are of the same order of magnitude of those verified for other substituted cyclopentadienyl complexes of nickel including $[Ni(\eta\text{-}MeC_5H_4)(dppe)]X$ (X = Cl, I, NCS), with values of Δ between 0.09 and 0.12 [12], or $[Ni(\eta\text{-}RC_5H_4)L_2]BF_4$ (R = Me, ^{t}Bu; L_2 = norbornadiene, 1,5-cyclooctadiene), with Δ varying from 0 to 0.41 [19]. However, this separation is significantly lower than in the binuclear **1** or $[Cl(PPh_3)Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)Cl]$ (Δ = 1.82 and 0.77, respectively [11]) or in other mononuclear Ni compounds containing PPh_3 including $[Ni(\eta\text{-}MeC_5H_4)(PPh_3)X]$ (X = Cl, Br, I, NCS), with Δ ranging from 0.90 to 1.66 [12]. The symmetry of **2**–**5** is further confirmed by the $^{13}C\{^1H\}$ spectra that exhibit one methyl resonance in the range δ 29.3–31.1, two peaks at δ 93.0–93.3 (C3/C4) and 95.2–96.0 (C2/C5), and one peak in the range δ 128.1–128.6 corresponding to the Cp *ipso* carbon resonance (C1), and by the ^{31}P spectra showing a single resonance in the range δ 40.7–42.1. In the ^1H NMR spectra, the H2/H5 and H3/H4 resonances multiplicities in compounds **3**–**5** show a deceptively simple AA′XX′ pattern, typical of monosubstituted cyclopentadienyl ligands [20]. However, in compound **2**, these two resonances appear as broadened singlets with no fine structure.

This latter feature exhibited by compound **2**, which reveals a higher lability of this less basic isocyanide ligand, may be eventually related to the difference in reactivity observed for compound **1** towards the presence of an excess of isocyanide. When attempting the synthesis of $[(CNR)_2Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(CNR)_2][PF_6]_2$, the addition of an excess of isocyanide to **1** did not lead to a reaction, except in the case of *S*-(−)-1-phenylethyl isocyanide, where **1** caused polymerisation to poly(*S*-(−)-1-phenylethyl isocyanide). Interestingly, the

neutral binuclear compound [Cl(PPh$_3$)Ni{μ-(η-C$_5$H$_4$)CMe$_2$(η-C$_5$H$_4$)}Ni(PPh$_3$)Cl] is not active in the polymerisation of the same isocyanide.

We have very recently reported that the related mononuclear [Ni(η-C$_5$H$_5$)(PPh$_3$)$_2$]PF$_6$ (**8**) is a good catalyst for the polymerisation of *S*-(−)-1-phenylethyl isocyanide, showing an activity similar to that of the corresponding indenyl analogue [Ni(η-C$_9$H$_7$)(PPh$_3$)$_2$]PF$_6$ but lower than that of the 2-methallyl derivative [Ni(η-CH$_2$C(Me)CH$_2$)(PPh$_3$)$_2$]PF$_6$ [10]. In this work, we found out that the polymerisation of *S*-(−)-1-phenylethyl isocyanide catalysed by the binuclear complex **1** also follows an overall second-order kinetic law ($r_p = k_p[Ni]_o[CNR]$). The second-order rate constant k_p obtained is slightly lower than that calculated for the reaction catalysed by the mononuclear **8** (reactions AFP73 versus AFP76 in Table 2), probably due to a higher steric hindrance imposed by the substituted Cp rings of **1** in the polymerisation initiation step. The initiation step will very likely involve the coordination of CNR ligands to **1** followed by insertion into the Ni–η^1–Cp bond giving rise to a Ni-iminoacyl group (vide infra), although the migratory insertion reaction of the cyclopentadienyl ligand is not yet a well-documented reaction [21].

In order to test whether binuclear **1** could give rise to polymers with different molecular weight when compared to **8**, we have carried out a set of polymerisation reactions for each of these catalysts in which the initial concentration ratio [CNR]$_o$/[Ni]$_o$ was varied (Fig. 2). The initial molar concentration of nickel atoms used was exactly the same for both catalysts but, since in **1** two Ni atoms are linked by a bridged bis(cyclopentadienyl) ligand, the molar ratio concentration of complex **8** is double that of **1**. If this was an ideal living polymerisation (very fast initiation: $k_i \gg k_p$, and absence of chain transfer or termination reactions) [22], the theoretical molecular weight expected for the polymerisation catalysed with **1** ($\overline{M}_n = 2M_{CNR}[CNR]_o/[Ni]_o$) would be double that expected with **8** ($\overline{M}_n = M_{CNR}[CNR]_o/[Ni]_o$) (Fig. 3) since the polymer growth would occur at both Ni centres of **1**, and both chains would be chemically linked by the 2,2′-dicyclopentadien-di-yl propane spacer, as shown in Scheme 2. In Fig. 2, it can be seen for both catalysts that the molecular weight polymerisation is not a living polymerisation system and hence chain tranfer and/or slow initiation processes are occurring. Nevertheless, it is clear that at lower [CNR]$_o$/[Ni]$_o$ ratios the binuclear catalyst **1** produces a poly(*S*(−)-1-phenylethyl isocyanide) with higher molecular weight than that obtained with the mononuclear catalyst **8**. We believe these results strongly suggest an initiation step proceeding from the migratory insertion of CNR into the Ni—Cp bond, although at higher ratios, $\overline{M}_n$ values of **1** and **8** become similar, which can be attributed to significant chain transfer reactions.

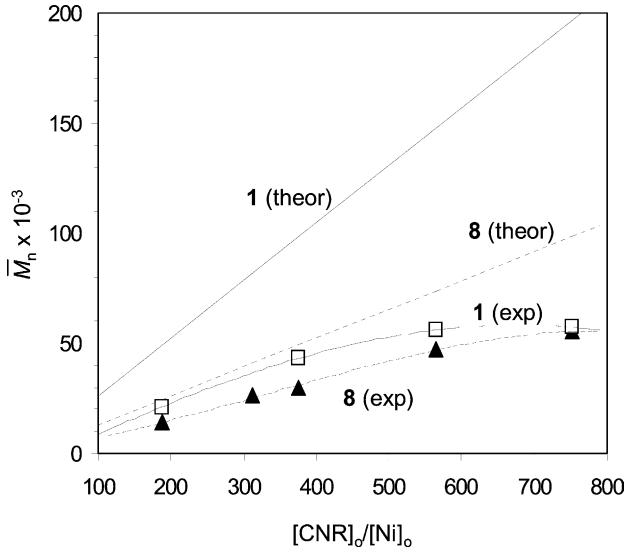

Fig. 2. Plots of the experimental $\overline{M}_n$ values of polyisocyanide *versus* the initial concentration [CNR]$_o$/[Ni]$_o$ obtained after 100% conversion of *S*-(−)-C≡NCH(Ph)Me catalysed by **1** (white squares, continuous line) and **8** (black triangles, dashed line). The straight lines represent the theoretical values expected for living polymerisation. Conditions: 25 °C; under N$_2$; [Ni]$_o$ = 1.44 mM; solvent: CH$_2$Cl$_2$, 4 ml.

Information on the propagation step was obtained by acquiring the EPR spectrum of the reaction mixture of polymerisation of *S*(−)-CNCH(Ph)Me catalysed by **1** after 10 min of reaction. The experimental spectrum obtained at 77 K and three simulated spectra are shown in

Table 2
Catalytic activities of compounds **1** and **8** in the polymerisation of *S*-(−)-C≡NCH(Ph)Me (solv: CH$_2$Cl$_2$ (4 ml); 25 °C; under N$_2$)

Reaction No.	Catalyst	[Ni]$_o$ (mM)	[CNR]$_o$/[Ni]$_o$	Time (min)	Conversion (%)	N_t[d] (min^{-1})	$k_p \pm 0.005$ (l mol^{-1} s^{-1})
AFP73	**1**	1.43	502	32.5	25.1	3.9	0.087

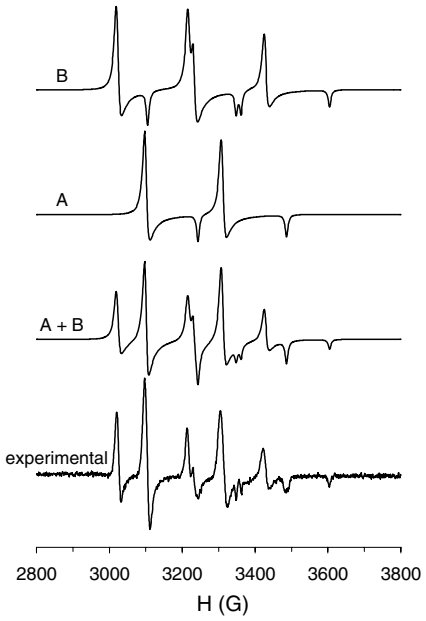

Fig. 3. EPR spectra (77 K) of the reaction mixture of the polymerisation of *S*-(−)-CNCH(Me)Ph catalysed by **1**, after 10 min, at 20 °C, under N_2, and corresponding simulations (**A**, **B** and **A** + **B** – see Scheme 3). Conditions: $[Ni]_o = 1.2 \times 10^{-2}$ M; $[CNR]_o/[Ni]_o = 312$; CH_2Cl_2 (100 μl).

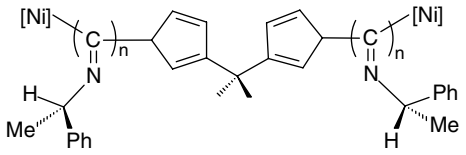
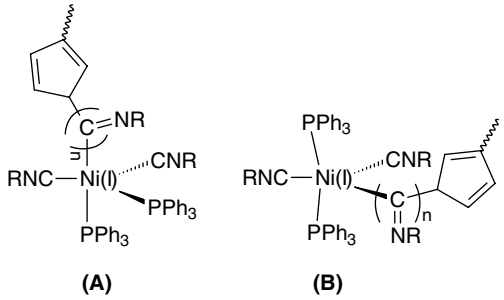


Scheme 2.

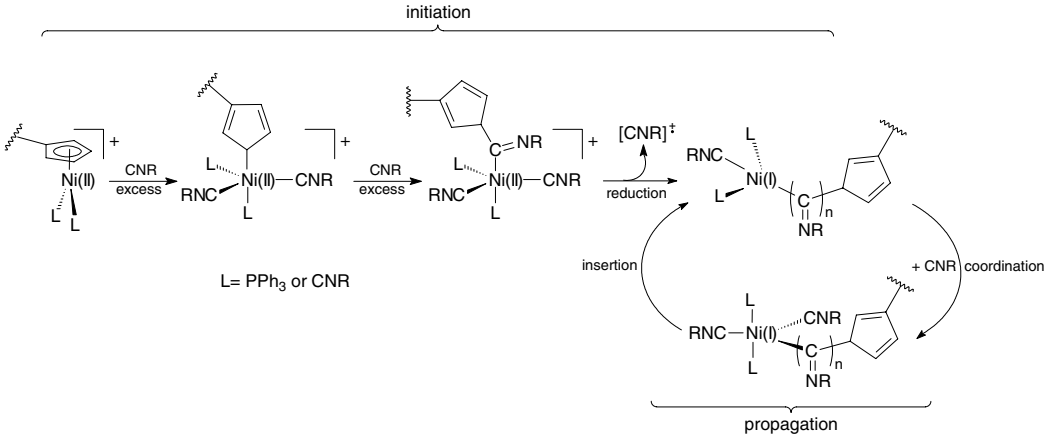
Fig. 3. The spectrum suggests the presence of a mixture of two nickel(I) pentacoordinated ($3d^9$) species, presumably **A** and **B** (Scheme 3), both with trigonal bipyramidal geometry and a d_{z^2} ground state [23]. The spectrum of species **A** was simulated with values of $g_\perp = 2.105$ and $g_\parallel = 2.005$ and hyperfine couplings to one phosphorus atom with $A_\perp = 210$ and $A_{||} = 243$ G. The chain propagating species **A** contains at least one coordinated phosphine ligand, which is positioned in the axial position, and the other phosphine ligand is either coordinated in the equatorial plane or dissociated from the metal atom (substituted by an isocyanide). The chain propagating species **B** shows an EPR spectrum that was simulated with $g_\perp = 2.092$ and $g_\parallel = 2.005$ and hyperfine couplings to two inequivalent phosphorus atoms: $A^1_\perp = 210$ and $A^1_\parallel = 256$ G and $A^2_\perp = 196$ and $A^2_\parallel = 243$ G. This result suggests that the two phosphine ligands occupy the axial positions of an axially distorted trigonal bipyramid. These observations are in good agreement with those of Deming and Novak [7] and our own previous results [10] concerning the formation of trigonal bipyramidal (TBP) Ni(I) species during the polymerisation of the same isocyanide catalysed by allyl derivatives of nickel. It was shown that the allyl group acts as a sacrificial ligand, undergoing a fast insertion of isocyanide into the Ni–allyl bond and hence giving rise to a rapid polymerisation initiation step. In the presence of an excess of isocyanide in the polymerisation mixture, the existence of pentacoordinated TBP Ni(II) species is favoured. The latter will be rapidly reduced to Ni(I) tetrahedral species by homolytic cleavage of a Ni—CNR bond in the TBP Ni(II) complex. This can be explained on the basis of the molecular orbital diagrams for TBP d^8 complexes, which show the molecular orbitals centered in e′ ($d_{x^2-y^2}$ and d_{xy}) are anti-bonding in character and thus coordination of strong donor ligands will induce the weakening of the equatorial Ni—CNR bond. [7,23d,24]. The excess of CNR in the reaction mixture induces the coordination of CNR to the Ni(I) tetrahedral complex generating the TBP Ni(I) species, which are clearly detected by EPR. The chain growth (propagation step) occurs by migratory insertion of isocyanide into the nickel–polyiminic chain bond. The mechanism proposed for the initiation and propagation steps of the polymerisation is shown in Scheme 4. A radical mechanism for this polymerisation is ruled out since reactions performed in the presence of 1–5 equivalents of radical traps like BHT or galvinoxyl (a stable free radical) do not change substantially the polymerisation rate constant k_p (reactions AFP136 and 137 versus AFP73 in Table 2). A detailed mechanistic study on the polymerisation of isocyanides with related cationic nickel complexes will be published elsewhere.



Scheme 3.

3. Experimental

All manipulations of air and/or moisture sensitive materials were carried out under an inert atmosphere using a dual vacuum/nitrogen line and standard Schlenk techniques. Nitrogen gas was supplied in cylinders by Air Liquide, and purified by passage through 4 Å molecular sieves. Solvents and solutions were trans-



Scheme 4. Mechanism proposal for the initiation and propagation steps of the polymerisation of *S*-(−)-1-phenylethyl isocyanide catalysed by **1**.

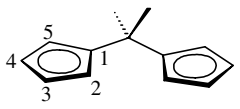
ferred using a positive pressure of nitrogen through stainless steel cannulae and mixtures were filtered in a similar way using modified cannulae that could be fitted with glass fibre filter disks. Unless otherwise stated, reagents were purchased from commercial suppliers (Aldrich, Fluka et sim.) and used without further purification. All solvents to be used under inert atmosphere were thoroughly deoxygenated and dehydrated before use. They were dried and purified by refluxing over a suitable drying agent followed by distillation under nitrogen. The following drying agents were used: sodium/benzophenone for toluene, benzene, tetrahydrofuran and diethyl ether; calcium hydride for hexane, dichloromethane and *o*-dichlorobenzene. Deuterated solvents were dried by storage over 4 Å molecular sieves and degassed by the freeze-pump-thaw method.

Nuclear magnetic resonance spectra were recorded on a Varian Unity 300 spectrometer at the following frequencies: ^{1}H at 299.995 MHz; ^{13}C at 75.4296 MHz; ^{31}P at 121.417 MHz. Spectra were referenced internally using the residual protio-solvent resonance relative to tetramethylsilane (^{1}H and ^{13}C, $\delta = 0$) or 85% H_3PO_4 (^{31}P, $\delta = 0$). All chemical shifts are quoted in δ (ppm) and coupling constants are given in Hz. Multiplicities are abbreviated as follows: singlet (s), doublet (d), triplet (t), heptet (h), multiplet (m), broad (br). Assignments were supported by one-dimensional nuclear Overhauser effect experiments and one- and two-dimensional homo- and hetero-correlations, as appropriate. Electron paramagnetic resonance spectra were recorded on a Bruker ESP-300E X-band spectrometer, at 77 K, and were simulated with the programme Win EPR Simfonia (Bruker). The FT-IR spectra were recorded on a Mattson FTIR 1000, either using KBr disks (organometallic compounds) or a NaCl liquid cell with a path length of 0.2 cm (polymerisation kinetics); the IR relative band intensities are abbreviated as follows: very strong (vs), strong (s), medium (m), weak (w). Elemental analyses were obtained from the IST elemental analysis service (Laboratório de Análises do IST). Masses are quoted in grams (g) for quantities above 1 g and milligrams (mg) for smaller amounts.

The compound $[(PPh_3)_2Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)_2][PF_6]_2$ (**1**) was prepared following the method described in the literature [11]. Cyclohexyl (R = Cy) [25], mesityl (R = 2,4,6-Me_3-C_6H_2) [25], *S*(−)-1-phenylethyl (R = *S*(−)-CH(Ph)Me) [26] and *tert*-butyl (R = ^{t}Bu) [27] isocyanides (C≡N—R) were synthesised according to the literature procedures, from their corresponding *N*-monosubstituted formamides (RNHCHO) which, in turn, were prepared from reaction of the parent amines with ethyl formate [28].

3.1. Synthesis of $[(S\text{-}(-)\text{-}C{\equiv}NCH(Ph)Me)(PPh_3)Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)(S\text{-}(-)\text{-}C{\equiv}NCH(Ph)Me)][PF_6]_2$ (**2**)

A solution of *S*-(−)-1-phenylethylisocyanide (66 μl, 0.48 mmol) in-*o*-dichlorobenzene (2 ml) was added to a brown-yellow solution of $[(PPh_3)_2Ni\{\mu\text{-}(\eta\text{-}C_5H_4)CMe_2(\eta\text{-}C_5H_4)\}Ni(PPh_3)_2][PF_6]_2$ (**1**) (196.5 mg, 0.12 mmol) in *o*-dichlorobenzene ODCB (10 ml). The reaction mixture turned very rapidly to green and, at the end of 2 h, the reaction mixture was concentrated to ca. a third of its volume by partial evaporation of the solvent under vacuum at 35 °C. Addition of Et_2O resulted in the precipitation of a brownish green oil. Filtration of the solvent and dissolution of the oil in CH_2Cl_2 followed by reprecipitation in Et_2O afforded a green powder. Recrystallisation in CH_2Cl_2–Et_2O, by double-layering at −20 °C, gave a green amorphous powder of **2** (160 mg). Yield: 97%. The atom labelling used for the identification of the bridging cyclopentadienyl ^{1}H and ^{13}C NMR resonances in compounds **2**–**5** is shown in the following scheme:



^{1}H NMR (300 MHz, CD_2Cl_2, 23 °C): δ 7.59–7.49 (m, 30H, PPh_3), 7.24–7.15 (m, 6H, $CH(C_6H_5)CH_3$, *meta* and *para*), 6.81 (m, 4H, $CH(C_6H_5)CH_3$, *ortho*), 5.41 (br, 4H, H2 and H5), 5.02 (br, 2H, C*H* $(C_6H_5)CH_3$), 4.91 (br, 4H, H3 and H4), 1.53 (s, 6H, $C(CH_3)_2$), 1.19 (br s, 6H, $CH(C_6H_5)CH_3$); $^{13}C\{^1H\}$ NMR (75.43 MHz, CD_2Cl_2, 23 °C): δ *C*$NCH(C_6H_5)CH_3$ (absent), 136.9 ($CH(C_6H_5)CH_3$, *ipso*), 133.7 (d, $^2J_{CP}$ = 11 Hz, PPh_3, *ortho*), 132.4 (PPh_3, *para*), 130.8 (d, $^1J_{CP}$ = 51 Hz, PPh_3, *ipso*), 129.6 (d, $^3J_{CP}$ = 11 Hz, PPh_3, *meta*), 129.3 ($CH(C_6H_5)CH_3$, *ortho*), 129.1 ($CH(C_6H_5)CH_3$, *para*), 128.6 (C1), 125.9 ($CH(C_6H_5)CH_3$, *meta*), 95.3 (C2 and C5), 93.1 (C3 and C4), 58.3 (*C* $H(C_6H_5)CH_3$), 34.7 (*C* $(CH_3)_2$), 30.4 ($C(CH_3)_2$), 23.0 ($CH(C_6H_5)C$ H_3); $^{31}P\{^1H\}$ NMR (121.44 MHz, CD_2Cl_2, 23 °C): δ 42.1 (s, *P* Ph_3), −143.7 (sept, $^1J_{PF}$ = 712 Hz, *P*F_6^-). FT-IR (KBr disk), cm^{-1}: 2196.2 ($\bar{\nu}$(C≡N), vs), 838.5 ($\bar{\nu}(PF_6^-)$, vs). *Anal.* Calc. for $C_{67}H_{62}F_{12}N_2P_4Ni_2$: C, 58.98; N, 2.05; H, 4.58. Found: C, 58.73; N, 2.11; H, 4.84%.

3.2. Synthesis of [(C≡NCy)(PPh$_3$)Ni{μ-(η-C$_5$H$_4$)CMe$_2$(η-C$_5$H$_4$)}Ni(PPh$_3$)(C≡NCy)][PF$_6$]$_2$ (3)

Following the same procedure as for **2**, a green microcrystalline powder of **3** was obtained. Yield: 96%.

^{1}H NMR (300 MHz, CD_2Cl_2, 23 °C): δ 7.70–7.53 (m, 30H, PPh_3), 5.43 (t, $^3J_{HH}$ = 2.1 Hz, 4H, H2 and H5), 5.02 (t, $^3J_{HH}$ = 2.1 Hz, 4H, H3 and H4), 3.67 (br, 2H, C_6H_{11}, H1′), 1.65 (s, 6H, $C(CH_3)_2$), 1.46 (br, 8H, C_6H_{11}, H2′ and H6′), 1.25–1.00 (m, 12H, C_6H_{11}, H3′, H4′ and H5′); $^{13}C\{^1H\}$ NMR (75.43 MHz, CD_2Cl_2, 23 °C): δ *C* $N(C_6H_{11})$ (absent), 133.9 (d, $^2J_{CP}$ = 10 Hz, PPh_3, *ortho*), 132.4 (PPh_3, *para*), 130.9 (d, $^1J_{CP}$ = 52 Hz, PPh_3, *ipso*), 129.8 (d, $^3J_{CP}$ = 11 Hz, PPh_3, *meta*), 128.4 (C1), 95.3 (C2 and C5), 93.0 (C3 and C4), 56.5 (C_6H_{11}, C1′), 34.7 ($C(CH_3)_2$), 31.7 (C_6H_{11}, C2′ and C6′), 30.5 ($C(CH_3)_2$), 24.7 (C_6H_{11}, C4′), 22.8 (C_6H_{11}, C3′ and C5′); $^{31}P\{^1H\}$ NMR (121.44 MHz, CD_2Cl_2, 23 °C): δ 40.8 (*P*Ph_3), −143.7 (sept, $^1J_{PF}$ = 712 Hz, *P*F_6^-). FT-IR (KBr disk), cm^{-1}: 2202.4 ($\bar{\nu}$(C≡N), vs), 839.2 ($\bar{\nu}(PF_6^-)$, vs). *Anal.* Calc. for $C_{63}H_{66}F_{12}N_2P_4Ni_2$: C, 57.30; N, 2.12; H, 5.04. Found: C, 57.53; N, 2.17; H, 5.03%.

3.3. Synthesis of [(CN^{t}Bu)(PPh$_3$)Ni{μ-(η-C$_5$H$_4$)CMe$_2$(η-C$_5$H$_4$)}Ni(PPh$_3$)(CN^{t}Bu)][PF$_6$] (4)

Following the same procedure as for **2**, lamellar green crystals of **4** were isolated. Yield: 92%. Crystals suitable for X-ray diffraction were available.

^{1}H NMR (300 MHz, CD_2Cl_2, 23 °C): δ 7.75–7.38 (m, 30H, PPh_3), 5.43 (t, $^3J_{HH}$ = 2.3 Hz, 4H, H2 and H5), 5.02 (t, $^3J_{HH}$ = 2.3 Hz, 4H, H3 and H4), 1.65 (s, 6H, $C(H_3)_2$ bridge), 1.01 (s, 18H, $C(CH_3)_3$); $^{13}C\{^1H\}$ NMR (75.43 MHz, CD_2Cl_2, 23 °C): δ *C* $NC(CH_3)_3$ (absent), 133.9 (d, $^2J_{CP}$ = 11 Hz, PPh_3, *ortho*), 132.5 (PPh_3, *para*), 130.9 (d, $^1J_{CP}$ = 52 Hz, PPh_3, *ipso*), 129.8 (d, $^3J_{CP}$ = 11 Hz, PPh_3, *meta*), 128.1 (C1), 95.2 (C2 and C5), 93.2 (C3 and C4), 60.6 s($C(CH_3)_3$), 34.8 ($C(CH_3)_2$ bridge), 30.4 ($C(CH_3)_2$ bridge), 29.3 ($C(CH_3)_3$); $^{31}P\{^1H\}$ NMR (121.44 MHz, CD_2Cl_2, 23 °C): δ 40.8 (*P*Ph_3), −143.7 (sept, $^1J_{PF}$ = 712 Hz, *P*F_6^-). FT-IR (KBr disk), cm^{-1}: 2196.3 ($\bar{\nu}$(C≡N), vs), 840.1 ($\bar{\nu}(PF_6^-)$, vs). *Anal.* Calc. for $C_{59}H_{62}F_{12}N_2P_4Ni_2$: C, 55.87; N, 2.21; H, 4.93. 3.5. Polymerisation reactions

Polymerisation reactions of *S*(−)-1-phenylethyl isocyanide catalysed by compound **1** were carried out in dried 10 cm^3 crown capped glass vials, sealed with rubber septa, containing a small magnetic stir bar and pump filled with nitrogen atmosphere. The reagents were added through the septa using liquid syringes or cannulae. The reaction mixtures were thermostated to 25 ± 0.5 °C in a water bath and the stirring speed kept constant at 500 rpm.

In a typical experiment, 3 cm^3 of a solution of **1** (5.21 μmol) in CH_2Cl_2 were measured in an inert atmosphere pipette and cannulated to the reaction vial. After ther-

mal equilibration, the reaction was initiated by transferring 2.79 mmol of *S*-(−)-CNCH(Ph)Me (312 μl, 300 mg) with a glass Hamilton syringe. For total conversion, the reaction was quenched after 16 h by the addition of a 0.01 M KOH/MeOH solution. The precipitated polymer was redissolved in CH_2Cl_2 and reprecipitated in MeOH with vigorous stirring. The polymer was filtered on a G5 glass sintered filter, washed several times with MeOH and dried under vacuum.

Kinetic data were obtained by collecting 100 μl aliquots of the reaction mixture at various time intervals, which were then diluted in 5 cm^3 volumetric flasks with $CHCl_3$. The concentration of non-reacted *S*(−)-1-phenylethyl isocyanide was determined by measuring the IR absorbance of these solutions at 2146 cm^{-1} (the wavenumber of the absorption peak of the C≡N stretching band) in NaCl liquid cells with a path length of 0.2 cm. The molar concentration of *S*(−)-1-phenylethyl isocyanide was determined using the experimentally measured molar absorptivity value of $\varepsilon_{2146\,cm^{-1}} = 229 \pm 7$ l mol^{-1} cm^{-1}.

The procedure used in the polymerisation reactions carried out in the presence of radical traps like BHT and galvinoxyl was similar to the one described above except that 2 cm^3 of a solution of **1** in CH_2Cl_2 were introduced in the reaction vial followed by the additions of the isocyanide and finally, after 2 min, 1 cm^3 of a CH_2Cl_2 solution containing 1–5 equivalents of the radical trap in relation to Ni.

3.6. Polymer characterisation

Polymer molecular weights were measured by gel permeation chromatography/size exclusion chromatographyon (GPC/SEC) a Waters 150 CV chromatograph, using a series of three columns Ultrastyragel, HR1, HR3, HR4 (10 μm; 7.8 × 300 mm), at 35 °C, in tetrahydrofuran and at a flow rate of 1 cm^3 min^{-1}; the calibration was made using polystyrene standards (TSK Tosoh Co.). The polymer powders, ranging from pale yellow (higher molecular weights) to deep red (lower molecular weights), could be characterised by FT-IR in the solid (KBr disks) or in $CHCl_3$ solutions (NaCl liquid cells) by the presence of a strong absorption peak corresponding to the C=N iminic bond vibration at 1628–1635 cm^{-1}. Selected polymer samples were characterised by ^1H and $^{13}C\{^1H\}$ NMR spectroscopies and their spectra confirmed to be similar to those reported in the literature for poly(*S*-(−)-1-pheneyletyl isocyanide) [29]. Some of the samples, dissolved in $CHCl_3$ (c = 1 g cm^{-3}), were also analysed by polarimetry, on an Atago Polax-L polarimeter (path length = 1 dm), and circular dichroism (CD) spectroscopy, on a Jasco 720 spectropolarimeter with a 175–800 nm photomultiplier, revealing identical features (negative specific rotations, $[\alpha]_D^{20}$, and CD spectra) to those found in the literature [30].

3.7. X-ray structure determination of *4*

Crystals of **4** suitable for diffraction measurements were sealed in glass capillaries under dinitrogen. Data was collected in a TURBO CAD4 rotating anode equipped with Cu Kα (λ = 1.5418 Å) radiation by the ω–2θ scan mode. Unit cell dimensions were obtained from the refinement of the setting angles of 25 reflections $17° < \theta < 20°$. Data was corrected for Lorentz polarisation and linear decay. No absorption correction was made. The Molen software (Enraf-Nonius) was used in the data reduction.

The structure was solved by direct methods using SIR-97 [31] and refined with SHELXL [32], programs included in WinGX v1.64.05 (PC version) [33]. All non-hydrogen atoms were refined with anisotropic thermal motion parameters based on F^2 and all hydrogen atoms were inserted in idealised positions and refined riding on the parent C atom. The poor diffracting power and low quality of the crystal precluded a better refinement and prevented the structural analysis with the accuracy we expected. All the final R values, as can be seen in Table 3, are very high, but this should be expected due to the

Available online 15 July 2004

Abstract

The reactions of $RuCl_2[P(C_6H_5)_3]_3$ with excesses of various aromatic amines led to six coordinate, pseudo-octahedral complexes. Thus, three equivalents of pyridazine or 3-methylpyridazine could be incorporated, or two equivalents of pyrazole or phthalazine, all as monodentate ligands. Reaction with 1,8-naphthyridine led to the incorporation of one bidentate ligand. X-ray structural data were obtained for the pyridazine, phthalazine and 1,8-naphthyridine complexes.

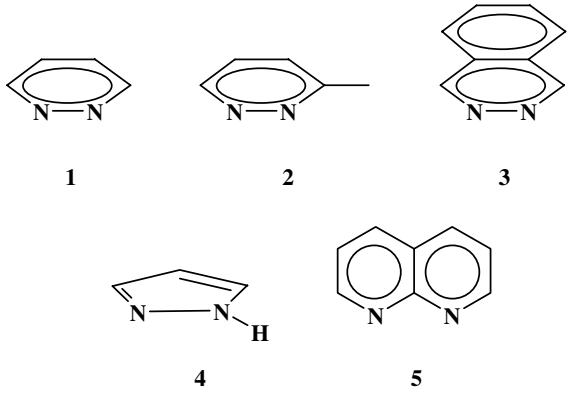
1. Introduction

The chemistry involving ruthenium complexes of aromatic amines such as pyridine, 2,2-bipyridine and pyrazine has been remarkably productive, yielding important contributions in a number of areas, including mixed valence compounds and photochemistry [1]. However, in the vast majority of these compounds, the ligand complements do not allow for direct Ru–Ru interactions, although these may easily be generated using a number of other ligands, such as the relatively simple acetate ion and various analogues [2]. We have therefore undertaken the preparations of ruthenium complexes containing aromatic polyamine ligands which could potentially lead to complexes with direct metal–metal interactions. In this study, we have examined reactions of $RuCl_2[P(C_6H_5)_3]_3$ with several relatively simple aromatic diamines, including pyridazine (**1**), 3-methylpyridazine (**2**), phthalazine (**3**), pyrazole (**4**) and 1,8-naphthyridine (**5**).



2. Experimental

All reactions were carried out under an atmosphere of nitrogen, using Schlenk techniques and apparatus. Solvents were dried and deoxygenated by distillation from CaH_2 (for CH_2Cl_2) or sodium benzophenone ketyl or by passing through columns of activated alumina, under a nitrogen atmosphere in each case. $RuCl_2[P(C_6H_5)_3]_3$ was prepared by a published procedure [3], while the diamines were all obtained from commercial sources. Elemental analyses were obtained from E&R Microanalytical Laboratories. NMR spectra were obtained as previously described [4].

2.1. Dichlorotris(pyridazine)(triphenylphosphine)ruthenium, $RuCl_2[P(C_6H_5)_3](C_4N_2H_4)_3$ (**6**)

To a magnetically stirred yellow-brown slurry of 1.0 g (1.0 mmol) $RuCl_2(PPh_3)_3$ in 20 ml THF were added 0.40 ml (5.5 mmol) of pyridazine via syringe. The solution rapidly changed color to a bright orange-red. The flask was swirled several times until all solids dissolved and then it was left undisturbed for 18 h. After several hours, bright red crystals began to precipitate from the solution. These crystals were isolated by removing the supernatant, washing with two 20 ml and one 10 ml portions of ether, and drying in vacuo. 0.56 g of product were isolated, corresponding to a yield of 80%. Monoclinic crystals suitable for a single crystal X-ray diffraction study were grown by layering a solution of the compound in CH_2Cl_2 with an equal volume of hexane. A similar procedure using a more concentrated solution led to orthorhombic crystals (space group *Pbca*, $a = 10.2872(3)$, $b = 23.6429(12)$, $c = 33.5918(17)$ Å at 293(1) K), having a higher solvent content, and yielding a similar, but less satisfactory, structural result.

^{1}H NMR (CD_2Cl_2 ambient): δ 10.74 (dt, 2H, H(1,9), $J = 5.7$, 1.4 Hz), 8.81 (dt, 1H, H5, $J = 6.0$, 1.4 Hz), 8.33 (m, 3H, H(4,8,12)), 7.55 (tt, 6H, $H_o(PPh_3)$, $J = 8.1$, 1.2 Hz), 7.43 (ddd, 2H, H(2,10), $J = 8.1$, 7.1, 2.1 Hz), 7.22 (ddd, 2H, H(3,11), $J = 8.0$, 6.5, 1.6 Hz), 7.12 (tq, 3H, $H_p(PPh_3)$, $J = 7.4$, 1.5 Hz), 6.97 (td, 6H, $H_m(PPh_3)$, $J = 7.7$, 1.8 Hz), 6.90 (ddd, 1H, H7, $J = 8.0$, 4.9, 1.5 Hz), 6.45 (ddd, 1H, H6, $J = 8.1$, 6.0, 2.1 Hz).

Anal. Calc. for $C_{30}H_{27}Cl_2PN_6Ru$: C, 53.42; H, 4.03; N, 12.46. Found: C, 53.77; H, 4.02; N, 12.13%.

2.2. Dichlorotris(3-methylpyridazine)(triphenylphosphine)ruthenium, $RuCl_2[P(C_6H_5)_3](3\text{-}CH_3C_4N_2H_3)$

To a stirred yellow-brown slurry of 0.50 g (0.52 mmol) $RuCl_2(PPh_3)_3$ in 20 ml of THF under nitrogen at ambient temperature were added 0.25 g (2.7 mmol) of 3-methylpyridazine via syringe. The reaction mixture rapidly converted to a bright red solution and was stirred overnight. After ca. 18 h, 50 ml of hexane were added with stirring to precipitate the product. The bright red-orange precipitate was collected on a medium frit, washed with 3×10 ml ether, and dried in vacuo. Yield: 285 mg, 75%.

^{1}H NMR ($CDCl_3$ ambient): δ 10.74 (d, 2H, H_o-Mepyd, $J = 5.7$ Hz), 8.52 (d, 1H, H_o-Mepyd, $J = 5.7$ Hz), 7.66 (t, 6H, H_m-PPh_3, $J = 8.4$ Hz), 7.26 (dd, 2H, H_m-Mepyd, $J = 7.8$, 6.0 Hz), 7.09 (t, 3H, H_p-PPh_3, $J = 6.9$ Hz), 7.02–6.90 (m, 8H, H_o-PPh_3 and H_p-Mepyd), 6.68 (d, 1H, H_p-Mepyd, $J = 7.8$ Hz), 6.48 (dd, 1H, H_m-Mepyd, $J = 7.8$, 6.0 Hz), 2.09 (s, 6H, Me), 1.90 (s, 3H, Me).

Anal. Calc. for $C_{33}H_{33}PCl_2N_6Ru$: C, 55.31; H, 4.64; N, 11.73. Found: C, 55.22; H, 4.53; N, 11.51%.

2.3. Dichlorobis(phthalazine)bis(triphenylphosphine)ruthenium, $RuCl_2[P(C_6H_5)_3]_2(C_8N_2H_6)_2$ (**7**)

To a stirred yellow-brown slurry of 0.50 g (0.52 mmol) $RuCl_2(PPh_3)_3$ in 20 ml THF under nitrogen at ambient temperature were added 0.15 g (1.1 mmol) of phthalazine as a solid. The mixture rapidly converted to a bright orange slurry. After 2 h of stirring, 50 ml of hexane were added and the reaction mixture was stirred for an additional 10 min. The resulting bright orange precipitate was collected on a medium frit, washed with 3×10 ml ether and dried in vacuo. The yield is virtually quantitative, with typical isolated yields greater than 90%. Crystals suitable for diffraction studies were grown in a closed system by slow diffusion of ether vapors into a concentrated CH_2Cl_2 solution of the product. A general description of a similar apparatus has been presented [5]; in this application, a solution of the complex was placed in one side and some ether was placed in the other side, thus leading to vapor phase transfer of each solvent to the other side. In other cases, simple evaporation of one solvent may be achieved by placing diphenylmethane in the other side.

Anal. Calc. for $C_{52}H_{42}P_2Cl_2N_4Ru$: C, 65.27; H, 4.42; N, 5.86. Found: C, 65.23; H, 4.82; N, 5.41%.

2.4. Dichloro(1,8-naphthyridine)bis(triphenylphosphine)-ruthenium, $RuCl_2[P(C_6H_5)_3]_2(1,8\text{-}C_8N_2H_6)$ (**8**)

To a stirred yellow-brown slurry of 0.50 g (0.52 mmol) $RuCl_2(PPh_3)_3$ in 20 ml of THF under nitrogen at ambient temperature were added 80 mg (0.61 mmol) of 1,8-naphthyridine as a solid. A rapid color change to bright purple was followed by the precipitation of a purple solid. After stirring for approximately 10 min, the supernatant appeared virtually colorless. The purple precipitate was collected on a medium frit, washed with 3×10 ml ether and dried in vacuo. Yields for this reaction appeared quantitative, with isolated yields typically above 90%. Crystals suitable for diffraction studies were grown in a Schlenk tube by carefully layering hexane onto a concentrated solution of the compound in CH_2Cl_2.

Anal. Calc. for $C_{44}H_{36}P_2Cl_2N_2Ru$: C, 63.93; H, 4.39; N, 3.39. Found: C, 63.85; H, 4.53; N, 3.18%.

2.5. Dichlorobis(pyrazole)bis(triphenylphosphine)ruthenium, $RuCl_2[P(C_6H_5)_3]_2(C_3N_2H_4)_2$ (**9**)

To a magnetically stirred slurry of 0.50 g (0.52 mmol) $RuCl_2(PPh_3)_3$ in 20 ml THF were added 0.10 g (1.5 mmol) of pyrazole. A rapid color change to red was observed, followed by a slower (2–3 min) transition to yellow. The color change to yellow occurred much more rapidly if a large excess of pyrazole was used. The solution was stirred for 18 h and the solvent removed in

vacuo to yield a thick yellow oily solid. The solid was washed with 3×10 ml pentane and dried in vacuo. The powdery residue was extracted with 3×10 ml CH_2Cl_2 and filtered through a coarse frit with a Celite pad. The bright yellow filtrate was concentrated to ca. 10 ml and carefully layered with 50 ml hexane. After the flask had been left undisturbed for 24 h, yellow crystals were deposited on the sides of the flask. The supernatant was removed and the crystals were washed with 3×10 ml ether and dried in vacuo. 0.370 g of product were isolated, corresponding to a yield of 85%. Solutions of the product rapidly turn green upon exposure to air.

2.6. Crystallographic studies

Single crystals for X-ray diffraction study were fixed to glass fibers using Paratone oil and thereafter transferred to a Nonius Kappa CCD diffractometer for study. Structures were solved using direct method programs provided in the SIR-97 or SHELXL-97 program packages. All non-hydrogen atoms were subjected to anisotropic refinement. For **6**, the hydrogen atoms were refined isotropically, including those in a molecule of solvent CH_2Cl_2. It can be noted that crystals having a higher CH_2Cl_2 content could also be obtained (see Section 2.1), but the solvent was poorly behaved, and a less satisfactory structure was obtained. The hydrogen atoms in **7** were also refined isotropically, except for those associated with the solvent molecules. These atoms were allowed to ride on their respective carbon atoms. Two CH_2Cl_2 molecules, one of half occupancy, were incorporated into this lattice. For **8**, all but one hydrogen atom, H44, could be refined isotropically. That one was refined with a fixed thermal parameter. A summary of crystal and data collection parameters is given in Table 1, while pertinent bonding parameters for **6**–**8** are listed in Tables 2–4.

3. Results and discussion

The reactions of $RuCl_2[P(C_6H_5)_3]_3$ with excesses of pyridazine, 3-methylpyridazine, phthalazine, pyrazole and 1,8-naphthyridine in each case led to a six-coordinate ruthenium(II) complex, as summarized in Scheme 1. The reactions involving pyridazine or 3-methylpyridazine resulted in the incorporation of three equivalents of the ligand, together with expulsion of two phosphine ligands. In contrast, the reactions with phthalazine, pyrazole or 1,8-naphthyridine brought about the loss of only one phosphine ligand, leading only to the incorporation of two phthalazines, two pyrazoles or one (chelating) 1,8-naphthyridine ligand(s). The constitutions of these complexes have been established through analytical data, NMR spectroscopy when solubility permitted, and for **6**–**8**, through single crystal X-ray diffraction studies. In each case where meaningful

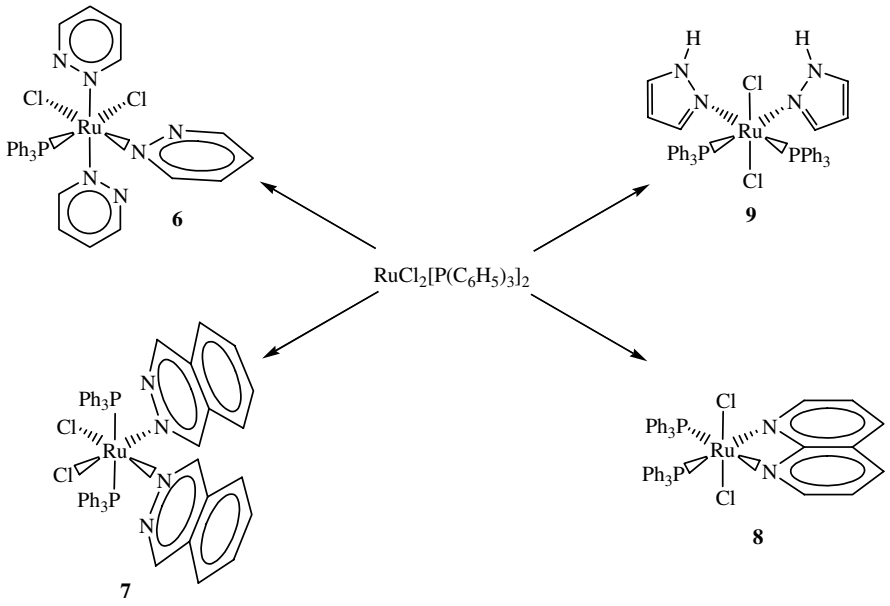
NMR data could be recorded, the spectral results were indicative of the presence of only one isomer, which was also consistent with the structural results.

The product of the reaction with excess pyridazine was found to adopt a *mer,cis* arrangement of ligands in a pseudooctahedral coordination environment (**6**), Fig. 1. A similar structure can be assumed for the 3-methylpyridazine complex, and this would be consistent with the NMR results which revealed two types of amine ligands in a 2:1 ratio. As would be expected, there is some evidence of inter-ligand steric repulsion involving the phosphine ligand, as the P–Ru–N angles all exceed 90° (91.22(5)–97.06(5)°), thereby leading to generally acute N–Ru–Cl2 angles (85.56(5)–90.05(5)°). While other angles also deviate from their ideal values, the presence of six aromatic rings in the complex can be expected to result in C–H/π [6] and/or π/π [7] interactions, whether intramolecular or intermolecular [8], which could play an even larger role than the steric effects and therefore complicate further comparisons.

Although there seem to be no other examples of structurally characterized ruthenium complexes containing both phosphine and the simple pyridazine ligands, and just a few for transition metals generally [9], some comparisons may be made with various more common poly(amine) species. Thus, the Ru–N distances of 2.060(2)–2.076(2) Å in **6** are similar to values of 2.049(2) and 2.084(3) Å in neutral pyridyl-substituted pyridazine complexes [10], as well as to those in a mixed valence Ru(II,III) complex [11], but longer than those in related cationic species (1.986(10)–2.031(7) Å) [12], and shorter than Ru–N bonds in trimetallic carbonyl complexes in which pyridazine coordinates to two adjacent ruthenium(0) centers (2.11(1)–2.136(4) Å) [13]. Likewise, the Ru–Cl distances of 2.4309(5) and 2.4665(5) Å are reasonably similar to values ranging from 2.392(1) to 2.431(1) Å in the related cationic or carbonyl-containing complexes. The Ru–P distance of 2.2976(5) Å may be compared to values in the range of 2.23–2.44 Å found for two modifications of $RuCl_2[P(C_6H_5)_3]_3$ [14].

Notably, the reaction of $RuCl_2[P(C_6H_5)_3]_3$ with phthalazine led only to the incorporation of two equivalents of ligand, rather than three. As the resulting $RuCl_2[P(C_6H_5)_3]_2(C_8H_6N_2)_2$ complex contains an extra phosphine ligand compared to **6**, the additional steric crowding may block access of a third amine ligand to the metal center; alternatively it could be that the lower solubility of this complex compared to its hypothetical pyridazine analogue led to **7**'s precipitation before a third incorporation could take place. Consequently, it could be possible to bring about the third incorporation using other solvents and/or more forcing conditions. A structural determination revealed the complex to have a *cis,trans,cis* pseudooctahedral geometry (Fig. 2), so the chloride ligands have remained *cis* to each other. The two $P(C_6H_5)_3$ ligands are located *trans* to each other, with one phenyl group from each pointed between the two chloride ligands. This results in the other phenyl groups being directed towards the phthalazine ligands,



Scheme 1.

presumably in order to optimize C–H/π and π/π interactions. It seems quite possible that these interactions could play a role in stabilizing the observed *cis,trans,cis* isomer, and if the additional fused rings of the phthalazine ligands do not engage in any substantial stabilizing intermolecular interactions, such an arrangement could be found for the analogous pyridazine complex which would be a likely intermediate in the formation of **6**.

While there are no other structurally characterized (phthalazine)ruthenium complexes to compare with **7**, and only a few transition metal complexes containing both phosphine and phthalazine ligands [9c,15], one can note that the Ru–N distances for **7** are slightly shorter than those for **6**. The two Ru–P bonds are lengthened relative to the one in **6**, but are similar to the nearly *trans* Ru–P bonds in $RuCl_2[P(C_6H_5)_3]_3$ [14], whereas as noted before, the unique Ru–P bond in $RuCl_2[P(C_6H_5)_3]_3$ (ca. 2.23 Å) is similar to the Ru–P distance in **6**. The lengthening of the Ru–P bonds in **7** thus appears to be electronic in origin. The Ru–Cl bond distances for **6** and **7** are not significantly different from each other, but are longer than the values of ca. 2.38–2.39 Å in $RuCl_2[P(C_6H_5)_3]_3$.

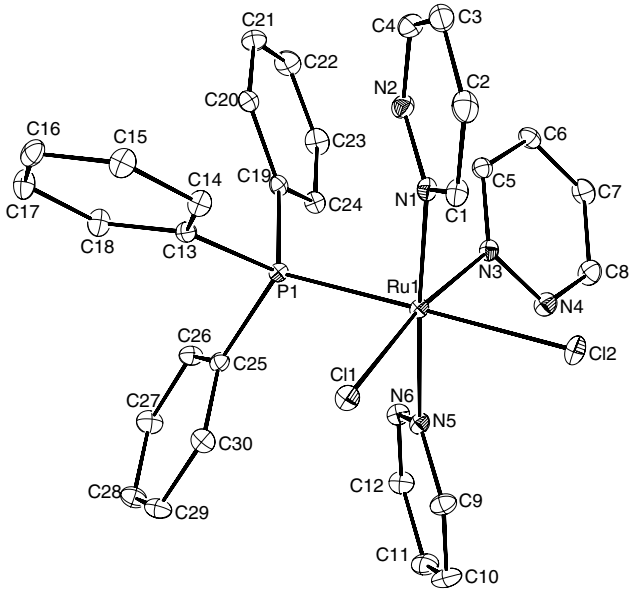


Fig. 1. Perspective view and numbering scheme for $RuCl_2[P(C_6H_5)_3](C_4N_2H_4)_3$ (**6**).

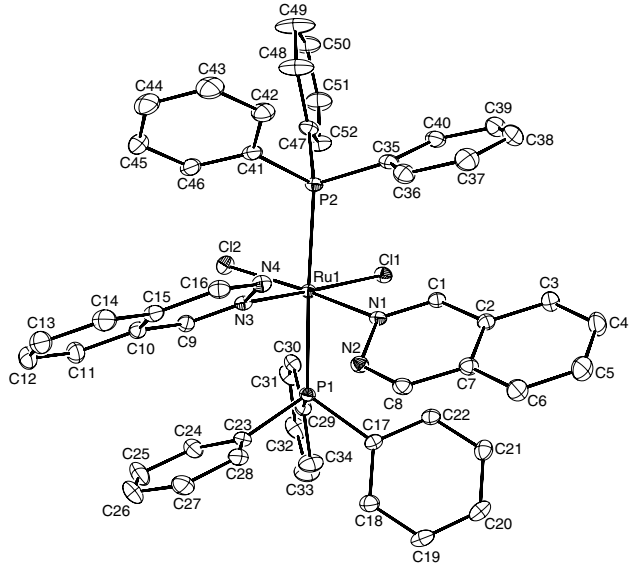

Fig. 2. Perspective view and numbering scheme for $RuCl_2[P(C_6H_5)_3]_2(C_8N_2H_6)_2$ (**7**).

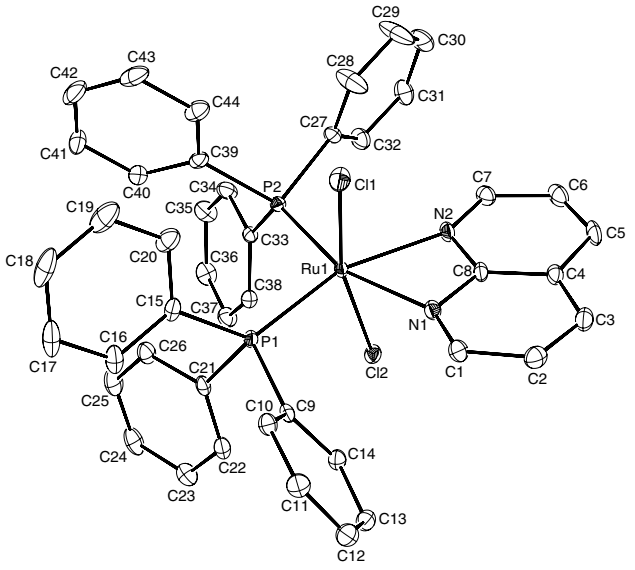

Fig. 3. Perspective view and numbering scheme for $RuCl_2[P(C_6H_5)_3]_2(1,8\text{-}C_8N_2H_6)$ (**8**).

The reaction of $RuCl_2[P(C_6H_5)_3]_3$ with 1,8-naphthyridine was unique in leading to the incorporation of only one ligand, at least under mild conditions, although a bidentate coordination mode was adopted in the product (**8**). Perhaps as a result of the smaller spatial requirements of the chelating diamine as compared to the two phthalazine ligands in **7**, the phosphine ligands in **8** adopt a *cis* rather than *trans* orientation, with the chlorides becoming *trans* (Scheme 1, Fig. 3). Nonetheless, the marked asymmetry in the Ru–P–C angles (Table 3) seems to reveal the presence of some steric interactions between the phosphine ligands. In contrast, the Ru–P–C angles in the other complexes were more regular, although $RuCl_2[P(C_6H_5)_3]_3$ also displays a distortion [14]. In any event, this arrangement leads to an apparently favorable orientation for intramolecular C–H/π interactions between two of the naphthyridine hydrogen atoms and two of the phosphine phenyl groups [6]. The N1–Ru–N2 angle is of necessity quite small, at 60.81(9)°, thereby allowing for the P1–Ru–P2 angle to expand to 97.45(3)°. The chloride ligands are bent away from the phosphines toward the diamine, with a Cl1–Ru–Cl2 angle of 164.89(3)°. Presumably due to the lack of alignment between the nitrogen lone pairs and the metal center, the Ru–N distances in **8** (2.217(3), 2.222(2) Å) are notably longer than those in **6** and **7**. In turn, however, the opposite trend is observed for **8**'s Ru–Cl (2.4050(9), 2.4242(9) Å) and Ru–P bonds (2.2819(7), 2.3040(8) Å).

Although there seem to be no structurally characterized examples of ruthenium complexes containing both phosphine and 1,8-naphthyridine ligands, two reports of chelating (naphthyridine)ruthenium complexes have appeared. The Ru–N distances in $Ru(2,2'\text{-}bpy)_2(1,8\text{-}C_8N_2H_6)^{2+}$ average 2.11(1) Å for the naphthyridine ligand [16], while in a more complicated, amino-substituted 1,8-naphthyridine complex [17], a highly asymmetric coordination is observed, with Ru–N distances of 2.066(6) and 2.377(7) Å. More common than the observed monometallic chelating coordination mode are the monodentate bonding mode (with Ru–N distances to date of 2.078(9)–2.137(6) Å) [16,18] and a bridging mode in which the nitrogen centers are coordinated to different ruthenium centers which generally would be connected by a Ru–Ru bond [17,19,20]. In these cases, the Ru–N distances range from 2.00(3) to 2.21(3) Å. Likewise, the monodentate coordination mode has been observed in phosphine-containing complexes of gold [21] and platinum [22], while the bridging mode has been observed in a dicopper phosphine complex [23].

The reaction of an excess of the five-membered ring ligand pyrazole with $RuCl_2[P(C_6H_5)_3]_3$ led only to the incorporation of two equivalents, and the expulsion of one phosphine ligand, analogous to the reaction involving phthalazine rather than to that of pyridazine. Attempts to incorporate a third equivalent of pyrazole using a large (10 equiv.) excess of pyrazole under reflux conditions did not lead to any observable change. The ^1H NMR spectrum demonstrated that the two phosphine ligands were equivalent, as were the two pyrazoles. The overall complex stoichiometery, $RuCl_2[P(C_6H_5)_3]_2(C_3N_2H_4)_2$, again corresponds to a six-coordinate, pseudo-octahedral complex. A structural study has revealed that it adopts a different arrangement than that of **7** (Scheme 1) [24].

4. Summary

The complex $RuCl_2[P(C_6H_5)_3]_3$ has been found to be a useful starting material for the formation of polybasic aromatic amine complexes of ruthenium. Despite the potential abilities of pyridazine, pyrazole, phthalazine and 1,8-naphthyridine to bridge more than one metal center, none of the complexes involved such bridging, although the 1,8-naphthyridine ligand did chelate a single metal center. Each complex retained one or two of the triphenylphosphine ligands, whose steric bulk may have prevented the formation of dimetallic complexes. To some extent the product that was isolated was determined by solubility considerations, suggesting that additional incorporations could be achieved in some cases. Likewise, for at least pyrazole and pyridazine, it appears possible to limit the extent of incorporation through stoichiometry [24]. Notably, initial attempts to incorporate additional metal centers into the pyridazine complex have tended to lead instead to ligand exchange reactions [24], as has been seen for pyrazine complexes [25]. Possibly the use of less acidic metal centers or the

deprotonation of coordinated pyrazole, which would lead to a more basic ligand that has been successfully employed for preparing heterobimetallic complexes [26], may be used to inhibit such exchanges. It is of final interest to note the recent report of a related Re(III) complex, $ReCl_3[P(C_6H_5)_3]$ $(C_3N_2H_4)_2$ [27].

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC, Nos. 236487-236489 for compounds **8**, **7** and **6**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ (fax: +44-1223-336033) or email deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk.

Abstract

The dialkyl complexes containing β-hydrogen atoms:W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$]R_2 (R = Et, *n*-Pr, *i*-Bu, CH_2CH_2Ph) have been prepared.These compounds are indefinitely stable in solution at room temperature in the absence of air and moisture.The diethyl complex reacts with PMe_3 at room temperature ($t_{1/2}$ = 12 min) to give ethane and the W(IV) ethylene complex, W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$](η^2-CH_2CH_2)$(PMe_3)_2$.A mechanistic study of this reaction has revealed that the reaction is first order in W and PMe_3, with $\Delta H^{\ddagger}$ = 5.1(0.6) kcal mol^{-1} and $\Delta S^{\ddagger}$ = −54.9(2.0) cal mol^{-1} K^{-1}.A large primary kinetic isotope effect (k_H/k_D = 6.1(0.5) at 20 °C) was observed for the transformation.These observations are consistent with the reaction proceeding via direct H transfer from the β-carbon of one ethyl group to the α-carbon of the other ethyl group.The (bis)phenethyl complex reacts with PMe_3 at elevated temperature to give ethylbenzene and the W(IV) styrene complex, W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$](η^2-CH_2CHPh)$(PMe_3)_2$.Significantly different activation parameters ($\Delta H^{\ddagger}$ = 13.7(0.8) kcal mol^{-1} and $\Delta S^{\ddagger}$ = −36.7(2.3) cal mol^{-1} K^{-1}) and a phosphine concentration dependent kinetic isotope effect (k_H/k_D = 6.4(5), [PMe_3] = 0 M; k_H/k_D = 4.3(3), [PMe_3] = 0.4 M; k_H/k_D = 2.4(4), [PMe_3] = 0.8 M; extrapolated to room temperature) were observed, suggesting two competing pathways (β-hydride elimination and β-H abstraction) are accountable for the transformation.

1. Introduction

Over the past 40 years, understanding of the reactivity of transition metal alkyl complexes has grown from the point of view that "the loss of a hydride ion from the β-carbon of suitable transition metal alkyl complexes may well be a general reaction" [1] to a realization that this type of transformation is all pervasive in the chemistry of metal alkyls. Given that transition metal complexes containing metal–carbon bonds play crucial roles in a variety of important catalytic reactions, a detailed understanding of the stability and reactivity of transition metal alkyl complexes remains an important topic in both organometallic chemistry and catalysis [2,41].

For transition metal dialkyl complexes, thermal decomposition often proceeds by intramolecular attack on a C–H bond of an ancillary ligand [3] and several modes of C–H activation, involving α [4], β [5], γ [6], or ε-hydrogen [7] transfer. Among these pathways, the β-elimination process is the most frequently observed thermolysis pathway. Investigating the factors that control the transformation by β-elimination is important to understand the mechanisms of the catalytic processes utilizing transition metal catalysts.

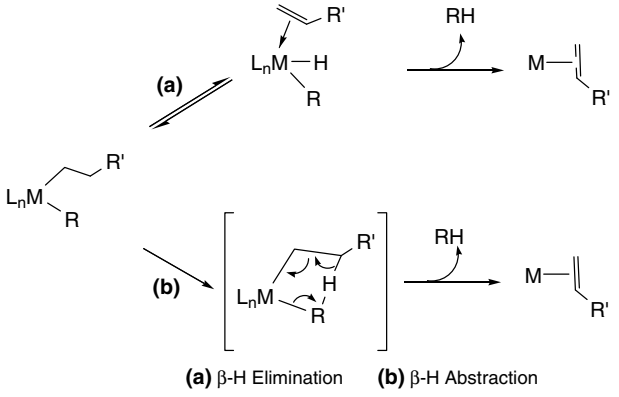
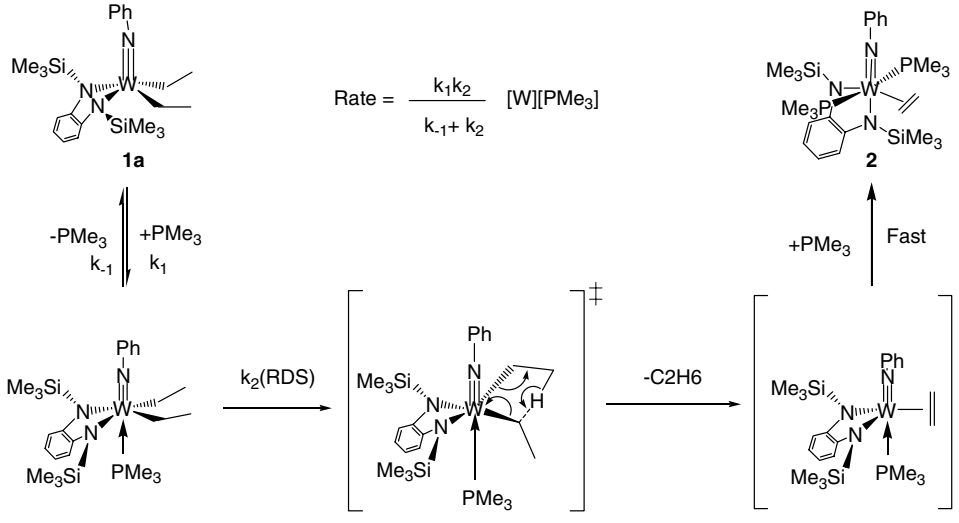
Recent efforts in our laboratory [8] and others [9–13] have focused on the preparation of complexes of early transition metals in groups 3–6 at their highest oxidation states that contain β-hydrogens in one or more substituents. Mechanistic investigations have also been carried out in order to gain insight into the olefin polymerization reactions in which β-H transfer serves as a key termination step. The majority of these studies suggest that the mechanism of β-H transfer proceeds by one of two mechanisms (Scheme 1). One is the well-known β-H elimination pathway [5] in which the hydrido olefin intermediate is formed followed by reductive elimination of the alkane. The other (less common) pathway proposed is β-H abstraction [8–10] in which the β-hydrogen is transferred directly from the β-carbon to another alkyl group in one step, without the formation of the metal hydride intermediate.

Due to the high reactivities of most β-H containing alkyl complexes, typically these complexes can only be observed as intermediates or when they are coordinatively saturated or can be isolated when sterically protected by bulky groups, such as $[(Me_3SiNCH_2CH_2)_3N]^{3-}$ [10]. Green and co-workers [11], Schrock and co-workers [12], and Bercaw and co-workers [13] have reported that the ethyl complexes of some d^0, early transition metals (Ti, Ta, and Sc), are stabilized by a β-agostic interaction. We now report the preparation and crystal structures of a series of coordinatively unsaturated tungsten(VI) dialkyl complexes containing β-hydrogens, the reactivities of these complexes towards trimethylphosphine, and a mechanistic study of the β-H transfer processes in these compounds, including kinetic activation parameters and deuterium isotope effects, for the formation of olefin complexes from **1a** and **1d**.



Scheme 1.

As can be seen in Scheme 1, the two pathways proceed through distinct steps that involve that involve C–H bond breaking and bond making. These pathways will result in different amplitudes of H vibration in the transition states involved in each pathway [14]. Therefore, a good way to distinguish these two pathways is by measurement of the primary kinetic isotope effect. β-H elimination followed by reductive elimination involves two steps in which there are C–H bond breaking or bond making. Thus, the isotope effect observed when reductive elimination is rate limiting is the product of the isotope effect for reductive elimination and the isotope effect associated with β-H elimination (which may be an equilibrium isotope effect). The isotope effect for a β-H elimination followed by reductive elimination usually falls into the range 1.4–2.5 at room temperature. Examples include $PdEt_2(PMePh_2)_2$ (KIE = 1.4) [15], $CoEt_2(acac)(PMe_2Ph)_2$ (KIE = 2.3) [16], $PtEt_2(PEt_3)_2$ (KIE = 1.4 to 1.7) [17], $Cp^*_2ScCH_2CH_2Ph$ (KIE = 2.0) [18] and $(CO)(PPh_3)_2IrCH_2CH_2C_6H_{13}$ (KIE = 2.3) [19]. By comparison, the isotope effect for a linear, symmetrical transition state as occurs in the β-H abstraction path is usually found to be 5–8 at room temperature [20]. Experimental data reported for



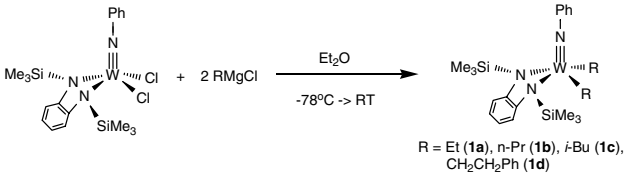
Scheme 2.

$Cp_2Zr(SCH_2Ph)(Me)$ [9], KIE = 5.2, and $[Me_3SiNCH_2CH_2]_3NTa(Et)_2$ [10], KIE = 5.7, are consistent with the proposed near linear transition state for the direct β-hydrogen abstraction pathway.

2. Results

2.1. Synthesis of tungsten(VI) dialkyl complexes

The tungsten(VI) dialkyl complexes **1a**–**1d** were synthesized by addition of two equivalents of Grignard reagent to a diethylether solution of $W(NPh)[o\text{-}(Me_3SiN)_2C_6H_4]Cl_2$ at −78 °C (Eq. (1)) [21]. Removal of solvent under reduced pressure and recrystallization from pentane gives the compounds in good to excellent yields as red-orange crystalline solids (**1c**,**1d**) or as oils (**1a**,**1b**).



(1)

It is surprising that, despite their coordinative and electronic unsaturation, complexes, **1a**–**1d**, are indefinitely stable at room temperature in the absence of coordinating ligands. All complexes were characterized by ^1H and ^{13}C NMR spectroscopy. Single crystals of **1c** and **1d** that were suitable for X-ray diffraction studies were obtained by slowly cooling pentane solutions of **1c** and **1d** to −20 °C. Thermal ellipsoid plots of **1c** and **1d** are shown in Figs. 1 and 2, respectively. General data collection and refinement data for both **1c** and **1d** are listed in Table 1, while a table of selected bond lengths and angles is shown in Table 2. The coordination geometry about W in both structures is a square pyramid with the imido N in the apical position and the $[o\text{-}(Me_3SiN)_2C_6H_4]^{2-}$ ligand and two alkyl ligands in the basal plane. The W-imido bond lengths (1.738(2) for **1c** and 1.728(4) for **1d**) are consistent with a W–N triple bond [22]. The geometry about the N atoms of the $[o\text{-}(Me_3SiN)_2C_6H_4]^{2-}$ ligand is planar as is observed in silyl amines [23]. Despite the unsaturation of the metal center (14 or $16e^-$, CN = 5), there is no evidence for an agostic interaction between the metal and ligand C–H bonds in either structure.

2.2. Equilibrium between SP and TBP isomers of *1C*

We have reported the crystal structures of related dialkyl complexes [21a] showing that the geometry of these dialkyl complexes is dependent on the size of the alkyl groups. For small alkyls (e.g., methyl), the complex possesses a square pyramidal geometry with the imido N in the apical position. For large alkyls (e.g., neopentyl), the coordination geometry about the metal center is a trigonal bipyramid (TBP) with the imido N and one of the the diamido ligand N atoms in the axial positions. Complexes **1a**, **1b**, and **1d** are all square pyramidal (SP) or are undergoing rapid equilibration

$S = [\hat{A}[w(F_o^2 - F_c^2)^2]/(n-p)]^{1/2}, w = 1/[s^2(F_o^2) + (0.0370p)^2 + 0.31p], p = [\max(F_o^2, 0) + 2F_c^2]/3$.

of the SP and TBP isomers, as determined by the equivalence of the trimethylsilyl groups in their ^{1}H and ^{13}C NMR spectra from room temperature to −80 °C (though **1d** displays considerable broadening of the Me_3Si resonances at −80 °C).

Complex **1c**, W(NPh)[*o*-$C_6H_4(NSiMe_3)_2$]$(CH_2CHMe_2)_2$, is also square pyramidal, according to the single crystal X-ray study (Fig. 1). However, when dissolved, the complex clearly undergoes an equilibrium between SP and TBP isomers as observed by low temperature NMR spectroscopy (Eq. (2)). The limiting low temperature ^{1}H NMR spectrum (−80 °C) shows a single Me_3Si peak for the SP isomer and two equal intensity Me_3Si peaks for the TBP isomer which integrate to a TPB:SP ratio of 2:3 ($K = 0.67$ (Eq. (2))). A van't Hoff plot of the equilibrium constants from −40 to −80 °C gives values of $\Delta H° = -0.66(3)$ kcal mol^{-1} and $\Delta S° = -4.3(4)$ cal mol^{-1} K^{-1} for the SP/TBP equilibrium (see Table 3). Thus, the TBP isomer is favored enthalpically while entropy favors the SP isomer at higher temperatures. Whether this is due to differences in internal degrees of freedom or solvation effects is unclear.

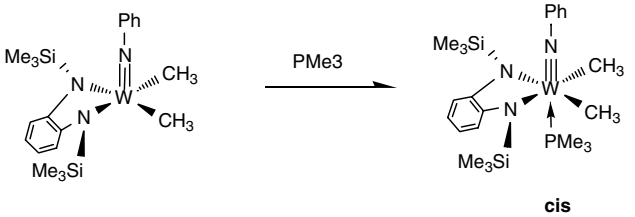
2.3. Reactivity of *1a–1d* with trimethylphosphine

Complexes **1a**–**1d** are coordinatively unsaturated tungsten species. It is reasonable to assume that coordination of trimethylphosphine to the d° metal center associated with a color change due to the ligand–metal charge transfer would be facile. However, no PMe_3 adduct was observed for **1a**–**1d** at room temperature. At low temperature, the equilibrium between free and coordinated phosphine is shifted enough so that adducts can be observed by ^{1}H, ^{13}C, and ^{31}P NMR spectroscopy. Previous studies in our group revealed the crystal structure of W(NPh)[*o*-(Me_3SiN)$_2C_6H_4$](PMe_3)Me_2 [21], in which the phosphine coordinates *trans* to the imido ligand (*cis* alkyls) and the molecule has a mirror plane containing the imido N, W and phosphine atoms, resulting in the equivalency of the two trimethylsilyl groups and the two alkyl groups (Eq. (3)).

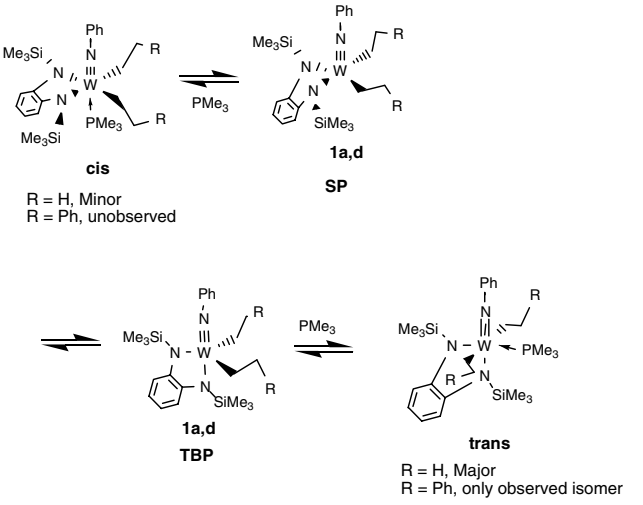


(3)

Table 3
Equilibrium constant (K) and free energy ($\Delta G°$) calculated for the isomerization of **1c**

T (K)	K	$\Delta G°$ (kcal mol^{-1})
233.15	0.49(6)	0.33(6)
223.15	0.52(4)	0.29(3)
193.15	0.66(3)	0.16(2)

Another coordination mode (*trans* alkyls) is found in the case of **1a** and **1d** in which the phosphine coordinates to the metal center between the two alkyls (Eq. (4)). The geometry was verified by observing two trimethylsilyl peaks along with equivalent phenethyl groups in the *trans* isomer in the low temperature ^{1}H and ^{13}C NMR spectra. While other arrangements of the PMe_3 ligand and



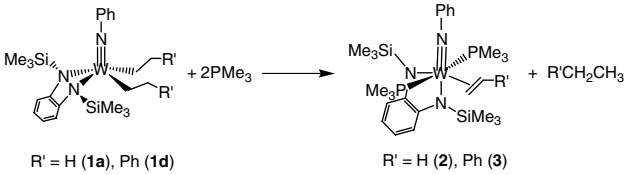
(4)

alkyl groups are possible, the *trans* geometry shown in Eq. (4) is the only one that gives inequivalent $SiMe_3$ groups and equivalent alkyls.

It is worthwhile to note that in the 5-coordinate SP complexes **1a**–**1d**, the LUMO is the d_{xy} orbital (z-axis coincident with the W-imido bond) [24]. Thus, the LUMO is not directed toward the vacant site of the SP isomers suggesting that the coordination of Lewis bases may be somewhat complicated since sterics suggest coordination *trans* to imido while electronics would direct coordination to the LUMO in the basal plane. In the TBP isomers, the LUMO is located in the equatorial plane suggesting that Lewis based should coordinate there. Evidently, the SP/TBP equilibrium plays a major role in directing the coordination of PMe_3 to these complexes. As the alkyl groups get larger, the TBP isomer becomes more favored in solution which apparently leads to a greater propensity to form the *trans* isomer as demonstrated in the bis(phenethyl) example, **1d**. For the dimethyl complex, which has the least propensity to form the TBP isomer, the coordination of PMe_3 occurs at the vacant site of the SP isomer, *trans* to the imido ligand.

Both isomers were observed for the PMe_3 adduct of **1a**, W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$](PMe_3)Et_2. The ^{31}P NMR of a toluene-d_8 solution of **1a** at −80 °C in the presence of 15 eq. of PMe_3 reveals two distinct peaks in a ratio of ca. 20:1 at δ −21.9 ($^1J_{P-W}$ = 240 Hz, major isomer, PMe_3 *cis* to imido and ethyl groups mutually *trans*) and δ −28.1 (broad, minor isomer with PMe_3 *trans* to imido and ethyl groups mutually *cis*). The low temperature ^{13}C NMR spectrum of this mixture is consistent with the proposed structure of the major isomer since two Me_3Si peaks are observed as is expected for the isomer with *trans* alkyl groups.

In the presence of trimethylphosphine, complexes **1a** and **1d** are converted to the ethylene complex, **2**, and the styrene complex, **3**, quantitatively (Eq. (5)). The crystal structure of



(5)

compound **2** has also been obtained and reported earlier [21b]. The formation of **2** proceeds much faster (<1 h at room temperature) than the formation of **3** (>6 h at 60 °C). Complex **1b** reacts with trimethylphosphine to form the propylene complex in low yield. The reaction between **1c** and trimethylphosphine proceeds at a negligible rate at room temperature and decomposition occurs at elevated temperature with the formation of isobutane and isobutylene. Although isobutylene complexes have been isolated for Hf [25], W [26], and Mo [27a], we were not able to isolate the desired complex, possibly because an isobutylene complex analogous to **2** is unstable at the high temperature needed to induce reaction of **1c**.

2.4. Mechanistic studies

Whitesides [28] proposed a mechanism for the decomposition of Pt(*n*-Bu)$_2$(PPh_3)$_2$ which is initiated by PPh_3 dissociation and illustrated the necessity to increase the stability of the complex by blocking the site for β-elimination by the ligand. Reger [29] also showed that the ligand dissociation to open a coordination site is required for β-elimination in the case of Fe(Cp)(CO)(PPh_3)R. However, the β-H transfer chemistry of **1a**–**1d** is promoted by adding a ligand to the metal center. This behavior is clearly unexpected since it implies that β-H transfer is induced by *increasing the coordination number and electron count of the complex*. To understand the role of PMe_3 and to clarify the mechanism, we have undertaken kinetic studies of the reactions of **1a** and **1d** with PMe_3.

2.5. Kinetics

The kinetics of the thermal decomposition of **1a** and **1d** in toluene-d_8 were examined by following the appearance and disappearance of the trimethylsilyl peaks of starting materials, **1a** and **1d**, and products, **2** and **3** using ^1H NMR spectroscopy in the presence of excess PMe_3. The data points were obtained by plotting the absolute peak intensity with respect to time for more than three half-lives.

Activation parameters for the conversion of **1a** to **2** were determined by reacting toluene-d_8 solutions (0.0486 M) of **1a** with PMe_3 (0.972 M) in the NMR probe at temperatures between 263 and 293 K (three samples at each temperature). Both the appearance of **2** and disappearance of **1a** follow first-order kinetics throughout the reaction with a pseudo first-order rate constant at 293 K of $k = 9.61(82) \times 10^{-4}$ s^{-1} ($t_{1/2}$ = 12 min). Conversion of **1a** to **2** is essentially quantitative and no ^1H NMR signals corresponding to any intermediate were observed. Activation parameters, obtained from an Eyring plot ($\Delta S^{\ddagger} = R$[(intercept) − 23.76]; $\Delta H^{\ddagger} = -R$(slope)), for the formation of **2** from **1a** are $\Delta H^{\ddagger}$ = 5.1(0.6) kcal mol^{-1} and $\Delta S^{\ddagger}$ = −54.9(2.0) cal mol^{-1} K^{-1}, which correspond to $\Delta G^{\ddagger}$ = 21.2 kcal mol^{-1} at 293 K.

The observation that the addition of ethylene has no effect on the rate of thermolysis as well as the large, negative entropy of activation suggests that liberation of ethylene does not occur prior to the rate-determining step in this reaction. The observed value of $\Delta S^{\ddagger}$ is a combination of the PMe_3 binding and the subsequent steps to reach the rate determining step. Values of $\Delta S^{\ddagger}$ between −30 and −40 cal mol^{-1} K^{-1} are often observed in purely associative substitution reactions. Thus, the majority of the observed value of $\Delta S^{\ddagger}$ is accounted for in the binding of PMe_3 [30]. Loss of the remaining 10 – 20 cal mol^{-1} K^{-1} is consistent with the formation of the highly constrained transition state necessary for the proposed β-H transfer [9]. Similar values of $\Delta S^{\ddagger}$ (−10 to −20 eu) have also been observed in direct α-abstraction reactions to form alkylidene complexes [31]. Graphs of representative first-order data and the Eyring plot are shown in Fig. 3.

The kinetics of the formation of **3** from **1d** were carried out by reaction of toluene-d_8 solutions (0.0309M) of **1d** with PMe_3 (0.662 M, 21 equiv.) over a temperature range 333–363 K (three samples at each temperature). The reaction follows first-order kinetics with a pseudo first-order rate constant at 333 K of $k = 6.9(4) \times 10^{-5}$ s^{-1} ($t_{1/2}$ = 167 min). Activation parameters for the formation of **3** from **1d** are $\Delta H^{\ddagger}$ = 13.7(0.8) kcal mol^{-1} and $\Delta S^{\ddagger}$ = −36.6(2.3) cal mol^{-1} K^{-1}, which correspond to $\Delta G^{\ddagger}$ = 25.9 kcal mol^{-1} at 333 K. Graphs of representative first-order data and an Eyring plot are shown in Fig. 4. The observation that the addition of styrene has no effect on the

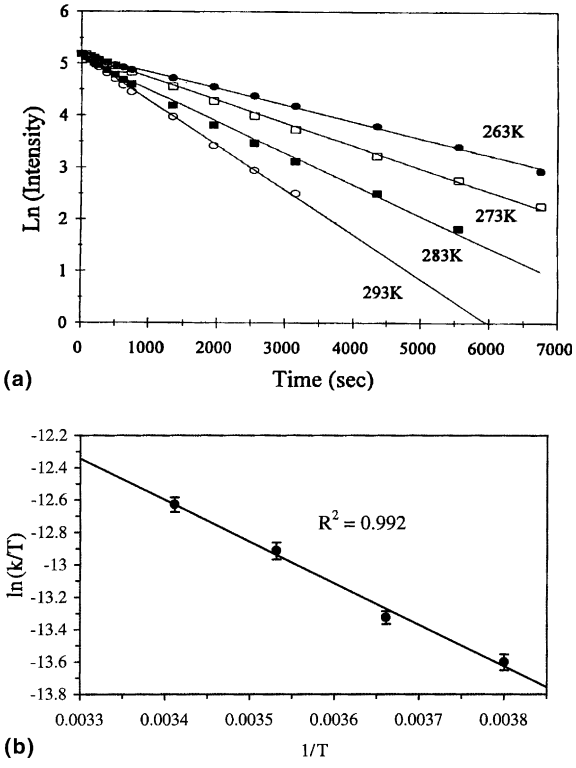


Fig. 3. First-order kinetics (a) and Eyring plot (b) for the formation of **2**.

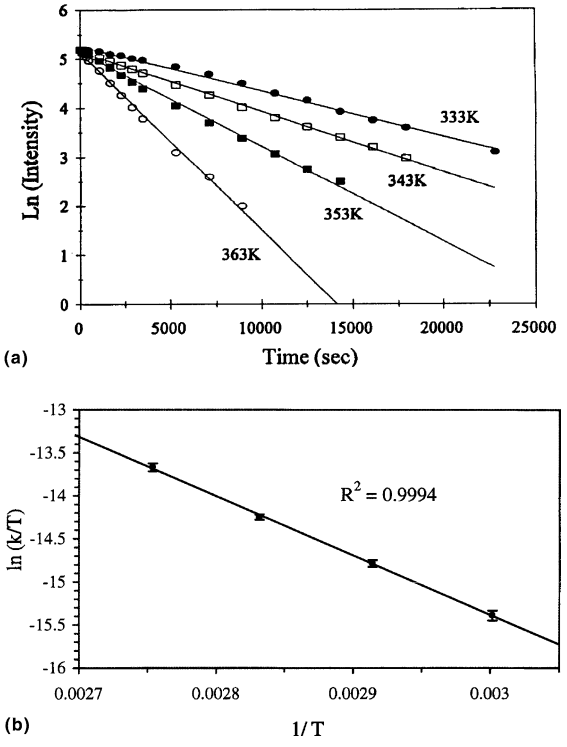

Fig. 4. First-order kinetics (a) and Eyring plot (b) for the formation of **3**.

rate of thermolysis suggests that the liberation of styrene does not occur prior to the rate-determining step in this reaction. The activation parameters in the conversion of **1d** to **3** are significantly different from those of **1a** to **2** ($\Delta\Delta H^{\ddagger} = 8.6$ kcal mol^{-1} and $\Delta\Delta S^{\ddagger} = 18.3$ cal mol^{-1} K^{-1}), suggesting that the two reactions follow different mechanisms. Rate constants obtained for both reactions studied are shown in Table 4. [1]

2.6. Phosphine dependence

The role of trimethylphosphine in the conversion of **1a** to **2** was examined by reacting **1a** (0.0243 M) with PMe_3 (0–1.7 M) at 283 K. In the absence of trimethylphosphine, the diethyl complex, **1a**, is stable in the solution with no decomposition observed within several hours. The rate constants were obtained through the same procedure as described above, but at different PMe_3 concentrations. The reaction is first order in PMe_3, according to the slope of 1.096 obtained from the plot of ln(k) vs. ln[PMe_3] (Fig. 5). Though saturation of the rate at high concentrations of PMe_3 is predicted, we were not able to observe such behavior even at PMe_3 concentrations of 1.7 M.

The phosphine dependence for the formation of **3** from **1d** was measured by examining the reaction of **1d** (0.0309M) with PMe_3 over a range 0–2 M. The reaction exhibits near linear behavior at high phosphine concentrations. However, if the phosphine concentrations are less than ca. 0.6 M (20 equiv.), there is no profound effect on the rate of thermolysis (Fig. 6) and a rate constant of 2.1×10^{-4} s^{-1} (measuring the disappearance of **1d**) was observed when no PMe_3 is added. The data suggests that more than one pathway, in which one of them is phosphine independent, are involved in the reaction. These results exclude the possibility of two parallel pathways where one is phosphine independent and one is first-order phosphine dependent, because the phosphine dependence of the rate constant of such a mechanism would result in a straight line with a positive intercept.

2.7. Deuterium labeling experiments

In order to establish the extent to which the β-elimination pathway, possibly responsible for the formation of olefin complexes, **2** and **3**, is reversible, the β-deuterated analogs of **1a** and **1d**, W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$]-$(CH_2CD_3)_2$, **1a**-d_6 and W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$]-$(CH_2CD_2Ph)_2$, **1d**-d_4 were prepared. If the β-elimination pathway involves a fast equilibrium between β-H elimination and olefin insertion [32] into metal–hydride bond, then scrambling of the deuterium labels [5a,5b,17] from the β-carbon into the α-carbon would give a mixture of d_2–d_6 ethane and a mixture of deuterated ethyl benzenes from **1d**.

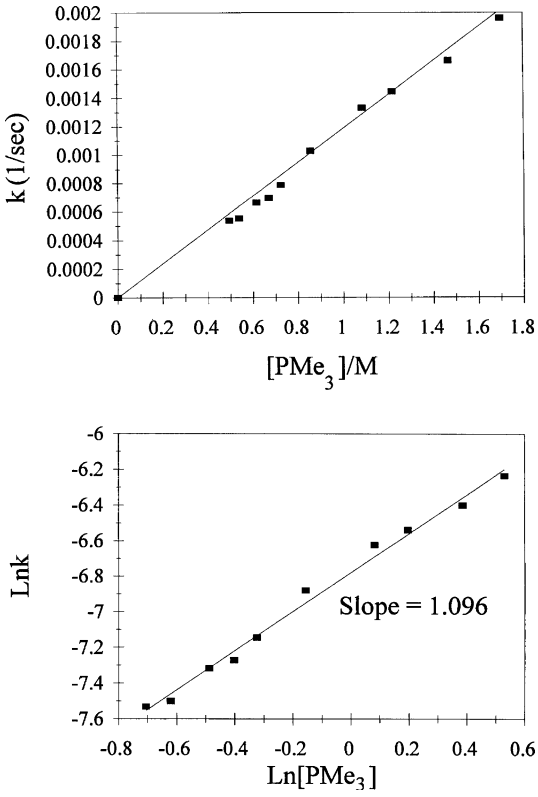

Fig. 5. PMe_3 dependence for the reaction of **1a** with PMe_3.

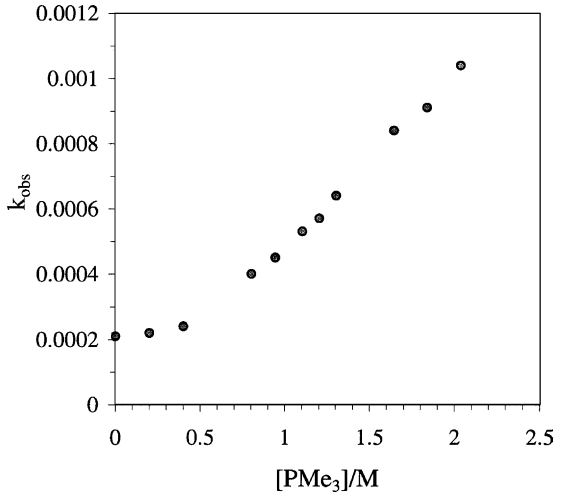

Fig. 6. PMe_3 dependence for the reaction of **1d** with PMe_3.

The conversion of **1a**-d_6 to **2**-d_2 was followed by ^2H NMR in toluene. In both the absence and presence of PMe_3, no scrambling of the deuterium labels among the α- and β-carbons was observed. The products of the reaction are exclusively W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$](η^2-CH_2CD_2)$(PMe_3)_2$, **2**-d_2, and CH_2DCD_3. The formation of CH_2DCD_3 is supported by the observation of a mass peak at 34 *m/e* in EI-MS experiments. The same mass spectrum is also observed for the product of the reaction between CD_3CH_2MgCl and D_2O. The above observations suggest an irreversible β-H abstraction process similar to that proposed by Yamamoto and co-workers [15]. Similar experiments performed on **1d** also suggest that no scrambling occurs.

The kinetic isotope effect for the transformation of **1a** to **2** was determined by reacting **1a**-d_6 with trimethylphosphine under the same conditions at 293 K, giving $k_D = 1.57(4) \times 10^{-4}$ s^{-1}. This corresponds to a k_H/k_D of 6.1(5), which strongly suggests a near linear transition state for the β-H transfer process. This is consistent with the direct transfer of one β-H to the other α-carbon atom as is proposed in Scheme 2. The large KIE in our system is significantly different from those compounds which decompose by β-elimination followed by reductive elimination [15–19]. Buchwald [33], Erker [34], Marks [35] and Schrock [36] have proposed the direct β-hydrogen abstraction process from an sp^2-hybridized carbon in the formation of alkyne/aryne complexes. Similar kinetic isotope effects have also been determined by Marks (6.5) [37] and Teuben (5.1) [38]. The KIE observed in our system is also consistent with those observed for $Cp_2Zr(SCH_2Ph)(Me)$, [9] KIE = 5.2, and $[Me_3SiNCH_2CH_2]_3NTa(Et)_2$, [10] KIE = 5.7, in which the direct β-hydrogen abstraction was proposed to be the most-likely pathway.

The kinetic isotope effect for the transformation of **1d** to **3** was determined by reacting **1d**-d_4 (0.031 M) with PMe_3 (0.8 M) at 343 K, giving $k_D = 0.62(4) \times 10^{-4}$ s^{-1}. This corresponds to a k_H/k_D of 2.1(2) (2.4 when extrapolated to room temperature, assuming linear Arrhenius [40] behavior). This is consistent with the data reported for the β-elimination pathway [15–19]. The unusual rate constants observed at low phosphine concentrations led us to study the kinetic isotope effect at different PMe_3 concentrations. With 0.4 M PMe_3 at 353 K, a kinetic isotope effect of 3.4(3) (4.3 at room temperature) was observed, whereas 4.8(5) (6.4 at room temperature) was observed for the thermolysis of **1d** in the absence

Table 5
KIE for the decomposition of **1d** (0.031 M) under different [PMe_3]

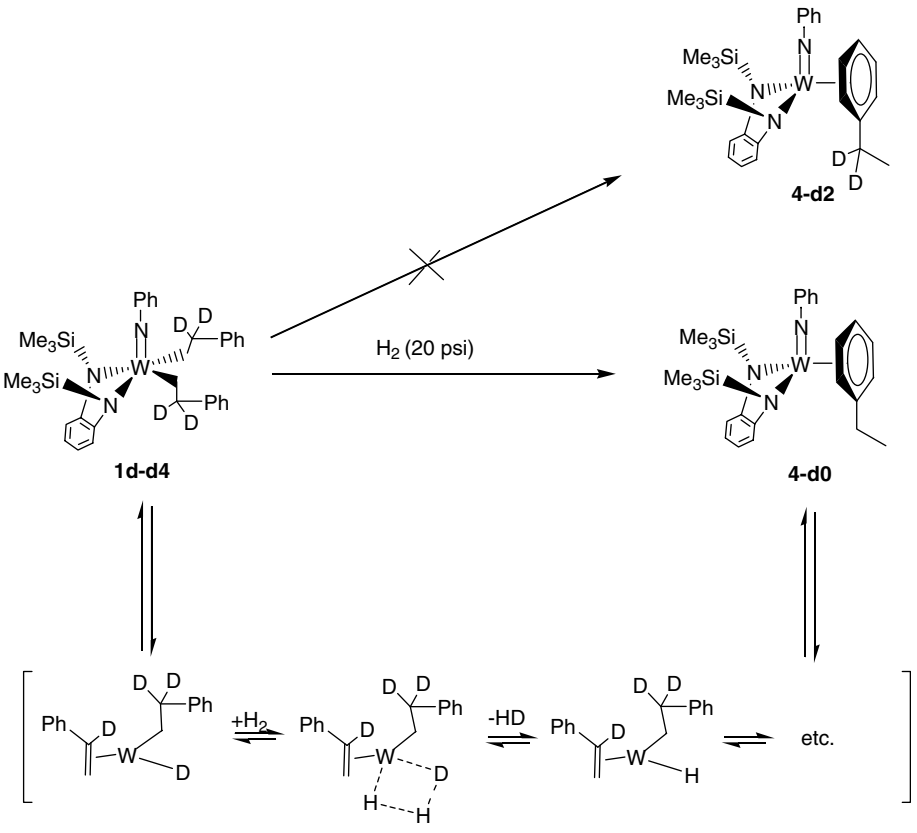
[PMe_3]/M	KIE/Temperature	KIE (extrapolated to room temperature, 298 K)
0	4.8(5)/353 K	6.4
0.4	3.4(3)/353 K	4.3
0.8	2.1(2)/343 K	2.4

of PMe_3. The difference in kinetic isotope effects at different PMe_3 concentrations (Table 5) is clear evidence that there is more than one pathway involved in the transformation. The large number (6.4) observed in the absence of PMe_3 is similar to that of **1a** (6.1), and suggests that the β-abstraction is the dominant pathway at low PMe_3 concentrations.

2.8. Mechanistic study of the formation of 2

Given the experimental data described above, an associative pathway in which the transformation is induced by pre-coordination of a ligand is the mechanism that we propose which accounts for all the observations. A rapid pre-equilibrium coordination of PMe_3 is proposed as the initial step for the transformation of **1a** to **2** due to the first order dependence on PMe_3 and the fact that the PMe_3 adduct, W(NPh)-[*o*-$(Me_3SiN)_2C_6H_4$](PMe_3)Et_2, **1a-P**, has been observed at −50 °C in the presence of excess PMe_3. This adduct exists as a mixture of two isomers as determined by ^{13}C and ^{31}P NMR spectroscopy. The major isomer has *trans* ethyl groups with PMe_3 coordinated *cis* to the imido ligand. The minor isomer has the PMe_3 coordinated *trans* to the imido ligand leaving the ethyl groups mutually *cis*. We suggest that the reaction proceeds through the minor isomer of **1a-P** in which the *cis* disposition of the ethyl groups is retained.

The reaction obeys first-order kinetics in both W and PMe_3. No deuterium scrambling was observed both in the presence and absence of PMe_3, which excludes a β-elimination process in which there is a rapid equilibrium between an olefin-hydride complex and the starting material. The observation of a large kinetic isotope effect (6.1) at 293 K suggests a symmetrical linear transition state, according to Kwart's study [14]. The observed value of $\Delta S^{\ddagger}$ (−54.9 eu) is consistent with the bimolecular nature of this reaction and the highly-ordered transition state, imposed by the geometric requirements of the β-hydrogen to transfer to the α-carbon of the other ethyl group. Evidently, the increased electron density on the metal center in

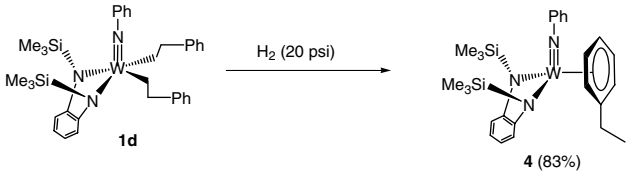


Scheme 3. Hydrogenolysis of W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$]$(CH_2CD_2Ph)_2$ (**1d**-d_4).

$W(NPh)[o\text{-}(Me_3SiN)_2C_6H_4](Et)_2(PMe_3)$ combined with the increased steric congestion induces the rapid β-H abstraction reaction.

2.9. β-H Elimination

The existence of a β-H elimination process, forming a hydrido-styrene intermediate during the conversion of **1d** to **3**, is supported by the observation of trace amounts of free styrene in the ^1H NMR spectrum of **1d** and the study of the hydrogenolysis reaction of **1d**. In the presence of hydrogen, complex **1d** is converted to a W(IV) arene complex $W(NPh)[o\text{-}(Me_3SiN)_2C_6H_4](\eta^6\text{-}C_6H_5Et)$ (**4**) as shown in Eq. (6) [27b].



(6)

When **1d**-d_4 was used for the hydrogenolysis reaction, all deuterium labels were washed out by the hydrogen (^2H NMR) and no deuterium label is observed in the product, **4**, that formed. This observation strongly suggests the presence of a hydrido intermediate (Scheme 3), which undergoes H/D exchange with H_2 [42].

2.10. Mechanistic study of the formation of *3*

The transformation of **1d** to **3** proceeds via more complicated pathways than that of **1a** based on the observations mentioned earlier. The near linear PMe_3 dependence at high concentration is similar to the conversion of **1a** to **2**. However, the kinetic isotope effect observed (2.1) implies that the β-H elimination pathway

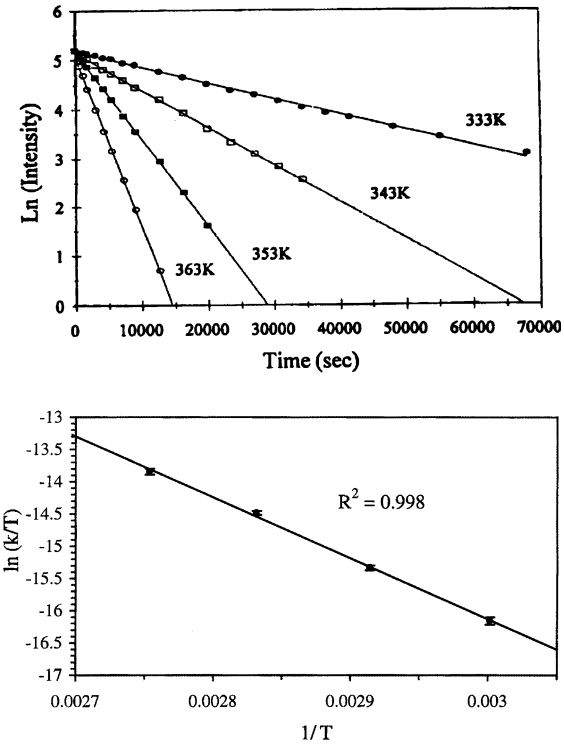


Fig. 7. First-order kinetics (top) and Eyring plot (bottom) for the thermolysis of **1d**.

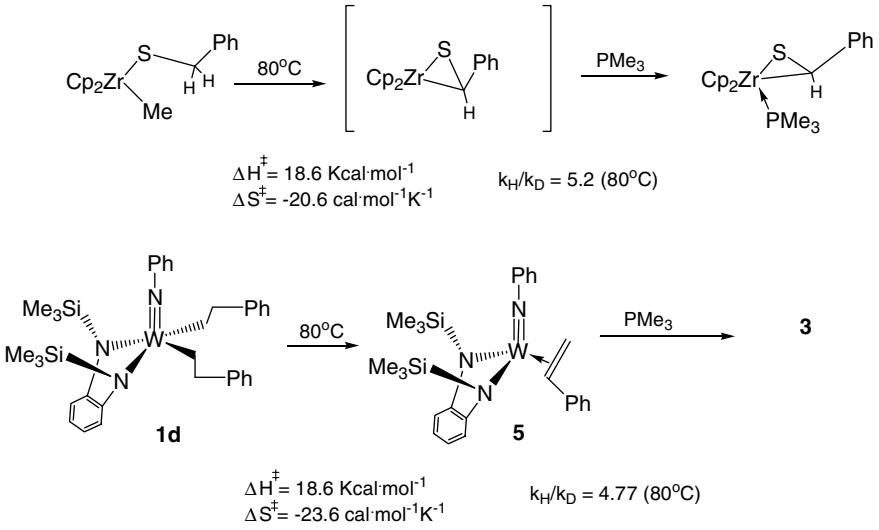
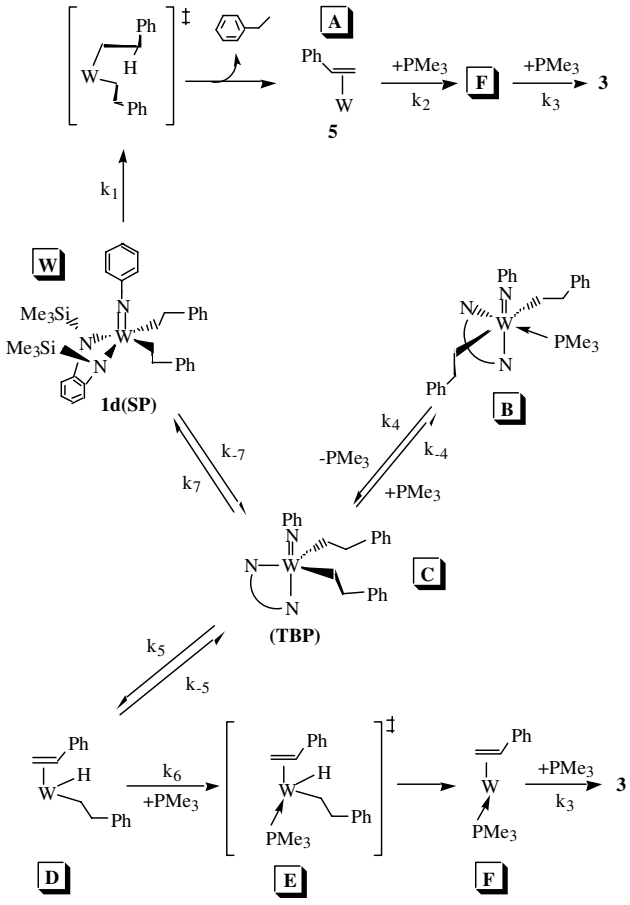
is more reasonable than a β-H abstraction pathway which gives a k_H/k_D of 6.1 for the transformation of **1a** to **2**.

In the absence of PMe_3, complex **5**, the product of the thermolysis of **1d**, was observed, associated with the ethylbenzene being released from tungsten center. A rate constant of $2.1 \times 10^{-4}\ s^{-1}$ and large kinetic isotope effect (6.4) are observed for the thermolysis of **1d**, suggesting that a similar β-abstraction pathway accounts for this



Scheme 4.



Scheme 5.

reaction. The styrene complex, **5** can be isolated as a dark brown solid. Upon further addition of PMe_3 to **5**, compound **3** is formed quantitatively. The kinetics of the thermolysis of **1d** were also performed (Fig. 7) over a temperature range of 333–363 K and in the absence of PMe_3. The reaction follows first-order kinetics with activation parameters being $\Delta H^{\ddagger} = 18.6(0.6)$ kcal mol^{-1} and $\Delta S^{\ddagger} = -23.3(1.6)$ cal mol^{-1} K^{-1}, which correspond to $\Delta G^{\ddagger} = 26.4$ kcal mol^{-1} at 333 K. The activation parameters obtained here are similar to related studies (Scheme 4) [9].

It should be noted once again that parallel pathways (one being PMe_3 independent and one being first order in PMe_3) *cannot* explain the non-linearity in Fig. 6. The PMe_3-dependent kinetic isotope effect and the deviation from linear PMe_3 dependence at low concentrations suggest that PMe_3 plays a crucial role in determining which pathway the reaction follows. A simple mechanism consisting of phosphine association/dissociation equilibrium followed by β-H elimination does not account for the phosphine dependence observed, since it will result in a linear dependence with a positive intercept in Fig. 6. Furthermore, we have established that the isomerization between trigonal bipyramidal and square pyramidal isomers exists in the solution. Therefore, we propose that the isomerization process shown in Scheme 5 takes place prior to the product forming step.

The *trans* isomer (referred to the *trans* alkyl groups) of the phosphine adduct, W(NPh)[*o*-$(Me_3SiN)_2C_6H_4$]$(PMe_3)(CH_2CH_2Ph)_2$, **B**, is proposed in Scheme 5 because no *cis* isomer has been observed at any temperature and only a small amount of the *cis* isomer of **1a** (which is much less sterically hindered than **1d**) is observed when **1a** is treated with PMe_3. Complex **C** is in equilibrium with the hydrido-styrene intermediate, **D** (which is the source of hydride that exchanges with free H_2). The coordination of PMe_3 to **D** forms a seven-coordinate transition state, **E**. Reductive elimination of ethylbenzene is assisted by the coordination of PMe_3 and is considered the rate limiting step in the second pathway. Reductive elimination from **D** without coordination of PMe_3 is ruled out since it will result in a linear PMe_3 dependence from the calculation of the rate equation. Under these conditions, at high enough concentrations of PMe_3, the rate of the reaction is predicted to be first order in PMe_3 and W with the rate determining step being k_6. With no PMe_3 present, the k_1 path is followed. At intermediate concentrations of PMe_3, a much more complicated set of reactions occurs because PMe_3 is involved in the establishment of the isomerization equilibria between **W**, **B**, **C** and **D**. Furthermore, PMe_3 must dissociate from **B** prior to the product forming step of the PMe_3 dependent pathway.

$$\text{Rate} = \frac{-\mathrm{d}[W]}{\mathrm{d}t} = k_1[W] - k_7[C] + k_{-7}[W]. \tag{7}$$

From Scheme 5, the rate of the reaction can be expressed as Eq. (7). Based on the fact that no intermediate was observed during the reaction, we are able to use the steady-state approximation for the concentration of **B**, **C**, and **D**, which gives the observed rate constant, k_{obs} (Eq. (8)), as a complex dependence on rate constants and phosphine concentrations (Scheme 6). [2]

The complexity of the PMe_3 dependence accounts for the non-linear behavior in Fig. 6. Although we are not able to measure rate constants for each step, an estimation of the rate constants can be made that is consistent with our observations. First, we find no profound effect

[2] $a = k_4k_{-5}k_{-5}k_7k_7; b = 2k_4k_5k_{-5}k_6k_7 + k_4k_{-5}k_6k_7k_7 + k_4k_{-4}k_{-5}k_{-5}k_7 + k_4k_{-5}k_6k_7k_7 - k_4k_{-4}k_{-5}k_6k_7; c = 3k_4k_{-4}k_{-5}k_6k_7 + 2k_{-5}k_6k_7k_7 - k_4k_{-4}k_{-5}k_6k_7; c = 3k_4k_{-4}k_{-5}k_6k_7 + 2k_4k_5k_6k_6k_7 + k_4k_{-4}k_5k_{-5}k_6 + k_4k_5k_5k_6k_6 + k_4k_6k_6k_7k_7 - k_4k_{-4}k_{-4}k_{-5}k_6 - k_4k_{-4}k_5k_6k_6 - k_4k_{-4}k_6 \quad k_6k_7; d = 2k_4k_{-4}k_5k_6k_6 + k_4k_{-4}k_6k_6k_7 + k_4k_{-4}k_{-4}k_{-5}k_6 - k_4k_{-4}k_{-4}k_6k_6; e = k_4k_{-4}k_{-4}k_6k_6; f = k_4k_5k_{-5}k_6k_7 \quad k_{-7} + k_4k_{-4}k_6k_6k_7k_{-7} - 2 \quad k_4k_{-4}k_{-5}k_6k_7k_{-7}; g = 2k_4k_{-4}k_{-5}k_6k_7k_{-7} + k_4k_{-4}k_5k_{-5}k_6k_{-7} + k_4k_5 \quad k_5k_6k_6k_{-7} + k_4k_5k_6k_6k_7k_{-7} - k_4k_{-4}k_{-4}k_{-5}k_6k_{-7} - k_4k_{-4}k_5k_6k_6k_{-7}; h = 2k_4k_{-4}k_5k_6k_6k_{-7} + k_4k_{-4}k_6k_6k_7k_{-7} + k_4k_{-4}k_{-4}k_{-5}k_6k_{-7} - k_4k_{-4}k_{-4}k_6k_6k_{-7}; i = k_4k_{-4}k_{-4}k_6k_6k_{-7}.$

$$\text{Assumption}: \frac{d[B]}{dt} = \frac{d[C]}{dt} = \frac{d[D]}{dt} = 0$$

$$k_{obs} = k_1 + \frac{f[PMe_3]+g[PMe_3]^2+h[PMe_3]^3+i[PMe_3]^4}{a+b[PMe_3]+c[PMe_3]^2+d[PMe_3]^3+e[PMe_3]^4} \quad (8)$$

(a-i: constants)[45]

Scheme 6. Derivation of the observed rate constant, k_{obs} for the formation of **3**.

on the overall rate in the presence of low concentration of phosphine and the rate only doubles when a large excess (ca. 25 equiv.) of PMe_3 is added. This indicates that rate constants for the phosphine dependent pathway are similar to those of the phosphine independent pathway ($k_1 = 0.00021$). Second, the square pyramidal structure of **1d**, obtained from a single crystal X-ray study, and the inability to observe the trigonal bipyramidal isomer at any temperature suggest that the isomerization process is probably very fast or the equilibrium lies predominantly toward the SP isomer ($k_7 \gg k_{-7}$). Furthermore, if the coordination of phosphines is actually much faster than all other steps, all three species, **1d**, **B**, and **C**, can be considered as one species, which should result in a linear PMe_3 dependence.

Given the complexity of the rate equation in Scheme 6, we have analyzed the rate data using a kinetics simulation program. Rate constants were assigned based on the above discussion and the KINFIT program was used to provide a reaction profile of the concentrations of all species involved in the reaction with respect to time. Rate constants were examined repeatedly until a set of numbers ($k_1 = 0.00021$; $k_4 = 0.04$; $k_{-4} = 0.08$; $k_5 = 0.01$; $k_{-5} = 0.01$; $k_6 = 0.001$; $k_7 = 0.02$; $k_{-7} = 0.002$) was found that fit the experimental results of both the phosphine dependence of k_{obs} (Fig. 8) and that gave a reaction profile that is consistent with the experimental observations (Fig. 9).

The simulation result shows well behaved kinetics with the dominant species being PMe_3, **1d**, **3** and ethylbenzene, which is consistent with the experimental observations. The rate constant obtained from the simulation result (e.g., $k_{obs(calc)} = 0.00023(2)\ s^{-1}$ for the

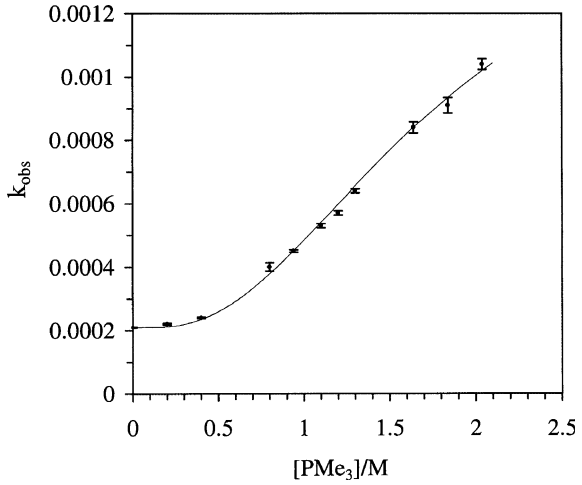

Fig. 8. Fit of the PMe_3 dependence of the observed rate constant, k_{obs}, (Solid line; $k_1 = 0.00021$; $k_4 = 0.04$; $k_{-4} = 0.08$; $k_5 = 0.01$; $k_{-5} = 0.01$; $k_6 = 0.001$; $k_7 = 0.02$; $k_{-7} = 0.002$).

consumption of **1d** and $k_{obs(calc)} = 0.00022(2)\ s^{-1}$ for the formation of **3**; $[PMe_3] = 0.4$ M) is in good agreement with the experimental data ($k_{obs} = 0.00024\ s^{-1}$). In the simulation results (both low and high PMe_3 concentrations), only trace amounts of intermediates are present, which is in accord with the assumptions of the steady-state approximation with k_1 and k_6 being rate limiting steps. The pre-equilibria between **1d**, **B**, **C** and **D** are supported by the noticeable amounts (4–7%) of intermediates **B**, **C** and **D** observed at the early stages of the reaction. However, due to the dynamic properties of these complexes, all of them show up in the ^1H NMR as an averaged peak, which is indistinguishable from the peak of **1d**, causing the intermediates to be "unobservable".

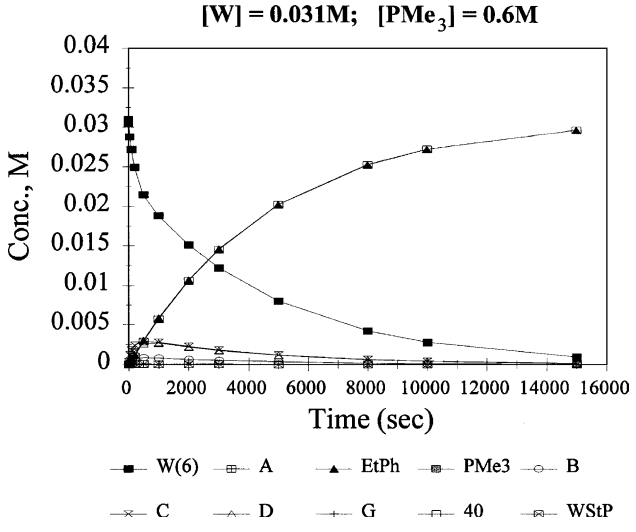

Fig. 9. Simulation of the mechanism proposed for the formation of **3** from **1d**. PMe_3 concentration (~ 0.6M) is out of the scale shown in this plot.

A referee has noted and we agree that this mechanistic simulation is underdetermined. We can only explicitly measure one of the 8 rate constants that are necessary for the simulation and the overall k_{obs} for the phosphine dependent path. Consequently, there is a large uncertainty inherent in the actual values of the rate constants that we calculate and other combinations of rate constants might also lead to reasonable simulations. We are encouraged that the values of the rate constants that we find are consistent with the results of the qualitative arguments given above as well as with the non kinetic mechanistic information.

3. Discussion and conclusion

We have proposed a mechanism for the formation of olefin complexes, **2** and **3**, from stable, coordinatively unsaturated W(VI) dialkyl complexes, **1a** and **1d**, induced by the addition of PMe_3 which accounts for all our observations. An alternative mechanism that involves transfer of the β-H atom to the imido nitrogen followed by α-abstraction of the N-H of the resultant amido group by the remaining ethyl group is also conceivable. While we have no direct evidence that excludes this pathway, we believe that such a mechanism is unlikely because of observations that we have made on the conversion of **1d** to the styrene complex, **3**. The conversion of **1d** to **3** occurs much more slowly ($t_{1/2}$ = 167 min at 333 K) than **1a** is converted to **2** ($t_{1/2}$ = 12 min at 293 K). Furthermore, the data indicates that the conversion of **1d** to **3** proceeds via a different mechanism (KIE = 2.3 at high [PMe_3]) than the conversion of **1a** to **2** (KIE = 6.1).

When complex **1d** binds PMe_3, only the isomer with PMe_3 *cis* to the imido group and the ethyl groups *trans* to one another is observed via low temperature NMR. Apparently, this is responsible for the change in mechanism that occurs when PMe_3 is present because the alkyl groups are no longer *cis* to one another. If transfer of the β-H to the imido is the mechanism that is followed, we would expect that changing the geometry of the PMe_3 adduct in this fashion would not cause such a dramatic change in the reaction rate because the alkyl groups remain *cis* to the imido group regardless of their relationship to one another.

Our observations of a large isotope effect, negative entropy of activation, and no deuterium scrambling are all consistent with the β-H abstraction mechanism proposed for the formation of the ethylene complex, **2**, from **1a** [8a]. We believe that β-H abstraction occurs from the *cis* (minor)isomer of the PMe_3 adduct of **1a** (Eq. (4)). The isotope effect and activation parameters of the transformation of **1d** to the styrene complex in the absence of PMe_3 are also consistent withβ-H abstraction. However, when PMe_3 is added to **1d** only the *trans* isomer of the PMe_3 adduct is observed and reaction of this material follows a different mechanism.

The PMe_3 dependent KIE and non-linear PMe_3 dependence support a change in the mechanism in the transformation of **1d** to **3** with increasing [PMe_3]. The combination of the bimolecular nature of this reaction and the highly-ordered transition state, imposed by the geometric requirements needed for the β-hydrogen transfer account for the large negative entropy value. It is evident that the change in the mechanism of the β-H transfer reaction is brought about by the presence of PMe_3 which effectively catalyzes the isomerization of the starting material. Evidently, β-H elimination is the preferred alkyl decomposition pathway in the TBP isomer and PMe_3 is necessary to induce reductive elimination of ethylbenzene from **D** in Scheme 5 to give the final product.

4. Experimental

4.1. General procedures

All reactions were conducted under dry argon atmosphere using standard Schlenk techniques or in a nitrogen atmosphere dry box. Diethyl ether (Et_2O) was distilled from sodium benzophenone ketyl. Toluene, pentane, and hexane were distilled from sodium. NMR solvents were stored over molecular sieves and degassed prior to use.

^{1}H-NMR spectra were measured at 300 MHz on a Varian Gemini 300 or VXR 300 spectrometer with C_6D_6 or C_7D_8 as solvents. The chemical shifts are reported in parts per million downfield from tetramethylsilane and were measured relative to the residual protons in the deuterated solvents. ^{13}C-NMR spectra were referenced to the central line of the solvents C_6H_6 (δ = 128.0 ppm) and C_7H_8 (δ = 20.4 ppm). The coupling constants (J) are reported in hertz. Elemental analyses (C, H, N) were performed by Atlantic Microlab, Inc., Norcross, GA.

4.2. $W(NPh)[(o\text{-}Me_3SiN)_2C_6H_4](CH_2CH_3)_2$ (**1a**)

$W(NPh)[(o\text{-}Me_3SiN)_2C_6H_4](Cl)_2$ (2.01g, 3.37 mmol) was dissolved in 100 ml of Et_2O and cooled to −78 °C. Two equivalents of EtMgCl (3.37 ml, 6.74 mmol; 2.0 M solution in Et_2O) were then added by a syringe. The reaction was allowed to warm to room temperature and was stirred for 1 h, during which time a brown color appeared and salts precipitated. The solvent was then removed under reduced pressure, and the remaining brown-black oil was dried in vacuo for 3 h. The oil was then extracted with pentane and filtered by filter cannula until filtrate was almost clear. The solvent was then removed under reduced pressure, and the

remaining brown oil was dried in vacuo for 2 h to yield 1.68 g of **1a** as a thick red oil. Yield: 85.3%. ^{1}H NMR: 0.29 (s, 18H, –Si(CH$_3$)$_3$, $^2J_{Si–H}$ = 6.6Hz); 1.86 (t, 6H, –CH$_2$C*H*$_3$); 1.91 (m, 2H, –C*H*$_2$CH$_3$); 2.31 (m, 2H, –C*H*$_2$CH$_3$); 6.86 (t, 1H, *p*-NPh-*H*); 7.04 (m, 2H, aromatic); 7.11 (t, 2H, *m*-NPh-*H*); 7.31 (d, 2H, *o*-NPh-*H*); 7.37 (m, 2H, aromatic). ^{13}C{^{1}H} NMR: 1.5 (–Si(CH$_3$)$_3$, $J_{C–H}$ = 119 Hz); 17.4 (–CH$_2$*C*H$_3$, $J_{C–H}$ = 122 Hz); 58.4 (–*C*H$_2$CH$_3$, $J_{C–H}$ = 120 Hz); 122.3, 123.9, 125.0, 125.6, 128.8, 135.1, 156.2 (aromatic).

4.3. W(NPh)[o-(Me$_3$SiN)$_2$C$_6$H$_4$](CH$_2$CD$_3$)$_2$ (**1a**-d$_6$)

Deuterated analog of **1a** was prepared in the same way as described above. Grignard reagent, CD$_3$CH$_2$MgCl, used for alkylation reaction, was prepared from CD$_3$CH$_2$Cl and Mg^0 metal. ^{1}H NMR: 0.29 (s, 18H, –Si(CH$_3$)$_3$, $^2J_{Si-H}$ = 6.6 Hz); 1.81 (m, 2H, –C*H*$_2$CD$_3$); 2.19 (m, 2H, –C*H*$_2$CD$_3$); 6.85 (t, 1H, *p*-NPh-*H*); 7.03 (m, 2H, aromatic); 7.11 (t, 2H, *m*-NPh-*H*); 7.26 (d, 2H, *o*-NPh-*H*); 7.34 (m, 2H, aromatic).

4.4. W(NPh)[(o-Me$_3$SiN)$_2$C$_6$H$_4$](CH$_2$CH$_2$CH$_3$)$_2$ (**1b**)

W(NPh)[(*o*-Me$_3$SiN)$_2$C$_6$H$_4$](Cl)$_2$ (1.00 g, 1.68 mmol) was dissolved in 100 ml of Et$_2$O and cooled to −78 °C. Two equivalents of *n*-PrMgCl (1.7 ml, 3.4 mmol; 2.0 M solution in Et$_2$O) were then added by a syringe. The reaction was allowed to warm to room temperature and was stirred for 1 h, during which time a brown color appeared and salts precipitated. The solvent was then removed under reduced pressure, and the remaining brown-black oil was dried in vacuo for 3 h. The oil was then extracted with pentane and filtered by filter cannula until filtrate was almost clear. The solvent was then removed under reduced pressure, and the remaining brown oil was dried in vacuo for 2 h. Yield: 78%. ^{1}H NMR: 0.53 (s, 18H, –Si(CH$_3$)$_3$, $^2J_{Si-H}$ = 6.6 Hz); 1.30 (t, 6H, –CH$_2$CH$_2$C*H*$_3$); 1.92 (m, 2H, –CH$_2$C*H*$_2$CH$_3$); 2.06 (d of t, 2H, –C*H*$_2$CH$_2$CH$_3$); 2.16 (m, 2H, –CH$_2$C*H*$_2$CH$_3$); 2.33 (d of t, 2H, –C*H*$_2$CH$_2$CH$_3$); 7.09 (t, 1H, *p*-NPh-*H*); 7.27 (m, 2H, aromatic); 7.34 (t, 2H, *m*-NPh-*H*); 7.53 (d, 2H, *o*-NPh-*H*); 7.57 (m, 2H, aromatic). ^{13}C{^{1}H} NMR: 1.49 (–Si(CH$_3$)$_3$, $J_{C–H}$ = 119.3 Hz); 21.79 (–CH$_2$CH$_2$*C*H$_3$, $J_{C–H}$ = 121.4 Hz); 26.70 (–CH$_2$*C*H$_2$CH$_3$, $J_{C–H}$ = 132.2 Hz); 69.29 (–*C*H$_2$CH$_2$CH$_3$, $J_{C–H}$ = 113.1 Hz); 122.36, 124.08, 125.04, 125.77, 128.64, 134.48, 156.42 (aromatic).

4.5. W(NPh)[(o-Me$_3$SiN)$_2$C$_6$H$_4$](CH$_2$CH(CH$_3$)$_2$)$_2$ (**1c**)

W(NPh)[(*o*-Me$_3$SiN)$_2$C$_6$H$_4$](Cl)$_2$ (1.2 g, 2.01 mmol) was dissolved in 100 ml of Et$_2$O and cooled to −78 °C. Two equivalents of *i*-BuMgCl (2.01 ml, 4.02 mmol; 2.0 M solution in Et$_2$O) were then added by a syringe. The reaction was allowed to warm to room temperature and was stirred for 1 h, during which time a brown color appeared and salts precipitated. The solvent was then removed under reduced pressure, and the remaining brown-black oil was dried in vacuo for 3 h. The oil was then extracted with pentane and filtered by filter cannula until filtrate was almost clear. The solution was concentrated to about 10 ml and cooled to −78 °C for 3 h. The resulting golden-brown solid was isolated by filtration and was dried under reduced pressure for 1 h to yield 0.78 g of **1c** as a brown crystalline solid. Yield: 63.7%. ^{1}H NMR: 0.33 (s, 18H, –Si(CH$_3$)$_3$); 0.93 (d, 6H, –CH$_2$CH(*CH*$_3$)$_2$); 1.10 (d, 6H, –CH$_2$CH(*CH*$_3$)$_2$); 1.72 (m, 2H, –C*H*$_2$CH(CH$_3$)$_2$); 1.94 (m, 2H, –C*H*$_2$CH(CH$_3$)$_2$); 2.55 (m, 2H, –CH$_2$C*H*(CH$_3$)$_2$); 6.84 (t, 1H, *p*-NPh-*H*); 7.01 (m, 2H, aromatic); 7.12 (t, 2H, *m*-NPh-*H*); 7.31 (d, 2H, *o*-NPh-*H*); 7.36 (m, 2H, aromatic). ^{13}C{^{1}H} NMR: 2.20 (–Si(CH$_3$)$_3$, $J_{C–H}$ = 119.3 Hz); 27.33 (–CH$_2$CH(*CH*$_3$)$_2$, $J_{C–H}$ = 125.8 Hz); 29.15 (–CH$_2$CH(*CH*$_3$)$_2$, $J_{C–H}$ = 126.5 Hz); 33.73 (–CH$_2$*C*H-(CH$_3$)$_2$, $J_{C–H}$ = 127.2 Hz); 80.01 (–*C*H$_2$CH(CH$_3$)$_2$); 121.79, 123.60, 125.46, 126.65, 128.62, 133.12, 155.97 (aromatic). *Anal.* Calc. for C$_{26}$H$_{45}$N$_3$Si$_2$W: C, 48.82; H, 7.09; N, 6.57. Found: C, 48.54; H, 7.11; N, 6.50%.

4.6. W(NPh)[(o-Me$_3$SiN)$_2$C$_6$H$_4$](CH$_2$CH$_2$Ph)$_2$ (**1d**)

W(NPh)[(*o*-Me$_3$SiN)$_2$C$_6$H$_4$](Cl)$_2$ (2 g, 3.36 mmol) was dissolved in 150 ml of Et$_2$O and cooled to −78 °C. Two equivalents of PhCH$_2$CH$_2$MgCl (3.4 ml, 3.4 mmol; 2.0 M solution in Et$_2$O) were then added via syringe. The reaction was allowed to warm to room temperature and was stirred for 2 h, during which time a brown color appeared and salts precipitated. The solvent was then removed under reduced pressure, and the remaining brown-orange solid was dried in vacuo for 3 h. The solid was then extracted with pentane and filtered by filter cannula until filtrate was almost clear. The solution was concentrated to about 10 ml and cooled to −78 °C for 3 h. The resulting orange solid was isolated by filtration and were dried under reduced pressure for 1 h to yield 1.68 g of **1d** as a orange crystalline solid. Yield: 68.2%. ^{1}H NMR: 0.30 (s, 18H, –Si(CH$_3$)$_3$); 2.09 (d of t, 2H, –C*H*$_2$CH$_2$Ph); 2.38 (d of t, 2H, –C*H*$_2$CH$_2$Ph); 2.91 (d of t, 2H, –CH$_2$C*H*$_2$Ph); 3.14 (d of t, 2H, –CH$_2$C*H*$_2$Ph); 6.86 (t, 1H, *p*-NPh-*H*); 6.99 (m, 5H, aromatic); 7.02 (m, 2H, aromatic); 7.08 (t, 2H, *m*-NPh-*H*); 7.15 (m, 5H, aromatic); 7.22 (d, 2H, *o*-NPh-*H*); 7.39 (m, 2H, aromatic). ^{13}C{^{1}H} NMR: 1.48 (–Si(CH$_3$)$_3$, $J_{C–H}$ = 118.3 Hz); 39.65 (–CH$_2$*C*H$_2$Ph, $J_{C–H}$ = 123.4 Hz); 65.61 (–*C*H$_2$CH$_2$Ph, $J_{C–H}$ = 119.2 Hz, $J_{W–C}$ = 77.2 Hz); 122.83, 125.01, 125.20, 125.43, 125.58, 128.14, 128.48, 128.62, 132.95, 149.20, 156.22 (aromatic). *Anal.* Calc. for

$C_{34}H_{45}N_3Si_2W$: C, 55.50; H, 6.17; N, 5.71. Found: C, 55.23; H, 6.09; N, 5.75%.

4.7. $W(NPh)[o\text{-}(Me_3SiN)_2C_6H_4](CH_2CD_2Ph)_2$ (**1d-d_4**)

Deuterated analog of **1d** was prepared in the same way as described above using Grignard reagent, $PhCD_2CH_2MgBr$, prepared from $PhCD_2CH_2Br$ and Mg^0. $PhCD_2CH_2Br$ was synthesized from $PhCD_2CH_2OH$ and PPh_3Br_2 in CH_2Cl_2. 2-Phenylethanol-2,2-d_2, $PhCD_2CH_2OH$, was prepared following the literature preparation methods [39]. NMR analysis showed 98% deuteration at the benzylic position. ^{1}H NMR: 0.25 (s, 18H, –Si(CH_3)$_3$); 2.08 (d, 2H, –CH_2CD$_2$Ph, $^2J_{H-H}$ = 12.6Hz); 2.38 (d, 2H, –CH_2CD$_2$Ph, $^2J_{H-H}$ = 12.9Hz); 6.78–7.42 (19H, aromatic). ^{13}C{^{1}H}NMR: 1.45 (s, –Si(CH_3)$_3$, J_{C-H} = 120.7 Hz); 38.93 (–CH_2CD_2Ph); 65.57 (–CH_2CD$_2$Ph, J_{C-H} = 122.3 Hz, J_{W-C} = 76.3 Hz); 122.86, 124.94, 125.22, 125.49, 125.64, 125.94, 128.54, 128.67, 133.04, 149.22, 156.30 (aromatic).

4.8. $W(NPh)[(o\text{-}Me_3SiN)_2C_6H_4](\eta^2\text{-}C_2H_4)(PMe_3)_2$ (**2**)

In a glass tube with a Teflon Young's joint, W(NPh)[(*o*-$Me_3SiN)_2C_6H_4$](CH_2CH_3)$_2$ (**1a**) (1.35 g, 2.32 mmol) was dissolved in 30 mL of pentane. Five equivalents of PMe_3 (1.19 ml, 11.56 mmol) were added via syringe, then the flask was sealed. The reaction was stirred at room temperature for 4 h, during which time the brown solution turned purple and purple crystals precipitated. The mixture was transferred to a Schlenk tube and purple crystals were isolated. The mother liquors were reduced in volume under reduced pressure and cooled to −78 °C to yield more solid. Total yield: 1.44 g, 88.3%. ^{1}H NMR: 0.31 (s, 9H, –Si(CH_3)$_3$); 0.60 (s, 9H, –Si′(CH_3)$_3$); 1.03 (s, 18H, –PMe_3); 1.91 (m, C_2H_4); 2.09 (m, C_2H_4); 6.61–7.42 (aromatic). ^{13}C{^{1}H} NMR: 2.67 (–Si(CH_3)$_3$); 6.34 (–Si′(CH_3)$_3$); 15.78 (s, –PMe_3); 38.13 (s, C_2H_4, J_{C-H} = 156.2Hz); 122.23, 123.13, 124.28, 125.51, 127.23, 128.91, 129.23, 129.78, 158.23 (aromatic); *Anal*. Calc. for $C_{26}H_{49}N_3Si_2P_2W$: C, 44.25; H, 7.00; N, 5.95. Found: C, 43.91; H, 6.79; N, 5.78%.

4.9. $W(NPh)[(o\text{-}Me_3SiN)_2C_6H_4](\eta^2\text{-}CH_2{=}CHCH_3)(PMe_3)_2$

W(NPh)[(*o*-$Me_3SiN)_2C_6H_4$](η^2-CH_2=$CHCH_3$)-(PMe_3)$_2$ can be observed in the reaction of **1b** with PMe_3. ^{1}H NMR: 0.44 (br, s, 18H, –Si(CH_3)$_3$); 1.02 (s, 18H, –PMe_3); 1.62 (d of d, 1H, –CH_2CHCH$_3$); 2.39 (d of d, 1H, –CH_2CHCH$_3$); 2.55 (d, 3H, –CH_2CHCH_3); 2.85 (m, 1H, –CH_2CHCH$_3$); 6.42–7.58 (aromatic).

4.10. $W(NPh)[(o\text{-}Me_3SiN)_2C_6H_4](\eta^2\text{-}CH_2{=}CHPh)(PMe_3)_2$ (**3**)

In a glass tube with a Rotoflo joint, W(NPh)[(*o*-$Me_3SiN)_2C_6H_4$](CH_2CH_2Ph)$_2$ (**1d**) (0.8 g, 1.09 mmol) was dissolved in 50 mL of pentane. Five equivalents of PMe_3 (0.56 ml, 5.45 mmol) were added by a syringe, then the flask was sealed. The reaction was heated to 80 °C and was stirred for 8 h, during which time the solution changed color from brown to purple. The solvent was then removed under reduced pressure and the remaining brown-purple oil was dried overnight. The oil was then redissolved in minimum amount of pentane and cooled to −78 °C for 2 h. The resulting brown-purple solid was isolated by filtration and was dried under reduced pressure for 1 h to give 0.48 g of **3**. Yield: 56.3%. ^{1}H NMR: 0.41 (s, 18H, –Si(CH_3)$_3$); 0.86 (s, 18H, –PMe_3); 2.62 (m, –CH_2CHPh); 2.80 (m, –CH_2CHPh); 3.87 (t, –CH_2CHPh); 6.41–7.24 (aromatic). *Anal*. Calc. for $C_{32}H_{53}N_3Si_2P_2W$: C, 49.16; H, 6.83; N, 5.38. Found: C, 48.80; H, 6.71; N, 5.22%.

4.11. Kinetics study

Samples were prepared by dissolving **1d** and **1d**-d_4 (ca. 10mg) in 0.44 ml of toluene-d_8 solution. The concentration of **1a** samples was obtained from a known concentration of (η^5-C_5H_5)$_2$Fe as internal standard. The samples were sealed and stored at −196 °C immediately after adding desired amount of PMe_3. The NMR probe was equilibrated to the desired temperature and the sample was thawed and well shaken prior to loading into the probe. Approximately 18 spectra were recorded at increasing intervals (more points for early stages of the reaction) over a duration of more than 3 half-lives. Absolute peak intensities of the trimethylsilyl peaks of both starting material and product were recorded for each spectrum. The observed rate constants were obtained from the slope of the plots of ln(Intensity) vs. time. Three samples were performed at each temperature and the rate constants reported were the average of all three runs. Activation parameters were obtained by measuring rate constants at four different temperatures. A plot of ln(k/T) vs. 1/T (T, temperature in Kelvin) results in a line with a slope of $-\Delta E^{\ddagger}/R$ and an intercept of [($\Delta S^{\ddagger}/R$) + 23.76]. Reported errors in the rate constants represent the standard deviation from the least squares fit of the experimental data. Reported errors in the activation parameters are obtained from all experimental data (12 points in the Eyring plot), using 2σ.

4.12. Phosphine dependence

Samples were prepared and experiments were carried out as described above. To determine the dependence of the PMe_3 concentration on the observed rate constants,

a series of experiments were carried out with **1a** and **1d** with various concentrations of PMe_3. Plotting the observed rate constants obtained from these experiments vs. the concentration of added PMe_3 gave a line in the case of **1a** and **1d** (at high concentration). The order in PMe_3 (**1a**) was determined from the slope (1.096) of the plot of ln*k* vs. ln[PMe_3].

4.14. X-ray experimental

Data for compound **1c** and **1d** were collected at 173 K on a Siemens SMART PLATFORM equipped with a CCD area detector and a graphite monochromator utilizing Mo Kα radiation (λ = 0.71073 Å). Cell parameters were refined using up to 8192 and 9856 reflections for **1c** and **1d**, respectively. A hemisphere of data (1381 frames) was collected using the w-scan method (0.3° frame width). The first 50 frames were remeasured at the end of data collection to monitor instrument and crystal stability (maximum correction on *I* was <1%). ψ scan absorption corrections were applied based on the entire data set.

Both structures were solved by the Direct Methods in SHELXTL5 [43], and refined using full-matrix least squares. The non-H atoms were treated anisotropically, whereas the hydrogen atoms were calculated in ideal positions and were riding on their respective carbon atoms. 470 parameters were refined (**1c**) in the final cycle of refinement using 6252 reflections with $I > 2\sigma(I)$ to yield R_1 and wR_2 of 1.65% and 3.94%, respectively. 362 parameters were refined (**1d**) in the final cycle of refinement using 5292 reflections with $I > 2\sigma(I)$ to yield R_1 and wR_2 of 3.40% and 7.29%, respectively. Refinement was done using F^2.

Abstract

^{15}N Solid state CP/MAS NMR spectroscopy has been used to study a dinitrogen-derived terminal nitride of molybdenum, $^{15}NMo(N[^tBu]Ar)_3$ (Ar = 3,5-$(CH_3)_2C_6H_3$). A number of Lewis acid adducts, including X_3E–$NMo(N[^tBu]Ar)_3$ (X = F, E = B; X = Cl, E = B, Al, Ga, In; X = Br, E = Al; X = I, E = Al) and Cl_2E–$NMo(N[^tBu]Ar)_3$ (E = Ge, Sn), were prepared by the combination of $^{15}NMo(N[^tBu]Ar)_3$ with 1 equiv. of Lewis acid. A series of cationic imido complexes, $[RNMo(N[^tBu]Ar)_3]X$ was prepared by the reaction of electrophiles, RX [R = CH_3, X = I; R = PhC(O) or Me_3Si, X = OTf (OTf = SO_3CF_3)], with $NMo(N[^tBu]Ar)_3$. Deprotonation of $[CH_3NMo(N[^tBu]Ar)_3]I$ by $LiN(SiMe_3)_2$ afforded the ketimide complex $H_2CNMo(N[^tBu]Ar)_3$, which has been shown to undergo a reaction with neat CH_3I to form $[CH_3CH_2NMo(N[^tBu]Ar)_3]I$. ^{15}N solid state CP/MAS NMR spectroscopy was employed in the characterization of each complex. Complementary density functional theory (DFT) studies of $^{15}NMo(N[^t$-$Bu]Ar)_3$ and derivatives enabled a detailed examination of the experimental solid state NMR parameters in terms of electronic structure at the labeled N-atom. Computational analysis demonstrated that significant paramagnetic contributions to the perpendicular components of the chemical shielding tensor (δ_{11} and δ_{22}) were responsible for the huge span of the tensor measured for $^{15}NMo(N[^t$-$Bu]Ar)_3$ (Ω = 1187 ppm). Perturbation of the electronic structure in $^{15}NMo(N[^tBu]Ar)_3$ upon coordination of a Lewis acid or formation of a cationic imido complex was attributed to stabilization of a σ-symmetric orbital. An upfield shift in the perpendicular components of the chemical shift tensor results from the reduced paramagnetic contribution to these tensor components upon increasing the energy gap between the magnetically coupled occupied and virtual orbitals ($e_{occ} - e_{vir}$).

1. Introduction

The use of isotopic labeling of compounds with ^{15}N to probe their structure and bonding by means of solid state NMR spectroscopy is most commonly seen in biological systems and organic molecules [1–9]. In contrast, solid state NMR spectroscopy of spin-active nuclei in transition metal complexes has been underutilized [10–16]. The isotropic chemical shift value determined in solution NMR measurements is the most reported spectroscopic parameter, but a wealth of additional information may be gained through the acquisition of solid state NMR spectra [17,18]. The use of ^{31}P solid state NMR

spectroscopy to probe the structure and bonding in a terminal molybdenum phosphide, $PMo(N[^tBu]Ar)_3$ (Ar = 3,5-$(CH_3)_2C_6H_3$) was reported previously [19]. The significant anisotropy of the ^{31}P chemical shift tensor and the enormous paramagnetic deshielding of the ^{31}P nucleus when the applied field is oriented perpendicular to the Mo–P triple bond were explained in terms of the magnetic coupling of filled and vacant molecular orbitals.

Herein, we extend our study of structure and bonding through the use of solid state NMR spectroscopy to the analogous terminal nitride of molybdenum, $NMo(N[^tBu]Ar)_3$ (**1**) [20]. The splitting of dinitrogen by a three-coordinate molybdenum(III) complex $Mo(N[^tBu]Ar)_3$ was first reported in 1995 [21]. The ^{15}N-labeled form of **1**, $^{15}NMo(N[^tBu]Ar)_3$ is readily prepared through the use of ^{15}N-isotopically-enriched dinitrogen gas, thereby making this complex amenable to study by ^{15}N NMR spectroscopy [22]. The potential of **1** to serve as a platform in N-atom transfer chemistry is currently under investigation in our laboratories. It is of interest to determine what insight solid state NMR spectroscopy can provide into the electronic structure for a molybdenum complex which is activated toward productive removal of the dinitrogen-derived N-atom into an organic product. The synthesis of several derivatives of **1** and subsequent measurement of their ^{15}N solid state CP/MAS NMR spectra are described.

Complementary density functional theory analyses of **1** and its derivatives were completed utilizing a simplified ligand framework (NH_2 ligands replacing $N[^tBu]Ar$). DFT permits a detailed analysis of experimental solid state NMR parameters (δ_{11}, δ_{22} and δ_{33}) via calculation of the absolute shielding tensors [23–27] together with correlation to calculated molecular orbitals. The validity of our analyses of electronic structure may be assessed by comparison of the experimental tensor values with those determined computationally.

2. Experimental

2.1. General information

Unless stated otherwise, all operations were performed in a vacuum atmospheres drybox under an atmosphere of purified dinitrogen. Diethyl ether, *n*-pentane and dichloromethane were dried and deoxygenated using the method of Grubbs and coworkers [28]. THF was distilled from purple Na/benzophenone ketyl and collected under dinitrogen. C_6D_6 and $CDCl_3$ were degassed and dried over 4 Å molecular sieves. $^{15}N_2$ was purchased from Cambridge Isotope Laboratories (CIL) in 0.1 mL break-seal glass vessels. CH_3I was, freeze–pump–thaw degassed and stored over 4 Å sieves prior to use. $Mo(N[^tBu]Ar)_3$ [20] and benzoyl triflate [29] were prepared according to the literature procedures. Other chemicals were purified and dried by standard procedures [30] or were used as received. Celite, alumina and 4 Å molecular sieves were dried in vacuo for 36 h at ~250 °C. Infrared spectra were recorded on a Bio-Rad 135 Series FT-IR spectrometer.

2.2. X-ray crystal structure determinations

The X-ray data collections were carried out on a Siemens Platform three-circle diffractometer mounted with a CCD or APEX CCD detector and outfitted with a low-temperature, nitrogen-stream aperture. The structures were solved by direct methods, with the exception of **1**-BF_3, which was solved using the Patterson Method, in conjunction with standard difference Fourier techniques and refined by full-matrix least-squares procedures. A summary of crystallographic data is given in Table 1, with full details found in the Supporting Information. The systematic absences in the diffraction data were uniquely consistent with the assigned space groups of $P2_1$ for **3** and $P2_13$ for both [**2b**]OTf and [**2d**]**I** (Flack parameters are 0.01(4), −0.01(4)and 0.00(3), respectively). No symmetry higher than triclinic was indicated in the diffraction data for **1**-BF_3. These choices led to chemically sensible and computationally stable refinements. All hydrogen atoms were placed in calculated positions, with the exception of the ketimide protons of **3**, which were located in the electron density map and refined isotropically. The Mo1–N2–C21 unit of [**2d**]**I** was found to be coincident with a three-fold axis of the $P2_13$ space group, thus imposing three-site positional disorder in the corresponding methyl group (C22). This disorder was modeled and no hydrogen atoms were generated for methylene carbon C21. Complex [**2c**]OTf crystallized in the centrosymmetric space group $P2_1/n$ with two-site positional disorder found for the triflate counter ion. This disorder was modeled to 70:30 occupancy over the two sites as indicated by the refinement statistics and resulted in chemically sensible geometries. Isomorphous **1**-$GeCl_2$ and **1**-$SnCl_2$ were found to crystallize in the centrosymmetric space group $P2_1/c$ and both contained two-site positional disorder of the aryl-ring and ECl_2 residues. Both possible chiral, three-blade propeller orientations of the aryl rings were present and were modeled each with 50% occupancy as indicated by the refinement statistics. Additionally, each aryl-ring orientation corresponded to distinct ECl_2 orientation and was similarly modeled. Only one orientation of **1**-$GeCl_2$ and **1**-$SnCl_2$ is presented in the text. No hydrogen atoms were generated for the aryl rings of **1**-$GeCl_2$ and **1**-$SnCl_2$ due to the disorder. All software for diffraction data processing and crystal-structure solution and refinement are contained in the SHELXTL (v6.14) program suite (G. Sheldrick, Bruker XRD, Madison, WI).

2.3. NMR measurements

Solution state ^{1}H, ^{13}C and ^{19}F NMR spectra were recorded on a Varian Mercury-300 spectrometer operating at 300 MHz for ^{1}H. Solution state ^{27}Al, ^{11}B and ^{119}Sn NMR spectra were recorded on a Varian INOVA-500 spectrometer operating at 500 MHz for ^{1}H. ^{15}N Solution state NMR spectra were acquired on a Bruker DRX600 spectrometer operating at 600 MHz for ^{1}H (60 MHz for ^{15}N) and equipped with a triple resonance ($^{1}H/^{13}C/^{15}N$) probe. All solution NMR chemical shifts are reported in parts per million (ppm) and coupling constants (J) in Hertz (Hz). ^{1}H and ^{13}C chemical shifts are reported with respect to the internal solvent (C_6D_6, 7.16 and 128.39; THF-d_8, 3.58 and 1.73, 67.57 and 25.37; $CDCl_3$, 7.27 and 77.0). ^{15}N chemical shifts are referenced to external neat CH_3NO_2 (δ = 380.2 ppm with respect to neat liquid NH_3 (0.0 ppm)) [22]. Other nuclei were referenced using an external standard, as follows: ^{19}F spectra were referenced with respect to $CFCl_3$ (0.0 ppm); ^{27}Al spectra were referenced to $Al(D_2O)_6^{3+}$ (1.0 M $AlCl_3$ in D_2O; 0.0 ppm); ^{11}B spectra were referenced to neat $BF_3 \cdot OEt_2$ (0.0 ppm); ^{119}Sn spectra were referenced to 0.5 M $Sn(CH_3)_4$ in CH_2Cl_2 (0.0 ppm). Solid state ^{15}N NMR spectra were acquired using a custom-designed spectrometer operating at 501 MHz for ^{1}H (50.8 MHz for ^{15}N). All spectra were acquired using a triple-resonance ($^{1}H/^{13}C/^{15}N$) magic-angle spinning (MAS) probe from Chemagnetics (Fort Collins, CO) configured for 4.0 mm zirconium rotors. Spinning frequencies of 3–6.5 kHz were used. The identity of the isotropic peak (δ_{iso}) was confirmed by measurement of the spectra at several different spinning speeds. Proton–nitrogen cross-polarization (CP) under the Hartmann–Hahn match was used to enhance the sensitivity of all ^{15}N NMR spectra [31]. Samples were referenced indirectly to the ^{13}C CP/MAS spectrum of adamantane or directly to the ^{15}N CP/MAS spectrum of NH_4Cl (acquired prior to each sample acquisition). Both solution and solid state NMR spectra were acquired at 20 °C. For further details of parameters used in the acquisition of solid state NMR spectra refer to the Supporting Information.

2.4. Simulation and calculation of solid state NMR spectra

The principal components of the chemical shift tensors were determined experimentally by fitting simulated spectra to the experimental data [32,33] using Simpson [34] (a general simulation program for NMR spectroscopy). The residuals between the simulated spectrum and the experimental spectrum could, in most cases, be reduced to <5%. The Simpson program was also used to calculate spectra based on values of the chemical shift tensor (in ppm) that were calculated using ADF. See the Supporting Information. for further details.

2.5. Computational details

Theoretical calculations were carried out using the Amsterdam Density Functional package (version *ADF2002.02*) [35–38]. The Slater-type orbital (STO) basis sets were of triple-ζ quality augmented with two polarization functions (ADF basis TZ2P). Full electronic configuration was used for all atoms. Relativistic effects were included by virtue of the zero order regular approximation (ZORA) [39–41]. The local density approximation (LDA) by Vosko, Wilk and Nusair (VWN) [42] was used together with the exchange correlation corrections of Becke [43] and Perdew [44] (BP-86).

The ^{15}N NMR chemical shielding calculations were performed using a multi-step procedure. First, the geometry of the compound of interest was optimized using X-ray parameters as a starting point. The optimized geometry was then subjected to a single-point calculation incorporating spin–orbit effects. The output of this calculation was used as the input for the ADF NMR utility [45].

Values of the absolute shielding tensor, calculated using density functional methods, were converted to referenced chemical shifts (δ ppm) using the following equation [46]

$$\delta(\mathrm{S},\ \mathrm{calc}) = \sigma(\mathrm{N_2},\ \mathrm{calc}) - \sigma(\mathrm{S},\ \mathrm{calc}) + \delta(\mathrm{N_2},\ \mathrm{ref}), \quad (1)$$

where δ(S, calc) is the calculated chemical shift (ppm) of the compound of interest (S), $\sigma(N_2, \mathrm{calc})$ is the calculated absolute shielding tensor for the reference compound (N_2 gas; $\sigma(N_2, \mathrm{calc}) = -80.012$ ppm), σ(S, calc) is the calculated absolute shielding tensor of S and $\delta(N_2, \mathrm{ref})$ is the experimental chemical shift (ppm) of the reference compound (N_2 gas). The NMR shielding (σ) of N_2 (with reference to neat nitromethane) = + 74.2 ppm, therefore δ (N_2, ref) = 380.2−74.2 = 306 ppm (referenced to liquid NH_3 at 0 ppm) [47,48].

2.6. Synthesis of $^{15}NMo(N[^{t}Bu]Ar)_3$ (*1*)

A 300-mL 3-neck flask fitted with a 0.1 L break-seal flask containing $^{15}N_2$ was charged with KH (3.52 g, 88 mmol). THF (50 mL) was added and the slurry was stirred while sparging with argon for 15 min. Stirring was paused and the headspace of the flask was evacuated. Under a static vacuum the break-seal was opened and the slurry was stirred vigorously as the headspace filled with $^{15}N_2$. In a second flask, $Mo(N[^{t}Bu]Ar)_3$ (5.5 g, 8.8 mmol) was dissolved in THF (35 mL) and the solution was stirred while sparging with argon for 10 min. Addition of the $Mo(N[^{t}Bu]Ar)_3$ solution via syringe to the KH/THF slurry afforded a dark orange mixture. Stirring was continued for 24 h after which time the solution was filtered through Celite. Solvent removal in vacuo gave an orange powder, which upon dissolution in pen-

tane and storage at −35 °C gave amber crystals of the desired terminal nitride complex, $^{15}NMo(N[^tBu]Ar)_3$ (4.72 g, 7.40 mmol, 84%). This procedure is a modification of previously reported syntheses for complex **1** [20,50,51].

2.7. Synthesis of lewis acid adducts *1*-*LA*

A solution of $NMo(N[^tBu]Ar)_3$ in *n*-pentane (5 mL) was prepared in a 20-mL scintillation vial and chilled to −35 °C. In a second vial a solution of the Lewis acid (1 equiv. in 2 mL pentane) was prepared and chilled to −35 °C. The Lewis acid solution was added to the $NMo(N[^tBu]Ar)_3$ solution and stirred at room temperature for 1 h. Upon addition of the Lewis acid a yellow solid precipitated from solution. Filtration of the suspension, washing with pentane and subsequent drying under a dynamic vacuum afforded the desired product. Recrystallization from a concentrated CH_2Cl_2 solution layered with pentane at −35 °C afforded yellow crystals of $X_3E–NMo(N[^tBu]Ar)_3$.

Isolated yield of yellow **1**-$BF_3 \cdot CH_2Cl_2$ (from 0.115 g of **1**): 0.092 g, 0.130 mmol, 72%. *Anal.* Calc. for $C_{36}H_{54}N_4MoBF_3$: C, 61.19; H, 7.70; N, 7.93. 2.8. Synthesis of $[CH_3NMo(N[^tBu]Ar)_3]I$ [**2a**]I

Crystalline **1** (0.120 g, 0.188 mmol) was dissolved in neat CH_3I (0.8 mL, 12.8 mmol) in a 20 mL vial. The solution was stirred at 25 °C for 20 h after which time removal of excess CH_3I in vacuo and a pentane wash afforded a bright yellow powder in 92% yield (0.137 g, 0.173 mmol). ^1H NMR (300 MHz, $CDCl_3$, 20 °C) δ: 6.99 (s, 3 H, *para*), 5.67 (br s, 6 H, *ortho*), 5.16 (s, 3 H, NCH_3), 2.19 (s, 18 H, $ArCH_3$), 1.29 (s, 27 H, $NC(CH_3)_3$). ^{13}C NMR (75.0 MHz, $CDCl_3$, 20 °C) δ: 145.3 (*ipso*), 138.6 (*meta*), 130.8 (*para*), 128.4 (*ortho*), 68.50 ($NC(CH_3)_3$), 65.60 (NCH_3), 32.30 ($NC(CH_3)_3$), 21.70 ($ArCH_3$). NMR data for ^{15}N-[**2a**]I: ^1H NMR (300 MHz, $CDCl_3$, 20 °C) δ: 5.11 (d, $^2J_{N-H}$ 3.3 Hz, 3 H, ^{15}N–CH_3). ^{15}N NMR (60 MHz, $CH_3I/CDCl_3$, 20 °C) δ: 462.6. *Anal.* Calc. for $C_{37}H_{39}D_{18}N_4MoI$: [49] C, 55.63; H, 7.19; N, 7.01. Found: C, 56.13; H, 7.64; N, 6.53%.

2.9. Synthesis of $[(CH_3)_3Si$–$NMo(N[^tBu]Ar)_3][SO_3CF_3]$ [**2b**]OTf

A 20-mL scintillation vial was charged with **1** (0.10 g, 0.157 mmol) and Et_2O (2 mL). In a second vial a solution of trimethylsilyl trifluoromethanesulfonate [$CF_3SO_3Si(CH_3)_3$] (0.174 g, 5 equiv., 0.783 mmol) in Et_2O (1 mL) was prepared. The contents of the two vials were combined and the solution stirred at 25 °C for 10 h. Solvent removal resulted in the isolation of a bright yellow-orange powder; yield 89% (0.120 g, 0.139 mmol). *Anal.* Calc.: C, 55.75; H, 7.32; N, 6.50. Found: C, 55.54; H, 7.75; N, 6.60%. ^1H (300 MHz, $CDCl_3$, 20 °C) δ: 6.91 (s, 3 H, *para*), 5.62 (br s, 6 H, *ortho*), 2.17 (s, 18 H, $ArCH_3$), 1.34 (s, 27 H, $N(CH_3)_3$), 0.69 (s, 9 H, $Si(CH_3)_3$). ^{13}C NMR (75.0 MHz, $CDCl_3$, 20 °C) δ: 147.7 (*ipso*), 137.5 (*meta*), 129.5 (*ortho*), 128.0 (*para*), 66.04 ($NC(CH_3)_3$), 32.44 ($NC(CH_3)_3$), 21.65 ($ArCH_3$), 1.94 ($Si(CH_3)_3$. ^{19}F NMR (282 MHz, $CDCl_3$, 20 °C) δ: −78.44 (s, SO_3CF_3). ^{15}N NMR (60 MHz, $CDCl_3$, 20 °C) δ: 537.

2.10. Synthesis of $[PhC(O)NMo(N[^tBu]Ar)_3]SO_3CF_3$ [**2c**]OTf

Crystalline **1** (0.200 g, 0.31 mmol) was dissolved in CH_2Cl_2 (2 mL) in a 20-mL scintillation vial and chilled to −35 °C. A solution of PhC(O)OTf (0.89 g, 0.37 mmol, 1.2 equiv.) in CH_2Cl_2 was prepared and similarly chilled to −35 °C. The PhC(O)OTf solution was added to the stirred solution of $NMo(N[^tBu]Ar)_3$ and an immediate darkening of the solution to a brown-orange color was noted. The solution was stirred at 25 °C for 1 h before concentration of the solution (to ~0.5 mL) and addition of cold Et_2O caused precipitation of a red powder. The solution was filtered and the precipitate washed with pentane to afford a red-orange powder in 72% yield (0.198 g, 0.225 mmol). Material suitable for elemental analysis and crystallographic characterization was prepared by recrystallization from a concentrated THF solution layered with pentane. *Anal.* Calc.: C, 58.63; H, 6.75; N, 6.36. Found: C, 59.04; H, 6.73; N, 6.20%. IR (KBr plates, THF); $v_{(CO)}$ 1668 cm^{-1}. ^1H NMR (500 MHz, $CDCl_3$, 20 °C) δ: 8.32 (m, 2 H, *meta* Ph), 7.83 (m, 1 H, *para* Ph), 7.77 (m, 2 H, *ortho* Ph), 7.10 (s, 3 H, *para*), 5.74 (br s, 6 H, *ortho*), 2.26 (s, 18 H, $ArCH_3$), 1.34 (s, 27 H, $NC(CH_3)_3$). ^{13}C NMR (125 MHz, $CDCl_3$, 20 °C) δ: 147.7 (*ipso*), 139.1 (*meta*), 136.3 (Ph), 131.5 (Ph), 131.42 (Ph), 130.0 (*para*), 126.8 (*ortho*), 72.0 ($NC(CH_3)_3$), 31.8 ($NC(CH_3)_3$), 21.7 ($ArCH_3$). ^{19}F NMR (282.23 MHz, $CDCl_3$, 20 °C) δ: −78.3.

2.11. Synthesis of $H_2CNMo(N[^tBu]Ar)_3$ (**3**)

To a chilled suspension of $[CH_3NMo(N[^tBu]Ar)_3]I$ (0.098 g, 0.126 mmol) in pentane (5 mL) was added a chilled solution of 1.1 equiv. $LiN[(Si(CH_3)_3]_2$ (0.023 g, 0.138 mmol) in pentane (4 mL). Within a few minutes of adding base the yellow suspension turned bright red. The suspension was stirred for 12 h at 25 °C after which time the solution had turned dark purple and no suspended solids were observed. The solution was filtered through Celite and solvent removed in vacuo to yield a dark red-purple solid. Recrystallization from Et_2O yielded dark red crystals 0.051 g (0.077 mmol, 62%). *Anal.* Calc.: C, 68.017; H, 8.579; N, 8.583. Found: C, 68.22; H, 8.51; N, 8.68%. m.p.: 124 −135 °C (dec). IR (Et_2O solution, cm^{-1}): 1600 (m, v_{NC}), 1587 (s, v_{Ar-CH_3}). ^1H NMR (300 MHz, C_6D_6, 20 °C) δ: 6.69 (s, 3 H, *para*), 6.289 (s, 3 H, *ortho*), 6.287 (s, 3 H, *ortho*), 5.91 (s, 2 H, NCH_2), 2.16 (s, 18 H, $ArCH_3$), 1.41 (s, 27 H, $NC(CH_3)_3$). ^{13}C NMR (75.0 MHz, C_6D_6, 20 °C); δ: 150.2 (*ipso*), 138.9 (NCH_2), 137.4 (*meta*), 129.9 (*ortho*), 127.7 (*para*), 63.1 ($NC(CH_3)_3$), 32.8 ($NC(CH_3)_3$), 22.1 ($ArCH_3$). **3**-^{15}N: ^1H NMR (300 MHz, C_6D_6, 20 °C) δ: 5.90 (d $^2J_{N-H}$ 1.37 Hz, 2 H, $^{15}NCH_2$). ^{13}C NMR (75.0 MHz, C_6D_6, 20 °C) δ: 138.9 (d $^1J_{N-C}$ 5.78 Hz, $^{15}NCH_2$). ^{15}N NMR (60 MHz, C_6D_6, 20 °C) δ: 454.6.

2.12. Synthesis of $[CH_3CH_2NMo(N[^tBu]Ar)_3]I$ [**2d**]I

Crystalline $H_2CNMo(N[^tBu]Ar)_3$ (**3**, 0.074 g, 0.113 mmol) was dissolved in neat CH_3I (0.8 mL) in a 20-mL scintillation vial. The solution was stirred at 25 °C

for 14 h after which time removal of excess CH_3I in vacuo and a pentane wash afforded a bright yellow powder in 96% yield (0.086 g, 0.109 mmol). Recrystallization from a concentrated CH_2Cl_2 solution layered with Et_2O afforded yellow crystals of [**2d**]I · CH_2Cl_2. ^{1}H NMR (300 MHz, $CDCl_3$, 20 °C) δ: 6.98 (s, 3 H, *para*), 5.60 (br s, 6 H, *ortho*), 5.38 (q, 2 H, $^3J_{HH}$ 7.2 Hz, NCH_2CH_3), 2.17 (s, 18 H, $ArCH_3$), 1.95 (t $^3J_{HH}$ 7.2 Hz, 3 H, NCH_2CH_3), 1.27 (s, 27 H, $NC(CH_3)_3$). ^{13}C NMR (75.0 MHz, $CDCl_3$, 20 °C) δ: 145.9 (*ipso*), 138.6 (*meta*), 130.7 (*para*), 128.3 (*ortho*), 77.6 (NCH_2CH_3), 68.1 ($NC(CH_3)_3$), 32.4 ($NC(CH_3)_3$), 21.7 ($ArCH_3$), 17.5 (NCH_2CH_3). *Anal.* Calc.: C, 57.43; H, 7.48; N, 7.55. Found: C, 57.52; H, 7.44; N, 7.89%.

3. Results and discussion

3.1. Synthesis and characterization

The first reported synthesis of $NMo(N[^tBu]Ar)_3$ (**1**) from $Mo(N[^tBu]Ar)_3$ required a 3 d incubation period at −35 °C during which time N_2 uptake takes place [20]. Subsequent work focusing on the redox-catalyzed binding and splitting of dinitrogen by $Mo(N[^tBu]Ar)_3$ has led to the development of a more efficient route to the terminal nitride **1** [50]. Most recently, Lewis bases were found to accelerate the uptake of N_2 by $Mo(N[^tBu]Ar)_3$ enabling its quantitative conversion to **1** within 24 h. Potassium hydride (10 equiv. in THF) was found to be the most efficient base for effecting this conversion (Fig. 1) [51].

Furthermore, the ease of separation of KH from the pentane soluble product (**1**) by filtration makes this route particularly attractive. Complete characterization for complex **1** was reported previously. We will however make note of the ^{15}N solution NMR shift of **1** (840 ppm) for comparison with values reported in the following discussions. While complex **1** has eluded characterization by single crystal X-ray diffraction, the structure of a related compound, $NMo(N[^tBu]Ph)_3$ [20], is pseudo tetrahedral with the Mo≡N bond aligned with a crystallographic C_3 axis.

A number of neutral Lewis acid adducts of formula X_3E–$NMo(N[^tBu]Ar)_3$ (X = F, E = B: X = Cl, E = B, Al, Ga, In; X = Br, E = Al; X = I, E = Al) and Cl_2E–$NMo(N[^tBu]Ar)_3$ (E = Ge, Sn), were prepared by simple combination of **1** with 1 equiv. of Lewis acid (Fig. 2). Yields were generally quite high and in the range of 59–91%. These adducts were typically bright yellow, or sometimes pale orange, exhibiting limited solubility in pentane, benzene and Et_2O. The decomposition of these adducts to starting materials was observed in 0.5–3 h in THF solution at 25 °C.

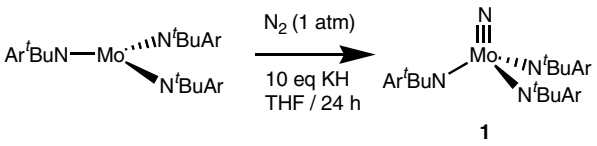

Fig. 1. Formation of complex **1** via the base-catalyzed cleavage of dinitrogen.

Infrared spectroscopy yielded little information with regard to the strength of the Mo–N or N–LA (LA = Lewis acid) interactions as a result of strong absorptions (attributed to the amide ligands) in the relevant regions of the spectrum.

A feature observed in the ^{1}H NMR spectrum of all complexes **1**-LA was significant broadening of the ~5.6 ppm resonance assigned to the six *ortho* protons of the $N[^tBu]Ar$ ligands. This broadening is attributed to hindered rotation about the Mo–N_{amide} bond due to increased steric congestion at the metal center.

As expected, the ^{11}B isotropic chemical shift for **1**-BF_3 (−2.8 ppm) and **1**-BCl_3 (3.9 ppm) showed an upfield shift of each resonance with respect to the uncoordinated Lewis acid (BF_3 = 10.0 ppm, BCl_3 = 46.5 ppm). [1] A similar upfield shift of the ^{27}Al resonance, with respect to the uncoordinated Lewis acid, was observed for the complexes **1**-$AlCl_3$, **1**-$AlBr_3$ and **1**-AlI_3 [52].

The ^{119}Sn NMR spectrum of **1**-$SnCl_2$ displayed a broad singlet at 333 ppm, which is shifted downfield of the resonance for $SnCl_2$ in THF solution (236 ppm) [53]. The ^{119}Sn resonance for **1**-$SnCl_2$ compares with other $SnCl_2$ · N-donor complexes such as $SnCl_2$ · pyridine in which the ^{119}Sn resonance occurs at 295 ppm [54].

In the ^{27}Al, ^{11}B and ^{119}Sn NMR spectra of ^{15}N-**1**-BX_3, ^{15}N-**1**-AlX_3 and ^{15}N-**1**-$SnCl_2$, coupling of the two spin active nuclei (e.g., ^{15}N–^{27}Al) could not be resolved. In each case the resonance for the spin-active Lewis acid center was broadened upon coordination to ^{15}N-**1** (e.g. ^{11}B NMR: ^{14}N-**1**-BCl_3 $\nu_{1/2}$ = 16.5 Hz; ^{15}N-**1**-BCl_3 $\nu_{1/2}$ = 36.6 Hz). Likewise, the ^{15}N solution NMR spectrum measured for ^{15}N-**1**-BF_3 displayed only a broad singlet at 592 ppm. This value is shifted upfield quite considerably (248 ppm) with respect to ^{15}N-**1**.

Crystallographic characterization of **1**-BF_3 confirmed the formation of a σ-bond through donation of the terminal nitride N-lone pair into the vacant p-orbital on the Lewis acidic boron center. [2] The N–B bond distance of 1.609(7) Å is similar to those reported in the literature for other Lewis acid adducts of nitridometal complexes [55–57]. Complex **1**-BF_3 crystallized in the space group $P\bar{1}$ with the B–F bonds of the Lewis acid staggered with

[1] NMR shifts reported in methylcyclohexane solution; referenced to $BF_3 \cdot OEt_2$ at 0.0 ppm.

[2] See Supporting Information for X-ray crystallographic details and an ORTEP plot of **1**-BF_3.

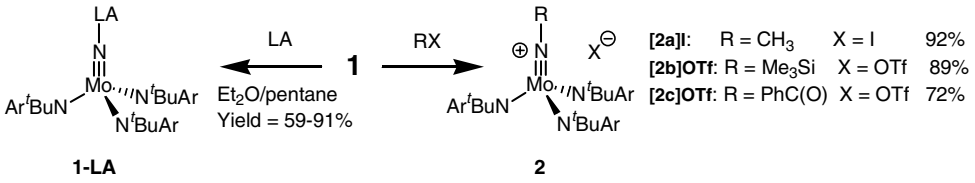

Fig. 2. Syntheses of **1**-LA and the cationic imido complexes [**2a**]I, [**2b**]OTf and [**2c**]OTf.

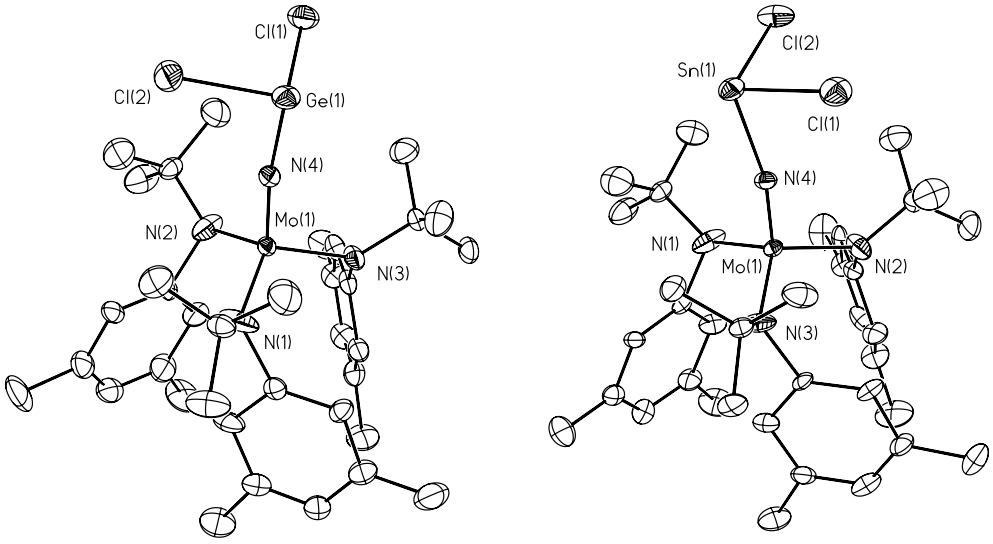

Fig. 3. 35% thermal ellipsoid (ORTEP) representations of **1**-$GeCl_2$ (left) and **1**-$SnCl_2$ (right).

respect to the $Mo–N_{amide}$ bonds. The Mo≡N bond length (1.678(4) Å) in **1**-BF_3 was identical (to within 3σ) to the Mo≡N bond in $NMo(N[^tBu]Ph)_3$ and, as expected, the Mo–N–B bond angle was nearly linear (177.6(4)°).

Complexes **1**-$GeCl_2$ and **1**-$SnCl_2$ were found (by X-ray crystallography) to be isomorphous (Fig. 3). To the best of our knowledge, complexes **1**-$GeCl_2$ and **1**-$SnCl_2$ represent the first examples of coordination at the terminally bound nitrogen in a nitridometal complex by a divalent germanium or tin halide [58,59]. Upon addition of $GeCl_2 \cdot$ dioxane or $SnCl_2$ to **1**, simple Lewis acid adducts analogous to those of the Group 13 **1**-LA complexes were formed. Complexes **1**-$GeCl_2$ and **1**-$SnCl_2$ were characterized by Mo≡N bond lengths of ~1.70 Å and N–Ge (or N–Sn) bond lengths typical of single bonds.

Transition-metal imido complexes containing an Mo≡NR bonding motif are well documented in the literature [60,61]. Reaction of **1** with electrophiles, RX

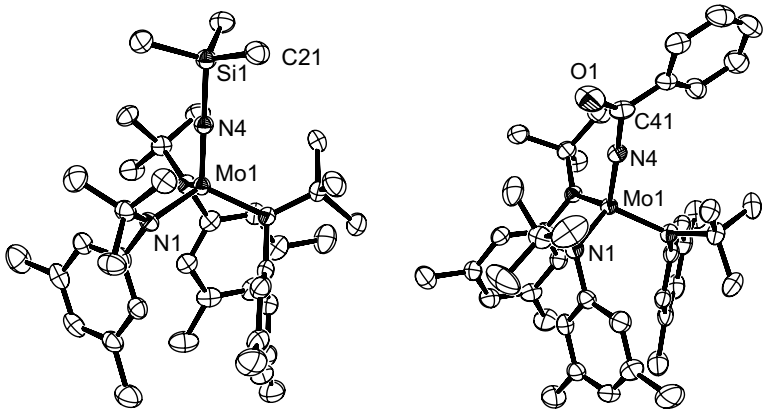

Fig. 4. 50% thermal ellipsoid (ORTEP) representations of cations [**2b**] (left) and [**2c**] (right).

(R = CH_3, X = I and R = Me_3Si, X = SO_3CF_3 = OTf), afforded the imido salts [**2a**]I [49] and [**2b**]OTf as bright yellow, pentane insoluble powders in high yield (92% and 89%, respectively, Fig. 2). In the ^1H NMR spectrum of ^{15}N-[**2a**]I a two-bond coupling ($^2J_{N-H}$) of 3.3 Hz was resolved for the methyl protons ($^{15}N–CH_3$). Solution $^{15}N\{^1H\}$ NMR spectra for [**2a**]I and [**2b**]OTf displayed resonances at 463 and 537 ppm, respectively.

The imido complex [**2b**]OTf crystallized in the cubic space group $P2_13$ (Fig. 4). The Mo–N–Si bond angle is linear as mandated by its alignment with the crystallographic C_3 axis. The Mo≡N bond distance of 1.715(6) Å was lengthened 0.057 Å with respect to the Mo≡N bond distance in **1** while the N–Si bond distance of 1.795(6) Å was slightly longer (~0.08 Å) than might be expected for a single N–Si bond [62]. While complex [**2a**]I has not been structurally characterized, the cation $[CH_3NMo(N[^tBu]Ar)_3]^+$ [**2a**] is presumably a 4-coordinate monomer related to the trimethylsilylimido cation $[(CH_3)_3Si–NMo(N[^tBu]Ar)_3]^+$ [**2b**].

Reaction of benzoyl triflate (PhC(O)OTf) with **1** in CH_2Cl_2 enabled isolation of the red-orange benzoylimido complex $[PhC(O)NMo(N[^tBu]Ar)_3]OTf$ [**2c**]OTf in 72% yield. There have been very few reports of the use of benzoyl triflate in synthetic inorganic chemistry despite this reagent's obvious utility as a potent electrophile [29,63,64]. There are similarly few reports of transition metal complexes containing a benzoylimido moiety i.e., PhC(O)N≡M [65–68]. X-ray crystallographic characterization of [**2c**]OTf showed that the Mo≡N bond is lengthened slightly with respect to the Mo≡N bond in complex **1** (Fig. 4). The N–C bond of 1.422(5) Å is in the range typical for an N–C single bond suggesting that resonance forms involving N–C multiple bond character do not provide added stabilization in this complex.

Dehydrohalogenation of [**2a**]I was achieved using lithium hexamethyldisilazide in pentane (Fig. 5) and resulted in isolation of the purple ketimide complex $H_2CNMo(N[^tBu]Ar)_3$ (**3**). Complex **3** provides a rare example of terminal $–NCH_2$ complexation [69–72], and represents the first example of such ligation to be structurally characterized (Fig. 6). The ketimide N–C bond distance of 1.300(7) Å is consistent with the presence of an N–C double bond. The Mo–N bond distance of 1.777(4) Å is in the range between that of a Mo–N double bond and that of a Mo–N single bond. This multiple bond character is the result of π-donation from a filled Mo d-orbital into the ketimide π*(N–C) molecular orbital and in the perpendicular plane, π-donation from the nitrogen lone pair of electrons into a vacant Mo d-orbital. Complex **3** has a distorted tetrahedral geometry

(average N–Mo–N_{amide} bond angle 101.7°) with pseudo-C_3 point symmetry courtesy of the nearly linear (178.0(4)°) Mo–N–C bond axis of the ketimide moiety (which lies along the pseudo-C_3 axis).

The overall sequence leading to complex **3** can be viewed as formal carbene (CH_2) addition to **1**. Addition of the Group 14 halides $GeCl_2$ and $SnCl_2$ to **1** did not give products analogous to **3** (i.e., oxidation $Ge/Sn^{II} \rightarrow Ge/Sn^{IV}$ with concomitant formation of a molybdenum(IV) complex $Cl_2E{=}NMo(N[^tBu]Ar)_3$). This observation is consistent with the increased stability of divalent Group 14 species as the group is descended [73].

Synthesis of the ethylimido complex $[CH_3CH_2NMo(N[^tBu]Ar)_3]I$ [**2d**]I, was achieved by reaction of **3** with CH_3I (Fig. 5). This reaction demonstrates the nucleophilicity of the ketimide carbon in **3** and is in direct contrast with organic ketimines ($RN{=}CH_2$) which are electrophilic at carbon [74]. Interestingly, we were unable to generate [**2d**] via the reaction of **1** with a suitable source of $[CH_3CH_2]^+$ (e.g., EtI, EtOTf, $[Et_3O]BF_4$). The inability to generate [**2d**] in this way is consistent with the dramatic decrease in rate observed for other nucleophilic substitution reactions (S_N2) upon increasing the steric bulk at the α-carbon of the alkyl electrophile (methyl ≫ ethyl > propyl) [75]. Crystallographic characterization of [**2d**]I showed that an N–C single bond (1.457(11) Å) and an Mo–N triple bond (1.708(9) Å) are formed upon the reaction of complex **3** with CH_3I.

3.2. ^{15}N Solid state CP/MAS NMR Spectroscopy of $^{15}NMo(N[^tBu]Ar)_3$ (**1**)

Measurement of the ^{15}N solid state CP/MAS NMR spectrum of $^{15}NMo(N[^tBu]Ar)_3$ (**1**) was carried out in order to probe experimentally the electronic structure at nitrogen. The principal components of the chemical shift tensor can be extracted from the experimental data by simulation of the experimental spectrum or by the analysis of the relative intensities of the spinning sidebands [32,33]. The experimentally measured values of the shift tensor components for **1** and each of its derivatives are presented in Table 2.

The experimental, simulated and DFT calculated ^{15}N solid state CP/MAS NMR spectra of **1** (calculated spectrum of complex **1m**) are presented in Fig. 7. In the absence of unusual averaging effects, the shift parameter measured in solution for a given complex is equal to the isotropic chemical shift, which is calculated as the average of the principal components of the chemical shift tensor $[\delta_{iso} = 1/3(\delta_{11} + \delta_{22} + \delta_{33})]$ [76]. Indeed, the isotropic shift (δ_{iso}) of 833 ppm determined for complex **1** from the solid state NMR spectrum is in close agreement with the ^{15}N solution NMR shift of 840 ppm. The axial symmetry of complex **1** constrains the orientation of the principal components of the ^{15}N chemical shift tensor such that the unique axis is aligned along the Mo≡N bond. Our experimental results confirm

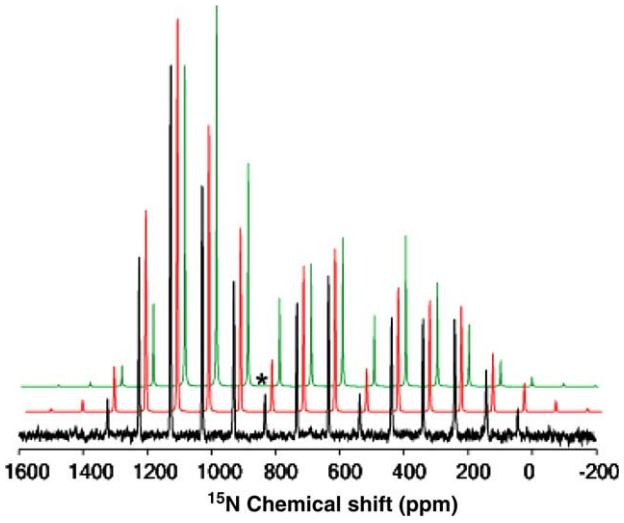

Fig. 7. Experimental (—) and simulated (---) ^{15}N solid state CP/MAS NMR spectra for complex **1** and DFT calculated (---) NMR spectrum for complex **1m**. The simulated and calculated spectra are offset with respect to the experimental spectrum for clarity. The isotropic peak (δ_{iso}) is indicated by an asterisk.

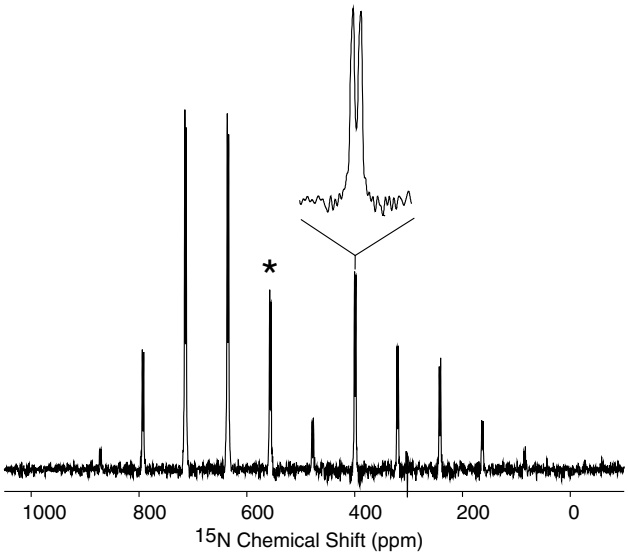

Fig. 8. Experimental ^{15}N solid state CP/MAS NMR spectrum of **1**-BCl_3. The expanded portion of the spectrum shows the multiplicity of one of the spinning sidebands. The isotropic peak is marked with an asterisk.

the axial nature of the chemical shift tensor ($\delta_{11} = \delta_{22} = 1229$ ppm).

A feature of the spectrum that is immediately obvious is the enormous span ($\Omega = \delta_{11}–\delta_{33}$) of the chemical shift anisotropy (CSA) tensor ($\Omega = 1187$ ppm). An understanding of the origin of this significant paramagnetic shift at nitrogen, when the external magnetic field is oriented perpendicular to the Mo≡N bond, was ascertained by analysis of density functional calculations (see Section 4.1) performed on the model complex $NMo(NH_2)_3$ (**1m**).

3.3. ^{15}N solid state CP/MAS NMR spectroscopy of the Lewis acid adducts of 1 (1-LA)

The isotropic shift of **1**-BF_3 ($\delta_{iso} = 593$ ppm) determined from the experimental ^{15}N solid state NMR spectrum is in excellent agreement with δ_{iso} (591 ppm) measured in solution. Complex **1**-BF_3 exhibited an axially symmetric chemical shift tensor wherein $\delta_{11} = \delta_{22} = 836$ ppm. Solid state ^{15}N NMR spectra obtained for complexes **1**-BCl_3, **1**-$AlCl_3$, **1**-$GaCl_3$ and **1**-$InCl_3$ indicate lower symmetry for the geometries of these complexes ($\kappa < 1$). The isotropic shift for the Lewis acid adducts (**1**-LA) studied was shifted upfield by 167 ppm (**1**-$SnCl_2$) to 278 ppm (**1**-BCl_3) with respect to the terminal nitride (**1**). This upfield shift in the magnitude of δ_{iso} can be explained by an increase in the energy gap between occupied frontier molecular orbitals and low-lying virtual molecular orbitals upon coordination of a Lewis acid to the terminally bound N-atom. This information can be extracted from density functional calculations performed on model complexes (**1m**-LA) and is discussed in Section 4.2.

The span (Ω) of the ^{15}N chemical shift tensor was reduced upon coordination of a Lewis acid, from 1187 ppm in **1** to between 866 ppm (**1**-$SnCl_2$) and 621 ppm (**1**-BCl_3). While the magnitude of the most shielded component δ_{33} varied over ca. 90 ppm for **1**-LA, the perpendicular components of the shift tensor, δ_{11} and δ_{22} (referred to as $\delta_\perp$), varied over ca. 180 ppm. Thus, the variation in the span may be attributed primarily to changes in the perpendicular component of the ^{15}N chemical shielding tensor ($\delta_\perp$). Again, this observation can be explained by analysis of the density functional calculations (Section 4.2).

The ^{15}N solid state NMR spectrum of **1**-BCl_3 displayed multiplicity in the isotropic peak and each of the associated spinning sidebands (Fig. 8).

Two unique sets of data, which differed in the magnitude of the isotropic shift (558 and 555 ppm) and the span of the chemical shift tensor (621 and 625 ppm), were obtained on simulation of the experimental spectrum. Similar multiplicity was observed in the spectra acquired for **1**-AlI_3 and **1**-$InCl_3$. This feature could be attributed either to coupling of ^{15}N with the adjacent spin-active nucleus or structural polymorphism [77–79].

3.4. ^{15}N solid state CP/MAS NMR spectroscopy of the imido complexes [2a]I, [2b]OTf, [2c]OTf and [2d]I

The axial symmetry of cation [**2a**] was apparent from the tensor components determined by simulation of the ^{15}N solid state NMR spectrum ($\delta_{11} = \delta_{22}$). The isotropic shift obtained from ^{15}N solid state NMR measurements (457 ppm) was in excellent agreement with δ_{iso} obtained in solution (463 ppm). The spectrum acquired for the

ethylimido complex [**2d**]I was very similar to that of the methylimido complex [**2a**]I in terms of the isotropic shift, span and skew of the chemical shift tensor.

Complex [**2b**]OTf showed unexpected asymmetry in the values of the chemical shift tensor (i.e., $\delta_{11} \neq \delta_{22}$). Interestingly, the spectrum of [**2b**]OTf was more reminiscent of those acquired for the Lewis acid adducts (e.g. **1**-BCl_3) in terms of the magnitude of the chemical shift tensors (δ_{nn}) and the span of the spectrum (Ω) than either of the imido complexes [**2a**]I or [**2d**]I. Again, δ_{iso} obtained for complex [**2b**]OTf from solid state NMR experiments (541 ppm) was in close agreement with the isotropic shift measured in solution (537 ppm).

The acylimido complex [**2c**]OTf is unique in the series of imido complexes that are presented in this study for two reasons: (i) significant asymmetry is present in [**2c**]OTf due to the coordination of the $[PhC(O)]^+$ electrophile to the terminal nitrogen; (ii) the presence of a carbonyl functional group on the fragment coordinated to N provides an opportunity for resonance stabilization of this imido complex. The asymmetric geometry of complex [**2c**]OTf was confirmed by the ^{15}N solid state NMR spectrum for which a rhombic chemical shift tensor ($\delta_{11} \neq \delta_{22} \neq \delta_{33}$) was observed ($\delta_{11} = 701$ ppm, $\delta_{22} = 493$ ppm and $\delta_{33} = 207$ ppm).

The span (Ω) of the ^{15}N chemical shift tensors for the four imido complexes was in the range of 420–581 ppm, which is smaller than for both **1** ($\Omega = 1187$ ppm) and the LA adducts (**1**-LA $\Omega = 866$–621 ppm). This reduction in the span could be attributed (in all four complexes) to the reduced magnitude of the most deshielded component of the chemical shift tensor, δ_{11}. Again, analysis of density functional calculations performed on model complexes enabled a rationalization of this effect in terms of perturbation of the electronic structure of **1** upon coordination of an electrophile (Section 4.3).

Multiplicity in the isotropic peak and the associated spinning sidebands was observed in the ^{15}N solid state NMR spectrum of [**2a**]I. [3] Four isotropic peaks were identified and the span of the chemical shift tensor varied between 420 and 475 ppm. Unlike the Lewis acid adducts (**1**-LA) for which this multiplicity might be attributed to the adjacent spin-active nucleus, complex [**2a**]I is thought to display this multiplicity due to structural polymorphism [77–79].

3.5. ^{15}N NMR spectroscopy of $H_2CNMo(N[^tBu]Ar)_3$ (**3**)

The experimental ^{15}N solid state NMR spectrum of **3** displays a number of noteworthy features. First, the principal components of the chemical shift tensor suggest that complex **3** is axially symmetric ($\delta_{11} = \delta_{22} = 591$ ppm). This symmetry is expected due to the Mo–N multiple bonding in **3** which is attributed to the π-donor/acceptor character of the ketimide (NCH_2) ligand. The isotropic peak in the ^{15}N solid state NMR spectrum was in close agreement with that obtained in solution. Complex **3** has the most shielded value of δ_{11} with respect to all other complexes measured in this study and a narrow span of the shift tensor ($\Omega = 436$ ppm).

4. Chemical shielding: experimental measurement and computational analysis [76]

The measurement of solid state NMR spectra allows for the experimental determination of the principal components (δ_{11}, δ_{22} and δ_{33}) of the chemical shift tensors. To complement our experimental measurements and enable a more complete analysis of these compounds at the electronic level, DFT calculations were performed on model complexes in which the bulky amido ligands N[^{t}Bu]Ar were replaced by three NH_2 ligands (for computational expediency). In most cases, the calculated tensors compared favorably with the experimental data [4] thus discussion of the electronic structure based on DFT calculations can be assumed to be valid. A summary of the analysis of the chemical shielding tensors, together with equations relevant to this analysis, are presented here in brief.

The absolute shielding tensor σ (calculated using DFT), is related to the chemical shift tensor δ

$$\delta = \sigma_{ref} - \sigma, \tag{2}$$

where σ_{ref} is the calculated absolute shielding tensor of the reference compound. NMR calculations based on the density functional method have been used to identify the individual contributions to the total shielding tensor made by the diamagnetic (σ_{dia}), paramagnetic (σ_{para}) and spin orbit (σ_{so}) components

$$\sigma_{total} = \sigma_{dia} + \sigma_{para} + \sigma_{so}. \tag{3}$$

For complexes presented in this study, spin–orbit contributions to the total shielding tensor were included [80,81] but in most cases this contribution was found to be negligible. [5] The diamagnetic contribution is dependent upon the core electron density and acts to reduce the applied magnetic field at the nucleus under observation. In the presence of an applied field σ_{dia} will generally show insignificant variation in its contribution to the total shielding tensor. The paramagnetic contribution

[3] See Supporting Information for experimental, simulated and calculated ^{15}N solid state CP/MAS NMR spectra for [**2a**]I.

[4] Supporting Information: Section 2.15. Plot of the experimental ^{15}N chemical shift tensor (δ_{11}, ppm) vs. Calculated ^{15}N chemical shift tensor (δ_{11}, ppm).

[5] For most of the complexes studied the spin–orbit contribution to the principal components of the chemical shift tensor was <5 ppm.

reinforces the applied field and is determined primarily by magnetic perturbation of the frontier molecular orbitals. Overall, σ_{para} shows the most significant variation in its contribution to the total shielding tensor due to the sensitivity of this term to changes in the electronic environment [82,83]. The paramagnetic contribution to the shielding tensor (σ_{para}) is proportional to the magnetic coupling of high-lying occupied molecular orbitals with low-lying virtual molecular orbitals (M_k) and inversely proportional to the energy difference between these orbitals ($e_{occ} - e_{vir}$). The gauge including atomic orbitals (GIAO) formalism makes it possible to analyze the contributions to the shielding in terms of orbital contributions [84–89]. A molecular orbital analysis of these contributions is contained within the NMR output file of a density functional calculation. [6] This analysis provides a list of the leading contributions to the k^{th} component ($k = 1, 2, 3$) of the magnetic field and includes information about the individual pairs of molecular orbitals (which mix in the applied field), the energy difference between these orbitals ($e_{occ} - e_{vir}$) and the magnitude of the coupling (M_k). Occasionally, one pair of magnetically coupled molecular orbitals is found to provide the major contribution to the paramagnetic deshielding for each component of the magnetic field (k_1, k_2 and k_3).

4.1. Theoretical studies on $^{15}NMo(N[^tBu]Ar)_3$ (1)

The NMR shift calculation for **1m** predicted an axially symmetric chemical shift tensor in which $\delta_{11(calc)} = \delta_{22(calc)} = 1137$ ppm. The primary contributions to $\delta_{11(calc)}$ and $\delta_{22(calc)}$ resulted from rotational mixing in the presence of an applied field of HOMO–3, σ(N p_z–Mo d_z^2) with LUMO, π* (N p_y–Mo d_{yz}) and LUMO + 1, π* (Np_x–Mo d_{xz}). There is a relatively small energy gap ($e_{occ} - e_{vir}$) between the filled N p_z orbital (of A symmetry in the point group C_3), which contains the nitrogen lone pair, and the empty π*(Mo–N) orbitals (a degenerate E set in C_3). Since the paramagnetic contribution to the chemical shielding tensor is proportional to the coupling between these virtual and occupied orbitals and inversely proportional to the energy gap between them, it follows that the components of the shift tensor (δ_{11} and δ_{22}) that are aligned perpendicular to the Mo≡N bond will exhibit extreme paramagnetic shifts.

The large paramagnetic contribution to the perpendicular components of the chemical shift tensor ($\delta_\perp$) is reminiscent of that observed for related terminal phosphide and carbide complexes [19,90]. In all three examples, the principal contributions to $\delta_\perp$ are the result of mixing in the applied field of a high-lying orbital of σ-symmetry with a relatively low-lying doubly degenerate E set of π-symmetry.

For **1** and the derivatives presented in this article, there is a much less significant variation in the magnitude of the most shielded component (δ_{33}) compared to either δ_{11} or δ_{22}. Where as $\delta_{11(expt)}$ varies over 653 ppm (1229–576 ppm), $\delta_{33(expt)}$ varies over a much smaller range of 165 ppm (from 207 to 42 ppm). This can be understood if one considers the chemical shift for a linear molecule. The shift in C_∞ symmetric molecules is dominated by the diamagnetic contribution; the paramagnetic contribution disappears completely along the molecular axis. In **1**, a paramagnetic component to the shift tensor is introduced when the C_∞ symmetry of the Mo≡N axis is broken by the addition of ligands to the metal. This paramagnetic component of δ_{33} is fairly constant for all of the complexes presented herein.

4.2. Theoretical studies on the Lewis acids adducts of 1 (1-LA)

DFT calculations performed on the model complexes **1m**-LA predicted the Lewis acid adducts to be axially symmetric, as evidenced by the calculated skew of the tensor ($\kappa = 1$ or 0.99 in all cases). Experimental ^{15}N solid state NMR spectra for **1**-BCl_3, **1**-$AlCl_3$ and **1**-$GaCl_3$, indicate that the geometry of these complexes is lower than the symmetry to which our DFT calculations converged ($\kappa < 1$). The optimized symmetry of **1m**-BF_3 predicted similar Mo–N and N–B bond lengths to those measured for **1**-BF_3, however, in the model complex the B–F bonds of the Lewis acid were eclipsed with respect to the Mo–N_{amide} bonds. Calculations were performed on model complexes in which either the eclipsed or staggered geometries were enforced in order to gauge the effect of rotation about the N–LA bond on the ^{15}N chemical shift. In general, calculations for the eclipsed and staggered geometries predicted very similar values of the principal components of the ^{15}N chemical shift tensor.

In each of the model Lewis acid adducts (**1m**-LA) the principal contributions to $\delta_\perp$ resulted from rotational mixing in the applied field of an occupied σ-orbital with a vacant π*(Mo–N) orbital. The occupied orbital is characterized by significant N p_z character, involved in donation of the N-lone pair into the vacant orbital on the Lewis acid's central atom. For example, analysis of the DFT calculation performed on **1m**-BCl_3 shows that the principal contributions to δ_{11} and δ_{22} are provided by mixing in the applied field of HOMO − 4, σ(N p_z–B p_z) with LUMO, π*(Np_y–Mo d_{yz}) and LUMO + 1, π*(N p_x–Mo d_{xz}), respectively. [7]

[6] Supporting Information: Section 2.13. Representative input and output files of an NMR calculation.

[7] See Supporting Information 2.17 for selected (calculated) orbitals of **1m**-BCl_3.

The energy gap ($e_{occ} - e_{vir}$) between the occupied σ(N–LA) bonding orbital and the vacant π(Mo–N) orbitals was found to depend principally on the extent to which Lewis acid coordination to the terminal N-atom lowers the energy of the σ(N p_z –LA sp) orbital. In **1**, the occupied (N p_z) orbital contains a non-bonding lone pair of electrons and is at a relatively high energy. Formation of a σ-bond to the Lewis acid lowers the energy of this orbital thereby increasing the energy gap between the magnetically coupled virtual and occupied orbitals ($e_{occ} - e_{vir}$). This in turn reduces the paramagnetic contribution to the perpendicular component of the chemical shift tensor resulting in more upfield shifted values of δ_{11} and δ_{22}.

Complex **1m**-BCl_3 has a smaller energy gap ($e_{occ} - e_{vir}$ = 3.65 eV) compared to **1m**-BF_3 ($e_{occ} - e_{vir}$ = 5.06 eV) but also a reduced paramagnetic contribution to the chemical shift, as evidenced by the more upfield shift of $\delta_{11(calc)}$. This apparently anomalous result can be explained if one accounts for the proportional relationship between the paramagnetic contribution to the chemical shift and the magnitude of the coupling (M_k) of occupied and virtual molecular orbitals in the presence of an applied magnetic field. Analysis of the DFT calculations for these two complexes shows that M_k in **1m**-BF_3 (0.438) is more than twice that calculated for **1m**-BCl_3 (0.206). This suggests that a much larger contribution to the paramagnetic term is made by N-based orbitals in **1m**-BF_3 compared to **1m**-BCl_3.

4.3. Theoretical studies on the imido cations [2a-m], [2b-m], [2c-m] and [2d-m]

Calculations performed on the model cation [**2a-m**] predicted an axially symmetric spectrum ($\delta_{11(calc)} \approx \delta_{22(calc)}$), which was in close agreement with the data obtained experimentally for this complex. Upon formation of an N–C single bond in cation [**2a-m**] there is a more significant lowering in energy of the σ(N–C) molecular orbital compared to that observed for the Lewis acid adducts (**1**-LA) discussed previously. This can be attributed to the build up of positive charge on the complex and the increased bond strength of the σ(N–C) bond compared to the σ(N–LA) bond. All four of the imido complexes exhibit a significant energy gap ($e_{occ} - e_{vir}$) between the filled σ(N–E) orbital to the lowest lying unoccupied orbitals of π-symmetry. The stabilization of this σ(N–E) bonding orbital prohibits its participation in mixing interactions that supplement the paramagnetic contribution to the chemical shift tensor. For the model cation [**2a-m**] the principal contributions to $\delta_{\perp}$ result from rotational mixing in the applied field of two occupied orbitals of π-symmetry (a doubly degenerate *E* set) with a vacant orbital of σ-symmetry (*A* symmetry in C_3). Analysis of the DFT calculation performed on [**2a-m**] shows that the principal contributions to δ_{11} and δ_{22} ($\delta_{11(calc)}$ = 606 ppm, $\delta_{22(calc)}$ = 603 ppm) are provided by mixing in the applied field of HOMO–2, π(Mo d_{xz}–N p_x) and HOMO−3, π(Mo d_{yz}–N p_y) with LUMO + 2, σ*(N p_z–C p_z).

Experimental data acquired for complex [**2b**]OTf displayed a rhombic ^{15}N chemical shift tensor wherein the skew of the shielding tensor κ = 0.91. Since calculations performed on cation [**2b-m**] provided the expected axially symmetric spectrum it is difficult to identify the electronic features of complex [**2b**]OTf that contribute to the asymmetry of the experimental spectrum.

The lack of an axis of symmetry in the optimized geometry for model cation [**2c-m**] is immediately apparent from the calculated values of the chemical shift tensor for [**2c-m**] ($\delta_{11(calc)}$ = 695 ppm, $\delta_{22(calc)}$ = 642 ppm and $\delta_{33(calc)}$ = 183 ppm). Our experimental results for complex [**2c**]OTf displayed greater asymmetry (κ = 0.16) compared to the calculated spectrum (κ = 0.79). Analysis of DFT calculations performed on cation [**2c-m**] shows that the principal contribution to $\delta_{11(calc)}$ is provided by mixing in the applied field of HOMO − 3, σ(N p_z–C p_z) with LUMO + 1, π*(Mo d_{xz}–N p_x). The principal contribution to $\delta_{22(calc)}$ is provided by mixing in the applied field of HOMO − 9, π(Mo d_{xz}–N p_x) with LUMO+2, σ*(N p_z–C p_z). For [**2c-m**] the σ(N p_z–C p_z) orbital is much higher in energy than the σ-orbital comprising the N–C bond in [**2a-m**] and [**2d-m**]. Indeed, the energy ordering of the frontier orbitals in [**2c-m**] is more reminiscent of that seen in the Lewis acid adducts (**1**-LA) than the other imido complexes. This implies that a weaker bonding interaction exists between the terminal N-atom and the electrophilic C-atom of the benzoyl fragment (compared to the interaction in other imido complexes) suggesting that resonance forms do not provide significant stabilization in complex [**2c**]OTf. These facts are consistent with the crystal structure of [**2c**]OTf in which the N–C single bond does not appear to be shortened through additional π-interactions.

4.4. Theoretical studies on $H_2CNMo(N[^tBu]Ar)_3$ (3)

The overall sequence leading to ketimide **3** embodies formal carbene (CH_2) addition to complex **1**, a process that encompasses C=N bond formation along with the reduction of molybdenum from the +6 to the +4 formal oxidation state. [8] Carbene addition to **1** is recognized as a potentially valuable means for the activation of complex **1** in the context of nitrogen atom transfer from N_2 into organic molecules [91]. It was therefore of interest to determine what insight solid state NMR spectroscopy could provide, in conjunction with DFT analysis of the experimental shift tensors into the electronic

[8] ΔH_{RXN} of CH_2 addition to $NMo(NH_2)_3$ is calculated to be −93 kcal mol^{-1}.

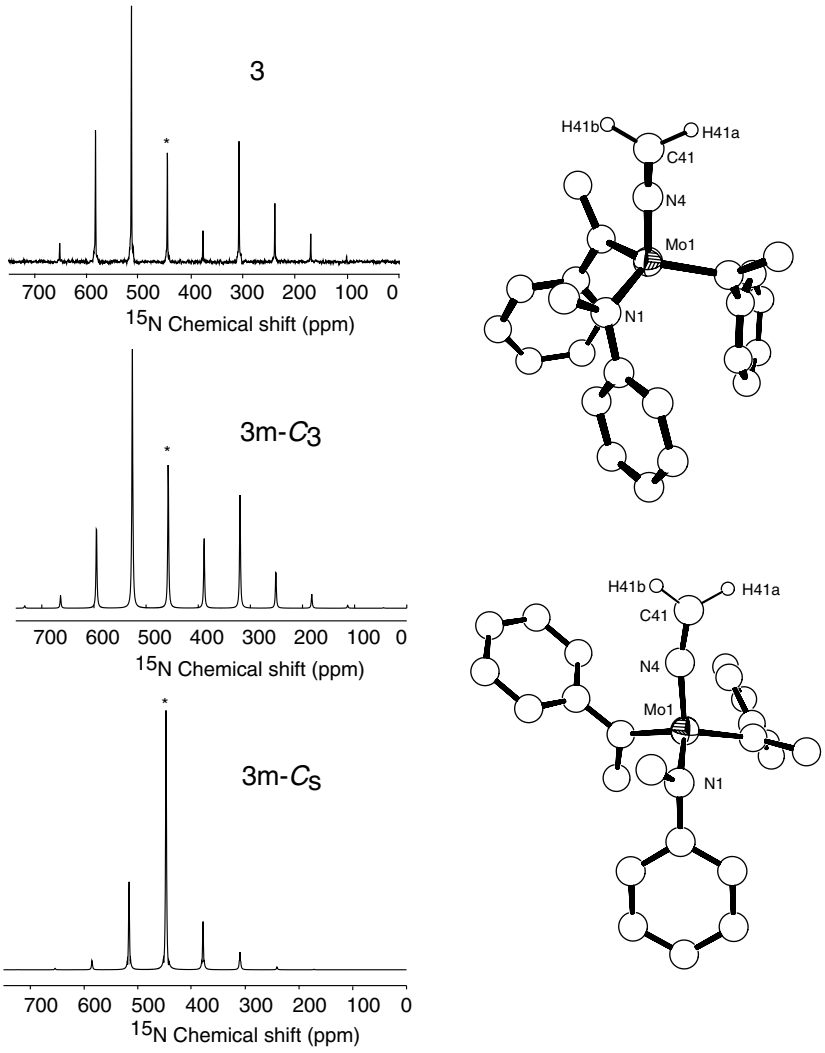

Fig. 9. Optimized geometries for the complexes **3m**-C_3 (top) and **3m**-C_s (bottom) and solid state ^{15}N spectra for complex **3**: experimental (top), calculated **3m**-C_3 (middle) and calculated **3m**-C_s (bottom). The isotropic peak is indicated by an asterisk.

structure at this N-atom which is activated toward productive removal from the molybdenum complex into an organic product.

Interestingly, attempts to use DFT to reproduce the observed ^{15}N solid state CP/MAS NMR spectrum of **3** using $H_2CNMo(NH_2)_3$, (the structure of which converged to near C_s symmetry) as the computational model were not entirely satisfactory. We probed further and found that the larger model $H_2CNMo(N[CH_3]Ph)_3$ (**3m**) converged either to a pseudo-C_s (**3m**-C_s) or to a pseudo-C_3 (**3m**-C_3) conformation depending upon the initial geometry employed. The ^{15}N spectrum calculated for **3m**-C_3 was a good match to the observed spectrum of **3** ($\chi^2 = 18$), while that calculated for **3m**-C_s deviated noticeably ($\chi^2 = 125$) (Fig. 9). The two local minima for **3m** differ with respect to rotation about the Mo–N_{amide} bonds, leading to differing Mo–N_{amide} dπ−pπ overlap, to which the ketimide nitrogen electronic environment is clearly sensitive. Analyses of the NMR calculation performed on **3m**-C_3 reveals that the principal contributions to the most deshielded components of the tensor, $\delta_{11(calc)}$ and $\delta_{22(calc)}$ (600 and 563 ppm, respectively), result from mixing in the applied field of HOMO, π(N–C) with LUMO, π^*(Mo d_{yz}–N p_y) and LUMO + 1, π^*(Mo d_{xz}–N p_x). The same orbitals are responsible for the paramagnetic contributions to $\delta_{11(calc)}$ and $\delta_{22(calc)}$ in **3m**-C_s ($\delta_{11} = 570$ ppm, $\delta_{22} = 457$ ppm) however, the energy gap ($e_{occ} - e_{vir}$) between the HOMO and LUMO orbitals in **3m**-C_3 is appreciably smaller than in **3m**-C_s (1.498 eV versus 1.696 eV). This increased energetic separation of the orbitals in **3m**-C_s reduces the degree of magnetic coupling and results in a more shielded value of δ_{11}.

In addition, the calculated molecular orbitals for **3m**-C_3 show significant p orbital contribution from the ketimide carbon to the HOMO. This indicates that the ketimide carbon has been rendered nucleophilic upon

dehydrohalogenation of the methylimido complex [**2a**]I. Experimental evidence for this is demonstrated by the reaction of **3** with CH_3I to generate the ethylimido complex [**2d**]I.

5. Conclusions

The electronic structure of a dinitrogen-derived terminal molybdenum nitride complex $NMo(N[^tBu]Ar)_3$ (**1**) has been studied by the combined use of ^{15}N solid state CP/MAS NMR spectroscopy and DFT calculations. Parallels may be drawn between the bonding observed in this terminal nitride complex and the analogous terminal phosphide and carbide complexes. Perturbation of the electronic structure in the terminal molybdenum nitride complex (**1**) upon coordination of a Lewis acid can be attributed to stabilization of a σ-symmetric orbital as a result of N–LA bond formation.

Upon formation of a Lewis acid adduct of **1**, the increased energy gap ($e_{occ} - e_{vir}$) between magnetically coupled occupied and virtual orbitals, is seen to correlate with a reduction in the magnitude of the perpendicular components of the chemical shift tensor (δ_{11} and δ_{22}).

The reaction of **1** with electrophiles RX, results in further stabilization of the σ-symmetric orbital containing the N-lone pair of electrons. The paramagnetic contribution to the chemical shift tensor in this series of cationic imido complexes results from rotational mixing in the applied field of high-lying π(Mo–N) orbitals with a low-lying σ(N–E) (E = C, Si) orbital.

Finally, the strength of this combined approach to studying the electronic structure of spin-active nuclei in transition metal complexes is highlighted by our investigations into a ketimide complex, $H_2CNMo(N[^tBu]Ar)_3$ (**3**). Computational studies performed on the model complex $H_2CNMo(N[CH_3]Ph)_3$ (**3**m) identified two geometries to which this complex could converge. The variation in Mo–N dπ–pπ overlap in the two structures is reflected in the calculated chemical shift tensors. A quantitative comparison of the experimental spectrum with the calculated spectra indicates that a closer match is provided by the pseudo-C_3 symmetric model, the optimized geometry of which is in good agreement with X-ray crystallographic data for complex **3**.

Acknowledgements

For support of this work, we are grateful to the US National Science Foundation (CHE 0316823) and the National Institutes of Health (EB002026). Christopher Clough is thanked for his assistance with crystallography. We thank Dr. Christopher D. Incarvito for his crystallographic expertise in the structural refinement of complex **1**-$SnCl_2$. N.M.L. thanks the National Institutes of Health for support via a National Research Service Award post-doctoral fellowship (F32 NS42425-01).

The authors acknowledge the significant contributions made to inorganic and organometallic chemistry by Prof. Malcolm L.H. Green and the inspiration his work has provided to many of his colleagues during the course of his distinguished career.

Appendix A. Supplementary material

Complete crystallographic data for complexes **1**-BF_3 (CCDC-236925), **1**-$GeCl_2$ (CCDC-236927), **1**-$SnCl_2$ (CCDC-236930), [**2b**]OTf (CCDC-236926), [**2c**]OTf (CCDC-236928), [**2d**]I (CCDC-236929) and **3** (CCDC-236924) have been deposited in the Cambridge Structural Database and can be obtained free of charge via www.ccdc.cam.ak/conts/retrieving.htm (or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB21EZ, UK; (fax: +44-1223-336-033; or deposit@ccdc.cam.ac.uk). Supplementary Information for this article includes the following materials: ORTEP plots, anisotropic displacement parameters, atomic coordinates, bond lengths and angles for complexes **1**-BF_3, **1**-$GeCl_2$, **1**-$SnCl_2$, [**2b**]OTf, [**2c**]OTf, [**2d**]I and **3**; details of DFT calculations including optimized geometries of all model complexes and selected (calculated) orbitals for complexes **1m**, **1m**-BCl_3, [**2b-m**], [**2c-m**] and **3m**-C_3; experimental information for the acquisition of solid state spectra; representative experimental, simulated and calculated solid state ^{15}N CP/MAS spectra. Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2004.08.010.

Abstract

Iridium(III) bis-terpyridine complexes have been prepared which incorporate aminobenzene or pyrene substituents at the 4′-position of the terpyridine. The homoleptic complexes, $[Ir(L^1)_2]^{3+}$ and $[Ir(L^2)_2]^{3+}$ {L^1 = 4′-(*p*-Me_2N-C_6H_4)-2,2′:6′,2″-terpyridine; L^2 = 4′-(*p*-Ph_2N-C_6H_4)-2,2′:6′,2″-terpyridine} display an intense absorption band in the visible region, which exhibits slight positive solvatochromism, due to an excited state of intra-ligand charge transfer (ILCT) character, in which the aminobenzene unit acts as the electron donor and the metal-bound terpyridyl unit as the acceptor. The complexes are weakly luminescent in the near infra-red (λ_{max} 750–800 nm); this short-lived, low-energy emission, whose likely origin is an excited state of primarily ILCT character, is in contrast to the long-lived $^3\pi$–π^* luminescence of previously studied bis-terpyridyl iridium complexes. The corresponding ILCT absorption band in the heteroleptic, pyrene-substituted complex, $[Ir(tpy)L^3]^{3+}$ {L^3 = 4′-(1-pyrenyl)-2,2′:6′,2″-terpyridine}, displays negative solvatochromism, owing to the excited state having lower polarity than the ground state. This complex emits weakly at slightly higher energy (710 nm). The switch to ILCT character upon appending the $[Ir(tpy)_2]^{3+}$ core with a pyrene substituent may be compared to the influence of the pyrene unit in $[PtL^3Cl]^+$, but contrasts with the triplet–triplet equilibrium that is established in structurally related ruthenium complexes incorporating pyrene pendants. The electrochemical properties of the pyrene-substituted ligand and complex in solution are also described.

1. Introduction

The excited state chemistry of transition metal complexes containing pyridyl-based ligands has long been of interest. A combination of rich photophysical and electrochemical properties makes many compounds of this type potentially appropriate for numerous applications, including photocatalysis, luminescent sensors, electroluminescence and electron transfer reagents for conversion of light to chemical energy [1]. The synthetic challenges associated with the preparation of complexes of iridium(III), particularly the kinetic inertness of this third-row d^6 metal ion with respect to ligand exchange processes, has rather retarded progress with this element compared to its neighbours in the periodic table [2]. However, recent results on the application of *fac*-[Ir(ppy)$_3$] (ppy = 2-phenylpyridyl) as a triplet harvesting agent in organic light emitting devices (OLEDs) has rekindled a great deal of interest in cyclometalated iridium(III) complexes [3]. At the same time, the longer lifetimes associated with derivatives of $[Ir(tpy)_2]^{3+}$,

doi:10.1016/j.poly.2004.08.009

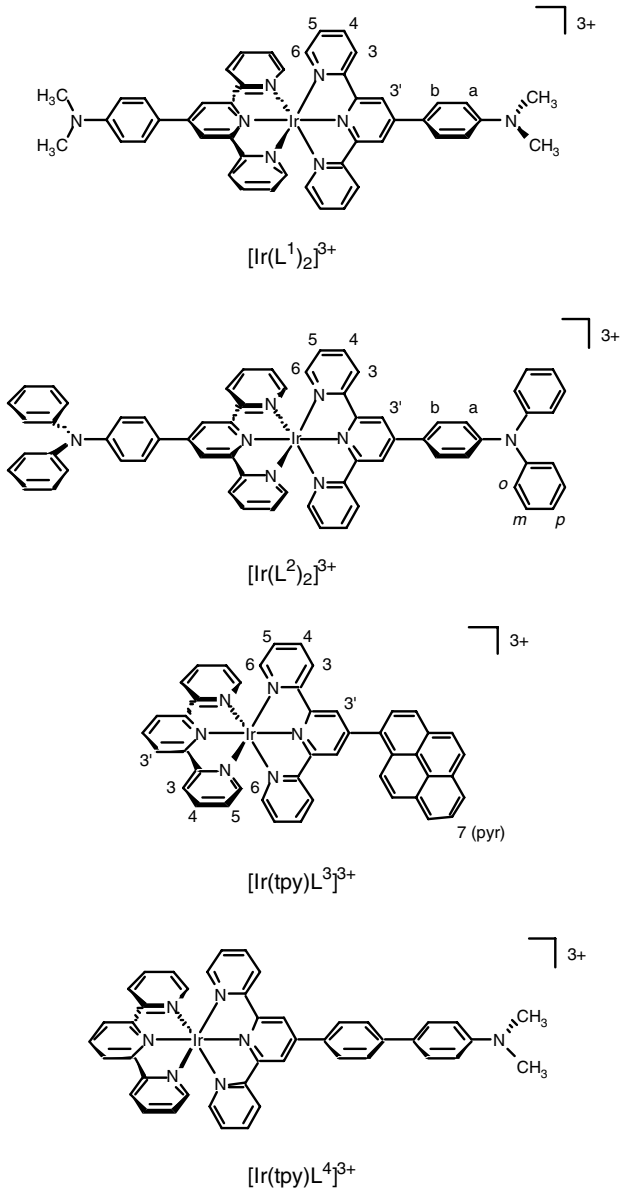
containing an N_6 coordination sphere, have initiated studies into their possible application as luminescent sensors or labels amenable to time-resolved detection procedures [4–6].

$[Ir(ppy)_3]$ and $[Ir(tpy)_2]^{3+}$ are, in fact, representative of the two main classes of iridium(III) complexes, in terms of luminescence behaviour. When some of the ligands (normally two or more) are anionic, as in cyclometalated compounds like $[Ir(ppy)_3]$, the emitting excited state usually has significant metal-to-ligand charge transfer (MLCT) character, with lifetimes often of the order of 500–1000 ns in degassed solution [2]. In the presence of exclusively neutral ligands, however, as in $[Ir(tpy)_2]^{3+}$, the electron density at the metal is lower, and metal-centred oxidation is unfavourable. In these cases, the HOMO resides largely on the ligand rather than the metal, the MLCT states are raised in energy, and the emitting state has primarily ligand-centred (LC) character, with longer lifetimes in the microsecond region [2,7,8]. Previous studies on derivatives of $[Ir(tpy)_2]^{3+}$ have shown that the introduction of simple, conjugating aryl substituents (e.g., tolyl) onto the 4′ position of the terpyridine leads to a stabilisation of the LC state and a lengthening of the excited state lifetime, an effect which is even more pronounced for a biphenyl substituent [8,9]. In this contribution, we describe how the introduction of more electron-rich aryl substituents into the same position of the terpyridine unit leads to a switch in the nature of the emission to a third class, namely intra-ligand charge transfer (ILCT).

2. Results and discussion

2.1. Synthesis of ligands and complexes

The complexes investigated in this study are shown in Scheme 1. Most synthetic routes to 4′-aryl-substituted terpyridines are based on the Tschitschibabin pyridine synthesis, involving condensation of the appropriate aryl aldehyde with two equivalents of 2-acetylpyridine, followed by ring closure of the resulting diketone intermediate with ammonia (or an equivalent thereof) at elevated temperatures, to form the central pyridine ring [10]. However, many of the simpler one-pot procedures are satisfactory only for simple aryl substituents, and suffer from low yields and difficult purifications when aryl aldehydes of lower reactivity are employed, including amino-benzaldehydes [11]. We have been exploring the utility of Suzuki cross-coupling of 4′-bromo-terpyridine (tpy-Br) with aryl boronic acids as a divergent and general method for preparing 4′-aryl-terpyridines, and this procedure was employed here to obtain L^1 {4′-(*p*-Me_2N-C_6H_4)-2,2′:6′,2″-terpyridine} in good yield by cross-coupling of tpy-Br with commercially available



Scheme 1. Structures of the complexes investigated.

4-*N*,*N*-dimethylaminobenzene boronic acid, as reported previously [12–14]. In order to prepare the diphenylamino analogue, L^2, the boronate ester 4-(neopentylglycolatoboron)-*N*,*N*-diphenylaniline was first prepared by palladium-catalysed cross-coupling of 4-bromo-*N*,*N*-diphenylaniline with bis-(neopentylglycolato)diboron, and subsequently coupled with tpy-Br as for L^1 [12,13]. 4′-(1-Pyrenyl)-2,2′:6′,2″-terpyridine L^3 [15] was prepared by condensation methodology, using the procedure of Constable for 4′-anthryl-terpyridine [16]. For these more hindered aryl groups, the enone generated upon treatment of the aryl aldehyde with 2-acetylpyridine is not sufficiently reactive to be attacked directly by the enol form of a second equivalent of 2-acetylpyridine [16]; instead, the latter must be converted to the

more reactive enolate through prior deprotonation with potassium *tert*-butoxide.

The homoleptic iridium(III) complexes $[Ir(L^1)_2](PF_6)_3$ and $[Ir(L^2)_2](PF_6)_3$ were prepared by direct reaction of $IrCl_3 \cdot 3H_2O$ with two or more equivalents of the corresponding ligand, in refluxing ethylene glycol, followed by anion exchange with potassium hexafluorophosphate. Whilst the fomer complex was readily purified by crystallisation, the latter proved more troublesome, requiring chromatography on silica followed by alumina in order to remove all traces of a fluorescent yellow impurity. Both complexes were deep red in colour, in striking contrast to the yellow or pale yellow colours of previously reported bis-terpyridyl iridium complexes, including the parent complex, $[Ir(tpy)_2](PF_6)_3$, and aryl substituted derivatives such as $[Ir(ttpy)_2](PF_6)_3$ (ttpy = 4′-tolylterpyridine). The complex $[Ir(tpy)L^3](PF_6)_3$ was obtained via a two-step strategy: the intermediate compound $[Ir(tpy)Cl_3]$, prepared by reaction of $IrCl_3 \cdot 3H_2O$ with one equivalent of terpyridine as reported previously [8], was first isolated, and then reacted with one equivalent of L^3 in ethylene glycol at reflux for 15 min. Subsequent anion exchange with KPF_6 and column chromatography on silica led to the desired complex as a red solid in 50% yield.

The complexes were characterised by high resolution electrospray ionisation mass spectrometry and by ^1H NMR spectroscopy. A combination of ^1H–^1H NOESY and COSY measurements allowed a full assignment of the ^1H NMR spectra of $[Ir(L^1)_2](PF_6)_3$ and $[Ir(L^2)_2](PF_6)_3$ to be made, with the NOESY data allowing the resonances on the pendent rings to be identified on the basis of through-space coupling between H^b and $H^{3'}$ (see Scheme 1 for atom numbering system). Unsurprisingly, several of the pyrenyl resonances in $[Ir(tpy)L^3](PF_6)_3$ overlap, but the terpyridyl protons are all resolved, providing unambiguous confirmation of the identity of the complex.

2.2. Absorption and fluorescence spectra of the ligands and electrochemistry of L^3

We previously reported on the photophysical properties of ligands L^1 and L^2 [12,13]. These compounds are intensely fluorescent, and their highly solvent-dependent fluorescence emission maxima, which shift to longer wavelengths with increasing solvent polarity, have been interpreted in terms of an intramolecular charge transfer (ICT) excited state. The amino substituent in these ligands raises the energy level of the pendent aryl group to such an extent that the lowest energy excited state corresponds to a π_{Ar}–π^*_{tpy} (ICT) transition, as opposed to the locally excited states (π_{tpy}–π^*_{tpy}) of other 4′-aryl-substituted terpyridines [17].

In the present study, the photophysical properties of the free, pyrene-substituted ligand L^3 have been examined. The absorption spectra in three different solvents of varying polarity are shown in Fig. 1, which show no significant differences in the absorbance maxima. This is consistent with initial excitation to a locally excited state (π_{tpy}–π^*_{tpy}) of similar polarity to the ground state (see also the excitation spectra in Fig. 2). On the other hand, the fluorescence emission maxima undergo significant shifts to longer wavelengths with increasing solvent polarity (Fig. 2), a trend directly analogous to that displayed by the amino substituted compounds L^1 and L^2. This indicates that the pyrene substituent has a similar effect, and that the emission again originates from an ICT state, (where the pyrene unit acts as the electron donor), formed indirectly following excitation to the locally excited state.

These conclusions, particularly regarding the electron-donating character of the pyrene unit in L^3, are supported by the electrochemistry of this ligand. The

ligand displays a one-electron reduction process at −1.66 V in solution in DMF at room temperature (Fig. 3 and Table 1). This value is substantially smaller (less negative) than the reduction potentials of both terpyridine and pyrene (which have very similar values to one another, Table 1), indicating that the pyrene-substituted terpyridine is much more readily reduced than either of its two constituent components. Since the reduction is a one-electron process, this demonstrates that the pyrene and terpyridine units are not acting independently, but rather that the electron enters a molecular orbital which is centred over the whole molecule; i.e., the LUMO in L^3 has a considerably extended π-system compared to the two components. In contrast, the oxidation potential of L^3 is very similar to that of pyrene itself (+1.49 and 1.47 V, respectively, Table 1), supporting the conclusion that the pyrenyl unit in L^3 is the site from which charge transfer occurs in the ICT process described above.

2.3. Absorption spectra of the complexes

All three complexes display strong absorption bands in the visible region of the spectrum, (responsible for the intense colours of the compounds), which are not present in the spectra of the free ligands; λ_{max} (CH_3CN)

[b] No oxidation wave observed within the solvent window (DMF displays a large decomposition peak above +1.8 V).

$[Ir(L^1)_2]^{3+}$ 504 nm, $[Ir(L^2)_2]^{3+}$ 493 nm, $[Ir(tpy)L^3]^{3+}$ 444 nm (Figs. 4 and 5; Table 2). These bands are attributed to an intraligand charge transfer (ILCT) transition, in which the pendent aminobenzene or pyrene group behaves as the donor, and the metal-bound terpyridyl moiety as the electron acceptor. The appearance of such bands in the complexes can be related to the increased acceptor properties of the terpyridyl π* orbitals upon coordination to the metal ion. Previously, we reported on a related, heteroleptic bis-terpyridyl iridium complex, incorporating a terpyridine appended with a *p*-(dimethylamino)-biphenyl unit, $[Ir(tpy)L^4]^{3+}$ (Fig. 1) [9]. This complex also displayed a strong, low-energy band in the same region (λ_{max} 476 nm), similarly assigned to an ILCT transition. In fact, a comparable phenomenon has also been observed upon coordination of zinc(II) to L^1 and L^2, leading to a band at 433 and 426 nm, respectively [13,12]; the longer wavelength of the bands in the iridium complexes can be related to the higher charge density of the iridium(III) ion compared to zinc(II). The bands are also lower in energy than that seen in the iridium chloro complex $[IrL^5Cl_3]$, {L^5 = 4′-(*p*-

[d] The emission from this complex was too weak to allow a reliable spectrum to be obtained.

Bu_2N-C_6H_4-)-terpyridine}, for which λ_{max} = 465 nm in $CHCl_3$ [18]; again, this is in line with the absence of anionic ligands in the present complexes, in contrast to the chloride ligands in $[IrL^5Cl_3]$, which will serve to counteract partially the positive charge of the metal ion. From Fig. 4, it may be noted that, of the two amino-substituted compounds, the dimethylamino complex displays marginally the lower energy band (by 11 nm), which is consistent with the more strongly electron-donating nature of the Me_2N–C_6H_4– moiety compared to Ph_2N–C_6H_4–, and hence with the ILCT formulation.

In the case of the pyrene-substituted complex, $[Ir(tpy)L^3]^{3+}$, the long wavelength band displays pronounced negative solvatochromism; for example, there is a large red-shift of 50 nm on going from acetonitrile solution (444 nm) to dichloromethane (494 nm) (see Fig. 5). Such negative solvatochromism can be explained in terms of the smaller dipole moment expected in the charge-transfer excited state compared to the ground state, and the fact that the charge-transfer axis is colinear with the dipole axis in this heteroleptic complex (C_{2v} symmetry) [19]. Negative solvatochromism was similarly observed in the aforementioned, heteroleptic amino-substituted complex, $[Ir(tpy)L^4]^{3+}$, described previously (e.g., λ_{max} 476 nm in CH_3CN and 420 nm in H_2O) [9]. In contrast, the bands in the homoleptic amino-substituted complexes display only a very small, positive solvatochromism (e.g., a 2 nm blue-shift for $[Ir(L^1)_2]^{3+}$ on going from acetonitrile to dichloromethane, and a 7 nm red-shift in water). In these homoleptic complexes with D_{2d} symmetry, there is no permanent dipole moment in the ground state, and formation of the ILCT excited state will be accompanied by a small increase in the polarity of the system, leading to the observed behaviour.

2.4. Electrochemistry of $[Ir(tpy)L^3]^{3+}$

The pyrene-substituted complex has a rich redox chemistry. The cyclic voltammogram shows the first two reductions at −0.65 and −0.78 V (Fig. 3) but there are two further reductions at −1.23 and −1.54 V. All reductions are one-electron steps. Thus, compared to the free ligands, complexation to the Ir^{3+} ion has resulted in the ligand-based reductions moving to more positive (less negative) potentials due to the influence of the tri-positive charge. Since L^3 is more readily reduced than terpyridine, as discussed above, it would seem reasonable to suggest that it is the pyrene-substituted ligand that is reduced first, followed by the unsubstituted terpyridine. However, the potential difference between the first two reductions is of the order of that expected for two terpyridine ligands bound to the same metal centre, and hence the site of reduction is ambiguous. In an attempt to identify which ligand is reduced initially, the reduction was probed by spectroelectrochemical methods (UV/vis/nir and epr) at 233 K. Unfortunately, however, the reduced iridium complex is not stable on the timescale of the spectroelectrochemical experiments, even at 233 K.

The complex shows a single, quasi-reversible, one-electron oxidation process at +1.59 V at room temperature. This is in marked contrast to other bis-terpyridyl iridium complexes studied to date, such as $[Ir(tpy)_2]^{3+}$ and $[Ir(ttpy)_2]^{3+}$, which show no oxidation process within the solvent window, supporting the notion that it is the pyrene unit which is the site of oxidation, and hence the origin of the ICT process. The oxidation potential is higher by 0.1 V than that of the free ligand L^3 (Table 1), consistent with the net positive charge on the complex mildly disfavouring oxidation at the remote pyrenyl site.

3. Luminescence of the complexes

3.1. Pyrene-susbtituted complex

Upon excitation into the ILCT band, $[Ir(tpy)L^3]^{3+}$ exhibits very weak red luminescence, centred at 710 nm in acetonitrile solution. The quantum yield was esti-

mated to be of the order of $4(\pm 2) \times 10^{-4}$, using $[Ru(bpy)_3]Cl_2$ as the standard; (the considerable uncertainty in the value stems from the low emission intensity and the poor response of the photomultiplier tube in this region). The emission intensity was too weak to measure the lifetime with available instrumentation; however, on the basis of the observation that the luminescence intensity was only marginally augmented upon degassing the solution, we suspect that the lifetime is short (probably <100 ns), and consistent with an excited state which is subject to severe non-radiative deactivation processes, leading to the low quantum yield. Given that this behaviour contrasts markedly with the long-lived $^3\pi$–π^* luminescence observed in almost all $[Ir(tpy)_2]^{3+}$ derivatives studied hitherto, it seems likely that the origin of the emission is a state comprising significant ILCT character, a hypothesis supported by DFT calculations using B3LYP. It is interesting to compare the behaviour of $[Ir(tpy)L^3]^{3+}$ with that of $[PtL^3Cl]^+$, investigated in detail by McMillin and co-workers [15,20]. In their study of the effect of appending the $[Pt(tpy)Cl]^+$ core with aryl substituents, a complicated yet fascinating picture emerges in the case of a pyrene pendant. Emission arises from two different excited states, of which one (emitting at 645 nm) is assigned as a ^{1}ILCT state and persists under aerated conditions, and the other is attributed to a triplet state (680 nm), probably incorporating both MLCT and ILCT character, and is efficiently quenched by oxygen. The lower energy of the observed emission in the Ir(III) system compared to the Pt(II) complex is fully consistent with the higher positive charge associated with the Ir(III) centre compared to the Pt(II)–Cl unit, stabilising the ILCT state.

The behaviour of the pyrene-substituted iridium compound contrasts with the results of several recent investigations into pyrene-appended $[Ru(bpy)_3]^{2+}$ or $[Ru(phen)_3]^{2+}$ complexes [21]. In such cases, the pyrene unit can act as a ''store'' of the excited state energy, with a triplet–triplet thermal equilibrium being established between the emissive ^{3}MLCT excited state of the ruthenium centre, and the $^3\pi$–π^* state of the pyrene unit. This leads to large augmentations of the observed luminescence lifetime compared to the unsubstituted complexes, for example, up to 148 μs for a *tris*-pyrenyl substituted $[Ru(phen)_3]^{2+}$ derivative [21b]. That the iridium complex does not profit from a similar effect is apparently due to the more highly oxidising nature of the IrN_6^{3+} core compared to RuN_6^{3+}, allowing the former to participate in the ILCT process.

3.2. Amino-substituted complexes

In the case of the amino-substituted complexes, the emission was too red-shifted and too weak to be recorded reliably using the conventional photomultiplier tube of our fluorimeter. However, emission spectra were successfully recorded using a single-photon avalanche detector (Fig. 6), revealing that the complexes do indeed emit in acetonitrile solution, albeit weakly, in the near infra-red region {λ_{max} from uncorrected spectra: $[Ir(L^1)_2]^{3+}$ 754 nm, $[Ir(L^2)_2]^{3+}$ 784 nm}. Again, the presence of oxygen had no effect on the spectral profile and little effect on the intensity of emission, consistent with emission from only one excited state, most probably of predominantly ILCT character. However, an interesting difference between the two compounds emerges in aqueous solution. The diphenylamino-substituted complex, $[Ir(L^2)_2]^{3+}$, emits in water (Fig. 7), with an emission intensity comparable to that observed in acetonitrile (for solutions isoabsorbant at the excitation wavelength of 532 nm). On the other hand, for the dimethylamino-substituted complex $[Ir(L^1)_2]^{3+}$, the emission in aqueous solution was too weak to be measured with the same instrumental set-up. Clearly, an additional non-radiative deactivation process must be operative for the Me_2N-

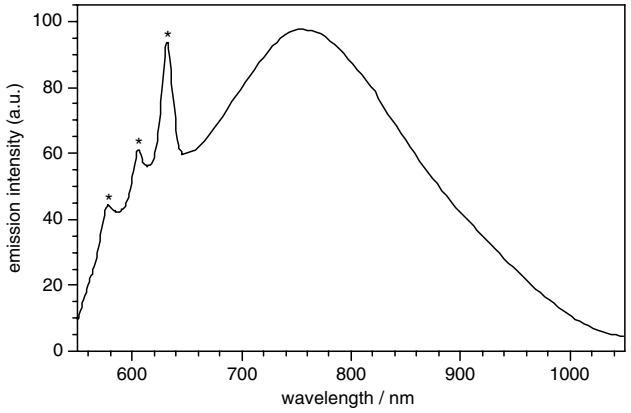

Fig. 6. Emission spectrum of $[Ir(L^1)_2]^{3+}$ in acetonitrile solution; λ_{ex} = 532 nm, 295 K. The bands marked with an asterisk are Raman bands of the solvent (C≡N and two C–H).

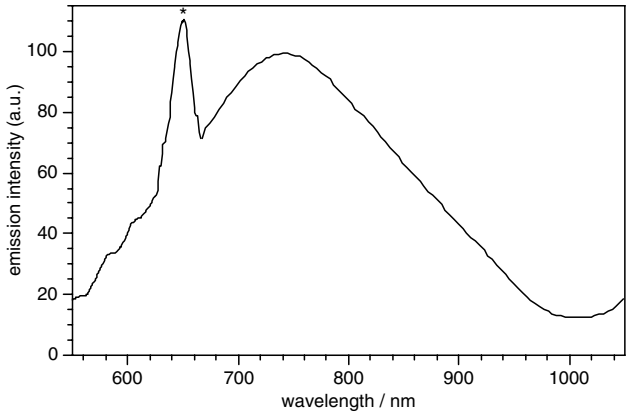

Fig. 7. Emission spectrum of $[Ir(L^2)_2]^{3+}$ in aqueous solution; λ_{ex} = 532 nm, 295 K. The Raman band of water is marked with an asterisk. (The onset of an increased signal at low energy is due to residual 1064 nm radiation in the frequency-doubled output of the Nd:YAG excitation source).

substituted system in water, which is absent (or at least less efficient), in the Ph_2N-analogue. In fact, our previous work on the photophysics of the free ligands revealed a related effect [12,13]. Thus, whilst the fluorescence quantum yield of L^2 in ethanol was comparable to the values in other, non-OH solvents (cyclohexane, THF and DCM), for L^1, in contrast, the emission intensity in ethanol solution was much lower than for the other solvents (e.g., ϕ was 30 times smaller in EtOH than in DCM). Since the fluorescence lifetime did not show a comparable reduction, the small ϕ of L^1 in EtOH was attributed to a reduction in the efficiency of formation of the emissive ICT state, following excitation to the initially populated excited state, as opposed to enhanced non-radiative deactivation. This may be due to hydrogen bonding between the $-NMe_2$ nitrogen atom and the –OH group of the solvent, inhibiting the twisting process that is thought to accompany the formation of the ICT state [22]; such hydrogen bonding will be absent (or only very weak) in the $-NPh_2$ analogue L^2, since triphenylamine is not basic. It is possible that a similar effect operates in the complex, $[Ir(L^1)_2]^{3+}$, reducing the efficiency with which the emissive excited state is formed in this case.

It is also noteworthy that whilst convincing emission spectra could be obtained for these two complexes, the luminescence of the related complex $[Ir(tpy)L^4]^{3+}$, prepared previously [9], is extremely weak, and attempts to obtain a reliable emission spectrum using the same instrumental set-up have met with little success. A possible explanation is that the presence of the additional phenyl ring in $[Ir(tpy)L^4]^{3+}$ (interposed between the metal terpyridyl core and the aminophenyl substituent) promotes non-radiative deactivation pathways, by offering additional C–C stretching vibrations able to act as energy-accepting modes for deactivation of the excited state, and perhaps also by facilitating interaction with the solvent molecules.

4. Conclusions

In summary, we have shown that the introduction of electron-donating amino or pyrenyl substituents into bis-terpyridyl iridium(III) complexes leads to a change in the nature of the lowest-lying excited state, to intramolecular charge transfer (ILCT). Excitation to the ILCT states leads to the appearance of low-energy solvatochromic bands in the absorption spectrum. Unusually, the ILCT states are emissive under ambient conditions (albeit only weakly so), giving rise to broad, structureless bands in the near infra-red. This behaviour contrasts with that of previously studied bis-terpyridyl iridium complexes, which normally display $^3\pi$–π^* luminescence. Given the current interest in near IR-emitting compounds for a variety of applications, complexes of this type may represent an intriguing extension of the future potential of luminescent polypyridyl iridium complexes.

5. Experimental

5.1. Synthetic details

Ligands L^1 and L^2 were prepared by Suzuki cross-coupling methodology from 4′-bromo-terpyridine, as described previously [12,13]. $[Ir(tpy)L^4]^{3+}$ was prepared from $[Ir(tpy)(tpy\text{-}C_6H_4\text{-}Br)]^{3+}$ by an in situ cross-coupling reaction, as described previously [9]. Solvents used were Analar quality or better; THF was distilled from sodium prior to use. Water was purified using the Purite Still-plus system. ^{1}H NMR spectra were recorded on a Varian Mercury-200, Unity-300 or a 500 MHz instrument, and referenced to residual protio-solvent resonances. Coupling constants are in Hertz. Electrospray ionisation mass spectra were acquired on a time-of-flight Micromass LCT instrument; high resolution spectra for accurate mass determinations were carried out either on this instrument or at the EPSRC National Mass Spectrometry Service Centre, Swansea.

3-(Pyren-1-yl)-1-(pyridin-2-yl)-propenone. 2-Acetylpyridine (0.54 g, 4.5 mmol) and 1-pyrenecarboxaldehyde were dissolved in a mixture of ethanol (30 mL) and dichloromethane (15 mL), and sodium hydroxide (0.3 g in 5 mL water) was added dropwise with stirring. The mixture was left for 18 h at room temperature with continuous stirring, and the resulting precipitate was isolated by filtration, and washed with cold ethanol, to give the desired compound as a bright orange solid; 1.1 g, (74%). ^{1}H NMR (500 MHz, $CDCl_3$): δ 9.14 (1H, d, J 16, vinylic H), 8.81 (1H, d, J 4.5, H^6), 8.61 (1H, d, J 16, vinylic H), 8.29 (1H, d, J 7.0, H^3), 8.27–8.00 (9H, m, pyrenyl protons), 7.94 (1H, td, J 7.0, 1.5, H^4), 7.54 (1H, t, J 5.5, H^5). MS (ES+): m/z 334 ($M + H^+$). ν_{max}(KBr) = 3043 (arom C-H), 1660 (C=O), 1588, 1574 cm^{-1} (C=C). $\lambda_{max}{}^{abs}$ (DCM): 270, 311, 340, 391, 425 nm. $\lambda_{max}{}^{em}$ (DCM): 526 nm.

4′-(Pyren-1-yl)-2,2′:6′,2″-terpyridine. The method was based on that described by Constable for 4′-anthryl-terpyridine [16], as also employed by McMillin [15]. 2-Acetylpyridine (0.22 mL, 1.84 mmol) was added to a stirred solution of potassium *tert*-butoxide (0.34 g, 3.00 mmol) in anhydrous THF (40 mL) and stirred at room temperature under nitrogen for 2 h. 3-(Pyren-1-yl)-1-(pyridin-2-yl)-propenone (0.5 g, 1.5 mmol) was added, and the solution stirred at room temperature for 18 h. Ammonium acetate (2.34 g, 30 mmol) and ethanol (40 mL) were added to the deep red solution, and the mixture heated at reflux for 4 h. The solvent was removed under reduced pressure and the residue taken up into a mixture of CH_2Cl_2 and water. The organic layer

was separated, washed with more water, dried over anhydrous K_2CO_3 and the solvent removed. The residue was recrystallised from $CHCl_3$/MeOH to give the desired product as a colourless solid; 0.44 g (68%). ^1H NMR (500 MHz, $CDCl_3$, assigned using ^1H–^1H NOESY and COSY): δ 8.77 (2H, s, $H^{3'}$), 8.76 (2H, d, J 7.2, H^3), 8.70 (2H, d, J 4.1, H^6), 8.09–8.28 (8H, m, pyrenyl protons), 8.04 (1H, t, J 7.5, H^7-pyr), 7.92 (2H, td, J 7.2, 1.5, H^4), 7.36 (2H, ddd, J 7.2, 4.1, 1.0, H^5). MS (ES+): m/z 433 (M^+). Calc. for $C_{31}H_{19}N_3$: C, 85.89, H, 4.42, N, 9.69%. Found C, 85.15, H, 4.89, N, 9.17%.

[Ir(L¹)₂](PF₆)₃. 4′-(*p*-*N*,*N*-Dimethylaminophenyl)-2,2′:6′, 2″-terpyridine (164 mg, 0.47 mmol) and $IrCl_3 \cdot 3H_2O$ (85 mg, 0.24 mmol) were dissolved in ethylene glycol (25 mL) and heated with stirring at 100 °C for 1.5 h, followed by a further 3 h at reflux (oil bath temperature 215 °C). After cooling to ambient temperature, the solution was added to a saturated aqueous solution of KPF_6, to precipitate the crude product as a red solid. Repeated recrystallisation from an acetone/toluene mixture led to the desired complex; 270 mg (83%). TLC (silica): $R_f = 0.6$, in 85% CH_3CN/14% H_2O/1% KNO_3(aq). ^1H NMR (300 MHz, $(CD_3)_2CO$): δ 9.42 (4H, s, $H^{3'}$), 9.14 (4H, d, J 7.8, H^3), 8.32 (12H, overlapping m, H^4, H^6 and H^b), 7.63 (4H, t, J 6.8, H^5), 7.05 (4H, d, J 9.0, H^a), 3.21 (12H, s, CH_3). ^1H NMR (200 MHz, CD_3CN): δ 8.96 (4H, s, $H^{3'}$), 8.70 (4H, d, J 8.0, H^3), 8.20 (4H, m overlapping with following signal, approx. J 7.5, H^4), 8.18 (4H, d, J 9.0, H^b), 7.70 (4H, d, 5.0, H^6), 7.46 (4H, td, J 7.2, 5.0, H^5), 7.04 (4H, d, J 9.0, H^a), 3.18 (12H, s, CH_3). MS (ES+): m/z 521 $(M^{3+} + PF_6^-)^{2+}$, 448 $(M^{3+} - H^+)^{2+}$, 299 (M^{3+}). HRMS (ES+): 1187.2292 $(M^{3+}+2PF_6^-)^+$. Calc. for $C_{46}H_{40}N_8IrP_2F_{12}$: 1187.2289.

[Ir(L²)₂](PF₆)₃. 4′-(*p*-*N*,*N*-Diphenylaminophenyl)-2,2′:6′, 2″-terpyridine (300 mg, 0.63 mmol) and $IrCl_3 \cdot 3H_2O$ (74.1 mg, 0.21 mmol) were dissolved in ethylene glycol (15 mL) and heated with stirring at 90 °C for 2 h, followed by a further 6 h at reflux (bath temperature 215 °C). The solution was then added to a saturated aqueous KPF_6 solution to precipitate the crude product. Unreacted ligand was removed by washing the solid with toluene, and the remaining material was then purified by column chromatography on silica; gradient elution from 100% CH_3CN to 91.6% CH_3CN, 8% H_2O and 0.4% $KNO_{3(aq)}$ followed by ion exchange of fractions containing product, using KPF_6. Further chromatography on a column of alumina was required to remove all traces of an unidentified fluorescent impurity; gradient elution from 100% CH_3CN to 93.4% CH_3CN, 6% H_2O and 0.6% KNO_3(aq). A final ion exchange led to the product as the hexafluorophosphate salt; 55 mg (17%). NMR (500 MHz, $(CD_3)_2CO$): δ 9.48 (4H, s, $H^{3'}$), 9.14 (4H, d, J 8.0, H^3), 8.37 (4H, t, J 7.8, H^4), 8.24 (4H, d, J 5.5, H^6), 8.23 (4H, d, J 8.5, H^b), 7.63 (4H, t, J 6.0, H^5), 7.46 (8H, t, J 8.0, *m*-Ph), 7.26 (16H, overlapping m, *o*-/*p*-Ph and H^a). MS (ES+): m/z 645 $(M^{3+} + PF_6^-)^{2+}$, 572 $(M^{3+} - H^+)^{2+}$. HRMS (ES+): 1435.3161 $(M^{3+} + 2PF_6^-)^+$. Calc. for $C_{66}H_{48}N_8IrP_2F_{12}$: 1435.3158.

[Ir(tpy)L³](PF₆)₃. A mixture of [Ir(tpy)Cl_3], (159 mg, 0.30 mmol, prepared as described previously [8]), and 4′-(pyren-1-yl)-2,2,′:6′,2″-terpyridine (130 mg, 0.30 mmol) in ethylene glycol (10 mL) was heated under vigorous reflux for 15 min (oil bath temperature 215 °C). After allowing to cool to room temperature, the red solution was diluted with water (30 mL). Addition of a saturated aqueous solution of potassium hexafluorophosphate (10 mL) led to a red precipitate, which was separated by centrifugation and washed with water (3×10 mL). The crude product was purified by preparative column chromatography, gradient elution from CH_3CN to 60% CH_3CN/37.5% H_2O/2.5% KNO_3(aq., sat'd). Fractions containing only the desired product were subject to a second anion exchange to give the hexafluorophosphate salt; yield 190 mg (50%). ^1H NMR (500 MHz, CD_3CN): δ 9.21 (2H, s, $H^{3'}$ on L^3), 8.93 (2H, d, J 8.3, $H^{3'}$ on tpy), 8.82 (1H, t, J 8.3, $H^{4'}$ on tpy), 8.65 (2H, d, J 8.0, H^3 on tpy), 8.72–8.63 (4H, m, pyrenyl protons), 8.48 (2H, d, H^3 on L^3), 8.51–8.37 (4H, m, pyrenyl protons), 8.47 (5H, overlapping m, H^7-pyr and H^4 on both ligands), 7.90 (2H, d, J 6.0, H^6 on tpy), 7.67 (2H, d, J 5.7, H^6 on L^3), 7.61 (2H, ddd, J 7.2, 6.0, 1.0, H^5 on tpy), 7.72 (2H, ddd, J 7.3, 5.7, 1.0, H^5 on L^3). MS (ES+): m/z 430 $(M - H)^{2+}$, 286 M^{3+}. HRMS (ES+): 286.4051 (M^{3+}). Calc. for $C_{46}H_{30}N_6Ir$, M^{3+}: 286.4055.

6. Electrochemical measurements

The redox chemistry was investigated using an Autolab Pstat30 potentiostat using GPES version 4.8 software. Cyclic voltammetry was carried out at room temperature in solution in dimethylformamide, in the presence of 0.1 M [^{t}Bu$_4$N][BF_4]. The working electrode was a Pt microdisc electrode, the counter electrode a Pt rod, and a Ag/AgCl electrode was used as the reference. The scan rate was 100 mV s^{-1}. Differential pulse voltammograms were measured under the same conditions, at 20 mV s^{-1}. All solutions studied electrochemically were deoxygenated and kept under an atmosphere of nitrogen. The electrochemical potentials quoted are referenced to the ferrocinium/ferrocene couple, which was measured at 0.55 V using the same experimental conditions.

7. Photophysical measurements

Absorption spectra were measured using a Biotek Instruments XS spectrometer, using matched quartz

cuvettes of 1 cm pathlength. The fluorescence excitation and emission spectra of the ligands and of the pyrene-substituted complex were recorded using a Jobin Yvon FluoroMax-2 spectrofluorimeter, equipped with a Hamamatsu R928 photomultiplier tube. The near infra-red emission spectra of the amino-substituted complexes were obtained by excitation at 532 nm with a frequency-doubled 10 mW CW Nd:YAG laser. The emitted light was passed through a Jobin Yvon Triax-320 monochromator with NIR gratings, and detected using a single photon-counting silicon avalanche photodiode (Perkin–Elmer SPCM-AQR-13). Samples were degassed via a minimum of three freeze–pump–thaw cycles, base pressure $<10^{-3}$ mbar, in 1 cm pathlength quartz cuvettes, modified to allow connection to the vacuum line. All solvents used were HPLC grade or pre-distilled.

Acknowledgements

We thank the University of Durham for a studentship (to W.L.) and the EPSRC National Mass Spectrometry Service Centre, Swansea, for high-resolution mass spectra of the complexes.

Dedicated to Malcolm L.H. Green on the occasion of his retirement

Abstract

The syntheses, structures and magnetic properties are reported of three new iron(III) clusters $[Fe_6(\mu_3\text{-}O)_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2]$ (**1**), $[Fe_6(\mu_3\text{-}O)_2(O_2CCH_2Cl)_6(moe)_6](NO_3)_2$ (**2**) and $[Fe_{12}(\mu_3\text{-}O)_8(\mu\text{-}OMe)_2(O_2CPh)_{12}(pam)_6]$ (**3**). Complex **1** was synthesised from the reaction of $[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3](O_2CCH_2Bu^t)$ with pyridine in MeCN. Complex **2** was prepared by treatment of $[Fe_3O(O_2CCH_2Cl)_6(H_2O)_3](O_2CCH_2Cl)$ and $Fe(NO_3)_3$ with methoxyethanol (moeH) in MeCN, and complex **3** was obtained from the reaction of $[Fe_3O(O_2CPh)_6(H_2O)_3](O_2CPh)$, *syn*-2-pyridinealdoxime (pamH) and NaOMe in MeCN. All three compounds can be structurally described as representing different ways of linking or fusing oxide-centered $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units. Thus, the Fe_6 core of **1** comprises two such units bridged at one of their edges to give a twisted boat conformation, whereas the Fe_6 core of the cation of **2** comprises two $[Fe_3(\mu_3\text{-}O)]^{7+}$ units face-to-face in a staggered manner to give an Fe_6 octahedron. The more complicated Fe_{12} core of **3** contains a central Fe_6 unit that can be described in various ways, one of which is as four edge-sharing $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units and two additional $[Fe_3(\mu_3\text{-}O)]^{7+}$ units attached to the flanks. One particular additional point of interest in **1** is the occurrence of a rare methanediolate group formed in situ and bound in an unusual μ_4-bridging mode. Variable-temperature solid-state magnetic susceptibility studies on complexes **1**–**3** in the temperature range 5.00–300 K reveal that the complexes all possess $S = 0$ ground state spins, consistent with the expected antiferromagnetic exchange interactions between the constituent iron(III) ions.

1. Introduction

The synthesis of high nuclearity iron(III) clusters is of interest for a number of reasons. These include the desire to understand and model the assembly of the polynuclear Fe/O core of the iron-storage protein ferritin, and the search for molecular species with unusual or novel magnetic properties. The latter encompasses the currently very active efforts to produce new examples of molecular species that can function as nanoscale magnetic particles, or so-called single-molecule magnets (SMMs), especially since the discovery of iron SMMs [1–5]. In such molecules the presence of a large ground state spin (S) combined with an Ising (or easy-axis) type of magnetoanisotropy (negative zero-field splitting parameter, D) leads to superparamagnet-like slow relaxation of the magnetization at low temperatures, and resulting out-of-phase AC magnetic susceptibility signals and magnetization versus applied DC field hysteresis loops [6,7]. Iron(III) is a good choice for the preparation of high nuclearity clusters given its high charge and resulting propensity to favor

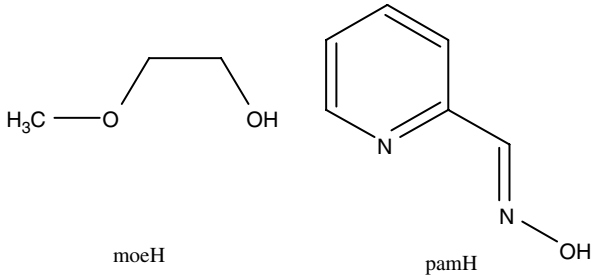
doi:10.1016/j.poly.2004.07.013

oxide-bridged units, and many large iron clusters have been reported, with nuclearities up to 19 [2,8–11]. Indeed, the formation of the Fe/O/OH core of ferritin relies also on this chemistry, and this protein core is effectively a nanoscale Fe/O particle. Thus, there is a continuing search for new synthetic methods that can yield new polynuclear Fe/O clusters. In this paper, we describe some recent results, two of which have resulted from the use of alcohol-based chelate ligands.

The chelates employed are shown in the scheme. The synthetic strategy was to react these organic molecules with the trinuclear $[Fe_3O(O_2CR)_6(H_2O)_3](O_2CR)$ complexes containing the triangular, oxide-centered $[Fe_3(\mu_3\text{-}O)]^{7+}$ core. Such trinuclear species have proven on many occasions to be excellent starting points for the synthesis of higher nuclearity Fe or Mn clusters [12–17]. The 2-methoxyethanol (moeH) [18,19] and *syn*-2-pyridinealdoxime (pamH) [20–22] ligands have been used on several previous occasions for inorganic synthesis, but there are only a very few examples of cluster compounds having been obtained with them. In particular, we are unaware of their use in reactions with $[Fe_3O(O_2CR)_6L_3]$ complexes. As a result, we felt that this approach could yield some interesting new cluster products. Indeed, this has turned out to be the case. We report that the use of moeH and pamH with $[Fe_3O(O_2CR)_6(H_2O)_3](O_2CR)$ species has led to two new high-nuclearity products, Fe_6 and Fe_{12}, respectively, and we describe the syntheses, crystal structures and magnetic properties of these complexes. In addition, we also describe a second Fe_6 complex, obtained from the reaction of $[Fe_3O(O_2CR)_6(H_2O)_3](O_2CR)$ with pyridine in the presence of MeOH. The combined results continue to demonstrate the flexibility and versatility of iron(III) chemistry for the synthesis of unusual high-nuclearity cluster compounds.



moeH pamH

2. Experimental

2.1. Compound preparations

All manipulations were performed under aerobic conditions using materials and solvents as received. $[Fe_3O(O_2CR)_6(H_2O)_3](O_2CR)$ complexes were prepared using the procedure reported previously [23].

2.1.1. $Fe_6O_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2]$ (**1**)

Method A. A solution of $[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3](O_2CCH_2Bu^t)$ (0.47 g, 0.50 mmol) and pyridine (0.64 ml, 7.80 mmol) in MeCN/MeOH (45/l5 ml) was stirred for 30 min to give an orange solution. This was layered with diethyl ether and left undisturbed at room temperature. After several weeks, the orange prism-shaped crystals of **1** that had slowly grown were collected in 25% yield. *Anal*. Calc. for **1** ($C_{83}H_{144}Fe_6N_2O_{28}$): C, 51.04; H, 7.43; N, 1.43. Found: C, 51.32; H, 7.11; N, 1.55%. Selected IR data (cm^{-1}): 3446 (br), 2955 (s), 1607 (m), 1557 (s), 1455 (m), 1412 (s), 1369 (m), 1061 (w), 898 (w), 643 (w), 562 (w).

Method B. A solution of $[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3](O_2CCH_2Bu^t)$ (0.24 g, 0.25 mmol), py (0.64 ml, 7.80 mmol) and 37% formaldehyde (0.50 ml, 6.6 mmol) in MeCN (45 ml) was stirred for 30 min to give an orange solution. This was left undisturbed at room temperature. After one day, the orange prism-shaped crystals of **1** that had slowly grown were collected by filtration in 75% yield. The material was spectroscopically identical (IR) with that from Method A.

2.1.2. $Fe_6O_2(O_2CCH_2Cl)_6(moe)_6](NO_3)_2$ (**2**)

A solution of $[Fe_3O(O_2CCH_2Cl)_6(H_2O)_3]$ (O_2CCH_2Cl) (0.23 g, 0.25 mmol), $Fe(NO_3)_3 \cdot H_2O$ (0.10 g, 0.25 mmol) and moeH (5 ml, 63 mmol) in MeCN (50 ml) was stirred for 15 min to give a green solution. This was layered with diethyl ether and left undisturbed at room temperature. After 7 days, yellow-green rectangular shaped crystals of **2** were collected in 55% yield based on total Fe. *Anal*. Calc. for **2** ($C_{30}H_{54}Cl_6Fe_6N_2O_{32}$): C, 23.98; H, 3.62; N, 1.86. Found: C, 23.87; H, 3.53; N, 1.55%. Selected IR data (cm^{-1}): 3436 (br), 2946 (s), 1600 (s), 1432 (s), 1384 (m), 1341 (m), 1265 (m), 1079 (s), 1038 (m), 916 (w), 614 (w), 578 (m), 527 (w).

2.1.3. $[Fe_{12}O_8(OMe)_2(O_2CPh)_{12}(pam)_6]$ (**3**)

A solution of $[Fe_3O(O_2CPh)_6(H_2O)_3](O_2CPh)$ (0.26 g, 0.25 mmol) in MeCN (30 ml) was added with stirring to a solution of pamH (0.061 g, 0.50 mmol) and NaOMe (0.054 g, 1.00 mmol) in MeCN (20 ml). The resulting dark red solution was left undisturbed at room temperature. After 7 days, dark red rectangular shaped crystals of $\mathbf{3} \cdot 4MeOH \cdot 2MeCN$ had formed and were collected in 37% yield. *Anal*. Calc. for $\mathbf{3} \cdot 4MeOH$ ($C_{126}H_{112}Fe_{12}N_{12}O_{44}$): C, 47.76; H, 3.56; N, 5.30. Found: C, 47.51; H, 3.23; N, 5.15%. Selected IR data (cm^{-1}): 3446 (br), 1602(s), 1541 (m), 1404 (s), 1122 (w), 1096 (m), 718 (m), 692 (w), 613 (w), 467 (m), 455 (w).

2.2. General and physical measurements

Elemental analyses (C, H and N) were performed in the in-house facilities of the University of Florida Chemistry Department. Infrared spectra in the 400–4000 cm^{-1} range were recorded in the solid state (KBr pellets) on a Nicolet Nexus 670 FTIR spectrometer. Variable temperature dc magnetic susceptibility data down to 5.0 K were collected using a Quantum Design MPMS-XL SQUID susceptometer equipped with a 7-T dc magnet. Pascal's constants were used to estimate the diamagnetic corrections, which were subtracted from the experimental susceptibilities to give the molar magnetic susceptibilities (χ_M). Microcrystalline samples were restrained in eicosane by suspending the solid for 15 min in eicosane maintained at a temperature above its melting point (35–37 °C), and then the temperature was gradually decreased below the melting point to solidify the eicosane.

2.2.1. X-ray crystallography and solution of structures

Data were collected using a Siemens SMART PLATFORM equipped with a CCD area detector and a graphite monochromator utilising Mo Kα radiation ($\lambda = 0.71073$ Å. Suitable crystals of **1**, **2** and **3** · 4MeOH · 2MeCN were attached to glass fibres using silicone grease and transferred to a goniostat where they were cooled to 173 K for data collection. An initial search of reciprocal space revealed monoclinic space group *C*2/*c* for complex **1** and triclinic space group $P\bar{1}$ for both **2** and **3** · 4MeOH · 2MeCN, which were confirmed by the subsequent solution and refinement of the structures. Cell parameters were refined using up to 8192 reflections. A full sphere of data (1850 frames) was collected using the ω-scan method (0.3° frame width). The first 50 frames were re-measured at the end of data collection to monitor instrument and crystal stability (maximum correction on *I* was <1%). Absorption corrections by integration were applied based on measured indexed crystal faces. The structures were solved by direct methods in SHELXTL-6 [24], and refined on F^2 using full-matrix least squares. The non-H atoms were treated anisotropically, whereas the hydrogen atoms were placed in calculated, ideal positions and refined as riding on their respective carbon atoms.

For complex **1**, a total of 557 parameters were included in the structure refinement using 4686 reflections with $I > 2\sigma(I)$. For compound **2**, a total of 448 parameters were included in the structure refinement using 12024 reflections with $I > 2\sigma(I)$. For compound **3**, a total of 907 parameters were included in the structure refinement using 7761 reflections with $I > 2\sigma(I)$. Unit cell data and the final refinement indices R_1 and wR_2 are listed in Table 1.

3. Results and discussion

3.1. Syntheses

As mentioned earlier, the reaction of a $[M_3O(O_2CR)_6L_3]^{0,+}$ (L = py, H_2O, etc.) complex with a chelating ligand represents a commonly employed and convenient synthetic route to a variety of higher nuclearity clusters of Fe and Mn. For example, the use of 2-(hydroxymethyl)pyridine (hmpH) has led to a large variety of products, depending on the precise reaction conditions and ratios, including Mn_7 [14], Mn_{10} [15], Mn_{12} [16], and Fe_6 [17] clusters. The alkoxide arm of the hmp^- ligand normally adopts a bridging mode, fostering formation of higher nuclearity products, and this was the primary reason for choosing to use moeH and pamH in the present work. However, not all the reactions in the present work involved a chelate; we also investigated the long-term stability of the $[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3]^+$ complex to MeOH, in the presence also of py as a proton acceptor, seeking the formation higher nuclearity products via methanolysis. Indeed this reaction led to a nuclearity change, although the isolated product contained no methoxide. The reaction slowly turned orange, and layering with Et_2O deposited orange crystals of $[Fe_6O_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2]$ (**1**) in 25% yield. Its formation is summarised in Eq. (1).

$$2[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3]^+ + 2py + CH_3OH + \tfrac{1}{2}O_2 \rightarrow [Fe_6O_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2] + 6H_2O + 2H^+ \quad (1)$$

When the same reaction in MeCN/MeOH was carried out in the presence of triethanolamine ($teaH_3$), the product was instead $[Fe_8O_3(O_2CCH_2Bu^t)_9(tea)(teaH)_3]$, structurally analogous to the benzoate complex $[Fe_8O_3(O_2CPh)_9(tea)(teaH)_3]$ reported recently [12].

The most remarkable feature of the reaction and the resulting structure of **1** (vide infra) is the formation of a rare methanediolate ($^-OCH_2O^-$) group. Such groups are generally unstable but can be formed and trapped in situ [25]. The formation of **1** is not readily amenable to mechanistic studies, but it is reasonable to assume that overall the methanediolate group is formed by iron (III)-promoted oxidation by O_2 of bound MeOH or methoxide, as summarized in Eq. (2), followed by its trapping as a fully deprotonated bridging ligand.

$$CH_3OH + \tfrac{1}{2}O_2 \rightarrow CH_2(OH)_2 \quad (2)$$

Since *gem*-diols are merely hydrated forms of aldehydes or ketones, we wondered whether a higher yield preparation of **1** might be available via a reaction in which formaldehyde (H_2CO) had been deliberately added. This turned out to be the case (Method B of Section 2). Thus, the reaction of $[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3]^+$, py and H_2CO in a 1:31:26 ratio in MeCN

[a] $I > 2\sigma(I)$.
[b] $R_1 = 100\sum(||F_o|-|F_c||)/\sum|F_o|$.
[c] $wR_2 = 100[\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]]^{1/2}$, $w = 1/[\sigma^2(F_o^2) + [(ap)^2 + bp]$, where $p = [\max(F_o^2, 0) + 2F_c^2]/3$.

gave an orange solution from which **1** crystallized and was isolated in 75% yield; the absence of MeOH lowers the solubility of **1**, and it crystallizes from MeCN without the addition of Et_2O. This much superior procedure is summarized in Eq. (3).

$$2[Fe_3O(O_2CCH_2Bu^t)_6(H_2O)_3]^+ + 2py + H_2CO \rightarrow [Fe_6O_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2] + 5H_2O + 2H^+ \quad (3)$$

The formation of the methanediolate group from formaldehyde is analogous to the more common in situ formation of the *gem*-diol form of di-2-pyridylketone, followed by its trapping as the doubly deprotonated diolate ligand to metal ions [26].

Treatment of an equimolar mixture of $[Fe_3O(O_2CCH_2Cl)_6(H_2O)_3]^+$ and $Fe(NO_3)_3$ in MeCN with an excess of moeH gave a yellow-green solution from which yellow-green rectangular shaped crystals of $[Fe_6O_2(O_2CCH_2Cl)_6(moe)_6](NO_3)_2$ (**2**) were obtained in 55% yield by layering with Et_2O. This is a more typical type of cluster synthesis reaction than the formation of **1**, with no unusual ligand transformations occurring. The formation of the cation of **2** is summarized in Eq. (4).

$$3[Fe_3O(O_2CCH_2Cl)_6(H_2O)_3]^+ + 3Fe^{3+} + 12moeH \rightarrow 2[Fe_6O_2(O_2CCH_2Cl)_6(moe)_6]^{2+} + 6ClCH_2CO_2H + 8H_2O + 8H^+ \quad (4)$$

The reaction contained a large excess of moeH over that required by Eq. (4), indicating that the product **2** is stable to further incorporation of chelate that might lead to smaller nuclearity products, perhaps even $[Fe(moe)_3]$. When the reaction was carried out in MeOH instead of MeCN, a mixture of products was obtained, yellow-green complex **2** and golden crystals of known $[Fe_{10}(OMe)_{20}(O_2CCH_2Cl)_{10}]$ [8]. The latter is a member of the 'ferric wheel' family of wheel-like complexes.

The reaction of $[Fe_3O(O_2CPh)_6(H_2O)_3]^+$, pamH and NaOMe in 1:2:4 ratio in MeCN gave a dark red solution from which dark red rectangular shaped crystals of $[Fe_{12}O_8(OMe)_2(O_2CPh)_{12}(pam)_6]$ (**3**) slowly formed in 37% yield. The reaction is likely a complicated equilibrium involving several species of various nuclearities, and the crystallization of the product directly from the reaction solution is undoubtedly beneficial in providing pure material; the filtrates are still coloured, but we have not pursued isolation of other species. The formation of this novel Fe_{12} cluster is summarised in Eq. (5).

$$4[Fe_3O(O_2CPh)_6(H_2O)_3]^+ + 6pamH + 2MeO^- \rightarrow [Fe_{12}O_8(\mu\text{-}OMe)_2(O_2CPh)_{12}(pam)_6] + 12PhCO_2H + 8H_2O + 2H^+$$

This reaction ratio and solvent represent the combination that was found to give a pure isolated product in reasonable yield. Small changes to the Fe:pamH ratio still gave the same Fe_{12} product. The NaOMe serves both as a base to deprotonate the pamH and also as a source of MeO^- bridges to foster formation of a high-nuclearity product. When NEt_3 or NMe_4OH and a mixed MeCN/MeOH reaction solvent were employed, complex **3** was again obtained but only in very poor isolated yields (<5%). This (and the larger but still relatively low yield of **3** using NaOMe) may be due to the fact that pamH is susceptible to hydrolysis [21]; in these cases, it is difficult to isolate such species in good yields.

3.2. Structural description of $[Fe_6O_2(O_2CH_2)(O_2CCH_2Bu^t)_{12}(py)_2]$ (1)

A labelled ORTEP plot and stereopair of **1** are presented in Fig. 1, and selected bond distances and angles are listed in Table 2. Complex **1** crystallizes in the monoclinic space group *C*2/*c*, with the asymmetric unit containing half the Fe_6 molecule.

The Fe_6 core of **1** has a twisted boat-like topology (Fig. 4(a)), comprising two $[Fe_3(\mu_3\text{-}O)]^{7+}$ oxide-centered triangular moieties linked between one of their edges (Fe2–Fe3 and the symmetry-related partner) by a μ_4-O_2CH_2group and two μ-$O_2CCH_2Bu^t$ groups in their familiar *syn*, *syn* binding mode. This edge of both triangular units is also bridged by a μ-$O_2CCH_2Bu^t$ group. The two remaining edges of each $[Fe_3(\mu_3\text{-}O)]^{7+}$ unit are each bridged by two *syn, syn* μ-$O_2CCH_2Bu^t$ groups. The two pyridine groups complete six-coordination at the end atoms Fe1 and Fe1a. The complex has crystallographic C_2 symmetry, and virtual C_{2v} symmetry if the slight twist in the Fe_6 boat structure is ignored. All Fe atoms are Fe(III) and possess near-octahedral geometries. The overall structure of **1** is similar to those of previously reported $[Fe_6O_2(OH)_2(O_2CBu^t)_{12}]$ [27], $[Fe_6O_2(OH)_2(O_2CPh)_{12}(py)_2]$ [28] and $[Fe_6O_2(OH)_2(O_2CMe)_{10}(C_7H_{11}N_2O)_2]$ [29], but of course differs in possessing the unusual μ_4-O_2CH_2 bridging group (O13, O13a) at the positions occupied by bridging OH^- groups in the above three complexes. The nearest analogue to this μ_4-O_2CH_2 group is found in $[Fe_6O_2(O_2)(O_2CPh)_{12}(H_2O)_2]$ [30] and $[Fe_6O_2(O_2)(O_2CBu^t)_{12}L_2]$ (L = Bu^t- CO_2H or py) [31]. In these

complexes, there is a central μ_4-O_2^{2-} peroxide group bridging analogously to the methanediolate in **1**, i.e., without the central CH_2 linker between O atoms O13 and O13a. The unusual μ_4-O_2CH_2 group of **1** has itself been seen previously only in a tetranuclear Mo cluster [25], where it bridges the Mo_4 core in the same fashion as that in the central Fe_4 unit of **1**.

3.3. Structural description of $[Fe_6O_2(O_2CCH_2Cl)_6(moe)_6](NO_3)_2$ (**2**)

A labelled ORTEP plot and stereopair of the cation of **2** are presented in Fig. 2, and selected bond distances and angles are listed in Table 3. Complex **2** crystallizes in the triclinic space group $P\bar{1}$, with the Fe_6 cation lying on an inversion centre.

The cation of **2** consists of two triangular $[Fe_3(\mu_3\text{-}O)]^{7+}$ units held together in a face-to-face fashion by six bridging moe^- ligands. Each moe^- group chelates one Fe atom and bridges with its O atom to another Fe atom in the neighboring $[Fe_3O]^{7+}$ unit. All Fe atoms are Fe(III). Each Fe_2 pair within a trinuclear unit is additionally bridged by a $CH_2ClCO_2^-$ group, completing six coordination at each Fe atom. The cation has crystallographic C_i symmetry but virtual S_6 symmetry, with the S_6 axis passing through the μ_3-O^{2-} oxygen atoms (O1, O1a). The Fe_6 cation can be also described as an Fe_6 octahedron (Fig. 4(b)) with two opposite faces bridged by μ_3-O^{2-} ions and six edges bridged by μ-O atoms from moe^- ligands. The Fe···Fe separation within the trinuclear $[Fe_3O]^{7+}$ units (average 3.311 Å) are only slightly shorter than those between $[Fe_3O]^{7+}$ units (average 3.431 Å); thus, the Fe_6 core is almost a regular octahedron. The Fe···Fe separations on the same axis of the octahedron are much longer (average 4.767 Å).

The cation of **2** is the first such cluster with moe^- groups, but the core structure of the cation is similar to those in other Fe_6 species with a recognizable octahedral Fe_6 topology, including $[Fe_6O_2(O_2CCH_2C(CH_3)_3)_6(hmp)_6]^{2+}$ [17] and $[Fe_6O(OMe)_3Cl_6(thme)_3]^{2-}$ [32]; the latter also contains a central μ_6-O^{2-} ion. In contrast, the $[Fe_6O_2(O_2)_3(O_2CMe)_9]^-$ anion contains two face-to-face $[Fe_3(\mu_3\text{-}O)]^{7+}$ units in an eclipsed arrangement giving an Fe_6 trigonal prism [33], rather than the

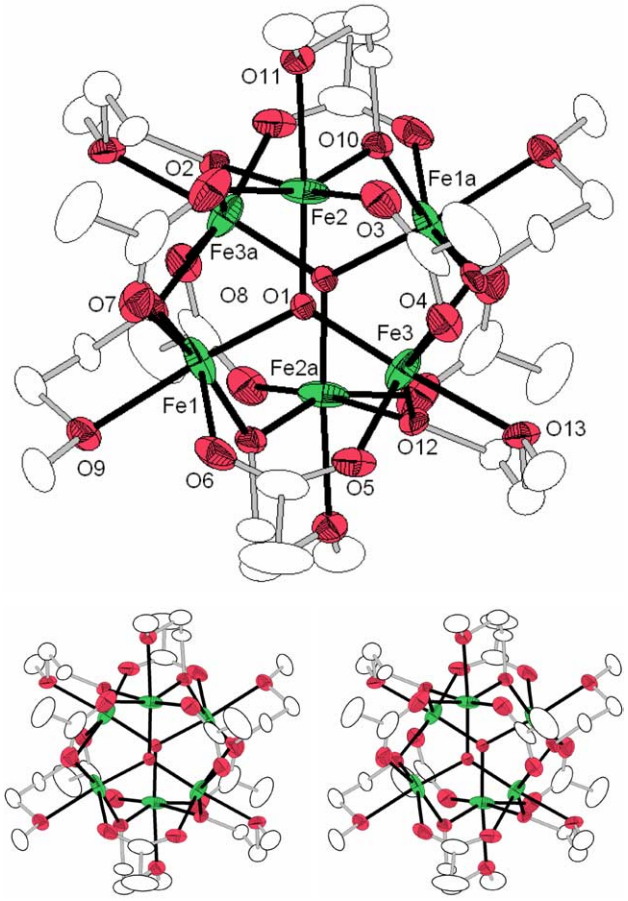

Fig. 2. ORTEP representation and stereopair of the cation of complex **2** at the 50% probability level, viewed almost along the virtual S_6 symmetry axis. All H atoms and the Cl atoms of $CH_2ClCO_2^-$ groups have been removed for clarity.

more common staggered arrangement that yields an Fe_6 octahedron.

3.4. Structural description of $[Fe_{12}O_8(OMe)_2(O_2CPh)_{12}(pam)_6]$ (3)

A labelled ORTEP plot and stereopair for complex **3** are presented in Fig. 3, and selected bond distances and angles are listed in Table 4. Complex **3** crystallizes in the triclinic space group $P\bar{1}$, with the Fe_{12} cluster lying on an inversion centre. The unprecedented core of this complex can be described in different ways. The central Fe_6 portion of the core (Fe4, Fe4a, Fe5, Fe5a, Fe6, Fe6a) can be considered as (i) comprising four face-sharing partial cubanes lacking an Fe atom at one vertex; or (ii) as a skewed Fe_6 ladder with μ_3-O atoms of O^{2-} (O4, O4a) or MeO^- (O5, O5a) ions alternately above and below the plane of the ladder; or (iii) as four edge-sharing $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units. A similar planar $[Fe_6O_4]^{10+}$ unit has been reported in the cation of

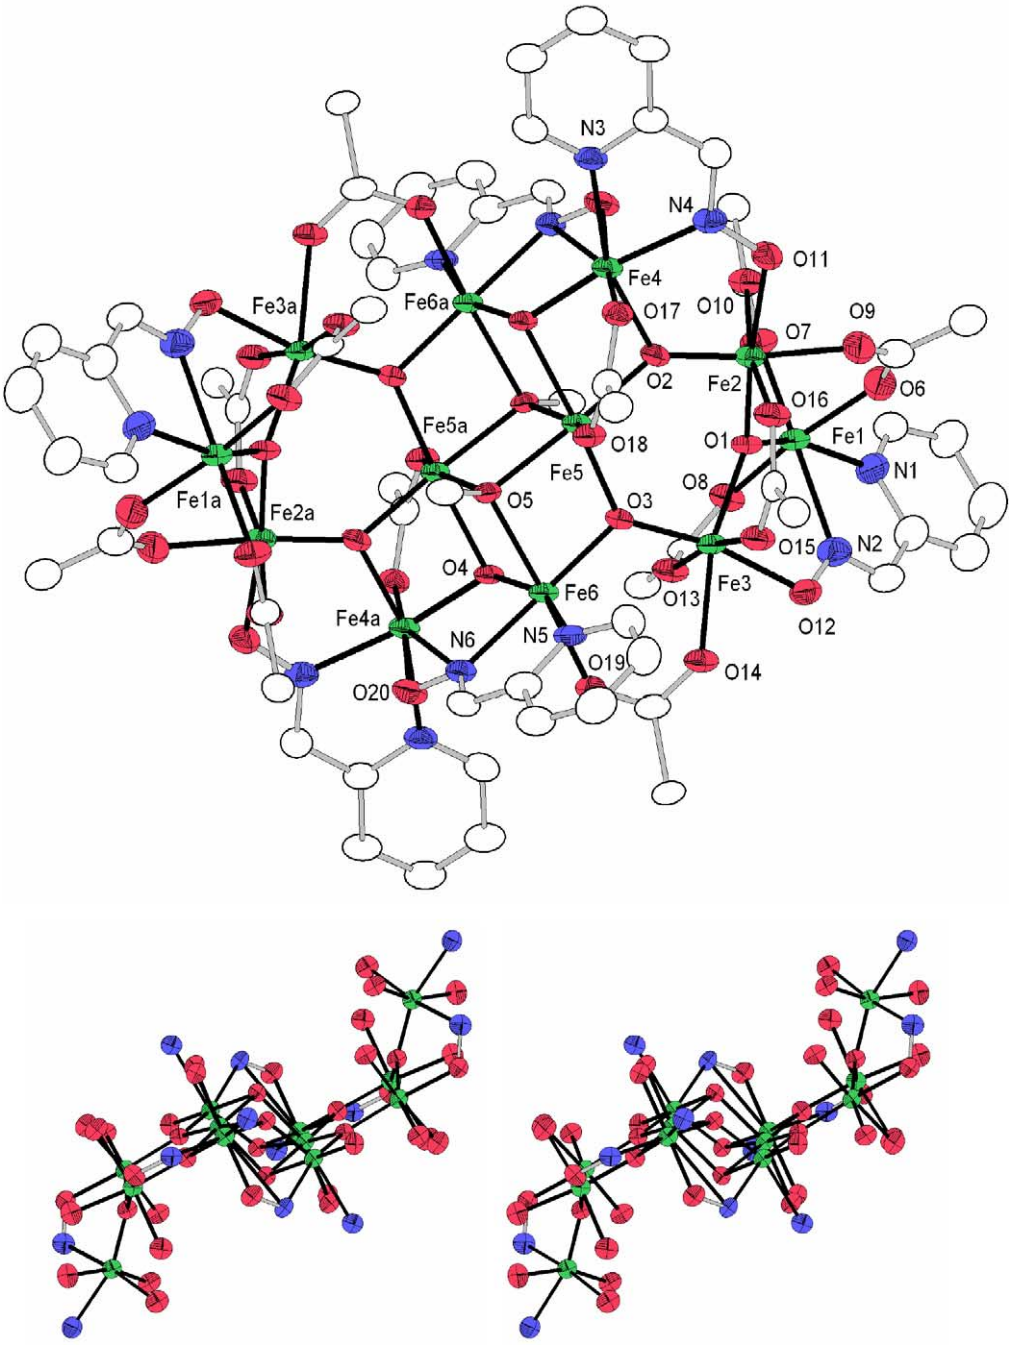

Fig. 3. Labelled ORTEP plot and stereopair at the 50% probability level of complex **3**. H atoms and benzoate phenyl groups have been removed for clarity.

$[Fe_6O_4Cl_4(O_2CPh)_4L_2][FeCl_4]_2$ [31], where however the Fe(III) ions are bridged exclusively via oxide ions. Attached to the central Fe_6 core of **3** by four O^{2-} bridges (O2, O3, O2a, O3a) are two triangular $[Fe_3(\mu_3\text{-}O)]^{7+}$ units (Fe1, Fe2, Fe3 and symmetry equivalents), disposed above and below the central Fe_6 plane. The resulting $[Fe_{12}O_{10}]$ core has an overall chair conformation, as is best seen in Fig. 4(c) where the three cores of **1**–**3** are compared. As is usually the case [2,17], the Fe–O^{2-} bonds (1.853–2.083 Å) are significantly shorter than the Fe–OMe bonds (2.112–2.168 Å). Ligation around the core is provided by the $PhCO_2^-$ and pam^- groups, and every Fe atom consequently has octahedral coordination.

Complex **3** is one of only a very small number of known dodecanuclear iron clusters. Other examples include $[Fe(OMe)_2(dbm)]_{12}$ with a wheel-like structure [37], and $[Fe_{12}O_2(OMe)_{18}(O_2CMe)_6(MeOH)_{4.67}]$ [9], which is mixed-valence 4Fe(III), 8Fe(II).

For all three compounds **1**–**3,** the oxidation states of the Fe atoms and the degree of protonation of O atoms were confirmed by bond valence sum (BVS) calculations, leading to the conclusions described above that all metal centers are Fe(III) and all inorganic O atoms are O^{2-} rather than OH^-. The BVS values obtained were in the 3.05–3.15, 3.10–3.28 and 2.88–3.09 for complexes **1**–**3**, respectively.

Fe6–O3	1.935(4)	Fe6–N6	2.201(6)
Bond angles			
Fe1–O1–Fe2	119.1(2)	Fe4–O2–Fe5	94.2(2)
Fe1–O1–Fe3	117.5(2)	Fe4–O4–Fe5	91.26(19)
Fe2–O1–Fe3	122.2(2)	Fe4–O4–Fe6a	122.4(2)
Fe2–O2–Fe4	123.5(2)	Fe5–O3–Fe6	104.3(2)
Fe2–O2–Fe5	141.1(2)	Fe5–O4–Fe6a	106.3(2)
Fe3–O3–Fe5	132.6(2)	Fe5–O5–Fe5a	102.90(18)
Fe3–O3–Fe6	122.8(2)	Fe6–O5–Fe5a	94.73(18)

The above structural descriptions of **1**–**3** emphasize that the three clusters can all be structurally related to the parent $[Fe_3O(O_2CR)_6(H_2O)_3]^+$ complexes and can thus all be said to be represent different ways of linking or edge-fusing a number of $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units, with the additional incorporation of other bridges such as MeO^-. This point is emphasized by the structural comparison of the three cores provided in Fig. 4.

3.5. Magnetochemistry

Variable-temperature, solid-state magnetic susceptibility (χ_M) studies were performed on microcrystalline samples of **1**–**3** in a 1-kG applied DC magnetic field in the 5.0 – 300 K range. The obtained data for **1** (○), **2** (●) and **3** (▲) are plotted as $\chi_M T$ versus T in Fig. 5. The $\chi_M T$ value for **1** decreases steadily with decreasing temperature from 11.42 $cm^3\,mol^{-1}\,K$ at 300 K to 0.14 $cm^3\,mol^{-1}\,K$ at 5.0 K, consistent with an $S = 0$ ground state. The $\chi_M T$ value at 300 K is well below the spin-only ($g = 2$) value of 26.3 $cm^3\,mol^{-1}\,K$ for six non-interacting Fe(III) ions, indicating strong antiferromagnetic interactions between the Fe(III) centers to give a singlet spin ground state. For complex **2**, the $\chi_M T$ value again decreases steadily with decreasing temperature from 7.13 $cm^3\,mol^{-1}\,K$ at 300 K to 0.11 $cm^3\,mol^{-1}\,K$ at 5.0 K, consistent with an $S = 0$ ground state. The $\chi_M T$ value at 300 K is far below the spin-only value of 26.3 $cm^3\,mol^{-1}\,K$ for six non-interacting Fe(III) ions, indicating even stronger antiferromagnetic interactions between the Fe(III) centers in **2** than in **1**, and again giving an $S = 0$ spin ground state. Similarly, the $\chi_M T$ value for **3** decreases steadily from 12.69 $cm^3\,mol^{-1}\,K$ at 300 K to 0.19 $cm^3\,mol^{-1}\,K$ at 5.0 K, again indicating an $S = 0$ spin ground state. Furthermore, the 300 K $\chi_M T$ value is very far below the spin-only value of 52.5 $cm^3\,mol^{-1}\,K$ for 12 non-interacting Fe(III) ions, which is indicative of very strong antiferromagnetic exchange interactions within this molecule.

The three complexes all thus have $S = 0$ ground states. This is by far the most common ground state for Fe_x clusters with x an even number [10,17,34–36], and is primarily the result of strong antiferromagnetic exchange interactions between $Fe(III)_2$ pairs. Although competing exchange antiferromagnetic interactions and spin frustration effects in higher nuclearity species can occasionally lead to non-zero ground state spins [2,10,29], this is clearly not the case in the present complexes. The $S = 0$ ground states for **1** and **2** can readily be rationalized on the basis of two

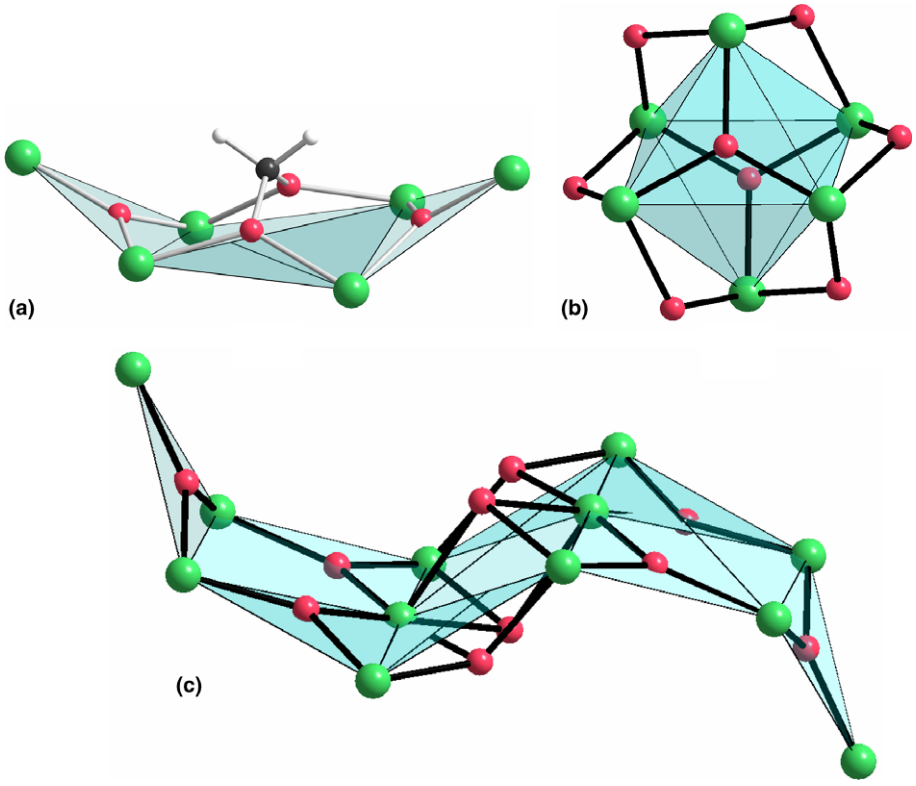

Fig. 4. Comparison of the cores of complexes: **1** (a), **2** (b) and **3** (c), emphasizing the presence of recognizable $[Fe_3O]$ oxide-bridged triangular subunits, and the overall structure of the cores as a twisted boat (a), an octahedron (b), and a chair (c).

$S = 5/2$ $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units antiferromagnetically coupled to each other through the bridging ligands connecting them. The ground state for **3** is not so easily rationalized, but the spin of the central Fe_6 unit is likely $S = 0$, as found for other compounds with such a planar, ladder-like Fe_6 topology [38,39], and then the $S = 5/2$ spins of the two $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular units on the flanks would be coupled antiferromagnetically through the central unit to give an overall $S = 0$ ground state.

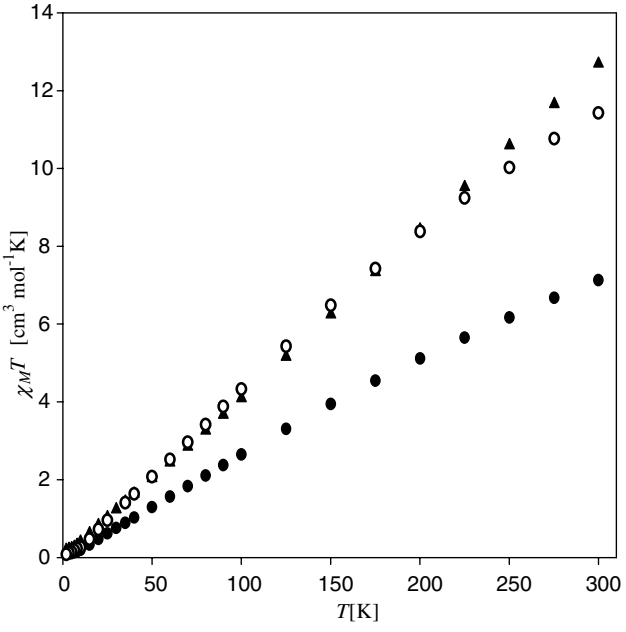

Fig. 5. Plot of $\chi_M T$ vs. T for complexes **1** (○), **2** (●) and **3** (▲).

4. Conclusions

Synthetic methods have been identified that can convert the triangular $[Fe_3O(O_2CR)_6(H_2O)_3]^+$ complexes to new Fe_6 and Fe_{12} products. The structures of the latter can be described as aggregates of Fe_3 triangular units. These results continue to emphasize the utility of small nuclearity clusters as stepping-stones to higher-nuclearity products through the use of alcohol-containing chelate ligands such as the moeH and pamH used in this work, or even by incorporation of methoxide bridges. The magnetic properties of the three complexes described indicate that they all possess $S = 0$ ground states, and this is not surprising given the dominance of antiferromagnetic interactions in high-spin Fe(III) chemistry. Nevertheless, iron(III) carboxylate chemistry continues to surprise with the structural variety and aesthetic beauty of its molecular complexes.

5. Supplementary material

Full crystallographic details have been deposited in CIF format with the Cambridge Crystallographic Data Centre. Copies of the data can be obtained free of charge on request from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336408, e-mail: deposit@ccdc.cam.ac.uk or www at http://www.ccdc.cam.ac.uk) quoting the deposition numbers CCDC 237027 (**1**), 237028 (**2**) and 237029 (**3**).

Available online 3 September 2004

Abstract

Three α-diimines, 2,3-dimethyl-*N,N'*-bis(cyclohexyl)-diaza-1,4-butadiene, Cy-DAD (**1**), (DAD = diaza-1,4-butadiene), bis{2,8-(4-methoxyphenylimino)}acenaphthene, *p*-OMe-BIAN (**3**), (BIAN = 2,8-bis(arylimino)acenaphthene) and bis{2,8-(2,6-di-isopropylphenylimino)}acenaphthene, 2,6-^{i}Pr-BIAN (**4**), were synthesised either via their zinc complexes, as a template, or by the direct reaction of the appropriate primary amine with the diketone. Compound **1** is a non-constrained analogue of the rigid, bidentate nitrogen ligands **3** and **4**. Syntheses of the zinc and palladium complexes of **3** and **4**, namely **2, 5**, **6** and **7**, are also reported herein. All compounds have been characterised spectroscopically, and the molecular structures of **1**, **3**, **4**, $ZnCl_2$(*p*-OMe-BIAN) $\cdot \frac{1}{2}CH_2Cl_2$ (**2**), $PdCl_2$(*p*-OMe-BIAN) (**6**) and $PdCl_2$(2,6-^{i}Pr-BIAN) (**7**) have been determined by single-crystal X-ray diffraction. Compound **1** adopts a *transoid* geometry and possesses a crystallographic inversion centre midway along the N═C–C═N backbone. Compounds **3** and **4** are inherently *cisoidal* and X-ray analysis highlights a twofold axis through the backbone. The Pd(II) centres of **6** and **7** both adopt square planar geometries whilst **6** contains four molecules per asymmetric unit and 1/2 molecule of benzonitrile per Pd atom and complex **7** is isomorphous with the known structure of PdCl(Me)(2,6-^{i}Pr-BIAN). The Zn complex **2** is pseudo tetrahedral as expected for Zn(II).

Keywords: X-ray structure; Diimine; Coordination complex; Zinc; Palladium

1. Introduction

Over the past decade there has been considerable interest in alternative ligands to phosphines, for the development of late transition metal catalysts. Examples of this include the substantial development by Brookhart and co-workers [1] of α-diimine ligands for nickel and palladium catalysed olefin polymerisation and recent developments in the zinc catalysed ring-opening polymerisation of epoxides and ε-caprolactone reported by Bochmann and co-workers [2]. Furthermore, other bidentate nitrogen donor ligands have been used in many catalytic studies including the enantioselective carbonylation of olefins [3], hydrogenation and hydrosilylation [4], the borylation of alkanes and alkenes [5], diboration [6] and reduction of nitrobenzene to aniline [7]. Routes to the diimines have been previously developed by Elsevier and co-worker [8a], Fukuda and co-worker [8b] and Dieck and Dietrich [8c].

Whilst most studies of the α-diimines have concentrated on the reactivity of their complexes, very little crystallographic information has been obtained. We report herein the synthesis and structural characterisation of *p*-OMe-BIAN (**3**), 2,6-^{i}Pr-BIAN (**4**), Cy-DAD (**1**), $ZnCl_2$(*p*-OMe-BIAN) $\cdot \frac{1}{2}CH_2Cl_2$ (**2**), $PdCl_2$(*p*-OMe-BIAN) (**6**) and $PdCl_2$(2,6-^{i}Pr-BIAN) (**7**) (shown in

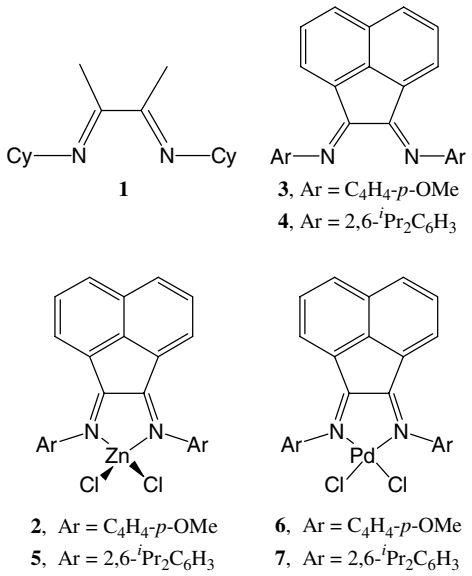

Scheme 1.

Scheme 1). Although the structure of 2,6-^{i}Pr-BIAN has been published previously [9a,9b] we note that the space group reported was wrong [9c].

2. Experimental

2.1. General

All chemicals were commercially available and were used as received. ^{1}H NMR spectra were obtained using a 400 MHz Bruker Avance and Mercury-200, Unity-300 and Inova-500 MHz Varian spectrometers; coupling constants are given in Hz. Mass spectra were obtained with Micromass AutoSpec (EI) and Micromass-LCT (ES) spectrometers. The elemental analyses were carried out with an Exeter Analytical Inc. CE-440 elemental analyser.

2.2. Synthesis of (Cy-DAD) (*1*)

The compound 2,3-dimethyl-*N,N′*-bis(cyclohexyl)-diaza-1,4-butadiene was prepared in a similar manner to that used by Dieck and Dietrich [8c]. Cyclohexylamine (20.25 ml, 180 mmol) was added dropwise to a cooled (0 °C) mixture of butane-2,3-dione (7.8 ml, 90 mmol), molecular sieves (10 g, 4 Å) and formic acid (1 ml, 98%) in chloroform (100 ml). After stirring for one day, the mixture was filtered and the chloroform removed in vacuo. The remaining yellow-white solid was re-crystallised from ethanol yielding colourless plates suitable for X-ray diffraction. Yield: 8.9 g, 40%. (Found: C, 77.40; H, 11.60; N, 11.28. $C_{16}H_{28}N_2$ requires: C, 77.36; H, 11.36; N, 11.28%). ES-MS [*m*/*z*]: 248 $[M]^+$, 205 $[M - C_3H_7]^+$, 166 $[M - C_6H_{10}]^+$. ^{1}H NMR [CD_2Cl_2, 200 MHz]: δ 3.5 (m, 4H, CH_2), 2.05 (s, 6H, CH_3), 1.8 (m, 4H, CH_2), 1.65 (m, 4H, CH_2), 1.4 (m, 8H, CH_2).

2.3. Synthesis of $ZnCl_2$(*p*-OMe-BIAN) · $\frac{1}{2}CH_2Cl_2$ (*2*)

This complex was synthesised in a similar manner to that described in the literature [8a]. A mixture of acenaphthenequinone (2.00 g, 11 mmol), anhydrous $ZnCl_2$ (1.71 g, 12.5 mmol) and 4-methoxyaniline was heated to 170 °C in a closed Young's-tap tube for 4 h. The mixture was then cooled to 20 °C and transferred to a beaker with Et_2O (2 × 50 ml) and glacial acetic acid (2 × 50 ml). Aluminium foil was placed over the beaker and the following day the red precipitate which had formed was collected by filtration and washed with Et_2O (5 × 20 ml). Crystals suitable for X-ray diffraction studies were grown from CH_2Cl_2. Yield: 5.51 g, 95%. (Found: C, 56.49; H, 3.71; N, 5.09. $C_{26}H_{20}Cl_2N_2O_2Zn \cdot \frac{1}{2}CH_2Cl_2$ requires: C, 55.72; H, 3.71; N, 4.90%). This suggests that CH_2Cl_2 may be slowly evaporating from the crystal lattice.) ES-MS [CH_2Cl_2, *m*/*z*]: 528 $[M]^+$, 391 $[M - H - ZnCl_2]^+$. ^{1}H NMR [DMSO; 200 MHz]: δ 8.12 (d, 2H, J = 8.3, $C_{10}H_6$), 7.57 (dd, 2H, J = 8.3, 7.2, $C_{10}H_6$), 7.09 (s, 8H, C_6H_4), 6.96 (d, 2H, J = 7.2, $C_{10}H_6$), 3.85 (s, 6H, OMe).

2.4. Synthesis of *p*-OMe-BIAN (*3*)

Compound **3** was prepared in a similar manner to that described in the literature [8a]. Thus, $ZnCl_2$ (*p*-OMe-BIAN) · $\frac{1}{2}CH_2Cl_2$ (**2**) (3.00 g, 5.25 mmol) was added to a solution of K_2CO_3 (25.00 g, 180 mmol) in water (250 ml) and the mixture was heated at reflux with vigorous stirring. After 17 h, the solid was collected by filtration and washed with water (5 × 30 ml) and then was extracted by soxhlet with ethanol for two days. On cooling, red crystals suitable for X-ray diffraction studies grew from solution. The reaction was filtered and the mother liquor concentrated to half volume to promote the formation of a second crop of crystals. Yield: 1.80 g, 81%. (Found: C, 79.32; H, 5.03; N, 7.17. $C_{26}H_{20}N_2O_2$ requires: C, 79.57; H, 5.14; N, 7.14%), EI-MS [CH_2Cl_2, *m*/*z*]: 391 $[M - 1]^+$, 377 $[M - CH_3]^+$, 361 $[M - OCH_3]^+$. ^{1}H NMR [DMSO; 200 MHz]: δ 8.07 (d, 2H, J = 7.8, $C_{10}H_6$), 7.53 (dd, 2H, J = 7.8, 7.0, $C_{10}H_6$), 7.07 (apparent d, 8H, J = 3.1, C_6H_4), 6.92 (d, 2H, J = 7.0, $C_{10}H_6$), 3.83 (s, 6H, OMe).

2.5. Synthesis of (2,6-^{i}Pr-BIAN) (*4*)

This compound was prepared via a similar method to that of Fukuda and co-workers [8b]. Acenaphthenequinone (1.35 g, 7.4 mmol) was dissolved in acetonitrile (65 ml) and glacial acetic acid (12 ml) and heated

to reflux. 2,6-Diisopropylaniline (3 ml, 16 mmol) was added dropwise and the mixture refluxed for 1.5 h. After cooling to room temperature the yellow solid was filtered, washed with hexane and re-crystallised with hexane/CH_2Cl_2 to yield crystals suitable for X-ray diffraction. Yield: 3.15 g, 85%. (Found: C, 86.20; H, 7.98; N, 5.65 $C_{36}H_{40}N_2$ requires: C, 86.35; H, 8.05; N, 5.59%). EI-MS [CH_2Cl_2, *m/z*]: 500 $[M]^+$, 457 $[M - C_3H_7]^+$, 340 $[M - C_6H_3(C_3H_7)_2 + 1]^+$. ^1H NMR [CD_2Cl_2; 400 MHz]:δ 7.91 (d, 2H, $J = 8.3$, $C_{10}H_6$), 7.58 (dd, 2H, $J = 8.3$, 7.1, $C_{10}H_6$), 7.3 (m, 6H, C_6H_3), 6.69 (d, 2H, $J = 7.1$, $C_{10}H_6$), 2.98 (sept, 2H, $J = 6.8$, $CHCH_3$), 1.30 (d, 6H, $J = 6.8$, CH_3), 1.0 (d, 6H, $J = 6.8$, CH_3).

2.6. Synthesis of $ZnCl_2$(2,6-^{i}Pr-BIAN) (5)

This zinc complex was prepared using a different method to that published by Asselt et al. [8a]. Thus, 2,6-^{i}Pr-BIAN (**4**) (2 g, 3.99 mmol) was added in one portion to a stirring solution of anhydrous $ZnCl_2$ (0.544 g, 3.99 mmol) in glacial acetic acid (50 ml). The yellow-orange solid which formed was collected by filtration, washed with Et_2O (3×30 ml) and dried in air. The product was recrystallised by layering Et_2O over CH_2Cl_2. Yield: 2.34 g, 92%. (Found: C, 67.77; H, 6.33; N, 4.42. $C_{36}H_{40}Cl_2N_2Zn$ requires: C, 67.88; H, 6.33; N, 4.40%). EI-MS [CH_2Cl_2, *m/z*]: 600 $[M - Cl + 1]^+$ 500 $[M - ZnCl_2]^+$, 457 $[M - ZnCl_2 - C_3H_7]^+$, 340 $[M - ZnCl_2 - C_6H_3(C_3H_7)_2 + 1]^+$. ^1H NMR [CD_2Cl_2; 200 MHz]: δ 8.17 (d, 2H, $J = 7.9$, $C_{10}H_6$), 7.58 (dd, 2H, $J = 7.9$, 7.4, $C_{10}H_6$), 7.46 (m, 6H, C_6H_3), 6.75 (d, 2H, $J = 7.4$, $C_{10}H_6$), 3.26 (sept, 2H, $J = 6.8$, $CHCH_3$), 1.36 (d, 6H, $J = 6.8$, CH_3), 0.87 (d, 6H, $J = 6.8$, CH_3).

2.7. Synthesis of $PdCl_2$(*p*-OMe-BIAN)·$\frac{1}{2}C_6H_5CN$ (6)

Cyclooctene (0.341 ml, 2.61 mmol) was added in one portion to a stirring solution of $PdCl_2(NCPh)_2$ (0.5 g, 1.324 mmol) in benzonitrile (10 ml). A solution of *p*-OMe-BIAN (**3**) (1.023 g, 2.608 mmol) in benzonitrile (10 ml) was then added and the reaction was stirred for 2 h. The solid formed was collected by filtration, washed with Et_2O and recrystallised from refluxing CH_2Cl_2/benzonitrile. Yield: 0.511 g, 67%. (Found: C, 56.65; H, 3.64; N, 5.64. $C_{26}H_{20}Cl_2N_2O_2Pd \cdot \frac{1}{2}C_6H_5CN$ requires: C, 57.02; H, 3.65; N, 5.64%). EI-MS [CH_2Cl_2, *m/z*]: 570 $[M]^+$, 391 $[M - PdCl_2 - 1]^+$, 377 $[M - PdCl_2 - CH_3]^+$, 361 $[M - PdCl_2 - OCH_3]^+$. ^1H NMR [DMSO; 300 MHz]: δ 8.27 (d, 2H, $J = 8.4$, $C_{10}H_6$), 7.63 (dd, 2H, $J = 8.4$, 7.3, $C_{10}H_6$), 7.34 (d, 4H, $J = 8.7$, C_6H_4), 7.13 (d, 4H, $J = 8.7$, C_6H_4), 6.73 (d, 2H, $J = 7.3$, $C_{10}H_6$), 3.86 (s, 6H, OMe).

2.8. Synthesis of $PdCl_2$(2,6-^{i}Pr-BIAN) (7)

This complex was prepared and crystallised as for **6** with the following quantities of materials: cyclooctene (0.166 ml, 1.27 mmol), $PdCl_2(NCPh)_2$ (0.244 g, 0.637 mmol) in benzonitrile (10 ml) and 2,6-^{i}Pr-BIAN (0.319 g, 0.637 mmol) in benzonitrile (10 ml). Yield: 0.314 g, 72%. (Found: C, 63.62; H, 5.95; N, 4.13. $C_{36}H_{40}Cl_2N_2Pd$ requires: C, 63.77; H, 5.95; N, 4.13%.) EI-MS [CH_2Cl_2, *m/z*]: 500 $[M - PdCl_2]^+$, 457 $[M - PdCl_2 - C_3H_7]^+$, 340.1 $[M - PdCl_2 - C_6H_3(C_3H_7)_2 + 1]^+$. ^1H NMR [CD_2Cl_2; 200 MHz]: δ 8.18 (d, 2H, $J = 8.4$, $C_{10}H_6$), 7.69 (m, 6H, C_6H_3), 7.41 (dd, 2H, $J = 8.4$, 7.2, $C_{10}H_6$), 6.55 (d, 2H, $J = 7.2$, $C_{10}H_6$), 3.50 (sept, 2H, $J = 6.8$, $CHCH_3$), 1.52 (d, 6H, $J = 6.8$, CH_3), 1.00 (d, 6H, $J = 6.8$, CH_3).

2.9. X-ray crystallography

X-ray diffraction experiments were performed on Bruker 3-circle diffractometers with SMART 6000 CCD area detectors, using graphite-monochromated Mo Kα radiation ($\bar{\lambda} = 0.71073$ Å). The low temperature of the crystals was maintained with Cryostream (Oxford Cryosystems) open-flow N_2 cryostats. The structures were solved by direct methods and refined by full-matrix least squares against F^2 of all reflections, using SHELXTL software [10]. All non-H atoms were refined with anisotropic ADP and all H atoms were located by difference Fourier synthesis and refined isotropically. The absolute structure of **5** has been determined from the anomalous dispersion of sulfur, the Flack parameter converging at 0.26(16) [11]. Crystal data and experimental details are given in Table 1.

3. Results and discussion

3.1. Crystal structures

Molecule **1** (shown in Fig. 1) lies at a crystallographic inversion centre, the C(1)–N=C(7)–C(7′)=N′–C(1′) moiety is planar, and *transoid* with respect to the central C(7)–C(7′) bond; the C(1)–N–C(7)–C(7′) torsion angle is −179.95(7)°. This *E*, s-*trans*-*E* conformation has been observed in CyN=CHCH=NCy [12] and is typical for previously reported 2,3-dimethyl-azabutadienes [13], while their analogues with larger substituents in the 2,3-positions usually adopt *gauche* conformations. The cyclohexyl ring adopts a chair conformation. The bond distances are usual, and indicative of localised C=N double bonds.

In the structure of $\mathbf{2} \cdot \frac{1}{2}CH_2Cl_2$, molecule **2** (Fig. 2) has no crystallographic symmetry, while the CH_2Cl_2 is chaotically disordered around an inversion centre. The

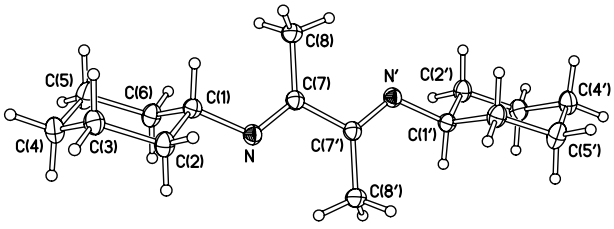

Fig. 1. Molecular structure of **1**. Atoms generated by the inversion centre are primed.

Zn atom has a distorted tetrahedral coordination with two Cl ligands and a nearly-planar chelating diazabutadiene moiety N(1)C(11)–C(12)N(2). In similar complexes with phenyl (and especially substituted phenyl) groups at the N atoms, the phenyl rings usually adopt a perpendicular orientation with respect to the diazabutadiene plane (plane *A*).

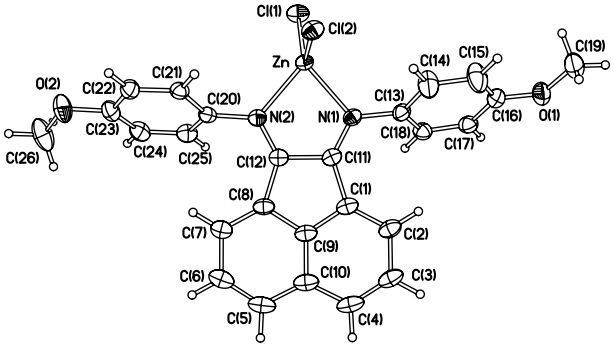

Fig. 2. Molecular structure of **2** in the crystal of **2** · $\frac{1}{2}CH_2Cl_2$.

In **2**, the phenyl rings form angles of 54.1° and 57.7° with the *A* plane and 13.1° between themselves. Thus, the molecule has an approximate mirror plane perpendicular to the acenaphthene plane (violated, however, by opposite orientations of the methyl groups) but loses the mirror plane coinciding with the acenaphthene plane. The two Cl ligands are sterically non-equivalent: Cl(2) faces more overcrowding than Cl(1), with the following results: (i) the Zn–Cl(2) bond is 0.017 Å longer than Zn–Cl(1); (ii) the Zn atom tilts out of the *A* plane by 0.12 Å in the direction of Cl(1); (iii) the N–Zn–Cl(1) angles are wider than N–Zn–Cl(2), averaging 116.5° and 110.2°, respectively; (iv) the naphthalene moiety is tilted out of the *A* plane by 5.1° towards Cl(2), i.e., in the direction of less hindrance on *its* side. Distortions (ii), (iii) and (iv) together make the angle between the acenaphthene plane and the Zn–Cl(2) bond 70.9° compared to 44.5° for Zn–Cl(1).

Molecule **3** lies on a crystallographic twofold axis, passing through atoms C(5), C(6) and the midpoint of the C(7)–C(7′) bond (Fig. 3(a)). The diazabutadiene moiety is planar, and the phenyl rings are inclined to its plane (*A*) by 57.6°; hence, the molecule has no local mirror symmetry but adopts a twisted overall conformation. The *A* and naphthalene planes form an angle $\varphi = 6.0°$, while the N–C(8) bond is tilted out of plane *A* in the opposite direction, with the torsion angles C(7′)–C(7)–N–C(8) 11.0° and C(2)–C(1)···N–C(8) 15.5°.

Molecule **4** also has crystallographic C_2 symmetry (Fig. 3(b)). Bulky ^{i}Pr groups enforce a more perpendicular orientation of the phenyl rings, which are inclined

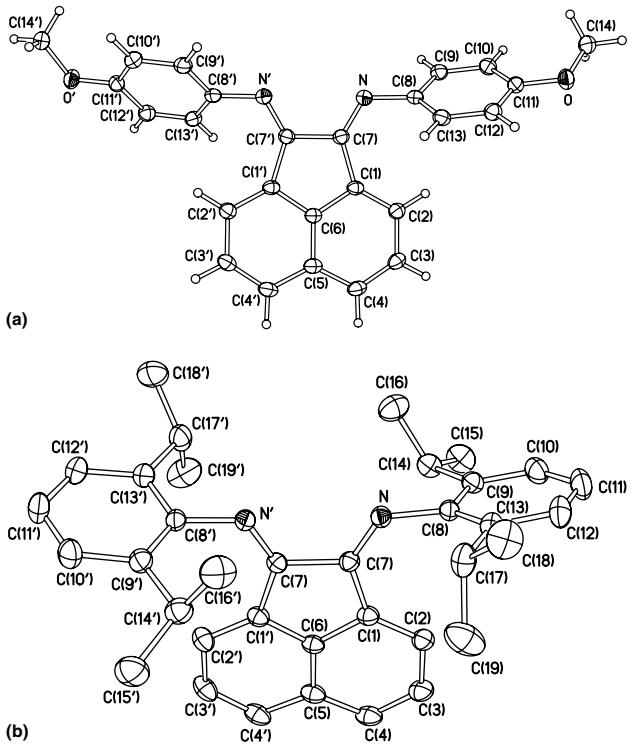

Fig. 3. Molecular structures of **3** (a) and **4** (b). Atoms generated by the twofold axis in each structure are primed.

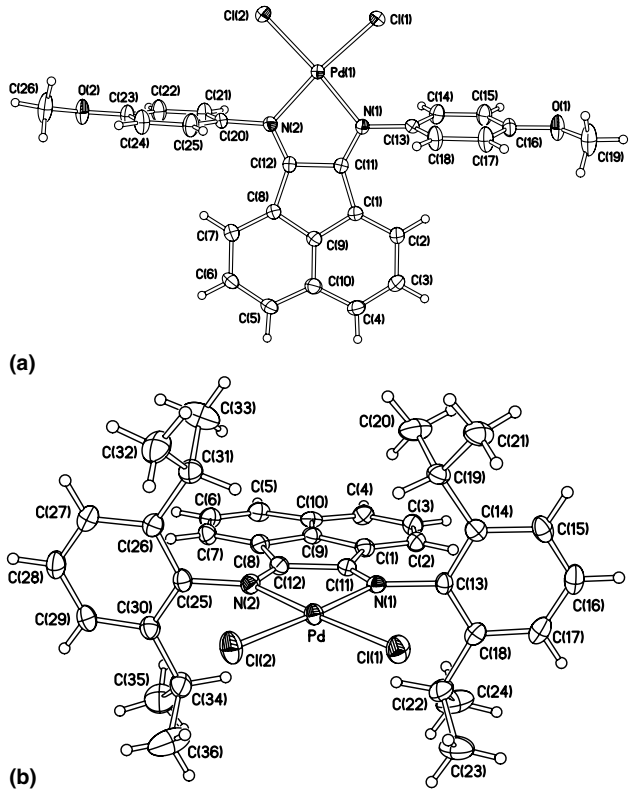

Fig. 4. Molecular structures of **6** (a) (one of the four independent molecules in the crystal of $\mathbf{6}\cdot\frac{1}{2}$PhCN) and **7** (b).

by 78.7° to the *A* plane, and the twist of the molecule is correspondingly smaller than in **3**, with the angles $\varphi = 2.8°$, C(7′)–C(7)–N–C(8) 3.5° and C(2)–C(1)···N–C(8) 5.1°.

While this work was in progress, the crystal structure of **4** was determined [9a,9b] at room temperature in space group *Cc* (No. 9), with the molecule in a general position. The lattice parameters reported, $a = 15.587(2)$ Å, $b = 8.856(2)$ Å, $c = 21.780(7)$ Å, $\beta = 93.85(2)°$, $V = 2999.7$ Å^3, were identical with our results (allowing for thermal expansion). A search for additional symmetry, performed on the atomic coordinates (ref. code WUSLIF) deposited at the CSD, using PLATON software [14], revealed the missing inversion centre with the coordinates (−0.030, 0, −0.212). Thus, the structure [9a,9b] is identical with the one reported herein, in the correct space group *C*2/*c* (No. 15) as already pointed out by Marsh [9c].

The asymmetric unit of $\mathbf{6}\cdot\frac{1}{2}$PhCN comprises four molecules of the complex and two of benzonitrile, all of them devoid of crystallographic symmetry (Fig. 4(a)). Acenaphthene systems of all molecules **6** in the structure are approximately parallel to the (1 0 −1) plane, and the four independent Pd atoms (although not the rest of the molecules) are related by peculiar pseudo-symmetrical operations, viz: (i) *x*, *y*, *z*; (ii) *x*, *y* + 1/2, *z*; (iii) 1/2 − *x*, *y* − 1/4, 1 − *z*; (iv) 1/2 − *x*, *y* − 1/4, 1 − *z*. The geometry and conformation of independent molecules is similar, with square-planar coordination of the Pd atom. Phenyl rings are approximately normal to the diazabutadiene moiety (interplanar angles 74.8°–89.9°). The acenaphthene moiety in molecule (ii) is practically planar and in three others show minor twist, of the same order as in molecule **4**.

The crystal structure of **7** (Fig. 4(b)) is isomorphous with that of chloro-bis{2,8-(2,6-di-isopropylphenylimino)-acenaphthene-N,N)-methylpalladium [5], which differs from **7** by a substitution of a methyl group for one of the chloro-ligands. The asymmetric unit comprises one molecule, without crystallographic symmetry. Molecule **7** is similar to **6** in the nearly perpendicular orientation of the phenyl rings (dihedral angles of 83.3° and 82.6° with plane *A*) and other conformational features.

The ionic radius of square-planar Pd^{2+} (0.64 Å) exceeds that of tetrahedral Zn^{2+} (0.60 Å) [20]. In fact, the Pd–Cl bond distances in **6** and **7** exceed Zn–Cl in **2** by an average of 0.065 Å, while the Pd–N bonds are actually *shorter* than Zn–N, by ca. 0.035 Å (Table 2). This is probably due to $d\pi \rightarrow p\pi$ back donation in the Pd complexes. The resulting π delocalisation in the chelate ring is indicated by small but significant lengthening of C═N bonds and shortening of the intermediate C–C bond in the Pd complexes compared to the free molecules, while coordination with Zn affects these distances insignificantly. It is noteworthy that coordination with

Zn reduces the transannular N···N distance by ca. 0.1 Å compared to free molecules, and coordination with Pd reduces it by 0.15 Å.

3.2. ^1H NMR properties

The ^{1}H NMR spectrum of compound **3** shows three signals at δ 8.07, 7.53 and 6.92 corresponding to positions **A**, **B** and **C**, respectively (see Fig. 5) of the acenaphthenequinone backbone, and an apparent doublet (AB spin system) at δ 7.07 for the C_6H_4 aromatic protons. On complexation to Zn, a very small downfield shift is observed for all of these signals and the apparent doublet collapses to a singlet, i.e., the two chemical environments lead to absolutely coincident signals. When Pd occupies the cavity, a more pronounced effect is observed. The signals relating to protons at positions **A** and **B** move downfield while that of **C** moves upfield. The major difference, however, is the splitting of the C_6H_4 AB signal into two doublets.

These effects may well be due to the Pd–N interaction being stronger than the analogous Zn–N interaction. Very little change is observed in the shift of the methoxy signal. An increase in all of the coupling constants is also observed in complexation of **3** to either Zn or Pd.

The proton signals of compound **4** exhibit very similar behaviour to that observed in **3**. While the ^{1}H signals at positions **A** and **C** move upfield and downfield as described for **3**, the signal for the protons at position **B** does not shift on complexing to Zn but moves upfield when **4** is bound to Pd. As in compound **3**, it is the ^{1}H signals for the aryl side arm that show the most significant shifts. The C_6H_3 signal remains a multiplet regardless of complexation; however, it moves downfield on binding to Zn (0.16 ppm) and Pd (0.39 ppm). This is also the case for the CH of the ^{i}Pr groups. There are two signals present for the methyl groups in compound **4** ($\Delta\delta = 0.3$ ppm), indicative of restricted rotation. The magnitude of separation increases on complexation to Zn ($\Delta\delta = 0.49$ ppm) and Pd ($\Delta\delta = 0.52$ ppm).

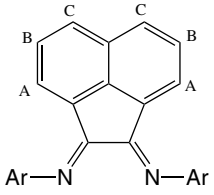

Fig. 5. Assignment of acenaphthenequinone proton positions.

4. Conclusions

Three α-diimines have been synthesised and two of these have been complexed to both $ZnCl_2$ and $PdCl_2$. The ^{1}H NMR spectra have been compared and compounds **1**, **2**, **3**, **4**, **6** and **7** have been structurally characterised by single-crystal X-ray diffraction, revealing the changes resulting from coordination to both tetrahedral Zn(II) and square-planar Pd(II) metal centres.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic data centre, CCDC Nos. 236150–236155. Copies of this data may be obtained free of charge from The Director CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44-1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Pyridinium-derived *N*-heterocyclic carbene ligands: syntheses, structures and reactivity of *N*-(2′-pyridyl)pyridin-2-ylidene complexes of nickel(II), palladium(II) and platinum(II) ☆

Nicholas A. Piro, Jonathan S. Owen, John E. Bercaw *

Arnold and Mabel Beckman Laboratories of Chemical Synthesis, California Institute of Technology, Pasadena, CA 91125, USA

Received 30 April 2004; accepted 14 June 2004
Available online 3 September 2004

Abstract

Pyridinium-derived *N*-heterocyclic carbene complexes $[(i\text{-BIPY})M(acac)]^+[OTf]^-$ (M = Ni (**2a**), Pd (**3a**), Pt (**4a**)) (*i*-BIPY = *N*-(2′-pyridyl)-4-*tert*-butylpyridin-2′-ylidene) are obtained as insoluble microcrystalline powders by cyclometallation of the ligand precursor $[i\text{-BIPY-H}]^+[OTf]^-$ (OTf = trifluormethylsulfonate) to $M(acac)_2$ (acac = acetylacetonate) in chlorobenzene at 160 °C. Consumption of the starting materials in the synthesis of **3a** and **4a** is complete after 18 h, providing (**4a**) and (**5a**) in good yields as analytically pure material after recrystallization. The reaction with $Ni(acac)_2$ is reversible and reaches equilibrium at approximately 75% completion. Removal by distillation of the acetylacetone produced in the cyclometallation drives the reaction to completion furnishing a good yield of pure **6a**. Salt metathesis with sodium tetraphenylborate in methanol yields the tetraphenylborate salts (**2b**–**4b**) that were used to grow X-ray quality crystals. Analysis of the M–O bond lengths confirms the larger *trans*-influence of the carbene donor compared with the pyridine donor. Ratios of the M–O(1)/M–O(2) bond lengths suggest that the carbene–metal bond strength follows the order **4b** ≈ **3b** > **2b**. Protonation of **2a**–**4a** with three equivalents of pyridinium hydrochloride produces $(i\text{-BIPY})MCl_2$ in the case of palladium (**5**) and platinum (**6**), while in the case of nickel it regenerates the starting $[i\text{-BIPY-H}]^+$ and paramagnetic nickel products.

1. Introduction

Imidazolium-derived *N*-heterocyclic carbenes are useful as ligands for many applications, including ruthenium-mediated olefin metathesis [1] and nickel- and palladium-catalyzed arylhalide cross-couplings [2]. We became interested in developing new carbene ligands based on other *N*-heterocycles, particularly in regard to their relative σ-donating and π-accepting characteristics. We recently reported the preparation of pyridinium-derived *N*-heterocyclic carbene complexes of platinum, e.g., $[(i\text{-BIPY})Pt(CH_3)(DMSO)]^+[B(C_6H_5)_4]^-$ ((*i*-BIPY) = *N*-(2′-pyridyl)pyridin-2-ylidene), using a synthetic strategy that involves loss of methane from dimethylplatinum starting materials [3]. In order to extend the scope of these *N*-heterocyclic carbene complexes to more readily available and easily handled starting materials, we have investigated the cyclometallation of *N*-(2′-pyridyl)-4-*tert*-butylpyridinium triflate with $M(II)(acac)_2$ (acac = acetylacetonate) starting materials. We chose to use the 4-*tert*-butyl substituted ligand precursor (**1**) due to its ease of synthesis, useful ^1H NMR features, and the higher solubilities and stabilities of its complexes. Here we present a scheme for the cyclometallation of this new ligand onto nickel(II), palladium(II) and platinum(II), along with their character-

2. Experimental

2.1. General

Nickel(II) acetylacetonate hydrate was purchased from Strem and water was removed by heating under vacuum in the presence of P_2O_5 for 3 days. Palladium(II) acetylacetonate and platinum(II) acetylacetonate were purchased from Aldrich and used as received. Chlorobenzene was purchased from Aldrich, dried over calcium hydride, vacuum distilled and stored under argon. *N*-(2′-pyridyl)-4-*tert*-butylpyridinium triflate (**1**) was prepared as previously reported [3]. Reactions were run under argon using standard Schlenk techniques with degassed solvents, while all isolations were performed in air.

2.2. Syntheses

2.2.1. Synthesis of nickel(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)(acetylacetonate) triflate (**2a**)

N-(2′-pyridyl)-4-*tert*-butylpyridinium triflate (725 mg, 2.0 mmol), nickel(II) acetylacetonate (1.027 g, 4.0 mmol) and chlorobenzene (7 mL) were combined in a Schlenk tube, degassed and heated under vacuum to 160 °C for 3 h. Volatiles were removed *in vacuo*, chlorobenzene was added to the solids, and heating continued for another 3 h. Volatiles were again removed, followed by readdition of solvent and heating for 18 h. The reaction mixture was cooled, methylene chloride (10 mL) was added and the mixture was filtered. The solvent was removed in vacuo to give the crude product as a yellow solid. This crude product was recrystallized from hot chlorobenzene to give the desired product (710 mg, 69% yield). ^{1}H NMR (300 MHz, DMSO-d_6): δ 9.34 (d, $J = 6.9$ Hz, 1H), 8.56 (d, $J = 5.5$ Hz, 1H), 8.47 (m, 2H), 7.88 (d, $J = 6.9$ Hz, 1H), 7.83 (s, 1H), 7.75 (m, 1H), 5.80 (s, 1H), 2.10 (s, 6H), 1.35 (s, 9H) ppm. *Anal*. Calc. for $C_{20}H_{23}F_3N_2O_5NiS$: C, 46.33; H, 4.47; N, 5.41. Found: C, 46.37; H, 4.41; N, 5.36%.

2.2.2. Synthesis of nickel(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)(acetylacetonate)tetraphenylborate (**2b**)

2a (520 mg, 1.0 mmol) was dissolved in methanol (50 mL) and a methanol solution (15 mL) of sodium tetraphenylborate (380 mg, 1.1 mmol) was added dropwise to immediately form an orange precipitate. The solution was cooled to −30 °C for 3 h, and the orange precipitate was collected by filtration and dried to give the desired product (655 mg, 95% yield). ^{1}H NMR (500 MHz, CD_2Cl_2): δ 8.54 (dd, $J = 1.6$, 5.9 Hz, 1H), 7.93 (d, $J = 2.1$ Hz, 1H), 7.74 (td, $J = 1.5$, 7.9 Hz, 1H), 7.47 (m, 8H), 7.32 (td, $J = 1.0$, 6.5 Hz, 1H), 7.01 (overlapping, 9H), 6.86 (t, $J = 7.4$ Hz, 4H), 6.28 (d, $J = 8.5$ Hz, 1H), 5.72 (s, 1H), 2.16 (s, 6H), 1.40 (s, 9H) ppm. ^{13}C{^{1}H} NMR(125 MHz, CD_2Cl_2): δ 189.10, 188.90, 175.89, 166.33, 164.66 (q, $J_{B-C} = 49$ Hz), 155.10, 148.13, 143.65, 136.31, 135.76, 129.81, 126.40, 125.34, 122.49, 121.52, 114.06, 102.62, 36.81, 30.11, 26.94, 26.90 ppm. *Anal*. Calc. for $C_{43}H_{43}BN_2NiO_2$: C, 74.92; H, 6.29; N, 4.06. Found: C, 74.61; H, 6.18; N, 3.99%.

2.2.3. Synthesis of palladium(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)(acetylacetonate) triflate (**3a**)

N-(2′-pyridyl)-4-*tert*-butylpyridinium triflate (714 mg, 1.97 mmol), palladium(II) acetylacetonate (600 mg, 1.97 mmol) and chlorobenzene (5 mL) were combined in a Schlenk tube, degassed, and heated under vacuum to 160 °C for 18 h. Filtration through a glass frit and washing with methylene chloride and warm acetonitrile removed palladium metal. The filtrate was dried by removal of solvent in vacuo. The crude product was recrystallized from hot acetonitrile. The desired product was collected as fine, pale yellow needles (825 mg, 74% yield). ^{1}H NMR (300 MHz, DMSO-d_6): δ 9.50 (d, $J = 6.6$ Hz, 1H), 8.74 (dd, $J = 5.5$, 1.6 Hz, 1H) 8.69 (d, $J = 8.8$ Hz, 1H), 8.58 (t, $J = 8.0$ Hz, 1H), 8.03 (overlapping, 2H), 7.93 (t, $J = 6.6$ Hz, 1H), 5.71 (s, 1H), 2.17 (s, 3H), 2.15 (s, 3H), 1.41 (s, 9H) ppm. *Anal*. Calc. for $C_{20}H_{23}F_3N_2O_5PdS$: C, 42.37; H, 4.09; N, 4.94. Found: C, 42.89; H, 4.08; N, 5.62%.

2.2.4. Synthesis of palladium(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)(acetylacetonate) tetraphenylborate (**3b**)

3a (240 mg, 0.35 mmol) was dissolved in methanol (120 mL) and sodium tetraphenylborate (135 mg, 0.40 mmol) was added dropwise as a methanol solution (10 mL). Crystals began to form, and the solution was cooled to −30 °C. The yellow crystalline product was collected after 18 h (240 mg, 93% yield). ^{1}H NMR (300 MHz, CD_2Cl_2): δ 8.75 (dd, $J = 1.6$, 5.5 Hz, 1H), 8.12 (d, $J = 1.6$ Hz, 1H), 7.85 (dt, $J = 1.6$, 8.2 Hz, 1H), 7.47 (dm, 9H), 7.06 (m, 2H), 9.69 (t, $J = 7.4$ Hz, 8H), 6.80 (t, $J = 7.2$ Hz, 4H), 6.34 (d, $J = 8.2$ Hz, 1H), 5.62 (s, 1H), 2.21 (s, 3H), 2.18 (s, 3H), 1.41 (s, 9H) ppm. ^{13}C{^{1}H} NMR(125 MHz, CD_2Cl_2): δ 190.04, 187.92, 174.74, 168.93, 164.72 (q, $J_{B-C} = 49$ Hz) 156.34, 147.93, 143.82, 136.73, 136.30, 128.17, 126.48, 126.28, 122.54, 121.48, 115.41, 102.28, 37.10, 30.10, 27.76,

27.40 ppm. *Anal*. Calc. for $C_{43}H_{43}BN_2O_2Pd$: C, 70.07; H, 5.88; N, 3.80. Found: C, 69.59; H, 5.83; N, 3.87%.

*2.2.5. Synthesis of platinum(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2- ylidene)(acetylacetonate)(triflate) (**4a**)*

N-(2′-pyridyl)-4-*tert*-butylpyridinium triflate (362 mg, 1.0 mmol), platinum(II) acetylacetonate (393 mg, 1.0 mmol) and chlorobenzene (7 mL) were combined in a Schlenk tube, degassed and heated under vacuum to 160 °C for 18 h. The crude reaction mixture was dissolved in methylene chloride and filtered. Solvent was removed in vacuo, the solid was dissolved in hot acetonitrile and the resulting solution was filtered. The product was recrystallized from hot acetonitrile, and a yellow solid was collected by filtration (152 mg, 77% yield). ^{1}H NMR (300 MHz, DMSO-d_6): δ 9.44 (d, J = 7.1 Hz, 1H), 9.04 (d, J = 5.4 Hz, 1H), 8.67 (d, J = 8.2 Hz, 1H), 8.59 (td, J = 1.2, 7.6 Hz, 1H), 8.03 (d, J = 2.0 Hz, 1H), 7.97 (dd, J = 2.0, 7.2 Hz, 1H), 7.91 (t, J = 7.2 Hz, 1H), 5.87 (s, 1H), 2.17 (s, 3H), 2.15 (s, 3H), 1.41 (s, 9H) ppm. *Anal*. Calc. for $C_{20}H_{23}F_3N_2O_5PtS$: C, 36.64; H, 3.54; N, 4.27. Found: C, 36.76; H, 3.59; N, 4.40%.

*2.2.6. Synthesis of platinum(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)(acetylacetonate) tetraphenylborate (**4b**)*

4a (300 mg, 0.46 mmol) was dissolved in methanol (180 mL) and a solution of sodium tetraphenylborate (170 mg, 0.50 mmol) in methanol (10 mL) was added dropwise. This mixture was stored at −30 °C after crystals began to form. The orange crystalline product was collected by filtration and dried (360 mg, 95% yield). ^{1}H NMR (500 MHz, CD_2Cl_2): δ 8.98 (dd, J = 1.5, 5.9 Hz, 1H), 8.08 (d, J = 2.1 Hz, 1H), 7.80 (td, J = 1.6, 8.3 Hz, 1H), 7.46 (bm, 8H), 7.41 (td, J = 1.0, 6.4 Hz, 1H), 7.12 (d, J = 7.3 Hz, 1H), 7.05 (dd, J = 2.4, 7.3 Hz, 1H), 6.97 (t, J = 7.5 Hz, 8H), 6.80 (t, J = 7.6 Hz, 4H), 6.30 (d, J = 8.6 Hz, 1H), 5.71 (s, 1H), 2.17 (s, 3H), 2.17 (s, 3H), 1.42 (s, 9H) ppm. ^{13}C{^{1}H} NMR(125 MHz, CD_2Cl_2): δ 188.49, 186.34, 168.92, 164.7 (q, $J_{B–C}$ = 49 Hz), 161.14, 157.54, 147.14, 143.24, 136.50, 136.34, 127.01, 126.44, 125.65, 122.52, 119.88, 115.51, 103.86, 36.86, 30.07, 27.94, 27.16 ppm. *Anal*. Calc. for $C_{43}H_{43}BN_2O_2Pt$: C, 62.55; H, 5.25; N, 3.39. Found: C, 62.23; H, 5.17; N, 3.34%.

*2.2.7. Synthesis of palladium(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)dichloride (**5**)*

3a (164 mg, 0.29 mmol) and pyridinium chloride (100 mg, 0.87 mmol) were added to a Teflon stoppered Schlenk tube with acetonitrile (10 mL) and heated to 100 °C for 1 h. After cooling the reaction mixture, the yellow precipitate was collected on a glass frit and washed with acetonitrile followed by ether. The yellow powder was dried under vacuum (90 mg, 80% yield). ^{1}H NMR (500 MHz, DMSO-d_6, 85 °C): δ 9.50 (s, 1H), 9.32 (d, J = 6.8 Hz, 1H), 8.79 (s, 1H), 8.52 (d, J = 8.3 Hz, 1H), 8.46 (t, J = 8.1 Hz, 1H), 7.85 (t, J = 6.4 Hz, 1H), 7.80 (dd, J = 7.1, 2.2 Hz, 1H), 1.40 (s, 9H) ppm. ^{13}C{^{1}H} NMR (125 MHz, DMSO-d_6, 85 °C): δ 172.2, 166.5, 156.3, 149.5, 142.0, 137.2, 130.9, 125.5, 119.3, 114.4, 35.9, 28.9 ppm. *Anal*. Calc. for $C_{19}H_{23}N_2O_2PdCl_2$: C, 43.16; H, 4.14; N, 7.19. Found: C, 43.37; H, 4.13; N, 7.18%.

*2.2.8. Synthesis of platinum(II)(N-(2′-pyridyl)-4-(tert-butyl)pyridin-2-ylidene)dichloride (**6**)*

4a (321 mg, 0.50 mmol) and pyridinium chloride (165 mg, 1.43 mmol) were added to a Teflon stoppered Schlenk tube with acetonitrile (10 mL) and heated to 100 °C for 45 min. After cooling the reaction mixture, the yellow precipitate was collected on a glass frit and washed with acetonitrile followed by ether. The bright yellow powder was dried under vacuum to give an orange powder (185 mg, 79% yield). ^{1}H NMR (500 MHz, DMSO-d_6): δ 9.78 (d, J = 5.9 Hz, $J_{Pt–H}$ = 36 Hz, 1H), 9.30 (d, J = 7.3 Hz, 1H), 8.62 (d, J = 2.0 Hz, $J_{Pt–H}$ = 27 Hz, 1H), 8.53 (m, 2H), 7.85 (t, J = 5.9 Hz, 1H), 7.81 (dd, J = 2.1, 6.3 Hz, 1H), 1.37 (s, 9H) ppm. ^{13}C{^{1}H} NMR(125 MHz, DMSO-d_6): δ 167.1, 160.0, 157.5, 148.5, 141.8, 137.3, 128.0, 126.0, 118.1, 115.2, 36.2, 29.3 ppm. *Anal*. Calc. for $C_{19}H_{23}N_2O_2PtCl_2$: C, 35.16; N, 5.86; H, 3.37; Cl, 14.83. Found: C, 34.92; N, 5.89; H, 3.37; Cl, 14.83%.

2.3. X-ray structures

Crystals of **2b** were grown from THF/diethyl ether. Crystals of **3b** and **4b** were grown from dichloromethane/THF/diethyl ether and dichloromethane/THF, respectively. Data for **2b**–**4b** were collected at 100K on a Bruker SMART 1000 using Mo Kα radiation. The structure was solved using SHELXS-97 by direct methods. The hydrogens in **2b** were placed by the difference Fourier map; those of **3b** and **4b** were placed geometrically. The crystals of **3b** appear to contain both water and THF. The water sits near a 4bar symmetry element and was modelled at half occupancy without the hydrogens. The THF molecule sits near a 4-fold axis and was modelled at half occupancy as a flat ring with riding hydrogens. The crystals of **4b** contained sites partially occupied with dichloromethane or THF, both of which were refined anisotropically. Full matrix least squares refinement on F^2 was carried out using SHELXL-97. Refinement of F^2 against ALL reflections. The weighted R-factor (wR) and goodness-of-fit (S) are based on F^2, conventional R-factors (R) are based on F, with F set to zero for negative F^2. The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R-factors (gt), etc., and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about

twice as large as those based on *F*, and *R*-factors based on ALL data will be even larger.

All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes. The details of the crystal, data collection and structure refinement are provided in Table 1.

3. Results and discussion

3.1. Synthesis of metal complexes

Ligand cyclometallation is a well precedented reaction and is a reliable way to make M–C bonds. Palladium(II) acetylacetonate and palladium(II) acetate have been used in the cyclometallation of 2-phenylpyridine and its derivatives to produce stable five-membered metallacycles [4]. Initial attempts to cyclometallate **1** with a variety palladium starting materials were plagued by palladium metal deposition, and as a result we tested the more thermally robust palladium(II) acetylacetonate. [1] Heating this commercially available starting material with **1** in chlorobenzene gave rise to the desired palladium(II) *N*-heterocyclic carbene complex **2a**. (Scheme 1). Similarly, reactions of nickel(II) and platinum(II) acetylacetonates afforded the analogous nickel **(3a)** and platinum **(4a)** complexes.

To obtain crystallographic support for the structure of **2–4** the triflate anion was exchanged for tetraphenylborate to improve the solubility and crystallinity. Precipitation of **2b–4b** from methanol by dropwise addition of sodium tetraphenylborate solutions to methanol solutions of **2a–4a** provided complexes suitable for the growth of X-ray quality crystals. Interestingly, in the ^{1}H NMR spectra of **2b–4b** the aromatic resonances showed an average upfield shift of ~1 ppm relative to the triflate salt **2a–4a** suggesting that the triflate ion is closely associated with the cationic coordination complex in DMSO solution.

3.2. Crystal structures

The X-ray diffraction data were able to confirm the identity and predicted geometries of **2b–4b**. ORTEP drawings for the cations of all three structures are shown in Fig. 2, and selected bond lengths and angles are provided in Tables 3–5.

The expected strong *trans*-influence of the carbene donor relative to pyridine is evident from these data, comparing the two *trans* M–O bond lengths. In complex **2b** the bond *trans* to carbene is longer by approximately 0.03 Å while in complexes **3b** and **4b** it is longer by 0.06 Å. The ratio of metal oxygen bond lengths (**4b** ≈ **3b** > **2b**) suggests that the *trans*-influence of the carbene relative to the pyridine increases for Pt ≈ Pd > Ni. These results suggest a stronger bonding interaction in **4b** and **3b** relative to **2b**. Slight shortening of the metal–carbon bond was observed in all cases when compared with M–Ph distances. [2]

3.3. Reactivity

While in the syntheses of the palladium and platinum complexes (Scheme 1), all of the starting pyridinium salt is consumed, reactions with Ni(acac)$_2$ reached equilibrium at ~75% completion upon heating for several days. Distillation of the acetylacetone from the reaction mixture resulted in further consumption of the starting pyridinum salt. In order to probe the equilibrium behavior, acetyl acetone was added to samples of **2b–4b** in

[1] Attempts to prepare complexes from palladium(II)acetate gave little reaction until palladium metal deposition occurred upon heating to higher temperature.

[2] Searching the Cambridge Crystallographic Database for M–Ph complexes showed that the M–C distances in **2b–4b** are in the top 4–6% of metal phenyl distances. The majority of complexes displaying shorter distances contained tridentate chelating ligands where the phenyl ligand is the central donor. Similar M–C distances were reported in [3].

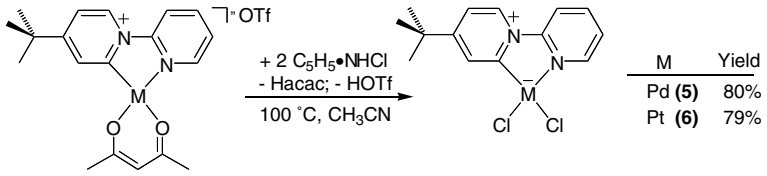
$C_2D_2Cl_4$ (used for solvating ability and temperature range) and heated to 100 °C. All samples showed partial disappearance of the metal complex. Complexes **3b** and **4b** each gave rise to their own set of new unidentifiable resonances and, in the case of palladium, deposition of colloidal metal [5]. In the case of **2b**, however, resonances for the free pyridinium salt **1** and obvious broadening of the sample due to the presence of paramagnetic $Ni(acac)_2$ were observed. Furthermore, by heating to 160 °C in $C_2D_2Cl_4$, either $Ni(acac)_2$ with **1**, or **2a** with two equivalents of acetylacetone, broad NMR spectra with peaks for both **1** and **2a** are observed. The relative intensities of the signals for **1** and **2a** are consistent in both experiments with an equilibrium constant of $K_{eq} \approx 3.5 \pm 1$ for the forward reaction [3] [6].

These observations support an equilibrium between the binding of acetylacetone and $[i\text{-BIPY}]^+$. While we cannot rule out such an equilibrium in the case of Pd and Pt, the isolated yields obtained without the distillation of acetylacetone (**3a** 74% and **4a** 77%) and the complete consumption of **1** suggest the reactions to form the desired *N*-heterocyclic carbene complexes are more favorable for Pd and Pt. We believe this is due to the stronger metal–ligand bonding observed for second and third row transition metals, which better support the large ligand field of the carbene donor, thus favoring ligation of *i*-BIPY over acac.

To further probe the stability of the metal's interaction with the carbene and acac ligands, a series of protonolysis experiments were carried out with **2a**–**4a**. Treatment of **2a**–**4a** with pyridinium hydrochloride in acetonitrile at 100 °C results in clean conversion of **3a** and **4a** to the dichlorides (**5** and **6**) (Scheme 2), which can be isolated as yellow and orange solids in 80% yield. In the case of **2a**, rapid protonolysis and de-coordination of the carbene ligand occurs. These results are consistent with the stronger carbene donor interactions for palladium and platinum, relative to nickel.

Studies of arylhalide cross-coupling have shown that monodentate phosphine and carbene ligands furnish the most active catalysts for aryl-halide cross-coupling reactions [7]. Accordingly, we briefly investigated the use of

[3] It should be noted, however, that the NMR tubes both showed some visible signs of solid side products. Further, integration of the peaks in the $Ni(acac)_2$ + **1** reaction is poor due to the very broad peaks.



Scheme 2.

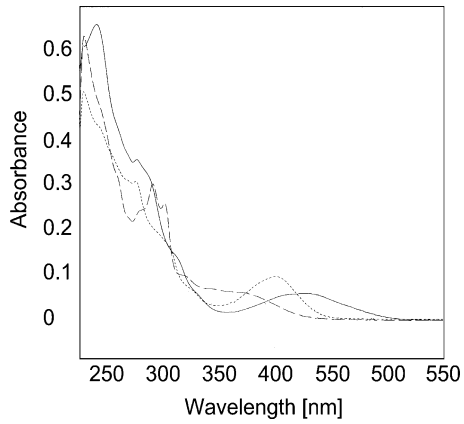


Fig. 1. Electronic absorption spectra for **2b** (–), **3b** (- -) and **4b** (···).

3b in the Heck-coupling of styrene and iodobenzene. The results of these trials indicate that catalysis with **3b** is not significantly faster than with $Pd_2(dba)_3$ [8].

3.4. Electronic absorption spectra

The UV–Vis absorption spectra of **2b**–**4b** in CH_2Cl_2 at concentrations of 10 mg/L were recorded and shown in Fig. 1. These spectra show two principle features: a very intense absorption in the UV ($\sim\lambda < 300$ nm) that is fairly uniform throughout the series, and a weaker absorption in the visible ($350 < \lambda < 450$ nm) that is responsible for the yellow colors of **2b**–**4b**.

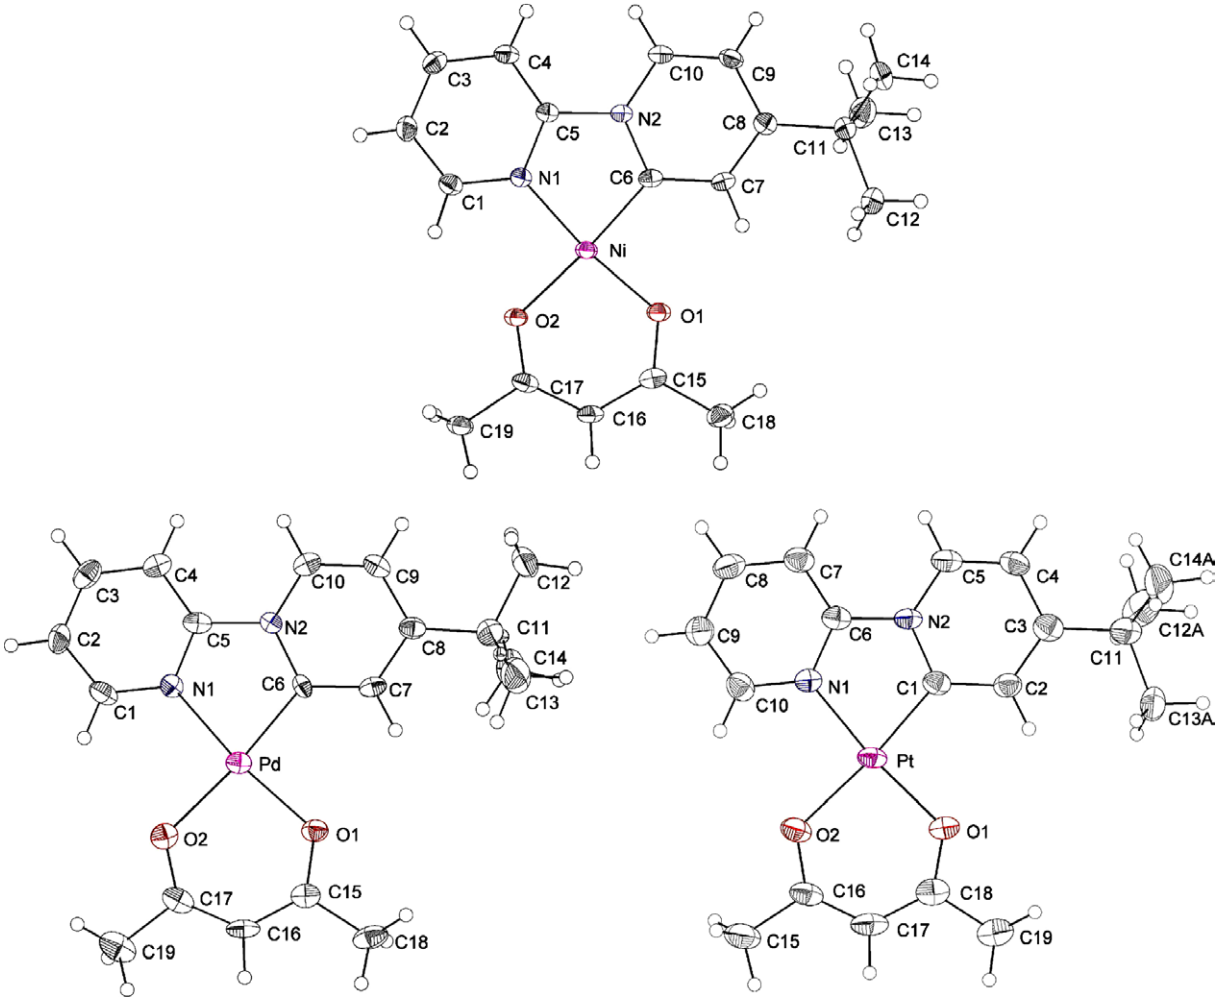

Fig. 2. ORTEP diagrams of **2b**–**4b** with thermal ellipsoids at 50%.

These weaker features have maxima that fall in the order $\nu_{Pd} > \nu_{Pt} > \nu_{Ni}$. This order and the large extinction coefficients of 4100–8300 $(M\ cm)^{-1}$ are consistent with a metal-to-ligand charge transfer (MLCT) assignment (See Table 2). Analogous compounds show similar spectral features where this lower energy transition has been assigned to $d_{z^2} \rightarrow \pi^*$ [9].

4. Conclusions

A series of Group 10 metal complexes with acetylacetonate and (4-*tert*-butyl)-*iso*-bipyridyl ligands can be conveniently obtained by the simple reaction of the pyridyl-pyridinium triflate and the metal(II) acetylacetonates. Structural data provided by X-ray crystal structures of the nickel, palladium and platinum complexes indicate weak π-bonding evidenced by the short metal carbon distances. The ratio of metal oxygen distances (**4b** ≈ **3b** > **2b**) observed in the crystal structures parallels the observed reactivity where the nickel carbene interaction is subject to protonolysis to a greater extent than in the palladium and platinum complexes. These results are consistent with the bond strengths implied from the structural data, though the observed reactivity is not necessarily linked to this ground-state energy difference.

5. Supplementary material

Crystallographic data for **2b** (CCDC 230757), **3b** (CCDC 231159) and **4b** (CCDC 236394) have been deposited with the Cambridge Crystallographic Data Centre. Copies can be obtained free of charge upon request from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk), by quoting the publication citation and the deposition number.

Acknowledgements

We thank Larry Henling and Michael Day for collection of X-ray data and assistance in solving of the crystal structures. We are also grateful to the Summer Undergraduate Research Fellowship Program for support of N.A.P. and the MC^2 Program sponsored by B.P. for financial support of this research.

[5] (a) Control reactions showed that acetylacetone does not react with **1** at 100 °C in $C_2D_2Cl_4$. Electrospray mass-spectra of the palladium reaction mixture shows evidence of *N*-(2′-pyridyl)-2-phenyl-4-*tert*-butyl-pyridinium (*m*/*z* = 289, 274, 259), the product of reductive elimination from a palladium phenyl complex, presumably generated by activation of tetraphenylborate. Furthermore, in attempts to alkylate **2b** with alkyl aluminum reagents, colloidal metal and alkylated pyridinium salts were observed by mass-spectral analysis. These results, while preliminary, may suggest that reductive elimination reactions involving the carbene carbon are a principal decomposition route. Such behavior has been documented for imidazolium-derived carbene complexes of palladium. For more details see: W.J. Marshall, V.V. Grushin, Organometallics 22 (8) (2003) 1591;

Dedicated to Malcolm Green, an inspiring chemist and friend

Abstract

New diiron(II) complexes having ligated water molecules were prepared and characterized by X-ray crystallography, IR spectroscopy and cyclic voltammetry. The compound $[Fe_2(OH_2)_2(\mu\text{-}O_2CAr^{4F\text{-}Ph})_2(O_2CAr^{4F\text{-}Ph})_2(THF)_2]$ (**1**), where $^{-}O_2CAr^{4F\text{-}Ph}$ is 2,6-di-(*p*-fluorophenyl)benzoate, has two distorted trigonal bipyramidal Fe(II) centers linked by two sterically hindered carboxylate ligands. The related molecules, $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ (**2**) and $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^{t}BuC_5H_4N)_2]$ (**3**), where $^{-}O_2CAr^{Tol}$ is 2,6-di-(*p*-tolyl)benzoate and 4-^{t}BuC$_5$H$_4$N is 4-*tert*-butylpyridine, contain a tetra-bridged diiron(II) core with a central $Fe_2(OH_2)_2$ planar quadrilateral. Vibrational spectroscopic and electrochemical measurements reveal that the ligated water molecules of **3** are in equilibrium between the bound and free forms.

1. Introduction

The activation of triplet ground state dioxygen and the hydroxylation of unactivated C–H bonds under ambient conditions by non-heme diiron enzymes are topics of much current interest [1–3]. The hydroxylase component of soluble methane monooxygenase (sMMOH), which utilizes dioxygen to convert CH_4 into CH_3OH, is a well-studied member of this class of enzymes [4]. The enzyme active site contains a diiron core coordinated by four glutamate carboxylate groups and two histidine imidazole ligands [5]. This diiron unit with a carboxylate-rich coordination environment is effectively utilized to bind, activate and transfer an oxygen atom from O_2 to the substrate. Similar diiron cores occur in related multicomponent dioxygen-dependent enzymes, including toluene monooxygenase [6], the R2 subunit of ribonucleotide reductase [7,8] and stearoyl-ACP Δ^9 desaturase [9].

To help understand how these enzymes achieve their physiological roles of O_2 activation and utilization at carboxylate-rich diiron cores, much effort has been devoted to reproducing the structures and functions of their active sites by small model complexes. Recently, our group and others have reproduced the carboxylate-rich composition of these diiron sites with the use of sterically hindered terphenyl-derived carboxylate ligands [10–13]. Although these model complexes are able to hydroxylate benzylic C–H bonds and to oxidize phosphine and sulfide moieties [13–17], the activation of strong C–H bonds, such as that in methane, has not yet been achieved. This situation directed us to revisit the diiron sites in the enzymes to identify features that had not been adequately incorporated into the model complexes. One compositional difference between most of the reported model complexes and the diiron(II) core

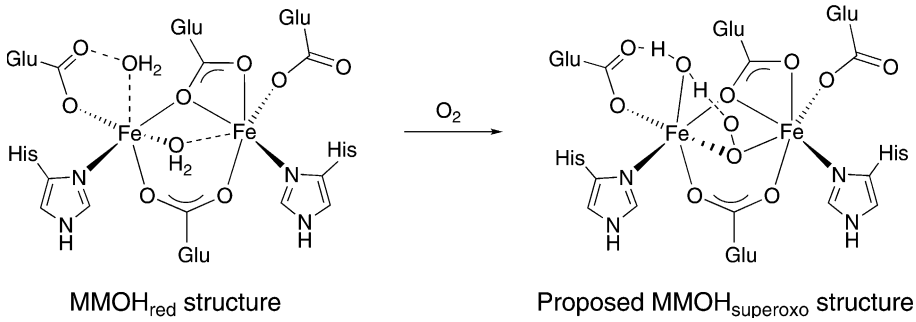

Chart 1.

at the active site of MMOH is the presence of two water molecules in the first and second coordination spheres (Chart 1). In recently published DFT calculations, the utilization of a coordinated H_2O molecule as a hydrogen-bond donor was considered to be a key component in the formation of reactive intermediate(s) upon oxygenation of the diiron(II) site [18–20]. The computational results strongly suggest that the ligated water molecules may be required to reproduce the function of the enzyme in model systems. Accordingly, we have undertaken the synthesis of model complexes containing water molecules in the coordination spheres of their carboxylate-bridged diiron(II) sites. Here, we report the result of our first efforts in this area, in which the synthesis and characterization of diiron(II) complexes with two ligated water molecules and sterically hindered terphenyl-based carboxylates are described.

2. Experimental

2.1. Materials and methods

2.1.1. General considerations

All reagents, including 4-*tert*-butylpyridine (4-^{t}Bu-C_5H_4N), were obtained from commercial suppliers and used as received unless otherwise noted. Dichloromethane, pentane and THF were saturated with argon and purified by passage through activated Al_2O_3 columns under argon [21]. Sodium 2,6-di-(*p*-tolyl)benzoate (NaO_2CAr^{Tol}) [22,23], sodium 2,6-di-(*p*-fluorophenyl)-benzoate ($NaO_2CAr^{4F\text{-}Ph}$) [23], $[Fe_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ [11] and $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ [11] were prepared as described in the literature. All syntheses and air-sensitive manipulations were carried out under nitrogen in an MBraun glovebox. FT-IR spectra were recorded with a Thermo Nicolet Avatar 360 spectrometer.

2.1.2. $[Fe_2(\mu\text{-}O_2CAr^{4F\text{-}Ph})_2(O_2CAr^{4F\text{-}Ph})_2(THF)_2(OH_2)_2]$ (1)

To a CH_2Cl_2 solution (15 ml) of $NaO_2CAr^{4F\text{-}Ph}$ (528 mg, 1.59 mmol) was added $Fe(BF_4)_2 \cdot 6H_2O$ (268 mg, 0.794 mmol) in THF (5 ml). The resulting suspension was stirred under reflux for 2 days, affording a white precipitate that was filtered through Celite. Colorless blocks of **1** (231 mg, 34% yield) were obtained by layering pentane onto the filtrate followed by slow evaporation, and they were analyzed by X-ray crystallography. FT-IR (KBr, cm^{-1}) 3600 (w, $\nu_{O\text{–}H}$), 3443 (m, br, $\nu_{O\text{–}H}$), 3059 (w), 2979 (w), 1606 (s), 1511 (s), 1455 (s), 1412 (s), 1382 (s), 1300 (w), 1221 (s), 1159 (s), 1095 (m), 1071 (w), 1036 (m), 1013 (w), 845 (m), 835 (m), 808 (s), 792 (m), 772 (m), 738 (w), 714 (m), 700 (m), 554 (s), 529 (s), 463 (m). *Anal.* Calc. for $\mathbf{1} \cdot 0.5(CH_2Cl_2)$ or $C_{84.5}H_{65}Fe_2F_8O_{12}Cl$: C, 64.58; H, 4.17. Found: C, 64.85; H, 4.26%.

2.1.3. $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ (2)

Method A. To a CH_2Cl_2 solution (9 ml) of NaO_2CAr^{Tol} (100 mg, 308 μmol) was added $Fe(BF_4)_2 \cdot 6H_2O$ (52 mg, 0.15 mmol) in THF (3 ml). The resulting suspension was stirred for a day. The white precipitate was filtered through Celite. Colorless blocks of **2** were obtained by pentane vapor diffusion (7 mg, 6% yield) and analyzed by X-ray crystallography.

Method B. To a portion (45.4 mg, 32.3 μmol) of $[Fe_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ [11] was added a THF solution (1 ml) containing 10 μl (0.56 mmol) of H_2O. The reaction mixture was stirred for 30 min. Colorless blocks of **2** (34.9 mg, 72% yield), obtained after 2 days by diffusing pentane into the solution, were analyzed by X-ray crystallography. FT-IR (KBr, cm^{-1}) 3555 (m, $\nu_{O\text{–}H}$), 3400 (w, br, $\nu_{O\text{–}H}$), 3051 (w), 3022 (m), 2918 (m), 1588 (s), 1571 (s), 1514 (s), 1454 (s), 1408 (s), 1381 (s), 1305 (w), 1211 (w), 1145 (w), 1070 (w), 1042 (m), 1019 (w), 914 (w), 890 (w), 853 (w), 835 (m), 822 (s), 802 (s), 787 (m), 765 (m), 736 (m), 714 (w), 701 (m), 584 (m), 547 (m), 523 (m). *Anal.* Calc. for $C_{92}H_{88}Fe_2O_{12}$: C, 73.80; H, 5.92. Found: C, 72.98; H, 5.98%.

2.1.4. $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$ (3)

A portion (50.5 mg, 31.8 μmol) of $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ [11] was added to THF (1 ml) containing 10 μl (0.56 mmol) of H_2O. Stirring effected dissolution within 30 min to yield a light yellow solution. Light yellow blocks of **3** (41.6 mg, 76% yield), obtained

by layering pentane onto the solution, were analyzed by X-ray crystallography. FT-IR (KBr, cm^{-1}) 3537 (s, ν_{O-H}), 3425 (w, br, ν_{O-H}), 3052 (m), 3020 (m), 2964 (s), 2919 (s), 2866 (m), 1613 (s), 1587 (s), 1514 (s), 1501 (w), 1451 (s), 1383 (s), 1273 (w), 1071 (m), 1021 (w), 909 (w), 842 (w), 830 (m), 813 (m), 786 (m), 764 (m), 726 (w), 706 (m), 584 (m), 568 (w), 526 (m), 459 (w). *Anal*. Calc. for $C_{102}H_{98}Fe_2N_2O_{10}$: C, 75.46; H, 6.08; N, 1.73. Found: C, 75.26; H, 6.14; N, 1.70%.

2.2. X-ray crystallography

Single crystals were mounted at room temperature on the tips of quartz fibers, coated with Paratone-N oil and cooled under a stream of cold nitrogen. Intensity data were collected on a Bruker (formerly Siemens) APEX CCD diffractometer running the SMART software package, with Mo Kα radiation (λ = 0.71073 Å). Data collection and reduction protocols are described in detail elsewhere [24]. The structures were solved by Patterson and direct methods and refined on F^2 using the SHELXTL software package [25]. Empirical absorption corrections were applied with SADABS [26], part of the SHELXTL program package, and the structures were checked for higher symmetry by the program PLATON [27]. All non-hydrogen atoms were refined anisotropically. In general, hydrogen atoms were assigned idealized positions and given thermal parameters equivalent to either 1.5 (methyl hydrogen atoms) or 1.2 (all other hydrogen atoms) times the thermal parameter of the carbon atom to which they were attached. Hydrogen atoms of O–H of the coordinated water molecule were identified from difference Fourier maps. In the structure of **1**, two CH_2Cl_2 solvent molecules were assigned in the lattice. In the structure of **2** there is slight disorder in the THF molecules that is not modeled. A monoclinic polymorph of **2** has also been observed with unit cell parameters a = 13.509(3) Å, b = 14.260(3) Å, c = 20.278(4) Å, and β = 104.703(3)°. The structure of **3** contains one THF and 0.5 pentane molecules. Data collection and experimental details for the complexes are summarized in Table 1 and relevant interatomic bond lengths and angles are listed in Table 2.

2.3. Electrochemistry

Cyclic voltammetric measurements were performed in an MBraun glovebox under nitrogen with an EG&G model 263 potentiostat. A three-electrode configuration consisting of a platinum working electrode, a $AgNO_3$/Ag (0.1 M in acetonitrile with 0.5 M $Bu_4N(PF_6)$) reference electrode and a platinum mesh auxiliary electrode was used. The supporting electrolyte was 0.5 M $Bu_4N(PF_6)$ in CH_2Cl_2. All cyclic voltammograms were externally referenced to the Cp_2Fe/Cp_2Fe^+ couple.

3. Results and discussion

3.1. Synthesis and characterization of the doubly bridged diiron(II) complex $[Fe_2(OH_2)_2(\mu\text{-}O_2CAr^{4F\text{-}Ph})_2(O_2CAr^{4F\text{-}Ph})_2(THF)_2]$ (1)

Compound **1** was prepared from a reaction between $Fe(BF_4)_2 \cdot 6H_2O$ and 2 equiv of $NaO_2CAr^{4F\text{-}Ph}$ in a

[a] L is the O-atom of THF in **1** and **2,** and the N-atom of 4-$^tBuC_5H_4N$ in **3**.

THF/CH_2Cl_2 solution. The structure comprises two distorted trigonal bipyramidal iron(II) centers straddling a crystallographic inversion center with an Fe ··· Fe separation of 3.4433(8) Å (Fig. 1). The coordination sites are occupied by two bridging $Ar^{4F\text{-}Ph}CO_2^-$ ligands and the oxygen atoms of THF, water and a monodentate terminal carboxylate group. The water molecule coordinated to Fe(1) with an Fe–O bond length of 2.157(2) Å is 3.107(2) Å from Fe(1A) and thus is not bridging the two iron atoms in this structure. A THF molecule is located trans to the water ligand. Strong intramolecular hydrogen bonding interactions occur between terminal metal-bound carboxylates and water molecules, with O ··· O distances of 2.608(3) Å.

*3.2. Synthesis and characterization of the diaqua-bridged diiron(II) complex $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ (**2**)*

Although the syntheses of related diaqua-bridged dinickel(II) and dicobalt(II) complexes have been described [28], an iron(II) analogue has not previously been reported. Only monoaqua-bridged diiron(II) complexes, including $[Fe_2(\mu\text{-}OH_2)(O_2CR)_4(tmen)_2]$ [tmen = tetramethylethylenediamine, R = CH_3 and C_6H_5] [29] and $[Fe_2(\mu\text{-}OH_2)(O_2Ac)_5(pyridine)_2]^-$ [30,31], have been characterized. The synthesis of compound **2** was initially achieved by self-assembly from $Fe(BF_4)_2 \cdot 6H_2O$ and 2 equiv of NaO_2CAr^{Tol} in poor yield, as described in Method A in the experimental section. The water molecules in **2** must derive from the iron(II) salt, $Fe(BF_4)_2 \cdot 6H_2O$, used in the synthesis. The reaction may proceed through the intermediate formation of $[Fe_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ in the reaction. This hypothesis was tested by treating independently synthesized $[Fe_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ with ~17 equiv of water (Method B), resulting in the isolation of compound **2** in excellent yield.

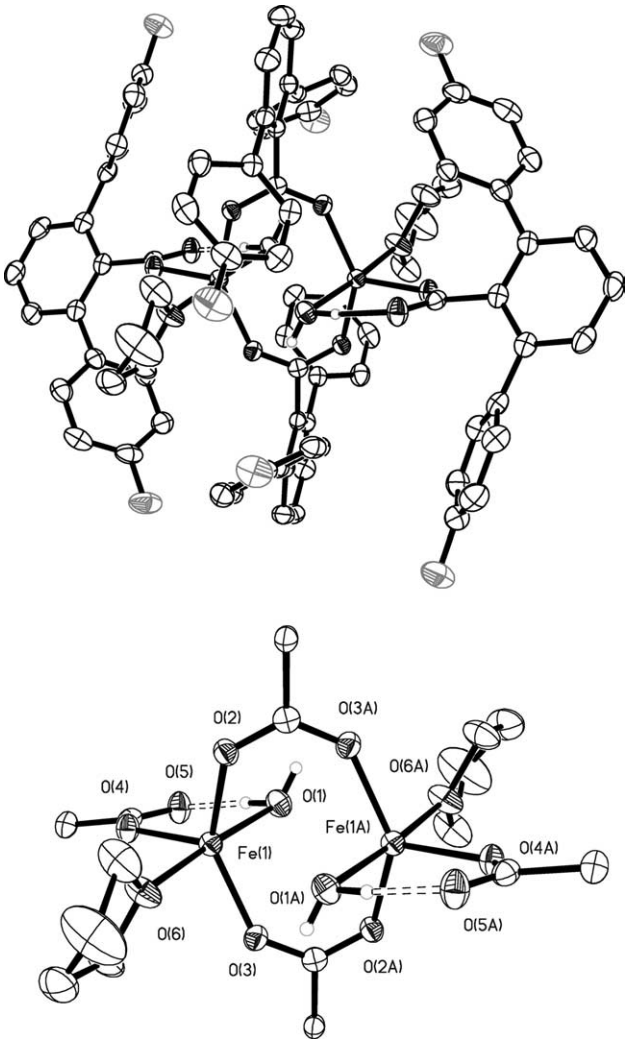

Fig. 1. Top: ORTEP diagram of $[Fe_2(OH_2)_2(\mu\text{-}O_2CAr^{4F\text{-}Ph})_2(O_2CAr^{4F\text{-}Ph})_2(THF)_2]$ (**1**) showing 50% probability thermal ellipsoids for all non-hydrogen atoms. Bottom: Drawing with the aromatic rings of $Ar^{4F\text{-}Ph}CO_2^-$ ligands omitted for clarity.

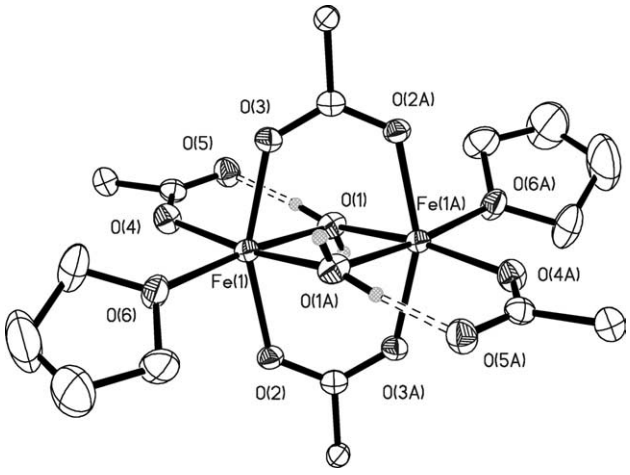

Fig. 2. ORTEP diagram of $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(THF)_2]$ (**2**) showing 50% probability thermal ellipsoids for all non-hydrogen atoms. The aromatic rings of the $Ar^{Tol}CO_2^-$ ligands are omitted for clarity.

The structure, displayed in Fig. 2, reveals two pseudo-octahedral iron(II) centers bridged by two carboxylate ligands and two water molecules. The Fe ··· Fe separation of 3.0430(7) Å is shorter by ~0.400 Å than that in **1**, owing to the presence of two additional water bridges. The assignment of these ligands as water rather than hydroxo groups is based on the Fe1-O(aqua) distances, which are 2.3977(16) and 2.3262(15) Å, by the location and refinement of the associated hydrogen atoms in the X-ray structure determination (O–H, 0.80 and 0.94 Å) and by charge considerations. This assignment is further supported by two O–H stretching bands at 3400 and 3555 cm^{-1} in the IR spectrum of **2**. The remaining coordination sites are occupied by THF and monodentate terminal carboxylate ligands. Strong intramolecular hydrogen bonding interactions occur between terminal metal-bound carboxylates and water molecules, with O ··· O distances of 2.588(2) Å.

3.3. Synthesis and characterization of the diaqua-bridged diiron(II) complex $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$ (3)

The compound $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ [11], which has a composition close to those of the MMOH [5], RNR–R2 [8] and ToMOH [6] diiron cores, is one of the better studied model complexes. To address how water in the coordination sphere might affect the properties of this complex, we synthesized a water-containing analogue. Compound **3** was prepared in excellent yield by addition of excess H_2O to $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$. The pseudo-octahedrally coordinated iron(II) atoms in **3** are related by a crystallographic inversion center and bridged by two water molecules and two carboxylates, resulting in an Fe ··· Fe distance of 3.0548(10) Å (Fig. 3). Additionally, two hydrogen bonding interactions between terminal carboxylates and bridging water groups further compact the diiron(II) sites. The O ··· O distance of 2.5519 (36) Å indicates a strong interaction. A broad IR band at 3434 cm^{-1} in the spectrum of **3** is consistent with strongly hydrogen-bonded water, and a relatively sharp O–H stretching band at 3573 cm^{-1} originates from the remaining proton on the ligand.

Although the structures of a series of Fe_2(II,II) [32], Fe_2(III,III) [33] and Fe_2(III,IV) [34] complexes having neutral polypyridine ligands and a central 2Fe2O quadrilateral are currently known, only recently have related units with biologically more relevant O-rich metal coordination environments become available (Chart 2) [10]. Compounds **2** and **3** complete one end of the series of diamond cores with O-rich metal coordination environments. As indicated in Chart 2, there are several noteworthy differences between members of the two series. The N-rich diiron complexes tend to have O-atom bridges with fewer protons. Thus, the diiron(II) sites in the neutral O-rich complex **3** are bridged by H_2O molecules, in contrast to the hydroxo bridges in the dicationic diiron(II) complex **A**. Similarly, hydroxo bridges occur in the neutral O-rich diiron(III) compound **E**, compared to the oxo bridges in the N-rich diiron(III) complex **C,** which is a dication. The aqua bridges that occur in the diiron(II) complexes $[Fe_2(\mu\text{-}OH_2)(O_2CR)_4(tmen)_2]$ [29] [R = CH_3 and C_6H_5] and $[Fe_2(\mu\text{-}OH_2)(O_2Ac)_5(pyridine)_2]^-$ [30,31] further substantiate this observation. It is now generally accepted that the diiron(II) sites in deoxyhemerythrin [3], which has a N-rich metal coordination environment, are bridged by a hydroxo moiety rather than water. Bridging H_2O molecule(s) are therefore anticipated in the diiron(II) site ligated by four carboxylates and two histidines in reduced ToMOH, as in MMOH. A second difference noted is the small variation in Fe ··· Fe distance through the O-rich series compared to the N-rich

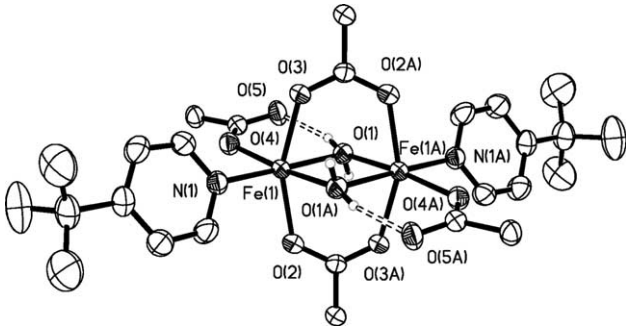

Fig. 3. ORTEP diagram of $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$ (**3**) showing 50% probability thermal ellipsoids for all non-hydrogen atoms. The aromatic rings of $Ar^{Tol}CO_2^-$ ligands are omitted for clarity.

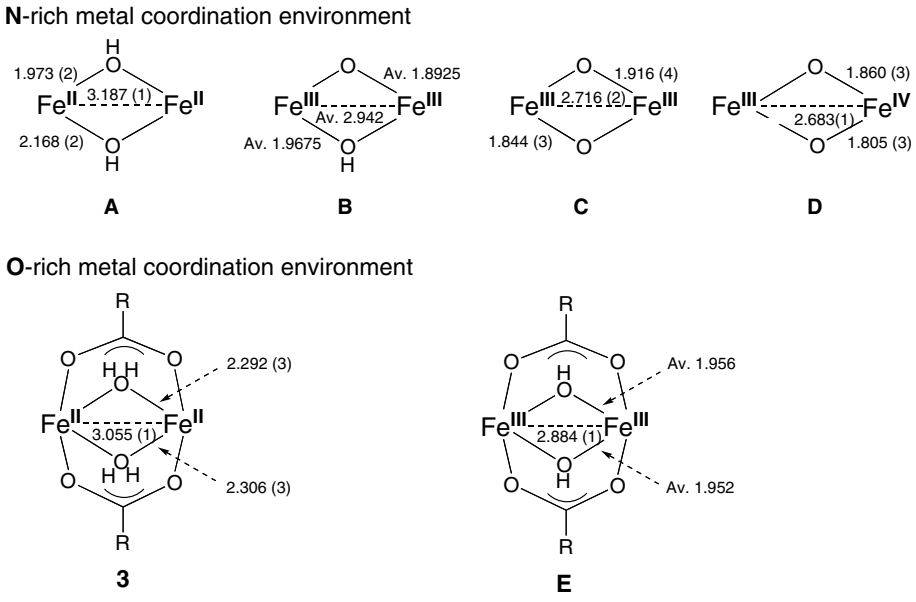

Chart 2.

one. The difference among diiron sites from **3** to **E** is only 0.171 Å, compared to the 0.471 Å spread from **A** to **C**. This property may be attributed to the presence of two additional bridging carboxylates in the O-rich series of compounds.

3.4. Vibrational and electrochemical properties

Fig. 4 displays the infrared spectra of compound **3** before and after heating at 100 °C under a nitrogen atmosphere. The disappearance of bands at 3573 and 3434 cm^{-1} after heating is attributed to the loss of coordinated water molecules in the solid state. The spectrum of **3** after heating matches that of the known compound $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ [11].

The electrochemical properties of **3** were investigated by cyclic voltammetry (Fig. 5). One quasi reversible oxidation at $E_{1/2} = -210$ mV ($\Delta E_p = 140$ mV; $i_{pa}/i_{pc} = 5.9$, scan rate = 50 mV/s) accompanied by a broad reduction wave at ca. −890 mV versus Cp_2Fe^+/Cp_2Fe was observed in CH_2Cl_2 solution. When the voltammogram was re-

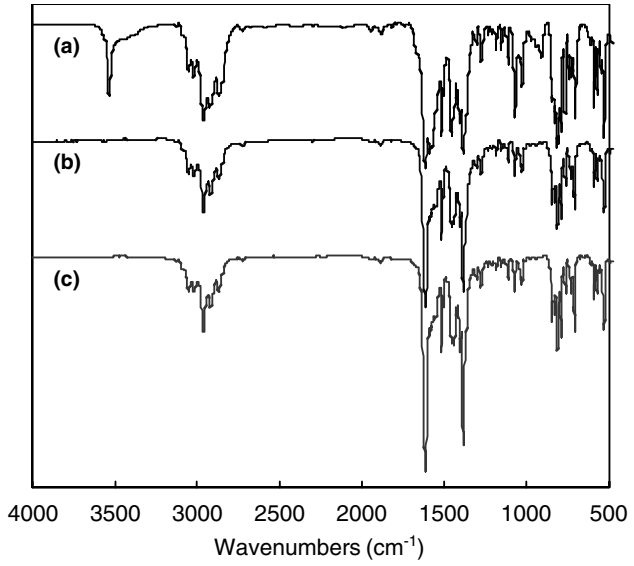

Fig. 4. IR spectra (a and b) of $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$ (**3**), before and after heating, and (c) $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$.

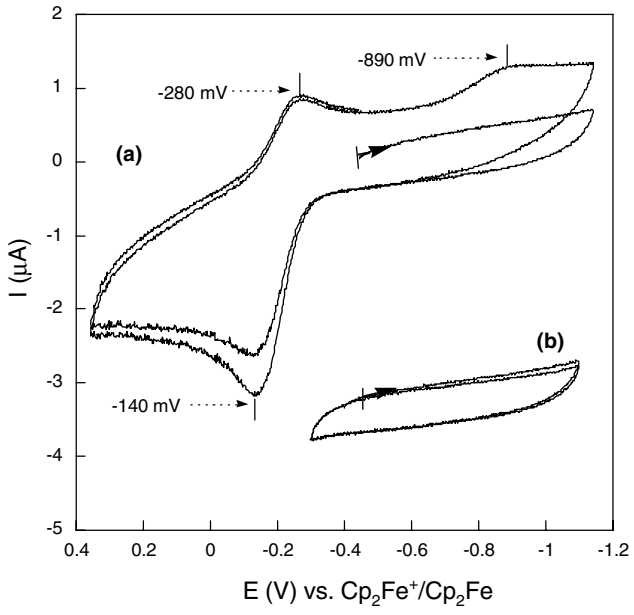

Fig. 5. Cyclic voltammograms of (a and b) $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$ (**3**) in CH_2Cl_2 with 0.5 M $(Bu_4N)PF_6$ as supporting electrolyte and a scan rate of 50 mV/s.

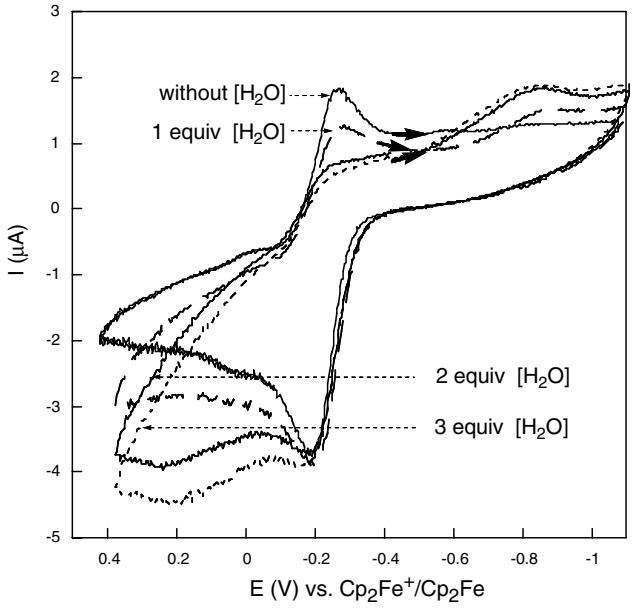

Fig. 6. Cyclic voltammograms of $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ with variable amounts of H_2O in CH_2Cl_2 with 0.5 M $(Bu_4N)PF_6$ as the supporting electrolyte and a scan rate of 50 mV/s.

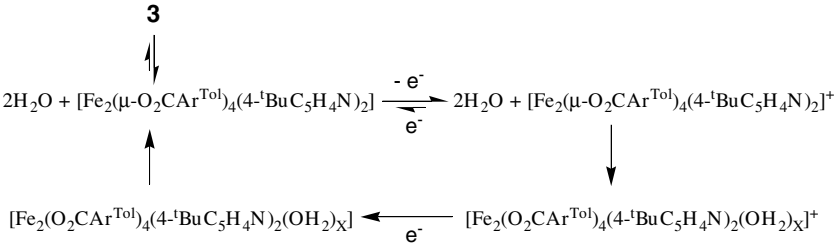
corded between −343 and −1143 mV, the reduction wave at −890 mV was no longer present (Fig. 5, graph (b)). Similar voltammograms (Fig. 6) were produced by addition of 0, 1, 2 and 3 equiv of H_2O to a CH_2Cl_2 solution of the compound $[Fe_2(\mu\text{-}O_2C\text{-}Ar^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$. Combined with the IR spectroscopic data, these results can be rationalized in the following manner (Scheme 1). Dehydration of **3** in CH_2Cl_2 can occur to afford two molecules of water and $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$, which has a reversible $Fe_2(II,II)/Fe_2(II,III)$ couple at $E_{1/2} = -216$ mV [35]. Oxidation of $[Fe_2(\mu\text{-}O_2C\text{-}Ar^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ provides the mixed-valent cation, $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4\ (4\text{-}^tBuC_5H_4N)_2]^+$, which is stable in the absence of water [35]. In presence of water molecules, however, an aquated $[Fe_2(O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2\text{-}(OH_2)_X]^+$ species may form, in which x can be one or two. This complex will exhibit different electrochemical behavior, and its reduction may give rise to the wave at ca −890 mV. The complex $[Fe_2(O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2(OH_2)_X]$, generated in this manner, would quickly lose water molecules to form $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$, resulting in no oxidation wave on the reverse sweep until a potential greater than −300 mV is attained. Uptake of water thus appears to lower the reduction potential of the diiron(II) core by ~610 mV, as might be expected from the addition of good σ donors to the dimetallic center. Both the reported dissociation of water from $[Fe_2(\mu\text{-}OH_2)(O_2CR)_4(tmen)_2]$ in solution by NMR studies [29] and the association/dissociation of water molecules of $\{Co_2(\mu\text{-}OH_2)_2\}^{4+}$ in the solid state [28] are consistent with our observations of reversible water loss from **3** in both the solid and solution states.

The diiron sites in **3** and MMOH both contain four carboxylates, two N-donor ligands and two water molecules. The two water molecules in the first and second coordination spheres of the kinetically labile diiron(II) sites in MMOH may also be in an equilibrium between bound and free forms, like **3**. Dissociation of water molecules in $MMOH_{red}$, together with a carboxylate shift, may generate the open coordination site(s) needed for dioxygen binding and activation [36]. In this respect it is noteworthy that, in the presence of the coupling and reductase components, MMOB and MMOR, the redox potential of the diiron center in MMOH changes significantly [37,38]. The present results suggest that this change may reflect loss of coordinated water molecules. On the other hand, DFT calculations of the MMOH reaction cycle identify an associated water molecule as a key component for generating oxygenated intermediate(s) [18–20]. A more complete understanding of the effects of water association and dissociation at carboxylate-bridged diiron sites, before and after the introduction of dioxygen, is clearly desirable. Although we now have clear evidence that the water molecules in **3** are reversibly bound, exactly when and how they may influence the oxygenation reactivity of diiron(II) sites remains to be determined. Efforts are underway to clarify the effect of water in the oxygenation pathways of model complexes with composition similar to that of MMOH.

4. Summary

The existence of water molecules at the diiron(II) active sites of carboxylate-bridged diiron enzymes directed us to explore water as a ligand in related complexes



Scheme 1.

supported by sterically hindered carboxylate groups. The first carboxylate rich di(aqua)-bridged diiron(II) complexes have been characterized, completing one end of this series of O-rich diamond core structures. Chemical, IR spectroscopic and electrochemical experiments indicate the reversible generation of the quadruply bridged diiron(II) complex $[Fe_2(\mu\text{-}O_2CAr^{Tol})_4(4\text{-}^tBuC_5H_4N)_2]$ by loss of two water molecules from the compound $[Fe_2(\mu\text{-}OH_2)_2(\mu\text{-}O_2CAr^{Tol})_2(O_2CAr^{Tol})_2(4\text{-}^tBuC_5H_4N)_2]$.

5. Supplementary data

Crystallographic data for the structures reported here have been deposited with Cambridge Crystallographic Data Center (CCDC), 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk), as supplementary publication numbers CCDC 234745, 234746 and 234747 for compounds **1**, **2** and **3**, respectively.

Honouring a special mentor, amazing chemist and humans Malcolm L.H. Greens on the occasion of his retirement.

Abstract

The first pyridine and picoline functionalised N-heterocyclic carbene complexes of nickel are described in this paper. The nature of the isolated complexes is critically dependent on the bite angle and the substituents of the ligand used and the synthetic method for the introduction of the ligand on the metal. From $NiBr_2$ (DME), DME=1,2-dimethoxyethane, by transmetallation with one equivalent of Ag(C^N)Cl, (C^N) = (3-R^1)[1-(α-picolyl)imidazol-2-ylidene, $R^1 = 2,6\text{-}Pr^i_2\text{-}C_6H_3$, 2,6-$Me_2$-4-$Bu^t$-$C_6H_2$, *tert*-butyl, the tetrahedral Ni(C^N)Br_2 (**1a**), (**1b**) and (**1c**) were obtained, respectively. Substitution of Br^- in (**1a**) by dtc^-, dtc^-=*N*,*N*-diethyldithiocarbamate, gave the derivative [Ni(C^N)(dtc)]Br (**2**). Transmetallation with two equivalents of Ag(C^N)Cl, (C^N) = (3-$Me_3C_6H_2$)[1-(α-picolyl)imidazol-2-ylidene], gave [Ni(C^N)$_2$]Br_2 (**3**). Transmetallation with Ag(C–N)Cl, (C–N) = [3-(2,6-$Pr^i_2C_6H_3$)][1-(2-pyridyl)imidazol-2-ylidene] afforded the bimetallic species [(C–N)$_2$Ni(μ-Br)$_2$ $NiBr_2$] (**4**), containing one octahedral and one tetrahedral nickel centre. Finally, from the reaction of $NiBr_2$ (DME) with free (C–N*), (C–N*) = 3-(2,6-$Pr^i_2C_6H_3$)-1-[2-(3-picolyl)]-imidazol-2-ylidene, good yields of Ni(C–N*)Br_2, (**6**) were obtained. Attempts to alkylate (**1**) were not successful.

Keywords: Nickel complexes; Heterocyclic carbenes; Functionalised carbenes; X-ray diffraction

1. Introduction

N-heterocyclic carbene (NHC) complexes of the late transition metals are now numerous and well established [1]. Especially, complexes with catalytically active metals are being investigated intensively. The unique donor and spatial characteristics of the NHC ligands are responsible for some unusual reactivity of the isolated complexes [2]. In recent developments NHCs functionalised with 'classical heteroatom' donors have been used as versatile multidentate spectators on a range of transition metal complexes. In this area we [3] and others [4] have reported pyridine-, picoline- and lutidine-functionalised NHC complexes of Ru, Rh, Ir and Pd. The notable absence of any functionalised NHC complexes of Ni is to be contrasted with the numerous Ni(0) and Ni(II) complexes with simple monodentate or chelating bidentate NHCs that have appeared in the literature [5]. The extensive applications of Ni complexes in catalysis, for example in polymerisation, telomerisation, C–C formation and C–F activation reactions prompted our attempts to explore the synthesis and characterisation of a range of pyridyl and picolyl functionalised NHC complexes of Ni. The compounds described in this paper are summarised in Scheme 1.

2. Experimental

2.1. General methods

Elemental analyses were carried out by the University College, London, microanalytical laboratory. All manipulations were performed under nitrogen in a M. Braun glove-box or using standard Schlenk techniques, unless stated otherwise. Solvents were dried using standard methods and distilled under nitrogen prior use. The light petroleum used throughout had a b.p. 40–60 °C.

The starting imidazolium salts and silver carbene complexes [6] were prepared according to literature procedures. All other materials used were purchased from Aldrich or Lancaster and used without further purification. NMR data were recorded on a Bruker AMX-300. The spectra were referenced internally using the signal from the residual protio-solvent (^{1}H) or the signals of the solvent (^{13}C). Mass spectra (electrospray ionisation) were obtained from acetonitrile solutions on a VG Biotec platform. The calculated isotopic envelopes agree well with the experimentally observed patterns. Magnetic susceptibilities in the solid state were measured at room temperature using a Johnson-Matthey balance. Diamagnetic corrections were ignored.

2.2. 3-(2,6-Di-iso-propylphenyl)-1-(2-pyridyl)]-imidazol-2-ylidene (*C–N*)

The corresponding imidazolium salt precursor was dried azeotropically prior to use using a Dean-Stark apparatus and stored in the glove box. In a Schlenk flask were placed the 3-(2,6-di-*iso*-propylphenyl)-1-(2-pyridyl)]-imidazolium salt (3.00 g, 7.8 mmol) and $KN(SiMe_3)_2$ (1.71 g, 8.6 mmol, 1.2 equiv.) and the solids cooled to −78 °C. Pre-cooled THF (30 cm^3) was added via cannula and the mixture was stirred until the bath temperature rose to −20 °C, and held at this temperature for 3 h. The solution was then allowed to warm to room temperature, and after evaporating the volatiles under reduced pressure, the pale residue was washed with petroleum (2 × 15 cm^3). The product was extracted into toluene (2 × 30 cm^3), filtered through Celite and the solvent removed in vacuo to yield a white crystalline product. Yield: 2.16 g, 90%; m.p. 138–140 °C (dec.). $\delta_H(C_6D_6)$: 1.1, 1.2 [2 × 6H, d, *i*Pr, $CH(CH_3)_2$, J = 7.32 Hz], 2.9 [2H, septet, *i*Pr$CH(CH_3)_2$, J = 7.32 Hz], 6.6 (1H, t, pyridyl *H*), 6.7 and 8.4 (2 × 1H, s, imidazol-2-ylidene backbone), 7.1 (1H, t, pyridyl H), 7.2 (2H, d, *i*Pr$_2$C$_6$*H*$_2$H, 7.44 Hz), 7.3 (1H, t, *i*Pr$_2$C$_6$H$_2$*H*, J = 7.44 Hz), 8.3 (1H, d, 3-pyr H), 8.8 (1H, d, 6-pyr

H). $\delta_C(C_6D_6)$, 22.6, 22.9 [*i*PrCH(C_3)$_2$], 27.1 [*i*Pr *C*(CH_3)$_2$], 113.3, 115.0 (4-,5-imidazol-2-ylidene), 119.8, 121.5, 122.3, 127.7 (*i*Pr$_2C_6H_3$), 136.6, 137.3, 144.8, 146.4, 152.9 (pyridyl) 218.3 (imidazol-2-ylidene). Found: C, 77.62; H, 7.54; N, 13.55. $C_{20}H_{23}N_3$ requires C, 78.65; H, 7.59; N, 13.76%.

2.3. 3-(2,6-di-iso-propyl-phenyl)-1-[2-(3-picolyl)]-imidazol-2- ylidene (*C–N**)

This was prepared following the method described above from the corresponding imidazolium salt (1.00 g, 2.5 mmol) and KN($SiMe_3$)$_2$ (0.55 g, 2.8 mmol). Yield: 0.78 g ca 97%; m.p. 150–155 °C. NMR, $\delta_H(C_6D_6)$: 1.20 and 1.40 [2 × 6H, d, J = 6.89 Hz, CH(CH_3)$_2$], 2.90 (3H, s, methyl H), 3.0 [2H, sept. J = 6.90 Hz, C*H*(CH_3)$_2$], 6.71 (1H, d, J = 1.8 Hz, imidazole backbone) 6.65 (1H, t, J = 4.54 Hz, 4-pyridyl) 7.81 (1H, m, 5-pyridyl), 7.38 (2H, d, J = 7.30 Hz, *m*-$C_6H_3Pr^i_2$), 7.419 (1H, t, J = 7.30 Hz, *p*-$C_6H_3Pr^i_2$), 8.05 (1H, d, 1.8 Hz, imidazole bakbone), 8.30 (1H, d, 4.54 Hz, 6-pyridyl H).

2.4. Preparation of [1-R^1-3-(α-picolyl)imidazol-2-ylidene]nickel dibromide. General method

To the appropriate silver carbene complex in dried dichloromethane (100 cm^3), was added one equivalent of $NiBr_2$ (DME) and the mixture refluxed for 8 h. Silver halide deposits were observed as the reaction progressed. On completion, the reaction mixture was allowed to cool before the solution was filtered through Celite and the solvent removed in vacuo to yield the product. Recrystallisation of samples from dichloromethane layered with petroleum yielded purple crystals.

2.5. 1-(2,6-di-iso-propylphenyl)-3-(α-picolyl)imidazol-2-ylidene]nickel dibromide (*1a*)

It was prepared following the method described above from [1-(2,6-di-*iso*-propylphenyl)-3-α-picolyl)imidazol-2-ylidene]silver bromide (0.16 g, 0.32 mmol) and Ni(DME)Br_2 (0.10 g, 0.32 mmol). Yield: 0.10 g, 59%. Found C, 46.76, H, 4.59, N, 7.36. $C_{21}H_{25}N_3Br_2Ni$ requires C, 46.89, H, 4.68, N, 7.81%. μ_{eff} = 3.3 BM.

2.6. 1-(2,6-dimethyl-4-tert-butyl)-3-(α-picolyl)imidazol-2- ylidene]nickel dibromide (*1b*)

It was prepared following the method described above from the corresponding silver complex (0.15 g, 0.3 mmol) and Ni(DME)Br_2 (0.10 g, 0.3 mmol). Yield: 61%, 0.10 g. MS(ES$^+$) *m*/*z* 320 (Ligand)$^+$. Found C, 46.73, H, 4.57, N, 7.79. $C_{21}H_{25}Br_2N_3Ni$ requires C, 46.89, H, 4.68, N, 7.81%. μ_{eff} = 3.2 BM.

2.7. 1-(tert-butyl)-3-(α-picolyl)imidazol-2-ylidene]nickel dibromide (*1c*)

It was prepared following the method described above from [1-(*tert*-butyl)-3-(α-picolyl)imidazol-2-ylidene]silver bromide (0.30 g, 0.7 mmol) and Ni(DME)Br_2 (0.23 g, 0.8 mmol). Yield: 56%, 0.18 g. Found C, 40.10, H, 4.40, N, 10.79. $C_{13}H_{17}N_3Br_2Ni$ requires C, 35.99, H, 3.95, N, 9.69%. μ_{eff} = 3.2 BM. The X-ray crystal structure shows partial occupation of the halide sites by chloride and bromide, which may account for the deviation between the theoretical and experimental analytical data. The origin of the chloride ion is the silver carbene reagent. Depending of the reaction conditions there is variable incorporation of chloride originating from the chlorinated solvent used during the preparation of the silver complex [6].

2.8. 1-(2,6-di-iso-propylphenyl)-3-(α-picolyl)imidazol-2-ylidene]nickel diethyldithiocarbamate bromide (*2*)

To a solution of **1a** (0.25 g, 0.46 mmol) in dichloromethane (30 cm^3) was added sodium diethyldithiocarbamate (0.87 g, 0.51 mmol) and the solution refluxed overnight. The purple solution changed to pale brown and salt deposits were observed. The supernatant was removed in vacuo and the product extracted into ether, filtered and concentrated to ca. 5 cm^3. On standing at room temperature X-ray quality crystals were formed. Yield: 62%, 0.17 g. MS (ES$^+$) *m*/*z* 525 [Ni(Ligand)(S_2CNEt_2)]$^+$, 320 (Ligand)$^+$. Found C, 50.24, H, 5.32, N, 9.72. $C_{25}H_{35}BrN_4NiS_2$ requires C, 50.53, H, 5.94, N, 9.43%. The ^{1}H NMR spectrum at RT (CD_2Cl_2) consists of broad lines centered at 1.5, [(CH_3)$_2$CH and CH_3CH_2N], 2.6 (CH_3CH_2N) and the aromatic region.

2.9. Bis[1-(2,4,6-trimethylphenyl)-3-(α-picolyl)imidazol-2-ylidene]nickel dibromide salt (*3*)

This was prepared following the general method using [1-(mesityl)-3-(α-picolyl)-imidazol-2-ylidene]silver bromide (0.15 g, 0.33 mmol) and $NiBr_2$ (DME) (0.05 g, 0.16 mmol) in dichloroethane (30 cm^3). The reaction mixture was refluxed overnight. Silver halide precipitated from the green solution. The mixture was filtered through a frit and the resulting pale yellow/green solution was concentrated to ca. 5 cm^3 and cooled to −30 °C giving X-ray quality crystals. Yield: 0.09 g, 74%. $\delta_H(CDCl_3)$: 2.1 (12H, s, *o*-mesityl CH_3), 2.5 (6H, s, *p*-mesityl CH_3), 5.5 (2H, s, CH_2), 6.7 and 7.3 (2 × 2H, s, 4-and 5-imidazol-2-ylidene), 6.9 (2H, s, mesityl H), 7.3 (1H, m, pyr H), 7.5 (1H, m, pyr H), 7.8 (1H, d, J = 8 Hz, pyr H), 8.5 (1H, d, J = 6.9 Hz, pyr H).

2.10. Compound (4)

This was prepared following the general method described above and using 1-(2,6-di-*iso*-propylphenyl)-3-(pyridin-2-yl)-imidazol-2-ylidene silver bromide (0.20 g, 0.4 mmol) and Ni(DME)Br_2 (0.12 g, 0.4 mmol). Yield 0.10 g, 26.5%. Found C, 45.03, H, 4.15, N, 7.55. $C_{40}H_{46}N_6Br_4Ni_2$ requires C, 45.85, H, 4.42, N, 8.02%. X-ray quality crystals were obtained by slow evaporation of dichloromethane solutions.

2.11. Reaction of Ni(DME)Br_2 with (C–N)

To a solution of 1-(2,6-di-*iso*-propylphenyl)-3-(pyridin-2-yl)-imidazol-2-ylidene (0.20 g, 0.65 mmol) in DME (dry, 30 cm^3) at −78 °C, was added Ni(DME)Br_2 (0.22 g, 0.72 mmol) and the reaction stirred for 30 min before being allowed to rise to room temperature. The colour of the solution changed from orange to green to brown. The solvent was removed in vacuo and the resulting brown solid was washed with petroleum (2×10 cm^3). Yield 0.10 g. Found C, 44.26, H, 5.09, N, 7.26. $C_{40}H_{46}N_6Br_4Ni_2$ requires C, 45.85, H, 4.42, N, 8.02%. Green X-ray quality co-crystals (5) were obtained by slow cooling of THF solutions. The product decomposed rapidly in $CDCl_3$ and was insoluble in C_6D_6.

2.12. 1-(2,6-di-iso-propylphenyl)-3-[2-(3-picolyl)]-imidazol-2- ylidene]nickel dibromide (6)

To a suspension of $NiBr_2$ (DME) (0.150 g, 0.485 mmol) in THF (30 cm^3) at −78 °C was added a solution of (C–N*) (0.155 g, 0.485 mmol) in THF precooled at −78 °C. The mixture was allowed to warm to room temperature and was stirred for 2 h. The resulting green solution was filtered and the solvent was then evaporated in vacuo. The green solid was crystallised from THF layered with petroleum. Yield: 0.21 g, 80%. Found C, 46.56, H, 4.59, N, 7.46. $C_{21}H_{25}N_3Br_2Ni$ requires C, 46.88, H, 4.68, N, 7.82%.

2.13. X-ray crystallography

A summary of the crystal data, data collection and refinement for compounds (**1b**), (**2**), (**3**), (**4**), (**C–N***), and (**6**) are given in Table 1. Data related to compounds (**1a**) and (**1c**) and (**C–N**) are included as supplementary information.

All data sets were collected on a Enraf Nonius Kappa CCD area detector diffractometer with rotating anode FR591 and an Oxford Cryosystems low-temperature device operating in omega scanning mode with phi and omega scans to fill the Ewald sphere. The programs used for control and integration were Collect, Scalepack and Denzo [7]. The crystals were mounted on a glass fibre with silicon grease, from Fomblin vacuum oil. All solutions and refinements were performed using the WINGX package [8] and all software packages within. All non-hydrogen atoms were refined using anisotropic thermal parameters and hydrogens were added using a riding model.

3. Results and discussion

The original syntheses of monodentate or bidentate NHC complexes of nickel involved the interaction of a

Selected bond lengths (Å) and angles (deg) with estimated standard deviations: Ni(1)–S(2) 2.1719(10); Ni(1)–S(1) 2.2324(10); C(8)–Ni(1) 1.880(4); C(8)–N(3) 1.347(4); C(8)–N(3) 1.347(4); N(2)–Ni(1) 1.943(3); C(8)–Ni(1)–N(2) 90.61(13); S(2)–Ni(1)–S(1) 79.08(4).

Ni(II) or Ni(0) precursor with isolated NHCs, prepared by deprotonation of the imidazolium preligands, or by direct metallation of imidazolium salts with $Ni(OAc)_2$. The former method could not be applied successfully to the synthesis of α-picolyl functionalised NHC complexes due to the problematical synthesis and instability of the free ligands at room temperature [3b]. The latter method when used for the synthesis of pyridine- and picoline-functionalised Ni complexes gave intractable mixtures [3d]. We therefore opted for a strategy involving transmetallation of the NHC from silver to nickel, originally reported by Wang and Lin [9a] and applied to the synthesis of palladium and rhodium complexes by us [3a] and [3b] and others [9b]. Reaction of one equivalent of the known silver NHC complexes with $NiBr_2$ (DME) gave selectively good yields of the targeted complexes Ni(C^N)Br_2, (**1a**), (**1b**) and (**1c**), as air stable, purple crystalline materials. The reaction rates were noticeably slower than those of analogous palladium systems as judged by the rate of precipitated silver halide. This may be due to the weaker M–C bonds being formed in the Ni(II) case. Since the products are paramagnetic their characterisation was carried out by analytical and single crystal X-ray diffraction methods. An ORTEP diagram of (**1b**) is shown in Fig. 1; details of the structures of (**1a**) and (**1c**) are included as supplementary information.

All three complexes are distorted tetrahedral [bite angle average 92.70(20)°, Br–Ni–Br average 128.5(4)°]. The Ni–C bond lengths [average 1.969(6) Å] are longer than those previously reported for other Ni(II)–NHC complexes [5]. Attempted substitution of the halide in (**1a**)–(**c**) with a variety of nucleophilic reagents, including alkyl lithium, magnesium and zinc reagents, gave intractable mixtures. However, substitution of one bromide in (**1a**) with pre-dried sodium diethyldithiocarbamate proceeded cleanly giving rise to (**2**) which was unequivocally characterised by analytical and diffraction methods. A diagram of the cation of (**2**) is given in Fig. 2.

In this case the geometry of the nickel centre is best described as square planar. The Ni–C [1.880(4) Å] is shorter than those observed in (**1a**)–(**1c**), and comparable to those reported in the literature for other square planar NHC complexes [5]. The bite angle of (C^N) is reduced to 90.61(13)°, demonstrating the ability of the six membered chelate ring to accommodate different coordination geometries. The dithiocarbamate chelate ring is slightly unsymmetrical due to the increased *trans* influence of the strong σ-donor NHC functional group. The adoption of square planar geometry may be due to the angular constraints imposed by the dtc ligand and the strengthening of metal–ligand σ- and π-bonding in this geometry. Complex (**2**) shows a very broad ^1H NMR spectrum, which may be due to fluxionality or planar–tetrahedral equilibria in solution. Attempts to sharpen the spectrum at lower temperatures (−60 °C) were unsuccessful.

Transmetallation using two equivalents of the silver–NHC complex gave clean products only when the mesityl substituted analogue was employed. In his case complex (**3**) was isolated as brown air stable crystalline material and characterised by analytical, spectroscopic and diffraction methods. A diagram of the cation in (**3**) is given in Fig. 3.

Here too the Ni center adopts a slightly distorted square planar geometry with the two NHC and two pyridine functional groups arranged *trans* to each other. The Ni–C bond lengths [1.908(3) Å] fall in the range typical for other square planar complexes [5]. The carbene

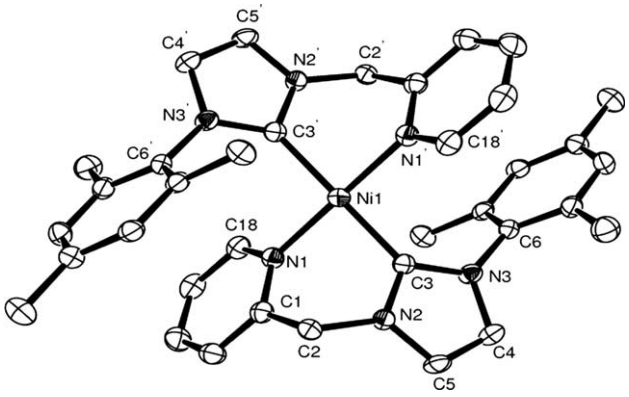

Fig. 3. ORTEP representation of the structure of the cation in **3** showing 50% probability ellipsoids. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (deg) with estimated standard deviations: C(3)–Ni(1) 1.908(3); N(1)–Ni(1) 1.928(2); C(3)–N(2) 1.344(4); C(3)–N(3) 1.365(4); C(3)–Ni(1)–N(1) 87.24(11); C(3)–Ni(1)–N(1)# 1 92.76(11)

heterocyclic ring is twisted by ca. 42° from the coordination plane. In addition, the planes of the aromatic rings of the NHC substituent and the pyridine of the second ligand are almost parallel with short interplanar distances (3.22–3.25 Å).

Attempts to prepare the pyridine functionalised analogues of (**1a**)–(**c**) by either transmetallation or substitution of labile ligands (DME or THF) of Ni(II) precursors by the free (C–N) gave unexpected results.

On refluxing $Ni(DME)Br_2$ with one equivalent of Ag(C–N)Br a deep purple solution was produced, which on cooling formed a light blue precipitate. This could be redissolved on heating giving a purple solution. From the latter on slow cooling light blue crystals of (**4**) precipitated. Complex (**4**) is paramagnetic and its identity was established by analytical and single crystal X-ray diffraction methods. A diagram of the molecule is shown in Fig. 4.

In the solid state (**4**) contains two nickel centres with different coordination geometries. The first, tetrahedral, is coordinated by two terminal and two bridging bromides and the second, octahedral, is hosting two (C–N) ligands and bridged to the other Ni centre through the bromides. The pyridine groups occupy mutually *trans* sites. The Ni–NHC bonds in this complex (2.009–2.019 Å) are longer than those observed with other tetrahedral (1.936–1.957 Å) and square planar (1.880–1.908 Å) examples discussed in this paper and elsewhere [5]. The same trend is observed with the M–pyridine bond lengths as expected. The planes of the aromatic rings of the NHC substituent and the pyridine of the second ligand in the octahedral center are parallel with short interplanar distances (3.15–3.20 Å). The reason for the selective isolation of (**4**) with the (C–N) ligand is not clear. The equilibrium given below is plausible and has been suggested for other Ni(II)/bidentate ligand systems [13]

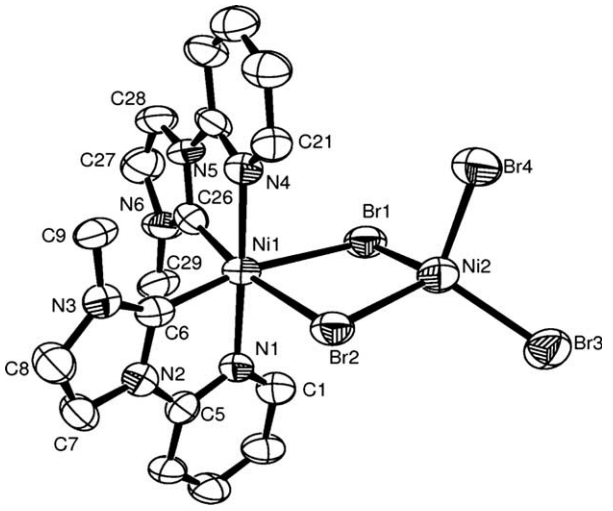

Fig. 4. ORTEP representation of the structure of **4** showing 50% probability ellipsoids. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (deg) with estimated standard deviations: N(1)–Ni(1) 2.103(5); N(4)–Ni(1) 2.102(5); Ni(1)–Br(1) 2.6642(11); Ni(1)–Br(2) 2.6898(12); Ni(2)–Br(4) 2.3525(14); Ni(2)–Br(3') 2.355(2); Ni(2)–Br(3) 2.381(5); Ni(2)–Br(1) 2.4093(13); C(6)–Ni(1) 2.009(7); C(26)–Ni(1) 2.018(7); N(1)–Ni(1) 2.103(5); N(4)–Ni(1) 2.102(5); Ni(1)–Ni(2) 3.597; C(26)–Ni(1)–N(4) 79.3(3); C(6)–Ni(1)–N(1) 80.1(2); C(26)–Ni(1)–N(1) 99.1(2).

$$NiBr_2(DME) \rightleftharpoons NiBr_2(C\text{–}N) \rightleftharpoons NiBr_2(C\text{–}N)_2$$

$$NiBr_2(DME) + NiBr_2(C\text{–}N)_2 \rightleftharpoons Br_2Ni(\mu\text{-}Br)_2Ni(C\text{–}N)_2 + DME$$

It may be speculated that (**4**) formed by dimerisation of $NiBr_2$ (DME) and $NiBr_2$ (C–N) is preferentially crystallising out of solution. Upon dissolving (**4**) to polar donor solvents (e.g., THF) the accompanying colour change could be ascribed to the splitting of the dimeric structure. Attempts to trap the products formed by addition of PMe_3 gave only $NiBr_2$ $(PMe_3)_3$ and white imidazolium salts as precipitates, which may imply dissociation of (C–N) in the presence of PMe_3. The structure of compound (**4**) is a rare example of a binuclear complex of Ni(II) with two centers of different coordination geometries. There are only a few examples of mixed geometry binuclear nickel complexes with extended pre-organised multi-dentate Schiff base ligands [10].

Reaction of $NiBr_2$ (DME) with one equivalent of the free ligand (C–N) gave a complicated reaction mixture from which blue-green crystals were obtained. A detailed X-ray diffraction study was hampered by the small size of the crystals formed, however it revealed the identity of the chemical species that were involved in the crystal. A mixture of the octahedral $\{[Ni(C\text{–}N)_2Br]_2\}^{2+}$, the tetrahedral $Ni(C\text{–}N)Br_2$ and $[NiBr_4]^{2-}$ were all present in the lattice [co-crystal (**5**) in Scheme 1]. Attempts to separate the neutral from the ionic components by selective extraction were not successful. Again the formation of co-crystal (**5**) can be rationalised

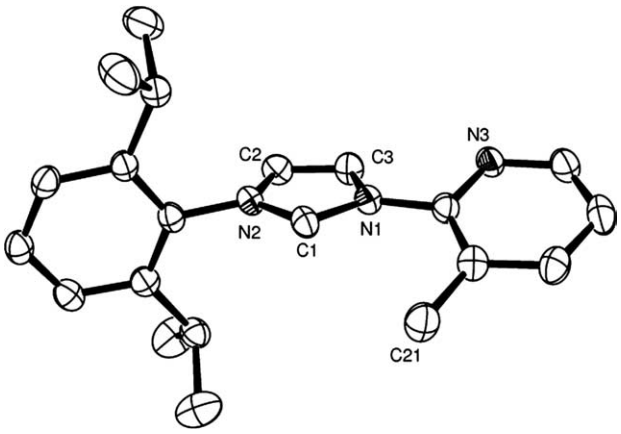

Fig. 5. ORTEP representation of the structure of (**C***–**N**) showing 50% probability ellipsoids. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (deg) with estimated standard deviations: N(1)–C(1) 1.381(4); N(1)–C(3) 1.391(4); N(2)–C(1) 1.357(4); C(2)–C(3) 1.330(4).

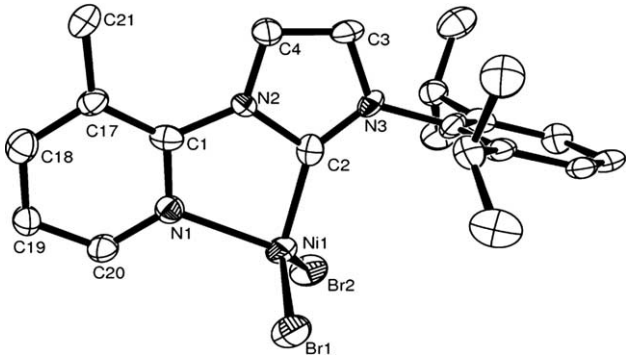

Fig. 6. ORTEP representation of the structure of **6** showing 50% probability ellipsoids. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (deg) with estimated standard deviations: C(2)–N(2) 1.391(7); C(2)–N(3) 1.331(8); C(2)–Ni(1) 1.937(7); N(1)–Ni(1) 2.032(5); Br(2)–Ni(1)–Br(1) 130.35(4); C(2)–Ni(1)–N(1) 81.4(3).

by postulating the establishment of an equilibrium involving mono- and di-substituted Ni containing species as described above for (**4**). It is expected that the position of this equilibrium would be dependent on the electronic and steric factors determining the stability of the species involved.

In an effort to study the effect of nature of the pyridine ring substituents on the electronic properties of the (C–N) ligands, we synthesised a (C–N) analogue with 3-methyl substituted pyridine ring. Following the general method described previously [6] we obtained high yields of the free pyridine functionalised NHC (**C**–**N***), which was characterised by spectroscopic, analytical and diffraction methods. A diagram of the molecule is given in Fig. 5; for comparison purposes the structure of the unsubstituted analogue (**C**–**N**) is also included as supplementary information. Both ligands show very similar metrical data with almost *anti*-arrangement of the pyridine and the NHC lone pairs [the average dihedral angle between the aromatic rings is 21° and 18.5° for (**C**–**N***) and (**C**–**N**), respectively]. Reaction of $NiBr_2$ (DME) with the (**C**–**N***) in THF gave high yields of the tetrahedral [Ni(C–N*)Br_2] **6** (Fig. 6). This was the only identifiable complex in the reaction mixture. A comparison of the structures of (**1a**) and (**6**) shows that both adopt distorted tetrahedral geometries, with the more severe distortions being observed in (**6**); [ligand bite angles 81.4(3)° in (**6**), 92.50° (14) in (**1a**), Br(1)–Ni(1)–Br(2) 130.35(4)° in (**6**), 131.12(3)° in (**1a**)]. The chelating ligand bite angle does not have a significant effect on the Br(1)–Ni(1)–Br(2) angle, the magnitude of which is possibly controlled by the bromide lone pair repulsions. Four coordinate complexes of type [(L–L)Ni(halide)$_2$] are square planar or tetrahedral [11]. The recently reported bidentate bis-NHC complexes [5e,f] invariably adopt square planar geometry. This geometry is also favoured by phosphine complexes of the type $NiBr_2$(L–L) [(L–L) = $R_2P(CH_2)_nPR_2$ n = 1–3, R = aryl, alkyl] [12]. However, Ni[$Me_2P(CH_2)_2PMe_2$]Cl_2 and complexes with large bite angle diphosphines adopt tetrahedral geometry [13].

Preliminary data show that complexes (**1a**), (**1b**) and (**1c**) in the presence of excess of MAO are poor catalysts for the polymerisation of ethylene at room temperature. The polymerisation activity of (**6**) will be reported in the future.

In summary, we have shown that the synthesis of picoline- and pyridine-functionalised NHC complexes of Ni(II) can be accomplished by using transmetallation or substitution synthetic strategies. Transmetallation yields selectively picoline-functionalised tetrahedral complexes of type [(C^N)$NiBr_2$]. Under forcing conditions the square planar [Ni(C^N)$_2$]Br_2 could be obtained. The same methodology when applied to pyridine-functionalised NHC ligands leads to the isolation of octahedral [(C–N)$_2$Ni(μ-Br_2)$NiBr_2$]. However, substitution of the labile DME with the free (C–N*) gave good yields of the tetrahedral [(C–N*)$NiBr_2$]. The preparation of organometallic complexes of [(C–N*)$NiBr_2$] is currently under progress.

Abstract

The synthesis of acyclic and macrocyclic transition metal dithiocarbamate complexes containing positively charged imidazolium moieties is reported. The assemblies have been characterised by a range of spectroscopic techniques and the ability of these compounds to bind various anions was also examined. UV–Vis spectroscopic binding studies revealed $H_2PO_4^-$ is complexed selectively in preference to F^- and Cl^- for the acyclic transition metal dithiocarbamate complexes containing the *N*-methylimidazolium moiety. Cyclic voltammetric studies demonstrated that the copper(II) dithiocarbamate imidazolium systems can electrochemically sense the binding of Cl^- and $H_2PO_4^-$.

1. Introduction

As a consequence of the fundamental roles played by negatively charged species in a range of biological, chemical, medical and environmental processes, there is intense current interest being shown in the syntheses of receptors designed to recognize and sense anions [1]. By incorporating redox- and photo-active transition metal inorganic signaling probes into various acyclic, macrocyclic and calixarene ligand frameworks [2], we have produced a series of selective spectral and electrochemical responsive reagents for anions. In an effort to construct new types of anion redox responsive receptors, we report here the synthesis and preliminary anion coordination investigations of new transition metal dithiocarbamate imidazolium receptor systems, including macrocyclic derivatives, using metal directed self-assembly.

The synthesis of potential macrocyclic anion receptor systems can prove to be problematic as their preparation often requires high dilution conditions and yields can be moderate [3]. Rare examples of using anion templation to circumvent this problem have recently appeared [4]. Metal directed self-assembly synthetic techniques may also be used to aide macrocycle formation [5]. Through careful consideration of ligand and preferred metal coordination geometry, among other factors, complicated and unusual molecular architectures are attainable. The dithiocarbamate (dtc) ligand has proven to be a useful structural motif in the metal directed assembly of a range of supramolecular architectures including nano-sized resorcarene-based assemblies [6], catenanes [7], assorted macrocycles [8], trinuclear cages [9] and cryptands [10]. There is intense current interest in the application of imidazolium compounds in ionic liquids [11] and as precursors to *N*-heterocyclic carbene ligands [12]. The imidazolium moiety has also been employed as an anion binding motif recently [4,13,14]. Combining the dithiocarbamate ligand with positively charged imidazolium moieties followed by transition metal directed assembly has led to the preparation of a series of acyclic

and macrocyclic receptors with the potential to recognize anionic guest species. Their synthesis, characterization and preliminary anion coordination properties are reported herein.

2. Results and discussion

2.1. Syntheses

The acyclic transition metal dtc complexes containing appended imidazolium moieties were prepared in good yields in four steps (Scheme 1). Condensation of benzaldehyde with *N*-(3-aminopropyl)imidazole (**1**) produced the corresponding imine (**2**), which was alkylated with iodomethane to give the imidazolium-imine ligand (**3**). The imidazolium-amine (**4**) was obtained, with an overall yield of 56%, by reduction of the imidazolium-imine (**3**) with $NaBH_4$. Receptor formation was achieved by metal directed synthesis. Typically, dtc complexes were prepared in a one-pot synthesis from the parent secondary amines by reaction with carbon disulfide, base and an appropriate transition metal salt. Using Ni(II), Cu(II) and Zn(II) acetate salts, crude powders were obtained and anion exchanged with aqueous NH_4PF_6 to afford the analytically pure products (**5a**), (**5b**) and (**5c**) in very good yields (Scheme 1).

The tripodal Co(III) derivative (**6**) was synthesised in 80% yield using cobalt(II) chloride as the transition metal salt (Scheme 1). Macrocyclic transition metal dtc imidazolium receptors (**11**) and (**12**) were prepared by alkylating the imidazole-imine precursor (**2**) with α,α′-dibromo-*p*-xylene and 2,7-bis(bromomethyl)naphthalene, respectively (Scheme 2), followed by dtc ligand formation, addition of the transition metal salt and anion exchange with aqueous NH_4PF_6 to give the pure products in yields of 95% and 81%, respectively (Fig. 1).

An imidazolium dtc cryptand complex was also synthesised (Scheme 3). Alkylation of imidazole imine (**2**) with 1,3,5-tri(chloromethyl)-2,4,6-triethylbenzene [15] followed by reduction of the imine produced the corresponding imidazolium tripod with secondary amine appendages (**14**). Treatment of (**14**) with carbon disulfide and triethylamine in acetonitrile followed by the addition of cobalt(II) chloride gave the cobalt(III) dtc imidazolium cryptand complex (**15**) (Scheme 3) in 82% yield.

All these new transition metal dtc imidazolium derivatives were characterised by a variety of techniques including ^1H NMR, ^{13}C NMR, UV–Vis spectroscopy and elemental analysis (see Section 4).

2.2. Preliminary anion binding studies

2.2.1. UV–Vis spectroscopy

The UV–Vis characterisation data obtained for the nickel(II) (**5a**, **11a** and **12a**), copper(II) (**5b**, **11b** and **12b**), zinc(II) (**5c** and **11c**) dtc complexes and cobalt(III) tripodal dtc systems (**6** and **15**) were comparable to literature values [16,17] of the corresponding transition metal diethyl–dithiocarbamate complexes, respectively (Table 1).

The binding of fluoride, chloride and dihydrogen phosphate anions with the range of transition metal

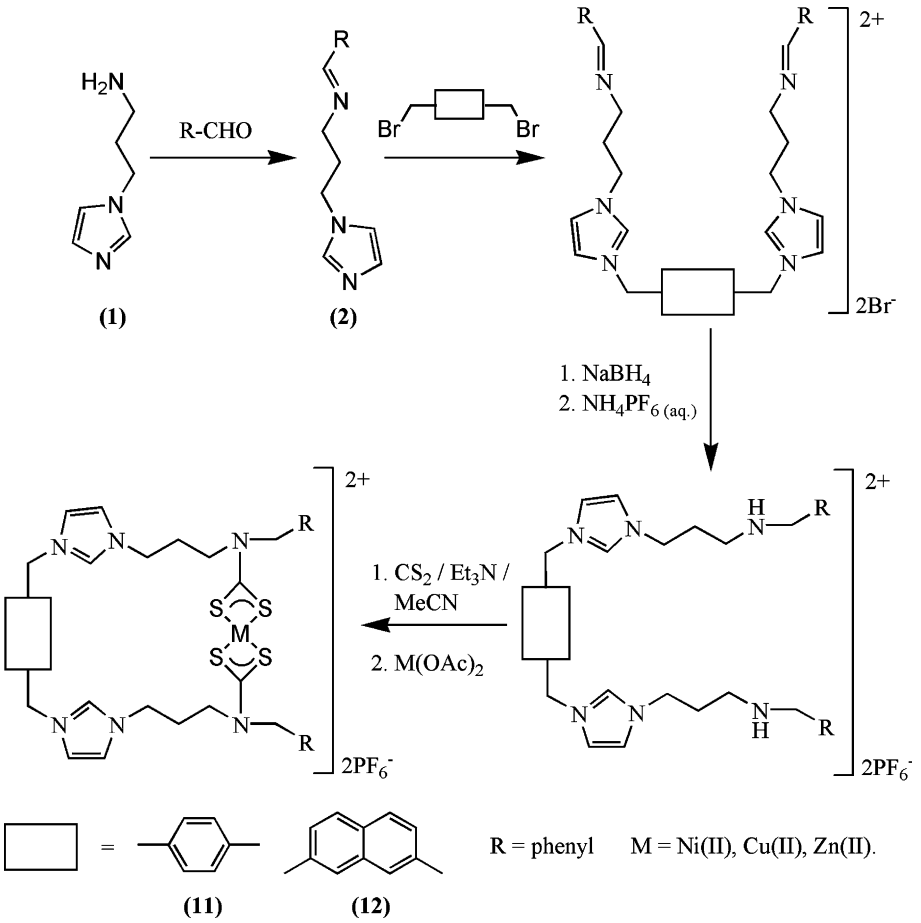

Scheme 2. Synthesis of macrocyclic transition metal dithiocarbamate imidazolium receptors.

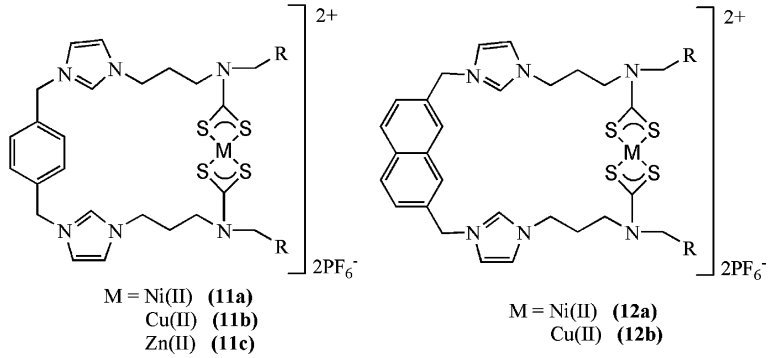

Fig. 1. Macrocyclic transition metal dithiocarbamate imidazolium receptors with xylene and naphthalene spacer groups.

dtc imidazolium derivatives was investigated initially by UV–Vis spectroscopy. Acetonitrile solutions of tetrabutylammonium fluoride, chloride and dihydrogen phosphate were titrated into 10^{-5} M solutions of the metal dtc complexes in acetonitrile, and perturbations in the electronic spectra were analysed using Spectfit [18]. For example, Fig. 2 shows the set of UV–Vis spectra from the titration of dihydrogen phosphate with the acyclic Ni(II) dtc imidazolium receptor (**5a**). The most prominent change in the electronic spectrum seen is the decrease in intensity of the MLCT band at 325 nm; the isobestic points indicate binding stoichiometry is well-behaved.

The acyclic Ni(II), Cu(II) and Zn(II) dithiocarbamate imidazolium receptors (**5a**), (**5b**) and (**5c**) all complexed $H_2PO_4^-$ with no evidence of binding F^- or Cl^-. Job plot analysis indicated 1:1 stoichiometric complexes with $H_2PO_4^-$ in each case. This is in good agreement with anion binding trends observed for an organic imidazolium receptor (**16**) containing a fluorescent anthracene moiety

[c] Literature values for Co(III) tris(diethyldithiocarbamate) are listed in brackets [17].

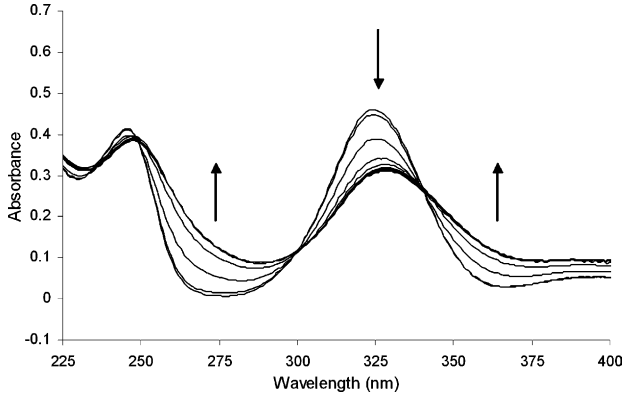

Fig. 2. UV–Vis spectra of the Ni(II) receptor (**5a**) on addition of $H_2PO_4^-$ in MeCN.

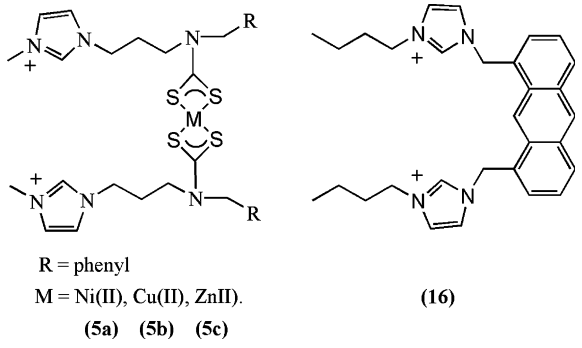

Fig. 3. Transition metal dithiocarbamate imidazolium complexes (**5**) and the anthracene imidazolium receptor (**16**) [13].

(Fig. 3) [13]. For their system, Kim et al. reported preferential binding for $H_2PO_4^-$ over Cl^-, Br^- and I^- as evidenced from fluorescence titration studies in acetonitrile [13].

The determined $H_2PO_4^-$ stability constant values displayed in Table 2 reveal Ni(II) and Cu(II) receptors (**5a**) and (**5b**) bind $H_2PO_4^-$ with similar strength, whereas weaker binding is found with the Zn(II) receptor (**5c**).

Table 2
Stability constant data (log β) for binding $H_2PO_4^-$ in acetonitrile at 298 K

Receptor	Log β
5a	4.3 ± 0.1
5b	3.9 ± 0.2
5c	2.4 ± 0.5

A tentative explanation for this result may be the difference in coordination geometry at the respective metal centre. Ni(II) and Cu(II) dithiocarbamates are known to exhibit square planar geometry whilst Zn(II) dithiocarbamates display distorted tetrahedral stereochemistry. Consequently, the angle between the two imidazolium appendages in these acyclic systems will differ. A square planar geometry at the metal centre apparently favours the tweezer-like binding of $H_2PO_4^-$.

The anion binding properties of macrocyclic systems were also examined by UV–Vis spectroscopy. No changes in the UV–Vis spectra with (**11**) and (**12**) were observed on anion addition which suggests either these systems are incapable of binding anions or anion complexation does not significantly affect the electronic spectra of the receptors.

2.2.2. Electrochemistry

Cyclic voltammetric investigations of the Cu(II) complexes (**5b**), (**11b**) and (**12b**) displayed broadened quasi-reversible Cu(II)/Cu(III) redox couples. (Fig. 4) which appear at more anodic potentials than the Cu(II) bis(diethyldithiocarbamate) system (Table 3).

This anodic displacement of the Cu(II)/Cu(III) redox couple can be attributed to the appended positively charged imidazolium moieties which destabilise the Cu(III) state. Hence, a higher potential is required to oxidise the Cu(II) centers to Cu(III). Cyclic voltammetric studies of the Co(III) complex (**6**) revealed a broadened quasi-reversible Co(III)/Co(IV) redox couple which is anodically shifted compared to the Co(III) tris(diethyldithiocarbamate) complex (Table 3). An irreversible Co(III)/Co(IV) oxidation process was observed at 750 mV for the Co(III) cryptand (**15**) (Table 3).

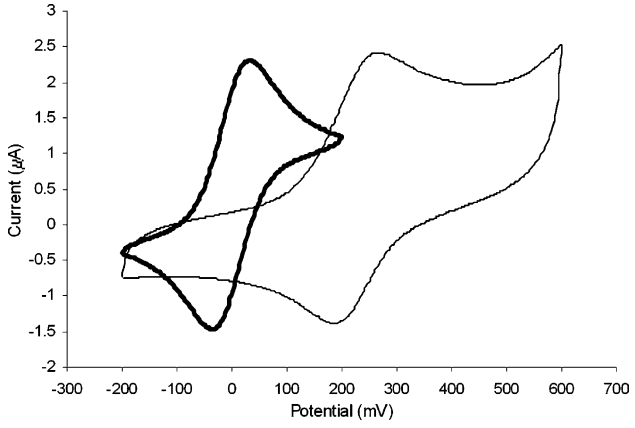

Fig. 4. Cyclic voltammogram of the Cu(II)/Cu(III) redox couple of the Cu(II) bis(diethyl dithiocarbamate) (thick line) and the Cu(II) receptor (**11b**) (fine line). (0.1 M $TBABF_4$/MeCN, 50 mV/s, vs. Ag/Ag^+).

Table 3
Electrochemical data [a]

Receptor	E_{pa} (mV)	E_{pc} (mV)	ΔE	I_{pa}/I_{pc}
Cu(II) bis(diethyl dtc) [b]	32	−36	68	1.07
5b [b]	296	222	74	1.25
11b [b]	272	180	92	1.24
12b [b]	278	166	112	1.13
Co(III) tris(diethyl dtc)	603	529	74	1.33
6 [c]	746	664	82	1.05
15 [b]	790	–	–	–

[a] Conditions: 10^{-4} M solutions of receptor in 0.1 M Bu_4NBF_4 in acetonitrile, scan rate 50 mV s^{-1}, glassy carbon working electrode, $Ag/AgNO_3$ reference electrode. Electrochemical potentials are quoted with errors of ±5 mV.
[b] Cu(II)/Cu(III) dtc redox couple.
[c] Co(III)/Co(IV) dtc redox couple.

The addition of Cl^- and $H_2PO_4^-$ anions to electrochemical solutions of the copper(II) dtc derivatives (**5b**), (**11b**) and (**12b**) resulted in significant cathodic shifts of the respective Cu(II)/Cu(III) redox couple (Table 4). The complexed anion in close proximity to the Cu(II) dtc centre stabilises the Cu(III) redox state, hence lower potentials are required for the oxidation of Cu(II) to Cu(III) [8]. Precipitation problems occurred with (**5b**) and (**6**) on addition of $H_2PO_4^-$ in acetonitrile. Table 4 shows that $H_2PO_4^-$ induced larger magnitudes of cathodic shift in the respective Cu(II)/Cu(III) dtc redox couple compared to Cl^-. This suggests a preferential binding interaction with the $H_2PO_4^-$ anion. It is noteworthy that with the Cu(II) bis(diethyldithiocarbamate) system, no anion induced redox perturbations were observed which suggests the presence of the imidazolium motif is essential for anion complexation. No detectable shifts were observed in the Co(III)/Co(IV) redox couple of the Co(III) dtc cryptand complex (**15**) on addition of anions.

With the diamagnetic transition metal dtc systems, ^1H NMR anion titration experiments were also undertaken. However, precipitation problems were always

Table 4
Electrochemical anion recognition data

Anion	$\Delta E_{1/2}$ (mV) [a]		
	5b	**11b**	**12b**
Cl^-	10	70	40
$H_2PO_4^-$	Precipitation	90	90

[a] Cathodic shifts of the Cu(II)/Cu(III) dtc oxidation potential produced by the presence of 5 equivalents of anion added as the tetrabutylammonium salt. Errors ±10 mV. Conditions: 10^{-4} M solutions of receptor in 0.1 M Bu_4NBF_4 in acetonitrile, scan rate 50 mV s^{-1}, glassy carbon working electrode, $Ag/AgNO_3$ reference electrode.

encountered which prevented the determination of stability constant values.

3. Conclusion

The synthesis of a range of potential acyclic and macrocyclic imidazolium-based anion receptors was achieved by metal directed self-assembly with the dithiocarbamate ligand. The assemblies have been characterised by ^{1}H NMR, ^{13}C NMR, UV–Vis spectroscopy, mass spectrometry and elemental analysis. Evidence for the binding of $H_2PO_4^-$ was observed in UV–Vis spectroscopy for the acyclic transition metal dithiocarbamate imidazolium receptors. In electrochemical studies, significant cathodic shifts of the respective Cu(II)/Cu(III) dtc redox couple of the acyclic and the macrocyclic receptors were observed on addition of Cl^- and $H_2PO_4^-$. Further work is in progress to improve receptor solubility and investigate the binding of a wider range of anions. In addition these systems offer the opportunity to prepare heterobimetallic complexes via *N*-heterocyclic carbene formation from the imidazolium functional groups.

4. Experimental

4.1. General details

NMR spectra were recorded on a Varian 300 MHz spectrometer. Mass spectrometry was carried out on a Micromass LCT electrospray mass spectrometer (ESMS, cone voltage = 20–50 V, desolvation temp = 80 °C, source temp = 60 °C). Elemental analysis was performed at the Inorganic Chemistry Laboratory, Oxford. Electronic spectra were recorded on a Perkin–Elmer Lambda 6 UV–Vis spectrometer. Cyclic and square wave voltammetry were performed on an EG & G Princeton Applied Research potentiostat/galvanostat model 273 linked to a PC via a National Instruments GPIB-PCII/IIA interface and controlled by EG & G Princeton Applied Research Model 270/250 Research Electrochemistry Software. A glassy carbon working electrode, Ag/Ag^+ reference electrode and platinum counter electrode were used in the instrumental setup. Tetabutylammonium tetrafluoroborate was used as the electrolyte.

4.2. Syntheses

4.2.1. Imidazole imine (**2**)

N-(3-aminopropyl)imidazole (3 g) and benzaldehyde (2.5 g) were dissolved in toluene (100 ml) and the solution was refluxed for 2 h using Dean–Stark apparatus. Toluene was removed and the yellow oil (5 g, 98% yield) was dried under vacuum.

^{1}H NMR (300 MHz, $CDCl_3$, 288 K) δ = 8.23 (s, 1H, imine), 7.71 (m, 2H, benzyl), 7.47 (s, 1H, imidazole), 7.40 (m, 3H, benzyl), 7.05 (s, 1H, imidazole), 6.92 (s, 1H, imidazole), 4.04 (t, 7.0 Hz, 2H, N–CH_2–), 3.51 (t, 7.0 Hz, 2H, –CH_2–N), 2.12 (quintet, 7.0 Hz, 2H, –CH_2–). MS (ESI positive ion, MeOH/CH_2Cl_2): *m*/*z* 214 ($M + H^+$).

4.2.2. Compound (**3**)

Compound (**2**) (0.5 g, 1 eqv.) and iodomethane (0.33 g, 1 eqv.) were dissolved in acetonitrile (50 ml) and the solution was stirred under reflux overnight. The solvent was removed and a yellow oily solid (0.5 g, 60% yield) was obtained after drying under vacuum.

^{1}H NMR (300 MHz, CD_3OD, 288 K) δ = 8.77 (s, 1H, imidazolium), 8.35 (s, 1H, imine), 7.73 (m, 2H, aromatic), 7.47 (m, 4H, aromatic), 7.37 (s, 1H, imidazolium), 4.34 (t, 6.9 Hz, 2H, N–CH_2–), 3.79 (s, 3H, CH_3), 3.63 (t, J = 6.9 Hz, 2H, –CH_2–N), 2.21 (m, 2H, CH_2). MS (ESI positive ion, MeOH): *m*/*z* 228 $[M - I^-]^+$.

4.2.3. Compound (**4**)

Compound (**3**) (0.5 g) was dissolved in methanol (50 ml) and sodium borohydride (0.2 g) was added portionwise to the stirring solution. The mixture was allowed to stir under nitrogen for 2 h and a saturated solution of ammonium hexafluorophosphate (10 ml) was added. The volume of methanol was reduced under vacuum and the resulting oil was taken up in CH_2Cl_2 (50 ml) and dried over anhydrous $MgSO_4$. A pale yellow oil (0.5 g, 95% yield) was obtained after solvent removal.

^{1}H NMR (300 MHz, CD_3OD, 288 K) δ = 8.67 (s, 1H, imidazolium), 7.29–7.45 (m, 7H, aromatic), 4.29 (t, 6.9 Hz, 2H, N–CH_2–), 3.82 (s, 5H, benzyl CH_2 and CH_3), 2.68 (t, J = 6.9 Hz, 2H, –CH_2–N), 2.09 (m, 2H, CH_2). MS (ESI positive ion, MeOH): *m*/*z* 230 $[M - PF_6^-]^+$.

4.2.4. Acyclic transition metal dtc imidazolium complexes (**5**)

Compound (**4**) (0.1 g), triethylamine (0.05 g) and carbon disulfide (0.05 g) were dissolved in acetonitrile (50 ml) and stirred for 10 min. The transition metal acetate salt (0.5 eqv.) was added to the solution and the mixture was stirred overnight. The volume of solvent was reduced and a saturated aqueous solution of ammonium hexafluorophosphate (10 ml) was added. The product was extracted with CH_2Cl_2 (50 ml) and a solid was obtained on solvent removal.

(**5a**) Ni: A pale green solid (0.1 g, 78% yield) was collected. ^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.45 (s, 2H, imidazolium), 7.29–7.43 (m, 14H, aromatic), 4.83 (s, 4H, benzyl–CH_2–), 4.14 (t, J = 7.2 Hz, 4H, N–CH_2–), 3.84 (s, 6H, CH_3), 3.57 (t, J = 7.2 Hz, 4H, –CH_2–N),

2.15 (m, 4H, –CH_2–). MS (ESI positive ion, MeCN): *m/z* 813 $[M - PF_6^-]^+$, 334 $[M - 2PF_6^-]^{2+}$. *Anal*. Calc. for $C_{30}H_{38}N_6S_4NiP_2F_{12}$: C, 37.55; H, 3.99; N, 8.76. Found: C, 37.50; H, 4.04; N, 8.70%.

(**5b**) Cu: A brown solid (0.1 g, 78% yield) was collected. MS (ESI positive ion, MeOH): *m/z* 818 $[M - PF_6^-]^+$, 373 $[M]^{2+}$. *Anal*. Calc. for $C_{30}H_{38}N_6S_4CuP_2F_{12}$: C, 37.36; H, 3.97; N, 8.71. Found: C, 36.35; H, 3.54; N, 8.63%.

(**5c**) Zn: A pale yellow solid (0.1 g, 78% yield) was collected. ^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.38 (s, 2H, imidazolium), 7.48 (s, 2H, imidazolium), 7.32–7.41 (m, 12H, aromatic), 5.12 (s, 4H, benzyl–CH_2–), 4.18 (m, 4H, N–CH_2–), 3.85 (m, 4H, –CH_2–N) 3.81 (s, 6H, CH_3), 2.27 (m, 4H, –CH_2–). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 219.5, 137.3, 136.3, 132.8, 131.4, 130.2, 129.4, 128.8, 128.6, 128.1, 125.1, 124.9, 123.5, 58.6, 53.7, 52.1, 48.2, 37.2, 28.0 ppm. MS (ESI positive ion, MeCN): *m/z* 819 $[M - PF_6^-]^+$, 337 $[M - 2PF_6^-]^{2+}$. *Anal*. Calc. for $C_{30}H_{38}N_6S_4ZnP_2F_{12}$: C, 37.29; H, 3.96; N, 8.70. Found: C, 37.02; H, 3.90; N, 8.53%.

4.2.5. Co(III) dtc imidazolium tripodal complex (6)

The same procedure was used as above except $CoCl_2$ was used as the source of cobalt. A green solid (0.1 g, 80% yield) was collected.

^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.47 (s, 1H, imidazolium), 8.42 (s, 1H, imidazolium), 8.39 (s, 1H, imidazolium), 7.31–7.41 (m, 21H, aromatic), 4.93 (m, 6H, benzyl–CH_2–), 4.20 (m, 6H, N–CH_2–), 3.81 (s, 3H, CH_3), 3.80 (s, 3H, CH_3), 3.79 (s, 3H, CH_3), 3.68 (m, 6H, –CH_2–N), 2.17 (m, 6H, –CH_2–). MS (ESI positive ion, MeCN): *m/z* 1264 $[M - PF_6^-]^+$, 559 $[M - 2PF_6^-]^{2+}$, 325 $[M - 3PF_6^-]^{3+}$. *Anal*. Calc. for $C_{45}H_{57}N_9S_6CoP_3F_{18}$: C, 38.33; H, 4.07; N, 8.94. Found: C, 38.38; H, 4.05; N, 8.94%.

4.2.6. Compound (7)

Compound (**2**) (5 g, 2 eqv.) and α,α′-dibromo-*p*-xylene (3.2 g, 1 eqv.) were dissolved in acetonitrile (100 ml) and the solution was stirred under reflux overnight. The solvent was removed and a yellow oily solid (7 g, 86% yield) was obtained after drying under vacuum.

^{1}H NMR (300 MHz, CD_3OD, 288 K) δ = 9.19 (s, 2H, imidazolium), 8.36 (s, 2H, imine), 7.72 (m, 4H, benzyl), 7.70 (m, 4H, aromatic), 7.61 (m, 4H, aromatic), 7.45 (m, 6H, benzyl), 5.38 (s, 4H, xylene–CH_2–), 4.38 (t, 6.9 Hz, 4H, N–CH_2–), 3.67 (t, 6.9 Hz, 4H, –CH_2–N), 2.28 (quintet, 6.9 Hz, 4H, –CH_2–). MS (ESI positive ion, MeOH): *m/z* 611 $[M–Br^-]^+$, 265 $[M–2Br^-]^{2+}$.

4.2.7. Compound (8)

Compound (**2**) (0.68 g, 2 eqv.) and 2,7-bis(bromomethyl)naphthalene (0.5 g, 1 eqv.) were dissolved in acetonitrile (100 ml) and the solution was stirred under reflux overnight. The solvent was removed and a yellow oily solid (1 g, 84% yield) was obtained after drying under vacuum.

^{1}H NMR (300 MHz, CD_3OD, 288 K) δ = 9.12 (s, 2H, imidazolium), 8.35 (s, 2H, imine), 7.4–8.0 (m, 20H, aromatic), 5.5–5.6 (m, 4H, xylene–CH_2–), 4.31 (t, 6.5 Hz, 4H, N–CH_2–), 2.96 (t, 6.5 Hz, 4H, –CH_2–N), 2.23 (m, 4H, –CH_2–). MS (ESI positive ion, MeOH): *m/z* 659 $[M–Br^-]^+$, 290 $[M–2Br^-]^{2+}$.

4.2.8. Compound (9)

Compound (**7**) (7 g) was dissolved in methanol (50 ml) and sodium borohydride (1 g) was added portionwise to the stirring solution. The mixture was allowed to stir under nitrogen for 2 h and a saturated solution of ammonium hexafluorophosphate (10 ml) was added. The volume of methanol was reduced under vacuum and the resulting precipitate was collected, washed with water and dried. A pale yellow solid (7 g, 84% yield) was obtained after drying.

^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.53 (s, 2H, imidazolium), 7.3–7.4 (m, 18H, aromatic), 5.29 (s, 4H, xylene–CH_2–), 4.23 (t, 7.2 Hz, 4H, N–CH_2–), 3.71 (s, 4H, benzyl–CH_2–), 2.56 (t, 7.2 Hz, 4H, –CH_2–N), 1.96 (m, 4H, –CH_2–). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 141.3, 137.0, 136.1, 130.5, 130.2, 129.6, 128.3, 124.3, 123.6, 54.2, 53.5, 48.8, 45.9, 30.2 ppm. MS (ESI positive ion, MeOH): *m/z* 679 $[M - PF_6^-]^+$, 267 $[M - 2PF_6^-]^{2+}$.

4.2.9. Compound (10)

Compound (**8**) (1 g) was dissolved in methanol (50 ml) and sodium borohydride (0.2 g) was added portionwise to the stirring solution. The mixture was allowed to stir under nitrogen for 2 h and a saturated solution of ammonium hexafluorophosphate (10 ml) was added. The volume of methanol was reduced under vacuum and the resulting precipitate was collected, washed with water and dried. A pale yellow solid (1 g, 84% yield) was obtained after drying.

^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.51 (s, 2H, imidazolium), 7.2–8.0 (m, 20H, aromatic), 5.45 (s, 4H, xylene–CH_2–), 4.25 (t, 6.6 Hz, 4H, N–CH_2–), 3.65 (s, 4H, benzyl–CH_2–), 2.53 (t, 6.6 Hz, 4H, –CH_2–N),d 1.97 (m, 4H, –CH_2–). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 142.2, 137.1, 134.3, 133.6, 130.4, 130.2, 130.3, 129.7, 129.6, 129.5, 128.8, 128.1, 124.3, 123.8, 54.4, 54.1, 49.0, 46.0, 30.5 ppm. MS (ESI positive ion, MeOH): *m/z* 729 $[M - PF_6^-]^+$, 292 $[M - 2PF_6^-]^{2+}$.

4.2.10. Macrocyclic transition metal dtc imidazolium complexes with xylene spacer (11)

Compound (**9**) (0.5 g), triethylamine (0.1 g) and carbon disulfide (0.1 g) were dissolved in acetonitrile (50 ml) and stirred for 10 min. The transition metal salt (1 eqv.) was added to the solution and the mixture was stirred overnight. The volume of solvent was reduced and a

saturated aqueous solution of ammonium hexafluorophosphate (10 ml) was added. The resulting precipitate was collected and washed with diethyl ether.

(**11a**) Ni: A pale green solid (0.6 g, 95% yield) was collected. ^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.78 (s, 2H, imidazolium), 7.3–7.5 (m, 14H, aromatic), 7.24 (s, 4H, xylene), 5.37 (s, 4H, xylene–CH_2–), 4.87 (s, benzyl–CH_2–), 4.19 (br, 4H, N–CH_2–), 3.51 (br, 4H, –CH_2–N), 2.16 (br, 4H, –CH_2–). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 208.9, 137.5, 135.8, 135.6, 130.3, 130.0, 129.7, 129.3, 125.1, 123.6, 53.5, 52.9, 47.9, 46.0, 27.9 ppm. MS (ESI positive ion, MeOH): *m/z* 887 $[M - PF_6^-]^+$, 371 $[M - 2PF_6^-]^{2+}$. *Anal.* Calc. for $C_{36}H_{40}N_6S_4NiP_2F_{12}$: C, 41.83; H, 3.90; N, 8.13. Found: C, 42.27; H, 4.01; N, 8.09%.

(**11b**) Cu: A brown solid (0.6 g, 95% yield) was collected. MS (ESI positive ion, MeOH): *m/z* 892 $[M - PF_6^-]^+$, 373 $[M - 2PF_6^-]^{2+}$. *Anal.* Calc. for $C_{36}H_{40}N_6S_4CuP_2F_{12}$: C, 41.64; H, 3.88; N, 8.09. Found: C, 41.59; H, 3.87; N, 8.27%.

(**11c**) Zn: A pale yellow solid (0.6 g, 95% yield) was collected. ^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.68 (s, 2H, imidazolium), 7.3–7.4 (br, 18H, aromatic), 5.32 (s, 4H, xylene–CH_2–), 5.12 (s, benzyl–CH_2–), 4.16 (br, 4H, N–CH_2–), 3.81 (br, 4H, –CH_2–N), 2.22 (br, 4H, –CH_2–). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 209.0, 137.5, 137.1, 135.7, 130.5, 130.1, 129.1, 128.7, 124.9, 123.5, 58.1, 53.6, 51.6, 48.4, 27.8 ppm. MS (ESI positive ion, MeOH): *m/z* 893 $[M - PF_6^-]^+$. *Anal.* Calc. for $C_{36}H_{40}N_6S_4ZnP_2F_{12}$: C, 41.56; H, 3.88; N, 8.08. Found: C, 43.80; H, 4.28; N, 8.34%.

*4.2.11. Macrocyclic transition metal dtc imidazolium complexes with naphthalene spacer (**12**)*

Compound (**10**) (0.15 g), triethylamine (0.05 g) and carbon disulfide (0.05 g) were dissolved in acetonitrile (50 ml) and stirred for 10 min. The transition metal salt (1 eqv.) was added to the solution and the mixture was stirred overnight. The volume of solvent was reduced and a saturated aqueous solution of ammonium hexafluorophosphate (10 ml) was added. The resulting precipitate was collected and washed with diethyl ether.

(**12a**) Ni: A pale green solid (0.15 g, 81% yield) was collected. ^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.56 (s, 2H, imidazolium), 7.2–8.0 (m, 20H, aromatic), 5.48 (br, 4H, naphthyl–CH_2–), 4.79 (br, benzyl–CH_2–), 4.14 (br, 4H, N–CH_2–), 3.53 (br, 4H, –CH_2–N), 2.10 (br, 4H, –CH_2–). MS (ESI positive ion, MeOH): *m/z* 937 $[M - PF_6^-]^+$, 396 $[M]^{2+}$. *Anal.* Calc. for $C_{40}H_{42}N_6S_4NiP_2F_{12}$: C, 44.33; H, 3.91; N, 7.76. Found: C, 44.25; H, 4.39; N, 7.75%.

(**12b**) Cu: A brown solid (0.15 g, 81% yield) was collected. MS (ESI positive ion, MeOH): *m/z* 942 $[M - PF_6^-]^+$, 398 $[M]^{2+}$. *Anal.* Calc. for $C_{40}H_{42}N_6S_4CuP_2F_{12}$: C, 44.14; H, 3.89; N, 7.72. Found: C, 43.87; H, 3.89; N, 8.06%.

*4.2.12. Compound (**13**)*

Compound (**2**) (0.56 g, 3 eqv.) and 1,3,5-tri(chloromethyl)-2,4,6-triethylbenzene [15] (0.3 g, 1 eqv.) were dissolved in acetonitrile (100 ml) and the solution was stirred under reflux overnight. The solvent was removed and a yellow oily solid (0.6 g, 65% yield) was obtained after drying under vacuum.

^{1}H NMR (300 MHz, CD_3OD, 288 K) δ = 9.77 (s, 3H, imidazolium), 8.24 (s, 3H, imine), 7.4–7.4 (m, 21H, aromatic), 5.36 (s, 6H, benzene–CH_2–), 4.42 (t, 7.0 Hz, 6H, N–CH_2–), 3.58 (m, 6H, –CH_2–N), 2.40 (m, 6H, benzene–CH_2–CH_3), 2.12 (m, 6H, –CH_2–), 1.06 (m, 9H, CH_3). MS (ESI positive ion, MeOH): *m/z* 910 $[M - Cl^-]^+$, 438 $[M - 2Cl^-]^{2+}$.

*4.2.13. Compound (**14**)*

Compound (**13**) (0.6 g) was dissolved in methanol (50 ml) and sodium borohydride (0.2 g) was added portionwise to the stirring solution. The mixture was allowed to stir under nitrogen for 2 h and a saturated solution of ammonium hexafluorophosphate (10 ml) was added. The volume of methanol was reduced under vacuum and the resulting precipitate was collected, washed with water and dried. A pale yellow solid (0.5 g, 62% yield) was obtained after drying.

^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 8.27 (s, 3H, imidazolium), 7.2–7.5 (m, 21H, aromatic), 5.38 (s, 6H, benzene–CH_2–), 4.23 (t, 6.6 Hz, 6H, N–CH_2–), 3.68 (s, 6H, benzyl–CH_2–N), 2.54 (m, 12H, benzene–CH_2–CH_3 and –CH_2–N), 1.12 (m, 6H, –CH_2–), 0.95 (t, 7.2 Hz, 9H, CH_3). ^{13}C NMR (300 MHz, CD_3CN, 288 K) δ = 149.5, 142.1, 136.3, 129.6, 128.1, 124.2, 123.4, 54.4, 49.1, 48.4, 46.1, 30.8, 24.6 ppm. MS (ESI positive ion, MeOH): *m/z* 1136 $[M - PF_6^-]^+$, 495 $[M - 2PF_6^-]^{2+}$.

*4.2.14. Co(III) dtc imidazolium cryptand complex (**15**)*

Compound (**14**) (0.2 g), triethylamine (0.05 g) and carbon disulfide (0.05 g) were dissolved in acetonitrile (50 ml) and stirred for 10 min. Cobalt(II) chloride (0.05 g, 1 eqv.) was added to the solution and the mixture was stirred overnight. The volume of solvent was reduced and a saturated aqueous solution of ammonium hexafluorophosphate (10 ml) was added. The resulting precipitate was collected and washed with diethyl ether. A green solid (0.2 g, 82% yield) was collected.

^{1}H NMR (300 MHz, CD_3CN, 288 K) δ = 7.32 (br, 21H, aromatic), 5.37 (br, 6H, benzene–CH_2–), 4.13 (br, 6H, N–CH_2–), 3.43 (br, 6H, benzyl–CH_2–N), 3.29 (br, 6H, –CH_2–N), 1.95 (br, 6H, –CH_2–), 1.13 (br, 9H, CH_3). MS (ESI positive ion, MeOH): *m/z* 637 $[M - 2PF_6^-]^{2+}$, 377 $[M]^{3+}$. *Anal.* Calc. for $C_{57}H_{69}N_9S_6CoP_3F_{18}$: C, 43.70; H, 4.44; N, 8.05. Found: C, 42.45; H, 4.51; N, 7.75%.

We are grateful for the extensive seminal contributions of Malcolm Green to the field of organometallic chemistry. The positive impact of both his documented productivity and his legendary personality is difficult to overestimate

Abstract

Reaction of Tp′W(O)(CO)(I) (**1**) with silver trifluoromethanesulfonate (silver triflate, AgOTf) in dichloromethane generates Tp′W(O)(CO)(OTf) (**2**) with triflate in the coordination sphere. Dissolution of neutral triflate adduct **2** in acetonitrile immediately produces the cationic tungsten(IV) nitrile complex [Tp′W(O)(NCMe)(CO)][OTf] (**3**). Exchange of the triflate anion in **3** for the large, non-coordinating tetrakis[3,5-bis(trifluoromethyl)phenyl]borate anion, $[BAr'_4]^-$, produces the isolable salt [Tp′W(O)(NCMe)(CO)][BAr'_4] (**4**). Photolysis of Tp′W(O)(CO)(I) complex (**1**) in acetonitrile promotes loss of carbon monoxide and generates the neutral tungsten(IV) nitrile complex Tp′W(O)(I)(NCMe) (**5**). Spectroscopic data for **5** is consistent with formation of an η^2-bound nitrile ligand. Chromatography of complex **5** on alumina led to oxidation to form an acylimido complex, Tp′W(O)(I)(NC(O)Me) (**6**). A dimeric complex, Tp′(O)(I)W(NC(Me)C(Me)N)W(I)(O)Tp′ (**7**) resulting from reductive coupling of two nitrile ligands was also isolated following alumina chromatography. Methylation of η^2-nitrile complex **5** by MeOTf generates the cationic η^2-iminoacyl complex [Tp′W(O)(I)(MeNCMe)][OTf] (**9**).

1. Introduction

Transition metal nitrile complexes are ubiquitous in organometallic chemistry as versatile precursors for a variety of chemical transformations [1]. Additionally, functionalization of nitrile substrates is a valuable route to nitrogen containing compounds. Activation of an organonitrile molecule by coordination to a metal center is one method for promoting chemical elaboration of nitrile substrates [2]. Stepwise reduction of acetonitrile bound to a metal center is representative of the reaction sequences accessible beginning with coordinated nitrile ligands [3]. Upon coordination to a chiral tungsten metal center, acetonitrile may be systematically reduced by alternate addition of hydride anions and protons to the nitrile ligand to generate intermediates including azavinylidene and imine complexes. Addition to imine ligands has been shown to be stereoselective in multiple cases [4]. The synthesis of chiral amines from nitrile reagents is of widespread importance in organic chemistry [5].

The vast majority of transition metal nitrile complexes display simple σ-coordination of the nitrile ligand to the metal through the nitrogen lone pair [1], but a

doi:10.1016/j.poly.2004.09.008

number of complexes exhibiting η^2-coordination of nitrile ligands are also known. Although rare compared to σ-coordination, binding of the nitrile through the N≡C triple bond, in an η^2-coordination, is well established [6–11,15].

When bound to a metal center through the C≡N triple bond, a nitrile ligand may act as both a π-acid ligand and as a π-base ligand in analogy to alkyne ligands [12]. One of the C≡N triple bond π-orbitals may donate electron density into a metal dπ orbital while a perpendicular C≡Nπ* orbital may accept electron density from a different metal dπ orbital [13].

Several insightful early reports identifying η^2-nitrile complexes were based on infrared spectroscopy. While σ-coordination of a nitrile ligand usually causes the frequency of ν(NC) to increase slightly relative to the free ligand [1], upon η^2-coordination to a metal the ν(NC) stretching frequency drops to dramatically lower wavenumbers. A common complication, however, is that the infrared absorption coefficient of η^2-bound nitrile ligands is often small, and frequently the ν(NC) stretch cannot be observed and identified unambiguously in the IR spectrum [7e].

In addition to IR spectroscopy, NMR spectroscopy can help distinguish between nitrile coordination modes. In the ^{1}H NMR spectrum, methyl singlets for σ-bound acetonitrile have typically been observed in the 2–3 ppm range; recall that the signal for the free acetonitrile appears at δ 1.94 ppm. For η^2-bound acetonitrile the methyl resonances may be shifted further downfield, by roughly one or two ppm, so that proton NMR signals for the nitrile methyl group of η^2–acetonitrile complexes are commonly observed between 3 and 4 ppm [6–11]. A nice example is provided by the two isomeric $[MoCl(NCMe)(dmpe)_2]^+$ complexes reported by Wilkinson and co-workers [7e], where the nitrile methyl signal was observed at 2.10 ppm for σ-coordination while the η^2-coordination mode produced a methyl resonance at 3.20 ppm. Because the ranges for σ- and η^2-coordination can overlap significantly in some cases, interpretation of the ^{1}H NMR chemical shift for nitrile ligands should be considered as indicative rather than as definitive. A recent well documented η^2–acetonitrile complex of nickel exhibits a methyl signal at 2.42 ppm, so no simple line of demarcation is provided by ^{1}H NMR spectroscopy [15a]. Supplemental characterization, such as by ^{13}C NMR, is generally required for decisive assignment of nitrile coordination modes.

For transition metal alkyne complexes the ^{13}C NMR chemicals shifts of the coordinated carbons have been used to assess the extent of electron donation from alkyne ligands [12]. Analogous to this technique, ^{13}C NMR spectroscopy may be used to discern nitrile coordination modes and electronic structure in nitrile complexes. In 1991, Green et al. [6c] exploited the utility of ^{13}C NMR spectroscopy for the detection of η^2-nitrile ligands. In complexes with σ-bound nitrile ligands the nitrile carbon resonates in the range of 120–150 ppm. In contrast, complexes possessing η^2-nitrile ligands that act as formal two-electron donors have ^{13}C shifts between δ 160 and 180 [6,7]. Here again the nickel system provides an example near the overlap region in that the nitrile carbon of (dippe)-Ni(η^2-CH_3CN) resonates at 160 ppm, not far from the sigma bond range [15a].

Akin to alkyne ligands, η^2-nitrile ligands may serve as variable electron donors (2–4 electrons). A number of tungsten complexes are known in which the nitrile ligand acts as a formal four-electron donor, and the nitrile carbons in these complexes resonate between 230 and 240 ppm [8–10]. More recently, Etienne [11] has reported η^2-nitrile complexes of niobium in which the η^2-nitrile acts as a formal three-electron donor ligand. Carbon-13 chemical shifts for these three-electron donor ligands are between 175 and 185 ppm [11].

X-ray crystallography remains the definitive characterization technique for identifying η^2-nitrile complexes [7–10,15]. X-ray characterization of $(Cp)_2$ Mo(NCMe) in 1986 showed η^2-coordination of the nitrile moiety in which the nitrile methyl group was bent away from the metal center at an angle of 138° relative to the C≡N bond [7g]. The R–C≡N moiety in this structure resembles the R–C≡C fragments found in η^2-alkyne complexes [12]. Other η^2-nitrile structures display this same type of bent nitrile ligand geometry [7–10,15].

Relatively little is known about the chemistry of transition metal η^2-nitrile complexes. In recent years they have been utilized in the investigation of C–C bond cleavage reactions. Parkin and co-workers [14] formed molybdenum methyl cyanide products from acetonitrile and ansa-molybdenocene reagents. In a particularly complete study, Garcia and Jones [15] have reported equilibria between an η^2-nitrile nickel(0) complex, (dippe)Ni(η^2-ArCN), and a C–C bond cleavage product containing a Ni(Ar)(CN) fragment. Transition metal η^2-nitrile complexes have been suggested as possible intermediates in other C–C bond [16] and C–H bond activation reactions [17].

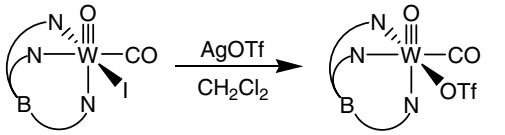
This paper reports the synthesis and spectroscopic characterization of W(IV) acetonitrile complexes. The acetonitrile ligand in one of these complexes, believed to be η^2-coordinated, is capable of adding oxygen, undergoing reductive C–C bond formation, or serving as a nucleophile toward methyl triflate.

2. Results and discussion

2.1. A cationic tungsten(IV) nitrile complex

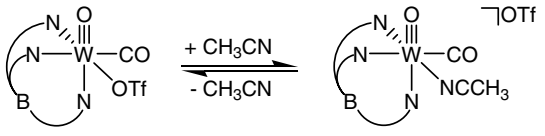
Reaction of purple Tp′W(O)(CO)(I) (**1**) with 1 equiv. of AgOTf in methylene chloride over 1 h generates a red

solution containing the triflate complex Tp′W(O)(CO)(OTf) (**2**) (Eq. (1)). Associated with this reaction is a small shift of the carbonyl stretching frequency from ν(CO) = 1991 cm^{-1} for the starting material to ν(CO) = 1996 cm^{-1}. The ^1H NMR displays three methine and six methyl signals consistent with Tp′ bound to a chiral metal center. The ^{19}F NMR shows a singlet for the triflate CF_3 group at −77.1 ppm. The carbonyl carbon and trifluoromethyl carbon appear at 271.4 and 119.6 ppm ($^1J_{CF}$ = 320 Hz), respectively. Under aerobic conditions complex **2** decomposes rapidly in solution, while it decomposes slowly, over a period of days, in the solid state. Under an inert atmosphere the complex is stable in the solid state for weeks. Efforts to purify the triflate complex by chromatography led to decomposition.



1 **2** (1)

Triflate complex **2** reacts cleanly with acetonitrile. Room temperature dissolution of the red triflate complex **2** in acetonitrile results in a deep purple solution of the cationic nitrile complex [Tp′W(O)(CO)(NCMe)][OTf] (**3**) (Eq. (2)). The IR spectrum of this solution shows a shift of the CO stretching frequency from 1996 cm^{-1} in the starting material to 2023 cm^{-1} in the product, consistent with formation of a cationic complex. The ^1H NMR of the solution shows signals typical of a Tp′ ligand in a chiral environment and an additional methyl signal for acetonitrile at 3.23 ppm.



2 **3** (2)

Isolation of this cationic complex has proven difficult. Either removal of solvent by vacuum evaporation or attempts to induce precipitation with non-polar solvents results in regeneration of the precursor triflate complex **2**. Replacement of the triflate anion with a larger and less nucleophilic anion might allow isolation of the cationic complex and allow comparison with independently synthesized [Tp′W(O)(CO)(NCMe)][BAr'_4] [18] prepared by acidification of Tp′W(O)(CO)(Me) in acetonitrile. Indeed, metathesis of the triflate counterion by the large, non-coordinating anion tetrakis-[3,5-bis(trifluoromethyl)phenyl]borate, [BAr'_4]$^-$, yields the readily isolable salt [Tp′W(O)(CO)(NCMe)]-[BAr'_4] (**4**) (Eq. (3)). The IR spectrum of **4** also shows the CO stretching frequency at 2023 cm^{-1}. Proton NMR characterization of **4** immediately after synthesis shows a signal for the nitrile methyl group at 3.07 ppm.

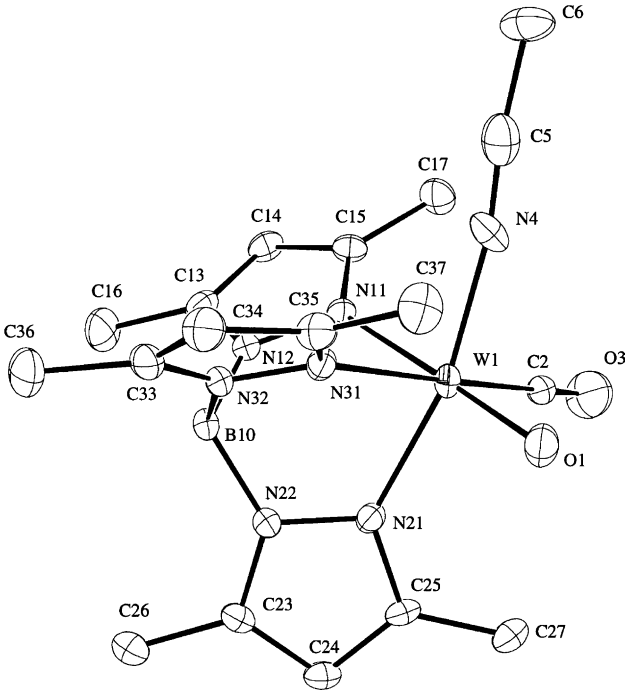

Fig. 1. ORTEP diagram of $[Tp'W(O)(CO)(NCMe)]^+$ (**4**).

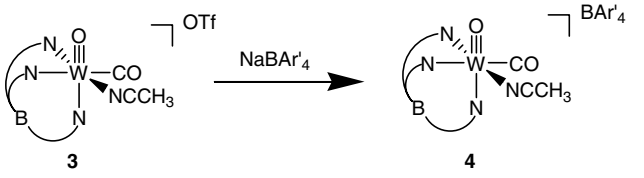


(3)

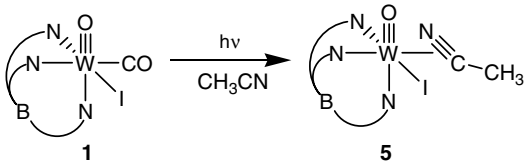
Crystals suitable for X-ray structural characterization (see Table 1) were grown by diffusion of pentane into a concentrated methylene chloride solution of **4** (Fig. 1). [1] In the solid state structure of **4** the nitrile ligand is coordinated to the tungsten metal center in an σ-fashion, with a nearly linear acetonitrile N(4)–C(5)–C(6) skeleton (173.9°). The W(1)–N(4) and N(4)–C(5) bond lengths are 2.017 and 1.197 Å, respectively (see Table 2). The ^{13}C NMR spectrum of the crystals of **4** show the nitrile carbon at 153.5 ppm. This value is near the border at the low end of the chemical shift range typical of simple nitrile σ-donor ligands, but it is nonetheless consistent with the presence of a σ-bound nitrile ligand, and likewise for the proton signal at 3.07 ppm. Thus for the cationic W(IV) complex only σ-bound acetonitrile has been observed. Replacement of the acetonitrile ligand in **4** by other neutral ligands has not been observed.

2.2. Neutral nitrile complexes

Photolysis of purple-pink W(IV) reagent **1** in acetonitrile for 3 h results in the formation of a dark orange solution that shows no terminal carbonyl absorbances in the IR spectrum. Photolytic excitation, loss of the CO ligand, and subsequent coordination of acetonitrile would yield the neutral tungsten complex, Tp′W(O)(I)(NCMe) (**5**) (Eq. (4)). The ^1H NMR of the orange reaction product shows signals indicative of Tp′ bound to a chiral metal center and an additional signal at 3.85 ppm for a nitrile methyl group (cf. 3.07 ppm for cationic nitrile complex **4**). In the ^{13}C NMR spectrum the nitrile carbon resonates downfield at 184.8 ppm (cf. 153 ppm for cationic nitrile complex **4**). The downfield shift of both the methyl group in the ^1H NMR spectrum and the nitrile carbon in the ^{13}C NMR spectrum point toward η^2-coordination of the acetonitrile.

Table 2
Selected bond distances and angles for $[Tp'W(O)(CO)(NCMe)][BAr'_4]$ (**4**)

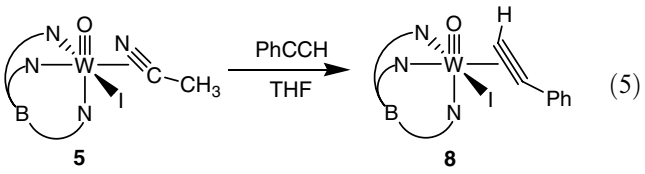
Bond distances			
W(1)–O(1)	1.781(4)	W(1)–N(4)	2.017(5)
W(1)–C(2)	2.080(6)	N(4)–C(5)	1.197(10)
C(2)–O(3)	1.067(8)	C(5)–C(6)	1.497(10)
W(1)–N(11)	2.220(4)	W(1)–N(31)	2.145(4)
W(1)–N(21)	2.158(4)		
Bond angles			
O(1)–W(1)–C(2)	91.35(20)	C(2)–W(1)–N(4)	93.64(21)
O(1)–W(1)–N(4)	96.31(19)	N(4)–C(5)–C(6)	173.9(7)



(4)

Reaction chemistry of η^2-nitrile complexes has not yet been extensively probed. As mentioned above, removal of acetonitrile from cationic complex **4** is not easily accomplished. Removal of the nitrile ligand in neutral nitrile complex **5**, however, is facile. Spectroscopic observation of protio-acetonitrile complex **5** in CD_3CN at room temperature reveals slow exchange of the unlabeled nitrile for the deuterated nitrile. In a related W(II) system reported by Young, phenylacetylene displaced acetonitrile in Tp′W(I)(CO)(MeCN) [9a]. For the tungsten(IV) oxo complex **5**, the nitrile ligand may be replaced by phenylacetylene in refluxing THF to give the complementary alkyne complex Tp′W(O)(I)(PhCCH) (**8**) (Eq. (5)). The ^1H NMR spectrum of the reaction mixture, with signature signals for terminal alkyne ligands at 12.3 and 11.0 ppm, shows a 1:1.5 ratio of isomers of complex **8**. These two isomers,related by alkyne rotation, can be separated by column chromatography. Refluxing a single isomer in toluene for two days shows no appreciable conversion to the other isomer, indicating that the barrier to alkyne rotation is >30 kcal/mol. Note that the barrier to alkyne rotation reported for the analogous propyne complex, Tp′W(O)(I)(MeCCH), was 25 kcal/mol [24].

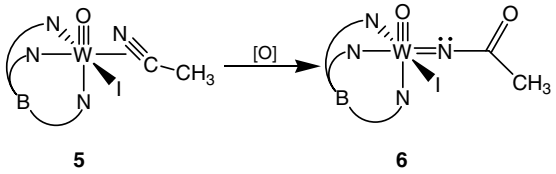
[1] The crystal structure contains the $[BAr'_4]$ anion and disordered pentane with 50% occupancy.



(5)

2.3. Oxidation

Attempts to purify neutral nitrile complex **5** by column chromatography were unsuccessful. However, one red band collected during chromatography on alumina showed signals for a new Tp′ tungsten complex as well as an additional methyl signal intermingled among the Tp′ methyl signals. Crystals of the red complex were grown (see Table 3), and an X-ray structure was obtained (Fig. 2) which identified the unknown complex as the acylimido complex Tp′W(O)(I)(NC(O)Me) (**6**) (Eq. (6)). Since complex **5** does not react with water or alumina under anaerobic conditions, acylimido complex **6** may result from the reaction of **5** with oxygen. The product reflects net addition of a single oxygen atom to the nitrile carbon atom of reagent **5**.



(6)

Young and co-workers [19] previously isolated an acylimido complex of tungsten(IV) which formed via oxidation of coordinated nitrile. Treatment of Tp′W(CO)(I)(η^2-NCMe) with pyridine N-oxide resulted in oxygen atom transfer to the nitrile carbon to form Tp′W(CO)(I)(NC(O)Me) [19]. A similar TpW(CO)(Cl)(NC(O)Me) acylimido tungsten(IV) complex formed by acylation of a terminal nitride ligand has also been reported [20]. Note that the Tp′W(O)(I)(NC(O)Me) product (**6**) formed here is a tungsten(VI) d^0 complex with an oxo ligand in place of the carbonyl ligand present in the acylimido complex prepared by Young [19]. Spectral similarity between some η^2-nitrile ligands and the acylimido fragment in [W=NC(O)CH_3] in both ^{1}H (CH_3 signal around 3–4 ppm) and ^{13}C (acyl C-13 signal around 170–190 ppm) NMR spectra requires caution in differentiating the two ligands.

Table 3

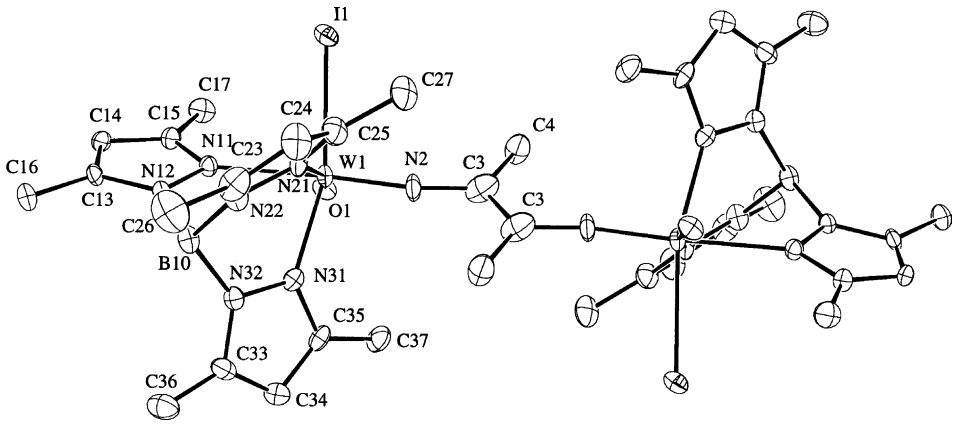

Fig. 3. ORTEP diagram of Tp′(O)(I)W(NC(Me)C(Me)N)W(I)(O)Tp′(**7**).

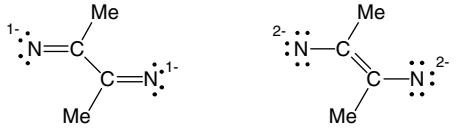
2.4. Reductive coupling

In addition to the acylimido complex formed during chromatography of neutral complex **5** on alumina, a second complex was identified from the chromatographed reaction mixture by X-ray characterization. This second complex was identified as the tungsten dimer Tp′(O)(I)W(NC(Me)C(Me)N)W(I)(O)Tp′ (**7**) (Fig. 3). [2] Reductive coupling of nitrile ligands has been observed in a number of complexes [21–23]. Dimerization of nitrile complexes can yield a bridging $[NC(Me)]_2$ ligand that has two possible formulations, either [*anti*-butane-2,3-diimino]$^{2-}$, or [(*E*)-butene-2,3-diimido]$^{4-}$ (Fig. 4). The two ligand formulations differ by two electrons and as such are not related by resonance structures. Four-electron reduction to form an enediimido tetraanion linkage from two acetonitrile ligands has been observed more often [22], but there are several examples in the literature of diiminato dianion bridges resulting from two electron reductive coupling of acetonitrile [21,23].

In dinuclear complex **7**, the W(1)–N(2) bond length of 1.791 Å is much shorter than typical W–N single bonds to the Tp′ ligand (2.1–2.3 Å) (Table 4) and is indicative of multiple W–N bond character. The N(2)–C(3) bond length was found to be 1.365(16) Å while the newly formed C(3)–C(3) bond is 1.37(3) Å in length. Based on these bond lengths and compatibility with a W(VI) d^0 formulation, the bridging ligand in **7** is best described as adopting an [(*E*)-butene-2,3-diimido]$^{4-}$ configuration, i.e. a four-electron reductive coupling product.

2.5. Methylation

Addition of 1 equiv. of MeOTf to a methylene chloride solution of neutral nitrile complex **5** generates the cationic iminoacyl complex, [TpW(O)(I)(MeNC-Me)][OTf] (**9**) (Eq. (7)). Complex **9** exists as two isomers in approximately a 5:1 ratio. The major isomer of **9** shows signals for the iminoacyl methyl groups at 4.31 and 3.88 ppm. Two-dimensional NMR spectroscopy indicates that the signal at 4.31 ppm is due to the methyl group bound to the nitrogen while the 3.88 ppm signal is assigned to the methyl group bound to the carbon. In the ^{13}C NMR spectrum, the iminoacyl carbon is observed at 210.6 ppm. The minor isomer of **9** shows the methyl bound to the nitrogen shifted downfield to 4.92 ppm and the methyl group bound to the acyl carbon is shifted upfield to 3.13 ppm.



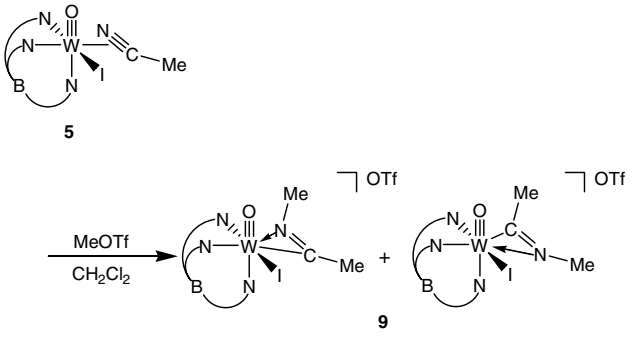
[*anti*-butane-2,3-diimino]$^{2-}$ [(*E*)-butene-2,3-diimido]$^{4-}$

Fig. 4. Possible dimeric configurations for reductive coupling of acetonitrile.

Table 4
Selected bond distances and angles for Tp′(O)(I)W(NC(Me)C-(Me)CN)W(I)(O)Tp′ (**7**)

Bond distances			
W(1)–O(1)	1.763(9)	W(1)–N(2)	1.791(8)
W(1)–I(1)	2.7283(8)	N(2)–C(3)	1.365(16)
W(1)–N(11)	2.292(7)	C(3)–C(4)	1.527(17)
W(1)–N(21)	2.290(8)	C(3)–C(3′)	1.37(3)
W(1)–N(31)	2.150(7)		
Bond angles			
O(1)–W(1)–I(1)	97.7(3)	N(2)–C(3)–C(4)	120.4(11)
O(1)–W(1)–N(2)	101.5(5)	N(2)–C(3)–C(3′)	118.2(12)
N(2)–W(1)–I(1)	99.3(4)	W(1)–N(2)–C(3)	166.1(8)
C(4)–C(3)–C(3′)	121.4(12)		
Torsion angles			
W(1)–N(2)–C(3)–C(4)	172.6(8)		

[2] There is a slight disorder (~10%) in which I(1) and O(1) are reversed. This has been modeled as I(1) 90% occupancy, O(1a) 10% occupancy and O(1) 90% occupancy, I(1a) 10% occupancy.



(7)

The iminoacyl ligand is isoelectronic with an alkyne ligand and will coordinate to the d^2 metal center such that the plane of the iminoacyl ligand is perpendicular to the W=O bond (Fig. 5). When bound to the Tp′W(O) fragment the iminoacyl ligand can accept electron density into a C=N π*-orbital from the occupied d_{xy} orbital while donating electron density into the unoccupied d_{xz} orbital from a C≡N π-orbital. In this configuration, perpendicular to the W=O bond, one of the methyl groups of the iminoacyl ligand is placed between two of the pyrazole rings and consequently would experience an upfield shift in the ^{1}H NMR spectrum. Presumably, the major isomer of **9** has the nitrogen methyl group positioned between two of the Tp′ pyrazole rings.

Iminoacyl ligands have been observed in a number of organometallic complexes. Typically these complexes are formed either through the insertion of an isocyanide ligand into a metal–alkyl bond or via electrophilic attack of an alkylating reagent on an isocyanide ligand [25]. The reaction of methyl triflate with an η^2-nitrile reported here is analogous to Parkin's report of methylation of the nitrogen of a π-bound nitrile ligand in the reaction of $(Cp^{t\text{-}Bu})_2Mo(NCMe)$ with MeI to generate the iminoacyl complex $[(Cp^{t\text{-}Bu})_2Mo(MeNCMe)][I]$ [26]. Addition of a proton to an η^2-nitrile three-electron donor ligand was postulated by Etienne as the first step along the route to a metallacyclic product reflecting coupling of the intermediate iminoacyl with an adjacent alkyne ligand [11b].

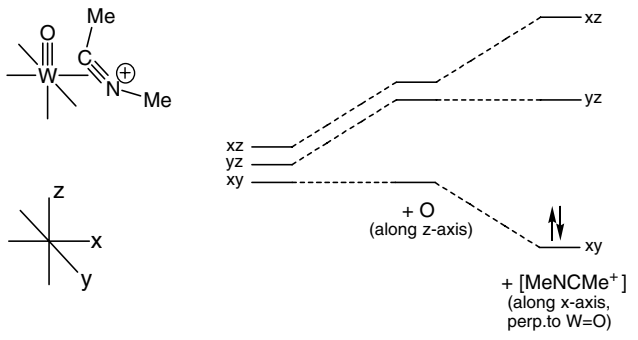


Fig. 5. Qualitative molecular orbital interactions in [Tp′W(O)(I)-(MeNCMe)][OTf] (**9**).

Iminoacyl complex **9** could result either by initial methylation at the metal center to give $[Tp(O)(I)W(Me)(NCMe)]^+$ and subsequent rearrangement to form iminoacyl complex **9** or, more likely, by direct electrophilic attack of the $[Me^+]$ reagent at the nitrile nitrogen. When a nitrile ligand is coordinated in a σ-fashion the nitrogen lone pair is bound to the metal center, and the nitrile carbon is activated towards nucleophilic addition. Less common, but now well established, is electrophilic attack [27] at the nitrile carbon of a σ-bound nitrile ligand. In contrast, when a nitrile ligand is bound in an η^2-fashion the nitrogen lone pair is accessible, and electrophilic attack of the $[Me^+]$ reagent can be easily envisioned.

3. Conclusion

The cationic tungsten(IV) acetonitrile complex $[Tp'W(O)(CO)(NCMe)]^+$ exhibits a σ-bound nitrile ligand and is representative of this large class of transition metal nitrile complexes. In contrast, the neutral tungsten(IV) acetonitrile complex Tp′W(O)(I)(NCMe) exhibits downfield shifts of both the ^{1}H and ^{13}C NMR signals for the acetonitrile ligand which may be indicative of an η^2-bound ligand. Slow displacement of the η^2-nitrile ligand in **5** has been observed with both CD_3CN and phenylacetylene, but more importantly, chromatography of **5** on alumina led to the acylimido complex Tp′W(O)(I)(NC(O)Me) (**6**) and Tp′(O)(I)WNC(Me)C(Me)NW(I)(O)Tp′ (**7**). Additionally, methylation of the nitrile ligand of **5** was accomplished with MeOTf to form the iminoacyl complex [Tp′W(O)(I)(MeNCMe)][OTf] (**9**). The array of reactions reported here suggests that η^2-nitrile ligands will exhibit a rich chemistry not accessible with σ-bound nitrile ligands.

4. Experimental

Reactions were performed under a dry nitrogen atmosphere using standard Schlenk techniques. Hexanes, methylene chloride, and pentane were purified by passage through an activated alumina column under a dry argon atmosphere. Tetrahydrofuran (THF) was distilled from sodium benzophenone ketyl under a dry nitrogen atmosphere. Deuterated solvents were dried using CaH_2 or sodium benzophenone ketyl and deoxygenated using standard freeze–pump–thaw techniques. Acetonitrile was distilled from CaH_2 and stored over 4 Å molecular sieves.

Syntheses of Tp′W(O)(CO)(I) [28] (**1**) and $[Tp'W(O)(CO)(NCMe)][BAr'_4]$ (**4**) [18] have been previously reported. Silver trifluoromethanesulfonate (AgOTf) was obtained and used directly as received

from Aldrich Chemical Company. Sodium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate, ($NaBAr'_4$), was prepared according to literature methods [29].

^1H NMR, ^{13}C NMR, and 2D NMR spectra were recorded on Bruker AMX300, DRX400, AMX400 and Avance500 spectrometers. Infrared spectra were recorded on an ASI Applied Systems ReactIR 1000 FT-IR spectrophotometer. Chemical analyses were performed by Atlantic Microlabs of Norcross, GA.

4.1. Tp′W(O)(CO)(OTf) (2)

In a 100 mL round-bottom flask, Tp′W(O)(CO)(I) (**1**) (0.203 g, 0.311 mmol) was dissolved in 25 mL of methylene chloride. This solution was cannulated into a separate 100 mL round-bottom flask containing AgOTf (0.080 g, 0.311 mmol) stirring in 15 mL methylene chloride. An immediate color change from purple-pink to a red-maroon was accompanied by concomitant precipitation of gray salts. The solution was allowed to stir for 2 h and was cannula filtered to a new flask, leaving behind the gray precipitate. Solvent was removed to yield a dark maroon solid. Yield 0.173 g (83%). IR (CH_2Cl_2): ν(BH) 2308 cm^{-1}, ν(CO) 2001 cm^{-1}, ν(CN) 1544 cm^{-1}. ^1H NMR (CD_2Cl_2): δ 6.19, 6.11, 5.74 (Tp′C*H*), 2.67, 2.54, 2.50, 2.50, 2.29, 2.21 (Tp′CH_3). ^{13}C NMR (CD_2Cl_2): δ 271.4 ($^1J_{WC}$ not observed, *C*O), 154.7, 153.6, 153.3, 148.5, 148.4, 147.4 (Tp′*C*CH_3), 119.7 (q, $^1J_{CF}$ = 320 Hz, O_3SCF_3), 109.0, 108.2, 108.0 (Tp′*C*H), 16.2, 14.7, 14.2, 13.0, 12.7, 11.2 (Tp′*C*H_3). *Anal.* Calc.: C, 30.29; H, 3.29; N, 12.47. Found: C, 30.49; H, 3.47; N, 12.13%.

4.2. [Tp′W(O)(CO)(NCMe)][OTf] (3)

In a 100 mL round-bottom flask, **2** (0.030 g, 0.050 mmol) was dissolved in 15 mL of CH_3CN. The solution immediately became a deep purple color. Removal of the solvent yielded a solid of mixed deep purple and maroon solids. NMR spectroscopy displayed a mixture of **3** and starting material **2**. ^1H NMR (CD_2Cl_2): δ 6.28, 6.19, 5.87 (Tp′C*H*), 3.23 (NCCH_3), 2.76, 2.54, 2.53, 2.49, 2.31, 2.26 (Tp′CH_3).

4.3. NMR observation of (3)

In an NMR tube, triflate complex **2** (0.014 g, 0.021 mmol) was dissolved in 0.7 mL CD_2Cl_2. Acetonitrile (0.005 mL, 5 equiv.) was added via a 10 μL syringe. The tube was shaken to mix the contents. Over a period of 24 h NMR signals for nitrile complex **3** slowly grew with concomitant disappearance of **2**.

4.4. [Tp′W(O)(CO)(NCMe)][BAr′4] (4)

In a 100 mL round-bottom flask, triflate complex **2** (0.121 g, 0.179 mmol) and $NaBAr'_4$ (0.159 g, 0.179 mmol) were dissolved in 15 mL of CH_3CN. The solution immediately became a deep purple color. Cannula filtration of the solution to a new flask and solvent removal yielded a deep purple solid. IR (KBr): ν(CO) 2026 cm^{-1}, ν(CN) 1544 cm^{-1}, ν(WO) 965 cm^{-1}. ^1H NMR (CD_2Cl_2): δ 7.74 (*o*-Ar′), 7.58 (*p*-Ar′) 6.24, 6.18, 5.82 (Tp′C*H*), 3.07 (CH_3CN), 2.64, 2.53, 2.50, 2.48, 2.28, 2.21 (Tp′CH_3). ^{13}C NMR (CD_2Cl_2): δ 248.1 ($^1J_{WC}$ = 190 Hz, *C*O), 162.1 (q, $^1J_{BC}$ = 50 Hz, *ipso* of BAr'_4), 153.5 (CH_3*C*N), 154.0, 152.8, 152.3, 149.4, 149.4, 149.1 (Tp′*C*CH_3), 135.2 (*o*-C of BAr'_4), 129.3 (q, $^2J_{CF}$ = 30 Hz, *m*-C of BAr'_4), 125.0 (q, $^1J_{CF}$ = 270 Hz, *C*F_3), 117.9 (*p*-C of BAr'_4), 109.3, 108.9, 108.8 (Tp′*C*H), 16.3, 15.2, 14.8, 13.0, 12.5, 12.5 (Tp′*C*H_3), 4.9 (*C*H_3CN).

4.5. Tp′W(O)(I)(NCCH3) (5)

In a 100 mL Schlenk tube, **1** (0.450 g, 0.690 mmol) was dissolved in 50 mL of CH_3CN. The purple-pink solution was photolyzed under bubbling nitrogen for 3 h to give a dark orange solution. Solvent was removed to yield an oily dark orange solid. The solid was re-dissolved in 5 mL methylene chloride and mixed with 50 mL hexanes. The orange solution was cannula filtered to remove any insoluble species and solvent was removed to yield a dark orange powder. Yield 0.327 g (71%). ^1H NMR (CD_2Cl_2): δ 6.17, 6.07, 5.61 (Tp′C*H*), 3.87 (CH_3CN), 2.80, 2.52, 2.45, 2.43, 2.30, 1.89 (Tp′CH_3). ^{13}C NMR (CD_2Cl_2) δ 278.6 (*C*O), 184.8 (N*C*CH_3), 155.4, 154.4, 152.5, 146.4, 145.6, 144.6 (Tp′*C*CH_3), 109.1, 108.7, 108.0 (Tp′*C*H), 27.0 (NC*C*H_3), 19.0, 15.9, 15.0, 13.0, 12.8, 12.5 (Tp′C_3).

4.6. Tp′W(O)(I)(NC(O)Me) (6) and Tp′(O)(I)W=NC(CH3)C(CH3)N=W(I)(O)Tp′ (7)

Complex **5** was synthesized as above. Column chromatography of the photolysis reaction product with alumina and CH_2Cl_2/hexanes (25/75) left a deep red band on the column. Addition of ca. 5 mL of THF to 100 mL of the eluent solution removed a red band from the column. Removal of the solvent yields a red powder. Crystals of **6** and **7** suitable for X-ray analysis were grown by diffusion of hexanes into a concentrated methylene chloride solution. **6**:^1H NMR (CD_2Cl_2): δ 6.02, 5.99, 5.88 (Tp′C*H*), 2.78, 2.61, 2.50, 2.50, 2.44, 2.39, 2.38 (Tp′CH_3 and NC(O)CH_3).

4.7. Tp′W(O)(I)(PhCCH) (8)

In a 100 mL round-bottomed flask **5** (0.048 g, 0.070 mmol) was dissolved in 40 mL dry THF. Phenylacetylene (0.079 mL, 10 equiv.) was syringed into the flask and the solution was stirred. The solution was refluxed for 19 h. Solvent was removed to yield a purple solid containing both isomers of **8**. ^1H NMR (CD_2Cl_2): δ

(major) 12.30 ($^2J_{WH}$ = 12 Hz, PhCC*H*), 7.16, 6.48 (m, 5H, *Ph*CCH), 6.11, 5.85, 5.57 (Tp′C*H*), 2.87, 2.49, 2.49, 2.39, 1.79, 1.78 (Tp′CH_3). δ (minor) 11.03 ($^2J_{WH}$ = 12.5 Hz, PhCC*H*), 7.93, 7.59, 7.42 (m, 5H, *Ph*CCH), 6.11, 6.10, 5.62 (Tp′C*H*), 2.87, 2.49, 2.47, 2.33, 2.30, 1.90 (Tp′CH_3). ^{13}C NMR (CD_2Cl_2): δ (major) 162.3 (Ph*C*CH), 157.4 155.7, 154.4, 152.7, 146.1, 145.8, 144.2 (Tp′*C*CH_3 and PhC*C*H), 136.7, 130.6, 129.0, 128.7 (*Ph*CCH), 108.9, 108.7, 108.0 (Tp′*C*H), 19.0, 15.8, 15.7, 13.0, 12.9, 12.6 (Tp′*C*H_3). δ (minor) 173.0 (Ph*C*CH), 155.0, 154.6, 153.5, 152.7, 145.6, 145.5, 144.2 (Tp′*C*CH_3 and PhC*C*H), 138.7, 134.4, 129.7, 128.3 (*Ph*CCH), 108.7, 108.6, 107.6 (Tp′*C*H), 16.6, 15.8, 14.1, 12.9, 12.8, 12.4 (Tp′*C*H_3).

4.8. [Tp′W(O)(I)(MeNCMe)][OTf] (9)

In a 100 mL round-bottom flask **5** (0.200 g, 0.307 mmol) was dissolved in 20 mL methylene chloride. To this orange solution was added MeOTf (0.035 μL, 0.307 mmol). No observable color change was observed. After 2 h, 60 mL of hexanes was added to the solution. The flask was chilled to 0 °C and stirred for 1 h forming a light brown precipitate on the sides of the flask. The solution was cannula filtered to a new flask leaving behind solid **9**. ^{1}H NMR (CD_2Cl_2): δ (major) 6.27, 6.25, 5.79 (TpC*H*), 4.31 (CH_3NCCH$_3$), 3.88 (CH$_3$NCCH_3), 2.77, 2.49, 2.48, 2.36, 2.35, 1.83 (Tp′CH_3). δ (minor) 6.24, 6.24, 5.80 (Tp′C*H*), 4.92 (CH_3NCCH$_3$), 3.13 (CH$_3$NCCH_3), 2.84, 2.48, 2.46, 2.36, 2.32, 1.87 (Tp′CH_3). ^{13}C NMR (CD_2Cl_2): δ 210.6 (CH$_3$N*C*CH$_3$), 157.4, 154.2, 153.0, 148.8, 148.8, 146.7 (Tp′*C*CH_3), 110.2, 110.0, 109.6 (Tp′*C*H), 39.5 (CH$_3$NC*C*H$_3$), 23.0 (*C*H$_3$NCCH$_3$), 19.5, 15.8, 15.5, 13.9, 13.0, 12.6 (Tp′*C*H$_3$). *Anal.* Calc. C, 27.52; H, 3.40; N, 11.83. Found: C, 27.52; H, 3.45; N, 12.50%.

Abstract

Alcoholysis of $W(OMe)_6$ afforded $(p\text{-}PhCH_2OC_6H_4O)_6W$ (**1**-OCH_2Ph), which could be hydrogenated (10% Pd/C, 1 atm H_2) to prepare $(p\text{-}HOC_6H_4O)_6W$ (**1**-OH). Related alcoholyses of WCl_6 with HOC_6H_4-*p*-X provided the hexaphenoxides $(p\text{-}XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, OCH_3, Cl, Br) through minor modifications of literature procedures. Acid catalyzed treatment of **1**-X with *p*-$HOC_6H_4OCH_2Ph$ provided a mixture of substitution products $(p\text{-}XC_6H_4O)_{6-x}W(OC_6H_4OCH_2Ph)_x$ ($x = 1$, **5**-X) that could be hydrogenated (10% Pd/C, 1 atm H_2) to a mixture of hydroxylated products. Chromatography permitted isolation of $(p\text{-}XC_6H_4O)_5W(OC_6H_4OH)$ (**6**-X, X = H, 19%; Me, 29%; OCH_3, 19%; Cl, 12%; Br, 11%) in modest yields. Hexaphenoxides **1**-X and **6**-X manifested two electrochemical reduction waves whose positions were a function of *para*-substituent. When oxidized, **6**-X and **1**-OH were proposed to behave as W(V)quinone mimics, albeit at potentials capable of oxidizing hydrocarbons as shown via a thermochemical cycle. If the proposed transients $(p\text{-}XC_6H_4O)_5W(OC_6H_4O)$ (**7**-X) were generated, degradation was apparently competitive with CH bond activation. The structure of oligomeric $\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty$ (**8**-Cl) is addressed, and comments on the nature of radical CH bond activation in this and related systems are presented.

1. Introduction

The direct conversion of alkanes to functionalized products is a tremendously important, yet very difficult chemical transformation facing the organotransition metal community. The stoichiometric activation of carbon–hydrogen bonds has now been achieved in numerous systems [1,2], but the capability to catalyze this reaction concomitant with oxidation of the substrate has rarely been successfully realized [3–14]. To date, only autoxidation processes mediated by cobalt and manganese have been shown to be commercially viable, and these are rather specialized applications (e.g., $^cC_6H_{12} \rightarrow HO_2C(CH_2)_4CO_2H$, $^tBuH \rightarrow {}^tBuOOH$, $p\text{-}MeC_6H_4Me \rightarrow p\text{-}HO_2CC_6H_4CO_2H$, etc.) that have a minimum of selectivity issues [15,16].

Organometallic approaches to C–H bond activation have generated at least one major conceptual advance. In stark contrast to known free radical chemistry, organometallic systems tend to oxidatively or otherwise add stronger CH bonds selectively over weaker. While some have argued for steric interpretations of these events, it seems clear that this CH bond activation selectivity stems from the greater *D*(M–R) derived from

doi:10.1016/j.poly.2004.08.006

activation of the stronger bond. For example, in Eqs. (1) and (2), if $\Delta G^0_{rxn} \sim \Delta H^0_{rxn}$ and the bonds in L_nMH (Eq. (1)) or L_nMXH (Eq. (2)) are relatively unaffected by R^1 versus R^2, then $\Delta H^0_{rxn} = \{D(M-R^2) - D(MR^1)\} + \{D(R^1H) - D(R^2H)\}$. As long as the *differences* in $D(M–R^n)$ are greater than the *differences* in $D(H–R^n)$ (i.e., $\Delta D(M–R^n)/\Delta D(H–R^n) > 1$), selectivities opposite to that of free radical activations prevail: sp-CH > Ar-H ⩾ sp^2-CH, including ^{c}PrH > MeH > 1°sp^3-CH > 2° sp^3-CH > 3°sp^3-CH, with benzylic and allylic CH bonds often modest exceptions [17–19]. It seems clear that when Green [20] discovered the proclivity of transiently generated tungstenocene to activate arene CH bonds (Eq. (3)), it was this selectivity that was first being witnessed. In most systems involving direct oxidative addition of carbon–hydrogen bonds, this selectivity is modest because binding of R^nH precedes C–H bond cleavage [17,18]. In cases where the actual CH activation is rate-determining [20], there is considerable optimism that problems such as methane to methanol and acetic acid [6,7], and terminal versus internal sp^3-CH activation and functionalization of acyclic alkanes will ultimately be solved [13,14].

$$L_nM(H)R^2 + R^1H \rightleftharpoons L_nM(H)R^1 + R^2H \quad (1)$$

$$L_nM(XH)R^2 + R^1H \rightleftharpoons L_nM(XH)R^1 + R^2H \quad (2)$$

$$Cp_2WH_2 \xrightarrow{h\nu} [Cp_2W] \xrightarrow{PhH} Cp_2W(H)Ph \quad (3)$$

Concerted types of C–H bond activations have been separated into various classes such as σ-bond metathesis, oxidative addition, 1,2-RH-addition and electrophilic activation [1]. While each represents a particular class of reactions, it is clear that electrophilic attack at the C–H bond, whether in a binding or cleavage event, is a common thread among these paths. Free radical and metalaradical (e.g., $L_nM + RH \rightarrow L_nMH + R^{\cdot}$, $L_nMX + RH \rightarrow L_nMXH + R^{\cdot}$, etc.) mechanisms for alkane activation may also yield some control, provided selectivity is built into the metal framework as in nature, or the precise $D(R^nH)$ limits of activation can be controlled and utilized.

Many bioinorganic systems, most notably methane monoxygenase [21], cytochrome P-450 [22], and related oxidases [23–25], have been examined in the context of CH bond activation. Some exciting recent results have been obtained by Que, who has employed the tetramethylcyclam ligand in stabilizing an Fe(IV) oxo complex [26], and has expanded his ligand arsenal to pentadentate ligands whose ligated Fe^{IV}=O groups are capable of hydroxylating cyclohexane and substrates containing weaker CH bonds [27]. Note that the metal functionality (MX) that reacts with RH need not be an oxo or multiple-bonded entity, but the transfer of a hydrogen atom to MX must satisfy certain thermodynamic requirements for it to occur with reasonable facility.

The thermodynamic feasibility of CH bond activation can be predicted with a thermochemical cycle devised by Parker and Tilset that use physically measurable parameters (i.e., E^0_{ox}, pK_a, C) to determine the homolytic bond dissociation energies (BDEs) of X–H species [28]. Fig. 1 illustrates such a cycle in which CH bond activation can be done electrocatalytically [4] provided the reactive intermediate, L_nMX, is generated at a potential positive enough to abstract a hydrogen atom. The sequence gives the BDE (sol) of the X–H bond, which constitutes a reasonable thermodynamic limit of the CH bond that can be broken through H atom abstraction by L_nMX. Mayer [29] has used similar cycles in rationalizing oxidations of permanganate [30] and MMO mimics [31]. Herein is explored the generation of a W^{VI}(semiquinone)/W^{V}(quinone) as a functionality that should be capable of the desired abstraction. Unfortunately, this specific system failed to generate products of CH activation, but a closer look at its features yields some surprises regarding CH bond activations by L_nMX.

2. Results

2.1. Syntheses

2.1.1. $(p\text{-}PhCH_2OC_6H_4O)_6W$ (1-OCH_2Ph) and $(p\text{-}HOC_6H_4O)_6W$ (1-OH)

In an earlier project designed with the synthesis of inorganic dendrimers, the robust character of the hexaaryloxidetungsten coordination environment was exploited as shown in Scheme 1. Treatment of $W(OMe)_6$, prepared from $W(OMe)_4Cl_2$, MeOH and NEt_3 [32], with p-$HOC_6H_4OCH_2Ph$ in toluene for 24 h

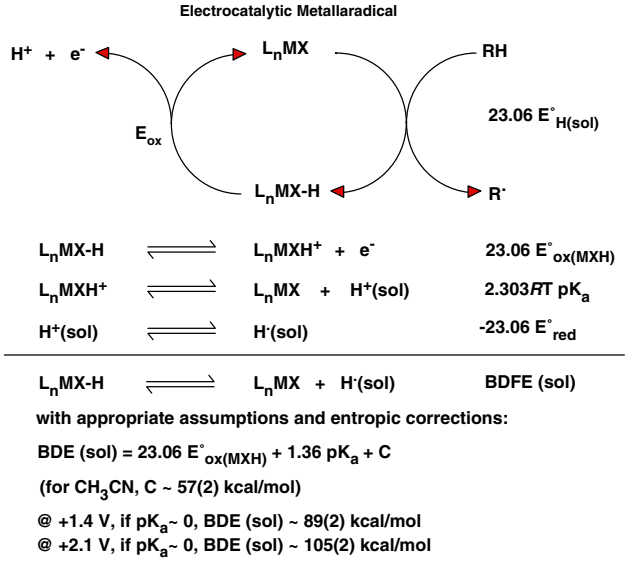

Fig. 1. Electrocatalytic metallaradical.

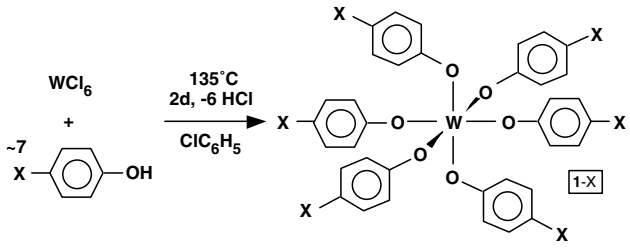
at 213 °C in a bomb reactor yielded the polybenzyl ether, (p-$PhCH_2OC_6H_4O)_6W$ (**1**-OCH_2Ph, 91%). Deprotection via hydrogenation (H_2 (1 atm), Pd/C) in ethanol/toluene ultimately yielded dark red (p-$HOC_6H_4O)_6W\cdot 2THF\cdot C_6H_6$ ((**1**-OH)$\cdot 2THF\cdot C_6H_6$) upon crystallization from THF/benzene. A structural investigation of (**1**-OH)$\cdot 2THF\cdot C_6H_6$ revealed a dense 3-D hydrogen-bonding network linking phenolic and THF sites. The addition of Lewis bases such as 4,4′-bipyridine and 1,2-di-4-pyridylethane to **1**-OH led to the hexabasic mononuclear complex (4,4′-bipy$\cdot HOC_6H_4O)_6W$ (**2**), the doubly interpenetrating 3-D network [{$W(OC_6H_4OH)_6$}{4,4′-$(NC_5H_4)_2(CH_2CH_2)$}$_2$]$_\infty$ (**3**), and the triply interpenetrating 3-D network [{$W(OC_6H_4OH)_6$}{4,4′-$(NC_5H_4)_2(CH_2CH_2)$}$_3\cdot$THF]$_\infty$ (**4**$\cdot$THF), according to X-ray crystallographic studies [33].

While the network solids were intriguing, the stabilization of pendant hydroxy functionalities on a high valent early transition metal center was a striking observation. Earlier studies of group 4 and 5 derivatives suggested that self-condensation was prevalent, yet no oligomerization chemistry was evident for (p-$HOC_6H_4O)_6W$ (**1**-OH). Now that the hydroxy functional group could be engineered into the W(VI) center, could reactivity other than hydrogen bond formation be exploited?

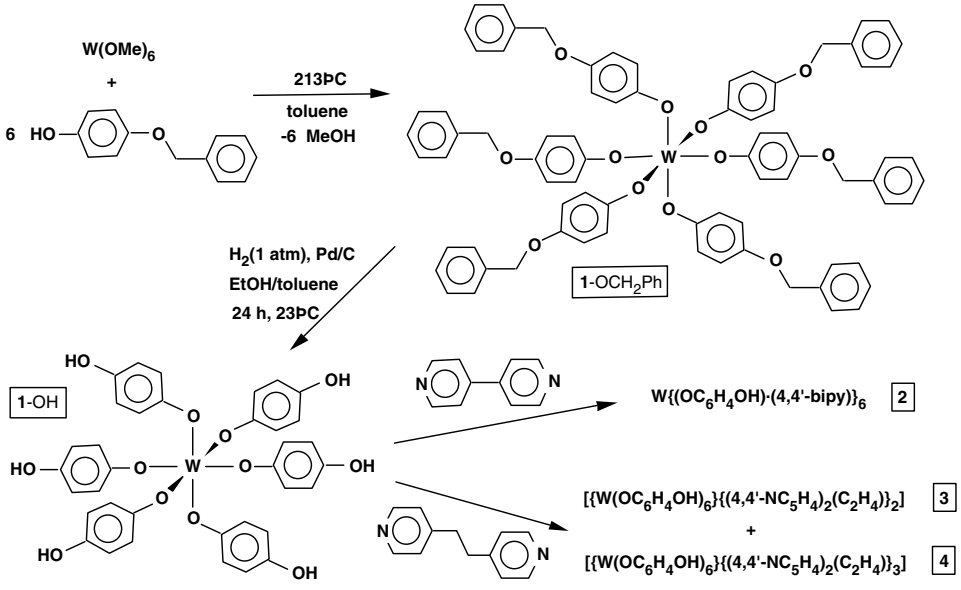
2.1.2. (p-$XC_6H_4O)_6W$ (**1**-X), (p-$XC_6H_4O)_5W(OC_6H_4OCH_2Ph)$ (**5**-X) and (p-$XC_6H_4O)_5W(OC_6H_4OH)$ (**6**-X, X = H, CH_3, OCH_3, Cl, Br)

para-Substituted tungsten hexaphenoxide complexes were synthesized via modification of methods developed by Beshouri and Rothwell [34], which in turn were modest variants of Funk and Baumann [35], and Mortimer and Strong [36]. Treatment of tungsten hexachloride with ~7 equiv. of p-XC_6H_4OH in refluxing chlorobenzene for 2 d formed (p-$XC_6H_4O)_6W$ (**1**-X, X = H, 82%; CH_3, 60%; OCH_3, 40%; Cl, 87%; Br, 68%) in varying yields.

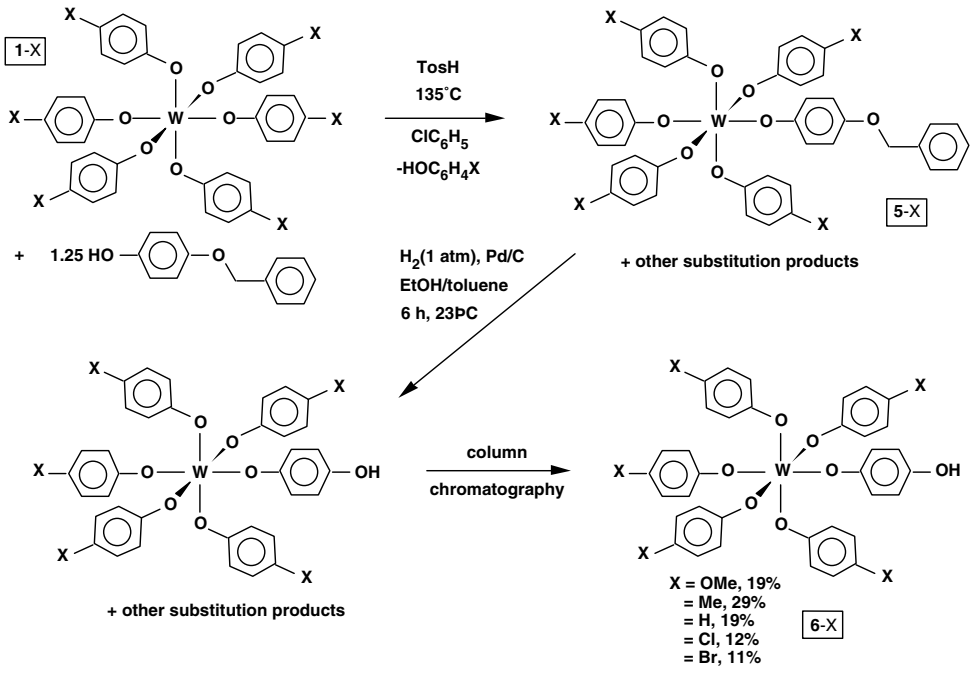


(4)

Since an entire [(p-$XC_6H_4O)_5W$] unit was considered as a tunable group for the ensuing electrochemical study, a protocol for the replacement of one phenoxide from **1**-X was needed. As Scheme 2 reveals, (p-$XC_6H_4O)_6W$ reacted with $HOC_6H_4OCH_2Ph$ in refluxing chlorobenzene with catalytic tosylic acid to yield a mixture of substituted products, (p-$XC_6H_4O)_{6-x}W(OC_6H_4O$-$CH_2Ph)_x$ ($x = 1$, **5**-X), as determined by TLC. The mixture of substituted products was hydrogenated (10% Pd/C, 1 atm H_2) in an EtOH/toluene mixture to a mixture of hydroxylated products, (p-$XC_6H_4O)_{6-x}W(OC_6H_4OH)_x$ ($x = 1$, **6**-X), also determined by TLC. The mono-hydroxylated species **6**-X were separated from the mixture by column chromatography and recrystallized from ethanol (X = H, 19%; Me, 29%; OCH_3, 19%; Cl, 12%; Br, 11%).



Scheme 1.

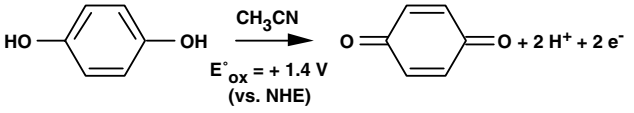


Scheme 2.

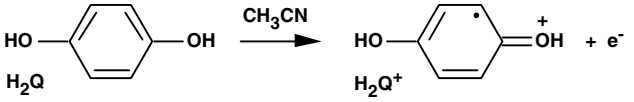
2.2. Electrochemistry

2.2.1. Quinone

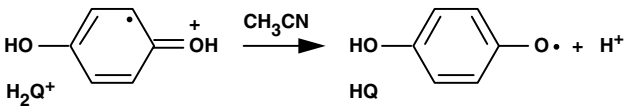
The 2-electron oxidation of hydroquinone in acetonitrile is irreversible and produces quinone with the release of two protons as shown in Eq. (5) The first step of this oxidation is a one electron oxidation of hydroquinone (**H_2Q**) to the radical cation (**H_2Q^+**, Eq. (6)) followed by rapid proton loss to form the resonance stabilized semiquinodal radical (**HQ**, Eq. (7)) [37,38]. If the $[(p\text{-}XC_6H_4O)_5W]^+$ unit of $(p\text{-}XC_6H_4O)_5W(O\text{-}C_6H_4OH)$ (**6**-X) is considered as a proton ''replacement'', than an analogous one electron oxidation pathway to a W(VI) semiquinone/W(V) quinone species can be envisaged (Eq. (8)).



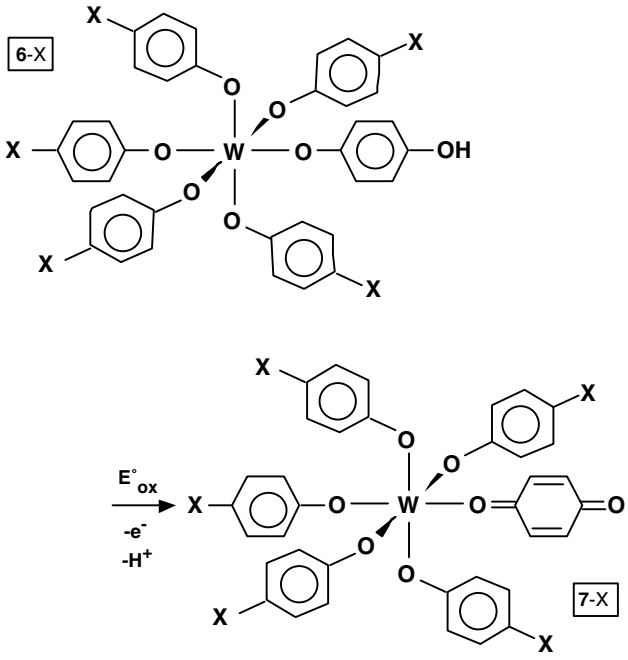
(5)



(6)



(7)



(8)

Application of the cycle shown in Fig. 1 to hydroquinone (HQ = L_nMXH) indicates that HQ ($E^0_{ox} \sim +1.4$ V versus NHE) could activate a CH bond of <89 (2) kcal/mol. However, if the E^0_{ox} potential of a hydroquinone like system could be raised to about +2.1 V (versus NHE), then activation of a 105(2) kcal/mol CH bond is possible. Would the *para*-substituents on **6**-X yield such an increase in oxidation potential?

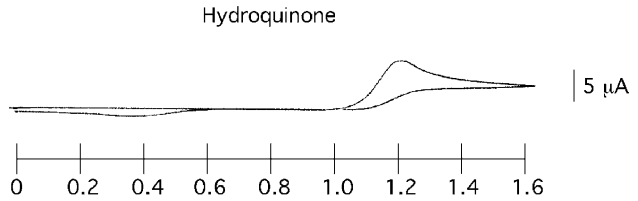


Fig. 2. Cyclic voltammogram of hydroquinone in acetonitrile: 0.5 mM QH_2, 0.1 M TBAH (tetra-*n*-butylammonium hexafluorophosphate), Ag wire reference, 100 mV/s.

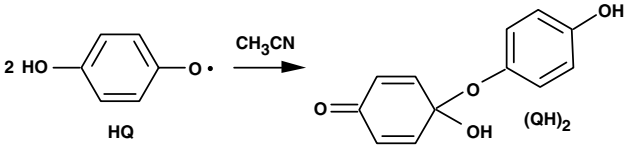
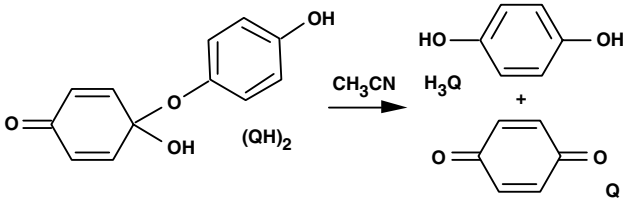
Fig. 2 shows the oxidation of hydroquinone at platinum electrodes in acetonitrile. The peak potential of the irreversible oxidation wave (wave I, +1.40 V versus NHE) and irreversible reduction wave (wave II, +0.55 V versus NHE) were similar to the values reported by Chambers and Eggins [37] (wave I, +1.36 V; wave II, +0.37 V versus NHE, 2 V/s), who found that the peak potential and width for wave II was highly dependent on scan rate and pH. Further investigation into the behavior of wave I led to a proposed mechanism whereby reversible one electron oxidation of hydroquinone (**QH_2**) forms the radical cation **QH_2^+** (Eq. (6)) followed by rapid, irreversible deprotonation to the protonated semiquinone **QH** (Eq. (7)). A hemiketal intermediate (**$(QH)_2$**) then forms via **HQ** dimerization (Eq. (9)), followed by disproportionation to yield **Q** and **H_2Q** (Eq. (10))



(9)



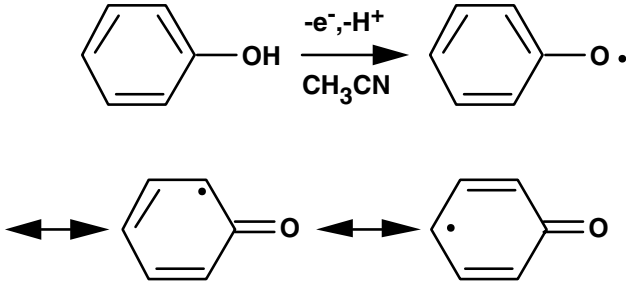
(10)

Wave II is the irreversible two electron reduction of the **Q**/H^+ mixture back to hydroquinone (Eq. (11)) [9]

$$\mathbf{Q} + H^+ + e^- \rightarrow \mathbf{HQ} \overset{e^-}{\rightarrow} \mathbf{QH^-} \overset{H^+}{\rightarrow} \mathbf{QH_2} \qquad (11)$$

2.2.2. Phenols

The oxidation of phenols can lead to a variety of products depending on the oxidant, catalyst, or substitution pattern of the phenol [39]. Treatment of 2,6-xylenol with a copper pre-catalyst in the presence of dioxygen yielded either diphenoquinone or polyphenylene ether depending on the pyridine to cuprous chloride ratio [40]. Lau and coworkers have found that in both water and acetonitrile oxidation of *p*-XC_6H_4OH (X = MeO, ^{t}Bu, Me, Cl, CN, H) by *trans*-$[Ru^{VI}(L)(O)_2]^{2+}$ (L = 1,12-dimethyl-3,4:9,10-dibenzo-1,12-diaza-5,8-dioxacyclopentadecane) proceeds via a hydrogen atom abstraction mechanism. The unstable phenoxy radical was further oxidized to *p*-benzoquinone and 4,4′-biphenoquinone via rapid competing steps [41]. Electrochemical studies on the mechanism of phenol oxidation suggest that the first step is an irreversible one electron oxidation of phenol followed by proton loss forming the resonance stabilized phenoxy radical shown in Eq. (12) [42]



(12)

*2.2.3. (p-$XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, OCH_3, Cl, Br, OH), (p-$XC_6H_4O)_5W(OC_6H_4OH)$, and p-XC_6H_4OH*

The impetus for attempting this project stemmed from three observations. First, cyclic voltammetry on (*p*-$HOC_6H_4O)_6W$ (**1**-OH) revealed multiple irreversible oxidation waves at ~1.29 V (versus NHE) and 1.63 V (Table 1). According to Fig. 1, if these events were indicative of a process such as that in Eq. (8), which is expected to be irreversible in analogy to **H_2Q/Q** electrochemistry, then C–H bonds of considerable strength could conceivably be attacked. In order to simplify the system, and to modulate the oxidation potentials of interest through *para*-substitution, (*p*-$XC_6H_4O)_5W(OC_6H_4OH)$ (**6**-X, X = H, CH_3, OCH_3, Cl, Br) were synthesized. Second, a 0.0–2.3 V (versus Ag wire) cyclic voltammogram of (*p*-$BrC_6H_4O)_5W(O$-$C_6H_4OH)$ (**6**-Br), which was chosen because it possesses a second oxidation wave at ~+1.95 V (versus NHE), showed a pronounced increase in current when excess Ph_3CH (3–10 equiv.; BDE ~ 81 kcal/mol) [43] was added to the solution. In concert with this experiment, the addition of dihydroanthracene (BDE ~ 79 kcal/mol) [31] to a solution of (*p*-$ClC_6H_4O)_5W(OC_6H_4OH)$ (**6**-Cl) caused a similar increase in current at ~+1.9 V (versus NHE) during another 0.0–2.3 V scan.

In view of the possibility of electrocatalytic C–H bond activation, some other cases seemed puzzling. Under similar conditions, no evidence of toluene (BDE ~ 89.8(6) kcal/mol) [43] or acetonitrile

Table 1
E^0_{red} and E^0_{ox} values (V vs. NHE, CH_3CN)[a] for p-XC_6H_4OH, (p-$XC_6H_4O)_6W$ (**1**-X) and (p-$XC_6H_4O)_5W(OC_6H_4OH)$ (**6**-X); X = H, Me, OMe, Cl, Br

[a] From cyclic volatammetry referenced to Ag wire with 0.1 M added tetra-*n*-butylammonium hexafluorophosphate (TBAH); the tabulated values are vs. NHE because the thermodynamic quantities in Fig. 1 use NHE as a reference. Typical samples were ~0.5 mM, and all scan rates were 100 mV/s.
[b] Appear as shoulders atop a generally featureless, increasing current.
[c] Multiple waves.
[d] Scan was only from −1.6 to +1.8 V.
[e] Possible shoulder at +1.9 V.
[f] Scan to 2.0 V, current still increasing.
[g] Other minor waves visible.

(BDE ~ 94.8(21) kcal/mol) [43] activation by any **6**-X species was noted, despite oxidation potentials that suggested such events were feasible according to the calculations of Fig. 1. It was also plausible that toluene might be activated by hydride transfer, but while a cycle similar to that in Fig. 1 can be constructed [44], not enough thermodynamic parameters are known for $RH \rightarrow R^+ + H^-$ to determine its feasibility. Regardless, cyclic voltammograms of **6**-X in the presence of toluene were unchanged. Finally, Fig. 4 illustrates another CV of (p-$BrC_6H_4O)_5W(OC_6H_4OH)$ (**6**-Br) taken from −2.2 to +2.3 V; when cycled in the presence of Ph_3CH, *this voltammogram was unchanged*. Whatever was generated in Fig. 3 does not persist when the scan is taken to −2.2 V for the longer period associated with it (Fig. 4).

Table 1 lists the electrochemical reduction and oxidation waves attributed to (p-$XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, OCH_3, Cl, Br, OH), (p-$XC_6H_4O)_5W(O$-$C_6H_4OH)$ (**6**-X), and p-XC_6H_4OH. In general, the phenols exhibit an irreversible oxidation wave (two in some cases) that increases in potential according to substituent from π-donors to σ-donors to σ-withdrawing groups: p-X = OH (easiest) < OMe < Me < Cl < Br < H. The oxidation wave appears as a featureless increase in current that is initiated at high potentials. The differences based on substituent are substantial, span 0.84 V, and the parent phenol is oxidized at an anomalously high potential of +2.24 V. Presumably Cl < Br because the former has some π-influence that contradicts its σ-effect. Ignoring hydroquinone and its special characteristics (vide supra), the phenols also exhibit a quasi-reversible reduction wave. Here the inductive contributions appear to play a greater role than any π-effects because the ease of reduction follows p-X = Cl (easiest) > OMe > Br > Me > H, and the range of potentials is 0.64 V. π-Type electrons on substituents are energetically closer to arene π-bonding orbitals than arene π*-orbitals. As a consequence, π-effects play a greater role facilitating oxidation of the phenols. The reduction trend sim-

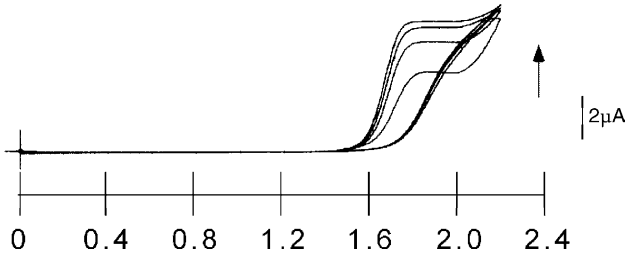

Fig. 3. Cyclic voltammogram of (p-$BrC_6H_4O)_5W(OC_6H_4OH)$ (**6**-Br) in CH_3CN showing the increase in current in successive scans after addition of Ph_3CH (~5 mM): ~0.5 mM **6**-Br, 0.1 M TBAH ($^nBu_4PF_6$), Ag wire reference, 100 mV/s.

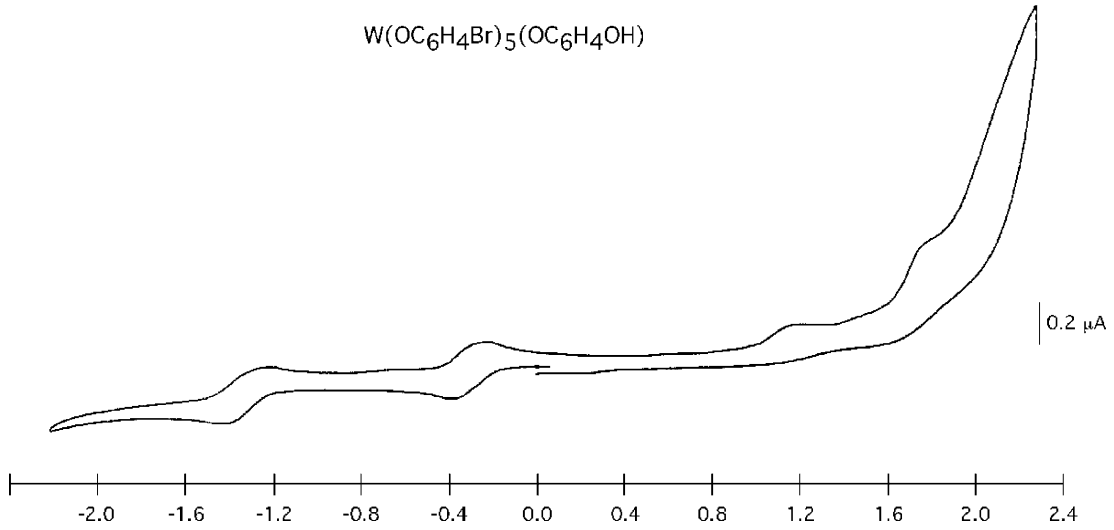

Fig. 4. Cyclic voltammogram of (p-$BrC_6H_4O)_5W(OC_6H_4OH$) (**6**-Br) in acetonitrile from −2.2 to +2.3 V: ~0.5 mM **6**-Br, 0.1 M TBAH (tetra-*n*-butylammonium hexafluorophosphate), Ag wire reference, 100 mV/s.

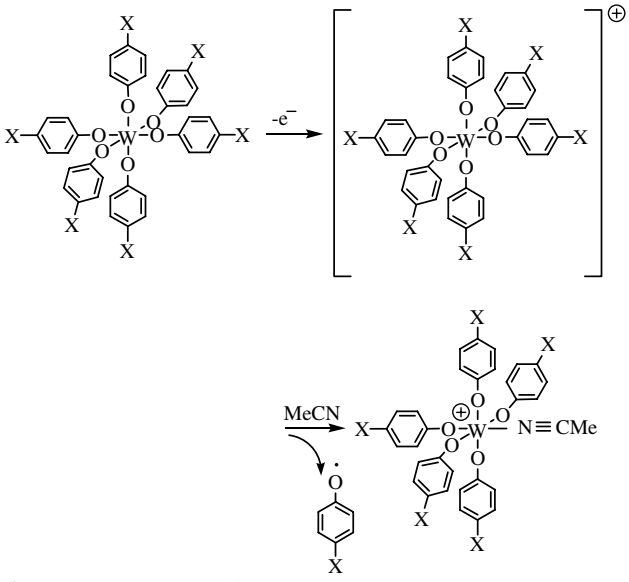
ply reflects inductive effects, which will tend to lower both the donor π-orbitals and the receptor π*-orbitals of the phenols as the substituents become more electron-withdrawing.

As previously observed for related compounds by Beshouri and Rothwell [34], (p-$XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, OCH_3, Cl, Br, OH) exhibit two reversible reduction waves corresponding to the formation of anions $[\mathbf{1}\text{-X}]^-$ and dianions $[\mathbf{1}\text{-X}]^{2-}$. In contrast to the phenols, these reductions reflect a substantial influence by π-components, which render the reductions more difficult. The trend of ease of the first reduction for **1**-X is p-X = Br ~ Cl (easiest) > H > OMe > OH > Me, and the range of potentials is 0.42 V. Inductively, the oxygenated substituents should be on par with Cl, but their π-donor capability renders them more difficult to reduce. The trend of the second reduction has roughly the same range (0.53 V) and the trend is also similar: p-X = Br (easiest) > Cl > OMe > H > Me > OH. π-Donors increase the π-donating ability of the phenoxides, which results in an increase in energy of the t_{2g} receptor orbitals on the pseudo-octahedral complexes. This counteracts the tendency of σ-withdrawing substituents to lower the t_{2g} set. The reductions can certainly be rationalized as metal in character, and quite different from the phenols.

The oxidations of (p-$XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, OCH_3, Cl, Br, OH) are complicated. A relatively clean irreversible wave ($E_{ox}(1)$) occurs for p-X = OH < OMe < Me < H ~ Cl < Br, which is basically the same trend – corresponding to the same effects – seen for the aforementioned phenol oxidations. The values are slightly less positive by 0.1–0.4 V, consistent with removal of an electron from ligand-based orbitals that are more "phenolate" in character. During and after this oxidation, there is a large increase in current, often with no readily discernable peak. The second oxidation ($E_{ox}(2)$), if it is clear, appears as a wave atop this increase. In the cyclic voltammogram of **1**-Br shown in Fig. 5, both oxidation waves are atop the current increase. The $E_{ox}(2)$ values, when clearly observed, reflect the previous trend. The similarities in $E_{ox}(2)$ and the oxidation waves of the parent phenols strongly suggest that the current increase observed is due to degradation of **1**-X and the release of phenol via phenoxy radical



1-X, X = H, CH_3, OCH_3, Cl, Br, OH

(13)

The reductions of (p-$XC_6H_4O)_5W(OC_6H_4OH$) (**6**-X, X = H, CH_3, OCH_3, Cl, Br) are essentially the same as

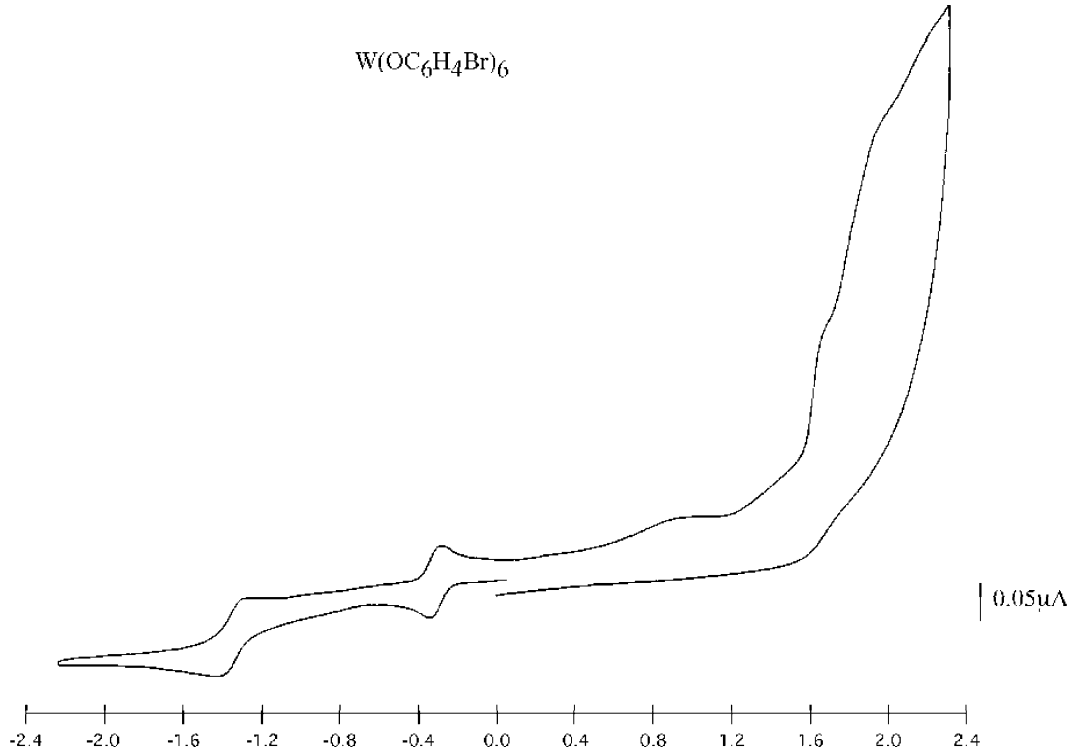


Fig. 5. Cyclic voltammogram of (p-$BrC_6H_4O)_6W$ (**1**-Br) in acetonitrile from −2.2 to +2.3 V: ~0.5 mM **1**-Br, 0.1 M TBAH (tetra-*n*-butylammonium hexafluorophosphate), Ag wire reference, 100 mV/s.

those of **1**-X within 0.1 V. The oxidations appear to reveal the problem in implementing electrocatalytic C–H bond activation. Each complex has an irreversible oxidation around +1.2 to 1.5 V that appears essentially at the onset of a large current increase. This is likely to be the oxidation of the p-HOC_6H_4O-ligand, since it is very close to the oxidations of **1**-OH and that of hydroquinone. The second oxidation, when observed atop the current increase, is near that of $E_{ox}(2)$ of **1**-X and the phenols. It is plausible that initial oxidation occurs at the p-HOC_6H_4O-ligand, perhaps via a process like that revealed in Eq. (8). If the W(V) quinone product (or W(VI) semiquinone) degrades before H atom abstraction can occur to regenerate **6**-X, degradation would lead to phenol loss. While the initial oxidation wave can be attributed to the HOC_6H_4O-ligand, a wave that would correspond to the reduction of free quinone is *not* evident, thus it is likely that protons generated upon oxidation are playing a role in the degradation.

Detection of phenol atop the general increase in current, which probably reflects the production of a number of oxidizable species, is a likely signature of catastrophic degradation.

2.3. Attempted generation of $(XC_6H_4O)_5W(OC_6H_4O)$ (7-X)

Although electrocatalytic C–H bond activation via Fig. 1 was not realized, it was still possible that the W(V) quinone/W(VI) semiquinone complex, (p-$XC_6H_4O)_5W(OC_6H_4O)$ (**7**-X, X = H, CH_3, OCH_3, Cl, Br, OH) was generated yet unstable under the electrochemical conditions. Early work suggested that the in situ preparation of **7**-X could be undertaken by utilizing a W(V) precursor. Funk et al. indicated that the reduction of (p-$XC_6H_4O)_6W$ (**1**-X, X = H, CH_3, Cl) by Raney nickel in the presence of potassium metal produced the five coordinate tungsten(V) aryloxides, "(p-$XC_6H_4O)_5W$" [45]. Despite product characterization that included molecular weight determination, EA, EPR and polarography, a five coordinate complex of this type would seem to be sterically capable of dimerizing to form $[(p\text{-}XC_6H_4O)_4W]_2(\mu\text{-}OC_6H_4X)_2$. Later work by Wilkinson and coworkers [46] showed that reduction of $W(OPh)_6$ by metallic lithium, sodium, or potassium in THF produced the octahedrally coordinated hexaphenoxotungstate(V) ion $[W(OPh)_6]^-$ as $[Li(thf)_2][W(OPh)_6]$, $Na[W(OPh)_6]\cdot NaOPh$, and $K[W(OPh)_6]$, respectively. The monomers $[Et_4N][W(OPh)_6]$, formed by treating $Na[W(OPh)_6]\cdot NaOPh$ with excess $[Et_4N]Br$, and $[Li(thf)_2][W(OPh)_6]$ were structurally characterized. EPR spectra were collected in frozen tetrahydrofuran at 100K for all of the $[W(OPh)_6]^-$ compounds as well as "$(PhO)_5W$", and the values appeared similar. Wilkinson and coworkers [46] proposed that "$(PhO)_5W$" in THF was most likely the axially distorted W^V monomer $W(OPh)_5(thf)$, although no further characterization was reported.

Following the Funk protocol [45], reduction of (p-$ClC_6H_4O)_6W$ (**1**-Cl) with Raney Ni (Et_2O:EtOH; 40:1) generated a red solution that turned yellow-orange upon addition of K^0. The addition of quinone caused an immediate color change to purple-red, and a black solid precipitated. ^1H NMR spectroscopy revealed only the formation of **1**-Cl. Since the solvent system appeared incompatible, the procedure was redone in Et_2O and THF-d_8 with similar results. As Eq. (14) shows, in Et_2O the reduction procedure yields $\{K[(p\text{-}XC_6H_4O)_6W]\}_\infty$ (**8**-X, X = H, 44%; Cl 61%) which can be isolated as orange crystals in 61% yield

$$(p\text{-}xC_6H_4O)_6W\ [\mathbf{1}\text{-}X(X = H, Cl)] \xrightarrow[Et_2O/EtOH(\sim 30:1)]{Raney Ni;K^\circ} \{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty [\mathbf{8}\text{-}X(X = H, Cl)] \quad (14)$$

Attempts to remove one of the phenoxide ligands from $\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty$ (**8**-Cl) by electrophilic attack with $[Me_3O][BF_4]$ or Me_3SiCl only resulted in oxidation to (p-$ClC_6H_4O)_6W$ (**1**-Cl). The phenoxide ligand resisted substitution by PhCN, but ^1H NMR spectroscopy indicated that benzonitrile breaks up the infinite chain into a monomeric species, $[(p\text{-}ClC_6H_4O)_6W][K(NCPh)_4]$ (**9**-Cl, Eq. (15))

$$\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty\ (\mathbf{8}\text{-Cl}) \xrightarrow[PhCN]{benzene\text{-}d_6} [(p\text{-}ClC_6H_4O)_6W][K(NCPh)_4]\ (\mathbf{9}\text{-Cl}) \quad (15)$$

2.4. X-ray crystal structure of $\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty$ (8-Cl)

Crystallographic data for $\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty$ (**8**-Cl) are presented in Table 2 and pertinent interatomic distances and angles are listed in Table 3 As Fig. 6. reveals, **8**-Cl forms a zig-zag chain of $[(p\text{-}ClC_6H_4O)_6W]^-$ anions and potassium cations. The potassium cation is coordinated by a distorted square plane of oxygen atoms ($\angle O\text{–}K\text{–}O_{cis}$ = 55.8(1)°, 124.2(1)°; $\angle O\text{–}K\text{–}O_{trans}$ = 180°) in addition to axial coordination by two asymmetrically bound aryl rings of two different $[(p\text{-}ClC_6H_4O)_6W]^-$ units (Fig. 7). A small distortion from octahedral coordination is observed in the WO_6 core ($\angle$O1–W1–O2 = 87.8(1)°; $\angle$O1–W1–O3 = 91.4(1)°; $\angle$O2–W1–O3 = 92.4(1)°) (Fig. 8). The average W–O bond distance (1.955(1) Å) is longer than the average distance of normal tungsten(VI) aryloxide bonds (1.889(14) Å) [33,47] reflecting partial population of the π* orbitals of d^1 pseudo-octahedral W(V). A shorter terminal W–O bond distance (1.946(1) Å) is found in comparison to the bridged W–O distances (d(W1–O1) = 1.960(2) Å; d(W1–O2) = 1.959(1) Å).

3. Discussion

3.1. Radical CH bond activation

3.1.1. Electrocatalyst lifetime

The premise of this project, electrocatalytic CH bond activation, was not realized. In an electrocatalytic process [4], either reduction or oxidation (this case) serves to regenerate a complex that undergoes a redox process, hence the electrode takes the place of a chemical redox partner that would be consumed (e.g., dioxygen) in the reaction. Rapid degradation of the electrochemically generated W(V) quinone or alternately described W(VI) semiquinone radical intermediate prior to H atom abstraction was considered as one possible cause of failure. In Fig. 3, the short potential range (0.0–2.3V) allowed degradation products (probably phenols) to be regenerated with a H atom source present, whereas the longer potential range in Fig. 4 (−2.2 to 2.3 V) and longer scan time yielded no behavior that could be misconstrued as "electrocatalytic".

In retrospect, the lifetime of the intermediate that must do the H atom abstraction must be substantial, and this factor was underappreciated in this study. For example, according to an Evans–Polanyi plot [48], the activation of dihydroanthracene by transient (p-$XC_6H_4O)_5W$(O-C_6H_4O) (**7**-X, X = H, CH_3, OCH_3, Cl, Br, OH) that was formed from $E^0_{ox} \sim +1.4$ V (Fig. 1) would occur at roughly 10 M^{-1} s^{-1}, hence the lifetime of **7**-X would need to be around a tenth

of a second; at 2.1 V, activation would occur at $\sim 10^6$ M^{-1} s^{-1} and its lifetime would need to be in the microsecond range. All oxidation waves found for $(p\text{-}XC_6H_4O)_5W(OC_6H_4OH)$ (**6**-X, X = H, CH_3, OCH_3, Cl, Br; X = OH, **1**-OH) on the 100 mV/s timescale were irreversible, and no reproducible reduction waves were ever seen in this region, even at higher scan speeds (100 V/s). Given the failure to achieve activation, no further elucidation of the electrochemistry or product analyses were attempted.

3.1.2. Solvent stability and ionization energy

An attempt at CH bond activation using an electrocatalytic cycle requires the use of a solvent that will support an electrolyte and not suffer activation. One might question the utility of such a process given the rather low BDEs of polar solvents such as acetonitrile (BDE ~ 94.8(21) kcal/mol, ~19 M) [43]. From the calculations in Fig. 1 acetonitrile should have been an excellent substrate for the putative quinone based chemistry projected for **6**-X.

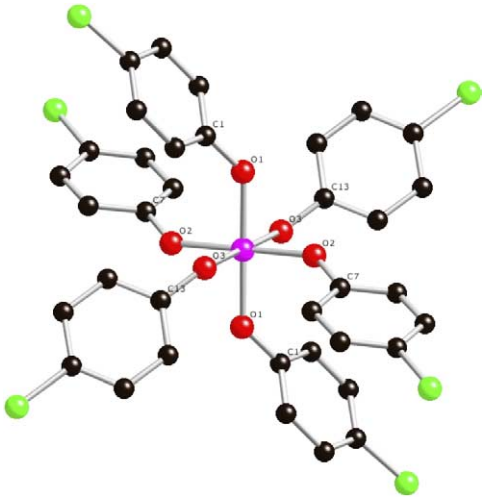

Fig. 8. Molecular view of the $[(p\text{-}ClC_6H_4O)_6W]^-$ ion in $\{K[(p\text{-}ClC_6H_4O)_6W]\}_\infty$ (**8**-Cl).

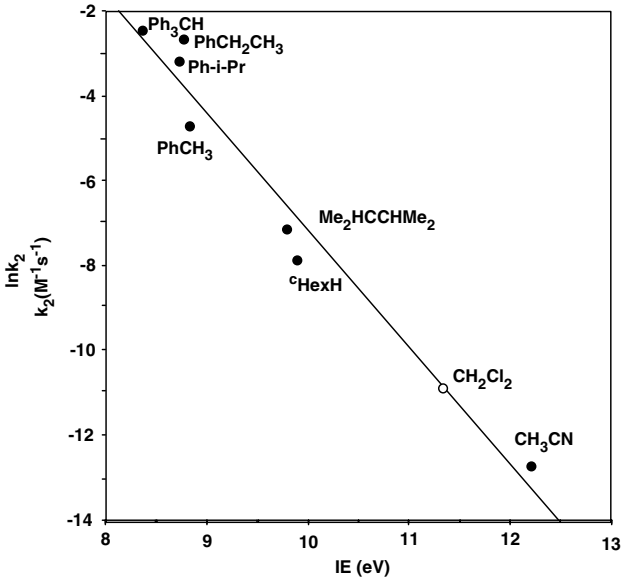

Fig. 9. Correlation of Que et al. hydrocarbon activation rates (k_2 in $M^{-1}\ s^{-1}$) by $[(Bn\text{-}tpen)FeO]^{2+}$ vs. IE (eV), assuming its degradation rate is that of CH_3CN activation. An estimate of methylene chloride activation based on its IE is given as an open circle.

Que has examined the remarkable oxidation of hydrocarbons by non-heme Fe(IV) oxo compounds in acetonitrile, thereby providing evidence to the contrary [27]. Que et al. generate $[\{(pyCH_2)_2NCH_2CH_2N\text{-}(CH_2py)_2\}FeO]^{2+}$ ($[(Bn\text{-}tpen)FeO]^{2+}$) in acetonitrile and measure second-order rate constants for the activation of several hydrocarbons, including cyclohexane, apparently without competition from solvent activation. They correlate the $\log k$(act) versus the BDE(substrate) in the usual fashion, but had acetonitrile been included as a "substrate", it would stand out as a dramatically outlying point. If one estimates the reaction of $[(Bn\text{-}tpen)FeO]^{2+}$ with acetonitrile as the compound's decomposition rate, one can rationalize the inexplicable stability of acetonitrile to H atom abstraction.

Fig. 9 plots the $\ln k_2$ (k_2 in $M^{-1}\ s^{-1}$) versus IE (eV) for the substrates used and acetonitrile, assuming its activation rate is that of the Fe(IV) oxo's degradation in the absence of added substrate [27]. A clean correlation is observed, with $R^2 = 0.955$; CH_2Cl_2, which is not used in Que's study, but has seen use in radical-based systems, is given a predicted activation $\ln k_2$ based on its IE. This plot is a reasonable alternative to the more conventional $\log k_2$ versus BDE employed by Que, and has the obvious advantage of being able to include acetonitrile, yet what is its interpretation?

In Fig. 10, two reaction paths for H atom abstraction are given: one implicates a synchronous transfer of proton and electron, and one reveals a transition state (e.g., the half-way point) that consists of greater electron transfer character than proton transfer. In such an instance, electron withdrawing groups on the substrate, such as the CN on acetonitrile or the chlorides on CH_2Cl_2 can attenuate the susceptibility to H atom abstraction, despite BDEs that would lead one to predict ready activation. Note that a non-synchronous

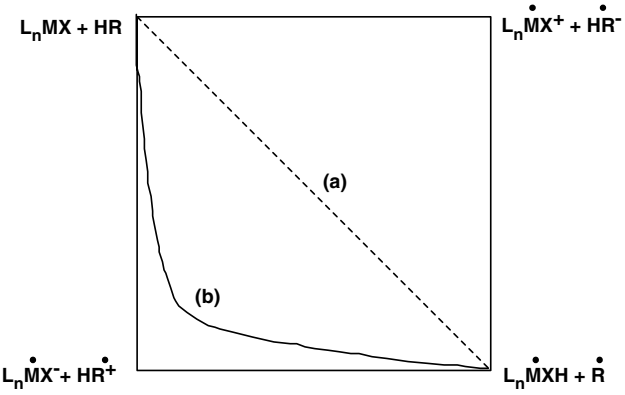

Fig. 10. Reaction coordinate for H atom transfer to L_nMX comparing: (a) direct path where the proton and electron travel simultaneously and (b) a path that possesses more electron transfer character at the transition state.

transfer could lower the frequencies of transition state vibrations that contribute heavily to the kinetic isotope effect (KIE) for H atom transfer (i.e., frequencies of a transition state with $RH^{\cdot+}$ character should be lowered considerably from that of $R^{\cdot}$). It has been shown that such low frequency vibrations are a significant contributor to some anomalously high KIEs [49].

3.2. Phenoxide complexes

The stability of tungsten *para*-hydroxy-phenoxide complexes to degradation via oligomerization and

condensation permitted the synthesis of (p-$XC_6H_4O)_5$-W(O-C_6H_4OH) (**6**-X, X = H, CH_3, OCH_3, Cl, Br; X = OH, **1**-OH) for this study. Their stability to excessive proton-induced ligand exchange, and chromatography conditions verifies their robust character. The complexes and their hexaphenoxide precursors exhibit clean, reversible reductions to anionic and dianionic species, but oxidations were irreversible and induced degradation. It was disappointing that variation of the (p-$XC_6H_4O)_5W$ fragment failed to substantially change the oxidation potential of the –OC_6H_4OH group, which was the first oxidation wave in each **6**-X, despite the wide variation in the oxidation potentials of the parent phenols. It was hoped that the variation in phenol oxidation potential would be transmitted to some extent to the W center and amplified given the five p-XC_6H_4O ligands, but this was not observed.

If one views the WOC_6H_4OH unit as a "phenoxide anion", precedent suggests that the premise of this study was thermodynamically doomed. Cheng et al. calculated several p-hydroquinone anion bond strengths to be ~66–74 kcal/mol, which are values incommensurate with the proposed CH bond activation. This work is certainly consistent with the relatively steady, irreversible $E^0_{ox}(1)$ values for **6**-X, which varied by only 0.28 V.

Clearly, while the concept of electrocatalytic CH bond activation according to Fig. 1. remains apparent, a system possessing higher oxidation potentials and greater stability of the oxidation product is needed for fruition. The more common cycle for Fig. 1 involves the pK_a of L_nMXH and the E^0_{ox} of L_nMX^-, but in this study the compounds were chosen as hydroquinone mimics, hence the pK_a of L_nMXH^+ should be <0, i.e., dissociation should occur spontaneously upon oxidation. Since the 1.36 pK_a factor is rather modest, this was not considered to be a serious detriment to the proposed CH bond activation, but it certainly could be a source of overestimation in terms of limiting the strength of the bonds potentially activated if the pK_a is much less than zero. For another view of this point, consider the more conventional way of estimating the OH bond strength of (p-$XC_6H_4O)_5$W(O-C_6H_4OH) (**6**-X). First, the pK_a of **6**-X would be determined (e.g., the pK_a of **6**-X would be >0), then the oxidation potential of (p-$XC_6H_4O)_5W(OC_6H_4O^-)$ would be measured. It is likely that the oxidation potential for this anionic species would be far less positive than for **6**-X, thereby compensating for the pK_a increase. Unfortunately, attempts to generate a stable anion of **6**-X via deprotonation failed, and mild bases afforded H-bonded coordination networks [33]. It is likely that (p-$XC_6H_4O)_5$W(O-$C_6H_4O^-$), which could also be considered as $[(p\text{-}XC_6H_4O)_5W^{IV}(OC_6H_4O)]^-$, is an unstable species.

4. Experimental

4.1. General considerations

All manipulations were performed using either glovebox or high vacuum line techniques. Hydrocarbon solvents containing 1–2 mL of added tetraglyme, and ethereal solvents were distilled under nitrogen from purple sodium benzophenone ketyl and vacuum transferred from same prior to use. C_6D_6 and acetonitrile were dried over activated 4 Å molecular sieves, vacuum transferred and stored under N_2. All other chemicals were purchased from commercial sources and used as received. All glassware was oven dried, and NMR tubes for sealed tube experiments were additionally flame-dried under dynamic vacuum. All phenols were purchased from Aldrich Chem. Co. and recrystallized prior to use.

NMR spectra were obtained using INOVA-400 and Unity-500 spectrometers, and chemical shifts are reported relative to C_6D_6 (^{1}H, 7.15; $^{13}C\{^1H\}$, 128.39) or acetone-d_6 (^{1}H, 2.05; $^{13}C\{^1H\}$, 29.92). Infrared spectra were recorded on a Nicolet Impact 410 spectrophotometer interfaced to a Gateway PC. Elemental analyses were performed by Oneida Research Services, Whitesboro, NY, or Robertson Microlit Laboratories, Madison, NJ. Magnetic moments were determined in C_6D_6 or thf-d_8 at room temperature using Evans method with an applied diamagnetic correction.

4.2. Procedures

4.2.1. (p-$PhCH_2OC_6H_4O)_6W$ (**1**-OCH_2Ph)

$W(OCH_3)_6$ (1.150 g, 3.11 mmol) and 4-benzyloxyphenol (5.00 g, 25.0 mmol) were combined in a large glass bomb with 40 mL toluene. The bomb was lowered into a salt bath until the solvent level was covered and the temperature settled at 173°C. After 24 h, the reaction was judged incomplete by a TLC using toluene as the eluting solvent. $W(OC_6H_4OCH_2C_6H_5)_6$ has an R_f of 0.70 while the R_f of $W(OC_6H_4OCH_2C_6H_5)_5(OCH_3)$ is 0.65 and other less substituted products have lower R_fs. The temperature was gradually increased, until after 24 h at 213 °C the reaction was complete except for a trace of a lower R_f spot. Toluene was added to the reaction mixture and it was washed with 3×350 mL 5% NaOH (aq). The deep red solution was dried over Na_2SO_4 and the solvent stripped on a rotary evaporator. The resulting dark red, very viscous oil was placed under high vacuum for several hours. ^{1}H NMR showed clean **1**-OCH_2Ph and toluene. The yield of 4.41 g translates to 3.89 g **1**-OCH_2Ph when the presence of toluene was accounted for, giving an actual yield of 91%.

4.2.2. (p-$HOC_6H_4O)_6W$ (**1**-OH)

1-OCH_2Ph (3.85 g, 2.79 mmol) was dissolved in 125 mL toluene/125 mL ethanol along with 500 mg 10% PdC. The

mixture was stirred under 1 atm H_2 and checked periodically by TLC using 100% ethyl acetate as the eluting solvent. Incompletely deprotected products have higher R_fs (0.85 or greater) than the final product ($R_f = 0.80$). After 4 h, the reaction was mostly complete, but required 24 h until only a trace spot at $R_f = 0.85$ remained. The reaction mixture was filtered through celite and the celite washed with ethanol. Volatiles were removed on a rotary evaporator and the product transferred to a 100 mL flask with THF. The THF was stripped and dry THF was added and removed. Dry THF was added and then stripped twice more to remove traces of water. The product was crystallized from 50 mL benzene/3–4 mL THF and dried under vacuum for 12 h (1.778 g, 60% based on $(p\text{-}HOC_6H_4O)_6W\cdot 2THF\cdot C_6H_6$) (**1**-OH·2THF·$C_6H_6$). ^{1}H NMR in acetone-$d_6$ indicated pure **1**-OH with 2.0 equivalents of THF and 0.9 equivalents of benzene. Elemental analysis indicated some loss of solvent before combustion: *Anal.* Calc. for $W(OC_6H_4OH)_6\cdot 1.5$ THF: C, 53.29; H, 4.47. Found: C, 53.11; H, 4.55%.

4.2.3. General (p-$XC_6H_4O)_6W$ (1-X, X = H, CH_3, OCH_3, Cl, Br)

To a 250 mL flask attached to a reflux condenser was added WCl_6 (5 g, 12.6 mmol). A sidearm flask containing p-XC_6H_4OH (81.7 mmol) was connected to the flask, which was attached to an argon line equipped with a bubbler. 100 mL of chlorobenzene was added and the phenol was gradually tapped into the flask and HCl (g) was evolved. The solution was refluxed for 12–24 h followed by an argon purge to remove residual HCl (g). The solution was washed twice with 10% NaOH (aq) and deionized water, then dried over $MgSO_4$. The solvent was removed under reduced pressure, and the product crystallized from petroleum ether (X = Me, Cl, Br) or ethanol (X = OMe, H).

*(a) (p-$MeOC_6H_4O)_6W$ (**1**-CH_3).* TLC (50% ethyl acetate:hexane): $R_f = 0.59$. ^{1}H NMR (acetone-d_6): δ 3.72 (s, Me), 6.78 (d, $J = 9$ Hz, CH), 6.85 (d, $J = 9$ Hz, CH). $^{13}C\{^1H\}$ NMR (acetone-d_6): δ 55.85 (Me), 114.67 (C_m), 121.91 (C_o), 156.71 (C_p), 156.93 (C_{ipso}).

*(b) (p-$MeC_6H_4O)_6W$ (**1**-CH_3).* TLC (25% ethyl acetate:hexane): $R_f = 0.66$. ^{1}H NMR (acetone-d_6): δ 2.33 (s, Me), 6.83 (d, $J = 9$ Hz, CH), 7.05 (d, $J = 9$ Hz, CH). $^{13}C\{^1H\}$ NMR (acetone-d_6): δ 20.69 (Me), 120.96 (C_o), 130.17 (C_m), 133.77 (C_p), 160.78 (C_{ipso}).

*(c) (p-$ClC_6H_4O)_6W$ (**1**-Cl).* TLC (25% ethyl acetate:hexane): $R_f = 0.73$. ^{1}H NMR (acetone-d_6): δ 7.01 (d, $J = 9$ Hz, CH), 7.32 (d, $J = 9$ Hz, CH). $^{13}C\{^1H\}$ NMR (acetone-d_6): δ 122.63 (C_o), 129.81 (C_p), 130.04 (C_m), 160.79 (C_{ipso}).

*(d) (p-$BrC_6H_4O)_6W$ (**1**-Br).* TLC (15% ethyl acetate:hexane): $R_f = 0.68$. ^{1}H NMR (acetone-d_6): δ 6.96 (d, $J = 9$ Hz, CH), 7.47 (d, $J = 9$ Hz, CH). $^{13}C\{^1H\}$ NMR (acetone-d_6): δ 123.07 (C_o), 133.07 (C_m), 161.24 (C_{ipso}), C_p obscured.

*(e) ($C_6H_5O)_6W$ (**1**-H).* TLC (25% ethyl acetate:hexane): $R_f = 0.60$. ^{1}H NMR (acetone-d_6): δ 6.90 (t, $J = 8$ Hz, CH_p), 6.96 (d, $J = 8$ Hz, CH), 7.27 (t, $J = 8$ Hz, CH_m). $^{13}C\{^1H\}$ NMR (acetone-d_6): δ 121.16 (C_o), 124.59 (C_p), 129.81 (C_p), 129.88 (C_m), 162.69 (C_{ipso}).

4.2.4. General (p-$XC_6H_4O)_5W(OC_6H_4OH)$ (6-X, X = OMe, Me, H, Cl, Br)

A 250 mL round bottom flask was charged with **1**-X (5.4 mmol), 4-(benzyloxy)phenol (10 mmol), p-toluenesulfonic acid monohydrate (1.1 mmol), and chlorobenzene (100 mL). The solution was refluxed under an argon atmosphere for 1–3 h and the reaction was monitored by TLC (silica plate) for optimization of the monosubstituted product (p-$XC_6H_4O)_5W(OC_6H_4OCH_2Ph)$ (**5**-X). Toluene (100 mL) was added to reaction solution and the mixture was washed three times with both 5% NaOH(aq) and de-ionized water. It was dried over $MgSO_4$, and the solvent was removed under reduced pressure. The resulting red oil was dissolved in a mixture of toluene (50 mL) and absolute ethanol (50 mL) followed by an argon purge. 10% Palladium on carbon (0.125 g) was added and the heterogeneous solution was stirred under hydrogen (1 atm) for 5 h. Analysis by TLC of the hydrogenated solution versus the starting solution indicated complete hydrogenation. The catalyst was removed by filtration and the volatiles were removed on a rotary evaporator. Purification was accomplished by column chromatography on silica using an appropriate mixture of ethyl acetate and hexane as the mobile phase. Further purification by recrystallization from methanol was performed when possible.

*(a) (p-$MeOC_6H_4O)_5W(O$-$C'_6H'_4OH)$ (**6**-OMe).* TLC(50% ethyl acetate:hexane): $R_f = 0.50$. ^{1}H NMR (acetone-d_6): δ 3.73 (s, 15H, Me), 6.71 (d, $J = 9$ Hz, 2H, H'_o or H'_m), 6.80 (m, 12H, H_m and $C'H'_o$ or $C'H'_m$), 6.86 (m, 10H, CH_o), 8.20 (s, 1H, OH). $^{13}C\{^1H\}$ NMR (acetone-d_6): 55.83 (Me), 114.63 (C_m), 115.98 (C'_m), 121.90 (C_o), 122.02 (C'_o), 154.43 (C'_p), 156.25 (C'_{ipso}), 156.60 (C_p), 156.98 (C_{ipso}). *Anal.* Calc for $C_{41}H_{40}O_{12}W$: C, 54.2; H, 4.5. Found: C, 54.2; H, 4.4%.

*(b) (p-$MeC_6H_4O)_5W(OC'_6H'_4OH)$ (**6**-Me).* TLC (25% ethyl acetate:hexane): R_f(**5**-Me) = 0.44; R_f(**6**-Me) = 0.18. ^{1}H NMR (acetone-d_6): δ2.32(s, 15H, Me), 6.71 (d, $J = 9$ Hz, 2H, $C'H'_o$ or $C'H'_m$), 6.82 (m, 12H, H_o and H'_o or H'_m) 7.05 (d, $J = 9$Hz, 10H, H_m), 8.31 (s, 1H, OH). $^{13}C\{^1H\}$ NMR (acetone-d_6): 20.86 (Me), 115.93 (C'_m), 120.92 (C_o), 122.20 (C'_o), 130.16 (C_m), 133.57 (C_p), 154.81 (C'_p), 156.13 (C'_{ipso}), 160.85 (C_{ipso}). *Anal.* Calc for $C_{41}H_{40}O_7W$: C, 59.4; H, 4.9. Found: C, 59.5; H, 4.8%.

*(c) (p-$BrC_6H_4O)_5W(OC'_6H'_4OH)$ (**6**-Br).* TLC (3% ethyl acetate:hexane): R_f(**5**-Br) = 0.75; R_f(**6**-Br) = 0.44. ^{1}H NMR (acetone-d_6): δ 6.71 (m, 2H, $C'H'_o$ or $C'H'_m$), 6.94 (m, 12H, H_o and $C'H'_o$ or $C'H'_m$) 7.46 (m, 10H, H_m), 8.62 (s, 1H, OH).

*(d) (p-ClC$_6$H$_4$O)$_5$W(OC$'_6$H$'_4$OH) (**6**-Cl).* TLC (3% ethyl acetate:hexane): R_f(**5**-Cl) = 0.70; R_f(**6**-Cl) = 0.41. 4-Chlorophenol could not be separated from **6**-Cl by column chromatography or crystallization and impeded definitive spectroscopic characterization.

*(e) (C$_6$H$_5$O)$_5$W(OC$'_6$H$'_4$OH) (**6**-H).* TLC (25% ethyl acetate:heptane): R_f(**5**-H) = 0.48; R_f(**6**-H) = 0.25. ^{1}H NMR (acetone-d$_6$): δ 6.72 (d, J = 8 Hz, 2H, C$'$H$'_o$ or C$'$H$'_m$), 6.93 (m, 17H, CH$_o$, CH$_m$ and C$'$H$'_o$ or C$'$H$'_m$), 7.26 (m, 10H, d), 8.32 (s, 1H, OH). ^{13}C{^{1}H} NMR (acetone-d$_6$): 115.99 (C$'_m$), 121.09 (C$_o$), 122.30 (C$'_o$), 124.31 (C$_p$), 129.83 (C$_m$), 154.31 (C$'_p$), 155.94 (C$'_{ipso}$), 162.81 (C$_{ipso}$).

4.2.5. {K[(p- ClC$_6$H$_4$O)$_6$W]}$_\infty$ (**8**-Cl)

A 25 mL round bottom flask was charged with **1**-Cl (0.300 g, 0.316 mmol), Raney Nickel (0.075 g, 1.28 mmol), diethyl ether (15 mL), and ethanol (0.40 mL). Potassium metal (0.02 g, 0.5 mmol) was added and the purple-red solution was stirred for 2 h. The resulting heterogeneous orange solution was filtered, and the filtrate layered with pentane yielding the product as orange crystals (0.191 g, 61%). *Anal.* Calc. for $C_{36}H_{24}O_6Cl_6KW$: C, 43.8; H, 2.5; Cl, 21.5. Found: C, 44.0; H, 2.5; Cl, 20.6%.

4.2.6. {K[(C$_6$H$_5$O)$_6$W]}$_\infty$ (**8**-H)

A 25 mL round bottom flask was charged with **1**-H (0.200 g, 0.269 mmol), Raney Nickel (0.050 g, 0.852 mmol), diethyl ether (10 mL), and ethanol (0.30 mL). Potassium metal (0.02 g, 0.5 mmol) was added and the purple-red solution was stirred for 2 h resulting in a yellow precipitate and light yellow solution. The solid was collected by filtration and separated from the remaining Raney Nickel by dissolution in minimal THF followed by filtration and crystallization by slow evaporation (0.093 g, 44%). ^{1}H NMR (thf-d_8): δ 4.96 ($v_{1/2} \sim 20$ Hz, 6H, H$_p$), 6.63 ($v_{1/2} \sim 40$ Hz, 12H, CH), 9.28 ($v_{1/2} \sim 20$ Hz, 12H, CH). The ^{1}H NMR spectrum is similar to that obtained by Wilkinson and coworkers [45] (acetone-d$_6$) for an independent synthesis of KW(OPh)$_6$. μ_{eff}(293K) = 1.5 μ_B (Evans' method in thf-d$_8$).

4.2.7. Preparation of [(p-ClC$_6$H$_4$O)$_6$W][K(PhCN)$_4$] (**9**-Cl)

A 10 mm O.D. glass tube was charged with **8**-Cl (0.081 g, mmol) and benzonitrile (4 mL). The solution was degassed, sealed, and heated at 100 °C for 5 d with no color change. The product was isolated as an orange solid (0.072 g, 63%) after solvent removal followed by trituration with pentane. ^{1}H NMR (thf-d_8): δ 7.12 ($v_{1/2} \sim 160$ Hz, 12H, CH), 7.51 (t, J = 8 Hz, 8H, PhCN H$_p$ or H$_m$), 7.63 (t, J = 8 Hz, 4H, PhCN H$_p$ or H$_m$), 7.69 (d, J = 8 Hz, 8H, PhCN H$_o$), 9.18 ($v_{1/2} \sim 10$ Hz, 12H, CH).

4.2.8. Electrochemistry: general procedure

The working electrode was a 1mm diameter platinum disk electrode sealed in glass. In cases where fast sweep rates were employed, a 75 μm platinum disk electrode, sealed in glass, was used. All measurements were carried out inside a glove-box (Vac. Atmospheres) at 25 °C. Acetonitrile (Burdick & Jackson; distilled in glass) and dried over 4 Å molecular sieves was used as the solvent. Tetra-*n*-butyl ammonium hexafluorophosphate (TBAG; G.F. Smith) used as supporting electrolyte was recrystallized 3× from absolute ethanol and dried under vacuum for 96 h. A Princeton Applied Research Model 173 Potentiostat with a model 175 Programmer were used. Data at sweep rates at or below 500 mV/s were recorded on a Soltec X–Y recorder. At faster sweep rates, data were recorded on a Tektronix digital storage oscilloscope. A background scan of solvent and supporting electrolyte out to the potential limits of the experiment, was always varied out. A sweep rate dependence of the peak current was carried out for all the materials involved and in all cases the current was proportional to the square root of the sweep rate (over a typical range of 50–1000 mV/s) as anticipated for a diffusion controlled process. A silver wire was employed in order to ensure rigorous exclusion of water, especially since experiments were done inside a dry box. Reproducibility of the peak potentials – even those that are irreversible – was roughly ±10–15 mV.

4.2.9. X-ray crystal structure determination: {K[(p-ClC$_6$H$_4$O)$_6$W]}$_\infty$ (8-Cl)

X-ray diffraction quality single crystals were obtained by layering a saturated diethyl ether solution of **8**-Cl with pentane. One orange crystal ($0.3 \times 0.15 \times 0.1$ mm) was selected, coated in polyisobutylene, and placed under a 173 K nitrogen stream on the goniometer head of a Siemens SMART CCD Area Detector system equipped with a fine-focus molybdenum X-ray tube (λ = 0.71073 Å). Preliminary diffraction data revealed a triclinic crystal system. A hemisphere routine was used for data collection. The data was subsequently processed with the Bruker SAINT program and the space group was determined to be $P\bar{1}$. The data was corrected for absorption with SADABS, solved by direct methods, completed by subsequent difference Fourier syntheses and refined by full-matrix least-squares procedures (SHELXTL). All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were included at calculated positions. [1]

Abstract

A series of imidazolium and triazolium chelate ligand precursors are metalated with $[Ir(coe)_2Cl]_2$ (coe = cyclooctene) or $[Ir(cod)Cl]_2$ (cod = 1,5-cyclooctadiene) to give iridium(III) *N*-heterocyclic carbene (NHC) chelates [(NHC)(linker)(NHC)IrI_2(OAc)]. The triazolium salts metalate more easily and give less electron donating NHCs as shown by IR spectroscopy on analogous iridium(I) carbonyl derivatives. The iridium(III) complexes show activity for the title catalytic reactions in 2-propanol that is very variable, depending on the nature of the linker and terminal *N*-substituents. Selective reduction of aldehydes over ketones becomes possible with K_2CO_3, an alternative base promoter to the usual KOH. TOFs of up to 1500/h were achieved.

Keywords: *N*-Heterocyclic carbenes; Homogenous catalysis; Transfer hydrogenation; Ketones; Aldehydes; Imines

1. Introduction

N-heterocyclic carbenes (NHCs) are sometimes considered phosphine alternatives for homogenous catalysis [1]. As their chemistry becomes better explored, however, differences have continued to emerge. There are many examples of monodentate NHCs, but only a few of chelating bis-carbene ligands [2]. Comparison with phosphine chemistry suggests that having a chelated bis-carbene ligand could be very useful. Chelated carbenes may have higher stability since one possible decomposition pathway, reductive elimination of the carbene, may be slower for this conformationally restricted case. Others [3] and we [4] have published chelating palladium bis-carbene compounds. Meanwhile, Peris and co-workers first synthesized the rhodium species [Rh(III)(bis-carbene)(OAc)I_2], [5] and we have synthesized the iridium species [Ir(III)(bis-carbene)(OAc)I_2] [6]. The rhodium and iridium bis-carbene compounds were subsequently studied for catalysis. We have prepared several iridium(III) bis-carbene complexes which are very active precatalysts under low catalyst loadings for the transfer hydrogenation of ketones and aldehydes [6,7]. These complexes are all very easy to synthesize and air-stable. Furthermore, their catalytic activity was completely unaffected by the presence of air. Most likely, these precatalysts [6] followed a monohydride mechanism, which has been observed before for other complexes [8].

In a variety of rhodium(I) and rhodium(III) chelates we found a strong effect on the chemistry as the linker length was varied [9]. In this paper we prepare robust

doi:10.1016/j.poly.2004.07.001

chelated iridium(III) bis-imidazole and bis-triazole complexes with different linking groups to see how the linker group affects the catalytic activity of these complexes. These complexes are screened for catalytic activity for the transfer hydrogenation of ketones, aldehydes and imines.

Reduction of C=N bonds is of great interest to the pharmaceutical industry because amines are present in many drugs. Reagents such as sodium borohydride or lithium aluminum hydride can of course be used in stoichiometric quantities to reduce ketones and imines. In addition, sodium cyanoborohydride can selectively reduce an imine formed from a ketone and an amine in reductive amination [10].

Catalytic reduction is preferred to stoichiometric reduction for large scale industrial use, and both ketone [11] and imine [12–14] hydrogenation are well known. Hydrogen gas presents considerable safety hazards especially for a large scale reaction [15].

The use of a solvent that can donate hydrogen overcomes these difficulties. 2-propanol is a popular reactive solvent for the transfer hydrogenation reaction since it is easy to handle (b.p. 82 °C), and is relatively non-toxic, environmentally benign, and inexpensive. The volatile acetone product can also be easily removed to shift an unfavorable equilibrium [16]. The formic acid:triethyl amine azeotrope allows reduction of imines under irreversible conditions with formation of carbon dioxide [16]. Noyori [16] has used this azeotrope to reduce imines with high enantiomeric excess under mild conditions. One advantage of 2-propanol is that it does not affect the pH of the reaction solution like formic acid [17]. We previously reported that the formic acid:triethyl amine azeotrope is not optimal for our precatalysts [6]. Imines are more difficult to reduce by homogenous transfer hydrogenation catalysis than ketones and aldehydes, and fewer examples of their transfer hydrogenation are known [18–29] versus ketones [30]. This may well be a result of imine lone pair coordination to the metal partially blocking catalysis.

2. Results and discussion

Robust ligand precursors were prepared with neopentanediyl and *o*-xylene linkers with neopentyl wingtip groups (Fig. 1). This wingtip group was chosen because it gave excellent results for transfer hydrogenation of ketones [6] and aldehydes [7] and also because the neopentyl wingtip group cannot decompose following a Hoffmann elimination pathway [31]. Finally, neopentyl wingtips have previously improved the solubility of the complex and given crystals where disorder problems were minimized.

2.1. Synthesis of ligands and iridium(I) and iridium(III) complexes

Chelating bis-imidazole ligand precursors **1** and **2**, were prepared (Fig. 1). Compound **1** has an *ortho*-xylene

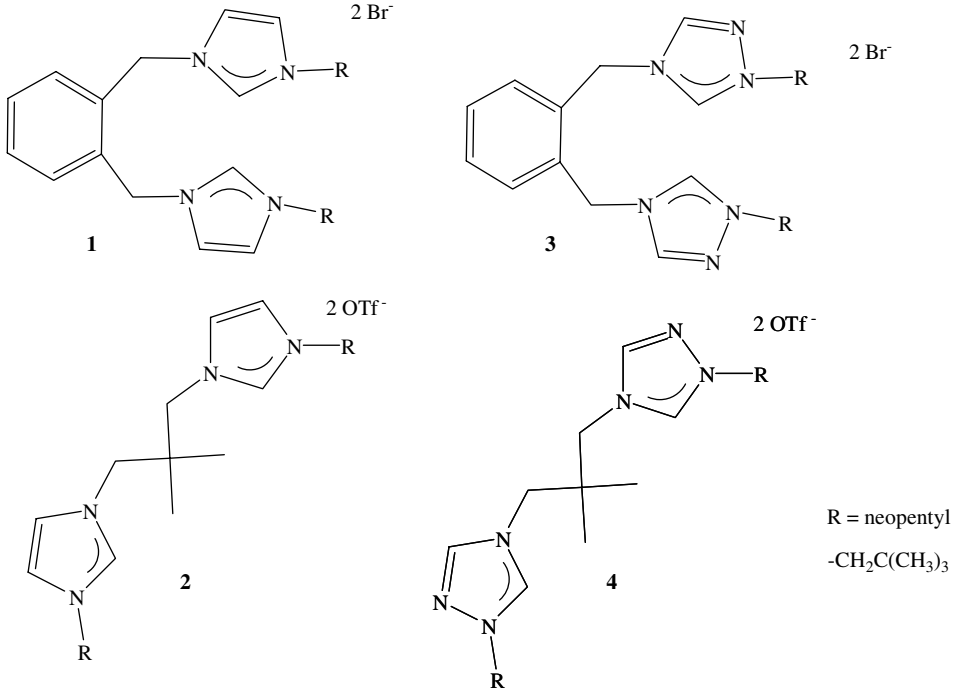

Fig. 1. Robust ligand precursors for iridium (III) bis-carbene complexes.

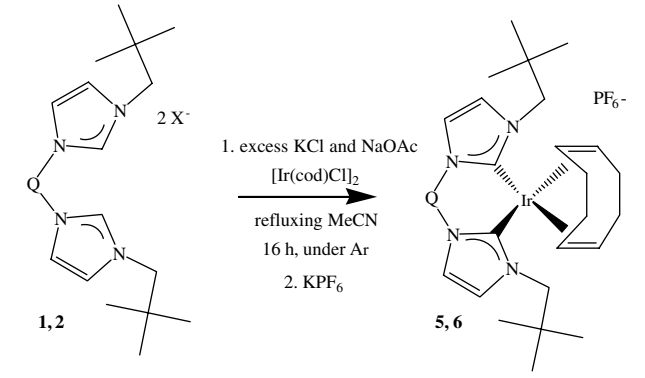
linker also used for rhodium by Peris and co-workers [32,33] Compound **2** has a neopentanediyl linking group also used by Hahn et al. [34].

In order to vary the electronic effect of the ligand, change of the aromatic core is more efficient than change of substituents at nitrogen, so we have moved to triazole, less electron donating than imidazole [35]. Bis-triazole analogs of **1** and **2** are also given in Fig. 1.

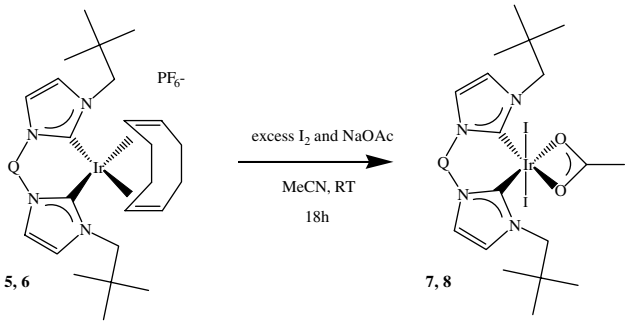
Ligand precursors **1**–**4** could be metalated to form iridium(III) products. It proved hardest to metalate **1** and **2**, but this was finally achieved with $[Ir(cod)Cl]_2$ (cod = 1,5-cyclooctadiene) following Eq. (1) where iridium is oxidized to iridium(III) according to Eq. (2) [32,33]. It seems to be a general pattern that triazole derivatives like **3**–**4** can be metallated more easily than their imidazole analogues.



1 (Q = *o*-xylene, X = Br)
2 (Q = neopentanediyl, X = triflate)

5 (Q = *o*-xylene)
6(Q=neopentanediyl)

(1)



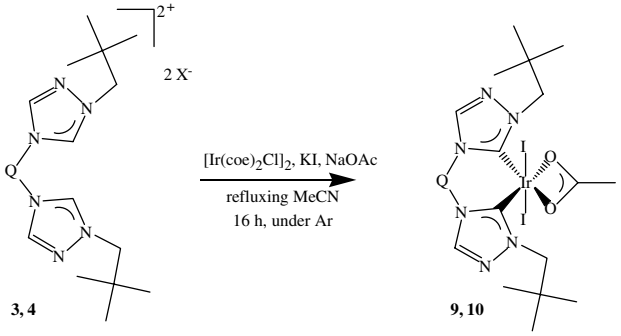
5 (Q = *o*-xylene)
6 (Q = neopentanediyl)

7 (Q = *o*-xylene)
8 (Q = neopentanediyl)

(2)

The iridium(III) products obtained in Eq. (1) followed by (2) were only available via this two step route and not in only one step from compounds **1** or **2**, as has proved possible for other ligand precursors using conditions previously published [5,6]. $[Ir(coe)_2Cl]_2$ (coe = cyclooctene) with more labile coe ligands gave approximately 10% higher yields than $[Ir(cod)Cl]_2$, normally used.

The chelating bis-triazole ligands could also be metalated according to Eq. (3). Unlike the bis-imidazole cases (Eqs. (1) and (2)), only one step was needed to obtain the iridium(III) product. For **9** and **10**, higher yields were again obtained with $[Ir(coe)_2Cl]_2$.

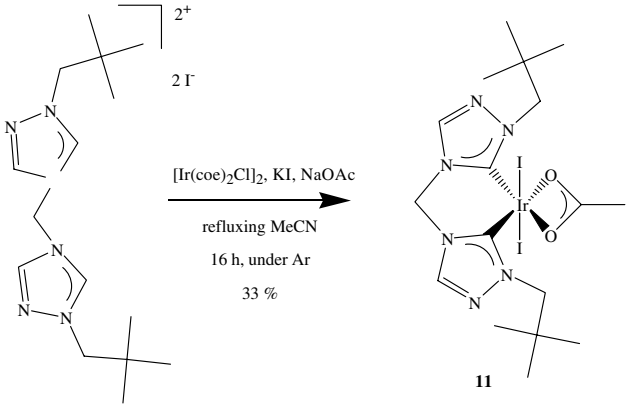


3 (Q = *o*-xylene, X = bromide)
4 (Q = neopentanediyl, X = triflate)

9 (Q = *o*-xylene)
10 (Q = neopentanediyl)

(3)

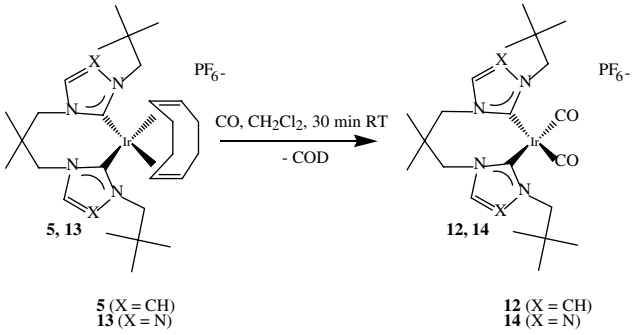
An iridium(III) compound **11**, was also synthesized from methylenebis(*N*-neopentyl) triazo-ligand precursor (Eq. (4)). This is the triazole analogue of an iridium(III) compound that we previously showed [6] is one of the most active catalysts known for transfer hydrogenation. It was therefore of interest to compare the catalytic activity of **11** to that of the very active prior compound.



(4)

2.2. Comparison of electron donating ability of bis-imidazole and bis-triazole iridium(I) compounds

Bis-chelating neopentylene imidazole (**12**) and triazole (**14**) iridium(I) compounds with two CO ligands could also be prepared following Eq. (5).



(5)

FT-IR spectra were obtained of **12** and **14**. The iridium(I) compound with a bis-imidazole ligand, **12**, has a CO average stretching frequency of 2036 cm^{-1}, while that with a bis-triazole ligand, **14**, has an average stretching frequency of 2051 cm^{-1}. This comparison, the first to our knowledge, indicates that the triazole compound is less electron donating than the imidazole compound [36]. We also attempted to prepare iridium(I) analogs of **12** and **14** with *n*-butyl wingtips or methyl wingtips, but, we were unable to synthesize the bis-triazole ligands with either *n*-butyl or methyl wingtips and a neopentanediyl linker. Thus, neopentyl wingtip groups are needed to prepare iridium(I) complexes with this linker. This illustrates the utility of the neopentyl wingtip group in facilitating metalation.

All of the iridium (bis-carbene) complexes are soluble in dichloromethane, chloroform, acetone, and tetrahydrofuran, but are insoluble in pentane and diethyl ether.

2.3. Spectroscopy

The structure of the iridium bis-carbene compounds was first deduced from NMR spectroscopy [6,7]. For complex **11**, only one set of signals has been detected for the protons of the carbene chelate. This is consistent with the two halves of the ligand being symmetry related. For the complexes with the less flexible neopentanediyl and *o*-xylene linkers (**5**–**10**), an AB pattern was observed for the protons in the chelate.

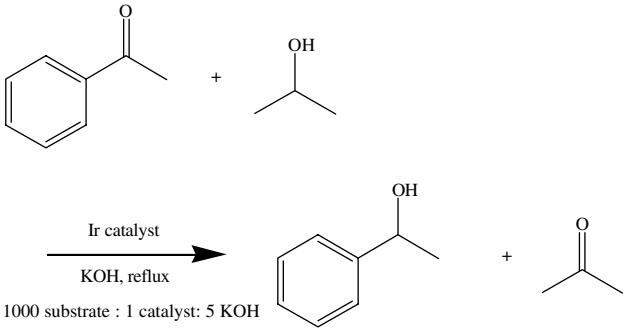
For **7**–**11**, in the $^{13}C\{^1H\}$ spectrum there is a low field singlet at approximately δ 132 ppm for the iridium bound carbon. The acetate anion gives rise to the expected NMR signals (δ_H 2.0, δ_C 190 and 25).

In the $^{13}C\{^1H\}$ spectrum the iridium(I) chelating carbene compounds **5**, **6** and **13**, show a low field singlet at approximately δ 179 ppm for the carbene carbon. In the ^1H NMR spectrum, the cyclooctadiene protons appear as three or four broad resonances in the δ 2.3 to 2.0 ppm region.

The iridium(I) biscarbonyl complexes **12** and **14**, show a low field singlet in the $^{13}C\{^1H\}$ spectrum at δ 171 ppm for the iridium bound carbon and the Ir-CO resonance occurs at δ 181 ppm. For complexes **12** and **14**, only one signal for the Ir-CO carbon has been detected indicating that the carbonyls are symmetry related.

2.4. Catalytic transfer hydrogenation of ketones

The iridium bis-carbene complexes **6**, **8**, **9**, **10**, and **11** catalyze the reduction of acetophenone to the corresponding alcohol via hydrogen transfer from the solvent, 2-propanol with potassium hydroxide as promoter (Eq. (6)). The iridium(III) compounds are efficient catalysts at a catalyst/base ratio of 0.2. The excess solvent drives the reaction by mass action.



(6)

We have screened the activity of the iridium (bis-carbene) catalysts in transfer hydrogenation using acetophenone as a substrate and substrate/catalyst/base ratio of 1000:1:5. The results in Table 1 show the influence of the linker group and the nature of the azole ring.

The results in Table 1 indicate that the bis-imidazole iridium(III) compounds exhibit higher catalytic activity than the bis-triazole compounds (e.g., entries 2–4 versus 5–7). The order of linker effectiveness is altered, however, methylene being best for imidazole, but neopentanediyl for triazole. The bis-imidazole version of compound **11**, compound **15**, is very active in transfer hydrogenation of acetophenone and other ketones with a maximum TOF (TON h^{-1}) of 50 000 [6]. Entry 8, with a substrate:precatalyst:base ratio of 1000:1:0, indicates that base, KOH, is required as a promoter for the reaction. Entry 9, carried out at 20 °C, shows reflux temperature is required for good activity.

2.5. Use of K_2CO_3 instead of KOH as a base for catalysis

Potassium carbonate, a weaker base than potassium hydroxide and essentially insoluble in 2-propanol, has been used very few times as a base for this reaction [37]. To screen the effectiveness of this base, acetophenone was reduced in the presence of 0.1 mol% catalyst (Eq. (8)). A substrate:precatalyst:base ratio of 1000:1:500 was followed. The results are summarized

Table 1
Influence of the linker group and NHC-ligand in transfer hydrogenation activity of acetophenone[a]

Entry	Catalyst	Linker	Bis-NHC ligand	Time	Yield (%)[b]	TOF[c] (TON h^{-1})

[a] Transfer hydrogenation of acetophenone. With K_2CO_3, a substrate:precatalyst:base ratio of 1000:1:500 was followed with 0.2 M substrate in 10 mL of 2-propanol at reflux temperature. With KOH, a substrate:precatalyst:base ratio of 1000:1:5 was followed with 0.2 M substrate in 10 mL of 2-propanol at reflux temperature. The KOH was added as a 10 mM solution in 2-propanol.
[b] The yields were determined using ^{1}H NMR.
[c] Estimated TOF = (TON/total reaction time).

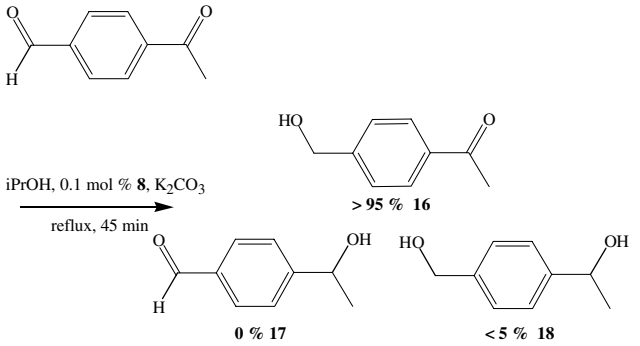
in Table 2. For comparison, the catalytic results with potassium hydroxide are also included, where the substrate:precatalyst:base ratio was 1000:1:5.

The results (Table 2) suggest that potassium carbonate can indeed be used as a base for transfer hydrogenation of acetophenone. The reaction occurs faster, though, with potassium hydroxide (Tables 1 and 2). An iridium(I) compound, **6**, was also tested for catalytic activity with potassium carbonate as a promoter but less than 20% of acetophenone was reduced after 20 h. This indicates that an iridium(III) starting material is needed for catalysis.

2.6. Selectivity

Precatalyst **8** catalyzed the transfer hydrogenation reduction of an equimolar mixture of acetophenone and phenylacetaldehyde. Here, a 500:500:1:500 ratio (acetophenone:phenylacetaldehyde:precatalyst **8**:K_2CO_3) was used with 0.2 M total substrate in 10 mL of 2-propanol at reflux temperature. After 1 h, there was complete conversion of phenylacetaldehyde to phenylethyl alcohol but no conversion of acetophenone. Even after 24 h, there was still no further conversion of acetophenone. There was no evidence of aldol products in the proton NMR.

To test intramolecular selectivity, complex **8** was used for the transfer hydrogenation of 4-acetylbenzaldehyde (Eq. (7)).



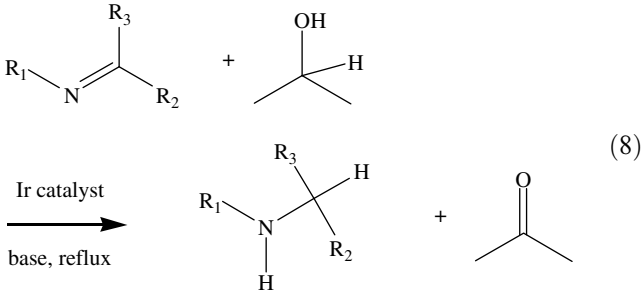
(7)

Of the three possible products possible in Eq. (7) only two are seen in the ^{1}H NMR spectrum with the aldehyde reduction product, **16**, in greater than 95% yield. Precatalyst **8** is therefore also selective for the intramolecular

transfer hydrogenation of aldehydes over ketones. No additional formation of **18** is seen after 90 min.

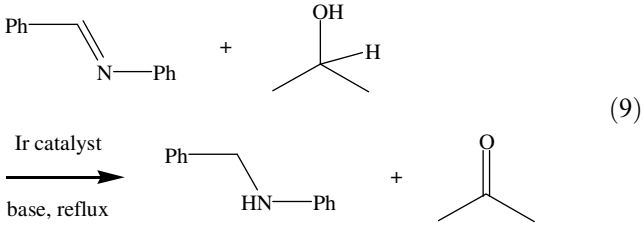
2.7. Transfer hydrogenation of imines

Because complexes **8**, **10**, and **15** are extremely active catalysts for the transfer hydrogenation of ketones and aldehydes, [6,7] they were also screened for the catalytic transfer hydrogenation of imines (Eq. (8)).



(8)

Precatalyst **15** was screened for catalytic activity in Eq. (9) (Table 3). Either KOH or an alkali carbonate base was utilized, and the products were determined by ^{1}H NMR and compared to authentic material. Prior work suggested that solid alkali carbonates would be useful bases, being milder than the conventional KOH. The imines were either purchased from commercial sources or prepared using known routes [38–40].



(9)

The results in Table 3 suggest that KOH and K_2CO_3 are the best bases for the transfer hydrogenation of *N*-benzylideneaniline (Eq. (9)). Economy dictates 0.1 mol% as a suitable catalyst loading since in all cases the catalytic reactions were complete within 20 min. For all catalytic reactions discussed below, either KOH or K_2CO_3 will be utilized as a base with either 0.1 or 1.0 mol% catalyst loading. Other imine substrates were subsequently screened for transfer hydrogenation activity (Eq. (8)) and the results are summarized in Table 4.

The results (Tables 3 and 4) suggest that catalyst **15** is only effective for certain types of imine substrates. It appears that bulky substituents must be present at both the carbon and the nitrogen on the imine for successful reduction (Table 3, entries 1–6; Table 4, entries 3–5, 9, 11). The best bases are either KOH or K_2CO_3, and other alkali carbonate bases require longer reaction times.

A low precatalyst loading (0.1 mol%) was sufficient for *N*-benzylideneaniline (PhCH=NPh) (Table 3, entries 1–2) and naphthalen-2-ylmethylene-phenyl-imine (NpCH=NPh) (Table 4, entry 3) but a 1.0 mol% catalyst loading was needed for the other substrates (Table 4, entries 9 and 11). Nevertheless, even higher catalyst loadings were needed for prior catalysts [41]. A very high turnover frequency (TOF) of 3000–6000 (TON h^{-1}) was seen for *N*-benzylideneaniline. Previous precatalysts never gave a TOF greater than 800 (TON h^{-1}) [42].

Precatalysts **8** and **10** also catalyzed transfer hydrogenation of *N*-benzylideneaniline (Table 5 and Eq. (9)).

8 and **10** could also be used as a precatalyst for the transfer hydrogenation reduction of benzylidene aniline but, longer reaction times were needed for this precatalyst when compared to **15** (Tables 3 and 4).

α,β-Unsaturated imines have been reduced previously [43] and one was also prepared according to the method described by Brady and Shieh [44]. These substrates can give several products upon transfer hydrogenation reduction shown in Eq. (10).

Table 3
Transfer hydrogenation of *N*-benzylideneaniline with precatalyst 15

Entry	Catalyst loading (mol%)[a]	Base	Time (min)	Yield (%)[b]	TOF[c] (TON h^{-1})

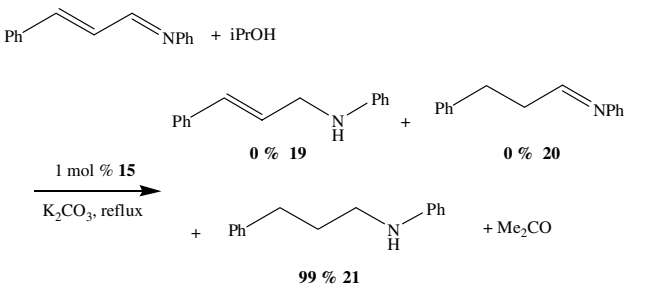
[a] Transfer hydrogenation of *N*-benzylideneaniline (Eq. (9)). The precatalyst was added to the reaction solution as a solution in 0.4 mL of thf.
[b] The yields were determined using ^{1}H NMR.
[c] Estimated TOF = (TON/total reaction time).
[d] Reaction conditions for KOH = 1000:10:50 (substrate:precatalyst:base) with 0.2 M substrate in 10 mL of 2-propanol at reflux temperature. The KOH was added from a 10 mM solution in 2-propanol.
[e] The reaction conditions were 1000:1:500 (substrate:precatalyst:base) or 1000:10:500 (substrate:precatalyst:base). When potassium carbonate was utilized, it was added as a solid to the reaction flask.



(10)

Precatalyst **15** gave the result shown in Eq. (10), and only the fully reduced product was formed, **21**, in 99% yield. After 30 min, a mixture of **19**–**21** were identified using ^{1}H NMR, an apparent inconsistency here because only **21** is reported in Eq. (10). Again, the products were identified with ^{1}H NMR and compared with authentic material.

Precatalyst **15** can also reduce isolated C=C bonds in amines. For example, the α,β unsaturated imine of Eq. (10) was reduced with sodium borohydride to give amine **19**, which was used as a substrate with precatalyst **15** (1 mol%) to give **21** in quantitative yield after 30 min. Amines often strongly deactivate homogenous catalysts, but this is not the case here. A phenyl substituent may be required on the C=C for amine reduction.

2.8. Competition experiments

Precatalyst **8** gave the transfer hydrogenation reduction of a mixture of acetophenone, phenylacetaldehyde, and *N*-benzylideneaniline (1:1:1 mol. equiv). For this

competition experiment, a 1000:1:500 (sum of substrates:precatalyst **8**:K_2CO_3) was used with 0.2 M total substrate in 10 mL of 2-propanol at reflux temperature. Precatalyst **8** (0.1 mol%) can reduce acetophenone independently in 20 min (Table 1), phenylacetaldehyde independently in 1 h, [45] and *N*-benzylideneaniline independently in 2 h (Table 5). In the competition reaction, after 1 h, there was complete conversion of phenylacetaldehyde to phenylethyl alcohol, but no evidence of *N*-phenylbenzylamine or *sec*-phenylethyl alcohol. After 19 h of total reaction time, there was, in addition, complete conversion of acetophenone to *sec*-phenylethyl alcohol and 73% conversion of *N*-benzylideneaniline to *N*-phenylbenzylamine. Thus, precatalyst **8** is selective for phenylacetaldehyde over acetophenone and *N*-benzylideneaniline. Precatalyst **8** was used instead of **15** because precatalyst **15** cannot reduce phenylacetaldehyde catalytically [7].

Precatalyst **8** catalyzed the transfer hydrogenation reduction of a 1 to 1 mixture of acetophenone and phenylacetaldehyde. Here, 500:500:1:500 (acetophenone:phenylacetaldehyde:precatalyst **8**:K_2CO_3) was used with 0.2 M total substrate in 10 mL of 2-propanol at reflux temperature. After 1 h, there was complete conversion of phenylacetaldehyde to phenylethyl alcohol but no conversion of acetophenone. Even after 24 h, there was still no further conversion of acetophenone.

Precatalyst **8** catalyzed the transfer hydrogenation reduction for a 1 to 1 mixture of phenylacetaldehyde and *N*-benzylideneaniline, with a ratio of 500:500:1:500 (phenylacetaldehyde:*N*-benzylideneaniline:precatalyst **8**:K_2CO_3) and 0.2 M total substrate in 10 mL of 2-propanol at reflux temperature. After 1 h, there was complete conversion of phenylacetaldehyde to phenylethyl alcohol but less than 5% of *N*-phenylbenzylamine. After 17 h, there was 17% of *N*-phenylbenzylamine present. Phenylacetaldehyde is therefore reduced most rapidly in all cases, a rather surprising result, since the imine is the better ligand. The imine no doubt has to attain a π-bound form to be reduced and so strong binding via the N lone pair is a disadvantage. The bulky substituent groups required for efficient imine reduction no doubt help attainment of the π-bound form.

3. Conclusions

We have developed a series of iridium bis-imidazole and bis-triazole precatalysts for the transfer hydrogenation of ketones. The choice of the linker group is important; the best results were obtained with methylene and neopentanediyl linkers. Precatalyst **8**, with a neopentanediyl linker, was selective for the transfer hydrogenation reduction of aldehydes over ketones. The mechanism remains to be defined.

Iridium(III) bis-carbene complexes **8**, **10**, **15** are efficient precatalysts for the transfer hydrogenation reduction of certain imine substrates. Precatalyst **15**, with a methylene linker, is more active than **8** or **10**. Competition experiments show precatalyst **8** is selective for phenylacetaldehyde over acetophenone, and *N*-benzylideneaniline. Further work is in progress.

4. Experimental

$[Ir(cod)Cl]_2$ [46] and $[Ir(coe)_2Cl]_2$ [47] were prepared according to literature procedures; all other reagents are commercially available and were used as received. NMR spectra were recorded at 25 °C on Bruker spectrometers at 400 or 500 MHz (^{1}H NMR or ^{19}F NMR) and 100 or 125 MHz (^{13}C NMR), respectively, and referenced to $SiMe_4$ (δ in ppm, J in Hz). Assignments are based either on distortionless enhancement of polarization transfer (DEPT) experiments or on homo- and heteronuclear shift correlation spectroscopy. Melting points are uncorrected. Elemental analyses were performed by Atlantic Microlab, Inc. (Norcross, GA); solvent of crystallization in the solids has been identified by ^{1}H NMR spectroscopy. Electrospray mass spectra were recorded on a Micromass ZQ instrument using nitrogen as a drying and nebulizing gas. When solvent of crystallization was needed for the analytical data, we verified the presence of that solvent in the sample by ^{1}H NMR spectroscopy. The syntheses of precatalysts **8**, **10**, **15**, complex **6**, ligand precursors **2** and **4**, 1-neopentyl-1,2,4 triazole and neopentanediyl bistriflate have been previously described and were synthesized [6,7].

4.1. Typical procedure for catalytic transfer hydrogenation

Ketone (2.0 mmol), catalyst (0.2 mL of a 10 mM THF solution), base (if KOH is used, it is added to the reaction solution from a 10 mM solution in *i*PrOH) (if alkali carbonate base is used, it is added as a solid to the reaction solution) and *i*PrOH (10 mL) were added in a 50 mL round bottom flask in a preheated oil bath. Aliquots (0.5 mL) were taken at fixed times, diluted in *n*-hexane (10 mL) and filtered through a short path column of SiO_2. The filtrate was evaporated to dryness and analyzed by ^{1}H NMR spectroscopy. The reported yields are a percent conversion of starting material. All data are averages of at least two runs. An internal standard, mesitylene, has been used previously for the transfer hydrogenation reduction of 2-phenylpropionaldehyde and hydrocinnamaldehyde and proton NMR experiments showed no aldehyde after 1 h and the alcohol as

the major product. GC–MS experiments were consistent with this result [7].

Imine (2.0 mmol), precatalyst (0.4 mL in a THF solution), base (if KOH is used, it is added to the reaction solution from a 10 mM solution in *i*PrOH) (if alkali carbonate base is used, it is added as a solid to the reaction solution) and *i*PrOH (10 mL) were added in a 50 mL round bottom flask in a preheated oil bath. The footnotes for each table give the reaction conditions that were followed. Aliquots (0.5 mL) were taken at fixed times, diluted in *n*-hexane (10 mL) and filtered through a short path column of SiO_2. The filtrate was evaporated to dryness and analyzed by ^1H NMR spectroscopy. All data are averages of at least two runs.

4.1.1. Methylenebis(N-neopentyl)triazolium diiodide

A solution of *N*-neopentyl triazole (1.404 g, 10.09 mmol) and CH_2I_2 (1.4084 g, 5.258 mmol) was stirred in refluxing toluene (10 mL) for 3 days. The formed precipitate was collected by filtration and recrystallized from hot MeOH at −20 °C to give the product as an off-white solid. (0.99 g, 36%). ^1H NMR (DMSO-D_6, 400 MHz, $SiMe_4$) δ 10.41 (s, 2H, NC*H*N), 9.40 (s, 2H, NC*H*N), 6.86 (s, 2H, NCH_2N), 4.32 (s, 4H, CH_2CMe_3), 0.98 (s, 18H, C(CH_3)$_3$). $^{13}C\{1H\}$ NMR (DMSO-D_6, 100 MHz, $SiMe_4$) δ 144.55 (NCHN), 143.88 (NCHN), 62.12 (CH_2CMe_3), 55.28 (NCH_2N), 32.24 ($C(CH_3)_3$), 26.57 (C(CH_3)$_3$). *Anal.* Calc. for $C_{15}H_{28}I_2N_6$ (546.23): C, 32.98; H, 5.17; N, 15.39. Found: C, 32.97; H, 5.24; N, 15.44%. Melting point 229–234 °C (dec).

4.1.2. o-Xylenebis(N-neopentyl)imidazolium dibromide (**1**)

A round bottom flask was charged with neopentyl imidazole (0.845 g, 6.11 mmol), α,α′ dibromo-*o*-xylene (0.8084 g, 3.066 mmol), and 1,4 dioxane (10 mL). This reaction solution was heated at reflux for two days after which a brown oil precipitate had formed. The 1,4 dioxane solution was decanted off and the brown oil was washed two times with 1,4 dioxane (10 mL each). The product was then dissolved in methanol (15 mL) and the product was precipitated with diethyl ether. The white flaky solid was collected via vacuum filtration and was washed three times with diethyl ether (40 mL each). Yield 1.3504 g, (82%). ^1H NMR (DMSO-D_6, 500 MHz, $SiMe_4$) δ 9.42 (s, 2H, NCHN), 7.86 (s, 2H, imid-H), 7.82 (s, 2H, imid-H), 7.49 (m, 2H, C_{aryl}-H), 7.28 (m, 2H, C_{aryl}-H), 5.75 (s, 4H, benzyl-CH_2), 4.05 (s, neopentyl-CH_2), 0.93 (s, 18H, neopentyl CH_3). $^{13}C\{^1H\}$ NMR (DMSO-D_6, 125 MHz, $SiMe_4$) δ 137.48 (NCHN), 133.39 (C_{ipso}), 129.98 (C_{aryl}), 129.66 (C_{aryl}), 124.75 (C_{imid}), 122.66 (C_{imid}), 59.98 (neopentyl *C*H_2), 49.42 (benzyl-*C*H_2), 32.27 ($CH_2C(CH_3)_3$), 27.05 ($CH_2C(CH_3)_3$). *Anal.* Calc. for $C_{24}H_{36}Br_2N_4$ (540.38) · $1H_2O$: C, 51.62; H, 6.86; N, 10.03. Found: C, 51.28; H, 6.68; N, 9.90%. Melting point 223–226 °C (dec).

4.1.3. o-Xylenebis(N-neopentyl)triazolium dibromide (**3**)

To a 50 mL schlenk flask, the following were added, neopentyl triazole (1.441 g, 10.35 mmol), α,α′ dibromo-*o*-xylene (1.0099 g, 3.825 mmol) and 1,4-dioxane (15 mL, degassed). This reaction was heated under reflux for 18 h under argon. After allowing the reaction mixture to cool, the white solid was collected via vacuum filtration. This product was washed three times with 1,4-dioxane (30 mL each) and three times with diethyl ether (50 mL each). Yield: 2.05 g (99%). ^1H NMR (DMSO-D_6, 500 MHz, $SiMe_4$) δ 10.54 (s, 2H, NCHN), 9.42 (s, 2H, NCHN), 7.54 (m, 4H, C_{aryl}-H), 5.82 (s, 4H, benzyl-CH_2), 4.25 (s, neopentyl-CH_2), 0.97 (s, 18H, neopentyl CH_3). $^{13}C\{^1H\}$ NMR (DMSO-D_6, 125 MHz, $SiMe_4$) δ 144.52 (NCHN), 143.24 (NCHN), 132.13 (C_{ipso}), 130.51 (C_{aryl}), 130.12 (C_{aryl}), 62.07 (neopentyl *C*H_2), 47.78 (benzyl-*C*H_2), 32.13 (-$CH_2C(CH_3)_3$), 26.77 ($CH_2C(CH_3)_3$). *Anal.* Calc. for $C_{22}H_{34}Br_2N_6$ (542.35): C 48.72, H: 6.32, N 15.50. Found: C, 48.54; H, 6.35; N, 15.27%. Melting point 204–207 °C (dec).

4.1.4. o-Xylenebis(N-neopentyl)imidazole-2-ylidene bis1,5 cyclooctadiene iridium(I) hexafluorophosphate (**5**)

The synthesis of the iridium (I) compound was accomplished by dissolving **1** (0.3120 g, 0.5773 mmol), KCl (0.2986 g, 3.884 mmol), NaOAc (0.3211 g, 3.914 mmol), $[Ir(cod)Cl]_2$ (0.2027g, 0.3018 mmol) in 15 mL of degassed MeCN. This yellow reaction mixture was stirred under argon for 2 min at RT and then stirred at reflux under argon for 18 h. The product solution was orange. The acetonitrile solvent was evaporated off under reduced pressure. The crude product was then purified using column chromatography (SiO_2, KPF_6, CH_2Cl_2/acetone 1:1). Yield: 0.331 g (80%). The product could be recrystallized from slow Et_2O diffusion into CH_2Cl_2. ^1H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.61 (m, 2H, aryl-H), 7.45 (m, 2H, aryl-H), 7.15 (s, 2H, imid-H), 7.00 (s, 2H, imid-H), 6.54 (d, J = 14.1 Hz, 2H, CH_2C$(CH_3)_3$), 4.99 (d, J = 14.1 Hz, 2H, CH_2C$(CH_3)_3$), 4.47 (d, J = 13.4 Hz, 2H, benzyl-CH_2), 4.14 (s, broad, 4H, cod C-H), 3.55 (d, J = 13.4 Hz, 2H, benzyl-CH_2), 2.34 (s, broad, 2H, cod-CH_2), 2.24 (s, broad, 2H, cod-CH_2), 2.07 (m, 2H, cod-CH_2), 2.00 (m, 2H, cod-CH_2), 1.08 (s, 18H, $CH_2C(CH_3)_3$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 177.09 (Ir-C), 134.74 (C_{ipso}), 132.42 (C_{aryl}), 130.35 (C_{aryl}), 121.69 (C_{imid}), 121.09 (C_{imid}), 74.92 (cod-CH), 63.03 (benzyl-CH_2), 51.40 ($CH_2C(CH_3)_3$), 32.37 ($CH_2C(CH_3)_3$), 31.36 (cod-CH_2), 31.27 (cod-CH_2), 28.82 ($CH_2C(CH_3)_3$). *Anal.* Calc. for $C_{32}H_{46}F_6IrN_4P$ (823.92) · $1CH_2Cl_2$: C, 43.61; H, 5.32; N, 6.16. Found: C, 43.92; H, 5.38; N, 6.16%. Melting point 165–170 °C (dec).

4.1.5. o-Xylenebis(N-neopentyl)imidazole-2-ylidene acetate (diiodo) iridium(III) (7)

This iridium(I) product, **5**, (0.1732 g, 0.2418 mmol) was reacted with iodine (0.1795 g, 0.7072 mmol), NaOAc (0.1073, 1.308 mmol) in MeCN (15 mL). This reaction solution was stirred for 4 h at RT. After the reaction was halted, the acetonitrile solvent was removed under reduced pressure. The product was purified using column chromatography. The excess iodine was eluted with (CH_2Cl_2/hexane 1:1), and the product was eluted with CH_2Cl_2. Yield: 0.102 g (48%). The orange product was recrystallized by a slow diffusion of pentane into a CH_2Cl_2 solution. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.35 (m, 2H, aryl-H), 7.27 (m, 2H, aryl-H), 7.04 (s, 2H, imid-H), 6.52 (s, 2H, imid-H), 5.18 (d, $J = 14.3$ Hz, $CH_2C(CH_3)_3$), 5.00 (d, $J = 15.6$ Hz, 2H, benzyl CH_2), 3.42 (d, $J = 15.6$ Hz, 2H, benzyl CH_2), 3.75 (d, $J = 14.4$ Hz, $CH_2C(CH_3)_3$), 2.05 (s, 3H, CH_3COO), 1.08 (s, 18H, $CH_2C(CH_3)_3$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 189.81 (CH_3COO) 136.37 (Ir-C), 130.67 (C_{aryl}), 129.13 (C_{aryl}), 126.68 (C_{ipso}), 123.40 (C_{imid}), 121.07 (C_{imid}), 62.34 ($CH_2C(CH_3)_3$), 54.74 ($CH_2C(CH_3)_2CH_2$), 33.20 ($CH_2C(CH_3)_3$), 28.32 ($CH_2C(CH_3)_3$), 25.94 (CH_3COO). *Anal*. Calc. for $C_{26}H_{37}I_2IrN_4O_2$ (883.62): C, 35.34; H, 4.22; N, 6.34. Found: C, 35.37; H, 4.69; N, 3.66%. Despite several attempts, no better elemental analysis could be obtained. Similar analysis problems with carbene complexes have been reported [48]. Melting point 210–213 °C (dec).

4.1.6. o-xylenebis(N-neopentyl)triazole-3-ylidene acetate (diiodo) iridium(III) (9)

The following were added to a schlenk flask: **3** (0.4694 g, 0.8655 mmol), $[Ir(coe)_2Cl]_2$ (0.3521 g, 0.4364 mmol), KI (0.6323 g, 3.809 mmol), NaOAc (0.4770 g, 5.815 mmol), and MeCN (15 mL). The reaction solution was stirred for 2 min under Ar at RT and then at reflux for 18 h under Ar. After cooling, all volatiles were removed under reduced pressure and the residue was purified using column chromatography. Column chromatography (SiO_2; CH_2Cl_2) gave the product as an orange solid. Yield: 0.214 g, (28%). Crystalline material was obtained by slow pentane diffusion into a CH_2Cl_2 solution of the titled product. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.64 (s, 2H, NCHN), 7.43 (m, 2H, C_{aryl}-H), 7.35 (m, 2H, C_{aryl}-H), 5.17 (d, $J = 13.9$ Hz, 2H, neopentyl-CH_2), 5.01 (d, $J = 16.1$ Hz, 2H, benzyl-CH_2), 4.55 (d, $J = 16.1$ Hz, 2H, benzyl-CH_2), 4.01 (d, $J = 13.9$ Hz, 2H, neopentyl-CH_2), 2.01 (s, 3H, CH_3COO), 1.09 (s, 18H, neopentyl CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 190.76 (CH_3COO), 142.39 (NCHN), 134.60 (C-Ir), 134.41 (C_{ipso}), 131.05 (C_{aryl}), 130.08 (C_{aryl}), 63.69 (neopentyl CH_2), 52.23 (benzyl-CH_2), 33.25 (-$CH_2C(CH_3)_3$), 28.46 ($CH_2C(CH_3)_3$), 25.73 (CH_3COO). *Anal*. Calc. for $C_{24}H_{35}I_2IrN_6O_2$ (885.60) · $1H_2O$: C, 31.90; H, 4.13; N, 9.30. Found: C, 31.52; H, 3.88; N, 8.88%. Melting point 245–248 °C (dec).

4.1.7. Methylenebis(N-neopentyl)triazole-3-ylidene acetate (diiodo) iridium(III) (11)

The following were added to a schlenk flask: Methylenebis(*N*-neopentyl)triazolium diiodide (0.2460 g, 0.4504 mmol), $[Ir(coe)_2Cl]_2$ (0.1860 g, 0.2305 mmol), KI (0.3099 g, 1.866 mmol), NaOAc (0.2397 g, 2.922 mmol), and MeCN (14 mL). The reaction solution was stirred for 2 min under Ar at RT and then at reflux for 18 h under Ar. After cooling, all volatiles were removed under reduced pressure and the residue was purified using column chromatography. Column chromatography (SiO_2; CH_2Cl_2/acetone (9:1)) gave the product as an orange solid. Yield: 0.117 g, (33%). Crystalline material was obtained by slow pentane diffusion into a CH_2Cl_2 solution of the titled product. ^{1}H NMR (acetone-D_6, 400 MHz, $SiMe_4$) δ 8.68 (s, 2H, NC*H*N), 6.66 (s, 2H, NCH_2N), 4.16 (s, 4H, CH_2CMe_3), 1.94 (s, 3H, CH_3COO), 1.08 (s, 18H, $C(CH_3)_3$). ^{13}C1H NMR (acetone-D_6, 100 MHz, $SiMe_4$) δ 190.55 (CH_3COO), 142.88 (NCHN), 133.96 (C-Ir), 63.00 (CH_2CMe_3), 59.65 (NCH_2N), 33.75 ($C(CH_3)_3$), 29.84 ($C(CH_3)_3$), 26.02 (CH_3COO). *Anal*. Calc. for $C_{17}H_{29}I_2N_6O_2$ (795.48): C, 25.67; H, 3.67; N, 10.56. Found: C, 25.80; H, 3.65; N, 10.48%. Melting point 320–323 °C (dec).

4.1.8. Neopentylenebis(N-neopentyl)imidazole-2-ylidene biscarbonyl iridium(I) hexafluorophosphate (12)

To a schlenk flask the following were added, **6** (0.0717 g, 0.0905 mmol) and 15 mL of CH_2Cl_2. CO gas (1 atm) was bubbled through this solution for 30 min and during this time period the solution changed from orange to yellow. 30 mL of *n*-hexane was added to the CH_2Cl_2 solution which was precipitated at −20 °C. The yellow solid was collected via vacuum filtration and washed three times (30 mL each) with diethyl ether. The product was dried in vacuo. Yield: 0.0472 g (70%). ^{1}H NMR (acetone-D_6, 500 MHz, $SiMe_4$) δ 7.44 (s, 2H, imid-H), 7.34 (s, 2H, imid-H), 5.00 (d, $J = 14.4$ Hz, 2H, CH_2), 4.46 (d, $J = 13.4$ Hz, 2H, CH_2), 4.09 (d, $J = 14.3$ Hz, 2H, CH_2), 3.91 (d, $J = 13.4$ Hz, 2H, CH_2), 1.24 (s, 3H, $CH_2C(CH_3)_2CH_2$), 1.09 (s, 18H, $CH_2C(CH_3)_3$), 1.05 (s, 3H, $CH_2C(CH_3)_2CH_2$). $^{13}C\{^1H\}$ NMR (acetone-d_6, 125 MHz, $SiMe_4$) δ 182.80 (Ir-CO), 170.38 (Ir-C), 126.03 (C_{imid}), 123.37 (C_{imid}), 63.12 (CH_2), 62.16 (CH_2), 36.88 ($CH_2C(CH_3)_2CH_2$), 33.48 ($CH_2C(CH_3)_3$), 29.30 ($CH_2C(CH_3)_3$), 29.15 ($CH_2C(CH_3)_2CH_2$), 21.08 ($CH_2C(CH_3)_2CH_2$). *Anal*. Calc. for $C_{23}H_{36}F_6IrN_4O_2P$ (737.74): C, 37.44; H, 4.92; N, 7.59. Found: C, 37.47; H, 4.87; N, 7.59%. Melting point 270–275 °C (dec).

4.1.9. Neopentylenebis(N-neopentyl)triazole-3-ylidene bis1,5 cyclooctadiene iridium(I) hexafluorophosphate (**13**)

First, a schlenk flask was charged with Neopentylenebis(*N*-neopentyl)triazolium bistriflate, (0.3038 g, 0.4698 mmol), KCl (0.3251 g, 4.360 g), NaOAc (0.3258, 3.972 mmol), $[Ir(cod)Cl]_2$ (0.1613 g, 0.2401 mmol) and MeCN (15 mL). The reaction solution was stirred at RT for 2 min under argon and then at reflux under argon for 18 h. The reaction solution changed from yellow to orange in color during this time. After the reaction solution cooled, the solvent was removed under reduced pressure. The residual product was then dissolved in CH_2Cl_2 (40 mL) and this solution was filtered to remove insoluble salts and neopentylenebis(*N*-neopentyl)triazole-3-ylidene bis1,5 cyclooctadiene iridium(I) chloride was isolated. Yield = 0.306 g (95%). ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.37 (s, 2H, triazole-H), 4.57 (d, J = 14.4 Hz, 2H, CH_2), 4.32 (d, J = 11.5 Hz, 2H, CH_2), 4.29 (d, J = 12.2 Hz, 2H, CH_2), 4.18 (s, broad, 4H, cod C-H), 3.73 (d, J = 13.3 Hz, 2H, CH_2), 2.30 (m, 4H, cod CH_2), 2.20 (m, 2H, cod CH_2), 2.06 (m, 2H, cod CH_2), 1.41 (s, 3H, $CH_2C(CH_3)_2CH_2$), 1.04 (s, 18H, $CH_2C(CH_3)_3$). 0.87 (s, 3H, $CH_2C(CH_3)_2CH_2$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 180.67 (Ir-C), 145.67 ($C_{triazole}$), 79.35 (cod C-H), 78.01 (cod C-H), 63.25 (CH_2), 58.92 (CH_2), 38.07 ($CH_2C(CH_3)_2CH_2$), 31.73 (cod CH_2), 31.27 (cod CH_2), 28.53 ($CH_2C(CH_3)_3$), 27.24 ($CH_2C(CH_3)_3$), 19.72 ($CH_2C(CH_3)_2CH_2$).

Then, the above product (0.1805 g, 0.2645 mmol) was dissolved in 50 mL CH_2Cl_2 and $AgPF_6$ was added (0.0724 g, 0.2864 mmol). This solution was stirred in the dark for 18 h. The resulting product was then filtered over Celite and the solvent was evaporated under reduced pressure. Yield: 0.208 g, (99%). ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.20 (s, 2H, triazole-H), 4.65 (d, J = 14.4 Hz, 2H, CH_2), 4.34 (d, J = 13.4 Hz, 2H, CH_2), 4.30 (s, broad, 4H, cod C-H) 4.12 (d, J = 14.5 Hz, 2H, CH_2), 3.83 (d, J = 13.4 Hz, 2H, CH_2), 2.31 (m, 2H, cod CH_2), 2.23 (m, 2H, cod CH_2), 2.17 (m, 2H, cod CH_2), 2.04 (m, 2H, cod CH_2) 1.34, (s, 3H, $CH_2C(CH_3)_2CH_2$), 1.06 (s, 18H, $CH_2C(CH_3)_3$). 0.94, (s, 3H, $CH_2C(CH_3)_2CH_2$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 181.10 (Ir-C), 146.04 ($C_{triazole}$), 79.90 (cod C-H), 78.62 (cod C-H), 63.25 (CH_2), 58.93 (CH_2), 37.81 ($CH_2C(CH_3)_2CH_2$), 32.45 (cod CH_2), 31.73 ($CH_2C(CH_3)_3$), 31.19 (cod CH_2), 28.55 ($CH_2C(CH_3)_3$), 22.80 ($CH_2C(CH_3)_2CH_2$). *Anal*. Calc. for $C_{27}H_{46}F_6IrN_6P$ (791.88) · $1H_2O$: C, 40.04; H, 5.97; N, 10.38. Found: C, 39.67; H, 5.69; N, 10.13%. Melting point 270–272 °C (dec).

4.1.10. Neopentylenebis(N-neopentyl)triazole-3-ylidene biscarbonyl iridium(I) hexafluorophosphate (**14**)

To a schlenk flask the following were added, **13** (0.1016 g, 0.1169 mmol) and 15 mL of CH_2Cl_2. CO gas (1 atm) was bubbled through this solution for 40 min and during this time period the solution changed from orange to yellow in color. 35 mL of *n*-hexane was added to the CH_2Cl_2 solution which was precipitated at −20 °C. The yellow solid was collected via vacuum filtration and washed three times (40 mL each) with diethyl ether. The product was dried in vacuo. Yield: 0.0780 g (82%). ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.51 (s, 2H, triazole-H), 4.62 (d, J = 14.5 Hz, 2H, CH_2), 4.30 (d, J = 14.5 Hz, 2H, CH_2), 4.24 (d, J = 14.3 Hz, 2H, CH_2), 3.77 (d, J = 13.1 Hz, 2H, CH_2), 1.36, (s, 3H, $CH_2C(CH_3)_2CH_2$), 1.08 (s, 18H, $CH_2C(CH_3)_3$). 0.95, (s, 3H, $CH_2C(CH_3)_2CH_2$). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 179.88 (Ir-CO), 172.26 (Ir-C), 146.57 ($C_{triazole}$), 64.46 (CH_2), 59.21 (CH_2), 36.71 ($CH_2C(CH_3)_2CH_2$), 33.35 ($CH_2C(CH_3)_3$), 28.18 ($CH_2C(CH_3)_3$), 26.48 ($CH_2C(CH_3)_2CH_2$), 19.57 ($CH_2C(CH_3)_2CH_2$). *Anal*. Calc. for $C_{21}H_{34}F_6IrN_6O_2P$ (739.71) · $1H_2O$: C, 33.29; H, 4.79; N, 11.09. Found: C, 33.48; H, 4.53; N, 10.81%. Melting point 255–260 °C (dec).

^{1}H and ^{13}C NMR spectra have not been reported for **16** and **18** and are reported below:

4.1.11. 1-(4-hydroxymethyl-phenyl)-ethanone (**16**)

This product was characterized after catalytic transfer hydrogenation of 4-acetylbenzaldehyde.^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.88 (d, ^3J = 8.2 Hz, 2H, CH), 7.38 (d, ^3J = 8.1 Hz, 2H, CH), 4.71 (s, 2H, CH_2), 2.54 (s, 3H, CH_3), 1.71 (broad s, 1H, OH). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 196.84 (C=O), 145.16 (C_{ipso}), 135.37 (C_{ipso}), 127.62 (CH), 125.61 (CH), 63.62 (CH_2), 25.63 (CH_3).

4.1.12. 1-(4-hydroxymethyl-phenyl)-ethanol (**18**)

This product was characterized by reducing 4-acetylbenzaldehyde with $NaBH_4$ following a procedure described by Blackburn and Taylor [49]. 4-acetylbenzaldehyde (0.083 g, 0.56 mmol) was stirred at 0 °C in 7 mL of MeOH for 5 min after which, $NaBH_4$ was added (0.037 g, 0.98 mmol). The contents were then stirred for 30 min. at 0 °C, after which the MeOH was removed under reduced pressure. The residue was taken up in about 25 mL of diethyl ether and 25 mL of saturated $NaHCO_3$. The ether layer was collected and the aqueous layer was washed two additional times with diethyl ether. The ether extracts were combined and dried over $MgSO_4$. The ether solution was filtered and the diethyl ether was removed under reduced pressure. Yield: 0.076 g (89%). ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.27 (m, 4H, CH), 4.81 (quartet, ^3J = 6.4 Hz, 1H, CH), 4.58 (s, 2H, CH_2), 1.98 (broad s, 2H, OH), 1.40 (d, ^3J = 6.5 Hz, 3H, CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$) δ 145.66 (C_{ipso}), 140.49 (C_{ipso}), 70.54 (CH(OH)), 65.40 (CH_2), 25.58 (CH_3).

Modern data are not available for the imines so we report them below.

4.2. Synthesis of imine substrates for catalysis:

4.2.1. Naphthalen-2-ylmethylene-phenyl-imine (NpCH=NPh)

Following the general procedure described by Neuvonen et al. [50], 2-napthaldehyde (0.5564 g, 3.562 mmol) was dissolved in 10 mL of absolute ethanol. To this solution, aniline (0.3375 g, 3.623 mmol) was added. The solution was allowed to stand at room temperature for 15 h after which, an off-white precipitate had formed. The ethanol was removed under reduced pressure. Yield 0.70 g (84 %). Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.55 (s, 1H, CHN), 8.14 (s, 1H), 8.10 (m, 1 H), 7.84 (m, 2 H), 7.81 (m, 1H), 7.47 (m, 2H), 7.36 (m, 2H), 7.20 (m, 3 H). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 160.76 (CHN), 152.50 (C_{ipso}), 135.45 (C_{ipso}), 134.35 (C_{ipso}), 133.52 (C_{ipso}), 131.65 (CH), 129.59 (CH), 129.19 (CH), 129.08 (CH), 128.35 (CH), 127.96 (CH), 127.02 (CH), 126.40 (CH), 124.24 (CH), 121.33 (CH). *Anal.* Calc. for $C_{17}H_{13}N$ (231.29): C, 88.28; H, 5.67; N, 6.06. Found: C, 87.73; H, 5.65; N, 6.00%.

4.2.2. (2,4,6-Trimethyl-benzylidene)-(2,4,6-trimethyl-phenyl)-imine (MesCH=NMes)

Following the procedure described by Texier-Boullet [51], mesityl aldehyde (1.4628 g, 9.869 mmol) was dispersed in 2.5368 g of alumina. To this mixture, mesityl amine (1.3374 g, 9.891 mmol) was added, which was dispersed in 2.7830 g of alumina. This mixture was stirred at RT for three days. After this time period, the residue was dissolved in 100 mL of CH_2Cl_2 and filtered. The CH_2Cl_2 was removed under reduced pressure and the product was an orange oil. Yield: 2.60 g (99%). Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.67 (s, 1H, CHN), 6.98 (d, ^3J = 8.6 Hz, 4H), 2.64 (s, 6H, CH_3), 2.38 (d, ^3J = 16.0 Hz, 6H, CH_3), 2.29 (s, 6H, CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 163.68 (CHN), 150.68 (C_{ipso}), 140.24 (C_{ipso}), 139.18 (C_{ipso}), 133.18 (C_{ipso}), 130.97 (CH), 130.729 (CH), 129.27 (CH), 127.17 (C_{ipso}), 21.75 (CH_3), 21.60 (CH_3), 21.14 (CH_3), 19.22 (CH_3).

4.2.3. (2,4,6-trimethyl-benzylidene)-phenyl imine (MesCH=NPh)

Following the procedure described by Texier-Boullet [49], mesityl aldehyde (1.473 g, 9.938 mmol) was dispersed in 2.5466 g of alumina. To this mixture, aniline (0.9294 g, 9.931 mmol) was added, which was dispersed in 2.5249 g of alumina. This mixture was stirred at RT for 15 h. After this time period, the residue was dissolved in 100 mL of CH_2Cl_2 and filtered. The CH_2Cl_2 was removed under reduced pressure and the product was an orange/brown oil that solidified at RT after 2h. Yield: 2.12 g (95%). Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.87 (s, 1H, CHN), 7.45 (m, 2H), 7.28 (m, 1H), 7.21 (m, 2H), 6.98 (s, 2H, CH), 2.51 (s, 6H, CH_3), 2.37 (s, 3H, CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 161.25 (CHN), 153.54 (C_{ipso}), 140.26 (C_{ipso}), 139.05 (C_{ipso}), 130.96 (CH), 130.20 (CH), 129.54 (CH), 125.95 (CH), 121.14 (CH), 21.66 (CH_3), 21.49 (CH_3).

4.2.4. (4-nitro-benzylidene)-phenyl-imine (p-$NO_2C_6H_4$-CH=NPh)

Following the general procedure described by Neuvonen et al. [48], 4-nitrobenzaldehyde (0.7455 g, 4.933 mmol) was dissolved in 10 mL of absolute ethanol. To this solution, aniline (0.4585 g, 4.923 mmol) was added. This solution was allowed to stand at RT for 16 h, and a yellow precipitate formed after this time. The ethanol was removed under reduced pressure. Yield: 1.03 g (93%). The product could be recrystallized from ethanol at −20 °C. Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.49 (s, 2H, CHN), 8.25 (AB d, 2H, ^3J = 8.7 Hz), 8.00 (AB d, 2H, ^3J = 8.7 Hz), 7.36 (m, 2H), 7.20 (m, 3H). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 157.74 (CHN), 151.33 (C_{ipso}), 149.70 (C_{ipso}), 141.98 (C_{ipso}), 129.80 (CH), 129.74 (CH), 127.47 (CH), 124.42 (CH), 121.35 (CH). *Anal.* Calc. for $C_{13}H_{10}N_2O_2$ (226.23) C, 69.02; H, 4.46; N, 12.38. Found: C, 69.00; H, 4.47; N, 12.38%.

4.2.5. Benzylidene-cyclohexyl-imine (PhCH=NC_6H_{11})

Following the procedure described by Texier-Boullet [49], benzylaldehyde (1.070 g, 10.08 mmol) was dispersed in 2.5806 g of alumina. To this mixture, cyclohexylamine (0.9986 g, 10.07 mmol) was added, which was dispersed in 2.5700 g of alumina. This mixture was stirred for 15 h at RT. After this time period, the residue was dissolved in 100 mL of CH_2Cl_2 and filtered. The CH_2Cl_2 was removed under reduced pressure and the product was a colorless oil. Yield: 1.84 g (97%). Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.35 (s, 1H, CHN), 7.76 (m, 2H, CH), 7.42 (m, 3H, CH), 3.23 (quintet, ^3J = 4.2 Hz, 1H, CH), 1.87 (m, 2H), 1.77 (m, 5H), 1.65 (m, 3H). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 158.98 (NCH), 137.05 (C_{ipso}), 130.72 (CH), 128.92 (CH), 128.80 (CH), 70.42 (CH), 34.80 (CH_2), 26.09 (CH_2), 25.24 (CH_2).

4.2.6. Benzyl-benzylidene-imine (PhCH=NCH_2Ph)

Following the procedure described by Texier-Boullet [49], benzylaldehyde (1.066 g, 10.04 mmol) was dispersed in 2.5348 g of alumina. To this mixture, benzyl amine (1.0798 g, 10.07 mmol) was added, which was dispersed in 2.5344 g of alumina. This mixture was stirred for 18 h at RT. After this time period, the residue was dissolved in 100 mL of CH_2Cl_2 and filtered. The CH_2Cl_2

was removed under reduced pressure and the product was a colorless oil. Yield: 1.86 g (95%). Only the *E* isomer was formed. ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.47 (s, 1H, CHN), 7.89 (m, 2H, CH), 7.50 (m, 3H, CH), 7.45 (m, 4H, CH), 7.35 (m, 1H, CH), 4.92 (s, 2H, CH_2). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 162.47 (CHN), 139.81 (C_{ipso}), 136.65 (C_{ipso}), 131.27 (CH), 129.10 (CH), 129.00 (CH), 128.79 (CH), 128.48 (CH), 127.50 (CH), 65.55 (CH_2).

4.2.7. Phenyl-(3-phenyl-allylidene)-imine (*PhCH=CH-CH=N-Ph*)

Following the procedure described by Brady and Shieh [52], *trans*-cinnamaldehyde (0.7048 g, 5.332 mmol) was dissolved in 20 mL of anhydrous diethyl ether. Aniline (0.4999 g, 5.367 mmol) was then added in 5mL of anhydrous diethyl ether to the reaction solution. This solution was allowed to stand at RT for 16 h, after which the ether was removed under reduced pressure. The product was a yellow crystalline solid. Yield = 1.04 g (94%). ^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.19 (d, ^3J = 7.2 Hz, 1H, NCH), 7.46 (d, 2H, ^3J = 7.4 Hz), 7.30 (m, 5H), 7.14 (m, 5H). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 162.06 (NCH), 152.12 (C_{ipso}), 144.44 (CH), 136.00 (C_{ipso}), 130.00 (CH), 129.59 (CH), 129.33 (CH), 129.00 (CH), 127.91 (CH), 126.53 (CH), 121.33 (CH).

The products from the catalytic reactions were compared with authentic material using ^{1}H NMR. If the amine products were not commercially available or previously characterized, [16,19] the imines were reduced stoichiometrically using $NaBH_4$ following the procedure described by Blackburn and Taylor [53].

4.3. General procedure for imine reduction using $NaBH_4$

In general, the imine (~0.2 mmol) was stirred at 0 °C in 6 mL of MeOH for 5 min after which, $NaBH_4$ was added (~0.3 mmol). The contents were then stirred for 1 h at 0 °C, after which the MeOH was removed under reduced pressure. The residue was taken up in about 25 mL of diethyl ether and 25 mL of saturated $NaHCO_3$. The ether layer was collected and the aqueous layer was washed two additional times with diethyl ether. The ether extracts were combined and dried over $MgSO_4$. The ether solution was filtered and the diethyl ether was removed under reduced pressure.

4.3.1. Phenyl-(3-phenyl-propyl)-amine (*PhCH$_2$CH$_2$CH$_2$-NHPh*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.14 (m, 7H), 6.51 (m, 1H), 6.49 (d, 2H, ^3J = 0.65 Hz), 3.53 (s, 1H, NH), 3.08 (t, 2H, ^3J = 7.0 Hz, CH_2), 2.66 (t, 2H, ^3J = 7.7 Hz, CH_2), 1.88 (septet, 2H, ^3J = 7.0 Hz, CH_2). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 148.75 (C_{ipso}), 142.06 (C_{ipso}), 129.63 (CH), 128.83 (CH), 128.81 (CH), 126.36 (CH), 117.62 (CH), 113.14 (CH), 43.82 (CH_2), 33.81 (CH_2), 31.48 (CH_2).

4.3.2. Naphthalen-2-ylmethylene-phenyl-amine (*NpCH$_2$NHPh*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.72 (m, 4H), 7.38 (m, 3H), 7.08 (m, 2H), 6.63 (d, ^3J = 9.0 Hz, 1H), 6.57 (d, ^3J, 10.3 Hz, 2H), 4.39 (d, ^3J = 6.7 Hz, 2H, CH_2), 4.21 (s, 1H, NH). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 148.59 (C_{ipso}), 137.36 (C_{ipso}), 133.90 (C_{ipso}), 133.17 (C_{ipso}), 129.69 (CH), 128.77 (CH), 128.16 (CH), 128.10 (CH), 126.55 (CH), 126.31 (CH), 126.13 (CH), 126.12 (CH), 118.03 (CH), 113.34 (CH), 48.90 (CH_2).

4.3.3. (2,4,6-trimethyl-benzyl)-(2,4,6-trimethyl-phenyl)-amine (*MesCH$_2$NHMes*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 6.79 (s, 2H, CH), 6.73 (s, 2H, CH), 4.00 (s, 2H, CH_2), 2.30 (s, 6H, CH_3), 2.16 (t, ^3J = 7.4 Hz, 12 H, CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 144.53 (C_{ipso}), 137.56 (C_{ipso}), 137.22 (C_{ipso}), 134.40 (C_{ipso}), 131.31 (C_{ipso}), 129.97 (CH), 129.56 (CH), 129.48 (C_{ipso}), 47.29 (CH_2), 21.30 (CH_3), 20.92 (CH_3), 20.17 (CH_3), 19.16 (CH_3).

4.3.4. (4-nitro-benzyl)-phenyl-amine (*p-NO$_2$C$_6$H$_4$CH$_2$-NHPh*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 8.11 (d, 2H, ^3J = 10.9 Hz, CH), 7.45 (d, 2H, ^3J = 10.9 Hz, CH), 7.10 (m, 2H), 6.68 (t, ^3J = 9.2 Hz, 1H, CH), 6.50 (d, 2H, ^3J = 9.6 Hz, CH), 4.41 (s, 2H, CH_2), 4.16 (s, 1H, NH). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 147.97 (C_{ipso}), 147.73 (C_{ipso}), 147.60 (C_{ipso}), 129.79 (CH), 128.11 (CH), 124.28 (CH), 118.63 (CH), 113.33 (CH), 48.03 (CH_2).

4.3.5. (4-methoxy-benzyl)-phenyl-amine (*p-MeOC$_6$H$_4$-CH$_2$NHPh*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.18 (d, 2H, ^3J = 8.4 Hz, CH), 7.07 (t, 2H, ^3J = 7.4 Hz, CH), 6.77 (d, 2H, ^3J = 8.6 Hz, CH), 6.62 (t, 1H, ^3J = 7.4 Hz, CH), 6.52 (d, 2H, ^3J = 7.8 Hz, CH), 4.14 (s, 2H, CH_2), 3.83 (broad s, 1H, NH), 3.69 (s, 3H, OCH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 159.29 (C_{ipso}), 148.66 (C_{ipso}), 131.87 (C_{ipso}), 129.68 (CH), 129.23 (CH), 117.91 (CH), 114.45 (CH), 113.28 (CH), 55.70 (CH_3), 48.21 (CH_2).

4.3.6. Benzyl-cyclohexyl-amine (*PhCH$_2$NHC$_6$H$_{11}$*)

^{1}H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.23 (m, 4H), 7.15 (m, 1H), 3.73 (s, 2H, CH_2), 2.40 (m, 1H), 1.82 (m, 2H), 1.66 (m, 2H), 1.53 (m, 1H), 1.10 (m, 6H). (1H, NH not observed). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 141.43 (C_{ipso}), 129.52 (CH aromatic), 128.78 (CH aromatic), 128.49 (CH aromatic), 127.31 (CH aromatic), 127.17 (CH aromatic), 56.59 (CH cyclohexyl),

51.47 (CH_2N), 33.99 (CH_2 cyclohexyl), 26.63 (CH_2 cyclohexyl), 25.43 (CH_2 cyclohexyl).

4.3.7. N-Phenyl-(2,4,6-trimethyl-benzylidene)-amine (Mes-CH_2NHPh)

^1H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.15 (m, 2H, CH), 6.82 (s, 2H, CH), 6.66 (t, $^3J = 8.0$ Hz, 1H, CH), 6.59 (m, 2H, CH), 4.11 (s, 2H, CH_2), 3.34 (s, 1H, NH), 2.27 (s, 6H, CH_3), 2.24 (s, 3H, CH_3). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 149.01 (C_{ipso}), 137.89 (C_{ipso}), 137.68 (C_{ipso}), 132.59 (C_{ipso}), 129.67 (CH), 129.46 (CH), 117.60 (CH), 112.81 (CH), 42.71 (CH_2), 21.33 (CH_3), 19.81 (CH_3).

4.3.8. Dibenzyl-amine ($PhCH_2NHCH_2Ph$)

^1H NMR ($CDCl_3$, 500 MHz, $SiMe_4$) δ 7.22 (m, 8H, CH), 7.15 (m, 2H, CH), 3.70 (s, 4H, CH_2), (1H, NH, not observed). $^{13}C\{^1H\}$ NMR ($CDCl_3$, 125 MHz, $SiMe_4$), δ 140.80 (C_{ipso}), 128.85 (CH), 128.61 (CH), 127.40 (CH), 53.62 (CH_2).

Synthesis and characterization of CpMn(dfepe)(L) complexes (dfepe = $(C_2F_5)_2PCH_2CH_2P(C_2F_5)_2$; L = CO, H_2, N_2): an unusual example of a dihydride to dihydrogen photochemical conversion

Abstract

The synthesis and properties of perfluoroalkylphosphine manganese complexes CpMn(dfepe)(L) (dfepe = $(C_2F_5)_2PCH_2CH_2P(C_2F_5)_2$; L = CO, H_2, N_2) are reported. CpMn(dfepe)(CO) (**1**) was prepared by treatment of $CpMn(CO)_2(thf)$ with excess dfepe. The observed ν(CO) (1934 cm^{-1}) and $E_{1/2}$(ox) (+1.09 V) values confirm the very electron-deficient nature of the CpMn(dfepe) moiety. Photolysis of **1** under a H_2 purge produced a 6:1 equilibrium isomeric mixture of the hydride complexes $CpMn(dfepe)(H)_2$ (**2a**) and $CpMn(dfepe)(\eta^2\text{-}H_2)$ (**2b**). Photolysis of a mixture of **2a** and **2b** in benzene resulted in complete conversion of **2a** to **2b**, which slowly thermally reconverted to an equilibrium mixture ($k \sim 2.3 \times 10^{-4}$ s^{-1}). The dihydrogen complex **2b** reacts with N_2 gas to produce $CpMn(dfepe)(N_2)$ (**3**) ($\nu(N_2)$ = 2113 cm^{-1}). Attempts to isolate **3** resulted in production of the corresponding N_2-bridged dimer, $[CpMn(dfepe)]_2(\mu\text{-}N_2)$ (**4**) (Raman: $\nu(N_2)$ = 2015 cm^{-1}).

1. Introduction

Cyclopentadienyl "piano-stool" complexes of the general formula $(\eta^n\text{-}C_nR_n)M(L)_x$ are a versatile and extensively examined class of organometallic compounds. Studies which have focused on both vertical (e.g., $CpM(CO)_3(H)$ (M = Cr, Mo, W), $CpM(CO)_2(Me)$ (M = Fe, Ru, Os) and horizontal (e.g., $(arene)M(CO)_3$ (M = Cr, Mo, W), $(arene)M(CO)_3^+$ (M = Mn, Re)) isoelectronic series provide valuable insights on metal–ligand binding trends and form the basis of many classic paradigms in this field of chemistry.

We have previously reported a series of perfluoroalkylphosphine piano-stool systems incorporating the acceptor phosphine chelate $(C_2F_5)_2PCH_2CH_2P(C_2F_5)_2$ ("dfepe"): $(\eta^6\text{-arene})Mo(dfepe)(L)$ (L = CO, N_2, py) [1], $(\eta^5\text{-}C_5R_5)Mo(dfepe)(CF_2)^+$ [2], $(\eta^5\text{-}C_5R_5)Ru(dfepe)(L)^{0,+}$ (L = halide, H, Me; CO, H_2) [3,4], $(\eta^6\text{-arene})Ru(dfepe)$ [5], and $(\eta^6\text{-arene})Ir(dfepe)^+$ [6]. We have generally observed chemical properties which mirror analogues where dfepe is replaced by two carbonyl ligands rather than donor phosphine derivatives. In this report, we present studies detailing the synthesis and properties of cyclopentadienyl manganese complexes, CpMn(dfepe)(L), where L = CO, N_2 or H_2, which are effective electronic equivalents to well-studied $CpMn(CO)_2(L)$ systems. The dihydrogen complex $CpMn(dfepe)(\eta^2\text{-}H_2)$ is found to be in equilibrium

doi:10.1016/j.poly.2004.06.017

with the classic dihydride CpMn(dfepe)$(H)_2$. More interestingly, an unusual photochemical conversion of this mixture exclusively to the nonclassical dihydrogen isomer, followed by thermal re-equilibration has been observed.

2. Experimental

2.1. General procedures

All manipulations were conducted under an atmosphere of purified nitrogen using Schlenk, high vacuum and/or glovebox techniques. Dry oxygen-free solvents were purified by vacuum distillation from sodium/benzophenone (tetrahydrofuran, petroleum ether and hexane). C_6D_6 was dried over activated 4 Å molecular sieves. Elemental analyses were performed by Desert Analytics. Infrared spectra were recorded on a Perkin–Elmer 1600 FTIR instrument as Nujol mulls, unless otherwise noted. Raman spectra were collected on a DeltaNu Advantage 200A spectrometer. NMR spectra were obtained with a JEOL JNM-FX270 or GSX-400 instrument. ^{31}P NMR spectra were referenced to an 85% H_3PO_4 external standard. $CpMn(CO)_3$ was prepared following literature methods [7]. Dfepe was prepared as described previously [8].

2.2. Synthesis of CpMn(dfepe)(CO) (1)

A photolysis reaction vessel (Ace Glass Inc.) was charged with 2.519 g (12.29 mmol) $CpMn(CO)_3$. Four-hundred milliliter THF was added and the mixture was cooled to 0 °C. The mixture was photolyzed for 3 h using a 240 W Hanovia mercury vapor lamp in order to generate $CpMn(CO)_2$(thf), at which time 6.97 g (12.3 mmol) dfepe was added under a nitrogen counterflow via syringe. The reaction was then allowed to stir in darkness for 5 h followed by an additional photolysis period. Monitoring the reaction by solution IR indicated that substitution of $CpMn(CO)_2$(thf) by dfepe was complete after 12 h (Note: care must be taken to minimize photolysis time after conversion to CpMn(dfepe)CO is complete, since the monocarbonyl product is itself photosensitive). The reaction was then warmed to ambient temperature and the volatiles were removed, yielding a dark red oil. Trituration of the oily residue with 20 ml petroleum ether yielded a yellow crystalline solid. Recrystallization from petroleum ether afforded 8.80 g (52.1%) of analytically pure **1**. *Anal*. Calc. for $C_{16}H_9F_{20}P_2OMn$: C, 26.91; H, 1.27. Found: C, 27.11; H, 1.17%. IR data (cm^{-1}): 1934(vs), 1211(s), 1100(s), 1033(m), 983(m), 811(m). ^1H NMR (C_6D_6, 400 MHz, 27 °C): δ 4.30 (s, 5H; C_5H_5), 1.85 (m, 2H; PCH_2), 1.60 (m, 2H; PCH_2). $^{31}P\{^1H\}$ NMR (C_6D_6, 161.7 MHz, 27 °C): δ 150.4 (s, br).

2.3. Preparation of CpMn(dfepe)$(H)_2$ (2a) + CpMn(dfepe)(η^2-H_2) (2b) isomeric mixture

A 450 ml jacketed Ace Glass photolysis reaction apparatus was charged with 1.082 g (1.52 mmol) of **1**. Four-hundred milliliter hexane was added and the mixture was cooled to 0 °C. The solution was purged with N_2 for 15 min, followed by a 15 min purging with hydrogen. At this point the solution was cooled to −10 °C, and photolysis was begun under a continuous H_2 purge (Pyrex-filtered 240 W Hanovia mercury lamp). The reaction was monitored by solution IR until the sharp CO band of **1** was no longer present (ca. 24 h total photolysis time). After photolysis completion, the solution was allowed to warm to ambient temperature and was transferred to a 250 ml round bottom flask and the volatiles were removed under vacuum. The resulting dark red/brown oil was slurried in petroleum ether, concentrated to ca. 2 ml, and cold filtered at −78 °C, yielding 258 mg (25%) of low-melting (~30 °C) red/orange crystals (6:1 mixture of **2a** and **2b**). Although the purity was >95% as judged by ^1H NMR, elemental analyses of this product mixture were consistently high in carbon. *Anal*. Calc. for $C_{15}H_{11}P_2F_{20}Mn$: C, 26.18; H, 1.61. Found: C, 27.33; H, 1.71%. ^1H NMR (C_6D_6, 400 MHz, 27 °C). **2a**: δ 4.29 (s, 5H; C_5H_5), 1.46 (m, 4H; PCH_2), −10.64 (t, 101 Hz, 2H; $Mn(H)_2$). **2b**: 4.18 (s, 5H; C_5H_5), 1.34 (m, 4H; PCH_2), −13.28 (br s, 2H; Mn(η^2-H_2)). $^{31}P\{^1H\}$ NMR (C_6D_6, 161.7 MHz, 27 °C). **2a**: δ 144.7 (s, br). **2b**: δ 160.3 (s, br).

2.4. Synthesis of [CpMn(dfepe)]$_2$(μ-N_2) (4)

A 450 ml jacketed Ace Glass photolysis reaction apparatus was charged with 502 mg (0.704 mmol) **1** and 400 ml hexane. The solution was cooled to 0 °C and then purged for 15 min with nitrogen followed by a 15 min hydrogen purge. The reaction mixture was then cooled to −10 °C under a continuous hydrogen purge and photolysis was begun (Pyrex-filtered 240 W Hanovia mercury lamp). The reaction was monitored by solution IR until the sharp CO band of **1** was no longer present. After 24 h the photolysis and hydrogen purge were stopped and the photolysis was resumed under a nitrogen purge. A noticeable N_2 stretch was observed in the IR after 3 h. The remaining solution was cannula transferred to a 250 ml round bottom flask and the volatiles were removed. As the nitrogen was pulled off and the solution concentrated, red needles began to precipitate and existed simultaneously with a dark red oil when all volatiles were absent. This mixture was brought up in petroleum ether and concentrated. Filtration followed by several washings yielded 140 mg (28%) of red crystalline **4**. Spectra of redissolved **4** showed only resonances due to **3**, however the elemental analysis of this sample was unsatisfactory: *Anal*. Calc. for $C_{30}H_{18}F_{40}Mn_2N_2P_4$: C, 25.73; H, 1.30; N, 2.00. Found: C, 22.55; H, 1.37; N,

1.01%. Spectroscopic data for **4**: $\nu(N_2)$ (Raman, cm^{-1}) = 2015. Spectroscopic data for **3**: IR (C_6D_6, cm^{-1}): $\nu(N_2)$ = 2113(s), 1292(s), 1214(vs), 1113(vs), 799(m). ^1H NMR (C_6D_6, 400 MHz, 27 °C): δ 4.18 (s, 5H; C_5H_5), 1.92 (m, 2H; PCH_2), 1.64 (m, 2H; PCH_2). $^{31}P\{^1H\}$ NMR (C_6D_6, 161.7 MHz, 27 °C): δ 154.1 (s, br).

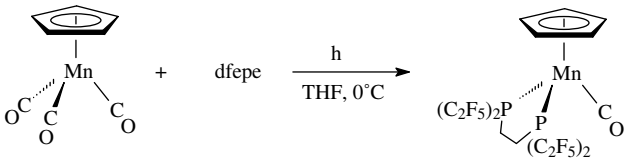
2.5. Electrochemical measurements

Cyclic voltammetry experiments were performed under a nitrogen atmosphere for complex **1** using a BAS 100A electrochemical analyzer. Measurements were taken at a platinum disk working electrode in acetonitrile containing 0.1 M *n*-$Bu_4N^+PF_6^-$ as the supporting electrolyte. $E_{1/2}$(ox) values (taken as $(E_{pa} + E_{p,c})/2$) were operationally referenced to $Ag/AgClO_4(0.4\ M)_{solv}$ and corrected to SCE using a ferrocene/ferrocenium couple as an internal standard. Under our conditions the $E_{1/2}$(ox) value for Cp_2Fe^+/Cp_2Fe was +0.440 V.

3. Results and discussion

3.1. Synthesis of CpMn(dfepe)(CO)

CpMn(dfepe)CO (**1**) was prepared in 52% yield by photolysis of in situ prepared $CpMn(CO)_2$(thf) in the presence of excess dfepe (Eq. (1)). The photolysis was closely monitored by solution IR and was stopped after CO bands due to $CpMn(CO)_2$(thf) at 1921 and 1974 cm^{-1}had disappeared. Exhaustive photolysis led to low yields of **1** due to its own intrinsic photosensitivity. The electron-poor nature of complex **1** is clearly indicated by infrared and electrochemical data. A single ν(CO) band appears in the infrared at 1934 cm^{-1}, higher in energy than reported for the fluorophosphine chelate $CpMn(Me_2NPF_2)_2(CO)$ (1920 cm^{-1}) [9] and substantially higher than typical donor phosphine values ($CpMn(PPh_3)_2(CO)$: 1824 cm^{-1}; $Cp'Mn(Ph_2PCH_2CH_2PPh_2)(CO)$: 1826 cm^{-1}) [10]. A cyclovoltammetric study of **1** showed a fully reversible Mn(I)/Mn(II) redox couple at +1.09 V in dichloromethane versus $Ag^+/AgCl$. This oxidation potential indicates that **4** is nearly as electron-poor as $Cp'Mn(CO)_3$ (+1.28 V) [11] and substantially more electron-poor than the arylphosphine analogue ($CpMn(PPh_3)_2(CO)$; −0.21 V) [10].

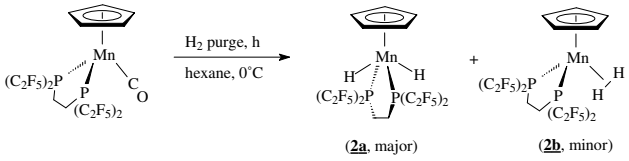


1 (1)

3.2. Synthesis of CpMn(dfepe)H₂

Direct carbonyl displacement reactions were initially examined as potential routes to other CpMn(dfepe)(L) derivatives. No reaction between 1 and 5 equiv. Me_3NO or NH_2OH(HCl) in acetonitrile up to 100 °C was observed. Attempts to reduce the CO ligand with hydride reagents such as KH/THF and $LiAlH_4$ or to produce $CpMn(dfepe)^{2-}$ by reduction with 2 equiv. KC_8 in THF were also unsuccessful. Photochemical substitution reactions have proven more effective. Direct photolytic displacement of CO from **1** under an N_2 purge did not lead to the measurable production of CpMn(dfepe)(N_2), presumably due to an efficient back reaction with photodissociated CO. However, photolysis of **1** in hexane under a purge of hydrogen gas at 0 °C produced a red/orange oil characterized by NMR as a 6:1 isomeric mixture of $CpMn(dfepe)(H)_2$ (**2a**) and CpMn(dfepe)(η^2-H_2) (**2b**) (Eq. (2)). The synthesis of hydride complexes **2a** and **2b** is very sensitive to the reaction parameters and is difficult to reproduce reliably. Synthesis attempts where the H_2 purge rate was insufficient or excessive lead to decomposition and fail to generate significant amounts of the desired product, and very careful monitoring this reaction is essential for success.

Proton spectra of the mixture show two unique cyclopentadienyl resonances (δ 4.29 for **2a**, 4.18 for **2b**) and their associated hydride resonances at δ −10.64 (t, $^2J_{HP}$ = 101 Hz) and −13.28 (br, s), respectively. Variable temperature T_1 measurements at 400 MHz reveal distinctly different T_1 (min) values for the hydride resonances of **2a** (159 ms, 203 K) and **2b** (12 ms, 213 K) which further support the structural assignment. The short T_1 value associated with **2b** falls within the range generally found for nonclassical dihydrogen coordination [12]. While caution must be exercised when interpreting T_1 data for spin-active metal systems such as manganese [13,16d], the R_{HMn} and $R_{Hligand}$ spin relaxation components to R_{obs} for both **2a** and **2b** should be very similar and the distinct difference in T_1 (min) values should therefore be primarily due to relaxation due to H–H dipolar interactions, R_{HH}.



(2)

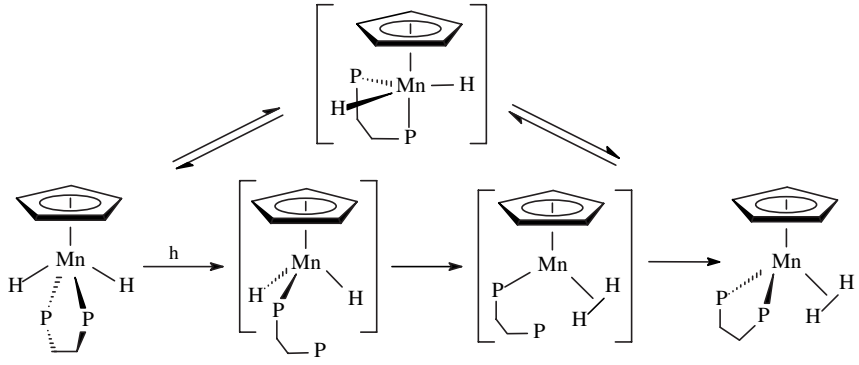
The related carbonyl complex $CpMn(CO)_2H_2$ [14], originally reported by Leong and Cooper, has been characterized as exclusively the dihydrogen isomer [15]. Other examples of manganese dihydrogen complexes which have been reported include the mixed phosphine–carbonyl cations $(R_3P)_nMn(CO)_{5-n}(\eta^2\text{-}H_2)^+$ [16,17], and the neutral hydride, $(R_2PCH_2CH_2PR_2)_2$-

$Mn(\eta^2\text{-}H_2)H$ (R = Me, Et) [18]. The isomeric mixture of **2** is thermally stable and does not react with excess acids ($HBF_4(Et_2O)$, HOTf) or bases (*n*-BuLi, $NaN(SiMe_3)_2$, NaH) to form the corresponding $CpMn(dfepe)(H)_3^+$ or $CpMn(dfepe)(H)^-$ derivatives. A determination of $^1J_{HD}$ would provide further support for dihydrogen coordination in **2b**. However, addition of stoichiometric or excess DOTf to mixtures of **2a** and **2b** in toluene-d_8 did not lead any significant isotopic scrambling to form $CpMn(dfepe)(\eta^2\text{-}HD)$.

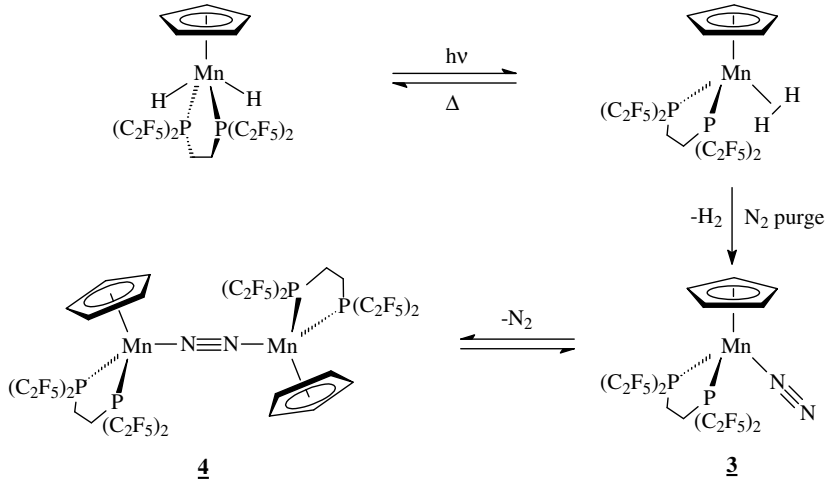
During a series of photolysis studies, it was noticed that the ratio between **2a** and **2b** was time-dependent, with the dihydrogen product **2b** being favored in freshly-photolyzed solutions. Indeed, ^1H NMR monitoring of the photolysis of an equilibrium mixture of **2a** and **2b** in C_6D_6 at 10 °C showed that complete conversion of dihydride **2a** to the dihydrogen complex **2b** occurred after 30 min, followed by a slow ($k \sim 2.3 \times 10^{-4}\ s^{-1}$) first order thermal re-equilibration. To our knowledge, this photochemical control of a dihydride–dihydrogen complex equilibrium is unprecedented. For related $CpRuL_2H_2^+$ chelating phosphine systems, Heinekey has proposed an intramolecular isomerization mechanism whereby the dihydrogen complex's "*cisoid*" phosphine chelate adopts an intermediate equatorial-axial position and subsequently "slides" between the two hydride ligands to form the *transoid* dihydride geometry [19]. However, this equilibration mechanism does not explain why **2a** is selectively driven to **2b** photolytically. An additional photochemical pathway involving photo-assisted chelate dissociation to a 3-legged piano stool geometry (where the hydride ligands must necessarily be *cis*) followed by reassociation of the dangling phosphine end to give the dihydrogen complex is therefore tentatively proposed (Scheme 1).

3.3. Synthesis of $CpMn(dfepe)(N_2)$ and $[CpMn(dfepe)]_2(\mu\text{-}N_2)$

Under an atmosphere of nitrogen, displacement of H_2 from **2b** occurs to form $CpMn(dfepe)(N_2)$ (**3**), identified by the appearance of a strong $\nu(N_2)$ band at 2113 cm^{-1} (Scheme 2). This monomeric dinitrogen complex could not be isolated due to facile loss of N_2 upon



Scheme 1.



Scheme 2.

solvent concentration to form the corresponding dimer, $[CpMn(dfepe)]_2(\mu\text{-}N_2)$ (**4**), which was isolated as sparingly-soluble red crystals from hexane. The absence of an infrared-active $\nu(N_2)$ band for **4** together with the observation of a Raman-active symmetrical $\nu(N_2)$ mode at 2015 cm^{-1}supports the depicted centrosymmetric dimeric geometry. Redissolving **4** in C_6D_6 under 590 Torr N_2 produces a single solution species with a cyclopentadienyl ^1H resonance at δ 4.18. Solution infrared indicates this species to be essentially pure monomeric **3**.

Photoisomerization of dihydride **2a** to the presumably more thermally labile dihydrogen isomer **2b** suggested a possible one-pot synthesis of **4**. After photolysis of CpMn(dfepe)(CO) at −10 °C under an H_2 purge for 24 h, the reaction mixture was placed under a dinitrogen purge and the photolysis was continued for an additional 3 h. Workup from petroleum ether afforded a modest yield (28%) of **4**.

4. Summary

A comparison of isomeric preferences for the isoelectronic series $(\eta^5\text{-}C_6H_5Me)Mo(dfepe)H_2$, $CpMn(dfepe)H_2$ and $CpRu(dfepe)H_2^+$ is informative. The observed 6:1 $M(H)_2$:$M(H_2)$ coordination preference for manganese falls between the exclusive classic dihydride coordination preference for $(\eta^5\text{-}C_6H_5Me)Mo(dfepe)H_2$ and the 1:6 $M(H)_2$:$M(H_2)$ dihydrogen coordination preference for $CpRu(dfepe)(L)^+$ [4]. For molybdenum, substitution studies with $(\eta^6\text{-}C_6H_5Me)Mo(dfepe)L$ have indicated considerable steric congestion about the metal center [1]. By assuming a "*transoid*" geometry with classical dihydride coordination, steric strain is relieved despite a presumed electronic preference for nonclassical coordination [20]. CpMn(dfepe) and $CpRu(dfepe)^+$ analogues should exhibit an even stronger steric preference for the *transoid* geometry due to decreasing metal size, but it is apparent that the accompanying decrease in metal electron density overcomes the steric preference and favors the dihydrogen isomer as we progress from group six to group eight. Nevertheless, the ready accessibility of a $(\eta^5\text{-}C_6H_5Me)Mo(dfepe)(\eta^2\text{-}H_2)$ intermediate in ligand substitution reactions and the direct observation of both hydride isomers for manganese and ruthenium piano stool complexes suggests that the energetic preferences are very small.

The photochemically-driven isomerization of the classical dihydride isomer **2a** to the nonclassical dihydrogen complex **2b** is similar the that reported for $CpRe(CO)_2(H)_2$ [21]. Both CO and phosphine photolabilization are well established in coordination chemistry [22], so the de-chelation of dfepe proposed in Scheme 1 is a reasonable possibility. Alternatively, Jones has proposed that the active intermediate in phosphine photosubstitution of $CpRe(Ph_3P)_2H_2$ is the allylic intermediate $(\eta^3\text{-}C_5H_7)Re(Ph_3P)_2$ formed via ring-slippage and hydride migration [23]. Further studies will be required to determine the mechanism of dihydride/dihydrogen photoisomerization in this manganese system.

Abstract

DFT calculations on dinuclear molybdenum complexes with bridging hydride and methyl ligands, namely $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$, indicate that the bonding is best described in terms of: (i) a 2-center-2-electron Mo–Mo single bond and (ii) a 3-center-2-electron Mo–H–Mo or Mo–Me–Mo bond. The presence of a 2-center-2-electron Mo–Mo single bond is in accord with an electron counting procedure that views the bridging hydride and methyl ligands as μ-LX ligands; in contrast, an electron counting procedure which apportions half of the valence electron of the hydrogen atom or methyl radical to each metal dictates a Mo=Mo double bond, a result that is contrary to the theoretical calculations. Consideration of a variety of other bridging hydride complexes indicates that the μ-LX electron counting method provides the best general description of the bonding by clearly distinguishing between the number of 3-center-2-electron M–H–M interactions and direct 2-center-2-electron M–M interactions.

1. Introduction

The ability to discern whether or not the proposed structure of a molecule is reasonable is paramount to understanding and predicting its properties, such as stability. While these issues can be addressed by theoretical studies of various levels of sophistication, the first order evaluation is normally performed by the application of simple qualitative and empirical rules, such as the octet rule and those embodied in valence shell electron pair repulsion theory. For example, the chemistry of carbon is dictated by the octet rule and application of this rule successfully predicts the existence of single, double, and triple bonds in ethane, ethylene, and acetylene, respectively. The transition metals, however, with their multiple valence states, are not so readily rationalized by such simple rules. Nevertheless, a notable exception pertains to the organometallic chemistry of the transition elements (and especially for the metals Groups 6–8), for which many structures are governed by the "18-electron rule" [1,2]. By analogy with the octet rule, the successful application of the 18-electron rule merely requires knowledge of how many electrons the ligand array contributes to the valence shell of the metal. For example, the Mn–Mn bond order in $(CO)_5Mn\text{–}Mn(CO)_5$ is predicted to be one on the basis that each $[Mn(CO)_5]$ fragment posseses a 17-electron configuration (cf. the single C–C bond in ethane is a consequence of the fact that each methyl radical possesses a 7-electron configuration). Despite this simplicity, inspection of the literature makes it evident that certain ligands cause confusion with respect to the number of electrons that they contribute to the metal center; bridging hydride and alkyl

ligands, in particular, are two of the most common ligands for which opinions differ. An important ramification of employing different electron counts for a given bridging ligand is that the inferred bond order between the two metal centers will vary. As an illustration, the molecule $Os_3(CO)_{10}(\mu_2\text{-}H)_2$ [3] has been represented in the literature with no less than five bonding descriptions in which the Os···Os bond order varies from zero to two, including variants with less certain bonding depictions (Fig. 1). Thus, although the formal classification of the bridging ligands and the resulting differences of the formal electron-count may be subjective, the consequences for predicting the electronic structure, of which the most salient feature is the nature of the metal–metal interaction, are significant. Therefore, we address this issue here by performing density functional theory (DFT) [4] electronic structure calculations on a series of dimolybdenum compounds with bridging hydride, methyl and chloride ligands. Specifically, evaluation and comparison of the derived Mo–Mo bond orders provides a means to assess which of the literature electron counting methods for treating symmetrically bridging hydride and methyl ligands is the most apt. The conclusion of this study is that symmetrically bridging hydride and methyl ligands are best represented as 3-center-2-electron interactions, and that electron counting schemes that apportion half of the valence electron of the hydrogen atom or methyl radical to each metal are not appropriate.

2. Results and discussion

2.1. Electron counting and bond order ambiguities

The theoretical calculations that are described in this paper are intended to evaluate which is the most appropriate method for counting electrons in complexes that possess [M(μ-X)M] (X = H, R) 3-center-2-electron interactions [5,6]. To place this work in context, it is pertinent to review the two basic methods for evaluating the number of electrons contributed to each metal center by symmetrically bridging hydride and alkyl ligands.

2.1.1. Method I: the "half-electron" method

This method merely apportions the electrons associated with the isolated hydride and alkyl ligands equally to both metals [7,8]. If one employs a neutral ligand electron counting procedure, this method has the outcome that a bridging hydrogen atom or alkyl radical contributes 0.5 electrons to the electron count at each metal center of a dinuclear complex [9].

2.1.2. Method II: the μ-LX "half-arrow" method

An alternative method to evaluate the number of electrons contributed to the metal center by bridging hydride and alkyl ligands fully recognizes the 3-center-2-electron nature of the [M(μ-X)M] interaction [10]. A simplified molecular orbital representation of the 3-center-2-electron [M(μ-H)M] interaction is illustrated in Fig. 2. An important point to note is that, depending upon the geometry of the system, the amount of direct M–M interaction can vary from being significant to insignificant; such extremes are termed "closed" and "open" 3-center-2-electron interactions and are illustrated in Fig. 3 [11]. As a consequence, while the MO description of the 3-center-2-electron interaction is unambiguous, the schematic depiction of this interaction is not definitive; thus, 3-center-2-electron [M(μ-H)M] bonds have been represented by a variety of means, as illustrated in Fig. 4. Dahl originally formulated [M(μ-H)M] interactions with two solid lines between M and H (**A**) [14,15], but this representation can give the mistaken impression that the two "bonds" at-

tached to hydrogen are independent 2-center-2-electron bonds. A simple modification of the Dahl representation involves joining the two bonds by a curved line around the hydrogen atom (**B**) to indicate that the two bonds are not independent and thereby emphasize the 3-center-2-electron nature of the interaction [16]. Churchill has employed a "dashed-bond" depiction of the 3-center-2-electron bond that also emphasizes the possible "open" (**C-open**) and "closed" (**C-closed**) nature of the interactions [17,18]. Bau, Koetzle and Kirtley have also proposed representations for "open" and "closed" 3-center-2-electron [M(μ-H)M] interactions by using "bent" (**D-open**) and "Y" (**D-closed**) bonds [12,13], a symbolism that is used in borane chemistry and which is intended to convey the same information portrayed by Churchill's "dashed-bond" depictions. While Churchill's "dashed-bond" depiction of the "closed" 3-center-2-electron [M(μ-H)M] interaction (**B-closed**) is a good representation, Dahl has noted that a problem which has arisen is that others have redrawn the dashed lines as solid lines, thereby implying the incorrect notion that *there is a separate M–M 2-center-2-electron bond in addition to the 3-center-2-electron M–H–M interaction* [15,19]. Another problem associated with each of the representions (**A**) to (**D**) is that they are not particularly useful for electron counting purposes. It is, therefore, significant that Green's μ-LX "half arrow" notation (**E**) (Fig. 4) is of particular benefit in this regard [20,21]. Thus, the representation M–H ⇀ M′ depicts the essence of the valence bond description of the 3-center-2-electron bond in that the pair of electrons associated with the M–H sigma bond (i.e. an "X" type interaction) [21] is donated into a vacant orbital on M′ (i.e. an "L" type interaction) [21], as illustrated in Fig. 5; obviously, by resonance, the bridge (M ↼ H–M′) is symmetric (Fig. 4,**E**). It is important to emphasize that the absence of a "line" between the M atoms bridged by the hydrogen atom in the "half arrow" notation does *not* imply that there is no interaction between

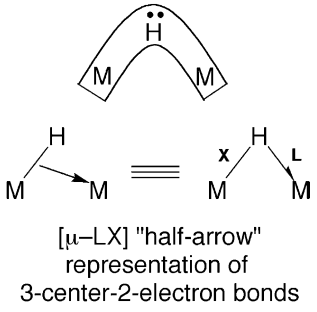

Fig. 5. The [μ-LX] "half-arrow" representation of a 3-center-2-electron M–H–M interaction; the hydrogen atom may be viewed as a μ-LX ligand, where X refers to the one electron contribution to the normal covalent M–H component and L is associated with donation of the pair of electrons associated of the M–H sigma bond into a vacant orbital on M′.

these atoms. Rather, the "half-arrow" notation indicates that any M···M interaction that does exist is one that is mediated by the bridging atom.

The "half arrow" notation is not restricted to M–H–M interactions, but applies equally well to other complexes that exhibit 3-center-2-electron bonds, such as those involving coordination of: (i) C–H bonds, e.g. agostic alkyl complexes [22] and hydrocarbon σ-complexes [M](σ-HR) [23,24], (ii) B–H bonds, e.g. diborane [5], borane adducts [25], and borohydride derivatives [26], and (iii) M–C bonds, e.g. symmetrically bridging methyl ligands.

The existence of two different electron counting procedures causes confusion with respect to the full bonding description of molecules that possess 3-center-2-electron [M(μ-X)M] (X = H, R) interactions, as exemplified by the various bonding descriptions of $Os_3(CO)_{10}(\mu_2\text{-}H)_2$ described above. Furthermore, even though Dahl reported in 1965 the first structure of a transition metal complex with a bridging hydride ligand, namely $[CpMo(CO)_2]_2(\mu\text{-}PMe_2)(\mu\text{-}H)$, and stated that "the bent, three-center Mo–H–Mo bond involving one electron from the two molybdenum atoms and one from the hydrogen accounts for the compound's diamagnetism without the invoking of a separate Mo–Mo bond" [14,15], more than thirty five years later closely related $[CpMo(CO)_2]_2(\mu\text{-}PRR')(\mu\text{-}H)$ derivatives are represented by some chemists with direct Mo–Mo bonds [27]. A further illustration of the confusion that may ensue is illustrated by the description of the bonding in $[(\eta^6\text{-}C_6H_6)Re]_2(\mu\text{-}H)(\mu\text{-}CHR)$. Thus, taking into account the 3-center-2-electron nature of the bonding, $[(\eta^6\text{-}C_6H_6)Re]_2(\mu\text{-}H)(\mu\text{-}CHR)$ was originally assigned a Re–Re single bond, a result that was also confirmed by calculations [28]; a subsequent report, however, does not properly recognize the nature of the bonding and states that the previous assignment is incorrect and that the bond order is three [29]!

To address these issues in more detail, and thereby provide evidence for which of the electron counting methods provides a better description of the bonding in molecules with bridging hydride and methyl ligands, we have used computational methods to investigate the bonding in a series of derivatives with bridging ligands, namely $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ [30] and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)$ (μ-X) (X = H, Me, Cl).

2.2. The Mo–Mo bond length and bond order in $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$

In contrast to bridging hydride derivatives, complexes with bridging methyl groups are uncommon [31,32]. Bridging methyl ligands also differ from bridging hydride ligands by virtue of the fact that a variety of coordination modes are possible, which may be classified as: (i) symmetric pyramidal, (ii) symmetric trigonal planar, (iii) monohapto agostic [33], (iv) dihapto agostic, and (v) trihapto agostic (Fig. 6) [30,31]. We are aware of only one dimolybdenum complex with a bridging methyl ligand that has been structurally characterized by X-ray diffraction, namely $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ **1** [30,34], as illustrated in Fig. 7. With chemically equivalent Mo–C bond lengths [2.300(7) and 2.301(7) Å] and an acute Mo–C–Mo bond angle [76.4(2)°], the bridging methyl group in $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ may be appropriately described as symmetric pyramidal. There is also a short Mo···H separation of 2.02 Å which suggests that some monohapto agostic character to the interaction could be considered, but the equivalence of the Mo–C bond lengths and the acute Mo–C–Mo bond angle is considered to be a more important indicator of the symmetric pyramidal coordination mode [35].

The Mo–Mo interaction in $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ is predicted to be a single bond using the

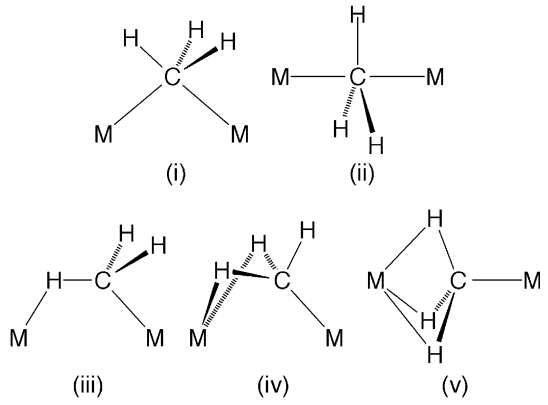

Fig. 6. Coordination modes of bridging methyl complexes.

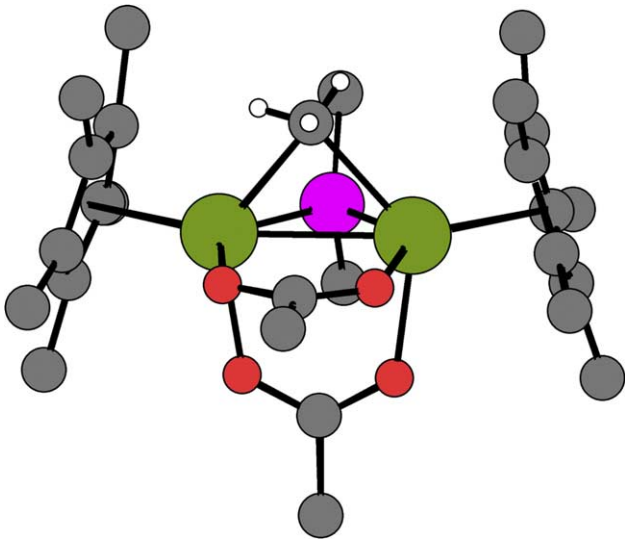

Fig. 7. Experimental molecular structure of $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$.

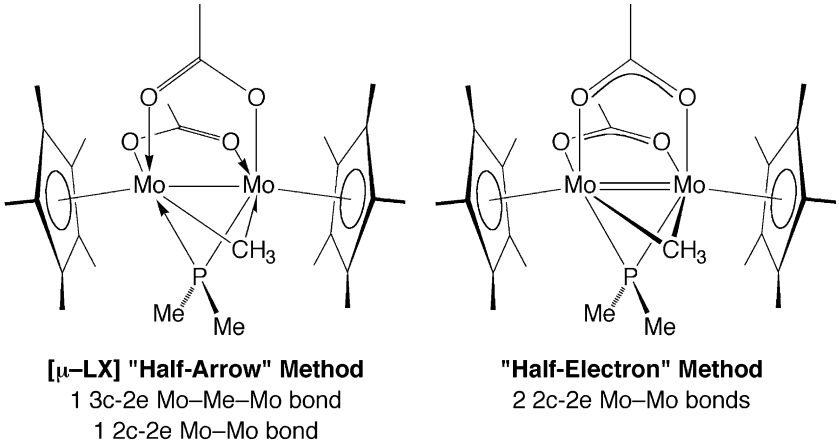

Fig. 8. Predicted Mo–Mo bond orders for $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ using two different electron counting procedures.

μ-LX "half-arrow" electron counting procedure that recognizes the 3-center-2-electron nature of the interaction, but a double bond using the "half-electron" procedure that does not consider the 3-center-2-electron nature of the interaction, as illustrated in Fig. 8. Specifically, application of the formula [7b]

$$m = (18n - N)/2,$$

where m is the number of 2-center-2-electron M–M bonds, n is the number of M atoms, and N is the total electron count, predicts a Mo=Mo double bond using the "half-electron" method. It is evident from this formula that the higher Mo–Mo bond order for the μ-LX "half-electron" method is merely a consequence of a reduced electron count (N) due to the 3-center-2-electron nature of the interaction not being recognized [7].

Experimental evidence for the Mo–Mo bond order in $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ could be expected to be procured from the Mo–Mo bond length, in a manner similar to that in which C–C bond distances may be used to distinguish between single (1.53 Å), double (1.32 Å) and triple (1.18 Å) bonds in organic compounds [36]. Indeed, it is evident from the summary of Mo–Mo bond lengths for dinuclear molybdenum complexes provided in Table 1 that Mo–Mo bond lengths span a substantial range; for example, the Mo–Mo single bond in $[CpMo(CO)_3]_2$ [3.235(1) Å] [37] is approximately 1 Å longer than in compounds with Mo≡Mo quadruple bonds, which are typically in the range 2.06–2.17 Å [38]. However, despite this large range of Mo–Mo bond lengths, the presence of bridging ligands creates a significant problem in attempting to correlate metal–metal distances with bond order because the steric and electronic requirements of the bridging group exert an additional influence that causes the metal–metal distance to be either shorter or longer than that in the absence of the bridge [39–42]. For example, complexes with bridging ligands may have Mo–Mo single bonds that are more than 0.5 Å shorter than the Mo–Mo single bond in unbridged $[CpMo(CO)_3]_2$ [3.235(1) Å] [37], as illustrated by $[CpMo(SMe)_2]_2$ [2.603(2) Å] [43], $[Cp^{Pr^i}Mo(\mu\text{-}Cl)_2]_2$ [2.607(1)Å] [44,45], and $[Cp^*Mo(\mu\text{-}I)_2]_2$ [2.708(3) Å] [46,47]. Furthermore, Mo–Mo single bond lengths in complexes with bridging ligands may be comparable to the formal Mo=Mo double bonds in complexes such as $[Cp^*Mo(\mu\text{-}S)(\mu\text{-}SH)]_2$ [2.573(1) Å] [46], $[CpMo(\mu\text{-}S)]_2(\mu\text{-}SPr^i)(\mu\text{-}PPh_2)$ [2.623(2) Å] [27c,48], and $[(Bu^tO)_2Mo_2(\mu\text{-}OBu^t)]_2(\mu\text{-}CO)$ [2.498(1) Å] [49]. Likewise, the Mo=Mo double bond lengths in these complexes are comparable to the formal Mo≡Mo triple bond lengths in $[CpMo(CO)_2]_2$ [2.448(1) Å] [50] and $[IndMo(CO)_2]_2$ [2.500(1) Å] [51,52]. It is, therefore, apparent that assigning a Mo–Mo bond order on the basis of the bond length may be fraught with difficulty. Nevertheless, it is apparent that the Mo–Mo bond length of 2.8447(5) Å for $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ is much more in accord with that of a Mo–Mo single bond than that of a Mo=Mo double bond. Moreover, the Mo–Mo bond in $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ is substantially shorter than that in $[CpMo(CO)_2]_2(\mu\text{-}PMe_2)(\mu\text{-}H)$ [3.267(7) Å], a compound that was reported by Dahl as having no direct Mo–Mo bond [14]. As such, these limited bond length comparisons support the notion that electron counting using the μ-LX "half-arrow" method, which recognizes the 3-center-2-electron nature of the interaction, is more appropriate than that of the "half-electron" method. However, in view of the aforementioned caveat, we deemed it essential to establish the Mo–Mo bond order using theoretical methods.

2.3. Geometry optimization of $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ and related complexes

The geometry optimized structure of $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ (**1**) is illustrated in Fig. 9 and the derived Mo–Mo bond length (2.88 Å) compares favorably with the experimental value (2.85 Å); likewise,

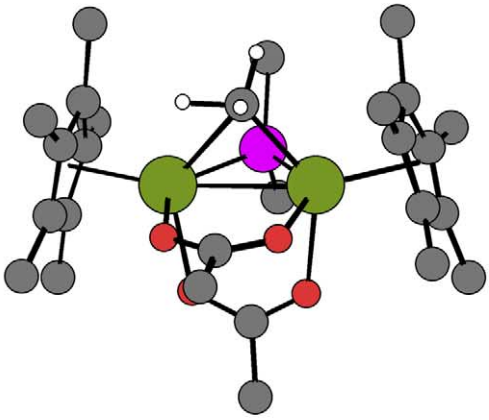
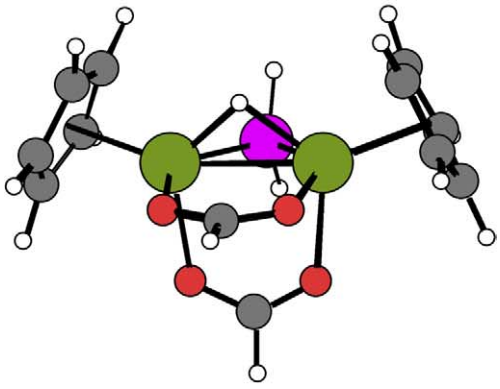
(18) Ref. [51].

there is good agreement between the calculated (75.3°) and experimental (76.4°) Mo–C–Mo bond angles [30,53]. However, whereas the experimental Mo–CH_3 bond lengths are identical (2.30 Å), the calculation predicts a slight asymmetry of the Mo–CH_3–Mo interaction, with Mo–CH_3 bond lengths of 2.23 and 2.45 Å, indicative of the presence of a weak agostic interaction [22]. We were unable to find a symmetric local minimum where the methyl group is oriented such that there is no agostic interaction. However, although the asymmetric orientation of the methyl group perturbs the shapes of the molecular orbitals, the agostic interaction is quite weak and does not change the overall bonding significantly (vide infra).

To facilitate the interpretation of the theoretical analysis, we have performed additional calculations on simpler derivatives with bridging hydride and chloride ligands, namely $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}X)$ (X = H, **2**; Cl, **3**) (Fig. 9). In particular, comparison of the bridging hydride and methyl complexes serves to highlight the electronic similarity of the two systems, while the chloride complex $CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ provides an example of an unambiguous Mo–Mo single bond (in the sense that both electron counting methods predict the same bond order due to the presence of lone pair electrons on chlorine). Comparisons with $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$(**4**$^-$) are also pertinent since the absence of a bridging X ligand results in the molecule possessing a formal Mo=Mo double bond according to both electron counting procedures. Thus, using the electronic structures of $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (**3**) and $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ (**4**$^-$) as reference points, it is possible to assess critically whether the characteristics of the Mo–Mo interaction in



[Cp*Mo(μ-O_2CMe)]$_2$(μ–PMe_2)(μ–Me), **1**



[CpMo(μ-O_2CH)]$_2$(μ–PH_2)(μ–H), **2**

Fig. 9. Geometry optimized structures of [Cp*Mo(μ-O_2CMe)]$_2$(μ-PMe_2)(μ-Me), [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-H), and [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-Cl).

[Cp*Mo(μ-O_2CMe)]$_2$(μ-PMe_2)(μ-Me) and [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-H) resemble those of a typical single or double bond.

2.4. Bond orders and bond lengths

Quantum mechanical calculations of the electronic structure of a molecule provide a means for determining bond order. In this regard, although bond orders are not observables in a quantum mechanical sense, such that their derivation is not uniquely defined, a number of protocols have been suggested in the literature [54], of which Wiberg's bond index W is particularly relevant to the goal of the present study [55]. Specifically, Wiberg has shown that the sum of squares of the off-diagonal elements of the density matrix P involving the atomic orbitals of the nuclei that are directly connected to each other gives a good estimate for the bond order

$$W = \sum_{\mu \in A} \sum_{\nu \in B} P_{\mu\nu}^2. \quad (1)$$

A slightly more robust and more generally applicable modification of the Wiberg bond index is the Mayer bond order (M) [56], where the orbital overlap matrix S is also included in the computation of the bond order

$$M = \sum_{\mu \in A} \sum_{\nu \in B} (PS)_{\mu\nu} (PS)_{\nu\mu}. \quad (2)$$

Mayer's protocol has been shown to give bond order values that are in fairly good agreement with intuitive expectations for both organic [57] and inorganic systems [58]. In the following discussion we utilize only the Mayer bond orders and list the Wiberg bond index only for comparison purposes (Table 2).

Examination of the array of complexes shown in Fig. 10 indicates how the computed Mayer bond orders vary as a function of the bridging ligand. Notably, the computed bond order of [Cp*Mo(μ-O_2CMe)]$_2$(μ-PMe_2)(μ-Me) is 0.72, while that of the bridging hydride derivative [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-H) is 0.97. These values are clearly too low to be assigned to a Mo=Mo double bond and more closely correspond to that of a Mo–Mo single bond. A particularly important comparison is with the chloride derivative, [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-Cl), which serves as a reference point for an undisputed formal Mo–Mo single bond since both electron counting methods predict the same bond order. In this regard, the Mayer Mo–Mo bond order of 0.78 for [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-Cl) is comparable to those of [Cp*Mo(μ-O_2CMe)]$_2$(μ-PMe_2)(μ-Me) (0.72) and [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-H) (0.97), thereby indicating that the Mo–Mo interactions are similar and thus support the assignment of a single Mo–Mo bond to each of these complexes.

Further evidence that the Mayer bond orders for the above derivatives correspond to formal Mo–Mo single bonds is provided by comparison with the hypothetical species {[CpMo(μ-O_2CH)]$_2$(μ-PH_2)}$^-$ which is derived by proton abstraction from [CpMo(μ-O_2CH)]$_2$(μ-PH_2)(μ-H). {[CpMo(μ-O_2CH)]$_2$(μ-PH_2)}$^-$ provides a convenient reference point for an undisputed formal Mo=Mo double bond according to both electron counting methods and this is reflected by the Mayer bond order for {[CpMo(μ-O_2CH)]$_2$(μ-PH_2)}$^-$ (1.53) being

Table 2
Comparison of calculated bond orders for a series of dinuclear molybdenum compounds with those predicted by two alternative electron counting methods. In each case, the bond order predicted by the [μ-LX] "half-arrow" method corresponds exactly to that obtained from the calculations, whereas the "half-electron" method fails for the compounds with bridging hydride and methyl ligands

	$d_{Mo\cdots Mo}$ (Å)	Wiberg bond index W	Mayer bond index M	Mo–Mo configuration and calculated bond order	Electron count bond order: [μ-LX] "half-arrow" method	Electron count bond order: "half-electron" method
$\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)\}^{2-}$ (**2**$^{2-}$)	3.07	0.39	0.45	$\sigma^2\delta^2\delta^{*2}\pi^{*2}$, BO = 0	0	1
$[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ (**1**)	2.88	0.61	0.72	$\sigma^2\delta^2\delta^{*2}$, BO = 1	1	2
$[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ (**2**)	2.77	0.87	0.97	$\sigma^2\delta^2\delta^{*2}$, BO = 1	1	2
$[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (**3**)	2.91	0.60	0.78	$\sigma^2\delta^2\delta^{*2}$, BO = 1	1	1
$\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ (**4**$^-$)	2.64	1.41	1.53	$\sigma^2\delta^2\pi^2\delta^{*2}$, BO = 2	2	2
$\{[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)\}^{2+}$ (**1**$^{2+}$)	2.81	1.02	1.17	$\sigma^2\delta^2$, BO = 2	2	3
$\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)\}^{2+}$ (**2**$^{2+}$)	2.67	1.40	1.52	$\sigma^2\delta^2$, BO = 2	2	3
$\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)\}^{2+}$ (**3**$^{2+}$)	2.83	1.10	1.23	$\sigma^2\delta^2$, BO = 2	2	2
$\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ (**4**$^+$)	2.35	2.17	2.38	$\sigma^2\delta^2\pi^2$, BO = 3	3	3

notably greater than the values for $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ (0.72), $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ (0.97), and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (0.78).

An additional comparison is provided by the cation $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ (**4**$^+$) which is derived by hydride abstraction from $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and provides a reference point for an undisputed formal Mo≡Mo triple bond according to both electron counting methods. As expected, the Mayer bond order for $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ (2.38) is substantially greater than that for $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ (1.53). Thus, consideration of the Mayer bond orders of $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (0.78), $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ (1.53), and $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ (2.38), which, respectively, have Mo–Mo single, double and triple bonds according to both electron counting methods, demonstrates that the Mayer bond orders are sensitive to the changes in Mo–Mo interaction in this system. In accord with the increase in Mayer bond order, a corresponding reduction in Mo–Mo bond length is observed for this series of complexes with formal single, double and triple Mo–Mo bonds: $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (2.91 Å), $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ (2.64 Å), and $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ (2.35 Å).

While $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$, $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$, and $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ provide examples of the changes expected in the Mayer bond order and bond length as a function of the formal Mo–Mo bond order, the comparison is not perfect because the presence of the bridging ligand exerts an intrinsic effect on bond length [39–42]. This problem can be circumvented by consideration of dicationic and dianionic counterparts of $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$, $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$. Thus, removal of two electrons from each of the aforementioned complexes is expected to increase the formal bond order by one, while addition of two electrons is expected to reduce the bond order by one (Table 2). As an illustration, the Mayer bond orders for the anionic, neutral, and cationic hydride bridged complexes increase progressively, concomitant with a reduction of Mo–Mo bond length: $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)\}^{2-}$ (**2**$^{2-}$) (0.45, 3.07 Å), $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ (**2**) (0.97, 2.77 Å), and $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)\}^{2+}$ (**2**$^{2+}$) (1.52, 2.67 Å).

2.5. Molecular orbital diagrams

While the Mayer bond orders provide a convenient and quantitative evaluation of the metal–metal interaction, a more detailed picture is required to understand fully the nature of the Mo–Mo interaction. Therefore, we have used the results of DFT calculations to deduce partial molecular orbital (MO) diagrams for the above systems and thereby identify the frontier orbitals that are involved in the Mo–Mo bonding.

Considering initially the hydride bridged complex, $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, it is evident that there are two possible fragmentation patterns for constructing the MO diagram, both of which are useful for understanding the electronic structure of the series of bridged complexes. Thus, the MO diagram can be constructed by using either: (i) an anionic dinuclear fragment, $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$, and the cationic form of the bridging ligand, H^+ or (ii) a cationic dinuclear fragment, $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$, and the anionic form of the ligand, H^-. The MO diagram constructed for the first possibility is illustrated in Fig. 11, where all 10 metal-d dominated MOs are shown as simplified iconic representations. Isosurface plots of the most important MOs are shown in Fig. 12.

It is important to note that the local coordinate system that is used for each molybdenum center is one in which the z-axis is defined as the Mo–Cp_{cent} vector and that these are *not* in alignment with the Mo–Mo

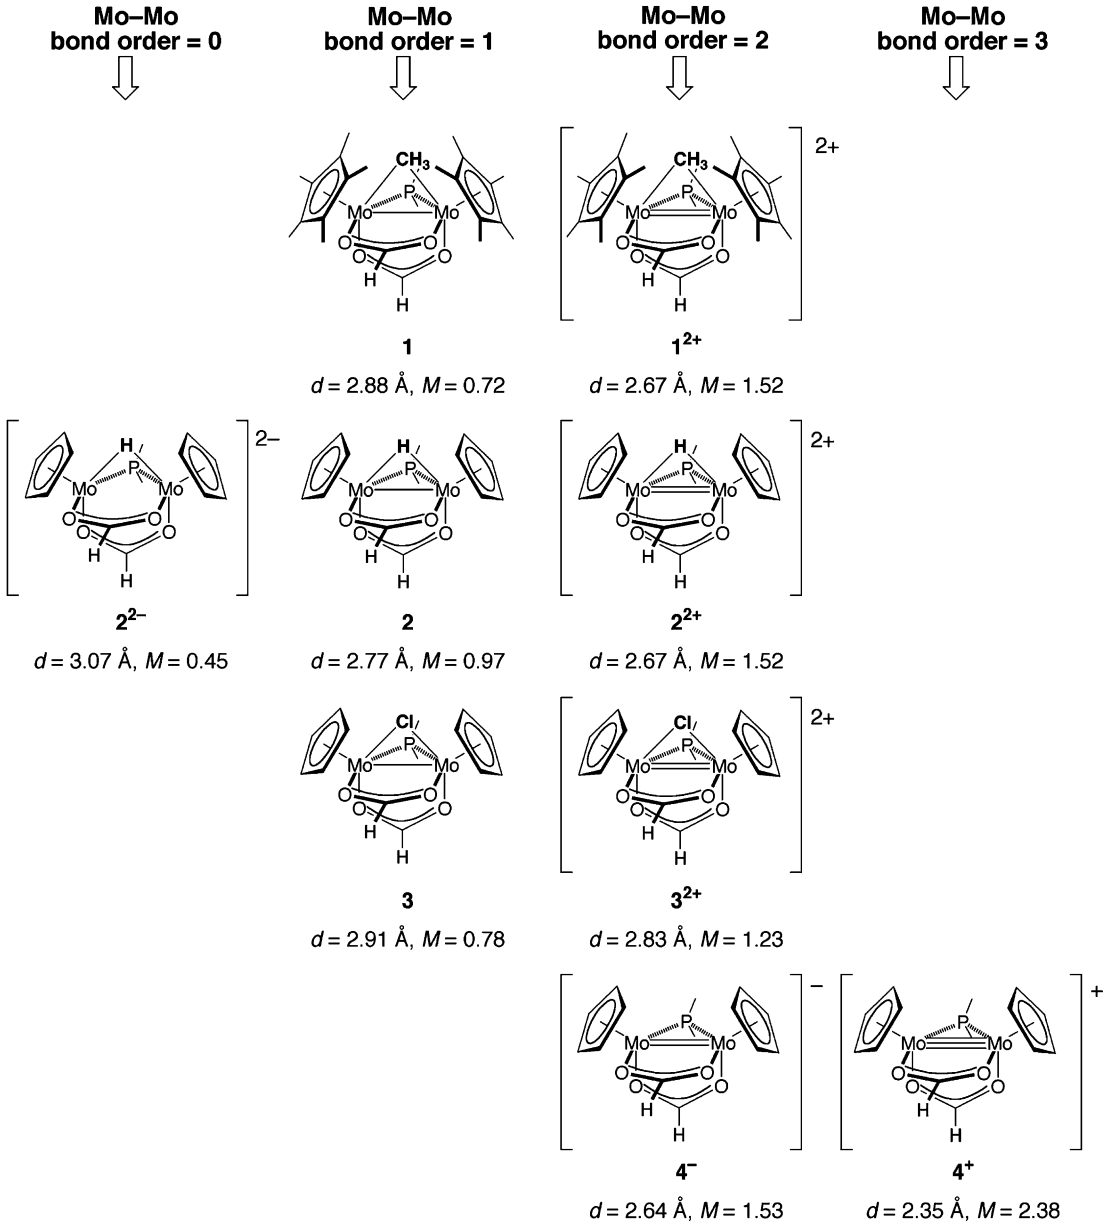

Fig. 10. Metal–metal distances (Å) and Mayer bond orders for a variety of dinuclear complexes. Note that for simplicity the lines between the bridging ligands and the molybdenum centers are only intended to convey connectivity and are not intended to be used for electron counting purposes; in this regard, the resonance structure on the left hand side of Fig. 8 illustrates the appropriate method for counting the bridging ligands.

vector. Thus, whereas the overlap of two d_{xy} orbitals would be expected to give rise to δ and δ* molecular orbitals, the lack of alignment of the Mo–Cp_{cent} and Mo–Mo vectors causes the derived orbitals to have some π-character such that they are best described as "slipped" δ and δ* orbitals. Correspondingly, the overlap of the two d_{xy} orbitals is normally expected to give rise to π and π* molecular orbitals, but the lack of alignment of the Mo–Cp_{cent} vector with the Mo–Mo vector causes these interactions to have some σ-character such that the MOs are best described as "slipped" π and π* orbitals. For brevity, however, we will simply refer to these orbitals as δ/δ* and π/π*, respectively.

The lowest metal-d dominated MO of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ fragment, [σ, MO-⟨57⟩], is an in-phase combination of the Mo-d_{z^2} orbitals and forms the basis of the Mo–Mo σ-bond (left hand side of Fig. 11). The second lowest metal-d dominated MO of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ fragment [δ, MO-⟨58⟩] is derived from overlap of the two Mo-d_{xy} orbitals, while the third lowest MO [π, MO-⟨59⟩] is derived from overlap of the two Mo-d_{xz} orbitals. This orbital is of particular importance with respect to the interaction with the bridging ligands and is therefore marked in red in Fig. 11. The highest occupied molecular orbital (HOMO) of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ is the

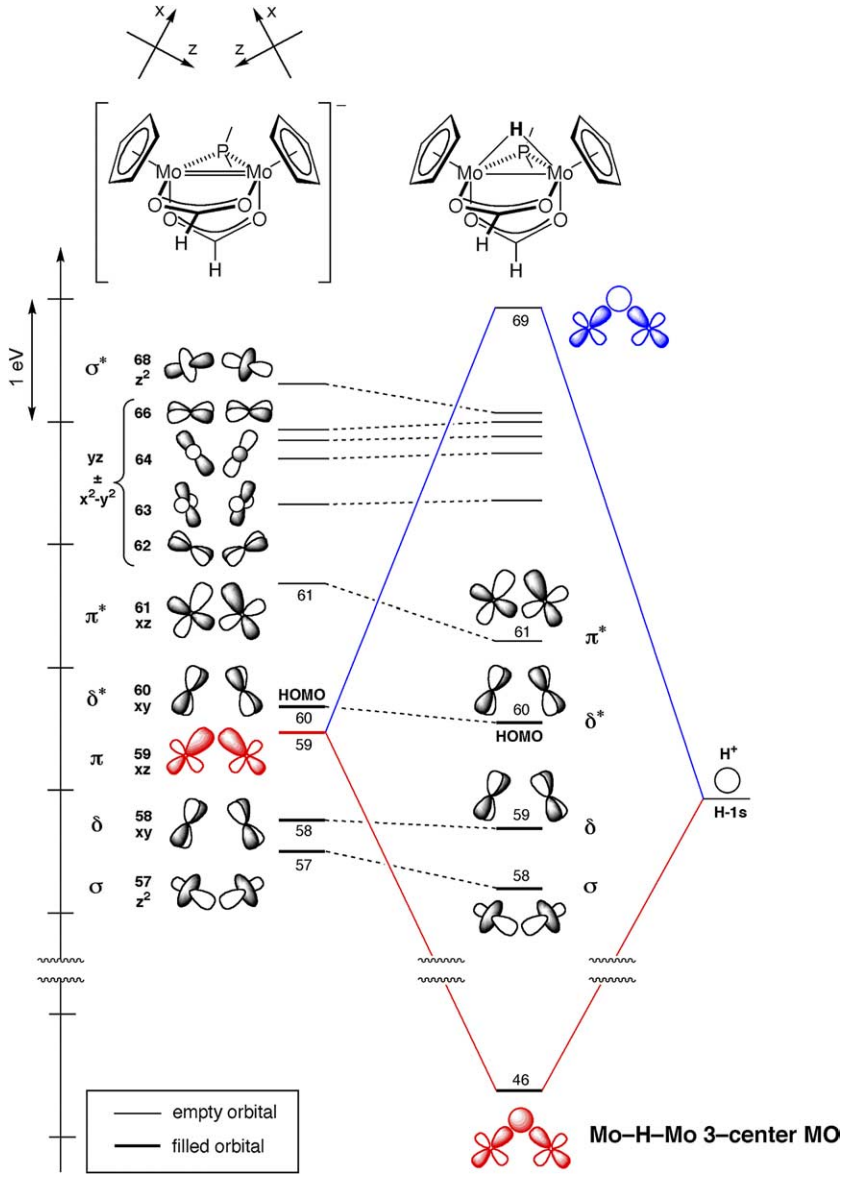

Fig. 11. MO diagram for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ derived from $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ and H^+ fragments. The d orbitals listed correspond to the significant component of the molecular orbital.

out-of-phase combination of the metal d_{xy} orbitals [δ*, MO-⟨60⟩], while the lowest unoccupied molecular orbital (LUMO) is the out-of-phase combination of the metal d_{xz} orbitals [π*, MO-⟨61⟩] [59]. With two Mo(II)-d^4 centers in the dinuclear fragment, it is evident that the $\sigma^2(\delta)^2(\pi)^2\text{-}(\delta^*)^2$ configuration corresponds to a formal Mo=Mo double bond in $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$, consisting of one σ and one π bond, which is in accord with the bond order predicted by both electron counting methods.

With respect to construction of the MO diagram for the bridging hydride complex $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ from the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ and H^+ fragments, it is only the π orbital [MO-⟨59⟩] of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ that has the appropriate symmetry and sufficient overlap with the empty 1s orbital of the proton fragment to give a significant electronic interaction. Thus, the in-phase combination gives rise to a three-center Mo–H–Mo bonding orbital [MO-⟨46⟩, $E = -9.76$ eV] which, as expected for a metal-ligand bonding orbital, is highly dominated by the ligand, i.e. the 1s orbital of hydrogen (Fig. 13). The out-of-phase combination of this interaction [MO-⟨69⟩, $E = -1.76$ eV] has metal based character and is of significantly higher energy (Fig. 14).

As a result of the transfer of electron density from the metal based π orbital to the bridging ligand, only three metal-dominated MOs remain occupied in $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, as shown in Figs. 11 and 14. Of these three MOs, the lowest in energy is the metal–metal

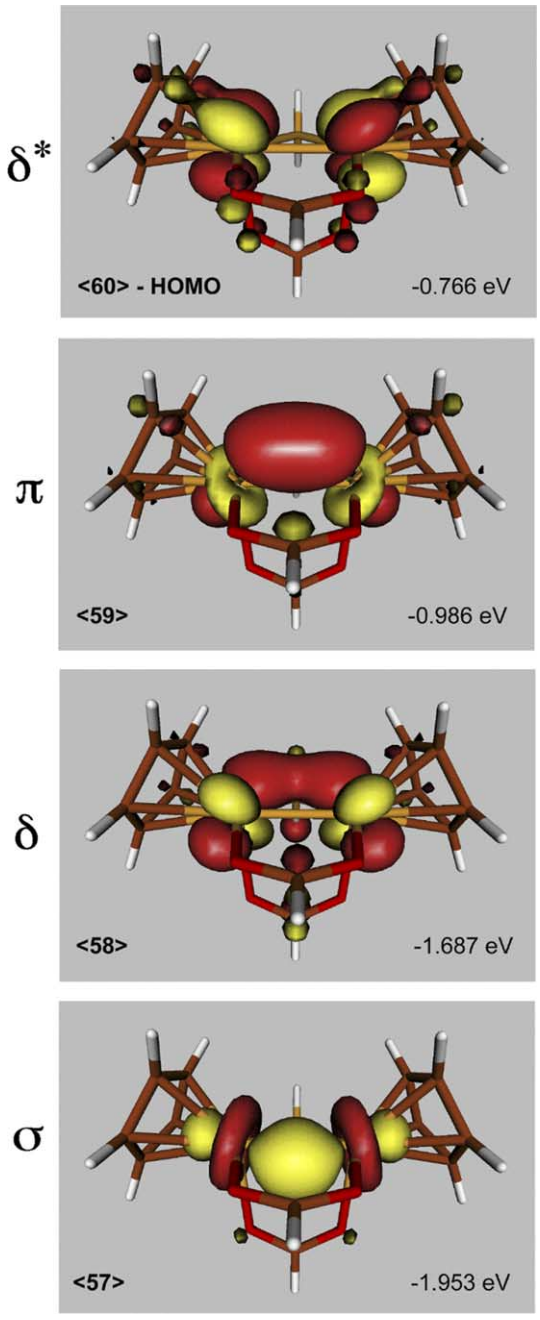

Fig. 12. Isosurface plots of the occupied σ, δ, π and δ* orbitals corresponding to the direct Mo–Mo interaction in $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$. The $\sigma^2(\delta)^2(\pi)^2(\delta^*)^2$ configuration corresponds to a formal Mo=Mo double bond.

σ-bonding orbital [MO-⟨58⟩]. The remaining two orbitals are δ-bonding and δ*-antibonding [MO-⟨59⟩ and MO-⟨60⟩], and since these are both occupied, there is a net zero δ-bonding interaction. Thus, the $\sigma^2(\delta)^2(\delta^*)^2$ configuration for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ is most consistent with a Mo–Mo single bond. In essence, the π-bond component of the double bond in $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ is destroyed as a consequence of removal of the π-bond electron density upon protonation.

As indicated above, an alternative approach for constructing the MO diagram for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ is to employ the cationic dinuclear species $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ and anionic hydride ligand as the fragments. This approach is chemically more meaningful since the bridging H is usually viewed as a hydride rather than a proton, and it allows for a more intuitive comparison with the bridging chloride derivative since Cl is normally treated as Cl^- rather than Cl^+. While the final MO diagram is, of course, unchanged, it is instructive to consider how the addition of H^- to $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ causes the formal Mo≡Mo triple bond to be reduced to a single Mo–Mo bond. In essence, there are two factors responsible for the two fold reduction of the Mo–Mo bond order: (i) the Mo–Mo π-bond is eradicated by virtue of the fact that it becomes a component of the three-center Mo–H–Mo interaction, (ii) the additional pair of electrons is elevated to an orbital that is Mo–Mo δ* antibonding (i.e. the LUMO of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$, [MO-⟨60⟩]), as illustrated in Fig. 15).

To understand in more detail the reason for why addition of H^- causes the formal Mo≡Mo triple bond in $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ to be reduced to a single Mo–Mo bond, the hypothetical transformation is traced in Fig. 15. Iconic representations of the frontier molecular orbitals of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ derived from interactions of the d orbitals are illustrated on the left hand side of Fig. 15, from which it is evident that the $\sigma^2(\delta)^2(\pi)^2$ configuration resulting from the two Mo(III)-d^3 centers predicts a formal Mo≡Mo triple bond in $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$. There are two factors that deserve attention upon the hypothetical coordination of H^- to $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$. Firstly, a significant structural distortion of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment is required to form the hydrogen bridged dimer, $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, with the Mo–Mo bond being required to expand from 2.35 to 2.77 Å upon hydride addition. Secondly, the negative charge density centered on the bridging hydride ligand introduces a purely Coulombic response from the dimetallic fragment. The results of these two changes are illustrated in the MO-correlation diagram shown in Fig. 15: the first step illustrates the consequence of distorting the geometry of the dinuclear $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment from its equilibrium structure to that of the hydrogen-bridged species $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, while the second step illustrates the result of incorporating a single negative point charge at the position of the hydride bridge. The elongation of the Mo–Mo distance in the first step has the effect of raising the energy of the MOs that are Mo–Mo bonding in character, while stabilizing the MOs that are Mo–Mo antibonding in character. At the distance of 2.77 Å, the HOMO (π) of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ in its equilibrium geometry becomes

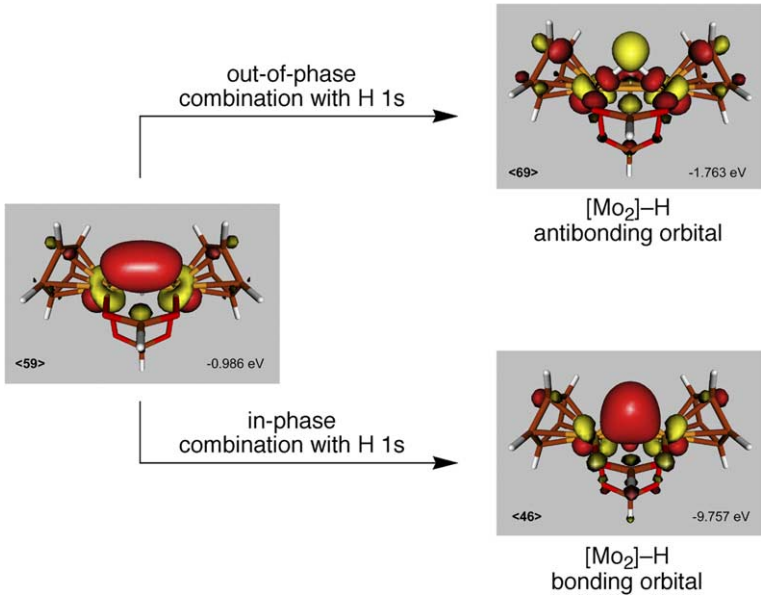

Fig. 13. Mo–H bonding and antibonding orbitals derived by interaction of the H^+ 1s orbital with the Mo–Mo π-bonding orbital of $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$.

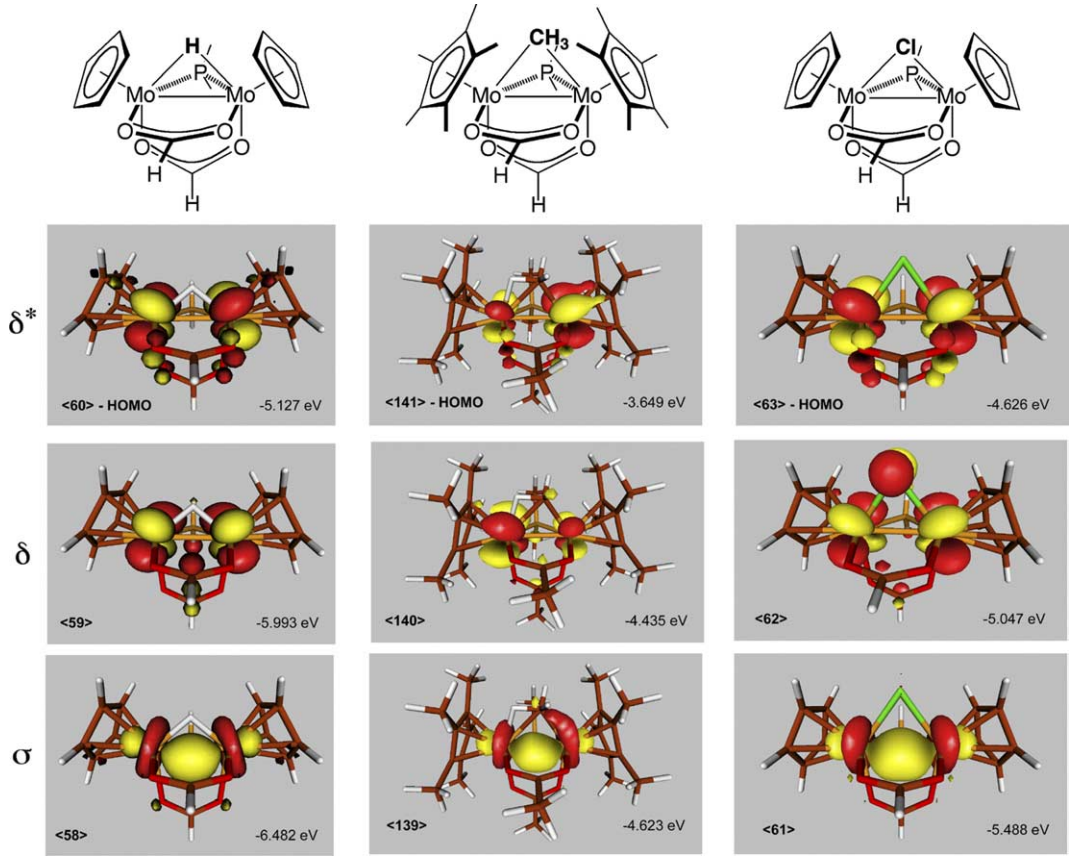

Fig. 14. Comparison of the occupied σ, δ, and δ* orbitals corresponding to the direct Mo–Mo interaction in $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$, and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$. The $\sigma^2(\delta)^2(\delta^*)^2$ configuration corresponds to a formal Mo–Mo single bond for each complex.

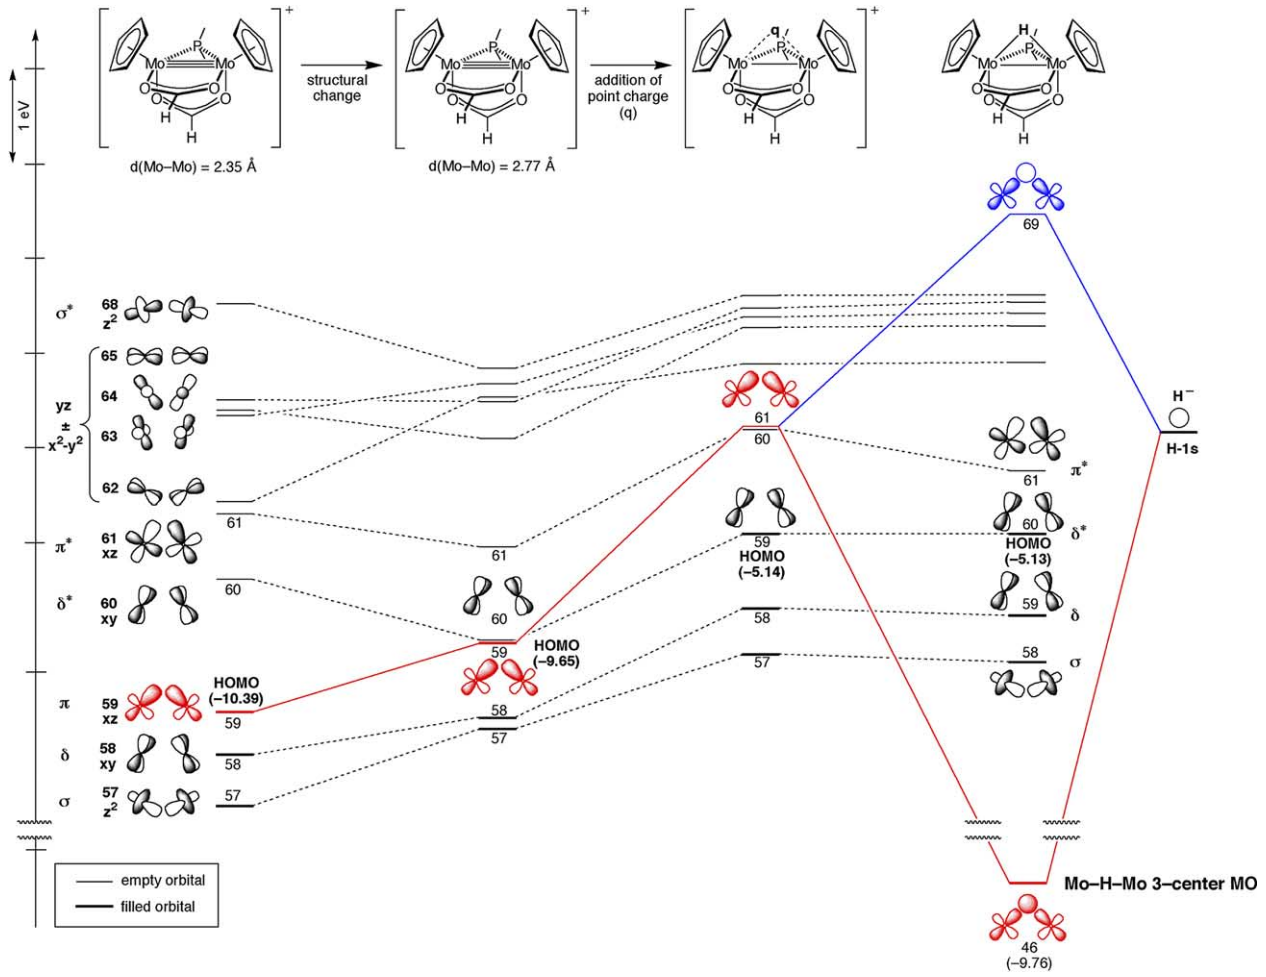

Fig. 15. MO diagram for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ derived from $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ and H^- fragments, highlighting the variation in orbital energies of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment resulting from: (i) the change in structure to that of $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and (ii) the Coulombic response to the negative charge of the hydride ligand.

almost degenerate with its LUMO (δ*). Upon addition of the negative point charge at the hydride site, all the MOs of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment are raised in energy, but especially so for the π HOMO because the shape of this orbital causes it to be fully exposed to the negative charge. As a consequence, the π orbital becomes higher in energy than δ* orbital, such that the latter becomes the HOMO of the hypothetical $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment. The $\sigma^2(\delta)^2(\delta^*)^2$ configuration thus predicts a formal Mo–Mo single bond for the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment with a point charge at the vacant hydride site. The subsequent interaction of this fragment with the 1s orbital of the hydride ligand is primarily with the Mo–Mo π orbital, which is empty as the result of the structural distortion and the presence of the Coulombic potential; this interaction corresponds to the Mo–H–Mo 3-center-2-electron bond, thereby resulting in a $\sigma^2(\delta)^2(\delta^*)^2$ configuration for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$, i.e. a single bond between the two molybdenum centers. As would be expected, the empty π orbital of the $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ fragment with a negative point charge (q) at the site to be occupied by the hydride ligand corresponds closely to the filled π* orbital of the anionic $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^-$ fragment that interacts with H^+ (Figs. 11 and 13).

The MO diagram for the chloride derivative $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ is illustrated in Fig. 16. Significantly, the $\sigma^2(\delta)^2(\delta^*)^2$ configuration indicates the presence of a Mo–Mo single bond that is formally identical to that of the hydride derivative. Indeed, comparison of the isosurface plots of the most important MOs of $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$, $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ (Fig. 14) indicates that the frontier orbital signatures of these complexes are essentially identical. Thus, even though the slight asymmetry of the bridging mode of the methyl ligand and the presence of high-energy p-orbitals on the chloride ligand give rise to small changes in the shapes of these frontier orbitals, these effects do not have a significant consequence for the qualitative classification of the Mo–Mo interactions.

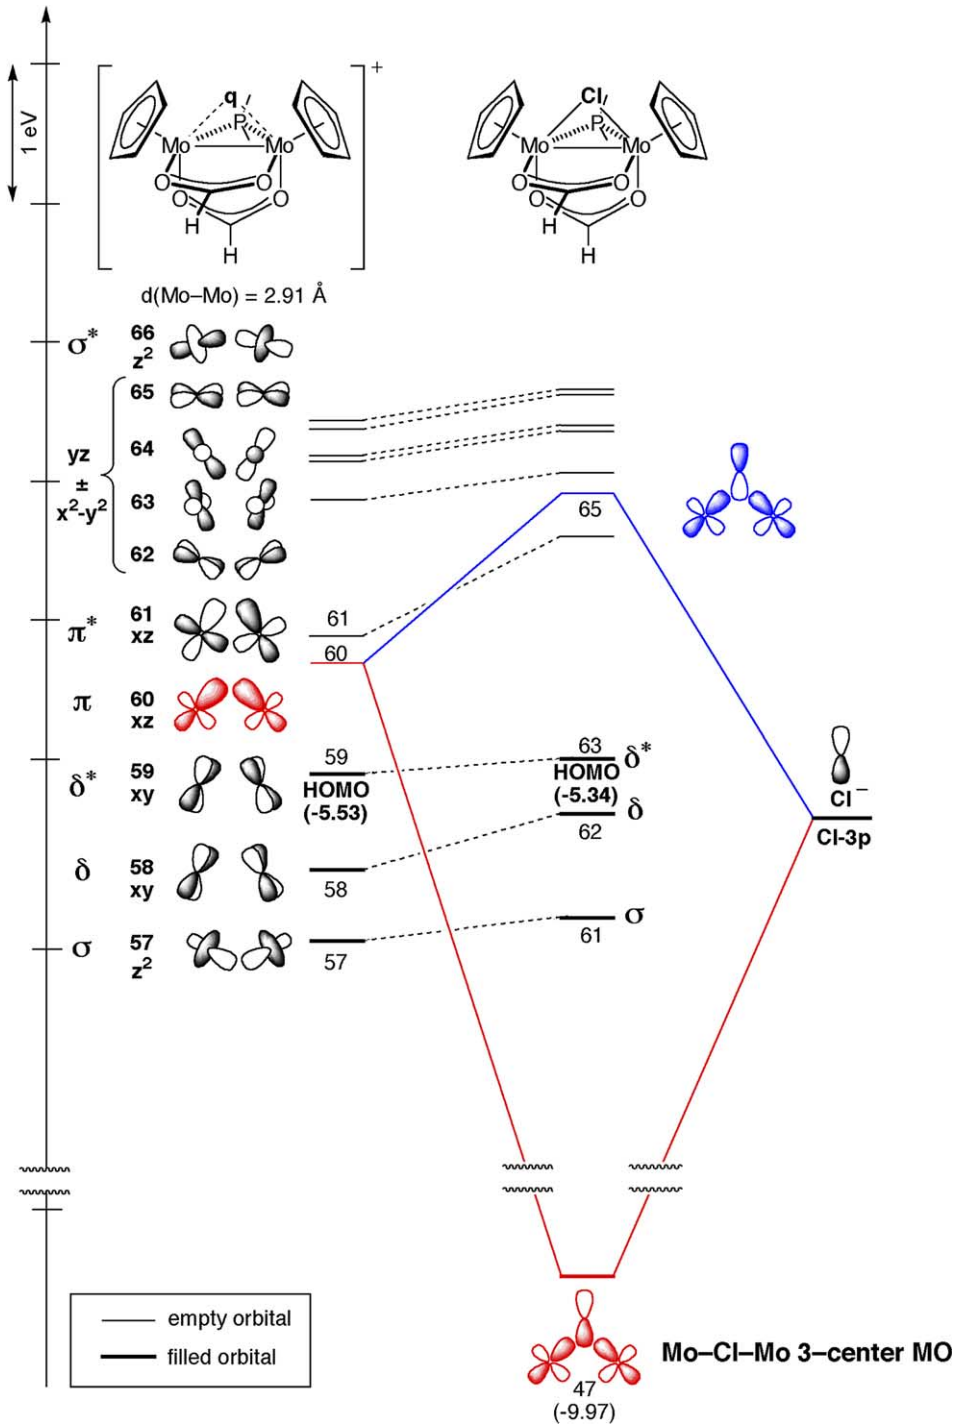

Fig. 16. MO diagram for $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ derived from $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ and Cl^- fragments; the orbital energies for $\{[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)\}^+$ correspond to the geometry in $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ and incorporate the Coulombic response to the negative charge of the chloride ligand.

2.6. Comparison of computed bond orders with those predicted by electron counting methods

Examination of the data in Table 2 indicates that there is qualitative agreement between the computed Wiberg and Mayer bond orders and the bond orders derived by consideration of the molecular orbital electronic configurations. It is also evident that, of the two methods for electron counting, there is a much better correspondence between calculated bond order and the μ-LX "half-arrow" method, i.e. the method that explicitly takes into account the 3-center-2-electron nature of

the interaction involving bridging hydrogen and alkyl groups. For example, while the $\sigma^2(\delta)^2(\delta^*)^2$ configuration of both $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}Cl)$ indicates a Mo–Mo single bond, in accord with the formal single bonds predicted using the μ-LX "half-arrow" method, the formal bond orders derived by using the "half-electron" method differ, with the latter being predicted to have a Mo=Mo double bond rather than a Mo–Mo single bond. Thus, in cases where ambiguities arise in the prediction of the Mo–Mo bond orders by the two electron counting methods, the μ-LX "half-arrow" method provides results that are closer to the theoretically predicted values since it clearly differentiates between the 3-center-2-electron M–H–M interactions and direct 2-center-2-electron M–M interactions.

In addition to the results described here, other studies are also in accord with the μ-LX "half-arrow" representations of bridging hydride ligands. For example, whereas the "half-electron" method predicts an Os=Os double bond in $Os_3(CO)_{10}(\mu\text{-}H)_2$ (Fig. 1A), the μ-LX "half-arrow" method predicts that there is no 2-center-2-electron Os–Os interaction (Fig. 1E and F). Both experimental and theoretical studies are more in accord with the latter description. For example, UV PES studies on $Os_3(CO)_{10}(\mu\text{-}H)_2$ and related bridging hydride complexes have been interpreted with the M(μ-H)M bonding orbital as being localized principally on the hydrogen atom, rather than the metal atoms; [60,61] as such, it would seem inappropriate to describe the Os–Os interaction as that of a Os=Os double bond. Furthermore, MO calculations also indicate that the major interaction between the two osmium centers is via the two 3-center-2-electron Os–H–Os bonds [62,63]. The cyclopentadienyl compound $[Cp^*(CO)Os]_2(\mu\text{-}H)_2$ contains a similar $[Os_2H_2]$ unit that has also been reported to have a Os=Os double bond; [64] by analogy to $Os_3(CO)_{10}(\mu\text{-}H)_2$, however, the direct 2-center-2-electron Os–Os bond order is reduced to zero upon consideration of the 3-center-2-electron nature of the Os–H–Os interactions.

$\{[(CO)_5M]_2(\mu\text{-}H)\}^-$ (M=Cr, Mo, W) [13] provide a classic series of complexes with single 3-center-2-electron M–H–M interactions for which the "half-electron" method predicts a M–M single bond, whereas the μ-LX "half-arrow" method indicates that there is no 2-center-2-electron M–M interaction (Fig. 17); calculations on these complexes also indicate that there is no direct M–M bond and that the interactions are exclusively through the hydride bridge [65]. The closely related complex $\{[(CO)_4W(\mu\text{-}H)]_2\}^{2-}$ [66], with two 3-center-2-electron W–H–W bridges, has also been investigated theoretically, and likewise demonstrates that there is effectively no direct W–W interaction, with the interactions being exclusively through the hydride bridge [67,68]. The results of the calculation are once again

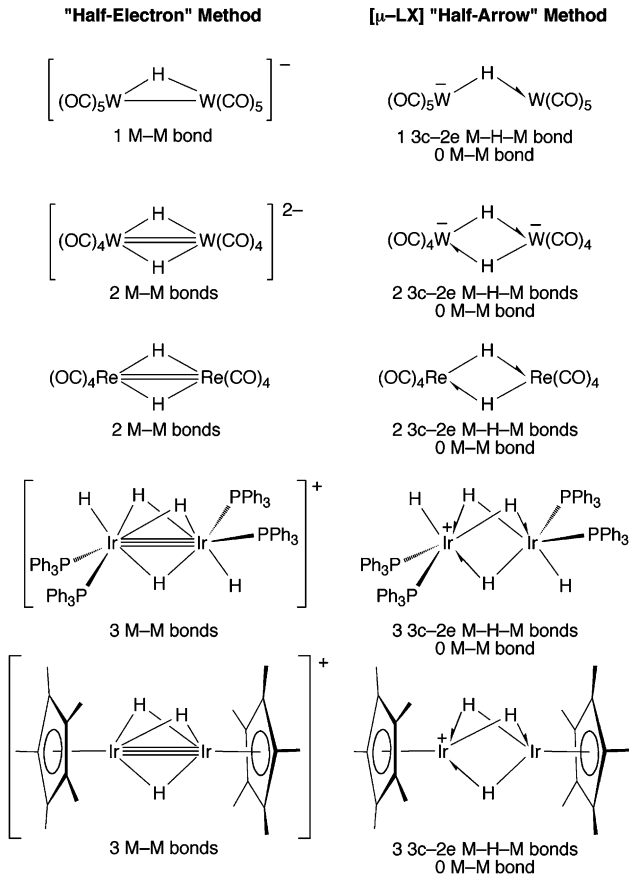

Fig. 17. Different descriptions of the metal–metal bond orders in some dinuclear complexes with bridging hydride ligands according to the electron counting method. The "half-electron" method does not explicitly take into account the 3-center-2-electron nature of the M–H–M interaction and thus results in a greater M–M bond order than would be predicted theoretically. In contrast, the [μ-LX] "half-arrow" method treats the 3-center-2-electron nature of the M–H–M interactions explicitly and thereby predicts a M–M bond order which is in accord with theory.

more in accord with the μ-LX "half-arrow" electron counting method that predicts no 2-center-2-electron W–W interaction, compared to the double bond predicted by the "half-electron" method (Fig. 17). Calculations also indicate that the isostructural neutral rhenium analogue $[(CO)_4Re(\mu\text{-}H)]_2$ [8] is predicted to have effectively no direct Re–Re interaction [67].

The dinuclear iridium complex $\{[(Ph_3P)_2HIr]_2(\mu\text{-}H)_3\}^+$ with three bridging hydride ligands was originally described as possessing a direct Ir≡Ir triple bond to satisfy the 18-electron rule [69]. However, upon recognizing the 3-center-2-electron nature of the interaction it was later realized that there is no direct Ir···Ir interaction and the shortness of the Ir···Ir separation is a geometric consequence of having three bridging hydrogen atoms [70,71] The cyclopentadienyl analogue $\{[Cp^*Ir]_2(\mu\text{-}H)_3\}^+$ was likewise originally reported to possess an Ir≡Ir triple bond [72], but by analogy to $\{[(Ph_3P)_2HIr]_2(\mu\text{-}H)_3\}^+$ can be viewed as possessing no direct Ir–Ir

bond. Structurally related isoelectronic complexes with three bridging hydride ligands that face the same bonding ambiguity description include $\{[(CO)_3Re]_2(\mu\text{-}H)_3\}^-$ [73] and $\{[\{MeC(CH_2PPh_2)_3\}Fe]_2(\mu\text{-}H)_3\}^+$ [74]. Interestingly, while the iron complex was reported to have a Fe≡Fe triple bond, the rhenium complex $\{[(CO)_3Re]_2(\mu\text{-}H)_3\}^-$ was *not* described as possessing a Re≡Re triple bond, but rather described as having 3-center-2-electron Re–H–Re bonds. Hoffmann [75] has analyzed the general class of $[LM]_2(\mu\text{-}H)_3$ molecules theoretically in terms of 3-center-2-electron interactions.

It is important to note that situations arise where the μ-LX "half–arrow" method does *not* predict an 18-electron configuration for both metals in a dinuclear complex with bridging hydrogen atoms. For example, the "half–arrow" method predicts that each of the metal centers in $[Cp^*Re(CO)_2]_2(\mu\text{-}H)_2$, $\{[\{MeC(CH_2AsPh_2)_3\}Co]_2(\mu\text{-}H)_3\}^+$, $[Cp^*Ru]_2(\mu\text{-}H)_4$, and $[(Et_2PhP)_2Re(H)_2]_2(\mu\text{-}H)_4$ would possess a 20-electron configuration (Fig. 18) [76]. However, rather than being a failure of the method, the prediction of a 20-electron configuration is actually a strength of the method since it indicates that the HOMO is an *antibonding* orbital. Occupation of this antibonding orbital thus weakens the bonding interaction that derives from the M–H–M 3-center-2-electron interactions, a notion that has been discussed by Hoffmann and coworkers [77], Dahl [15], and Bursten [78]. As an illustration, consider the hypothetical protonation of a dinuclear system in which there is no formal 2-center-2-electron M–M bond because both bonding and antibonding components are occupied (Fig. 19). The hydrogen 1s orbital interacts specifically with the bonding component, thereby forming the 3-center-2-electron bond. Since the M–M bonding orbital is effectively converted to the M–H–M 3-center-2-electron bond, the pair of electrons that remains in the M–M antibonding orbital constitutes an "antibond". Whereas a bond is conventionally represented by a line between two atoms, an antibond may be depicted by using a crossed-dashed M–×–M representation in which the cross is intended to emphasize that the direct interaction is *antibonding*. Despite the presence of an "antibond", the overall interaction between the two metal centers is favorable because of the stabilization resulting from the formation of the 3-center-2-electron bond. For example, Casey has described the bonding of the $[Re_2H_2]$ unit of $[Cp^*Re(CO)_2]_2(\mu\text{-}H)_2$ as being composed of two 3-center-2-electron Re–H–Re bonds and a Re–×–Re "antibond", such that there is a *net* bond order of one between the two rhenium centers [79].

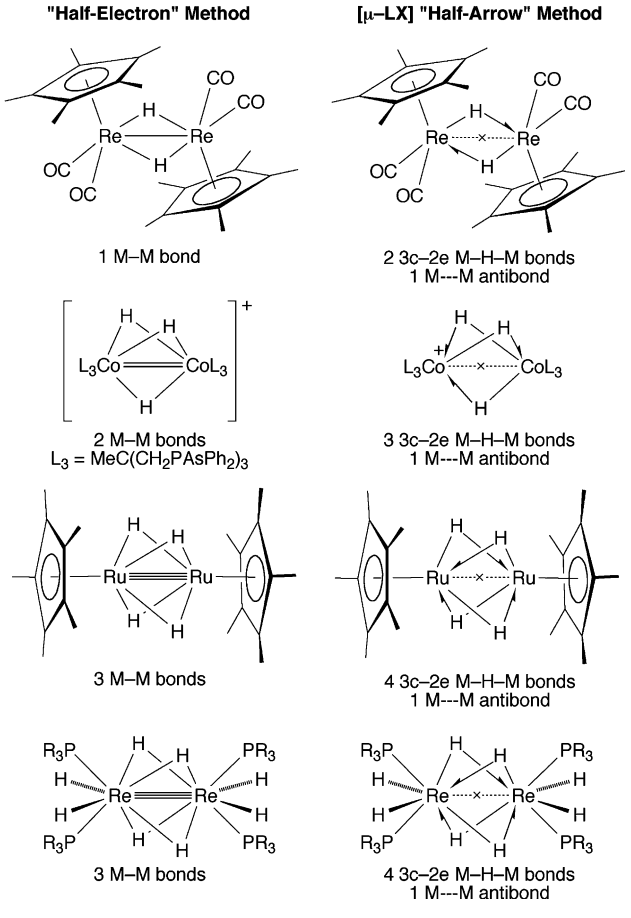

Fig. 18. Examples of compounds that exhibit M–×–M antibonding interactions resulting from a 20-electron configuration that places a pair of electrons in a M–M antibonding orbital. In contrast, the formula employing the "half-electron" method defines each metal center as possessing an 18-electron configuration and so the true nature of the M–M interaction is not evident.

Another illustration is provided by the tetrahydride bridged ruthenium complex $[Cp^*Ru]_2(\mu\text{-}H)_4$ which, on the basis of electron counting according to the "half-electron" method, was proposed to have a Ru≡Ru triple bond [80,81]. However, calculations by Morokuma indicate that the direct Ru–Ru interaction is *repulsive*, and that the two ruthenium centers are only held together by the 3-center-2-electron Ru–H–Ru bonds [82,83]. Again, the μ-LX "half-arrow" method predicts a 20-electron configuration for each ruthenium, thereby correctly suggesting that the direct Ru–Ru interaction is antibonding. An Fe≡Fe triple bond has also been considered as a possibility for the iron counterpart $[Cp^*Fe]_2(\mu\text{-}H)_4$, but has been recognized to be erroneous on the basis of the theoretical study on the ruthenium analogue [84].

$[(Et_2PhP)_2Re(H)_2]_2(\mu\text{-}H)_4$ belongs to the same category of complex that was described as possessing a formal Re≡Re triple bond [85], but the μ-LX "half-arrow" notation would indicate a Re–×–Re antibonding interaction (Fig. 18), which is also in accord with the $\sigma^2(\delta^*)^2(\sigma^*)^2$ electronic configuration that has been calculated for $[(H_3P)_2Re(H)_2]_2(\mu\text{-}H)_4$ [77]. Likewise, the cobalt complex $\{[\{MeC(CH_2AsPh_2)_3\}Co]_2(\mu\text{-}H)_3\}^+$ was proposed to have a double Co=Co bond [74], but is now recognized to have Co–×–Co antibonding interaction (Fig. 18) [77].

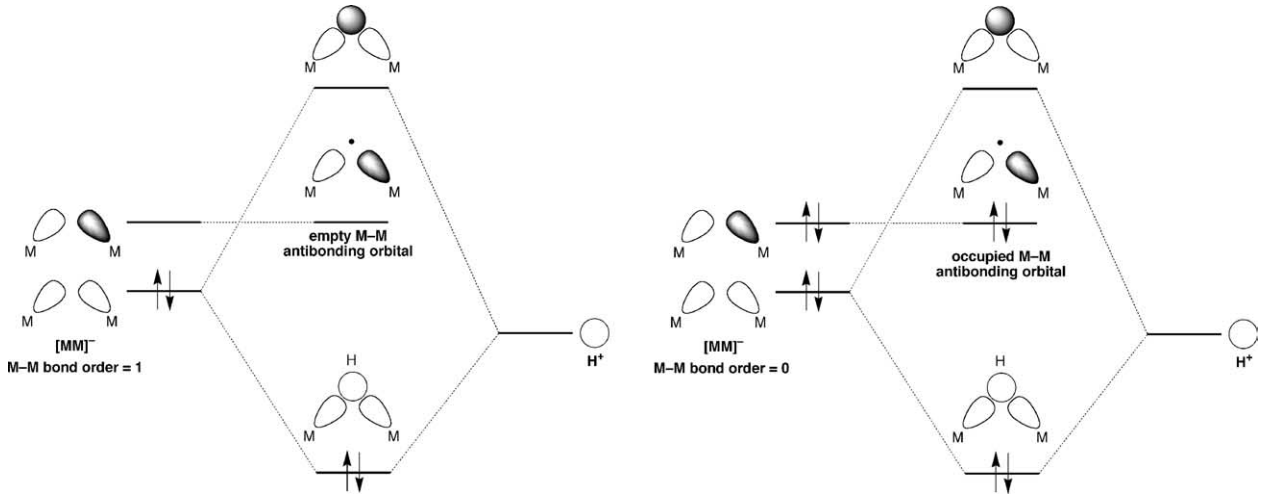

Fig. 19. Molecular orbital description of a M–×–M antibonding interaction in a [MHM] species derived by interaction of $[M_2]^-$ and H^+ fragments in which each atom uses a single orbital. Protonation of the $[M_2]^-$ fragment results in the interaction of the H 1s orbital with the M–M bonding orbital, thereby forming the 3-center-2-electron M–H–M bonding and antibonding orbitals. The M–M antibonding orbital does not have the appropriate symmetry to interact with the H 1s orbital and thus remains M–H nonbonding. If the $[M_2]^-$ fragment possesses two electrons only the M–M bonding orbital is occupied and there is a M–M bond order of one; upon protonation these electrons occupy the 3-center-2-electron M–H–M bonding orbital and the direct M–M bond is eradicated. A similar situation arises for a $[M_2]^-$ fragment that possesses four electrons such that both the M–M bonding and antibonding orbitals are occupied and the M–M bond order is zero; however, in this case, a pair of electrons remains in the M–M antibonding orbital after protonation so that the direct M–M interaction becomes repulsive, i.e. an *antibond*.

Consideration of the above complexes with bridging hydrogen ligands demonstrates that for every 3-center-2-electron M–H–M interaction, the ''half-electron'' method over counts the M–M bond order by one from the value predicted by the μ-LX ''half-arrow'' method. At one level, this is not really an issue once it is recognized that the M–M bond orders derived by the two different electron counting methods are merely *formalisms* and, as such, do not necessarily reflect reality. Problems of this type are commonplace in chemistry. For example, the formal charge [86] on an atom does not necessarily bear any relationship to the actual charge, viz. the formal charge on nitrogen in NH_4^+ is +1, whereas the actual charge is *negative* [87,88]. At another level, the derivation of different M–M bond orders for the same compound is an issue because, from a pedagogical point of view, it causes confusion (as aptly demonstrated by the various descriptions of $Os_3(CO)_{10}(\mu\text{-}H_2)$ shown in Fig. 1). Recognizing that both methods are formalisms, it is more appropriate to adopt the formalism that approximates more closely to the bond orders that are derived theoretically. For all of the examples discussed above, the μ-LX ''half-arrow'' electron counting method provides the best description of the bonding by clearly distinguishing between the number of 3-center-2-electron M–H–M interactions and direct 2-center-2-electron M–M interactions.

Two additional examples serve to point out the inadequacies of electron counting using the ''half-electron'' method. Firstly, the ''half-electron'' method would predict a Zr=Zr double bond in dinuclear $[Cp_2Zr(H)]_2(\mu\text{-}H)_2$ [89] whereas the μ-LX ''half-arrow'' method indicates that each Zr center can attain an 18-electron configuration without forming two 2-center-2-electron Zr–Zr bonds. The latter description is clearly preferable because the Zr center of mononuclear Cp_2ZrH_2 is d^0 and, as such, is incapable of forming a 2-center-2-electron Zr–Zr bond with the Zr center of another molecule. Secondly, the metal–metal bond order predicted by the ''half-electron'' method is *independent* of whether or not the hydrogen atoms bridge the two metals. As an illustration, the three isomers of $[CpReH_3]_2$ with: (i) no bridging hydrogens, $[CpReH_3]_2$, (ii) two bridging hydrogens, $[CpReH_2]_2(\mu\text{-}H)_2$ and (iii) four bridging hydrogens, $[CpReH]_2(\mu\text{-}H)_4$ are each predicted by the ''half-electron'' method to have Re≡Re triple bonds (Fig. 20) [78]. The notion that the Re–Re bond order is not influenced by whether or not the hydrogen atoms bridge is far from intuitive. In contrast, the μ-LX ''half-arrow'' method for counting electrons predicts that the Re–Re bond order decreases from a triple bond in $[CpReH_3]_2$ to a single bond in $[CpReH_2]_2(\mu\text{-}H)_2$, and to an ''antibond'' in $[CpReH_2]_2(\mu\text{-}H)_2$ (Fig. 20). Indeed, calculations by Bursten [78] are in accord with the changes predicted by the μ-LX ''half-arrow'' method. Thus, focusing on the metal-based orbitals: (i) the $\sigma^2(\pi)^4$ electronic configuration for $[CpReH_3]_2$ indicates a direct Re≡Re triple bond, (ii) the $(\sigma/\delta)^2(\pi)^2(\delta^*)^2$ configuration of $[CpReH_2]_2(\mu\text{-}H)_2$ indicates a direct Re–Re single bond, and (iii) the $(\sigma/\delta)^2(\delta^*)^2(\delta^*)^2$ configuration of $[CpReH]_2(\mu\text{-}H)_4$ indicates a direct Re–×–Re antibonding interaction [78].

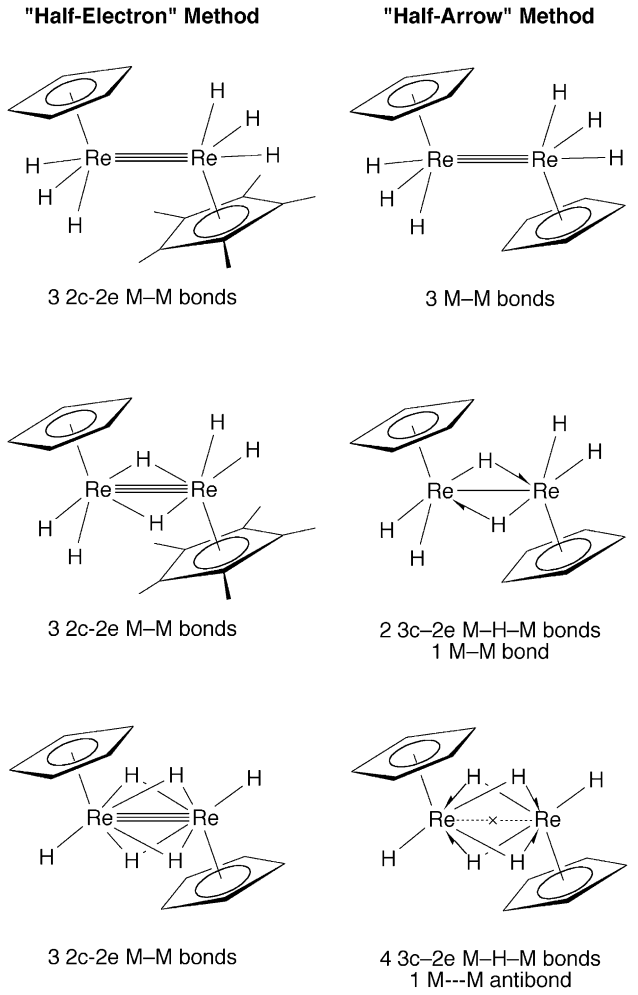

Fig. 20. Three postulated isomeric rhenium hydride complexes for which formal Re≡Re triple bonds were invoked to satisfy the 18-electron rule (left hand side); the corresponding description of their bonding in terms of 3-center-2-electron bonds and direct Re–Re bonds (right hand side).

Why does the "half-electron" method predict the same bond order for the above rhenium complexes regardless of whether or not the hydrogen atoms bridge? This counter-intuitive result is, in essence, a consequence of the "half-electron" method assigning the same number of electrons to bridging and terminal hydride ligands [7]. As such the "half-electron" method fails to address properly the 3-center-2-electron nature of the [M–H–M] bridge.

Hoffmann has aptly concluded that for complexes with 3-center-2-electron bonds "it is best not to argue over whether there is or is not metal–metal bonding in these molecules. The orbitals in question are delocalized and are used to bond a metal atom *both* to its metal partner and to the bridging group" [75]. It is, however, important to emphasize that: (i) the "direct" M···M component for a 3-center-2-electron interaction cannot be viewed as equivalent to that of a normal 2-center-2-electron M–M bond [90], and (ii) there may be additional direct M···M interactions that do not have a significant component from the bridging ligands. These issues are not addressed by the "half-electron" method for counting electrons which merely applies a formula to predict the M–M bond order [7], a formula that does not even require knowledge of the structure of the molecules since the same result is obtained regardless of whether or not the hydrogen atoms bridge. In contrast, the μ-LX "half-arrow" method of counting electrons requires one to draw the structure of the molecule prior to determining the electron count at a metal center from which the M–M bond order is inferred. The μ-LX "half-arrow" method thus provides a more complete picture of the bonding by clearly distinguishing between: (i) the number of 3-center-2-electron M–H–M interactions and (ii) the number of direct 2-center-2-electron M–M interactions. Furthermore, by not forcing an 18-electron count on a metal center (which is *explicitly* forced by the formula employed by the "half-electron" method [7]), the μ-LX "half-arrow" method has the advantage of providing an indication of whether or not a M–M antibonding interaction exists.

One of the significant features of separating the bonding into 3-center-2-electron M–H–M interactions and 2-center-2-electron M–M interactions is that it provides a greater understanding of the bonding. In fact, these two interactions may be viewed as the "*s*" and "*y*" counterparts in Lipscomb's *styx* nomenclature, [91] that has found much use in evaluating the topological structures of boranes [92], and which has also been extended to the structures of metal-hydride clusters [60b].

3. Computational details

All calculations were carried out using density functional theory as implemented in the Jaguar 4.1 suite [93] of quantum chemistry programs, Amsterdam Density Functional 2000.02 package (ADF) [94] and DMOL3 version 2.1 [95,96]. Geometries were optimized using Jaguar and the B3LYP [97] functional with the 6-31G** basis set. Molybdenum was represented using the Los Alamos LACVP** basis [98] that includes relativistic effective core potentials. Vibrational frequency calculation results based on analytical second derivatives at the B3LYP/6-31G** level of theory were used to confirm proper convergence to local minima. Owing to computational cost vibrational frequencies for $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$ and $\{[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)\}^{2+}$ were not computed. Additional single point calculations on the Jaguar-optimized structures were carried out using ADF to obtain fragment wavefunctions that were helpful for constructing the MO-diagrams. In these calculations, a double-ζ STO basis set was utilized, with one set of polarization

functions as provided in the ADF package (Basis Set III – frozen core), together with the BLYP functional. Relativistic effects on Mo are included using the "zeroth-order regular approximation" (ZORA) [99]. Mayer bond order [56,57] calculations were carried out using DMOL3 [95,97] and the Jaguar-optimized geometries. The BLYP functional was used in combination with the DNP basis set, which corresponds to the 6-31G** basis. Note that the B3LYP functional is not available in "pure DFT" packages, such as ADF and DMOL. Some of the calculations presented above incorporate a point charge placed at appropriate coordinates in space to mimic the electrostatic effect of bridging ligand moieties on the orbitals of the dinuclear metal fragment. In these calculations, the Coulombic potential generated by the point charge in space is included natively in the self-consistent field procedure as implemented in ADF [100].

4. Conclusions

DFT calculations on dinuclear molybdenum complexes with bridging hydride and methyl ligands, namely $[CpMo(\mu\text{-}O_2CH)]_2(\mu\text{-}PH_2)(\mu\text{-}H)$ and $[Cp^*Mo(\mu\text{-}O_2CMe)]_2(\mu\text{-}PMe_2)(\mu\text{-}Me)$, indicate that the bonding is best described in terms of: (i) a 2-center-2-electron Mo–Mo single bond and (ii) a 3-center-2-electron Mo–H–Mo or Mo–Me–Mo bond. The presence of a 2-center-2-electron Mo–Mo single bond is in accord with the prediction of the "half-arrow" electron counting method that views the bridging hydride and methyl ligands as μ-LX ligands. In contrast, the "half-electron" counting procedure, which apportions half of the valence electron of the hydrogen atom or methyl radical to each metal, predicts a Mo=Mo double bond, a result that is contrary to the theoretical calculations. Consideration of the structures of a variety of other bridging hydride complexes indicates that the "half-arrow" electron counting method provides the best general description of the bonding by clearly distinguishing between the number of 3-center-2-electron M–H–M interactions and direct 2-center-2-electron M–M interactions. Several simple examples serve to highlight the failings of the "half-electron" method, namely:

1. The "half-electron" counting procedure predicts a Zr=Zr double bond for $[Cp_2Zr(H)]_2(\mu\text{-}H)_2$. A Zr=Zr double bond is clearly implausible because the Zr center of each Cp_2ZrH_2 fragment is d^0 and is thereby *incapable* of forming a 2-center-2-electron Zr–Zr bond with a second fragment. In contrast, the μ-LX "half-arrow" method predicts that there is no direct Zr–Zr bond in $[Cp_2Zr(H)]_2(\mu\text{-}H)_2$.
2. The M–M bond order predicted by the "half-electron" method is *independent* of whether or not the hydrogen atoms bridge the two metals. As an illustration of this counter-intuitive prediction, the three isomers of $[CpReH_3]_2$ with: (i) no bridging hydrogens, $[CpReH_3]_2$, (ii) two bridging hydrogens, $[CpReH_2]_2(\mu\text{-}H)_2$ and (iii) four bridging hydrogens, $[CpReH]_2(\mu\text{-}H)_4$ are each predicted to have Re≡Re triple bonds by the "half-electron" method. Calculations by Bursten, however, demonstrate that the Re–Re bond orders do indeed vary with the number of bridging hydrogens, in a manner as predicted exactly by the "half-arrow" method.
3. The M–M bond order that is determined by the "half-electron" method is derived by forcing the metal centers to have an 18-electron configuration. In contrast, the M–M bond order derived by the μ-LX "half-arrow" electron counting method does not enforce such a restriction. For example, the μ-LX "half-arrow" electron counting method predicts $[Cp^*Ru]_2(\mu\text{-}H)_4$ to have a 20-electron configuration for each ruthenium. The 20-electron configuration indicates that the HOMO is a Ru–×–Ru *antibonding* orbital which reduces the overall bonding associated with the four Ru–H–Ru 3-center-2-electron interactions. This prediction is in full accord with a theoretical study by Morokuma which indicates that the direct Ru–Ru interaction is *repulsive*, a result that is in marked contrast to the Ru≡Ru triple bond predicted by the "half-electron" method.

In conclusion, the "half-arrow" method is the procedure of choice for counting electrons for complexes that possess 3-center-2-electron M–×–M interactions. In all cases evaluated, the "half-arrow" method provides results that are much more in accord with theoretical calculations than those obtained by the "half-electron" method.

[11] It should be noted that the "open" and "closed" nomenclature for [M(μ-H)M] is not completely analogous to that used in boron hydride chemistry for B_3 fragments. Specifically, the "open" B–B–B interaction employs a p-orbital on the central boron, such that the outer boron atoms are required by symmetry arguments to exhibit an out-of-phase antibonding interaction. For situations with a bridging hydrogen atom, the two outer atoms will always exhibit a bonding interaction, and the classification of "open" and "closed" relates to the magnitude of the interaction. See [12,13].

[19] The 3-center-2-electron M–H–M interaction has also been described as a protonated metal–metal bond of the anionic $[M–M]^-$ moiety [17c]. While this is a perfectly good description of the interaction, it must be emphasized that the protonated "metal–metal bond" is no longer the same as that in the hypothetical anionic $[M–M]^-$ fragment.

[42] Indeed, the metal–metal separation in dinuclear complexes with bridging ligands and no metal–metal bond may be shorter than unbridged complexes with a metal–metal bond. See, for example: H. Vahrenkamp, Angew. Chem., Int. Ed. Engl. 17 (1978) 379.

[47] Note that these specific compounds have been selected because the bond order assignment is independent of electron count method used because none of the bridges are involved in 3-center-2-electron interactions.
[48] MO calculations on axially symmetric complexes of the type $[CpMo(\mu\text{-}X)_2]_2$ indicate that the δ* orbital may be lower in energy than the δ orbital. Specifically, the δ orbital interacts with an appropriate combination of p orbitals of the $(\mu\text{-}X)_4$ fragment whereas the δ* orbital does not; if this destabilization of the δ orbital is sufficiently strong, the energies of the δ and δ* orbitals may be reversed. An important consequence of this reversal pertains to "d^2–d^2" dimers such that rather than have a $\sigma^2\delta^2$ configuration, and hence a Mo=Mo double bond, a $\sigma^2\delta^{*2}$ configuration results such that the Mo–Mo bond order is zero. See [45].

[52] It should, however, be noted that compounds with substantially shorter formal Mo≡Mo triple bonds are known for non-cyclopentadienyl derivatives, e.g. $Mo_2(NMe_2)_6$ [2.214(3) Å][a] and $Mo_2(OCH_2CMe_3)_6$ [2.222(2) Å][b]:

[59] There are five more unoccupied metal-dominated MOs to complete the set of 10 MOs relevant for the dimetallic complex, all of which are indicated in Fig. 11. However, because they are not of much significance for the goal of this investigation, they are not further discussed.
[60] Specifically, the ionization bands assigned to the M(μ-H)M interactions showed a marked variation in intensity in the HeI and HeII spectra, indicating a significant contribution from the hydrogen 1s orbital which is known to be sensitive to such changes:

[62] D.E. Sherwood, M.B. Hall, Inorg. Chem. 21 (1982) 3458.
[63] It should be noted that there is an additional way of describing the structure of 4–membered $[M(\mu\text{-}H)_2M]$ fragments. Specifically, rather than describing the interaction as two 3-centered-2-electron bonds, it is permissible to describe the interaction as one 4-centered-2-electron $[M(\mu\text{-}H)_2M]$ bond and one 2-centered M–M bond. However, a double 2-centered-2-electron M=M interaction is not a viable alternative since there would be no orbitals available on M for interaction with the hydrogen atoms. See, for example:

[76] 20-electron compounds, such as Cp_2Ni, are known and their stability requires that a low energy antibonding orbital is available to accept the electrons. In addition to bona fide 20-electron complexes, there are several examples, such as Cp_3ZrX and $W(R_2C_2)_3CO$ where the apparently >18electron count is deceiving because one of the ligand orbital combinations remains nonbonding as a result of there being no metal based orbital of appropriate symmetry with which to interact; the electron count at the metal in such complexes is thus reduced from 20 to 18. See, for example:

Structural and spectroscopic studies of three-coordinate copper(I) supported by bis(phosphino)borate ligands

J. Christopher Thomas, Jonas C. Peters *

Contribution from the Division of Chemistry and Chemical Engineering, Arnold and Mabel Beckman Laboratories of Chemical Synthesis, California Institute of Technology, Pasadena, CA 91125, USA

Received 1 July 2004; accepted 25 August 2004
Available online 28 October 2004

Dedicated to Professor Malcolm H. Green, an inspiring organometallic chemist

Abstract

The bis(phosphino)borates [(*p*-^{t}BuPh)$_2$B(CH$_2$PPh$_2$)$_2$][ASN] (**1**[ASN]; ASN = 5-azonia-spiro[4.4]nonane), [Ph$_2$B(CH$_2$P^{i}Pr$_2$)$_2$]-Li(THF)$_2$ (**2**[Li]), and [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]$^-$ (**3**[Li] and **3**[Tl]) react with copper(I) reagents to generate anionic and neutral complexes. Reaction of **1**[ASN] with CuI provides the 1:1 adduct [[(*p*-^{t}BuPh)$_2$B(CH$_2$PPh$_2$)$_2$]CuI][ASN] (**4**). CuCl reacts with **3**[Li] in THF to afford [[(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]CuCl][Li(THF)$_4$] (**5**), along with a minor byproduct, the three-coordinate bis(phosphine) adduct {(3,5-Me$_2$Ph)B(CH$_2$P^{t}Bu$_2$)$_2$}CuCl (**6**). An analogous neutral complex, {PhB(CH$_2$P^{t}Bu$_2$)$_2$}CuCl (**7**), can be synthesized directly by reacting CuCl with the neutral phosphino borane PhB(CH$_2$P^{t}Bu$_2$)$_2$. Reaction of the substituted copper(I) halide Me$_2$S · CuBr with **3**[Tl] provides the anionic dimer complex [{[(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]Cu}$_2$(μ-Br)]Tl (**8**). The neutral solvent adducts [Ph$_2$B(CH$_2$P^{i}Pr$_2$)$_2$]Cu(NCCH$_3$) (**9**) and [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]Cu(NCCH$_3$) (**10**) are prepared by the reactions between [Cu(CH$_3$CN)$_4$][PF$_6$] and **2**[Li] or **3**[Li], respectively. Neutral **10** is a useful precursor to several other neutral species via substitution of the labile acetonitrile ligand, including [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]Cu(PMe$_2$Ph)(**11**), [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]-Cu(S=PMe$_3$) (**12**), [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$] Cu(2,6-lutidine) (**13**), and [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]Cu(CN^{t}Bu) (**14**). Attempts to isolate a neutral monocarbonyl adduct, [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]Cu(CO) (**15**), are frustrated by the high lability of the CO ligand. The solid-state crystal structures of complexes **6**, **8**, **9**, **10**, and **11** have been determined and are described.

1. Introduction

Copper(I) complexes play a significant role in many catalytic and stoichiometric processes, including catalytic hydrocarbon functionalization reactions [1], catalytic oxidation reactions [2], and biomimetic dioxygen activation [3]. Several well-defined copper(I) systems have been developed recently using ligands designed to control both steric and electronic factors that dictate overall reactivity profiles. These include modified bis- and tris(pyrazolyl)borates [4], β-diketiminates [5], *N*-heterocyclic carbenes [6], and a host of other nitrogenous ligands [7].

We recently reported the synthesis of a new family of bis(phosphino)borate ligands that are both sterically and electronically tunable [8]. These ligands are anionic relatives to the better known bis(pyrazolyl)borate and β-diketiminate ligands, and their fundamental coordination chemistry is therefore of comparative interest. In this contribution, we introduce a series of well-defined copper(I) complexes supported by monoanionic

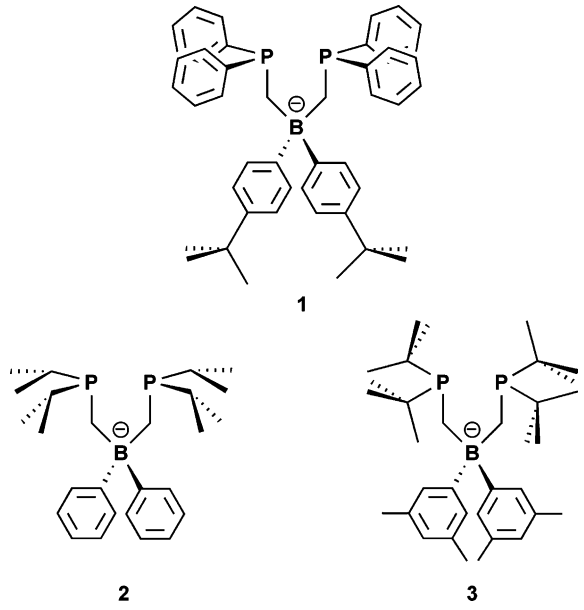

Fig. 1. Bis(phosphino)borate ligands used to prepare copper(I) complexes.

bis(phosphino)borates. The aim of this initial study is to develop reliable protocols for the generation and isolation of these new copper species, to establish their structural characterization, and to assess their ligand substitution chemistry. In this context, we examine the copper(I) coordination chemistry of the three bis(phosphino)borate ligands: $[(p\text{-}^t\text{BuPh})_2\text{B}(\text{CH}_2\text{PPh}_2)_2]$[ASN] (**1**[ASN]), $[\text{Ph}_2\text{B}(\text{CH}_2\text{P}^i\text{Pr}_2)_2]\text{Li}(\text{THF})_2$ (**2**[Li]), and $[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]^-$ (**3**[Li] and **3**[Tl]) (Fig. 1). In particular, we emphasize the use of the sterically encumbered *tert*-butyl phosphine ligand **3** due to its ability to enforce three-coordinate geometries for a host of copper(I) complexes. Our hope is that the complexes described will serve as useful "$[\text{BP}_2]\text{Cu}^\text{I}(\text{L})$" sources in the context of future group transfer studies.

2. Experimental

2.1. General considerations

General procedures were performed according to previously published methods [9]. The compounds $[(p\text{-}^t\text{BuPh})_2\text{B}(\text{CH}_2\text{PPh}_2)_2]$[ASN] (**1**[ASN]), $[\text{Ph}_2\text{B}(\text{CH}_2\text{P}^i\text{Pr}_2)_2]\text{Li}(\text{THF})_2$ (**2**[Li]), $[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]\text{Li}(\text{OEt}_2)$ (**3**[Li]), $[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]\text{Tl}$ (**3**[Tl]), and $\text{Me}_3\text{P}{=}\text{S}$ were prepared by published methods [8]. ^{t}BuNC was distilled under dinitrogen and dried over 3 Å molecular sieves prior to use. 2,6-Lutidine was sparged with dinitrogen and then dried with CaH_2 and distilled under dinitrogen. $\text{PhB}(\text{CH}_2\text{P}^t\text{Bu}_2)_2$ was generated by the addition of PhBCl_2 to a cold ethereal suspension of $\text{LiCH}_2\text{P}^t\text{Bu}_2$.[1] All other reagents were purchased from commercial vendors and used without further purification.

2.2. Syntheses of complexes

2.2.1. $[[(p\text{-}^t\text{BuPh})_2\text{B}(\text{CH}_2\text{PPh}_2)_2]\text{CuI}][\text{ASN}]$ (**4**)

Solid CuI (83.6 mg, 439 μmol) and $[(p\text{-}^t\text{BuPh})_2\text{B}(\text{CH}_2\text{PPh}_2)_2]$[ASN] (351.8 mg, 438.7 μmol) were combined with THF (4 mL) and ethanol (0.3 mL). The reaction mixture was stirred for 2.5 h. Volatiles were removed under reduced pressure. The resulting solids were washed with diethyl ether (3 mL) and dried under reduced pressure, providing analytically pure white **4** (432.8 mg, 99.4%). ^{1}H NMR (300 MHz, acetone-d_6): δ 7.60 (m, 8H), 7.12 (m, 16H), 6.82 (d, 4H), 3.69 (m, 8H), 2.24 (m, 8H), 1.76 (br, 4H), 1.21 (s, 16H). $^{13}\text{C}\{^1\text{H}\}$ NMR (75.4 MHz, acetone-d_6): δ 162.7 (br), 144.55, 141.80 (d, $^1J_{\text{P–C}} = 12.3$ Hz), 141.64 (d, $^1J_{\text{P–C}} = 12.3$ Hz), 133.83, 133.71 (d, $^2J_{\text{P–C}} = 8.0$ Hz), 133.60 (d, $^2J_{\text{P–C}} = 8.0$ Hz), 128.72, 128.49 (d, $^3J_{\text{P–C}} = 4.3$ Hz), 128.43 (d, $^3J_{\text{P–C}} = 4.0$ Hz), 123.51, 63.78 (t, $(\text{CH}_2\textit{C}\text{H}_2)_2\text{N}$, $^1J_{\text{N–C}} = 3.4$ Hz), 34.42 (Ph-$\textit{C}(\text{CH}_3)_3$), 32.15 (Ph-C($\textit{C}\text{H}_3)_3$), 22.84 (($\textit{C}\text{H}_2\text{CH}_2)_2\text{N}$), 22.0 (br, $\text{B}(\textit{C}\text{H}_2\text{PPh}_2)_2$). $^{31}\text{P}\{^1\text{H}\}$ NMR (121.4 MHz, acetone-d_6): δ −13.08. $^{11}\text{B}\{^1\text{H}\}$ NMR (128.3 MHz, acetone-d_6): δ −12.5. *Anal.* Calc. for $\text{C}_{54}\text{H}_{66}\text{BCuINP}_2$: C, 65.36; H, 6.70; N, 1.41. Found: C, 65.08; H, 6.94; N, 1.21%.

2.2.2. $[[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]\text{CuCl}][\text{Li}(\text{THF})_4]$ (**5**)

Solid CuCl (26.5 mg, 268 μmol) was suspended in THF (1.5 mL), stirred vigorously, and a THF solution (4 mL) of $[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]\text{Li}(\text{OEt}_2)$ (166.2 mg, 268.2 μmol) was then added to the stirring suspension. After stirring for 24 h, analysis by $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy revealed the formation of one major product, along with two minor byproducts. The reaction mixture was then filtered. The resulting filtrate was concentrated under reduced pressure to 0.5 mL. Vapor diffusion of petroleum ether into the THF solution provided white crystalline solids over several days. The isolated solids were dried under reduced pressure to provide the major product, $[[(3,5\text{-Me}_2\text{Ph})_2\text{B}(\text{CH}_2\text{P}^t\text{Bu}_2)_2]\text{CuCl}][\text{Li}(\text{THF})_4]$ (163.9 mg, 65.5%). ^{1}H NMR (300 MHz, C_6D_6/THF-d_8, 6:1): δ 7.59 (s, 4H, *ortho*-

[1] The synthesis of $\text{PhB}(\text{CH}_2\text{P}^t\text{Bu}_2)_2$ and its use as a ligand building block to other borate ligands will be reported separately (C.M. Thomas, J.C. 2.2.3. {(3,5-Me_2Ph)B($CH_2P^tBu_2)_2$}CuCl (6)

Yellow crystals of the minor byproduct, **6**, were isolated from a separate reaction, carried-out in an analogous fashion to that used in the preparation of **5**, by petroleum ether diffusion into a THF solution of the crude reaction mixture. A $^{31}P\{^1H\}$ NMR spectrum of the solution prior to crystallization showed **6** to be present as approximately 15% of the observed diamagnetic phosphorus containing products. $^{31}P\{^1H\}$ NMR (121.4 MHz, THF): δ 23.75. The identity of **6** was established by XRD analysis (see Fig. 2), and by comparison to the spectral properties of independently prepared **7**.

2.2.4. {PhB($CH_2P^tBu_2)_2$}CuCl (7)

Solid $PhB(CH_2P^tBu_2)_2$ 1 (25.4 mg, 62.5 μmol) and CuCl (6.2 mg, 63 μmol) were combined in THF (4 mL) and stirred for 1 h, forming a homogeneous yellow solution. The solution was filtered, and volatiles were removed under reduced pressure, forming microcrystalline yellow {$PhB(CH_2P^tBu_2)_2$}CuCl (30.7 mg, 97.2%). ^1H NMR (300 MHz, C_6D_6): δ 7.88 (m, 2H), 7.28 (m, 3H), 1.73 (br, 4H, $B(CH_2P^tBu)_2$), 1.22 (d, 18H, $P(C(CH_3)_3)_2$, $^3J_{P-H} = 6.3$ Hz), 1.20 (d, 18H, $P(C(CH_3)_3)_2$, $^3J_{P-H} = 6.6$ Hz). $^{13}C\{^1H\}$ NMR (75.4 MHz, C_6D_6): δ 134.60, 133.29, 129.05, 34.47 (m, $CH_2P(C(CH_3)_3)_2$), 29.82 (m, $CH_2P(C(CH_3)_3)_2$), 18.8 (br, BC H_2P). $^{31}P\{^1H\}$ NMR (121.4 MHz, C_6D_6): δ 23.11. $^{11}B\{^1H\}$ NMR (160.4 MHz, C_6D_6): δ 75.2. *Anal*. (a) Solid **10** (11.3 mg, 17.5 μmol) was dissolved in THF-d_8 (0.7 mL) and placed in a J. Young NMR tube. The tube was partially evacuated. CO gas (approximately 1 atm) was introduced to the J. Young tube, and the tube was sealed. The solution was analyzed by NMR spectroscopy. ^{1}H NMR (300 MHz, THF-d$_8$): δ 7.00 (s, 4H, *ortho*-(Me$_2$C$_6$$H_3$)$_2$B), 6.36 (s, 2H, *para*-(Me$_2$C$_6$$H_3$)$_2$B), 2.12 (s, 12H, (($CH_3$)$_2C_6H_3$)$_2$B), 2.03 (s, 3H, C$H_3$CN), 1.53 (br, 4H, B(C$H_2$P^{t}Bu)$_2$), 1.14 (d, 18H, P(C(C$H_3$)$_3$)$_2$, $^3J_{P-H}$ = 6.3 Hz), 1.12 (d, 18H, P(C(CH_3)$_3$)$_2$, $^3J_{P-H}$ = 6.3 Hz). ^{13}C{^{1}H} NMR (125.7 MHz, THF-d$_8$): δ 186.21(*C*O), 165.82 (br q, $^1J_{B-C}$ = 48 Hz), 134.66, 131.48, 124.55, 118.78 (CH$_3$$C$N), 34.70 (d, P($C$(CH$_3$)$_3$)$_2$, $^1J_{P-C}$ = 7.2 Hz), 34.64 (d, P(C(CH$_3$)$_3$)$_2$, $^1J_{P-C}$ = 7.2 Hz), 30.72 (br, P(C(CH$_3$)$_3$)$_2$), 22.28 (((CH$_3$)$_2$C$_6$H$_3$)$_2$B), 12.76 (br q, B(CH$_2$P^{t}Bu)$_2$, $^1J_{B-C}$ = 42 Hz), 1.01 (CH$_3$CN). ^{31}P{^{1}H} NMR (121.4 MHz, THF-d_8): δ 42.33. ^{11}B{^{1}H} NMR (128.3 MHz, THF-d$_8$): δ −13.9.

(b) In a 25 mL Schlenk flask, solid **10** (14.3 mg, 22.2 μmol) was dissolved in THF (1.5 mL) with a stirbar. The solution was stirred under a stream of CO gas until dry, producing pale green solids. ^{1}H NMR (300 MHz, C$_6$D$_6$): δ 7.56 (s, 4H, *ortho*-(Me$_2$C$_6$$H_3$)$_2$B), 6.72 (s, 2H, *para*-(Me$_2$C$_6$$H_3$)$_2$B), 2.35 (s, 12H, (($CH_3$)$_2C_6H_3$)$_2$B), 1.86 (br, 4H, B(C$H_2$P^{t}Bu)$_2$), 1.07 (d, 18H, P(C(C$H_3$)$_3$)$_2$, $^3J_{P-H}$ = 6.3 Hz), 1.12 (d, 18H, P(C(CH_3)$_3$)$_2$, $^3J_{P-H}$ = 6.3 Hz). IR: (THF/KBr, cm^{-1}) ν_{CO} = 2084 (st).

2.3. X-ray crystallography

The general X-ray experimental procedure was performed according previously published methods [9]. Crystallographic information is provided in Table 1. The structures of **8 · THF · pentane** and **10 · 0.56THF · 0.22 pentane** contained sites of disordered solvent molecules.

3. Results and discussion

3.1. Copper(I) complexes containing halides

The formation of low-coordinate copper complexes using bis(phosphino)borate ligands was examined using several Cu(II) precursors, such as CuCl$_2$ · 0.8THF [10], anhydrous Cu(OAc)$_2$, and Cu(OTf)$_2$. As has been observed in previous efforts to develop Cu(II)–phosphine chemistry [11], we found that Cu(II) was easily reduced to Cu(I) in the presence these reducing phosphine ligands to provide ill-defined degradation products. In comparison, copper(I) starting materials provide in many cases clean 1:1 adducts with monoanionic bis(phosphino)borate ligands. Anionic complexes of copper(I) halides were prepared using both the phenyl substituted phosphine ligand [(*p*-^{t}BuPh)$_2$B(CH$_2$PPh$_2$)$_2$]$^-$ (**1**) and the *tert*-butyl substituted phosphine ligand [(3,5-Me$_2$Ph)$_2$B(CH$_2$P^{t}Bu$_2$)$_2$]$^-$ (**3**). For example, reacting **1**[ASN] with CuI in THF/EtOH solution resulted in the near quantitative generation of [[(*p*-^{t}BuPh)$_2$B(CH$_2$PPh$_2$)$_2$]CuI][ASN] (**4**), which could be isolated in high yield (Eq. (1)). Reactions using the [Ph$_2$B(CH$_2$PPh$_2$)$_2$][ASN] ligand [8] provided similar results with CuI and CuCl; however, the presence of *tert*-butyl substituents in the backbone of the ligand framework increases the hydrocarbon solubility of these complexes.

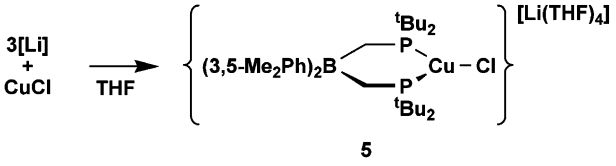
Similar attempts to prepare 1:1 adducts of copper(I) halides using the alkyl substituted phosphine ligands **2**[Li] or **3**[Li] gave more complicated results. For example, the reaction of copper(I) iodide with either **2**[Li] or **3**[Li] resulted in the immediate precipitation of black sediment with concomitant phosphine degradation, ascertained by $^{31}P\{^{1}H\}$ and $^{11}B\{^{1}H\}$ NMR spectroscopies. By contrast, combining copper(I) chloride and **3**[Li] in THF solution provided one major product ($^{31}P\{^{1}H\}$ NMR). Spectroscopic and elemental analysis proved consistent with the formation of [[(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]CuCl][Li(THF)$_4$] (**5**) (Eq. (2)). The clean preparation of copper(I) halides using the alkyl substituted phosphine ligands **2** and **3** appears to require a less redox susceptible copper(I) synthon (i.e., CuCl instead of CuI).



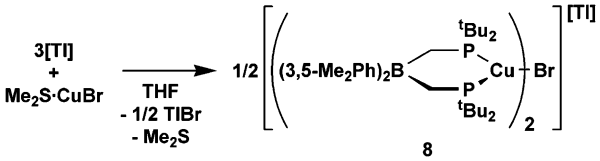
(2)

A significant body of work on {P_2CuX} complexes (P = phosphine, X = Cl, Br, I) shows that their coordination geometry can vary between three-coordinate (P_2CuX) or four-coordinate with bridging halides ($\{P_2Cu(\mu\text{-}X)\}_2$) [12,13]. For some phosphines, such as PPh_3, structural data have been obtained for both forms [12b,12c]. A related example containing the *tert*-butyl substituted chelating bis(phosphine) ligand dtbpe (dtbpe = $^tBu_2PCH_2CH_2P^tBu_2$) provided the dimeric structure $\{(dtbpe)Cu(\mu\text{-}Cl)\}_2$ [14]. It is therefore possible that **4** and **5** exist as either three-coordinate monomers, or four-coordinate, bridged dimers in solution. An equilibrium mixture of the two conformations may also prevail in solution.

The reaction between **3**[Li] and several copper(I) halide reagents provides a common secondary product. For instance, the reaction between **3**[Li] and CuCl provided a mixture of three phosphine containing products ($^{31}P\{^{1}H\}$ NMR). Along with the formation of the dominant product **5** (>80%), two minor products were observed. One of the minor products proved to be isolable by fractional crystallization, and XRD analysis of crystals thus obtained established its identity as {(3,5-$Me_2Ph)B(CH_2P^tBu_2)_2$}CuCl (**6**) (Fig. 2). Neutral **6** results from the loss of an aryl ring from the borate ligand, generating a neutral bis(phosphino)borane ligated to copper(I) chloride. Potentially related examples of (phosphino)borate ligand degradation have been observed previously [15]. In all of these cases, a boron–carbon bond is cleaved at the boron–methylene link. The present example demonstrates that the boron–aryl link is also susceptible to cleavage.

The spectroscopic identification of **6** was supported by the independent synthesis of a structurally analogous species, {$PhB(CH_2P^tBu_2)_2$}CuCl (**7**). The reaction between the neutral borane $PhB(CH_2P^tBu_2)_2$ and CuCl in THF solution provided a high yield route to **7** (97% yield) 1. The phosphine precursor $PhB(CH_2P^tBu_2)_2$ was readily generated by the addition of two equiv of $LiCH_2P^tBu_2$ to $PhBCl_2$ in diethyl ether. Neutral **7** has two important spectroscopic features. First, its $^{11}B\{^{1}H\}$ NMR spectrum (singlet at 75.2 ppm) confirms the three-coordinate nature of the boron atom [16]. Second, the $^{31}P\{^{1}H\}$ NMR chemical shift of **7** (23.11 ppm) is consistent with the resonance ascribed to **6** (23.75 ppm).

To circumvent ligand degradation pathways, alternative copper(I) sources and the use of thallium phosphine reagents were examined. Upon addition of a THF solution of **3**[Tl] to $Me_2S \cdot CuBr$, thallium bromide precipitated from solution. NMR analysis of the reaction solution showed one major product. XRD analysis of crystals obtained from the reaction solution provided the unexpected molecular structure, [{[(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu}$_2$(μ-Br)]Tl (**8**), shown in Fig. 3. As is evident, only one-half of an equivalent of TlBr is lost in the reaction (Eq. (3)).



(3)

The structure of **8** shows two copper centers connected by a linear bromide bridge, thus providing a monoanionic dinuclear copper species with one thallium counter-cation. A common plane cuts through each of the phosphine, copper, bromide, and boron atoms of **8**. The chelate phosphine ligand exists in its typical twisted boat conformation [8,17]. In the molecular structure, the thallium atom resides in the pocket formed by the two aryl rings of the borate anion. This thallium coordination environment is similar to that observed in the molecular structure of $[Ph_2B(CH_2PPh_2)_2]Tl$ (**3**[Tl]) [8]. Halide-bridged systems are well known for copper(I), although there are few structurally characterized examples of copper centers bridged by a single halide [18]. This example appears to be structurally unique amongst phosphine-coordinated copper(I) species. In addition, all previous structurally characterized exhibit a copper–halide–copper angle that is significantly bent. The present example contains a linear halide bridge (Cu1–Br–Cu2 = 178.00(6)°). Attempts to induce loss of TlBr in solution by the addition of a donor ligand to **8**, such as PMe_3, pyridine, or acetonitrile, have not been successful.

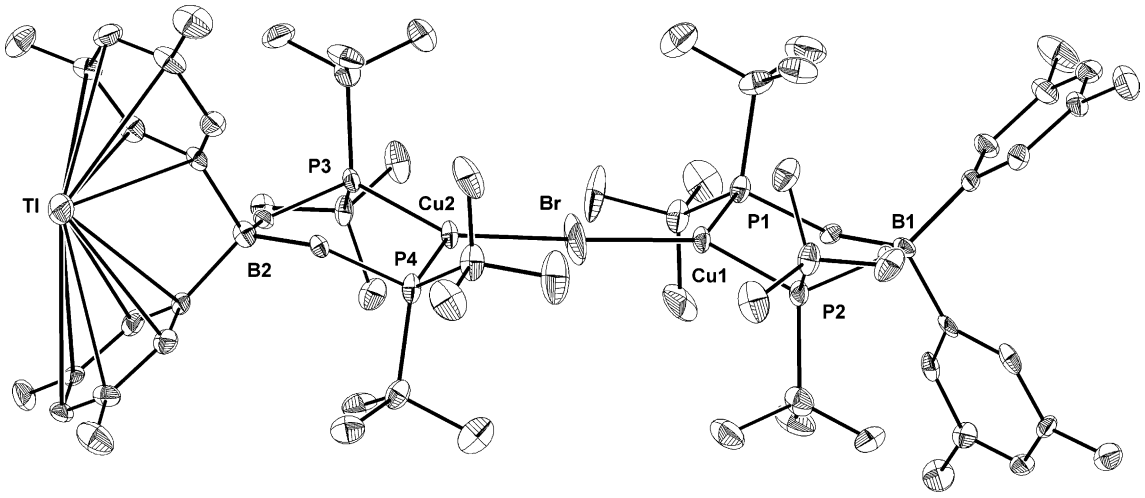


Fig. 3. Displacement ellipsoid representation (50%) of [{[(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu}$_2$(μ-Br)]Tl · THF · pentane (**8 · THF · pentane**). Hydrogen atoms and solvent molecules are omitted for clarity. Selected interatomic distances (Å) and angles (°): P1–Cu1, 2.238(2); P2–Cu1, 2.230(2); P3–Cu2, 2.235(2); P4–Cu2, 2.231(2); Cu1–Br, 2.3660(12); Cu2–Br, 2.3638(12); B1–Cu1, 3.819(8); B2–Cu2, 3.829(8) and P1–Cu1–P2, 110.67(7); P1–Cu1–Br, 125.55(7); P2–Cu1–Br, 123.78(7); P3–Cu2–P4, 110.60(7); P3–Cu2–Br, 124.63(7); P4–Cu2–Br, 124.70(7); Cu1–Br–Cu2, 178.00(6).

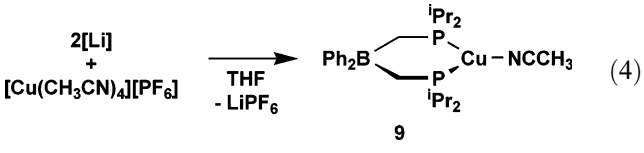
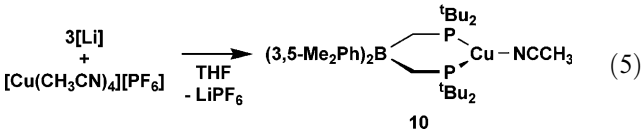
3.2. Neutral three-coordinate acetonitrile copper(I) complexes

To access more substitutionally labile copper(I) complexes, the copper(I) reagent [$Cu(CH_3CN)_4$][PF_6] proved effective. Reaction of the alkyl-substituted phosphine ligands **2**[Li] or **3**[Li] with [$Cu(CH_3CN)_4$][PF_6] in THF solution led to rapid formation of the three-coordinate products [$Ph_2B(CH_2P^iPr_2)_2$]Cu(NCCH $_3$) (**9**) and [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu(NCCH$_3$) (**10**) (Eqs. (4) and (5)). Isolated yields of pure **9** were low (ca. 40%) due to the difficulty in separating [Li(solvent)$_x$][PF_6] from **9**. In comparison, **10** was isolated in much higher yield (80%). Both compounds have been thoroughly characterized by NMR spectroscopy and elemental analysis. The IR spectra for **9** and **10** show ν_{CN} bands at 2265 and 2267 cm^{-1}, respectively. These stretches are consistent with acetonitrile acting as a weakly bound σ-donor. Previously reported IR data for phosphine-coordinated copper(I) acetonitrile complexes show a wide range of C≡N stretching frequencies (2268–2361 cm^{-1}), all of which are above the value for the free ligand (CH_3CN, thin film on KBr: 2253 cm^{-1}) [19].



9 (4)



10 (5)

An X-ray diffraction study verified the three-coordinate nature of **9** (Fig. 4). The bis(phosphino)borate ligand is again in a twisted boat conformation. Two parameters of further note from the molecular structure of **9** are the B–Cu distance and the nature of the coordinated acetonitrile ligand. In other structures of transition metal complexes coordinated by bis(phosphino) borate ligands, the B–Cu distance in the twisted-boat conformation has typically been observed at B–M = 3.91–4.12 Å (M = Fe, Co, Rh, Pd, Pt). In the structure of **9** and the other three-coordinate structures presented in the present study, the B–M distance is relatively short (**9**: B–Cu = 3.823(2) Å). This is due to an

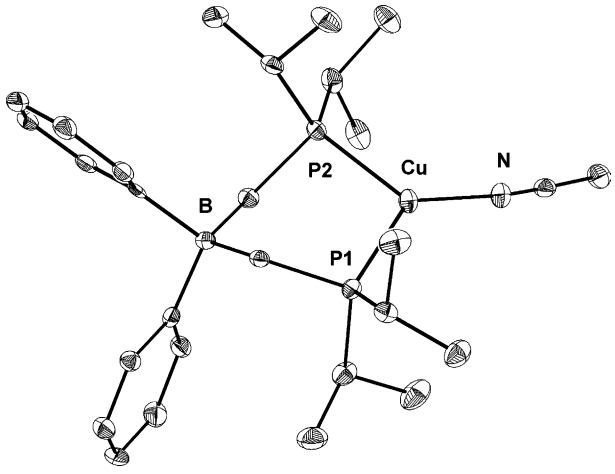


Fig. 4. Displacement ellipsoid representation (50%) of [$Ph_2B(CH_2P^iPr_2)_2$]Cu(NCCH$_3$) (**9**). Hydrogen atoms are omitted for clarity. Selected interatomic distances (Å) and angles (°): P1–Cu, 2.2349(6); P2–Cu, 2.2556(6); Cu–N, 1.934(2); B–Cu, 3.823(2) and P1–Cu–P2, 103.35(2); P1–Cu–N, 133.25(5); P2–Cu–N, 118.98(5).

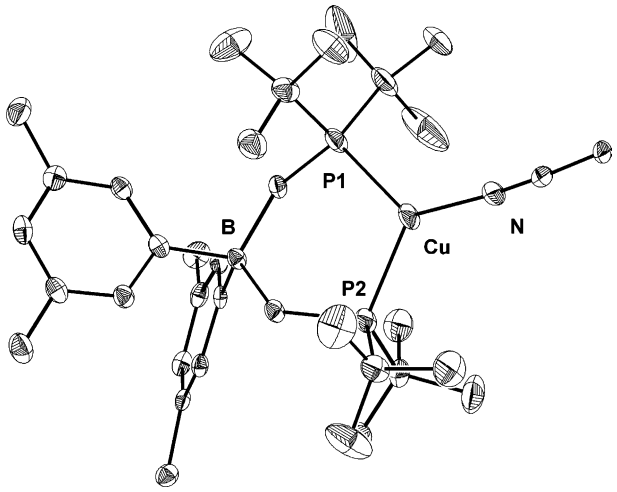

Fig. 5. Displacement ellipsoid representation (50%) of [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu($NCCH_3$) · 0.56THF · 0.22pentane (**10 · 0.56 THF · 0.22pentane**). Hydrogen atoms and solvent molecules are omitted for clarity. Selected interatomic distances (Å) and angles (°): P1–Cu, 2.2421(8); P2–Cu, 2.2333(8); Cu–N, 1.930(2); B–Cu, 3.861(3) and P1–Cu–P2, 108.55(3); P1–Cu–N, 124.94(7); P2–Cu–N, 126.49(7).

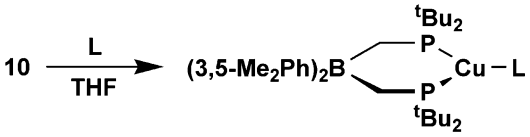
expansion of the P–M–P angle (103.35(2)°) that results from the three-coordinate structure and the sterically small acetonitrile ligand. The acetonitrile ligand of **9** adopts a distorted coordination mode. Rather than bisecting the P–Cu–P linkage, the nitrile is canted below the plane of these three atoms, favoring one side of the C_2 axis. This is likely a solid-state phenomenon: the solution spectra of **9** are consistent with a molecule that contains a C_2 axis.

An X-ray diffraction study carried out on **10** also shows a trigonal planar three-coordinate copper center (Fig. 5). The structural parameters of **10** are quite similar to those found for **9**, with two minor differences. First, the acetonitrile ligand is coincident with the C_2 axis of the molecule and thus colinear with the B–Cu vector. Second, the P–Cu–P angle is modestly wider (108.55(3)°) than that observed in **9** (103.35(2)°). The slightly wider bite angle of the bis(phosphine) does not result in a corresponding contraction of the B–Cu distance; instead, a slight increase in the B–Cu distance of **10** as compared to **9** (3.861(3) vs. 3.823(2) Å) is observed. The acetonitrile compounds **9** and **10** are structurally distinctive examples of monomeric, phosphine-supported nitrile adducts of 3-coordinate copper(I). A few related examples of phosphine-coordinated copper nitrile complexes have been structurally characterized previously [20]. These examples are each either four-coordinate, or contain multiple metal centers (e.g., Cu_2 or RhCu).

3.3. Substitution chemistry of the sterically encumbered complex *10*

The well-defined three-coordinate acetonitrile complexes **9** and **10** serve as useful precursors to other three coordinate donor adduct complexes. Accordingly, replacement of the labile acetonitrile complex **10** is affected by a variety of donor ligands (Eq. (6)). Reaction of **10** with dimethylphenylphosphine (PMe_2Ph), trimethylphosphine sulfide ($S{=}PMe_3$), 2,6-lutidine, and *tert*-butylisonitrile (^{t}BuNC) in THF solution provides the corresponding complexes [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]-Cu($PMe_2Ph$) (**11**), [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]-Cu($S{=}PMe_3$) (**12**), [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu(2,6-lutidine) (**13**), and [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu($CN^t$-Bu) (**14**). All of these products can be isolated in high yield (85–95%) and the reactions are complete in less than 15 min at ambient temperature. In addition to PMe_2Ph, several other phosphine donors were also examined. Triethylphosphine provided a well-defined three-coordinate adduct complex, whereas $PMePh_2$ provided a mixture of the expected three-coordinate adduct complex and also a second, unidentified diamagnetic product. PPh_3 does not substitute the acetonitrile ligand of **10**, presumably due to steric congestion. Addition of the phosphite ligand $P(OPh)_3$ gradually consumes **10**, but results in overall complex degradation to ill-defined products. Substitution reactions of **10** by simple olefins was also surveyed. No reaction was observed (^{1}H and $^{31}P\{^1H\}$ NMR) between **10** and the potentially η^2-donors ethylene, 1-hexene, styrene, and azobenzene (1–10 equiv) in THF solution. This lack of reactivity is consistent with previous literature studies that suggest that copper(I) complexes supported by phosphine ligands do not form stable olefin adducts readily. Those that have been observed have typically required the presence of a large excess of the olefin [21] or chelation effects [22] to provide a Cu-olefin adduct species.



(6)

L = PMe_2Ph, 11; $S{=}PMe_3$, 12; 2,6-lutidine, 13; CN^tBu, 14

The tris(phosphine) complex **11** was structurally characterized by X-ray diffraction, verifying its three-coordinate geometry (Fig. 6). The structural parameters of **11** reflect the incorporation of a more sterically demanding phosphine donor ligand relative to the acetonitrile ligand of **10**. For example, the P–Cu–P angle is reduced (103.87(3)° in **11** versus 108.55(3)° in **10**) and the B–Cu distance is increased (3.972(3) Åin **11** versus 3.861(3) Å in **10**). Also, the average P–Cu bond lengths for the bis(phosphino)borate ligand are modestly longer (2.27 Å in **11** versus 2.24 Å in **10**), likely reflecting the greater electron-releasing nature of PMe_2Ph as compared to acetonitrile.

Neutral **11** is similar to previous structurally characterized P_3Cu complexes (P = trialkyl phosphine). Several

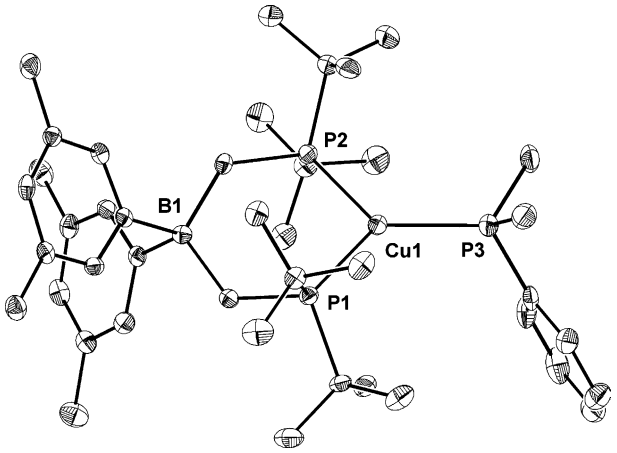


Fig. 6. Displacement ellipsoid representation (50%) of [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu($PMe_2Ph$) (**11**). Second molecule in the asymmetric unit and hydrogen atoms are omitted for clarity. Selected interatomic distances (Å) and angles (°): P1–Cu1, 2.2714(8); P2–Cu1, 2.2707(8); Cu1–P3, 2.2477(8); B1–Cu1, 3.972(3) and P1–Cu1–P2, 103.87(3); P1–Cu1–P3, 127.29(3); P2–Cu1–P3, 128.84(3).

structures reported for $[(Ph_3P)_3Cu]^+$ [23] and the related $[\{(p\text{-MeOPh})_3P\}_3Cu]^+$ cation [24] have shown a mean Cu–P length of 2.295 Å and P–Cu–P angles near 120°. Also, Mathey and coworkers reported a macrocyclic P_3-phosphinine ligand system in which a copper center lies in a distorted trigonal planar coordination geometry [25]. Additionally, there are two reports of bimetallic $[Cu_2(\eta^1{:}\eta^1\text{-}L_2)_3]^{2+}$ (L_2 = dmpm, $(Ph_2P)_2py$), where the copper centers are both in highly symmetric trigonal planar environments [26]. The structures of these homoleptic phosphine adducts are relatively C_3 symmetric, whereas the structure of **11** is better described as C_{2v} due to the geometric constraint imposed by the chelated bis(phosphine) ligand. A similarly distorted structure has been reported for dicationic $[\{(dppf)Cu\}_2(\eta^1{:}\eta^1\text{-}dppf)]^{2+}$ [27], which has Cu–P bond lengths of 2.280 Å, 2.283 Å, and 2.260 Å and P–Cu–P angles of 124.6°, 123.4°, and 111.3°.

A complex related to **11** is the phosphine sulfide adduct [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu(S=$PMe_3$) (**12**). A structurally related species has been reported: $[\{(dppf)Cu\}_2(\eta^1{:}\eta^1\text{-}dppfS_2)][BF_4]_2$ [28]. Complex **12** exhibits remarkably poor solubility (<5 mg/mL) in benzene and THF solution, distinct from **11**, **13**, and **14**.

Similar to **12**, the lutidine derivative [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu(2,6-lutidine) (**13**) contains an uncommon coordination environment for copper(I). The sterically hindered pyridines 2,6-lutidine and 2,4,6-collidine have been used previously to prepare two- and three-coordinate copper complexes [29–32]. In almost all of these cases, the complexes are homoleptic pyridine cations, or include a single halide or pseudo-halide donor [29–31]. One notable exception reported by Omary et al. [32] is the fluorinated bis(pyrazolyl)borate derivative, $[H_2B(3,5\text{-}(CF_3)_2Pz)_2]$Cu(2,4,6-collidine). Similar to **13**, the monoanionic borate-based $[H_2B(3,5\text{-}(CF_3)_2Pz)_2]^-$ provides a neutral, three-coordinate copper(I) center.

The isonitrile complex [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]-Cu($CN^tBu$) (**14**) is structurally distinct in that it represents what is to our knowledge the only example of a phosphine-supported, three-coordinate monoisonitrile complex of copper(I). Four-coordinate copper(I) complexes featuring terminal isocyanide ligands more typically feature either three phosphine ligands and one isonitrile ligand, or two phosphines and two isocyanide ligands [33–37]. A key spectroscopic feature of metal-bound isocyanides is their infrared signature. The infrared spectrum of **14** shows a ν_{CN} band at 2162 cm^{-1}. This value is presented in Table 2 along with several other previously reported copper(I) complexes containing a single *tert*-butyl isonitrile ligand [38–43]. As can be seen, most of the examples have ν_{CN} values greater than that observed for free CN^tBu. This increase in the C≡N stretching frequency has been attributed to both poor back-donation from the copper d-orbitals into the ligand π* orbitals, and to a strong σ-donor effect that polarizes the C≡N bond [44,45]. Thus, the isonitrile ligand in **14** can be considered as primarily a strong σ-donor in this context.

We also surveyed the generation of a monocarbonyl copper complex analogous to **14**. To our knowledge, there are as yet no examples of well-defined copper carbonyl complexes supported by phosphine ligands. This is consistent with the observations of related isonitrile complexes, where copper(I) has been characterized as a relatively poor π-donor. We have found that the reaction between **10** and excess CO gas results in the formation of an unstable carbonyl adduct species that can be formulated as [(3,5-$Me_2Ph)_2B(CH_2P^tBu_2)_2$]Cu(CO) (**15**). In THF solution, excess carbon monoxide appears to displace the acetonitrile ligand, resulting in a shift in the $^{31}P\{^1H\}$ NMR resonance from 36.4 to 42.3 ppm. If CO is removed under vacuum, the acetonitrile adduct is

Table 2
Infrared resonances (ν_{CN}) for some copper(I) monoisonitrile complexes

Complex	ν_{CN} (cm^{-1})	Ref.
[HB{3,5-$(CF_3)_2pz\}_3$]Cu(CN^tBu)	2196[a]	[38]
[$(Ph_3P)_3$Cu(CNEt)][BF_4]	2193[b]	[37]
CpCu(CN^tBu)	2170[a]	[39]

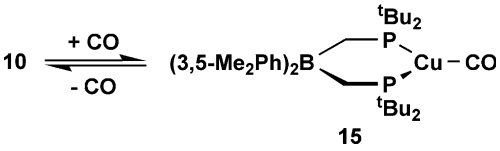
regenerated as indicated by the return of the 36.4 ppm resonance. Infrared analysis of green solids isolated by drying a sample of **10** under a stream of CO gas revealed a single infrared band at 2084 cm^{-1}, consistent with a metal-bound monocarbonyl species. The carbonyl species **15** is not stable in the absence of excess CO, apparently decaying to solvent-bound species with concomitant loss of CO. For instance, if a THF solution of **10** is dried under a stream of CO gas, the resulting pale green solids that are isolated display a $^{31}P\{^{1}H\}$ NMR resonance at 44 ppm upon dissolution in benzene-d_6. This resonance gradually disappears unless a blanket of CO is preserved above the NMR sample solution. A single new resonance grows in at 38 ppm, which may be indicative of a benzene solvent adduct of Cu(I). The lability of the putative monocarbonyl species is consistent with previous observations for phosphine-supported copper [20n].



(7)

In summation, we have prepared and characterized several neutral and anionic copper complexes supported by chelating, monoanionic bis(phosphino)borate ligands. In particular, the sterically encumbered *tert*-butyl substituted bidentate phosphine **3** is useful for stabilizing three-coordinate species with a host of donor ligands occupying the third coordination site. The substitution chemistry of the available to the acetonitrile complex **10** is key to the preparation of numerous donor adduct complexes in this series. These synthons should expand the reaction chemistry available to neutral and anionic phosphine-chelated copper(I) systems. In particular, the 3-coordinate systems described may serve as useful entry points to group transfer reactions that would generate $[BP_2]Cu^{III}$ = E species.

4. Supplementary material

Crystallographic data for the structural analyses have been deposited at the Cambridge Crystallographic Data Centre, CCDC numbers 238116 (**6**), 238119 (**8** · THF · pentane), 238120 (**9**), 238118 (**10** · **0.56 THF** · **0.22 pentane**), and 238117 (**11**). Open shell metallocenes and exchange splitting of ligand bands: a reassignment of the photoelectron spectra of manganocene ☆

Jennifer C. Green *, Claire Burney

Department of Chemistry, University of Oxford, Inorganic Chemistry Laboratory, South Parks Road, Oxford OX1 3QR, UK

Received 24 May 2004; accepted 6 July 2004
Available online 12 September 2004

Abstract

Unrestricted density functional calculations on the neutral molecular and ion states of $Mn(\eta\text{-}C_5H_5)_2$ indicate a reassignment of its photoelectron spectrum. The ordering of the occupied spin orbitals is inverted with respect to the normal metallocene orbital ordering with the metal orbitals lying below the ligand e_1 π orbitals. The spin orbitals can be related directly to the observed ion states with one minor reversal of ordering.

1. Introduction

Metallocenes were among the early candidates for the application of gas-phase photoelectron spectroscopy (PES) to transition metal compounds [1–4]. Their volatility made them experimentally accessible and their high symmetry theoretically tractable. These studies were fundamental to the development of methods for predicting the number and relative intensity of PE bands of open shell molecules based on fractional parentage coefficients [5]. Also the wealth of data on ion states further informed ligand field treatments of these systems [6].

The availability of experimental data was also a challenge to the development of quantum mechanical methods for predicting ionization energies and hence served as a validation of electronic structure descriptions of transition metal complexes [7].

Variable energy PES, first with He I and II radiation [8], and subsequently with synchrotron sources [9,10], gave valuable information on covalency in metallocenes and confirmed the majority of the assignments.

In spite of all these extensive studies, there remained some paradoxes in the assignment of $MnCp_2$ ($Cp = (\eta^5\text{-}C_5H_5)$). $MnCp_2$ is unusual among the first transition series metallocenes in showing a high spin state with $S = 5/2$. Magnetic measurements demonstrate that this is the ground state when magnetically dilute in $MgCp_2$ [11]. However, ESR has established that the more constrained sites of $FeCp_2$ and $RuCp_2$ promote a low spin state with $S = 1/2$ [12]. In the gas-phase $MnCp_2$ is predominantly high spin with a $^6A_1$ ground state [3,13]. PES has shown that a small amount of a $^2E_2$ low spin state is also present [3]. Assignment of the PE bands [3] (Fig. 1) of the high spin species gave ion states associated with the d ionizations at 7.01 ($^5E_1$a) 10.25 ($^5A_1$c) and 10.50 eV ($^5E_2$d). Application of ligand field theory to these energies leads directly to values of Δ_1 and Δ_2 of 3.24 and 0.25 eV for $[MnCp_2]^+$. The derived value of Δ_1 is very large [14,15]. This is the first puzzle.

The second unresolved question is the presence of an extra unassigned band, x, at 11.1 eV. This is far removed from the ligand band, b, associated with ionization of

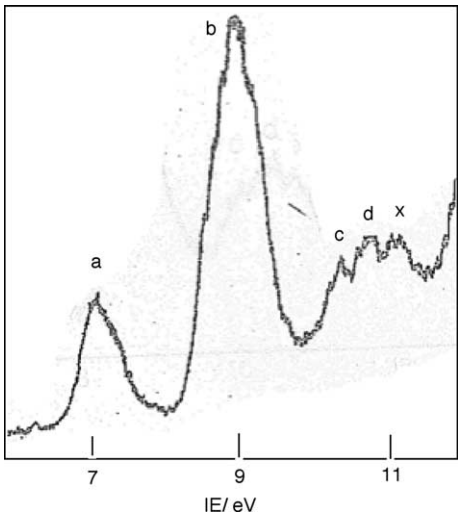

Fig. 1. Low IE region of the He I PE spectrum of $MnCp_2$.

the Cp e_1 π electrons, which is found centred on 8.85 eV, and is redundant to the assignment of the ionization of the d^5 configuration which predicts only three d bands. A very weak band associated with a very small amount of the compound in the low spin state is observed at 6.26 eV, but band x is too intense for this low spin species and is in the wrong IE region. Band x was originally assigned to an impurity [3] but it appears reproducibly in various measurements of $MnCp_2$.

In this paper, we describe unrestricted density functional calculations of the PE spectrum of $MnCp_2$ that account well for all features.

2. Computational methods

Calculations were performed using density functional methods of the Amsterdam Density Functional Package (version 2002.02) [16]. Type V basis sets were used with triple ξ accuracy sets of Slater type orbitals, with a single polarisation function added to the main group atoms. The cores of the atoms were frozen up to 2p for Mn and 1s for C. The generalised gradient approximation (GGA non-local) method was used, using Vosko, Wilk and Nusair's local exchange correlation [17] with non-local exchange corrections by Becke [18] and non-local correlation corrections by Perdew [19,20]. The structure was optimised in an unrestricted calculation. The molecule was assumed to have five unpaired electrons so the spin S was set at 5/2. The calculation therefore placed five more electrons in α spin orbitals than β spin orbitals. A single point restricted calculation was carried out using the optimised structure with S=O with the configuration fixed to the same occupancy as that determined by the unrestricted calculation, namely $1e''_1(4)1e'_1(4)1e'_2(2)1a'_1(1)2e''_1(2)$ (see Fig. 2). Ionisation energies were calculated by direct unrestricted calculations on the molecular ions in their ground and appropriate excited states, and subtraction of the energy of the neutral molecule.

3. Results and discussion

Recent calculations have demonstrated that modern computational methods give good structural and vibrational data for the first row metallocenes [21]. Both pure density functional and hybrid methods were compared for ferrocene and the B3LYP hybrid was selected to model the open shell metallocenes. In these studies we have employed the ADF program suite [16] because of its facility for fixing configurations when calculating energies of excited states. ADF does not support hybrid methods so the BP86 functional was used, which also gave a good account for ferrocene, though pure density functionals are approximate in handling the exchange correlation problem and may overestimate covalency.

The geometry of $MnCp_2$ was optimised with an unrestricted calculation assuming D_{5h} symmetry and a spin of 5/2. The resulting Mn–C and C–C distances of 2.42 and 1.44 Å are in reasonable agreement with the experimental values (2.380(6) and 1.429(2) Å) obtained by gas-phase electron diffraction [13,22].

The energies of the seven highest occupied spin orbitals are given in Table 1 together with their AO composition.

Using the optimised geometry from the unrestricted calculation, a spin restricted calculation was carried out with the same configuration as the unrestricted calculation, namely $1e''_1(4)1e'_1(4)1e'_2(2)1a'_1(1)2e''_1(2)$. These restricted orbitals have AO compositions typical of a metallocene (Table 1). The $1e'_1$ orbitals show a small amount of mixing with the Mn 4p orbitals. The $1a'_1$ and $1e'_2$ are more than 90% metal in character. The largest mixing is between the ligand and Mn e''_1 orbitals resulting in a predominantly ligand bonding orbital, $1e''_1$, and a predominantly metal anti-bonding orbital, $2e''_1$, the latter being the HOMO.

Their energies are represented diagramatically in Fig. 2 and are related to those obtained with the spin unrestricted calculation. In the latter, the metal based $1a'_1$ and $1e'_2$ α spin orbitals are lowered substantially in energy by over 2 eV and are more stable than the primarily ligand levels. The $1e'_1$ orbitals, which have no Mn 3d character, show a small exchange splitting of 0.2 eV and are unshifted in energy. In all these cases the orbital composition is very similar in the two calculations. The e''_1 orbitals show substantial reorganisation. The $2e''_1\alpha$ spin orbital is stabilised by 1.28 eV and becomes more ligand than metal based. The $1e''_1\alpha$ spin orbital is stabilised by 0.94 eV and becomes more metal than ligand based. The $1e'_1$ β spin orbital is slightly raised in energy and increases its ligand character. The consequence

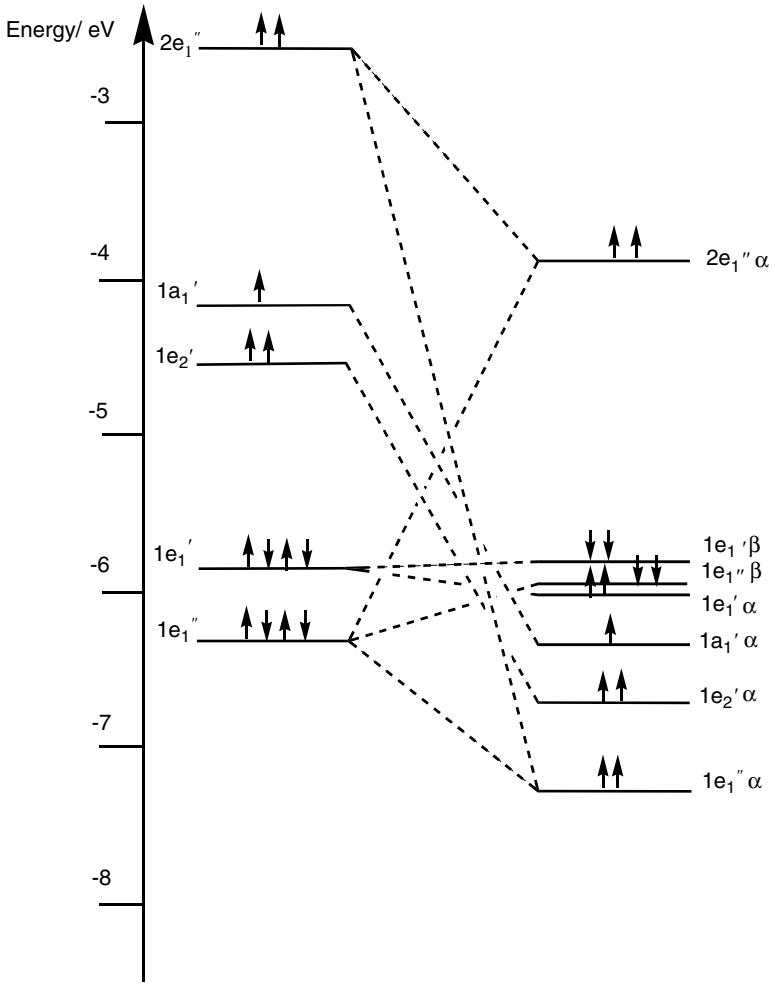

Fig. 2. Correlation of MO energy levels from restricted and unrestricted calculations on $MnCp_2$. On the left the energies of the orbitals from the restricted calculations are given and on the right the spin orbitals energies are shown.

is that all predominantly metal orbitals lie below the predominantly ligand orbitals. The exchange stabilisation in this high spin compound is sufficient to invert the normal metal ligand energy ordering [23].

The energies of the ion states associated with the seven spin orbitals were calculated by fixing the configuration with a hole in the associated vacant spin orbital. The resulting state energies are given in Table

1. Calculated ionization energies (IE) are compared with the experimental values in Table 1.

The ion state ordering is very similar to that of the spin orbitals, thus the spin unrestricted calculation gives a good guide to assignment of the PE bands. An exception is that the $^5E_1''$ ion state lies between the $^5A_1'$ and $^5E_2'$ ion states whereas the $1e_1''$ spin orbital is the most stable of the set. The $^5A_1'$ and $^5E_2'$ ion states have a greater energy separation from the E_1' ion states than do the corresponding spin orbitals from each other, indicating additional relaxation of the metal d orbitals in the ion. This is consistent with the reordering suggested by the calculation.

Inspection of the orbital composition of the hole states in the ion state calculations show that the description of the spin orbitals corresponds closely to that of the holes. Thus in this respect too the unrestricted ground state calculation gives a good description of the ionisation process.

Direct mapping of the calculated IE onto the experimental bands reassigns the bands. The principal difference from the original assignment is that the higher $^5E_1''$ ionization is now assigned to band d rather than the ligand band b. Also the $^5E_2'$ state is assigned to band x rather than band d. Thus the origin of the additional band is accounted for.

Both cobaltocene and nickelocene show low intensity bands at higher energies than the main ligand band. As they also have unpaired electrons in $2e_1''$ orbitals it is likely that they have a similar origin to band d of manganocene.

Orbitals with higher d character are expected to show higher He II/He I intensity ratios when the photon energy dependence of the PE spectrum is determined. For $MnCp_2$ the highest He II/He I ratio was found for band a, which we are now assigning as having less than 50% 3d character [8]. In general, PE studies of the He II/He I band intensity ratios of the metallocenes established the ordering for the originating orbitals of $2e_1'' > 1a_1' > 1e_2' > 1e_1'' > 1e_1'$. It was pointed out that these results were in accord with expectations from MO calculations except for the $2e_1''$ ionization band, as this was the anti-bonding partner of the orbital where the greatest metal d – carbon 2p mixing occurs. In this sense the large increase in the intensities of the $2e_1''$ band in the He II spectra of $MnCp_2$, $CoCp_2$ and $NiCp_2$ was deemed anomalous [8]. Further light was thrown on this anomaly by synchrotron studies of the metallocenes. Though $MnCp_2$ was not included in this study, the $2e_1''$ band was studied for both $CoCp_2$ and $NiCp_2$ [10]. Two particular features in the cross section were noted. One was the 3p–3d resonance, generally indicative of a d orbital contribution to the ionizing orbital; the intensity of this feature was less than that found in the a_1' and e_2' based bands in accord with expectations from MO calculations. The second was the presence of a shape resonance around 40 eV. (He II photons have an energy of 40.8 eV.) This was present in all 3d based ionizations and is a general feature of sandwich compounds [24], but was particularly strong in the $2e_1''$ band. Subsequent calculations of the cross sections of $CoCp_2$ reproduced this very strong shape feature and assigned it to excitation to an $f(xz^2)$ wave localised within the molecular potential at this energy [25]. Thus the intensity of the feature is not directly related to d character and the HeII/HeI ratios are non-indicative of metal character.

The inverted ordering found for this high spin molecule means that naïve application of the ligand field model is inappropriate for this system.

4. Conclusions

Unrestricted density functional calculations of $MnCp_2$ lead to a reassignment of its PE spectrum that accounts for all observed features. Agreement between experimental and calculated IE is good, the calculations underestimate the ionization energies by around 0.5 eV. The spin orbitals of an unrestricted calculation of the neutral molecule map directly onto the calculated ion states with one exception. In this calculation the exchange stabilization of the α spin orbitals leads to all predominantly metal orbitals being more stable than the cyclopentadienyl e_1 δ orbitals, an inversion from the normal metallocene ordering.

Five-coordinate iron(II) complexes bearing tridentate nitrogen donor ligands as catalysts for atom transfer radical polymerisation

Rachel K. O'Reilly, Vernon C. Gibson *, Andrew J.P. White, David J. Williams

Dedicated to Malcolm Green for his inspiring contributions to chemistry

Abstract

A series of five-coordinate complexes of iron(II) containing tridentate nitrogen donor ligands has been synthesised and evaluated for the atom transfer radical polymerisation of styrene. The molecular structures of two derivatives are described. Cyclic voltammetric studies show that the redox potential for the Fe(II)/Fe(III) couple strongly depends on the donor capacity of the complexing ligand, and styrene polymerisations reveal that ligands derived from alkyl amine or pyridine groups are the most active for ATRP, although slower than for their four-coordinate relatives due to unfavourable steric interactions. In general, catalyst activity decreases in the order of donor group: alkyl amine ≈ pyridine > alkyl imine ≫ aryl imine > aryl amine, with the aryl derivatives being almost completely inactive in ATRP. The trend in polymerisation activity correlates with the redox potential of the corresponding complexes. Complexes derived from aryl-imine or -amine ligands afford catalytic chain transfer rather than ATRP catalysis.

1. Introduction

Atom transfer radical polymerisation (ATRP) allows the preparation of a wide range of well-defined polymeric materials with controlled molecular weights and complex architectures [1]. Following key reports by Matyjaszewski and Sawamoto in the mid-1990s, of highly efficient ATRP catalysts based on copper(I) and ruthenium(II) respectively, a number of different metal–ligand combinations have been investigated, including systems based on Rh, Pd, Ni and Fe [2–12]. There remains, however, a need to understand the factors important for efficient ATRP catalysis.

Since the process of ATRP is dependent upon the reversible binding of a halogen atom (Scheme 1), it is important that the metal complex has a relatively open coordination sphere, especially in its reduced form, and that neither the reduced nor the oxidised metal species are prone to decomposition. This may, for example, rule out three-coordinate complexes for many metals unless ligands are chosen that would stabilise the low coordination number. However, such ligands tend to be very bulky and not necessarily pre-disposed towards allowing the metal to accept another ligand.

Recently, we described a new family of four coordinate iron-based catalysts stabilised by α-diimine ligands [13,14]. These four-coordinate iron(II) complexes showed evidence for accessible and reversible redox couples to the corresponding iron(III) species depending on the nature of the imine substituents. The high catalytic

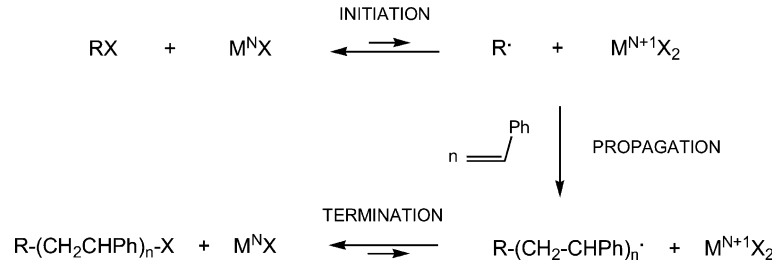

Scheme 1. Generalised mechanism for atom transfer radical polymerisation of styrene.

efficiency of these catalysts may be related to the fact that the reduced Fe(II) species possess a relatively uncluttered tetrahedral geometry and are, therefore, able to accept an additional halogen atom without any severe steric conflict arising between the co-ligands. In the five-coordinate oxidised form, the flexibility in the coordination geometry (via pseudo rotation) may assist the complex in achieving a coordination environment suited to the dissociation of a halogen atom (certain six-coordinate environments, e.g. d^3 and d^6 octahedral systems, have reduced kinetic lability). Thus, the 4–5 coordination manifold might be anticipated to possess important attributes for the efficient functioning of ATRP catalysts.

In order to further probe the effect of coordination geometry on the efficiency of ATRP catalysis, we decided to target a series of five-coordinate Fe(II) chloride complexes bearing tridentate nitrogen ligands and evaluate their performance in ATRP catalysis. These complexes possess an additional nitrogen donor relative to the (α-diimine)$FeCl_2$ catalysts reported recently, and would therefore be expected to afford lower oxidation potentials and render them more electronically suited to ATRP catalysis. However, these catalysts necessarily have to operate by interconverting between five- and six-coordinate species which may lead to increased steric conflict in the oxidised form of the catalyst.

Earlier work by Göbelt and Matyjaszewski examined tridentate bis(imino)pyridine and bis(amino)pyridine ligands bearing *N*-octyl substituents, in conjunction with copper(I) bromide and iron(II) bromide [15]. They found that the bis(imino)pyridine ligand formed an active catalyst in both systems, whereas, the bis(amino)pyridine ligand formed an active catalyst only in conjunction with copper(I) bromide. The use of bromide as the transferable group is recognised to hold advantages in terms of C–halogen bond strengths, though the thermodynamic advantage may be off-set by the increased steric demands of bromine atoms coordinated to the metal centre. In this study we focus on a series of metal–chloride derivatives containing tridentate ligands with a view to obtaining an improved understanding of the factors influencing efficient ATRP catalysis in iron-based systems.

2. Results and discussion

2.1. Synthesis and characterisation

The series of tridentate [NNN] ligands, **I**–**VI**, containing a central pyridine or amine unit and two peripheral imine or amine donors with either *N*-alkyl or *N*-aryl substituents was synthesised (Fig. 1). Ligand **I** (PMDETA) is commercially available, while **II**, **III**, **V** and **VI** were synthesised using literature procedures[16–21]. Ligand **IV** was synthesized by a modification of a literature preparation using $Si(OEt)_4$ and recovered as a yellow solid in 62% yield [22]. Ligands **I**–**VI** were reacted with iron(II) dichloride to afford the corresponding monochelate complexes (**1**–**6**) in good yields.

Complexation of **I** to iron(II) dichloride was first reported in 1966, by Ciampolini and Speroni [23]. At that time, **1** was the first reported high spin five-coordinate iron(II) complex. In 1999, Calderazzo and co-workers [24] structurally characterized **1** and reported a distorted square pyramidal structure with a chlorine atom occupying the apical position. Ligand **II** has previously been

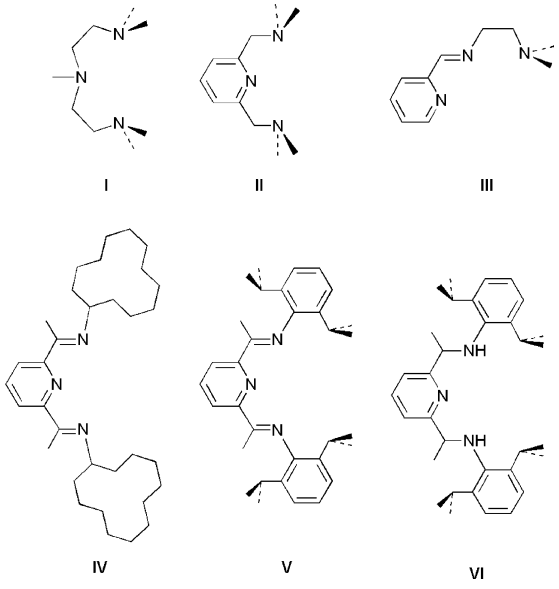

Fig. 1. Ligands **I**–**VI**.

complexed to mid and late transition metals such as ruthenium and zinc by the groups of van Koten and Reinhoudt [18,25]. It was synthesised by reaction of 2,6-bis(bromomethyl)pyridine with dimethylamine and complexed to iron(II) to afford **2**, as a yellow microcrystalline solid. Single crystals of **2** were grown by slowly cooling a saturated solution of **2** in hot tetrahydrofuran. X-ray single crystal analysis revealed the structure (which has molecular C_S symmetry about a plane containing the iron, the two chlorides and the pyridine nitrogen atom) to have a distorted square pyramidal geometry around the iron centre (Fig. 2). The four basal atoms {Cl(1),N(1),N(7),N(8)} are coplanar to within 0.06 Å with the iron lying ca. 0.68 Å out of this plane in the direction of the apical atom Cl(2); the *trans*-basal angles are 136.1(2) and 147.0(2)°, and the apical–basal angles range between 106.2(2) and 111.4(2)°. The Fe–Cl bond lengths are noticeably asymmetric, with that to the apical chloride being significantly shorter [2.291(2) Å] than to its basal counterpart [2.341(2) Å]; the Fe–N distances are unexceptional [21,24,26]. The two five-membered chelate rings both have envelope geometries with in each case the amino nitrogen lying out of the plane of the other four atoms [by ca. 0.57 Å for N(7) and ca. 0.68 Å for N(8)] which are coplanar to within 0.02 Å. The only intermolecular packing interaction of note is a π–π stacking between adjacent pyridyl rings with centroid···centroid and mean interplanar separations of 3.72 and 3.55 Å, respectively. Subsequent to this determination, Grubbs and co-workers [27] reported the room temperature (298 K) structure of the same polymorph of **2** in a private communication; taking into account the 115 K difference in temperature, the unit cells are the same.

Ligand **III** has recently been complexed to late transition metals such as copper and palladium [28,29]. Complex **3** was synthesised by reaction of **III** with iron(II) dichloride in diethyl ether and was isolated as a dark red, microcrystalline solid. This complex was first reported in 1969 and, based on magnetic and spectroscopic techniques, a five-coordinate geometry around the iron centre was proposed [30]. We confirmed this assignment by determining the solid state X-ray structure of crystals of **3** obtained by slow diffusion of an equal volume of heptane into a saturated solution of **3** in dichloromethane. This study revealed **3** to have a structure (Fig. 3) closely related to that of its zinc dibromide analogue [31]. The geometry at iron can be considered as intermediate between square pyramidal, with Cl(2) occupying the apical position, and trigonal bipyramidal with N(1) and N(10) defining the major axis, though being somewhat closer to the latter description. Considered as square pyramidal, the metal centre lies ca. 0.58 Å [0.64 Å] out of the basal plane which is only coplanar to within 0.18 Å [0.30 Å]. Viewed as trigonal bipyramidal, the axial atoms subtend an angle of 147.21(14)° [150.2(2)°] at the metal, and the angles within the equatorial plane range between 108.30(11) and 141.54(11)° [111.8(2) and 133.9(2)°]; the iron lies ca. 0.06 Å [0.04 Å] out of the equatorial plane in the direction of N(10). (The values in square parentheses refer to the zinc dibromide analogue [31].) The five-membered N(1)/N(7) chelate ring is almost planar with the metal lying ca. 0.09 Å [<0.01 Å] out of the plane of the other four atoms which are coplanar to better than 0.01 Å. By contrast, the N(7)/N(10) five-membered chelate ring has a twisted envelope conformation with N(10) displaced by ca. 0.72 Å [0.76 Å] out of the plane of the other atoms, which are coplanar to within 0.08 Å [0.12 Å]. The pattern of bonding around the metal centre is generally the same between the $FeCl_2$ species **3** and its previously reported $ZnBr_2$ analogue, though it is noticeable that, whereas in the $ZnBr_2$ complex the M–N(pyridyl) and M–N(amino) distances are the same [2.245(8) and

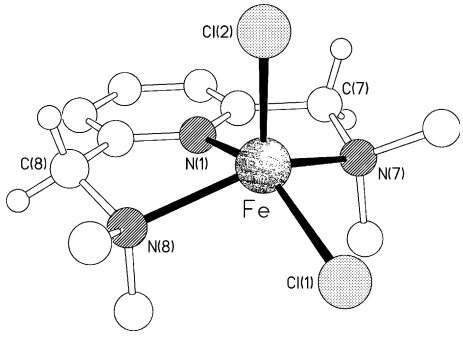

Fig. 2. The molecular structure of **2**. Fig. 3. The molecular structure of **3**. Selected bond lengths (Å) and angles (°); Fe–Cl(1) 2.3034(12), Fe–Cl(2) 2.3361(13), Fe–N(1) 2.185(4), Fe–N(7) 2.129(3), Fe–N(10) 2.236(4), C(7)–N(7) 1.258(6), N(7)–Fe–N(1) 74.04(14), N(7)–Fe–N(10) 75.98(14), N(1)–Fe–N(10) 147.21(14), N(7)–Fe–Cl(1) 141.54(11), N(1)–Fe–Cl(1) 93.79(10), N(10)–Fe–Cl(1) 101.55(10), N(7)–Fe–Cl(2) 108.30(11), N(1)–Fe–Cl(2) 102.39(10), N(10)–Fe–Cl(2) 99.34(11), Cl(1)–Fe–Cl(2) 109.94(5).

2.236(7) Å, respectively], in **3** the M–N(pyridyl) bond length is noticeably shorter [2.185(4) Å] than that to the amino nitrogen [2.236(4) Å]. The Fe–N bond lengths differ noticeably from those in, for example, (2-((2,6-di-*iso*propylphenyl)iminomethyl)-6-(1-(2,6-di-*iso*propylphenylamino)ethyl)pyridine-*N*,*N*′,*N*″)dichloroiron(II) and other related complexes with the bond to the pyridine nitrogen being longer and that to the imino nitrogen shorter [25]. The Fe–Cl bond lengths in **3** are noticeably asymmetric, with that to the pseudo-apical chloride Cl(2) being significantly longer [2.3661(13) Å] than to its pseudo-basal counterpart Cl(1) [2.3034(12) Å]. The only intermolecular packing feature of note is a π–π stacking of the pyridine rings of centrosymmetrically related pairs of molecules; the centroid···centroid and mean interplanar separations are 3.54 and 3.38 Å, respectively. An analogous contact is seen in the zinc dibromide species with centroid–centroid and mean interplanar separations of 3.56 and 3.36 Å, respectively.

Complex **4** was synthesized by a similar route to that reported in the literature for the *N*-aryl derivative, **5** [32]. After washing with diethyl ether and extraction into tetrahydrofuran, **4** was isolated as a dark grey microcrystalline solid. The *N*-aryl pyridine(bis)imino and pyridine(bis)amino complexes, **5** and **6**, have both been reported recently by this group and were synthesized as described in the literature reports [32,33]. Both of these complexes have previously been structurally characterized and found to possess a five-coordinate distorted square pyramidal geometry.

Complexes **1**–**6** are all air-stable paramagnetic solids, with magnetic moments (determined by the Evans' NMR method) in the range 4.9–5.3 μ_B [34–36]. The magnetic moments are consistent with the presence of four unpaired electrons and a quintet ground state ($S = 2$) for the iron(II) centres [37].

2.2. Cyclic voltammetry

Matyjaszewski and co-workers [38] have investigated the structure–activity relationship for a series of tridentate nitrogen donor ligands in copper-based ATRP. The redox properties of these complexes were measured using CV techniques and their electrochemistry was correlated to their activity as ATRP catalysts for styrene and MMA polymerisation [39]. By comparison with Matyjaszewski's findings in copper-based ATRP, it would be predicted that the series of complexes should exhibit the following order of reducing power: **1** < **2** < **3** < **4** ≪ **5** < **6**. Experimentally determined electrochemical parameters for **1**–**6** are collected in Table 1 and confirm this trend. Table 1 also shows the oxidation potentials, E_{ox}, for this series of complexes. Since this parameter can be correlated with the ease of oxidation of the complex, E_{ox} should provide an indication of activities in ATRP catalysis.

Table 1
Cyclic voltammetry results for **1**–**6**

	E_{ox} (mV)	$E_{1/2}$ (mV)	ΔE_p (mV)
1	−370	−280	170
2	−240	−150	170
3	−190	−100	180
4	−150	−70	170
5	180	330	310
6	260	410	320

Complexes **1**–**4** all have low oxidation potentials (−370 to −150 mV) and redox potentials (−280 to −70 mV) indicating that they are easy to oxidise, unlike **5** and **6** whose high oxidation potentials indicate the opposite. Thus, it would be predicted that **1**–**4** should be active ATRP catalysts since they are easily oxidised and possess an accessible and reversible one-electron redox couple. In fact, **1**–**4** have lower redox potentials than the previously reported *N*-alkyl diimine complexes ($E_{1/2}$ ca.−100 mV) and thus would be predicted to be faster ATRP catalysts [13]. However, **5** and **6**, which are supported by ligands possessing *N*-aryl groups have irreversible ($\Delta E_p > 300$ mV) and less accessible ($E_{1/2} > 300$ mV) redox couples and thus would be predicted to have low activity in ATRP.

2.3. Polymerisation results

Complexes **1**–**6** were screened for the ATRP of styrene (200 equiv.) at 120 °C using 1-phenylethyl chloride (1-PECl) as an initiator and the results are presented in Table 2. **1**–**4** polymerised styrene in a controlled manner, with linear kinetics and with molecular weights increasing with monomer conversion [40]. Analysis of the polymer produced using **1**–**4** revealed the presence of a halogen end group by ^{1}H NMR spectroscopy and also by microanalysis [for **2**, M_n = 5100% Cl, found (calc.): 0.64 (0.70)]. The more reducing the complex, the lower the redox potential, and the faster the ATRP catalyst cf. **1** versus **3** (Fig. 4).

However, these complexes are slower ATRP catalysts than their α-diimine counterparts (e.g. for 1,2-bis(cyclo-

Table 2
Results of styrene polymerisations using **1**–**6**

	k_{obs} (h^{-1})	% Conv. in 24 h	$M_{n,calc}$[a]	M_n	M_w/M_n
1	0.04	65	13700	15100	1.62
2	0.03	52	10900	11800	1.53
3	0.02	39	8200	8500	1.59
4	0.02	37	7800	8700	1.56
5		72	15100	2900	2.07
6		45	9500	2100	1.92

Conditions: 120 °C, bulk, $[1\text{-PECl}]_0$:$[\text{catalyst}]_0$:$[\text{styrene}]_0$ = 1:1:200. Control polymerisation of styrene at 120 °C with no catalyst > 90% conversion in 24 h, M_n ca. 200000.

[a] $M_{n,calc}$ is calculated M_n based on degree of conversion.

hexylimino)ethane iron(II) dichloride, $k_{obs} = 0.25\ h^{-1}$, cf. $k_{obs} = 0.04\ h^{-1}$ for **1**), despite their significantly lower redox potentials (for 1,2-bis(cyclohexylimino)ethane iron(II) dichloride, $E_{1/2} = -120$ mV cf. $E_{1/2} = -280$ mV for **1**) [13]. This can be attributed to the less favourable steric environment around the metal in these five-coordinate complexes as compared with the four-coordinate tetrahedral α-diimine complexes. Thus, the rate of Cl atom transfer from RCl to **1**, for example, is slowed due to steric crowding, despite **1** having more favourably disposed redox chemistry. This may also explain the loss of control and broadening of the polydispersity of the polymers produced using these five-coordinate systems compared to their α-diimine relatives.

For **5** and **6**, which both possess *N*-aryl substituents, the polymerisation did not proceed in a controlled manner and low molecular weight polymers were produced throughout, the molecular weight of which were independent of the degree of conversion (Fig. 5). The polymer produced had unsaturated end groups by ^{1}H NMR spectroscopy and zero halide content by microanalysis. Thus, complexes **5** and **6** do not polymerize styrene by an ATRP mechanism, but rather chain propagation is accompanied by catalytic chain transfer (CCT). Here, the polystyrenyl radical reacts with the Fe(II) catalyst to generate an organometallic Fe(III) species which undergoes β-hydrogen elimination to release the polymer chain bearing an unsaturated end-group. This is presumed to occur in an analogous manner to that proposed for the α-diimine catalyst system shown in Scheme 2 [14]. The capacity of the aryl derivatives to support CCT, we believe, is a result of a lower spin ($S = 3/2$) ground state for the oxidised Fe(III) species containing aryl substituents (the alkyl derivatives are all high spin) affording stronger Fe–C bonds and consequently more stable organometallic intermediates.

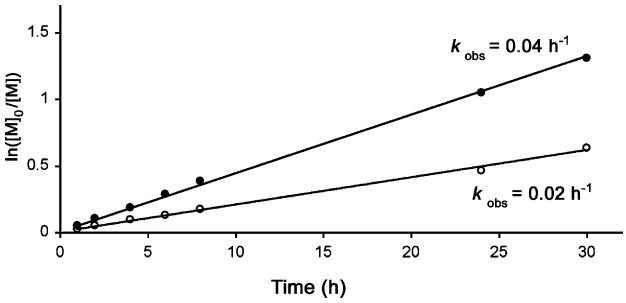

Fig. 4. Plot of $\ln([M]_0/[M])$ vs. time for complexes **1** (•) and **3** (○).

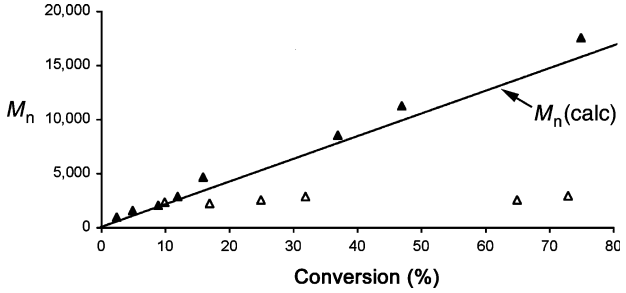

Fig. 5. Plot of M_n vs. conversion for **4** (▲) and **5** (Δ).

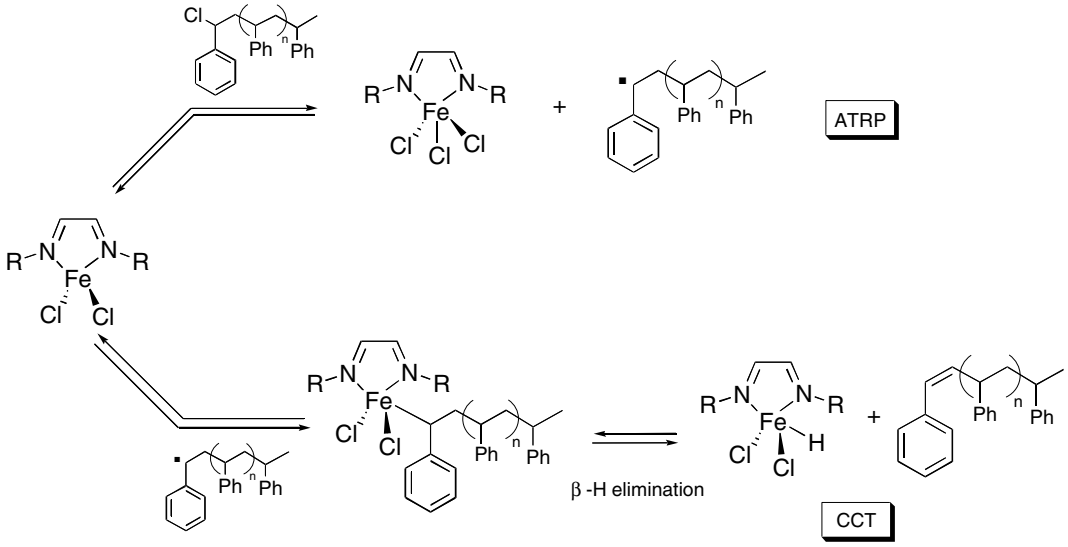
3. Conclusions

Iron(II) dichloride complexes containing neutral tridentate [NNN] ligands are found to be active ATRP catalysts, and their activities correlate well with their oxidation potentials. Although their electrochemical properties suggest that they should be more efficient catalysts than four-coordinate α-diimine iron systems, they are in fact much slower. This is explained by the increased steric hindrance at the metal for the oxidised six-coordinate species, which prevents fast and facile atom transfer from occurring. Thus the hypothesis made



Scheme 2. ATRP vs. CCT pathways for α-diimine iron catalysts.

at the outset of this study, that a four/five-coordinate equilibrium should be more favourable than a five/six-coordinate equilibrium for efficient ATRP catalysis in iron complexes appears to hold.

4. Experimental

4.1. General

All manipulations of water and/or moisture sensitive compounds were performed by means of standard high vacuum Schlenk and cannula techniques. Air sensitive compounds were transferred to a nitrogen filled glovebox and, unless stated otherwise, stored at room temperature. Crystal data were collected on Siemens P4/PC or P4/RA diffractometers. NMR spectra were recorded on a Bruker AC-250 MHz, DRX-400 MHz or AM-500 MHz spectrometers. Infra-red spectra were obtained with thin sample films on NaCl plates or as KBr discs on a Perkin–Elmer 1710X FT-IR spectrometer. Mass spectra were recorded on either a VG Autospec or a VG Platform II spectrometer. Elemental analyses were performed by the microanalytical services of the Chemistry departments of London Metropolitan University and University College London. Magnetic susceptibilities were determined by the Evans NMR method. Gel permeation chromatography (GPC) was performed using Viscotek Trisec software connected to a Knauer differential refractometer. Samples were injected onto two linear 10 μm columns using chloroform as elutant (conventionally calibrated prior to use, using polystyrene standards (PSS Mainz)) at a flow rate of 1.0 $cm^3 min^{-1}$ at room temperature. Cyclic voltammetry (CV) was performed using a MacLab potentiostat operated by EChem 1.3.2. software. The working electrode and reference electrode were purchased from Bioanalytical (ref: MF-2013 and RE-5B).

All solvents were dried by prolonged reflux over a suitable drying agent under an atmosphere of nitrogen, being freshly distilled prior to use. All solvents were degassed prior to use unless otherwise stated. Styrene (St) was purified by vacuum distillation and then stored under an inert atmosphere over 4 Å molecular sieves at −15 °C. 1-PECl was synthesized according to literature methods and purified by column chromatography [41]. All amines and anilines were freshly distilled before use. All other reagents are commercially available and were used without further purification. Compounds **1**[23] **5**[21] and **6**[33] were prepared by literature procedures.

All polymerisations were set up and performed under an atmosphere of oxygen-free, dry dinitrogen using standard Schlenk-line techniques. In an ampoule equipped with a magnetic stirrer bar, were placed in order, monomer, initiator and catalyst in various ratios and the ampoule was then sealed. In all cases the catalyst was soluble in the monomer solution. The ampoules were heated in an oil bath, at 120 °C. After stirring for the allotted period of time, an aliquot (0.1 ml) was removed and quenched with THF (1 ml). Conversion was determined by integration of the monomer versus polymer backbone resonances in the ^1H NMR spectrum of the crude product in $CDCl_3$. After the reaction time, usually 24 h, the contents of the ampoules were dissolved in THF. This solution was added dropwise to an approximately 20-fold excess of rapidly stirred acidified methanol (1% HCl v/v). The precipitate that formed was filtered off and washed with methanol. The precipitate was dried for 24 h in a vacuum oven at 60 °C. Samples were then analysed by GPC.

CV was performed using a sample vial (50 × 24 mm) as a cell. The counter electrode was a section of 0.5 mm platinum wire, the working electrode was a platinum disk electrode and the reference electrode was a Ag/AgCl electrode. Electrolyte ($[^nBu_4N][PF_6]$ (1.00 mmol)) and the complex under study (0.01 mmol) was loaded into the cells before being degassed by evacuation and admission of dinitrogen, acetonitrile (10 cm^3) was then added.

4.2. Preparation of 2,6-bis-[(dimethylamino)methyl]-pyridine) (*II*)

Dimethylamine (6.0 g, 0.133 mol) was quickly added to 30 ml of precooled (ca. 5 °C) C_6H_6 after which a solution of 2,6-bis(bromomethyl)pyridine (3.51 g, 0.013 mol) in 80 ml of C_6H_6 was added dropwise over 30 minutes [12,13]. After stirring at room temperature for 30 min, the reaction mixture was filtered under suction and the residue was washed with Et_2O. The C_6H_6 and Et_2O fractions were combined and reduced in vacuo to yield a pale yellow oil. This oil was vacuum distilled at 60 °C and 8 mm/Hg to afford a colourless oil (2.45 g, 95%). *Anal.* Calc. for $C_{11}H_{19}N_3$: C, 68.4; H, 9.9; N, 21.7. Found: C, 67.7; H, 9.5; N, 21.7%. δ_H ($CDCl_3$) 7.50 (1H, t, *J*(HH) 8 Hz, 1Ar–*H*), 7.15 (2H, d, *J*(HH) 8 Hz, 2Ar–*H*), 3.46 (4H, m, 2CH_2), 2.15 (12H, s, 4CH_3); δ_C (CD_3COCD_3) 159.6 (s, 2Ar–*C*), 137.3 (s, 1Ar–*C*), 121.5 (s, 2Ar–*C*), 66.5 (s, 2*C*H_2), 45.9 (s, 4*C*H_3); MS (CI^+) (*m*/*z*) 194 $[M+H]^+$.

4.3. Preparation of 2,6-bis-(cyclododecylimino)pyridine (*IV*)

A solution of 2,6-diacetylpyridine (5.0 g, 0.03 mol) and cyclododecylamine (13.8 g, 0.075 mol) in $Si(OEt)_4$ (14.05 g, 0.067 mol) with a few drops of concentrated H_2SO_4 was placed in a round bottom flask and attached to a side arm and air condenser which was stoppered with a round bottom flask [18]. The solution was heated overnight with stirring at 130 °C, after which time etha-

nol (ca. 3 ml) had been distilled over from the reaction mixture. The solid reaction mixture was dissolved in CH_2Cl_2, washed with saturated solutions of $NaHCO_3$ (2×10 ml) and brine (2×10 ml) and then dried over $MgSO_4$. The solvent was removed in vacuo to afford a yellow solid. Washing this solid with cold petroleum ether (20 ml) afforded ligand **IV** as a bright yellow solid (9.17 g, 62%). *Anal.* Calc. for $C_{35}H_{55}N_3$: C, 80.3; H, 11.2; N, 8.5. Found: C, 79.6; H, 11.1; N, 8.7%. 4.4. Preparation of 2,6-bis-[(dimethylamino)methyl]-pyridine) iron(II) chloride (2)

To a solution of $FeCl_2(THF)_{1.5}$ (0.58 g, 0.0025 mol) in toluene (20 ml) was added dropwise, with stirring, ligand **II** (0.48 g, 0.0025 mol) also in toluene (20 ml) and the resulting suspension stirred overnight at room temperature. The mixture was then cooled to 0 °C and filtered; the filtrate was reduced to ca. 10 ml and stored overnight at −10 °C, after which time crystals of **2** had formed. These yellow crystals were isolated by filtration and dried overnight in vacuo. This afforded **2** as a microcrystalline bright yellow solid (0.67 g, 84%). Slow cooling of a solution of **2** in hot THF afforded crystals suitable for X-ray analysis. *Anal.* Calc. for $C_{11}H_{19}N_3Cl_2Fe$: C, 41.2; H, 6.0; N, 13.1. Found: C, 41.2; H, 6.0; N, 13.0%. IR/cm^{-1} 3584m, 3397s, 2349w, 2282w, 1653m, 1559w, 1541w, 1507w, 1457w, 1073w, 666w; MS (CI^+) (*m*/*z*) 319 $[M]^+$; μ_{eff} = 5.05 μ_B.

4.5. Preparation of N,N-dimethyl-N′-pyridin-2-ylmethylene-ethane-1,2-diamino iron(II) chloride (3)

To a suspension of $FeCl_2$ (1.27 g, 0.01 mol) in Et_2O (20 ml) was added dropwise, with stirring *N*,*N*-dimethyl-*N*′-pyridin-2-ylmethylene-ethane-1,2-diamine, **III** (1.77 g, 0.01 mol) in Et_2O (10 ml) [24]. The reaction mixture was stirred overnight at room temperature and then filtered and the filtrate reduced under reduced pressure. The solid residue was extracted into CH_2Cl_2 and then the solvent was removed. The resultant solid was dried in vacuo and this afforded **3** as a purple microcrystalline solid (2.01 g, 66%). Slow diffusion of a solution of **3** in $CH_2Cl_2$with an equal volume of heptane afforded crystals suitable for X-ray analysis. *Anal.* Calc. for $C_{10}H_{15}N_3Cl_2Fe$: C, 39.5; H, 5.0; N, 13.8. Found: C, 39.1; H, 5.0; N, 13.2%. IR/cm^{-1} 3447m, 2966m, 2838w, 1615w, 1568m, 1507w, 1457w, 1279w, 1174w, 1117w, 1026w, 923w, 750w; MS (CI^+) (*m*/*z*) 318 $[M+NH_4]^+$; μ_{eff} = 4.96 μ_B.

4.6. Preparation of 2,6-bis-(cyclododecylimino)pyridine iron(II) chloride (4)

To a suspension of $FeCl_2$ (0.92 g, 0.007 mol) in ^{n}BuOH (20 ml) was added dropwise, with stirring, **IV** (4 g, 0.008 mol) also in ^{n}BuOH (10 ml) and the reaction mixture stirred overnight at 90 °C. After this time it was allowed to cool and the solvent was then removed in vacuo at 60 °C for 4 h. The residue was washed with Et_2O (3×10 ml) and then extracted into THF (20 ml). The solution was reduced to ca. 10 ml and stored at −10 °C overnight. After this time, dark grey crystals of **4** had formed which were isolated by filtration and dried (3.30 g, 73%). *Anal.* Calc. for $C_{33}H_{55}N_3Cl_2Fe$: C, 63.9; H, 8.9; N, 6.8; Cl, 11.4. Found: C, 63.7; H, 8.7; N, 6.8; Cl, 10.3%. IR/cm^{-1} 2938s, 2864s, 2362w, 1703m, 1585w, 1470m, 1446m, 1359w, 1292w, 1268w, 1205w, 1163w, 1075w, 1020w, 994w, 813w, 740w; MS (FAB^+) (*m*/*z*) 584 $[M-Cl]^+$; μ_{eff} = 5.11 μ_B.

4.7. X-ray crystallography

Crystal data for **2**: $C_{11}H_{19}N_3Cl_2Fe$, M = 320.04, tetragonal, $P4_32_12$ (no. 96), a = 10.5887(5), c = 26.080(3) Å, V = 2924.1(4) Å^3, Z = 8, D_c = 1.454 gcm^{-3}, μ(Cu Kα) = 11.491 mm^{-1}, T = 183 K, yellow platy prisms; 2142 independent measured reflections, F^2 refinement, R_1 = 0.054, wR_2 = 0.122, 1720 independent observed absorption-corrected reflections [$|F_o| > 4\sigma(|F_o|)$, $2\theta_{max}$ = 120°], 155 parameters. The absolute structure of **1** was determined by a combination of *R*-factor tests [$R_1^+ = 0.0541$, $R_1^- = 0.1025$] and by use of the Flack parameter [$x^+ = -0.013(14)$]. CCDC 239659.

Crystal data for **3**: $C_{10}H_{15}N_3Cl_2Fe\cdot0.5CH_2Cl_2$, M = 346.46, monoclinic, I 2/*a* (no. 15), a = 14.870(3), b = 10.2360(8), c = 20.545(4) Å, β = 104.216(11)°, V = 3031.4(9) Å^3, Z = 8, D_c = 1.518 gcm^{-3}, μ(Mo Kα) = 1.508 mm^{-1}, T = 293 K, very dark red/brown needles; 2666 independent measured reflections, F^2 refinement, R_1 = 0.046, wR_2 = 0.103, 2011 independent observed absorption-corrected reflections [$|F_o| > 4\sigma(|F_o|)$, $2\theta_{max}$ = 50°], 173 parameters. CCDC 239660.

5. Supplementary material

Full crystallographic details have been deposited in CIF format with the Cambridge Crystallographic Data Centre. Synthesis and structural studies of bis-amino-functionalised ferrocene salts and ferrocenium salts

Kenneth D. Camm, Stephen J. Furtado, Andrew L. Gott, Patrick C. McGowan *

School of Chemistry, University of Leeds, Woodhouse Lane, Leeds LS6 3BZ, UK

Received 16 June 2004; accepted 9 July 2004
Available online 26 October 2004

Dedicated to Professor Malcolm L.H. Green – an inspiration to many and a great scientist to all.

Abstract

A number of bis-amino-functionalised ferrocene salts and ferrocenium salts have been synthesised and characterised. There are interesting structural features in the solid state, including N–H···O and N–H···F hydrogen bonds.

1. Introduction

There has been interest in the synthesis and properties of ionic ferrocene compounds for their use in asymmetric catalysis [1], sequestering metal ions [2] and molecular recognition [3]. Ferrocenium compounds have been shown to act as mild 1-electron oxidising agents [4] as well as chelating ligands with a redox active centre [5,6]. With respect to biological systems a range of ferrocenium compounds have been reported for their cytotoxic activity, which is thought to be based on their ability to generate oxygen active species [7]. Previous examples of amino–functionalised ferrocenium compounds have also been reported [5,6,8,9]. Primary ferrocenes, such as 1,1-bis(amino)ferrocene [10], have received attention recently from a number of research groups due to their potential as ligands in polymerisation catalysis [5,11–14]. One of the reasons for this renewed activity in the area is due to improvements in the synthesis of 1,1-bis(amino)ferrocenes [5].

We have been interested in the synthesis and bonding of amino-functionalised ferrocene systems [8,15–17]. In this paper, we report the synthesis of primary amino-functionalised ferrocene salts and ferrocenium salts with an alkyl spacer between the cyclopentadienyl (cp) moiety and primary amine. This paper also reports a series of tertiary amino-functionalised ferrocene and ferrocenium salts. We have been also interested also in functionalised cp systems to stabilise metal centres and as a way of making organometallic/coordination compounds water soluble [8,16,18–21].

2. Results and discussion

$NaC_5H_4(CH_2)_2NMe_2$ (**1**) was used in the preparation of the orange oil $Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_2\}_2$ (**2**). Compound **2** was characterised by ^1H and $^{13}C\{^1H\}$ NMR spectroscopy and mass spectrometry.

The compounds $[Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_3\}_2]^{2+}2[CF_3COO]^-$ (**3**) and $[Fe\{\eta\text{-}C_5H_4(CH_2)_3NH_3\}_2]^{2+}2[CF_3COO]^-$ (**4**) were prepared by addition of CF_3COOH to ether solutions of **2** and $Fe\{\eta\text{-}C_5H_4(CH_2)_3NH_2\}_2$ to yield light orange powders (as shown in Scheme 1). The compounds $[Fe\{\eta\text{-}C_5H_4(CH_2)_2NHMe_2\}_2]^{2+}2[CF_3COO]^-$ (**5**) and

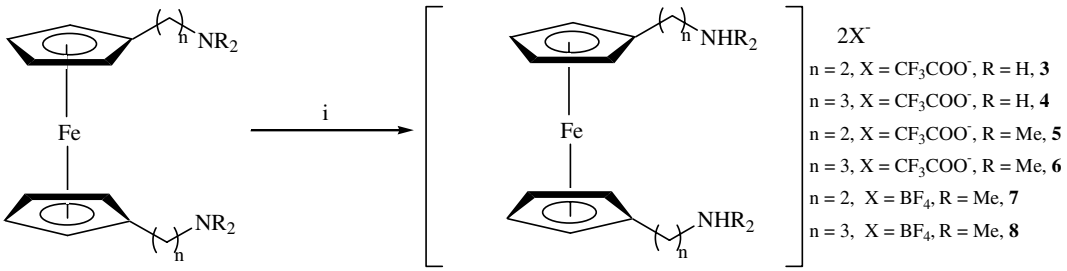

Scheme 1. i = HBF_4 or CF_3COOH in diethyl ether.

$[Fe\{\eta\text{-}C_5H_4(CH_2)_3NHMe_2\}_2]^{2+}2[CF_3COO]^-$ (**6**) were prepared by addition of the corresponding sodium salts $NaC_5H_4(CH_2)_2NMe_2$ and $NaC_5H_4(CH_2)_3NMe_2$ to $FeCl_2$ followed by addition of CF_3COOH (Scheme 1). Compounds **3–6** were characterised by ^1H and ^{13}C NMR spectroscopy, mass spectrometry and elemental analyses and additionally in the case of **6**, by X-ray crystallography. The ^1H and $^{13}C\{^1H\}$ NMR spectra of compounds **3–6** show similarities to those of other bis-functionalised analogues [16].

The compounds $[Fe\{\eta\text{-}C_5H_4(CH_2)_2NHMe_2\}_2]^+2[BF_4]^-$ (**7**) and $[Fe\{\eta\text{-}C_5H_4(CH_2)_3NHMe_2\}_2]^+2[BF_4]^-$ (**8**) were synthesised by addition of two equivalents of the corresponding sodium salts $NaC_5H_4(CH_2)_2NMe_2$ and $NaC_5H_4(CH_2)_3NMe_2$ to $FeCl_2$ followed by addition of $HBF_4 \cdot OEt_2$. The yellow solids were isolated by filtration and washed with petroleum ether (b.p. 40–60 °C). Compounds **7–8** were characterised by ^1H and ^{13}C NMR spectroscopy, mass spectrometry and elemental analyses.

Excess $HBF_4 \cdot OEt_2$ was added to solutions of compounds **2** and $Fe\{\eta\text{-}C_5H_4(CH_2)_3NH_2\}_2$ in diethyl ether in the presence of *p*-benzoquinone, resulting in the formation of $[Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_3\}_2]^{3+}3[BF_4]^-$ (**9**) and $[Fe\{\eta\text{-}C_5H_4(CH_2)_3NH_3\}_2]^{3+}3[BF_4]^-$ (**10**) (as shown in Scheme 2). This procedure was carried out following a method similar to Connelly and Geiger [4]. Repeated attempts at acquiring micro-analytical data for compounds **9** and **10** proved to be unsuccessful. The compounds $[Fe\{\eta\text{-}C_5H_4(CH_2)_2NHMe_2\}_2]^{3+}3[BF_4]^-$ (**11**) and $[Fe\{\eta\text{-}C_5H_4(CH_2)_3NHMe_2\}_2]^{3+}3[BF_4]^-$ (**12**) were synthesised by addition of the corresponding sodium salts $NaC_5H_4(CH_2)_2NMe_2$ and $NaC_5H_4(CH_2)_3NMe_2$ to $FeCl_2$ in the presence of a solution of *p*-benzoquinone and $HBF_4 \cdot OEt_2$ (as shown in Scheme 2). Compounds **11–12** were obtained as blue solids and characterisation of these paramagnetic compounds was achieved using mass spectrometry, elemental analyses and X-ray crystallography.

The bis-functionalised ferrocene compound $[Fe\{C_5H_3\text{-}1\text{-}SiMe_3\text{-}3\text{-}CH(CH_2)_4\ NHMe\}_2]$ has been previously reported [8]. The compound $[Fe\{(C_5H_3\text{-}1\text{-}SiMe_3\text{-}3\text{-}CH(CH_2)_4NHMe\}_2]^{2+}\ 2[CF_3CO_2]^-$ (**13**) was synthesised by addition of $LiC_5H_3\text{-}1\text{-}SiMe_3\text{-}3\text{-}CH(CH_2)_4NMe$ to $FeCl_2$ in THF followed by removal in vacuo and extraction of the product in petroleum ether (b.p. 40–60 °C). Addition of CF_3COOH afforded a yellow precipitate which was washed in petroleum ether (b.p. 40–60 °C), and subsequently isolated. Compound **13** was characterised by ^1H and ^{13}C NMR spectroscopy, mass spectrometry and elemental analyses.

3. Crystallographic data collection and structure analysis

3.1. X-ray crystallography

Data for compounds **6**, **11** and **12** were collected on a Nonius Kappa CCD area-detector diffractometer using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) using 1.0° ϕ-rotation frames. Pertinent crystallographic details are given in Table 1. The structures of all three compounds were solved by direct methods using SHELXS-86. Refinement by full-matrix least-squares on F^2 using SHELXL-97 was similar for

all three compounds. Hydrogen atoms were constrained to idealised positions using a riding model (with free rotation for methyl groups).

The molecular structure of $[Fe\{\eta\text{-}C_5H_4(CH_2)_3NHMe_2\}_2]^{2+}2[CF_3CO_2]^-$ (**6**) is shown in Fig. 1 (Table 2 for selected bond lengths and angles) and the cyclopentadienyl rings are eclipsed with the *N*,*N*-dimethylaminopropyl side chains lying *trans* to each other (ca. 180°). There are two trifluoroacetate ions in the asymmetric unit and the fluorine atoms of one of the counter ions are disordered over two sites with a partial occupancy of 0.5. There are two hydrogen bond interactions between the N–H groups and the oxygen atoms of the adjacent trifluoroacetic acid counter ions, for which the bond lengths and angles are shown in Table 3; these have typical values for N–H···O hydrogen bonds.

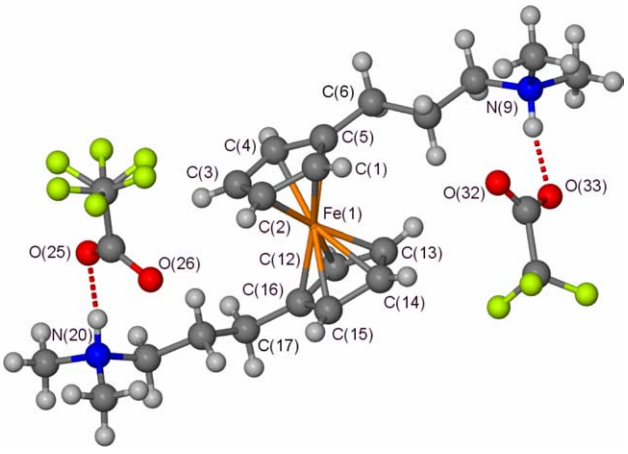

Fig. 1. The molecular structure of compound **6**, showing the hydrogen bonding interactions.

rings are staggered with the *N*,*N*-dimethylaminoethyl side chains *trans* to each other (ca. 180°). There are three BF_4^- counter ions associated with each ferrocenium molecule. Two of the BF_4^- counter ions are hydrogen bonded to the N–H groups (hydrogen bond lengths and angles shown in Table 5) as well as being attached to the adjacent ferrocenium fragment in an μ^2 fashion, as shown in Fig. 2(b). The BF_4^- counter ions involved in the hydrogen bonding are disordered with respect to the fluorine atoms which are orientated over two sites with a partial occupancy of 0.5. The third BF_4^- counter ion is not disordered or involved in hydrogen bonding.

The molecular structure of $[Fe\{\eta\text{-}C_5H_4(CH_2)_3\text{-}NHMe_2\}_2]^{3+}3[BF_4]^-$ (**12**) showed two independent half molecules per asymmetric unit on inversion centres of symmetry and is shown in Fig. 3 (with bond lengths and angles in Table 6). The cyclopentadienyl rings are staggered with the *N*,*N*-dimethylaminopropyl side chains lying *trans* to each other (180°). There are three

N(1)–H(1N)	0.9100	2.0942	149.21	2.9135	F(11)
N(1)–H(1N)	0.9100	2.0879	141.02	2.8533	F(11A)
N(2)–H(2N)	0.9099	1.9761	152.83	2.8164	F(13)

and the other BF_4^- has three disordered fluorine atoms, which have a partial occupancy of 0.5. In a similar fashion to compound **11**, there are hydrogen bond interactions between the N–H groups and the fluorine atoms of two of the three BF_4^- counter ions and the bond lengths and angles are shown in Table 7. A number of reported amino-functionalised ferrocenium salts have been structurally characterised and their bond lengths and angles are similar to these compounds [8,22].

4. Conclusion

In conclusion, this paper reports the synthesis of a number of primary and tertiary bis-amino-functionalised ferrocene and ferrocenium salts. Structural studies have been carried out showing a number of interesting features, including N–H···O and N–H···F hydrogen bonds.

5. Experimental

5.1. General

Standard inert atmosphere techniques were used throughout. Petrol (40-60°), diethyl ether, and THF were distilled from Na/Ph_2CO. NMR solvents were degassed by three freeze–pump–thaw cycles and stored over 3 Å molecular sieves in a dry box. All reagents were purchased in reagent grade and used without further purification.

5.2. Instrumentation

^1H and ^{13}C NMR spectra were recorded on Bruker 250 MHz, 300 MHz and 500 MHz spectrometers. High resolution mass spectrometry was performed by the University of Leeds mass spectral service. Elemental analyses were performed by the University of Leeds microanalytical services.

5.3. $NaC_5H_4(CH_2)_2NH_2$ (*1*)

To a Schlenk tube charged with NaH (1.2 g, 0.005 mol) and THF (100 ml) was added $C_5H_5(CH_2)_2NH_2$ (6.39 g, 0.06 mol) in THF (50 ml) dropwise with stirring. Evolution of a gas and formation of a pale brown precipitate was observed. The reaction mixture was stirred for ca. 24 h. THF was then removed in vacuo and the product was washed with petroleum ether (b.p. 40–60 °C) (3 × 30 ml) to give a pale brown powder. (3.0 g, 0.027 mol, 47%). ^1H NMR (CD_3CN, 300.1 MHz, 300 K) δ 5.42, 5.32 [2 × s, 4H, CH of C_5H_4], 2.64 [t, 2H, $^3J(^1H–^1H)$ = 5.0Hz, CH_2 of $CH_2CH_2NH_2$], 2.44 [t, 2H, $^3J(^1H–^1H)$ = 5.0 Hz, CH_2 of $CH_2CH_2NH_2$] (s, 3H); $^{13}C\{^1H\}$ NMR (CD_3CN, 75.5 MHz, 300K) δ 103.2 [CH of C_5H_4], 102.6 [CH of C_5H_4], 45.0 [CH_2 of $CH_2C_2NH_2$], 33 8 [CH_2 of $C_2CH_2NH_2$].

5.4. $Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_2\}_2$ (*2*)

To a Schlenk tube charged with $FeCl_2$ (0.25 g, 0.002 mol) and THF (50 ml) was added a suspension of **1** (0.59 g, 0.004 mol) in THF (30 ml). The reaction mixture was stirred overnight. The solvent was removed in vacuo. The product was extracted in diethyl ether (3 × 30 ml). The extracts were combined and removal of the solvent afforded the product as a viscous orange oil. (0.38 g, 0.00125 mol, 63%). EI mass spectrum: *m/z* 272.1 – $Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_2\}_2$ ^1H NMR ($CDCl_3$, 500 MHz, 300 K) δ 3.94 [2 × virt. d, 8H, $C_5H_4CH_2CH_2NH_2$], 2.73 [t, 2H, $^3J(^1H–^1H)$ = 6.9 Hz $CH_2CH_2NH_2$], 2.40 [t, 2H, $^3J(^1H–^1H)$ = 6.9 Hz $CH_2CH_2NH_2$], 1.31 [br. S, 2H, $CH_2CH_2NH_2$]; $^{13}C\{^1H\}$ NMR ($CDCl_3$, 500 MHz, 300 K) δ 86.7 [s, $C(CH_2)2NH_2$], 69.4, 68.5 [2 × s, CH of

$C_5H_4(CH_2)_2NH_2]$, 44.0 [s, $CH_2CH_2NH_2$)], 34.2 [s, $C_2CH_2NH_2$].

5.5. $Fe\{\eta\text{-}C_5H_4(CH_2)_2NH_3\}_2]^{2+}2[CF_3CO_2]^-$ (3)

To a Schlenk tube charged with **2** (1.5 g, 0.006 mol) in diethyl ether (100 ml) was added CF_3CO_2H (1.14 g, 0.01 mol). A yellow precipitate was immediately formed. The mixture was allowed to stir (1 h) and stand (5 min). The product was isolated via filtration, washed with diethyl ether (3×15 ml) and dried in vacuo to afford a yellow powder. (1.72 g, 0.003 mol, 65.0%). *Anal*. Calc. for $FeC_{18}H_{22}N_2F_6O_4$: C, 43.2; H, 4.4; N, 5.6. Abstract

A detailed, reproducible synthesis of 1,1′-diaminocobaltocenium hexafluorophosphate is provided. The compound can be made on gram scales in several steps starting from 1,1′-dimethylcobaltocenium salts. The X-ray structures of 1,1′-diaminocobaltocenium hexafluorophosphate and a related 1,1′-diaminoferrocenium salt, are described.

Keywords: Metallocene; Ferrocenium; Cobaltocenium; Crystal structure

1. Introduction

We [1–6], and others [7–16], have recently described a wide assortment of new chemistry based on 1,1′-diaminoferrocene, much of it based on use of this compound to prepare new ligands for use in olefin polymerization catalysts. Extension of this work to the isoelectronic cobalt species was, in our view, a logical synthetic goal. Nevertheless, in contrast to their ferrocene counterparts, relatively little is known regarding the chemistry of 1,1′-substituted diaminocobaltocenium species. The parent cation $(C_5H_4NH_2)_2Co^+$ was first described in the literature many years ago; nevertheless, its synthesis is not well-documented despite the fact that extensive characterization data have appeared [17,18]. These species are of interest since, unlike their ferrocene analogs, cobaltocenium derivatives show strong resistance to oxidation, as well as to electrophilic and radical attack. Also, due to the ionic character of cobaltocenium derivatives, they exhibit good solubility in polar solvents [17].

The purpose of this paper is to provide a detailed, reproducible synthesis of 1,1′-diaminocobaltocenium hexafluorophosphate, to describe its reactivity in comparison to the ferrocene analog, and to present its X-ray crystal structure alongside data for the homologous 17-electron iron(III) counterpart.

2. Results and discussion

Although 1,1′-diaminocobaltocenium hexafluorophosphate was first described 20 years ago, a detailed procedure for its synthesis has not, to the best of our knowledge, been reported. Nevertheless, El Murr reported its characterization by IR, UV, and ^{1}H NMR

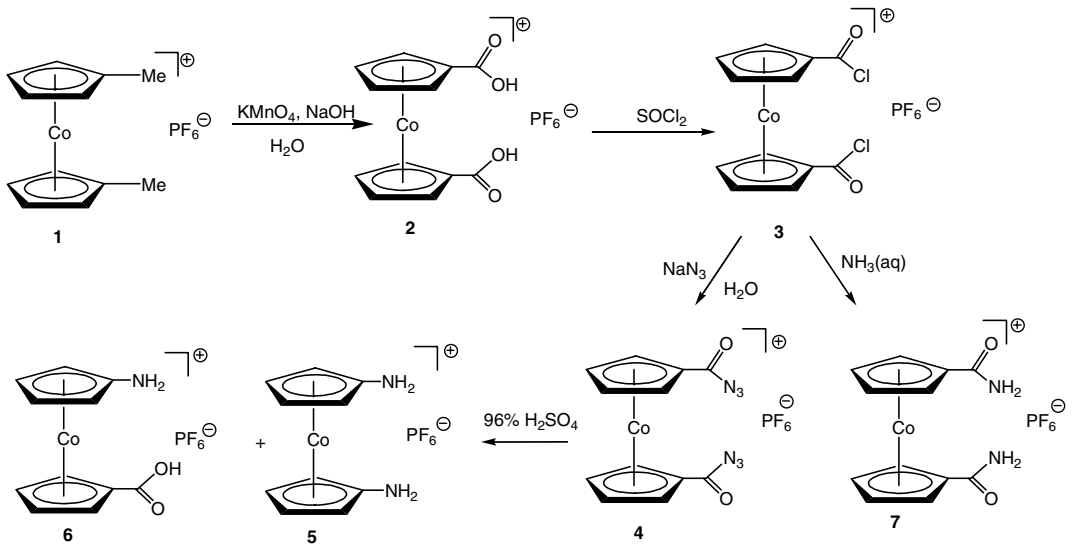

Scheme 1.

spectroscopy, along with its redox behavior in 1976 [17,18]; a general sequence of reaction steps was also given, but with no experimental details (Scheme 1). In contrast, the preparation of monoaminocobaltocenium hexafluorophosphate using related procedures was described in detail.

Following El Murr's outline for the synthesis of the 1,1′-diaminocobaltocenium hexafluorophosphate, the first two steps entailed synthesis of the dimethylcobaltocenium cation **1** from CpLi and $CoCl_2$, followed by oxidation to dicarboxycobaltocenium **2** using potassium permanganate in alkaline aqueous solution. The oxidation reaction was complete in 3 h, affording a reasonable yield of the diacid. The latter was then transformed in high yield into the corresponding diacid chloride **3** by refluxing in thionyl chloride for ca. 5 h. Conversion of the bis(acid chloride) **3** to the bis(azidocarbonyl) **4** was carried out using a 30% aqueous solution of sodium azide in almost quantitative yield.

We caution that while large amounts of the bis(azidocarbonyl) **4** complex have been isolated without incident, the material has been shown to be shock and heat sensitive, especially when dry. Thus, we strongly recommend that the material from this step be taken on to the final step without excessive drying and that appropriate safety precautions be taken when handling this material.

Curtius rearrangement of the bis(azidocarbonyl) was conducted using 96% sulfuric acid, affording the desired 1,1′-diaminocobaltocenium hexafluorophosphate **5** in moderate yields (typically ca. 30%). The reaction mixture included 1-amino-1′-carboxycobaltocenium isolated in 30% yield as well as 10–20% of unreacted diacid. These products presumably arise from the partial or complete hydrolysis of **4** during the reaction.

Attempts to prepare diaminocobaltocenium in higher yield using a Hoffman rearrangement under standard conditions from diamidocobaltocene were tried but were unsuccessful. While diamidocobaltocenium hexafluorophosphate (**7**) was prepared from **3** in good yields, attempts to convert this material to **5** resulted in black tarry mixtures from which no pure products could be isolated.

Schiff-base condensation and silylation reactions with diamine were attempted, in efforts to prepare ligands analogous to those described for ferrocene-based systems [4]. However, due to the strong electron withdrawing nature of the cobaltocenium moiety, diaminocobaltocenium proved to be less reactive than the isoelectronic diaminoferrocene. Schiff-base condensations with aldehydes were unsuccessful under typical acidic or basic catalytic conditions. Efforts to shift the equilibrium of the reaction by removing water with molecular sieves were also unsuccessful.

Attempts to silylate 1,1′-diaminocobaltocinium with trimethylsilylchloride using conditions similar to those employed in the preparation of the ferrocene analog resulted in no reaction [3].

Based on these results, the chemical properties of the NH_2 groups in diaminocobaltocenium would appear to resemble those of iminium moieties rather then of traditional amines (Fig. 1).

This resonance structure is consistent with the low reactivity and low basicity of these amino groups ($pK_b^1 = 13.5$ compared to 10.5 in isoelectronic diaminoferrocene. $pK_b^2 = 18.1$).

X-ray quality crystals of $[(C_5H_4NH_2)_2Co][PF_6]$ were grown from a CD_2Cl_2 solution. The compound crystallized in a chiral space group $P4_32_12$ with the Co and the P atoms residing on a crystallographic C_2 axis. The mol-

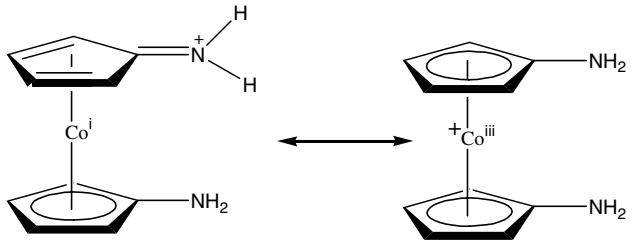

Fig. 1. Resonance structures of 1,1′-diaminocobaltocenium.

ecule adopts an eclipsed synclinal conformation, i.e. the two Cp rings are eclipsed and the amino groups are in the 1 and 2′ positions. An analogous conformation was observed for one of the crystallographically independent molecules of 1,1′-diaminoferrocene [1]. The 1,2′-substitution pattern renders each molecule chiral, which, in this case, translates into a chiral space group. The Co–Cp(centroid) distance of 1.644 is very slightly shorter than the average Fe–Cp(centroid) distance of 1.654 in diaminoferrocene. The C–N distance of 1.373(4) is considerably shorter compared to that in diaminoferrocene, where the C–N distance is 1.412(5). This is consistent with our assumption of contributions from the resonance structure shown in Fig. 2.

As reported earlier [1], cyclic voltammetry of diaminoferrocene exhibited a reversible oxidation wave with $E_{1/2} = -0.602$ V versus $Fc^{0/+}$ couple. Simple chemical oxidation using Ag^+ salts resulted in clean conversion to the paramagnetic (solution $\mu_{eff} = 2.1$ BM) ferrocenium salts (as OTf (**8**) and PF_6 (**9**) salts). In marked contrast to the air-stable cobaltocenium salts, these Fe(III) species are sensitive to oxygen, but exhibit similar solublities, in line with their related structures.

Green crystals of $[Fc(NH_2)_2][OTf]$ (**8**) suitable for X-ray diffraction were grown from a CH_3CN/CH_2Cl_2 solution at −30 °C. The compound crystallizes in the monoclinic space group $P2_1/c$. Two crystallographically independent $Fc(NH_2)_2^+$ cations were located in the asymmetric portion of the unit cell (Fig. 3). Both cations adopt a fully eclipsed synclinal conformation (i.e. the two amino groups are located on the same side of the cation). The oxygen atoms of each triflate anion are hydrogen-bonded to the amino groups of two different $Fc(NH_2)_2^+$ cations. Therefore, discrete "rings" are formed composing of two $Fc(NH_2)_2^+$ cations bridged by two triflate anions. The average Fe–C bonds in **8** [2.079(5) and 2.084(5) Å for two independent cations] are slightly longer that the average Fe–C bond in the neutral diaminoferrocene [2.051(7) and 2.052(8) Å for two independent molecules], although the differences are not very significant in light of the fairly high standard deviations of the Fe–C bond lengths.

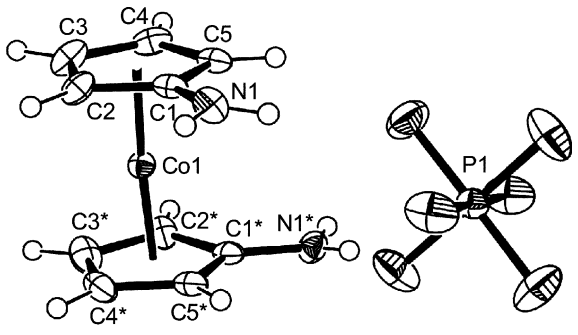

Fig. 2. ORTEP diagram of 1,1′-diaminocobaltocenium hexafluorophosphate shown with 50% thermal ellipsoids.

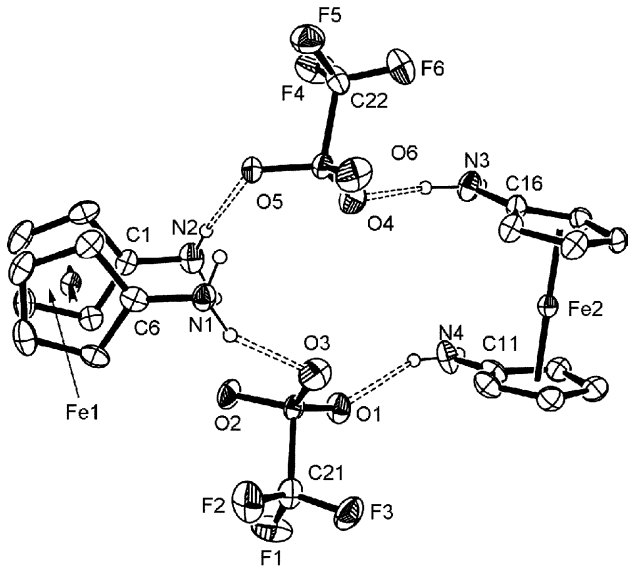

Fig. 3. ORTEP diagram (40% thermal ellipsoids) of $[Fc(NH_2)_2][OTf]$ (**8**) showing the hydrogen-bonded "rings" are formed by two $Fc(NH_2)^{2+}$ cations and two triflate anions. Selected hydrogen bonds are shown as dashed lines. Only the amine hydrogen atoms are shown.

3. Experimental

3.1. General considerations

Standard Schlenk-line and glove box techniques were used unless otherwise indicated. CH_3CN was distilled over CaH_2 under a nitrogen atmosphere. All other solvents were passed through a column of activated alumina and degassed with argon prior to use. $CDCl_3$ and CD_3CN were vacuum transferred from CaH_2. All other chemicals were purchased from Aldrich. Melting points were determined in sealed capillary tubes under nitrogen and are uncorrected. NMR spectra were recorded at ambient temperature on a Bruker AMX-300 or DRX-500 spectrometer. ^1H NMR chemical shifts are given relative to C_6D_5H (7.16 ppm), $CHCl_3$ (7.26 ppm) and CHD_2CN (2.09 ppm). Solution magnetic susceptibilities were determined using Evans NMR method

[19] with CD_3CN as solvent. IR samples were prepared either as Nujol mulls and taken between KBr plates, or as pressed KBR discs. Elemental analyses were determined at the Microanalytical Laboratory of the College of Chemistry, University of California, Berkeley. Single crystal X-ray structure determinations were performed at CHEXRAY, University of California, Berkeley.

3.2. 1,1′-Dimethylcobaltocenium hexafluorophosphate (*1*)

$CoCl_2$ (12.9 g, 0.10 mol) was added to a cooled (−78 °C) solution of $Li(C_5H_4Me)$ (17 g, 0.19 mol) in 250 ml of THF. The black reaction mixture was allowed to warm to room temperature and stirring was continued for an additional 12 h. The solvent was removed under reduced pressure and the resulting residue was dissolved in 250 ml of hot water. The mixture was filtered and washed with diethyl ether (2×100 ml) to remove unreacted organic species. The yellow aqueous phase was cooled and 1,1′-dimethylcobaltocenium was precipitated by dropwise addition of a solution of potassium hexafluorophosphate (40 g, 022 mol) in 150 ml of water. The resulting yellow solid was obtained by filtration. Yield: 17 g (46%). ^{1}H NMR (dmso-d_6, 300 MHz): δ 2.11 (s, 6H), 5.7 (s, 8H).

3.3. 1,1′-Dicarboxycobaltocenium hexafluorophosphate (*2*)

Potassium permanganate (58 g, 0.36 mol), sodium hydroxide (10 g, 0.25 mol) and 1,1′-dimethylcobaltocenium hexafluorophosphate (22 g, 0.06 mol) were mixed in 200 ml of water. The mixture was warmed to 95 °C and was stirred for 3 h. After cooling to room temperature and filtration to remove manganese dioxide, potassium hexafluorophosphate (10 g 0.05 mol) in 50 ml of water was added. The solution was chilled and any unreacted dimethylcobaltocenium complex was filtered off. Dropwise addition of 20 ml (0.12 mol) of 6 M HCl produced a yellow precipitate. Filtration afforded 12 g (55%) of the product in the form of a yellow solid. ^{1}H NMR (dmso-d_6, 300 MHz): δ 6.02 (t, 4H), 6.21 (t, 4H). IR (Nujol; cm^{-1}) 1736 (s), 1163 (m), 833 (s), 558 (m). *Anal.* Calc. for $C_{12}H_{10}O_4PF_6Co$: C, 34.12; H, 2.36. Found: C, 34.44; H, 2.44%.

3.4. 1,1′-Dichlorocarboxycobaltocenium hexafluorophosphate (*3*)

1,1′-Dicarboxycobalticinium hexafluorophosphate (10 g, 0.022 mol) was refluxed in 50 ml (large excess) of thionyl chloride for 5 h. The solution was concentrated to 15 ml and chilled to 0°. The yellow precipitate of the bis-chlorocarbonyl derivative was collected on a sintered glass filter, washed with anhydrous ether and stored in a desiccator. Yield: 8.5 g (83%). IR (Nujol; cm^{-1}) 1773 (s), 1741 (s), 1239 (s), 1056 (m), 944 (s), 843 (s), 559 (s).

3.5. 1,1′-Bis(azidodicarbonyl)cobaltocenium hexafluorophosphate (*4*)

A suspension of 1,1′-bis-chlorocarbonyl cobalticinium hexafluorophosphate (8.5 g, 18.2 mmol) was stirred with 75 ml of 30% aqueous sodium azide for 30 min. When the reaction was complete, the solution was chilled to 0° and the yellow precipitate was collected and washed with anhydrous ether. Yield: 8.7 g (98%) IR (Nujol; cm^{-1}): 3120, 2240, 2200, 2150, 1730, 1680, 1457, 1393, 1370, 1215, 1180 (s), 1065, 1030, 900, 880, 833, 820, 760.

3.6. 1,1′-Diaminocobaltocenium hexafluorophosphate (*5*)

1,1′-Dicarbonylazidocobaltocenium hexafluorophosphate (8.5 g, 0.018 mol) was dissolved in 25 ml concentrated sulfuric acid in a 250 ml round-bottomed flask resulting in evolution of a gas that persisted for ca. 15 min. When gas evolution had ceased, the solution was heated on a steam bath for 2 h, cooled and poured over 100 g ice. The solution was neutralized with concentrated KOH until slightly basic. Ethanol (200 ml) was added and a precipitate of potassium sulfate was collected and extracted with ethanol. The combined ethanol fraction was concentrated to one third of their original volume. The resulting solution was treated with charcoal and filtered. Precipitation of the product was induced by a dropwise addition of a saturated aqueous solution of ammonium hexaflurophosphate. Yield: 1.8 g (28%). ^{1}H NMR (CD_2Cl_2, 300 MHz): δ 4.26 (s, 4H), 4.87 (t, 4H), 4.99 (t, 4H). IR (1% in KBr; cm^{-1}) 3415, 3390, 3118, 1636, 1522, 1379, 1293 1047, 1032, 833, 741, 558. *Anal.* Calc. for $C_{10}H_{12}N_2PF_6Co$: C, 33.0; H, 3.32; N, 7.69. Found: C, 33.46; H, 3.55; N, 8.23%. The mother liquor was acidified to pH 1.0 with 6.0 M HCl and 1-amino-1′-carboxycobalticinium hexafluorophosphate was precipitated by dropwise addition, with stirring, of saturated aqueous NH_4PF_6. Yield: 3.0 g (42%).

3.7. 1,1′-Diamidocobaltocenium hexafluorophosphate (*7*)

A 2.37 g (5.2 mmol) sample of 1,1′-dichlorocarboxycobaltocenium hexafluorophosphate was stirred with 30 ml of saturated aqueous ammonia solution for 3 h. Filtration afforded 1.98 g (72%) of product in the form of a dark-green solid. ^{1}H NMR (dmso-d_6, 300 MHz): δ 5.92 (t, 4H), 6.20 (t, 4H), 7.92 (s, 2H), 8.19 (s, 2H). *Anal.* Calc. for $C_{12}H_{12}O_2N_2PF_6Co$: C, 34.3; H, 2.88; N, 6.67. Found: C, 35.41; H, 2.86; N, 6.66%.

3.8. General procedures for X-ray crystallography

A crystal of appropriate size was mounted on a glass capillary using Paratone-N hydrocarbon oil. The crystal was transferred to a Siemens SMART [20] diffractome-

ter/CCD area detector, centered in the beam, and cooled by a nitrogen flow low-temperature apparatus that had been previously calibrated by a thermocouple placed at the same position as the crystal. Preliminary orientation matrix and cell constants were determined by collection of sixty 10-s frames, followed by spot integration and least squares refinement. An arbitrary hemisphere of data was collected and the raw data were integrated using SAINT [21]. Data were analyzed for agreement and possible absorption using XPREP [22]. An empirical absorption correction based on comparison of redundant and equivalent reflections was applied using SADABS [23]. The data were corrected for Lorentz and polarization effects, but no correction for crystal decay was applied. Cell dimensions were calculated from all reflections with $I > 10\sigma(I)$. The structures were solved and refined with teXsan software package [24]. ORTEP diagrams were created using ORTEP-3 software package [25].

3.9. Crystallographic detail for $[(C_5H_4NH_2)_2Co][PF_6]$ (**5**)

Crystals were grown from CH_2Cl_2 −30 °C. X-ray quality crystals were grown from a CD_2Cl_2 solution. Based on the systematic absences the space group choice was narrowed to the enantiomorphic pair $P4_12_12/P4_32_12$ (#92/96). The structure was solved in $P4_12_12$, but $P4_32_12$ was chosen as the correct space group based on the Flack parameter and a lower R-factor ($R = 4.1\%$ in $P4_12_12$ and 2.6% in $P4_32_12$). All non-hydrogen atoms were refined anisotropically. The amine hydrogen atoms were located in a difference Fourier map and their positional parameters allowed to refine. The remaining hydrogen atoms were included in geometrically calculated positions and were not refined. (See Table 1.)

3.10. Crystallographic detail for $[Fc(NH_2)_2][OTf]$ (**8**)

Crystals were grown from CH_2Cl_2/CH_3CN at −30 °C. Space group $P2_1/c$ was assigned based on the systematic absences. All non-hydrogen atoms were refined isotropically. The amine hydrogen atoms were located in a difference Fourier map and their positional parameters allowed to refine. The remaining hydrogen atoms were included in geometrically calculated positions and were not refined. (See Table 1.)

4. Supplementary material

The crystal structures have been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition numbers CCDC 240121, 240122. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336-033, e-mail: deposit@ccdc.ac.uk, or on the web: www.ccdc.cam.ac.uk.

Abstract

Cationic rhodium methyl complexes, $[Cp^*(PMe_3)Rh(Me)(CH_2Cl_2)]BAr'_4$ (**1**) and $[Cp^*(P(OMe)_3)Rh(Me)(CH_2Cl_2)]BAr'_4$ (**3**), react with benzene to yield the corresponding phenyl complexes, $[Cp^*(PMe_3)Rh(Ph)(CH_2Cl_2)]BAr'_4$ (**6**) and $[Cp^*(P(OMe)_3)Rh(Ph)(CH_2Cl_2)]BAr'_4$ (**7**). First-order rate constants observed in 1.1 M benzene in CD_2Cl_2 at 25 °C are $(2.1 \pm 0.2) \times 10^{-5}$ s^{-1} and $(1.9 \pm 0.2) \times 10^{-5}$ s^{-1}, respectively. Reactions of **1** and **3** with *p*-X-substituted benzaldehydes (X = $-CF_3$, $-CH_3$, and –OMe) initially produce the σ-aldehyde adducts, $[Cp^*(L)Rh(Me)(p\text{-}XC_6H_4CHO)]BAr'_4$ (L = PMe_3 (**15**), $P(OMe)_3$ (**16**)). Exchange of free with bound aldehyde occurs via a dissociative process and quantitative NMR rate measurements show that complexes of **1** exchange faster than those of **3** and that less basic aldehydes exchange faster than more basic aldehydes (*p*-$CF_3C_6H_4CHO$ > *p*-$CH_3C_6H_4CHO$ > *p*-$CH_3OC_6H_4CHO$). The aldehyde adducts undergo C–H bond activation to produce initially methane plus acyl aldehyde adducts, $[Cp^*(L)Rh(C(O)C_6H_4X)(p - XC_6H_4CHO)]BAr'_4$ (L = PMe_3 (**17**), $P(OMe)_3$ (**18**)). Rates of C–H activation are correlated with aldehyde exchange rates; activation barriers of weakly bound aldehydes are lower than more strongly bound aldehydes. In the case of L = PMe_3, decarbonylation of the aldehyde adducts occurs cleanly to form aryl carbonyl complexes, $[Cp^*(PMe_3)Rh(C_6H_4X)(CO)]BAr'_4$. For L = $P(OMe)_3$, decarbonylation is a more complicated process; some intermediates and products have been identified by NMR spectroscopy.

Keywords: C–H bond activation; Rhodium(III); Benzene activation; Aldehyde activation

1. Introduction

Early examples of the oxidative addition reactions of alkane C–H bonds, leading to hydrido(alkyl)metal complexes, take place at metal centers in relatively low formal oxidation states. This has led to the general perception that electron-rich complexes are required in order to make this important oxidative addition process exergonic and therefore capable of generating stable products.

However, the platinum-based alkane functionalization reactions observed many years ago by Shilov and his coworkers [1], and the dehydrogenation

doi:10.1016/j.poly.2004.09.005

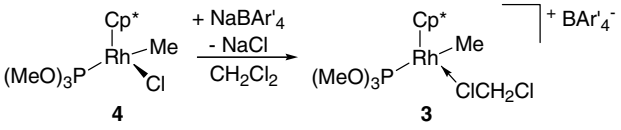
reactions subsequently observed using high-valent iridium and rhenium complexes by the Crabtree [2] and Felkin [3] groups, were early indications that more electron-deficient metal centers could also undergo C–H oxidative addition. More recently, direct observation of C–H oxidative addition reactions at iridium (III) [4], as well as analogous reactions that take place in Pt(II) complexes [5], have made clear that such processes can occur at metal centers that are relatively electrophilic, and in some cases can be overall exergonic. This has given rise to a substantial increase in the number of studies directed toward alkane activation reactions involving higher-valent late transition metal complexes in recent years.

The cationic Ir(III) C–H oxidative addition reactions referred to above lead to relatively rare examples of organometallic positively-charged Ir(V) intermediates [6]. Many of these have been generated only in transient form, but a few have been found to be stable enough to isolate or detect in solution. In contrast to this growing body of research on Ir(III) C–H activation, much less attention has been directed toward the search for analogous reactions at Rh(III). In view of the fact that pentamethylcyclopentadienylrhodium(I) complexes were ultimately discovered to undergo C–H oxidative addition reactions analogous to those of their iridium congeners [7], we felt it would be interesting to look for Rh(III)-to-Rh(V) C–H oxidative addition reactions in related systems as well. This manuscript reports the results of our investigation of C–H bond activations of benzene and aryl aldehydes by $[Cp^*(L)Rh(Me)(CH_2Cl_2)]BAr'_4$ (L = PMe_3 (**1**), $P(OMe)_3$ (**3**)).

2. Results and discussion

2.1. Synthesis of cationic rhodium(III) methyl complexes, $[Cp^*(L)Rh(Me)(CH_2Cl_2)]BAr'_4$ (L = PMe_3 (**1**), $P(OMe)_3$ (**3**), Ar′ = 3,5-$(CF_3)_2C_6H_3$)

Synthesis of $[Cp^*(PMe_3)Rh(Me)(CH_2Cl_2)]BAr'_4$ (**1**) by treatment of Cp*(PMe_3)Rh(Me)(Cl) (**2**) with $NaBAr'_4$ has been previously reported by us [8]. This complex was fully characterized by NMR spectroscopy and X-ray diffraction studies. The phosphite analogue $[Cp^*(P(OMe)_3)Rh(Me)(CH_2Cl_2)]BAr'_4$ (**3**) was synthesized in a similar manner (Eq. (1)). The rhodium methyl chloride complex, Cp*($P(OMe)_3$)Rh(Me)(Cl) (**4**), was prepared by reaction of previously reported Cp*($P(OMe)_3$)$RhCl_2$ [9] with MeLi. The ^{1}H NMR spectrum of **3** in CD_2Cl_2 showed signals at 3.78 (d, $^3J_{P-H}$ = 11.4 Hz) for $P(OMe)_3$, 1.63 ppm (d, $^4J_{P-H}$ = 4.2 Hz) for Cp*, and 1.02 ppm (dd, $^3J_{P-H}$ = 5.5 Hz, $^2J_{Rh-H}$ = 1.5 Hz) for the Rh–CH_3 group. The $^{31}P\{^1H\}$ NMR signal appeared at 126.9 ppm (d, $^1J_{Rh-P}$ = 269 Hz), and the $^{13}C\{^1H\}$ NMR resonance of the Rh–CH_3 group exhibited a signal at 1.19 ppm (dd, $^2J_{P-C}$ = 37.1 Hz, $^1J_{Rh-C}$ = 22.0 Hz).



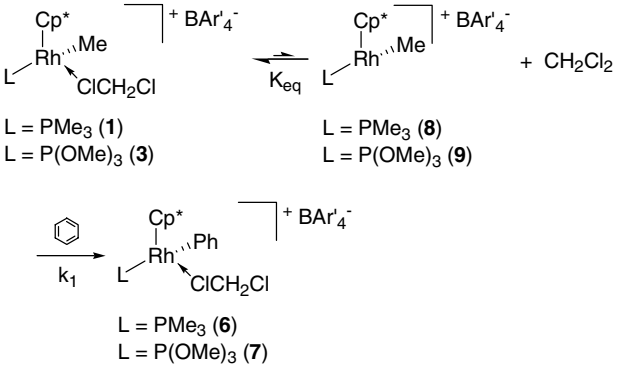
(1)

2.2. Carbon–hydrogen bond activation studies

In contrast to Bergman's cationic iridium (III) complex, $[Cp^*(PMe_3)Ir(Me)(CH_2Cl_2)]BAr'_4$ (**5**) [4b], the analogous rhodium methyl complex **1** does not react with alkanes to any appreciable extent, even at 45 °C. Addition of 500 equivalents of pentane to a CD_2Cl_2 solution of **1** resulted in the observation of only trace amounts of methane (by ^{1}H NMR) over the course of several days at 25 °C. Similar results were obtained with the corresponding Rh phosphite compound **3**. Given the inertness toward alkanes, studies of C–H bond activations using **1** and **3** focused on the more reactive substrates: benzene and aryl aldehydes.

2.3. Carbon–hydrogen bond activation of benzene

Rhodium methyl complexes **1** and **3** react with benzene to yield methane and the cationic rhodium phenyl complexes **6** and **7**, respectively (Eq. (2)). To further verify the structure of product **6**, this compound was independently synthesized and fully characterized by NMR spectroscopy and X-ray diffraction studies (see below). Product **7** was directly isolated from the C–H activation reaction of benzene and characterized by NMR spectroscopy.



(2)

The rates of these reactions are sufficiently slow that clean conversions can be achieved only by using high ratios of benzene to rhodium complex. Under these conditions, the reactions exhibit clean pseudo-first order kinetics, as determined by integrations of ^{1}H NMR signals. Table 1 summarizes the observed first-order rate

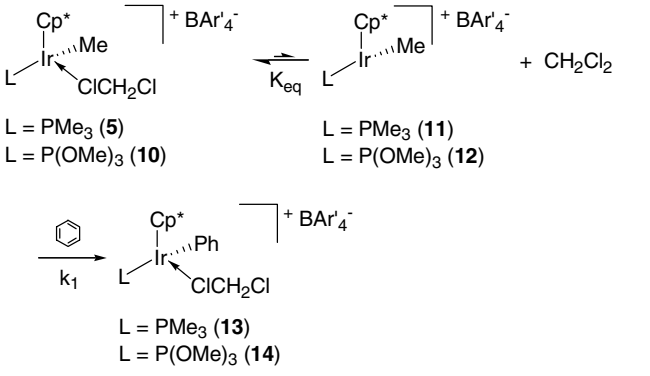
Table 1
First-order rate constants for C–H activation of benzene by **1**, **3**, **5**, and **10**

$[Cp^*(L)M(Me)(CH_2Cl_2)]BAr'_4$	L = PMe_3	L = $P(OMe)_3$	Rate ratio
M = Rh[a]	$(2.1 \pm 0.2) \times 10^{-5}$ s^{-1}	$(1.9 \pm 0.2) \times 10^{-5}$ s^{-1}	(**1/3**) = 1.1
M = Ir[b]	$(8.4 \pm 0.8) \times 10^{-3}$ s^{-1}	$(3.0 \pm 0.3) \times 10^{-4}$ s^{-1}	(**5/10**) = 28.0

[a] 1.1 M C_6H_6 in CD_2Cl_2, 25 ± 2 °C.
[b] 0.26 M C_6H_6 in CD_2Cl_2, 0 °C.

constants for the reactions of **1** and **3** (0.02 M) with 1.1 M benzene in CD_2Cl_2 at 25 ± 2 °C. [1] For comparison, the reported rate constants [10] for the corresponding iridium analogues **5** and $[Cp^*(P(OMe)_3)Ir(Me)(CH_2Cl_2)]BAr'_4$ (**10**) reacting at 0 °C with 0.26 M benzene in CD_2Cl_2 are also listed.

In general, the iridium complexes **5** and **10** are far more reactive toward benzene than rhodium analogues **1** and **3**. Correcting for benzene concentrations, **5** reacts with benzene ca. 10^3 times faster than either **1** or **3** at a considerably lower temperature (0 °C vs. 25 °C). A significant feature of these comparisons is that, in the case of the Ir examples, the PMe_3 complex exhibits a rate ca. 30× that of the $P(OMe)_3$ complex; in contrast, the rates are comparable in the rhodium systems. Bergman has postulated that these reactions occur through the 16-electron species **11** and **12** (Eq. (3)) and that, while the presumably more electrophilic species **12** is expected to be more reactive (k_1 for $P(OMe)_3 > k_1$ for PMe_3), the value of K_{eq} for $P(OMe)_3$ is much less than K_{eq} for (PMe_3), resulting in $K_{eq(PMe_3)}k_{1(PMe_3)} > K_{eq(P(OMe)_3)}k_{1(P(OMe)_3)}$ [10]. In the case of the rhodium complexes, it appears that the $k_{1(PMe_3)} : k_{1(P(OMe)_3)}$ ratio is counterbalanced by the $K_{eq(P(OMe)_3)} : K_{eq(PMe_3)}$ ratio, and the observed rates of benzene activation are essentially equal (see Eq. (2)). The assumptions that Rh phosphite complex **9** is more electrophilic than the Rh phosphine complex **8** and that $K_{eq(PMe_3)} > K_{eq(P(OMe)_3)}$ receive independent support from observations described below in connection with the C–H bond activation of aryl aldehydes.



(3)

[1] Reactions of **1** and **3** in 2.2 M benzene in CD_2Cl_2 at 25 ± 2 °C give pseudo first-order rate constants of $(3.2 \pm 0.2) \times 10^{-5}$ s^{-1} and $(3.8 \pm 0.4) \times 10^{-5}$ s^{-1}, respectively. These data establish a clear dependence of the rate on benzene concentration.

2.4. Independent synthesis and characterization of $[Cp^*(PMe_3)Rh(Ph)(CH_2Cl_2)]BAr'_4$ (6)

To verify the identity of the product derived from C–H activation of benzene by rhodium methyl complex **1**, the cationic rhodium phenyl complex (**6**) was independently synthesized by adding $NaBAr'_4$ to a dichloromethane solution of previously reported $Cp^*(PMe_3)Rh(Ph)(Cl)$ [11]. X-ray quality, orange–red crystals of **6** were isolated in 70% yield. This compound is more thermally and air-sensitive than the rhodium methyl complex **1**, but can be stored under inert conditions at −30 °C for extended periods of time. An ORTEP diagram of **6** is shown in Fig. 1, with some selected bond distances and bond angles listed in Table 2. The bond distance between Rh and the ipso aryl carbon of the phenyl ring is 2.026(8) Å, which is shorter than the Rh–CH_3 bond length (2.106(5) Å) of complex **1** [8], as is expected for a metal bonded to an sp^2-hybridized carbon versus an sp^3 carbon. However, the Rh–Cl distance of phenyl complex **6** is 2.512(2) Å and differs only by 0.02 Å relative to the bond distance of 2.488(1) Å observed for the Rh–Cl bond of methyl complex **2** [8].

2.5. Carbon–hydrogen bond activation of aryl aldehydes

Bergman has shown that the iridium (III) complex $Cp^*(PMe_3)Ir(Me)(OTf)$ reacts rapidly with benzaldehyde at −80 °C to form an η^1-(O)-bound aldehyde

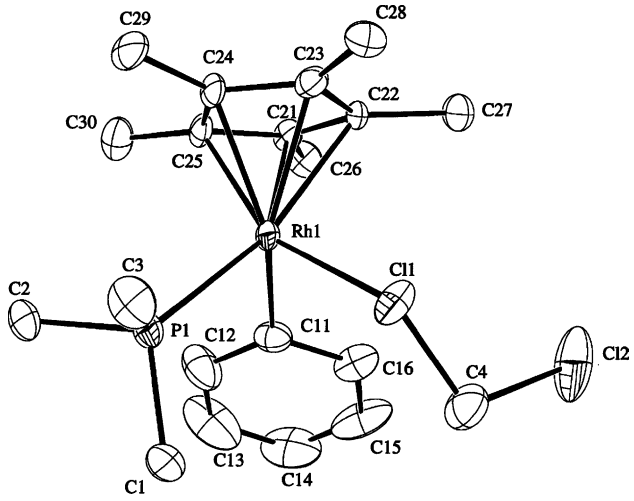


Fig. 1. ORTEP diagram of $[Cp^*(PMe_3)Rh(Ph)(CH_2Cl_2)]^+$ (**6**, BAr'_4^- counterion omitted for clarity).

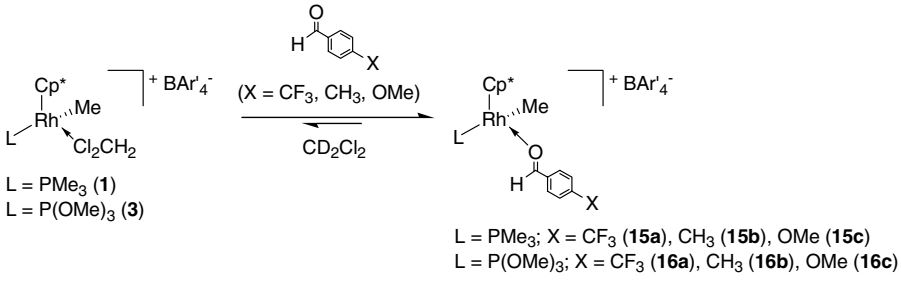
Table 2
Selected bond distances and bond angles for complex **6**

	Bond distance (Å)		Bond angle (°)
Rh(1)–C(24)	2.195(6)	C(24)–Rh(1)–P(1)	101.5(2)
Rh(1)–P(1)	2.374(2)	C(11)–Rh(1)–Cl(1)	98.3(2)
Rh(1)–C(11)	2.026(8)	P(1)–Rh(1)–C(11)	87.9(3)
Rh(1)–Cl(1)	2.512(2)	P(1)–Rh(1)–Cl(1)	84.9(8)

adduct [12]. Upon warming to −60 °C, the adduct undergoes C–H bond activation and decarbonylation to form the iridium phenyl carbonyl complex, [Cp*(PMe_3)Ir(Ph)(CO)]OTf, and methane. Similarly, the cationic rhodium methyl complexes **1** and **3** react with aryl aldehydes (tolualdehyde, anisaldehyde, and 4-(trifluoromethyl)benzaldehyde) in CD_2Cl_2 at −80 °C to form η^1-aldehyde adducts (Eq. (4)).



(4)

When reactions with **1** and **3** are carried out using excess aldehyde as substrate, ^{1}H NMR resonances for the aldehydic proton of both the bound and free aldehydes can be detected at low temperatures. The lack of rhodium coupling to the aldehydic hydrogen supports the η^1 structure. Upon warming, these resonances broaden and coalesce. The rates for loss of bound aldehydes from Rh were assessed by measuring the changes in line-width at half-height of the aldehydic protons and applying the slow exchange equation, $k = \pi(\Delta w)$. A key finding is that the linewidth and thus the rate of exchange of the bound aldehyde is *independent* of the concentration of free aldehyde. This clearly indicates the exchange occurs through a dissociative process. Table 3 summarizes the $\Delta G^{\ddagger}$ values obtained from line broadening experiments together with ^{1}H NMR shifts for free and bound aldehyde at −88 °C.

The trends follow the expected electronic effects. For both series **15a**–**15c** and **16a**–**16c** the order of dissociation is *p*-$CF_3C_6H_4CHO$ > *p*-$CH_3C_6H_4CHO$ > *p*-$CH_3OC_6H_4CHO$ which inversely parallels the order of basicity of the aldehydes. In comparing **15a**–**15c** with **16a**–**16c** in each of the three pairs the barrier to dissociation of aldehyde from the more electron-deficient $P(OMe)_3$ complex is ca. 1.7 kcal/mol higher than that for the more electron-rich PMe_3 complex. The strongest Rh(III)-aldehyde interaction is between the more electrophilic phosphite complex **16** and the most electron-rich aldehyde, *p*-$CH_3OC_6H_4CHO$. The weakest interaction is between the less electrophilic PMe_3 complex **15** and the most electron-deficient aldehyde, *p*-$CF_3C_6H_4CHO$.

The C–H activation chemistry of aryl aldehydes by rhodium complexes **1** and **3** is similar to the iridium chemistry but more complex in the case of **3**. Deinsertion products can react with **3** which complicates kinetic measurements and gives rise to a mixture of products. The most definitive kinetic studies were carried out using a large excess of aldehyde. First, this approach ensures that the equilibrium between the methylene chloride adducts **1** and **3** and the aldehyde adducts **15a**–**15c** and **16a**–**16c** lies strongly in favor of the aldehyde adducts. Second, and critical in the case of **3**, the C–H activation reactions result in generation of the Rh acyl aldehyde adducts **17** and **18**. Little deinsertion occurs under these conditions. The aldehyde adduct intermediate **15** or **16** builds up to high concentrations and clean first-order kinetics for conversion to **17** or **18**, respectively, are exhibited over ca. two half-lives (Eq. (5)). Rates and free energies of activation are summarized for these C–H bond activation reactions in Tables 4 and 5.

Table 3

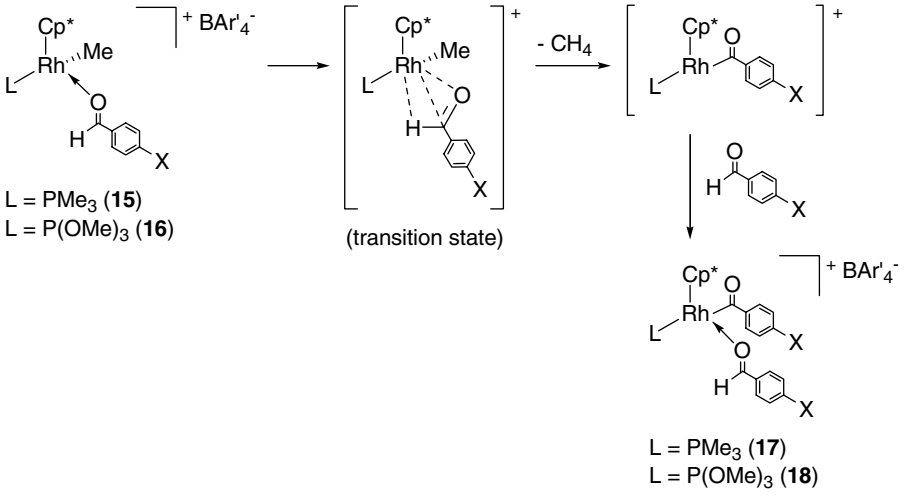
(5)

As noted earlier, C–H bond activation of benzene by **1** and **3** occurs at essentially equal rates. In these cases benzene is a weakly binding substrate and does not compete with CH_2Cl_2. That is, no benzene adduct is observed during the activation reaction. In the case of aryl aldehyde activation, the aldehyde adducts, **15a**–**15c** and **16a**–**16c**, rather than the CH_2Cl_2 adducts, are the more stable species, and as shown in Scheme 1, C–H bond activation is initiated from these species. The rates of C–H bond activation of these complexes correlate qualitatively with the rates of dissociation of the aldehydes. The more electron-rich PMe_3 complexes show higher rates of dissociation and higher rates of C–H bond activation than their $P(OMe)_3$ congeners. Similarly, the more electron-deficient aldehydes show faster rates of dissociation and higher rates of C–H bond activation (**15a** > **15b** > **15c**; **16a** > **16b** > **16c**). These rate trends can be rationalized by considering the expected substituent effects on the ground state aldehyde complexes relative to the transition state for C–H bond activation (Scheme 1). In the σ-aldehyde complexes there will be substantial partial positive charge on the carbonyl carbon due to polarization of the C=O π bond upon binding to the Lewis acidic Rh center. Ground state energies of these σ-complexes will be significantly affected by resonance and inductive effects of *para* substituents. In the four-centered transition state for C–H bond activation, Lewis acidic rhodium will no longer be bound exclusively to oxygen, thus *para*-substituent effects, especially π effects, should be less significant in affecting relative transition state energies. In short, electron-donating substituents will stabilize the aldehyde adducts **15** and **16** more than the corresponding transition states and thus retard the rate of C–H bond activation.



Scheme 1.

When 5 equivalents of tolualdehyde is allowed to undergo reaction with cationic Rh methyl complex **1** at room temperature, facile C–H bond activation and decarbonylation occurs, as evidenced by extrusion of methane and formation of $[Cp^*(PMe_3)Rh(C_6H_4CH_3)(CO)]BAr'_4$ (**19**). X-ray quality orange crystals of **19** were isolated via pentane layering of the reaction mixture. The ORTEP diagram is shown in Fig. 2, with some selected bond distances and bond angles listed in Table 6.

Contrary to the reaction described above between **1** and tolualdehyde, the reactions of Rh phosphite complex **3** with aryl aldehydes do not result in clean formation of decarbonylation products. A variety of species can be detected by ^1H and $^{31}P\{^1H\}$ NMR spectroscopy. The concentrations of these species fluctuate as a function of time, and vary with the particular aldehyde used along with the initial ratio of Rh complex to aldehyde. In the case of the reaction between **3** and tolualdehyde, several reaction products and intermediates have been identified by independent synthesis. Prior to proposing a sequence of reactions for the C–H activation and decarbonylation process, generation of potential intermediates is outlined below.

The ^{13}C-labeled Rh methyl carbonyl complex, $[Cp^*(P(OMe)_3)Rh(Me)(^{13}CO)]BAr'_4$ (**20′**), was readily generated in situ by exposure of a CD_2Cl_2 solution of **3** to ^{13}CO at 25 °C (Eq. (6)).

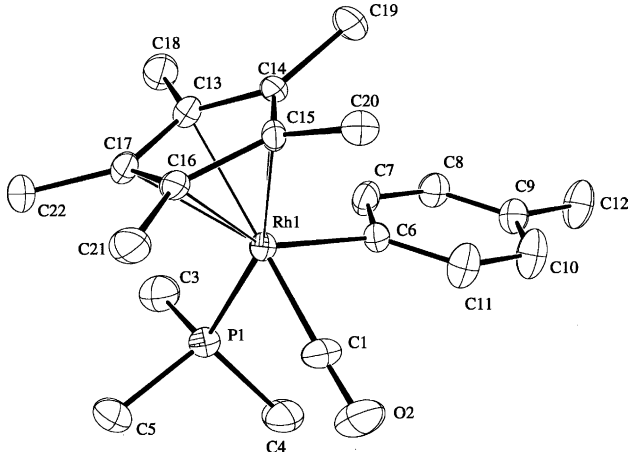


Fig. 2. ORTEP diagram of $[Cp^*(PMe_3)Rh(C_6H_4CH_3)(CO)]^+$ (**19**, BAr'^-_4 counterion omitted for clarity).

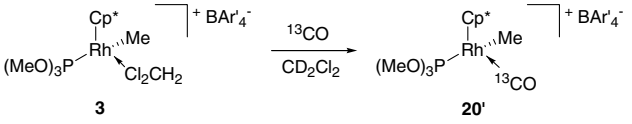
Table 6
Selected bond distances and bond angles for complex **19**

	Bond distance (Å)		Bond angle (°)
Rh(1)–C(16)	2.246(7)	C(16)–Rh(1)–P(1)	124.3(2)
Rh(1)–P(1)	2.298(3)	C(6)–Rh(1)–C(1)	89.4(3)
Rh(1)–C(6)	2.091(8)	P(1)–Rh(1)–C(6)	87.2(2)
Rh(1)–C(1)	1.879(8)	P(1)–Rh(1)–C(1)	89.0(3)
C(1)–O(2)	1.134(10)	Rh(1)–C(1)–O(2)	174.6(8)



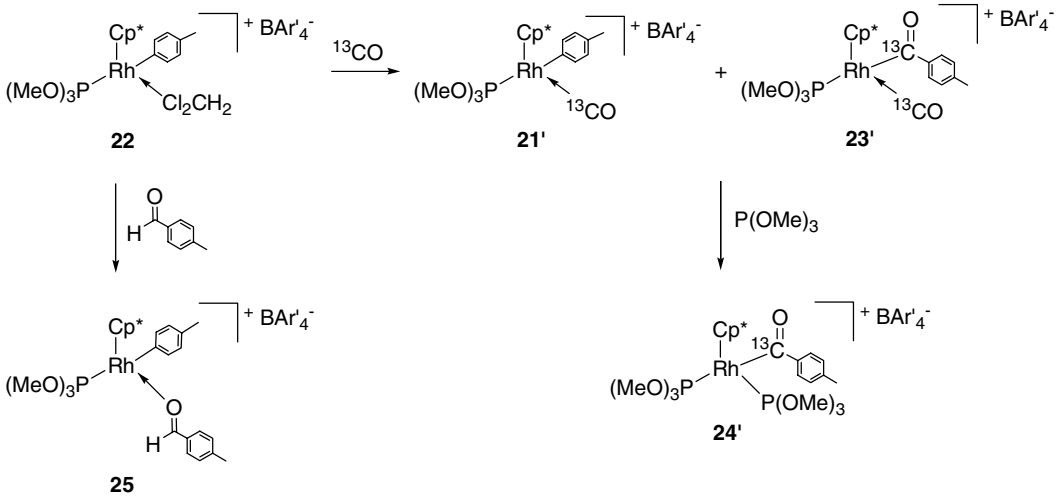
(6)

The corresponding ^{13}C-labeled Rh tolyl carbonyl complex, $[Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(^{13}CO)]BAr'_4$ (**21′**), was generated by an analogous reaction using $[Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(CH_2Cl_2)]BAr'_4$ (**22**), as shown in Scheme 2. The independent synthesis and characterization of **22** is detailed in Section 4. Interestingly, formation of **21′** by exposure of a CD_2Cl_2 solution of **22** to ^{13}CO was accompanied by formation of a rhodium acyl carbonyl complex (**23′**), which results from migratory insertion of carbon monoxide from **21′** followed by trapping with additional ^{13}CO (Scheme 2). Addition of excess $P(OMe)_3$ to a mixture of **21′** and **23′** led to the Rh bis-phosphite acyl complex $[Cp^*(P(OMe)_3)_2Rh(^{13}C(O)C_6H_4CH_3)]BAr'_4$ (**24′**). To generate Rh tolyl aldehyde adduct **25**, excess tolualdehyde was added to a CD_2Cl_2 solution of **22** (Scheme 2). NMR parameters for these species, which have been generated in situ, are summarized in Section 4.

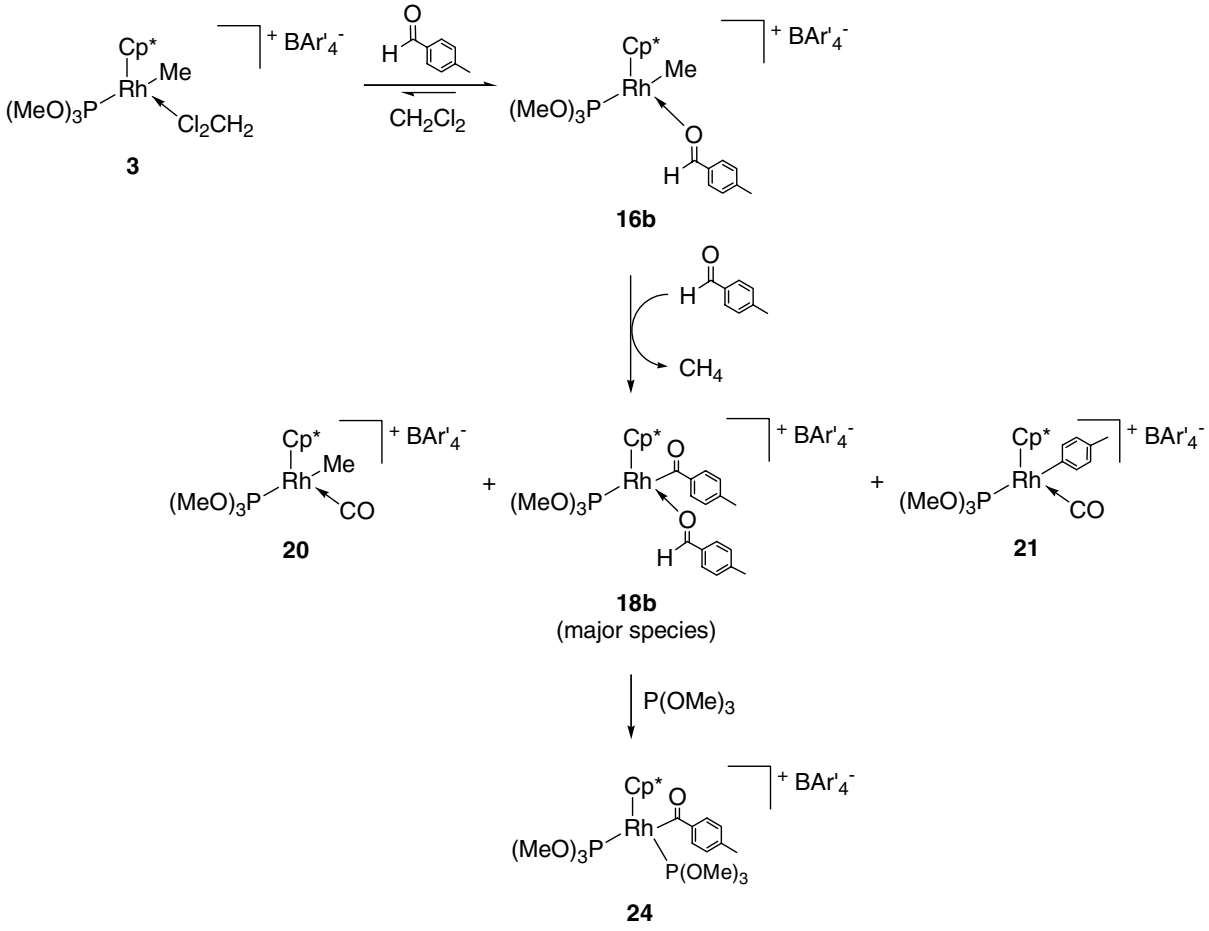
Scheme 3 summarizes a proposed reaction sequence which accounts for the various species observed during the C–H activation and decarbonylation process involving cationic Rh methyl **3** and tolualdehyde. This reaction proceeds over the course of several days at room temperature, and was monitored by NMR spectroscopy.

As noted above, treatment of **3** with excess tolualdehyde (25–50 equivalents) results in immediate formation of Rh aldehyde adduct **16b**. After ca. 4 days, the C–H activation product, Rh acyl aldehyde **18b**, is formed as the major species (Scheme 3). Exchange of free aldehyde with bound aldehyde in **18b** is rapid at room temperature, but distinct aldehydic proton resonances for free and η^1-bound aldehyde could be observed by ^1H NMR spectroscopy at −88 °C. Treatment of **18b** with one equivalent of $P(OMe)_3$ results in complete conversion to the Rh bis-phosphite acyl complex $[Cp^*(P(OMe)_3)_2Rh(C(O)C_6H_4CH_3)]BAr'_4$ (**24**). In addition to the presence of **18b** as the major species, the Rh tolyl carbonyl complex $[Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(CO)]BAr'_4$ (**21**) and the Rh methyl carbonyl complex $[Cp^*(P(OMe)_3)Rh(Me)(CO)]BAr'_4$ (**20**) were also detected, along with small amounts of unidentified rhodium compounds (Scheme 3). Formation of **20** can be attributed to transfer of CO from **21** to either **3** (CO displaces coordinated dichloromethane) or **16b** (CO displaces coordinated aldehyde).

Treatment of **3** with 5 equivalents of tolualdehyde results in formation of **16b**, which decays predominantly to **20** and **21**. In this case we see very little build-up of



Scheme 2.



Scheme 3.

18b due to the low concentration of aldehyde present. After 16 days, the only identifiable product remaining is Rh methyl carbonyl **20**, which presumably, is the most stable species. When anisaldehyde or 4-(trifluoromethyl)benzaldehyde are used in the reaction with **3**, similar reactivity patterns emerge. However, the Rh acyl anisaldehyde adduct (the analogue of **18b**) is more stable than the Rh acyl tolualdehyde adduct (**18b**) due to the

tighter binding of the more basic anisaldehyde. The least basic aldehyde, 4-(trifluoromethyl)benzaldehyde, forms the least stable Rh acyl aldehyde adduct.

3. Conclusions

The work described here has provided new insights into the primary steps involved in C–H activation reactions that occur at cationic Group 9 M(III) centers. It has also revealed significant differences between the way such reactions take place at rhodium and iridium. Specifically, the focus on rhodium in this work has allowed us to measure the rates of exchange of free and bound aldehyde in the rhodium aldehyde complexes **15** and **16**. It has also revealed that in the presence of high concentrations of aldehyde, Rh acyl complexes, formed by decarbonylation of aryl aldehydes, can be stabilized by coordination of a second molecule of aldehyde, leading to cationic Rh acyl aldehyde complexes that are stable enough to be characterized in solution.

Our ability to observe the coordination and exchange of aldehyde at cationic Rh(III), and the subsequent C–H activation reaction, has allowed us to examine and compare the electronic effects on both processes. The factors that contribute to strong or weak aldehyde binding to the Rh^+ center appear to be dominated by σ-donation effects, as one would expect for a relatively electrophilic metal center. The rates of exchange and C–H activation are strongly correlated. The primary influence on the overall C–H activation rate is a ground state effect: when the aldehyde is strongly bound to the Rh^+ center, this binding retards its rearrangement to the transition state for C–H activation. Conversely, a more loosely-held aldehyde rearranges more easily to the transition state, facilitating the C–H activation process. Thus this system reflects a property often noted for enzymes: strong coordination of substrate to an active site does not necessarily promote efficient catalysis, and in fact can have the opposite effect [13]. The optimum situation for catalysis involves relatively weak binding of substrate in the ground state, so that this interaction does not counteract the binding energy of the rearranging substrate to the active site in the transition state.

4. Experimental

4.1. General considerations

Unless otherwise noted, all reactions and manipulations were performed using standard high-vacuum, Schlenk, or drybox techniques. Argon and nitrogen were purified by passage through columns of BASF R3-11 catalyst (Chemalog) and 4 Å molecular sieves. ^1H and ^{13}C NMR chemical shifts were referenced to residual ^1H and ^{13}C NMR signals of the deuterated solvents, respectively. ^{31}P NMR chemical shifts were referenced to an 85% H_3PO_4 sample used as an external standard. Elemental analyses were performed by Atlantic Microlab Inc. of Norcross, GA.

4.2. Materials

All solvents were deoxygenated and dried via passage over a column of activated alumina [14]. Deuterated solvents (Cambridge Isotope Laboratories) were purified by vacuum transfer from CaH_2 and stored over 4 Å molecular sieves. Unless otherwise noted, all chemicals were purchased from Aldrich and used without further purification. ^{13}C-labeled CO was purchased from Cambridge Isotope Laboratories. $NaBAr'_4$ was purchased from Boulder Scientific and used without further purification. Solutions of 1.5 M MeLi and PhLi in Et_2O were purchased from Acros and used without further purification. Organometallic complexes **1** [8], **2** [15], Cp*(P(OMe)$_3$)$RhCl_2$ [9], and Cp*(PMe_3)Rh(Ph)(Cl) [11] have been previously reported and were synthesized according to literature procedures.

4.3. Spectral data for BAr'^-_4

The ^1H and ^{13}C NMR resonances of the BAr'_4 (Ar′ = 3,5-$(CF_3)_2C_6H_3$) counteranion in CD_2Cl_2 were essentially invariant for all cationic complexes discussed here and spectroscopic data are not repeated for each compound. ^1H NMR (400 MHz, CD_2Cl_2) δ 7.73 (s, 8 H, H_{ortho}), 7.57 (s, 4 H, H_{para}). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 161.9 (q, $^1J_{C-B} = 49.8$, C_{ipso}), 135.0 (s, C_{ortho}), 129.0 (q, $^2J_{C-F} = 31.4$, C_{meta}), 124.7 (q, $^1J_{C-F} = 272.6$, CF_3), 117.7 (s, C_{para}).

4.4. Synthesis of $[Cp^*(P(OMe)_3)Rh(Me)(CH_2Cl_2)]BAr'_4$ (**3**)

A vial was charged with 172 mg (0.412 mmol) of **4** and 408 mg (0.461 mmol) of $NaBAr'_4$. The reactants were dissolved in 5 mL of CH_2Cl_2 and the resulting mixture was stirred for 5 min. The contents were filtered and stored at −35 °C for 24 h. Red–orange crystals of **3** were isolated in 55% yield. ^1H NMR (300 MHz, CD_2Cl_2) δ 5.33 (s, CH_2Cl_2), 3.78 (d, $^3J_{P-H} = 11.4$ Hz, 9 H, P(OMe)$_3$), 1.63 (d, $^4J_{P-H} = 4.2$ Hz, 15 H, Cp*), 1.02 (dd, $^3J_{P-H} = 5.5$ Hz, $^2J_{Rh-H} = 1.5$ Hz, 3 H, Me). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 126.9 (d, $^1J_{Rh-P} = 268.6$ Hz, P(OMe)$_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 103.3 (s, Cp*–Ar), 54.34 (d, $^2J_{P-C} = 8.0$ Hz, P(OMe)$_3$), 54.19 (s, CH_2Cl_2), 9.16 (d, $^3J_{P-C} = 1.4$ Hz, Cp*–Me), 1.19 (dd, $^2J_{P-C} = 37.1$ Hz, $^1J_{Rh-C} = 22.0$ Hz, Me).

4.5. Synthesis of $Cp^*(P(OMe)_3)Rh(Me)(Cl)$ (**4**)

To a flame-dried Schlenk flask under argon, 2.5 g (6.9 mmol) of $Cp^*(P(OMe)_3)RhCl_2$ was dissolved in 100 mL dry ether. The solution was cooled to −78 °C and methyllithium (7.6 mmol in THF) was added to the solution, which was then brought to room temperature. The reaction was opened to air and quenched with 10 mL of water, the ether phase was removed, and the red/orange product isolated by roto-evaporation. The crude product was dissolved in 20 mL CH_2Cl_2 to which hexanes were added (50 mL) until the solution became cloudy. Red–orange crystals were isolated in 50% yield. ^1H NMR (300 MHz, CD_2Cl_2) δ 3.68 (d, $^3J_{P-H}$ = 11.4 Hz, 9 H, $P(OMe)_3$), 1.61 (d, $^4J_{P-H}$ = 4.1 Hz, 15 H, Cp*), 0.73 (dd, $^3J_{P-H}$ = 5.1 Hz, $^2J_{Rh-H}$ = 2.1 Hz, 3 H, Me). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 138.36 (d, $^1J_{Rh-P}$ = 259.9 Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 100.00 (vt, $^1J_{Rh-C} = {}^2J_{P-C}$ = 4. 2 Hz, Cp*–Ar), 53.00 (d, $^2J_{P-C}$ = 4.38 Hz, $P(OMe)_3$), 8.94 (d, J = 2.25 Hz, Cp*–Me), −2.57 (dd, $^1J_{Rh-C}$ = 22.2 Hz $^2J_{P-C}$ = 20.6 Hz, Me).

4.6. Synthesis of $[Cp^*(PMe_3)Rh(Ph)(CH_2Cl_2)]BAr'_4$ (**6**)

A Schlenk flask was charged with 50 mg (0.117 mmol) of $Cp^*(PMe_3)Rh(Ph)(Cl)$ and 109 mg (0.123 mmol) of $NaBAr'_4$ and sealed with a rubber stopper. The flask was placed in an ice bath and 5 mL of CH_2Cl_2 was introduced via syringe. The contents of the flask were stirred for 5 min and then filtered through Celite supported by a glass frit. The filtrate was concentrated in vacuo and the flask placed in a freezer (−30 °C) for 3 d. Orange–red crystals of **6** (110 mg, 0.082 mmol) were isolated in 70% yield and can be stored at −30 °C for weeks. ^1H NMR (400 MHz, CD_2Cl_2, 0 °C) δ 7.19 (br m, 2 H, Ph), 7.07 (br m, 3 H, Ph), 5.33 (s, CH_2Cl_2), 1.51 (d, $^4J_{P-H}$ = 2.7 Hz, 15 H, Cp*), 1.46 (d, $^2J_{P-H}$ = 10.1 Hz, 9 H, PMe_3). $^{31}P\{^1H\}$ NMR (162 MHz, CD_2Cl_2, 0 °C) δ 1.1 (d, $^1J_{Rh-P}$ = 168.2 Hz, PMe_3). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2, 0 °C) δ 158.3 (dd, $^1J_{Rh-C}$ = 32.0 Hz, $^2J_{P-C}$ = 17.5 Hz, Ph–C_{ipso}), 136.2 (d, $^2J_{Rh-C}$ = 4.6 Hz, Ph–C_{ortho}), 130.2 (s, Ph–C_{meta}), 125.1 (s, Ph–C_{para}), 103.1 (s, Cp*–Ar), 54.1 (s, CH_2Cl_2), 15.31 (d, $^1J_{P-C}$ = 32.0 Hz, PMe_3), 9.66 (s, Cp*–Me).

4.7. Synthesis of $[Cp^*(P(OMe)_3)Rh(Ph)(CH_2Cl_2)]BAr'_4$ (**7**)

In a J-Young NMR tube, 15.9 mg (0.01 mmol) of **3** was dissolved in 0.5 mL of 1.1 M benzene in CD_2Cl_2. After 24 h, the volatile materials were removed to yield a light orange powder in quantitative yields. ^1H NMR (400 MHz, CD_2Cl_2) δ 7.30 (m, 5 H, Ph), 3.74 (d, $^3J_{P-H}$ = 11.2 Hz, 9 H, $P(OMe)_3$), 1.56 (d, $^4J_{P-H}$ = 4.4 Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (162 MHz, CD_2Cl_2) δ 121.7 Hz (d, $^1J_{Rh-P}$ = 268.4 Hz, $P(OMe)_3$).

4.8. Generation of $[Cp^*(P(OMe)_3)Rh(Me)(p\text{-}CH_3C_6H_4CHO)]BAr'_4$ (**16b**)

In a J-Young NMR tube 15.0 mg (0.01 mmol) of **3** was dissolved in 0.5 mL CD_2Cl_2, and tolualdehyde (5 equivalents, 6.0 μL, 0.055 mmol) was added to the solution. At −68 °C, **16b** and the aldehydic protons of both the bound and free aldehyde were observable by NMR spectroscopy. ^1H NMR (300 MHz, CD_2Cl_2, −68 °C) δ 9.11 (s, 1 H, $CH_3C_6H_4CO$-*H*), 3.69 (d, $^3J_{P-H}$ = 11.7 Hz, 9 H, $P(OMe)_3$), 1.64 (d, $^4J_{P-H}$ = 4.2 Hz, 15 H, Cp*), 0.96 (dd, $^3J_{P-H}$ = 5.4 Hz, $^2J_{Rh-H}$ = 1.6 Hz, 3 H, Me). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2, −68 °C) δ 132.1 Hz (d, $^1J_{Rh-P}$ = 266 Hz, $P(OMe)_3$).

4.9. Generation of $[Cp^*(P(OMe)_3)Rh(C(O)C_6H_4CH_3)(p\text{-}CH_3C_6H_4CHO)]BAr'_4$ (**18b**)

In a J-Young NMR tube 15.0 mg (0.01 mmol) of **3** was dissolved in 0.5 mL CD_2Cl_2 and 50 μL of tolualdehyde was added to the solution. After 3 days, the solution was cooled to −68 °C to allow for the resolution (by NMR spectroscopy) of the aldehydic proton of bound aldehyde in **18b**.^1H NMR (300 MHz, CD_2Cl_2, −68 °C) δ 9.58 (s, 1 H, $CH_3C_6H_4CO$–*H*), 3.81 (d, $^3J_{P-H}$ = 11.1 Hz, 9 H, $P(OMe)_3$), 1.71 (d, $^4J_{P-H}$ = 5.3 Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2, −68 °C) δ 115.4 Hz (d, $^1J_{Rh-P}$ = 235 Hz, $P(OMe)_3$).

4.10. Synthesis of $[Cp^*(PMe_3)Rh(C_6H_4CH_3)(CO)]BAr'_4$ (**19**)

A Schlenk flask was charged with 30 mg (0.023 mmol) of **1** and 1 mL of dichloromethane. A dichloromethane solution of tolualdehyde (0.115 mmol) was added via syringe and the contents of the flask were allowed to stir overnight. To afford crystals, 1 mL of pentane was added and the flask placed in a freezer at −30 °C. After 6 d, 12 mg (0.0093 mmol) of X-ray quality orange crystals were isolated in 39% yield. ^1H NMR (400 MHz, CD_2Cl_2) δ 6.99 (d, ^3J = 7.7 Hz, 2 H, tolyl-Ar), 6.91 (d, $^3J_{H-H}$ = 7.7 Hz, 2 H, tolyl-Ar), 2.28 (s, 3 H, tolyl-Me), 1.84 (d, $^4J_{P-H}$ = 2.9 Hz, 15 H, Cp*), 1.50 (d, $^2J_{P-H}$ = 10.8 Hz, 9 H, PMe_3). $^{31}P\{^1H\}$ NMR (162 MHz, CD_2Cl_2) δ 4.1 (d, $^1J_{Rh-P}$ = 129.1 Hz, PMe_3). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 188.8 (dd, $^1J_{Rh-C}$ = 72.5 Hz, $^2J_{P-C}$ = 21.9 Hz, CO), 138.5 (br m, C_{ipso} of tolyl-Ar), 136.0 (s, tolyl-Ar), 131.9 (s, tolyl-Ar), 130.1 (s, tolyl-Ar), 107.6 (s, Cp*–Ar), 20.59 (s, tolyl-Me), 16.43 (d, $^1J_{P-C}$ = 35.6 Hz, PMe_3), 9.89 (s, Cp*–Me). *Anal.* Calc. for $C_{53}H_{43}OBF_{24}PRh$: C, 49.10; H, 3.34. Found: C, 48.93; H, 3.12%.

4.11. Synthesis of $[Cp^*(P(OMe)_3)Rh(p\text{-}C_6H_4CH_3)(CH_2Cl_2)]BAr'_4$ (**22**)

In the glove box, a vial was charged with 36 mg (0.075 mmol) of $Cp^*(P(OMe)_3)Rh(C_6H_4\ CH_3)(Cl)$ (see below for synthesis of this compound) and 72 mg (0.081 mmol) of $NaBAr'_4$. The reactants were dissolved in 2 mL of CH_2Cl_2. The contents were filtered and stored at −35 °C for 24 h. An orange powder was isolated in 40% yield. ^1H NMR (300 MHz, CD_2Cl_2) δ 6.95 (d, $J = 8.1$ Hz, 2 H, tolyl-H), 7.26 (d, J = 7.2 Hz, 2 H, tolyl-H), 3.68 (d, $^3J_{P-H} = 10.8$ Hz, 9 H, $P(OMe)_3$), 2.24 (s, 3 H, tolyl-CH_3), 1.48 (d, $^4J_{P-H} = 4.5$ Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 126.8 Hz (d, $^1J_{Rh-P} = 260$ Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (75.5 MHz, CD_2Cl_2) δ 131.1 (s, tolyl-Ar) 102.6 (s, Cp*–Ar), 54.72 (d, $^2J_{P-C} = 7.6$ Hz, $P(OMe)_3$), 20.44 (s, tolyl-Me), 8.71 (s, Cp*–Me).

4.12. Synthesis of $Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(Cl)$

To a flame dried Schlenk flask under argon, $Cp^*(P(OMe)_3)RhCl_2$ was dissolved in 40 mL dry THF and the resulting solution was cooled to −78 °C. Tolyl-lithium (2.3 equivalents, 321 mg, 3.28 mmol) [16] was dissolved in 10 mL of THF, and the resulting solution was cooled to −78 °C and cannula-transferred into a stirred solution of $Cp^*(P(OMe)_3)RhCl_2$ at which point the color changed from red to orange. After being brought to room temperature the solvent was removed to yield an orange foam, which was then extracted with 3×20 mL toluene and filtered through celite. Concentration of this solution under vacuum yielded a red oil which, upon addition of pentane and cooling to −78 °C afforded an orange powder in 46% yield. ^1H NMR (300 MHz, CD_2Cl_2) δ 7.36 (d, $J = 7.2$ Hz, tolyl-H), 6.80 (d, $J = 7.6$ Hz, tolyl-H), 3.49 (d, $^3J_{P-H} = 11.4$ Hz, 9 H, $P(OMe)_3$), 2.22 (s, tolyl-Me), 1.50 (d, $^4J_{P-H} = 4.1$ Hz, 15 H, Cp*), $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 135.56 (d, $^1J_{Rh-P} = 247.0$ Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 139.41 (s, tolyl-Ar), 131.97 (s, tolyl-Ar), 128.93 (s, tolyl-Ar), 101.60 (d, $J = 4.6$ Hz, Cp*–Ar), 53.66 (d, $^3J_{P-C} = 4.6$ Hz, $P(OMe)_3$), 21.14 (s, tolyl-*C* H_3), 9.29 (d, $J = 1.61$ Hz, Cp*–Me).

4.13. Synthesis of $[Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(p\text{-}CH_3C_6H_4CHO)]\ BAr'_4$ (**25**)

In a J-Young NMR tube 15.0 mg (0.010 mmol) of **22** was dissolved in 0.5 mL CD_2Cl_2 and 25 μL of tolualdehyde was added to the solution. The solution was cooled to −68 °C to allow for the resolution of the aldehydic proton of bound aldehyde. ^1H NMR (300 MHz, CD_2Cl_2, −68 °C) δ 8.98 (s, *p*-$CH_3C_6H_4CO$-*H*), 6.95 (d, J = 7.7 Hz, 2 H, tolyl-H), 7.26 (d, partially obscured, 2 H, *m*-Ar–H), 3.68 (d, $^3J_{P-H} = 10.8$ Hz, 9 H, $P(OMe)_3$), 2.13 (s, 3 H, tolyl-CH_3), 1.50 (d, $^4J_{P-H} = 4.5$ Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2, −68 °C) δ 126.8 Hz (d, $^1J_{Rh-P} = 260$ Hz, $P(OMe)_3$).

4.14. Generation of $[Cp^*(P(OMe)_3)Rh(Me)(^{13}CO)]BAr'_4$ (**20′**)

In a J-Young NMR tube 15.0 mg (0.011 mmol) of **3** was dissolved in 0.5 mL CD_2Cl_2. The solution was subject to three freeze–pump–thaw cycles, at which point the headspace of the tube was backfilled with ^{13}CO. Upon shaking of the tube, the solution turned from orange to light yellow. ^1H and ^{31}P NMR spectroscopy showed complete conversion of **3** to **20′**. ^1H NMR (300 MHz, CD_2Cl_2) δ 3.77 (d, $^3J_{P-H} = 12.0$ Hz, 9 H, $P(OMe)_3$), 1.87 (d, $^4J_{P-H} = 4.8$ Hz, 15 H, Cp*), 0.78 (dd, $^3J_{P-H} = 3.9$ Hz, $^2J_{Rh-H} = 2.1$ Hz, 3 H, Me). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 121.6 Hz (d, $^1J_{Rh-P} = 217$ Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 187.1 (dd, $^1J_{Rh-C} = 70.7$ Hz, $^2J_{P-C} = 32.0$ Hz, ^{13}CO).

4.15. Generation of $[Cp^*(P(OMe)_3)Rh(C_6H_4CH_3)(^{13}CO)]BAr'_4$ (**21′**)

A J-Young tube with 35 mg of **22** in 0.5 mL CD_2Cl_2 was freeze–pump-thawed three times and backfilled with ^{13}CO. The solution was shaken, and excess ^{13}CO was evacuated from the headspace and backfilled with argon while the solution was frozen. ^1H, ^{13}C and ^{31}P NMR spectroscopy showed the presence of both **21′** and **23′** (see below) in solution. ^1H NMR (300 MHz, CD_2Cl_2) δ 6.98 (d, $J = 7.8$ Hz, 2 H, tolyl-H), 7.05 (d, J = 7.8 Hz, 2 H, tolyl-H), 3.63 (d, $^3J_{P-H} = 12.0$ Hz, 9 H, $P(OMe)_3$), 2.25 (s, 3 H, tolyl-CH_3), 1.77 (d, $^4J_{P-H} = 4.8$ Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 116.9 Hz (dd, $^1J_{Rh-P} = 215$ Hz, $^2J_{P-C} = 32.8$ Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 187.5 (dd, $^1J_{Rh-C} = 68.3$ Hz, $^2J_{P-C} = 38.4$ Hz, ^{13}CO).

4.16. Generation of $[Cp^*(P(OMe)_3)Rh(^{13}C(O)\text{-}C_6H_4CH_3)(^{13}CO)]BAr'_4$ (**23′**)

A J-Young tube charged with 35 mg of **22** in 0.5 mL CD_2Cl_2. The contents were freeze–pump-thawed three times and backfilled with ^{13}CO. The solution was shaken, and excess ^{13}CO was evacuated from the headspace and backfilled with argon while the solution was frozen. ^1H, ^{13}C and ^{31}P NMR spectroscopy showed the presence of both **21′** and **23′** in solution. ^1H NMR (300 MHz, CD_2Cl_2) δ 7.31 (m, 4 H, Ar–H), 3.74 (d, $^3J_{P-H} = 11.7$ Hz, 9 H, $P(OMe)_3$), 2.39 (s, 3 H, tolyl-CH_3), 1.88 (d, $^4J_{P-H} = 3.9$ Hz, 15 H, Cp*). $^{31}P\{^1H\}$ NMR (121.5 MHz, CD_2Cl_2) δ 114.7 (ddd, $^1J_{Rh-P} = 226$ Hz, $^2J_{P-C} = 35.2$ Hz, $^2J_{P-C} = 12.1$ Hz, $P(OMe)_3$). $^{13}C\{^1H\}$ NMR (101 MHz, CD_2Cl_2) δ 223.6 (ddd, $^1J_{Rh-C} =$

23.3 Hz, $^{2}J_{P-C}$ = 10.9,$^{2}J_{C-C}$ = 3.0 Hz, Rh–acyl-^{13}CO), 188.5 (ddd, $^{1}J_{Rh-C}$ = 74.7 Hz, $^{2}J_{P-C}$ = 34.8Hz,$^{2}J_{C-C}$ = 3.0 Hz, Rh–^{13}CO).

4.17. Generation of [Cp*(P(OMe)$_3$)$_2$Rh(^{13}C(O)C$_6$H$_4$CH$_3$)]BAr′$_4$ (24′)

A J-Young tube containing a mixture of **21′** and **23′** in CD_2Cl_2 solution (product from synthesis of **21′**) was brought into the glove box where 3.1 μL of trimethyl phosphite was introduced. After 1 day at room temperature, the resulting yellow solution was decanted from precipitate, at which point **24′** was the only species detected in solution. Alternatively, **24′** can be generated by the addition of trimethyl phosphite to a solution of **18b**. ^{1}H NMR (300 MHz, CD_2Cl_2) δ 7.35 (m, 2 H, tolyl-H$_{ortho}$), 7.19 (d, J = 8.1 Hz, 2 H, tolyl-H$_{meta}$), 3.72 (t, J = 5.7 Hz, 18 H, P(OMe)$_3$), 2.39 (s, 3 H, tolyl-CH$_3$), 1.66 (t, $^{4}J_{P-H}$ = 4.6 Hz, 15 H, Cp*). ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2) δ 119.1 (dd, $^{1}J_{Rh-P}$ = 244 Hz, $^{2}J_{P-C}$ = 11.9 Hz, P(OMe)$_3$). ^{13}C{^{1}H} NMR (75.5 MHz, CD_2Cl_2) δ 233.21 (dt, $^{1}J_{Rh-C}$ = 29.1 Hz, $^{2}J_{P-C}$ = 12.2 Hz, Rh–^{13}*C*O-tolyl), 142.90 (s, tolyl-Ar), 128.8 (br d, tolyl-Ar), 128.5 (br d, tolyl-Ar), 125.1 (s, tolyl-Ar), 106.1 (m, Cp*–Ar), 55.17 (m, P(OMe)$_3$), 21.27 (tolyl-Me), 9.67 (s, Cp*–Me).

4.18. Kinetics of C–H activation reactions of aldehydes using 1 and 3

Reactions using 10–20 mg of **1** or **3** (0.03 M) with aldehydes (1.5 M) were carried out in J-Young NMR tubes in CD_2Cl_2. Values of k_{obs} were determined by integration of the rhodium–methyl and Cp* peaks relative to the invariant BAr'_4 peaks during reaction of **1** and **3** with 50 equivalents of aldehyde over the course of days at room temperature.

4.19. Determination of $\Delta G^{\ddagger}$ for dissociative exchange of aldehydes in 15 and 16

Solutions of 10 mg of **1** or **3** in CD_2Cl_2 were combined with 5 equivalents of aldehyde and cooled to −88 °C. At this temperature, the natural $w_{1/2}$ of the aldehydic proton was determined. The $w_{1/2}$ was again measured at a temperature where the width had reached 5–10 times the natural line width. Rate constants for exchange and $\Delta G^{\ddagger}$ were calculated from this data using the slow exchange equation $k = \pi(\Delta w)$.

4.20. Crystallographic studies

For complexes **6** and **19**, data were collected at −100 °C on a Bruker SMART diffractometer, using the omega scan mode. Crystal data and collection parameters are given in Table 7. All computations were performed using the NRCVAX suite of programs [17].

Abstract

The photophysical and photochemical properties of a series of rhenium(I) tricarbonyl complexes with photoisomerizable ligands (styryl and azobenzene substituted 2,2′-bipyridines (bpy); a pyridyl substituted dithienylperfluorocyclopentene (py-DTPCP)) are reported. A complex with a 4,4′-distyryl-bpy ligand exhibits photoswitchable luminescence, but decomposes over time when exposed to the UV wavelengths required for *trans* ↔ *cis* photoisomerization of the styryl moieties. A rhenium(I) tricarbonyl 1,10-phenanthroline(phen) complex with the py-DTPCP ligand in its open form exhibits yellow Re(I)-phen MLCT luminescence. Upon 350-nm irradiation, py-DTPCP photocyclizes, thereby quenching the MLCT emission; 620-nm light triggers the reverse reaction, and the luminescence is fully recovered.

1. Introduction

The luminescence and photoredox properties of rhenium(I) tricarbonyl diimines have been extensively investigated over the past 30 years [1–3]. Such complexes are being used as luminescent (redox) probes in proteins [4,5], chemical sensors [6,7] and in new functional materials [8–11]. We have synthesized a series of rhenium(I) tricarbonyl diimines with photoisomerizable ligands and shown that some of them can function as photoswitchable systems (Scheme 1).

2. Experimental

Physical measurements including infrared spectroscopy, mass and ^{1}H NMR spectroscopy, as well as optical absorption and luminescence spectroscopy were performed as described in [12].

1 was crystallized as yellow plates by slow diffusion of pentane into a dichloromethane solution at room temperature. **3** was crystallized as red needles by the same method. X-ray diffraction and structure solution/refinement were performed as described in [12].

2.1. Materials

Trans,*trans*-4,4′-distyryl-2,2′-bipyridine (*tt*-distybpy) was synthesized from 4,4′-dimethyl-2,2′-bipyridine and benzaldehyde as described in [13].

Trans-4-styryl-2,2′-bipyridine (*t*-stybpy) was prepared in an analogous reaction using 4-methyl-2,2′-bipyridine as the starting material. The latter was prepared following a published procedure [14]. ESI-MS *m*/*z*: 259.0 ($M + H^+$), 281.2 ($M + Na^+$). ^{1}H NMR ($CDCl_3$). δ 8.71 (d, 1H, 4.8 Hz), 8.64 (d, 1H, 5.7 Hz), 8.52 (s, 1H), 8.43 (d, 1H, 7.8 Hz), 7.82 (t, 1H, 6.0 Hz),

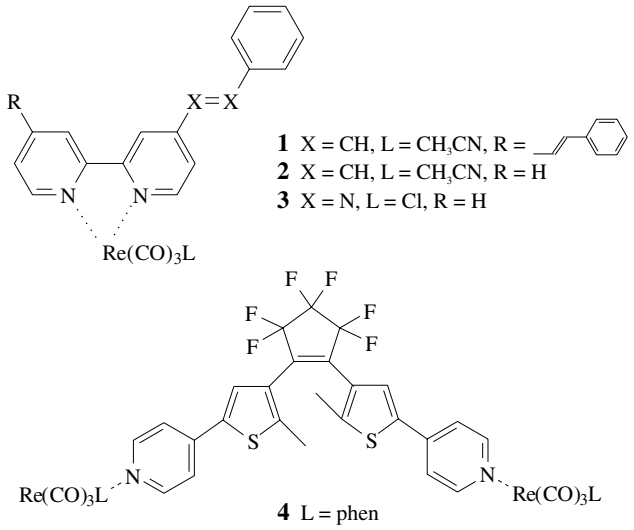

Scheme 1.

7.55 (d, 2H, 7.5 Hz), 7.43 (1H, A of AB, 16.5 Hz), 7.45-7.32 (m, 5H), 7.11 (B of AB, 1H, 16.5 Hz).

4-Phenylazo-2,2′-bipyridine (4-PAbpy) was made from 4-amino-2,2′-bipyridine and nitrosobenzene following a published protocol for the synthesis of phenylazopyridines [15]. 4-Amino-bpy was prepared as described in [16]. ESI-MS *m/z*: 261.0 ($M + H^+$). ^1H NMR ($CDCl_3$). δ 8.86 (d, 1H, 4.8 Hz), 8.82 (s, 1H), 8.74 (d, 1H, 4.5 Hz), 8.47 (d, 1H, 8.1 Hz), 8.00 (d, 2H, 4.2 Hz), 7.85 (t, 1H, 6.9 Hz), 7.57-7.52 (m, 3H), 7.74 (d, 1H, 5.4 Hz), 7.35 (t, 1H, 6.9 Hz).

The dithienylperfluorocyclopentene (py-DTPCP) ligand was synthesized following [17], and the rhenium complexes were prepared from $Re(CO)_5Cl$ as described in [3].

*[[Re(phen)(CO$_3$)]$_2$(py-DTPCP)](PF$_6$)$_2$ (**4**).* ESI-MS *m/z*: 1566.5, 1567.5, 1568.5, 1569.5 ($M^{2+} + PF_6^-$), 970.8, 972.9 ($M^+ - Re(phen)(CO)_3$). ^1H NMR (CD_3CN): δ 9.61 (d, 4H, 5.7 Hz), 8.84 (d, 4H, 8.7 Hz), 8.17 (s, 4H), 8.13 (d, 4H, 5.1 Hz), 8.15-8.10 (m, 4H), 7.51 (s, 2H), 7.25 (d, 4H, 6.6 Hz), 1.81 (s, 6H).

3. Results and discussion

Fig. 1 shows the X-ray crystal structure of the BF_4^- salt of **1**. The *tt*-distybpy ligand is nearly planar; the C_7–C_8–C_{18}–C_{19} and C_{12}–C_{13}–C_{26}–C_{31} dihedral angles are 10° and 17°, i.e., *tt*-distybpy shows a high degree of π-conjugation. Nonetheless, the energetic position, bandshape, and lifetime (90 ± 10 ns) of the luminescence of a deaerated acetonitrile solution of **1** (left part of Fig. 2, solid line) are indicative of a lowest excited state with predominant MLCT (metal-to-ligand charge transfer) character. In absorption, the MLCT band is hidden below the more intense *tt*-distybpy π–π* systems. 400-nm irradiation leads to *trans* → *cis* (*t* → *c*) photoisomerization of the styryl moieties on the *tt*-distybpy ligand; ^1H NMR experiments reveal that this isomerization is moderately efficient for the first styryl substituent (*tt* → *tc* quantum yield: 0.23) and inefficient for the second substituent (*tt* → *cc* and *tc* → *cc* quantum yield <0.05). After long irradiation times (30 min; photon flux 8×10^{15} s^{-1}), a steady state comprised of roughly 55% *tt*, 40% *tc*, and 5% *cc* isomers is reached. The absorption spectrum of this solution (Fig. 2, dashed line) shows weaker low energy features and a stronger high energy (>36 000 cm^{-1}) band than the 100% *tt*-isomer solution, consistent with the loss of π-conjugation typically associated with *t* → *c* isomerization in styrene and azoben-

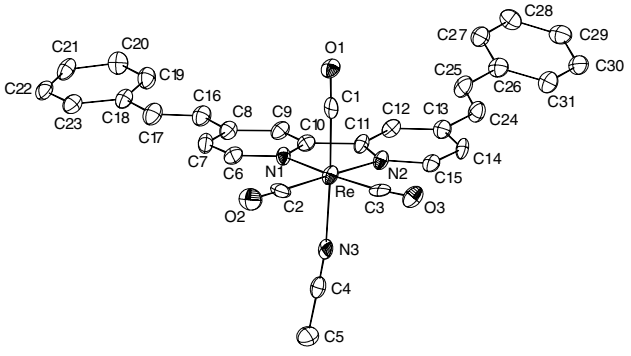

Fig. 1. X-ray crystal structure of the cation of **1**. Displacement ellipsoids are drawn to the 50% probability level. H-atoms are omitted for clarity. Crystal system: triclinic, space group P-1, cell parameters: $a = 10.0913(17)$ Å, $b = 12.606(2)$ Å, $c = 14.528(2)$ Å, $\alpha = 100.985(2)°$, $\beta = 107.128(2)°$, $\gamma = 90.488(2)°$. $V = 1729.7(5)$ Å^3, $Z = 2$, $\rho = 1.783$ g/cm^3. Collection parameters: Mo Kα radiation (0.71073 Å), $T = 100$ K, 27 258 reflections, 7728 independent reflections. Refinement: least-squares fit on F^2, 445 parameters, $R[F^2 > 2\sigma(F^2)]$: 0.0536, R(all data): 0.0872, Goodness-of-fit: 1.887. CCDC deposition number: 214272.

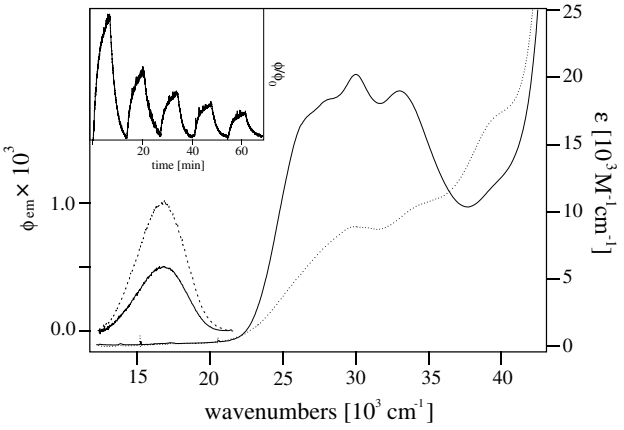

Fig. 2. Luminescence (left) and absorption (right) spectra of a dichloromethane solution of **1** before (solid line) and after (dashed line) 400-nm irradiation. The inset plots the luminescence intensity as a function of irradiation time at 400 nm (increasing intensities) and 260 nm (decreasing intensities).

zene derivatives: in $[Re(phen)(CO)_3(dpe)]^+$, dpe = 1,2-di(4-pyridyl)ethylene, the dihedral angle between the two dpe-pyridyl moieties increases from 16° to 51° upon $t \rightarrow c$ photoisomerization [12], resulting in a ~4000 cm^{-1} blue shift of the lowest dpe π–π* transitions. The $tt \rightarrow tc$ isomerization in **1** is accompanied by a factor of 2 increase in luminescence quantum yield; the lowest excited state of the *tc*-distybpy complex has purer MLCT (less distybpy π–π*) character, and the luminescence is more competitive with nonradiative relaxation than in the *tt*-distybpy complex. The reverse $c \rightarrow t$ styryl isomerizations are induced by irradiating at 260 nm, decreasing the luminescence quantum yield. Repeated 400- and 260-nm irradiations induce luminescence intensity switchings as shown in the inset of Fig. 2. The maximum emission intensity decreases exponentially with the number of on/off cycles; this is attributed to photochemical decomposition of the sample when exposed to 260-nm light.

Complex **2** exhibits similar photoisomerization behavior: 365-nm irradiation induces *trans* → *cis* isomerization of the styryl substituent ($\phi_{tc} = 0.15$), whereas 250-nm light triggers the reverse process as well as photochemical decomposition. The luminescence is blue shifted by 1000 cm^{-1} with respect to **1**, and its quantum yield is about an order of magnitude higher, in accord with the energy-gap law for rhenium(I) tricarbonyl diimines [18]. The luminescence quantum yield is virtually identical for the *t*- and *c*-stybpy complexes; i.e., the luminescence is not photoswitchable. The stybpy π–π* levels are roughly 3000 cm^{-1} higher in energy than those of distybpy and consequently, in **2**, the lowest excited state is relatively pure MLCT and experiences little perturbation upon photoisomerization of the stybpy ligand.

3 is nonluminescent. The PAbpy ligand has low lying *n*-π* levels, from which nonradiative relaxation to the ground state is the most efficient excited state depopulation mechanism. Neither luminescence nor photoisomerization is competitive with this process. In the crystal structure of **3** [19], the dihedral angle between the bpy and phenyl planes is about 53°, but this appears to be caused by crystal packing.

A dichloromethane solution of **4** with the py-DTPCP ligand in its open form (scheme in Fig. 4) exhibits the absorption spectrum shown in Fig. 3(a) (dashed line). The weak shoulder around 25 000 cm^{-1} is the Re(I)-phen MLCT. The more intense bands at higher energy are py-DTPCP (29 000 cm^{-1}) and phen (35 000 cm^{-1}) ligand π–π* absorptions. On 400-nm irradiation, this compound exhibits yellow MLCT emission as shown in Fig. 3(b) (dashed line). Excitation into the py-DTPCP absorption band at 350 nm induces a photocyclization reaction, as schematically shown in Fig. 4. ^1H NMR experiments reveal that this isomerization occurs with a quantum yield of about 0.1, and extended irradiation leads to about 85% conversion of the open to the closed py-DTPCP form (^1H NMR spectra in Fig. 4). The cyclization reaction generates a basically planar DTPCP conformation with extended π-conjugation; the resulting closed form of **4** has an intense π–π* absorption band centered at 16 000 cm^{-1} (Fig. 3(a), solid line). These low lying py-DTPCP localized states quench the Re(I)-phen MLCT emission (Fig. 3(b), solid line). The reverse ring-opening reaction is induced after irradiation into the visible py-DTPCP absorption band at 620 nm; thus **4** is converted completely back to its open form, and the MLCT luminescence is fully recovered. Importantly, the MLCT emission can be switched on and off multiple times (Fig. 3(b), inset), i.e., photodecomposition of **4** is not pronounced. In contrast to the work of Lehn and

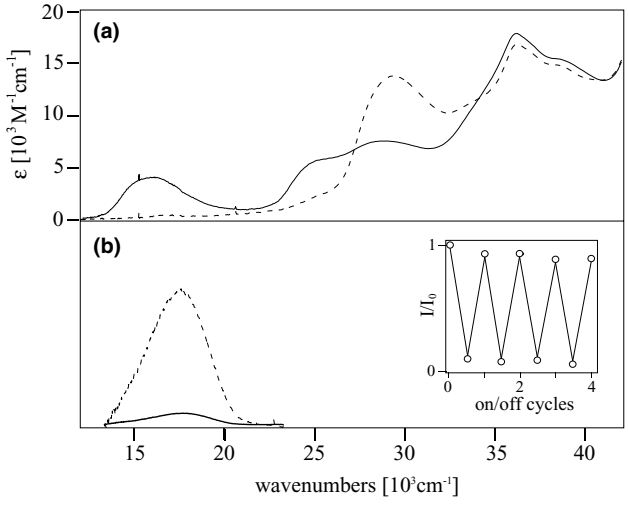

Fig. 3. Absorption (a) and luminescence (b) spectra of a dichloromethane solution of **4** with the py-DTPCP ligand in its open (dashed line) and closed (solid line) forms. The inset illustrates the reversibility of the switching process.

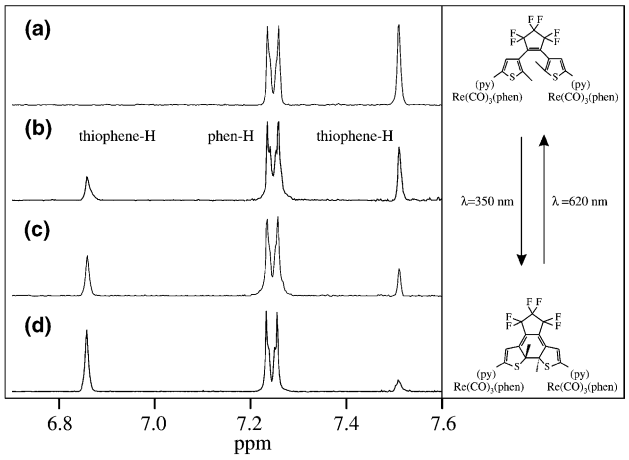

Fig. 4. ^{1}H NMR spectral changes of a CD_3CN solution of **4** during irradiation at 350 nm. Trace a is the spectrum of **4** with the py-DTPCP ligand purely in its open form.

coworkers [20] on similar transition metal/dithienylperfluorocyclopentene systems, we observe MLCT luminescence switching instead of intraligand π–π* emission switching.

4. Summary and conclusions

The behavior of **1** is analogous to that of previously investigated rhenium(I) tricarbonyl complexes with photoisomerizable ligands [12,21,22]: off-switching is induced after irradiation at very short wavelengths (<260 nm), which excites the rhenium(I) complexes into highly dissociative ligand-field excited states, inducing the loss of CO ligands [23]. Photochemical decomposition of **4**, on the other hand, is inefficient for two main reasons: (i) substantially longer irradiation wavelengths (>350 nm) are used to induce photoisomerization; and (ii) photocyclization in dithienylperfluorocyclopentenes is highly reversible [24]. Thus, complex **4** is an example of a reversible luminescent photoswitch.

Abstract

$[Ir(COD)(\mu\text{-}Cl)]_2$ reacts with two equivalents of 1,2-bis(diisopropylphosphino)ethane (dippe) to produce $[Ir(dippe)(\mu\text{-}Cl)]_2$ (**1a**) in yields that are dependent upon the solvent. Its single crystal X-ray structure shows a hinge angle θ of 132.2°, which is larger than in other reported iridium analogs, but smaller than in $[Rh(dippe)(\mu\text{-}Cl)]_2$ (**1b**). $[Ir(dippe)_2][Ir(dippe)Cl_2]$ (**2**), whose anion is without literature precedent, is an intermediate species in the conversion of **1a** to $[Ir(dippe)_2]Cl$ (**3**). Complex **3** reacts with dihydrogen to produce $[Ir(dippe)_2H_2]Cl$ (**4**).

1. Introduction

$[Rh(dippe)(\mu\text{-}H)]_2$ is one of a class of $[L_2Rh]_n(\mu\text{-}H)_n$ compounds that was developed by Fryzuk and coworkers in the 1980s [1]. They found that $[Rh(dippe)(\mu\text{-}H)]_2$ reacts with olefins, phenol, *N*-benzylideneaniline, aldimines, silanes, nitriles and dialkylzinc reagents often to form hydrido-X-bridged rhodium dimers, as well as other products. Interest in $[Rh(dippe)(\mu\text{-}H)]_2$ for homogeneous catalysis arises from the fact that it is an electronically and coordinatively unsaturated molecule that, by all evidence, remains a dimer as it reacts with substrates [2].

One salient feature of rhodium and iridium dimers of the type $M_2(\mu\text{-}X)_2$ is that all but one adopt bent conformations as opposed to being planar molecules [3]. This behavior is attributed to d-orbital diffuseness that allows for better p_z/d_{z^2} overlap between the two metal centers in each of the bridged dimers [4]. The choice of the bridging atom influences the degree of bending, as well.

In the course of the investigation of the reactions between $[Rh(dippe)(\mu\text{-}H)]_2$ and dibenzothiophenic substrates [5], we became interested in the unknown iridium analog, $[Ir(dippe)(\mu\text{-}H)]_2$. Consequently, $[Ir(dippe)(\mu\text{-}Cl)]_2$ (**1a**) was synthesized and characterized for the first time [6] with the intent that it would provide a reactive precursor for $[Ir(dippe)(\mu\text{-}H)]_2$. Herein, is a report on the synthesis, structural characteristics and reactivity of $[Ir(dippe)(\mu\text{-}Cl)]_2$, a secondary product that was identified as $[Ir(dippe)_2][Ir(dippe)Cl_2]$, and $[Ir(dippe)_2]Cl$, as well as reactions with dihydrogen.

2. Experimental

All operations were performed under a nitrogen atmosphere unless otherwise stated. Benzene, THF

and hexanes were distilled from dark purple solutions of benzophenone ketyl/tetraglyme. Acetonitrile and dichloromethane were dried and distilled over CaH_2. $[Ir(COD)(\mu\text{-}Cl)]_2$ was purchased from Strem Chemicals and dried under vacuum before it was used. 1,2-Bis(diisopropylphosphino)ethane was prepared as described in the literature [7]. A Siemens-SMART 3-Circle CCD diffractometer was used for X-ray crystal structure determination (see Supporting Information for experimental details). Elemental analyses were obtained from Desert Analytics and Complete Analysis Laboratories, Inc. All ^1H, ^{31}P and ^{13}C spectra were recorded on a Bruker Avance400 NMR spectrometer. All ^1H chemical shifts are reported relative to the residual proton resonance in the deuterated solvent. All ^{31}P chemical shifts are reported relative to 85% H_3PO_4.

2.1. Preparation of *[Ir(dippe)(μ-Cl)]$_2$* (**1a**)

Dippe (1.35 g, 5.16 mmol) in approximately 4 mL of CH_3CN was added dropwise to a stirred 50 mL CH_3CN solution of $[Ir(COD)(\mu\text{-}Cl)]_2$ (1.65 g, 2.46 mmol). The solution color changed immediately from yellow to dark green. After 30 min, the solvent was evaporated under vacuum to yield a yellow solid. The solid was washed with CH_3CN and then hexanes to remove $[Ir(dippe)_2][Ir(dippe)Cl_2]$ and other unidentified products to leave a bright yellow solid. The solid was redissolved in THF and the resulting solution was chilled at −30 °C to yield bright yellow crystals (1.97 g, yield = 81.6%). ^1H NMR (THF-d_8, 25 °C): δ 2.01 (m, 8H), 1.26 (dd, J = 7.1, 7.5 Hz, 24H), 1.21 (d, J = 9.6 Hz, 8H), 1.05 (dd, J = 7.0, 6.0 Hz, 24H). $^{13}C\{^1H\}$ NMR (THF-d_8, 25 °C): δ 26.28 (d, J = 32.9 Hz), 23.30 (m), 20.17 (s), 18.91 (s). $^{31}P\{^1H\}$ NMR (THF-d_8, 25 °C): δ 67.80 (s). *Anal.* Calc. for $C_{28}H_{64}Ir_2P_4Cl_2$: C, 34.32; H, 6.58. Found: C, 33.85; H, 6.47%.

2.2. Preparation of *[Ir(dippe)$_2$][Ir(dippe)Cl$_2$]* (**2**)

Dippe (1.156 g, 4.41 mmol) in approximately 4 mL of THF was added dropwise to a stirred 50 mL THF solution of $[Ir(COD)(\mu\text{-}Cl)]_2$ (1.41 g, 2.09 mmol). The solvent was evaporated under vacuum to leave a dark red solid. The solid was washed with hexanes to leave a bright orange-red powder. The powder was redissolved in CH_3CN and vacuum-filtered, which left a yellow solid on the frit and a bright orange-red filtrate. The filtrate was concentrated and then chilled at −30 °C to yield a bright orange-red powder (2.00 g, yield = 77.4%). ^1H NMR (THF-d_8, 25 °C): δ 2.60 (sept, J = 6.9 Hz, 8H), 2.27 (oct, J = 7.5 Hz, 4H), 1.89 (m, 8H), 1.27 (m, 64H), 0.99 (m, 12H). $^{13}C\{^1H\}$ NMR (THF-d_8, 25 °C): δ 29.86 (m), 22.45 (s), 20.97 (m), 20.40 (m), 19.78 (s), 19.25 (m), 19.09 (m). $^{31}P\{^1H\}$ NMR (THF-d_8, 25 °C): δ 65.25 (s), 64.59 (s). *Anal.* Calc. for $C_{42}H_{96}Ir_2P_6Cl_2$: C, 40.60; H, 7.79. Found: C, 40.38; H, 8.05%.

2.3. Preparation of *[Ir(dippe)$_2$]Cl* (**3**)

Dippe (45.0 mg, 0.17 mmol) in THF was added dropwise to a stirred 25 mL THF solution of $[Ir(COD)(\mu\text{-}Cl)]_2$ (84.0 mg, 0.125 mmol). The resulting mixture was stirred for approximately 3 h, during which time an orange solid precipitated. The solvent was evaporated under vacuum and the resulting orange solid was washed, first with diethylether and then with hexanes to remove excess dippe, and then dried under vacuum (150.9 mg, yield = 63.9%). ^1H NMR (CD_2Cl_2, 25 °C): δ 2.42 (sept, J = 7.0 Hz, 8H), 1.68 (br t, J = 6.7 Hz, 8H), 1.22 (m, 48H). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 25 °C): δ 29.36 (pseudo quint, J = 7.4 Hz), 21.98 (s), 20.15 (quint, J = 12.2 Hz), 19.25 (s). $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 25 °C): δ 64.93 (s). *Anal.* Calc. for $C_{29}H_{66}IrP_4Cl_3$ (includes one molecule of CH_2Cl_2): C, 41.60; H, 7.95. Found: C, 41.87; H, 8.14%.

2.4. Preparation of *[Ir(dippe)$_2$H$_2$]Cl* (**4**)

Approximately 760 mm Hg of H_2 was added to a storage flask that contained a degassed CH_3CN solution of **3** (65.5 mg, 0.069 mmol). Within 15 min, the solution color had changed from bright orange to yellow and after one day it was colorless. The solvent was removed under vacuum and a colorless solid was obtained (41.6 mg, yield = 63.3%). ^1H NMR (CD_3CN, 25 °C): δ 2.18 (m, 8H), 1.72 (m, 8H), 1.15 (m, 42H), 0.94 (dd, J = 15.3, 7.0 Hz, 6H), −15.16 (dm, J = 90.8, 16.8 Hz, 2H). $^{13}C\{^1H\}$ NMR (CD_3CN, 25 °C): δ 30.25 (m), 28.18 (m), 26.96 (m), 25.87 (m), 24.80 (m), 23.20 (m), 21.43 (s), 21.08 (s), 19.79 (s), 19.66 (s), 19.06 (m), 18.81 (s), 17.77 (s). $^{31}P\{^1H\}$ NMR (CD_3CN, 25 °C): δ 53.83 (t, J = 7.5 Hz), 26.16 (m). *Anal.* Calc. for $C_{28}H_{66}IrP_4Cl$: C, 44.58; H, 8.82. Found: C, 44.22; H, 8.61%.

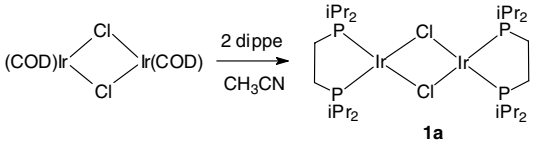
2.5. Preparation of *[Rh(dippe)(μ-Cl)]$_2$* (**1b**)

Using a modification of the literature prep [8], 2.1 equiv. of dippe (568 mg, 2.17 mmol) in THF was added dropwise to a rapidly stirred 50 mL THF suspension of $[Rh(COD)(\mu\text{-}Cl)]_2$ (509 mg, 1.03 mmol). The resulting mixture was stirred for 24 h as a portion of the product precipitated out of solution. The solvent was evaporated to dryness under vacuum and the solid was washed three times with hexanes. The solid was then placed under vacuum for three days (502 mg, 60.7%). ^1H NMR (THF-d_8, 25 °C): δ 2.05 (m, 8H), 1.34 (dd, $J_{(H-H)}$ = 7.1 Hz, $J_{(H-P)}$ = 7.7 Hz, 24H), 1.31 (d, $J_{(H-P)}$ = 14.0Hz, 8H), 1.10 (dd, $J_{(H-H)}$ = 7.0 Hz, $J_{(H-P)}$ = 5.6 Hz, 24H). $^{31}P\{^1H\}$ NMR (THF-d_8, 25 °C): δ 102.20 (d, $J_{(P-Rh)}$ = 199.9 Hz).

3. Results

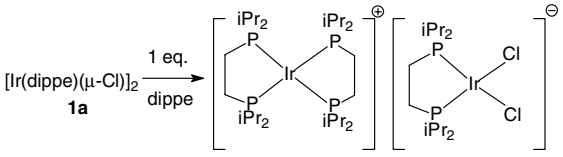
3.1. Synthesis of complexes

The reaction between $[Ir(COD)(\mu\text{-}Cl)]_2$ and two equivalents of dippe to produce $[Ir(dippe)(\mu\text{-}Cl)]_2$ (**1a**) was run in several different solvents under the same experimental conditions (Eq. (1)). The reaction was non-selective in CH_2Cl_2, C_6H_6, THF and acetone in that it produced a large number of phosphorus-containing products as evidenced by ^{31}P NMR spectroscopy. Yet, the reaction was highly selective when conducted in CH_3CN solvent, with a singlet at δ 67.80 in the ^{31}P NMR spectrum for **1a** as the only major product. However, additional side products appeared with increasing reaction times if **1a** was allowed to stir in solution. In CH_2Cl_2, C_6H_6, THF and acetone, both $[Ir(dippe)_2][Ir(dippe)Cl_2]$ (**2**) and $[Ir(dippe)_2]Cl$ (**3**) were formed as prominent secondary products. In THF-d_8, **2** exhibits two singlets at δ 65.25 and 64.54 in the ^{31}P NMR spectrum. The downfield singlet, which corresponds to $[Ir(dippe)_2]^+$, is twice the intensity of the upfield singlet that is produced by the anion. The cation of **3** produces a singlet in the same region of the ^{31}P NMR spectrum at δ 65.25. The choice of solvent also determines the relative amounts of **1a**, **2** and **3** that are formed in this reaction. As Table 1 illustrates, **[3 + 2]**:**1a** is lowest for CH_3CN and highest for acetone. Furthermore, differences in solvent electronic properties fail to account for the observed trend in the ratio of **[3 + 2]** to **1a**.

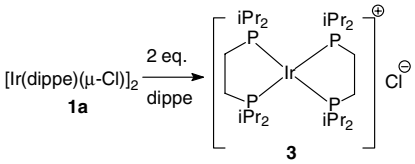


1a (1)

Complex **1a** converts to **3** upon standing in CD_3CN solution. Moreover, **2** appears to be an intermediate species in going from **1a** to **3**. In one experiment, a mixture of **1a**, **2** and **3** in THF-d_8 in a 0.9:1:0.4 ratio was totally converted to **3** when THF-d_8 was removed under vacuum and the mixture was redissolved in CD_3CN. Compound **2** can be synthesized best by adding 1 equiv. of dippe to **1a** (Eq. (2))). Compound **3** can be synthesized cleanly by adding 2 equiv. of dippe to **1a** (Eq. (3)). Complex **2** is sparingly soluble in THF-d_8. Consequently, attempts were made to use CD_3CN and CD_2Cl_2 for the sake of better ^1H and ^{31}P NMR spectra. However, **2** converted to **3** upon dissolution in each of these solvents. Again, this supports the idea that **2** is an intermediate in going from **1a** to **3**.



2 (2)



3 (3)

3.2. X-ray structures

Complex **1a** crystallizes from THF at −30 °C in the $P2_1/n$ space group (Fig. 1). Complex **1a** is bent along the Cl–Cl axis, which creates a dihedral angle θ of 132.2°. Moreover, a slight propeller twist exists in the molecule that is brought about by the ethylene backbone of the terminal dippe ligands. For comparison, the structure was determined for the rhodium analog $[Rh(dippe)(\mu\text{-}Cl)]_2$ (**1b**, Fig. 2), which showed a dihedral angle of 137.1°.

The novel complex salt $[Ir(dippe)_2][Ir(dippe)Cl_2]$ (**2**) whose X-ray crystal structure is shown in Fig. 3, is without literature precedent. While a diphos analog of the cation is known [9], the anion is the first of its kind. It crystallizes from THF at −30 °C in the space group $P2_1/c$. Tables 2 and 3 include a list of bond lengths and angles in **2** that are of interest.

The $[Ir(dippe)_2]^+$ cation is a four-coordinate, tetraphosphine iridium(I) complex with an average Ir–P bond length of 2.3185(34) Å (Fig. 4). Its geometry in the solid state is distorted square-planar with a dihedral

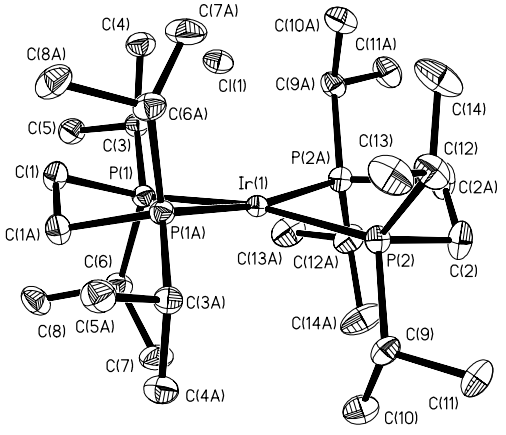

Fig. 4. ORTEP diagram of $[Ir(dippe)_2]Cl$ (**3**). Ellipsoids are shown at the 30% probability level. All hydrogen atoms are omitted for clarity. Selected distances (Å): Ir(1)–P(1), 2.3330(10); Ir(1)–P(2), 2.3220(10).

angle between the P_{11}–Ir–P_{21} and P_{31}–Ir–P_{41} planes of 22.3°. The average dippe bite angle in $[Ir(dippe)_2]^+$ is 83.6°. The cation of **2** displays D_{2h} symmetry upon going from the solid phase into solution, as all isopropyl substituents become equivalent in the ^1H NMR spectrum.

The anion $[Ir(dippe)Cl_2]^-$ has square planar geometry with average Ir–P and Ir–Cl bond lengths of 2.1712(23) and 2.4201(23) Å, respectively. In contrast to $[Ir(dippe)_2]^+$, distortion is minimal. While the iridium center is slightly displaced from the mean IrP_2Cl_2 plane, the greatest deviation, which corresponds to P_{12}, is only −0.0721 Å. Furthermore, the dihedral angle between the P–Ir–P and Cl–Ir–Cl planes is nominal at 4.8°, and the average *trans*-P–Ir–Cl angle is 176.63 (9)°.

The same cation as found in **2** appears in **3**, which has also been structurally characterized. The complex appears as a twisted square plane just as in **2**, with a slightly smaller dihedral angle between the P_1–Ir–P_{1A} and P_2–Ir–P_{2A} planes of 13.8°. The average dippe bite angle in $[Ir(dippe)_2]^+$ is 83.6°, just as in **2**.

3.3. Reaction with dihydrogen

Complex **3** behaves in a like manner to its analog $[Ir(dppe)_2]Cl$ in that it reacts with dihydrogen (Eq. (4)) [9]. Both a crystal structure (CCDC 247139) and ^1H and ^{31}P NMR spectra indicate that the six coordinate Ir^{III} salt $[Ir(dippe)_2H_2]Cl$ (**4**) was formed. The ^1H NMR spectrum in CD_3CN, that is shown in Fig. 5, displays a doublet of multiplets at δ −15.24, which corresponds to the hydride ligands of $[Ir(dippe)_2H_2]^+$. The hydrides couple to the magnetically inequivalent *cis* and *trans* groups of phosphorus atoms. The ^{31}P NMR spectrum in the same solvent consists of a multiplet at δ 53.83 and a broad singlet at δ 26.15.

$$\underset{\mathbf{3}}{[Ir(dippe)_2]Cl} \xrightarrow{H_2} \underset{\mathbf{4}}{[Ir(dippe)_2H_2]Cl} \quad (4)$$

Exposure to UV light labilizes the hydride ligands of $[Ir(dippe)_2H_2]^+$ reversibly to produce $[Ir(dippe)_2]^+$, as illustrated in Scheme 1. The addition of approximately 1 atm of H_2 to a CD_3CN solution of **3** in a resealable NMR tube results in the formation of **4**, which is stable even after the reaction mixture is degassed. When the tube with its contents is irradiated with UV light, the initial orange color returns and is accompanied by the appearance of the singlet at δ 65 in the ^{31}P NMR spectrum, characteristic of **3**. Upon standing, **3** reconverts back to **4**.

4. Discussion

The rhodium dimer $[Rh(dippe)(\mu\text{-}Cl)]_2$ (**1b**) is easily synthesized in high yield from $[Rh(COD)(\mu\text{-}Cl)]_2$, and so it was reasonable to expect similar results for the synthesis of the iridium analog **1a**. In contrast, the synthesis of **1a** from $[Ir(COD)(\mu\text{-}Cl)]_2$ and two equivalents of dippe results in a mixture of products in varying relative amounts that is highly influenced by the choice of solvent. It is especially interesting that two of the products are monomeric salts. The relationship of **1a**, **2** and **3** differ by the dippe:iridium stoichiometry, with ratios of 1:1, 1.5:1 and 2:1, respectively, for these three complexes. The conversion of **1a** to **2** and then **3** has been demonstrated by the addition of dippe. It is interesting, however, that this conversion also occurs if **1a** is allowed to stand in solution, implying that an 'IrCl' fragment is ejected in balancing the stoichiometry for this conversion.

One factor affecting the stability of **1a** is the ability of dippe to stabilize the bridging chloride dimer. For example, EH MO calculations for $[Rh(PH_3)_2(\mu\text{-}Cl)]_2$ and $[Rh(dtbpm)(\mu\text{-}Cl)]_2$ (dtbpm = di-*tert*-butylphosphinomethane) have indicated that P–Rh–P angles that deviate from 90° result in weaker Rh(μ-Cl) bonds. Moreover, experimentally determined Rh(μ-Cl) distances in $[Rh(dtbpm)(\mu\text{-}Cl)]_2$ and $[Rh(P^iPr_3)_2(\mu\text{-}Cl)]_2$, which have P–Rh–P angles of approximately 75° and 105°, respectively, support the theoretical results [10,11]. The former is even known to dissociate into its monomers when it is in solution. Yet, the average bite angle of the dippe ligands in **1a** is only about 4° smaller than the optimal 90°, suggestive that the chelate bite angle is not responsible for the instability of **1a**.

There are other factors that need to be considered, as well, in determining the effect of the terminal dippe ligand on the formation of **1a**. It has been reported that the stabilities of rhodium and iridium $[ML_2(\mu\text{-}X)]_2$ and $[M(LL)(\mu\text{-}X)]_2$ complexes, where X = halide, are affected to a large degree by steric and electronic characteristics of the phosphine. Phosphines that are

sterically demanding and are poor σ-donors favor dimeric products while phosphines that are less sterically demanding and are good σ-donors favor the monomeric products [12]. The cone angle about a phosphorus atom in dippe can be estimated [13] as being between 151° and 160°, rendering it as a sterically demanding ligand that should favor the formation of **1a**. It is worthwhile to note that the syntheses of both $[Ir(dippp)(\mu\text{-}Cl)]_2$ and $[Ir(dtbpp)(\mu\text{-}Cl)]_2$ have been reported, but their X-ray structures were not determined [14].

The hinge angle of **1a** is comparable to those found in other chloro-bridged iridium dimers with terminal phosphines [12,15–17]. A listing of these complexes and their measured hinge angles (θ) is found in Table 4. **1a** possesses the largest angle among the members of the group (132.2°). In regard to other related Ir and Rh analogs that contain a M_2X_2 core, where X = Cl and S, θ has been found to increase by no greater than 1.2° when Rh is replaced with Ir, as illustrated in Table 5. The difference between **1a** and **1b** is larger and in the opposite direction, by about 5° [18–21].

The cation of **2** and **3**, $[Ir(dippe)_2]^+$, bears a resemblance to species such as $[Ir(dppe)_2]^+$, $[Rh(dppe)_2]^+$ and $[Rh(dmpe)_2]^+$ in terms of metal oxidation state, coordination number and connectivity to two bidentate phosphorus ligands [9,22]. Yet, it displays slightly different solid-state structural characteristics when it is a constituent of **3** as opposed to **2**. First, the tetrahedral distortion that is created by the steric interaction between the isopropyl substituents of the dippe ligands is less pronounced for $[Ir(dippe)_2]^+$ in **3** [23,24]. The dihedral angle between the P–Ir–P planes decreases from 22.3° in **2** to 13.8° in **3**. Also, the deviation from the mean Ir–P plane is less in **3**: the iridium center is in the plane while all of the phosphorus atoms are displaced less than 0.2 Å from it. Second, the iridium–phosphorus core of $[Ir(dippe)_2]^+$ is less compact in **3**; the mean Ir–P bond length is approximately 0.05 Å larger.

The fact that the average Ir–P bond length in $[Ir(dippe)_2]^+$ is approximately 0.15 and 0.14 Å longer than the values that are found in the anion of **2** and in **1a**, respectively, can be attributed to two phenomena. First, the longer distance may be a result of the σ-donating ability of dippe that gives rise to a substantially large *trans*-influence. Second, steric interaction between the isopropyl substituents of the dippe ligands may result in the longer bond distances. Evidence for steric repulsion between the isopropyl groups of the opposing dippe ligands is found in the effect that the substitution of one bidentate ligand by two chlorides has on the P–Ir–P angle: the bite angle in $[Ir(dippe)Cl_2]^-$ is approximately 3.4° larger than in $[Ir(dippe)_2]^+$. Furthermore, evidence for a direct relationship between metal–phosphorus bond lengths and phosphine cone angle was found in the study of a series of 19 trialkylphosphine $Cr(CO)_5$ complexes [25]. Of particular relevance to the formation of this anion is the report by Roddick et al. that $[Ir(COD)(\mu\text{-}Cl)]_2$ reacts with silver triflate and dfepe (dfepe = bis-diperfluoroethylphosphinoethane) to give [Ir(dfepe)(COD)] + $[(dfepe)Ir(OTf)]^-$ [26].

The anion, $[Ir(dippe)Cl_2]^-$, is the only example of a Group 9 d^8 metal bisphosphine dichloride complex to be found in the literature. Several rhodium and cobalt bisphosphine dichloride species have been made and structurally characterized, but all of them are neutral with d^7 metal centers [27].

Table 4
Hinge angles, θ, in selected $[IrP_2(\mu\text{-}Cl)]_2$ complexes

Complex	θ (°)	Ref.
$[Ir(dippe)(\mu\text{-}Cl)]_2$	132.2	this work
$[Ir(dtbpm)(\mu\text{-}Cl)]_2$	130	[15]
$[Ir(dfepe)(\mu\text{-}Cl)]_2$	128	[12]
$[Ir(PF_3)_2(\mu\text{-}Cl)]_2$	107	[16]
$[Ir(binap)Cl]_2$	125	[17]

Table 5
Hinge angles, θ, in Rh and Ir analogs with a M_2S_2 core

Complex	Rh	Ir	Ref.
$[M(dippe)(\mu\text{-}Cl)]_2$	137.1	132.2	this work
$[M(COD)(\mu\text{-}SPh)]_2$	114.5	115.0	[18,19]
$[M(COD)(\mu\text{-}S(CH_2)_3NMe_2)]_2$	104.7	105.9	[20,21]

5. Conclusions

In summary, the reaction between $[Ir(COD)(\mu\text{-}Cl)]_2$ and dippe selectively produces **1a** in CH_3CN, but converts to **2** and **3** when allowed to remain in solution. This observed instability is in contrast to its rhodium analog **1b**. The complex salt **2** appears to be an intermediate in going from **1a** to **3**, and is without literature precedent. The salt **3** reacts with dihydrogen to form **4**.

Appendix A. Supplementary material

Tables of complete crystallographic information for compounds **1a**, **1b**, **2**, **3**, and **4** have been deposited with the Cambridge Crystallographic Center, CCDC Nos. 242508–242511 and 247139. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2, IEZ, UK (fax: +44-1233-336-033, email: deposit@ccdc.cam.ac.uk or www:http//www.ccdc.cam.ac.uk). Abstract

Cycloalkeno-1,2,3-selenadiazoles react with a mixture of $[Pd_2(dba)_3]$ (dba = dibenzylideneacetone) and a trialkylphosphine, in toluene under reflux, to yield the complexes $[PdL(PR_3)]$ ($L = SeC(R^1)=C(R^2)N=NC(R^1)=C(R^2)Se$; $R^1–R^2 = (CH_2)_{n-2}$; $n = 6$, 7, 8; R = Et, Bu), which contain a novel Se, N, Se tridentate ligand formed by the coupling of two 1,2,3-selenadiazole molecules; the structures of cyclohexeno-1,2,3-selenadiazole and the product with R = Bu and $n = 6$ have been determined by X-ray crystallography.

1. Introduction

The use of organoselenium compounds as ligands in transition metal coordination chemistry has increased during the last few years, in part as a result of the recognition that they may confer significantly different properties from their sulfur analogues on the resultant complexes [1]. We have previously demonstrated that 1,2,3-selenadiazoles may serve as precursors to a range of selenium-containing ligands in combination with the cyclopentadienylcobalt moiety [2–5], and also reported on the reaction of cycloocteno-1,2,3-selenadiazole with $[Pt(PPh_3)_4]$ [6]. The palladium compound $[Pd(PPh_3)_4]$ behaves differently from its platinum analogue, yielding novel dinuclear diselenolenes [7]. We have now studied the reactivity of a series of cycloalkeno-1,2,3-selenadiazoles (**1a**–**c**) towards palladium(0) trialkylphosphine complexes, generated in situ from $[Pd_2(dba)_3]$ (dba = dibenzylideneacetone), **2**. A preliminary report of part of this work has previously been published [8].

2. Results and discussion

A toluene solution of **2**, four equivalents of one of the 1,2,3-selenadiazoles **1a**–**c**, and two equivalents of triethylphosphine or tributylphosphine, turns deep purple on heating to reflux for one hour. The intensely coloured product **3a**–**c** or **4a**–**c** may be isolated in good yield by column chromatography (Scheme 1). Compounds **3a**–**c**, **4a**–**c** have the general formula $[PdL(PR_3)]$ and contain the first examples of a new type of formally dianionic ligand $L = SeC(R^1)=C(R^2)N=NC(R^1)=C(R^2)Se$, which may be considered as an alicyclic analogue of an azo-dye.

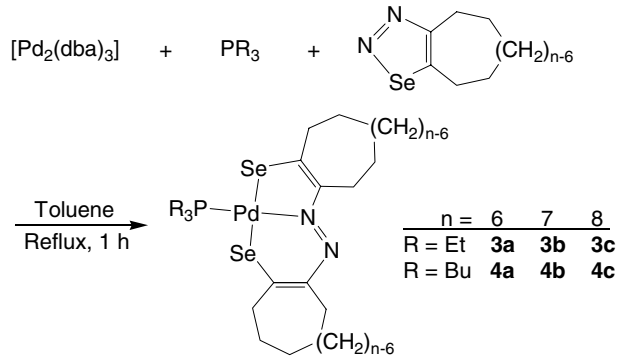
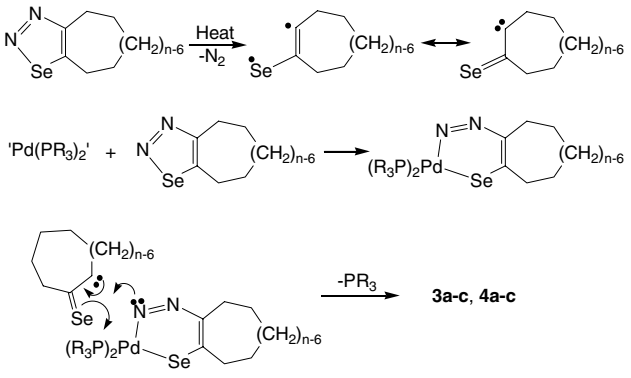


Scheme 1.



Scheme 2.

Although the detailed mechanism of this reaction has not been determined, some inferences can be drawn on the basis of previous work. Most reactions of 1,2,3-selenadiazoles proceed via the elimination of dinitrogen to yield a selenaketocarbene, the fate of which then determines the outcome of the reaction [9]. As far as we are aware, attack by this fragment on another molecule of intact 1,2,3-selenadiazole is unprecedented. We therefore, postulate insertion of palladium(0) into the selenium–nitrogen bond of a 1,2,3-selenadiazole molecule, followed by 1,3 dipolar addition of a selenaketocarbene to the Pd–N bond of the palladium(II) intermediate thus formed (Scheme 2). It is interesting to note that behaviour analogous to that of $[Pd(PPh_3)_4]$ (i.e., formation of the diselenolene) is not observed. This we ascribe to the greater basicity of the trialkylphosphines used in this study, when compared with that of triphenylphosphine. Oxidative addition of palladium(0) is expected to be more favourable in this case.

The molecular structure of **4a** has been determined by X-ray crystallography and is shown in Fig. 1. Here we add details to the preliminary communication [8], giving the results of the final refinement of the structure. Selected bond lengths and angles are listed in Table 1. The palladium atom is square planar coordinated, with the phosphine *trans*- to a nitrogen atom of the novel tridentate Se, N, Se ligand. The positions of the nitrogen atoms in the azo-group, affected by disorder, have been re-examined, leading to improvements with respect to the previous model [8] (see Section 3). Two orientations

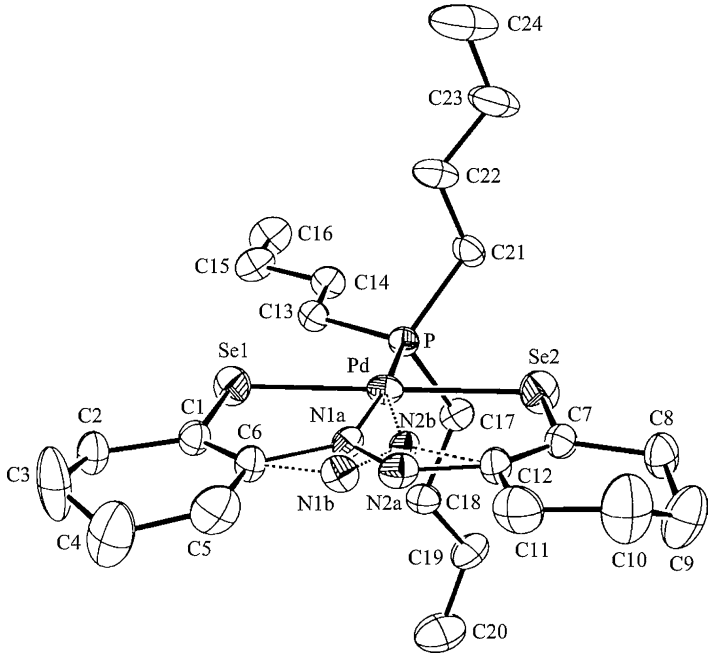


Fig. 1. Molecular structure of $[Pd\{(SeC_6H_8)_2N_2\}(PBu_3)]$, **4a**. 20% probability ellipsoids are shown; H atoms are omitted for clarity. Both the major azo-group orientation (N(1a) and N(2a) sites, thin continuous bonds) and the minor, complementary, orientation (N(1b) and N(2b), dashed bonds) are shown.

[a] The atom pairs N(1a) and N(2a) and, respectively, N(1b) and N(2b) belong to two complementary fractions of the disordered azo-chain. N(1a) and N(2a) have 0.63(4) population parameter.

of the –N=N– group have been identified, according to which either nitrogen atom is coordinated to the metal, although with different probability, one orientation being about twice as probable than the other. Two mutually exclusive N—Pd bond directions result, forming a 22.8(5)° angle with each other. The present picture appears to be overall more detailed and satisfactory than the previous one, that consisted of a single chain orientation with large effects of thermal motion, although even the present model yields a few non-ideal values of bond angles at the connections between the azo-group and the alicyclic rings, presumably as a residual effect of disorder, difficult to account for in greater detail. This may be associated with a "pedal motion", common in compounds such as stilbenes and azobenzenes [10]. The metal and donor atoms deviate by $\leqslant$0.10(2) Å from their best plane, by far the largest deviations being exhibited by the fractional N sites. The twelve atoms associated with the π-system of the ligand (Se–C(C)=C(C)—N=N—C(C)=C(C)—Se) are also coplanar, with deviations $\leqslant$0.14(1) Å from their least-squares plane (this forms a 3.71(6)° angle with the above coordination plane). This part of the molecule is therefore virtually flat, and visually only the three *n*-butyl groups on the phosphine appear to protrude significantly from the coordination plane. The Pd–Se bond lengths in **4a** [2.370(1), 2.371(1) Å] are almost identical to that in [PdCl($SeCH_2CH_2NMe_2$)(PPh_3)] (2.3710(6) Å [11]), and significantly shorter than most of the one hundred thus far reported in the literature (average value 2.45 Å; see for example [12–14]). In the related complexes [Pd{PhSeNC(4-MeC_6H_4)NNC(4-MeC_6H_4)NSePh}(PPh_3)] [15] and [PdCl{5-MeC_6H_3-2-(N=N-4′-MeC_6H_3-2′-SePh)}] [16] the Pd–Se distances are 2.375(1) Å, and 2.4495(4) Å, respectively. The 2.264(2) Å Pd–P distance in **4a** is within the 2.22–2.29 Å range found for Pd(II) complexes with *trans* PBu_3 phosphorus and nitrogen donor atoms [17–19]. The Pd–N distance, of 2.10(2) or 2.13(3) Å, depending on the arrangement of the azo-group being considered, is rather long (cf. 1.98–2.05 Å values in [15–18]). Larger values (2.139(6) and 2.140(5) Å) than the present ones are found for a dimetal system [19] where geometric coordination constraints may play a role; overall the present values seem to be indicative of a rather weak and not strongly directional Pd–N interaction.

For comparative purposes we have also determined the structure of cyclohexeno-1,2,3-selenadiazole, **1a**, as shown in Fig. 2. Suitable crystals were obtained from a hexane solution of the compound at −20 °C. Table 2 lists selected bond lengths and angles. Although this class of compounds has been known for many years, the only example previously to have been structurally characterised is 4,5,6,10,11,12-hexahydrocyclodeca-(1,2-d:6,7-d′)-bis(1,2,3-selenadiazole), **5** [20]. The bond lengths and angles in the heterocyclic ring of **1a** are almost identical to those observed in **5**, and similar to those found for the coordinating heterocyclic molecule in the metal complex pentacarbonyl(4-methyl-1,2,3-selenadiazole)chromium [21] (bond distances in the heterocyclic ring of **1a** are, overall, 0.018 Å larger than those in the coordinating molecule of the latter compound). The structure of **1a** is essentially planar, with only the outer carbon atoms in the hydrocarbon ring deviating slightly (C(4) by 0.23(2) Å and C(5) by 0.30(2) Å, in opposite directions) from the notional molecular plane.

If features of the five-membered heterocyclic ring present in the structures of both **1a** and **4a** are com-

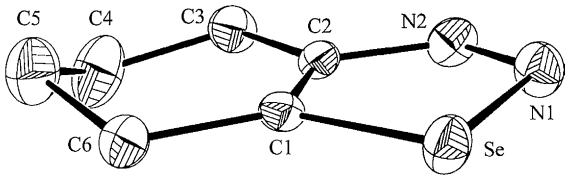

Fig. 2. Molecular structure of cyclohexeno-1,2,3-selenadiazole, **1a**. 20% probability ellipsoids are shown; H atoms are omitted for clarity.

Table 2
Selected bond lengths (Å) and angles (°) in the structure of **1a**

Bond lengths			
C(1)–Se	1.824(11)	Se–N(1)	1.888(10)
N(1)–N(2)	1.260(13)	N(2)–C(2)	1.394(14)
C(1)–C(2)	1.33(2)		
Bond angles			
C(1)–Se–N(1)	86.4(4)	Se–N(1)–N(2)	110.8(7)
N(1)–N(2)–C(2)	116.5(9)	N(2)–C(2)–C(1)	116.0(1.0)
C(2)–C(1)–Se	110.3(8)		

pared, the Se–C bond is found to be 0.04 Å longer and the C=C bond possibly shorter (by 0.01 Å) in **4a**. This may be understood in terms of the loss of the aromatic character of **1a** as well as the larger size of the palladium atom in **4a** compared to the nitrogen atom in **1a**.

The NMR spectroscopic data (Tables 3–5) show that the structure observed in the solid state is maintained in solution for **4a**, and that the structures of **3a**–**c** and **4b**–**c** are similar. The selenium atoms are inequivalent and give rise to two signals in the ^{77}Se NMR spectrum, each of which shows a small splitting (J = 9 Hz) due to coupling to the phosphorus atom in the *cis*-position. This feature is also evident in the ^{31}P NMR spectra, where the single peak has clearly defined ^{77}Se satellites. A second pair of satellites flanks the central ^{31}P resonance due to coupling with the α-carbon atoms of the alkyl chains, ^{1}J (^{13}C–^{31}P) = 30 Hz. For the PBu_3 complexes ^{31}P coupling to the β-carbons is also observed, so that the ^{13}C resonance for these atoms is a doublet with $^{2}J(^{13}C–^{31}P)$ = 14 Hz. No corresponding splitting of the signal for the methyl group occurs in the ^{13}C NMR spectra of the analogous PEt_3 complexes. As expected, for all the compounds, each atom in the two alicyclic rings gives a separate ^{13}C resonance. This asymmetry leads to considerable complexity in the ^{1}H NMR spectra, but a number of features are clear. There are four well-spaced multiplets at relatively low field which may be assigned to the α-CH_2 groups. The methyl groups of the phosphine alkyl chains give rise to a well-defined triplet at higher field, which is further split in the case of the PEt_3 complexes by coupling to phosphorus (the contrast with the absence of ^{13}C–^{31}P coupling for this group is notable).

Table 3
^{1}H NMR spectroscopic data for **3a**–**c**, **4a**–**c** in $CDCl_3$ solution

[a] Recorded using FAB; figures are for isotopomers containing ^{80}Se, ^{106}Pd.

The mass spectrometric data are in accord with the proposed formulations (Table 6). In the mass spectrum of each compound there is an intense cluster due to the molecular ion, with the expected isotope distribution, and the base peak corresponds to the protonated trialkylphosphine.

The infrared spectrum of **4a** contains typical absorptions for compounds having aliphatic CH_2 and CH_3 groups. A feature corresponding to the N=N stretch of the azo-group might also have been expected. If seen, it should occur in the range 1350–1600 cm^{-1} [22], but this band is often weak or absent [23]. An unequivocal assignment of the spectrum in this region is not possible. The observation of ν (N=N) has been reported for the related complex $[Pd\{C_6H_4N{=}NCH{=}C(Me)O\}(PPh_3)]$ [24] but no details were given.

Complexes **3a–c** and **4a–c** are an intense purple colour. Examination by ultraviolet/visible spectroscopy showed that their absorption spectra are all very similar (Table 7). There are two intense bands in the ultraviolet, and three weaker bands in the visible region. Only the two lowest energy bands show any dependence on the size of the alicyclic rings, where the shifts in λ_{max} are small (±10 nm) but significant. The nature of the trialkylphosphine appears to have no effect. It may therefore be supposed that the transitions responsible for these absorptions are predominantly ligand-based.

The complexes **3a–c** and **4a–c** may be expected to resemble diselenolenes and dithiolenes in having delocalised metal–ligand bonding. We therefore anticipate rich and varied chemical and physical behaviour for these compounds and their derivatives.

3. Experimental

All reactions were performed using standard Schlenk techniques and pre-dried solvents under an atmosphere of dinitrogen. ^{1}H and ^{13}C NMR spectra: Bruker AC400; tetramethylsilane as internal standard. ^{31}P and ^{77}Se NMR spectra: Bruker WM250; 85% phosphoric acid or dimethyl selenide as external standard. IR spectra: Perkin–Elmer 1725X. UV/VIS spectra: Perkin–Elmer Lambda 9. Mass spectra were recorded by the EPSRC Mass Spectrometry Centre, using Fast Atom Bombardment (FAB).

Cycloalkeno-1,2,3-selenadiazoles (**1a–c**) [8] and $[Pd_2(dba)_3]$.dba (**2**.dba) [25] were prepared by literature methods. Triethyl- and tributylphosphine were obtained commercially and used without further purification.

3.1. Synthesis of *3a–c* and *4a–c*

In a typical experiment, a solution containing $[Pd_2(dba)_3]$.dba, **2**.dba (0.28 g, 0.24 mmol), PBu_3 (0.10

250 (10,000)	250 (11,000)		250 (9700)	250 (10,000)	250 (10,000)

[a] λ_{max}/nm (ε/dm^3 mol^{-1} cm^{-1}); recorded as 10^{-4} mol dm^{-3} solutions in hexane.

g, 0.50 mmol) and cyclohexeno-1,2,3-selenadiazole, **1a** (0.19 g, 1.00 mmol), in toluene (100 cm^3) was heated under reflux for one hour. After this time the solution had darkened considerably. Removal of the solvent under reduced pressure left an intensely coloured oily solid, which was purified by column chromatography on alumina using a 2:1 mixture of toluene and hexane. Collection of the bright purple band and recrystallisation from hexane gave **4a** as an analytically pure solid. Yield: 0.17 g. IR (ν/cm^{-1}; KBr disk; selected bands only): 2929 vs, 2857 s, 1578 m, 1479 m, 1450 m, 1405 m, 1359 m, 1307 w, 1262 m, 1091 vs, 1050 s, 904 m, 802 s, 720 w.

Yields, spectroscopic and analytical data are summarised in Tables 3–7.

3.2. X-ray crystallography

X-ray data for both **1a** and **4a** were collected at room temperature on an Enraf-Nonius CAD4 diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). Cell constants were determined by least-squares refinement of the setting angles of 25 reflections with $20° < 2\theta < 30°$. Details of data collection and structure refinement procedures are reported in Table 8. A 15% overall decay in intensities was observed at data collection time for **1a** and was corrected for; no decay was observed for **4a**. An empirical correction for absorption, by ψ scans, was applied to the data of **4a**, but it could not be applied for **1a**, whose crystal was lost soon after data collection, probably as an effect of partial decomposition. In the case of **1a** an empirical correction for absorption with DIFABS [26] was applied after the structure was solved, at isotropic convergence; this procedure was preferred to the use of uncorrected data, which yielded higher R values, more scattered thermal parameters and slightly worse agreement with the values of distances formed by the Se and N atoms in the related structure of [20]. Differences between values of structural parameters from refinements with absorption-corrected, or uncorrected, data for **1a** were, however, small ($<2\sigma$). Both structures were solved by direct methods, with SIR-97 [27], and were extended and refined on F^2 with SHELXL-97 [28]. Repeated effort and improved software facilities [29] with respect to those used for the previous report on **4a** [8] (CCDC deposition No. 182/872, reference code PIJQII), allowed us to improve the model for the azo-chain in the tridentate ligand of that compound. Two orientations of the diatomic group were identified, the more probable one corresponding to the unique arrangement of the previous report. In the least-squares cycles the two fractions were assigned complementary population parameters and were imposed a mild geometrical restraint, forcing the N–N distances to be similar in the two images. Besides being more detailed than the previous model, the present one yielded slightly lower final R values. In the final refinement cycles anisotropic temperature factors were assigned to all non-hydrogen atoms, including those with fractional occupancy factors. Hydrogen atoms were in calculated positions, riding on the respective carrier atom (methyl groups being treated as rigid bodies), with $U_H = 1.2U_C^{eq}$ ($U_H = 1.5U_C^{eq}$ for methyl hydrogens). The highest peaks in the final difference syntheses could not be assigned any chemical significance. Computer programs used included PARST [30] for geometry calculations, and ORTEP [29,31] for graphics.

Table 8
Crystallographic data for compounds **1a** and **4a**

Compound	**1a**	**4a**

Abstract

The molecular structure of ferrocene in toluene solution is examined for the first time, using neutron scattering with hydrogen isotope substitution on the ferrocene hydrogen atoms. The results are interpreted via a computer-simulated model of ferrocene and toluene molecules at the same concentration and density as the experiment. It is found that the solvation shell of ferrocene is highly anisotropic, with concentrations of toluene in the axial and equatorial regions around the ferrocene molecule. In addition these toluene molecules show a strong orientational correlation with their position in the solvation shell of ferrocene. The ferrocene molecule itself can be slightly bent at times (up to about 30° although most molecules are much straighter than this) along the axis joining the centroids of the two cyclopentadienyl rings. There is a weak torsional correlation between the two rings on the ferrocene molecule at the temperature of the present experiment, which is 313 K.

1. Introduction

Knowledge of structure is fundamental to the understanding of the nature of bonding, properties and reactivity in chemical systems. Structural determinations are routinely carried out by diffraction of radiation from an appropriate source by a sample, from which information about the interatomic distances and atomic identities can be ascertained [1–5]; the majority of these determinations are conducted in the solid state, using a crystalline sample, either as a single crystal or a microcrystalline powder.

In this paper, we present the results of a set 'proof of concept' experiments that allows the investigation of a structurally complex organometallic in solution, using neutron diffraction augmented with isotopic substitution. It is the first set of experiments of which we are aware in which the scientific focus is the structure of the solute alone.

Elastic neutron scattering is a complementary technique to the more conventional diffraction methods, which use usually X-rays or occasionally electrons. Both X-rays and electrons are scattered by electron density and therefore the scattering intensity is directly coupled to the *chemical identity* of the scattering atom. In contrast, neutron scattering is decoupled from the chemical identity of the atom; for the purposes of this report, neutrons can be considered to be scattered solely by the atomic nucleus and it is the composition of the nucleus that determines the strength of the elastic nuclear scattering cross-section. At current levels of nuclear theory, the a priori prediction of the strength of the scattering interaction for a particular isotope in not possible [6] and empirical scattering parameters are tabulated in the literature [7] and on the World Wide Web [8].

The determination of chemical structure in the solid state is greatly assisted by the long range order of the crystal, which imposes rigorously defined symmetries on any proposed structure. For a crystalline molecular system, the structure can be defined in either reciprocal or real space via a convolution of the intermolecular structure, P and the structure of the individual structural motifs, a such that $M = a \otimes P$. In a crystalline material, this representation of structure is transparent: P represents the lattice and a the asymmetric unit [1–3]. Interpretation of Bragg diffraction from a crystal is therefore simplified by the inherent periodicity, which truncates the description of the structure, or any property of the crystalline system, allowing, in principle, a tractable yet complete description.

The liquid state is clearly an important chemical milieu and for inorganic systems and the correlation between the solid state structure and the structure in the liquid state is less strong than in an organic system; factors such as fluxionality and dissociation can profoundly affect the structure of an inorganic system. The key problem with the liquid state is the disordered nature of the phase; with a disordered material, i.e. one which lacks the long range order of a crystal, there are no constraints on the structure. The diffraction pattern from a disordered material is much simpler in form as there is no Bragg contribution. However the *interpretation* of that structure is much more ambiguous than in the crystalline case, precisely because of the lack of symmetry and periodicity to impose structural constraints. Real progress in understanding disordered structures is only made by generating a model of the disordered material which includes as much prior knowledge as possible. Ideally, the model will include molecular structure and symmetry, likely minimum distances of approach between atom pairs, possible force models for atom pair interaction, amongst other contributions.

In a liquid sample, all correlations between all pairs of atoms contribute to the interference of the scattered waves, i.e. the diffraction pattern. For a sample containing N atom types, there are $N(N + 1)/2$ site–site correlations between atom pairs. For even a modestly complicated system therefore the diffraction pattern is a weighted average of these correlations, making it difficult to interpret the data directly. In a solution, the inherent problem with the liquid phase is exacerbated by the dominance of both the intra- and intermolecular structure in the diffraction pattern. The unique ability of neutron diffraction is that it can, by means of isotope labelling, dissect the diffraction pattern into subsets of the total set of correlation functions: the scattering cross-section can be perturbed while retaining the structure of the sample through isotopic labelling, because to a good approximation the nuclear nature of the scattering process depends on the isotope of the scattering atom, not on its chemical situation. Through isotopic substitution of specific atoms, the scattering properties of the atom in question are changed, without major changes to the chemical bonding, which highlights the structure around the labelled atom. The most common substitution is that of deuterium for hydrogen, but other isotopic substitutions have also been used [9–13].

In this paper, we apply this technique to solutions of ferrocene, substituting the cyclopentadienyl hydrogen atoms with deuterium, to provide the isotopic contrast, while keeping the isotopic nature of the solvent identical between samples.

In the liquid state, the major methods of structural determination are spectroscopic, either using a vibrational technique, such as infra-red or Raman spectroscopy, or nuclear magnetic resonance. Direct structural information, in terms of interatomic distances and identities on a par with a crystalline diffraction experiment, is therefore necessarily absent using these methods, though their utility in solving inorganic structural problems is not in question. This paper shows that structural information in a solute structure can be accessed using diffraction techniques.

Ferrocene holds a seminal position in the field of organometallics, being the first π-bound organometallic 'sandwich' complex to be identified [14–16]. The discovery of the then unique structure led to an explosion of work in the field and the correct assignment of the structure [17–19] and the subsequent development of the field led to the award of the Nobel Prize in 1973 to Wilkinson [20,21] and Fischer [22,23].

The structure of ferrocene has been determined in the crystalline solid state using both neutron and X-ray diffraction [19,24–27]. The structure in the gas phase has also been determined using gas phase electron diffraction [28–30]. The two symmetrical *extrema*, corresponding to D_{5h} and D_{5d} symmetry, are the eclipsed and staggered conformations around the ring centroid–Fe–ring centroid vector. The interconversion process has been extensively investigated [26–29,31–35] and the height of the barrier is ~4 kJ mol^{-1}.

In this report, the diffraction patterns of h_5-(η–Cp)$_2$Fe and d_5-(η–Cp)$_2$Fe in toluene solution are reported. Analysis of the first order difference between the two diffraction patterns using empirical potential structure refinement (EPSR) [36] reveals the structure of the molecule, together with the structure of the solvation shell around this molecule.

2. Theory

The quantity measured in a neutron diffraction experiment is the differential scattering cross-section, $d\sigma/d\Omega$, where

$$\frac{d\sigma}{d\Omega} = \frac{d\sigma}{d\Omega_{self}} + \frac{d\sigma}{d\Omega_{distinct}} = \sum_{\alpha} c_\alpha b_\alpha^2 (1 + P(Q,\theta)) + F_N(Q). \quad (1)$$

Here $P(Q,\theta)$ is the contribution which arises from inelastic scattering, $F_N(Q)$ is the structure factor arising from the 'distinct scattering', c_α is the atomic concentration and b_α the scattering length of isotope α [37]. The scattering lengths in this and the following equations are averaged over the spin and isotope states for each nucleus. Q is the wave vector change in the scattering experiment.

The words "self" and "distinct" refer, respectively, to scattering by single atoms and scattering by distinct pairs of atoms. Distinct scattering is sometimes also called "interference scattering" which indicates that it contains the important structural information of the material in question, while the self scattering represents a background which needs to be subtracted from the measured data prior to attempting to analyse the distinct scattering. The self scattering also serves a useful function in helping to ensure that the sample composition is as planned: the scattering level from the self scattering is quite sensitive to the detailed sample composition, e.g. if there is any light hydrogen present.

The function $F_N(Q)$ itself splits into two terms, a molecular form factor which corresponds to interference scattering between atoms within the same molecule, sometimes called "intramolecular" correlations $F_{intra}(Q)$, and an intermolecular term which corresponds to interferences between atoms on different molecules, $F_{inter}(Q)$, i.e. $F_N(Q) = F_{intra}(Q) + F_{inter}(Q)$. Since the former consists only of correlations within the same molecule it is straightforward to calculate the orientational average of this quantity, since it will be independent of how the molecule is oriented relative to other molecules

$$F_{intra}(Q) = \sum_j x_j \sum_{\alpha\beta\neq\alpha} b_\alpha^{(j)} b_\beta^{(j)} \frac{\sin Q d_{\alpha\beta}^{(j)}}{Q d_{\alpha\beta}^{(j)}} \exp\left[-\frac{Q^2\sigma_{\alpha\beta}^2}{2}\right], \quad (2)$$

where x_j is the mole fraction of molecules j, $b_\alpha^{(j)}$ is the scattering length for atom α on the j th molecule, and $d_{\alpha\beta}^{(j)}, \sigma_{\alpha\beta}^2$ are the mean separation and standard deviation, respectively, of atoms α and β on this molecule.

For the intermolecular term this simple average is not possible since the orientation of one molecule may well be correlated with its position relative to another. Instead the intermolecular interference term is normally written in terms of the Faber–Ziman partial structure factors, $S_{\alpha\beta}(Q)$, by the following equation:

$$F_{inter}(Q) = \sum_{\alpha,\beta\geqslant\alpha} (2 - \delta_{\alpha\beta}) c_\alpha b_\alpha c_\beta b_\beta [S_{\alpha\beta}(Q) - 1], \quad (3)$$

where c_α is the atomic fraction of component α, and the partial structure factors are related to their corresponding real space site–site radial distribution functions (SSRDF) by Fourier transform

$$S_{\alpha\beta}(Q) - 1 = 4\pi\rho \int_0^\infty r^2 [g_{\alpha\beta}(r) - 1] \frac{\sin Qr}{Qr}\, dr. \quad (4)$$

If there are N distinct atomic types in a material there will be $N(N+1)/2$ distinct partial structure factors needed to define the atomic structure. In the present experiments, use was also made of the ability to isotopically substitute light hydrogen for deuterium on the ferrocene molecule. This changes the neutron scattering length of the hydrogen atoms on the ferrocene molecule only, and enables a "first order difference" to be calculated which only contains correlations which involve the hydrogen atoms on the ferrocene molecule

$$\begin{aligned}\Delta_H(Q) &= F_N^{(D)}(Q) - F_N^{(H)}(Q) \\ &= [b_D - b_H]\left\{\sum_j x_j \sum_{\alpha=H,\beta\neq\alpha} b_\beta^{(j)} \frac{\sin Q d_{\alpha\beta}^{(j)}}{Q d_{\alpha\beta}^{(j)}} \exp\left[-\frac{Q^2\sigma_{\alpha\beta}^2}{2}\right]\right. \\ &\quad \left. + \sum_{\alpha=H,\beta\geqslant\alpha} (2 - \delta_{H\beta}) c_\alpha c_\beta b_\beta [S_{\alpha\beta}(Q) - 1]\right\}, \end{aligned} \quad (5)$$

where the summations over atoms α in (5) includes only those atoms that have been substituted. The first order difference, calculated by subtraction of the diffraction pattern of h_5-$(\eta$–$Cp)_2Fe$ from that of d_5-$(\eta$–$Cp)_2Fe$, therefore contains only that part of the interference function that depends on the labelled site. This partial pattern will therefore contain the internal structure of the molecule and the structure of the solvation sphere, with the bulk solvent correlations being removed as they are unperturbed by the isotopic substitution and are therefore the same in both diffraction patterns.

In the present experiment there are five distinct atom types to be identified. These are C_S and H_S, representing the carbon and hydrogen atoms on the solvent (toluene) molecule, and Fe, C_{Cp} and H_{Cp}, representing, respectively, the iron, carbon and hydrogen atoms of the ferrocene molecule. Only the H_{Cp} atoms were isotopically substituted in this experiment with the remaining hydrogen atoms deuterated. In the present experiment each of the datasets was normalised to the sum of intermolecular weights to give a set of total structure factors:

$$S_N^{(D)}(Q) = \frac{F_N^{(D)}(Q)}{\left(\sum_{\alpha,\beta\geqslant\alpha} (2 - \delta_{\alpha\beta}) c_\alpha c_\beta b_\alpha b_\beta\right)}, \quad (6)$$

$$S_N^{(H)}(Q) = \frac{F_N^{(H)}(Q)}{\left(\sum_{\alpha,\beta\geqslant\alpha} (2 - \delta_{\alpha\beta}) c_\alpha c_\beta b_\alpha b_\beta\right)} \quad (7)$$

and

$$\Delta S(Q) = \frac{\Delta_H(Q)}{\left((b_D - b_H)\sum_{\alpha=H,\beta\geqslant\alpha}(2-\delta_{H\beta})c_H c_\beta b_\beta\right)}. \quad (8)$$

The normalised intermolecular weights outside each partial structure factor are listed in Table 1 for the diffraction datasets from the 0.5 M $(\eta\text{–}d_5\text{Cp})_2\text{Fe}$, 0.5 M $(\eta\text{–}h_5\text{Cp})_2\text{Fe}$, and the first order difference. Notice how by taking the first order difference many of the strongest correlations in the total structure factors are eliminated. The weights for the protiated sample are slightly larger than for the deuterated sample because the negative neutron scattering length for protons compared to neutrons means that the normalisation constant for the protiated sample is slightly smaller than for the deuterated sample. Obviously this normalisation is only done after the first order difference has been calculated.

3. Experimental and data analysis

Neutron diffraction measurements were performed at 40 °C on two solutions of $(\eta\text{–}h_5\text{Cp})_2\text{Fe}$ and $(\eta\text{–}d_5\text{Cp})_2\text{Fe}$ dissolved in d_8-toluene at a concentration of 0.5 M, using the SANDALS diffractometer [38] at the ISIS Pulsed Neutron Facility, the temperature of experiment being chosen to eliminate any possibility of crystalline material being present in the sample. The samples were contained in flat-plate 2 mm internal thickness titanium–zirconium containers of wall thickness 1 mm (each) with a gold O-ring seal. The neutron diffraction data were corrected for container scattering, attenuation, absorption, multiple scattering, and inelastic scattering using standard analysis procedures [39].

Table 1
Normalised neutron weightings for each partial structure factor for the different datasets

Partial structure factor	$S_N^{(D)}(Q)$	$S_N^{(H)}(Q)$	$\Delta S(Q)$
C_S–C_S	0.1639	0.2003	–
C_S–H_S	0.3760	0.4595	–
C_S–Fe	0.0071	0.0086	
C_S–C_{Cp}	0.0493	0.0602	–
C_S–H_{Cp}	0.0495	−0.0339	0.4251
H_S–H_S	0.2157	0.2636	–
H_S–Fe	0.0081	0.0099	–
H_S–C_{Cp}	0.0565	0.0691	–
H_S–H_{Cp}	0.0568	−0.0389	0.4876
Fe–Fe	0.0001	0.0001	–
Fe–C_{Cp}	0.0011	0.0013	–
Fe–H_{Cp}	0.0011	−0.0007	0.0092
C_{Cp}–C_{Cp}	0.0037	0.0045	–
C_{Cp}–H_{Cp}	0.0074	−0.0051	0.0639
H_{Cp}–H_{Cp}	0.0037	0.0014	0.0141

The normalised structure factors defined in (6)–(8) above have been subjected to an EPSR, developed by one of us [43,44]. Briefly, the EPSR performs a standard Monte Carlo computer simulation of the solution in question, starting from physical constraints on the molecular geometry and an assumed reference site–site pair interaction potential. This is then perturbed iteratively for each of the site–site interactions until the simulated total structure factors converge to a satisfactory fit of the diffraction data. This perturbation is called the empirical potential (EP).

After convergence, molecular configurations, compatible with the experimental data, were recorded and the whole set of SSRDF were estimated, as well as other structural properties of interest, which are not available from a direct Fourier transform of the total structure factors. Among these the so called spatial density function (SDF) describes how the molecules of one kind are distributed around those of another at the origin [45]. The orientational correlation functions (OCF) can then be used to explore the relative orientations of the two molecules in specified directions through the SDF. Alternatively one can calculate so called ''bond angle distributions'', which show the angular distribution between pairs of atoms on different molecules, averaged over all directions in the SDF.

The EPSR method has the advantage of fitting all the measured data simultaneously to a single atomistic model of the scattering system, instead of the traditional Fourier transform of individual structure factors. Of course this cannot necessarily be done unambiguously, but the use of a starting potential serves to eliminate physically unreasonable structures, so that any structure that is constructed will not contain unphysical atom overlaps. In that sense the EPSR method can be thought of generating a set of plausible structures which are consistent with a given set of data.

The starting reference potential was generated from a series of site–site Lennard–Jones potentials of the form:

$$U_{\alpha\beta}^{(\mathrm{ref})}(r) = 4\varepsilon_{\alpha\beta}\left[\left(\frac{\sigma_{\alpha\beta}}{r}\right)^{12} - \left(\frac{\sigma_{\alpha\beta}}{r}\right)^{6}\right], \quad (9)$$

where,

$$\varepsilon_{\alpha\beta} = \sqrt{\varepsilon_\alpha \varepsilon_\beta} \quad (10)$$

and

$$\sigma_{\alpha\beta} = \frac{1}{2}(\sigma_\alpha + \sigma_\beta), \quad (11)$$

the so-called Lorentz–Berthelot mixing rules. Table 2 lists the Lennard–Jones parameters used for the present set of simulations. The cubic simulation box was of dimension 33.73 Å and contained 200 toluene molecules and 10 ferrocene molecules. Periodic boundary conditions and the minimum image convention were applied in the usual way, but no correction for the long range

Table 2
Lennard–Jones parameters used for the EPSR simulations on ferrocene in toluene

Atom	ε_α (kJ/mole)	σ_α (Å)
C_S	0.30	3.0
H_S	0.10	1.0
Fe	0.60	3.3
C_{Cp}	0.30	3.0
H_{Cp}	0.10	1.0

part of the potential was made. No Coulombic charges appeared on any of the atoms. There was no particular reason for this particular choice of parameters, other than they gave a reasonable simulated energy and pressure and did not lead to any obvious atomic overlap. At this time there do not appear to have been any previous computer simulations of ferrocene in solution from which to derive a set of starting parameters for the reference potential. Fig. 2 shows the diffraction data and their EPSR fits, using the molecular models for toluene and ferrocene as described in Section 4.

The fits in *r*-space are shown in Fig. 3, where the Fourier transforms are given by

$$G_N^{(D)}(r) = 1 + \frac{1}{2\pi^2\rho}\int_0^\infty r^2 S_N^{(D)}(Q)\frac{\sin Qr}{Qr}\,dr \qquad (12)$$

and

$$\Delta G(r) = 1 + \frac{1}{2\pi^2\rho}\int_0^\infty r^2 \Delta S(Q)\frac{\sin Qr}{Qr}\,dr\Delta(r), \qquad (13)$$

so that these functions are weighted sums of the corresponding SSRDF with the same weights as those given in Table 1.

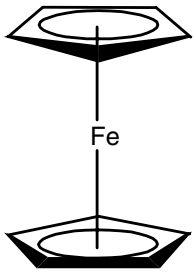

Fig. 1. Schematic structure of Cp_2Fe.

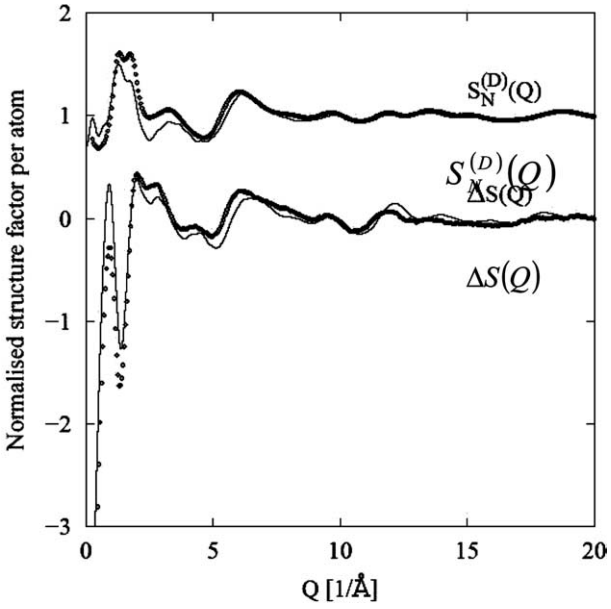

Fig. 2. Normalised structure factors for first order difference $\Delta S(Q)$ (bottom) and total structure factor, $S_N^{(D)}(Q)$, (top, fully deuteriated sample). The diffraction data are shown as the points and the EPSR fits to the data are shown as lines.

4. Results and discussion

4.1. Intramolecular structure

The structure of ferrocene has been determined several times by both neutron [24,40] and X-ray studies [15,19,25] on crystalline samples at varying temperatures. Ferrocene has a classical 'sandwich' structure in which two cyclopentadienyl (Cp) rings are arranged in a coplanar manner, with the Fe atom lying between them on the centroid–centroid vector and equidistant from both rings. The structure is shown schematically in Fig. 1.

For the EPSR simulations in the present work it was necessary to set up a model of the ferrocene and toluene molecules. Ferrocene was constructed from two C_5H_5 pentagonal rings held roughly parallel to one another at a separation of 3.32 Å and perpendicular to a common axis through the centre of each ring (see Fig. 1.). The iron atom was placed on this axis and midway between the two rings. In this model, the C_{Cp}–C_{Cp} near neighbour distance was set to 1.36 Å, the C_{Cp}–H_{Cp} distance was set nominally to 1.08 Å, and the distance between each C_{Cp} atom and the centre of each pentagon was 1.16 Å, these distances being consistent with the diffraction data, though no attempt to actually refine the molecular structure against the data was made. There were no specific torsional forces inhibiting free rotation of one ring relative to the other about the common axis, although the atoms on opposite rings interacted via the usual dispersion and atomic overlap forces. The toluene molecule was modelled starting from a benzene ring with an extra CH_3 group attached to one of the carbons on the ring. The C_S–C_S distance was set to 1.38 Å in all cases, the C_S–H_S distance to 1.08 Å, and the methyl group was allowed to adopt random rotational displacements about the relevant C_S–C_S bond. Again there was no specific attempt to fit the structure of the molecule to the diffraction experiment, although the chosen distances were consistent with those indicated by the data.

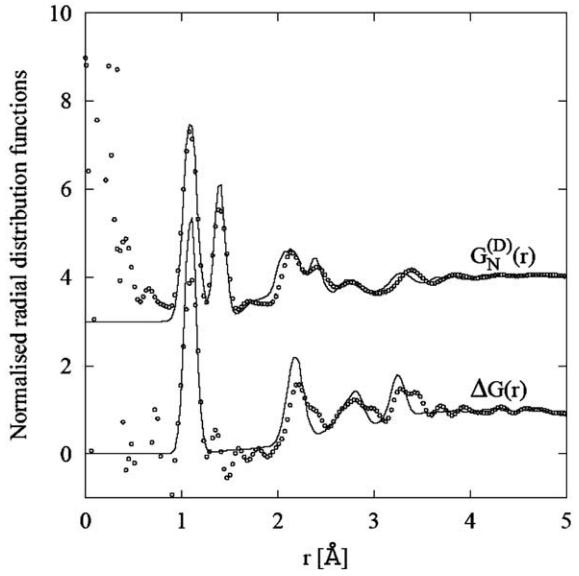

Fig. 3. Fourier transforms of the data shown in Fig. 2, as defined in Eqs. (12) and (13). Fourier transforms of the data are shown as points, while the lines are the EPSR reconstruction using the simulated radial distribution functions.

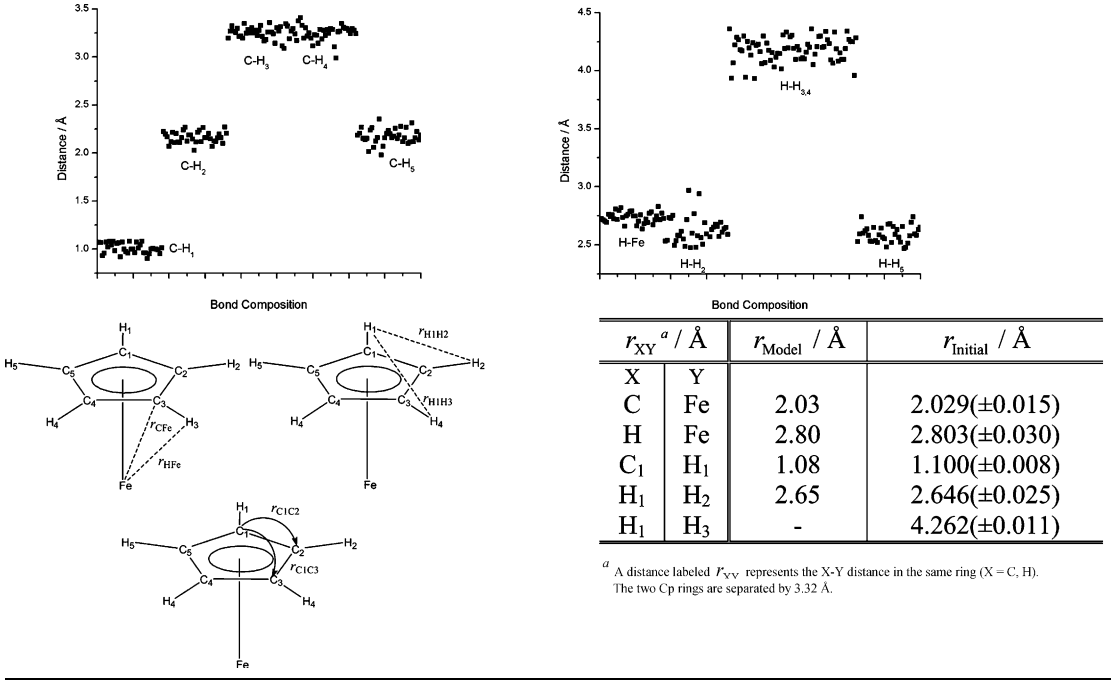
The cyclopentadienyl rings were assumed to be planar and regular pentagons. The toluene ring was also assumed to be a regular hexagon. However some distortion of the ideal geometries was permitted to reproduce the zero point displacements that would inevitably occur in the real molecules.

Salient intramolecular structural parameters are collated in Table 3. These are comparable with those given in the Cambridge Crystallographic Structure Database [41,42]. However the assumed C–H distance is 1.08 for both the Cp and toluene rings, which is larger than the value of 1.008 given by the Cambridge database. The fits to the short distance data in *r*-space are shown graphically in Fig. 3, and these do not show any obvious discrepancy in the position of the first peak at 1.08, so it is likely the crystallographic values do not represent the true local distances in the liquid state as shown here. Particularly for the first order difference data there appears to be some slight mismatch between the assumed model for ferrocene and the measured data, but overall it is clear that the model has captured the principle features of the molecular structure in both toluene and ferrocene.

Fig. 4 shows the distribution of angles subtended by the iron atom with the centres of the two Cp rings. If the rings were exactly parallel this angle would be $\theta = 180°$ ($\cos\theta = z = -1$). In practice a small deviation from linearity is observed along this axis, with $\cos\theta$ up to −0.88, or $\theta = 151°$, indicating that although the most probable angle is 180° (straight line along the molecular axis) some bending of the axis up to about 30° is observed in a few cases.

Table 3
Average distances for the ferrocene molecule as found in the EPSR simulation, together with their crystallographic counterparts



r_{XY} [a] / Å		r_{Model} / Å	$r_{Initial}$ / Å
X	Y		
C	Fe	2.03	2.029(±0.015)
H	Fe	2.80	2.803(±0.030)
C_1	H_1	1.08	1.100(±0.008)
H_1	H_2	2.65	2.646(±0.025)
H_1	H_3	-	4.262(±0.011)

[a] A distance labeled r_{XY} represents the X-Y distance in the same ring (X = C, H). The two Cp rings are separated by 3.32 Å.

Numbers in parenthesis show the r.m.s. deviation of these numbers within the simulation.

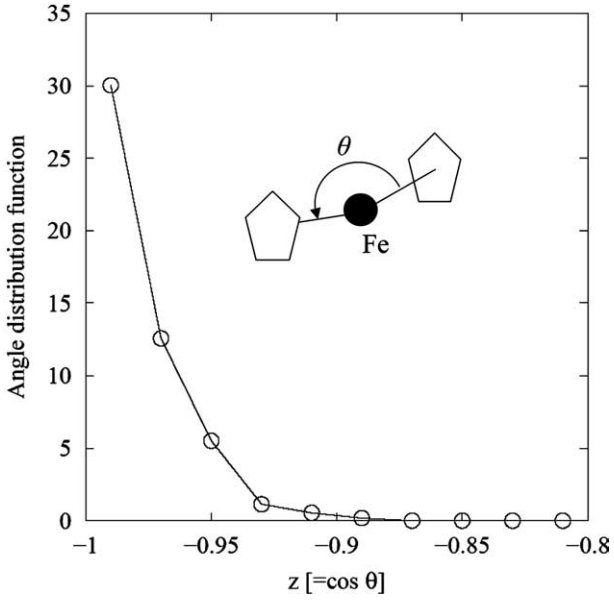


Fig. 4. Angle probability distribution along the axis of a ferrocene molecule. The angle is measured between the vector joining the Fe atom with the centre of one Cp ring and the vector from the Fe atom to the centre of the other Cp ring (see inset). The variable z is defined as $z = \cos\theta$.

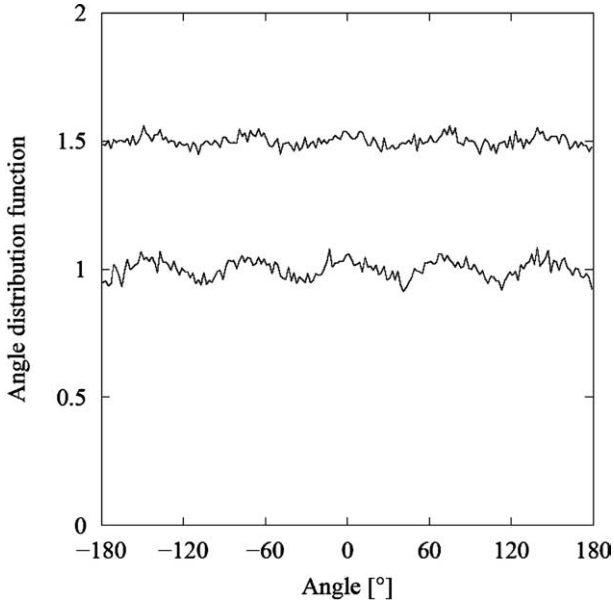

Fig. 5. Torsional angle distribution function for the Cp rings in ferrocene in toluene. The torsional angle is measured as the degree of rotation of one ring relative to the other about the common axis joining their centres. The bottom curve shows the result using the reference potential parameters as listed in Table 2. The top curve shows the effect of increasing σ_{Cp} to 3.4 Å.

A second angle distribution of interest is the distribution of torsional angles along the ferrocene axis. The torsional angle is measured by choosing any pair of carbon atoms on opposite Cp rings and measuring their torsional angle relative to an axis drawn between the centres of the two rings. Thus there are many pairs of carbon atoms that could have been chosen, each of which would give equivalent results. Fig. 5 shows the distribution of torsion angles averaged over some 4000 molecular configurations and over five such pairs of carbon atoms on opposite rings. It can be seen that a small undulation appears in this distribution, with peaks at 0°, ±72°, and ±144°, indicating that the eclipsed configuration is slightly preferred over the staggered configuration, when using the present reference and empirical potentials. The effect is fairly subtle and only appears after accumulating a large number of Monte Carlo configurations. At the present time it is not clear whether the data have sufficient sensitivity to really pick this correlation out, and or whether the assumed reference potential is really responsible for the observed correlation. The relevant average inter-ring distances in the first order difference function are C_{Cp}–H_{Cp} (about 4.1 Å) and H_{Cp}–H_{Cp} (about 4.5 Å) which are sufficiently far out in the correlation function to show no strong correlation, although with the rings separated by about 3.32 Å on average, these distances would range down to about 3.32 Å, depending on the precise orientation of the rings. With the staggered configuration the H_{Cp}–H_{Cp} distance increases to ~3.57 Å. A second reference potential was attempted (see Fig. 5, top curve), with somewhat larger $\sigma_{C_{Cp}}$, to try to make the carbon–carbon potential on opposite rings more repulsive. The chosen value ensured that when in the eclipsed position the C_{Cp} atoms on opposite rings would be inside their repulsive cores. Even so the effect remained, but was weaker, indicating that there may be some weak aspect in the data which requires the rings to adopt the eclipsed configuration marginally more often than the staggered configuration. It is not however a strong contributor to the structure factor, at least at the temperature of the present experiment, 40 °C.

4.2. Solvation structure

Ferrocene has an inter-ring dimension of 3.32 Å, calculated from the assumed Fe–Cp centroid distance of 1.66 Å, and the diameter of the Cp ring is ca. 4 Å. Given that, in solution, the molecule shows no preferred orientation, and is very nearly dimensionally isotropic, the solvation of the molecule might be assumed to be also spherical and the solvation cage should then show little structure in the first coordination sphere. Indeed, the NMR of ferrocene gives no information as to the solvation structure – the ^{13}C and ^{1}H NMR spectra show a singlet at all temperatures in solution. However, from the EPSR analysis of the data, this is found not to be the case. In order to extract the structure of the solvation of the

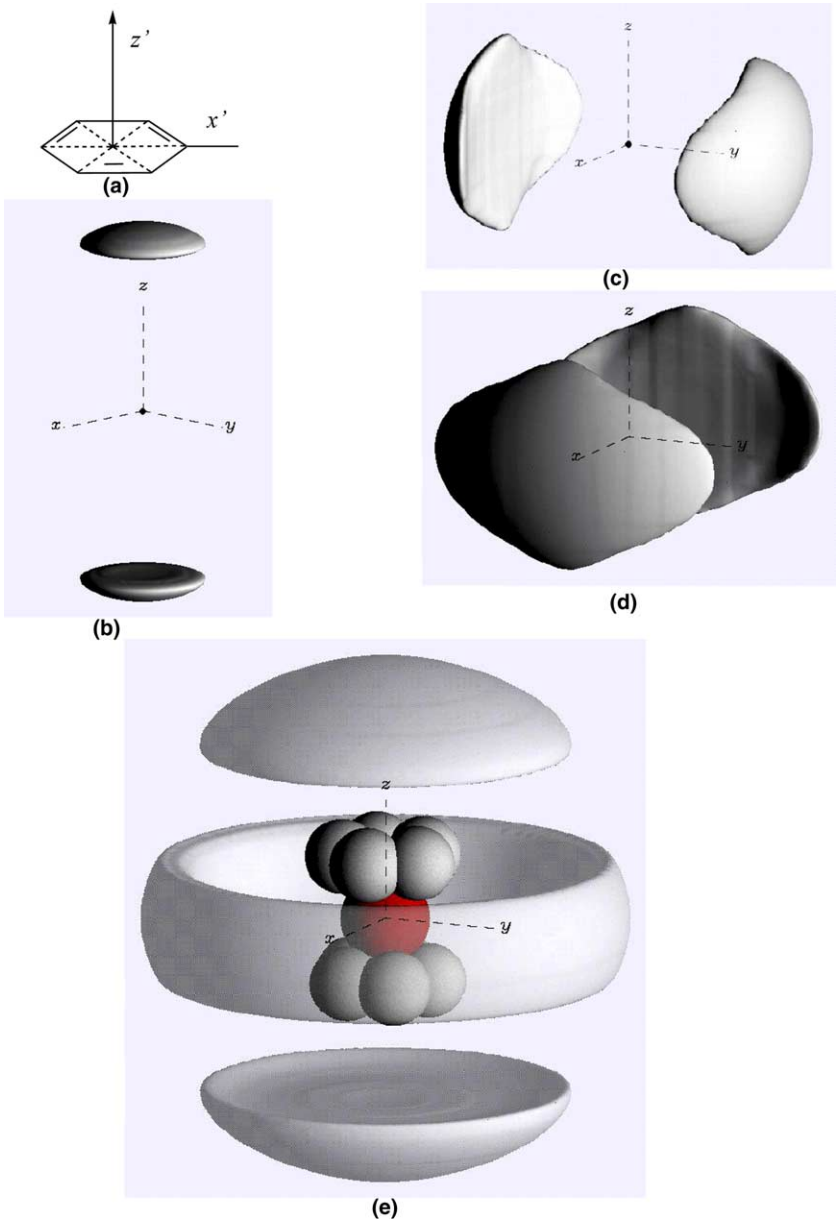

Fig. 6. (a) Internal coordinates of the toluene molecule. The axis is normal to the plane of the aromatic ring of the toluene molecule, while the x' axis passes through the methyl group. The y' axis is normal to both of these axes and points into the paper. (b) The distribution of the orientation of the z' axis about the z axis, with z being defined as the Cp_{cent}–Fe–Cp_{cent} vector, for toluene molecules that lie directly above or below one of the Cp rings. (c) and (d) show the same type of distribution but in the equatorial plane of a central ferrocene molecule along the y and x axes, respectively. (e) shows the total distribution of toluene molecules in the first solvation shell of a ferrocene molecule, averaged over orientations of the toluene molecule. These indicate that toluene prefers to occupy the polar positions above and below the ferrocene molecule and also the equatorial plane between the two Cp rings. However, as plots (b)–(d) demonstrate, in practice the orientation of the toluene molecule is strongly dependent on the direction of the toluene relative to the central ferrocene molecule, indicating there are strong orientational as well as spatial correlations in the first solvation shell.

molecule, the distribution of vectors normal to the plane of the d_8-toluene rings was extracted. Fig. 6 shows the vector used in the extraction of the solvent orientational correlations from the model, together with the distribution of these vectors around the average ferrocene molecule. It is clear that there is a strong orientational correlation in the first solvation shell of ferrocene in toluene solution and that the idea of an isotropically solvated molecule are not supported by the data or the analysis. Moreover, the orientational correlations are intuitively obvious; the aromatic portion of the solvent is preferentially orientated towards the maxima of electron density in the molecule – the Cp rings and the iron atoms, whereas the less polarisable areas – the C–H bonds show less preferential solvation.

5. Conclusion

The study presented is probably the first of its kind of an organometallic compound in solution. We find clear evidence for a non-spherical solvation shell around the ferrocene molecule in toluene solution (Fig. 6), and the toluene molecules show a high degree of orientational correlation in the first solvation shell, tending to lie flat and parallel above or below the Cp rings in ferrocene, but in the equatorial plane they lie mostly vertical, with the plane of the toluene molecule facing the iron of the ferrocene molecule. Some slight torsional correlation is observed between the ends of the ferrocene molecule. It remains to be seen how this develops as the solution temperature is lowered. In addition a slight bending of the Cp centroid to Cp centroid axis about the Fe atom midway is observed.

Given these initial results we expect to study a variety of related compounds in the near future.

Abstract

The structure of two thallium scorpionates derived from 3(5),4-trimethylene- and 3(5),4-hexamethylenepyrazole was determined by multinuclear NMR, both in solution and in the solid state. The isomeric distribution is the same in both phases suggesting a kinetic origin. A $^{1}J(^{15}N–^{205}Tl)$ coupling of 862 Hz was measured for $[Tl(Tp^{(3,4-(CH_2)_6)})]$ in the solid state.

1. Introduction

When an asymmetric pyrazole, i.e., a pyrazole that has different substituents at positions 3 and 5, reacts with potassium borohydride to afford a tris(pyrazol-1-yl)borate (a scorpionate) [1–3], four different isomers can be obtained (Scheme 1):

Even if the solid compound is formed regioselectively, when dissolved it can rearrange into a mixture of isomers [4]. Related to this are the examples of scorpionates that isomerize during complexation due to a boratropic rearrangement [5–7], for instance, during the preparation of the thallium complexes. In the present paper, we will discuss the case of two new thallium scorpionates, $[Tl(Tp^{(3(5),4-(CH_2)_3)})]$ and $[Tl(Tp^{(3(5),4-(CH_2)_6)})]$ derived from two fused 3(5),4-polymethylene pyrazoles **5** and **6** (Scheme 2).

2. Experimental

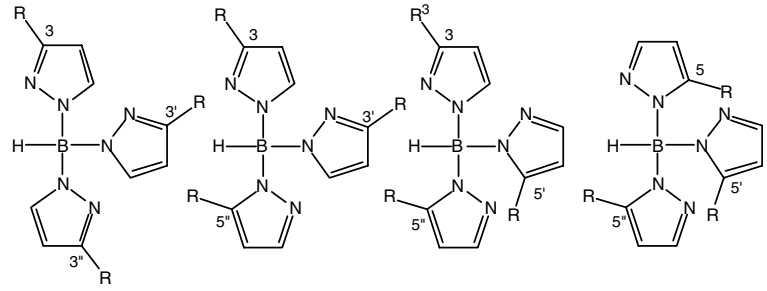
2.1. Chemical synthesis

2.1.1. 3(5),4-Trimethylenepyrazole (5)

This pyrazole was prepared by the method described below for cyclooctanone but starting from cyclopentanone; it was obtained after distillation in vacuo in 68% yield and was recrystallized from hexane. m.p. 61–62 °C. *Anal.* Calc. for $C_6H_8N_2$ (108.14): C, 66.7; H, 7.41; N, 26.7. Found: C, 66.9; H, 7.53; N, 26.6%. ^{1}H NMR (ppm): $\delta = 2.43$ (m, 2H), 2.64 (t, 2H), 2.71 (t, 2H), 7.14 (s, 1H), 11.6 (s, vb, N–H).

2.1.2. 3(5),4-Hexamethylenepyrazole (6)

A mixture of 300 g (2.38 mol) cyclooctanone and 400 g (5.6 mol) ethyl formate was added in one portion to a rapidly stirred slurry of 129 g (2.38 mol) dry sodium methoxide in 2 L toluene. After a short induction period the slurry turned amber, cleared up,



1, the 3,3',3"-regioisomer **aaa**

2, the 3,3',5"-regioisomer **aab**

3, the 3,5',5"-regioisomer **abb**

4, the 5,5',5"-regioisomer **bbb**

Scheme 1.

Scheme 2.

and then the sodium salt precipitated. The salt was extracted with 1.5 L water, and then the extracts were treated with 145 mL (2.38 mol) hydrazine hydrate and 150 mL (2.4 mol) acetic acid. An amber oil separated. It was taken up in methylene chloride, the extracts were separated, stripped, and distilled in vacuo. The main fraction, b.p. 136–140 °C/2.6 Torr, was obtained in 240 g (67%) yield. *Anal.* Calc. for $C_9H_{14}N_2$ (150.12): C, 72.0; H, 9.33; N, 18.7. Found: C, 72.0; H, 9.39; N, 18.6%. ^{1}H NMR (ppm): $\delta = 1.43$ (m, 4H), 1.60 (m, 2H), 1.70 (m, 2H), 2.58 (t, 2H), 2.79 (t, 2H), 7.26 (s, 1H), 12.3 (s, vb, N–H). ^{13}C NMR (ppm): $\delta = 22.1$, 24.3, 25.2, 25.6, 30.5, 117.3, 132.8, 145.5.

2.1.3. Thallium hydrotris(3(5),4-trimethylenepyrazol-1-yl)borate [$Tl(Tp^{3(5),4-(CH_2)_3})$] (7)

This was prepared from 35 g (0.32 mol) 3(5),4-trimethylenepyrazole and 4.8 g (0.090 mol) KBH_4 in 150 mL reluxing 4-methylanisole. Hydrogen evolution was rapid and in 4 h the theoretical amount was evolved. After distilling off the solvent in vacuo, the residue was dissolved in THF and converted to the Tl salt as below. This compound was obtained in 37 g (68%) yield. IR: BH at 2430 cm^{-1}. *Anal.* Calc. for $C_{18}H_{22}BN_6Tl$: C, 40.2; H, 4.10; N, 15.6. Found: C, 40.3; H, 4.19; N, 15.5%.

2.1.4. Thallium hydrotris(3(5),4-hexamethylenepyrazol-1-yl)borate [$Tl(Tp^{3(5),4-(CH_2)_6})$] (8)

A mixture of 48 g (0.32 mol) 3,4-hexamethylenepyrazole and 2.9 g (0.054 mol) KBH_4 was heated in an oil bath, up to 220 °C, at which point the theoretical amount of hydrogen was evolved. The excess pyrazole was distilled off in vacuo. The residue was cooled, dissolved in THF, filtered through Celite, and stirred with excess aqueous $TlNO_3$. The product was extracted with methylene chloride, the extracts were filtered through a bed of alumina, and evaporated to dryness. The residue was stirred with methanol and then filtered yielding, after washing with methanol and drying, 27 g (75%) of the Tl salt. IR: BH 2434 cm^{-1}. *Anal.* Calc. for $C_{27}H_{40}BN_6Tl$: C, 48.9; H, 6.03; N, 12.7. Found: C, 49.1; H, 6.13; N, 12.6%.

2.2. NMR measurements

NMR spectra were recorded on a Bruker DRX 400 (9.4 T, 400.13 MHz for ^{1}H, 100.62 MHz for ^{13}C and 40.56 MHz for ^{15}N) spectrometer. Chemical shifts (δ in ppm) are given from internal solvent $CDCl_3$ 7.26 for ^{1}H and 77.0 for ^{13}C, and for ^{15}N NMR nitromethane was used as external standard. 2D gs-COSY (^{1}H–^{1}H) and 2D inverse proton detected heteronuclear shift correlation spectra, gs-HMQC (^{1}H–^{13}C), gs-HMBC

(^{1}H–^{13}C) and gs-HMBC (^{1}H–^{15}N), were obtained using the standard pulse sequences [8]. Solid state ^{13}C (50.32 MHz) CPMAS NMR and ^{15}N (20.28 MHz) CPMAS NMR spectra have been obtained on a Bruker AC-200 spectrometer at 298 K using a 7 mm BRUKER DAB 7 probehead that achieves rotational frequencies of 3.5–4.5 kHz. Samples were carefully packed in ZrO_2 rotors and the standard CPMAS sequence was employed. ^{13}C spectra were originally referenced to a glycine sample and then the chemical shifts were recalculated to Me_4Si (for the carbonyl atom δ(glycine) = 176.1 ppm) and ^{15}N spectra to $^{15}NH_4Cl$ (these were converted to the nitromethane scale using the relationship: δ^{15}N(nitromethane) = δ^{15}N(ammonium chloride) −338.1 ppm) [9].

3. Results and discussion

Before starting the discussion, a few words about the prototropic tautomerism of *N*-unsubstituted pyrazoles and their reactivity [10,11] are given. Pyrazoles such as **5** and **6** exist in solution as rapidly equilibrating mixtures of tautomers **5a/5b** and **6a/6b**. The prototropy is usually so fast that only average signals are observed by NMR. The knowledge of the equilibrium constant is irrelevant on discussing their reactivity: there is a simple relationship between tautomers and *N*-substituted isomers.

These compounds can exist, in principle, in four isomeric forms depending on the substitution pattern (see Scheme 1). Since there are three pyrazoles per scorpionate ligand, in the reaction of the free pyrazole with potassium borohydride, four isomers can be formed: **aaa**, **aab**, **abb** and **bbb**. In a first approximation, the distribution should follow a binomial expression of the form $(\mathbf{a} + \mathbf{b})^3$, for instance, for identical populations (pop. **a** = pop. **b** = 50%), 12.5% of **aaa**, 37.5% of **aab**, 37.5% of **abb** and 12.5% of **bbb** and for the frequent case in which the 3,4-isomer (pop. **a** = 75%) is more stable than the 4,5 one (pop. **b** = 25%), 42.2% of **aaa**, 42.2% of **aab**, 14.1% of **abb** and 1.5% of **bbb**. Remember that here we refer to isomers, not to tautomers.

The NMR data necessary for the discussion are gathered in Table 1 (^{1}H NMR) and Table 2 (^{13}C NMR). The assignment of the signals will be discussed separately for compounds **7** and **8**.

The case of thallium hydrotris[3(5),4-trimethylenepyrazol-1-yl]borate [Tl($Tp^{(3(5),4-(CH_2)_3)}$)] (**7**). The sample used for the NMR study contains 75 mg of **7** in 0.6 mL $CDCl_3$.

In the ^{1}H NMR spectrum the H-3 pyrazole protons of isomers **7aab**, **7abb** and **7bbb** appear as an unique broad signal at 7.24 ppm and the H-5 protons of **7aaa**, **7aab** and **7abb** at 7.37, 7.38 and 7.36 ppm (see Fig. 1(a)). Five groups of signals for the methylene protons at 2.44, 2.54, 2.62, 2.77 and 2.86 ppm appear as multiplets in the spectrum (see Fig. 1(b)), and their assignment has been achieved taking into account the corresponding chemical shift values described for substituted 3,4- or 4,5-trimethylenepyrazoles in which δH-b < δH-a < δH-c [12]. Besides, δH-c in the 4,5-isomers is shifted downfield in comparison to the corresponding one in 3,4-isomers. The integral also shows that several H-b protons of the 4,5-substituted pyrazoles appear together with the H-a protons at 2.62 ppm. (^{1}H–^{1}H) COSY correlations between the following pairs of signals: 2.44 ↔ 2.63, 2.44 ↔ 2.77, 2.54 ↔ 2.62 and 2.54 ↔ 2.86, allows the complete assignment.

The ^{13}C-CPD NMR spectra, gs-HMQC (^{1}H–^{13}C) and gs-HMBC (^{1}H–^{13}C) 2D correlations permitted the assignments shown in Table 2, where the expected relative intensity of the signals according to the populations of the different isomers has also been considered. The pyrazole carbons chemical shifts C-3, C-4 and C-5 are in agreement with those found in substituted 3,4- or 4,5-trimethylenepyrazoles [12,13].

The case of thallium hydrotris[3(5),4-hexamethylenepyrazol-1-yl]borate [Tl($Tp^{(3(5),4-(CH_2)_6)}$)] (**8**). Here again, the sample used for the NMR study contains 75 mg of **8** in 0.6 mL $CDCl_3$.

In the ^{1}H NMR spectrum the H-5 pyrazole protons of isomers **8aaa**, **8aab** and **8abb** appear as an unique broad signal at 7.32 ppm and the H-3 protons of **8aab** and **8abb** at 7.22 and 7.24 ppm (see Fig. 2(a)). For the methylene protons, signals at 1.30 (broad multiplet),

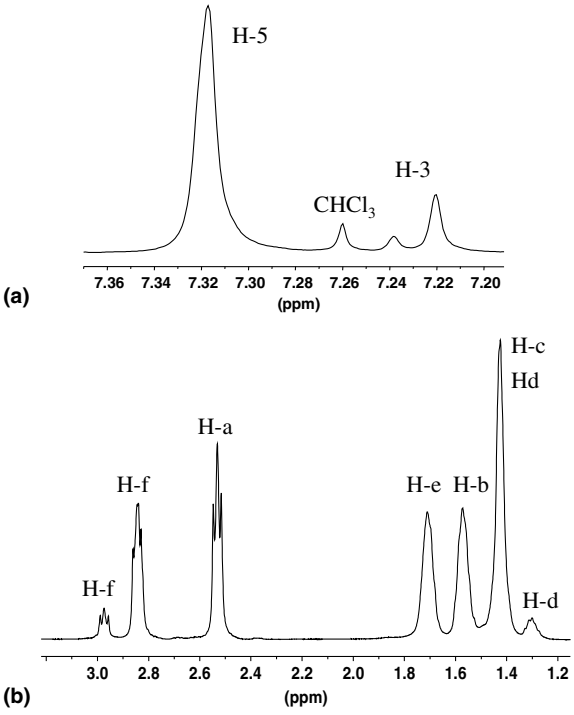

Fig. 2. ^1H NMR of isomers **8**: (a) pyrazole protons; (b) methylene protons.

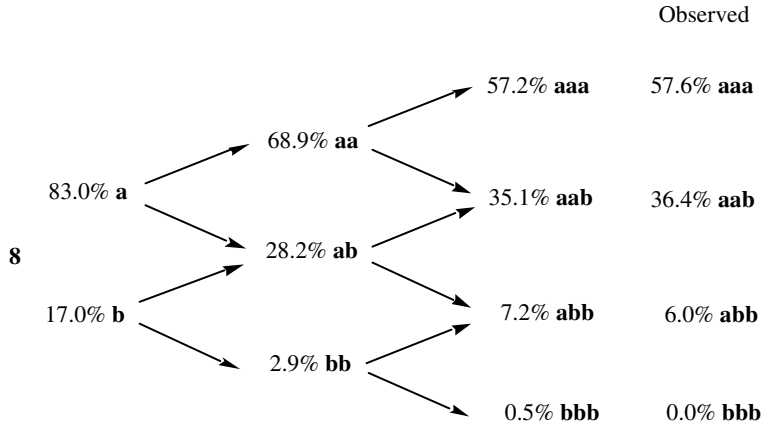


Scheme 3.

1.42 (broad multiplet), 1.57 (broad multiplet), 1.71 (broad multiplet), 2.52 (triplet), 2.84 (triplet) and 2.97 (triplet) ppm are shown (see Fig. 2(b)). The assignment has been achieved taking into account the following: (i) (^{1}H–^{1}H) COSY correlations between the following pairs of signals: 1.30 ↔ 1.42, 1.30 ↔ 1.71, 1.42 ↔ 1.57, 1.42 ↔ 1.71, 1.57 ↔ 2.52, 1.71 ↔ 2.84, 1.71 ↔ 2.97 and 2.62 ↔ 2.86; (ii) the corresponding chemical shift values described for substituted 3,4- or 4,5-hexamethylenepyrazoles in which δH-a < δH-f [12,13]; (iii) the chemical shifts found in isomers of thallium scorpionate **7**.

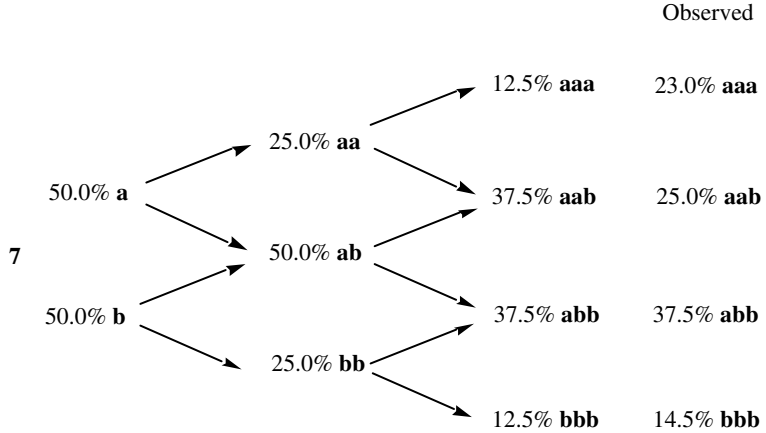
Once the ^{1}H NMR assignment was established, the relative ratio between the three isomers **8aaa**, **8aab** and **8abb** could be determined as discussed below. ^{13}C NMR chemical shifts gathered in Table 2 were obtained with the help of gs-HMQC (^{1}H–^{13}C) and gs-HMBC (^{1}H–^{13}C) 2D correlations.

In the case of the hexamethylene derivative **8** the populations are 57.6% of **aaa**, 36.4% of **aab** and 6.0% of **abb**; the **bbb** isomer was not observed. This corresponds, almost perfectly, to 83% of **a** and 17% of **b** (Scheme 3).

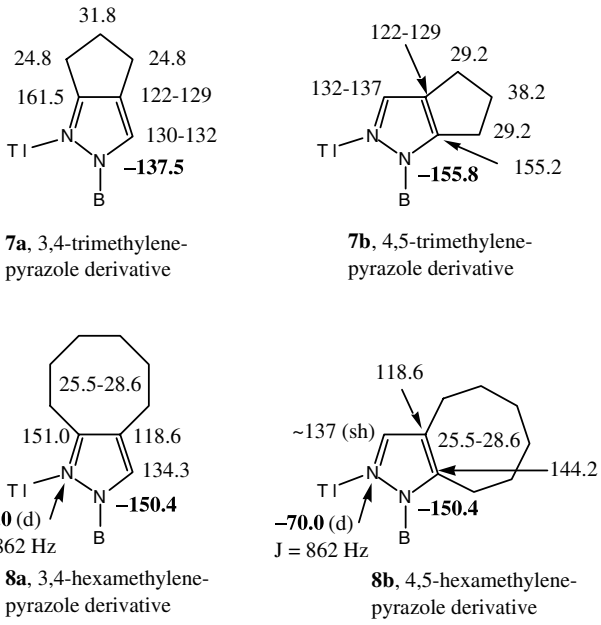
In the case of the trimethylene derivative **7** the determination of the populations is less precise but, based on a deconvolution treatment of the ^{1}H NMR signals, the following populations have been estimated: 23.0% of **aaa**, 25.0% of **aab**, 37.5% of **abb** and 14.5% of **bbb**. In this case, they do not correspond to an exact binomial distribution, see Scheme 4. Nevertheless, it is clear that the populations of isomers **a** and **b** are less different in this case, probably because the "cyclopentene" ring is less steric demanding than the "cyclooctene" one so both isomers should have similar stabilities. According to Scheme 4, there is an 11% excess of **aaa** and a 12% default of **aab**, probably due to an incomplete equilibration.

It should be noted that the ^{15}N chemical shifts in $CDCl_3$ of N(1) are very similar for both isomers in [Tl(Tp$^{(3(5),4-(CH_2)_6)}$)] (**8**) [−154.2 (**a**) and −150.5 ppm (**b**)] and rather different for [Tl(Tp$^{(3(5),4-(CH_2)_3)}$)] (**7**) [−141.5 (**a**) and −160.3 ppm (**b**)]. This fact has already been reported for simple *N*-methyl derivatives of polymethylenepyrazoles [14] and it has been related to the Mills–Nixon effect [13].

The solid state results are essential to discuss an important aspect of the structure of scorpionates. First hypothesis: the solid compound is a pure regioisomer, for instance **aaa**, and when dissolved in $CDCl_3$ it rearranges into the statistical distribution $(\mathbf{a} + \mathbf{b})^3$. This



Scheme 4.



7a, 3,4-trimethylene-pyrazole derivative

7b, 4,5-trimethylene-pyrazole derivative

8a, 3,4-hexamethylene-pyrazole derivative

8b, 4,5-hexamethylene-pyrazole derivative

Scheme 5.

means that the percents correspond to an equilibrium mixture, *a thermodynamic mixture*. Second hypothesis: the solid compound is already a mixture of the three (in the case of **8**) or four regioisomers (in the case of **7**) in the same ratio as in solution, this corresponds to *a kinetic mixture*.

Since ^{1}H CPMAS is not easily obtainable and ^{15}N CPMAS is not useful in some cases, this part must be mainly based on ^{13}C CPMAS NMR. The problem is that the resolution is not good enough to observe the different regioisomers. In the case of compound **8**, in ^{15}N NMR only *one* type of pyrazole is observed (the same for **a** and **b**), while in ^{13}C NMR both are observed *but independent of the remaining pyrazoles* of the scorpionate (for instance, the **a** signals are the same for the **aaa** as for the **aab** regioisomers). The assignments are reported in Scheme 5, the use of the NQS sequence (Non-suppression of Quaternary signals) has been useful for carbons C[3(5)] and C(4) of pyrazoles.

In the case of compound **7**, in ^{13}C NMR the signals of quaternary carbons at 161.5 and 155.2 ppm are of about the same intensity (see Fig. 3) and the same happens for the ^{15}N signals at −137.5 and −155.8 ppm; therefore, in the solid state there is the same amount of **a** and **b** isomers. The trimethylene part of the ^{13}C CPMAS NMR spectrum (see Fig. 4) shows that the signals of the **b** part are very narrow while those of the **a** part are very broad. We assign this difference to a larger conformational mobility of the cyclopentene-like envelope in the case of the latter, less hindered than the former.

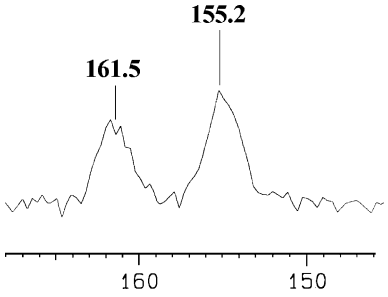


Fig. 3. ^{13}C CPMAS NMR quaternary carbons C-3 and C-5 of isomers **7**.

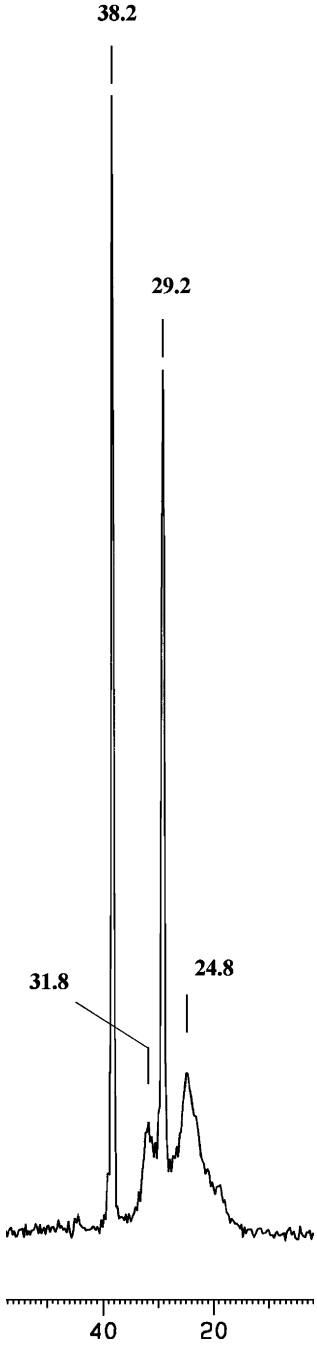

Fig. 4. ^{13}C CPMAS NMR methylene carbons of isomers **7**.

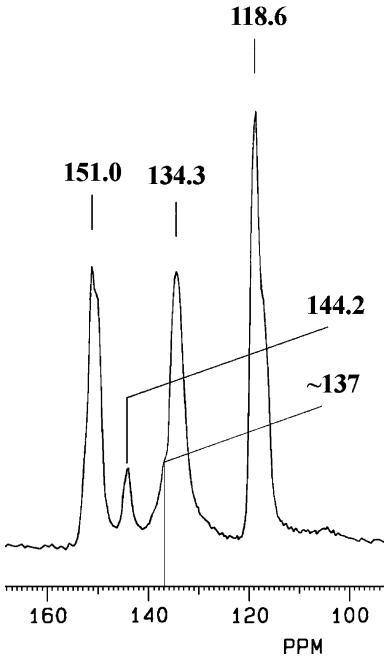

Fig. 5. ^{13}C CPMAS NMR pyrazole carbons of isomers **8**.

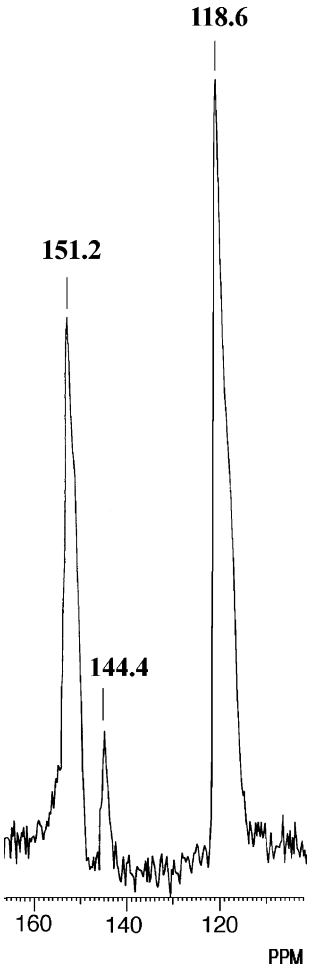

Fig. 6. ^{13}C CPMAS NMR quaternary carbons C-3, C-4 and C-5 of isomers **8**.

In the case of compound **8**, the pyrazole signals of both types of isomers (**a** and **b**) are clearly apparent (see Fig. 5) but the most useful spectrum is the ^{13}C NQS CPMAS one (see Fig. 6): the signals at 151.2 (**a**) and 144.4 (**b**) ppm are in an approximate 90/10% ratio.

4. Conclusions

It appears that the second hypothesis is valid: in the solid state, compound **7** is a mixture of 50% **a** – 50% **b** while compound **8** is much richer in the less hindered isomer **a** (80–90% **a** – 10–20% **b**), these behaviors being maintained in solution. Therefore, if the statistical distribution is not followed, like in the case of the trimethylene derivative, the reason should be that in the purification, the mixture is altered. Finally, it is reasonable to suppose that if a single crystal is obtained for X-ray structure determination, probably it would be formed by a unique regioisomer.

Abstract

Density functional theory has been used to explore the energetics and bonding of the symmetric and unsymmetric isomeric sandwich complexes $(\eta^5\text{-}C_5H_5)_2M$, $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$, and $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ (M = Fe, Ru, Os). For each metal atom, the symmetric "5–5" metallocene was found to be the most stable isomer, with the "4–6" and "3–7" isomers ca. 40 and 80 kcal/mol higher in energy, respectively. Bonding analysis shows that $(\eta^4\text{-}C_4H_4)Fe(\eta^6\text{-}C_6H_6)$ is best considered as a $(\eta^4\text{-}C_4H_4)Fe$ fragment interacting with a C_6H_6 ligand, although the interactions become less separable as the metal is changed to Ru and Os. Similarly, the dominant bonding in $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ is that of a $M(\eta^7\text{-}C_7H_7)$ perturbed by the interaction with a C_3H_3 ligand.

1. Introduction

The name of M.L.H. Green will forever be associated with the keen understanding of how metal–ligand interactions influence the structures, bonding, and reactivity of organometallic complexes. In particular, Green's work has explored the impact of cyclic C_nH_n ligands on organometallic chemistry, from his first paper with Pratt and Wilkinson [1] on the synthesis and properties of Cp_2ReH ($Cp = \eta^5\text{-}C_5H_5$) to his pioneering studies in the use of metal–vapor techniques for the synthesis of sandwich complexes [2] and his explorations of the nature of cycloheptatrienyl complexes [3]. One of the many themes of Green's research has been the comparison of symmetric sandwich complexes, such as the bis(benzene) complexes $(\eta^6\text{-}C_6H_6)_2M$ (M = Cr, Mo, W) with isomeric unsymmetric complexes, such as the CpMCht (Cht = η^7-C_7H_7) systems [4]. These unsymmetric "5–7" sandwich complexes are known for a variety of electron counts, including 16, 17, and 18 electron complexes [5–7].

We have been inspired by this latter aspect of "Green chemistry" to explore the bonding in some seemingly simple 18-electron sandwich complexes that are isomers of the symmetric metallocenes Cp_2M (M = Fe, Ru, Os) and have yet to be synthesized. The synthesis of ferrocene in 1951 by two independent research groups [8,9] and the subsequent independent determinations of the famous sandwich-structure of ferrocene by Wilkinson [10] and Fischer [11] transformed organometallic chemistry. Ferrocene (Cp_2Fe; **1**), ruthenocene (Cp_2Ru; **2**) and osmocene (Cp_2Os; **3**) have since been extensively studied and reviewed [12–15] and the 50th anniversary of the synthesis of ferrocene was widely celebrated [16]. The sandwich bonding in these metallocenes, which rests on the interactions of the π-system of the Cp ligands

with the *n*d, (*n* + 1)s, and (*n* + 1)p orbitals of the metal atom, now appears in most standard inorganic and organometallic textbooks.

The remarkable stability of the metallocenes is generally attributed to the strong metal–ligand π-bonding and the formulation of the ligand as a Cp^- anion, which is a six π-electron Hückel aromatic system. Since the discovery of the metallocenes, a plethora of sandwich and sandwich-like compounds have been synthesized and studied including half-sandwich complexes, multidecker sandwich complexes, and bent sandwich complexes. Many of these complexes are based on other π-coordinated η^n-C_nH_n rings from (η^3-C_3H_3) to (η^8-C_8H_8), which can all be formulated to be formally Hückel aromatic depending on the formal charge placed on the ring. Whether the rings are charged and the question of the degree of aromaticity in the various complexes formed is still a lively debate [17], and will not be discussed in detail in this work. All of these ring systems are known to bond in a π-fashion to transition metals, however cyclopentadiene and benzene rings are most commonly found as sandwich ligands. Complexes with the unsubstituted cyclic rings are known for all of these ligands except for C_3H_3; the cyclopropenyl complexes reported to date involve substituted C_3R_3 rings with typically Ph or *t*-Bu substituents on the ring, such as (η^5-C_5H_5)Ni(η^3-C_3 Ph_3), (η^3-C_3Ph_3)Co(CO)$_3$, and (η^3-C_3(*t*-Bu)$_3$)M(CO)$_3$ [18–22].

One of the more notable half-sandwich complexes is cyclobutadiene iron tricarbonyl, (η^4-C_4H_4)Fe(CO)$_3$ [23], which in addition to exhibiting unusual binding also serves as a synthon for the unstable and unisolable cyclobutadiene molecule in organic synthesis. Longuet-Higgens and Orgel [24] predicted that cyclobutadiene would be stabilized by transition metals before there was any experimental evidence for cyclic π-system complexes other than the metallocenes. This prediction was soon realized in 1959 with the synthesis of tetraphenylcyclobutadiene iron tricarbonyl, (η^4-$C_4(C_6H_5)_4$)Fe(CO)$_3$ [25] and tetramethylcyclobutadiene nickel chloride dimer, [(η^4-$C_4(CH_3)_4$)$NiCl_2$]$_2$ [26]. The successful synthesis of cyclobutadiene complexes is a nice example of theoretical prediction predating experimental realization, as has been recently reviewed by Seyferth [27].

The existence and properties of unsubstituted CbFe(CO)$_3$ (Cb = η^4-C_4H_4) has stimulated a large number of experimental and theoretical studies of this and other cyclobutadiene complexes [28,29]. Both X-ray [30] and gas-phase electron diffraction [31] studies of CbFe(CO)$_3$ showed that the cyclobutadiene ligand is square-planar and thus appears to be an example of the coordination of an archetypal Hückel antiaromatic molecule. The complex underwent electrophilic substitution and Friedel-Crafts acylation reactions [32] similar to Hückel aromatic organic species as well as ferrocene. In 1979, we coined the term "metalloaromaticity" [33] to describe the seemingly aromatic behavior of the coordinated cyclobutadiene ligand. In essence, the strong π-interactions between the C_4H_4 ligand and the Fe center turned the four π-electron antiaromatic ligand into a six π-electron metalloaromatic system. The concept of metalloaromaticity has recently been extended to describe all-metal analogs of organic systems that exhibit unusual stability [34].

In this paper, we will use density functional theory (DFT) to examine some simple 18-electron mixed-sandwich isomers of the metallocenes. The electronic structures of the group 8 metallocenes have been extensively discussed and we will examine them only briefly to provide evidence that the computational methods used provide accurate results for these types of systems. We will subsequently focus on the structure, energetics, and bonding of the cyclobutadiene metal benzene complexes (η^4-C_4H_4)M(η^6-C_6H_6) (M = Fe, **4**; Ru, **5**; Os, **6**) and cyclopropenyl metal cycloheptatrienyl complexes (η^3-C_3H_3)M(η^7-C_7H_7) (M = Fe, **7**; Ru, **8**; Os, **9**). We will discuss the iron isomers **1**, **4**, and **7** in depth before examining the changes that are observed when progressing down the periodic table. Of the complexes examined in this study, only the metallocenes (**1**, **2**, and **3**) are known experimentally. There has been one previous theoretical study related to **4** by Jemmis et al. [35] who examined the viability of an (η^4-C_4H_4)Fe fragment coordinated to the surface of C_{60} and C_{70} clusters. There has been no experimental evidence for, or against, the existence of group 8 mixed-sandwich isomers, although we would be surprised if there have not been efforts to replace the three CO ligands of CbFe(CO)$_3$ with an arene ligand. Through our investigations we hope to provide insights into the possible viability of these series of complexes in relation to the well-known metallocenes.

2. Computational details

DFT calculations were performed using the Amsterdam density functional (ADF) package, version 2003.01, developed by Baerends et al. [36–38] The frozen-core approximation was applied to all atoms except H. 1s was frozen for C and 1s–2p were frozen for Fe, and 1s–(*n* − 1)d were frozen for Ru and Os. All atoms utilized the ADF Basis TZ2P, which is a core double-zeta, valence triple-ζ Slater-type orbital (STO) doubly polarized basis set. Relativistic effects were included in all calculations containing Ru and Os through the use of the zero-order regular approximation (ZORA) formalism [39,40,41] and ZORA TZ2P Basis. The generalized gradient approximation (GGA) exchange and correlation corrections developed by Perdew and Wang (PW91) [42–44] were used for all calculations. Geometry optimizations were carried out with an integration

parameter of at least 6.0, and were optimized to a maximum gradient of no more than 0.0001 hartree/Å.

3. Results and discussion

3.1. Calculated structures

Studies of the structure, bonding, and properties of ferrocene (**1**) are numerous, and only the salient features will be repeated here for comparison to other $MC_{10}H_{10}$ isomers. It is useful to compare experimental data on the Group 8 metallocenes to the calculated structures and properties to provide a benchmark for the DFT methods used in these studies. A representative calculated structure for $(\eta^5\text{-}C_5H_5)_2M$ (Fe: **1**; Ru: **2**; Os:**3**) is shown in Fig. 1 and selected geometric parameters are given in Table 1. The calculated structures of **1**, **2**, and **3** agree extremely well with the available experimental data [45–49] (Table 2). The barrier to rotation for **1** is calculated to be 1.02 kcal/mol, with the eclipsed structure being the lowest energy structure. The experimentally measured [50] rotation energy of ferrocene is 0.9 ± 0.3 kcal/mol, and after much debate it was finally determined that ferrocene is eclipsed in the gas phase [51], and that the crystal structure was nearly eclipsed at low temperature [52]. The eclipsed structure was also calculated to be the lowest-energy for **2** and **3**, with the difference in energy between the eclipsed and staggered structures of 0.61 and 0.77 kcal/mol, respectively.

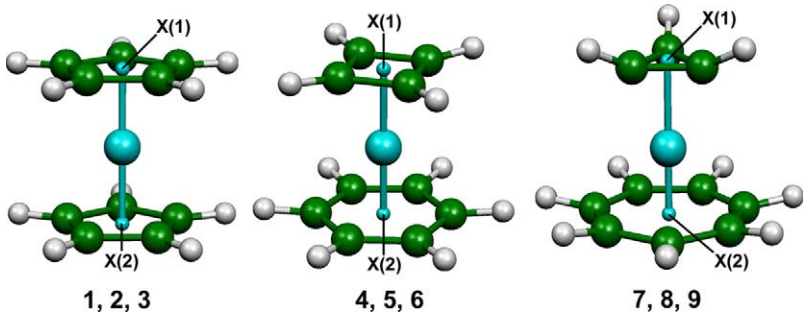

Fig. 1. Representative 3D structures for $MC_{10}H_{10}$ complexes: $(\eta^5\text{-}C_5H_5)_2M$ (M = Fe, **1**; Ru, **2**; Os, **3**), $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$ (M = Fe, **4**; Ru, **5**; Os, **6**), and $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ (M = Fe, **7**; Ru, **8**; Os, **9**). The centroids of Ring 1 and Ring 2 are labeled X(1) and X(2), respectively.

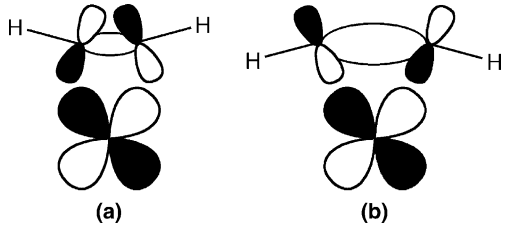
Experimental values for the rotation energies of ruthenocene and osmocene have not yet been accurately determined.

Cyclobutadiene metal benzene $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$ complexes **4**, **5**, and **6** have not been previously reported. A representative calculated structure for **4**, **5**, and **6** is shown in Fig. 1, with geometric parameters given in Table 1. The C_6 ring of the benzene ligand is slightly puckered away from planarity; the average C_a–C_b–C_c/C_b–C_c–C_d dihedral angle, which would be 0° for a perfectly planar ring, is 1.73°, 2.57°, and 3.29° for **4** (Fe), **5** (Ru), and **6** (Os), respectively. By comparison, the C_4 rings of the cyclobutadiene ligands in **4**, **5**, and **6** are rigorously planar, with nearly identical C–C bond lengths in all three complexes. The out-of-plane bending of the C–H bonds on the two rings is more pronounced than in the metallocenes (**1**–**3**) due to the increased hybridization of C atoms to reorient the pπ orbitals for maximum overlap with the metal orbitals. Because of the small size of the C_4H_4 ring, the C–H bonds on the cyclobutadiene ring bend away from the metal in order to cause the pπ orbitals to tip outward (Scheme 1(a)). By comparison, the C–H bonds on the benzene ring show the opposite behavior, bending toward the metal because the ring is slightly too large (Scheme 1(b)). In general, as the size of the metal increases from Fe to Os the ring-size-mismatch with cyclobutadiene becomes larger and increases the C–H bending angle away from the metal, while the mismatch with benzene becomes smaller and decreases the C–H bending angle toward the metal.

The $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ complexes **7**, **8**, and **9** also have not been previously studied, experimentally or theoretically. In the optimized structures (Fig. 1, Table 1) the out-of-plane bending of the C–H bonds on the C_3H_3 ring is severe (>20° from planarity) due to the large mismatch in size and location of the pπ orbitals relative to the metal orbitals. As the size of the metal increases from Fe to Os, the M–C_3H_3 size mismatch and out-of-plane bending become larger as expected. However, the M–C_7H_7 size mismatch remains relatively constant throughout the series, due in part to the significant deviation from planarity of the C_7 ring of the C_7H_7 ligand: The average dihedral angle within the C_7 ring varies non-monotonically, from 5.94° for **7** (Fe) to 10.85° for **8** (Ru) to 1.96° for **9** (Os).

The data in Table 1 also allow us to examine the changes that occur upon changing the metal from Fe to Ru to Os. As would be expected, for each of the three series of complexes the changes in the metric parameters when replacing Fe with Ru are larger than those when Ru is replaced with Os. This observation is entirely consistent with the more severe change in metal atomic radius from Fe to Ru as compared to Ru to Os.



Scheme 1.

3.2. Isomer energies

The calculated relative energies of the Fe, Ru, and Os complexes **1** through **9** are presented in Table 3. We can use these energies to compare the relative energies of the isomers of each metal (Fe: **1**, **4**, **7**; Ru: **2**, **5**, **8**; Os: **3**, **6**, **9**). It is notable that the hypothetical isomerization reactions

$$(\eta^5\text{-}C_5H_5)_2M \rightarrow (\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$$
$$\rightarrow (\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$$

are isodesmic processes [53] that should allow for meaningful comparisons of the relative isomer energies.

The data in Table 3 show not surprisingly that for each of the metallocene $(\eta^5\text{-}C_5H_5)_2M$ is the most stable isomer for each of the three metal series. The relative stability of the metallocenes is a consequence of the best ring-size match discussed above and specific orbital interactions, as will be discussed below. The relative energies as one proceeds from the "5–5" to the "4–6" to the "3–7" isomer are roughly the same regardless of the metal – the relative energies rise by approximately

Table 3
Relative energies (kcal/mol) for complexes **1** through **9**

Complex	Relative energy
$FeC_{10}H_{10}$	
1	0.00
4	39.18
7	88.12
$RuC_{10}H_{10}$	
2	0.00
5	39.15
8	86.65
$OsC_{10}H_{10}$	
3	0.00
6	38.48
9	84.52

40 kcal/mol for each –CH unit shifted from one ring to the other. The higher energies of the 4–6 and 3–7 isomers are doubtless due in part to ring strain in the ligands, particularly the C_4H_4 and C_3H_3 rings. Because of the ambiguities in assigning specific charges to the ligands (vida infra), we have not yet attempted to partition the energy differences into metal–ligand bonding and intraligand contributions.

3.3. Bonding analysis – $FeC_{10}H_{10}$

The bonding in **1** is well understood, and we will avoid a detailed reanalysis of the subject here. Under D_{5h} symmetry, the dominant metal–ligand interaction in **1** is donation from the formally filled e_1'' combination of the Cp^- (π_2, π_3) orbitals into the Fe 3dπ (d_{xz}, d_{yz}) orbitals, with lesser donation from the a_1' ligand π-orbital into the Fe 4s orbital. The formally d^6 complex corresponds to an electron configuration of $(d\delta)^4(d\sigma)^2(d\pi)^0$ at the Fe center. Complete molecular orbital diagrams and discussions of the eclipsed and staggered forms may be found in many modern inorganic textbooks [54].

Bonding analyses for the mixed sandwich complexes are necessarily more complex than those of the metallocenes owing to the presence of two different sandwich rings and the concomitant reduction in symmetry. We will discuss the bonding of the iron isomers **4** and **7** in detail first, followed by discussion of any changes in the bonding upon replacing Fe with Ru and Os. For the ligands in our systems it is generally assumed that the σ system of the ring will play a very small role in the bonding, and therefore we only consider the relevant ring π orbitals in our analysis. It is also reasonable to assume that the interaction of each ring with the metal will retain much of the symmetry characteristics of the ring, independent of the overall symmetry of the molecule. For that reason, we will use higher localized pseudo-symmetry than might exist overall in the complex.

Fragment analysis will be used to examine the dominant bonding in **4** to determine whether it should be viewed as a FeC_4H_4 fragment perturbed by a benzene ligand or a FeC_6H_6 fragment perturbed by a cyclobutadiene ligand. We have proposed earlier that the interaction of a cyclobutadiene ligand and an Fe atom arises from a strong covalent π-bonding interaction between the e_g (2π) Cb π orbitals (which are half-filled in neutral square C_4H_4) and the Fe $3d_{xz}$ and $3d_{yz}$ orbitals [33]. We find that the present ADF calculations on (η^4-C_4H_4)Fe yield results similar to those previously reported by Bursten and Fenske on this fragment: as shown in Fig. 2, the Fe 3d orbitals match well energetically with the e_g orbitals of the cyclobutadiene ligand, facilitating a strong covalent π interaction. The π bonding 1e orbital is 48.0% Cb 2π and 38.2% Fe 3dπ, and the π* 2e orbital is 49.1% Fe 3dπ and 33.22% Cb 2π. By comparison, the interaction between a benzene ligand and an Fe atom is due mainly to δ-bonding interactions between the e_{2u} (3π) orbitals of benzene and the Fe $3d_{x^2-y^2}$ and $3d_{xy}$ orbitals, although there is a small π-bonding interaction between the e_{1g} (2π) benzene MOs and the Fe $3d_{xz}$ and $3d_{yz}$ orbitals. The δ-bonding interaction in Fe(η^6-C_6H_6) is weaker than the π-bonding interaction in the (η^4-C_4H_4)Fe fragment because of both the smaller orbital overlap and an energy mismatch between the benzene π orbitals and the iron 3d orbitals.

We previously used the energetic ordering of fragment orbitals to determine whether (η^4-C_4H_4)Fe$(CO)_3$ is better considered as a (η^4-C_4H_4)Fe fragment perturbed by three CO ligands, or as an Fe$(CO)_3$ fragment perturbed by a C_4H_4 ligand – in that case, the C_4H_4–Fe π-bonding interaction dominates and the first description is more appropriate [33]. We have performed a similar orbital analysis for (η^4-C_4H_4)Fe(η^6-C_6H_6) (**4**). If **4** should be viewed as a (η^4-C_4H_4)Fe fragment that has been affected by a benzene ligand, the MO diagram of **4** will have the π-bonding (η^4-C_4H_4)Fe e orbitals below the δ-bonding C_6H_6 orbitals. On the other hand, if this complex is best considered to be an Fe(η^6-C_6H_6) fragment interacting with a cyclobutadiene ligand, the MO diagram of **4** should have the reverse situation – the Fe(η^6-C_6H_6) δ-bonding orbitals should be below the π-bonding C_4H_4 orbitals. Fig. 3 shows the interaction of a (η^4-C_4H_4)Fe fragment with a benzene ligand. The π-bonding orbitals of the FeC_4H_4 fragment are relatively unaffected by the presence of the benzene ligand, although the Fe–C_4H_4 e* antibonding orbitals between are pushed up in energy. There is a stabilization of the $d_{x^2-y^2}$ and d_{xy} orbitals due to the δ-bonding interaction with benzene. Nevertheless, the metal orbital ordering remains similar to that of the (η^4-C_4H_4)Fe fragment, with the π-bonding e orbitals of the (η^4-C_4H_4)Fe fragment below the δ-bonding interaction of Fe with benzene. A similar interaction diagram between a C_4H_4 ligand with a Fe(η^6-C_6H_6) fragment (not shown) shows a large perturbation of the metal-based orbitals of the Fe(η^6–C_6H_6) moiety. Thus, the fragment analysis

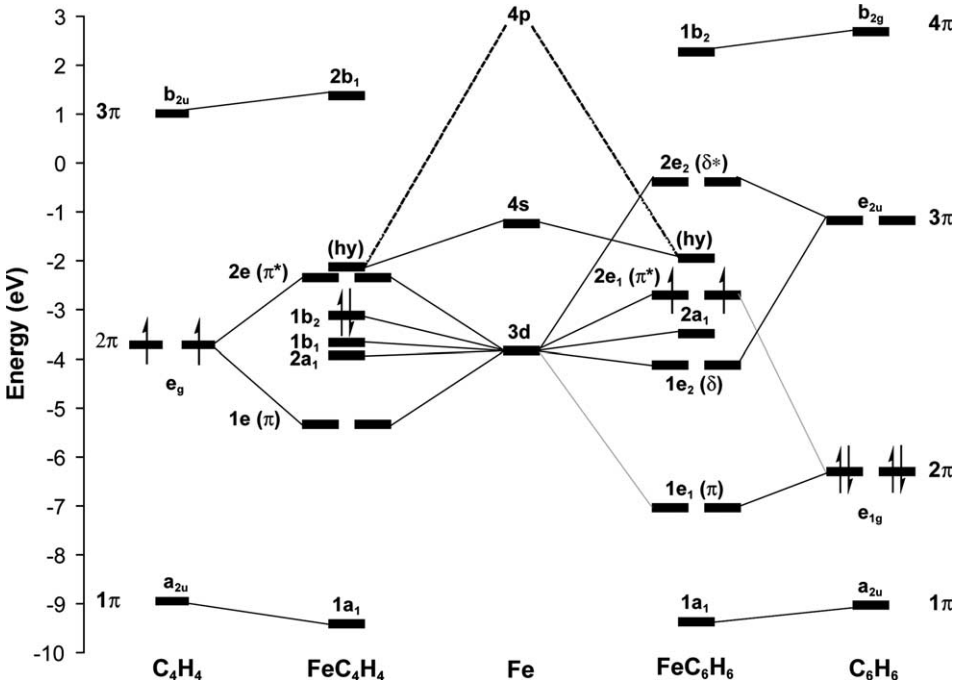


Fig. 2. Orbital interaction diagrams showing the formation of (η^4-C_4H_4)Fe and (η^6-C_6H_6)Fe fragments from the interactions of an Fe atom with the cyclic ligands.

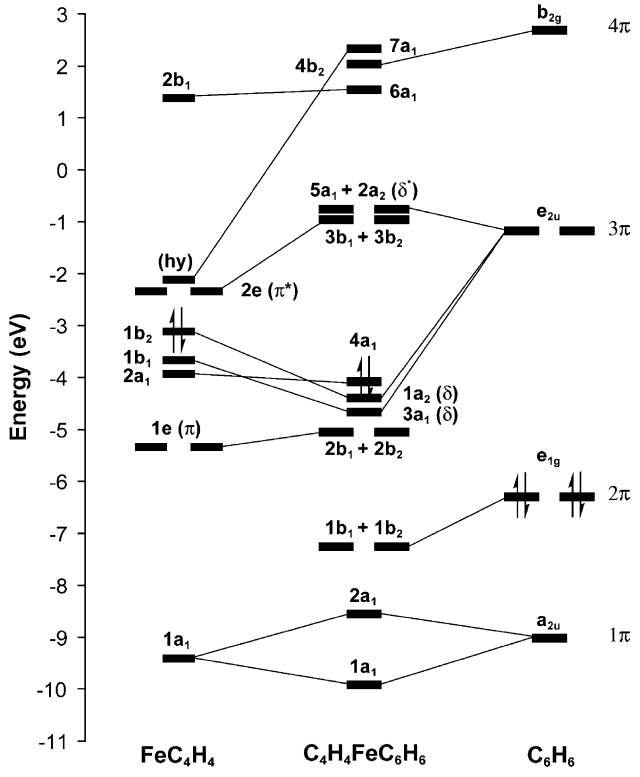

Fig. 3. Interaction diagram showing the development of the orbitals of (η^4-C_4H_4)Fe(η^6-C_6H_6) from (η^4-C_4H_4)Fe and C_6H_6.

clearly indicates that **4** is better viewed as a metalloaromatic (η^4-C_4H_4)Fe fragment interacting with a C_6H_6 ligand, similar to the description of (η^4-C_4H_4)Fe(CO)$_3$. Given that Fe(η^6-C_6H_6) is isolobal to Fe(CO)$_3$ [55], this conclusion is not surprising.

We can apply the same orbital analysis to (η^3-C_3H_3)Fe(η^7-C_7H_7) (**7**). Fig. 4 compares the interactions of an Fe atom with C_3H_3 and C_7H_7 to form (η^3-C_3H_3)Fe and Fe(η^7-C_7H_7), respectively. In the case of (η^3-C_3H_3)Fe, the only significant interaction between Fe and C_3H_3 is a π-bonding interaction between the e″ (2π) orbitals of the ligand and the Fe 3dπ orbitals (Fig. 4). Because the C_3H_3 e″ orbitals are higher in energy than the Fe 3d orbitals, the resultant π-bonding e MO of (η^3-C_3H_3)Fe has greater Fe character than ligand character. In addition, because of the size and orbital orientation mismatch between the C_3H_3 ring and Fe 3d orbitals, there is significant mixing of the Fe $d_{x^2-y^2}$ and d_{xy} orbitals in the π-bonding orbitals as well as significant mixing of the Fe 4p orbitals in the π* orbitals. In contrast, C_7H_7 and Fe have a very small π-bonding interaction because of the large energy mismatch between the C_7H_7 e_1'' (2π) and the Fe 3d orbitals; as shown in Fig. 4, the dominant bonding in Fe(η^7-C_7H_7) is due to the δ interaction between the C_7H_7 e_2'' (3π) orbitals and the Fe 3dδ ($3d_{x^2-y^2}$ and $3d_{xy}$) orbitals. Thus, these metal–ligand interactions lead to distinctly different ordering of the Fe-based MOs of the fragments: The Fe 3dπ MO is the lowest energy metal-based orbital in (η^3-C_3H_3)Fe whereas the Fe 3dδ is lowest in Fe(η^7-C_7H_7).

A comparison of the orbital interactions shows clearly that **7** is better considered as a Fe(η^7-C_7H_7) fragment interacting with a C_3H_3 ligand. Fig. 5 shows these

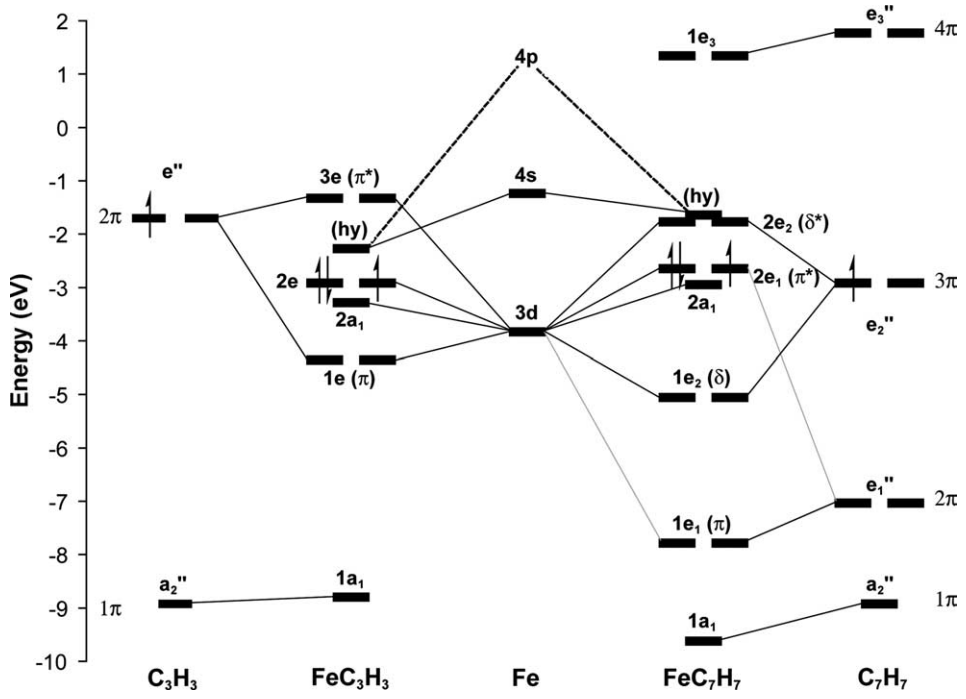

Fig. 4. Orbital interaction diagrams showing the formation of (η^3-C_3H_3)Fe and (η^7-C_7H_7)Fe fragments from the interactions of an Fe atom with the cyclic ligands.

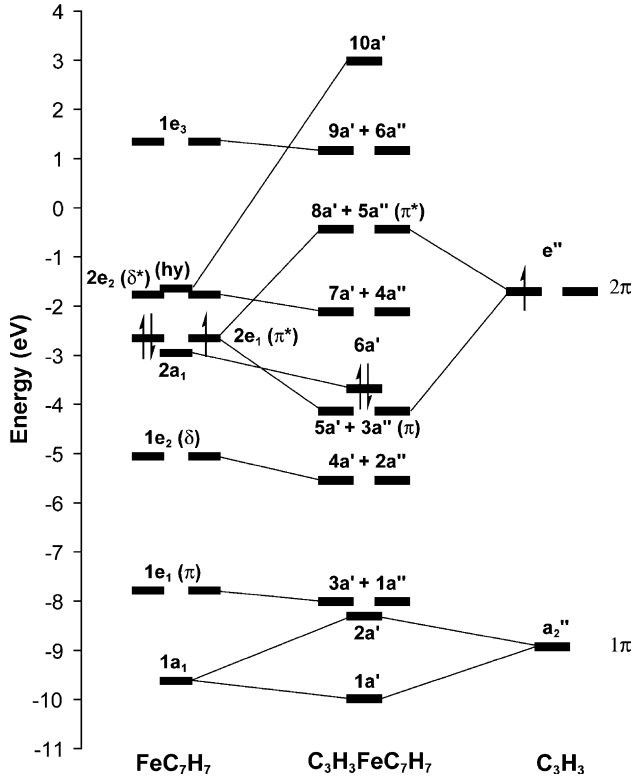

Fig. 5. Interaction diagram showing the development of the orbitals of (η^3-C_3H_3)Fe(η^7-C_7H_7) from (η^7-C_7H_7)Fe and C_3H_3.

orbital interactions and clearly indicates good transferability of the MOs of the Fe(η^7-C_7H_7) fragment to those of **7**; in particular, the lowest metal-based orbital of **7** is the Fe 3dδ MO derived from the Fe(η^7-C_7H_7) fragment. By comparison, the transferability of the (η^3-C_3H_3)Fe fragment onto the overall MO diagram for **7** is poor. The HOMO of **7** is predicted to be the largely unperturbed Fe $3d_{z^2}$ orbital, similar to what has been found experimentally and theoretically by Green et al. [56,57] for 17- and 18-electron unsymmetric (η^5-C_5H_5)M(η^7-C_7H_7) complexes.

The difference in the dominant fragment in complexes **4** and **7** illustrates an important point about mixed sandwich complexes – neither the distance of the ligand centroid from the metal nor the symmetry of the bonding necessarily dictate the dominantly bound fragment. In **4** the dominantly bound fragment is C_4H_4, the centroid of which is further from the metal than that of C_6H_6; in **7** the C_7H_7 ring is the dominant fragment and its centroid is much closer to the metal center than that of C_3H_3. In addition, the dominant fragment is bound in two different ways in these two complexes: in **4** the Fe–C_4H_4 bonding is due primarily to a metal–ligand interaction of π symmetry whereas in **7** the dominant Fe–C_7H_7 interaction has δ symmetry. Although we normally do not consider primary bonding in organometallic species to be of a δ-bonding type, we can see in **7** that the δ-bonding is strong and mainly covalent. This conclusion is in nice accord with that of Green et al., who used variable-photo-energy photoelectron spectroscopy to demonstrate the significance of metal–ligand δ-bonding in Cr(η^6-C_6H_6)$_2$ and Mo(η^6-C_6H_5Me)$_2$ [58]. Frenking et al. [59] have recently reported a computational study

that supports the conclusion that δ-bonding is the dominant bonding type in $Cr(\eta^6\text{-}C_6H_6)_2$.

3.4. Analysis of the formal charges in 1, 4, and 7

Thus far in our discussion, we have avoided assigning formal charges to the cyclic ligands in complexes **1**, **4**, and **7**. We can provide a simple analysis of the formal ligand charges based on the relative orbital energetics presented in Figs. 2 and 4 as well as the usual description of ferrocene. Ferrocene is generally considered to be a complex in which two formally Cp^- ligands are bonded to a d^6 Fe(II) center. This description is consistent with the relative orbital energetics of the Cp ligand and the Fe 3d orbitals, i.e. the e_1'' HOMO of Cp^- is at a lower energy than the Fe 3d orbitals, so the Cp–Fe π-bonding MOs are dominantly Cp in character.

In **4**, the e_g HOMO of neutral C_4H_4 is nearly isoenergetic with the Fe 3d orbitals (Fig. 2), which leads to the strong covalent bonding description we have presented previously [33]. We therefore believe that the C_4H_4-Fe π-bonding is essentially equally shared between the ligand and the metal, which is consistent with considering C_4H_4 as a neutral ligand. The C_6H_6 ligand in **4** is also best considered a neutral ligand inasmuch as all of the filled and empty orbitals of neutral C_6H_6 are lower and higher in energy, respectively, than the Fe 3d orbitals. Thus, this simple analysis suggests that **4** is best considered formally as a d^8 Fe(0) complex with neutral C_4H_4 and C_6H_6 ligands. A similar analysis of **7**, based on Fig. 4, suggests that both C_3H_3 and C_7H_7 be considered cationic ligands: Both the e'' π orbitals of C_3H_3 and the e_2'' π orbitals of C_7H_7 are higher in energy than the Fe 3d orbitals. This observation leads to the unusual proposal that **7** be considered a d^{10} Fe(−2) complex with formal $C_3H_3^+$ and $C_7H_7^+$ ligands, both of which are Hückel aromatic π systems. We are thus left with the intriguing description that the movement of a C–H group from one ring to another in going from **1** to **4** and **4** to **7** is accompanied by a formal two-electron reduction of the Fe center, at least within this simplified, orbital-energy-driven description.

Our proposal that the cht ligand be considered as $C_7H_7^+$ runs counter to convincing experimental and theoretical studies by Green and Kaltsoyannis [56,57]. Based on their studies of 16-, 17- and 18-electron $(\eta^5\text{-}C_5H_5)M(\eta^7\text{-}C_7H_7)$ (M = Ti, V, Nb, Ta, Mo) complexes, these authors concluded that the cht ligand should not be considered as a 1+ nor a 3− ligand – rather it is best described as a seven-electron ligand and that three metal-based electrons are required to form the M-cht bond. We note that the Fe, Ru, and Os complexes examined here involve later metals that are expected to compete more effectively for electrons than do the early metals of these other studies.

Because of the intriguing differences in these descriptions, we have used population analysis to examine the conclusion about the charges on the Fe atom and the ligands in complexes **1**, **4**, and **7.** Table 4 presents the Mulliken and Hirshfeld charges [60] on the Fe atom and on the ligands in **1**, **4**, and **7**. There is reasonable agreement between these two methodologies for partitioning the charge among the portions of the molecules. The Mulliken charge on the Fe monotonically decreases from **1** to **4** to **7**, although the magnitude of the changes are rater small; the Hirshfeld charges on the Fe atom are nearly invariant from one complex to another. Interestingly, the two methods both show that the charges on the C_nH_n ligands become monotonically more positive as n increases, i.e. the C_3H_3 ligand is the most negatively charged whereas the C_7H_7 ligand is the most positively charged. We will be exploring the effects of these charges on the relative energetics of the isomeric complexes further.

3.5. Bonding analysis – $RuC_{10}H_{10}$ and $OsC_{10}H_{10}$

Fig. 6 shows the changes in the metal-based MO energies that occur when progressing down the periodic table from Fe to Os. In the $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$ series (**4**–**6**) the complex has a significant change in bonding: the C_4H_4-M π-interaction is destabilized, and the C_6H_6-M δ-interaction is strengthened from Fe to Os (Fig. 6(a)). In **6** the benzene MOs of δ symmetry and the cyclobutadiene MOs of π symmetry are essentially

Table 4
Mulliken and Hirshfeld charges for the Fe atom and ligands in complexes **1**, **4**, and **7**

Complex	Fragment	Mulliken charge	Hirshfeld charge
$(\eta^5\text{-}C_5H_5)_2Fe$	Fe	0.154	0.040
	$\eta^5\text{-}C_5H_5$	−0.077	−0.020
$(\eta^4\text{-}C_4H_4)Fe(\eta^6\text{-}C_6H_6)$	Fe	0.107	0.035
	$\eta^4\text{-}C_4H_4$	−0.124	−0.070
	$\eta^6\text{-}C_6H_6$	0.017	0.035
$(\eta^3\text{-}C_3H_3)Fe(\eta^7\text{-}C_7H_7)$	Fe	0.066	0.040
	$\eta^3\text{-}C_3H_3$	−0.173	−0.134
	$\eta^7\text{-}C_7H_7$	0.106	0.093

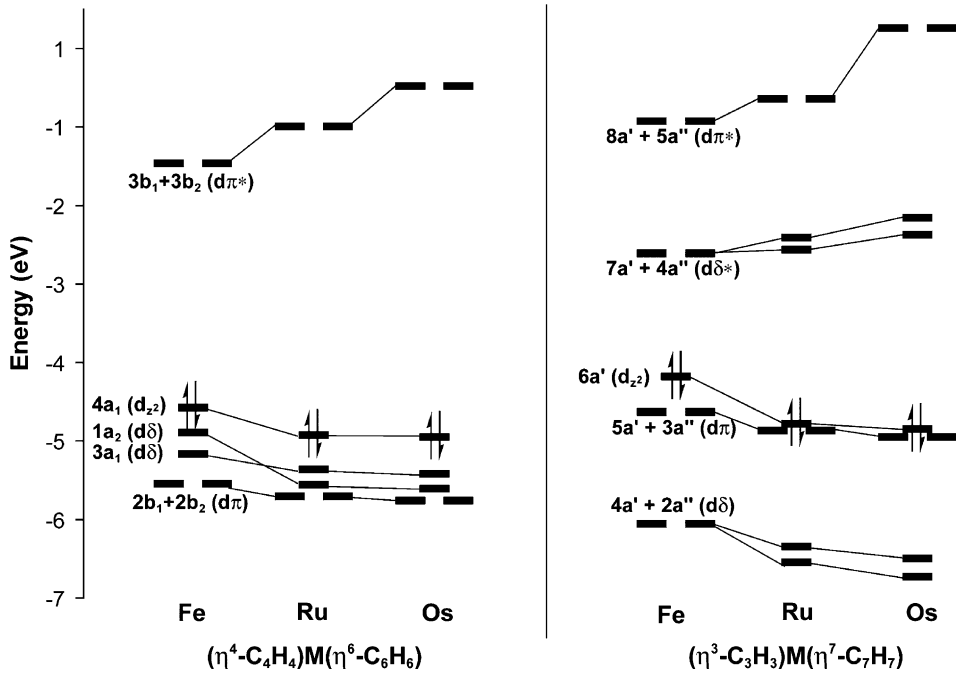

Fig. 6. Correlation diagram showing the energetic changes of the M *n*d-based MOs as M is changed from Fe to Ru to Os. Left: $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$. Right: $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$.

isoenergetic, implying that the bonding of each ligand is competitive with the other – there is no longer a dominantly bound ligand in this complex. The increased size and diffuseness of the Os 5d orbitals, as compared to the Fe 3d orbitals, allow for better π overlap with the benzene e_2'' orbitals and causes a decreased overlap with the cyclobutadiene e″ orbitals (as seen by the increased C–H bending on C_4H_4 in **6**).

Similar effects are seen in the $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ complexes (**7**–**9**). As the d orbitals increase in size from Fe to Ru to Os, the interaction with the smaller C_3H_3 ligand becomes less effective and that with the larger C_7H_7 ligand increases. In this case, however, the dominant interaction in the complex involves the δ interaction of the metal with the C_7H_7 ligand, Thus, the bonding effects seen in the Fe complex are reinforced in this series of complexes, i.e. the dominance of the $M(\eta^7\text{-}C_7H_7)$ increases as we progress from Fe to Ru to Os.

4. Conclusions

The calculations that we have presented here suggest that the metallocenes are the most stable of the $(\eta\text{-}C_nH_n)M(\eta\text{-}C_{10-n}H_{10-n})$ sandwich complexes examined. In one sense that is a satisfying and sensible conclusion given the central role that the metallocenes play in organometallic chemistry viz-á-viz the nonexistence of the unsymmetric sandwich complexes. Nevertheless, the calculations suggest that the metal–ligand bonding interactions in the "4–6" and "3–7" complexes are, in principle, robust enough to allow these complexes to exist, especially given that there would be no easy route for these to isomerize to the metallocenes.

In future contributions we will look more closely at some of the energetic contributions to the different isomer stabilities. We will also be presenting a similar analysis of sandwich complexes of the type $(\eta\text{-}C_nH_n)M(\eta\text{-}C_{12-n}H_{12-n})$ (M = Cr, Mo, W), the chemistry of which has been indelibly affected by Malcolm L.H. Green.

Syntheses and crystal structures of three novel Cu(II) coordination polymers of different dimensionality constructed from Cu(II) carboxylates (carboxylate = malonate (mal), 2 acetate (ac), fumarate (fum)) and conformationally flexible 1,4-bis(imidazole-1-yl-methylene)benzene (IX)

Abstract

We herein report three new coordination polymers generated from Cu(II) carboxylates (mal, 2ac, fum) and conformationally flexible bifunctional IX as building blocks. All the three complexes adopt unique structures in the solid state. The complex $[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$ crystallizes as orthorhombic co-linear rods with space group P2(1) P2(1) P2(1). Each rod is further formed of two tightly intertwined strings. The second polymer $[Cu_2(ac)_4(IX)_2]_n$ crystallizes with space group P1 which consists of two sets of intersecting 2D sheets composed of parallel rods which interpenetrate to form a fully interlocked 3D structure. In both these complexes IX coordinates in the *anti* mode. The third polymer $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$ possesses a monoclinic crystal system with space group C_2/c and crystallizes as 1D straps. Cu–fum–Cu forms the base of the string which is alternatively garlanded by a macrocycle derived from $Cu_2(IX)_2$ unit, where IX coordinates in the *syn* fashion. The present study suggests that the use of a rigid building block with a flexible organic ligand leads to a better prediction of the final structure of the polymeric array.

Keywords: Flexible; Carboxylates; IX; Coordination polymer; Architecture

1. Introduction

Self-assembly of molecular rods and tubes and their use is a fast growing area of material science [1–12]. Such materials are useful for the study of long distance interaction phenomena particularly electron and energy transfer and magnetic coupling in transition metal ions. Furthermore, molecular rods offer an opportunity to position two active centers at a known distance apart and connect them by spacers with desired properties.

Cu(II) salts or preformed Cu(II) species react with rigid bidentate spacers viz. terephathalate [13–17], 1,4-bis(4-pyridyl)butadiyne [18], piperazine [19], 2,7-diazapyrene [20], 4,4′ bipyridine(bpy) [21–26], 3,4′-bpy [26], 3,3′-bpy [26] and 4,4′-bipyridine dioxide [27] to afford exciting new structures with vast diversity ranging from one dimensional zigzag polymeric chains to interlocked 3D networks. However, all these structures lack any flexibility. Even in nature a slight distortion in angles is prevalent to afford flexibility in structure. Until

recently only little attention has been diverted towards the use of flexible and angular bifunctional ligands.The topological isomerism which exists in such ligands, results in different ligand-metal coordination connectivity and introduces an additional ability in such ligands to adopt the most suitable structural architecture. It further offers an opportunity for the construction of polymeric networks with motifs hitherto unknown in the literature. Polymers exhibiting structural isomerism due to more than one isomeric forms and interpenetration of two frameworks with different conformations of the same ligand have been reported in a series of complexes generated from bis(pyridyl)alkane (R = methane, ethane, propane) [28–35]. The situation is further complicated if the complexes are derived from a chiral ligand. A study of structurally similar disulfide ligands such as bis(phenylthio)alkanes (methane and butane) and bis(4-pyridyl)disulfide result in a variety of networks exhibiting both chiral and topological isomerism [36–38]. Currently the greatest challenge of modern inorganic chemistry is to design molecular extended systems possessing original architecture and predictable physical properties. Although with rigid ligands the present state of art is that sufficient data is available to rationalize the final structure of the architecture, more subtle changes are observed with flexible ligands and an extensive study of M-organic reactions using such ligands is demanded to develop proper synthetic strategies to generate designed frameworks with useful functions.

Bifunctional semiflexible angular 1,4-bis(imidazole-1-yl-methylene)benzene can adopt either *syn* or *anti* conformation with imidazole N binding metal ions with angles as diverse as 90° and 180° (Fig. 1). This ligand can assemble into convergent products resulting in discrete architectures or aggregate into extended arrays, which can be viewed as divergent products of similar reactions. However, currently efforts are being made to hybrid the two processes by assembling the discrete molecular products into polymeric arrays by bridging

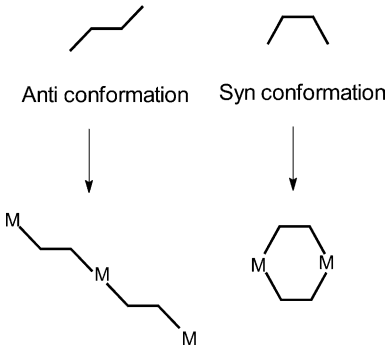

Fig. 1. *Syn* and *anti* conformation of the ligand leading to divergent and convergent products with suitable metal ions.

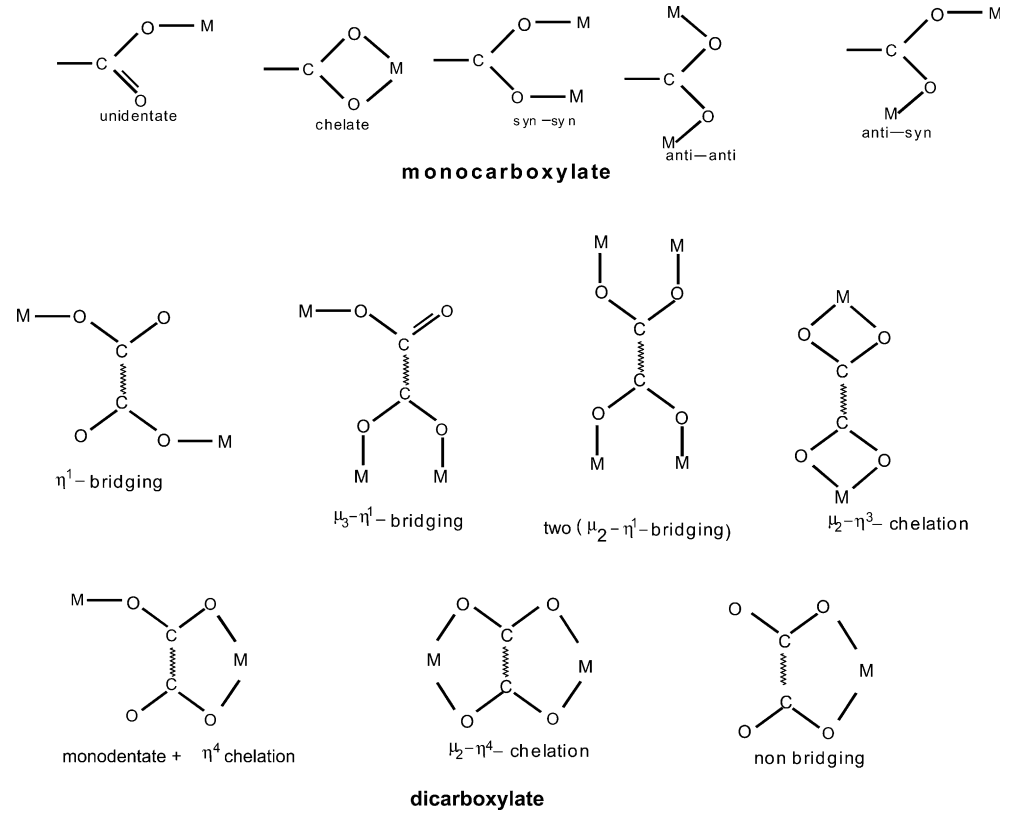

Fig. 2. Various modes of coordination of the carboxylate ligand.

the metal atoms of metallocycles, using suitable bifunctional moieties for which carboxylates fit very well. During the present investigations the selection of Cu carboxylates for generation of assemblies is especially interesting because of many other reasons. They are able to generate robust, neutral and thermally stable frameworks with large pore sizes [39–41]. Assemblies are known in which the original structure of the carboxylate is undisturbed [19]. Moreover, because of their versatility to adopt various bonding modes (non-chelating, chelating and bridging) they generally yield a rich fascinating chemistry (Fig. 2). Nevertheless, polymeric structures employing carboxylate as a coligand with other bifunctional neutral ligands are relatively limited. To explore the influence of the orientation of the carboxylate moiety in these Cu carboxylates on a supramolecular architecture we selected mononuclear copper malonate, dinuclear copper acetate and polymeric copper fumarate. These three metal salts also vary in terms of their flexibility as well as steric hindrance. The combination of conformationally flexible IX and versatility of carboxylate is expected to generate fascinating chemistry. Herein, we report the syntheses and characterization of three polymers $[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$, $[Cu_2(ac)_4(IX)_2]_n$ and $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$.

2. Experimental

2.1. Materials

Copper malonate was prepared by a known method [42]. Copper acetate, sodium fumarate, *p*-xylene, imidazole and copper chloride were procured from Ranbaxy, Chandigarh and were used as received. All the solvents were A. R. grade and were employed as such without further purification.

2.2. Techniques

Elemental analysis for C, H and N was carried out with a Carlo Erba 1106 microanalyser. The Infrared spectra were recorded using KBr pellets on a FTIR 8101M Shimadzu spectrometer in the 4000–400 cm^{-1} range. TGA-DTA curves were recorded on a simultaneous thermal analyzer Shimadzu DT-40 model. X-ray powder diffraction (XRPD) data were recorded on a PW1710 diffractometer at 3 kV and 20 mA for Cu Kα (λ = 1.54060 Å) radiation with a continuous scan and a step size of 0.5° in 2θ. The sample was subjected to magnetization measurements as a function of temperature, *M* vs *T*, as well as applied field, *M* versus *H*, using a Vibration Sample Magnetometer Model 4500 (EG&G Priceton Applied Research). The temperature dependence of magnetization was studied by carrying out field-cooled magnetization (FCM), zero field-cooled magnetization (ZFCM). FCM data were obtained after cooling the sample in 500 Oe applied field and then recording the magnetization while warming the sample up from 4.5 to 35 K, keeping the field on. The field dependence of the magnetization M versus H plots were recorded at 4.5 K under an applied field of −10 000 to 10 000 Oe. ^1H and ^{13}C NMR spectra of the ligand were recorded on a Bruker A. C. 200MHz instrument in $CDCl_3$. The mass spectrum of the ligand was recorded on a GCMS-QP-2000 mass spectrometer by the EI method.

2.2.1. X-ray data collection

The single-crystal X-ray diffraction was done with a Nonius Kappa CCD diffractometer with graphite monochromatized μ_0Kα (λ = 0.71073 Å) radiation. Collect-software was used in the measurement and DENZO-SMN [43] in processing of the data. The structures were solved and refined by full-matrix least-squares on F^2 with the WINGX-software package [44] utilizing SHELXS-97 [45] and SHELXL-97 [46] modules. Hydrogen atoms were refined by a riding model. The graphic presentations of the structures were created with the software DIAMOND [47].

2.3. Syntheses

2.3.1. Synthesis of IX

The ligand was synthesized by reacting 1,4-dibromobenzene and imidazole in dry acetonitrile under PTC conditions by a known method [48]. Yield 60%; m.p. 74 °C; MS: *m/z* 238 (72.9%, M^+), 171 (86.9%, M^+ − imidazole), 104 (100%, $M^+ - 2$ imidazole), ^1H NMR ($CDCl_3$); δ 7.54 (s, 2H, —N=), 7.09 (dd, 4H), 7.16 (m, 4H), 5.10 (s, 4H); ^{13}C NMR ($CDCl_3$): 50.2 (CH_2), 119.1 (CH), 127.7(CH), 129.9(CH), 136.4(C), 137.2(CH).

2.3.2. $[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$ (1)

To an aqueous solution of $[Cu(mal)]\cdot 2H_2O$ (0.290 g, 1.0 mmol in 5 ml) was added a methanolic solution of IX (0.240 g, 1.0 mmol in 5 ml). A blue complex, in 70% yield (0.320 g) based upon metal, separated out immediately, and was filtered, washed with methanol, water and dried in vacuo. Calc. for $C_{34}H_{44}Cu_2N_8O_{14}$: C, 44.7; H, 4.8; N, 12.2. Found: C, 44.0; H, 4.2; N, 11.9%. Single crystals of the complex were obtained by layering a methanolic solution of IX over an aqueous solution of $[Cu(mal)]\cdot 2H_2O$. Slow evaporation of the resulting solution yielded blue needles.

2.3.3. $[Cu_2(ac)_4(IX)_2]_n$ (2)

A methanolic solution (10 ml) of $Cu(CH_3COO)_2.H_2O$ (0.190 g, 1.0 mmol) and IX (0.240 g, 1.0 mmol) was refluxed for 1 h. The resulting solution upon concentration yielded the desired product in 75% yield (0.315 g). Found: C, 50.9; H, 4.5; N, 13.0 Calc. for $C_{36}H_{40}Cu_2N_8O_8$ C, 51.4; H, 4.76; N, 13.3. Single crystals were

obtained by slow diffusion of ether containing a mixture of $Cu(CH_3COO)_2 \cdot H_2O$ and IX in methanol over a period of one week.

2.3.4. $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$ (3)

A mixture of $CuCl_2$ (0.017 g, 0.1 mmol) sodium fumarate (0.160 g, 1.0 mmol) and IX (0.230 g, 1.0 mmol) in 10 ml H_2O–CH_3OH(1:1) yielded a blue product which was recrystallized from dilute ammonia. Calc. for $C_{36}H_{36}Cu_2N_8O_{10}$: C, 49.8; H, 4.15; N, 12.9. Found: C, 49.4; H, 4.0; N, 12.5%. Precipitates of **3** dissolved in ammonia solution were left for slow evaporation, which yielded fine needles suitable for X-ray diffraction studies.

3. Results and discussion

The reaction between Cu(II) carboxylates (carboxylate = mal, 2ac, fum) and IX in a 1:1 stoichiometric ratio in CH_3OH–H_2O mixture yielded crystalline products $[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$ (**1**), $[Cu_2(ac)_4(IX)_2]_n$ (**2**) and $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$ (**3**). The compositions of the complexes remained the same even on employing the reactants in 1:2 (M:L) molar ratio. All the three polymers were insoluble in water and other common organic solvents. Tables 1 and 2 report the crystal data and selected bond lengths and bond angles in the three polymers.

3.1. IR spectra

Selected IR peaks are summarized in Table 3. All the polymers exhibit intense absorption bands in the region, 1600–1620 and 1380–1450 cm^{-1} which are associated with asymmetric and symmetric stretching mode in carboxylates. The Δv values of above 160 cm^{-1} are indicative of the monodentate mode of coordination of carboxylate group in all these complexes.

3.2. Crystal structure of $[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$

Complex 1 consists of a Cu(II)mal-IX adduct in a 1:1 stoichiometric ratio and its elemental analysis corresponds to the formula $C_{34}H_{44}Cu_2N_8O_{14}$. The perspective view of the compound with the numbering scheme is represented in Fig. 3. The geometry around Cu(II) is square pyramidal. Each Cu(II) is coordinated to two nitrogen atoms from imidazoles of different IX ligands (average Cu–N bond distance 1.99 Å), two oxygen atoms from the chelating malonate (average Cu–O distance 1.96 Å) and the apical position is taken up by oxygen of water with a Cu–O distance of 2.21 Å. This apparent axial elongation is attributed to Jahn–Teller distortion. IX acts as a bridging ligand and propagates the chain in a zigzag manner along the 0 0 1 direction. The nearest copper–copper distance within the chain is 10.6 Å. The IX ligand coordinates two Cu(II) ions in *anti* conformation with its phenyl group in a parallel position.

Two strands are twined together to form a co-linear rod-like structure which is composed of parallel IX units. The rod is stabilized by aromatic π-stacking interactions between the phenyl rings of two strands which are nearly parallel as shown in Fig. 4. The distance between the two phenyl rings is 3.4 Å, which is well within the range for π–π interactions. Two water molecules are non-coordinated and are sandwiched by weak and classical hydrogen bonds serving a mediating role in connecting the rods between the two strands. The malonate is chelated to the metal center in a bis-mono-

dentate fashion. The malonate rings are directed above and below the rod in a symmetrical alternate manner. This configuration is imposed by the more stable trans conformation of the ligand. The rods are stacked along the *c*-axis in such a manner that coordinated water molecule as well as malonate of two adjoining threads are interdigitated to maximize the packing.

The packing of rods (Fig. 5) when seen along the *c*-axis reflects that the alkyl parts of IX are pointing inward, in the middle of the two individual dimers of rods, repelled by water molecules between rod-dimers. The malonate carbonyl groups of adjacent dimeric moieties are facing each other with the water molecules situated in between them.

3.3. Structure of $[Cu_2(ac)_4(IX)_2]_n$

Polymer **2** is consistent with the formula $[Cu_2(ac)_4(IX)_2]_n$. The geometry around the Cu(II) ion is essentially square planar. Fig. 6 describes the asymmetric unit together with the labelling scheme. The two acetate groups coordinate in an unidentate mode and are trans to each other. The non-coordinating oxygen of two acetate groups are positioned in an *anti* manner. The other two coordinating sites are occupied by two imidazole nitrogens from different IX ligands. IX acts as a building block connecting two Cu(II) ions. The polymer crystallizes as 1D zigzag chains which run parallel to one another resulting in 2D sheets making an angle of 65.5° with the axis. The metal ions within the sheets are all coplanar and the IX ligand is present in an *anti* conformation. There are two series of 1D polymeric chains extending along the *bc* and *ac* planes which traverse each other at an angle of 45° (Fig. 7a). The sheets interpenetrate to yield a three dimensional network. Fig. 7b

represents the mode of packing with the chains of layer **a** running parallel to the plane of paper and the chains of layer **b** at an approximately 45° angle with respect to it. The horizontal lines of the chains of layer **a** represent the linear part of the chain formed by two imidazoles coordinated to the copper. The diagonal straight lines present the phenyl rings and the angles are the methylene groups providing the *anti* conformation of the ligand units.

The neighboring chains of the same layer are held together by weak hydrogen bonding ($CH_2\ldots O{=}C$ distances ~2.84 Å) and imidazole ring $\pi\ldots\pi$ bonding (distances ~3.65 Å), between the angles where the chains come close to contact. The layers **a** and **b** are held together by interactions between the CH_2 and acetate carbonyls (d = 2.53 Å) as well as $CH\ldots\pi$ interactions between the imidazole rings (d = 3.0 Å).

3.4. Structure of $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$

Polymer **3** $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$ can be described as an assembly of ID straps in which Cu(II) is of square pyramidal type with equatorial CuN_2O_2 from two fum-

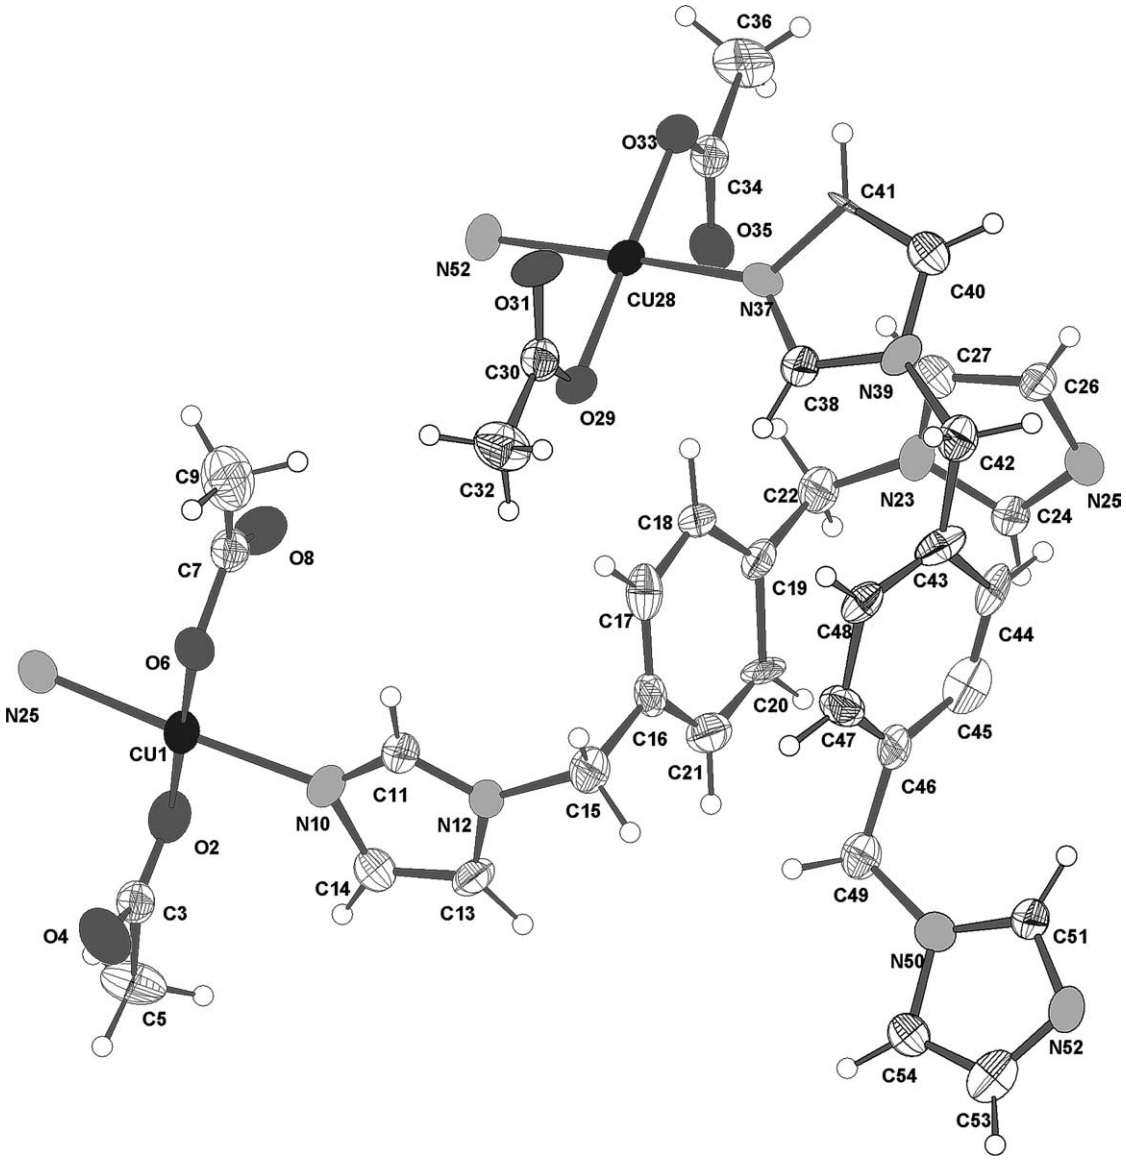

Fig. 6. View of the Cu(II) coordination environment in **2** indicating the labelling scheme adopted.

arate and two IX ligands in trans positions [Cu–O = 1.976 Å (average), Cu–N = 2.01 Å (average)] and a water molecule resides in the apical position (Cu–O = 2.334Å) (Fig. 8). The copper equatorial plane is essentially planar with a maximum bond deviation of 2.580°. Each Cu(II) provides four connecting nodes. The polymer crystallizes in the form of an aggregation of linear rods. Both fumarate and IX act as building sub-units.

The polymer can be viewed as an aggregation of metallocycles which is a convergent product of IX and Cu. Each metallocycle is derived from 2Cu and 2IX units where the Cu is doubly trans bridged by 2-N from imidazole of different IX ligands. The IX coordinates with a convergent *syn* conformation. Each Cu node provides two further linkages for 2 oxygen atoms from two different fumarate groups. The cavity of the macrocycle is being traversed by a fumarate molecule. The Cu–fum–Cu acts as a template around which two IX ligands assemble to form a cycle. Each metallocycle is further linked to another fumarate moiety aggregating the discrete macrocyclic units into a string. Overall, the Cu–fum–Cu forms the base of the string. The coordinating oxygen atoms of fumarate are in an *anti* position with respect to adjacent H atoms. All the Cu(II) ions within the string are essentially co-planar, and overall the string is alternatively garlanded by metallocycles around Cu(II) nodes (Fig. 9).

The various straps runs in the 110 direction and are held together by π–π stacking of phenyl rings of the adjacent strap to form an extended 2D sheet (Fig. 10) in the *ac* plane. The sheet placed immediately above runs along the bc direction (Fig. 11).

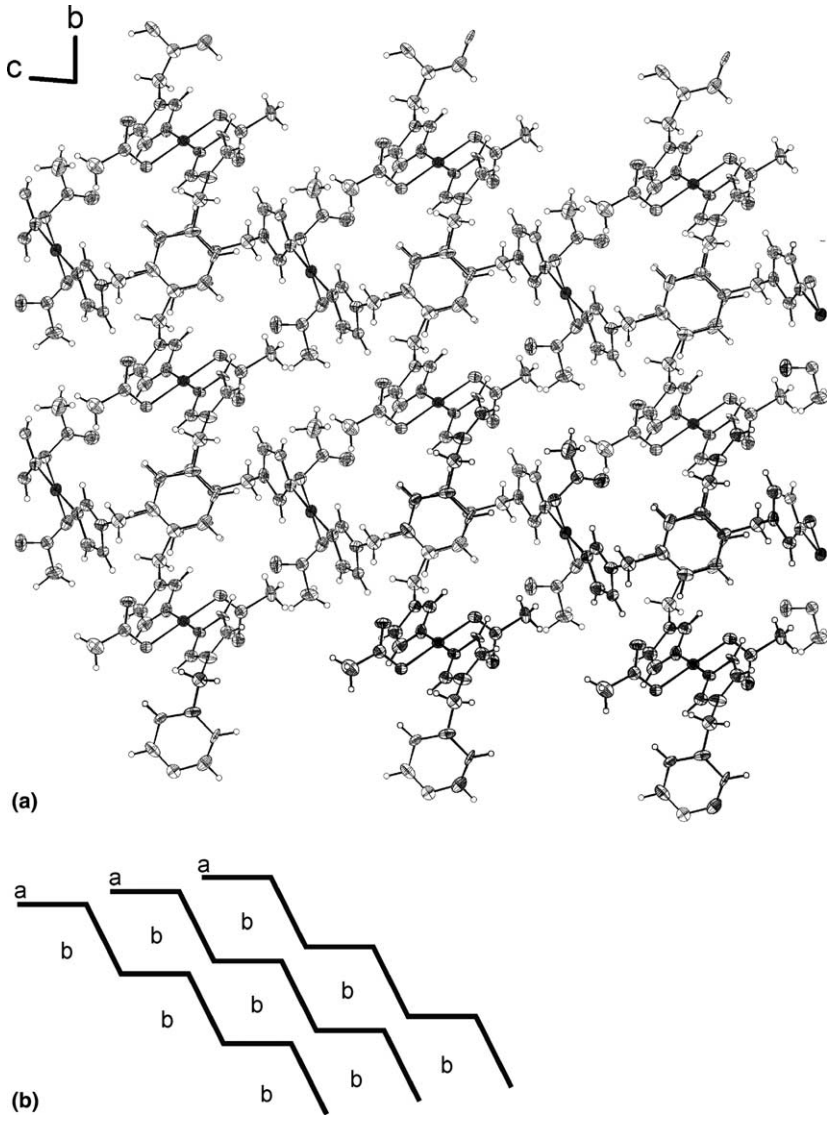

Fig. 7. (a) Schematic representation of packing of chains of $[Cu_2(ac)_4(IX)_2]_n$. (b) Two sheets along the *bc* and *ac* planes traversing at an angle of 45° in polymer **2**.

3.5. Magnetic moment studies

The temperature dependent magnetic moments were measured in the range of 0–200 K. For all the three complexes plots of χ_m versus T indicate that χ_m values increase only slowly and then abruptly as the temperature is lowered, suggesting the existence of ferromagnetic interactions between the metal centers (Fig. 12). Good quality fits were obtained by keeping $g = 2.05$ and $J = 0.005$ cm^{-1} for complexes **1** and **2**, and $g = 2.2$ and $J = 2.75$ cm^{-1} for complex **3**. These values were calculated using Baker's equation

$$\chi_M = \frac{Ng^2\beta^2}{4kT}\left[\frac{N}{D}\right]^{2/3},$$

where $N = 1 + 5.7979916y + 16.902653y^2 + 29.376885y^3 + 29.832959y^4 + 14.036918y^5$; $D = 1 + 2.7979916y + 7.0086780y^2 + 8.653644y^3 + 4.5743114y^4$; and $y = J/kT$.

The parameters β and k have their usual meanings.

Lack of any practical interaction in first two complexes can be attributed to the large Cu–Cu intramolecular distance. The enhanced J value of the fumarate complex may have resulted from magnetic interactions between paramagnetic centers not through IX but through the fumarate bridge. To determine whether these complexes undergo a metamagnetic transition, magnetization versus applied field experiments were carried out. As shown in Fig. 13, the samples do not undergo any magnetic transition up to 10 000 Oe.

3.6. TGA and XRPD of the copper complexes

The TGA curve of complex **1** reveals that loss of first lattice water molecule occurs at 99 °C with a weight loss 3.5% (calc. 3.9%) while the loss of second lattice water

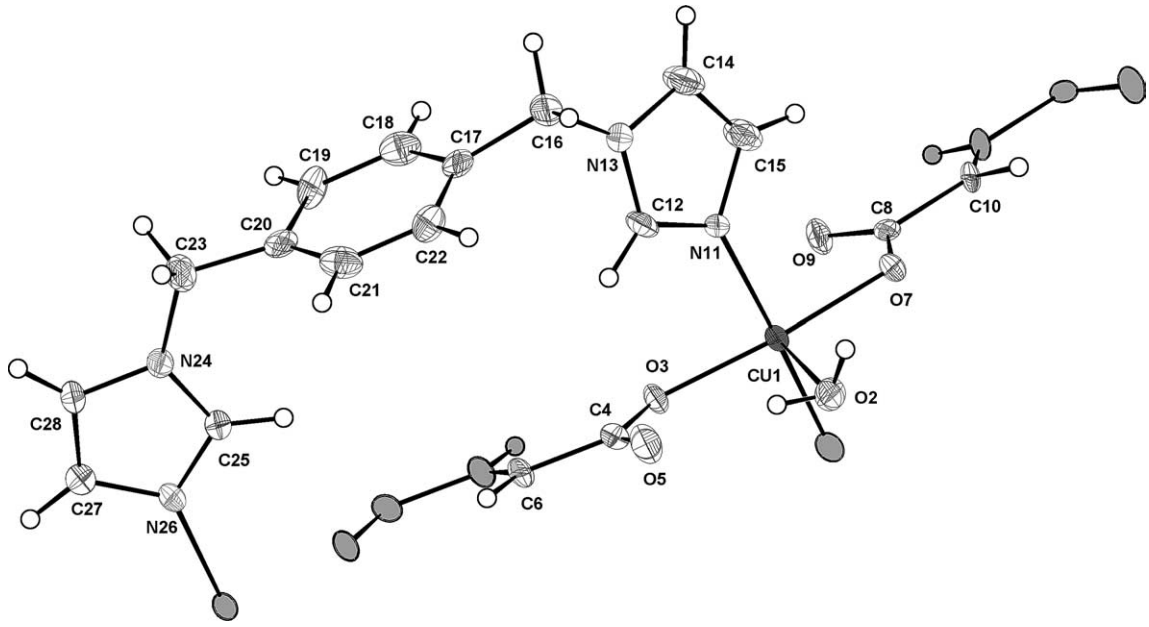

Fig. 8. Thermal ellipsoid presentation and numbering scheme in **3**.

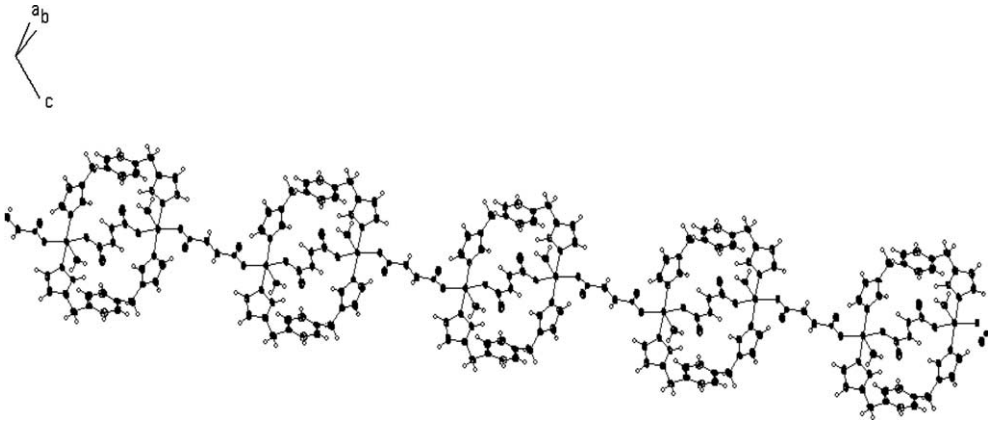

Fig. 9. Individual polymeric strings formed by units of **3**.

molecule is complete at 170 °C. This is followed by the removal of a coordinated water molecule corresponding to another weight loss of 3.9% at 203 °C. Further, the loss of 22.3% corresponds to the decomposition of the malonate molecule with the loss of CO_2 through pyrolysis. Thereafter the complex degrades almost continuously (Fig. 14).

The powder X-ray diffraction data was collected for complex **1** and its dried product at 100 °C and 250 °C (The samples were dried by heating at the desired temperature for 4 h). The XRPD of the sample dried at 100 °C is essentially identical with regard to the intensity, position and line width to that of parent complex. The diffraction pattern yielded by the sample after heating at 250 °C (which corresponds to the loss of all three water molecules) showed significant changes indicating that the structure does not remain stable after the elimination of the coordinated water molecule (Fig. 15).

The loss of only coordinated water molecule from complex **3** is complete at 150 °C (calc. 4.4%; found 4.0%), as suggested by TGA of the complex (Fig. 14). The sample was heated at 150 °C for 4 h to dehydrate it. The XRPD of the original sample and its dried product are identical indicating that the framework maintains its integrity after the removal of the coordinated water molecule (Fig. 16). But above 200 °C the degradation was continued up to 450 °C.

4. Discussion

Three Cu(II) carboxylates [mal, 2ac and fum] of different nuclearity and of different orientation, steric hindrance and flexibility of carboxylate groups have been reacted with angular and conformationally flexible IX. All structures are formed with the same stoichiometry

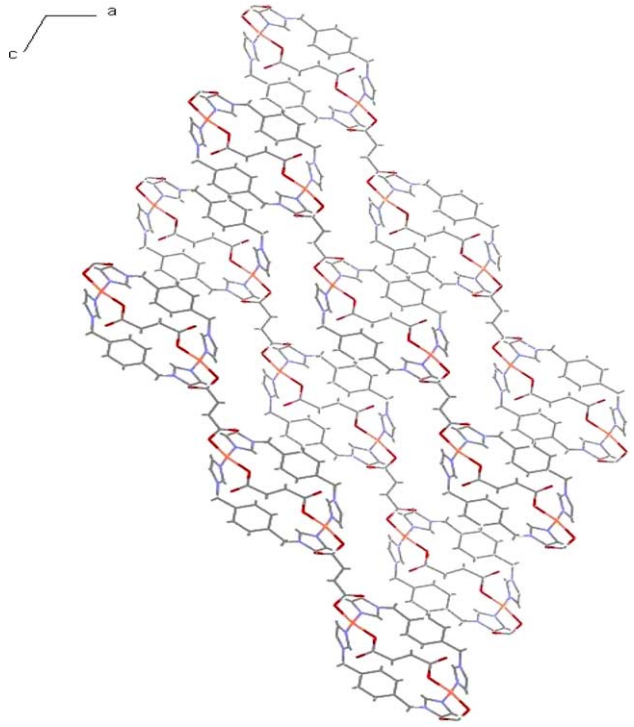

Fig. 10. 1D sheet formation of individual strings of **3** along the ac axis.

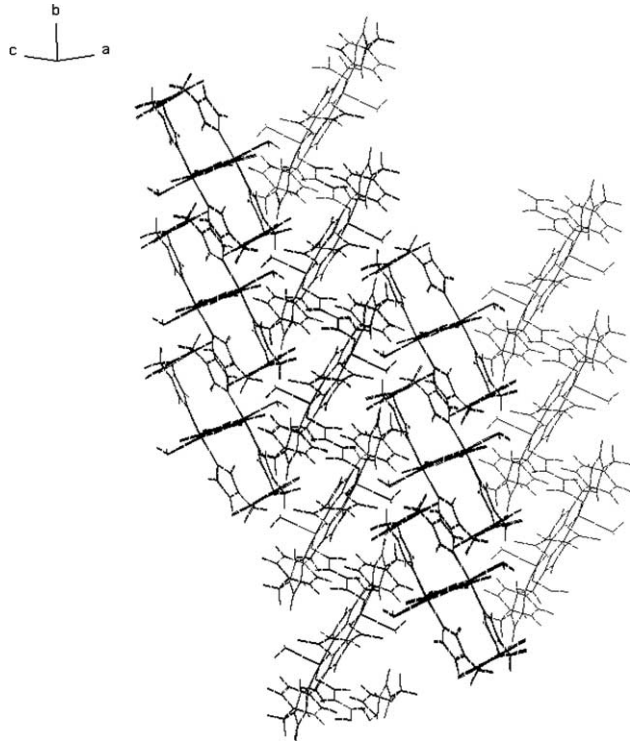

Fig. 11. Packing of strings along the *ac* and *bc* axis in a vertical orientation.

and are rods yet overall display very different and complex structural architectures ranging from 1D to 3D. The synthetic chemistry of coordination polymers has

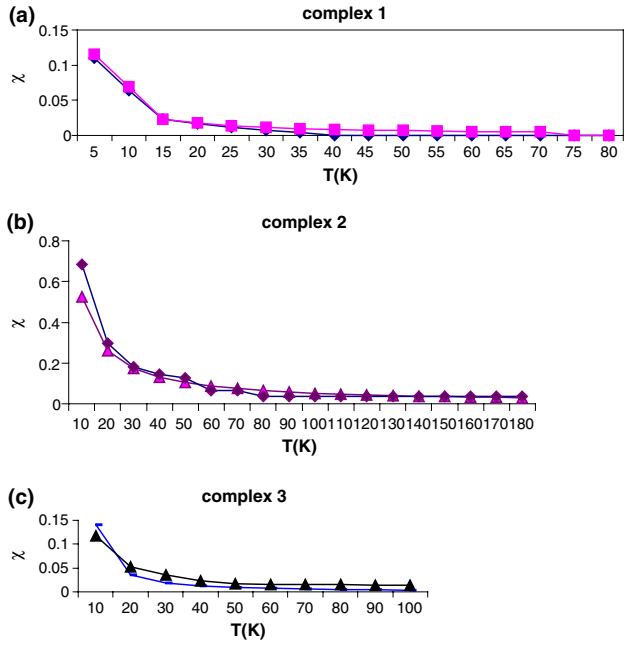

Fig. 12. Temperature dependence of χ_m for (a) complex **1** (b) complex **2** and (c) complex **3**.

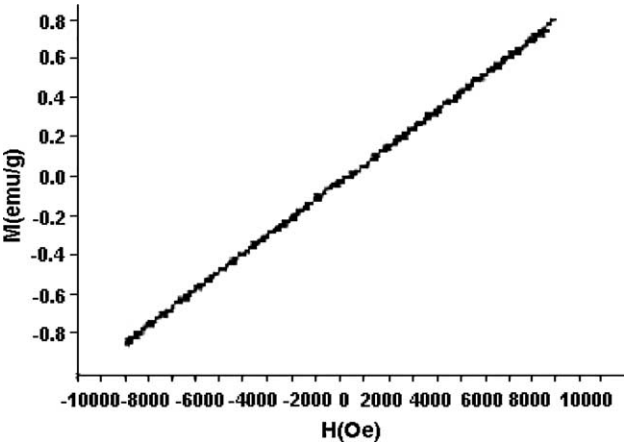

Fig. 13. Magnetization vs. applied field for the three complexes at $T = 4.5$.

so far been mainly focused on the transition metals and rigid organic ligands. The final framework results from the topology and geometry of both organic linear ligand and metal cation and they are regarded as framework builders. The anions used to balance the charge and act as framework regulators. Although sufficient data is available to rationalize the final bulk physical and chemical properties and function of the polymeric array employing linear rigid organic ligands, subtle changes are often observed with their flexible counterparts which make the structural prediction much more cumbersome and uncertain. However, literature survey reveals that polymeric metal halides act both as frame-

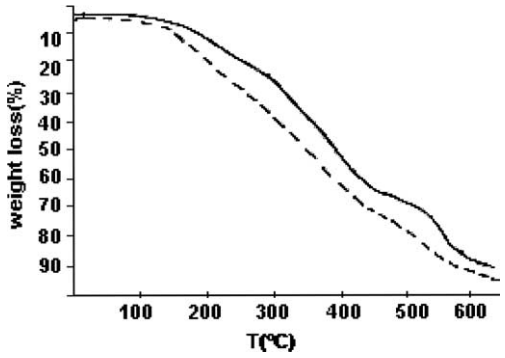

Fig. 14. Thermogravimetric mass loss profiles for complex **1** (—) and complex **3** (----).

work regulators and framework builders and preorganise the system to propagate in a certain direction [49,50].

The present study has been carried out with the aim to examine the effect of rigidity of metal carboxylates on the structure of the polymeric array. However, with monomeric flexible Cu(II) malonate, the malonate group behaves either as a framework builder or a structural regulator. In combination with linear 4,4′-bipyridine, malonate acts as a framework builder and a two dimensional square network enclosing giant cavities of the dimensions 15.776×15.786 Å are generated (Fig. 17) [42]. In our case malonate acts a as framework regulator where the two carboxylate groups of malonate are in the chelate mode and IX and Cu join to build the network as linear rods. The original structure of Cu malonate is retained. The rods only twin successfully placing the alternate malonate on the opposite side of the Cu(II) node which maximizes packing. However, it may be due to the steric influence of malonate group that various rods fail to interpenetrate.

Cu(II) acetate itself exists as a dimer which predisposes the ligand to arrange in a linear manner at the apical position and the original structure of Cu(II) acetate is generally not disturbed. Monodentate ligands coordinate to generate a five coordinate Cu(II) ion and a non-chelating bidentate ligand such as 1,4-diazabicyclo[2,2,2]octane bridges the dimer unit to generate a chain structure [51]. Therefore Cu(II) acetate acts as a framework builder as well as a framework regulator. With IX the dimer breaks to generate monomeric Cu(II) acetate. This may be due to the larger steric bulk of IX. The Cu(II) ion acts as a framework builder and acetate as a framework regulator. The reaction ultimately generates rods which are interlocked in a 3D fashion. Similar effects have been observed with 2,5-bis(4-pyridyl)-1,3,4-oxadiazole which reacts with Cu(II) acetate to yield a monomer [52].

Compound 3 represents a polymeric network with fascinating structural features. With the use of 1D Cu(II) fumarate as a building block, the resulting network is partly locked into place and is tuned to facilitate

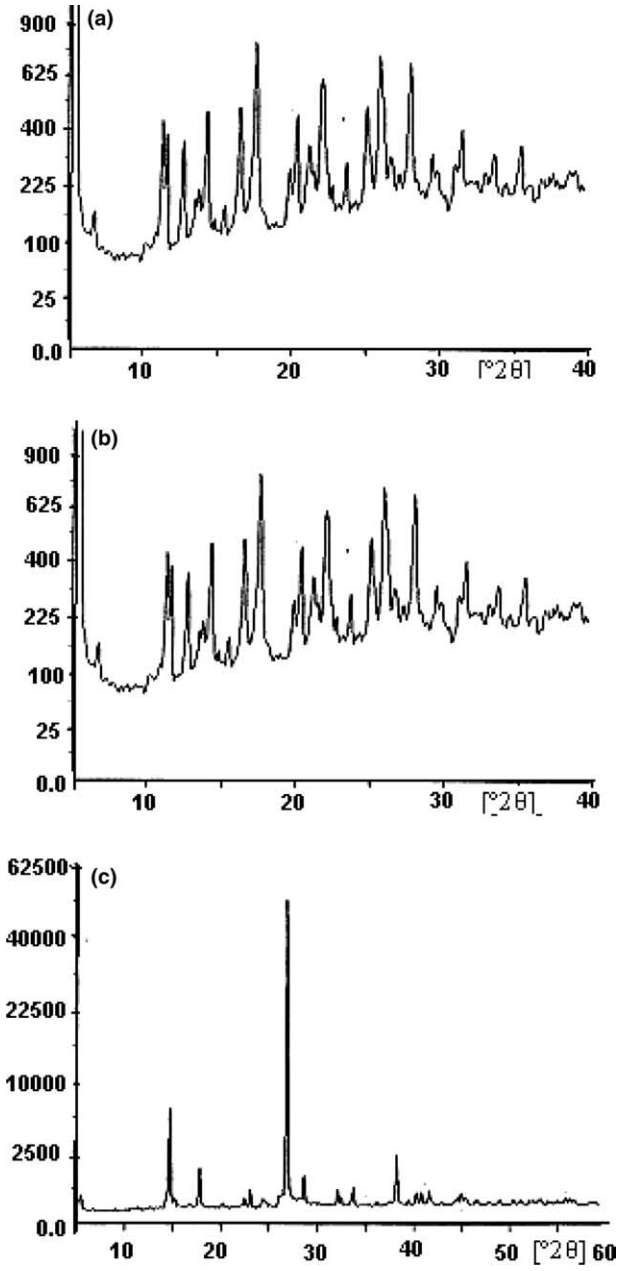

Fig. 15. The XRPD pattern of complex **1**: (a) synthesized material, (b) dried solid at 100 °C and (c) solid resulting from heating at 250 °C.

the bonding of flexible IX in a desired direction resulting in better structural prediction and control of assembly. The IX ligand takes up the less favorable *syn* configuration to generate a cycle around Cu(II) fumarate probably due to size compatibility of the fumarate and IX. It may be regarded as an example of a transition polymer between the convergent metallocycle and the divergent aggregated coordinated polymer. In another similar study by employing polymeric zinc carboxylates (malonate and oxalate) with IX we have demonstrated that it is the preorganization of dicarboxylate which directs the self-assembly to adopt a particular motif [53].

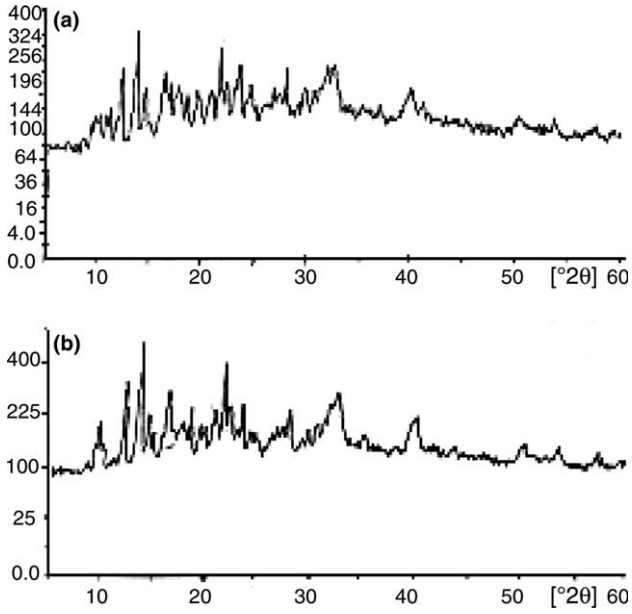

Fig. 16. The XRPD pattern of complex **1**: (a) synthesized material, (b) dried solid at 150 °C.

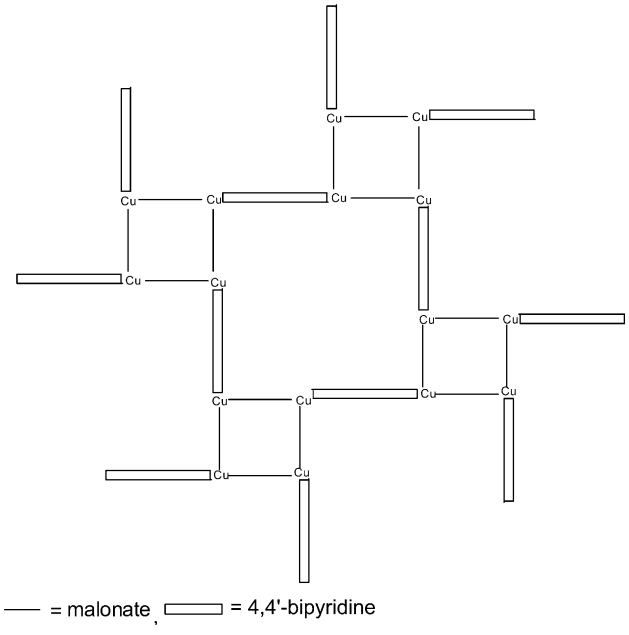

Fig. 17. Stick model representation of $[Cu_2(C_3H_2O_4)_2(H_2O)_2(4,4'\text{-bpy})] \cdot H_2O$.

5. Conclusion

The above study reveals that although due to conformational freedom of flexible ligand the final structure of the architecture becomes much less predictable, the geometry can be better controlled by selecting a combination of a rigid metal building block with a flexible organic ligand.

Abstract

The complexes $[Te(etu)_4][SiF_6]$ (**1**), $[Te(etu)_4][SiF_6] \cdot H_2O$ (**2**), $[Te(trtu)_4][SiF_6]$ (**3**), $[Te(etu)_4][GeF_6] \cdot H_2O$ (**4**), $[Te(trtu)_4][GeF_6]$ (**5**) and $[Te(etu)_4][SnF_6]$ (**6**) (etu = ethylenethiourea, trtu = trimethylenethiourea) have been prepared and their crystal structures determined by X-ray crystallographic methods. The crystals of **1**, **3** and **5** are tetragonal; space groups *P*4*cc* (No. 103) with $Z = 4$ for **1**, *P*4*nc* (No. 104) with $Z = 2$ for **3**, and *I*4 (No. 79) with $Z = 2$ for **5**. The crystals of **2**, **4** and **6** are orthorhombic, space group *Pccn* (No. 56) with $Z = 8$ for **2** and **4** and $Z = 4$ for **6**; those of **2** and **4** being isomorphous. The cations contain square planar or slightly distorted square planar TeS_4 coordination groups. In **1**, **3** and **5** the Te atoms are located on fourfold rotation axes; the cations have fourfold rotational symmetry and the four thiourea ligands extend to the same side of the TeS_4 plane. These are the first examples of $[TeL_4]^{2+}$ conformers of this type. In **2** and **4** the Te atoms lie on general positions; the cations are distorted versions of those in **1**, and also in these the four ligands extend to the same side of the TeS_4 plane. In **6** the Te atoms are located on twofold rotation axes, the conformation of the cations corresponds to the point group C_2 with two neighbouring ligands extending to one side of the coordination plane and the remaining two to the opposite side. In **1**–**5** each of the four ligands forms a N–H···F bond to the same F atom in the counter ion. The crystals of **1**–**5** are red, and those of **6** are yellow. The red colour is attributed to interactions of Te and S lone electron pairs caused by ligand TeS_4/TeSC tilt angles markedly different from 90°.

Keywords: Te(II) thiourea complexes; Novel conformations; Unexpected colours; X-ray crystallography; Supramolecular associations

1. Introduction

The incentive for the present work was an earlier observation made by one of us (O.F.) in an exploratory experiment on $[Te(etu)_4]^{2+}$ fluorides (etu = ethylenethiourea): when a hydrofluoric acid solution of tellurium dioxide and etu in a molar ratio 1:6 came in contact with glass, a red deposit formed. Crystals of $[Te(etu)_4]^{2+}$ salts are usually yellow. Formation of $[SiF_6]^{2-}$ was possible under these conditions and might somehow be responsible for the unusual colour. It was therefore decided to prepare a series of $[Te(etu)_4]^{2+}$ and $[Te(trtu)_4]^{2+}$ (trtu = trimethylenethiourea) salts with octahedral fluoride anions of the type $[MF_6]^{2-}$, where M = Si, Ge and Sn, and to study their structures in order to find the cause of the red colour.

2. Experimental

2.1. General

The complex salts were prepared either by the exchange of chloride anions by $[MF_6]^{2-}$ in the complex salts $[Te(stu)_4]Cl_2 \cdot 2H_2O$, where M = Si or Ge, and stu is etu or trtu; or alternatively by the following disproportionation reaction: $Te^{4+} + 6stu + [MF_6]^{2-} = [Te(stu)_4][MF_6] + stu_2^{2+}$, where stu is etu or trtu and M is Si, Ge or Sn. The hexafluorosilicic acid solution used was obtained by saturating 48% hydrofluoric acid with fine-mesh silicon dioxide. The trimethylenethiourea and ethylenethiourea were commercial compounds supplied by Aldrich-Chemie, D-7924 Steinheim, Germany. Operations were performed in polythene beakers.

2.2. Synthesis

2.2.1. The complex $[Te(etu)_4][SiF_6]$ (**1**)

$[Te(etu)_4]Cl_2 \cdot 2H_2O$ (0.50 g, 0.78 mmol) was dissolved under stirring in dimethylformamide (DMF) (15 ml) and methanol (35 ml). The solution was heated gently and 3 ml H_2SiF_6 added. After a few hours at room temperature, the mixture was filtered and the crystals obtained were washed with methanol and then diethyl ether. Yield: 0.34 g (71.7%) of red tetragonal prisms [110]. *Anal.* Calc. for $C_{12}H_{24}F_6N_8S_4SiTe$: C, 21.24; H, 3.57; N 16.52. Found: C, 21.30; H, 3.60; N, 16.57%.

2.2.2. The complex $[Te(etu)_4][SiF_6] \cdot H_2O$ (**2**)

A hot solution of etu (7.0 g, 68.5 mmol) in H_2O (100 ml) was added to TeO_2 (1.6 g, 10.0 mmol) dissolved in HF (48%, 25 g), then 3 ml H_2SiF_6 solution was added. Yield, after standing and treatment as above, 5.0 g (71.6%) of red flat prisms. *Anal.* Calc. for $C_{12}H_{26}F_6N_8OS_4SiTe$: C, 20.70; H, 3.76; N, 16.09. Found: C, 20.80; H, 3.81; N, 16.10%.

2.2.3. The complex $[Te(trtu)_4][SiF_6]$ (**3**)

A hot solution of trtu (7.5 g, 64.5 mmol) in 96% ethanol (70 ml) was added to TeO_2 (1.6 g, 10.0 mmol) in HF (48%, 15 g), and then 3 ml H_2SiF_6 solution was added. After standing overnight and filtering and washing as above, the yield was 7.0 g (95.0%) of red tetragonal prisms 110. The complex also crystallized out when 2 ml H_2SiF_6 solution was added to a solution of $[Te(trtu)_4]Cl_2 \cdot 2H_2O$ (0.50 g, 0.72 mmol) in a mixture of methanol (30 ml) and DMF (2 ml). Yield: 0.49 g (95.2%). *Anal.* Calc. for $C_{16}H_{32}F_6N_8S_4SiTe$: C, 26.17; H, 4.39; N, 15.26. Found: C, 26.82; H, 4.50; N, 15.70%.

2.2.4. The complex $[Te(etu)_4][GeF_6] \cdot H_2O$ (**4**)

A hot mixture of etu (3.5 g, 34.3 mmol) in 40 ml hot H_2O was added to GeO_2 (0.53 g, 5.1 mmol) and TeO_2 (0.80 g, 5.0 mmol) dissolved in HF (48%, 10.0 g). After 2 h at room temperature, the mixture was filtered, the crystals washed with acetone and then diethyl ether. Yield: 2.3 g (61.9%) of red flat prisms. *Anal.* Calc. for $C_{12}H_{26}F_6GeN_8OS_4Te$: C, 19.45; H, 3.54; N, 15.13. Found: C, 21.93; H, 3.77; N, 14.91%.

2.2.5. The complex $[Te(trtu)_4][GeF_6]$ (**5**)

$[Te(trtu)_4]Cl_2 \cdot 2H_2O$ (0.50 g, 0.72 mmol) in warm methanol (15 ml) was added to GeO_2 (0.15 g, 1.43 mmol) dissolved in HF (48%, 5.0 g), and then 10 ml diethyl ether was added. After 2 h in a refrigerator, and then filtering and washing as above (for **4**), the yield was 0.34 g (75.7%) of red tetragonal prisms 110. *Anal.* Calc. for $C_{16}H_{32}F_6GeN_8S_4Te$: C, 24.67; H, 4.14; N, 14.39. Found: C, 25.73; H, 4.20; N, 14.36%.

The red crystals were stable for months when kept in a refrigerator. At room temperature they became yellow and polycrystalline after a few weeks.

2.2.6. The complex $[Te(etu)_4][SnF_6]$ (**6**)

A solution of etu (3.5 g, 34.3 mmol) in hot H_2O (40 ml) was added to TeO_2 (0.80 g, 5.0 mmol) and $(NH_4)_2[SnCl_6] \cdot H_2O$ (2.0 g, 5.2 mmol) in HF (48%, 16 g). This was followed by addition of hot methanol (50 ml). After standing overnight, and treating as above, the yield was 2.4 g (62.2%) of yellow prisms and bipyramids. *Anal.* Calc. for $C_{12}H_{24}F_6N_8S_4SnTe$: C, 18.74; H, 3.15; N, 14.57. Found: C, 18.73; H, 3.24; N, 14.43%.

2.3. Crystal stability

None of the six complexes had normal melting points, instead they all decomposed at higher temperatures yielding black elemental Te and a mostly solid residue. Complexes **1**, **2** and **6** decomposed in the range 170–180 °C. The red complex **5** first slowly converted into a yellow version at room temperature, see above. This was unfit for X-ray analysis. By heating the yellow crystals, decomposition started at 190 °C. Complexes **3** and **4** started to decompose around 130 and 150 °C, respectively.

2.4. Crystallography

Intensities at 293(1) K were recorded on a CAD 4 diffractometer using λ-scans and graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å. Three reference reflections were recorded every 2 h of exposure time. Intensities were corrected for absorption using face-indexing and Gaussian quadrature methods. For **5** intensities were recorded twice on the same crystal and under the same conditions, and the two sets averaged: $R_{int} = 0.018$ for 12 778 reflections, 0.015 for 8211 with $I > 3(\sigma I)$; this gave a noticeable improvement of confidence factors and standard uncertainties.

Crystal data are listed in Table 1. Anisotropic displacement parameters were used for non-hydrogen atoms. Part of the ligand in complex **3** was disordered over two positions, with occupancies of 0.6 and 0.4. Hydrogens were input as riding atoms with C–H(CH_2), N–H(NH) and O–H(O_{water}) distances of 0.97, 0.86 and 0.85 Å, respectively. The isotropic displacement parameters of the H atoms were fixed at 1.2 U_{eq} of their parent atoms.

The structures of complexes **1**–**3** were solved by Patterson and difference Fourier methods, and that of **6** by direct methods. Results and intensity files of the final refinements using the SDP-PLUS program [1] were converted to and re-refined with SHELXL as contained in the SHELXTL package [2]. The latter was used for graphical presentations and PLATON [3] for further geometry calculations.

3. Results and discussion

With $[Te(etu)_4]^{2+}$ or $[Te(trtu)_4]^{2+}$ as cations and $[SiF_6]^{2-}$, $[GeF_6]^{2-}$ or $[SnF_6]^{2-}$ as anions, red crystals of the following salts have been prepared and their X-ray structures at 293(1) K determined: $[Te(etu)_4][SiF_6]$ (**1**), tetragonal, space group *P4cc* with $Z = 4$; $[Te(etu)_4][SiF_6]\cdot H_2O$ (**2**), orthorhombic, space group *Pccn* with $Z = 8$; $[Te(trtu)_4][SiF_6]$ (**3**), tetragonal, space group *P4nc* with $Z = 2$; $[Te(etu)_4][GeF_6]\cdot H_2O$ (**4**), orthorhombic, isomorphous with **2**; $[Te(trtu)_4][GeF_6]$ (**5**), tetragonal, space group *I* 4 with $Z = 2$. Also yellow crystals of $[Te(etu)_4][SnF_6]$ (**6**) were prepared and studied by X-ray crystallographic methods. They are orthorhombic, same space group as **2** and **4** but with $Z = 4$. The TeS_4 coordination groups of the cations of the complexes **1**–**6** are square planar or nearly so, the anions have their usual octahedral shape. In **1**–**5** cation–anion pairs are held together by four N–H···F hydrogen bonds to the same F atom, one from each ligand. Selected bond lengths and angles are listed in Tables 2–8 and the molecular structures of the cations are shown in Figs. 1–5. A cation–anion pair is illustrated in Fig. 6, using **1b** as a model. Supramolecular interactions of representative complex salts are shown in Figs. 7–9 for **2**, **3** and **6** and the hydrogen bond lengths and angles of complexes **1**–**6** are listed in Table 9.

3.1. The tetragonal complexes *1*, *3* and *5*

The Te atom of the cations and three-atom sequences F–Si–F or F–Ge–F of the anions are located on fourfold axes. In **1** there are two crystallographically independent cation–anion units, one on the fourfold axis at $x = 0$, $y = 0$, (**1a**), and the other on the fourfold axis at $x = 1/2$, $y = 1/2$ (**1b**). The three tetragonal structures are closely related. The space groups are polar. The Te···F–Si–F and Te···F–Ge–F sequences on the fourfold axes all point the same way throughout the crystal. With origin at the Te position in **5**, space group *I*4 with $Z = 2$, identical cation–anion units in the same orientations occur at the corners and centre of the cell. In **3**, space group *P4nc* with $Z = 2$, the unit at the centre is reflected by an *n* glide plane. In **1**, space group *P4cc* with $Z = 4$, the *c* axis is nearly doubled compared to **3** and **5**. Every other unit along the axis, Te now at $z \approx 0$ and 1/2, is reflected by a *c* glide plane; the unit at $x = 1/2$, $y = 1/2$ is crystallographically independent, with Te slightly removed from $z = 1/4$, and is likewise reflected, along $x = 1/2$, $y = 1/2$ by a *c* glide plane.

Seen along the fourfold axis of a cation–anion unit of **3**, the directions of the Te–S bonds and equatorial Si–F bonds are almost parallel, the closest S–Te···Si–F torsion angle is 1.33(6)°. In the two crystallographically independent units of **1** these torsion angles are 36.78(5) and 34.42(5)°, for **1a** and **1b**, respectively, and in **5**, with Ge instead of Si, it is 8.96(7)°. In **1b**, at $x = 1/2$, $y = 1/2$, the Te–S bonds point slightly away from the anion, forming F_{axial}···Te–S angles of 95.08(2)°; the distance of Te from the S_4 plane is quite large at 0.237(1) Å making the coordination pyramidally distorted. In **1a**, the F···Te–S angles are 89.61(2)°; the distance of Te from the S_4 plane is 0.018(1) Å, in **3** the corresponding values are 89.93(3)° and 0.003(2) Å, and in **5**, 90.82(3)° and 0.038(2) Å.

3.2. The monohydrates *2* and *4*

In these $[Te(etu)_4]^{2+}$ salts, with $[SiF_6]^{2-}$ as anion in **2** and $[GeF_6]^{2-}$ in **4**, there is no molecular symmetry; all atoms lie in general positions. The cations are distorted versions of those in the tetragonal crystals; also here the four ligands extend to the same side of the TeS_4 plane, toward the anion. The TeS_4 groups are slightly pyramidal, the TeS_1S_2/TeS_3S_4 plane angle in **2** is 8.62(3)° and in **4** 8.50(3)°. The TeS_4 least-squares plane makes an angle of 12.30(1)° with the *c* plane in **2** and 12.09(1)° in **4**, and angles of 14.35(3)° and 13.43(3)°, respectively, with the equatorial $[SiF_6]^{2-}$ and $[GeF_6]^{2-}$ least-squares planes.

3.3. The yellow complex, *6*

The central atoms of the $[Te(etu)_4]^{2+}$ cation and $[SnF_6]^{2-}$ anion both lie on twofold symmetry axes. The cation axis lies in the least-squares TeS_4 plane passing between two sets of neighbouring S atoms. The TeS_4 group here is also slightly pyramidal, by a rotation of ca. 6.5° about the twofold axis of the two halves relative to each other. Although the space groups are different, the structure of the cation in **6** is similar to that in $[Te(etu)_4][TeCl_6]$ [4]. The crystals of the hexachloro analogue of **6**, $[Te(etu)_4][SnCl_6]$, are isomorphous with those of the hexachlorotellurate [5].

3.4. Dimensions of the anions

In the two independent $[SiF_6]^{2-}$ ions in **1** and the one in **3** with F–Si–F on fourfold axes, the F atom of the Si–F bond in the axial Te···F–Si sequence is engaged in four N–H···F hydrogen bonds. This is therefore the longest Si–F bond and the Si–F bond *trans* to it the shortest. The four equivalent equatorial Si–F bonds are intermediate. The lengths of the three bonds, respectively, are as follows: 1.740(2), 1.660(3), 1.6712(13) Å in **1a**, 1.709(2), 1.670(3), 1.6733(12) Å in **1b**, 1.722(3), 1.656(4), 1.6799(16) Å in **3**, the averages are 1.690 Å in **1a**, 1.684 Å in **1b** and 1.686 Å in **3**. In the asymmetric $[SiF_6]^{2-}$ ion in **2** the Si-F bonds vary in a similar way from 1.663(2) to 1.7101(19) Å, with an average of 1.682 Å. These bond lengths may be compared to 1.694(13) Å, an average value found for SiF_6^{2-} anions [6].

In the tetragonal $[GeF_6]^{2-}$ salt **5**, the Ge–F bonds show the same pattern as the Si–F bonds in **1** and **3**: corresponding bond lengths are 1.812(3), 1.786(3), 1.7853(17) Å, average 1.794 Å. In the asymmetric

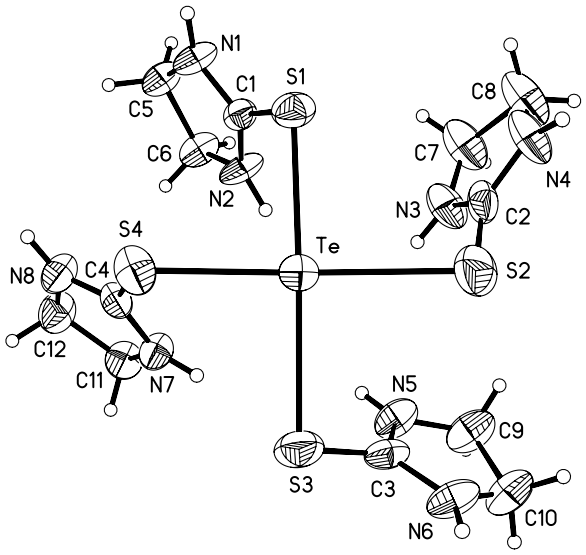

Fig. 3. The structure of the cation of **4** (**2** is isomorphous with **4** and has the same structure).

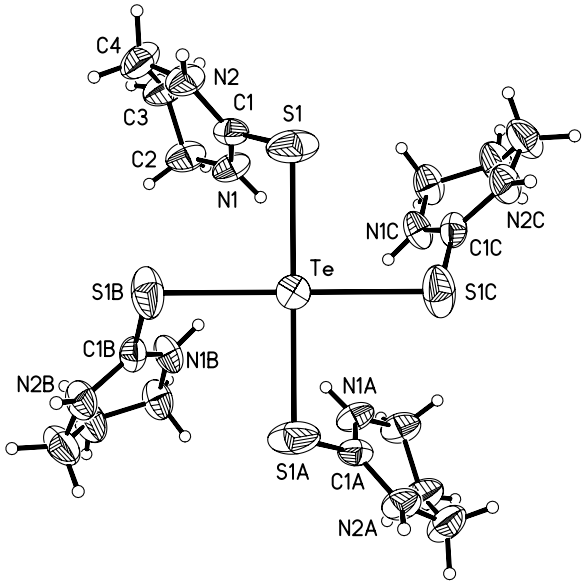

Fig. 4. The structure of the cation of **5**.

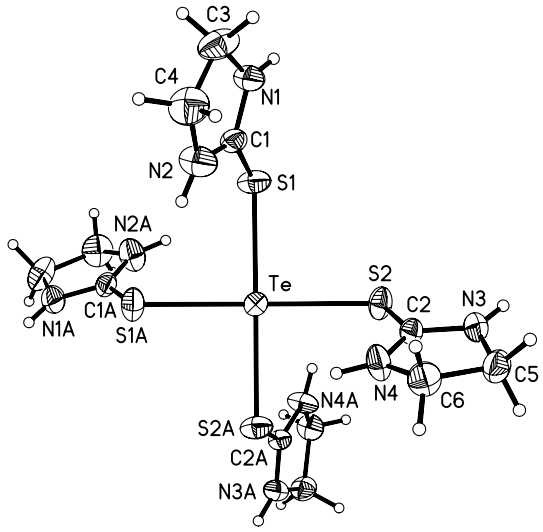

Fig. 5. The structure of the cation of **6**.

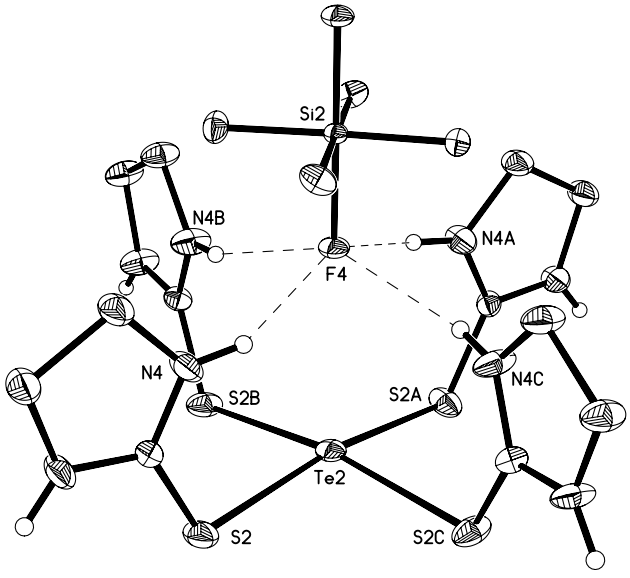

Fig. 6. The structure of the cation–anion pair of **1b** (i.e., the second molecule in the asymmetric unit). Hydrogen bonds are indicated by dashed lines.

$[GeF_6]^{2-}$ ion in **4**, the Ge–F bond lengths vary in the same way as the Si–F bonds in **2**. They range from 1.7702(19) to 1.8035(18) Å; average 1.783 Å. In the $[SnF_6]^{2-}$ salt **6**, the Sn atom lies on a twofold axis, with Sn–F bond lengths of 1.9683(15), 1.9501(18), 1.9440(19) Å; with an average of 1.954 Å.

3.5. Dimensions of the cations

The principal data are shown in Tables 2–8. Tilt and twist angles [7,8] are represented by the TeS_4/TeSC and TeSC/SCN_2 interplanar angles, respectively; the acute angles are listed in Table 2. The TeS_4 and SCN_2 planes are the least-squares planes, except for **6** where the tilt angles refer to the TeS_2 planes of S atoms related by the twofold axis. Where the TeS_4 groups are not exactly planar, as in the present case, the tilt angles for **1**–**5** differ slightly from the *cis*-S–Te–S–C torsion angles, but are close to the average of the acute values of the torsion angles based on each of the two neighbouring sulfur atoms.

The Te–S bond lengths in the tetragonal complexes **1**, **3** and **5** lie in the usual range [9]. In various Te(II) complexes containing centrosymmetric TeS_4 or TeS_2X_2 coordination groups, the three-centre four-electron Te–S bonds vary from 2.651(6) to 2.728(4) Å; the weighted

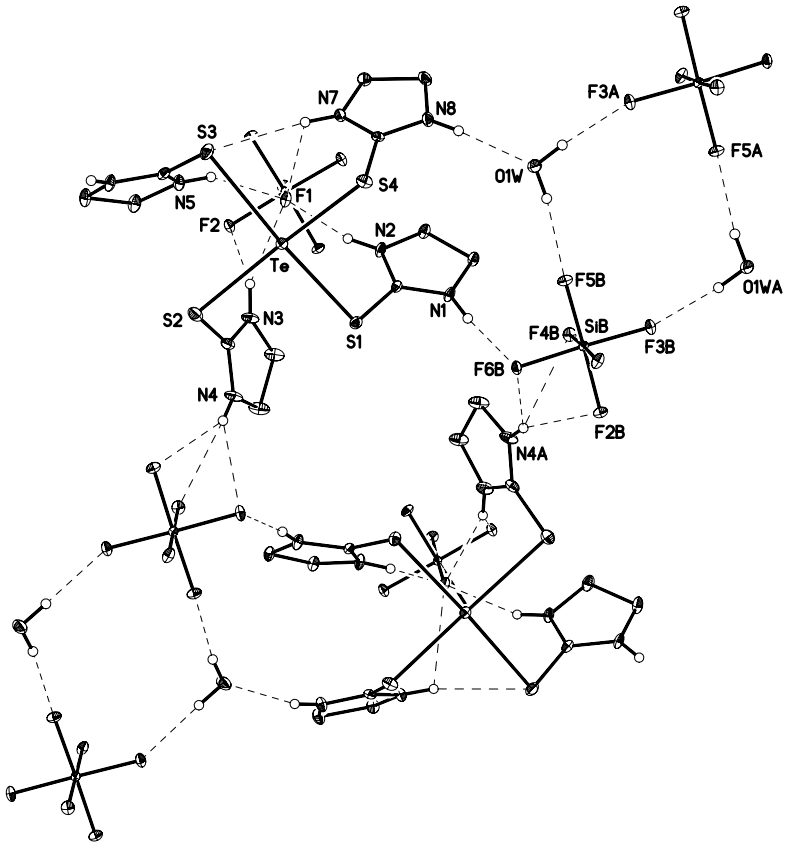

Fig. 7. The molecular packing in **2** with hydrogen bonds indicated by dashed lines.

average of 20 values is 2.682(3) Å. The average Te–S bond length for **1**–**6** is 2.689 Å in good agreement with this. In the centrosymmetric TeS_4 groups of $[Te(etu)_4]Cl_2$ [10], $[Te(trtu)_4]Cl_2 \cdot 2H_2O$ and $[Te(trtu)_4](ClO_4)_2$ [8] the Te–S bond lengths are 2.681(1) and 2.666(1), 2.680(1) and 2.684(1), and 2.667(1) and 2.701(1) Å, respectively. The different Te–S bond lengths in **3** and **5**, 2.6963(8) and 2.6726(10) Å, where the structures are otherwise so similar, remains unexplained. However, this has been observed before in Te complexes with thiourea ligands [11]. The main difference between **1a** and **1b** is found in their Te–S–C angles which differ by nearly 13°; also the TeS_4 group is more planar in **1a** than in **1b** (see above).

In the asymmetric TeS_4 groups of **2** and **4**, the longest and shortest Te–S bonds occur for the smallest and largest tilt angles, respectively. The smaller tilt angles are associated with larger twist angles. A rough correlation between Te–S bond length and thiourea twist angle in centrosymmetric Te(II) complexes has been noted earlier [8].

3.6. The thiourea ligands

All ligands have normal C–S bonds ranging from 1.686(4) to 1.732(4) Å with an average value of 1.716 Å. This may be compared to free thioureas where the average value is 1.681(20) Å [6], and the difference is due to the weakening of the bond upon complexation to Te. In **2** and **4**, the asymmetry in the Te–S bonds is reflected in the corresponding C–S bond length. To a long Te–S bond of average length 2.787 Å, corresponds a short C–S bond of average length 1.701 Å, and to a short Te–S bond of average length 2.601 Å, a long C–S bond of average length 1.728 Å. This asymmetry is further reflected in the C–N bonds, a long C–S bond corresponds to a short C–N bond and vice versa.

The average $C(sp^2)$–N bond length in the thiourea ligands of **1**–**6** is 1.315 Å. This is comparable to 1.326 Å, the average found in some *trans*-dihalodithioureatellurium(II) complexes with similar S–Te–S sequences [12,13]. In free thioureas, the corresponding average is 1.346(23) Å [6]. The C–S and $C(sp^2)$–N bond lengths illustrates the partial double bonding in the central SCN_2 part of the thiourea ligands. The average $C(sp^3)$–N and C–C bond lengths in **1**–**6** are normal at 1.454 and 1.516 Å, respectively (C–C in disordered **3** is not included). The bond angles agree with sp^2 hybridization of the N atoms and of the C atom bonded to S. In the complexes **1**–**5** with the special ion pair formation, the S–C–N angles involving the $N–H\cdots F1_{axial}$ hydrogen bonds between the ion pairs are consistently larger than

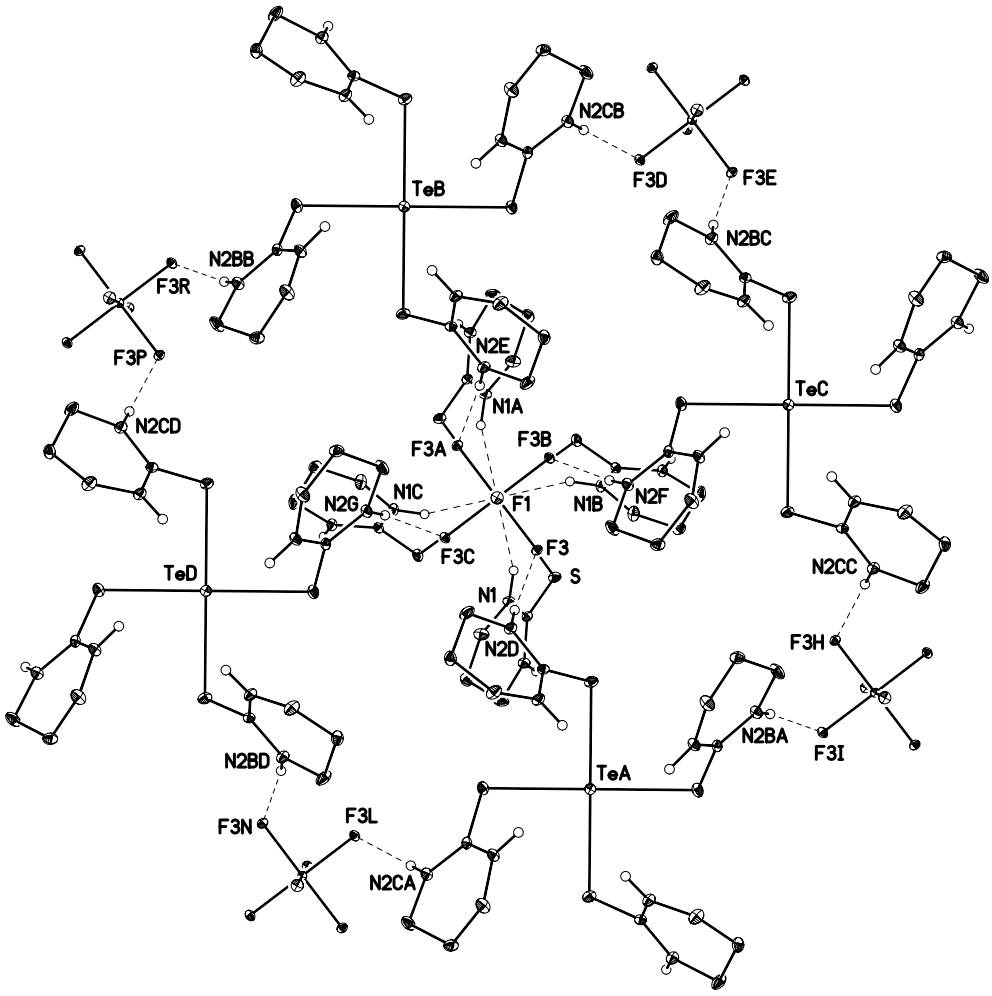

Fig. 8. The molecular packing in **3** with hydrogen bonds indicated as in Fig. 7. The Te atom (not labelled) in the centre lies below atom F1.

the other S–C–N angles. The average difference is ca. 4° and this probably results in an optimal orientation of the ligand with respect to H-bonding and packing.

4. Conformations of the cations

In the $[TeL_4]^{2+}$ cations of the square planar complexes **1**–**5**, the four etu or trtu ligands extend to the same side of the TeS_4 plane. These are the first examples of conformers of this type. In **1**, **3** and **5** the cations have fourfold rotation symmetry, in the isomorphous hydrates **2** and **4** they have a more asymmetric and distorted shape, but the deviations from fourfold symmetry is not great.

Elder et al. [14] determined the crystal structure of $[Te(etu)_4]Cl_2 \cdot 2H_2O$ and discussed the orientations of the etu ligands. In this dihydrate, two independent Te atoms lie on twofold axes, and *cis*-positioned ligands extend to different sides of the TeS_4 plane. The authors regard this, a +−+− conformation in their notation, as the favoured one; it minimizes mutual steric interference of ligands. In ++++ conformers with all four ligands extending to the same side of the TeS_4 plane, and in +++− conformers, "– the steric crowding will be severe and these conformations are unlikely to be observed". However, in the present complexes **1**–**5** ++++ conformers occur, and there are no particularly close inter-ligand contacts.

In complex **6** the Te atoms lie on twofold axes; pairs of *cis*-positioned ligands extend to opposite sides of the TeS_4 plane, in a distorted centrosymmetric ++−− arrangement. In fact, this is the conformation, mostly with the Te atom on a centre of symmetry, that predominates in such complexes [11].

5. Packing and hydrogen bonding

In the Te···F–Si–F and Te···F–Ge–F sequences on the fourfold axes; the Te···F distances are rather short: 3.431(2) and 3.277(2) Å in **1a** and **1b**, 3.378(3) Å in **3** and

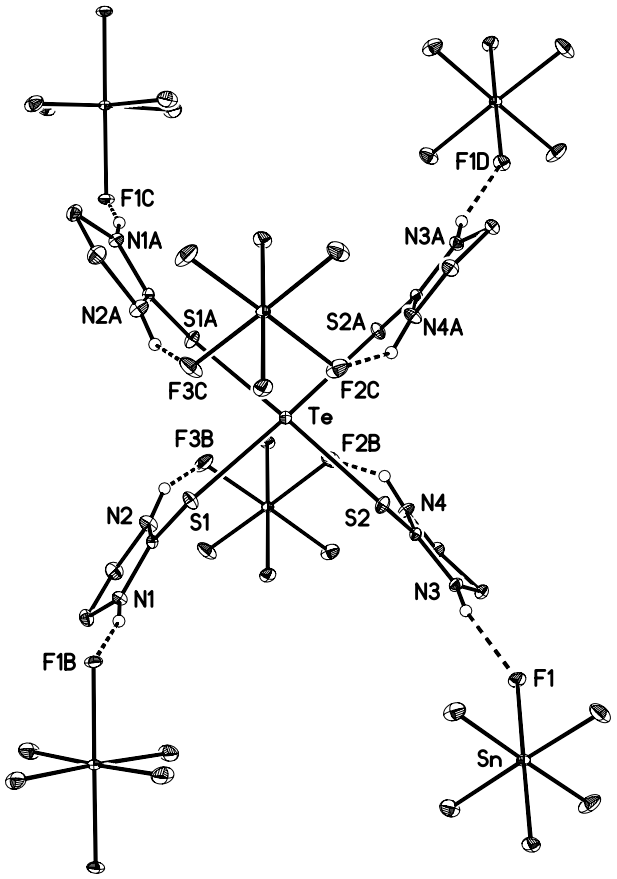

Fig. 9. The molecular packing in **6** with hydrogen bonds indicated as in Fig. 7.

3.348(3) Å in **5**. The cyclic parts of the four etu or trtu ligands of each cation, are all located on the same side of the TeS_4 plane on account of the fourfold axes. Complexes **2** and **4**, in the absence of fourfold symmetry, surprisingly have a similar structure. The closest Te···F distance, on the ligand sides of the TeS_4 plane, is 3.556(2) Å in **2** and 3.544(2) Å in **4**, with S–Te···F angles 81.22(4)° 98.29(4)° in **2** and 81.54(4)° 98.53(4)° in **4.** These Te···F distances are significantly shorter than 3.53 Å, the sum of the van der Waals radii of the respective atoms for **1**, **3** and **5** [15], and this is probably due to the N–H···F hydrogen bonding involving this fluorine atom. For **2** and **4**, the distance is comparable to a van der Waals contact, but here the relevant N–H···F bonding is weaker (Table 9). There are no close Te···F contacts at the other side of the TeS_4 plane in **1**–**5**. The cations of **1**–**5** form basket-like structures with the ligand C, N and H atoms making up the sides of the basket and TeS_4 the bottom with Te in its centre. Into this basket, the lower axial F of the MF_6^{2-} approaches the Te atom. This F atom is now in position to form N–H···F hydrogen bonds with all four ligands of the cationic complex resulting in an unusual situation with the same fluorine atom hydrogen bonded to four different N–H donors, one from each ligand. Such a cation–anion pair is shown in Fig. 6 for **1b**. The N···F distances in these hydrogen bonds range from 2.816(4) to 3.256(4) Å. If one excludes two very weak such bonds, one in **2** and one in **4**, the top of the range becomes 3.105(4) Å (Table 9). Similar N–H···F bonding with the same F atom involved in at least four hydrogen bonds is rare. A search of the Cambridge Crystallographic Data Base show that a single F^- ion can be involved in five and six hydrogen bonds [16,17]. With F bonded to other atoms as in SiF_6^{2-}, the maximum number of hydrogen bonds to F is four [18,19]. The above bonds connect the cation–anion pairs of the asymmetric units in **1**–**5** (Fig. 6). It is probably these interactions between pairs of cations and anions that contribute most to stabilize the unusual ++++ conformations of the complex cations. Why **6** has another structure is difficult to explain. The main difference is the size of the anion as SnF_6^{2-} in **6** is larger than SiF_6^{2-} and GeF_6^{2-} found in **1**–**5**. Thus packing forces may induce a different packing of the complex ions. A further indication that size may be important is that **5** is less stable (loses its red colour and becomes yellow) than **4**. They both share the same anion GeF_6^{2-} which is larger than SiF_6^{2-}, but the thiourea ligand in **5** is trtu which is larger than etu found in **4**. It is also likely that **5** upon its colour change converts its conformation to ++−−.

In addition, there is a series of intermolecular hydrogen bonds connecting the cation–anion pairs in **1**, **3** and **5**. From the second N atom of each ligand, N–H···F hydrogen bonds extend to equatorial F atoms of cation–anion units on neighbouring fourfold axes: 2.967(2) and 2.776(2) Å in **1a** and **1b**, 2.858(3) Å in **3** and 2.803(3) Å in **5**. The hydrogen bonds are listed in Table 9. Fig. 8 shows the supramolecular interactions in **3**, which is fairly representative of these interactions in **1**, **3** and **5**. They connect the ions into an essentially three-dimensional network where layers of anions separate layers of cations. In the isomorphous monohydrate complexes **2** and **4** the intermolecular N–H···F bonding is similar to that found in **1**, **3** and **5**, but there is also a weak N–H···F hydrogen bond involving the second axial F atom. In addition the H_2O molecule takes part in three hydrogen bonds in both complexes. Two O–H···F hydrogen bonds have O···F distances of 2.791(4) and 2.812(4) Å and one N–H···O hydrogen bond has an N···O distance of 2.822(4) Å in **2**. The corresponding distances in **4** are 2.789(4), 2.792(4) and 2.812(5) Å, respectively. These hydrogen bonds connect the cation–anion pairs into a three-dimensional network. There is also an intramolecular N–H···S hydrogen bond in the cations of **2** and **4**, the respective N···S distances being 3.574(3) and 3.569(3) Å. This agrees well with the intramolecular N–H···S bond found in chlorotris (*N*,*N*′-dicyclohexylthiourea)tellurium(II) chloride, where N···S is 3.5618(12) Å [20] and with other N–H···S hydrogen bonds [21]. The supramolecular interactions in **2** are shown in Fig. 7. In **6**, the two etu ligands of the asym-

Bond distances are in Å, angles in degrees.
Where the transformation of A is indicated as "none", the hydrogen bonds are between cation–anion pairs within the asymmetric unit.

metric unit each takes part in two N–H···F hydrogen bonds, of lengths 2.902(3), 2.832(3) Å for one ligand and 2.798(3), 2.745(3) Å for the other, the hydrogen bonding is shown in Fig. 9. The N–H···F hydrogen bonds in the present work are relatively weak compared to the strong such bonds observed recently in two fluoromanganates(III) complexes where the N···F distances are 2.657(2) and 2.668(3) Å [22].

6. The red colour

The crystals of complexes **1**–**5** are red, those of **6** yellow; $[Te(etu)_4]^{2+}$ or $[Te(trtu)_4]^{2+}$ salts with colourless anions are usually pale yellow, some with a green tinge [14,23,24]. However, in solution all the six complexes had the same yellow-orange colour. This shows that a conformational change takes place in **1**–**5** upon

crystallization as the special cation–anion pairs form in the solid state.

The "red shift" of disulfides, X–S–S–X, or diselenides, X–Se–Se–X, occurs when the torsion angle at the S–S or Se–Se bond differs from its preferred value of ca. 90°. A smaller torsion angle results in considerable overlap of the two sulfur or selenium lone pair p orbitals to give rise to doubly occupied π and π* molecular orbitals. The red shift results from an electronic transition from the higher lying π* orbital to a σ* molecular orbital, the energy of the first is increasing with decreasing torsion angle while latter is independent of the torsion angle [25–27]. In the crystals of $R_2NC(S)Se–Se(S)CNR_2$ with R = cyclohexyl, the torsion angle at the Se–Se bond is 84.4° and the crystals are yellow, whereas with R = ethyl the torsion angle is 180° and the crystals are red [28].

In the crystals of the $[Te(etu)_4]^{2+}$ and $[Te(trtu)_4]^{2+}$ complex cations a ligand TeS_4/TeSC tilt angle (≈*cis*-S–Te–S–C torsion angle) different from ca. 90° will give rise to overlap of the filled Te 5p orbital, normal to the TeS_4 plane, and the Spπ orbital, with change of energy levels and red shift as in the disulfides and diselenides. A red square planar Te(II) complex containing a planar TeS_4 coordination group has been encountered earlier; the complex of Te dibenzenethiosulfonate with tetramethylthiourea, *trans*-$[Te(S_2O_2Ph)_2(tmtu)_2]$ [29]. The space group is $P2_1/c$ (No. 14) with $Z = 2$; the Te atom lies on a centre of symmetry. Its crystal structure was determined by Åse and Roti [30]. A deviation of 11.51(51)° from the ideal 90° of the S–Te–S angles was found, and this was thought to be a possible cause of the red colour [30]. However, from the given coordinates a TeS_4/TeSC tilt angle as small as 5.9(6)° for the tetramethylthiorea ligand is calculated. Thus the *cis*-S–Te–S–C torsion angle is close to 180°, and this is clearly the cause.

7. Supplementary data

Deposition numbers CCDC 235767–235772 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif, or by emailing to data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033.

Abstract

With a hydrothermal technique, a layered titanium phosphate with the formula $Ti_2(H_2PO_4)(HPO_4)(PO_4)_2 \cdot 0.5C_6N_2H_{16}$ (denoted **TP-J2**) has been prepared by treating the $Ti/H_3PO_4/H_2O$/1-methylpiperazine system directly. The as-synthesized products were characterized by powder X-ray diffraction, CP-MAS solid-state ^{31}P NMR spectroscopy, thermogravimetric and differential thermal analyses (TG-DTA). The structure was solved by single-crystal X-ray diffraction analysis and it presents an extended γ-phase intercalated with organic amine. Crystal data: triclinic, $P\bar{1}$, $a = 8.106$ (2) Å, $b = 8.197$ (2) Å, $c = 11.658$ (2) Å. $\alpha = 78.32$ (3)°, $\beta = 80.85$ (3)°, $\gamma = 77.90$ (3)°, $Z = 2$. Additionally, the intercalation behavior of **TP-J2** with *n*-alkyl monoamine ($n = 2$, 3, 4, 6, 8, 10 and 12) was investigated. Owing to the strong brønsted base, *N*,*N*′-dimethylpiperazine, resides in the interlayer, it presented unusual features of **TP-J2** in contrast with that of γ-Tip.

1. Introduction

The intercalation chemistry of layered metal (IV) phosphates has been extensively studied because of their special functionalities in the field of photochemistry, electrochemistry, molecular recognition, ion exchange and catalysis [1]. Being members of the layered metal phosphates family, layered titanium phosphates of tetravalent metals have been of considerable interest recently[2]. At the present time, two main types, α- and γ-phase, of layered titanium (IV) phosphates, represented as $Ti(HPO_4)_2 \cdot H_2O$ and $Ti(H_2PO_4)(PO_4) \cdot 2H_2O$ (denote α-Tip and γ-Tip, respectively), are well known. Nevertheless, the number of published papers on the intercalation and the ion-exchange properties of γ-layered phosphates are much fewer than those of the α-phases, though the γ-layers are more rigid, thicker and acidic (owing to the presence of more terminal –OH groups bonded to the phosphorus) to be propitious to intercalate than that of the α-layered phosphates. This is probably due to the fact that structure of the γ-phase was only proposed and not well defined [3]. Therefore, precise structural data of γ-Tip is needed [4].

In recent years, we have devoted efforts towards the hydrothermal and solvothermal syntheses of single crystals of titanium phosphates to obtain possible new types of materials with valuable properties. Up to now, we have prepared 1-D chiral chain titaniumphosphates $[Ti_3P_6O_{27}] \cdot 5[NH_3CH_2CH_2NH_3] \cdot 2[H_3O]$ (JTP-A) and $[NH_3CH_2CH_2NH_3] \cdot [TiO(HPO_4)_2]$ (JTP-B) with zigzag

chains under solvothermal conditions [5,6], 2-D layer titaniumphosphates $[H_3NC_2H_4NH_2]TiOPO_4$ (TP-J1) and $Ti_2(HPO_4)_2(PO4)_2 \cdot C_2N_2H_{10}$ [7,8], as well as 3-D open-framework structures $Ti_3(H_2PO_4)(HPO_4)_{3.5}(PO_4)_2 \cdot C_2N_2H_{10}$, $Ti_2(HPO_4)_3(PO_4) \cdot 0.5C_4N_2H_{12}$, $Ti_7(HPO_4)_6(PO_4)_6 \cdot C_6N_2H_{14}$, with unique P/Ti ratios of 6/13, 1/2 and 7/12, respectively [8,9].

In this paper, a lamellar titanium phosphate, $Ti_2(H_2\text{-}PO_4)(HPO_4)(PO_4)_2 \cdot 0.5C_6N_2H_{16}$ denoted **TP-J2** (J=Jilin university), with an extended γ-phase (the arrangement of the macroanionic sheets are similar to that of the γ-phase) intercalated with organic amine, is reported. The structure was determined by single-crystal methods. Additionally, the intercalation behavior of **TP-J2** with *n*-alkyl monoamine ($n = 2$, 3, 4, 6, 8, 10 and 12) was investigated and presented some special features in contrast with that of γ-Tip.

2. Experimental

2.1. Synthesis

TP-J2 was hydrothermally prepared from a mixture of titanium powder (Shanghai Chemical Plant, 99%), phosphoric acid (Beijing Chemical Plant, 85 wt%), 1-methylpiperazine (ACROS, 99%) and distilled water. In a typical synthesis, 0.5 g of titanium powder was dissolved in 10.5 mL of phosphoric acid beforehand by heating, followed by the addition of distilled water and 2.8 mL of 1-methylpiperazine. The molar ratio of the initial mixture was 1.0 Ti:15 H_3PO_4:2.0 1-methylpiperazine:10 H_2O (pH 1.0). The mixture was aged at room temperature for 2 h, followed by transferring to a 16 mL Teflon-lined stainless-steel autoclave and heating under autogenous pressure at 240 °C for 6 days. The resulting products, with colorless plate crystals, were recovered by filtration, washed thoroughly with distilled water and dried overnight at 50 °C.

2.2. Intercalation by n-alkyl monoamine

The intercalation was performed by a batch method. In a typical procedure 300 mg of **TP-J2**, previously ground, was suspended in 10 mL of an aqueous solution of each *n*-alkyl monoamine ($n_c = 2$, 3, 4, 6, 8, 10, 12), ranging in concentration between 0.1 and 1 mol mL^{-1}. For each sample, the solution was stirred for 3–24 h at room temperature. Then the products were separated by centrifugation and dried at 50 °C.

2.3. Characterization

The powder X-ray diffraction (XRD) patterns were collected on a Siemens D5005 diffractometer with Cu Kα radiation ($\lambda = 1.5418$ Å) with a graphite monochromator. The step size was 0.02°, and the count time was 2 s. The elemental analysis was performed on a Perkin–Elmer 2400 analyzer and the inductively coupled plasma (ICP) analysis on a Perkin–Elmer Optima 3300 DV ICP spectrometer. Thermogravimetric (TG) and differential thermal analysis (DTA) were conducted on a Netzsch STA 449C thermogravimetric analyzer in air with a heating rate of 20 °C min^{-1}. CP-MAS solid-state ^{31}P NMR spectra was recorded on a Infinity-plus400WB instrument and referenced to 85% H_3PO_4 as external standard (downfield shifts positive). The pH measurements of the titration were made with a HANNA pH 211 Microprocessor pH Meter.

2.4. Determination of crystal structure

A suitable single crystal was selected for single-crystal XRD analysis. The data were collected on a Rigaku RAXIS RAPID IP diffractometer [λ(Mo Kα) = 0.71073 Å] at -80 ± 2 °C. Data processing was accomplished with the Process-Auto processing program. The structure was solved by direct methods and refined by full-matrix, least squares based on F^2 using the SHELXTL-5.1 [10] software package. The Ti and P atoms were first located, and the C, N and O atoms were found in difference Fourier maps. The hydrogen atoms residing on the amine molecules and inorganic frameworks were placed by geometrical considerations with d(N–H)=0.89 Å, d(C–H) = 0.97 Å and d(O–H) = 0.82 Å. All non-hydrogen atoms were refined anisotropically. Final refinement converged to $R_1 = 0.0284$ and $wR_2 = 0.1221$ ($I > 2\sigma(I)$). Crystal data and details of data collection and refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis and analysis

Generally, γ-Tip is obtained by the reflux method and the product is a powder [11,12]. Recently, Férey and ourselves reported an extended γ-Tip intercalated with ethylenediamine, determined by single-crystal XRD analysis [8,13], but the P atoms were disordered and the structure determination was of poor quality. Herein, with the hydrothermal technique, we obtained an extended γ-Tip intercalated into amine with a rigid structure by treating the Ti/H_3PO_4/H_2O/1-methylpiperazine system directly, and the structure was solved by single-crystal X-ray diffraction analysis. By the structure determination, it is interesting to note that the organic species between the inorganic layers of **TP-J2** is *N*,*N*′-dimethylpiperazine rather than 1-methylpiperazine which was added in the initial reaction mixture. The result was proved by ^{13}C NMR spectra of the as-synthesized products, as shown in supporting information. It is perhaps

explained that *N*,*N*′-dimethylpiperazine is formed by a decomposed-recomposed process of 1-methylpiperazine under high temperature and pressure conditions (513 K, hydrothermal autogenous pressure conditions), as given by Scheme 1.

The powder XRD pattern of **TP-J2** (Fig. 1) is entirely consistent with that simulated on the basis of the single-crystal structure. The diffraction peaks in both measured and simulated patterns correspond well to each other in position, indicating the phase purity of the as-synthesized sample. The ICP and elemental analysis results show that **TP-J2** contains Ti: 17.21, P: 23.08, C: 6.42, H: 2.72, and N: 2.65 wt%, in good agreement with the calculated values (Ti: 17.84, P: 23.10, C: 6.76, H: 2.05, and N: 2.60 wt%) based on the single-crystal structure formula.

CP-MAS solid-state ^{31}P NMR spectra of the as-synthesized compound are shown in Fig. 2. **TP-J2** gave shifts of −13.64, −17.97, −26.56, −30.03 ppm with equal intensity. On the basis of the previous studies on titanium phosphates and zirconium phosphates [13–15], we assigned the NMR peaks at −13.64 ppm to the H_2PO_4 group and −17.97 ppm to the HPO_4 group. The signals at −26.56 and −30.03 ppm can be attributed to the PO_4 groups. These assignments are all in good agreement with the structure derived from the single-crystal X-ray diffraction. The TG-DTA analyses of **TP-J2** have been performed in the temperature range 25–1000 °C. From Fig. 3, we can see **TP-J2** is thermally stable until 410 °C. A mass loss of 12.6 wt% (cal. 12.48 wt%) at 410–750 °C corresponds to the decomposition of the amine molecules and the partial dehydroxylation (forming of 0.5 mol water). Then the structure collapses and converts to an amorphous phase after calcination at 700 °C, as confirmed by powder X-ray diffraction. Finally, the amorphous phase recrystallizes to form a TiP_2O_7 phase (JCPDS: 38-1468) at 880–950 °C. The

DTA curve exhibits three exothermic peaks corresponding to the decomposition of the template.

3.2. Structure description of *TP-J2*

The asymmetric unit of **TP-J2** is shown in Fig. 4. It contains two crystallographically distinct Ti sites, each being coordinated octahedrally by oxygen atoms. The Ti–O bond lengths and O–Ti–O bond angles are in the range 1.877(2)–1.994(2) Å and 84.97(10)–178.16(9)°, which are in good agreement with those reported previously for other titanium phosphates. Of the four crystallographically distinct P sites, P(1) and P(2) share four bridging oxygen atoms with adjacent Ti atoms, with the P–O distances varying between 1.507(2) and 1.536(2) Å. P(3) and P(4) both share two bridge oxygens with adjacent Ti atoms, leaving two oxygens on their terminal. But the terminal oxygens of the two phosphate tetrahedron are different. For P(3), the longer bond length of P(3)–O(13) (1.573 (3) Å) indicates that a proton is bonded to O(13). The distance of the P(3)–O(10) bond is slightly shorter (1.527(2) Å), but for charge balance, an H atom must also be bonded to O(10). For P(4), the two terminal P(4)–O bond lengths are 1.502(2) Å (P(4)–O(14)) and 1.567(2) Å (P(4)–O(12)), which imply the presence of one P=O group and one hydroxyl group. The final atomic coordinates, selected bond lengths and angles are listed in Tables 2 and 3, respectively.

Although neither unit cells nor space group are correlated, analysis shows the arrangement of the topological structure of **TP-J2** is similar to that of γ-TiP, $[Ti(PO_4)(H_2PO_4)]_2H_2O$. Thus, the individual $[Ti_2(H_2PO_4)(HPO_4)(PO_4)_2]^-$ macroanionic sheet is constructed from infinite corner-sharing 4-ring chains formed by PO_4 tetrahedra and TiO_6 octahedra alternatively. The chains are linked by sharing oxygen atoms so as to form a 2-D network. A highlight of the difference from γ-TiP is the alignment of the terminal P–O groups, located alternatively above and below the sheets. The dihydrogenphosphate groups of γ-TiP are tilted to one side of the adjacent plane, whereas the directions of H_2PO_4 and HPO_4 groups in **TP-J2** are tilted to the left and right relative to the layer by about 30° and 60°, respectively (Fig. 5). The alignment perhaps achieves maximum hydrogen bonding. The diprotonated *N*,*N*′-dimethylpiperazine cations are sandwiched between the sheets which relate to the intercalation of amine into γ-TiP. Extensive H-bonds exist between the organic cations and the framework oxygens. Each proton of the N atoms in the organic cations forms a H-bond with O(14) attached to the phosphate groups (d(N1–H1…O14) = 2.702 Å), and there are strong intralayer H-bonds between O12–H12…O13 = 2.663 Å, O13–H13…O6 = 3.044 Å.

3.3. Intercalation behavior

Owing to the structural similarity of the lamellae between **TP-J2** and γ-TiP, it is essential to investigate the intercalation behavior of **TP-J2**. Herein, a systematic study of the intercalation of **TP-J2** with *n*-alkyl monoamines (n = 2, 3, 4, 6, 8 and 12) has been carried out. There are more differences of intercalation behavior in comparison with that of γ-TiP.

Generally, titration curves of the layered metal phosphates can present the steps of formation of intermediate intercalation compounds and the amount of amine intercalated at various stages of addition can be deduced directly because the added amines are quantitatively intercalated [16]. However, in our preliminary work of intercalation, it was found that the titration curves (present in Fig. 6) increased quickly from the initial pH value of about 3.0 to pH 9.5 where a plateau was presented and the maximum uptake of amine per formula weight of **TP-J2** was only about 0.2 mol, which is far less than that of the previous report (about 1.0–1.5 mol per formula weight of γ-phase at pH >9.0) [17–19]. Furthermore, the pH value declined extremely slowly (over about 12 h) to neutral and the interlayer distance of the final phase was the same as that of initial phase (d_{001} = 13.3 Å). It can be concluded that the added amines did not quantitatively intercalate into **TP-J2** immediately and the titration curve was not suit for this intercalation system. This behavior may be attributed to the difference of the ''guest'' molecules residing in the interlayer. For γ-TiP, the guest molecules are neutral water, a very weak brønsted base. For **TP-J2**, however, the diprontonated *N*,*N*′-dimethylpiperazine cations are anchored between the layers and strong H-bonds exist between the organic cations and the framework oxygens to ensure the stability of the structure (see structure description). It is difficult to exchange the *N*,*N*′-dimethylpiperazine cations or enlarge the interlayer distance to permit the intercalation of the alkylamines. Only if decreasing the energy between the organic cations and the inorganic anions sheet, that is, increasing the additional amine and deprontonating the *N*,*N*′-dimethylpiperazine cations,

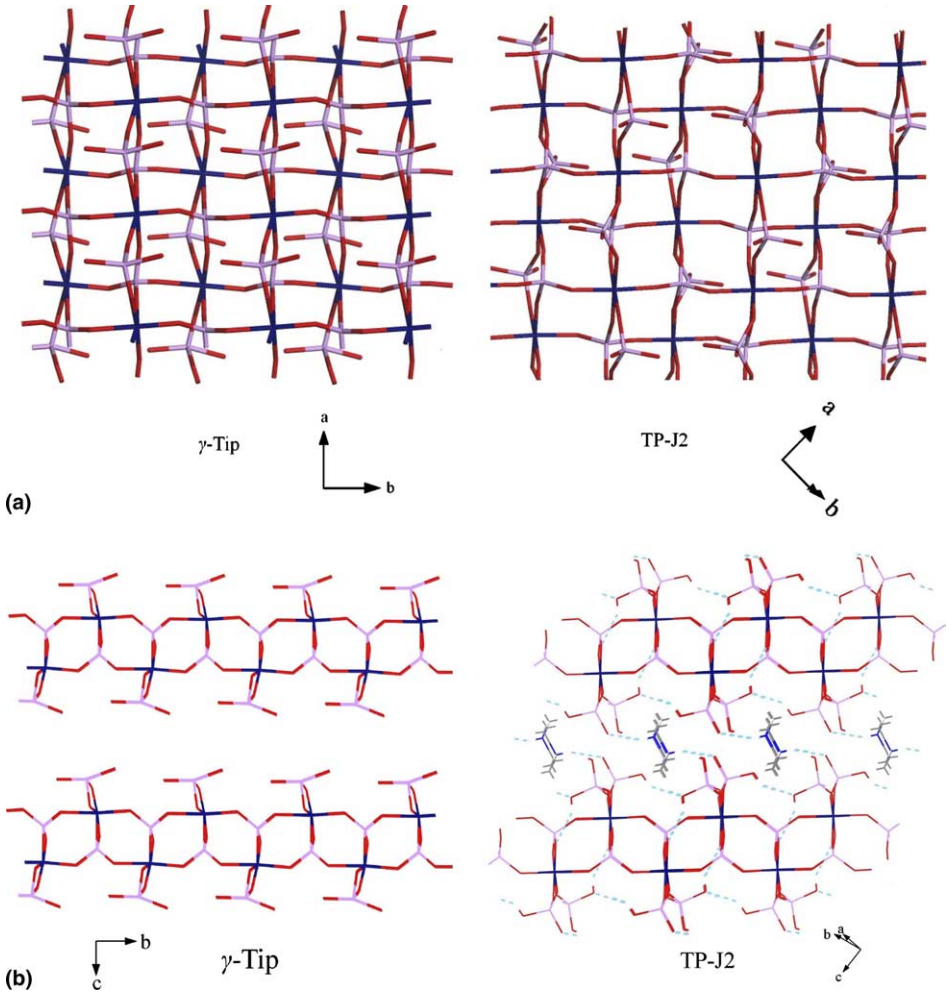

Fig. 5. (a) The sheets of γ-TiP and **TP-J2** viewed along the [0 0 1] direction. (b) Comparison of the structures between γ-TiP and **TP-J2**. Note the difference of orientation of the terminal P–O groups located alternatively above and below the sheets. Hydrogen bonds involving the organic amine molecules and hydroxyl groups of **TP-J2** are marked.

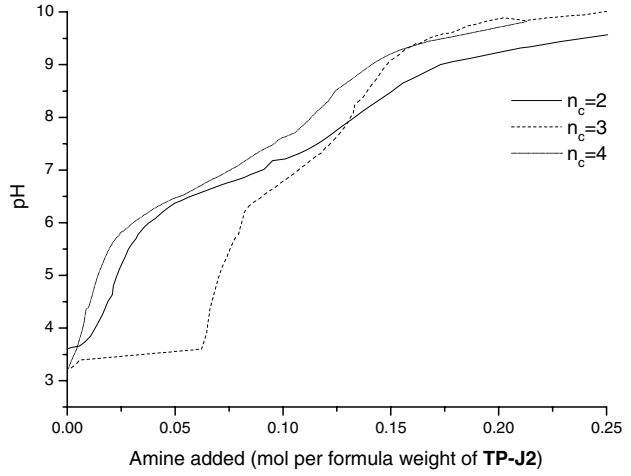

Fig. 6. Potentiometric titration curves for TP-J2 with aqueous solutions of ethylamine, propylamine and butylamine.

can the intercalation behavior proceed. From the titration curves, the plateau present at pH >9.5 and the uptake of amine per formula weight of **TP-J2** higher than 0.2 mol, is the process of deprontonation of the *N*,*N*′-dimethylpiperazine cations. Once the deprontonation of the *N*,*N*′-dimethylpiperazine cations is accomplished, the intercalation phases can be obtained at lower energy.

Consideration of overcoming the energy barrier between the *N*,*N*′-dimethylpiperazine cations and the interlamellae, an excess amount of *n*-alkyl monoamines (about 10 mol amine per formula weight of **TP-J2**) were added into the intercalation system. The final intercalated compounds were expected and characterized by XRD, thermogravimetric and elemental analysis. From XRD patterns, as shown in Fig. 7(a), it can be observed the interlayer distance corresponding to the intercalation compounds of *n*-alkyl monoamine appeared at a lower angle than that ($d = 13.3$) of the host **TP-J2**. As in previous reports, with the exception of the intercalation compound with ethylamine, the interlayer distances increase linearly with the increase of the number of carbon atoms, which suggests that the alkyl monoamines intercalated are regularly

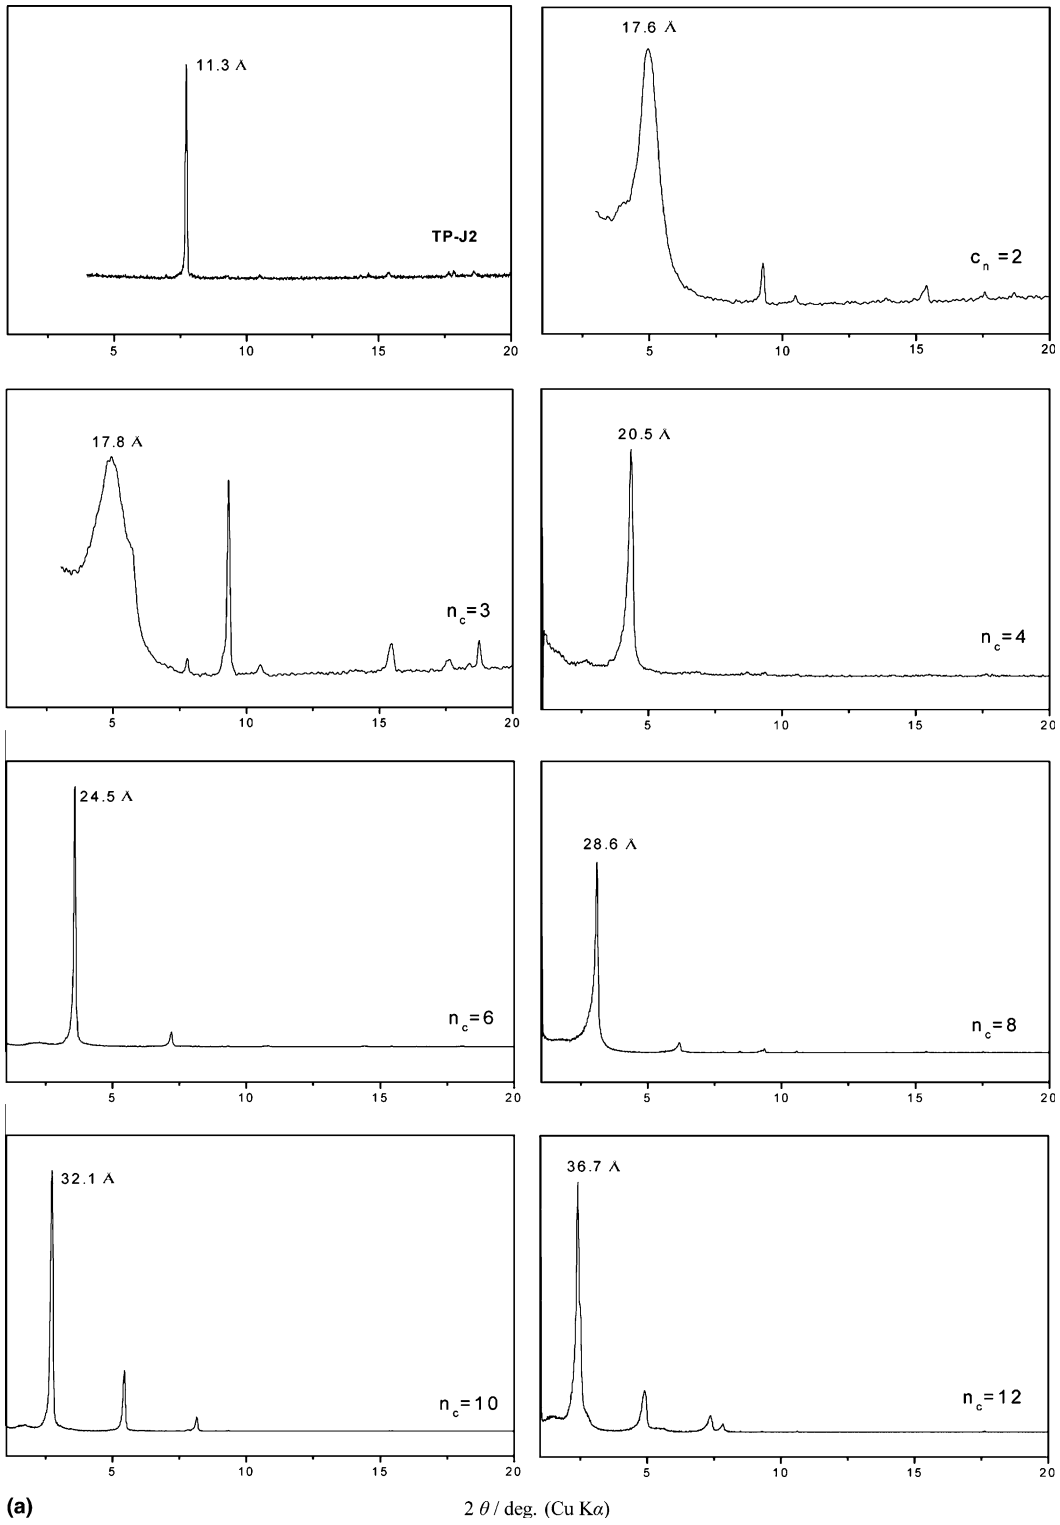

Fig. 7. (a) XRD patterns of **Tp-J2** and intercalation compounds with *n*-alkyl monoamines (*n* = 2, 3, 4, 6, 8 and 12). (b) TGA curves of **Tp-J2** and intercalation compounds with *n*-alkyl monoamines (*n* = 2, 3, 4, 6, 8 and 12).

oriented in the interlayer region of **TP-J2** and the angle to the layer is constant (Fig. 8). In the case of the intercalation compound with ethylamine, the formation of a thin film or membrane through removal of water by slightly heating was observed, and it should be exfoliated in packets of a few lamellae [20]. By elemental and thermogravimetric analysis, the formula is $Ti_2H_{2.75}(PO_4)_4 \cdot 1.25C_2H_5NH_3 \cdot H_2O$, indicating that

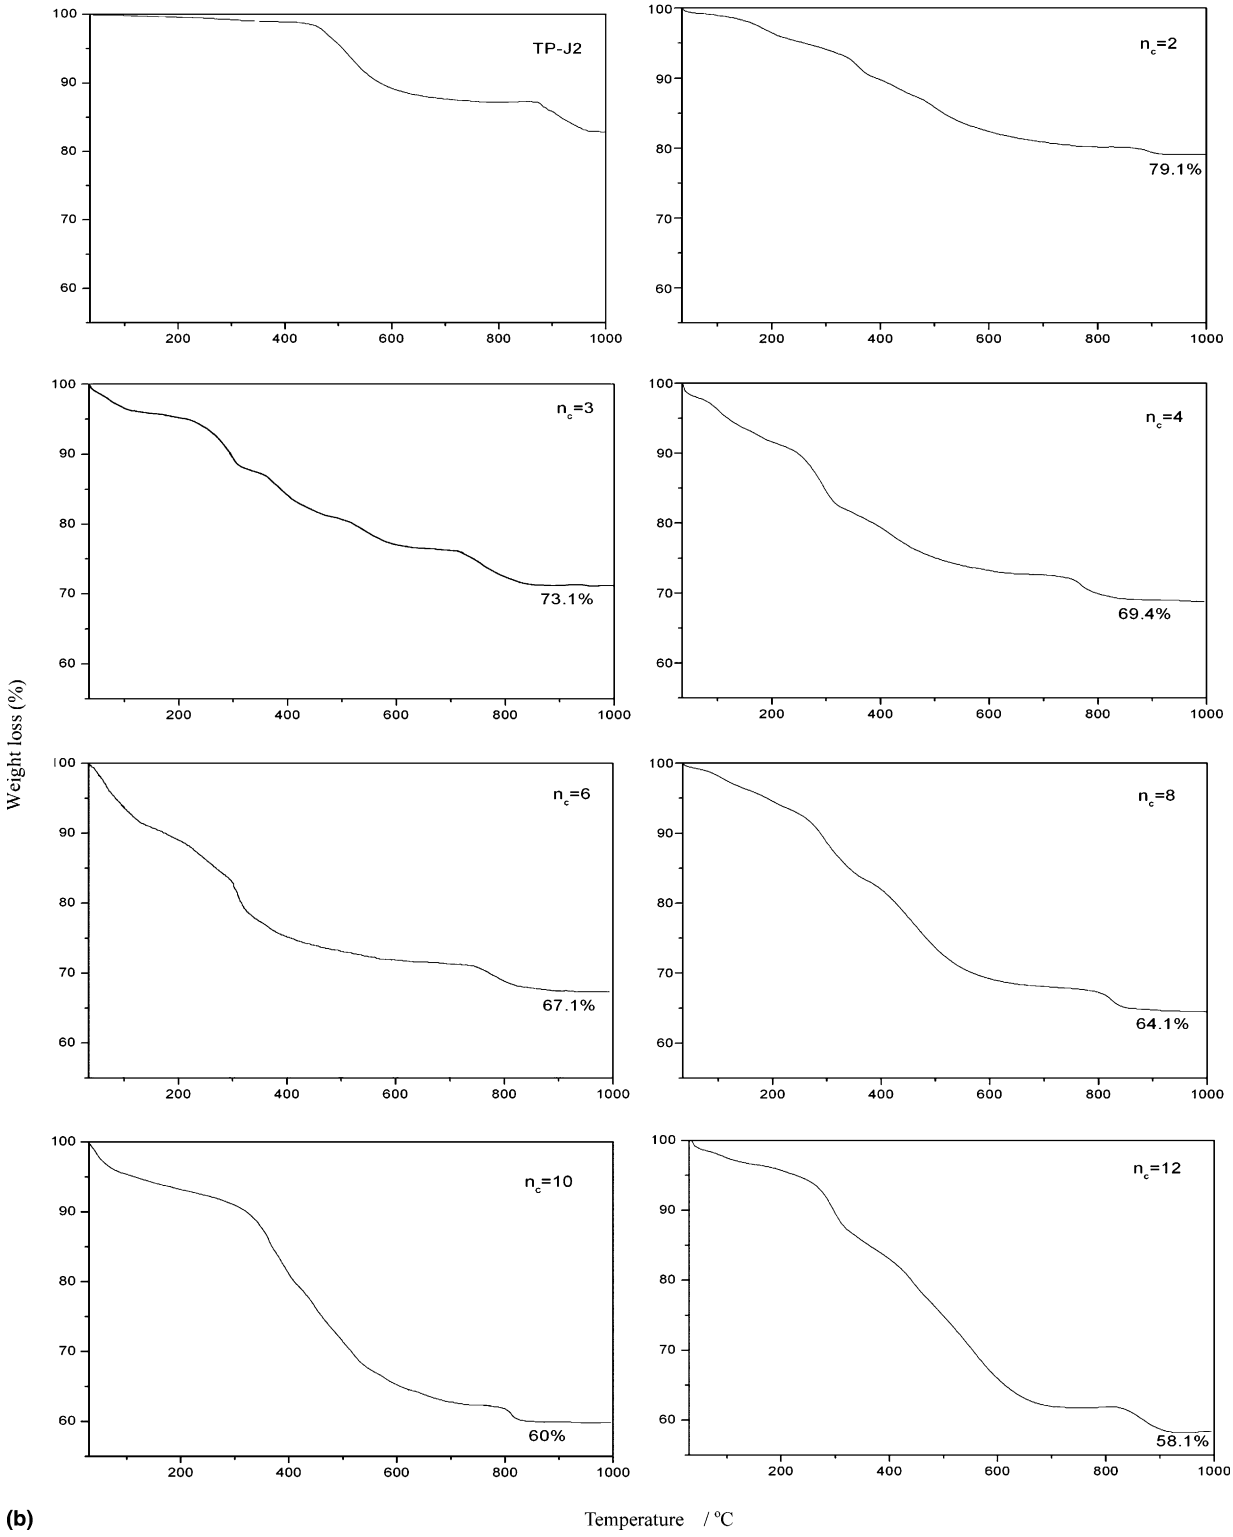

Fig. 7 (*continued*)

the initial *N*,*N*′-dimethylpiperazines were fully displaced by ethylamine. However, for *n*-alkyl mononamines with $n_c = 3$, 4, 6, 8, 10 and 12, the components were more complex. By means of C and N analysis, the C/N ratios corresponding to the intercalation compounds with alkyl chains amines were about 3.0, 3.67, 5.0, 6.33, 7.67 and 9.0, respectively. Nevertheless, the C/N ratios for *n*-alkylmonamine ($n_c = 3$, 4, 6, 8, 10, 12) were equal to their C atom numbers. Therefore, some *N*,*N*′-dimethylpiperazines must remain in the

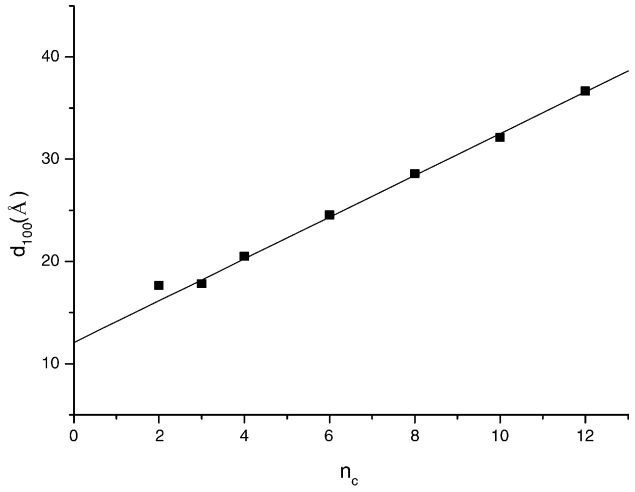

Fig. 8. Interlayer distances of intercalation compounds of **TP-J2** with *n*-alkylamines vs. the number of carbon atoms in the alkyl chain.

interlayer of the intercalated compounds. Considering the C/N ratios, 1/4 mol *N*,*N*′-dimethylpiperazine plus 1 mol $C_nH_{2n+1}NH_3$ is consistent with the experiment values, so it is believed the organic formulas of the intercalated compounds are $[1/4C_6N_2H_{16} + C_nH_{2n+1}NH_3]$. By the thermal decomposition of the intercalation compounds, whose the weight loss curves are shown in Fig. 7(b) and are similar to those reported previously, we can obtain their general formula: $Ti_2(PO_4)_4H_{2.125} \cdot 1.25[0.25C_4N_2H_{16} \cdot C_nH_{2n+1}NH_3] \cdot H_2O$. The experimental and calculated values are in good agreement (see Table 4). The reaction may be represented by Eq. (1).

$$Ti_2(H_2PO_4)(HPO_4)(PO_4)_2 \cdot 0.5C_6N_2H_{16} + 1.25C_nH_{2n+1}NH_2 \rightarrow Ti_2(PO_4)_4H_{2.125} \cdot 1.25[0.25C_4N_2H_{16} \cdot C_nH_{2n+1}NH_3] \cdot H_2O + 0.175C_6N_2H_{14} \quad (1)$$

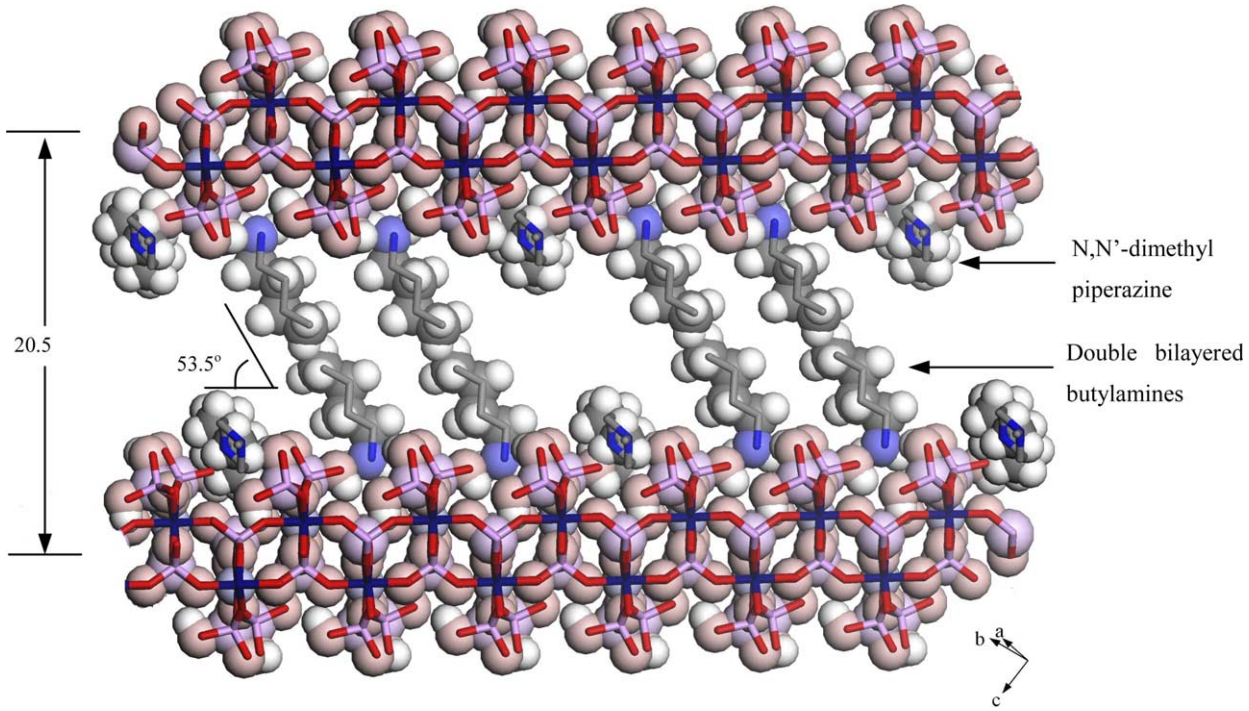

Fig. 9. Schematic model of the arrangement of *N*,*N*′-dimethylpiperazines and butylamines between the lamellae.

The compositions of the final intercalation products indicate that there is only partial exchange of the *N*,*N*′-dimethylpiperazine by the *n*-alkylamines compared with the full intercalation of ethylamine. We tried to increase amount of the additional amine and length of the reaction time of intercalation, but the compositions of the final products were unchanged. A reasonable explanation is that the interaction energy of host–guest in these phases is stronger which makes the structures more stable. Energy calculations and computer models with the help of *Cerius*[2] package are proceeding and will be reported in a separated paper. Herein, a schematic arrangement representation of the intercalation with butlyamine derived from the analysis of the correlation between the interlayer distances and the number of carbon atoms in the alkyl chain is given, as shown in Fig. 9. Between the lamellae, *N*,*N*′-dimethylpiperazines were well-distributed alternatively with double bilayered butylamines. The inclination of the bilayered butylamine chains with respect to the plane is 53.5°, by means of the slope of the straight line of 2.04 pm per carbon atom, expressed in Eq. (2)

$$\alpha = \sin^{-1}(2.04/(2 \times 1.27)) = 53.5^{\circ}. \quad (2)$$

4. Conclusions

TP-J2, $Ti_2(H_2PO_4)(HPO_4)(PO_4)_2 \cdot 0.5C_6N_2H_{16}$, with an extended γ-phase intercalated into organic amine, was prepared directly under hydrothermal conditions. The organic specie was believed to be formed through a decompose-recomposed process of 1-methylpiperazine under high temperature and pressure conditions. The intercalation behavior of TP-J2 was investigated by comparison with that of γ-TiP. There are more differences because of the presence of the *N*,*N*′-dimethylpiperazine cations between the layers of **TP-J2**. The general formula of the final intercalation products was $Ti_2(PO_4)_4H_{2.125} \cdot 1.25[0.25C_4N_2H_{16} \cdot C_nH_{2n+1}NH_3] \cdot H_2O$, and possible arrangements of organic species between the layers were given. The structure and intercalation behavior of **TP-J2** increased our understanding of γ-phase titanium phosphate. The further intercalation of active species and computer models are in progress.

Synthesis, crystal structures and magnetic properties of Cu(II) compounds bridged by the terephthalate ligand and hydrogen bonds

Chang Seop Hong *, Young Sin You

Department of Chemistry and Center for Electro- and Photo-Responsive Molecules, Korea University, Seoul 136-701, Korea

Received 30 July 2004; accepted 1 September 2004

Abstract

A 3D network $[Cu(tmen)(tp)(H_2O)_2]_n$ (**1**) (tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine; tp = terephthalate) and a 2D sheet $[Cu(pyrazole)_2(tp)]_n$ (**2**), featuring 1D chains interwoven by hydrogen bonds, have been prepared and characterized by means of X-ray analyses and magnetic measurements. For **1**, coordinative zigzag chains contain Cu(II) centers capped by the chelate ligand tmen, in which the tetragonal structure is elongated due to Jahn–Teller distortion. Coordinated water molecules are hydrogen-bonded to two free carboxylate oxygens of tp bridges, leading to the observed 3D structure. The use of the non-chelating capping ligand pyrazole produced the covalent-bonded 1D linear compound **2** with hydrogen bonds. A severe octahedral distortion of the Cu(II) center arises from a small bite angle (52.3(1)°) of two carboxylate oxygen atoms of tp, which are in turn hydrogen-bonded to the N–H groups of pyrazole ligands coordinated to Cu(II) atoms in neighboring chains. Magnetic data were fitted with the high-temperature series expansion for the Heisenberg chain spin Hamiltonian $H = -J\sum_i S_i \cdot S_{i+1}$ together with consideration of the molecular field approximation (zJ'). Both compounds interestingly exhibit ferromagnetic interactions with $g = 2.17$, $J = 4.08$ cm^{-1}, $zJ' = -0.28$ cm^{-1} for **1** and $g = 2.09$, $J = 1.47$ cm^{-1}, $zJ' = -0.04$ cm^{-1} for **2**. By taking into account structural parameters of distances between Cu atoms, it is reasonably assigned that the ferromagnetic couplings ($J > 0$) in these systems originate from the hydrogen bonds. The spin density of the $d_{x^2-y^2}$ orbital on a Cu(II) atom in a chain is propagated and induced over the d_{z^2} orbital of another Cu(II) atom in an adjacent chain. This orbital orthogonality gives rise to such interactions. The negative zJ' term suggests that the tp bridges communicate only tiny antiferromagnetic interactions.

1. Introduction

Molecule-based magnetic materials have been one of the actively studied subjects with the hope of potential applications to magnetic devices [1]. To attain molecular magnets with desirable properties, the fundamental understanding of magnetic interactions between spin centers is an important prerequisite. In this context, a large number of coordination polymers have been prepared and characterized structurally and magnetically [2–4]. They provide useful insights into structure–property relationship, and also confer synthetic strategies how to construct magnetically coupled systems with higher dimensionality that is essentially required for high T_C molecular magnets [5].

To achieve magnetic materials with fascinating characteristics, one of the most basic components considered is ligands to be used as bridges between metal ions. Bridging ligands sit on a central position in the design of magnetically interesting systems because they are in charge of transmitting magnetic interactions between paramagnetic metal ions. The crucial factors for ligands as bridges include multibinding abilility and effectiveness

doi:10.1016/j.poly.2004.09.019

of magnetic exchange coupling. In this vein, the tp ligand is one of the good candidates since it acts in monodentate and bidentate bridging modes, capable of linking up to four metal ions within a metal–metal separation of about 11 Å at the same time [6–9]. The long magnetic pathway through tp enables us to quest for an adequate answer to how far magnetic coupling can propagate. From a magnetic point of view, the tp ligand can mediate weak antiferromagnetic interactions, $J \leqslant -2.2\ cm^{-1}$ based on the Hamiltonian $H = -JS_1 \cdot S_2$, for Cu(II), Ni(II), Co(II) and Mn(II) compounds [10–12]. Some weak ferromagnetic Cu(II) compounds bridged by tp ligands have also been reported [12–15]. Therefore, the weak magnetic interactions via the tp linkage are compatible with those through hydrogen bonds.

To probe the genuine role of the hydrogen bond in magnetic nature we have attempted to make 1D chain Cu(II) compounds bridged by a tp ligand and concurrently connected by hydrogen bonds. Herein we report the synthesis, crystal structures and magnetic properties of two tp-bridged Cu(II) complexes. To obtain structural and magnetic variations, we have utilized chelating (tmen) and non-chelating (pyrazole) capping ligands, producing covalent-linked zigzag $[Cu(tmen)(tp)(H_2O)_2]_n$ (**1**) and linear chain $[Cu(pyrazole)_2(tp)]_n$ (**2**). Both compounds possess hydrogen bonds that interweave adjacent chains, leading to the formation of an extended 3D network (**1**) and a 2D sheet (**2**). Magnetic measurements indicate that the hydrogen bonds communicate ferromagnetic interactions between chains that can be accounted for by the overlap of orthogonal magnetic orbitals, while the tp bridges mediate very weak antiferromagnetic couplings.

2. Experimental

2.1. Materials

All chemicals and solvents were purchased from commercial sources and were used without further purification. Potassium tp was readily prepared by reacting terephthalic acid with a stoichiometric amount of KOH in water.

2.2. Preparation of $[Cu(tmen)(tp)(H_2O)_2]_n$ (*1*)

The bidentate ligand tmen (1.0 mmol) was slowly added by syringe to an aqueous solution (10 ml) of copper(II) perchlorate hexahydrate (1.0 mmol). The resulting solution was treated with an aqueous solution (10 ml) of dipotassium tp (1.0 mmol), immediately forming blue precipitates. After filtration of the solution the filtrate was left undisturbed giving blue crystals of **1** suitable for X-ray crystallography. The total yield corresponds to 65% based on Cu. The reaction of copper nitrate hemipentahydrate with tmen and dipotassium tp gave the same product. *Anal*. Calc. for $C_{14}H_{24}CuN_2O_6$ (**1**): C, 14.3; H, 6.37; N, 7.37. Found: C, 14.6; H, 6.24; N, 7.56%. Selected IR data (cm^{-1}, KBr pellet): 3437 (m), 3262 (m), 3044 (w), 3024 (w), 2984 (w), 2912 (w), 1647 (m, HOH bending), 1585, 1574 (s, tp$\nu_a(CO_2^-)$), 1498 (m), 1470 (m), 1365, 1348 (s, tp$\nu_s(CO_2^-)$), 1297 (m), 1280 (m), 1145 (w), 1122 (w), 1092 (w), 1043 (w), 1016 (m), 1001 (w), 955 (w), 895 (w), 832 (m), 807 (m), 757 (m), 669 (w), 573 (w), 506 (w).

2.3. Preparation of $[Cu(pyrazole)_2(tp)]_n$ (*2*)

A 10 ml aqueous solution of pyrazole (2.0 mmol) was added to an aqueous solution (10 ml) of copper(II) nitrate hemipentahydrate (1.0 mmol) with stirring. A 10 ml aqueous solution of dipotassium tp (1.0 mmol) was mixed with the resulting solution. Immediately, cobalt-violet precipitates were formed and collected by filtration, washed with water, and dried in air. The filtrate was left to stand for several days, providing cobalt-violet single crystals of **2**. The total yield amounts to 87% based on Cu. *Anal*. Calc. for $C_{14}H_{12}CuN_4O_4$: C, 46.2; H, 3.32; N, 15.4. Found: C, 45.9; H, 3.38; N, 15.6%. Selected IR data (cm^{-1}, KBr pellet): 3286 (m), 3125 (w), 1601 (s, tp$\nu_a(CO_2^-)$), 1509 (w), 1466 (w), 1363, 1345 (s, tp$\nu_s(CO_2^-)$), 1251 (w), 1143 (w), 1110 (m), 1067 (m), 1051 (m), 1020 (w), 952 (w), 908 (w), 889 (w), 823 (m), 780 (m), 741 (m), 603 (w), 500 (w).

2.4. Physical measurements

Elemental analyses for C, H and N were performed at the Elemental Analysis Service Center of the Korea Basic Science Institute. Infrared spectra were obtained from KBr pellets with an EQUINOX 55 spectrometer. Magnetic susceptibilities for **1** and **2** were carried out using a Quantum Design MPMS-7 SQUID susceptometer. Diamagnetic corrections of **1** and **2** were estimated from Pascal's Tables.

2.5. X-ray structural analyses

Data were collected at 293 K using an Enraf-Nonius CAD4TSB diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were calculated by least-squares refinement of 25 well-centered reflections. All data were corrected for Lorentz polarization effects. A total of 2782 (**1**) and 1230 (**2**) reflections with a maximum 2θ of 49.94° (**1**) and 49.94° (**2**) were measured and 2470 (**1**) and 1075 (**2**) reflections were assumed to be observed applying the condition $F_o > 4\sigma(F_o)$. Crystallographic data and details of data collection are listed in Table 1.

The structures were solved with the SHELXS-86 program (**1**) and the SIR-92 program (**2**), and refined by least-squares analysis using anisotropic thermal parameters for non-hydrogen atoms with the SHELXL-97 program for **1** and **2** [16–18]. H atoms were calculated at idealized positions ($d_{CH} = 0.970$ for methylene, 0.960 for methyl and 0.930 Å for phenyl) and refined riding on the corresponding carbon atoms with isotropic thermal parameters [$U = 1.2U(C_{methylene})$, $1.5U(C_{methyl})$ and $1.2U(C_{phenyl})$].

3. Results and discussion

3.1. Syntheses and characterization

Compound **1** was prepared by the stoichiometric reaction of the Cu(II) ion with dipotassium tp in the presence of the chelating capping ligand tmen in water. In the IR spectrum, the conspicuous carboxylate stretchings present at 1585 and 1574 cm^{-1} are assignable to the antisymmetric stretching frequency $\nu_a(CO_2^-)$, and those at 1365 and 1348 cm^{-1} are responsible for the symmetric frequency $\nu_s(CO_2^-)$. The binding modes of the carboxylate ligands can be determined based on the difference (Δ) between $\nu_a(CO_2^-)$ and $\nu_s(CO_2^-)$. The calculated Δ value is bigger than 200 cm^{-1}, which compared with the value ($\Delta = 170$ cm^{-1}) of dipotassium tp suggests that the tp ligand in **1** behaves in the monodentate mode [19]. It is also noted that the characteristic broad OH peaks at 3437 and 3262 cm^{-1} indicate the presence of hydrogen bonds.

In order to explore structural and magnetic variations depending on the geometries of the magnetic centers, we prepared a new tp-bridged copper(II) complex (**2**) by employing the non-chelating capping ligand pyrazole, instead of the bidentate tmen. The IR spectrum of **2** reveals that the diagnostic carboxylate stretching vibrations occur at 1601 cm^{-1} for $\nu_a(CO_2^-)$ and 1363, 1345 cm^{-1} for $\nu_s(CO_2^-)$. The difference ($\Delta > 200$ cm^{-1}) supports that the tp bridge in **2** serves as a monodentate ligator, consistent with **1** [19]. The broad band centered at 3286 cm^{-1}, attributable to the N–H stretchings of the pyrazole ligands, denotes the presence of hydrogen bonds, which is confirmed by the X-ray structure below.

3.2. Description of the structures

The structure of **1**, with the asymmetric unit and symmetry related fragments, is shown in Fig. 1a. Selected bond distances and angles are given in Table 2. The inversion centers are placed at the middle of the benzene rings of the tp ligands. The molecular arrangement of the Cu(II) ion is octahedral with a tetragonal distortion. The basal plane consists of two nitrogen atoms of the tmen ligand [Cu1–N1 = 2.072(3), Cu1–N2 = 2.076(3) Å] and two oxygen atoms of two tp ligands [Cu1–O1 = 1.963(2) and Cu1–O3 = 1.962(2) Å], comparable to tp-bridged Cu(II) compounds in a bis-monodentate fashion [20]. The largest deviation from the O1O3N1N2 equatorial least-squares plane is 0.112(2)

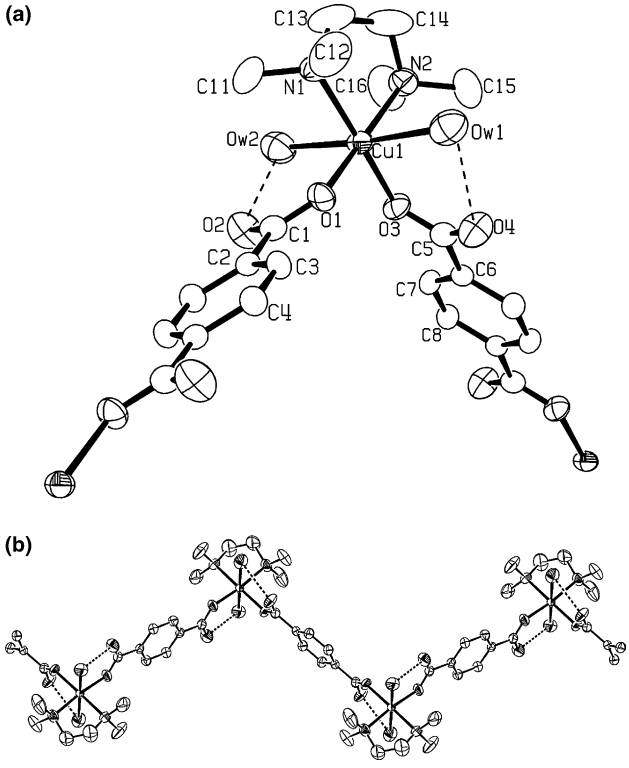

Fig. 1. Molecular structure of **1** showing (a) the asymmetric unit and symmetry-related atoms along with the atom-labelling scheme, and (b) the zigzag chain. The broken lines represent hydrogen bonds.

[a] Symmetry code: (a) $-x$, $2-y$, $1-z$ and (d) $-x$, $2-y$, $-z$.

Å at N1 and the Cu1 atom lies −0.002(2) Å out of the plane toward the apical site (Ow2). The two axial positions are occupied by water molecules that are substantially elongated from the Cu center [Cu1–Ow1 = 2.613(4) and Cu1–Ow2 = 2.613(4) Å]. The dihedral angles of carboxylate groups and benzene rings are 2.5° for O1-linked tp and 2.3° for O3-linked tp, which are smaller than that (10.6°) of an en-capped Cu(II) chain compound and similar to that (2.3°–5.5°) of the 1D chain compound Cutp$(H_2O)_2$[13,15]. Two adjacent benzene rings are tilted by 102.3°, forming a 1D zigzag chain structure as seen in Fig. 1b. It is found that the dihedral angles of the basal O_2N_2 plane and the benzene rings for O1-linked tp as well as for O3-linked tp are equal to 98.9° and 98.8°, respectively, larger than those of zigzag tetranuclear or chain complexes with bismonodentate tp bridges [12,13]. The intrachain Cu···Cu distances are 11.224(2) and 11.215(2) Å via the O1- and O3-linked tp bridges, respectively, similar to reported values for tp-bridged Cu(II) systems [6–15,21].

The coordinated water molecules are hydrogen-bonded to the free carboxylate oxygen atoms of tp ligands in a chain [Ow1···O4 = 2.754(5) and Ow2···O2 = 2.752(5) Å], which is completely different from the μ-tp zigzag Cu(II) chain compound where unbound carboxylate oxygen atoms have intermolecular hydrogen bonds to one of amine hydrogen atoms of en [13]. Such N–H···O contacts found in the en-capped Cu system do not exist in **1** due to the absence of amine hydrogen atoms in tmen [13]. In fact, one of the water molecules (Ow2) forms an additional hydrogen bond to a carboxylate oxygen atom (O2a) in an adjacent chain (Ow2···O2a = 2.831(5) Å; a: $-x$, $2-y$, $1-z$), consequently leading to the shortest interchain Cu···Cu distance of 6.539(1) Å, which is longer than that of the en-capped Cu(II) chain, possibly due to the existence of bulky methyl groups on the chelating tmen ligand with respect to the en ligand (Fig. 2) [13]. Thus, two zigzag chains are connected together through intermolecular hydrogen bonds. In the two zigzag chains, the remote Cu–Cu separation of Cu1b···Cu1c (b: x, $-1+y$, z and c: $-1-x$, $1-y$, $-z$) is 12.903(2) Å. The other apical water molecule (Ow1) also has hydrogen bond to a free carboxylate oxygen in another chain (Ow1···O4d = 2.832(5) Å; d: $-x$, $2-y$, $-z$). These hydrogen bonds run along the *c*-axis, finally resulting in a 3D network array as illustrated in Fig. 3.

An ORTEP diagram showing the structure of **2** with the symmetry related fragments and atom-numbering scheme is shown in Fig. 4. Selected bond distances and angles are summarized in Table 3. The Cu(II) atom, with an inversion center, adopts a distorted octahedral geometry comprising two nitrogen atoms of two pyrazole ligands [Cu1–N1 = 1.987(3) Å] and two oxygen atoms of two different tp ligands [Cu1–O1 = 1.932(2) Å]. The N_2O_2 moiety defines the equatorial plane of the octahedron. It is noted that two carboxylate oxygen atoms of two different tp bridges in a chain having very weak bond strength [Cu1–O2 = 2.797(3) Å], larger than that for the tp-bridged Cu(II) binuclear compound [10], are placed at the axial positions of the distorted octahedron. In the equatorial plane, the angles between the *cis*-

positioned atoms are close to 90° and those of the *trans*-positioned atoms are identical to180° since the Cu atom resides at the inversion center. However, the bite angle (O1–Cu1–O2) of the carboxylate group is acute, 52.3(1)°, significantly deviated from 90°, which gives the main distortion on the octahedral environment. This value is compatible with that of the Cu(II) binuclear compound and smaller than those of Ni(II), Co(II) and Mn(II) binuclear complexes [10]. The dihedral angle of the carboxylate group and benzene ring of tp is found to be 2.5°, which agrees well with that of **1**. The benzene rings of neighboring tp bridges are parallel, while the average dihedral angle of the benzene ring of tp and the pyrazole plane is 96.4°. The intrachain Cu1···Cu1a (a: x, $1+y$, $1-z$) distance via the tp bridge is 10.932(2) Å, shorter than that of **1**. It is worth noting that the use of the non-chelating capping ligand leads to the formation of the linear chain structure (**2**), which is compared with the zigzag chain (**1**) built from the bidentate tmen.

As expected from the IR spectrum, the hydrogen atom in the N–H group of each pyrazole ring serves as a hydrogen donor to the carboxylate oxygen atoms (Fig. 5). The N–H(N2c) unit bound to Cu1d is first hydrogen-bonded to a carboxylate oxygen atom (O1d) within the same chain (N2c···O1d = 2.878(4) Å; c: $1-x$, $-y$, $2-z$; d: $1+x$, y, z). The second hydrogen bond of the N–H moiety is generated with a carboxylate oxygen atom (O2) in a neighboring chain [N2c···O2 = 2.802(4) Å]. Likewise, additional hydrogen bonds between Cu1 and Cu1d are created through the N–H group of the pyrazole ring coordinated to the Cu1 center, which is symmetry-related to the N2c–H event. Consequently, the two Cu centers in the different chains are doubly interconnected via the hydrogen bonds. The overall structure of **2** can be eventually viewed as a 2D sheet made up of the combination of the coordinative 1D chains and the non-covalent forces between them. The shortest interchain Cu···Cu distance is 5.030(1) Å, much shorter than that of **1**.

3.3. Magnetic results

The magnetic susceptibility measurement of **1** is plotted in Fig. 6. At 300 K, the $\chi_m T$ value is 0.44 cm^3 K

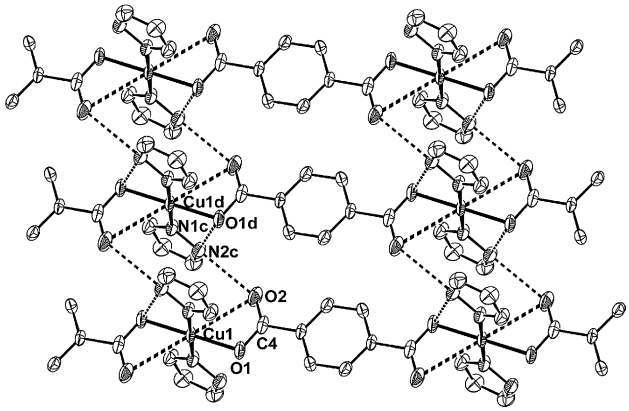

Fig. 5. Extended molecular view of **2** exhibiting hydrogen bonds between chains. The thin broken lines present hydrogen bonds and the thick ones show weak bond interactions between Cu atoms and carboxylate oxygens. Symmetry codes used to generate equivalent atoms: (c) $1-x$, $-y$, $2-z$ and (d) $1+x$, y, z.

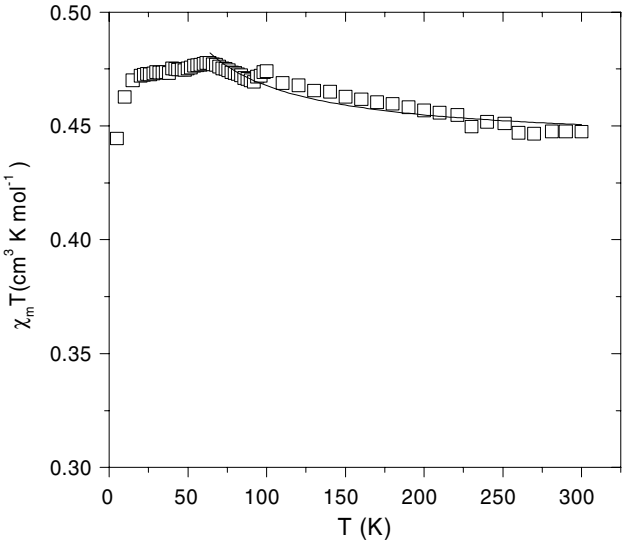

Fig. 6. Plots of χ_m^{-1} and $\chi_m T$ vs. T for **1**. The solid lines denote the best theoretical fits.

mol^{-1}, which is somewhat larger than the value (0.38 cm^3 K mol^{-1}) expected for a non-interacting Cu(II) ion, implying the presence of ferromagnetic interactions in **1**. When the temperature is lowered, $\chi_m T$ rises smoothly to reach a maximum of 0.48 cm^3 K mol^{-1} at 64 K and then decreases down to a value of 0.44 cm^3 K mol^{-1} at 5 K. The variation of the inverse magnetic susceptibility ($1/\chi_m$) with temperature shows a linear dependence down to 64 K and thus follows the Curie–Weiss relation. The calculated parameters of C (Curie constant) = 0.44 cm^3 K mol^{-1} and θ (Weiss constant) = 6.7 K evidence that the magnetic centers in **1** are ferromagnetically coupled.

There are two possible magnetic coupling routes: one is via hydrogen bonds and the other through tp. So, the magnetic data were fit to the high-temperature series expansion derived by Baker et al. for the Heisenberg chain spin Hamiltonian $H = -J\sum_i S_i \cdot S_{i+1}$ together with the consideration of the molecular field correction [22,23]

$$\chi_{chain} = \{Ng^2\beta^2/4kT\}[A/B]^{2/3}$$
$$A = 1.0 + 5.7979916x + 16.902653x^2 + 29.376885x^3 + 29.832959x^4 + 14.036918x^5$$
$$B = 1.0 + 2.7979916x + 7.0086780x^2 + 8.6538644x^3 + 4.5743114x^4 \quad x = J/2kT, \tag{1}$$

$$\chi_m = \chi_{chain}/[1 - (zJ'/Ng^2\beta^2)\chi_{chain}]. \tag{2}$$

The best fit in the high-temperature region 64–300 K yields magnetic parameters of $g = 2.17$, $J = 4.08$ cm^{-1} and $zJ' = -0.28$ cm^{-1}. The measure of the goodness of fit R, defined as $R = \Phi/(n-k)$ where n is the number of data points, k is the number of parameters, and $\Phi = \sum[(\chi_m T)_i^{obs} - (\chi_m T)_i^{calc}]^2$, is equal to 1.0×10^{-5}. The positive J value demonstrates that ferromagnetic interactions in **1** are operative. Kahn and coworkers [20] investigated magnetic properties of tp-bridged binuclear Cu(II) compounds capped by ligands with different bulky groups that brings about the variation of intermolecular Cu···Cu distances, and concluded that intermolecular interactions would play a major role in observed magnetism rather than intramolecular couplings through tp. It is generally accepted that magnetic strength depends on distance between magnetic centers. Thus, the concept of distance–magnetic strength is reasonably applied to this system. Since the shortest intermolecular Cu···Cu distance (6.54 Å) connected with hydrogen bonds is almost half of the intramolecular Cu···Cu length (11.2 Å), sizable magnetic exchange would occur through hydrogen bonds. In view of the magnetic pathways between magnetic centers via hydrogen bonds, the magnetic orbital $d_{x^2-y^2}$ of Cu1 lying in the equatorial plane enables evolvement over two magnetic σ-pathways, that is, Cu1–O1–C1–O2–Ow2a–Cu1a and Cu1–O1–C1–O2–Ow2a–O2a–C1a–O1a–Cu1a skeletons. The first route is shorter and allows the $d_{x^2-y^2}$ spin character on Cu1 to be delocalized through hydrogen bonds and induced on the Cu1b atom, which has d_{z^2} character, hence affording orthogonality between them [24]. Given the total magnetic interaction (J) is divided into an antiferromagnetic term (J_{AF}) and a ferromagnetic term (J_F), J_{AF} can be unequivocally governed by the overlap between the magnetic orbitals. Accordingly, the orthogonality of the relevant orbitals forces J_{AF} to be negligible and as a result the remaining J_F is responsible for the observed overall ferromagnetic behavior in **1** [24–27]. This is in good agreement with the data reported for Cutp systems containing hydrogen bonds [12,15]. The other magnetic pathways giving antiferromagnetic exchange coupling, for instance, Cu1–Ow2–O2a–Ow2a–Cu1a, mediate relatively weak interactions due to the much longer route through the bonds than the major ferromagnetic one. It is thus noted that hydrogen bonds enable the transmission of ferromagnetic interactions in **1**, which are consistent with magnetic results found in organic radicals showing ferromagnetic couplings via hydrogen bonds [28]. As the tp ligand usually exhibits very weak antiferromagnetic interactions, it is appropriate that the calculated zJ' value is assigned to magnetic exchange interactions through the tp linkage, as reported for related metal complexes [10]. The low temperature deviation may arise from antiferromagnetic interactions between Cu(II) ions via hydrogen bonds along the c-axis.

The magnetic susceptibility data for **2** were measured in the temperature range 1.8–300 K, as shown in Fig. 7. The $\chi_m T$ value of 0.41 cm^3 K mol^{-1} at 300 K is slightly larger than the value derived from an isolated Cu(II)

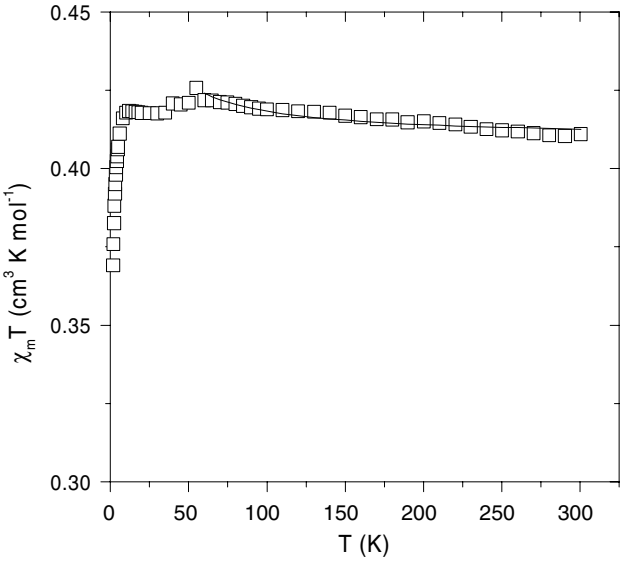

Fig. 7. Plots of χ_m^{-1} and $\chi_m T$ vs. T for **2**. The solid lines indicate the best theoretical fits.

ion. The $\chi_m T$ value increases gradually on cooling, then reaches a value of 0.43 cm^3 K mol^{-1} at 55 K, exhibiting typical ferromagnetic behavior. The inverse magnetic susceptibility data for **2** were fitted to the Curie–Weiss law in the high-temperature region 60–300 K. The parameters determined were equal to $C = 0.41$ cm^3 K mol^{-1} and $\theta = 2.7$ K, supportive of the existence of dominant ferromagnetic interactions as found in **1**.

As shown in Fig. 5, two possible magnetic exchange coupling pathways for **2** are taken into consideration as for **1**: one is via hydrogen bonds and the other through tp. The high-temperature data ($T > 60$ K) were fitted with Eqs. (1) and (2), giving parameters of $g = 2.09$, $J = 1.47$ cm^{-1} and $zJ' = -0.04$ cm^{-1} with $R = 1.6 \times 10^{-6}$. The obtained J value results from exchange coupling between magnetic centers in adjacent chains transmitted by hydrogen bonds since the hydrogen-bonded Cu···Cu separation (5.030 Å) is considerably shorter than the intrachain Cu···Cu distance (10.932 Å) linked by tp. The spin density on the magnetic orbital $(d_{x^2-y^2})$ of Cu1, sitting in the equatorial N_2O_2 plane, is propagated over the $d_{x^2-y^2}$ orbital of Cu1d through the σ-pathway of the Cu1–O1–C4–O2–N2c–(N1c or O1d)–Cu1d backbone. By the way, the more effective route for magnetic interaction is through the Cu1–O2–N2c–(N1c or O1d)–Cu1d backbone owing to the shorter pathway by 0.912 Å. The orbital of Cu1 in the latter route is associated with an admixture of $d_{x^2-y^2}$ and d_{z^2} characters, emanating from the distorted octahedron with the angle (O1–Cu1–O2) of 52.3° deviated from 90°. The main d_{z^2} character along the Cu1–O2 direction is essentially coupled with the $d_{x^2-y^2}$ character in Cu1d, leading to minimal overlap between them [24]. This gives rationale for the ferromagnetic interactions, as manifested in **1** and many oxalato-bridged copper complexes [24–27]. Since the tp ligand is well known to act as a weak magnetic mediator, it is plausible that the zJ' value contributes from the long tp bridge as found in **1** [10]. The drop of $\chi_m T$ at low temperatures is likely attributed to antiferromagnetic interactions between the intersheet Cu(II) centers.

In summary, we have synthesized two tp-bridged Cu(II) compounds showing zigzag and linear structures. It is worth noting that both coordination polymers, with a 3D extended network array (**1**) and a 2D sheet structure (**2**), are formed by incorporating hydrogen bonds into 1D systems. The magnetic data indicate that both complexes exhibit ferromagnetic interactions in the high temperature regime through hydrogen bonds. The magnetic feature can be understood by the fact that the magnetic orbital $(d_{x^2-y^2})$ can propagate through hydrogen bonds and interact with the d_{z^2} orbital by the most effective and shortest pathways. This orthogonality between the orbitals allows antiferromagnetic contribution to be negligible and promotes dominant ferromagnetic couplings. Therefore, it is rationalized that if Cu(II) systems bridged by tp contain hydrogen bonds through which much shorter Cu···Cu separations are established, prevalent magnetic couplings virtually stem not from tp but from hydrogen bonds.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 246238 and 246134 for complexes **1** and **2**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

A series of chiral Schiff base ligands **1**–**4**, derived from (*1R*,*2S*)-(+)-*cis*-1-amino-2-indanol and other chiral amines with substituted salycilaldehydes were synthesized and transformed to the corresponding Cu(II) complexes. Molecular structures of six Cu(II) complexes were determined by X-ray crystallographic studies. The structures show the metal ion in a distorted square planar geometry with dimeric or monomeric structures, depending on the ligand denticity. The potential use of these complexes in asymmetric Cyclopropanation was explored.

1. Introduction

Considerable interest exists in the coordination chemistry of transition metals with Schiff bases due to the wide range of applications and structural aspects of the resulting complexes [1–4]. Particular attention has been devoted to salicylidene Schiff base derivatives because they can promote chelation and provide extra stability to the metal centers. Among other applications, this type of complexes have been used as catalysts in reactions such as oxidation of olefins [5–7], polymerization of olefins [8–10], enantioselective epoxidation of olefins [11–13], enantioselective trimethylsilylcyanation of carbonyl compounds [14,15], enantioselective ring opening of meso aziridines [16], asymmetric hetero-Diels Alder reactions [17], and enantioselective Cyclopropanation of olefins [18–20].

A previous report from this laboratory described the use of chiral Schiff base ligands, derived from *cis*-1-amino-2-indanol and salicylaldeydes with titanium(IV) isopropoxide to carry out cyanohydration of benzaldehyde in moderate to very good e.e.'s (enantiomeric excess) [14].

Copper(II) complexes of *N*-substituted salicylideneaminates have been extensively studied as active catalysts in the asymmetric cyclopropanation of olefins [21]. Having had good e.e.'s in the cyanohydration reaction with titanium, we turned our attention to the synthesis and characterization of new Cu(II) complexes with these ligands as well as other less rigid Schiff bases derived from chiral *N*-substituted amines to investigate their use in the enantioselective cyclopropanation of alkenes.

Several structural studies of Cu(II) complexes with non-chiral tetradentate [22,23], tridentate [24,25], and bidentate [26–28] *N*-substituted salicylideneaminate ligands have been reported. However, reports on structures with chiral ligands of this type are rather scarce [19,29–32].

We describe here the synthesis and characterization of new Cu(II) complexes derived from chiral ligands **1**–**4**. The molecular structures of complexes **1b-Cu**, **2a-Cu**, **2d-Cu**, **3d-Cu**, **4b-Cu** and **4c-Cu** were determined by X-ray diffraction studies. The potential use of these complexes in the asymmetric cyclopropanation of styrene was explored.

2. Results and discussion

2.1. Ligands

Ligands **1**–**4** were prepared in good yields by condensation of the corresponding substituted salicylaldehydes and chiral amines in refluxing methanol according to a literature procedure [14]. Tridentate ligands **1** are derived from (*1R,2S*)-(+)-*cis*-1-amino-2-indanol. Bidentate ligands **2**–**4** are derived from (*S*)-(−)-α-methylbenzylamine, (*R*)-(+)-1-(1-naphthyl)ethylamine and (*R*)-(−)-1-cyclohexylethylamine, respectively. The main spectroscopic features of these ligands are as follows. In the infrared, an absorption band in the range 1623–1633 cm^{-1}, characteristic of the imine C=N stretching [33], and one broad band at 3454–3425 cm^{-1} due to the phenolic proton hydrogen bonded to the imine nitrogen (O–H···N) [33,34]; in the ^{1}H NMR spectra, a one proton singlet at 7.59–8.59 ppm characteristic of the proton on the imine carbon (H–C=N), a one proton multiplet in the range 3.01–5.60 ppm for the proton on the chiral carbon, and a one proton singlet between 13.5–14.5 ppm for the hydrogen bonded phenolic proton [35]; in the $^{13}C\{^{1}H\}$ NMR spectra, a signal in the range 157.1–177.8 ppm for the imine carbon (C=N), a signal between 149.0 and 161.7 ppm for the phenolic carbon, and a signal between 63.5 and 70.7 ppm for the chiral carbon.

a) $R_1 = R_2 = R_3 = H$
b) R_1 = *tert*-Butyl; $R_2 = R_3 = H$
c) $R_1 = R_2$ = *tert*-Butyl; $R_3 = H$
d) $R_1 = H$; R_2, R_3 = Naphthyl

2.2. Synthesis and spectroscopy of complexes

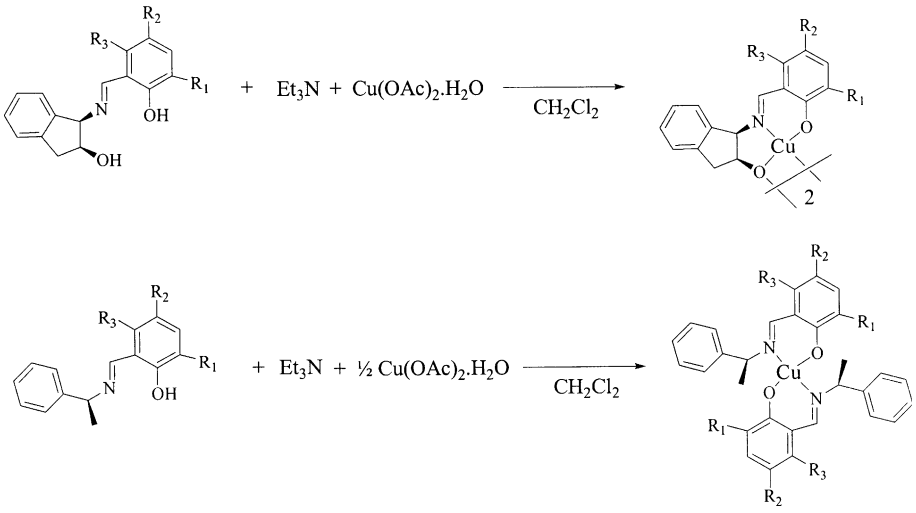
The synthesis of Cu(II) complexes of ligands **1**–**4** is shown in Scheme 1. Combination of a solution of the ligand and triethylamine in dichloromethane with solid copper(II) acetate resulted in the formation of a green to brown solution of the complexes. After work up of the reaction mixture the copper complexes were isolated as green solids in yields ranging from 46% to 99%.

The infrared analysis of the resulting complexes revealed the disappearance of the broad band between 3454 and 3425 cm^{-1} in the free ligand indicating deprotonation of the ligand and replacement by the metal ion [36]. A shift to lower frequencies (1608–1624 cm^{-1}) of the band for the imine group is observed upon metal coordination relative to the free ligand (1623–1633 cm^{-1}), indicating participation of the nitrogen atom in metal complexation [37].

The electronic spectra of the complexes show broad bands in the ranges 218–282 and 324–422 nm attributed to the benzene π–π* transitions [38], and the imine π–π* and *n*–π* transitions [39], respectively. The bands between 592 and 672 nm are assigned to the d–d transitions of the metal, characteristic of tetrahedral distortions of square planar geometries [40]. All the molar absortivities (ε) are about the same order of magnitude (96–295 $1\,cm^{-1}\,mol^{-1}$), which eliminates the possibility of MLCT transitions [41].

2.3. Molecular structures of complexes

The structures of copper(II) complexes with ligands **1b**, **2a**, **2d**, **3d**, **4b** and **4c** were determined by X-ray crystallography. The structure of complex **1b-Cu** is illustrated in Fig. 1. Select bond distances and bond angles are listed in Table 1. Details of the crystal and data collection are outlined in Table 2. The structure of **1b-Cu** consists of two ligands and two copper ions to form a dimeric complex. Each metal is bonded to the ONO coordinating sites of the ligand. Each alkoxy oxygen in the indanol group is bonded to both copper centers forming a bridge for the dimer. The crystal structure of an analogous compound shows the same dimeric structure [19,29]. The molecule has an overall C_2-symmetry with the amino alcohol fragment of both ligands pointing towards the same side of the complex in a *syn* orientation. The copper centers are in a distorted square planar environment defined by the alkoxy oxygen, phenoxy oxygen and the imine nitrogen with the forth coordination position occupied by the bridging alkoxy oxygen from the second ligand. The dihedral angle be-



Scheme 1.

tween the planes defined by O(2)–Cu(1)–N(1) and O(1)–Cu(1)–O(2′), and by O(2′)–Cu(1′)–N(1′) and O(1′)–Cu(1′)–O(2) are 6.1° and 3.3°, respectively. A deviation from co-planarity of the two units in the dimer is shown by a twist of 43.0° between the planes defined by O(1)–Cu(1)–N(1) and O(1′)–Cu(1′)–N(1′). This distortion may be attributed to the rigidity of the ligand. The O(1)–Cu–O(2), O(1)–Cu–N(1) and N(1)–Cu–O(2) bond angles of 179.4(3)°, 94.3(3)° and 85.4(3)°, respectively, and Cu–O(1), Cu–O(2) and Cu–N(1) bond distances of 1.876(5), 1.948(5) and 1.896(6) Å, respectively, are in agreement with the values in related complexes with a chiral tridentate dianionic Schiff base ligands [29,30].

The structures of complexes **2a-Cu**, **2d-Cu**, **3d-Cu**, **4b-Cu** and **4c-Cu** are illustrated in Figs. 2–6. Select bond distances and angles are listed in Table 3. Details of the crystal data and collection are outlined in Table 4. The structures of these complexes show that the copper ion is bonded to the oxygen and nitrogen donor atoms of the bidentate ligand molecules in the usual *trans* arrangement (O–Cu–N) to form monomeric species with an overall C_2-symmetry. The chiral substituents on the amine fragment are pointing towards the same face of the complex in a *syn* orientation, in contrast with the common *anti* orientation in complexes with non-chiral Schiff base ligands [23,28,42]. As in **1b-Cu**, the copper centers in complexes **2a-Cu**, **2d-Cu**, **3d-Cu**, **4b-Cu** and

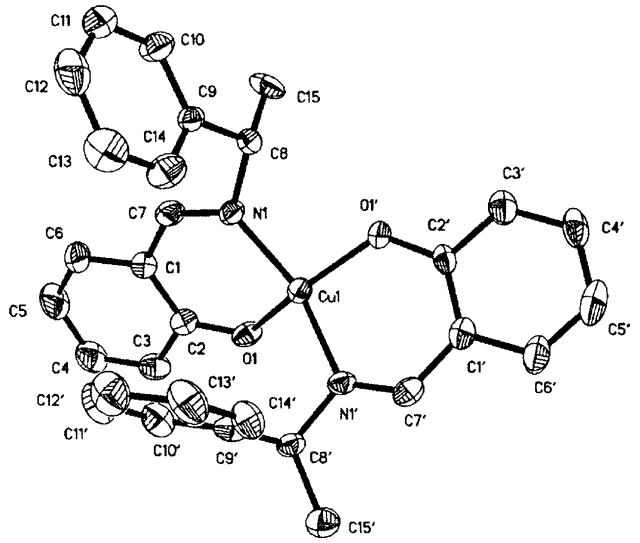

Fig. 2. Structure of **2a-Cu**. Bond distances and angles are given in Table 3.

4c-Cu are in a distorted square planar environment where the dihedral angle between the two coordination planes defined by O(1)–Cu(1)–N(1) and O(1′)–Cu(1)–N(1′) is 38.8°, 28.6°, 38.4° (31.1°), 28.6° and 29.8°, respectively. Bond angles also show that the coordination geometry about the copper atom is distorted square planar, with N–Cu–O angles ranging between 90.6(5)° and 94.8(4)°; O–Cu–O and N–Cu–N angles are in the range 151.0(4)°–159.0(3)° and 150.8(4)°–160.8(6)°, respectively. Cu–O and Cu–N bond lengths are 1.869(9)–1.916(8) and 1.946(8)–1.981(10) Å, respectively, and are in general agreement with similar non-chiral Schiff base complexes [43]. A more pronounced twist from planar toward tetrahedral coordination is observed compared to complex **1b-Cu.** The increased distortion may be attributed to the bulkiness and flexibility of the imine substituent groups.

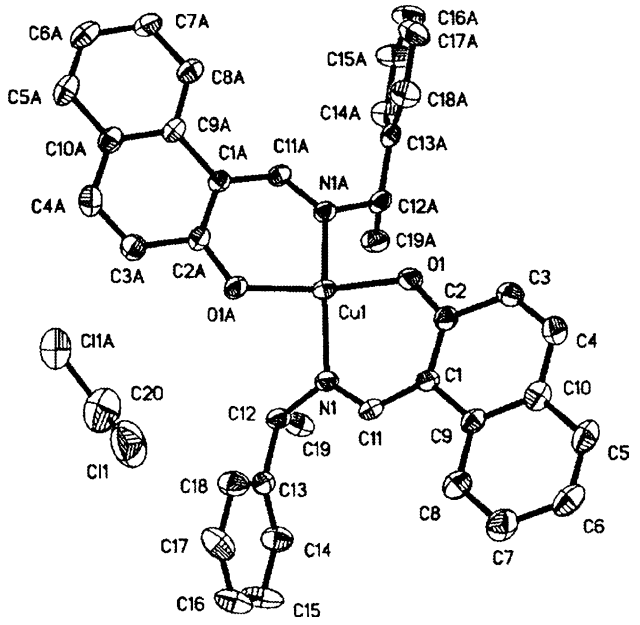

Fig. 3. Structure of **2d-Cu · CH_2Cl_2**. Bond distances and angles are given in Table 3.

The unit cell of **2d-Cu** shows a molecule of CH_2Cl_2, which accounts for the empirical formula found to be $C_{39}H_{32}Cl_2CuN_2O_2$ in the X-ray study. In the unit cell of complex **3d-Cu**, there are two crystallographically independent but very similar molecules differing mainly in the magnitude of the dihedral angle between the two

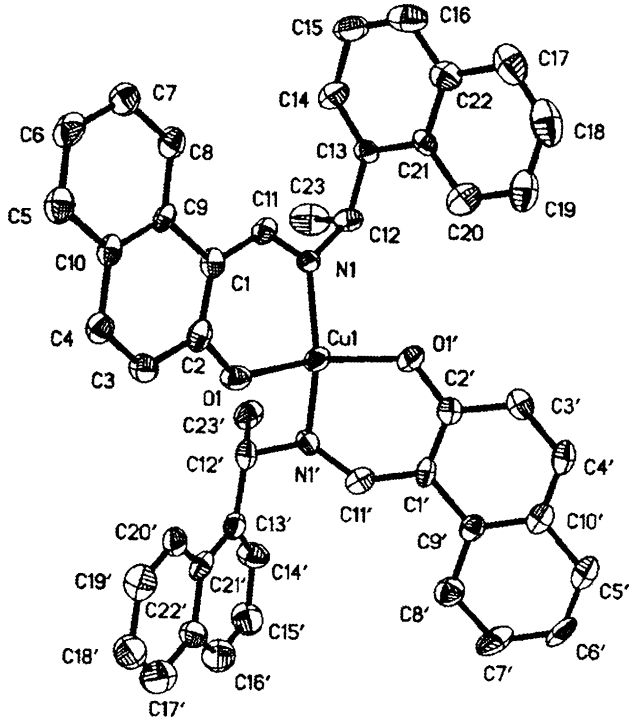

Fig. 4. Structure of **3d-Cu**. Bond distances and angles are given in Table 3.

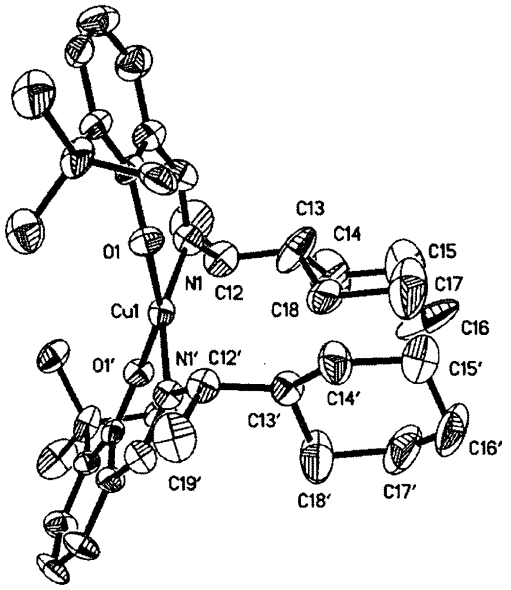

Fig. 5. Structure of **4b-Cu**. Bond distances and angles are given in Table 3.

coordination planes defined by O(1)–Cu(1)–N(1) and O(1′)–Cu(1)–N(1′) of 38.4° in one molecule, and O(1a)–Cu(1a)–N(1a) and O(1b)–Cu(1a)–N(1b) of 31.1° in the other.

One additional feature of these complexes is that a distortion from co-planarity of the aromatic rings on the salicylaldehyde fragment is observed, with twist angles of 57.5° in the dimeric complex **1b-Cu** and in the range 35.7–52.0° in the monomeric complexes **2a-Cu**, **2d-Cu**, **3d-Cu**, **4b-Cu** and **4c-Cu**.

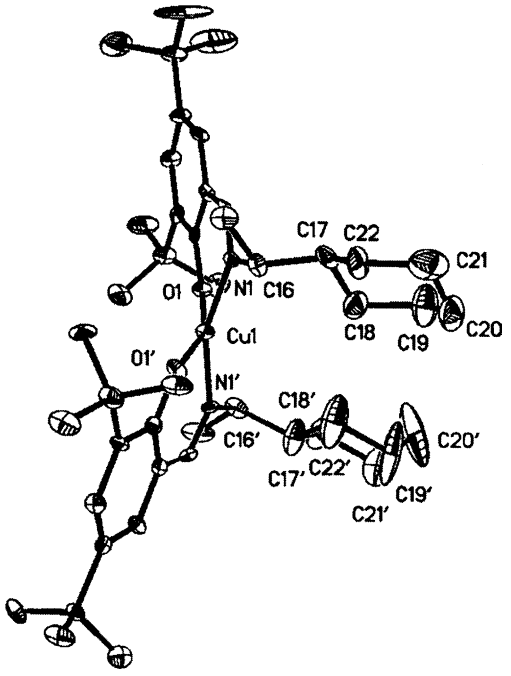

Fig. 6. Structure of **4c-Cu**. Bond distances and angles are given in Table 3.

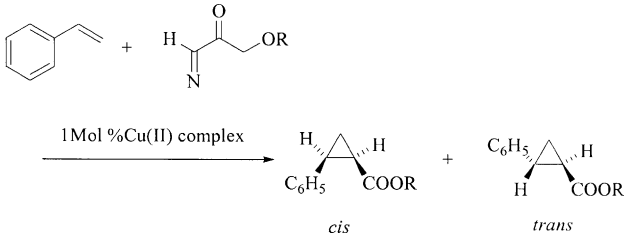
2.4. Cyclopropanation of styrene

The potential use of these copper(II) complexes as catalyst in the cyclopropanation of styrene using diazoacetates was attempted according to reaction in the following equation. Overall yields, *cis*/*trans* ratios and enantiomeric excess are presented in Table 5. *t*-Butyl diazoacetate was also tested with selected complexes with no substantial improvement on e.e.'s



The above cyclopropanation results (high yield and low enantioselectivity) suggest that in the cases examined with Cu(II) complexes with Schiff base ligands, the metal is more open (square planar) and lack steric crowding around the metal to induce any enantioselectivity. As seen in the case of Aratani's Schiff base ligands [19], these complexes probably need conformationally flexible, yet bulky substituents on the amino alcohol portion of the ligand in order to increase the face selection in the cyclopropanation reaction.

2.5. Conclusion

In summary, we have synthesized 16 new Cu(II) complexes with chiral Schiff base ligands, six of which were characterized by X-ray crystallography. The structural studies revealed that tridentate ligands derived from (*1R*,*2S*)-(+)-*cis*-1-amino-2-indanol form dimeric structures of the type M_2L_2 with the alkoxy groups bridging the two metal centers, while those derived from chiral amines yield monomeric complexes of type ML_2. Unexpectedly their catalytic activity in the enantioselective cyclopropanation of styrene was found to be rather poor. Fine tuning of the ligands to improve the catalytic properties of their complexes is currently underway.

3. Experimental

3.1. General

All reactions, except when indicated, were carried out under argon atmosphere using standard Schlenk techniques. Methanol and dichloroethane were dried by

Optical rotation measurements were determined in CH_2Cl_2 in a 10 cm path length cell using Rudolph Research Flanders automatic polarimeter. Elemental analyses were performed at Inorganic Chemistry Department, Universidad de Alcalá de Henares (ligands) and at NuMega Resonance Labs, Inc. (complexes). All samples for elemental analysis and HRMS were dried under vacuum at room temperature for at least 24 h.

3.2. General procedure for the preparation of Schiff base ligands *1*–*4*

The synthesis of ligands **1** derived from (*1R*,*2S*)-*cis*-1-amino-2-indanol, was reported elsewhere [14]. The condensation of salicylaldehydes with aliphatic or aromatic amines (ligands **2**–**4**) was carried out in the following manner using ligand **2a** as an example: (S)-(−)-α-methylbenzylamine (0.500 g, 4.12 mmol) and 2-hydroxybenzaldehyde (0.503 g, 4.12 mmol) were dissolved in dry methanol (25 ml), and anhydrous sodium sulfate (2 g) was added to the solution as a drying agent. The reaction mixture was refluxed at 65 °C and stirred for 6–24 h. The reaction was followed by TLC. The solution was filtered and the solvent was removed under reduced pressure to afford **2a (S)-(+)-(α-methylbenzyl)-salicylaldimine** as a yellow solid (0.853 g, 91.8%): m.p. 72–74 °C, $[\alpha]_D$ = +159.67 (c 0.04, CH_2Cl_2); IR (cm^{-1}, KBr): 3454, 3023, 2879, 1623, 1577, 1371, 1277, 1080, 761; ^1H NMR (200 MHz, $CDCl_3$): δ 13.50 (s, 1H), 8.33 (s, 1H), 7.30–7.10 (m, 7H), 6.90 (dd, J_1 = 7.6, J_2 = 1.2 Hz, 1H), 6.80 (dt, J = 7.6, 1.2 Hz, 1H), 4.48 (q, J = 6.6 Hz, 1H), 1.56 (d, J = 6.8 Hz, 3H); $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ 163.6, 161.3, 144.0, 132.2, 131.6, 128.9, 128.8, 127.5, 127.4, 126.7, 126.5, 118.9, 117.1, 68.7, 25.2; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 218 nm, ε = 44 l cm^{-1} mol^{-1}; λ 328 nm, ε = 599 l cm^{-1} mol^{-1}; λ 338 nm, ε = 591 l cm^{-1} mol^{-1}. 3.3. General procedure for the synthesis of Schiff base–copper(II) complexes

The synthesis of Schiff base–copper(II) complexes is described using ligand **1a** (molar ratio 1:1) as an example. For the complexes with ligands **2**–**4** the same procedure was followed, except that the molar ratio was changed to 2:1. To a solution of Schiff base **1a** (0.150 g, 0.0592 mmol) in dichloromethane (5 ml), was added Et_3N (0.119 g, 1.18 mmol) at room temperature and stirred for 30 min. To the deprotonated ligand solution, solid hydrate copper(II) acetate (0.118 g, 0.0592 mmol) was added and stirred for 1 h. The solution was washed (3×50 ml) with water, and the organic layer dried over anhydrous Na_2SO_4, filtered and the solvent removed under reduced pressure to yield **1a-Cu** {di-μ-oxo-(1*R*,2*S*)-*N*-[2-indanol]-*N*-salicylaldiminato}copper(II) as a green solid (0.183 g, 98.2%): m.p. 138–142 °C; IR (cm^{-1}, KBr): 2023, 2909, 1623, 1528, 1442, 1319, 747; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 224 nm, ε = 295 l cm^{-1} mol^{-1}; λ 338 nm, ε = 656 l cm^{-1} mol^{-1}; λ 614 nm, ε = 144 l cm^{-1} mol^{-1}. *Anal*. 3.3.1. {Di-μ-oxo-(1R,2S)-N-[2-indanol]-N-3-terbutylsalicylaldiminato}copper(II) (**1b-Cu**)

Green crystals (0.160 g, 89.0%): m.p. 259–262 °C (dec.); (cm^{-1}, KBr): 3014, 2937, 2889, 1623, 1600, 1542, 1414, 1190, 1147, 861, 747; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 246 nm, ε = 229 l cm^{-1} mol^{-1}; λ 328 nm, ε = 685 l cm^{-1} mol^{-1}; λ 602 nm, ε = 209 l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{40}H_{43}Cu_2N_2O_4$ [M + H] 741.1815. Found: 741.1845.

3.3.2. {Di-μ-oxo-(1R,2S)-N-[2-indanol]-N-3′,5′-di-tbutylsalicylaldiminato}copper(II) (**1c-Cu**)

Green solid (0.061 g, 76.8%): m.p. 216–218 ° C (dec); (cm^{-1}, KBr): 3062, 2947, 2899, 1619, 1523, 1428, 1319,1161, 1095, 742, 533; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 226 nm, ε = 264 l cm^{-1} mol^{-1}; λ 324 nm, ε = 683 l cm^{-1} mol^{-1}; λ 604 nm, ε = 200 l cm^{-1} mol^{-1} . *Anal*. Calc. for $C_{48}H_{58}N_2O_4Cu_2$: C, 67.50; H, 6.84; N, 3.27. Found: C, 67.40; H, 6.99; N, 3.12%.

3.3.3. {Di-μ-oxo-(1R,2S)-N-[2-indanol]-N-2-oxo-1-naphthaldiminato}copper(II) (**1d-Cu**)

Green solid (0.077 g, 93%): m.p. 218–220 °C (dec); (cm^{-1}, KBr): 3043, 2889, 1619, 1533, 1428, 1395, 1357, 1185, 823, 738; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 220 nm, ε = 317 l cm^{-1} mol^{-1}; λ 402 nm, ε = 763 l cm^{-1} mol^{-1}; λ 592 nm, ε = 185 l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{40}H_{30}Cu_2N_2O_2Na$ [M + Na] 751.0695. Found: 751.0670.

3.3.4. Bis[(*S*)-(α-methylbenzyl)-salicylaldiminato]copper(II) (**2a-Cu**)

Green amber crystals (0.123 g, 72.0%): m.p. 137–139 °C; IR (cm^{-1}, KBr): 3023, 2966, 1614, 1533, 1365, 757; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 264 nm, ε = 332 l cm^{-1} mol^{-1}; λ 408 nm, ε = 824 l cm^{-1} mol^{-1}; λ 618 nm, ε = 102 l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{30}H_{28}CuN_2O_2Na$ [M + Na] 534.1345. Found: 534.1368.

3.3.5. Bis[(*S*)-(α-methylbenzyl)-3-t-butylsalicylaldiminato]copper(II) (**2b-Cu**)

Brown solid (0.0657 g, 46.3%): m.p. 168–172 °C; IR (cm^{-1}, KBr): 3027, 2953, 2868, 1622, 1593, 1544, 1422,

1313, 1142, 751, 701; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 262 nm, $\varepsilon = 341$ l cm^{-1} mol^{-1}; λ 362 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 640 nm, $\varepsilon = 201$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{38}H_{44}N_2O_2Cu$: C, 73.10; H, 7.10; N, 4.48. Found: C, 72.96; H, 6.72; N, 4.52%.

3.3.6. *Bis[(S)-(α-methylbenzyl)-3,5-di-t-butylsalicylaldiminato]copper(II)* (**2c-Cu**)

Dark green solid (0.102 g, 93.5%): m.p. 184–186 °C; IR (cm^{-1}, KBr): 3031, 2957, 2866, 1624, 1533, 1456, 1256, 1167, 698; UV–Vis (CH_2Cl_2, 5×10^{-3}M): λ 228 nm, $\varepsilon = 344$ l cm^{-1} mol^{-1}; λ 314 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 646 nm, $\varepsilon = 200$ l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{46}H_{61}CuN_2O_2$ [M + H] 736.4129. Found: 736.4096.

3.3.7. *Bis[(S)-(α-methylbenzyl)-2-oxo-1-naphthaldiminato]copper(II)* (**2d-Cu**)

Dark green solid (0.166 g, 90.7%): m.p. 191–194 °C; IR (cm^{-1}, KBr): 3043, 2947, 1614, 1538, 1365, 823, 733; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 266 nm, $\varepsilon = 337$ l cm^{-1} mol^{-1}; λ 462 nm, $\varepsilon = 825$ l cm^{-1} mol^{-1}; λ 634 nm, $\varepsilon = 157$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{38}H_{32}N_2O_2Cu$: C,74.55; H, 5.26; N, 4.57. Found: C, 74.54; H, 5.12; N, 4.62%.

3.3.8. *Bis[(R)-[1-(1-naphthyl)ethyl]salicylaldiminato]copper(II)* (**3a-Cu**)

Green solid (0.267 g, 56.2%): m.p. 175–177 °C; IR (cm^{-1}, KBr): 2961, 1615, 1539, 1446, 1323, 1145, 757; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 282 nm, $\varepsilon = 349$ l cm^{-1} mol^{-1}; λ 410 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 598 nm, $\varepsilon = 141$ l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{38}H_{32}CuN_2O_2Na$ [M + Na] 634.1658. Found 634.1639.

3.3.9. *Bis[(R)-[1-(1-naphthyl)ethyl]-3-t-butylsalicylaldiminato]copper(II)* (**3b-Cu**)

Green solid (0.0602 g, 68.8%): m.p. 227–230 °C; IR (cm^{-1}, KBr): 3046, 2951, 2870, 1618, 1544, 1422, 1336, 1142, 779, 749; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 218 nm, $\varepsilon = 348$ l cm^{-1} mol^{-1}; λ 330 nm, $\varepsilon = 823$ l cm^{-1} mol^{-1}; λ 672 nm, $\varepsilon = 267$ l cm^{-1} mol^{-1}. HRMS (ES$^+$): *m/z* Calc. for $C_{46}H_{49}CuN_2O_2$ [M + H] 724.3190. Found: 724.3265.

3.3.10. *Bis[(R)-[1-(1-naphthyl)ethyl]-3,5-di-t-butylsalicylaldiminato]copper(II)* (**3c-Cu**)

Green crystals (0.0494 g, 57.1%): m.p. 218–22 °C; IR (cm^{-1}, KBr): 3048, 2954, 2861, 1618, 1530, 1431, 1316, 1253, 1167, 777; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 284 nm, $\varepsilon = 356$ l cm^{-1} mol^{-1}; λ 408 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 626 nm, $\varepsilon = 291$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{54}H_{64}N_2O_2Cu$: C, 77.52; H, 7.71; N, 3.34. Found: C, 77.37; H, 7.98; N, 3.36%.

3.3.11. *Bis[(R)-[1-(1-naphthyl)ethyl]-2-oxo-l-naphthaldiminato]copper(II)* (**3d-Cu**)

Green crystals (0.052 g, 82%): m.p. 239–242 °C; IR (cm^{-1}, KBr): 3046, 2961, 2926, 1610, 1539, 1435, 1362, 778, 742; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 280 nm, $\varepsilon = 303$ l cm^{-1} mol^{-1}; λ 386 nm, $\varepsilon = 823$ l cm^{-1} mol^{-1}; λ 626 nm, $\varepsilon = 80$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{46}H_{36}N_2O_2Cu$: C, 77.56; H, 5.09; N, 3.93. Found: C, 77.49; H, 4.95; N, 4.03%.

3.3.12. *Bis[(R)-(1-cyclohexylethyl)-salicylaldiminato]copper(II)* (**4a-Cu**)

Bis[(*R*)-(1-cyclohexylethyl)-salicylaldiminato]copper (II) (**4a-Cu**), could not be further purified for characterization.

3.3.13. *Bis[(R)-(1-cyclohexylethyl)-3-t-butyl-salicylaldiminato]copper(II)* (**4b-Cu**)

Dark green solid (0.056 g, 50%): m.p. 165–168 °C; IR (cm^{-1}, KBr)): 3051, 2928, 2851, 1623, 1345, 1425, 1144, 861, 749; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 286 nm, $\varepsilon = 367$ l cm^{-1} mol^{-1}; λ 420 nm, $\varepsilon = 825$ l cm^{-1} mol^{-1}; λ 606 nm, $\varepsilon = 142$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{38}H_{56}N_2O_2Cu$: C, 71.71; H, 8.86; N, 4.40. Found: C, 71.41; H, 8.48; N, 4.42%.

3.3.14. *Bis[(R)-(1-cyclohexylethyl)-3,5-di-t-butyl-salicylaldiminato]copper(II)* (**4c-Cu**)

Dark green solid (0.138 g, 96.6%): m.p. 199–203 °C; IR (cm^{-1}, KBr): 2928, 2853, 1621, 1532, 1439, 1255, 1169, 835, 786; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 220 nm, $\varepsilon = 353$ l cm^{-1} mol^{-1}; λ 328 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 656 nm, $\varepsilon = 177$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{46}H_{72}N_2O_2Cu$: C, 73.80; H, 9.69; N, 3.74. Found: C, 73.59; H, 9.28; N, 3.83%.

3.3.15. *Bis[(R)-(1-cyclohexylethyl)-2-oxo-1-naphthaldiminato]copper(II)* (**4d-Cu**)

Dark green solid (0.099 g, 89%): m.p. 158–160 °C; IR (cm^{-1}, KBr): 3050, 2964, 2924, 2848, 1608, 1539, 1361, 827, 745 745; UV–Vis (CH_2Cl_2, 5×10^{-3} M): λ 286 nm, $\varepsilon = 371$ l cm^{-1} mol^{-1}; λ 348 nm, $\varepsilon = 824$ l cm^{-1} mol^{-1}; λ 632 nm, $\varepsilon = 141$ l cm^{-1} mol^{-1}. *Anal.* Calc. for $C_{38}H_{44}N_2O_2Cu$: C, 73.10; H, 7.10; N, 4.48. Found: C, 73.17; H, 7.08; N, 4.49%.

3.4. *Cyclopropanation of styrene*

Under argon, to a solution of **1a-Cu** (6.3 mg, 0.010 mmol) and styrene (1 ml) in dichloroethane (2 ml), a solution of ethyl diazoacetate (0.114 g, 1.00 mmol) in dichloroethane (2 ml) was added by means of a syringe pump at 60 °C, over a period of 6 h with vigorous stirring. After the addition ceased, the reaction mixture was stirred for another 16 h at room temperature. The crude mixture was directly passed through a short silica gel column eluting with 10 ml of dichloromethane to remove the excess styrene and the catalyst. The % e.e.'s were determined by GC (chiral column β-DEX^{TM} 120, 30×0.25 mm $\times$ 0.25 μm, Column temperature 130°C,

isothermically). The eluant was concentrated under reduced pressure to obtain the *cis* and *trans* cyclopropanes as a mixture of isomers by column flash chromatography on silica gel. The yields were determined based on the weight of the ethyl diazoacetate.

3.5. X-ray crystallographic procedures

Good quality crystals for X-ray structure determination were obtained at room temperature by vapor phase diffusion of CH_2Cl_2/pentane (complexes **1b-Cu**, **2a-Cu**, **2d-Cu** and **3d-Cu)** or by slow evaporation of acetone (**4b-Cu** and **4c-Cu**). Crystals were isolated from the mother liquor and were immersed in epoxy. A crystal was selected for the X-ray diffraction study and mounted on a quartz fiber, and data were collected using a Siemens P4 diffractometer. Corrections for the effects of absorption anisotropy were made. Structure solutions were performed by direct methods and structure refinement was done with the programs SHELXS [44].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, for **1b-Cu**: CCDC No. 219093; for **2a-Cu**: CCDC No. 219096; for **2d-Cu**: CCDC No. 219092; for **3d-Cu**: CCDC No. 219091; for **4b-Cu**: CCDC No. 219094; for **4c-Cu**: CCDC No. 219095. Abstract

When the polymeric complex $[Ag(im)]_n$ (Him = imidazole) is reacted with PPh_3 (PPh_3 = triphenylphosphine), it yields the $[Ag_2(\mu_2\text{-im})_2(PPh_3)_3]_n$ and $[Ag(\mu_2\text{-im})(PPh_3)_2]_n$ species, shown to contain wavy chains of metal ions, singly bridged by *N*,*N*′-*exo*-bidentate imidazolate ligands. The former, crystallised as the CH_2Cl_2 solvate, contains two non-equivalent silver(I) ions, differing in the number of coordinated phosphines (one, in trigonal planar stereochemistry, or two, having tetrahedral geometry). The latter has a unique independent silver(I) ion in a tetrahedral environment, with two coordinated PPh_3 ligands. The reactivity of known silver(I) azolates with PPh_3, as well as the solution behaviour and (when available) the crystal structures of the corresponding derivatives are taken into consideration for a due comparison.

Keywords: Coordination polymers; Silver; Imidazolate; X-ray structure

1. Introduction

In the recent past, a non negligible number of homoleptic transition metal azolates have been synthesised and shown to possess valuable properties, such as high thermal stability [1], magnetic hysteresis [2] and luminescence [3], as well as anticorrosive [4], sorption [5] and protein staining [6] activities. To highlight both the origin of such properties and their possible optimisation by means of a complete structural insight, we have been actively working to prepare and fully characterise by X-ray powder diffraction (XRPD) manifold 3d-transition metal coordination complexes bearing simple diazaheterocycles: Fe(III), Co(III), Co(II), Ni(II) [7], Cu(I), Ag(I) [8], Zn(II), Cd(II) and Hg(II) [9] pyrazolates, Cu(I), Ag(I) [10] and Cu(II) [11] imidazolates, Co(II), Ni(II), Zn(II) [12], Cu(I) [13] and Ag(I) [14] pyrimidin-2-olates and Co(II), Ni(II) and Zn(II) pyrimidin-4-olates [15].

In the pharmaceutical field, an important role is played by certain silver(I) and gold(I) azolates. Actually, it has been recently discovered that the simple $[Ag(\mu_2\text{-im})]_n$ polymer (Him = imidazole) shows a wide spectrum of antimicrobial activities against bacteria, yeast and even mould [16]. A comparable spectral range against bacteria and yeast, yet not against mould, has been demonstrated by Ag(1,2,4-triz) [17] and Ag(tetz) [18], while a more modest one, involving a few bacteria, has been observed with Ag(1,2,3-triz) [17] (Htriz = triazole, Htetz = tetrazole). The easy rupture of the Ag(I)–N bond upon dissolution has been invoked as one of the key factors of these performances. To better characterise this and other key factors in the quoted (and related) pharmaceutically active silver(I) complexes and to tune

doi:10.1016/j.poly.2004.09.023

their molecular design, the syntheses, solution behaviour investigation and structural determination of their PPh_3 derivatives (PPh_3 = triphenylphosphine) have been carried out. With this aim, the $Ag(im)(PPh_3)_3$ [19], $[Ag(\mu_2\text{-}1,2,3\text{-triz})(PPh_3)_3]_n$, $[Ag(\mu_2\text{-}1,2,4\text{-triz})(PPh_3)_2]_n$ [17] and $[Ag(\mu_2\text{-tetz})(PPh_3)_2]_n$ [18] species have been prepared and their solution behaviour has been characterised (especially) by variable temperature ^{31}P NMR; as in the case of the previously studied $[Ag_2(\mu_2\text{-pz})_2(PPh_3)_3]$ (Hpz = pyrazole) [20], the concomitant presence of mononuclear species of different $Ag(az)(PPh_3)_n$ formulation (Haz = azole), due to fast PPh_3 dissociation equilibria, has been proved. The pharmaceutical activities of $Ag(im)(PPh_3)_3$ [19], $[Ag(\mu_2\text{-}1,2,3\text{-triz})(PPh_3)]_n$, $[Ag(\mu_2\text{-}1,2,4\text{-triz})(PPh_3)]_n$ [17] and $[Ag(\mu_2\text{-tetz})(PPh_3)_2]_n$ [18] have been properly tested, while a full X-ray structural characterisation has been obtained for the tri- and tetra-azolates only.

Within this context, we report hereafter on the synthesis and the single crystal X-ray structural characterisation of two new derivatives of $[Ag(\mu_2\text{-im})]_n$ with triphenylphosphine, the polymeric $[Ag_2(\mu_2\text{-im})_2(PPh_3)_3]_n$ and $[Ag(\mu_2\text{-im})(PPh_3)_2]_n$ species. A detailed comparison is drawn to the reactivity of Ag(pz), Ag(1,2,3-triz), Ag(1,2,4-triz) and Ag(tetz) with PPh_3, as well as to the solution behaviour and the crystal structure of the corresponding derivatives.

2. Experimental

2.1. General procedures

All reactions were carried out under an atmosphere of dry nitrogen in order to avoid moisture. All chemicals (Aldrich Chemical Co.) were used as supplied. Solvents were purified and dried by standard methods. Elemental analyses were carried out at the Microanalytical Laboratory of this University.

2.2. Synthesis of $[Ag_2(im)_2(PPh_3)_3]_n$ (**1**)

To a suspension of $[Ag(im)]_n$ [10] (0.50 g, 2.9 mmol) in 20 mL of CH_2Cl_2, PPh_3 (1.3 g, 5.0 mmol) was added under stirring. In a few minutes $[Ag(im)]_n$ dissolved, giving a clear solution. The solution was stirred for an additional hour and then evaporated to dryness. The residue was treated with 10 mL of diethyl ether giving a white solid, which was filtered, washed with diethyl ether and dried under vacuum (90% yield). *Anal.* Calc. for $C_{60}H_{51}N_4P_3Ag_2$: C, 63.40; H, 4.49; N, 4.93. Found: C, 63.54; H, 4.50; N, 4.89%. Crystals suitable for X-ray analysis were obtained by slow diffusion of diethyl ether into a dichloromethane solution of **1** containing PPh_3 ($Ag{:}PPh_3$ ratio = 1:1).

2.3. Synthesis of $[Ag(im)(PPh_3)_2]_n$ (**2**)

Complex **2** was obtained in the form of well shaped crystals suitable for X-ray analysis by slow diffusion of a saturated diethyl ether solution of PPh_3 into a dichloromethane solution of **1** (71% yield). *Anal.* Calc. for $C_{39}H_{33}N_2P_2Ag$: C, 66.96; H, 4.72; N, 4.00. Found: C, 70.10; H, 4.68; N, 3.97%. Complexes **1** and **2** are not significantly light sensitive and no particular precautions were taken in order to avoid light exposure. However, direct exposure to intense sunlight for prolonged times (>3 h) causes a superficial darkening of the crystals.

2.4. X-ray crystallography

Suitable colourless flat ($0.25 \times 0.20 \times 0.05$ mm, $\mathbf{1 \cdot CH_2Cl_2}$) and prismatic ($0.13 \times 0.09 \times 0.07$ mm, **2**) crystals were mounted in air on a goniometer head. Data were collected on a Nonius CAD4 diffractometer, equipped with graphite-monochromatised Mo Kα radiation ($\lambda = 0.71073$ Å), by the ω-scan method, acquiring in both cases all unique reflections in the $5° < 2\theta < 50°$ range. Empirical corrections for absorption and Lorentz polarisation effects were applied to the integrated reflections (ψ-scans method [21]). The structures were solved by direct methods [22] and refined with full-matrix least-square calculations on F^2 [23]. Anisotropic temperature factors were assigned to all atoms except hydrogen atoms which were refined riding on their parent atoms with a common isotropic displacement parameter chosen as 1.2 times that of the pertinent parent.

2.4.1. $[Ag_2(im)_2(PPh_3)_3]_n \cdot (CH_2Cl_2)$, ($\mathbf{1 \cdot CH_2Cl_2}$)

$Ag_2(C_3H_3N_2)_2(PPh_3)_3 \cdot (CH_2Cl_2)$, $C_{61}H_{53}Cl_2N_4P_3Ag_2$, $M = 1221.68$ g mol^{-1}; monoclinic, $P2_1/c$, $a = 10.678(1)$, $b = 39.858(12)$, $c = 13.310(2)$ Å, $\beta = 91.31(1)°$, $V = 5663(2)$ Å^3, $Z = 4$; $T = 298(2)$ K, $D_c = 1.43$ g cm^{-3}, μ(Mo Kα) = 0.91 mm^{-1}, $F(000) = 2480$; 644 parameters, no restraints, 9926 unique reflections measured, of which 3633 observed [$I > 2\sigma(I)$]; $R_{obs} = 0.0433$, $wR_{2\ all} = 0.0787$, highest peak and deepest hole = 0.40 and −0.48 e Å^{-3}, GOF = 0.791.

2.4.2. $[Ag(im)(PPh_3)_2]_n$, (**2**)

$Ag(C_3H_3N_2)(PPh_3)_2$, $C_{39}H_{33}N_2P_2Ag$, $M = 699.52$ g mol^{-1}; monoclinic, $P2/_1n$, $a = 14.561(5)$, $b = 9.674(5)$, $c = 24.463(5)$ Å, $\beta = 91.56(2)°$, $V = 3445(1)$ Å^3, $Z = 4$; $T = 298(2)$ K, $D_c = 1.349$ g cm^{-3}, μ(Mo Kα) = 0.71 mm^{-1}, $F(000) = 1432$; 397 parameters, no restraints, 6037 unique reflections measured, of which 4222 observed [$I > 2\sigma(I)$]; $R_{obs} = 0.0263$, $wR_{2\ all} = 0.0685$, highest peak and deepest hole = 0.32 and −0.51 e Å^{-3}, GOF = 0.971.

Relevant bond distances and angles, with estimated standard deviations, are reported throughout the text and are collected in the captions to Figs. 1 and 2.

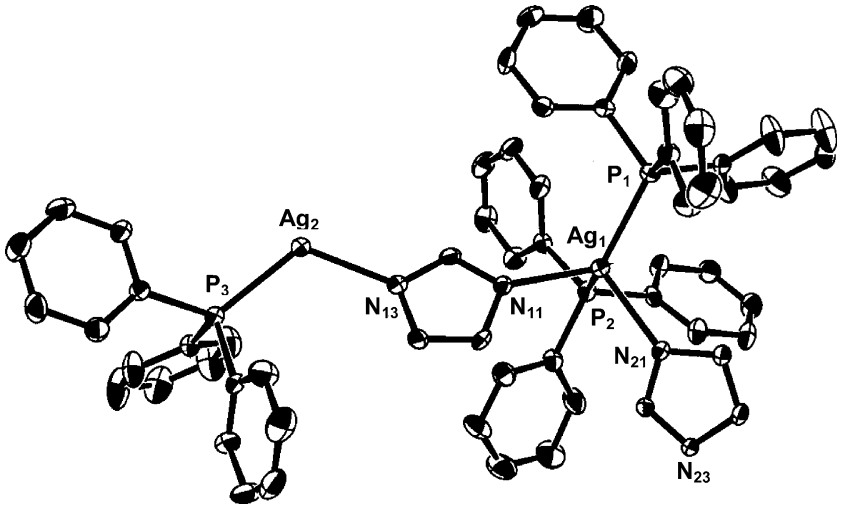

Fig. 1. ORTEP drawing, at 20% probability level, of the asymmetric unit in $[Ag_2(im)_3(PPh_3)_3]\cdot CH_2Cl_2$ (**1 · CH_2Cl_2**). Hydrogen and solvent atoms are omitted for clarity. Significant distances (Å) and angles (°) (e.s.d.'s in parentheses): Ag_1–N_{11} = 2.290(4), Ag_1–N_{21} = 2.301(4), Ag_2–N_{13} = 2.249(5), Ag_2–N_{23} = 2.196(4), Ag_1–P_1 = 2.450(2), Ag_1–P_2 = 2.595(2), Ag_2–P_3 = 2.395(2); N_{11}–Ag_1–N_{21} = 109.25(16), P_1–Ag_1–P_2 = 118.40(5), N_{11}–Ag_1–P_1 = 117.36(12), N_{11}–Ag_1–P_2 = 102.14(12), N_{21}–Ag_1–P_1 = 113.47(13), N_{21}–Ag_1–P_2 = 93.21(12), N_{13}–Ag_2–N_{23} = 109.47(17), N_{13}–Ag_2–P_3 = 118.43(13), N_{23}–Ag_2–P_3 = 131.09(13); $Ag_1\cdots Ag_2$ = 6.433(1) and 6.575(1).

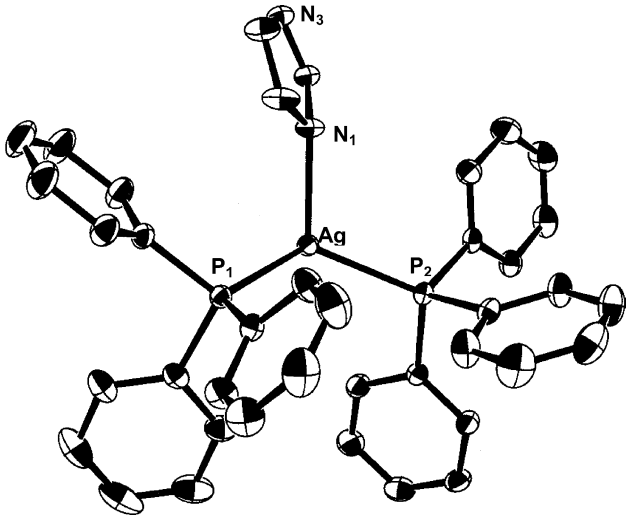

Fig. 2. ORTEP drawing, at 20% probability level, of the asymmetric unit in $[Ag(im)_2(PPh_3)_2]$ (**2**). Hydrogen atoms are omitted for clarity. Significant distances (Å) and angles (°) (e.s.d.'s in parentheses): Ag–N_1 = 2.296(2), Ag–N_3 = 2.294(2), Ag–P_1 = 2.471(1), Ag–P_2 = 2.456(1); N_1–Ag–N_3 = 97.92(8), P_1–Ag–P_2 = 124.22(3), N_1–Ag–P_1 = 105.22(6), N_1–Ag–P_2 = 114.01(6), N_3–Ag–P_1 = 105.78(6), N_3–Ag–P_2 = 106.25(6); Ag···Ag = 6.555(1).

3. Results

3.1. Synthesis and characterization

On reacting the $[Ag(\mu_2\text{-im})]_n$ polymer [10] with PPh_3 in CH_2Cl_2 at room temperature (with an Ag:PPh_3 ratio of 1:1.7) a white product of $Ag_2(im)_2(PPh_3)_3$ formulation, **1**, can be isolated (Eq. (1))

$$2/n[Ag(im)]_n + 3PPh_3 \rightarrow [Ag_2(im)_2(PPh_3)_3]_n \quad (1)$$

On layering diethyl ether over a CH_2Cl_2 solution of **1**, colourless single crystals suitable for X-ray diffraction (**1 · CH_2Cl_2**) are obtained by slow diffusion. At variance, upon layering an excess of PPh_3 dissolved in diethyl ether, the formation of white crystals of a different formulation, $[Ag(im)(PPh_3)_2$, **2**], is observed (Eq. (2))

$$[Ag_2(im)_2PPh_3]_n \overset{PPh_3}{\rightarrow} 2[Ag(im)(PPh_3)_2]_n \quad (2)$$

In both cases, to recover analytically pure products, we found it necessary to operate in a slight excess of PPh_3 with respect to the stoichiometric amount required; only under these conditions is the dissociation of the already coordinated, labile phosphines inhibited. Actually, on suspending **2** in diethyl ether, loss of PPh_3 with concomitant formation of **1** takes place (from IR evidence). Seemingly, to obtain **2**, the required PPh_3 excess lies in the 1:1.7–1:3 range. Actually, on working with a large excess of PPh_3 (i.e., with an Ag:PPh_3 ratio of 1:3 or higher), $Ag(im)(PPh_3)_3$ can be isolated [19].

3.2. Crystallographic aspects

Compound **1 · CH_2Cl_2** is characterised by single-stranded wavy chains of $Ag_2(im)_2(PPh_3)_3$ formulation and clathrated molecules of dichloromethane (Figs. 1 and 3(a)). The chains evolve along **a** with a translation step of 10.678(5) Å (*a*) and pack creating a herringbone motif appreciable down [1 0 0]. Within each chain, two crystallographically independent metal ions [$Ag_1\cdots Ag_2$ = 6.433(1) $Ag_1\cdots Ag_2$ = 6.575(1) Å, $Ag_1\cdots Ag_2\cdots Ag_1$ = 110.3°] are singly bridged by imidazolate anions, which act in their usual *N,N′-exo*-bidentate coordination mode. Both in a general

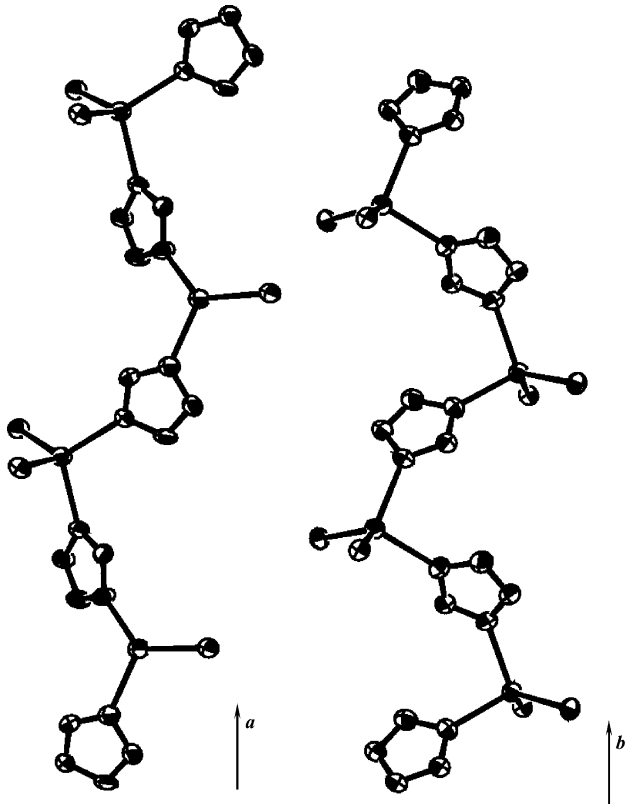

Fig. 3. Schematic representation of the single-stranded chain in $\mathbf{1 \cdot CH_2Cl_2}$ (a) and **2** (b). Phenyl carbons and hydrogen atoms are omitted for clarity.

position, the two metal centres exploit different coordination numbers and geometries: Ag_1, bonded to *two* phosphine ligands, is actually the centre of a distorted $Ag(N)_2(P)_2$ tetrahedral moiety; Ag_2, bonded to just *one* PPh_3 ligand, shows an almost planar trigonal stereochemistry (emerging by 0.06 Å from the plane of the three atoms coordinated to it). A non-negligible distortion of the Ag_1 tetrahedral stereochemistry is highlit by both the discrepancy between $Ag_1–P_{1,2}$ bond distances and the actual spread of the $L–Ag_1–L$ bond angles from the ideal tetrahedral one (L = N or P; see caption to Fig. 1). The observed distortion can be tentatively ascribed to the steric demands of the two PPh_3 ligands, resulting in their different positions with respect to the Ag–N···N–Ag skeleton. Indeed, both ligands point outwards from the polymeric spine: yet $P_2–Ag_1–N$ angles are smaller than those involving P_1 and are compensated by an $Ag_1–P_2$ bond that is longer than $Ag_1–P_1$. This asymmetry is not transferred to the $Ag_1–N$ bonds, $Ag_1–N_{11}$ and $Ag_1–N_{21}$ being almost comparable. Even the Ag_2 stereochemistry is somewhat distorted: its PPh_3 is more proximate to the N_{23}-imidazolate than to the N_{13}-one, this, however, only slightly differentiates $Ag_2–N_{13}$ and $Ag_2–N_{23}$. Solvent molecules are located among the chains and always face the less hindered Ag_2 ions, with a short $Ag_2···Cl_2$ non-bonding contact of 3.567(3) Å.

Even **2** is composed of single-stranded wavy chains (though of $Ag(im)(PPh_3)_2$ formulation) winding up about the monoclinic axis as 2_1 degenerate helices of pitch 9.674(5) Å (see Figs. 2 and 3(b)). The skeleton of each chain is formed by consecutive, non collinear, metal ions [Ag···Ag = 6.555(1) Å and Ag···Ag···Ag = 95.1°], singly bridged by *N*,*N*′-*exo*-bidentate imidazolate ligands. Each metal, in a generic position, is further bonded to *two* independent PPh_3 ligands, thus showing a heavily distorted tetrahedral arrangement due to the steric hindrance of the PPh_3 moieties (see caption to Fig. 2). The crystal packings of both $\mathbf{1 \cdot CH_2Cl_2}$ and **2** show a few C···C contacts between the phenyl rings, the shortest values falling in the usual 3.3–3.4 Å range.

Focusing on the most significant structural aspects, a comparison can be made between $\mathbf{1 \cdot CH_2Cl_2}$ or **2** and related triphenylphosphine derivatives of silver(I) azolates, i.e., the $[Ag(\mu_2\text{-pz})(PPh_3)]_2$ and $[Ag_2(\mu_2\text{-pz})_2(PPh_3)_3]_2$ dimers [20] and the $[Ag(\mu_2\text{-1,2,3-triz})(PPh_3)_2]_n$, $[Ag(\mu_2\text{-1,2,4-triz})(PPh_3)_2]_n$ [17] and $[Ag(\mu_2\text{-tetz})(PPh_3)_2]_n$ [18] polymers.

The pitch characterising the 2_1 helices of **2** is shorter than the translation step of $\mathbf{1 \cdot CH_2Cl_2}$, but almost comparable to those found for the $[Ag(\mu_2\text{-1,2,3-triz})(PPh_3)_2]_n$, $[Ag(\mu_2\text{-1,2,4-triz})(PPh_3)_2]_n$ and $[Ag(\mu_2\text{-tetz})(PPh_3)_2]_n$ polymers [9.119(5), 9.525(6) and 9.471(3) Å, respectively]. Indeed, both the Ag···Ag contacts and the N–Ag–N angles characterising these species (Table 1) confirm the presence of a more 'relaxed' N–Ag···Ag–N skeleton in the crystals of $\mathbf{1 \cdot CH_2Cl_2}$. No reasonable comparison can obviously be made to the metal···metal contacts of the *doubly bridged* $[Ag(\mu_2\text{-pz})(PPh_3)]_2$ and $[Ag_2(\mu_2\text{-pz})_2(PPh_3)_3]_2$ dimers. The latter can be included when considering the Ag–N bond distances. Those departing from tetrahedral centres span the 2.29–2.34 Å range (Table 1), couples of bonds on the same metal ion not always being comparable within experimental error. Noteworthy, is that the quoted range partially overlaps with that spanned by the Ag–N bonds of trigonal metal centres (2.20–2.31 Å, Table 1), thus evidencing, for the Ag–N vectors of the two stereochemistries, a lack of internal consistency. The situation appears somewhat different for Ag–P bond distances, the intervals for tetrahedral and trigonal silver(I) ions being clearly differentiated (2.44–2.59 and 2.37–2.39 Å, respectively; Table 1). Once again, however, couples of bonds on the same metal centre may differ more than allowed by the related e.s.d.'s. The only bond angles showing a certain regularity are N–Ag–N, insisting on three-coordinated metal ions; the other L–Ag–P angles (L = N or P) cover rather wide ranges, though, for a given compound, adhering to the N–Ag–N < N–Ag–P and N–Ag–N < N–Ag–P < P–Ag–P

orderings for trigonal and tetrahedral coordinations, respectively (Table 1).

4. Discussion

Already for the long-known $[Ag(\mu_2\text{-pz})]_n$ polymer, the reaction with PPh_3 allows the recovery of different species, $Ag(\mu_2\text{-pz})(PPh_3)$ and $Ag_2(\mu_2\text{-pz})_2(PPh_3)_3$, depending on the Ag:$PPh_3$ ratio employed (1:1.5 and >1:5, respectively) [20]. In the present case, i.e., with the imidazolate analogue, the required excess of PPh_3 not only prevents the dissociation of the already coordinated ligands, but, at an earlier stage of the reaction, also promotes depolymerisation of the starting silver(I) species: actually, as confirmed by single crystal X-ray data collections, both $Ag(\mu_2\text{-pz})(PPh_3)$ and $Ag_2(\mu_2\text{-pz})_2(PPh_3)_3$ consist of truly molecular dinuclear species (their correct formulation being thus $[Ag(\mu_2\text{-pz})(PPh_3)]_2$ and $Ag_2(\mu_2\text{-pz})_2(PPh_3)_3$, respectively). The different amplitude of the *N*,*N*′-*exo*-bidentate coordination bite in imidazolate and pyrazolate suggests the impossibility of forming doubly bridged dinuclear species in the case of **1** · $\mathbf{CH_2Cl_2}$ and **2**, thus suggesting either cyclic oligomers of higher nuclearity, or monodimensional polymers such as $[Ag(\mu_2\text{-1,2,3-triz})(PPh_3)_2]_n$, $[Ag(\mu_2\text{-1,2,4-triz})(PPh_3)_2]_n$ [17] and $[Ag(\mu_2\text{-tetz})(PPh_3)_2]_n$ [18]. In the latter species, N_1 and N_3 (strictly paralleling the reciprocal position of nitrogens in imidazolate), N_1 and N_4, or N_1 and N_3, respectively, are involved in metal bridging, N_2 (retraceable to the only other bite available in pz) being uncoordinated in all three cases. Thus, at least in the solid state, the presence of multiple N donor sites (as in 1,2,3-triz, 1,2,4-triz and tetz) results in *N*,*N*′-*exo*-bidentate (bridging) azolates, strictly avoiding the coordination of adjacent N atoms. The structural features of **1** · $\mathbf{CH_2Cl_2}$ and **2**, established by X-ray single crystals experiments (see above), definitely support these considerations.

The reaction of Ag(az) with PPh_3, depending on the azolate moiety, leads to different products, also on the basis of the Ag:PPh_3 reaction ratios employed, dimeric or polymeric species being typically obtained. The only monomeric tris–triphenylphosphine silver(I) azolate so far isolated is $Ag(im)(PPh_3)_3$; however, variable temperature ^{31}P NMR has shown that, although never recovered from $Ag_2(\mu_2\text{-pz})_2(PPh_3)_3$ solutions, $Ag(pz)(PPh_3)_3$ is stable (in solution) when a large excess of PPh_3 is employed [20]. The existence of other $Ag(az)(PPh_3)_3$ species has been proven, in solution, for az = 1,2,3-triz, 1,2,4-triz (variable temperature ^{31}P NMR) and tetz (r.t. ^{31}P NMR evidences). Noteworthy, with tetz, the Ag:PPh_3 ratio required to obtain $Ag(im)(PPh_3)_3$ (1:3) leads directly to the $[Ag(\mu_2\text{-az})(PPh_3)_2]_n$ polymer [17,18]. Thus, even if "naturally" addressed as a homogeneous set of species, there are still some distinct peculiarities within the $Ag(az)(PPh_3)_n$ family (witnessed, inter alia, by their different pharmacological activity); moreover, among

the missing members of the pyrazolato and imidazolato systems studied in our group, we need to mention $[Ag(\mu_2\text{-pz})(PPh_3)_2]_2$ (with two phosphines per silver(I) ion [20]) and $[Ag(\mu_2\text{-im})(PPh_3)]_n$ [with only one phosphine per silver(I) ion], which could never be prepared, regardless of the $Ag:PPh_3$ ratio applied.

5. Conclusions

Two novel polymeric silver-imidazolate derivatives, $[Ag_2(\mu_2\text{-im})_2(PPh_3)_3]_n$, (**1**), and $[Ag(\mu_2\text{-im})(PPh_3)_2]_n$, (**2**), have been synthesised and characterized, complementing a recent report on the solution and structural chemistry of silver(I) complexes with polyimidazolyl derivatives and tertiary phosphines [24].

Although lacking pharmaceutical investigations, the results herein reported may non-negligibly contribute to the development of pharmaceutically active silver(I) azolates, throwing light on their remarkably different versatility towards phosphorous donor ligands. Actually, Nomiya et al. [17–19] have often remarked that, independently from the solid state organisation, the phosphine derivatives are, once dissolved, markedly less active than the corresponding homoleptic parents, possibly because of the higher affinity of silver(I) toward softer ligands (phosphines vs. azolates). Nevertheless, the stoichiometry, the reactivity and the structural features of the new species presented certainly add significant information on the nature of the complexes which can exist, in equilibrium with the more active species, in physiological conditions.

6. Supplementary material

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre, supplementary publications Nos. CCDC 235858 and 235859. Copies of this data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk; or on the web: http://www.ccdc.cam.ac.uk].

Acknowledgements

The Italian MIUR (PRIN 2003), the University of Insubria (Progetto di Eccellenza "Sistemi Poliazotati") and the Fondazione Provinciale Comasca are acknowledged for funding. A special acknowledgement is due to Prof. Angelo Sironi (Dipartimento di Chimica Strutturale e Stereochimica Inorganica, Università degli Studi di Milano) for the generous loan of the X-ray single crystal equipment.

[10–13]. There are also some recent reports on structural studies and spectral characteristics of *N*(4)-phenyl 4-benzoylpyridine thiosemicarbazone [14]. It was found that the presence of a bulky group at the terminal nitrogen *N*(4) considerably increased the activity [15]. We have recently reported structural and spectral studies of copper(II) complexes of 2-benzoylpyridine *N*(4),*N*(4)-(butane-1,4-diyl)thiosemicarbazone [16]. In addition, iron(III) complexes of 2-acetylpyridine-*N*(4),*N*(4)-(butane-1,4-diyl) thiosemicarbazone are also reported [17]. This paper describes the syntheses, structural, spectral and antimicrobial studies of six new Cu(II) complexes of 2-benzoylpyridine *N*(4)-cyclohexyl thiosemicarbazone (HL).

2. Experimental

Cyclohexyl isothiocyanate (Fluka), hydrazine hydrate (Lancaster), 2-benzoylpyridine (Lancaster) were used as received. The HL was prepared by a reported procedure [18].

2.1. Synthesis of complexes

To a methanolic solution of cupric chloride (2 mmol), a methanolic solution of HL (2 mmol) was added and refluxed for 4 h to prepare [CuLCl] (**1**). The resulting solution, on cooling, yielded blue coloured crystals, which were filtered, washed with methanol and ether and dried over P_4O_{10} in vacuo. [{CuLBr}$_2$] (**2**), [CuL-NO_3] (**3**), [CuL_2SO_4]·$2H_2O$ (**6**) were prepared by similar method using the appropriate copper salts. Compounds [CuLNCS] (**4**) and [$CuLN_3$]·$3H_2O$ (**5**) were prepared by a metathetical displacement of the acetate anion of the copper acetate complex by the addition of 1 mmol each of the methanolic solutions of KCNS and NaN_3, respectively, to the reaction mixture containing the ligand and copper acetate in methanol. The resulting solution was refluxed for 3 h and left overnight. The solids, which separated were filtered, washed with methanol and ether and dried over P_4O_{10} in vacuo.

2.2. Physical methods

Carbon, hydrogen and nitrogen analyses of the ligand and the complexes were done on a Heraeus elemental analyser at CDRI, Lucknow, India. The IR spectra were recorded on a Shimadzu DR 8001 series FT-IR instrument using KBr pellets in the range 400–4000 cm^{-1} and far IR spectra were recorded in the range 50–500 cm^{-1} on a Nicolet Magna 550 FT-IR spectrometer using polyethylene pellets at RSIC, IIT, Bombay, India. The solid-state reflectance spectra of the ligand and the complexes were recorded on an Ocean Optics, Inc. SD2000 Fibre Optic Spectrometer. Electronic spectra of the ligand and the complexes in DMF solution were recorded on a Shimadzu 160A UV–Vis. spectrophotometer. The EPR spectra of the complexes were recorded in a Varian E-112 Spectrometer using TCNE as the standard at RSIC, IIT, Bombay. The magnetic susceptibility measurements were carried out at the Indian Institute of Technology, Roorkee, at room temperature in the polycrystalline state on a PAR model 155 Vibrating Sample Magnetometer at 5 K Oersted field strength. The molar conductances of the complexes of the solutions in dimethylformamide (ca. 10^{-3} M) at room temperature were measured using a direct reading conductivity meter.

2.3. X-ray crystallography

Single crystals of compound **1** for X-ray analysis were grown by slow evaporation of the complex in a chloroform–methanol mixture. A deep blue monoclinic crystal of compound [CuLCl] (**1**) was mounted on a glass fibre using epoxy cement. The X-ray diffraction data were measured in frames with increasing θ (width of 0.3°/frame) at room temperature (293 K) using a Bruker SMART APEX CCD diffractometer, equipped with a fine focus sealed tube X-ray source. The SMART software was used for data acquisition and the SAINT software for data extraction [19]. Empirical absorption corrections were made on the intensity data [20]. The structure was solved by the heavy atom method and refined by full-matrix least squares using the SHELX system of programs [21] and the graphics tool was PLATON for windows [22]. All non-hydrogen atoms of the complex cations were refined anisotropically. Few hydrogen atoms were located from the difference Fourier map and the rest were generated, assigned isotropic thermal parameters and refined using a riding model. The hydrogen atoms were used for structure factor calculation only. Similarly, a deep blue crystal of [{CuLBr}$_2$] (**2**) and a light green coloured crystal of [CuLNCS] (**4**) were analysed and the crystallographic data along with the structural refinements are given in Table 2.

2.4. Antimicrobial activity

For antimicrobial activity, two Gram positive and three Gram negative bacteria were used as test organisms. The disc diffusion method was used for screening the antimicrobial property and determining the MIC (minimum inhibitory concentration) of the compounds.

3. Results and discussion

3.1. Synthesis of the complexes

All the complexes were synthesized by refluxing HL with the corresponding copper salt in ethanol. The col-

Table 1
Colours and partial elemental analysis data of the complexes

Compound	Color	Found (Calc.)%			μ (B.M.)
		C	H	N	
[CuLCl] (**1**)	blue	52.62 (52.29)	4.94 (4.82)	12.72 (12.84)	1.52
[{CuLBr}$_2$] (**2**)	blue	47.16 (47.45)	4.55 (4.37)	11.70 (11.65)	1.80
[CuLNO$_3$] (**3**)	green	49.35 (49.29)	4.62 (4.54)	14.73 (15.13)	1.62
[CuLNCS] (**4**)	green	52.40 (52.34)	4.70 (4.58)	15.03 (15.26)	1.94
[CuLN$_3$]·3H$_2$O (**5**)	blue	45.46 (45.96)	4.94 (5.43)	20.14 (19.74)	1.97
[Cu$_2$(L)$_2$SO$_4$]·2H$_2$O (**6**)	dark green	48.87 (48.87)	5.03 (4.93)	11.99 (12.00)	1.66

ours, stoichiometries, elemental analyses and magnetic moments of the Cu(II) complexes are given in Table 1. All the Cu(II) complexes prepared are either blue or green in colour. The elemental analysis data of all the compounds suggest a formula [MLX], where X is Cl, Br, NO_3, NCS, N_3 and L is the deprotonated ligand. However, the sulfato complex is found to have the formula [Cu$_2$(L)$_2$SO$_4$]·2H$_2$O. The compounds **5** and **6** contain water molecules and the IR data suggest that the water molecules are not coordinated, but exist as lattice water [23].

All the complexes are found to be non-conductors in DMF solution. These facts along with the elemental analysis data indicate that the anion and the deprotonated ligand are coordinated to the central Cu(II). Magnetic moments of the complexes are calculated from magnetic susceptibility measurements and the values of all the Cu(II) complexes at room temperature are found to be in the range 1.5–1.9 B.M. The values of the magnetic moments, which are close to the spin only value of 1.7 B.M. indicate the presence of one unpaired electron.

3.2. Crystal structures of [CuLCl], [{CuLBr}$_2$] and [CuLNCS]

The structures of [CuLCl] (**1**), [{CuLBr}$_2$] (**2**) and [CuLNCS] (**4**) along with the atom labelling are shown in Figs. 1–3, respectively. Crystal data are given in Table 2 and a comparison of selected bond lengths and bond angles of HL, with compounds **1**, **2** and **4**, is summarized in Table 3.

3.2.1. [CuLCl]

The compound CuLCl (**1**) crystallizes into a monoclinic lattice with a $P2_1/n$ space group symmetry. There are two crystallographically independent molecules, A and B, in the asymmetric unit of the compound, with bond lengths and angles, which agree with each other and are within normal ranges. The compound shows a square planar geometry with the Cu atom lying in an approximate plane with the N1, N3, S1 and Cl1 atoms. Due to coordination, the C13–S1 bond length of the thiosemicarbazone moiety approaches the value corresponding to a C–S single bond, as evident from the increased value of 1.746(3) Å in the complex, compared to 1.675(15) Å in the ligand. The C13–S1 distance in **1** compares well with those reported for the related thiosemicarbazone complexes, in which the coordination by the thiolate tautomers has been definitely established by X-ray structural determinations [24,25]. A slight distortion from the square planar geometry is evidenced by the bond angles, N1–Cu1–N2 (80.31(9)°), N2–Cu1–S1 (84.21(7)°), N1–Cu1–Cl1 (98.15(7)°) and Cl1–Cu1–S1 (97.22(4)°). The bonding parameters reveal that the Cu1–N1 (2.036(2) Å) and Cu1–N2 (1.966(2) Å) bond lengths are much smaller than the Cu1–Cl1 (2.2099(10) Å) bond length. This implies stronger Cu–N bonds compared to the Cu–Cl bond, indicating the domination of the thiosemicarbazone moiety in the bonding. The repeating unit in the crystal packing consists of three molecules where two of them set in an offset fashion are self-assembled by the intermolecular (N2H–S1) hydrogen bonding interactions, while the third molecule is arranged in a face to face manner with the neighbouring molecule. The repeating units are packed in an offset fashion and a three dimensional packing is effected by the π–π stacking, ring–metal and CH–π interactions.

3.2.2. [{CuLBr}$_2$]

Compound **2** is a thiolate bridged copper(II) dimer complex crystallized into a triclinic lattice with $P\bar{1}$ symmetry. Thiolate bridging by sulfur ligands are well reported [26–28], and recently the metal complexes of Schiff bases [29,30] and thiosemicarbazone [31] involving phenolate oxygen bridging are reported. Each CuLBr unit in the molecule assembles into a symmetric binuclear complex by bridging through the thiolate sulfur atom of the adjacent thiosemicarbazone via axial ligation. Thus, the Cu(II) ions reveal a distorted pentacoordinated viz, (4 + 1) (N1N2SBr + S′) square-based pyramidal geometry in the complex. The basal plane is occupied by the thiolate sulfur, azomethine nitrogen, pyridyl nitrogen and the bromine atoms. The bond lengths Cu1–S1 (2.289(2) Å), Cu1–N2 (1.978(4) Å),

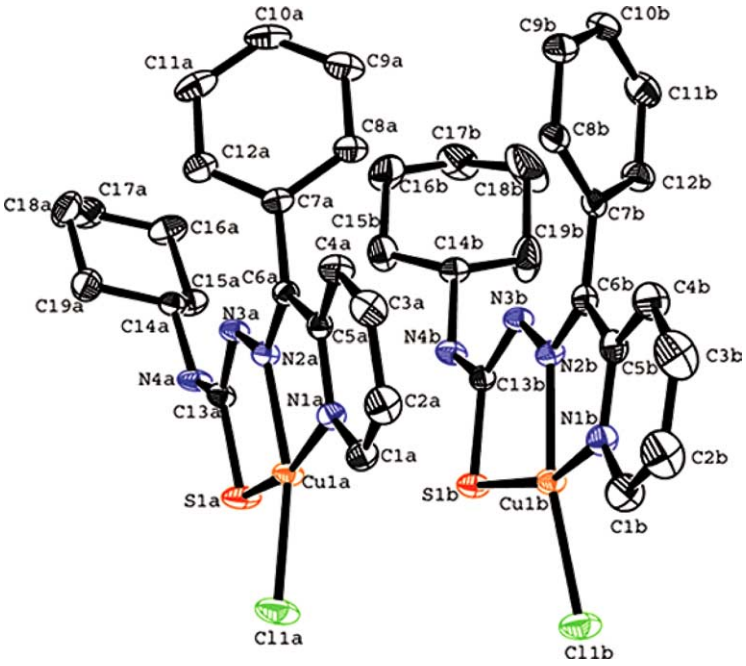

Fig. 1. ORTEP diagram for CuLCl (**1**), displacement ellipsoids are drawn at the 50% probability level and hydrogen atoms are shown as small spheres of arbitrary radii.

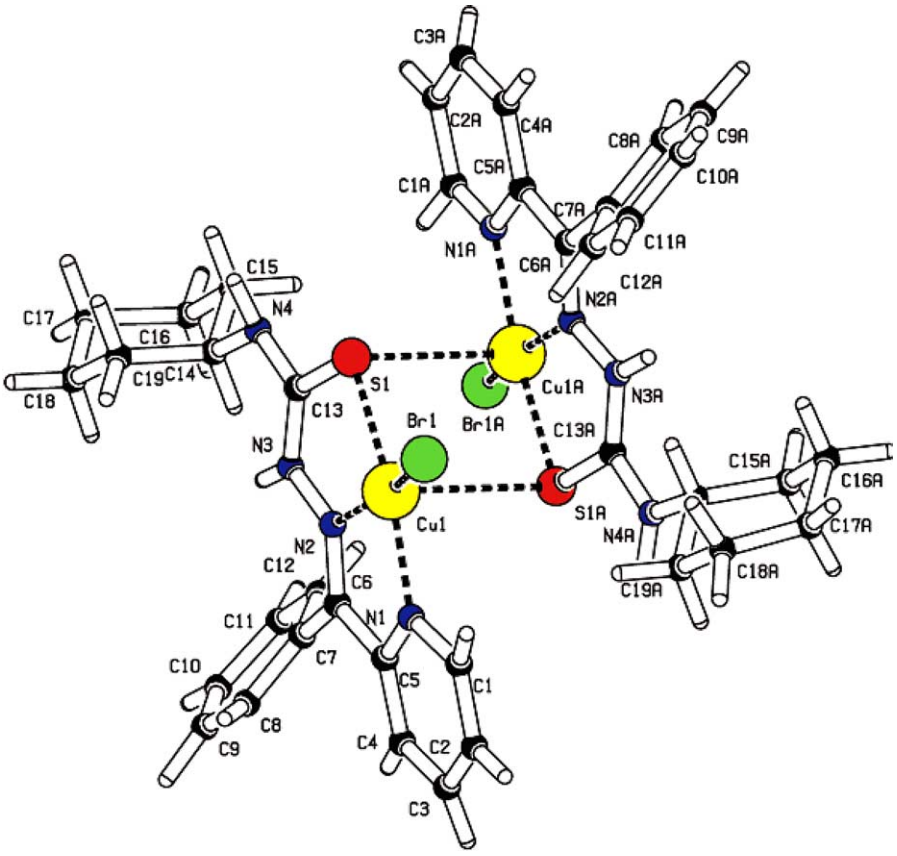

Fig. 2. PLATON diagram for [{CuLBr}$_2$] (**2**).

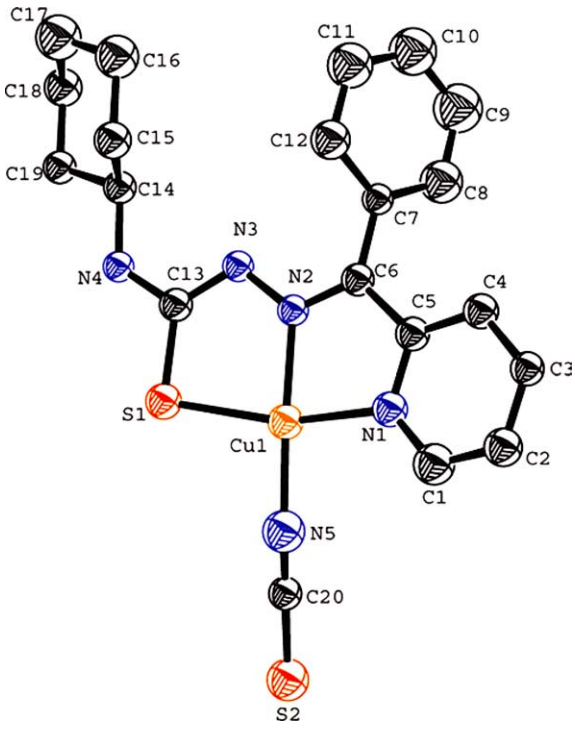

Fig. 3. ORTEP diagram for CuLNCS (**4**), displacement ellipsoids are drawn at the 50% probability level and hydrogen atoms are shown as small spheres of arbitrary radii.

Cu1–N1 (2.028(5) Å) and Cu1–Br1 (2.371(12) Å) are consistent with the other similar bond distances of square pyramidal copper complexes [32]. The apical position of the square pyramid is occupied by the thiolate sulfur of the second unit, at a Cu–Cu distance of ca. 3.523 Å with the Cu1–S1–Cu1A or Cu1–S1A–Cu1A angle being ca. 84.47°. In the Cu_2S_2 plane, the Cu1–S1 or Cu1A–S1A and Cu1–S1A or Cu1A–S1 bond lengths are ca. 2.266 and 2.937 Å, respectively, and the non-equivalent bonds give rise to the asymmetric binuclear thiolate double bridged structure. The basal planes around Cu1 and Cu1A are essentially planar with mean deviations being 0.1905(5) and 0.1891(5) Å, respectively. The significantly longer Cu–S axial bond length of ca. 2.937 Å is likely to reduce the spin–spin coupling between Cu1 and Cu1A centres. The Cu_2S_2 unit in the complex is planar with a mean deviation of 0.0073(5) Å. The Cu_2S_2 plane is observed at angles of 81.76(2)° and 80.60(2)°, respectively, with the basal planes around Cu1 and Cu1A. The crystal packing is effected by the wide network of CH –π interactions and the π–π stacking interactions involving the phenyl, pyridyl and metal chelate rings. The thiolate bridging structure is further stabilized by the comparatively stronger π–π interactions between the centroids Cg(3) and Cg(9) consisting of Cu(1), S(1), Cu(1A), S(1A) and Cu(1A), N(1A),

C(5A), C(6A), N(2A), respectively, which is observed at a remarkably shorter distance of 2.7632(3) Å.

3.2.3. [CuLNCS]

The crystal is developed into a triclinic lattice with $P\bar{1}$ symmetry and it reveals a distorted square planar N_3S coordination sphere with the copper centre. The thiosemicarbazone ligand occupies three positions and the thiocyanate nitrogen the fourth position of an approximate square plane. The C13–S1 bond length of 1.675(15) Å in the ligand HL is an evidence for the thione form in the solid state, which is shifted to 1.746(2) Å in the complex, confirming the coordination via the thiolate sulfur in **4**. The N2–N3 bond length of 1.367(17) Å in the uncomplexed thiosemicarbazone is found to remain unchanged in the complex, whereas, the C13–N3 bond length of 1.364(18) Å in HL is shifted to 1.325(3) Å in **4**. This is in support for the shifting of the thione form of the thiosemicarbazone to the thiol form during complexation. The ligand is deprotonated at N3 and the complex carries two five-membered chelate rings. The two planes through Cu1, N1, C5, C6, N2 and Cu1, N2, N3, C13, S1 show that the sets of atoms are almost coplanar, with a dihedral angle of 9.52(2)°. This small deviation from coplanarity would certainly not hinder the delocalization of electrons in the coordination sphere, and the stability of the complex is sustained. The distorted square planar structure is evidenced by the acute value displayed by the thiosemicarbazone bite angles, viz., N1–Cu1–N2 (80.40(7) Å) and N2–Cu1–S1 (84.43(6) Å) [33]. The bond angles of the trans donor atoms, i.e., N1–Cu1–S1 (160.36(6)°) and N5–Cu1–N2 (176.88(8)°) are $\geqslant$160° in **4**, which is consistent with the work on copper(II) complexes of 2-benzoylpyridine *N*(4)-substituted thiosemicarbazones by West et al. [10]. In the crystal lattice, the unit cell contains two molecules and the adjacent molecules are packed in a face to face manner facilitated by the π–π, CH–π and ring-metal interactions. It is also interesting to note that in all three crystals, the torsion angle values and the ring puckering analyses show that the metal chelate ring comprising of Cu1, S1, C13, N3 and N2 adopts an envelope conformation, whereas the cyclohexyl ring exists in the chair form. Atoms C14, C16, C17 and C19 constitute the best-fitting

plane of the cyclohexyl ring, while the atoms C15 and C18 deviate by 1.2415(6) and −1.2491(6) Å, respectively, on either side of the plane.

3.3. Vibrational spectra

The tentative assignments of the significant IR spectral bands of HL and its copper(II) complexes are presented in Table 4. The ν(C=N) band of the thiosemicarbazone at 1582 cm^{-1} is found to be shifted to lower energies in the spectra of the complexes indicating coordination via the azomethine nitrogen. This is confirmed by the bands in the range 440–464 cm^{-1}, which have been assigned to the ν(Cu–N) bond [34]. The ν(N–N) of the thiosemicarbazone is found at 1118 cm^{-1}. The increase in frequency of this band in the spectra of complexes is due to the increase in bond strength, again confirming the coordination via the azomethine nitrogen. In the uncomplexed thiosemicarbazone, a strong band at 833 cm^{-1} is assigned to ν(C=S), whereas in the complexes, this band is found to be shifted to lower frequencies in the range 783–794 cm^{-1}. This negative shift of the ν(C=S) band in the complexes is indicated by the coordination via the thiolate sulfur atom. Strong bands observed in the region 340–353 cm^{-1} have been assigned to the ν(Cu–S) band. In all the copper complexes a strong band is observed in the region 266–280 cm^{-1}, which is consistent with the ν(Cu–N) of pyridine as suggested by Clark and Williams [35]. Based on the above spectral evidences, it is confirmed that the ligand is coordinated to the Cu(II) ion as a tridentate anion, coordinating via the azomethine nitrogen, pyridyl nitrogen and thiolate sulfur. In the chloro complex, a strong band observed at 304 cm^{-1} has been assigned to the ν(Cu–Cl) band. The ν(Cu–Br) frequency is observed at 247 cm^{-1} in the bromo complex. The ν(Cu–Br) and ν(Cu–Cl) frequencies are consistent with terminal chloro and bromo ligands. In the IR spectrum of the complex containing nitrate as the gegenion, the band observed at 268 cm^{-1} can be assigned to ν(Cu–ONO_2), consistent with the bands at 253–280 cm^{-1} reported earlier for Cu–ONO_2 in metal complexes [36]. Moreover, in the nitrato complex of HL, two strong bands at 1280 and 1410 cm^{-1} corresponding to ν_1 and ν_4 modes of nitrato groups with a separation of 130 cm^{-1} indicate the presence of a terminally bonded monodentate nitrate group [23]. In the azido complex, a strong band observed at 2037 cm^{-1} is assigned to ν_a of the azide group, indicative of azide coordination [37]. Other bands due to N_3 such as ν_s(NNN) are difficult to assign because of the richness of the spectrum of the complex. In the thiocyanato complex, the very strong band observed at 2093 cm^{-1} corresponds to ν(C=N). Bands observed at 783, 481 and 461 cm^{-1} are assigned to ν(C=S), δ(NCS) and ν(Cu–N), respectively. These facts indicate that thiocyanate group is N-coordinated to copper [38]. In the sulfato complex, the fourth coordination position is occupied by the oxygen atom of the sulfate ion which belongs to the high symmetry point group T_d. The symmetry of the sulfate is reduced to C_{2v} when it functions as a bidentate ligand in the complex. The IR spectrum of compound **6** contains strong bands at 1002, 1117, 1204 cm^{-1} due to ν_3, 960 cm^{-1} due to ν_1 and 465 cm^{-1} due to ν_2, and these can be assigned to a bridging bidentate sulfato group [23]. This type of bidentate bridging by a sulfato group has been proved by a single crystal X-ray diffraction study for a thiosemicarbazone derived from di-2-pyridyl ketone [39]. According to Stefov et al. [40], coordinated water should exhibit frequencies at 825, 575 and 500 cm^{-1}. The absence of spectral bands in these regions in the spectra of complexes **3** and **6** indicates that the water molecules in these complexes are not coordinated but are present as lattice water.

3.4. Electronic spectra

The energies of the electronic transitions for the thiosemicarbazone HL and its Cu(II) complexes (solid state and DMF solution) are listed in Table 5. The solid-state electronic spectra of the thiosemicarbazone HL consists of a broadband at ca. 29 000 cm^{-1} which is the $n \rightarrow \pi^*$ band of the pyridine ring. Another $n \rightarrow \pi^*$ band of the thiosemicarbazone moiety is present in the 24 000 cm^{-1} region [12]. The molar absorptivity for $n \rightarrow \pi^*$ transitions for the solution spectrum is $>10^4$, which is consistent with the previously studied heterocyclic thiosemicarbazones [10]. The electronic spectra of the Cu(II) complexes consist of a $n \rightarrow \pi^*$ band of the pyridine ring at ca. 30 000 cm^{-1}. Additional bands observed in the range 23 000–25 000 cm^{-1} are assigned to S → Cu

Table 4

and py → Cu charge-transfer bands [41,42]. In the chloro complex (**1**), a shoulder observed at 31250 cm^{-1} is assigned to the Cl → Cu charge-transfer transition. The solid state spectra of all the Cu(II) complexes have a broadband in the region 15000–19000 cm^{-1}. This is consistent with a broad structured band for square planar complexes in the range 13000–20000 cm^{-1} [43].

3.5. Electron paramagnetic resonance spectra

The EPR spectra of a polycrystalline sample at 298 K and in different solutions at 298 and 77 K were recorded in the X band, using the 100 KHz field modulation; g factors were quoted relative to the standard marker TCNE ($g = 2.00277$). The EPR parameters of the Cu(II) complexes are presented in Table 6. The EPR spectra of CuLCl and Cu$_2$(L)$_2$SO$_4$ in the polycrystalline state at 298 K show only one broad signal at $g = 2.125$ and 2.063, respectively. Such isotropic spectra, consisting of a broad signal, and hence only one g value, arise from extensive exchange coupling through misalignment of the local molecular axes between different molecules in the unit cell (dipolar broadening) and enhanced spin lattice relaxation. These types of spectra unfortunately give no informa-

Table 6

[a] A values are given in 10^{-4} cm^{-1}.

tion on the electronic ground state of the Cu(II) ion present in the complexes. The spectra of [{CuLBr}$_2$] and [CuLNCS] are rhombic with three g values. The spectra of the other compounds show typical axial spectra with well-defined $g_\parallel$ and $g_\perp$ values. The spectra are often broad because of the broadening resulting from the fast spin–lattice relaxation time and exchange coupling. The geometric parameter G, which is a measure of the exchange interaction between copper centres in the polycrystalline compound, is calculated and the value of G is found to be in the range 2.3–4.0. In all the copper(II) complexes $g_\parallel > g_\perp > 2.0023$ and a G value less than 4.1 is consistent with a $d_{x^2-y^2}$ ground state [44,45]. The EPR spectral studies are in agreement with the X-ray diffraction studies for complexes **1**, **2** and **4**. All the complexes in DMF solution at 298 K clearly show four well-resolved hyperfine lines (^{65}Cu, $I = 3/2$). The EPR spectra of the complexes in glassy state at 77 K were recorded in different solvents, such as DMF, $CHCl_3$ and in a 1:1 mixture of $CHCl_3$ and toluene. Solutions of compounds **1** and **2** in chloroform–toluene mixture show well-resolved four hyperfine lines corresponding to monomeric Cu(II) complexes. The spectra have five nitrogen superhyperfine lines on the high field copper hyperfine splitting component, which arise from the coupling of the electron spin with the nuclear spin of the two nitrogen atoms. The EPR spectrum of compound **5** shows four well-resolved hyperfine lines with seven nitrogen superhyperfine lines on the high field copper hyperfine splitting component. The seven superhyperfine lines arise from the coupling of the electron spin with the nuclear spin of the three nitrogen atoms, i.e., one azomethine nitrogen, one nitrogen of pyridine ring and one nitrogen from the azido anion coordinated to the Cu(II) centre. The EPR spectra of compounds **3**, **4** and **6** in DMF solution at 77 K show four hyperfine lines. The EPR spectra of compounds **1** and **5** are given in Figs. 4 and 5, respectively.

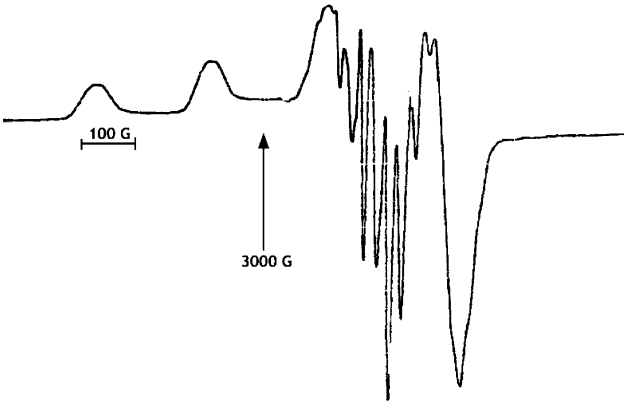

Fig. 4. EPR spectrum of CuLCl (**1**) in DMF solution at 77 K.

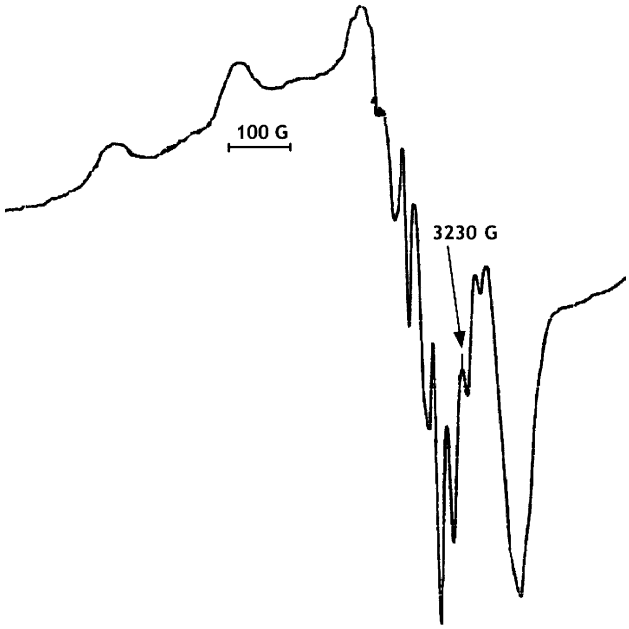

Fig. 5. EPR spectrum of $CuLN_3$ (**5**) in DMF solution at 77 K.

The $g_\parallel$ values of all the compounds are found to be almost the same, which indicates that the bonding is dominated by the thiosemicarbazone moiety. Kivelson and Nieman [46] have reported that $g_\parallel$ values less than 2.3 indicate considerable covalent character to M–L bonds, while a value greater than 2.3 indicate ionic character. The $g_\parallel$ values of all the compounds are found to be less than 2.3, which indicates considerable covalent character to the M–L bond.

The EPR parameters $g_\parallel$, $g_\perp$, g_{av}, $A_\parallel$ (Cu) and $A_\perp$ (Cu) and the energies of the d–d transition were used to evaluate the bonding parameters α^2, β^2 and γ^2, which may be regarded as measures of the covalency of the in-plane σ bonds, in-plane π bonds and out-of-plane π-bonds, respectively (Table 7) [3].

The value of the in-plane sigma bonding parameter α^2 was calculated [44] using the expression

$$\alpha^2 = -A_\parallel/0.036 + (g_\parallel - 2.0023) + 3/7(g_\perp - 2.0023) + 0.04.$$

The orbital reduction factors, $K_\parallel = \alpha^2\beta^2$ and $K_\perp = \alpha^2\gamma^2$ were calculated using the following expressions:

$$K_\parallel^2 = (g_\parallel - 2.0023)E_{d\text{-}d}/8\lambda_0,$$

$$K_\perp^2 = (g_\perp - 2.0023)E_{d\text{-}d}/2\lambda_0,$$

where λ_0 is the spin–orbit coupling constant, with a value of -828 cm^{-1} for a copper(II) d^9 system.

According to Hathaway [44], for pure σ bonding, $K_\parallel \approx K_\perp \approx 0.77$, and for in-plane π bonding, $K_\parallel < K_\perp$; while for out-of-plane π bonding, $K_\perp < K_\parallel$. In all the complexes, it is observed that $K_\parallel < K_\perp$ which indicates

Table 7
Bonding parameters and orbital reduction parameters of the Cu(II) complexes of HL

Compound	α^2	β^2	γ^2	$K_{\parallel}$	$K_{\perp}$	K_0	f
[CuLCl]	0.6810	0.9455	0.9862	0.6439	0.6716	0.3283	129.99
[{CuLBr}$_2$]	0.6667	0.8518	0.8590	0.5687	0.5735	0.3312	120.70
[CuLNO$_3$]	0.7537	0.9250	0.9575	0.6972	0.7217	0.3440	121.32
[CuLNCS]	0.7062	0.9226	0.9643	0.6516	0.6810	0.3581	129.30
[CuLN$_3$]·3H$_2$O	0.6538	0.8750	0.8782	0.5720	0.5742	0.2997	124.43
[Cu$_2$(L)$_2$SO$_4$]·2H$_2$O	0.7165	0.9355	0.9600	0.6658	0.6834	0.3394	128.54

the presence of significant in-plane π bonding. This is further confirmed by the bonding parameters α^2, β^2 and γ^2, which are less than 1.0 expected for purely ionic character of the bonds, and decreases with increasing covalent nature of the bonding. Therefore the evaluated values of α^2, β^2 and γ^2 are consistent with both in-plane σ and in-plane π bonding [47].

The empirical factor $f = g_{\parallel}/A_{\parallel}$ cm^{-1} is an index of tetragonal distortion and its value may vary from 105 to 135 for small to extreme distortion in square planar complexes, and that depends on the nature of the coordinated atom [48]. The f values of the complexes are found to be in the range 121–130, indicating significant distortion from planarity.

Recent studies have shown that biological activity is related to the geometry at the metal sites. Complexes with more tetrahedral distortion are reported to display higher activity [49]. The studies of antimicrobial activity among the six complexes revealed the chloro compound to have the greatest activity, which is consistent with the above statement since compound **1** shows the maximum f value of 129.99. However, compound **4**, with almost the same f value (129.30), is found to be less active.

3.6. Antimicrobial activity

The ligand HL and the Cu(II) complexes were tested for their antimicrobial activity. Test substances which produce a zone of inhibition of diameters 9 mm or more are regarded as positive, i.e. having constructive antimicrobial activity; while in those cases where the diameter is below 9 mm, the bacteria are resistant to the sample tested and the sample is said to have no antimicrobial activity. The following bacteria, isolated from clinical samples, were used as test organisms: (1) *Staphylococcus aureus*, (2) *Bacillus* sp. (Gram positive), (3) *Escherichia coli*, (4) *Salmonella paratyphi*, (5) *Vibrio cholerae O1* (Gram negative).

The disc diffusion method was used for screening the antimicrobial property of the test samples. The MIC (minimum inhibitory concentration) of the compounds showing a positive antimicrobial property was found using the same method. 1% solutions of the samples in DMF were used. The medium used for growing the culture was nutrient agar. The ligand HL was found to be inactive, but all the copper(II) complexes were found to be active (Table 8). The copper(II) complexes **1** and **3** were found to be active against *Bacillus* sp. *V. cholerae O1* and *S. aureus*. Compound **6** was found to be active against *Bacillus* sp., *V. cholerae O1* and *S. paratyphi.* Compound **5** was found to be active against *V. cholerae O1* and *S. paratyphi* and compounds **2** and **4** were found to be active against *V. cholerae O1*. The MIC values of the complexes are given in Table 9.

4. Supplementary data

Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data centre, CCDC 227455 for compound [CuLCl] (**1**), CCDC 227456 for compound [CuLNCS] (**4**) and CCDC 227457 for compound [{CuLBr}$_2$] (**2**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge,

procedures before use in electrochemical measurements [15]. The Schiff base ligand HL was prepared by a reported method [16]. The elemental analysis was carried out using a Heraeus CHN-O rapid instrument. The infrared and electronic spectral measurements were recorded using Perkin–Elmer Spectrum One FT-IR and Lambda 55 spectrometers, respectively. The variable temperature magnetic susceptibility measurements in the temperature range 18–300 K were carried out using a George Associates Inc. (Berkeley, CA, USA) Lewis-coil-force magnetometer. $Hg[Co(NCS)_4]$ was used as a standard. Theoretical fitting of the experimental susceptibility data using the Curie-Weiss equation $\chi_M = C/(T-\theta)$ gave a linear fit with a θ value of 3.5 K. Cyclic voltammetric measurements were made at 25 °C on a EG&G PAR 253 VersaStat potentiostat/galvanostat using a three electrode configuration consisting of a glassy carbon working electrode, a platinum wire auxiliary and a saturated calomel reference (SCE) electrode. Ferrocene ($E_{1/2}$ = 0.41 V) and $K_4[Fe(CN)_6]$ ($E_{1/2}$ = 0.18 V) were used as standards in MeCN–0.1 M $[Bu^n_4N]$-ClO_4 (TBAP) and 0.05 M Tris–HCl/0.1 M KCl buffer medium, respectively. Conductivity measurement was made at 25 C using a Control Dynamics conductivity meter. Solution infrared spectral studies were carried out using a silver chloride Quick Cell Kit from Aldrich (USA).

2.2. Synthesis of [Cu(HL)(ClO$_4$)](ClO$_4$) (1)

A 1.6 g quantity (4.3 mmol) of $Cu(ClO_4)_2\cdot 6H_2O$ taken in 20 ml methanol was reacted with 1.15 g (4.3 mmol) Schiff base ligand dissolved in 20 ml methanol under magnetic stirring for 30 min at 60 °C. The reaction mixture was cooled to an ambient temperature and the blue crystalline product thus obtained was separated, washed with cold methanol and dried in vacuum over P_4O_{10} (Yield: 1.6 g, ~70%). Calc. for $C_{16}H_{16}Cl_2CuN_4O_9$: C, 33.9; H, 3.4; N, 10.6. Found: C, 34.2; H, 3.5; N, 10.8%. FT-IR data in KBr phase (cm^{-1}): 3215br, 2928w, 2903w, 1648m, 1596s, 1483w, 1432m, 1318m, 1225m, 1148vs, 1123vs, 1089vs, 1019m, 985w, 786m, 623s, 580w, 520w, 485w, 425w (br, broad; vs, very strong; s, strong; m, medium; w, weak).

2.3. X-ray crystallography

Single crystals of **1** were grown by a diffusion technique using a MeCN solution of the complex and chlorobenzene. A rectangular shaped blue crystal was mounted on a glass fiber with epoxy cement. All geometric and intensity data were collected using an Enraf-Nonius CAD4 diffractometer equipped with graphite monochromated Mo Kα radiation. Intensity data, collected using the $\omega-2\theta$ scan mode, were corrected for Lorentz-polarization effects and for absorption [17]. The structure was solved and refined by full-matrix least-squares techniques using the SHELX system of programs [18]. The lattice perchlorate ion showed positional disorder. The bound perchlorate anion showed high thermal motion. The peaks for the lattice perchlorate ion were modelled for a tetrahedral structure with geometrical restraints using SADI provisions in the SHELX program. The alcoholic OH group of the propanol moiety of the Schiff base showed positional disorder with two peaks and the concerned oxygen atom was refined as O(1) and O(1a) with site occupancy factors of 0.7 and 0.3, respectively. This group showed the presence of intra- and intermolecular weak hydrogen bonding interactions involving the perchlorate ions. The structure refined well giving the highest residual peak of 1.24 e Å^{-3} located at ~0.8 Å from the O(22) atom of the lattice perchlorate ion. The perspective view of the molecule was obtained using ORTEP [19]. Selected crystallographic data are given in Table 1.

3. Results and discussion

3.1. Synthesis and general aspects

Complex **1** is prepared in high yield from the reaction of copper(II) perchlorate with the multidentate Schiff base ligand (HL) (Scheme 1). The complex has been characterized from analytical and physicochemical data (Table 2). Complex **1** is 1:2 electrolytic in nature in MeCN [20]. It shows infrared bands at 1148 and 1123 cm^{-1} for the metal-bound perchlorate ion and at 1089 cm^{-1} for the lattice perchlorate ion. The IR bands at 3215 and 1648 cm^{-1} are assignable to ν(O–H) and ν(C=N), respectively [21]. The complex displays a d–d band at 640 nm in its electronic spectrum in MeCN. The complex exhibits an essentially reversible cyclic voltammetric response at 0.01 V versus SCE (ΔE_p = 74 mV at 50 mV s^{-1} scan rate) in MeCN–0.1 M TBAP due to the copper(II)/copper(I) couple. In 0.05 M Tris–HCl/0.1 M KCl buffer medium, the copper(II)/copper(I) couple is observed at −0.24 V (ΔE_p = 90 mV at 50 mV s^{-1}), indicating better stability of the cupric state in the aqueous medium.

3.2. Crystal structure and magnetic property

The complex crystallizes in the monoclinic space group $P2_{1/C}$ with four molecules in the unit cell. The asymmetric unit consists of a mononuclear complex motif and a lattice perchlorate anion. An ORTEP view of the cationic complex is shown in Fig. 1. Selected bond distances and angles are given in Table 3. The complex forms a one-dimensional coordination polymer in which the {Cu(HL)} units are linked by the perchlorate ligand (Fig. 2). It has a six coordinate (4+2) CuN_4O_2 coordina-

tion geometry in which the Schiff base binds the copper as a tetradentate ligand at the basal plane with two pyridine nitrogen and two imine nitrogen atoms. The elongated axial site has the perchlorate ligand with a Cu(1)–O(11) distance of 2.528(6) Å. The other axial bond in the polymeric structure, formed by the perchlorate of the adjacent unit, is 2.61(1) Å. The weakness of the axial bonds is evidenced from the 1:2 electrolytic nature of the complex in a solution phase. The bite angles involving the Schiff base pertaining to the 5- and 6-membered chelate rings are ~81.5° and 92.7°, respectively.

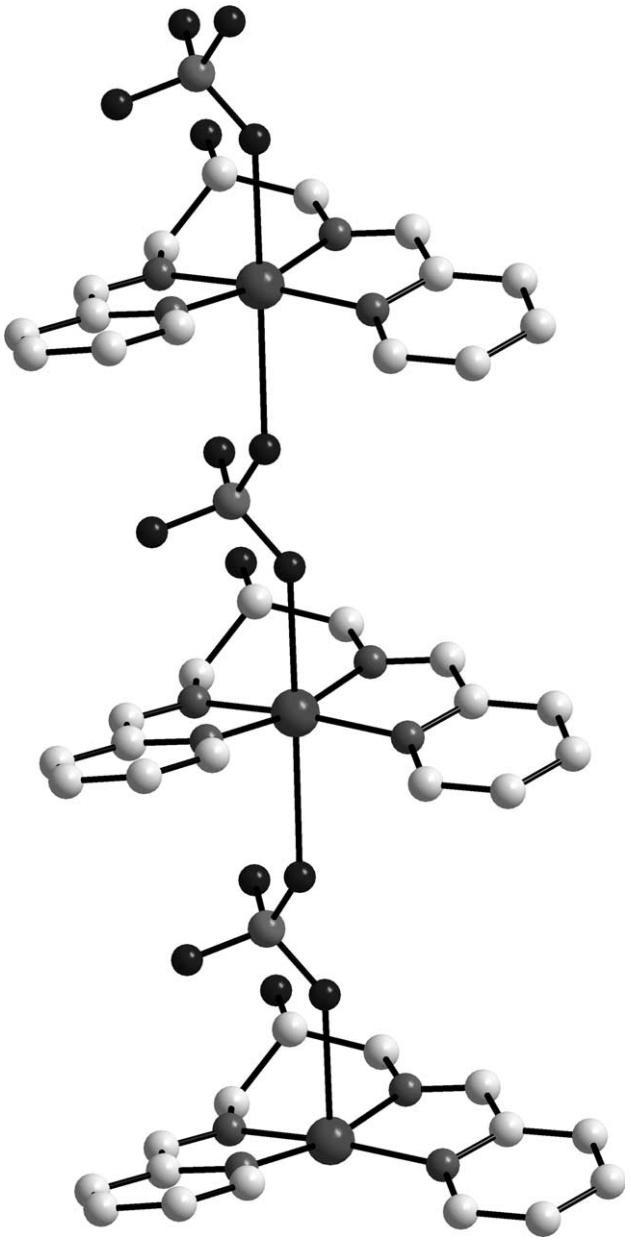

Fig. 2. The perspective view of the one-dimensional coordination polymeric structure of $[Cu(HL)(ClO_4)](ClO_4)$ (**1**). The positional disorder of the hydroxyl group is not shown for clarity.

While the 5-membered ring shows an envelope conformation, the 6-membered ring displays a twist-boat conformation. The complex is one-electron paramagnetic in nature. The 1D chain coordination polymeric structure of **1** does not show any significant magnetic exchange interaction along the chain as evidenced from the linear χ_M^{-1} versus T plot with a θ value of 3.5 K (Fig. 3) [22].

3.3. Imine bond activation

The reaction of the complex with H_2O_2 in an aqueous tetrahydrofuran mixture (1:4 v/v) has been monitored by

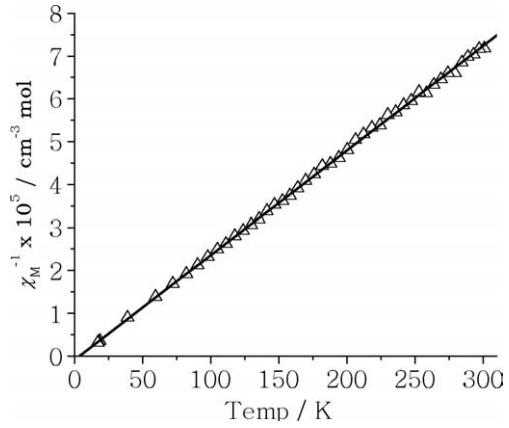

Fig. 3. The χ_M^{-1} vs. T plot for the 1D polymeric complex $[Cu(HL)(ClO_4)](ClO_4)$ (**1**). The solid line is the theoretical fit of the experimental data.

infrared spectroscopy. The spectral traces are shown in Fig. 4. The reaction proceeds with gradual formation of a bis(picolinato)copper(II) species as evidenced from an IR band near 1620 cm^{-1}. An additional band develops near 1685 cm^{-1} with the progress of the reaction. This band is assignable to the amido group formed from the imine moiety. The intensity of this band, however, gets reduced prior to the completion of the reaction, possibly due to conversion of the amido species to the relatively stable picolinic acid. We have isolated the bis(picolinato)copper(II)·dihydrate species in the crystalline form from the reaction of **1** with 30% H_2O_2 in aqueous methanol. The unit cell parameters of the violet colored crystals of the product compare well with the reported crystal data of the picolinato complex which in an aqueous THF medium shows a band at 1638 cm^{-1}, assignable to the carbonyl group of the carboxylate [23]. We have also isolated ammonium perchlorate from the synthetic reaction as a byproduct. It is likely that the

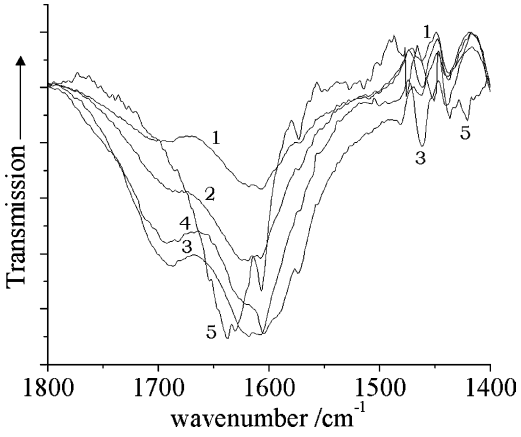

Fig. 4. IR spectral traces of $[Cu(HL)(ClO_4)](ClO_4)$ (**1**) in aqueous tetrahydrofuran (1:4 v/v) on reaction with 30% H_2O_2 at different time intervals: 1, 2 h; 2, 4 h; 3, 6 h; 4, 8 h; 5, pure sample of bis(picolinato)copper(II) complex.

conversion of azomethine to carboxylate promoted by hydrogen peroxide proceeds via formation of the amide bond as an intermediate species giving a reaction sequence: $-CH=N- \rightarrow -C(=O)-NH- \rightarrow -CO_2^- + H_2N-$. In addition, the formation of the amido species as an intermediate is inferred from the observation of a band at 1462 cm^{-1}. This band is assignable to the symmetric valence vibration of the O=C—N moiety of the amide. This band intensity also gets reduced on completion of the reaction (Fig. 4) [23].

4. Conclusions

A new copper(II) complex containing a multidentate Schiff base ligand has been prepared and structurally characterized by X-ray crystallography. The complex shows nearly reversible redox chemistry. It undergoes oxidative conversion to a bis(picolinato)copper(II) species on reaction with hydrogen peroxide through the formation of an intermediate amido species as evidenced from the solution infrared spectral studies.

In previous papers, VCl_4 and water was used to prepare thin films of V_2O_5 [9] and VO_2 [10] by an APCVD method whereas, $VOCl_3$ and water always produced V_2O_5, which requires further reduction to form VO_2 thin films [9]. In this paper, we describe the APCVD of various phases of vanadium oxide thin films from $VOCl_3$ and water. It was found that the phase of vanadium oxide produced was affected by the substrate temperature and the relative concentrations of the gaseous precursors. Significantly vanadium(IV) oxide could be prepared directly from $VOCl_3$ and water, without the need for a post-production reduction step.

2. Results and discussion

2.1. Film preparation and characterisation

The idealised reaction for the APCVD of VO_2 from $VOCl_3$ and water is given in Eq. (1).

$$VOCl_3 + H_2O \rightarrow VO_2 + 2HCl + 1/2Cl_2 \quad (1)$$

The films produced from $VOCl_3$ and water gave different phases of vanadium oxide depending on the conditions used. A summary of the conditions used and products obtained from the APCVD reaction of $VOCl_3$ and water are given in Table 1. As can be seen from Table 1, most conditions result in orange/yellow V_2O_5 but at higher substrate temperature and with a slight excess of water over the stoichiometric amount idealised in Eq. (1), reduced phases of vanadium oxide could be formed. The reduced phases occurred in two discernable areas. At the leading edge of the substrate a thick, green area consisting of a mixed phase of V_6O_{13} and V_2O_5 was formed. Closer to the exhaust end of the substrate single phase, dark yellow VO_2 was formed. Varying the total gas-flow rate through the CVD reactor could control the relative amount of these two phases, a decrease in total gas-flow rate would decrease the size of the mixed phase V_2O_5/V_6O_{13} region and enable the majority (95%) of the substrate to be coated with VO_2. With total gas-flow rates below 1.0 L min^{-1} the region of mixed phase V_2O_5/V_6O_{13} covered only 1–2 cm of the substrate at the inlet end of the reactor. In all cases the films covered the substrate entirely. The films formed were progressively thinner towards the exhaust end of the substrate suggesting that the film growth may be mass transport controlled. The thickness did not appear to be affected by the variations in temperature across the substrate precluding the kinetic growth mechanism.

The Raman spectra for the vanadium oxide films matched those reported by Barreca [11]. The XRD patterns match database patterns. The Raman spectrum for a vanadium(IV) oxide thin film prepared from $VOCl_3$ and water (Fig. 1(a)) shows bands at 193, 223, 309, 394, 499, 571 and 615 cm^{-1}. The positions of the bands are ±2 cm^{-1} of the bands for literature spectra of vanadium(IV) oxide [12–14].

The Raman spectrum (Fig. 1(b)) for a film prepared from $VOCl_3$ and water and determined by X-ray diffraction (Fig. 2) to be a mixed phase V_6O_{13}–V_2O_5 thin film shows bands at 106, 144, 166, 200, 269, 284, 297, 407, 489, 528, 700, 849, 880, 936, 994, and 1035 cm^{-1}. The bands at 106, 144, 200, 284, 407, 489, 528 and 994 cm^{-1} are the Raman bands of V_2O_5. The Raman spectra of V_2O_5 and V_6O_{13} have similar band positions [15] and overlap of bands will occur in a mixed phase situation. The band at 700 cm^{-1}, when compared to Fig. 1(c), appears to have a shoulder on the low wavenumber side. This is due to the band at 684 cm^{-1} for V_6O_{13}. The same situation occurs for the band at 407 cm^{-1}, with the V_6O_{13} band at 403 cm^{-1} causing broadening of the V_2O_5 band. All bands that show overlap of V_6O_{13} and V_2O_5 are labelled * in Fig. 1(b). The bands at 166, 849, 880, 936 and 1035 cm^{-1}, do not correspond to

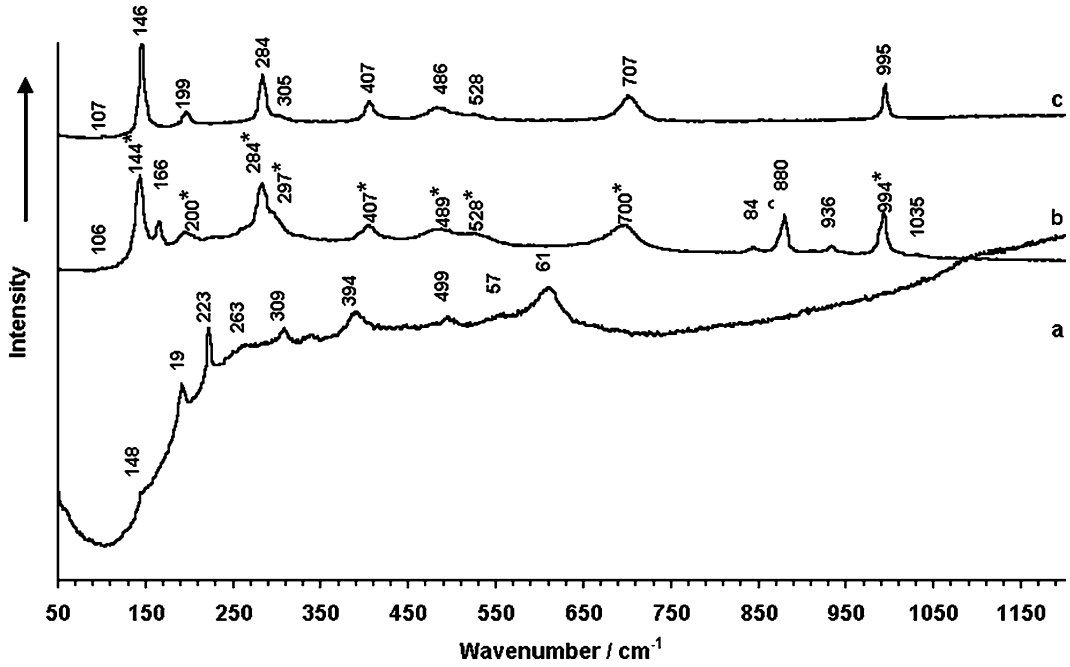

Fig. 1. Raman spectra of: (a) vanadium(IV) oxide; (b) mixed phase V_2O_5/V_6O_{13}; (c) V_2O_5 thin films from the APCVD reaction of $VOCl_3$ and H_2O.

V_6O_{13} or V_2O_5 and may be due to a phase of vanadium oxide not detected in the X-ray diffraction (XRD) pattern. These bands cannot be matched to any of the published Raman spectra for other vanadium oxides (VO_2 [16,14], V_2O_3 [17,18]) so are, at present unassigned.

The Raman spectrum for a vanadium(V) oxide thin film prepared from the APCVD reaction of $VOCl_3$ and water (Fig. 1(c)) show bands at 107, 146, 199, 284, 307, 407, 489, 531, 707 and 995 cm^{-1}, which are ± 2 cm^{-1} of the band positions of literature Raman spectrum for a thin film of vanadium(V) oxide [15].

From the XRD patterns Figs. 2–4, the films appeared to be quite crystalline. Fig. 2 shows the XRD pattern for a mixed phase, V_2O_5/V_6O_{13} film deposited at the leading edge of the substrate when a slight excess of water over $VOCl_3$ is used. Miller indices were assigned by comparison with literature patterns. A weak reflection at 27.8° due the (0 1 1) plane of monoclinic vanadium(IV) oxide is observed in the XRD pattern of the mixed phase deposit. As vanadium(IV) oxide is present further along the substrate, its presence in the partially reduced phase is not surprising.

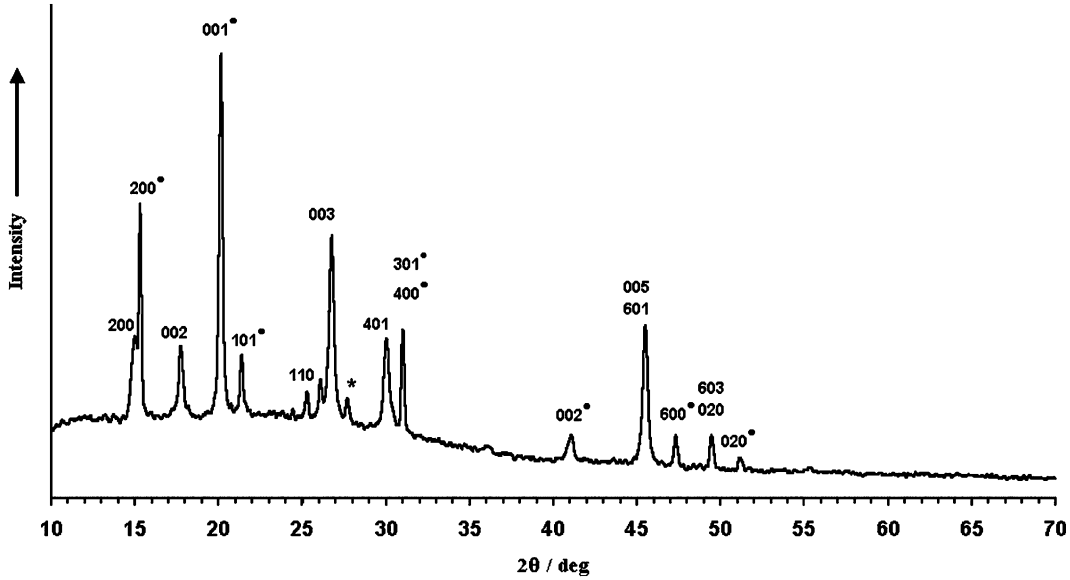

Fig. 2. X-ray diffraction pattern of mixed phase V_6O_{13}–V_2O_5 formed from the APCVD reaction of $VOCl_3$ and H_2O. Reflections marked • are V_2O_5, unmarked reflections are V_6O_{13}. Reflection marked * is assigned to the (0 1 1) reflection of monoclinic vanadium(IV) oxide.

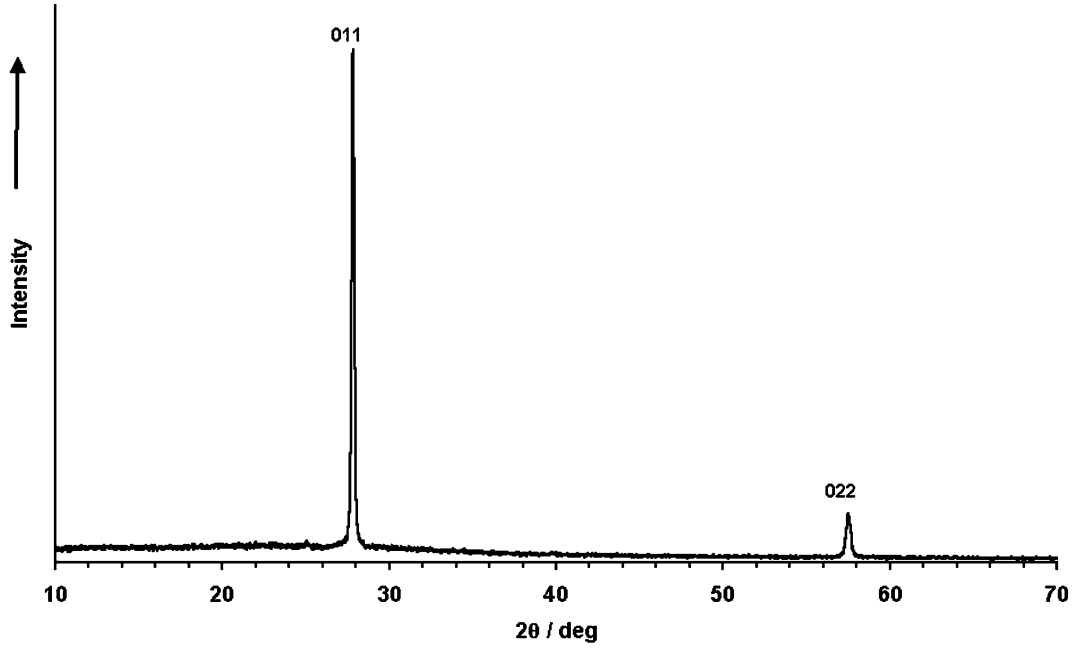

Fig. 3. X-ray diffraction pattern of yellow VO_2 area of film prepared from the APCVD reaction of $VOCl_3$ and H_2O (indexing from JCPDS file 43-0252).

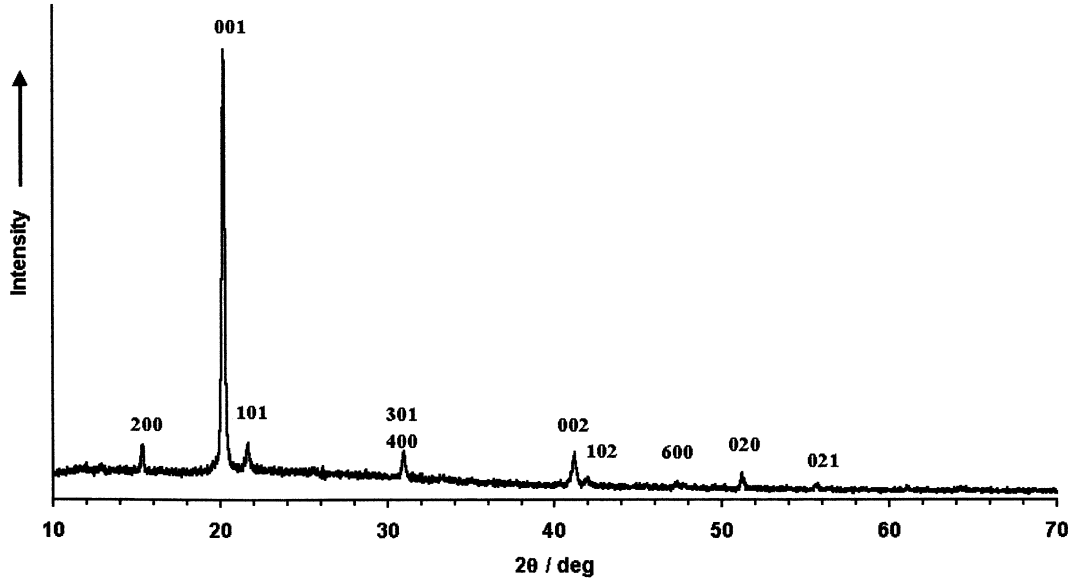

Fig. 4. X-ray diffraction pattern of V_2O_5 film prepared from the APCVD reaction $VOCl_3$ and H_2O.

The VO_2 films formed from $VOCl_3$ showed only one reflection at 27.8° corresponding to the (0 1 1) plane of the monoclinic phase, indicating that the films were potentially preferentially orientated on the substrate. Significantly no reflections due to other phases of vanadium oxide were observed, suggesting a single-phase material was deposited.

The films consisting of V_2O_5 showed no preferential orientation and could be indexed to an orthorhombic unit cell with cell parameters $a = 11.55(2)$ (Å), $b = 9.48(2)$ (Å) and $c = 4.94(2)$ (Å). The b and c cell parameters are slightly larger than those of the literature patterns and is probably due to the limited number of reflections observed in the thin film that incompletely represent the vanadium(V) oxide lattice.

The morphology of thin films of vanadium(IV) oxide grown from $VOCl_3$ and water is shown in Fig. 5. They show what appear to be 50-nm diameter rod-like particles and aggregates growing perpendicular to the substrate, which may account for the preferential orientation observed in the XRD pattern. Growth rates were typically 500 nm min^{-1} at a deposition temperature of 650 °C (as measured from side on SEM studies on glass 3 cm from the reactor inlet).

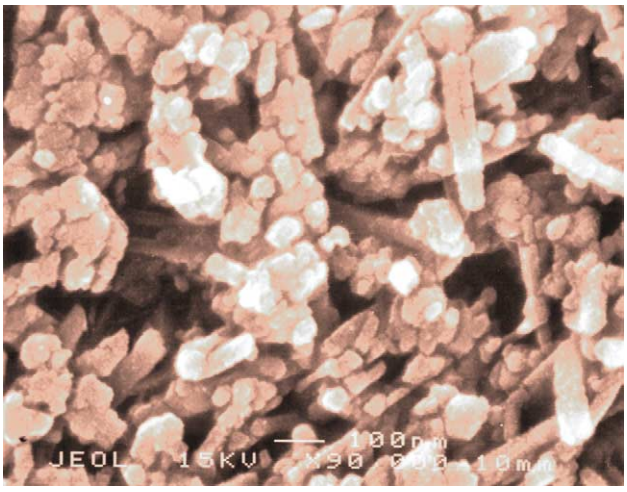

Fig. 5. SEM image of VO_2 thin film from the APCVD reaction of $VOCl_3$ and H_2O.

The films of VO_2 were all a dark yellow colour and could be scratched by a scalpel and removed by wiping with a tissue. Most films passed the Scotch tape test. All of the films were unaffected by organic solvents (toluene, propanone, IMS, dichloromethane) and water but were attacked by oxidising acids (2 mol dm^{-3} HNO_3) non-oxidising acids (2 mol dm^{-3} HCl) and alkali (2 mol dm^{-3} NaOH). The amphoteric nature of vanadium oxides is well known for the bulk materials [19]. The films displayed no significant hydrophilic effect, after 1 h of irradiation with a UV lamp (265 nm), the contact angle measurement for a water droplet of a VO_2 thin film prepared from $VOCl_3$ and water gave a contact angle of 62.8° and a V_2O_5 thin film prepared from VCl_4 and water gave a contact angle of 66.1°. A plain glass substrate gives a water contact angle of 70° indicating no significant hydrophilic effect compared to a plain glass substrate. None of the films displayed photocatalytic activity as shown by the stearic acid test.

In order to further elucidate the composition of the vanadium oxide films and to obtain an insight into the oxidation states of the ions present, a selection of the films were submitted to X-ray photoelectron spectroscopy (XPS) analysis. An analysis of the bulk of the film was obtained by argon ion etching. A broad range survey scan was used as a qualitative measure of the elements present in the film and high resolution scans of the characteristic regions of these elements were used for the quantitative analysis and peak fitting, to determine oxidation states.

For all vanadium oxide films, the elements present on the surface were determined to be V, O, C, Si and N. Nitrogen was a surface contaminant adsorbed from the atmosphere and the inert gas used to fill the sample entry air-lock to the ultra-high vacuum analysis chamber. Most of the contaminant is removed in the ultra-high vacuum but some may still remain due the particulate, high surface area morphology of the films. Carbon contamination can be attributed to atmospheric contamination also, but the major source is saturated hydrocarbons from the oil diffusion pumps in the analysis chamber [20]. The XPS signal due to surface carbon was used as a charge compensation reference peak when assigning binding energies to the regions of the XPS experiment. The surface contaminants could be removed by a single argon ion etching to reveal a clean film surface. The signal assigned to silicon was due to the glass substrate, the films contained a few pinhole defects exposing the glass substrate through the film. No chlorine contamination from the chloride precursors was detected by XPS in any of the vanadium oxide thin films.

Peak fitting analysis of the $V2p_{3/2}$ XPS peak of a thin film prepared from $VOCl_3$ and water (gas-phase molar ratio 1:3) and identified as vanadium(IV) oxide by Raman and XRD analysis, revealed that on the surface of the film some of the vanadium ions were V^{5+}, due to surface oxidation, with the majority present as V^{4+}. As the surface layers were etched and the bulk of the film exposed, the oxidation state of the vanadium ions was determined to be V^{4+} with a binding energy of 515.6 eV, as shown in Fig. 6, confirming the presence of vanadium(IV) oxide. The O1s XPS peak of this level could be deconvoluted to two components. The peak at 532.6 eV was assigned to residual surface contamination of carbon containing species, probably CO_2. The peak at 530.9 eV was assigned to the oxygen of vanadium(IV) oxide. The peak area ratio, corrected for elemental sensitivity factors to give atom% values, of the $V2p_{3/2}$ to O1s (O–V) peak was calculated to be 1.00:2.00, confirming the composition as VO_2. As the film was further etched away some V^{3+} became apparent with a lower $V2p_{3/2}$ binding energy of 515.0 eV, this is most likely due to the preferential removal of lighter elements, especially oxygen, during the sputtering process that will result in reduced forms of vanadium being present in the films.

For a vanadium(V) oxide film, prepared at 500 °C from $VOCl_3$ and water (gas-phase molar ratio 3.5:1), only V^{5+} ions were observed on the surface layer and in the bulk with a binding energy of 517.1 eV, with some reduced species after substantial etching due to preferential sputtering of oxygen. At the surface layers the O1s XPS peak could be deconvoluted to two peaks, one with a binding energy of 532.4 eV could be assigned to carbon containing species contaminating the surface, the second with a binding energy of 530.1 eV was assigned to the oxygen of V_2O_5. Corrected peak area ratios, giving atom% values, for the $V2p_{3/2}$ to O1s for V_2O_5 were 2.0:5.0 confirming the presence of vanadium(V) oxide. Again, this is the expected result and reinforces that the film is single phase V_2O_5.

X-ray photoelectron spectroscopy was also performed on a film at the leading edge of a substrate

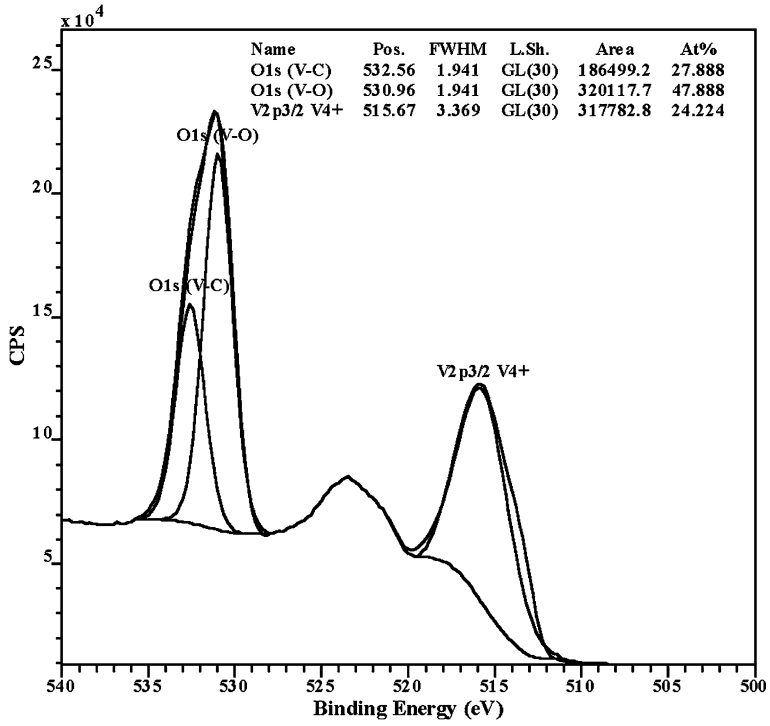

Fig. 6. Deconvoluted XPS spectrum of V2p–O1s region for vanadium(IV) oxide thin film prepared by the APCVD reaction of $VOCl_3$ and H_2O at 650 °C, molar ratio $VOCl_3$:H_2O 1:3.

prepared at 600 °C from $VOCl_3$ and water (gas-phase molar ratio 1:7) and determined to be mixed phase V_6O_{13}–V_2O_5 by Raman and XRD analysis. This film was established to consist of vanadium ions in both the +5 and +4 oxidation states. The V^{5+} XPS peak had a binding energy of 516.9 eV and the V^{4+} XPS peak had a binding energy of 515.5 eV. The O1s XPS peaks close to the surface of the film could be deconvoluted to two peaks. A peak with a binding energy of 532.4 could be assigned to residual carbon containing contaminants for example a carbonate. A second O1s peak with a binding energy of 530.4 eV could be assigned to oxygen bound to vanadium. This again is the expected result as V_2O_5 contains only V^{5+} and V_6O_{13} has V^{4+} and V^{5+} ions. From an analysis of the atom% ratios the V^{4+} and V^{5+} ions there the film consisted of approximately 25% V_6O_{13}. All binding energy assignments were matched to literature [21] and database [22] values.

2.2. Deposition onto silicon

As mentioned in the introduction, thin films of vanadium(IV) oxide have potential uses as infrared modulators in thermal imaging sensors and missile guidance systems. These applications require the deposition of vanadium(IV) oxide onto silicon wafers. Using silicon wafers supplied by Quinetiq, the deposition of vanadium(IV) oxide onto silicon was attempted. The starting point was the conditions found previously to prepare vanadium(IV) oxide on glass.

Raman analysis indicated that single phase vanadium(IV) oxide thin films were deposited at a substrate temperature of 650 and 600 °C (Fig. 7). Raman bands at 144, 191, 222, 260, 283, 307, 337, 388, 441, 499 and 614 cm^{-1} can all be assigned to vanadium(IV) oxide. The bands at 337 and 441 cm^{-1} were very weak in spectra from thin films of vanadium(IV) oxide on glass substrates and were not observed but are observed in spectra from single crystals [13,14,16] and are both assigned to B_g symmetry modes [13]. The band at 571 cm^{-1} is not obvious on the films deposited on silicon, this band not being always observed in spectra from single crystals [16]. This may indicate a more stoichiometric or crystalline phase being produced on the silicon substrates from the APCVD reaction of $VOCl_3$ and water. The ability to prepare vanadium(IV) oxide on silicon substrates is important as it opens up further applications for the APCVD of vanadium(IV) oxide thin films from halide based precursors.

The morphology of the vanadium oxide films deposited onto a silicon substrate (Fig. 8) is also distinct from that of films deposited onto glass. SEM shows that 500-nm long rod-like particles, with a diameter of 50 nm, are deposited above a layer of island growth. The particle appear randomly orientated on the substrate. The layer of island growth directly

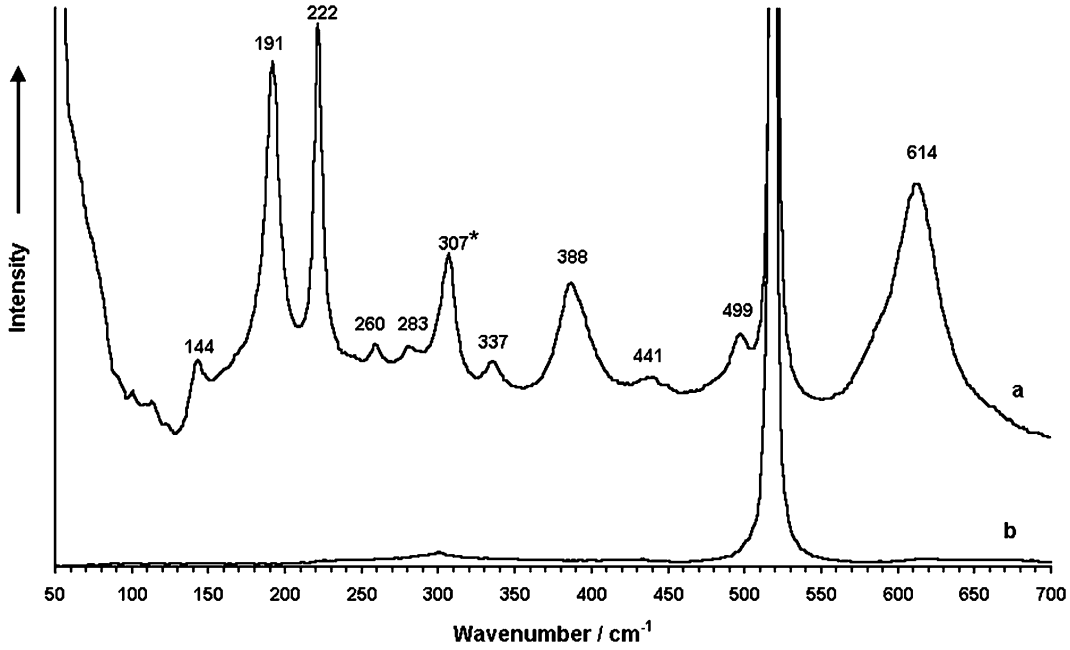

Fig. 7. Raman spectrum of: (a) vanadium(IV) oxide thin film on silicon from the APCVD reaction of $VOCl_3$ and H_2O at 650 °C, gas-phase molar ratio 2:1, (b) silicon substrate.

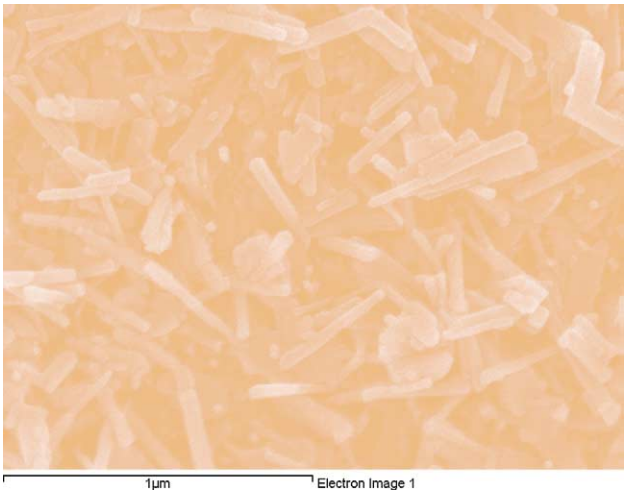

Fig. 8. SEM image of VO_2 thin film deposited on silicon from the APCVD reaction of $VOCl_3$ and H_2O at 650 °C with gas-phase molar ratio $VOCl_3$:H_2O of 2:1.

on the substrate shows particles of approximately 10 nm thickness.

The silicon and glass substrates showed a surprising difference in the morphology of the VO_2 produced. The glass substrate used had a SiO_2 barrier layer (50 nm). It is to be expected that as the Si wafer was not cleaned by any special technique it too would have a thin SiO_2 overlayer (ca. 2 nm). It is probable that the surface structure of the SiO_2 coated glass and wafer derived SiO_2 overlayer would be different – especially as they are formed at different temperatures and on different substrates. This probably accounts for the difference in VO_2 morphology.

2.3. Thermochromic properties of VO_2 thin films on glass substrates

The thermochromic properties of thin films of vanadium(IV) oxide were analysed by two methods, glancing angle XRD and IR transmittance spectroscopy.

The thermochromic transition was studied by glancing angle XRD at different temperature. The (0 1 1) reflection of the monoclinic phase transforming into the (1 1 0) reflection of the tetragonal phase is particularly easy to observe and the results of this study are shown in Fig. 9. The first order transition is well shown in this study, the monoclinic and tetragonal phases of VO_2 are both seen to be present as the transition occurs indicating that different regions undergo the transition at different times. This is a result of the energy involved in the transition being unable to be instantaneously transferred between the system and the environment so mixed-phase regimes are observed. The transition temperature (T_c) is shown to be where the intensities of the reflections for the monoclinic (0 1 1) plane and the tetragonal (1 1 0) plane are approximately equal. This occurs at a temperature of 67 °C on the heating cycle, which agrees with values reported in the literature for single crystals and thin films of pure vanadium(IV) oxide. On the cooling cycle the transition occurs at 54 °C, illustrating the broad hysteresis of the thermochromic transition of the thin films of vanadium(IV) oxide.

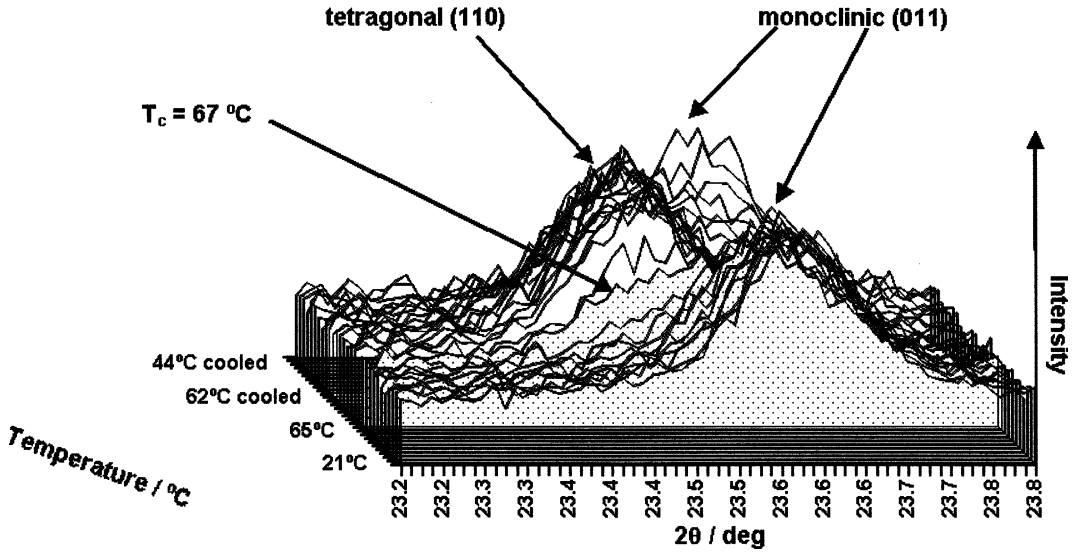

Fig. 9. XRD patterns at different temperatures of monoclinic (0 1 1) reflection to tetragonal (1 1 0) reflection for VO_2 thin film prepared from $VOCl_3$ and water.

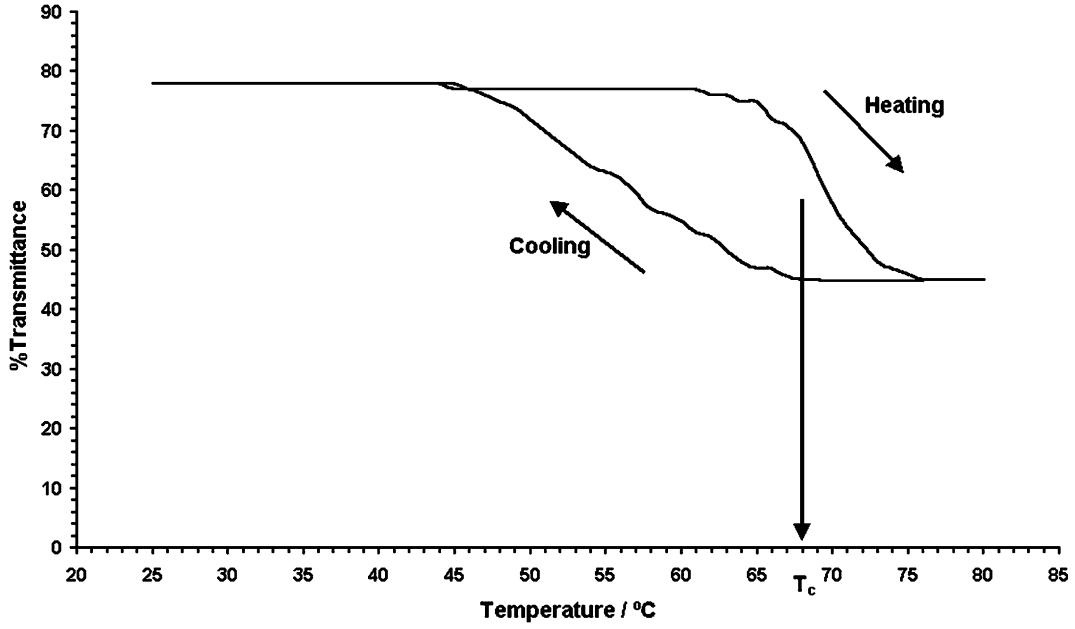

Fig. 10. Hysteresis curve of the IR transmittance at 2.5 μm for a VO_2 thin film on glass substrate.

The hysteresis curve of the transmittance, at 2.5 μm, of a vanadium(IV) oxide thin film is shown in Fig. 10. The optical contrast between the semiconducting and metallic states is particularly large at this wavelength, making its measurement easy and an indication of the effectiveness of the material as an intelligent window coating can be obtained.

The temperature at which the transition occurs on the heating cycle (67 °C) agrees with the result obtained from the XRD study. The hysteresis width is quite broad, which is often observed in thin films of VO_2 and is generally attributed to the polycrystalline nature of the films [23]. The transmittance of the semiconducting phase is 78% which drops to 45% when the temperature is increased to above the MST, this is comparable to the contrast obtained for PVD [23] and sol–gel [24] derived thin films of VO_2.

3. Conclusion

Different phases of vanadium oxide could be prepared from the dual source APCVD reaction of $VOCl_3$ and H_2O. On glass substrates, at reactor temperatures above 600 °C and an excess of water over $VOCl_3$, thermochromic thin films of vanadium(IV) oxide could be pre-

pared. The thin films of VO_2 showed a MST at 67 °C, typical of the material. Under the conditions for VO_2 production, small regions of a mixed phase of V_2O_5 and V_6O_{13} were also produced, the size of which could be controlled by total flow rates through the reactor. Reactor temperatures below 600 °C, or where an excess of $VOCl_3$ over H_2O, where used, V_2O_5 thin films were prepared.

4. Experimental

4.1. Film preparation

The APCVD experiments were performed on a custom built cold-wall apparatus using a previously described procedure [10]. Vanadium(V) oxytrichloride (95%,Strem, UK) was transferred to a bubbler and water was injected into the plain-line gas-flow using a fixed rate syringe driver (1.33 cm min^{-1}). Nitrogen (99.999%, BOC UK) was used as the system gas in all CVD reactions. The substrates were float glass that had a 50-nm thick SiO_2 barrier layer to stop diffusion of ions from the glass into the film (Pilkington Glass, UK), 15 cm × 4.5 cm × 0.3 cm, or 2″silicon wafers broken in half and mounted onto a large glass slide for easy extraction from the CVD reactor.

The substrates were cleaned before use by wiping with a water-soaked tissue and then a propan-2-ol soaked tissue and then rinsed with propan-2-ol. The substrates were allowed to dry in air prior to mounting in the CVD chamber.

A series of films were prepared in which the effect of substrate temperature and gas-phase precursor ratio was investigated. Deposition times were kept constant at one minute per run.

4.2. Film analysis

Analysis of the resulting thin films consisted of XRD, XPS, Raman spectroscopy and scanning electron microscopy with energy dispersive analysis of X-rays (SEM/EDX). X-ray analysis of the films was determined on a Siemens D5000 machine using primary Cu Kα radiation at 1.5418 (Å) in $\theta 2\theta$ mode. Diffraction patterns at different temperatures were obtained at station 2.3 of the CCLRC synchrotron radiation source at Daresbury, UK using 1.2981 (Å) radiation with a 1.5° incident angle. The temperature was controlled using an aluminium temperature cell controlled by *RS* resistive heaters, Eurotherm temperature controllers and k-type thermocouples was used to manipulate sample temperature. Sample temperature was measured by a k-type thermocouple taped to the film surface. X-ray photoelectron spectrometry was performed on a VG ESCALAB 2201 XL instrument using monochromatic Al Kα X-rays with a pass energy of 50 eV. XPS data was analyzed using CasaXPS software version 2.0.11. Raman spectroscopy was performed on a Renishaw 1000 spectrometer using a 632.8-nm laser at 2 mW and 50× magnification, sample temperature was controlled by a Linkam THMS600 variable temperature cell with a liquid nitrogen pump. SEM images to determine film thickness were obtained on a Hitachi S-570 scanning electron microscope at 20 kV accelerating voltage. Samples were prepared by deeply scoring the film side of the substrate to cause shelling of the film and hence a distinct edge between the film and substrate. EDX was performed on a Philips XL30 ESEM instrument using Inca analytical software (Oxford Instruments).

evidence that oxophilic uranium can bond to weakly coordinating O-donor anions.

Our attention has now turned to the tetrafluoroborate anion. Coordination of $[BF_4]^-$ to a metal centre is unusual, and the vast majority of these are d-block metal complexes (mainly Cu and Ag) [9]. There is only one crystallographically characterised example of tetrafluoroborate coordinating to an f-block element; $[\{U(\eta^5\text{-}C_5H_3(SiMe_3)_2)_2(\mu\text{-}BF_4)(\mu\text{-}F)\}_2]$ [10], in which two fluorides and two tetrafluoroborate anions bridge two U(IV) centres. $[BF_4]^-$ groups are more commonly used as counter-ions, but despite there being several hundred structurally characterised (mainly d-block) examples listed in the Cambridge Structural Database (CSD) [9], only two of these are actinide complexes; the monomeric, equatorially 5-coordinate uranyl compounds, $[UO_2(dmso)_5][BF_4]_2$ [11] and $[UO_2(dmf)_5][BF_4]_2$ [12].

We report our success in preparing a number of novel complexes from an investigation of $\{UO_2\}^{2+}/[BF_4^-]$/phosphide oxide reaction systems, with triphenylphosphine oxide (TPPO), tri-*n*-butylphosphine oxide (TBPO) or bis(diphenylphosphine oxide)methane ($DPPMO_2$) as organic ligands. However, in no case have we been able to isolate crystalline samples containing $[BF_4]^-$ coordinated directly to $\{UO_2\}^{2+}$, with instead fluoride abstraction by the fluorophilic actinyl dication dominating reactivity.

2. Experimental

Caution. Both natural and depleted uranium were used during the course of these experiments. Uranium is a toxic metal and both ^{235}U and ^{238}U are radioactive isotopes. Good laboratory practices should be employed when working with any uranic material.

2.1. Materials and measurements

UO_3 was obtained from the radiochemical stocks at The Centre for Radiochemistry Research at the University of Manchester. All other chemicals were purchased from standard chemical suppliers. A Carlo Erba Instruments CHNS-O EA1108 Elemental Analyser was used for C, H and N analysis. All metal analysis was measured on a Fisons Horizon Elemental Analysis ICP-OED spectrometer. IR data were collected on a Bruker Equinox 55 spectrometer using a "Golden Gate" ATR (attenuated total reflectance) attachment in the mid – (4000–760 cm^{-1}) and far – (400–240 cm^{-1}) IR regions. A Bruker FRA 106/S Raman instrument with a Coherent laser (1064 nm, 500 mW) was used to collect the Raman scattering from solid samples held in the laser beam path. Solid state diffuse reflectance spectra were recorded on an Ocean Optics SD2000 spectrometer with a fibre optic probe using a deuterium–halogen DH-200 light source over the range 200–1000 nm. $BaSO_4$ was used as a reference.

2.2. Synthesis of $[\{UO_2(\mu\text{-}F)(TPPO)_3\}_2][BF_4]_2$ (**1**)

A solution of TPPO (1.05 mmol, 0.292 g) in hexane (1.5 cm^3) was carefully layered on the surface of a solution containing a stoichiometric amount of UO_3 (0.35 mmol, 0.10 g) dissolved in HBF_4 (0.70 mmol, 0.089 cm^3) and H_2O (1.5 cm^3). Yellow plate crystals formed after two weeks, during which time the solution was kept away from direct sunlight. The crystals were collected and dried in air. Yield: 0.30 g, 70%. (Elemental *Anal*. Calc. for $C_{108}H_{90}O_{10}P_6B_2F_{10}U_2$: C, 53.55; H, 3.72; P, 7.69; B, 0.91; F, 7.85; U, 19.67. Found: C, 53.55; H, 3.74; P, 7.62; B, 1.04; F, 7.31; U, 19.28%).

2.3. Synthesis of $[\{UO_2(\mu\text{-}F)(TBPO)_3\}_2][BF_4]_2$ (**2**)

A solution of TBPO (2.10 mmol, 0.457 g) in hexane (2 cm^3) was added to a solution containing a stoichiometric amount of UO_3 (0.70 mmol, 0.20 g) dissolved in HBF_4 (1.40 mmol, 0.246 cm^3). The resulting sticky yellow precipitate was dissolved in EtOH (5 cm^3) and left to evaporate in air, away from direct sunlight. Irregular yellow crystals coated in a thin layer of viscous oil formed after two weeks. Only a small number of crystals were suitable for single crystal X-ray diffraction and these were removed and dried in air. Yield: 0.02 g, 3%. There was insufficient product to perform elemental analysis.

2.4. Synthesis of $[UO_2(\mu\text{-}F)(F)(DPPMO_2)]_2$ (**3**)

UO_3 (0.35 mmol, 0.10 g) was dissolved in HBF_4 (0.70 mmol, 0.089 cm^3) and evaporated to dryness to produce a yellow solid that was dried in a desiccator. This solid was dissolved in MeOH (4 cm^3) and added to a stirred solution of $DPPMO_2$ (0.70 mmol, 0.291 g) in MeOH (4 cm^3). The solution was left to evaporate in air, away from direct sunlight. Yellow plate crystals formed after 1 week and were collected by filtration and dried in air. Yield: 0.20 g, 80%. (Elemental *Anal*. Calc. for $C_{50}H_{44}O_8P_4F_4U_2$: C, 41.45; H, 3.06; P, 8.55; F, 5.25; U, 32.86. Found: C, 41.98; H, 3.34; P, 8.14; F, 4.92; U, 32.40%).

2.5. X-ray crystallographic analysis

Compound **1** was measured on a Rigaku RAXIS diffractometer at 293 K. Diffraction data for **2** and **3** were measured on a Bruker APEX SMART platform CCD at 100 K. All three structures were solved by direct methods using SIR92 [13] (**1**), SHELXL97[14] (**1**–**3**) and SHELXTL [15] (**2** and **3**). The cell parameters were refined by full-matrix least squares. All non-hydrogen atoms were refined anisotropically, while hydrogen atoms were in-

cluded in calculated positions. Details of the crystal data and refinement for these compounds are collected in Table 1.

As stated previously, the data for **1** were collected using the RAXIS diffractometer, which allows phi rotation only. Although 330° of data were collected, because of the low symmetry of the crystal, only about two-thirds of the data were accessible for recording, the remainder occurring in the blind region.

3. Results and discussion

3.1. Crystallographic characterisation

$[\{UO_2(\mu\text{-}F)(TPPO)_3\}_2][BF_4]_2$ (**1**) is a cationic uranyl complex. The pentagonal bipyramidal uranyl groups are bridged by a pair of μ_2-F anions in a centrosymmetric dimer. The coordination of each U centre is completed by three TPPO groups in the equatorial plane. Two non-coordinating $[BF_4]^-$ anions are present to balance the charge. The structure is shown in Fig. 1 with bond distances and angles given in Table 2. The mean $U–O_{(TPPO)}$ bond length (2.375 Å) compares well with the $U–O_{(eq)}$ distance (2.37(9) Å) quoted by Burns et al. [16], and is similar to the average distances found in the dimeric peroxo-bridged compounds $[\{(UO_2)(TPPO)_3\}_2(\mu\text{-}O_2)][ReO_4]_2$ [7] (2.367 Å) and $[\{(UO_2)(TPPO)_3\}_2(\mu\text{-}O_2)][ClO_4]_2$ [17] (2.368 Å). The difluoride bridge is effectively symmetrical (U–F bond lengths are 2.331(5) and 2.345(5) Å, respectively and F1–U1–F1* is 62.77(16)°), with similar bond lengths and angles being found in the related bridging difluoride compounds $[UO_2(\mu\text{-}F)(F)\{CO(NH_2)_2\}_2]_2$ [18] (2.36(2) and 2.39(2) Å; 65.3(7)°) and *catena*-$[UO_2(\mu\text{-}F_2)(dmso)]$ [19] (2.31(1) and 2.34(1) Å; 65.4(4)°). The uncoordinated tetrafluoroborate is slightly distorted away from tetrahedral geometry, perhaps by anion-cation interactions. This distortion is comparable to that found for uncoordinated $[BF_4]^-$ in both $[UO_2(C_2H_6OS)_5][BF_4]_2$ [11] and $[UO_2(C_3H_7NO)_5][BF_4]_2$ [12]. The uranyl ion is essentially linear (179.8(2)°), unlike analogous bridging peroxo complexes [7,17]. A solid state packing diagram (Supporting data) reveals that the hydrophilic uranyl

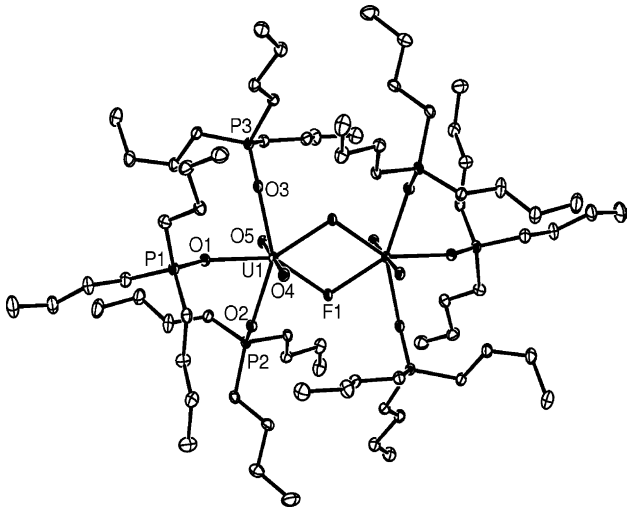

Fig. 2. Molecular structure of [{UO_2(μ-F)$(TBPO)_3$}$_2$][BF_4]$_2$ (**2**). Probability ellipsoids of 30% are shown.

moieties are partially surrounded by their organic ligands while two $[BF_4]^-$ anions lie against the outside of this hydrophobic TPPO "shell". The stacking of molecules on top of one another in a zig–zag arrangement allows TPPO groups to help to complete the hydrophobic "shells" of adjacent molecules. Hydrophilic $[BF_4]^-$ anions in the lattice are encapsulated by the TPPO groups of the cation, and those from neighbouring molecules. The lattice appears to be held together by strong interatomic interactions between F-atoms on the $[BF_4]^-$ groups and H-atoms from TPPO groups on neighbouring molecules, which have F–H distances of 2.158(7) Å at the closest point.

[{UO_2(μ-F)$(TBPO)_3$}$_2$][BF_4] (**2**) is a cationic uranyl complex of similar structural type to **1**, although the TPPO ligands are replaced by three monodentate TBPO ligands in the equatorial coordination sphere of $\{UO_2\}^{2+}$. The structure is shown in Fig. 2 with bond distances and angles given in Table 3. The equatorial plane of each U centre accommodates 2 long (2.375(3) and (2.369(3) Å) and 1 short (2.352(3) Å) U–$O_{(TBPO)}$ bonds, only the shortest bond being comparable to that in *trans*-[$UO_2(NO_3)_2(TBPO)_2$] [20] (2.347(6) Å). The three U–O–P bond angles are all different and are less obtuse (130.97(19)°, 140.16(18)° and 145.14(19)°) compared to those in [$UO_2(NO_3)_2(TBPO)_2$] [20] (average 146.0(5)°). The unsymmetrical difluoride bridge contains two different U–F bond lengths (2.329(2) and 2.340(2) Å), the average being comparable to bond distances found in **1**, [UO_2(μ-F)(F){$CO(NH_2)_2$}$_2$]$_2$ [18] (2.36(2) and 2.39(2) Å) and *catena*-[UO_2(μ-F_2)(dmso)] [19] (2.31(1) and 2.34(1) Å). The F1–U1–F1* angle of 64.01(10)° is within the range previously observed in **1** and related compounds [18,19] (62.77(16)°–65.4(4)°). The uncoordinated $[BF_4]^-$ is slightly distorted away from tetrahedral geometry with F–B–F bond angles of 108.4(5)°–111.8(5)°, although the B–F bond lengths are all the same within error (average 1.368 Å), and are similar to those in **1** (average 1.359 Å) and [$UO_2(C_2H_6OS)_5$][$(BF_4)_2$] [11] (averages 1.35 and 1.37 Å). Molecules pack in a zig–zag arrangement, similar to **1**, allowing TBPO groups to form a hydrophobic "shell" around the hydrophilic uranyl groups. We believe that strong interactions between the F-atoms of $[BF_4]^-$ and H-atoms of neighbouring TBPO groups (2.366(4) Å at the closest point) hold the lattice together, a situation similar to that in **1**.

[UO_2(μ-F)(F)$(DPPMO_2)$]$_2$ (**3**) is a neutral uranyl complex with some structural similarities to **1** and **2**. As with compounds **1** and **2**, two pentagonal bipyrami-

dal uranyl groups are bridged by a pair of μ_2-F anions in a centrosymmetric dimer. However, in **3**, equatorial coordination at each U centre is completed by a bidentate $DPPMO_2$ ligand and a monodentate F anion, whereas in **1** and **2**, equatorial coordination is completed by 3 monodentate P=O donor ligands yielding cationic complexes. There are two identical complexes in the unit cell accompanied by four molecules of MeOH remote from the U coordination spheres. The structure is shown in Fig. 3 with bond distances and angles given in Table 4. Three $\{UO_2\}^{2+}$ complexes with chelating $DPPMO_2$ have been previously structurally characterised, $[UO_2(Cl)(DPPMO_2)_2]$ and $[UO_2(ReO_4)(DPPMO_2)_2]$ [5] as well as $[UO_2(NO_3)_2(DPPMO_2)]$ [21].

Unlike $[UO_2(ReO_4)(DPPMO_2)_2[ReO_4]$ [5] and the related Fe and Ni d-transition metal complexes [22,23], **3** has two similar U–$O_{(DPPMO2)}$ bond distances (2.417(3) and 2.420(2) Å). Symmetrical $DPPMO_2$ groups are not uncommon, and are observed in $[TlCl_2(DPPMO_2)_2][TlCl_4] \cdot 2thf$ [24] (2.321(13) and 2.355(14) Å) and $[Na(DPPMO_2)_3]Cl \cdot 2H_2O \cdot C_6H_6$ [25] (2.4566(14) Å) as well as in $[UO_2(NO_3)_2(DPPMO_2)]$ [21] (2.370(9) and 2.407(10) Å). The U–$O_{(DPPMO2)}$ bonds are long in comparison to those in $[UO_2(ReO_4)(DPPMO_2)_2[ReO_4]$ (average 2.386 Å), but comparable to the U–$O_{(DPPMO2)}$ bonds in $[UO_2(NO_3)_2(DPPMO_2)]$ [21]. The bite angle of the $DPPMO_2$ ligand is fairly normal (71.55(8)°) and comparable to the $DPPMO_2$ bite angles in $[UO_2(ReO_4)(DPPMO_2)_2[ReO_4]$ (73.1(2)° and 72.9(2)°) [5] and bite angle in $[UO_2(NO_3)_2(DPPMO_2)]$ (71.5(4)°) [21]. The fluoride bridge is effectively symmetrical and has bond lengths (average 2.322 Å) and an F1–U1–F1* angle (65.69(9)°) similar to those found in **1**, **2** and related uranyl difluoride-bridged compounds [18,19]. The terminal fluorine atom has a U1–F2 bond distance of 2.199(2) Å, which is comparable to terminal F-atoms in $[UO_2(\mu\text{-}F)(F)\{CO(NH_2)_2\}_2]_2$ [18] (2.23(2) Å) and $[U_2O_4F_6(C_4N_2H_{12})]$ [26] (2.196(8) Å). The mean U=O distance is 1.772 Å, similar to the mean distances found in **1** and **2** (1.768 and 1.770 Å). The uranyl bond angle (178.50(12)°) is within the range expected [16], but is significantly more bent than the essentially linear $\{UO_2\}^{2+}$ in **1** and **2** (179.8(2)° and 179.51(15)°). The solid state packing of the molecule appears to be heavily influenced by F–H interatomic interactions. The $DPPMO_2$ groups are not large enough to encapsulate much of the diuranyl core of the molecule, but a zig–zag packing arrangement exists in a situation similar to that in **1** and **2**. Intermolecular interactions between H-atoms of neighbouring organic ligands and terminal F-atoms (closest separation = 2.292(2) Å) aid the formation of a hydrophobic "shell" around the diuranyl centre, which also incorporates MeOH solvent molecules in the lattice and $DPPMO_2$ groups from neighbouring molecules.

ν(U–F)$_{(terminal)}$	IR	x	x	381 m
ν(P=O)$_{(coord)}$	IR	1072 sh	1080 s	1100 m

Notes: 'x', not applicable; '–', not observed; 's', strong; 'm', medium; 'w', weak; 'sh', shoulder; 'v', very.

the mid-IR spectra was recorded. Table 5 lists selected IR and Raman vibrations for **1**–**3** with the spectra and the remaining P=O donor ligand bands given in the Supporting data. Bands could be assigned to coordinated P=O (shifting to lower energy on coordination by 118, 75 and 86 cm^{-1}, respectively, for **1**–**3**) and U=O [27], B–F [28] and U–F [29] vibrations. Due at least in part to overlapping P=O donor ligand vibrations identifying bands to $[BF_4]^-$ vibrations proved challenging. The presence of formally IR inactive B–F stretches for unccordinated $[BF_4]^-$ (principally ν_1) in the IR spectra of **1** and **3** can probably be attributed to distortion in the T_d geometry of uncoordinated anion, as discussed previously. Tomlinson et al. [30] have cautioned against the use of IR spectroscopy for the determination of coordinated versus uncoordinated tetrafluoroborate. Diffuse reflectance visible spectra for **1** and **3** display the fine structure typical of the uranyl ion (see Supporting data) [1].

3.3. Summary

Three novel, equatorially 5-coordinate uranyl complexes have been structurally and spectroscopically characterised. Two of these (**1** and **2**) have very similar structures; dimeric uranyl groups bridged by a pair of μ_2-F anions, 3 monomeric phosphine oxide ligands coordinated to each U(VI) centre, and 2 tetrafluoroborate groups remote from the U coordination sphere balancing the charge. Compound **3** is also a U(VI) dimer, bridged by a pair of μ_2-F anions, but the equatorial coordination sphere of each U centre is completed by a bidentate phosphine oxide ligand, and a monodentate F^- anion, which balances the charge. The elemental analysis and supporting spectroscopic data are consistent with the single crystal X-ray structural characterisations.

The syntheses of compounds **1** and **2** were similar, in that the phosphine oxide was added to a solution of UO_3 dissolved in HBF_4, from which crystalline material was isolated. Compound **3** was synthesised by reacting the phosphine oxide with a dried yellow solid (prepared from the dissolution of UO_3 in HBF_4) in MeOH. The fluorophilicity of uranium is well known [1], and the bond dissociation energies of U–F and B–F bonds (at 298 K) are close enough (659 and 757 kJ mol^{-1}, respectively [31]) to assume that under these reaction conditions, the affinity of U for F is sufficient to break B–F bonds. The propensity of fluorine to bridge between metal centres is well known [18,19,26], and allows the 3 complexes to achieve an equatorially 5-coordinate geometry around the U(VI) centre. It is, however, interesting to note that both $[UO_2(dmso)_5][BF_4]_2$ [11] and $[UO_2(dmf)_5][BF_4]_2$ [12] were obtained as single crystals suitable for X-ray diffraction from aqueous dmso or aqueous dmf respective, following addition of HBF_4 to UO_3. In contrast, **1**–**3** were obtained as bulk crystalline samples from aqueous hexane and neat ethanol and methanol solutions, respectively.

4. Conclusions

Our attempts to prepare $\{UO_2\}^{2+}$ complexes with coordinated $[BF_4]^-$ through similar synthetic strategies to those employed for the synthesis of complexes with $\{UO_2\}^{2+}/[ReO_4]^-/P{=}O$ donor ligand have proved unsuccessful. In each case the fluorophilicity of $\{UO_2\}^{2+}$ has led to fluorine abstraction from $[BF_4]^-$ and the resultant formation of dimeric complexes with bridging fluorides. In the case of **1** and **2** the +2 charge on the cationic complexes is balanced by two $[BF_4]^-$ counter anions, which do not displace P=O donor ligand (TPPO and TBPO, respectively) coordinated to the uranyl centres. In **3**, additional terminal fluoride coordination results in the formation of a neutral complex. Clearly any further attempts to coordinate $\{UO_2\}^{2+}$ to $[BF_4]^-$ would require a different synthetic approach.

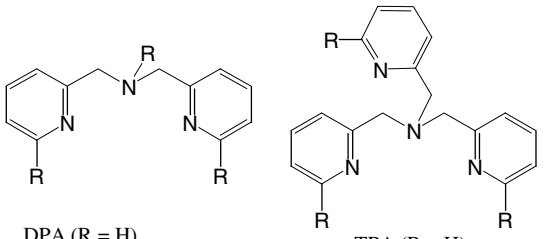

Fig. 1. DPA and TPA ligands and their derivatives.

2. Results and discussion

2.1. Reaction of MCl_2 with TPA

Treatment of anhydrous MCl_2 with one equivalent of TPA in *n*-BuOH at 90 °C afforded [(TPA)MCl_2] (M = Co (**1**), Fe (**2**)) and [(TPA)CoCl]Cl (**3**) in good yield (Scheme 1). All products have been characterised by FAB mass spectrometry, magnetic susceptibility and by elemental analysis (see Table 1). In addition, crystals of **1**–**3** have been subject to single-crystal X-ray diffraction studies.

Crystals of **1** and **2** · MeCN were grown by the slow cooling of a hot acetonitrile solution of each complex. The structures are similar and will be discussed together. The molecular structure of **1** is shown in Fig. 2; selected bond distances and angles are listed for both **1** and **2** · MeCN in Table 2. The discrete molecules consist of a single metal(II) centre bound by a TPA ligand coordinated in a tripodal, tetradentate fashion, with the two other coordination sites filled by terminally bound chloride ligands. The metal centres in each complex adopt an approximately octahedral geometry with Cl(1) *trans* to the tertiary amine [N(1)] and Cl(2) *trans* to one of the pyridine moieties. The angles between Cl(1) and its *cis*-neighbours are significantly larger than 90° [Cl(1)–M(1)–Cl(2) 96.579(17)° (**1**), 97.86(3)° (**2**); Cl(1)–M(1)–N(2) 101.86(4)° (**1**), 102.18(5)° (**2**); Cl(1)–M(1)–N(3) 102.65(4)° (**1**), 107.20(5)° (**2**); Cl(1)–M(1)–N(4) 93.86(4)° (**1**), 93.80(5)° (**2**)]. The metal nitrogen distances range from 2.1205(15) to 2.2191(14) Å in **1** and 2.1885(17)–2.2841(18) Å in **2**, with the tertiary amine nitrogen–metal distance [N(1)–M(1) 2.2191(14) Å (**1**), 2.2841(18) Å (**2**)] the most elongated in each case. Amongst the three M–N(pyridyl) distances, the pyridine group *trans* to Cl(2) has the longest distance [M(1)–N(4) 2.1691(15) (**1**), 2.2162(17) (**2**) *vs.* M(1)–N(3) 2.1205(15) (**1**), 2.1885(17) (**2**) and M(1)–N(2) 2.1363(14) (**1**), 2.1912(17) (**2**) Å], presumably as a consequence of the *trans* effect of the chloride. Notably, in the non-solvated form of **2**, the *trans* effect of the chloride leads to Fe–

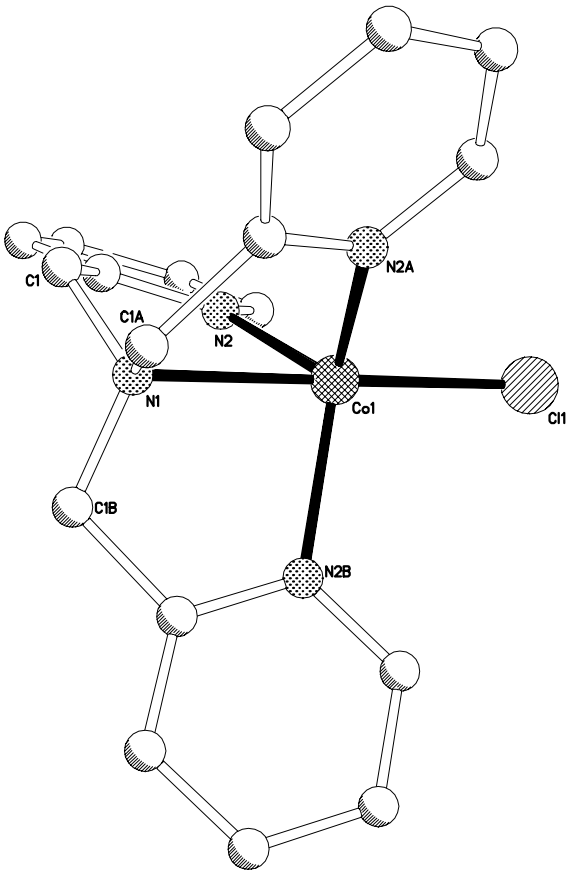

Fig. 3. Molecular structure of the cationic unit in **3** including the atom numbering scheme. All the hydrogen atoms have been omitted for clarity. N(1), Co(1) and Cl(1) are located on a 3-fold axis; N2A, N2B are generated by the symmetry operations (+*z*, +*x*, +*y* and +*y*, +*z*, +*x*).

Crystals of **3** were grown by the slow cooling of a hot acetonitrile solution containing the complex. The molecular structure of **3** is shown in Fig. 3; selected bond distances and angles are given in Table 3. The structure reveals **3** to be composed of a discrete cationic unit along with a chloride counterion. The cationic unit displays a distorted trigonal bipyramidal geometry for the Co(II) ion with the three pyridyl groups in the equatorial plane [N(2)–Co(1)–N(2A) 115.23(2)°] and the amine and the chloride ligands in the apical positions. As with **1**, the tertiary amine nitrogen–metal distance [N(1)–Co(1) 2.2122(18) Å] is

Table 3
Selected bond distances (Å) and angles (°) for **3**

Bond distances	
Co(1)–N(1)	2.2122(18)
Co(1)–N(2)	2.0649(11)
Co(1)–Cl(1)	2.2759(6)
Bond angles	
N(1)–Co(1)–N(2)	77.19(3)
N(2)–Co(1)–N(2A)	115.23(2)
N(2)–Co(1)–Cl(1)	102.81(3)

the most elongated, while the M–N(pyridyl) distances, as a result of the threefold symmetry axis, are all identical [Co(1)–N(2) 2.0649(11) Å]. The cationic unit in **1** resembles closely the five coordinate geometries found in the independent cations in $[(TPA)CoCl]_2[CoCl_4]$ (**4**) and, indeed, the Co–ligand distances are identical within experimental error [10].

The formation of **4** as the sole product from the reaction of cobalt dichloride with one equivalent of TPA in methanol or ethanol at room temperature has been previously reported [9,10]. It is unclear as to the reason why only **1** and **3** are generated when the reaction is performed with equimolar quantities of reagents in *n*-BuOH. Notably, if the reaction is carried out with an excess of $CoCl_2$ in *n*-BuOH, **4** can be isolated in high yield (Scheme 1).

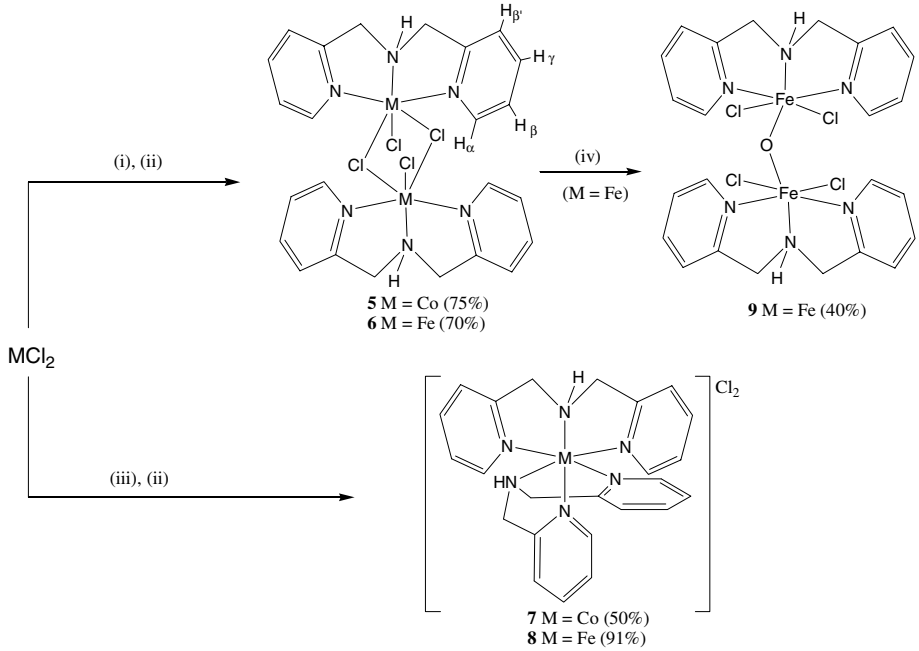
The Fe and Co complexes exhibit different electronic environments. All of the complexes are paramagnetic with the Fe(II) complex (**2**) affording a magnetic moment of 4.8 BM, consistent with four unpaired electrons ($S = 2$), while the Co(II) complexes (**1**, **3** and **4**) have moments ca. 4.1 BM consistent with three unpaired electrons ($S = 3/2$) (Table 1).

The paramagnetic behaviour of **1**–**4** in the solid state is also observed in solution (acetonitrile-d_3) with broad paramagnetically shifted peaks. The spectrum of **2** · MeCN is as described by Mandon et al. [8] for the non-solvated form. Equally, the spectrum for **4** is in agreement with that previously reported [10] and, interestingly, essentially identical to that for six-coordinate **1** and five-coordinate **3** (see Section 4). It would seem therefore likely that **1** in solution can readily undergo chloride dissociation to give **3**.

2.2. Reaction of MCl_2 with DPA

The reaction of DPA was found to be highly dependent on the stoichiometry of the starting materials. Thus, addition of one equivalent of DPA to a solution of MCl_2 in *n*-BuOH at 90 °C gave, on crystallisation from hot acetonitrile, $[(fac\text{-DPA})MCl(\mu\text{-}Cl)]_2$ (M = Co (**5**), Fe (**6**)) in good yield. On the other hand, introduction of two equivalents of DPA gave, following crystallisation, the bis(ligand) complexes $[(fac\text{-DPA})_2M]Cl_2$ (M = Co (**7**), Fe (**8**)) (Scheme 2). Needless to say, mixtures of **5** and **7** or **6** and **8** were obtained when 1.5 equivalents of DPA was employed. X-ray diffraction studies have been performed on **6**–**8**.

Single crystals of $\mathbf{6} \cdot 1\frac{2}{3}CH_2Cl_2$ suitable for the study were grown by the prolonged standing of a solution of the complex in dichloromethane. The molecular structure of **6** is shown in Fig. 4; selected bond distances and angles are listed in Table 4. The structure consists of a dimeric unit in which the iron centres are bridged by two chloride ligands and bound terminally by a chloride and a DPA ligand to give a distorted octahedral geometry at each metal centre. The DPA ligands adopt *facial* bonding modes such that the central amines are *trans* to a terminal chloride and the pyridyl groups *trans* to the bridging chlorides. At each metal centre the pyridyl nitrogen–iron distances [Fe(1)–N(1) 2.174(3), Fe(1)–N(2) 2.181(3) and Fe(2)–N(4) 2.143(3) Å, Fe(2)–N(5) 2.167(3) Å] are marginally shorter than the corresponding iron–secondary amine distances [Fe(1)–N(1) 2.185(2), Fe(2)–N(6) 2.175(3) Å], but not as significantly as that observed in $[(N\text{-Et-DPA})FeCl(\mu\text{-}Cl)]_2$ [11]. The Fe–μ-Cl distances are similar [2.501(1), 2.499(1),



Scheme 2. Reagents and conditions: (i) DPA, *n*-BuOH, 90 °C; (ii) MeCN; (iii) 2 DPA, *n*-BuOH, 90 °C; (iv) air, MeCN.

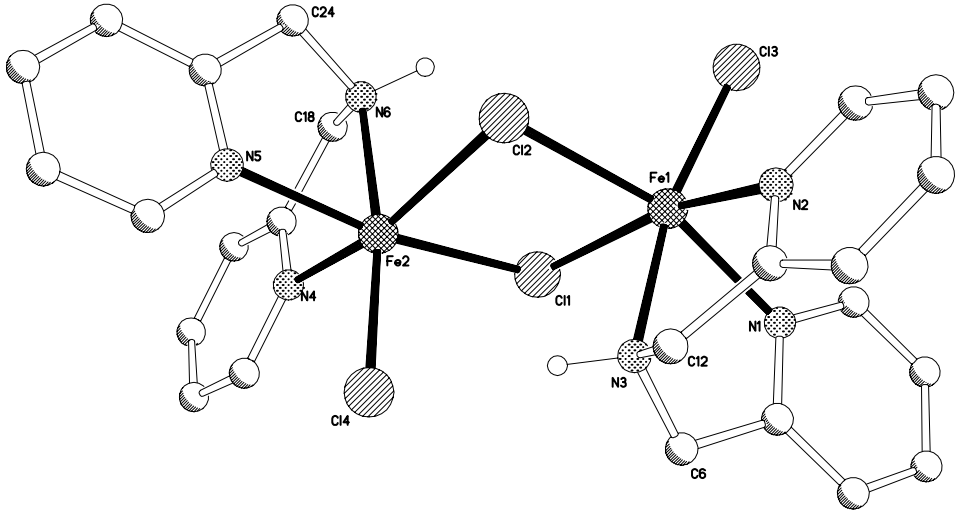


Fig. 4. Molecular structure of **6** including the atom numbering scheme. All hydrogen atoms except for H3 and H6 have been omitted for clarity.

2.500(1), 2.490(1) Å] and fall at the top end of the range found for related complexes [11,13–16]. As expected, the Fe–Cl(terminal) bond distances [Fe(1)–Cl(3) 2.306(1), Fe(2)–Cl(4) 2.315(1) Å] are shorter than those seen for the bridging chlorides but at the top end of the range observed in structurally related complexes [11,13–16]. The $ClFe(\mu\text{-}Cl)_2FeCl$ motif has been found in a number of crystallographically characterised complexes with the transannular Fe···Fe separation in **6** [3.713(1) Å] amongst the longest [11,13–16].

In **6**, the room temperature magnetic moment is observed at 7.4 BM and consistent with two non-interacting high spin Fe(II) centres (Table 1). Indeed, lowering the temperature of the measurement shows little variation in the value [17]. The ^{1}H NMR spectrum of **6** (recorded in acetonitrile-d_3) supports its paramagnetic nature with broad and shifted peaks between 117 and 7 ppm. Assignment of the spectrum for **6** is possible on comparison with previously reported high spin polypyridyl ferrous compounds [8,18,19]. Thus, H_α, $H_\beta/H_{\beta'}$ and H_γ protons of the coordinated pyridyl arms are found at δ 116.5, 54.7/51.8 and 7.8 while the methylene protons are seen at δ 70.8. The spectroscopic data for **5** is essentially as previously reported [10]. However, the FAB mass spectrum does show fragmentation peaks corresponding to the loss of chloride ions from the parent ion for both mono- and di-meric species and in a similar manner to that observed for **6**; we have therefore tentatively ascribed **5** as a dimeric structure.

Crystals of **7** · 3MeCN and **8** · 3MeCN were grown by the slow cooling of a hot acetonitrile solution of each complex. The structures are similar and will be discussed

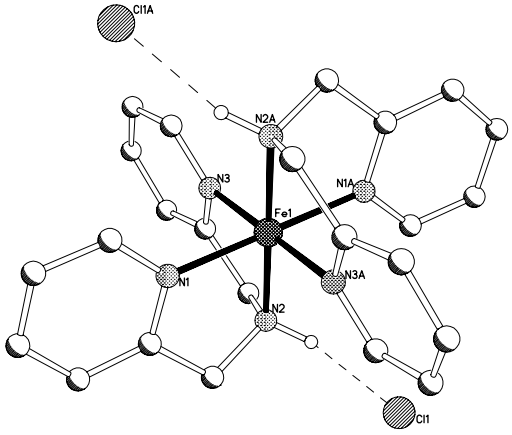

Fig. 5. Molecular structure of **8** showing the atom numbering scheme. All the hydrogen atoms except for H2 have been omitted for clarity.

together. The molecular structure of **8** is shown in Fig. 5; selected bond distances and angles are listed for both **7** and **8** in Table 5. The metal(II) centres in **7** and **8** are surrounded by two DPA ligands, each coordinating in a tridentate fashion to give pseudooctahedral dicationic units. The anionic units are made up of two chloride ions which undergo weak hydrogen bonding interactions with the secondary amine moieties of the DPA ligands [H(2)···Cl(1) 2.269(3) Å (**7**), 2.313(3) Å (**8**)]. The DPA ligands are facially coordinated such that the central amines are mutually *trans* in each complex (i.e., *trans–facially* coordinated). In both cases the pyridyl nitrogen–metal distances [Co(1)–N(1) 2.140(1), Co(1)–N(3) 2.124(1) Å (**7**); Fe(1)–N(1) 1.986(2) Å, Fe(1)–N(3) 1.981(2) Å (**8**)] are shorter than the metal–secondary amine distances [M(1)–N(2) 2.149(1) Å (**7**), 2.020(3) Å (**8**)], presumably as a consequence of some dπ–pπ overlap between metals and pyridyl nitrogen atoms. Crystallographically characterised complexes containing two facially coordinated DPA ligands have been reported for divalent Mn [20], Fe [21], Ni [22],

Cu [23], Zn [20], Cd [20,24] and Hg [25]. Notably, in [(*fac*-DPA)$_2$Fe](BF$_4$)$_2$ [21] the DPA ligands are *cis-facially* coordinated as compared to the *trans–facial* coordination mode adopted in **8**; the metal–nitrogen bond lengths in each isomer fall in the same range.

As has previously been reported by Nelson and Rodgers [12], complex **8** adopts a low spin configuration at ambient temperature and the non-zero value for the magnetic moment can be attributed to a paramagnetic impurity [probably iron(III)]. In contrast, the magnitude of the magnetic moment (4.4 BM) for **7** suggests a high spin configuration ($S = 3/2$). Further support for the difference in spin configuration between the iron complexes **8** and **6** can be seen by comparison of the Fe–N bond lengths. In **8** the average Fe–N distance is ca. 0.2 Å shorter than in **6**, an observation that is consistent with **8** being low spin and **6** high spin [18].

All the iron complexes **2**, **6** and **8** studied in the work have proved air sensitive. Notably for **6**, red crystals of the Fe(III) species [{(*fac*-DPA)FeCl$_2$}$_2$(μ-O)] (**9**) have been isolated on prolonged standing of an acetonitrile solution of **6** (Scheme 2). The molecular structure of **9** is shown in Fig. 6; selected bond distances and angles are listed in Table 6. The structure consists of a discrete dimeric unit with the two metal centres linked by an oxo group. The approximately octahedral geometry at each metal centre is completed by two chloride ligands and a facially bound DPA ligand. The coordination environments at each metal centre differ, however, with the bridging oxide *trans* to a pyridyl nitrogen [N(2)] at Fe(1) while at Fe(2), the bridging oxide is *trans* to the secondary amine nitrogen [N(6)]. The Fe–O–Fe angle [150.0(11)°] falls in the mid-range for related iron(III)–oxo dimeric complexes [26].

3. Conclusions

In summary, simple halide complexes of iron and cobalt containing TPA and DPA have been prepared and fully characterised. In all the cases the TPA ligands bind to metal centres in a tetradentate fashion and the DPA ligands in a tridentate facial fashion. Dissociation of chloride ligands to form chloride-salts is a feature for both TPA and DPA systems.

4. Experimental

4.1. General

All reactions were carried out under an atmosphere of dry, oxygen-free nitrogen, using standard Schlenk techniques or in a nitrogen purged glove box. Solvents were distilled under nitrogen from appropriate drying agents and degassed prior to use [27]. The infrared spectra were recorded as Nujol mulls between 0.5 mm NaCl plates on a Perkin–Elmer 1600 series. The FAB mass spectra were recorded using a Kratos Concept spectrometer with methanol or NBA as the matrix. ^{1}H NMR spectra were recorded on Bruker ARX spectrometers (250 or 300 MHz); chemical shifts (ppm) are referred to the residual protic solvent peaks and relaxation times (τ_1) are in seconds. Magnetic Susceptibility studies were performed using an Evans Balance (Johnson Matthey) at room temperature. The magnetic moment was calculated following standard methods [28] and corrections for underlying diamagnetism were applied to data [29,30]. Elemental analyses were performed at the Department of Chemistry, University of North London by Dr. S. Boyer.

The metal dichlorides were purchased from Aldrich Chemical Co. and used without further purification. The compounds DPA [31] and TPA [32] were prepared according to previously reported procedures. All other chemicals were obtained commercially and used without further purification.

4.2. Syntheses of [(TPA)CoCl$_2$] (**1**) and [(TPA)CoCl]Cl (**3**)

An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $CoCl_2$ (0.035 g, 0.27 mmol) and dissolved in *n*-butanol (10 cm^3) at 90 °C. TPA (0.079 g, 0.27 mmol) was introduced and the blue solution stirred at 90 °C for 1 h. On cooling to room temperature the reaction mixture was concentrated and hexane added to induce precipitation. The suspension was filtered, washed with hexane (2×30 cm^3) and dried under reduced pressure to give a mixture of [(TPA)CoCl$_2$] (**1**) and [(TPA)CoCl]Cl (**3**) as a blue powder. Recrystallisation from a hot acetonitrile solution gave dark green crystals of **1** and purple crystals of **3** suitable for single-crystal X-ray structure determination. **1**: Yield: 41% (0.046 g, 0.11 mmol). **3**: Yield: 34% (0.038 g, 0.09 mmol). Complex **1**: ^{1}H NMR (acetonitrile-d$_3$, 293 K): δ 131.0 (0.6 ms, H$_\alpha$), 106.1 (1.1 ms, NCH$_2$), 58.4 (17.9 ms, H$_\beta$), 46.2 (10.0 ms, H$_{\beta'}$), −2.0 (29.3 ms, H$_\gamma$). Complex **3**: ^{1}H NMR (acetonitrile-d$_3$, 293 K) δ 131.1 (0.6 ms, H$_\alpha$), 106.3 (1.1 ms, NCH$_2$), 58.4 (16.2 ms, H$_\beta$), 46.3 (9.5 ms, H$_{\beta'}$), −2.2 (22.7 ms, H$_\gamma$).

4.3. Synthesis of [(TPA)FeCl$_2$] · MeCN (**2** · MeCN)

Using the same procedure and molar ratios of reagents as in Section 4.2 using TPA (0.070 g, 0.24 mmol) and $FeCl_2$ (0.030 g, 0.24 mmol), gave [(TPA)FeCl$_2$] (**2**) as an orange powder. Recrystallisation from hot acetonitrile gave orange crystals of **2** · MeCN suitable for sin-

gle-crystal X-ray structure determination. Yield: 81% (0.091 g, 0.23 mmol).

4.4. Synthesis of [(TPA)CoCl]$_2$ [CoCl$_4$] (4)

Using the same procedure as in Section 4.2 using TPA (0.079 g, 0.27 mmol) and 1.5 equivalents of $CoCl_2$ (0.050 g, 0.41 mmol) gave [(TPA)CoCl]$_2$[CoCl$_4$] (**4**) as a blue solid. Recrystallisation from a hot acetontrile solution gave blue crystals of **4** suitable for single-crystal X-ray structure determination. Yield: 78% (0.075 g, 0.18 mmol).

4.5. Syntheses of [(DPA)CoCl(μ-Cl)]$_2$ (5) and [(DPA)$_2$Co]Cl$_2$ (7)

(a) An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $CoCl_2$ (0.100 g, 0.50 mmol) in *n*-butanol (10 cm^3) at 90 °C and a solution of DPA (0.094 g, 0.47 mmol) in *n*-butanol was introduced. After being stirred at 90 °C for 1 h, the reaction was allowed to cool to room temperature. The reaction mixture was concentrated and hexane was added to induce precipitation of [(DPA)CoCl(μ-Cl)]$_2$ (**5**) as a purple solid. Yield: 75% (0.125 g, 0.19 mmol). Compound **5**: IR/cm^{-1}, 3242w (N–H). All other spectroscopic data for **5** are as previously reported [10].

(b) Using an analogous procedure as above in (a) employing DPA (0.242 g, 1.56 mmol) and $CoCl_2$ (0.100 g, 0.78 mmol) gave [(DPA)CoCl]Cl**$_2$** (**7**) as a blue solid. Recrystallisation from hot acetonitrile solution gave golden crystals of **7** suitable for a single-crystal X-ray structure determination. Yield: 50% (0.205 g, 0.39 mmol).

4.6. Syntheses of [(DPA)FeCl(μ-Cl)]$_2$ (6) and [(DPA)$_2$Fe]Cl$_2$ (8)

(a) An oven-dried Schlenk flask equipped with a magnetic stir bar was evacuated and backfilled with nitrogen. The flask was charged with $FeCl_2$ (0.060 g, 0.47 mmol) in *n*-butanol (10 cm^3) at 90 °C and a solution of DPA (0.094 g, 0.47 mmol) in *n*-butanol was introduced to form a yellow solution. After being stirred at 90 °C for 1 h, the reaction was allowed to cool to room temperature. The reaction mixture was concentrated and hexane was added to induce precipitation of [(DPA)FeCl(μ-Cl)]$_2$ (**6**) as a yellow solid. The suspension was stirred overnight, filtered, washed with hexane (2×30 cm^3) and dried under reduced pressure. Recrystallisation by slow cooling of a hot acetonitrile solution or prolonged standing of a dichloromethane solution of the complex gave yellow crystals of **6** suitable for a single-crystal X-ray structure determination. Yield: 70% (0.120 g, 0.18 mmol). Complex **6**: ^{1}H NMR (acetonitrile-d$_3$, 293 K) δ 116.5 (0.4 ms, H_α), 107.0 (1.3 ms, N*H*), 70.8 (1.1 ms, CH_2), 54.7 (10.1 ms, H_β), 51.8 (9.1 ms, $H_{\beta'}$), 7.8 (H_γ). IR/cm^{-1}, 3238w (N–H).

(b) Using an analogous procedure as above in (a) employing DPA (0.187 g, 0.94 mmol) and $FeCl_2$ (0.060 g, 0.47 mmol) gave [(DPA)$_2$Fe]Cl$_2$ (**8**) as a red solid. The suspension was stirred overnight, filtered, washed with hexane (2×30 cm^3) and dried under reduced pressure. Recrystallisation by slow cooling of a hot acetonitrile solution gave red crystals of **8** suitable for a single-crystal X-ray structure determination. Yield: 91% (0.225 g, 0.43 mmol).

4.7. Synthesis of [{(fac-DPA)FeCl$_2$}$_2$(μ-O)] (9)

Prolonged standing of a solution of **6** (0.010 g, 0.016 mmol) in acetonitrile (1 cm^3) gave **9** as red crystals. Yield: 40% (0.004 g, 0.006 mmol).

4.8. Crystallography

Data for **1**, **2** · MeCN, **3**, **6** · $1\frac{2}{3}$CH$_2$Cl$_2$, **7** · 3MeCN, **8** · 3MeCN and **9** were collected on a Bruker APEX 2000 CCD diffractometer. Details of data collection, refinement and crystal data are listed in Table 7. The data were corrected for Lorentz and polarisation effects and empirical absorption corrections applied. Structure solution by Patterson methods and structure refinement on F^2 employed SHELXTL version 6.10 [33,34]. Hydrogen atoms were included in calculated positions (C–H = 0.96 Å) riding on the bonded atom with isotropic displacement parameters set to 1.5 U_{eq}(C) for methyl H atoms and 1.2 U_{eq}(C) for all other H atoms. All non-H atoms were refined with anisotropic displacement parameters. For **6** · $1\frac{2}{3}$CH$_2$Cl$_2$ there are 1.5 metal complex molecules in the asymmetric unit, one on a general position and the other on an inversion centre $(-x, -y, 1-z)$.

5. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 243697–243703. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk).

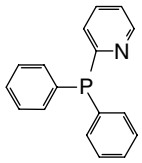

Fig. 1.

(M = Rh, Ir) dimers [10]. In a continuation of our previous work, we report in this communication the syntheses of neutral and chiral amine complexes of *p*-cymene ruthenium as well as hexamethylbenzene ruthenium complexes with the diphenyl(2-pyridyl)phosphine ligand.

2. Experimental

All the solvents were dried and distilled before use following the standard procedures. $RuCl_3 \cdot 3H_2O$ was purchased from Arora Matthey Ltd. and used as received. α-Phellandrene (Fluka), hexamethylbenzene (Acros Organics), benzylamine (Merck), diphenyl(2-pyridyl)phosphine (Aldrich) and 1,1-diphenyl-2-propyn-1-ol (Aldrich) were used as received. The precursor complexes [{(η^6-arene)Ru(μ-Cl)Cl}$_2$] [arene = *p*-cymene (**1**), hexamethylbenzene (**7**)] and [(η^6-*p*-cymene)Ru(PPh_3)Cl_2] (**3**) were prepared according to the literature procedures [11,12]. Elemental analyses were performed in a Perkin–Elmer 2400 CHN/O analyzer. Infrared spectra were recorded on a Perkin–Elmer Model 983 spectrophotometer with samples prepared as KBr and CsI pellets. Electronic spectra were recorded on a Hitachi-300 spectrophotometer. NMR spectra were taken on Bruker AMX-400 (400 MHz) and Bruker ACF-300 (300 MHz) spectrometers with tetramethylsilane as an internal standard. ^{31}P {^1H} NMR chemical shifts are reported relative to H_3PO_4 (85%).

2.1. Preparation of [(η^6-*p*-cymene)Ru($NH_2CH_2C_6H_5$)Cl_2] (**2**)

A mixture of [{(η^6-*p*-cymene)Ru(μ-Cl)Cl}$_2$] (**1**) (0.1 g, 0.163 mmol) and benzylamine (0.44 g, 0.408 mmol) in dichloromethane (20 ml) was stirred at room temperature for 3 h. The orange solution was concentrated under reduced pressure. The residue was extracted with dichloromethane and filtered through a short silica gel column. The resulting solution was reduced in volume to about 2 ml and hexane (20 ml) was added to give an orange-yellow compound, which was recrystallized from the mixture of dichloromethane and hexane to give orange crystals.

Yield: 89.62% (0.12 g). Elemental *Anal*. Calc. (%) for $C_{17}H_{23}RuNCl_2$: C, 49.39; H, 5.61; N, 3.38. Found: C, 49.41; H, 5.94; N, 3.34%.

^1H NMR ($CDCl_3$, δ): 1.30 (d, 6H, J_{H-H} = 6.96 Hz, CH_3), 2.23 (s, 3H, CH_3), 2.98 (sep, 1H), 3.17 (b, 2H, NH_2), 4.14 (t, 2H, J_{H-H} = 7.64 Hz, CH_2), 5.22 (d, 2H, J_{H-H} = 5.88 Hz, cymene), 5.39 (d, 2H, J_{H-H} = 5.88 Hz, cymene), 7.31–7.38 (m, 5H, Ph).

IR (KBr pellets, cm^{-1}): *v*(N–H) 3287 (s), 3221 (s). IR (CsI pellets, cm^{-1}): *v*(Ru–Cl) 286 (s).

UV–vis (CH_2Cl_2): λ_{max} = 393 nm.

2.2. Preparation of chiral complexes

2.2.1. Preparation of [(η^6-*p*-cymene)Ru(PPh_3)($NH_2CH_2C_6H_5$)Cl]PF_6 (**4a**)

A mixture of [(η^6-*p*-cymene)Ru(PPh_3)Cl_2] (**3**) (0.1 g, 0.175 mmol), benzylamine (0.028 g, 0.263 mmol) and NH_4PF_6 (0.043 g, 0.263 mmol) in dichloromethane and methanol (2:1) (15 ml) mixture was stirred at room temperature for 2 h. The orange-yellow solution was concentrated to dryness. The residue was dissolved in dichloro-methane and filtered to remove NH_4Cl. The filtrate was concentrated to 2 ml, and addition of excess hexane gave an orange-yellow complex. The complex was filtered and washed with diethylether and dried under vacuum.

Yield: 71.01% (0.098 g). Elemental *Anal*. Calc. (%) for $C_{35}H_{38}RuNClP_2F_6$: C, 53.54; H, 4.87; N, 1.78. Found: C, 53.51; H, 4.66; N, 1.82%.

^1H NMR ($CDCl_3$, δ): 1.19 (d, 3H, J_{H-H} = 6.36 Hz, CH_3), 1.34 (d, 3H, J_{H-H} = 6.76 Hz, CH_3), 2.17 (s, 3H, CH_3), 2.72 (b, 2H, NH_2), 2.98 (sep, 1H, CH), 4.08 (t, 2H, J_{H-H} = 10.4 Hz, CH_2), 5.29 (d, 2H, J_{H-H} = 5.64 Hz, cymene), 5.42 (d, 2H, J_{H-H} = 5.64 Hz, cymene), 7.54–7.17 (m, 20H, Ph).

^{31}P {^1H} NMR ($CDCl_3$, δ): 36.05 (s).

IR (KBr pellets, cm^{-1}): *v*(N–H) 3287 (s), 3224 (s), *v*(P–F) 839 (s). IR (CsI pellets, cm^{-1}): *v*(Ru–Cl) 276 (s).

2.2.2. Preparation of [(η^6-*p*-cymene)Ru(PPh_3)($NH_2C_6H_4$-*p*-Cl)Cl]BF_4 (**4b**)

A mixture of [(η^6-*p*-cymene)Ru(PPh_3)Cl_2] (**3**) (0.1 g, 0.175 mmol), *p*-chloroaniline (0.044 g, 0.35 mmol) and NH_4BF_4 (0.037 g, 0.35 mmol) in methanol was refluxed for 2 h. The solvent was removed under reduced pressure. The residue was dissolved in CH_2Cl_2 and then filtered. The solution was concentrated to 2 ml and an excess of hexane was added for precipitation. The orange compound was washed with diethylether and dried under vacuum.

Yield: 70.23% (0.092 g). Elemental *Anal*. Calc. (%) for $C_{34}H_{35}RuNCl_2PBF_4$: C, 54.64; H, 4.72; N, 1.87. Found: C, 54.61; H, 4.68; N, 1.84%.

^1H NMR ($CDCl_3$, δ): 1.10 (d, 3H, J_{H-H} = 6.92 Hz, CH_3), 1.25 (d, 3H, J_{H-H} = 6.92 Hz, CH_3), 2.16 (s, 3H, CH_3), 2.87 (sep, 1H, CH), 4.90 (s, 2H, NH_2), 4.98 (d, 2H, J_{H-H} = 5.84 Hz, cymene), 5.03 (d, 2H, J_{H-H} = 5.4 Hz), 5.08 (d, 2H, J_{H-H} = 5.84 Hz, cymene), 5.23 (d, 2H, J_{H-H} = 6.08 Hz), 7.31–7.88 (m, 15H, Ph).

^{31}P {^1H} NMR ($CDCl_3$, δ): 21.25 (s).

2.2.3. Preparation of [(η^6-p-cymene)Ru(PPh_3)(NH_2-C_6H_4-p-NO_2)Cl]BF_4 (**4c**)

A mixture of [(η^6-*p*-cymene)Ru(PPh_3)Cl_2] (**3**) (0.1 g, 0.175 mmol), *p*-nitroaniline (0.048 g, 0.35 mmol) and NH_4BF_4 (0.037 g, 0.35 mmol) in methanol was stirred at room temperature for 14 h. A yellow colored product separated out. The complex was washed with diethylether and dried under vacuum.

Yield: 71.42% (0.095 g). Elemental *Anal*. Calc. (%) for $C_{34}H_{35}RuN_2O_2ClPBF_4$: C, 53.88; H, 4.65; N, 3.69. Found: C, 53.82; H, 4.56; N, 3.71%.

^{1}H NMR ($CDCl_3$, δ): 1.12 (d, 3H, J_{H-H} = 7.56 Hz, CH_3), 1.31 (d, 3H, J_{H-H} = 6.92 Hz, CH_3), 2.19 (s, 3H, CH_3), 2.95 (sep, 1H, CH), 4.40 (s, 2H, NH_2), 5.37 (d, 2H, J_{H-H} = 5.96 Hz), 5.50 (d, 2H, J_{H-H} = 5.88 Hz, cymene), 6.69 (d, 2H, J_{H-H} = 5.86 Hz, cymene), 7.68–7.34 (m, 15H, Ph), 8.10 (d, 2H, J_{H-H} = 8.96 Hz).

2.3. Preparation of [(η^6-p-cymene)Ru(PDA)Cl]BF_4 (**5**) (PDA = 1,2-phenylenediamine)

A suspension of the complex [{(η^6-*p*-cymene)Ru(μ-Cl)Cl}$_2$] (**1**) (0.1 g, 0.163 mmol) in methanol (20 ml) was treated with 1,2-phenylenediamine (0.035 g, 0.326 mmol) and NH_4BF_4 (0.05 g, 0.489 mmol) and allowed to stir at room temperature for 10 h. The solvent was removed under reduced pressure. The orange mass was dissolved in dichloromethane and filtered. The filtrate was concentrated to 2 ml and an excess of hexane added for precipitation. The orange-colored product was washed with diethylether and dried under vacuum.

Yield: 58.55% (0.089 g). Elemental *Anal*. Calc. (%) for $C_{16}H_{22}RuN_2ClBF_4$: C, 41.26; H, 4.76; N, 6.01. Found: C, 41.42; H, 4.93; N, 5.96%.

^{1}H NMR ($CDCl_3$, δ): 0.86 (d, 3H, J_{H-H} = 2.45 Hz, CH_3, cymene), 1.15 (d, 3H, J_{H-H} = 2.91 Hz, CH_3, cymene), 2.26 (s, 2H, CH_3, cymene), 3.00 (sep, 1H), 5.00 (d, 4H, J_{H-H} = 12.23 Hz, NH_2), 5.70 (d, 2H, J_{H-H} = 5.76 Hz, cymene), 5.93 (d, 2H, J_{H-H} = 5.76 Hz, cymene), 7.16 (dd, 2H, 2.27 Hz), 8.37 (d, 2H, 8.58 Hz).

IR (KBr pellets, cm^{-1}): ν(N–H) 3346 (s), 3232 (s), ν(B–F) 1082 (s).

2.4. Preparation of [(η^6-p-cymene)Ru(PPh_3)(PDA)](BF_4)$_2$ (**6**)

This complex was prepared by following the above-mentioned procedure (**5**), except that the complex [(η^6-*p*-cymene)Ru(PPh_3)Cl_2] (**3**) was used in place of complex [{(η^6-*p*-cymene)Ru(μ-Cl)Cl}$_2$] (**1**). The complex was isolated as an orange-red micro-crystalline solid.

Yield: 70.8% (0.097 g). Elemental *Anal*. Calc. (%) for $C_{34}H_{37}RuN_2PB_2F_8$: C, 52.40; H, 4.78; N, 3.59. Found: C, 52.06; H, 4.82; N, 3.37%.

^{1}H NMR ($CDCl_3$, δ): 0.93 (d, 3H, J_{H-H} = 6.69 Hz, CH_3), 1.11 (d, 3H, J_{H-H} = 6.67 Hz, CH_3), 2.20 (s, 3H, CH_3), 2.87 (sep, 1H), 4.61 (d, 4H, J_{H-H} = 10.74 Hz, NH_2), 5.63 (d, 2H, J_{H-H} = 5.85 Hz, cymene), 5.86 (d, 2H, J_{H-H} = 5.85 Hz, cymene), 6.92 (d, 2H, J_{H-H} = 6.46 Hz), 7.16–7.76 (m, 17H, Ph).

IR (KBr pellets, cm^{-1}): ν(N–H) 3326(s), 3192(s), ν(B–F) 1089(s).

2.5. Preparation of [(η^6-C_6Me_6)Ru(PPh_2Py)Cl_2] (**8**)

A mixture of [{(η^6-C_6Me_6)Ru(μ-Cl)Cl}$_2$] (**7**) (0.1 g, 0.149 mmol) and diphenyl(2-pyridyl)phosphine (PPh_2Py) (0.098 g, 0.374 mmol) in dichloromethane (20 ml) was stirred at room temperature for 1 h. The orange solution was concentrated to 3 ml and an excess of hexane was added for precipitation. The orange microcrystalline product was washed with diethylether and dried under vacuum.

Yield: 79.21% (0.141 g). Elemental *Anal*. Calc. (%) for $C_{29}H_{32}RuNCl_2P$: C, 58.29; H, 5.39; N, 2.34. Found: C, 58.32; H, 5.36; N, 2.39%.

^{1}H NMR ($CDCl_3$, δ): 1.76 (s, 18H, HMB), 7.13–8.11 (m, 13H), 8.57 (d, 1H, J_{H-H} = 6.24 Hz).

^{31}P {^{1}H} NMR ($CDCl_3$, δ): 25.88 (s). IR (CsI pellets, cm^{-1}): ν(Ru–Cl) 286 (s).

2.6. Preparation of [(η^6-C_6Me_6)Ru(PPh_2Py)Cl]BF_4 (**9**)

Method 1: A mixture of [{(η^6-C_6Me_6)Ru(μ-Cl)Cl}$_2$] (**7**) (0.1 g, 0.149 mmol), diphenyl(2-pyridyl)phosphine (PPh_2Py) (0.196 g, 0.748 mmol) and NH_4BF_4 (0.078 g, 0.748 mmol) in methanol were stirred at room temperature for 2 h. The yellow solution was concentrated under reduced pressure. The yellow residue was dissolved in dichloro-methane and filtered. The filtrate was concentrated to 2 ml and an excess of hexane was added for precipitation. The yellow-colored product was washed with diethylether and dried under vacuum.

Yield: 82.47% (0.16 g). Elemental *Anal*. Calc. (%) for $C_{29}H_{32}RuNClPBF_4$: C, 53.68; H, 4.97; N, 2.15. Found: C, 53.61; H, 5.01; N, 2.03%.

^{1}H NMR ($CDCl_3$, δ): 2.08 (s, 18H, HMB), 7.09–7.79 (m, 11H), 7.89 (t, 1H, J_{H-H} = 4.36 Hz), 8.01 (t, 1H, J_{H-H} = 4.42 Hz), 8.67 (d, 1H, J_{H-H} = 5.12 Hz).

^{31}P {^{1}H} NMR ($CDCl_3$, δ): −11.25 (s).

IR (KBr pellets, cm^{-1}): ν(B–F) 1089 (s). IR (CsI pellets, cm^{-1}): ν(Ru–Cl) 280 (s).

Method 2: A mixture of the complex [(η^6-C_6Me_6)Ru(PPh_2Py)Cl_2] (**8**) (0.1 g, 0.167 mmol) and NH_4BF_4 (0.052 g, 0.501 mmol) in methanol (15 ml) was stirred at room temperature for 4 h. The clear orange yellow

solution was then rotary evaporated. The residue was extracted with dichloromethane and filtered to remove insoluble material. The filtrate was then reduced to about 2 ml and addition of excess hexane gave a yellow solid.

Yield: 80.41% (0.156 g).

2.7. Preparation of $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)(NCCH_3)](BF_4)_2$ (**10**)

A mixture of complex **9** (0.06 g, 0.092 mmol) and NH_4BF_4 (0.019 g, 0.184 mmol) was refluxed in acetonitrile (15 ml) under a nitrogen atmosphere for 2 h, and the yellow solution turned light yellow in color. The solvent was rotary evaporated. The yellow solid was dissolved in CH_2Cl_2 and filtered. The filtrate was concentrated to 2 ml and an excess of hexane was added for precipitation. The light yellow product was washed with diethylether and dried under vacuum.

Yield: 78.07% (0.089 g). Elemental *Anal*. Calc. (%) for $C_{31}H_{35}RuN_2PB_2F_8$: C, 50.23; H, 4.75; N, 3.78. Found: C, 50.46; H, 4.57; N, 3.92%.

^{1}H NMR ($CDCl_3$, δ): 2.06 (s, 18H, HMB), 2.18 (s, 3H, CH_3), 7.69–8.01 (m, 13H, Ph), 8.76 (d, 1H).

^{31}P $\{^1H\}$ NMR ($CDCl_3$, δ): −13.57 (s).

IR (KBr pellets, cm^{-1}): ν(B–F) 1082 (s).

2.8. Preparation of $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)\{=C=C=C(Ph)_2\}](BF_4)_2$ (**11**)

A mixture of complex **9** (0.06 g, 0.092 mmol), 1,1-diphenyl-2-propyn-1-ol (0.048 g, 0.23 mmol) and NH_4BF_4 (0.029, 0.27 mmol) was refluxed in methanol (15 ml) under a nitrogen atmosphere for 3 h, the yellow suspension gradually turning brown in color. The solvent was removed under reduced pressure. The brown solid was dissolved in CH_2Cl_2 and filtered. The filtrate was concentrated to 2 ml and an excess of hexane was added for precipitation. The brown colored product was washed with diethylether and dried under vacuum.

Yield: 76.83% (0.063 g). Elemental *Anal*. Calc. (%) for $C_{44}H_{42}RuNPB_2F_8$: C, 59.35; H, 4.75; N, 1.57. Found: C, 59.43; H, 4.69; N, 1.59%.

^{1}H NMR ($CDCl_3$, δ): 1.83 (s, 18H, HMB), 7.15–7.71 (m, 14H), 8.05–8.08 (m, 6H), 8.29–8.31 (m, 3H), 8.95 (d, 1H, J_{H-H} = 5.97 Hz).

^{31}P $\{^1H\}$ NMR ($CDCl_3$, δ): −15.32 (s).

IR (KBr pellets, cm^{-1}): ν(C=C=C) 1964(s), ν(B–F) 1082(s).

3. Crystallographic investigations

X-ray quality crystals of complex **2** were grown by slow diffusion of hexane into a dichloromethane solution of the complex, while those of complex **8** were grown by slow diffusion of diethyl ether into a dichloromethane solution. Crystals of complex **9** were grown by slow diffusion of hexane into an acetone solution. The orange crystals of complexes **2** and **8** and the yellow crystals of complex **9** were mounted on a Bruker Apex CCD diffractometer in a full reciprocal sphere equipped with a CCD detector, and were used for data collection.

X-ray intensity data were collected with graphite monochromated Mo Kα radiation at 293(2) K, with the 0.3°ω scan mode and 10 s per frame. The intensity data were corrected for Lorentz and polarization effects. Absorption correction was done using the SAINT program [13]. A summary of the crystal data, data collection parameters and convergence results is compiled in Table 1. An empirical absorption correction was made by modeling a transmission surface by spherical harmonics employing equivalent reflections with $I > 3\sigma(I)$ (program SADABS) [14]. The structure was solved by direct methods [15]. All the non-hydrogen atoms were refined anisotropically using the full-matrix least-squares technique on F^2 using the SHELXL-97 software [16]. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of an isotropic refinement and as per the ''riding'' model. Figs. 2–4 display the ORTEP [17] representations of the molecules with 50% probability thermal ellipsoids. Refinement converged at final R_1 values of 0.0274, 0.0661 and 0.0515 (for observed data F) for complexes **2**, **8** and **9**, respectively.

4. Results and discussion

4.1. Amine complexes

The dinuclear complex $[\{(\eta^6\text{-}p\text{-cymene})Ru(\mu\text{-}Cl)Cl\}_2]$ (**1**) undergoes a bridge cleavage reaction with benzylamine to yield neutral complex **2** (Scheme 1). The complex $[(\eta^6\text{-}p\text{-cymene})Ru(PPh_3)Cl_2]$ (**3**) reacts with amines resulting in the formation of chiral complexes (Scheme 2). Complexes **1** and **3** also react with 1,2-phenylenediamine (PDA) giving the cationic complexes $[(\eta^6\text{-}p\text{-cymene})Ru(PDA)Cl]^+$ (**5**) and $[(\eta^6\text{-}p\text{-cymene})Ru(PPh_3)(PDA)]^{2+}$ (**6**) (Scheme 1, reaction (1)). These complexes are stable in air and are soluble in polar solvents such as dichloromethane and acetone, but insoluble in non-polar solvents such as pentane and hexane. The infrared spectra of these complexes show strong bands in the range 3221–3429 cm^{-1} for the ν_{N-H} mode of the amine group [5b] and a strong band in the range 273–286

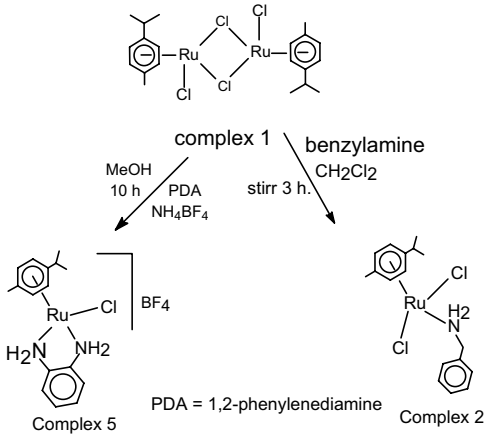
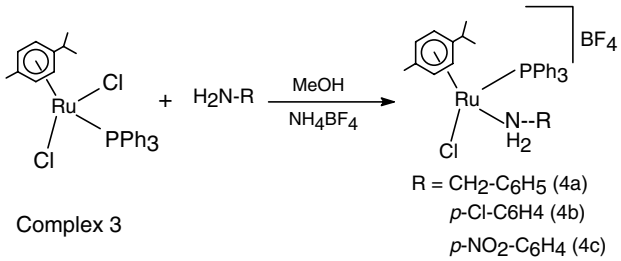
cm^{-1} for the ν_{Ru-Cl} mode [5b]. All these complexes (**4–6**) exhibit a strong band at 1089 cm^{-1} due to the ν_{B-F} mode of the BF_4 group.

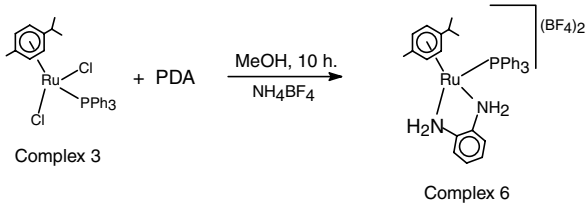


Scheme 1.



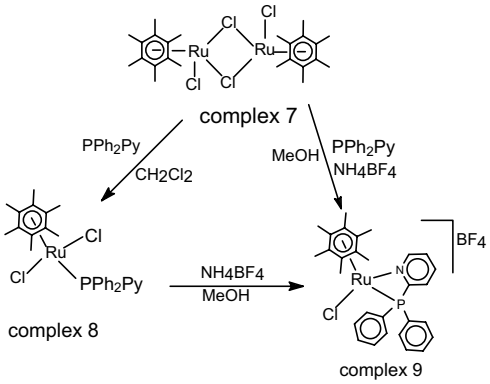
Scheme 2.

The ^{1}H NMR spectrum of complex **2** exhibits a doublet at 1.30 ppm (J = 6.96 Hz) while a septet at 2.98 ppm is observed for the isopropyl group protons. The two doublets observed at 5–6 ppm correspond to the aromatic *p*-cymene ring CH protons. The phenyl group of the benzylamine ligand gives multiplets in the range 7.31–7.40 ppm. The ^{1}H NMR spectra of the mononuclear complexes **4** exhibit two doublets for the methyl protons of the isopropyl group. This is due to the diastereotopic nature of these complexes (**4a–c**) (Scheme 2) since the ruthenium metal is a chiral center. The complexes **5** and **6** also exhibit two doublets for the methyl groups of the *p*-cymene ligand due to the steric nature of the bulky 1,2-phenylenediamine ligand.



(1)

The ^{1}H NMR spectrum of complex **5** exhibits two doublets at 7.16 and 8.23 ppm for the ring protons of 1,2-phenylenediamine. In the case of complex **6**, the signals for these protons merge with those for the phenyl group protons of the triphenylphosphine ligand, thereby exhibiting multiplets in the range 6.93–7.76 ppm. Both



Scheme 3.

the complexes show broad peaks around 4.5–5.0 ppm due to the coordinated NH_2 group. The structure of complex **2** is shown in Fig. 2.

The electronic spectrum of complex **2** in dichloromethane features a UV–vis pattern similar to the analogous ruthenium polypyridyl complexes [18], which arises from the metal-to-ligand charge transfer at 393 nm.

4.2. Complexes of diphenyl-2-pyridylphosphine (*8–11*)

The reaction of $[\{(\eta^6\text{-}C_6Me_6)Ru(\mu\text{-}Cl)Cl\}_2]$ (**7**) with diphenyl(2-pyridyl)phosphine in dichloromethane yields the neutral P-coordinated complex **8**. However, in methanol, the P,N-chelated cationic complex $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl]^+$ (**9**) is isolated as the tetrafluoroborate salt **9**$[BF_4]$. Complex **8** with an excess of NH_4BF_4 in methanol gives the complex **9**$[BF_4]$ (Scheme 3). These complexes are stable in air and soluble in polar solvents such as chloroform and dichloromethane, but are insoluble in non-polar solvents such as hexane and pentane.

The spectroscopic data clearly suggests the coordination of the ligand to the metal as evident from the shift of the phosphorus and proton resonance compared to the starting complex **7**. The ^1H NMR spectrum of complex **8** shows a singlet at 1.76 ppm for the hexamethylbenzene protons (an upfield shift compared to the starting compound) and also in the aromatic region at 7.13–8.11 ppm for the phosphine ligand. The ^{31}P NMR shows one singlet at 25.88 ppm for the phosphine ligand, where a significant downfield shift is observed after coordination to the metal as compared to the free ligand (−3.43 ppm). The far IR spectrum shows a strong band at 286 cm^{-1} for the Ru–Cl stretching vibration mode.

The ^1H NMR spectrum of complex **9** shows a pattern of signals different from the spectrum of complex **8**. The pyridine ring protons appear as two triplets at 7.89 and 8.01 ppm and one doublet at 8.67 ppm. The phenyl group protons appear as a multiplet in the aromatic region at 7.09–7.79 ppm. The singlet at 2.08 ppm for the hexamethyl-benzene protons indicates a downfield shift compared to complex **8**. The ^{31}P $\{^1H\}$ NMR spectrum of complex **9** exhibits a singlet at −11.25 ppm (upfield compared to complex **8**). The far IR spectrum shows a band at 280 cm^{-1}, which is assigned to the terminal stretching vibration of ν_{Ru-Cl}. In addition, the IR spectrum contains a strong band at 1089 cm^{-1} due to the ν_{B-F} mode of the BF_4 group. However, we do not observe formation of a pyridylphosphine-coordinated complex of the type $[Ru(PPh_2Py)_2Cl_2]$ in these reactions, as was the case for the *p*-cymene ruthenium dimer [19].

Treatment of the complex $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl]BF_4$ (**9**) with acetonitrile and 1,1-diphenyl-2-propyn-1-ol ligands generated the cationic complexes **10** and **11** (reactions (2) and (3)), which can be isolated in good yield as their BF_4 salts. Formation of the allenylidene complex **11** is confirmed by the appearance of the ν(C═C═C) absorption mode (asymmetric stretching vibration) as a strong band at 1964 cm^{-1} [20]. The ^1H NMR spectrum of complex **10** shows a singlet for the acetonitrile methyl protons at 2.18 ppm. The phenyl protons appear in the aromatic region in the range of 7.15–8.95 ppm for both complexes. HMB protons are observed at 2.06 ppm for complex **10** and at 1.83 ppm for complex **11**. The ^{31}P $\{^1H\}$ NMR spectrum of complexes exhibits a sharp peak at 13.57 ppm for complex **10** and at 15.32 ppm for complex **11**.

5. Molecular structures

In order to confirm the structures suggested by the spectroscopic data, molecular structures of complexes **2**, **8** and **9** were determined using single-crystal X-ray diffraction studies. The summary of the single-crystal X-ray structure analyses is shown in Table 1. ORTEP drawings of the complexes **2**, **8** and **9** are shown in Figs. 2–4, respectively.

The structure of complex **2** consists of a ruthenium atom η^6-coordinated to a *p*-cymene molecule, two chlorine atoms and one benzylamine ligand (through the N atom) leading to the usual 'three-legged piano stool' structure. The complex $[(\eta^6\text{-}p\text{-cymene})Ru(NH_2CH_2C_6H_5)Cl_2]$ (**2**) crystallizes in the monoclinic space group $P2_1/c$ (Fig. 2). The average Ru–C bond distance is 2.1726 Å, whereas the distance between the ruthenium atom and the centroid of the ring is 1.670 Å at the axis $x = 0.3938$, $y = 0.3638$ and $z = 0.1334$. These bond lengths are closely related to those in other reported complexes [21]. The Ru–N bond length involving benzylamine is 2.1445(18) Å, which is within the usual range of Ru–N bond distances [22]. The Ru–Cl bond lengths are 2.4282(6) and 2.4297(6) Å, well in accord with the

literature values [23]. The geometry of the complex is octahedral with a piano-stool structure and is marked by the nearly 90° value for the bond angles between the non-*p*-cymene ligands at the metal centre, viz., Cl(1)–Ru–Cl(2) (87.66(2)°), N–Ru–Cl(1) (80.97(6)°) and N–Ru–Cl(2) (80.65(5)°).

Complex **8** crystallizes in the monoclinic space group *C*2/*c*. The geometry around the ruthenium atom in complex **8** is octahedral where the hexamethylbenzene occupies three-coordination positions. Complex **8** also has a 'three-legged piano stool' type structure. Fig. 3 shows an ORTEP representation of complex **8**. The Ru–Cl(1) and Ru–Cl(2) bond distances (2.417(2) and 2.422(2) Å) are closely related to other reported values (2.4299 Å) [24]. The Ru–P bond distance 2.3573(19) Å is within the range of the literature values [24a]. The average bond distance between ruthenium and hexamethylbenzene is 2.227 Å, and the distance between ruthenium and the centroid of the ring is 1.740 Å. The bond angles P–Ru–Cl(1), P–Ru–Cl(2) and Cl(1)–Ru–Cl(2) are 88.51(7)°, 88.20(7)° and 86.41(8)°, respectively, indicating a piano stool type structure.

Complex **9** crystallizes with one molecule of acetone; the complex cation and the BF_4^- anion are joined by coulombic forces. Complex **9** contain a ruthenium atom η^6-coordinated to a hexamethylbenzene ring and bonded to a chlorine atom and a bidentate PPh_2Py ligand through the P and N atoms. Fig. 4 is an ORTEP representation of complex **9**. Complex **9** crystallizes in the monoclinic space group $P2_1$. The Ru–P bond distance 2.3412(13) Å is shorter than in complex **8**. This is because the diphenyl(2-pyridyl)phosphine ligand restricts the bite angle of the four-membered chelating ring using both the P and N atoms. The Ru–Cl and Ru–N(52) bond distances 2.3981(14) and 2.107(2) Å fall within the range of reported values [25]. The bond angles around the ruthenium are P–Ru–Cl 86.97(5)° and N(52)–Ru–Cl 82.95(7)°. The rigid bond distance between the nitrogen and phosphorus atoms (P∩N) of pyridylphosphine is approximately 3.1 Å, whereas the rigid narrow angle N(52)–Ru–P in complex **9** is 67.72(6)°. The average bond distance between ruthenium and the hexamethylbenzene carbons is 2.204 Å, while that between the centroid of the arene and the metal atom is 1.705 Å.

6. Concluding remarks

We have prepared some new η^6-arene ruthenium(II) complexes containing amines and diphenyl(2-pyridyl)phosphine ligands. The *p*-cymene ruthenium dimer $[(\eta^6\text{-}C_{10}H_{14})RuCl_2]_2$ with diphenyl(2-pyridyl)phosphine in the presence of methanol under refluxing conditions yields two types of products – one having an organic fragment, viz., $[(\eta^6\text{-}p\text{-cymene})Ru(PPh_2Py)Cl]BF_4$, and the other without an organic fragment, viz., $[RuCl_2(PPh_2Py)_2]$ [19]. The hexamethylbenzene ruthenium(II) dimer $[(\eta^6\text{-}C_6Me_6)RuCl_2]_2$ under the same conditions gave only one product having an organic fragment, viz., $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl]BF_4$. This is a clear indication that hexamethylbenzene binds to the metal quite strongly for the latter case due to the high electron-donating ability of the $\eta^6\text{-}C_6Me_6$ moiety relative to the η^6-*p*-cymene in these ruthenium complexes.

dichloride products of 5,14-dihydro-6,8,15,17-tetramethyldibenzo[b,I][1,4,8,11]tetraazacyclotetradecine which were subsequently reacted with the appropriate amine to yield the desired amino complex in good yields. The amino complexes formed are explained in terms of nucleophillic attack of the amine on the carbonyl carbon within the *meso* substituents of the macrocycle. It is clear the the diallylamine group is potentially capable of interesting transformations.

We have an ongoing interest in hemilabile ligands [10–14] and bis(diphenylphosphino)amines [15] are of interest since they relate to the well known ligand bis(diphenylphosphino)methane, $Ph_2PCH_2PPh_2$ (dppm) [16–18]. Coordination of dppm to metal centres can occur through the lone pair of electrons at one or both of the phosphorus centres as well as by deprotonation of the methylene(or NH) group to form a tridentate ligand (see Fig. 1).

However, diphosphinoamines have received significantly less attention [19,20] and we have a program of study into the synthesis of P–N–P phosphines [21–30]. Here we report the preparation new phosphine and disphosphine that contains the diallyl and allyl group and have the potential to act as a hemilabile ligand. Selected coordination complexes have also been prepared.

2. Results and discussion

Reaction of diallylamine with one equivalent of Ph_2PCl in the presence of NEt_3 proceeds in thf to give **1** (Eq. (2), 83% yield), δ_P 64.3 ppm. In the IR spectrum bands are observed at 1638, 1433 and 993 cm^{-1}, which are assigned to $\nu_{C=C}$, ν_{PPh2} and ν_{PN} respectively. The microanalysis gave satisfactory results.

The oxide (**2**) $Ph_2P(O)N(C_3H_5)_2$ was easily prepared by addition of urea hydrogen peroxide to a dichloromethane solution of **1**, whilst the sulfur (**3**) and seleno (**4**) analogues were prepared by the addition of elemental S or Se to the ligand in toluene. Satisfactory microanalysis was obtained for the **4** though only fairly satisfactory results were obtained for **3** and **4** possible due to difficulties in purifying the oily products formed and the EI^+ mass spectral data gave the expected parent ion and fragmentation patterns. The $^{31}P\{^1H\}$ NMR show single resonances ($CDCl_3$) at δ_P 31.3 and 69.8 ppm for the oxide and sulfide respectively. The seleno analogue exhibits a single $^{31}P\{^1H\}$ NMR resonance ($CDCl_3$) at δ_P 58.1 ppm with selenium satellites $^1J(^{31}P–^{77}Se)$ 756 Hz which is typical for a P=Se group.

Reaction of $[PtCl_2(cod)]$ with $Ph_2PN(C_3H_5)_2$ gave interesting results. Reaction of $[PtCl_2(cod)]$ with three equivalents of $Ph_2PN(C_3H_5)_2$ gives $[Pt\{Ph_2PN(C_3H_5)_2\}_3][Cl_2]$ (**5**). The FAB mass spectrum of **5** contains the expected parent ion and fragmentation pattern and the complex exhibits three different resonances (Fig. 2) with platinum satellites in the $^{31}P\{^1H\}$ NMR spectrum ($\delta(P_A)$ 83.7 ppm, $^1J\{^{31}P_A–^{195}Pt\}$ 4800 Hz; $\delta(P_X)$ 74.5 ppm, $^1J\{^{31}P_X–^{195}Pt\}$ 2052 Hz, $^2J\{^{31}P_A–^{31}P_X\}$ 9 Hz, $^2J\{^{31}P_X–^{31}P_Y\}$ 44 Hz; $\delta(P_Y)$ 47.9 ppm, $^2J\{^{31}P_Y–^{195}Pt\}$ 281 Hz) which indicates the presence of three phosphorus ligands around the platinum centre, and by comparison of the chemicals shifts and coupling constants we propose the structure shown in Eq. (2). If the reaction was performed with a 2:1 ligand/metal molar ratio, $^{31}P\{^1H\}$ NMR indicated the presence of **5** and another complex. Reaction of $[PtCl_2(cod)]$ with one equivalent of $Ph_2PN(C_3H_5)_2$ gives the second product observed in the 2:1 reaction, $[PtCl_2\{Ph_2PN(C_3H_5)_2\}]$ (**6**), in good yield (65%). Microanalysis gave satisfactory results for the formation of the chelate complex and FAB mass spectral analysis gives the expected parent ion and fragmentation pattern. The complex displays a single resonance with platinum satellites in the $^{31}P\{^1H\}$ NMR spectrum (δ_P 701. ppm, $^1J(^{31}P–^{195}Pt)$ 3491 Hz) and the IR spectrum has ν_{PPh2} and ν_{PN} vibrations at 1434 and 1010 cm^{-1}, respectively and two ν_{PtCl} bands at 317 and 295 cm^{-1} which suggest a *cis* geometry. $[PdCl_2(cod)]$ behaved slightly differently to $[PtCl_2(cod)]$; a 2:1 ratio reaction [ligand:metal] gave two products, however, in the presence of three equivalents of **1** only the 2:1 complex, $[PdCl_2\{Ph_2PN(C_3H_5)_2\}_2]$ (**7**) is obtained. The $^{31}P\{^1H\}$ NMR of **7** has two signals [δ_P 109.2

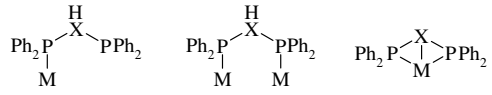

Fig. 1. Coordination modes of dppm, dppa and their respective anions (X=CH or N).

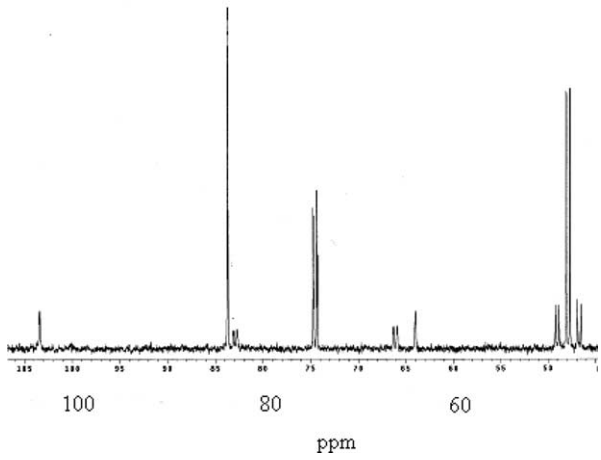

Fig. 2. ^{31}P NMR from the crude the reaction of three equivalents of $Ph_2PN(C_3H_5)_2$ with $[PtCl_2(cod)]$.

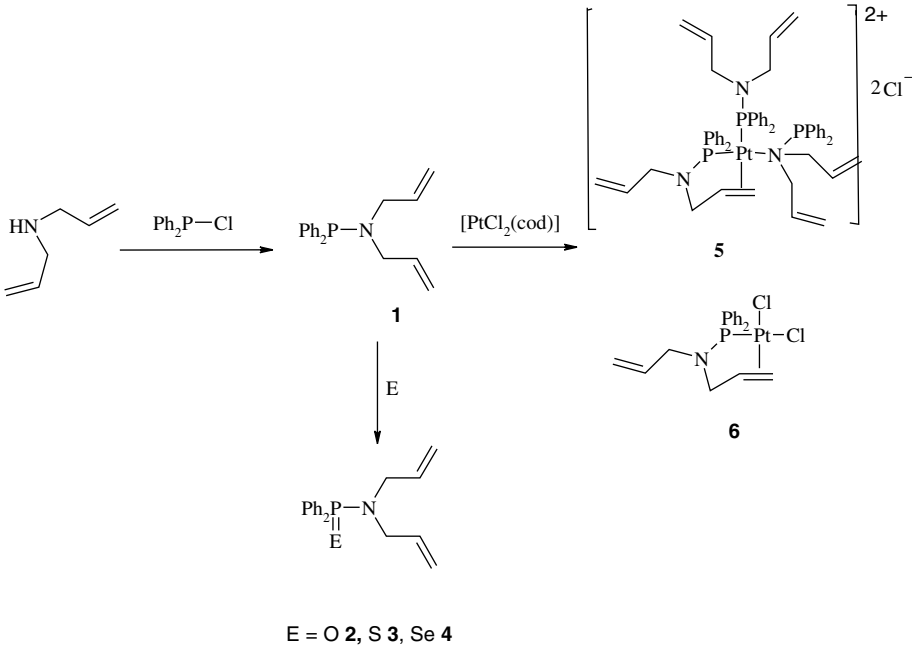

(2)

and 44.7 ppm, $^{2}J\{^{31}P_{A}–^{31}P_{X}\}$ 18 Hz] indicating two phosphorus environments within the complex. The FAB mass spectrum gives the expected parent ion and microanalysis is found to be fairly satisfactory. The IR spectrum has bands at 1435 and 995 cm^{-1} that correspond to ν_{PPh2} and ν_{PN}, respectively and two ν_{PdCl} bands at 292 and 277 cm^{-1}. As might be anticipated, the reaction of one equivalent of $Ph_2PN(C_3H_5)_2$ with [$PdCl_2$ (cod)] gives [$PdCl_2\{Ph_2PN(C_3H_5)_2\}$] (**8**) in good yield. The crystal structure of **8** (Fig. 3) shows that the molecule is *cis*-square planar. The ligand is bound to the palladium metal via phosphorus [P(1)–Pd(1) 2.2247(6) Å] and one of the olefinic arms of the ligand.

The reaction of [$PtMe_2$(cod)] with one equivalent of **1** gave the expected chelate complex, [$PtMe_2\{Ph_2PN$ $(C_3H_5)_2\}$ (**9**). The FAB mass spectral data obtained gave the expected parent ion and in the IR spectrum $\nu_{C=C}$, ν_{PPh2} and ν_{PN} vibrations were observed at 1636, 1432 and 992 cm^{-1}, respectively. The $^{31}P\{^{1}H\}$ NMR (CD_2Cl_2) showed a single resonance with platinum satellites (δ_P 90.7 ppm, $^{1}J\{^{31}P–^{195}Pt\}$ 1937 Hz).

Reaction of **1** with [$Mo(CO)_4$(nbd)] gives [Mo $(CO)_4\{Ph_2PN(C_3H_5)_2\}$] (**10**) as a yellow solid. Monodentate *P*-[$RuCl_2\{Ph_2PN(C_3H_5)_2\}(\eta^6$-*p*-$MeC_6H_4{}^{i}Pr)$] (**11**) was prepared from [{RuCl(α-Cl)(η^6-*p*-Me-$C_6H_4{}^{i}Pr)_2\}_2$] and **1**. [RhCl{$Ph_2PN(C_3H_5)_2$}] (**12**) was obtained from [{Rh(α-Cl)(cod)}$_2$]. The $^{31}P\{^{1}H\}$ NMR ($CDCl_3$) shows a two resonances with rhodium satellites ($\delta(P_A)$ 115.5 ppm, $^{1}J(^{31}P_{A}–^{103}Rh)$ 154 Hz. $\delta(P_X)$ 84.7 ppm, $^{1}J\{^{31}P_{X}–^{103}Rh\}$ 114 Hz. $^{2}J\{^{31}P_{A}–^{31}P_{X}\}$ 25 Hz). The IR spectrum has bands at 1433, 990 and 251 cm^{-1} that correspond to ν_{PPh2} and ν_{PN} and ν_{RhCl} vibrations, respectively.

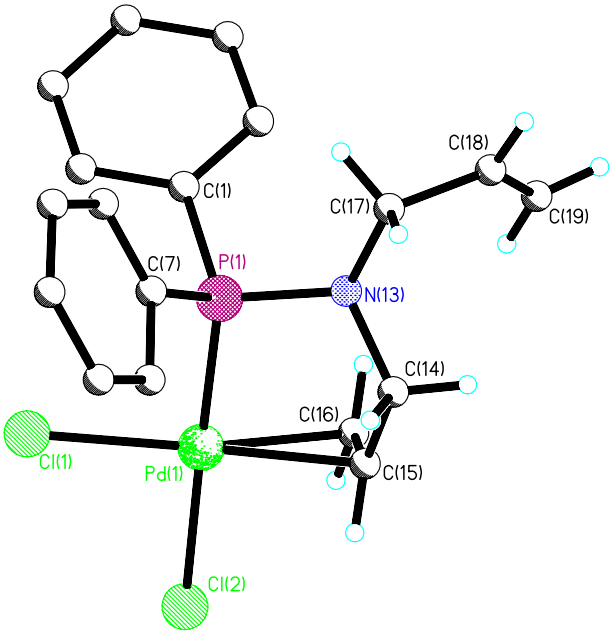

Fig. 3. The X-ray structure of [$PdCl_2\{Ph_2PN(C_3H_5)_2\}$] (**8**), selected bond lengths (Å) and angles (°) : Pd(1)–Cl(1) 2.2983(7), Pd(1)–Cl(2) 2.3641(7), Pd(1)–P(1) 2.2247(6), Pd(1)–C(15) 2.192(2), Pd(1)–C(16) 2.177(3), P(1)–N(13) 1.6719(19), N(13)–C(14) 1.465(3), N(13)–C(17) 1.466(3), C(15)–C(16) 1.361(4). P(1)–Pd(1)–Cl(1) 88.07(2), N(13)–P(1)–M(1) 103.54(7), P(1)–M(1)–Cl(2) 178.67(20).

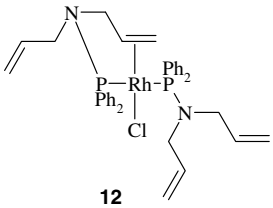
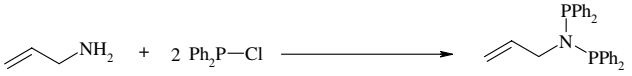


12

Reaction of allylamine with two equivalents of Ph_2PCl in the presence of NEt_3 proceeds in thf to give **13** in good yield, δ_P 62.9 ppm. The IR spectrum has bands observed at 1635, 1434 and 993 cm^{-1}, which are assigned to $\nu_{C=C}$, ν_{PPh} and ν_{PN}, respectively.



(3)

Reaction of $[MCl_2(cod)]$ with $(C_3H_5)N(PPh_2)_2$ gives $[PtCl_2\{(C_3H_5)N(PPh_2)_2\}]$ (M=Pt **14,** Pd **15**) in good yield. The FAB^+ mass spectrum showed the expected parent ion and the complex has δ_P 19.1 ppm, $^1J\{^{31}P–^{195}Pt\}$ 3296 Hz. The IR spectrum showed bands at 1635, 1435, 995, 291 and 245 cm^{-1}, which are assigned to $\nu_{C=C}$, ν_{PPh}, ν_{PN} and two ν_{PtCl} vibrations respectively.

The crystal structure of **14** (Fig. 4) shows that it is approximately square planar at platinum. The bite angle of the chelating phosphine is significantly lower than the ideal 90° {P(2)–Pt(1)–P(1) 72.03(8)°}.

We prepared a number of other simple complexes of **13**, thus $[Mo(CO)_4\{(Ph_2P)_2N(C_3H_5)\}]$ (**16**) $[\{(C_3H_5)N(PPh_2)_2\}(AuCl)_2]$ (**17**), $[RuCl_2\{(Ph_2P)_2N(C_3H_5)\}_2]$ (**18**), $[RhCl(\alpha\text{-}Cl)(\eta^5\text{-}C_5Me_5)\{(Ph_2P)_2N(C_3H_5)\}]$ (**19**) and $[IrCl(\alpha\text{-}Cl)(\eta^5\text{-}C_5Me_5)\{(Ph_2P)_2N(C_3H_5)\}]$ (**20**) were all obtained. The crystal structure of **18** (Fig. 5) reveals bidentate coordination [bite angle P(2)–Pt(1)–P(1) 69.10(3)°].

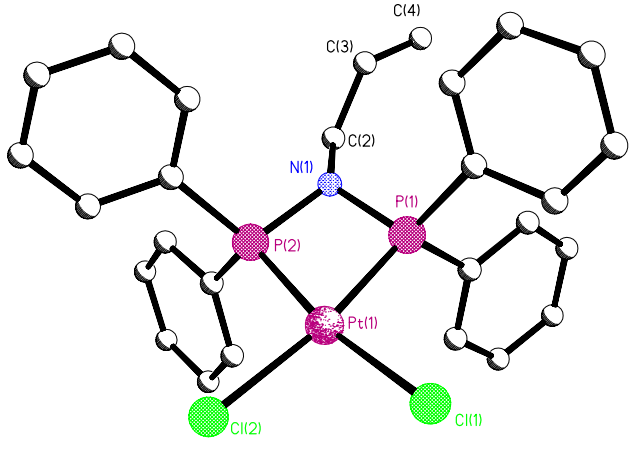


Fig. 4. The X-ray structure of $[PtCl_2\{(C_3H_5)N(PPh_2)_2\}]$ (**14**). Selected bond lengths and angles: Pt(1)–Cl(1),2.352(2), Pt(1)–Cl(2) 2.347(2), Pt(1)–P(1) 2.201(2), Pt (1)–P(2) 2.197(2), P(1)–N(1) 1.696(7), P(2)–N(1) 1.703(7) Å, P(2)–Pt(1)–P(1) 72.10(8), P(2)–Pt(1)–Cl(1) 97.44(9), P(1)–Pt(1)–Cl(2) 98.73(9), Cl(2)–Pt(1)–Cl(1) 91.78(9), P(2)–N(1)–P(1) 99.2(4)°.

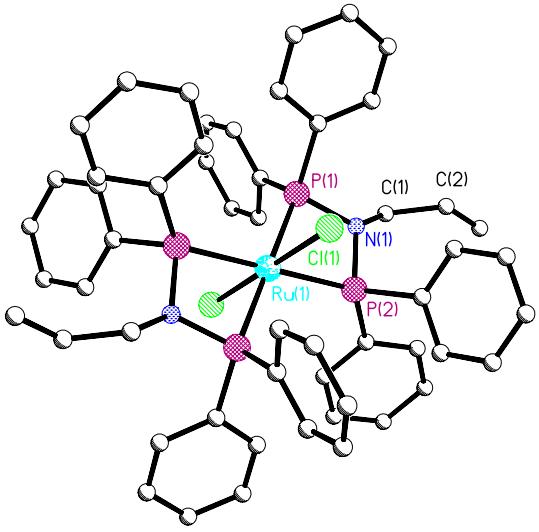

Fig. 5. The X-ray structure of $[RuCl_2\{(Ph_2P)_2N(C_3H_5)\}_2]$ (**18**). Selected bond lengths and angles: Ru(1)–Cl(1) 2.4189(7), Ru(1)–P(2) 2.3585(8), Ru(1)–P(1) 2.3356(7), P(2)–N(1) 1.721(2), P(1)–N(1) 1.710(2) Å P(2)–Ru(1)–P(1) 69.10(3), P(2)–Ru(1)–Cl(1) 85.65(2), P(1)–Ru(1)–Cl(1) 89.65(2), P(2)–N(1)–P(1) 101.78(12)°.

This work clearly demonstrates the ability of allyl aminophosphines to bind using a variety of motifs.

3. Experimental

3.1. $[Ph_2PN(C_3H_5)_2]$ (1)

Diallylamine (2.841 g, 29.2 mmol) and triethylamine (3.107 g, 30.7 mmol) were added together in dry thf (50 cm^3). Chlorodiphenylphosphine (6.453 g, 29.2 mmol) in dry thf (50 cm^3) was added dropwise with stirring overnight. Triethylamine hydrochloride was removed by filtration under nitrogen and the solvent removed in vacuo to yield a colourless oil. Yield: 6.840 g, 83%. Microanalysis: Found (calculated for $C_{18}H_{20}NP$): C, 74.47 (76.85); H, 7.79 (7.17); N, 4.72 (4.98)%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 64.3 ppm. ^1H NMR ($CDCl_3$) δ 7.5 (m, 10 H, Ph), 5.65 (m, 2H, $CH{=}CH_2$), 5.05 (m, 4H, CH_2), 3.45 (m, 4H, CH_2) ppm. IR (thin film): 1638, 1433, 933 cm^{-1}.

3.2. $Ph_2P(O)N(C_3H_5)_2$ (2)

$Ph_2PN(C_3H_5)_2$ (256 mg, 0.9 mmol) was dissolved in CH_2Cl_2 (20 cm^3) and cooled to 0 °C before addition of urea hydrogen peroxide (86 mg, 0.9 mmol) was added and the reaction mixture was stirred overnight. The product was extracted from the CH_2Cl_2 by addition of distilled water, washed with CH_2Cl_2 (3×5 cm^3), dried

over magnesium sulfate and evaporated to dryness to yield a colourless oil. Yield: 254 mg, 94%. Microanalysis: Found (calculated for $C_{18}H_{20}NOP$): C, 68.61 (72.71); H, 6.58 (6.78); N, 4.46 (4.71)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 31.3 ppm. ^{1}H ($CDCl_3$) δ 7.55 (m, 10H, Ph), 5.65 (m, 2H, CH=CH_2), 5.05 (m, 4H, CH_2), 3.45 (m, 4H, CH_2) ppm. EI^+ MS: *m/z* 297 $[M]^+$. IR (thin film): 1635, 1433, 1181, 992 cm^{-1}.

3.3. $Ph_2P(S)N(C_3H_5)_2$ (**3**)

$Ph_2PN(C_3H_5)_2$ (766 mg, 2.7 mmol) and elemental sulfur (87 mg, 2.7 mmol) were dissolved in dry toluene (10 cm^3) to yield a yellow solution which was stirred overnight. The reaction mixture was cooled to room temperature and the solvent removed before addition of CH_2Cl_2 (2 cm^3) and filtering through Celite to remove any remaining inorganic solid. After removing the CH_2Cl_2 colourless oil was yielded. Yield: 753 mg, 88%. Microanalysis: Found (calculated for $C_{18}H_{20}NPS$): C, 66.03 (68.98); H, 7.48 (6. 43); N, 4.80 (4.47)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 69.8 ppm. ^{1}H NMR ($CDCl_3$) δ 7.55 (m, 10H, Ph), 5.65 (m, 2H, CH=CH_2), 5.05 (m, 4H, CH_2), 3.45 (m, 4H, CH_2) ppm. EI^+: *m/z* 273 $[M]^+$. IR (thin film): 1638, 1434, 997, 689 cm^{-1}.

3.4. $Ph_2P(Se)N(C_3H_5)_2$ (**4**)

$Ph_2PN(C_3H_5)_2$ (235 mg, 1.0 mmol) and grey selenium (77 mg, 1.0 mmol) were refluxed in dry toluene (10 cm^3) for 1 h before cooling to room temperature and filtering through a Celite plug to remove any insoluble material. The solvent was reduced to 1 cm^3 to yield a colourless solid that was isolated by suction filtration and dried in vacuo. Yield: 269 mg, 86%. Microanalysis: Found (calculated for $C_{18}H_{20}NPSe$): C, 59.93 (60.01); H, 6.80 (5.60); N, 4.28 (3.89)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 58.1 ppm $^{1}J(^{31}P–^{77}Se)$ 756 Hz. ^{1}H NMR ($CDCl_3$) δ 7.55 (m, 10H, Ph), 5.65 (m, 2H, CH=CH_2), 5.05 (m, 4H, CH_2), 3.45 (m, 4H, CH_2) ppm. EI^+ MS: *m/z* 361 $[M + H]^+$. IR (KBr disc): 1636, 1435, 995, 573 cm^{-1}.

3.5. $[Pt\{Ph_2PN(C_3H_5)_2\}_3][Cl_2^-]$ (**5**)

$Ph_2PN(C_3H_5)_2$ (165 mg, 0.6 mmol) and $[PtCl_2(cod)]$ (73 mg, 0.2 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield a pale yellow solution that was stirred for 30 min. The solvent was reduced to 1 cm^3 before precipitating a colourless solid upon addition of diethyl ether (cm^3) that was isolated by suction filtration. Yield: 140 mg, 64%. Microanalysis: Found (calculated for $C_{54}H_{60}P_3N_3PtCl_2$): C, 58.84 (58.43); H, 5.38 (5.45); N, 3.73 (3.79)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 83.7 (d) ppm, $^{1}J(^{31}P_A–^{195}Pt)$ 4800 Hz. $\delta(P_X)$ 74.5 ppm, $^{1}J(^{31}P_X–^{195}Pt)$ 2052 Hz. $^{2}J(^{31}P_A–^{31}P_X)$ 9 Hz. $^{2}J(^{31}P_Y–^{31}P_X)$ 44 Hz. $\delta(P_Y)$ 47.9 (d) ppm, $^{2}J(^{31}P_Y–^{195}Pt)$ 281 Hz. ^{1}H NMR ($CDCl_3$) δ 7.55 (m, 30H, Ph), 5.65 (m, 4H, CH=CH_2), 5.05 (m, 2H, chelate CH=CH_2), 4.85 (m, 8H, CH_2), 4.45 (m, 4H, chelate CH_2), 3.45 (m, 12H, CH_2) ppm. FAB^+ MS: *m/z* 1075 $[M – Cl]^+$. IR (KBr disc): 1637, 1436, 997, 296 cm^{-1}.

3.6. $[PtCl_2\{Ph_2PN(C_3H_5)_2\}]$ (**6**)

$Ph_2PN(C_3H_5)_2$ (197 mg, 0.7 mmol) in CH_2Cl_2 (5 cm^3) was added dropwise to a CH_2Cl_2 (5 cm^3) solution of $[PtCl_2(cod)]$ (262 mg, 0.7 mmol) over 2.5 h. The solvent was reduced to 1 cm^3 before addition of hexane (10 cm^3) to yield an off white sticky solid on reduction of solvent. The sticky solid was subsequently dissolved in CH_2Cl_2 (0.5 cm^3) before addition of petroleum ether (40–60) (10 cm^3) to yield a colourless solid that was isolated by suction filtration. Yield: 248 mg, 65%. Microanalysis: Found (calculated for $C_{18}H_{20}NPPtCl_2$): C, 40.02 (39.50); H, 3.50 (3.68); N, 3.41 (2.56)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 70.1 ppm $^{1}J(^{31}P–^{195}Pt)$ 3491 Hz. ^{1}H NMR ($CDCl_3$) δ 7.6 (m, 10H, aromatic), 5.3 (m, 2H, CH), 5.1 (m, 2H, CH_2), 4.7 (d, 1H, $^{3}J\{^{195}Pt–^{1}H\}$ 54 Hz, $^{2}J\{^{31}P–^{1}H\}$ 8 Hz, CH_2), 4.1 (d, 1H,$^{3}J\{^{195}Pt–^{1}H\}$ 59 Hz, $^{2}J\{^{31}P–^{1}H\}$ 13 Hz, CH_2) 3.5 (m, 4H, NCH_2) ppm. FAB^+ MS: *m/z* 569 $[M + Na]^+$, 547 $[M + H]^+$, 511 $[M – Cl]^+$, 474/6 $[M – 2Cl]^{2+}$. IR (KBr disc): 1634, 1434, 1010, 317, 295 cm^{-1}.

3.7. $[PdCl_2\{Ph_2PN(C_3H_5)_2\}_2]$ (**7**)

$(Ph_2P)_2N(C_3H_5)_2$ (124 mg, 0.4 mmol) and $[PdCl_2(cod)]$ (42 mg, 0.1 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield an orange solution that was stirred for 30 min. The solvent was reduced to 1 cm^3 before precipitating a pale yellow solid upon addition of diethyl ether (20 cm^3) that was isolated by suction filtration. Yield: 100 mg, 92%. Microanalysis: Found (calculated for $C_{36}H_{40}P_2N_2PdCl_2$): C, 57.56 (58.43); H, 5.22 (5.45); N, 3.40 (3.79)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 109.2 ppm. $\delta(P_X)$ 44.7 ppm. $^{2}J\{^{31}P_A–^{31}P_X\}$ 18 Hz. ^{1}H NMR ($CDCl_3$) δ 7.55 (m, 20H, Ph), 5.65 (m, 3H, CH=CH_2), 5.05 (m, 1H, chelate CH=CH_2), 4.85 (m, 6H, CH $_2$), 4.45 (m, 2H, chelate CH_2), 3.45 (m, 8H, CH_2) ppm. FAB^+ MS: *m/z* 704 $[M – Cl]^+$, 667/8 $[M – 2Cl]^{2+}$. IR (KBr disc): 1638, 1435, 995, 292, 277 cm^{-1}.

3.8. $[PdCl_2\{Ph_2PN(C_3H_5)_2\}]$ (**8**)

$Ph_2PN(C_3H_5)_2$ (111 mg, 0.4 mmol) in CH_2Cl_2 (5 cm^3) was added dropwise to CH_2Cl_2 (5 cm^3) solution of $[PdCl_2(cod)]$ (112 mg, 0.4 mmol). After stirring for 30 min the solvent was reduced in vacuo to 0.5 cm^3 before precipitating a yellow microcrystalline solid upon addition of hexane (10 cm^3) and isolation by suction

filtration. Yield: 164 mg, 91%. Microanalysis: Found (calculated for $C_{18}H_{20}PNPdCl_2$): C, 46.76 (47.14); H, 4.18 (4.40); N, 2.70 (3.05)%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 101.3 ppm. ^1H NMR ($CDCl_3$) δ 7.55 (m, 10H, Ph), 5.65 (m, 1H, CH=CH_2), 5.05 (m, 1H, chelate CH=CH_2), 4.85 (m, 2H, CH_2), 4.45 (m, 2H, chelate CH_2), 3.45 (m, 4H, CH_2) ppm. FAB^+ MS: *m/z* 422 $[M - Cl]^+$, 386 $[M - 2Cl]^{2+}$. IR (KBr disc): 1634, 1435, 999, 317, 290 cm^{-1}.

3.9. $[PtMe_2\{Ph_2PN(C_3H_5)_2\}]$ (**9**)

$Ph_2PNH(C_3H_5)_2$ (96 mg, 0.3 mmol) in CH_2Cl_2 (5 cm^3) was added dropwise to a CH_2Cl_2 (5 cm^3) solution of [$PtMe_2$(cod)] (114 mg, 0.3 mmol) over 2.5 h. The solvent was reduced to 1 cm^3 before addition of hexane (10 cm^3) to yield an off white sticky solid on reduction of solvent. The sticky solid was subsequently dissolved in CH_2Cl_2 (0.5 cm^3) before addition of petroleum ether (40–60) (10 cm^3) to yield a colourless solid that was isolated by suction filtration. Yield: 92 mg, 53%. Microanalysis: Found (calculated for $C_{20}H_{26}NPPt$) C, 46.90 (47.42); H, 4.46 (5.18); N, 2.35 (2.77)%. $^{31}P\{^1H\}$ NMR (CD_2Cl_2): 90.7 ppm $^1J(^{31}P–^{195}Pt)$ 1937 Hz. ^1H NMR (CD_2Cl_2) δ 7.55 (m, 10H, aromatic), 5.3 (m, 2H, CH), 5.1 (m, 2H, CH_2), 4.7 (d, 1 H, $^3J(^{195}Pt–^1H)$ 54 Hz, $^2J\{^{31}P–^1H\}$ 8 Hz, CH_2), 4.1 (d, 1H,$^3J\{^{195}Pt–^1H\}$ 59 Hz, $^2J\{^{31}P–^1H\}$ 13 Hz, CH_2) 3.5 (m, 4H, NCH_2) ppm. FAB^+ MS: *m/z* 490 $[M - Me]^+$, 476 $[M - 2Me]^{2+}$. IR (KBr disc): 1636, 1432, 992 cm^{-1}.

3.10. $[Mo(CO)_4\{Ph_2PN(C_3H_5)_2\}]$ (**10**)

To a CH_2Cl_2 (10 cm^3) solution of [$Mo(CO)_4$(nbd)] (184 mg, 0.6 mmol) was added dropwise a CH_2Cl_2 (10 cm^3) solution of $(Ph_2P)N(C_3H_5)_2$ (172 mg, 0.6 mmol). After stirring for 30 min the solvent was reduced to 2 cm^3 before addition of petroleum ether (b.p. 40–60) (20 cm^3) and storing overnight at −18 °C. The yellow solid precipitated was isolated by filtration and dried in vacuo. Yield: 95 mg, 32%. Microanalysis: Found (calculated for $C_{22}H_{20}PNO_4Mo$): C, 54.04 (54.00); H, 3.16 (4.12); N, 2.76 (2.86)%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 116.2 ppm. ^1H NMR ($CDCl_3$) δ 7.3 (m, 10H, aromatic), 5.3 (m, 1H, CH), 5.0 (m, 2H, CH_2), 4.7 (m, 1H, CH), 4.0 (m, 2H, chelate CH_2), 3.5 (m, 4H, NCH_2) ppm. FAB^+ MS: *m/z* $[M]^+$, $[M - CO]^+$, $[M - 2CO]^+$, $[M - 3CO]^+$ 523 $[M - 4CO]^+$. IR (KBr disc): 1893, 1434, 987 cm^{-1}.

3.11. $[RuCl_2\{Ph_2PN(C_3H_5)_2\}(\eta^6\text{-}p\text{-}MeC_6H_4{}^iPr)]$ (**11**)

$(Ph_2P)N(C_3H_5)_2$ (122 mg, 0.4 mmol) and [RuCl(α-Cl)(η^6-*p*-$MeC_6H_4{}^iPr)_2$] (133 mg, 0.2 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield a dark red solution. The solvent was reduced to 1 cm^3 before addition of diethyl ether (10 cm^3) to precipitate an orange solid that was isolated by suction filtration. Yield: 118 mg, 92%. Microanalysis: Found (calculated for $C_{28}H_{34}PNRuCl_2$): C, 57.33 (57.24); H, 5.65 (5.83); N, 2.21 (2.38)%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 74.1 ppm. ^1H NMR ($CDCl_3$) δ 7.3 (m, 14H, aromatic), 5.9 (m, 2H, CH), 4.8 (m, 4H, CH_2), 3.5 (m, 4H, NCH_2), 2.7 (m, 1 H, CH), 1.9 (s, 3H, $ArCH_3$), 1.2 (m, 6H, CH_3) ppm. FAB^+ MS: *m/z* 552 $[M - Cl]^+$, 515/7 $[M - 2Cl]^{2+}$. IR (KBr disc): 1637, 1432, 994, 299, 278 cm^{-1}.

3.12. $[RhCl\{Ph_2PN(C_3H_5)_2\}_2]$ (**12**)

$(Ph_2P)N(C_3H_5)_2$ (148 mg, 0.5 mmol) and [{Rh(α-Cl)(cod)}$_2$] (65 mg, 0.1 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield a dark red solution. The solvent was reduced to 1 cm^3 before addition of diethyl ether (10 cm^3) to precipitate an orange solid that was isolated by suction filtration. Yield: 88 mg, 96%. Microanalysis: Found (calculated for $C_{36}H_{40}P_2N_2RhCl$): C, 61.00 (61.70); H, 6.12 (5.75); N, 3.83 (4.00) $^{31}P\{^1H\}$ NMR ($CDCl_3$): $\delta(P_A)$ 115.5 (d) ppm, ^1J ($^{31}P_A–^{103}Rh$) 154 Hz. $\delta(P_X)$ 84.7 (d) ppm, $^1J(^{31}P_X–^{103}Rh)$ 114 Hz. $^2J(^{31}P_A–^{31}P_X)$ 25 Hz. ^1H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.9 (m, 4H, CH), 4.8 (m, 8H, CH_2), 3.5 (m, 8H, NCH_2) ppm. FAB^+ MS: *m/z* 665 $[M - Cl]^+$. IR (KBr disc): 1638, 1433, 990, 251 cm^{-1}.

3.13. $(Ph_2P)_2N(C_3H_5)$ (**13**)

Allylamine (2.319 g, 40.6 mmol) and triethylamine (8.219 g, 81.2 mmol) were dissolved in thf (50 cm^3). Chlorodiphenylphosphine (17.922 g, 81.2 mmol) in thf (50 cm^3) was added dropwise with stirring overnight to yield triethylamine hydrochloride that was isolated by filtration. The solvent was removed in vacuo to yield a colourless solid that was dried in vacuo. Yield: 13.434 g, 78%. Microanalysis: Found (calculated for $C_{27}H_{25}P_2N$): C, 75.19 (76.22); H, 6.20 (5.92); N, 3.34 (3.29)%. $^{31}P\{^1H\}$ NMR ($CDCl_3$): 62.9 ppm. ^1H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.3 (m, 1H, CH), 4.8 (m, 2H, CH_2), 3.9 (m, 2H, NCH_2) ppm. EI^+ MS: *m/z* 424 $[M]^+$. IR (KBr disc): 1635, 1434, 993 cm^{-1}.

3.14. $[PtCl_2\{(Ph_2P)_2N(C_3H_5)\}]$ (**14**)

$(Ph_2P)_2N(C_3H_5)$ (88 mg, 0.2 mmol) and [$PtCl_2$(cod)] (77 mg, 0.2 mmol) were dissolved in CH_2Cl_2 (10 cm^3) to yield a pale yellow solution that was stirred for 30 min. The solvent was reduced to 1 cm^3 before precipitating a colourless solid upon addition of diethyl ether (20 cm^3) that was isolated by suction filtration. Yield: 101 mg, 71%. Microanalysis: Found (calculated for $C_{27}H_{25}P_2NPtCl_2$): C, 47.81

(46.90); H, 2.53 (3.64); N, 1.56 (2.03)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 19.1 ppm, $^{1}J(^{31}P–^{195}Pt)$ 3296 Hz. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.3 (m, 1H, CH), 4.9 (m, 2H, CH_2), 3.5 (m, 2H, NCH_2) ppm. FAB^+ MS: *m/z* 713/4 $[M + Na]^+$, 691 $[M]^+$, 656 $[M - Cl]^+$, 621 $[M - 2Cl]^{2+}$. IR(KBr disc): 1635, 1435, 995, 302, 291 cm^{-1}.

3.15. $[PdCl_2\{(Ph_2P)_2N(C_3H_5)\}]$ (**15**)

$(Ph_2P)_2N(C_3H_5)$ (104 mg, 0.2 mmol) and $[PdCl_2(cod)]$ (70 mg, 0.2 mmol) were dissolved in CH_2Cl_2 (10 cm^3) to yield an orange solution that was stirred for 30 min. The solvent was reduced to 1 cm^3 before precipitating a pale yellow solid upon addition of diethyl ether (20 cm^3) that was isolated by suction filtration. Yield: 125 mg, 85%. Microanalysis: Found (calculated for $C_{27}H_{25}P_2NPdCl_2$): C, 52.65 (53.80); H, 4.11 (4.18); N, 2.15 (2.32)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 33.1 ppm. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20 H, aromatic), 5.3 (m, 1H, CH), 4.9 (m, 2H, CH_2), 3.6 (m, 2H, NCH_2) ppm. FAB^+ MS: *m/z* 568 $[M - Cl]^+$, 531 $[M - 2Cl]^{2+}$. IR(KBr disc): 1638, 1435, 995, 329, 286 cm^{-1}.

3.16. $[Mo(CO)_4\{(Ph_2P)_2N(C_3H_5)\}]$ (**16**)

To a CH_2Cl_2 (10 cm^3) solution of $[Mo(CO)_4(nbd)]$ (100 mg, 0.3 mmol) was added dropwise a CH_2Cl_2 (10 cm^3) solution of $(Ph_2P)_2N(C_3H_5)$ (141 mg, 0.3 mmol). After stirring for 30 min the solvent was reduced to 2 cm^3 before addition of petroleum ether (b.p. 40–60) (20 cm^3) and storing overnight at −18 °C. The yellow solid precipitated was isolated by filtration and dried in vacuo. Yield: 127 mg, 60%. Microanalysis: Found (calculated for $C_{31}H_{25}P_2NO_4Mo$): C 58.44 (58.78), H 3.83 (3.98), N 2.18 (2.21)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 92.1 ppm. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.3 (m, 1H, CH), 4.7 (m, 2H, CH_2), 3.5 (m, 2H, NCH_2) ppm. FAB^+ MS: *m/z* 635 $[M]^+$, 579 $[M - 2CO]^+$, 523 $[M - 4CO]^+$. IR (KBr disc): 1887, 1434, 999 cm^{-1}.

3.17. $[\{(C_3H_5)N(PPh_2)_2\}(AuCl)_2]$ (**17**)

$(Ph_2P)_2N(C_3H_5)$ (21 mg, 0.05 mmol) and [AuCl(tht)] (32 mg, 0.1 mmol) were dissolved in $CHCl_3$ (2 cm^3) to yield a colourless solution. Diethyl ether (15 cm^3) was added to precipitate a colourless solid that was isolated by suction filtration. Yield: 20 mg, 45%. Microanalysis: Found (calculated for $C_{27}H_{25}P_2NAu_2Cl_2$): C, 36.22 (36.43); H, 2.67 (2.83); N, 1.55 (1.57)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 83.8 ppm. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.3 (m, 1H, CH), 4.8 (m, 2H, CH_2), 3.9 (m, 2H, NCH_2), ppm. FAB^+ MS: *m/z* 853 $[M - Cl]^+$, 819 $[M - 2Cl]^{2+}$. IR (KBr disc): 1655, 1436, 997, 282 cm^{-1}.

3.18. $[RuCl_2\{(Ph_2P)_2N(C_3H_5)\}_2]$ (**18**)

$(Ph_2P)_2N(C_3H_5)$ (150 mg, 0.4 mmol) and $[RuCl(\alpha\text{-}Cl)(\eta^6\text{-}p\text{-}MeC_6H_4{}^{i}Pr)_2]$ (54 mg, 0.1 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield a dark red solution. The solvent was reduced to 1 cm^3 before addition of diethyl ether (10 cm^3) to precipitate a red solid that was isolated by suction filtration. Yield: 57 mg, 63%. Microanalysis: Found (calculated for $C_{54}H_{50}P_4N_2RuCl_2$) C 62.64 (63.41), H 5.39 (4.93), N 2.90 (2.74)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 79.7 ppm. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 40H, aromatic), 5.9 (m, 2H, CH), 4.8 (m, 4H, CH_2), 3.5 (m, 4H, NCH_2) ppm. FAB^+ MS: *m/z* 1022 $[M]^+$, 987 $[M - Cl]^+$, 951 $[M - 2Cl]^{2+}$. IR (KBr disc): 1637, 1434, 998, 289, 273 cm^{-1}.

3.19. $[RhCp^*Cl_2\{(Ph_2P)_2N(C_3H_5)\}]$ (**19**)

$(Ph_2P)_2N(C_3H_5)$ (67 mg, 0.2 mmol) and $[\{RhCl(\alpha\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (49 mg, 0.1 mmol) were dissolved in CH_2Cl_2 (5 cm^3) to yield a blood red solution. The solvent was reduced to 0.5 cm^3 before addition of diethyl ether (20 cm^3) to precipitate an orange solid that was isolated by suction filtration. Yield: 97 mg, 84%. Microanalysis: Found (calculated for $C_{37}H_{40}P_2NRhCl_2.0.25CH_2Cl_2$): C, 58.71 (59.20); H, 5.36 (5.40); N, 1.90 (1.85)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 70.9 ppm, $^{1}J\{^{31}P–^{103}Rh\}$ 120 Hz. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.5 (m, 1H, CH), 4.9 (m, 2H, CH_2), 3.8 (m, 2H, NCH_2), 1.6 (m, 15H, Cp*) ppm. FAB^+ MS: *m/z* 733 $[M]^+$, 698 $[M - Cl]^+$. IR (KBr disc): 1629, 1434, 997, 297, 273 cm^{-1}.

3.20. $[IrCp^*Cl_2\{(Ph_2P)_2N(C_3H_5)\}]$ (**20**)

$(Ph_2P)_2N(C_3H_5)$ (54 mg, 0.1 mmol) and $[\{IrCl(\alpha\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (51 mg, 0.05 mmol) were dissolved in CH_2Cl_2 (10 cm^3) to yield a yellow solution. The solvent was reduced to 0.5 cm^3 before addition of diethyl ether (20 cm^3) to precipitate a yellow solid that was isolated by suction filtration and dried in vacuo. Yield: 76 mg, 72%. Microanalysis: Found (calculated for $C_{37}H_{40}P_2NIrCl_2.0.5CH_2Cl_2$): C, 51.64 (51.99); H, 4.54 (4.77); N, 1.59 (1.62)%. $^{31}P\{^{1}H\}$ NMR ($CDCl_3$): 37.3 ppm. ^{1}H NMR ($CDCl_3$) δ 7.3 (m, 20H, aromatic), 5.3 (m, 1H, CH), 4.8 (m, 2H, CH_2), 3.9 (m, 2H, NCH_2), 1.6 (m, 15H, Cp*) ppm. FAB^+ MS: *m/z* 823 $[M]^+$, 788 $[M - Cl]^+$. IR (KBr disc): 1629, 1434, 997, 310, 304 cm^{-1}.

4. Crystal data

Single crystal X-ray diffraction studies on crystals were performed using a Bruker SMART diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The structures were solved by direct

methods, the non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were fixed. Structural refinements were by the full-matrix least-squares method on F^2 using SHELXTL. **8** $C_{18}H_{20}Cl_2NPPd$, $M = 458.62$, Monoclinic, $a = 8.5139(2)$, $b = 10.6276(2)$, $c = 20.3072(1)$ Å, $\beta = 90.214(1)°$. $U = 1837.4(1)$ Å^3, $T = 125$ K, space group $P2_{1/c}$, $Z = 4$, ∞(Mo Kα) = 1.386 mm^{-1}. Of 7708 measured data, 2624 were unique, to give $R_1[I > 2\sigma(I)] = 0.0187$, wR 0.0460. **14** $C_{27}H_{25}NP_2Cl_2Pt$, $M = 691.41$, monoclinic, $a = 10.8188(16)$, $b = 14.661(2)$ $c = 16.563(2)$ Å, $\beta = 94.512(2)°$, $U = 2618.9(7)$ Å^3, space group $P2_{1/n}$, $Z = 4$, ∞(Mo Kα) = 5.700 mm^{-1}. Of 12 794 measured data, 3717 were unique to give $R_1[I > 2\sigma(I)] = 0.0430$ and $wR_2 = 0.1032$. **18** $C_{54}H_{50}N_2P_4Cl_2Ru$, $M = 1022.81$, triclinic, $a = 10.1826(17)$, $b = 11.1207(19)$ $c = 12.597(2)$ Å, $\alpha = 111.490(3)°$, $\beta = 95.557(3)°$, $\gamma = 113.376(3)°$, $U = 1168.3(3)$ Å^3, space group $P2_{1/n}$, $Z = 4$, ∞(Mo Kα) = 0.627 mm^{-1}. Of 5901 measured data, 3306 were unique to give $R_1[I > 2\sigma(I)] = 0.0288$ and $wR_2 = 0.0701$.

5. Supplementary material

Crystallographic Data for the structural analyses has been deposited with the Cambridge Crystallographic data centre, CCDC Nos. 242186–242188. Chart 1. Structures of the *gauche* and *anti* conformations of the bte molecule.

(bte) and cadmium(II) salts with different anions NO_3^-, NO_2^-, ClO_4^- and NCS^-, and the structural characterization of five cadmium complexes, $\{[Cd(bte)_3](NO_3)_2\}_n$ (**1**), $\{[Cd(bte)_2(H_2O)_2](NO_3)_2\}_n$ (**2**), $\{[Cd(bte)(NO_2)_2]\}_n$ (**3**), $\{[Cd(bte)_2(H_2O)_2](H_2O)_2(ClO_4)_2\}_n$ (**4**) and $[Cd(bte)(NCS)_2]_n$ (**5**).

2. Experimental

2.1. General procedures

The flexible ligand 1,2-bis(1,2,4-triazol-1-yl)ethane (bte) was synthesized according to the literature method [12]. All other reagents and solvents employed were commercially available and used as received without further purification. The C, H, N microanalyses were carried out with a Perkin–Elmer 240C analyser. IR spectra were obtained for KBr pellets on a Nicolet 170SX FT-IR spectrophotometer in the 4000–400 cm^{-1} region. Thermogravimetric data were collected on Thermal Analyst 2100 TA Instrument and SDT 2960 Simutaneous TGA-DTA Instrument in flowing dinitrogen at a heating rate 10 °C/min.

2.2. Preparation of the complexes

2.2.1. $\{[Cd(bte)_3](NO_3)_2\}_n$ (*1*)

This compound was prepared under hydrothermal conditions. $Cd(NO_3)_2 \cdot 3H_2O$ (0.093 g, 0.3 mmol) and bte (0.148 g, 0.90 mmol) in the molar ratio of 1:3 in 16 ml H_2O were heated at 140 °C for three days. After cooling, the resultant solution was filtered and well-shaped colorless single crystals of **1** were obtained after the filtrate was allowed to stand at room temperature for two weeks. Yield: 0.142 g, 65%. *Anal.* Calc. $C_{18}H_{24}CdN_{20}O_6$: (728.97): C, 29.66; H, 3.32; N, 38.44. Found: C, 29.69; H, 3.37; N, 38.50%. IR data (cm^{-1}): 3109m, 1516s, 1462w, 1385vs, 1281s, 1211m, 1126s, 1015w, 984w, 961w, 884w, 694w, 683w, 656w.

2.2.2. $\{[Cd(bte)_2(H_2O)_2](NO_3)_2\}_n$ (*2*)

A methanolic solution (10 ml) of bte (0.098 g, 0.60 mmol) was added to an aqueous solution (10 ml) of $Cd(NO_3)_2 \cdot 3H_2O$ (0.093 g, 0.3 mmol) with stirring. The colorless single crystals of **2** were obtained after the mixture was allowed to stand for two weeks. Yield: 0.101 g, 56%. *Anal.* Calc. $C_{12}H_{20}CdN_{14}O_8$ (600.82): C, 23.99; H, 3.36; N, 32.65. Found: C, 24.01; H, 3.39; N, 32.71%. IR data (cm^{-1}): 3383m, 3113m, 1628w, 1528s, 1385vs, 1335s, 1285s, 1219w, 1138s, 1022w, 1007w, 899w, 833w, 675w, 656m.

2.2.3. $\{[Cd(bte)(NO_2)_2]\}_n$ (*3*)

An aqueous solution (2 ml) KNO_2 (0.077g, 0.9 mmol) was added to an aqueous solution (2 ml) of $Cd(ClO_4)_2 \cdot 6H_2O$ (0.126 g, 0.3 mmol) with stirring. The resultant solution was filtered. A methanolic solution (10 ml) of bte (0.098 g, 0.60 mmol) was added to the filtrate with stirring. The colorless single crystals of **3** were obtained after the mixture was allowed to stand for one week. Yield: 0.057 g, 51%. *Anal.* Calc. $C_6H_8CdN_8O_4$: (368.60): C, 19.55; H, 2.19; N, 30.41. Found: C, 19.56; H, 2.23; N, 30.47%. IR data (cm^{-1}): 3129m, 1528s, 1466w, 1354w, 1277s, 1215vs, 1130vs, 1011w, 988w, 899w, 853w, 675w, 648w.

2.2.4. $\{[Cd(bte)_2(H_2O)_2](H_2O)_2(ClO_4)_2\}_n$ (*4*)

A methanolic solution (10 ml) of bte (0.098 g, 0.6 mmol) was added slowly to an aqueous solution (10 ml) of $Cd(ClO_4)_2 \cdot 6H_2O$ (0.126 g, 0.3 mmol) with stirring. The mixture was stirred at room temperature and the resultant solution was filtered. After the filtrate was allowed to stand for three days, colorless single crystals of **4** were obtained. Yield: 0.113 g, 53%. *Anal.* Calc. $C_{12}H_{24}CdCl_2N_{12}O_{12}$: (711.74): C, 20.25; H, 3.40; N, 23.62. Found: C, 20.27; H, 3.45; N, 23.68%. IR data (cm^{-1}): 3438m, 3110m, 3090m, 1519s, 1474w, 1273s, 1216m, 1125vs, 1089vs, 1009m, 984m, 891w, 682m, 627m.

2.2.5. $[Cd(bte)(SCN)_2]_n$ (*5*)

A H_2O/MeOH (1:1, v/v) solution (15 ml) of $Cd(NO_3)_2 \cdot 3H_2O$ (0.154 g, 0.5 mmol) and KSCN (0.097 g, 1 mmol) was added to one side of a "H-shape" tube equipped with a frit, and 15 ml H_2O/MeOH solution (1:1, v/v) of bte (0.082 g, 0.5 mmol) was added to the another side of the "H-shape" tube. After about one month, well-shaped colorless single crystals of **5** were obtained. Yield: 0.071 g, 36%. *Anal.* Calc. $C_8H_8CdN_8S_2$: (392.74): C, 24.47; H, 2.05; N, 28.54. Found: C, 24.50; H, 2.07; N, 28.59%. IR data (cm^{-1}): 3118w, 2110vs, 1524s, 1445w, 1386w, 1288m, 1208w, 1135s, 1010w, 984w, 904w, 872w, 707w, 674w, 644w.

2.3. X-ray crystallography

All data collections were performed at a temperature of 193.15 K on a Rigaku Mercury CCD diffractometer with the ω-scan technique. The structures were solved by direct methods and refined with the full-matrix

least-squares technique using the SHELXS-97 and SHELXL-97 programs [13]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms of the bte ligands were generated geometrically. The hydrogen atoms of the water molecules were located from the difference Fourier maps. The crystallographic data for **1**–**5** are listed in Table 1. The selected bond lengths and angles for **1**–**5** are listed in Table 2.

3. Results and discussion

3.1. Preparation of the complexes

The hydrothermal reaction of bte and $Cd(NO_3)_2 \cdot 3H_2O$ resulted in a double interpenetrating three-dimensional α-poloniumn cubic network, **1**. Direct treatment of bte and cadmium salts with poor coordination ability anions, NO_3^- and ClO_4^-, under the same reaction conditions produced a two-dimensional (4,4) network, **2**, and an infinite double chain, **4**. For compounds **2** and **4**, we found that they both have a Cd/bte molar ratio of 1:2. The different structures of **2** and **4** show that the supramolecular topologies are highly influenced by the counteranions. The key factor governing the structural topologies of **1** and **2** is the Cd/bte molar ratio (1:3 in **1** and 1:2 in **2**). As NO_2^- and NCS^- not only can act as counteranions to sustain neutral charge, but also have various coordination modes, and thus can provide a suitable "building block" for assembling novel inorganic/organic hybrid materials. We want to introduce these anion ligands into the Cd/bte reaction mixture as co-ligands in order to prepare some novel bte/Cd complexes. Mixing of $Cd(ClO_4)_2 \cdot 6H_2O$, KNO_2 and bte with a molar ratio of 1:2:1 in $MeOH/H_2O$ solution resulted in a two-dimensional rhombic network, **3**, via nitrato bridging and a Cd/bte molar ratio of 1:1. $Cd(NO_3)_2 \cdot 3H_2O$ and KNCS react with bte with a molar ratio of 1:2:1 or 1:2:2 in $MeOH/H_2O$ solution through the slow diffusion method to produce a two-dimensional rhombic network, **5**, via NCS^- bridging.

3.2. Crystal structures

The X-ray analysis revealed that **1** is composed of a $[Cd(bte)_3]_n^{2n+}$ macrocation and disordered NO_3^- anions. Each cadmium(II) atom is located on a $\bar{3}$ position with an octahedral geometry (Fig. 1). Each cadmium(II) atom is coordinated by six exodentate nitrogen atoms at the 4-position of the triazole rings from the six individual bte ligands, all of which are equivalent. The N–Cd–N bond angles are close to 90° [89.14(7)° and 90.86(7)°]. Each bte ligand adopts the *anti* conformation and bridges two adjacent cadmium(II) atoms, building up polymers to an open three-dimensional α-poloniumn cubic network (Fig. 2(a)). The Cd···Cd separation is 12.2825(15) Å through the bte ligand. There are double interpenetrating α-poloniumn cubic networks in the crystal (Fig. 2(b)) and channels with dimensions of approximately 6×6 Å are formed, which are filled by disordered NO_3^- anions.

The structure of **2** consists of a two-dimensional (4,4) network, which is obviously different from the open three-dimensional α-poloniumn cubic network in **1**. The key factor governing the structural topologies of **1**

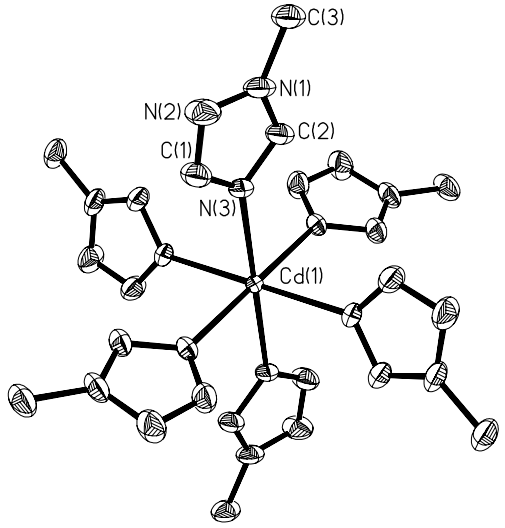

Fig. 1. ORTEP drawing of **1** with the atom numbering, showing the cadmium(II) coordination environment.

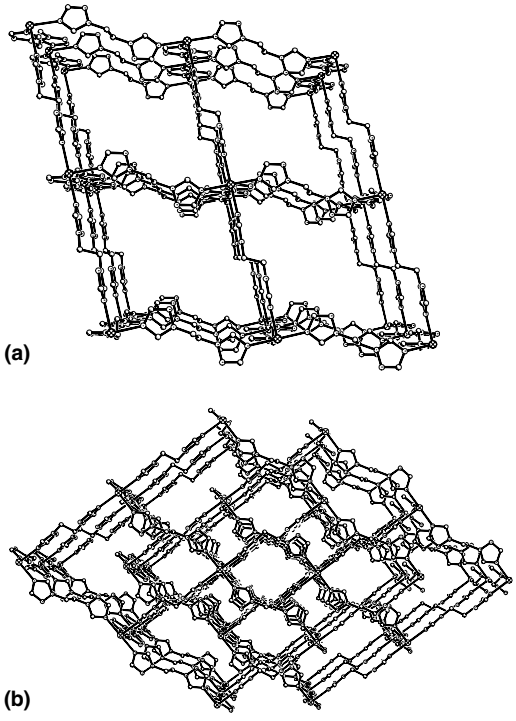

Fig. 2. (a) View of the three-dimensional α-poloniumn cubic network in **1** showing the channels and (b) view of the double interpenetrating three-dimensional α-poloniumn cubic networks in **1**.

and **2** is the Cd/bte molar ratio (1:3 in **1** and 1:2 in **2**). The local geometry of the cadmium(II) atom in **2** is a distorted octahedral arrangement with two water molecules in *trans* positions and four triazole nitrogen atoms from the four bte ligands in the basal plane (Fig. 3). Each bte ligand connects two cadmium(II) atoms to form a two-dimensional (4,4) network containing square $Cd_4(bte)_4$ units (Fig. 4(a)). The two-dimensional network structure consists of puckered rhombus grids with dimensions of 8.1×8.1 Å. The most intriguing feature of the structure is that the basic grid of the two-dimensional network is puckered [14] (Fig. 4(b)), which is different from those observed in the previous grid-like structures where the basic grids are usually coplanar or quasi-coplanar [15]. The puckered shape of the basic grid in **2** is understandable because the bte ligand exhibits the *gauche* conformation in **2**. We note that the ultimate structure of a two-dimensional network is wave-like with a tightly puckered structure containing nitrate anions. There are hydrogen bonding interactions between the hydrogen atoms of the coordination water molecules and the oxygen atoms of the nitrate anions [O(1)–H(WA)···O(3) (x, $-y+0.5$, $z+0.5$), 2.722 Å and O(1)–H(WB)···O(4), 2.850 Å].

The structure of **3** is composed of a two-dimensional rhombic network. The coordination geometry of the cadmium(II) atom is a distorted pentagonal–bipyramid with two nitrogen atoms from the two bte ligands in

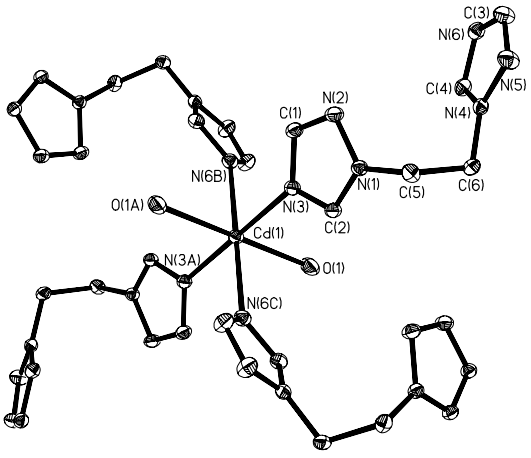

Fig. 3. ORTEP drawing of the cadmium(II) coordination environment in **2** and the atom numbering scheme.

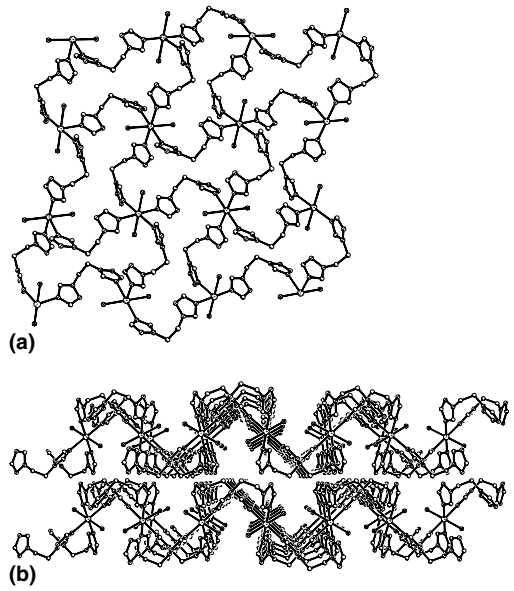

Fig. 4. (a) View of the two-dimensional (4,4) network in **2** along the *a* direction and (b) view of the tightly packed structure in **2** along the *c*-direction, only two layers are shown for clarity.

axial positions and five oxygen atoms from the three nitrite anions in the basal plane (Fig. 5(a)). This cadmium(II) coordination geometry is similar to that of di(nitrito)bis(isonicotonamide)aquacadmium, in which the cadmium(II) atom is in a distorted pentagonal–bipyramidal coordination with the two bidentate NO_2^- groups and one H_2O molecule in the equatorial plane and two nitrogen atoms from the two monodentate isonicotinamide ligands occupying the apexes [16]. There are two kinds of nitrite anions in **3**. One is a disordered nitrite anion with the end-to-end $\mu_{1,3}$-ONO-bridging mode, which is common in nitrite compounds [17]. An occupancy factor of 0.5 was assigned to the N(8), N(9), O(3), O(4), O(5) and O(6) atoms for the disordered nitrite. The other is a tridentate nitrite anion $\mu_{1,3}$-ONO chelating one cadmium(II) atom and one oxygen atom bridging two cadmium(II) atoms. This tridentate nitrite coordination, which was first reported by Kahn in $[Ni(en)_2(NO_2)]_2[B(C_6H_5)_4]$ [17b], has not been observed before in cadmium compounds. The tridentate nitrite anions link the cadmium(II) atoms and form a one-dimensional linear chain with a Cd···Cd distance of 4.453(3) Å. Each bte ligand has an *anti* conformation and links two cadmium(II) atoms with Cd···Cd distances of 12.357(3) and 12.457(3) Å, building up the one-dimensional chains to form a two-dimensional rhombic network with dimensions of 4.4×12.4 Å (Fig. 5(b)).

The structure of **4** is a one-dimensional double chain. The coordination geometry of the cadmium(II) atom in **4** is a distorted octahedral, in the equatorial plane of which is located four nitrogen atoms from the four bte ligands, and the axial positions are occupied by two oxygen atoms from the two water molecules (Fig. 6(a)), which is similar to the coordination geometry of the cadmium(II) atom in **2**. The Cd/bte molar ratios are both

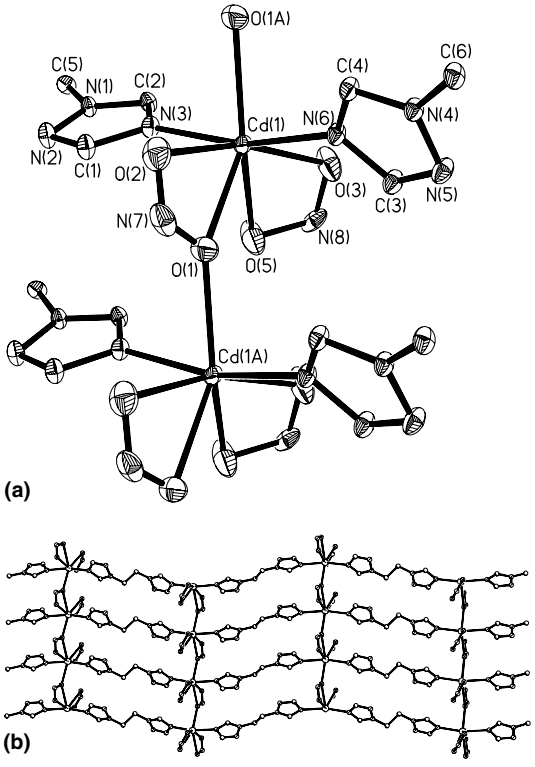

Fig. 5. (a) Drawing of the cadmium(II) coordination environment in **3** and the atom numbering scheme and (b) view of the two-dimensional rhombic network in **3**.

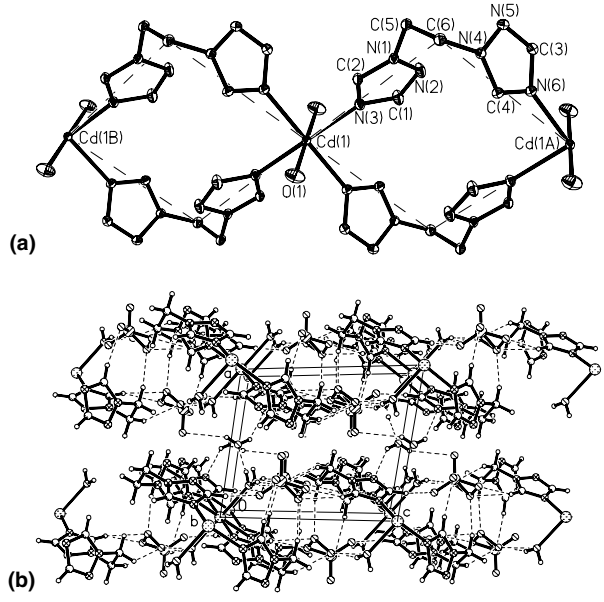

Fig. 6. (a) Drawing of the cadmium(II) coordination environment in **4** and the atom numbering scheme and (b) view of the cell stacking in **4**.

1:2 for compounds **2** and **4**. The differences between **4** and **2** are that one bte ligand bridges two equivalent cadmium(II) atoms in **2** while two bte ligands bridge two equivalent cadmium(II) atoms in **4**. So **4** forms a one-dimensional double chain while **2** forms a two-dimensional (4,4) network. The different structures of **2** and **4** show that the supramolecular topologies are highly influenced by the counteranions. The bte ligand exhibits the *gauche* conformation in **4**. Two bte ligands are wrapped around each other and are held together by cadmium(II) atoms forming a one-dimensional double chain. A rhombic network with a size of 6.6×5.8 Å is formed. As in other double-stranded chain complexes [4c,5b,8,10a,10c,14,18], each chain consists of 18-membered rings, $[Cd_2(bte)_2]$, in which two cadmium(II) atoms are joined by two bte molecules. The Cd···Cd separation across the bte ligand is 8.601(2) Å, which is similar to the Cd···Cd separation of 8.118(2) Å in **2**.

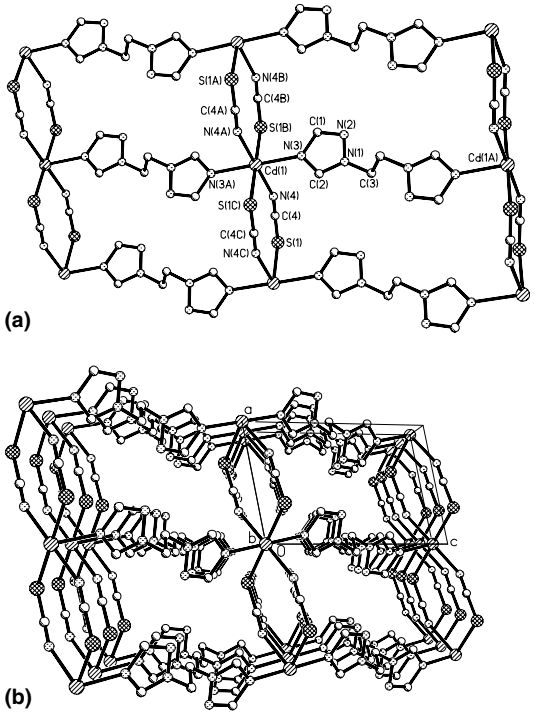

Fig. 7. (a) Drawing of the cadmium(II) coordination environment in **5** and the atom numbering scheme and (b) view of the stacking layers in **5** along the *b*-direction.

There are hydrogen bonding interactions between the coordination water molecules and the solvent water and the perchlorate anions [O(1)–H(W1)···O(8) ($x + 1$, $y - 1$, z) 2.687 Å; O(1)–H(W2)···O(7), 2.690 Å] (Fig. 6(b)). These are also hydrogen bonding interactions between the solvent water molecule and the perchlorate anion and the uncoordinated nitrogen atom of the triazole rings of the bte ligand [O(8)–H(W3)···O(2) ($-x$, $-y + 1$, $-z$) 3.185 Å, O(8)–H(W4)···N(2) 2.978 Å].

The crystal structure of **5** is a two-dimensional rhombic network. Each cadmium(II) atom in **5** is located on an inversion center and coordinated by two thiocyanate nitrogen atoms [Cd–N(SCN), 2.3082(18) Å] and two thiocyanate sulfur atoms [Cd–S(SCN), 2.7560(8) Å] in a *trans* geometry in the equatorial plane, resulting in a two-dimensional network containing eight-membered $[Cd_2(SCN)_2]$ rings (Fig. 7(a)). The μ-SCN-*N*,*S* coordination mode for the cadmium(II) atom is one of the usual coordination fashions [19] since the cadmium(II) atom is between hard base and soft base according to the hard–soft acid–base concept. Two nitrogen atoms of two bte ligands complete the remaining two axial positions around the six-coordinate cadmium(II) center in the distorted octahedron [Cd–N(bte), 2.3237(16) Å]. The bte ligands exhibit the *anti* conformation in **5**. The cadmium(II) atoms are bridged by the bte ligands and the double μ-NCS^- anions, resulting in the two-dimensional rhombic network. The Cd···Cd distances bridged via the μ-NCS^- anions and the bte ligands are 5.904(2) and 12.350(3) Å, respectively. The rhombic network is composed of Cd_4 units with dimensions of 12.35 Å $\times$ 5.90 Å. The parallel two-dimensional network sheets stack on each other along the *b*-direction and the distance between adjacent sheets is 6.529(2) Å (Fig. 7(b)).

The conformations of the bte ligands, the $N_{triazoe}$–$(C–C)_{ethane}$–$N_{triazole}$ torsion angles, the dihedral angles between the two triazole rings of the bte ligands and the Cd···Cd distances through the bte ligands in the five complexes are listed in Table 3. The bte ligands act in the *anti* conformation in **1**, **3** and **5** and in the *gauche* conformation in **2** and **4**. The torsion angles and the dihedral angles show great differences between the bte ligands with the *gauche* and *anti* conformations. The torsion angles and the dihedral angles of the bte ligands

Table 3
The dihedral angles (°) of the two triazole rings and the N–$(C–C)_{ethane}$–N torsion angle (°) of the bte ligands and Cd···Cd separations through the bte ligands (Å) for the five complexes

Complexes	Dihedral angle of the two triazole planes	Torsion angle $N_{triazole}$–$(C–C)_{ethane}$–$N_{triazole}$	Cd···Cd separations *through* the bte ligands
1	0.00	180.00	12.2825(15)
2	35.37(13)	67.38(28)	8.118(2)
3	0.00	180.00	12.357(3), 12.457(3)
4	56.54(15)	63.39(34)	8.601(2)
5	0.00	180.00	12.350(3)

with the *anti* conformation are 180.0° and 0.0°, respectively, in **1**, **3** and **5**. The torsion angles of the bte ligands with the *gauche* conformation show slight differences, 67.38(28)° in **2** and 63.39(34)° in **4**, but the dihedral angles of the bte ligands with the *gauche* conformation show large differences, 35.37(13)° in **2** and 56.54(15)° in **4**, which may be ascribed to the different coordination modes of the bte ligands. The Cd···Cd distances through the bte ligands with the *gauche* conformation are 8.118 Å in **2** and 8.601(2) Å in **4**, and the Cd···Cd distances through the bte ligands with the *anti* conformation are 12.2825(15) Å in **1**, 12.357(3), 12.457(3) Å in **3** and 12.350(3) Å in **5**. The structural data shows the flexibility of the bte ligand in the five coordination polymers.

3.3. IR and thermogravimetric analysis

The very strong absorption at 1385 cm^{-1} in **1** and **2** is attributed to the free nitrate anions. The very strong absorption bands at 1215 and 1130 cm^{-1} and weak absorption at 853 cm^{-1} in **3** suggest two coordinating mode of the nitrite anions [17], which was confirmed by the X-ray diffraction analysis. The very strong absorption bands at 1125vs and 1089vs in **4** are attributed to the perchlorate anions. The very strong C≡N stretching vibration of the thiocyanate anions in **5** at 2110 cm^{-1} suggests a bridging mode [20].

Thermal analysis of **1** shows that **1** is stable up to 252 °C. Thermal analysis of **2** shows that the coordinated water molecules are lost in a continuous fashion (Obsd. 6.3; Calcd. 6.0%) between 110 and 170 °C, then the bte ligands begin to be lost in a continuous fashion. **3** is stable up to 240 °C. Thermal analysis of **4** shows that the water molecules are lost in a continuous fashion in 60–120 °C (Obsd. 10.2; Calc. 10.1%) and the bte ligands begin to be lost above 322 °C. Complex **5** is stable up to 180 °C.

4. Conclusion

In spite of the similarity of the building blocks used, the products display quite different structures. The isolated five coordination complexes include a double interpenetrating three-dimensional α-poloniumn cubic network (**1**), a two-dimensional (4,4) network (**2**), a two-dimensional rhombic network (**3** and **5**), and a one-dimensional double chain (**4**) formed by coordination bonds. The variety of the observed structural motifs confirms that the rationalization of the resulting topologies is still difficult. Many factors play a role in the formation of the final products: (i) the counterions effects (NO_3^- in **1** and **2**, NO_2^- in **3**, ClO_4^- in **4** and NCS^- in **5**); (ii) the conformational flexibility of the bte ligand (the *anti* conformation in **1**, **3** and **5**, the *gauche* conformation in **2** and **4**); (iii) the synthesis methods (direct reaction of $Cd(NO_3)_2 \cdot 3H_2O$ with the bte ligand) resulted in the two-dimensional (4,4) network **2**, while the hydrothermal reaction of $Cd(NO_3)_2 \cdot 3H_2O$ and the bte ligand resulted in the three-dimensional α-poloniumn cubic network **1**; (iv) the molar ratios of the metal: ligand (1:3 in **1**, 1:2 in **2** and **4**, 1:1 in **3** and **5**). The results demonstrate the feasibility of achieving various polymeric frameworks by self-assembly of the flexible bis(triazole) ligand and metal salts and may provide useful information for crystal engineering.

$[NH_4]_2[MoS_4]$, $[NH_4]_2[WS_4]$ [12], and 3,5-dimethylpyrazole [13] were prepared by published methods. The infrared spectra (4000–400 cm^{-1}) were recorded from KBr disks with a BOMEN MB102 FT-IR spectrometer. UV–Vis spectra of the ligands and complexes were recorded on a JASCO model 7850 spectrophotometer. ^1H NMR spectra were obtained using a Bruker DRX 500 AVANCE spectrometer. Elemental analyses were performed on a Carlo-Erba 1106 elemental analyser.

2.2. Preparation of $MoS_4Cu_4(pz^{Me2})_6Cl_2$ (1)

$[n\text{-}Bu_4N]_2[MoS_4Cu_4Cl_4]$ (1.104 g, 1 mmol) was dissolved in acetone (25 ml). Excess 3,5-dimethylpyrazole (0.672 g, 7 mmol) was added to the solution and the mixture was stirred at room temperature for 12 h. After filtration, the filtrate was vacuum evaporated to dryness, and the residue was washed with distilled water (2×2 ml), ethanol (2×2 ml) and diethyl ether (2×5 ml) and dried in vacuo to give a brown powder. Yield: 65%. Dark purple crystals were obtained after two days by slow evaporation of a saturated solution of the complex in acetone. *Anal.* for (**1**): C, 31.90; H, 4.25; N, 14.80. Calc. C, 32.00; H, 4.30; N, 14.93%.

2.3. Preparation of $WS_4Cu_4(pz^{Me2})_6(Cl/Br)_2$ (2)

n-Bu_4NBr (0.805 g, 2.5 mmol) was added to a suspension of $[NH_4]_2[WS_4]$ (0.348 g, 1 mmol) in analar acetone (30 ml) and the mixture was stirred for 1 h. CuCl (0.398 g, 4 mmol) was added to this solution and the mixture was stirred for another 3 h. After addition of excess 3,5-dimethylpyrazole (0.672 g, 7 mmol), the solution was stirred for an additional 12 h at room temperature. The precipitated NH_4Br was removed by filtration and the filtrate was vacuum evaporated to dryness, leaving a residue that was washed with distilled water (2×5 ml), ethanol (2×2 ml) and diethyl ether (2×5 ml) and dried in vacuo to give a dark red powder. Yield: 60%. Red crystals of the compound were obtained in the same way as for $MoS_4Cu_4(pz^{Me2})_6Cl_2$. *Anal.* for (**2**): C, 29.00; H, 3.90; N, 13.65. Calc. C, 28.84; H, 3.87; N, 13.45%, for the composition established by crystallographic refinement.

2.4. X-ray crystallography

Crystal data and other information on the structure determinations are listed in Table 1. All measurements were made on Bruker–Nonius SMART (**1**) and KappaCCD (**2**) diffractometers with narrow-frame ω scans. Mo Kα radiation ($\lambda = 0.71073$ Å) was employed for data collection at 150 K. Absorption corrections were based on the high redundancy of symmetry-equivalent and repeated reflections. The structures were solved by direct methods and refined by full-matrix least-squares on all F^2 values. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions and refined with isotropic displacement parameters, riding on their parent atoms, except that those bonded to N were refined freely. In the structure of **2** the Cl atoms are randomly substituted by Br in the proportion 0.6:0.4, arising from the use of *n*-Bu_4NBr in the synthesis. A common position was refined for Cl and Br, as it proved impossible to refine them independently. Programs were standard Bruker–Nonius control and integration software, SADABS [14] and SHELXTL [15].

3. Result and discussion

3.1. Infrared spectra

The IR spectra of $MS_4Cu_4(pz^{Me2})_6X_2$ exhibit characteristic strong bands at 447 and 420 cm^{-1} for compound **1** and 437 and 419 cm^{-1} for compound **2**, assigned to stretching vibrations of the MS_4 group [16]. In general, attachment of copper atoms to the $[MS_4]^{2-}$ anion to form an MS_4Cu_n ($n = 1$–4) core shifts the M–S stretching frequencies to lower values as n increases; this is consistent with the longer $M–S_b$ bonds, as confirmed by X-ray crystallography. The ν(N–H) and ν(C–H, aliphatic) stretching vibrations of the pz^{Me2} ligands appear as multiple bands in the region 2858–3351 cm^{-1}. The other absorption peaks of the pz^{Me2} ligands appear at 1700–650 cm^{-1}.

3.2. Electronic spectra

The UV–Vis spectra of the two compounds in DMF are similar in profiles, wavelength and intensity to the electronic spectra of $[Et_4N]_2[MS_4Cu_4(SCN)_2(2\text{-pic})_4]$ (M = W, Mo) [17] in the same solvent. They have absorption bands at 286 and 506 nm for the Mo cluster **1**, and at 256 and 426 nm for the W cluster **2**. The first of these in each case may be attributed to charge transfer from the ligand to Cu, and the other can be assigned as a charge-transfer band of the type $(\pi)S \rightarrow (d)M$ (M = Mo, W), arising from the MS_4 moiety, which is red-shifted compared to that for the free $[MS_4]^{2-}$ anion (397 nm for W and 472 nm for Mo).

3.3. ^1H NMR spectra

The ^1H NMR spectrum of $MoS_4Cu_4(pz^{Me2})_6Cl_2$ in $CDCl_3$ solution at room temperature exhibits three signals, as expected for pz^{Me2} ligands. The resonance at 2.346 ppm is associated with the methyl protons in the 3- and 5-positions of the pyrazole rings, indicating that all of these protons are magnetically equivalent. There are two other signals at 5.941 and 9.787 ppm (br), asso-

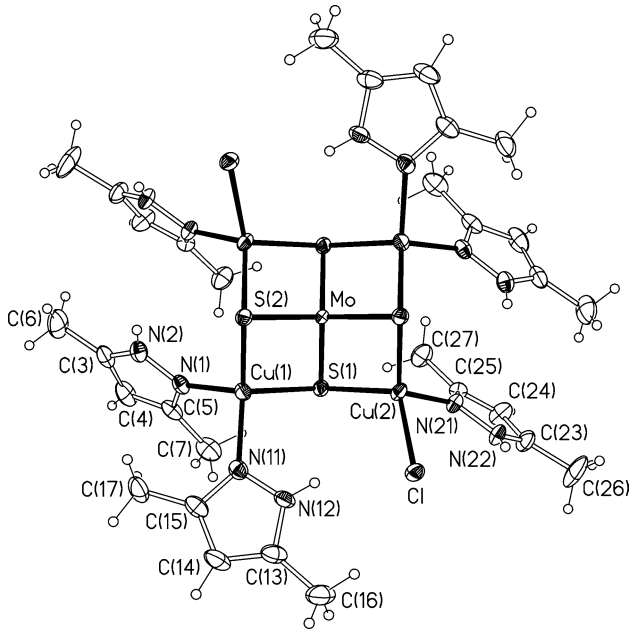

Fig. 1. A perspective view of the structure of the neutral cluster $MoS_4Cu_4(pz^{Me2})_6Cl_2$ (**1**). Non-hydrogen atoms of the asymmetric unit are labelled. Displacement ellipsoids are drawn at the 50% probability level, and H atoms are represented as spheres of arbitrary radius.

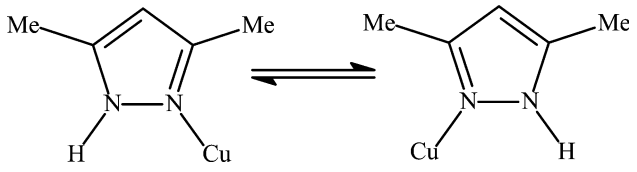
ciated with the H_4 and H_1 protons of the pz^{Me2} rings. As for compound **1**, the ^{1}H NMR spectrum of $WS_4Cu_4(pz^{Me2})_6X_2$ (**2**) also shows three signals, at 2.223, 5.907 and 11.619 ppm, due to the methyl protons in the 3- and 5-positions, and the H_4 and H_1 protons; these resonances are in the ratio 6:1:1. This result indicates that rapid exchange is occurring between coordinated copper and the H_1 proton of the pyrazole ring (Scheme 1).

3.4. Crystal structures

The solid-state molecular structure of the pentanuclear neutral cluster **1** is shown in Fig. 1; that of compound **2** is very similar, and the two compounds are isomorphous. Selected bond lengths and angles are in Table 2. The description here concentrates on the details for compound **1**. The structures are similar to those of $MS_4Cu_4(SCN)_2(NC_5H_5)_6$ (M = Mo, W) [18].

The structural core consists of one Mo, four Cu and four μ_3-S atoms in an MoS_4Cu_4 aggregate. The neutral cluster lies on a crystallographic twofold rotation axis, which is perpendicular to the mean plane of the five metal atoms. The four Cu atoms bridge four of the six edges of the central MoS_4 tetrahedron, selected symmetrically in a way that generates two Cu–S bonds for each sulfur atom and places the Cu atoms as far apart as possible.



Scheme 1.

The Mo and Cu atoms are tetrahedrally coordinated. The geometry around Mo does not deviate markedly from ideal tetrahedral, and the Mo–S bonds are somewhat longer than those of the free $[MoS_4]^{2-}$ anion, as expected [2.17 Å in the ammonium salt]. The Cu atoms are of two types, with pairs of equivalent Cu atoms lying opposite each other. Cu(1) is coordinated by two μ_3-S atoms and two nitrogen atoms of pz^{Me2} rings, giving a distorted tetrahedral CuS_2N_2 arrangement, while Cu(2) is coordinated by two μ_3-S atoms, one nitrogen atom of pz^{Me2}, and one terminal Cl ligand, producing a distorted tetrahedral CuS_2NCl unit. The Cu–S bonds of Cu(2) are longer than those of Cu(1), while Cu(2) has a shorter Cu–N bond than those of Cu(1). The bond lengths involving Cu are comparable to those found in the related compounds $[Et_4N]_2[(Bp')CuMoS_4Cu_2(\mu\text{-}Bp')_2Cu_2MoS_4Cu(Bp')]$ [19] (mean Cu–S = 2.27 Å, Cu–N = 2.04 Å) and $[Et_4N]_2[MoS_4Cu_2(\mu\text{-}Bp')_2]\cdot CH_3CN$ [20] [$Bp' = H_2B(3,5\text{-}Me_2pz)_2$] (mean Cu–S = 2.27 Å, Cu–N = 2.08 Å). The angle between the two terminal ligands at Cu(1) is rather larger than that at Cu(2), as a result of the greater steric bulk of the pz^{Me2} ligand compared with chloride.

The N–H groups of the three independent pz^{Me2} ligands act as donors in intramolecular and intermolecular

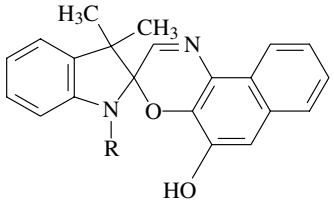
(SO) **(MC)**

Scheme 1.

2. Experimental

2.1. Materials

The photochromic molecules were two spiro[indolinonaphthooxazines]: 1,3,3-trimethyl-5′-hydroxyspiro-(indoline-2,3′-[3H]naphth[2,1-b][1,4]oxazine) (**1**) and 1-butyl-3,3-dimethyl-5′-hydroxyspiro(indoline-2,3′-[3H] naphth[2,1-b][1,4]oxazine) (**2**). The compounds were recently prepared and characterized in our laboratory [18,19]. The p.a. grade metal salts were obtained from Fluka and were used without further purification. The solvents were used after distillation.



1: R = CH_3

2: R = C_4H_9

2.2. Instrumentation

Absorption spectra were recorded on a SPECORD UV–Vis (Carl Zeiss, Jena) spectrophotometer using quartz cells. For absorption measurements at varying temperatures the reaction cell was enclosed in a thermostatic water jacket placed inside the spectrophotometer sample chamber. A 250 W medium-pressure mercury lamp was used for producing the coloured form. Photochemical reactions were carried out in the spectrophotometric quartz cell with a homogeneously spread light on the cell window to avoid stirring [20,21]. Measurements were made on aerated solutions. EPR spectra were taken at 77 K on an X-band BRUKER B-ER 420 spectrometer using 100 kHz modulation of the magnetic field.

2.3. Kinetics measurements

The effects of metal ions on the **SO** ⇌ **MC** process were studied in 1:1 aqueous/acetone or aqueous/ethanol mixtures at a constant spironaphthooxazine concentration of 5×10^{-5} M and varying the ratio between the **SO** and the metal ion from 2:1 to 1:20.

The kinetics of the thermal colouration in the presence of metal ions was measured at different temperatures in the range 20–50 °C, ca. 30 min after having set the temperature control in order to allow the initial solutions to reach the appropriate temperature in separate vessels. The absorbance was measured at the wavelength of maximum absorption (λ_{max}) directly in the sample cell at 30 s intervals after the insertion of 10 equiv. of aqueous metal ion solution in ethanol solutions of **1** or **2**. First order build up rate constants were obtained from the linear dependences of ln A versus time. The activation energies along with the frequency factors of thermal ring opening were determined from Arrhenius plots.

In the photocolouration experiment the cuvette was irradiated for several seconds after thermal equilibration of the reaction mixture containing **SO** and the metal ion in 1:1 aqueous/ethanol. Trial and error experiments enabled the optimum exposure time to be determined for maximum build-up of the complex. The ring-closure reaction after photocolouration was monitored directly after the removal of the light, scanning at the wavelength of maximum absorption of the complex between the **MC** form and the metal ion (λ_{compl}) at 15 s intervals over a period of 30–50 min at room temperature. First order rate constants of thermal re-equilibration were obtained from the linear ln A versus time descending curves. by extrapolation of the obtained ln A/t plots to zero time, the absorbance A_o of the complexes at $t = 0$ was related to their "colourabilities" [21–24] using the expression $A_o/c_{\mathbf{SO}}b$ in which $c_{\mathbf{SO}}$ was the initial concentration of **SO** and b was the optical path length.

3. Results and discussion

The colourless spiro compounds **1** and **2** give no complexes with the metal ions. However, their merocyanines form complexes with Cu(II), Fe(II) and Al(III) in polar solvents, while Cr(III), Mn(II), Ni(II), Co(II), Ba(II) and Mg(II) do not affect the equilibrium between **SO** and **MC** in Scheme 1.

3.1. Absorption spectra

Visible spectra of photomerocyanines, obtained upon UV illumination of **1** or **2** in polar solvents [19], are characterized by an absorption in the range 600–620 nm which remains unchanged upon UV illumination in the presence of Cr(III), Mn(II), Ni(II), Co(II), Ba(II) and Mg(II). Irradiation of **1** and **2** in the presence of 1 equiv. of Cu(II), Fe(II) or Al(III) generates a new photo-reversible absorption band in the range 540–600 nm, with band intensity dependent on the [M(II),(III)]/[**SO**] ratio and highest effectiveness obtained at 10 equiv. of added metal ion. Less effective is irradiation in the presence of Zn(II) and Pb(II), with absorption bands appearing between 600 and 592 nm. The observed λ_{max} values (Table 1) are slightly blue-shifted and the same is observed at a 10-fold molar excess of M(II),(III). It is obvious that UV irradiation of **SO** in the presence of the appropriate metal ion yields a **MC**–M(II),(III) complex and this process is considered as photoinduced complexation.

Thermal coordination to the metal ion also takes place, giving a complex which is spectroscopically identical to the photoinduced product. The colouration obtained in the dark becomes more intense upon UV illumination and reverses back to its initial level after removing of the light. The time needed for re-establishing equilibria is sensitive to the metal ion and is substantially prolonged compared to the non-complexed merocyanine.

Photoirradiation of the parent unsubstituted spiroindolinonaphthooxazine (Scheme 2) in the presence of a metal salt [25] induces irreversible photo-degradation without any complexation, indicating that the nitrogen atom at the 1′ position in the naphthooxazine moiety takes no part in chelation.

3.2. EPR spectra

Fig. 1 shows a typical EPR spectrum of the photoinduced **MC**–Cu(II) complex in ethanol immediately frozen at 77 K after irradiation. The spin-Hamiltonian parameters: $A_{\parallel} = 112 \pm 2$ G, $g_{\parallel} = 2.317 \pm 0.002$ and $g_{\perp} = 2.010 \pm 0.002$ indicate a strong anisotropy, consistent with the Jahn–Teller deformation of the molecule to a square-planar geometry [26]. The isotropic value $g_o = 2.112 \pm 0.002$, calculated by using the $g_{\parallel}$ and $g_{\perp}$ parameters, seems to be the average of the *g*-values [27,28] of bis(acetylacetonato)Cu(II) with the chromophore CuO_4 ($g_o = 2.219 \pm 0.002$) and bis(8-quinolinolato)Cu(II) with the chromophore CuO_2N_2 ($g_o = 2.105 \pm 0.002$). Since the unpaired electron occupies a 'group' orbital with the participation of Cu and four donor atoms, these results indicate an averaged covalence within the chromophore of **MC**–Cu(II) as compared to CuO_4 and CuO_2N_2. Following the 'additive rule' [28,29] we suggest the chromophore CuO_3N for **MC**–Cu(II), i.e. the formation of a mixed-ligand complex (**3** in Scheme 3) with one chelate ligand and two ethanol molecules coordinated in the *xy*-plane. For comparison, the spin-Hamiltonian parameters of the EPR spectrum (77 K) of an ethanol solution of $CuCl_2$ are $A_{\parallel} = 115 \pm 2$ G, $g_{\parallel} = 2.26$ and $g_{\perp} = 2.06$ [30].

Table 1
Absorption maxima of the complexes obtained upon UV illumination of 5×10^{-5} M solutions of **1** and **2** in the presence of 1 equiv. of metal ion

SO	Solvent	λ_{compl} (nm)

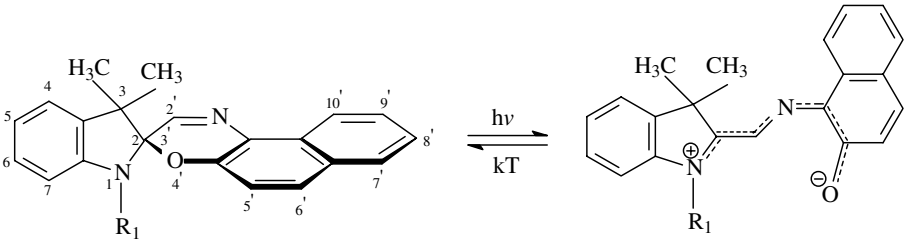

Scheme 2.

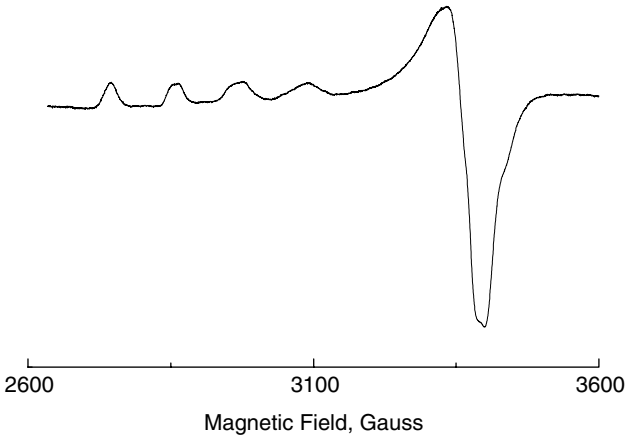

Fig. 1. Typical EPR spectrum of Cu(II)-**MC** in ethanol, 77 K.

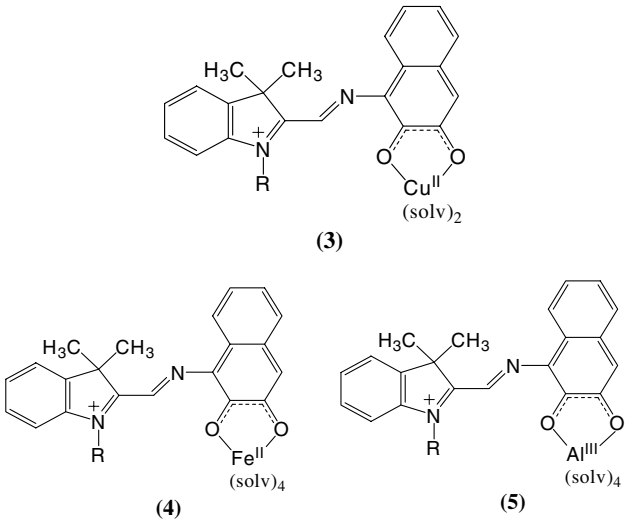

Scheme 3.

By analogy with **MC**–Cu(II), for the cases of higher metal ion concentration than that of **SO,** we suggest one merocyanine and four ethanol molecules as ligands for Fe(II) or Al(III) in Scheme 3. The spectral and kinetic data (Figs. 1–5) also indicate this possibility for [**SO**] ≈ [M(II),(III)]. Job's [31], which is commonly used for determination of the stoichiometry, cannot be applied to our case since the ligand **MC** concentration cannot be varied independently of [M(II),(III)].

3.3. Thermal colouration and decolouration in the presence of metal ions

Typical spectral changes obtained in a few minutes after mixing 1×10^{-4} M ethanol solutions of **1** or **2** with 0.5–10 equiv. of aqueous Al(III), Fe(II) or Cu(II) are given in Fig. 2(a) and (b). The observed changes correspond to the thermal conversion of **SO** to a **MC**–Al(III) complex as indicated by the position of the visible absorption. It seems that chelation affects the thermal equilibrium **SO** ⇌ **MC** and promotes the formation of the open form at room temperature in the absence of light, according to one of the following pathways [32]:

$$\mathbf{SO} \rightleftharpoons \mathbf{MC} + \mathrm{M(II),(III)} \rightarrow \mathbf{MC} - \mathrm{M(II),(III)} \qquad \text{(a)}$$

$$\mathbf{SO} + \mathrm{M(II),(III)} \rightleftharpoons \mathbf{SO} - \mathrm{M(II),(III)} \rightarrow \mathbf{MC} - \mathrm{M(II),(III)} \qquad \text{(b)}$$

$$\mathbf{SO} \rightarrow \mathbf{MC} + \mathrm{M(II),(III)} \rightleftharpoons \mathbf{MC} - \mathrm{M(II),(III)} \qquad \text{(c)}$$

Fig. 2(a) and (b) depicts only a slow increase of intensity of the **MC**–Al(III) absorption band of **2**, getting a saturation after 15–20 min in the dark. The concentration of the metal ion has no effect on the rate of chelation, but the time for saturation and the amount of the obtained

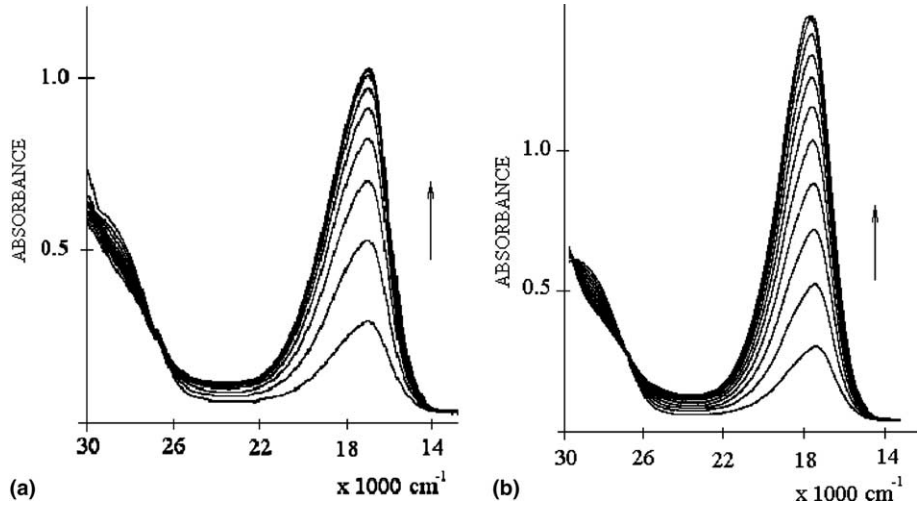

Fig. 2. Visible absorption spectra of an ethanol solution of **2** taken every 2 min in the dark after insertion of: 0.5 (a) and 10 (b) equiv. of aqueous Al(III); $c_{\mathbf{SO}} = 5 \times 10^{-5}$ M.

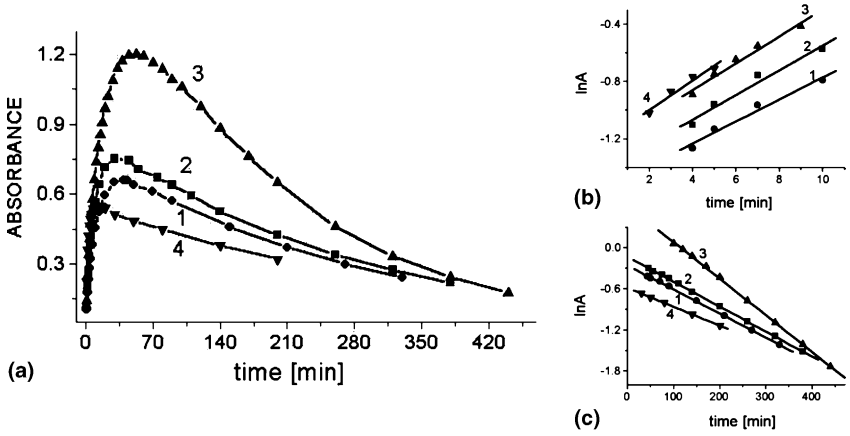

Fig. 3. (a) Kinetic runs at λ_{compl} of 5×10^{-5} M ethanol solution of **2** taken in the dark after insertion of aqueous: Al(III) 1, 2 and 10 equiv. (plots 1–3) or Cu(II) 10 equiv. (plot 4) at 20 °C; (b,c) ln A vs. time dependence.

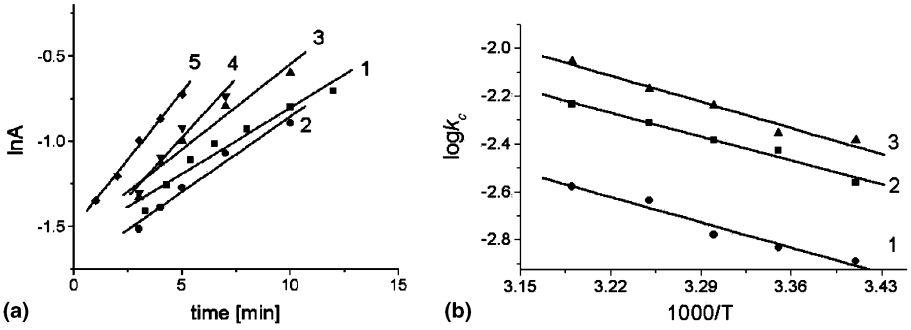

Fig. 4. (a) Plots of ln A vs. time at 585 nm obtained in the dark after insertion of 10 equiv. of aqueous Al(III) in 5×10^{-5} M ethanol solution of **1** at 20 (1), 25 (2), 30 (3), 35 (4) and 40 °C (5); (b) Arrhenius plots of: (1) **MC**–Al(III) using the data of (a); (2) **MC**–Cu(II) and (3) **MC**–Fe(II) under the same experimental conditions.

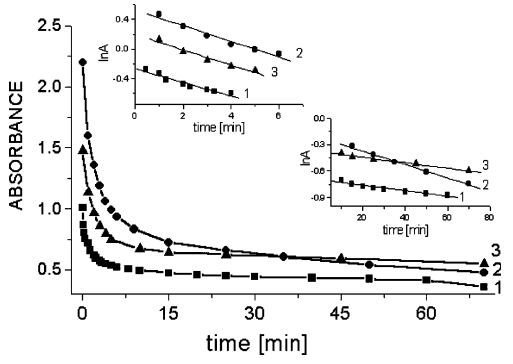

Fig. 5. Absorbance changes at 600 nm following 15 s UV illumination of an ethanol solution of **1** after insertion of: (1) 0.5 or (2) 10 equiv. of Cu(II) in ethanol and (3) 10 equiv. of aqueous Cu(II). Insets: ln A vs. time plots, initial (0.5–6 min) and final (10–70 min).

complex are higher at a larger metal ion excess. After reaching a saturation, the colouration slowly bleaches with longer reaction times (Fig. 3(a)).

Kinetic plots (1)–(3) of **MC**–Al(III) and (4) of **MC**–Cu(II) in Fig. 3(a) are typical of the colouration and decolouration processes of all studied systems. The plots of the linear dependences of ln A versus time at λ_{compl} (Fig. 3(b)), analysed by the least squares method, give k_c values of ca. $(1–2) \times 10^{-3}$ s^{-1} at 20 °C for the rate constants of chelation of all complexes, without any effect of the metal ion. It seems from these data that route (c) is the reaction pathway of chelation since for (a) and (b) the rate constants will depend on the nature of the metal ions, while for (c) metal ions react readily with the coloured form **MC** as it is formed thermally from **SO**.

The first order build-up kinetics of **MC**–Al(III) studied in the range 20–40 °C in 1:1 aqueous/ethanol (Fig. 4(a)) gives the plot (1) of log k_c versus $1/T$ in Fig. 4(b) and similar kinetics runs of **MC**–Fe(II) and **MC**–Cu(II) under the same experimental conditions give the plots (2) and (3). From the linear dependences in Fig. 4(b), the activation energies (E_a) of chelation and the pre-exponential factors are derived. The pre-exponential factors for **3**–**5** vary from 10^{12} to 10^{14} s^{-1}, but the values for E_a are 27–30 kJ mol^{-1} showing no effect of the metal ion, as the process of thermal ring opening of the spiro-form is the rate limiting step of chelation. Thermal

degradation of the complexes (Fig. 3(c)) is also a first order reaction with a metal-dependant rate constant k_d of ca. $(5–9) \times 10^{-5}$ s^{-1}.

3.4. Effect of chelation on the photocolouration and on the thermal re-equilibration of photomerocyanines

In the absence of metal ion, the first order decay of the photomerocyanines of **1** and **2** occurs with $k_r \sim 0.1$ s^{-1} [19] and their relaxation time in acetone and ethanol is $\tau_{\mathbf{MC–SO}} \sim 10$ s. Taking into account that the colouring and fading times are important characteristics of the photochromic systems, we have studied the effect of chelation on the kinetics of photochromic transformations of spironaphthooxazines. In contrast to the lack of effect of Cr(III), Mn(II), Ni(II), Co(II), Ba(II) or Mg(II) on the decolouration of the free **MC** forms of **1** and **2**, Cu(II), Fe(II) and Al(III) have a significant effect on the ring closure reaction and the light enhanced colouration disappears much slower after illumination.

A typical picture of bleaching after irradiation of **1** and **2** in the presence of Al(III), Cu(II) or Fe(II) is depicted in Figs. 5 and 6. Kinetic runs in Fig. 5 followed at λ_{compl} immediately after illumination of ethanol (plots 1 and 2) or 1:1 aqueous/ethanol (plot 3) solutions indicate that the photoinduced **MC**–Cu(II) complex of **1** undergoes spontaneous thermal decolouration which is first order in the concentration of the starting complex, as the plots of ln A versus time (initial inset in Fig. 5) are linear ($\rho > 0.98$) about 50% of reaction completion and similar changes are observed in Fig. 6 for the **MC**–Cu(II) complex of **2**. The strongly descending part of the curves associated with the thermal spironaphthooxazine ring closure, analysed by the least squares method, give metal-dependant values of the re-equilibration rate constant k_r ranging from 1.5 to 2.6×10^{-3} s^{-1} at 20 °C.

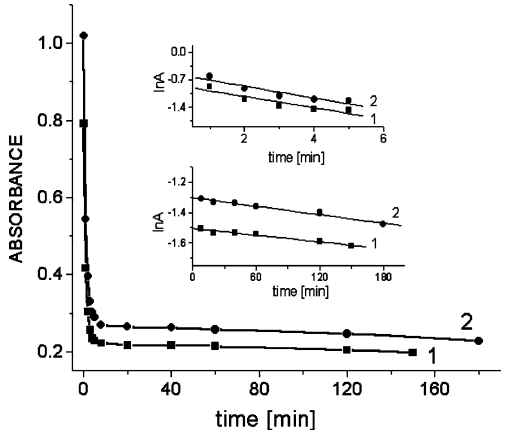

Fig. 6. Absorbance changes at 600 nm following 15 s UV illumination of an ethanol solution of **2** after insertion of: (1) 0.5 or (2) 1 equiv. of aqueous Cu(II). Insets: ln A vs. time plots, initial (1–5 min) and final (10–180 min).

Relaxation times ($\tau_{com–\mathbf{SO}}$) of 5–10 min were obtained using the expression $\tau = 1/k_r$. Data obtained about all the studied systems suggest that complexation with Cu(II), Fe(II) and Al(III) strongly inhibits thermal reversion of **MC** to **SO**.

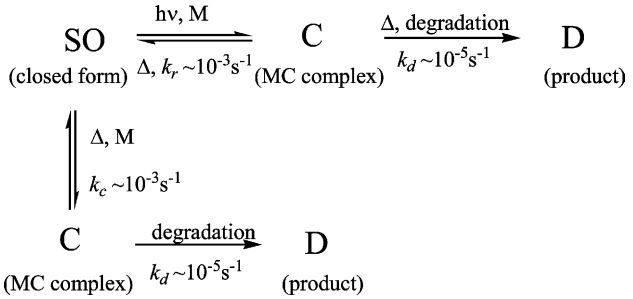
From the absorbances A_o obtained by extrapolation to $t = 0$ of the room temperature linearly descending kinetic curves ln A/t of spironaphthooxazine ring closure immediately after UV irradiation (Figs. 5 and 6) are calculated "colourability" [21–24] values up to 34 000.

Kinetic runs at larger reaction times in Figs. 5 and 6 are much slower. The rate constants calculated by the least squares method from the final ln A versus time linear plots ca. 5×10^{-5} s^{-1} for **1** and 1×10^{-5} s^{-1} for **2** in 1:1 aqueous/ethanol (up to 1×10^{-4} s^{-1} in ethanol) are near to the obtained k_d values of thermal degradation.

These observations suggest two parallel reactions of the photoinduced complexes proceeding simultaneously (Scheme 4):

- thermal relaxation (k_r ca. 10^{-3} s^{-1}) approaching the steady state concentration of the complex **C** in polar solvents.
- thermal degradation (k_d ca. 10^{-5} s^{-1}) of the complex yielding the product D.

Special experiments were carried out to check the reversibility of the photocolouration. Kinetic runs in Fig. 7(a) depict the increasing intensity with time of the **MC**–Cu(II) absorption band at 600 nm (spectra 1–5), reaching a saturation (spectra 4–5) on keeping its 1:1 aqueous/ethanol solution in the dark. The consequent increase in intensity upon 10 and 30 s UV illuminations is given in Fig. 7(b) (spectra 6–7) together with the kinetic runs of thermal decolouration on keeping the irradiated sample for 0.5, 1, 2 and 3 h in the dark (spectra 8–11) due to the parallel relaxation and degradation processes in Scheme 4. Spectrum 12 in Fig. 7(b), obtained after a further 20 s photoirradiation of the final solution, clearly indicates a reversible photocolouration of **SO**, remaining unaffected by degradation. Similar changes are obtained with **MC**–Fe(II) and **MC**–Al(III).



Scheme 4.

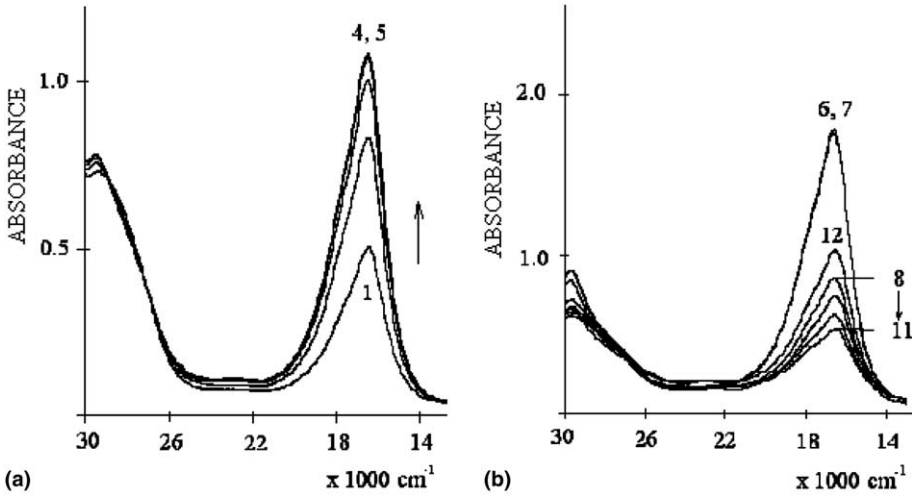


Fig. 7. Visible absorption spectra taken after insertion of 2 equiv. of aqueous Cu(II) into a 5×10^{-5} M ethanol solution of **1**: (a) – every 2 min in the dark (1–5); (b) – (5) upon consecutive 10 and 30 s UV illuminations (6–7); (7) kept for 0.5, 1, 2 and 3 h in the dark (8–11); (11) after a new 20 s UV illumination (12).

4. Conclusions

Coordination of Al(III), Fe(II) and Cu(II) with the open **MC** form of two 5′-(hydroxy)spiroindolinonaphthooxazines takes place both thermally (slowly) and photochemically in ethanol, acetone and their 1:1 water mixtures giving a reversibly photochromic complex. The thermal build-up reaction ($\sim 10^{-3}$ s^{-1}) is independent of the metal ion thus implying that the ring opening is the rate determining step. Chelation induces a 10–45 nm hypsochromic shift of the visible absorption band of the photomerocyanine and drastically slows down its thermal re-equilibration in the dark.

or phthalonitrile to an insoluble polymer, making it react with a different diiminoisoindoline and, after removal of the symmetric phthalocyanine, releasing the unsymmetrical phthalocyanine from the polymer support. A third method has been described by Kobayashi and co-workers [16,17] and involves the ring expansion of a subphthalocyanine to a phthalocyanine using a phthalonitrile unit which bears a different type of substituent to that on the subphthalocyanine.

Over the past few years, palladium catalysed cross-coupling reactions provide a further and important means of functionalising the phthalocyanine ring with interesting grouping. This has produced various derivatives that include alkynyl and alkenyl functionalised phthalocyanines including some unsymmetrical phthalocyanines. Examples of some of these compounds and related structures have interesting NLO effects [18,19].

We have previously reported peripherally substituted symmetrical and unsymmetrical phthalocyanines [20–22]. The incorporation of macrocyclic groups such as dioxadiaza and triaza-macrocycles has enhanced the solubility of these compounds [23,24]. A consequence of incorporating a sulfanyl function on the periphery has been a shift of the Q-band absorption to longer wavelengths [25]. This is preferred for a number of applications such as with IR absorbers and photosensitizers. In the present work, we report on the synthesis and characterization of unsymmetrical metallophthalocyanines which carry two peripheral hexylthio substituents on each of three of the benzenoid groups while the fourth one carries two phenylethynyl groups.

2. Experimental

IR spectra were recorded on a Mattison 1000 FTIR spectrophotometer using KBr pellets, electronic spectra on a Unicam UV2 spectrophotometer. Elemental analyses were performed by the Instrumental Analysis Laboratory of the TUBITAK Marmara Research Centre. ^{1}H NMR spectra were recorded on a Bruker 250 MHz spectrometer using TMS as an internal reference. All reagents and solvents were of reagent grade quality obtained from commercial suppliers. The homogeneity of the products was tested in each step by TLC. 4,5-Dichlorophthalonitrile (**1**) [26] and 4,5-di(hexylthio)phthalonitrile (**2**) [27] were synthesized according to published methods.

Electrochemical techniques were carried out with a Princeton Applied Research Model 273 potentiostat/galvanostat controlled by an external PC using the computer program HEADSTRT and utilising a three-electrode configuration at 25 ± 1 °C. An Origin 6.0 graph program was used to evaluate Headstrt software data, to draw voltammograms, and to analyse them. A Pt spiral wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode. The working electrode was a Pt plate with an area of 1.0 cm^2. Electrochemical grade tetrabutylammonium-perchlorate (TBAP) in extra pure DCM was employed as the supporting electrolyte at a concentration of 0.1 mol dm^{-3}. High purity N_2 was used for deaeration and to maintain a nitrogen blanket for at least 15 min prior to each run. For controlled potential coulometric (CPC) studies, a Pt gauze working electrode (10.5 cm^2 surface area), a Pt gauze counter electrode separated with a double bridge, a saturated calomel reference electrode (SCE) and a model 377/12 Synchronous stirrer were used. The potential of the working electrode was set to the E_p value obtained in the CV experiments. Then the solution was electrolysed with efficient stirring.

2.1. 4,5-Di(phenylethynyl)phthalonitrile (3)

To a solution of 1 g (5.10 mmol) of **1** dissolved in 100 ml of triethylamine was added 0.20 g (0.30 mmol) of bis(triphenylphosphine)palladium(II)chloride, 0.04 g (0.20 mmol)of copper(I)iodide and then 3.34 ml (30.45 mmol) of phenylacetylene. The reaction mixture was heated to 90 °C for 24 h under N_2. As the reaction proceeded, a dark brown precipitate was formed. The resulting suspension was filtered off and the brown solid collected was washed with hexane. The yellow product was obtained by column chromatography with silica gel using $CHCl_3$/hexane (50:1) as eluent. Yield: 0.67 g, 40%; m.p. 190 °C. IR (KBr), ν (cm^{-1}): 3080 (Ar–H), 2238(C≡N), 2212 (C≡C), 1600, 1523, 1446, 911, 782, 706 cm^{-1}; ^{1}H NMR ($CDCl_3$):δ: 7.92 (s, 2H, Ar–H), 7.59 (d, 4H, Ar–H), 7.42 (m, 6H, Ar–H); UV–Vis λ_{max} (nm) (log ε) in $CHCl_3$: 279 (4.62), 307 (4.70), 349 (4.34). *Anal*. Calc. for $C_{24}H_{12}N_2$: C, 87.79; H, 3.68; N, 8.53. Found: C, 87.07, H, 3.66; N, 8.33%.

2.2. 2,3,9,10,16,17-Hexakis(hexylthio)-23,24-bis(phenylethynyl)-29H, 31H-phthalocyaninato zinc (II) (4)

A mixture of 0.16 g of **2** (0.49 mmol), 0.53 g of **3** (1.46 mmol), 0.09 g of anhydrous $Zn(CH_3COO)_2$ (0.49 mmol), 32 μl of DBU and 5 ml of anhydrous *n*-pentanol was refluxed with stirring for 24 h under N_2. The dark green mixture was cooled to room temperature and then diluted with ethanol until the crude product precipitated. The precipitate was filtered off and washed several times with hot ethanol and methanol to remove unreacted materials. Finally, the green precipitate was chromatographed on silica gel and eluted with $CHCl_3$/CH_3OH (50:1). Yield: 0.10 g, 14%; m.p. > 200 °C. IR (KBr), ν (cm^{-1}): 3080 (H–Ar), 2987–2870 (alkyl CH), 2212 (C≡C) 1600, 1523, 1421, 1395, 1089, 987, 757, 706 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ: 0.94 (t, 18H, CH_3), 1.62 (m, 36H, CCH_2C), 1.88 (qnt, 12H, $SCCH_2$), 3.18 (t, 12H, SCH_2),7.42–7.90 (m, 18H, Ar–H); UV–Vis λ_{max}

(nm) (log ε) in $CHCl_3$: 277 (4.68), 329 (4.80), 727 (4.93). *Anal.* Calc. for $C_{84}H_{96}N_8S_6Zn$: C, 68.41; H, 6.51; N, 7.60. Found: C, 68.28; H, 6.49; N, 7.47%.

2.3. 2,3,9,10,16,17-Hexakis(hexylthio)-23,24-bis(phenylethynyl)-29H,31H-phthalocyaninatonickel (II) (5)

A mixture of 0.40 g of **2** (1.22 mmol), 1.32 g of **3** (3.66 mmol), 0.16 g of anhydrous $NiCl_2$ (1.22 mmol) and 80 μl of DBU was refluxed in 13 ml of anhydrous *n*-hexanol with stirring for 36 h under N_2. The resulting suspension was cooled to room temperature and the crude product was precipitated by addition of ethanol. It was filtered off and washed first with hot ethanol, then with methanol. The green product was isolated on a silica gel column first with hexane/THF (5:1) and then with THF/DMF (5:1) as eluent. Yield 0.09 g, 5%. Melting point > 200 °C. IR (KBr), *v* (cm^{-1}): 3080 (H–Ar), 2987–2870 (alkyl CH), 2212 (C≡C) 1600, 1523, 1421, 1395, 1089, 989, 756, 706 cm^{-1}; ^1H NMR ($CDCl_3$ 250 MHz): 0.97 (t, 18H, CH_3), 1.66 (m, 36H, CCH_2C), 1.93 (qnt, 12H, $SCCH_2$), 3.22 (t, 12H, SCH_2), 7.38–7.91 (m, 18H, Ar–H), 7.78 (s, 2H); UV–Vis λ_{max} (nm) (log ε) in $CHCl_3$: 322 (4.89), 703 (4.83). *Anal.* Calc. for $C_{84}H_{96}N_8S_6Ni$: C, 68.72; H, 6.54; N, 7.63. Found: C, 68.53; H, 6.41; N, 7.33%.

2.4. 2,3,9,10,16,17-Hexakis(hexylthio)-23,24-bis(phenylethynyl)-29H,31H-phthalocyaninatocobalt (II) (6)

A mixture of 0.30 g of **2** (0.92 mmol), 0.99 g of **3** (2.75 mmol), 0.12 g of anhydrous $CoCl_2$ (0.92 mmol) was refluxed in 10 ml anhydrous *n*-pentanol in the presence of 60 μl of DBU under N_2 with stirring for 24 h. The reaction mixture was cooled and the crude product was precipitated by addition of ethanol. It was filtered off and washed several times with hot ethanol and acetone. The green product was chromatographed on silica gel with hexane/THF (2:1) as eluent. Yield 0.11 g, 8%. Melting point > 200 °C. IR (KBr), *v* (cm^{-1}): 3080m (H–Ar), 2987–2870 (alkyl CH), 2212 (C≡C) 1600, 1523, 1421, 1395, 1089, 987, 757, 706 cm^{-1}; UV–Vis λ_{max} (nm) (log ε) in $CHCl_3$: 270 (3.98), 329 (4.19), 711 (4.00). *Anal.* Calc. for $C_{84}H_{96}N_8S_6Co$: C, 68.71; H, 6.54; N, 7.63. Found: C, 68.35; H, 6.36; N, 7.50%.

3. Results and discussion

3.1. Synthesis and characterisation

Different strategies to synthesise unsymmetrically substituted phthalocyanines (A_3B) have been reported, the most common one being the statistical condensation reaction between two different phthalonitriles or diiminoisoindolines. Statistical considerations predict that reaction of two different phthalonitriles of the same reactivity in a 3:1 ratio will afford a mixture of products in the following percentages: A_4 (33%), A_3B (44%), other cross-condensation products (23%) [14]. Using phthalonitriles with different solubility characteristics may permit separation of the unsymmetrical phthalocyanines by virtue of the different solubilities of the compounds present in the resulting statistical mixture. The attachment of alkylthio groups at the peripheral positions of one of the starting compounds facilitates the isolation of the A_3B product, as this substituent confers solubility in organic solvents and disfavours aggregation of the macrocycles [28].

4,5-Di(hexylthio) phthalonitrile (**2**) and 4,5-di(phenylethynyl)phthalonitrile (**3**) were chosen as starting materials for this study. **2** was prepared from 4,5-dichlorophthalonitrile and hexanethiol in DMF. K_2CO_3 was used as the base for this nucleophilic aromatic displacement [27]. Leznoff and Suchozak [29] have reported the synthesis of **3** from 4,5-diiodophthalonitrile. In the present work, **3** was synthesised from 4,5-dichlorophthalonitrile which is easily obtained from commercially available 4,5-dichloro-1,2-benzenedicarboxylic acid in four steps [26]. Under typical Sonogashira reaction conditions [30], the cross-coupling reaction between an excess of phenylacetylene and 4,5-dichlorophthalonitrile in triethylamine with bis(triphenylphosphine)palladium(II)chlorideand copper(I)iodide as catalysts at 90 °C under nitrogen atmosphere produced **3** in 40% yield.

Mixed condensation of 4,5-di(phenylethynyl)phthalonitrile with 4,5-di(hexylthio) phthalonitrile in the presence of the corresponding metal(II) salt afforded the unsymmetrical zinc-, nickel- and cobalt-substituted complexes **4**–**6**. Some experiments with different molar ratios were carried out to raise the yield of the desired unsymmetrically substituted phthalocyanines **4**–**6**. A 1:3 ratio of the two precursors was found to be the most appropriate for dinitriles **2** and **3**. The unsymmetrical phthalocyanines were separated by column chromatography from the corresponding totally symmetrical octahexylthiophthalocyanine formed in the statistical condensation. The unsymmetrical phthalocyanines **4**–**6** show good solubility in common organic solvents such as dichloromethane, chloroform and tetrahydrofuran (see Scheme 1).

The spectroscopic characterisation of the newly synthesised compounds included ^1H NMR, IR and UV–Vis. Spectral investigations and the results are in accord with the proposed structures. In the IR spectrum of **3** the intense absorption band at 2238 cm^{-1}, corresponding to C≡N vibrations, disappears after its conversion into the phthalocyanines. The ^1H NMR spectrum of **3** indicates aromatic protons at δ 7.92, 7.59 and 7.42 ppm.

The ^1H NMR spectra of the unsymmetrical phthalocyanines **4** and **5** are in excellent agreement with the

	4	5	6
M	Zn^{2+}	Ni^{2+}	Co^{2+}

Scheme 1.

proposed structures. The dominant features in the NMR spectra of **4** and **5** are the hexylthio group resonances. These resonances are shifted downfield by the phthalocyanine ring current relative to the precursor compound **2** [27]. ^{1}H NMR spectrum of **4** exhibited the aromatic protons at around δ 7.42–7.90 ppm as multiplets, the SCH_2, $SCCH_2$ protons at δ 3.18 and 1.88 ppm as a triplet and a quintet, respectively, and the aliphatic CH_3 protons as a triplet at δ 0.94 ppm. The ratio of aromatic to aliphatic protons appears to show that the benzo groups with two different substituents are present in a 3:1 ratio. The presence of alkylthio side chains in **4** was also confirmed by IR spectroscopy which showed an intense aliphatic C–H stretching at 2987–2870 cm^{-1}. The ^{1}H NMR spectrum of **5** is similar to that of **4**.

The UV–Vis spectra of **4–6** recorded in chloroform show the typical pattern of phthalocyaninatometal complexes. They are dominated by the π–π^* transitions within the heteroaromatic 18-π-electron system. The electronic absorption spectra of **4–6** exhibit a Q band absorption at 727, 703 and 711 nm, respectively. B bands of these phthalocyanines appear in the UV region at about 329 nm. The Q-bands of octakis alkylthio-substituted phthalocyanines are above 700 nm [27], the replacement of one of the benzenoid rings by a phenylethynyl ring gives rise to a bathochromic shift. The different Q band absorptions of **4–6** are attributable to the nature of the central metal ion.

In conclusion, unsymmetrical metallophthalocyanines **4–6** substituted with one phenylethynyl and three

hexylthio groups were synthesised by a statistical condensation route. Their spectral properties in a given solvent depends strongly on the central metal ion.

3.2. Electrochemical measurements

The electrochemical properties of metallophthalocyanine (MPc) complexes are well known [31–44]. Reduction and oxidation reactions can occur at either the Pc ring or central metal or both. Oxidation at the Pc ring in MPc(−2) occurs by successive loss of one or two electrons from the highest occupied molecular orbital (HOMO) resulting in the formation of the $[MPc(-1)]^{+}$ or $[MPc(0)]^{+2}$ cations, respectively. Reduction of the Pc ring occurs by the successive gain of one to four electrons by the lowest unoccupied molecular orbital (LUMO) of the MPc complex, resulting in the formation of MPc(−3), MPc(−4), MPc(−5) and MPc(−6) species, as commonly shown to indicate the oxidation states of the phthalocyanine ligand in the literature related with the electrochemistry of this compounds [1,6,31,40–44].

It has been demonstrated that substituents on the periphery of the phthalocyanine ligand strongly influence the solution redox chemistry of these materials. Electron-donating groups lead to a negative shift of the redox potentials and electron-withdrawing groups to a positive shift. This has been observed with both redox inactive metals like nickel, copper and zinc and redox active metals like cobalt [1].

Cyclic voltammograms of CoPc (**6**) (Fig. 1) show four well-defined redox couples (I–IV) within the available potential range of the TBAP/DCM solvent system at −0.313 and 0.644 V, easily attributed to Co^{II}/Co^{I} (I) and Co^{II}/Co^{III} (IV), and at 0.327 and −1.247 V at 0.100 V s^{-1} scan rate easily attributed to Pc^{2-}/Pc^{3-} (II) and Pc^{2-}/Pc^{1-} (III) redox couples, respectively. It is clearly indicated that first-row transition metallophthalocyanines differ from those of the main-group metallophthalocyanines due to the fact that metal "d" orbitals may be positioned between the HOMO and LUMO of the phthalocyanine (Pc^{2-}) ligand. This has been well established by several papers published by Lever et al. [1,42–44]. According to these studies, electrochemistry of metallophthalocyanines containing a redox active metal center such as Mn, Fe and Co can conveniently be split into two sections, that referring to non-donor solvents, and that referring to donor solvents. For CoPc complexes, donor solvents or coordinating counter anions strongly favour Co(III)Pc by coordinating along the axis to form a six-coordinate $L_2Co(III)Pc$ species. If a donor solvent is not present, such as DCM used in this study, then oxidation to Co(III)Pc is inhibited and ring oxidation occurs first. So in this study, it is possible to assign the first oxidation of the CoPc species at 0.33 V to the ring oxidation and the second one at 0.64 V to the metal center. According to this behaviour of CoPc in DCM, the electron transfer sequence would be [Co(III)/(II)]Pc(1−) > Co(II)[Pc(1−)/(2−)] > [Co(II)/(I)] Pc(2−) > Co(I)[Pc(2−)/(3−)].

The separation between the first reduction and first oxidation processes (640 mV) of **6**, which reflects the HOMO–LUMO gap of the complexes, is smaller than that in the reported CoPc papers [1,31–44]. This is not very surprising since extended π-conjugation of **6** may cause a decrease in the HOMO–LUMO gap of the complex. This voltammetric data was confirmed by the shifting of the Q band towards a longer wavelength in the

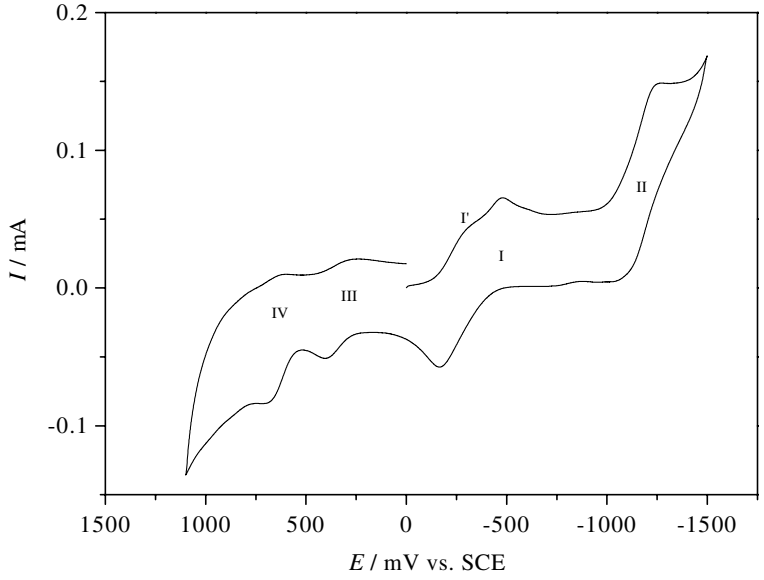

Fig. 1. Cyclic voltammogram of 1.0×10^{-3} mol dm^{-3} CoPc (**6**) in 0.1 mol dm^3 TBAP/DCM at 100 mV s^{-1} scan rate.

UV–Vis spectrum of the complex. The separation between the metal based reduction and the ring reduction was found to be 0.930 V, which is in agreement with the separation reported for CoPc's [31–45]. In Table 1, the CV data, cathodic to anodic peak separation (ΔE_p) and peak current ratios (I_{pa}/I_{pc}) of **6** are listed together with those of ZnPc (**4**), NiPc (**5**) and MPc's containing a similar metal centre and substituents reported in the literature.

The observation of two closely spaced reduction peaks (I′ and I) has been attributed to the presence of both the aggregated and unaggregated forms of **6** in solution. At the concentration employed for voltammetric studies in this work, aggregation of the CoPc derivatives is expected and was confirmed by a shoulder of the Q band in the UV–Vis spectra of **6** [46]. Characterisation of this couple could not be done as a result of the splitting of the reduction peak. The process II recorded at −1.247 V was quasi-reversible in that it shows a more enhanced forward (cathodic) peak compared to the return (anodic) peak and a large ΔE_p value (200 mV at 100 mV s^{-1}). Peak current ratios (I_{pa}/I_{pc}) of this couple were smaller than unity at slow scan rates and approached unity with increasing scan rates. This behaviour of the process indicated the existence of a chemical reaction following the electron transfer reaction (EC mechanism) [47–49]. Both of the oxidation processes (III and IV) of **6** exhibited a quasi-reversible peak character with moderate ΔE_p values (157 and 147 mV at 100 mV s^{-1}, respectively). For these processes, the anodic peak currents increased linearly with the square root of the scan rates for scan rates ranging from 10 to 500 mV s^{-1}, indicating that the electrode reaction is purely diffusion-controlled. For both the III and IV couple, peak current ratios (I_{pa}/I_{pc}) were smaller than unity at slow scan rates, but move towards unity by increasing the scan rates, indicating the complication of the mass transport mechanism of the complex probably with a proceeding or succeeding chemical reaction.

Complex **4** and **5** exhibited very similar voltammetric behaviours. Fig. 2 shows the cyclic voltammograms of**4** recorded at 100 mV s^{-1} scan rate. As shown in the figure, two well-defined reduction processes, (I and II) at −0.780 and −1.027 V attributed to the Pc^{2-}/Pc^{3-} and Pc^{3-}/Pc^{-4} redox couples, and two well-defined oxidation processes, (III and IV) at 0.633 and 0.814 V attributed to the Pc^{2-}/Pc^{1-} and Pc^{1-}/Pc^{0} redox couples, are observed. Since the central Zn(II) metal is redox inactive, all oxidation and reduction processes observed are ring-based [38]. Ring-based redox potentials of complex **4** are considerably different to those of complex **6**. The potential of the [Pc(2−)/(1−)] couple of complex **4** is shifted to positive potentials compared with that of complex **6**. The potential of the [Pc(2−)/(1−)] couple of complex **4** is 0.63 V and the [Pc(2−)/(1−)] couple of **6** is 0.33 V. Similar behaviour was observed for the ring reduction potentials of the complexes. The [Pc(2−)/(3−)] couple of **4** is shifted to a more positive potential compared with that of the **6**. The difference between the first

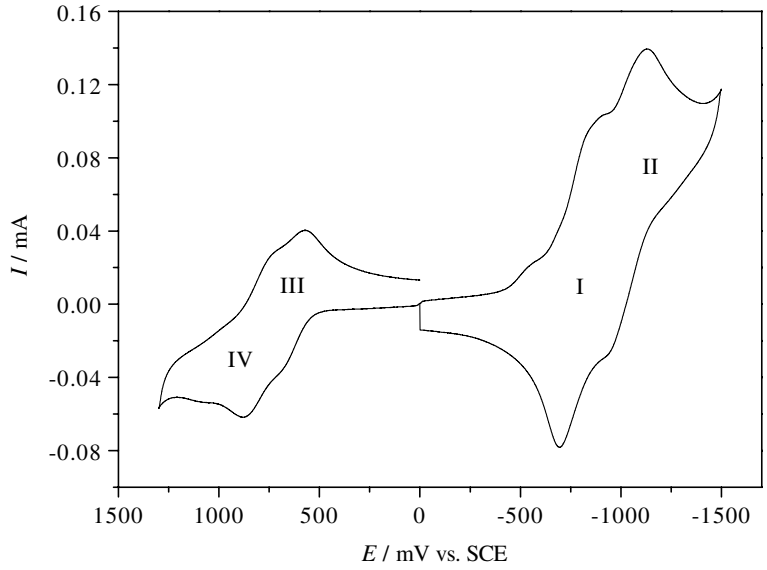

Fig. 2. Cyclic voltammogram of 1.0×10^{-3} mol dm^{-3} ZnPc (**4**) in 0.1 mol dm^3 TBAP/DCM at 100 mV s^{-1} scan rate.

and second reduction processes for **4** is 0.244 V, which is compatible with the average value for the separation of the first and second reduction processes of similar metal phthalocyanine complexes [1]. The potential separation between the first ring oxidation and the first ring reduction (ΔE), which corresponds to the magnitude of the energy difference between the HOMO and LUMO, is approximately between 1.5 and 1.8 V [1,31]. However, the ΔE value of ~1.413 V for **4** is smaller than the range reported for similar complexes. Exchange of one hexylthio substituent of ZnPc bearing an octakis(hexylthio) substituent (ΔE value = 1.475 V) [31] with the diphenylethynylgroup cause a decrease in the ΔE value of **4** of about 62 mV.This is perhaps the result of the decreasing HOMO–LUMO gap by the effect of the extended π-conjugation of the complex. The cyclic voltammograms of **5** also gave two one-electron diffusion controlled quasi-reversible reduction processes at −0.817 and −1.032 V vs. SCE, attributed to the Pc^{2-}/Pc^{3-} and Pc^{3-}/Pc^{-4} redox couples, and two one-electron diffusion controlled quasi-reversible oxidation processes at 0.536 and 0.837 V, attributed to the Pc^{2-}/Pc^{1-} and Pc^{1-}/Pc^{0} redox couples. The difference between the first and second reduction processes (0.215 V) and the small ΔE value (1.393 V) for **5** is compatible with those of **4**. Moreover, the individual potentials for the first reduction and the first oxidation of **4** and **5** varied remarkably due to the function of the polarising power of the central metal ion. In general the more polarising the central metal ions, the easier it is to reduce the ring, and the more difficult to oxidise the ring.

During controlled potential coulometric (CPC) studies, complete electrolysis of the solution at the working electrode at constant potential (E_{pc} of the redox couple) was achieved, and the time integration of the electrolysis current was recorded. The electroactive species in the solution were depleted during the electrolysis, and the charge, Q, at the end of the electrolysis was calculated using the current–time response of solution. *Faraday*'s law was used to estimate the number of electrons transferred. The CPC studies indicated that the number of electrons transferred for all electron transfer reactions of the compounds studied is one.

catalyze the hydrogenation of styrene and imines with practically 100% conversion is described in the literature [4,5]. Thus the high efficiency of these complexes as pre-catalysts in hydrogenation reactions assumes crucial importance in finding out simple routes for their synthesis.

Face-sharing bi-octahedral complexes are of great importance due to two facts: (1) these species are potential catalysts in hydrogenation reactions [4,5]; (2) at least three different oxidation states can be generated in solution [6]. Due to these facts binuclear ruthenium phosphine complexes containing a face-sharing bioctahedral Ru–(μ-Cl)$_3$–Ru core have received considerable attention [1,2,6–8].

In this work, we present the synthesis of a series of binuclear complexes based on the reactivity of the *mer*-[RuCl$_3$(P–P)H$_2$O] complexes and their synthesis is summarized in Eq. (1):

$$[RuCl_3(P\text{–}P)H_2O] + [RuCl_2(P\text{–}P)'PR_3] \rightarrow [(P\text{–}P)ClRu\text{–}(\mu\text{-}Cl)_3\text{–}RuCl(P\text{–}P)'] + H_2O + PR_3 \quad (1)$$

PR$_3$ = PPh$_3$ (triphenylphosphine), P-ptol$_3$ (tri-*p*-tolylphosphine); (P–P) = dppb (1,4-bis(diphenylphosphino)butane) or *S*-diop ((2S–2S)-*o*-isopropylidene-2,3-dihydroxy-1,4-bis(diphenylphosphino)butane); (P–P)′ = dppb, *S*-diop, *S*-binap ((S)-2,2′-bis (diphenylphosphino)1,1′-binaphthyl), dppn (1,5-bis(diphenylphosphino) pentane), (PPh$_3$)$_2$, (P-ptol$_3$)$_2$ or (SbPh$_3$)$_2$ (triphenylstibine).

2. Experimental

2.1. Materials and instrumentation

All manipulations were carried out under purified Ar using standard Schlenk techniques. Reagent grade solvents were appropriately distilled and dried before use. RuCl$_3 \cdot n$H$_2$O, dppb, PPh$_3$, P-ptol$_3$, dppn, *S*-diop, *S*-binap, dpae (1,2-bis(diphenylarsino)ethane), dppe (1,2-bis(diphenylphosphino)ethane), 1,3-cyclohexadiene, benzonitrile (PhCN) were used as received from Aldrich. Imines were prepared by condensation of the appropriate aldehyde and amines [5] and stored under Ar in the dark. *mer*-[RuCl$_3$(dppb)H$_2$O] (**1**) [1], *mer*-[RuCl$_3$(*S*-diop)H$_2$O] (**2**) [1], [RuCl$_2$(*S*-diop)PPh$_3$] [9], [RuCl$_2$(*S*-Binap)PPh$_3$] [10], [RuCl$_2$(dppb)PPh$_3$] [11], [RuCl$_2$(PPh$_3$)$_3$] [12], [Ru$_2$Cl$_4$(dppn)$_3$] [13], [RuCl$_2$(P-ptol$_3$)$_3$] [14], [RuCl$_2$(SbPh$_3$)$_3$] [12] and [(η^6-C$_6$H$_6$)RuCl(dpae)]Cl [15] were prepared according to the above mentioned literature procedures.

Hydrogenation reactions were carried out in a stainless steel autoclave equipped with a high-pressure regulator and connected to a vacuum line. Oxygen was removed from the system by evacuating the autoclave and refilling it up with Ar three times, and purging three times with H$_2$ before adjusting it to the desired pressure. Conversions of imines to amines were determined by ^{1}H NMR experiments.

IR spectra (cm^{-1}) were recorded as CsI pellets in the 4000–200 cm^{-1} region, on a Bomen–Michelson 102 instrument; UV–Visible (UV–Vis) and near-infrared (NIR) spectra were recorded in solution on a Hewlett-Packard 8452A diode array or Cary 500 spectrophotometers, respectively, and are presented as λ_{max}(nm)/ε_{max} (M^{-1} cm^{-1}). Cyclic voltammetry (CV) experiments were carried out at room temperature in CH$_2$Cl$_2$ containing 0.10 mol l^{-1} Bu$_4$N$^+$ClO$_4^-$ (TBAP) (Fluka Purum) using a BAS-100B/W Bioanalytical Systems Instruments. The working and auxiliary electrodes were stationary Pt foils, and the reference electrode was Ag/AgCl, 0.10 mol l^{-1} TBAP in CH$_2$Cl$_2$, a medium in which ferrocene is oxidized at 0.43 V (Fc$^+$/Fc).

All NMR experiments were run on BRUKER, DRX400 9.4 Tesla equipment, in a BBO 5 mm probe at 298 K, using CDCl$_3$ (^{1}H) and CH$_2$Cl$_2$(^{31}P{^{1}H}) as a solvent, TMS and H$_3$PO$_4$ 85% for internal and external reference for ^{1}H and ^{31}P, respectively. Effective magnetic moments (μ_{eff}) were determined at room temperature (~25 °C) by the Gouy method using a Johnson Matthey magnetic susceptibility balance.

Elemental analyses were performed in the Chemistry Department of Universidade Federal de São Carlos.

2.2. X-ray crystallographic analysis of [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (5) and [(η^6-C$_6$H$_6$)Ru–(μ-Cl)–RuCl-(dppb)] (11)

X-ray data of crystals of compounds (**5**) and (**11**) were measured on an Enraf-Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα (λ = 0.71073 Å) radiation. Data were collected up to 50° in 2θ, with a redundancy of 4. The final unit cell parameters were based on all reflections. Data collections were carried out using the COLLECT program [16]. Integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [17]. Absorption corrections were carried out using the multi-scan method [18].

The structures were solved by direct methods with SHELXS-97 [19]. Models were refined by full-matrix least-squares on F^2 using SHELXL-97 [20]. All hydrogen atoms were stereochemically positioned and refined with the riding model [21].

Data collection and experimental details for complexes (**5**) and (**11**) are summarized in Table 1. Relevant interatomic bond lengths and bond angles are listed in Table 2. ORTEP projections of the structures are shown in Figs. 1 and 2.

2.3. Reactivity of mer-[$RuCl_3$(dppb)H_2O] with other Ru(II) or Ru(III) complexes

The procedure for the preparation of binuclear complexes is similar to that used for complex (**3**):

2.3.1. [(*S*-diop)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**3**)

A suspension of (**1**) (0.0848 g, 0.1301 mmol) and [$RuCl_2$(*S*-diop)PPh_3] (0.1214 g, 0.1301 mmol) in CH_2Cl_2 (50 ml) was stirred at room temperature for 3 h. The solution volume was reduced to ~5 ml and addition of *n*-hexane (10 ml) precipitated a brown solid, which was collected, washed well with methanol and *n*-hexane, and dried under vacuum. Yield (0.1528 g, 90%). *Anal.* Calc. for $C_{59}H_{60}O_2Cl_5P_4Ru_2$: C, 54.33; H, 4.64. Found: C, 54.34; H, 4.64%. UV–Vis (CH_2Cl_2): 372 (3400), 448 (1930), 525 (1380). μ_{eff} 1.80 μ_B/dimer.

2.3.2. [(*S*-binap)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**4**)

Complex (**1**) (0.0294 g, 0.0450 mmol) and [$RuCl_2$(*S*-Binap)PPh_3] (0.0476 g, 0.0450 mmol). Yield (0.0488 g, 76%). *Anal.* Calc. for $C_{72}H_{60}Cl_5P_4Ru_2$: C, 60.54; H, 4.23. Found: C, 60.39; H, 4.56%. UV–Vis (CH_2Cl_2): 340 (3440), 398 (2840), 534 (1780). μ_{eff} 1.95 μ_B/dimer.

2.3.3. [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**5**)

Complex (**1**) (0.0353 g, 0.0542 mmol) and [$RuCl_2$(dppb)PPh_3] (0.0466 g, 0.0542 mmol). Yield (0.0467 g, 70%). *Anal.* Calc. for $C_{56}H_{56}Cl_5P_4Ru_2$: C, 54.58; H, 4.58. Found: C, 54.51; H, 4.77%. UV–Vis (CH_2Cl_2): 374 (3500), 436 (2730), 550 (1850). μ_{eff} 2.01 μ_B In this case to a dichloromethane solution of (**5**) *n*-hexane was added until cloudiness and it was left undisturbed in a freezer. After 2 days a crop of reddish-brown crystals suitable for X-ray analysis were recovered.

2.3.4. [(PPh_3)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**6**)

Complex (**1**) (0.0450 g, 0.0690 mmol) and [$RuCl_2(PPh_3)_3$] (0.0662 g, 0.0690 mmol). Yield (0.0615 g, 67%). *Anal.* Calc. for $C_{64}H_{58}Cl_5P_4Ru_2$: C, 57.78; H, 4.39. Found: C, 57.90; H, 4.66%. UV–Vis (CH_2Cl_2): 378 (3650), 444 (1930), 536 (1720). μ_{eff} 1.78 μ_B/dimer.

Table 2

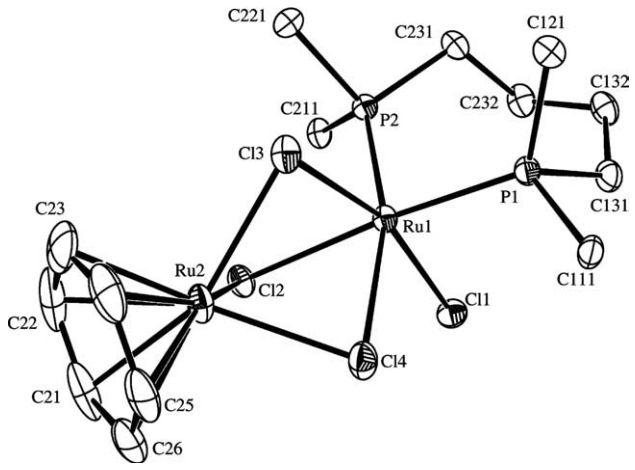

Fig. 2. ORTEP view of the complex $[(\eta^6\text{-}C_6H_6)Ru\text{–}(\mu\text{-}Cl)_3\text{–}RuCl(dppb)]$. $C_2H_4Cl_2$ (**11**), showing the atom labelling and the 50% probability ellipsoids.

2.3.9. *[(η⁶-C₆H₆)Ru–(μ-Cl)₃–RuCl(dppb)] (**11**)*

A suspension of (**1**) (0.0200 g, 0.0307 mmol) and $[(\eta^6\text{-}C_6H_6)RuCl(dpae)]Cl$ (0.0226 g, 0.0307 mmol) in 1, 2-dichloroethane (30 ml) was refluxed for 24 h. Surprisingly, a crop of red crystals was obtained during the reaction and crystals suitable for X-ray analysis were separated from the solution Addition of *n*-hexane to the solution yielded a brown solid that was washed well with *n*-hexane and dried under vacuum. The red crystals and the brown solid are the same compound as proved by $^{31}P\{^1H\}$, ^1H NMR and elemental analysis.

Yield (0.0208 g, 80%). *Anal.* Calc. for $C_{34}H_{34}Cl_4P_2Ru_2$: C, 48.13; H, 4.04. Found: C, 48.17; H, 4.08%. $^{31}P\{^1H\}$, ppm: δ P_B 54.00 (s). ^1H ($CDCl_3$): δ 1.27 (br, s, 2H, CH_2), 1.81 (br, m, 2H, CH_2), 2.04 (br, m, 2H, CH_2), 3.12 (br, m, 2H, CH_2), 6.20 (s, 6H, $\eta^6\text{-}C_6H_6$), 7.20–7.65 (m, 20H, Ph).

2.4. Reactivity of mer-[RuCl₃(dppb)H₂O] with dihydrogen

2.4.1. *[(dppb)ClRu–(μ-Cl)₂–RuCl(dppb)] (**12**)*

A suspension of (**1**) (0.0990 g, 0.1519 mmol) in CH_2Cl_2 (20 ml) and methanol (5 ml) was stirred under H_2 (1 atm) for 48 h at room temperature (RT). The volume of the orange solution was reduced (~10 ml) and addition of methanol (30 ml) precipitated an orange solid that was collected, washed well with methanol and dried under vacuum. Yield (0.0907 g, >99%). *Anal.* Calc. for $C_{56}H_{56}Cl_4P_4Ru_2$: C, 56.20; H, 4.72. Found: C, 56.12; H, 4.60%. $^{31}P\{^1H\}$, ppm: δ P_A 55.30 (d), P_B 63.50 (d) ($^2J P_AP_B$ 30 Hz).

^1H ($CDCl_3$): δ 1.35 (br, m, 4H, CH_2), 1.64 (br, m, 4H, CH_2), 2.05 (br, m, 4H, CH_2), 2.62 (br, m, 4H, CH_2), 6.9–7.7 (m, 40H, Ph).

2.4.2. *[(dppb)(CO)Ru–(μ-Cl)₃–RuCl(dppb)] (**13**)*

A suspension of (**1**) (0.083 g, 0.1273 mmol) in N,N′-dimethylacetamide (20 ml) was stirred under H_2 (1 atm) for 24 h, at room temperature. To the obtained orange solution methanol (30 ml) was added and stirred under H_2 for 3h. An orange solid was collected and washed well with methanol and dried under vacuum. Yield (0.0741 g, 95%). *Anal.* Calc. for $C_{57}H_{56}OCl_4P_4Ru_2$: C, 55.89; H, 4.61. Found: C, 55.35; H, 4.67%. IR (cm^{-1}) 1970 ν(CO). $^{31}P\{^1H\}$, ppm: δ P_A 53.90 (d), P_B 53.35 (d) ($^2J P_AP_B$ 45 Hz), P_C 47.71 (d), P_D 35.07 (d) ($^2J P_CP_D$ 30 Hz).

2.4.3. *[H₂NEt₂][(dppb)ClRu–(μ-Cl)₃–RuCl(dppb)] (**14**)*

A suspension of (**1**) (0.100 g, 0.1534 mmol) in CH_2Cl_2 (10 ml) and an excess of triethylamine (1 ml) was stirred under H_2 (1 atm) for 24 h, at room temperature. The orange solution volume was reduced (~5 ml) and passed through a Celite®. Addition of *n*-hexane precipitated a brown solid that was collected, washed well with methanol and dried under vacuum. Yield (0.0862 g, 86%). *Anal.* Calc. for $C_{60}H_{68}NCl_5P_4Ru_2$: C, 55.16; N, 1.07; H, 5.24. Found: C, 55.23; N, 1.07; H, 5.15%. $^{31}P\{^1H\}$, ppm: δ 49 (s). ^1H ($CDCl_3$): δ 1.22 (br, s, 6H, $CH_3H_2NEt_2$), 1.35 (br, m, 4H, CH_2), 1.64 (br, m, 4H, CH_2), 2.05 (br, m, 4H, CH_2), 2.82 (br, m, 4H, CH_2), 2.92 (br, m, 4H, $CH_2H_2NEt_2$), 6.9–7.5 (m, 40H, Ph), 7.9 (br, s, 2H, NH_2).

3. Results and discussion

The magnetic moments of the mixed-valent complexes (**3–10**) μ_{eff} = 1.78–2.01 are consistent with one unpaired electron per molecule.

The X-ray structure of (**5**) (Fig. 1) shows that the Ru cation is in an approximate C_2 environment, as was reported by Nicholson [22] for $[(P^nBu_3)_2ClRu\text{–}(\mu\text{-}Cl)_3\text{–}RuCl(P^nBu_3)_2]$; this local symmetry is lower than that in [(chiraphos)ClRu–(μ-Cl)$_3$–RuCl(chiraphos)], previously determined [23], which belongs to an approximate C_{2v} point group in which one octahedron was rotated by 120° about the Ru–Ru vector, as compared with the situation in the complex (**5**). The bridging chlorides *trans* to the phosphorus atoms (Ru(2)–Cl(1) = 2.4877(15); Ru(2)–Cl(3) = 2.4839(13); Ru(1)–Cl(2) = 2.4607(14) and Ru(1)–Cl(1) = 2.4422(14) Å) show longer Ru–Cl distances than the bridging chlorides *trans* to the terminal chlorides (Ru(1)–Cl(1) = 2.3402(15) and Ru(2)–Cl(2) = 2.3729(15) Å). This fact can be attributed to the strong *trans* influence of the phosphine ligands. The Ru–Ru distance (3.174(6) Å) is well outside of the range (2.28–2.95 Å) usually found for a Ru–Ru bond [24–30] and shorter than that found for the chiraphos analog (3.25 Å) [23]. The Ru–Cl–Ru bond angles

(81.48°, average) are larger than the expected value for two octahedra sharing one face (70.5°). The bond angles P(1)–Ru–P(2) = 95.33(6)° and P(3)–Ru–P(4) = 93.02(2)° are within the range of other Ru(dppb) core complexes [31,32].

The X-ray structure of (**5**) is similar to the [(dcypb)ClRu–(μ-Cl)$_3$–RuCl(dcypb)] [33] complex, which adopts the same approximate C_2 point group (considering the local symmetry only). As observed for complex (**5**) [(dcypb)ClRu–(μ-Cl)$_3$–RuCl(dcypb)] also presents longer Ru–Cl bond lengths for chlorides *trans* to phosphorus than for chlorides *trans* to chlorides. The Ru–Ru distance for [(dcypb)ClRu–(μ-Cl)$_3$–RuCl(dcypb)] (3.278 Å) is higher than for complex (**5**).

The reaction of *mer*-[RuCl$_3$(dppb)H$_2$O] (**1**) and [(η^6-C$_6$H$_6$)RuCl(dpae)]Cl produces the binuclear complex (**11**). The possible mechanism for this reaction involves the formation of the intermediate ''RuCl$_2$(dppb)'' since the reduction of the *mer*-[RuCl$_3$(dppb)H$_2$O] (**1**) complex by the dpae ligand generates this Ru(II) species which can be dimerized forming the binuclear [(dppb)ClRu–(μ-Cl)$_2$–RuCl(dppb)] [2] (**12**) complex, similar to that found for the dissolution of [RuCl$_2$(dppb)(PPh$_3$)] [11], which once in solution dissociates PPh$_3$ and dimerizes. The ^{31}P{^{1}H} NMR spectrum of the triply chloride-bridged [(η^6-C$_6$H$_6$)Ru–(μ-Cl)$_3$–RuCl(dppb)] complex shows only a singlet at δ 54.0 ppm in CDCl$_3$.

The electrochemical behavior of (**1**) is well documented and the products formed after partial and exhaustive electrolysis were described elsewhere by our research group and collaborators [1]. This reaction is similar to the one of [RuCl$_2$(dppb)(PPh$_3$)] with [(η^6-cymene)RuCl$_2$]$_2$ producing [(η^6-cymene)ClRu–(μ-Cl)$_3$–RuCl(dppb)] [32], which strongly confirms our suggestion regarding the mechanism involved in our reaction.

The binuclear arene complex (**11**) presents two distorted octahedra sharing one face as in [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)]. The Ru–P bond lengths (2.2463(8) and 2.2777(8) Å) are slightly smaller than those found for complex (**5**) and are in the expected range for Ru(II)–P bond lengths [32–35]. The Ru–Cl bond lengths for the bridged chlorides are longer than for terminal ones (see Table 2).

The most relevant manifestation of metal–metal interaction is the separation of electrochemical couples [36–38]. In complexes with similar donor atoms coordinated to both metal centers this separation is related to the comproportionation constant (K_c). In binuclear complexes with apparent similar donor atoms in both metal sites, an increase in the metal–metal interaction is accompanied by increasing separation of electrochemical couples. Separation of electrochemical couples $\Delta E_{1/2}$ of about 0.60 V [39] (for complexes with a similar coordination sphere) show a strong metal–metal interaction and high comproportionation constant and can be considered as belonging to the Class III classification [40].

The cyclic voltammetric studies of mixed-valence complexes (**3–10**) synthesized in this work only reveal two reversible one-electron transfer processes, which correspond to the couples designated in Eq. (2).

$$[\mathrm{Ru(II)–Cl_3–Ru(II)}^-] \underset{E_{1/2}(1)}{\overset{+e^-}{\rightleftharpoons}} [\mathrm{Ru(II)–Cl_3–Ru(III)}] \underset{E_{1/2}(2)}{\overset{-e^-}{\rightleftharpoons}} [\mathrm{Ru(III)–Cl_3–Ru(III)}^+] \quad (2)$$

The observation of only two redox processes in complexes such as [(PPh$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] avoid the possibility of the presence of two symmetrically mixed-valence complexes [(PPh$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(PPh$_3$)$_2$] and [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)]. Of note is the electrochemical behavior of [(SbPh$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (discussed below) in which only two redox processes are observed with a separation $\Delta E_{1/2}$ = 0.21 V. If two symmetrically mixed-valence complexes had been formed, the observation of well separated ($\Delta E_{1/2}$ = 0.62 V) redox processes due to [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] in addition to the observed processes should be expected, but this is not the case. The same argument can be used for the complex [(*S*-diop)ClRu–(μ-Cl)$_3$–RuCl(dppb)].

Fig. 3 shows the cyclic voltammogram of the [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**5**) complex. The separations between half-wave potential $E_{1/2}$(1) and $E_{1/2}$(2) for the complexes in Table 3 are small when compared with those found for unsymmetric complexes such as [(PPh$_3$)$_2$(CO)Ru–(μ-Cl)$_3$–RuCl$_2$(PPh$_3$)] [7] (1.57 V) and [(AsPh$_3$)$_2$(CO)Ru–(μ-Cl)$_3$–RuCl$_2$(AsPh$_3$)] [8] (1.66 V). This observation suggests that in symmetric species (same donor atoms) there is a stronger contribution of the metal–metal interaction, increasing the half-wave potential separations; for unsymmetric complexes (different donor atoms) such as [(PPh$_3$)$_2$(CO)Ru–(μ-Cl)$_3$–RuCl$_2$(PPh$_3$)] this separation is mainly due to the ligand characteristics since the orbital energies of the metal centers are different, the metal–metal interactions are weak and each metal center behaves as a monomer.

[(*S*-diop)ClRu–(μ-Cl)$_3$–RuCl(*S*-diop)] (**10**)	0.18	0.79	0.61	2.2×10^{10}

The electrochemical behaviors of the mixed valence complexes are similar to those found in the literature with the general formula [L$_2$ClRu–(μ-Cl)$_3$–RuClL$_2$] (L = arsines and phosphines) [41,42]. The separation of the half-wave potentials (Table 3) are ca. 0.60 V which give K_c values in the range (10^9–10^{10}), greater than the value for the classical Creutz-Taube mixed valence ions type of complexes (7–10^3) [38,43]. Complex (**9**) is the only one in our series that shows a different behavior where the separation between half-wave potentials ($\Delta E_{1/2}$ = 0.21 V) is too small; this can be attributed to the fact that for each metal center there are different donor atoms coordinated. This behavior is also reflected in the intervalence charge transfer energy detected in the near infrared region (Table 4), where the intervalence charge transfer bands are shifted to higher energy values.

These binuclear complexes show two intervalence charge transfer absorptions in the near-IR spectra. One suggestion for this behavior in this kind of triply-chlorine-bridged mixed valence di-ruthenium(II,III) compound was given by James et al. [23], who proposed that the second absorption at higher energy is due to the presence of a tetranuclear species in solution. We do not believe that this applies to our case as the structure proposed for the tetranuclear species is very different from the dimer and if tetramers were formed in solution a different behavior in the cyclic voltammetry experiments would be expected, a fact we did not observe. Another suggestion based on the work developed by Heath et al. [6] ascribes the presence of the second absorption in the near-IR spectra to another transition in binuclear complexes of the type [(R$_3$P)$_3$Ru–(μ-Cl)$_3$–Ru(PR$_3$)$_3$], described as $\sigma \rightarrow \sigma^*$ and $\delta^* \rightarrow \sigma^*$.

We are thus inclined to suggest that the two absorptions observed in our experiments belong to the same complexes in solution.

The presence of donor solvents as methanol, acetonitrile, dimethylsulfoxide make the intervalence charge transfer bands (near-infrared region) disappear due to disproportionation of the dimers into Ru(II) and Ru(III) species and this behavior was previously observed for similar systems [23].

3.1. Reactivity of *mer*-[RuCl$_3$(dppb)H$_2$O] with dihydrogen

The reactivity of *mer*-[RuCl$_3$(dppb)H$_2$O] (**1**) with H$_2$ is dependent upon the reaction conditions. Thus, the reaction in CH$_2$Cl$_2$/MeOH leads to the formation of the known [2] complex [(dppb)ClRu–(μ-Cl)$_2$–RuCl(dppb)] (**12**) (identified by ^{31}P{^{1}H} NMR and elemental analysis). The AB quartet [δ P$_A$ 55.30 (d) and δ P$_B$ 63.50 (d); ^2JP$_A$P$_B$, 30 Hz] for the doubly chloride-bridged [(dppb)ClRu–(μ-Cl)$_2$–RuCl(dppb)] (**12**) complex is in agreement with those reported in the literature [2]. In this case the P$_B$ phosphorus atom is *trans* to the bridged chloride (see Fig. 4).

An "in situ" ^{31}P{^{1}H} NMR experiment was done using complex *mer*-[RuCl$_3$(dppb)H$_2$O] (**1**) in CH$_2$Cl$_2$/MeOH (1:1) and H$_2$ (1 atm). After 24 h of reaction, a mixture of complexes was detected by ^{31}P{^{1}H} NMR experiments, namely [(dppb)ClRu–(μ-Cl)$_2$–RuCl(dppb)] (**12**) [2] (δ_{PA} = 63.5, δ_{PB} = 55.3 ppm; $^2J_{AB}$ = 30 Hz), [(dppb)(η^2-H$_2$)Ru–(μ-Cl)$_3$–RuCl(dppb)] [3] (δ_{PA} = 55.8, δ_{PB} = 40.6; $^2J_{AB}$ = 34 Hz; δ_{PC} = 54.2, δ_{PD} = 52.1 ppm; $^2J_{CD}$ = 45 Hz) and [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)]$^-$

Table 4
Near infrared spectral data for the mixed-valence complexes in CCl$_4$

Complexes	λ_{max} (nm)	ε (M^{-1} cm^{-1})
[(*S*-diop)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**3**)	1860/961	940/930
[(S-binap)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**4**)	1900/980	780/720
[(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**5**)	1856/980	1180/890
[(PPh$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**6**)	1856/978	740/880
[(dppn)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**7**)	1736/967	520/495
[(P-ptol$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**8**)	1889/970	770/728
[(SbPh$_3$)$_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**9**)	1648/849	640/665
[(*S*-diop)ClRu–(μ-Cl)$_3$–RuCl(*S*-diop)] (**10**)	1858/968	1145/890

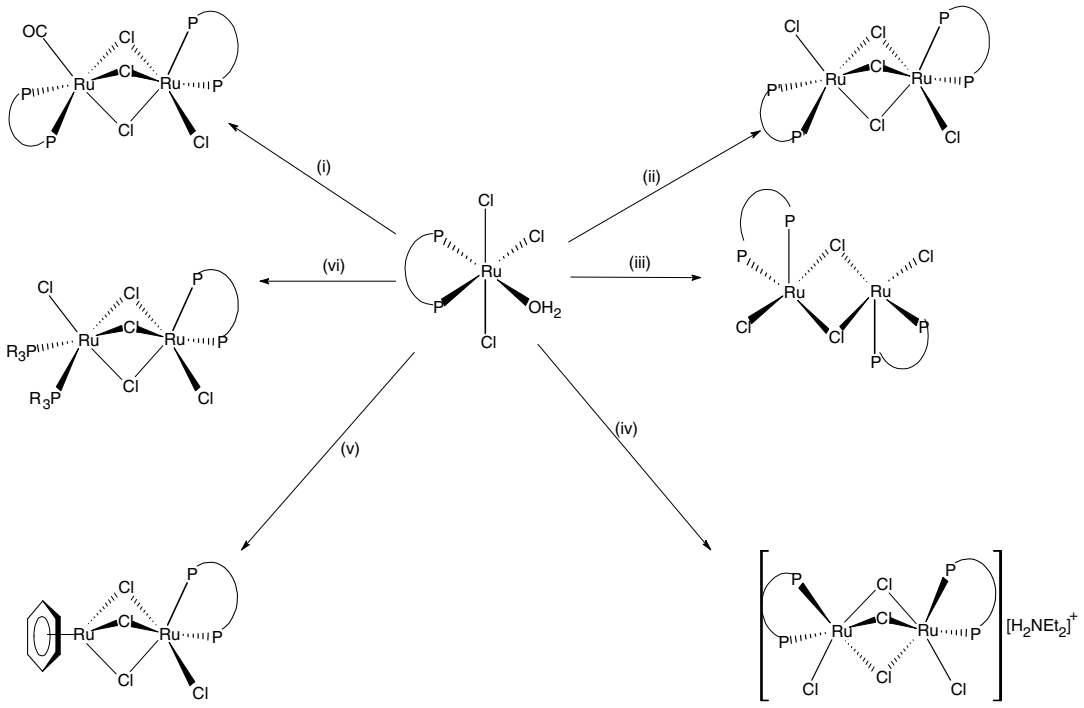

Fig. 4. General scheme for the reactivity of *mer*-[$RuCl_3$(dppb)H_2O] (**1**): (i) in DMA (24 h, RT); (ii) [$RuCl_2$(dppb)(PPh_3)] in CH_2Cl_2 (3 h, RT); (iii) H_2 in CH_2Cl_2/MeOH (48 h, RT); (iv) H_2 in CH_2Cl_2 and NEt_3 (excess, 24 h, RT); (v) [$RuCl(\eta^6$-$C_6H_6)$(dpae)] in $ClCH_2CH_2Cl$ under reflux; (v) [$RuCl_2(PR_3)_3$] in CH_2Cl_2 (3 h, RT).

(**14**) [3] ($\delta_{PA,B}$ = 49 ppm). Evacuation of H_2 from the NMR tube and refilling it with Ar led to the observation of the presence of [(dppb)ClRu–(μ-Cl)$_2$–RuCl(dppb)] (**12**) and [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)]$^-$ (**14**). Complex (**12**) was also identified as being key in the reactivity of *mer*-[$RuCl_3$(dppb)H_2O] (**1**) in the formation of [(dppb)(CO)Ru–(μ-Cl)$_3$–RuCl(dppb)] (**13**) [2], since in a short reaction time (2–3 h) of (**1**) with H_2, complex (**12**) appears as a by-product, while keeping the reaction going for a longer period (24 h) only complex (**13**) was obtained. In the [(dppb)(CO)Ru–(μ-Cl)$_3$–RuCl(dppb)] complex ν(CO) at 1972 cm^{-1} is present in the IR spectrum and an AB quartet is present in the $^{31}P\{^1H\}$ NMR spectrum. For this complex the signals at δ P_A 53.90 (d), δ P_B 53.35 (d) ($^2J_{PAPB}$ 45 Hz) can be assigned to the resonances of the (μ-Cl)$_3$–RuCl(dppb)] side of the molecule while δ P_C 47.71 (d), δ P_D 35.07 (d) ($^2J_{PCPD}$ 30 Hz) belong to the [(dppb)(CO)Ru–(μ-Cl)$_3$ part of the same molecule. On the other hand, stirring complex (**14**) in methanol leads to the formation of (**12**) (under these conditions chloride dissociation is observed).

Similar reactivity of (**1**) was found upon electrochemical reduction [1,44]. Complex (**12**) is obtained in quantitative yield and in this case the mixed-valence compound (**5**) is the intermediate, as proved by partial electrolysis.

Complex (**14**) can be synthesized in high yield by the reaction of *mer*-[$RuCl_3$(dppb)H_2O] with H_2 in CH_2Cl_2 and triethylamine (excess). This procedure has advantages over the published synthesis [3], since it uses mild conditions, short reaction time, gives a high yield and the resulting solution is phosphine free. The symmetric [H_2NEt_2][(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] complex, as expected, shows only a singlet at δ 49.00 ppm.

We have tried to synthesize complex (**12**) as described by James et al. [2] using the reaction of the mixed valence complex (**5**) with H_2 in DMA. In this case the product obtained quantitatively was the carbonyl species (**13**), formed by DMA decarbonylation. Similar behavior was found as described before for complex (**1**) under the same conditions. The desired penta-coordinated double chloride-bridged (**12**) was synthesized from complex (**1**) or (**5**) in a solvent mixture (CH_2Cl_2/MeOH) and H_2. We found that this route was clean since complex (**12**) was obtained quantitavely.

Reactivity of *mer*-[$RuCl_3$(dppb)(H_2O)] is sumarized in Fig. 4.

3.2. Homogeneous hydrogenation of imines

We have performed studies on the hydrogenation of imines catalyzed by some of the complexes described in this work. Hydrogenation of imines is less studied than for alkenes and carbonyl substrates and as a consequence is less understood. Yet, it is an important pathway for the synthesis of amines and is particularly important for the enantioselective reductions of imines that are only achieved in good enantiomeric excess employing homogeneous catalysts [45].

Table 5
Hydrogenation of the imines Ph–CH_2–N=CH–Ph (**15**) and Ph–N=CH–Ph (**16**)

Entry	Complexes	Yield(%) (**15**)[a]	Yield(%) (**16**)[a]
1	[(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**5**)	99	49
2	[$(PPh_3)_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**6**)	99	nd[b]
3	[(dppn)ClRu–(μ-Cl)$_3$–RuCl(dppn)] (**7**)	nd[b]	15
4	[$(P\text{-ptol}_3)_2$ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**8**)	100	23

6	[(dppb)(4-Phpy)Ru–(μ-Cl)$_3$–RuCl(dppb)][c]	75	24
7	[(dppb)(PhCN)Ru–(μ-Cl)$_3$–RuCl(dppb)][c]	80	22

[a] 1000 psi H_2, MeOH (10 ml), [Ru] = 1.3×10^{-4} mol l^{-1}, [Ru]/[imine] = 1/200, 24 h, rt.
[b] Not determined.
[c] Synthesized as described in [9].

In Table 5 the results for the hydrogenation of N-benzylidene-benzylamine (Ph–CH_2–N=CH–Ph) and N-benzylidene-aniline (Ph–N=CH–Ph) are presented. It is evident that for the mixed valence Ru(II)–Ru(III) complexes (Entries 1 and 4) the Ph–CH_2–N=CH–Ph (**15**) is reduced at a higher rate than Ph–N=CH–Ph (**16**). A similar behavior is presented by (**1**) (entry 5) which in a first step generates (**5**) under the reaction conditions. Considering the results for the hydrogenation of (**16**) (entries 1, 3 and 4), the ligand dppb seems to be important on the stabilization/activity of the catalytic system as its substitution by dppn decreased the yield of the hydrogenated products.

For the reduction of the aldimines R–N=CHPh; R = methyl, isopropyl, cyclohexyl, benzyl (**15**), phenyl (**16**), catalyzed by (**5**) James et al. [5] have found that the rate of hydrogenation decreased in the order benzyl > methyl > isopropyl ~ cyclohexyl > phenyl. It has been pointed out that the rate of hydrogenation decreased with the bulkiness of R. Since the rate of the reduction of (**15**) was higher than the reduction of CH_3N=CHPh [5], this suggests that the electronic effects play an important role in the process. Indeed, another correlation can be done: as the positive inductive effect of R increased, the rate of hydrogenation decreased. A distinct interpretation should be given for (**16**) as the lone electron pair on nitrogen is conjugated to the aromatic ring (negative mesomeric effect). Thus, even though the mixed valence complexes are reduced to Ru(II) complexes in the presence of dihydrogen and a base (imine), it seems that the Ru(III) centre plays an important role for the hydrogenation of the imines studied.

A more detailed study taking into account not only the catalyst role, but also the role of the substrate should be carried out in order to elucidate these effects.

4. Conclusions

We have shown in this study the versatility in the reactivity of *mer*-[$RuCl_3$(P–P)H_2O] complexes. These complexes are good precursors for inorganic synthesis and there are at least three reasons for this: (1) the ruthenium(III) species are air stable and easy to handle, (2) they can be easily reduced chemically or electrochemically leading to chloride dissociation [1,44], and (3) products will not be contaminated with free triphenylphosphine.

A wide range of binuclear mixed valence diruthenium(II,III) complexes can be synthesized from them and some of their derivatives present high activity in imines hydrogenation.

Asymmetric hydrogenation of imines and ketones studies using (**3**), (**4**) and (**2**) and other chiral ruthenium complexes are currently ongoing in our laboratory.

5. Supplementary material

Coordinates and other crystallographic data have been deposited with the CCDC, deposition number CCDC 203371 for complex (**5**) and CCDC 203372 for complex (**11**). Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk).

ligand-to-ligand charge transfer (MMLLCT) or ligand-to-ligand charge transfer (LLCT). In all these cases the LUMO is predominantly centered on the diimine ligand.

Square-planar complexes containing both easily oxidisable and reducible ligands were found to show a LLCT transition [16]. These transitions were highly solvatochromic, of which some of them exhibit the remarkable property of being luminescent in solution [17]. Metal complexes possessing such a transition have become the focus for numerous photochemical studies due to large molar absorptivity of the transition [16]. The LLCT excited states had previously been noted in some Zn(II) and Pt(II) complexes containing both diimine and aromatic thiolate (dithiolate) ligands [16c,16f]. Dance and Miller [16a] described the observation of a LLCT band for the first time in a Ni(II) complex containing α-diimine and dithiolate. In general, both electron-donating substituents on the thiolate and electron-withdrawing substituents on the diimine ligands would lower the LLCT transition energy. On the contrary, electron-withdrawing groups on the thiolate and electron-donating substituents on the diimine increase the transition energy. Thus, selective fine tuning of this excited state could be achieved by altering the ligands (diimine or dithiolate) or changing the substituents on the ligand(s) or the metal ion(s) [16,17].

The LLCT transitions have also been reported for a variety of d^8 metal complexes with catecholate and α-diimine ligands [18], where the charge transfer takes place from the catecholate ligand to the diimine ligand. Here too, the electron-withdrawing substituents on the diimine and the electron-donating substituents on the catechol lower the LLCT transition energy and electron-donating substituents on the diimine and the electron-withdrawing substituents on the catechol increase the LLCT transition energy. However, the solution-state emission from these complexes has not been reported. Many of them were found to be potential candidates for generation of singlet molecular oxygen ($^1O_2$) since they produce $^1O_2$ upon irradiation at the LLCT band [18b,18c]. Here we report, for the first time, the solution-state luminescence of such complexes. We also report the spectral and electrochemical behaviour of these complexes. An attempt to make a correlation between redox potentials and the energy of the absorption maxima is made. In addition, we synthesized two dinuclear complexes for comparison of the electronic properties since dinuclear complexes have been known to luminesce at higher wavelength compared to related monomers. It has been shown that dinuclear complexes possess a low-lying excited state due to a large decrease in the energy of the lowest π* orbital of the bridging ligands upon complexation [3]. We also report the solvatochromic LLCT transition and solution state luminescence of these complexes.

The various diimines used are 4,7-diphenyl-1,10-phenanthroline, 2,2′-bipyridine, 2,2′-biquinoline and 1,10-phenanthroline. The metal ions used are Pt(II) and Pd(II). 3,4-Dihydroxybenzaldehyde and 3,4-dihydroxybenzoic acid are used as the dianionic ligand. 3,3′,4,4′-Tetrahydroxybenzaldazine is used as the tetraanionic ligand to synthesise the dinuclear complexes.

2. Experimental

2.1. Starting materials

Potassium tetrachloroplatinate(II), palladium chloride, 1,10-phenanthroline monohydrate, 4,7-diphenyl-1,10-phenanthroline (Loba-Chemie Indoauatranal Co., India), 2,2′-biquinoline, potassium hydroxide (Merck, India), 3,4-dihydroxybenzoic acid, 3,4-dihydroxybenzaldehyde (Fluka AG, Switzerland), hydrazine hydrochloride, ammonia, acetic acid (s.d.fine-CHEM Ltd., India) and 2,2′-bipyridine (Glaxo Industries, India) were bought, of reagent grade and used as such. The reagent grade solvents were purified before use by standard procedures [19]. Solvents of spectroscopic grade were used for cyclic voltammetry and spectroscopic measurements.

2.2. Physical measurements

The chemical analyses of carbon, hydrogen and nitrogen for the complexes were performed using a Carlo Erba Strumentazion Elemental Analyzer, Model 1106, at R.S.I.C., Central Drug Research Institute, Lucknow. The IR spectra of the complexes in KBr pellets were recorded with a Nicolet 170-Sx FT-IR spectrophotometer in the region 4000–600 cm^{-1}. Electronic absorption spectra of the complexes in various solvents were obtained using a Shimadzu UV-265 UV–VIS spectrophotometer. The proton nuclear magnetic resonance (^1H NMR) spectra of the complexes were acquired using a Varian VXR-300s NMR spectrometer in deuterated dimethyl sulfoxide [$(CD_3)_2SO$]. Tetramethylsilane was used as the internal reference. All the spectra were recorded in the range of 0–11 ppm. The cyclic voltammograms of the complexes in acetonitrile ($\sim 10^{-3}$ M) containing 0.1 M tetra(*n*-butyl)ammonium hexafluorophosphate as supporting electrolyte were obtained on a Model CV-IB Bioanalytical Cyclic Voltammetry apparatus equipped with an Omnigraphic 2000 Recorder. A single compartment cell was employed with an Ag/AgCl reference-electrode (−0.041 V versus standard calomel electrode, SCE), a platinum wire counter electrode and a platinum working electrode (6 mm outer diameter). The scan rate used was 200 mV/s. The solutions were degassed for 15 min before recording the cyclic voltammogram. Room-temperature excitation and

luminescence spectra of the metal complexes were recorded in a Spex spectrofluorimeter equipped with a Hamamadzu R928 photomultiplier tube (PMT). The PMT was cooled externally by circulating cold water. The emission spectra were corrected for excitation lamp intensity variation and solvent emission. The fluorescence quantum yields were measured by an optically dilute method [24] using tryptophan in water as a standard [25]. The quantum yield values were corrected for solvent refractive index. Fluorescence lifetime measurements were carried out by the single photon counting technique using a nanosecond fluorescence spectrometer from Applied Photophysics (model SP-170) with a bright and stable nanosecond flash-lamp operating at frequencies up to 200 kHz. The lamp was filled with nitrogen gas. The PMT type XP 2020Q was used for photodetection. Output of the multichannel analyzer was analyzed for single, double or multi exponential decay functions. The solutions were excited at 296, 316 or 337 nm. Phosphorescence measurements were made using a SPEX 1934C phosphorimeter with a RCA C13034 photomultiplier attachment having the facility to provide corrected emission spectra. Metal complexes dissolved in EPA mixture (10^{-6} M) were frozen in liquid nitrogen (77 K) in a 10 mm quartz cuvette and the spectra were recorded using different wavelengths of excitation.

2.3. Synthetic procedures

[M(N-N)Cl_2] {where M = Pd(II) or Pt(II) and N-N is 2,2′-bipyridine (BPY), 2,2′-biquinoline (BIQ), 4,7-diphenyl-1,10-phenanthroline (DPP) and 1,10-phenanthroline (PHEN)} were prepared by the reported procedures [20] and characterized by the methods from the literature [21,22].

2.3.1. [Pd(BPY)(DHB)] (1)

0.2 mmol of [Pd(BPY)Cl_2] was dissolved in 25 cm^3 of hot acetonitrile (60 °C). The solution was filtered while hot to remove any undissolved material. To this 0.2 mmol of H_2DHB dissolved in 1.6 cm^3 of 0.25 N KOH in methanol was added slowly and stirred for 30 min at the same temperature. Then the solution was cooled to room temperature and kept in a refrigerator overnight to obtain crystals of the complex. The compound was filtered and washed with small amounts of cold acetonitrile, water and methanol successively and dried in a vacuum desiccator over anhydrous calcium chloride. The compound was recrystallized from DMF and 70% yield was obtained. ^{1}H NMR [$(CD_3)_2SO$]: 8.58 (d, 2H, 3, 3′), 8.36 (dt, 2H, 4, 4′), 7.81 (t, 2H, 5, 5′), 8.64 (d, 2H, 6, 6′), 6.92 (dd, 1H, B), 6.77 (d, 1H, C), 6.46 (d, 1H, A), 9.5 (s, 1H, D). *Anal.* Calc. for $C_{17}H_{12}N_2O_3Pd$: C, 51.21; H, 3.03; N, 7.02. Found: C, 50.87; H, 3.05; N, 6.98%.

2.3.2. [Pd(PHEN)(DHB)] (2)

[Pd(PHEN)Cl_2] (0.2 mmol) was dissolved in 50 cm^3 of DMF. To this, 0.2 mmol of H_2DHB dissolved in 1.6 cm^3 of 0.25 N KOH in methanol was added slowly. The solution was stirred for 30 min. Then the solution was evaporated to 5 cm^3 and cooled overnight. The precipitate formed was filtered and recrystallized from DMF and dried in a vacuum desiccator over anhydrous $CaCl_2$. The yield obtained was 45%. ^{1}H NMR [$(CD_3)_2SO$]: δ 8.85 (d, 2H, 2, 9), 8.91 (d, 2H, 4, 7), 8.23 (s, 2H, 5, 6), 8.08 (m, 2H, 3, 8), 6.64 (d, 1H, B), 6.68 (s, 1H, C), 6.39 (d, 1H, A), 9.5 (s, 1H, D). *Anal.* Calc. for $C_{19}H_{12}N_2O_3Pd$: C, 53.98; H, 2.86; N, 6.63. Found: C, 53.54; H, 2.85; N, 6.59%.

2.3.3. [Pd(BIQ)(DHB)] (3)

This complex was prepared according to the protocol given for **1**, replacing [Pd(BIQ)Cl_2] with [Pd(BPY)Cl_2]. The yield obtained was 60%. ^{1}H NMR [$(CD_3)_2SO$]: δ 9.35 (d, 1H, 3), 9.25 (d, 1H, 3′), 9.01 (d, 2H, 4, 4′), 8.85 (d, 2H, 5, 5′), 8.23 (d, 2H, 6, 6′), 7.89 (t, 2H, 7, 7′), 8.07 (m, 2H, 8, 8′), 6.92 (dd, 1H, B), 6.82 (d, 1H, C), 6.51 (d, 1H, A), 9.55 (s, 1H, D). *Anal.* Calc. for $C_{25}H_{16}N_2O_3Pd$: C, 60.19; H, 3.23; N, 5.62. Found: C, 59.80; H, 3.25; N, 5.66%.

2.3.4. [Pd(DPP)(DHB)] (4)

The complex was prepared by the procedure described for **2** using [Pd(DPP)Cl_2] in place of [Pd(PHEN)Cl_2]. The yield obtained was 52%. ^{1}H NMR [$(CD_3)_2SO$]: δ 8.89 (m, 2H, 2, 9), 7.74 (s, 2H, 4, 7), 7.88 (s, 2H, 5, 6), 7.66 (m, 2H, 3, 8), 6.66 (d, 1H, B), 6.49 (s, 1H, C), 6.17 (d, 1H, A), 9.40 (s, 1H, D). *Anal.* Calc. for $C_{31}H_{20}N_2O_3Pd$: C, 64.76; H, 3.51; N, 4.87. Found: C, 64.96; H, 3.49; N, 4.86%.

2.3.5. [Pt(BPY)(DHB)] (5)

[Pt(BPY)Cl_2] (0.2 mmol) was dissolved in 25 cm^3 of DMF and filtered. To this 0.2 mmol of H_2DHB dissolved in 1.6 cm^3 of 0.25 N KOH in methanol was added. The solution was stirred for 24 h at 60 °C, then the solvent was evaporated at 40 °C. The crude product obtained was recrystallized from chloroform and dried in a vacuum desiccator over anhydrous calcium chloride. The yield obtained was 62%. ^{1}H NMR [$(CD_3)_2SO$]: 8.55 (d, 2H, 3, 3′), 8.38 (dt, 2H, 4, 4′), 7.78 (t, 2H, 5, 5′), 9.08 (d, 2H, 6, 6′), 6.96 (d, 1H, B), 6.94 (s, 1H, C), 6.64 (d, 1H, A), 9.6 (s, 1H, D). *Anal.* Calc. for $C_{17}H_{12}N_2O_3Pt$: C, 41.89; H, 2.48; N, 5.75. Found: C, 41.60; H, 2.45; N, 5.79%.

2.3.6. [Pt(PHEN)(DHB)] (6)

This complex was prepared by the method described for **5** using [Pt(PHEN)Cl_2] instead of [Pt(BPY)Cl_2]. The yield obtained was 42%. ^{1}H NMR [$(CD_3)_2SO$]: δ 9.59 (d, 2H, 2, 9), 8.99 (d, 2H, 4, 7), 8.23 (s, 2H, 5, 6), 8.12 (q,

2H, 3, 8), 6.94 (d, 1H, B), 6.90 (s, 1H, C), 6.60 (d, 1H, A), 9.62 (s, 1H, D). *Anal.* Calc. for $C_{19}H_{12}N_2O_3Pt$: C, 44.62; H, 2.37; N, 5.48. Found: C, 45.21; H, 2.35; N, 5.48%.

2.3.7. [Pt(BIQ)(DHB)] (7)

Preparation of this complex was made possible by following the procedure given for **5** using $[Pt(BIQ)Cl_2]$ instead of $[Pt(BPY)Cl_2]$. The yield obtained was 62%. ^1H NMR $[(CD_3)_2SO]$: δ 9.49 (d, 2H, 3), 9.40 (d, 1H, 3′), 8.94 (d, 2H, 4, 4′), 8.19 (d, 2H, 5, 5′), 8.03 (d, 2H, 6, 6′), 7.85 (dt, 2H, 7, 7′), 8.64 (m, 2H, 8, 8′), 6.96 (d, 1H, B), 6.94 (s, 1H, C), 6.64 (d, 1H, A), 9.63 (s, 1H, D). *Anal.* Calc. for $C_{25}H_{16}N_2O_3Pt$: C, 51.11; H, 2.75; N, 4.77. Found: C, 51.27; H, 2.75; N, 4.80%.

2.3.8. Pt(DPP)(DHB) (8)

The complex was prepared according to the procedure described for **5** using $[Pt(DPP)Cl_2]$ in place of $[Pt(BPY)Cl_2]$. The yield obtained was 48%. ^1H NMR $[(CD_3)_2SO]$: δ 9.09 (t, 2H, 2, 9), 7.79 (s, 12H, 4, 7, 3, 8), 7.79 (s, 2H, 5, 6), 6.83 (m, 2H, B, C), 6.47 (d, 1H, A), 9.56 (s, 1H, D). *Anal.* Calc. for $C_{31}H_{20}N_2O_3Pt$: C, 56.11; H, 3.04; N, 4.22. Found: C, 55.96; H, 3.01; N, 4.18%.

2.3.9. Synthesis of 3,3′,4,4′-tetrahydroxybenzaldazine (H_4THB)

A solution of H_2DHB (276 mg, 2 mmol in 10 cm^3 of methanol) was added dropwise to a solution containing a mixture of 0.05 cm^3 of hydrazinehydrochloride, 9 cm^3 of distilled water and 1.5 cm^3 of concentrated ammonia solution. The contents were stirred for 3h at room temperature, then the solution was neutralized with 1N acetic acid to remove excess ammonia and cooled to get yellow crystals of the compound. The product was recrystallized from 50% methanol and the yield was 62%. The purity of the compound was checked using TLC. ^1H NMR $[(CD_3)_2SO]$: δ 9.54 (s, 2H, E, E′), 9.25 (s, 2H, F, F′), 8.46 (s, 2H, D), 7.29 (d, 2H, C), 7.08 (dd, 2H, B), 6.81 (d, 2H, A). *Anal.* Calc. for $C_{14}H_{12}N_2O_4$: C, 61.76; H, 4.44; N, 10.29. Found: C, 62.02; H, 2.49; N, 10.21%.

2.3.10. $[Pd_2(BPY)_2(THB)]$ (9)

This complex was prepared according to the method reported for **1** by adding 0.1 mmol of H_4THB instead of 0.2 mmol of H_2DHB. The compound was recrystallized twice from acetonitrile and dried in a vacuum desiccator over anhydrous calcium chloride. The yield was 25%. ^1H NMR $[(CD_3)_2SO]$: δ 8.52 (d, 2H, 3, 3′), 8.31 (dt, 4H, 4, 4′), 7.78 (m, 4H, 5, 5′), 8.59 (d, 4H, 6, 6′), 6.87 (dd, 2H, B), 6.72 (d, 2H, C), 6.41 (d, 2H, A), 9.52 (s, 2H, D). *Anal.* Calc. for $C_{34}H_{24}N_6O_4Pd_2$: C, 51.47; H, 3.05; N, 10.59. Found: C, 51.27; H, 3.05; N, 10.57%.

2.3.11. $[Pt_2(BPY)_2(THB)]$ (10)

$[Pt(BPY)Cl_2]$ (0.2 mmol) was dissolved in 25 cm^3 DMF and filtered. To this 0.1 mmol of H_4THB dissolved in 1.6 cm^3 of 0.25 N KOH in methanol was added. The solution was stirred for 24 h at 60 °C, then the solvent was evaporated at 40 °C. The crude product obtained was recrystallized from chloroform and dried in a vacuum desiccator over anhydrous calcium chloride. The yield obtained was 62%. ^1H NMR $[(CD_3)_2SO]$: δ 8.58 (d, 2H, 3, 3′), 8.40 (d, 4H, 4, 4′), 7.83 (m, 4H, 5, 5′), 9.48 (d, 4H, 6, 6′), 6.94 (dd, 2H, B), 6.65 (d, 2H, C), 6.65 (d, 2H, A), 9.6 (s, 2H, D). *Anal.* Calc. for $C_{34}H_{24}N_6O_4Pt_2$: C, 42.07; H, 2.49; N, 8.66. Found: C, 41.89; H, 2.53; N, 8.72%.

The complexes [Pt(BPY)(DHBA)] (**11**), [Pt(PHEN)(DHBA)] · H_2O (**12**) [Pt(BIQ)(DHBA)] (**13**) and [Pt(DPP)(DHBA)] · H_2O (**14**) were prepared and characterized as reported in the literature [23].

3. Results and discussion

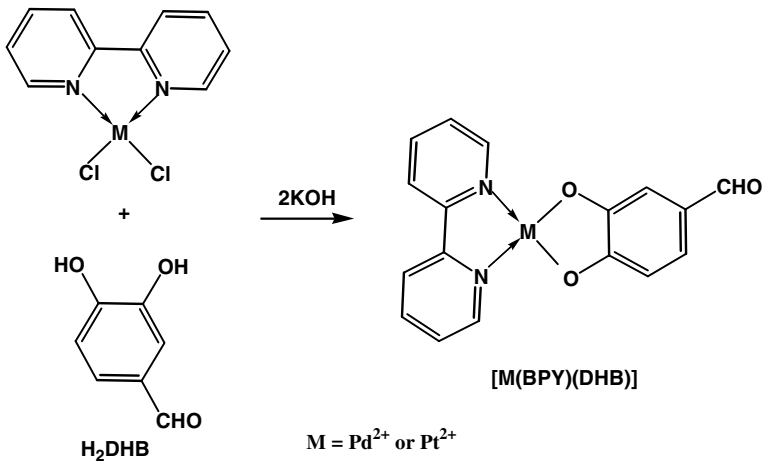
3.1. Syntheses and characterization

Eight complexes of the formula, [M(N-N)(DHB)] {where M = Pd(II) or Pt(II), N-N = 2,2′-bipyridine (BPY), 2,2′-biquinoline (BIQ), 4,7-diphenyl-1,10-phenanthroline (DPP), 1,10-phenanthroline (PHEN) and DHB = dianion of 3,4-dihydroxybenzaldehyde (H_2DHB)} were prepared and characterized. In general these complexes were prepared by reacting stoichiometric quantities of the starting material, $[M(N\text{-}N)Cl_2]$ with H_2DHB in the presence of an appropriate amount of KOH under a nitrogen atmosphere. An illustrative example of the synthesis of [M(BPY)(DHB)] is shown in Scheme 1.

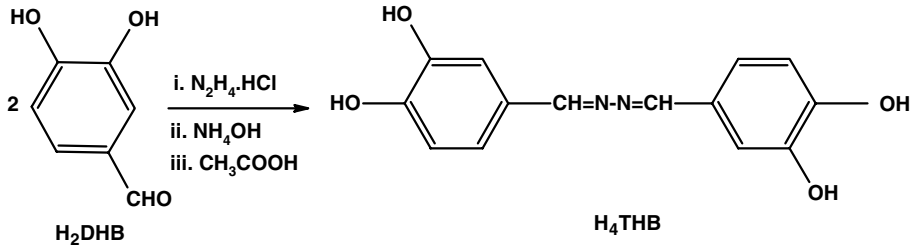
The various complexes prepared are [Pd(BPY)(DHB)] (**1**), [Pd(PHEN)(DHB)] (**2**), [Pd(BIQ)(DHB)] (**3**), [Pd(DPP)(DHB)] (**4**), [Pt(BPY)(DHB)] (**5**), [Pt(PHEN)(DHB)] (**6**), [Pt(BIQ)(DHB)] (**7**) and [Pt(DPP)(DHB)] (**8**).

The tetradentate ligand H_4THB was synthesized by coupling two molecules of H_2DHB with hydrazinehydrochloride in the presence of liquid ammonia as depicted in Scheme 2.

Two complexes of the formula $[M_2(BPY)_2(THB)]$ {where M is Pd(II) or Pt(II) and BPY is 2,2′-bipyridine and THB is the tetraanion of tetrahydroxy benzaldazine} were prepared using the starting material H_4THB. The complexes prepared were $[Pd_2(BPY)_2(THB)]$ (**9**) and $[Pt_2(BPY)_2(THB)]$ (**10**). Four more platinum complexes, namely [Pt(BPY)(DHBA)] (**11**), [Pt(PHEN)(DHBA)] · H_2O (**12**), [Pt(BIQ)(DHBA)] (**13**) and [Pt(DPP)(DHBA)] · H_2O (**14**) were prepared for luminescence studies, according to the reported procedure [23].



Scheme 1. Synthesis of [M(N-N)(DHB)] complexes.



Scheme 2. Synthesis of H_4THB.

Changes in the IR spectra in the ligand segment of the [M(N-N)(DHB)] complexes are compared with that of the parent chloro compounds of the formula [M(N-N)Cl_2], as well as with the free ligands. The ring frequency of the α-diimine moiety is shifted to higher frequency on complexation as compared to the free ligand. The presence of two additional sharp bands around 1250 and 1460 cm^{-1} confirms the bonding of DHB to the metal ion through ionized hydroxyl groups [26,27]. The band at 1460 cm^{-1} is due to the skeletal stretching vibration of the aromatic ring of DHB and the band at 1250 cm^{-1} corresponds to the C–O stretching vibration of DHB. In the case of binuclear complexes, the IR spectra show a peak around 1560 cm^{-1} due to the –CH=N– group. There are strong peaks at 1275 cm^{-1} (which is due to the –C–O– stretching) and around 1475 cm^{-1} (which is due to the aromatic ring stretching of THB). Observation of these two peaks indicates the binding of THB to the metal ion through the $–O^-$ group.

The ^1H NMR spectra of the complexes are compared with the parent dichloro compounds in order to determine the bonding mode and stoichiometry of the complexes. The signals are assigned on the basis of chemical shifts and spin-spin interaction. The structure and numbering scheme of the ligand protons of the complexes are given in Figs. 1 and 2. The α-diimine protons of the complexes generally experience upfield shifts when compared to the parent chloro compound. This could be due to stronger binding of DHB to the metal ion than the chloride ions, or more back bonding from the metal d-orbital to π* orbitals of the α-diimine ligands as compared to chloride ions [20c,28]. The upfield shift is remarkable (0.48 and 0.93 ppm for **1** and **5**, respectively) for the $H_{6,6'}$ protons of [M(BPY)(DHB)] complexes. The $H_{2,9}$ protons of [M(PHEN)(DHB)] complexes experience maximum upfield shift (0.51 and 0.1 ppm for **2** and **6**, respectively). A similar trend is also observed in [M(DPP)(DHB)] complexes. The $H_{2,9}$ protons of **4** and **8** show upfield shifts of 0.52 and 0.66 ppm, respectively. The phenyl protons in the fourth and seventh positions experienced little upfield shifts when compared to their parent chloro compounds. In the ^1H NMR spectra of [M(BIQ)(DHB)] complexes, all the protons of BIQ experience up- or downfield shifts except the $H_{6,6'}$ protons. The protons $H_{4,4'}$ and $H_{8,8'}$ of **3** experience downfield shifts of 0.25 and 0.33 ppm, respectively, whereas the $H_{5,5'}$ and $H_{7,7'}$ protons experience upfield shifts of 0.09 and 0.26 ppm correspondingly as compared to the parent chloro compound. The protons H_3 and $H_{3'}$ of complexes **3** and **6** appear as two separate doublets rather than a single doublet as in the parent chloro compound. This could be due to the fact that the compound lacks planarity in solution which

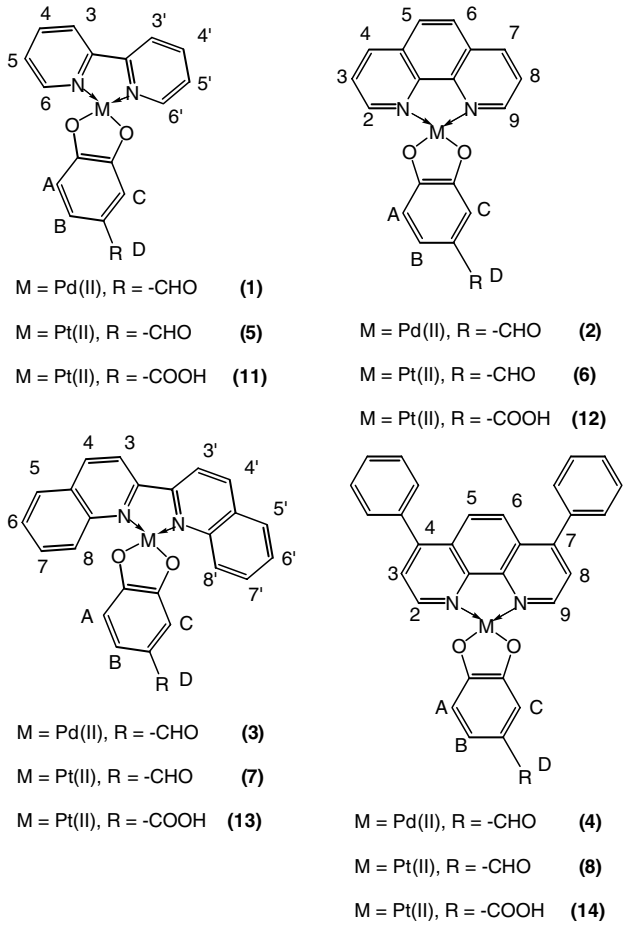


Fig. 1. Structure and numbering scheme of the protons of [M(N-N)(DHB)] and [Pt(N-N)(DHBA)] complexes.

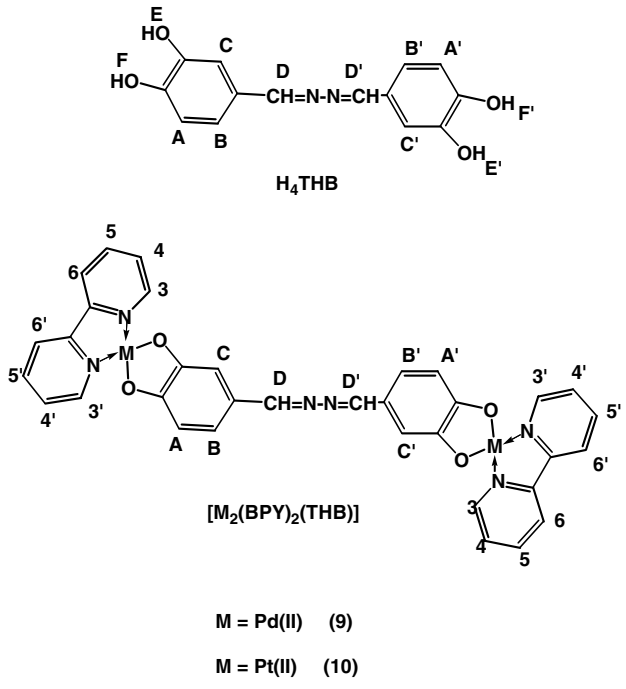

Fig. 2. Structure and numbering scheme of the protons of H_4THB and $[M_2(BPY)_2(THB)]$ complexes.

makes the protons have different electronic environments. Thus, the protons H_3 and $H_{3'}$ could resonate at different frequencies. Similar behaviour was observed earlier in the case of [M(BIQ)(DHBA)] [23]. The free ligand, 3,4-dihydroxybenzaldehyde shows two peaks at 10.11 and 9.55 ppm due to the phenolic –OH protons, but they are absent in the metal complexes. All other protons (H_A, H_B, H_C and H_D) experience upfield shifts in the complexes as compared to the free ligand, indicating the bonding of DHB to the metal ions. Similarly, H_4THB shows two peaks for the four phenolic –OH protons at 9.54 and 9.29 ppm. These two peaks are absent in the metal complexes. The protons H_D, H_C and H_B experienc considerable upfield shifts in the complex as compared to the free ligand. The structure and numbering scheme of the protons in the ligand and complexes are given in Figs. 1 and 2. The ^3J (^{195}Pt–^1H) couplings in these complexes have not been observed due to a decrease of chemical shielding anisotropy with an increase in the magnetic field strength [28].

These data suggest that both ligands are bonded to the metal ion in the mixed-ligand complexes. The integrated areas obtained for the protons of α-diimine and DHB indicate the stoichiometry of these complexes corresponds to [M(N-N)(DHB)]. Similarly, the proton ratio of BPY and THB indicate a stoichiometry of $[M_2(BPY)_2(THB)]$. The sharp ^1H NMR spectral signals observed in these complexes suggest them to be diamagnetic. The proton NMR spectral, the IR and the elemental analysis data confirm the synthesis and the structures assigned to them as shown in Figs. 1 and 2.

3.2. Electronic absorption spectra

The electronic absorption spectral data of these complexes are given in Table 1. A representative spectrum is shown in Fig. 3. The chloro complexes of the formula, $[M(N\text{-}N)Cl_2]$ show four bands (bands are numbered in increasing order of energy), whereas the complexes of the formula [M(N-N)(DHB)] show five band maxima. The bands in the UV region have been assigned on the basis of band assignments of chloro complexes [20c,29,30]. Thus, the bands 2 and 4 have been assigned to charge-transfer transitions from a metal d-orbital to π-antibonding orbitals of the α-diimine (MLCT). Bands 3 and 5 are assigned as the intra-ligand π–π* transition of the α-diimine (IL). In addition, these complexes exhibit a band in the visible region, which is strongly dependent on the polarity of the solvent (band 1). The absorption maximum of this band is found to shift with a change of solvent. The energy of this band increases with an increase in the polarity of the solvent (hydroxylic as well as non-hydroxylic). The observed shift in band maxima to higher energy in solvents of increasing polarity is indicative of a polar ground state and non-polar excited state as reported by Cummings and Eisen-

Table 1
Electronic absorption spectral data of [M(N-N)(DHB)], [Pt(N-N)(DHBA)] and [$M_2(BPY)_2(THB)$] complexes in DMF at 298 K

berg [12b]. This is in contrast to the small degree of solvatochromism observed for the MLCT band of transition metal diimine complexes such as $[Ru(bpy)_3]^{2+}$ and related systems [8]. The effect of various solvents on the λ_{max} of this band is given in Table 2. An excellent correlation of absorption band energy with solvent polarity was found using Reichardt's scale [31]. The plots of Reichardt's parameter (E_T) of the solvents against absorption maxima gave two separate lines, one for hydroxylic solvents and the other for non-hydroxylic solvents [18,29,30]. A typical plot for **2** is given in Fig. 4. This band was not observed in a solution containing a 1:1 mixture of [M(N-N)Cl_2] and H_2DHB.

The energy of this band decreases when the α-diimine is changed from BPY to BIQ. However, small changes were observed when N-N was replaced from BPY to PHEN or DPP. An increase in energy of this band was observed when compared to [M(N-N)(DHBA)] [23] and [M(N-N)(CAT)] [32]. Based on these observations this band has been assigned as a LLCT transition from the HOMO of DHB to the LUMO of α-diimine via the metal [23,32]. The observed trends in the energy of this band can also be explained based on the above assignment. Thus, the decrease in energy of [M(BIQ)(DHB)] complexes when compared to [M(BPY)(DHB)] complexes can be explained to be due to the additional fused rings on the bipyridine, which pulls down the LUMO to lower energy. The two phenyl groups are perpendicular to the plane of 1,10-phenanthroline in the DPP complexes and are therefore not expected to contribute much to conjugation in the complex [33]. Hence, there is a small change in the energy of transition between PHEN and DPP complexes. Because of the electron-withdrawing group (–CHO) on the phenyl ring of DHB, the HOMO of the complexes, [M(N-N)(DHB)] further drops to lower energy. Thus, the energy of transition for [M(N-N)(DHB)] complexes increases when compared to the unsubstituted catechol complexes, [M(N-N)(CAT)] or those substituted with a carboxylic group, [M(N-N)(DHBA)] complexes [23]. This band assignment is supported by the solvent studies. With the increase in polarity of the solvent, the HOMO is stabilized more and leads to an increase in the energy of transition [29,30]. The LLCT band of palladium complexes is at higher energy as compared to the platinum counterparts. This is due to increase in the ligand field of Pt(II) by 30–50% when compared to Pd(II).

The electronic spectra of the dinuclear complexes are similar to the mononuclear complexes. There is a little change in the position of the LLCT band but the molar

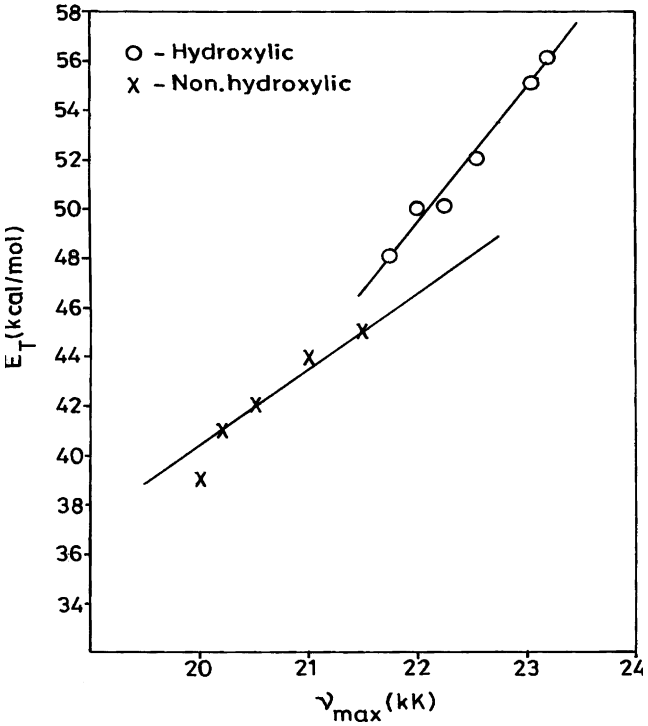

Fig. 4. Plot of E_T vs. ν_{max} for the LLCT band of **2**.

extinction coefficient of this band is higher for the dimer as compared to the monomer, and the position of the MLCT band is considerably red-shifted in the dimer. Since the binuclear complexes were found be soluble in very few solvents, a complete solvent-studies could not be made.

3.3. Electrochemical studies

The cyclic voltammetric data of complexes **1**–**8** are given in Table 3. In general these complexes show diffuse, irreversible and successive two one-electron reductions and one quasi-reversible one-electron oxidation. Irreversibility of the reduction peaks was confirmed by the absence of the peak in the reversible scan or by the large difference in potentials between two counter peaks. The general electron transfer series for the complexes can be represented by the following equations:

Table 3
Electrochemical data of [M(N-N)(DHB)] complexes in CH_3CN at 298 K

Complex	Reduction		Oxidation	
	I	II	I	II
1	−0.825[a]	−1.213	0.750	0.950
2	−0.838	−1.250	0.725	0.950

[a] Potentials in volts vs. Ag/AgCl.

$$[M(N\text{-}N)(DHB)]^{+} \underset{-e^-}{\overset{+e^-}{\rightleftharpoons}} [M(N\text{-}N)(DHB)]^{0} \quad (1)$$

$$[M(N\text{-}N)(DHB)]^{0} \underset{-e^-}{\overset{+e^-}{\rightleftharpoons}} [M(N\text{-}N)(DHB)]^{-1} \quad (2)$$

$$[M(N\text{-}N)(DHB)]^{-1} \underset{-e^-}{\overset{+e^-}{\rightleftharpoons}} [M(N\text{-}N)(DHB)]^{-2} \quad (3)$$

The formation of a charge transfer to the α-diimine excited state formally involves the oxidation of the HOMO and reduction of the α-diimine-based LUMO [12b]. Thus, the potentials of the first reduction and oxidation of the complexes can be related to the nature of the orbitals in these redox processes. These orbitals are the LUMO, consisting exclusively of α-diimine [34,35], and the HOMO of DHB, and they are involved in the charge-transfer transition (band 1) as described above. The first reduction potential of [M(BIQ)(DHB)] complexes lies at lower values as compared to [M(BPY)(DHB)] complexes. This can be explained in terms of the electron-withdrawing effect with increased delocalizing effect of additional fused rings in the former

compared to the latter. Similarly, the oxidation potentials of [M(BIQ)(DHB)] are higher than that of the [M(BPY)(DHB)] counter parts. The [M(DPP)(DHB)] complexes have a much smaller negative value for the first reduction potential than [M(PHEN)(DHB)] complexes. This could be due to the electron-withdrawing nature of the substituted phenyl groups in DPP [33]. However, only a small change was noticed in the position of the absorption bands (band 1) of [M(PHEN)(DHB)] and [M(DPP)(DHB)]. The observed difference in redox potentials of an electron transfer process is normally controlled by both kinetic and thermodynamic parameters [36,37], whereas the absorption band position is purely thermodynamically controlled. Similar observations were found for another series of complexes [23]. Cyclic voltammograms on the dinuclear complexes could not be recorded due to insufficient solubility of these complexes in acetonitrile.

3.4. Luminescence studies

The luminescence studies of the complexes were carried out in acetonitrile at room temperature. These complexes do not show emission on excitation at the LLCT band at room temperature. However, these complexes were found to be luminescent at room temperature on excitation at the MLCT/ILCT band. Only the platinum derivatives were found to show emission at room temperature. This may be due to the lack of structural rigidity of the Pd(II) complexes as compared to the Pt(II) complexes. The parent dichloro complexes of Pt(II) did not show emission at room temperature. The luminescence band maxima of these complexes are given in Table 4. Representative luminescence and excitation spectra are given in Fig. 5(a) and (b). The energies of the MLCT (band 2) and IL (band 3) lie very close to each other in the electronic spectra of these complexes. On excitation at these bands, these complexes show luminescence at room temperature. The energy of the emission maxima of these complexes lies in the following order: **4** ~ **8** > **6** ~ **10** > **5** ~ **7** ~ **9**. This order can be explained in terms of π-conjugation. The difference in energy between **5**, **7** and **9** is very small. This may be due to the only one additional double bond present in **5** and **9** as compared to **7**. The difference in energy between **6**, **10** and **5**, **9** can be attributed to the presence of two additional phenyl groups in DPP. Similar behaviour has earlier been observed by Watts and Crosby [38] for ruthenium complexes. In the case of **4** and **8** the larger red shift in emission maximum is due to the additional fused rings in the BIQ system. The large Stokes shift observed in the excitation spectra of these complexes indicates that the ground state geometry of these complexes differs largely with the excited state. The quantum yields of luminescence (ϕ_L) of these complexes are included in Table 4. The ϕ_L values were determined with reference to tryptophan in water [25]. The DPP derivative is found to show a larger quantum yield than any other complex. Similar behaviour was earlier reported for DPP complexes of ruthenium [39].

Table 4
Photophysical data of [Pt(N-N)(DHB)], [Pt(N-N)(DHBA)] and $[Pt_2(BPY)_2(THB)]$ complexes in CH_3CN

Complex	Luminescence maxima (λ_{max}/nm)	Luminescence excitation maxima (λ_{max}/nm)	τ[a] (ns)	Φ_L[a] ($\times 10^2$)
5	364	294	2.40 8.68	0.188
6	368	291	2.80 7.30	0.278
7	419	333	4.28 4.29	0.295
8	416 398	355 319 284	3.49 10.70	0.409

11	364	291	1.40 8.77	0.881
12	363	290	1.53 8.74	0.232
13	422	332	3.80 5.60	0.292
14	414 394	350 319 299	4.80 12.20	2.788

[a] Experimental error is less than 5%.

Two of the complexes were tested for phosphorescence at low temperature. Both complexes **1** and **5** were found to show phosphorescence at 77 K. They were excited at various wavelengths to obtain the same spectrum. The phosphorescence spectrum of **5** is shown in Fig. 6. The phosphorescence spectrum of **5** shows a band around 600 nm which is due to the emission from the lowest excited state, namely the LLCT state as reported earlier for a similar complex [40].

The fluorescence lifetime measurements were done in acetonitrile. The fluorescence lifetime shows a bi-exponential decay. The multiple lifetimes found for these complexes suggest the possibility of more than one emitting state for these complexes. Multiple state luminescence has been reported for a number of metal complexes [41]. Hence, it is concluded that there is a mixing of MLCT and IL excited states as proposed by Balzani and co-workers [42] for a different set of Pt(II) complexes.

4. Conclusion

This study shows that various mixed-ligand complexes of Pt(II) and Pd(II) can exhibit a LLCT band. The platinum complexes of this series were found to emit from a low-energy state at low temperature and a high-energy state at room temperature.

Appendix A. Supplementary data

A representative lifetime trace is available from the publishers. Supplementary data associated with this article can be found, in the online version at doi:10.1016/j.poly.2004.09.029.

1. Introduction

The biogeochemical cycle of Al is so dominated by abiotic events that less than 0.001% of cycled Al is found in biota at any one time [1]. The relative paucity of Al in biota is explained by neither its high abundance in the lithosphere, for example, calcium is present at half the abundance of Al whereas almost 35% of cycled calcium is present in biota, nor its lack of biological essentiality, for example, the non-essential metal cadmium is approximately seven times more abundant in biota than in the Earth's crust. It is, in fact, a consequence of the extremely efficient cycling of Al through increasingly insoluble, and biologically unavailable, mineral phases.

Hydroxyaluminosilicates (HAS) which are formed by the reaction of Al with $Si(OH)_4$ are probably the major secondary mineral phase controlling Al solubility in natural environments [2–6]. They have been studied for at least the last 50 years [7] and recent research has determined the structure and stoichiometry of two discrete forms, HAS_A which is formed in solutions in which $[Al] \geqslant [Si(OH)_4]$ and HAS_B which is only formed when $[Si(OH)_4] > [Al]$ [6]. These 'synthetic' HAS were shown to be structurally similar to the naturally occurring HAS, protoimogolite (HAS_A) and protoimogolite/allophane (HAS_B) [8]. Neither HAS_A nor HAS_B will form in solutions which are undersaturated with respect to $Al(OH)_{3(s)}$ [9] and this has prompted the suggestion that the mechanism of their formation includes the competitive condensation of $Si(OH)_4$ at an aluminium hydroxide template [10]. In nature HAS are most likely formed in the constrained environments of soil waters where concentrations of $Si(OH)_4$ could be as high as 1 mmol/L. In spite of the abundance of $Si(OH)_4$ in soil waters there have been only a few attempts to include the formation and dissolution of HAS in predictions of Al solubility control [2,5,11–15]. Many have chosen to ignore the contribution of HAS in Al solubility control and this may stem from a lack of reliable thermodynamic data to describe both their formation and solubilities. In the majority of soil waters the non-stoichiometric dissolution of aluminosilicate minerals [16] combined with the dissolution of other silicates will ensure that the concentration of $Si(OH)_4$ will be in excess of Al and, therefore, that the major HAS phase formed will be HAS_B. Herein, we have made the first attempt to derive a solubility expression for this phase and, in particular, we have highlighted both the assumptions which were required to enable its determination and the constraints which must be considered in its application in modelling Al solubility control in the natural environment.

2. Experimental

2.1. Preliminary investigations

A classic method to determine the solubility of an ionic solid would involve the addition of the solid to a known volume of solvent to form a saturated solution. We used this simple technique to investigate the dissolution of precipitates of HAS_A, HAS_B and $Al(OH)_{3(s)}$ each of which had been previously prepared and characterised structurally in our laboratory [6]. A known mass of each precipitate was suspended in a dialysis chamber (MWCO 1000 Da) which was immersed in a known volume of 0.1 mol/L KNO_3 (and 0.1% NaN_3 to prevent the growth of micro-organisms) adjusted to pH 6.5 and stored at 4 °C (Table 1). The dialysis chamber had a volume of 0.5 mL, was fully permeable to $Si(OH)_4$ and monomeric Al and was used to ensure that the original HAS material could not be present in the bulk volume. The dissolution of duplicate precipitates was followed over an 18 month period by measuring $[Si(OH)_4]$ and [Al] in the bulk volume. No attempt was made to control the pH of the bulk solutions during this time (Table 1). Neither of the HAS appeared to form a saturated solution during the 18 month period of dissolution. The concentration of $Si(OH)_4$ which was in quasi-equilibrium with HAS_B increased steadily from 5 months of ageing (19.4 and 21.2 μmol/L), through 8 (24.9 and 28.3 μmol/L) and 12 (41.0 and 45.5 μmol/L) to 18 (59.9 and 66.0 μmol/L) months. Al (0.15 and 0.34

Table 1
The concentrations of both $Si(OH)_4$ and total Al in the bulk solution following dissolution of duplicate precipitates of HAS_A, HAS_B and $Al(OH)_3$ after 18 months incubation in 0.1 mol/L KNO_3 at 4 °C

Solid phase	Si:Al of solid phase	Solid phase added (mg)	Solution volume (mL)	Final solution pH	$[Si(OH)_4]$ (μmol/L)	[Al] (μmol/L)
HAS_A (1)	0.36	30	100	6.33	21.1	0.65
HAS_A (2)	0.33	46	120	5.93	15.5	0.61
HAS_B (1)	1.03	30	100	6.34	59.9	0.15
HAS_B (2)	1.04	30	100	6.19	66.0	0.34
$Al(OH)_3$ (1)		45	120	6.07		1.12
$Al(OH)_3$ (2)		44	120	6.10		1.03

μmol/L) was only detected in bulk volumes after 18 months ageing. A similar trend for $[Si(OH)_4]$ in quasi-equilibrium with solid phase was also observed for HAS_A with $[Si(OH)_4]$ increasing from 5 months of ageing (7.9 and 11.2 μmol/L), through 8 (10.2 and 15.7 μmol/L) and 12 (14.2 and 14.4 μmol/L) to 18 (21.1 and 15.5 μmol/L) months. Al was detected in bulk volumes at 12 (0.15 and 0.58 μmol/L) and 18 (0.65 and 0.61 μmol/L) months. $Al(OH)_{3(s)}$ was also slow to dissolve and Al was only detected after 12 (0.54 and 0.33 μmol/L) and 18 (1.12 and 1.03 μmol/L) months of ageing.

These simple experiments showed that the dissolution of both HAS was non-stoichiometric in that $Si(OH)_4$ was released steadily over the 18 month period with almost no release of Al over the same period. It was interesting that the $[Si(OH)_4]$ in bulk volumes were proportional to the Si content of the original solid phases. The non-stoichiometric release of $Si(OH)_4$ for both HAS may have resulted in the formation of Al-enriched surfaces [16] which would then become the predominant determinants of Al solubility and hence explain the release of Al after 12–18 months. Of course, as the [Al] released approached saturation for $Al(OH)_{3(amorphous)}$ the formation of HAS_B would occur and this might then limit any further dissolution of Al. Alternatively, $Si(OH)_4$ might condense across hydroxy-aluminium groups at the surface of the dissolving precipitate and hence limit further the dissolution of both $Si(OH)_4$ and Al. Whilst the outcome of these experiments was ambiguous they did confirm that the dissolution of HAS, like other aluminosilicate phases [16], were non-stoichiometric and that an alternative experimental approach would be required to derive a quantitative solubility expression for $HAS_{B(s)}$.

The ability of HAS to limit the biological availability of Al (i.e., to control the concentration of monomeric and other rapidly equilibrating forms of Al, hereafter denoted as fast reacting Al or Al_r) will depend upon both their formation and, critically, their aggregation towards a kinetically stable solid phase. The attainment of this quasi-equilibrium between solid phase $HAS_{B(s)}$ and the solution phase could be followed by measuring the change in concentration of Al_r against time and the quasi-equilibrium $[Al_r]$ could then be used in combination with the appropriate formation/dissolution equation to derive a solubility expression. This approach was adopted for $HAS_{B(s)}$ and $Al(OH)_{3(s)}$ when prepared under identical experimental conditions.

2.2. The solubility expression

HAS_B will be the only HAS formed when $[Si(OH)_4]$ is significantly in excess (>2-fold) of [Al] and it will have an idealised stoichiometry of Si:Al of 1.0 [6]. HAS are formed via the competitive condensation of $Si(OH)_4$ at an aluminium hydroxide template [10] and so the dissolution of $HAS_{B(s)}$ might be described by the following idealised equation:

$$HAS_{B(s)} \leftrightarrow 2Al^{3+}_{(aq)} + 2Si(OH)_{4(aq)} + 6OH^- \quad (1)$$

This equation can be used to derive a solubility expression for HAS_B

$$K^*HAS_B = [Al^{3+}]^2[Si(OH)_4]^2[OH^-]^6 \quad (2)$$

K^*HAS_B is written in the form of a solubility product at thermodynamic equilibrium. However, the equation in this form is not directly applicable to the solubility of HAS_B as the solubility of this secondary mineral phase will not be defined by $[Al^{3+}]$ but by $[Al_r]$. It will be this fraction of Al which will be in quasi-equilibrium with $HAS_{B(s)}$ and this will be a precise estimate of how effectively the biological availability of Al is controlled by this solid phase. The determination of $K^*HAS_{B(s)}$ will require the measurement of solution pH, $[Si(OH)_4]$ and $[Al^{3+}]$ ($[Al_r]$). An experimental protocol was designed in which solution pH were determined by a non-invasive buffer, the $[Si(OH)_4]$ were in huge excess such that their concentrations were unaffected by the dissolution of $HAS_{B(s)}$ and $[Al^{3+}]$ ($[Al_r]$) could be estimated using the fluor, morin.

2.3. The measurement of $[Al^{3+}]$ as $[Al_r]$

There are no direct means whereby submicromolar concentrations of Al^{3+} can be measured. We need to obtain a best estimate (Al_r) using as non-invasive a method as is possible and we have used the formation and measurement of the fluorescent morin-Al complex (AlM) for this purpose [17]. We have previously shown that AlM is an excellent estimate of Al_r, the biologically available fraction of Al [18].

The experimental solutions were prepared in ultrapure water (0.067 μS/cm; Elga, High Wycombe, UK) and included a background electrolyte of 100 mmol/L KNO_3. The solutions were buffered at pH 6.5 ± 0.05 using PIPES and included a range of [Al] (0–6 μmol/L) and either 0, 100, 1000 or 2000 μmol/L $Si(OH)_4$. All solutions were prepared at room temperature (20 °C) and pressure using an established method [19]. $Si(OH)_4$ was prepared by cation exchange of a 2 mmol/L Na_4SiO_4 solution and was then substituted for ultrapure water to prepare solutions which contained 100, 1000 or 2000 μmol/L $Si(OH)_4$. Al was added from a certified standard solution (Perkin–Elmer, Beaconsfield, UK). Sodium azide was added to each solution at 0.05% w/v to prevent growth of microorganisms during storage. The solutions were stored in the dark for 12 weeks during which time their AlM fluorescence

was monitored every week using the following protocol. A new morin (2,3,4,5,7-pentahydroxyflavone) stock solution (125 μmol/L) was prepared as required and was added to a 5 mL aliquot of the solution in question to give a morin concentration of 12.5 μmol/L. The concentrations of morin in the stock and experimental solutions were carefully chosen to ensure that only 1:1 complexes of AlM were formed and that the fluorescence signal ($\lambda_{ex} = 420$ nm, $\lambda_{em} = 500$ nm) was optimal for the range of [Al] used [17]. Preliminary experiments showed that the formation of the fluorescent AlM complex plateaued 10–15 min after addition of morin and so the fluorescence intensity of AlM in each solution was measured after 15 min incubation with morin. The time-dependent formation of AlM was indicative of small changes in solution equilibria and further exemplified that what was being measured in the solutions was a fast reactive form of Al (Al_r) and not Al^{3+}. In all of the aged solutions, and particularly so in those which included 2000 μmol/L $Si(OH)_4$, the fluorescence intensity of AlM reached a plateau within the 12 week incubation period.

Following the determination of AlM fluorescence each sample was acidified to 1% concentrated HNO_3 (in the cuvette) and its total [Al] was measured by GFAAS using matrix-matched standards [20]. The procedure of acidifying the sample in the quartz cuvette directly after the measurement of its AlM fluorescence enabled each AlM fluorescence to be directly equated with an absolute (as opposed to nominal) total [Al] and circumvented a number of problems associated with sampling potentially inhomogeneous solutions.

The next step towards obtaining reliable estimates of [Al_r] in equilibrium with $HAS_{B(s)}$ (and $Al(OH)_{3(s)}$) was to convert the measured fluorescence intensities (AlM) into concentrations of morin-available Al (i.e., [Al^{3+}] in the solubility expression and [Al_r] in reality). This was achieved by preparing a calibration curve of AlM versus total [Al] such that the chosen [Al] were all undersaturated with respect to $Al(OH)_{3(amorphous)}$ at pH 6.5 [21]. The latter prerequisite was important in that AlM measured for each total [Al] would be a direct reflection of the proportion of the total morin-available Al or [Al_r]. It is this concept of proportionality which enabled the use of a calibration curve to estimate [Al_r] in each of the samples. Al standards of nominal concentrations 0.1, 0.2, 0.3, 0.4 and 0.5 μmol/L (absolute [Al] were determined by GFAAS following acidification in the cuvette) were prepared in triplicate at pH 6.5 and their corresponding AlM were measured. Linear regression analysis was then applied to AlM recorded for each combination of [Al] and [$Si(OH)_4$] to obtain best estimates of [Al_r] in equilibrium with $HAS_{B(s)}$ and $Al(OH)_{3(s)}$ (Table 2).

Table 2
Concentrations of Al_r (μmol/L) in quasi-equilibrium with solid phases ($Al(OH)_{3(s)}$ and $HAS_{B(s)}$) formed in the presence of 0, 100, 1000 and 2000 μmol/L $Si(OH)_4$ after equilibration for 12 weeks at pH 6.5 and 20 °C and the estimated solubility constants (K^*) for each of the solid phases

3. Results

After 12 weeks ageing at a solution pH of 6.5 and in the absence of added $Si(OH)_4$ [Al_r] in quasi-equilibrium with $Al(OH)_{3(s)}$ increased up to a plateau concentration (mean ± SD; 224.4 ± 27.15 nmol/L; $n = 7$) which was reached at between 2.0 and 4.0 μmol/L total Al (Fig. 1 and Table 2). The presence of 2000 μmol/L $Si(OH)_4$ completely abolished any dose-response to increasing total [Al] and the equilibrium [Al_r] reached a plateau (mean ± SD; 17.2 ± 1.57 nmol/L; $n = 17$) from the low-

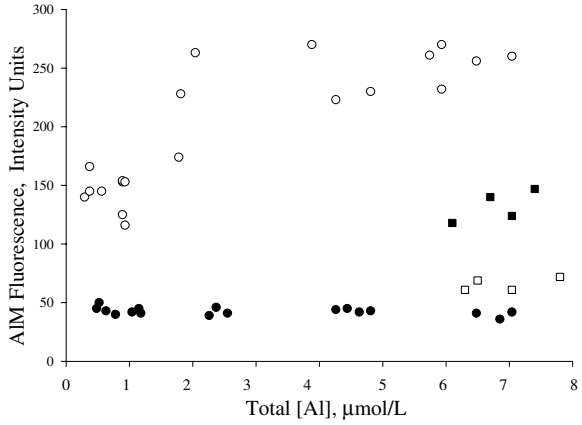

Fig. 1. Morin-available Al (AlM) in quasi-equilibrium with total Al at pH 6.5 in the presence of; 0 (open circles); 100 (closed squares); 1000 (open squares) and 2000 (closed circles) μmol/L $Si(OH)_4$ after 12 weeks ageing.

est measured total [Al]. Thus, relative to a system in which hydroxide was the major ligand for Al, the additional presence of $Si(OH)_4$ significantly reduced the concentration of [Al_r] at each of the [Al] tested (Fig. 1 and Table 2). A limited number of additional solutions in which the initial [Al] was ca. 6.0 μmol/L and [$Si(OH)_4$] were 100 and 1000 μmol/L resulted in quasi-equilibrium [Al_r] of 80.9 ± 12.25 ($n = 4$) and 30.2 ± 3.38 ($n = 4$) nmol/L, respectively, and showed that the quasi-equilibrium [Al_r] was dependent upon [$Si(OH)_4$].

The individual data for each of the solutions used to compute the mean equilibrium [Al_r] were then used to determine the solubilities (K^*) for $Al(OH)_{3(s)}$ (0 $Si(OH)_4$) and $HAS_{B(s)}$ (100, 1000 and 2000 μmol/L $Si(OH)_4$). When these data were substituted into the 'classical' solubility expression for $HAS_{B(s)}$ (i.e., Eq. (2)) the computed K^*s were extremely low (10^{-60}) and unrealistically so in comparison to K^* computed for $Al(OH)_{3(s)}$ (10^{-25}). Whilst the raw data confirmed that $HAS_{B(s)}$ was less soluble than $Al(OH)_{3(s)}$ the difference could not be by the orders of magnitude suggested by the computed K^*s. The value for $K^*HAS_{B(s)}$ was, in particular, heavily biased by the contribution of OH^- from the assumed dissolution of two moles of $Al(OH)_{3(s)}$ via the prior dissolution of only one mole of $HAS_{B(s)}$ (see Eq. (1)). It was clear from the fluorescence data that $HAS_{B(s)}$ was significantly more insoluble than $Al(OH)_{3(s)}$ since it reduced the quasi-equilibrium [Al_r] from ca. 224 to 17 nmol/L. The problem was in attributing a realistic K^* to the observed decrease in solubility. The solution may reside in not treating the solubility of $HAS_{B(s)}$ in the orthodox manner described in Eqs. (1) and (2) but to write a solubility expression which will take into account the incongruent dissolution of $HAS_{B(s)}$. In particular, that $HAS_{B(s)}$ initially dissolved to release only one solution species ($Si(OH)_4$) and that it would be the environmental concentration of this species, via the common ion effect, which would dictate $HAS_{B(s)}$ solubility at any one pH. Thus, a solubility expression was required which would include the contribution of [$Si(OH)_4$] and an estimate of [Al_r] at the experimental pH.

If $HAS_{B(s)}$ was treated as an hydroxide of an aluminosilicate the following hypothetical dissolution equation could be written:

$$Al_2Si_2O_5(OH)_4 \leftrightarrow Al_2O^{4+} + 2SiO_2 + 4OH^- \quad (3)$$

Whilst neither Al_2O^{4+} nor SiO_2 are true products of the dissolution of $HAS_{B(s)}$ these theoretical forms are convenient in that they can be substituted for [Al^{3+}] and [$Si(OH)_4$] in the 'classical' solubility expression without sacrificing electroneutrality and they better reflect the known non-stoichiometric dissolution of $HAS_{B(s)}$. The latter is further supported by the inclusion of only four moles of OH^- which again, will accurately reflect that the dissolution of $HAS_{B(s)}$ would not necessarily involve the further dissolution of two moles of $Al(OH)_{3(s)}$.

The solubility expression might now be written as

$$K^*Al_2Si_2O_5(OH)_4 = [Al_2O^{4+}][SiO_2]^2[OH^-]^4 \quad (4)$$

or, substituting in Al_r and $Si(OH)_4$

$$K^*HAS_B = [Al_r][Si(OH)_4]^2[OH^-]^4 \quad (5)$$

This solubility expression is neither balanced stoichiometrically nor electrically neutral, however, when this expression was applied to data for [Al_r] estimated in the presence of each of the [$Si(OH)_4$] at pH 6.5 (see Table 2) the computed solubility product for 2000 μmol/L $Si(OH)_4$ was $10^{-40.6 \pm 0.15}$ ($n = 17$) (20 °C/$I = 0.1$ mol/L) and those for 1000 and 100 μmol/L were not significantly different to this value (Table 2). The fact that the K^*s for each [$Si(OH)_4$] were not significantly different from each other does suggest that the unorthodox manner by which they were computed may have some validity. However, the validity of the method would be further supported if it also predicted a reliable estimate for the solubility of $Al(OH)_{3(s)}$. Applying the same criteria (i.e., $Al(OH)_{3(s)}$ is treated as the hydroxide of an hypothetical dimeric aluminium oxide) to data for [Al_r] in the absence of added $Si(OH)_4$ at pH 6.5

$$Al_2O(OH)_4 \leftrightarrow Al_2O^{4+} + 4OH^- \quad (6)$$

We get the solubility expression for $Al(OH)_{3(s)}$

$$K^*Al_2O(OH)_4 = [Al_2O^{4+}][OH^-]^4 \quad (7)$$

This gives a $K^* = 10^{-30.8 \pm 0.27}$ ($n = 7$) (20 °C/$I = 0.1$ mol/L) which considering it is for an aluminium hydroxide phase which has been aged for only 12 weeks is reassuringly similar to the literature value for $Al(OH)_{3(gibbsite)}$ of $10^{-33.9}$ [22].

4. Discussion

When the solubilities of Al at pH 6.5 in the presence and absence of a significant excess of $Si(OH)_4$ were compared it was found that the solid phase formed in the presence of $Si(OH)_4$ was significantly less soluble. Al solubility appeared to be related to [$Si(OH)_4$] such that solubility was reduced at higher concentrations of $Si(OH)_4$. The insoluble phase formed in the presence of $Si(OH)_4$ was an HAS which we have previously called HAS_B [6]. The task was to ascribe a credible solubility (K^*) to $HAS_{B(s)}$ based upon the experimental data. The difficulty was in writing a dissolution equation for $HAS_{B(s)}$ which would accurately reflect the non-stoichiometric dissolution of this secondary mineral and enable the formulation of a representative solubility expression. In particular, the solubility expression must have included a component which took strict account of the influence

of $[Si(OH)_4]$ on the measured Al solubility. The chosen solubility expression (see Eq. (4)) was based upon a dissolution equation which though it included hypothetical dissolution products (Al_2O^{4+}, SiO_2) was considered to be a good estimate of the stoichiometries (1:2:4) of the expected dissolution products (Al_r, $Si(OH)_4$, OH^-). In particular, the solubility expression emphasised the relative importance of $[Si(OH)_4]$ over $[Al_r]$ and the computed K^* for $HAS_{B(s)}$ of $10^{-40.6\pm0.15}$ ($n = 17$) was found to be independent of $[Si(OH)_4]$ (Table 2). Further validation of this unconventional approach towards the computation of the solubility of secondary mineral phases was offered by the value computed for $Al(OH)_{3(s)}$ of $10^{-30.8\pm0.27}$ ($n = 7$) which was in line with the literature value for $Al(OH)_{3(gibbsite)}$ of $10^{-33.9}$ [22]. For example, for a solution at pH 5.0, the solubility expression used herein to describe the dissolution of $Al(OH)_{3(s)}$ and the corresponding computed K^* predict a soluble [Al] of ca. 37.0 μmol/L as compared to the literature values of ca. 50.1 μmol/L and 1.6 μmol/L for $Al(OH)_{3(amorphous)}$ ($K_{Sol} = 10^{10.7}$) and $Al(OH)_{3(gibbsite)}$ ($K_{Sol} = 10^{9.2}$), respectively [21].

The concentration of Al which was in quasi-equilibrium with either $Al(OH)_{3(s)}$ or $HAS_{B(s)}$ was measured by its interaction with an excess of morin over a 15 min period of incubation. Denoted herein as $[Al_r]$ it was only an estimate of $[Al^{3+}]$ and so could not be used to derive a solubility product (K_{SP}) which, conventionally, would require that $[Al^{3+}]$ at thermodynamic equilibrium was known. The solubility expressions for $Al(OH)_{3(s)}$ and $HAS_{B(s)}$ determined using $[Al_r]$ are likely to over estimate their solubilities at thermodynamic equilibrium though they may still be useful in predicting solubility control by secondary mineral phases in the natural environment where thermodynamic equilibrium is rarely approached. For example, if K^*HAS_B was used to predict Al solubility control in the natural environment we would find a strict reliance upon the environmental $[Si(OH)_4]$. For example, in a soil solution at pH 4.0, a fall in $[Si(OH)_4]$ from 2000 through 1000 to 100 μmol/L would predict an increase in soluble [Al] from ca. 4.0 through 15.0 to 1500.0 μmol/L. The latter [Al] is approximately equivalent to that predicted by $Al(OH)_{3(gibbsite)}$ at the same pH and this is a good demonstration of how the environmental $[Si(OH)_4]$ may contribute towards the solubility of $HAS_{B(s)}$. At a soil pH of 5.0 the same reductions in $[Si(OH)_4]$ would result in the soluble [Al] increasing from ca. 0.4 through 1.5 to 150 nmol/L. The latter [Al] is ten times lower than that predicted by $Al(OH)_{3(gibbsite)}$ (ca. 1.6 μmol/L) and this is an excellent demonstration of how the influence of $[Si(OH)_4]$ can be reinforced at less acidic pH.

It should be possible to test the validity of our estimate of the solubility of $HAS_{B(s)}$ in the natural environment. If we consider that this phase will form in any environment in which $[Si(OH)_4] \gg [Al]$ then it should be the predominant secondary mineral phase for Al in all but the most acidified catchments, such as those impacted by acidic deposition. We are not aware from the literature of other reported solubility products for an HAS with a Si:Al ratio of 1.0 and so we have nothing to compare it with. There have been a number of attempts to ascribe an equilibrium constant to the solubility of imogolite-like phases [23] in which the Si:Al ratio is 0.5 (similar to HAS_A) and these have predicted a solubility somewhere between $Al(OH)_{3(amorphous)}$ and $Al(OH)_{3(gibbsite)}$. This type of HAS will only be formed in environments in which $[Si(OH)_4] \leqslant [Al]$ and so it will only be important in limiting the solubility of Al in, for example, environments undergoing a progressive acidification. We found that the dissolution of HAS_A was, like HAS_B, also incongruent (see Table 1) and that the solubility of Al was initially dependent upon the release of $Si(OH)_4$. For this reason it is probable that previous measurements based upon solubility equations expressing stoichiometric dissolution of $Si(OH)_4$ and Al will have under-estimated the insolubility of HAS_A, though this remains to be confirmed by experiment.

$K^*HAS_{B(s)}$ cannot be used to predict the formation of HAS in the natural environment. For example, at pH 4.0 it is not possible to make a saturated solution of HAS_B by adding Al to a 2000 μmol/L $Si(OH)_4$ solution such that the total [Al] > 4.0 μmol/L. The formation of both HAS_A and HAS_B will require as a prerequisite the formation of an $Al(OH)_3$ template and as such is dependent upon the prior formation of a saturated solution of $Al(OH)_3$. At pH 4.0 the latter will only form at [Al] greater than 1000 μmol/L and only then in the absence of competitive ligands such as organic acids [24] or inorganic anions such as fluoride and phosphate.

It is clear from our attempts to quantify the solubility of $HAS_{B(s)}$ that this is neither a trivial task nor one that is immediately accessible to conventional solubility expressions. Our unconventional approach in which we have tried to take account of the incongruent dissolution of HAS has used the concentration of a fast-reactive form of Al (Al_r) at a predefined quasi-equilbrium to determine a solubility expression for $HAS_{B(s)}$ which may prove to be useful in identifying Al solubility control (and hence, the biological availability of Al) in the natural environment. HAS are integral to the cycling and recycling of Al in the lithospheric cycle [1] and only where the environmental $[Si(OH)_4]$ is significantly depleted, such as will happen during catchment acidification [10], will this geochemical control of the biological availability of Al be lost to allow the accumulation of Al in biota.

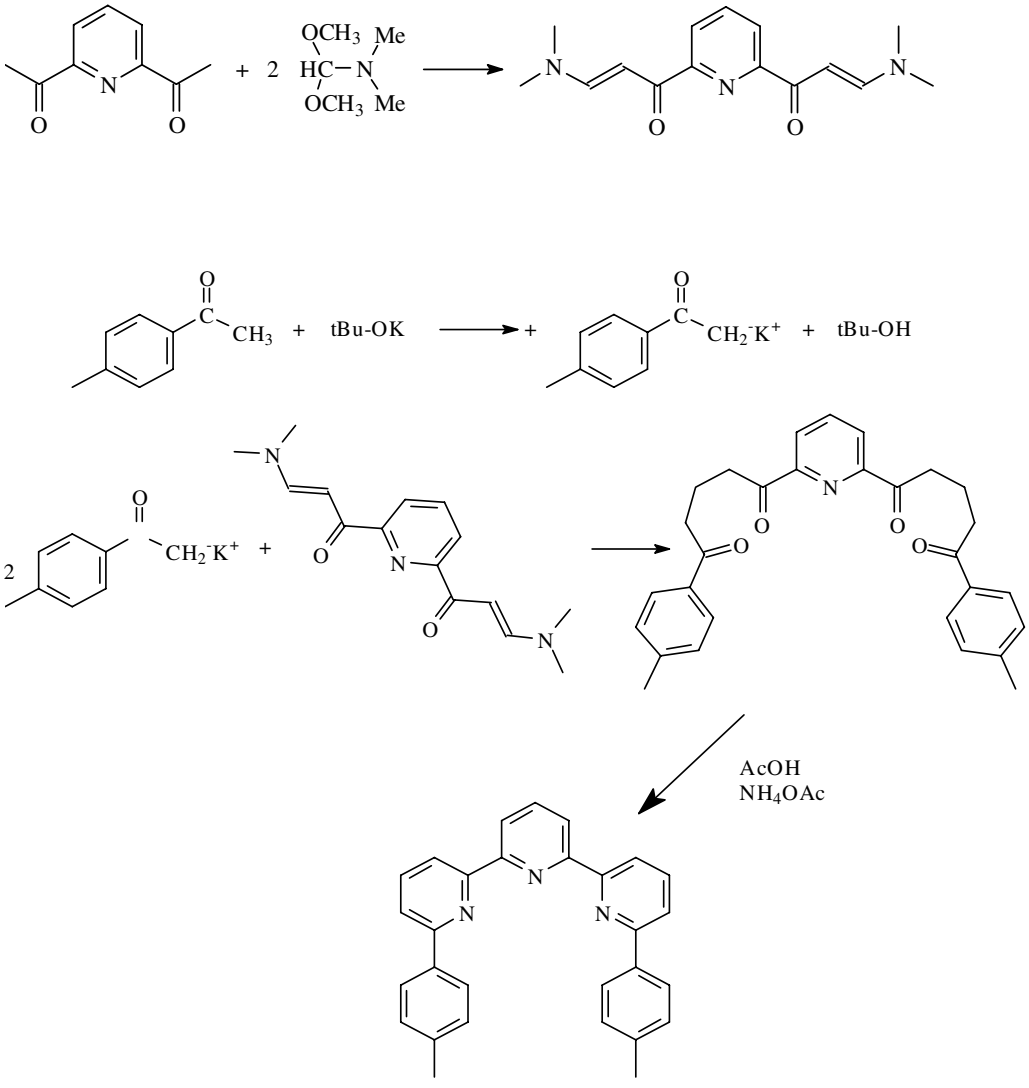
L^1 L^2

Scheme 1. Ligands examined in this study.

potassium salt of *p*-Me-acetophenone in THF, before addition of ammonium acetate and acetic acid, suitable work-up and recrystallisation from dichloromethane/hexane afforded the product as an off-white powder (Scheme 2).

Reaction of L^1 with $FeCl_2$ in THF at room temperature yielded an almost insoluble grey-purple powder whose elemental analysis and infrared spectrum ($\nu_{Fe-Cl} = 304\ cm^{-1}$) are consistent with the formulation L^1FeCl_2. Attempts to recrystallize this powder from warm THF under an inert atmosphere did lead to violet crystals with the same infrared spectrum than the starting material ($\nu_{Fe-Cl} = 304\ cm^{-1}$) formed just over the solution and an orange microcrystalline complex in the solution. The two different crystals were however unsuitable for X-ray analysis. The orange microcrystalline complex seems to result in fact from the conversion of the violet one, and its formation looks reversible. It gives rise to two ν_{Fe-Cl} absorptions at 326 and 307 cm^{-1}, as well as additional bands assignable to bound THF ($\nu_{C-O} = 1028\ cm^{-1}$), and corresponds probably to the THF adduct $L^1FeCl_2(THF)$. In an attempt to obtain better crystals for an X-ray investigation, we heated the orange microcrystalline complex in THF over a longer period of time and at higher temperatures. Thus bigger orange crystals were obtained with other products. The strong IR absorption at 378 cm^{-1}, character-



Scheme 2. Synthesis of L^1.

istic of the iron (III) anion $FeCl_4^-$ [5], indicated that we were in the presence of a third complex. An X-ray diffraction study allowed us to confirm this conclusion and to identify this complex as $(L^1)_2Fe^{2+}(FeCl_4^-)_2$. The highly distorted and compressed molecular structure of the iron (II) cation (Fig. 1) is close to that of the analogous complex containing ligands 6,6″-diphenyl-2,2′:6′,2″-terpyridine [6]. Most notably, the long iron–nitrogen bonds are indicative of a high-spin complex and the observation of two even longer distances of 2.422 Å between iron and the nitrogen atom of one of the two lateral pyridyl units of each terpyridine ligand suggests that these two ligands may be considered as only bidentate. Extensive intramolecular π-stacking of the phenyl and pyridyl rings is also remarkable [6]. The structure of the $FeCl_4^-$ anions is unexceptional [5]. The oxidizing agent at the origin of their formation could not be identified. In our case, partial oxidation by accidental air introduction could be favoured by the longer heating period. The presence of the paramagnetic $FeCl_4^-$ counter anion obviously only little modifies the ^1H NMR spectrum of the paramagnetic cationic complex, which remains close to that of the previously reported analogous species that had diamagnetic perchlorate counteranions [6].

Ligand 2,6-bis(3-Mes-*N*-pyrazolyl)pyridine (L^2) [7] was synthesized following the methods reported previously and coordinated to iron (II) chloride by the procedure described for L^1. This afforded a yellow precipitate. The iron-chlorine stretching vibration is found at 308 cm^{-1} for the yellow complex obtained, for which formula L^2FeCl_2 can hence be assigned with some confidence. Again, however, dissolution in MeCN (r.t.) or in THF (70 °C) leads to conversion of this neutral complex into its ionic form $(L^2)_2Fe^{2+}FeCl_4^{2-}$. No important colour change is observed in this case, but the IR absorption assigned to iron–chlorine stretching is shifted to 282 cm^{-1} (the approximate position of the $FeCl_4^{2-}$ anion [5]) for the yellow crystalline solid obtained from these solutions.

The precise nature of complex $(L^2)_2Fe^{2+}FeCl_4^{2-}$ was established by X-ray crystallography at room temperature because a lower temperature destroys the crystal. We could not find a greater symmetry for this crystal so we are in presence of the not centered Pn group not either chiral these explains the rather bad xflack value obtained. The unit cell contains two independent dications whose octahedral coordination geometry and overall structural parameters (Fig. 2) are similar to those of the corresponding cobalt (II) [8a], nickel (II) [8a] and copper (II) [8b] complexes and recently the iron analogue has been described with PF_6^- as the counter anion [8c]. In particular, the two mesityl rings of each ligand are π-stacked with the pyridine ring of the other ligand.

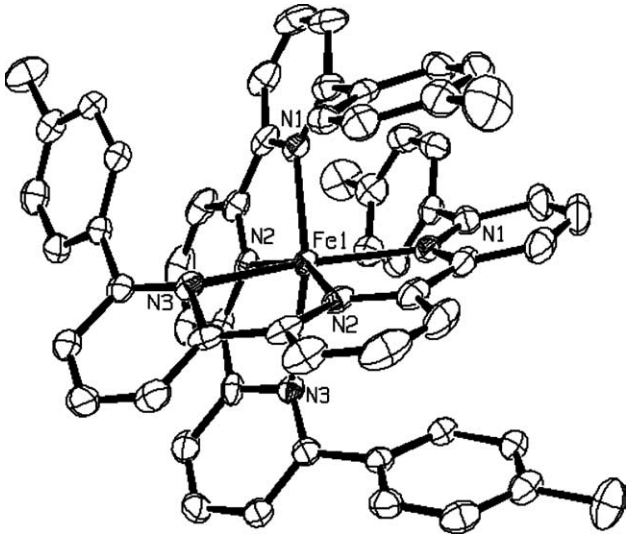


Fig. 1. Ortep view and numbering scheme of the C_2-symmetric cationic part of compound $(L^1)_2Fe^{2+}(FeCl_4^-)_2$ at 173 K (50% probability thermal ellipsoids). Hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and bond angles (°): Fe1–N1 = 2.227(3), Fe1–N2 = 2.100(3), Fe1–N3 = 2.422(3), N1–Fe1–N1 = 89.0(2), N1–Fe1–N2 = 75.1(1), N1–Fe1–N2 = 124.2(1), N1–Fe1–N3 = 147.3(1), N1–Fe1–N3 = 103.3(1), N2–Fe1–N2 = 155.3(2), N2–Fe1–N3 = 73.0(1), N2–Fe1–N3 = 88.4(1), N3–Fe1–N3 = 82.6(1).

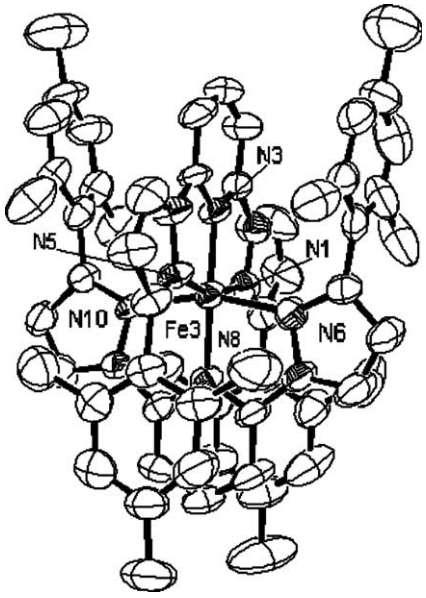

Fig. 2. Ortep view and numbering scheme of one of the two independent dications in the crystal of $(L^2)_2Fe^{2+}FeCl_4^{2-}$ at 293 K (50% probability thermal ellipsoids). Hydrogen atoms are omitted for clarity. Selected bond lengths (Å) and bond angles (°): Fe3–N1 = 1.987(8), Fe3–N3 = 1.874(7), Fe3–N5 = 1.999(8), Fe3–N6 = 2.015(6), Fe3–N8 = 1.883(7), Fe3–N10 = 1.962(6), N1–Fe3–N3 = 81.2(4), N1–Fe3–N5 = 161.7(3), N1–Fe3–N6 = 91.7(3), N1–Fe3–N8 = 98.0(3), N1–Fe3–N10 = 91.3(3), N3–Fe3–N5 = 80.6(4), N3–Fe3–N6 = 99.2(3), N3–Fe3–N8 = 178.7(3), N3–Fe3–N10 = 99.9(3), N5–Fe3–N6 = 90.0(3), N5–Fe3–N8 = 100.2(3), N5–Fe3–N10 = 93.0(3), N6–Fe3–N8 = 79.8(3), N6–Fe3–N10 = 160.9(3), N8–Fe3–N10 = 81.1(3).

Much shorter Fe–N bond distances than in $(L^1)_2Fe^{2+}$ (Fig. 1) indicate however that this complex is low-spin [9], while the cobalt complex is high-spin over a wide temperature range. Furthermore, the parent iron (II) complex containing two non-substituted ligands 2,6-bis(*N*-pyrazolyl)pyridine is low-spin only at low temperature and if the counteranion is BF_4^-, and becomes high-spin at room temperature [10]. The low-spin nature of complex $(L^2)_2Fe^{2+}$ is hence rather unexpected since incorporation of sterically demanding substituents adjacent to the ligand donor atoms, as well as higher temperatures, are known to favour high-spin states [5,11]. The paramagnetic counteranions $FeCl_4^{2-}$ play possibly an important role in this behaviour. By comparison with the crystal structure of the low-spin parent complex [10a], it can be concluded that the introduction of the mesityl substituents on the pyrazolyl rings only slightly lengthens the Fe–N_{pz} bonds (+0.011 Å average) and shortens the Fe–N_{py} bonds (−0.014 Å average).

Although of very similar geometry, the two independent dications show distinctive distortions that are visualized in Fig. 3. In the one already presented in Fig. 2, the two bispyrazolylpyridine ring systems are nearly planar, the three π-stacked aryl rings are almost perfectly eclipsed, and one ligand is coordinated much more asymmetrically than the other (Fe3–N6 = 2.015(6) Å, Fe3–N10 = 1.962(6) Å, Fig. 2). This latter difference is less pronounced in the second molecule, in which a slight deviation from planarity is indeed observed for both bispyrazolylpyridine ring systems. The individual aromatic rings remain planar, but the two pyrazolyl rings of a given ligand are twisted towards each side of the adjacent pyridine plane. The average dihedral angle between the pyrazolyl planes and the pyridine ones is 5.1°. This causes the corresponding mesityl substituents and the pyridine ring with which they are π-stacked to become significantly staggered (Fig. 3). Finally, the $FeCl_4^{2-}$ high-spin dianion [12] exists as well as two independent molecules that show ca. 0.11 Å longer Fe–Cl bond distances than the $FeCl_4^-$ anions of complex $(L^1)_2Fe^{2+}(FeCl_4^-)_2$. One of them is also more dissymmetric than the other.

Reacting ligand L^2 with iron (III) chloride (1 equiv) in MeCN is followed by partial reduction of the metal centers and formation of the same dicationic iron (II) complex in combination with the iron (III) counteranions $FeCl_4^-$. No neutral precursor could be detected, and a fraction (≈1/3) of the initial ligand L^2 remains uncomplexed in the reaction mixture. We obtained this result when the reaction was carried out at 70 °C and we verified that the same result is obtained when the reaction was done at room temperature. Brown-red crystals of the solvated complex $(L^1)_2Fe^{2+}(FeCl_4^-)_2(THF)_4$ were obtained when the crude product is dissolved in THF at room temperature, nice crystals were produced, and were analyzed by infrared spectroscopy (ν_{Fe-Cl} = 380 cm^{-1}) and X-ray crystallography.

All these complexes (mono or bis ligands) were tested for the polymerization of ethylene in the presence of methylaluminoxane. Although for the bis ligand complexes the results were in some way expected [13], none of them produced polymers.

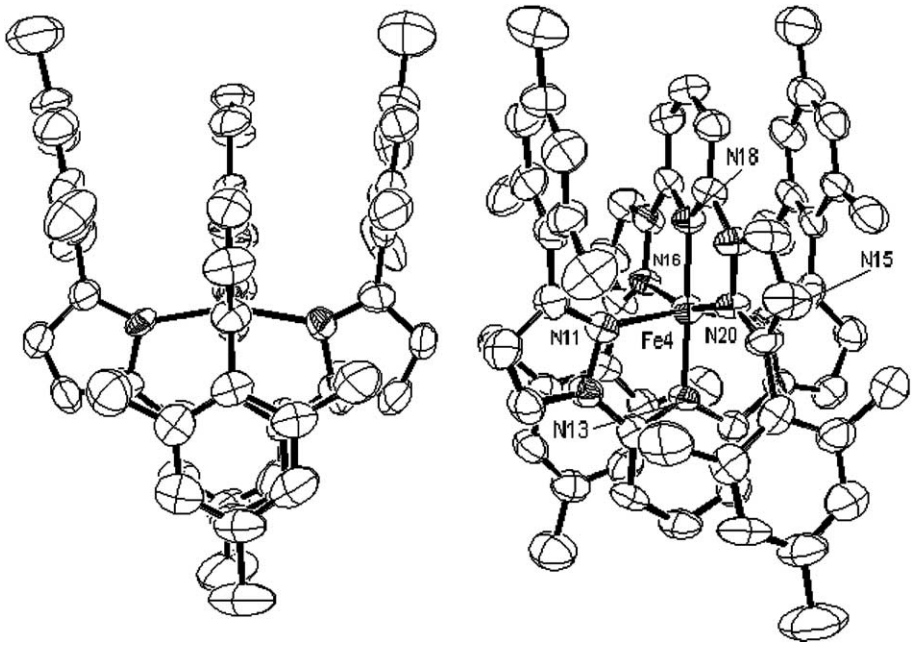

Fig. 3. Ortep view of the two independent dications in the crystal of $(L^2)_2Fe^{2+}FeCl_4^{2-}$ at 293 K (50% probability thermal ellipsoids). Hydrogen atoms are omitted for clarity. The left hand molecule is the one already shown in Fig. 2. Selected bond lengths (Å) for the right hand molecule: Fe4–N11 = 1.998(7), Fe4–N13 = 1.893(7), Fe4–N15 = 1.983(7), Fe4–N16 = 1.988(6), Fe4–N18 = 1.889(6), Fe4–N20 = 1.967(6).

3. Experimental

3.1. General

As the inorganic compounds described herein are air-sensitive, all experiments were performed in a glove box under controlled nitrogen atmosphere. THF, diethyl ether, pentane were dried over Na-benzophenone and acetonitrile over CaH_2 before distillation under nitrogen. Anhydrous $FeCl_2$ (Strem) and $FeCl_3$ were used as purchased. Ligand L^2 was synthesized according to procedures described previously in the literature [8]. ^1H NMR spectra were recorded on Bruker AC-200 or Avance-300 spectrometers at ambient temperature, chemical shifts are reported in parts per million versus $SiMe_4$ and were determined by reference to the residual solvent peaks. The infrared spectra were recorded on a Perkin–Elmer 1650 FT instrument. Mass spectrum was performed by the Service de Spectrométrie de Masse de l'Institut Le Bel (Strasbourg) and elemental analysis by the Service de Microanalyse de l'Institut Charles Sadron (Strasbourg).

3.2. Synthesis

3.2.1. Synthesis of ligand L^1

tert-BuOK (2 g, 17.8 mmol) and *p*-methylacetophenone (1 g, 7.4 mmol) were dissolved in 40 mL of THF at room temperature. After 2 h, 2,6-bis(3-chlorodimethylaminium-1-oxopropyl)pyridine (1 g, 3.7 mmol) was added. After 8 h, 10 g of ammonium acetate, and 14 mL of acetic acid were added to the red solution to yield a yellow solution. The solution was refluxed for 24 h. The solvent was evaporated under vacuum and the acid was neutralized by addition of an aqueous saturated solution of sodium hydrogenocarbonate. The product was extracted with dichloromethane (three times 100 mL) and filtered over a neutral alumina column. After evaporation of the solvent, the solid residue was recrystallized from CH_2Cl_2/hexane to afford a greyish powder. Yield 600 mg (40%). ^1H NMR ($CDCl_3$, 300 MHz): δ 8.70 (2H, d, J 8 Hz, H^3), 8.59 (2H, d, J 8 Hz, $H^{3'}$), 8.09 (4H, d, J 8 Hz, H^0), 8.01 (1H, t, J 8 Hz, H^4), 7.92 (2H, t, J 8 Hz, $H^{4'}$), 7.78 (2H, d, J 8 Hz, $H^{5'}$), 7.33 (4H, d, J 8 Hz, H^m) 2.44 (6H, s, Me). IR (CsI, Nujol) ν (cm^{-1}): 1567.5, 1461.8, 1377.0, 794.7. MS (FAB) m/z: 414.2.

3.2.2. Synthesis of $FeCl_2[L^1]$

$FeCl_2$ (32 mg, 0.25 mmol) and one equivalent of L^1 (103 mg, 0.25 mmol) were maintained under magnetic stirring in 12 mL of THF at room temperature for 24 h. The dark suspension was then isolated and washed with 2 mL of THF affording 107 mg (80%, yield) of a dark powder. IR ν_{Fe-Cl}: 304 cm^{-1}. *Anal.* Calc. for $C_{29}N_3H_{23}FeCl_2$: C, 64.47; H, 4.29; N, 7.78. Found: C, 64.44; H, 4.31; N, 7.65%.

3.2.3. Synthesis of $FeCl_2[L^1][THF]$

$FeCl_2$ [L^1] (50 mg, $9.25.10^{-2}$ mmol) of a dark powder very sparingly soluble with 10 mL of THF were heated at 90 °C in an oil bath in a 50 mL closed screw cap bottle and PTFE-faced rubber liner. Two kinds of crystals were produced by this way, none of them were suitable for an X-ray study. Ones were very small orange crystals attributed to $FeCl_2[L^1][THF]$, with ν_{Fe-Cl}: 307 and 326 cm^{-1} and ν_{C-O}(THF): 1028 cm^{-1}. The other ones were violet crystals produced at the interface of the liquid and were identical to the starting product.

3.2.4. Synthesis of $Fe[L^1]_2^{2+}[FeCl_4]_2^-$

In order to obtain crystals suitable for an X-ray investigation, five tightly closed flasks containing each 10 mg of the complex $FeCl_2[L^1][THF]$ with 2 mL of THF were heated at 120 °C over a long period of time (several days). At this temperature, only a little part of the complex was in solution which was only very slightly colored. By this way, big enough orange crystals were obtained that revealed to be $Fe[L^1]_2{}^{2+}[FeCl_4]_2{}^-$ of the same color than the starting complex that was still present in some amount (confirmed by infrared), as well as other compounds that could not be characterized.

^1H NMR (CDCl3, 300 MHz): δ: 77.45 (2H, s, H^3/H^5), 67.62 (2H, s, $H^{3\prime}$), 58.19 (2H, s, H^3/H^5), 14.42 (2H, s, H^4), 1.87 (6H, s, Me), 0.78 (8H, large, Ar_{tol}), −19.21 (1H, s, $H^{4'}$). IR (CsI, Nujol) ν_{Fe-Cl}: 378 cm^{-1}. ES+MS in $CHCl_3$: gives the isotopic pattern with the corresponding intensities for the dicationic fragment in good agreement with the simulation: $[FeN_6C_{58}H_{46}]^{2+}$: m/z: 440.15, 440.65, 441.15, 441.65, 442.15, and 442.65.

3.2.5. Synthesis of $FeCl_2[L^2]$

$FeCl_2$ (32 mg, 0.25 mmol) and one equivalent of L^2 (112 mg, 0.25 mmol) were maintained under magnetic stirring in 12 mL of THF at room temperature for 12 h. The amorphous yellow complex in suspension were then isolated and washed with 2 mL of THF affording 125 mg (87%, yield) of a yellow powder. IR ν_{Fe-Cl}: 308 cm^{-1}.

3.2.6. Synthesis of $Fe[L^2]_2^{2+}[FeCl_4]_2^-$

About 100 mg of the yellow powder $FeCl_2[L^2]$ was heated up in 10 mL of THF at 80 °C for 4 h.The solution is only slightly colored and an almost quantitative amount of orange crystals are formed. IR ν_{Fe-Cl}: 282 cm^{-1}.

3.2.7. Synthesis of $Fe[L^2]_2^{2+}[FeCl_4]_2^- \cdot 4THF$

$FeCl_3$ (40 mg, 0.25 mmol) was poured into 20 mL of acetonitrile, then one equivalent of L^2 (112 mg, 0.25 mmol) was added and the mixture was maintained under magnetic stirring for 2 h. Some product remained insoluble. Heating at 80 °C completed the dissolution. After cooling, a product crystallized, the IR revealed the unreacted ligand L^2. After separation of excess L^2 and evaporation of the solvent under vacuum a yellow

brown compound was obtained. The IR revealed ν_{Fe-Cl}: 386 cm^{-1}. The crude product was then dissolved in a minimum of THF (2 mL) and after a while nice brown crystals were formed. The IR revealed the same ν_{Fe-Cl}: 386 cm^{-1} and supplementary bands at 1052 and 897 cm^{-1} attributed to THF. The crystals are suitable for an X-ray analysis. ES + MS in $CHCl_3$: gives the isotopic pattern with the corresponding intensities for the dicationic fragment in good agreement with the simulation: $[FeN_{10}C_{58}H_{58}]^{2+}$: *m*/*z*: 474.21, 474.71, 475.21, 457.71, 476.21, and 476.71.

3.3. X-ray crystallography

Data were collected on a Nonius Kappa CCD diffractometer (graphite Mo Kα radiation, 0.71073 Å). The structure was solved using the Nonius OpenMoleN package and refined by full matrix least-squares with anisotropic thermal parameters for all non-hydrogen atoms. Data collection parameters, solution and refinements results are given in Table 1.

4. Supplementary material

Crystallographic data for structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 203433, 203434, 203435 for $(C_{58}H_{58}Cl_4Fe_2N_{10})$ $\{(L^2)_2Fe^{2+}FeCl_4^{2-}\}$, $(C_{58}H_{46}Cl_8Fe_3N_6)$ $\{(L^1)_2Fe^{2+}(FeCl_4^-)_2\}$ and $(C_{74}H_{90}Cl_8Fe_3N_{10}O_4)$ $\{(L^2)_2Fe^{2+}(FeCl_4^-)_2(THF)_4\}$, respectively. These data can be obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif, by emailing data_request@ccdc.cam.ac.uk, or by contacting The Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033.

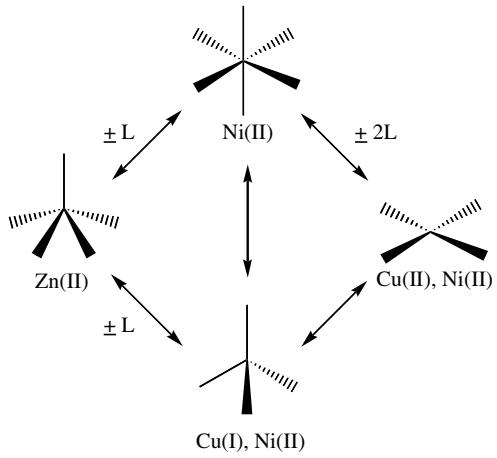

Fig. 1. The geometries available to tetradentate Schiff's base ligands coordinated to the late transition metals, nickel, copper and zinc. Td: tetrahedral; Oh: Octahedral; Sbp: square based pyramid and Sp: square planar.

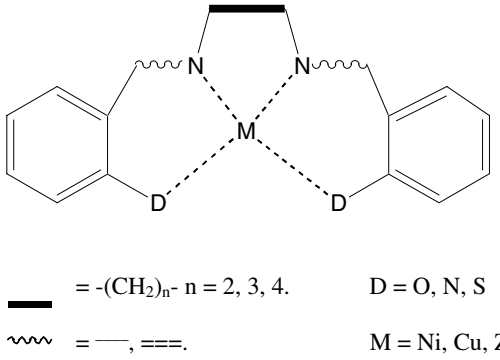

Fig. 2. Design of the simple unsubstituted parent complexes. Conformational flexibility is induced by the systematic expansion of the polymethylene chain between the two internal nitrogen donors (—), and the hydrogenation of the imine bond (〰).

copper and zinc complexes using the salen family of ligands have been carried out previously [9–17].

Square planar nickel complexes of salen and *N*,*N*′-bis-(salicylidene)-1,3-diaminopropane (salpr) have been structurally characterised [18,19]. A red diamagnetic complex of *N*,*N*′-bis-(salicylidene)-1,4-diaminobutane (salbut) has been reported [20] as has a four coordinate green paramagnetic form [21]. The appearance of two isomers of Nisalbut demonstrates that with a longer methylene backbone the structures can shift from the planar towards a more tetrahedral motif. Furthermore, in the presence of additional donors (MeOH, DMF, DMSO) salpr and salbut would seem to support the formation of trimetallic species such as bis-((μ^2-acetato)-(*N*,*N*′-bis-(*o*-salicylidene)-1,3-diaminopropane)(methanol) nickel)nickel ({[Ni(Salpr)(HOCH$_3$)]$_2$(μOAc)$_2$Ni}) and bis-((μ^2-acetato)-(*N*,*N*′-bis-(*o*-salicylidene)-1,4-diaminobutane)(dimethylformamido)nickel)-nickel ({[Ni(Salbut)(DMF)]$_2$(μOAc)$_2$Ni}) where the nickel atoms adopt an octahedral geometry [17,21]. In contrast to salpr, salbut is considerably more flexible thus allowing the additional two donors in the octahedral motif (Fig. 1) to adopt both *cis* and *trans* configurations [17].

The effect of the flexibility of the larger methylene chains on geometry is also observed in the series of copper(II)N_2O_2 Schiff's base complexes where a shift from square planar to a tetrahedrally distorted geometry is observed [12,13]. A similar effect is observed for an analogous series of Cu(I)N_2S_2 species where a shift from distorted square planar to tetrahedral geometry is seen [22]. However, although it has been shown that increasing the backbone length can lead to a wide variety of geometries, work on the related unsubstituted N_2S_2 and N_4 donor ligands remains incomplete. As part of our on-going interest in geometric flexibility we wished to establish a structural basis for these beginning here with a study on nickel.

Several Ni(II) complexes with N_2D_2 donor sets (D = N, S) and backbones with two to four methylene units have been structurally characterised and the structures of many others have also been proposed based on spectroscopic and magnetic data [8,18,19,23–25]. Of the three previously prepared [8] tetradentate N_4 complexes (Fig. 2) desired for this study, (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,2-diaminoethane)nickel (Niamben), (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,3-diaminopropane)nickel (Niambpr) and (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,4-diaminobutane)nickel (Niambut), only the structure of Niamben has been reported [23]. Although visible, NMR and electronic absorption spectroscopy and magnetic susceptibility studies suggest the Niambpr and Niambut complexes also have the planar monomeric structure, a more detailed understanding of their structural parameters remains important to us.

Nickel (N_2S_2) complexes have been of interest recently since nickel centres with sulfur coordination environments have been found to be central to the activity of a wide range of important enzymes [26]. Since the heterobimetallic nature of the active site of these systems was revealed [27], modelling has centred on the design and synthesis of bimetallic complexes. This has left the structural characterisation of four coordinate Ni(II) N_2S_2 complexes incomplete, which in turn suggests that our interpretation of more sophisticated systems may be less than comprehensive.

A second related class of complexes are the hydrogenated Schiff's bases. The effects of hydrogenation on flexibility and therefore the wider range of geometries available to the metal complexes have not been thoroughly investigated and as yet no simple unsubstituted complexes have been structurally characterised. As such we have structurally characterised the corresponding nickel complexes of two hydrogenated ligands namely *N*,*N*′-bis-(*o*-aminobenzyl)-1,2-diaminoethane (H_4amben) and *N*,*N*′-bis-(*o*-aminobenzyl)-1,3-diaminopropane (H_4ambpr).

2. Experimental

All chemicals were commercially obtained and used without further purification. *o*-Amino-benzaldehyde was prepared by published methods [28]. All NMR spectra were recorded on a Bruker DPX400 instrument operating at 400.1 MHz for ^{1}H and 100 MHz for ^{13}C. The spectra were referenced to internal solvent peaks and thus to TMS. Mass spectrometry was carried out on a ThermoFinnigan LCQ mass spectrometer with ESI ionisation, spray voltage 4.5 kV, capillary temperature 200 ° C. Samples were dissolved in MeOH/H_2O 0.1% formic acid.

Crystals were coated in mineral oil and mounted on glass fibres. Data were collected at 123 K on a Nonius Kappa CCD diffractometer using graphite monochromated Mo Kα radiation. The heavy atom positions were determined by Patterson methods and the remaining atoms located in difference electron density maps. Full matrix least-squares refinement was based on F_2, with all non-hydrogen atoms anisotropic. While hydrogen atoms were mostly observed in the difference maps, they were placed in calculated positions riding on the parent atoms except those involved in hydrogen bonding which were refined isotropically. The structure solution and refinement used the programs SHELX-97 [29] and SIR-92 [30] and the graphical interface WinGX [31]. A summary of the crystallographic parameters is given in Table 1. Selected metrical parameters are reported in Table 2.

2.1. Preparation of N,N′-bis-(o-aminobenzilidene)-1,3-diaminopropane (ambpr) and N,N′-bis-(o-aminobenzilidene)-1,4-diaminobutane (ambut)

Ambpr and ambut were prepared according to reported methods [8,28]. Briefly: *o*-nitrobenzaldehyde (0.04 moles), ferrous sulphate (0.38 moles) and conc. HCl (0.5 ml) were suspended in water (175 ml) and heated to 90 °C. Concentrated ammonia solution (25 ml) was added followed by three further 10 ml portions of concentrated ammonia solution at 1-min intervals, and the product retrieved by steam distillation as a creamy yellow suspension. Precipitation was completed by the addition of saturated aqueous NaCl at 0 °C. The *o*-aminobenzaldehyde was collected by filtration, washed with water and dried. The product is prone to self-condensation and is best used immediately.

The Schiff's base compounds ambpr and ambut were prepared by refluxing *o*-aminobenzaldehyde (20 mmol) with the appropriate amine (10 mmol) in ethanol (100 ml) for 1 h. The solution was cooled and the volume reduced yielding a white powder, which was recrystallised from ethanol. Yields typically better than 40% (based on *o*-nitrobenzaldehyde) were obtained for both species.

Ambpr. *Anal*. Calc. for $C_{17}H_{20}N_4$: C, 72.82; H, 7.20; N, 19.98. Found: C, 72.66; H, 7.30; N, 19.74%. δ_H ($CDCl_3$) 8.37 (s, 2H, –CH=), 7.12 (dt, 4H, arom), 6.66 (m, 4H, arom), 6.38 (br s, 4H, NH_2), 3.69 (t, 4H, –NCH_2–), 2.09 (p, 2H, –CH_2–). δ_C ($CDCl_3$) 165, 149, 134, 131, 118, 116 (arom), 115 (C=N), 60 (∼N–CH_2–), 33 (–CH_2–); m.p. 111–112 °C.

Ambut. *Anal*. Calc. for $C_{18}H_{22}N_4$: C, 73.43; H, 7.53; N, 19.03. Found: C, 73.23; H, 7.61; N, 18.80%. δ_H ($CDCl_3$) 8.34 (s, 2H, –CH=), 7.14 (dt, 4H, arom), 6.66 (dt, 4H, arom), 6.36 (br s, 4H, NH_2), 3.61 (t, 4H, –NCH_2–), 1.78 (p, 4H, –CH_2–). δ_C ($CDCl_3$) 164, 149, 134, 131, 118, 116 (arom), 115 (–C=N), 62 (–NCH_2–), 29 (–CH_2–); m.p. 136–138 °C.

2.2. Preparation of (N,N′-bis-(o-amidobenzilidene)-1,3-diaminopropane)nickel(II) (Niambpr) and (N,N′-bis-(o-amidobenzilidene)-1,4-diaminobutane)nickel(II) (Niambut)

Nickel acetate (0.09 g, 0.36 mmol) was added to a refluxing solution of the desired ligand (0.36 mmol) in methanol (20 ml) resulting in a green solution. On addition of NaOH (0.04 g, 1 mmol) the solution turned brown. The solution was refluxed for 90 mins., hot filtered and allowed to cool overnight. A dark red powder and dark red/brown prisms formed, the latter being used for crystallographic analysis. The powders were recrystallised by slow diffusion of hexane into a THF solution of the product.

Ni(II)ambpr. *Anal*. Calc. for $C_{17}H_{18}N_4Ni$: C, 60.57; H, 5.38; N, 16.62. Found: C, 60.02; H, 5.46; N, 16.32%. δ_H ($CDCl_3$) 7.54 (s, 2H, –CH=), 7.16 (d, 4H, arom), 6.57 (s, 2H, arom), 6.26 (s, 2H, arom), 3.64 (s, 4H, –NCH_2–), 1.98 (s, 2H, –CH_2–).

Ni(II)ambut. *Anal*. Calc. for $C_{18}H_{20}N_4Ni$: C, 61.57; H, 5.74; N, 15.96. Found: C, 60.51; H, 5.66; N, 15.51%. δ_H ($CDCl_3$) 7.74 (s, 2H, –CH=), 7.01 (d, 4H, arom), 6.70 (s, 2H, arom), 6.27 (s, 2H, arom), 3.72 (s, 4H, –NCH_2–), 1.88 (s, 4H, –CH_2–).

2.3. Preparation of N,N′-bis(o-aminobenzyl)-1,2-diaminoethane (H_4amben) and N,N′-bis(o-aminobenzyl)-1,3-diaminopropane (H_4ambpr)

Hydrogenation of the imine bonds was carried out by slight modification of Fournea's method [32]. $NaBH_4$ (0.45 g, 12 mmol) was added in small portions to a stirred mixture of the desired ligand (3 mmol) in methanol (50 ml) under an N_2 atmosphere. The solution was stirred at room temperature for 65 h after which time the solvent was carefully removed under reduced pressure to yield an off white solid. The solid was resuspended in water (50 ml), made alkaline by the addition of a pellet of sodium hydroxide and extracted into chloroform (3×50 ml). The chloroform extracts were combined,

2.4. Preparation of {bis-O-acetato-(N,N′-bis-(o-aminobenzyl)-1,2- diaminoethane)}nickel(II) [Ni(H_4amben)($OAc)_2$] and {bis-O-acetato- (N,N′-bis-(o-aminobenzyl)-1,3-diaminopropane)}nickel(II) [Ni(H_4ambpr)($OAc)_2$]

Nickel acetate (0.125 g, 0.5 mmol) and the desired ligand (0.5 mmol) were refluxed gently for 1 h in methanol (25 ml) giving brown solutions. The solvent was removed under reduced pressure yielding a purple/brown powder [Ni(H_4amben)($OAc)_2$] and in the case of [Ni(H_4ambpr)($OAc)_2$] a red/brown oil.

Diethyl-ether (5 ml) was added to the oil [Ni(H_4ambpr)($OAc)_2$] and the solution sonicated for 5 min precipitating a pale brown powder which was collected by filtration. Crystals suitable for crystallographic analysis were grown by vapour diffusion, using chloroform/diethyl-ether to produce blue crystals of [Ni(H_4ambpr)($OAc)_2$], and methanol/diethyl-ether to produce pink crystals of [Ni(H_4amben)($OAc)_2$].

[Ni(H_4amben)($OAc)_2\cdot H_2O$]. *Anal*. Calc. for $C_{20}H_{30}N_4NiO_5$: C,51.64; H, 6.50; N, 11.94. Found: C, 51.33; H, 6.68; N, 12.04%.

2.5. Preparation of {bis-acetonitrile-(N,N′-bis-(o-aminobenzyl)-1,2- diaminoethane)nickel(II)} tetrafluoroborate [Ni(H_4amben)($NCMe)_2$][$BF_4]_2$

$Ni(BF_4)_2\cdot 6H_2O$ (0.20 g, 0.5 mmol) and H_4amben (0.135 g, 0.5 mmol) were refluxed in methanol (25 ml) for 1 h giving a brown solution. The solution was hot filtered and the solvent removed to leave a red/brown oil. The oil was resuspended in a small volume of acetonitrile (5 ml) and the mixture filtered through celite. Purple/pink crystals suitable for X-ray analysis were obtained by slow diffusion of the acetonitrile solution with diethyl-ether (Yield 80%).

[Ni(H_4amben)($NCMe)_2$][$BF_4]_2$. *Anal*. Calc. for $C_{20}H_{28}B_2F_8N_6Ni$: C, 41.07; H, 4.82; N, 14.37. Found: C, 41.06; H, 4.86; N, 14.26%.

2.6. Preparation of (N,N′-bis-(o-thiobenzylidine)1,4-diaminobutane)nickel(II) (Nitsalbut)

Nitsalbut was prepared through modification of Eichorn's synthesis of Nitsalen [33], i.e., the reaction of 2,2'-dithiobenzaldehyde (DTDB) and 1,4-butanediaminenickel(II)dichloride.

DTDB was prepared by the method of Kasmai and Mischke [34]. Briefly: $LiAlH_4$ (2.12 g, 55.1 mmol) was dissolved in dry THF (50 ml), to which a solution of thiosalicylic acid (3.4 g, 22.0 mmol) in dry THF (80 ml) was added dropwise with cooling. The reaction was stirred under nitrogen for 24 h. Ethylacetate (10 ml) was added, followed by the dropwise addition (care!) of a 10% aqueous solution of H_2SO_4 (100 ml). The mixture was filtered, the organic layer separated and dried over anhydrous sodium sulphate. The solvent was removed under reduced pressure to yield 2-(hydroxymethyl)benzenethiol as a pale yellow oil (Yield 93.8%). The 2-(hydroxymethyl)benzenethiol was dissolved in dry toluene (220 ml) under nitrogen. Excess MnO_2 was added and the reaction stirred at room temperature for 24 h. The solution was filtered and the MnO_2 washed with toluene. The solvent was evaporated to yield a pale yellow powder (Yield 30%).

(1,4-Butanediamine)nickel(II) dichloride was prepared using the method of State for the preparation of tris(ethylenediamine)nickel(II) chloride [35]. Briefly: a 70% aqueous solution of 1,4-diaminobutane (3.2 ml, 31.8 mmol) was added to a solution of $NiCl_2\cdot 6H_2O$ (1.59 g, 6.7 mmol) in H_2O (15 ml). A pale green precipitate formed on the addition of the diamine. The solution was heated to 110 °C and 2 drops of 1,4-diaminobutane added. The solvent was allowed to evaporate and the product recrystallised from ethanol (Yield 35%).

(1,4-Butanediamine)nickel(II) dichloride (47.2 mg, 0.22 mmol) was dissolved in ethanol (5–10 ml) and brought to reflux. A solution of DTDB (0.20 g, 0.73 mmol) in the minimum volume of dichloromethane was added to the solution whereupon it turned brown. The reaction was refluxed for 1 h, allowed to cool and the solvent removed under reduced pressure. The brown solid was resuspended in chloroform and filtered through a silica gel filter stick (3 cm × 0.5 cm) using further aliquots of chloroform. The bulk of the chloroform was removed and the product crystallised by vapour diffusion with diethyl ether (Yield 85 % based on DTDB). Crystals suitable for X-ray analysis were obtained by slow diffusion of cyclohexane into a dioxane solution of the product obtained above.

Anal. Calc. for $C_{18}H_{18}N_2NiS_2\cdot(C_4H_8O_2)_{0.5}$: C, 55.96; H, 5.17; N, 6.52. Found C, 55.15; H, 4.43; N, 6.61%. δ_H ($CDCl_3$) 7.87 (s, 2H, –CH=), 7.70 (d, 2H, arom), 7.21 (d, 2H, arom), 7.15 (t, 2H, arom), 7.01 (t, 2H, arom), 3.88 (t, 4H, d $–NCH_2–$), 1.97 (p, 4H, $–CCH_2–$).

3. Results and discussion

Previous studies on copper(II) *N*,*N*′-bis-(salicylidene)-diamine [13,14,19] complexes have demonstrated how increasing the number of methylene units between the imines allows the complex to move from a planar towards a distorted tetrahedral motif. For transition metals capable of adopting higher coordination numbers, such as nickel, the ability of the larger ring sizes generated by *N*,*N*′-bis-(salicylidene)-1,3-diaminopropane (salpr) and *N*,*N*′-bis-(salicylidene)-1,4-diaminobutane (salbut) complexes would seem to support the formation of a wider range of geometries [17]. In the belief that similar trends may be observed with different donor sets (Fig. 2, D = N, S) we have prepared and structurally characterised the three complexes (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,3-diaminopropane)nickel (Niambpr), (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,4-diaminobutane)nickel (Niambut) and (*N*,*N*′-bis-(*o*-thiobenzilidine)-1,4-diaminobutane)nickel(II) (Nitsalbut), thus completing the series of nickel complexes with 1,2-ethane, 1,3-propane and 1,4-butane backbones with N_2N_2 and N_2S_2 donor sets. The three new structures are shown in Fig. 3, the key bond lengths and angles for the complete series of six complexes being given in Table 2. Consistent with the reported structure of Niamben [23] and the spectroscopic data of Niambpr and Niambut [8,24] the amines deprotonate on chelation and the structures obtained for N_2N_2 are amides.

The *trans* N–Ni–D angles (Table 2) obtained from the six related complexes indicate that they all adopt a square planar geometry. As might be expected the complexes derived from 1,4-diaminobutane show the great-

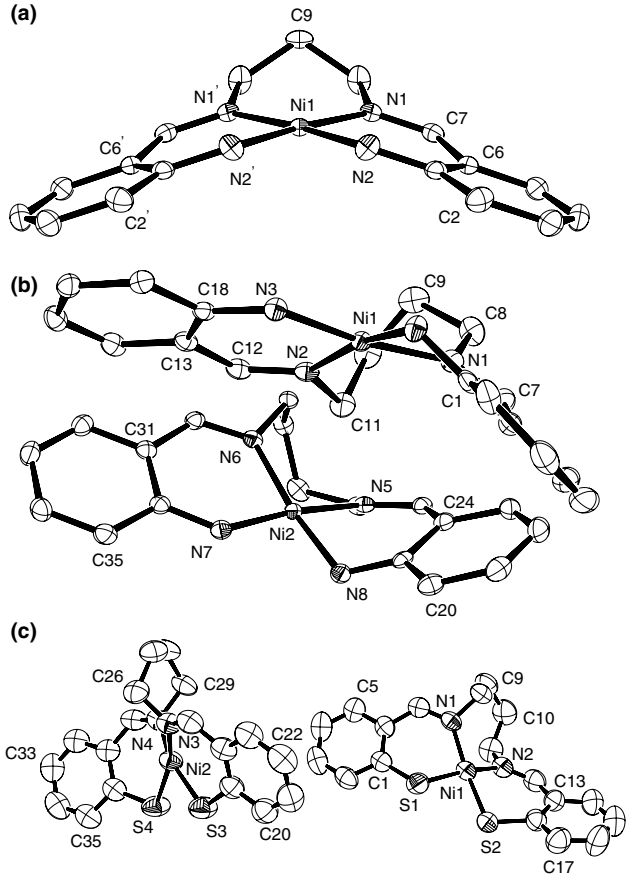

Fig. 3. The X-ray crystal structures of (a) (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,3-diamino-propane)nickel (Niampr), (b) (*N*,*N*′-bis-(*o*-amidobenzilidene)-1,4-diamino-butane)nickel (Niambut) and (c) (*N*,*N*′-bis-(*o*-thiobenzilidine)-1,4-diamino-butane)nickel (Nitsalbut). Hydrogens omitted for clarity; thermal ellipsoids are at 50%, the latter was collected at room temperature.

est distortion (162.02(11)–172.67(6)°). Whilst the square planar nature of the N_2N_2 complexes have been previously proposed [8,24] it is interesting to see how these ligands are able to cope with the geometric preference of the metal centre. As the chain length increases past two methylene units the Ni–$N_{iminato}$ bond lengths (Table 2) increase in order to accommodate the larger backbones. Whereas the 1,3-propanediimine can adopt an apposite chair conformation, the butane backbone is heavily buckled and is positioned out of the plane of the rest of the molecule in comparison with the arrangements in Nitsalbut (Fig. 3(c)) and Cu(II)salbut [36], where the backbone traverses the metal ligand plane in an S-shape allowing the geometry at the metal centre to be slightly tetrahedrally distorted.

The N_2S_2 complexes do not maintain the square planar geometry (178.63°–162.02(11)°) quite as effectively as the N_2N_2 complexes (176.6(7)°–168.11(6)°) as the backbone is lengthened. There is a greater shift towards a tetrahedral distortion, however, this is still small in comparison with the shifts observed in the Cu(II)salen series [17]. There is only very small lengthening of the imine metal bonds, and by allowing a slightly greater distortion from square planar the backbones are not under as much strain, particularly in the butane complex. This probably arises from the subtle differences in the π-contribution in the Ni–S and Ni–NH interactions.

An alternative way of introducing additional flexibility into the polymethylene backbone is to hydrogenate the imine moieties, thus allowing some rotation at the internal nitrogen donors. In the belief that this freedom would be more evident with ligands containing shorter backbones, nickel complexes of *N*,*N*′-bis(*o*-aminobenzyl)-1,2-diaminoethane (H_4amben) and *N*,*N*′-bis-(*o*-aminobenzyl)-1,3-diaminopropane (H_4ambpr) were prepared and isolated (Fig. 4).

In the presence of non-coordinating anions ($[BF_4]^-$) octahedral complexes, e.g., $[Ni(H_4amben)(MeCN)_2]^{2+}$ are formed in which the solvents (acetonitrile) occupy the two remaining sites (Fig. 4(a)). In contrast to the parent imine species the hydrogenated ligand twists to such an extent that the peripheral amine donors are found *trans* to one another (175.58(8)°) and the solvents cis (86.65(8)°). Without the electron withdrawing influence of the conjugated π-system, the pK_a of the external amines rise and they fail to deprotonate thus producing cationic amino complexes (cf. the neutral amido complexes Niamben etc). These differences account for the shorter N–Ni bond distances in the amido complexes (e.g., Niamben) compared to their respective amino complex (NiH_4amben, Table 2).

Synthesising these species from the acetate, we obtained a neutral complex with coordinated acetate ligands in the *trans* arrangement (Fig. 4(b)), and the tetradentate ligand occupying the meridial plane. Close inspection of the structure indicates that hydrogen bonds form between the acetates and the terminal NH_2 groups and it is clear that it is these interactions which define the conformation adopted. However, even when confined to the meridial plane the hydrogenated ligand still shows a slight tetrahedral distortion of the nitrogen donors out of the plane. This distortion extends out towards the aromatic rings where they adopt positions above and below the plane, as apposed to the umbrella arrangement seen in the imine complex (Fig. 3).

Although there are a few notable exceptions (didentate ligands [37,38], multiple bonds [39,40] and bulky ligands [41–43]), typically unidentate ligands predominantly adopt axial positions in the parent ethylenediamine based tetradentate Schiff's base complexes. However a picture is emerging which suggests the analogous hydrogenated species may prefer the additional ligands to adopt a cis conformation [44,45]. Again there are exceptions to this [46,47]. Crucially the acetate complexes give us an insight into just how delicate the balance between the choice of conformation, i.e., *cis* (Fig. 4(a)) and *trans* (Fig. 4(b)), can be and alludes to

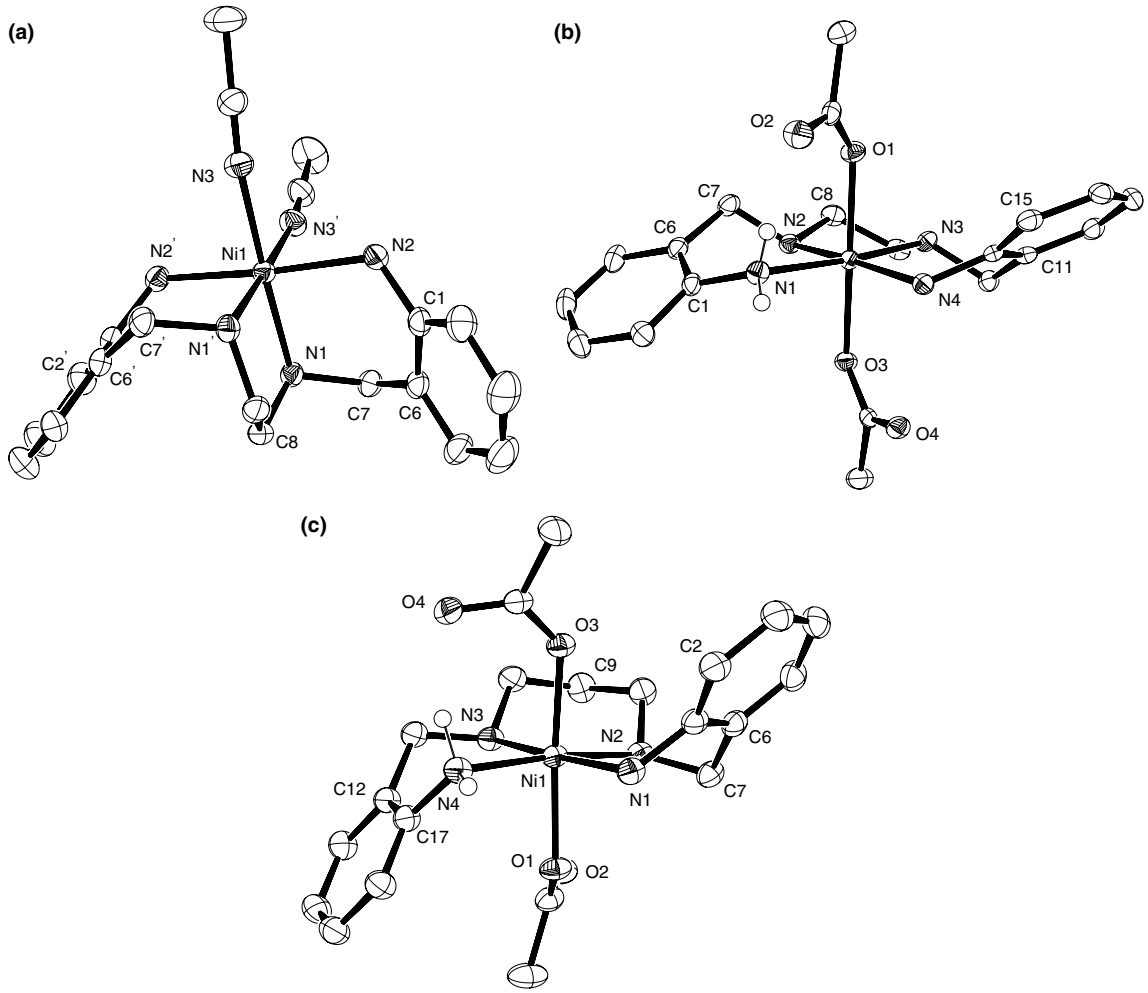

Fig. 4. The X-ray crystal structure of (a) {(bis-acetonitrile)}(*N*,*N*′-bis-(*o*-aminobenzyl)-1,2-diaminoethane)nickel tetrafluroborate, (b) {bis-*O*-acetato-(*N*,*N*′-bis-(*o*-aminobenzyl)-1,2-diaminoethane)}nickel(II) and (c) {(bis-*O*-acetato)}(*N*,*N*′-bis-(*o*-aminobenzyl)-1,3-diaminopropane)nickel. Hydrogens omitted for clarity, except those involved in hydrogen bonding to the acetates (NH—O Å; ethane 2.043, propane 1.921); thermal ellipsoids are at 50%.

the possibility of exchange between them (Fig. 1) during chemical reactions.

4. Supplementary data

Crystallographic data have been deposited with the Cambridge Crystallographic data Centre, CCDC Nos. 249874–249879. Fig. 1. Pyridylphosphines.

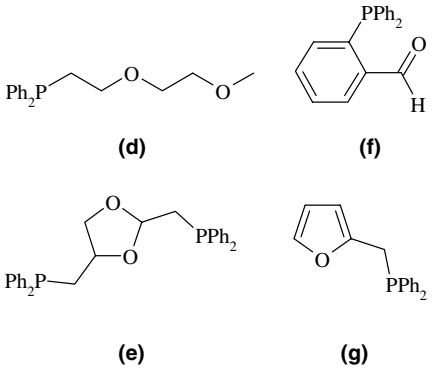

Fig. 2. Phosphorus–oxygen ligands.

Dpppa was recrystallised from boiling methanol to give a colourless crystalline solid in a tolerable yield (55%) and is relatively air stable; however exposure to air for prolonged periods resulted in degradation. It is readily soluble in chlorinated solvents, acetone, thf, somewhat less so in toluene, methanol and diethyl ether. A singlet is observed in the ^{31}P spectra of dpppa (in $CDCl_3$) at δ(P) 22.0 ppm. The ^{1}H NMR clearly shows the presence of an amide proton at δ(H) 8.65 ppm, as a doublet $^2J_{P-H} = 4$ Hz. The IR spectra shows a weak ν(N–H) band at 3297 cm^{-1}, and bands attributable to ν(pyCN) and ν(P–N) at 1452 and 996 cm^{-1} respectively. The expected ν(C=O) signature is visible at 1691 cm^{-1}. Satisfactory microanalysis was also obtained. The crystal structure of dpppa (Table 1 and Fig. 3) reveals that the P(1)–N(2)–C(3)–O(3) backbone is essentially planar

Table 1
Selected bond lengths (Å) and angles (°) for dpppa, dppaO and dppaS

	Dpppa **1**	DpppaO **2**	DpppaS **3**
Bond lengths			
P–O/S		1.478(2)	1.9475(9)
P(1)–N(2)	1.702(3)	1.683(2)	1.699(2)
N(2)–C(3)	1.355(5)	1.370(4)	1.378(3)
C(3)–C(4)	1.500(6)	1.506(4)	!.502(5)
C(3)–O(3)	1.221(5)	1.217(3)	1.219(3)

O(3)–C(3)–N(2)	122.1(4)	123.1(3)	123.4(2)
O(3)–C(3)–C(4)	121.7(4)	122.6(3)	122.6(2)
N(2)–H(2)···N(5)	129(3)	109(3)	111(2)

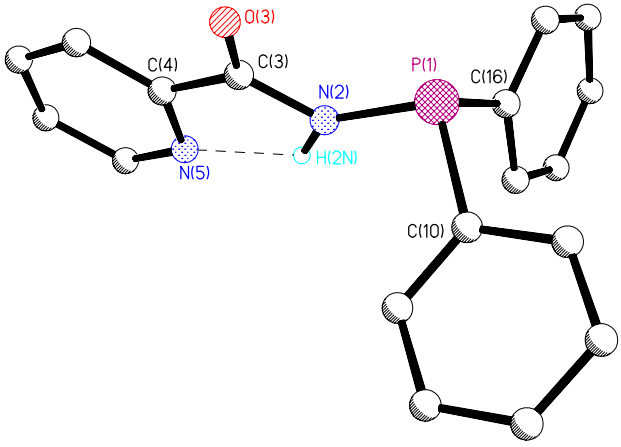

Fig. 3. The crystal structure of dpppa (**1**).

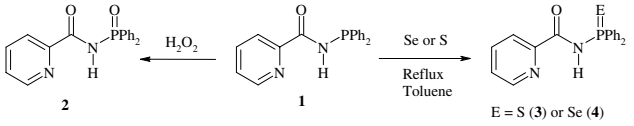
with an intramolecular hydrogen bond between the amide proton and the pyridyl nitrogen, generating an effective five-membered ring that is almost planar [N(2)–N(5) 2.67 Å] The phosphorus–nitrogen bond length of 1.702(3) Å is well within acceptable boundaries previously established in aminophosphine chemistry.



(2)

The oxide, sulfide and selenide of dpppa were also synthesised as seen in Eq. (2). The expected downfield shift is found in the ^{31}P NMR spectra of all three compounds (Table 2), the $^1J_{P-Se}$ is 788 Hz which is typical for a phosphorus–selenium double bond.

In **2**, the P–N bond is somewhat shorter than in dpppa (Table 1 and Fig. 4), the C(4)–C(3)–N(2)–P(1) backbone is essentially planar [mean deviation of 0.0391 Å] and as in **1** there is an H-bonded five-membered ring linking N(5) and H(2) [N(2)–N(5) is 2.653 Å, N(2)–H(2)···N(5) 109°]. It has been shown that the oxides and sulfides of phosphorus(III) ligands can display different solid state motifs [17]. We found that the sulfide **3** crystallises in a dimer arrangement rather than favouring the internal bonding seen in the oxide. The backbone of the molecule remains mostly planar, with the N(2) and N(5) distance [2.65 Å] indicating that the N(2)–H(2)···N(5) hydrogen bond interaction is retained (Table 1 and Fig. 5).

We formed a number of monodentate complexes, thus dpppa reacts with [$PtCl_2$(cod)] in dichloromethane to give *cis*-[$PtCl_2$(dpppa-P_2)] (**5**) as a white crystalline solid in good yield [80%] which is in marked contrast to 2-(diphenylphosphino)aminopyridine (dppap) which is reported to give [PtX(Ph_2PNHpy-*P*,*N*)(Ph_2 PNHpy-*P*)][Cl] (X = Cl or Me) [1–3]. The ^{31}P NMR ($CDCl_3$) of **5** is a singlet at δ(P) 31.2 ppm [$^1J_{Pt-P} = 3984$ Hz],

Table 2
Spectroscopic data for $Ph_2P(E)C(O)NHpy$

Compound	$\delta(^1H)$		$\delta(^{31}P)$	IR (cm^{-1})			
	NH	Aromatics	P	P=E	C=O	NH	CN(py)
1	8.7	8.5–7.2	22.0	N/A	1691	3297	1452

3	9.3	8.6–7.4	54.4	837	1689	3268	1447
4	9.3	8.6–7.1	48.7[a]	Obscured	1698	3288	1391

[a] $^1J_{P-Se}$ = 788 Hz.

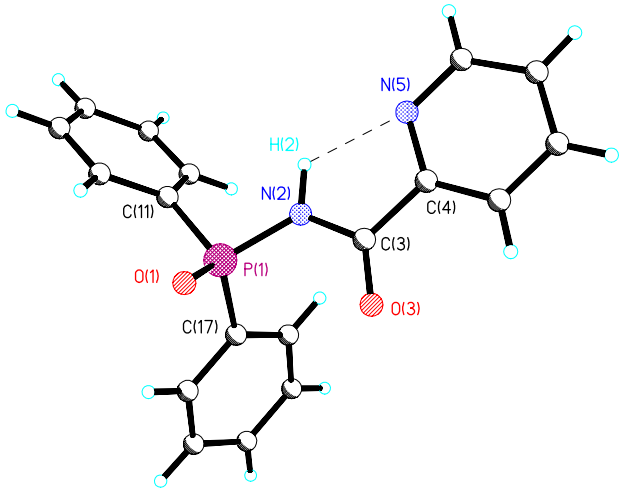

Fig. 4. The crystal structure of dpppaO (**2**).

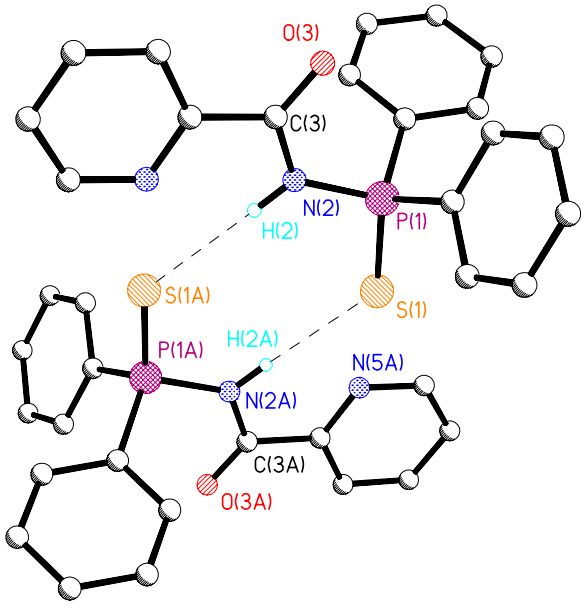

Fig. 5. Crystal structure of dpppaS (**3**).

whilst in the ^1H NMR it displays some significant changes from the free ligand. The amine proton is shifted to δ(H) 10.7 ppm, and $^2J_{P-H}$ at 15 Hz is significantly increased Two Pt–Cl stretches are visible in the IR spectrum (320 and 302 cm^{-1}), further evidence of a *cis*-conformation for **5**. In contrast, reaction of $[PdCl_2(cod)]$ with dpppa gives $[PdCl_2(dpppa\text{-}P)_2]$ (**6**), which is insoluble and displays only one Pd–Cl stretch (310 cm^{-1}), suggesting a *trans*-arrangement, the other expected IR peaks are observed clearly, ν(N–H) at 3232, ν(C=O) at 1694, ν(P–N) at 997 cm^{-1}. This *trans*-arrangement is consistent with previous examples of pyridylaminophosphines found in the literature [1–3].

A series of palladium complexes were synthesised bearing only one dpppa monodentate bound via the phosphorus (Fig. 6). Complexes $[PdCl(allyl)(dpppa\text{-}P)]$ (**7**), $[PdCl(C_{10}H_6NO)(dpppa\text{-}P)]$ (**8**), $[PdCl(C_9H_{12}N)(dpppa\text{-}P)]$ (**9**), $[PdCl(C_{12}H_{12}N)(dpppa\text{-}P)]$ (**10**), were all synthesised via bridge cleavage reactions of the respective dimer starting materials. Complex **7** is a yellow solid which shows the expected singlet at δ(P) 54.5 ppm. The amide proton is shifted downfield in the ^1H NMR spectra ($CDCl_3$), to δ(H) 10.7 ppm, this mirrors the shift of the amide proton in **5**, and also in common with **5** the $^2J_{P-H}$ coupling constant is enlarged, stretching to 22 Hz. The IR spectrum shows the ν(N–H) stretch has shifted to a much greater extent than seen in **5**, this could be due to much stronger hydrogen bonding interaction being present in **7**, and once again the ν(C=O) is relatively unmoved in comparison with the free ligand being found at 1686 cm^{-1}. In the solid state (Table 3 and Fig. 7), complex **7** has a hydrogen-bonds between H(2)–N(5) and H(2)–Cl(1) [N(2)–Cl(1) 3.204 Å and N(2)–N(5) 2.67(8) Å]. The interaction with Cl(1) causes the five-membered ring to distort with a N(5)–C(4)–C(3)–N(2) torsion angle of −15.08°.

Complexes **8**, **9** and **10** are similar and display the expected spectroscopic properties.

Complexes of ruthenium, rhodium and iridium were synthesised to further investigate the coordination of dpppa. $[RuCl_2(p\text{-Cymene})(dpppa\text{-}P)]$ (**11**) was generated by reaction of $[RuCl(\mu\text{-}Cl)(p\text{-Cymene})]_2$ with dpppa and isolated as a red solid. The rhodium and iridium complexes were synthesised by reaction with $[MCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)]_2$ (where M = Rh or Ir), and dpppa, to give complexes of the type $[MCl_2(\eta^5\text{-}C_5\ Me_5)(dpppa\text{-}P)]$ (where M = Rh (**12**) or Ir (**13**)). Crystals of **12** and **13** proved to be isomorphous; here we will only consider **13** (Table 3 and Fig. 8). On inspection of the ligand

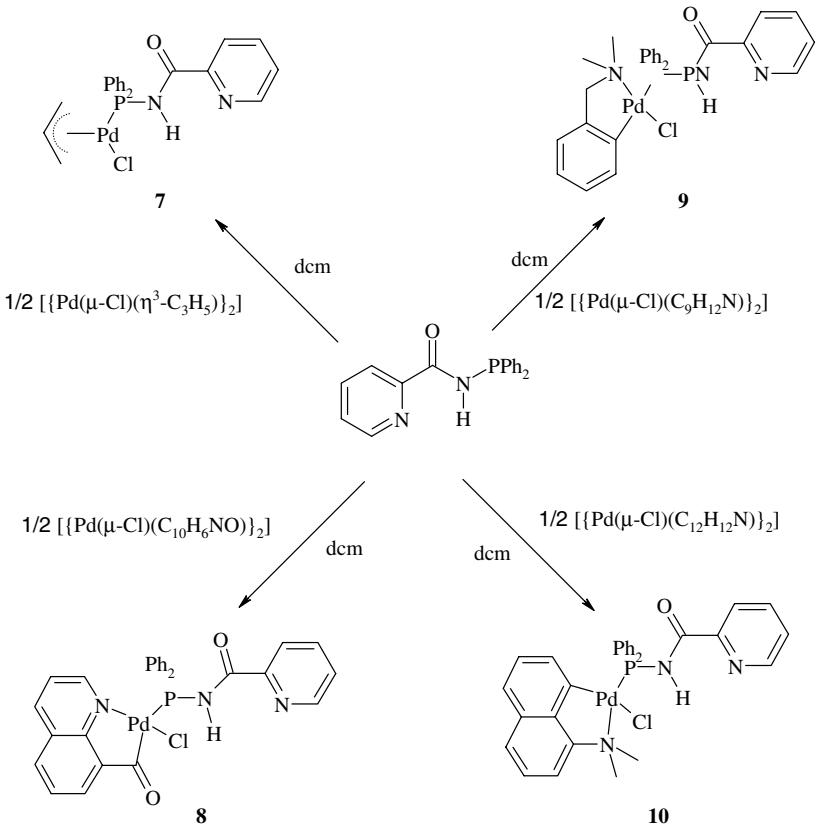

Fig. 6. Reaction of dpppa with palladium dimers.

N(2)–C(3)–C(4)	114.1(3)	114.6(6)	113.1(5)	113.3(6)

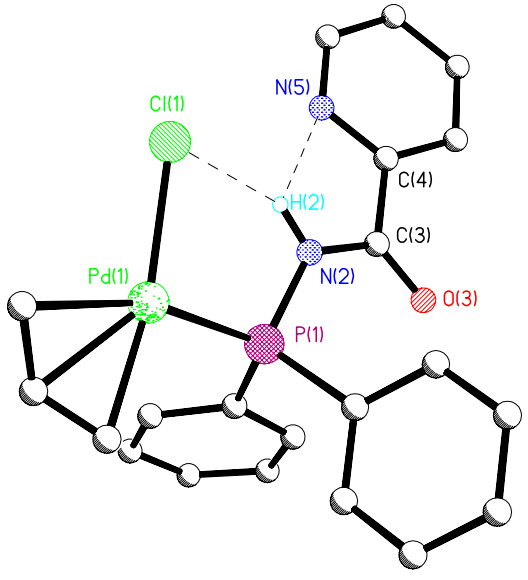

Fig. 7. Crystal structure of [PdCl(allyl)(dpppa-*P*)] (**7**).

backbone, we observe a modest shift out of plane, with the mean deviation of C(3)–N(2)–P(1)–Ir(1) being 0.1160Å, this is the highest deviation seen so far with monodentate dpppa complexes but is not unexpected the analogous complex formed with 2-(diphenylphosphino)hydrazinopyridine displays a similar deviation [18]. Also as seen with the 2-(diphenylphosphino)hydrazinopyridine example there are two types of hydrogen bonding displayed, the first is between the amine proton and one of the chlorides [N(2)···Cl(2) 3.403 Å]. The second type of hydrogen bonding observed in the complex is of

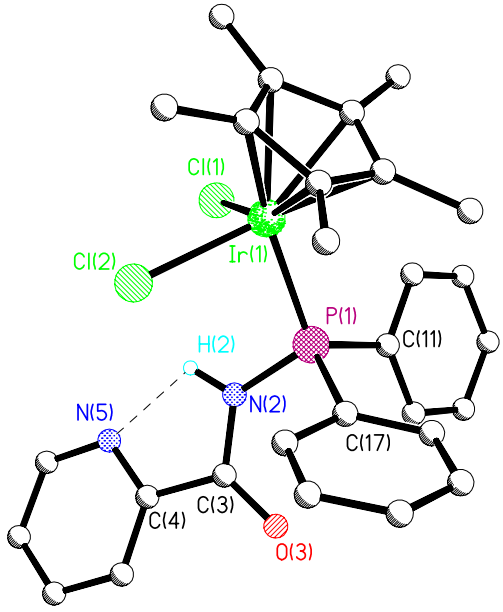

Fig. 8. Crystal structure of [IrCl2(η^5-C_5Me_5)(dpppa-*P*)] (**13**).

a similar motif to that found in the free ligand, oxide and sulfide [N(2)–N(5) 2.71(1) Å].

Dpppa reacts with [{PtCl(μ-Cl)(PR_3)}$_2$](PR_3=PMe_2Ph or PEt_3), to give complexes of the type *cis*-[$PtCl_2$(dpppa-*P*)(PR_3)](PR_3=PMe_2Ph (**14**) or PEt_3 (**15**)). Monodentate binding was the only observed mode of coordination in both instances. The ^{31}P NMR shows the expected AM spectra and the large $^1J_{Pt-P}$ coupling constants and the small $^2J_{P-P}$ couplings are consistent with a *cis*-arrangement of phosphorus around the platinum centre.

In **15** (Table 3 and Fig. 9), the C(3)–N(2)–P(1)–Pt(1) backbone is essentially planar, with a mean deviation of 0.0334 Å, which is consistent with the other structures

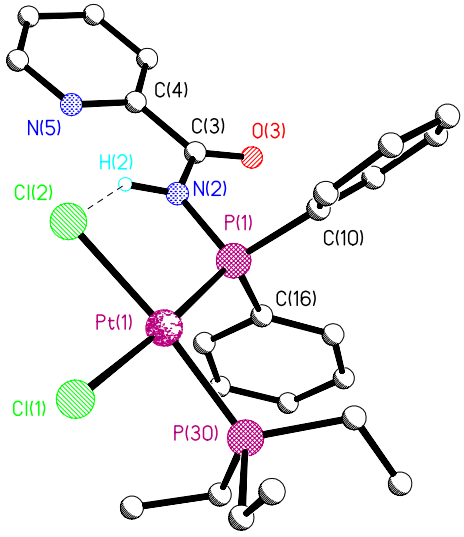

Fig. 9. Crystal structure of [$PtCl_2$(dpppa-*P*)(PEt_3)] (**15**).

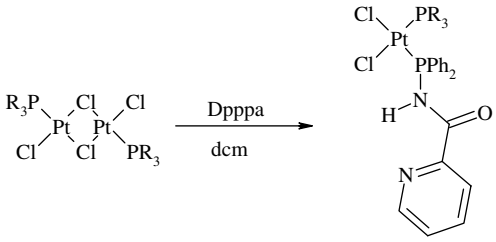
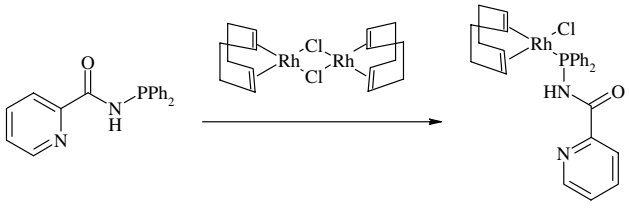
described above. Two different hydrogen bonding motifs are again observed within the complex [N(2)–Cl(2) 3.011, N(2)–N(5) 2.64(7) Å]



(3)

PR_3 = Me_2PhP (**14**) or Et_3 (**15**)

Reaction of dpppa with [RhCl(cod)]$_2$ in dichloromethane gave [RhCl(cod)(dpppa-*P*)] (**16**) as a yellow solid in average yield (63%), (P) 58.3 $^1J_{Rh-P}$ = 162 Hz.

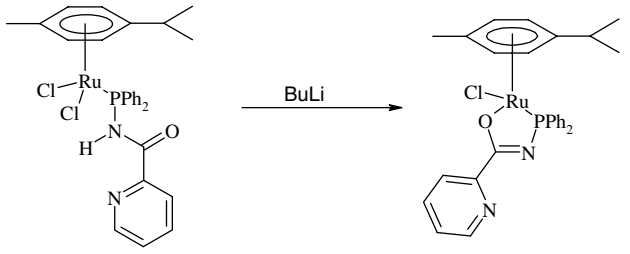


16

(4)

When dpppa was reacted with [AuCl(tht)] in dichloromethane the anticipated monodentate [AuCl(dpppa-*P*)] (**17**) complex was generated as a colourless solid, δ(P) 53.5 ppm, On inspection of the crystal data (Table 3 and Fig. 10), we see the now familiar hydrogen-bonding pattern [N(2)···N(5) 2.64 Å, N(2)–H(2)–N(5) 114°].

Chelation of dpppa was achieved by reaction of a chloride containing monodentate complex with BuLi



11 **18**

(5)

As can be seen this generates a five-membered 'true' heterocycle, with the oxygen binding to the metal centre. The ^{31}P NMR shows a downfield shift in the complex, to δ(P) 101.5 ppm, indicating chelation. As expected the amide proton disappears from the ^{1}H spectrum, and the pyC[6]H shift and coupling constant is relatively unchanged. The IR spectrum also confirms the loss of the amide proton, and shows a ν(C–O) stretch at 1351 cm^{-1}, confirming C–O is present and not C=O. Acceptable microanalytical data was obtained. The five-membered

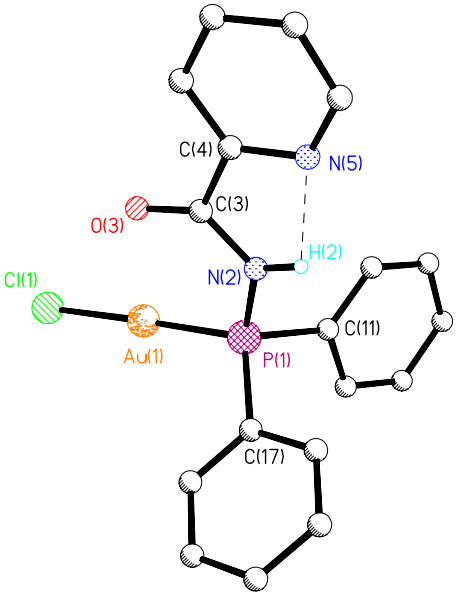


Fig. 10. Crystal structure of [AuCl(dpppa-*P*)] (**17**).

ring that is formed is essentially planar (Fig. 11 and Table 4), the Ru–O and Ru–P bond lengths within the ring are normal whilst the angles are typical for a five membered ring.

A second mode of chelation [via the pyridyl nitrogen] is possible for dpppa. This was facilitated by reaction of the appropriate monodentate complex with a halide abstractor [$AgBF_4$ or $AgClO_4$] generating the cationic species [RuCl(*p*-Cymene)(dpppa-*P*,*N*)][ClO_4] (**19**) and [RhCl(η^5-C_5Me_5)(dpppa-*P*,*N*)][BF_4] (**20**) in good yield (93% and 74%, respectively). The ^{31}P NMR shows the downfield shift generated by chelate ring formation with δ(P) 98.1 and 85.2 ppm for **19** and **20**, respectively, also the amine proton is shifted back toward the free ligand

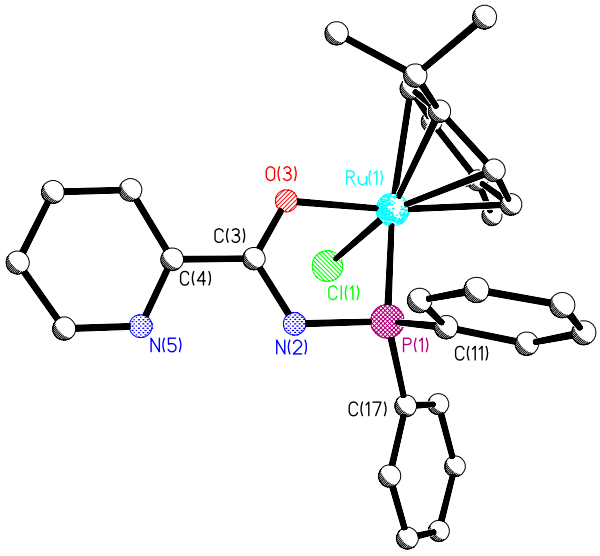

Fig. 11. Crystal structure of [RuCl(p-Cymene)(dpppa-*P*,*O*)] (**18**).

(6)

3. Experimental

3.1. General conditions

All manipulations were carried out in an atmosphere of nitrogen, unless stated otherwise. All solvents were either freshly distilled from an appropriate drying agent (thf, Et_2O from sodium, CH_2Cl_2 from calcium hydride) or obtained as anhydrous grade from Aldrich. ^{1}H and ^{31}P NMR spectra were recorded using a Jeol Delta FT (270 MHz) spectrometer. IR spectra were recorded as KBr discs (prepared in air) on a Perkin–Elmer 2000 FTIR/Raman spectrometer. All significant peaks (>800 cm^{-1}) are quoted to serve as a fingerprint. Silver salts, 2-picolinamide (Aldrich Chemical Co.) and BuLi (2.5 M, Lancaster) were purchased and used as received. Triethylamine and chlorodiphenylphosphine were distilled prior to use. Dimethylaminopyridine (DMAP) was sublimed before use. The various metal starting materials were made by the appropriate literature methods; [AuCl(tht)] [19], [MCl_2(cod)] (M = Pt or Pd; cod = cycloocta-1,5-diene) [20,21], [PdCl(L–L)]$_2$ dimers [22], [{PtCl(μ-Cl)(PMe_2 Ph)}$_2$] [23], [{MCl(μ-Cl)-(Cp*)}$_2$] (M = Rh or Ir) [24], [{Rh(μ-Cl)(cod)}$_2$] [25],

$[\{RuCl(\mu\text{-}Cl)(\eta^6 p\text{-}MeC_6H_4^iPr)\}_2]$ [26], $[\{PdCl(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)\}_2]$ [27].

3.1.1. 2-Diphenylphosphinopicolinamide (*1*)

Chlorodiphenylphosphine (3.7 cm^3, 20 mmol) was added to a solution of 2-picolinamide (2.5 g, 20 mmol), triethylamine (3.0 cm^3, 21 mmol) and DMAP (240 mg, 2.0 mmol) in thf (100 cm^3) and refluxed overnight. The reaction mixture was filtered to remove a white solid (Et_3NHCl) and washed with thf (50 cm^3). The solvent was removed in vacuo leaving a pale yellow solid. This solid was recrystallised by cooling a concentrated methanol solution at 4 °C overnight (yield: 3.38 g, 55%). *Anal.* Calc. for $C_{18}H_{15}N_2OP$: C, 70.6; H, 4.9; N, 9.1. Found: C, 70.29; H, 4.58; N, 8.95%. ν_{max}/cm^{-1}: 3297, 1691, 1452, 1412, 996. ^{31}P NMR δ 22.0 ppm ^1H NMR ($CDCl_3$), 8.65 (1H, d, $J = 4$ Hz, N–H), 8.54 (1H, d, $J = 5$ Hz, pyC[6]H), 8.26 (1H, d, $J = 8$ Hz, pyC[3]H), 7.85 (1H, t, $J = 8$ Hz, pyC[5]H), 7.6–7.2 (11H, m, aromatic).

3.1.2. 2-Diphenylphosphinopicolinamide oxide (*2*)

Aqueous H_2O_2 (30% w/w, 0.0071 cm^3, 0.065 mol) was added dropwise over 5 min to a solution of dpppa (200 mg, 0.065 mol) in thf (10 cm^3) and the mixture stirred for 30 min and then reduced to dryness. The residue was dissolved in CH_2Cl_2, and filtered while hot and subsequently dried over $MgSO_4$. The filtrate was stored at −4 °C during which time a crystalline solid was deposited and filtered and dried. Yield: 85 mg, 41%. *Anal.* Calc. for $C_{18}H_{15}N_2O_2P$: C, 67.1; H, 4.69; N, 8.69. Found: C, 66.7; H, 4.26; N, 8.41%. ν_{max}/cm^{-1}: 3302, 1694, 1451, 1403, 1215, 998. ^{31}P NMR δ 22.1 ppm. ^1H NMR ($CDCl_3$), δ 9.46 (1H, d, $J = 9$ Hz, N–H), 8.58 (1H, d, $J = 4$ Hz, pyC[6]H), 8.1–7.7 (6H, m, aromatic), 7.5–7.2 (7H, m, aromatic).

3.1.3. 2-Diphenylphosphinopicolinamide sulfide (*3*)

Sulfur (105 mg, 3.3 mmol) was added to a solution of 2-diphenylphosphinopicolinamde (1 g, 3.3 mmol) in toluene (100 cm^3) and refluxed overnight. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystallised by cooling a concentrated toluene solution at 4 °C overnight (yield: 900 mg, 82%). *Anal.* Calc. for $C_{18}H_{15}N_2OPS$: C, 63.9; H, 4.47; N, 8.28. Found: C, 63.6; H, 4.22; N, 8.26%. ν_{max}/cm^{-1}: 3268, 1689, 1387, 997. ^{31}P NMR δ 54.4 ppm. ^1H NMR ($CDCl_3$), δ 9.3 (1H, d, $J = 11$ Hz, N–H), 8.6 (1H, d, $J = 1$ Hz, pyC[6]H), 8.1–7.8 (6H, m, aromatic), 7.6–7.4 (7H, m, aromatic).

3.1.4. 2-Diphenylphosphinopicolinamide selenide (*4*)

Selenium (52 mg, 0.65 mmol) was added to a solution of 2-diphenylphosphinopicolinamde (200 mg, 0.65 mmol) in toluene (5 cm^3) and refluxed overnight. The solvent was removed in vacuo leaving an off-white solid. This solid was recrystallised by cooling a concentrated toluene solution at 4 °C overnight (yield: 105 mg, 48%). *Anal.* Calc. for $C_{18}H_{15}N_2OPSe$: C, 56.1; H, 3.92; N, 7.27. Found: C, 56.4; H, 3.77; N, 7.05%. ν_{max}/cm^{-1}: 3288, 1698, 1391, 998. ^{31}P NMR ($CDCl_3$) δ 47.8, $^1J_{P-Se} = 788$ Hz. ^1H NMR ($CDCl_3$), δ 9.3 (1H, d, $J = 13$ Hz, N–H), 8.6 (1H, d, $J = 1$ Hz, pyC[6]H), 8.2–7.7 (6H, m, aromatic), 7.5–7.3 (7H, m, aromatic).

3.1.5. $[PtCl_2(dpppa\text{-}P)_2]$ (*5*)

Dpppa (50 mg, 0.16 mmol) and $[PtCl_2(cod)]$ (30 mg, 0.08 mmol) were weighed into a schlenk type flask and CH_2Cl_2 (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was precipitated after addition of Et_2O (20 cm^3) then isolated by filtration and washed with further ether (10 cm^3) (yield: 57 mg, 80%). *Anal.* Calc. for $C_{36}H_{30}N_4O_2P_2Cl_2Pt(CH_2Cl_2)_{0.5}$: C, 47.6; H, 3.39; N, 6.08. Found: C, 47.5; H, 3.20; N, 5.81%. ν_{max}/cm^{-1}: 3251, 1692, 1446, 1391, 998, 320, 302. ^{31}P NMR ($CDCl_3$) δ 31.2 ppm, $^1J_{Pt-P} = 3984$ Hz. ^1H NMR ($CDCl_3$), 10.7 (2H, d, $J = 15$ Hz, N–H), 8.5 ((2H, d, $J = 4$ Hz), pyC[6]H), 7.7–7.2 (26H, m, aromatic).

3.1.6. $[PdCl_2(dpppa\text{-}P)_2]$ (*6*)

Dpppa (258 mg, 0.86 mmol) and $[PdCl_2(cod)]$ (120 mg, 0.43 mmol) were weighed into a schlenk type flask and CH_2Cl_2 (10 cm^3) added. The solution was stirred for 10 min. This resulted in precipitation of the desired product, which was filtered and washed with ether (10 cm^3). Yield: 307 mg, 92%. *Anal.* Calc. for $C_{36}H_{30}N_4O_2P_2Cl_2Pd$: C, 54.6; H, 3.83; N, 7.09. Found: C, 53.9; H, 3.64; N, 6.85%. ν_{max}/cm^{-1}: 3232, 1694, 1446, 1392, 997, 310.

3.1.7. $[PdCl(allyl)(dpppa\text{-}P)]$ (*7*)

Reaction followed as for **5**. Dpppa (84 mg, 0.27 mmol) and $[\{Pd(\mu\text{-}Cl)(\eta^3\text{-}C_3H_5)\}_2]$ (50 mg, 0.13 mmol) gave a pale yellow solid, (yield: 117 mg, 87%). *Anal.* Calc. for $C_{21}H_{20}N_2OPClPd$: C, 51.5; H, 4.12; N, 5,72. Found: C, 51.8; H, 3.93; N, 5.61%. ν_{max}/cm^{-1}: 3193, 1686, 1446, 1396, 1103, 998. ^{31}P NMR ($CDCl_3$) δ 54.5 ppm. ^1H NMR ($CDCl_3$), 10.5 (1H, d, $J = 22$ Hz, N–H), 8.7 (1H, d, $J = 4$ Hz, pyC[6]H), 7.8–7.4 (12H, m, aromatic), 5.5 (1H, m, allyl), 4.7 (1H, t, $J = 7$ Hz, allyl), 3.7 (1H, t, $J = 13$ Hz, allyl), 3.3 (1H, d, $J = 7$ Hz, allyl), 2.6 (1H, d, $J = 13$ Hz, allyl).

3.1.8. $[PdCl(C_{10}H_6NO)(dpppa\text{-}P)]$ (*8*)

Dpppa (205 mg, 0.66 mmol) and $[Pd(\mu\text{-}Cl)(C_{10}H_6NO)]_2$ (200 mg, 0.33 mmol) were weighed into a schlenk type flask and CH_2Cl_2 (10 cm^3) added. The solution was stirred for 10 min. This resulted in precipitation of the desired product, which was filtered and washed with ether (10 cm^3) (yield: 371 mg, 95%). *Anal.* Calc. for $C_{28}H_{21}N_3O_2PClPd$: C, 55.6; H, 3.50; N, 6.95.

Found: C, 55.7; H, 3.18; N, 6.04%. ν_{max}/cm^{-1}: 3231, 1673, 1446, 1394, 996, 322. FAB MS: *m/z* 568 ($[M - Cl]^+$).

3.1.9. [PdCl(C9H12N)(dpppa-P)] (9)

Dpppa (223 mg, 0.72 mmol) and $[Pd(\mu\text{-}Cl)(C_9H_{12}N)]_2$ (200 mg, 0.36 mmol) gave a yellow solid, (yield: 136 mg, 64%). *Anal.* Calc. for $C_{27}H_{25}N_3OPClPd(CH_2Cl_2)_{0.5}$: C, 52.9; H, 4.51; N, 6.73. FAB MS: *m/z* 546 ($[M - Cl]^+$).

3.1.10. [PdCl(C12H12N)(dpppa-P)] (10)

Reaction followed as for **5**. Dpppa (197 mg, 0.64 mmol) and $[Pd(\mu\text{-}Cl)(C_{12}H_{12}N)]_2$ (200 mg, 0.32 mmol) gave a yellow/green solid, (yield: 176 mg, 44%). *Anal.* Calc. for $C_{30}H_{27}N_3OPClPd$: C, 58.2; H, 3.40; N, 6.80. Found: C, 58.09; H, 2.92; N, 6.62%. ν_{max}/cm^{-1}: 3203, 1678, 1446, 1388, 997. ^{31}P NMR ($CDCl_3$) δ 64.3 ppm. ^1H NMR ($CDCl_3$) 11.3 (1H, d, $J = 18$ Hz, N–H), 8.7 (1H, d, $J = 5$ Hz, pyC[6]H), 8.2 (4H, m, aromatic), 8.0 (1H, d, aromatic), 7.8 (1H, d, aromatic), 7.6 (1H, d, aromatic), 7.5–7.4 (10H, m, aromatic), 6.7 (1H, m, aromatic), 6.5 (1H, m, aromatic), 3.5 (6H, d, $J = 3$ Hz, NMe–H).

3.1.11. [RuCl2(p-Cymene)(dpppa-P)] (11)

Prepared as for **5**. Dpppa (200 mg, 0.66 mmol) and $[\{RuCl(\mu\text{-}Cl)(p\text{-Cymene})\}_2]$ (200 mg, 0.33 mmol) gave a red solid, (yield: 324 mg, 84%). *Anal.* Calc. for $C_{28}H_{29}N_2OPCl_2Ru$: C, 54.9; H, 4.77; N, 4.57. 3.1.12. [RhCl2(η5-C5Me5)(dpppa-P)] (12)

Prepared as for **5**. Dpppa (198 mg, 0.65 mmol) and $[\{RhCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (200 mg, 0.32 mmol) gave a orange solid, (yield: 363 mg, 91%). *Anal.* Calc. for $C_{28}H_{30}N_2OPCl_2$ Rh: C, 54.6; H, 4.91; N, 4.55. Found: C, 54.0; H, 4.65; N, 4.40%. ν_{max}/cm^{-1}: 3298, 1678, 1449, 1410, 997, 282. ^{31}P NMR ($CDCl_3$) δ 62.8 ppm, J_{RhP} 150 Hz. ^1H NMR ($CDCl_3$) δ 9.9 (1H, d, $J = 18$ Hz, N–H), 8.6 (1H, d, $J = 5$ Hz, pyC[6]H), 8.1 (4H, m, aromatic), 7.9 (1H, d, aromatic), 7.7 (1H, m, aromatic), 7.5 (7H, m, aromatic), 7.3 (1H, m, aromatic), 1.4 (15H, d, $J = 12$ Hz, Cp*–H).

3.1.13. [IrCl2(η5-C5Me5)(dpppa-P)] (13)

Prepared as for **5**. Dpppa (77 mg, 0.25 mmol) and $[\{IrCl(\mu\text{-}Cl)(\eta^5\text{-}C_5Me_5)\}_2]$ (100 mg, 0.13 mmol) gave a yellow/orange solid, (yield: 162 mg, 91%). *Anal.* Calc. for $C_{28}H_{30}N_2OPCl_2Ir$: C, 47.6; H, 4.29; N, 3.98. Found: C, 47.1; H, 4.27; N, 3.83%. ν_{max}/cm^{-1}: 3288, 1678, 1450, 1412, 997. ^{31}P NMR ($CDCl_3$) δ 32.7 ppm. ^1H NMR ($CDCl_3$) δ 10.2 (1H, d, $J = 17$ Hz, N–H), 8.6 (1H, d, $J = 4$ Hz, pyC[6]H), 8.1–7.7 (6H, m, aromatic), 7.4 (6H, m, aromatic), 1.4 (15H, d, $J = 2$ Hz, Cp*–H).

3.1.14. [PtCl2(Me2PhP)(dpppa-P)] (14)

Prepared as for **5**. Dpppa (76 mg, 0.25 mmol) and $[\{PtCl(\mu\text{-}Cl)(PMe_2Ph)\}_2]$ (100 mg, 0.12 mmol) gave a white solid, (yield: 114 mg, 65%). *Anal.* Calc. for $C_{26}H_{26}N_2OP_2Cl_2Pt$: C, 44.0; H, 3.69; N, 3.95. Found: C, 43.77; H, 3.61; N, 3.82%. ν_{max}/cm^{-1}: 1686, 1447, 1384, 1107. ^{31}P NMR ($CDCl_3$) δ 30.9 ($^1J_{Pt-P} = 3930$), −14.5 ($^1J_{Pt-P} = 3500$), $^2J_{P-P} = 19$ Hz. ^1H NMR ($CDCl_3$) δ 11.1 (1H, d, $J = 15$ Hz, N–H), 8.6 (1H, d, $J = 4$ Hz, pyC[6]H), 8.0–7.7 (6H, m, aromatic), 7.5–7.0 (12H, m, aromatic), 1.6–1.5 (6H, d, $J = 11$ Hz, Me–H).

3.1.15. [PtCl2(Et3P)(dpppa-P)] (15)

A solution of $[\{PtCl(\mu\text{-}Cl)(PEt_3)\}_2]$ (50 mg, 0.07 mmol), in CH_2Cl_2 (10 cm^3) was added dropwise to a solution of dpppa (40 mg, 0.13 mmol) in CH_2Cl_2 (10 cm^3). The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A white solid was precipitated after addition of Et_2O then isolated by filtration and washed with further ether (10 cm^3) (yield: 55 mg, 66%). *Anal.* Calc. for $C_{24}H_{30}N_2OP_2Cl_2Pt$: C, 41.9; H, 4.38; N, 4.06. Found: C, 42.8; H, 3.60; N, 4.15%. ν_{max}/cm^{-1}: 3162, 1687, 1446, 1385, 998, 310. ^{31}P NMR ($CDCl_3$) δ 30.0 ($^1J_{Pt-P} = 4010$), 7.6 ($^1J_{Pt-P} = 3360$), $^2J_{P-P} = 19$ Hz. ^1H NMR ($CDCl_3$) δ 11.4 (1H, d, $J = 16$ Hz, N–H), 8.7 (1H, d, $J = 1$ Hz, pyC[6]H), 8.2 (2H, m, aromatic), 7.9–7.7 (5H, m, aromatic), 7.5–7.3 (3H, m, aromatic), 7.1 (1H, m, aromatic), 1.5 (6H, m, $-CH_2-$), 0.9 (9H, m, Me–H).

3.1.16. [RhCl(cod)(dpppa-P)] (16)

Dpppa (125 mg, 0.41 mmol), and $[\{Rh(\mu\text{-}Cl)(cod)\}_2]$ (100 mg, 0.20 mmol) were weighed into a schlenk type flask and toluene (5 cm^3) added. The solution was stirred for 10 min and the majority of the solvent removed in vacuo. A yellow solid was precipitated after addition of *n*-hexane (20 cm^3) then isolated by filtration and washed with further hexane (10 cm^3) (yield: 142 mg, 63%). *Anal.* Calc. for $C_{26}H_{27}N_2OPClRh$: C, 56.5; H, 4.92; N, 5.07. Found: C, 56.05; H, 4.76; N, 4.90%. ν_{max}/cm^{-1} : 3194, 1698, 1448, 1407, 997. ^{31}P NMR

($CDCl_3$) δ 58.3 ($^1J_{Rh-P}$ = 162 Hz). ^1H NMR (270 MHz, $CDCl_3$) δ 10.4 (1H, d, J = 21Hz, N–H), 8.6 (1H, d, J = 2Hz, pyC[6]H), 8.0–7.8 (6H, m, aromatic), 7.6–7.2 (6H, m, aromatic), 2.3 (4H, br.s, cod), 2.0 (8H, br.s, cod).

3.1.17. [AuCl(dpppa-P)] (17)

Prepared as for **5**, Dpppa (67 mg, 0.021 mmol) and [AuCl(tht)] (70 mg, 0.021 mmol) reacted in CH_2Cl_2 gave a white solid, (yield: 78 mg, 70%). *Anal.* Calc. for $C_{15}H_{15}N_2OPClAu$: C, 40.0; H, 2.80; N, 5.20. Found: C, 39.5; H, 2.75; N, 5.09%. ν_{max}/cm^{-1} : 3288, 1698, 1391, 998. ^{31}P NMR ($CDCl_3$) 53.5 ppm. ^1H NMR ($CDCl_3$) 9.1 (1H, d, J = 13 Hz, N–H), 8.6 (1H, d, J = 1 Hz, pyC[6]H), 8.2–7.5 (13H, m, aromatic).

3.1.18. [RuCl(p-Cymene)(dpppa-P,O)] (18)

A solution of BuLi (65 μ l,. 0.16 mmol) in THF (2 cm^3) was added dropwise to a solution of [$RuCl_2$-(*p*-Cymene)(dpppa-*P*)] (100 mg, 0.16 mmol) in THF (5 cm^3) at 0 °C. The solution was stirred for 10 min and allowed to reach room temperature, and filtered through a bed of celite. The majority of the solvent removed in vacuo. A dull beige solid was precipitated after addition of Et_2O then isolated by filtration and washed with further ether (10 cm^3) (yield: 47 mg, 52%). Recryst from CH_2Cl_2/hexane. *Anal.* Calc. for $C_{28}H_{28}N_2OPCl$-$Ru(CH_2Cl_2)$: C, 52.7; H, 4.57; N, 4.24. Found: C, 51.9; H, 4.00; N, 4.38%. ν_{max}/cm^{-1}: 3312, 1351, 249. ^{31}P NMR ($CDCl_3$) δ 101.5. ^1H NMR (270 MHz, $CDCl_3$) δ 8.4 (1H, d, J = 8 Hz, pyC[6]H), 7.9–7.7 (3H, m, aromatic), 7.6–7.2 (10H, m, aromatic), 6.0 (1H, d, J = 6 Hz, *p*-Cy-H), 5.7 (1H, d, J = 4 Hz, *p*-Cy-H), 5.4 (1H, d, J = 6 Hz, *p*-Cy-H), 5.0 (1H, d, J = 4 Hz, *p*-Cy-H), 2.5 (1H, m, C–H), 2.0 (3H, s, Me–H), 1.1 (6H, d, J = 10 Hz, Pr^i-H).

3.1.19. [RuCl(p-Cymene)(dpppa-P,N)][ClO_4] (19)

$AgClO_4$ (33 mg, 0.16 mmol) was added under dark conditions to a solution of [$RuCl_2$(*p*-Cy)(dpppa-*P*)] (100 mg, 0.16 mmol) in CH_2Cl_2 (5 cm^3). The solution was stirred overnight and filtered through a celite bed. The majority of the solvent was removed in vacuo. An orange solid was precipitated after addition of Et_2O then isolated by filtration and washed with further ether (10 cm^3) (yield: 87 mg, 0.15 mmol, 93%). *Anal.* Calc. for $C_{28}H_{28}N_2O_5PCl_2Ru(CH_2Cl_2)_{0.5}$: C, 47.6; H, 4.21; N, 3.90. Found: C, 47.2; H, 4.00; N, 3.89%. ν_{max}/cm^{-1}: 1482, 1084. ^{31}P NMR ($CDCl_3$) δ 98.1 ppm. ^1H NMR ($CDCl_3$) δ 8.6 (1H, d, J = 5 Hz, N–H), 8.2 (1H, d, J = 8 Hz, pyCH), 8.0 (1H, t, J = 8 Hz, pyCH), 7.8 (2H, m, aromatic), 7.7–7.5 (10H, m, aromatic), 5.8 (2H, m, *p*-Cymene-H), 5.6 (2H, m, *p*-Cymene-H), 2.8 (1H, m, C–H), 2.1 (3H, s, Me–H), 1.3 (6H, t, J = 6 Hz, Pr^i-H).

*3.1.20. [RhCl(η⁵-C₅Me₅)(dpppa-P,N)][BF₄] (**20**)*

$AgBF_4$ (31 mg, 0.16 mmol) was added under dark conditions to a solution of $[RhCl_2(\eta^5\text{-}C_5Me_5)$(dpppa-*P*)] (100 mg, 0.16 mmol) in CH_2Cl_2 (5 cm^3). The solution was stirred overnight and filtered through a celite bed. The majority of the solvent was removed in vacuo. An orange solid was precipitated after addition of Et_2O then isolated by filtration and washed with further ether (10 cm^3) (yield: 70 mg, 0.12 mmol, 74%). *Anal.* Calc. for $C_{28}H_{30}N_2OPClRhBF_4$: C, 50.4; H, 4.54; N, 4.20. Found: C, 49.8; H, 4.25; N, 4.04%. ν_{max}/cm^{-1}: 1684, 1477, 1421. ^{31}P NMR ($CDCl_3$) δ 85.2 ppm. ^1H NMR ($CDCl_3$) δ 8.6 (1H, d, $J = 4$ Hz, pyC[6]H), 8.3 (1H, d, $J = 8$ Hz, pyC[3]H), 8.0 (1H, t, $J = 8$ Hz, pyC[5]H), 7.8 (2H, m, aromatic), 7.6 (8H, m, aromatic), 1.6 (15H, d, $J = 4$ Hz, Cp*-H).

4. X-ray crystallography

Details of the structure determination are given in Table 5. X-ray diffraction measurements were made with graphite-monochromated Mo Kα X-radiation using a Bruker SMART diffractometer or with Cu Kα radiation and a Rigaku Mercury diffractometer. In both cases, intensity data were collected using ω/ϕ steps accumulating area detector frames spanning a hemisphere of reciprocal space for all structures. All data were corrected for Lorentz, polarisation and long-term intensity fluctuations. Absorption effects were corrected on the basis of multiple equivalent reflections or by semi-empirical methods. Structures were solved by direct methods and refined by full-matrix least-squares against F^2 (SHELXTL). Hydrogen atoms were assigned isotropic displacement parameters and were constrained to idealised geometries. Complex **7** contains some disorder; in both **7** and **18** not all of the protons could be included in the final refinement. Refinements converged to residuals given in Table 5. All calculations were made with SHELXTL [28].

5. Supplementary material

Atomic coordinates, thermal parameters and bond lengths and angles have been deposited at the Cambridge Crystallographic data centre (CCDC) Nos 238211–238218. Any request to CCDC for this material should quote the full literature citation and the reference number. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or at www: http://www.ccdc.cam.ac.uk).

Subject Index to Volume 23

Absorption spectra
Carbohydrate, Cobalt complex, Circular dichroism, Optical activity, 1341
Absorption spectra
Complexation, Kinetics, Photochromism, Spiroindolinonaphthooxazines, 3147
Acetate ligands
Iron complexes, η^2-Coordination modes, Schiff bases, β-Cis arrangements, 963
Acetonitrile reduction
Amine oxidation, Imido, Metal-nitrogen pi bonding, Regioselectivity of nucleophile and electrophile additions, 311
Acetylacetonato complexes
Rhodium, Pentachlorophenolato complexes, Carboxylato complexes, Diazoalkane complexes, C–C coupling reactions, 2645
Actinide
Lanthanide, Oxides, Carbene, Uranium, 2689
Adducts
Cobalt, Oxide, β-diketonates, Structures, MOCVD, 735
Adsorption
Silica gel, Immobilization, 2-Aminomethylpyridine, Epoxide, Thermodynamic, 719
AFM
Schiff-base, Polypyrrole, Electropolymerization, Iron complex, Polymer, 1953
Aldehyde activation
C–H bond activation, Rhodium(III), Benzene activation, 2943
Aldehydes
N-Heterocyclic carbenes, Homogenous catalysis, Transfer hydrogenation, Ketones, Imines, 2857
Aliphatic amino ligands
One-dimensional, Silver(I), Coordination polymers, Tubes, Topology, Supramolecular chemistry, Self assembly, Nanotubes, 2075
Alkali metal ions
Uranyl ion, Calixarenes, Homooxacalixarenes, Crystal structures, 649
Alkali metals
Alkoxides, Enolates, β-Diketonates, Carboxylates, Alkaline earth metals, Cluster compounds, 1479
Alkali metals
Lithium, Phosphorus–carbon bond cleavage, Chelates, O Ligands, 2499
Alkaline earth metal complexes
Crystal structures, 2183
Alkaline earth metals
Alkoxides, Enolates, β-Diketonates, Carboxylates, Alkali metals, Cluster compounds, 1479
Alkaline earth metals
Self-assemble, Carboxylate bridges, Copper complexes, Dipeptides, Magnetic properties, 2125
Alkoxides
Lanthanides, Neodymium, X-ray structures, Pyrazolylborates, Borohydrides, 253
Alkoxides
Enolates, β-Diketonates, Carboxylates, Alkali metals, Alkaline earth metals, Cluster compounds, 1479
Alkylation
Zinc, Enzyme, Thiolate, 481
Alkylation
Parabanic acid, Iron, Cyclopentadienyl, Carbonyl, Thallium, Gold (I) complex, 1441
Alkylthiolate
Heteroscorpionate, Tripodal, Imidazole, Iron, Zinc, 471
Alkyne complex
Hydrotris(pyrazolyl)borate, Scorpionate ligands, Tantalum, Metal–metal multiple bond, Tetrahydrothiophene complex, 379
Aluminium
Oxoalkoxides, Precursor hydrolysis, X-ray, Structure studies, 109
Aluminium
Hydroxyaluminosilicate, Silicic acid, Aluminium solubility, Aluminium biological availability, 3185
Aluminium biological availability
Hydroxyaluminosilicate, Aluminium, Silicic acid, Aluminium solubility, 3185
Aluminium solubility
Hydroxyaluminosilicate, Aluminium, Silicic acid, Aluminium biological availability, 3185
Aluminium(III)
Catecholates, Salicylates, Complexation, Proton exchange, NMR, 2393
Aluminum
Bipyridine, Titanium, Coordination compound, Crystal structure, 561
Aluminum
Enolato, Enamido, Zirconium, Titanium, 1587
Amide
Nitronyl nitroxide, Imino nitroxide, Manganese complexes, Copper complexes, Cobalt complexes, 763
Amine oxidase
Lawsone, Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Copper complexes, Antiferromagnetic coupling, H-bonding, EPR, 2541
Amine oxidation
Acetonitrile reduction, Imido, Metal-nitrogen pi bonding, Regioselectivity of nucleophile and electrophile additions, 311
Amines
Hexamethylbenzene, *p*-Cymene, Diphenyl-2-pyridylphosphine, Ruthenium complexes, 3115
Amino acid
Copper, Dendrimers, Electrochemistry, Electron spin resonance, Ligand, 1709
Amino acid
Nickel(II), Lanthanides(III), Heptanuclear, Cluster compound, 2265
Amino acid containing peroxovanadates
Dinuclear peroxovanadate, Peroxo-bridged divanadate, Peroxidative bromination, Heteroligand peroxovanadate, 1097
2-Aminomethylpyridine
Silica gel, Immobilization, Epoxide, Adsorption, Thermodynamic, 719
Aminopolycarboxylate
Copper(II), Ferromagnetic coupling, π–π stacking, Cylindrical channels, 1081
3-Aminopyridine
Mn(II) and Cd(II) complexes, Azides, Synthesis, Spectra, X-ray structures, Thermal properties, 2349
Ammonolysis
Liquid ammonia/toluene two-phase system, Potassium, Zirconium, 1125
Aniline
Dioxygen, Osmium, Oxidation, Electron transfer self-exchange, 323

doi:10.1016/S0277-5387(04)00440-1

Anion exchange
Pseudoephedrine, Nickel, Triangulo, Cluster, 1837
Anion role
Cadmium complex, Bis(triazole) ligand, Crystal structure, 3133
Anisotropic approximation
EDAX analyses, Cluster anions, Heterometal cluster complexes, 599
Anti-fungal
Bis-imidazole, Bis(imidazol-2-yl)methane, X-ray structures, Silver(I), Argentophilicity, Candida albicans, 1249
Antiferromagnetic coupling
Lawsone, Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Copper complexes, H-bonding, EPR, 2541
Antiferromagnetic dimer
Copper dimer, Magnetic properties, Crystal structure, 1695
Antiferromagnetic interaction
Macrobicylic ligands, Compartmental, Copper(II) complexes, Electrochemistry, Catalytic study, 519
Antimicrobial activity
Copper(II) complexes, 2-Benzoylpyridine, Thiosemicarbazone, EPR, Crystal structure, 3069
Antimicrobial studies
Copper(II) complexes, Thiosemicarbazone, 2-Hydroxyacetophenone, EPR, Cyclic voltammetry, X-ray crystallography, 2549
Antimony
Ferrocenylcarboxylate, Crystal structures, Antitumor activity, 823
Antitumor activity
Antimony, Ferrocenylcarboxylate, Crystal structures, 823
Aqueous organometallic chemistry
Molybdenum, Polyoxometallate, Pentamethylcyclopentadienyl ligands, 2605
Aquo complex
Hydrotris(pyrazolyl)borate, Ruthenium, Hydrogen bond, Oxidation, 225
Architecture
Flexible, Carboxylates, IX, Coordination polymer, 3007
Arene ligand
Ferrocene carboxylic acid, Ferrocene derivative, Ruthenium, 687
Argentophilicity
Bis-imidazole, Bis(imidazol-2-yl)methane, X-ray structures, Silver(I), Anti-fungal, Candida albicans, 1249
Aromatic aminoacidate
Cobalt(III), Non-covalent interactions, Octahedral inversion, Tetradentate ligands, NMR, 1749
Arsenazo III
Dawson lacunary heteropolyanion, Complex formation constants, Lanthanides, 1579
Arsine
Titanium iodide, Phosphine, Iron iodide, Crystal structures, 605
Arsine ligands
Rhenium nitrosyl complexes, Pyrazole, X–ray structure, Density functional theory calculations, 2523
2-[(*E*)-2-(aryl)-1-diazenyl]pyridine
Hg(II) complexes, NMR, Crystal structures, 2323
Arylazoimidazoles
Cadmium(II) complexes, End-on and end-to-end bridging, X-ray structure, 1D chain, Sheet structure, 1669
Aryloxide
Lanthanides, Ytterbium, Crystal Structures, Tris(pyrazolyl)borate, Divalent, 263
Aryloxide derivatives
Tris(pyrazolyl)hydroborate (Tp) ligands, Lanthanum, Neodymium, Salt metathesis, 2437
Ascorbate oxidase model
Tricopper(II) complex, Schiff bases, Crystal structure, Magnetic properties, 643
Ascorbic oxidation
Copper(II) complex, Crystal structure, Imidazole, 2515
Assembly
Sulfonatothiacalixarene, Capsules, Diaza-Crown ether, Transition metal ions, 1461
Asymmetric oxidation
Chiral copper(II) complexes, Schiff base, Sulfide, Seven-membered, 1131
Aurates
S ligands, Coordination chemistry, Thianthrenes, 1351
Aza ether
Phthalocyanine, Metallo phthalocyanine, Liquid crystal, Metallo mesogen, Crown ether, 1931
1-azaallyls
Group 11 phosphine complexes, X-ray crystallography, Iminoalkyl bonding mode, 2273
Azide
Manganese(III), N,O ligands, X-ray structure, Magnetochemistry, Dimer, 1811
Azides
Polyamines, Copper(II) complexes, Crystal structures, Magnetic properties, Coordination polymers, 1243
Azides
Mn(II) and Cd(II) complexes, 3-Aminopyridine, Synthesis, Spectra, X-ray structures, Thermal properties, 2349
Azoimidazoles
Ruthenium(II)-tris-chelates, X-ray structure, Electrochemistry, 727
Azomethine H
Borate complex, Boric acid, Complexation, ^{11}B NMR, 955

^{11}B NMR
Thallium, B–H coupling, Tris(pyrazolyl)-borate, Pyrazole, 2533
B–H coupling
Thallium, ^{11}B NMR, Tris(pyrazolyl)borate, Pyrazole, 2533
^{11}B NMR
Borate complex, Azomethine H, Boric acid, Complexation, 955
Back-bonding
Crystal structure, Ruthenium complex, NO, Reactivity, Molecular, 1063
Benzene activation
C–H bond activation, Rhodium(III), Aldehyde activation, 2943
Benzimidazole
Platinum, Imine, Benzoxazole, Benzothiazole, Pyridine, 155
N-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithiocarboimine
Zinc(II) cobalt(II) compounds from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl-ester, 1-Benzothiazol-2-ylid-3-methyl-thiourea, 1-Benzothiazol-2-yl-2,3-dimethyl-*iso*-thiourea, 2481
Benzimidazole
Rhenium, Bibenzimidazole, Crystal structure, Paramagnetic NMR, 1139
Benzothiazole
Platinum, Imine, Benzimidazole, Benzoxazole, Pyridine, 155
1-Benzothiazol-2-yl-2,3-dimethyl-*iso*thiourea
Zinc(II) cobalt(II) compounds from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester, 1-Benzothiazol-2-ylid-3-methyl-thiourea, *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithio-carboimine, 2481
1-Benzothiazol-2-ylid-3-methyl-thiourea
Zinc(II) cobalt(II) compounds from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester, 1-Benzothiazol-2-yl-2,3-dimethyl-*iso*thiourea, *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl-dithio-carboimine, 2481
2-Benzoylpyridine
Copper(II) complexes, Thiosemicarbazone, EPR, Antimicrobial activity, Crystal structure, 3069
Benzoxazole
Platinum, Imine, Benzimidazole, Benzothiazole, Pyridine, 155
Bibenzimidazole
Rhenium, Benzimidazole, Crystal structure, Paramagnetic NMR, 1139
Bicapped trigonal prism
Eight-coordinate, Stereochemistry, Dodecahedron, Square antiprism, Molecular mechanics, 145
Bidentate
Ligand, Bridging, X-ray, Phosphine, 2569
Bidentate chelate
Bis(diphenylphosphino)methane dioxide, Uranyl nitrate, Uranyl bis(β-diketonates), Monodentate, Bridging bidentate, Coordination modes, 1527
Bidentate diamine
$Cu^{II}N_4Cl$ chromophores, Bidentate diimine, π–π Interactions, Hydrogen bonding, Magnetic property, 1961
Bidentate diimine
$Cu^{II}N_4Cl$ chromophores, Bidentate diamine, π–π Interactions, Hydrogen bonding, Magnetic property, 1961

Bidentate donors
2-Diphenylphosphinopicolinamide (dpppa 1), Coordination chemistry, Monodentate donors, 3211
Bidentate ligand
Dinuclear copper(II) complex, Magnetic properties, Crystal structure, UV–Vis, EPR and IR spectra, 1309
Bidentate NS Schiff base
S-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride), Tridentate NNS and NSS Schiff bases, Ni(II) complexes, Dithiocarbazate derivative, 161
Binuclear complexes
Nickel(II) compounds, Crystal structures, Terephthalate ligand, Magnetic properties, 1379
Binuclear compounds
Isocyanides, Nickel, Polymerisation, Ring-coupled bis-cyclopentadienyl ligand, X-ray molecular structure, 2715
Binuclear copper complex
EPR, Half-field, Superhyperfine, X-ray, Electrochemical, 1115
Binuclear ruthenium complexes
Mixed valent Ru(II)/Ru(III) complexes, Catalysis, Imine hydrogenation, 3163
Bioactivity
1,3,4-thiadiazole, Zinc, Crystal structure, Thermal decomposition, Kinetics, 1851
Biphase catalysis
Hydroformylation, Ionic liquids, High-pressure NMR, Rhodium complexes, 2679
Bipodal ligands
P,*S*-metallocycles, Supramolecular chemistry, Crystal structures, Macrocycles, Phosphorylated urea complexes, 2243
Bipyridine
Titanium, Aluminum, Coordination compound, Crystal structure, 561
Bipyridine
Distortions, 2081
2,2′-Bipyridine
Hydrazones, Copper(II) hydrazonate complexes, 1,10- Phenanthroline, X-ray single crystal structure, EPR, 575
2,2′-Bipyrimidine complexes
Iron(III) carboxylate complexes, Oxo-bridged iron(III) complexes, π–π stacking interactions, X-ray crystal structure, 1271
4,4′-Bipyridine
Lead(II), Coordination polymers, Lone pair, π–π staking interaction, Crystal structure, 2427
4,4′-Bipyridyl
Diorganotin, Dicyanoethylene-1,2-dithiolate, 1,10-Phenanthroline, X-ray crystal structure, Co-crystallization, 1207
Bis(2-pyridylmethyl)amine
Iron(II) complexes, Cobalt(II) complexes, X-ray crystal structures, Tris(2-pyridylmethyl)amine, 3105
Bis(2-pyridylmethyl)amino acids
Self-assembly, Crystal structures, Ferromagnetism, One-dimensional chains, Copper(II) complexes, 903
Bis(8-quinolinyl)amine
Cobalt, Copper, Zinc, Structures, 831
Bis(diphenylphosphino)methane dioxide
Uranyl nitrate, Uranyl bis(β-diketonates), Monodentate, Bidentate chelate, Bridging bidentate, Coordination modes, 1527
Bis(ethylenedithio)tetrathiafulvalene (ET)
Radical salts, Crystal structures, Electrical conductivity, 1185
Bis(imidazol-2-yl)methane
Bis-imidazole, X-ray structures, Silver(I), Argentophilicity, Anti-fungal, Candida albicans, 1249
Bis(imido)
Tris(pyrazolyl)borate, Molybdenum, Synthesis, Structures, 189
Bis(mercaptoimidazolyl)borate complexes
Nickel, Tris(mercaptoimidazolyl)borate complexes, Diphosphine, Hydrogenases, Crystal structure, 395
Bis(mercaptoimidazolyl)borate complexes
Thallium, Crystal structure, 617
Bis(methoxycarbimido)amine
MP2 geometry optimization, Topological analysis of electron density, 2235
Bis(triazole) ligand
Cadmium complex, Crystal structure, Anion role, 3133
Bis-(2-pyridylmethyl)amine
Iron, (μ-O)di-iron complex, Oxalato, Hydrogen bonding, Mössbauer spectra, 1419
Bis-imidazole
Bis(imidazol-2-yl)methane, X-ray structures, Silver(I), Argentophilicity, Anti-fungal, Candida albicans, 1249
Bis-imidazole
Metal complexes, X-ray structures, Manganese(II), Copper(II), Zinc(II), 1731
Bis[monochloro(μ-*N*-salicylidenemyristoylhydrazine) ONO′(−1)]dicopper(II)
N-salicylidene-*n*-alkanoylhydrazines, Copper(II) complexes, Magnetochemical studies, X-ray crystal and molecular structure, 23
Bis[tris(pyrazolyl)methane] complexes
Electron-transfer reactions, Spin-exchange reactions, Low-spin configurations, High-spin configurations, 1037
1,3-Bis(4-pyridyl)propane
Zinc, 4,4′-Pyridine, Polymeric network, X-ray crystallography, 999
2,3-Bis(α-pyridyl)pyrazine
Ruthenium, Cyclopentadienyl, 1,3,5-Tris (pyridyl)-2,4,6-triazine, 2,3,5,6-Tetrakis (pyridyl)pyrazine, 1069
2,5-Bis(2-pyridyl)-1,3,4-thiadiazole
Zinc, Energy minimization, Crystal structures, Monomeric complexes, 1903
Bitopic heteroscorpionate ligand
Square planar silver complex, 291
Boat conformations
Iridium, Cyclometalated Ir(II) complexes, Pyrazolyl ancillary ligands, Luminescent, Electroluminescence, 419
Bond cleavage
Molybdenum complexes, Carbonyl complexes, Pentafluorophenyl, Oxidation, Reductive elimination, 1371
Bond valence
Ruthenium arene complexes, Pyrazole, Dimethylpyrazole, X-ray structure, 885
Bonding
Organometallics, Sandwich complex, Metallocene, Density functional theory, Orbital analysis, 2993
Borate complex
Azomethine H, Boric acid, Complexation, ^{11}B NMR, 955
Boric acid
Borate complex, Azomethine H, Complexation, ^{11}B NMR, 955
Borohydrides
Lanthanides, Neodymium, X-ray structures, Alkoxides, Pyrazolylborates, 253
Boron
Multiple-decker sandwich complex, Ferrocene, Lithium, Crystal structure, 2597
Boron
Zwitterions, Monoanionic ligands, Phosphines, Syntheses, Structures, 2901
Boron neutron capture therapy
closo-Dodecaborate, Hydroxy and acyl derivatives, Disubstituted functional derivatives, 2135
Bridging
Iron (III), Dinuclear, Carboxylate, Complexes, Mössbauer, 1869
Bridging
Ligand, Bidentate, X-ray, Phosphine, 2569
Bridging bidentate
Bis(diphenylphosphino)methane dioxide, Uranyl nitrate, Uranyl bis(β-diketonates), Monodentate, Bidentate chelate, Coordination modes, 1527
Bridging boryls
Rhodium hydrides, Catalyzed hydroborations, 2665
Bridging Tp ligands
κ^2-Tp ligands, Rhodium dicarbonyl complexes, Isomers, X-ray structure, 301
Bromotrimethylsilane
Lanthanide oxides, O-donor ligands, Complexes of lanthanide bromides, Crystal structure, Coordination number, 2293
Building block approach
Octamolybdate, Hydrothermal synthesis, Three-dimensional oxide, Organic–inorganic hybrid, Hartree–Fock calculations, 1145

^{59}Co NMR
Multidentate ligand, Cobalt(III), Sinambic, 2217
C–C coupling reactions
Rhodium, Acetylacetonato complexes, Pentachlorophenolato complexes, Carboxylato complexes, Diazoalkane complexes, 2645
C–H activation
Trispyrazolylborate, Rhodium, 413

C–H activation
Ruthenium, Scorpionate, Tris(pyrazolyl)-borate, Hydride, 439
C–H bond activation
Rhodium(III), Benzene activation, Aldehyde activation, 2943
Cadmium
Coordinate, Polymers, Ligands, Supramolecular, 1003
Cadmium
Thiosemicarbazone, 2-pyridineformamide, Crystal structure, Zinc, 2303
Cadmium
Xanthate, Diamine, Zinc, CdS, Nanoparticles, 2315
Cadmium complex
Zinc complex, 2-Oxo-1,3-dithiole-4,5-dithiolate, Synthesis, Crystal structure, Density functional calculation, 1701
Cadmium complex
Bis(triazole) ligand, Crystal structure, Anion role, 3133
Cadmium(II)
Calcium(II), Manganese(II), Synthesis, Crystal structures, Tetrazolate complexes, 1217
Cadmium(II)
Chloranilate anions, Phenanthroline, Square antiprism, Crystal structures, Chain polymers, 2587
Cadmium(II) complexes
Arylazoimidazoles, End-on and end-to-end bridging, X-ray structure, 1D chain, Sheet structure, 1669
Cadmium(II)thiocyanate
Polymer, Schiff base, Imidazole, Supramolecular synthon, 2045
Cage complexes
Rotational barriers, Polyphosphoxane, Cone angles, 125
Calcium phosphates
Hydroxyapatite, Complex, EDTA, Hydrothermal, Low temperature, 1897
Calcium(II)
Cadmium(II), Manganese(II), Synthesis, Crystal structures, Tetrazolate complexes, 1217
Calixarenes
Uranyl ion, Alkali metal ions, Homooxacalixarenes, Crystal structures, 649
Candida albicans
Bis-imidazole, Bis(imidazol-2-yl)methane, X-ray structures, Silver(I), Argentophilicity, Anti-fungal, 1249
Capsules
Sulfonatothiacalixarene, Diaza-Crown ether, Transition metal ions, Assembly, 1461
Capsules
Sulfonatothiacalixarene, Diaza-18-crown-6, Lanthanide ions, 2055
Carbene
Actinide, Lanthanide, Oxides, Uranium, 2689
Carbohydrate
Cobalt complex, Absorption spectra, Circular dichroism, Optical activity, 1341
Carbon allotropes
Polyynes, Carbyne, Dicyanopolyynes, Cyanopolyynes, Electric arc, Graphite, Liquid nitrogen, 1889
Carbon monoxide
Hydrocarboxylation, Oligomerization, Catalysis, Rhodium complexes, Ethylene, 1677
Carbonyl
Sodium, Copper, Tris(pyrazolyl)borate, Fluorinated, 273
Carbonyl
Parabanic acid, Iron, Cyclopentadienyl, Thallium, Gold (I) complex, Alkylation, 1441
Carbonyl complexes
Molybdenum complexes, Pentafluorophenyl, Oxidation, Bond cleavage, Reductive elimination, 1371
Carborane
Spectroscopy, DFT calculations, X-ray crystallography, 629
Carboxylate
Iron (III), Dinuclear, Complexes, Bridging, Mössbauer, 1869
Carboxylate
Coordination polymer, Double betaine, Hydrate, Hydrogen bonding, π–π Interaction, Silver nitrate, 2413
Carboxylate bridge
Cu(II)–Ln(III) complexes, Dipeptides, Hexanuclear cations, Crystal structures, Magnetic properties, 2253
Carboxylate bridges
Self-assemble, Copper complexes, Dipeptides, Alkaline earth metals, Magnetic properties, 2125
Carboxylates
Alkoxides, Enolates, β-Diketonates, Alkali metals, Alkaline earth metals, Cluster compounds, 1479
Carboxylates
Flexible, IX, Coordination polymer, Architecture, 3007
Carboxylato complexes
Rhodium, Acetylacetonato complexes, Pentachlorophenolato complexes, Diazoalkane complexes, C–C coupling reactions, 2645
Carbyne
Carbon allotropes, Polyynes, Dicyanopolyynes, Cyanopolyynes, Electric arc, Graphite, Liquid nitrogen, 1889
Catalysis
Ligand, X-ray structure, Complex, 693
Catalysis
Synthesis, Crystal structures, Indenyl ligand, Nickel complex, 1473
Catalysis
Hydrocarboxylation, Oligomerization, Rhodium complexes, Ethylene, Carbon monoxide, 1677
Catalysis
Mixed valent Ru(II)/Ru(III) complexes, Binuclear ruthenium complexes, Imine hydrogenation, 3163
Catalyst
Neutral palladium(II) complex, X-ray crystallography, Methylaluminoxane, Norbornene, Vinylic polymerizaition, 1619
Catalyst
Iron, Radical, Styrene, Polymerisation, 2921
Catalysts
Chiral, Schiff base, Copper, Cyclopropanation, Crystal structures, 3051
Catalytic enantioselective reduction
trans-1,2-Diaminocyclohexane, Crystal structure, Zinc complex, 2063
Catalytic study
Macrobicylic ligands, Compartmental, Copper(II) complexes, Electrochemistry, Antiferromagnetic interaction, 519
Catalyzed hydroborations
Rhodium hydrides, Bridging boryls, 2665
Catecholates
Aluminium(III), Salicylates, Complexation, Proton exchange, NMR, 2393
CdS
Xanthate, Diamine, Zinc, Cadmium, Nanoparticles, 2315
Cerium
Oxazolines, Chiral, Thermal decomposition, MOCVD, β-ketoesterates, 1467
Chain polymers
Cadmium(II), Chloranilate anions, Phenanthroline, Square antiprism, Crystal structures, 2587
Charge transfer
Ion pair complex, Hydrogen bonding network, Non-covalent interaction, Near-IR absorption, 1235
Charge transfer compounds
Tetrathiafulvalene, Copper(II), Electrical conductivity, 2111
Charge-transfer
Iridium, Luminescence, Terpyridine, Near infra-red, Intra-ligand charge transfer, 2769
Chelates
Alkali metals, Lithium, Phosphorus–carbon bond cleavage, O Ligands, 2499
Chelating phosphines
Iridium complexes, 2959
Chemical vapour deposition
Thermochromism, Thin films, Vanadium dioxide, 3087
Chiral
Cyclophosphazenes, Spirocyclic, X-ray structure, 979
Chiral
Cerium, Oxazolines, Thermal decomposition, MOCVD, β-ketoesterates, 1467
Chiral
Coordination polymers, Nicotinate, Open channel, Grid, 1947
Chiral
Schiff base, Copper, Cyclopropanation, Catalysts, Crystal structures, 3051
Chiral copper(II) complexes
Asymmetric oxidation, Schiff base, Sulfide, Seven-membered, 1131

Chirality
Scorpionate ligands, Tripod ligands, Prochirality, Menthone, 245
Chirality
Tetra-azamacrocycles, Template reaction, Pendent arm, Conformational isomers, 869
Chloranilate anions
Cadmium(II), Phenanthroline, Square antiprism, Crystal structures, Chain polymers, 2587
Chromium complexes
Phosphanylalkylcyclopentadienyl ligands, Polymerisation studies, 1393
Chromophores
Scorpionands, Copper(II), Macrocycles, Nickel(II), 373
β-Cis arrangements
Iron complexes, Acetate ligands, η^2-Coordination modes, Schiff bases, 963
Circular dichroism
Carbohydrate, Cobalt complex, Absorption spectra, Optical activity, 1341
Cluster
Uranium, Schiff base, Crystal structure, 623
Cluster
Pseudoephedrine, Nickel, Triangulo, Anion exchange, 1837
Cluster anions
EDAX analyses, Anisotropic approximation, Heterometal cluster complexes, 599
Cluster complexes
Fe(III) carboxylate chemistry, Magnetochemistry, Crystal structures, 2779
Cluster compound
Nickel(II), Lanthanides(III), Amino acid, Heptanuclear, 2265
Cluster compounds
Alkoxides, Enolates, β-Diketonates, Carboxylates, Alkali metals, Alkaline earth metals, 1479
Clusters
Phosphorus, Sulfur, Phosphorus sulfides, Laser ablation synthesis, TOF mass spectrometry, 1199
Clusters
Electron density distribution, Polarizability, Spherical potential well, Finite electric field, 1519
Clusters
Complexity, Nanochemistry, Polyoxomolybdates, 2381
Clusters
Crystal structures, Copper, Molybdenum, Tungsten, Nitrogen heterocycle ligands, Pyrazole, 3143
Co(II) and Ni(II) complexes
Isoorotic acid, Hydrothermal synthesis, Hydrogen bonds, Supramolecular frameworks, 2227
Co-crystallization
Diorganotin, Dicyanoethylene-1,2-dithiolate, 4,4′-Bipyridyl, 1,10-Phenanthroline, X-ray crystal structure, 1207
Cobalt
Oxide, β-diketonates, Adducts, Structures, MOCVDf, 735
Cobalt
Polyoxometalates, Hydrothermal synthesis, Crystal structure, Keggin, 773
Cobalt
Phthalocyanine, Zinc, Nickel, Naphthalene, 787
Cobalt
Copper, Zinc, Bis(8-quinolinyl)amine, Structures, 831
Cobalt
Porphyrazine, EPR, Naphthalene, Copper, Zinc, 1845
Cobalt complex
Carbohydrate, Absorption spectra, Circular dichroism, Optical activity, 1341
Cobalt complexes
Nitronyl nitroxide, Imino nitroxide, Amide, Manganese complexes, Copper complexes, 763
Cobalt(II) complex
Lawesson's Reagent, Thiophosphoryl compound, Sulfur-rich complex, Nickel(II) complex, 1799
Cobalt(II) complexes
Immobilization, Silica support, H_2O_2, 59
Cobalt(II) complexes
2-Methanolpyridine, 2,6-Dimethanolpyridine, 2-Ethanolpyridinium, Crystal structures, 841
Cobalt(II) complexes
Iron(II) complexes, X-ray crystal structures, Bis(2-pyridylmethyl)amine, Tris(2-pyridylmethyl)amine, 3105
Cobalt(III)
Semicarbazone, 2-Hydroxyacetophenone, NMR spectra, IR spectra, Electronic spectra, X- ray crystal structure, 41
Cobalt(III)
Aromatic aminoacidate, Non-covalent interactions, Octahedral inversion, Tetradentate ligands, NMR, 1749
Cobalt(III)
Multidentate ligand, Sinambic, ^{59}Co NMR, 2217
Cobalt(III) complex
Crystal structure, Thiazine, Nickel(II) complex, Pyridine, 1453
Cobalt(III) complexes
Synthesis, Spectroscopy, Pyrazolyl thiosemicarbazone, X-ray crystallography, 5
Cobalt(III) complexes
Ozone, X-ray crystal structure, Silver(II) complexes, Manganese(III) complexes, 2631
Cobaltocenium
Metallocene, Ferrocenium, Crystal structure, 2937
Compartmental
Macrobicylic ligands, Copper(II) complexes, Electrochemistry, Antiferromagnetic interaction, Catalytic study, 519
Complex
Ferrocene, Enaminone, Ligand, Copper, X-ray crystallography, 15
Complex
Ferrocene, Dithiocarbazate, Ligand, Tin, Crystal structure, 567
Complex
Ligand, Catalysis, X-ray structure, 693
Complex
Hydrazones, Lanthanide, X-ray, Spectroscopy, Crystal structures, 1191
Complex
Crystal structure, Molecular assembly, 1,3-Dithiole-2-thione, 1447
Complex
Ferrocene, Enaminone, Ligand, Copper, X-ray crystallography, 1541
Complex
Hydroxyapatite, EDTA, Hydrothermal, Low temperature, Calcium phosphates, 1897
Complex formation
Uranium, Glycerol phosphate, Potentiometric titration, TRLFS, 1793
Complex formation constants
Dawson lacunary heteropolyanion, Lanthanides, Arsenazo III, 1579
Complexation
Borate complex, Azomethine H, Boric acid, ^{11}B NMR, 955
Complexation
Aluminium(III), Catecholates, Salicylates, Proton exchange, NMR, 2393
Complexation
Absorption spectra, Kinetics, Photochromism, Spiroindolinonaphthooxazines, 3147
Complexation
Terpyridine, Pyridyl bispyrazolyl, Iron, Rearrangement, X-ray structures, 3193
Complexes
Ferrocene, Enaminone, Ligands, X-ray crystallography, 749
Complexes
Iron (III), Dinuclear, Carboxylate, Bridging, Mössbauer, 1869
Complexes
Palladium, Selenium, X-ray, 2967
Complexes of lanthanide bromides
Lanthanide oxides, Bromotrimethylsilane, O-donor ligands, Crystal structure, Coordination number, 2293
Complexity
Clusters, Nanochemistry, Polyoxomolybdates, 2381
Cone angles
Rotational barriers, Polyphosphoxane, Cage complexes, 125
Conformational isomers
Chirality, Tetra-azamacrocycles, Template reaction, Pendent arm, 869
Coordinate
Cadmium, Polymers, Ligands, Supramolecular, 1003
Coordination
Phosphine, Synthesis, X-ray structure, 2575

Coordination chemistry
Scorpionates, Polypyrazolylborates, Nitrogen ligands, 197
Coordination chemistry
S ligands, Aurates, Thianthrenes, 1351
Coordination chemistry
2-Diphenylphosphinopicolinamide (dpppa 1), Monodentate donors, Bidentate donors, 3211
Coordination complex
X-ray structure, Diimine, Zinc, Palladium, 2789
Coordination compound
Bipyridine, Titanium, Aluminum, Crystal structure, 561
Coordination environment
Nickel(II) complexes, Crystal structures, Hydrotris(pyrazolyl)borate complexes, Scorpionates, 211
Coordination framework
Copper, 4,7-Phenanthroline, Host–guest properties, Polymers, Extended structures, 55
Coordination geometry
Nickel, Schiff's bases, Hydrogenated Schiff's bases, X-ray crystal structures, Polymethylene chains, 3201
Coordination modes
Bis(diphenylphosphino)methane dioxide, Uranyl nitrate, Uranyl bis(β-diketonates), Monodentate, Bidentate chelate, Bridging bidentate, 1527
η^2-Coordination modes
Iron complexes, Acetate ligands, Schiff bases, β-Cis arrangements, 963
Coordination number
Lanthanide oxides, Bromotrimethylsilane, O-donor ligands, Complexes of lanthanide bromides, Crystal structure, 2293
Coordination polymer
Lanthanide nitrate, N,N′-dioxide, Self-assembly, 169
Coordination polymer
Crystal structure, Hydrogen bonds, Copper(II), 553
Coordination polymer
Europium, Hydrogen bonds, Luminescence, Supramolecular, Terbium, 711
Coordination polymer
Lanthanum trifluoromethanesulfonate, Isonicotinic acid, N-oxide, Mixed ligands, 857
Coordination polymer
Manganese maleate, Temperature effect, Helical architecture, Hydrogen bonds, π–π interactions, 987
Coordination polymer
Copper, *N*-ligands, Thioethers, Multi-armed ligands, X-ray structures, 1055
Coordination polymer
Hydrothermal synthesis, Magnetic property, Transition metal, Square grid structure, 1,4-Naphthalenedicarboxylic acid, 1257
Coordination polymer
Lead, Hydrothermal synthesis, X-ray structure determination, 2161
Coordination polymer
Carboxylate, Double betaine, Hydrate, Hydrogen bonding, π–π Interaction, Silver nitrate, 2413
Coordination polymer
Flexible, Carboxylates, IX, Architecture, 3007
Coordination polymer
Copper(II) complex, Schiff base, X-ray structure, Imine activation, 3081
Coordination Polymers
Polypyrazolylborate complexes, Copper complexes, Rhodium complexes, Scorpionates, Nitrile coordination, 235
Coordination polymers
Azides, Polyamines, Copper(II) complexes, Crystal structures, Magnetic properties, 1243
Coordination polymers
Chiral, Nicotinate, Open channel, Grid, 1947
Coordination polymers
One-dimensional, Silver(I), Aliphatic amino ligands, Tubes, Topology, Supramolecular chemistry, Self assembly, Nanotubes, 2075
Coordination polymers
Copper(II) complex, Crystal structure, Magnetic properties, 2203
Coordination polymers
4,4′-Bipyridine, Lead(II), Lone pair, π–π staking interaction, Crystal structure, 2427
Coordination polymers
Silver, Imidazolate, X-ray structure, 3063
Copper
Ferrocene, Enaminone, Ligand, Complex, X-ray crystallography, 15
Copper
4,7-Phenanthroline, Coordination framework, Host–guest properties, Polymers, Extended structures, 55
Copper
Sodium, Tris(pyrazolyl)borate, Fluorinated, Carbonyl, 273
Copper
Tetrakis(3-isopropylpyrazolyl)borate, Solvent extraction, Single-crystal X-ray diffraction, Zinc, 283
Copper
Cobalt, Zinc, Bis(8-quinolinyl)amine, Structures, 831
Copper
Structure, Magnetism, Dinuclear, EPR, 993
Copper
N-ligands, Thioethers, Multi-armed ligands, X-ray structures, Coordination polymer, 1055
Copper
Crystal structure, Dimer, Spectral properties, Magnetic properties, 1303
Copper
Nickel, Zinc, Imidazole, α-Hydroxycarboxylato complexes, Thermal behaviour, Crystal structures, 1505
Copper
Ferrocene, Enaminone, Ligand, Complex, X-ray crystallography, 1541
Copper
Amino acid, Dendrimers, Electrochemistry, Electron spin resonance, Ligand, 1709
Copper
Self-assembly, N,O-ligands, Dinuclear, EPR, 1769
Copper
Porphyrazine, EPR, Naphthalene, Zinc, Cobalt, 1845
Copper
Structure, Infrared, Hydrogen bonds, Distortion isomers, 1969
Copper
3,5-Dinitrosalicylate complex, Trimer, Crystal structure, Magnetic properties, Spectral properties, 2447
Copper
Chiral, Schiff base, Cyclopropanation, Catalysts, Crystal structures, 3051
Copper
Crystal structures, Clusters, Molybdenum, Tungsten, Nitrogen heterocycle ligands, Pyrazole, 3143
Copper complexes
Polypyrazolylborate complexes, Rhodium complexes, Scorpionates, Coordination Polymers, Nitrile coordination, 235
Copper complexes
Crystal structures, Zinc complexes, Molecular rectangles, 673
Copper complexes
Nitronyl nitroxide, Imino nitroxide, Amide, Manganese complexes, Cobalt complexes, 763
Copper complexes
Schiff base complexes, Tripeptide complexes, 849
Copper complexes
Di-2-pyridylamine, Nitrito complexes, Plasticity effect, *cis*-Distorted octahedron, Fluxional behaviour, 1685
Copper complexes
Self-assemble, Carboxylate bridges, Dipeptides, Alkaline earth metals, Magnetic properties, 2125
Copper complexes
Lawsone, Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Antiferromagnetic coupling, H-bonding, EPR, 2541
Copper dimer
Magnetic properties, Antiferromagnetic dimer, Crystal structure, 1695
Copper dimers
Triazolopyrimidine, Zn complexes, EPR, 743
Copper(I) complexes
Tetrathiomolybdate, Tetrathiotungstate, Dihydridobis(pyrazolyl)borate, Crystal structure, Model compounds, 637
Copper(I) complexes
Hexafluorocetylacetonate, Olefin complexes, Divinyl organics, Crystal structure, Thermal analysis, 809

Copper(II)
Scorpionands, Chromophores, Macrocycles, Nickel(II), 373
Copper(II)
Coordination polymer, Crystal structure, Hydrogen bonds, 553
Copper(II)
Aminopolycarboxylate, Ferromagnetic coupling, π–π stacking, Cylindrical channels, 1081
Copper(II)
Bis-imidazole, Metal complexes, X-ray structures, Manganese(II), Zinc(II), 1731
Copper(II)
Tetrathiafulvalene, Charge transfer compounds, Electrical conductivity, 2109
Copper(II) complex
Crystal structure, Magnetic properties, Coordination polymers, 2203
Copper(II) complex
Pyridylthioazophenol ligands, Crystal structure, 2457
Copper(II) complex
Ascorbic oxidation, Crystal structure, Imidazole, 2515
Copper(II) complex
Schiff base, X-ray structure, Imine activation, Coordination polymer, 3081
Copper(II) complexes
N-salicylidene-*n*-alkanoylhydrazines, Magnetochemical studies, Bis[monochloro-(μ-*N*-salicylidenemyristoylhydrazine) ONO′(−1)]dicopper(II), X-ray crystal and molecular structure, 23
Copper(II) complexes
Macrobicylic ligands, Compartmental, Electrochemistry, Antiferromagnetic interaction, Catalytic study, 519
Copper(II) complexes
Self-assembly, Crystal structures, Bis(2-pyridylmethyl)amino acids, Ferromagnetism, One-dimensional chains, 903
Copper(II) complexes
Azides, Polyamines, Crystal structures, Magnetic properties, Coordination polymers, 1243
Copper(II) complexes
Crystal structure, Dihydroxo-bridged, Roof-shaped, Triply bridged, 1641
Copper(II) complexes
Thioether ligands, Stability constants, Monophosphono dipeptides, Potentiometry, Vis, CD, EPR spectroscopy, 1939
Copper(II) complexes
Dithiocarbazates, Saccharin complexes, 2031
Copper(II) complexes
Pyrazolone, Crystal structures, ESR study, 2465
Copper(II) complexes
Thiosemicarbazone, 2-Hydroxyacetophenone, EPR, Antimicrobial studies, Cyclic voltammetry, X-ray crystallography, 2549
Copper(II) complexes
2-Benzoylpyridine, Thiosemicarbazone, EPR, Antimicrobial activity, Crystal structure, 3069
Copper(II) compounds
Crystal structures, Terephthalate ligand, One-dimensional complexes, Magnetic properties, 3043
Copper(II) hydrazonate complexes
Hydrazones, 1,10- Phenanthroline, 2,2′-Bipyridine, X-ray single crystal structure, EPR, 575
Copper(III)
Imine-oxime ligand, Diols, Kinetics, Mechanism, Electron transfer, 583
CPMAS
Pyrazolylborates, Thallium, NMR, 2985
Crown ether
Ion recognition, Schiff base complexes, UV–Vis, Lanthanides, 1401
Crown ether
Phthalocyanine, Metallo phthalocyanine, Liquid crystal, Metallo mesogen, Aza ether, 1931
Crown thioethers
Thioether complexes, Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Diimine complexes, 1361
Cryptate
Lanthanide, Crystal structure, ES-MS, 49
Crystal engineering
Zinc(II)azide, Mononuclear, Dinuclear, 2,2′-Dipyridylamine, Luminescence, 545
Crystal engineering
Supramolecular chemistry, Self-assembly, Polymers, Transition metal, 1877
Crystal structure
Gold complex, Selenourea, MAS NMR, 1
Crystal structure
Lanthanide, Cryptate, ES-MS, 49
Crystal structure
Hypodentate, Tripodal amine ligand, Cu(II) complexes, Five-coordinate, 97
Crystal structure
Nickel, Bis(mercaptoimidazolyl)borate complexes, Tris(mercaptoimidazolyl)borate complexes, Diphosphine, Hydrogenases, 395
Crystal structure
Ionic complex, Rheological phase reaction, Photoluminescence, Europium, Zinc, 529
Crystal structure
Coordination polymer, Hydrogen bonds, Copper(II), 553
Crystal structure
Bipyridine, Titanium, Aluminum, Coordination compound, 561
Crystal structure
Ferrocene, Dithiocarbazate, Ligand, Complex, Tin, 567
Crystal structure
Thallium, Bis(mercaptoimidazolyl)borate complexes, 617
Crystal structure
Uranium, Schiff base, Cluster, 623
Crystal structure
Tetrathiomolybdate, Tetrathiotungstate, Dihydridobis(pyrazolyl)borate, Copper(I) complexes, Model compounds, 637
Crystal structure
Tricopper(II) complex, Schiff bases, Ascorbate oxidase model, Magnetic properties, 643
Crystal structure
Vanadium(V) peroxo mandelato complex, IR spectra, ^{51}V NMR spectra, 655
Crystal structure
Polyoxometalates, Hydrothermal synthesis, Keggin, Cobalt, 773
Crystal structure
2-Mercapto-6-nitrobenzothiazole, Organotin(IV), Non-bonded interaction, X-ray crystallography diffraction, 779
Crystal structure
Copper(I) complexes, Hexafluorocetylacetonate, Olefin complexes, Divinyl organics, Thermal analysis, 809
Crystal structure
Dimeric complex, Manganese(III), Ferromagnetic behaviour, 949
Crystal structure
Back-bonding, Ruthenium complex, NO, Reactivity, Molecular, 1063
Crystal structure
Tetrahydrofurfurylindenyl, Lanthanide chlorides, Ionic radius, 1075
Crystal structure
Mn(II) complex, Isonicotinic acid, N-oxide, Luminescence, 1109
Crystal structure
Rhenium, Benzimidazole, Bibenzimidazole, Paramagnetic NMR, 1139
Crystal structure
Platinum, Palladium, Phosphorus–nitrogen donor, 1159
Crystal structure
Copper, Dimer, Spectral properties, Magnetic properties, 1303
Crystal structure
Dinuclear copper(II) complex, Magnetic properties, Bidentate ligand, UV–Vis, EPR and IR spectra, 1309
Crystal structure
Molecular assembly, 1,3-Dithiole-2-thione, Complex, 1447
Crystal structure
Thiazine, Cobalt(III) complex, Nickel(II) complex, Pyridine, 1453
Crystal structure
Phase transition, Isotope effect, Hydrogen bond, NQR, Tetrachloroaurate(III), 1605
Crystal structure
Copper(II) complexes, Dihydroxo-bridged, Roof-shaped, Triply bridged, 1641
Crystal structure
Ph_2Te_2, Metal–metal bond, Molybdenum complex, Mo_2Te_4 complex, 1663
Crystal structure
Copper dimer, Magnetic properties, Antiferromagnetic dimer, 1695
Crystal structure
Zinc complex, Cadmium complex, 2-Oxo-1,3-dithiole-4,5-dithiolate, Synthesis, Density functional calculation, 1701

Crystal structure
2-Thiopheneacetic acid, Polymeric copper(II) complex, Vibrational spectra, Metal isotope effect, 1785
Crystal structure
Heteroaromatic carboxylic acid, Triphenyltin, Synthesis, 1805
Crystal structure
1,3,4-thiadiazole, Zinc, Thermal decomposition, Kinetics, Bioactivity, 1851
Crystal structure
1H-5-mercapto-1,2,3-triazolato, Organotin, Organogermanium(IV), X-ray crystallography, 1981
Crystal structure
trans-1,2-Diaminocyclohexane, Zinc complex, Catalytic enantioselective reduction, 2063
Crystal structure
Iron, Spin-crossover, Magnetic measurements, 2141
Crystal structure
Transformation, Molybdenum phosphate, Hydrothermal synthesis, 2153
Crystal structure
Dicopper(II) complex, 1D Coordination polymer, Magnetic properties, Schiff base, 2177
Crystal structure
Copper(II) complex, Magnetic properties, Coordination polymers, 2203
Crystal structure
Uranium, N, O donor ligands, 2285
Crystal structure
Lanthanide oxides, Bromotrimethylsilane, O-donor ligands, Complexes of lanthanide bromides, Coordination number, 2293
Crystal structure
Thiosemicarbazone, 2-pyridineformamide, Zinc, Cadmium, 2303
Crystal structure
Nickel(II) complexes, MagnetismPseudohalides,, 2337
Crystal structure
Hydrothermal synthesis, Iron phosphatooxalate, Template, Oxalate acid, Piperazine, 2357
Crystal structure
Manganese, Hydrogen bond, Magnetism, EPR, 2387
Crystal structure
4,4′-Bipyridine, Lead(II), Coordination polymers, Lone pair, π–π staking interaction, 2427
Crystal structure
Copper, 3,5-Dinitrosalicylate complex, Trimer, Magnetic properties, Spectral properties, 2447
Crystal structure
Copper(II) complex, Pyridylthioazophenol ligands, 2457
Crystal structure
Copper(II) complex, Ascorbic oxidation, Imidazole, 2515
Crystal structure
Multiple-decker sandwich complex, Ferrocene, Boron, Lithium, 2597
Crystal structure
Metallocene, Ferrocenium, Cobaltocenium, 2937
Crystal structure
Copper(II) complexes, 2-Benzoylpyridine, Thiosemicarbazone, EPR, Antimicrobial activity, 3069
Crystal structure
Cadmium complex, Bis(triazole) ligand, Anion role, 3133
Crystal structure of Cd(II) complex
S-methyldithiocarbazate (SMDTC), NS Schiff base, Dithiocarbazate derivatives, 1385
Crystal structures
Manganese(II) carboxylate chemistry, Magnetochemistry, Metal-assisted reactions, 2-Pyridinealdoxime complexes, 83
Crystal structures
Nickel(II) complexes, Hydrotris(pyrazolyl)borate complexes, Coordination environment, Scorpionates, 211
Crystal Structures
Lanthanides, Ytterbium, Aryloxide, Tris(pyrazolyl)borate, Divalent, 263
Crystal structures
Titanium iodide, Phosphine, Arsine, Iron iodide, 605
Crystal structures
Uranyl ion, Alkali metal ions, Calixarenes, Homooxacalixarenes, 649
Crystal structures
Copper complexes, Zinc complexes, Molecular rectangles, 673
Crystal structures
Antimony, Ferrocenylcarboxylate, Antitumor activity, 823
Crystal structures
2-Methanolpyridine, 2,6-Dimethanolpyridine, 2-Ethanolpyridinium, Cobalt(II) complexes, 841
Crystal structures
Manganese(II) hexafluoroacetylacetonate, 4-cyanopyridine-N-oxide, Magnetic properties, Ferromagnetic interactions, 879
Crystal structures
Self-assembly, Bis(2-pyridylmethyl)amino acids, Ferromagnetism, One-dimensional chains, Copper(II) complexes, 903
Crystal structures
Solvothermal synthesis, Thiostannates, Nickel, Thermoanalysis, 937
Crystal structures
Rhenium(I), Phosphinite ligands, Dichloromethane complexes, 1045
Crystal structures
Dithiocarbimates, Platinum complexes, 1153
Crystal structures
Radical salts, Bis(ethylenedithio)tetrathiafulvalene (ET), Electrical conductivity, 1185
Crystal structures
Hydrazones, Complex, Lanthanide, X-ray, Spectroscopy, 1191
Crystal structures
Cadmium(II), Calcium(II), Manganese(II), Synthesis, Tetrazolate complexes, 1217
Crystal structures
Azides, Polyamines, Copper(II) complexes, Magnetic properties, Coordination polymers, 1243
Crystal structures
Zinc complexes, Schiff-bases, IR, UV and NMR spectroscopy, Thermal analysis, 1293
Crystal structures
Nickel(II) compounds, Terephthalate ligand, Binuclear complexes, Magnetic properties, 1379
Crystal structures
Manganese, Pheylcyanamide, Magnetic properties, 1409
Crystal structures
Synthesis, Indenyl ligand, Nickel complex, Catalysis, 1473
Crystal structures
Nickel, Copper, Zinc, Imidazole, α-Hydroxycarboxylato complexes, Thermal behaviour, 1505
Crystal structures
Hydrothermal syntheses, Gallophosphates, Templating effect, 1535
Crystal structures
1-(4-Hydroxyphenyl)-1H-tetrazole-5-thiol, Organotin(IV), Hydrogen bonding, π–π stacking interaction, X-ray crystallography, 1547
Crystal structures
Uranyl ions, Diols, Hydrogen bonding, 1613
Crystal structures
2,5-Bis(2-pyridyl)-1,3,4-thiadiazole, Zinc, Energy minimization, Monomeric complexes, 1903
Crystal structures
Indomethacin, Diorganotin, Spectroscopic studies, 2021
Crystal structures
Alkaline earth metal complexes, 2183
Crystal structures
Iron(II) complexes, Trithiocyanuric acid, Mössbauer spectra, Spectroscopic properties, DFT calculations, 2193
Crystal structures
P,*S*-metallocycles, Supramolecular chemistry, Bipodal ligands, Macrocycles, Phosphorylated urea complexes, 2243
Crystal structures
Cu(II)–Ln(III) complexes, Dipeptides, Carboxylate bridge, Hexanuclear cations, Magnetic properties, 2253
Crystal structures
Diaza-fluorene, Silver complexes, Intermolecular interactions, Electronic spectra, 2259
Crystal structures
2-[(*E*)-2-(aryl)-1-diazenyl]pyridine, Hg(II) complexes, NMR, 2323
Crystal structures
Tris(cyclohexyl)tin, Halostannanes, 2331

Crystal structures
Pyrazolone, Copper(II) complexes, ESR study, 2465
Crystal structures
Cadmium(II), Chloranilate anions, Phenanthroline, Square antiprism, Chain polymers, 2587
Crystal structures
Fe(III) carboxylate chemistry, Magnetochemistry, Cluster complexes, 2779
Crystal structures
Copper(II) compounds, Terephthalate ligand, One-dimensional complexes, Magnetic properties, 3043
Crystal structures
Chiral, Schiff base, Copper, Cyclopropanation, Catalysts, 3051
Crystal structures
Clusters, Copper, Molybdenum, Tungsten, Nitrogen heterocycle ligands, Pyrazole, 3143
Crystalline structure
Cu-NIRs, Model complex, Tripodal ligand, Polyimidazole ligand, 511
Cu(II) complexes
Hypodentate, Tripodal amine ligand, Crystal structure, Five-coordinate, 97
Cu(II) complexes
Herometallacrown, Malonate, *o*-Pthalate, 943
Cu(II) complexes
Dithiocarbazate Schiff base, Saccharin complexes, *S*-Methyldithiocarbazate, Tridentate NNS Schiff base, 2491
Cu(II)–Ln(III) complexes
Dipeptides, Carboxylate bridge, Hexanuclear cations, Crystal structures, Magnetic properties, 2253
Cu-NIRs
Model complex, Crystalline structure, Tripodal ligand, Polyimidazole ligand, 511
$Cu^{II}N_4Cl$ chromophores
Bidentate diimine, Bidentate diamine, π–π Interactions, Hydrogen bonding, Magnetic property, 1961
Cyanide bridged clusters
Iron(III) complex, Tris(pyrazolyl)borate, Magnetic properties, 1333
Cyanopolyynes
Carbon allotropes, Polyynes, Carbyne, Dicyanopolyynes, Electric arc, Graphite, Liquid nitrogen, 1889
4-cyanopyridine-*N*-oxide
Manganese(II) hexafluoroacetylacetonate, Crystal structures, Magnetic properties, Ferromagnetic interactions, 879
Cyclic telluranes
Metathetical reactions, Intermolecular, Secondary bonding, Supramolecular networks, 1629
Cyclic voltammetry
Macrocyclic complexes, X-ray crystallography, Imidazole, 1317
Cyclic voltammetry
Nickel complex, Tripodal ligand, 1829
Cyclic voltammetry
Copper(II) complexes, Thiosemicarbazone, 2-Hydroxyacetophenone, EPR, Antimicrobial studies, X-ray crystallography, 2549
Cyclic voltammetry
Non-heme iron, Water coordination, X-ray structure, Sterically hindered carboxylate, 2805
Cyclic voltammetry
Phthalocyanine, Unsymmetrical, Phenylacetylene, 3155
Cycloaddition
Titanium, Tin, Tetrazole, Nitride precursor, 801
Cyclometalated Ir(II) complexes
Iridium, Pyrazolyl ancillary ligands, Boat conformations, Luminescent, Electroluminescence, 419
Cyclooctadiene
Polypyrazolylborate, Rhodium(I), Norbornadiene, Structure, NMR, 219
Cyclopentadienyl
Ruthenium, 2,3-Bis(α-pyridyl)pyrazine, 1,3,5-Tris(pyridyl)-2,4,6-triazine, 2,3,5,6-Tetrakis(pyridyl)pyrazine, 1069
Cyclopentadienyl
Indenyl, Phosphino, Phosphido, Molybdenum, Metallocenes, 1263
Cyclopentadienyl
Parabanic acid, Iron, Carbonyl, Thallium, Gold (I) complex, Alkylation, 1441
Cyclopentadienyl
Schiff bases, Pyridine-2-carboxaldehyde, Ruthenium, 1567
Cyclophosphazene
Dendrimers, Metal–nitrile complexes, Iron complexes, 1027
Cyclophosphazenes
Chiral, Spirocyclic, X-ray structure, 979
Cyclopropanation
Chiral, Schiff base, Copper, Catalysts, Crystal structures, 3051
Cylindrical channels
Copper(II), Aminopolycarboxylate, Ferromagnetic coupling, π–π stacking, 1081
Cymene
Ruthenium, X-ray, 2695
p-Cymene
Hexamethylbenzene, Diphenyl-2-pyridylphosphine, Amines, Ruthenium complexes, 3115
Cytotoxicity
Pyridinecarboxaldimine, Platinum, Palladium, Fluorine, 2169

2D antiferromagnets
Malonate complexes, Weak ferromagnetism, 929
1D, 2D, 3D topological structure
Silver coordination complex polymers, Multi-nitriles, 2209
Dawson lacunary heteropolyanion
Complex formation constants, Lanthanides, Arsenazo III, 1579
Decaazacyclooctadecane
Template synthesis, Nickel(II) complexes, Macrocycle, 1325
Dendrimers
Cyclophosphazene, Metal–nitrile complexes, Iron complexes, 1027
Dendrimers
Amino acid, Copper, Electrochemistry, Electron spin resonance, Ligand, 1709
Density functional calculation
Zinc complex, Cadmium complex, 2-Oxo-1,3-dithiole-4,5-dithiolate, Synthesis, Crystal structure, 1701
Density functional theory
Organometallics, Sandwich complex, Metallocene, Bonding, Orbital analysis, 2993
Density functional theory calculations
Rhenium nitrosyl complexes, Pyrazole, Arsine ligands, X–ray structure, 2523
1D chain
Arylazoimidazoles, Cadmium(II) complexes, End-on and end-to-end bridging, X-ray structure, Sheet structure, 1669
1D Coordination polymer
Dicopper(II) complex, Crystal structure, Magnetic properties, Schiff base, 2177
DFT calculations
Carborane, Spectroscopy, X-ray crystallography, 629
DFT calculations
Rhenium complexes, Pyrazole ligand, X-ray structure, 1819
DFT calculations
Rhenium complexes, Pyrazole ligand, X-ray structure, 2005
DFT calculations
Iron(II) complexes, Trithiocyanuric acid, Mössbauer spectra, Crystal structures, Spectroscopic properties, 2193
DFT calculations
Rhenium, Nitrosyls, Phosphine complexes, 2363
DFT calculations
^{15}N solid state NMR, Molybdenum nitride, Imido complexes, Lewis acids, 2751
(μ-O)di-iron complex
Iron, Bis-(2-pyridylmethyl)amine, Oxalato, Hydrogen bonding, Mössbauer spectra, 1419
Di-2-pyridyl ketone
Thiosemicarbazone, Ni(II) thiosemicarbazone complex, Electronic spectra, IR spectra, X-ray crystal structure, 1225
Di-2-pyridyl ketone salicyloylhydrazone
Zinc(II) complexes, Stability constants, Spectroscopy, Thermal analysis, 2095
Di-2-pyridylamine
Copper complexes, Nitrito complexes, Plasticity effect, *cis*-Distorted octahedron, Fluxional behaviour, 1685
2,6-diacetylpyridine Schiff bases of S-alkyldithiocarbazates
Tin(IV) complexes, Dithiocarbazates, Seven-coordinate tin(IV) complexes, 2037

Diamine
Xanthate, Zinc, Cadmium, CdS, Nanoparticles, 2315
Diaza-18-crown-6
Sulfonatothiacalixarene, Capsules, Lanthanide ions, 2055
Diaza-Crown ether
Sulfonatothiacalixarene, Capsules, Transition metal ions, Assembly, 1461
Diaza-fluorene
Silver complexes, Crystal structures, Intermolecular interactions, Electronic spectra, 2259
Diazoalkane complexes
Rhodium, Acetylacetonato complexes, Pentachlorophenolato complexes, Carboxylato complexes, C–C coupling reactions, 2645
Dichloromethane complexes
Rhenium(I), Phosphinite ligands, Crystal structures, 1045
Dicopper(II) complex
1D Coordination polymer, Crystal structure, Magnetic properties, Schiff base, 2177
Dicyanoethylene-1,2-dithiolate
Diorganotin, 4,4′-Bipyridyl, 1,10-Phenanthroline, X-ray crystal structure, Co-crystallization, 1207
Dicyanopolyynes
Carbon allotropes, Polyynes, Carbyne, Cyanopolyynes, Electric arc, Graphite, Liquid nitrogen, 1889
Diethylenetriamine
Ruthenium(II) complexes, Polypyridine ligands, 815
Differential pulse voltammetry
Electropolymerisation, Ru-complexes, Thiophene, 4-((2-Thienyl)-ethenyl)-2,2′-bipyridine, Redox-polymers, 589
Dihydridobis(pyrazolyl)borate
Tetrathiomolybdate, Tetrathiotungstate, Copper(I) complexes, Crystal structure, Model compounds, 637
Dihydroxo-bridged
Copper(II) complexes, Crystal structure, Roof-shaped, Triply bridged, 1641
Diimine
X-ray structure, Coordination complex, Zinc, Palladium, 2789
Diimine complexes
Thioether complexes, Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Crown thioethers, 1361
Diiminediaminediphenolate macrocycle
Vanadium, Magnetochemistry, EPR, FTIR, Spectroelectrochemistry, 2069
Diketiminato
Lanthanides, Yttrium, 183
β-diketonates
Cobalt, Oxide, Adducts, Structures, MOCVD, 735
β-Diketonates
Alkoxides, Enolates, Carboxylates, Alkali metals, Alkaline earth metals, Cluster compounds, 1479
2,6-Dimethanolpyridine
2-Methanolpyridine, 2-Ethanolpyridinium, Cobalt(II) complexes, Crystal structures, 841
Dimer
Copper, Crystal structure, Spectral properties, Magnetic properties, 1303
Dimer
Manganese(III), N,O ligands, X-ray structure, Magnetochemistry, Azide, 1811
Dimeric complex
Manganese(III), Crystal structure, Ferromagnetic behaviour, 949
Dimerization
η^2-nitrile, Tungsten, Oxo, Oxidation, Methylation, 2831
Dimethylpyrazole
Ruthenium arene complexes, Pyrazole, X-ray structure, Bond valence, 885
3,5-Dinitrosalicylate complex
Copper, Trimer, Crystal structure, Magnetic properties, Spectral properties, 2447
Dinuclear
Zinc(II)azide, Mononuclear, 2,2′-Dipyridylamine, Luminescence, Crystal engineering, 545
Dinuclear
Copper, Structure, Magnetism, EPR, 993
Dinuclear
Self-assembly, Copper, N,O-ligands, EPR, 1769
Dinuclear
Iron (III), Carboxylate, Complexes, Bridging, Mössbauer, 1869
Dinuclear complex
Silver(I) complexes, Mononuclear complex, 2117
Dinuclear copper(II) complex
Magnetic properties, Bidentate ligand, Crystal structure, UV–Vis, EPR and IR spectra, 1309
Dinuclear peroxovanadate
Peroxo-bridged divanadate, Peroxidative bromination, Heteroligand peroxovanadate, Amino acid containing peroxovanadates, 1097
Diols
Copper(III), Imine-oxime ligand, Kinetics, Mechanism, Electron transfer, 583
Diols
Uranyl ions, Hydrogen bonding, Crystal structures, 1613
Diorganostannate
Methanesulfonate, Ionic metathesis, Organotin oxide, 71
Diorganotin
Dicyanoethylene-1,2-dithiolate, 4,4′-Bipyridyl, 1,10-Phenanthroline, X-ray crystal structure, Co-crystallization, 1207
Diorganotin
Indomethacin, Crystal structures, Spectroscopic studies, 2021
N,*N*′-dioxide
Lanthanide nitrate, Self-assembly, Coordination polymer, 169
Vic-dioximes
Thiazolidine, Ferrocene, Transition metal complexes, Electrochemistry, 1987
Dioxomolybdenum (VI) and oxomolybdenum (IV) complexes
Dithiocarbazate, Schiff bases, X-ray structures, 1595
Dioxomolybdenum(VI) thionates
Oxotransfer catalysts, 537
Dioxygen
Osmium, Aniline, Oxidation, Electron transfer self-exchange, 323
Dipeptides
Self-assemble, Carboxylate bridges, Copper complexes, Alkaline earth metals, Magnetic properties, 2125
Dipeptides
Cu(II)–Ln(III) complexes, Carboxylate bridge, Hexanuclear cations, Crystal structures, Magnetic properties, 2253
2-Diphenylphosphinopicolinamide (dpppa 1)
Coordination chemistry, Monodentate donors, Bidentate donors, 3211
Diphenyl-2-pyridylphosphine
Hexamethylbenzene, *p*-Cymene, Amines, Ruthenium complexes, 3115
Diphosphine
Nickel, Bis(mercaptoimidazolyl)borate complexes, Tris(mercaptoimidazolyl)borate complexes, Hydrogenases, Crystal structure, 395
Diporphyrins
Zinc(II) complexes, Nitrogen base ligation, Stability constants, 33
2,2′-Dipyridylamine
Zinc(II)azide, Mononuclear, Dinuclear, Luminescence, Crystal engineering, 545
Diruthenium compounds
Metal–metal bonds, Triazenido complexes, Formamidinato complexes, Multiple bonds, Low spin complexes, 2637
Diruthenium(II)
Rhodium(III) Ruthenium(II), Heterodinuclear complexes, Polypyridine complexes, Electrochemistry, 913
Dispersion processing
Magnesium carboxylate, Meltable, Thermal properties, 1739
cis-Distorted octahedron
Copper complexes, Di-2-pyridylamine, Nitrito complexes, Plasticity effect, Fluxional behaviour, 1685
Distortion isomers
Copper, Structure, Infrared, Hydrogen bonds, 1969
Distortions
Bipyridine, 2081
Disubstituted functional derivatives
closo-Dodecaborate, Hydroxy and acyl derivatives, Boron neutron capture therapy, 2135
Dithiocarbamate
Nickel, PPh_3, Dppe, X-ray crystal structure, NMR, 77
Dithiocarbazate
Ferrocene, Ligand, Complex, Tin, Crystal structure, 567

Dithiocarbazate
Dioxomolybdenum (VI) and oxomolybdenum (IV) complexes, Schiff bases, X-ray structures, 1595
Dithiocarbazate derivative
S-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride), Bidentate NS Schiff base, Tridentate NNS and NSS Schiff bases, Ni(II) complexes, 161
Dithiocarbazate derivatives
S-methyldithiocarbazate (SMDTC), NS Schiff base, Crystal structure of Cd(II) complex, 1385
Dithiocarbazate Schiff base
Cu(II) complexes, Saccharin complexes, *S*-Methyldithiocarbazate, Tridentate NNS Schiff base, 2491
Dithiocarbazates
Copper(II) complexes, Saccharin complexes, 2031
Dithiocarbazates
Tin(IV) complexes, 2,6-diacetylpyridine Schiff bases of S-alkyldithiocarbazates, Seven-coordinate tin(IV) complexes, 2037
Dithiocarbazates
Tin(IV) complexes, 2-Quinolinecarboxaldehyde Schiff bases of *S*-alkyl/aryl dithiocarbazates, 2405
Dithiocarbimates
Platinum complexes, Crystal structures, 1153
1,3-Dithiol-2-thione
Mercury(II), Pyridyl, ^{1}H NMR, Solid UV, 115
1,3-Dithiole-2-thione
Crystal structure, Molecular assembly, Complex, 1447
Divalent
Lanthanides, Ytterbium, Aryloxide, Crystal Structures, Tris(pyrazolyl)borate, 263
Divalent metals
Heteroscorpionate ligands, Hydrogen bond, X-ray crystallography, 239
Divinyl organics
Copper(I) complexes, Hexafluorocetylacetonate, Olefin complexes, Crystal structure, Thermal analysis, 809
closo-Dodecaborate
Hydroxy and acyl derivatives, Disubstituted functional derivatives, Boron neutron capture therapy, 2135
Dodecahedron
Eight-coordinate, Stereochemistry, Square antiprism, Bicapped trigonal prism, Molecular mechanics, 145
Double betaine
Carboxylate, Coordination polymer, Hydrate, Hydrogen bonding, π–π Interaction, Silver nitrate, 2413
Dppe
Nickel, Dithiocarbamate, PPh_3, X-ray crystal structure, NMR, 77

EDAX analyses
Anisotropic approximation, Cluster anions, Heterometal cluster complexes, 599
EDTA
Hydroxyapatite, Complex, Hydrothermal, Low temperature, Calcium phosphates, 1897
EHMO
Naphthylazoimidazole, Silver(I) complexes, Helical structure, 793
Eight-coordinate
Stereochemistry, Dodecahedron, Square antiprism, Bicapped trigonal prism, Molecular mechanics, 145
Electric arc
Carbon allotropes, Polyynes, Carbyne, Dicyanopolyynes, Cyanopolyynes, Graphite, Liquid nitrogen, 1889
Electrical conductivity
Radical salts, Bis(ethylenedithio)tetrathiafulvalene (ET), Crystal structures, 1185
Electrical conductivity
Tetrathiafulvalene, Copper(II), Charge transfer compounds, 2109
Electrochemical
Binuclear copper complex, EPR, Half-field, Superhyperfine, X-ray, 1115
Electrochemistry
Macrobicylic ligands, Compartmental, Copper(II) complexes, Antiferromagnetic interaction, Catalytic study, 519
Electrochemistry
Magnetic properties, Oximinato monocopper(II) and mononickel(II) complexes, Unsymmetrical oximinato dicopper(II) complexes and unsymmetrical oximinato dinickel(II) complexes, 665
Electrochemistry
Ruthenium(II)-tris-chelates, Azoimidazoles, X-ray structure, 727
Electrochemistry
Diruthenium(II), Rhodium(III) Ruthenium(II), Heterodinuclear complexes, Polypyridine complexes, 913
Electrochemistry
Phthalocyanine, Spectroelectrochemistry, Pyridine binding, 1279
Electrochemistry
Amino acid, Copper, Dendrimers, Electron spin resonance, Ligand, 1709
Electrochemistry
Vic-dioximes, Thiazolidine, Ferrocene, Transition metal complexes, 1987
Electroluminescence
Iridium, Cyclometalated Ir(II) complexes, Pyrazolyl ancillary ligands, Boat conformations, Luminescent, 419
Electron density distribution
Clusters, Polarizability, Spherical potential well, Finite electric field, 1519
Electron spin resonance
Amino acid, Copper, Dendrimers, Electrochemistry, Ligand, 1709
Electron transfer
Copper(III), Imine-oxime ligand, Diols, Kinetics, Mechanism, 583
Electron transfer self-exchange
Dioxygen, Osmium, Aniline, Oxidation, 323
Electron-transfer reactions
Spin-exchange reactions, Bis[tris(pyrazolyl)methane] complexes, Low-spin configurations, High-spin configurations, 1037
Electronic spectra
Cobalt(III), Semicarbazone, 2-Hydroxyacetophenone, NMR spectra, IR spectra, X- ray crystal structure, 41
Electronic spectra
Di-2-pyridyl ketone, Thiosemicarbazone, Ni(II) thiosemicarbazone complex, IR spectra, X-ray crystal structure, 1225
Electronic spectra
Diaza-fluorene, Silver complexes, Crystal structures, Intermolecular interactions, 2259
Electronic structure
Sulfite oxidase, Pyranopterin molybdenum enzymes, Molybdenum complexes, MCD (Magnetic Circular Dichroism), EPR (Electron Paramagnetic Resonance), 499
Electropolymerisation
Ru-complexes, Thiophene, Differential pulse voltammetry, 4-((2-Thienyl)-ethenyl)-2,2′-bipyridine, Redox-polymers, 589
Electropolymerization
Schiff-base, Polypyrrole, Iron complex, AFM, Polymer, 1953
Enamido
Enolato, Zirconium, Titanium, Aluminum, 1587
Enaminone
Ferrocene, Ligand, Copper, Complex, X-ray crystallography, 15
Enaminone
Ferrocene, Ligands, Complexes, X-ray crystallography, 749
Enaminone
Ferrocene, Ligand, Copper, Complex, X-ray crystallography, 1541
Enaminones
Molybdenum(VI) complexes, Molybdenum(V) complexes, Pyrone, X-ray crystal structure, NMR spectra, 1859
End-on and end-to-end bridging
Arylazoimidazoles, Cadmium(II) complexes, X-ray structure, 1D chain, Sheet structure, 1669
Energy minimization
2,5-Bis(2-pyridyl)-1,3,4-thiadiazole, Zinc, Crystal structures, Monomeric complexes, 1903
Enolates
Alkoxides, β-Diketonates, Carboxylates, Alkali metals, Alkaline earth metals, Cluster compounds, 1479
Enolato
Enamido, Zirconium, Titanium, Aluminum, 1587
Enzyme
Zinc, Thiolate, Alkylation, 481
Epoxide
Silica gel, Immobilization, 2-Aminomethylpyridine, Adsorption, Thermodynamic, 719

EPR
Hydrazones, Copper(II) hydrazonate complexes, 1,10-Phenanthroline, 2,2′-Bipyridine, X-ray single crystal structure, 575
EPR
Triazolopyrimidine, Zn complexes, Copper dimers, 743
EPR
Copper, Structure, Magnetism, Dinuclear, 993
EPR
Binuclear copper complex, Half-field, Superhyperfine, X-ray, Electrochemical, 1115
EPR
Self-assembly, Copper, N,O-ligands, Dinuclear, 1769
EPR
Porphyrazine, Naphthalene, Copper, Zinc, Cobalt, 1845
EPR
Vanadium, Diiminediaminediphenolate macrocycle, Magnetochemistry, FTIR, Spectroelectrochemistry, 2069
EPR
Crystal structure, Manganese, Hydrogen bond, Magnetism, 2387
EPR
Lawsone, Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Copper complexes, Antiferromagnetic coupling, H-bonding, 2541
EPR
Copper(II) complexes, Thiosemicarbazone, 2-Hydroxyacetophenone, Antimicrobial studies, Cyclic voltammetry, X-ray crystallography, 2549
EPR
Copper(II) complexes, 2-Benzoylpyridine, Thiosemicarbazone, Antimicrobial activity, Crystal structure, 3069
EPR (Electron Paramagnetic Resonance)
Sulfite oxidase, Pyranopterin molybdenum enzymes, Electronic structure, Molybdenum complexes, MCD (Magnetic Circular Dichroism), 499
EPR spectra
Iron(III) complexes, Thiosemicarbazone, Single crystal X-ray diffraction, Mössbauer spectra, IR spectra, 969
EPR spectroscopy
Hydrazido ligand, Mixed-valence, Ruthenium complexes, Spectroelectrochemistry, 701
ES-MS
Lanthanide, Cryptate, Crystal structure, 49
ESR study
Pyrazolone, Copper(II) complexes, Crystal structures, 2465
2-Ethanolpyridinium
2-Methanolpyridine, 2,6-Dimethanolpyridine, Cobalt(II) complexes, Crystal structures, 841
Ethylene
Hydrocarboxylation, Oligomerization, Catalysis, Rhodium complexes, Carbon monoxide, 1677
Europium
Ionic complex, Rheological phase reaction, Crystal structure, Photoluminescence, Zinc, 529
Europium
Coordination polymer, Hydrogen bonds, Luminescence, Supramolecular, Terbium, 711
Extended structures
Copper, 4,7-Phenanthroline, Coordination framework, Host–guest properties, Polymers, 55

Fe(III) carboxylate chemistry
Magnetochemistry, Crystal structures, Cluster complexes, 2779
Ferrocene
Enaminone, Ligand, Copper, Complex, X-ray crystallography, 15
Ferrocene
Dithiocarbazate, Ligand, Complex, Tin, Crystal structure, 567
Ferrocene
Enaminone, Ligands, Complexes, X-ray crystallography, 749
Ferrocene
Palladium, Phosphine, Suzuki–Miyaura coupling, Ortho-metallated complexes, X-ray crystallography, 921
Ferrocene
Enaminone, Ligand, Copper, Complex, X-ray crystallography, 1541
Ferrocene
Vic-dioximes, Thiazolidine, Transition metal complexes, Electrochemistry, 1987
Ferrocene
Multiple-decker sandwich complex, Boron, Lithium, Crystal structure, 2597
Ferrocene carboxylic acid
Arene ligand, Ferrocene derivative, Ruthenium, 687
Ferrocene derivative
Arene ligand, Ferrocene carboxylic acid, Ruthenium, 687
Ferrocenes
Oxazolines, Non-symmetrical ligands, X-ray diffraction, 611
Ferrocenium
Metallocene, Cobaltocenium, Crystal structure, 2937
Ferrocenylcarboxylate
Antimony, Crystal structures, Antitumor activity, 823
Ferromagnetic behaviour
Dimeric complex, Manganese(III), Crystal structure, 949
Ferromagnetic coupling
Copper(II), Aminopolycarboxylate, π–π stacking, Cylindrical channels, 1081
Ferromagnetic interactions
Manganese(II) hexafluoroacetylacetonate, 4-cyanopyridine-N-oxide, Crystal structures, Magnetic properties, 879
Ferromagnetism
Self-assembly, Crystal structures, Bis(2-pyridylmethyl)amino acids, One-dimensional chains, Copper(II) complexes, 903
Finite electric field
Clusters, Electron density distribution, Polarizability, Spherical potential well, 1519
Five-coordinate
Hypodentate, Tripodal amine ligand, Cu(II) complexes, Crystal structure, 97
Flexible
Carboxylates, IX, Coordination polymer, Architecture, 3007
Fluorescence
Silicon, Phosphorus, Hypercoordination, Hypervalency, Spectroscopy, X-ray crystallography, 2615
Fluoride
Uranyl, Phosphine oxide ligands, Structural study, Spectroscopic characterisation, 3097
Fluorinated
Sodium, Copper, Tris(pyrazolyl)borate, Carbonyl, 273
Fluorine
Pyridinecarboxaldimine, Cytotoxicity, Platinum, Palladium, 2169
Fluoroionophore
Ruthenium, X-ray, Metallacrown, 1719
Fluxional behaviour
Copper complexes, Di-2-pyridylamine, Nitrito complexes, Plasticity effect, *cis*-Distorted octahedron, 1685
Formamidinato complexes
Diruthenium compounds, Metal–metal bonds, Triazenido complexes, Multiple bonds, Low spin complexes, 2637
FTIR
Vanadium, Diiminediaminediphenolate macrocycle, Magnetochemistry, EPR, Spectroelectrochemistry, 2069
Functionalised carbenes
Nickel complexes, Heterocyclic carbenes, X-ray diffraction, 2813

Gallophosphates
Hydrothermal syntheses, Crystal structures, Templating effect, 1535
Glycerol phosphate
Uranium, Complex formation, Potentiometric titration, TRLFS, 1793
Glyoxylic acid
Kinetics, Mechanism, Redox, Silver, 895
Gold (I) complex
Parabanic acid, Iron, Cyclopentadienyl, Carbonyl, Thallium, Alkylation, 1441
Gold complex
Crystal structure, Selenourea, MAS NMR, 1
Graphite
Carbon allotropes, Polyynes, Carbyne, Dicyanopolyynes, Cyanopolyynes, Electric arc, Liquid nitrogen, 1889
Grid
Chiral, Coordination polymers, Nicotinate, Open channel, 1947
Group 11 phosphine complexes
1-azaallyls, X-ray crystallography, Iminoalkyl bonding mode, 2273

H-bonding
Lawsone, Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Copper complexes, Antiferromagnetic coupling, EPR, 2541
^{1}H NMR
Mercury(II), 1,3-Dithiol-2-thione, Pyridyl, Solid UV, 115
H_2O_2
Immobilization, Silica support, Cobalt(II) complexes, 59
Half-field
Binuclear copper complex, EPR, Superhyperfine, X-ray, Electrochemical, 1115
Halostannanes
Tris(cyclohexyl)tin, Crystal structures, 2331
Hartree–Fock calculations
Octamolybdate, Hydrothermal synthesis, Three-dimensional oxide, Organic–inorganic hybrid, Building block approach, 1145
Head–head
Triazolopyrimidine, Palladium dimers, Head–tail, 2373
Head–tail
Triazolopyrimidine, Palladium dimers, Head–head, 2373
Helical architecture
Manganese maleate, Coordination polymer, Temperature effect, Hydrogen bonds, π–π interactions, 987
Helical structure
Naphthylazoimidazole, Silver(I) complexes, EHMO, 793
Hemilabile
Phosphine, X-ray structure, 3125
Hemilabile ligands
Heteroscorpionates, Ruthenium, Hydrides, Phosphine complexes, 361
Heptanuclear
Nickel(II), Lanthanides(III), Amino acid, Cluster compound, 2265
Herometallacrown
Malonate, *o*-Pthalate, Cu(II) complexes, 943
Heteroaromatic carboxylic acid
Triphenyltin, Synthesis, Crystal structure, 1805
Heterobimetallic
Palladium, Platinum, Phosphine, Oxadiazole ligand complexes, 2013
N-Heterocyclic carbenes
Homogenous catalysis, Transfer hydrogenation, Ketones, Aldehydes, Imines, 2857
Heterocyclic carbenes
Nickel complexes, Functionalised carbenes, X-ray diffraction, 2813
Heterodinuclear complexes
Diruthenium(II), Rhodium(III) Ruthenium(II), Polypyridine complexes, Electrochemistry, 913
Heteroligand peroxovanadate
Dinuclear peroxovanadate, Peroxo-bridged divanadate, Peroxidative bromination, Amino acid containing peroxovanadates, 1097
Heterometal cluster complexes
EDAX analyses, Anisotropic approximation, Cluster anions, 599
Heteroscorpionate
Tripodal, Alkylthiolate, Imidazole, Iron, Zinc, 471
Heteroscorpionate ligands
Hydrogen bond, X-ray crystallography, Divalent metals, 239
Heteroscorpionates
Ruthenium, Hydrides, Phosphine complexes, Hemilabile ligands, 361
Hexafluorocetylacetonate
Copper(I) complexes, Olefin complexes, Divinyl organics, Crystal structure, Thermal analysis, 809
Hexamethylbenzene
p-Cymene, Diphenyl-2-pyridylphosphine, Amines, Ruthenium complexes, 3115
Hexanuclear cations
Cu(II)–Ln(III) complexes, Dipeptides, Carboxylate bridge, Crystal structures, Magnetic properties, 2253
Hg(II) complexes
2-[(*E*)-2-(aryl)-1-diazenyl]pyridine, NMR, Crystal structures, 2323
High-pressure NMR
Hydroformylation, Ionic liquids, Biphase catalysis, Rhodium complexes, 2679
High-spin configurations
Electron-transfer reactions, Spin-exchange reactions, Bis[tris(pyrazolyl)methane] complexes, Low-spin configurations, 1037
Homogenous catalysis
N-Heterocyclic carbenes, Transfer hydrogenation, Ketones, Aldehydes, Imines, 2857
Homooxacalixarenes
Uranyl ion, Alkali metal ions, Calixarenes, Crystal structures, 649
Host–guest properties
Copper, 4,7-Phenanthroline, Coordination framework, Polymers, Extended structures, 55
Hydrate
Carboxylate, Coordination polymer, Double betaine, Hydrogen bonding, π–π Interaction, Silver nitrate, 2413
Hydrazido ligand
EPR spectroscopy, Mixed-valence, Ruthenium complexes, Spectroelectrochemistry, 701
Hydrazones
Copper(II) hydrazonate complexes, 1,10-Phenanthroline, 2,2′-Bipyridine, X-ray single crystal structure, EPR, 575
Hydrazones
Complex, Lanthanide, X-ray, Spectroscopy, Crystal structures, 1191
Hydride
Ruthenium, Scorpionate, Tris(pyrazolyl)-borate, C–H activation, 439
Hydrides
Heteroscorpionates, Ruthenium, Phosphine complexes, Hemilabile ligands, 361
Hydrides
Zwitterions, Monoanionic ligands, Syntheses, Structures, Methyl, 489
Hydrocarboxylation
Oligomerization, Catalysis, Rhodium complexes, Ethylene, Carbon monoxide, 1677
Hydroformylation
Ionic liquids, Biphase catalysis, High-pressure NMR, Rhodium complexes, 2679
Hydrogen bond
Hydrotris(pyrazolyl)borate, Ruthenium, Oxidation, Aquo complex, 225
Hydrogen bond
Heteroscorpionate ligands, X-ray crystallography, Divalent metals, 239
Hydrogen bond
Crystal structure, Phase transition, Isotope effect, NQR, Tetrachloroaurate(III), 1605
Hydrogen bond
Crystal structure, Manganese, Magnetism, EPR, 2387
Hydrogen bonding
Iron, (μ-O)di-iron complex, Bis-(2-pyridylmethyl)amine, Oxalato, Mössbauer spectra, 1419
Hydrogen bonding
1-(4-Hydroxyphenyl)-1H-tetrazole-5-thiol, Organotin(IV), π–π stacking interaction, Crystal structures, X-ray crystallography, 1547
Hydrogen bonding
Uranyl ions, Diols, Crystal structures, 1613
Hydrogen bonding
$Cu^{II}N_4Cl$ chromophores, Bidentate diimine, Bidentate diamine, π–π Interactions, Magnetic property, 1961
Hydrogen bonding
Vanadium complexes, Nitrilotriacetate, X-ray crystal structure, 1975
Hydrogen bonding
Carboxylate, Coordination polymer, Double betaine, Hydrate, π–π Interaction, Silver nitrate, 2413
Hydrogen bonding network
Ion pair complex, Non-covalent interaction, Charge transfer, Near-IR absorption, 1235
Hydrogen bonds
Coordination polymer, Crystal structure, Copper(II), 553
Hydrogen bonds
Coordination polymer, Europium, Luminescence, Supramolecular, Terbium, 711
Hydrogen bonds
Manganese maleate, Coordination polymer, Temperature effect, Helical architecture, π–π interactions, 987
Hydrogen bonds
Tetranuclear copper(II) complex, Structural elucidation, 1169
Hydrogen bonds
Copper, Structure, Infrared, Distortion isomers, 1969

Hydrogen bonds
Lanthanide(III) complexes, Hydrothermal syntheses, Isoorotic acid, Supramolecule, 2085
Hydrogen bonds
Isoorotic acid, Co(II) and Ni(II) complexes, Hydrothermal synthesis, Supramolecular frameworks, 2227
Hydrogenases
Nickel, Bis(mercaptoimidazolyl)borate complexes, Tris(mercaptoimidazolyl)borate complexes, Diphosphine, Crystal structure, 395
Hydrogenated Schiff's bases
Nickel, Schiff's bases, Coordination geometry, X-ray crystal structures, Polymethylene chains, 3201
Hydrogermane
Polystyrene supported, Reduction, Recycle, 177
Hydrothermal
Hydroxyapatite, Complex, EDTA, Low temperature, Calcium phosphates, 1897
Hydrothermal
Layered, Titanium phosphate, Intercalation behavior, γ-Phase, 3033
Hydrothermal syntheses
Crystal structures, Gallophosphates, Templating effect, 1535
Hydrothermal syntheses
Lanthanide(III) complexes, Isoorotic acid, Hydrogen bonds, Supramolecule, 2085
Hydrothermal synthesis
Polyoxometalates, Crystal structure, Keggin, Cobalt, 773
Hydrothermal synthesis
Octamolybdate, Three-dimensional oxide, Organic–inorganic hybrid, Building block approach, Hartree–Fock calculations, 1145
Hydrothermal synthesis
Coordination polymer, Magnetic property, Transition metal, Square grid structure, 1,4-Naphthalenedicarboxylic acid, 1257
Hydrothermal synthesis
Transformation, Molybdenum phosphate, Crystal structure, 2153
Hydrothermal synthesis
Lead, Coordination polymer, X-ray structure determination, 2161
Hydrothermal synthesis
Isoorotic acid, Co(II) and Ni(II) complexes, Hydrogen bonds, Supramolecular frameworks, 2227
Hydrothermal synthesis
Crystal structure, Iron phosphatooxalate, Template, Oxalate acid, Piperazine, 2357
Hydrotris(pyrazol-1-yl)borates
Scorpionates, Polypyrazolylborates, Photoelectron spectra, 429
Hydrotris(pyrazolyl)borate
Ruthenium, Hydrogen bond, Oxidation, Aquo complex, 225
Hydrotris(pyrazolyl)borate
Scorpionate ligands, Tantalum, Metal–metal multiple bond, Alkyne complex, Tetrahydrothiophene complex, 379
Hydrotris(pyrazolyl)borate complexes
Nickel(II) complexes, Crystal structures, Coordination environment, Scorpionates, 211
Hydroxy and acyl derivatives
closo-Dodecaborate, Disubstituted functional derivatives, Boron neutron capture therapy, 2135
2-Hydroxyacetophenone
Cobalt(III), Semicarbazone, NMR spectra, IR spectra, Electronic spectra, X- ray crystal structure, 41
2-Hydroxyacetophenone
Copper(II) complexes, Thiosemicarbazone, EPR, Antimicrobial studies, Cyclic voltammetry, X-ray crystallography, 2549
Hydroxyaluminosilicate
Aluminium, Silicic acid, Aluminium solubility, Aluminium biological availability, 3185
Hydroxyapatite
Complex, EDTA, Hydrothermal, Low temperature, Calcium phosphates, 1897
4-Hydroxycoumarin
Kinetics, Permanganate, Oxidation, 2507
α-Hydroxycarboxylato complexes
Nickel, Copper, Zinc, Imidazole, Thermal behaviour, Crystal structures, 1505
2-Hydroxy-1
Lawsone, Quinones, 4-Naphthoquinone, Amine oxidase, Copper complexes, Antiferromagnetic coupling, H-bonding, EPR, 2541
1-(4-Hydroxyphenyl)-1H-tetrazole-5-thiol
Organotin(IV), Hydrogen bonding, π–π stacking interaction, Crystal structures, X-ray crystallography, 1547
Hypercoordination
Silicon, Phosphorus, Hypervalency, Spectroscopy, Fluorescence, X-ray crystallography, 2615
Hypervalency
Silicon, Phosphorus, Hypercoordination, Spectroscopy, Fluorescence, X-ray crystallography, 2615
Hypodentate
Tripodal amine ligand, Cu(II) complexes, Crystal structure, Five-coordinate, 97

Imidazolate
Coordination polymers, Silver, X-ray structure, 3063
Imidazole
Heteroscorpionate, Tripodal, Alkylthiolate, Iron, Zinc, 471
Imidazole
Macrocyclic complexes, Cyclic voltammetry, X-ray crystallography, 1317
Imidazole
Nickel, Copper, Zinc, α-Hydroxycarboxylato complexes, Thermal behaviour, Crystal structures, 1505
Imidazole
Cadmium(II)thiocyanate, Polymer, Schiff base, Supramolecular synthon, 2045
Imidazole
Copper(II) complex, Ascorbic oxidation, Crystal structure, 2515
Imido
Acetonitrile reduction, Amine oxidation, Metal-nitrogen pi bonding, Regioselectivity of nucleophile and electrophile additions, 311
Imido complexes
^{15}N solid state NMR, DFT calculations, Molybdenum nitride, Lewis acids, 2751
Imine
Platinum, Benzimidazole, Benzoxazole, Benzothiazole, Pyridine, 155
Imine activation
Copper(II) complex, Schiff base, X-ray structure, Coordination polymer, 3081
Imine hydrogenation
Mixed valent Ru(II)/Ru(III) complexes, Binuclear ruthenium complexes, Catalysis, 3163
Imine-oxime ligand
Copper(III), Diols, Kinetics, Mechanism, Electron transfer, 583
Imines
N-Heterocyclic carbenes, Homogenous catalysis, Transfer hydrogenation, Ketones, Aldehydes, 2857
Imino nitroxide
Nitronyl nitroxide, Amide, Manganese complexes, Copper complexes, Cobalt complexes, 763
Iminoalkyl bonding mode
Group 11 phosphine complexes, 1-azaallyls, X-ray crystallography, 2273
Immobilization
Silica support, Cobalt(II) complexes, H_2O_2, 59
Immobilization
Silica gel, 2-Aminomethylpyridine, Epoxide, Adsorption, Thermodynamic, 719
Indenyl
Cyclopentadienyl, Phosphino, Phosphido, Molybdenum, Metallocenes, 1263
Indenyl ligand
Synthesis, Crystal structures, Nickel complex, Catalysis, 1473
Indium
Metalloporphyrins, Thallium, 1777
Indomethacin
Diorganotin, Crystal structures, Spectroscopic studies, 2021
Infrared
Copper, Structure, Hydrogen bonds, Distortion isomers, 1969
π–π interactions
Manganese maleate, Coordination polymer, Temperature effect, Helical architecture, Hydrogen bonds, 987
π–π Interactions
$Cu^{II}N_4Cl$ chromophores, Bidentate diimine, Bidentate diamine, Hydrogen bonding, Magnetic property, 1961
π–π Interaction
Carboxylate, Coordination polymer, Double betaine, Hydrate, Hydrogen bonding, Silver nitrate, 2413
Intercalation behavior
Hydrothermal, Layered, Titanium phosphate, γ-Phase, 3033

Intermolecular
Cyclic telluranes, Metathetical reactions, Secondary bonding, Supramolecular networks, 1629
Intermolecular interactions
Diaza-fluorene, Silver complexes, Crystal structures, Electronic spectra, 2259
Intra-ligand charge transfer
Iridium, Luminescence, Terpyridine, Near infra-red, Charge-transfer, 2769
Ion exchange
Six coordinate silicates, Transition metals, Ligand environment, Thermal studies, Magnetism, 679
Ion pair complex
Hydrogen bonding network, Non-covalent interaction, Charge transfer, Near-IR absorption, 1235
Ion recognition
Schiff base complexes, Crown ether, UV–Vis, Lanthanides, 1401
Ionic complex
Rheological phase reaction, Crystal structure, Photoluminescence, Europium, Zinc, 529
Ionic liquids
Hydroformylation, Biphase catalysis, High-pressure NMR, Rhodium complexes, 2679
Ionic metathesis
Diorganostannate, Methanesulfonate, Organotin oxide, 71
Ionic radius
Tetrahydrofurfurylindenyl, Lanthanide chlorides, Crystal structure, 1075
IR
Zinc complexes, Schiff-bases, Crystal structures, UV and NMR spectroscopy, Thermal analysis, 1293
IR spectra
Cobalt(III), Semicarbazone, 2-Hydroxyacetophenone, NMR spectra, Electronic spectra, X- ray crystal structure, 41
IR spectra
Crystal structure, Vanadium(V) peroxo mandelato complex, ^{51}V NMR spectra, 655
IR spectra
Iron(III) complexes, Thiosemicarbazone, Single crystal X-ray diffraction, Mössbauer spectra, EPR spectra, 969
IR spectra
Di-2-pyridyl ketone, Thiosemicarbazone, Ni(II) thiosemicarbazone complex, Electronic spectra, X-ray crystal structure, 1225
Iridium
Cyclometalated Ir(II) complexes, Pyrazolyl ancillary ligands, Boat conformations, Luminescent, Electroluminescence, 419
Iridium
Luminescence, Terpyridine, Near infrared, Charge-transfer, Intra-ligand charge transfer, 2769
Iridium complexes
Chelating phosphines, 2959
Iron
Heteroscorpionate, Tripodal, Alkylthiolate, Imidazole, Zinc, 471
Iron
(μ-O)di-iron complex, Bis-(2-pyridylmethyl)amine, Oxalato, Hydrogen bonding, Mössbauer spectra, 1419
Iron
Parabanic acid, Cyclopentadienyl, Carbonyl, Thallium, Gold (I) complex, Alkylation, 1441
Iron
Spin-crossover, Crystal structure, Magnetic measurements, 2141
Iron
Radical, Styrene, Catalyst, Polymerisation, 2921
Iron
Terpyridine, Pyridyl bispyrazolyl, Complexation, Rearrangement, X-ray structures, 3193
Iron (III)
Dinuclear, Carboxylate, Complexes, Bridging, Mössbauer, 1869
Iron clusters
Solid-state reactions, Third-order nonlinear optical properties, 755
Iron complex
Schiff-base, Polypyrrole, Electropolymerization, AFM, Polymer, 1953
Iron complexes
Acetate ligands, η^2-Coordination modes, Schiff bases, β-Cis arrangements, 963
Iron complexes
Dendrimers, Cyclophosphazene, Metal–nitrile complexes, 1027
Iron iodide
Titanium iodide, Phosphine, Arsine, Crystal structures, 605
Iron phosphatooxalate
Hydrothermal synthesis, Crystal structure, Template, Oxalate acid, Piperazine, 2357
Iron–platinum compounds
Pyrolysis, Organometallic compounds, 63
Iron(II) complexes
Trithiocyanuric acid, Mössbauer spectra, Crystal structures, Spectroscopic properties, DFT calculations, 2193
Iron(II) complexes
Cobalt(II) complexes, X-ray crystal structures, Bis(2-pyridylmethyl)amine, Tris(2-pyridylmethyl)amine, 3105
Iron(III) carboxylate complexes
2,2′-Bipyrimidine complexes, Oxo-bridged iron(III) complexes, π–π stacking interactions, X-ray crystal structure, 1271
Iron(III) complex
Cyanide bridged clusters, Tris(pyrazolyl)-borate, Magnetic properties, 1333
Iron(III) complexes
Thiosemicarbazone, Single crystal X-ray diffraction, Mössbauer spectra, EPR spectra, IR spectra, 969
Isocyanides
Binuclear compounds, Nickel, Polymerisation, Ring-coupled bis-cyclopentadienyl ligand, X-ray molecular structure, 2715
Isomers
κ^2-Tp ligands, Bridging Tp ligands, Rhodium dicarbonyl complexes, X-ray structure, 301
Isonicotinic acid
Lanthanum trifluoromethanesulfonate, N-oxide, Mixed ligands, Coordination polymer, 857
Isonicotinic acid
Mn(II) complex, N-oxide, Crystal structure, Luminescence, 1109
Isoorotic acid
Lanthanide(III) complexes, Hydrothermal syntheses, Hydrogen bonds, Supramolecule, 2085
Isoorotic acid
Co(II) and Ni(II) complexes, Hydrothermal synthesis, Hydrogen bonds, Supramolecular frameworks, 2227
Isotope effect
Crystal structure, Phase transition, Hydrogen bond, NQR, Tetrachloroaurate(III), 1605
IX
Flexible, Carboxylates, Coordination polymer, Architecture, 3007

Keggin
Polyoxometalates, Hydrothermal synthesis, Crystal structure, Cobalt, 773
β-ketoesterates
Cerium, Oxazolines, Chiral, Thermal decomposition, MOCVD, 1467
Ketones
N-Heterocyclic carbenes, Homogenous catalysis, Transfer hydrogenation, Aldehydes, Imines, 2857
Kinetics
Copper(III), Imine-oxime ligand, Diols, Mechanism, Electron transfer, 583
Kinetics
Mechanism, Redox, Silver, Glyoxylic acid, 895
Kinetics
1,3,4-thiadiazole, Zinc, Crystal structure, Thermal decomposition, Bioactivity, 1851
Kinetics
Permanganate, Oxidation, 4-Hydroxycoumarin, 2507
Kinetics
Absorption spectra, Complexation, Photochromism, Spiroindolinonaphthooxazines, 3147

Lanthanide
Cryptate, Crystal structure, ES-MS, 49
Lanthanide
Hydrazones, Complex, X-ray, Spectroscopy, Crystal structures, 1191
Lanthanide
Actinide, Oxides, Carbene, Uranium, 2689
Lanthanide
Samarium, Nitric oxide, Nitrite, Pyrazolylborate, Redox, 2709
Lanthanide chlorides
Tetrahydrofurfurylindenyl, Crystal structure, Ionic radius, 1075

Lanthanide complex
Proton sponge, Macrocyclic tetramine, 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane, 1089
Lanthanide ions
Sulfonatothiacalixarene, Capsules, Diaza-18-crown-6, 2055
Lanthanide nitrate
N,*N*′-dioxide, Self-assembly, Coordination polymer, 169
Lanthanide oxides
Bromotrimethylsilane, O-donor ligands, Complexes of lanthanide bromides, Crystal structure, Coordination number, 2293
Lanthanide(III) complexes
Hydrothermal syntheses, Isoorotic acid, Hydrogen bonds, Supramolecule, 2085
Lanthanides
Yttrium, Diketiminato, 183
Lanthanides
Neodymium, X-ray structures, Alkoxides, Pyrazolylborates, Borohydrides, 253
Lanthanides
Ytterbium, Aryloxide, Crystal Structures, Tris(pyrazolyl)borate, Divalent, 263
Lanthanides
Ion recognition, Schiff base complexes, Crown ether, UV–Vis, 1401
Lanthanides
Dawson lacunary heteropolyanion, Complex formation constants, Arsenazo III, 1579
Lanthanides(III)
Nickel(II), Amino acid, Heptanuclear, Cluster compound, 2265
Lanthanum
Tris(pyrazolyl)hydroborate (Tp) ligands, Neodymium, Salt metathesis, Aryloxide derivatives, 2437
Lanthanum trifluoromethanesulfonate
Isonicotinic acid, N-oxide, Mixed ligands, Coordination polymer, 857
Laser ablation synthesis
Phosphorus, Sulfur, Clusters, Phosphorus sulfides, TOF mass spectrometry, 1199
Lawesson's Reagent
Thiophosphoryl compound, Sulfur-rich complex, Nickel(II) complex, Cobalt(II) complex, 1799
Lawsone
Quinones, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Copper complexes, Antiferromagnetic coupling, H-bonding, EPR, 2541
Layered
Hydrothermal, Titanium phosphate, Intercalation behavior, γ-Phase, 3033
Lead
Coordination polymer, Hydrothermal synthesis, X-ray structure determination, 2161
Lead(II)
4,4′-Bipyridine, Coordination polymers, Lone pair, π–π staking interaction, Crystal structure, 2427
Lewis acids
^{15}N solid state NMR, DFT calculations, Molybdenum nitride, Imido complexes, 2751
Ligand
Ferrocene, Enaminone, Copper, Complex, X-ray crystallography, 15
Ligand
Ferrocene, Dithiocarbazate, Complex, Tin, Crystal structure, 567
Ligand
Catalysis, X-ray structure, Complex, 693
Ligand
Ferrocene, Enaminone, Copper, Complex, X-ray crystallography, 1541
Ligand
Amino acid, Copper, Dendrimers, Electrochemistry, Electron spin resonance, 1709
Ligand
Bidentate, Bridging, X-ray, Phosphine, 2569
Ligand environment
Six coordinate silicates, Ion exchange, Transition metals, Thermal studies, Magnetism, 679
Ligand oxidation
Nickel complexes, Pyrazoline, Ring opening, Structures, 1997
Ligands
Ferrocene, Enaminone, Complexes, X-ray crystallography, 749
Ligands
Cadmium, Coordinate, Polymers, Supramolecular, 1003
N-ligands
Copper, Thioethers, Multi-armed ligands, X-ray structures, Coordination polymer, 1055
Liquid ammonia/toluene two-phase system
Ammonolysis, Potassium, Zirconium, 1125
Liquid crystal
Phthalocyanine, Metallo phthalocyanine, Metallo mesogen, Crown ether, Aza ether, 1931
Liquid nitrogen
Carbon allotropes, Polyynes, Carbyne, Dicyanopolyynes, Cyanopolyynes, Electric arc, Graphite, 1889
Lithium
Alkali metals, Phosphorus–carbon bond cleavage, Chelates, O Ligands, 2499
Lithium
Multiple-decker sandwich complex, Ferrocene, Boron, Crystal structure, 2597
LLCT
Luminescence, Phosphorescence, Pt(II) and Pd(II), 3173
Lone pair
4,4′-Bipyridine, Lead(II), Coordination polymers, π–π staking interaction, Crystal structure, 2427
Low spin complexes
Diruthenium compounds, Metal–metal bonds, Triazenido complexes, Formamidinato complexes, Multiple bonds, 2637
Low temperature
Hydroxyapatite, Complex, EDTA, Hydrothermal, Calcium phosphates, 1897
Low-spin configurations
Electron-transfer reactions, Spin-exchange reactions, Bis[tris(pyrazolyl)methane] complexes, High-spin configurations, 1037
Luminescence
Zinc(II)azide, Mononuclear, Dinuclear, 2,2′-Dipyridylamine, Crystal engineering, 545
Luminescence
Coordination polymer, Europium, Hydrogen bonds, Supramolecular, Terbium, 711
Luminescence
Mn(II) complex, Isonicotinic acid, N-oxide, Crystal structure, 1109
Luminescence
Iridium, Terpyridine, Near infra-red, Charge-transfer, Intra-ligand charge transfer, 2769
Luminescence
LLCT, Phosphorescence, Pt(II) and Pd(II), 3173
Luminescent
Iridium, Cyclometalated Ir(II) complexes, Pyrazolyl ancillary ligands, Boat conformations, Electroluminescence, 419

Mössbauer spectra
Iron(II) complexes, Trithiocyanuric acid, Crystal structures, Spectroscopic properties, DFT calculations, 2193
Mössbauer
Iron (III), Dinuclear, Carboxylate, Complexes, Bridging, 1869
Mössbauer spectra
Iron(III) complexes, Thiosemicarbazone, Single crystal X-ray diffraction, EPR spectra, IR spectra, 969
Mössbauer spectra
Iron, (μ-O)di-iron complex, Bis-(2-pyridylmethyl)amine, Oxalato, Hydrogen bonding, 1419
Macrobicylic ligands
Compartmental, Copper(II) complexes, Electrochemistry, Antiferromagnetic interaction, Catalytic study, 519
Macrocycle
Template synthesis, Decaazacyclooctadecane, Nickel(II) complexes, 1325
Macrocycles
Scorpionands, Chromophores, Copper(II), Nickel(II), 373
Macrocycles
P,*S*-metallocycles, Supramolecular chemistry, Bipodal ligands, Crystal structures, Phosphorylated urea complexes, 2243
Macrocyclic complexes
Cyclic voltammetry, X-ray crystallography, Imidazole, 1317
Macrocyclic tetramine
Proton sponge, Lanthanide complex, 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane, 1089

Magnesium carboxylate
Meltable, Dispersion processing, Thermal properties, 1739
Magnetic measurements
Iron, Spin-crossover, Crystal structure, 2141
Magnetic properties
Tricopper(II) complex, Schiff bases, Ascorbate oxidase model, Crystal structure, 643
Magnetic properties
Electrochemistry, Oximinato monocopper(II) and mononickel(II) complexes, Unsymmetrical oximinato dicopper(II) complexes and unsymmetrical oximinato dinickel(II) complexes, 665
Magnetic properties
Manganese(II) hexafluoroacetylacetonate, 4-cyanopyridine-N-oxide, Crystal structures, Ferromagnetic interactions, 879
Magnetic properties
Azides, Polyamines, Copper(II) complexes, Crystal structures, Coordination polymers, 1243
Magnetic properties
Copper, Crystal structure, Dimer, Spectral properties, 1303
Magnetic properties
Dinuclear copper(II) complex, Bidentate ligand, Crystal structure, UV–Vis, EPR and IR spectra, 1309
Magnetic properties
Cyanide bridged clusters, Iron(III) complex, Tris(pyrazolyl)borate, 1333
Magnetic properties
Nickel(II) compounds, Crystal structures, Terephthalate ligand, Binuclear complexes, 1379
Magnetic properties
Manganese, Pheylcyanamide, Crystal structures, 1409
Magnetic properties
Nickel(II), Thiodiglycolic acid complexes, X-ray structures, 1573
Magnetic properties
Copper dimer, Antiferromagnetic dimer, Crystal structure, 1695
Magnetic properties
Self-assemble, Carboxylate bridges, Copper complexes, Dipeptides, Alkaline earth metals, 2125
Magnetic properties
Dicopper(II) complex, 1D Coordination polymer, Crystal structure, Schiff base, 2177
Magnetic properties
Copper(II) complex, Crystal structure, Coordination polymers, 2203
Magnetic properties
Cu(II)–Ln(III) complexes, Dipeptides, Carboxylate bridge, Hexanuclear cations, Crystal structures, 2253
Magnetic properties
Copper, 3,5-Dinitrosalicylate complex, Trimer, Crystal structure, Spectral properties, 2447
Magnetic properties
Copper(II) compounds, Crystal structures, Terephthalate ligand, One-dimensional complexes, 3043
Magnetic property
Hydrothermal synthesis, Coordination polymer, Transition metal, Square grid structure, 1,4-Naphthalenedicarboxylic acid, 1257
Magnetic property
$Cu^{II}N_4Cl$ chromophores, Bidentate diimine, Bidentate diamine, π–π Interactions, Hydrogen bonding, 1961
Magnetism
Six coordinate silicates, Ion exchange, Transition metals, Ligand environment, Thermal studies, 679
Magnetism
Copper, Structure, Dinuclear, EPR, 993
Magnetism
Crystal structure, Manganese, Hydrogen bond, EPR, 2387
Magnetism
Crystal structure, Nickel(II) complexes, Pseudohalides, 2337
Magnetochemical studies
N-salicylidene-*n*-alkanoylhydrazines, Copper(II) complexes, Bis[monochloro(μ-*N*-salicylidenemyristoylhydrazine) $ONO'(-1)$]dicopper(II), X-ray crystal and molecular structure, 23
Magnetochemistry
Crystal structures, Manganese(II) carboxylate chemistry, Metal-assisted reactions, 2-Pyridinealdoxime complexes, 83
Magnetochemistry
Manganese(III), N,O ligands, X-ray structure, Dimer, Azide, 1811
Magnetochemistry
Vanadium, Diiminediaminediphenolate macrocycle, EPR, FTIR, Spectroelectrochemistry, 2069
Magnetochemistry
Fe(III) carboxylate chemistry, Crystal structures, Cluster complexes, 2779
Malonate
Herometallacrown, *o*-Pthalate, Cu(II) complexes, 943
Malonate complexes
2D antiferromagnets, Weak ferromagnetism, 929
Manganese
Pheylcyanamide, Magnetic properties, Crystal structures, 1409
Manganese
Crystal structure, Hydrogen bond, Magnetism, EPR, 2387
Manganese complexes
Nitronyl nitroxide, Imino nitroxide, Amide, Copper complexes, Cobalt complexes, 763
Manganese maleate
Coordination polymer, Temperature effect, Helical architecture, Hydrogen bonds, π–π interactions, 987
Manganese(II)
Cadmium(II), Calcium(II), Synthesis, Crystal structures, Tetrazolate complexes, 1217
Manganese(II)
Bis-imidazole, Metal complexes, X-ray structures, Copper(II), Zinc(II), 1731
Manganese(II) carboxylate chemistry
Crystal structures, Magnetochemistry, Metal-assisted reactions, 2-Pyridinealdoxime complexes, 83
Manganese(II) hexafluoroacetylacetonate
4-cyanopyridine-N-oxide, Crystal structures, Magnetic properties, Ferromagnetic interactions, 879
Manganese(III)
Dimeric complex, Crystal structure, Ferromagnetic behaviour, 949
Manganese(III)
N,O ligands, X-ray structure, Magnetochemistry, Dimer, Azide, 1811
Manganese(III) complexes
Ozone, X-ray crystal structure, Silver(II) complexes, Cobalt(III) complexes, 2631
MAS NMR
Crystal structure, Gold complex, Selenourea, 1
MCD (Magnetic Circular Dichroism)
Sulfite oxidase, Pyranopterin molybdenum enzymes, Electronic structure, Molybdenum complexes, EPR (Electron Paramagnetic Resonance), 499
Mechanism
Copper(III), Imine-oxime ligand, Diols, Kinetics, Electron transfer, 583
Mechanism
Kinetics, Redox, Silver, Glyoxylic acid, 895
Meltable
Magnesium carboxylate, Dispersion processing, Thermal properties, 1739
Menthone
Scorpionate ligands, Tripod ligands, Chirality, Prochirality, 245
Mercury(II)
1,3-Dithiol-2-thione, Pyridyl, ^1H NMR, Solid UV, 115
2-Mercapto-6-nitrobenzothiazole
Organotin(IV), Non-bonded interaction, Crystal structure, X-ray crystallography diffraction, 779
1H-5-mercapto-1,2,3-triazolato
Organotin, Organogermanium(IV), Crystal structure, X-ray crystallography, 1981
Metal complexes
Bis-imidazole, X-ray structures, Manganese(II), Copper(II), Zinc(II), 1731
Metal isotope effect
2-Thiopheneacetic acid, Polymeric copper(II) complex, Crystal structure, Vibrational spectra, 1785
Metal–metal bond
Ph_2Te_2, Molybdenum complex, Mo_2Te_4 complex, Crystal structure, 1663
Metal–metal bonds
Diruthenium compounds, Triazenido complexes, Formamidinato complexes,

Multiple bonds, Low spin complexes, 2637
Metal–metal multiple bond
Hydrotris(pyrazolyl)borate, Scorpionate ligands, Tantalum, Alkyne complex, Tetrahydrothiophene complex, 379
Metal–nitrile complexes
Dendrimers, Cyclophosphazene, Iron complexes, 1027
Metal-assisted reactions
Crystal structures, Manganese(II) carboxylate chemistry, Magnetochemistry, 2-Pyridinealdoxime complexes, 83
Metal-nitrogen pi bonding
Acetonitrile reduction, Amine oxidation, Imido, Regioselectivity of nucleophile and electrophile additions, 311
Metallacrown
Ruthenium, Fluoroionophore, X-ray, 1719
Metallo mesogen
Phthalocyanine, Metallo phthalocyanine, Liquid crystal, Crown ether, Aza ether, 1931
Metallo phthalocyanine
Phthalocyanine, Liquid crystal, Metallo mesogen, Crown ether, Aza ether, 1931
Metallocene
Ferrocenium, Cobaltocenium, Crystal structure, 2937
Metallocene
Organometallics, Sandwich complex, Bonding, Density functional theory, Orbital analysis, 2993
Metallocenes
Cyclopentadienyl, Indenyl, Phosphino, Phosphido, Molybdenum, 1263
P,*S*-metallocycles
Supramolecular chemistry, Bipodal ligands, Crystal structures, Macrocycles, Phosphorylated urea complexes, 2243
Metalloporphyrins
Indium, Thallium, 1777
Metathetical reactions
Cyclic telluranes, Intermolecular, Secondary bonding, Supramolecular networks, 1629
Methanesulfonate
Diorganostannate, Ionic metathesis, Organotin oxide, 71
2-Methanolpyridine
2,6-Dimethanolpyridine, 2-Ethanolpyridinium, Cobalt(II) complexes, Crystal structures, 841
Methyl
Zwitterions, Monoanionic ligands, Syntheses, Structures, Hydrides, 489
Methylaluminoxane
Neutral palladium(II) complex, X-ray crystallography, Catalyst, Norbornene, Vinylic polymerizaition, 1619
Methylation
η^2-nitrile, Tungsten, Oxo, Oxidation, Dimerization, 2831
S-Methyldithiocarbazate
Cu(II) complexes, Dithiocarbazate Schiff base, Saccharin complexes, Tridentate NNS Schiff base, 2491
S-methyldithiocarbazate (SMDTC)
NS Schiff base, Crystal structure of Cd(II) complex, Dithiocarbazate derivatives, 1385
Mixed ligands
Lanthanum trifluoromethanesulfonate, Isonicotinic acid, N-oxide, Coordination polymer, 857
Mixed valent Ru(II)/Ru(III) complexes
Binuclear ruthenium complexes, Catalysis, Imine hydrogenation, 3163
Mixed-valence
EPR spectroscopy, Hydrazido ligand, Ruthenium complexes, Spectroelectrochemistry, 701
Mn(II) and Cd(II) complexes
Azides, 3-Aminopyridine, Synthesis, Spectra, X-ray structures, Thermal properties, 2349
Mn(II) complex
Isonicotinic acid, N-oxide, Crystal structure, Luminescence, 1109
Mo_2Te_4 complex
Ph_2Te_2, Metal–metal bond, Molybdenum complex, Crystal structure, 1663
MOCVD
Cobalt, Oxide, β-diketonates, Adducts, Structures, 735
MOCVD
Cerium, Oxazolines, Chiral, Thermal decomposition, β-ketoesterates, 1467
Model complex
Cu-NIRs, Crystalline structure, Tripodal ligand, Polyimidazole ligand, 511
Model compounds
Tetrathiomolybdate, Tetrathiotungstate, Dihydridobis(pyrazolyl)borate, Copper(I) complexes, Crystal structure, 637
Molecular
Crystal structure, Back-bonding, Ruthenium complex, NO, Reactivity, 1063
Molecular assembly
Crystal structure, 1,3-Dithiole-2-thione, Complex, 1447
Molecular mechanics
Eight-coordinate, Stereochemistry, Dodecahedron, Square antiprism, Bicapped trigonal prism, 145
Molecular rectangles
Crystal structures, Copper complexes, Zinc complexes, 673
Molecular structures
Zwitterionic ferrocenyldithiophosphonates, 2281
Molybdenum
Tris(pyrazolyl)borate, Bis(imido), Synthesis, Structures, 189
Molybdenum
Cyclopentadienyl, Indenyl, Phosphino, Phosphido, Metallocenes, 1263
Molybdenum
^{95}Mo NMR, X-ray structures, Phosphine oxide, 1915
Molybdenum
Polyoxometallate, Aqueous organometallic chemistry, Pentamethylcyclopentadienyl ligands, 2605
Molybdenum
Crystal structures, Clusters, Copper, Tungsten, Nitrogen heterocycle ligands, Pyrazole, 3143
Molybdenum complex
Ph_2Te_2, Metal–metal bond, Mo_2Te_4 complex, Crystal structure, 1663
Molybdenum complexes
Sulfite oxidase, Pyranopterin molybdenum enzymes, Electronic structure, MCD (Magnetic Circular Dichroism), EPR (Electron Paramagnetic Resonance), 499
Molybdenum complexes
Carbonyl complexes, Pentafluorophenyl, Oxidation, Bond cleavage, Reductive elimination, 1371
Molybdenum nitride
^{15}N solid state NMR, DFT calculations, Imido complexes, Lewis acids, 2751
Molybdenum phosphate
Transformation, Hydrothermal synthesis, Crystal structure, 2153
Molybdenum(V) complexes
Enaminones, Molybdenum(VI) complexes, Pyrone, X-ray crystal structure, NMR spectra, 1859
Molybdenum(VI) complexes
Enaminones, Molybdenum(V) complexes, Pyrone, X-ray crystal structure, NMR spectra, 1859
^{95}Mo NMR
Molybdenum, X-ray structures, Phosphine oxide, 1915
Monoanionic ligands
Zwitterions, Syntheses, Structures, Methyl, Hydrides, 489
Monoanionic ligands
Zwitterions, Phosphines, Syntheses, Structures, Boron, 2901
Monodentate
Bis(diphenylphosphino)methane dioxide, Uranyl nitrate, Uranyl bis(β-diketonates), Bidentate chelate, Bridging bidentate, Coordination modes, 1527
Monodentate donors
2-Diphenylphosphinopicolinamide (dpppa 1), Coordination chemistry, Bidentate donors, 3211
Monomeric complexes
2,5-Bis(2-pyridyl)-1,3,4-thiadiazole, Zinc, Energy minimization, Crystal structures, 1903
Mononuclear
Zinc(II)azide, Dinuclear, 2,2′-Dipyridylamine, Luminescence, Crystal engineering, 545
Mononuclear complex
Silver(I) complexes, Dinuclear complex, 2117
Monophosphono dipeptides
Copper(II) complexes, Thioether ligands, Stability constants, Potentiometry, Vis, CD, EPR spectroscopy, 1939
MP2 geometry optimization
Bis(methoxycarbimido)amine, Topological analysis of electron density, 2235

Multi-armed ligands
Copper, *N*-ligands, Thioethers, X-ray structures, Coordination polymer, 1055
Multi-nitriles
Silver coordination complex polymers, 1D, 2D, 3D topological structure, 2209
Multidentate ligand
Cobalt(III), Sinambic, ^{59}Co NMR, 2217
Multiple bonds
Diruthenium compounds, Metal–metal bonds, Triazenido complexes, Formamidinato complexes, Low spin complexes, 2637
Multiple-decker sandwich complex
Ferrocene, Boron, Lithium, Crystal structure, 2597

^{15}N solid state NMR
DFT calculations, Molybdenum nitride, Imido complexes, Lewis acids, 2751
N, O donor ligands
Uranium, Crystal structure, 2285
N,O ligands
Manganese(III), X-ray structure, Magnetochemistry, Dimer, Azide, 1811
N,O-ligands
Self-assembly, Copper, Dinuclear, EPR, 1769
N-oxide
Lanthanum trifluoromethanesulfonate, Isonicotinic acid, Mixed ligands, Coordination polymer, 857
N-oxide
Mn(II) complex, Isonicotinic acid, Crystal structure, Luminescence, 1109
Nanochemistry
Clusters, Complexity, Polyoxomolybdates, 2381
Nanoparticles
Xanthate, Diamine, Zinc, Cadmium, CdS, 2315
Nanotubes
One-dimensional, Silver(I), Aliphatic amino ligands, Coordination polymers, Tubes, Topology, Supramolecular chemistry, Self assembly, 2075
Naphthalene
Phthalocyanine, Cobalt, Zinc, Nickel, 787
Naphthalene
Porphyrazine, EPR, Copper, Zinc, Cobalt, 1845
1,4-Naphthalenedicarboxylic acid
Hydrothermal synthesis, Coordination polymer, Magnetic property, Transition metal, Square grid structure, 1257
4-Naphthoquinone
Lawsone, Quinones, 2-Hydroxy-1, Amine oxidase, Copper complexes, Antiferromagnetic coupling, H-bonding, EPR, 2541
Naphthylazoimidazole
Silver(I) complexes, Helical structure, EHMO, 793
Near infra-red
Iridium, Luminescence, Terpyridine, Charge-transfer, Intra-ligand charge transfer, 2769
Near-IR absorption
Ion pair complex, Hydrogen bonding network, Non-covalent interaction, Charge transfer, 1235
Neodymium
Lanthanides, X-ray structures, Alkoxides, Pyrazolylborates, Borohydrides, 253
Neodymium
Tris(pyrazolyl)hydroborate (Tp) ligands, Lanthanum, Salt metathesis, Aryloxide derivatives, 2437
Neutral palladium(II) complex
X-ray crystallography, Catalyst, Methylaluminoxane, Norbornene, Vinylic polymerizaition, 1619
Ni(II) complexes
S-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride), Bidentate NS Schiff base, Tridentate NNS and NSS Schiff bases, Dithiocarbazate derivative, 161
Ni(II) thiosemicarbazone complex
Di-2-pyridyl ketone, Thiosemicarbazone, Electronic spectra, IR spectra, X-ray crystal structure, 1225
Nickel
Dithiocarbamate, PPh_3, Dppe, X-ray crystal structure, NMR, 77
Nickel
Bis(mercaptoimidazolyl)borate complexes, Tris(mercaptoimidazolyl)borate complexes, Diphosphine, Hydrogenases, Crystal structure, 395
Nickel
Phthalocyanine, Cobalt, Zinc, Naphthalene, 787
Nickel
Solvothermal synthesis, Thiostannates, Crystal structures, Thermoanalysis, 937
Nickel
Copper, Zinc, Imidazole, α-Hydroxycarboxylato complexes, Thermal behaviour, Crystal structures, 1505
Nickel
Pseudoephedrine, Triangulo, Cluster, Anion exchange, 1837
Nickel
Binuclear compounds, Isocyanides, Polymerisation, Ring-coupled bis-cyclopentadienyl ligand, X-ray molecular structure, 2715
Nickel
Schiff's bases, Hydrogenated Schiff's bases, Coordination geometry, X-ray crystal structures, Polymethylene chains, 3201
Nickel complex
Synthesis, Crystal structures, Indenyl ligand, Catalysis, 1473
Nickel complex
Tripodal ligand, Cyclic voltammetry, 1829
Nickel complexes
Pyrazoline, Ring opening, Ligand oxidation, Structures, 1997
Nickel complexes
Heterocyclic carbenes, Functionalised carbenes, X-ray diffraction, 2813
Nickel(II)
Scorpionands, Chromophores, Copper(II), Macrocycles, 373
Nickel(II)
Thiodiglycolic acid complexes, X-ray structures, Magnetic properties, 1573
Nickel(II)
Lanthanides(III), Amino acid, Heptanuclear, Cluster compound, 2265
Nickel(II) complex
Crystal structure, Thiazine, Cobalt(III) complex, Pyridine, 1453
Nickel(II) complex
Lawesson's Reagent, Thiophosphoryl compound, Sulfur-rich complex, Cobalt(II) complex, 1799
Nickel(II) complexes
Crystal structures, Hydrotris(pyrazolyl)-borate complexes, Coordination environment, Scorpionates, 211
Nickel(II) complexes
Template synthesis, Decaazacyclooctadecane, Macrocycle, 1325
Nickel(II) complexes
Schiff bases, Salicylketimine ligands, X-ray crystallography, 1649
Nickel(II) complexes
Crystal structure, MagnetismPseudohalides,, 2337
Nickel(II) compounds
Crystal structures, Terephthalate ligand, Binuclear complexes, Magnetic properties, 1379
Nicotinate
Chiral, Coordination polymers, Open channel, Grid, 1947
Nitric oxide
Samarium, Lanthanide, Nitrite, Pyrazolylborate, Redox, 2709
Nitride precursor
Titanium, Tin, Tetrazole, Cycloaddition, 801
η^2-nitrile
Tungsten, Oxo, Oxidation, Methylation, Dimerization, 2831
Nitrile coordination
Polypyrazolylborate complexes, Copper complexes, Rhodium complexes, Scorpionates, Coordination Polymers, 235
Nitrilotriacetate
Vanadium complexes, X-ray crystal structure, Hydrogen bonding, 1975
Nitrite
Samarium, Lanthanide, Nitric oxide, Pyrazolylborate, Redox, 2709
Nitrito complexes
Copper complexes, Di-2-pyridylamine, Plasticity effect, *cis*-Distorted octahedron, Fluxional behaviour, 1685
Nitrogen base ligation
Diporphyrins, Zinc(II) complexes, Stability constants, 33
Nitrogen heterocycle ligands
Crystal structures, Clusters, Copper, Molybdenum, Tungsten, Pyrazole, 3143

Nitrogen ligands
Scorpionates, Polypyrazolylborates, Coordination chemistry, 197
Nitronyl nitroxide
Imino nitroxide, Amide, Manganese complexes, Copper complexes, Cobalt complexes, 763
Nitrosyls
Rhenium, Phosphine complexes, DFT calculations, 2363
NMR
Nickel, Dithiocarbamate, PPh_3, Dppe, X-ray crystal structure, 77
NMR
Polypyrazolylborate, Rhodium(I), Cyclooctadiene, Norbornadiene, Structure, 219
NMR
Pyrazine, Pyridine, X-ray, Stacking, Twist, 1011
NMR
Aromatic aminoacidate, Cobalt(III), Non-covalent interactions, Octahedral inversion, Tetradentate ligands, 1749
NMR
2-[(*E*)-2-(aryl)-1-diazenyl]pyridine, Hg(II) complexes, Crystal structures, 2323
NMR
Aluminium(III), Catecholates, Salicylates, Complexation, Proton exchange, 2393
NMR
Pyrazolylborates, Thallium, CPMAS, 2985
NMR spectra
Cobalt(III), Semicarbazone, 2-Hydroxyacetophenone, IR spectra, Electronic spectra, X- ray crystal structure, 41
NMR spectra
Enaminones, Molybdenum(VI) complexes, Molybdenum(V) complexes, Pyrone, X-ray crystal structure, 1859
NO
Crystal structure, Back-bonding, Ruthenium complex, Reactivity, Molecular, 1063
Non-bonded interaction
2-Mercapto-6-nitrobenzothiazole, Organotin(IV), Crystal structure, X-ray crystallography diffraction, 779
Non-covalent interaction
Ion pair complex, Hydrogen bonding network, Charge transfer, Near-IR absorption, 1235
Non-covalent interactions
Aromatic aminoacidate, Cobalt(III), Octahedral inversion, Tetradentate ligands, NMR, 1749
Non-heme iron
Water coordination, X-ray structure, Cyclic voltammetry, Sterically hindered carboxylate, 2805
Non-symmetrical ligands
Ferrocenes, Oxazolines, X-ray diffraction, 611
Norbornadiene
Polypyrazolylborate, Rhodium(I), Cyclooctadiene, Structure, NMR, 219
Norbornene
Neutral palladium(II) complex, X-ray crystallography, Catalyst, Methylaluminoxane, Vinylic polymerizaition, 1619
Novel conformations
Te(II) thiourea complexes, Unexpected colours, X-ray crystallography, Supramolecular associations, 3021
NQR
Crystal structure, Phase transition, Isotope effect, Hydrogen bond, Tetrachloroaurate(III), 1605
NS Schiff base
S-methyldithiocarbazate (SMDTC), Crystal structure of Cd(II) complex, Dithiocarbazate derivatives, 1385

O Ligands
Alkali metals, Lithium, Phosphorus–carbon bond cleavage, Chelates, 2499
O-donor ligands
Lanthanide oxides, Bromotrimethylsilane, Complexes of lanthanide bromides, Crystal structure, Coordination number, 2293
Octahedral inversion
Aromatic aminoacidate, Cobalt(III), Non-covalent interactions, Tetradentate ligands, NMR, 1749
Octahedral structure
Ruthenium(II) carbonyl complexes, Tertiary phosphine chalcogenides, ''Soft–Hard'' and ''Soft–Soft'' interactions, X-ray crystal structure, 1657
Octamolybdate
Hydrothermal synthesis, Three-dimensional oxide, Organic–inorganic hybrid, Building block approach, Hartree–Fock calculations, 1145
Olefin complexes
Copper(I) complexes, Hexafluorocetylacetonate, Divinyl organics, Crystal structure, Thermal analysis, 809
Oligomerization
Hydrocarboxylation, Catalysis, Rhodium complexes, Ethylene, Carbon monoxide, 1677
Oligosilanes
Silanoles, Siloxides, Titanium, Zirconium, 2475
One-dimensional
Silver(I), Aliphatic amino ligands, Coordination polymers, Tubes, Topology, Supramolecular chemistry, Self assembly, Nanotubes, 2075
One-dimensional chains
Self-assembly, Crystal structures, Bis(2-pyridylmethyl)amino acids, Ferromagnetism, Copper(II) complexes, 903
One-dimensional complexes
Copper(II) compounds, Crystal structures, Terephthalate ligand, Magnetic properties, 3043
One-dimensional compounds
Organotin complexes, Organorhodium complexes, Organorhodiumtin complexes, Two-dimensional compounds, Rhodium carbonyl complexes, 103
Open channel
Chiral, Coordination polymers, Nicotinate, Grid, 1947
Open frame material
S,N ambidentate borate ligands, Synthesis, X-ray structure, 205
Optical activity
Carbohydrate, Cobalt complex, Absorption spectra, Circular dichroism, 1341
Orbital analysis
Organometallics, Sandwich complex, Metallocene, Bonding, Density functional theory, 2993
Organic–inorganic hybrid
Octamolybdate, Hydrothermal synthesis, Three-dimensional oxide, Building block approach, Hartree–Fock calculations, 1145
Organogermanium(IV)
1H-5-mercapto-1,2,3-triazolato, Organotin, Crystal structure, X-ray crystallography, 1981
Organometallic compounds
Pyrolysis, Iron–platinum compounds, 63
Organometallics
Sandwich complex, Metallocene, Bonding, Density functional theory, Orbital analysis, 2993
Organorhodium complexes
Organotin complexes, Organorhodiumtin complexes, One-dimensional compounds, Two-dimensional compounds, Rhodium carbonyl complexes, 103
Organorhodiumtin complexes
Organotin complexes, Organorhodium complexes, One-dimensional compounds, Two-dimensional compounds, Rhodium carbonyl complexes, 103
Organotin
1H-5-mercapto-1,2,3-triazolato, Organogermanium(IV), Crystal structure, X-ray crystallography, 1981
Organotin complexes
Organorhodium complexes, Organorhodiumtin complexes, One-dimensional compounds, Two-dimensional compounds, Rhodium carbonyl complexes, 103
Organotin derivatives
Pyrolysis, Tin sulfide, 2102
Organotin oxide
Diorganostannate, Methanesulfonate, Ionic metathesis, 71
Organotin(IV)
2-Mercapto-6-nitrobenzothiazole, Non-bonded interaction, Crystal structure, X-ray crystallography diffraction, 779
Organotin(IV)
1-(4-Hydroxyphenyl)-1H-tetrazole-5-thiol, Hydrogen bonding, π–π stacking interaction, Crystal structures, X-ray crystallography, 1547
Ortho-metallated complexes
Palladium, Ferrocene, Phosphine, Suzuki–Miyaura coupling, X-ray crystallography, 921
Osmium
Dioxygen, Aniline, Oxidation, Electron transfer self-exchange, 323

Osmium
Rhenium, Polypyridyl, Synthesis, Spectroscopy, 1427
Oxadiazole ligand complexes
Palladium, Platinum, Heterobimetallic, Phosphine, 2013
Oxalate acid
Hydrothermal synthesis, Crystal structure, Iron phosphatooxalate, Template, Piperazine, 2357
Oxalato
Iron, (μ-O)di-iron complex, Bis-(2-pyridylmethyl)amine, Hydrogen bonding, Mössbauer spectra, 1419
Oxazolines
Ferrocenes, Non-symmetrical ligands, X-ray diffraction, 611
Oxazolines
Cerium, Chiral, Thermal decomposition, MOCVD, β-ketoesterates, 1467
Oxidation
Hydrotris(pyrazolyl)borate, Ruthenium, Hydrogen bond, Aquo complex, 225
Oxidation
Dioxygen, Osmium, Aniline, Electron transfer self-exchange, 323
Oxidation
Molybdenum complexes, Carbonyl complexes, Pentafluorophenyl, Bond cleavage, Reductive elimination, 1371
Oxidation
Kinetics, Permanganate, 4-Hydroxycoumarin, 2507
Oxidation
η^2-nitrile, Tungsten, Oxo, Methylation, Dimerization, 2831
Oxide
Cobalt, β-diketonates, Adducts, Structures, MOCVDf, 735
Oxides
Actinide, Lanthanide, Carbene, Uranium, 2689
Oximinato monocopper(II) and mononickel(II) complexes
Electrochemistry, Magnetic properties, Unsymmetrical oximinato dicopper(II) complexes and unsymmetrical oximinato dinickel(II) complexes, 665
2-Oxo-1,3-dithiole-4,5-dithiolate
Zinc complex, Cadmium complex, Synthesis, Crystal structure, Density functional calculation, 1701
Oxo
η^2-nitrile, Tungsten, Oxidation, Methylation, Dimerization, 2831
Oxo-bridged iron(III) complexes
2,2′-Bipyrimidine complexes, Iron(III) carboxylate complexes, π–π stacking interactions, X-ray crystal structure, 1271
Oxoalkoxides
Aluminium, Precursor hydrolysis, X-ray, Structure studies, 109
Oxotransfer catalysts
Dioxomolybdenum(VI) thionates, 537
Ozone
X-ray crystal structure, Silver(II) complexes, Manganese(III) complexes, Cobalt(III) complexes, 2631

^{31}P NMR
Phosphine chalcogenides, X-ray structure, Tellurium, Selenium, 1923
Palladium
Ferrocene, Phosphine, Suzuki–Miyaura coupling, Ortho-metallated complexes, X-ray crystallography, 921
Palladium
Crystal structure, Platinum, Phosphorus–nitrogen donor, 1159
Palladium
Platinum, Heterobimetallic, Phosphine, Oxadiazole ligand complexes, 2013
Palladium
Pyridinecarboxaldimine, Cytotoxicity, Platinum, Fluorine, 2169
Palladium
X-ray structure, Diimine, Coordination complex, Zinc, 2789
Palladium
Selenium, Complexes, X-ray, 2967
Palladium dimers
Triazolopyrimidine, Head–head, Head–tail, 2373
Parabanic acid
Iron, Cyclopentadienyl, Carbonyl, Thallium, Gold (I) complex, Alkylation, 1441
Paramagnetic NMR
Rhenium, Benzimidazole, Bibenzimidazole, Crystal structure, 1139
Pendent arm
Chirality, Tetra-azamacrocycles, Template reaction, Conformational isomers, 869
Pentachlorophenolato complexes
Rhodium, Acetylacetonato complexes, Carboxylato complexes, Diazoalkane complexes, C–C coupling reactions, 2645
Pentafluorophenyl
Molybdenum complexes, Carbonyl complexes, Oxidation, Bond cleavage, Reductive elimination, 1371
Pentalene
Tantalum, Synthesis, Structures, 2625
Pentamethylcyclopentadienyl ligands
Molybdenum, Polyoxometallate, Aqueous organometallic chemistry, 2605
Permanganate
Kinetics, Oxidation, 4-Hydroxycoumarin, 2507
Peroxidative bromination
Dinuclear peroxovanadate, Peroxo-bridged divanadate, Heteroligand peroxovanadate, Amino acid containing peroxovanadates, 1097
Peroxo-bridged divanadate
Dinuclear peroxovanadate, Peroxidative bromination, Heteroligand peroxovanadate, Amino acid containing peroxovanadates, 1097
Ph_2Te_2
Metal–metal bond, Molybdenum complex, Mo_2Te_4 complex, Crystal structure, 1663
γ-Phase
Hydrothermal, Layered, Titanium phosphate, Intercalation behavior, 3033
Phase transition
Crystal structure, Isotope effect, Hydrogen bond, NQR, Tetrachloroaurate(III), 1605
1,10-Phenanthroline
Hydrazones, Copper(II) hydrazonate complexes, 2,2′-Bipyridine, X-ray single crystal structure, EPR, 575
1,10-Phenanthroline
Diorganotin, Dicyanoethylene-1,2-dithiolate, 4,4′-Bipyridyl, X-ray crystal structure, Co-crystallization, 1207
Phenanthroline
Cadmium(II), Chloranilate anions, Square antiprism, Crystal structures, Chain polymers, 2587
4,7-Phenanthroline
Copper, Coordination framework, Host–guest properties, Polymers, Extended structures, 55
Phenylacetylene
Phthalocyanine, Unsymmetrical, Cyclic voltammetry, 3155
Pheylcyanamide
Manganese, Magnetic properties, Crystal structures, 1409
Phosphanylalkylcyclopentadienyl ligands
Chromium complexes, Polymerisation studies, 1393
Phosphido
Cyclopentadienyl, Indenyl, Phosphino, Molybdenum, Metallocenes, 1263
Phosphine
Titanium iodide, Arsine, Iron iodide, Crystal structures, 605
Phosphine
Palladium, Ferrocene, Suzuki–Miyaura coupling, Ortho-metallated complexes, X-ray crystallography, 921
Phosphine
Phosphonic acid, Platinum, 1375
Phosphine
Palladium, Platinum, Heterobimetallic, Oxadiazole ligand complexes, 2013
Phosphine
Ligand, Bidentate, Bridging, X-ray, 2569
Phosphine
Synthesis, Coordination, X-ray structure, 2575
Phosphine
Hemilabile, X-ray structure, 3125
Phosphine chalcogenides
X-ray structure, ^{31}P NMR, Tellurium, Selenium, 1923
Phosphine complexes
Heteroscorpionates, Ruthenium, Hydrides, Hemilabile ligands, 361
Phosphine complexes
Rhenium, Nitrosyls, DFT calculations, 2363
Phosphine oxide
Molybdenum, ^{95}Mo NMR, X-ray structures, 1915

Phosphine oxide ligands
Uranyl, Fluoride, Structural study, Spectroscopic characterisation, 3097
Phosphines
Zwitterions, Monoanionic ligands, Syntheses, Structures, Boron, 2901
Phosphinite ligands
Rhenium(I), Dichloromethane complexes, Crystal structures, 1045
Phosphino
Cyclopentadienyl, Indenyl, Phosphido, Molybdenum, Metallocenes, 1263
Phosphonic acid
Phosphine, Platinum, 1375
Phosphorescence
LLCT, Luminescence, Pt(II) and Pd(II), 3173
Phosphorus
Sulfur, Clusters, Phosphorus sulfides, Laser ablation synthesis, TOF mass spectrometry, 1199
Phosphorus
Silicon, Hypercoordination, Hypervalency, Spectroscopy, Fluorescence, X-ray crystallography, 2615
Phosphorus sulfides
Phosphorus, Sulfur, Clusters, Laser ablation synthesis, TOF mass spectrometry, 1199
Phosphorus–carbon bond cleavage
Alkali metals, Lithium, Chelates, O Ligands, 2499
Phosphorus–nitrogen donor
Crystal structure, Platinum, Palladium, 1159
Phosphorylated urea complexes
P,*S*-metallocycles, Supramolecular chemistry, Bipodal ligands, Crystal structures, Macrocycles, 2243
Photochromism
Absorption spectra, Complexation, Kinetics, Spiroindolinonaphthooxazines, 3147
Photoelectron spectra
Hydrotris(pyrazol-1-yl)borates, Scorpionates, Polypyrazolylborates, 429
Photoluminescence
Ionic complex, Rheological phase reaction, Crystal structure, Europium, Zinc, 529
Phthalocyanine
Cobalt, Zinc, Nickel, Naphthalene, 787
Phthalocyanine
Electrochemistry, Spectroelectrochemistry, Pyridine binding, 1279
Phthalocyanine
Metallo phthalocyanine, Liquid crystal, Metallo mesogen, Crown ether, Aza ether, 1931
Phthalocyanine
Unsymmetrical, Phenylacetylene, Cyclic voltammetry, 3155
S-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride)
Bidentate NS Schiff base, Tridentate NNS and NSS Schiff bases, Ni(II) complexes, Dithiocarbazate derivative, 161
Piperazine
Hydrothermal synthesis, Crystal structure, Iron phosphatooxalate, Template, Oxalate acid, 2357
Plasticity effect
Copper complexes, Di-2-pyridylamine, Nitrito complexes, *cis*-Distorted octahedron, Fluxional behaviour, 1685
Platinum
Imine, Benzimidazole, Benzoxazole, Benzothiazole, Pyridine, 155
Platinum
Crystal structure, Palladium, Phosphorus–nitrogen donor, 1159
Platinum
Phosphine, Phosphonic acid, 1375
Platinum
Palladium, Heterobimetallic, Phosphine, Oxadiazole ligand complexes, 2013
Platinum
Pyridinecarboxaldimine, Cytotoxicity, Palladium, Fluorine, 2169
Platinum complexes
Dithiocarbimates, Crystal structures, 1153
Platinum complexes
Thioether complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Diimine complexes, Crown thioethers, 1361
Platinum nuclear magnetic resonance
Thioether complexes, Platinum complexes, Trithiacyclononane, Diimine complexes, Crown thioethers, 1361
Polarizability
Clusters, Electron density distribution, Spherical potential well, Finite electric field, 1519
Polyamines
Azides, Copper(II) complexes, Crystal structures, Magnetic properties, Coordination polymers, 1243
Polyimidazole ligand
Cu-NIRs, Model complex, Crystalline structure, Tripodal ligand, 511
Polymer
Schiff-base, Polypyrrole, Electropolymerization, Iron complex, AFM, 1953
Polymer
Cadmium(II)thiocyanate, Schiff base, Imidazole, Supramolecular synthon, 2045
Polymeric copper(II) complex
2-Thiopheneacetic acid, Crystal structure, Vibrational spectra, Metal isotope effect, 1785
Polymeric network
Zinc, 1,3-Bis(4-pyridyl)propane, 4,4′-Pyridine, X-ray crystallography, 999
Polymerisation
Binuclear compounds, Isocyanides, Nickel, Ring-coupled bis-cyclopentadienyl ligand, X-ray molecular structure, 2715
Polymerisation
Iron, Radical, Styrene, Catalyst, 2921
Polymerisation studies
Phosphanylalkylcyclopentadienyl ligands, Chromium complexes, 1393
Polymers
Copper, 4,7-Phenanthroline, Coordination framework, Host–guest properties, Extended structures, 55
Polymers
Cadmium, Coordinate, Ligands, Supramolecular, 1003
Polymers
Supramolecular chemistry, Self-assembly, Transition metal, Crystal engineering, 1877
Polymethylene chains
Nickel, Schiff's bases, Hydrogenated Schiff's bases, Coordination geometry, X-ray crystal structures, 3201
Polyoxometalates
Hydrothermal synthesis, Crystal structure, Keggin, Cobalt, 773
Polyoxometallate
Molybdenum, Aqueous organometallic chemistry, Pentamethylcyclopentadienyl ligands, 2605
Polyoxomolybdates
Clusters, Complexity, Nanochemistry, 2381
Polyphosphoxane
Rotational barriers, Cage complexes, Cone angles, 125
Polypyrazolylborate
Rhodium(I), Cyclooctadiene, Norbornadiene, Structure, NMR, 219
Polypyrazolylborate complexes
Copper complexes, Rhodium complexes, Scorpionates, Coordination Polymers, Nitrile coordination, 235
Polypyrazolylborates
Scorpionates, Coordination chemistry, Nitrogen ligands, 197
Polypyrazolylborates
Hydrotris(pyrazol-1-yl)borates, Scorpionates, Photoelectron spectra, 429
Polypyridine complexes
Diruthenium(II), Rhodium(III) Ruthenium(II), Heterodinuclear complexes, Electrochemistry, 913
Polypyridine ligands
Ruthenium(II) complexes, Diethylenetriamine, 815
Polypyridyl
Osmium, Rhenium, Synthesis, Spectroscopy, 1427
Polypyrrole
Schiff-base, Electropolymerization, Iron complex, AFM, Polymer, 1953
Polystyrene supported
Hydrogermane, Reduction, Recycle, 177
Polyynes
Carbon allotropes, Carbyne, Dicyanopolyynes, Cyanopolyynes, Electric arc, Graphite, Liquid nitrogen, 1889
Porphyrazine
EPR, Naphthalene, Copper, Zinc, Cobalt, 1845

Potassium
Ammonolysis, Liquid ammonia/toluene two-phase system, Zirconium, 1125
Potentiometric titration
Uranium, Glycerol phosphate, Complex formation, TRLFS, 1793
Potentiometry
Copper(II) complexes, Thioether ligands, Stability constants, Monophosphono dipeptides, Vis, CD, EPR spectroscopy, 1939
PPh_3
Nickel, Dithiocarbamate, Dppe, X-ray crystal structure, NMR, 77
Precursor hydrolysis
Oxoalkoxides, Aluminium, X-ray, Structure studies, 109
Prochirality
Scorpionate ligands, Tripod ligands, Chirality, Menthone, 245
Proton exchange
Aluminium(III), Catecholates, Salicylates, Complexation, NMR, 2393
Proton sponge
Macrocyclic tetramine, Lanthanide complex, 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane, 1089
Pseudoephedrine
Nickel, Triangulo, Cluster, Anion exchange, 1837
Pseudohalides
Crystal structure, Nickel(II) complexes, Magnetism, 2337
Pt(II) and Pd(II)
LLCT, Luminescence, Phosphorescence, 3173
o-Pthalate
Herometallacrown, Malonate, Cu(II) complexes, 943
Pyranopterin molybdenum enzymes
Sulfite oxidase, Electronic structure, Molybdenum complexes, MCD (Magnetic Circular Dichroism), EPR (Electron Paramagnetic Resonance), 499
Pyrazine
Pyridine, X-ray, NMR, Stacking, Twist, 1011
Pyrazole
Ruthenium arene complexes, Dimethylpyrazole, X-ray structure, Bond valence, 885
Pyrazole
Rhenium nitrosyl complexes, Arsine ligands, X–ray structure, Density functional theory calculations, 2523
Pyrazole
Thallium, ^{11}B NMR, B–H coupling, Tris(pyrazolyl)borate, 2533
Pyrazole
Crystal structures, Clusters, Copper, Molybdenum, Tungsten, Nitrogen heterocycle ligands, 3143
Pyrazole ligand
Rhenium complexes, X-ray structure, DFT calculations, 1819
Pyrazole ligand
Rhenium complexes, X-ray structure, DFT calculations, 2005
Pyrazoline
Nickel complexes, Ring opening, Ligand oxidation, Structures, 1997
Pyrazolone
Copper(II) complexes, Crystal structures, ESR study, 2465
Pyrazolyl ancillary ligands
Iridium, Cyclometalated Ir(II) complexes, Boat conformations, Luminescent, Electroluminescence, 419
Pyrazolyl thiosemicarbazone
Synthesis, Spectroscopy, Cobalt(III) complexes, X-ray crystallography, 5
Pyrazolylborate
Samarium, Lanthanide, Nitric oxide, Nitrite, Redox, 2709
Pyrazolylborates
Lanthanides, Neodymium, X-ray structures, Alkoxides, Borohydrides, 253
Pyrazolylborates
Thallium, NMR, CPMAS, 2985
Pyridine
Platinum, Imine, Benzimidazole, Benzoxazole, Benzothiazole, 155
4,4′-Pyridine
Zinc, 1,3-Bis(4-pyridyl)propane, Polymeric network, X-ray crystallography, 999
Pyridine
Pyrazine, X-ray, NMR, Stacking, Twist, 1011
Pyridine
Crystal structure, Thiazine, Cobalt(III) complex, Nickel(II) complex, 1453
2-Pyridinealdoxime complexes
Crystal structures, Manganese(II) carboxylate chemistry, Magnetochemistry, Metal-assisted reactions, 83
Pyridine binding
Phthalocyanine, Electrochemistry, Spectroelectrochemistry, 1279
Pyridine-2-carboxaldehyde
Cyclopentadienyl, Schiff bases, Ruthenium, 1567
Pyridinecarboxaldimine
Cytotoxicity, Platinum, Palladium, Fluorine, 2169
2-pyridineformamide
Thiosemicarbazone, Crystal structure, Zinc, Cadmium, 2303
Pyridyl
Mercury(II), 1,3-Dithiol-2-thione, ^1H NMR, Solid UV, 115
Pyridyl bispyrazolyl
Terpyridine, Iron, Complexation, Rearrangement, X-ray structures, 3193
Pyridylthioazophenol ligands
Copper(II) complex, Crystal structure, 2457
Pyrolysis
Organometallic compounds, Iron–platinum compounds, 63
Pyrolysis
Organotin derivatives, Tin sulfide, 2102
Pyrone
Enaminones, Molybdenum(VI) complexes, Molybdenum(V) complexes, X-ray crystal structure, NMR spectra, 1859
Quinones
Lawsone, 2-Hydroxy-1, 4-Naphthoquinone, Amine oxidase, Copper complexes, Antiferromagnetic coupling, H-bonding, EPR, 2541
2-Quinolinecarboxaldehyde Schiff bases of *S*-alkyl/aryl dithiocarbazates
Tin(IV) complexes, Dithiocarbazates, 2405

Radical
Iron, Styrene, Catalyst, Polymerisation, 2921
Radical salts
Bis(ethylenedithio)tetrathiafulvalene (ET), Crystal structures, Electrical conductivity, 1185
Reactivity
Crystal structure, Back-bonding, Ruthenium complex, NO, Molecular, 1063
Rearrangement
Terpyridine, Pyridyl bispyrazolyl, Iron, Complexation, X-ray structures, 3193
Recycle
Polystyrene supported, Hydrogermane, Reduction, 177
Redox
Kinetics, Mechanism, Silver, Glyoxylic acid, 895
Redox
Samarium, Lanthanide, Nitric oxide, Nitrite, Pyrazolylborate, 2709
Redox-polymers
Electropolymerisation, Ru-complexes, Thiophene, Differential pulse voltammetry, 4-((2-Thienyl)-ethenyl)-2,2′-bipyridine, 589
Reduction
Polystyrene supported, Hydrogermane, Recycle, 177
Reductive elimination
Molybdenum complexes, Carbonyl complexes, Pentafluorophenyl, Oxidation, Bond cleavage, 1371
Regioselectivity of nucleophile and electrophile additions
Acetonitrile reduction, Amine oxidation, Imido, Metal-nitrogen pi bonding, 311
Rhenium
Scorpionate ligands, Technetium, Uranium, 331
Rhenium
Benzimidazole, Bibenzimidazole, Crystal structure, Paramagnetic NMR, 1139
Rhenium
Osmium, Polypyridyl, Synthesis, Spectroscopy, 1427
Rhenium
Nitrosyls, Phosphine complexes, DFT calculations, 2363
Rhenium cluster, 2611
Rhenium complexes
Pyrazole ligand, X-ray structure, DFT calculations, 1819
Rhenium complexes
Pyrazole ligand, X-ray structure, DFT calculations, 2005

Rhenium nitrosyl complexes
Pyrazole, Arsine ligands, X–ray structure, Density functional theory calculations, 2523
Rhenium(I)
Phosphinite ligands, Dichloromethane complexes, Crystal structures, 1045
Rheological phase reaction
Ionic complex, Crystal structure, Photoluminescence, Europium, Zinc, 529
Rhodium
Trispyrazolylborate, C–H activation, 413
Rhodium
Acetylacetonato complexes, Pentachlorophenolato complexes, Carboxylato complexes, Diazoalkane complexes, C–C coupling reactions, 2645
Rhodium carbonyl complexes
Organotin complexes, Organorhodium complexes, Organorhodiumtin complexes, One-dimensional compounds, Two-dimensional compounds, 103
Rhodium complexes
Polypyrazolylborate complexes, Copper complexes, Scorpionates, Coordination Polymers, Nitrile coordination, 235
Rhodium complexes
Hydrocarboxylation, Oligomerization, Catalysis, Ethylene, Carbon monoxide, 1677
Rhodium complexes
Hydroformylation, Ionic liquids, Biphase catalysis, High-pressure NMR, 2679
Rhodium dicarbonyl complexes
κ^2-Tp ligands, Bridging Tp ligands, Isomers, X-ray structure, 301
Rhodium hydrides
Bridging boryls, Catalyzed hydroborations, 2665
Rhodium(I)
Polypyrazolylborate, Cyclooctadiene, Norbornadiene, Structure, NMR, 219
Rhodium(III)
C–H bond activation, Benzene activation, Aldehyde activation, 2943
Rhodium(III) Ruthenium(II)
Diruthenium(II), Heterodinuclear complexes, Polypyridine complexes, Electrochemistry, 913
Ring opening
Nickel complexes, Pyrazoline, Ligand oxidation, Structures, 1997
Ring-coupled bis-cyclopentadienyl ligand
Binuclear compounds, Isocyanides, Nickel, Polymerisation, X-ray molecular structure, 2715
Roof-shaped
Copper(II) complexes, Crystal structure, Dihydroxo-bridged, Triply bridged, 1641
Rotational barriers
Polyphosphoxane, Cage complexes, Cone angles, 125
Ru-complexes
Electropolymerisation, Thiophene, Differential pulse voltammetry, 4-((2-Thienyl)-ethenyl)-2,2′-bipyridine, Redox-polymers, 589
Ruthenium
Hydrotris(pyrazolyl)borate, Hydrogen bond, Oxidation, Aquo complex, 225
Ruthenium
Heteroscorpionates, Hydrides, Phosphine complexes, Hemilabile ligands, 361
Ruthenium
Scorpionate, Tris(pyrazolyl)borate, Hydride, C–H activation, 439
Ruthenium
Arene ligand, Ferrocene carboxylic acid, Ferrocene derivative, 687
Ruthenium
Cyclopentadienyl, 2,3-Bis(α-pyridyl)pyrazine, 1,3,5-Tris(pyridyl)-2,4,6-triazine, 2,3,5,6-Tetrakis(pyridyl)pyrazine, 1069
Ruthenium
Cyclopentadienyl, Schiff bases, Pyridine-2-carboxaldehyde, 1567
Ruthenium
Fluoroionophore, X-ray, Metallacrown, 1719
Ruthenium
Cymene, X-ray, 2695
Ruthenium arene complexes
Pyrazole, Dimethylpyrazole, X-ray structure, Bond valence, 885
Ruthenium complex
Crystal structure, Back-bonding, NO, Reactivity, Molecular, 1063
Ruthenium complexes
EPR spectroscopy, Hydrazido ligand, Mixed-valence, Spectroelectrochemistry, 701
Ruthenium complexes
Hexamethylbenzene, *p*-Cymene, Diphenyl-2-pyridylphosphine, Amines, 3115
Ruthenium(II) carbonyl complexes
Tertiary phosphine chalcogenides, ''Soft–Hard'' and ''Soft–Soft'' interactions, X-ray crystal structure, Octahedral structure, 1657
Ruthenium(II) complexes
Polypyridine ligands, Diethylenetriamine, 815
Ruthenium(II)-tris-chelates
Azoimidazoles, X-ray structure, Electrochemistry, 727

N-salicylidene-*n*-alkanoylhydrazines
Copper(II) complexes, Magnetochemical studies, Bis[monochloro(μ-*N*-salicylidene-myristoylhydrazine) ONO′(−1)]dicopper(II), X-ray crystal and molecular structure, 23
S ligands
Coordination chemistry, Aurates, Thianthrenes, 1351
S,N ambidentate borate ligands
Synthesis, X-ray structure, Open frame material, 205
Saccharin complexes
Copper(II) complexes, Dithiocarbazates, 2031
Saccharin complexes
Cu(II) complexes, Dithiocarbazate Schiff base, *S*-Methyldithiocarbazate, Tridentate NNS Schiff base, 2491
Salicylates
Aluminium(III), Catecholates, Complexation, Proton exchange, NMR, 2393
Salicylketimine ligands
Nickel(II) complexes, Schiff bases, X-ray crystallography, 1649
Salt metathesis
Tris(pyrazolyl)hydroborate (Tp) ligands, Lanthanum, Neodymium, Aryloxide derivatives, 2437
Samarium
Lanthanide, Nitric oxide, Nitrite, Pyrazolylborate, Redox, 2709
Sandwich complex
Organometallics, Metallocene, Bonding, Density functional theory, Orbital analysis, 2993
Schiff base
Uranium, Cluster, Crystal structure, 623
Schiff base
Asymmetric oxidation, Chiral copper(II) complexes, Sulfide, Seven-membered, 1131
Schiff base
Cadmium(II)thiocyanate, Polymer, Imidazole, Supramolecular synthon, 2045
Schiff base
Dicopper(II) complex, 1D Coordination polymer, Crystal structure, Magnetic properties, 2177
Schiff base
Chiral, Copper, Cyclopropanation, Catalysts, Crystal structures, 3051
Schiff base
Copper(II) complex, X-ray structure, Imine activation, Coordination polymer, 3081
Schiff base complexes
Copper complexes, Tripeptide complexes, 849
Schiff base complexes
Ion recognition, Crown ether, UV–Vis, Lanthanides, 1401
Schiff bases
Tricopper(II) complex, Ascorbate oxidase model, Crystal structure, Magnetic properties, 643
Schiff bases
Iron complexes, Acetate ligands, η^2-Coordination modes, β-Cis arrangements, 963
Schiff bases
Cyclopentadienyl, Pyridine-2-carboxaldehyde, Ruthenium, 1567
Schiff bases
Dioxomolybdenum (VI) and oxomolybdenum (IV) complexes, Dithiocarbazate, X-ray structures, 1595
Schiff bases
Nickel(II) complexes, Salicylketimine ligands, X-ray crystallography, 1649
Schiff's bases
Nickel, Hydrogenated Schiff's bases, Coordination geometry, X-ray crystal structures, Polymethylene chains, 3201
Schiff-base
Polypyrrole, Electropolymerization, Iron complex, AFM, Polymer, 1953

Schiff-bases
Zinc complexes, Crystal structures, IR, UV and NMR spectroscopy, Thermal analysis, 1293
Scorpionands
Chromophores, Copper(II), Macrocycles, Nickel(II), 373
Scorpionate
Ruthenium, Tris(pyrazolyl)borate, Hydride, C–H activation, 439
Scorpionate ligands
Tripod ligands, Chirality, Prochirality, Menthone, 245
Scorpionate ligands
Technetium, Rhenium, Uranium, 331
Scorpionate ligands
Hydrotris(pyrazolyl)borate, Tantalum, Metal–metal multiple bond, Alkyne complex, Tetrahydrothiophene complex, 379
Scorpionates
Polypyrazolylborates, Coordination chemistry, Nitrogen ligands, 197
Scorpionates
Nickel(II) complexes, Crystal structures, Hydrotris(pyrazolyl)borate complexes, Coordination environment, 211
Scorpionates
Polypyrazolylborate complexes, Copper complexes, Rhodium complexes, Coordination Polymers, Nitrile coordination, 235
Scorpionates
Hydrotris(pyrazol-1-yl)borates, Polypyrazolylborates, Photoelectron spectra, 429
Secondary bonding
Cyclic telluranes, Metathetical reactions, Intermolecular, Supramolecular networks, 1629
Selenium
Phosphine chalcogenides, X-ray structure, ^{31}P NMR, Tellurium, 1923
Selenium
Palladium, Complexes, X-ray, 2967
Selenourea
Crystal structure, Gold complex, MAS NMR, 1
Self assembly
One-dimensional, Silver(I), Aliphatic amino ligands, Coordination polymers, Tubes, Topology, Supramolecular chemistry, Nanotubes, 2075
Self-assemble
Carboxylate bridges, Copper complexes, Dipeptides, Alkaline earth metals, Magnetic properties, 2125
Self-assembly
Lanthanide nitrate, *N*,*N*′-dioxide, Coordination polymer, 169
Self-assembly
Crystal structures, Bis(2-pyridylmethyl)amino acids, Ferromagnetism, One-dimensional chains, Copper(II) complexes, 903
Self-assembly
Copper, N,O-ligands, Dinuclear, EPR, 1769
Self-assembly
Supramolecular chemistry, Polymers, Transition metal, Crystal engineering, 1877
Semicarbazone
Cobalt(III), 2-Hydroxyacetophenone, NMR spectra, IR spectra, Electronic spectra, X- ray crystal structure, 41
Seven-coordinate tin(IV) complexes
Tin(IV) complexes, Dithiocarbazates, 2,6-diacetylpyridine Schiff bases of S-alkyldithiocarbazates, 2037
Seven-membered
Asymmetric oxidation, Chiral copper(II) complexes, Schiff base, Sulfide, 1131
Sheet structure
Arylazoimidazoles, Cadmium(II) complexes, End-on and end-to-end bridging, X-ray structure, 1D chain, 1669
Silanoles
Siloxides, Titanium, Zirconium, Oligosilanes, 2475
Silica gel
Immobilization, 2-Aminomethylpyridine, Epoxide, Adsorption, Thermodynamic, 719
Silica support
Immobilization, Cobalt(II) complexes, H_2O_2, 59
Silicic acid
Hydroxyaluminosilicate, Aluminium, Aluminium solubility, Aluminium biological availability, 3185
Silicon
Phosphorus, Hypercoordination, Hypervalency, Spectroscopy, Fluorescence, X-ray crystallography, 2615
Siloxides
Silanoles, Titanium, Zirconium, Oligosilanes, 2475
Silver
Kinetics, Mechanism, Redox, Glyoxylic acid, 895
Silver
Coordination polymers, Imidazolate, X-ray structure, 3063
Silver complexes
Diaza-fluorene, Crystal structures, Intermolecular interactions, Electronic spectra, 2259
Silver coordination complex polymers
1D, 2D, 3D topological structure, Multinitriles, 2209
Silver nitrate
Carboxylate, Coordination polymer, Double betaine, Hydrate, Hydrogen bonding, π–π Interaction, 2413
Silver(I)
Bis-imidazole, Bis(imidazol-2-yl)methane, X-ray structures, Argentophilicity, Antifungal, Candida albicans, 1249
Silver(I)
One-dimensional, Aliphatic amino ligands, Coordination polymers, Tubes, Topology, Supramolecular chemistry, Self assembly, Nanotubes, 2075
Silver(I) complexes
Naphthylazoimidazole, Helical structure, EHMO, 793
Silver(I) complexes
Dinuclear complex, Mononuclear complex, 2117
Silver(II) complexes
Ozone, X-ray crystal structure, Manganese(III) complexes, Cobalt(III) complexes, 2631
Sinambic
Multidentate ligand, Cobalt(III), ^{59}Co NMR, 2217
Single crystal X-ray diffraction
Iron(III) complexes, Thiosemicarbazone, Mössbauer spectra, EPR spectra, IR spectra, 969
Single-crystal X-ray diffraction
Tetrakis(3-isopropylpyrazolyl)borate, Solvent extraction, Zinc, Copper, 283
Six coordinate silicates
Ion exchange, Transition metals, Ligand environment, Thermal studies, Magnetism, 679
Sodium
Copper, Tris(pyrazolyl)borate, Fluorinated, Carbonyl, 273
"Soft–Hard" and "Soft–Soft" interactions
Ruthenium(II) carbonyl complexes, Tertiary phosphine chalcogenides, X-ray crystal structure, Octahedral structure, 1657
Solid UV
Mercury(II), 1,3-Dithiol-2-thione, Pyridyl, ^{1}H NMR, 115
Solid-state reactions
Iron clusters, Third-order nonlinear optical properties, 755
Solvent extraction
Tetrakis(3-isopropylpyrazolyl)borate, Single-crystal X-ray diffraction, Zinc, Copper, 283
Solvothermal synthesis
Thiostannates, Nickel, Crystal structures, Thermoanalysis, 937
Spectra
Mn(II) and Cd(II) complexes, Azides, 3-Aminopyridine, Synthesis, X-ray structures, Thermal properties, 2349
Spectral properties
Copper, Crystal structure, Dimer, Magnetic properties, 1303
Spectral properties
Copper, 3,5-Dinitrosalicylate complex, Trimer, Crystal structure, Magnetic properties, 2447
Spectroelectrochemistry
EPR spectroscopy, Hydrazido ligand, Mixed-valence, Ruthenium complexes, 701
Spectroelectrochemistry
Phthalocyanine, Electrochemistry, Pyridine binding, 1279
Spectroelectrochemistry
Vanadium, Diiminediaminediphenolate macrocycle, Magnetochemistry, EPR, FTIR, 2069
Spectroscopic characterisation
Uranyl, Fluoride, Phosphine oxide ligands, Structural study, 3097
Spectroscopic properties
Iron(II) complexes, Trithiocyanuric acid, Mössbauer spectra, Crystal structures, DFT calculations, 2193

Spectroscopic studies
Indomethacin, Diorganotin, Crystal structures, 2021
Spectroscopy
Synthesis, Pyrazolyl thiosemicarbazone, Cobalt(III) complexes, X-ray crystallography, 5
Spectroscopy
Carborane, DFT calculations, X-ray crystallography, 629
Spectroscopy
Hydrazones, Complex, Lanthanide, X-ray, Crystal structures, 1191
Spectroscopy
Osmium, Rhenium, Polypyridyl, Synthesis, 1427
Spectroscopy
Di-2-pyridyl ketone salicyloylhydrazone, Zinc(II) complexes, Stability constants, Thermal analysis, 2095
Spectroscopy
Silicon, Phosphorus, Hypercoordination, Hypervalency, Fluorescence, X-ray crystallography, 2615
Spherical potential well
Clusters, Electron density distribution, Polarizability, Finite electric field, 1519
Spin-crossover
Iron, Crystal structure, Magnetic measurements, 2141
Spin-exchange reactions
Electron-transfer reactions, Bis[tris(pyrazolyl)methane] complexes, Low-spin configurations, High-spin configurations, 1037
Spirocyclic
Cyclophosphazenes, Chiral, X-ray structure, 979
Spiroindolinonaphthooxazines
Absorption spectra, Complexation, Kinetics, Photochromism, 3147
Square antiprism
Eight-coordinate, Stereochemistry, Dodecahedron, Bicapped trigonal prism, Molecular mechanics, 145
Square antiprism
Cadmium(II), Chloranilate anions, Phenanthroline, Crystal structures, Chain polymers, 2587
Square grid structure
Hydrothermal synthesis, Coordination polymer, Magnetic property, Transition metal, 1,4-Naphthalenedicarboxylic acid, 1257
Square planar silver complex
Bitopic heteroscorpionate ligand, 291
Stability constants
Diporphyrins, Zinc(II) complexes, Nitrogen base ligation, 33
Stability constants
Copper(II) complexes, Thioether ligands, Monophosphono dipeptides, Potentiometry, Vis, CD, EPR spectroscopy, 1939
Stability constants
Di-2-pyridyl ketone salicyloylhydrazone, Zinc(II) complexes, Spectroscopy, Thermal analysis, 2095
Stacking
Pyrazine, Pyridine, X-ray, NMR, Twist, 1011
π–π stacking
Copper(II), Aminopolycarboxylate, Ferromagnetic coupling, Cylindrical channels, 1081
π–π stacking interactions
2,2′-Bipyrimidine complexes, Iron(III) carboxylate complexes, Oxo-bridged iron(III) complexes, X-ray crystal structure, 1271
π–π stacking interaction
1-(4-Hydroxyphenyl)-1H-tetrazole-5-thiol, Organotin(IV), Hydrogen bonding, Crystal structures, X-ray crystallography, 1547
π–π staking interaction
4,4′-Bipyridine, Lead(II), Coordination polymers, Lone pair, Crystal structure, 2427
Stereochemistry
Eight-coordinate, Dodecahedron, Square antiprism, Bicapped trigonal prism, Molecular mechanics, 145
Sterically hindered carboxylate
Non-heme iron, Water coordination, X-ray structure, Cyclic voltammetry, 2805
Structural elucidation
Tetranuclear copper(II) complex, Hydrogen bonds, 1169
Structural study
Uranyl, Fluoride, Phosphine oxide ligands, Spectroscopic characterisation, 3097
Structure
Polypyrazolylborate, Rhodium(I), Cyclooctadiene, Norbornadiene, NMR, 219
Structure
Copper, Magnetism, Dinuclear, EPR, 993
Structure
Copper, Infrared, Hydrogen bonds, Distortion isomers, 1969
Structure studies
Oxoalkoxides, Aluminium, Precursor hydrolysis, X-ray, 109
Structures
Tris(pyrazolyl)borate, Bis(imido), Molybdenum, Synthesis, 189
Structures
Zwitterions, Monoanionic ligands, Syntheses, Methyl, Hydrides, 489
Structures
Cobalt, Oxide, β-diketonates, Adducts, MOCVDf, 735
Structures
Cobalt, Copper, Zinc, Bis(8-quinolinyl)amine, 831
Structures
Nickel complexes, Pyrazoline, Ring opening, Ligand oxidation, 1997
Structures
Tantalum, Pentalene, Synthesis, 2625
Structures
Zwitterions, Monoanionic ligands, Phosphines, Syntheses, Boron, 2901
Styrene
Iron, Radical, Catalyst, Polymerisation, 2921
Sulfide
Asymmetric oxidation, Chiral copper(II) complexes, Schiff base, Seven-membered, 1131
Sulfite oxidase
Pyranopterin molybdenum enzymes, Electronic structure, Molybdenum complexes, MCD (Magnetic Circular Dichroism), EPR (Electron Paramagnetic Resonance), 499
Sulfonatothiacalixarene
Capsules, Diaza-Crown ether, Transition metal ions, Assembly, 1461
Sulfonatothiacalixarene
Capsules, Diaza-18-crown-6, Lanthanide ions, 2055
Sulfur
Phosphorus, Clusters, Phosphorus sulfides, Laser ablation synthesis, TOF mass spectrometry, 1199
Sulfur-rich complex
Lawesson's Reagent, Thiophosphoryl compound, Nickel(II) complex, Cobalt(II) complex, 1799
Superhyperfine
Binuclear copper complex, EPR, Half-field, X-ray, Electrochemical, 1115
Supramolecular
Coordination polymer, Europium, Hydrogen bonds, Luminescence, Terbium, 711
Supramolecular
Cadmium, Coordinate, Polymers, Ligands, 1003
Supramolecular associations
Te(II) thiourea complexes, Novel conformations, Unexpected colours, X-ray crystallography, 3021
Supramolecular chemistry
Self-assembly, Polymers, Transition metal, Crystal engineering, 1877
Supramolecular chemistry
One-dimensional, Silver(I), Aliphatic amino ligands, Coordination polymers, Tubes, Topology, Self assembly, Nanotubes, 2075
Supramolecular chemistry
P,*S*-metallocycles, Bipodal ligands, Crystal structures, Macrocycles, Phosphorylated urea complexes, 2243
Supramolecular frameworks
Isoorotic acid, Co(II) and Ni(II) complexes, Hydrothermal synthesis, Hydrogen bonds, 2227
Supramolecular networks
Cyclic telluranes, Metathetical reactions, Intermolecular, Secondary bonding, 1629
Supramolecular synthon
Cadmium(II)thiocyanate, Polymer, Schiff base, Imidazole, 2045
Supramolecule
Lanthanide(III) complexes, Hydrothermal syntheses, Isoorotic acid, Hydrogen bonds, 2085
Suzuki–Miyaura coupling
Palladium, Ferrocene, Phosphine, Orthometallated complexes, X-ray crystallography, 921

Syntheses
Zwitterions, Monoanionic ligands, Structures, Methyl, Hydrides, 489
Syntheses
Zwitterions, Monoanionic ligands, Phosphines, Structures, Boron, 2901
Synthesis
Spectroscopy, Pyrazolyl thiosemicarbazone, Cobalt(III) complexes, X-ray crystallography, 5
Synthesis
Tris(pyrazolyl)borate, Bis(imido), Molybdenum, Structures, 189
Synthesis
S,N ambidentate borate ligands, X-ray structure, Open frame material, 205
Synthesis
Cadmium(II), Calcium(II), Manganese(II), Crystal structures, Tetrazolate complexes, 1217
Synthesis
Osmium, Rhenium, Polypyridyl, Spectroscopy, 1427
Synthesis
Crystal structures, Indenyl ligand, Nickel complex, Catalysis, 1473
Synthesis
Zinc complex, Cadmium complex, 2-Oxo-1,3-dithiole-4,5-dithiolate, Crystal structure, Density functional calculation, 1701
Synthesis
Heteroaromatic carboxylic acid, Triphenyltin, Crystal structure, 1805
Synthesis
Mn(II) and Cd(II) complexes, Azides, 3-Aminopyridine, Spectra, X-ray structures, Thermal properties, 2349
Synthesis
Phosphine, Coordination, X-ray structure, 2575
Synthesis
Tantalum, Pentalene, Structures, 2625

Tantalum
Hydrotris(pyrazolyl)borate, Scorpionate ligands, Metal–metal multiple bond, Alkyne complex, Tetrahydrothiophene complex, 379
Tantalum
Pentalene, Synthesis, Structures, 2625
Te(II) thiourea complexes
Novel conformations, Unexpected colours, X-ray crystallography, Supramolecular associations, 3021
Technetium
Scorpionate ligands, Rhenium, Uranium, 331
Tellurium
Phosphine chalcogenides, X-ray structure, ^{31}P NMR, Selenium, 1923
Temperature effect
Manganese maleate, Coordination polymer, Helical architecture, Hydrogen bonds, π–π interactions, 987
Template
Hydrothermal synthesis, Crystal structure, Iron phosphatooxalate, Oxalate acid, Piperazine, 2357
Template reaction
Chirality, Tetra-azamacrocycles, Pendent arm, Conformational isomers, 869
Template synthesis
Decaazacyclooctadecane, Nickel(II) complexes, Macrocycle, 1325
Templating effect
Hydrothermal syntheses, Crystal structures, Gallophosphates, 1535
Terbium
Coordination polymer, Europium, Hydrogen bonds, Luminescence, Supramolecular, 711
Terephthalate ligand
Nickel(II) compounds, Crystal structures, Binuclear complexes, Magnetic properties, 1379
Terephthalate ligand
Copper(II) compounds, Crystal structures, One-dimensional complexes, Magnetic properties, 3043
Terpyridine
Iridium, Luminescence, Near infra-red, Charge-transfer, Intra-ligand charge transfer, 2769
Terpyridine
Pyridyl bispyrazolyl, Iron, Complexation, Rearrangement, X-ray structures, 3193
Tertiary phosphine chalcogenides
Ruthenium(II) carbonyl complexes, "Soft–Hard" and "Soft–Soft" interactions, X-ray crystal structure, Octahedral structure, 1657
2,3,5,6-Tetrakis(pyridyl)pyrazine
Ruthenium, Cyclopentadienyl, 2,3-Bis(α-pyridyl)pyrazine, 1,3,5-Tris(pyridyl)-2,4,6-triazine, 1069
1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane
Proton sponge, Macrocyclic tetramine, Lanthanide complex, 1089
Tetra-azamacrocycles
Chirality, Template reaction, Pendent arm, Conformational isomers, 869
Tetrachloroaurate(III)
Crystal structure, Phase transition, Isotope effect, Hydrogen bond, NQR, 1605
Tetradentate ligands
Aromatic aminoacidate, Cobalt(III), Non-covalent interactions, Octahedral inversion, NMR, 1749
Tetrahydrofurfurylindenyl
Lanthanide chlorides, Crystal structure, Ionic radius, 1075
Tetrahydrothiophene complex
Hydrotris(pyrazolyl)borate, Scorpionate ligands, Tantalum, Metal–metal multiple bond, Alkyne complex, 379
Tetrakis(3-isopropylpyrazolyl)borate
Solvent extraction, Single-crystal X-ray diffraction, Zinc, Copper, 283
Tetranuclear copper(II) complex
Structural elucidation, Hydrogen bonds, 1169
Tetrathiafulvalene
Copper(II), Charge transfer compounds, Electrical conductivity, 2111
Tetrathiomolybdate
Tetrathiotungstate, Dihydridobis(pyrazolyl)borate, Copper(I) complexes, Crystal structure, Model compounds, 637
Tetrathiotungstate
Tetrathiomolybdate, Dihydridobis(pyrazolyl)borate, Copper(I) complexes, Crystal structure, Model compounds, 637
Tetrazolate complexes
Cadmium(II), Calcium(II), Manganese(II), Synthesis, Crystal structures, 1217
Tetrazole
Titanium, Tin, Nitride precursor, Cycloaddition, 801
Thallium
Bis(mercaptoimidazolyl)borate complexes, Crystal structure, 617
Thallium
Parabanic acid, Iron, Cyclopentadienyl, Carbonyl, Gold (I) complex, Alkylation, 1441
Thallium
Metalloporphyrins, Indium, 1777
Thallium
^{11}B NMR, B–H coupling, Tris(pyrazolyl)-borate, Pyrazole, 2533
Thallium
Pyrazolylborates, NMR, CPMAS, 2985
Thermal analysis
Copper(I) complexes, Hexafluorocetylacetonate, Olefin complexes, Divinyl organics, Crystal structure, 809
Thermal analysis
Zinc complexes, Schiff-bases, Crystal structures, IR, UV and NMR spectroscopy, 1293
Thermal analysis
Di-2-pyridyl ketone salicyloylhydrazone, Zinc(II) complexes, Stability constants, Spectroscopy, 2095
Thermal behaviour
Nickel, Copper, Zinc, Imidazole, α-Hydroxycarboxylato complexes, Crystal structures, 1505
Thermal decomposition
Cerium, Oxazolines, Chiral, MOCVD, β-ketoesterates, 1467
Thermal decomposition
1,3,4-thiadiazole, Zinc, Crystal structure, Kinetics, Bioactivity, 1851
Thermal properties
Magnesium carboxylate, Meltable, Dispersion processing, 1739
Thermal properties
Mn(II) and Cd(II) complexes, Azides, 3-Aminopyridine, Synthesis, Spectra, X-ray structures, 2349
Thermal studies
Six coordinate silicates, Ion exchange, Transition metals, Ligand environment, Magnetism, 679
Thermoanalysis
Solvothermal synthesis, Thiostannates, Nickel, Crystal structures, 937
Thermochromism
Chemical vapour deposition, Thin films, Vanadium dioxide, 3087

Thermodynamic
Silica gel, Immobilization, 2-Aminomethylpyridine, Epoxide, Adsorption, 719
Thianthrenes
S ligands, Coordination chemistry, Aurates, 1351
Thiazine
Crystal structure, Cobalt(III) complex, Nickel(II) complex, Pyridine, 1453
Thiazolidine
Vic-dioximes, Ferrocene, Transition metal complexes, Electrochemistry, 1987
1,3,4-thiadiazole
Zinc, Crystal structure, Thermal decomposition, Kinetics, Bioactivity, 1851
4-((2-Thienyl)-ethenyl)-2,2′-bipyridine
Electropolymerisation, Ru-complexes, Thiophene, Differential pulse voltammetry, Redox-polymers, 589
2-Thiopheneacetic acid
Polymeric copper(II) complex, Crystal structure, Vibrational spectra, Metal isotope effect, 1785 Thin films
Chemical vapour deposition, Thermochromism, Vanadium dioxide, 3087
Thiodiglycolic acid complexes
Nickel(II), X-ray structures, Magnetic properties, 1573
Thioether complexes
Platinum complexes, Trithiacyclononane, Platinum nuclear magnetic resonance, Diimine complexes, Crown thioethers, 1361
Thioether ligands
Copper(II) complexes, Stability constants, Monophosphono dipeptides, Potentiometry, Vis, CD, EPR spectroscopy, 1939
Thioethers
Copper, *N*-ligands, Multi-armed ligands, X-ray structures, Coordination polymer, 1055
Thiolate
Zinc, Enzyme, Alkylation, 481
Thiophene
Electropolymerisation, Ru-complexes, Differential pulse voltammetry, 4-((2-Thienyl)-ethenyl)-2,2′-bipyridine, Redox-polymers, 589
Thiophosphoryl compound
Lawesson's Reagent, Sulfur-rich complex, Nickel(II) complex, Cobalt(II) complex, 1799
Thiosemicarbazone
Iron(III) complexes, Single crystal X-ray diffraction, Mössbauer spectra, EPR spectra, IR spectra, 969
Thiosemicarbazone
Di-2-pyridyl ketone, Ni(II) thiosemicarbazone complex, Electronic spectra, IR spectra, X-ray crystal structure, 1225
Thiosemicarbazone
2-pyridineformamide, Crystal structure, Zinc, Cadmium, 2303
Thiosemicarbazone
Copper(II) complexes, 2-Hydroxyacetophenone, EPR, Antimicrobial studies, Cyclic voltammetry, X-ray crystallography, 2549
Thiosemicarbazone
Copper(II) complexes, 2-Benzoylpyridine, EPR, Antimicrobial activity, Crystal structure, 3069
Thiostannates
Solvothermal synthesis, Nickel, Crystal structures, Thermoanalysis, 937
Third-order nonlinear optical properties
Iron clusters, Solid-state reactions, 755
Three-dimensional oxide
Octamolybdate, Hydrothermal synthesis, Organic–inorganic hybrid, Building block approach, Hartree–Fock calculations, 1145
Tin
Ferrocene, Dithiocarbazate, Ligand, Complex, Crystal structure, 567
Tin
Titanium, Tetrazole, Nitride precursor, Cycloaddition, 801
Tin sulfide
Pyrolysis, Organotin derivatives, 2102
Tin(IV) complexes
Dithiocarbazates, 2,6-diacetylpyridine Schiff bases of S-alkyldithiocarbazates, Seven-coordinate tin(IV) complexes, 2037
Tin(IV) complexes
Dithiocarbazates, 2-Quinolinecarboxaldehyde Schiff bases of *S*-alkyl/aryl dithiocarbazates, 2405
Titanium
Bipyridine, Aluminum, Coordination compound, Crystal structure, 561
Titanium
Tin, Tetrazole, Nitride precursor, Cycloaddition, 801
Titanium
Enolato, Enamido, Zirconium, Aluminum, 1587
Titanium
Silanoles, Siloxides, Zirconium, Oligosilanes, 2475
Titanium iodide
Phosphine, Arsine, Iron iodide, Crystal structures, 605
Titanium phosphate
Hydrothermal, Layered, Intercalation behavior, γ-Phase, 3033
TOF mass spectrometry
Phosphorus, Sulfur, Clusters, Phosphorus sulfides, Laser ablation synthesis, 1199
Topological analysis of electron density
MP2 geometry optimization, Bis(methoxycarbimido)amine, 2235
Topology
One-dimensional, Silver(I), Aliphatic amino ligands, Coordination polymers, Tubes, Supramolecular chemistry, Self assembly, Nanotubes, 2075
κ^2-Tp ligands
Bridging Tp ligands, Rhodium dicarbonyl complexes, Isomers, X-ray structure, 301
trans-1,2-Diaminocyclohexane
Crystal structure, Zinc complex, Catalytic enantioselective reduction, 2063
Transfer hydrogenation
N-Heterocyclic carbenes, Homogenous catalysis, Ketones, Aldehydes, Imines, 2857
Transformation
Molybdenum phosphate, Hydrothermal synthesis, Crystal structure, 2153
Transition metal
Hydrothermal synthesis, Coordination polymer, Magnetic property, Square grid structure, 1,4-Naphthalenedicarboxylic acid, 1257
Transition metal
Supramolecular chemistry, Self-assembly, Polymers, Crystal engineering, 1877
Transition metal complexes
Vic-dioximes, Thiazolidine, Ferrocene, Electrochemistry, 1987
Transition metal ions
Sulfonatothiacalixarene, Capsules, Diaza-Crown ether, Assembly, 1461
Transition metals
Six coordinate silicates, Ion exchange, Ligand environment, Thermal studies, Magnetism, 679
Triangulo
Pseudoephedrine, Nickel, Cluster, Anion exchange, 1837
Triazenido complexes
Diruthenium compounds, Metal–metal bonds, Formamidinato complexes, Multiple bonds, Low spin complexes, 2637
Triazolopyrimidine
Zn complexes, Copper dimers, EPR, 743
Triazolopyrimidine
Palladium dimers, Head–head, Head–tail, 2373
Tricopper(II) complex
Schiff bases, Ascorbate oxidase model, Crystal structure, Magnetic properties, 643
Tridentate NNS and NSS Schiff bases
S-2-picolyldithiocarbazate (Hydrazine carbodithioic acid pyridinium-2-yl methyl ester chloride), Bidentate NS Schiff base, Ni(II) complexes, Dithiocarbazate derivative, 161
Tridentate NNS Schiff base
Cu(II) complexes, Dithiocarbazate Schiff base, Saccharin complexes, *S*-Methyldithiocarbazate, 2491
Trimer
Copper, 3,5-Dinitrosalicylate complex, Crystal structure, Magnetic properties, Spectral properties, 2447
Tripeptide complexes
Copper complexes, Schiff base complexes, 849
Triphenyltin
Heteroaromatic carboxylic acid, Synthesis, Crystal structure, 1805
Triply bridged
Copper(II) complexes, Crystal structure, Dihydroxo-bridged, Roof-shaped, 1641
Tripod ligands
Scorpionate ligands, Chirality, Prochirality, Menthone, 245

Tripodal
Heteroscorpionate, Alkylthiolate, Imidazole, Iron, Zinc, 471
Tripodal amine ligand
Hypodentate, Cu(II) complexes, Crystal structure, Five-coordinate, 97
Tripodal ligand
Cu-NIRs, Model complex, Crystalline structure, Polyimidazole ligand, 511
Tripodal ligand
Nickel complex, Cyclic voltammetry, 1829
1,3,5-Tris(pyridyl)-2,4,6-triazine
Ruthenium, Cyclopentadienyl, 2,3-Bis(α-pyridyl)pyrazine, 2,3,5,6-Tetrakis(pyridyl)pyrazine, 1069
Tris(2-pyridylmethyl)amine
Iron(II) complexes, Cobalt(II) complexes, X-ray crystal structures, Bis(2-pyridylmethyl)amine, 3105
Tris(cyclohexyl)tin
Halostannanes, Crystal structures, 2331
Tris(mercaptoimidazolyl)borate complexes
Nickel, Bis(mercaptoimidazolyl)borate complexes, Diphosphine, Hydrogenases, Crystal structure, 395
Tris(pyrazolyl)borate
Bis(imido), Molybdenum, Synthesis, Structures, 189
Tris(pyrazolyl)borate
Lanthanides, Ytterbium, Aryloxide, Crystal Structures, Divalent, 263
Tris(pyrazolyl)borate
Sodium, Copper, Fluorinated, Carbonyl, 273
Tris(pyrazolyl)borate
Ruthenium, Scorpionate, Hydride, C–H activation, 439
Tris(pyrazolyl)borate
Cyanide bridged clusters, Iron(III) complex, Magnetic properties, 1333
Tris(pyrazolyl)borate
Thallium, ^{11}B NMR, B–H coupling, Pyrazole, 2533
Tris(pyrazolyl)hydroborate (Tp) ligands
Lanthanum, Neodymium, Salt metathesis, Aryloxide derivatives, 2437
Trispyrazolylborate
C–H activation, Rhodium, 413
Trithiacyclononane
Thioether complexes, Platinum complexes, Platinum nuclear magnetic resonance, Diimine complexes, Crown thioethers, 1361
Trithiocyanuric acid
Iron(II) complexes, Mössbauer spectra, Crystal structures, Spectroscopic properties, DFT calculations, 2193
TRLFS
Uranium, Glycerol phosphate, Complex formation, Potentiometric titration, 1793
Tubes
One-dimensional, Silver(I), Aliphatic amino ligands, Coordination polymers, Topology, Supramolecular chemistry, Self assembly, Nanotubes, 2075
Tungsten
η^2-nitrile, Oxo, Oxidation, Methylation, Dimerization, 2831
Tungsten
Crystal structures, Clusters, Copper, Molybdenum, Nitrogen heterocycle ligands, Pyrazole, 3143
Twist
Pyrazine, Pyridine, X-ray, NMR, Stacking, 1011
Two-dimensional compounds
Organotin complexes, Organorhodium complexes, Organorhodiumtin complexes, One-dimensional compounds, Rhodium carbonyl complexes, 103

Unexpected colours
Te(II) thiourea complexes, Novel conformations, X-ray crystallography, Supramolecular associations, 3021
Unsymmetrical
Phthalocyanine, Phenylacetylene, Cyclic voltammetry, 3155
Unsymmetrical oximinato dicopper(II) complexes and unsymmetrical oximinato dinickel(II) complexes
Electrochemistry, Magnetic properties, Oximinato monocopper(II) and mononickel(II) complexes, 665
Uranium
Scorpionate ligands, Technetium, Rhenium, 331
Uranium
Schiff base, Cluster, Crystal structure, 623
Uranium
Glycerol phosphate, Complex formation, Potentiometric titration, TRLFS, 1793
Uranium
Crystal structure, N, O donor ligands, 2285
Uranium
Actinide, Lanthanide, Oxides, Carbene, 2689
Uranyl
Fluoride, Phosphine oxide ligands, Structural study, Spectroscopic characterisation, 3097
Uranyl bis(β-diketonates)
Bis(diphenylphosphino)methane dioxide, Uranyl nitrate, Monodentate, Bidentate chelate, Bridging bidentate, Coordination modes, 1527
Uranyl ion
Alkali metal ions, Calixarenes, Homooxacalixarenes, Crystal structures, 649
Uranyl ions
Diols, Hydrogen bonding, Crystal structures, 1613
Uranyl nitrate
Bis(diphenylphosphino)methane dioxide, Uranyl bis(β-diketonates), Monodentate, Bidentate chelate, Bridging bidentate, Coordination modes, 1527
UV and NMR spectroscopy
Zinc complexes, Schiff-bases, Crystal structures, IR, Thermal analysis, 1293
UV–Vis
Ion recognition, Schiff base complexes, Crown ether, Lanthanides, 1401
UV–Vis, EPR and IR spectra
Dinuclear copper(II) complex, Magnetic properties, Bidentate ligand, Crystal structure, 1309

^{51}V NMR spectra
Crystal structure, Vanadium(V) peroxo mandelato complex, IR spectra, 655
Vanadium
Diiminediaminediphenolate macrocycle, Magnetochemistry, EPR, FTIR, Spectroelectrochemistry, 2069
Vanadium complexes
Nitrilotriacetate, X-ray crystal structure, Hydrogen bonding, 1975
Vanadium dioxide
Chemical vapour deposition, Thermochromism, Thin films, 3087
Vanadium(V) peroxo mandelato complex
Crystal structure, IR spectra, ^{51}V NMR spectra, 655
Vibrational spectra
2-Thiopheneacetic acid, Polymeric copper(II) complex, Crystal structure, Metal isotope effect, 1785
Vinylic polymerizaition
Neutral palladium(II) complex, X-ray crystallography, Catalyst, Methylaluminoxane, Norbornene, 1619
Vis, CD, EPR spectroscopy
Copper(II) complexes, Thioether ligands, Stability constants, Monophosphono dipeptides, Potentiometry, 1939

Water coordination

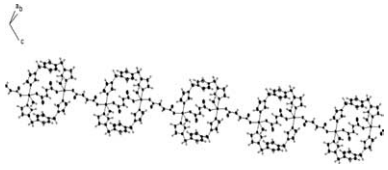
Polyhedron 23 (2004) 3007

Syntheses and crystal structures of three novel Cu(II) coordination polymers of different dimensionality constructed from Cu(II) carboxylates (carboxylate = malonate (mal), 2 acetate (ac), fumarate (fum)) and conformationally flexible 1,4-bis(imidazole-1-yl-methylene)benzene (IX)

Three new coordination polymers $[[Cu_2(mal)_2(IX)_2(H_2O)_6]_n$, $Cu_2(ac)_4(IX)_2]_n$ and $[Cu_2(fum)_2(IX)_2(H_2O)_2]_n$ are generated by employing Cu(II) carboxylates (mononuclear mal, binuclear 2ac, polynuclear fum) and conformationally flexible bifunctional IX as building blocks. The advantage of using the discrete framework of the building blocks in the form of metal carboxylates with a flexible ligand is demonstrated.

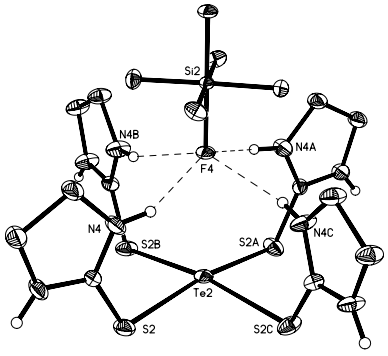


Olav Foss, Steinar Husebye, Karl W. Törnroos, Philip E. Fanwick

Polyhedron 23 (2004) 3021

Synthesis and X-ray crystal structures of six $[TeL_4][MF_6]$ salts, where L is ethylene- or trimethylene-thiourea, and M is Si, Ge or Sn. Five Te(II) complexes with a novel type of structure linked together by unusual N–H···F hydrogen bonds

Six novel tellurium(II) complex salts $[Te(etu)_4][SiF_6]$ (**1**), $[Te(etu)_4][SiF_6] \cdot H_2O$ (**2**), $[Te(trtu)_4][SiF_6]$ (**3**), $[Te(etu)_4][GeF_6] \cdot H_2O$ (**4**), $[Te(trtu)_4][GeF_6]$ (**5**) and $[Te(etu)_4][SnF_6]$ (**6**) (etu = ethylenethiourea, trtu = trimethylenethiourea) have been prepared and characterized, mainly by X-ray crystallographic methods. All the Te(II) complex cations are square planar, but **1**–**5** have an unusual conformation as all four thiourea ligands are extending to the same side of the coordination plane. This conformation is probably stabilized by the supramolecular interactions shown in the figure. The red colour of **1**–**5** is also surprising and is explained on the basis of the *cis*-S–Te–S–C torsion angles near to 180°, which results in a red shift in the UV–Vis spectrum. In **6** this torsion angle is close to 90° and the colour is yellow.

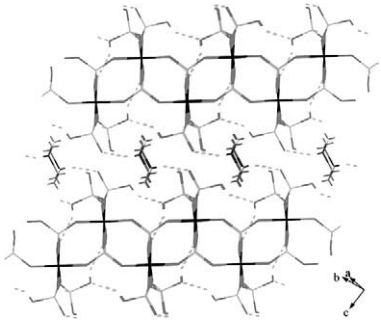


Chao Chen, Yu-Lin Yang, Kun-Lin Huang, Zhen-Hua Sun, Wei Wang, Zhuo Yi, Yun-Ling Liu, Wen-Qin Pang

Polyhedron 23 (2004) 3033

Hydrothermal synthesis and intercalation behavior of a layered titanium phosphate $Ti_2(H_2PO_4)(HPO_4)(PO_4)_2 \cdot 0.5C_6N_2H_{16}$, with an extended γ-phase intercalated into organic amine

The structure exhibits an extended γ-phase intercalated into organic amine, but the interaction behavior presented unusual features because of the presence of *N*,*N*′-dimethylpiperazine cations between the layers.



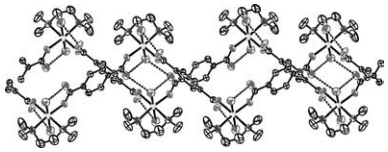
Elsevier Ltd.

Chang Seop Hong, Young Sin You

Polyhedron 23 (2004) 3043

Synthesis, crystal structures and magnetic properties of Cu(II) compounds bridged by the terephthalate ligand and hydrogen bonds

Two tp-bridged Cu(II) compounds, $[Cu(tmen)(tp)(H_2O)_2]_n$ (**1**) (tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine; tp = terephthalate) and $[Cu(pyrazole)_2(tp)]_n$ (**2**), showing coordinative zigzag and linear structures, respectively, were characterized by means of X-ray crystallography and magnetic measurements. Both coordination polymers, with a 3D extended network array (**1**) and a 2D sheet structure (**2**), are formed by incorporating hydrogen bonds into 1D chains. Magnetic data indicate that they exhibit weak ferromagnetic interactions through hydrogen bonds and weak antiferromagnetic couplings via tp ligands.

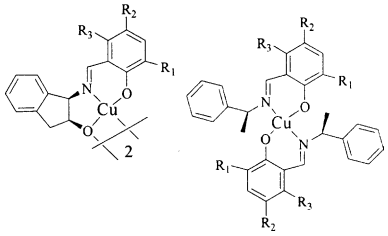


Ana L. Iglesias, Gerardo Aguirre, Ratnasamy Somanathan, Miguel Parra-Hake

Polyhedron 23 (2004) 3051

New chiral Schiff base–Cu(II) complexes as cyclopropanation catalysts

A series of chiral Schiff base ligands and their Cu(II) complexes have been synthesized. X-ray structures show the metal ion in a distorted square planar geometry with dimeric or monomeric structures, depending on the ligand denticity. Unexpectedly the analysis of their catalytic capacity in asymmetric cyclopropanation reactions resulted in rather poor e.e.'s (enantiomeric excess).



G. Attilio Ardizzoia, Stefano Brenna, Fulvio Castelli, Simona Galli, Girolamo LaMonica, Norberto Masciocchi, Angelo Maspero

Polyhedron 23 (2004) 3063

Metal imidazolato polymers: synthesis, characterization and crystal structure of new silver(I) triphenylphosphine derivatives

On reacting polymeric $[Ag(im)]_n$ (Him = imidazole) with different amounts of PPh_3, the $[Ag_2(\mu_2\text{-im})_2(PPh_3)_3]_n$ and $[Ag(\mu_2\text{-im})(PPh_3)_2]_n$ species, containing wavy chains of metal ions, singly bridged by *N*,*N*′-*exo*-bidentate imidazolate ligands but differing in the number of coordinated phosphines thus in the stereochemistry, are obtained.

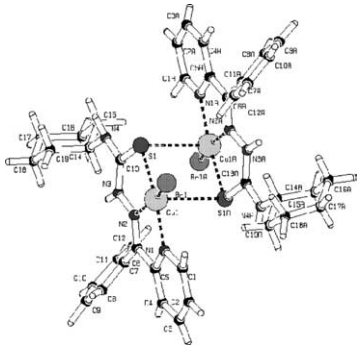
Polyhedron 23 (2004) 3069

Structural, spectral and antimicrobial studies of copper(II) complexes of 2-benzoylpyridine *N*(4)-cyclohexyl thiosemicarbazone

Six new copper(II) complexes of 2-benzoylpyridine *N*(4)-cyclohexyl thiosemicarbazone (HL) have been synthesized and characterized by different physicochemical techniques. Five of the complexes have been found to possess the stoichiometry [CuLX]. The complex prepared from copper sulfate has the composition $[Cu_2L_2SO_4]\cdot(H_2O)_2$. The metal–ligand bonding parameters evaluated from the EPR spectra indicate strong in-plane σ and in-plane π bonding. The antimicrobial activity of the ligand and the copper complexes were tested against five types of bacteria isolated from clinical samples.

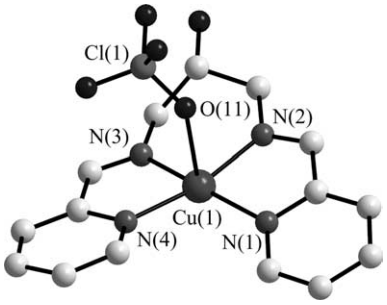


Arindam Mukherjee, Munirathinam Nethaji, Akhil R. Chakravarty

Polyhedron 23 (2004) 3081

Synthesis, crystal structure and imine bond activation of a copper(II) Schiff base complex

A new copper(II) complex $[Cu(HL)(ClO_4)](ClO_4)$ containing a tetradentate Schiff base has been synthesized and structurally characterized by X-ray crystallography. It undergoes oxidative activation of the azoimine moiety through an amido intermediate on reaction with H_2O_2 to form a bis(picolinato)copper(II) species.

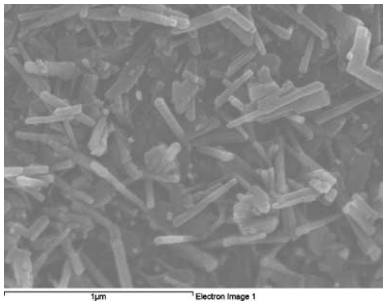


Troy D. Manning, Ivan P. Parkin

Polyhedron 23 (2004) 3087

Vanadium(IV) oxide thin films on glass and silicon from the atmospheric pressure chemical vapour deposition reaction of $VOCl_3$ and water

The dual source atmospheric pressure chemical vapour deposition reaction of $VOCl_3$ and H_2O was used to prepare thin films of vanadium oxides on glass and silicon substrates. Reactor temperatures below 600 °C or with a gas-phase excess of $VOCl_3$ over water, V_2O_5 thin films were produced. Vanadium(IV) oxide thin films were prepared at 600 °C. These films show a thermochromic transition temperature of 67 °C.

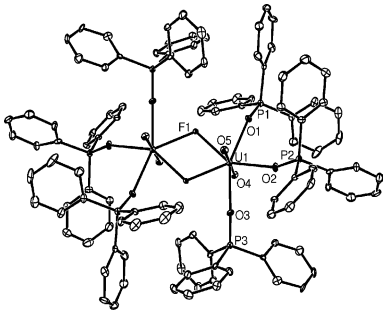


Gordon H. John, Iain May, David Collison, Madeleine Helliwell

Polyhedron 23 (2004) 3097

Synthesis, structural and spectroscopic characterisation of three di-μ-fluoro-bis[dioxouranyl] complexes

We report the synthesis and structural characterisation of three novel dimeric uranyl complexes with organic phosphine oxide ligands and bridging fluorides. Two of the complexes, $[\{UO_2(\mu\text{-}F)(TPPO)_3\}_2][BF_4]_2 \cdot C_6H_{14}$ and $[\{UO_2(\mu\text{-}F)(TBPO)_3\}_2][BF_4]_2$, are dicationic, charge balanced by two uncoordinated tetrafluoroborate anions each. The third complex, $[UO_2(\mu\text{-}F)(F)(DPPMO_2)]_2 \cdot 2MeOH$, is neutral with terminal fluoride also coordinated to both metal centres.

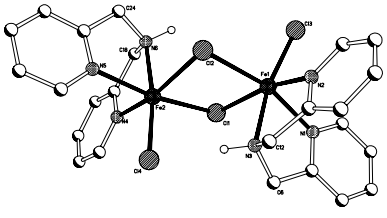


Christopher J. Davies, Gregory A. Solan, John Fawcett

Polyhedron 23 (2004) 3105

Synthesis and structural characterisation of cobalt(II) and iron(II) chloride complexes containing bis(2-pyridylmethyl)amine and tris(2-pyridylmethyl)amine ligands

Divalent cobalt and iron chloride complexes of the type $[LMCl_2]_n$ (n = 1 or 2), $[LMCl]Cl$, $[LMCl]_2[MCl_4]$ and $[L_2M]Cl_2$ are accessible on treatment of L [L = bis (2-pyridylmethyl)-amine (DPA) and tris(2-pyridylmethyl)amine-(TPA)] with anhydrous MCl_2 in n-BuOH at elevated temperatures; complex $[(DPA)FeCl_2]_2$ undergoes oxidation in air to give the oxo-bridged species, $[\{(DPA)FeCl_2\}_2(\mu\text{-}O)]$. All the complexes have been spectroscopically and structurally characterised.

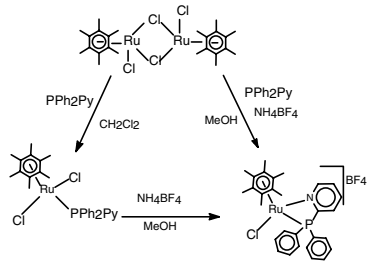


P. Govindaswamy, Yurij A. Mozharivskyj, Mohan Rao Kollipara

Polyhedron 23 (2004) 3115

New neutral and cationic η^6-arene ruthenium complexes with phosphine and amine ligands: syntheses and molecular structures of $[(\eta^6\text{-}p\text{-cymene})Ru(NH_2CH_2C_6H_5)Cl_2]$, $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl_2]$ and $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl]^+$

The dimeric complex $[(\eta^6\text{-}C_6Me_6)Ru(\mu\text{-}Cl)Cl]_2$ reacts with diphenyl-2-pyridyl-phosphine to yield a neutral P-coordinated ruthenium(II) complex $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl_2]$ as well as a cationic P,N-chelating complex $[(\eta^6\text{-}C_6Me_6)Ru(PPh_2Py)Cl]$ The monomeric complex $[(\eta^6\text{-}p\text{-cymene})Ru(PPh_3)Cl_2]$ can react with amine ligands to yield chiral complexes. Representative complexes have been characterized by single-crystal X-ray study.

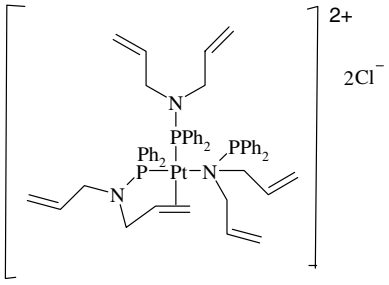


Alexandra M.Z. Slawin, Heather L. Milton, Joanne Wheatley, J. Derek Woollins

Polyhedron 23 (2004) 3125

Preparation and coordination chemistry of *N*-diallylaminodiphenylphosphine and *N*-allylaminobis(diphenyl)phosphine

N-diallylaminodiphenylphosphine coordinates using P, N or C=C whereas *N*-allylaminobis(diphenylphosphine)phosphine is a simple P donor.

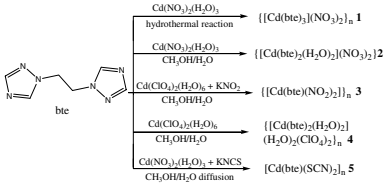


Baolong Li, Xia Zhu, Junhui Zhou, Yanfen Peng, Yong Zhang

Polyhedron 23 (2004) 3133

Syntheses and structures of five cadmium(II) coordination polymers from 1,2-bis(1,2,4-triazol-1-yl)ethane

Five structually distinct cadmium(II) coordination polymers based on 1,2-bis(1,2,4-triazol-1-yl)ethane have been synthesized and structurally characterized.

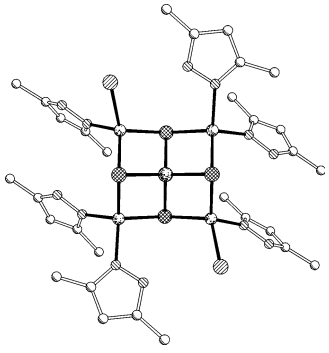


Azizolla Beheshti, Neil R. Brooks, William Clegg, Saeedeh Ebad Sichani

Polyhedron 23 (2004) 3143

Synthesis, crystal structures and spectroscopic characterization of two neutral heterobimetallic clusters $MS_4Cu_4(pz^{Me2})_6X_2$ (where M = Mo (**1**) or W (**2**), X = Cl (**1**) or disordered Cl/Br (**2**), and pz^{Me2} = 3,5-dimethylpyrazole)

The title complexes each contain five coplanar metal atoms; Mo or W is tetrahedrally surrounded by triply-bridging S atoms. Each Cu atom has distorted tetrahedral coordination involving two bridging sulfides, but two Cu atoms additionally have two substituted pyrazole ligands while the other two have one pyrazole and one halide ligand.

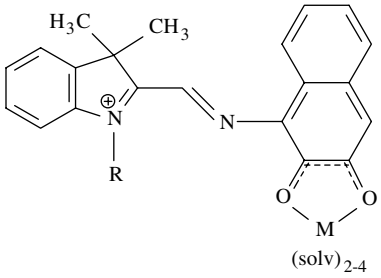


Stela Minkovska, Monika Fedieva, Bojana Jeliazkova, Todor Deligeorgiev

Polyhedron 23 (2004) 3147

Thermally activated and light-induced metal ion complexation of 5′-(hydroxy)spiroindolinonaphthooxazines in polar solvents

Coordination of Cu(II), Fe(II) or Al(III) with the open form of 5′-(hydroxy)spiroindolinonaphthooxazines takes place thermally (slowly) and photochemically in acetone, ethanol and their 1:1 aqueous mixtures resulting a reversibly photochromic complex. Chelation induces a slight hypsochromic shift of the visible absorption of the photomerocyanine and drastically slows down its thermal bleaching in the dark.



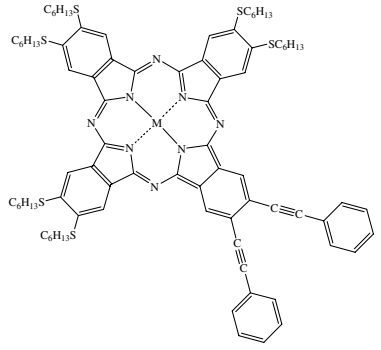
M = Cu(II), Fe(II) or Al(III)

Ayfer Kalkan, Atıf Koca Zehra, Altuntaş Bayır

Polyhedron 23 (2004) 3155

Unsymmetrical phthalocyanines with alkynyl substituents

We report on the synthesis and characterisation of unsymmetrical metallophthalocyanines (M = Zn, Ni, Co) which carry two peripheral hexylthio substituents on each of three of the benzenoid groups, while the fourth one carries two phenylethynyl groups.

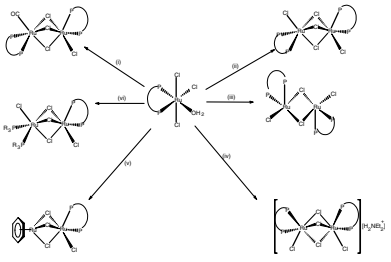


Márcio P. de Araujo, Eliana M.A. Valle, Javier Ellena, Eduardo E. Castellano, Eduardo N. dos Santos, Alzir A. Batista

Polyhedron 23 (2004) 3163

mer-[$RuCl_3$(P–P)H_2O] (P–P = dppb or diop) as a starting material for the synthesis of binuclear complexes. Crystallographic structures of [(dppb)ClRu–μ$(Cl)_3$–RuCl(dppb)] and [(η^6-C_6H_6)Ru–μ$(Cl)_3$–RuCl(dppb)]. Imine hydrogenation using mono- and binuclear ruthenium complexes

In this work the reactvity of *mer*-[$RuCl_3$(P–P)H_2O] (P–P = chiral and achiral chelating ditertiary phosphine) with H_2, ruthenium(II) and ruthenium(III) complexes was studied. Several new and known complexes (Ru_2(II,II) and Ru_2(II,III)) were isolated. The activity of some complexes was tested for the hydrogenation of imines and the results are discussed. X-ray structures of [(dppb)ClRu–(μ-Cl)$_3$–RuCl(dppb)] (**5**) and [(η^6-C_6H_6)Ru–(μ-Cl)–RuCl(dppb)] are presented.



V. Anbalagan, T.S. Srivastava

Polyhedron 23 (2004) 3173

Spectral and photophysical properties of mono and dinuclear Pt(II) and Pd(II) complexes: An unusual emission behaviour

Mononuclear complexes of the formula [M(N-N)(DHB)] and dinuclear complexes of the formula [M_2(BPY)$_2$(THB)] were synthesized and characterized. These complexes were found to show an optically active LLCT band and the platinum complexes of the series were found to show dual emitting states.

The solubility of an hydroxyaluminosilicate

Silicic acid, $Si(OH)_4$, reacts with aluminium to form hydroxyaluminosilicates (HAS). When $Si(OH)_4$ is in excess (twofold) an HAS with a Si:Al ratio of 1.0 is formed (HAS_B) which upon its aggregation towards a critical nucleus (the size of which is as yet unknown) is precipitated. Herein, we provide the first estimate of the solubility of HAS_B.

Iron complexes of terdentate nitrogen ligands: formation and X-ray structure of three new dicationic complexes

The synthesis and X-ray structure of the iron complexes $(L^1)_2Fe^{2+}(FeCl_4^-)_2$, $(L^2)_2Fe^{2+}FeCl_4^{2-}$ and $(L^2)_2Fe^{2+}(FeCl_4^-)_2(THF)_4$ (L = 6,6″-di(*p*-tolyl)-2,2′:6′,2″-terpyridine and L = 2,6-bis-(3-mesitylpyrazol-1-yl)pyridine) are presented. $(L^1)_2Fe$ was shown to be a high-spin complex, whereas $(L^2)_2Fe^{2+}$ was low-spin.

Polyhedron 23 (2004) 3201

Coordination geometry of tetradentate Schiff's base nickel complexes: the effects of donors, backbone length and hydrogenation

The crystal structures of six tetradentate Schiff's base nickel complexes have been determined. These have been used to analyse the effects of backbone length, donor set, hydrogenation and hydrogen bonding on the coordination geometries of the complexes they are capable of forming.

Crystal structure, thermal decomposition kinetics and antimicrobial activities of $[Zn(eatz)_2(OAc)_2]$ (eatz=5-ethyl-2-amino-1,3,4-thiadiazole)

A signal crystal of $[Zn(eatz)_2(OAc)_2]$ has been synthesized and determined by X-ray diffraction. The structural unit is a distorted tetrahedron. Thermal analysis reveals that the complex decomposes in three transitions in N_2 atmosphere. The thermal decomposition kinetic analysis and antimicrobial activities assays have also been reported.

Synthesis, characterization and crystal structures of molybdenum(VI) and (V) complexes with differently N-substituted β′-hydroxy-β-enaminones

Mononuclear molybdenum(VI) $[MoO_2L_2]$ and dinuclear molybdenum(V) $[Mo_2O_4(L^{1b})_2(CH_3OH)_2]$ complexes have been prepared by the reaction of $[MoO_2(acac)_2]$ or $[Mo_2O_3(acac)_4]$ (acac=acetylacetonate ion), respectively, with the appropriate β′-hydroxy-β-enaminones. All compounds have been characterized by means of chemical analyses, IR and one- and two-dimensional NMR spectroscopy, and some of them by X-ray crystallography.

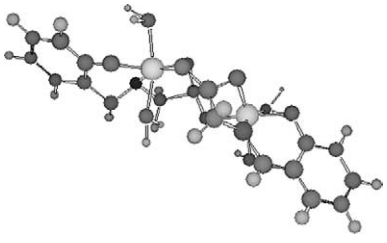
Polyhedron 23 (2004) 1869

Electronic and magnetic properties of iron (III) dinuclear complexes with carboxylate bridges

Dinuclear iron (III) complexes with a carboxylate bridges of the type $[Fe_2L_2(H_2O)_4](NO_3)_2(H_2O)_m$, where L=a Schiff base, have been prepared and characterised by different spectroscopic techniques, magnetic susceptibility, and electrochemical measurements. Mössbauer Spectroscopy for dinuclear iron (III) complexes show two inequivalent hexacoordinated atoms in high spin. Temperature dependence of the reciprocal molar susceptibility indicate a weakly antiferromagnetically coupled system.

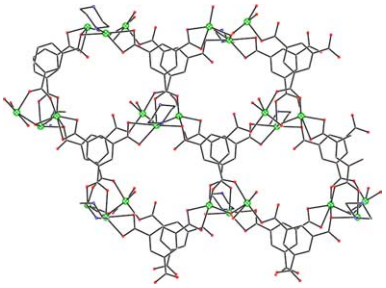


Jian-Xin Chen, Shi-Xiong Liu, En-Qing Gao

Polyhedron 23 (2004) 1877

Syntheses, structures and fluorescence of three novel 3D coordination polymers $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)] \cdot H_2O$, $Cd_2Na_2(TMA)_2(H_2O)_4$ and $[Cd_2Co(TMA)_2(H_2O)_4] \cdot 2H_2O$ (TMA=trimesic acid, PRZ=piperazine)

Three novel coordination polymers $[Cd_3(TMA)_2(H\text{-}PRZ)(H_2O)_3(OH)] \cdot H_2O$ (**1**), $Cd_2Na_2(TMA)_2(H_2O)_4$ (**2**) and $[Cd_2Co(TMA)_2(H_2O)_4] \cdot 2H_2O$ (**3**) have been synthesized via a hydrothermal route and characterized. Complex **1** is a sandwich-like 2D coordination polymer with a porous dimension of ca. 7.5×5.5 Å; complex **2** is a 3D polymer based on tetranuclear heterometallic clusters and the complex **3** is the first trimesate complex containing two different transitional metals.



Franco Cataldo

Polyhedron 23 (2004) 1889

Polyynes: a new class of carbon allotropes. About the formation of dicyanopolyynes from an electric arc between graphite electrodes in liquid nitrogen

A mixture of dicyanopolyynes having the general formula $N{\equiv}C{-}(C{\equiv}C)_n{-}C{\equiv}N$ with $n = 2$, 3 and 4 is formed and collected in a simple apparatus when graphite electrodes are arced in liquid nitrogen. As secondary products regular polyynes, i.e. hydrogen-terminated polyynes with the general formula $H{-}(C{\equiv}C)_n{-}H$, are formed. This study has confirmed the key role played by the graphite electrodes as the source of elemental carbon in the form of sp-hybridized carbon chains which are then terminated by atoms derived from the medium where the electric arc is struck. Nitrogen end groups of the cyanopolyynes are derived from the plasmalysis of molecular nitrogen.

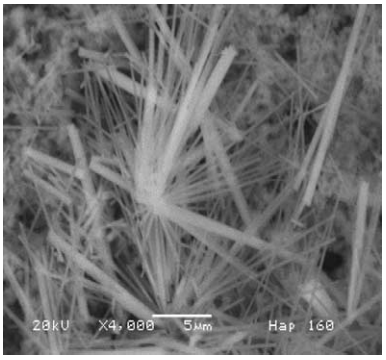
Polyhedron 23 (2004) 1897

Effect of pH and temperature on the formation of hydroxyapatite at low temperatures by decomposition of a Ca–EDTA complex

Hydroxyapatite (HAp) was synthesized through the decomposition of a Ca(EDTA) complex in presence of phosphate ions. Ion concentrations are much higher than previously reported. This route allows the formation of HAp at temperatures below 140 °C and at different pH values.



Fouad Bentiss, Michel Lagrenée, Hervé Vezin, Jean-Pierre Wignacourt, Elizabeth M. Holt

Polyhedron 23 (2004) 1903

Syntheses and crystal structures of two mononuclear Zn(II) complexes with the 2,5-bis(2-pyridyl)-1,3,4-thiadiazole ligand

The structures of the monomeric zinc (diaquo-2,5-bis(2-pyridyl)-1,3,4-thiadiazole) cationic complexes with zinc tetrachloride (**II**) and perchlorate (**III**) as counter ions are reported. Comparison of the energy-minimized structure of the solid-state uncoordinated ligand and of the two monomeric zinc(2,5-bis(2-pyridyl)-1,3,4-thiadiazole)$_2$ complexes permits an evaluation of the relative importance of conformation and planarity in complex formation. From this information, the potential of the ligand as a bridging unit may be evaluated.

Polyhedron 23 (2004) 1909

New β-aminovinylketonates with annealated 1,2-benzothiazine-1,1-dioxide fragment

New β-aminovinylketones with heterocyclic 1,2-benzothiazine-1,1-dioxide and antipyrine moieties (LH) and their 3d-metal (Co^{II}, Ni^{II}, Cu^{II}, Zn^{II}) chelates have been synthesized via traditional and electrochemical techniques and characterized. It is shown that, depending on the metal nature, the studied ligand system may behave as an ambidentate ligand, forming metal-chelates with both distorted tetrahedral (Cu^{2+} and Zn^{2+}) or octahedral (Co^{2+} and Ni^{+}) geometries around the metal center.

Polyhedron 23 (2004) 1939

Copper(II) complexes of several monophosphono dipeptides: the role of phosphonic oxygen and thioether sulfur in complex stabilization

The coordination in $[CuLH_{-1}]^-$, the major species in the studied systems, is realized by the $\{PO_3^{2-}, NH_2, N^-\}$ donor set but both ligands Gly–(Bz)Cys(P) are more effective chelating agents than other ones. In this case both benzyl ring and thioether group can stabilize this complex by competition with the phosphonic oxygen towards copper ion coordination in an axial position.

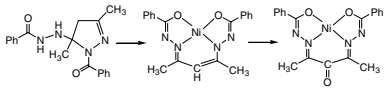
Polyhedron 23 (2004) 1997

Complexes of nickel with tetradentate ligands formed by ring opening of 1-benzoyl-3,5-dimethyl-5-(1′-benzoylhydrazido)pyrazoline

Treatment of the pyrazoline obtained from acetylacetone and benzoylhydrazine with nickel(II) causes the ring opening and formation of a neutral complex with a trianionic tetradentate ligand, which in the presence of moisture and oxygen produces a square-planar nickel(II) complex wherein the methine fragment is transformed to keto group.



Barbara Machura, M. Jaworska, Rafal Kruszynski

Polyhedron 23 (2004) 2005

DFT calculation and X-ray structure of the $[ReCl_3(pzH)_3]$ complex

The $[ReCl_3(pzH)_3] \cdot H_2O \cdot HCl$ complex has been obtained in the reaction of $[ReOCl_3(PPh_3)_2]$ with an excess of pzH in wet benzene under argon atmosphere. The well-known capacity of PPh_3 to interact with the Re≡O bond in rhenium(V) oxo-complexes explains the course of the reaction. The rhenium atom of $[ReCl_3(pzH)_3]$ is in a distorted octahedral environment and the two groups of ligands (halide ions and pyrazole molecules) are arranged in a *meridional* fashion. The geometric parameters of $[ReCl_3(pzH)_3]$ have been examined using the density functional theory (DFT) method. The UV–Vis spectrum of $[ReCl_3(pzH)_3]$ has been discussed on the basis of the electronic transitions calculated with the time-dependent DFT method (TDDFT).

Polyhedron 23 (2004) 2037

The preparation and characterization of seven-coordinate tin(IV) complexes of the 2,6-diacetylpyridine Schiff bases of *S*-alkyl/aryl-dithiocarbazates and the X-ray crystal structure of the $[Sn(dapsme)I_2]$ complex (dapsme=doubly deprotonated form of the 2,6-diacetylpyridine Schiff base of *S*-methyldithiocarbazate)

The complexes, $[Sn(SNNNS)I_2]$ ($SNNNS^{2-}$= doubly deprotonated forms of the 2,6-diacetylpyridine Schiff bases of *S*-methyl- and *S*-benzyldithiocarzates) have been prepared and characterized. An X-ray structure analysis shows that the complex, $[Sn(dapsme)I_2]$ has a seven-coordinate pentagonal-bipyramidal geometry with the Schiff base coordinated to the tin(IV) ion via the pyridine nitrogen atom, the two azomethine nitrogen atoms and the two thiolate sulfur atoms. The iodo ligands are coordinated to the tin(IV) ion at axial positions.

Polyhedron 23 (2004) 1303

Crystal structure, magnetic and spectral properties of tetrakis(2-nitrobenzoato)di-(aqua)dicopper(II) dihydrate

The synthesis, characterization and structure of $[Cu_2(2\text{-}NO_2bz)_4(H_2O)_2] \cdot 2H_2O$ are reported. The structure is centrosymmetric and the copper(II) atom has a square–pyramidal coordination by four oxygen atoms of carboxylate groups and the apical position is occupied by a water molecule. The electronic and infrared spectra exhibit typical features consistent with the observed structure. The magnetic susceptibility measurements of a polycrystalline sample proved the dimeric structure.

Polyhedron 23 (2004) 1309

Synthesis of new pyrazole-containing binuclear and mononuclear Cu(II) complexes: crystal structure, EPR, magnetic and spectroscopic properties

Reaction of 1-hydroxymethyl-3,5-dimethylpyrazole (LOH) with copper(II) salts yields new dinuclear $[CuLLONO_3]_2$ (**1**) or mononuclear $CuL_3(NO_3)_2$ (**2**) co-ordination compounds (L – 3,5-dimethylpyrazole; LO – 1-methoxy-3,5-dimethylpyrazole). The type of the obtained complex strongly depends on the solvent used during the preparation. The structural feature of (**1**) is compared with that observed previously for two similar $[CuL(LO)X]_2$ complexes where $X=BF_4^-$(3) or ClO_4^- (**4**) instead of NO_3^- (**1**). Variable-temperature EPR spectra (77–295 K) and magnetic susceptibility measurements (1.9–300 K) indicate the antiferromagnetic exchange interaction dependent on the compensating ligand.

Crystal structure and electrochemistry of copper(II) macrocycles containing terpyridine

The macrocycle L, prepared by template condensation of bis-6,6″-(α-methylhidrazino)-4′-phenyl-2,2′:6″,2′-terpyridine with glyoxal, forms a stable crystalline complex of copper(II) $[Cu(L)(H_2O)_2][PF_6]_2$ which has been used as a starting material to prepare, for electrochemical studies, a series of seven coordinate copper(II) complexes $[Cu(L)X_2][PF_6]_2$ (X=pyridine, 4-cyanopyridine, 4-aminopyridine, 4-dimethylaminopyridine, pyrazine, imidazole, 1-methylimidazole, 2-methylimidazole, and trimethylphosphite).

Polyhedron 23 (2004) 1361

Heteroleptic platinum(II) complexes with crown thioethers and diimine ligands: the crystal structures of [Pt(9S3)(2,2′-bipy)](PF$_6$)$_2$ and [Pt(9S3)(4,4-dimethyl-2,2′-bipy)](PF$_6$)$_2$ · 2.5CH$_3$NO$_2$

A series of heteroleptic Pt(II) complexes with the thiacrown 9S3 and several diimines show a *cis*-PtS$_2$N$_2$ coordination sphere. The third sulfur from the 9S3 forms a long distance interaction with the Pt center, but these distances demonstrate that better π acids, in fact, do not result in shorter Pt–S axial distances as previously proposed.

New examples of the unusual X-phenylcyanamido bridging ligands. Crystal structure and magnetic properties of Mn^{II} derivatives

Several new Mn^{II} compounds with X-phenylcyanamido (Xpcyd) and 1,10-phenantroline (phen) ligands have been characterised. These compounds contain the unusual double end-to-end R-cyanamide bridge and give supramolecular one-dimensional networks by means of H-bonds involving the N-amide atoms of the phenylcyanamide ligands. Susceptibility measurements on these new systems confirm moderate AF coupling mediated by the R–NCN pathway. Coupling constants related with the phenylcyanamido bridges are compared with the superexchange model recently proposed for ligands of this kind.

X-ray and spectroscopic characterisation of cobalt(III) and nickel(II) complexes with 2-(2-pyridyl)iminotetrahydro-1,3-thiazine hydrochloride · water (1/2) ($PyTzHCl \cdot 2H_2O$) in the solid state and study of its interaction with cobalt(II) and nickel(II) in aqueous solution

Mononuclear cobalt(III) and nickel(II) complexes have been prepared with 2-(2-pyridyl)iminotetrahydro-1,3-thiazine hydrochloride · water (1/2) ($PyTzHCl \cdot 2H_2O$). Their molecular structures and the physico-chemical properties are presented here. In these complexes, PyTz is a chelating ligand. The nitrogen atom of the thiazine ring and the imino nitrogen atom are donors in the coordinate bonds. The environment around the central ion for both complexes may be described as a distorted octahedral geometry. The stability constants of the Co(II) and Ni(II) complexes with the studied ligand in aqueous solution have been determined by a potentiometric method.

Polyhedron 23 (2004) 1097

Synthesis of new dinuclear and mononuclear peroxovanadium(V) complexes containing biogenic co-ligands: a comparative study of some of their properties

Dinuclear vanadium compounds with a μ-peroxo moiety, $[V_2O_2(O_2)_3L_3] \cdot H_2O$, L=asn(**1**) and gln(**2**), were found to be distinctly different in nature, stability and reactivity from the monomeric complexes, $Na[VO(O_2)_2L] \cdot H_2O$, L=asn(**3**) and gln(**4**), with side-on bound peroxo groups. The experiments confirm the reactivity of synthetic μ-peroxovanadate dimer in producing bromination competent intermediate at physiological pH.

Synthesis and characterization of $[Cu_2(L)_2(OCOCH_3)(OCH_3)]ClO_4$ {L=2-[(4-methyl-pyridin-2-ylimino)-methyl]-phenol}: EPR and X-ray studies

A dicopper complex of a Schiff's base, 2-[(4-methyl-pyridin-2-ylimino)-methyl]-phenol, with a bridging acetato ligand has been synthesized and characterized by single crystal XRD, EPR, magnetic susceptibility, IR, UV–Vis, CV and elemental analysis. One of the copper atoms in the binuclear complex adopts a square-pyramidal geometry, while the other copper assumes a square-planar geometry. A seven line pattern observed at half-field in the frozen solution EPR spectrum confirms the interaction between the two copper ions.

Polyhedron 23 (2004) 1199

Laser ablation synthesis of new phosphorus and phosphorus-sulfur clusters and their TOF mass spectrometric identification

Laser ablation of elemental phosphorus, sulfur, theirs mixtures or some phosphorus sulfides connection with simultaneous TOF mass spectrometry was done. Formation of singly charged P_n^+ ($n = 1$–189) and P_n^- ($n = 1$–225) and S_m^+ ($m = 1$–11) and S_m^- ($m = 1$–15) clusters was proved. Similarly to laser ablation of red phosphorus, P_nS_m clusters generated from P_4S_3 and P_4S_{10} with odd number of phosphorus atoms were much higher than those with even numbers. Various mixed clusters were also obtained via direct laser ablation of a mixture of the elements while higher yield of the mixed clusters was obtained when the mixture was first homogenised using ultrasound. Totally, 68 new P_nS_m clusters were formed and detected. The laser ablation represents a new method to synthesise mixed P_nS_m clusters.

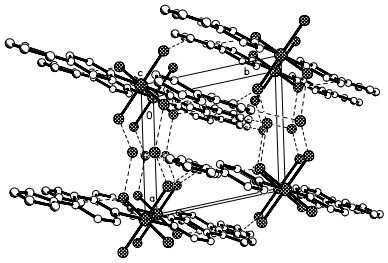
Polyhedron 23 (2004) 1217

Synthesis and characterization of three 5-(4-pyridyl)tetrazolato complexes obtained by reaction of 4-cyanopyridine with metal azides from aqueous solutions

Two isomorphic mononuclear compounds $[M(4\text{-PTZ})_2(H_2O)_4] \cdot 2H_2O$, [M=Mn, Cd; (4-PTZ=5-(4-pyridyl)tetrazolate)] and the chain system $[Ca_{1.5}((4\text{-PTZ})_2H)(N_3)_2(H_2O)_5](H_2O)_{0.3}$ have been synthesized and characterized by structural, spectral and thermoanalytical methods.



Varughese Philip, V. Suni, Maliyeckal R. Prathapachandra Kurup, Munirathinam Nethaji

Polyhedron 23 (2004) 1225

Structural and spectral studies of nickel(II) complexes of di-2-pyridyl ketone N^4,N^4-(butane-1,4-diyl) thiosemicarbazone

Three Ni(II) complexes with general formula $[NiLX] \cdot \frac{1}{2}H_2O$ (X=Cl, N_3 and NCS) were synthesized using di-2-pyridyl ketone N^4,N^4-(butane-1,4-diyl) thiosemicarbazone (HL). X-ray diffraction studies of compounds NiLCl and $NiL(N_3)$ reveal a square planar geometry where the thiosemicarbazone acts as an NNS donor ligand. Spectral data for compound NiL(NCS) suggest a structure similar to the chloro and azido derivatives.

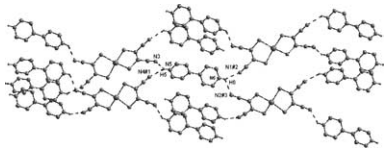
Polyhedron 23 (2004) 1235

Near-IR absorption due to supramolecular electronic interaction in an extended 3D hydrogen-bonding network material: synthesis, crystal structure and properties of [4,4′-H_2bpy][$Cu(mnt)_2$]

Reaction of $[Bu_4N]_2[Cu(mnt)_2]$ with [4,4′-H_2bpy]Cl_2 affords ion-pair complex [4,4′-H_2bpy][$Cu(mnt)_2$] showing three-dimensional supramolecular network in the solid state; the relevant interaction involves bifurcated (bpyN)–H···(NC–mnt) hydrogen bonds and the compound exhibits ion-pair charge transfer transition in the near-IR region.

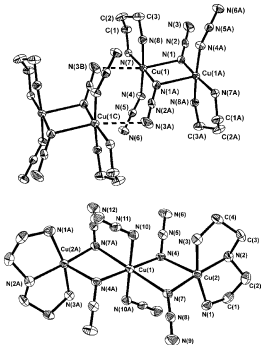


Jun Luo, Xi-Geng Zhou, Song Gao, Lin-Hong Weng, Ze-Huai Shao, Chun-Mei Zhang, Yan-Rong Li, Jie Zhang, Rui-Fang Cai

Polyhedron 23 (2004) 1243

Synthesis and characterization of copper(II) azide complexes containing polyamines as co-ligands

Two new copper(II) azide complexes $Cu_2(pn)_2(N_3)_4$ (**1**) and $Cu_3(dien)_2(N_3)_6$ (**2**) (pn=1,3-diaminopropane and dien=diethylenetriamine) have been synthesized and characterized by single crystal X-ray diffraction. Magnetic susceptibility measurement for complex **2** in the range 2–300 K showed weak antiferromagnetic exchange between the copper(II) ions ($J = -2.09(8)$ cm^{-1}) in the trinuclear unit.

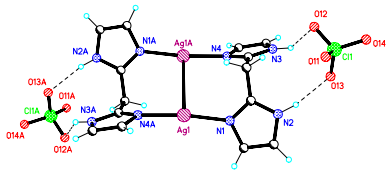


Suaad Abuskhuna, John Briody, Malachy McCann, Michael Devereux, Kevin Kavanagh, Julia Barreira Fontecha, Vickie McKee

Polyhedron 23 (2004) 1249

Synthesis, structure and anti-fungal activity of dimeric Ag(I) complexes containing bis-imidazole ligands

Five Ag(I) complexes containing the ligands bis(imidazol-2-yl)methane (2-BIM) and its derivatives were prepared and $[Ag_2(2\text{-}BIM)_2](ClO_4)_2$ and $[Ag_2(2\text{-}BIM(Bz)OH)_2](ClO_4)_2 \cdot EtOH$ were characterised using X-ray crystallography. In each dimer the two Ag(I) ions are two-coordinate and there are small but definite argentophilic Ag–Ag (d^{10}–d^{10}) interactions. All of the complexes display anti-fungal activity when tested in vitro against the fungal pathogen *Candida albicans*.



Xiang-Jun Zheng, Li-Cun Li, Song Gao, Lin-Pei Jin

Polyhedron 23 (2004) 1257

Hydrothermal syntheses, structures and magnetic properties of two transition metal coordination polymers with a square grid framework

Coordination polymers $[M(NDA)(4,4'\text{-}bpy)(H_2O)_2] \cdot nH_2O]$ (M=Co, Ni) with a square grid metal-organic framework constructed by M(II), 1,4-naphthalenedicarboxylate and 4,4′-bipyridine shows weak antiferromagnetic and ferromagnetic exchange interaction between the Co^{2+} ions and Ni^{2+} ions, respectively.

Polyhedron 23 (2004) 1263

Synthesis and structure of diphenylphosphine derivatives of molybdenocene

The phosphino molybdenocene complex $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ **(1)** ($Cp = \eta^5\text{-}C_5H_5$) was prepared by reaction of Cp_2MoI_2 with PPh_2H and excess of $TlBF_4$ in NCMe. The synthesis of the monocation $[Cp_2MoI(PPh_2H)]^+$ **(2)** as the BF_4^- or I^- salt is also reported. The molecular structures of $[Cp_2Mo(PPh_2H)_2][BF_4]_2$ and $[Cp_2MoI(PPh_2H)]^+$ have been determined by single-crystal X-ray diffraction.

Polyhedron 23 (2004) 1271

2,2′-Bipyrimidine (bpym) in iron(III) carboxylate chemistry: preparation and characterization of $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$, and the influence of weak interactions in the formation of metal clusters

The reaction system $Fe(ClO_4)_3 \cdot 6H_2O/NaO_2CMe/bpym$ (bpym=2,2′-bipyrimidine) in MeCN leads to complex $[Fe_2O(O_2CMe)_2(bpym)_2(H_2O)_2](ClO_4)_2$ **(3)**, which contains the $\{Fe_2(\mu\text{-}O)(\mu\text{-}O_2CMe)_2\}^{2+}$ core. The crystal structure is stabilized by hydrogen bonds and π–π interactions. These aspects of the crystal structure are considered responsible for the failure to isolate larger molecular aggregates.

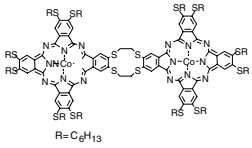
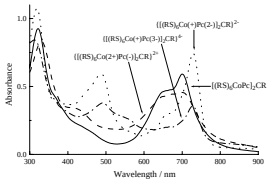
Polyhedron 23 (2004) 1279

Electrochemical, spectroelectrochemical, and pyridine binding properties of tetrathia macrocycle-bridged dimeric cobalt phthalocyanine

Tetrathia macrocycle-bridged dimeric cobalt phthalocyanine, $[(RS)_6CoPc]_2CR$ where R= C_6H_{13}, CR=[1,4,7,10-tetrathia-(12-crown-4)], was investigated electrochemically and spectroelectrochemically. The pyridine-binding properties of the complex were also investigated by spectrophotometric technique in the solution of dichloromethane. A highly aggregated neutral complex resulted in monomeric forms for the mono-and doubly reduced species of the complex in CH_2Cl_2. The pyridine binding properties of the complex confirms the formation of mono-pyridine adduct.





Erratum to: "Synthesis, characterization and crystal structures of (*Z*)-1-(triarylstannyl)-3-phenyl-1-buten-3-ols and their arylhalostannyl derivatives" [Polyhedron 22 (2003) 3523] 1287

Polyhedron 23 (2004) 711

Syntheses and solid state structures of europium and terbium complexes of *N*, *N*′-bis(2-pyridylmethyl)urea and *N*, *N*′-bis(3-pyridylmethyl)oxalamide

The synthesis, structural characterization and luminescence properties of three new lanthanide-containing compounds are reported. Two display a molecular structure, while the third is a one-dimensional polymeric chain. Hydrogen bonds assemble the molecular structures in one-dimension and the chain-like structure in three dimensions.

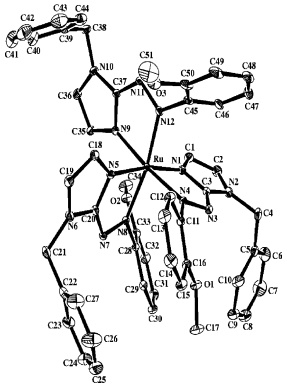
Polyhedron 23 (2004) 727

Synthesis, spectral studies, crystal structure and redox properties of homoleptic tris-chelated ruthenium(II)-arylazoimidazoles

The one pot syntheses of tris-chelated [Ru(*o*/*p*-RaaiR′)$_3$]Cl$_2$ (RaaiR′=1-alkyl-(2-arylazo)-imidazole) are described. Solution spectra show a MLCT transition. The complexes show Ru(II)/Ru(III) and three successive ligand reduction couples. The EHMO results support the spectral and electrochemical properties.



Sergej Pasko, Liliane G. Hubert-Pfalzgraf, Adulfas Abrutis, Jacqueline Vaissermann

Polyhedron 23 (2004) 735

Synthesis and molecular structures of cobalt(II) β-diketonate complexes as new MOCVD precursors for cobalt oxide films

Complexes of cobalt(II) 2,4-pentanedionate (acac) and 2,2,6,6-tetramethyl-3,5-heptanedionate (thd) with TMEDA and 1-dimethylamino-2-propanol (DMAPH) or 2-dimethylaminoethanol (DMAEH), were synthesized. X-ray diffraction showed $Co(acac)_2$(TMEDA) (**1**) to be monomeric and $[Co(acac)_2(DMAPH)]_2$ (**2**) dimeric due to H-bonds. The most stable and volatile adducts **1** and $Co(thd)_2$(TMEDA) (**4**), the first adduct of $Co(thd)_2$ reported, were used for cobalt oxide deposition by liquid injection MOCVD. Films of Co_3O_4 were characterized by XRD and XPS. Epitaxial films can be obtained by using both TMEDA adducts.

Polyhedron 23 (2004) 743

Divalent transition metal complexes of the anionic form of 4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-7-one: crystal structure of the zinc(II) compound

Divalent metal (Mn, Fe, Co, Ni, Cu, Zn and Cd) complexes of the anion of 4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-7-one have been isolated and characterized. The crystal structure of the Zn compound has been solved showing that it is mononuclear and octahedral with the ligand coordinated via N3. Spectroscopic and magnetic data suggest analogous structures for the other compounds except for Cu, which is dinuclear according to magnetic and EPR data.

Polyhedron 23 (2004) 749

Copper and nickel complexes of the tetradentate ligand derived from the condensation of ferrocenoylacetone with 1,2-diaminoethane

Ferrocenoylacetone reacts with 1,2-diaminoethane to yield three isolated isomers $\mathbf{H_2L}$, $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$. Reaction of the tetradentate enaminone ligand $[C_5H_5FeC_5H_4C(O)CH{=}C(CH_3)NHCH_2]_2$($\mathbf{H_2L}$) with copper acetate and nickel acetate affords complexes **I** and **II**. The X-ray crystallography of complexes **I** and **II** reveals that complex **I** exists as a mixture of *anti* and *syn* isomers whereas complex **II** as a single *syn* isomer.

Polyhedron 23 (2004) 773

Hydrothermal synthesis and structure characterization of a Keggin tungstocobaltate $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}] \cdot 9.5H_2O$

The Keggin tungstocobaltate $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}] \cdot 9.5H_2O$, consisting of a Keggin anion $[CoW_{12}O_{40}]^{6-}$ and two isolated chiral ions $[Co(2,2'\text{-bipy})_2]^{2+}$, was obtained by a hydrothermal synthesis for the first time. EPR spectra reveal two Co^{2+} coordination environments, high spin state ($g = 5.1$, 4.2) and low spin state ($g = 2.0$), exhibited in the title compound. Furthermore, when the temperature increases from 110 K to room temperature, the signal $g = 5.1$ of high spin Co^{2+} disappears, caused by the negative zero-field splitting.

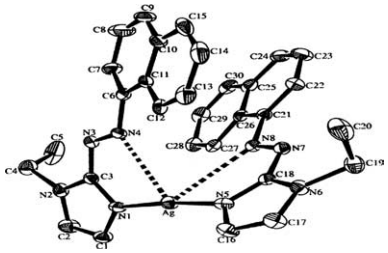
Polyhedron 23 (2004) 793

Silver(I) complexes of the naphthyl-azoimine function: single crystal X-ray structure of bis-[1-ethyl-2-(naphthyl-α-azo)imidazole]silver(I) perchlorate

Silver(I) complexes of 1-alkyl-2-(naphthyl-(α/β)-azo)imidazole are described. The single crystal X-ray diffraction study of bis-[1-ethyl-2-(naphthyl-α-azo)imidazole]silver(I) perchlorate confirms the structure of the complexes. The complexes show intra-molecular and intermolecular H-bonding leading to a 1D helical framework.



Michael S. Hill, Peter B. Hitchcock, Nikki Smith

Polyhedron 23 (2004) 801

Routes to titanium tetrazole complexes

Potential routes to titanium tetrazole derivatives for use as molecular precursors to TiN are described. Direct reaction of 5-phenyltetrazole and $TiCl_4$ produced a six-coordinate adduct. Attempted reaction of $TiCl_4$ and a tributylstannyl tetrazole derivative, synthesised by cycloaddition of Bu_3SnN_3 and 2-toluinitrile, gave only incomplete elimination of the expected Bu_3SnCl by-product.

Polyhedron 23 (2004) 809

Homobinuclear copper(I) hexafluoroacetylacetonate complexes with non-cyclic diene ligands

Binuclear copper(I) hexafluoroacetylacetonate complexes with non-cyclic divinyl ligands of $[Cu^I(hfac)]_2L$ composition (**1**) L = 1,5-hexadiene, (**2**) L = allyl ether, (**3**) L = diallyldimethylsilane, (**4**) L = 1,3-divinyltetramethyldisiloxane were prepared as yellow crystalline solids. Complexes **1** and **4** are most stable and can be sublimated at 50–70 °C in a vacuum with good yield. The $[Cu^I(hfac)]_2L$ composition for both complexes is realized by copper(I) ions coordination to a chelate-bound β-diketonate and η^2-coordinated vinyl unit. A possible copper–silicon interaction is postulated for compound **4**.

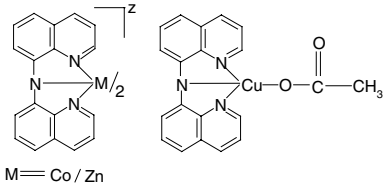
Polyhedron 23 (2004) 831

Synthesis, structure, spectral and electron-transfer properties of octahedral-$[Co^{III}(L)_2]^+$/$[Zn^{II}(L)_2]$ and square planar-$[Cu^{II}(L)\{OC(=O)CH_3\}]$ complexes incorporating anionic form of tridentate bis(8-quinolinyl)amine $[N^1C_9H_6\text{–}N^2\text{–}C_9H_6N^3, L^-]$ ligand

The reactions of bis(8-quinolinyl)amine $[N^1C_9H_6\text{–}N^2H\text{–}C_9H_6N^3, LH]$ with $Co^{II}(ClO_4)_2 \cdot 6H_2O$, $Zn^{II}(ClO_4)_2 \cdot 6H_2O$ and Cu^{II}-acetate result in octahedral-$[Co^{III}(L^-)_2]^+$ and $[Zn^{II}(L^-)_2]$ and square planar-$[Cu^{II}(L^-)\{^-OC(=O)CH_3\}]$ complexes, respectively, incorporating an sp^2-amido nitrogen center (N^2) in the coordinated ligand frame of L. The structural, spectral and electrochemical aspects of the complexes have been described.

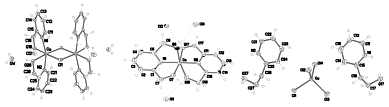


Veysel T. Yilmaz, Sevim Hamamci, Carsten Thöne

Polyhedron 23 (2004) 841

Cobalt(II) complexes of 2-methanol-, 2,6-dimethanol- and 2-ethanolpyridines: syntheses, spectroscopic, thermal and structural characterizations of $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$, $[Co(dmpy)_2]Cl_2$ and $[Co(Cl)_4](Hpyet)_2$ (mpy = 2-methanolpyridine; dmpy = 2,6-dimethanolpyridine and Hpyet = 2-ethanolpyridinium)

Cobalt(II) complexes of 2-methanol-, 2,6-dimethanol- and 2-ethanolpyridines are reported. The 2-methanolpyridine (mpy) complex $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$ is dimeric with chloro bridges and each cobalt(II) ion has an octahedral coordination with two chloro and two bidentate (N, O) ligands. In the 2,6-dimethanolpyridine (dmpy) complex $[Co(dmpy)_2]Cl_2$, dmpy exhibits a tripodal chelating coordination mode through the N and two hydroxyl O atoms. The protonated 2-ethanolpyridinium cation Hpyet in $[Co(Cl)_4](Hpyet)_2$ serves as a non-coordinating, but hydrogen bonded counter ion.

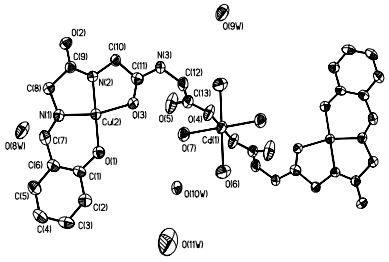


Wen-Long Liu, Yang Zou, Chun-Lin Ni, Zhao-Ping Ni, Yi-Zhi Li, Yuan-Gen Yao, Qing-Jin Meng

Polyhedron 23 (2004) 849

Synthesis and characterization of copper(II) Schiff base complexes derived from salicylaldehyde and glycylglycylglycine

Two new copper(II) tripeptide Schiff base complexes: $[Mg(H_2O)_6][CuL]_2 \cdot 3.5H_2O$ (**1**) and $[Cd(H_2O)_4(CuL)_2] \cdot 3.5H_2O$, (**2**) ($H_3L$ = *N*-salicylideneglycylglycylglycine) have been synthesized and structurally characterized. The UV–Vis, IR, ESR spectra and magnetic properties are reported.

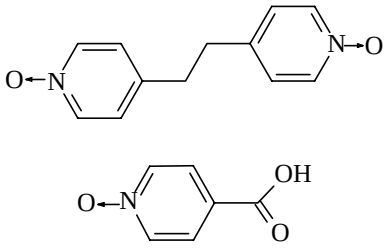


Lin-Ping Zhang, Miao Du, Wen-Jie Lu, Thomas C.W. Mak

Polyhedron 23 (2004) 857

Porous coordination networks generated from lanthanum trifluoromethanesulfonate and single/mixed N-oxide spacer linkers

Porous coordination networks are found in $\{[La(\mu\text{-}L)_2L(H_2O)_2](CF_3SO_3)_3\}_n$ (**1**), $\{[La(\mu\text{-}L')(CF_3SO_3)(H_2O)_2(\mu\text{-}L)_{0.5}L](H_2O)_3(CF_3SO_3)\}_n$ (**2**) and $\{[La(\mu\text{-}L')_2(\mu\text{-}L)](H_2O)_{1.5}(CF_3SO_3)\}_n$ (**3**) prepared by the reaction of $La(CF_3SO_3)_3$ with 1,2-bis(4-pyridyl)ethane-*N*,*N*′-dioxide (L), or with mixed N-oxide ligands L and L′ (HL′ = isonicotinic acid N-oxide) in different molar ratios. Compounds **2** and **3** represent the first metal complexes containing two different N-oxide bridging ligands. Thermogravimetric analysis (TGA) studies revealed that the ligands L and L′ are bound differently in compounds **1**–**3** due to their distinctive coordination modes.



M. Rodriguez i Zubiri, Heather L. Milton, Alexandra M.Z. Slawin, J. Derek Woollins

Polyhedron 23 (2004) 865

The preparation and coordination of 1,3-C_6H_4-$\{C(O)N(PPh_2)CH_2Ph\}_2$ – a new multidentate ligand

The new ligand 1,3-C_6H_4-$\{C(O)N(PPh_2)$-$CH_2Ph\}_2$ gives the P,P',C tridentate [Pt(Cl)l{1,3-C_6H_4-$\{C(O)N(PPh_2)CH_2Ph\}_2$}] which contains two fused six-membered rings and [$\{PdCl(C_3H_5)\}_2${1,3-C_6H_4{C(O)-$N(PPh_2)CH_2Ph\}_2$}] in which the ligand bridges two palladium centres.

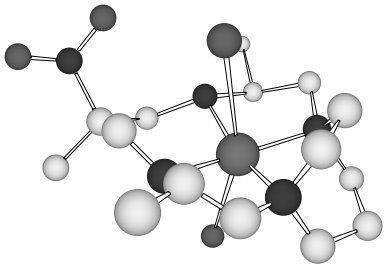
Polyhedron 23 (2004) 869

Stereocontrol in complexes of cyclam-like macrocycles – influences of chirality

Cyclam-like ligands with unusual coordination characteristics can be generated by a combination of conventional organic synthesis and a template reaction to provide derivatives of 3,7-diazacycloheptane.

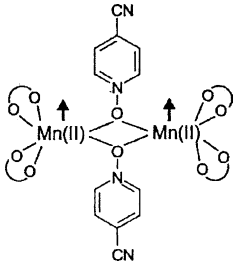


Mikhail Ryazanov, Sergey Troyanov, Marek Baran, Ritta Szymczak, Natalia Kuzmina

Polyhedron 23 (2004) 879

Synthesis, crystal structure and magnetic properties of dinuclear manganese(II) diketonate with cyanopyridine-N-oxide bridging ligands $[Mn(hfac)_2(4\text{-}cpyNO)]_2$

A new manganese(II) hexafluoroacetylacetonate adduct with 4-cyanopyridine N-oxide is described along with its crystal structure and magnetic studies, that revealed the presence of a ferromagnetic intramolecular interaction between the manganese atoms.

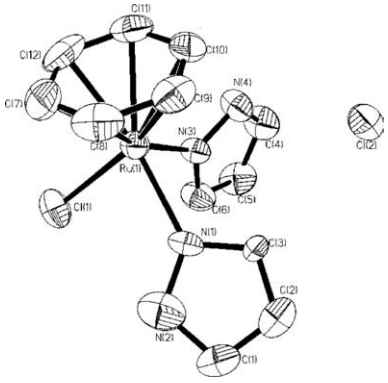


J.G. Małecki, J.O. Dzięgielewski, M. Jaworska, R. Kruszynski, T.J. Bartczak

Polyhedron 23 (2004) 885

Synthesis, molecular, crystal and electronic structures of $[(C_6H_6)RuCl(HPz)_2]Cl$ and $[(C_6H_6)RuCl_2(Me_2HPz)]$

The reactions of $(C_6H_6)RuCl_2]_2$ complex with pyrazole and dimethylpyrazole have been examined. The ruthenium complexes – $[(C_6H_6)RuCl(C_3N_2H_4)_2]Cl$ and $[(C_6H_6)RuCl(C_5N_2H_8)_2]$ have been obtained and characterized by IR, UV–Vis and 1H NMR measurements. Crystal, molecular and electronic structures of the complexes have been determined. The geometries of the complexes were optimized with the DFT method and their UV–Vis spectra were calculated with the TDDFT method.

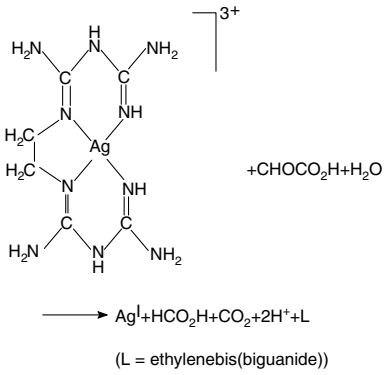


Amit Das, Subrata Mukhopadhyay

Polyhedron 23 (2004) 895

Kinetics of oxidation of glyoxylic acid by [ethylenebis(biguanide)]silver(III) in aqueous media

In aqueous media [ethylenebis(biguanide)]-silver(III) quantitatively oxidises glyoxylic acid to formic acid and carbon dioxide possibly by successive one-electron transfer.



Validation and deposition of crystallographic data I

Polyhedron 23 (2004) 2117

Dinuclear silver(I) complexes of *N*, *N*′-dibenzyl-4,13-diaza-18-crown-6-ether and dibenzo-24-crown-8-ether

Three silver(I) coordination complexes of diaza- and dibenzo-crown ethers, [Ag(DDAC)](CF_3SO_3) (**1**), [Ag_2(DDAC)(CF_3SO_3)$_2$]$_2$ (**2**) and Ag_2(DB24C8)(CF_3SO_3)$_2$ (**3**), have been synthesized and characterized structurally. The X-ray structure analyses reveal mononuclear complex **1**, and dinuclear complexes **2** and **3** based on metal-oxygen and metal-nitrogen bonds.

Polyhedron 23 (2004) 2125

Self-assembly, structure and magnetic properties of carboxylate-bridged Cu(II)–M(II) (M=Mg, Ca, Sr, Ba) complexes with a new metalloligand as a building block

The carboxylate-bridged Cu(II)–M(II) (M=Mg, Ca, Sr, Ba) mononuclear entity, polynuclear clusters, extended 1D ladder-like and 2D layer coordination polymers were self-assembled and structurally characterized. The UV–Vis, IR spectra and magnetic properties are reported.

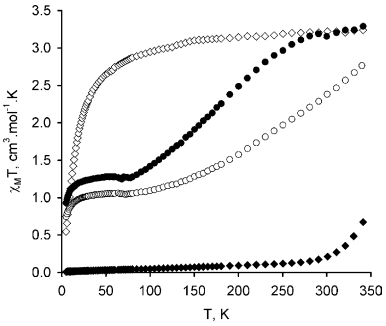
Polyhedron 23 (2004) 2141

Iron complexes of 3-(pyrazinyl)-1,2,4-triazole ligands

Different salts of the homoleptic iron(II) complexes of 3-(pyrazinyl)-1,2,4-triazole and 1-methyl-3-(pyrazinyl)-1,2,4-triazole show varying spin-state regimes, with most of the compounds examined undergoing a spin-state transition upon cooling or warming. Synthesis of these compounds is complicated by autooxidation of the reaction mixtures, yielding in one case an oxo-bridged diiron(III) complex.

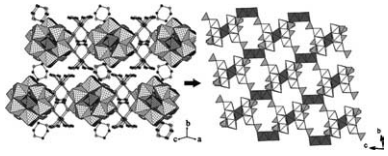


Xin He, Ping Zhang ,Tian-You Song, Zhong-Cheng Mu, Jie-Hui Yu, Yue Wang, Jia-Ning Xu

Polyhedron 23 (2004) 2153

Hydrothermal synthesis and structure of a molybdenum(VI) phosphate cluster and a three dimensional cobalt molybdenum(V) phosphate

Two new molybdenum phosphates $[Co(en)_3][C_4H_{12}N_2]_{0.5}[(Mo_5O_{15})(HOPO_3)_2]\cdot 3H_2O$ (**1**), (en=ethylenediamine) and $(C_4N_2H_{10})_5[Co_3Mo_{12}O_{18}(HOPO_3)_6(PO_4)_2(OH)_{12}(H_2O)_4]\cdot 9H_2O$ (**2**) have been synthesized hydrothermally. It was demonstrated the three-dimensional **2** was synthesized from the zero-dimensional **1** under hydrothermal reaction.



Karen J. Nordell, Kristin N. Schultz, Khadine A. Higgins, Mark D. Smith

Polyhedron 23 (2004) 2161

Hydrothermal synthesis of two new lead-containing coordination polymers: $^2{}_\infty[PbCl_2(4,4'\text{-bipy})]$ and $^2{}_\infty[Pb_2(NO_3)_4(H_2O)_2(4,4'\text{-bipy})_2](4,4'\text{-bipy})_2$

Hydrothermal reaction of $Pb(II)X_2$ ($X=Cl^-$, NO_3^-) and 4,4′-bipyridine in a molar ratio of 1:1 resulted in the formation of two new Pb(II) coordination polymers, $^2{}_\infty[PbCl_2(4,4'\text{-bipy})]$ and $^2{}_\infty[Pb_2(NO_3)_4(H_2O)_2(4,4'\text{-bipy})_2](4,4'\text{-bipy})_2$.

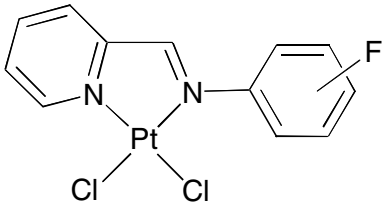
Polyhedron 23 (2004) 2169

Synthesis, characterization, and cytotoxicities of palladium(II) and platinum(II) complexes containing fluorinated pyridinecarboxaldimines

Sixteen palladium and platinum dichloride pyridinecarboxaldimine complexes containing fluorine have been prepared and characterized fully. Cytotoxicities of the complexes have been investigated against OV2008 (human ovarian carcinoma) and the analogous cisplatin-resistant cell line C13.



Arindam Mukherjee, Manas K. Saha, Munirathinam Nethaji, Akhil R. Chakravarty

Polyhedron 23 (2004) 2177

Dicopper(II) Schiff base aminobenzoates with discrete molecular and 1D-chain polymeric structures

Discrete dimeric *o*-aminobenzoate and 1D-chain polymeric *p*-aminobenzoate complexes having a $[Cu_2(\mu\text{-}OR)(\mu\text{-}O_2CR)]$ core, with the endogenic alkoxide bridge derived from a trianionic pentadentate Schiff base (L), are prepared and structurally characterized. Magnetic studies show antiferromagnetic properties of the complexes.

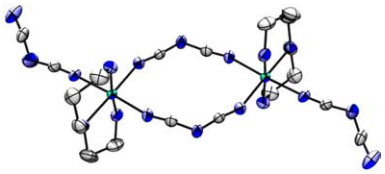
Polyhedron 23 (2004) 2337

Versatile coordination mode of dicyanamide in nickel(II) complexes containing polyamines as blocking ligands

Triethylenetetramine (L^4) and dipropylenetriamine (L^3) were used as blocking ligands that, after complexation with Ni^{II}, leave two or three sites ready for ligation with $N(CN)_2^-$. The formed complexes are $[Ni(\mathbf{N}CNCN)_2L^4]$ – mononuclear (**1**), $[(NCN\text{-}C\mathbf{N})L^3Ni(\mathbf{N}CNCN)_2NiL^3(\mathbf{N}CNCN)]$ – binuclear (**2**) and $[Ni(\mathbf{N}CNC\mathbf{N})L^4](ClO_4)$ – polymeric (**3**). The magnetic susceptibility measurements for **1** confirm that the Curie law is obeyed at higher temperatures whereas the zero-field splitting is effective below 10 K ($D/hc = -4$ cm^{-1}); **2** shows a weak antiferromagnetic coupling ($J/hc = -0.6$ cm^{-1}); **3** exhibits a negligible exchange coupling ($J/hc \approx 0$).



Mohamed A.S. Goher, Afaf K. Hafez, Morsy A.M. Abu-Youssef, Ahmed M.A. Badr, Christian Gspan, Franz A. Mautner

Polyhedron 23 (2004) 2349

New metal(II) complexes containing monodentate and bridging 3-aminopyridine and azido ligands

Three new metal(II)complex: $[Mn(3\text{-ampy})_4(N_3)_2]$, $[Cd(3\text{-ampy})(H_2O)_4]_n(SO_4)_n(H_2O)_n$ and $[Cd(3\text{-ampy})(N_3)_2]_n$ (3-ampy = 3-aminopyridine), have been synthesized and found by X-ray crystallography to contain monodentate, and bridging 3-ampy and azido ligands.

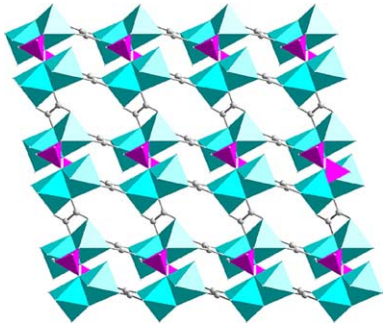
Polyhedron 23 (2004) 2357

Hydrothermal synthesis and characterization of a new 3D iron phosphatooxalate templated by organo-amine

A new organically templated iron(II) phosphatooxalate, $(N_2C_4H_{12})[Fe_4(C_2O_4)_3(HPO_4)_2(H_2O)]$, **I** has been synthesized under hydrothermal conditions, in which oxalate groups act as bidentate ligands to Fe and hold the structure together by strong interlayer P–O–H-oxalate hydrogen bonds.

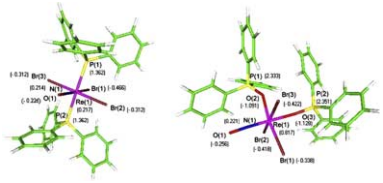


Barbara Machura

Polyhedron 23 (2004) 2363

Electronic structure and UV–Vis spectroscopy of $[Re(NO)Br_3(PPh_3)_2]$ and $[Re(NO)Br_3(OPPh_3)_2]$ complexes

Density functional calculations for $[ReBr_3(NO)(PPh_3)_2]$ (**1**) and $[ReBr_3(NO)(OPPh_3)_2]$ (**2**) complexes have been carried out using the DFT method with the B3LYP functional. The experimentally characterised molecular structures of **1** and **2** have been properly reproduced by the B3LYP method. The UV–Vis spectra of both complexes have been interpreted on the basis of the electronic transitions calculated with the time-dependent DFT method (TDDFT) for **1** and **2**.



Mohammad Abul-Haj, Miguel Quirós, Juan M. Salas

Polyhedron 23 (2004) 2373

Dinuclear Pd(II) complexes with the anionic form of 4,5-dihydro-1,2,4-triazolo[1,5-a]pyrimidine-5-one

The compounds $[PdCl_2(5HtpO)_2]$, $[Pd_2(5tpO)_4] \cdot 4H_2O$ and $[Pd_2(a–a)_2\ (5tpO)_2] \cdot nH_2O$ with 5HtpO = 4,5-dihydro-1,2,4-triazolo[1,5-a]pyrimidine-5-one and a–a = bipyridine (bpy), phenanthroline (phen) or *trans*-diaminocyclohexane (*t*-dach) have been synthesized. The relative disposition of the ligands is, according to single crystal X-ray analysis, head–tail–head–tail for $[Pd_2(5tpO)_4] \cdot 4H_2O$ and head–tail for the compounds with a–a = phen or *t*-dach. On the contrary, the NMR data for the compound with a–a = bpy indicates a head–head disposition in solution.

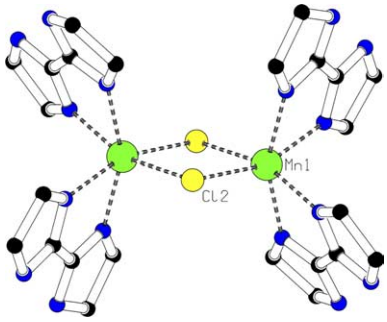
Polyhedron 23 (2004) 2387

A dinuclear Mn(II) chloro-bridged compound with a weak ferromagnetic Mn–Mn interaction

A novel Mn(II) di-chloro-bridged dinuclear compound with the ligand 2,2′-bi-imidazoline has been synthesised and characterised, possessing a weak ferromagnetic interaction of $J = 0.33(1)\ cm^{-1}$ between the cation pairs.



Sébastien Giroux, Sabrina Aury, Patrice Rubini, Stéphane Parant, Jean-Roger Desmurs, Michel Dury

Polyhedron 23 (2004) 2393

A spectroscopic investigation of the complexing ability of catecholate or salicylate derivatives towards aluminium(III)

This paper reports the study of the complexation of the Al(III) ion with four ligands: 2,3-dihydroxybenzoic acid (2,3-dhba), 5-nitrosalicylic acid (5-nsa), 4-nitrocatechol (4-ncat) and 3,5-dinitrocatechol (3,5-dncat) in aqueous solutions as a function of pH. Besides the pH-potentiometric study that allowed us to propose a set of complexes for each Al(III)/ligand system, an extensive spectroscopic investigation was made (IR, UV–visible and especially ^{1}H and ^{13}C NMR) to confirm the potentiometric results and to obtain information on the structure and the dynamics of the complexes. Additionally, the proton exchange kinetics between the OH function and the phenolate form of 5-nsa could be studied.

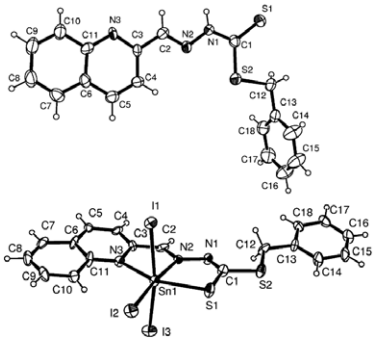
Polyhedron 23 (2004) 2405

The preparation and characterization of tin(IV) complexes of 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarbazates and the X-ray crystal and molecular structures of the 2-quinolinecarboxaldehyde Schiff base of *S*-benzyldithiocarbazate (Hqaldsbz) and its tin(IV) complex [Sn(qaldsbz)I_3]

The complexes, [Sn(NNS)I_3] (NNS = anionic forms of the 2-quinolinecarboxaldehyde Schiff bases of *S*-methyl- and *S*-benzyldithiocarzates) have been prepared and characterized. The structures of the free ligand, Hqaldsbz and its tin(IV) complex, [Sn(qaldsbz)I_3] have been determined by X-ray diffraction. The complex, [Sn(qaldsbz)I_3] has a distorted octahedral geometry with the Schiff base coordinated to the tin atom via the quinoline nitrogen atom, the azomethine nitrogen atom and the thiolate sulfur atom. The three iodo ligands are coordinated meridionally to the tin atom.

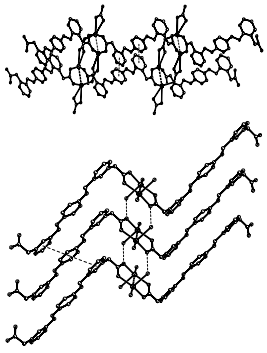


Lin-Ping Zhang, Chi-Keung Lam, Hai-Bin Song, Thomas C.W. Mak

Polyhedron 23 (2004) 2413

Crystalline hydrates and polymeric Ag(I) complexes of isomeric flexible double betaines 1,4-bis(*n*-picolyloxyl)benzene-*N*,*N*′-diacetate (*n* = 2,3,4)

The synthesis and structural characterization of the stoichiometric hydrates and silver (I) complexes of three isomeric double betaines 1,4-bis(2-picolyloxyl)benzene-*N*,*N*′-diacetate (L^1), 1,4-bis(3-picolyloxyl)benzene-*N*,*N*′-diacetate (L^2) and 1,4-bis(4-picolyloxyl)benzene-*N*,*N*′-diacetate (L^3) are reported. The silver complexes exhibit different coordination frameworks, which may be attributed to the varied positions of the betaine moieties in the relevant molecular skeletons.

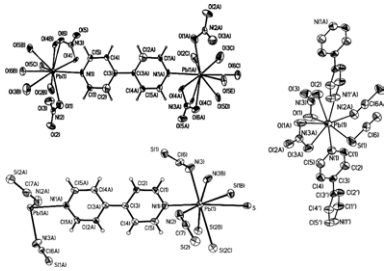


Ali Morsali, Alireza Mahjoub

Polyhedron 23 (2004) 2427

Coordination polymers of lead(II) with 4,4′-bipyridine: syntheses and structures

Some lead(II) complexes with the 4,4′-bipyridine (4,4′-bipy) ligand have been synthesized and characterized by CHN elemental analysis, IR, ^{1}H NMR and ^{13}C NMR spectroscopy.

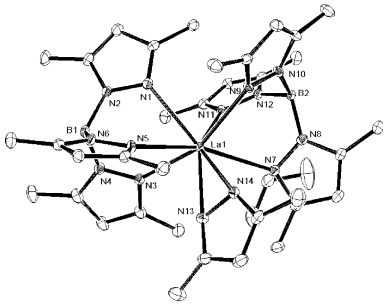


Fábio A. Kunrath, Osvaldo L. Casagrande Jr., Loic Toupet, Jean-François Carpentier

Polyhedron 23 (2004) 2437

Synthesis and reactivity in salt metathesis reactions of trivalent [La(Tp^{Me2})$_2$X] (X = Cl, I) complexes: crystal structures of [La(Tp^{Me2})$_2$Cl] and [La(Tp^{Me2})$_2$(κ^2-pz^{Me2})]

The side-formation of a pyrazolato complex La(Tp^{Me2})$_2$(κ^2-pz^{Me2}) (**2**; see structure below) that results during the preparation by salt metathesis of bis-Tp^{Me2} complexes [La(Tp^{Me2})$_2$X] is reported. An effective synthesis of [Ln(Tp^{Me2})(OC_6H_2-2,6-^{t}Bu-4-Me)$_2$] (Ln = La, Nd) derivatives is described.



Dušan Valigura, Milan Melník, Marian Koman, Ladislav Martiška, Maria Korabik, Jerzy Mrozińsky, Tadeusz Glowiak

Polyhedron 23 (2004) 2447

Structural confirmation of the 3,5-dinitrosalicylato anion coordination ability to metal ion: crystal structure, spectral and magnetic properties of the [Cu_3{3,5-$(NO_2)_2sal^{2-}$}$_2${3,5-$(NO_2)_2sal^{1-}$}$_2$($H_2O)_4$] · 4H_2O

Reaction 3,5-dinitrosalicylic acid with copper(II) salts gives the compound [Cu_3-{3,5-$(NO_2)_2sal^{2-}$}$_2${3,5-$(NO_2)_2sal^{1-}$}$_2$($H_2O)_4$] · 4H_2O. Structure of the complex consists of linear trimeric complex molecules held together by hydrogen bonds system and van der Waals interactions. The stacked packing of the molecules allows weak antiferromagnetic intermolecular interaction in addition to significant ferromagnetic intramolecular interaction.

Polyhedron 23 (2004) 2457

Copper(II) complexes of new tetradentate NSNO pyridylthioazophenol ligands: synthesis, spectral characterization and crystal structure

Three sets of copper(II) complexes of a series of new tetradentate NSNO ligands have been synthesized and characterized spectroscopically, using different copper(II) salts. The geometry about the copper ion of the complexes is dependent on the counter anion (Cl^-, SCN^- and ClO_4^-) in the copper salt used. The five-coordinated copper ion is distorted square pyramidal when SCN^- or Cl^- ligate with the copper(II) ion, occupying the equatorial position, whereas the geometry about the four-coordinated copper ion is square planar when the counter anion is perchlorate in the cationic copper(II)–pyridylthioazophenols complexes.

Cobalt(II) and zinc(II) compounds with unsaturated ligands derived from 2-aminobenzothiazole

Four zinc(II) (**6**, **8**, **10** and **12**) and four cobalt(II) (**5**, **7**, **9** and **11**) compounds derived from *N*-(benzothiazol-2-yl)-dithiocarbamic methyl ester (**1**) (**5** and **6**), 1-benzothiazol-2-ylid-3-methyl-thio urea (**2**) (**7**, **8**), 1-benzothiazol-2-yl-2,3-dimethyl-*iso* thiourea (**3**) (**9** and **10**) and *N*-(benzothiazol-2-yl)-*S*,*S*′-dimethyl dithio-carboimine (**4**,**11**,**12**) are reported. The complexes were characterized by UV–Vis–NIR diffuse reflectance, IR, mass spectrometry and **5**, **9**–**12** by X-ray diffraction analyses. In all cases two ligand molecules are bonded to a tetracoordinated metal atom. In **5**–**10** the ligand is anionic and bidentate with the metal in the center of spirocyclic structures formed by two planar unsaturated six membered rings. In **7**–**10** the metal is linked to four N and in **5** and **6** to two S and two N atoms. In **11** and **12** the ligand is neutral and monodentate and the metal ion remains coordinated to the chlorine atoms.

Polyhedron 23 (2004) 2491

Synthesis, characterization and bioactivity of mixed-ligand Cu(II) complexes containing *S*-methyldithiocarbazate derivatives and saccharinate ligands and the X-ray crystal structure of the copper–saccharinate complex containing *S*-methyl-β-*N*-(6-methylpyrid-2-yl)methylenedithiocarbazate

Mixed-ligand complexes of general empirical formula, $[Cu(NNS)(sac)(H_2O)]$(NNS′=*S*-methyl-β-*N*-(6-methylpyrid-2-yl)-methylenedithiocarbazate, NNS″=*S*-methyl-β-*N*-(2-acetylpyrid-2-yl)-methylene-dithiocarbazate and NNS‴=*S*-methyl-β-*N*-(2-benzoylpyrid-2-yl) methylene-dithio-carbazate, sac=saccharinate anion) are reported. The complexes were characterized by elemental analyses and various physico-chemical techniques. X-ray structure analysis of $[Cu(NNS')$-$(sac)(H_2O)]$ indicates a distorted square-pyramidal structure where the Schiff base coordinates as a uninegative tridentate NNS ligand, the fourth and fifth coordination positions of the five-co-ordinate copper(II) ion being occupied by the imino nitrogen of the saccharinate anion and oxygen atom of the aqua ligand. The bioactivity of these complexes has been investigated.

Polyhedron 23 (2004) 2499

Solid-state studies of the Horner–Wittig reagent $[\{\{Ph_2P(O)\}_2CHLi \cdot (THF)\}_2 \cdot THF]$ and its mixed-anion intermediate $[\{\{Ph_2P(O)\}_2$-$CHLi\}_4 \cdot \{Ph_2P(O)_2Li\}_2 \cdot 8C_6H_6]$ formed by reaction with dioxygen

The bis(phosphoryl)-stabilized carbanion $[\{\{Ph_2P(O)\}_2CHLi \cdot (THF)\}_2 \cdot THF]$ (**1**) has been characterized by X-ray crystallography and found to adopt a chelated dimeric structure with a Li_2O_2 ring core. The controlled reaction of **1** with O_2 results in P–C bond cleavage and formation of the mixed-anion complex $[\{\{Ph_2P(O)\}_2CHLi\}_4 \cdot \{Ph_2P(O)_2Li\}_2 \cdot 8C_6H_6]$ (**2**). The crystal structure of **2** shows an unusual hexalithium cage composed of four- and six-membered rings.

Polyhedron 23 (2004) 2523

Synthesis, crystal, molecular and electronic structure of the $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex

The $[ReBr_3(NO)(AsPh_3)(pzH)]$ complex has been obtained in high yield in the reaction of $[ReBr_3(NO)(AsPh_3)_2]$ with pyrazole. The rhenium atom is in a distorted octahedral environment with the bromine ligands in *meridional* geometry and the linear N–O group *trans* to the pyrazole molecule and *cis* to the $AsPh_3$ ligand. The geometric parameters of $[ReBr_3(NO)(AsPh_3)(pzH)]$ have been examined using the density functional theory (DFT) method. Considering the molecular orbital composition and positive total charge on the NO group, the character of the nitrosyl ligand in $[ReBr_3(NO)(AsPh_3)(pzH)]$ may be described as NO^+. The UV–Vis spectrum of $[ReBr_3(NO)(AsPh_3)(pzH)]$ has been discussed on the basis of the electronic transitions calculated with the time-dependent DFT method.

Three dimensional hydrogen-bonding network in a copper complex of 2-hydroxy-1,4-naphthoquinone: structural, spectroscopic and magnetic properties

Three types of intermolecular H-bondings between H_2O and ONQ molecules result in a supramolecular 3D structure of complex **1**, $[Cu(II)(ONQ)_2(H_2O)_2]_n$. The magneto-structural correlation is explained by magnetic chains with antiferromagnetic exchange (J=−3.26 cm^{-1}) between Cu(II)ions in **1** via non-covalent H-bondings together with interchain exchange (zJ'=0.01 cm^{-1}) using the Bonner and Fisher model.

New copper(II) complexes of 2-hydroxyacetophenone *N*(4)-substituted thiosemicarbazones and polypyridyl co-ligands: structural, electrochemical and antimicrobial studies

Seven new copper(II) complexes of 2-hydroxyacetophenone *N*(4)-substituted thiosemicarbazones (H_2L) and bidentate polypyridyl compounds 2,2′-bipyridine and 1,10-phenanthroline (B) were prepared and characterized. The thiosemicarbazones bind to the metal as dianionic ONS donors (L^{2-}) and yield compounds of the stochiometry [MLB]. Spin Hamiltonian and bonding parameters of the compounds calculated from the EPR spectra suggest square pyramidal (SPY) structure for the compounds. The cyclic voltammetric study of the complexes shows irreversible redox peaks corresponding to Cu(II/I) couple and quasi-reversible redox peaks corresponding to copper(II/III) oxidation. The thiosemicarbazones and their copper complexes show significant growth inhibitory activity against bacteria *Escherichia coli*, *Staphylococcus aureus*, and fungi *Candida albicans* and *Aspergillus flavus*.

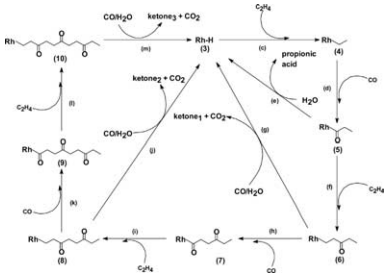
Polyhedron 23 (2004) 1677

Hydrocarboxylation and stepwise alternating oligomerization of carbon monoxide and ethylene catalyzed by *cis*-$[Rh(CO)_2(amine)_2](PF_6)$ complexes in a wet liquid tetrabutylammonium hydrogensulfate

Rhodium complexes of the type, *cis*-$[Rh(CO)_2(amine)_2](PF_6)$ where (amine=4-picoline, 3-picoline, 2-picoline, pyridine, or 2,6-lutidine) dissolved in aqueous tetrabutylammonium hydrogensulfate (0.2 M) catalyzed the stepwise co-oligomerization of CO/ethylene to penta-3-one, octane-3,6-dione and undecane-3,6,9-trione. Also the hydrocarboxylation of ethylene to propionic acid was observed.

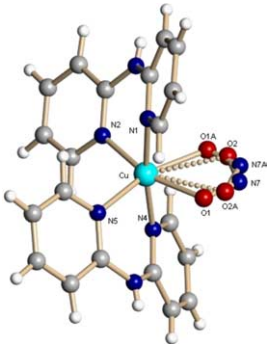


Sujittra Youngme, Pongthipun Phuengphai, Saksit Booncoon, Narongsak Chaichit

Polyhedron 23 (2004) 1685

The crystal structure and electronic properties of a *cis*-distorted octahedral CuN_4O_2 chromophore: $[Cu(dpyam)_2(OXO)]^+$, OXO= ONO^-, O_2CH^- and ONO_2^-

The crystal structures and electronic properties of $[Cu(dpyam)_2(NO_2)](NO_2)$ (**I**) and $[Cu(dpyam)_2(O_2CH)](ClO_4)$ (**II**) and $[Cu(dpyam)_2(ONO_2)](BF_4)$ (**III**) have been examined in the context of fluxional behaviour. In **I**, the copper atom and the asymmetrically bonded nitrito group lie on a crystallographic C_2-axis. The nitrito group is clearly disordered about the C_2-axis giving a square pyramidal *cis*-distorted octahedral $(4 + 1 + 1^*)$ chromophore rather than a pseudo-regular *cis*-distorted octahedral chromophore previously reported. In **II** and **III**, a distortion of the *cis*-distorted CuN_4O_2 chromophore towards a square pyramidal $(4 + 1 + 1^*)$ stereochemistry is also present.



Montserrat Barquín, María J. González Garmendia, Sergio Pacheco, Elena Pinilla, José M. Seco, María R. Torres

Polyhedron 23 (2004) 1695

Synthesis, spectroscopic, magnetic and EPR results and crystal structure of di-μ-(*N*-methyl-*N*-methoxy-2-pyridinamine)bis[(2,2′-bipyridine)copper(II)]hexaflourophosphate

The dinuclear complex $[\{Cu(bipy)\}_2\{\mu\text{-}Me(OCH_2)Npy\}_2](PF_6)_2$ has been synthesized by the reaction of $[\{Cu(bipy)\}_2(\mu\text{-}OH)_2](PF_6)_2$ with MeNHpy. The X-ray crystal structure shows a distorted square-planar pyramidal coordination for Cu(II). The compound is slightly antiferromagnetic ($2J = -3.6$ cm^{-1}). In the Q-band EPR spectrum signals of triplet ($D > hv$) are observed.

Polyhedron 23 (2004) 1709

Copper amino-acid complexes – towards encapsulated metal centres

Two new copper complexes have been investigated by electrochemical and electron spin resonance techniques to determine the extent of encapsulation of the copper ions. There were significant differences between the two complexes, indicating that the copper ion in each of these complexes experiences different microenvironments.

Polyhedron 23 (2004) 1719

Synthesis, characterization and X-ray crystallography of a metallacrown ether complex containing a $Ru^{II}(bpy)_2^{2+}$ chromophore and its $Mo(CO)_4$ analog

The new metallacrown ether complexes *cis*-$[Ru(bpy)_2((2,2'\text{-}C_{12}H_8O_2)P(CH_2CH_2O)_4P(2,2'\text{-}O_2C_{12}H_8))](O_3SCF_3)_2$ and *cis*-$[Mo(CO)_4((2,2'\text{-}C_{12}H_8O_2)P(CH_2CH_2O)_4P(2,2'\text{-}O_2C_{12}H_8))]$ have been prepared. The effect of interactions of the metallacrown ether complex with selected monoatomic cations on the emissive properties of the $Ru(bpy)_2^{2+}$ chromophore were studied by steady-state and time-dependent emission spectroscopy. The complex interacts weakly with Li^+, Na^+ and Hg^{2+}, and subtle changes are observed in its photophysical properties.

Polyhedron 23 (2004) 1731

Synthesis and structure of Mn(II), Cu(II) and Zn(II) complexes containing bis-imidazole ligands

A family of bis-imidazole ligands based on the parent bis(imidazol-2-yl)methane structure, and which can mimic multi-histidine coordination in biological systems, have been complexed to Mn(II), Cu(II) and Zn(II) centres. Five complexes were characterised by X-ray crystallography. A common structural feature of the ligands is that the two imidazole rings, which have a single spacer tetrahedral carbon atom between them, form stable, six-membered *N*,*N*′ chelate rings with the metals.

Solution studies and structure of a dinuclear-based double-stranded helicate of [Cu_2-(*p*-xysal)$_2$] (H_2-*p*-xysal=bis(hydroxylbenzyl) diaminoxylene)

The complex Cu_2(*p*-xysal)$_2$ has been obtained by reaction of H_2-*p*-xysal with copper(II) perchlorate. The compound shows a double-stranded helicate structure, constructed from two slightly different units of dinuclear Cu(II). All the copper(II) ions have distored tetrahedral geometries. Solution studies have been done by different methods (UV/Vis, ESI-MS, EPR, cyclic voltammetry measurement). The intra- and inter-molecular interactions are demonstrated to play important roles in the formation and the stabilization of the molecular architectures of the complex.

Polyhedron 23 (2004) 1505

Solid state coordination chemistry of mononuclear mixed-ligand complexes of Ni(II), Cu(II) and Zn(II) with α-hydroxycarboxylic acids and imidazole

Several metal complexes of α-hydroxycarboxylates (HL′) with imidazole as a coligand have been synthesised and structurally characterized. The octahedral Ni(II) complexes present two formulae: $[Ni(HL')_2(Im)_2]$ and $[Ni(HB')_2(Im)_3]$, HB=benzylate. The Cu(II) complexes of formula [Cu(HL′)(Im)] presents a square pyramidal coordination geometry. The octahedral Zn(II) complexes have two formulae: $[Zn(HL')_2(Im)_2]$ and $[Zn(Im)_6](HB)_2$. Spectroscopic data and the thermal behaviour are presented and discussed.

Polyhedron 23 (2004) 1519

Electron density distribution, polarizability and bonding in the octahedral clusters $[Mo_6S_8(CN)_6]^{6-}$, $[Re_6S_8(CN)_6]^{4-}$ and $Rh_6(CO)_{16}$

Geometrical structure, electron density distribution and polarizabilities were calculated for $[Mo_6S_8(CN)_{12}]^{6-}$, $[Re_6S_8(CN)_6]^{4-}$ and $Rh_6(CO)_{16}$. The noticeable electron density in the inner part of the M_6 octahedrons leads to the model of the clusters with octahedral cores, in which the mobile electrons are moving in a potential well of spherical symmetry. The high values of the calculated polarizabilities of the compounds under consideration are in accord with the suggested model.

Polyhedron 23 (2004) 1641

The novel dinuclear doubly and triply bridged copper(II) compound with monoatomic bridges

The novel planar di-μ-hydroxo-bridged copper (II) compound, $[Cu_2(dpyam)_2(\mu\text{-}OH)_2I_2] \cdot 2H_2O$ (**1**), contains a dinuclear $[I(dpyam)Cu(\mu\text{-}OH)_2$-$Cu(dpyam)I]^+$ unit with a strictly planar CuO_2 network. Each copper(II) ion is in a tetrahedrally distorted square pyramidal coordination geometry of the CuN_2O_2I chromophore. The novel dinuclear copper(II) compound containing three monoatomic bridges with homospecies, $[Cu_2(dpyam)_2(\mu\text{-}OH)_3]Cl \cdot 3H_2O$ (**2**) involves the $[(dpyam)Cu(m\text{-}OH)_3Cu(dpyam)]^+$ unit. The triply bridged Cu(II) ions show a distorted square pyramidal coordination. The fifth apical ligand is a longer bonded bridging OH^- group, which joins the basal CuN_2O_2 planes in a roof-shaped configuration.

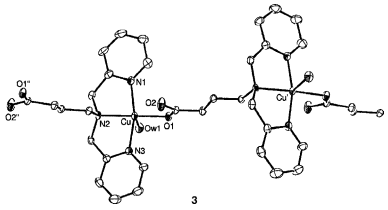
Polyhedron 23 (2004) 903

Synthesis and characterization of *syn–anti* carboxylate-bridged one-dimensional copper(II) complexes with bis(2-pyridylmethyl)-amino acids

One-dimensional polymeric chain complexes $\{[Cu(\mu\text{-pmea})](ClO_4) \cdot H_2O\}_n$ (**1**), $\{[Cu(\mu\text{-pmpa})](ClO_4) \cdot 2H_2O\}_n$ (**2**) and $\{[Cu(\mu\text{-pmba})(H_2O)](ClO_4) \cdot 3H_2O\}_n$ (**3**) were synthesized and structurally characterized. Each copper atom is coordinated by *syn–anti* carboxylate bridges to form a one-dimensional polymeric chain. Magnetic behaviors for all complexes exhibit very weak ferromagnetic interactions.

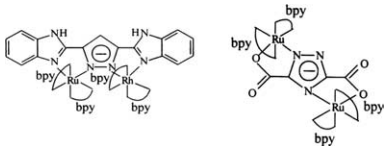


Sujoy Baitalik, Bula Dutta, Kamalaksha Nag

Polyhedron 23 (2004) 913

Spectroscopic and redox properties of $Rh^{III}Ru^{II}$ and $Ru^{II}Ru^{II}$ complexes derived from 2,2′-bipyridine, pyrazole-3,5-bis(benzimidazole) and 1,2,4-triazole-3,5-dicarboxylic acid as bridging ligands

The heterodinuclear complex $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2](ClO_4)_4 \cdot 3H_2O$ and the homodinuclear complex $[(bpy)_2Ru^{II}(trzdc)Ru^{II}(bpy)_2](ClO_4) \cdot 5H_2O$ have been synthesized and characterized by their IR, UV–Vis, luminescence and ^1H NMR spectra. The redox behavior of the complexes has been studied.

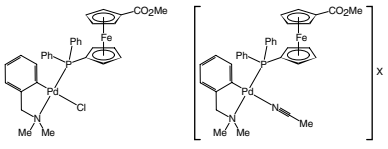


Petr Štěpnička, Martin Lamač, Ivana Císařová

Polyhedron 23 (2004) 921

Preparation, structure and catalytic activity of palladium(II) complexes with a carboxyferrocenylphosphine and an ortho-metallated C,N-ligand

Complexes **3** and **5** (X = ClO_4 (**a**), BF_4, (**b**)) were synthesized by reacting $[\{Pd(\mu\text{-}Cl)(C_6H_4CHNMe_2\text{-}\kappa^2C^1,P)\}_2]$ and $[Pd(C_6H_4CHNMe_2\text{-}\kappa^2C^1,P)(MeCN)_2]X$ (**4**), respectively, with methyl 1′-(diphenylphosphino) ferrocenecarboxylate. Solid-state structures of **4a** and **5a** were determined. Complexes **3** and **5b**, and catalysts based on the related ferrocene phosphines were tested in Suzuki–Miyaura coupling.

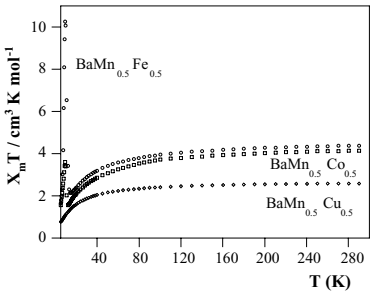


Izaskun Gil de Muro, Luis Lezama, Maite Insausti, Teófilo Rojo

Polyhedron 23 (2004) 929

Layered $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ (M = Fe, Co or Cu) solid solutions: thermal, spectroscopic and magnetic properties

Isostructural metallo-organic complexes $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ (M = Fe, Co and Cu) exhibit two-dimensional arrangements of M–malonate layers. All the iron and cobalt compounds show 2D antiferromagnetic interactions with the presence of a weak ferromagnetism. The copper solid solution also shows 2D antiferromagnetic interactions, unlike the BaCu complex which exhibits ferromagnetic interactions.

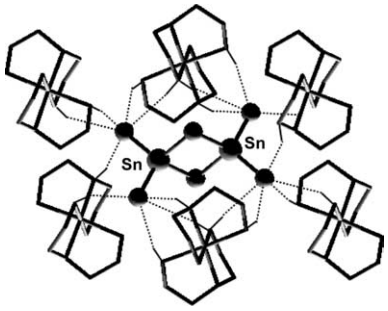


Ding-Xian Jia, Jie Dai, Qin-Yu Zhu, Yong Zhang, Xiao-Mei Gu

Polyhedron 23 (2004) 937

Syntheses, crystal structures and thermoanalyses of thiostannates $[Ni(en)_3]_2Sn_2S_6$ and $[Ni(dien)_2]_2Sn_2S_6$

Two tiostannates $[Ni(en)_3]_2Sn_2S_6$ (**1**) (en = ethylenediamine) and $[Ni(dien)_2]_2Sn_2S_6$ (**2**) (dien = diethylenetriamine) were prepared by the reaction of $SnCl_4 \cdot 5H_2O$, $NiCl_2 \cdot 6H_2O$ and S_8. Both compounds are composed of the discrete $[Sn_2S_6]^{4-}$ anions. The coordinated cations $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ act as structure directing agents which lead to different packing of the $[Sn_2S_6]^{4-}$ anions. The hydrogen bonds are considered to be one of the important reasons for their difference in decomposition temperature.

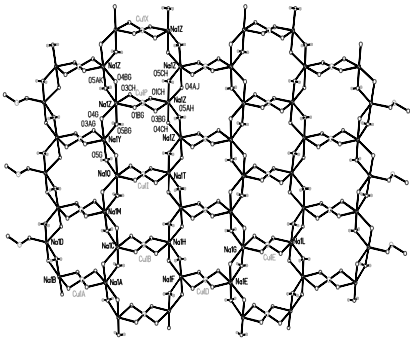


Hong-Lei Liu, Hong-Yan Mao, Hong-Yun Zhang, Chen Xu, Qing-An Wu, Gang Li, Yu Zhu, Hong-Wei Hou

Polyhedron 23 (2004) 943

Two novel heterometallacrowns: syntheses and crystal structures of two copper(II) complexes with malonate and *o*-pthalate

Two copper(II) sodium(I) coordination compounds of the formulae $[C_{16}H_{12}CuNa_2O_{10}]$ (**1**) and $[C_6H_8CuNa_2O_{10}]$ (**2**) were prepared and their structures were characterized by single-crystal X-ray diffraction, IR spectra and thermal analyses.

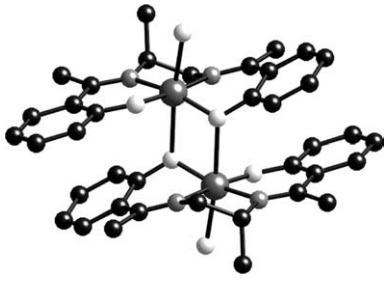


Ruma Karmakar, Chirantan Roy Choudhury, Georges Bravic, Jean-Pascal Sutter, Samiran Mitra

Polyhedron 23 (2004) 949

A novel manganese(III) quadridentate Schiff-base dimeric complex: synthesis, crystal structure and magnetic properties

One new dimeric manganese(III) complex $[MnL(H_2O)]_2(ClO_4)_2 \cdot H_2O$ (**1**) where [L = *N*,*N*′-bis(2-hydroxyacetophenylidene)-1,2-diaminopropane] has been synthesised and characterised by spectroscopic and electrochemical study, and the single crystal structure of the complex was determined.

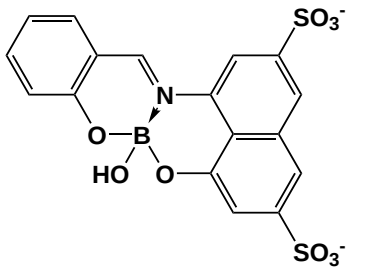


Hidenobu Matsuo, Yoshinobu Miyazaki, Hiroyuki Takemura, Shiro Matsuoka, Hirofumi Sakashita, Kazuhisa Yoshimura

Polyhedron 23 (2004) 955

^{11}B NMR study on the interaction of boric acid with Azomethine H

A ^{11}B NMR study quantitatively clarified the complexation of boric acid with Azomethine H. The interaction between boric acid and Azomethine H yields a 1:1 bischelate complex. The reaction includes two chemical equilibria; one is related to the ligand formation and the other to the complex formation.

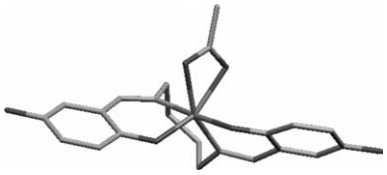


Jesús Sanmartín, Ana M. García-Deibe, Matilde Fondo, Débora Navarro, Manuel R. Bermejo

Polyhedron 23 (2004) 963

Synthesis and crystal structure of a mononuclear iron(III) (η^2-acetato) complex of a β-*cis* folded salen type ligand

Fe(H_2SB)(η^2-O_2CMe) · MeCN [H_4SB: *N*,*N*′-bis(5-hydroxysalicylidene)-1,4-diaminobutane] was synthesised via an electrochemical procedure and its crystal structure was determined.

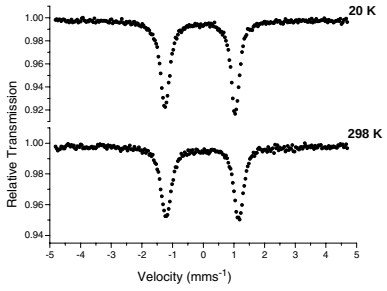


Anandaram Sreekanth, M.R. Prathapachandra Kurup

Polyhedron 23 (2004) 969

Synthesis, EPR and Mössbauer spectral studies of new iron(III) complexes with 2-benzoylpyridine-N(4), N(4)-(butane-1,4-diyl) thiosemicarbazone (HBpypTsc): X-ray structure of [Fe(BpypTsc)$_2$]$FeCl_4$ · $2H_2O$ and the free ligand

Three novel iron(III) complexes of 2-benzoylpyridine N(4), N(4)-(butyl-1,4-diyl) thiosemicarbazone (HBpypTsc), [Fe(BpypTsc)$_2$]ClO_4, [Fe(BpypTsc)$_2$]NO_3 and [Fe(BpypTsc)$_2$]$FeCl_4$ were synthesized and characterized by partial elemental analyses, magnetic measurements, UV–Vis and IR spectroscopies. The spin Hamiltonian parameters were assigned by variable temperature EPR. Isomer shifts and quadrupolar splitting values of the complexes were evaluated from Mössbauer spectra.

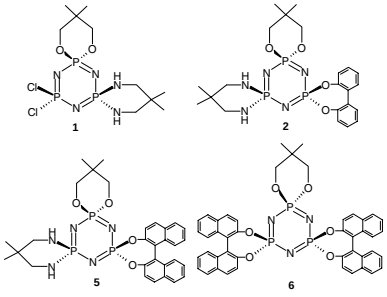


N. Satish Kumar, K.C. Kumara Swamy

Polyhedron 23 (2004) 979

Synthesis and structures of unsymmetrical bis- and tris-cyclotriphosphazenes

Synthesis and structures of an unsymmetrical bis-spirocyclic (**1**) and the first example of an unsymmetrical tris-spirocyclic (**2**) cyclotriphosphazene is reported. In addition, several chiral cyclotriphosphazenes (e.g., **5** and **6**) using 1,1′-bi-2-naphthol have been synthesized.

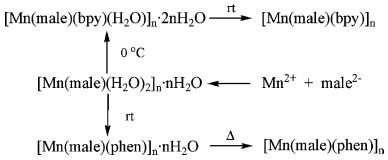


Hong-Bin Chen, Hui Zhang, Jin-Mei Yang, Zhao-Hui Zhou

Polyhedron 23 (2004) 987

Transformation of maleato manganese(II): temperature effect and coordination modes

Reaction of maleato manganese with 2,2′-bipyridine at 0 °C results in the formation of a hepta-coordinated one-dimensional coordination polymer $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**), which undergoes dehydration to form the hexacoordinated two-dimensional polymer $[Mn(male)(bpy)]_n$ (**2**) at ambient temperature.

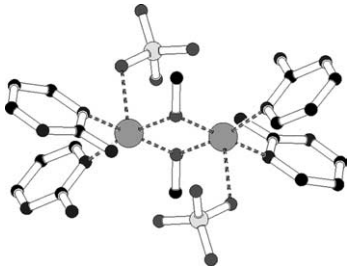


Gerard A. van Albada, Ilpo Mutikainen, Urho Turpeinen, Jan Reedijk

Polyhedron 23 (2004) 993

Synthesis, spectroscopy, crystal structure and magnetism of tetrakis(2-aminopyrimidine) bis(μ-methoxo)bis(perchlorato)dicopper(II): a rare case of distortion isomerism

A new dinuclear methoxo-bridged Cu(II) compound with the ligand 2-aminopyrimidine and a strong antiferromagnetism of $J = -621\ cm^{-1}$ is reported in this study.

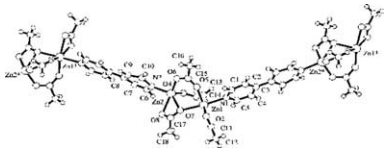


Ting-Wai Lee, Jasmine Po-Kwan Lau, Wing-Tak Wong

Polyhedron 23 (2004) 999

Synthesis and characterization of coordination polymers of Zn(II) with 1,3-bis(4-pyridyl)propane and 4,4′-pyridine ligands

The title complexes $[Zn_2(bpy)(OAc)_4]_n$ (**1**) and $[Zn(bpp)(NO_3)_2]_n$ (**2**) were synthesized by the layering method using Zn(II) ions, bpy and bpp ligands. They are structurally characterized by single-crystal X-ray diffraction analyses. Complexes **1** and **2** were both found to be one-dimensional coordination polymers.

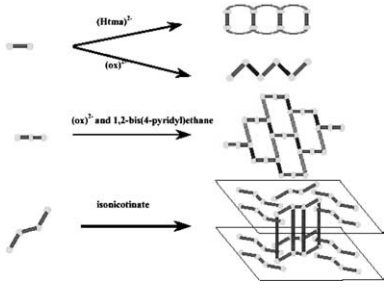


Sheng-Qing Xia, Sheng-Min Hu, Jing-Cao Dai, Xin-Tao Wu, Zhi-Yong Fu, Jian-Jun Zhang, Wen-Xin Du

Polyhedron 23 (2004) 1003

Syntheses and structures of 1D, 2D, 3D cadmium(II) coordination polymers with oxalate and aromatic co-ligands

The use of different co-ligands affects the building units of cadmium oxalate polymers, and infinite 1D, 2D and 3D frameworks can be obtained, which feature dinuclear (for **1** and **2**), trinuclear (for **3**) and tetranuclear (for **4**) units. **TGA** experiments on these polymers show they have relatively high thermal stability.

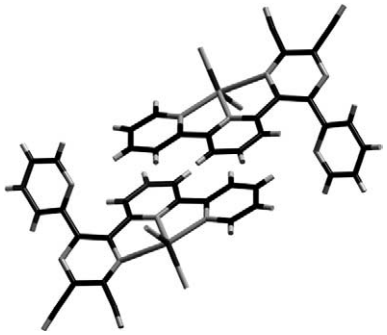


S.I.G. Dias, Fenton Heirtzler, T. Bark, Gael Labat, Antonia Neels

Polyhedron 23 (2004) 1011

Helical zinc complexes of pyrazine–pyridine hybrids

Reaction of the sterically-hindered pyrazine–pyridine hybrid ligands **1a** and **1b** with zinc(II) chloride affords the helically twisted complexes **1a**$ZnCl_2$ and **1b**$ZnCl_2$. The introduction of the nitrile groups into the structure of **1b** appears to cause an incomplete preference for a dimeric structure, as indicated from mass spectroscopic and X-ray crystallographic studies.

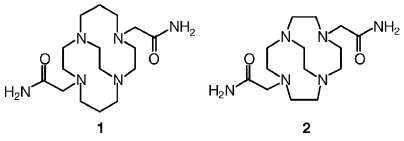


Weijun Niu, Edward H. Wong, Gary R. Weisman, Lev N. Zakharov, Chris D. Incarvito, Arnold L. Rheingold

Polyhedron 23 (2004) 1019

Copper(II) and zinc(II) complexes of amide pendant-armed cross-bridged tetraamine ligands

Copper(II) and zinc(II) complexes of the amide-armed cross-bridged tetraamine ligands **1** and **2** have been synthesized and characterized spectrally and structurally. The cyclam-derived **1** clearly provides a better fit for both metal cations compared to the cyclen-derived **2**. These complexes of **1** also provide the first examples of a [2233]/[2233] cross-bridged cyclam conformation.

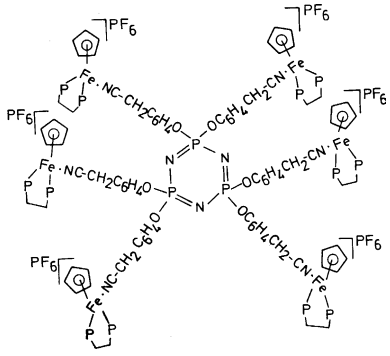


Carlos Díaz, Miguel Barbosa, Zaida Godoy

Polyhedron 23 (2004) 1027

Monobranched and hyperbranched dendrimers based on cyclophosphazene containing nitrile and phosphine donors and their Fe and Ru organometallic derivatives

The series of complexes $[N_3P_3(OC_6H_5)_5X.ML_n]PF_6$, $X=OC_6H_4CH_2CN$, $N(CH_3)(CH_2)_2CN$ or $OC_6H_4PPh_2$, and $[N_3P_3(X)_6 \cdot (ML_n)_6](PF_6)_6$ $X=OC_6H_4CH_2CN$ or $N(CH_3)(CH_2)_2CN$ with ML_n=CpFe(dppe) and $CpRu(PPh_3)_2$ have been synthesized. The new compounds were characterized by elemental analysis and IR, UV–Visible and multinuclear NMR spectroscopy. The hexametallic molecules, one of them is shown in the picture, exhibits non-interaction between the metal centers indicating that the cyclophosphazenes dendrimers act as insulators between the organometallics centers.

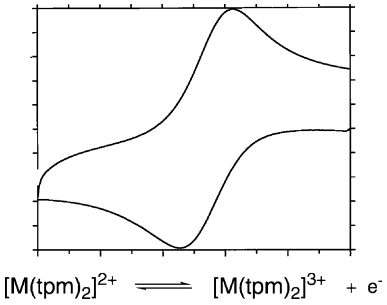


Josie R. Sheets, Franklin A. Schultz

Polyhedron 23 (2004) 1037

Coupled electron-transfer and spin-exchange reactions of metal–bis[tris(pyrazolyl)methane] complexes

Electrochemical M^{2+} to M^{3+} oxidation of bis[tris(pyrazolyl)methane] complexes is accompanied by a change in metal atom spin-state. The influence of metal ion and ligand substituents on the kinetics and thermodynamics of such reactions is described.

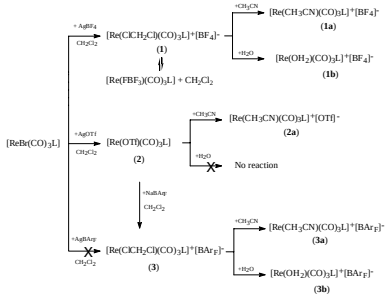


María C. Rodríguez, Jorge Bravo, Eduardo Freijanes, Enrique Oñate, Soledad García-Fontán, Pilar Rodríguez-Seoane

Polyhedron 23 (2004) 1045

Synthesis and reactivity of [Re($ClCH_2Cl$)-($CO)_3$L][A] and [Re(OSO_2CF_3)($CO)_3$L] (L= $Ph_2PO(CH_2)_2OPPh_2$; A=BF_4, [B{3,5-$(CF_3)_2$-C_6H_3}$_4$]): the crystal structure of [Re(OSO_2-CF_3)($CO)_3$L] and [Re($NCCH_3$)($CO)_3$L][BF_4]

The complex [ReBr($CO)_3$L] (L = 1,2-bis[diphenylphosphinite]ethane) was reacted with $AgBF_4$ and with AgOTf in dichloromethane to yield *fac*-[Re($ClCH_2Cl$)($CO)_3$L][BF_4] (**1**) (presumably in equilibrium with [Re-(FBF_3)($CO)_3$L] in solution), and *fac*-[Re-(OTf)($CO)_3$L] (**2**), respectively. Substitution of the loosely held ligands $ClCH_2Cl$ and OTf resulted in the formation of the compounds showed in the scheme. The new complexes were characterized by IR and NMR spectroscopies, and in the case of **2** and [Re-(CH_3CN)($CO)_3$L][BF_4], the crystal structures are reported.

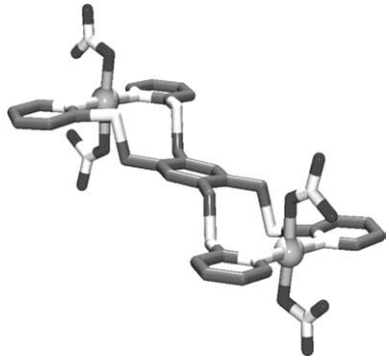


David A. McMorran, Christopher M. Hartshorn, Peter J. Steel

Polyhedron 23 (2004) 1055

Copper(II) complexes of bis- and tetrakis-(2-pyridylsulfanylmethyl)benzenes

Copper(II) salts react with new multi-armed ligands, which contain either two or four 2-pyridylsulfanylmethyl arms appended to a benzene core, to give, in the case of the two-armed ligand, a one-dimensional polymer, while, for the four-armed ligands, discrete bimetallic complexes are observed. Weak Cu–S interactions contribute to the observed structures.

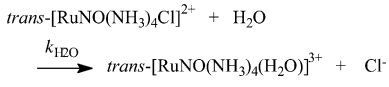


Welter C. Silva, Eduardo E. Castellano, Douglas W. Franco

Polyhedron 23 (2004) 1063

Structural and reactivity changes in ruthenium ammines induced by the NO ligand

The structural, thermodynamic and kinetic data of the [$Ru(NH_3)_5(OH_2)]_2(S_2O_6)_3 \cdot 2H_2O$ and *trans*-$Ru(NH_3)_4NO(OH_2)]Cl_3$ complexes are compared, in order to understand the NO influence on reactivity metal complex.

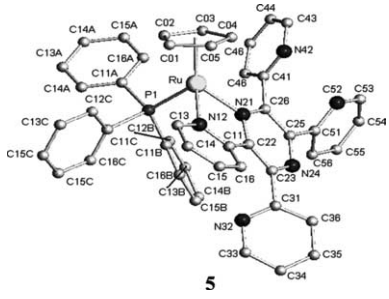


R. Lalrempuia, P. Govindaswamy, Yurij A. Mozharivskyj, Mohan Rao Kollipara

Polyhedron 23 (2004) 1069

Reactivity studies of cyclopentadienyl bis (triphenylphosphine)ruthenium(II) complex towards some polypyridyl ligands

The reaction of some potential bridging polypyridyl ligands with [$CpRu(PPh_3)_2Cl$] in methanol resulted in the dissociation of one of the triphenylphosphines and the chloride ligands from the latter, finally giving cationic monomeric chelate complexes. Alteration of the molar ratios of the reactants fails to give anticipated dimers.

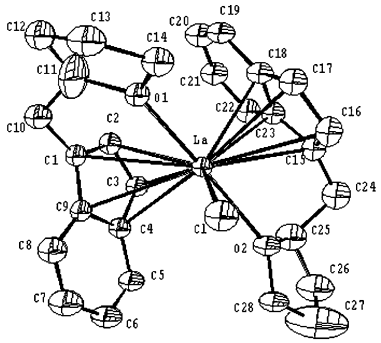


Jianhua Cheng, Dongmei Cui, Wenqi Chen, Tao Tang, Baotong Huang

Polyhedron 23 (2004) 1075

Syntheses and crystal structures of bis(tetrahydrofurfurylindenyl) lanthanocene chlorides $(C_4H_7OCH_2C_9H_6)_2LnCl$ (Ln=La, Lu)

$(C_4H_7OCH_2C_9H_6)_2LnCl$(Ln = La, Lu) were synthesized and characterized. Compared with other lanthanides of these series complexes, the detail relations between the rare earth ionic radii and the structures are described. The changes of the bond length of Ln–C(ring), Ln–Cent, Ln–Cl, and △M–C are consistent with lanthanide contraction.

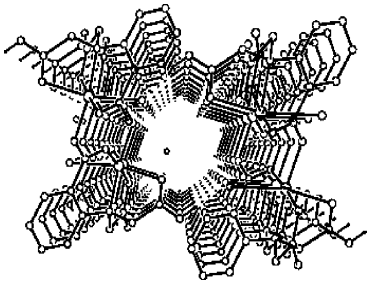


Susmita Bandyopadhyay, Ansuman Das, G.N. Mukherjee, Andrea Cantoni, Gabriele Bocelli, Siddhartha Chaudhuri, Joan Ribas

Polyhedron 23 (2004) 1081

Synthesis, X-ray crystal structures, physicochemical and magnetic studies on copper(II) *N*-(2-carboxyphenyl) iminodiacetate polymers

Crystal lattices of $\{[Cu(Hcpida)] \cdot H_2O\}_n$ (**1**) and $\{[Cu(Hcpida)(H_2O)] \cdot H_2O\}_n$ (**2**) are made up of 1D polymer of ferromagnetically coupled square pyramidal and distorted octahedral Cu(II) units, respectively, linked by carboxylato bridges in *syn–anti* (equatorial–equatorial) bonding mode, stabilized by H-bonding and π–π stacking interactions. Complex **2** forms cylindrical channels that host the lattice H_2O molecules.



Wen-Jie Lu, Lin-Ping Zhang, Hoi-Shan Chan, Tze-Lock Chan, Thomas C.W. Mak

Polyhedron 23 (2004) 1089

Di-protonated 1,4,8,11-tetramethyl-1,4,8,11-tetraazacyclotetradecane tetra-*N*-oxide, a bulky di-cation that induces the assembly of unusual lanthanide(III) complexes

The new di-cation $[Me_4cyclam(OHO)_2]^{2+}$ takes the *RSSR* configuration and induces the formation of lanthanide(III) complexes $[Ln(NO_3)_6]^{3-}$ (Ln = Ce, La, Nd), $[Er(NO_3)_3(H_2O)_3]$ and *catena*-$[Ce(NO_3)_4(\mu\text{-}NO_3)]_n^{2n-}$, the latter being a novel linear coordination polymer constructed by chelating and μ-*O*, *O*, *O*′, *O*″ nitrate groups.

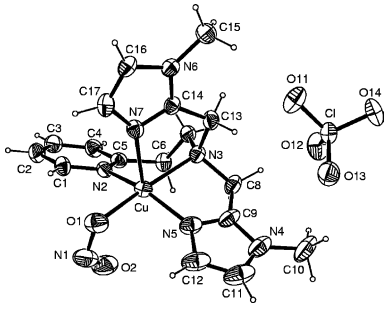
Polyhedron 23 (2004) 511

A structural model for oxidized type II copper nitrite reductase with a polyimidazole tripodal ligand

This paper describes a new Cu^{II}–nitrite complex (**2**) with a tripodal ligand, which was characterized by X-ray crystallography, spectroscopic and electrochemical techniques. Some aspects concerning the formation constant of **2** are also discussed. The arrangements of the ligand and nitrite coordination allow considering **2** a potential structural model for type II copper in nitrite reductases.

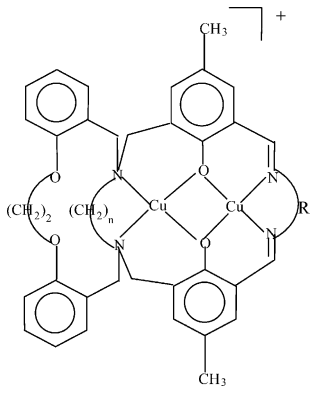


M. Thirumavalavan, P. Akilan, P. Amudha, M. Kandaswamy

Polyhedron 23 (2004) 519

Compartmental unsymmetrical lateral macrobicyclic ligands with an aromatic backbone providing a phenoxo bridge: synthetic, spectral, magnetic, electrochemical and kinetic features of mono and binuclear copper(II) complexes

New types of lateral macrobicyclic compartmental ligands with an aromatic backbone and their mono and binuclear copper(II) complexes were synthesized. Spectral, magnetic, electrochemical and catalytic studies of the complexes were carried out. Magnetic studies rationalize the presence of antiferromagentic coupling in the binuclear complexes. Cyclic voltammetric studies show quasireversible one electron reduction waves in the cathodic region. The catalytic activities of the complexes towards catechol oxidation increase with macrocyclic ring size. Spectral, electrochemical and catalytic studies evidence the distortion in the geometry with the increasing size of the macrocycle.

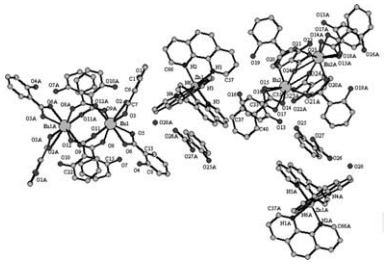


Ming-Cai Yin, Liang-Jie Yuan, Chang-Chun Ai, Chi-Wei Wang, E-Ting Yuan, Ju-Tang Sun

Polyhedron 23 (2004) 529

Synthesis, structure and luminescence properties of europium and zinc ionic complexes

Two europium and zinc ionic complexes $[Eu_2(Hsal)_8][Zn(phen)_3] \cdot (H_2sal)(H_2O)$ (**1**) and $[Eu_2(TPA)_8][Zn(TPA)(Phen)_2]_2 \cdot (H_2O)_2$ (**2**) have been synthesized and structurally characterized. Interestingly, in complex **1**, there are two types of dimeric Eu1 units with inversion centers. These two complexes emit strong red light when irradiated by UV light.

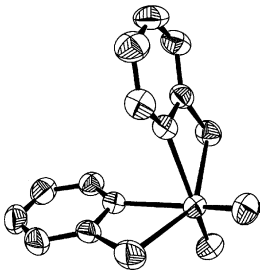


Francisco J. Arnáiz, Rafael Aguado, Mara R. Pedrosa, Miguel A. Maestro

Polyhedron 23 (2004) 537

Dioxomolybdenum(VI) thionates: molecular structure of dioxobis(pyridine-2-thiolate-*N*,*S*)molybdenum(VI)

Dioxomolybdenum(VI) thionates have been prepared in high yield by reacting MoO_2Cl_2 with thallium thionates. They behave as Lewis acids and addition compounds with N-donor ligands have been prepared. The molecular structure of dioxobis(pyridine-2-thiolate-*N*,*S*)molybdenum(VI) has been established by X-ray diffraction analysis.

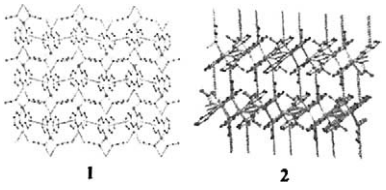


Doyel Bose, Sk Hafijur Rahaman, Golam Mostafa, Rosa D. Bailey Walsh, Michael J. Zaworotko, Barindra K. Ghosh

Polyhedron 23 (2004) 545

Synthesis, structure and properties of $[Zn(dpa)(N_3)_2]$ and $[Zn(dpa)(N_3)(NO_3)]_2$ (dpa=2,2′-dipyridylamine): composition tailored architectures

Two new zinc(II)azido complexes of types $[Zn(dpa)(N_3)]_2$ (**1**) and $[Zn(dpa)(N_3)(NO_3)]_2$ (**2**) containing a tailored diimine, 2,2′-dipyridylamine (dpa), have been synthesized and X-ray crystallographically characterized, of which **1** forms a 2D sheet and **2** shows a 3D continuum through cooperative hydrogen bonds and – interaction; the photoluminescence behaviours are described in the background of their structures.

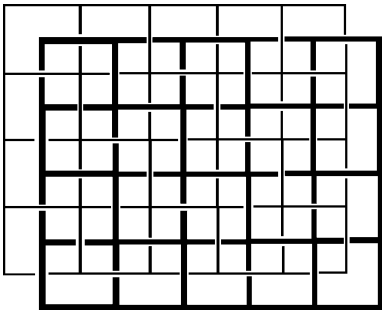


Jian-Fang Ma, Jin Yang, Guo-Li Zheng, Li Li, Yong-Mei Zhang, Fang-Fang Li, Jing-Fu Liu

Polyhedron 23 (2004) 553

Four new coordination polymers of Cu(II) with 1,1′-(1,4-butanediyl)bis(imidazole)

Cu(II) ions are bridged by 1,1′-(1,4-butanediyl)bis(imidazole) to form infinite (4,4) networks, and two (4,4) networks are interpenetrated in parallel mode to form a layer.

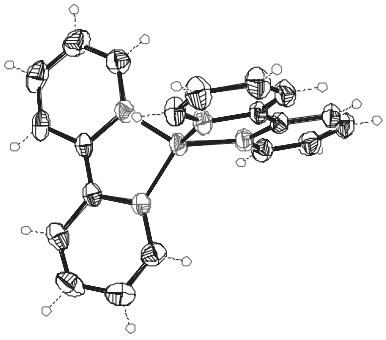


Grigori B. Nikiforov, Herbert W. Roesky, Mathias Noltemeyer, Hans-Georg Schmidt

Polyhedron 23 (2004) 561

Reactivity of $Ti(bipy)_3$ and preparation of the $Li(THF)_4[Al(bipy)_2]$ complex with the dinegative bipy ligand

A ligand transfer in the $Ti(bipy)_3$–$LiAlH_4$ system leads to formation of $[Al(bipy)_2]^-$ with the dinegatively charged bipy ligand.

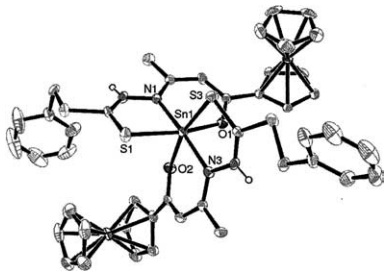


Yao-Cheng Shi, Hua-Mei Yang, Hai-Bin Song, Chao-Guo Yan, Xiao-Ya Hu

Polyhedron 23 (2004) 567

Syntheses and crystal structures of the potential tridentate ligand formed from condensation of ferrocenoylacetone and S-benzyldithiocarbazate and its bivalent metal complexes

Reaction of ferrocenoylacetone and S-benzyldithiocarbazate in refluxing benzene leads to a new potential tridentate ligand ($\mathbf{H_2L}$). Reaction of ($\mathbf{H_2L}$) with a bivalent metal salt ($M(OAc)_2 \cdot xH_2O$, M=Cu, Ni, Mn, Hg, Zn; $SnCl_2 \cdot 2H_2O$) affords the corresponding metal complexes $M(\mathbf{HL})_2$ **(I–VI).** The single-crystal X-ray analysis indicates that the ligand exists as a single iminone isomer in the solid state. The crystallography of complex **VI** shows that the ligand acts as monoanionic tridentate coordinated to the tin atom via the carbonyl oxygen, deprotanated enamine nitrogen and thione sulfur atoms and the coordination geometry of the central metal is a distorted octahedron.

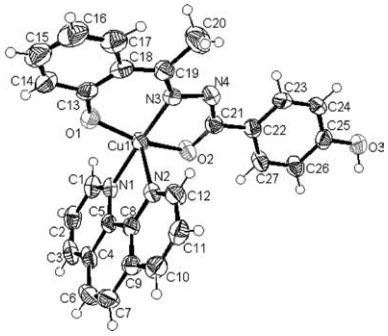


P.B. Sreeja, M.R. Prathapachandra Kurup, Archana Kishore, C. Jasmin

Polyhedron 23 (2004) 575

Spectral characterization, X-ray structure and biological investigations of copper(II) ternary complexes of 2-hydroxyacetophenone 4-hydroxybenzoic acid hydrazone and heterocyclic bases

Two new heterocyclic base adducts of copper(II) complexes of general formula CuLB have been synthesized and characterized by different physicochemical methods. The electronic and IR spectroscopic data indicate that the complexes have square pyramidal geometry with one dibasic tridentate ligand L^{2-}, and one bidentate heterocyclic base. The magnetic susceptibility values at room temperature are consistent with the spin only value for monomeric copper(II) species. EPR studies of all compounds gave axial spectra. The crystal and molecular structure of CuLphen was determined by single crystal X-ray diffraction method. Investigations on antimicrobial activities showed that the compounds are moderately active against *Gram negative* bacteria.



Yousif Sulfab, Fawziyah M. Al-Sogair

Polyhedron 23 (2004) 583

Kinetics and mechanism of reduction of 3, 9-diethyl-4,8-diaza-3,8-undeca-2,10-dionedioximatocopper(III) complex by p-methoxyphenol, 1,2-dihydroxybenzene, 1,4-dihydroxybenzene and some of its derivatives in aqueous acidic solutions

The copper(III)–imine–oxime complex was readily reduced by catechol (H_2Cat), *p*-methoxyphenol (*p*MHP), hydroquinone (H_2Q), 2-methylhydroquinone (MH_2Q), 2-chlorohydroquinone (ClH_2Q) in aqueous weakly acidic solutions. The kinetics were of the second-order; first-order in each reactant. The second-order rate constant showed a complex dependence on $[H^+]$. The experimental rate constants were compared with calculated values using Marcus equation.

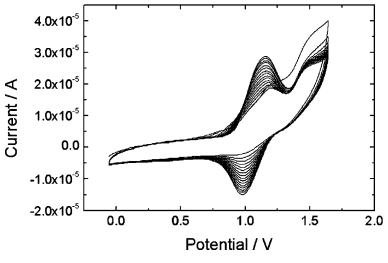
Polyhedron 23 (2004) 589

Electropolymerisable bipyridine ruthenium(II) complexes: synthesis, spectroscopic and electrochemical characterisation of 4-((2-thienyl) ethenyl)- and 4,4′-di((2-thienyl) ethenyl)-2, 2′-bipyridine ruthenium complexes

Four new ruthenium polypyridyl complexes with mono- or di-((2-thienyl) ethenyl) substituted 4,4′-bipyridines have been synthesized and characterized by NMR, elemental analysis, UV–Vis absorption and electrochemistry. Electroactive polymer films of these complexes have been prepared by oxidative electropolymerisation and characterized.

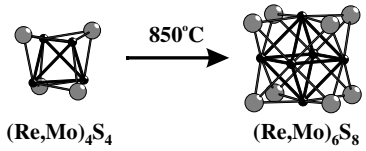


Nikolai G. Naumov, Konstantin A. Brylev, Yuri V. Mironov, Alexander V. Virovets, Dieter Fenske, Vladimir E. Fedorov

Polyhedron 23 (2004) 599

Synthesis and structures of new octahedral water-soluble heterometal rhenium–molybdenum clusters

The interaction of polymeric $Re_3MoS_4Te_4$ with molten KCN at 850 °C results in rearrangement of the tetrahedral $\{Re_3MoS_4\}$ cluster core to an octahedral one, $\{Re_{6-x}Mo_xS_8\}$, and formation of two new molecular octahedral heterometal rhenium–molybdenum thiocyanide cluster complexes, $[Re_5MoS_8(CN)_6]^{5-}$ and $[Re_4Mo_2S_8(CN)_6]^{5-}$, co-existing in the crystals $Cs_5[Re_{4.5}Mo_{1.5}(\mu_3\text{-}S)_8(CN)_6] \cdot 2H_2O$.



William Levason, Melissa L. Matthews, Bhavesh Patel, Gillian Reid, Michael Webster

Polyhedron 23 (2004) 605

Titanium(IV) iodide complexes with phosphine and arsine donor ligands and the crystal structures of the iron(II)/(III) redox pair $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]^{0/+}$

Rare examples of titanium(IV) iodide complexes, $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ and $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ have been prepared and characterised, but reports of 2:1 complexes are shown to be in error. The structures of two iron–diarsine complexes $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ and $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]I_3 \cdot 2CH_2Cl_2$ arising from iron iodide impurities in one commercial sample of TiI_4 are reported.

Polyhedron 23 (2004) 623

Crystal structure of the first octanuclear uranium(IV) complex with compartmental Schiff base ligands

The compartmental Schiff base *N*,*N*′-*bis*(3-hydroxysalicylidene)-1,2-phenylenediamine (H_4L) is able to complex uranium(IV) ions both in its inner N_2O_2 and outer O_4 coordination sites. Further phenoxide-, oxo- and chlorine-bridging results in the formation of an octanuclear dianionic $[U_8L_4Cl_{10}O_4]^{2-}$ cluster, in which the eight metal atoms define four edge-sharing tetrahedra with central μ_4-oxo atoms.

Polyhedron 23 (2004) 649

Hetero(tri- and tetra-)nuclear complexes of uranyl and alkali metal (Li^+, K^+) ions with *p-tert*-butylhexahomotrioxacalix[6]arene

Heteropolymetallic complexes are obtained when uranyl nitrate is reacted with *p-tert*-butylhexahomotrioxacalix[6]arene in the presence of alkali metal hydroxides. Depending on the size of the alkali cation, a monomeric heterotrinuclear species is obtained in the case of Li^+ and a dimeric tetranuclear one in the case of K^+. In the latter complex, two potassium ions ensure the bridging of two homooxacalixarenes and a K–oxo(uranyl) bond is also observed.

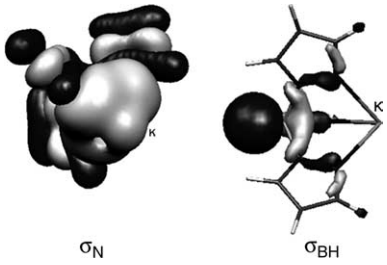
Polyhedron 23 (2004) 429

Photoelectron spectra of potassium salts of hydrotris(pyrazol-1-yl)borates: electronic structure of the electron withdrawing scorpionates $Tp^{(CF_3)_2}$, Tp^{*Cl} and comparison to Tp* and Tp

The electronic structures of KTp*, KTp^{*Cl} and $KTp^{(CH_3)_2}$ have been investigated by gas-phase photoelectron spectroscopy and compared to KTp using density functional theory. Use of HeI and HeII excitation energies provides distinct experimental assignments of the nitrogen σ-donor orbitals (σ_N) and the σ_{BH} molecular orbitals.

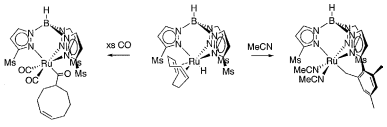


Chandi Pariya, Christopher D. Incarvito, Arnold L. Rheingold, Klaus H. Theopold

Polyhedron 23 (2004) 439

Preparation and ligand substitution reactions of Tp^{Ms}Ru(COD)H including intramolecular ligand metalation

Reaction of $[RuH(COD)(NH_2N(CH_3)_2)_3]BPh_4$ (COD=1,5-cyclooctadiene) with Tp^{Ms}Tl (Tp^{Ms}=hydrotr is(3-mesitylpyrazolyl)borate) yielded Tp^{Ms}Ru(COD)H (**1**). Treatment of **1** with CO afforded acyl complex $Tp^{Ms}Ru(CO)_2$-$C(O)C_8H_{13}$ (**2**). Reaction of **1** with acetonitrile produced $Tp^{Ms@}Ru(NCCH_3)_2$ (**3**). The molecular structures of complexes **1**–**3** have been determined by single crystal X-ray diffraction methods.



Christopher A. Dodds, Małgorzata Jagoda, John Reglinski, Mark D. Spicer

Polyhedron 23 (2004) 445

Soft scorpionate complexes of the fourth and fifth period elements arsenic and tin

We report the synthesis and structure of arsenic (III) and tin(IV) adducts of the hydrotris(methimazolyl)borate anion (Tm^{Me}). Both species are found to be $[E(\kappa^3Tm^{Me})_2]^{n+}$ anions (E=As, $n = 1$; E=Sn, $n = 2$). Comparisons are made between each of these species and the compounds formed with their heavier and larger group partners bismuth and lead.

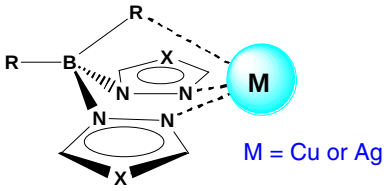
Polyhedron 23 (2004) 451

Copper and silver derivatives of scorpionates and related ligands

A review of the syntheses and of spectroscopic, analytical and structural data of silver(I), copper(I), and copper(II) complexes containing scorpionate and related ligands.

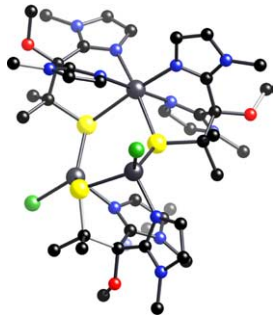


Vivek V. Karambelkar, Robert C. diTargiani, Christopher D. Incarvito, Lev N. Zakharov, Arnold L. Rheingold, Charlotte L. Stern, David P. Goldberg

Polyhedron 23 (2004) 471

Multiple bonding modes exhibited by heteroscorpionate N_2S(alkylthiolate) ligands with Zn(II) and Fe(II)

A related pair of heteroscorpionate N_2S(alkylthiolate) ligands, L^1H and L^2H, have been reacted with Zn(II) and Fe(II) to give monomeric $(L^2)_2Fe$, dimeric $[(L^2)_2Zn_2Br_2]$, and trimeric $[(L^1)_3Zn_3Br_2]Br$ complexes. Structural characterization of these complexes show that the ligands L^1 and L^2 can adopt a wide range of bonding modes. Structural and electronic factors influencing the preferred coordination of L^1 and L^2 are discussed.

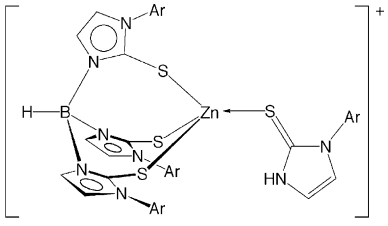


Arefa Docrat, Melissa M. Morlok, Brian M. Bridgewater, David G. Churchill, Gerard Parkin

Polyhedron 23 (2004) 481

N–H···O hydrogen bonding interactions in tetrahedral $[ZnS_4]$ complexes of relevance to zinc enzymes: the synthesis, structures and reactivity of *tris*(2-mercapto-1-arylimidazolyl)hydroborato zinc(2-mercapto-1-arylimidazole) complexes, $\{[Tm^{Ar}]Zn(mim^{Ar})\}[ClO_4]$ (Ar=Ph, *p*-Tol)

The *tris*(2-mercapto-1-arylimidazolyl) hydroborato complexes $\{[Tm^{Ar}]Zn(mim^{Ar})\}[ClO_4]$, which feature tetrahedrally coordinated zinc centers in a sulfur rich environment, may be prepared by the reaction of $[Tm^{Ar}]Li$ with $Zn(ClO_4)_2$ in the presence of 2-mercapto-1-arylimidazole (mim^{Ar}; Ar= Ph, *p*-Tol).

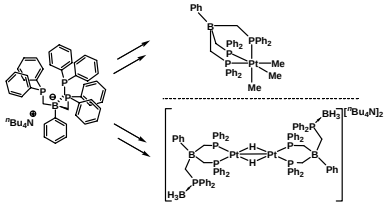


J. Christopher Thomas, Jonas C. Peters

Polyhedron 23 (2004) 489

Platinum-alkyl and hydride complexes supported by a tris(phosphino)borate ligand: structural and spectroscopic studies

The synthesis and characterization of platinum-methyl and hydride complexes containing the ligand $[PhBP_3]$ ($[PhBP_3]$= $[PhB(CH_2PPh_2)_3]^-$) are described. Metallation of $[PhBP_3][TBA]$ (**1[TBA]**, [TBA]= $[^nBu_4N]^+$) with platinum methyl precursors provided the corresponding phosphine methyl platinum species $[PhBP_3]PtMe_3$ (**2**) and $[[\kappa^2\text{-}PhBP_3]PtMe_2][TBA]$ (**3**). The reactivity of octahedral **2** and square planar **3** are discussed, and their X-ray diffraction structures are reported.



Martin L. Kirk, Katrina Peariso

Polyhedron 23 (2004) 499

Ground and excited state spectral comparisons of models for sulfite oxidase

Ground and excited state spectra have been analyzed and compared for models of the one-electron reduced sulfite oxidase active site. Use of the heteroscorpionate ligand (2-dimethylethanethiol) bis(3,5-dimethylpyrazolyl)methane (L3SH) has provided the framework for an oxo-molybdenum(V) model complex that possesses both thiolate and ene-1,2,-dithiolate donors in the equatorial plane. The complex [(L3S)MoO(bdt)] possesses a constrained O–Mo–$S_{thiolate}$–C torsion angle that is close to the ~90° O–Mo–S_{Cys}–C torsion angle observed in the structure of chicken liver sulfite oxidase. The constrained torsion angle in [(L3S)MoO(bdt)] allows for the examination in how second-coordination sphere effects influence the electronic structure of the Mo site in the enzyme.

Preface: Special Issue in Honour of Professor Malcolm L.H. Green 2595

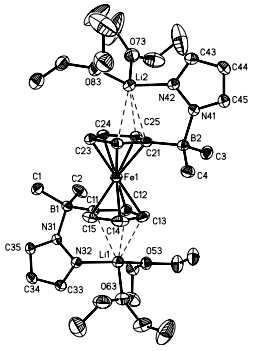
Papers

Alireza Haghiri Ilkhechi, Matthias Scheibitz, Michael Bolte, Hans-Wolfram Lerner, Matthias Wagner

Polyhedron 23 (2004) 2597

On the way to ferrocene-based multiple-decker sandwich complexes

Three ferrocene derivatives, $Li[FcBH_3]$, $Li_2[1,1'\text{-fc}(BMe_3)_2]$ and $Li_2[1,1'\text{-fc}(BMe_2pz)_2]$ [Fc = $(C_5H_5)Fe(C_5H_4)$, fc = $(C_5H_4)_2Fe$, pz = pyrazolyl], have been synthesized and structurally characterized to investigate the interaction of the negatively charged sandwich complex with its Li^+ counterion(s) in the solid state.

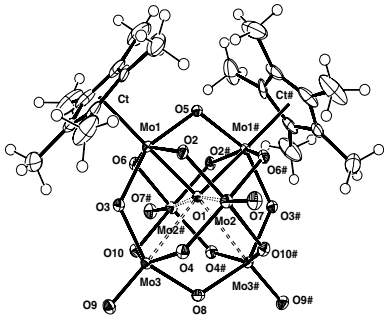


Edmond Collange, Laurent Metteau, Philippe Richard, Rinaldo Poli

Polyhedron 23 (2004) 2605

Synthesis and structure of a new organometallic polyoxomolybdate, $Cp^*_2Mo_6O_{17}$

The new organometallic polyoxomolybdate $Cp^*_2Mo_6O_8$ has been obtained by the straightforward combination of organometallic and inorganic oxomolybdenum(VI) reagents.



Nobuaki Sakai, Taro Saito

Polyhedron 23 (2004) 2611

Synthesis and structures of tetranuclear rhenium–cobalt mixed metal sulfide clusters $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$

An isomeric pair of rhenium–cobalt sulfide clusters $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$ was synthesized by the reaction of $[(Ph_3P)_2N]$-$[Re_3S_4Cl_6(PMe_2Ph)_3]$ with $CoCl_2$ in the presence of PMe_2Ph and their crystal structures were determined. The isomers differ in the orientation of the dimethylphenylphosphine ligands, which controls the coordination of three μ-S atoms in the starting cluster to the cobalt atom.

Polyhedron 23 (2004) 2615

Hypercoordinate silicon and phosphorus acetylene compounds: crystal structure determinations and fluorescence spectroscopic study

The steady-state fluorescence, fluorescence excitation spectra and fluorescence lifetime of pentacoordinate [8-(dimethylamino-κ*N*)-1-naphthalenyl-κ*C*]diethynylmethylsilicon as a function of excitation and emission wavelengths were investigated in solvents of various polarities at room temperature. The crystal structure of the silicon monomer shows a monocapped tetrahedral geometry in which the N atom is opposite one of the acetylene groups.

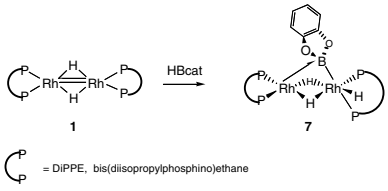
Polyhedron 23 (2004) 2665

Reactions of hydroborating reagents with phosphinorhodium hydride complexes: molecular structures of a Rh_2B_3 metallaborane cluster, an $L_2Rh(\eta^2\text{-}H_2BR_2)$ complex and a mixed valence Rh dimer containing a semi-bridging Bcat (cat=1,2-$O_2C_6H_4$) group

Reactions of hydroborating reagents with phosphinorhodium complexes have been investigated in detail. While alkylboranes proceed via initial insertion of B–H into a Rh–H bond, reactions with catecholborane show an enhanced tendency towards oxidative addition. Implications for rhodium-catalyzed hydroborations are addressed.

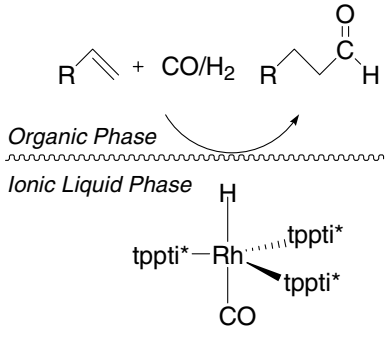


Christian P. Mehnert, Raymond A. Cook, Nicholas C. Dispenziere, Edmund J. Mozeleski

Polyhedron 23 (2004) 2679

Biphasic hydroformylation catalysis in ionic liquid media

A series of ionic liquids have been investigated as reaction media for biphasic hydroformylation catalysis. In the study the rhodium/tppti* (tppi* = tri(*m*-sulfonyl) triphe-nyl phosphine 1,2-dimethyl-3-butyl-imidazolium salt) catalyst system was investigated together with hexene-1 as the substrate. The activity of the biphasic ionic liquid system containing the Rh/tppti* catalyst was approximately one order of magnitude lower than that observed for the conventional Rh/PPh_3 catalyst in toluene.

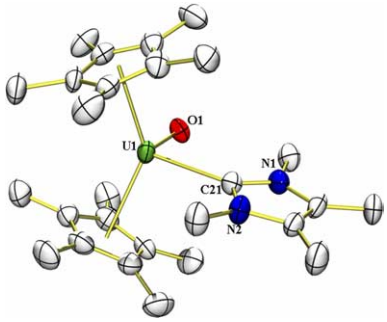


William J. Evans, Stosh A. Kozimor, Joseph W. Ziller

Polyhedron 23 (2004) 2689

Bis(pentamethylcyclopentadienyl) U(III) oxide and U(IV) oxide carbene complexes

Oxidation of the sterically crowded complex $(C_5Me_5)_3U$ provides access to two new classes of uranium compounds that previously were unknown, a U(III) oxide and a U(IV) carbene: $[(C_5Me_5)_2U]_2(\mu\text{-O})$, **1**, and $(C_5Me_5)_2U(O)[C(NMeCMe)_2]$, **2**, respectively. The structure of **1** allows a direct actinide versus lanthanide comparison within the $[(C_5Me_5)_2M]_2(\mu\text{-O})$ class. The structure of **2**, shown here, contains a rare terminal U(IV) oxide as well as a carbene.



Emma Hodson, Stephen J. Simpson

Polyhedron 23 (2004) 2695

Synthesis and characterisation of $[(\eta^6\text{-cymene})Ru(L)X_2]$ compounds: single crystal X-ray structure of $[(\eta^6\text{-cymene})Ru(P\{OPh\}_3)Cl_2]$ at 203 K

Treatment of the chloro bridged dimer $\{[(\eta^6\text{-cymene})RuCl]_2(\mu\text{-Cl})_2\}$ (**1**) with the donor molecules in hot hexane causes bridge splitting reactions that produce the monomeric compounds $[(\eta^6\text{-cymene})Ru(L)Cl_2]$.

Polyhedron 23 (2004) 2769

Near infra-red luminescence from bis-terpyridyl iridium(III) complexes incorporating electron-rich pendants

Iridium(III) bis-terpyridine complexes have been prepared which incorporate aminobenzene or pyrene substituents at the 4′-position of the terpyridine. The complexes are weakly luminescent in the near infra-red (λ_{max} 750–800 nm); this short-lived, low-energy emission, whose likely origin is an excited state of primarily ILCT character, is in contrast to the long-lived $^3\pi$–π^* luminescence of previously studied bis-terpyridyl iridium complexes. The electrochemical properties of the pyrene-substituted ligand and complex in solution are also described.

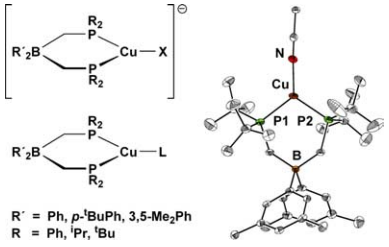
Polyhedron 23 (2004) 2901

Structural and spectroscopic studies of three-coordinate copper(I) supported by bis(phosphino)borate ligands

Monoanionic and neutral three-coordinate complexes of copper(I) have been prepared using several bis(phosphino)borate ligands. Substitution of a labile acetonitrile ligand in $[(3,5\text{-}Me_2Ph)_2B(CH_2P^tBu_2)_2]Cu(NCCH_3)$ provides access to a variety of $[BP_2]Cu^I\text{-}L$ species that should serve as a useful entry point to future group transfer studies.



Jennifer C. Green, Claire Burney

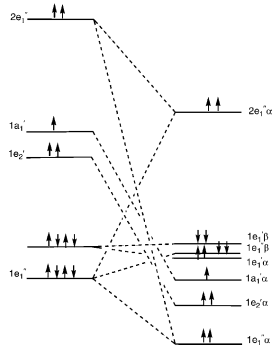
Open shell metallocenes and exchange splitting of ligand bands: a reassignment of the photoelectron spectra of manganocene

Open shell metallocenes and exchange splitting of ligand bands: a reassignment of the photoelectron spectra of manganocene.

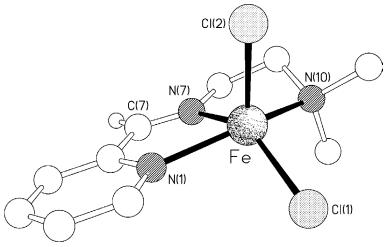


Rachel K. O'Reilly, Vernon C. Gibson, Andrew J.P. White, David J. Williams

Polyhedron 23 (2004) 2921

Five-coordinate iron(II) complexes bearing tridentate nitrogen donor ligands as catalysts for atom transfer radical polymerisation

Five-coordinate iron complexes containing tridentate nitrogen donor ligands have been evaluated for the atom transfer radical polymerisation of styrene. Catalyst activities decrease in the order of donor group: alkyl amine ≈ pyridine > alkyl imine ≫ aryl imine > aryl amine. The trend in polymerisation activity correlates with the redox potential of the corresponding complexes. Complexes derived from aryl-imine or -amine ligands afford catalytic chain transfer rather than ATRP catalysis.

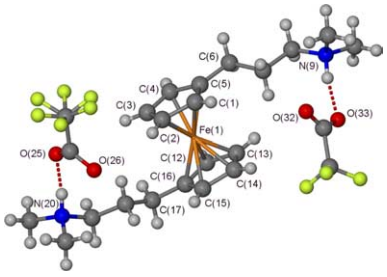


Kenneth D. Camm, Stephen J. Furtado, Andrew L. Gott, Patrick C. McGowan

Polyhedron 23 (2004) 2929

Synthesis and structural studies of bis-amino-functionalised ferrocene salts and ferrocenium salts

New bis-amino-functionalised ferrocene salts and ferrocenium salts have been synthesised and characterised, some of which have N–H···O and N–H···F hydrogen bonds.

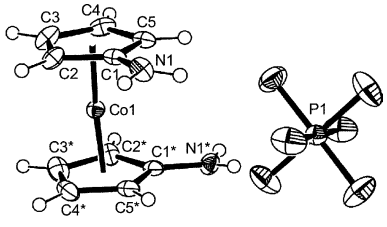


Sviatoslav Inyushin, Alexandr Shafir, John E. Sheats, Michael Minihane, Charles E. Whitten Jr., John Arnold

Polyhedron 23 (2004) 2937

Synthesis and X-ray structures of metallocenium diamines of iron and cobalt

A detailed, reproducible synthesis of 1,1′-diaminocobaltocenium hexafluorophosphate is provided. The X-ray structures of 1,1′-diaminocobaltocenium hexafluorophosphate and a related 1,1′-diaminoferrocenium salt, are described.

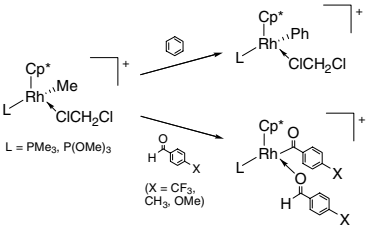


Britton K. Corkey, Felicia L. Taw, Robert G. Bergman, Maurice Brookhart

Polyhedron 23 (2004) 2943

Aromatic and aldehyde carbon–hydrogen bond activation at cationic Rh(III) centers. Evaluation of electronic substituent effects on aldehyde binding and C–H oxidative addition

Cationic rhodium methyl complexes, $[Cp^*(L)Rh(Me)(CH_2Cl_2)]^+$ (L = PMe_3, $P(OMe)_3$) react with benzene to yield the corresponding phenyl complexes, $[Cp^*(L)Rh(Ph)(CH_2Cl_2)]^+$. Reactions of $[Cp^*(L)Rh(Me)(CH_2Cl_2)]^+$ with *p*-X-substituted benzaldehydes (X = $-CF_3$, $-CH_3$, and –OMe) produce acyl aldehyde adducts, $[Cp^*(L)Rh(C(O)C_6H_4X)(p\text{-}XC_6H_4CHO)]^+$. In the case of L = PMe_3, decarbonylation of the aldehyde adducts occurs cleanly to form $[Cp^*(PMe_3)Rh(C_6H_4X)(CO)]^+$. For L = $P(OMe)_3$, decarbonylation is a more complicated process.

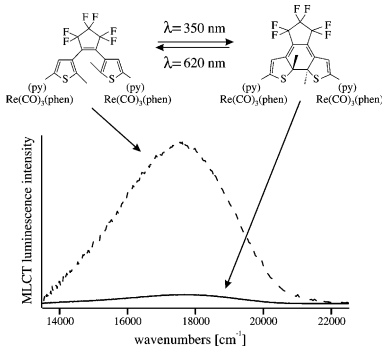


Oliver S. Wenger, Lawrence M. Henling, Michael W. Day, Jay R. Winkler, Harry B. Gray

Polyhedron 23 (2004) 2955

Rhenium(I) tricarbonyl complexes with photoisomerizable ligands

A rhenium(I) complex with a photoisomerizable pyridyl-dithienylperfluorocyclopentene ligand exhibits reversible photoswitchable luminescence. Rhenium(I) tricarbonyls with styryl and azobenzene substituted 2,2′-bipyridines also undergo photoisomerization reactions.

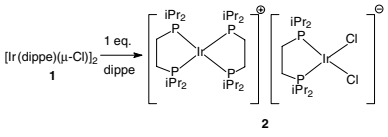


Stephen S. Oster, William D. Jones

Polyhedron 23 (2004) 2959

Synthesis, structure and reactivity of $[Ir(dippe)(\mu\text{-}Cl)]_2$, $[Ir(dippe)_2][Ir(dippe)Cl_2]$ and $[Ir(dippe)_2]Cl$

$[Ir(COD)Cl]_2$ reacts with varying stoichiometries of bis-(diisopropylphosphino)ethane to give either a μ-chloro-dimer, a cation/anion pair or a fully substituted cation. Solvent is also found to affect the species formed.

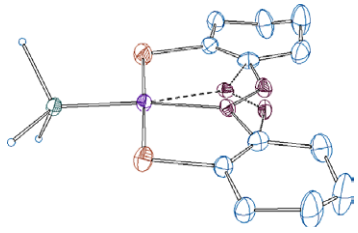


Christopher P. Morley, Susan Ford, Massimo Di Vaira

Polyhedron 23 (2004) 2967

Palladium complexes of novel azo-compounds derived from cycloalkeno-1,2,3-selenadiazoles: X-ray crystal structure of cyclohexeno-1,2,3-selenadiazole

Cycloalkeno-1,2,3-selenadiazoles react with $[Pd_2(dba)_3]/PR_3$ to yield the Pd(II) complexes $[PdL(PR_3)]$, containing a novel Se, N, Se tridentate ligand (L) formed by the coupling of two 1,2,3-selenadiazole molecules; the structures of cyclohexeno-1,2,3-selenadiazole and one of the products have been determined by X-ray crystallography.

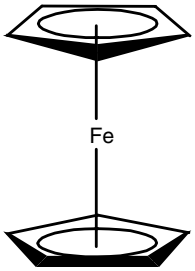


John F.C. Turner, Alan K. Soper

Polyhedron 23 (2004) 2975

On the determination of the structure of ferrocene in solution

The molecular structure of ferrocene in toluene solution is examined for the first time, using neutron scattering with hydrogen isotope substitution on the ferrocene hydrogen atoms. The results are interpreted via a computer-simulated model of ferrocene and toluene molecules at the same concentration and density as the experiment.

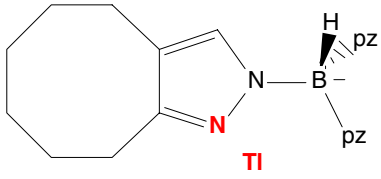


Rosa M. Claramunt, M. Dolores Santa María, José Elguero, Swiatoslaw Trofimenko

Polyhedron 23 (2004) 2985

Isomer distribution in thallium hydrotris(polymethylenepyrazol-1-yl)borates (thallium scorpionates): a multinuclear NMR study

The structure of two thallium scorpionates derived from 3(5),4-trimethylene- and 3(5),4-hexamethylenepyrazole was determined by multinuclear NMR, both in solution and in the solid state. The isomeric distribution is the same in both phases suggesting a kinetic origin. A $^{1}J(^{15}N\text{-}^{205}T1)$ coupling of 862 Hz was measured for $[T1(Tp^{(3,4-(CH_2)_6)})]$ in the solid state.



Constance M. Brett, Bruce E. Bursten

Polyhedron 23 (2004) 2993

Theoretical studies of 18-electron $M(C_nH_n)(C_{10-n}H_{10-n})$ (M = Fe, Ru, Os; n = 3, 4, 5) sandwich complexes

DFT has been used to explore the energetics and bonding of the isomeric sandwich complexes $(\eta^5\text{-}C_5H_5)_2M$, $(\eta^4\text{-}C_4H_4)M(\eta^6\text{-}C_6H_6)$, and $(\eta^3\text{-}C_3H_3)M(\eta^7\text{-}C_7H_7)$ (M = Fe, Ru, Os). The symmetric "5–5" metallocenes were the most stable isomers, with the "4–6" and "3–7" isomers ca. 40 and 80 kcal/mol higher in energy, respectively. Orbital analysis is used to explore the dominant bonding in the unsymmetric complexes.

Polyhedron Reports

REPORTS EDITOR

G. Christou

Polyhedron Reports are specially commissioned critical reports reviewing research of topical importance. Such articles will be commissioned by the Reports Editor of *Polyhedron* from recognised authorities in the appropriate field. Subject to availability, back issues of *Polyhedron* containing *Polyhedron Reports* may be obtained from the Publisher. Please send enquiries to Elsevier B.V., PO Box 211, 1000 AE, Amsterdam, the Netherlands.

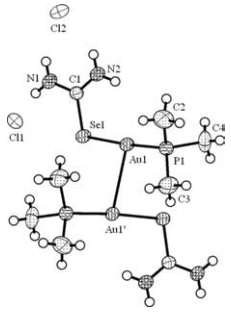
Polyhedron 23 (2004) 1

X-ray structure and ^{77}Se, ^{31}P and ^{13}C MAS NMR of the dinuclear complex 1,2-*bis*(selenourea)-1\κSe,2\κSe-1,2-*bis*(trimethylphosphine)digold(I) chloride

The single crystal X-ray structure of the compound $[(Me_3P\text{-}Au\text{-}Selenourea)_2^{2+}\ 2Cl^-]$ has been determined. The $[Me_3P\text{-}Au\text{-}(selenourea)]$ units are dimerized and adopt a binuclear structure characterized by a metal–metal interaction (Au–Au:3.0386(5) Å). The principal components of the ^{77}Se, ^{31}P and ^{13}C shielding tensors were determined from solid-state NMR data.

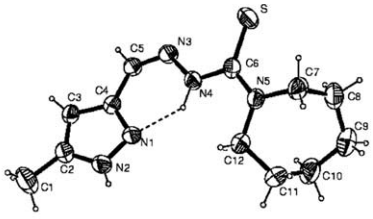


Dhiman Kumar Sau, Ray J. Butcher, Siddhartha Chaudhuri, Nityananda Saha

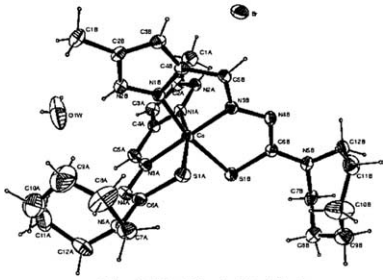
Polyhedron 23 (2004) 5

Synthesis and spectroscopic characterization of new cobalt(III) complexes with 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone (HMPz3Hex): X-ray crystallographic identification of HMPz3Hex and $[Co(MPz3Hex)_2]Br \cdot H_2O$ with evidence for unusual rotation about the azomethine double bond of the ligand on complexation with cobalt(III)

The synthesis and spectroscopic characterization of 5-methyl-3-formyl pyrazole 3-hexamethyleneiminyl thiosemicarbazone (HMPz 3Hex) and its cobalt(III) complexes, $[Co(MPz3Hex)_2]X{\cdot}nH_2O$ (X=Cl, Br, NO_3, ClO_4 or BF_4; $n = 1$ to 2) are reported. X-ray structure analysis of the complex $[Co(MPz3Hex)_2]Br{\cdot}H_2O$, as a representative species, has authenticated a CoN_4S_2 octahedral coordination with a monoprotic NNS tridentate function of the primary ligand system with two azomethine nitrogen atoms in *trans* positions and the pyrazolyl nitrogen atoms and thiolato sulfurs in *cis* positions. Comparison with the crystal structure of the free ligand (HMPz3Hex) has shown that there is an unusual rotation about the azomethine double bond during complexation. A plausible reaction mechanism for this observation has been proposed.



HMPz3Hex



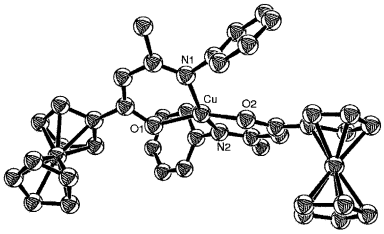
$[Co(MPz3Hex)_2]Br.H_2O$

Yao-Cheng Shi, Hua-Mei Yang, Wen-Bin Shen, Chao-Guo Yan, Xiao-Ya Hu

Polyhedron 23 (2004) 15

Syntheses and crystal structures of ferrocene-containing enaminones and their copper complexes

Reaction of the ferrocene-containing β-diketone $[C_5H_5FeC_5H_4C(O)CH_2C(O)R]$ (**1**, R=CH_3; **2**, R=C_6H_5) and the corresponding aniline $[H_2NAr]$ (Ar=Ph, 2-$CH_3C_6H_4$, 2,6-$(CH_3)_2C_6H_3$) yields a series of enaminones $[C_5H_5FeC_5H_4C(O)CH=C(NHAr)R]$ (**HL^1**–**HL^6**). Reaction of the enaminones (**HL^1**–**HL^5** and copper acetate affords complexes **I**–**V**. Their structures have been determined by the X-ray crystallography of enaminone **HL^6** and complex **I**.

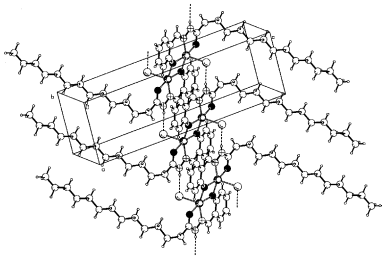


Magdi F. Iskander, Laila El-Sayed, Nahed M.H. Salem, Wolfgang Haase, Hans Jorg Linder, Sabine Foro

Polyhedron 23 (2004) 23

Synthesis, characterization and magnetochemical studies of some copper(II) complexes derived from *n*-salicylidene-*n*-alkanoylhydrazins: X-ray crystal and molecular structure of bis [monochloro(μ-*n*-salicylidenemyristoylhydrazine)ono(−1)] dicopper(II)

Three types of copper(II) complexes, $[Cu(HL)Cl{\cdot}H_2O]{\cdot}xH_2O$, $[\{Cu(HL)Cl\}_2]$ and $[\{Cu(L)\}_2]$, derived from *N*-Salicylidene-*n*-alkanoylhydrazines (H_2L) have been synthesized and characterized by elemental analyses, infrared spectra and field desorption mass spectra as well as variable temperature magnetic susceptibility measurements. The X-ray molecular structure of bis[monochloro(μ-*N*-salicylidene myristoylhydrazine)ONO′(−1)] dicopper(II) showed that this complex is a centrosymmetric dimer in which each copper(II) is in a distorted square pyramidal environment.

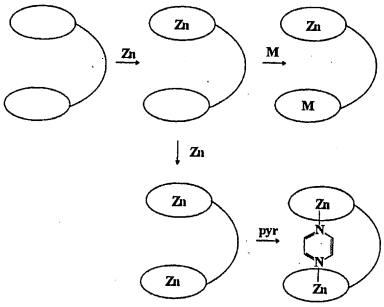


Joanna Borowiec, Irena Trojnar, Stanisław Wołowiec

Polyhedron 23 (2004) 33

Mono- and dizinc complexes of diporphyrins with flexible spacers of variable length

The efficient synthetic route to mono-zinc complexes of diporphyrins with flexible hydrocarbon spacers was described. Monozincdiporphyrin complexes were demonstrated to be useful substrates for heterodimetalodiporphyrins. The discriminating factor in complementary binding of azaheteroaromatic bases: bipyridyl and pyrazine to dizincdiporphyrins was the length of spacer.

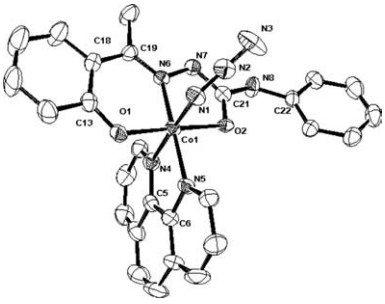


A. Sreekanth, U.L. Kala, Chandini R. Nayar, M.R. Prathapachandra Kurup

Polyhedron 23 (2004) 41

Cobalt(III) complexes of 2-hydroxyacetophenone N(4)-phenyl semicarbazone containing heterocyclic coligands: syntheses, structure and spectral studies

A series of four novel mixed ligand Co(III) complexes of 2-hydroxyacetophenone 4-phenyl semicarbazone (H_2L), heterocyclic base, B [1,10-phenanthroline (phen), piperidine (pip) and pyrrolidine (pyrr)] and azide/thiocyanate (X) with a general formula $[CoLB_xX]$ were prepared and their structures and spectra studied.

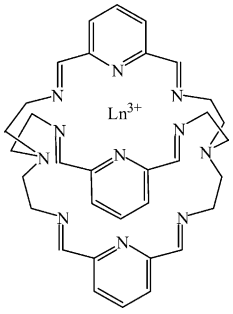


Xue-Lei Hu, Yi-Zhi Li, Qin-Hui Luo

Polyhedron 23 (2004) 49

Characterization and crystal structure of lanthanide cryptates of a ligand derived from 2,6-diformyl-pyridine

Seven lathanide cryptates $[LnL](NO)_3{\cdot}nH_2O$ ($n = 1$–3; Ln=La, Ce, Pr, Sm, Eu, Gd, Tb) were synthesized by the reactions of lanthanide nitrates with free ligand L (L was derived from the (2+3) condensation of 2,6-diformyl-pyridine (*dfp*) with tris-(2-aminoethyl) amine (*tren*)). The crystal structure of Eu(III) cryptate displays a tricapped prismatic coordination geometry



Hui Huang, Shu-Yan Yu, Hong-Bo Liu, Mei Shi

Neutral coordination frameworks with host–guest properties constructed by dicopper(II) units and 4,7-phenanthroline

Reaction of $[Cu_2(O_2CR)_4]$ [R=Me(**1**), Ph(**2**)] with 4,7-phenanthroline produced neutral coordination frameworks $\{[Cu_2(O_2CR)_4](C_{12}N_2H_8)\}_n$ showing inclusion behavior toward solvent molecules; through variation of the equatorial ligands of the dimetal units, the channels size and host–guest properties of the coordination polymers can be controlled.

A silica immobilized cobalt complex: absorption of dioxygen and the redox ability in aqueous solution

A new dioxygen carrier has been synthesized through the tethering of a dinuclear chelating ligand to the surface of mesoporous silica. The material is extremely efficient for the selective absorption of dioxygen and displays good catalytic activity for the disproportionation of H_2O_2.

Synthesis, structural characterisation and thermal decomposition of [{Pt(dppf)(2-SPy)}{BF_4}] (dppf = 1,1′-bisdiphenylphosfinoferrocene and 2-SPy = 2-mercaptopyridine) – a source for a Fe–Pt containing alloy

The reaction of 2-PySK with [Pt(dppf)Cl_2] [dppf=1,1′-bis(diphenylphosfinoferrocene and 2-PyS=2-mercaptopyridine] produced Pt(dppf)(2-SPy)$_2$ (**1**) and its subsequent reaction with $SnBu_2(BF_4)_2$ or $SnBu_3(BF_4)$ yielded [{Pt(dppf)(2-SPy)}{BF_4}] (**2**). A thermal decomposition study was carried out with **2** in three different atmosphere: oxygen, nitrogen or hydrogen. The residues were characterised by X-ray powder diffraction (XRD), X-ray electron probe microanalysis (EPMA), scanning electron microscopy (SEM) and ^{57}Fe Mossbauer spectroscopy. The results have shown the formation of a disordered $Pt_{1-x}Fe_x$ based alloy when the pyrolysis process was performed in H_2, simultaneously with small amount of Fe(II) and Fe(III) phosphides. Furthermore, in oxygen and nitrogen the thermal decomposition of **2** produced metallic agglomerates of Pt dispersed in a combination of Fe(II) and Fe(III) phosphates in O_2, and an intricate mixture of sulphides and phosphides in N_2.

Reactivity behavior of (hydroxy)diorganotin(IV)methanesulfonates with ionic nucleophiles – synthesis and structural characterization of novel diorganostannate salts, [$R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2$ $2Bu_4N$

The reaction of $R_2Sn(OH)OSO_2Me$ [R=*n*-Pr (**1a**) or *n*-Bu (**1b**)] with Bu_4NNO_3 proceeds by nucleophilic addition of NO_3^- ion to the Lewis acidic tin center to yield the novel stannates, [$R_2Sn(\mu\text{-}OH)(OSO_2Me)(ONO_2)]_2$ $2Bu_4N$ [R=*n*-Pr (**2a**), *n*-Bu (**2b**)]. The use of strong nucleophiles such as Bu_4NX (X=F^-, OAc^-) or RLi (R=*n*-Bu, Me), however favors ionic metathesis involving the cleavage of Sn–OSO_2Me group.

Effect of free and chelating phosphine coordination environments on the NiS_2P_2 chromophore: synthesis, NMR and other spectral studies. Crystal and molecular structures of (*N*,*N*-dipropyldithiocarbamato)di(triphenylphosphine)nickel(II) perchlorate and (*N*,*N*-dipropyldithiocarbamato)1,2-bis((diphenylphosphino)ethane)nickel(II) tetraphenylborate

Planar [Ni(dnpdtc)(PPh_3)$_2$]ClO_4·PPh_3 (**1**) and [Ni(dnpdtc)(dppe)]BPh_4 (**2**) complexes were prepared. NMR spectra of the complexes show very large (~20 ppm) ^{31}P chemical shifts in both the compounds. The most important $N^{13}CS_2$ chemical shifts appear at 199.17 and 201.88 ppm for (**1**) and (**2**) respectively. Structural implications are very large for (**2**) compared to (**1**) when free phosphines are replaced by chelating dppe with the P-Ni-P angle shrinking to approximately 12°.

2-Pyridinealdoxime [(py)CHNOH] in manganese(II) carboxylate chemistry: mononuclear, dinuclear, tetranuclear and polymeric complexes, and partial transformation of (py)CHNOH to picolinate(−1)

The reactions of 2-pyridinealdoxime, (py)CHNOH, with various manganese(II) sources lead to complexes $[Mn_4(O_2CPh)_6\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ (**1**), $[Mn(O_2CPh)\{(py)CO_2\}\{(py)CHNOH\}]_n$ (**2**), $[Mn_2(O_2CMe)_2\{(py)CO_2\}_2\{(py)CHNOH\}_2]$ (**3**) and $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$ (**4**) which have been structurally characterised. The most interesting feature in the synthesis of **1**–**3** is the in situ formation of the picolinate(−1) ligand, $(py)CO_2^-$, while the $CF_3CO_2^-$ ligand present in **4** is one of the decomposition products of the hexafluoroacetylacetonate(−1), $hfac^-$, ligand.

Polyhedron 23 (2004) 103

New one- and two-dimensional rhodium–tin polynuclear complexes, synthesis, properties and structural characterization

New dendritic tin–rhodium complexes $[Sn\{CH_2CH_2CNRhCl(CO)_2\}_4]{\cdot}CH_2Cl_2$ and $[Sn_2\{CH_2CH_2CNRhCl(CO)_2\}_4(CH_2CH_2CN)_2]\cdot CHCl_3$ have been synthesized and described. Owing to the interactions between the rhodium atoms, complexes in the solid state have one-dimensional and two-dimensional structure. Unexpectedly the ditin(III) moiety shows an eclipsed conformation. The latter compound in solutions decomposes giving $[Rh_6(CO)_{16}]$.

Novel mercury(II) complexes of 1,3-dithiole-2-thiones containing the 2-pyridyl moiety: syntheses, X-ray crystal structures and solution behavior

The reaction of 2PyEDT-DTT (**1**) with HgX_2 (X=Cl, Br, I) leads to the formation of $[Hg(2PyEDT\text{-}DTT)X_2]_2$ (**2**) and $Hg(2PyDT\text{-}DTT)_2$ (**3**). The crystal structures of **1**, **2** (X=Br, I) and **3** have been determined by X-ray structure analysis. It is disclosed that the intermolecular Hg···S and Hg···N interactions in **2** are cleaved by H_2O in the KBr matrix as well as in organic solvents. In complex **3**, the 2PyDT-DTT ligand is reversibly transformed to 2PyEDT-DTT and Hg(II) in the organic solvent, which was evidenced by the time-dependent UV–Vis and ^1H NMR measurements.

Synthesis, characterization and bio-activity of *S*-2-picolyldithiocarbazate (S2PDTC), some of its Schiff bases and their Ni(II) complexes and X-ray structure of *S*-2-picolyl-β-*N*-(2-acetylpyrrole)dithiocarbazate

A new dithiocarbazate ligand, *S*-2-picolyldithiocarbazate (S2PDTC) was synthesized using 2-picolylchloride hydrochloride. Tridentate Schiff bases were prepared with pyridine-2-carbox-aldehyde (NNS′), 2-acetylpyrrole (NNS″) and 2-acetylthiophene (NSS), while a bidentate Schiff base (NS) was prepared with 2-acetylfuran. Complexes with Ni(II) salts were synthesized and characterized by elemental analyses and various physico-chemical techniques. The bioactivity of these compounds has been investigated.
