(β-diketone), Syntheses, Antibacterial activity, 1721
Catalytic study
Ruthenium(II), Binuclear, Bis(β-diketone), Triphenylarsine, Syntheses, Antibacterial activity, 219
Catecholate ligands
Lanthanide, Polyaza ligands, Stability constants, Potentiometry, 1393
Catecholate-like ligand
Vanadium complexes, Caffeic acid complexes, IR spectra, UV–Vis spectra, Potentiometric titrations, 1979
Cation–π interaction
Thallium(I) complexes, Scorpionate ligands, Crystal packing, π-Stacking, 553
Cations
Solutions, Equilibria, Hydrolysis, Titration, Masking, 1369
C_3-chiral triamidostannate
Amides, Tin, Lithium, 629
CCSD(T)
B3LYP, Germanium, Arsenic, 579
Cd(II) and Hg(II) complexes
Spectroscopic properties, Normal coordinate, Force constant, 2-Phenylenediamine, 2-Aminophenol, 987
^{111}Cd NMR
Cadmium(II), Aspartate, Structures, 935
CD spectra
Optically active Schiff bases, Co(II), Cu(II) and Ni(II) complexes, Co(II) paramagnetic ^{1}H NMR, 2711
CD spectroscopy
Copper(II), Nickel(II), Palladium(II), Peptides, Methionine, 2149
Cerium
Fluoroalkoxides, Structures, Complexes, MOCVD, Films, 1985
C–H activation
Cyclometallation, Phosphorus ligands, Schiff bases, Palladium, 39
Chain complex
Crystal structures, Nickel(II) complexes, Hexaazamacrocycle, Organic ligands, 1913
Charge transfer
Polyoxometalates, Keggin, Photochromism, 2537
Chelate complexes
$Ph_2P(CH_2)_nNHP^iPr_2$, Diphosphine ligands, 2639
Chelates
Bis(phosphine) monoxides, Cu(I), NMR, Electrochemistry, Hard–soft acids and bases, 2793
Chelate
Titanium, Coordination chemistry, Structure elucidation, 8-Hydroxyquinolinate, 1081
Chelating agents
Hydroxypyridinones, Hydroxypyridinonate complexes, Bifunctional ligand, 2609
Chelex 100
Natural metal complexes, Natural ligands, Resin titration, Ligand titration, 1343
Chelidamic acid
Manganese(II) complexes, 2-Pyrazine carboxylic acid, 2,6-Pyridinedicarboxylic acid, Crystal structures, Catalytic disproportionation, Hydrogen peroxide, 1063
Chemical and electrochemical synthesis
Trinuclear metal chelates, β-Aminovinylimines, 2081
Chemical bonding
Polyoxometalates, Transition metals, Molecular orbitals, Density–functional theory, 2201
Chemical bonding topology
Superconductors, Magnesium diboride, Cuprate superconductors, 2347
Chemical vapor deposition
Silver(I) complexes, Non-fluorinated β-diketonate ligands, Monothio-β-ketonate, β-Ketoiminate, Crystal structures, 1289
Chemosensors
Polyazaalkanes ligand, Fluorogenic receptors, 1397
CH–π interaction
Arene ruthenium, Absolute configuration, Crystal structures, 2D NMR, 1929
Chiral benzodiazepine ligands
Zinc complexes, Palladium complexes, Spectroscopy, X-ray structure analysis, Cytostatic and antiviral activity, 2567
Chiral complexes
Macrocycles, Lanthanide complexes, Crystal structures, NMR of paramagnetic compounds, 811
Chiral complexes
Vanadyl complexes, Schiff bases, EPR, X-ray structures, 2021
Chiral iminophosphine ligand
Palladium complexes, Platinum complexes, 1043
Chirality
Palladium, Nickel, Bidentate nitrogen ligands, Crystal structures, 27
Chiral recognition
Nickel(II), Amino acid, Coordination chemistry, Hydrogen bond, 817
Chloride ligands
Oxo ligands, Phenolates, Tungsten, 349
Chloridotellurate anions
Tellurium dichloride, X-ray crystallography, NMR spectroscopy, 1089
Chloro-bridged complexes
Cyclometallated palladium(II) compounds, *N*-(Benzylidene)xylylendiamines, 2063
$C_{10}H_{20}N_2S_4Zn\cdot C_5H_5N$
Isomorphism, Structures, ^{15}N CP/MAS NMR spectroscopy, 2727
Chromium
Crystal structures, Homogeneous catalyst, Electron spin resonance, Polyethylene, 867
Chromium(III) complexes
Trans influence, Crystal structures, Ligand-field strength, Tripodal tridentate phosphine, Acetylacetonate complexes, 835
Chromium
Pivalate, Mass spectrometry, Paramagnetic, NMR, X-ray photoelectron spectroscopy, 155
Circular dichroism
Carbohydrates, Cobalt complexes, Sucrose complexes, ^{1}H NMR, Semi-empirical calculations, 2215
cis-1,2-Bis(diphenylphosphino)ethene
Nickel, Thiolate, X-ray structures, 421
Cluster complexes
Molybdenum, Crystal structures, Acetates,

Reduction, 147
Cluster compounds
Polycations, Crystal structures, Bismuth, Iridium, Rhodium, 651
Cluster
Optical limiting properties, Crystal structures, 2675
Clusters
Crystal structures, Intermetallic compounds, Lead, Zintl phases, 641
Clusters
Ruthenium, Osmium, Acetylide, Alkyne, 1105
^{13}C NMR spectra
Dimethylthallium(III), Thiosemicarbazones, Crystal structures, IR spectra, ^{1}H, 1651
^{13}C NMR spectroscopy
Sulfur dicyanide $S_y(CN)_2$, Polythiocyanogens, Paracyanogen $(CN)_x$, 1825
Cobalt complexes
Carbohydrates, Circular dichroism, Sucrose complexes, ^{1}H NMR, Semi-empirical calculations, 2215
Cobalt complexes
Isopolyoxomolybdates, Heteropolyoxomolybdates, Hydrothermal synthesis, 1921
Cobalt(I) clusters
Crystal structures, Interstitial phosphorus atom, Heterocyclic phosphide, Semi-bridging carbonyl, Substituted site, 1073
Cobalt(II) complexes
Benzoate ligands, Di-2-pyridyl ketone complexes, End-on azide ligands, Magnetic properties, 2027
Cobalt(II)
Cubane complexes, Carbacylamidophosphates, X-ray data, 963
Cobalt(III) chelate
Lanthanide(III) chelate, Binuclear complexes, Inner-sphere coordination, Outer-sphere coordination, Stability constant, 805
Cobalt(III) complexes
Synthesis, 4-Methyl-2,6-dibenzoylphenol, NMR, TGA, Cyclic voltammetry, X-ray structures, 1787
Cobalt(III) complexes
Tetradentate ligands, Bidentate ligands, Eddp, 2277
Cobalt(III)
Pyrazolylthiosemicarbazone, ^{1}H NMR, X-ray crystallography, 779
Cobalt(III)
Thiosemicarbazone, X-ray crystal studies, ^{1}H NMR, IR, Electronic spectra, 2515
Cobalt(II)
One-dimensional structures, Zinc(II), Coordination complexes, 2705
Cobalt(II)
Schiff base complexes, Nickel(II), Zinc(II), Tetrahedral, Crystal structures, 2733
Cobalt
Phthalocyanine, Cyanide, Sulfur dioxide, Kinetics, Equilibria, 133
Cobalt
Phthalocyanines, Phthalonitrile derivatives, Electrochemistry, Nickel, Zinc, 255
Cocrystallization
Dinuclear platinum complexes, One-dimensional polymers, 715
Co(II), Cu(II) and Ni(II) complexes
Optically active Schiff bases, CD spectra, Co(II) paramagnetic ^{1}H NMR, 2711
Co(III) complexes
Pyrazole, Dithiocarbazate, Synthesis, Spectroscopy, X-ray crystal structures, 1
Co(II)
Ni(II), Tetramines, Adenosine 5′-monophosphate, Mixed-ligand complexes, 745
Co(II) paramagnetic ^{1}H NMR
Optically active Schiff bases, Co(II), Cu(II) and Ni(II) complexes, CD spectra, 2711
Complexes
Boron, Lithium, Imido, X-ray, 549
Complexes
Cerium, Fluoroalkoxides, Structures, MOCVD, Films, 1985
Complexes
Lanthanides(III), Oxygen donors, 2,2′-Oxydiethylamine, Dimethylsulfoxide, Thermodynamics, 1385
Complexes
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, *N*-[2-(4-Methoxyphenyl telluro)-propyl]phthalimide, Palladium(II), Platinum(II), Ruthenium(II), Crystal structures, 667
Complexes
Silver(I), *N*-methylated polyamines, Dimethylsulfoxide, Thermodynamics, 1337
Complex-formation equilibria
Copper complexes, Nickel complexes, Lysyl–glycyl–histidyl–lysine, 1469
Complex history
Complex pioneers, Thermodynamics group, Coordination chemistry, 1313
Complex pioneers
Complex history, Thermodynamics group, Coordination chemistry, 1313
Cone angle
Dimesitylphosphine, Secondary phosphine, X-ray crystallography, NMR, Fluxional, 2409
Conformational change
Four or five coordinate geometry, Metal centre, Transition metals, 2175
Conformational change
Schiff's base ligands, Octahedral systems, Transition metals, 2167
Cooperativity effect
Statistical thermodynamic model, Site constant, Cooperativity potential, Polyamines, 1503
Cooperativity
Partition function, Equilibria in solution, Site affinity, Buffer capacity, Heat capacity, 1439
Cooperativity potential
Statistical thermodynamic model, Cooperativity effect, Site constant, Polyamines, 1503
Coordination bonding
Cyclophosphazene, Supramolecular polymer, Hairy-rod structure, Lamellar packing, 1573
Coordination chemistry
Complex history, Complex pioneers, Thermodynamics group, 1313
Coordination chemistry
Crystal structures, Piperazine, Homopiperazine, 1729
Coordination chemistry
Mono-helical, Single-helical-strand, Mono-bridged species, Transition metals, X-ray crystallography, 1177
Coordination chemistry
Nickel(II), Amino acid, Hydrogen bond, Chiral recognition, 817
Coordination chemistry
Titanium, Chelate, Structure elucidation, 8-Hydroxyquinolinate, 1081
Coordination complexes
One-dimensional structures, Zinc(II), Cobalt(II), 2705
Coordination compounds
Azamacrocycles, Aromatic pendant arms, Metallic polymer, 333
Coordination mode
Copper(I), Anions, Dppe, Solid state structures, 2433
Co-ordination number asymmetry
Crystal structures, Zinc(II) complexes, 1957
Coordination
Polyamine, Bithiophene, Cu(II)-electrochemical pattern, Potentiometry, 1523
Coordination polymer
Nickel, Malic acid, Malate, Asymmetric catalysis, Crystal structures, Electroplating, 787
Coordination polymers
Cadmium(II) complexes, Crystal structures, Symbiosis, 2293
Coordination polymers
Cyanometalate, Crystal structures, Cadmium(II) complexes, 721
Coordination polymers
Solventothermal synthesis, Crystal structures, Copper methoxide, Single crystals, 2017
Coordination structures
EPR spectroscopy, Rare earth complexes, 4f-Electron, 2127
Copper complexes
Crystal structures, Di-2-pyridylamine complexes, Tetrathionate complexes, Trifluoromethanesulfonate complexes, Sulfate complexes, Hexafluorophosphate complexes, 247
Copper complexes
Crystal structures, Lumazine complexes, Zinc complexes, 1961
Copper complexes
Crystal structures, Nitrate complexes, Di-2-pyridylamine complexes, 943
Copper complexes
Crystal structures, Tungsten complexes, Pyrazole, 1547
Copper complexes

Nickel complexes, Complex-formation equilibria, Lysyl–glycyl–histidyl–lysine, 1469
Copper complexes
Stereochemistry, X-ray structures, Steric properties, 1031
Copper complexes
Structures, Spectroscopic properties, Oxadiazole complexes, 2257
Copper
Cork, Solid state ^{13}C MAS and CP-MAS NMR, Nickel, Potentiometric titration, Metal uptake, 1363
Copper
Formato, Dinuclear complexes, Antiferromagnetic, EPR, 1057
Copper
Hinokitiol, X-ray, Adduct, 1761
Copper(I)
2-Anilinopyridine, Crystal structures, Antiferromagnetic dimers, Dinuclear acetates, 457
Copper(I)
Anions, Dppe, Coordination mode, Solid state structures, 2433
Copper(I) complexes
Autoxidation, Kinetic data, Catalytic activity, 181
Copper(I) complexes
Pyridine-2-thione, Tri-*p*-tolylphosphine, Triphenylphosphine, Sulfur-bridged dimer, 1603
Copper(II)
Alkoxo-bridged, Magnetism, Benzimidazoles, Crystal structures, 141
Copper(II)
CD spectroscopy, Nickel(II), Palladium(II), Peptides, Methionine, 2149
Copper(II) complex
Crystal structures, EDTA, Adeninium, Ion pair, Molecular recognition, 1451
Copper(II) complexes
Alkali metal ions, Doubly layered 2D sheet, 1273
Copper(II) complexes
Binucleating ligand, Nickel(II) complexes, Electrochemistry, Magnetic properties, 2767
Copper(II) complexes
Crystal structures, Cyclohexanediols, Separation of isomers, 1133
Copper(II) complexes
Crystal structures, Nitrite complexes, Sulfate complexes, di-2-Pyridylamine complexes, Thiocyanato complexes, 1279
Copper(II) complexes
Cyclodextrins, 2-Methylaminopyridine, 1531
Copper(II) complexes
Electron paramagnetic resonance (EPR) spectroscopy, Amino acids, *N*,*N*-dimethyl-L-α-isoleucine, 1643
Copper(II) complexes
Imidazole, 9,10-dihydro-9-oxo-10-acridineacetate, Crystal structures, Spectra, Magnetic measurements, 2381
Copper(II) complexes
Mixed-ligand complexes, 2,2′-Bipyridine complexes, Lactic acid, 2-Methyllactic acid, Mandelic acid, Crystal structures, 2811
Copper(II) complexes
Mixed-ligand complexes, Five-coordinate complexes, Aminohydroxamic acids, EPR spectra, Vis spectra, 295
Copper(II) complexes
Oxalato complexes, Oxalato-bridged complexes, Magnetic properties, Crystal structures, 1203
Copper(II) complexes
Spectral properties, Crystal structures, Pyridinecarboxylate complexes, Mononuclear complexes, 365
Copper(II) halides
Aminoguanidonium, Crystal structures, Tetrachlorocuprate(II), 409
Copper(II)
N-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
Copper(II) peptide complexes
α-Aminoisobutyryl-α-aminoisobutyric acid (H–Aib–Aib–OH), Spectroscopic characterization, X-ray crystal structures, 229
Copper(II)
Trinuclear complexes, Single crystal structures, Silver(I), Carboxylate, Thioether, 33
Copper methoxide
Solventothermal synthesis, Crystal structures, Coordination polymers, Single crystals, 2017
Copper
Nickel, Zinc, Cadmium, Saccharinate, X-ray structures, 395
Copper
Self-assembly, Supramolecules, X-ray structures, 1621
Cork
Solid state ^{13}C MAS and CP-MAS NMR, Copper, Nickel, Potentiometric titration, Metal uptake, 1363
CO
Synthesis, Mo/Fe/S cluster, Structures, $S{=}PEt_3$ ligand, 2523
Counter-cation
Uranyl, Dimethylmelonate, CPMAS ^{13}C NMR, X-ray crystallography, 69
CPMAS ^{13}C NMR
Uranyl, Dimethylmelonate, Counter-cation, X-ray crystallography, 69
CPMAS ^{13}C NMR
Uranyl, Malonato complexes, X-ray crystallography, 81
15-Crown-5
Potassium, Rubidium, Amide ligands, Crystal structures, 2451
Crown thioethers
Thioether complexes, Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Phosphine complexes, 879
Crystal and molecular structure
N-Benzoylthiourea derivatives, Gold, Palladium, Solvent extraction, Ion selective electrode, 1429
Crystal and molecular structures
Base hydrolysis kinetics, Equilibria, 2283
Crystal packing
Thallium(I) complexes, Scorpionate ligands, π-Stacking, Cation–π interaction, 553
Crystal structure
Nickel(0), Vinylcyclosilazane complexes, 1261
Crystal structure of Cd(II) complexes
Metal complexes, *S*-Benzyldithiocarbazate, Bioactivity of Schiff bases, Bioactivity of metal complexes, 2547
Crystal structure
Platinum, Hexamethyleneimine, 1,1-Cyclobutanedicarboxylato, Synthesis, 2659
Crystal structure
Platinum(II), Homopiperazines, Disubstituted sulfides, Synthesis, 125
Crystal structures
Alkali metal ions, Sodium ion, Caesium ion, Calix[4]arene, 2497
Crystal structures
Alkoxides, Lithium, Tungsten, Methoxide, 193
Crystal structures
Aluminium, Diols, Trinuclear complexes, 2,2′-Di(hydroxymethyl)biphenyl, Alkylaluminium diolates, 281
Crystal structures
Aminoguanidonium, Copper(II) halides, Tetrachlorocuprate(II), 409
Crystal structures
2-Anilinopyridine, Antiferromagnetic dimers, Dinuclear acetates, Copper(I), 457
Crystal structures
Arene ruthenium, Absolute configuration, CH–π interaction, 2D NMR, 1929
Crystal structures
Binuclear nickel(II) complexes, Magnetic properties, Terminal thiocyanato ion complexes, Terminal cyanato ion complexes, Pentadentate ligands, 2457
Crystal structures
Bis-sulfamide, Tantalum(V), Diamide, 1051
Crystal structures
Boron complexes, Benzohydroximate anion, Synthesis, 2351
Crystal structures
Cadmium(II) complexes, Coordination polymers, Symbiosis, 2293
Crystal structures
Chromium, Homogeneous catalyst, Electron spin resonance, Polyethylene, 867
Crystal structures
Clusters, Intermetallic compounds, Lead, Zintl phases, 641
Crystal structures
Cobalt(I) clusters, Interstitial phosphorus

atom, Heterocyclic phosphide, Semi-bridging carbonyl, Substituted site, 1073
Crystal structures
Coordination chemistry, Piperazine, Homopiperazine, 1729
Crystal structures
Copper complexes, Di-2-pyridylamine complexes, Tetrathionate complexes, Trifluoromethanesulfonate complexes, Sulfate complexes, Hexafluorophosphate complexes, 247
Crystal structures
Copper complexes, Lumazine complexes, Zinc complexes, 1961
Crystal structures
Copper complexes, Nitrate complexes, Di-2-pyridylamine complexes, 943
Crystal structures
Copper(II), Alkoxo-bridged, Magnetism, Benzimidazoles, 141
Crystal structures
Copper(II) complex, EDTA, Adeninium, Ion pair, Molecular recognition, 1451
Crystal structures
Copper(II) complexes, Cyclohexanediols, Separation of isomers, 1133
Crystal structures
Copper(II) complexes, Imidazole, 9,10-dihydro-9-oxo-10-acridineacetate, Spectra, Magnetic measurements, 2381
Crystal structures
Copper(II) complexes, Nitrite complexes, Sulfate complexes, di-2-Pyridylamine complexes, Thiocyanato complexes, 1279
Crystal structures
Copper(II) complexes, Oxalato complexes, Oxalato-bridged complexes, Magnetic properties, 1203
Crystal structures
Copper(II) complexes, Spectral properties, Pyridinecarboxylate complexes, Mononuclear complexes, 365
Crystal structures
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
Crystal structures
Cyanometalate, Coordination polymers, Cadmium(II) complexes, 721
Crystal structures
Dibenzotetraaza[14]annulenes, Macrocyclic Ni(II) complexes, Succinyl dichloride, Solid state supramolecular complexes, 7
Crystal structures
Dimethylthallium(III), Thiosemicarbazones, IR spectra, ^{1}H, ^{13}C NMR spectra, 1651
Crystal structures
Diruthenium carboxylates, Urea and thiourea derivatives, Infrared spectroscopy, 1235
Crystal structures
Dithiocarbamates, Cu(II) complexes, Ethylenediamine, Mixed-ligands Cu(II) chelates, 1899
Crystal structures
Dithiocarbimates, Triphenylphosphine, Nickel complexes, 2243
Crystal structures
1,3-Dithiole-2-thione-4,5-dithiolates, 1,3-Dithiole-2-one-4,5-dithiolates, Antimony(III), 2107
Crystal structures
Dithiophosphate complexes, Dithiophosphonate complexes, Macrocycle complexes, Pentacoordinate nickel(II) complexes, 1935
Crystal structures
1D nickel(II) azido complexes, Pyridine derivative complexes, Preparation, Magnetic data, Spectra, 1871
Crystal structures
Hemidirected, Lead(II) complexes, Thiocyanate ligands, 1223
Crystal structures
Idp-type ligand, *N*,*N*-Di(2-carboxyethyl)-*p*-toluidine, *p*-Toluidine-*N*,*N*-di-3-propionic acid, Square pyramidal copper(II) complexes, 2719
Crystal structures
Imidato complexes, Cyclometallated palladium(II) complexes, 1589
Crystal structures
Imidazole-4-acetic acid, Polymeric zinc(II) complexes, Vibrational spectra, Density functional calculations, 2819
Crystal structures
Iron(II) complexes, Hydrogen-bonded network, Hydrogen maleate, 1189
Crystal structures
Isotope effect, Hydrogen bond, Dimer, NQR, Tetrachloroaurate(III), 2207
Crystal structures
Lanthanide contraction, Anion controlled assembly, Magnetic properties, 1097
Crystal structures
Macrocycles, Germanium(IV) tmtaa complexes, Six-coordinate geometry, *Trans*-positions, 969
Crystal structures
Macrocycles, Lanthanide complexes, Chiral complexes, NMR of paramagnetic compounds, 811
Crystal structures
Magnesium, Niobium, Alkoxides, Oxoalkoxides, Mass-spectra, 1629
Crystal structures
Magnesium phthalocyanines, Magnesium complexes, IR spectroscopy, Raman spectroscopy, UV–Vis spectroscopy, 265
Crystal structures
Magnetic properties, Thermal properties, Tetrabromocuprate(II), *n*-Ethylpyridinium, 19
Crystal structures
Manganese(II) complexes, 2-Pyrazine carboxylic acid, 2,6-Pyridinedicarboxylic acid, Chelidamic acid, Catalytic disproportionation, Hydrogen peroxide, 1063
Crystal structures
Mercury(II) halides, Phosphine complexes, 1845
Crystal structures
Metal-organic frameworks (MOF), Synthesis, TGA–DTA, 175
Crystal structures
Mixed-ligand complexes, Copper(II) complexes, 2,2′-Bipyridine complexes, Lactic acid, 2-Methyllactic acid, Mandelic acid, 2811
Crystal structures
Molybdenum, Cluster complexes, Acetates, Reduction, 147
Crystal structures
Molybdenum, Tin, Metathesis, Polymerisation, Norbornadiene, NMR spectra, 2505
Crystal structures
Mononuclear complexes, Rhodium complexes, Hydrido complexes, Nitrogen ligands, 1613
Crystal structures
Mononuclear complexes, Triazole derivatives, 797
Crystal structures
Nickel complexes, Palladium complexes, 2071
Crystal structures
Nickel(II) chromate and dichromate complexes of phenanthroline, Monodentate coordination of CrO_4^{2-}, IR and UV–Vis–NIR band analysis, 997
Crystal structures
Nickel(II) complexes, Hexaazamacrocycle, Organic ligands, Chain complex, 1913
Crystal structures
Nickel, Malic acid, Malate, Coordination polymer, Asymmetric catalysis, Electroplating, 787
Crystal structures
Nickel, Palladium, Platinum, Oxalate, Magnetic properties, DFT calculations, 2631
Crystal structures
Nitrogenase, Hydrazido(2-), Molybdenum, Spectroelectrochemistry, 849
Crystal structures
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, *N*-[2-(4-Methoxyphenyl telluro)propyl]phthalimide, Palladium(II), Platinum(II), Ruthenium(II), Complexes, 667
Crystal structures of Zn(II) complexes
S-methyldithiocarbazate (SMDTC), NS Schiff base, Cu(II), Ni(II), Zn(II) complexes, 2683
Crystal structures
Optical limiting properties, Cluster, 2675
Crystal structures
Organotin, Halides, *N*-Thiocyanate, Azide, Acetate, 1667
Crystal structures
Organotin(IV) complexes, Dimethylpyrimidinethione, 1149
Crystal structures
Palladium(II) complexes, Benzyl 8-quino-

lyl sulfide, Phenethyl 8-quinolyl, 843
Crystal structures
Palladium, Nickel, Chirality, Bidentate nitrogen ligands, 27
Crystal structures
Physico-chemical properties, Spectroscopy, X-ray diffraction, Imidiazole complexes, 1857
Crystal structures
3-Piperidine, Thiosemicarbazone, 2-Pyridineformamide, Nickel(II), Spectra, 859
Crystal structures
Platinum, Cyclometallation, Imine, Fluorine, Phosphine, 105
Crystal structures
Platinum(II) complexes, Heptamethyleneimine, Synthesis, 2369
Crystal structures
Polycations, Cluster compounds, Bismuth, Iridium, Rhodium, 651
Crystal structures
Polydentate Ni(II) edta-type complexes, 2667
Crystal structures
Potassium, Rubidium, Amide ligands, 15-Crown-5, 2451
Crystal structures
Pyrazineformamide, Thiosemicarbazone, Zinc, Cadmium, Electrochemical synthesis, 1553
Crystal structures
2-Pyridineformamide, Thiosemicarbazone, Nickel(II), Zinc(II), Cadmium(II), 729
Crystal structures
Rhenium(III) complexes, Iridium(III) complexes, S-bridged polynuclear complexes, UV–Vis absorption spectra, Cyclic voltammetry, 1809
Crystal structures
Ruthenium monoterpyridine complexes, Ancillary functions, 2033
Crystal structures
Schiff base complexes, Cobalt(II), Nickel(II), Zinc(II), Tetrahedral, 2733
Crystal structures
Schiff base ligands, Cadmium(II) complexes, Dithiocarbazate Schiff base crystal structures, Metal complexes, Bioactivity, 2691
Crystal structures
Silver(I) complexes, Non-fluorinated β-diketonate ligands, Monothio-β-ketonate, β-Ketoiminate, Chemical vapor deposition, 1289
Crystal structures
Solventothermal synthesis, Coordination polymers, Copper methoxide, Single crystals, 2017
Crystal structures
Synthesis, X-ray diffraction, 1883
Crystal structures
Ternary complexes, Kinetic studies, 2045
Crystal structures
Tetranuclear copper(II) complexes, Magnetism, Antiferromagnetic coupling, Molecular orbital calculation, 1539
Crystal structures
Thermochromism, Benzimidazolium, Tetrachlorocuprate, 2561
Crystal structures
Thiadiazole, M = Co, M = Ni, M = Cu, Monomeric complexes, 403
Crystal structures
Trans influence, Ligand-field strength, Tripodal tridentate phosphine, Acetylacetonate complexes, Chromium(III) complexes, 835
Crystal structures
Trinuclear complexes, Cyano-bridge, Spectroscopic study, 2237
Crystal structures
Tungsten complexes, Pyrazole, Copper complexes, 1547
Crystal structures
Tungsten, Tin, Oxidative addition, Hydride, NMR, 1817
Crystal structures
Uranyl ion, Calixarenes, Homooxacalixarenes, Supramolecular assembly, 1125
Crystal structures
Uranyl ion, Polyphenols, Oligophenols, 1949
Crystal structures
Zinc(II) complexes, Co-ordination number asymmetry, 1957
Crystal structures
Zn(II)–N bonds, Zn(II) complexes, Piperazine and piperazin-1-ium ligands, 2161
Crystal structure
Thallium(I) complexes, Nitrophenoxide complexes, 2555
Cubane complexes
Cobalt(II), Carbacylamidophosphates, X-ray data, 963
Cu(I)
Bis(phosphine) monoxides, Chelates, NMR, Electrochemistry, Hard–soft acids and bases, 2793
Cu(II) complexes
Dithiocarbamates, Ethylenediamine, Mixed-ligands Cu(II) chelates, Crystal structures, 1899
Cu(II) complexes
Ternary complexes, Peptide–Cu(II)–isocytosine complexes, Isocytosine complexes, 1197
Cu(II)-electrochemical pattern
Polyamine, Bithiophene, Coordination, Potentiometry, 1523
Cu(II), Ni(II), Zn(II) complexes
S-methyldithiocarbazate (SMDTC), NS Schiff base, Crystal structures of Zn(II) complexes, 2683
Cu(II) stereochemistry
X-ray structures, Magnetism, EPR spectra, 2473
Cuprate superconductors
Chemical bonding topology, Superconductors, Magnesium diboride, 2347
Cyanide
Cobalt, Phthalocyanine, Sulfur dioxide, Kinetics, Equilibria, 133
Cyano-bridge
Trinuclear complexes, Crystal structures, Spectroscopic study, 2237
Cyanometalate
Coordination polymers, Crystal structures, Cadmium(II) complexes, 721
Cyano
Rhodium, Dioxygen, Enhanced reactivity, Structures, 1775
Cyano(selenone)gold(I) complexes
Synthesis, ^{13}C and ^{15}N NMR spectroscopy, 2099
Cyclic voltammetry
Carboranes, Carba metallaboranes, Dicarbollides, Liquid–liquid extraction, Lanthanide and actinide extaction, 975
Cyclic voltammetry
2-(3,5-Dimethylpyrazol-1-ylmethyl)pyridine, Bis-ligand and anion-bound copper(II) complexes, X-ray structure, Absorption and EPR spectra, 1245
Cyclic voltammetry
Five-coordinated chlorocopper(II) complexes, 1,10-Phenanthroline and its 5,6-disubstituted derivatives, X-ray structures, Electronic absorption and diffuse reflectance spectra, 2143
Cyclic voltammetry
Iron complexes, Aminohydroxamate complexes, Electrochemical reduction, EC mechanism, 1661
Cyclic voltammetry
Photoinduced electron transfer, Supramolecular pre-association, Ruthenium(II) complexes, 2,2′:6′,2″-Terpyridine, 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid, 49
Cyclic voltammetry
Rhenium(III) complexes, Iridium(III) complexes, S-bridged polynuclear complexes, Crystal structures, UV–Vis absorption spectra, 1809
Cyclic voltammetry
Salen Cu(II) complexes, Schiff-base ligands, Hammett substituent constants, 55
Cyclic voltammetry
Synthesis, Cobalt(III) complexes, 4-Methyl-2,6-dibenzoylphenol, NMR, TGA, X-ray structures, 1787
Cyclisation
P-Ligands, 2*H*-Azaphosphirene complexes, 2*H*-1,2-Azaphosphole complexes, 1,3-Dipoles, 119
Cycloaddition
Iminophosphorane, Four-membered ring compounds, Thermolysis, Aza-Wittig reaction, X-ray analysis, 657
Cyclo-addition
Metallacycles, oxo ligands, P ligands, Palladium, Structure elucidation, 2653
1,1-Cyclobutanedicarboxylato
Platinum, Hexamethyleneimine, Synthesis, Crystal structure, 2659
Cyclodextrins
Copper(II) complexes, 2-Methylaminopyridine, 1531
Cyclohexanediols
Crystal structures, Copper(II) complexes,

Separation of isomers, 1133
Cyclometalation
Amido, Amine, Triflate, Platinum, Diphosphazane, 1305
Cyclometallated paladium(II) complexes
Imidato complexes, Crystal structures, 1589
Cyclometallated palladium(II) compounds
N-(Benzylidene)xylylendiamines, Chloro-bridged complexes, 2063
Cyclometallation
C–H activation, Phosphorus ligands, Schiff bases, Palladium, 39
Cyclometallation
Platinum, Imine, Fluorine, Phosphine, Crystal structures, 105
1,5-Cyclooctadiene
Oxidative addition reaction, Perfluoro-*n*-butyl iodide, Fluoroalkyls, 2357
Cyclopentadienyl iron complexes
Organometallic phosphine, Multimetallic, π-Allyl molybdenum, Iron carbonyl complexes, 2301
Cyclophosphazene
Dendrimers, Metal–nitrile complexes, 909
Cyclophosphazenes
Polyphosphazenes, Phenolic phosphine, Macromolecular complexes, Carbonyls, Spectroscopic characterization, 2579
Cyclophosphazene
Supramolecular polymer, Coordination bonding, Hairy-rod structure, Lamellar packing, 1573
Cysteamine
Cysteine, Sulfur, Hydrogen bonding, 225
Cysteine
Cysteamine, Sulfur, Hydrogen bonding, 225
Cysteine ligand
Solvation parameter model, Partition coefficient, Hydrophobic moment, Iron–sulfur protein, Mixed-valence non-integer oxidation number, 1357
Cytostatic and antiviral activity
Chiral benzodiazepine ligands, Zinc complexes, Palladium complexes, Spectroscopy, X-ray structure analysis, 2567
Cytotoxicity
Rhenium(I), Carbonyl, Aminoalcohol, Oxidative-alkoxylation, Hydrogen-bonding, 1991

Dca ligand
Cadmium complexes, Double end-to-end, Zigzag chain, π–π interaction, 893
dcbpy
Ru(II) complexes, bdmpp, Thiocyanato ligands, Sensitizing ability, 2773
Dendrimers
Cyclophosphazene, Metal–nitrile complexes, 909
Density functional calculations
Imidazole-4-acetic acid, Polymeric zinc(II) complexes, Crystal structures, Vibrational spectra, 2819
Density functional theory
Face-shared dimers, Metal–metal bonding, High spin/low spin crossover, Electron delocalization, Broken-symmetry, Antiferromagnetic coupling, 1969
Density–functional theory
Polyoxometalates, Transition metals, Chemical bonding, Molecular orbitals, 2201
Desulfurization
Triosmium cluster, Tetramethylthiourea, Sulfido, X-ray structures, 381
DFT calculations
Dinuclear transition metal complexes, Electron transfer, Magnetic coupling, Metal–metal bonding, Spin polarization, 1163
DFT calculations
Ferrocenyl Schiff bases, Isomerism, 2361
DFT calculations
Isoquercitrin, Al(III) complexes, Stoichiometry, UV–Vis Spectroscopy, FT Raman, 2801
DFT calculations
Nickel, Palladium, Platinum, Oxalate, Crystal structures, Magnetic properties, 2631
2,6-Diacetylpyridine
Lanthanide(III) complexes, Macrocyclic ligands, 3-Substituted-1,2-diaminopropanes, 425
Dialkyldithiophosphates
Gallium, Indium, Dithiocarbamates, ^{71}Ga NMR, Structures, 239
Diamide
Bis-sulfamide, Tantalum(V), Crystal structures, 1051
Diarylchlorogermanes
Halogermylenes, Donor side-chain, Intramolecular coordination, 2827
1,4-Diaza-1,3-diene
Niobium complexes, Heterodiene, X-ray crystal structures, 305
1,5-Diaza-3,7-diphosphacyclooctane
Ferrocenylmethylphosphine, Phosphino amino acids, 1,3-Diaza-5-phosphacyclohexane, Water-soluble complexes, Trinuclear complexes, 2251
1,3-Diaza-5-phosphacyclohexane
Ferrocenylmethylphosphine, Phosphino amino acids, 1,5-Diaza-3,7-diphosphacyclooctane, Water-soluble complexes, Trinuclear complexes, 2251
Dibenzotetraaza[14]annulenes
Macrocyclic Ni(II) complexes, Succinyl dichloride, Crystal structures, Solid state supramolecular complexes, 7
Dibenzoylmethane
Europium complexes, X-ray crystallography, Luminescence property, 2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 313
Dibenzylamine
Trialkylaluminum, Aminoalane, NMR, Mass spectrometry, Molecular structure, 1747
Dicarbollides
Carboranes, Carba metallaboranes, Cyclic voltammetry, Liquid–liquid extraction, Lanthanide and actinide extaction, 975
Diethylene triamine
Hg(II) complexes, Dimer, X-ray crystal structures, 2195
Digermene
Germylene, X-ray crystallographic analysis, Dissociation, Equilibrium, Bond dissociation energy, Dioxadigermetane, Terminal tungsten complexes, 563
2,2′-Di(hydroxymethyl)biphenyl
Aluminium, Diols, Trinuclear complexes, Crystal structures, Alkylaluminium diolates, 281
Diimine
Molybdenum complexes, oxo-Hydrazido complexes, Methyl-molybdenum complexes, Phenyl-molybdenum complexes, X-ray structures, 2531
1,2-Diimine
Ruthenium promoted reactions, Dimerization of aromatic amines, Structures, Redox, 97
β-Diketiminate
Low valent indium, Bulky ligands, Metal–metal bonds, 525
Dimanganese decacarbonyl
Diphosphine disulfide, Phosphido, Phosphidosulfide, 791
Dimer
Hg(II) complexes, Diethylene triamine, X-ray crystal structures, 2195
Dimer
Isotope effect, Hydrogen bond, Crystal structures, NQR, Tetrachloroaurate(III), 2207
Dimerization of aromatic amines
Ruthenium promoted reactions, 1,2-Diimine, Structures, Redox, 97
Dimesitylphosphine
Secondary phosphine, X-ray crystallography, NMR, Cone angle, Fluxional, 2409
2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline
Europium complexes, X-ray crystallography, Luminescence property, Dibenzoylmethane, 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 313
Dimethylmelonate
Uranyl, Counter-cation, CPMAS ^{13}C NMR, X-ray crystallography, 69
2-(3,5-Dimethylpyrazol-1-ylmethyl)pyridine
Bis-ligand and anion-bound copper(II) complexes, X-ray structure, Absorption and EPR spectra, Cyclic voltammetry, 1245
Dimethylpyrimidinethione
Organotin(IV) complexes, Crystal structures, 1149
Dimethylsulfoxide
Lanthanides(III), Oxygen donors, 2,2′-Oxydiethylamine, Complexes, Thermodynamics, 1385
Dimethylsulfoxide
Silver(I), *N*-methylated polyamines, Complexes, Thermodynamics, 1337

Dimethylthallium(III)
Thiosemicarbazones, Crystal structures, IR spectra, ^{1}H, ^{13}C NMR spectra, 1651
Di-*n*-butylhydroxytin(IV)
Tin enolates, Diorganohydroxytin, Diorganotin, Sn(IV) complexes, Malonates, 417
Dinuclear acetates
2-Anilinopyridine, Crystal structures, Antiferromagnetic dimers, Copper(I), 457
Dinuclear complexes
Copper, Formato, Antiferromagnetic, EPR, 1057
Dinuclear
Guanidinate, 1,3,4,6,7,8-Hexahydro-2*H*-pyramido[1,2-*a*]pyramidinate, Tin, Mononuclear, 619
Dinuclear platinum complexes
Cocrystallization, One-dimensional polymers, 715
Dinuclear transition metal complexes
DFT calculations, Electron transfer, Magnetic coupling, Metal–metal bonding, Spin polarization, 1163
Diols
Aluminium, Trinuclear complexes, 2,2′-Di(hydroxymethyl)biphenyl, Crystal structures, Alkylaluminium diolates, 281
Diop
Nitrosyl complexes, Ruthenium(II), NMR spectra, X-ray structures, Dppb, 2221
Diorganohydroxytin
Tin enolates, Diorganotin, Sn(IV) complexes, Malonates, Di-*n*-butylhydroxytin(IV), 417
Diorganotin
Tin enolates, Diorganohydroxytin, Sn(IV) complexes, Malonates, Di-*n*-butylhydroxytin(IV), 417
Dioxadigermetane
Digermene, Germylene, X-ray crystallographic analysis, Dissociation, Equilibrium, Bond dissociation energy, Terminal tungsten complexes, 563
Dioxadithiadiazamacrobicycle
Nickel(II) complexes, Heterotrinuclear complexes, BF_2^+-capped complexes, Template effect, *vic*-Dioxime, 1865
Dioxomolybdenum(VI) bromides
Oxotransfer catalysts, Thiol oxidation, 1635
Dioxomolybdenum(VI) complexes
Thiocarbodihydrazone Schiff base, X-ray structures, 1023
Dioxouranium(VI) polyhalides
Actinides, Uranyl polyhalides, Polybromides, Polyiodides, 2755
Dioxygen reactivity
Iron(II), Zinc(II), Schiff base, X-ray crystal structures, ^{1}H NMR spectroscopy, 705
Dioxygen
Rhodium, Cyano, Enhanced reactivity, Structures, 1775
Diperoxovanadate
Vanadyl, EDTA inhibition, EDTA bridged heteroligand peroxovanadates, Catalase resistance, Oxo-bridged peroxovanadates containing sulphate, 389
3,5-diphenylpyrazole
Gallium pyrazole complexes, Tetrachlorogallate salt, Gallium trichloride, 1117
Diphosphazane
Amido, Amine, Triflate, Platinum, Cyclometalation, 1305
Diphosphine disulfide
Dimanganese decacarbonyl, Phosphido, Phosphidosulfide, 791
Diphosphine ligands
$Ph_2P(CH_2)_nNHP^iPr_2$, Chelate complexes, 2639
Diplumbenes
Stannylenes, Plumbylenes, Distannenes, Lewis-amphoteric behavior, 587
1,3-Dipoles
P-Ligands, 2*H*-Azaphosphirene complexes, 2*H*-1,2-Azaphosphole complexes, Cyclisation, 119
Dipyridine
Macrocycles, Cadmium, Polyamines, Phenanthroline, 1329
Di-2-pyridylamine complexes
Crystal structures, Copper complexes, Tetrathionate complexes, Trifluoromethanesulfonate complexes, Sulfate complexes, Hexafluorophosphate complexes, 247
di-2-Pyridylamine complexes
Crystal structures, Copper(II) complexes, Nitrite complexes, Sulfate complexes, Thiocyanato complexes, 1279
Di-2-pyridyl ketone benzoylhydrazone
Nickel(II) complexes, Spectroscopy, Thermal analyses, 2375
Di-2-pyridyl ketone complexes
Benzoate ligands, Cobalt(II) complexes, End-on azide ligands, Magnetic properties, 2027
Diruthenium carboxylates
Urea and thiourea derivatives, Crystal structures, Infrared spectroscopy, 1235
Disilenes
Silenes, Silanones, Matrix isolation, Photolysis, 467
Dissociation
Digermene, Germylene, X-ray crystallographic analysis, Equilibrium, Bond dissociation energy, Dioxadigermetane, Terminal tungsten complexes, 563
Distannenes
Stannylenes, Plumbylenes, Diplumbenes, Lewis-amphoteric behavior, 587
Disubstituted sulfides
Platinum(II), Homopiperazines, Synthesis, Crystal structure, 125
Dithiocarbamates
Cu(II) complexes, Ethylenediamine, Mixed-ligands Cu(II) chelates, Crystal structures, 1899
Dithiocarbamates
Gallium, Indium, Dialkyldithiophosphates, ^{71}Ga NMR, Structures, 239
Dithiocarbazate
Co(III) complexes, Pyrazole, Synthesis, Spectroscopy, X-ray crystal structures, 1
Dithiocarbazate Schiff base crystal structures
Schiff base ligands, Cadmium(II) complexes, Crystal structures, Metal complexes, Bioactivity, 2691
Dithiocarbimates
Triphenylphosphine, Nickel complexes, Crystal structures, 2243
1,3-Dithiole-2-one-4,5-dithiolates
1,3-Dithiole-2-thione-4,5-dithiolates, Antimony(III), Crystal structures, 2107
1,3-Dithiole-2-thione-4,5-dithiolates
1,3-Dithiole-2-one-4,5-dithiolates, Antimony(III), Crystal structures, 2107
Dithiophosphate complexes
Dithiophosphonate complexes, Macrocycle complexes, Pentacoordinate nickel(II) complexes, Crystal structures, 1935
Dithiophosphonate complexes
Dithiophosphate complexes, Macrocycle complexes, Pentacoordinate nickel(II) complexes, Crystal structures, 1935
1D nickel(II) azido complexes
Pyridine derivative complexes, Preparation, Crystal structures, Magnetic data, Spectra, 1871
2D NMR
Arene ruthenium, Absolute configuration, Crystal structures, CH–π interaction, 1929
Donor side-chain
Halogermylenes, Intramolecular coordination, Diarylchlorogermanes, 2827
Double end-to-end
Cadmium complexes, Dca ligand, Zigzag chain, π–π interaction, 893
Doubly layered 2D sheet
Alkali metal ions, Copper(II) complexes, 1273
Dppb
Nitrosyl complexes, Ruthenium(II), NMR spectra, X-ray structures, Diop, 2221
Dppe
Copper(I), Anions, Coordination mode, Solid state structures, 2433
DTA
Pentacyaninotrosylferrate(2−) ion, Metastable excited states, X-ray diffraction, FIRRS, TGA, 1767

EC mechanism
Iron complexes, Aminohydroxamate complexes, Electrochemical reduction, Cyclic voltammetry, 1661
Eddp
Cobalt(III) complexes, Tetradentate ligands, Bidentate ligands, 2277
EDTA bridged heteroligand peroxovanadates
Diperoxovanadate, Vanadyl, EDTA inhibition, Catalase resistance, Oxo-bridged peroxovanadates containing sulphate, 389
EDTA
Copper(II) complex, Crystal structures, Adeninium, Ion pair, Molecular recognition, 1451
Edta-derived macrocycles
Macrocyclic ether bis(lactones), Stability constants, EPR of Cu(II) complexes, EPR of dinuclear Cu–Cu complexes, Hydro-

lysis of macrocycles, 2265
EDTA inhibition
Diperoxovanadate, Vanadyl, EDTA bridged heteroligand peroxovanadates, Catalase resistance, Oxo-bridged peroxovanadates containing sulphate, 389
Eight-coordinate
Schiff base, Zirconium complexes, X-ray crystal structure, Synthon, Heteroleptic, 211
Electrocatalysis
Synthesis and electrochemistry, Asymmetric 14-π nickel(II) tetraazaannulene, Hammett plot, 917
Electrochemical reduction
Iron complexes, Aminohydroxamate complexes, Cyclic voltammetry, EC mechanism, 1661
Electrochemical synthesis
Pyrazineformamide, Thiosemicarbazone, Zinc, Cadmium, Crystal structures, 1553
Electrochemistry
Binucleating ligand, Copper(II) complexes, Nickel(II) complexes, Magnetic properties, 2767
Electrochemistry
Bis(phosphine) monoxides, Cu(I), Chelates, NMR, Hard–soft acids and bases, 2793
Electrochemistry
2-Mercaptobenzoxazole, Pentacyanoferrate, Kinetics, Equilibrium constants, 2137
Electrochemistry
Phthalocyanines, Phthalonitrile derivatives, Nickel, Zinc, Cobalt, 255
Electrochemistry
Tertiary amines, Ruthenium complexes, Photochemistry, 61
Electron counts
Aluminum, Metalloid clusters, 503
Electron delocalization
Density functional theory, Face-shared dimers, Metal–metal bonding, High spin/low spin crossover, Broken-symmetry, Antiferromagnetic coupling, 1969
Electronic absorption and diffuse reflectance spectra
Five-coordinated chlorocopper(II) complexes, 1,10-Phenanthroline and its 5,6-disubstituted derivatives, X-ray structures, Cyclic voltammetry, 2143
Electronic spectra
Cobalt(III), Thiosemicarbazone, X-ray crystal studies, ^{1}H NMR, IR, 2515
Electronic states
Linear disilaketenylidene (SiSiO), Renner effect, Analogous multiple bonded systems, 599
Electronic structures
Rhenium, Nitrosyl, X-ray structures, Nitric oxide, 2617
Electron paramagnetic resonance (EPR) spectroscopy
Copper(II) complexes, Amino acids, *N*,*N*-dimethyl-L-α-isoleucine, 1643
Electron spin resonance
Chromium, Crystal structures, Homogeneous catalyst, Polyethylene, 867
Electron transfer
DFT calculations, Dinuclear transition metal complexes, Magnetic coupling, Metal–metal bonding, Spin polarization, 1163
Electron transfer
Mixed-valence compound, Iron, Trinuclear, Iodoacetate, Heat capacity, 1299
Electron transfer
Ruthenium-ammine, Benzotriazole, Polynuclear complexes, Mixed-valence, Molecular wires, 2089
Electroplating
Nickel, Malic acid, Malate, Coordination polymer, Asymmetric catalysis, Crystal structures, 787
Elemental analyses
Tris(pentamethylphenyl)gallium, Pentamethylphenylmagnesium bromide, Single crystal X-ray diffraction, 531
Emprirical correlations
Zinc adducts, Calorimetry, Infrared spectroscopy, 1677
End-on azide ligands
Benzoate ligands, Cobalt(II) complexes, Di-2-pyridyl ketone complexes, Magnetic properties, 2027
Enhanced reactivity
Rhodium, Cyano, Dioxygen, Structures, 1775
Epoxide
Silica gel, Immobilization, Propane-1,3-diamine, 2647
EPR
Copper, Formato, Dinuclear complexes, Antiferromagnetic, 1057
EPR of Cu(II) complexes
Edta-derived macrocycles, Macrocyclic ether bis(lactones), Stability constants, EPR of dinuclear Cu–Cu complexes, Hydrolysis of macrocycles, 2265
EPR of dinuclear Cu–Cu complexes
Edta-derived macrocycles, Macrocyclic ether bis(lactones), Stability constants, EPR of Cu(II) complexes, Hydrolysis of macrocycles, 2265
EPR
Salen ligands, Ni(I) complexes, Nickel(II) complexes, 1695
EPR spectra
Copper(II) complexes, Mixed-ligand complexes, Five-coordinate complexes, Aminohydroxamic acids, Vis spectra, 295
EPR spectra
Cu(II) stereochemistry, X-ray structures, Magnetism, 2473
EPR spectroscopy
Rare earth complexes, Coordination structures, 4f-Electron, 2127
EPR
Vanadyl complexes, Schiff bases, Chiral complexes, X-ray structures, 2021
Equilibria
Base hydrolysis kinetics, Crystal and molecular structures, 2283
Equilibria
Cobalt, Phthalocyanine, Cyanide, Sulfur dioxide, Kinetics, 133
Equilibria in solution
Partition function, Cooperativity, Site affinity, Buffer capacity, Heat capacity, 1439
Equilibria
Solutions, Cations, Hydrolysis, Titration, Masking, 1369
Equilibria
Synthesis, Binuclear complexes, Polyamines, 1351
Equilibrium constant
Adduct formation, Thermodynamics, Tin compounds, Porphyrins, Spectral method, 683
Equilibrium constants
2-Mercaptobenzoxazole, Pentacyanoferrate, Kinetics, Electrochemistry, 2137
Equilibrium
Digermene, Germylene, X-ray crystallographic analysis, Dissociation, Bond dissociation energy, Dioxadigermetane, Terminal tungsten complexes, 563
Esterification
Metal alkoxides, Single-crystal X-ray, Group V, Tantalum, Niobium, 2333
3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline
Europium complexes, X-ray crystallography, Luminescence property, Dibenzoylmethane, 2-(4′-Dimethylaminophenyl)-imidazo[4,5-f]1,10-phenanthroline, 313
Ethylenediamine
Dithiocarbamates, Cu(II) complexes, Mixed-ligands Cu(II) chelates, Crystal structures, 1899
Europium complexes
X-ray crystallography, Luminescence property, Dibenzoylmethane, 2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 313
Europium
Photoluminescence, Perchlorate, Methylpyridylacetamide, Intensity parameters, 1837
Experimental design
Artificial neural networks, Stability constants, Metal complexes, Ion selective electrodes, Metal–ligand equilibria, 1375

Face-shared dimers
Density functional theory, Metal–metal bonding, High spin/low spin crossover, Electron delocalization, Broken-symmetry, Antiferromagnetic coupling, 1969
4f-Electron
EPR spectroscopy, Rare earth complexes, Coordination structures, 2127
Ferrocenylmethylphosphine
Phosphino amino acids, 1,3-Diaza-5-phosphacyclohexane, 1,5-Diaza-3,7-diphosphacyclooctane, Water-soluble complexes, Trinuclear complexes, 2251
Ferrocenyl Schiff bases

Isomerism, DFT calculations, 2361
Films
Cerium, Fluoroalkoxides, Structures, Complexes, MOCVD, 1985
FIRRS
Pentacyaninotrosylferrate(2−) ion, Metastable excited states, X-ray diffraction, TGA, DTA, 1767
Five-coordinate complexes
Copper(II) complexes, Mixed-ligand complexes, Aminohydroxamic acids, EPR spectra, Vis spectra, 295
Five-coordinated chlorocopper(II) complexes
1,10-Phenanthroline and its 5,6-disubstituted derivatives, X-ray structures, Electronic absorption and diffuse reflectance spectra, Cyclic voltammetry, 2143
Fluorescence quenching
Zinc(II)tetrasulfophthalocyanine, Sulfur dioxide, Association constants, 951
Fluorine
Platinum, Cyclometallation, Imine, Phosphine, Crystal structures, 105
Fluoroalkoxides
Cerium, Structures, Complexes, MOCVD, Films, 1985
Fluoroalkyls
Oxidative addition reaction, Perfluoro-*n*-butyl iodide, 1,5-Cyclooctadiene, 2357
Fluorogenic receptors
Polyazaalkanes ligand, Chemosensors, 1397
Fluxional
Dimesitylphosphine, Secondary phosphine, X-ray crystallography, NMR, Cone angle, 2409
Force constant
Cd(II) and Hg(II) complexes, Spectroscopic properties, Normal coordinate, 2-Phenylenediamine, 2-Aminophenol, 987
Formation constants
Mercapto-carboxylic acid, Potentiometry, IR, Ionisation constants, 1319
Formato
Copper, Dinuclear complexes, Antiferromagnetic, EPR, 1057
Four-membered ring compounds
Iminophosphorane, Cycloaddition, Thermolysis, Aza-Wittig reaction, X-ray analysis, 657
Four or five coordinate geometry
Conformational change, Metal centre, Transition metals, 2175
FT Raman
Isoquercitrin, Al(III) complexes, Stoichiometry, UV–Vis Spectroscopy, DFT calculations, 2801

Gallium
Aryloxide, Hydrogen bonding, Hydrolysis, 1877
Gallium–gallium bonds
Macrocycles, Supramolecular chemistry, 511
Gallium(II)
Subvalent indium and gallium, Indium(I), Indium(II), Halide complexes, Raman spectra, 519
Gallium
Indium, Dithiocarbamates, Dialkyldithiophosphates, ^{71}Ga NMR, Structures, 239
Gallium
Indium, Platinum, Heterobimetallic complexes, X-ray structure analysis, Quantum chemical calculations, 535
Gallium pyrazole complexes
Tetrachlorogallate salt, Gallium trichloride, 3,5-diphenylpyrazole, 1117
Gallium trichloride
Gallium pyrazole complexes, Tetrachlorogallate salt, 3,5-diphenylpyrazole, 1117
^{71}Ga NMR
Gallium, Indium, Dithiocarbamates, Dialkyldithiophosphates, Structures, 239
Gas sensing
Iron(II) phthalocyanine, Backscatter Mössbauer spectroscopy, 115
Geometrical isomers
Arylazopyrimidines, Osmium(II) complexes, X-ray structures, MLCT transitions, Redox property, 753
Germanium
Azide, Tin, Silver, Tris(pyrazolyl)borate, Aminotroponimine, 611
Germanium
B3LYP, CCSD(T), Arsenic, 579
Germanium(IV) tmtaa complexes
Macrocycles, Crystal structures, Six-coordinate geometry, *Trans*-positions, 969
Germylene
Digermene, X-ray crystallographic analysis, Dissociation, Equilibrium, Bond dissociation energy, Dioxadigermetane, Terminal tungsten complexes, 563
Glycine-conjugated bile acids
Acidity parameter, Aqueous solution, Hydroxy groups, 1421
Glycine methyl ester hydrolysis
Palladium(II) complexes, Bioligands, 167
Gold
N-Benzoylthiourea derivatives, Palladium, Solvent extraction, Ion selective electrode, Crystal and molecular structure, 1429
Group 13 metals
Low valent, Multiply bonded derivatives, Matrix isolation, 473
Group V
Metal alkoxides, Esterification, Single-crystal X-ray, Tantalum, Niobium, 2333
Guanidinate
1,3,4,6,7,8-Hexahydro-2*H*-pyramido[1,2-*a*]pyramidinate, Tin, Mononuclear, Dinuclear, 619

Hairy-rod structure
Cyclophosphazene, Supramolecular polymer, Coordination bonding, Lamellar packing, 1573
Halide complexes
Subvalent indium and gallium, Gallium(II), Indium(I), Indium(II), Raman spectra, 519
Halide complexes
Zinc, Thiosemicarbazones, Ligand, 1217
Halides
Organotin, Crystal structures, *N*-Thiocyanate, Azide, Acetate, 1667
Halogen exchange
Boron monochloride, Polyboron halides, 543
Halogermylenes
Donor side-chain, Intramolecular coordination, Diarylchlorogermanes, 2827
Hammett plot
Synthesis and electrochemistry, Asymmetric 14-π nickel(II) tetraazaannulene, Electrocatalysis, 917
Hammett substituent constants
Salen Cu(II) complexes, Schiff-base ligands, Cyclic voltammetry, 55
Hard–soft acids and bases
Bis(phosphine) monoxides, Cu(I), Chelates, NMR, Electrochemistry, 2793
2*H*-Azaphosphirene complexes
P-Ligands, 2*H*-1,2-Azaphosphole complexes, Cyclisation, 1,3-Dipoles, 119
2*H*-1,2-Azaphosphole complexes
P-Ligands, 2*H*-Azaphosphirene complexes, Cyclisation, 1,3-Dipoles, 119
^{1}H
Dimethylthallium(III), Thiosemicarbazones, Crystal structures, IR spectra, ^{13}C NMR spectra, 1651
Heat capacity
Mixed-valence compound, Electron transfer, Iron, Trinuclear, Iodoacetate, 1299
Heat capacity
Partition function, Equilibria in solution, Cooperativity, Site affinity, Buffer capacity, 1439
Hemidirected
Lead(II) complexes, Thiocyanate ligands, Crystal structures, 1223
Heptamethyleneimine
Platinum(II) complexes, Synthesis, Crystal structures, 2369
Heterobimetallic complexes
Gallium, Indium, Platinum, X-ray structure analysis, Quantum chemical calculations, 535
Heterobimetallics
Organometallics, Organoruthenium, Catalysis, Mössbauer, NMR, 2323
Heterocyclic nitrogen ligands
Metallic carbonyl complexes, Manganese, 439
Heterocyclic phosphide
Crystal structures, Cobalt(I) clusters, Interstitial phosphorus atom, Semi-bridging carbonyl, Substituted site, 1073
Heterocyclic thioamides
Osmium, Ruthenium, 2-Mercapto-1-methylimidazole, X-ray structures, 885
Heterodiene
Niobium complexes, 1,4-Diaza-1,3-diene, X-ray crystal structures, 305
Heteroleptic
Eight-coordinate, Schiff base, Zirconium complexes, X-ray crystal structure, Synthon, 211

Heteroleptic
X-ray, Mononuclear tungsten(VI) complexes, Ligand, 1017
Heterologous protein
Capillary electrophoresis, Hydrophobic interaction chromatography, BPTI, *Saccharomyces cerevisiae*, 1405
Heteropolyanions
Polyoxometalates, Ti(IV) complex, Wells-Dawson structure, 353
Heteropolyoxometalate
Arsenic, Tungstate, Lacunary, Synthesis, Redox chemistry, 959
Heteropolyoxomolybdates
Isopolyoxomolybdates, Hydrothermal synthesis, Cobalt complexes, 1921
Heterotrinuclear complexes
Nickel(II) complexes, BF_2^+-capped complexes, Dioxadithiadiazamacrobicycle, Template effect, *vic*-Dioxime, 1865
Hexaazamacrocycle
Crystal structures, Nickel(II) complexes, Organic ligands, Chain complex, 1913
Hexafluorophosphate complexes
Crystal structures, Copper complexes, Di-2-pyridylamine complexes, Tetrathionate complexes, Trifluoromethanesulfonate complexes, Sulfate complexes, 247
1,3,4,6,7,8-Hexahydro-2*H*-pyramido[1,2-*a*]pyramidinate
Guanidinate, Tin, Mononuclear, Dinuclear, 619
Hexamethyleneimine
Platinum, 1,1-Cyclobutanedicarboxylato, Synthesis, Crystal structure, 2659
Hexaniobate
Niobates, Hydrothermal synthesis, $NaNbO_3$, 2009
HF/ECP calculations
Niobium sulphide metallacycles, X-ray structures, 2227
Hg(II) complexes
Dimer, Diethylene triamine, X-ray crystal structures, 2195
High spin/low spin crossover
Density functional theory, Face-shared dimers, Metal–metal bonding, Electron delocalization, Broken-symmetry, Antiferromagnetic coupling, 1969
Hinokitiol
Copper, X-ray, Adduct, 1761
^{1}H NMR
Carbohydrates, Cobalt complexes, Circular dichroism, Sucrose complexes, Semi-empirical calculations, 2215
^{1}H NMR
Cobalt(III), Pyrazolylthiosemicarbazone, X-ray crystallography, 779
^{1}H NMR
Cobalt(III), Thiosemicarbazone, X-ray crystal studies, IR, Electronic spectra, 2515
^{1}H NMR spectroscopy
Iron(II), Zinc(II), Schiff base, X-ray crystal structures, Dioxygen reactivity, 705
Homogeneous catalyst
Chromium, Crystal structures, Electron spin resonance, Polyethylene, 867
Homolytic hydride cleavage
Ruthenium(II) complexes, Semiquinone monochelates, 2761
Homooxacalixarenes
Uranyl ion, Calixarenes, Supramolecular assembly, Crystal structures, 1125
Homopiperazine
Coordination chemistry, Crystal structures, Piperazine, 1729
Homopiperazines
Platinum(II), Disubstituted sulfides, Synthesis, Crystal structure, 125
Hydrazido(2-)
Nitrogenase, Molybdenum, Crystal structures, Spectroelectrochemistry, 849
Hydrides
Tantalum, Metallocenes, Metallophosphines, Bimetallics, X-ray structures, 371
Hydride
Tungsten, Tin, Oxidative addition, Crystal structures, NMR, 1817
Hydrido complexes
Mononuclear complexes, Rhodium complexes, Nitrogen ligands, Crystal structures, 1613
Hydrogen-bonded network
Crystal structures, Iron(II) complexes, Hydrogen maleate, 1189
Hydrogen bonding
Aryloxide, Gallium, Hydrolysis, 1877
Hydrogen bonding
Cysteamine, Cysteine, Sulfur, 225
Hydrogen bonding
Phosphoranes, Pentacoordinated, X-ray structures, 1155
Hydrogen bonding
Pyridine N-oxide ligands, copper(II) complexes, X-ray structures, Magnetism, 1561
Hydrogen-bonding
Rhenium(I), Carbonyl, Aminoalcohol, Cytotoxicity, Oxidative-alkoxylation, 1991
Hydrogen-bonding
Silanol, Amine, Adducts, Acridine, 4,4′-bipyridine, Phenylpyridine, 1689
Hydrogen bond
Isotope effect, Dimer, Crystal structures, NQR, Tetrachloroaurate(III), 2207
Hydrogen bond
Nickel(II), Amino acid, Coordination chemistry, Chiral recognition, 817
Hydrogen bond
Silver(I), Nicotinamide, Nicotinic acid, Sulfonate, Ag–Ag interaction, Assembly chemistry, 689
Hydrogen maleate
Crystal structures, Iron(II) complexes, Hydrogen-bonded network, 1189
Hydrogen peroxide
Manganese(II) complexes, 2-Pyrazine carboxylic acid, 2,6-Pyridinedicarboxylic acid, Chelidamic acid, Crystal structures, Catalytic disproportionation, 1063
Hydrolysis
Aryloxide, Gallium, Hydrogen bonding, 1877
Hydrolysis of macrocycles
Edta-derived macrocycles, Macrocyclic ether bis(lactones), Stability constants, EPR of Cu(II) complexes, EPR of dinuclear Cu–Cu complexes, 2265
Hydrolysis
Solutions, Equilibria, Cations, Titration, Masking, 1369
Hydrophobic interaction chromatography
Capillary electrophoresis, Heterologous protein, BPTI, *Saccharomyces cerevisiae*, 1405
Hydrophobic moment
Solvation parameter model, Partition coefficient, Iron–sulfur protein, Mixed-valence non-integer oxidation number, Cysteine ligand, 1357
Hydrothermal synthesis
Isopolyoxomolybdates, Heteropolyoxomolybdates, Cobalt complexes, 1921
Hydrothermal synthesis
Niobates, $NaNbO_3$, Hexaniobate, 2009
Hydrothermal synthesis
Polyoxovanadates, Organic–inorganic hybrid, Mixed-valence, Cage-like structure, 2601
1-Hydroxybenzotriazolate complexes
Acetylacetonate complexes, Magnetic properties, Nickel(II), 2117
Hydroxy groups
Acidity parameter, Aqueous solution, Glycine-conjugated bile acids, 1421
Hydroxylamine
Silver, Kinetics, Mechanism, Redox, Catalysis, 1893
2-Hydroxynicotinic acid
Palladium, Platinum, X-ray crystal structures, Raman spectra, 2783
Hydroxypyridinonate complexes
Hydroxypyridinones, Chelating agents, Bifunctional ligand, 2609
Hydroxypyridinones
Hydroxypyridinonate complexes, Chelating agents, Bifunctional ligand, 2609
8-Hydroxyquinolinate
Titanium, Chelate, Coordination chemistry, Structure elucidation, 1081

Idp-type ligand
N,*N*-Di(2-carboxyethyl)-*p*-toluidine, *p*-Toluidine-*N*,*N*-di-3-propionic acid, Square pyramidal copper(II) complexes, Crystal structures, 2719
Imidato complexes
Cyclometallated paladium(II) complexes, Crystal structures, 1589
Imidazole-4-acetic acid
Polymeric zinc(II) complexes, Crystal structures, Vibrational spectra, Density functional calculations, 2819
Imidazole, 9,10-dihydro-9-oxo-10-acridineacetate
Copper(II) complexes, Crystal structures, Spectra, Magnetic measurements, 2381
Imidiazole complexes
Crystal structures, Physico-chemical properties, Spectroscopy, X-ray diffraction, 1857

Imido
Boron, Lithium, Complexes, X-ray, 549
Imido transfer
Osmium porphyrin, Phosphines, Kinetics, 1889
Imine–phenol function
Ruthenium aryls, Pyridine-2-thiolates of ruthenium, 899
Imine
Platinum, Cyclometallation, Fluorine, Phosphine, Crystal structures, 105
Iminophosphorane
Cycloaddition, Four-membered ring compounds, Thermolysis, Aza-Wittig reaction, X-ray analysis, 657
Immobilization
Silica gel, Epoxide, Propane-1,3-diamine, 2647
Indium
Gallium, Dithiocarbamates, Dialkyldithiophosphates, ^{71}Ga NMR, Structures, 239
Indium
Gallium, Platinum, Heterobimetallic complexes, X-ray structure analysis, Quantum chemical calculations, 535
Indium(II)
Subvalent indium and gallium, Gallium(II), Indium(I), Halide complexes, Raman spectra, 519
Indium(I)
Subvalent indium and gallium, Gallium(II), Indium(II), Halide complexes, Raman spectra, 519
Infrared spectroscopy
Diruthenium carboxylates, Urea and thiourea derivatives, Crystal structures, 1235
Infrared spectroscopy
Zinc adducts, Emprirical correlations, Calorimetry, 1677
Inner-sphere coordination
Lanthanide(III) chelate, Cobalt(III) chelate, Binuclear complexes, Outer-sphere coordination, Stability constant, 805
Inorganic polymer
Polyphosphazene, Metal–polymer complexes, 2587
Intensity parameters
Europium, Photoluminescence, Perchlorate, Methylpyridylacetamide, 1837
π–π interaction
Cadmium complexes, Dca ligand, Double end-to-end, Zigzag chain, 893
Interconversion
Schiff bases, Salicylaldimine adducts, X-ray crystal structures, Zinc complexes, Zwitterion, 697
Intermediates
Aluminum(I) halides, Metalloid clusters, Nanosized clusters, Metal lattice, X-ray structural analysis, 489
Intermetallic compounds
Clusters, Crystal structures, Lead, Zintl phases, 641
Intermolecular nucleophilic attack
Molecular orbital, Ab initio, Mechanism, Titanium, Ylid, 2699
Interstitial phosphorus atom
Crystal structures, Cobalt(I) clusters, Heterocyclic phosphide, Semi-bridging carbonyl, Substituted site, 1073
Intramolecular coordination
Halogermylenes, Donor side-chain, Diarylchlorogermanes, 2827
Iodoacetate
Mixed-valence compound, Electron transfer, Iron, Trinuclear, Heat capacity, 1299
Ionisation constants
Mercapto-carboxylic acid, Potentiometry, IR, Formation constants, 1319
Ion pair
Copper(II) complex, Crystal structures, EDTA, Adeninium, Molecular recognition, 1451
Ion selective electrode
N-Benzoylthiourea derivatives, Gold, Palladium, Solvent extraction, Crystal and molecular structure, 1429
Ion selective electrodes
Artificial neural networks, Experimental design, Stability constants, Metal complexes, Metal–ligand equilibria, 1375
IR and UV–Vis–NIR band analysis
Nickel(II) chromate and dichromate complexes of phenanthroline, Monodentate coordination of CrO_4^{2-}, Crystal structures, 997
IR
Cobalt(III), Thiosemicarbazone, X-ray crystal studies, ^{1}H NMR, Electronic spectra, 2515
Iridium(III) complexes
Rhenium(III) complexes, S-bridged polynuclear complexes, Crystal structures, UV–Vis absorption spectra, Cyclic voltammetry, 1809
Iridium
Polycations, Cluster compounds, Crystal structures, Bismuth, Rhodium, 651
IR
Mercapto-carboxylic acid, Potentiometry, Formation constants, Ionisation constants, 1319
Iron
Acetylide, Vinylidene, Propadienylidene, 1755
Iron carbonyl complexes
Organometallic phosphine, Multimetallic, π-Allyl molybdenum, Cyclopentadienyl iron complexes, 2301
Iron complexes
Aminohydroxamate complexes, Electrochemical reduction, Cyclic voltammetry, EC mechanism, 1661
Iron(II) complexes
Crystal structures, Hydrogen-bonded network, Hydrogen maleate, 1189
Iron(III) dialkyldithiocarbamates
Mössbauer spectra, Magnetic moment, Thermal decomposition, Spin crossover, 2489
Iron(III)
Single-crystal X-ray, N-donor, Terpyridyl, 2055
Iron(II) phthalocyanine
Backscatter Mössbauer spectroscopy, Gas sensing, 115
Iron(II)
Zinc(II), Schiff base, X-ray crystal structures, ^{1}H NMR spectroscopy, Dioxygen reactivity, 705
Iron
Mixed-valence compound, Electron transfer, Trinuclear, Iodoacetate, Heat capacity, 1299
Iron–sulfur protein
Solvation parameter model, Partition coefficient, Hydrophobic moment, Mixed-valence non-integer oxidation number, Cysteine ligand, 1357
IR spectra
Dimethylthallium(III), Thiosemicarbazones, Crystal structures, ^{1}H, ^{13}C NMR spectra, 1651
IR spectra
Vanadium complexes, Caffeic acid complexes, UV–Vis spectra, Potentiometric titrations, Catecholate-like ligand, 1979
IR spectroscopy
Magnesium phthalocyanines, Magnesium complexes, Crystal structures, Raman spectroscopy, UV–Vis spectroscopy, 265
Isatin
X-ray, Thiosemicarbazone, Metal complexes, 2593
Isocytosine complexes
Cu(II) complexes, Ternary complexes, Peptide–Cu(II)–isocytosine complexes, 1197
Isomerism
Ferrocenyl Schiff bases, DFT calculations, 2361
Isomorphism
$C_{10}H_{20}N_2S_4Zn\cdot C_5H_5N$, Structures, ^{15}N CP/MAS NMR spectroscopy, 2727
Isopolyoxomolybdates
Heteropolyoxomolybdates, Hydrothermal synthesis, Cobalt complexes, 1921
Isoquercitrin
Al(III) complexes, Stoichiometry, UV–Vis Spectroscopy, DFT calculations, FT Raman, 2801
Isotope effect
Hydrogen bond, Dimer, Crystal structures, NQR, Tetrachloroaurate(III), 2207
Isoxazolidines
Pd-, Zn-, Cu-complexes, Syntheses, X-ray, NMR, 769

Keggin
Polyoxometalates, Charge transfer, Photochromism, 2537
β-Ketoiminate
Silver(I) complexes, Non-fluorinated β-diketonate ligands, Monothio-β-ketonate, Chemical vapor deposition, Crystal structures, 1289
Kinetic data
Copper(I) complexes, Autoxidation, Catalytic activity, 181

Kinetics
Cobalt, Phthalocyanine, Cyanide, Sulfur dioxide, Equilibria, 133
Kinetics
2-Mercaptobenzoxazole, Pentacyanoferrate, Equilibrium constants, Electrochemistry, 2137
Kinetics
Osmium porphyrin, Imido transfer, Phosphines, 1889
Kinetics
Silver, Hydroxylamine, Mechanism, Redox, Catalysis, 1893
Kinetic studies
Ternary complexes, Crystal structures, 2045

Lactic acid
Mixed-ligand complexes, Copper(II) complexes, 2,2′-Bipyridine complexes, 2-Methyllactic acid, Mandelic acid, Crystal structures, 2811
Lacunary
Heteropolyoxometalate, Arsenic, Tungstate, Synthesis, Redox chemistry, 959
Lamellar packing
Cyclophosphazene, Supramolecular polymer, Coordination bonding, Hairy-rod structure, 1573
Lantern-type complexes
Platinum(III) compounds, Amidate bridging ligands, X-ray structure, 275
Lanthanide and actinide extaction
Carboranes, Carba metallaboranes, Dicarbollides, Cyclic voltammetry, Liquid–liquid extraction, 975
Lanthanide complexes
Macrocycles, Crystal structures, Chiral complexes, NMR of paramagnetic compounds, 811
Lanthanide contraction
Anion controlled assembly, Crystal structures, Magnetic properties, 1097
Lanthanide(III) chelate
Cobalt(III) chelate, Binuclear complexes, Inner-sphere coordination, Outer-sphere coordination, Stability constant, 805
Lanthanide(III) complexes
Macrocyclic ligands, 2,6-Diacetylpyridine, 3-Substituted-1,2-diaminopropanes, 425
Lanthanide(III) complexes
tert-Butylcalix[4]arenes, Amide, Sodium complexes, Yttrium(III) complexes, X-ray structures, 763
Lanthanide
Polyaza ligands, Catecholate ligands, Stability constants, Potentiometry, 1393
Lanthanides(III)
Oxygen donors, 2,2′-Oxydiethylamine, Dimethylsulfoxide, Complexes, Thermodynamics, 1385
Lead
Clusters, Crystal structures, Intermetallic compounds, Zintl phases, 641
Lead(II) complexes
Hemidirected, Thiocyanate ligands, Crystal structures, 1223
Lead(II)
Tris(pyrazolyl)borate and 2,6-pyridyl-diimine ligands, Thiocyanate, Cadmium(II), 1795
Lewis-amphoteric behavior
Stannylenes, Plumbylenes, Distannenes, Diplumbenes, 587
LH_4
vic-Dioxime, Nickel(II), Cobalt(II), Copper(II), Iron(II), Uranyl(IV), Electrochemistry, $N_2O_2S_2$ macrocyle, 825
Ligand-field strength
Trans influence, Crystal structures, Tripodal tridentate phosphine, Acetylacetonate complexes, Chromium(III) complexes, 835
Ligand titration
Natural metal complexes, Natural ligands, Resin titration, Chelex 100, 1343
Ligand
X-ray, Mononuclear tungsten(VI) complexes, Heteroleptic, 1017
Ligand
Zinc, Halide complexes, Thiosemicarbazones, 1217
Linear disilaketenylidene (SiSiO)
Electronic states, Renner effect, Analogous multiple bonded systems, 599
Linear polyamines
Metal complexes, Polyamine complexes, 1459
Liquid–liquid extraction
Carboranes, Carba metallaboranes, Dicarbollides, Cyclic voltammetry, Lanthanide and actinide extaction, 975
Lithium
Alkoxides, Crystal structures, Tungsten, Methoxide, 193
Lithium
Boron, Imido, Complexes, X-ray, 549
Lithium
C_3-chiral triamidostannate, Amides, Tin, 629
Low valent indium
β-Diketiminate, Bulky ligands, Metal–metal bonds, 525
Low valent
Multiply bonded derivatives, Group 13 metals, Matrix isolation, 473
Lumazine complexes
Crystal structures, Copper complexes, Zinc complexes, 1961
Luminescence property
Europium complexes, X-ray crystallography, Dibenzoylmethane, 2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 313
Lysyl–glycyl–histidyl–lysine
Copper complexes, Nickel complexes, Complex-formation equilibria, 1469

Macrocycle complexes
Dithiophosphate complexes, Dithiophosphonate complexes, Pentacoordinate nickel(II) complexes, Crystal structures, 1935
Macrocycles
Cadmium, Polyamines, Dipyridine, Phenanthroline, 1329
Macrocycles
Gallium–gallium bonds, Supramolecular chemistry, 511
Macrocycles
Germanium(IV) tmtaa complexes, Crystal structures, Six-coordinate geometry, *Trans*-positions, 969
Macrocycles
Lanthanide complexes, Crystal structures, Chiral complexes, NMR of paramagnetic compounds, 811
Macrocyclic compound
Binuclear complexes, Magnetic properties, 359
Macrocyclic ether bis(lactones)
Edta-derived macrocycles, Stability constants, EPR of Cu(II) complexes, EPR of dinuclear Cu–Cu complexes, Hydrolysis of macrocycles, 2265
Macrocyclic ligands
Lanthanide(III) complexes, 2,6-Diacetylpyridine, 3-Substituted-1,2-diaminopropanes, 425
Macrocyclic Ni(II) complexes
Dibenzotetraaza[14]annulenes, Succinyl dichloride, Crystal structures, Solid state supramolecular complexes, 7
Macromolecular complexes
Cyclophosphazenes, Polyphosphazenes, Phenolic phosphine, Carbonyls, Spectroscopic characterization, 2579
Magnesium complexes
Magnesium phthalocyanines, Crystal structures, IR spectroscopy, Raman spectroscopy, UV–Vis spectroscopy, 265
Magnesium complexes
Phoshocreatine, ^{31}P NMR spectroscopy, Sodium complexes, Potassium complexes, 1481
Magnesium diboride
Chemical bonding topology, Superconductors, Cuprate superconductors, 2347
Magnesium(II) complexes
Aminomethane-1,1-diphosphonic acids, Zinc(II) complexes, Calcium(II) complexes, Potentiometry, NMR, 321
Magnesium
Niobium, Alkoxides, Oxoalkoxides, Mass-spectra, Crystal structures, 1629
Magnesium phthalocyanines
Magnesium complexes, Crystal structures, IR spectroscopy, Raman spectroscopy, UV–Vis spectroscopy, 265
Magnetic coupling
DFT calculations, Dinuclear transition metal complexes, Electron transfer, Metal–metal bonding, Spin polarization, 1163
Magnetic data
1D nickel(II) azido complexes, Pyridine derivative complexes, Preparation, Crystal structures, Spectra, 1871
Magnetic measurements

Copper(II) complexes, Imidazole, 9,10-dihydro-9-oxo-10-acridineacetate, Crystal structures, Spectra, 2381
Magnetic moment
Iron(III) dialkyldithiocarbamates, Mössbauer spectra, Thermal decomposition, Spin crossover, 2489
Magnetic properties
Acetylacetonate complexes, 1-Hydroxybenzotriazolate complexes, Nickel(II), 2117
Magnetic properties
Benzoate ligands, Cobalt(II) complexes, Di-2-pyridyl ketone complexes, End-on azide ligands, 2027
Magnetic properties
Binuclear nickel(II) complexes, Crystal structures, Terminal thiocyanato ion complexes, Terminal cyanato ion complexes, Pentadentate ligands, 2457
Magnetic properties
Binucleating ligand, Copper(II) complexes, Nickel(II) complexes, Electrochemistry, 2767
Magnetic properties
Copper(II) complexes, Oxalato complexes, Oxalato-bridged complexes, Crystal structures, 1203
Magnetic properties
Crystal structures, Thermal properties, Tetrabromocuprate(II), *n*-Ethylpyridinium, 19
Magnetic properties
Lanthanide contraction, Anion controlled assembly, Crystal structures, 1097
Magnetic properties
Macrocyclic compound, Binuclear complexes, 359
Magnetic properties
Nickel, Palladium, Platinum, Oxalate, Crystal structures, DFT calculations, 2631
Magnetism
Copper(II), Alkoxo-bridged, Benzimidazoles, Crystal structures, 141
Magnetism
Cu(II) stereochemistry, X-ray structures, EPR spectra, 2473
Magnetism
Pyridine N-oxide ligands, copper(II) complexes, X-ray structures, Hydrogen bonding, 1561
Magnetism
Tetranuclear copper(II) complexes, Crystal structures, Antiferromagnetic coupling, Molecular orbital calculation, 1539
Magnetochemical studies
X-ray crystallography, Manganese oxide clusters, 1779
Malate
Nickel, Malic acid, Coordination polymer, Asymmetric catalysis, Crystal structures, Electroplating, 787
Malic acid
Nickel, Malate, Coordination polymer, Asymmetric catalysis, Crystal structures, Electroplating, 787
Malonates
Tin enolates, Diorganohydroxytin, Diorganotin, Sn(IV) complexes, Di-*n*-butylhydroxytin(IV), 417
Malonato complexes
Uranyl, CPMAS ^{13}C NMR, X-ray crystallography, 81
Mandelic acid
Mixed-ligand complexes, Copper(II) complexes, 2,2′-Bipyridine complexes, Lactic acid, 2-Methyllactic acid, Crystal structures, 2811
Manganese(II) complexes
2-Pyrazine carboxylic acid, 2,6-Pyridinedicarboxylic acid, Chelidamic acid, Crystal structures, Catalytic disproportionation, Hydrogen peroxide, 1063
Manganese
Metallic carbonyl complexes, Heterocyclic nitrogen ligands, 439
Manganese oxide clusters
X-ray crystallography, Magnetochemical studies, 1779
Masking
Solutions, Equilibria, Cations, Hydrolysis, Titration, 1369
Mass-spectra
Magnesium, Niobium, Alkoxides, Oxoalkoxides, Crystal structures, 1629
Mass-spectrometric study
Trimetallic alkoxides, Molecular structure, X-ray study, Rhenium methoxides, Niobium methoxide, Tantalum methoxide, 2317
Mass spectrometry
Chromium, Pivalate, Paramagnetic, NMR, X-ray photoelectron spectroscopy, 155
Mass spectrometry
Trialkylaluminum, Aminoalane, Dibenzylamine, NMR, Molecular structure, 1747
Matrix isolation
Disilenes, Silenes, Silanones, Photolysis, 467
Matrix isolation
Low valent, Multiply bonded derivatives, Group 13 metals, 473
M = Co
Thiadiazole, M = Ni, M = Cu, Crystal structures, Monomeric complexes, 403
M = Cu
Thiadiazole, M = Co, M = Ni, Crystal structures, Monomeric complexes, 403
Mechanism
Molecular orbital, Ab initio, Intermolecular nucleophilic attack, Titanium, Ylid, 2699
Mechanism
Silver, Hydroxylamine, Kinetics, Redox, Catalysis, 1893
2-Mercaptobenzoxazole
Pentacyanoferrate, Kinetics, Equilibrium constants, Electrochemistry, 2137
Mercapto-carboxylic acid
Potentiometry, IR, Formation constants, Ionisation constants, 1319
2-Mercapto-1-methylimidazole
Heterocyclic thioamides, Osmium, Ruthenium, X-ray structures, 885
Mercury(II)
Arylmetal complexes, Boron, The 2,6-bis(dimethylamino)phenyl ligand, 635
Mercury(II) halides
Phosphine complexes, Crystal structures, 1845
Mercury(II)
Phosphine chalcogenide, Seven-membered, Palladium(II), Metallacyclic rings, bis(diphenylthiophosphinyl)ethane, 205
Metal alkoxides
Esterification, Single-crystal X-ray, Group V, Tantalum, Niobium, 2333
Metal centre
Conformational change, Four or five coordinate geometry, Transition metals, 2175
Metal complexes
Artificial neural networks, Experimental design, Stability constants, Ion selective electrodes, Metal–ligand equilibria, 1375
Metal complexes
Linear polyamines, Polyamine complexes, 1459
Metal complexes
S-Benzyldithiocarbazate, Bioactivity of Schiff bases, Bioactivity of metal complexes, Crystal structure of Cd(II) complexes, 2547
Metal complexes
Schiff base ligands, Cadmium(II) complexes, Crystal structures, Dithiocarbazate Schiff base crystal structures, Bioactivity, 2691
Metal complexes
X-ray, Thiosemicarbazone, Isatin, 2593
Metallacycles, oxo ligands
Cyclo-addition, P ligands, Palladium, Structure elucidation, 2653
Metallacyclic rings
Phosphine chalcogenide, Seven-membered, Palladium(II), Mercury(II), bis(diphenylthiophosphinyl)ethane, 205
Metallation
Palladium, Schiff base, Phosphorus ligands, X-ray diffraction, 2309
Metal lattice
Aluminum(I) halides, Metalloid clusters, Nanosized clusters, Intermediates, X-ray structural analysis, 489
Metallic carbonyl complexes
Manganese, Heterocyclic nitrogen ligands, 439
Metallic polymer
Azamacrocycles, Aromatic pendant arms, Coordination compounds, 333
Metal–ligand equilibria
Artificial neural networks, Experimental design, Stability constants, Metal complexes, Ion selective electrodes, 1375
Metallocene
Molybdenum, Metallocenium, Pentaphenylcyclopentadienyl, 1707
Metallocenes
Tantalum, Hydrides, Metallophosphines, Bimetallics, X-ray structures, 371

Metallocenium
Molybdenum, Metallocene, Pentaphenylcyclopentadienyl, 1707
Metalloid clusters
Aluminum(I) halides, Nanosized clusters, Intermediates, Metal lattice, X-ray structural analysis, 489
Metalloid clusters
Electron counts, Aluminum, 503
Metallophosphines
Tantalum, Metallocenes, Hydrides, Bimetallics, X-ray structures, 371
Metal–metal bonding
Density functional theory, Face-shared dimers, High spin/low spin crossover, Electron delocalization, Broken-symmetry, Antiferromagnetic coupling, 1969
Metal–metal bonding
DFT calculations, Dinuclear transition metal complexes, Electron transfer, Magnetic coupling, Spin polarization, 1163
Metal–metal bonds
β-Diketiminate, Low valent indium, Bulky ligands, 525
Metal–metal interactions
Molybdenum, Pyridylphosphines, Rhodium, 1737
Metal–nitrile complexes
Dendrimers, Cyclophosphazene, 909
Metal-organic frameworks (MOF)
Synthesis, Crystal structures, TGA–DTA, 175
Metal–polymer complexes
Inorganic polymer, Polyphosphazene, 2587
Metal uptake
Cork, Solid state ^{13}C MAS and CP-MAS NMR, Copper, Nickel, Potentiometric titration, 1363
Metastable excited states
Pentacyaninotrosylferrate(2−) ion, X-ray diffraction, FIRRS, TGA, DTA, 1767
Metathesis
Molybdenum, Tin, Crystal structures, Polymerisation, Norbornadiene, NMR spectra, 2505
Methionine
CD spectroscopy, Copper(II), Nickel(II), Palladium(II), Peptides, 2149
Methoxide
Alkoxides, Crystal structures, Lithium, Tungsten, 193
2-Methylaminopyridine
Cyclodextrins, Copper(II) complexes, 1531
4-Methyl-2,6-dibenzoylphenol
Synthesis, Cobalt(III) complexes, NMR, TGA, Cyclic voltammetry, X-ray structures, 1787
Methylene group contribution
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-heptylbenzoate, Potassium *p*-*n*-octylbenzoate, Apparent molar enthalpies of, Partial molar enthalpies of, Micellization enthalpy, 1497
2-Methyllactic acid
Mixed-ligand complexes, Copper(II) complexes, 2,2′-Bipyridine complexes, Lactic acid, Mandelic acid, Crystal structures, 2811
Methyl-molybdenum complexes
Molybdenum complexes, oxo-Hydrazido complexes, Phenyl-molybdenum complexes, Diimine, X-ray structures, 2531
Methylpyridylacetamide
Europium, Photoluminescence, Perchlorate, Intensity parameters, 1837
Methyltin(IV) tribromide
Porphyrins, Sitting–Atop complexes, Organotin(IV) halide adducts, Tin compounds, Spectral method, 1255
Mg(II)
Adenosine-5′-triphosphate (ATP), NOESY, Torsion angle (χ), 435
Micellization enthalpy
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-heptylbenzoate, Potassium *p*-*n*-octylbenzoate, Apparent molar enthalpies of, Partial molar enthalpies of, Methylene group contribution, 1497
Mixed-ligand complexes
Copper(II) complexes, 2,2′-Bipyridine complexes, Lactic acid, 2-Methyllactic acid, Mandelic acid, Crystal structures, 2811
Mixed-ligand complexes
Copper(II) complexes, Five-coordinate complexes, Aminohydroxamic acids, EPR spectra, Vis spectra, 295
Mixed-ligand complexes
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
Mixed-ligand complexes
Ni(II), Co(II), Tetramines, Adenosine 5′-monophosphate, 745
Mixed-ligand complexes
Zinc(II) complexes, Aminohydroxamic acids, Polyamines, NMR spectra, Potentiometry, 2183
Mixed-ligands Cu(II) chelates
Dithiocarbamates, Cu(II) complexes, Ethylenediamine, Crystal structures, 1899
Mixed-valence compound
Electron transfer, Iron, Trinuclear, Iodoacetate, Heat capacity, 1299
Mixed-valence non-integer oxidation number
Solvation parameter model, Partition coefficient, Hydrophobic moment, Iron–sulfur protein, Cysteine ligand, 1357
Mixed-valence
Polyoxovanadates, Organic–inorganic hybrid, Hydrothermal synthesis, Cage-like structure, 2601
Mixed-valence
Ruthenium-ammine, Benzotriazole, Polynuclear complexes, Electron transfer, Molecular wires, 2089
MLCT transitions
Arylazopyrimidines, Osmium(II) complexes, Geometrical isomers, X-ray structures, Redox property, 753
M = Ni
Thiadiazole, M = Co, M = Cu, Crystal structures, Monomeric complexes, 403
MOCVD
Cerium, Fluoroalkoxides, Structures, Complexes, Films, 1985
Mo/Fe/S cluster
Synthesis, Structures, S=PEt_3 ligand, CO, 2523
Molecular orbital
Ab initio, Mechanism, Intermolecular nucleophilic attack, Titanium, Ylid, 2699
Molecular orbital calculation
Tetranuclear copper(II) complexes, Crystal structures, Magnetism, Antiferromagnetic coupling, 1539
Molecular orbitals
Polyoxometalates, Transition metals, Chemical bonding, Density–functional theory, 2201
Molecular recognition
Copper(II) complex, Crystal structures, EDTA, Adeninium, Ion pair, 1451
Molecular recognition
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Thermal stability, Spectral and magnetic properties, 1485
Molecular structures
Tridentate Schiff base ligand, Potassium permanganate, Photosystem II, 1139
Molecular structure
Trialkylaluminum, Aminoalane, Dibenzylamine, NMR, Mass spectrometry, 1747
Molecular structure
Trimetallic alkoxides, X-ray study, Mass-spectrometric study, Rhenium methoxides, Niobium methoxide, Tantalum methoxide, 2317
Molecular wires
Ruthenium-ammine, Benzotriazole, Polynuclear complexes, Mixed-valence, Electron transfer, 2089
Molybdenum complexes
oxo-Hydrazido complexes, Methyl-molybdenum complexes, Phenyl-molybdenum complexes, Diimine, X-ray structures, 2531
Molybdenum
Crystal structures, Cluster complexes, Acetates, Reduction, 147
Molybdenum
Metallocene, Metallocenium, Pentaphenylcyclopentadienyl, 1707
Molybdenum
Metal–metal interactions, Pyridylphosphines, Rhodium, 1737
Molybdenum
Nitrogenase, Hydrazido(2-), Crystal structures, Spectroelectrochemistry, 849
Molybdenum

Tin, Crystal structures, Metathesis, Polymerisation, Norbornadiene, NMR spectra, 2505
Mono-bridged species
Mono-helical, Single-helical-strand, Coordination chemistry, Transition metals, X-ray crystallography, 1177
Monodentate coordination of CrO_4^{2-}
Nickel(II) chromate and dichromate complexes of phenanthroline, Crystal structures, IR and UV–Vis–NIR band analysis, 997
Mono-helical
Single-helical-strand, Mono-bridged species, Coordination chemistry, Transition metals, X-ray crystallography, 1177
Monomeric complexes
Thiadiazole, M = Co, M = Ni, M = Cu, Crystal structures, 403
Mononuclear bis(imido) Mo(VI) complexes
Pyrazole, X-ray crystal structures, 1211
Mononuclear complexes
Copper(II) complexes, Spectral properties, Crystal structures, Pyridinecarboxylate complexes, 365
Mononuclear complexes
Rhodium complexes, Hydrido complexes, Nitrogen ligands, Crystal structures, 1613
Mononuclear complexes
Triazole derivatives, Crystal structures, 797
Mononuclear
Guanidinate, 1,3,4,6,7,8-Hexahydro-2*H*-pyramido[1,2-*a*]pyramidinate, Tin, Dinuclear, 619
Mononuclear tungsten(VI) complexes
X-ray, Ligand, Heteroleptic, 1017
Monothio-β-ketonate
Silver(I) complexes, Non-fluorinated β-diketonate ligands, β-Ketoiminate, Chemical vapor deposition, Crystal structures, 1289
Morphologies
Uranyl complexes, Schiff base ligand, 2421
Mössbauer
Organometallics, Heterobimetallics, Organoruthenium, Catalysis, NMR, 2323
Mössbauer spectra
Iron(III) dialkyldithiocarbamates, Magnetic moment, Thermal decomposition, Spin crossover, 2489
Multimetallic
Organometallic phosphine, π-Allyl molybdenum, Iron carbonyl complexes, Cyclopentadienyl iron complexes, 2301
Multiply bonded derivatives
Low valent, Group 13 metals, Matrix isolation, 473

$NaNbO_3$
Niobates, Hydrothermal synthesis, Hexaniobate, 2009
Nanosized clusters
Aluminum(I) halides, Metalloid clusters, Intermediates, Metal lattice, X-ray structural analysis, 489
Naphthalocyanine
Raman, Rare earth, Sandwich complexes, 1905
Natural ligands
Natural metal complexes, Resin titration, Ligand titration, Chelex 100, 1343
Natural metal complexes
Natural ligands, Resin titration, Ligand titration, Chelex 100, 1343
N-Benzoylthiourea derivatives
Gold, Palladium, Solvent extraction, Ion selective electrode, Crystal and molecular structure, 1429
N-(Benzylidene)xylylendiamines
Cyclometallated palladium(II) compounds, Chloro-bridged complexes, 2063
^{15}N CP/MAS NMR spectroscopy
$C_{10}H_{20}N_2S_4Zn \cdot C_5H_5N$, Isomorphism, Structures, 2727
N-donor
Iron(III), Single-crystal X-ray, Terpyridyl, 2055
N-donor ligands
Platinum chloride complexes, X-ray structures, ^{15}N NMR, 1,2,4-Triazolo-[1,5α]-pyrimidines, 343
n-Ethylpyridinium
Crystal structures, Magnetic properties, Thermal properties, Tetrabromocuprate(II), 19
Nickel complexes
Copper complexes, Complex-formation equilibria, Lysyl–glycyl–histidyl–lysine, 1469
Nickel complexes
Crystal structures, Palladium complexes, 2071
Nickel complexes
Dithiocarbimates, Triphenylphosphine, Crystal structures, 2243
Nickel complexes
Sulfonamide complexes, 8-Aminoquinoline, X-ray crystal structures, 1229
Nickel
Copper, Zinc, Cadmium, Saccharinate, X-ray structures, 395
Nickel
Cork, Solid state ^{13}C MAS and CP-MAS NMR, Copper, Potentiometric titration, Metal uptake, 1363
Nickel(II)
Acetylacetonate complexes, 1-Hydroxybenzotriazolate complexes, Magnetic properties, 2117
Nickel(II)
Amino acid, Coordination chemistry, Hydrogen bond, Chiral recognition, 817
Nickel(II)
CD spectroscopy, Copper(II), Palladium(II), Peptides, Methionine, 2149
Nickel(II) chromate and dichromate complexes of phenanthroline
Monodentate coordination of CrO_4^{2-}, Crystal structures, IR and UV–Vis–NIR band analysis, 997
Nickel(II), Cobalt(II), Copper(II), Iron(II), Uranyl(IV), Electrochemistry
vic-Dioxime, LH_4, $N_2O_2S_2$ macrocyle, 825
Nickel(II) complexes
Binucleating ligand, Copper(II) complexes, Electrochemistry, Magnetic properties, 2767
Nickel(II) complexes
Crystal structures, Hexaazamacrocycle, Organic ligands, Chain complex, 1913
Nickel(II) complexes
Di-2-pyridyl ketone benzoylhydrazone, Spectroscopy, Thermal analyses, 2375
Nickel(II) complexes
Heterotrinuclear complexes, BF_2^+-capped complexes, Dioxadithiadiazamacrobicycle, Template effect, *vic*-Dioxime, 1865
Nickel(II) complexes
Salen ligands, Ni(I) complexes, EPR, 1695
Nickel(II)
Crystal structures, 3-Piperidine, Thiosemicarbazone, 2-Pyridineformamide, Spectra, 859
Nickel(II)
2-Pyridineformamide, Thiosemicarbazone, Zinc(II), Cadmium(II), Crystal structures, 729
Nickel(II)
Schiff base complexes, Cobalt(II), Zinc(II), Tetrahedral, Crystal structures, 2733
Nickel
Malic acid, Malate, Coordination polymer, Asymmetric catalysis, Crystal structures, Electroplating, 787
Nickel
Palladium, Chirality, Bidentate nitrogen ligands, Crystal structures, 27
Nickel
Palladium, Platinum, Oxalate, Crystal structures, Magnetic properties, DFT calculations, 2631
Nickel
Phthalocyanines, Phthalonitrile derivatives, Electrochemistry, Zinc, Cobalt, 255
Nickel
Thiolate, *cis*-1,2-Bis(diphenylphosphino)ethene, X-ray structures, 421
Nickel(0)
Vinylcyclosilazane complexes, Crystal structure, 1261
Nicotinamide
Silver(I), Nicotinic acid, Sulfonate, Hydrogen bond, Ag–Ag interaction, Assembly chemistry, 689
Nicotinic acid
Silver(I), Nicotinamide, Sulfonate, Hydrogen bond, Ag–Ag interaction, Assembly chemistry, 689
Ni(I) complexes
Salen ligands, Nickel(II) complexes, EPR, 1695
Ni(II)
Co(II), Tetramines, Adenosine 5′-monophosphate, Mixed-ligand complexes, 745
Niobates
Hydrothermal synthesis, $NaNbO_3$, Hexaniobate, 2009
Niobium complexes
Heterodiene, 1,4-Diaza-1,3-diene, X-ray crystal structures, 305

Niobium
Magnesium, Alkoxides, Oxoalkoxides, Mass-spectra, Crystal structures, 1629
Niobium
Metal alkoxides, Esterification, Single-crystal X-ray, Group V, Tantalum, 2333
Niobium methoxide
Trimetallic alkoxides, Molecular structure, X-ray study, Mass-spectrometric study, Rhenium methoxides, Tantalum methoxide, 2317
Niobium sulphide metallacycles
X-ray structures, HF/ECP calculations, 2227
Nitrate complexes, Di-2-pyridylamine complexes
Crystal structures, Copper complexes, 943
Nitric oxide
Rhenium, Nitrosyl, X-ray structures, Electronic structures, 2617
Nitrite complexes
Crystal structures, Copper(II) complexes, Sulfate complexes, di-2-Pyridylamine complexes, Thiocyanato complexes, 1279
Nitrogenase
Hydrazido(2-), Molybdenum, Crystal structures, Spectroelectrochemistry, 849
Nitrogen dioxide
Phthalocyanines, Scanning electron microscopy, X-ray microprobe, UV–Vis and FTIR spectroscopy, X-ray powder diffractometry, 677
Nitrogen ligands
Mononuclear complexes, Rhodium complexes, Hydrido complexes, Crystal structures, 1613
Nitrophenoxide complexes
Thallium(I) complexes, Crystal structure, 2555
Nitrosyl complexes
Ruthenium(II), NMR spectra, X-ray structures, Diop, Dppb, 2221
Nitrosyl
Rhenium, X-ray structures, Electronic structures, Nitric oxide, 2617
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide
N-[2-(4-Methoxyphenyl telluro)propyl]phthalimide, Palladium(II), Platinum(II), Ruthenium(II), Complexes, Crystal structures, 667
N-[2-(4-Methoxyphenyl telluro)propyl]phthalimide
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, Palladium(II), Platinum(II), Ruthenium(II), Complexes, Crystal structures, 667
N-methylated polyamines
Silver(I), Complexes, Dimethylsulfoxide, Thermodynamics, 1337
NMR
Aminomethane-1,1-diphosphonic acids, Zinc(II) complexes, Magnesium(II) complexes, Calcium(II) complexes, Potentiometry, 321
NMR and IR analysis
Platinum(II) complexes, Ribavirin, X-ray structures, 2001
NMR
Bis(phosphine) monoxides, Cu(I), Chelates, Electrochemistry, Hard–soft acids and bases, 2793
NMR
Chromium, Pivalate, Mass spectrometry, Paramagnetic, X-ray photoelectron spectroscopy, 155
NMR
Dimesitylphosphine, Secondary phosphine, X-ray crystallography, Cone angle, Fluxional, 2409
NMR
Isoxazolidines, Pd-, Zn-, Cu-complexes, Syntheses, X-ray, 769
NMR of paramagnetic compounds
Macrocycles, Lanthanide complexes, Crystal structures, Chiral complexes, 811
NMR
Organometallics, Heterobimetallics, Organoruthenium, Catalysis, Mössbauer, 2323
NMR
Poly(3-Rpyrazolyl)borate cobalt(II) complexes, Structures, 2743
NMR spectra
Molybdenum, Tin, Crystal structures, Metathesis, Polymerisation, Norbornadiene, 2505
NMR spectra
Nitrosyl complexes, Ruthenium(II), X-ray structures, Diop, Dppb, 2221
NMR spectra
Zinc(II) complexes, Mixed-ligand complexes, Aminohydroxamic acids, Polyamines, Potentiometry, 2183
NMR spectroscopy
Tellurium dichloride, Chloridotellurate anions, X-ray crystallography, 1089
NMR studies
Silver(I) complexes, Thiones, 1267
NMR
Synthesis, Cobalt(III) complexes, 4-Methyl-2,6-dibenzoylphenol, TGA, Cyclic voltammetry, X-ray structures, 1787
NMR
Trialkylaluminum, Aminoalane, Dibenzylamine, Mass spectrometry, Molecular structure, 1747
NMR
Triphenylantimony(V), Oximes, X-ray, 2387
NMR
Tungsten, Tin, Oxidative addition, Crystal structures, Hydride, 1817
N,*N*-Di(2-carboxyethyl)-*p*-toluidine
Idp-type ligand, *p*-Toluidine-*N*,*N*-di-3-propionic acid, Square pyramidal copper(II) complexes, Crystal structures, 2719
N,*N*-dimethyl-L-α-isoleucine
Electron paramagnetic resonance (EPR) spectroscopy, Copper(II) complexes, Amino acids, 1643
^{15}N NMR
Platinum chloride complexes, X-ray structures, N-donor ligands, 1,2,4-Triazolo-[1,5α]-pyrimidines, 343
NOESY
Adenosine-5′-triphosphate (ATP), Mg(II), Torsion angle (χ), 435
Nona-nuclear copper complex
Trinuclear copper complex, Structural and magnetic properties, 1715
Non-fluorinated β-diketonate ligands
Silver(I) complexes, Monothio-β-ketonate, β-Ketoiminate, Chemical vapor deposition, Crystal structures, 1289
Norbornadiene
Molybdenum, Tin, Crystal structures, Metathesis, Polymerisation, NMR spectra, 2505
Normal coordinate
Cd(II) and Hg(II) complexes, Spectroscopic properties, Force constant, 2-Phenylenediamine, 2-Aminophenol, 987
$N_2O_2S_2$ macrocyle
vic-Dioxime, Nickel(II), Cobalt(II), Copper(II), Iron(II), Uranyl(IV), Electrochemistry, LH_4, 825
N-oxides
Uranyl bis(β-diketonates), Adduct compounds, X-ray structures, 2403
N-(2-Pyridylmethyl)iminodiacetate(2-) ion
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
N-(2-Pyridylmethyl)iminodiacetic acid
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
NQR
Isotope effect, Hydrogen bond, Dimer, Crystal structures, Tetrachloroaurate(III), 2207
NS Schiff base
S-methyldithiocarbazate (SMDTC), Cu(II), Ni(II), Zn(II) complexes, Crystal structures of Zn(II) complexes, 2683
N-Thiocyanate
Organotin, Crystal structures, Halides, Azide, Acetate, 1667
Nucleotides
Supramolecular interactions, Tripodal ammonium, Ternary complexes, Zn(II), 1005

Octahedral systems
Conformational change, Schiff's base ligands, Transition metals, 2167
Oligophenols
Uranyl ion, Polyphenols, Crystal structures, 1949
One-dimensional polymers
Cocrystallization, Dinuclear platinum complexes, 715
One-dimensional structures

Zinc(II), Cobalt(II), Coordination complexes, 2705
Optical limiting properties
Crystal structures, Cluster, 2675
Optically active Schiff bases
Co(II), Cu(II) and Ni(II) complexes, CD spectra, Co(II) paramagnetic ^{1}H NMR, 2711
Organic–inorganic hybrid
Polyoxovanadates, Mixed-valence, Hydrothermal synthesis, Cage-like structure, 2601
Organic ligands
Crystal structures, Nickel(II) complexes, Hexaazamacrocycle, Chain complex, 1913
Organometallic phosphine
Multimetallic, π-Allyl molybdenum, Iron carbonyl complexes, Cyclopentadienyl iron complexes, 2301
Organometallics
Heterobimetallics, Organoruthenium, Catalysis, Mössbauer, NMR, 2323
Organometallic
Yttrium, Salen, Amide, Aryloxide, 1683
Organoruthenium
Organometallics, Heterobimetallics, Catalysis, Mössbauer, NMR, 2323
Organotin
Crystal structures, Halides, *N*-Thiocyanate, Azide, Acetate, 1667
Organotin(IV)
Bis(pyrazol-1-yl)alkane, X-ray structures, 873
Organotin(IV) complexes
Dimethylpyrimidinethione, Crystal structures, 1149
Organotin(IV) halide adducts
Porphyrins, Sitting–Atop complexes, Methyltin(IV) tribromide, Tin compounds, Spectral method, 1255
Osmium
Heterocyclic thioamides, Ruthenium, 2-Mercapto-1-methylimidazole, X-ray structures, 885
Osmium(II) complexes
Arylazopyrimidines, Geometrical isomers, X-ray structures, MLCT transitions, Redox property, 753
Osmium(II) complex
Redox activity, Proton-coupled redox process, Pyrazole-3,5-bis(benzimidazole), 2481
Osmium porphyrin
Imido transfer, Phosphines, Kinetics, 1889
Osmium
Ruthenium, Acetylide, Alkyne, Clusters, 1105
Outer-sphere coordination
Lanthanide(III) chelate, Cobalt(III) chelate, Binuclear complexes, Inner-sphere coordination, Stability constant, 805
Oxadiazole complexes
Copper complexes, Structures, Spectroscopic properties, 2257
Oxalate
Nickel, Palladium, Platinum, Crystal structures, Magnetic properties, DFT calculations, 2631
Oxalato-bridged complexes
Copper(II) complexes, Oxalato complexes, Magnetic properties, Crystal structures, 1203
Oxalato complexes
Copper(II) complexes, Oxalato-bridged complexes, Magnetic properties, Crystal structures, 1203
Oxalic acid
Uranyl oxalates, UV–Vis spectrophotometry, Speciation, Stability constants, Aqueous solutions, 1411
Oxidative addition reaction
Perfluoro-*n*-butyl iodide, 1,5-Cyclooctadiene, Fluoroalkyls, 2357
Oxidative addition
Tungsten, Tin, Crystal structures, Hydride, NMR, 1817
Oxidative-alkoxylation
Rhenium(I), Carbonyl, Aminoalcohol, Cytotoxicity, Hydrogen-bonding, 1991
Oximes
Triphenylantimony(V), NMR, X-ray, 2387
Oxoalkoxides
Magnesium, Niobium, Alkoxides, Mass-spectra, Crystal structures, 1629
Oxo-bridged peroxovanadates containing sulphate
Diperoxovanadate, Vanadyl, EDTA inhibition, EDTA bridged heteroligand peroxovanadates, Catalase resistance, 389
oxo-Hydrazido complexes
Molybdenum complexes, Methyl-molybdenum complexes, Phenyl-molybdenum complexes, Diimine, X-ray structures, 2531
Oxo ligands
Chloride ligands, Phenolates, Tungsten, 349
Oxotransfer catalysts
Dioxomolybdenum(VI) bromides, Thiol oxidation, 1635
Oxovanadium(IV) complexes
Carnosine, Potentiometric and spectrophotometric studies, Stability constants, 1513
2,2′-Oxydiethylamine
Lanthanides(III), Oxygen donors, Dimethylsulfoxide, Complexes, Thermodynamics, 1385
Oxygen donors
Lanthanides(III), 2,2′-Oxydiethylamine, Dimethylsulfoxide, Complexes, Thermodynamics, 1385

Palladium
C–H activation, Cyclometallation, Phosphorus ligands, Schiff bases, 39
Palladium complexes
Chiral benzodiazepine ligands, Zinc complexes, Spectroscopy, X-ray structure analysis, Cytostatic and antiviral activity, 2567
Palladium complexes
Crystal structures, Nickel complexes, 2071
Palladium complexes
Platinum complexes, Chiral iminophosphine ligand, 1043
Palladium
Cyclo-addition, Metallacycles, oxo ligands, P ligands, Structure elucidation, 2653
Palladium
2-Hydroxynicotinic acid, Platinum, X-ray crystal structures, Raman spectra, 2783
Palladium(II)
CD spectroscopy, Copper(II), Nickel(II), Peptides, Methionine, 2149
Palladium(II) complexes
Benzyl 8-quinolyl sulfide, Phenethyl 8-quinolyl, Crystal structures, 843
Palladium(II) complexes
Bioligands, Glycine methyl ester hydrolysis, 167
Palladium(II)
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, *N*-[2-(4-Methoxyphenyl telluro)-propyl]phthalimide, Platinum(II), Ruthenium(II), Complexes, Crystal structures, 667
Palladium(II)
Phosphine chalcogenide, Seven-membered, Mercury(II), Metallacyclic rings, bis(diphenylthiophosphinyl)ethane, 205
Palladium
Metallation, Schiff base, Phosphorus ligands, X-ray diffraction, 2309
Palladium
N-Benzoylthiourea derivatives, Gold, Solvent extraction, Ion selective electrode, Crystal and molecular structure, 1429
Palladium
Nickel, Chirality, Bidentate nitrogen ligands, Crystal structures, 27
Palladium
Nickel, Platinum, Oxalate, Crystal structures, Magnetic properties, DFT calculations, 2631
Paracyanogen $(CN)_x$
Sulfur dicyanide $S_y(CN)_2$, Polythiocyanogens, ^{13}C NMR spectroscopy, 1825
Paramagnetic
Chromium, Pivalate, Mass spectrometry, NMR, X-ray photoelectron spectroscopy, 155
Partial molar enthalpies of
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-heptylbenzoate, Potassium *p*-*n*-octylbenzoate, Apparent molar enthalpies of, Micellization enthalpy, Methylene group contribution, 1497
Partition coefficient
Solvation parameter model, Hydrophobic moment, Iron–sulfur protein, Mixed-valence non-integer oxidation number, Cysteine ligand, 1357
Partition function
Equilibria in solution, Cooperativity, Site affinity, Buffer capacity, Heat capacity, 1439
Pb(II) salts
BTZ ligands, X-ray crystallography, π–π stacking interaction, 197
Pd-, Zn-, Cu-complexes

Isoxazolidines, Syntheses, X-ray, NMR, 769
Pentacoordinated
Phosphoranes, X-ray structures, Hydrogen bonding, 1155
Pentacoordinate nickel(II) complexes
Dithiophosphate complexes, Dithiophosphonate complexes, Macrocycle complexes, Crystal structures, 1935
Pentacyaninotrosylferrate(2−) ion
Metastable excited states, X-ray diffraction, FIRRS, TGA, DTA, 1767
Pentacyanoferrate
2-Mercaptobenzoxazole, Kinetics, Equilibrium constants, Electrochemistry, 2137
Pentadentate ligands
Binuclear nickel(II) complexes, Crystal structures, Magnetic properties, Terminal thiocyanato ion complexes, Terminal cyanato ion complexes, 2457
Pentagonal bipyramidal
Acyclic, Binuclear, Pyrazole bridged, Asymmetric unit, 925
Pentamethylphenylmagnesium bromide
Tris(pentamethylphenyl)gallium, Elemental analyses, Single crystal X-ray diffraction, 531
Pentaphenylcyclopentadienyl
Molybdenum, Metallocene, Metallocenium, 1707
Peptide–Cu(II)–isocytosine complexes
Cu(II) complexes, Ternary complexes, Isocytosine complexes, 1197
Peptides
CD spectroscopy, Copper(II), Nickel(II), Palladium(II), Methionine, 2149
Perchlorate
Europium, Photoluminescence, Methylpyridylacetamide, Intensity parameters, 1837
Perfluoro-*n*-butyl iodide
Oxidative addition reaction, 1,5-Cyclooctadiene, Fluoroalkyls, 2357
1,10-Phenanthroline and its 5,6-disubstituted derivatives
Five-coordinated chlorocopper(II) complexes, X-ray structures, Electronic absorption and diffuse reflectance spectra, Cyclic voltammetry, 2143
Phenanthroline
Macrocycles, Cadmium, Polyamines, Dipyridine, 1329
Phenethyl 8-quinolyl
Palladium(II) complexes, Benzyl 8-quinolyl sulfide, Crystal structures, 843
Phenolates
Chloride ligands, Oxo ligands, Tungsten, 349
Phenolic phosphine
Cyclophosphazenes, Polyphosphazenes, Macromolecular complexes, Carbonyls, Spectroscopic characterization, 2579
2-Phenylenediamine
Cd(II) and Hg(II) complexes, Spectroscopic properties, Normal coordinate, Force constant, 2-Aminophenol, 987
Phenyl-molybdenum complexes
Molybdenum complexes, oxo-Hydrazido complexes, Methyl-molybdenum complexes, Diimine, X-ray structures, 2531
Phenylpyridine
Hydrogen-bonding, Silanol, Amine, Adducts, Acridine, 4,4′-bipyridine, 1689
PH-functionalised phosphanylalkyl(silyl)cyclopentadienyl ligands
Zirconium complexes, Titanium complexes, Polymerisation studies, 2445
Phoshocreatine
^{31}P NMR spectroscopy, Sodium complexes, Potassium complexes, Magnesium complexes, 1481
Phosphido
Diphosphine disulfide, Dimanganese decacarbonyl, Phosphidosulfide, 791
Phosphidosulfide
Diphosphine disulfide, Dimanganese decacarbonyl, Phosphido, 791
Phosphine chalcogenide
Seven-membered, Palladium(II), Mercury(II), Metallacyclic rings, bis(diphenylthiophosphinyl)ethane, 205
Phosphine complexes
Mercury(II) halides, Crystal structures, 1845
Phosphine complexes
Thioether complexes, Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Crown thioethers, 879
Phosphine oxide
Scandium, Arsine oxide, X-ray structures, ^{45}Sc NMR, 1579
Phosphine oxide
Yttrium, Arsine oxide, X-ray structures, 445
Phosphine
Platinum, Cyclometallation, Imine, Fluorine, Crystal structures, 105
Phosphines
Osmium porphyrin, Imido transfer, Kinetics, 1889
Phosphino amino acids
Ferrocenylmethylphosphine, 1,3-Diaza-5-phosphacyclohexane, 1,5-Diaza-3,7-diphosphacyclooctane, Water-soluble complexes, Trinuclear complexes, 2251
Phosphoranes
Pentacoordinated, X-ray structures, Hydrogen bonding, 1155
Phosphorus ligands
C–H activation, Cyclometallation, Schiff bases, Palladium, 39
Phosphorus ligands
Palladium, Metallation, Schiff base, X-ray diffraction, 2309
Photobleaching
Zinc phthalocyanine, Sensitizer, Singlet oxygen, 2463
Photochemistry
Tertiary amines, Ruthenium complexes, Electrochemistry, 61
Photochromism
Polyoxometalates, Keggin, Charge transfer, 2537
Photoinduced electron transfer
Cyclic voltammetry, Supramolecular preassociation, Ruthenium(II) complexes, 2,2′:6′,2″-Terpyridine, 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid, 49
Photoluminescence
Europium, Perchlorate, Methylpyridylacetamide, Intensity parameters, 1837
Photolysis
Disilenes, Silenes, Silanones, Matrix isolation, 467
Photosystem II
Tridentate Schiff base ligand, Potassium permanganate, Molecular structures, 1139
$Ph_2P(CH_2)_nNHP^iPr_2$
Diphosphine ligands, Chelate complexes, 2639
Phthalocyanine
Cobalt, Cyanide, Sulfur dioxide, Kinetics, Equilibria, 133
Phthalocyanines
Nitrogen dioxide, Scanning electron microscopy, X-ray microprobe, UV–Vis and FTIR spectroscopy, X-ray powder diffractometry, 677
Phthalocyanines
Phthalonitrile derivatives, Electrochemistry, Nickel, Zinc, Cobalt, 255
Phthalonitrile derivatives
Phthalocyanines, Electrochemistry, Nickel, Zinc, Cobalt, 255
Physico-chemical properties
Crystal structures, Spectroscopy, X-ray diffraction, Imidiazole complexes, 1857
α-Picolylamine
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
Piperazine and piperazin-1-ium ligands
Zn(II)–N bonds, Crystal structures, Zn(II) complexes, 2161
Piperazine
Coordination chemistry, Crystal structures, Homopiperazine, 1729
3-Piperidine
Crystal structures, Thiosemicarbazone, 2-Pyridineformamide, Nickel(II), Spectra, 859
Pivalate
Chromium, Mass spectrometry, Paramagnetic, NMR, X-ray photoelectron spectroscopy, 155
Platinum
Amido, Amine, Triflate, Diphosphazane, Cyclometalation, 1305
Platinum chloride complexes
X-ray structures, N-donor ligands, ^{15}N NMR, 1,2,4-Triazolo-[1,5α]-pyrimidines, 343
Platinum complexes
Palladium complexes, Chiral iminophosphine ligand, 1043

Platinum complexes
Thioether complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Phosphine complexes, Crown thioethers, 879
Platinum
Cyclometallation, Imine, Fluorine, Phosphine, Crystal structures, 105
Platinum
Gallium, Indium, Heterobimetallic complexes, X-ray structure analysis, Quantum chemical calculations, 535
Platinum
Hexamethyleneimine, 1,1-Cyclobutanedicarboxylato, Synthesis, Crystal structure, 2659
Platinum
2-Hydroxynicotinic acid, Palladium, X-ray crystal structures, Raman spectra, 2783
Platinum(II) complexes
Heptamethyleneimine, Synthesis, Crystal structures, 2369
Platinum(II) complexes
Ribavirin, X-ray structures, NMR and IR analysis, 2001
Platinum(II)
Homopiperazines, Disubstituted sulfides, Synthesis, Crystal structure, 125
Platinum(III) compounds
Lantern-type complexes, Amidate bridging ligands, X-ray structure, 275
Platinum(II)
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, *N*-[2-(4-Methoxyphenyl telluro)propyl]phthalimide, Palladium(II), Ruthenium(II), Complexes, Crystal structures, 667
Platinum
Nickel, Palladium, Oxalate, Crystal structures, Magnetic properties, DFT calculations, 2631
Platinum nuclear magnetic resonance
Thioether complexes, Platinum complexes, Trithiacyclononane, Phosphine complexes, Crown thioethers, 879
P ligands
Cyclo-addition, Metallacycles, oxo ligands, Palladium, Structure elucidation, 2653
P-Ligands
2*H*-Azaphosphirene complexes, 2*H*-1,2-Azaphosphole complexes, Cyclisation, 1,3-Dipoles, 119
Plumbylenes
Stannylenes, Distannenes, Diplumbenes, Lewis-amphoteric behavior, 587
^{31}P NMR spectroscopy
Phoshocreatine, Sodium complexes, Potassium complexes, Magnesium complexes, 1481
Polyamine
Bithiophene, Coordination, Cu(II)-electrochemical pattern, Potentiometry, 1523
Polyamine complexes
Linear polyamines, Metal complexes, 1459
Polyamines
Cadmium(II) complexes, X-ray structures, 739
Polyamines
Macrocycles, Cadmium, Dipyridine, Phenanthroline, 1329
Polyamines
Statistical thermodynamic model, Cooperativity effect, Site constant, Cooperativity potential, 1503
Polyamines
Synthesis, Equilibria, Binuclear complexes, 1351
Polyamines
Zinc(II) complexes, Mixed-ligand complexes, Aminohydroxamic acids, NMR spectra, Potentiometry, 2183
Polyazaalkanes ligand
Fluorogenic receptors, Chemosensors, 1397
Polyaza ligands
Lanthanide, Catecholate ligands, Stability constants, Potentiometry, 1393
Polyboron halides
Boron monochloride, Halogen exchange, 543
Polybromides
Actinides, Dioxouranium(VI) polyhalides, Uranyl polyhalides, Polyiodides, 2755
Polycations
Cluster compounds, Crystal structures, Bismuth, Iridium, Rhodium, 651
Polydentate Ni(II) edta-type complexes
Crystal structures, 2667
Polyethylene
Chromium, Crystal structures, Homogeneous catalyst, Electron spin resonance, 867
Polyiodides
Actinides, Dioxouranium(VI) polyhalides, Uranyl polyhalides, Polybromides, 2755
Polymeric zinc(II) complexes
Imidazole-4-acetic acid, Crystal structures, Vibrational spectra, Density functional calculations, 2819
Polymerisation
Molybdenum, Tin, Crystal structures, Metathesis, Norbornadiene, NMR spectra, 2505
Polymerisation studies
PH-functionalised phosphanylalkyl(silyl)cyclopentadienyl ligands, Zirconium complexes, Titanium complexes, 2445
Polynuclear complexes
Ruthenium-ammine, Benzotriazole, Mixed-valence, Electron transfer, Molecular wires, 2089
Polyoxometalates
Heteropolyanions, Ti(IV) complex, Wells-Dawson structure, 353
Polyoxometalates
Keggin, Charge transfer, Photochromism, 2537
Polyoxometalates
Transition metals, Chemical bonding, Molecular orbitals, Density–functional theory, 2201
Polyoxovanadates
Organic–inorganic hybrid, Mixed-valence, Hydrothermal synthesis, Cage-like structure, 2601
Polyphenols
Uranyl ion, Oligophenols, Crystal structures, 1949
Polyphosphazene
Inorganic polymer, Metal–polymer complexes, 2587
Polyphosphazenes
Cyclophosphazenes, Phenolic phosphine, Macromolecular complexes, Carbonyls, Spectroscopic characterization, 2579
Poly(3-Rpyrazolyl)borate cobalt(II) complexes
Structures, NMR, 2743
Polythiocyanogens
Sulfur dicyanide $S_y(CN)_2$, ^{13}C NMR spectroscopy, Paracyanogen $(CN)_x$, 1825
Porphyrins
Adduct formation, Thermodynamics, Tin compounds, Equilibrium constant, Spectral method, 683
Porphyrins
Sitting–Atop complexes, Methyltin(IV) tribromide, Organotin(IV) halide adducts, Tin compounds, Spectral method, 1255
Potassium complexes
Phoshocreatine, ^{31}P NMR spectroscopy, Sodium complexes, Magnesium complexes, 1481
Potassium permanganate
Tridentate Schiff base ligand, Molecular structures, Photosystem II, 1139
Potassium *p*-*n*-heptylbenzoate
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-octylbenzoate, Apparent molar enthalpies of, Partial molar enthalpies of, Micellization enthalpy, Methylene group contribution, 1497
Potassium *p*-*n*-hexylbenzoate
Potassium *p*-*n*-heptylbenzoate, Potassium *p*-*n*-octylbenzoate, Apparent molar enthalpies of, Partial molar enthalpies of, Micellization enthalpy, Methylene group contribution, 1497
Potassium *p*-*n*-octylbenzoate
Potassium *p*-*n*-hexylbenzoate, Potassium *p*-*n*-heptylbenzoate, Apparent molar enthalpies of, Partial molar enthalpies of, Micellization enthalpy, Methylene group contribution, 1497
Potassium
Rubidium, Amide ligands, 15-Crown-5, Crystal structures, 2451
Potentiometric and spectrophotometric studies
Oxovanadium(IV) complexes, Carnosine, Stability constants, 1513
Potentiometric titration
Cork, Solid state ^{13}C MAS and CP-MAS NMR, Copper, Nickel, Metal uptake, 1363
Potentiometric titrations
Vanadium complexes, Caffeic acid complexes, IR spectra, UV–Vis spectra, Catecholate-like ligand, 1979

Potentiometry
Aminomethane-1,1-diphosphonic acids, Zinc(II) complexes, Magnesium(II) complexes, Calcium(II) complexes, NMR, 321
Potentiometry
Lanthanide, Polyaza ligands, Catecholate ligands, Stability constants, 1393
Potentiometry
Mercapto-carboxylic acid, IR, Formation constants, Ionisation constants, 1319
Potentiometry
Polyamine, Bithiophene, Coordination, Cu(II)-electrochemical pattern, 1523
Potentiometry
Zinc(II) complexes, Mixed-ligand complexes, Aminohydroxamic acids, Polyamines, NMR spectra, 2183
Preparation
1D nickel(II) azido complexes, Pyridine derivative complexes, Crystal structures, Magnetic data, Spectra, 1871
Propadienylidene
Iron, Acetylide, Vinylidene, 1755
Propane-1,3-diamine
Silica gel, Immobilization, Epoxide, 2647
Proton-coupled redox process
Osmium(II) complex, Redox activity, Pyrazole-3,5-bis(benzimidazole), 2481
p-Toluidine-*N*,*N*-di-3-propionic acid
Idp-type ligand, *N*,*N*-Di(2-carboxyethyl)-*p*-toluidine, Square pyramidal copper(II) complexes, Crystal structures, 2719
4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid
Photoinduced electron transfer, Cyclic voltammetry, Supramolecular pre-association, Ruthenium(II) complexes, 2,2′:6′,2″-Terpyridine, 49
2-Pyrazine carboxylic acid
Manganese(II) complexes, 2,6-Pyridinedicarboxylic acid, Chelidamic acid, Crystal structures, Catalytic disproportionation, Hydrogen peroxide, 1063
Pyrazineformamide
Thiosemicarbazone, Zinc, Cadmium, Crystal structures, Electrochemical synthesis, 1553
Pyrazole-3,5-bis(benzimidazole)
Osmium(II) complex, Redox activity, Proton-coupled redox process, 2481
Pyrazole bridged
Acyclic, Binuclear, Asymmetric unit, Pentagonal bipyramidal, 925
Pyrazole
Co(III) complexes, Dithiocarbazate, Synthesis, Spectroscopy, X-ray crystal structures, 1
Pyrazole
Crystal structures, Tungsten complexes, Copper complexes, 1547
Pyrazole
Mononuclear bis(imido) Mo(VI) complexes, X-ray crystal structures, 1211
Pyrazolylthiosemicarbazone
Cobalt(III), ^{1}H NMR, X-ray crystallography, 779
Pyridinecarboxylate complexes
Copper(II) complexes, Spectral properties, Crystal structures, Mononuclear complexes, 365
Pyridine derivative complexes
1D nickel(II) azido complexes, Preparation, Crystal structures, Magnetic data, Spectra, 1871
2,6-Pyridinedicarboxylic acid
Manganese(II) complexes, 2-Pyrazine carboxylic acid, Chelidamic acid, Crystal structures, Catalytic disproportionation, Hydrogen peroxide, 1063
2-Pyridineformamide
Crystal structures, 3-Piperidine, Thiosemicarbazone, Nickel(II), Spectra, 859
2-Pyridineformamide
Thiosemicarbazone, Nickel(II), Zinc(II), Cadmium(II), Crystal structures, 729
Pyridine N-oxide ligands, copper(II) complexes
X-ray structures, Hydrogen bonding, Magnetism, 1561
Pyridine-2-thiolates of ruthenium
Ruthenium aryls, Imine–phenol function, 899
Pyridine-2-thione
Tri-*p*-tolylphosphine, Triphenylphosphine, Sulfur-bridged dimer, Copper(I) complexes, 1603
2-(2′-Pyridyl)benzimidazole
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, Spectral and magnetic properties, 1485
2-Pyridylmethanol
Saccharin complexes, Single crystal structures, Thermal analysis, 2393
Pyridylphosphines
Metal–metal interactions, Molybdenum, Rhodium, 1737

Quantum chemical calculations
Gallium, Indium, Platinum, Heterobimetallic complexes, X-ray structure analysis, 535

Raman
Naphthalocyanine, Rare earth, Sandwich complexes, 1905
Raman spectra
2-Hydroxynicotinic acid, Palladium, Platinum, X-ray crystal structures, 2783
Raman spectra
Subvalent indium and gallium, Gallium(II), Indium(I), Indium(II), Halide complexes, 519
Raman spectroscopy
Magnesium phthalocyanines, Magnesium complexes, Crystal structures, IR spectroscopy, UV–Vis spectroscopy, 265
Rare earth complexes
EPR spectroscopy, Coordination structures, 4f-Electron, 2127
Rare earth
Naphthalocyanine, Raman, Sandwich complexes, 1905
Redox activity
Osmium(II) complex, Proton-coupled redox process, Pyrazole-3,5-bis(benzimidazole), 2481
Redox chemistry
Heteropolyoxometalate, Arsenic, Tungstate, Lacunary, Synthesis, 959
Redox property
Arylazopyrimidines, Osmium(II) complexes, Geometrical isomers, X-ray structures, MLCT transitions, 753
Redox
Ruthenium promoted reactions, Dimerization of aromatic amines, 1,2-Diimine, Structures, 97
Redox
Silver, Hydroxylamine, Kinetics, Mechanism, Catalysis, 1893
Reduction
Molybdenum, Crystal structures, Cluster complexes, Acetates, 147
Renner effect
Electronic states, Linear disilaketenylidene (SiSiO), Analogous multiple bonded systems, 599
Resin titration
Natural metal complexes, Natural ligands, Ligand titration, Chelex 100, 1343
Rhenium complexes
Trigonal prismatic geometry, 2-Amidothiophenolato complexes, 1597
Rhenium(I)
Carbonyl, Aminoalcohol, Cytotoxicity, Oxidative-alkoxylation, Hydrogen-bonding, 1991
Rhenium(III) complexes
Iridium(III) complexes, S-bridged polynuclear complexes, Crystal structures, UV–Vis absorption spectra, Cyclic voltammetry, 1809
Rhenium methoxides
Trimetallic alkoxides, Molecular structure, X-ray study, Mass-spectrometric study, Niobium methoxide, Tantalum methoxide, 2317
Rhenium
Nitrosyl, X-ray structures, Electronic structures, Nitric oxide, 2617
Rhodium complexes
Mononuclear complexes, Hydrido complexes, Nitrogen ligands, Crystal structures, 1613
Rhodium
Cyano, Dioxygen, Enhanced reactivity, Structures, 1775
Rhodium
Metal–metal interactions, Molybdenum, Pyridylphosphines, 1737
Rhodium
Polycations, Cluster compounds, Crystal structures, Bismuth, Iridium, 651
Ribavirin
Platinum(II) complexes, X-ray structures, NMR and IR analysis, 2001

RP-HPLC
Urinary trypsin inhibitors, Bubble extraction, Affinity chromatography, 1475
Rubidium
Potassium, Amide ligands, 15-Crown-5, Crystal structures, 2451
Ru(II) complexes
dcbpy, bdmpp, Thiocyanato ligands, Sensitizing ability, 2773
Ruthenium-ammine
Benzotriazole, Polynuclear complexes, Mixed-valence, Electron transfer, Molecular wires, 2089
Ruthenium aryls
Pyridine-2-thiolates of ruthenium, Imine–phenol function, 899
Ruthenium complexes
Tertiary amines, Photochemistry, Electrochemistry, 61
Ruthenium
Heterocyclic thioamides, Osmium, 2-Mercapto-1-methylimidazole, X-ray structures, 885
Ruthenium(II)
Binuclear, Bis(β-diketone), Triphenylarsine, Syntheses, Antibacterial activity, Catalytic study, 219
Ruthenium(II) complexes
Binuclear, Thiobis(β-diketone), Syntheses, Catalytic oxidation, Antibacterial activity, 1721
Ruthenium(II) complexes
Photoinduced electron transfer, Cyclic voltammetry, Supramolecular pre-association, 2,2′:6′,2″-Terpyridine, 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid, 49
Ruthenium(II) complexes
Semiquinone monochelates, Homolytic hydride cleavage, 2761
Ruthenium(II)
Nitrosyl complexes, NMR spectra, X-ray structures, Diop, Dppb, 2221
Ruthenium(II)
N-[2-(4-Methoxyphenyltelluro)ethyl]benzamide, *N*-[2-(4-Methoxyphenyl telluro)-propyl]phthalimide, Palladium(II), Platinum(II), Complexes, Crystal structures, 667
Ruthenium monoterpyridine complexes
Ancillary functions, Crystal structures, 2033
Ruthenium
Osmium, Acetylide, Alkyne, Clusters, 1105
Ruthenium promoted reactions
Dimerization of aromatic amines, 1,2-Diimine, Structures, Redox, 97

Saccharinate
Nickel, Copper, Zinc, Cadmium, X-ray structures, 395
Saccharin complexes
2-Pyridylmethanol, Single crystal structures, Thermal analysis, 2393
Saccharomyces cerevisiae
Capillary electrophoresis, Hydrophobic interaction chromatography, Heterologous protein, BPTI, 1405
Salen Cu(II) complexes
Schiff-base ligands, Cyclic voltammetry, Hammett substituent constants, 55
Salen ligands
Ni(I) complexes, Nickel(II) complexes, EPR, 1695
Salen
Yttrium, Amide, Aryloxide, Organometallic, 1683
Salicylaldimine adducts
Schiff bases, Interconversion, X-ray crystal structures, Zinc complexes, Zwitterion, 697
Sandwich complexes
Naphthalocyanine, Raman, Rare earth, 1905
S-Benzyldithiocarbazate
Metal complexes, Bioactivity of Schiff bases, Bioactivity of metal complexes, Crystal structure of Cd(II) complexes, 2547
S-bridged polynuclear complexes
Rhenium(III) complexes, Iridium(III) complexes, Crystal structures, UV–Vis absorption spectra, Cyclic voltammetry, 1809
Scandium and lanthanide
Triflates, Triphenylphosphine oxide complexes, Single crystal X-ray diffraction, Catalysis, 287
Scandium
Phosphine oxide, Arsine oxide, X-ray structures, ^{45}Sc NMR, 1579
Scanning electron microscopy
Phthalocyanines, Nitrogen dioxide, X-ray microprobe, UV–Vis and FTIR spectroscopy, X-ray powder diffractometry, 677
Schiff base complexes
Cobalt(II), Nickel(II), Zinc(II), Tetrahedral, Crystal structures, 2733
Schiff base
Eight-coordinate, Zirconium complexes, X-ray crystal structure, Synthon, Heteroleptic, 211
Schiff base
Iron(II), Zinc(II), X-ray crystal structures, ^{1}H NMR spectroscopy, Dioxygen reactivity, 705
Schiff base ligands
Cadmium(II) complexes, Crystal structures, Dithiocarbazate Schiff base crystal structures, Metal complexes, Bioactivity, 2691
Schiff-base ligands
Salen Cu(II) complexes, Cyclic voltammetry, Hammett substituent constants, 55
Schiff base ligand
Uranyl complexes, Morphologies, 2421
Schiff base
Palladium, Metallation, Phosphorus ligands, X-ray diffraction, 2309
Schiff bases
C–H activation, Cyclometallation, Phosphorus ligands, Palladium, 39
Schiff bases
Salicylaldimine adducts, Interconversion, X-ray crystal structures, Zinc complexes, Zwitterion, 697
Schiff bases
Vanadyl complexes, Chiral complexes, EPR, X-ray structures, 2021
Schiff's base ligands
Conformational change, Octahedral systems, Transition metals, 2167
^{45}Sc NMR
Scandium, Phosphine oxide, Arsine oxide, X-ray structures, 1579
Scorpionate ligands
Thallium(I) complexes, Crystal packing, π-Stacking, Cation–π interaction, 553
Secondary phosphine
Dimesitylphosphine, X-ray crystallography, NMR, Cone angle, Fluxional, 2409
Self-assembly
Copper, Supramolecules, X-ray structures, 1621
Self-propagating
Silicides, Solid state metathesis, 187
Semi-bridging carbonyl
Crystal structures, Cobalt(I) clusters, Interstitial phosphorus atom, Heterocyclic phosphide, Substituted site, 1073
Semi-empirical calculations
Carbohydrates, Cobalt complexes, Circular dichroism, Sucrose complexes, ^{1}H NMR, 2215
Semiquinone monochelates
Ruthenium(II) complexes, Homolytic hydride cleavage, 2761
Sensitizer
Zinc phthalocyanine, Singlet oxygen, Photobleaching, 2463
Sensitizing ability
Ru(II) complexes, dcbpy, bdmpp, Thiocyanato ligands, 2773
Separation of isomers
Crystal structures, Copper(II) complexes, Cyclohexanediols, 1133
Seven-membered
Phosphine chalcogenide, Palladium(II), Mercury(II), Metallacyclic rings, bis(diphenylthiophosphinyl)ethane, 205
Silanol
Hydrogen-bonding, Amine, Adducts, Acridine, 4,4′-bipyridine, Phenylpyridine, 1689
Silanones
Disilenes, Silenes, Matrix isolation, Photolysis, 467
Silenes
Disilenes, Silanones, Matrix isolation, Photolysis, 467
Silica gel
Immobilization, Epoxide, Propane-1,3-diamine, 2647
Silicides
Solid state metathesis, Self-propagating, 187
Silver
Azide, Germanium, Tin, Tris(pyrazolyl)borate, Aminotroponimine, 611
Silver
Hydroxylamine, Kinetics, Mechanism, Redox, Catalysis, 1893

Silver(I) complexes
Non-fluorinated β-diketonate ligands, Monothio-β-ketonate, β-Ketoiminate, Chemical vapor deposition, Crystal structures, 1289
Silver(I) complexes
Thiones, NMR studies, 1267
Silver(I)
Nicotinamide, Nicotinic acid, Sulfonate, Hydrogen bond, Ag–Ag interaction, Assembly chemistry, 689
Silver(I)
N-methylated polyamines, Complexes, Dimethylsulfoxide, Thermodynamics, 1337
Silver(I)
Trinuclear complexes, Single crystal structures, Copper(II), Carboxylate, Thioether, 33
Single crystals
Solventothermal synthesis, Crystal structures, Coordination polymers, Copper methoxide, 2017
Single crystal structures
2-Pyridylmethanol, Saccharin complexes, Thermal analysis, 2393
Single crystal structures
Trinuclear complexes, Copper(II), Silver(I), Carboxylate, Thioether, 33
Single crystal X-ray diffraction
Triflates, Triphenylphosphine oxide complexes, Scandium and lanthanide, Catalysis, 287
Single crystal X-ray diffraction
Tris(pentamethylphenyl)gallium, Pentamethylphenylmagnesium bromide, Elemental analyses, 531
Single-crystal X-ray
Iron(III), N-donor, Terpyridyl, 2055
Single-crystal X-ray
Metal alkoxides, Esterification, Group V, Tantalum, Niobium, 2333
Single-helical-strand
Mono-helical, Mono-bridged species, Coordination chemistry, Transition metals, X-ray crystallography, 1177
Singlet oxygen
Zinc phthalocyanine, Sensitizer, Photobleaching, 2463
Site affinity
Partition function, Equilibria in solution, Cooperativity, Buffer capacity, Heat capacity, 1439
Site constant
Statistical thermodynamic model, Cooperativity effect, Cooperativity potential, Polyamines, 1503
Sitting–Atop complexes
Porphyrins, Methyltin(IV) tribromide, Organotin(IV) halide adducts, Tin compounds, Spectral method, 1255
Six-coordinate geometry
Macrocycles, Germanium(IV) tmtaa complexes, Crystal structures, *Trans*-positions, 969
S-methyldithiocarbazate (SMDTC)
NS Schiff base, Cu(II), Ni(II), Zn(II) complexes, Crystal structures of Zn(II) complexes, 2683
Sn(IV) complexes
Tin enolates, Diorganohydroxytin, Diorganotin, Malonates, Di-*n*-butylhydroxytin(IV), 417
Sodium complexes
Phoshocreatine, ^{31}P NMR spectroscopy, Potassium complexes, Magnesium complexes, 1481
Sodium complexes
tert-Butylcalix[4]arenes, Amide, Yttrium(III) complexes, Lanthanide(III) complexes, X-ray structures, 763
Sodium ion
Alkali metal ions, Caesium ion, Calix[4]arene, Crystal structures, 2497
Solid state ^{13}C MAS and CP-MAS NMR
Cork, Copper, Nickel, Potentiometric titration, Metal uptake, 1363
Solid state metathesis
Silicides, Self-propagating, 187
Solid state structures
Copper(I), Anions, Dppe, Coordination mode, 2433
Solid state supramolecular complexes
Dibenzotetraaza[14]annulenes, Macrocyclic Ni(II) complexes, Succinyl dichloride, Crystal structures, 7
Solutions
Equilibria, Cations, Hydrolysis, Titration, Masking, 1369
Solvation parameter model
Partition coefficient, Hydrophobic moment, Iron–sulfur protein, Mixed-valence non-integer oxidation number, Cysteine ligand, 1357
Solvent extraction
N-Benzoylthiourea derivatives, Gold, Palladium, Ion selective electrode, Crystal and molecular structure, 1429
Solventothermal synthesis
Crystal structures, Coordination polymers, Copper methoxide, Single crystals, 2017
Speciation
Uranyl oxalates, Oxalic acid, UV–Vis spectrophotometry, Stability constants, Aqueous solutions, 1411
Spectra
Copper(II) complexes, Imidazole, 9,10-dihydro-9-oxo-10-acridineacetate, Crystal structures, Magnetic measurements, 2381
Spectra
Crystal structures, 3-Piperidine, Thiosemicarbazone, 2-Pyridineformamide, Nickel(II), 859
Spectra
1D nickel(II) azido complexes, Pyridine derivative complexes, Preparation, Crystal structures, Magnetic data, 1871
Spectral and magnetic properties
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Thermal stability, 1485
Spectral method
Adduct formation, Thermodynamics, Tin compounds, Porphyrins, Equilibrium constant, 683
Spectral method
Porphyrins, Sitting–Atop complexes, Methyltin(IV) tribromide, Organotin(IV) halide adducts, Tin compounds, 1255
Spectral properties
Copper(II) complexes, Crystal structures, Pyridinecarboxylate complexes, Mononuclear complexes, 365
Spectroelectrochemistry
Nitrogenase, Hydrazido(2-), Molybdenum, Crystal structures, 849
Spectroscopic characterization
α-Aminoisobutyryl-α-aminoisobutyric acid (H–Aib–Aib–OH), Copper(II) peptide complexes, X-ray crystal structures, 229
Spectroscopic characterization
Cyclophosphazenes, Polyphosphazenes, Phenolic phosphine, Macromolecular complexes, Carbonyls, 2579
Spectroscopic properties
Cd(II) and Hg(II) complexes, Normal coordinate, Force constant, 2-Phenylenediamine, 2-Aminophenol, 987
Spectroscopic properties
Copper complexes, Structures, Oxadiazole complexes, 2257
Spectroscopic study
Trinuclear complexes, Cyano-bridge, Crystal structures, 2237
Spectroscopy
Chiral benzodiazepine ligands, Zinc complexes, Palladium complexes, X-ray structure analysis, Cytostatic and antiviral activity, 2567
Spectroscopy
Co(III) complexes, Pyrazole, Dithiocarbazate, Synthesis, X-ray crystal structures, 1
Spectroscopy
Crystal structures, Physico-chemical properties, X-ray diffraction, Imidiazole complexes, 1857
Spectroscopy
Di-2-pyridyl ketone benzoylhydrazone, Nickel(II) complexes, Thermal analyses, 2375
S=PEt$_3$ ligand
Synthesis, Mo/Fe/S cluster, Structures, CO, 2523
Spin crossover
Iron(III) dialkyldithiocarbamates, Mössbauer spectra, Magnetic moment, Thermal decomposition, 2489
Spin polarization
DFT calculations, Dinuclear transition metal complexes, Electron transfer, Magnetic coupling, Metal–metal bonding, 1163
Square pyramidal copper(II) complexes
Idp-type ligand, *N*,*N*-Di(2-carboxyethyl)-

p-toluidine, *p*-Toluidine-*N*,*N*-di-3-propionic acid, Crystal structures, 2719
Stability constant
Lanthanide(III) chelate, Cobalt(III) chelate, Binuclear complexes, Inner-sphere coordination, Outer-sphere coordination, 805
Stability constants
Artificial neural networks, Experimental design, Metal complexes, Ion selective electrodes, Metal–ligand equilibria, 1375
Stability constants
Edta-derived macrocycles, Macrocyclic ether bis(lactones), EPR of Cu(II) complexes, EPR of dinuclear Cu–Cu complexes, Hydrolysis of macrocycles, 2265
Stability constants
Lanthanide, Polyaza ligands, Catecholate ligands, Potentiometry, 1393
Stability constants
Oxovanadium(IV) complexes, Carnosine, Potentiometric and spectrophotometric studies, 1513
Stability constants
Uranyl oxalates, Oxalic acid, UV–Vis spectrophotometry, Speciation, Aqueous solutions, 1411
π–π stacking interaction
BTZ ligands, X-ray crystallography, Pb(II) salts, 197
π-Stacking
Thallium(I) complexes, Scorpionate ligands, Crystal packing, Cation–π interaction, 553
Stannylenes
Plumbylenes, Distannenes, Diplumbenes, Lewis-amphoteric behavior, 587
Statistical thermodynamic model
Cooperativity effect, Site constant, Cooperativity potential, Polyamines, 1503
Stereochemistry
Copper complexes, X-ray structures, Steric properties, 1031
Steric properties
Copper complexes, Stereochemistry, X-ray structures, 1031
Stoichiometry
Isoquercitrin, Al(III) complexes, UV–Vis Spectroscopy, DFT calculations, FT Raman, 2801
Structural and magnetic properties
Nona-nuclear copper complex, Trinuclear copper complex, 1715
Structure elucidation
Cyclo-addition, Metallacycles, oxo ligands, P ligands, Palladium, 2653
Structure elucidation
Titanium, Chelate, Coordination chemistry, 8-Hydroxyquinolinate, 1081
Structures
Cadmium(II), Aspartate, ^{111}Cd NMR, 935
Structures
Cerium, Fluoroalkoxides, Complexes, MOCVD, Films, 1985
Structures
$C_{10}H_{20}N_2S_4Zn\cdot C_5H_5N$, Isomorphism, ^{15}N CP/MAS NMR spectroscopy, 2727
Structures
Copper complexes, Spectroscopic properties, Oxadiazole complexes, 2257
Structures
Gallium, Indium, Dithiocarbamates, Dialkyldithiophosphates, ^{71}Ga NMR, 239
Structures
Poly(3-Rpyrazolyl)borate cobalt(II) complexes, NMR, 2743
Structures
Rhodium, Cyano, Dioxygen, Enhanced reactivity, 1775
Structures
Ruthenium promoted reactions, Dimerization of aromatic amines, 1,2-Diimine, Redox, 97
Structures
Synthesis, Mo/Fe/S cluster, S=PEt$_3$ ligand, CO, 2523
3-Substituted-1,2-diaminopropanes
Lanthanide(III) complexes, Macrocyclic ligands, 2,6-Diacetylpyridine, 425
Substituted site
Crystal structures, Cobalt(I) clusters, Interstitial phosphorus atom, Heterocyclic phosphide, Semi-bridging carbonyl, 1073
Subvalent indium and gallium
Gallium(II), Indium(I), Indium(II), Halide complexes, Raman spectra, 519
Succinyl dichloride
Dibenzotetraaza[14]annulenes, Macrocyclic Ni(II) complexes, Crystal structures, Solid state supramolecular complexes, 7
Sucrose complexes
Carbohydrates, Cobalt complexes, Circular dichroism, ^{1}H NMR, Semi-empirical calculations, 2215
Sulfate complexes
Crystal structures, Copper complexes, Di-2-pyridylamine complexes, Tetrathionate complexes, Trifluoromethanesulfonate complexes, Hexafluorophosphate complexes, 247
Sulfate complexes
Crystal structures, Copper(II) complexes, Nitrite complexes, di-2-Pyridylamine complexes, Thiocyanato complexes, 1279
Sulfido
Triosmium cluster, Tetramethylthiourea, Desulfurization, X-ray structures, 381
Sulfonamide complexes
Nickel complexes, 8-Aminoquinoline, X-ray crystal structures, 1229
Sulfonate
Silver(I), Nicotinamide, Nicotinic acid, Hydrogen bond, Ag–Ag interaction, Assembly chemistry, 689
Sulfur-bridged dimer
Pyridine-2-thione, Tri-*p*-tolylphosphine, Triphenylphosphine, Copper(I) complexes, 1603
Sulfur
Cysteamine, Cysteine, Hydrogen bonding, 225
Sulfur dicyanide $S_y(CN)_2$
Polythiocyanogens, ^{13}C NMR spectroscopy, Paracyanogen $(CN)_x$, 1825
Sulfur dioxide
Cobalt, Phthalocyanine, Cyanide, Kinetics, Equilibria, 133
Sulfur dioxide
Zinc(II)tetrasulfophthalocyanine, Fluorescence quenching, Association constants, 951
Superconductors
Chemical bonding topology, Magnesium diboride, Cuprate superconductors, 2347
Supramolecular assembly
Uranyl ion, Calixarenes, Homooxacalixarenes, Crystal structures, 1125
Supramolecular chemistry
Gallium–gallium bonds, Macrocycles, 511
Supramolecular interactions
Tripodal ammonium, Nucleotides, Ternary complexes, Zn(II), 1005
Supramolecular polymer
Cyclophosphazene, Coordination bonding, Hairy-rod structure, Lamellar packing, 1573
Supramolecular pre-association
Photoinduced electron transfer, Cyclic voltammetry, Ruthenium(II) complexes, 2,2′:6′,2″-Terpyridine, 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid, 49
Supramolecules
Copper, Self-assembly, X-ray structures, 1621
Symbiosis
Cadmium(II) complexes, Coordination polymers, Crystal structures, 2293
Syntheses
Binuclear, Ruthenium(II) complexes, Thiobis(β-diketone), Catalytic oxidation, Antibacterial activity, 1721
Syntheses
Isoxazolidines, Pd-, Zn-, Cu-complexes, X-ray, NMR, 769
Syntheses
Ruthenium(II), Binuclear, Bis(β-diketone), Triphenylarsine, Antibacterial activity, Catalytic study, 219
Synthesis and electrochemistry
Asymmetric 14-π nickel(II) tetraazaannulene, Hammett plot, Electrocatalysis, 917
Synthesis
Boron complexes, Benzohydroximate anion, Crystal structures, 2351
Synthesis
Cobalt(III) complexes, 4-Methyl-2,6-dibenzoylphenol, NMR, TGA, Cyclic voltammetry, X-ray structures, 1787
Synthesis
Co(III) complexes, Pyrazole, Dithiocarbazate, Spectroscopy, X-ray crystal structures, 1
Synthesis
Crystal structures, X-ray diffraction, 1883
Synthesis
Cyano(selenone)gold(I) complexes, ^{13}C and ^{15}N NMR spectroscopy, 2099
Synthesis
Equilibria, Binuclear complexes, Polyamines, 1351
Synthesis

Heteropolyoxometalate, Arsenic, Tungstate, Lacunary, Redox chemistry, 959
Synthesis
Metal-organic frameworks (MOF), Crystal structures, TGA–DTA, 175
Synthesis
Mo/Fe/S cluster, Structures, S=PEt$_3$ ligand, CO, 2523
Synthesis
Platinum, Hexamethyleneimine, 1,1-Cyclobutanedicarboxylato, Crystal structure, 2659
Synthesis
Platinum(II) complexes, Heptamethyleneimine, Crystal structures, 2369
Synthesis
Platinum(II), Homopiperazines, Disubstituted sulfides, Crystal structure, 125
Synthon
Eight-coordinate, Schiff base, Zirconium complexes, X-ray crystal structure, Heteroleptic, 211

Tantalum
Metal alkoxides, Esterification, Single-crystal X-ray, Group V, Niobium, 2333
Tantalum
Metallocenes, Hydrides, Metallophosphines, Bimetallics, X-ray structures, 371
Tantalum methoxide
Trimetallic alkoxides, Molecular structure, X-ray study, Mass-spectrometric study, Rhenium methoxides, Niobium methoxide, 2317
Tantalum(V)
Bis-sulfamide, Diamide, Crystal structures, 1051
Tellurium dichloride
Chloridotellurate anions, X-ray crystallography, NMR spectroscopy, 1089
Template effect
Nickel(II) complexes, Heterotrinuclear complexes, BF_2^+-capped complexes, Dioxadithiadiazamacrobicycle, *vic*-Dioxime, 1865
Terminal cyanato ion complexes
Binuclear nickel(II) complexes, Crystal structures, Magnetic properties, Terminal thiocyanato ion complexes, Pentadentate ligands, 2457
Terminal thiocyanato ion complexes
Binuclear nickel(II) complexes, Crystal structures, Magnetic properties, Terminal cyanato ion complexes, Pentadentate ligands, 2457
Terminal tungsten complexes
Digermene, Germylene, X-ray crystallographic analysis, Dissociation, Equilibrium, Bond dissociation energy, Dioxadigermetane, 563
Ternary complexes
Crystal structures, Kinetic studies, 2045
Ternary complexes
Cu(II) complexes, Peptide–Cu(II)–isocytosine complexes, Isocytosine complexes, 1197
Ternary complexes
Supramolecular interactions, Tripodal ammonium, Nucleotides, Zn(II), 1005
2,2′:6′,2″-Terpyridine
Photoinduced electron transfer, Cyclic voltammetry, Supramolecular pre-association, Ruthenium(II) complexes, 4′-*p*-Tolyl-2,2′:6′,2″-terpyridine-4-carboxylic acid, 49
Terpyridyl
Iron(III), Single-crystal X-ray, N-donor, 2055
tert-Butylcalix[4]arenes
Amide, Sodium complexes, Yttrium(III) complexes, Lanthanide(III) complexes, X-ray structures, 763
Tertiary amines
Ruthenium complexes, Photochemistry, Electrochemistry, 61
Tetrabromocuprate(II)
Crystal structures, Magnetic properties, Thermal properties, *n*-Ethylpyridinium, 19
Tetrachloroaurate(III)
Isotope effect, Hydrogen bond, Dimer, Crystal structures, NQR, 2207
Tetrachlorocuprate(II)
Aminoguanidonium, Copper(II) halides, Crystal structures, 409
Tetrachlorocuprate
Thermochromism, Crystal structures, Benzimidazolium, 2561
Tetrachlorogallate salt
Gallium pyrazole complexes, Gallium trichloride, 3,5-diphenylpyrazole, 1117
Tetradentate ligands
Cobalt(III) complexes, Bidentate ligands, Eddp, 2277
Tetrahedral
Schiff base complexes, Cobalt(II), Nickel(II), Zinc(II), Crystal structures, 2733
Tetramethylthiourea
Triosmium cluster, Desulfurization, Sulfido, X-ray structures, 381
Tetramines
Ni(II), Co(II), Adenosine 5′-monophosphate, Mixed-ligand complexes, 745
Tetranuclear copper(II) complexes
Crystal structures, Magnetism, Antiferromagnetic coupling, Molecular orbital calculation, 1539
Tetrathionate complexes
Crystal structures, Copper complexes, Di-2-pyridylamine complexes, Trifluoromethanesulfonate complexes, Sulfate complexes, Hexafluorophosphate complexes, 247
TGA–DTA
Metal-organic frameworks (MOF), Synthesis, Crystal structures, 175
TGA
Pentacyaninotrosylferrate(2−) ion, Metastable excited states, X-ray diffraction, FIRRS, DTA, 1767
TGA
Synthesis, Cobalt(III) complexes, 4-Methyl-2,6-dibenzoylphenol, NMR, Cyclic voltammetry, X-ray structures, 1787
Thallium(I) complexes
Crystal structure, Nitrophenoxide complexes, 2555
Thallium(I) complexes
Scorpionate ligands, Crystal packing, π-Stacking, Cation–π interaction, 553
The 2,6-bis(dimethylamino)phenyl ligand
Arylmetal complexes, Mercury(II), Boron, 635
Thermal analyses
Di-2-pyridyl ketone benzoylhydrazone, Nickel(II) complexes, Spectroscopy, 2375
Thermal analysis
2-Pyridylmethanol, Saccharin complexes, Single crystal structures, 2393
Thermal decomposition
Iron(III) dialkyldithiocarbamates, Mössbauer spectra, Magnetic moment, Spin crossover, 2489
Thermal properties
Crystal structures, Magnetic properties, Tetrabromocuprate(II), *n*-Ethylpyridinium, 19
Thermal stability
Copper(II), *N*-(2-Pyridylmethyl)iminodiacetic acid, *N*-(2-Pyridylmethyl)iminodiacetate(2-) ion, 2-(Aminomethyl)pyridine, α-Picolylamine, 2-(2′-Pyridyl)benzimidazole, Crystal structures, Mixed-ligand complexes, Aromatic π,π-staking interactions, Molecular recognition, Spectral and magnetic properties, 1485
Thermochromism
Crystal structures, Benzimidazolium, Tetrachlorocuprate, 2561
Thermodynamics
Adduct formation, Tin compounds, Porphyrins, Equilibrium constant, Spectral method, 683
Thermodynamics group
Complex history, Complex pioneers, Coordination chemistry, 1313
Thermodynamics
Lanthanides(III), Oxygen donors, 2,2′-Oxydiethylamine, Dimethylsulfoxide, Complexes, 1385
Thermodynamics
Silver(I), *N*-methylated polyamines, Complexes, Dimethylsulfoxide, 1337
Thermolysis
Iminophosphorane, Cycloaddition, Four-membered ring compounds, Aza-Wittig reaction, X-ray analysis, 657
Thiadiazole
M = Co, M = Ni, M = Cu, Crystal structures, Monomeric complexes, 403
Thin film
Tin phosphide, APCVD, 1943
Thiobis(β-diketone)
Binuclear, Ruthenium(II) complexes, Syntheses, Catalytic oxidation, Antibacterial activity, 1721
Thiocarbodihydrazone Schiff base
Dioxomolybdenum(VI) complexes, X-ray structures, 1023
Thiocyanate ligands
Hemidirected, Lead(II) complexes, Crystal

structures, 1223
Thiocyanate
Tris(pyrazolyl)borate and 2,6-pyridyl-diimine ligands, Cadmium(II), Lead(II), 1795
Thiocyanato complexes
Crystal structures, Copper(II) complexes, Nitrite complexes, Sulfate complexes, di-2-Pyridylamine complexes, 1279
Thiocyanato ligands
Ru(II) complexes, dcbpy, bdmpp, Sensitizing ability, 2773
Thioether complexes
Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Phosphine complexes, Crown thioethers, 879
Thioether
Trinuclear complexes, Single crystal structures, Copper(II), Silver(I), Carboxylate, 33
Thiolate
Nickel, *cis*-1,2-Bis(diphenylphosphino)-ethene, X-ray structures, 421
Thiol oxidation
Dioxomolybdenum(VI) bromides, Oxo-transfer catalysts, 1635
Thiones
Silver(I) complexes, NMR studies, 1267
Thiosemicarbazone
Cobalt(III), X-ray crystal studies, ^{1}H NMR, IR, Electronic spectra, 2515
Thiosemicarbazone
Crystal structures, 3-Piperidine, 2-Pyridineformamide, Nickel(II), Spectra, 859
Thiosemicarbazone
Pyrazineformamide, Zinc, Cadmium, Crystal structures, Electrochemical synthesis, 1553
Thiosemicarbazone
2-Pyridineformamide, Nickel(II), Zinc(II), Cadmium(II), Crystal structures, 729
Thiosemicarbazones
Dimethylthallium(III), Crystal structures, IR spectra, ^{1}H, ^{13}C NMR spectra, 1651
Thiosemicarbazones
Zinc, Halide complexes, Ligand, 1217
Thiosemicarbazone
X-ray, Isatin, Metal complexes, 2593
Ti(IV) complex
Polyoxometalates, Heteropolyanions, Wells-Dawson structure, 353
Tin
Azide, Germanium, Silver, Tris(pyrazolyl)borate, Aminotroponimine, 611
Tin
C_3-chiral triamidostannate, Amides, Lithium, 629
Tin compounds
Adduct formation, Thermodynamics, Porphyrins, Equilibrium constant, Spectral method, 683
Tin compounds
Porphyrins, Sitting–Atop complexes, Methyltin(IV) tribromide, Organotin(IV) halide adducts, Spectral method, 1255
Tin enolates
Diorganohydroxytin, Diorganotin, Sn(IV) complexes, Malonates, Di-*n*-butylhydroxytin(IV), 417
Tin
Guanidinate, 1,3,4,6,7,8-Hexahydro-2*H*-pyramido[1,2-*a*]pyramidinate, Mononuclear, Dinuclear, 619
Tin
Molybdenum, Crystal structures, Metathesis, Polymerisation, Norbornadiene, NMR spectra, 2505
Tin phosphide
Thin film, APCVD, 1943
Tin
Tungsten, Oxidative addition, Crystal structures, Hydride, NMR, 1817
Titanium
Chelate, Coordination chemistry, Structure elucidation, 8-Hydroxyquinolinate, 1081
Titanium complexes
PH-functionalised phosphanylalkyl(silyl)cyclopentadienyl ligands, Zirconium complexes, Polymerisation studies, 2445
Titanium
Molecular orbital, Ab initio, Mechanism, Intermolecular nucleophilic attack, Ylid, 2699
Titration
Solutions, Equilibria, Cations, Hydrolysis, Masking, 1369
Torsion angle (χ)
Adenosine-5′-triphosphate (ATP), Mg(II), NOESY, 435
Trans influence
Crystal structures, Ligand-field strength, Tripodal tridentate phosphine, Acetylacetonate complexes, Chromium(III) complexes, 835
Transition metals
Conformational change, Four or five coordinate geometry, Metal centre, 2175
Transition metals
Conformational change, Schiff's base ligands, Octahedral systems, 2167
Transition metals
Mono-helical, Single-helical-strand, Mono-bridged species, Coordination chemistry, X-ray crystallography, 1177
Transition metals
Polyoxometalates, Chemical bonding, Molecular orbitals, Density–functional theory, 2201
Trans-positions
Macrocycles, Germanium(IV) tmtaa complexes, Crystal structures, Six-coordinate geometry, 969
Trialkylaluminum
Aminoalane, Dibenzylamine, NMR, Mass spectrometry, Molecular structure, 1747
Triazole derivatives
Mononuclear complexes, Crystal structures, 797
1,2,4-Triazolo-[1,5α]-pyrimidines
Platinum chloride complexes, X-ray structures, N-donor ligands, ^{15}N NMR, 343
Tridentate Schiff base ligand
Potassium permanganate, Molecular structures, Photosystem II, 1139
Triflate
Amido, Amine, Platinum, Diphosphazane, Cyclometalation, 1305
Triflates
Triphenylphosphine oxide complexes, Single crystal X-ray diffraction, Scandium and lanthanide, Catalysis, 287
Trifluoromethanesulfonate complexes
Crystal structures, Copper complexes, Di-2-pyridylamine complexes, Tetrathionate complexes, Sulfate complexes, Hexafluorophosphate complexes, 247
Trigonal prismatic geometry
Rhenium complexes, 2-Amidothiophenolato complexes, 1597
Trimetallic alkoxides
Molecular structure, X-ray study, Mass-spectrometric study, Rhenium methoxides, Niobium methoxide, Tantalum methoxide, 2317
Trinuclear complexes
Aluminium, Diols, 2,2′-Di(hydroxymethyl)biphenyl, Crystal structures, Alkylaluminium diolates, 281
Trinuclear complexes
Cyano-bridge, Crystal structures, Spectroscopic study, 2237
Trinuclear complexes
Ferrocenylmethylphosphine, Phosphino amino acids, 1,3-Diaza-5-phosphacyclohexane, 1,5-Diaza-3,7-diphosphacyclooctane, Water-soluble complexes, 2251
Trinuclear complexes
Single crystal structures, Copper(II), Silver(I), Carboxylate, Thioether, 33
Trinuclear copper complex
Nona-nuclear copper complex, Structural and magnetic properties, 1715
Trinuclear metal chelates
β-Aminovinylimines, Chemical and electrochemical synthesis, 2081
Trinuclear
Mixed-valence compound, Electron transfer, Iron, Iodoacetate, Heat capacity, 1299
Triosmium cluster
Tetramethylthiourea, Desulfurization, Sulfido, X-ray structures, 381
Triphenylantimony(V)
Oximes, NMR, X-ray, 2387
Triphenylarsine
Ruthenium(II), Binuclear, Bis(β-diketone), Syntheses, Antibacterial activity, Catalytic study, 219
Triphenylphosphine
Dithiocarbimates, Nickel complexes, Crystal structures, 2243
Triphenylphosphine oxide complexes
Triflates, Single crystal X-ray diffraction, Scandium and lanthanide, Catalysis, 287
Triphenylphosphine
Pyridine-2-thione, Tri-*p*-tolylphosphine, Sulfur-bridged dimer, Copper(I) complexes, 1603
Tripodal ammonium
Supramolecular interactions, Nucleotides,

Ternary complexes, Zn(II), 1005
Tripodal tridentate phosphine
Trans influence, Crystal structures, Ligand-field strength, Acetylacetonate complexes, Chromium(III) complexes, 835
Tri-*p*-tolylphosphine
Pyridine-2-thione, Triphenylphosphine, Sulfur-bridged dimer, Copper(I) complexes, 1603
Tris(pentamethylphenyl)gallium
Pentamethylphenylmagnesium bromide, Elemental analyses, Single crystal X-ray diffraction, 531
Tris(pyrazolyl)borate and 2,6-pyridyl-diimine ligands
Thiocyanate, Cadmium(II), Lead(II), 1795
Tris(pyrazolyl)borate
Azide, Germanium, Tin, Silver, Aminotroponimine, 611
Trithiacyclononane
Thioether complexes, Platinum complexes, Platinum nuclear magnetic resonance, Phosphine complexes, Crown thioethers, 879
Tungstate
Heteropolyoxometalate, Arsenic, Lacunary, Synthesis, Redox chemistry, 959
Tungsten
Alkoxides, Crystal structures, Lithium, Methoxide, 193
Tungsten
Chloride ligands, Oxo ligands, Phenolates, 349
Tungsten complexes
Crystal structures, Pyrazole, Copper complexes, 1547
Tungsten
Tin, Oxidative addition, Crystal structures, Hydride, NMR, 1817

Uranyl bis(β-diketonates)
N-oxides, Adduct compounds, X-ray structures, 2403
Uranyl complexes
Morphologies, Schiff base ligand, 2421
Uranyl
Dimethylmelonate, Counter-cation, CPMAS ^{13}C NMR, X-ray crystallography, 69
Uranyl ion
Calixarenes, Homooxacalixarenes, Supramolecular assembly, Crystal structures, 1125
Uranyl ion
Polyphenols, Oligophenols, Crystal structures, 1949
Uranyl
Malonato complexes, CPMAS ^{13}C NMR, X-ray crystallography, 81
Uranyl oxalates
Oxalic acid, UV–Vis spectrophotometry, Speciation, Stability constants, Aqueous solutions, 1411
Uranyl polyhalides
Actinides, Dioxouranium(VI) polyhalides, Polybromides, Polyiodides, 2755
Urea and thiourea derivatives
Diruthenium carboxylates, Crystal structures, Infrared spectroscopy, 1235
Urinary trypsin inhibitors
Bubble extraction, Affinity chromatography, RP-HPLC, 1475
UV–Vis absorption spectra
Rhenium(III) complexes, Iridium(III) complexes, S-bridged polynuclear complexes, Crystal structures, Cyclic voltammetry, 1809
UV–Vis and FTIR spectroscopy
Phthalocyanines, Nitrogen dioxide, Scanning electron microscopy, X-ray microprobe, X-ray powder diffractometry, 677
UV–Vis spectra
Vanadium complexes, Caffeic acid complexes, IR spectra, Potentiometric titrations, Catecholate-like ligand, 1979
UV–Vis spectrophotometry
Uranyl oxalates, Oxalic acid, Speciation, Stability constants, Aqueous solutions, 1411
UV–Vis Spectroscopy
Isoquercitrin, Al(III) complexes, Stoichiometry, DFT calculations, FT Raman, 2801
UV–Vis spectroscopy
Magnesium phthalocyanines, Magnesium complexes, Crystal structures, IR spectroscopy, Raman spectroscopy, 265

Vanadium complexes
Caffeic acid complexes, IR spectra, UV–Vis spectra, Potentiometric titrations, Catecholate-like ligand, 1979
Vanadyl complexes
Schiff bases, Chiral complexes, EPR, X-ray structures, 2021
Vanadyl
Diperoxovanadate, EDTA inhibition, EDTA bridged heteroligand peroxovanadates, Catalase resistance, Oxo-bridged peroxovanadates containing sulphate, 389
Vibrational spectra
Imidazole-4-acetic acid, Polymeric zinc(II) complexes, Crystal structures, Density functional calculations, 2819
vic-Dioxime
Nickel(II), Cobalt(II), Copper(II), Iron(II), Uranyl(IV), Electrochemistry, LH_4, $N_2O_2S_2$ macrocyle, 825
vic-Dioxime
Nickel(II) complexes, Heterotrinuclear complexes, BF_2^+-capped complexes, Dioxadithiadiazamacrobicycle, Template effect, 1865
Vinylcyclosilazane complexes
Nickel(0), Crystal structure, 1261
Vinylidene
Iron, Acetylide, Propadienylidene, 1755
Vis spectra
Copper(II) complexes, Mixed-ligand complexes, Five-coordinate complexes, Aminohydroxamic acids, EPR spectra, 295

Water-soluble complexes
Ferrocenylmethylphosphine, Phosphino amino acids, 1,3-Diaza-5-phosphacyclohexane, 1,5-Diaza-3,7-diphosphacyclooctane, Trinuclear complexes, 2251
Wells-Dawson structure
Polyoxometalates, Heteropolyanions, Ti(IV) complex, 353

X-ray analysis
Iminophosphorane, Cycloaddition, Four-membered ring compounds, Thermolysis, Aza-Wittig reaction, 657
X-ray
Boron, Lithium, Imido, Complexes, 549
X-ray
Copper, Hinokitiol, Adduct, 1761
X-ray crystallographic analysis
Digermene, Germylene, Dissociation, Equilibrium, Bond dissociation energy, Dioxadigermetane, Terminal tungsten complexes, 563
X-ray crystallography
BTZ ligands, Pb(II) salts, π–π stacking interaction, 197
X-ray crystallography
Cobalt(III), Pyrazolylthiosemicarbazone, ^1H NMR, 779
X-ray crystallography
Dimesitylphosphine, Secondary phosphine, NMR, Cone angle, Fluxional, 2409
X-ray crystallography
Europium complexes, Luminescence property, Dibenzoylmethane, 2-(4′-Dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 3-Ethyl-2-(4′-dimethylaminophenyl)imidazo[4,5-f]1,10-phenanthroline, 313
X-ray crystallography
Magnetochemical studies, Manganese oxide clusters, 1779
X-ray crystallography
Mono-helical, Single-helical-strand, Mono-bridged species, Coordination chemistry, Transition metals, 1177
X-ray crystallography
Tellurium dichloride, Chloridotellurate anions, NMR spectroscopy, 1089
X-ray crystallography
Uranyl, Dimethylmelonate, Counter-cation, CPMAS ^{13}C NMR, 69
X-ray crystallography
Uranyl, Malonato complexes, CPMAS ^{13}C NMR, 81
X-ray crystal structure
Eight-coordinate, Schiff base, Zirconium complexes, Synthon, Heteroleptic, 211
X-ray crystal structures
α-Aminoisobutyryl-α-aminoisobutyric acid (H–Aib–Aib–OH), Copper(II) peptide complexes, Spectroscopic characterization, 229
X-ray crystal structures
Co(III) complexes, Pyrazole, Dithiocarbazate, Synthesis, Spectroscopy, 1
X-ray crystal structures
Hg(II) complexes, Dimer, Diethylene triamine, 2195
X-ray crystal structures
2-Hydroxynicotinic acid, Palladium, Pla-

tinum, Raman spectra, 2783
X-ray crystal structures
Iron(II), Zinc(II), Schiff base, ^{1}H NMR spectroscopy, Dioxygen reactivity, 705
X-ray crystal structures
Nickel complexes, Sulfonamide complexes, 8-Aminoquinoline, 1229
X-ray crystal structures
Niobium complexes, Heterodiene, 1,4-Diaza-1,3-diene, 305
X-ray crystal structures
Pyrazole, Mononuclear bis(imido) Mo(VI) complexes, 1211
X-ray crystal structures
Schiff bases, Salicylaldimine adducts, Interconversion, Zinc complexes, Zwitterion, 697
X-ray crystal studies
Cobalt(III), Thiosemicarbazone, ^{1}H NMR, IR, Electronic spectra, 2515
X-ray data
Cobalt(II), Cubane complexes, Carbacylamidophosphates, 963
X-ray diffraction
Crystal structures, Physico-chemical properties, Spectroscopy, Imidiazole complexes, 1857
X-ray diffraction
Palladium, Metallation, Schiff base, Phosphorus ligands, 2309
X-ray diffraction
Pentacyaninotrosylferrate(2−) ion, Metastable excited states, FIRRS, TGA, DTA, 1767
X-ray diffraction
Synthesis, Crystal structures, 1883
X-ray
Isoxazolidines, Pd-, Zn-, Cu-complexes, Syntheses, NMR, 769
X-ray microprobe
Phthalocyanines, Nitrogen dioxide, Scanning electron microscopy, UV–Vis and FTIR spectroscopy, X-ray powder diffractometry, 677
X-ray
Mononuclear tungsten(VI) complexes, Ligand, Heteroleptic, 1017
X-ray photoelectron spectroscopy
Chromium, Pivalate, Mass spectrometry, Paramagnetic, NMR, 155
X-ray powder diffractometry
Phthalocyanines, Nitrogen dioxide, Scanning electron microscopy, X-ray microprobe, UV–Vis and FTIR spectroscopy, 677
X-ray structural analysis
Aluminum(I) halides, Metalloid clusters, Nanosized clusters, Intermediates, Metal lattice, 489
X-ray structure analysis
Chiral benzodiazepine ligands, Zinc complexes, Palladium complexes, Spectroscopy, Cytostatic and antiviral activity, 2567
X-ray structure analysis
Gallium, Indium, Platinum, Heterobimetallic complexes, Quantum chemical calculations, 535
X-ray structure
2-(3,5-Dimethylpyrazol-1-ylmethyl)pyridine, Bis-ligand and anion-bound copper(II) complexes, Absorption and EPR spectra, Cyclic voltammetry, 1245
X-ray structure
Platinum(III) compounds, Lantern-type complexes, Amidate bridging ligands, 275
X-ray structures
Arylazopyrimidines, Osmium(II) complexes, Geometrical isomers, MLCT transitions, Redox property, 753
X-ray structures
Bis(pyrazol-1-yl)alkane, Organotin(IV), 873
X-ray structures
Cadmium(II) complexes, Polyamines, 739
X-ray structures
Copper complexes, Stereochemistry, Steric properties, 1031
X-ray structures
Copper, Self-assembly, Supramolecules, 1621
X-ray structures
Cu(II) stereochemistry, Magnetism, EPR spectra, 2473
X-ray structures
Dioxomolybdenum(VI) complexes, Thiocarbodihydrazone Schiff base, 1023
X-ray structures
Five-coordinated chlorocopper(II) complexes, 1,10-Phenanthroline and its 5,6-disubstituted derivatives, Electronic absorption and diffuse reflectance spectra, Cyclic voltammetry, 2143
X-ray structures
Heterocyclic thioamides, Osmium, Ruthenium, 2-Mercapto-1-methylimidazole, 885
X-ray structures
Molybdenum complexes, oxo-Hydrazido complexes, Methyl-molybdenum complexes, Phenyl-molybdenum complexes, Diimine, 2531
X-ray structures
Nickel, Copper, Zinc, Cadmium, Saccharinate, 395
X-ray structures
Nickel, Thiolate, *cis*-1,2-Bis(diphenylphosphino)ethene, 421
X-ray structures
Niobium sulphide metallacycles, HF/ECP calculations, 2227
X-ray structures
Nitrosyl complexes, Ruthenium(II), NMR spectra, Diop, Dppb, 2221
X-ray structures
N-oxides, Uranyl bis(β-diketonates), Adduct compounds, 2403
X-ray structures
Phosphoranes, Pentacoordinated, Hydrogen bonding, 1155
X-ray structures
Platinum chloride complexes, N-donor ligands, ^{15}N NMR, 1,2,4-Triazolo-[1,5α]-pyrimidines, 343
X-ray structures
Platinum(II) complexes, Ribavirin, NMR and IR analysis, 2001
X-ray structures
Pyridine N-oxide ligands, copper(II) complexes, Hydrogen bonding, Magnetism, 1561
X-ray structures
Rhenium, Nitrosyl, Electronic structures, Nitric oxide, 2617
X-ray structures
Scandium, Phosphine oxide, Arsine oxide, ^{45}Sc NMR, 1579
X-ray structures
Synthesis, Cobalt(III) complexes, 4-Methyl-2,6-dibenzoylphenol, NMR, TGA, Cyclic voltammetry, 1787
X-ray structures
Tantalum, Metallocenes, Hydrides, Metallophosphines, Bimetallics, 371
X-ray structures
tert-Butylcalix[4]arenes, Amide, Sodium complexes, Yttrium(III) complexes, Lanthanide(III) complexes, 763
X-ray structures
Triosmium cluster, Tetramethylthiourea, Desulfurization, Sulfido, 381
X-ray structures
Vanadyl complexes, Schiff bases, Chiral complexes, EPR, 2021
X-ray structures
Yttrium, Phosphine oxide, Arsine oxide, 445
X-ray study
Trimetallic alkoxides, Molecular structure, Mass-spectrometric study, Rhenium methoxides, Niobium methoxide, Tantalum methoxide, 2317
X-ray
Thiosemicarbazone, Isatin, Metal complexes, 2593
X-ray
Triphenylantimony(V), Oximes, NMR, 2387

Ylid
Molecular orbital, Ab initio, Mechanism, Intermolecular nucleophilic attack, Titanium, 2699
Yttrium(III) complexes
tert-Butylcalix[4]arenes, Amide, Sodium complexes, Lanthanide(III) complexes, X-ray structures, 763
Yttrium
Phosphine oxide, Arsine oxide, X-ray structures, 445
Yttrium
Salen, Amide, Aryloxide, Organometallic, 1683

Zigzag chain
Cadmium complexes, Dca ligand, Double end-to-end, π–π interaction, 893
Zinc adducts
Emprirical correlations, Calorimetry, Infrared spectroscopy, 1677
Zinc complexes
Chiral benzodiazepine ligands, Palladium

complexes, Spectroscopy, X-ray structure analysis, Cytostatic and antiviral activity, 2567
Zinc complexes
Crystal structures, Copper complexes, Lumazine complexes, 1961
Zinc complexes
Schiff bases, Salicylaldimine adducts, Interconversion, X-ray crystal structures, Zwitterion, 697
Zinc
Halide complexes, Thiosemicarbazones, Ligand, 1217
Zinc(II) complexes
Aminomethane-1,1-diphosphonic acids, Magnesium(II) complexes, Calcium(II) complexes, Potentiometry, NMR, 321
Zinc(II) complexes
Crystal structures, Co-ordination number asymmetry, 1957
Zinc(II) complexes
Mixed-ligand complexes, Aminohydroxamic acids, Polyamines, NMR spectra, Potentiometry, 2183
Zinc(II)
Iron(II), Schiff base, X-ray crystal structures, ^{1}H NMR spectroscopy, Dioxygen reactivity, 705
Zinc(II)
One-dimensional structures, Cobalt(II), Coordination complexes, 2705
Zinc(II)
2-Pyridineformamide, Thiosemicarbazone, Nickel(II), Cadmium(II), Crystal structures, 729
Zinc(II)
Schiff base complexes, Cobalt(II), Nickel(II), Tetrahedral, Crystal structures, 2733
Zinc(II)tetrasulfophthalocyanine
Sulfur dioxide, Fluorescence quenching, Association constants, 951
Zinc
Nickel, Copper, Cadmium, Saccharinate, X-ray structures, 395
Zinc phthalocyanine
Sensitizer, Singlet oxygen, Photobleaching, 2463
Zinc
Phthalocyanines, Phthalonitrile derivatives, Electrochemistry, Nickel, Cobalt, 255
Zinc
Pyrazineformamide, Thiosemicarbazone, Cadmium, Crystal structures, Electrochemical synthesis, 1553
Zintl phases
Clusters, Crystal structures, Intermetallic compounds, Lead, 641
Zirconium complexes
Eight-coordinate, Schiff base, X-ray crystal structure, Synthon, Heteroleptic, 211
Zirconium complexes
PH-functionalised phosphanylalkyl(silyl)cyclopentadienyl ligands, Titanium complexes, Polymerisation studies, 2445
Zn(II) complexes
Zn(II)–N bonds, Crystal structures, Piperazine and piperazin-1-ium ligands, 2161
Zn(II)–N bonds
Crystal structures, Zn(II) complexes, Piperazine and piperazin-1-ium ligands, 2161
Zn(II)
Supramolecular interactions, Tripodal ammonium, Nucleotides, Ternary complexes, 1005
Zwitterion
Schiff bases, Salicylaldimine adducts, Interconversion, X-ray crystal structures, Zinc complexes, 697
