[CuL^{2a}](ClO$_4$): [CuL^{2a}](ClO$_4$) was synthesized by following the previously described procedure for [CuL^{1a}](ClO$_4$), using PC-2 instead of PC-1. The compound obtained was dark green. Yield: 1.21 g (76%). Analytical data for $C_{45}H_{46}O_8N_5ClCu$: Calc.: C, 61.08; H, 5.20; N, 7.91. Found: C, 61.16; H, 5.31; N, 8.01%. Selected IR (KBr): 1620 (s), 1100 (s), 623 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 133. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 610 (179), 420 (29,700), 355 (13,100), 274 (33,300). $g_{\|}$: 2.23, $g_{\perp}$: 2.04; μ_{eff}: 1.70 B.M.

[CuL^{2b}](ClO$_4$): [CuL^{2b}](ClO$_4$) was synthesized by following the previously described procedure for [CuL^{1b}](ClO$_4$), using PC-2 instead of PC-1. The compound obtained was dark green. Yield: 1.29 g (76%). Analytical data for $C_{49}H_{48}O_8N_5ClCu$: Calc.: C, 62.95; H, 5.13; N, 7.49. Found: C, 63.01; H, 5.20; N, 7.56%. Selected IR (KBr): 1626 (s), 1100 (s), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 149. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 625 (141), 362 (12,200), 330 (38,600), 272 (32,200). $g_{\|}$: 2.18, $g_{\perp}$: 2.03; μ_{eff}: 1.71 B.M.

2.4. Synthesis of macrobicyclic binuclear copper(II) complexes

[Cu$_2$L^{1a}(ClO$_4$)](ClO$_4$): A methanolic solution of copper(II)perchlorate hexahydrate (0.676 g, 1.8 mmol) was added to the hot solution of PC-1 (1.085 g, 1.8 mmol) in $CHCl_3$ followed by the addition of *o*-phenylenediamine (0.195 g, 1.8 mmol) and triethylamine (0.251 g, 1.8 mmol) in methanol. After one hour copper(II) perchlorate (0.676 g, 1.8 mmol) was added and the whole reaction mixture was refluxed on a water bath for 24 h. After the reaction was over, the reaction mixture was filtered and allowed to stand at room temperature (25 °C). After slow evaporation of the solvent at 25 °C, the dark green compound obtained was washed with methanol and dried in vacuum. Attempts to obtain crystals were unsuccessful. Yield: 1.49 g (77%). Analytical data for $C_{46}H_{46}O_{12}N_6Cl_2Cu_2$: Calc.: C, 51.54; H, 4.29; N, 7.84. Found: C, 51.62; H, 4.36; N, 7.98%. Selected IR (KBr): 1621 (s), 1089, 1096, 1100 (w), 628 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 148. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 610 (255), 420 (20,500), 365 (12,300), 308 (39,600), 275 (32,500). $g = 2.11$; μ_{eff}: 1.35 B.M.

[Cu$_2$L^{1b}(ClO$_4$)](ClO$_4$): [Cu$_2$L^{1b}(ClO$_4$)](ClO$_4$) was synthesized by following the previously described procedure for [Cu$_2$L^{1a}(ClO$_4$)](ClO$_4$), using 1,8-diaminonaphthelene instead of *o*-phenylenediamine. The compound obtained was dark green. Yield: 1.62 g (80%). Analytical data for $C_{50}H_{48}O_{12}N_6Cl_2Cu_2$: Calc.: C, 53.52; H, 4.28; N, 7.49. Found: C, 53.59; H, 4.37; N, 7.59%. Selected IR (KBr): 1624 (s), 1087, 1096, 1101 (w), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 138. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 630 (245), 360 (12,300), 305 (37,300), 272 (32,500). $g = 2.10$; μ_{eff}: 1.39 B.M.

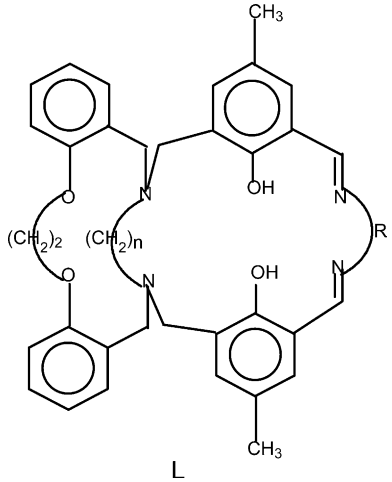
[Cu$_2$L^{2a}(ClO$_4$)](ClO$_4$): [Cu$_2$L^{2a}(ClO$_4$)](ClO$_4$) was synthesized by following the previously described procedure for [Cu$_2$L^{1a}(ClO$_4$)](ClO$_4$), using PC-2 instead of PC-1. The compound obtained was dark green. Yield: 1.51 g (77%). Analytical data for $C_{47}H_{48}O_{12}N_6Cl_2Cu_2$: Calc.: C, 51.98; H, 4.42; N, 7.74. Found: C, 52.07; H, 4.53; N, 7.88%. Selected IR (KBr): 1627 (s), 1084, 1099, 1106 (w), 625 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 139. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 620 (280), 420 (29,400), 355 (12,400), 320 (36,600), 278 (34,900). $g = 2.10$; μ_{eff}: 1.36 B.M.

[Cu$_2$L^{2b}(ClO$_4$)](ClO$_4$): [Cu$_2$L^{2b}(ClO$_4$)](ClO$_4$) was synthesized by following the previously described procedure for [Cu$_2$L^{1b}(ClO$_4$)](ClO$_4$), using PC-2 instead of PC-1. The compound obtained was dark green. Yield: 1.52 g (74%). Analytical data for $C_{51}H_{50}O_{12}N_6Cl_2Cu_2$: Calc.: C, 53.92; H, 4.40; N, 7.40. Found: C, 54.11; H,

4.54; N, 7.60%. Selected IR (KBr): 1625 (s), 1086, 1098, 1102 (w), 624 (s) cm^{-1}. Conductance (Λ_m/S cm^2 mol^{-1}) in CH_3CN: 137. λ_{max} (nm) (ε/M^{-1} cm^{-1}) in CH_3CN: 640 (253), 360 (12,070), 310 (38,600), 277 (33,200). $g = 2.11$; μ_{eff}: 1.42 B.M.

3. Results and discussion

Using the template method various macrobicyclic mono and binuclear copper(II) complexes were synthesized by Schiff's base condensation of the precursor compounds with diamines in the presence of the metal ion. The synthetic pathway of mono and binuclear complexes is shown in Scheme 1. The structure of the ligand can be represented graphically as follows:



L

Our previous studies [12] rationalize the crystal structure of a similar type of mono and binuclear copper(II) complexes. Hence, in accordance with this, it is proposed that the geometry around the copper(II) ion in the mononuclear complex is distorted square planar and one of the tertiary nitrogen atoms is protonated. In the binuclear copper(II) complex one copper(II) ion is four coordinated and another copper(II) ion is five coordinated. Conductivity measurements also vindicate that both mono and binuclear copper(II) complexes are 1:1 electrolytes. Spectral, magnetic, electrochemical and catalytic studies of the complexes were carried out.

3.1. Spectral studies

In the IR spectra of the complexes a ν(C=N) peak [19] is observed at 1620–1626 cm^{-1}. The effective schiff base condensation is indicated by the formation of this new peak and the disappearance of the ν(C=O) peak at 1678 cm^{-1} in the complexes. The mononuclear complexes show peaks near 1100 and 620 cm^{-1} characteristic of the uncoordinated perchlorate ion. The binuclear complexes show two peaks near 1100 cm^{-1} and one peak near 620 cm^{-1}. Among the two peaks, one peak shows splittings [20], which is due to the presence of coordinated perchlorate ion, and the other peak due to the presence of uncoordinated perchlorate ion does not show any splitting. The electronic spectra of the complexes were observed as three main transitions. A weak band observed in the range 590–640 nm is due to a d–d transition of the metal ion. An increase in λ_{max} (red shift) [21] of the d–d transition of the Cu(II) ion in the complexes from L^{1a} to L^{1b} and L^{2a} to L^{2b} was observed for both mono and binuclear copper(II) complexes. A moderately intense band observed in the range 350–365 nm is due to a ligand to metal charge transfer transition and the strong band observed in the range 270–274 nm is due to an intraligand charge transfer transition [22]. Apart from these, additional peaks are observed due to the presence of the aromatic ring in the imine nitrogen compartment.

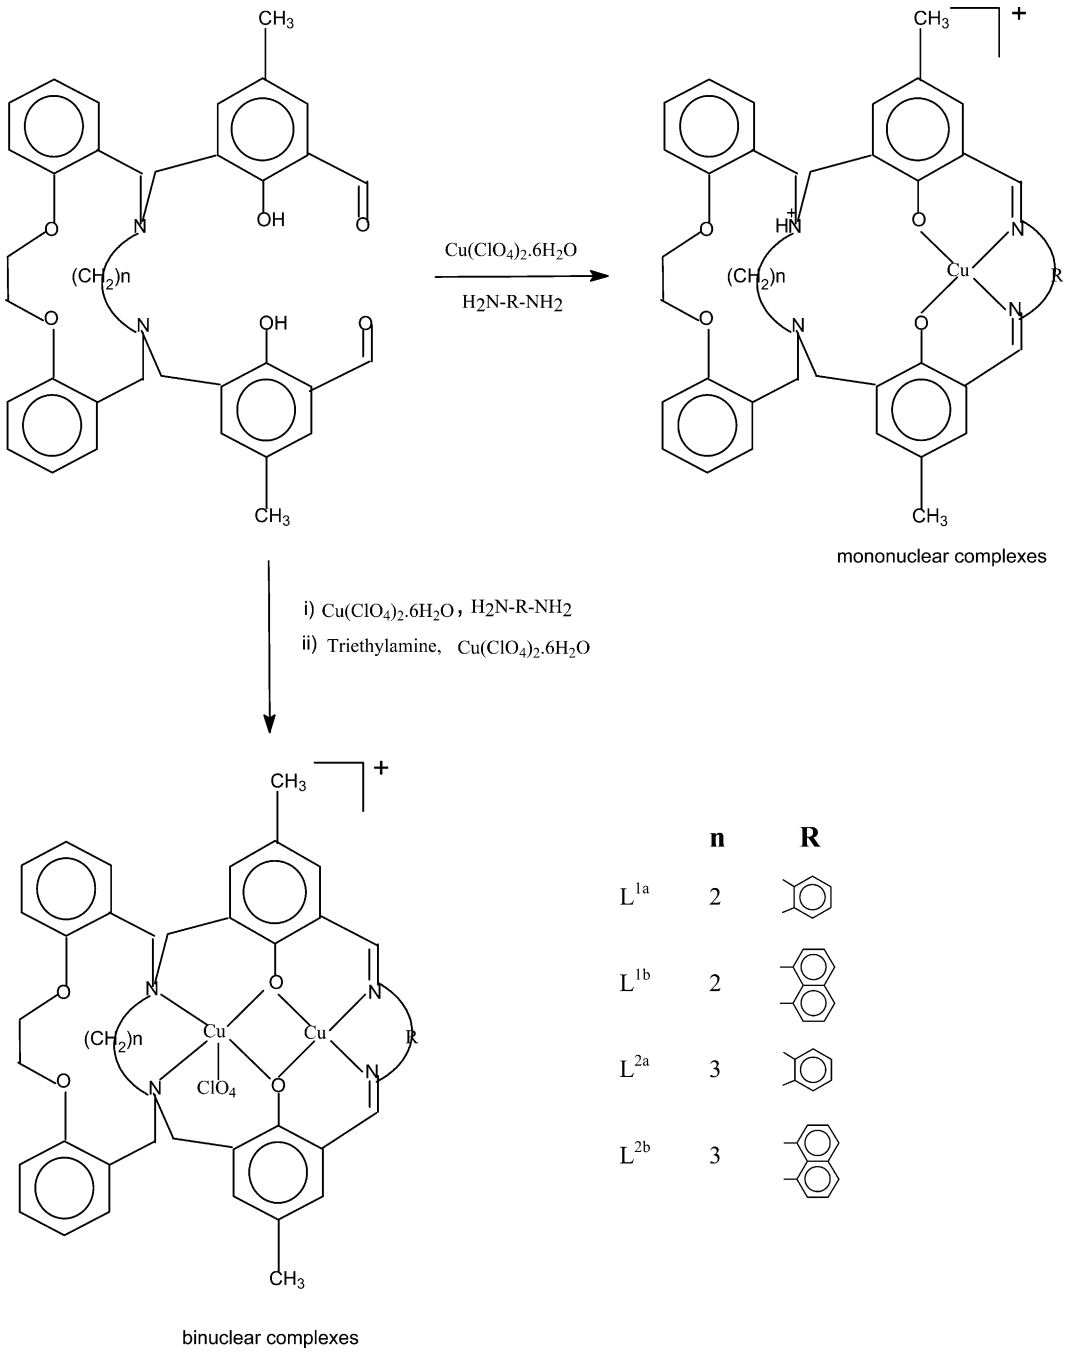
Hyperfine splittings of the solid state ESR spectra of the mononuclear copper(II) complexes show four lines with nuclear hyperfine spin 3/2. For mononuclear complexes the observed $g_{\|}$ values range from 2.19 to 2.22 and $g_{\perp}$ values vary from 2.03 to 2.06. The binuclear copper(II) complexes show a broad spectra centred at g; 2.10–2.11, which testifies the presence of an antiferromagnetic interaction between the two copper ions. Fig. 1 shows the ESR spectra of the mono and binuclear copper(II) complexes of ligand L^{1b}.

3.2. Magnetic studies

It is worth noting to infer that the probe of room temperature magnetic studies of the mononuclear copper(II) complexes resulted in the magnetic moment values range 1.69–1.71 B.M., which is very close to that of the spin only value (1.73 B.M.) expected for complexes having one copper(II) ion [23] with a single unpaired electron sited in an essentially $d_{x^2-y^2}$ orbital. The observed room temperature magnetic moment values for the binuclear copper(II) complexes ranges from 1.35 to 1.42 B.M. conveying the presence of an antiferromagnetic interaction between the two copper(II) ions. To evaluate the singlet–triplet energy separation ($-2J$), a variable-temperature magnetic study of the binuclear complexes was carried out in the temperature range 77–300 K and the experimental magnetic susceptibility values were fitted to the modified Bleany–Bowers equation [24].

$$\chi_m = (Ng^2\beta^2/3kT)[3 + \exp(-2J/kT)]^{-1}(1 - P) + 0.45P/T + N_\alpha.$$

In which N_α and g have been fixed as 60×10^{-6} cm^3 M^{-1} and 2.20, respectively. χ_m is the molar magnetic susceptibility corrected for diamagnetism, P is the percentage of monomeric impurities and other symbols



Scheme 1. Synthesis of macrobicyclic mono and binuclear copper(II) complexes.

have their usual meaning. The $-2J$ values were evaluated by a nonlinear regression analysis in which $-2J$, P and g are variables. Fig. 2 depicts the temperature dependent magnetic properties of complexes $[Cu_2L^{1a}(ClO_4)](ClO_4)$ and $[Cu_2L^{1b}(ClO_4)](ClO_4)$.

Magneto-structural correlations for several phenoxo bridged [25] dicopper complexes show that the major factor controlling the exchange interactions is the Cu–O–Cu bridge angle; however other factors [26] such as degree of distortion from planarity [27] and the dihedral angle [28] between the two copper planes also have an influence on the extent of spin–spin interaction. Generally phenoxo-bridged planar dicopper complexes with $Cu–O_{ph}–Cu$ bridge angles greater than 99° show exchange coupling values greater than 420 cm^{-1} and for the complexes with bridge angles less than 99° the exchange interaction is less (<70 cm^{-1}) [22]. Thompson et al. [25] reported that for symmetrical planar complexes with a bridge angle greater than 99° the $-2J$ values are ≈500–700 cm^{-1}. But Okawa et al. [27]

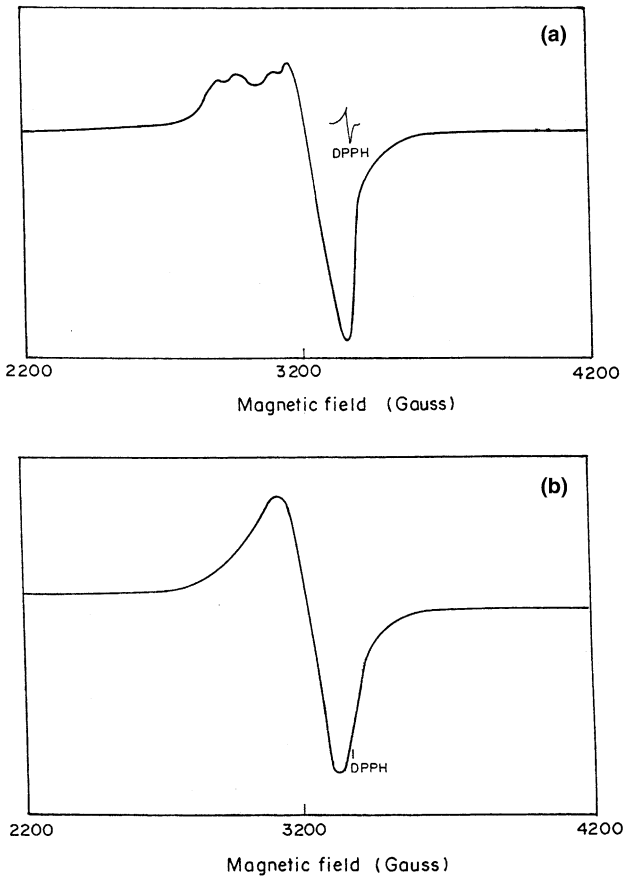


Fig. 1. ESR spectra of (a) $[CuL^{1b}]ClO_4$, (b) $[Cu_2L^{1b}(ClO_4)](ClO_4)$.

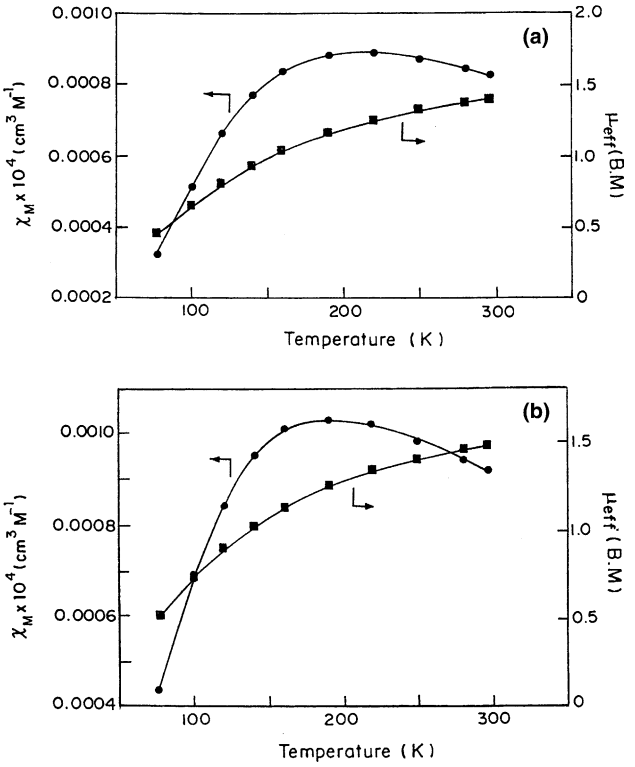

Fig. 2. Temperature dependent magnetic properties of complex (a) $[Cu_2L^{1a}(ClO_4)](ClO_4)$, (b) $[Cu_2L^{1b}(ClO_4)](ClO_4)$.

reported for distorted copper(II) complexes the $-2J$ values are 220 cm^{-1}. This low value is due to the distortion of the geometry of one of the Cu(II) ions, which causes deviation from co-planarity. For the complexes $[Cu_2L^{1a}(ClO_4)](ClO_4)$ and $[Cu_2L^{1b}(ClO_4)](ClO_4)$ the observed exchange interaction values ($-2J$) are 240 and 219 cm^{-1}, respectively. The distortion of the geometry [27] and the deviation from co-planarity [26] may be the possible reasons for this low exchange interaction value. The observed room temperature magnetic moment value of the binuclear copper(II) complex of L^{1a} is lower than that of L^{1b}. This is mainly because of the reason that the planarity of N_2O_2 of the imine nitrogen compartment is more in the case of L^{1a}. In the case of L^{1b} the planarity is lowered due to the presence of a bulky group, which makes L^{1b} comparatively flexible and hence the exchange interaction is lowered to some extent. Thus the greater planarity causes the higher exchange interaction and hence the low magnetic moment values.

3.3. Electrochemistry

The range of conductance values from 129 to 151 Λ_m/S cm^2 mol^{-1} of mono and binuclear copper(II) complexes in acetonitrile resulted from the conductivity measurements [20] implies that the complexes are of 1:1 electrolyte type. Usually phenoxo copper complexes undergo reduction at negative potentials due to the electronegativity and hard nature of the phenoxide atoms in the ligands [29,30]. Electrochemical properties of the complexes reported in the present work were studied by cyclic voltammetry in the potential range 0 to −1.5 V in dimethylformamide containing 10^{-1} M tetra(*n*-butyl)ammonium perchlorate and the data are summarized in Table 1. The cyclic voltammograms for the mononuclear complexes are shown in Fig. 3. Each voltammogram shows one quasireversible reduction wave at negative potential in the range −0.80 to −0.88 V. Controlled potential electrolysis carried out at 100 mV more negative than the reduction wave ratifies the consumption of one electron per molecule ($n = 0.96$) and the experiment reports the couple corresponding to the one electron transfer process. Fig. 4 represents the cyclic voltammograms of the binuclear complexes. Binuclear complexes are acquainted with two quasireversible reduction waves. The first reduction potential ranges from −0.84 to −0.94 V and the second reduction potential lies in the range −1.25 to −1.40 V. Controlled potential electrolysis was also carried out and the experiment reports that each couple corresponds to a one electron transfer process. So, the two redox processes are assigned as follows,

Table 1
Electrochemical data[a] of mono and binuclear copper(II) complexes in DMF medium

Complexes	E^1_{pc} (V)	E^1_{pa} (V)	$E^1_{1/2}$ (V)	ΔE (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E^2_{1/2}$ (V)	ΔE (mV)	K_{con}
$[CuL^{1a}](ClO_4)$	−0.88	−0.72	−0.80	160

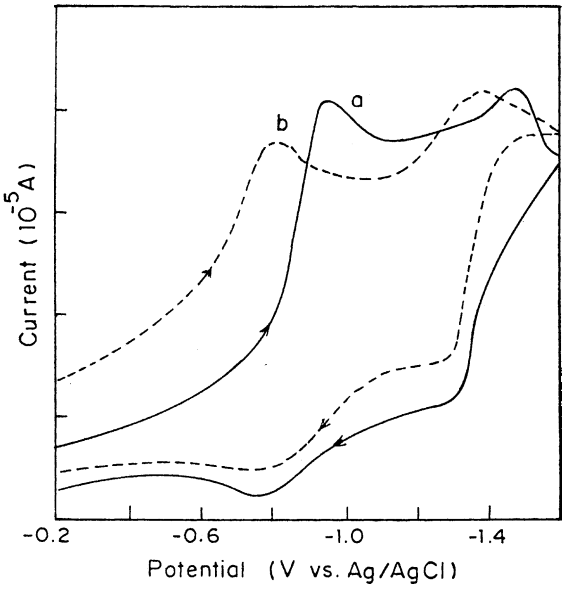

Fig. 4. Cyclic voltammograms of the binuclear copper(II) complexes (1×10^{-3} M) (a) $[Cu_2L^{1a}(ClO_4)](ClO_4)$, (b)$[Cu_2L^{1b}(ClO_4)](ClO_4)$.

$$Cu^{II}Cu^{II} \rightleftharpoons Cu^{II}Cu^{I} \rightleftharpoons Cu^{I}Cu^{I}$$

The conproportionation constant for the equilibrium

$$Cu^{II}Cu^{II} + Cu^{I}Cu^{I} \overset{K_{con}}{\rightleftharpoons} 2Cu^{II}Cu^{I}$$

was calculated using the relationship $\log K_{con} = \Delta E/0.0591$.

It is of interest to compare the electrochemical behaviour of the complexes heedfully. The reduction potential of the mononuclear copper(II) complexes of ligands L^{1a} to L^{1b} and L^{2a} to L^{2b} shifts anodically from −0.88 to −0.85 V and from −0.86 to −0.80 V, respectively, as the macrocyclic ring size increases due to the presence of the bulky group. This imparts more flexibility to the macrocycle [31–34] and tries to stabilize the copper(I) complex. The observed ΔE values for mononuclear complexes are found to be larger than the corresponding binuclear complexes and the reason may be attributed to the occurrence of electrochemical interconversion (translocation) [35] of the reduced cation Cu(I) from the rigid imine nitrogen compartment (N_2O_2) to the flexible tertiary nitrogen compartment (N_2O_2), which favours the tetrahedral geometry. The larger ΔE values also indicate that the reduction process is associated with an ECE mechanism. It is also noticed that the decrease in ΔE value as the chain length between two imine nitrogens increases, eases the translocation process and favours the tetrahedral geometry [12–14] moving from the complexes of ligands L^{1a} to L^{1b} and L^{2a} to L^{2b}. The interesting feature connoted for the binuclear complexes is anodic shifting of both first and second reduction potentials as the size of the macrocycle is increased. For example the complex $[Cu_2L^{1a}(ClO_4)](ClO_4)$ has $E^1_{pc} = -0.94$ V and $E^2_{pc} = -1.40$ V, which is more negative compared to the complex $[Cu_2L^{1b}(ClO_4)](ClO_4)$ ($E^1_{pc} = -0.88$ V, $E^2_{pc} = -1.30$ V) and the same observation is inferred for the complexes of L^2 also. Thus due to the presence of a bulky group in the imine compartment, the whole macrocyclic ring becomes more flexible and hence undergoes easy reduction. Thus the large size of cavity easily holds the reduced cation and stabilizes the formation of Cu(I) in

the compartment. Concern in the calculation of K_{con} values of binuclear copper(II) complexes leads to another interesting feature. The decrease in K_{con} values for the complexes of ligands L^{1a} to L^{1b} (6.07×10^7, 1.89×10^7) and of ligands L^{2a} to L^{2b} (4.11×10^7, 8.66×10^6) explains that as the ring size increases the stability of the mixed-valent species, formed as a result of the one electron reduction of complexes, decreases. This is because of the reason that the increase in ring size produces more distortion of the geometry around the metal center and the added electron is localized in the first metal ion itself and its impact on the other metal ion is negligible. Thus the lowered interaction between the two metal ions in the distorted geometry makes the reduction of the second metal ion easier.

An intensive speculation can be made concerning the comparison of reduction potentials of copper(II) complexes of ligands L^1 and L^2, which leads to the observation that the complexes of ligand L^2 get reduced at less negative potentials than the complexes of ligand L^1, because of the flexibility due to increase in the ring size of the macrocycle.

3.4. Kinetic studies of oxidation of catechol

Emphasis has been indeed made to carry out kinetic studies of the complexes. All the complexes synthesized were subjected for catecholase activity. The product *o*-quinone is considerably stable and has a strong absorbance at 390 nm. For this purpose, 10^{-3} mol dm^{-3} solutions of the complexes in acetonitrile were treated with 50 equivalents of 3,5-ditertiarybutylcatechol in the presence of air.

The course of the reaction was followed at 390 nm for nearly 45 min at regular time intervals. The slope was determined by the method of initial rates by monitoring the growth of the 390 nm band of the product *o*-quinone. A linear relationship for initial rate and the complex concentration obtained for all the complexes shows a first order dependence on the complex concentration for the systems.

A plot of $\log(A_\infty/A_\infty - A_t)$ versus time for catecholase activity of the mono and binuclear complexes are obtained and shown in Figs. 5 and 6, respectively. The rate constant values are also reported in Table 2. The first apparent result was that the reactivities of the complexes differ significantly, as the size of the macrocycle increases. The binuclear complexes have higher activities than the mononuclear complexes [36–40]. For example the binuclear complexes $[Cu_2L^{1a}(ClO_4)](ClO_4)$, $[Cu_2L^{1b}(ClO_4)](ClO_4)$, $[Cu_2L^{2a}(ClO_4)](ClO_4)$, and $[Cu_2L^{2b}(ClO_4)](ClO_4)$ have the rate constant values 1.24×10^{-2}, 2.17×10^{-2}, 1.56×10^{-2}, and 2.56×10^{-2} min^{-1}, respectively, whereas the mononuclear complexes $[CuL^{1a}](ClO_4)$, $[CuL^{1b}](ClO_4)$, $[CuL^{2a}](ClO_4)$ and $[CuL^{2b}](ClO_4)$ have the rate constant values 5.06×10^{-3}, 5.84×10^{-3}, 5.53×10^{-3} and 6.67×10^{-3} min^{-1}, respectively. The oxidation of catechol to *o*-quinone requires the presence of two metal ions in close proximity and

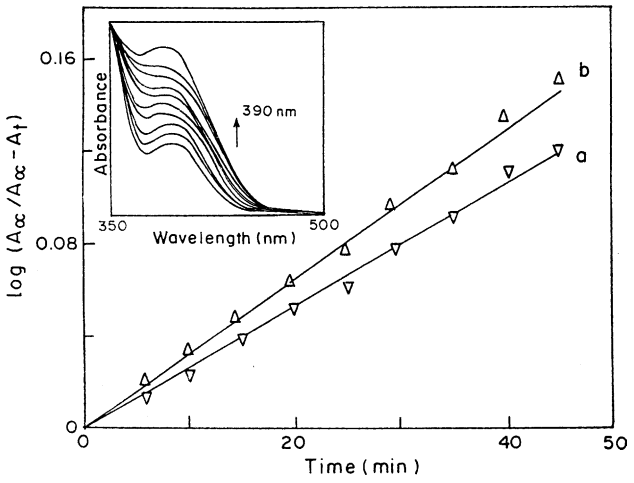

Fig. 5. Catecholase activity of mononuclear copper(II) complexes (a) $[CuL^{2a}](ClO_4)$, (b) $[CuL^{2b}](ClO_4)$.

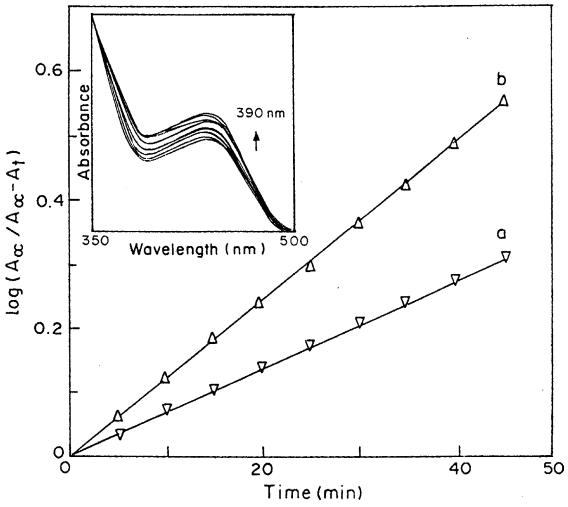

Fig. 6. Catecholase activity of the binuclear copper(II) complexes (a) $[Cu_2L^{2a}(ClO_4)](ClO_4)$, (b) $[Cu_2L^{2b}(ClO_4)](ClO_4)$.

Table 2
Catecholase activity[a] of mono and binuclear copper(II) complexes

Complexes	Rate constant (min^{-1})
$[CuL^{1a}](ClO_4)$	5.06×10^{-3}
$[CuL^{1b}](ClO_4)$	5.84×10^{-3}
$[CuL^{2a}](ClO_4)$	5.53×10^{-3}
$[CuL^{2b}](ClO_4)$	6.67×10^{-3}
$[Cu_2L^{1a}(ClO_4)](ClO_4)$	1.24×10^{-2}
$[Cu_2L^{1b}(ClO_4)](ClO_4)$	2.17×10^{-2}
$[Cu_2L^{2a}(ClO_4)](ClO_4)$	1.56×10^{-2}
$[Cu_2L^{2b}(ClO_4)](ClO_4)$	2.56×10^{-2}

[a] Measured spectrophotometrically in CH_3CN medium. Concentration of the complexes: 1×10^{-3} M, concentration of 3,5-ditertiarybutylcatechol: 1×10^{-1} M.

hence the rate constant values of binuclear complexes are comparatively high. The catalytic activities of both mono and binuclear complexes are found to increase as the macrocyclic ring size increases due to the intrinsic flexibility because of which the metal ion easily gets reduced and binds with the substrate and the same was supported by both spectral and electrochemical studies. The study implies that for mononuclear complexes the observed variation in the value of rate constant is very small when compared to the binuclear complexes. It can be stated that the planarity that is associated with the aromatic ring imparts the lesser catalytic efficiency due to the rigidity of the systems as observed in the case of electrochemical reduction of the complexes.

The observation on the comparison of catalytic activities of the complexes of ligands L^1 and L^2 unambiguously evinces that the complexes of ligand L^2 are accomplished with enhanced catalytic activity. It is indeed noteworthy to say that the increase in flexibility due to increase in the ring size of macrocycle is the possible reason for the observed higher rate constant value of the complexes of ligand L^2.

4. Conclusion

Various mono and binuclear copper(II) complexes of tricompartmental ligands containing aromatic units in the imine nitrogen compartment have been synthesized and spectral, magnetic, electrochemical and catalytic studies were carried out. These studies vividly indicate that a small variation in the ligand framework influences the spectral, magnetic, electrochemical and catalytic properties of the complexes.

Abstract

Two europium and zinc ionic complexes $[Eu_2(Hsal)_8][Zn(phen)_3]\cdot(H_2sal)(H_2O)$ (**1**) and $[Eu_2(TPA)_8][Zn(TPA)(Phen)_2]_2\cdot(H_2O)_2$ (**2**) (where H_2sal = salicylic acid, TPA = α-thiophene carboxylic acid, phen = 1,10-phenanthroline) have been synthesized by the rheological phase reaction method and structurally characterized by IR spectra and X-ray crystallography. The results show that in both complexes the carboxylate groups adopt three modes: bidentate bridging, bidentate chelating and tridentate chelating-bridging. Complex **1** consists of a discrete dinuclear $[Eu_2(Hsal)_8]^{2-}$ anion, $[Zn(phen)_3]^{2+}$ cation, free salicylic acid and a lattice water molecule. Interestingly, in the unit cell there are two types of dimeric $[Eu_2(Hsal)_8]^{2-}$ anions with inversion centers. The hydrogen bonds between the chelating carboxylate groups and the lattice water molecules link the dimeric Eu1 units into 1-D chains. Complex **2** comprises of a dimeric $[Eu_2(TPA)_8]^{2-}$ anion, two $[Zn(TPA)(Phen)_2]^{+}$ cations and two lattice water molecules. One obvious difference from complex **1** is that besides phen ligands, the TPA^- group also coordinates to the Zn^{2+} ion. The C–H···O, O–H···O hydrogen bonds and π–π stacking interactions play an important role in the crystal structure. These two complexes emit strong red light when irradiated by UV light. The emission bands at about 590, 610 nm correspond to the characteristic $^5D_0 \rightarrow {}^7F_1$,$^5D_0 \rightarrow {}^7F_2$ transitions of Eu^{3+} ions. The large intensity ratio of $^5D_0 \rightarrow {}^7F_2/{}^5D_0 \rightarrow {}^7F_1$ indicates the low symmetry of Eu^{3+} ion sites in both complexes, consistent with the results of the structure determination.

1. Introduction

Lanthanide ions, especially Eu^{3+}, Tb^{3+} and Sm^{3+}, are very attractive luminescent centers owing to the high color purity and high luminescence efficiency. However, because of their low ultraviolet absorption ability, the luminescence intensity is very weak. The remedial method is to chelate the lanthanide ions with appropriate ligands, which have broad intense absorption bands and can enhance the emission intensity greatly [1–6]. Aromatic carboxylic acids, which commonly possess a large conjugated π-electron system and multiple coordination modes, are good activators of lanthanide ions luminescence. A large number of lanthanide aromatic carboxylates have been reported [7–10]. They often exhibit fascinating structures and strong luminescence, e.g., the luminescence of the Tb^{3+} ion is enhanced 10^4-fold by dipicolinic acid [7]. Studies have also shown that luminescent lanthanide aromatic carboxylates have potential applications as emitters in electroluminescence (EL) devices [11–13].

In order to further enhance the luminescence intensity of lanthanide ions, new approaches have also been developed. Some investigations have shown that the introduction of an auxiliary ligand or a second metal ion can alter not only the architectures but also the photoluminescence properties [14,15]. Numerous ternary

aromatic carboxylates of europium and terbium have been studied, which usually occur in dimeric forms and display intense luminescence [16–19]. However, they are commonly prepared by conventional solution reaction methods. In this paper, a rheological phase reaction method [20] was used for the synthesis of two europium and zinc ionic complexes, $[Eu_2(Hsal)_8][Zn(phen)_3]\cdot(H_2sal)(H_2O)$ (**1**) and $[Eu_2(TPA)_8][Zn(TPA)(Phen)_2]_2\cdot(H_2O)_2$ (**2**) (where H_2sal = salicylic acid, TPA = α-thiophene carboxylic acid, phen = 1,10-phenanthroline). The crystal structures and luminescence properties of these two complexes are reported here.

2. Experimental

2.1. Materials and methods

$EuCl_3\cdot 5H_2O$ was prepared by dissolving Eu_2O_3 in hydrochloric acid and then drying. All other chemicals were analytical reagent grade and used without further purification. The IR spectra were recorded on a Thermo Nicolet Avatar 360 FT-IR spectrophotometer as KBr pellets. Elemental analyses were carried out with a Perkin–Elmer 240B elemental analyzer. The excitation and emission spectra of the solid sample were measured on a Shimadzu RF-5301PC spectrofluorophotometer from 220 to 750 nm at room temperature.

2.2. Synthesis of complexes

2.2.1. Synthesis of $[Eu_2(Hsal)_8][Zn(phen)_3]\cdot(H_2sal)(H_2O)$ (**1**)

0.08 g (1.0 mmol) ZnO, 0.35 g (1.0 mmol) $EuCl_3\cdot 5H_2O$, 0.70 g (5.0 mmol) H_2sal, 0.39 g (2.0 mmol) phen·H_2O and 1.8 ml distilled water were placed in a closed container to get a rheological body [20]. It was kept at 80 °C for 3 days and then cooled to room temperature slowly. The product was washed with acetone and dried at ambient temperature. Block-shaped light red crystals were obtained (0.36 g, yield 33.3% based on Eu). *Anal*. Calc. for **1**: C, 54.95; H, 3.37; N, 3.88. Found: C, 54.61; H, 3.57; N, 3.69%. 2.2.2. Synthesis of $[Eu_2(TPA)_8][Zn(TPA)(Phen)_2]_2\cdot(H_2O)_2$ (**2**)

0.08 g (1.0 mmol) ZnO, 0.17 g (0.5 mmol) Eu_2O_3, 0.63 g (5.0 mmol) α-thiophene carboxylic acid, 0.39 g (2.0 mmol) phen·H_2O and 2.2 ml distilled water were placed in a closed container to get a rheological body. Reacted at 80 °C for 3 days and then cooled to room temperature slowly, colorless crystals were formed (0.43 g, yield 32.5% based on Eu). *Anal*. Calc. for **2**: C, 47.79; H, 2.70; N, 4.55. Found: C, 47.76; H, 2.66; N, 4.50%. IR (KBr, cm^{-1}): 3061 (w), 1601 (s), 1570 (s), 1518 (s), 1428

2.3. X-ray crystallographic analyses

The diffraction data of complexes **1** and **2** were collected at 291(2) K on a RIGAKU R-AXIS IV imaging plate diffractionmeter with graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). The structures were solved by direct methods and refined by a full-matrix least-squares technique based on F^2 using the SHELXL-97 and SHELXS-97 programs [21]. All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained refinement. A summary of the crystallographic data of complexes **1** and **2** is given in Table 1. The selected bond lengths are listed in Table 2.

3. Results and discussions

3.1. Synthesis

In this paper, two ionic complexes were obtained by the rheological phase reaction method. Since the reaction speed is essentially dictated by the starting materials, an appropriate selection of the latter is key to the successful synthesis of the product. In the experiment, ZnO and $EuCl_3 \cdot 5H_2O$ were used to prepare **1**, while ZnO and Eu_2O_3 were used for **2**. When $EuCl_3 \cdot 5H_2O$ was replaced by Eu_2O_3 in the preparation of **1**, only a polycrystalline powder was obtained. This is probably due to the fact that salicylic acid ($pK_a = 3.00$) is stronger than HTPA ($pK_a = 3.53$), and when two metal oxides were used, the reaction is too fast for the formation of a crystalline product. In contrast, the use of $EuCl_3 \cdot 5H_2O$ lowers the pH value of the reaction system, which can suppress the deprotonation of salicylic acid and weaken the coordination ability of phen since its N atoms are liable to be protonated, so as to decrease the reaction speed.

These two complexes are very stable in air, soluble in methanol, CH_3CN, DMF and DMSO, but almost insoluble in acetone, chloroform and benzene.

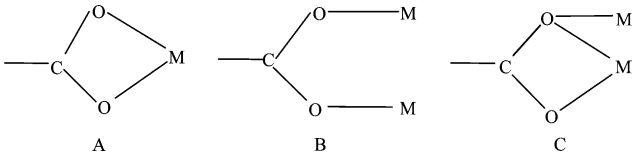
3.2. Infrared spectra

The IR spectra of complexes **1** and **2** both show the characteristic bands of carboxylate and phen ligands (see Section 2). The δ_{C-H} (out-of-plane bending vibration) bands of the phen ligand appear at 850, 726 cm^{-1} for **1** and 856, 719 cm^{-1} for **2**. The stretching vibration band of C=N at 1588 cm^{-1} for the free phen is shifted to 1519 cm^{-1} for these two complexes, indicating that the N atoms coordinate to the metal ions. The asymmetric and symmetric stretching vibration bands of carboxylate groups emerge at 1626, 1462, 1391 cm^{-1} for **1** and 1570, 1428, 1389 cm^{-1} for **2**, suggesting the presence of two or more coordination modes. The vibration bands of the Eu(Zn)–O bond and Zn–N bonds are seen at 534, 456 cm^{-1} in **1** and 509, 419 in **2** [22].

3.3. Crystal structure

X-ray single-crystal analyses indicate that both complexes **1** and **2** are ionic complexes containing

europium and zinc. Interestingly, in complex **1** the harder O donors only bind to Eu atoms and the softer N donors only bind to Zn atoms, while in complex **2** the O donors of TPA^- also coordinate to Zn atoms. This is probably due to the pH difference in the two reaction systems. For complex **1**, the stronger acidity in the reaction system decreases the deprotonation rate of salicylic acid and the Zn^{2+} ion is prone to be coordinated by three phen ligands. However, in the preparation of complex **2**, the reaction rate of Eu_2O_3 may be comparable with that of ZnO, so the two ligands, α-thiophene carboxylic acid and phen, coordinate to Eu and Zn atoms, respectively. Since the molar ratio of Zn:phen in the starting material is only 1:2, the other coordination sites of Zn^{2+} ion are completed by a TPA^- group.



Scheme 1. Coordination modes of carboxylate groups in complexes **1** and **2**.

In complexes **1** and **2**, the carboxylate groups both adopt three coordination modes: bidentate chelating (A), bidentate bridging (B) and tridentate chelating-bridging (C) (as shown in Scheme 1).

3.3.1. Structure of complex *1*

The molecular structure of complex **1** is shown in Fig. 1. It is composed of a discrete dinuclear $[Eu_2(Hsal)_8]^{2-}$ anion, $[Zn(phen)_3]^{2+}$ cation, free salicylic acid and a lattice water molecule. It is worth noting that in a unit cell there are two types of $[Eu_2(Hsal)_8]^{2-}$ anions. Eu1 is in an eight-coordinate environment and Eu2 is in a nine-coordinate one.

The dimeric Eu1 and Eu2 units are both located on inversion centers. Eu1 is coordinated by eight oxygen atoms: four from two chelating salicylate groups and four from bidentate bridging ones. The Eu–O distances range from 2.316(4) to 2.528(4) Å. Two Eu^{3+} ions are linked together by the four bridging salicylate groups with an Eu1···Eu(1A) separation of 4.3385(12) Å.

Eu2 is coordinated by four oxygen atoms from two chelating salicylate groups, two oxygen atoms from two bidentate bridging salicylate groups and three oxygen

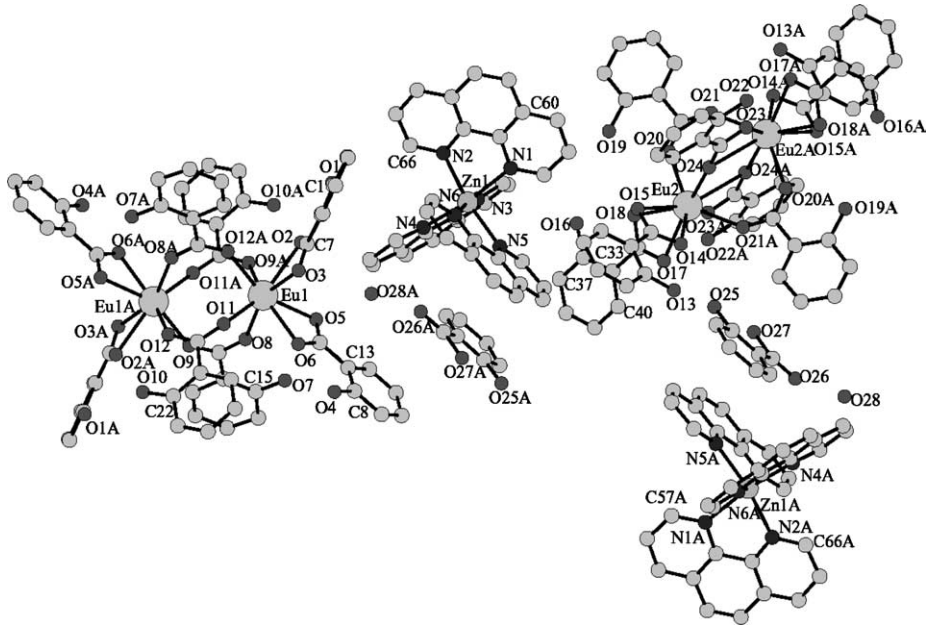


Fig. 1. Molecular structure of complex **1** with atom numbering scheme. Hydrogen atoms are omitted for clarity.

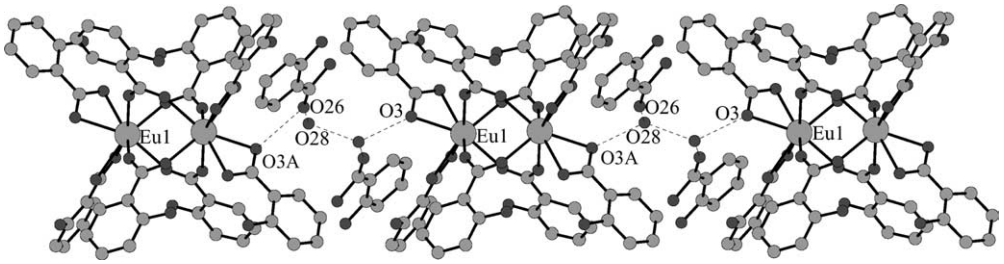

Fig. 2. Fractional structure showing the hydrogen bonds linking the dimeric Eu1 units into a 1-D chain.

atoms from two tridentate chelating-bridging salicylate groups to furnish a ninefold coordination. The Eu–O distances lie in the range from 2.337(5) to 2.544(4) Å, similar to that for Eu1, whereas the bond length of Eu2–O24 (the oxygen atom of the tridentate chelating-bridging salicylate group) is 3.102 Å, much longer than the other Eu2–O bonds and the literature value, which is only 2.549(3) or 2.800(4) Å [16,19]. Two Eu2 ions are connected together by two bidentate bridging and two tridentate chelating-bridging salicylate groups. The Eu2···Eu(2A) distance is 4.14 Å, shorter than Eu1···Eu(1A) owing to the existence of the tridentate chelating-bridging coordination mode.

In the $[Zn(phen)_3]^{2+}$ cation, the Zn atom is in a distorted octahedral geometry, surrounded by six nitrogen atoms from three chelating phen ligands. The Zn–N bonds are slightly different, ranging from 2.137(5) to 2.191(5) Å.

Weak intermolecular hydrogen bonds are formed between the lattice water molecules and the oxygen atoms of chelating salicylate groups [$O28_w\cdots O(3A)_{carboxylate} = 3.07$ Å, $O28_w\cdots O(28A)_w = 3.00$ Å, $O(28A)_w\cdots O3_{carboxylate} = 3.07$ Å]. These hydrogen bonds link the Eu1 units into 1-D chains along the *a*-axis. Further hydrogen bonds also exists between the free salicylic acid and the lattice water molecule ($O26_{salicylic\ acid}\cdots O28_w = 2.76$ Å) (Fig. 2). The $[Zn(phen)_3]^{2+}$ cations lie between these 1-D chains and the discrete dimeric Eu2 anions.

In the crystal, each anion is surrounded by six $[Zn(phen)_3]^{2+}$ cations and simultaneously each cation is surrounded by six $[Eu_2(Hsal)_8]^{2-}$ anions, three dimeric Eu1 units and three Eu2 ones. The hydrogen bonds and

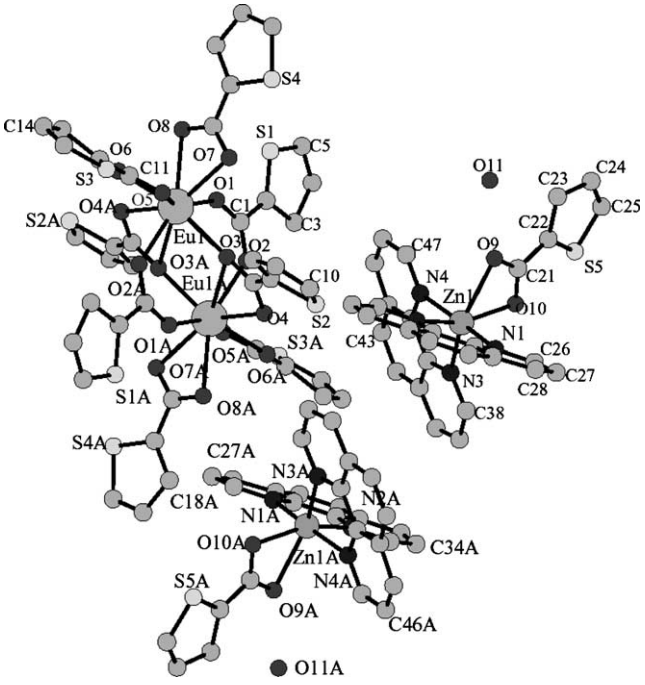

Fig. 3. Molecular structure of complex **2** with atom numbering scheme. Hydrogen atoms are omitted for clarity.

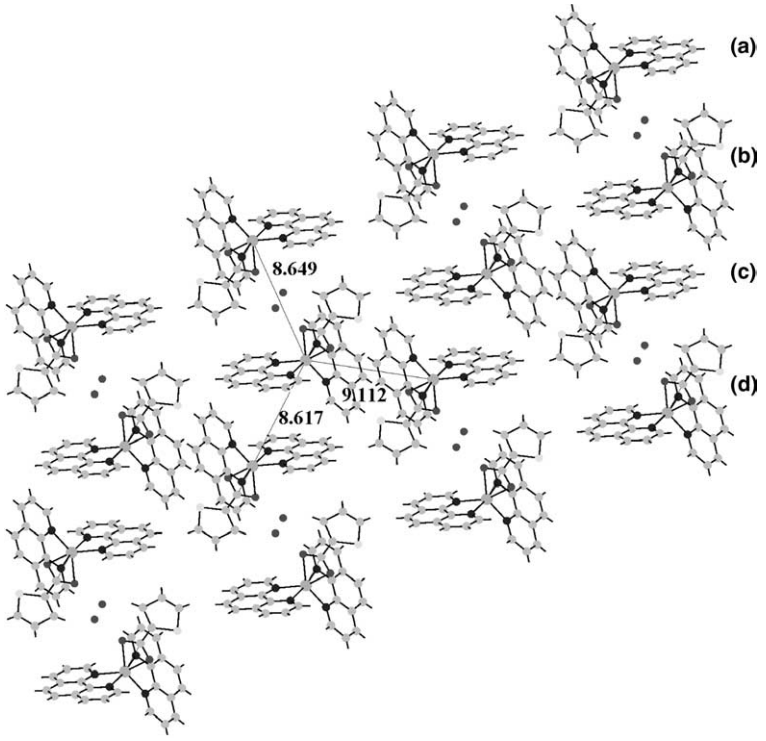

Fig. 4. The arrangment of $[Zn(TPA)(phen)_2]^+$ cations in **2**.

eletrostatic attractions existing among them result in stabilization of the crystal structure.

3.3.2. Structure of complex 2

Complex **2** consists of a discrete dimeric $[Eu_2(TPA)_8]^{2-}$ anion, two $[Zn(TPA)(phen)_2]^+$ cations and two lattice water molecules (Fig. 3).

The dimeric $[Eu_2(TPA)_8]^{2-}$ anion resembles the dimeric Eu2 anion in **1**. Each Eu^{3+} ion is coordinated by four oxygen atoms from two chelating TPA^- groups, two oxygen atoms from two bidentate bridging TPA^- groups and three oxygen atoms from two tridentate chelating-bridging TPA^- groups to complete a ninefold coordination. The Eu–O distances vary from 2.331 to 2.902 Å, similar to the Eu2–O bonds in complex **1**. The Eu–O bonds of the chelating TPA^- groups (2.455–2.637 Å are a little longer than those of the bridging TPA^- groups (2.331–2.442 Å) as expected, except for Eu–O(3A) (2.902 Å).

In the $[Zn(TPA)(phen)_2]^+$ cation, the Zn^{2+} center is six-coordinated by four nitrogen atoms from two chelating phen ligands and two oxygen atoms from a chelating TPA^- group. The Zn–N bonds are in the range from 2.125 to 2.150 Å, much shorter than the Zn–N bonds in complex **1**, which has a larger steric effect than complex **2**. The Zn–O bonds are 2.142 Å (Zn–O9) and 2.348 Å (Zn–O10). The Zn–O10 bond is much longer than Zn–O9 because of hydrogen bond formation between O9 and the lattice water molecule (O9···O11 = 2.645 Å).

In the crystal, the $[Zn(TPA)(phen)_2]^+$ cations are arranged in the manner shown in Fig. 4. The shortest Zn···Zn distances between the layers A, B, C and D are 8.649, 8.617 and 9.112 Å, respectively.

The two neighboring $[Zn(TPA)(phen)_2]^+$ cations separated by 8.649 Å are linked through hydrogen bonds (O9···O11 = 2.645 Å mentioned above and C23–H(23A)···O11 = 2.175 Å), as shown in Fig. 5(a). Two adjacent Zn cations with a separation of 9.112 Å are held together by the π–π stacking interactions existing between the two parallel phen(N3, N4) ligands (Fig. 5(b)). The average distance between the ring C(41A)–C(44A) and the ring C38–C41 is 3.708 Å. Through the hydrogen bonds between TPA^- and phen ligands (C34–H(34A)···O6 = 2.650 Å; C38–H(38A)···O6 = 2.574 Å), two adjacent Zn cations separated by

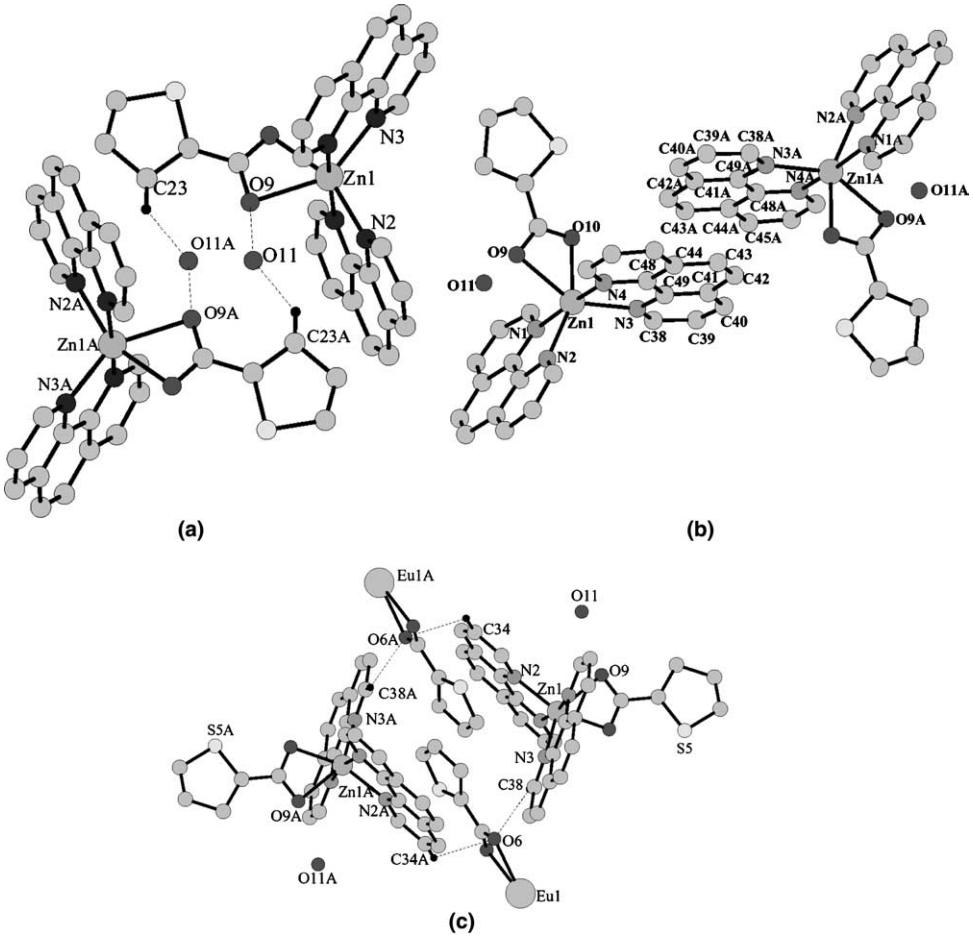

Fig. 5. The interactions linking the Zn cations and the dimeric Eu units in **2**. Hydrogen bonds are represented by the dotted lines and the hydrogen atoms not involved in the hydrogen bonds are omitted for clarity.

8.617 Å are linked (Fig. 5(c)). These hydrogen bonds and the electrostatic attractions between the dimeric Eu anions and Zn cations connect them to form a network.

Notably, the Zn and Eu centers in the ionic compounds **1** and **2** are both discrete, different from heterometallic complexes in which the two metal centers are linked together via bridging groups [23–25].

3.4. Photoluminescence

Under the excitation of UV light, complexes **1** and **2** emit strong red light. The luminescent properties of the solid-state samples at room temperature are shown in Fig. 6.

The broad excitation bands at 280, 335 nm for **1** and 345 nm for **2** are attributed to the $n\pi^*$ or $\pi\pi^*$ states of the aromatic carboxylate groups. The sharp bands at 383, 393, 414, 463, 534 nm are assigned to the Eu^{3+}-centred $^7F_1 \rightarrow {}^5L_7$, $^7F_0 \rightarrow {}^5L_6$, $^7F_1 \rightarrow {}^5D_3$, $^7F_0 \rightarrow {}^5D_2$, $^7F_1 \rightarrow {}^5D_1$ transitions, respectively [26]. One obvious difference between them is that for complex **1**, the excitation bands of the Eu^{3+} ion are much more strong than those of the $Hsal^-$ group, whereas for complex **2** the contrary is true. It indicates a more efficient energy transfer from the TPA^- ligand to the Eu^{3+} ions occurs in **2**.

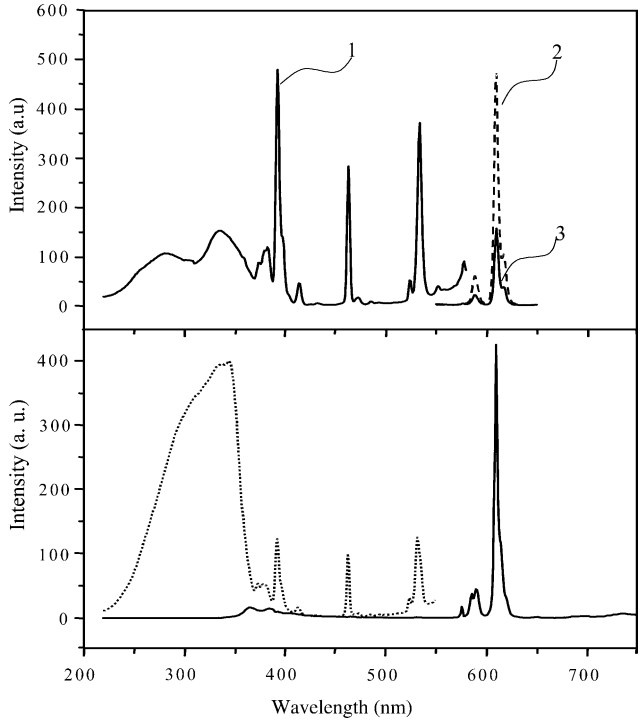

Fig. 6. The excitation and emission spectra of complex **1** (top) and complex **2** (bottom). (top: 1, $\lambda_{em} = 610$ nm; 2, $\lambda_{em} = 393$ nm; 3, $\lambda_{em} = 335$ nm) bottom: left, $\lambda_{em} = 610$ nm; right, $\lambda_{em} = 345$ nm).

The emission bands of **1** and **2** are essentially identical. The peaks at about 590 and 610 nm correspond to the characteristic $^5D_0 \rightarrow {}^7F_1$ and $^5D_0 \rightarrow {}^7F_2$ transitions of Eu^{3+} ions. The large intensity ratios of $^5D_0 \rightarrow {}^7F_2$/$^5D_0 \rightarrow {}^7F_1$ show the low symmetry of Eu^{3+} ion sites in both complexes [27], in agreement with the structure analyses.

It is well known that pure europium salicylate $Eu(Hsal)_3 \cdot H_2O$ has no luminescence (both salicylate and Eu^{3+} ion) under the excitation of UV light, possibly owing to the energy mismatch between the lowest triplet state of the salicylate group and the first excited state of the Eu^{3+} ion [28]. However, complex **1** emits the characteristic luminescence of Eu^{3+} ion when excited by UV light although the phen ligands are not directly coordinated to the Eu^{3+} ion. Furthermore, in the experiment no excitation and emission bands of phen ligands were observed. The specific luminescence mechanism is not clear now and further studies are underway.

4. Supplementary materials

X-ray crystallographic files in CIF format for complexes **1** and **2** have been deposited at the Cambridge Crystallographic Data Center, CCDC No. 210827 for **1**, 214067 for complex **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 IEZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Dioxomolybdenum(VI) thionates were readily isolated from the reactions of MoO_2Cl_2 with thallium salts of representative thiones [2-mercaptopyridine (Py-SH), 2-mercaptopyrimidine (Pym-SH), 2-mercapto-4-methylpyrimidine (MePym-SH), 2-mercaptobenzothiazol (BzTz-SH), 2-mercaptobenzoxazol (BzOx-SH) and 2-mercaptonicotinic acid methyl ester (MeNic-SH)]. They behave as Lewis acids and addition compounds with pyridines could be readily prepared. The molecular structure of dioxobis(pyridine-2-thiolate-*N*,*S*)molybdenum(VI), $MoO_2(Py\text{-}S)_2$, has been established by X-ray diffraction analysis. It displays catalytic activity in oxotransfer reactions from dimethyl sulfoxide (DMSO) to phosphines and phosphites in mild conditions.

Keywords: Dioxomolybdenum(VI) thionates; Oxotransfer catalysts

1. Introduction

Heterocyclic thiones, characterized by thione–thiol tautomerism, have a coordination chemistry that makes extensive use of the exocyclic thione sulfur atom [1–5]. Thiones and thionates, the latter readily obtained by deprotonating the parent thiones, are electron-rich and polyfunctional ligands that lie on the borderline of stability between the +5 and +6 oxidation states of molybdenum. Thus, although a number of derivatives of thiones with molybdenum in oxidation states ranging from +2 to +5 have been prepared and characterized [6–13], there are only a few reports on Mo(VI) complexes. Zubieta and his co-workers [14,15] prepared and structurally characterized the Mo(VI) species $MoCl_2(2\text{-}SC_5H_3N\text{-}3\text{-}SiMe_3)_2(NNMePh)$ and $Mo(NNMePh)_2(2\text{-}SC_5H_3N\text{-}3\text{-}SiMe_3)_2$ and soon after a couple of dioxomolybdenum(VI) complexes, those derived from Py-SH and Pym-SH, were reported [16]. More recently a series of complexes with esters of 2-mercaptonicotinic acid has been isolated in low yield (below 15%) and structurally characterized [17].

As part of an ongoing study on oxomolybdenum complexes we have undertaken the preparation of dioxomolybdenum(VI) derivatives of a number of common thiones. To this purpose, we tested the behavior of sodium molybdate and $MoO_2(acac)_2$ with the thiones; and that of MoO_2Cl_2 as well as that of the readily available $MoO_2Cl_2(DMF)_2$ [18,19] with thallium thionates. Previously, we found that a number of addition compounds of MoO_2Cl_2 and MoO_2Br_2 with O-donor ligands oxidize a variety of thiols in mild conditions [20–22]. In this paper, we report the synthesis of representative dioxomolybdenum(VI) thionates along with the crystal structure of $MoO_2(Py\text{-}S)_2$.

2. Experimental

2.1. General procedures and measurements

Unless otherwise specified all operations were carried out in air. Diethyl ether and tetrahydrofuran (THF) were distilled over Na-benzophenone ketyl prior to use.

Acetone was distilled immediately prior to use from $KMnO_4$. Acetonitrile was purified by distillation from $KMnO_4$ and then from CaH_2. 2-Mercaptonicotinic acid methyl ester was prepared by reacting 2-mercaptonicotinic acid with methanol and sulfuric acid and purified by crystallization. Thallium thionates were prepared by adding solutions of the thiones in ethanol (methanol for 2-mercaptonicotinic acid methyl ester) over aqueous TlOH; the precipitates were washed (water and then acetone) and dried under vacuum. $MoO_2(acac)_2$ was prepared as previously reported [23]. All other reagents were commercial products and were used without further purification. Elemental analyses (C, H, N, S) were performed on a LECO CHNS-932 analyzer (Module VTF-900 for O). Molybdenum was eventually determined by titration with lead(II) nitrate [24]. IR spectra (KBr dispersion, 4000–400 cm^{-1} range) were recorded on a Nicolet Impact 410 (Software Omnic for Windows) spectrometer. NMR spectra were recorded on a Varian Unity Inova-400 spectrometer (400 MHz for ^1H and 161.92 MHz for ^{31}P) at 20 °C. Chemical shifts are relative to TMS (^1H), or external 85% H_3PO_4 (^{31}P), with downfield values reported as positive. Coupling constants J are given in Hertz.

2.2. Preparation of thionates

2.2.1. Preparation of MoO_2(L-N,S)$_2$ (L-N,S = Py-S, Pym-S, MePym-S, MeNic-S)

A mixture of 0.100 g (0.5 mmol) of MoO_2Cl_2, 1 mmol of thallium thionate and 25 ml of acetonitrile was stirred for 2 h at r.t. The solid was filtered off and the filtrate was concentrated to approximately 5 ml. Then 20 ml of diethyl ether was added and the precipitate formed was collected by filtration, washed with diethyl ether (3 × 2 ml) and dried under vacuum.

MoO_2(Py-S)$_2$: Yield 0.156 g (89.6%). IR(cm^{-1}): ν(Mo=O) 897(s), 928(s). ^1H NMR(acetone-d_6): 8.52 ppm (dq, $^3J_{H-H} = 4.5$ Hz, 2H, for protons on C_6); 7.83 ppm (dt, $^3J_{H-H} = 7.5$ Hz, $^4J_{H-H} = 1.8$ Hz, 2H, for protons on C_4); 7.37 ppm (dd, $^3J_{H-H} = 7.5$ Hz, $^4J_{H-H} = 1.5$ Hz, 2H, for protons on C_3); 7.19 ppm (ddd, $^3J_{H-H} = 7.5$ Hz, $^3J_{H-H} = 4.5$ Hz, $^4J_{H-H} = 1.3$ Hz, 2H, for protons on C_5). *Anal.* Calc. for $C_{10}H_8MoN_2O_2S_2$: C, 34.49; H, 2.32; N, 8.04; S, 18.41. Found: C, 34.61; H, 2.22; N, 8.11; S, 18.10%.

MoO_2(Pym-S)$_2$: Yield 0.157 g (89.7%). IR(cm^{-1}): ν(Mo=O) 901(s), 934(s). ^1H NMR (acetone-d_6): 8.78 ppm (d, $^3J_{H-H} = 5$ Hz, 4H, for protons on C_4 and C_6); 7.30 ppm (t, $^3J_{H-H} = 5$ Hz, 2H, for protons on C_5). *Anal.* Calc. for $C_8H_6MoN_4O_2S_2$: C, 27.44; H, 1.73; N, 16.00; S, 18.31. Found: C, 27.20; H, 1.68; N, 15.72; S, 18.02%.

MoO_2(MePym-S)$_2$: Yield 0.163 g (86.2%). IR(cm^{-1}): ν(Mo=O) 911(s), 937(s). ^1H NMR (acetone-d_6): 8.56 ppm (d, $^3J_{H-H} = 5$ Hz, 2H, for protons on C_6); 7.20 ppm (d, $^3J_{H-H} = 5$ Hz, 2H, for protons on C_5); 1.27 ppm (s, 6H, CH_3). *Anal.* Calc. for $C_{10}H_{10}MoN_4O_2S_2$: C, 31.75; H, 2.66; N, 14.81; S, 16.95. Found: C, 31.50; H, 2.85; N, 14.58; S, 16.66%.

MoO_2(MeNic-S)$_2$: Yield 0.198 g (85.3%). IR(cm^{-1}): ν(Mo=O) 903(s), 932(s). ^1H NMR (acetone-d_6): 8.73 ppm (dd, $^3J_{H-H} = 5.3$ Hz, $^4J_{H-H} = 1.7$ Hz, 2H, for protons on C_6); 7.33 ppm (dd, $^3J_{H-H} = 8.0$ Hz, $^3J_{H-H} = 5.3$ Hz, 2H, for protons on C_5); 8.42 ppm (dd, $^3J_{H-H} = 8.0$ Hz, $^4J_{H-H} = 1.7$ Hz, 2H, for protons on C_4); 3.92 ppm (s, 6H, CH_3). *Anal.* Calc. for $C_{14}H_{12}MoN_2O_6S_2$: C, 36.22; H, 2.61; N, 6.06; S, 13.81. Found: C, 34.53; H, 2.69; N, 5.56; S, 13.20%.

2.2.2. Preparation of MoO_2(L-N,S)$_2$ (L-N,S = BzTz-S, BzOx-S)

A mixture of 0.100 g (0.5 mmol) of MoO_2Cl_2, 1 mmol of thallium thionate and 25 ml of THF was stirred for 2 h at r.t. The solid was filtered off and the filtrate was concentrated to approximately 5 ml. Then 20 ml of diethyl ether was added and the precipitate was collected by filtration, washed with diethyl ether (3 × 2 ml) and dried under vacuum. All operations were carried out under dry nitrogen.

MoO_2(BzTz-S)$_2$: Yield 0.195 g (84.7%). ν(Mo=O) 903(s), 932(s). *Anal.* Calc. for $C_{14}H_8MoN_2O_2S_4$: C, 36.52; H, 1.75; N, 6.08; S, 27.85. Found: C, 35.96; H, 1.42; N, 5.74; S, 26.40%.

MoO_2(BzOx-S)$_2$: Yield 0.186 g (86.9%). ν(Mo=O) 909(s), 952(s). *Anal.* Calc. for $C_{14}H_8MoN_2O_4S_2$: C, 39.26; H, 1.88; N, 6.54; S, 14.97. Found: C, 38.41; H, 1.35; N, 6.17; S, 13.95%.

2.2.3. Preparation of Mo_2O_3(L-N,S)$_4$ (L-N,S = Py-S, Pym-S, MePym-S, MeNic-S)

To a solution of 0.3 mmol of dioxomolybdenum(VI) thionate in 10 ml of acetonitrile, 0.2 mmol of triphenyl phosphine (PPh_3) was added. The mixture was stirred under nitrogen for 2 h and then 20 ml of diethyl ether was added. The precipitate was filtered, washed with diethyl ether (3 × 2 ml) and dried under vacuum.

Mo_2O_3(Py-S)$_4$: Yield 0.087 g (85.2%). IR(cm^{-1}): ν(Mo=O) 945(s). ^1H NMR (acetone-d_6): 8.41 ppm (dq, $^3J_{H-H} = 4.5$ Hz, 4H, for protons on C_6); 7.82 ppm (dt, $^3J_{H-H} = 7.5$ Hz, $^4J_{H-H} = 1.8$ Hz, 4H, for protons on C_4); 7.37 ppm (dd, $^3J_{H-H} = 7.5$ Hz, $^4J_{H-H} = 1.5$ Hz, 4H, for protons on C_3); 7.19 ppm (ddd, $^3J_{H-H} = 7.5$ Hz, $^3J_{H-H} = 4.5$ Hz, $^4J_{H-H} = 1.3$ Hz, 4H, for protons on C_5). *Anal.* Calc. for $C_{20}H_{16}Mo_2N_4O_3S_4$: C, 35.30; H, 2.37; N, 8.23; S, 18.85. Found: C, 34.96: H, 2.51; N, 8,21; S, 18.63%.

Mo_2O_3(Pym-S)$_4$: Yield 0.078 g (76.0%). IR(cm^{-1}): ν(Mo=O) 958(s). ^1H NMR (acetone-d_6): 8.77 ppm (d, $^3J_{H-H} = 5$ Hz, 8H, for protons on C_4 and C_6); 7.35 ppm (t, $^3J_{H-H} = 5$ Hz, 4H, for protons on C_5). *Anal.* Calc. for $C_{16}H_{12}Mo_2N_8O_3S_4$: C, 28.08; H, 1.77; N, 16.74; S, 18.74. Found: C, 27.74, H, 2.12; N, 15.98; S, 18.24%.

Mo_2O_3(MePym-S)$_4$: Yield 0.082 g (73.8%). IR(cm^{-1}): ν(Mo=O) 950(s). ^{1}H NMR (acetone-d$_6$): 8.45 ppm (d, $^3J_{H-H} = 5$ Hz, 4H, for protons on C_6); 7.15 ppm (d, $^3J_{H-H} = 5$ Hz, 4H, for protons on C_5); 1.27 ppm (s, 12H, CH_3). *Anal*. Calc. for $C_{20}H_{20}Mo_2N_8O_3S_4$: C, 32.44; H, 2.72; N, 15.13; S, 17.32. Found: C, 31.85; H, 3.10; N, 14.61; S, 16.80%.

Mo_2O_3(MeNic-S)$_4$: Yield 0.115 g (84.0%). IR(cm^{-1}): ν(Mo=O) 956(s). ^{1}H NMR (acetone-d$_6$): 8.36 ppm (dd, $^3J_{H-H} = 5.2$ Hz, $^4J_{H-H} = 1.7$ Hz, 4H, for protons on C_6); 7.33 ppm (dd, $^3J_{H-H} = 8.0$ Hz, $^3J_{H-H} = 5.2$ Hz, 4H, for protons on C_5); 8.42 ppm (dd, $^3J_{H-H} = 8.0$ Hz, $^4J_{H-H} = 1.7$ Hz, 4H, for protons on C_4); 3.92 ppm (s, 12H, CH_3). *Anal*. Calc. for $C_{28}H_{24}Mo_2N_4O_{11}S_4$: C, 36.85; H, 2.65; N, 6.14; S, 14.05. Found: C, 36.96; H, 2.99; N, 6.08; S, 14.03%.

2.2.4. Preparation of MoO_2(Py-S)$_2L_2$ (L = pyridine (Py), 4-methylpyridine (MePy), 1/2 2,2′-bipyridine (Bipy))

To a solution of 0.100 g (0.29 mmol) of MoO_2(Py-S)$_2$ in 10 ml of acetonitrile 1 mmol of Py or MePy, or 0.5 mmol of Bipy, dissolved in 2 ml of acetonitrile, was added. After stirring the mixture for 15 min the precipitate was filtered, washed with acetonitrile (3 × 2 ml) and dried under vacuum.

MoO_2(Py-S)$_2$Py$_2$: Yield 0.128 g (84.3%). IR(cm^{-1}): ν(Mo=O) 908(s), 941(s). ^{1}H NMR (DMSO-d$_6$): 8.58 ppm (dt, $^3J_{H-H} = 4.5$ Hz, $^4J_{H-H} = 1.5$ Hz, 6H, for Py protons on C_2 and C_6 and thionate protons on C_6); 7.86 ppm (tt, $^3J_{H-H} = 7.6$ Hz, $^4J_{H-H} = 1.5$ Hz, 4H, for Py protons on C_4 and and thionate protons on C_4); 7.44 ppm (ddd, $^3J_{H-H} = 7.6$ Hz, $^3J_{H-H} = 7.5$ Hz, $^4J_{H-H} = 1.5$ Hz, 8H, for Py protons on C_3 and C_5 and thionate protons on C_3 and C_5). *Anal*. Calc. for $C_{20}H_{18}MoN_4O_2S_2$: C, 47.43; H, 3.58; N, 11.06; S, 12.66. Found: C, 48.01; H, 3.23; N, 10.21; S, 12.86%.

MoO_2(Py-S)$_2$(MePy)$_2$: Yield 0.131 g (81.7%). 2.3. Crystal-structure determinations

Suitable single crystals were grown at r.t. by diffusion of diethyl ether on acetone solutions of the complex in a dry atmosphere. Crystal data for MoO_2(Py-S)$_2$: monoclinic, $P2_1/c$, $a = 6.8605(4)$ Å, $b = 15.2004(9)$ Å, $c = 12.1751(8)$ Å, $\alpha = \gamma = 90°$, $\beta = 98.491(1)°$, $V = 1255.73(13)^3$ Å^3, $Z = 4$, $R = 0.0246$, $R_w = 0.0636$.

Crystals of MoO_2(Py-S)$_2$ (block, yellow, dimensions $0.50 \times 0.15 \times 0.15$ mm) were used for the structure determination. X-ray data were collected using a Bruker SMART CCD area detector single-crystal diffractometer with graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) by the $\phi - \omega$ scan method. 2171 Frames of intensity data were collected. The first 50 frames were recollected at the end of data collection to monitor for decay. The crystal used for the diffraction study showed little decomposition during data collection (0.4%). The integration processes yield a total 7404 reflections, of which 2476 were independent [$R_{int} = 0.0262$]. Absorption corrections were applied using SADABS [25] program (maximum and minimum transmission coefficients, 1.000 and 0.6458) for MoO_2(Py-S)$_2$. The structure was solved using the Bruker SHELXTL-PC [26] software by direct methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were included in calculated positions and refined in the riding mode. For MoO_2(Py-S)$_2$ convergence was reached at a final $R_1 = 0.0246$ [for $I > 2\sigma(I)$], $wR_2 = 0.0661$ [for all data], 186 parameters, 0 restraints, with allowance for the thermal anisotropy for all non-hydrogen atoms. The weighting scheme employed was $w = [\sum^2(F_o^2 + (0.112P)^2 + 0.1345P]$ and $P = (|F_o|^2 + 2|F_c|^2)/3$. Residual electron densities extremes were 0.301 and −0.559 e Å^{-3} and the goodness-of-fit on F^2 was 1.073 for all observed reflections. Crystal data and details on the data collection and refinement are given in the supplementary material.

2.4. Catalytic activity

The measurement of the catalytic activity of MoO_2(Py-S)$_2$ in the oxidation of PPh_3 with DMSO was followed by ^{31}P NMR spectroscopy as previously reported [27].

3. Results and discussion

3.1. Synthesis and characterization of dioxomolybdenum(VI) thionates

It is well known that a variety of dioxomolybdenum(VI) chelatocomplexes – such as oxinates, diketonates and dialkyl dithiocarbamates – are readily isolated from aqueous media by treating acidic solutions of molybdates with the corresponding ligands or their soluble salts [28]. So we tested the reactions of hydrochloric solutions of sodium molybdate with solutions of the thiones in the acid. In general the reactions are immediate at r.t. as evidenced by changes in the coloration of the resulting solutions and/or formation of precipitates. The analytical data (C, H, N, S) for the products were not in agreement with those expected for dioxomolybdenum(VI) thionates. Also, the characteristic couple of bands for dioxomolybdenum(VI) species, around 900 cm^{-1}, was absent in the IR spectra of the products. In view that the preparation of compounds such as dialkyl dithiocarbamates by this procedure require a fine control of pH to avoid redox processes leading to formation of dinuclear oxomolybdenum(V) complexes [29], we examined these reactions in a wide range of conditions (pH, temperature and concentration). Despite our efforts, we have been unable to establish the conditions, if any, to obtain dioxomolybdenum(VI) thionates as primary products.

Since the reported dioxomolybdenum(VI) thionates [16,17] were prepared by reacting MoO_2(acac)$_2$ with the thiones we also attempted to extend this procedure to the synthesis of other related thionates. To this respect it should be noted that the complexes derived from the esters of mercaptonicotinic acid were prepared in warm alcohols with yields below 15%, and that important amounts of both oxomolybdenum(V) thionates and disulphides were simultaneously produced. To minimize redox processes we conducted the reactions in acetone at r.t. Under these conditions acetone thioketals did not form and after 48 h stirring a significant amount of solid separated from the solutions. Analytical data and IR spectra for these solids were consistent with those expected for dinuclear oxomolybdenum(V) thionates, such as the prototypical Mo_2O_3(Py-S)$_4$ [6]. The mother liquors from which the solids separated were treated with diethyl ether and the precipitates formed were analyzed (C, H, N, S and IR spectroscopy). The results were consistent with those expected for mixtures of dioxomolybdenum(VI) thionates and the corresponding disulfides. Thus, the behavior of these thiones towards

$MoO_2(acac)_2$ is closely related to that of the esters of 2-mercaptonicotinic acid previously reported [17].

The air-stable, readily available $MoO_2Cl_2(DMF)_2$ [19] reacted with thallium thionates at r.t. in acetone or acetonitrile. The soluble products of the reactions showed characteristic patterns for new dioxomolybdenum(VI) compounds in the IR spectra. However, unsatisfactory analytical results were obtained assuming they were the foreseen thionates. We also found evidence of DMF in some of the products. For example, the ^1H NMR spectrum of the product derived from 2-thiolpyridine in acetone-d_6 showed, in addition to the signals for the thionate ligand, three singlets at 3.07, 3.14 and 8.25 ppm, close to those of DMF in the parent $MoO_2Cl_2(DMF)_2$. In general the composition of the products is in agreement with the formulation $MoO_2(thionate)_2(DMF)_x$ ($x < 2$). It should be noted that we did not find evidences for redox processes under these conditions.

These results suggest that metathesis involving dioxomolybdenum(VI) halides and thionates in aprotic media may be a convenient way to prepare the corresponding dioxomolybdenum(VI) thionates, but also that the reactions should be conducted in low coordinating solvents to allow coordination of the thionate ligands in a N–S bidentate manner. According to this assumption, when we treated MoO_2Cl_2 with thallium thionates in solvents such as acetonitrile, acetone or THF at r.t. we were able to obtain the expected dioxomolybdenum(VI) thionates in good yield without evidences of competitive redox reactions.

All compounds are yellow-brown. To this respect it should be noted that the purple color associated to the dioxomolybdenum(VI) thionates previously reported [16,17] is very probably due to contamination with dinuclear oxomolybdenum(V) species. Indeed, the products we obtained by reaction of $MoO_2(acac)_2$ with the thiones, while having essentially the same IR spectra and in occasions the same elemental composition than those prepared from MoO_2Cl_2 and thallium thionates, are considerable darker.

A significant difference toward moisture could be appreciated among the dioxomolybdenum(VI) thionates. Those having the nitrogen atom(s) into a six-membered ring, MoO_2(L-*N*,*S*)$_2$ (L-*N*,*S* = Py-S, Pym-S, MePym-S, MeNic-S), are considerably more stable than those having it into a five-membered ring, MoO_2(L-*N*,*S*)$_2$ (L-*N*,*S* = BzTz-S, BzOx-S). The former could be prepared and handled in air without special precautions while the latter required the use of a dry atmosphere, especially during the preparation.

The compounds are insoluble in hexane and diethyl ether; moderately soluble in THF, acetone and acetonitrile, solvents from which they could be crystallized; and very soluble in DMF and DMSO, solvents from which they could not be recovered. They have a low thermal stability and decompose before melting. However, they can be stored for weeks at r.t. in the dark and in a dry atmosphere without noticeable decomposition.

Dioxomolybdenum(VI) thionates react with common organophosphines and phosphites at r.t. leading to purple, sometimes green solutions. However, only the dinuclear oxomolybdenum(V) complexes derived from the thiones having the nitrogen atom(s) into a six-membered ring, Mo_2O_3(L-*N*,*S*)$_4$ (L-*N*,*S* = Py-S, Pym-S, MePym-S, MeNic-S), could be isolated.

The results obtained from the reactions of $MoO_2Cl_2(DMF)_2$ with thallium thionates suggest that the thionate ligands may also behave as monodentate. So we tested the behavior of two representative thionates, $MoO_2(Py\text{-}S)_2$ and $MoO_2(BzTz\text{-}S)_2$, toward a variety of N- and O-donor ligands. As a result we could isolate addition compounds with Py, MePy and Bipy. Although at present we have been unable to obtain crystals for X-ray structural characterization of these compounds we believe that the strained chelating thionate ligand, in the presence of strong bases, becomes monodentate S-coordinated. These addition compounds are noticeably less soluble in common organic solvents, and less intense colored (from white to pale yellow) than the parent thionates.

The IR spectra of dioxomolybdenum(VI) thionates are characterized by two strong bands in the region 880–950 cm^{-1} which indicates that, as usual for dioxomolybdenum(VI) species, all of them contain the *cis*-MoO_2 moiety [30]. We find it difficult to establish correlations between the position of these bands and the nature of the ligands. Thus, from the fact that pyridines coordinate to molybdenum, presumably displacing the coordinated nitrogen atoms in MoO_2(L-*N*,*S*)$_2$, we could expect lower values for ν(Mo=O) in the addition compounds than in the parent thionates (the π-donation from the oxo ligands to molybdenum should be influenced by the electronic density on the metal). However, this is only applicable to adducts of Bipy.

No special features are observed in the ^1H NMR spectra of the complexes. In the addition compounds with pyridine and its derivatives the signals characteristic for the free ligands are shifted, as usual, to lower fields upon coordination, though competition of DMSO-d_6 with the neutral ligands for the coordination sphere of molybdenum could be appreciated.

3.2. Molecular structure

Based on the stoichiometry and structure for similar complexes it is probable that all compounds be closely related. The molecular structure for $MoO_2(Py\text{-}S)_2$ was determined from single-crystal X-ray diffraction analysis. A view of $MoO_2(Py\text{-}S)_2$ is shown in Fig. 1. Selected bond lengths and angles are listed in Table 1.

The molybdenum is coordinated in a pseudo-octahedral fashion by two *cis* oxo functions and two che-

O(1)–Mo(1)–S(1)	93.93(7)	S(1)–Mo(1)–S(2)	144.84(3)
O(2)–Mo(1)–S(1)	106.66(7)		

lating Py–S ligands. Distortions from the ideal octahedral geometry (see Table 1) mainly arise from the disparate donor atom set and the restricted bite of the Py–S ligands, which subtend angles at the molybdenum center of approximately 65°. The Py–S ligands are arranged so that the two sulfur atoms are approximately *trans* to each other [S–Mo–S 144.84(3)°] compelling the nitrogen atoms to occupy approximate *cis*-positions [N–Mo–N 77.39(7)°]. The two equivalent Mo=O bond distances, and the *cis*-MoO_2 angle, are within the range usually found in dioxomolybdenum(VI) compounds (1.65–1.75 Å and 95°–110°, respectively) [31]. The two Mo–S bond distances are not equivalent and the same is applicable to the Mo–N distances. However, an intraligand compensation of distances can be perceived so that the shortest M–N and the largest M–S distances occur in the same ligand. The cause of the disparity in the mode of coordination of the Py–S ligands can be traced, more than to the *trans* influence of the oxo ligands (both N-donor atoms occupy positions *trans* to an oxo function with identical O–Mo–N angles), to packing forces. As could be expected, all distances and angles are in the range of those reported for dioxomolybdenum(VI) complexes with the esters of 2-mercaptonicotinic acid [17].

3.3. Catalytic tests in oxotransfer reactions

The behavior of dioxomolybdenum(VI) thionates toward phosphines and phosphites is indicative of oxotransfer processes from the dioxomolybdenum center to

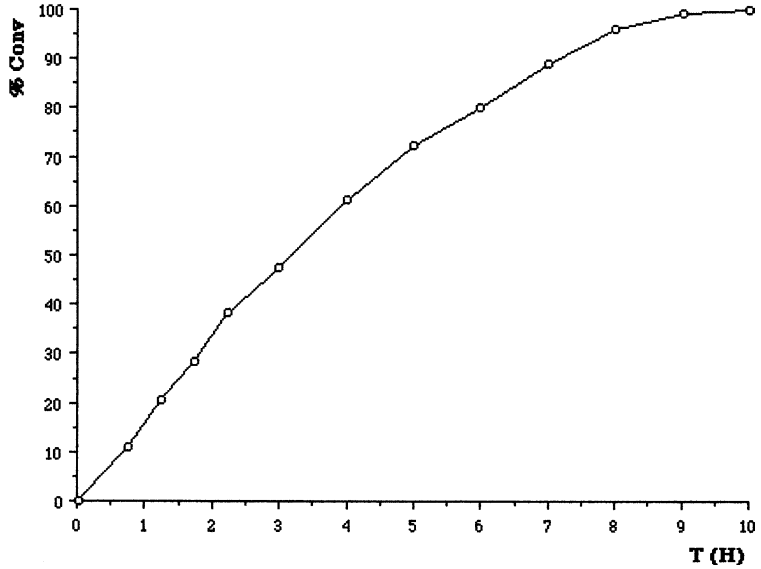

Fig. 2. Oxidation of PPh_3 to $OPPh_3$ by DMSO-d_6 at 60 °C as a function of time for [Mo] = 0.02 mol dm^{-3} and $[PPh_3]_0/[Mo] = 20$.

the P-oxoaceptor. Evolution of the foul-smelling dimethyl sulphide was detected when DMSO was added to the resulting mixtures oxoaceptor-MoO_2(L-*N*,*S*)$_2$, suggesting the potential of the thionatocomplexes to work as oxotransfer catalysts from sulfoxides to phosphorus(III) compounds. In the vicinity of r.t. the catalytic activity of MoO_2(Py-S)$_2$ for the conversion of PPh_3 into $OPPh_3$ by DMSO is very low, presumably due to the stability of the dinuclear species Mo_2O_3(Py-S)$_4$. However the activity dramatically increases with the temperature. Thus, while only 10% conversion was produced after 24 h at 20 °C, complete oxidation to $OPPh_3$ was observed in 10 h at 60 °C (see Fig. 2).

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 213716. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: + 44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The synthetic details, characterization data and single crystal X-ray structural analyses of $[Zn(dpa)(N_3)_2]$ (**1**) and $[Zn(dpa)(N_3)(NO_3)]_2$ (**2**) (dpa = 2,2′-dipyridylamine) are described. Structural study reveals that the zinc(II) centre in **1** is in a pseudotetrahedral ZnN_4 environment ligated by two terminal azide N atoms and two pyridine N atoms of the chelator. The coordination polyhedron around each metal ion in dinuclear **2** is best described as a ZnN_4O_2 distorted octahedron linked by two end-on azido bridges. The mononuclear units in **1** are engaged in bifurcated intermolecular hydrogen bonding (N–H...N) between amine N of dpa and coordinated N of azide along with aromatic π–π stacking leading to a 2D sheet. In **2**, the dinuclear units participate in intermolecular N–H...O hydrogen bonding between amine N of dpa and bound O of bidentate nitrate in combination with π–π interactions resulting to a 3D supramolecular continuum. **1** and **2** display high energy intraligand $^1(\pi–\pi^*)$ fluorescence and intraligand $^3(\pi–\pi^*)$ phosphorescence in glassy solutions (DMF at 77 K). A band (372 nm) observed for both **1** and **2** in their solid-state emission spectra is an excimeric emission arising due to aromatic π–π interaction. The role of dpa, a tailored diimine (–N=C–NH–C=N–) in **1** and **2** is discussed towards functionalisation on crystal engineering and luminescence behaviour.

1. Introduction

The development of supramolecular architectures [1–4] of inorganic organic hybrid molecules with various shapes and sizes [5] formed through control and manipulation of weak interaction [6,7] via non-covalent forces is an exciting area of research that has implications for the rational design of functional materials [8–17]. The fascinating structures of these compounds, coupled with their specific functionality, have made them highly promising to be used as catalysts [8], electrical conducting materials [9,10], molecular magnetic materials [11,12], non-linear optical materials [13,14], liquid crystals (mesogens) [15], sensor materials [16] and molecular recognitions [17]. Self-assembly [18] of suitable molecular components is an efficient way for facile tuning of structural and electronic functions on materials research [8–17] and in the interpretation of electron/energy transport in the bio-active molecules [19] as well. Exploiting the veracity of coordination geometry around metal centres, diverse network topologies can be accessed with the use of ligand building blocks. The purpose is to tailor the composition, structure and function of materials, which may lead to new properties for well-known standard materials and hence to new applications. We are interested in this approach for the construction of metallo-organic supramolecule through variation of ligand backbone and metal ion coordination environment. 2,2′-Dipyridylamine (dpa), a

doi:10.1016/j.poly.2003.10.012

tailored diimine (–N=C–NH–C=N–) is important in this regard because of its ability to form hydrogen bonded network through active amine (–NH–) hydrogen [20–23] and to luminescence through π–π^* transitions [24]. Zinc is well suited [25–27] as its d^{10} configuration permitting a wide variety of symmetries and coordination numbers and it has drawn special attention for its importance in bioinorganic chemistry [28,29]. Azide is a versatile [30–32] ligand and may bind to metal ion through terminal or bridges with end-on or end-to-end motif. Report on blue photoluminescence [26,27] of some zinc(II) complexes of dpa by Che et al. has prompted us to develop new luminous materials with polymeric supramolecular structures. Successfully we have synthesized and X-ray crystallographically characterized one mononuclear [Zn(dpa)$(N_3)_2$] (**1**) and one dinuclear [Zn(dpa)$(N_3)(NO_3)]_2$ (**2**) complexes. **1** and **2** show self-assembled superstructures in solid state via cooperative hydrogen bonds and aromatic π–π interactions [33]. In this paper an emphasis has been made to show how use of such non-covalent forces may be effectively harnessed to synthesize non-molecular solids of varied architectures. The individual zero-dimensional (0D) unit in **1** is engaged in N–H. . .N hydrogen bonding resulting 1D chains, which thereby yield a sheet-like supramolecular architecture via π–π interactions. In **2**, a two-dimensional (2D) sheet is the result through N–H. . .O hydrogen bonds followed by π–π stackings to yield a 3D continuum.

2. Experimental

2.1. Materials

High purity 2,2′-dipyridylamine (Fluka, Germany), zinc nitrate hexahydrate (E. Merck, India) and sodium azide (E. Merck, India) were purchased from respective concerns and used as received. Zinc perchlorate hexahydrate was prepared on treatment of zinc carbonate (E. Merck, India) with perchloric acid (E. Merck, India) followed by slow evaporation on steam-bath, filtration through a fine glass-frit, and preservation in a desiccator containing concentrated sulphuric acid for subsequent use. All other chemicals and solvents were AR grade and were used as received.

Caution! Azido compounds and perchlorate salts of metal ions are potentially explosive. Only a small amount of material should be prepared and handled with care.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed on a Perkin-Elmer 2400 CHNS/O elemental analyzer. IR spectra (KBr discs, 4000–300 cm^{-1}) were recorded using a JASCO FTIR model 420 spectrometer. Molar conductances were measured using a Systronics conductivity meter where the cell constant was calibrated with 0.01 M KCl solution and dry DMF was used as solvent. Ground state absorption and steady-state fluorescence measurements were made with a JASCO model V-530 UV–Vis spectrophotometer and Hitachi model F-4010 spectrofluorimeter, respectively. Time-resolved fluorescence measurements were carried out using a time-correlated single photon counting (TCSPC) spectrometer Edinburgh Instruments, model 199; a hydrogen filled coaxial flash lamp with a pulse width of 1.2 ns at FWHM and a Philips XP-2020Q Photomultiplier tube were respectively used as the excitation source and the fluorescence detector.

2.3. Preparation of the complexes

Mononuclear **1** was prepared from both nitrate and perchlorate salts of zinc(II) using the same (1:1:2) mole ratio of the metal, dpa and azide. **2** was prepared using a 1:1:1 ratio of zinc(II) nitrate, dpa and azide; the corresponding ratio with perchlorate salt resulted mononuclear **1** but with low yield. The typical syntheses are described below.

2.3.1. *[Zn(dpa)$(N_3)_2$] (**1**)*

An acetonitrile solution (5 cm^3) of dpa (0.056 g, 0.324 mmol) was added to a solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (0.121 g, 0.324 mmol) in the same solvent (10 cm^3) followed by NaN_3 (0.043 g, 0.656 mmol) in water (5 cm^3). The mixture was filtered and the supernatant liquid was kept in air for slow evaporation. After a few days ***1*** was separated, washed with toluene and dried in vacuo over silica gel indicator. Yield, 0.068 g (80%). *Anal*. Found: C, 37.75; H, 2.96; N, 39.85. Calc. for $C_{10}H_9N_9Zn$ (**1**): C, 37.46; H, 2.83; N, 39.32%. IR (KBr, cm^{-1}): ν(N–H) 3304 (br); ν(N=N=N) 2073; ν(C=N) 1590. Λ_M (DMF, $ohm^{-1}\,cm^2\,mol^{-1}$): 5; UV–Vis (λ, nm): 255, 315.

2.3.2. *[Zn(dpa)$(N_3)(NO_3)]_2$ (**2**)*

To an acetonitrile solution (10 cm^3) of $Zn(NO_3)_2 \cdot 6H_2O$ (0.096 g, 0.324 mmol) were added dpa (0.056 g, 0.324 mmol) in the same solvent (5 cm^3) and NaN_3 (0.021 g, 0.328 mmol) in water (5 cm^3). The colourless solution was filtered and was kept for slow evaporation. After 7 days ***2*** was separated and was processed as in ***1***. Yield, 0.172 g (75%). *Anal*. Found: C, 35.65; H, 2.84; N, 28.95. Calc. for $C_{20}H_{18}N_{14}O_6Zn_2$ (**2**): C, 35.26; H, 2.66; N, 28.79%. IR (KBr, cm^{-1}): ν(N–H) 3324 (br); ν(N=N=N) 2071; ν(C=N) 1592; $\nu(NO_3)$ 1384. Λ_M (DMF, $ohm^{-1}\,cm^2\,mol^{-1}$): 10; UV–Vis (λ, nm): 257, 315.

2.4. X-ray crystallographic analyses

Single crystals were obtained by slow evaporation of 3:1 MeCN–H_2O solution of the reaction mixtures.

Colourless crystals suitable for X-ray crystallographic analyses were selected following examination under a microscope. Diffraction data were collected on a Bruker-AXS SMART APEX/CCD diffractometer using Mo Kα radiation, which were corrected for Lorentz and polarization effects and for absorption using the SADABS [34] program. The structure was solved by direct methods and the structure solution and refinement were based on $|F^2|$. All non-hydrogen atoms were refined with anisotropic displacement parameters whereas hydrogen atoms were placed in calculated positions when possible and given isotropic U values 1.2 times that of the atom to which they are bonded. The crystallographic calculations were conducted with the SHELXTL v. 6.1 [35] program package. The crystal data and data collection parameters of **1** and **2** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and formulation

The tetracoordinated mononuclear complex $[Zn(dpa)(N_3)_2]$ (**1**) was prepared as a colourless powder through one-pot reactions of a 1:1:2 molar ratio of the metal perchlorate/nitrate, organic blocker and the pseudohalide from an aqueous acetonitrile solution. The hexacoordinated dinuclear $[Zn(dpa)(N_3)(NO_3)]_2$ (**2**) was obtained with a 1:1:1 molar ratio of metal nitrate, dpa and azide; however, use of a similar ratio but a change to perchlorate salt instead of nitrate leads to mononuclear **1** with albeit lower yield which again increases if the required ratio (1:1:2) is employed. Attempts to prepare hexacoordinated mononuclear compound of the composition $[Zn(dpa)_2(N_3)_2]$ with a ratio of 1:2:2 of the metal nitrate/perchlorate, dpa and azide resulted **1**. Similarly, started with 1:2:1 ratio of Zn(II) salt, dpa and azide to have hexacoordinated dinuclear compound of the type $[Zn(dpa)_2(N_3)]_2(Y)_2$ ($Y = ClO_4$ or NO_3) resulted **2** with metal nitrate and **1** with perchlorate. This shows inherent tendency towards formation of compounds **1** and **2** due to some kind of stability associated with themselves. Microanalytical (C, H and N) results and spectroscopic data (see Section 2) are useful in this regard to formulate the products. The air-stable moisture-insensitive complexes **1** and **2** are insoluble in common solvents like, methanol, ethanol, dichloromethane, acetonitrile, but has poor solubility in warm dimethylformamide and dimethylsulfoxide. In dimethylformamide the compounds behave as non-electrolytes as are evident [36] from their low conductivity values (5–10 ohm^{-1} cm^2 mol^{-1}); however **2** shows an increase in conductance value if it is left in solution, which is expected from dissociation of the nitrate ion from the coordination zone due to its weak coordinating property.

In IR spectra the point of interest is the band due to azide in **1** and both azide and nitrate, in **2**. The asymmetric stretch, $\nu_{as}(N_3)$ appears [37] as a strong band at 2073 cm^{-1} in **1** and at 2071 cm^{-1} in **2**. The azido symmetric stretch, $\nu_s(N_3)$ corresponding to the end-on (EO) bridging mode is observable as a band of medium intensity at about 1330 cm^{-1}. The inactiveness of this band for symmetrical end-to-end (EE) coordination supports the presence of EO motif in **2**. The presence of $\nu(NO_3)$ band at 1384 cm^{-1} in **2** is noticed. The splitting in the nitrate stretch indicates the presence of some kind of hydrogen bonding in **2**. Furthermore, the IR spectra of **1** and **2** feature the bands characteristic [38] of dpa molecule, seen in the stretching and bending modes of C–C and C–N bands in the ranges between 1645–1390 and 1270–750 cm^{-1}. The –NH– band is noticeable at ~3300 cm^{-1}. Reflectance spectra [**1**: λ, 257, 315 nm; **2**: λ, 259, 315 nm] in nujol and electronic spectra [**1**: λ, 255, 315 nm; **2**: λ, 257, 315 nm] in DMF solutions are akin in both complexes reflecting gross structure and electronic structure in solid state and in solution.

3.2. Structure

The structural analyses show that mononuclear **1** and dinuclear **2** consist of 2D sheet and 3D supramolecular continuum respectively formed by cooperative hydrogen bonds and π–π interactions. The ORTEP diagram of mononuclear unit, perspective view of the 2D sheet and arrangement of these sheets in **1** are shown in Figs. 1–3, respectively. Figs. 4–6 show the structure of the dimeric unit, hydrogen bonded 2D sheet with one kind of π–π interaction and 3D continuum with further π–π inter-

action in **2**. Selected bond distances and bond angles relevant to the Zn coordination spheres in **1** and **2** are given in Tables 2 and 3, respectively. The significant hydrogen bonding and π–π interaction parameters are set in Table 4.

The coordination polyhedron around Zn in **1** is best described as distorted tetrahedron with ZnN_4 chromophore. The coordination includes (Fig. 1) the chelated tailored diimine (–N=C–NH–C=N–) ligated by two pyridine N atoms (N4, N4A) and two terminal azide N atoms (N1, N1A). All the four Zn–N bond lengths lie within a close range [1.943(3)–1.997(3) Å]. The N1–N2 distance [1.187(5) Å] is greater than N2–N3 distance [1.165(5) Å] as expected, and the values are very similar to different transition metal azido complexes [31]. The bite [N4–Zn1–N4A, 94.94(18)°] is less than the angle [N1–Zn1–N1A, 98.9(2)°] between the two bound azides (Table 2), and both are substantially less than the ideal tetrahedral value [109.5°]. Interestingly, in $[Zn(dpa)(CN)_2]$ the bite is very close [92.3(2)°] to this one but non-bite C–Zn–C angle is 118.3(2)° which is significantly greater [26]. In **1** the low dihedral angle [0.4(2)°] between the two planar pyridine rings in dpa reflects almost planarity of the organic ligand.

The NH group in **1** acts as a hydrogen-bond donor to N1 and symmetry related N1A [H5...N1, 2.500 Å; N5...N1, 3.248(5) Å; <N5–H5...N1, 144.0° (Table 4)] forming 1D chain through bifurcated hydrogen bonds. The N–H...N bonds generate a cyclic motif $R_2^1(4)$ in Etter's graph notation [39]. The chains running in anti-parallel fashion in *bc*-plane form 2D sheet (Fig. 2) through face-to-face π–π interaction. The dihedral angle between the interacting pyridyl rings is within 0.0°–5.83° and the perpendicular distance between baricentres of these planes is in range 3.587 Å. The arrangement of the sheets is shown in Fig. 3.

The structure (Fig. 4) of **2** is made up of a centro-symmetric binuclear $[Zn(dpa)(N_3)(NO_3)]_2$ unit. Each metal centre is linked by two pyridine N atoms of organic blocker, two bridging azide N atoms and two O atoms of the bidentate chelating nitrate. The geometry around each zinc centre is distorted octahedral with a ZnN_4O_2 chromophore. The nitrogens (N4, N4A) of doubly bridging end-on azido, one pyridine nitrogen (N1) of dpa, and oxygen (O2) from nitrate define the equatorial plane around Zn1, whereas axial positions are occupied by N3 from the other pyridine ring of the same dpa unit and O1, the second coordinated oxygen of the nitrate. The maximum deviation of Zn atom from

N(7)–O(2)–Zn(1)	101.45(17)	Zn(1)–N(4)–Zn(1A)	101.53(10)

the mean plane passing through the equatorial plane is 0.20 Å. The Zn–N distances are in the range [2.062(2)–2.130(2) Å] which are consistent with corresponding values of analogous octahedrally coordinated zinc(II) complexes [25]. The Zn–O lengths [Zn1–O1, 2.423(2) Å, Zn1–O2, 2.155(2) Å] reflect asymmetric and weak coordination of a nitrate. The three N–O distances [N7–O1, 1.289(3); N7–O2, 1.256(3) and N7–O3, 1.197(3) Å] and O1–N7–O2 angle of 115.0(2)° consistent with an asymmetric bidentate coordination [40]. The *cisoid* [55.57(7)°–111.55(9)°] and *transoid* [147.64(8)°–168.47(8)°] angles (Table 3) around Zn are in line with strong distortion from an idealised octahedron. The Zn1–N4–Zn1A bridging angle is 101.53(10)° – an usual feature of azide bridges in most metal complexes [30–32]. The Zn...Zn separation is 3.269(3) Å. The dpa ligand is slightly folded as the value of the dihedral angle between the planar pyridine rings is 5.80(4)°. The dpa bite [90.61(8)°] is less than that in **1** as expected for crowded octahedral environment compared to open coordination sphere in a tetrahedron.

In **2**, each NH group acts as a hydrogen-bond donor to one metal bound oxygen, O1 of the chelating nitrate [H11...O1, 2.040 Å; N2...O1, 2.939(3) Å; <N2–H11...O1, 175.0° (Table 4)]. The nitrates are so oriented around the metal centre that they point to two quite opposite directions and at the same time come very close to the vicinity of amine hydrogen of the next unit thereby facilitating hydrogen bonding in two directions. The sheet structure is further strengthened by a face-to-face π–π interaction (dihedral angles = 5.80°, perpendicular distance between baricentres = 3.60 Å) (Fig. 5). These sheets are linked by another face-to-face π–π interaction (dihedral angles = 16.4°, perpendicular distance between baricentres = 3.40 Å) to form a 3D continuum in solid state (Fig. 6).

3.3. Luminescence spectra

The spectroscopic data are listed in Table 5. Complexes with dpa, feature [27] two intense absorptions at 257 and 315 nm which are assigned to intraligand π–π* transitions. The emission energy of **1** and **2** in DMF solutions at 298 K is almost same ($\lambda_{max} \approx 350$ nm) and is assignable to intraligand fluorescence [26,27]. The lifetimes of the fluorescence of **1** and **2** are 2.63 and 2.59

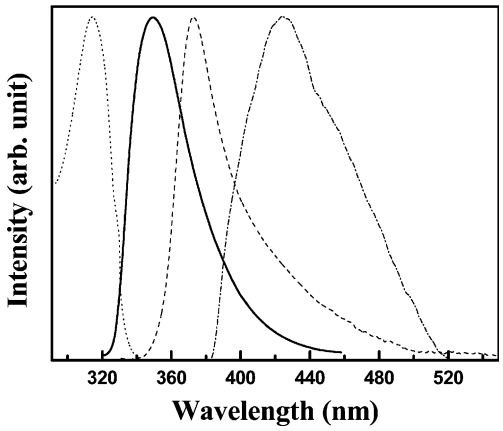

Fig. 7. Emission spectra of **1**: UV in DMF solution at 298 K (···), fluorescence in DMF solution at 298 K (—), phosphorescence in DMF glassy solution (-·-·-·-), fluorescence in solid state at 298 K (- - -).

ns, respectively. In glassy solutions (DMF at 77 K) both fluoresce and $^3(\pi–\pi^*)$ phosphorescence is observed at 425 nm. In solid state they show distinct emission band at 372 nm differing from their fluorescence spectra in DMF. This emission is expected to be due to excimer formation arising from the π–π aromatic stacking in solid state (Fig. 7).

4. Conclusion

To the best of our knowledge, **2** is the first example of hexacoordinated zinc compound and **1**, the second [26] tetracoordinated one containing tailored diimine (dpa) where cooperative hydrogen bonds and π–π interaction lead to network and sheet structures, respectively. The advantage of amine group with active hydrogen in dpa over polypyridines like 2,2′-bipyridine, 1,10-phenanthroline [41] with no such tailoring, afford superstructures. The difference in long-range structures in **1** and **2** above show how composition may tailor topology with different architectures through malleable coordination interaction and using strong and weak non-covalent forces in coordination polymers behaving as luminous materials. The preparation of these compounds illustrates a potentially versatile approach to the construction of uncharged inorganic organic hybrid [42] coordination network which is an exciting area of research for the rational design [43] of functional materials. The long range structural motif through use of tailored organic spacer, dpa, ensures us further study of it in combination with different pseudohalides like NCS^-, NCO^-, $NCSe^-$ and carboxylates in different 3d and 4d metal ions environments towards extended structures [2,3].

5. Supplementary data

These have been deposited with the Cambridge Crystallographic Data Centre nos. 203075 (**1**) and 203076 (**2**). Department of Chemistry, Northeast Normal University, No. 138 Renmin Street, Changchun 130024, PR China

Received 31 July 2003; accepted 8 October 2003

Abstract

Four new complexes, namely $[CuL(IN)_2(H_2O)_2]\cdot 4H_2O$ (**1**), $[CuL_2(H_2O)]Cl_2\cdot 5H_2O$ (**2**), $[CuL_2(H_2O)](NO_3)_2\cdot H_2O$ (**3**) and $[CuL_2]SO_4\cdot 8H_2O$ (**4**), where IN = isonicotinate anion, were obtained from self-assembly of the corresponding copper(II) salts with 1,1′-(1,4-butanediyl)bis(imidazole) (**L**), and their structures were determined by X-ray diffraction method. In complex **1**, each copper(II) cation is six-coordinated by two water molecules and four nitrogen atoms from two L molecules and two isonicotinate anions. Each L molecule coordinates to two copper(II) cations, acting as a bridging ligand. The copper(II) cations are bridged by L to form an infinite zigzag chain structure. In complexes **2** and **3**, the copper(II) cation is five-coordinated by one water molecule and four nitrogen atoms from four L molecules. In **4** the copper(II) cation is four-coordinated by four nitrogen atoms from four L molecules. Copper(II) cations are bridged by L ligands to form infinite $(4,4)$ networks that contain 44-membered rings in **2**, **3** and **4**. No interpenetration occurs in **2** and **3**, while in **4** two $(4,4)$ networks are interpenetrated in parallel fashion to form a layer.

1. Introduction

The synthesis and characterization of coordination polymers with infinite two- and three-dimensional networks have been an area of rapid growth in recent years because of the potential of these polymers in various applications, such as catalysis, electrical conductivity, host–guest chemistry and magnetism [1–4]. Much of the work has so far been focused on coordination polymers with rigid ligands, such as 4,4′-bipyridine and pyrazine [5,6]. The linear and bifunctional ligand 4,4′-bipyridine and its analogs upon reaction with transition metals are known to form several types of coordination networks that include one-dimensional networks (ladders, linear chains and railroads) [7–12], two-dimensional networks (square and rectangular grids, brick-wall and bilayers) [13,14] and three-dimensional networks (octahedral and diamondoid) [15]. Most of these structures have relatively large voids and potential interest for host–guest interaction and molecular recognition. Some transition metal complexes with flexible ligands have been investigated [16] and we are interested in coordination polymers containing flexible ligands. Based on its structure, 1,1′-(1,4-butanediyl)bis(imidazole) (**L**) can be used as a flexible divergent ligand to fabricate coordination polymer materials [17]. In this paper, we present the preparation and crystal structures of four coordination polymers of L with copper(II) salts, namely $[CuL(IN)_2(H_2O)_2]\cdot 4H_2O$ (**1**), $[CuL_2(H_2O)]Cl_2\cdot 5H_2O$ (**2**), $[CuL_2(H_2O)](NO_3)_2\cdot H_2O$ (**3**) and $[CuL_2]SO_4\cdot 8H_2O$ (**4**).

2. Experimental

All materials were commercially available and used as received. The FT-IR spectra were recorded from KBr pellets in range 4000–400 cm^{-1} on a Mattson Alpha-Centauri spectrometer. Elemental analyses were carried out with a Carlo Erba 1106 elemental analyzer.

2.1. Synthesis of 1,1′-(1,4-butanediyl)bis(imidazole) (*L*)

A mixture of imidazole (3.4 g, 50 mmol) and NaOH (2.0 g, 50 mmol) in DMSO (10 ml) was stirred at 60 °C for 1 h, then 1,4-dichlorobutane (3.2 g, 25 mmol) was added. The mixture was cooled to room temperature after stirring at 60 °C for 2 h, then poured into 200 ml of water and a white solid formed immediately which weighted 4.1 g after drying in air. *Anal.* Calc. for $C_5H_7N_2$: C, 63.16; H, 7.37, N, 29.47. Found: C, 63.11; H, 7.42; N, 29.31%.

2.2. Synthesis of $[CuL(IN)_2(H_2O)_2]\cdot 4H_2O$ (*1*)

A mixture of $CuCl_2\cdot 2H_2O$ (0.171 g, 1 mmol) and NaOH (0.08 g, 2 mmol) in water was stirring for 10 min at room temperature, then the $Cu(OH)_2$ solid was filtered. Isonicotinic acid (0.246 g, 2 mmol) was added to the $Cu(OH)_2$ suspension in water with constant stirring and give blue precipitation. Then L (0.380 g, 2 mmol) was added to the precipitation with stirring for 1 h and blue solution was obtained. Blue crystals were obtained from the filtrate after standing at room temperature for several days (68% yield based on Cu). *Anal.* Calc. for $C_{22}H_{34}CuN_6O_{10}$: C, 43.56; H, 5.61; N, 13.86. Found: C, 43.67; H, 5.52; N, 13.93%. IR (cm^{-1}, KBr): 3431(s), 3130(m), 2344(w), 1610(vs), 1551(s), 1450(m), 1382(vs), 1234(w), 1110(m), 1057(w), 951(w), 846(w), 779(w), 688(w), 669(m).

2.3. Synthesis of $[CuL_2(H_2O)]Cl_2\cdot 5H_2O$ (*2*)

A mixture of $CuCl_2\cdot 2H_2O$ (0.171 g, 1 mmol) and L (0.380 g, 2 mmol) in water (20 ml) was refluxed for 30 min, then filtered whilst hot. Blue crystals were obtained from the filtrate after standing at room temperature for several days (73% yield based on Cu). *Anal.* Calc. for $C_{20}H_{40}Cl_2CuN_8O_6$: C, 38.52; H, 6.42; N, 17.98. Found: C, 38.67; H, 6.31; N, 18.08%. IR (cm^{-1}, KBr): 3449(s), 3125(m), 2950(w), 1640(m), 1526(m), 1451(m), 1285(w), 1238(s), 1107(vs), 1099(vs), 948(w), 849(w), 771(w), 756(m), 664(s), 627(w).

2.4. Synthesis of $[CuL_2(H_2O)](NO_3)_2\cdot H_2O$ (*3*)

A mixture of $Cu(NO_3)_2$ (0.126 g, 1 mmol) and L (0.380 g, 2 mmol) in water (20 ml) was refluxed for 30 min and blue precipitate was obtained. It was filtered

2.6. X-ray crystallography studies

Experimental details of the X-ray analyses are provided in Table 1. Diffraction intensities for the compounds **1**–**4** were collected on a Rigaku RAXIS-RAPID image plate diffractometer using ω scan technique with Mo Kα radiation ($\lambda = 0.71069$ Å). Absorption corrections were applied using multi-scan technique [18]. The structures were solved with the direct method of SHELXS-97 [19] and refined with full-matrix least-squares techniques using the SHELXL-97 program [20] within WINGX [21]. Non-hydrogen atoms were refined anisotropically. Analytical expression of neutral-atom scattering factors were employed, and anomalous dispersion corrections incorporated [22]. Drawings were produced with SHELXTL PLUS [23].

3. Results and discussion

Selected bond distances and angles for complexes **1**–**4** are listed in Table 2. Fig. 1(a) shows the coordination environments of the copper(II) cations in $[CuL(IN)_2(H_2O)_2]\cdot 4H_2O$ **1**. The copper(II) cation lies at an inversion center. Each copper(II) cation is six-coordinated by two water molecules and four nitrogen atoms from two L molecules and two isonicotinate anions. The presence of an un-coordinated carboxylate group is somewhat unexpected because the carboxylate group of isonicotinate anion is a better coordinating group than water oxygen atom for copper(II) cation. In the related compound, $\{[Cu_2(IN)_4\cdot 3H_2O]\cdot[Cu_2(IN)_4\cdot 2H_2O]\}\cdot 3H_2O$ [24], the carboxylate oxygen atom coordinated to the copper(II) cation. The Cu–N (isonicotinate) distance of 2.0554(15) Å is similar to that of copper(II) isonicotinate complex [25]. The distance between the copper(II) cation and the nitrogen atom from L molecule is 2.0067(15) Å. The Cu–O (water) distance of 2.4163(14) Å is near to those of other copper(II) complexes [26,27]. Due to Jahn–Teller effects the axial Cu–O (water) distance is much longer than those of Cu–N (IN and L). The distance between the neighboring copper(II) cations is 8.654 Å. Each L molecule coordinates to two copper(II) cations, acting as a bridging ligand to form an infinite zigzag chain structure [Fig. 1(b)]. In **1**, one carboxylate oxygen atom H-bonds to one lattice water molecule and one coordinated water molecule of the neighboring Cu(II) cation within the same polymeric chain while the other carboxylate oxygen atom H-bonds to one lattice water molecule and one coordinated water molecule from adjacent polymeric chain. The extended structure was formed through H-bonds interactions between adjacent chains as illustrated in Fig. 1(c).

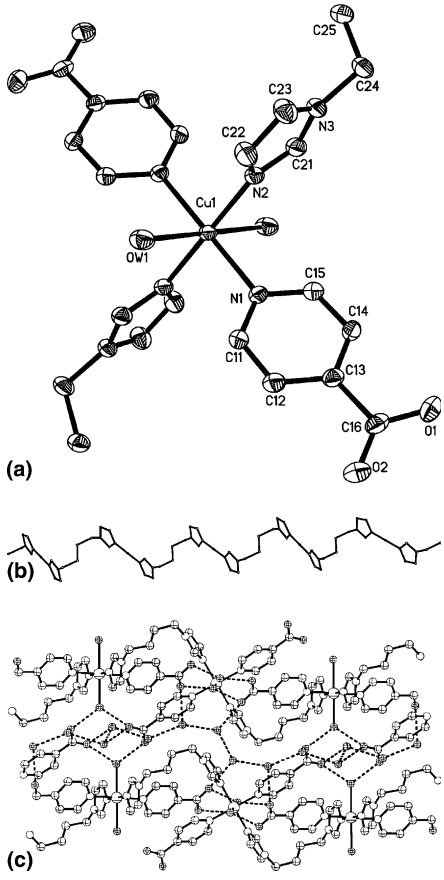

Fig. 1. (a) An ORTEP drawing of the local coordination of Cu(II) cation in complex **1**. Atoms are shown 50% probability ellipsoids. (b) The infinite zigzag polymeric chain of **1** (The water molecules and isonicotinate anions are omitted for clarity). (c) The extended structure of **1** through H-bonds interactions between adjacent chains.

Part of the structure of $[CuL_2(H_2O)]Cl_2\cdot 5H_2O$ (**2**) and $[CuL_2(H_2O)](NO_3)_2\cdot H_2O$ (**3**) are shown in Figs. 2(a) and 3(a), respectively. The coordination geometries of the copper(II) cation are all completed by four nitrogen atoms from four L molecules and by one water molecule. Both the chloride anions and nitrate anions only play a role of un-coordinating counter-anions. In **2**, there exist inversion centers at the mid-points of the C_{24}–C_{24}* and C_{34}–C_{34}# bonds. In **3**, Cu_1 cation and Ow_1 lie on a twofold axis, and there are inversion centers at the mid-points of C_{15}–C_{15}* and C_{25}–C_{25}# bonds. The average Cu–N distance and the Cu–O (water) distance in **2** and **3** are quite near to those of **1**. Each L molecule coordinates to two copper(II) cations, bridging the copper(II) cations to form infinite $(4,4)$ networks [Figs. 2(b) and (c), 3(b) and (c)]. In **2**, chloride ions and some lattice water molecules are encapsulated in the 44-membered rings of the $(4,4)$ network, one chloride ion H-bonds to one coordinated water molecule and three lattice water molecules while the other chloride ion H-bonds to three lattice water molecules. The adjacent $(4,4)$ networks are interconnected through hydrogen bonds as shown in Fig. 2(d). In **3**, nitrate ions are encapsulated in the 44-membered rings of the $(4,4)$ network, and each nitrate ion H-bonds to one coordinated water molecule from the adjacent $(4,4)$ networks as shown in Fig. 3(d). The uncoordinating counter-anions and water molecules filled in the networks may be the main reason for the non-interpenetrating structures of **2** and **3**.

As shown in Fig. 4(a), **4** consists of two crystallographically unique Cu(II) ions in the asymmetric unit. Both of them lie at the inversion center and have the similar coordination environment. The copper(II) cation of **4** is coordinated by four nitrogen atoms from four L molecules. In the related compound, $[ZnL_{1.5}(H_2O)(SO_4)]\cdot 6H_2O$ complex with infinite $(6,3)$ networks, the sulfate anion coordinates to the central zinc(II) cation [17a]. But in the present complex the sulfate anions play a role of counter-anion. The Cu–N (L) distances of 2.00(2) and 2.04(2) Å are similar to those in complex **1**, **2** and **3**. In complex **4**, copper(II) ions are bridged by L to form infinite $(4,4)$ networks [Fig. 4(b)], and two $(4,4)$ networks are interpenetrated in parallel mode to form a layer [Fig. 4(c)]. The sulfate anions and water molecules

(c) Extended structure of **3** (water and nitrate anions are omitted for clarity). (d) The H-bonds interactions between adjacent layers.

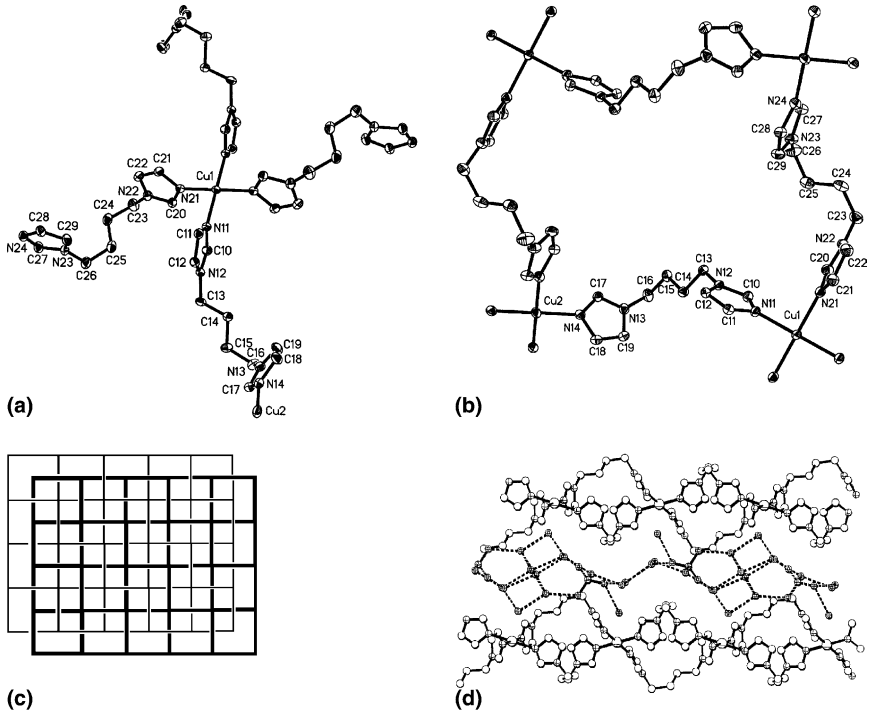

Fig. 4. (a) An ORTEP drawing of the local coordination of Cu(II) in complex **4**. Atoms are shown 50% probability ellipsoids. (b) The large ring of the $(4,4)$ network in **4.** (c) Schematic representation of the mode of interpenetration. (d) The alternative H-bonding layers and $[CuL_2]^{2+}$ layers.

are intercalated into the layers, and each sulfate ion H-bonds to six lattice water molecules. The extended structure was formed by stacking the layer of hydrogen-bonded water molecules and sulfate ions and the layer of polymeric $[CuL_2]^{2+}$ alternatively [Fig. 4(d)]. The number of different ways two $(4,4)$ nets could theoretically interpenetrate in the parallel fashion may be given by systematic study of the topology of interpenetration [28]. The interpenetrating structures of related complexes, $[MnL_3(BF_4)_2]$ [29] and $[ZnL_{1.5}(H_2O)(SO_4)]\cdot 6H_2O$ [17a] have been reported. The reported $[MnL_3(BF_4)_2]$ complexes are composed of two equivalent, mutually interpenetrating three-dimensional networks, while in complex $[ZnL_{1.5}(H_2O)(SO_4)]\cdot 6H_2O$, the networks are interpenetrated in an inclined mode by symmetry related, identical networks to give an interlocked three-dimensional structure.

In complexes **1**, **2**, **3** and **4** each L molecule coordinates to two copper(II) cations through its two aromatic nitrogen atoms acting as a bridging bidentate ligand. Copper(II) cations are bridged by L molecules to form one-dimensional chain in **1**, $(4,4)$ networks in **2**, **3** and **4**. The networks contain square grids (44-membered) with a copper(II) cation at each corner and a molecule of L at each edge connecting two copper(II) cations. The lengths of the opposite edges are equal in **2**, **3** and **4**. The edge lengths are 12.317 and 12.724 Å for **2**, 11.886 and 14.225 Å for **3**, 11.812 and 11.564 Å for **4**.

The structures of these complexes imply a role of counter-anions in the fabrication of the framework. Since isonicotinate anion is a better ligand for Cu(II) than other three anions, isonicotinate anions are coordinated to copper(II) ion in **1** while in other complexes the anions are non-coordinating. In each compound the anions are connected to water molecules through H-bonding interactions, and it can be seen that the polymeric networks can be tailored by using different anions.

4. Supplementary material

CCDC-198614 (for **1**), 198615 (for **2**), 198616 (for **3**) and 198617 (for **4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The reaction of $Ti(bipy)_3$ with BF_3 resulted in the formation of $[Ti(bipy)_3]BF_4$ (**1**), whereas the interaction of $Ti(bipy)_3$ with the $LiAlH_4$ yielded the unforeseen aluminum complex $Li(THF)_4[Al(bipy)_2]$ (**2**). The complexes **1** and **2** were characterized by NMR, mass spectra and elemental analysis. Complex **2** was investigated by X-ray structural analysis and consists of cationic $[Li(THF)_4]^+$ and anionic $[Al(bipy)_2]^-$ units containing the coordinated dinegatively charged [bipy] ligand.

1. Introduction

Various complexes of transition and non-transition metals with bipyridyl $[bipy]^-$ and $[bipy]^{2-}$ anions have been synthesized (for selected references, see [1]). The formation of $[bipy]^-$ and $[bipy]^{2-}$ anions from bipy and lithium metal was briefly described in 1968 [1b]. The complex $Ti(bipy)_3$ was first prepared by Herzog and Taube [2] and later it has been studied by several authors in connection with the metal oxidation state [1g,4b,3]. Analysis of the EPR, NMR, electronic spectra and chemical behavior of the complex led to the conclusion that the ligands in $Ti(bipy)_3$ carries a considerable negative charge and a formulation employing integral oxidation numbers of the metal and the ligands is not recommended [3b,3c,3f]. To the best of our knowledge complexes of non-transition metals with the negatively charged 2,2′-bipyridyl ligands were structurally characterized only for sodium in 1999 [1c,1d]. The complexes containing bipy anions were extensively studied for decades due to their interesting chemical and physical properties. A number of reactions of bipy complexes have been reported involving electron and proton transfer processes. In these reactions the bipy ligand is suggested to act as a kind of an electron reservoir [4].

Herein we report the reaction of the $Ti(bipy)_3$ complex with the Lewis acid BF_3, interaction of $Ti(bipy)_3$ with the reducing agent $LiAlH_4$ and synthesis and characterization of the monomeric aluminum complex $Li(THF)_4[Al(bipy)_2]$ with the negatively charged bipy ligand.

2. Experimental

2.1. General procedures and starting materials

All operations were performed using standard Schlenk line and dry box techniques under purified nitrogen and argon atmosphere. Water-free titanium trichloride used was of commercial reagent quality (Aldrich, purity 99.99%); the titanium tetrachloride of commercial reagent quality (Aldrich, purity 99%) was refluxed with $SOCl_2$ prior to use. The 2,2′-dipyridyl of commercial reagent quality (Aldrich, purity 99%) was sublimed in vacuum. The lithium aluminum hydride

doi:10.1016/j.poly.2003.10.008

powder (Aldrich, purity 97%) and the boron trifluoride (Aldrich, purity 99.5%) were used as received. The titanium complex $Ti(bipy)_3$ was prepared by the reaction of $TiCl_3$ or $TiCl_4$ with three equivalents of bipy and excess of Li metal in THF. The purity of $Ti(bipy)_3$ was checked by elemental analysis, ^1H and ^{13}C NMR spectra. The proton NMR spectrum for $Ti(bipy)_3$ is consistent with those previously reported for this substance [4b]. THF, Et_2O were dried over Na/benzophenone and distilled under nitrogen prior to use, C_6D_6 and [D_8] THF were dried over Na and degassed. CD_2Cl_2 and CH_2Cl_2 were dried over CaH_2 and degassed. Proton NMR spectra were recorded using Bruker AM 500 NMR spectrometer. Chemical shifts are reported in δ units downfield from Me_4Si with the solvent as the reference resonance. Mass spectra were recorded using a Finnigan MAT 8230 mass spectrometer, and elemental analysis were carried out at the Analytical Laboratories of the Institute of Inorganic Chemistry at the University of Göttingen. Melting points were measured in sealed capillary tubes under nitrogen and are not corrected.

2.2. Reaction between $Ti(bipy)_3$ with excess of BF_3 in CH_2Cl_2

Gaseous BF_3 (22 mmol) was condensed in trap I by cooling with liquid nitrogen. The solid BF_3 in trap I was kept 15 min under dynamic vacuum. Then the liquid nitrogen was removed from trap I and the content of trap I is allowed to warm slowly. The volatile BF_3 was passed through the stirred solution of $Ti(bipy)_3$ (0.85 g, 1.6 mmol) in CH_2Cl_2 at −79 °C (solid CO_2 in acetone) (Schlenk flask) under dynamic vacuum and condensed into a second trap with the help of liquid nitrogen. Finally, the Schlenk flask with the reaction mixture was closed and the remaining BF_3 condensed into the second trap neutralized while passing through the aqueous solution of $CaCl_2$. The reaction mixture was stirred at −79 °C for 30 min, allowed to warm to −20 °C and stirred for additional 30 min. The solution was filtered, concentrated and left undisturbed at −24 °C. After 4 days, violet solid (0.41 g) was deposited from the CH_2Cl_2 solution and separated by filtration. Yield of compound **1** 0.41 g (43 %). M.p.: 170–172 °C. EI-MS: m/z (%) = 503(1) [$TiC_{29}H_{23}N_6^+$], 474 (1) [$TiC_{29}H_{22}N_4^+$], 429 (2) [$Ti(bipy)_2BF_3^+$], 401 (1) [$TiC_{18}H_{13}N_4BF_3^+$], 373 (3) [$TiF_4C_{15}H_{12}N_4^+$], 354 (3) [$TiF_3C_{15}H_{12}N_4^+$], 340 (3) [$TiF_3C_{15}H_{12}N_3^+$], 300 (5) [$TiN_2(bipy)BF_3^+$], 281 (6) [$TiN_2BF_2(bipy)^+$], 267 (3) [$TiNBF_2(bipy)^+$], 232 (2) [$Ti(bipy)N_2^+$], 225 (6) [$Ti(bipy)F^+$], 207 (8) [$Ti(bipy)^+$], 156 (100) [$bipy^+$], 128 (25) [$(bipy)^+$–C_3H_3N]. ^{11}B MAS NMR(15 KHz, BF_3OEt_2 r.t.) $\delta = 0$ ppm, satellites 117, −117 ppm. ^1H NMR (500 MHz, C_6D_6, r.t.), $\delta = -26.50$, −25.20, −8.39, −3.96, 1.76, 2.30, 3.67, 7.19, 7.41, 8.10, 8.71, 9.63, 10.09, 17.80 ppm.

2.3. Reaction of $Ti(bipy)_3$ with $LiAlH_4$

A mixture of $Ti(bipy)_3$ (1.2 g, 2.3 mmol) and $LiAlH_4$ (0.35 g, 9.2 mmol) in a 100 ml Schlenk flask in THF (40 ml) was stirred for 36 h. The supernatant solution was filtered and all volatiles were removed in vacuum, the residue was extracted with Et_2O (50 ml). The resulting solution was filtered and concentrated, while two liquid layers were observed. The heavy violet liquid on the bottom of the flask slowly crystallized at r.t. to afford black crystals of **2**. The crystals of **2** are extremely air sensitive and start immediately burning when contacted to air. Yield of $Li(THF)_4[Al(bipy)_2]$ **2** (0.58 g, 40%). M.p.: 123–125 °C. EI-MS: m/z (%) = 281(0.2) [$Al(bipy)_2^+$–C_3H_5N], 207 (0.5) [$Li(THF)_3^+$–CH_4], 182 (1) [$Al(bipy)^+$], 156 (100) [$bipy^+$], 128 (25) [$(bipy)^+$–C_3H_3N], 106 (15) [$(bipy)^+$–C_5H_4N], 79 (18) [$Li(THF)^+$], 72 (22) [THF^+]. ^1H NMR (500 MHz, C_6D_6, r.t.), $\delta = 1,11$ (t, 4H, $J = 6.1$ Hz, CH_2, THF), 1.42 (t, 4H, $J = 6.2$ Hz, CH_2, THF), 2.1, 3.0, 3.3 (q, 4H, $J = 7.0$ Hz, CH_2, THF), 3.4, 3.6 (t, 4H, $J = 6.1$ Hz, CH_2, THF), 4.9, 5.5, 6.4, 6.7 ppm.

2.4. Computational detail

All computations were done with program GAUSSIAN 98, Revision A.6 [5]. The geometry of $[Al(bipy)_2]^-$ was optimized at the UHF/3-21G* level followed by UMPW1PW91/6-31G* and at the HF/6-31++G** level followed by B3LYP/6-31++G**, gas phase, C_1 symmetry and singlet ground state. The calculations were performed starting from the experimental structural data. Frequency calculations were performed at the UMPW1PW91/6-31G* level and the structure represents true minima without imaginary frequencies on the respective hypersurface. For the anionic species Mulliken population analysis has been performed using the B3LYP/6-31++G** or UMPW1PW91/6-31G* electron densities. Proton chemical shifts were calculated at the B3LYP/6-31++G** and UMPW1PW91/6-31G* level. For the calculation of chemical shifts CH_2Cl_2 was used as a reference. The geometry of CH_2Cl_2 was optimized at the UHF/3-21G* followed by UMPW1PW91/6-31G* level and at the HF/6-31++G** followed by B3LYP/6-31++G** level (gas phase). The proton chemical shift of CH_2Cl_2 was calculated at the B3LYP/6-31++G** and UMPW1PW91/6-31G* level.

2.5. Crystallography

Intensity data for the crystal structure of **2** was collected on a Stoe-Siemens four-circle diffractometer. The structure was solved by direct methods (SHELXS-97) and refined against F^2 using SHELXS-97 [6]. The heavy atoms were refined anisotropically. Hydrogen atoms were

included using the riding model with U_{iso} tied to U_{iso} of the parent atoms.

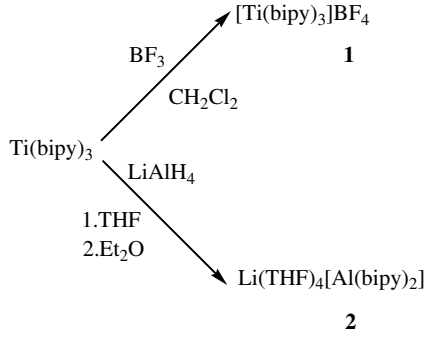
Crystal data: empirical formula: $C_{36}H_{48}AlLiN_4O_4$; $M = 634.70$, crystal size $1.00 \times 0.80 \times 0.20$ mm, black block, triclinic, space group $P\bar{1}$, $a = 9.108(2)$ Å, $b = 10.311(2)$ Å, $c = 11.040(2)$ Å, $\alpha = 114.94(3)°$, $\beta = 97.46(3)°$, $\gamma = 107.14(3)°$, $V = 858.7(3)$ Å^3, $Z = 1$, $D_c = 1.227$ g cm^3, μ (Mo Kα, $\lambda = 0.71073$ Å) $= 0.103$ mm^{-1}, $T = 203(2)$ K, 3544 reflections measured, 3544 unique. Scan range $\theta = 3.56°$–$25.03°$, completeness to $\theta_{max}(25.03°) = 99.4\%$, $F(000) = 340$, index ranges: $-10 \leqslant h \leqslant 10$, $-12 \leqslant k \leqslant 11$, $-11 \leqslant l \leqslant 13$; data/restrains/parameters 3544/3/415. Refinement on all F^2, final $R_1 = 0.0553$ (for reflections with $I > 2\sigma(I)$) $R_1 = 0.0567$ (for all data), $wR_2 = 0.1513$ (for all data), goodness-of-fit on $F^2 = 1.043$, maximum/minimum electron density 0.396/−0.377 (e Å^{-3}). Program: SHELXS-97 [6].

3. Results and discussion

3.1. Reaction of Ti(bipy)$_3$ with BF$_3$

The titanium complex Ti(bipy)$_3$ treated with an excess of gaseous BF_3 in CH_2Cl_2 at −79 °C yielded a violet air sensitive polycrystalline solid **1** that was crystallized from CH_2Cl_2 at −24 °C (Scheme 1). The same reaction in the presence of the electron donor solvents THF and Et_2O led to a colourless oil, whereas reaction of Ti(bipy)$_3$ and BF_3 in MeCN afforded a grey insoluble solid.

The resulting solid **1** is soluble in CH_2Cl_2 and $CHCl_3$. The ^{19}F NMR spectrum of **1** in CD_2Cl_2 exhibits a resonance at 11.2 ppm. It was found that the chemical shift of this resonance is close to that of the BF_4^- anion ($(Ph_3C)BF_4$ δ 11.0 ppm in CD_2Cl_2). In the solid state ^{11}B MAS NMR spectrum of **1** is observed one strong resonance with two weak satellites, which suggests tetrahedral symmetric environment for the ^{11}B nucleus. This observation is in agreement with a BF_4^- anion. The proton NMR spectrum of **1** in CD_2Cl_2 exhibits a set of resonances in the range from −26.6 to 19.6 ppm, connected with the paramagnetic nature of **1**. While the neutral Ti(bipy)$_3$ complex is diamagnetic, the anionic complex [Ti(bipy)$_3$]$^-$ was shown to be paramagnetic and electronic spectra of it suggested the presence of the negatively charged bipy$^-$ and bipy^{2-} ligands [3b]. Similar features have been observed in the electronic and IR spectra of the tris(2,2′-bipyridyl) complexes [M(bipy)$_3$]$^-$, [M(bipy)$_3$], [M(bipy)$_3$]$^{n+}$ ($n = 1, 2$), M = Ti, V, Cr, Fe [3b,3c,3f] and these complexes are considered containing negatively charged bipy ligands. Therefore, complex **1** can be formally described containing bipy^0, bipy$^-$ and bipy^{2-} ligands. The presence of bipy$^-$ ligand might be responsible for the paramagnetism of **1**. However, an estimate of the actual composition of the ground state of **1** in terms of metal and the various ligand orbital contributions will be possible on the basis of detailed MO calculations using experimentally determined bond lengths and angles.



Scheme 1. Synthesis of complexes **1** and **2**.

Solid **1** was investigated by means of mass spectrometry. The fragment with the largest m/z corresponds to the [(Ti(bipy)$_3$–CH)$^+$] cation. In addition several fragments of [Ti(bipy)$_3$]BF$_4$ were observed including a strong signal for [bipy$^+$]. The elemental analysis of **1** is close to the [Ti(bipy)$_3$]BF$_4$ composition, however, it does not correspond exactly to this composition possibly due to the high reactivity of **1** toward air.

Thus, the soluble reaction product **1**, obtained by interaction of Ti(bipy)$_3$ with an excess of BF_3 in CH_2Cl_2, was confirmed. The conversion of complex Ti(bipy)$_3$ to the [Ti(bipy)$_3$]$^+$ cation can be promoted with the strong Lewis acid BF_3, that acts under the reported reaction conditions as an electron acceptor under formation of the BF_4^- anion. It should be pointed out, that oxidation of Ti(bipy)$_3$ with iodine was studied by Herzog and Taube [2] but they did not find experimental evidence for the oxidation of Ti(bipy)$_3$ to [Ti(bipy)$_3$]$^+$. In general, the molecular low valent titanium complexes can be oxidized and form the corresponding cationic complexes [7].

3.2. Reaction of Ti(bipy)$_3$ with LiAlH$_4$

Reaction of Ti(bipy)$_3$ with $LiAlH_4$ in THF followed by crystallization from Et_2O affords the unforeseen complex Li(THF)$_4$[Al(bipy)$_2$] **2** (Scheme 1). Complex **2** is extremely air and moisture sensitive and starts immediately to burn when exposed to air. All attempts to accomplish elemental analysis were unsuccessful due to the high reactivity of **2**. The melting point of **2** is in the range from 123 to 125 °C. Complex **2** exhibits a signal for the [Al(bipy)$^+$] ion as well as [bipy$^+$] and [LiTHF$^+$] cations in the EI-MS spectrum.

Complex **2** is soluble in THF, Et_2O and toluene. The ^{1}H NMR spectrum of **2** in C_6D_6 showed a strong THF resonance and four weak and broadened resonances in

the range from 6.7 to 4.9 ppm that can be assigned to the coordinated bipy. The intensive colour change observed upon complexation with bipy suggests the presence of a considerable negative charge on the coordinated ligand. The negative charge on the bipy ligand in **2** seems to be even larger compared to the titanium complex $Ti(bipy)_3$, since the proton resonances of $[Al(bipy)_2]^-$ are shifted upfield by ca. 0.5–1 ppm relative to the resonances of $Ti(bipy)_3$ [4b].

To assign the resonances in the ^1H NMR spectrum, the anionic complex $[Al(bipy)_2]^-$ was optimized at the B3LYP/6-31++G** and UMPW1PW91/6-31G* DFT levels (C_1 symmetry, singlet ground state) (Fig. 1). The calculation is in qualitatively good agreement with the available experimental data. The C–C and C–N bond lengths of the coordinated bipyridyl ligand (Table 2) and the Al–N distances 1.84 Å (exp.) vs. 1.87 Å (calcd.) within the calculated anion of **2** have acceptable deviations. The calculated bond lengths are overestimated of about 0.03–0.05 Å which is common for DFT calculations. The calculated partial charge residing on the Al atom is 2.48 at the B3LYP/6-31++G** level, that is in agreement with the formal approach, where the formal charge on the aluminum atom should be +3. The calculated partial charge on the Al atom is only 0.88 using the open shell method UMPW1PW91. The chemical shift of the proton resonances for $[Al(bipy)_2]^-$ calculated with the B3LYP/6-31++G** level differs (1.4–1.2 ppm) substantially from the experimental values. The open shell method UMPW1PW91/6-31G* gives, however, smaller deviations and the calculated resonances are shifted by 0.9–0.4 ppm upfield. The calculated chemical shifts can be rescaled. Adding the 1.2 ppm to the chemical shifts of the proton resonances calculated with the B3LYP/6-31++G** level and the 0.7 ppm to the chemical shifts of the proton resonances calculated with the UMPW1PW91/6-31G* afford deviations less than 0.5 ppm (Table 1).

Table 1
Calculated ^1H chemical shifts for the $[Al(bipy)_2]^-$ anion

Number of protons	δ (# B3LYP/6-31++G**) + 1.2 ppm	δ (#UMPW1PW91/6-31G*) + 0.7 ppm	δ (exp.), ppm
26	4.7	4.7	4.9
27	7.1	7.0	6.7
28	6.5	6.4	6.4
29	5.5	5.4	5.5
30	5.5	5.4	5.5
31	6.5	6.4	6.4
32	7.1	7.0	6.7
33	4.7	4.7	4.9
34	4.7	4.7	4.9
35	7.1	7.0	6.7
36	6.5	6.4	6.4
37	5.5	5.4	5.5
38	5.5	5.4	5.5
39	6.5	6.4	6.4
40	7.1	7.0	6.7
41	4.7	4.7	4.9

Complex **2** crystallizes in the triclinic space group $P\bar{1}$. The X-ray structural analysis revealed that compound **2** is monomeric and contains separated $[Li(THF)_4]^+$ cations and $[Al(bipy)_2]^-$ anions (Fig. 2). The two bipy ligands coordinate to the Al1 atom through the nitrogen atoms. The coordination number at the aluminum atom in **2** is four and the geometry around the metal atom is distorted tetrahedral. The empirical bond-valence-method [8] can be applied for the description of the coordination sphere around the Al1 atom. Since the $[Al(bipy)_2]^-$ can formally be described as an Al(III) complex, the sum of the aluminum bond valency is expected to be 3. The sum of four Al–N bond valency is 3.45 indicating that the aluminum coordination sphere in **2** can be represented as AlN_4. The deviation from 3 might be connected with the non-integral oxidation number of the metal center in $[Al(bipy)_2]^-$, similarly to those in complexes $[M(bipy)_3]^n$ ($n = -1$ to -3), (M = Ti, V, Cr) [3].

(e)	1.43	1.37	1.36	1.44	1.36	1.43	1.38
(f)	1.44	1.37	1.36	1.45	1.37	1.43	1.39

See text for references, labeling see Scheme 2.

The bipy ligands are nearly planar, the first one with the N4 and N12 atoms has deviation of 0.03 Å from planarity, the second one with the N13 and N24 atoms has a deviation of 0.02 Å (aluminum atoms are 0.05 and 0.02 Å out of the plane). The two bipy ligands are rotated by 88.9° to each other. The C–C and C–N bond lengths in the two bipy ligands are close to those in the known complexes $[Na_2(bipy)(DME)_2]$ (DME = dimethoxyethane) [1c,1d], $[Yb(\mu\text{-}N_2C_{10}H_8)(THF)_2]_3$ [1e,1f] where the bipy ligands were formally described as dianionic (Table 2; Scheme 2).

The Al–N distances in **2** (Table 3) are considerably shorter than those in the aluminum complex $[AlCl_2(bipy)_2]Cl \cdot MeCN$ (Al–N 2.020(3)–2.042(3) Å) [9] between aluminum and coordinated neutral bipy ligand and are comparable with the Al–N single bond length in $(2,6\text{-}iPr_2C_6H_3)N(SiMe_3)AlMe_2$, (Al–N 1.823(2) Å) [10], $[K \cdot THF(2,6\text{-}iPr_2C_6H_3N(SiMe_3)Al(C{\equiv}CPh)_3)]_2$ (Al–N 1.836(2) Å) [11].

Finally, a comparison of the Al–N bond lengths, C–C and C–N distances in the anionic complex $[Al(bipy)_2]^-$ (c), (d) (Table 2) and the distances of a coordinated $bipy^{2-}$ in known complexes (a) and (b) (Table 2) [1c–1f] reveals that complex $[Al(bipy)_2]^-$ formally can be described as an Al(III) complex with two $bipy^{2-}$ dianionic antiaromatic ligands. On the other side essential electron density can be located on the aluminum atom. Calculation of chemical shifts with the open shell method UMPW1PW91 giving the partial charge on the Al atom (0.88) leads to reasonable small deviations from experimental values (Table 1). Therefore the bipy ligands in the anionic form of **2** are essentially carrying the negative charge, corresponding to a successive filling of the LUMO of the neutral bipy. It is possible to conclude that the oxidation number of the aluminum and the bipy ligands is likely to be non-integral, this is in agreement with the previous assumption for the oxidation state of the metals and bipy in $[M(bipy)_3]^n$ ($n = -1$ to -3), (M = Ti, V, Cr) complexes [3].

4. Conclusions

The reaction between $Ti(bipy)_3$ and BF_3 leads to the conversion of the titanium complex to the corresponding cationic complex $[Ti(bipy)_3]^+$. The strong Lewis acid BF_3 acts as an electron acceptor under the reaction conditions given and promotes the electron transfer process. A transfer of a negatively charged bipy ligand was observed from the titanium to the aluminum center in the $Ti(bipy)_3$–$LiAlH_4$ system. The resulting anionic complex $[Al(bipy)_2]^-$ carries the bipy ligands with a considerable negative charge.

5. Supplementary material

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 214500. Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk].

Abstract

A new potential tridentate ligand (**H_2L**) was synthesized from condensation of ferrocenoylacetone ($C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$) with S-benzyldithiocarbazate in refluxing benzene. Reaction of the ligand (**H_2L**) with a bivalent metal salt ($M(OAc)_2 \cdot xH_2O$, M = Cu, Ni, Mn, Hg, Zn; $SnCl_2 \cdot 2H_2O$) afforded the corresponding bivalent metal complexes M(**HL**)$_2$ (**I**, M = Cu; **II**, M = Ni; **III**, M = Mn; **IV**, M = Hg; **V**, M = Zn; **VI**, M = Sn). All the new compounds have been characterized by elemental analyses, ^{1}H NMR, IR and UV spectroscopies. A single-crystal X-ray analysis indicates that the ligand exists as a single iminone and not a tautomeric mixture of the iminone and enaminone. Crystallography of complex **VI** shows that the ligand acts as monoanionic tridentate coordinated to the tin atom via the carbonyl oxygen, deprotonated enamine nitrogen and thione sulfur atoms and the coordination geometry of the central metal is a distorted octahedron.

1. Introduction

N-substituted acid hydrazides are well-known to act as chelating agents [1–4]. Furthermore, these compounds and their metal complexes exhibit a broad spectrum of biological, bactericidal and fungicidal activities [5–7]. Since the discovery of ferrocene in 1951, it has played an important role in developing a knowledge of electronic structures of organometallic compounds and materials chemistry. A considerable number of ferrocene derivatives have been prepared directly or indirectly from ferrocene and their properties have been extensively studied. Among them, some have been reported to display biological activity and act as β-lactamase inhibitors [8,9]. In view of relatively few studies on reactions of 1,3-diketones and acylhydrazides, here we report the syntheses and crystal structures of the potential tridentate ligand [$C_5H_5FeC_5H_4C(O)CH_2C(CH_3)=NNHCSSCH_2C_6H_5$] (**$H_2L$**) formed from condensation of ferrocenoylacetone and S-benzyldithiocarbazate and its bivalent metal complexes [10,11].

2. Experimental

2.1. Reagents and general procedures

All chemicals were of analytical grade and used without further purification. S-benzyldithiocarbazate and ferrocenoylacetone were synthesized according to the literature methods [12–14]. Progress of the reaction was monitored by TLC (silica gel H). The ^{1}H NMR spectra were determined with a Bruker Avance 500 spectrometer using TMS as an external standard in $CDCl_3$. IR spectra were recorded on a Perkin–Elmer 402 as KBr disks in the range of 400–4000 cm^{-1}. UV spectra were measured with a Shimadzu UV-240 spectrometer using a solution in DMF. Analyses for C, H

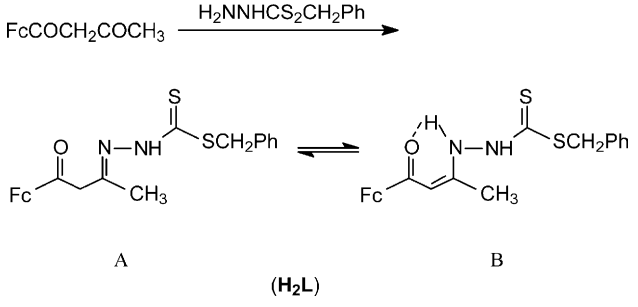
and N were performed on an Elementa Vario EL III microanalytical instrument. Melting points were measured on a Yanagimoto apparatus and uncorrected.

2.2. Synthesis of ligand

S-benzyldithiocarbazate (1.98 g, 10 mmol) was added to a solution of ferrocenoylacetone ($C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$) (2.7 g, 10 mmol) in 30 ml of benzene, the mixture was refluxed for 5 h and then evaporated to dryness and finally isolated by vacuum liquid chromatography (VLC), using a mixed solvent of CH_2Cl_2 and petroleum ether (v/v, 5:1) to afford the ligand. **H_2L** as orange red crystals, yield: 3.51 g (78%). M.p. 141–142 °C. *Anal.* Found: C, 58.48; H, 4.58; N, 5.89. Calc. for $C_{22}H_{22}FeN_2OS_2$: C, 58.66; H, 4.93; N, 6.22%. ^{1}H NMR (500 Mz, δ, in $CDCl_3$): iminone A isomer (shown in Scheme 1), 2.18 (s, CH_3), 3.73 (s, SCH_2), 3.94 (s, CH_2), 4.23 (s, C_5H_5), 4.55, 4.82 (s, s, ^{3}H/^{4}H and ^{2}H/^{5}H of C_5H_4 ring), 7.22–7.41 (m, C_6H_5), 6.54 (s, br, NH); enaminone B isomer (shown in Scheme 1), 2.07 (s, CH_3), 3.54, 3.58, 3.83, 3.86 (q, $^2J_{HH}$ = 18.6 Hz, SCH_2), 4.21 (s, C_5H_5), 4.68, 4.78 (s, s, ^{3}H/^{4}H and ^{2}H/^{5}H of C_5H_4 ring), 5.73 (s, CH), 7.22–7.41 (m, C_6H_5), 9.82 (s, $NHCS_2$), 11.67 ppm (s, NH). IR (KBr disk): ν(NH) 3431(w, br), ν(C=O) 1665 (vs), ν(C=N) 1637 (m), ν(C=S) 1068 (vs), ν(C–S) 1035 (m), ν(N–N) 984 (m) cm^{-1}. UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$, in dm^3 mol^{-1} cm^{-1}) 405 (1.8) (K-band), 553 (0.053) (R-band). Single crystals of the ligand for X-ray determination were obtained by slow evaporation of its solution in dichloromethane and petroleum ether.

2.3. Syntheses of complexes

A solution of an appropriate metal acetate or $SnCl_2 \cdot 2H_2O$ (0.5 mmol) in 5 ml of absolute ethanol was added dropwise to a stirred solution of the ligand (**H_2L**) (0.45 g, 1 mmol) in 20 ml of absolute ethanol. The mixture was stirred for 6 h at room temperature and then filtered to afford the crude product. The resulting solid recrystallized from dichloromethane and petroleum ether gave the corresponding complex (**I** to **VI**).



Scheme 1. Synthesis of ligand.

Complex **I** as a black solid, yield: 0.847 g (88%). M.p. 131–132 °C. *Anal.* Found: C, 54.54; H, 3.95; N, 5.42. Calc. for $C_{44}H_{42}Fe_2N_4O_2S_4Cu$: C, 54.92; H, 4.40; N, 5.82%. Single crystals of complex **VI** for X-ray determination were obtained by slow evaporation of its solution in dichloromethane and petroleum ether.

2.4. Crystal structure determination

For each of compounds (**H_2L** and **VI**), a selected single crystal was mounted on a Bruker SMART 1000 CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. Data collection and reduction were performed using the SMART and SAINT software [15]. An empirical absorption correction was applied using the SADABS program [16]. The structures were solved by direct methods and refined by full-matrix least-squares methods, based on F^2 with anisotropic thermal parameters for all non-hydrogen

atoms and hydrogen atoms were included in the model at their calculated positions and refined isotropically using the SHELXTL program package [17]. Crystal structure data and refinement details for both compounds are summarized in Table 1. Selected bond distances and angles are given in Tables 2 (**H_2L**) and 3 (**VI**).

3. Results and discussion

3.1. Syntheses of ligand and its complexes

Syntheses of ligand and its complexes are shown in Schemes 1 and 2. Reaction of ferrocenoylacetone ($C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$) and S-benzyldithiocarbazate in refluxing benzene via removal of water affords a new ligand (**H_2L**) as orange-red crystals. The ligand (**H_2L**) reacts with bivalent metal ions forming neutral complexes M(**HL**)$_2$ (**I,** M = Cu; **II,** M = Ni; **III,** M = Mn; **IV,** M = Hg; **V,** M = Zn; **VI,** M = Sn). TLC analysis of **H_2L** shows, that it exists as an equilibrium mixture of two isomers (major orange–red and minor brown spots) in solution. However, it can crystallize in an orange–red isomer. All complexes listed in Section 2 are soluble in polar organic solvents such as DMF, THF and dichloromethane and insoluble in non-polar organic solvents such as benzene, toluene and petroleum ether.

$$2\mathbf{H_2L} + M(OAc)_2 \xrightarrow{\text{Ethanol}} (\mathbf{HL})_2M + 2\mathbf{H}OAc \quad (M = Cu,Ni,Mn,Hg,Zn)$$

$$2\mathbf{H_2L} + SnCl_2 \xrightarrow{\text{Ethanol}} (\mathbf{HL})_2Sn + 2\mathbf{H}Cl$$

Scheme 2. Syntheses of complexes **I**–**VI**.

3.2. ^1H NMR Spectra

The ^{1}H NMR spectral data of ligand (**H_2L**) and complexes **II** and **VI** are listed in Section 2. Although **H_2L** contains the thioamide $NHCS_2$ functional group, in principle, it can exhibit thione–thiol tautomerism. However, its ^{1}H NMR spectrum does not display any signal at approximately 4.00 ppm due to the H–S proton, indicating even in solution it exists as the thione tautomers (iminone A and enaminone B isomers) as shown in Scheme 1 [12], which is in agreement with the above TLC

analysis of $\mathbf{H_2L}$. Two methyl groups of tautomers A and B exhibit two well-resolved singlets at δ 2.18 and 2.07 ppm. According to relative intensities of both singlets, two tautomers A and B exist in a 3:2 ratio in solution at room temperature. For tautomer A, the protons of SCH_2 and $COCH_2C$ moieties display two singlets at δ 3.73 and 3.94 ppm. The substituted cyclopentadienyl ring shows two singlets at δ 4.55 and 4.82 ppm which are due to protons of 3, 4- and 2, 5-positions, whereas a singlet at δ 4.23 ppm is due to protons on the unsubstituted cyclopentadienyl ring. The NH absorption appears at δ 6.54 ppm as a broad peak [11,19]. For tautomer B, the protons of COCH=C moiety displays a singlet at δ 5.73 ppm while the protons of SCH_2 moiety exhibits a typical doublet–doublet quartet ($^2J_{HH} = 18.55$ Hz) [14,18]. The substituted cyclopentadienyl ring shows two singlets at δ 4.68 and 4.78 ppm which are due to protons of 3, 4- and 2, 5-positions, whereas a singlet at δ 4.21 ppm is due to protons on the unsubstituted cyclopentadienyl ring. The $NHCS_2$ (thioamide) and HN (enamine) absorptions appear at δ 9.82 and 11.67 ppm, respectively [14,19]. For both tautomers, benzene rings show three slightly-resolved multiplets at δ 7.22–7.41 ppm.

The ^{1}H NMR spectral data of complexes **II** and **VI** are characterized by the absence of the δ 3.94 ppm signal of $COCH_2C$ in the tautomer A or the δ 11.67 ppm signal of HN (enamine) in the tautomer B and the appearance of the methine (CH) at δ 5.28 and 5.39 ppm in complexes **II** and **VI** [14]. Therefore, the above evidence indicates that the ligand is deprotonated and bonded to the metal ion, which is also supported by the crystal structure of complex **VI** as described below. In addition, all the signals of protons in complex **II** display high-field shifts compared with those in the tautomer B, which may be due to the increase of electron density resulting from deprotonation and nickel-to-ligand feedback after forming the planar–square complex [2,14].

3.3. Crystal structures of ligand and complex VI

3.3.1. Crystal structure of ligand

The crystal structure of the ligand together with the atomic numbering scheme is shown in Fig. 1. The O(1)–C(11) (1.221(4) Å) and N(1)–C(13) (1.271(5) Å) bond distances indicate that these correspond to typical double bonds [20,21], so the ligand in the solid state exists in the form of the tautomeric iminone A. The N(1)–N(2) bond distance is 1.395(4) Å, which is slightly shorter than the single bond distance of 1.411(7) Å [11,21]. The C–S bond distances are 1.749(4) (S(1)–C(14)) and 1.820(4) Å (S(1)–C(15)). Of the two distances, one is close to the C–S distance of 1.81 Å, while the other shows an intermediate value between the single and double bond distances, indicating partial double bond character. The S(2)–C(14) distance (1.667(4) Å) is close to the C=S distance of 1.69 Å, suggesting that this is a

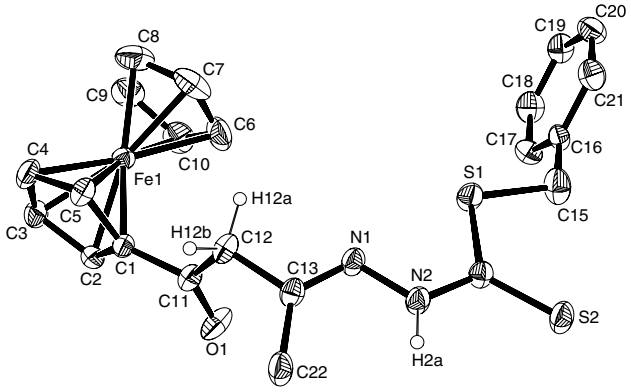

Fig. 1. Crystal structure of ligand.

double bond. Therefore, the above data indicate, that the bonding mode in the $NNCS_2CH_2Ph$ moiety is very similar to that in the S-benzyldithiocarbazate [22]. The average distance of iron to carbon in the ferrocenyl group is 2.042(4) Å and very close to 2.045 Å in ferrocene [23]. The mean C–C distances in the cyclopentadienyl rings with and without the side-chain are 1.422(5) and 1.403(7) Å and also close to 1.41 Å in ferrocene [23]. The distances of N(1)···S(1) (2.756(3) Å) and S(1)···S(2) (3.027 Å) fall in the range of the sum of van der waals radii of the corresponding two atoms (3.35 and 3.6 Å), which indicates that there is a weak interaction between the two atoms. Similarly, the distances of S(2)···H(2A) and S(2)···H(22A) show the existence of N(2)–H(2A)···S(2) and C(22)–H(22A)···S(2) intramolecular hydrogen bondings, whereas the O(1)···H(4) distance displays an O(1)···H(4)–C(4) intermolecular hydrogen bonding [24].

3.3.2. Crystal structure of complex VI

The crystal structure of the new tin complex **VI** together with the atomic numbering scheme is shown in Fig. 2. The complex consists of two monoanionic tridentate ligands ($\mathbf{HL^-}$), each of which coordinates to the Sn(II) ion via carbonyl oxygen, deprotonation enamine

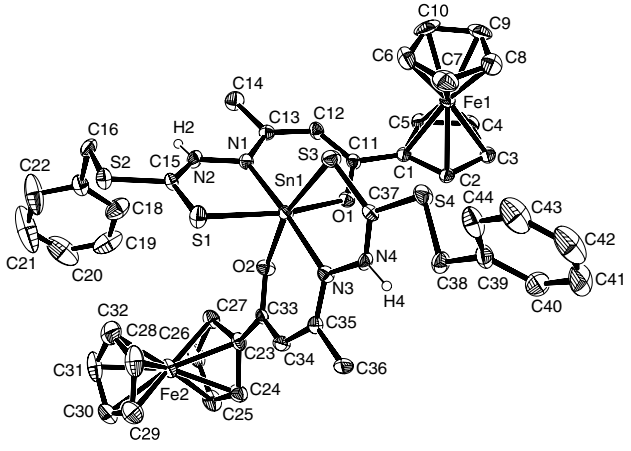

Fig. 2. Crystal structure of complex **VI**.

nitrogen and thione sulfur (ONS donor set), viz., through the deprotonated tautomer B. The coordination geometry of the central metal ion is a distorted octahedron, the bond angle of N(1)–Sn–N(3) being 172.5(2)°. The Sn–S, Sn–O and Sn–N bond distances are larger than values reported for a related complex (2.458(3), 2.396(3) and 2.187(4) Å) [25].

A comparison of the bond distances within the coordinated $\mathbf{HL}^-$ ligands shows extensive delocalization to be present. The N–N bond at mean 1.379(8) Å, which is singnificantly shorter than the single bond distance of 1.411(7) Å, is observed to have some double bond character [12,21]. More double bond character is present in the C–N bond of the $HNCS_2$ moiety as judged from its bond distance of mean 1.271(8) Å. This very clearly indicates a pronounced lone pair delocalization between carbon and nitrogen, namely the p–π conjugation. More interestingly, formal C=S and C–S bonds in the $HNCS_2$ moiety also display marked electron delocalization [12,21]. The C–N bond distances (1.348(8) and 1.333(9) Å) in the $CH{=}C(CH_3)N$ moiety are close to the value of the C–N single bond (1.335(4) Å) of the $HNCS_2$ moiety in the free ligand while the C=O bonds are longer than the corresponding bond in the free ligand [20,21]. In addition, delocalization evidence is further supported by the fact that the hybridized states of C (attached to N and O atoms) and N atoms are all sp^2. Although that the protons of thioamide $NHCS_2$ functional groups are not removed on complexation are unusual, similar cases also appear in two metal complexes of thiosemicarbazone and dithiocarbazate ligands [26,27]. The average distance of iron to carbon (2.026(7) Å) and mean C–C distances with and without side-chains (1.42(1) and 1.39(1) Å) in the ferrocenyl groups are all shorter than those in the free ligand [2]. The distance of N(2)···H(16B) (2.43 Å) indicates that there is the C(16)–H(16B)···N(2) intramolecular hydrogen bonding in complex **VI**. It is more noted that although it contains the NH group no intermolecular hydrogen bonding about the NH group in complex **VI** is observed because of the steric hindrance from the methyl and benzyl groups. However, the S(2)···H(36A) distance (2.85 Å) may display a weak S(2)···H(36A)–C(36) intermolecular hydrogen bonding [24].

3.4. IR spectra

The important IR absorptions of the ligand ($\mathbf{H_2L}$) and its complexes are given in Section 2. The ligand shows bands at ca. 3169, 1665, 1637, 1068, 1035 and 983 cm^{-1} which are assignable to ν(NH), ν(C=O), ν(C=N), ν(C=S), ν(C–S) and ν(N–N), respectively. The ν(C=N) band disappears and new bands at 1513–1622 and 1220–1287 cm^{-1}, which can be assigned to ν(C=C) and ν(C–N), are observed. For complexes **I, II, IV** and **V,** the ν(C=O) band remains nearly unchanged, whereas for complexes **III** and **VI** the corresponding band shows a significant red-shift compared with the free ligand. These facts indicate that the ligand possesses two bonding modes: as an NS bidentate bonded to Cu, Ni, Hg and Zn ions and as an ONS tridentate coordinated to Mn and Sn ions (N, deprotonation enamine nitrogen and S, thione sulfur) [12,14]. The ONS bonding mode has confirmed by the above crystal structure of complex **VI,** however efforts to grow single crystals of complex **I, II, IV** or **V** in order to further support the NS bonding mode were unsuccessful.

3.5. UV spectra

The UV spectral data of the ligand ($\mathbf{H_2L}$) and its complexes are listed in Section 2. The UV spectrum of the ligand shows two absorptions at 405 and 553 nm, which are attributable to the K-band of the skelton $[C(O)CH{=}C(CH_3)N]$ and the R-band ($n \rightarrow \pi^*$ transition) [12,18,21]. For complex **I,** the shortest wavelength absorption which is assigned as the B-band of the benzene and cyclopentadienyl rings. However, complex **V** exhibits two B-bands of the benzene and cyclopentadienyl rings. Interestingly, the K-bands in all complexes show hypsochromic shifts compared with that of the free ligand [2].

4. Summary and conclusions

Reaction of ferrocenoylacetone and S-benzyldithiocarbazate yields a new ligand ($\mathbf{H_2L}$). The ligand exists as a single iminone in the solid state while as a tautomeric mixture of the iminone and enaminone (3:2) in solution.

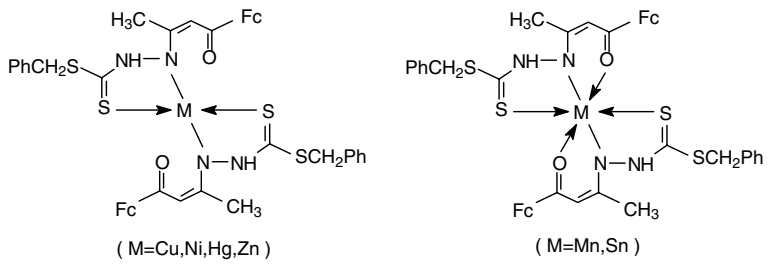

Fig. 3. Proposed structures of complexes.

Upon coordinating to the bivalent metal ion, the ligand exhibits two bonding modes (NS and ONS donor sets). In complexes **I, II, IV** and **V** (**I,** M = Cu; **II,** M = Ni; **IV,** M = Hg; **V,** M = Zn), the ligand acts as a monoanionic bidentate coordinated to the metal ion via the deprotonated enamine nitrogen and thione sulfur atoms (NS donor set) whereas in complexes **III** and **VI** (**III,** M = Mn; **VI,** M = Sn) as a monoanionic tridentate via the carbonyl oxygen, deprotonated enamine nitrogen and thione sulfur atoms (ONS donor set). Suggested structures for new complexes are shown in Fig. 3.

5. Supplementary material

Full crystallographic data (CCDC No. 213725 for ligand and CCDC No. 211558 for complex **VI**) have been deposited at the Cambridge Crystallographic Database Centre and are available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http//www.ccdc.cam.ac.uk).

Received 14 August 2003; accepted 14 October 2003

Abstract

Two new heterocyclic base adducts of copper(II) complexes of the general formula CuLB, where L is the dianion of 2-hydroxyacetophenone 4-hydroxybenzoic acid hydrazone and B is the heterocyclic base, 2,2′-bipyridine (bipy) or 1,10-phenanthroline (phen), have been synthesized and characterized by different physicochemical methods. The molar conductivity measurements in DMF solution indicate the non-electrolyte nature of both complexes. The electronic and IR spectroscopic data indicate that the complexes have square pyramidal geometry with one dibasic tridentate ligand L^{2-} and one bidentate heterocyclic base. The coordination takes place through the deprotonated hydroxyl group, azomethine nitrogen and oxygen from the hydrazide moiety. The magnetic susceptibility values at room temperature are consistent with the spin only value for monomeric copper(II) species. EPR studies of all compounds gave axial spectra. Simulation EPR spectra gave the best values for g and A for each compound. The g values indicate that the unpaired electron resides in the $d_{x^2-y^2}$ orbital. The crystal and molecular structure of CuLphen was determined by the single crystal X-ray diffraction method. Investigations on antimicrobial activities showed that the compounds are moderately active against *Gram negative* bacteria.

Keywords: Hydrazones; Copper(II) hydrazonate complexes; 1,10- Phenanthroline; 2,2′-Bipyridine; X-ray single crystal structure; EPR

1. Introduction

The chemical properties of hydrazones have been intensively investigated in several research areas because of their chelating capability and their pharmacological applications. The antibacterial and antifungal properties of bis acyl hydrazone and their complexes with some first transition metal ions was studied and reported by Carcelli et al. [1]. They have noted good activity against *Gram positive* bacteria in vitro for some of the complexes. The copper(II) complex of salicylaldehyde benzoylhydrazone was shown to be a potent inhibitor of DNA synthesis and cell growth. This hydrazone also has mild bacteriostatic activity and a range of analogues has been investigated as potential oral iron chelating drugs for genetic disorders such as thalassemia [2–4]. Intriguingly, the copper(II) complexes were shown to be significantly more potent than the metal free chelate, leading to the suggestion that the metal complex was the biologically active species. Prior to this, the ligand was found to possess mild bacteriostatic activity [5]. Because of the biological interest in these types of chelate systems, several structural studies have been carried out on its copper(II) complexes [6,7] with salicylaldehyde and its analogues. This type of diprotic ligand typically acts as a tridentate planar chelating agent coordinating through the phenolic and amide oxygens and imine nitrogen.

doi:10.1016/j.poly.2003.11.005

Acyl hydrazones of salicylaldehyde also display radioprotective properties [8], and a range of acyl hydrazones have been shown to be cytotoxic, the copper(II) complexes again showing enhanced activity.

2. Experimental

2.1. Materials

2-Hydroxyacetophenone (BDH), 4-hydroxybenzoic acid hydrazide (Fluka), 2,2′-bipyridine (S.D. Fine. Chem. Ltd), 1,10-phenanthroline (Merk) and copper(II) chloride dihydrate (BDH) were of Analar grade and used without further purification. All the solvents were dried using standard methods before use.

2.2. Preparation of ligand

4-Hydroxybenzoic acid hydrazide (1 mmol) dissolved in methanol was refluxed with a methanolic solution of 2-hydroxyacetophenone (1 mmol), in the presence of a few drops of glacial acetic acid for 6 h. On cooling the reactant media, crystals of hydrazone were separated out. The compound was recrystallised from methanol and characterized by analytical and different spectral methods (see Fig. 1).

2.3. Preparation of complexes

Mixed ligand complexes CuLB, where L is the dianion of 2-hydroxyacetophenone 4-hydroxybenzoic acid hydrazone and B is the heterocyclic base, 2,2′-bipyridine or 1,10-phenanthroline, were prepared as follows. To a hot ethanolic solution of 1 mmol of the appropriate heterocyclic base, H_2L (0.27 g, 1 mmol) a filtered solution of copper(II) chloride dihydrate (0.2 g, 1 mmol) in ethanol was added. Resultant homogeneous green solution was stirred for 2 h. The green product formed was filtered and washed with hot ethanol, followed by ether, and dried in vacuo over P_4O_{10}. The X-ray quality single crystal of CuLphen was obtained from DMF solution by slow evaporation over a period of 2 weeks.

2.4. Physical measurements and instrumentation

Elemental analyses were carried out using a Heraeus Elemental Analyzer at the Regional Sophisticated Instrumentation Center, Central Drug Research Institute, Lucknow, India. IR spectra, in the range of 4000–400 cm^{-1} were recorded on a Shimadzu DR 8001 series FTIR instrument as KBr pellets at the Regional Sophisticated Instrumentation Center, Central Drug Research Institute, Lucknow, India. Far-IR spectra were recorded in a polyethylene matrix on an IFS 66 V FT-IR spectrometer in the range 500–50 cm^{-1}. Magnetic susceptibility measurements at room temperature were made using a Vibrating Sample Magnetometer at the Indian Institute of Technology, Roorkee, India. EPR spectra were recorded in a Varian E-112 spectrometer at X-band, using TCNE as the standard at the Regional Sophisticated Instrumentation Center, Indian Institute of Technology, Bombay, India. Solid state reflectance was measured using an Ocean Optics, Inc. SD-2000 Fiber Optic Spectrometer.

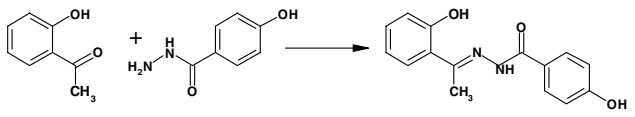

Fig. 1. Scheme of the synthesis of H_2L.

2.5. X-ray data collection, structure solution and refinement

A dark green monoclinic crystal of CuLphen having approximate dimensions $0.275 \times 0.225 \times 0.175$ mm was sealed in a glass capillary, and intensity data were measured at 212 K on an Enraf–Nonius CAD-4 diffractometer equipped with graphite-monochromated Mo Kα ($\lambda = 0.70930$ Å) radiation. The crystallographic data along with details of the structure solution refinements are given in Table 5. Unit cell dimensions were obtained using 25 centered reflections in the θ range 5.54–12.20°. The intensity data were collected by the ω-scan mode within $1.75° < \theta < 24.92°$ for *hkl* ($0 \leqslant h \leqslant 10, 0 \leqslant k \leqslant 18, -21 \leqslant l \leqslant 21$) in the monoclinic system. The trial structure was obtained by direct methods using SHELXS-97 [9], and refinement by full matrix least square on F_2 (SHELXL-97) [10]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were geometrically fixed and allowed to refine using a riding model. Absorption corrections were employed using ψ-scan ($T_{max} = 1.000$ and $T_{min} = 0.982$).

3. Results and discussion

The ^1H NMR spectrum of H_2L shows four singlets corresponding to $-^1OH$, –NH, $-^2OH$ and $-CH_3$ (see Fig. 2). The singlet at $\delta = 13.3$ ppm and $\delta = 11.1$ ppm represent $-^1OH$ and $-^3NH$, respectively. The signal for $-^1OH$ is obtained downfield due to the possibility of the formation of intramolecular hydrogen bonding with the azomethine nitrogen. Upon addition of D_2O the intensities of both OH and NH protons significantly decrease. This supports the assignment. The peak at $\delta = 10.2$ ppm is assigned to the $-^2OH$ which is also an exchangeable proton. Another singlet is at $\delta = 2.5$ ppm which represents the aliphatic $-CH_3$. The aromatic protons appear as multiplets at 6.9–7.9 ppm.

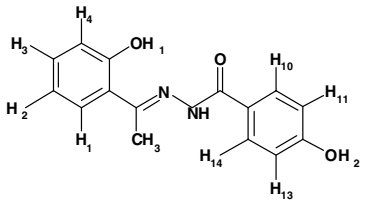

Fig. 2. Formula of H_2L.

The colors, elemental analyses, stoichiometries of H_2L and its complexes are presented in Table 1. The elemental analyses data are consistent with a 1:1:1 ratio of the metal ion:hydrazone:heterocyclic base for the complexes prepared. The complexes are insoluble in most common polar and non-polar solvents. They are soluble in DMF and DMSO. The conductivity measurements in DMF showed that the complexes are non-electrolytes.

The magnetic moment in the polycrystalline state at 300 K of the complexes were found to be 1.85–1.93 BM, which are consistent with the spin only values for mononuclear d^9 copper(II) systems [11].

3.1. EPR spectra

The EPR parameters obtained for the complexes in frozen DMF solution are presented in Table 2.

The EPR spectra of the Cu(II) complexes in frozen DMF solution (77 K) gave axial spectra (see Fig. 4). The spectra of the complexes consist of four well defined hyperfine lines due to copper nuclei in the parallel region. However, for CuLphen the four line hyperfine splitting due to the copper nucleus is observed in the perpendicular region also. The super hyperfine splitting due to coordinated nitrogen is not visible for both the complexes. The $g_{\|} > g_{\perp}$ value suggest a distorted square pyramidal structure and rules out the possibility of a trigonal bipyramidal structure which would be expected to have $g_{\perp} > g_{\|}$. Thus, the polyhedron consists of one phenanthroline/bipyridine nitrogen, azomethine nitrogen, phenolate oxygen and enolate oxygen of hydrazone which form the base of the pyramid, and the remaining nitrogen of the heterocyclic base occupies the apical position of the square pyramid [12,13]. EPR spectra are simulated to get accurate values of various magnetic parameters. The energies of d–d transitions were used to evaluate the bonding parameters α^2, β^2 and γ^2 which

Table 2
EPR and bonding parameters of copper(II) complexes

	CuLphen	CuLbipy
$g_{\|}$	2.2402	2.2194
$g_{\perp}$	2.0586	2.0481
$g_{av/iso}$	2.1193	2.1052
$A_{\|}$ (cm^{-1})	186.2×10^{-4}	175.1×10^{-4}
$A_{\perp}$ (cm^{-1})	13.6×10^{-4}	13.5×10^{-4}
$A_{av/iso}$ (cm^{-1})	68.1×10^{-4}	64.9×10^{-4}
G	4.09	4.562
α^2	0.818	0.764
β^2	0.936	0.955
γ^2	0.911	0.882
K_0	0.313	0.297
$K_{\|}$	0.767	0.731
$K_{\perp}$	0.74	0.674
f (cm)	120.24	126.70

may be regarded as measures of covalency of in-plane σ bonds, in-plane π bonds and out-of-plane π bonds, respectively (see Fig. 3).

The geometric parameter, $G = (g_{\|} - 2/g_{\perp} - 2)$, for axial spectra measures the exchange interaction between copper(II) centers in the polycrystalline state. If $G > 4.0$, the exchange interaction is negligible and if it is less than 4.0 considerable exchange interaction is indicated. In this complex $G = 4.09$ to 4.56 indicating the exchange interaction is negligible. The observed g values in the complex lie above 2.040 with $G > 4.0$, which are consistent with a $d_{x^2-y^2}$ ground state and with square base pyramidal stereochemistry [14,15]. The relatively high

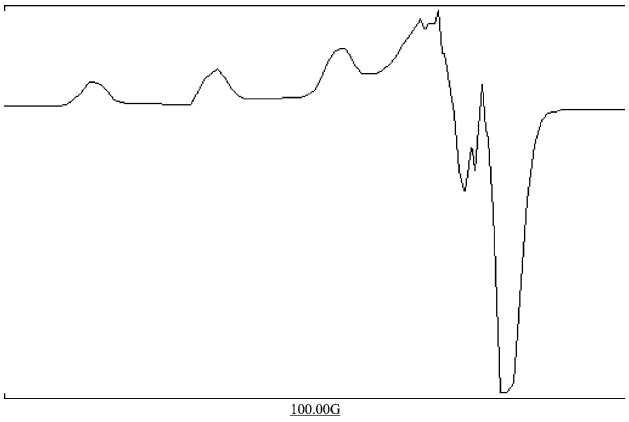

Fig. 4. Solution EPR spectra of CuLphen at 77 K.

values of $A_{\parallel}$ ($>150 \times 10^{-4}$ cm^{-1}) suggests small axial interaction [16].

The value of the in-plane π bonding parameter α^2 can be estimated from the expression and is found to be ~0.78:

$$\alpha^2 = -A_{\parallel}/0.036 + (g_{\parallel} - 2.0023) + 3/7(g_{\perp} - 2.0023) + 0.04.$$

The orbital reduction factors $K_{\parallel} = \alpha^2\beta^2$ and $K_{\perp} = \alpha^2\gamma^2$ were calculated using the following expressions:

$$K_{\parallel}^2 = (g_{\parallel} - 2.0023)\Delta E(d_{xy} \rightarrow d_{x^2-y^2})/8\lambda_0,$$

$$K_{\perp}^2 = (g_{\perp} - 2.0023)\Delta E(d_{xz,yz} \rightarrow d_{x^2-y^2})/2\lambda_0,$$

where λ_0 is the spin–orbit coupling constant and is of the value −828 cm^{-1} for a copper(II) d^9 system.

According to Hathaway for pure σ bonding $K_{\parallel} \approx K_{\perp} \approx 0.75$, for in-plane π bonding $K_{\parallel} < K_{\perp}$, while for out-of-plane π bonding $K_{\parallel} > K_{\perp}$. In this complex, $K_{\parallel} > K_{\perp}$ indicates stronger out-of-plane π bonding. The metal–ligand in-plane σ bond is purely ionic if α^2 is unity. The trend of the β^2 value is opposite to that observed for α^2, indicating the competitive mechanism of in-plane σ and π bonding. The value of γ^2 shows there is appreciable out-of-plane π bonding, which is further supported by $K_{\parallel} > K_{\perp}$.

The Fermi contact hyperfine interaction term, which is the measure of contribution of the s electron to the hyperfine interaction, can be estimated from the expression:

$$K_0 = A_{iso}/P\beta^2 + (g_{av} - 2.0023)/\beta^2,$$

where P is the free ion dipolar term and its value is 0.036. K_0 is a dimensionless quantity and is generally found to have a value of 0.30. The K_0 value obtained is in good agreement with the theoretical one, indicating the mixing of the 4s orbital with the d orbital possessing an unpaired electron.

The empirical factor $f = g_{\parallel}/A_{\parallel}$ is an index of tetragonal distortion, and is calculated as 120.24 cm for CuLphen and 126.70 cm for CuLbipy. The value may vary from 105 to 135 for small to extreme distortion. The f values for the compounds indicate a medium distortion from the square pyramidal geometry. The greater tetrahedral distortion may be due to the flexible structure or the in vivo environment in which the complex is located in the solvent system. Recent studies have shown that the biological activity is related to the geometry at the metal site in terms of SOD like activity. The compounds with more tetrahedral distortion are reported to display higher activity [17–19].

3.2. Electronic spectra

The significant electronic absorption bands in the spectra of the complexes recorded in the solid state are presented in Table 3. The hydrazone ligands have $\pi \rightarrow \pi^*$ at 42 553 and $n \rightarrow \pi^*$ at 31 746 cm^{-1}. A second $n \rightarrow \pi^*$ band is found at 27 778 cm^{-1}. There is a slight shift in these bands during complexation. The charge transfer maxima range from 21 978 to 28 736 cm^{-1} for the complexes and may be assigned to an $O \rightarrow Cu$ charge transfer transition, LMCT [20]. The d–d absorption maxima range from 16 394 to 11 560 cm^{-1} and tend to be indicative of tetragonal geometries [21,22].

3.3. IR spectra

The tentative assignment of H_2L, CuLphen and CuLbipy are presented in Table 4. The peak at 1610 cm^{-1} corresponding to ν(C=N) in the IR spectrum of uncomplexed hydrazone shifts to ~1592 cm^{-1} upon complexation indicating azomethine nitrogen coordination [12,13,23]. Further proof for the complexation for azomethine nitrogen is obtained from the appearance of a new band ~423 cm^{-1} which is assignable for the ν(Cu–N) for the complexes. The increase in ν(N–N) in the spectra of the complexes from 1001 to ~1020 cm^{-1}, is due to the increase in the double bond character offsetting the loss of electron density via donation to metal and is a further confirmation of coordination of the ligand through the azomethine atom. The spectral band of ν(N–

H) of hydrazone disappears in the complexes indicating the deprotonation of the N–H proton and coordination via the enol oxygen. The IR spectra show a sharp band at ~1500 cm^{-1} which indicates the newly formed uncomplexed N=C by enolisation, confirming the coordination of hydrazone takes place in the form of the enol rather than the keto form. The loss of the OH proton is indicated by the absence of a band at ~3400 cm^{-1} in the complexes. The ν(C–O) also decrease from 1279 to ~1240 cm^{-1} when compared to the uncomplexed ligand. The fourth and fifth positions are occupy by the nitrogen atoms of the heterocyclic bases, these ν(Cu–N) bands are assigned to the 400–291 cm^{-1} region, indicated by the heterocyclic ring breathing in the fingerprint region of 1400–600 cm^{-1}. The second OH group in the aromatic ring remains uncomplexed indicated by a band at ~3057 cm^{-1} in the complexes (see Fig. 5).

3.4. Crystal structure of CuLphen

The molecular structure of the complex along with selected bond angles and bond lengths are summarized in Tables 5 and 6. The compound crystallized in a monoclinic lattice with a space group $P2_1/c$. The unit cell volume contains four molecules. The copper in the

mononuclear complex is five coordinate and has approximate square pyramidal geometry. The basal coordination positions (see Fig. 6) are occupied by the phenolato oxygen O(1), azomethine nitrogen N(3), enolate oxygen O(2) of the hydrazone, and phen nitrogen N(1). The apical position occupied by the second nitrogen of phen N(2) is at a larger distance than compared to N(1). The four basal atoms are coplanar showing a significant distortion from square geometry indicated by the O(1)–Cu(1)–O(2) bond angle. The central copper atom is displaced from the basal plane in the direction of the axial nitrogen, which is evident from the bond angles of N(1)–Cu(1)–N(3) and O(1)–Cu(1)–N(3). The bond angles O(1)–Cu(1)–N(2), N(1)–Cu(1)–N(2) and N(3)–Cu(1)–N2 indicate the distortion from the perfect square pyramidal geometry. One of the reasons for the deviation from an ideal stereochemistry is the restricted bite angle imposed by both the L and phen ligands. The O(1)–Cu(1)–N(2) bond angle is 101.34° and the O(2)–Cu(1)–N(2) bond angle is 95.79° indicating a slight tilting of the axial Cu(1)–N(2) bond in the direction of the O(2)–Cu(1) bond, away from the O(1)–Cu(1) bond. The variation in Cu(1)–N(1), Cu(1)–N(2), and Cu(1)–N(3) bond lengths indicate the different strength of the bond formed by each of the coordination nitrogen atoms. The difference in bond lengths can be attributed the difference in extent of π back donating between the phen and hydrazone moieties [13]. The packing of the complex is stabilized by intermolecular hydrogen bonding interactions and C–H π interaction between the atoms (see Fig. 7). The H-bonding parameters are listed in Tables 7 and 8.

3.5. Biological activities

The synthesized chemical ligands and complexes were tested for their antimicrobial activity. The antimicrobial agent may be either bacteriostatic or bactericidal. The effectiveness of an antimicrobial agent in sensitivity testing is based on the size of the zones of inhibition when the test substances are introduced onto a lawn of bacterial culture by the disc diffusion method.

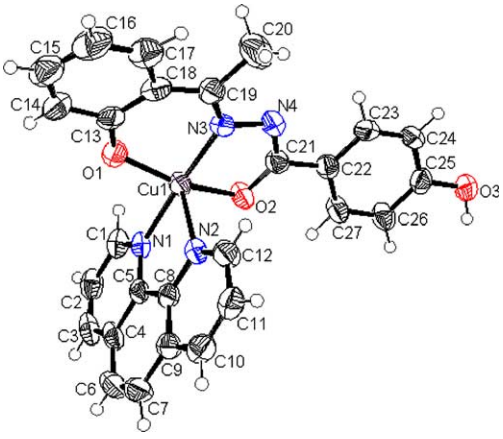

Fig. 6. A view of the compound CuLphen with the atom numbering scheme. Displacement ellipsoids are drawn at the 50% probability level and hydrogen atoms are shown as small spheres of arbitrary radii.

Abstract

The kinetics of the reduction a copper(III)–imine–oxime complex $[Cu^{III}L]^+$ ($H_2L = 3,9$-diethyl-4,8-diaza-3,8-undecadiene-2,10-dione dioxime) by catechol (H_2Cat), *p*-methoxyphenol (*p*MHP), hydroquinone (H_2Q), 2-methylhydroquinone (MH_2Q), and 2-chlorohydroquinone (ClH_2Q), have been studied in aqueous acidic solutions. The rate law showed a first order dependence on both the oxidant and the reductant. The second-order rate constant, k_2, for H_2Q, MH_2Q and *p*MHP decreased with increasing pH over the entire range studied. Both H_2Cat and ClH_2Q showed complex behavior, and in theses cases k_2 decreases then increases with increasing pH. The complex pH dependence is interpreted in terms of the involvement of protonated and deprotonated reactants in the rate determining step. In the case of H_2Cat not only one, but two protons are lost from the diol in the rate-determining step in the high pH range. It is very unlikely that the doubly deprotonated species Cat^{2-} is formed to an appreciable extent at pH < 5 ($pK_{a2} = 13$). It was therefore necessary to invoke an interaction between $[Cu^{III}L]^+$ and $HCat^-$ in which the high charge on Cu^{III} facilitates the loss of the second proton. It seems that the proximity of the OH in the ortho position is important as none of the other diols showed an inverse second-order dependence on $[H^+]$. The oxidation of deprotonated H_2Cat is believed to proceed by an inner-sphere mechanism. Observed rate constants for the pathway showing a first-order dependence on $[H^+]$ correlate well with those calculated from the Marcus equation.

1. Introduction

The oxidation of 1,2- and 1,4-dihydroxybenzene and their derivatives has been the subject of many reports. These compounds are well characterized as two-electron reducing agents and are important in biological transport systems [1]. The availability of varying substituent groups on the benzene ring provides a wide range of reduction potentials [2]. This has facilitated the examination of Marcus theory [3] for outer-sphere electron transfer over several orders of magnitude of rate constants. Outer-sphere electron transfer mechanisms were proposed in the reduction of the substitution inert complexes $[Fe^{III}(NN)_3]^{3+}$ (NN = 1,10-phenanthroline or 2,2′-bipyridine), $[Ir^{IV}Cl_6]^{2-}$, $[Co^{III}(H_2O)_6]^{3+}$, $[Mo^{V}(CN)_8]^{3-}$, $[Fe(CN)_6]^{3-}$, $[Ni^{III}cyclam]^{3+}$ (cyclam = 1,4,8,11-tetraazacyclotetradecane) and $[Ni^{IV}N_6]^{2+}$ (N_6 = 3,14,-dimethyl-4,7,10,13-tetraazahexadeca-3,13-diene-2,15-dione dioxime) [4–9]. The aqua metal ions Fe^{III}, Mn^{III}, and Tl^{III}, were also used to oxidize 1,2- and 1,4-dihydroxybenzene and their derivatives [10–13]. A number of kinetic studies involving monomeric and mixed-valent manganese complexes have

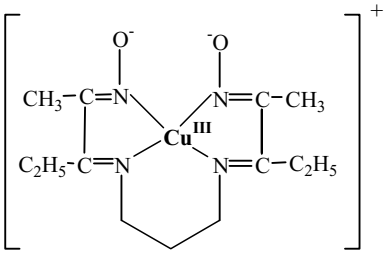
doi:10.1016/j.poly.2003.10.011

been reported using H_2Q and H_2Cat [14–16]. Both outer- and inner-sphere mechanisms seem to be operative depending on the nature of the oxidant. It was not always possible to assign definitively either an outer- or an inner-sphere mechanism for some of the systems despite the fact that linear free energy relationships were obtained between $\Delta G^{\#}$ and ΔG^0. Marcus theory for outer-sphere electron transfer was reported to be applicable to weak inner-sphere electron transfer as well as for hydrogen atom transfer reactions [17,18].

Margerum and coworkers initially proposed that Cu^{III}–peptide complexes undergo electron transfer via an outer-sphere mechanism [19]. Applying Marcus's theory for outer-sphere electron transfer, the self-exchange rate constant for $Cu^{III/II}$–peptide couples was estimated as 7×10^7 M^{-1} s^{-1}. Direct measurement of the self-exchange rate constant of $Cu^{III/II}$–peptide couples using ^1H NMR broadening gave a value of $\sim 5.5 \times 10^5$ M^{-1} s^{-1}, which is below that calculated using the Marcus theory by about two orders of magnitude. It was, therefore, concluded that in reactions where a bridging ligand is available, as in the cases of $[Ir^{III}Cl_6]^{3-}$ and $[Fe^{II}(CN)_6]^{4-}$, electron transfer proceeds via a weak inner-sphere pathway [20,21].

We have previously reported that Cu^{III} is stabilized by tetradentate imine–oxime ligands [22].



(I)

In this work we report the results of the kinetic study of the reduction of Cu^{III}–imine–oxime complex (**I**) by 1,2-dihydroxybenzene (H_2Cat), 1,4-dihydroxybenzene (H_2Q), 2-chloro-1,4-dihydroxybenzene (ClH_2Q), 2-methy-1,4-dihydroxybenzene (MH_2Q) and *p*MHP in weakly acidic solutions.

Cyclic voltammetry has shown that complex (**I**) undergoes a reversible one-electron transfer according to Eq. (1).

$$[Cu^{III}L]^+ + H^+ + e \rightleftharpoons [Cu^{II}HL]^+ \quad (1)$$

The reduction potential E^0 obtained from a linear plot of E against pH was found to be 1.16 V at 25 °C (versus n.h.e., normal hydrogen electrode). The reduction potential E^0 of (**I**) in the region where E is independent of pH (Eq. (2)) was determined as 0.51 V [22].

$$[Cu^{III}L]^+ + e \rightleftharpoons [Cu^{II}L] \quad (2)$$

2. Experimental

2.1. Materials

The syntheses of the imine–oxime ligand and Cu^{II}–imine–oxime complex have been reported previously [22]. Stock solutions of the Cu^{II} complexes were prepared by weight. The Cu^{III} complex was generated by chemical oxidation of buffered solutions of the Cu^{II} complex by PbO_2 immediately before each kinetic run. 1,2-Dihydroxybenzene (BDH) was recrystallized from toluene and washed with ether. 1,4-Dihydroxybenzene (BDH), and 2-methy-1,4-dihydroxybenzene (Aldrich Gold label) were used as received. 2-Chloro-1,4-dihydroxybenzene (BDH) and *p*MHP were recrystallized from petroleum ether. Stock solutions of the reductants were prepared by weight in oxygen-free distilled water and were used in the same day. Buffer solutions were prepared using $CH_3CO_2H/NaCH_3CO_2$ or $HNO_3/NaCH_3CO_2$. The ionic strength was maintained at 0.10 M using $NaNO_3$. The concentration of the $CH_3CO_2^-$ ion was always maintained at 0.01 M. The UV–Vis absorption spectrum of the Cu^{III} complex showed no noticeable change when recorded using 0.09 M $NaNO_3$ and 0.01 M acetate buffer; the typical concentrations used in maintaining ionic strength. The pH of the reaction mixture was measured using a Radiometer digital pH meter Model PHM 62.

The stoichiometry of each reaction was determined spectrophotometrically by the addition, at pH 4.60, of known amounts of the reductant to excess Cu^{III}. The unreacted Cu^{III} was then determined spectrophotometrically. Kinetic measurements were carried out under pseudo-first order conditions with the reductant concentrations being at least $\geqslant$10-fold excess over that of the Cu^{III} complex. The reactions were followed by monitoring the disappearance of Cu^{III} at λ_{max} (518 nm) using a thermostated Hi-Tech stopped-flow spectrophotometer Model SF.3L. The signal and trigger pulse from the stopped-flow were fed into a DL-901 transient recorder, where the information was stored in the memory in digital form and displayed continuously on an oscilloscope. The transient recorder was interfaced with a Hewlett–Packard 9825 B desktop calculator that was used to analyze the absorbance data. At all pH values, plots of $\ln(A_t - A_\infty)$ against time were linear for at least three half-lives.

3. Results and discussion

The stoichiometry of the reduction the Cu^{III}–imine-oxime complex (**I**), by each of the four benzene diols and *p*-methoxyphenol, in mildly acidic solutions indicates that 1.95 ± 0.06 mol of each Cu^{III} is consumed by 1 mol of the reductant. This is consistent with the reduction of

Cu^{III} complex to the corresponding Cu^{II}–imine–oxime complex and the formation of the dehydro-derivatives of the diols and *p*-methoxyphenol. The formation of the product quinones was confirmed spectrophotometrically. The overall reactions may be represented by Eq. (3) where H_2A represents any of the reductants and A the corresponding quinone.

$$2[Cu^{III}L]^+ + H_2A \rightarrow 2[Cu^{II}HL]^+ + A \quad (3)$$

Pseudo-first order plots, using excess of reductant, were linear to beyond three half-lives. The magnitudes of the pseudo-first order rate constants at fixed pH, ionic strength and temperature, are independent of the initial concentration of Cu^{III} complex (Table 1). Fig. 1 shows the linear dependence of k_{obs} on the reductant concentration. The rate law for the reduction of the Cu^{III} complex at constant reaction conditions obeyed Eq. (4).

$$-d[Cu^{III}L^+]/dt = 2k_2[Cu^{III}L^+][H_2A]_T \quad (4)$$

The overall second order rate constant k_2 ($k_2 = k_{obs}/2[H_2A]_T$) was measured at 25.0 ± 0.1 °C over a wide pH range. The effect of pH on k_2 is complex and depends on both the reductant and Cu^{III} complex. In the reduction of complex (**I**) by H_2Q, MH_2Q and *p*MPH, k_2 decreases with increasing pH over the entire range studied for each reductant, 2.07–4.82, 2.68–5.25 and 1.19–4.83 respectively. In the reduction of (**I**) by both ClH_2Q and H_2Cat, k_2 increases with decreasing pH below 3.94 and 3.73, respectively. Above these pH values, k_2 increases with increasing pH. This behavior is consistent with the lower pK_{a1} values of ClH_2Q and H_2Cat and it seems that deprotonated species of these reductants are involved in the redox reactions (Table 3).

Fig. 2 shows a variation of k_2 with $[H^+]$ for the reduction of (**I**) by H_2Q and MH_2Q in the lower pH range. Similar plots were obtained for the reduction of (**I**) by the other three reductants. The dependence k_2 on $[H^+]$, in the lower pH range for the reduction of (**I**) obeys Eq. (5).

$$k_2 = k_3 + k_4[H^+] \quad (5)$$

Values of k_3 and k_4, obtained from the intercepts and slopes respectively of plots of k_2 against $[H^+]$, are collected in Table 2. The values of k_3 showed high degree of uncertainty. The dependence of k_2 on $[H^+]$, in the higher pH range for the oxidation of ClH_2Q by (**I**) obeys Eq. (6), and a plot of k_2 against $[H]^{-1}$ is shown in Fig. 3. Values of k_5 and k_6 obtained from the intercept and slope of Fig. 3, respectively are collected in Table 2.

$$k_2 = k_5 + k_6[H^+]^{-1} \quad (6)$$

The oxidation of H_2Cat by (**I**) showed a more complex behavior over the high pH range. The dependence of k_2 on $[H^+]$ obeys Eq. (7) and a polynomial fit of the results is shown in Fig. 4. Values of k_7, k_8 and k_9 obtained from the polynomial plot are collected in Table 2.

$$k_2 = k_7 + k_8[H^+]^{-1} + k_9[H^+]^{-2} \quad (7)$$

A full reaction sequence for the reduction of complex (**I**) by the reductants H_2Q, MH_2Q, Cl_2H_2Q and *p*MHP may be described by Eqs. (8)–(13).

$$[Cu^{III}L]^+ + H^+ \rightleftharpoons [Cu^{III}HL]^{2+} \quad K_1 \quad (8)$$

Table 1
Dependence of k_{obs} on the initial concentration of complex (**I**) at $[H_2Q] = 1.26 \times 10^{-3}$, pH 4.08, $\mu = 0.10$ M ($NaNO_3$), $T = 25.0 \pm 0.1$ °C

10^5 [Cu^{III}] (M)	k_{obs} (s^{-1})

$$H_2A \rightleftharpoons HA^- + H^+ \quad K_a \tag{9}$$

$$[Cu^{III}HL]^{2+} + H_2A \xrightarrow{k_a} [Cu^{II}HL]^+ + H_2A^{\cdot +} \tag{10}$$

$$[Cu^{III}HL]^{2+} + HA^- \xrightarrow{k_b} [Cu^{II}HL]^+ + HA^{\cdot} \tag{11}$$

$$[Cu^{III}L]^+ + H_2A \xrightarrow{k_c} [Cu^{II}L] + H_2A^{\cdot +} \tag{12}$$

$$[Cu^{III}L]^+ + HA^- \xrightarrow{k_d} [Cu^{II}L] + HA^{\cdot} \tag{13}$$

The semiquinone radicals produced in Eqs. (10)–(13) react rapidly with another Cu^{III} complex species to produce the corresponding quinones. The rate law for the disappearance of complex (**I**) is given by Eq. (14).

$$\frac{-d[Cu^{III}L^+]}{dt} = \frac{2\{k_aK_1[H^+] + k_bK_1K_a + k_c + k_dK_a[H^+]^{-1}\}[Cu^{III}L^+]_T[H_2A]_T}{(1 + K_1[H^+])(1 + K_a/[H^+])} \tag{14}$$

In the low pH range, where the reductants are undissociated, $1 \gg K_a/[H^+]$; and if $1 \gg K_1[H^+]$ and only reactions (10) and (12) are important, the dependence of k_2 on $[H^+]$ is given by Eq. (15) which has the same form as that of Eq. (5). From Eqs. (5) and (15) it can be seen that $k_3 = k_c$ and $k_4 = k_aK_1$

$$k_2 = k_c + k_aK_1[H^+] \tag{15}$$

In the higher pH range reactions (11) and (13) are expected to dominate. The lower reduction potentials of deprotonated HA^- would facilitate the oxidation of these substrates and their rates of oxidation were observed to be several orders of magnitude higher than those of H_2A by the same oxidant [9]. The condition that $1 \gg K_a/[H^+]$ and $1 \gg K_1[H^+]$ seems to hold also at the higher pH range for the oxidation of ClH_2Q. The dependence of k_2 on $[H^+]$, given by Eq. (16), is similar to that shown in Eq. (6), with $k_5 = k_bK_1K_a$ and $k_6 = k_dK_a$. The value of K_{a_1} has been estimated as 4.6×10^{-9} M, using the approach of Perrin et al. [23]. Values of pK_a obtained using this approach are in fairly good agreement with experimental results. The lower pK_a values calculated for ClH_2Q are consistent with the known electron withdrawing property of the Cl substituent. The value of k_d can be obtained from the relation $k_d = k_6/K_a$

Table 3
Proton equilibrium constants and reduction potentials for the benzene diols and *p*-methoxyphenol

Reductant	pK_{a1}	pK_{a2}	E_1 (V)	E_2 (V)
MH_2Q	10.05	11.6	1.02	0.38
H_2Q	9.85	11.4	1.06	0.45
*p*MHP[a]	10.21		1.11	
ClH_2Q	8.34[b]	10.57[b]	1.09	0.41[c]
H_2Cat	9.24	13.00	1.12	0.49

Unless otherwise mentioned the values are taken from [9].
[a] Ref. [26].
[b] pK_{a1} and pK_{a2} calculated using [23] (agreement with experimental values is within ±10%).
[c] E_2 calculated using Marcus equation.

$$\frac{-d[Cu^{III+}]}{dt} = \frac{2\{k_aK_1[H^+] + k_bK_1K_a + k_c + k_eK_aK_2[H^+]^{-1} + k_fK_aK_2K_3[H^+]^{-2}\}[Cu^{III}L^+]_T[H_2A]_T}{(1 + K_1[H^+])(1 + K_a/[H^+])} \quad (21)$$

as 6.8×10^6 M^{-1} s^{-1}. The reduction potential of $ClHQ^-$/$ClHQ^{\cdot}$ couple is not known and has been estimated using the value of k_d and $k_{22} = 2 \times 10^6$ M^{-1} s^{-1} as 0.41 V. This value seems to be in fairly good agreement with the values obtained for the other HA/HA$^{\cdot}$ couples (Table 3).

$$k_2 = k_bK_1K_a + k_dK_1[H^+]^{-1} \quad (16)$$

Reactions of the protonated Cu^{III} complex are much more rapid than those of the unprotonated form. This in agreement with reactions involving the protonated and unprotonated Ni^{III} complex ($[Ni^{III}HL]^{2+}$) and $[Ni^{III}L]^+$) with H_2Q, H_2MQ and H_2Cat, where the former was found to be more reactive than the latter [9]. It is to be noted that both ClH_2Q and H_2Cat because of their lower first pK_a values dissociate more readily than the other reactants and show an increase in reaction rate with increasing pH.

The oxidation of H_2Cat in the lower pH range can be described by Eqs. (8)–(12). However, over the high pH range the oxidation of H_2Cat by complex (**I**) can be described by Eqs. (17)–(20).

$$[Cu^{III}L]^+ + HA^- \rightleftharpoons [Cu^{III}LHA] \quad K_2 \quad (17)$$

$$[Cu^{III}LHA] \rightleftharpoons [Cu^{III}LA]^- + H^+ \quad K_3 \quad (18)$$

$$[Cu^{III}LHA] \xrightarrow{k_e} [Cu^{II}L] + HA^{\cdot} \quad (19)$$

$$[Cu^{III}LA]^- \xrightarrow{k_f} [Cu^{II}L] + A^{\cdot -} \quad (20)$$

The mechanism represented by reactions (11) and (13) does not explain the inverse second order dependence on $[H^+]$. This may arise from the involvement of completely deprotonated H_2Cat. It is very unlikely that H_2Cat loses both protons in the pH range investigated. For the second proton to be lost, it is necessary to invoke an interaction with the Cu^{III} complex. An increase in the acidity of the proton of the second OH group may be due to coordination the monodeprotonated $HCat^-$ to the positively charged Cu^{III} complex. It is very likely that these processes involve an inner-sphere mechanism in which the oxygen of the deprotonated hydroxyl group coordinates axially to the Cu^{III} complex. The formation of a five-coordinate species in the transition state is plausible as low-spin d^8 square planar complexes are known to undergo substitution reactions by an associative mechanism [24].

The rate law given by Eq. (21) is obtained by considering the scheme (8)–(12) together with (17)–(20).

From Eq. (21) it can be seen that in the high pH range, where reactions (11), (12), (19) and (20) are important, the variation of the second-order rate constant varies with $[H^+]$ according to Eq. (22). Under conditions where $1 > K_1[H^+]$ and $1 > K_a/[H^+]$.

$$k_2 = \{k_bK_1K_a + k_c + k_eK_aK_2[H^+]^{-1} + k_fK_aK_2K_3[H^+]^{-2}\} \quad (22)$$

Eq. (22) is of the same form as Eq. (7), with $k_7 = k_bK_1K_a + k_c$, $k_8 = k_eK_aK_2$, and $k_9 = k_fK_aK_2K_3$. The values of k_7, k_8 and k_9, obtained from the polynomial fit shown in Fig. 4 are: 464 M^{-1} s^{-1}, 4.21×10^{-2} s^{-1} and 2.87×10^{-6} M s^{-1}, respectively. The values of K_2 and K_3 are not known and it was not possible to calculate the values of k_e and k_f.

The rate constants are observed to increase with the decrease in the reduction potentials of the semiquinone radicals. Such observations have previously been used as an indication for the operation of an outer-sphere electron transfer mechanism in the rate-determining step [2]. Marcus theory for outer-sphere electron transfer has been utilized to rationalize the relationship between the rate constant for a cross-reaction, k_{12}, and the self-exchange rate constants for the oxidant (k_{11}) and reductant (k_{22}) reactions, and the equilibrium constant for the cross-reaction K_{12}. In its simplest form Marcus relationship is given by Eqs. (23) and (24) and Z is the collision frequency in solution, usually taken as 10^{11} s^{-1}.

$$k_{12} = (K_{12}k_{11}k_{22}f)^{1/2}, \quad (23)$$

$$\log f = (\log K_{12}/4\log(k_{11}k_{22}/Z^2). \quad (24)$$

The self-exchange rate constant k_{11} for complex (**I**) has previously been estimated as $\sim 5 \times 10^5$ M^{-1} s^{-1} [25]. Reported estimates of the self-exchange rate constants

Table 4
Calculated and observed rate constants for the reaction $[Cu^{III}HL]^{2+} + H_2A \rightarrow [Cu^{II}HL]+H_2A^{\cdot +}$

H_2A	k_{obs}[a] ($M^{-2}\,s^{-1}$)	k_{calc} ($M^{-1}\,s^{-1}$)
MH_2Q	6.00×10^7	6.38×10^{7b}
H_2Q	2.73×10^7	3.18×10^{7c}
ClH_2Q	5.21×10^6	3.80×10^{6d}
pMPH	2.61×10^6	2.60×10^{6d}
H_2Cat	1.85×10^6	2.13×10^{6d}

[a] k_{obs} is k_4 (k_2 at $[H^+] = 1.0$ M).
[b] $f = 0.7$.
[c] $f = 0.8$.
[d] $f = 0.9$.

of the hydroquinone/semiquinone couples (k_{22}), for both neutral and anionic species, vary over the 2×10^6–5×10^7 $M^{-1}\,s^{-1}$ range [2]. The value of K_{12} for each cross-reaction was calculated from the known reduction potentials of $Cu^{III/II}$ and the hydroquinone/semiquinone couples [9,26] and these are collected in Table 4. It is to be noted that the reduction potentials reported for $H_2A/H_2A^{\cdot +}$ show some variation and are not known with certainty. Thus for $H_2Q/H_2Q^{\cdot +}$, the reported reduction potential covers the range 1.02–1.09 V [9,26]. It was found that using the average value of 1.06 V for H_2Q gives a better result for the reaction reported here. In the application of Marcus theory the value of k_2 at $[H^+] = 1.0$ M (k_4 in Eq. (5)) was used. The values of the cross-reaction rate constants were calculated using $k_{22} = 5 \times 10^7$ $M^{-1}\,s^{-1}$. This value gave reasonably good results with MH_2Q and H_2Q as shown in Table 4. However, using this value for H_2Cat, ClH_2Q and *p*MPH, the calculated value for each reductant is much higher than the experimental value. Good agreement was obtained between the calculated and the experimental values as shown in Table 4 by using $k_{22} = 2 \times 10^6$ $M^{-1}\,s^{-1}$. It thus seems that 1,4-dihydroxybenzene and its derivatives with electron donating substituents have an exchange rate constant $k_{22} \sim 5 \times 10^7$. The exchange rate constant $k_{22} \sim 2 \times 10^6$ seems to be applicable to derivatives of 1,4-dihydroxybenzene with electron withdrawing substituents, as well as for 1,2-dihydroxybenzene and its derivatives [2a].

The rate constants obtained from the slope of Eq. (5) only were used in testing Marcus equation as the values obtained from the intercepts are less reliable. The agreement between the calculated and experimental values does not completely rule out an inner-sphere mechanism as the OH of the diol can form a weak bond with Cu^{III} in the axial position.

Received 16 July 2003; accepted 21 October 2003

Abstract

Four new ruthenium polypyridyl complexes with mono- or di-((2-thienyl) ethenyl) substituted bipyridines have been synthesized. The complexes were characterized by NMR, elemental analysis, UV–Vis absorption and electrochemistry (differential pulse and cyclic voltammetry). Electroactive polymer films of these complexes have been prepared by oxidative electropolymerisation and characterized by UV–Vis absorption spectroscopy and electrochemistry. The electrochemically induced polymerisation of the complexes resulted in a significant shift of the oxidation potential of the Ru(II)–Ru(III) process towards more positive potentials. Also, MLCT absorption band of the polymeric complexes is shifted towards shorter wavelengths. These results are interpreted in terms of an interruption of the conjugated system of the (2-thienyl)ethenyl-substituted bipyridine ligands due to a radical polymerisation mechanism affecting rather the ethenyl part of the ligand than the thienyl.

1. Introduction

Nano-structured dye-sensitized photoelectrochemical solar cells (NSCs) and solar cells based on conjugated polymers are considered as promising routes to decrease significantly the price of electricity by means of solar power in the future [1,2]. Moreover, these types of solar cells have features like flexibility and lightweight, which give them an even higher market potential. Nevertheless, polymer-based solar cells are currently using either Buckminsterfullerenes or polymers as electron acceptors which is costly or triggers stability problems. On the other side, the highly efficient nano-structured solar cells based on TiO_2 as electron acceptor are incorporating liquid electrolytes for the transport of charge, which is problematic in terms of stability and production. With this background it can be very beneficial to combine the advantages of conducting polymers and nano-structured TiO_2 in the design of a solar cell. In this context we are currently investigating Ru-complexes, which can act as dye sensitizers in NSCs, which are modified with thiophene substituents on the bipyridine ligands. These thienyl groups are thought to be used as starting points for a covalent link between the dye and a solid electrolyte as, e.g., polythiophene. Also, an extension of the absorbtion spectrum together with an increased hydrophobicity improving stability of the NSC towards water penetration gives these substituents a bright future in the field of photoelectrochemical solar cells. However, in order to apply this type of dyes in a complex system such

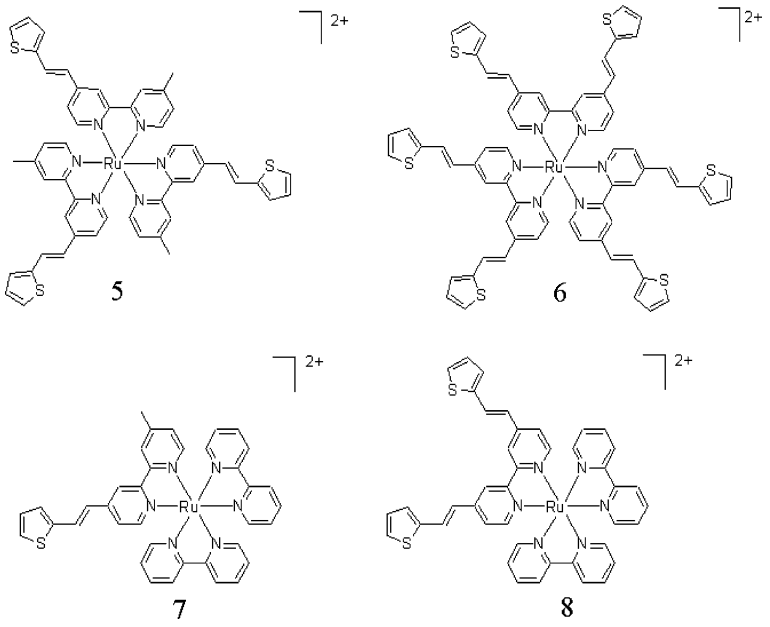


Scheme 1.

as the NSC, the study of models compounds **5–8** (Scheme 1) is a necessity.

In the past we have presented the synthesis and properties of ruthenium *tris*-bipyridyl complexes with methoxystyryl substituents and the characteristics of electrochemically produced polymers [3]. Following up this investigation, we here report the synthesis and the study of some ruthenium polypyridyl complexes with hydrophobic polymer precursors as ethylene-thiophene. Electroactive polymers of these complexes have been prepared by oxidative electropolymerisation. The resulting materials have been characterized with UV–Vis spectroscopy and by means of electrochemistry.

2. Experimental

2.1. Materials

All reagents were from commercial sources and were used without further purification. Solvents were HPLC grade and were used without further purification with the following exceptions: Tetrahydrofuran (THF) was distilled from sodium, diisopropylamine (DIPA) and triethylamine (Et_3N), which were distilled from CaH_2. For electrochemical experiments, acetonitrile (Fluka, $H_2O \leqslant 0.001\%$) stored over molecular sieves was used. Butyl lithium (BuLi) was stored in a desiccator under nitrogen and used as fresh (no precipitate) 1.6 M solutions in hexane. Trifluoroacetic acid (TFA) and trifluoroacetic acid anhydride (TFAA) were stored at −18 °C and used as received. Tetrabutylammonium hexafluorophosphate ((TBA)PF_6) (Aldrich, 98%) was dried under vacuum at 120 °C for 48 h before performing electrochemistry. Syntheses were performed under a nitrogen atmosphere. Transparent conducting oxide electrodes of fluorine-doped tin oxide (FTO) on a 3-mm glass support (sheet resistance 8 Ω/square) were purchased from Liffey–Owens–Ford. Elemental analyses were performed by the Analytische Laboratorien, Lindlar, Germany.

2.2. Physical characterisation

NMR spectra (^{1}H NMR at 400 MHz and ^{13}C NMR at 100 MHz) were recorded on a Varian Unity 400 spectrometer for $CDCl_3$ and CD_3COCD_3 solutions unless otherwise stated. The chloroform signals at 7.26 ppm (for ^{1}H) or 77.0 ppm (for ^{13}C) and the acetone signals at 2.04 ppm (for ^{1}H) or 29.8 ppm (for ^{13}C) were used as indirect reference to TMS.

UV–Vis absorption spectra were recorded using a Hewlett-Packard 8453 diode-array spectrophotometer and referenced against a solvent blank (CH_3CN). The fluorine-doped tin oxide (FTO) electrodes with polymer films deposited on the surface were positioned against the wall of a 1-cm quartz cuvette containing CH_3CN. The absorption of the FTO glass substrates was substracted from the measured spectra of the compound.

Electrochemistry was performed using a CH Instruments Model 660. Electrochemical workstation and a conventional three electrode cell with a silver wire as pseudo-reference electrode. After the experiments ferrocene was added as an internal reference and all potentials given are quoted against the ferrocene–ferrocenium redox couple.

2.3. Synthesis

2.3.1. Ligands

*2.3.1.1. 4-Methyl-4′-(2-hydroxy-2-(2-thienyl) ethyl)-2,2′-bipyridine (**1**).* LDA was formed by mixing 1.54 mL BuLi (1.6 M in hexane) with 0.39 mL of DIPA in 10 mL THF at −60 °C under N_2. The mixture was then stirred at room temperature for 1/2 h. Thereafter, 4,4′-dimethyl-2,2′-bipyridine (0.50 g, 2.48×10^{-3} mol) dissolved in 15 mL THF was added through a double tipped needle after the temperature was cooled to −40 °C. The black reaction mixture was then stirred at room temperature during 1 h. The aldehyde (0.25 mL, 2.72×10^{-3} mol) was diluted in 10 mL THF and added the same fashion to the reaction mixture to form a yellow precipitate. After stirring for 1 h, the reaction was stirred into water and extracted with dichloromethane. The organic phase was then washed with brine and dried over $MgSO_4$. The dried solution was then concentrated. NMR of the crude product showed more than 85% of conversion compared to the aldehyde and complete conversion compared to the bipyridine. The crude product was used in the next step without further purification. ^{1}H NMR (400 MHz) ($CDCl_3$) δ 8.54 (1H, d, $J = 4.8$ Hz, aromatic pyridine), 8.50 (1H, $J = 4.8$ Hz, d, aromatic pyridine), 8.30 (1H, broad s, aromatic pyridine), 8.21 (1H, broad s, aromatic pyridine), 7.26 (1H, multiplet, thiophene), 7.13 (2H, multiplet, aromatic pyridine), 6.96 (2H, multiplet, thiophene), 5.29 (1H, dd, $J = 7.6$ Hz, $J = 6$ Hz, benzylic alcohol), 3.21 (1H, d, $J = 7.6$ Hz, benzylic), 3.21 (1H, d, $J = 6$ Hz, benzylic), 2.43 (3H, s).

*2.3.1.2. 4,4′-(2-hydroxy-2-(2-thienyl) ethyl)-2,2′-bipyridine (**2**).* LDA was formed by mixing 3.72 mL BuLi (1.6 M in hexane) with 0.83 mL of DIPA in 20 mL THF at −60 °C under N_2. The mixture was then stirred at room temperature for 1/2 h. Thereafter, 4,4′-dimethyl-2,2′-bipyridine (0.50 g, 2.48×10^{-3} mol) dissolved in 15 mL THF was added through a double-tipped needle after the temperature was cooled to −40 °C. The black reaction mixture was then stirred at room temperature during 1 h. The aldehyde (0.52 mL, 5.96×10^{-3} mol) was diluted in 10 mL THF and added in the same fashion to the reaction mixture to form a yellow precipitate. After stirring for 1 h, the reaction was stirred into water and extracted with dichloromethane. The organic phase was then washed with saturated aq. NaCl and dried over $MgSO_4$. The dried solution was then concentrated yielding 0.836 g (2.04×10^{-3}, 75%) of the product.^{1}H NMR (400 MHz) ($CDCl_3$) δ 8.58 (2H, m, aromatic pyridine), 8.30 (2H, broad s, aromatic pyridine), 7.26 (2H, multiplet, thiophene), 7.15 (2H, multiplet, aromatic pyridine), 6.99 (4H, multiplet, thiophene), 5.29 (2H, m, benzylic alcohol), 3.21 (2H, m, benzylic).

*2.3.1.3. 4-Methyl-4′-(2-(2-thiophene) ethenyl)-2,2′-bipyridine (**3**).* 4-Methyl-4′-(2-hydroxy-2-(2-thienyl) ethyl)-2,2′-bipyridine (2.30 mmol) was dissolved in 10 mL of CH_2Cl_2 under nitrogen. As trifluoroacetic anhydride (TFA) (3.90 mL, 27.6 mmol) was added dropwise, the reaction mixture became orange. The mixture was stirred overnight and then concentrated to dryness, dissolved into EtOAc (50 mL), washed with water (2×50 mL), dried over $MgSO_4$ and concentrated to dryness. The product was afforded as yellow crystals in 96% yield (0.616 g, 2.21 mmol). ^{1}H NMR (400 MHz) ($CDCl_3$) δ 8.85 (1H, d, $J = 5.6$ Hz, aromatic pyridine), 8.78 (1H, $J = 5.2$ Hz, d, aromatic pyridine), 8.55 (1H, broad s, aromatic pyridine), 8.35 (1H, broad s, aromatic pyridine), 7.81 (1H, d, $J = 16$ Hz, alkene), 7.60 (1H, dd, $J = 5.6$ Hz, $J = 1.2$ Hz, pyridine), 7.52 (1H, d, $J = 5.2$ Hz, pyridine), 7.42 (1H, d, $J = 5.6$ Hz, thiophene), 7.33 (1H, d, $J = 3.6$ Hz, thiophene), 7.11 (1H, dd, $J = 3.6$ Hz, $J = 5.2$ Hz, thiophene), 6.93 (1H, d, $J = 16$ Hz, alkene), 2.63 (3H, s, Methyl). ^{13}C NMR, 154.7, 151.2, 148.3, 147.9, 146.2, 146.0, 140.6, 131.6, 131.7, 130.9, 128.5, 128.4, 127.3, 124.4, 122.7, 122.4, 119.6, 21.8.

*2.3.1.4. 4,4′-(2-(2-thiophene) ethenyl)-2,2′-bipyridine (**4**).* Crude **2** (2.04×10^{-3} mol) was dissolved in 15 mL of CH_2Cl_2 under nitrogen. As trifluoroacetic anhydride (TFAA) (3.90 mL, 27.6×10^{-3} mol) was added dropwise, the reaction mixture turned orange. The mixture was stirred overnight and then concentrated to dryness, dissolved into EtOAc (50 mL), washed with water (2×50 mL), dried over $MgSO_4$ and concentrated to dryness. The product was afforded as a yellow powder in 37% yield (0.281 g, 7.54×10^{-3} mol). ^{1}H NMR (400 MHz) ($CDCl_3$) δ 8.73 (1H, d, $J = 5.2$ Hz, aromatic pyridine), 8.65 (1H, broad s, aromatic pyridine), 7.70 (1H, d, $J = 16$ Hz, alkene), 7.41 (1H, d, $J = 4.8$ Hz, pyridine), 7.32 (1H, d, $J = 4.8$ Hz, thiophene), 7.24 (1H, m, thiophene), 7.06 (1H, dd, $J = 3.6$ Hz, $J = 4.8$ Hz, thiophene), 6.94 (1H, d, $J = 16$ Hz, alkene). ^{13}C NMR, 148.1, 141.5, 131.1, 129.7, 129.4, 129.0, 128.4, 127.4, 124.2, 122.3, 119.3.

2.3.2. Homoleptic complexes

*2.3.2.1. Tris-(4-methyl-4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate (**5**).* $RuCl_3 \cdot xH_2O$ (0.079 g, 0.38 mmol) and **L** (0.321 g, 1.15 mmol) were stirred at reflux in a 20 mL mixture of EtOH and H_2O (1:1), under nitrogen during 24 h. The solution turned dark red. NH_4PF_6 (1.24 g, 7.66 mmol) dissolved in water was added to the reaction mixture, after which a brown precipitate appeared. The precipitate was filtered off, washed with water and ether. The product was dried under reduced pressure during 24 h and was afforded in 24% yield (0.115 g, 0.095 mmol). *Anal.* Calc. for $Ru(Bpy\text{-}Th_1)_3(PF_6)_2 + 4H_2O$ (Mol Form.: $C_{51}H_{42}$

$F_{12}N_6P_2RuS_3 \cdot 4H_2O$): C, 47.19; H, 3.88; N, 6.47. Found: C, 46.82; H, 3.89; N, 5.85%.

*2.3.2.2. Tris-(4,4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate (**6**).* $RuCl_3 \cdot xH_2O$ (0.079 g, 0.89 mmol) and **L** (0.100 g, 0.268 mmol) were stirred at reflux in a 20 mL mixture of EtOH and H_2O (1:1), under nitrogen during 24 h. The solution turned dark red. NH_4PF_6 (0.145 g, 0.89 mmol) dissolved in water was added to the reaction mixture, after which a brown precipitate appeared. The precipitate was filtered off, washed with water and ether. The product was dried under reduced pressure during 24 h and was afforded in 68% yield (0.092 g, 0.45 mmol). *Anal.* Calc. for Ru(Bpy-$Th_2)_3(PF_6)_2 + 5H_2O$ (Mol Form.: $C_{66}H_{48}F_{12}N_6P_2RuS_6 \cdot 5H_2O$): C, 49.59; H, 3.66; N, 5.26; Found: C, 49.23; H, 3.83; N, 4.50%.

2.3.3. Heteroleptic complexes

2.3.3.1. Bis-2,2′-bipyridyl ruthenium dichloride [4]. $RuCl_3 \cdot xH_2O$ (0.200 g, 0.96 mmol), 2,2′-bipyridyine (0.316 g, 2.02 mmol) and LiCl (0.173 g, 4.08 mmol) were stirred at reflux in 20 mL reagent grade DMF under argon for 8 h. After the reaction had cooled to room temperature, 100 mL of reagent grade acetone was added. The solution was then refrigerated overnight at 0 °C. Filtration gave a red violet solution and dark green crystals. Those were washed with water (3 × 15 mL) and with ether (3 × 15 mL). The product was then dried at room temperature under reduced pressure for 24 h. ^{1}H NMR ($CDCl_3$) δ 10.07 (d, $J = 5.6$ Hz, 2H, aromatic), 8.15 (d, $J = 8$ Hz, 2H, aromatic), 7.99 (d, $J = 8$ Hz, 2H, aromatic), 7.84 (t, $J = 8$ Hz, 2H, aromatic), 7.55 (m, 4H, aromatic), 7.46 (t, $J = 8$ Hz, 2H, aromatic), 6.87 (t, $J = 5.6$ Hz, 2H, aromatic). ^{13}C NMR, 160.4, 157.9, 153.9, 152.6, 134.5, 133.4, 125.5, 124.7, 121.9, 121.7.

*2.3.3.2. Bis-2,2′-bipyridyl-(4-methyl-4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate (**7**).* *Bis*-2,2′-bipyridyl ruthenium dichloride (0.050 g, 0.10 mmol) and 4,4′-(2-thienylethenyl)-2,2′-bipyridine (0.027 g, 0.10 mmol) were stirred at reflux in a 20 mL mixture of EtOH and H_2O (1:1), under argon for 1 h. The solution turned red. $NaPF_6$ (0.250 g, ~20 eq) was added to the reaction mixture, which was stirred overnight (18 h), resulting in an orange precipitate. The precipitate was filtered and dried under reduced pressure during 24 h to give 0.043 g (0.044 mmol, 42% yield) of *bis*-2,2′-bipyridyl-(4-methyl-4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate. ^{1}H NMR (CD_3COCD_3) δ 8.95 (substituted bipyridine, d, $J = 1.2$ Hz, 1H), 8.81 (non-substituted bipyridine, d, $J = 7.2$ Hz, 4H), 8.76 (substituted bipyridine, s, 1H), 8.23-8.18 (non-substituted bipyridine, m, 4H), 8.16 (substituted bipyridine, d, $J = 0.8$ Hz, 1H), 8.15–8.04 (non-substituted bipyridine, m, 4H), 7.98 (–C*H*=C*H*–, d, $J = 16$ Hz, 1H), 7.91 (substituted bipyridine, d, $J = 6$ Hz, 1H), 7.86 (substituted bipyridine, d, $J = 5.4$ Hz, 1H), 7.64 (substituted bipyridine, dd, $J_1 = 6.4$ Hz, $J_2 = 2$ Hz, 1H), 7.62–7.55 (non-substituted bipyridine, m, 4H), 7.42 (substituted bipyridine, unresolved dd, 1H), 7.38 (substituted bipyridine, d, $J = 3.2$ Hz, 1H), 7.13 (substituted bipyridine, dd, $J_1 = 5.2$ Hz, $J_2 = 4$ Hz, 1H), 2.59 (–CH_3, s, 3H). *Anal.* Calc. for $C_{37}H_{30}F_{12}N_6P_2RuS \cdot 2H_2O$: C, 43.66; H, 3.37; N, 8.26; Found: C, 43.82; H, 3.21; N, 8.09%.

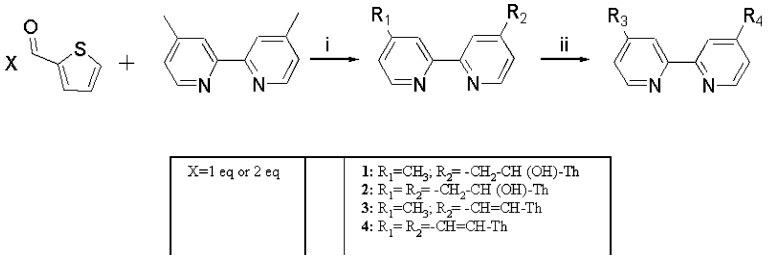
*2.3.3.3. Bis-2,2′-bipyridyl-(4,4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate (**8**).* *Bis* 2,2′-bipyridyl ruthenium dichloride (0.050 g, 0.10 mmol) and 4,4′-(2-thienylethenyl)-2,2′-bipyridine (0.038 g, 0.10 mmol) were stirred at reflux in a 20 mL mixture of EtOH and H_2O (1:1), under argon for 1 h. The solution turned red. $NaPF_6$ (0.250 g, ~20 eq) was added to the reaction mixture, which was stirred overnight (18 h), resulting in an orange precipitate. The precipitate was filtered and dried under reduced pressure during 24 h to give 0.065 g (0.6 mmol, 60% yield) of *bis*-2,2′-bipyridyl-(4,4′-(2-thienylethenyl)-2,2′-bipyridine) ruthenium dihexafluorophosphate. ^{1}H NMR (CD_3COCD_3) δ 8.98 (substituted bipyridine, s, 2H), 8.81 (non-substituted bipyridine, d, $J = 8$ Hz, 4H), 8.21 (non-substituted bipyridine, t, $J = 8$ Hz, 4H), 8.16 (substituted bipyridine, d, $J = 5.6$ Hz, 2H), 8.05 (substituted bipyridine, d, $J = 5.2$ Hz, 2H), 7.97 (–C*H*=C*H*–, d, $J = 16$ Hz, 2H), 7.91 (substituted bipyridine, d, $J = 8$ Hz, 2H), 7.68 (dd, $J_1 = 6.4$ Hz, $J_2 = 2$ Hz, 2H), 7.62–7.55 (non-substituted bipyridine + substituted bipyridine, m, 4 + 2H), 7.40 (substituted bipyridine, broad d, $J = 3.8$ Hz, 2H), 7.68 (substituted bipyridine + –C*H*=C*H*–, dd + d, $J_1 = 5.2$ Hz, $J_2 = 3.8$ Hz, $J_3 = 16$ Hz, 4H). ^{13}C NMR, 157.7, 157.5, 152.0, 151.6, 146.8, 141.37, 138.2, 130.1, 129.8, 128.6, 128.1, 124.6, 124.1, 123.4, 122.6, 121.1. *Anal.* Calc. for $C_{42}H_{32}F_{12}N_6P_2RuS_2 \cdot 8H_2O$: C, 41.35; H, 3.97; N, 6.89; Found: C, 40.94; H, 3.41; N, 7.10%.

3. Results and discussion

3.1. Synthesis

A two-step synthesis was used to afford 4-methyl-4′-(2-(2-thiophene) ethenyl)-2,2′-bipyridine (ligand **3**), or 4,4′-(2-(2-thiophene) ethenyl)-2,2′-bipyridine (ligand **4**) as pictured in Scheme 2.

First, a nucleophilic addition of the mono- or di-anion of 4,4′-dimethyl-2,2′-bipyridine to 2-thiophenecarboxaldehyde (one or two equivalents) gave the corresponding alcohol (**1** or **2**) [4]. Dehydration was achieved using trifluoroacetic anhydride (TFAA) followed by precipitation. The preparation of the homo-



Scheme 2.

leptic complexes **5** and **6** was done in methoxyethanol (MeOEtOH) by mixing one equivalent of the ruthenium salt with three equivalents of the desired ligand (**1** or **2**). After the reaction mixture became dark red, the solution was cooled and the complex precipitated out of the solution by addition of (NH_4PF_6)-saturated water. The complex was filtered and dried under vacuum.

The heteroleptic complexes were prepared using a two-step synthesis. The dichloro bis-bipyridyl ruthenium complex was prepared according to a literature procedure [5]. The third ligand was introduced by mixing the dichloro bis-bipyridyl ruthenium salt to one equivalent of the mono- or di-substituted ligands followed by an exchange of the counter ion by addition of (NH_4PF_6)-saturated water.

3.2. Absorption properties

The absorption spectra for the ligands **2** and **4** were compared and clearly showed the substituent influence (see Fig. 1): [1] The very typical Ligand Centered Charge Transfer (LCCT/π–π^*) for bipyridine ligands is represented around 280 nm in both cases, and the conjugated thiophene gives an extra LCCT at ~340 nm [6].

The absorption properties of the different complexes have been recorded in acetonitrile and are shown in Fig. 2. [1]

The metal to ligand charge transfer (MLCT) correlates very well with the number of substituents on the molecules (see Table 1).

The more extended conjugated system is expected to have a smaller energy difference between its HOMO and its LUMO, which corresponds to a shift of the MLCT towards longer wavelengths.

The extinction coefficients reflect as well the structures of the complexes: The more extended conjugation on the complex leads to a shift of the MLCT towards longer wavelengths and a higher ε-value, although the variation between ε_{MLCT} for **7** and **8** is not significant, showing the little difference between the presence of one or two thiophene groups as substituents.

[1] The symbols are for orientation purposes only and the spectra were measured with a 1 nm resolution.

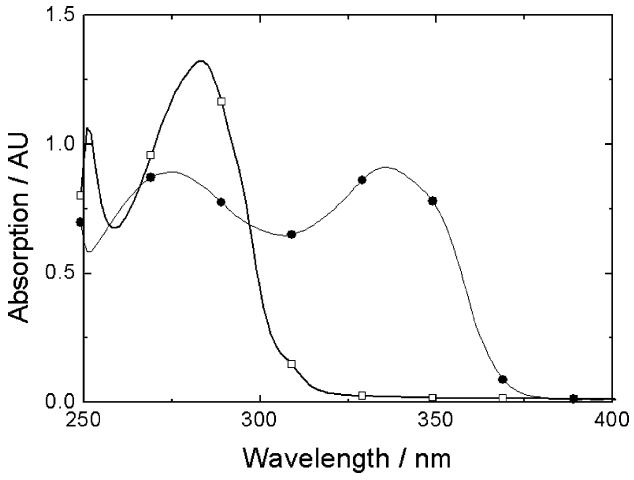


Fig. 1. Absorption spectra for both the conjugated and the non-conjugated thiophene substituted ligands 2 (-○-) and 4 (-●-) [7].

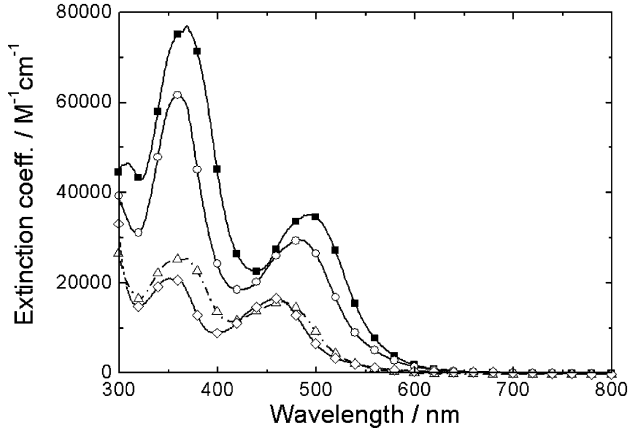

Fig. 2. Absorption spectra for the different complexes **5**–**8** (complex **5**: -○-; complex **6**: -■-; complex **7**: -◇-; complex **8**: -△-) (Footnote 1).

Table 1
Absorption properties of complexes **5**–**8** in acetonitrile

Complex	LCCT (nm)	ε_{LCCT}[a] (mol^{-1} cm^{-1})	MLCT (nm)	ε_{MLCT}[a] (mol^{-1} cm^{-1})
5	362	61 700	483	29 500
6	368	76 950	493	35 000
7	350	20 900	458	16 600
8	369[b]	25 200	463	15 700

[a] Extinction coefficient for the absorption maximum in the visible region.

[b] The relatively high value is due to an artefact from the absorption spectrum. The average would be around 358.

Table 2
Electrochemical data for complexes **5**–**8** as determined by differential pulse voltammetry[a,b]

Complex	Oxidation (V)		Reduction (V)		
3	1.08		−1.24		
4	1.08		−1.24

[a] In Volts. A glassy carbon electrode was used as working electrode, the redox couple Fc/Fc^+ was used as internal reference and (TBA), PF_6 as electrolyte. The scan rate was 100 mV s^{-1}. The solvent was acetonitrile.

[b] The values given in brackets are measured in dichloromethane

3.3. Electrochemical properties

The electrochemistry of complexes **5**–**8** was measured. All complexes were electrochemically active in CH_2CL_2 and acetonitrile solution with 0.1 M (TBA)PF_6 as supporting electrolyte. [2] For comparison purposes also the ligands **3** and **4** were electrochemically investigated. The results are summarized in Table 2.

The redox potentials listed were measured by differential pulse voltammetry (DPV). A significant difference to numbers determined by cyclic voltammetry (CV) was not observed.

3.3.1. Oxidation

All complexes **5**–**8** showed in CV experiments at least one fully reversible peak in the oxidative region of the potential window, which can be assigned to the oxidation of Ru(II)–Ru(III). The position of the signal depends on the substitution of the bipyridine ligands. This oxidation characteristic is illustrated in Fig. 3.

As can be seen from Table 1, the Ru(II)–Ru(III) redox process of the homoleptic complexes **5** and **6** is shifted by slightly more than 100 mV towards less positive potentials in comparison to the heteroleptic complexes **7** and **8** and 200 mV relative to $[Ru(bpy)_3]^{2+}$. This experimental result can be interpreted as a stabilisation of the Ru(III)-ion in these complexes relative to $[Ru(bpy)_3]^{3+}$. Having two chemically very different substituents on the bpy-ligands (–CH_3 and –CH=CH–Th), the separation of the effects on the electronic structure within the complexes is difficult, but literature data of related compounds point out that both substituents are electron donating, which is stabilizing the oxidized state of the complex (Table 2) [7,8].

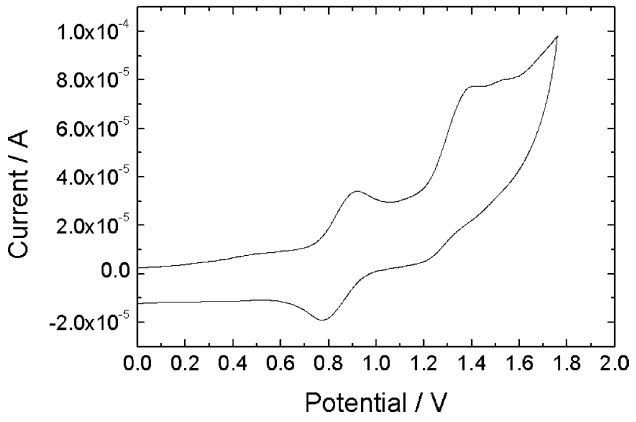

Fig. 3. Cyclic voltammogram of complex **7**. A glassy carbon electrode was used and the voltammogram was measured in acetonitrile with (TBA)PF_6 as supporting electrolyte at a scan speed of 0.1 V s^{-1}.

Beside the Ru(II)–(III) transition another – irreversible – oxidation process was observed for all complexes **5**–**8**. We assign these signals to a ligand-centred oxidation of the ethylene–thiophene substituent. A comparison with the electrochemistry of the uncoordinated ligand supports this assumption (see Table 2). Also in the literature, an oxidation of thiophene substituted polypyridine complexes was described at similar potentials [9,10].

Besides the influence of the different ligands on the oxidation potentials, an effect of the solvent was observed: Whereas the Ru(II)–Ru(III) transition remains at the same position when switching the solvent, the peaks assigned to the ethylene–thiophene oxidation were shifted by more than 100 mV to less positive potentials when changing the solvent from acetonitrile to CH_2Cl_2. To a smaller extent, such an effect was observed for thiophene oligomers for which the authors found a shift of 50 mV to less positive potentials when switching the solvent from acetonitrile to dichloromethane [11]. In the same contribution it was pointed out that the radical produced due to electrochemical oxidation is strongly stabilized by dichloromethane, which also was described generally before [12]. Therefore, we assign the shift of the second oxidation of the complexes to a solvent induced energetic stabilisation of the produced radical.

3.3.2. Reduction

Beside the electrochemical characteristics in the oxidative region of the potential window, the reduction of complexes **5**–**8** and the ligands **3** and **4** were investigated. The results are summarized in Table 2.

[2] The complexes **5** and **6** showed only poor solubility in acetonitrile and dichloromethane ($<0.5 \times 10^{-4}$ mol/l), which is reflected in the low intensity of the electrochemistry shown in Fig. 3.

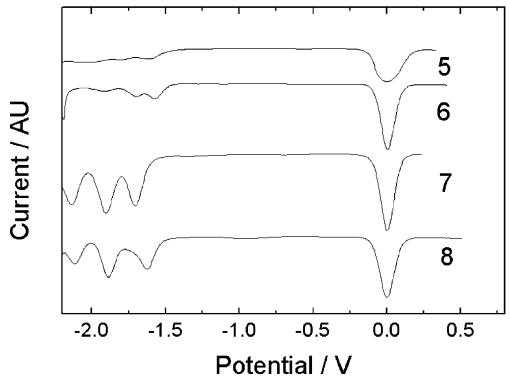

Fig. 4. DPV for compounds **5**–**8** (reductive region of the potential window). A glassy carbon electrode was used as working electrode, the redox couple Fc/Fc^{+} was employed as internal reference and $(TBA)PF_6$ (0.1 M in acetonitrile) as electrolyte.

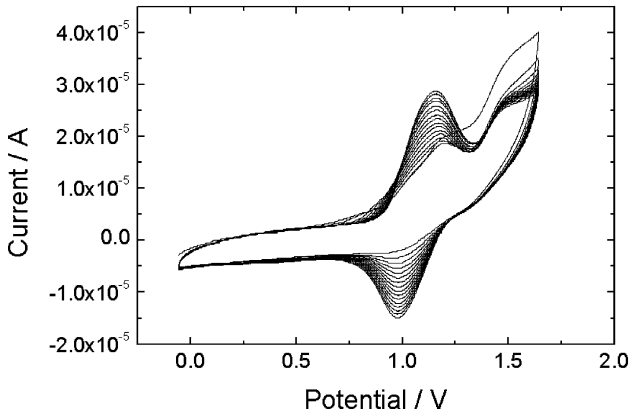

Fig. 5. Cyclic voltammogram for complex **6**. A glassy carbon electrode was used as working electrode, the redox couple Fc/Fc^{+} was employed as internal reference and $(TBA)PF_6$ (0.1 M in dichloromethane) as electrolyte at a scan rate of 100 $mV\,s^{-1}$.

For all complexes at least three signals were detected in CV and DPV (see Fig. 4) experiments at negative potentials within the potential window of acetonitrile and CH_2Cl_2 with $(TBA)PF_6$ as the supporting electrolyte, which correspond to the successive reduction of the three bipyridine ligands [13].

As expected from this type of complexes, the difference in potential between the processes is close to 200 mV. A further reduction of the bpy-ligands was also observed as expected but not analysed [3] [13].

Relative to the reduction potentials of $[Ru(bpy)_3]^{2+}$, the values for the homoleptic complexes **5** and **6** are significantly shifted to less negative potentials for all three ligand centred processes. It can be assumed that the expansion of the conjugated system by the substitution of the bpy ligand with ethylene–thiophene groups is responsible for the lowering of the LUMO. On the other side, the methyl substituents seem to have a smaller or even opposite effect since the reductions of complex **5** are located at more negative potentials than for complex **6**. For the heteroleptic complex **7**, no significant shift of the reduction potentials relative to $[Ru(bpy)_3]^{2+}$ were observed pointing out that methyl groups are rather lifting the LUMO level. This can be confirmed by a comparison with $[Ru(bpyMe_2)_3]^{2+}$ (Table 2). For complex **8**, we measured a less negative reduction process only for one ligand whereas the other two reductions are taking place at the same potentials as the equivalent processes in $[Ru(bpy)_3]^{2+}$. This allows us to attribute the first reduction of complex **8** to a localisation on the ethylene-thiophene substituted bpy-ligand.

[3] Differential pulse voltammetry had to be deployed for the determination of redox potentials since the cyclic voltammograms were dominated for the compounds **5**, **6** and **8** by polymerisation processes as discussed in the following section.

3.3.3. Electrochemical polymerisation at positive potentials

For complexes **5**, **6** and **8**, an increase in intensity of the oxidation waves in the CV experiments were observed from one cycle to the next (see Fig. 5): The first scan gives an oxidation wave for the ruthenium center as well as a strong oxidation corresponding to the irreversible oxidation of the thiophene groups [14].

The oxidation waves merge together after the first scan in combination with a substantial growth of the peaks. One can also see a red-orange film deposited on the working electrode after the experiment. These effects was only seen when the potential window of the voltammetry experiments reached the oxidation of the complexes associated with the oxidation of the ethylene-thiophene ligand substituents. We assign these observations to a radical induced polymerisation as other authors described it for similar complexes leading to three-dimensional networks with the Ru in the backbone [15–21]. This polymerisation process was mainly observed in dichloromethane, whereas a stable effect in acetonitrile could only be seen for complex **6**. As discussed earlier, a stabilisation of radical cations was observed in dichloromethane relative to acetonitrile. It seems likely that besides the shift of the oxidation potential, the stabilisation of radicals favours a successful polymerisation, since the longer lifetime increases the probability of finding a thiophene counterpart for polymerisation. Also, the shift of the ligand centred oxidation towards less positive potential in dichloromethane increased the accessibility of the process within the potential window, decreasing the interferences with traces of water or solvent related processes. A typical example for the electrochemically induced polymerisation is given in Fig. 5 for complex **6**.

By cyclic voltammetry and DPV, one can see a tremendous shift (over 100 mV) of the oxidation potential of the Ru(II)–Ru(III) redox wave, indicating a change of

Table 3
Absorption and electrochemical properties of the complexes **5**–**8** (non-polymerized and oxidatively polymerized on FTO-glass support)

Complex	λ_{max}, MLCT (nm)		E_0 (V) (vs. Fc/Fc^+)[a]	
	Monomer	Polymer	Monomer	Polymer
5	483	472	0.72	0.85
6	493	475	0.74	1.07
7	485		0.85	
8	463	450	0.85	1.02

[a] E_0 was determined in dichloromethane. The electrodes modified with a polymer were removed from the complex solution after polymerisation, rinsed with dichloromethane and then measured in dichloromethane/$(TBA)PF_6$ without the corresponding complex.

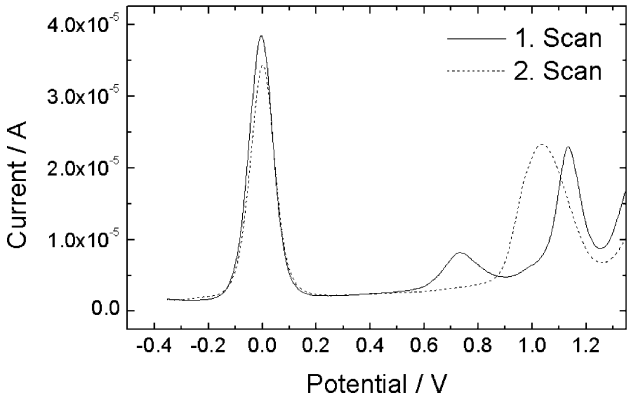

Fig. 6. DPV for complex **6**. A glassy carbon electrode was used as working electrode, the redox couple Fc/Fc^+ was used as internal reference and $(TBA),PF_6$ (0.1 M in acetonitrile) as electrolyte. First scan – solid line and second scan - - - - dashed line.

the ligand's substituents polarity (see also Table 3). This effect can be seen most clearly for the polymerisation of complex **6** in acetonitrile. [4] In Fig. 6 two successive DPVs are shown: The first scan shows two distinct peaks for the Ru(II)–Ru(III) and the ligand centred process, whereas the second scan only shows one strong peak – presumably the oxidation of the polymeric material on the electrode surface.

As discussed previously, the low oxidation potentials of complexes **5**–**8** relative to $[Ru(bpy)_3]^{2+}$ has its origin in the increased size of the conjugated system of the bpy-ligand, therefore the strong shift of the oxidation potential is indicative of a loss of this conjugation. At the same time, the disappearance of the strong oxidation peak at 1.42 V is indicative of either a consumption or a cut of the thiophene groups from the conjugated system moving the oxidation potential of the group outside the potential window due to the polymerisation.

[4] The same effect was also observed for complexes **5**, **6** and **8** in dichloromethane, but due to the close vicinity of the ligand and metal centred oxidations, the shift of oxidation due to polymerisation is less obvious than for the electrochemistry of **6** in acetonitrile.

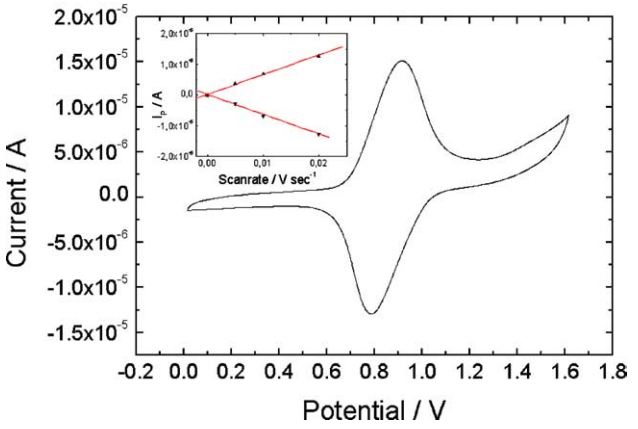

Fig. 7. Cyclic voltammogram of the polymer of complex **5** in CH_2Cl_2 with $(TBA)PF_6$ as supporting electrolyte and scan rate dependency of the peak current (inset).

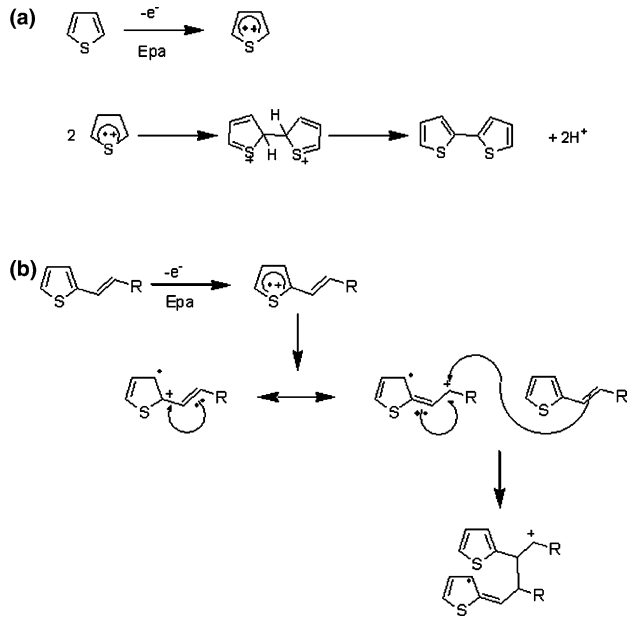
The electrochemistry of the polymers was also measured in monomer-free electrolyte. A typical cyclic voltammogram is presented in Fig. 7, and the values for the oxidation potentials are given in Table 3.

In all cases we find only one oxidation peak, which we relate to the Ru(II)–Ru(III) redox couple, whereas no further ligand-located oxidation as for the monomer was detected within the potential window. For a surface bound species, the separation between the oxidation and reduction peak is even at moderate scan rates rather high for a surface bound species. For the given example it is 130 mV at a scan rate of only 20 mV s^{-1}, which is an indication of slow electron transport and transfer processes [15]. On the other side, the scan rate dependency of the peak current shows the linear behaviour expected for surface bound electro-active material, where the scan rate dependency is not influenced by its diffusion to and from the electrode (see Fig. 7, inset). [5]

Two possible mechanisms for the polymerisation can be taken into account and are pictured in Scheme 3.

Thiophenes are known to dimerize via a radical cation mechanism through the 2- and 5-positions (Scheme 3A) [22], which eventually leads for complexes with multiple thiophene substituents on the ligands to polythiophene type polymers with metal complexes in the backbone. However, in the present case the positive

[5] From the area under the redox signals, the charge and therefore the absolute number of complex entities deposited on the electrode and incorporated into the polymer network can be calculated. For example, the evaluation of the redox peaks shown in Fig. 7 gives a total charge of 3.5×10^{-5} C, which corresponds to 3.6×10^{-10} mol of complex **5** deposited on the electrode. Taking into account the surface of the electrode and that a monolayer of these complexes includes about 7.7×10^{-11} mol cm^{-2} (J. Am. Chem. Soc. 116 (1994) 5444), the thickness of the polymer is equivalent to 66 monolayers and therefore the thickness of the polymer layer is in the order of 50–100 nm after 16 deposition cycles, assuming an average Ru–Ru distance of 15–20 Å.



Scheme 3.

charge can delocalize towards the olefinic double bond, which will eventually dimerize (Scheme 3B) and therefore offers a alternative pathway for reaction of the oxidized species [22–26].

Absorption spectra of the polymers on FTO-glass have been recorded, and the influence of the polymerisation method is clearly seen, as exemplified for **6** (see Fig. 8) and listed in Table 3.

The blue shift of the MLCT, which we find for all oxidatively produced polymers, points towards a loss of conjugation as it is depicted in Fig. 8. The disappearance of the LC-transition for the substituted ligand at 360 nm confirms the loss of conjugation in the ligand structure (see Fig. 8).

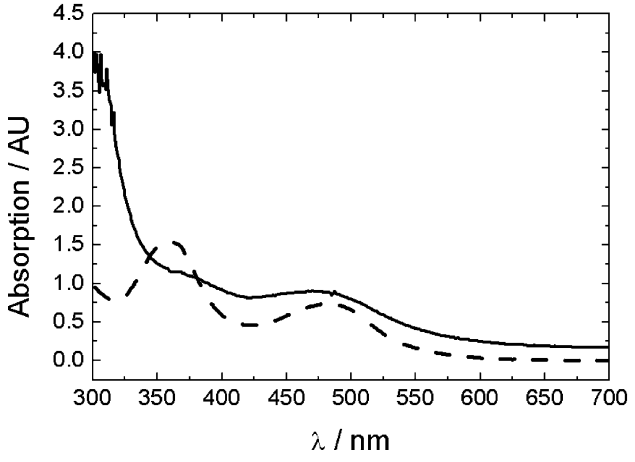


Fig. 8. Absorption spectra of polymer films of 5, deposited on glass with a conducting layer of fluorine doped tin oxide (FTO) (solid line), and of the monomer 5 in solution (dashed line).

4. Conclusions

We have reported the synthesis, characterisation and polymerisation behaviour of four thiophene substituted ruthenium complexes. The polymerisation behaviour of the complexes at positive potentials showed the behaviour of a redox active film. No polymerisation was observed at negative potentials showing the low reactivity of the vinyl functionality in these complexes. The shift of the MLCT band of the absorption spectra towards shorter wavelengths in combination with an oxidation potential at less positive potentials implied a loss of conjugation within the ligands **3** and **4** due to a radical polymerisation through the vinyl functionality after delocalisation instead of the expected thiophene–thiophene coupling. Nevertheless, an interesting feature for an application in the NSC is the broader absorption spectrum of the dye compared to a ruthenium *tris*-bipyridyl complex. Also, the introduction of a thiophene-group makes this type of dye a possible base to form a solid-state solar cell by polymerisation. These compounds, used as a model, lay the ground for the development of new dyes possessing broader absorption properties and better water tolerance for solar cell application.

Abstract

The interaction of polymeric $Re_3MoS_4Te_4$ with molten KCN at 850 °C results in rearrangement of the tetrahedral $\{Re_3MoS_4\}$ cluster core to an octahedral one, $\{Re_{6-x}Mo_xS_8\}$, and formation of two new molecular octahedral heterometal rhenium–molybdenum thiocyanide cluster complexes, $[Re_5MoS_8(CN)_6]^{5-}$ and $[Re_4Mo_2S_8(CN)_6]^{5-}$, co-existing in the crystals $Cs_5[Re_{4.5}Mo_{1.5}(\mu_3\text{-}S)_8(CN)_6]\cdot 2H_2O$. The EDAX analyses and magnetic measurements data confirm the presence of a mixture of cluster anions with $x = 1$ and 2.

1. Introduction

Among a variety of octahedral chalcogenide cluster compounds of transition metals (1–4 and references herein) there are few examples containing mixed-metal cluster cores $Mo_{6-x}M_xQ_8$ (M = Re, Q = S, Se, Te, $x = 4$; M = Ru, Q = Se, Te, $0 \leqslant x \leqslant 2$; M = Rh, Q = Te, $x = 0.5$, 1.33) [5], $Nb_{6-x}Ru_xTe_8$ ($2.50 \leqslant x \leqslant 3.17$) [6], $Cs_3Re_5OsS_{11}$ [7]. These compounds have been prepared by routine solid state synthesis and are insoluble in water and common organic media. The only soluble heterometal cluster complexes $Cs_3Re_{6-x}Os_xSe_8Cl_6$ ($x = 1$, 2) and $K_2[Re_3Os_3Se_8Cl_6][Re_4Os_2Se_7Cl_7]$ were reported very recently [8].

In the present work we report the synthesis and crystal structure of the first soluble mixed metal rhenium–molybdenum cluster complexes with terminal cyano-ligands $[Re_{6-x}Mo_x(\mu_3\text{-}S)_8(CN)_6]^{5-}$. The compound was prepared with moderate yield by the reaction of polymeric solid $Re_3MoS_4Te_4$ containing a tetrahedral cluster core with molten KCN at 850 °C.

2. Experimental

2.1. Materials and methods

X-ray powder diffraction patterns were collected on a Philips APD 1700 diffractometer (Cu Kα radiation, graphite monochromator) in the 2θ range 5°–80°. UV–Vis spectra were recorded on an Ultrospec 3300 pro spectrophotometer in the range of 200–1100 nm. IR spectra were recorded on a Bruker IFS-85 spectrometer in KBr pellets. KCN, CsCl were used as purchased. $Re_{4-x}Mo_xS_4Te_4$ ($x = 0.67$, 1, 1.33 and 2) were prepared as described in [9]. X-ray diffractometry revealed the identity of these phases. The $Re_2Mo_2S_4Te_4$ sample contained traces of MoS_2, other samples were single phase.

A mixture of $Re_3MoS_4Te_4$ (1 g, 0.773 mmol) and KCN (0.5 g, 7.678 mmol) was placed in a quartz tube. The tube was evacuated, sealed and kept at 850 °C for 48 h. The products of the reaction were put in 50 ml of water, boiled until potassium polytelluride decomposed and was filtered off. CsCl (0.5 g, 2.970 mmol) was added to the solution. The dark-brown solution was reduced to 2 ml and slowly cooled. The well shaped dark-brown crystals were separated by filtration and dried in air. The yield of the crystals of **1** was 0.612 g (56.67%). Chemical analysis, %: found (calcd.) Cs 31.50 (31.72), Re 39.90 (40.00), Mo 6.92 (6.87), S 12.10 (12.25). EDAX for different crystals: energy dispersive spectrometry (EDS) analyses performed on two selected single-crystals led to the following average atomic percentage, Cs/Re/Mo/S: 5.05/4.20/1.80/7.90 for crystal **1** and Cs/Re/Mo/S: 4.95/4.40/1.60/8.05 for crystal **2**. IR, cm^{-1}: 1605 (δ_{HOH}), 2106 (ν_{CN}), 3574 (ν_{OH}), UV–Vis [λ/nm (ε/M^{-1} cm^{-1} per cluster)] 455 (747), 472 (720), 490 (651) and 526 (276). $\mu_{eff} = 1.08$ μ_B (300 K).

2.1.1. Crystallography

X-ray structural analysis was carried out for two crystals on a STOE Stadi4 four-circle diffractometer (Mo K_α, $\lambda = 0.7107$ Å, graphite monochromator, standard techniques). Both crystals of $Cs_5[Re_{6-x}Mo_x(\mu_3\text{-}S)_8(CN)_6]\cdot 2H_2O$ in the form of dark brown hexagonal prisms were manually selected from the bulk sample.

2.1.2. Crystal data for the first crystal (data were collected at 211 K, size: 0.15 × 0.14 × 0.10 mm)

$C_6H_4Cs_5Mo_{1.79}N_6O_2Re_{4.21}S_8$, $M = 2068.82$, trigonal crystal system, space group $P\bar{3}c1$, $a = 9.792(3)$ Å, $c = 19.14(2)$ Å, $V = 1589.7(18)$ Å^3, $Z = 2$, $D_c = 4.322$ g cm^{-3}. A total of 2116 reflections were collected up to $2\theta_{max} = 50°$, of which 946 were unique ($R_{int} = 0.0598$). Absorption corrections ($\mu = 22.835$ mm^{-1}) were applied by integration from the crystal shape, transmission factors ranging from 0.0614 to 0.0190. The crystal is merohedry twin with law of (1 0 0/0 1 0/0 0 −1). The structure was solved by direct methods and refined by full-matrix least-squares on F^2 with an anisotropic approximation using SHELX-97 [10]. Hydrogen atoms were not located. Metal atom positions correspond to the mixture of Mo and Re atoms. The relative occupancy factors were refined together with the rest parameters without constrains. Final R values: $R_1 = 0.0378$, $wR_2 = 0.0903$ for 808 $F_o \geqslant 4\sigma(F)$, $R_1 = 0.0527$, $wR_2 = 0.0967$, GOF = 1.100 for all unique data, relative weights of twin components are 0.313(3) and 0.687(3).

2.1.3. Crystal data for the second crystal (data were collected at room temperature, size: 0.19 × 0.18 × 0.12 mm)

$C_6H_4Cs_5Mo_{1.64}N_6O_2Re_{4.36}S_8$, $M = 2082.81$, trigonal crystal system, space group $P\bar{3}c1$, $a = 9.838(3)$ Å, $c = 19.195(6)$ Å, $V = 1608.9(9)$ Å^3, $Z = 2$, $D_c = 4.299$ g cm^{-3}. A total of 4051 reflections were collected up to $2\theta_{max} = 50°$, of which 1240 were unique ($R_{int} = 0.0954$). Absorption corrections ($\mu = 23.084$ mm^{-1}) were applied by integration from the crystal shape, transmission factors ranging from 0.9952 to 0.5312. The crystal is merohedry twin with law of (1 0 0/0 1 0/0 0 −1). The structure was solved by direct methods and refined by full-matrix least-squares on F^2 with an anisotropic approximation using SHELX-97 [10]. As in the first crystal, metal atom positions correspond to the mixture of Mo and Re atoms. The relative occupancy factors also were refined together with the rest parameters without constrains. Hydrogen atoms were not located. Final R values: $R_1 = 0.0406$, $wR_2 = 0.0765$ for 808 $F_o \geqslant 4\sigma(F)$, $R_1 = 0.0678$, $wR_2 = 0.0905$, GOF = 1.125 for all unique data. Relative weights of twin components are 0.408(3) and 0.592(3).

Crystal data and selected bond lengths for the two crystals are given in the Tables 1 and 2, respectively.

3. Discussion

The concurrent formation of Re_4 and Re_6 clusters realized in high temperature reactions is known. The study of Re–Te–Cl and Re–Se–Cl systems showed that Re_4 clusters are stable below 400 °C, while above this temperature Re_6 ones are stable [11]. Up to now $Re_4S_4Te_4$ [12] found in the ternary Re–S–Te system is the only tetrahedral cluster compound stable at 900 °C.

Our preliminary study of the interaction of the $Re_4S_4Te_4$ with molten KCN at 850 °C showed that the reaction resulted in rearrangement from a Re_4 to Re_6 cluster core and formation of a compound isostructural to the known cubic phase $Cs_3K[Re_6(\mu_3\text{-}S)_6(\mu_3\text{-}Te_{0.66}S_{0.34})_2(CN)_6]$ [13] with cell parameters $a = 17.80(1)$ Å, $V = 5640$ Å^3. Therefore we could expect that heterometallic $Re_{4-x}Mo_xS_4Te_4$ [9] clusters can be used as starting materials for preparation of new compounds with an octahedral $\{Re_{6-x}Mo_x\}$ cluster core.

The interaction of the tetrahedral heterometallic cluster compound $Re_3MoS_4Te_4$ under the conditions reported in Section 2 leads to the formation of a compound with an average composition $Cs_5[Re_{4.5}Mo_{1.5}(\mu_3\text{-}S)_8(CN)_6]\cdot 2H_2O$. EDAX for a set of single crystals showed that the Re/Mo ratio for them vary in the range $Re_{4.2}Mo_{1.8}$–$Re_{4.5}Mo_{1.5}$, while the Cs/(Re,Mo) ratio is nearly constant. No remarkable amount of tellurium presents in the tested crystals. All crystals in the synthesis have the same shape, hexagonal prisms. It should mean that all of them have the same structure, which was confirmed by measuring the powder diffraction pattern. The X-ray powder diffraction and EDAX data show that we have a typical solid solution with variable

composition, namely, different crystals belonging to the same structural type have variable Re/Mo ratio. To investigate this phenomenon we have selected two crystals for X-ray structural analysis. Both of them appeared to be merohedry twins which is typical for trigonal crystals with hexagonal shape. As expected the structures of both crystals were the same but relative Re/Mo occupancies are different.

The cluster anion in the structure of the reported compounds (Fig. 1) has a structure which is similar to well-known $[M_6Q_8(CN)_6]^{n-}$ octahedral chalcocyanide cluster complexes (M = Re, Q = S, Se, Te, $n = 3$, 4 [13,14]; M = Mo, Q = S, Se, $n = 6$, 7 [15,16]; M = W, Q = S, $n = 6$ [17]). As usual, the metal octahedron is surrounded by eight μ_3-S ligands forming a S_8 cube. Additionally each metal atom is coordinated by the linear CN ligand through the C atom. Average bond lengths are given in Table 3 together with the data for other related compounds. We can see that Re–Re bond distances in $[Re_6S_8(CN)_6]^{4-}$ (2.603 Å) are significantly shorter than Mo–Mo bond distances in $[Mo_6S_8(CN)_6]^{7-}$ (2.666 Å). X-ray structural analysis shows that the metal–metal bond distances in our heterometallic phase, $[Re_{6-x}Mo_x(\mu_3\text{-}S)_8(CN)_6]^{5-}$, depend on the value of x (2.619(2)–2.620(1) and 2.624(1)–2.627(1) for $x = 1.79$ and $x = 1.63$, respectively, Table 3), lying in the range between Re–Re and Mo–Mo. The M–S distances for all $[M_6S_8(CN)_6]^{n-}$ (M = Mo, W, Re; $n = 4$, 5, 6, 7) anions are almost the same and therefore are not sensitive to the nature of the metal atoms. The crystal packing is shown in Fig. 2.

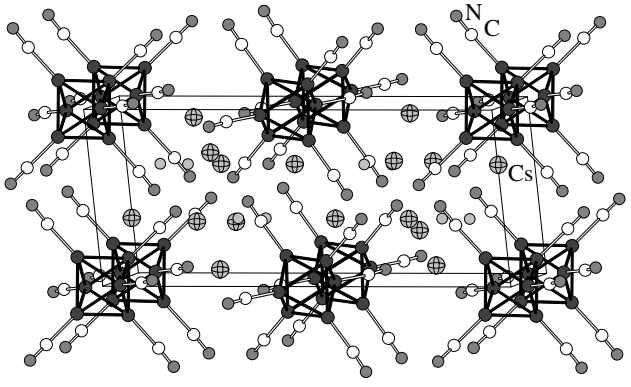

Fig. 2. Crystal packing in **2**. Sulfur atoms are omitted for clarity.

All the experimental data show that the prepared phase is the solid solution of cesium salts of different $[Re_{6-x}Mo_xS_8(CN)_6]^{5-}$ anions. Because the average value of x is close to 1.5 we can expect that we have mixture of $[Re_5MoS_8(CN)_6]^{5-}$ and $[Re_4Mo_2S_8(CN)_6]^{5-}$ clusters. The structural and EDAX data show that the Cs/(Re,Mo) ratio is constant. It means that both anions have the same charge, −5. From this it is possible to conclude that the valence electron concentration (VEC) for the $[Re_5MoS_8(CN)_6]^{5-}$ anion is equal to 24 electrons and this anion is diamagnetic, while $[Re_4Mo_2S_8(CN)_6]^{5-}$ has a VEC = 23 and is paramagnetic. The measured value of effective magnetic moment, 1.08 MB, is in good agreement with the suggestion that only half of the cluster units contain an unpaired electron.

We also have investigated the reaction of other phases in the $Re_{4-x}Mo_xS_4Te_4$ series [9] with molten KCN and found that under similar experimental conditions similar phases with different Re/Mo ratio were formed. The crystallization with CsCl resulted in phases isostructural to crystals **1** and **2**. EDAX analysis made on several crystals gave compositions summarized in Table 4. We can suppose that these phases contain {Re_5Mo}, {Re_4Mo_2} and {Re_3Mo_3} octahedral clusters.

In conclusion, interaction of tetrahedral $Re_{4-x}Mo_xS_4Te_4$ cluster compounds with molten KCN leads to the formation of octahedral heterometallic $[Re_{6-x}Mo_xS_8(CN)_6]^{5-}$ cluster anions, $x = 1$, 2 co-existing in the crystals $Cs_5[Re_{6-x}Mo_x(\mu_3\text{-}S)_8(CN)_6]\cdot 2H_2O$. The solubility of these salts opens the way for further study of the chemical properties of Re–Mo heterometallic cluster complexes.

4. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition Nos. 391226 and 391227.

Titanium(IV) iodide complexes with phosphine and arsine donor ligands and the crystal structures of the iron(II)/(III) redox pair $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]^{0/+}$

Abstract

Red-brown $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ and $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ have been prepared from the ligands and TiI_4 in a 1:1 molar ratio in anhydrous CH_2Cl_2. They have been characterised by analysis, IR, ^1H and $^{31}P\{^1H\}$ NMR and UV–Visible spectroscopy as appropriate and have six-coordinate (*cis*) octahedral geometries. Investigation of the yellow or fawn products from reactions of TiI_4 and the ligands in a 1:2 molar ratio, and suggested in the literature to be bis(ligand)-Ti(IV) complexes, have shown that these are mixtures containing iodinated and oxidised ligands, but do not contain Ti(IV)–iodide complexes. The crystal structures of two iron–diarsine complexes $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ and $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]I_3 \cdot 2CH_2Cl_2$ arising from iron iodide impurities in one commercial sample of TiI_4 are reported. The complexes constitute a redox pair and the iron(III) complex is the first *pseudo*-octahedral iron(III) iodide complex to be structurally characterised.

1. Introduction

Titanium(IV) chloride is a strong Lewis acid and forms many complexes with neutral ligands with Groups 15 or 16 donor atoms [1,2]. The majority are six-coordinate $[TiCl_4L_2]$ or $[TiCl_4(L–L)]$ (L = monodentate, L–L = bidentate ligand), but with a very limited number of diphosphine or diarsine ligands, including $o\text{-}C_6H_4(PMe_2)_2$, $Me_2PCH_2CH_2PMe_2$ and $o\text{-}C_6H_4(AsMe_2)_2$, both six-coordinate $[TiCl_4(L–L)]$ and eight-coordinate $[TiCl_4(L–L)_2]$ can be isolated [3,4]. Titanium(IV) bromide generally forms similar complexes, although its Lewis acidity is weaker than the chloride and the complexes are more extensively dissociated in solution. In marked contrast, very little is known about the complexes of titanium(IV) iodide, which is a weak Lewis acid. Early studies reported the formation of dark coloured oils or solids on reaction with ethers or amines [5,6], none of which has been thoroughly characterised. With $o\text{-}C_6H_4(AsMe_2)_2$ a yellow product, suggested to be $[TiI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]I_2$ has been reported [7], but with little data and its nature is unclear. A weakly paramagnetic yellow $[TiI_4L_3]$ (L_3 = the triarsine $MeAs(CH_2CH_2CH_2AsMe_2)_2$) has also been mentioned, but is similarly ill-defined [8]. We have reported two red-brown diselenoether complexes $[TiI_4(L–L)]$ (L–L = $MeSeCH_2CH_2SeMe$, $o\text{-}C_6H_4(SeMe)_2$) [9].

We recently re-examined the complexes formed by $TiCl_4$ and $TiBr_4$with a variety of diphosphines and diarsines and obtained detailed characterisations of six- ($[TiX_4(L–L)]$) and eight-coordinate ($[TiX_4(L–L)_2]$) (X = Cl or Br) complexes [4], including multinuclear NMR studies of their solution behaviour and crystallographic studies of several examples. The most stable complexes were produced by L–L = $o\text{-}C_6H_4(PMe_2)_2$ and $o\text{-}C_6H_4(AsMe_2)_2$ and these also offer the possibility of obtaining

doi:10.1016/j.poly.2003.10.010

both six- and eight-coordinate examples [4]. In view of the paucity of titanium(IV) iodide complexes, we have examined the reactions of these two ligands with TiI_4 under a variety of conditions, and show that whilst six-coordinate $[TiI_4(L–L)]$ can be isolated, there is no evidence for eight-coordination, and that the yellow products described in the literature are not titanium(IV) complexes.

2. Results and discussion

2.1. $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ and $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$

The reaction of TiI_4 in rigorously anhydrous CH_2Cl_2 with one equivalent of $o\text{-}C_6H_4(PMe_2)_2$ gave a red-brown solid identified as $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ by analysis. The solid is stable under dry dinitrogen, but is rapidly hydrolysed on exposure to air, and instantly decomposed in solution by trace moisture with loss of the colour. The complex is less soluble in chlorocarbons than the corresponding chloride or bromide and these initially red-brown solutions pale over several days, indicative of decomposition. Repeated attempts to obtain crystals for an X-ray study have been unsuccessful. The dark red-brown $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ was made analogously and has very similar properties. The Nujol mull IR spectra of both complexes are similar to those of the corresponding chloro- or bromo-complexes except for the absence of Ti–halogen stretches, which are expected to lie <200 cm^{-1} in the iodides, outside the range of the spectrometer. The UV–Visible spectra show broad features >20 000 cm^{-1} which are attributed to $\sigma(P, As) \rightarrow Ti(t_{2g})$ charge transfer bands [4], and notably, very broad intense features centred at ca. 17 500 cm^{-1} which tail down to ca. 13 000 cm^{-1}, assigned as $\pi(I) \rightarrow Ti(t_{2g})$ and which are responsible for the dark red-brown colours. The assignment of the latter bands as $\pi(I) \rightarrow Ti(t_{2g})$ follows the expected bathochromic shifts in $\pi(X) \rightarrow Ti(t_{2g})$ as X changes $Cl \rightarrow Br \rightarrow I$ [10], and is clear evidence for the presence of Ti(IV)–iodide bonds.

The ^1H NMR spectrum of $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ in dry CD_2Cl_2 solution showed a single second order multiplet δ(Me) resonance, which was unchanged on cooling the solution to 190 K, showing that dissociation of the diphosphine is negligible. The $^{31}P\{^1H\}$ NMR spectrum was a singlet at $\delta = 18$, which compares with the values in the "free" ligand (δ −55), and in $[TiCl_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ (δ 29.5) and $[TiBr_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ (δ 24.5) [4], showing a stepwise decrease in coordination shift along the series Cl > Br > I, consistent with the reduced Lewis acidity in the same order. The ^1H NMR spectrum of $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ in dry CD_2Cl_2 solution shows partial dissociation of the ligand with a singlet (Me) at 2.11 attributed to the coordinated $AsMe_2$ groups, and one at 1.20 due to "free" $AsMe_2$ groups, with approximately equal intensities (and corresponding aromatic resonances). This continues the pattern found with the lighter halides [4] – whilst $[TiCl_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ shows only a singlet δ(Me) due to coordinated ligand, in solutions of $[TiBr_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ resonances due to both "free" and coordinated diarsine groups are present. It was also noted that in rigorously dry CH_2Cl_2 solutions, neither $[TiCl_4\{o\text{-}C_6H_4(PMe_2)_2\}]$ or $[TiBr_4\{o\text{-}C_6H_4(PMe_2)_2\}_2]$ underwent halogen exchange with $^nBu_4NI$ (on the basis of their $^{31}P\{^1H\}$ NMR spectra recorded 30 min after mixing), showing the expected preference of hard Ti(IV) for the lighter halide. Although we have been unable to obtain crystallographic confirmation of the structure, the spectroscopic properties of these two complexes are entirely consistent with their formulation as *cis pseudo*-octahedral monomers.

2.2. The "$TiI_4(L–L)_2$" complexes

The addition of a second equivalent of $o\text{-}C_6H_4(AsMe_2)_2$ to a solution of $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ in dry CH_2Cl_2, or direct reaction of two equivalents of $o\text{-}C_6H_4(AsMe_2)_2$ with TiI_4 in dry CH_2Cl_2, produces yellow solutions which precipitate (in poor yield) yellow or fawn powders on concentration. The products hydrolyse rapidly in air and contain Ti, As and I (EDX study). [1] However the UV–Vis spectrum of the solid shows only intense, ill-defined features >26 000 cm^{-1} and no significant absorption <20 000 cm^{-1}. Crucially this rules out the presence of Ti(IV)–I bonds, compare $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$ (above). Notably, in the $[TiX_4\{o\text{-}C_6H_4(AsMe_2)_2\}_n]$ (X = Cl or Br, $n = 1$ or 2) the $\pi(X) \rightarrow Ti(t_{2g})$ differ little in energy between the six- and eight-coordinate centres [4]. The ^1H NMR spectra in anhydrous $CDCl_3$ of different samples of the yellow substance show a mixture of species present, with Me resonances in two groups ca. δ 1.2 (corresponding to "free" $AsMe_2$ groups) and ca. 1.85–2.2. The latter resonances could be due to coordinated $AsMe_2$ groups but are similar to those found in solutions of the diarsine in $CDCl_3$ treated with diiodine. The relative intensities of the resonances differ between samples. Significantly, none of the resonances are attributable to $[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}]$, which would have been expected to be formed by dissociation of a 1:2 complex [4]. On this basis the products are formulated as mixtures of partially iodinated diarsine, e.g., $o\text{-}C_6H_4(AsMe_2)(AsMe_2I_2)$, possibly arsine oxide (formed by hydrolysis), and lower oxidation state titanium species. Studies of the reaction of tertiary

[1] C, H analysis is not helpful. We found values for our samples C, 22 ± 1%; H, ca. 3 ± 0.5%. Calculated for $[TiI_4(\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$: C, 21.3; H, 2.9%. $[TiI_3(\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$: C, 24.0; H, 3.2%. $o\text{-}C_6H_4(AsMe_2)(AsMe_2I_2)$: C, 22.3; H, 3.0%.

arsines with diiodine have shown that a variety of R_3AsI_2, R_3AsI_4 and more complex materials form [11,12]. Little is known about complexes of titanium iodides in lower oxidation states, although a brown $[Ti_2I_6(PMe_3)_4]$ has been structurally characterised [13], and the presence of Ti(III) would account for the paramagnetism reported for some titanium iodide–arsine complexes in the older literature [8].

The reaction of TiI_4 with o-$C_6H_4(PMe_2)_2$ in a 1:2 ratio also gives a fawn-yellow solid with generally similar properties. The $^{31}P\{^1H\}$ NMR spectrum of this material in dry CH_2Cl_2 shows resonances at δ −47 (v br), −26, +33 and +38 along with some other much weaker features; species with δ −47 (v br), +37, +38 are formed by treating o-$C_6H_4(PMe_2)_2$ in CH_2Cl_2 with I_2, and no resonance at δ 18, which would indicate some $[TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}]$, was found. It seems clear that the product of reacting TiI_4 with two equivalents of o-$C_6H_4(PMe_2)_2$ is also a mixture containing substantial amounts of iodinated diphosphine and no Ti(IV). We note that Cotton and Kibala [12] reported isolation of $[(Ph_3PI)_2I_3]I_3$ as a by-product of the reactions of ZrI_4 with Ph_3P – reduction of Zr(IV) is considerably harder than of Ti(IV). It is probable that eight-coordination (as in $[TiI_4\{o\text{-}C_6H_4(EMe_2)_2\}_2]$) is sterically precluded for the larger iodide ligands, and instead Ti(IV) is reduced by the excess phosphine or arsine present.

2.3. Diarsine complexes of Fe(II) and Fe(III) Iodide

Many attempts were made to obtain crystals from the samples of "$[TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$" by slow evaporation of solutions in rigorously dry chlorocarbons or by layering chlorocarbon solutions with dry hexane. Most failed, producing only pale yellow powders. However, from two independently prepared solutions containing TiI_4 and o-$C_6H_4(AsMe_2)_2$ in a 1:2 ratio in CH_2Cl_2, allowed to evaporate slowly in a dry glove-box, a few brown and red-purple crystals were isolated (along with much decomposed material). X-ray data were collected on both, and initial solution and refinement proceeded to yield structures which appeared to be $[TiI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ and $[TiI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]I_3$. The apparent formation of Ti(II) was very unexpected, and more detailed examination of the "Ti–As" and "Ti–I" bond lengths showed these were unreasonably short, and it was also apparent that the thermal parameters associated with the metal centres were unusually large. Comparison of the parameters with published collected bond length tables [14], suggested that the "Ti" atom might in fact be Fe, and refinement of the data using iron gave a much better model with sensible bond lengths (Table 1) and thermal parameters. Examination of the crystals using EDX (energy dispersive X-ray spectroscopy) confirmed the presence of iron, arsenic and iodine, with no detectable titanium, and thus is it clear that the crystals were actually $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ and $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]I_3$. EDX examination of the TiI_4 sample used in these syntheses showed significant amounts of iron (ca. 5%) whereas other samples of TiI_4 used in this study, including the synthesis of the 1:1 complexes in Section 2.2, showed no iron present. The $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ is easily made from $[FeCl_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]$ and LiI [15,16], but iron(III) iodide itself is unstable at ambient temperatures [17] and very few complexes have been described [18–20]. Some years ago we [16] described the synthesis of $[FeI_2\{o\text{-}C_6H_4(EMe_2)_2\}_2]BF_4$ (E = P or As) by HNO_3 oxidation of $[FeI_2\{o\text{-}C_6H_4(EMe_2)_2\}_2]$ suspended in HBF_4 at 0 °C. Their instability in solution prevented growth of crystals for an X-ray study, but Fe–I and Fe–P(As) bond lengths were obtained via Fe K-edge EXAFS data. The X-ray determined bond lengths in the present study are in generally good agreement with the EXAFS data within the usual precision of the latter (±0.02 Å) (Table 1). The two iron complexes constitute a redox pair $[FeI_2\{o\text{-}C_6H_4(AsMe_2)_2\}_2]^{0/+}$ with both the Fe species being centrosymmetric (Figs. 1 and 2) and comparison of the heavy atom bond lengths show that on oxidation from Fe(II) to Fe(III) the Fe–I

bonds shorten and the Fe–As bonds lengthen. The metal centres are both low-spin (d^6 and d^5, respectively) and thus the contraction in Fe–I bond length on oxidation is consistent both with the slightly smaller radius of Fe(III) over Fe(II), and with stronger interaction between the charged iodide and the harder metal centre. The lengthening of the Fe–As bonds on oxidation can be attributed to weaker interaction between the soft neutral arsenic ligand and the harder metal centre. The trends are also compatible with the Orpen–Connelly model [21] of metal–phosphine/arsine bonding, which would predict a reduced π-backbonding component when the metal has a higher oxidation state and hence a longer Fe–As bond. This latter model also predicts that π-backbonding Fe → As uses the C–As σ* as acceptor orbitals and should be accompanied by a lengthening of the C–As bonds. However, the differences in the C–As bond lengths between the structures are not significant and, as is often the case, this test cannot be applied. The origin of the iron in this particular TiI_4 sample is unknown, possibly it arises from ilmenite ($FeTiO_3$) which may have been the original ore source for the titanium. It is possible that similar impurities could go some way to accounting for the poor reproducibility of titanium iodide species described in the older literature.

3. Experimental

All reactions were carried out using Schlenk techniques and samples were handled in a glove-box (<5 ppm water). Solvents were dried as described [4,9] and freshly distilled before use. Physical measurements were made as described elsewhere [4,9]. The ligands were made by literature methods [22,23]. Titanium(IV) iodide was obtained from Strem or Aldrich and checked for impurities by EDX (see Discussion). EDX measurements were obtained on a Philips XL30 ESEM fitted with an EDAX Phoenix detector.

3.1. [$TiI_4\{o\text{-}C_6H_4(PMe_2)_2\}$]

TiI_4 (0.20 g, 0.36 mmol) was dissolved in gently refluxing dry CH_2Cl_2 (80 ml), the solution filtered to remove any residual solid, cooled, and the deep purple solution treated with o-$C_6H_4(PMe_2)_2$ (0.07 g, 0.36 mmol) in CH_2Cl_2 (10 ml). The dark red solution produced, was stirred at ambient temperature for 30 min, then concentrated in vacuum to 5 ml. Dry hexane (20 ml) was added dropwise with stirring to form a purple precipitate, which was filtered off and dried in vacuo. Yield 0.08 g, 31%. *Anal*. Found: C, 15.8; H, 2.2. Calc. for $C_{10}H_{16}I_4P_2Ti$: C, 15.9; H, 2.1%. ^{1}H NMR (300 K, CD_2Cl_2): 7.60–7.75 (m), 2.28 (m). $^{31}P\{^1H\}$ NMR (300 K, CD_2Cl_2): 18.0. UV–Visible (diffuse reflectance (DR) in $BaSO_4$)/cm^{-1}: 34 200, 27 500, 22 700(sh), 17 800.

3.2. [$TiI_4\{o\text{-}C_6H_4(AsMe_2)_2\}$]

Was made similarly to the above using o-$C_6H_4(AsMe_2)_2$ (0.103 g, 0.36 mmol). Dark red-brown solid. Yield 26%. *Anal.* Found: C, 14.5; H, 2.1. Calc. for $C_{10}H_{16}As_2I_4Ti$: C, 14.3; H, 1.9%. ^{1}H NMR (300 K, CD_2Cl_2): 7.70–7.55 (m), 7.50–7.30 (m), 2.11 (s), 1.20 (s). UV–Visible (DR in $BaSO_4$)/cm^{-1}: 28 300, 22 200, 17 500.

3.3. X-ray studies

Brief details of the crystallographic data collection and refinement are given in Table 2. The crystals of the iron complexes were obtained as described in the text. Data collection used a Nonius Kappa CCD diffractometer equipped with an Oxford Cryosystems low temperature device operating at 150 K, and with graphite monochromated Mo-Kα radiation ($\lambda =$ 0.71073 Å). Data solution [24] and refinement [25] were routine, except for the initial modelling of the iron centres as titanium (see text).

4. Conclusions

We have shown that TiI_4 forms six-coordinate 1:1 complexes with o-$C_6H_4(AsMe_2)_2$ and o-$C_6H_4(PMe_2)_2$ which are analogous to the complexes formed by $TiCl_4$ and $TiBr_4$, although rather less stable and more prone to dissociation in solution. The reported 1:2 complexes do not appear to exist, the products suggested to be such in previous work, appear to be mixtures containing partially oxidised or iodinated ligands, and probably lower oxidation states of titanium, which would account for the paramagnetism of some samples. The absence of any intense UV–Visible absorptions <20 000 cm^{-1} rules out the presence of Ti(IV)–I bonds. Structures of two unusual iron complexes arising from iron impurity in the titanium(IV) iodide have also been determined.

5. Supplementary data

Crystallographic data for the structures have been deposited with the Cambridge Crystallographic Data Centre (CCDC) and given number 219522 (Fe(II)) and 219523 (Fe(III)). Copies of the data can be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 22 September 2003; accepted 24 October 2003

Abstract

New ferrocenyl-arenylethenyl-oxazoline derivatives have been prepared (**5**–**10**) from the mono- and (1,1′)-disubstituted (nitrile-ethenylaryl)ferrocene compounds (**1** and **2**) and the appropriated β-aminoalcohol (**3** and **4**) in one step synthesis. The X-ray crystal structure of one of the ferrocenyl-ethenylaryl-oxazoline (**5**) is described, revealing the unusual quasi-planarity of the oxazoline ring with the phenyl and cyclopentadienyl cycles. Two compounds end-capped (**9** and **10**) with both, nitrile and oxazoline groups, are the key intermediates to obtain the non-symmetrical bis(oxazoline) **11**, containing two different substituted heterocycles.

1. Introduction

During the last three decades, much attention has been devoted to the chemistry of ferrocenyl complexes because ferrocene combines chemical versatility with high thermal stability. These properties, together with the exceptional electrochemical properties of ferrocene, make ferrocene-based complexes good candidates for the preparation of new materials with applications in organic synthesis, catalysis and materials science [1,2].

In the search of new materials with electronic communication between terminal subunits, we have focused our interest on the preparation of new conjugated ferrocenyl complexes with end capped nitro [3], pyridine [4] and nitrile [5] groups. End-capping ferrocene with pyridine and nitrile, allowed the ferrocenyl subunit to link to different metallic fragments, affording interesting bimetallic complexes, in which the terminal metallic fragments are connected by a conjugated bridge. In all cases, our compounds showed excellent coordination capabilities which made them appropriate to obtain highly stable heterometallic complexes [5c,6]. In the last decade, an increasing eager effort to the introduction of ferrocene fragments in the design of new homogeneous catalysts has been done [1,7]. Since one of the most useful tools in organic synthesis is asymmetric catalysis, a great effort has been devoted to the synthesis of chiral ferrocenyl ligands, some of which show the planar chirality in the ferrocenyl moiety [8], and some others also in the ancillary ligands [9]. Among the latter ones, oxazoline-type ligands have shown excellent coordination properties [10], which make them good candidates to the synthesis of a large variety of chiral catalysts [11].

Despite the number of ferrocene-oxazoline compounds reported so far is large, most of the examples that we can find in the literature are phosphine based [12]. In this work, we report the synthesis and characterization of new phosphine-free ferrocenyl-oxazoline ligands from our previously reported ferrocenyl-ethenylaryl-nitrile ligands [5a,5b]. The introduction of the ethenylaryl bridge between the ferrocene and the

doi:10.1016/j.poly.2003.10.013

terminal oxazoline unit introduces a new dimension to this new type of complexes, since all of the ferrocene-oxazoline compounds reported so far have the oxazoline fragment directly bound to ferrocene, because of the ortho directing behaviour of this functional group which leads to the synthesis of planar chiral ferrocenes [7,13]. In this exploratory work, racemic amino alcohols have been used. Preliminary attempts to coordinate these compounds to Pd and Au failed.

2. Experimental

2.1. General data

All compounds were prepared under a purified nitrogen atmosphere using standard Schlenk and vacuum-line techniques. The solvents were purified by standard procedures [14] and distilled under nitrogen. Ethenyl-ferrocene derivatives **1** and **2** were prepared as previously described [5a,5b]. 2-aminobutanol (Fluka) and leucinol (Aldrich) were used without previous purification. NMR spectra were recorded on JEOL Eclipse 400, Bruker DRX 500 (^{1}H, standard $SiMe_4$) and Varian Gemini 200 (^{13}C, 50 MHz, standard $SiMe_4$) in $CDCl_3$. Chemical shifts were reported downfield from standards. IR spectra were recorded on a Nicolet 520 FT-IR and FTIR Nicolet Impact 400 spectrometers. FAB mass chromatograms were obtained on a Fisons V6-Quattro instrument. Optical rotations were measured on a Perkin Elmer 241MC spectropolarimeter. Elemental analyses were carried out by the *Serveis Científico-Tècnics de la Universitat de Barcelona* in an Eager 1108 microanalyzer.

2.2. 1-Ethenyl-(4-(4′-ethyl-3′,4′-dihydrooxazol-2′-yl)phenyl)ferrocene, **5**

0.100 g (0.227 mmol) of 1-(ethenyl-4-cianophenyl)ferrocene, 0.155 g (1.74 mmol) of 2-aminobutanol and a catalytic amount of zinc chloride were dissolved in 10 cm^3 of toluene at room temperature. The mixture was refluxed for 8 days (monitored by TLC). The mixture was filtered off and the solvent was removed under reduced pressure, affording an oil, which was chromatographied over SiO_2 using ethyl acetate/hexane (1/1) as eluent. After removing the solvent, **5** was obtained as a red solid. Yield: 0.045 g (52%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 1.01 (t, 7.0 Hz, 3H), 1.72 (m, 2H), 4.05 (m, 2H), 4.28 (m, 1H), 4.32 (2, 5H), 4.46 (m, 4H), 6.65 (d, 16.0 Hz, 1H), 6.76 (d, 16.0 Hz, 1H), 7.69 (d, 8.0 Hz, 2H), 7.81 (d, 8.0 Hz, 2H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$) δ 12.00, 22.00, 25.20, 44.35, 64.00, 65.40, 68.00, 68.10, 71.50, 82.00, 123.90, 124.30, 127.40, 127.70, 164.00 ppm. IR (KBr) 1650 (C=N) cm^{-1}. *Anal.* Calc. for $C_{23}H_{23}NOFe$: C, 71.70; H, 6.02; N, 3.64. Found C, 70.50; H, 6.00; N, 3.50%. MS (FAB positive) m/z 385 ([M]$^+$).

2.3. 1-Ethenyl-(4-(4′-isobutyl-3′,4′-dihydrooxazol-2′-yl)-phenyl)ferrocene, **6**

Compound prepared following the methodology described for **5**. Starting materials: 0.100 g (0.227 mmol) of 1-(ethenyl-4-cianophenyl)ferrocene, 0.204 g (1.74 mmol) of leucinol and a catalytic amount of zinc chloride. Yield: 0.068 g (73%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 0.95 (m, 3H), 0.97 (m, 3H), 1.40 (m, 1H), 1.80 (m, 2H), 3.98 (t, 8.0 Hz, 1H), 4.13 (s, 5H), 4.29 (m, 2H), 4.47 (m, 2H), 6.69 (d, 16.0 Hz, 1H), 6.94 (d, 16.0 Hz, 1H), 7.42 (d, 8.0 Hz, 2H), 7.88 (d, 8.0 Hz, 2H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$) δ 21.62, 21.93, 24.46, 44.54, 64.06, 65.97, 68.17, 68.24, 71.93, 81.69, 124.13, 124.35, 127.43, 127.86, 163.0 ppm. IR (KBr) 1640 (C=N) cm^{-1}. *Anal.* Calc. for $C_{25}H_{27}NOFe$: C, 72.65; H, 6.58; N, 3.39. Found C, 71.90; H, 6.80; N, 3.10%. MS (FAB positive) m/z 413 ([M]$^+$).

2.4. 1,1′-Bis(ethenyl-(4-(4′-ethyl-3′,4′-dihydrooxazol-2′-yl)phenyl))ferrocene, **7**

0.200 g (0.454 mmol) of 1,1′-bis(ethenyl-4-cianophenyl)ferrocene, 0.624 g (7.0 mmol) of 2-aminobutanol and a catalytic amount of zinc chloride. The mixture was filtered off and the solvent was removed under reduced pressure, affording an oil, which was chromatographied over SiO_2 using dichloromethane/hexane (1/1) as eluent. The product corresponded to the fractions with $R_f = 0.4$ on the TLC sheet. After removing the solvent, **7** was obtained as a red solid. Yield (based on **2**): 0.053 g (20%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 0.98 (t, 7.5 Hz, 6H), 1.63 (m, 2H), 1.77 (m, 2H), 4.05 (t, 8.0 Hz, 2H), 4.28 (m, 2H), 4.29 (m, 4H), 4.42 (m, 4H), 4.44 (dd, 11.8 Hz, 8.0 Hz, 2H), 6.61 (d, 16.5 Hz, 2H), 6.85 (d, 16.5 Hz, 2H), 7.31 (d, 8.4 Hz, 4H), 7.81 (d, 8.4 Hz, 4H) ppm. IR (KBr) 1645 (C=N) cm^{-1}. *Anal.* Calc. for $C_{36}H_{36}N_2O_2Fe$: C, 73.97; H, 6.21; N, 4.79. Found C, 74.30; H, 6.40; N, 4.55%. MS (FAB positive) m/z 585 ([M]$^+$).

2.5. 1,1′-Bis(ethenyl-(4-(4′-isobutyl-3′,4′-dihydrooxazol-2′-yl)phenyl))ferrocene, **8**

0.200 g (0.454 mmol) of 1,1′-bis(ethenyl-4-cianophenyl)ferrocene, 0.820 g (7.0 mmol) of leucinol and a catalytic amount of zinc chloride. The mixture was filtered off and the solvent was removed under reduced pressure, affording an oil, which was chromatographied over SiO_2 using dichloromethane/hexane (1/1) as eluent. The product corresponded to the fractions with $R_f = 0.4$ on the TLC sheet. After removing the solvent, **8** was obtained as a red solid. Yield (based on **2**): 0.047 g (16%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 0.98 (m, 12H), 1.39 (m, 2H), 1.73 (m, 2H), 1.76 (m, 2H), 3.98 (t, 8.0 Hz, 2H), 4.14 (m, 8H), 4.29 (m, 4H), 4.46 (m, 4H), 6.52 (dd,

11.8 Hz, 8.0 Hz, 2H), 6.69 (d, 16.0 Hz, 2H), 6.96 (d, 16.0 Hz, 4H), 7.43 (d, 8.0 Hz, 4H), 7.88 (d, 8.0 Hz, 4H) ppm. *Anal*. Calc. for $C_{40}H_{44}N_2O_2Fe$: C, 74.95; H, 6.92; N, 4.37. Found C, 74.40; H, 7.05; N, 4.40%. MS (FAB positive) m/z 641 ($[M]^+$).

2.6. 1-Ethenyl-(4-(4′-ethyl-3′,4′-dihydrooxazol-2′-yl)phenyl)-1′-ethenyl-(4-cianophenyl)ferrocene, 9

Co-product obtained with **7** (see preparation of **7**) by condensation of **2** with **3**. The compound **9** corresponded to the eluted fractions with $R_f = 0.6$ on the TLC sheet, on the column chromatography over SiO_2 using dichloromethane/hexane (1/1) as eluent. Yield (based on **2**): 0.082 g (41%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 1.01 (t, 7.2 Hz, 3H), 1.65 (m, 1H), 1.80 (m, 1H), 4.09 (t, 8.1 Hz, 1H), 4.20 (m, 1H), 4.29 (m, 2H), 4.32 (m, 2H), 4.45 (m, 4H), 4.55 (dd, 8.0 Hz, 9.5 Hz, 2H), 6.45 (d, 16.1 Hz, 1H), 6.52 (d, 16.5 Hz, 1H), 6.65 (d, 16.1 Hz, 1H), 6.67 (d, 16.5 Hz, 1H), 7.14 (d, 8.5 Hz, 2H), 7.16 (d, 8.5 Hz, 2H), 7.33 (d, 8.5 Hz, 2H), 7.69 (d, 8.5 Hz, 2H) ppm. *Anal*. Calc. for $C_{32}H_{28}N_2OFe$: C, 75.01; H, 5.51; N, 5.47. Found C, 75.30; H, 5.60; N, 5.30%. MS (FAB positive) m/z 512 ($[M]^+$).

2.7. 1-Ethenyl-(4-(4′-isobutyl-3′,4′-dihydrooxazol-2′-yl)-phenyl)-1′-ethenyl-(4-cianophenyl)ferrocene, 10

Co-product obtained with **8** (see preparation of **8**) by condensation of **2** with **4**. The compound **10** corresponded to the eluted fractions with $R_f = 0.6$ on the TLC sheet, on the column chromatography over SiO_2 using dichloromethane/hexane (1/1) as eluent. Yield (based on **2**): 0.076 g (31%). ^{1}H NMR (500 MHz, $CDCl_3$) δ 0.98 (m, 6H), 1.42 (m, 2H), 1.75 (m, 2H), 1.82 (m, 2H), 4.02 (t, 8.0 Hz, 2H), 4.28 (m, 2H), 4.31 (m, 2H), 4.35 (m, 2H), 4.44 (m, 4H), 4.55 (dd, 8.0 Hz, 9.5 Hz, 2H), 6.45 (d, 16.0 Hz, 1H), 6.51 (d, 16.0 Hz, 1H), 6.66 (pt, 16.8 Hz, 2H), 7.13 (d, 7.0 Hz, 2H), 7.15 (d, 8.5 Hz, 2H), 7.32 (d, 8.5 Hz, 2H), 7.68 (d, 8.5 Hz, 2H) ppm. ^{13}C NMR (50 MHz, $CDCl_3$) δ 22.68, 22.99, 25.57, 45.59, 65.26, 68.10, 68.14, 68.30, 70.21, 70.48, 73.11, 77.20, 83.21, 84.07, 109.28, 119.22, 124.81, 125.19, 125.68, 126.11, 127.34, 128.47, 130.01, 132.27, 140.18, 141.86, 163.03 ppm. *Anal*. Calc. for $C_{34}H_{32}N_2OFe$: C, 75.56; H, 5.97; N, 5.18. Found C, 75.00; H, 6.05; N, 5.25%. MS (FAB positive) m/z 540 ($[M]^+$).

2.8. 1-Ethenyl-(4-(4′-isobutyl-3′,4′-dihydrooxazol-2′-yl)-phenyl)-1′-ethenyl-(4-(4′-ethyl-3′,4′-dihydrooxazol-2′-yl)-phenyl)ferrocene, 11

0.100 g (0.220 mmol) of **9**, 0.400 ml (2.386 mmol) of leucinol and a catalytic amount of zinc chloride. The mixture was filtered off and the solvent was removed under reduced pressure, affording an oil, which was chromatographied over SiO_2 using dichloromethane/hexane (1/1) as eluent. After removing the solvent, **11** was obtained as a red solid. Yield: 0.015 g (11%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 0.91 (t, 3H), 0.99 (7, 6H), 1.30 (m, 2H), 1.41 (m, 2H), 1.82 (m, 1H), 4.17 (t, 8.0 Hz, 1H), 4.22 (m, 1H), 4.29(m, 1H), 4.32 (m, 2H), 4.45 (m, 2H), 4.48 (m, 1H), 6.43 (d, 16.3 Hz, 1H), 6.53 (d, 16.0 Hz, 1H), 6.63 (d, 16.0 Hz, 1H), 6.68 (d, 16.3Hz, 1H), 7.05–7.15 (m, 4H), 7.15 (d, 8.5 Hz, 2H), 7.32 (d, 8.5 Hz, 2H), 7.68 (d, 8.5 Hz, 2H) ppm. *Anal*. Calc. for $C_{38}H_{40}N_2O_2Fe$: C, 74.50; H, 6.58; N, 4.57. Found C, 75.00; H, 6.40; N, 4.55%.

2.9. Crystallography

Single crystals were grown by slow diffusion of hexane into concentrated CH_2Cl_2 solution of **5** and mounted on a glass fiber in a random orientation. Data collection was performed at room temperature on a Siemens Smart CCD diffractometer using graphite

Largest diffraction peak and hole (e Å^{-3})	0.319 and −0.329

monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) with a nominal crystal to detector distance of 4.0 cm. An hemisphere of data was collected based on three ω-scans runs (starting $\omega = -28°$) at values $\phi = 0°$, 90° and 180° with the detector at $2\theta = 28°$. At each of these runs, frames (606, 435 and 230, respectively) were collected at 0.3° intervals and 40 s per frame. Space group assignments are based on systematic absences, E statistics and successful refinement of the structures. Structure was solved by direct methods with the aid of successive difference Fourier maps and were refined using the SHELXTL 5.1 software package [15]. All non-hydrogen were refined anisotropically. Hydrogen atoms were assigned to ideal positions and refined using a riding model. Details of the data collection and cell dimensions are given in Table 1 and structure refinement. The diffraction frames were integrated using the SAINT package and corrected for absorption with SADABS [16].

3. Synthesis and characterization

Ferrocenyl-ethenylphenyl-oxazoline compounds **5**–**10** have been obtained (Scheme 1), by zinc-catalyzed reaction of the corresponding nitrile derivative (**1** or **2**) [5b,5c] with the appropriate β-aminoalcohol (*rac*-**3** or *rac*-**4**), as described in the literature for related compounds [17]. The products were obtained in moderate to good yields (up to ca. 70% on the pure product) and fully characterized by usual techniques (IR and NMR spectroscopies, FAB-mass spectra, elemental analysis and X-ray diffraction).

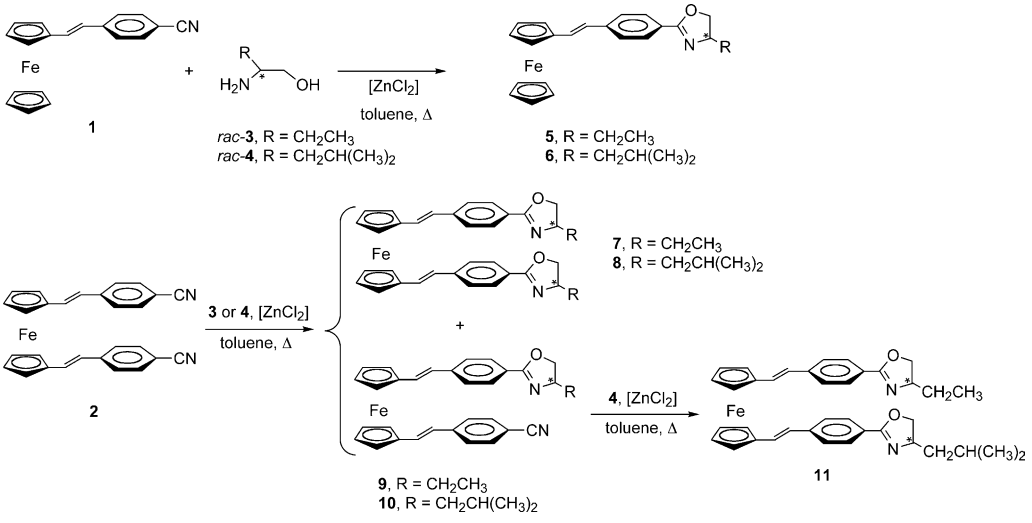
Monoxazolines **5** and **6** were obtained in one-step synthesis from **1** and the aminoalcohol **3** and **4**, respectively (see Scheme 1). Suitable monocrystals for **5** were obtained by slow evaporation from dichloromethane/hexane solution.

Reaction of the ferrocenyl-dinitrile **2** with the aminoalcohols **3** or **4** gave a mixture of the bis(oxazoline) (**7** or **8**) and nitrile-oxazoline (**9** or **10**) compounds (Scheme 1), after one week in refluxing toluene. The nitrile-oxazoline compounds (**8** and **10**) were the major products obtained, with a bis(oxazoline):nitrile-oxazoline molar ratio of ca. 1:2. Further silica column chromatography (dichloromethane/hexane (1/1) used as eluent) of crude led to the separation of both compounds: nitrile-oxazoline ligands (**9** and **10**) and bis(oxazoline) compounds (**7** and **8**), as described in the experimental section. Starting material **2**, was also recovered (ca. 50–60%).

One of the main goals of our work is that the synthesis of pure **9** and **10** allowed the synthesis of non-symmetrical bis(oxazoline) compounds, containing different substituents in the oxazoline ring. Therefore, **11** was obtained by reaction of **9** with the aminoalcohol **4** in low yield (11%), following the same methodology described above.

3.1. Molecular structure of 5

Slow diffusion of a CH_2Cl_2 solution of a racemic mixture of **5** in hexane afforded orange crystals suitable for X-ray diffraction. Compound **5** crystallizes in the centrosymmetric space group $P2(1)/n$. The unit cell contains four molecules, two corresponding to each of the enantiomeric forms because racemic mixture of aminoalcohol was used in the synthesis of the product. As seen in Fig. 1, the molecule displays a quasiplanar arrangement between the ferrocenyl, the phenyl and the oxazoline groups, which facilitates conjugation. The distances from iron to cyclopentadienyl rings, and the C–C distances within the rings lie in the expected range.



Scheme 1. Synthesis of compounds **5**–**11**.

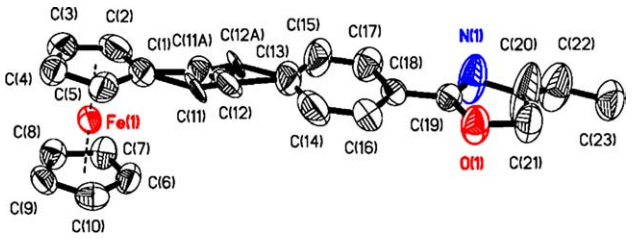


Fig. 1. Molecular structure and atomic labelling scheme for **5**. All hydrogens and double bond disorder have been omitted for clarity. Anisotropic displacement ellipsoids at 50%. Selected bond distances (Å) and angles (°). Fe-Cp(centr.) = 1.65; Fe–C (Cp) = 2.04; C(18)–C(19) = 1.480(8); C(19)–N(1) = 1.237(7); C(19)–O(1) = 1.342(6); O(1)–C(21) = 1.457(7); N(1)–C(20) = 1.493(9); C(20)–C(21) = 1.429(10); N(1)– C(19)–O(1) = 118.7(5); C(19)–O(1)–O(21) = 104.4(4); C(19)–N(1)–C(20) = 105.7(6); N(1)–C(20)–C(21) = 105.2(6). Planes: Cp_{subs}–Cp = 1.03(0.43); Cp_{subs}–Ph = 8.31(0.40); Ph–Oxazoline ring = 2.82(0.49).

The molecular structure presents a disorder in a 1:1 ratio with regard to the orientation of the *trans* olefinic moieties. This kind of disorder has been observed in similar molecules [4,18].

3.2. NMR studies

^{1}H NMR spectra of bis(oxazoline) products (**7**, **8**, **11**) do not exhibit the evidence of isomers in solution (^{1}H NMR spectra were recorded in the temperature range 223–323 K), in spite of the formation of diastereomers due to the racemic aminoalcohols employed in their syntheses. We can establish that average structures are observed, because polarimetry results (for **7** and **8**) indicate that no optically enriched compounds are obtained.

Preliminary coordination tests of these ligands towards gold, [AuCl(PPh$_3$)], and palladium, [PdCl$_2$-(PhCN)$_2$], precursors led to decomposition products, using several solvents (chloroform, dichloromethane, toluene) at different temperatures (253–298 K).

In conclusion, we have prepared new oxazoline compounds from ferrocene ethenylaryl conjugated bridge derivatives, describing for the first time a non-symmetrical bis(oxazoline). Unfortunately, these ligands are not good candidates to stabilize coordination compounds with transition metals.

4. Supplementary material

^{1}H NMR spectra of compounds **8**, **9** and **11**.

The crystal structure of **5** has been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition number CCDC 215315. Abstract

Thallium(I) bis(mercaptoimidazolyl)borates Tl(Bm^R) (R = Me, Bz, Bu^t, *p*-Tol) have been conveniently obtained in a one-pot reaction by metathesis of thallium(I) acetate and the corresponding sodium derivatives Na(Bm^R), in turn generated in high yield from $NaBH_4$ and the appropriate 2-mercapto-1-alkylimidazoles. In contrast to polymeric Tl(Bm^{Me}), the *tert*-butyl-substituted complex Tl(Bm^{tBu}) consists of discrete dimeric molecules in the solid state, as determined by single-crystal X-ray diffraction, and is highly soluble in aromatic hydrocarbons.

Keywords: Thallium; Bis(mercaptoimidazolyl)borate complexes; Crystal structure

1. Introduction

Despite their contemporary genesis, progress in the chemistry of bis(mercaptoimidazolyl)borates has lagged behind that experienced by the closely related tris(mercaptoimidazolyl)borates (Fig. 1), for which literally dozens of compounds have now been prepared [1–26]. Relatively few complexes of Bm^R ligands have been isolated since the synthesis of Li(Bm^{Me}) was first reported by Parkin in 1997 [27]. Together with the mesityl-substituted analogue Li(Bm^{Mes}), these lithium species were used to obtain the corresponding thallium compounds Tl(Bm^R) (R = Me, Mes) and some zinc derivatives thereof, including (Bm^{Me})ZnX (X = I, Me), Zn(Bm^{Me})$_2$, and (Bm^{Mes})$ZnNO_3$ [28]. Subsequently, a number of $[Bm^R]^-$ complexes of technetium, rhenium, and uranium have been isolated by Santos [29–32] and we have synthesized the homoleptic nickel(II) complexes Ni(Bm^R)$_2$ (R = Me, Bz, Bu^t, *p*-Tol) as structural models for the nickel center in the active site of [NiFe] hydrogenases [33]. More recently, the X-ray structure of (Bm^{Me})Au(PPh_3) has been disclosed [34] and several group 12 derivatives M(Bm^R)$_2$ (M = Zn, Cd, Hg), including the first complete series of Bm^R complexes to be structurally characterized, have been obtained [35].

Interested in further developing Bm^R coordination chemistry, we envisioned that a systematic investigation of thallium complexes Tl(Bm^R) may produce valuable species for ensuing reactivity studies. In this regard, thallium reagents, despite their inherent toxicity and cost, have played a conspicuous role in the development of modern inorganic and organometallic chemistry. For example, thallium(I) cyclopentadienyls and tris(pyrazolyl)borates, usually regarded as milder (less reducing) transfer reagents than their alkali metal counterparts, have been extensively used to introduce these ubiquitous ligands to the coordination sphere of both main group and transition metals [36–38]. In addition, effective driving forces in their metathesis reactions with metal halide or metal alkyl complexes are the formation of insoluble thallium(I) halides or the decomposition of

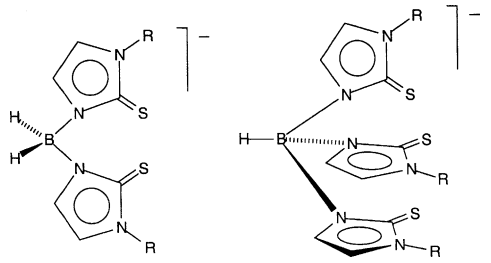

Fig. 1. The bis(mercaptoimidazolyl)borate (Bm^R) and tris(mercaptoimidazolyl)borate (Tm^R) ligand systems.

thermodynamically unstable thallium(I) alkyl by-products, respectively. We report in this paper an improved synthesis of $Tl(Bm^{Me})$ and the preparation and characterization of the hitherto unknown benzyl, *tert*-butyl, and *para*-tolyl derivatives $Tl(Bm^R)$ (R = Bz, Bu^t, *p*-Tol).

2. Results and discussion

2.1. Thallium bis(mercaptoimidazolyl)borates

The thallium(I) complexes $Tl(Bm^R)$ (R = Me, Mes) were originally obtained in ca. 70% yield by the metathetical reactions of thallium(I) acetate with the corresponding lithium precursors $Li(Bm^R)$ in methanol [28]. Following an analogous strategy, but taking advantage of our almost quantitative protocol for generating $Na(Bm^{Me})$ [35], $Tl(Bm^{Me})$ was prepared by reacting a methanolic solution of $Na(Bm^{Me})$ with an aqueous solution of TlOAc, as illustrated in Eq. (1), and typically isolated in 90–95% yield.

$$Na(Bm^{ME}) + TlOAc \overset{MeOH/H_2O}{\rightarrow} Tl(Bm^{Me}) + NaOAc \quad (1)$$

The new thallium(I) bis(mercaptoimidazolyl)borates $Tl(Bm^R)$ (R = Bz, Bu^t, *p*-Tol) were similarly synthesized in 75–80% yield from the corresponding $Na(Bm^R)$ derivatives, accessed in turn by reacting $NaBH_4$ with 2 molar equiv. of the appropriate mercaptoimidazoles in tetrahydrofuran (THF) [35]. The four $Tl(Bm^R)$ complexes described above are white (R = Me, Bz, *p*-Tol) or pale yellow (R = Bu^t) air-stable solids, very soluble in chloroform, dichloromethane, and dimethyl sulfoxide (DMSO) but insoluble in diethyl ether, methanol, or water. In addition, some of the compounds are also soluble in acetone (R = *p*-Tol), acetonitrile (R = Me, *p*-Tol), benzene or toluene (R = Me, Bu^t, *p*-Tol), and THF (R = Bz, *p*-Tol).

The thallium complexes $Tl(Bm^R)$ (R = Me, Bz, Bu^t, *p*-Tol) were characterized by a combination of analytical and spectroscopic techniques, including elemental analyses (CHN) and IR and NMR spectroscopies. For example, the IR spectra of $Tl(Bm^R)$, obtained as KBr pellets, show the expected medium-intensity ν_{B-H} bands between 2350 and 2440 cm^{-1}. ^{1}H and ^{13}C NMR data for all the complexes are similar to those of the corresponding $Na(Bm^R)$ species [35], with only modest downfield chemical shifts observed for both the imidazolyl hydrogen and carbon atoms upon complexation to thallium. However, unlike the $Na(Bm^R)$ derivatives, small broad singlet peaks assigned to the H_2B groups (δ = 3.89–4.06 ppm) are readily observed in the case of the thallium complexes.

2.2. Molecular structure of $Tl(Bm^{tBu})$

Single crystals of $Tl(Bm^{tBu})$ suitable for an X-ray diffraction study were obtained by slow evaporation at room temperature of a saturated benzene solution of the complex. There are two chemically similar but crystallographically independent half molecules in the asymmetric unit, with selected bond lengths and angles for both summarized in Table 1. As shown in Fig. 2, each of the two thallium atoms in the centrosymmetric dinuclear molecules is coordinated to a single thione group from one $[Bm^{tBu}]^-$ ligand and both from the other. In addition, each H_2B moiety also partakes in a weak Tl···H–B interaction of the type prevalent in Bm^R chemistry [28,29,32,33,35]. A similar coordination environment about each metal has been observed for $Li(Bm^{Mes})$, which is dimeric in the solid state as well [28]. The S–Tl–S angles subtended at each metal center in $Tl(Bm^{tBu})$ are in the approximate range 91–131° and the almost rectangular $[Tl_2S_2]$ core [Tl(1)–S(2)–Tl(1A) = 88.91(4)°, S(2)–Tl(1)–S(2A) = 91.09(4)°] is thus virtually identical to that present within polynuclear $Tl(Bm^{Me})$ [28]. However, there are no non-bonded (i.e., intermolecular) Tl–S distances shorter than 3.6 Å in $Tl(Bm^{tBu})$, a phenomenon that effectively precludes the formation of the extended structure observed for $Tl(Bm^{Me})$.

The Tl–S bond lengths in $Tl(Bm^{tBu})$, varying from 2.928(2) to 3.228(2) Å, are comparable to the corre-

Table 1
Selected bond lengths (Å) and bond angles (°) for the two crystallographically independent molecules of $Tl(Bm^{tBu})$

	Molecule 1	Molecule 2
Bond lengths		
Tl(1)–S(1)	2.973(2)	2.961(2)
Tl(1)–S(2)	2.928(2)	2.903(2)
Tl(1)–S(2A)	3.058(2)	3.228(2)
Tl(1)···B(1)	3.835(7)	3.517(6)
Tl(1)···B(1A)	3.525(6)	4.087(6)
Tl(1)···Tl(1A)	4.193(1)	4.199(1)
S(2)···S(2A)	4.273(3)	4.480(3)
Bond angles		
S(1)–Tl(1)–S(2)	101.12(4)	92.98(4)
S(1)–Tl(1)–S(2A)	102.59(4)	131.39(4)
S(2)–Tl(1)–S(2A)	91.09(4)	93.73(4)
Tl(1)–S(2)–Tl(1A)	88.91(4)	86.27(4)
Tl(1)–S(1)–C(1)	123.4(2)	114.6(2)
Tl(1)–S(2)–C(8)	100.6(2)	113.0(2)

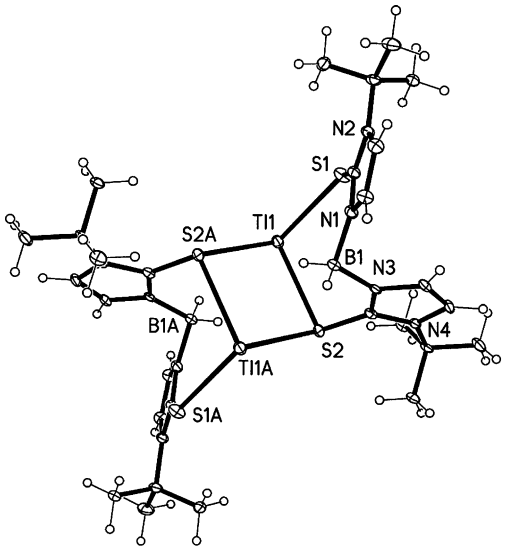

Fig. 2. Molecular structure of Tl(Bm^{tBu}) with thermal ellipsoids at the 30% probability level (only one of the two crystallographically independent molecules in the unit cell is shown).

sponding values found in Tl(Bm^{Me}), in the range 3.043(2)–3.206(2) Å [28]. Similarly, the closest Tl···H–B interactions in the former [d(Tl···B) = 3.52 and 3.53 Å for the two crystallographically independent molecules] are only marginally longer than those in the latter [d(Tl···B) = 3.50 Å]. Predictably, the S–C bond distances for the terminal thione groups (i.e., those bound to a single thallium) in Tl(Bm^{tBu}), 1.693(6) and 1.710(5) Å, are slightly shorter than the corresponding values found in the bridging mercaptoimidazolyl moieties [1.725(5) and 1.733(5) Å]. This situation was also verified in Tl(Bm^{Me}), for which the difference between such terminal and bridging interactions, 1.707(5) and 1.712(5) Å, respectively, is nevertheless less noticeable. More significantly, the Tl···Tl separations in the two crystallographically independent molecules of Tl(Bm^{tBu}), 4.193(1) and 4.199(1) Å, suggest that neither compound [nor Tl(Bm^{Me}), where [d(Tl···Tl) = 4.37 Å] exhibits any discernible thallium–thallium bonding, the very nature of which has been under intense scrutiny in recent years [39,40].

3. Conclusions

The new thallium(I) complexes Tl(Bm^{R}) (R = Bz, Bu^t, *p*-Tol), together with the known methyl-substituted derivative Tl(Bm^{Me}), have been readily prepared in ca. 75–95% yield. The *tert*-butyl derivative displays in the solid state a discrete dinuclear structure that results in an enhanced solubility in organic solvents relative to that of polymeric Tl(Bm^{Me}). The Tl(Bm^{R}) compounds described herein constitute a potentially useful family of reagents for the transfer of bis(mercaptoimidazolyl)borate ligands to transition metals. In this regard, it is worth noting that the Tl(Bm^{R}) reagents, unlike their sodium counterparts, cleanly react with the nickel(II) diphosphine complexes (dppe)NiX_2 (X = Cl, Br) to produce derivatives of general formula (dppe)Ni(Bm^{R})X, the syntheses and characterization of which will be reported separately [41].

4. Experimental

4.1. General considerations

All reactions were performed in the air except for the syntheses of the Na(Bm^{R}) intermediates, which were carried out under dry oxygen-free nitrogen in an Innovative Technology System One-M-DC glovebox or under argon using high-vacuum techniques [42–44]. Solvents were purified and degassed by standard procedures and all commercially available reagents, including methimazole (Acros or Aldrich), were used as received. The 2-mercapto-1-alkylimidazoles $Hmim^{R}$ (R = Bz, Bu^t, *p*-Tol) were prepared by the acid-catalyzed cyclization of aminoacetaldehyde diethyl acetal [$H_2NCH_2CH(OEt)_2$] and the appropriate alkylisothiocyanates (RNCS) following literature procedures [45,46]. ^{1}H and ^{13}C NMR spectra were obtained on General Electric QE 300 or Varian Gemini (300 MHz) FT spectrometers. Chemical shifts (δ) are reported in parts per million relative to $SiMe_4$ (δ = 0 ppm) and were referenced internally with respect to the solvent resonances (^{1}H δ: 2.49 for d_5-DMSO; ^{13}C δ: 39.5 for d_6-DMSO); coupling constants are given in hertz (Hz). IR spectra were recorded as KBr pellets on a Thermo Mattson Satellite 3000 FT-IR spectrophotometer and are reported in cm^{-1}; relative intensities of the absorptions are indicated in parentheses (vs, very strong; s, strong; m, medium; w, weak). Elemental analyses were determined by Atlantic Microlab, Inc. (Norcross, GA).

4.2. Synthesis of Tl(Bm^{Me})

A suspension of $NaBH_4$ (0.500 g, 13.22 mmol) and 2-mercapto-1-methylimidazole (3.000 g, 26.28 mmol) in tetrahydrofuran (55 mL) was heated to reflux for 15 h under an atmosphere of argon. The resulting clear colorless solution was allowed to cool to room temperature and the solvent was removed under reduced pressure to give crude Na(Bm^{Me}) as a white solid residue. The solid was dissolved in methanol (55 mL) and the slightly cloudy solution was treated with a solution of thallium(I) acetate (3.460 g, 13.13 mmol) in water (50 mL), resulting in the formation of an off-white precipitate. After stirring the suspension for 15 min, the product was isolated by filtration, washed with water (2 × 15 mL), and dried in vacuo for 2.5 h (5.649 g, 97%); m.p. = 218

°C (dec). NMR data (in d_6-DMSO): ^{1}H δ: 3.42 (s, 6H, CH_3), 3.92 (br s, 2H, H_2B), 6.74 (s, 2H, imidazole *H*), 7.01 (s, 2H, imidazole *H*); ^{13}C δ: 34.3 (q, $^1J_{C-H} = 140$, 2C, *C*H$_3$), 118.7 (dd, $^1J_{C-H} = 195$, $^2J_{C-H} = 12$, 2C, imidazole *C*), 122.6 (dd, $^1J_{C-H} = 194$, $^2J_{C-H} = 10$, 2C, imidazole *C*), 160.1 (s, 2C, *C*=S). IR data (cm^{-1}): 3144 (w), 3114 (m), 3077 (w), 2963 (w), 2935 (w), 2404 (w), 2360 (m), 2345 (m), 2262 (w), 2211 (w), 1655 (w), 1554 (w), 1452 (m), 1410 (w), 1372 (s), 1299 (w), 1261 (w), 1201 (m), 1186 (m), 1166 (w), 1151 (w), 1109 (s), 889 (w), 801 (w), 750 (m), 729 (s), 696 (w), 680 (w), 519 (w), 500 (w), 459 (w). *Anal.* Calc. for $C_8H_{12}BN_4S_2Tl$: C, 21.7; H, 2.7; N, 12.6. Found: C, 22.0; H, 2.8; N, 12.2%.

4.3. Synthesis of Tl(Bm^{Bz})

A suspension of $NaBH_4$ (0.050 g, 1.32 mmol) and 2-mercapto-1-benzylimidazole (0.500 g, 2.63 mmol) in tetrahydrofuran (40 mL) was heated to reflux for 18 h under an atmosphere of argon. The resulting clear colorless solution was allowed to cool to room temperature and the solvent was removed under reduced pressure to give crude Na(Bm^{Bz}) as a white solid residue. The solid was dissolved in methanol (40 mL) and the slightly cloudy solution was treated with a solution of thallium(I) acetate (0.345 g, 1.31 mmol) in water (25 mL), resulting in the formation of an off-white precipitate. After stirring the suspension for 15 min, the product was isolated by filtration, washed with water (2×10 mL), and dried in vacuo for 20 h (0.623 g, 80%); m.p. = 200 °C (dec). NMR data (in d_6-DMSO): ^{1}H δ: 3.93 (br s, 2H, H_2B), 5.20 (s, 4H, CH_2C$_6$H$_5$), 6.84 (s, 2H, imidazole *H*), 7.02 (s, 2H, imidazole *H*), 7.2–7.4 (m, 10H, CH$_2$C$_6H_5$); ^{13}C δ: 49.4 (t, $^1J_{C-H} = 140$, 2C, *C*H$_2$C$_6$H$_5$), 117.3 (dd, $^1J_{C-H} = 195$, $^2J_{C-H} = 12$, 2C, imidazole *C*), 123.2 (dd, $^1J_{C-H} = 193$, $^2J_{C-H} = 10$, 2C, imidazole *C*), 127.2 (d, $^1J_{C-H} = 160$, 2C, C_p in Bz), 127.6 (d, $^1J_{C-H} = 159$, 4C, C_o or C_m in Bz), 128.3 (dd, $^1J_{C-H} = 160$, $^2J_{C-H} = 6$, 4C, C_o or C_m in Bz), 137.6 (s, 2C C_{ipso} in Bz), 160.7 (s, 2C, *C*=S). IR data (cm^{-1}): 2920 (w), 2437 (m), 2391 (w), 1495 (w), 1442 (w), 1418 (w), 1390 (m), 1361 (w), 1327 (m), 1223 (w), 1172 (w), 1147 (m), 1115 (w), 1057 (w), 724 (m), 695 (m), 674 (w), 334 (vs), 321 (w), 313 (w). *Anal.* Calc. for $C_{20}H_{20}BN_4S_2Tl$: C, 40.3; H, 3.4; N, 9.4. Found: C, 40.0; H, 3.3; N, 9.1%.

4.4. Synthesis of Tl(Bm^{tBu})

A suspension of $NaBH_4$ (0.061 g, 1.60 mmol) and 2-mercapto-1-*tert*-butylimidazole (0.501 g, 3.21 mmol) in tetrahydrofuran (35 mL) was heated to reflux for 20 h under an atmosphere of argon. The resulting clear colorless solution was allowed to cool to room temperature and the solvent was removed under reduced pressure to give crude Na(Bm^{tBu}) as a white solid residue. The solid was dissolved in methanol (30 mL) and the slightly cloudy solution was treated with a solution of thallium(I) acetate (0.421 g, 1.60 mmol) in water (25 mL), resulting in the formation of a pale yellow precipitate. After stirring the suspension for 15 min, the product was isolated by filtration, washed with water (2×10 mL), and dried in vacuo for 20 h (0.660 g, 78%); m.p. = 208 °C (dec). NMR data (in d_6-DMSO): ^{1}H δ: 1.69 [s, 18H, C(CH_3)$_3$], 4.06 (br s, 2H, H_2B), 6.64 (d, $^3J_{H-H} = 2.3$, 2H, imidazole *H*), 7.08 (d, $^3J_{H-H} = 2.3$, 2H, imidazole *H*); ^{13}C δ: 28.3 [q, $^1J_{C-H} = 127$, 6C, C(*C*H$_3$)$_3$], 57.5 [s, 2C, *C*(CH$_3$)$_3$], 115.7 (dd, $^1J_{C-H} = 194$, $^2J_{C-H} = 13$, 2C, imidazole *C*), 121.6 (dd, $^1J_{C-H} = 193$, $^2J_{C-H} = 9$, 2C, imidazole *C*), 158.6 (s, 2C, *C*=S). IR data (cm^{-1}): 3176 (w), 3132 (m), 3094 (w), 2970 (s), 2927 (s), 2372 (vs), 2211 (w), 1710 (w), 1686 (w), 1562 (m), 1481 (m), 1468 (w), 1449 (w), 1421 (m), 1404 (m), 1395 (m), 1354 (vs), 1298 (w), 1281 (w), 1253 (w), 1224 (w), 1199 (w), 1162 (w), 1111 (w), 1088 (w), 1026 (w), 978 (w), 966 (w), 929 (w), 875 (w), 819 (w), 735 (s), 723 (s), 704 (s), 681 (s), 627 (w), 583 (w), 554 (w), 482 (m). *Anal.* Calc. for $C_{14}H_{24}BN_4S_2Tl$: C, 31.9; H, 4.6; N, 10.6. Found: C, 32.1; H, 4.6; N, 10.5%.

4.5. Synthesis of Tl(Bm$^{p\text{-}Tol}$)

A suspension of $NaBH_4$ (0.050 g, 1.32 mmol) and 2-mercapto-1-*p*-tolylimidazole (0.501 g, 2.63 mmol) in tetrahydrofuran (40 mL) was heated to reflux for 19 h under an atmosphere of argon. The resulting clear colorless solution was allowed to cool to room temperature and the solvent was removed under reduced pressure to give crude Na(Bm$^{p\text{-Tol}}$) as a white solid residue. The solid was dissolved in methanol (40 mL) and the slightly cloudy solution was treated with a solution of thallium(I) acetate (0.348 g, 1.32 mmol) in water (25 mL), resulting in the formation of a pale yellow precipitate. After stirring the suspension for 15 min, the product was isolated by filtration, washed with water (3×10 mL), and dried in vacuo for 18 h (0.598 g, 76%). Melting point = 114 °C (dec). NMR data (in d_6-DMSO): ^{1}H δ: 2.33 (s, 6H, CH_3), 3.89 (br s, 2H, H_2B), 7.04 (s, 2H, imidazole *H*), 7.12 (s, 2H, imidazole *H*), 7.24 (d, $^3J_{H-H} = 8.1$, 4H, H_o or H_m in *p*-Tol), 7.43 (d, $^3J_{H-H} = 8.1$, 4H, H_o or H_m in *p*-Tol); ^{13}C δ: 20.6 (q, $^1J_{C-H} = 126$, 2C, *C*H$_3$), 118.7 (dd, $^1J_{C-H} = 197$, $^2J_{C-H} = 13$, 2C, imidazole *C*), 123.9 (dd, $^1J_{C-H} = 193$, $^2J_{C-H} = 9$, 2C, imidazole *C*), 126.1 (dd, $^1J_{C-H} = 163$, $^2J_{C-H} = 5$, 4C, C_o or C_m in *p*-Tol), 129.0 (d, $^1J_{C-H} = 160$, 4C, C_o or C_m in *p*-Tol), 136.2 (s, 2C, C_{ipso} or C_p in *p*-Tol), 136.8 (s, 2C, C_{ipso} or C_p in *p*-Tol), 160.6 (s, 2C, *C*=S). IR data (cm^{-1}): 3130 (w), 3032 (w), 2918 (w), 2380 (m), 1555 (w), 1584 (w), 1560 (w), 1515 (s), 1419 (m), 1354 (vs), 1308 (w), 1263 (w), 1156 (m), 1179 (w), 1104 (m), 1020 (w), 818 (m), 711 (w), 680 (w), 602 (w), 563 (w). *Anal.* Calc. for $C_{20}H_{20}BN_4S_2Tl$: C, 40.3; H, 3.4; N, 9.4. Found: C, 41.1; H, 3.5; N, 9.6%.

Table 2
Crystallographic data for $Tl(Bm^{tBu})$

Formula	$C_{28}H_{48}B_2N_8S_4Tl_2$
Formula weight	1055.34
Crystal system	monoclinic
Space group	$P2_1/c$ (no. 14)
Temperature (K)	100(2)
Unit cell dimensions	
a (Å)	15.925(3)
b (Å)	13.295(3)
c (Å)	17.543(4)
β (°)	91.324(4)
V (Å^3)	3713.5(13)
Z	4
ρ_{calc} (g cm^{-3})	1.888
μ(Mo Kα) (mm^{-1})	8.924
θ_{max} (°)	26.00
Number of data	7195
Number of parameters	397
$R_1(I > 2\sigma(I))$[a]	0.0419
$wR_2(I > 2\sigma(I))$[a]	0.1060

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum|F_o|$; $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

4.6. X-ray structure determination

A summary of crystal data collection and refinement parameters for $Tl(Bm^{tBu})$ is given in Table 2. A colorless crystal suitable for data collection was selected and mounted on a glass fiber using Paratone-N oil and then placed in the cold nitrogen stream of a Siemens/Bruker P4 diffractometer using Mo Kα radiation ($\lambda = 0.71073$ Å) and equipped with a SMART CCD detector. The data were corrected for absorption using the program SADABS and the space group was uniquely determined as $P2_1/c$. The structure was solved by direct methods and all non-hydrogen atoms were refined anisotropically by least-squares Fourier analysis. Hydrogen atoms were placed in idealized positions and fitted to their attached atoms with U_{eq} of 1.2 or 1.5. High residual electron densities greater than 1 e Å^{-3} found for 10 peaks which were less than 1 Å from neighboring thallium atoms suggests a relatively poor correlation with the SADABS absorption model. All software used is contained in the SMART, SAINT, SADABS, and SHELXTL program libraries [47].

5. Supplementary data

Crystallographic data (excluding structure factors) for $Tl(Bm^{Me})$ have been deposited with the Cambridge Crystallographic Data Centre with CCDC No. 210721. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk; www: http://www.ccdc.cam.ac.uk).

Abstract

The crystal structure of the dianionic $[U_8L_4Cl_{10}O_4]^{2-}$ cluster [$H_4L = N,N'$-*bis*(3-hydroxysalicylidene)-1,2-phenylenediamine] is built up of four U_2LCl_2O subunits which are held together by eight μ_2-phenoxo bridges, four μ_4-oxo bridges and two additional μ_2-chloro bridges. The four U atoms in the external cavities of the bicompartmental hexadentate Schiff base ligands and the four μ_4-oxo ions form an unprecedented U_4O_4 cubane arrangement. The U_8O_4 core consists of four distorted uranium tetrahedra, each of them sharing a common edge with its three neighbours and containing a μ_4-oxo ion at its centre. This complex is one of the highest nuclearity assemblages in the chemistry of uranium compounds.

1. Introduction

The design of polynuclear, nanometer-sized metal complexes has received a new impulse in recent years due to the use of methods of self-assembly in an attempt to model the structural and functional aspects of multimetal active sites in biological processes or to prepare nanometric materials and single molecule magnets [1–3]. In the particular case of uranium, which has been the subject of relatively little attention up to now, discrete polynuclear species including up to six [4] and even eight [5,6] uranyl [dioxouranium(VI)] ions are known, as well as two clusters comprising six uranium(V) [7] or six uranium(III,IV) [8] centres. We have reported previously the crystal structure of an octanuclear uranium(IV) compound with the cp*py ligand [tetramethyl-5-(2-pyridyl)cyclopentadiene], which is the assemblage of highest nuclearity in the molecular chemistry of uranium (uranyl excluded) [9]. In order to investigate the magnetic behaviour of heterobi- and heterotrimetallic complexes containing paramagnetic 5f (U^{IV}) and 3d metal ions, we turned recently to the use of hexadentate Schiff bases as associating ligands [10–12]. In these compounds, the internal N_2O_2 cavity of the Schiff base is adequate for the complexation of the 3d ion and the external O_4 cavity is well suited for the f ion. However, several crystal structures reported in the literature show that the U^{IV} ion can also be located in the inner N_2O_2 coordination site [13,14]. In the course of this study, we serendipitously synthesized bi- and tetranuclear uranyl/3d metal ions complexes [15] and the title compound containing an octanuclear uranium(IV) cluster. The crystal structure of the latter, which is described herein, gives a new example of a high nuclearity uranium complex and it also evidences the ability of Schiff base ligands to build polynuclear assemblies.

2. Results and discussion

The crystal structure of $(Hpy)_2[U_8L_4Cl_{10}O_4]\cdot 10py$ shows the presence of a dianionic octanuclear cluster, represented in Fig. 1, and two pyridinium ions which are hydrogen bonded to two pyridine molecules [N5···N6 2.67(2) Å]; additionally, the crystal contains 10

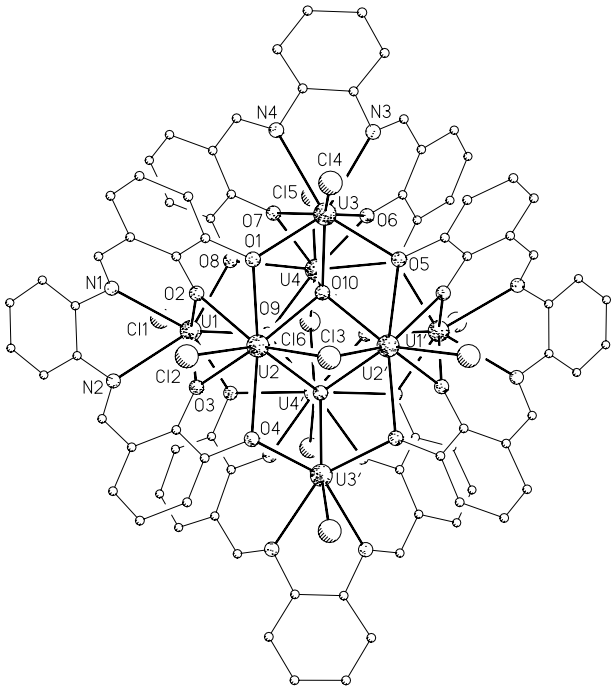

Fig. 1. View of the $[U_8L_4Cl_{10}O_4]^{2-}$ cluster. Hydrogen atoms, counter-ions and solvent molecules are omitted for clarity. Atoms are represented as spheres, the carbon ones being arbitrarily reduced. Symmetry code: $' = -x, y, 0.5 - z$.

encapsulated molecules of pyridine. The axis defined by the two bridging chlorine atoms Cl3 and Cl6 is a crystallographic twofold symmetry axis and, apart from the counter-ions and solvent molecules, the asymmetric unit contains four uranium atoms and two Schiff base ligands (Fig. 2). The C_2 axis, which is also a pseudo-S_4 symmetry axis, is perpendicular to two pseudo binary axes; one of those associates U1 to U3, U2 to U4 and O9 to O10, as can be seen in Fig. 2, and the other associates U1 to U3′, U2 to U4′ and O9 to O10′. Two non-crystallographic dihedral symmetry planes σ_d intersect along C_2, one of them containing U1, U2, U1′ and U2′ and the other U3, U4, U3′ and U4′. The cluster thus exhibits a pseudo-D_{2d} symmetry and can be viewed as four binuclear U_2LCl_2O subunits which are held together by eight μ_2-phenoxo bridges from the L ligand (O1, O4, O5, O8 and their symmetric counterparts), four μ_4-oxo bridges, (O9, O10, O9′, O10′), in addition to the two μ_2-chloro bridges (Cl3 and Cl6). In each U_2LCl_2O subunit, the two uranium, two chlorine and the μ_4-oxygen atoms are lying in the σ_d pseudo-symmetry plane; the U1U2 and U3U4 vectors making angles of $\sim$30° with the C_2 axis and 41.2° one with the other. As observed in the mononuclear $UL'(acac)_2 \cdot thf$ compound [14] [$L' = N,N'$-*bis*(3-hydroxysalicylidene)-2-methyl-1,2-propanediamine] and the series of heterobi-, tri- and tetranuclear complexes in which uranium ions are associated to d transition metal ions [10–12,15], the Schiff base ligands in the present complex are in an *umbrella* conformation but the dihedral angles between the two external aromatic rings, with values of 74.7(4)° and 75.4(4)°, are much larger than those in the above compounds, which vary from 7° to 27°. When viewed along the C_2 axis, the four Schiff bases have their concave sides alternately up and down, and the dihedral angles between the N_2O_2 planes defining the inner bonding sites and the symmetry axis are 32.6° and 31.8° for the two Schiff bases in the repeat unit. Overall, the four ligands assume a rather flat saddle shape. The complex itself is

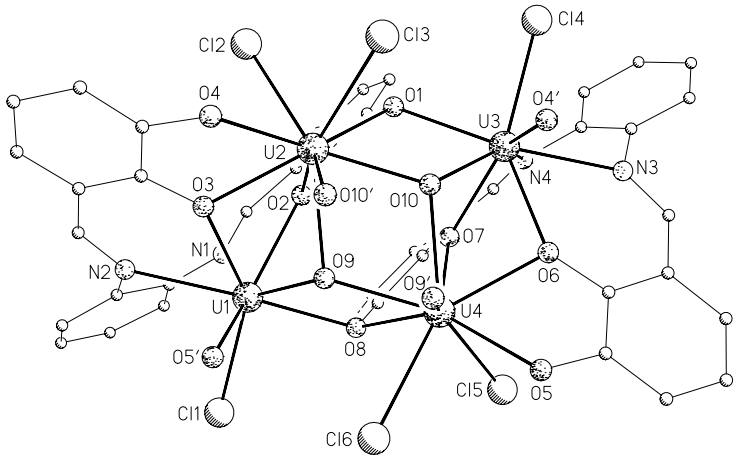

Fig. 2. View of the environment of the uranium atoms in the repeat unit. Atoms are represented as spheres, the carbon ones being arbitrarily reduced. Selected distances (Å): U1–O2 2.367(9), U1–O3 2.346(9), U1–O5′ 2.366(9), U1–O8 2.359(8), U1–O9 2.264(8), U1–N1 2.598(12), U1–N2 2.612(11), U1–Cl1 2.679(4), U2–O1 2.510(8), U2–O2 2.378(9), U2–O3 2.406(8), U2–O4 2.525(8), U2–O9 2.473(8), U2–O10 2.329(8), U2–O10′ 2.311(8), U2–Cl2 2.708(3), U2–Cl3 2.810(4), U3–O1 2.368(8), U3–O4′ 2.348(9), U3–O6 2.358(8), U3–O7 2.335(8), U3–O10 2.261(8), U3–N3 2.596(11), U3–N4 2.604(11), U3–Cl4 2.662(4), U4–O5 2.525(8), U4–O6 2.399(8), U4–O7 2.405(8), U4–O8 2.516(8), U4–O9 2.341(8), U4–O9′ 2.343(8), U4–O10 2.528(9), U4–Cl5 2.709(4), U4–Cl6 2.819(4), U1···U2 3.5907(7), U1···U3 5.9222(7), U1···U4 3.9646(7), U1···U4′ 3.9714(7), U2···U2′ 3.5236(9), U2···U3′ 3.9661(7), U3···U4 3.5885(7), U4···U4′ 3.5299(9). Symmetry code: $' = -x, y, 0.5 - z$.

roughly cylinder-shaped, with a diameter of about 18 Å and a height of about 9 Å (along the binary axis).

The U1, U3 and U2, U4 atoms occupy respectively the inner N_2O_2 and outer O_4 cavities of the Schiff bases. The two metal atoms in each subunit are bridged by the oxygen atoms of the salicylidene fragments (O2, O3 or O6, O7), as are the d transition metal and uranium ions in the bi- and trinuclear complexes $CuLUCl_2(py)_2$ and $(ZnL)_2U$ [16] and other CuU and M_2U compounds (M = Cu, Zn) associated with Schiff base ligands [10–12]. The four oxygen atoms of the O_4 cavity define a mean plane with a small maximum deviation of 0.009(5) and 0.023(5) Å for the planes associated with U2 and U4, respectively, and the uranium atoms are at 0.573(5) and 0.583(5) Å from these planes, with mean U–O bond lengths of 2.45(7) and 2.46(7) Å. The atoms U2 and U4 are much more displaced out of the external cavity of the L ligand than in the aforementioned hetero bi- and trinuclear complexes [16], in which the uranium atom is located at 0.184(3) and 0.091(6) Å (mean value) from the O_4 plane, with mean U–O distances of 2.37(6) and 2.35(6) Å. However, in the octanuclear cluster, the phenoxide oxygen atoms at the 3-position of the ligand L (O1, O4 or O5, O8) are also in bridging positions, between U2 and U3 or U1 and U4 or their symmetry equivalents; the corresponding U–O distances range from 2.348(9) to 2.368(8) Å, with an average value of 2.360(9) Å. Thus, the external U atom of each binuclear subunit is linked to the internal U atoms of the two adjacent subunits. The U atoms in the external cavities of the four binuclear subunits are also linked via the four μ_4-oxo ions which ensure the unusually high nuclearity of the cluster. The metal atoms U2, U4, U2′, U4′ and the oxo atoms O9, O10, O9′ and O10′ display a much distorted cubane-type arrangement located at the very centre of the complex (Fig. 3). While the cubane

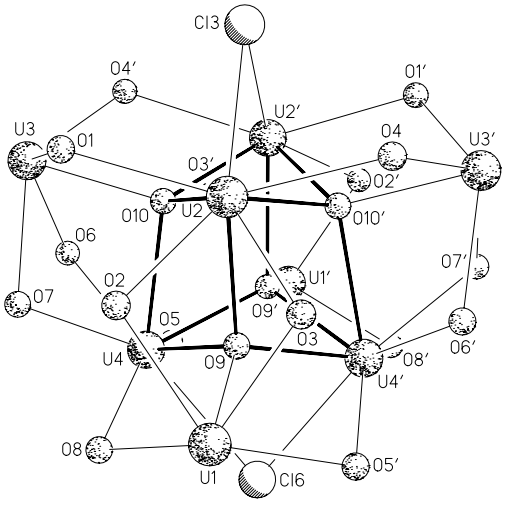

Fig. 3. View of the U_8 cluster with the bridging chlorine and oxygen atoms. The U_4O_4 cubane-type central motif is highlighted.

assemblage is commonly observed in structures of metal-oxo compounds [17–19], this edifice is, to the best of our knowledge, unprecedented in the molecular chemistry of uranium. The U–O bond lengths in the cubane moiety vary from 2.311(8) to 2.528(9) Å, with an average value of 2.39(9) Å. The U2 and U4 atoms are further bound to one terminal Cl atom [U2–Cl2 2.708(3), U4–Cl5 2.709(4) Å] and one μ_2-chloro ion [U2–Cl3 2.810(4) Å, U2–Cl3–U2′ 77.66(12)° and U4–Cl6 2.819(4) Å, U4–Cl6–U4′ 77.53(12)°] showing the expected bond lengthening for the bridging species. The coordination geometry of the nine-coordinate U2 and U4 ions may perhaps best be viewed as a very distorted tricapped trigonal prism, with respectively O9, Cl2 and Cl3 and O10, Cl5 and Cl6 in the capping positions [20].

The four atoms (O2, O3, N1 and N2) and (O6, O7, N3 and N4) of the internal coordination site of the Schiff bases define a mean plane with a maximum deviation of 0.009(5) and 0.007(5) Å, respectively, and the uranium atoms U1 and U3 are strongly displaced from these planes, by 1.566(5) and 1.579(5) Å. This large displacement differs from the distance measured in the mononuclear $UL'(acac)_2 \cdot thf$ compound, which is 0.088(3) Å [14]. This feature is likely due to the coordination of U1 and U3 to the 3-phenoxide atoms of the Schiff bases of the adjacent binuclear subunits (O1, O4 and O5, O8), and to the μ_4-oxygens O9 and O10, respectively; the U1–O9 and U3–O10 distances are equal to 2.264(8) and 2.261(8) Å. The U1 and U3 atoms are also bound to one terminal Cl atom, Cl1 and Cl4, with bond lengths of 2.679(4) and 2.662(4) Å, respectively. The coordination geometry of the eight-coordinate atoms U1 and U3 can be viewed as that of a slightly distorted square antiprism. If the eight uranium and the μ_4-oxo atoms only are considered, the central octa-metallic core can be viewed as an assemblage of four very distorted uranium tetrahedra, each of them sharing a common edge with its three neighbours and containing a μ_4-oxo ion located at its centre, surrounding a central, empty tetrahedron built from the four uranium atoms of the cubane moiety (Fig. 4). A search of the Cambridge Structural Database [21] gives our previous complex $U_8Cl_{24}O_4(cp^*py)_2^{2-}$ as the only other compound containing such μ_4-oxo ions [9]. In the latter, the U–O bond lengths involving the μ_4-oxo group are in the range 2.303(7)–2.493(8) Å, with a mean value of 2.40(9) Å, larger than the present value, which is closer to the mean value of 2.24(7) Å for the μ_3-oxo bridges reported in the Database. The mean U–O–U angle is 110(5)° in the previous compound and it is 110(9)° for both O9 and O10 in the present case. It may be noted that a μ_6-oxo group is present in the U(V) hexanuclear isopolyoxometalate complex reported by Duval et al. [7], with a mean U–O bond length of 2.6(1) Å.

This structure of the octanuclear $[U_8L_4Cl_{10}O_4]^{2-}$ cluster evidences the assembling ability of hexadentate

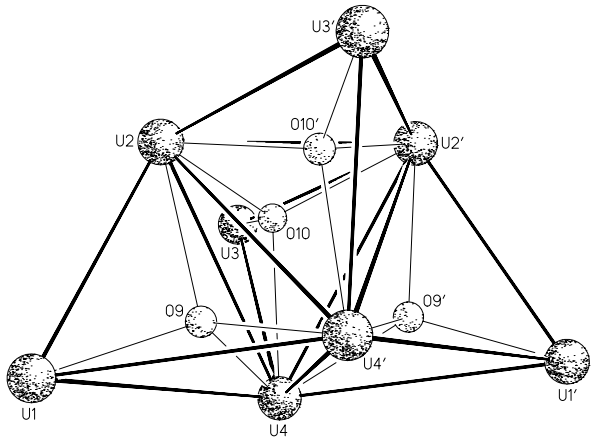

Fig. 4. View of the central U_8O_4 core showing the four assembled distorted tetrahedra in bold lines.

Schiff bases, which has recently been demonstrated in the case of a cluster of eight zinc atoms [22,23]. In this compound, the flexible ligand *N*,*N*′-*bis*(3-hydroxysalicylidene)-1,4-butanediamine leads to an octanuclear assemblage involving four Schiff bases with, as in the present case, extended μ-phenoxide bridging, but with no other bridging species. The high bridging ability, versatility and flexibility of the Schiff base have been considered to play a crucial role in the building of this polynuclear zinc complex. The high bridging ability is also involved in the present case, albeit in a somewhat lesser degree, but, considering the increased rigidity of the phenylene diamino chain, it appears that a high flexibility is not a prerequisite for such polynuclear assembling. However, even if the overall metal/Schiff base stoichiometry is identical in both compounds, the much different geometrical requirements of uranium and zinc atoms clearly result in different detailed coordination and assembling features. An assemblage of eight Cu(II) ions, four pentadentate, trianionic Schiff bases [*N*,*N*′-(2-hydroxypropane-1,3diyl)*bis*(salicylaldimine)] and four bridging hydroxy groups has also been described very recently [24]. All these results evidence the potential of Schiff bases as associating ligands for the design of supramolecular, polynuclear complexes, either with 3d transition metal ions or, as exemplified here for the first time, with larger 5f metal ions.

3. Experimental

3.1. Synthesis

UCl_4 was synthesized as reported in the literature [25]. The zinc complex ZnH_2L was synthesized by reaction of H_4L with one equivalent of $Zn(acac)_2$ in thf. The mononuclear metal complex was mixed in a 1:1 ratio with UCl_4 in pyridine. Adventitious traces of oxygen and/or water probably entered the reaction flask during prolonged heating at 80 °C, which resulted in the formation of orange crystals of the octanuclear compound $(Hpy)_2[U_8L_4Cl_{10}O_4]\cdot 10py$ following the substitution of Zn for U. Attempts to prepare this complex in a controlled way, by introducing measured quantities of water into the reaction mixture, were unsuccessful.

3.2. Crystallography

Data were collected at 100(2) K on a Nonius Kappa-CCD area detector diffractometer [26] using graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and processed with DENZO-SMN [27]. The structure was solved by direct methods with SHELXS-97 and refined by full-matrix least-squares on F^2 with SHELXL-97 [28]. Absorption effects were empirically corrected with the program DELABS from PLATON [29]. All non-hydrogen atoms were refined with anisotropic displacement parameters. One solvent pyridine molecule has been found disordered over two positions related by a symmetry centre and sharing two atoms, which have been refined with 0.5 occupancy factors. Another pyridine is disordered over a binary axis. Some restraints on bond lengths, angles and displacement parameters have been applied to all solvent pyridine molecules. The hydrogen atoms were introduced at calculated positions (except in the disordered parts) as riding atoms with an isotropic displacement parameter equal to 1.2 times that of the parent atom. Some short H···H contacts involving protons from the pyridine molecules are likely due to the low resolution and resulting imperfect location of these molecules. The molecular plots were drawn with SHELXTL [30].

Crystal data and structure refinement details. $(Hpy)_2[U_8L_4Cl_{10}O_4]\cdot 10py$: $C_{140}H_{110}Cl_{10}N_{20}O_{20}U_8$, $M = 4651.22$, monoclinic, space group $C2/c$, $a = 34.9432(12)$, $b = 14.4932(9)$, $c = 31.8143(18)$ Å, $\beta = 120.339(3)°$, $V = 13905.5(13)$ Å^3, $Z = 4$, $D_c = 2.222$ g cm^{-3}, $\mu = 9.547$ mm^{-1}, $F(000) = 8624$. $R_1 = 0.055$, $wR_2 = 0.119$, $S = 1.022$, $\Delta\rho_{max} = 1.17$ e Å^{-3} for 12 366 independent reflections out of 43 999 measured reflections ($R_{int} = 0.096$) and 851 parameters.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 215918. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The structures of 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**1**), 1-Ph-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**2**) and 1-Ph-2-COPh-1,2-*closo*-$C_2B_{10}H_{10}$ (**3**) have been determined by X-ray crystallography. In **1** the orientation of the COOH group is defined by $\theta_{COOH} = 65.0(2)_{syn}°$, and this group H-bonds to that in a second molecule via a centrosymmetric eight-membered ring, $R_2^2(8)$. DFT calculations on the parent species 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ reveal that the structure with $\theta_{COOH} = 90_{syn}°$ is preferred, with a barrier to COOH rotation of $\approx$17 kJ mol^{-1}. Similar calculations on **1** yield a lower rotational barrier, $\approx$7 kJ mol^{-1}, because internal H-bonding is now denied. In compound **2** the COOH group is twisted to lower θ values [5.0(3)° and 39.7(3)°] but both crystallographically independent molecules exist as dimers in the solid state by virtue of $R_2^2(8)$ rings. Compound **2** crystallises from wet solvent as a monohydrate, the structure of which reveals a non-planar centrosymmetric $R_4^4(12)$ ring and near-orthogonal Ph and COOH substituents [$\theta_{Ph} = 6.7(2)$ and $\theta_{COOH} = 78.0(2)_{syn}°$]. In compound **3** molecular association by H-bonding is blocked, so **3** serves as a useful comparative structure for **2**.

1. Introduction

Over the last few years the field of crystal engineering, part of which involves the development of rational strategies for the design of new crystalline materials, has emerged as an area of significant research activity [1]. Although the use of heteroboranes in studies of crystal engineering has begun to be exploited only fairly recently [2] the potential is vast. Heteroboranes are generally chemically and thermally stable species, existing as polyhedra or fragments of polyhedra of differing size and shape, but having architectures that are well-understood [3]. Isomeric possibilities mean that C-substituted (hetero)carboranes have the potential to function as supramolecular building blocks with differing directionalities in two-dimensions, which can further be expanded into three-dimensions via additional B-atom substitution [4]. Moreover, heteroboranes are usually neutral or anionic, but can also be cationic [5], thus further extending their potential applications as building block units.

There are currently two main strategies for crystal engineering, based on the use of either co-ordinate bonds or weaker intermolecular interactions. Within the latter area, H-bonding has attracted most interest due to its relative strength and directionality [6]. Carboxylic acid groups are frequently used in the field of crystal engineering because they are capable of forming various types of hydrogen bonds between themselves and/or with other species such as solvents [7]. Accordingly, we have begun a systematic study of the crystal structures of carboxylic acid carboranes, their derivatives, and related species, in order further to increase our understanding of the effect of the carboxy group on the cage and any other substituents. We have already described 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ [2m] (a dimer), 1,2-$(COOH)_2$-1,2-*closo*-$C_2B_{10}H_{10}\cdot 1/2C_2H_5OH$ [2p] and 1-CH_2OMe-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ [2q] (both tetramers). Herein we report the structures of the methyl and phenyl derivatives 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ and 1-Ph-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$, as well as that of the related species 1-Ph-2-COPh-1,2-*closo*-$C_2B_{10}H_{10}$. Although the compounds described in this paper do not themselves give rise to extended arrays via H-bonding they do afford us a greater understanding of substituent effects in carborane structures that will be important if carboranes are to be used for crystal engineering in the future.

2. Experimental

2.1. Synthetic and spectroscopic studies

Experiments were performed under dry, oxygen-free N_2 using standard Schlenk techniques, with some subsequent manipulation in the open laboratory. Toluene, diethylether and 40–60° petroleum ether were freshly distilled over Na. IR spectra were recorded as a CH_2Cl_2 solution or a KBr disk on a Perkin–Elmer Spectrum RX or 337 FTIR spectrophotometer. NMR spectra were recorded on a Varian Unity 300 or Bruker DPX 400 spectrometer as $CDCl_3$ solutions at ambient temperature, chemical shifts being recorded relative to $SiMe_4$ or $CHCl_3$ (^{1}H), $BF_3\cdot OEt_2$ (^{11}B) and $CDCl_3$ (^{13}C). Some ^{11}B NMR peak assignments were determined with the aid of ^{1}H–{^{11}B} (selective) spectra. ^{13}C NMR peak assignments corresponding to the aromatic carbons were determined with the benefit of ^{13}C coupled spectra. Mass spectra were recorded on a VG Micromass 7070E instrument operating in the EI mode at 70 eV. Elemental analyses were determined by the departmental services at Heriot–Watt and Durham. The starting materials 1-Me-1,2-*closo*-$C_2B_{10}H_{11}$ [8] and 1-Ph-1,2-*closo*-$C_2B_{10}H_{11}$ [9] were prepared by literature methods or slight variants thereof. All other reagents were used as supplied.

2.1.1. Synthesis of 1-Me-2-COOH-1,2-closo-$C_2B_{10}H_{10}$ (**1**)

To a stirred solution of 1-Me-1,2-*closo*-$C_2B_{10}H_{11}$ (0.8 g, 5 mmol) in diethylether (25 ml) at 0 °C was added dropwise 1.1 equivalents of MeLi (as an ether solution). The solution was allowed to warm to room temperature, at which point gaseous CO_2 was bubbled through the solution for about 20–30 min. The milky solution thus formed was hydrolysed with 2 M HCl and transferred to a separating funnel. The ethereal layer plus ethereal washings of the aqueous layer were dried over $MgSO_4$ overnight. Removal of solvent afforded 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**1**) as an off-white microcrystalline solid. Yield: 0.69 g, 67%. *Anal*. Found: C, 23.7; H, 7.3. Calc. for $C_4H_{14}B_{10}O_2$: C, 23.8; H, 7.0%. IR ν(cm^{-1}): 2630–2560 (s, BH), 1724 (s, CO). ^{1}H NMR, δ(ppm): 2.22 (s, CH_3). ^{11}B–{^{11}H} NMR, δ(ppm): 2.7 (1B), −2.4 (1B), −6.3 (8B).

2.1.2. Synthesis of 1-Ph-2-COOH-1,2-closo-$C_2B_{10}H_{10}$ (**2**)

Starting from 1-Ph-1,2-*closo*-$C_2B_{10}H_{11}$ (2.2 g, 10 mmol) in toluene (40 ml) and using one equivalent of *n*-butyllithium as deprotonating reagent, was similarly prepared 1-Ph-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**2**) as a white solid, recrystallised from 40–60° petroleum ether. Yield: 1.48 g, 56%. *Anal*. Found: C, 40.6; H, 6.1; M_r (EI mass spectrum) 264 with typical carborane isotope pattern 258–268. Calc. for $C_9H_{16}B_{10}O_2$: C, 40.9; H, 6.1%; M_r 264. IR ν(cm^{-1}): 3200–2800 (OH), 2651–2570 (s, BH), 1724 (s, CO). ^{1}H NMR, δ(ppm): 7.53 (d, 2H, *o*-C_6H_5), 7.36 (t, 1H, *p*-C_6H_5), 7.25 (t, 2H, *m*-C_6H_5), 3.05 (2H, B3,6*H*), 2.58 (1H, B9*H*), 2.49 (2H), 2.43 (3H, inc. B12*H*), 2.35 (2H). ^{11}B–{^{11}H} NMR, δ(ppm): −0.2 (1B, B9), −3.2 (1B, B12), −9.4 (4B), −10.3 (2B), −11.3 (2B, B3,6). ^{13}C NMR, δ(ppm): 162.8 (CO), 130.7 (*i*, *o*-C_6H_5), 130.5 (*p*-C_6H_5), 128.6 (*m*-C_6H_5), 83.6 (C1), 75.3 (C2). Compound **2** can be recrystallised pure from dry 40–60° petroleum ether, or recrystallised from wet solvents as the 1:1 water solvate, **2**·**H$_2$O**. *Anal*. Found: C, 38.3; H, 6.6; Calc. for $C_9H_{16}B_{10}O_2\cdot H_2O$: C, 38.3; H 6.4%.

2.1.3. Synthesis of 1-Ph-2-COPh-1,2-closo-$C_2B_{10}H_{10}$ (**3**)

The compound 1-Ph-1,2-*closo*-$C_2B_{10}H_{11}$ (1.2 g, 5 mmol) in toluene (40 ml) was treated with *n*-butyllithium (2 ml of 2.5 M solution = 5 mmol). After heating to reflux for 30 min and cooling, PhCOCl (0.7 g, 5 mmol) was added. After further heating to reflux for 2 h, solvents were removed in vacuo and the residue dissolved in Et_2O and washed successively with $NaHCO_3$ (3 × 20 ml) and H_2O (4 × 30 ml). The ethereal layer was separated and dried over $MgSO_4$ overnight. Removal of solvent and recrystallisation from 40–60° petroleum ether afforded 1 Ph-2-COPh-1,2-*closo*-$C_2B_{10}H_{10}$ (**3**) as large white crystals. Yield: 1.00 g, 62%. *Anal*. Found: C, 55.6; H, 6.0; M_r (EI mass spectrum) 324, typical carborane isotope

pattern 318–327. Calc. for $C_{15}H_{20}B_{10}O$: C, 55.5; H, 6.2%; M_r 324. IR ν(cm^{-1}): 2621–2562 (s, BH), 1701 (s, CO). ^1H NMR, δ(ppm): 7.48 (d, 2H, *o*-C_6H_5), 7.40 (t, 1H, *p*-C_6H_5), 7.28–7.23 (m, 7H, C_6H_5), 3.15 (2H, B3,6*H*), 2.55 (3H, inc. B9*H*), 2.39 (3H, inc. B12*H*), 2.33 (2H). ^{11}B–$\{^1H\}$ NMR, δ(ppm): 0.2 (1B, B9), −3.0 (1B, B12), −9.3 (4B), −10.5 (4B, inc. B3,6). ^{13}C NMR, δ(ppm): 185.5 (CO), 136.3 (*i*-COC_6H_5), 132.5 (*p*-COC_6H_5), 130.8 (*o*-C_6H_5), 130.6 (*i*,*p*-C_6H_5), 128.5 (*o*-COC_6H_5, *m*-C_6H_5), 127.9 (*m*-COC_6H_5), 85.0 (C1), 82.6 (C2).

2.2. Crystallographic studies

Single crystals of compounds **1**, **2**, **2 · H₂O** and **3** were grown from MeCN, dry 40–60° petroleum ether, CH_2Cl_2/40–60° petroleum ether, and hexane, respectively. Compounds **1** and **2** were studied at 160(2) K on a Bruker P4 diffractometer (Heriot-Watt University) with graphite-monochromated Mo Kα radiation ($\lambda = 0.71069$ Å) using ω scans. Compounds **2 · H₂O** and **3** were studied at 293(2) and 150(2) K, respectively, on a Rigaku AFC6S diffractometer (University of Durham) with graphite-monochromated Cu Kα radiation ($\lambda = 1.54178$ Å) using ω scans. All structures were solved by direct and difference Fourier methods and refined by full-matrix least-squares against F^2, with non-hydrogen atoms assigned anisotropic displacement parameters [10]. For **1**, all H atoms were refined positionally and thermally. For **2**, only the hydroxy H atoms were allowed such refinement, all other H atoms being treated as riding. For **2 · H₂O** and **3** non-phenyl H atoms were refined independently and phenyl H atoms treated as riding. Table 1 lists details of unit cell data, intensity data collection and structure refinement.

2.3. Computational studies

DFT calculations on 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ and 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ were performed using the ADF1999 programme [11] with the BP86 functional [12] and incorporating the quasi-relativistic corrections of Snijders and co-workers [13]. A double-ζ plus polarisation STO basis set was employed for all atoms and the frozen core approximation was applied (C, B: 1s). The C2–C1–C=O torsion angle, τ, was varied in nine steps of 22.5° from 0° to 180°, with full optimisation of the structure at every step. Within the COOH group the H–O–C=O torsion angle was originally set at 0° and did not deviate significantly from this during optimisation.

3. Results and discussion

3.1. Syntheses and spectroscopy

The carboxycarboranes 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**1**) and 1-Ph-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**2**)

[a] $R = \sum ||F_o| - |F_c|| / \sum |F_o|$, $wR_2 = [\sum[w(F_o^2 - F_c^2)^2] / \sum w(F_o^2)^2]^{1/2}$, (where $w^{-1} = [\sigma^2(F_o)^2 + (aP)^2 + bP]$ and $P = [0.333(F_o)^2 + 0.667(F_c)^2]$), $S = [\sum[w(F_o^2 - F_c^2)^2]/(n-p)]^{1/2}$, (where *n* is the number of data and *p* the number of parameters).

were prepared in good yields by the established [14,15] method of deprotonation of the corresponding 1-R-1,2-*closo*-$C_2B_{10}H_{11}$ species with LiR′, addition of CO_2, and protonation during aqueous work-up. Although **1** and **2** are known species [14,15], spectroscopic characterisation has not previously been reported.

Spectroscopically, both **1** and **2** are consistent with time-averaged C_s molecular symmetry (or, of course, simple coincidence), arising from C(O)OH/C(OH)O exchange and/or rotation of the COOH group about the C_{cage}–C bond. The ^{11}B–$\{^1H\}$ NMR spectrum of **1** at 128 MHz is fairly uninformative, with only three resonances of relative integrals 1:1:8 (high frequency to low frequency), each appearing as doublets ($^1J_{BH}$ ≈140 Hz) in the proton-coupled spectrum. In contrast, the ^{11}B–$\{^1H\}$ spectrum of **2** is somewhat more informative. The presumed 2+2+2+2 low-frequency co-incidence of **1** (assuming time-averaged C_s symmetry) is partially resolved (appearing as a 4[2+2]:2:2 set of three peaks). Moreover, the highest and lowest frequency resonances have been assigned. Given that we assign the highest-frequency B*H* resonance in the ^1H spectrum (3.05 ppm) of **2** to B3,6*H* on the basis of several precedents [16], then by ^1H–$\{^{11}B\}$ (selective) spectroscopy the lowest-frequency ^{11}B resonance (–11.3 ppm) is due to B3,6. It is well established that B atoms antipodal to C in closo carboranes occur at high frequency [17], and therefore the two resonances at –0.2 and –3.2 ppm are due to B9 and B12. Of these we assign the resonance at –0.2 ppm to B9 and that at –3.2 ppm to B12 by analogy with the B9,12 chemical shifts in the disubstituted analogues 1,2-$(COOH)_2$-1,2-*closo*-$C_2B_{10}H_{10}$ (0.3 ppm) [2p] and 1,2-Ph_2-1,2-*closo*-$C_2B_{10}H_{10}$ (–2.7 ppm), [1] respectively. In the ^1H NMR spectra of **1** and **2** the OH peak shift varies with concentration and the presence of water. The ^{13}C NMR spectrum of **2** is fully assigned, albeit with overlapping resonances at 130.7 ppm.

We have also prepared 1-Ph-2-COPh-1,2-*closo*-$C_2B_{10}H_{10}$ (**3**), a further known compound [18,19] not previously characterised spectroscopically. Both the ^1H and ^{11}B spectra are only partially assigned, but reveal clear evidence for time-averaged C_s molecular symmetry (which must involve rotation of the COPh group about the C_{cage}–C bond that is rapid on the NMR timescale at 293 K). Thus H3 and H6 are equivalent (3.15 ppm) and the ^{11}B spectrum appears as a 1:1:2+2:2+2 pattern (high to low frequency). Again the two highest-frequency ^{11}B resonances are due to the B atoms antipodal to C [17], with that at higher frequency (δ 0.2, B9) opposite the carboxy substituent. The ^{13}C NMR spectrum of **3** is fully assigned, albeit with overlapping resonances at 130.6 and 128.5 ppm.

[1] 128.38 MHz, $CDCl_3$, δ relative to neat $BF_3 \cdot OEt_2$ at 0 ppm: –2.6 (2B, B9,12), –9.3 (4B, B4,5,7,11), –10.6 (2B, B8,10), –11.6 (2B, B3,6).

3.2. Structural and computational studies

We performed crystallographic analyses of compounds **1** and **2** to investigate the influence (if any) of adjacent Me and Ph substituents on the ability of the COOH group to participate in intermolecular H-bonding. A structural study of **3** was undertaken for comparison with that of **2**, since in **3** H-bonding is blocked by the OH unit of **2** having been replaced by Ph.

In broad terms, compound **1** forms a double H-bonded dimer in the solid state (Fig. 1) via the mutual association of two carboxylic acid groups in an eight-membered ring about a crystallographic inversion centre, denoted $R_2^2(8)$ in graph-set terminology [20]. Essentially the same situation is seen in both crystallographically independent molecules of **2**, Fig. 2 showing the dimer of molecule **A**. In the water solvate **2 · H₂O** two molecules of H_2O are incorporated into the H-bonded ring to give a 12-membered ring, $R_4^4(12)$, shown in Fig. 3.

3.2.1. Intramolecular parameters in 1 and 2

Since we have previously reported crystallographic studies of 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ (**I**) [2m] and 1,2-$(COOH)_2$-1,2-*closo*-$C_2B_{10}H_{10} \cdot 1/2C_2H_5OH$ (**II**) [2p] it is instructive, on more detailed analysis, to consider first the influence of the Me and Ph groups of **1** and **2** on intramolecular parameters involving the COOH group. Table 2 summarises C1–C2, C–COOH, and θ_{COOH} (the modulus of the average C_{cage}–C_{cage}–C–O torsion angle) for **1**, **2** (two independent molecules) and **2 · H₂O**, as well as for the mono- and dicarboxycarboranes referred to above. For completeness, θ_{Ph} [21] (the modulus of the average C_{cage}–C_{cage}–C_{Ph}–C_{Ph} torsion angle) is also given for **2** and **2 · H₂O**. Our definition of θ_{COOH} here [2p,2q]

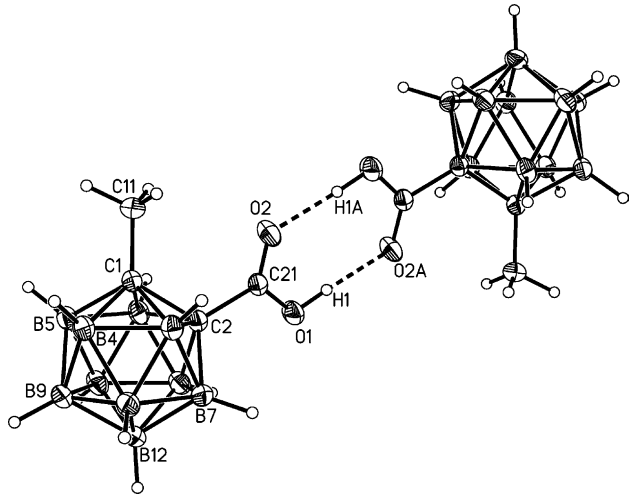

Fig. 1. Perspective view of the H-bonded dimer of compound **1**. Thermal ellipsoids are drawn at the 50% probability level, except for H atoms.

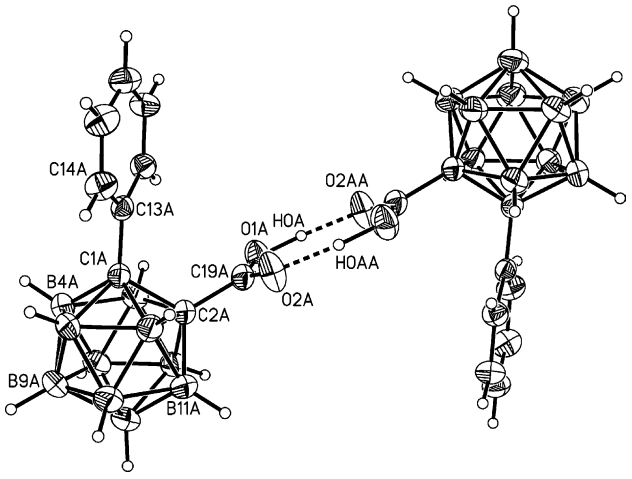

Fig. 2. Perspective view of the H-bonded dimer of compound **2** (molecule A only). Thermal ellipsoids are drawn at the 30% probability level, except for H atoms.

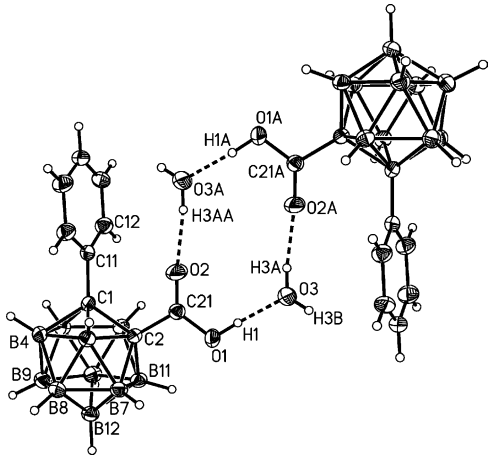

Fig. 3. Perspective view of the H-bonded dimeric unit of compound **2·H₂O**. Thermal ellipsoids are drawn at the 50% probability level, except for H atoms.

differs from that originally used [2m] for 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ and 1,2-$(COOH)_2$-1,2-*closo*-$C_2B_{10}H_{10}$ but is preferred as it is now calculated in an analogous way to θ_{Ph}. Complete listings of derived molecular parameters for **1**, **2** and **2·H₂O** have been deposited as supplementary material.

In compound **1** the orientation of the COOH group with respect to C1 is specified by $\theta_{COOH} = 65.0(2)_{syn}°$, the subscript [necessary for large θ_{COOH} ($\geqslant 45°$) values] identifying that the C=O moiety is roughly syn to C1. The C1–C2 distance, 1.6694(17) Å and C2–C21 distance, 1.5172(16) Å, are 0.04 and 0.01 Å longer, and the C1–C2–C21 angle, 118.75(10)°, is 4° wider, than the corresponding parameters in **I**, collectively suggesting a degree of intramolecular steric crowding between the Me and COOH substituents in **1**. [2] Since such crowding could have been relieved by re-orientation of the COOH group, we were prompted to investigate the preferred orientation of the carboxy group in carboxycarboranes **I** and **1** by DFT calculations. Fig. 4 shows (upper plot) the energy of **I** as a function of fixed C_{cage}–C_{cage}–C=O torsion angle, τ, varied in 22.5° steps from 0° to 180°, with full structural optimisation at each stage; $\tau = 0°$ corresponds to $\theta_{COOH} = 90_{syn}°$, $\tau = 90°$ corresponds to $\theta_{COOH} = 0°$, and $\tau = 180°$ corresponds to $\theta_{COOH} = 90_{anti}°$. The orientation $\theta_{COOH} = 90_{syn}°$ is preferred to $\theta_{COOH} = 90_{anti}°$ by $\approx$6 kJ mol^{-1}, and the barrier to rotation is $\approx$17 kJ mol^{-1}. In **I** the observed [2m] orientation, $87.5(2)_{syn}°$, is close to the optimal one predicted.

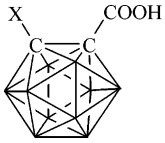
The lower plot in Fig. 4 shows the result of a similar DFT calculation on **1** drawn on the same scale as the upper plot. This time the energy profile is flatter (barrier to rotation $\approx$7 kJ mol^{-1}) which we ascribe to the $\theta_{COOH} = 90_{anti}°$ and (particularly) the $\theta_{COOH} = 90_{syn}°$ orientations no longer being stabilised by intramolecular H-bonding, as was the case with **I**. Such intramolecular H-bonding, involving the relatively acidic proton on C2, has recently been noted [22] in 1-(C_5H_4N-2′)-1,2-*closo*-$C_2B_{10}H_{11}$ and its 4′-Br analogue, both of which have a C_{cage}–C_{cage}–C–N torsion angle close to 0°. In **1** the observed 25° twist about the C–COOH bond [$\theta_{COOH} = 65.0(2)_{syn}°$], presumably due to the steric influence of the adjacent Me group, is accurately reproduced in the calculations, which show a minimum energy when τ is $\approx$30°.

The 1,2-dicarboxycarborane crystallises as the $\cdot 1/2C_2H_5OH$ solvate, **II** [2p]. In **II** there are four crystallographically independent carborane molecules arranged in two centrosymmetric tetrameric units held together by H-bonding that incorporates the solvate. Every carborane has one COOH in a low and one COOH in a high θ orientation (half the high θ orientations are syn, half are anti). The experimental data in Table 2 reveal a definite pattern – high θ (whether syn or anti) is associated with a C–COOH bond length of $\approx$1.51 Å and low θ is associated with a measurably longer C–COOH bond, $\approx$1.52–1.53 Å. This pattern is reproduced in the DFT calculations on **I**, which give C–COOH 1.515 ($\theta = 90_{syn}°$), 1.514 ($\theta = 90_{anti}°$) and 1.525 Å ($\theta = 0°$).

Compound **2** crystallised from dry solvent has two crystallographically independent molecules (**A** and **B**) per asymmetric unit. In both **A** and **B** the orientations of Ph and COOH substituents are characterised by low θ

[2] Further evidence for intramolecular crowding in **1** is demonstrated from fully optimised MP2/6-31G* geometries of 1-Me-1,2-*closo*-1,2-$C_2B_{10}H_{11}$ and **1** where the C–C–C(Me) angle widens from 118.4° to 120.6°, respectively. The crystallographic structure of the carborane 1-Me-1,2-*closo*-1,2-$C_2B_{10}H_{11}$ remains unreported (search of the Cambridge Crystallographic Database, version 5.24, July 2003).

Table 2
Summary of C1–C2 and C–COOH distances (Å) and Ph and COOH orientations (°) for carboxycarboranes



Compound	X	C1–C2	C–COOH	θ_{Ph}[a]	θ_{COOH}[b]	Reference
I	H	1.631(2)	1.507(2)	–	$87.5(2)_{syn}$	[2m]
II (A)[c]	COOH	1.660(2)	1.527(3)	–	5.3(2)	[2p]
			1.515(3)		$74.5(2)_{anti}$	
II (B)	COOH	1.651(2)	1.523(3)	–	0.6(2)	[2p]
			1.510(3)		$87.9(2)_{syn}$

			1.510(3)		$89.2(2)_{syn}$	
II (D)	COOH	1.653(2)	1.522(3)	–	14.1(2)	[2p]
			1.514(3)		$60.2(2)_{anti}$	
1	Me	1.6694(17)	1.5172(16)	–	$65.0(2)_{syn}$	this work
2(A)[d]	Ph	1.678(3)	1.509(4)	26.6(3)	5.0(3)	this work
2(B)	Ph	1.691(3)	1.504(4)	16.2(3)	39.7(3)	this work
2 · H₂O	Ph	1.705(2)	1.517(2)	6.7(2)	$78.0(2)_{syn}$	this work

[a] θ_{Ph} defined [21] as the modulus of the average C_{cage}–C_{cage}–C_{Ph}–C_{Ph} torsion angle.
[b] θ_{COOH} defined as the modulus of the average C_{cage}–C_{cage}–C–O torsion angle. For high values of θ_{COOH} it is instructive also to specify the conformation of the C = O moiety of the COOH group relative to the C_{cage} atom to which COOH is *not* bound as either syn or anti. These terms correspond to τ values of 0° and 180° respectively (Fig. 4).
[c] Four crystallographically independent molecules.
[d] Two crystallographically independent molecules.

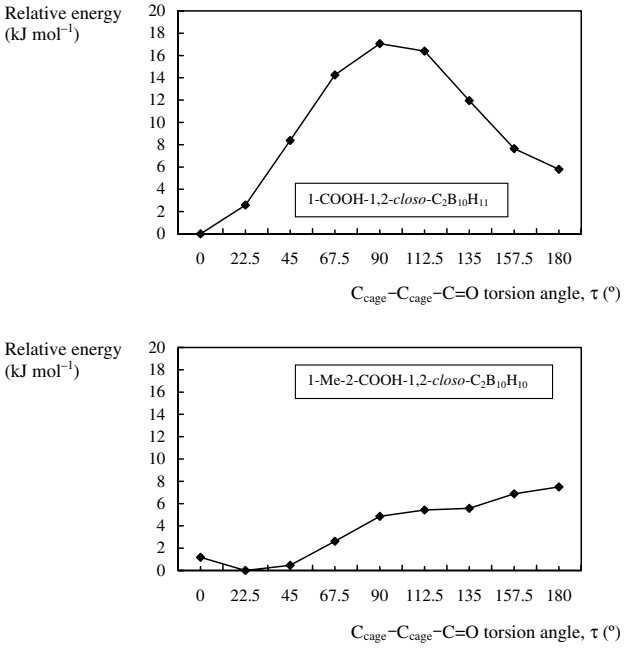

Fig. 4. Plot of relative energy of 1-COOH-1,2-*closo*-$C_2B_{10}H_{11}$ (**I**) and 1-Me-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ (**1**) as a function of the C_{cage}–C_{cage}–C=O torsion angle, τ, by DFT calculation.

values (broadly similar to the situation observed in 1,2-diaryl-1,2-*closo*-C_2B_{10} species [23]), but in **2(A)** the Ph group is the more twisted [$\theta_{Ph} = 26.6(3)°$, $\theta_{COOH} = 5.0(3)°$] whilst in **2(B)** θ_{COOH} is the greater [$\theta_{Ph} = 16.2(3)°$, $\theta_{COOH} = 39.7(3)°$]. In **2** C1–C2 distances are marginally larger, and C–COOH distances marginally shorter, than those in **1**.

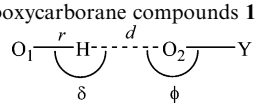
When crystallised from wet solvent, 1-Ph-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ crystallises as the monohydrate **2 · H₂O** and incorporates two molecules of H_2O in an extended (12-membered) H-bonded ring system. In **2 · H₂O** the COOH group stands effectively perpendicular to the Ph ring, $\theta_{COOH} = 78.0(2)_{syn}°$, reminiscent of its relative orientation in **1**. The C–COOH distance in **2 · H₂O** is identical to that in **1**, but C1–C2 is the longest of all the structures described herein.

3.2.2. Intermolecular parameters in *1* and *2*

As previously noted, both **1** and **2** form centrosymmetric eight-membered H-bonded rings in the solid state [$R_2^2(8)$] whilst **2·H₂O** forms a centrosymmetric 12-membered ring that incorporates water [$R_4^4(12)$]. Parameters involved in these H-bonding rings are summarised in Table 3.

According to current conventions [24], all the H-bonds observed in this study are classified as "strong", with H···O distances (d) < 2 Å and O–H··· O angles (δ) close to 180°. The planar eight-membered cyclic H-bonded homodimer of two COOH groups observed in **1** and **2** is ubiquitous [7] for this well-known supramolecular synthon [1] and dimensions within it are quite standard. The 12-membered H-bonded ring of **2·H₂O** is of approximate chair conformation. Within it, H3A···O2$^{\#}$, $d = 1.87(4)$ Å, appears somewhat weaker than H1···O3, $d = 1.65(3)$ Å, and the former is accompanied by an angle ϕ at the COOH acceptor that is close to 180° (c.f. ϕ in **1** and **2** near 120°). A search of the Cambridge Crystallographic Database (version 5.24,

Table 3
Hydrogen bonding distances (Å) and angles (°) in the carboxycarborane compounds **1** and **2**



Compound	O_1	H	O_2	*Y*	*r*	*d*	*δ*	*ϕ*
1	O1	H1	O2[a]	C21[a]	0.90(2)	1.75(2)	175(2)	122(2)
2(A)	O1A	HOA	O2A[a]	C19A[a]	1.11(6)	1.55(6)	171(4)	128(4)

[a] Atom generated by inversion in centre of H-bonding ring.

July 2003) reveals 57 similar 12-membered rings involving two COOH groups and two H_2O molecules in the current literature, of which 42 do not involve charged species. In only 15 cases are all four H···O distances <2 Å, with the shortest distances [$H_{COOH}\cdots O_{H2O}$ 1.43; $H_{H2O}\cdots O_{COOH}$ 1.61 Å] recorded for 1,3,5-cyclohexanetricarboxylic acid monohydrate [25]. The H-bonded distances observed in **2·H$_2$O** are most clearly mirrored in 2,3-dihydroxysuccinic acid monohydrate [26] [$H_{COOH}\cdots O_{H2O}$ 1.64; $H_{H2O}\cdots O_{COOH}$ 1.90 Å].

3.2.3. The structure of *3*

As a complement to the crystallographic study of **2** we have also determined the structure of the phenylbenzoylcarborane **3**. Fig. 5 shows a perspective view of a single molecule and Table 4 hosts selected intramolecular parameters.

Compound **3** crystallises as discrete molecules with no significant intermolecular contacts – replacing the carboxy group of **2** with the benzoyl group prevents association via H-bonding. As far as we are aware this structural study is the first reported of a simple carborane ketone, i.e. carborane-C(O)–R. The C1–C2 distance, 1.695(3) Å, identical to that in related acetato compound [{1-Ph-2-COO(Sn^{n}Bu$_2$)-1,2-*closo*-$C_2B_{10}H_{10}$}$_2$O]$_2$ [27]

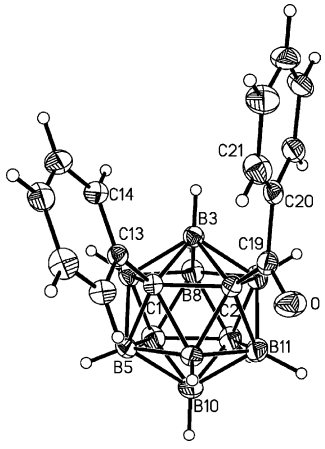

Fig. 5. Perspective view of compound **3**. Thermal ellipsoids are drawn at the 50% probability level, except for H atoms.

Table 4
Selected interatomic distances (Å) and interbond angles (°) for **3**

Bond distances			
C(1)–C(2)	1.695(3)	C(19)–O	1.210(3)
C(1)–C(13)	1.507(3)	C(19)–C(20)	1.485(3)
C(2)–C(19)	1.547(3)		
Bond angles			
C(2)–C(19)–C(20)	124.2(9)	O–C(19)–C(20)	93.48(9)
C(2)–C(19)–O	117.2(9)		

and similar to those in **2**, is shorter than that in 1,2-Ph$_2$-1,2-*closo*-$C_2B_{10}H_{10}$ [23a] [1.727(6) Å, averaged over the two crystallographically independent molecules]. The cage-bound Ph group is oriented with $\theta_{Ph} = 6.9(2)°$. The primary benzoyl orientation θ_{benz} (the modulus of the average C1–C2–C19–O and C1–C2–C19–C20 torsion angles) is 12.3(2)°, and there is a twist of 48.8(2)° about the C19–C20 bond, as is clearly evident from Fig. 5.

4. Conclusions

In the solid state the substituted carboxy carboranes 1-R-2-COOH-1,2-*closo*-$C_2B_{10}H_{10}$ give rise to homodimers with eight-membered H-bonded rings (R = Me, **1**; R = Ph, **2**). The monohydrate **2·H$_2$O** crystallises with a 12-membered H-bonded ring incorporating two carboxylic acid groups and one water molecule. In **1** the orientation of the COOH group is close to that shown computationally to be preferred and a similar orientation persists in **2·H$_2$O**, whilst in **2** it is twisted to a much lower θ_{COOH} value. In the context of the relative orientations of cage substituents, **2** is similar to 1-Ph-2-COPh-1,2-*closo*-$C_2B_{10}H_{10}$ (**3**), which crystallises as discrete monomers.

5. Supplementary material

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 214908 (**1**), 214909 (**2**), 214910 (**2·H$_2$O**) and 214911 (**3**). Copies of this infor-

mation may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1233-336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http//www.ccdc.cam.ac.uk).

Abstract

Two new copper(I) complexes containing the $[MS_4]^{2-}$ core (M = Mo or W) and anionic bis(pyrazolyl)borate (Bp) ligands have been prepared from the reactions of $(Et_4N)_2[MS_4]$, CuCl and KBp. In addition to elemental analysis, their IR, UV–Vis, ^1H and ^{13}C NMR spectra have been studied. The structure of $(NEt_4)_2[WS_4(CuBp)_4]$ has been determined by single-crystal X-ray diffraction. In the pentanuclear dianion, $[WS_4(CuBp)_4]^{2-}$, which has crystallographic S_4 symmetry, the coordination environment around each copper atom is distorted tetrahedral, with two N donors of the bidentate Bp ligands and two S donors of the WS_4 core, representing a structural model for some copper proteins. The W atom retains the tetrahedral geometry of the free $[WS_4]^{2-}$ anion.

1. Introduction

The synthesis and characterization of clusters containing tetrathiometallate anions of tungsten and molybdenum, $[MS_4]^{2-}$ (M = Mo, W), has been a fertile area of research with respect to their physico-chemical, bioinorganic, and structurally oriented coordination chemistry [1–8]. In particular, the chemistry of these multidentate chelating ligands with copper(I), because of their high tendency to form Cu–S bonds, has continued to attract attention [8–13]. The first biological function of Mo/S/Cu clusters was recognized in ruminants [14]. Tetrathiomolybdates, which are formed in the complex stomach of ruminants from molybdate and electron-rich sulfide, can act as efficient chelating ligands for positively charged, albeit π electron-rich ('soft'), metal ions such as Cu^+ and cause copper deficiency in them [15]. Recently, some medicinal applications of tetrathiomolybdate have been reported [16,17].

Poly(pyrazolyl)borates, $[H_nB(Pz)_{4-n}]^-$, are anionic nitrogen-donor ligands, which form a wide variety of stable inorganic and organometallic compounds with structural and functional importance [18–23]. Because of the close similarity between the imidazole of the amino acid histidine and pyrazole, copper complexes with these ligands are also of interest from the bioinorganic point of view and can be considered as model compounds of several copper proteins such as plastocyanin [24,25].

Recently we have reported some Mo–S–Cu–N systems which were the first complexes containing both Bp′ (= H_2B(3,5-Me_2Pz)$_2$) and $[MS_4]^{2-}$ ligands [26,27], offering potential models of copper proteins [28]. Continuing this interest, we report here two pentanuclear complexes of this type, the first ones containing four chelating Bp (= H_2BPz_2) ligands and four Cu(I) atoms around the $[MS_4]^{2-}$ core.

2. Experimental

2.1. General procedures

Starting materials were purchased from commercial sources and purified by standard procedures [29]. Literature methods were used for the preparation of KBp [30], $(NH_4)_2[MS_4]$ and $(NEt_4)_2[MS_4]$ [31]. CuCl (reagent grade) was washed with acetic acid on a filter several times and with absolute ethanol three times, and the white product was treated with dry diethyl ether and dried under vacuum. The complexes were initially prepared under a dry nitrogen atmosphere, but crystallization and other manipulations were performed in air. Solvents were dried and distilled before use [29].

2.2. Physical measurements

UV–Vis spectra of the ligands and complexes were recorded on a JASCO model 7850 spectrophotometer. IR spectra were obtained on FT BRUKER or SHIMADZU IR-470 infrared spectrophotometers using pressed KBr disks with polystyrene as reference. ^1H and ^{13}C NMR spectra were obtained using a BRUKER DRX500 AVANCE spectrometer.

2.3. Synthesis of $(NEt_4)_2[WS_4(CuBp)_4]$ (1)

To a dichloromethane solution (70 ml) of $(NEt_4)_2[WS_4]$ (0.29 g, 0.5 mmol), solid CuCl (0.21g, 2.1 mmol) was added. After vigorous stirring for 10 h, the resulting yellow solution was filtered. KBp (0.37 g, 2 mmol) and THF (10 ml) were added to the filtrate and the mixture was stirred for 40 h at room temperature and filtered. The yellow–orange precipitate was collected, triturated with THF (2×20 ml) and toluene (2×20 ml) to remove the excess KBp, washed with *n*-hexane (2×25 ml) and diethyl ether (2×25 ml) and dried in vacuo. Dissolving the crude product in CH_3CN and drying the filtrate removed the co-precipitated KCl. Suitable crystals for X-ray crystallography were obtained by diffusing diethyl ether into a saturated CH_3CN solution of **1** and leaving it for 5–6 days in a refrigerator. The crystals were washed with diethyl ether several times. Yield: 80%. IR (KBr, cm^{-1}): ν(W–S) 448 (s); ν(B–H) 2258 and 2365 (doublet). Electronic spectrum (DMF, λ nm, absorbance): 494 (0.198), 367 (0.490), 309 (0.904), 304 (0.893), 266 (1.186). ^1H NMR (CH_3CN-d_3, δ): 1.106 (t, 3H, CH_3), 3.127 (q, 2H, CH_2), 5.998 (s, 1H, ^{4}HPz), 7.118 (s, 1H, ^{3,5}HPz), 7.551 (s, 1H, ^{3,5}HPz). ^{13}C NMR (CH_3CN-d_3, δ): 8.752 (CH_3, Et_4N), 52.855 (t,CH_2, Et_4N), 104.783 (^{4}CPz), 135.824 (^{3,5}CPz), 141.137 (^{3,5}CPz). *Anal.* Calc. for $C_{40}H_{72}B_4Cu_4N_{18}S_4W$: C, 33.93; H, 5.08; N, 17.81; S, 9.05; Cu, 17.95. Found: C, 33.91; H, 5.03; N, 17.94; S, 9.09; Cu, 18.01%.

2.4. Synthesis of $(NEt_4)_2[MoS_4(CuBp)_4]$ (2)

$(NEt_4)_2[MoS_4]$ (0.25 g, 0.5 mmol) was dissolved in acetone (100 ml) and CuCl (0.21 g, 2.1 mmol) was added to the pink solution. After vigorous stirring for 4 h, the solution was filtered. KBp (0.37 g, 2 mmol) was added to the filtrate and the mixture was stirred for 8 h at room temperature. Precipitated KCl was removed by filtration and the deep violet filtrate evaporated on a vacuum pump. The resultant solid was triturated in toluene (2×30 ml) to remove the excess of KBp, washed with *n*-hexane (2×30 ml) and diethyl ether (3×25 ml) and dried in vacuo. Yield: 75%. IR (KBr, cm^{-1}): ν(Mo–S) 442(s); ν(B–H) 2255 and 2365 (doublet). Electronic spectrum (DMF, λ nm, absorbance): 524 (0.263), 392 (sh), 313 (1.204), 304 (0.893), 287 (1.823), 266 (1.299). ^1H NMR (acetone-d_6, δ): 1.166 (t, 3H, CH_3), 3.185 (q, 2H, CH_2), 5.954 (s, 1H, ^{4}HPz), 6.973 (s, 1H, ^{3,5}HPz), 7.521 (s, 1H, ^{3,5}HPz). ^{13}C NMR (acetone-d_6, δ): 6.824 (CH_3, Et_4N), 51.190 (t, CH_2, Et_4N), 102.785 (^{4}CPz), 134.149 (^{3,5}CPz), 139.078 (^{3,5}CPz). *Anal.* Calc. for $C_{40}H_{72}B_4Cu_4N_{18}S_4Mo$: C, 36.18; H, 5.43; N, 18.99; S, 9.65; Cu, 19.14. Found: C, 36.14; H, 5.39; N, 19.07; S, 9.67; Cu, 19.19%.

2.5. X-ray crystallography

Crystal data for **1**: $C_{40}H_{72}B_4Cu_4N_{18}S_4W$, $M = 1414.7$, tetragonal, space group $I4_1/a$, $a = 13.3299(3)$, $c = 32.4399(15)$ Å, $V = 5764.1(3)$ Å^3, $Z = 4$, $D_{calc} = 1.630$ g cm^{-3}, $\mu = 3.63$ mm^{-1} (Mo Kα, $\lambda = 0.71073$ Å), $T = 160$ K, crystal size $0.20 \times 0.18 \times 0.15$ mm; 25 818 reflections measured, 3615 unique, $R_{int} = 0.0649$; transmission factors 0.53–0.61; $R(F, F^2 > 2\sigma) = 0.0291$, R_w (F^2, all data) = 0.0635, goodness of fit = 1.093 for all F^2 values and 165 refined parameters; final difference map extremes +1.28 and −0.79 e Å^{-3}.

Data were collected on a Bruker AXS SMART CCD diffractometer with narrow frames (0.3° in ω). Absorption corrections were semi-empirical from symmetry-equivalent and repeated reflections. The structure was solved by direct methods and refined by full-matrix least-squares on all unique F^2. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions and refined with isotropic displacement parameters riding on those of the parent atoms. Programs were standard Bruker AXS control and integration software, and SHELXTL [32].

3. Result and discussion

3.1. Synthesis

Generally, MCuS complexes can be prepared by self-assembly (reaction (1)), or ligand substitution (reaction (2)) [8d,31]:

$$(Et_4N)_2[MS_4] + 4CuCl \rightarrow (Et_4N)_2[MS_4(CuCl)_4] \quad (1)$$

$$(Et_4N)_2[MS_4(CuCl)_4] + 4KBp \rightarrow (Et_4N)_2[MS_4(CuBp)_4] + 4KCl \quad (2)$$

The $(Et_4N)_2[MS_4(CuCl)_4]$ precursor complexes were prepared simply through one-pot reaction by direct mixing of the reagents; nevertheless, our attempt to synthesize **1** and **2** by the self-assembly method via direct mixing of reactants led to oily or unwanted compounds. It seems that the ligand substitution process is a more reliable route for preparing complexes of the type **1** and **2**, according to our previous experiences also [26,27]. It is likely that the steric crowding of the chelating Bp ligands makes self-assembly more difficult. We have found that the order of addition of reactants, the stoichiometric ratios, and the counterion can affect the final product [8,27]. The compounds **1** and **2** are air-stable and can be stored for months in desiccators.

3.2. Infrared spectra

The 400–500 cm^{-1} region of the IR spectra of heterothiometallic cluster compounds containing the $[MXS_3]^{2-}$ (X = O, S; M = V, Mo, W, Re) moiety has proven valuable in arguments concerning their electronic and structural characteristics [1,9]. A single sharp band in this region indicates symmetrical coordination around the MS_4^{2-} core [33] and ν(M–S) decreases on increasing the number of coordinated hetero-metal atoms [9,34]. The spectra of **1** and **2** exhibit a single strong band at 443 and 441 cm^{-1}, respectively, which can be attributed to the ν(M–S) stretching vibrations. Comparing these values with corresponding ones for $(NEt_4)_2[WS_4]$ (458 cm^{-1}) and $(NEt_4)_2[MoS_4]$ (470 cm^{-1}) reveals some red shift to lower frequencies, indicating weakening of the M–S bonds as a result of coordination. As expected, the ν(B–H) frequencies are observed as doublet bands at 2365 and 2258 cm^{-1} and at 2360 and 2255 cm^{-1} for **1** and **2**, respectively, verifying the presence of Bp ligands in the complexes. The simultaneous presence of absorption bands arising from B–H and M–S stretching in IR spectra can be used as a facile and distinctive criterion for the formation of these complexes.

3.3. Description of the crystal structure of $(NEt_4)_2[WS_4(CuBp)_4]$ (1)

The structure of **1** is constructed from four CuBp and one WS_4 fragment through bridging sulfur atoms, similar to those of other monomeric compounds $[MS_4(CuX)_4]^{2-}$ (M = Mo, W; X = Cl, Br) [35,36]. There is no significant interaction among the dianion $[MS_4(CuBp)_4]^{2-}$ and the two Et_4N^+ counterions other than normal coulombic and van der Waals forces. A view of the dianion of complex **1**, with the atomic labelling scheme for the unique atoms, is shown in Fig. 1 and selected bonding parameters are presented in Table 1. The symmetrical coordination of four copper atoms does not lower the symmetry of the WS_4 core essentially; the anion has S_4 symmetry overall, and the two independent S–W–S angles are very similar. The W–S distance of 2.2413(8) Å is slightly longer than those of the bis-coordinated analogue $(NEt_4)_2[WS_4(CuBp')_2]$ (2.210 Å) [27] and rather longer than in the free $[WS_4]^{2-}$ anion (2.165 Å in the ammonium salt) [37,38]. This elongation of W–S and reduction of its double bond character as a result of coordination is in agreement with the decrease of the ν(W–S) frequency in the IR spectrum. The very acute angles about the sulfur atoms bridging Cu and W [72.13(3)° and 72.75(3)°], together with the short W···Cu distance (2.688 Å) are suggestive of direct tungsten-copper bonding interactions within the $Cu(S_b)_2W$ rings. Although no definitive statement can be made about the existence of a metal–metal bond, the observed distances are consistent with a strong attractive interaction between Cu and W atoms, as expected when placing two metals with greatly different formal oxidation states, d^{10} Cu(I) and d^0 W(VI), in close proximity, as they are in this pentanuclear cluster.

The coordination environment of each copper atom is highly distorted tetrahedral, with angles about Cu ranging from 122.21(11)° for S–Cu–N(21) to 92.54(13)° for N(11)–Cu–N(21), and each Cu atom is coordinated by two sulfur atoms from WS_4 and two nitrogen atoms of Bp ligands. The bond distances in CuS_2N_2 units are 2.3224(13) and 2.2896(12) Å for Cu–S and 2.021(3) and 2.093(3) Å for Cu–N. These values are in agreement

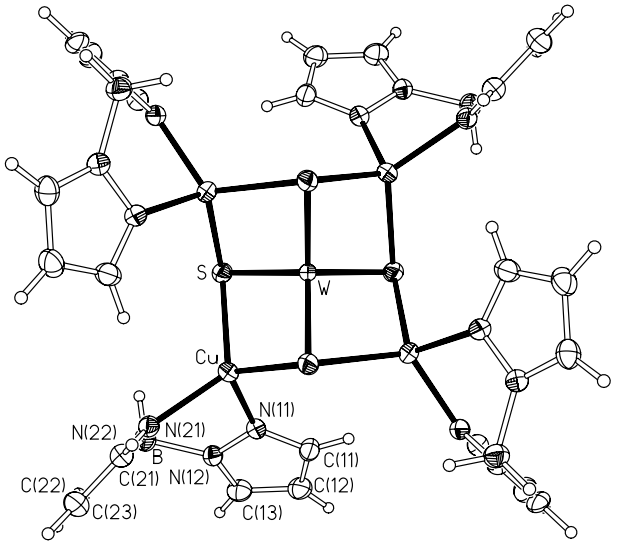

Fig. 1. Structure of the $[WS_4(CuBp)_4]^{2-}$ anion in **1**, showing 50% probability displacement ellipsoids and the numbering scheme for atoms of the asymmetric unit.

Table 1
Selected bond lengths (Å) and angles (°) for (**1**)

Bond lengths			
W–S	2.2413(8)	Cu–S	2.3224(13)
W···Cu	2.6875(5)	Cu–S(B)	2.2896(12)
Cu–N(11)	2.093 (3)	Cu–N(21)	2.021(3)
N(11)–N(12)	1.361(4)	N(21)–N(22)	1.362(4)
N(12)–B	1.548(6)	N(22)–B	1.556(5)
Bond angles			
S–W–S(A)	108.91(2)	S–W–S(C)	110.59(4)
S–Cu–S(B)	104.53(4)	N(11)–Cu–N(21)	92.54(13)
N(11)–Cu–S	105.49(9)	N(11)–Cu–S(B)	111.87(9)
N(21)–Cu–S	122.21(11)	N(21)–Cu–S(B)	118.76(9)
W–S–Cu	72.13(3)	W–S–Cu(A)	72.75(3)
Cu–S–Cu(A)	111.80(4)		

Symmetry operations for equivalent atoms: A $y-1/4, -x+5/4, -z+1/4$; B $-y+5/4, x+1/4, -z+1/4$; C $-x+1, -y+3/2, z$.

with previously reported ones for compounds of this type [26,27] or for similar compounds {e.g. 2.290(5) Å for Cu–S and 2.02(1) Å for Cu–N in $[WS_4Cu_3Cl(bpy)_2]$ [39]}.

In addition to the similarity between pyrazole (as N-donor in **1** and **2**) and imidazole of amino acids of living systems, the arrangement and coordination environment of Cu atoms in **1** are comparable to those found in the active sites of some copper proteins such as poplar plastocyanin, cuperedoxin, cytochrome *c* oxides, etc. [28,40,41], leading to the possibility of using these complexes **1** and **2** as models for copper proteins. It is also noeworthy that, as far as we know, the compounds **1** and **2** are the first ones containing four chelate ligands around the MS_4Cu_4 core except for a dithiocarbamate complex [42], and **1** is the first crystallographically characterized complex containing the Bp ligand.

4. Supplementary material

Crystallographic data, excluding structure factors, have been deposited at the Cambridge Crystallographic Data Centre, CCDC No. 215465. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

A new angular trinuclear copper(II) complex $[Cu_3L^1L^2(1\text{-MeIm})(H_2O)](ClO_4)$ (**1**), where H_3L^1 and H_2L^2 are penta and tetradentate Schiff base ligands, is prepared from a reaction of $[CuL^2]$ and $[Cu_2L^1(\mu\text{-Br})]$ in the presence of 1-methylimidazole (1-MeIm) and isolated as a perchlorate salt. The complex which crystallizes in the monoclinic space group $P2_1/n$ shows the presence of a discrete angular trinuclear copper(II) core in which the monomeric precursor is linked with the dimeric precursor through phenoxo bridges. The core structure resembles well with the active site structure of blue multicopper oxidases. The Cu···Cu separations of ca. 3.3 Å in the angular unit is 0.4 Å shorter than those observed in the active site of the oxidized form of ascorbate oxidase. The complex displays a visible band at 620 nm ($\varepsilon = 500\ M^{-1}\ cm^{-1}$) in DMSO. It shows magnetic moment values of 3.07 and 2.18 μ_B at 300 and 18 K, respectively, for the Cu_3 cluster. The complex models the structural and magnetic properties of the trinuclear active site of blue copper oxidases.

Keywords: Tricopper(II) complex; Schiff bases; Ascorbate oxidase model; Crystal structure; Magnetic properties

1. Introduction

Blue multi-copper oxidases are copper containing metalloproteins that catalyze the four-electron reduction of dioxygen to water [1–6]. The active site of such oxidases has an angular trinuclear copper unit that consists of a putative type-2 (mononuclear) and type-3 (dinuclear) copper centers. The trinuclear core is located ~12 Å from a type-1 copper center in ascorbate oxidase [7]. Within the active site, the type-2 (or normal) copper center is bonded to two histidines and an aqua ligand, while the dicopper type-3 unit which is strongly antiferromagnetically (AF) coupled unit, has each copper bonded to three histidines and one bridging hydroxide giving a four-coordinate structure in its oxidized form (Chart 1). The average Cu···Cu distance is 3.74 Å. The reduced form of the oxidase shows an increase of the Cu···Cu distance in absence of any hydroxide bridge. The role of type-1 copper is to transfer electron to the trinuclear unit via His506–Cys507–His508 amino acid sequence in ascorbate oxidase to effect simultaneous four-electron reduction of dioxygen. The trinuclear active site has generated lot of interest in modeling the structural, magnetic and functional properties of the blue multicopper oxidases [8].

The majority of the reported trinuclear copper(II) complexes have either a linear arrangement of the metal centers or a $Cu_3(\mu_3\text{-X})$ unit (X = Cl, OH) [9–11]. Some angular tricopper(II) complexes are also known in the literature [12–19] but the model complexes resembling well to the active site structure are rare [12,15]. We have been interested to model the active site by following a new synthetic methodology involving the formation of the trinuclear core by linking of a type-2 mimic monomeric copper(II) complex with a type-3 mimic dinuclear copper(II) complex. We have recently reported trinuclear copper(II) complexes of formulation $[Cu_3(HL^1)L^1L'](ClO_4)$ by reacting $[Cu(HL^1)]$ and $[Cu_2L^1(\mu\text{-Br})]$ in the presence of imidazole bases like 1-methylimidazole or imidazole (L′), where H_3L^1 is a pentadentate Schiff base, *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldi-

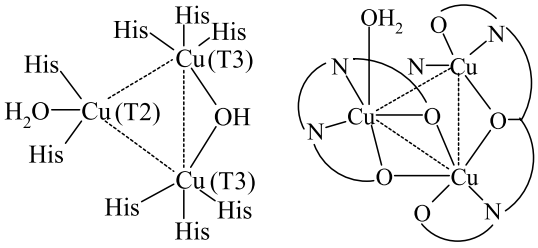

Chart 1. Trinuclear active site of ascorbate oxidase and the core structure of the model complex **1**.

mine) [20]. While these complexes model the structural and magnetic properties of the active site of ascorbate oxidase, they, however, show the formation of network structures involving the hydrogen atom of the uncoordinated hydroxypropane unit of the Schiff base. The present work stems from our interest to improve the synthetic methodology for the preparation of a discrete angular trinuclear copper(II) complex. For that purpose we have chosen a new type-2 mimic using a tetradentate Schiff base, *N*,*N*′-(propane-1,3-diyl)bis(salicylaldimine) (H_2L^2) for the monomeric precursor, and [Cu_2L^1(μ-Br)] as a type-3 mimic dimeric precursor having a pentadentate Schiff base (H_3L^1). The reaction of [CuL^2] with [Cu_2L^1(μ-Br)] in presence of 1-methylimidazole forms a trinuclear complex that has been isolated as a perchlorate salt of composition [$Cu_3L^1L^2$(1-MeIm)(H_2O)](ClO_4) (**1**). The significant result is the observation of discrete molecular nature of the complex which shows structural resemblance to the active site structure of ascorbate oxidase (Chart 1).

2. Experimental

2.1. Materials and measurements

Chemicals and reagents were purchased from commercial sources. Solvents were purified by standard procedures. The Schiff bases *N*,*N*′-(2-hydroxypropane-1,3-diyl)bis(salicylaldimine) (H_3L^1), *N*,*N*′-(propane-1,3-diyl) bis(salicylaldimine) (H_2L^2) and the precursor complexes [Cu_2L^1(μ-Br)] and [CuL^2] were prepared by literature procedures [21]. The elemental analysis was done using a Heraeus CHN–O Rapid instrument. The infrared and electronic spectra were recorded on a Bruker Equinox 55 and Hitachi U3000 spectrometers, respectively. Variable temperature magnetic susceptibility data for the polycrystalline sample of **1** were obtained in the temperature range 18–300 K using Model 300 Lewis Coil Force magnetometer (George Associates Inc., Berkeley, CA), equipped with a closed cycle cryostat (Air Products) and a Cahn balance. Hg[$Co(NCS)_4$] was used as a standard. Experimental susceptibility data were corrected for diamagnetic contributions and for temperature-independent paramagnetism [22]. Electrochemical measurements were made at 25 °C under dinitrogen atmosphere using a EG&G PAR Model 253 Versastat Potentiostat/Galvanostat with an electrochemical analysis software 270 for the cyclic voltammetric work using a three-electrode setup consisting of a glassy carbon working, a platinum wire auxiliary and a saturated calomel reference electrode (SCE). The electrochemical data were uncorrected for junction potentials. A 0.1 M tetrabutylammonium perchlorate (TBAP) was used as a supporting electrolyte in MeCN. Ferrocene was used as a standard to monitor the reference electrode showing the Fe(III)/Fe(II) couple at 0.38 V (vs. SCE) under similar experimental conditions in MeCN–0.1 M TBAP. Conductivity measurement was made at 25 °C using a Control Dynamics conductivity meter with a 10^{-3} M MeCN solution of complex **1**.

2.2. Synthesis

Complex **1** was prepared by reacting a 0.22 g (0.59 mmol) quantity of [CuL^2] taken in 15 ml of chloroform with 0.3 g (0.59 mmol) of [Cu_2L^1(μ-Br)] in a 20 ml MeCN–MeOH mixture (1:1 v/v) whilst stirring for 15 min. The reaction mixture was initially refluxed for 30 min followed by addition of 0.048 g 1-methylimidazole (0.59 mmol) and the reflux was continued for a further period of 1 h. The solution was then cooled to an ambient temperature and 0.073 g sodium perchlorate (0.59 mmol) was added to the reaction mixture. The solution was filtered and the solid product was isolated on slow evaporation of the solvent. It was washed with petroleum ether and water, and finally dried in vacuum over P_4O_{10} (yield: ~60%). Single crystals suitable for X-ray diffraction and other analytical studies were obtained from the mother liquor on slow evaporation. *Anal.* Calc. for $C_{38}H_{39}N_6O_{10}ClCu_3$ (**1**): C, 47.25; H, 4.07; N, 8.70. Found: C, 47.34; H, 4.06; N, 8.79%. FT-IR (KBr phase), cm^{-1}: 3413 br, 3133 w, 2922 w, 2359 w, 1634 s, 1447 s, 1303 s, 1194 m, 1093 vs, 903 m, 754 s, 626 m (br, broad; vs, very strong; s, strong; m, medium; w, weak). Electronic spectral data in DMSO [λ_{max}, nm (ε, M^{-1} cm^{-1})]: 620 (500), 370 (21 400), 273 (39 000). Magnetic susceptibility data [χ_M^{corr} (per copper), cm^3 M^{-1}]: 1.32×10^{-3} at 300 K; 1.21×10^{-2} at 18 K. Magnetic moment (μ_{eff}) per copper (per cluster): 1.78 μ_B (3.07 μ_B) at 300 K; 1.28 μ_B (2.18 μ_B) at 18 K. Complex **1** is air stable and soluble in common organic solvents other than hydrocarbons and water. *It contains perchlorate anion and as perchlorate salts of metal complexes with organic ligands are potentially explosive, only small quantity of the complex was handled with caution.*

2.3. Crystallographic studies

The intensity data were collected using a Bruker SMART APEX CCD diffractometer, equipped with a

fine focus 1.75 kW sealed tube Mo Kα X-ray source, with increasing ω (width of 0.3°/frame) at a scan speed of 12 s/frame. The SMART software was used for data acquisition and SAINT software was used for data extraction. Empirical absorption corrections were made on the intensity data using SADABS program [23]. The structure was solved and refined with SHELX programs [24]. Perspective view of the complex was obtained by ORTEP [25]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were generated in their calculated positions and refined using a riding model. The hydrogen atoms were used for structure factor calculation only. Selected crystallographic data are given in Table 1.

3. Results and discussion

3.1. Synthesis and general aspects

Complex **1** has been prepared in high yield using a modified synthetic method to the one reported by us for analogous trinuclear copper(II) complexes [20]. In this synthetic methodology, a monomeric copper(II) complex (**I**) which is a structural mimic for type-2 copper centers has been linked to a dinuclear type-3 structural mimic (**II**) to form a trinuclear core (Scheme 1). The formation of this trinuclear core is facile in the presence of a unidentate ligand that is 1-methylimidazole in the

present synthesis. The monomeric precursor complex has a tetradentate Schiff base ligand. The dinuclear precursor, on the other hand, has a pentadentate Schiff base. A linkage of **I** and **II** has formed a trinuclear complex which is found to be a discrete molecular species.

The complex has been characterized from analytical and spectral data (Table 2). Complex **1** is 1:1 electrolytic in nature and shows an IR band at 1093 cm^{-1} assignable to the perchlorate anion. It displays a d–d band at 620 nm in its electronic spectrum in dimethylsulfoxide (DMSO). The complex exhibits a cathodic peak at −1.05 V with an anodic response at −0.95 V for the Cu(II)/Cu(I) couple in the cyclic voltammogram at 50 mV s^{-1} in MeCN–0.1 M TBAP. The ΔE_p value of 100 mV suggests quasireversible nature of the redox process.

3.2. Magnetic properties

The variable temperature magnetic susceptibility data for **1** in the temperature range 300–18 K show an overall antiferromagnetic behavior of the complex (Fig. 1). The complex has a magnetic moment value of 1.78 μ_B at 300 K per copper(II) center. This suggests near paramagnetic behavior of the complex at room temperature. At lower temperatures, the complex exhibits antiferromagnetic interaction giving a magnetic moment value of

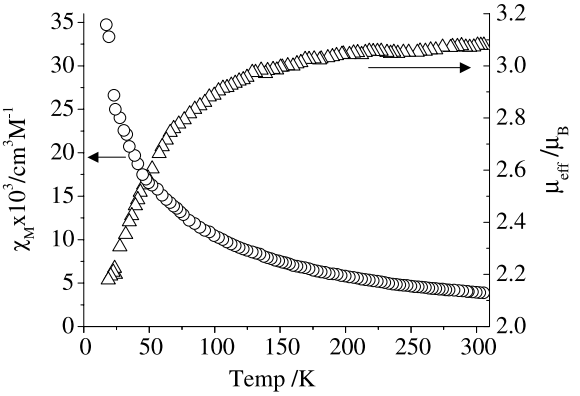

Fig. 1. Temperature dependence of magnetic susceptibility (o, per cluster) and the magnetic moment (Δ, per cluster) for $[Cu_3L^1L^2(1\text{-MeIm})(H_2O)](ClO_4)$ (**1**).

1.28 μ_B per copper at 18 K. The μ_{eff} value per cluster at 18 K is 2.18 μ_B which is close to the value of a core having a single paramagnetic copper(II) center and one strongly AF coupled dicopper(II) unit. The magnetic behavior of **1** thus models the magnetic property of the trinuclear active site of the ascorbate oxidase at the low temperature limit.

3.3. Crystal structure

The complex crystallizes in the monoclinic space group $P2_1/n$ with four molecules in the unit cell. The asymmetric unit consists of a trinuclear complex and a perchlorate anion. An ORTEP view of the cationic complex is shown in Fig. 2. Selected bond distances and angles are given in Table 3. The structure shows binding of the monomeric precursor to one copper center of the dinuclear precursor through the phenoxo oxygen atom O(3). The Cu(1) atom has a four coordinate geometry in a CuN_2O_2 coordination environment. This metal atom is bonded to the terminal phenoxo O(1), imine N(1), 1-methylimidazole N(5) and the bridging alkoxo O(2)

O(3)–Cu(2)–O(5)	89.91(9)		

atom. The copper atom is essentially in the basal plane showing a deviation of 0.025(1) Å from the plane. The Cu(2) atom has a five coordinate structure in a $CuNO_4$ environment. In this axially elongated structure, the metal is displaced by 0.235(1) Å from the plane formed by O(2), N(2), O(3) and O(4) atoms. The O(5) atom occupies the axial site showing a Cu(2)–O(5) distance of 2.153(2) Å. The Cu(2) atom belonging to the dinuclear precursor is linked to two other copper atoms through alkoxo O(2) and phenoxo O(4) atoms. The Cu(3) atom has the dianionic Schiff base ligand L^2 showing chelating tetradentate bonding mode. The metal has a square pyramidal geometry with the Schiff base at the basal plane and an aqua ligand occupying the axial site. The Cu(3) atom is 0.126(1) Å displaced from the basal plane.

Complex **1** has an angular trinuclear copper(II) core. A structural comparison to the active site of ascorbate oxidase is made in Chart 1. The Cu···Cu distances in the trinuclear unit is ~3.25 Å which is shorter than that observed in the active site (3.74 Å) of the oxidized form of the enzyme [7]. The av. Cu···Cu···Cu angle in **1** is 60°. The basal planes in **1** are not coplanar. The angle between two basal planes containing Cu(1) and Cu(2) atoms is 80.43(6)°. The angle between Cu(2) and Cu(3) planes is 89.02(7)°. Such a structural feature of **1** in which the dihedral angles between the basal planes are ~90° is expected to make the Cu(3) center paramagnetic by retaining its type-2 mimic properties while the alkoxo bridged Cu(1) and Cu(2) atoms form an AF coupled dicopper(II) unit. As a consequence, the complex models the magnetic and structural properties of the active site.

While AF coupling between Cu(2) and Cu(3) atoms are possible through O(4) atom located at the basal planes of two units, the dihedral angle of ~90° could reduce the extent of magnetic interaction significantly. Again, the interaction between two metal atoms through O(5) atom should be negligible considering the involvement of $d_{x^2-y^2}$ of Cu(3) and d_{z^2} of Cu(2) atom. The interaction between Cu(1) and Cu(2) atoms involving the alkoxo bridge is expected to be antiferromagnetic in nature considering the Cu(1)–O(2)–Cu(2) angle of 110.8° [26] The structural and magnetic results of **1** are of significance as the majority of known model complexes do not resemble to the active site structure. Another significant structural aspect of **1** is the discrete molecular nature of the complex. The aqua ligand bound to Cu(3) atom shows hydrogen bonding interaction only with the perchlorate anion [O(6)···O(12), 2.979(6) Å] and there is no other non-covalent interaction observed in the crystal structure of the complex. This makes complex **1** significantly different from its analogues with a pendant hydroxy group in the monomeric precursor that forms the hydrogen bonded network structure [20].

In summary, a new angular trinuclear copper(II) complex has been prepared from the reaction of a mononuclear copper(II) complex with a dinuclear copper(II) precursor in presence of 1-methylimidazole. The complex models the active site structure of ascorbate oxidase. It also models the magnetic properties of the active site but at a lower temperature giving one-electron magnetic moment for the trinuclear cluster at 18 K indicating the presence of a strong antiferromagnetically coupled dicopper(II) unit (type-3 mimic) and a copper(II) center (type-2 mimic). The synthetic methodology has been found to be useful for the preparation of discrete molecular angular trinuclear copper(II) complexes.

4. Supplementary data

Crystallographic data for the structural analysis of **1** have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 218816. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-366-033; e-mail: deposit@ccdc.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

In the presence of lithium or potassium hydroxides, *p-tert*-butylhexahomotrioxacalix[6]arene (LH_6) gives uranyl complexes different from those obtained with amine bases. The dianionic trinuclear complex $[(UO_2)_2Li(OH)L(py)]$ is a monomeric species containing two tri-phenoxide-coordinated and hydroxo-bridged uranyl ions and a lithium ion bound to two phenoxide and one ether groups and a pyridine molecule. In the neutral $[UO_2K(LH_3)(H_2O)_2]_2$ complex, each macrocycle contains a tri-phenoxide-coordinated uranyl ion. The potassium ion is bound to two phenolic and one ether groups, to one of the uranyl oxo groups, to two bridging water molecules and to a phenoxide atom of a neighboring molecule. The latter bonds give rise to a centrosymmetrical, tetranuclear dimer.

1. Introduction

In spite of their suitable size and versatility, calixarenes have been little used in the design of heteropolymetallic complexes with transition metal ions and only recently a Re/Pd complex of *p-tert*-butylcalix[4]arene has been described [1]. However, several heteropolymetallic species involving alkali metal ions as one of the components were reported [2] and, following our previous work on uranyl ion complexes with calixarenes and homooxacalixarenes [3], we published recently the synthesis and crystal structures of mixed uranyl/alkali metal ions complexes with homooxacalixarenes [4,5]. We began this work with the rather simple case of *p-tert*-butyltetrahomodioxacalix[4]arene, which is perfectly suited for tetra-phenoxide complexation of a single uranyl ion. When deprotonation is carried out with alkali metal hydroxides in place of the usual amines, the uranyl complex core does not change, but oxo(uranyl)-coordination of the alkali metals ensues as a general trend [4]. Depending on the size and predominantly 'hard' or 'soft' character of the alkali metal, different arrangements are obtained, monomeric with Li^+, dimeric with Na^+ and polymeric with K^+ and Cs^+, 'endo' coordination associated with cation–π interactions being favoured for the larger cations. The much larger and versatile *p-tert*-butyloctahomotetraoxacalix[8]arene, when deprotonated with rubidium hydroxide, does not give the tetra-uranate internal complex obtained in the presence of triethylamine [6], but a dimeric capsule in which two calixarenes are held by $[(UO_2)_2(OH)_2]$ links and which contains the disordered Rb^+ ions [5]. We report herein the results of a similar investigation involving *p-tert*-butylhexahomotrioxacalix[6]arene, which is intermediate in size between the two previous ones (Scheme 1). This ligand has been shown to be of a convenient size to complex a $[(UO_2)_3(OH)_3]$ core in the presence of 1,4-diazabicyclo[2.2.2]octane (DABCO) [7]. The difficulties encountered in growing single crystals of suitable quality prevented the complete series

of alkali metal ions to be investigated, but crystal structures of complexes with two cations very different in size, Li^+ and K^+, are herein described and discussed.

2. Experimental

2.1. Synthesis

The ligand *p-tert*-butylhexahomotrioxacalix[6]arene LH_6 was synthesized as previously reported [8].

2.1.1. $[(UO_2)_2Li(OH)L(py)][Li(H_2O)_3(py)]\cdot(Hpy)\cdot H_2O\cdot 4.5py$ (**1**)

LH_6 (17 mg, 0.016 mmol) and an excess of $LiOH\cdot H_2O$ (9 mg, 0.21 mmol) were heated to reflux in $CHCl_3/CH_3OH$ (70/10 ml). A solution of $UO_2(NO_3)_2\cdot 6H_2O$ (26 mg, 0.052 mmol) in CH_3OH (10 ml) was then added dropwise, resulting in a bright orange solution which was stirred for 15 min. The powder obtained after complete evaporation of the solution was dissolved in pyridine and yielded orange single crystals, mixed with powder, on slow evaporation. No chemical or spectroscopic analysis could be performed due to the heterogeneous nature of the sample.

2.1.2. $[UO_2K(LH_3)(H_2O)_2]_2\cdot 14py$ (**2**)

LH_6 (20 mg, 0.019 mmol) was dissolved in $CHCl_3$ (70 ml) in the presence of an excess of KOH (10 mg, 0.18 mmol) in CH_3OH (10 ml). $UO_2(NO_3)_2\cdot 6H_2O$ (30 mg, 0.060 mmol) in CH_3OH (25 ml) was added dropwise at room temperature, giving a dark orange solution. Recrystallization in pyridine afforded dark orange single crystals mixed with an orange powder. No chemical or spectroscopic analysis could be performed due to the heterogeneous nature of the sample.

2.2. Crystallography

The data were collected on a Nonius Kappa-CCD area detector diffractometer [9] using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The crystals were introduced in glass capillaries with a

protecting 'Paratone-N' oil (Hampton Research) coating. The unit cell parameters were determined from ten frames, then refined on all data. A 180° φ-range was scanned with 2° steps during data collection, with a crystal-to-detector distance fixed to 28 mm. The data were processed with DENZO-SMN [10]. The structures were solved by Patterson map interpretation with SHELXS-97 and subsequent Fourier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [11]. Absorption effects were corrected empirically with the program DELABS from PLATON [12]. In compound **1**, one *tert*-butyl group was found to be rotationally disordered over two positions and three pyridine molecules were found to be disordered over two sites each. These positions were refined with occupancy parameters constrained to sum to unity. The pyridinium ion (as indicated by possible hydrogen bonds) is also disordered over two positions, corresponding to N2 and N3, which cannot be occupied simultaneously and have been affected with a 0.5 occupancy parameter. In compound **2**, one pyridine molecule was found disordered over two sites which were refined with occupancy parameters constrained to sum to unity, and the nitrogen atom was not located in another, badly resolved, pyridine molecule. In both **1** and **2**, some pyridine molecules have been refined as idealized hexagons. In both compounds, all non-hydrogen atoms were refined with anisotropic displacement parameters (except some of the disordered ones) with some restraints for some badly behaving atoms. The hydrogen atoms bound to oxygen and nitrogen atoms in **1** were not found, nor introduced, whereas those bound to oxygen atoms in **2** (except those of the water oxygen atom O13) were found on a Fourier-difference map. The other hydrogen atoms were introduced at calculated positions, except in the disordered parts. All hydrogen atoms were treated as riding atoms with a displacement parameter equal to 1.2 (OH, CH, CH_2) or 1.5 (CH_3) times that of the parent atom. Crystal data and structure refinement details are given in Table 1 and selected bond lengths and angles in Table 2. The molecular plots were drawn with SHELXTL [13]. All calculations were performed on a Silicon Graphics workstation.

3. Results and discussion

The uranyl complex obtained in the presence of lithium hydroxide, $[(UO_2)_2Li(OH)L(py)][Li(H_2O)_3(py)] \cdot (Hpy) \cdot H_2O \cdot$ 4.5py (**1**) contains the trimetallic dianionic species $[(UO_2)_2Li(OH)L(py)]$ in which the three cations are complexed in 'internal' fashion (Fig. 1). The two uranyl ions are bound to three phenoxide groups and a central hydroxide ion, which results in a distorted square bipyramidal environment for the uranium atoms, and the lithium ion is bound to two phenoxide and one ether oxygen atoms and a pyridine molecule. This arrangement is different from the pseudo-trigonal geometry of the previously reported tri-uranate complex with the same ligand [7], in which the trianionic complex core $[(UO_2)_3(OH)_3L]$ contains three cations, each of them bound to two phenoxide groups (separated by a methylene link) and two hydroxide ions in their equatorial plane. The mean U–O(phenoxide) bond length in **1** is

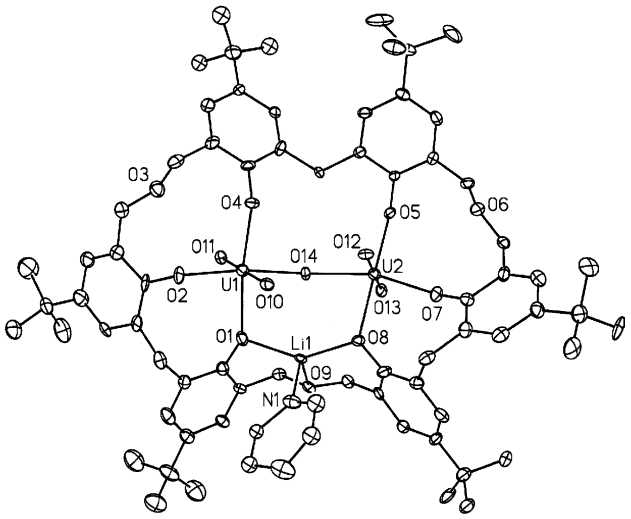

Fig. 1. View of the complex $[(UO_2)_2Li(OH)L(py)][Li(H_2O)_3(py)] \cdot (Hpy) \cdot H_2O \cdot 4.5py$ (**1**). Hydrogen atoms, counter-ions and solvent molecules have been omitted for clarity. Displacement ellipsoids are drawn at the 30% probability level.

2.28(5) Å, in agreement with usual values. However, the bond lengths involving the atoms O1 and O8, which are also bound to Li^+, are significantly larger than the other ones [mean values 2.325(9) versus 2.25(3) Å]. The mean U–O(hydroxide) bond length, 2.332(6) Å, as well as the U1–O14–U2 angle, 139.7(4)°, are comparable to the values in similar cases [7]. The four donor atoms around each uranyl ion define a mean plane with a maximum deviation of 0.042(4) Å, the uranium atoms being separated by 0.067(4) and 0.076(4) Å from these planes, which define a dihedral angle of 52.1(2)°. The space left in the macrocycle cavity by the absence of the third uranyl ion is occupied by the lithium ion, which is chelated by two phenoxide groups (not bound to the same uranium atom) and the ether atom O9. The mean Li1–O(phenoxide) bond length, 2.04(9) Å is in the range 1.87–2.09 Å reported for the literature values [14] and the Li1–N1 bond length, 2.07(2) Å, agrees well with the mean Li–N(pyridine) bond length value of 2.07(7) Å for the structures reported in the Cambridge Structural Database [15]. The environment of Li^+ is a very distorted tetrahedron, with the O1–Li1–O8 angle much larger than the other ones, due to geometrical constraints. Li^+ is located at 0.568(18) Å above the plane defined by the three atoms O1, O8 and O9 from the calixarene and can thus be considered to be complexed in an 'internal' mode.

Whereas the conformation of the macrocycle in the previous, tri-uranate complex was that of a rather regular trigonal cone, it is rather flat and very distorted in the present case. All three ether links define two *anti* torsion angles, which, in the case of O9, brings this atom closer to Li1. However, the phenolic rings orientation is such that the complex possesses no pseudo-symmetry, even approximate. If we adopt the notation of Kanamathareddy and Gutsche [16] and introduce the ether bridges as (b), the conformation of L in **1** can be represented by the sequence [uu(b)ud(b)du(b)]. As a result, Li1 has a different position with respect to the two mean equatorial planes corresponding to U1 and U2, being at 1.51(2) Å from the first and 0.03(2) Å from the second and thus located in the plane corresponding to U2.

The repeat unit contains also two counter-cations and several solvent molecules. The second Li^+ cation is bound to three water molecules and one disordered pyridine molecule and it is thus isolated from the uranyl complex moiety. The presence of a pyridinium ion, disordered over two positions, can be inferred from N···O(phenoxide, ether) distances indicative of hydrogen bonds [N2···O4 3.17(2), N3···O6 3.12(2) Å]. Among the solvent pyridine molecules, one is hydrogen bonded to the hydroxide group [O14···N5 2.77(1) Å], and two others to lithium-bound water molecules.

The complex obtained in the presence of potassium hydroxide, $[UO_2K(LH_3)(H_2O)_2]_2 \cdot 14py$ (**2**), is dimeric in nature and different from **1** as well as from the tri-uranate species. The asymmetric unit contains the heterobinuclear unit $[UO_2K(LH_3)(H_2O)_2]$, represented in Fig. 2, and pyridine solvent molecules. As in complex **1**, the uranyl ion is bound to three phenoxide groups and the potassium ion to two phenol and one ether groups. However, at variance with **1**, the macrocycle is not completely deprotonated and contains two cations only. The uranyl ion completes its coordination sphere with a water molecule (O12) to give the usual square bipyra-

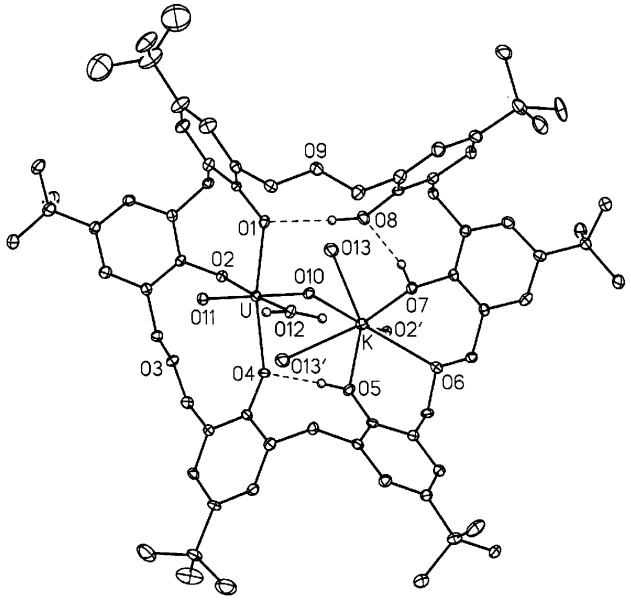

Fig. 2. View of one unit in the dimeric complex $[UO_2K(LH_3)(H_2O)_2]_2 \cdot 14py$ (**2**). Hydrogen atoms (except for the hydrogen bonded ones) and solvent molecules have been omitted for clarity. Intramolecular hydrogen bonds are represented as dashed lines. Displacement ellipsoids are drawn at the 20% probability level. Symmetry code: $' = 2 - x, 2 - y, 1 - z$.

midal geometry around the uranium atom, with a mean U–O(phenoxide) bond length of 2.27(6) Å. The four donor atoms define a mean equatorial plane with a maximum deviation of 0.141(3) Å, which contains also the uranium atom [deviation of 0.058(3) Å]. The mean K–O(phenol) bond length is 2.74(7) Å, which is in the range 2.544–3.160 Å for the literature values [14] and agrees also with the value 2.731(6) Å in the uranyl/potassium complex of *p-tert*-butyltetrahomodioxacalix[4]arene [4]. The K–O(ether) bond length, 2.733(6) Å, is slightly shorter than the mean value in the latter complex, 2.808(5) Å, which is likely due to the different geometrical constraints arising from much different potassium locations. It is noticeable that, considering the macrocycle only, K^+ in **2** is bonded in a similar way as Li^+ in **1**, the bridging phenoxide groups being replaced by hydrogen bonded phenolic ones. Apart from the three oxygen atoms from the macrocycle, the potassium ion is bound to the oxo group of the uranyl ion, with a K–O10 bond length of 2.757(5) Å which perfectly matches the mean value of 2.8(3) Å in the *p-tert*-butyltetrahomodioxacalix[4]arene complex (in which, however, each oxo atom is bound to two potassium ions), two water molecules (O13 and its symmetry-related equivalent) and the phenoxide atom O2 from a neighboring molecule. The potassium is thus hepta-coordinated, and the environment geometry can best be viewed as a much distorted capped octahedron with the oxo atom O10 in capping position [17]. K^+ is located at a distance of 2.016(4) Å from the plane defined by the three atoms O5, O6 and O7 from the calixarene and, in contrast with Li^+ in **1**, it can thus be considered to be complexed in an 'external' mode. It is noteworthy that, at variance with the previous UO_2/K complex [4] and several other calixarene complexes [14,18,19], the potassium cation in **2** is not involved in obvious cation–π interactions. The only possibly significant K···C(arom) interaction involves the carbon atom bound to O2 in the second calixarene, but the corresponding K···C distance, 3.423(7) Å, is larger than the shortest contact in the previous complex, 3.180(8) Å [4]. The three phenolic protons are involved in intramolecular hydrogen bonds [O5···O4 2.653(7), O7···O8 2.839(7) and O8···O1 2.894(8) Å]. The bonding of the potassium atom to a phenoxide of a neighboring molecule as well as the bridging character of the water molecules (O13 and its symmetry-related equivalent) ensure the formation of a centrosymmetrical, tetranuclear dimer, represented in Fig. 3. This dimeric species can be viewed as a capsule built from two uranyl-containing macrocycles facing each other, with a $K_2(H_2O)_2$ group occupying the central cavity and ensuring the cohesion of the whole assembly.

The macrocycle adopts a conformation which can be described as a double partial cone, with the three phenoxide units bound to the uranyl ion building one subunit and the two bound to the potassium ion and the non-coordinated one the second subunit (it may be noted that a similar conformation is adopted by calix[6]arene in its di-potassium complexes [19]). The overall appearance is somewhat analogous to a saddle shape. The two partial cones are connected by one methylene and one ether-containing bridges and they are also linked by two intramolecular hydrogen bonds. The dihedral angle between the planes defined by O1, O2, O4 in the first part and O5, O7, O8 in the second is 77.5(2)°. The water molecules bound to the uranium atoms are located in each homooxacalixarene cavity and are hydrogen bonded to two pyridine molecules [O12···N2 2.709(9), O12···N3 2.631(8) Å]. Two other pyridine molecules are hydrogen bonded to the bridging water molecules [O13···N1 2.801(10) Å].

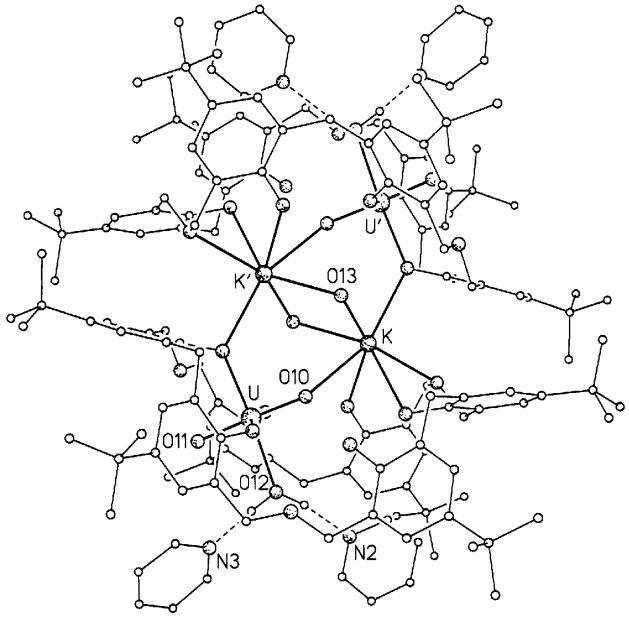

Fig. 3. View of the complex $[UO_2K(LH_3)(H_2O)_2]_2 \cdot 14py$ (**2**). The hydrogen atoms (except those of the water oxygen atom O12) and some solvent molecules have been omitted for clarity. Intermolecular hydrogen bonds are represented as dashed lines. Carbon atoms have been arbitrarily reduced for clarity. Symmetry code: $' = 2 - x, 2 - y, 1 - z$.

4. Conclusion

In spite of the characterization of uranyl/alkali metal ions complexes with the ligand LH_6 having been performed for Li^+ and K^+ only, the large difference in size, and hence in behavior, between these two cations permits some conclusions to be drawn. In the previously investigated case of *p-tert*-butyltetrahomodioxacalix[4]arene, these two cations give much different complexes, both of them including the same uranyl complex core. Li^+ leads to a monomeric complex in which each of the two lithium ions is bound to an oxo(uranyl) atom, one in the macrocycle cavity and the other outside, and to three water/methanol molecules. With K^+, a polymeric species is formed (as with Cs^+), the two potassium ions being

located in the cavity and bound both to the oxo atom directed inside and to the oxo atom of a neighboring molecule, and also to an ether oxygen atom and water and pyridine molecules. In the present case, we observe the same tendency for Li^+ to give rise to monomeric species by completing its coordination sphere with solvent molecules rather than with an oxygen atom of a neighboring macrocycle (complete dissociation of the lithium counterion has also been observed in the case of the uranyl complex of an homoazacalixarene [20]). As mentioned above, the potassium ion in **2** is not involved in cation–π interactions as it was the case in the previous complex, but the K^+—oxo bonding is still present. Furthermore, the larger size of this cation, with respect to that of Li^+, enables its bonding to a phenoxide unit of a neighboring complex, which results in dimerization. As noticed above, Li^+ and K^+ are similarly chelated by two phenol/phenoxide and one ether groups of the homooxacalixarene. The differences between the two complexes arise from the larger coordination sphere and resulting higher bridging ability of potassium.

With respect to the nuclearity of complexes **1** and **2**, it can be noted that in none of them is the available space so efficiently occupied than in the tri-uranate complex [4]. **1** is also a trinuclear species, but one uranyl ion and two hydroxide bridges of the tri-uranate complex are replaced by one Li^+ cation only, whereas the macrocycle in **2** contains two cations only, with furthermore, K^+ located largely outside the macrocycle. We have shown previously that the highest uranyl nuclearity which can be expected on the basis of the calixarene/homooxacalixarene size alone [6] can be reduced in the case of less optimal homooxacalixarene positional isomers [21] or in the presence of coordinating solvents which prevent oxo/hydroxo bridging of the uranyl units [22]. As illustrated here, replacement of amine bases by alkali metal hydroxides can also be a source of global nuclearity reduction, in the case of macrocycles sufficiently large to complex more than one cation and for which uranyl and alkali metal ions compete for the bonding sites.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 220661 and 220662. Abstract

Vanadium(V) oxo peroxo mandelato complexes were prepared from aqueous solution and characterized by elemental analysis, IR, UV–Vis and ^{51}V NMR spectroscopies. The single crystal X-ray studies of $(NMe_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot 6.5H_2O$ (**3**), $(NMe_4)(NH_4)[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot 2H_2O$ (**4**) and $(NEt_4)_2[V_2O_2(O_2)_2(R\text{-mand})_2]$ (**8**) revealed that the mandelato ligand behaves as a bidentate chelator adopting the (O^-, COO^-) donor set. The complex anions in structures of **3** and **8** contain a dinuclear V_2O_2 core with cyclic arrangement of two vanadium atoms and two hydroxyl oxygen atoms from the bridging mand ligands. Each vanadium atom is coordinated by six oxygen atoms arising from two hydroxyl and one carboxyl groups, η^2-peroxo ligand and one end-bonded oxo ligand. The coordination polyhedron can be described as distorted pentagonal pyramid. The structure of **4** is unique as it contains in the unit cell differently coordinated water molecules in two types of dinuclear anions: $[V_2O_2(O_2)_2(R\text{-mand})_2(H_2O)]^{2-}$, with nearly symmetrically bonded bridging water molecule and pentagonal bipyramidal arrangement arround both vanadium atoms, and $[V_2O_2(O_2)_2(S\text{-mand})_2(H_2O)]^{2-}$, with the water molecule coordinated only to one vanadium atom. The vanadium atoms thus have different coordination geometries: pentagonal pyramidal and pentagonal bipyramidal, the latter exhibiting a better planarity of the fitted atoms of the pentagonal plane and a smaller deviation of the vanadium atom from this plane.

1. Introduction

Over the past years, an increased attention has been paid to the chemistry of peroxovanadium(V) complexes, due to their important role in biological systems and application in oxidation reactions. Vanadium is thought to be a trace metal in most of the higher animals and it is known to be essential to some organisms, including tunicates and mushrooms. The best evidence for the biological role of this element comes from bacteria and plants (vanadium containing nitrogenase and haloperoxidases) [1].

Vanadium, both in cationic and anionic forms and in its several oxidation states, has an exceptional ability to interact with biomolecules. Among the biological functions of vanadium, many important therapeutic effects have been described, including hormonal, cardiovascular, anticarcinogenic and insulin mimetic activities [2]. Vanadium and hydrogen peroxide were shown to act synergistically to mimic insulin activity [3] and such mimetic ability has also been found for several peroxovanadium complexes [2,4–6]. These complexes are also known to have antitumour activity [7], and have been studied as functional models for the vanadium haloperoxidase enzymes [8–10] which are involved in catalysis

of the oxidation of halides by hydrogen peroxide, and probably also in the biosynthesis of a large number of natural marine products, many of them with potent antifungal, antibacterial or antiviral (e.g., HIV) properties [11].

As the coordination compounds of vanadium and their reactivity play a predominant role in physiological effects, the complexation behaviour of vanadium with organic ligands is of great interest. The anions of α-hydroxycarboxylic acids are involved in many basic biochemical processes and represent thus an important group of biogenic ligands. That is the reason why peroxovanadium complexes with α-hydroxycarboxylato ligands are currently investigated. In particular, the monoperoxo complexes of citric, malic, tartaric, glycolic and mandelic acids were isolated and characterized [7,12–17].

The solid state structures have been determined for a large number of mono- and diperoxovanadium(V) complexes by X-ray diffraction. The studies showed that the most common geometry for the monomeric oxo peroxo complexes is the pentagonal bipyramid and that the peroxo group is always bound in the equatorial plane relative to the axial oxo ligand [3]. The remaining equatorial and one apical positions in the coordination polyhedron are occupied by the heteroligand/s.

For the α-hydroxycarboxylato oxo peroxo complexes of vanadium, an interesting coordination number ambiguity has been observed. If we consider the value d(V–L) ≈ 2.5 Å as limiting for the apical covalent V–L bond [18], then some of the complexes (glycolato- or lactato-) exhibit pentagonal pyramidal geometry, while others (tartrato-, citrato- or malato-) are pentagonal bipyramidal. In the mandelato complex, $(NBu_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot R,S\text{-}H_2$mand ($H_2$mand is mandelic acid) [14], the coordination number of the vanadium atom can be considered to be six. However, there is a weak interaction ($d \approx 2.55$ Å) between the vanadium atom and carboxyl oxygen from the neutral molecule of mandelic acid, which indicates a certain tendency of the vanadium atom to complete the coordination polyhedron to the pentagonal bipyramid. We have also described the stereospecific formation and different structures of the lactato oxo peroxo complexes of vanadium(V) as a consequence of different combinations of the ligand enantiomers in the dinuclear anion [15].

This paper is focused on the synthesis and characterization of peroxovanadium(V) complexes with mandelic acid. We have tried to address both actual problems of the stereochemistry of the α-hydroxycarboxylato oxo peroxo complexes of vanadium(V): the stereospecifity of formation and the ambiguity of the coordination number of vanadium.

2. Experimental

2.1. Synthesis of complexes

All chemicals were of analytical grade and used as supplied by Aldrich. The crystallization of all complexes proceeded in refrigerator at 278 K.

2.1.1. $(NH_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot R,S\text{-}H_2mand\cdot 2H_2O$ (**1**)

NH_4VO_3 (0.585 g, 5 mmol) was dissolved in a diluted H_2O_2 solution (1 ml 30% H_2O_2 and 10 ml H_2O) under stirring and under cooling in ice bath. Racemic H_2mand (0.76 g, 5 mmol) was dissolved in 5 ml H_2O and added under continuous stirring to the solution of peroxovanadate. The red crystals of **1** were isolated from mother solution after 5 days. Calc. for $C_{24}H_{32}N_2O_{17}V_2$: C, 39.9; H, 4.5; N, 3.9; O_2^{2-}, 8.8; V, 14.0. Found: C, 39.7; H, 4.4; N, 3.3; O_2^{2-}, 9.3; V, 13.5%.

2.1.2. $(NEt_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]$ (**2**)

NEt_4OH (2.1 ml, 5 mmol; 35%) was added to a solution of NH_4VO_3(0.585 g, 5 mmol) in 5 ml H_2O. The ammonia was removed from the resulting solution by brief boiling. The solution was cooled and added to a solution of R,S-H_2mand (0.76 g, 5 mmol) in 10 ml H_2O. A solution of H_2O_2 (30%, 1 ml) was then added under vigorous stirring. The obtained solution was allowed to crystallize, and the product formed within few days was isolated. The red crystals of **2** were obtained by recrystallization from acetonitrile. Calc. for $C_{32}H_{52}N_2O_{12}V_2$: C, 50.6; H, 6.9; N, 3.7; O_2^{2-}, 8.4; V, 13.4. Found: C, 50.2; H, 7.3; N, 3.6; O_2^{2-}, 8.9; V, 13.2%.

2.1.3. $(NMe_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot 6.5H_2O$ (**3**)

V_2O_5 (0.2 g, 1.1 mmol) was dissolved in a solution of 25% NMe_4OH (0.8 ml, 2.2 mmol). To the vanadate solution, a solution of R,S-H_2mand (0.334 g, 2.2 mmol) in 10 ml H_2O and H_2O_2 (30%, 0.4 ml) were then added under stirring. The resulting solution was allowed to crystallize. The red crystal of **3** were isolated after 5 days. Calc. for $C_{24}H_{49}N_2O_{18.5}V_2$: C, 37.7; H, 6.5; N, 3.7; O_2^{2-}, 8.3; V, 13.3. Found: C, 39.7; H, 6.0; N, 3.7; O_2^{2-}, 9.3; V, 13.9%.

2.1.4. $(NMe_4)(NH_4)[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot 2H_2O$ (**4**)

To a solution of NH_4VO_3 (0.585 g, 5 mmol) in 5 ml H_2O, 25% NMe_4OH (1.8 ml, 5 mmol) was added. The solution was heated for a short time, then cooled and added to a solution of R,S-H_2mand (0.76 g, 5 mmol) in 10 ml H_2O. Finally, 0.8 ml H_2O_2 (30%) was added under vigorous stirring. The obtained solution was allowed to crystallize, the red crystals of **4** were isolated after few days. Calc. for $C_{20}H_{34}N_2O_{15}V_2$: C, 37.3; H, 5.3; N, 4.3;

O_2^{2-}, 9.9; V, 15.8. Found: C, 36.1; H, 4.6; N, 3.9; O_2^{2-}, 9.7; V. 14.9%.

*2.1.5. $(NMe_4)_2[V_2O_2(O_2)_2(S\text{-}mand)_2]\cdot 0.5S\text{-}H_2mand\cdot 7H_2O$ (**5**)*

V_2O_5 (0.2 g, 1.1 mmol) was dissolved in a solution of 5 ml H_2O and 25% NMe_4OH (0.8 ml, 2.2 mmol). The solution was then mixed under stirring with a solution of *S*-H_2mand (0.334 g, 2.2 mmol) in 10 ml H_2O and H_2O_2 (30%, 0.4 ml). The obtained solution was allowed to crystallize, and the red-orange crystals of **5** were isolated after 4 days. Calc. for $C_{28}H_{54}N_2O_{20.5}V_2$: C, 39.6; H, 6.4; N, 3.3; O_2^{2-}, 7.5; V, 12.0. Found: C, 39.4; H, 4.8; N, 3.2; O_2^{2-}, 6.9; V, 10.7%.

*2.1.6. $(NEt_4)_2[V_2O_2(O_2)_2(S\text{-}mand)_2]$ (**6**)*

V_2O_5 (0.2 g, 1.1 mmol) was dissolved in aqueous 35% NEt_4OH (0.92 ml, 2.2 mmol). A solution of *S*-H_2mand (0.334 g, 2.2 mmol) in 10 ml H_2O and a solution of H_2O_2 (30%, 0.4 ml) were then added under continuous stirring. The obtained solution was allowed to crystallize, the red crystals of **6** were isolated after few days. Calc. for $C_{32}H_{52}N_2O_{12}V_2$: C, 50.7; H, 6.9; N, 3.7; O_2^{2-}, 8.4; V, 13.4. Found: C, 48.9; H, 7.2; N, 3.4; O_2^{2-}, 8.4; V, 13.1%.

*2.1.7. $(NH_4)_2[V_2O_2(O_2)_2(S\text{-}mand)_2]\cdot S\text{-}H_2mand\cdot 2H_2O$ (**7**)*

NH_4VO_3 (0.585 g, 5 mmol) was dissolved in a diluted H_2O_2 solution (0.7 ml 30% in 10 ml H_2O) under cooling in ice bath. *S*-H_2mand (0.76 g, 5 mmol) was dissolved in 5 ml H_2O and added under continuous stirring to the solution of peroxovanadate. The light red crystals of **7** were isolated from mother solution after 4 days. Calc. for $C_{24}H_{32}N_2O_{17}V_2$: C, 39.9; H, 4.5; N, 3.9; O_2^{2-}, 8.8; V, 14.1. Found: C, 39.6; H, 4.7; N, 3.4; O_2^{2-}, 9.0; V, 13.9%.

*2.1.8. $(NEt_4)_2[V_2O_2(O_2)_2(R\text{-}mand)_2]$ (**8**)*

NH_4VO_3 (0.585 g, 5 mmol) was dissolved in a stirred solution of NEt_4OH (2.1 ml 35%, 5 mmol) in 5 ml H_2O. The ammonia was removed from the solution by brief boiling. The solution was cooled and 10 ml H_2O, *R*-H_2mand (0.76 g, 5 mmol) and H_2O_2 (30%, 1 ml) were added under vigorous stirring. The red solution obtained was allowed to stand at 278 K, and 5 ml acetonitrile were added after 2 days. The red crystals of **8** were isolated after few days. Calc. for $C_{32}H_{52}N_2O_{12}V_2$: C, 50.7; H, 6.9; N, 3.7; O_2^{2-}, 8.4; V, 13.4. Found: C, 46.7; H, 6.6; N, 3.2; O_2^{2-}, 8.4; V, 13.2%.

*2.1.9. $(NMe_4)_2[V_2O_2(O_2)_2(R\text{-}mand)_2]\cdot H_2O$ (**9**)*

NH_4VO_3 (0.234 g, 2 mmol) was dissolved in a solution of 5 ml H_2O and 25% NMe_4OH (0.73 ml, 2 mmol). Ammonia was removed from the vanadate solution by brief boiling. After cooling, a solution of *R*-H_2mand (0.304 g, 2 mmol) in 5 ml H_2O and H_2O_2 (30%, 0.3 ml) were added under stirring. The red complex crystallized within few days. Calc. for $C_{24}H_{38}N_2O_{13}V_2$: C, 43.4; H, 5.8; N, 4.2; O_2^{2-}, 9.6; V, 15.3. Found: C, 43.1; H, 6.0; N, 5.4; O_2^{2-}, 9.9; V, 14.9%.

*2.1.10. $(NH_4)_2[V_2O_2(O_2)_2(S\text{-}mand)_2]\cdot 5H_2O$ (**10**)*

NH_4VO_3 (0.292 g, 2.5 mmol) was dissolved in diluted H_2O_2 (0.5 ml 30% in 10 ml H_2O) under cooling in ice bath. *R*-H_2mand (0.38 g, 2.5 mmol) was dissolved in 5 ml H_2O and added under stirring to the solution of peroxovanadate. The light red crystals of **10** crystallized within 3 days. Calc. for $C_{16}H_{30}N_2O_{17}V_2$: C, 30.8; H, 4.8; N, 4.5; O_2^{2-}, 10.2; V, 16.3. Found: C, 30.2; H, 4.0; N, 4.5; O_2^{2-}, 9.8; V, 16.6%.

2.2. Measurements and analysis

Infrared spectra in KBr pellets or in nujol mulls were measured on Nicolet 750 Magna FT IR spectrometer. UV–Vis spectra were measured on a Hewlett–Packard 84-52 A spectrophotometer. ^{51}V NMR spectra were recorded on a Varian Gemini 2000 spectrometer operating at 78.94 MHz, the chemical shifts were referenced to $VOCl_3$ as external standard. Peroxidic oxygen was determined by titration with $KMnO_4$. Vanadium(V) was determined by titrating with $FeSO_4$. C, H, N were determined on a CHN-analyzer (Carlo Erba). The results of elemental analysis were not always satisfactory because of the instability of the compounds.

2.3. X-ray structure determination

Low-temperature X-ray measurements were made on a KUMA KM4 + CCD diffractometer with monochromated (monochromator Enhance, Oxford Diffraction, UK) Mo Kα radiation using rotation method with ω-scan technique. Cell parameters and an orientation matrix for data reduction were obtained from all strong reflections. For data collection, cell refinement and data reduction we used the CrysAlis (Oxford Diffraction, 2002) software package. Data were not corrected for absorption effects. All calculations for data reduction, structure solution and refinement were done using the SHELX 97 program [19].

In the structure of **8**, there is a disorder involving alternative positions of the peroxo (O2–O3) and oxo (O1) ligands (alternative donor atoms are O2N–O3N and O1N). The sum of s.o.f.s. was constrained to be unity during refinement which converged to the occupation factor 0.7(1). Fig. 2 depicts the major arrangement. The structure of **3** could be refined only to $R_1 = 0.0817$, because of rapid decomposition of the complex after removing it from the mother liquor.

3. Results and discussion

The red or orange-red peroxo complexes of vanadium(V) of composition $(NR_4)_2[V_2O_2(O_2)_2(mand)_2]\cdot xH_2O\cdot yH_2mand$ (R = H, Me or Et, $x = 0$, 1, 2, 5, 6.5 or 7, and $y = 0$, 0.5 or 1) were obtained by crystallization from the aqueous NH_4VO_3–H_2mand–H_2O_2, V_2O_5–H_2mand–NMe_4OH/NEt_4OH–H_2O_2 or NH_4VO_3–H_2mand–NMe_4OH/NEt_4OH–H_2O_2 reaction solutions. The complexes decompose at room temperature, both in the solid state and in aqueous solution. The release of peroxidic oxygen is followed by reduction of vanadium(V) to vanadium(IV) which manifests itself by colour change from red, through brown and green, to black.

3.1. IR spectra

The IR spectra of complexes prepared are listed in Table 1. The bands at 1708, 1709 and 1732 cm^{-1} in the spectra of complexes **1**, **5** and **7** containing neutral ligand molecules, H_2mand, prove the presence of protonated and uncoordinated carboxylic groups [13]. The monodentate coordination of the deprotonated carboxylate groups in mand is apparent from the band positions corresponding to asymmetric $\nu_{as}(COO^-)$ and symmetric $\nu_s(COO^-)$ vibrations in the regions 1601–1656 and 1386–1349 cm^{-1}, respectively. The above mentioned coordination mode is substantiated by the difference value, $\Delta = \nu_{as}(COO^-) - \nu_s(COO^-)$, which is in all cases larger than 200 cm^{-1} [20]. The characteristic bands of the $VO(O_2)$ group were observed in the expected region [21,22] at 969 to 984 cm^{-1} for $\nu(V{=}O)$, 914 to 938 cm^{-1} for $\nu(O_p–O_p)$, and at 539–585 cm^{-1} for $\nu(V–O_p)$.

3.2. Crystal and molecular structures

The crystal parameters and details for data collection for the complexes **3**, **4** and **8** are given in Table 2, and the selected interatomic distances and bond angles are listed in Tables 3–5, respectively. The ORTEP diagrams of the complex anions in structures of **3** and **8** are shown in Figs. 1 and 2. Two vanadium atoms of the anion are doubly bridged by two deprotonated hydroxyl oxygen atoms, O6 and O12, of two mand ligands to give a central V_2O_2 core. Moreover, each mand ligand coordinates to one vanadium atom via the carboxyl oxygen atom to form five-membered chelate. The coordination geometry of each vanadium atom can be described as

distorted pentagonal pyramid formed by two hydroxyl and one carboxyl oxygen atoms, the oxo ligand and two peroxo oxygen atoms. All interatomic distances and bond angles for **3** and **8** are in expected ranges (Tables 3 and 4). The molecular structures of both complexes are typical for vanadium(V) oxo peroxo complexes with two identical enantiomers of the α-hydroxycarboxylato ligands in the dinuclear unit: the V_2O_2 core is non-planar and the oxygen atoms of the terminal V=O groups are *cis* oriented with respect to the vanadium atoms of the core [15].

The unit cell of **8** contains four $[V_2O_2(O_2)_2(R\text{-mand})_2]^{2-}$ anions and eight NEt_4^+ cations, whereas that of **3** eight $[V_2O_2(O_2)_2(R,S\text{-mand})_2]^{2-}$ anions (four with *R*-mand and four with *S*-mand ligands) and 16 NMe_4^+ cations.

An interesting feature of the crystal structure of **4** is the different coordination mode of water molecules in two types of dinuclear ions present: $[V_2O_2(O_2)_2(R\text{-mand})_2(H_2O)]^{2-}$ with almost symmetrically bonded bridging water molecule and pentagonal bipyramidal surroundings of both vanadium atoms (Fig. 3), and the asymmetric $[V_2O_2(O_2)_2(S\text{-mand})_2(H_2O)]^{2-}$ ion, in which

the water molecule is coordinated only to one vanadium atom (Fig. 4). In the latter anion, one vanadium atom has the coordination number six while the other one is seven-coordinated. This situation, when the coordination spheres of two vanadium atoms of the core differ just by the presence/absence of the coordinated water molecule, provides a rare possibility to ascertain how the structural parameters are influenced by the change of

geometry from pentagonal pyramidal to pentagonal bipyramidal. Thus, the comparison of the interatomic distances in the coordination polyhedra of V_1–V_4 with

the literature data enables estimation of the extend of structural *trans* influence. For the compounds $M_2[V_2O_2(O_2)_4H_2O]\cdot nH_2O$ [23–25], where the coordinated water molecule is in the *cis* position to the double bonded oxygen atom, the V–OH_2 bond lengths are significantly shorter (1.998–2.030 Å) than the d(V–OH_2) distances in structure of **4** with *trans* positioned water molecules: 2.395–2.475 Å. The deviations of the vanadium atoms from the least squares pentagonal plane are: 0.4588 Å for the six-coordinated V1 atom and 0.3166–0.3464 Å for the seven-coordinated V2, V3 and V4 atoms. As expected, both V_2O_2 cores in the above described different molecular structures in **4** are non-planar, nevertheless, the bridging water molecule induces larger deviations of atoms in the V_2O_2 core from the planarity when compared with asymmetric anion (the sums of internal angles are 347.55° and 358.54°, respectively). The unit cell of **4** contains eight $[V_2O_2(O_2)_2(mand)_2]^{2-}$ anions (four with *R*- and four with *S*-mand ligands) and 16 cations (eight NH_4^+ and eight NMe_4^+).

In structures of **3**, **4** and **8**, the dinuclear anions contain the same enantiomers of the heteroligand: $[V_2O_2(O_2)_2(S\text{-mand})_2]^{2-}$ or $[V_2O_2(O_2)_2(R\text{-mand})_2]^{2-}$. The formation of the $[V_2O_2(O_2)_2(S\text{-mand})(R\text{-mand})]^{2-}$ stereoisomer was not observed. The complexes crystallize either as pure enantiomers **8** or as racemic compounds **3** and **4**.

3.3. ^{51}V NMR spectral measurements

The ^{51}V NMR spectra of α-hydroxycarboxylato oxo peroxo complexes of vanadium(V) have been currently studied [17,26–30] and the chemical shifts for the 2:2 (vanadium:α-hydroxycarboxylate) species were observed at about −580 ppm. The ^{51}V NMR spectrum of the aqueous solution of $(NH_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot R,S\text{-}H_2mand\cdot 2H_2O$ (Fig. 5, spectrum 1) exhibits two peaks at −555 and −570 ppm of very low intensity, and thus almost undistinguishable in the figure, and two major species at −524 (**A**) and −588 (**B**). While the origin of the signals of low integral intensity is unclear, the species **A** can be attributed to a decomposition product and **B** is obviously the species with the same structure as found in the solid state structure. The chemical shift assignment for **A** we have based on the measurements of in situ formation and decomposition of the mandelato peroxo complexes in aqueous vanadate–H_2mand–H_2O_2 solutions. As can be seen from the time course of the ^{51}V NMR spectra (Fig. 5, spectra 2–6), the concentration of **B** decreases with time, but the concentration of **A** increases and then decreases after reaching a maximum. The final decomposition product is the non-peroxo complex **C** with $\delta_V = -535$ ppm, which we consider, based on the ^{51}V NMR spectrum of the aqueous vanadate–H_2mand solution (Fig. 5, spectrum 7) and the literature data [30], to be the dinuclear dioxo mandelato complex, $[V_2O_4(mand)_2]^{2-}$. The spectra 2–6 in Fig. 5 also exhibit peaks of $H_xV_{10}O_{28}^{(6-x)-}$ (**D**) or $[VO(O_2)_2(H_2O)_x]^-$ (**E**) at −507 and −698 ppm, respectively.

As the decomposition process of $[V_2O_2(O_2)_2(R,S\text{-mand})_2]^{2-}$ in solution seems to be analogous to that of the glycolato and lactato complexes [17,27,30], we propose the species **A** to be the asymmetric monoperoxodivanadate with two non-equivalent vanadium atoms, $[V_2O_3(O_2)(mand)_2]^{2-}$, formed by release of oxygen atom from one of two peroxo ligands in **B**. For the

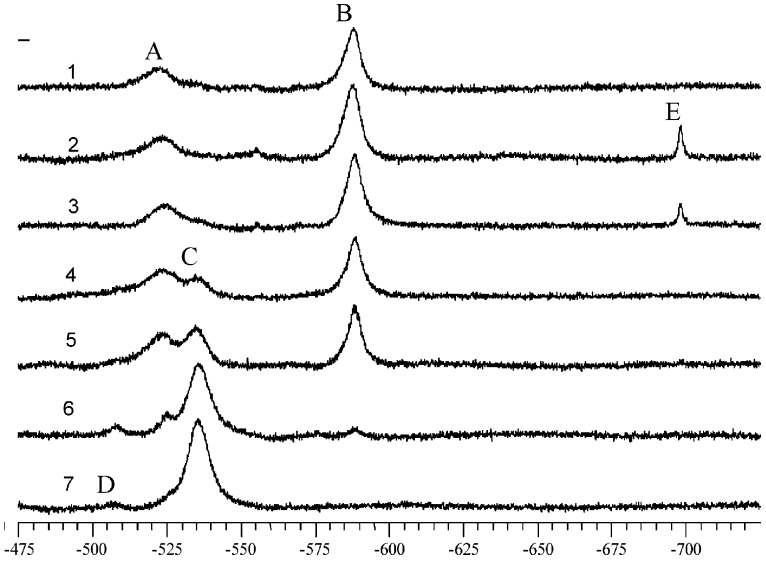

Fig. 5. The ^{51}V NMR spectra of aqueous solution of vanadium(V) peroxo mandelato complexes. (**1**) 0.02 M solution of $(NH_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot R,S\text{-}H_2mand\cdot 2H_2O$. (**2**)–(**6**) Solutions prepared by mixing of aqueous NH_4VO_3 (final concentration 0.02 mol/dm^3), mandelic acid (0.02 mol/dm^3) and H_2O_2 (0.02 mol/dm^3), $T = 278$ K: **2**, 15 min; **3**, 79 min; **4**, 198 min; **5**, 315 min; **6**, 25 h after preparation. (**7**) Solution prepared by mixing of aqueous NH_4VO_3 (final concentration 0.02 mol/dm^3) and mandelic acid (0.02 mol/dm^3), $T = 278$ K, 45 min after preparation.

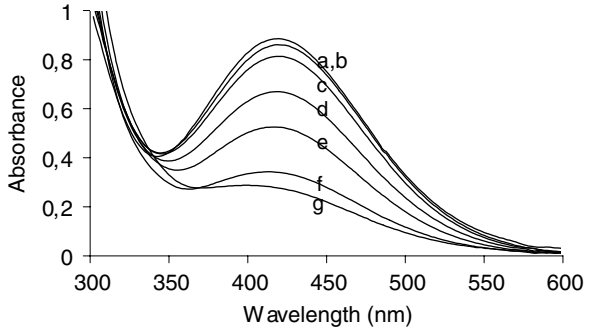

Fig. 6. UV–Vis spectra of 10^{-3} M $(NMe_4)_2[V_2O_2(O_2)_2(R,S\text{-mand})_2]\cdot 6.5H_2O$ in CH_3CN at $T = 278$ K and: 50 min (a), 24 h (b), 3 days (c), 4 days (d), 5 days (e), 7 days (f), 9 days (g) after dissolution.

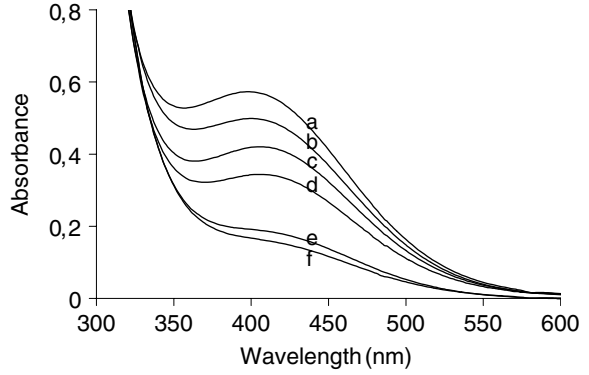

Fig. 7. UV–Vis spectra of 10^{-3} M $(NMe_4)_2[V_2O_2(O_2)_2(S\text{-mand})_2]\cdot 0.5S\text{-}H_2mand\cdot 7H_2O$ in H_2O at $T = 278$ K and: 11 min (a), 19 min (b), 33 min (c), 47 min (d), 81 min (e), 90 min (f) after dissolution.

$[V_2O_3(O_2)(mand)_2]^{2-}$ ion we should expect two ^{51}V NMR signals: one for the vanadium atom without coordinated peroxo group ($\delta_V = -524$ ppm), and the second one in the region observed for the α-hydroxycarboxylato monoperoxo complexes of vanadium(V). This second signal is lacking in the spectra but it might be hidden in the signal at −588 ppm.

3.4. UV–Vis spectroscopy

The UV–Vis spectra of the complexes in CH_3CN and water exhibit a LMCT band (O_2^{2-}–V) with maximum at 420 and 400 nm, respectively; which is characteristic of the monoperoxovanadium(V) complexes [31,32]. In solution, the peroxo oxygen release from the complex can be monitored on the basis of decreasing absorbance at λ_{max}. As follows from Figs. 6 and 7, the decomposition of the complexes is much faster in the protic then in the aprotic solvent.

4. Conclusions

Dinuclear mandelato bridged oxo peroxo complexes of vanadium(V) were synthesized. Besides the coordinated mandelato(2−) ligand, the structures of some of these complexes also contain uncoordinated molecules of mandelic acid. Stereospecifity of the formation, i.e., dependence of the molecular structure of the dinuclear complex anions on combination of the ligand enantiomers, was not observed. The reaction with *R*-mandelic acid gave a complex in form of a pure enantiomer, while the products of synthesis with racemic mandelic acid were racemic compounds. The vanadium atoms in dinuclear complexes have different coordination numbers. This seems to be a characteristic property of α-hydroxycarboxylatooxoperoxovanadates. The usual pentagonal pyramidal arrangement arround the vanadium atom may be, in some complexes, completed by water molecule or by a very weak bond with neutral acid molecule to form a pentagonal bipyramid. The decomposition of the complexes in aqueous solution proceeds through an intermediate, which is probably a dinuclear complex with the $n(O_2^{2-})/n(V)$ molar ratio equal to 0.5.

Received 8 September 2003; accepted 11 November 2003

Abstract

New mononuclear and unsymmetrical binuclear copper(II) and nickel(II) complexes of the general formula $[ML^1](ClO_4)\cdot H_2O$, $[M_2L^1](ClO_4)_2\cdot 2H_2O$, $[ML^2](ClO_4)\cdot H_2O$ and $[M_2L^2](ClO_4)_2\cdot 2H_2O$ have been prepared by the condensation of 2-formyl-4-methyl-6-[(4-methylpiperazine-1yl)methyl]phenol (**1**) with *N*-β-aminoethyl isonitrosoethyl methyl ketimine(PCI) or *N*-β-aminomethylethyl isonitrosoethyl methyl ketimine(PCII) in the presence of M(II) salts (where M = Cu and Ni). The complexes were characterized by elemental and spectral analysis. Cyclic voltammetric studies evidenced one quasireversible reduction wave for all mononuclear complexes in the cathodic region. Two quasireversible one electron reduction waves are obtained for all binuclear complexes in the cathodic region. The binuclear copper(II) complexes illustrate an antiferromagnetic interaction (μ_{eff}: 1.55–1.58 BM) at 298 K with a broad EPR signal ($g = 2.1$). Variable temperature magnetic susceptibility study of the binuclear copper(II) complex $[Cu_2L^1](ClO_4)_2\cdot 2H_2O$ (**5**) shows the observed $-2J$ value is 283 cm^{-1}. The mononuclear copper(II) complexes have a magnetic moment value close to the spin only value with four hyperfine EPR signals.

Keywords: Electrochemistry; Magnetic properties; Oximinato monocopper(II) and mononickel(II) complexes; Unsymmetrical oximinato dicopper(II) complexes and unsymmetrical oximinato dinickel(II) complexes

1. Introduction

Several types of ligand system, which can bind two metal ions in close proximity, have been used as biomimetic studies of binuclear metalloenzyme and metallo proteins due to their interesting catalytic properties, their ability to stabilize unusual oxidation states and possibilities for magnetic interaction between two metal ions [1–4]. From a bioinorganic viewpoint, oximes are known to be present as ligands in metalloproteins, although oxime-containing tetrapeptides with antibacterial, cytotoxic or anti-inflammatory activity have been found in marine sponges [5]. Also, the enzyme ammonia monooxygenase produces hydroxylamine [6], which forms oximes upon reaction with aldehydes or ketones. The asymmetric nature of a number of homodinuclear or heterodinuclear transition metal-derived metallobiosites and the ability of the individual metal ions (Cu, Ni, Mn, Co and Fe) has quite distinct roles in the functioning of the metalloenzyme [7–9]. Synthesis of unsymmetrical binucleating ligands and their copper(II) complexes has gained attention in recent years with the establishment of the unsymmetrical nature of the active site of hemocyanin and tyrosinase and also in multinuclear proteins like laccase, ceruloplasmin, catechol oxidase and ascorbate oxidase [10–14]. The enzymes that depend on nickel are urease, carbon monoxide dehydrogenase, hydrogenase and methyl-*S*-coenzyme-M-methyl reductase [15–17]. Most of the work is concerned

with the studies of symmetrical dinuclear complexes, and the study of unsymmetrical dinuclear complexes is sparse. Until now only a limited number of unsymmetrical dicopper and dinickel complexes were available [18–22]. In physiochemical aspects these dicopper complexes have significance as new inorganic materials capable of showing peculiar magnetic and redox properties and hence these model complexes have a wealth of application in magneto chemistry [23,24]. With the continuation of our previous work [25–27], the present work deals with the synthesis of unsymmetrical end-off mono and binuclear copper and nickel complexes and their spectral, electrochemical and magnetic behavior were studied. The synthetic pathway is shown in Scheme 1.

2. Experimental

2.1. Physical measurements

Elemental analysis of the complexes was obtained in a Heraeus CHN rapid analyzer. Electronic spectral studies were carried out on a Hitachi 320-model double beam spectrophotometer in the range 200–800 nm in acetonitrile. IR spectra were recorded on a Perkin–Elmer model 598 spectrophotometer on KBr disks in the range 4000–400 cm^{-1}. The electrochemical measurements were performed at room temperature in DMF by using a CH instrument electrochemical analyzer. Three electrode cell assembly was used in which the working electrode is glassy carbon, the counter electrode is a platinum wire and the saturated Ag/AgCl electrode is the reference electrode. The ferrocene/ferrocenium(1+) couple was used as an internal standard. All potentials are reported relative to the Ag/AgCl reference electrode. The $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental conditions is 470 mV in DMF and ΔE_p for Fc/Fc^+ is 70 mV. Tetra(*n*-butyl)ammonium perchlorate was used as the supporting electrolyte. All electrochemical measurements were carried out in solutions purged with pure nitrogen for 30 min in advance. The conductivity measurements were carried out on an Elico digital conductivity bridge model CM-88 using freshly prepared solutions of the complexes in acetonitrile. Room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. Variable-temperature magnetic studies were performed on a PAR model 155 vibrating-sample magnetometer in the temperature range 77–300 K, and the instrument was calibrated using metallic nickel. X-band ESR spectra were recorded at 25 °C on a Varian EPR-E 112 spectrometer using diphenylpicrylhydrazine (DPPH) as the reference. The Atomic absorption spectral data were recorded using Varian spectra AA-200 model atomic absorption spectrophotometer.

2.2. Materials

5-Methylsalicylaldehyde [28], 2-formyl-4-methyl-6-[(4-methylpiperazine-1-yl)methyl] phenol [18] (I) and *N*-β-aminoethyl isonitrosoethyl methyl ketimine [29] (PCI) were prepared by following the literature procedure. Tetrabutyl ammoniumperchlorate (TBAP) was obtained from Fluka and recrystallized from methanol. (*Caution*! All perchlorate salts are explosive and hence care should be taken while handling.) DMF and acetonitrile (HPLC) were obtained from Qualigens and used as such for spectral analysis. All other chemicals and solvents were of reagent grade. Solvents methanol, diisopropyl ether and acetonitrile were purified according to standard procedure.

2.3. Synthesis of N-β-aminomethylethyl isonitrosoethyl methyl ketimine (PC II)

This compound was synthesized by following the procedure [29] used for the synthesis of PC I. 1,2-Diaminopropane (3.7 g, 0.05 m) was added to a solution of biacetyl monoxime (5.055 g, 0.05 m) in dry isopropyl ether. The mixture was heated to reflux for 30 min and

then cooled to room temperature in a stoppered flask. After 5 h a yellowish crystalline product was obtained, filtered off and washed with diisopropyl ether and dried over calcium chloride. Yield: 6.4 g (80%), m.p.: 100 °C. *Anal.* Calc. for $C_7H_{15}N_3O$: C, 53.50; N, 26.53; H, 9.37. Found: C, 53.34; N, 26.72; H, 9.61%. ^{1}H NMR ($CDCl_3$, δ): 1.24 (d, 3H, 2-methyl protons), 2.1 (s, 6H, isonitroso ethyl methyl protons), 3.2 (m, 1H, proton of –CH– between amino and 2-methyl), 3.4 (d, 2H, $-CH_2$ between ketimine N and amino substituted carbon), 4.49 (bs, 3H, protons of –OH and NH_2). Selected IR (KBr disc, ν/cm^{-1}): 3213 (m), 3134 (m), 2750 (br), 1633 (sh).

2.4. Synthesis of complexes

2.4.1. $[CuL^1]ClO_4 \cdot H_2O$ (**1**)

A methanolic solution of compound I (2-formyl-4-methyl-6-[(4-methylpiperazine-1-yl)methyl] phenol) (0.5 g, 0.002 mol) was slowly added to a stirred solution of PC I (*N*-β-aminoethyl isonitrosoethyl methyl ketimine) (0.286 g, 0.002 mol) in methanol (20 ml) and refluxed for 1 h. To this solution, a methanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 0.002 mol) was added and refluxed for 5 h. Then the green solution was filtered off. The green coloured product obtained on evaporation at room temperature was recrystallized from acetonitrile. Yield: 1.0 g (69%). *Anal.* Calc. for $C_{20}H_{30}N_5O_2Cu(ClO_4) \cdot H_2O$: C, 43.4; N, 12.6; H, 5.8; Cu, 11.5. Found: C, 43.3; N, 12.6; H, 5.7; Cu, 11.4%. Selected IR (KBr disc, ν/cm^{-1}): 3439 (br), 2760 (br), 1633 (sh), 1230 (m), 1091 (br), 624 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 168. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 581 (148), 365 (1090), 275 (2380).

2.4.2. $[NiL^1]ClO_4 \cdot H_2O$ (**2**)

This complex was prepared by following the above procedure used for $[CuL^1]ClO_4 \cdot H_2O$ using $Ni(ClO_4)_2 \cdot 6H_2O$ (0.73 g, 0.002 mol) instead of $Cu(ClO_4)_2 \cdot 6H_2O$. A brick red compound was obtained by recrystallization from acetonitrile. Yield: 2.0 g (83%). *Anal.* Calc. for $C_{20}H_{30}N_5O_2Ni(ClO_4) \cdot H_2O$: C, 43.8; N, 12.8; H, 5.8; Ni, 11.1. Found: C, 43.7; N, 12.7; H, 5.8; Ni, 11.2%. Selected IR (KBr disc, ν/cm^{-1}): 3446 (br), 2756 (br), 1627 (sh), 1236 (m), 1093 (br), 622 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 165. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 524 (138), 407 (2780), 326 (8040).

2.4.3. $[CuL^2]ClO_4 \cdot H_2O$ (**3**)

This complex was prepared by following the above procedure used for $[CuL^1]ClO_4 \cdot H_2O$ using PC II (*N*-β-aminomethylethyl isonitrosoethyl methyl ketimine) (0.32 g, 0.002 mol) instead of PC I (*N*-β-aminoethyl isonitrosoethyl methyl ketimine). A green coloured compound was obtained by recrystallization from acetonitrile. Yield: 0.83 g (74%). *Anal.* Calc. for $C_{21}H_{32}N_5O_2Cu(ClO_4) \cdot H_2O$: C, 44.4; N, 12.3; H, 6.1; Cu, 11.2. Found: C, 44.4; N, 12.7; H, 6.0; Cu, 11.3%. Selected IR (KBr disc, ν/cm^{-1}): 3437 (br), 2762 (br), 1630 (sh), 1230 (m), 1094 (str), 628 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 161. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 590 (147), 363 (1080), 275 (2380).

2.4.4. $[NiL^2]ClO_4 \cdot H_2O$ (**4**)

This complex was prepared by following the above procedure used for $[NiL^1]ClO_4 \cdot H_2O$ using PC II (*N*-β-aminomethylethyl isonitrosoethyl methyl ketimine) (0.32 g, 0.002 mol) instead of PC I (*N*-β-aminoethyl isonitrosoethyl methyl ketimine). A brick red compound was obtained by recrystallization from acetonitrile. Yield: 0.89 g (79%). *Anal.* Calc. for $C_{21}H_{32}N_5O_2Ni(ClO_4) \cdot H_2O$: C, 44.8; N, 12.4; H, 6.1; Ni, 10.4. Found: C, 44.8; N, 12.4; H, 6.0; Ni, 10.5%. Selected IR (KBr disc, ν/cm^{-1}): 3444 (br), 2758 (br), 1630 (sh), 1236 (m), 1094 (br), 624 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 163. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 553 (148), 403 (2760), 319 (2040).

2.4.5. $[Cu_2L^1](ClO_4)_2 \cdot 2H_2O$ (**5**)

A methanolic solution of compound I (2-formyl-4-methyl-6-[(4-methylpiperazine-1-yl)methyl] phenol) (0.5 g, 0.002 mol) was added to a stirred solution of PC I (*N*-β-aminoethyl isonitrosoethyl methyl ketimine) (0.286 g, 0.002 mol) in methanol (20 ml) and refluxed for 1 h. To this, one mole of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 0.002 mol) in methanol (20 ml) was added and the solution was refluxed for 1 h, then triethylamine (0.27 ml, 0.002 mol) and another mole of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 0.002 mol) in methanol (15 ml) were added and refluxed for a further 6 h. The resulting green solution yielded dark green crystals on slow evaporation. Yield: 1.2 g (80%). *Anal.* Calc. for $C_{20}H_{29}N_5O_2Cu_2(ClO_4)_2 \cdot 2H_2O$: C, 32.7; N, 9.6; H, 4.5; Cu, 17.1. Found: C, 32.7; N, 9.5; H, 4.4; Cu, 17.2%. Selected IR (KBr disc, ν/cm^{-1}): 3437 (br), 1633 (sh), 1228 (m), 1085 (br), 628(m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 202. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 600 (306), 380 (3420), 270 (4940).

2.4.6. $[Ni_2L^1](ClO_4)_2 \cdot 2H_2O$ (**6**)

This complex was prepared by following the above procedure used for $[Cu_2L^1](ClO_4)_2 \cdot 2H_2O$, using nickel(II) perchlorate hexahydrate (1.46 g, 0.004 mol) instead of copper(II) perchlorate. Brown coloured compound. Yield: 1.46 g (76%). *Anal.* Calc. for $C_{20}H_{29}N_5O_2Ni_2(ClO_4)_2 \cdot 2H_2O$: C, 33.2; N, 9.7; H, 4.6; Ni, 16.2. Found: C, 33.1; N, 9.6; H, 4.5; Ni, 16.1%. Selected IR (KBr disc, ν/cm^{-1}): 3440 (br), 1624 (sh), 1248 (m), 1083 (br), 632 (m) Conductance (Λ_m/S cm^2

mol^{-1}) in acetonitrile 209. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 550 (280), 408 (4200), 322 (6380).

2.4.7. $[Cu_2L^2](ClO_4)_2 \cdot 2H_2O$ (7)

This complex was prepared by following the procedure used for the synthesis of $[Cu_2L^1](ClO_4)_2 \cdot 2H_2O$ using PC II (0.32 g, 0.002 mol) instead of PC I. Dark green coloured compound. Yield: 1.98 g (70%). *Anal.* Calc. for $C_{21}H_{31}N_5O_2Cu_2(ClO_4)_2 \cdot 2H_2O$: C, 33.7; N, 9.4; H, 4.7; Cu, 17.0. Found: C, 33.7; N, 9.3; H, 4.6; Cu, 16.9%. Selected IR (KBr disc, ν/cm^{-1}): 3440 (br), 1635 (sh), 1247 (m), 1083 (br), 628 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 217. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 625 (290), 350 (3800), 275 (5600).

2.4.8. $[Ni_2L^2](ClO_4)_2 \cdot 2H_2O$ (8)

This complex was synthesised by following the procedure used for the synthesis of $[Ni_2L^1](ClO_4)_2 \cdot 2H_2O$ using PC II (0.32 g, 0.002 mol) instead of PC I. Brick red compound. Yield: 2.2 g (87%). *Anal.* Calc. for $C_{21}H_{31}N_5O_2Ni_2(ClO_4)_2 \cdot 2H_2O$: C, 34.2; N, 9.5; H, 4.7; Ni, 16.8. Found: C, 34.1; N, 9.4; H, 4.7; Ni, 16.7%. Selected IR (KBr disc, ν/cm^{-1}): 3513 (br), 1625 (sh), 1250 (m), 1087 (br), 631 (m). Conductance (Λ_m/S cm^2 mol^{-1}) in acetonitrile 225. UV–Vis [λ_{max}(nm) (ε, M^{-1} cm^{-1})] in acetonitrile: 580 (304), 408 (3420), 328 (4530).

3. Results and discussion

3.1. Spectral studies

The IR spectrum of the precursor compound II shows characteristic NH_2 (3213 and 3134 cm^{-1}), OH (2750 cm^{-1}) and C=N (1633 cm^{-1}) stretching frequencies. The low frequency and broadness of the OH band suggest that the system is hydrogen bonded. This is consistent with the earlier report [29]. The IR spectra of mononuclear complexes **1**–**4** show bands in the range 1627–1633 and 1230–1236 cm^{-1} due to ν(C=N) and ν(N–O), respectively, and a broad band observed at about 2760 cm^{-1} due to ν(OH) of the oxime group. The binuclear complexes **4**–**8** show bands at 1624 and 1248 cm^{-1} due to ν(C=N) and ν(N–O), respectively, and the absence of a peak around 2750 cm^{-1} indicates the absence of ν(OH) due to complexation. A broad band in the region around 3450 cm^{-1} indicates the presence of ν(OH) of water molecules for all the complexes. The presence of uncoordinated perchlorate anions in all complexes **1**–**8** are inferred from single broad bands at 1100 cm^{-1} (ν_3-antisymmetric stretching) which are not split and at 650 cm^{-1} (ν_4-antisymmetric bending). The intense band around 930 cm^{-1} (ν_2-symmetric stretching) due to coordinated perchlorate is not observed and this vividly indicates that no perchlorate ions are coordinated in the complexes [30–32]. The absorption spectra of the complexes exhibit three main features: one or two intense peaks below 300 nm assigned to the intraligand charge transfer transition, a peak or shoulder in the range 390–430 nm due to phenolate to copper charge transfer transitions and a weak band in the visible region (580–600 nm) is due to d–d transitions. Even though the metal ions are present in two different compartments (N_2O_2 and N_3O), we observed a broad d–d band which could not be further resolved. The broad band was observed for all mono and dinuclear Cu(II) complexes **1**, **3**, **5** and **7** in the region 580–625 nm which are assigned to the d–d transition of the Cu(II) ions [33]. The mono and homo dinuclear Ni(II) complexes **2**, **4**, **6** and **8** show a single weak d–d band in the region 524–580 nm due to an $^1A_{1g} \rightarrow {}^1A_{2g}$ transition and this indicates that the Ni(II) complexes have a square planar structure [33,34].

3.2. Electrochemical studies

The conductance measurement of all the complexes was carried out in acetonitrile. For the mononuclear complexes, the conductance value was found to be in the range 160–170 (Λ_m/S cm^2mol^{-1}) suggesting that the mononuclear complexes belong to 1:1 electrolytes. Conductance values of the binuclear complexes are in the range 200–225 (Λ_m/S cm^2 mol^{-1}) indicating that the complexes are 1:2 electrolytes [35].

3.3. Cyclic voltammetric studies

3.3.1. Reduction process

Electrochemical properties of the complexes were studied by cyclic voltammetry in the potential range 0 to −2.0 V in DMF containing 0.1 M tetrabutylammonium perchlorate and the data are summarized in Table 1. The cyclic voltammograms for mononuclear complexes **2** and **4** are depicted in Fig. 1. The mononuclear copper(II) and nickel(II) complexes **1**–**4** show quasireversible one electron transfer reduction in the cathodic region. The reduction potential of $Cu[L^2](ClO_4) \cdot H_2O$ (**3**) and $Ni[L^2](ClO_4) \cdot H_2O$ (**4**) complexes are reduced at lesser negative potential than $Cu[L^1](ClO_4) \cdot H_2O$ (**1**) and $Ni[L^1](ClO_4) \cdot H_2O$ (**2**). This may be due to the substitution of the CH_3 group on the ligand periphery (i.e. CH_3 substituted on *N*-β-amino ethyl carbon), which causes a distortion in the geometry of the complex. When compared with tertiary amine nitrogen, azomethine nitrogen coordination is stronger [36] and the oxime compartment has more chelation than the piperazine compartment. Hence the metal ion may be coordinated with the oxime compartment. The dicopper(II) complexes **5** and **7** show two quasireversible one electron reduction processes in the cathodic region. The first process corresponds to the $Cu^{II}Cu^{II}/Cu^{II}Cu^{I}$ couple and the second process to the $Cu^{II}Cu^{I}/Cu^{I}Cu^{I}$ couple.

Table 1
Electrochemical data of copper(II) and nickel(II) complexes (reduction at cathodic potential)

Number	Complex	E^1_{pc} (V)	E^1_{pa} (V)	$E^1_{1/2}$ (V)	ΔE (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E^2_{1/2}$ (V)	ΔE (mV)	K_{con}
1	$[CuL^1](ClO_4)\cdot H_2O$	−0.74	−0.67	−0.70	70					
2	$[NiL^1](ClO_4)\cdot H_2O$	−0.88	−0.72	−0.80	160					
3	$[CuL^2](ClO_4)\cdot H_2O$	−0.63	−0.52	−0.57	110					
4	$[NiL^2](ClO_4)\cdot H_2O$	−0.76	−0.63	−0.69	130					
5	$[Cu_2L^1](ClO_4)_2\cdot 2H_2O$	−0.76	−0.41	−0.58	350	−1.35	−1.20	−1.27	150	4.73×10^{11}
6	$[Ni_2L^1](ClO_4)_2\cdot 2H_2O$	−0.92	−0.76	−0.84	160	−1.82	−1.65	−1.73	170	1.14×10^{15}
7	$[Cu_2L^2](ClO_4)_2\cdot 2H_2O$	−0.65	−0.32	−0.49	330	−1.20	−1.08	−1.14	120	9.96×10^{10}
8	$[Ni_2L^2](ClO_4)_2\cdot 2H_2O$	−0.85	−0.71	−0.78	140	−1.72	−1.60	−1.66	120	7.76×10^{14}

Measured by CV at 25 mV/s. *E* vs Ag/AgCl conditions: GC working and Ag/AgCl reference electrode; supporting electrolyte TBAP; concentration of complex, 1×10^{-3} M; concentration of TBAP, 1×10^{-1} M.

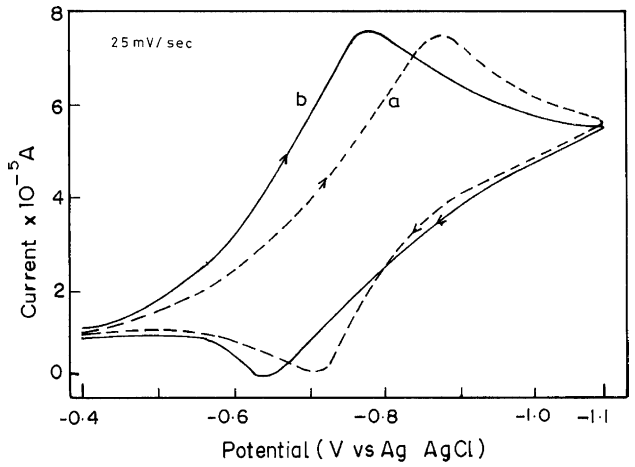

Fig. 1. Cyclic voltammograms of the mononuclear complex: (a) $Ni[L^1](ClO_4)\cdot H_2O$ (**2**); (b) $Ni[L^2](ClO_4)\cdot H_2O$ (**4**) (reduction process).

The copper(II) ion present in the oxime compartment reduces at a lesser potential compared to the other copper(II) ion present in the piperazine compartment, because the oxime compartment has three imino nitrogen coordinating sites [37]. The Cu(II) ion present in the piperazine compartment reduces at −1.2 to −1.3 V. The higher reduction potential is due to the influence of the electron density on the Cu(I) in the oxime compartment through exchange interaction between the two copper ions through bridging sites. Complex **7** reduces at a lesser negative potential (−1.20 V) than complex **5** (−1.35 V). This may be due to the distortion in geometry of the metal center by CH_3 substitution in the ligand periphery, which minimizes the exchange interaction between the two copper(II) ions in complex **7** when compared to the unsubstituted complex **5**. The difference between the half-wave potential of the two redox processes is a measure of the relative stability of the mixed valent $Cu^{II}Cu^{I}$ species. This approach obviously cannot be applied to asymmetrical complexes with two copper ions in different coordination environments. However K_{con} still characterizes the stability of mixed valent species [15]. The differences in half-wave potentials are sometimes very high for complexes with ligands possessing significantly different coordination sites [38,39]. The K_{con} value for complexes **5** and **7** are 4.73×10^{11} and 9.96×10^{10}. Binuclear nickel(II) complexes **6** and **8** show two quasireversible reduction waves. The first process corresponds to the $Ni^{II}Ni^{II}/Ni^{II}Ni^{I}$ couple and the second process to the $Ni^{II}Ni^{I}/Ni^{I}Ni^{I}$ couple. As observed in the binuclear Cu(II) complexes, the methyl substituted complex **8** reduces at lower potential than the unsubstituted complex **6**. The K_{con} value for complexes **6** and **8** are 1.14×10^{15} and 7.76×10^{14}. Cyclic voltammograms of the complexes **6** and **8** are shown in Fig. 2. The two reduction processes are assigned generally as follows,

$$M^{II}M^{II} \rightleftharpoons M^{II}M^{I} \rightleftharpoons M^{I}M^{I}.$$

The conproportionation constant for the equilibrium

$$M^{II}M^{II} + M^{I}M^{I} \overset{K_{con}}{\rightleftharpoons} 2M^{II}M^{I}$$

was calculated using the relationship $\log K_{con} = \Delta E/0.0591$.

3.3.2. Oxidation process

The electrochemical data for the complexes at the positive potential region is given in Table 2. The cyclic

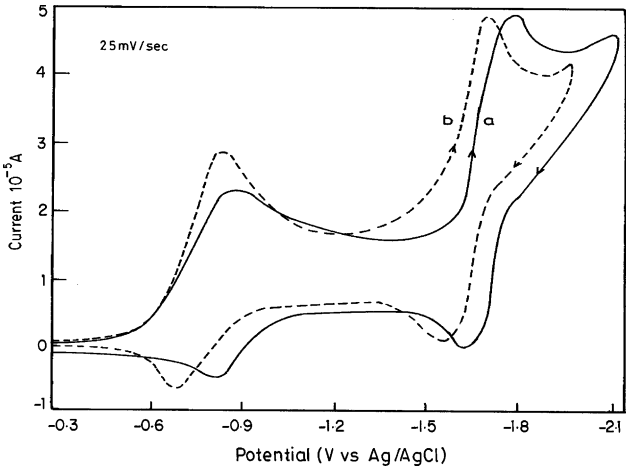

Fig. 2. Cyclic voltammograms of the binuclear complex: (a) $Ni^2[L^1](ClO_4)_2\cdot 2H_2O$ (**6**); (b) $Ni_2[L^2](ClO_4)_2\cdot 2H_2O$ (**8**) (reduction process).

Table 2
Electrochemical data of the nickel(II) complexes (oxidation at anodic potential)

Number	Complex	E^1_{pa} (V)	E^1_{pc} (V)	$E^1_{1/2}$ (mV)	ΔE^1_p (V)	E^2_{pa} (V)	E^2_{pc} (V)	$E^2_{1/2}$ (mV)	ΔE^2_p (V)	K_{con}
2	$[NiL^1](ClO_4)\cdot H_2O$	0.85	0.68	0.76	170					
4	$[NiL^2](ClO_4)\cdot H_2O$	0.93	0.75	0.84	180					
6	$[Ni_2L^1](ClO_4)_2\cdot 2H_2O$	0.83	0.69	0.76	140	1.20	1.02	1.11	180	8.55×10^5
8	$[Ni_2L^2](ClO_4)_2\cdot 2H_2O$	0.88	0.77	0.82	110	1.38	1.22	1.30	160	1.36×10^8

Measured by CV at 25 mV/s. *E* vs Ag/AgCl conditions: GC working and Ag/AgCl reference electrode; supporting electrolyte TBAP; concentration of complex, 1×10^{-3} M; concentration of TBAP, 1×10^{-1} M.

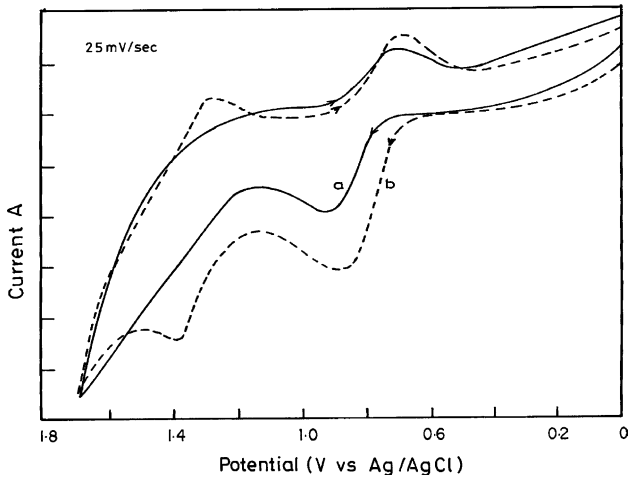

Fig. 3. Cyclic voltammograms of the binuclear nickel complex: (a) $Ni[L^2](ClO_4)\cdot H_2O$ (**4**); (b) $Ni_2[L^2](ClO_4)_2\cdot 2H_2O$ (**8**) (oxidation process).

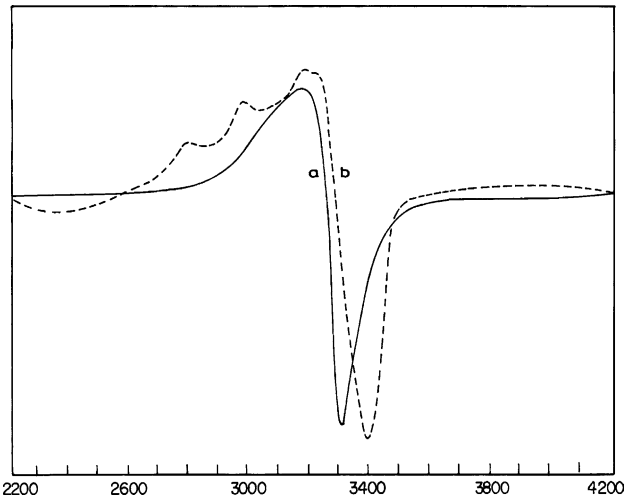

Fig. 4. ESR spectra of binuclear: (a) $Cu_2[L^1]$ $(ClO_4)_2\cdot 2H_2O$ (**5**) and mononuclear; (b) $Cu[L^1](ClO_4)\cdot H_2O$ (**1**) complexes.

voltammogram of the nickel complexes **4** and **8** in the anodic potential region is given in Fig. 3. The mononuclear nickel(II) complexes show one quasireversible oxidation and dinuclear nickel(II) complexes show two quasireversible single electron oxidation waves in the anodic region. The methyl substituted (on the oxime compartment) complex **4** has the higher oxidation potential than the unsubstituted complex **2**. This is because as the substitution on the oxime compartment increases, the distortion of the geometry around the metal ion increases. Similarly, for dinuclear nickel(II) complex **8** oxidation waves are observed at higher positive potential than unsubstituted binuclear nickel(II) complex **6**. The K_{con} value for complexes **6** and **8** are $8.55\times10^5$and 1.36×10^8, respectively. The two oxidation processes are assigned generally as follows,

$$M^{II}M^{II} \rightleftharpoons M^{III}M^{II} \rightleftharpoons M^{III}M^{III}.$$

3.4. Electron spin resonance

The solution ESR spectra of the complexes were recorded in the X-band region. The ESR spectra of mononuclear complex $Cu[L^1](ClO_4)\cdot H_2O$ (**1**) and binuclear complex $Cu_2[L^1](ClO_4)_2\cdot 2H_2O$ (**5**) are shown in Fig. 4. ESR spectra of the mononuclear copper(II) complexes show four lines [40] with a nuclear hyperfine spin 3/2, having $g_{\|}$ values in the range 2.21–2.29 and a $g_{\perp}$ value of 2.09. A broad [41] spectrum with no hyperfine splitting of the parallel component was obtained for both the dicopper complexes **3** and **5** with $g = 2.1$ centered at 3200 G indicating the presence of an antiferromagnetic interaction between the two copper ions. Owing to the favorable relative orientation of the magnetic orbitals and in spite of the Cu–Cu separation, an antiferromagnetic interaction is observed. All the nickel(II) complexes are diamagnetic in nature (see Table 3).

3.5. Magnetic studies

The measured magnetic susceptibility of the mononuclear copper(II) complex $[CuL^1](ClO_4)\cdot H_2O$ at room temperature (298 K) is 1.73 BM and that is equal to the spin only value. Room temperature magnetic susceptibilities of the binuclear copper(II) complexes $[Cu_2L^1](ClO_4)_2\cdot 2H_2O$ and $[Cu_2L^2](ClO_4)_2\cdot 2H_2O$ are 1.55 and 1.58 BM which are lower than the spin only value. In order to find out the magnetic exchange interaction, the magnetic moment of the complex $[Cu_2L^1](ClO_4)_2\cdot 2H_2O$ was measured in the temperature range 77–300 K. The temperature dependence of the magnetic property of the complex was interpreted using the modified Bleaney–Bowers equation [42]

Table 3
ESR spectral data of the copper(II) complexes

Number	Complex	$g_{\parallel}$	$g_{\perp}$	$A_{\parallel}$ (G)	g	μ_{eff} (BM) (RT)	$-2J$ cm^{-1}
1	$[CuL^1](ClO_4)\cdot H_2O$	2.27	2.02	172		1.73	
3	$[CuL^2](ClO_4)\cdot H_2O$	2.28	2.08	202		1.75	
5	$[Cu_2L^1](ClO_4)_2\cdot 2H_2O$				2.10	1.55	283
7	$[Cu_2L^2](ClO_4)_2\cdot 2H_2O$				2.15	1.58	

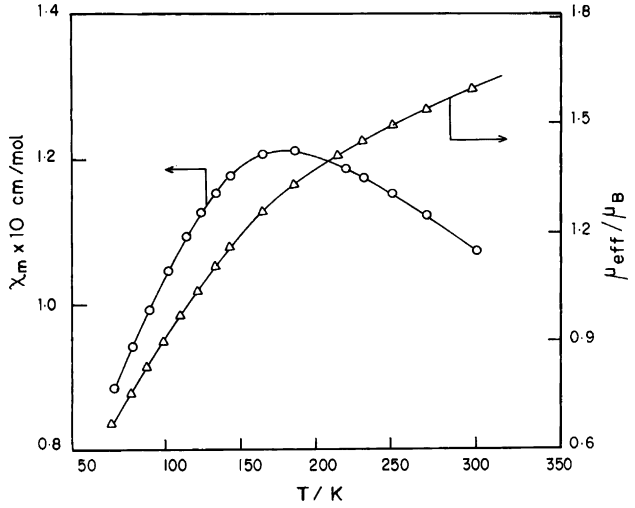

Fig. 5. Temperature dependence of the magnetic properties for complex $Cu_2[L^1](ClO_4)_2\cdot 2H_2O$ (**5**).

$$\chi_m = (Ng^2\beta^2)/(3kT)[3+\exp(-2J/kT)]^{-1}(1-P) + (0.45P/T) + N_\alpha,$$

where χ_m is the molar magnetic susceptibility of the complex, P is the percentage of monomeric impurities, N is Avagadro's number, β is the Boltzman constant, g is the average gyromagnetic ratio, $-J$ is the singlet–triplet separation and N_α is the temperature independent paramagnetism (120×10^6 cgs units). A nonlinear least-square fitting program was employed to calculate $-2J$, g and P. The temperature dependence of the magnetic properties for complex $[Cu_2L^1](ClO_4)_2\cdot 2H_2O$ is given in Fig. 5. The antiferromagnetic exchange interaction $-2J$ value 283 cm^{-1} observed with $g = 2.12$ and $p = 0.03$ for the complex $[Cu_2L^1](ClO_4)_2\cdot 2H_2O$ is similar to that of the analogous unsymmetrical complexes reported by Kandaswamy and coworkers [25]. Magneto structural correlation in phenoxo-bridged dicopper(II) complexes reveal that the dominant pathway for super exchange interaction through the oxygen atom involves interaction of the two copper ($d_{x^2-y^2}$) orbitals and the p orbitals on the oxygen.

4. Summary

New unsymmetrical binucleating copper(II) and nickel(II) complexes have been prepared and characterized. Both the variable temperature magnetic and ESR spectral studies of the binuclear copper(II) complexes ratify the presence of magnetic exchange interaction between the two copper atoms. The cyclic voltammetric study of the complexes in the cathodic as well as anodic region implies that the substitution on the ligand periphery affects the redox potentials.

Dedicated to Professor Pedro Aymonino on the occasion of his 75th anniversary

Abstract

The syntheses and crystal structures of two new polynuclear complexes are reported: $_{\infty}^{1}[Cu_2L^1(acdca)]\cdot CH_3OH\cdot 4H_2O$ (**1**) and $[(CuZnL^2)_2(bpete)_2](ClO_4)_4\cdot 4.5CH_3OH$ (**2**) (H_2L^1 is the Schiff-base proligand resulted from the condensation reaction of 2,6-diformyl-4-methyl-phenol with 1,3-diamino-propane; H_2L^2 is a dissymmetric macrocyclic Robson proligand resulted from 2,6-diformyl-4-methyl-phenol, ethylenediamine and diethylenetriamine). The two compounds have been obtained by reacting binuclear [Cu_2] and [CuZn] complexes with the dianion of the of the acetylene-dicarboxylic acid ($acdca^{2-}$), and, respectively, bis(4-pyridyl)ethylene, bpete. The structure of **1** consists of linear chains resulted by connecting the $\{Cu_2L^1\}$ moieties through $acdca^{2-}$ linkers. The copper(II) ions within the chains exhibit an elongated octahedral geometry. Compound **2** contains cationic $[Cu_2Zn_2]$ rectangles, with the copper(II) ions, as well as the zinc(II) ions, diagonally disposed.

1. Introduction

The self-assembly processes of coordination compounds into well-defined architectures is of current interest in supramolecular chemistry [1]. The synthetic effort is oriented towards discrete species with predetermined nuclearities and topologies of the metallic centers (molecular squares and rectangles, boxes, grids, ladders, racks, helicates) [2], and towards compounds exhibiting extended structures, 1D, 2D, 3D, with a large variety of solid-state architectures [3].

In a series of papers we have shown that homo- and heterobinuclear complexes can be successfully used as starting materials for the synthesis of either discrete high-nuclearity species, or of high-dimensionality systems [4–6]. We are currently using the following types of coordination compounds as building-blocks in designing supramolecular polymetallic architectures: (i) binuclear copper(II) species with end-off compartmental Schiff-base ligands [4]; (ii) alkoxo-bridged copper(II) species [5]; (iii) heterobinuclear 3d–4f species with side-off Schiff-base ligands [6]. In the first case, we have shown that the reaction between $[L(\mu\text{-}OH)Cu_2](ClO_4)_2$ (L stands for a compartmental end-off ligand, 2,6-bis[*N*-2-pyridylethyl)formimidoyl]-phenolato), and *exo*-dentate ligands [bis-(4-pyridyl)-derivatives, the fumarate anion, fum^{2-}, and the isonicotinato anion, IN^{-}] represents a straightforward synthetic route toward tetranuclear copper(II) complexes with both short and long distances between the metallic centers. The second case represents an extension of the classical 'node-and-spacer' approach (see, for example [7]). It also broadens the synthetic concept proposed by Cotton et al. [8], which is based on binuclear metal–metal bonded cationic entities as building units. Finally, the heterobinuclear nodes are very attractive, since they afford extended structures with interesting magnetic properties, emerging from those pre-existing within the nodes.

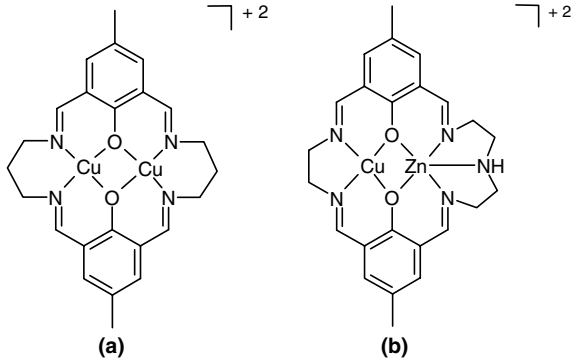

Scheme 1.

We are now developing this synthetic approach by using: (a) binuclear copper(II) complexes with macrocyclic Robson-type ligands; (b) heterobinuclear complexes with dissymmetric macrocyclic Robson-type ligands. In this paper, we report on two such complexes, a 1D coordination polymer with macrocyclic platforms, and a $[Cu_2Zn_2]$ molecular rectangle, which have been constructed starting from the binuclear complexes depicted in Scheme 1.

2. Experimental

The chemicals were purchased from commercial sources and all manipulations were performed using materials as received. The starting materials, $[Cu_2L^1]Cl_2 \cdot 6H_2O$ and $CuZnL^2](ClO_4)_2 \cdot CH_3OH \cdot H_2O$ were prepared as outlined in literature [9,10].

2.1. $_\infty{}^1[Cu_2L^1(acdca)] \cdot CH_3OH \cdot 4H_2O$ (1)

To the methanolic solution (20 ml) of the binuclear precursor, $[Cu_2L^1]Cl_2 \cdot 6H_2O$ (0.05 mmol) has been added a methanolic solution (10 ml) of acetylenedicarboxylic acid (0.05 mmol) and triethylamine (0.05 mmol). The slow evaporation of the resulting mixture gave after several days green single crystals suitable for X-ray analysis. Yield: 80%. IR bands (KBr, cm^{-1}): 3209br, 2927w, 2861w, 1637vs, 1592s, 1570s, 1441m, 1419m, 1328s, 1242w, 1197w, 1121m, 1073w, 976m, 945w, 821m, 784m, 761m, 675m. Diffuse reflectance spectrum: 700 nm, 480 nm (shoulder), 400 nm (shoulder). Elem. *Anal*. Calc.: C, 46.71; H, 5.13; N, 7.51. Found: C, 45.9; H, 5.3; N, 7.5%.

2.2. $[(CuZnL^2)_2(bpete)_2](ClO_4)_4 \cdot 4.5CH_3OH$ (2)

To the acetonitrile solution (20 ml) of the binuclear precursor $[CuZnL^2](ClO_4)_2 \cdot CH_3OH \cdot H_2O$ (0.05 mmol), an acetonitrile solution (10 ml) of *trans*-1,2-bis(4-pyridyl)-ethylene (0.05 mmol) has been added. The slow evaporation of the resulting solution gave, after several days, light blue–green rectangular crystals suitable for X-ray analysis. Yield: 60%. IR bands (KBr, cm^{-1}): 3407br, 2925m, 2857m, 1640vs, 1553m, 1435m, 1419m, 1327m, 1261s, 1092vs, 804s, 690w, 622m, 548w. Diffuse reflectance spectrum: 390 nm, 570 nm). Elem. *Anal*. Calc. C, 46.00; H, 4.54; N, 9.82. Found: C, 45.7; H, 4.3; N, 9.8%. The 1:1 Zn:Cu molar ratio was determined by electron microscopy.

Caution! Perchlorate salts are potentially explosive and should be handled in small quatities.

The IR spectra (KBr pellets) were recorded with a BIO-RAD FTS 135 spectrophotometer. UV–Vis spectra (diffuse reflectance technique) were recorded with a UV4 (Unicam) spectrophotometer, using MgO as a standard.

The crystals were measured on a Bruker AXS SMART diffractometer (Mo Kα radiation monochromator). The structures were solved by direct methods and refined by full-matrix least-squares techniques based on F^2. The non-H atoms were refined with anisotropic displacement parameters. Calculations were performed using SHELX-97 crystallographic software package [11]. The crystallographic data and other pertinent information are collected in Table 1.

3. Results and discussion

The first step of our study was to emphasize the role of the compartmental ligand, holding the two copper(II) ions, on the nature of the polynuclear species resulting from the self-assembly process. The reaction between

$[L(\mu\text{-}OH)Cu_2](ClO_4)_2$ (H_2L is the end-off compartmental proligand resulted from the reaction of 2,6-diformyl-4-methyl-phenol and 2-(2-aminoethyl-pyridine) and the dianion of a dicarboxylic acid (fumarate, acetylenedicarboxylate) led to tetranuclear complexes [4b,4c]. By replacing now the end-off compartmental ligand with a macrocyclic one, L^1 (H_2L^1 is the Schiff-base proligand resulted from the condensation reaction of 2,6-diformyl-4-methyl-phenol with 1,3-diamino-propane), the process involving the corresponding binuclear copper(II) complex (Scheme 1(a)) and the anion of the acetylenedicarboxylic acid leads to a linear coordination polymer, **1**, the binuclear nodes being connected through the dicarboxylato linkers (Fig. 1). The copper atoms are quadruply bridged: two preexisting phenoxo oxygen atoms arising from the macrocyclic ligand, and two carboxylato groups, exhibiting the classical *syn–syn* bridging mode (Fig. 2). Selected bond distances and angles are gathered in Table 2. Each copper(II) ion is hexacoordinated, with an elongated octahedral geometry. The apical positions are occupied by the carboxylato oxygen atoms [Cu(1)–O(2) = 2.536(2) Å; Cu(2)–O(3) = 2.610(2) Å]. The basal plane distances are very close: Cu(1)–N(1) = 1.963(4) Å, Cu(2)–N(2) = 1.976(4) Å; Cu(1)–O(1) = 1.971(3) Å, Cu(2)–O(1) = 1.974(2) Å. The distance between the quadruply bridged copper(II) ions is 3.052 Å, while the distance between the copper(II) ions belonging to two neighboring platforms is 10.21 Å. A similar 1D coordination polymer, namely an infinite ladder with macrocyclic platforms, has been obtained by reacting the analogous $[Zn_2]$ derivative with 4,4′-bipyridine [12].

The packing diagram of crystal **1** reveals interesting features. First of all we notice that the phenyl rings from the macrocyclic ligands arising from three coordination polymers interact through graphite-like π–π staking (Fig. 3). The distances between the phenyl rings range between 3.37 and 3.74 Å. The infinite chains run along the crystallographic *c* axis. The solid-state architecture is expanded through such interactions involving both phenyl rings of each macrocyclic ligand. This particular

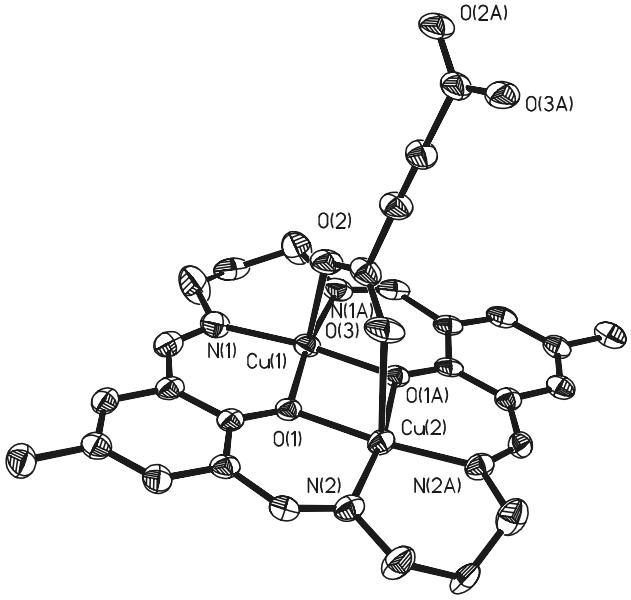

Fig. 2. Perspective view of the repeating unit in **1**, along with the labeling scheme.

packing generates channels, which parallel the polynuclear chains (Fig. 4). The channels are filled by the solvent molecules, which are interconnected through hydrogen bonds.

The electronic spectrum of compound **1** consists of three bands with maxima located at 400, 480, and 700 nm. The last two bands arise from d-d transitions from the lower d orbitals to the $d_{x^2-y^2}$ orbital, in an elongated octahedral stereochemistry [13]. The first band is most probably due to a charge transfer transition.

By employing a heterobinuclear [CuZn] complex as a starting material (Scheme 1(b)), and bis(4-pyridyl)-ethylene (bpete) as a linker, we obtained a heterotetranuclear complex, $[(CuZnL^2)_2(bpete)_2](ClO_4)_4 \cdot 4.5CH_3OH$ (**2**), with the metal ions located in the corners of a rectangle (Fig. 5). Selected bond distances and angles are given in Table 2. To the best of our knowledge, this compound is the first molecular heterometal rectangle obtained by using Werner-type complexes as building

blocks. The starting heterobinuclear complex has been obtained by employing a dissymmetric macrocyclic compartmental ligand $(L^2)^{2-}$ [7]. The copper(II) and, respectively, the zinc(II) ions are diagonally disposed. The copper(II) ions are pentacoordinated with a square planar geometry, in which the apical position is occupied by the nitrogen atom arising from the bpete linker [Cu(1)–N(6) = 2.297(6) Å]. The basal plane is formed by two nitrogen atoms arising from the Schiff-base ligand, and two phenoxo oxygen atoms, with the Cu–O and Cu–N distances falling in the range 1.919(5)–1.949(5) Å. The zinc ions are coordinated by two imino nitrogen atoms arising from the Schiff-base [Zn(1)–N(4) = 2.080(9) Å; Zn(1)–N(2) = 2.032(7) Å], two phenoxo oxygens [Zn(1)–O(1) = 2.220(5) Å; Zn(1)–O(2) = 2.168(5) Å] and one nitrogen atom from the bpete bridge [Zn(1)–N(7) = 2.059(6) Å]. The secondary amine nitrogen, N(5), can be considered as being semi-coordinated [Zn(1)–N(5) = 2.650(2) Å]. The values of the Cu–O–Zn angles

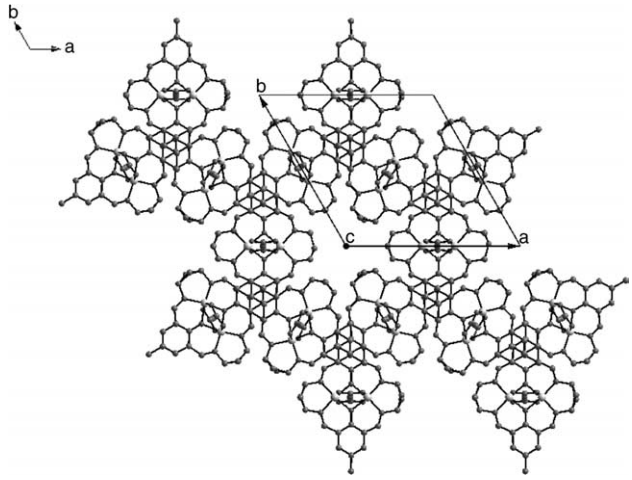

Fig. 4. Detail of the packing diagram for crystal **1** (view along the crystallographic *c* axis).

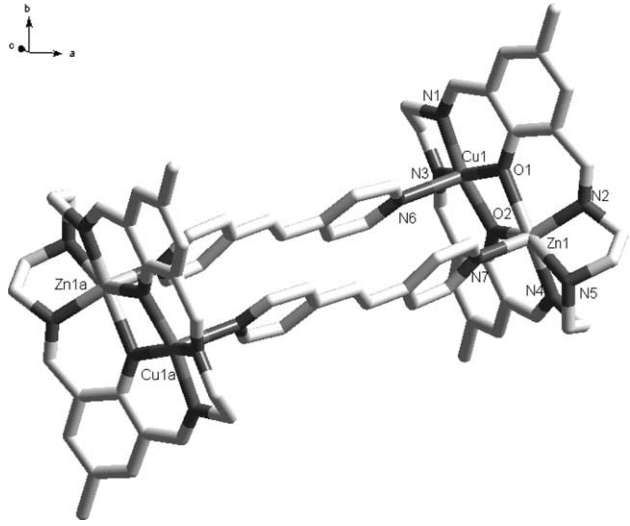

Fig. 5. Perspective view of the $[Cu_2Zn_2]$ molecular rectangle, **2**, along with the atom numbering scheme.

are: Cu(1)–O(1)–Zn(1) = 100.90(22)° and Cu(1)–O(2)–Zn(1) = 101.81(26)°. The Cu(1)···Zn(1) distance is 3.198 Å. The distance between the diagonally disposed metal ions are: Cu(1)···Cu(1a) = 13.84 Å and Zn(1)···Zn(1a) = 14.28 Å.

The packing of the tetranuclear entities in the crystal generates channels, which are occupied by the perchlorate ions as well as by the solvent molecules (Fig. 6).

The solid-state electronic spectrum of compound **2** exhibits one band with maximum at 390 nm, and a large unsymmetrical band with maximum at 570 nm and a tail on its low-energy side. This last band is characteristic for copper(II) chromophores with a square pyramidal geometry [14]. The band with the maximum located at 390 nm can be ascribed to a charge transfer transition.

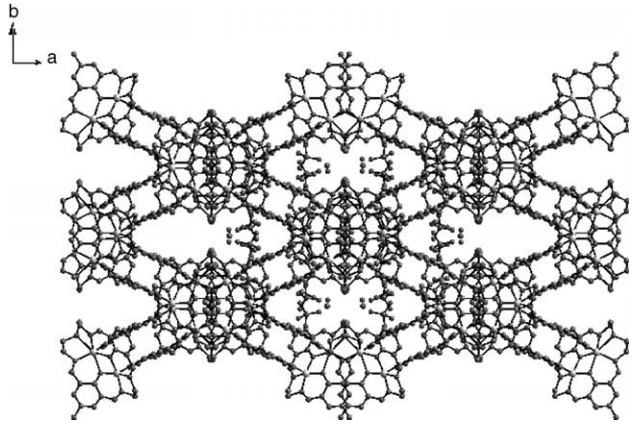

Fig. 6. Packing diagram for crystal **2** (view along the crystallographic *c* axis).

The room temperature value of the $\chi_M T$ product (χ_M is the paramagnetic susceptibility) is in line with the presence of two isolated, uncoupled copper(II) ions: 0.90 $cm^3\ mol^{-1}\ K$ (the calculated value, assuming $g = 2.2$, is 0.91 $cm^3\ mol^{-1}\ K$).

The examples discussed here in, together with those already published by us, illustrate that homo- and heterobinuclear complexes are useful and attractive building-blocks for the design of polynuclear complexes with various nuclearities or dimensionalities.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 221213 and 221214. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336-033; deposit@ccdc.cam.ac.uk or www.ccdc.cam.ac.uk).

Dianionic silicate derivatives of transition metals: synthesis by a facile ion exchange route, characterization and thermolysis studies

P. Bindu, J.V. Kingston, M.N. Sudheendra Rao *

Department of Chemistry, Indian Institute of Technology – Madras, Chennai 600 036, India

Received 2 October 2003; accepted 13 November 2003

Abstract

A new series of transition metal complexes [M = Cr(III) (**1**), Mn(II) (**2**), Co(III) (**3**), Ni(II) (**4a–d**), and Cu(II) (**5a–b**)] with the dianionic hypervalent, tris(catecholato)silicate, $[Si(C_6H_4O_2)_3]^{2-}$, have been synthesized by an ion exchange method under both aqueous and non-aqueous conditions using bis(triethylammonium) tris(catecholato)silicate and a cationic transition metal complex, $[ML_n]X$ [L = ethylenediamine (en), diethylenetriamine (dien), ammonia or water and X = Cl^-, SO_4^{2-}]. Different ammonium tris(catecholato)silicates [viz. morpholinium, diisopropylammonium and diethylammonium] also serve as appropriate for the ion exchange reaction. Ligands like H_2O and NH_3 afford less stable complexes compared to the ligands en and dien. The powdered form of Ni(II) complexes, $[NiL_6][Si(C_6H_4O_2)_3]$ (L = H_2O, NH_3), readily convert to $[Ni(en)_3][Si(C_6H_4O_2)_3]$ quantitatively when treated with en. The new derivatives have been characterized on the basis of analytical, spectroscopic (IR, UV–Vis, solid state NMR, EPR and MS) and magnetic data. The results of TG and EG analysis of the complexes **1**–**5** reveal (i) different decomposition behaviour compared to ammonium catecholatosilicates and (ii) the influence of the bulky tris(catecholato)silicate anion on the thermal stability of these complexes. The bulk pyrolysis study of the above complexes provides a stoichiometric mixture of the corresponding metal oxide and silica except in case of Co(III) which gave the orthosilicate, Co_2SiO_4. Variable temperature magnetic susceptibility measurements indicate a weak antiferromagnetic interaction in case of $[Ni(en)_3][Si(C_6H_4O_2)_3]$ and $[Cu(en)_2][Si(C_6H_4O_2)_3]$.

Keywords: Six coordinate silicates; Ion exchange; Transition metals; Ligand environment; Thermal studies; Magnetism

1. Introduction

Studies on six coordinate silicates, which are also known as examples of hypervalent silicon systems, have afforded many novel findings with regard to their structural and reactivity behaviour [1–3]. Kost and co-workers [4,5] have also designed neutral six coordinate silicon systems and unraveled their structural dynamics behaviour. Very recently, Tacke and co-workers [6,7] have synthesized six coordinate silicates of many new chelating ligands and observed interesting structural details arising due to inter ionic interactions assisted by hydrogen bonding. Studies from our laboratory have also revealed similar findings [8–10]. Further, these studies have proved relevant to both catalysis [11,12] and biology [13–17]. Tris(catecholato)silicates have been reported in the literature with different alkali metal cations (Li, Na, K) as well [18,19]. However, the use of transition metals as counter cations in their synthesis have not been considered so far, excepting a brief report on this in 1977 [20]. Of late, synthesis of silicon compounds containing transition metals have proved advantageous for the development of new types of catalysts [21] and materials especially as precursors to metal silicides [1,22]. Interestingly, salt elimination strategy has been made use of in some of their syntheses [23]. This scenario and our continued interest in search of new reaction behaviour for ammonium tris(catecholato)silicates [9] has prompted us to verify an ion exchange approach for obtaining transition metal incorporated six coordinate silicate systems of $[Si(C_6H_4O_2)_3]^{2-}$. We report here a simple and high yield synthesis of several such compounds of chromium,

manganese, cobalt, nickel and copper, and their characterization. A study on their thermal behaviour (TG, DT, EG and bulk pyrolysis) and a comparison of the same with ammonium tris(catecholato)silicate precursors is also described. For the first time, a facile ion exchange reaction of general applicability for obtaining transition metal containing tris(catecholato)silicate has been demonstrated.

2. Experimental

2.1. Instrumentation

Elemental analyses (C, H, N) were performed with a Heraeus CHN rapid microanalyser. Metal estimations were done by using a Varian Spectr AA – 20 Atomic Absorption Spectrometer as well as standard wet chemical analysis procedures [24]. IR (Nujol mull, 4000–400 cm^{-1}), UV–Vis (Nujol mull, 180–800 nm) and ^1H, ^{13}C NMR (400 MHz; D_3-acetonitrile as solvent, TMS as internal standard) spectra were recorded on Perkin Elmer 1430, Shimadzu UV-240 (and/or Shimadzu NIR 3100) and JEOL JNM JGX-400 instruments, respectively. The Cross-Polarization Magic Angle Spinning (CP-MAS) ^{29}Si NMR spectra were recorded on a JEOL JNM GSX-400 FT NMR spectrometer at the Larmour frequency of 79.464 MHz as reported previously [9]. Mass spectral analyses were carried out on Finnigan MAT 8230 and Hewlett Packard 6890 GC attached to a micromass GC time of flight mass spectrometer. Perkin Elmer TGA-7 and Balzers GAM 440 were used for TG and EG analysis, respectively. Powder XRD patterns were obtained by the Rigaku Miniflex table top model with Co Kα radiation source ($\lambda = 1.7902$ Å). EPR spectra were recorded on Varian E-112 and Bruker Win EPR spectrometers. The room temperature magnetic susceptibility measurements were done on a Par model 155 vibrating sample magnetometer (5000 Oe) and variable temperature magnetic susceptibility (SQUID) measurements were carried out on a George Associates model 300 Lewis Coil force magnetometer at a field of 1.0 T in the temperature range 2–290 K.

2.2. Synthesis

All syntheses and subsequent manipulations performed in non-aqueous media were carried out under argon atmosphere by conventional Schlenk techniques. Solvents (CH_3CN, CH_3OH, Et_2O), catechol and amines [Et_3N, Et_2NH, OC_4H_8NH, $(C_3H_7)_2NH$] were purified by standard procedures [25]. Tetraethoxysilane, TEOS (Metkem silicon, 99% pure) was used as such.

All the precursors needed for the present study, namely ammonium tris(catecholato)silicates, $R_2[Si(C_6H_4O_2)_3]$ (amsicats) [R = (i) Et_3NH, (ii) Et_2NH_2, (iii) $OC_4H_8NH_2$ and (iv) $(C_3H_7)_2NH_2$] and transition metal complexes, $[Cr(en)_3]Cl_3$, $[Mn(en)_3]Cl_2$, $[Co(en)_3]Cl_3$, $[Co(en)_3]Cl(SO_4)$, $[Co(en)_3]Cl$(*d*-tartarate), $[Ni(en)_3]Cl_2$, $[Ni(dien)_2]Cl_2$, $[Ni(NH_3)_6]Cl_2$, $[Ni(H_2O)_6]Cl_2$, $[Cu(en)_3]SO_4$ and $[Cu(en)_2]SO_4$ were synthesized according to reported procedures [26,27] and their identities established on the basis of their IR, UV–Vis and NMR (^1H, ^{13}C) spectra [9] before use.

2.3. Synthesis of tris(catecholato)silicate complexes of transition metals

2.3.1. $[Cr(en)_3][Si(C_6H_4O_2)_3]Cl$ (1)

To a stirred solution of bis(triethylammonium) tris(catecholato)silicate (1.39 g, 2.50 mmol) in acetonitrile (25 mL), a fine powder of $[Cr(en)_3]Cl_3$ (0.86 g, 2.50 mmol) was added at RT in small quantities over 15 min and stirred for 8 h. The dull yellow precipitate formed was filtered, washed with methanol (3×5 mL), ether (3×5 mL) and dried in vacuo.

Other silicate complexes viz. $[Mn(en)_3][Si(C_6H_4O_2)_3]$ (**2**), $[Co(en)_3][Si(C_6H_4O_2)_3]Cl$ (**3**), $[Ni(en)_3][Si(C_6H_4O_2)_3]$ (**4a**), $[Cu(en)_2][Si(C_6H_4O_2)_3]$ (**5a**) and $[Cu(en)_3][Si(C_6H_4O_2)_3]$ (**5b**) were synthesized in a similar way.

Table 1

[a] Strong bands are given.
[b] Broad with a shoulder.

2.3.2. *[Ni(dien)$_2$][Si(C$_6$H$_4$O$_2$)$_3$] (**4b**)*

To a stirred solution of bis(diethylammonium) tris(catecholato)silicate (1.00 g, 2.00 mmol) in acetonitrile (20 mL), a solution of [Ni(dien)$_2$]Cl$_2$ (0.67 g, 2.00 mmol) in acetonitrile (10 mL) was added dropwise over 15 min and stirred for 1 h. The pale purple precipitate was filtered and washed quickly with methanol (3×5 mL), ether (3×5 mL) and dried in vacuo.

2.3.3. *[Ni(H$_2$O)$_6$][Si(C$_6$H$_4$O$_2$)$_3$] (**4c**)*

To a stirred solution of bis(diethylammonium) tris(catecholato)silicate (1.00 g, 2.00 mmol) in acetonitrile (20 mL), a solution of $NiCl_2 \cdot 6H_2O$ (0.48 g, 2.0 mmol) in methanol (15 mL) was added and stirred for 30 min to isolate a pale green precipitate. The precipitate was washed quickly with methanol (3×5 mL), ether (3×5 mL) and dried in vacuo.

In a similar way, a bluish grey precipitate of [Ni(NH$_3$)$_6$][Si(C$_6$H$_4$O$_2$)$_3$] (**4d**) was also isolated. In selected cases, the exchange reaction was repeated with other 'amsicats' mentioned above to isolate the same complexes. Additional preparative details and characterization data of the above complexes are given in Tables 1 and 2.

3. Results and discussion

Bis(triethylammonium) tris(catecholato)silicate, TEASICAT readily participates in an ion exchange reaction with cationic transition metal complexes to afford the corresponding metal derivatives having the six coordinate silicate ion (Eq. (1))

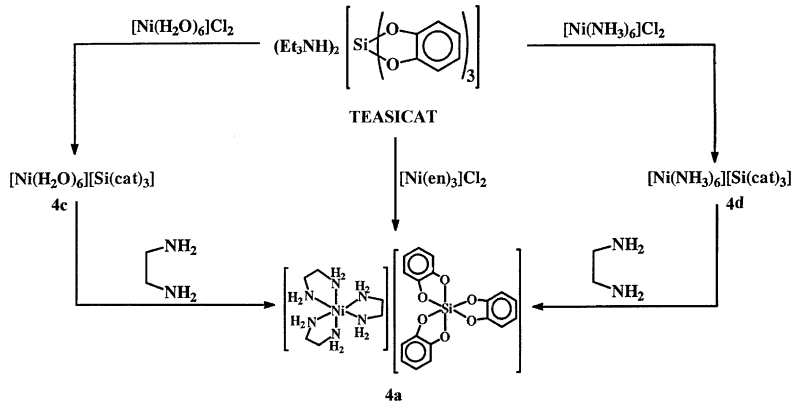
$$[(C_2H_5)_3NH]_2[Si(C_6H_4O_2)_3] + [ML_n]X_2 \rightarrow [ML_n][Si(C_6H_4O_2)_3] + 2[(C_2H_5)_3NH]X. \quad (1)$$

Reactions proceed smoothly in non-aqueous media (CH_3CN, CH_3OH) and at room temperature to afford the complexes in very good yield (Table 1). Exchanges were also effective for different choice of the 'amsicats' and different anions of the transition metal complexes (experimental). Interestingly, complexes having both the silicate and chloride ions were isolated when trivalent metal complexes were considered for the reaction (2)

$$[M(en)_3]Cl_3 + (TEA)_2SICAT \rightarrow [M(en)_3]SICAT(Cl) + 2TEACl, \quad [M = Cr \text{ and } Co]. \quad (2)$$

Further, in case of cobalt, different anions employed namely chloride, sulfate and tartrate got exchanged with the tris(catecholato)silicate ion with equal ease. However, reactions with nickel complexes comprising of different ligands afforded the silicate derivatives having different stabilities. Powdered samples of complexes, **4c** and **4d**, are found to slowly change their colour even in a sealed tube while **4a** and **4b** posed no problem of stability, indicating the importance of the ligand environment around the metal ion for obtaining stable complexes of six coordinate silicates. This was further substantiated by the observation that **4c** and **4d** readily convert to **4a** in the solid state itself, upon addition of a slight excess of ethylenediamine (Scheme 1). This indicates that chelating ligands impart greater stability and thus facilitate their isolation in much higher yields.

Prior to this study, the only work in the literature on such complexes was by Sackerer and Nagorsen [20] who reported the isolation and structural characterization of a copper derivative, [Cu(en)$_2$][Si(C$_6$H$_4$O$_2$)$_3$] (**5a**). This complex was obtained by treating aqueous solutions of silicic acid and Cu(en)$_2$SO$_4$ with an excess of catechol in



Scheme 1. Facile interconversion reactions of **4c** and **4d** to **4a**.

the presence of concentrated ammonia and keeping the mixture in an ampule at 50 °C for 24 h. The role of $[NH_4]_2[Si(C_6H_4O_2)_3]$ in the formation of the copper derivative was also mentioned which implies an ion exchange step.

For the first time in this study, several complexes of different transition metals having a hexacoordinate silicate ion have been prepared from an ion exchange reaction involving ammonium tris(catecholato)silicate. An interesting observation made with the transition metal 'sicat' derivatives, **1**–**5** is that in all cases the colour of the exchanged product was found to be less intense than the precursors. In addition, excepting **4c** and **4d**, all are found to be air and thermally stable and highly insoluble in nature.

3.1. Characterization

The important IR and UV–Vis spectral assignments of **1**–**5** are given in Tables 1 and 2, respectively. Infrared spectra of **1**–**5** are very similar and provide an unambiguous clue to the presence of tris(catecholato)silicate ion by showing all the strong peaks of the $[Si(C_6H_4O_2)_3]^{2-}$ ion of the precursor approximately at the same positions (Table 2). The presence of the transition metal ion is revealed by observing the expected NH/OH stretching frequencies due to the ligand part in the region 3360–3150 cm^{-1}. Electronic spectra of **1**–**5** (recorded as Nujol mulls) also provide useful clues to their characterization. The visible absorption bands indicate the presence of the metal ion and the UV bands found at approximately the same positions in all of them was characteristic of the hypervalent silicate ion. A millimolar solution of Teasicat in CH_3CN gave absorption maxima at 248 and 310 nm. A small shift observed in the absorption band positions and intensity is suggestive of interaction between the oppositely charged ions (Table 2).

Mass spectra of complexes **1**, **2**, **3**, **4a** and **5** (**a** and **b**) recorded in EI mode, gave peaks corresponding to m/z 110 (catechol$^+$) and 61 (enH$^+$) providing evidence for the presence of both metal ion and the $[Si(C_6H_4O_2)_3]$

[c] Decomposition of $M[Si(cat)_2]$.

ion. Several low mass fragments were common to all and the base peak was due to ethylenediamine, in most of the cases. A comparison with those of ammonium tris(catecholato)silicates revealed some important differences [9]. Contrary to the peak due to spirosilane, $[Si(C_6H_4O_2)_2]$ (m/z = 244) observed in the case of $[RR'R''NH]_2[Si(C_6H_4O_2)_3]$, none of the metal derivatives, **1–5** gave this peak thereby suggesting that their decomposition pathway may be entirely different. Besides, some fragments of low intensity which are assignable to those formed with exchange of ligands between the metal and silicon [eg., Si(cat)(en) (m/z = 196); $Si(cat)(en)_2$ (m/z = 256); $Ni(cat)(en)_2$ (m/z = 286)] were found in some cases.

NMR studies of **1–5** posed difficulty for two reasons. They are highly insoluble and except **3**, all others have paramagnetic metal centres. However, in two cases, namely **3** (diamagnetic cobalt) and **5a** (paramagnetic copper), solid state CPMAS-^{29}Si NMR spectra could be recorded which is shown in Fig. 1. Both of them gave a sharp signal at −140.9 and −157.9 ppm, respectively, in evidence for the presence of the tris(catecholato)silicate ion [8,9]. A slightly broad and more shielded signal observed in the case of **5a** could possibly be due to the paramagnetic influence of copper.

X-band polycrystalline EPR spectra of **1**, **2**, **4a**, **5a** and **5b** were recorded both at 300 and 77 K. All of them gave a single broad signal. The g_{iso} observed (Table 2) were well within the range reported for similar examples [28–33]. All the complexes did not exhibit any appreciable change in the EPR signal pattern when the temperature was lowered. The broad nature of the signal is presumably due to the dipolar broadening caused by the presence of the bulky anionic tris(catecholato) silicate moiety.

Magnetic susceptibility measurements at 300 K were carried out for **1**, **2**, **4a**, **5a** and **5b** and the corresponding magnetic moments are given in Table 2. In all cases, the anticipated value for the corresponding oxidation state and geometry of each of the metal ion was observed

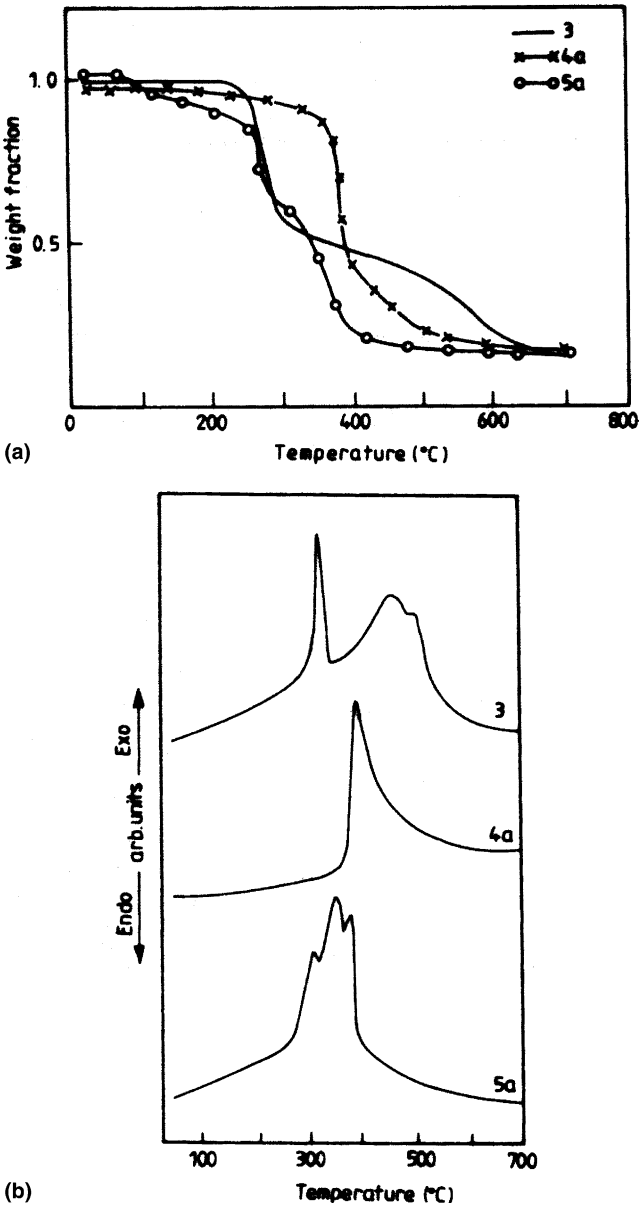

Fig. 2. (a) TGA and (b) DTA plots of **3**, **4a** and **5a**.

[28–33]. However, the trend in some cases presented an interesting variation. A comparison of the observed value reveals that **4a** and **5a** are in good agreement with the reported values, which may be due to the prevailing intermolecular antiferromagnetic exchange interaction.

Variable temperature magnetic susceptibility measurements (SQUID) were also carried out over the temperature 290–2 K in case of **4a** and **5a**. The plots of effective magnetic moments per molecule (μ_{eff}) versus T are given in Fig. 4. Over the temperature range 290–2 K, the magnetic moment values for **4a** and **5a** are found to lie in the range 2.93–2.59 and 1.77–1.52 BM, respectively [34,35].

3.2. Thermal studies

Thermogravimetric (TG) analysis of compounds **1**–**5** was carried out to understand the influence of the bulky hypervalent silicate anionic moiety on the thermal behaviour of these complexes and the results are given in Table 3. The thermograms of **1**–**5** recorded in the temperature range, RT to 800 °C (in air), indicate that the decomposition temperature is different for various complexes and their observed order of thermal stability is **4a** > **5b** > **2**–**3** > **5a** > **1**. A comparison of TGA and DTA plots of **3**, **4a** and **5a** (Fig. 2) show that complex **4a** is the most stable and **5a** is the least stable. A noteworthy feature is that the ligand 'en' coordinated to Ni(II) in **4a** does not get expelled even at high temperature (~200 °C) and its onset of decomposition temperature is found to be well above 200 °C. Similar to the mass spectral behaviour, the TGA plots also revealed that these complexes do not undergo 'spirosilane' formation, unlike ammonium tris(catecholato)silicates [9]. Further, the exothermic nature of these processes (DTA plots) is also in contrast to the endothermic nature of the process observed for the formation of the spirosilane. Evolved gas analysis profiles of **1**–**5** (Fig. 3) clearly show evidence for the expulsion of both catechol ($m/z = 110$) and ethylenediamine ($m/z = 60$) from these complexes upon heating. It is seen from both TG and EG data that the expulsion of ethylenediamine ligand gets completed only around 330 °C.

3.3. Pyrolysis studies

Bulk scale pyrolysis of **1**–**5** were carried out by heating a known weight of the complex in an electrical furnace at 800 °C in static air for 4 h. Excepting cobalt complex **3**, which gave the corresponding orthosilicate, Co_2SiO_4, all other complexes gave the oxide mixtures as products of pyrolysis. These products were identified by IR spectra and powder XRD data [36].

Received 23 October 2003; accepted 13 November 2003

Abstract

2,3,4,7-Tetrahydro-1*H*-inden-2-ol (**1**) has been synthesised by Birch reduction of indan-2-ol. A single-crystal X-ray structure analysis of **1** shows the compound to exist as hydrogen-bonded polymers along the *c*-axis due to the presence of a series of hydrogen-bonds between hydroxo functions. The ferrocene ester derivatives, ferrocene carboxylic acid 2,3,4,7-tetrahydro-1*H*-inden-2-yl ester (**2**) and ferrocene carboxylic acid indan-2-yl ester (**3**) have been prepared by peptidic coupling of ferrocene carboxylic acid with **1** and with indan-2-ol, respectively. The single-crystal X-ray structure analyses of **2** and **3** reveal in both cases the cyclopentadienyl rings to adopt an eclipsed conformation with the indenyl substituent being rotated out of the Cp ester plane by almost 90°, allowing no efficient interaction between the π-system of the Cp ring and the indene moiety. The dienyl derivative **2** reacts with $RuCl_3 \cdot nH_2O$ in refluxing ethanol to afford $[Ru(arene)Cl_2]_2$ (**4**) (arene = ferrocene carboxylic acid indan-2-yl ester) as a mixture of isomers.

Keywords: Arene ligand; Ferrocene carboxylic acid; Ferrocene derivative; Ruthenium

1. Introduction

A wide variety of methods for the synthesis of ferrocenoyl ester derivatives are found in the literature, among them reaction of $FeCl_2$ with cyclopentadienyl ester derivatives [1], condensation of chlorocarbonylferrocene with hydroxo derivatives [2], oxazoline ring-opening reaction of ferrocenoyloxazole derivatives [3], reaction of ferrocene carboxylic acid with diazomethane [4], reaction of ferrocenoyl imidazolide with hydroxo derivatives [5], haloferrocene with acids [6], reaction of ferrocene carboxylic acid with hydroxo derivatives [7], and reaction of 2-(*N*,*N*-dimethylaminoethylferrocene)carboxylic acid with sodium bicarbonate and methyl iodide [8].

Recently, we reported the synthesis of ferrocene ester derivatives by standard peptidic coupling conditions [9]. The method has been proven to be an efficient synthetic route for the synthesis of ferrocene ester derivatives [10]. Herein, we report the synthesis of two new ferrocenoyl ester derivatives by coupling of ferrocene carboxylic acid with 2,3,4,7-tetrahydro-1*H*-inden-2-ol and indan-2-ol. The dienyl-ester derivative reacts with $RuCl_3 \cdot nH_2O$ to form a dinuclear arene–ruthenium complex incorporating ferrocenoyl groups. The single-crystal structure analyses of ferrocene carboxylic acid 2,3,4,7-tetrahydro-1*H*-inden-2-yl ester, ferrocene carboxylic acid indan-2-yl ester and the new 2,3,4,7-tetrahydro-1*H*-inden-2-ol are presented.

2. Experimental

2.1. General

All manipulations were carried out using routine procedures, under a nitrogen atmosphere. Organic solvents were distilled under nitrogen prior to use. NMR spectra were recorded using a Varian Gemini 200 MHz spectrometer and a Bruker 400 MHz spectrometer. IR spectra were recorded on a Perkin–Elmer Spectrum One

FT-IR spectrometer (4000–400 cm^{-1}). Microanalyses were performed by the Laboratory of Pharmaceutical Chemistry, University of Geneva (Switzerland). Electrospray mass spectra were obtained in positive-ion mode with an LCQ Finnigan mass spectrometer. All reagents were purchased (Fluka or Aldrich) and used as received.

2.2. Syntheses

2.2.1. 2,3,4,7-Tetrahydro-1H-inden-2-ol (1)

1 was synthesised by sodium reduction of indan-2-ol in liquid ammonia by analogy to published methods [11]. Crystals suitable for X-ray analysis were obtained by slow evaporation of a dichloromethane solution of **1**.

Spectroscopic data for **1**: ^{1}H NMR (400 MHz, $CDCl_3$): $\delta = 5.75$ (m, 2H, ethylenic *H*), 4.50 (m, 1H, –C*H*OH), 2.66 (m, 4H, –C=C–CH_2–), 2.62 (m, 2H, –CH_2CHOH), 2.34 (s, 1H, –CHO*H*), 2.22 (dd, 2H, $^2J = 17.02$ Hz, $^3J = 1.02$ Hz, –CH_2CHOH). $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$): $\delta = 129.91$, 124.89, 70.90, 46.08, 27.70. MS (EI, acetone): *m*/*z*: 136 $[M]^+$. *Anal.* Calc. for $C_9H_{12}O$: C, 79.37; H, 8.88. Found: C, 79.41; H, 8.82%.

2.2.2. Ferrocene carboxylic acid 2,3,4,7-tetrahydro-1H-inden-2-yl ester (2)

A solution of ferrocene carboxylic acid (3.30 g, 14.34 mmol), *N*,*N*-dicyclohexylcarbodiimide (4.54 g, 22.06 mmol), 4-(dimethylamino)pyridine (1.35 g, 11.03 mmol), 4-pyrrolidinopyridine (1.63 g, 11.03 mmol), and 2,3,4,7-tetrahydro-1*H*-inden-2-ol (1.50 g, 11.03 mmol) in CH_2Cl_2 (150 mL) was stirred under nitrogen at room temperature for 3 days. The resulting solution was filtered through celite to remove *N*,*N*-dicyclohexylurea, and the filtrate concentrated under reduce pressure. The residue was separated by column chromatography on silica gel eluting with hexane/acetone (20:1). The pure product was isolated from the first fraction, giving **2** as red-orange solid. Yield: 3.50 g (91%). Crystals suitable for X-ray analysis were grown by slow evaporation of an acetone/hexane solution of **2**.

Spectroscopic data for **2**: IR (KBr, cm^{-1}): $\nu = 1709$ vs (C=O ester), 1460m, 1277s, 1134s. ^{1}H NMR (400 MHz, $CDCl_3$): $\delta = 5.80$ (m, 2H, ethylenic *H*), 5.53 (m, 1H, –C*H*O–), 4.84 (m, 2H, Cp*H*), 4.42 (m, 2H, Cp*H*), 4.24 (s, 5H, Cp*H*), 2.81 (dd, 2H, $^2J = 16.38$ Hz, $^3J = 6.14$ Hz, –CH_2CHO–), 2.71 (m, 4H, –C=C–CH_2–), 2.42 (dd, 2H, $^2J = 16.38$ Hz, $^3J = 2.36$ Hz, –CH_2CHO). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): $\delta = 171.84$, 129.84, 129.77, 71.96, 71.46, 71.68, 70.09, 70.00, 43.01, 27.47. MS (EI, acetone): *m*/*z*: 348 $[M]^+$. *Anal.* Calc. for $C_{20}H_{20}Fe_1O_2$: C, 68.98; H, 5.79. Found: C, 68.93; H, 5.82%.

2.2.3. Ferrocene carboxylic acid indan-2-yl ester (3)

A solution of ferrocene carboxylic acid (2.00 g, 8.70 mmol), *N*,*N*-dicyclohexylcarbodiimide (2.75 g, 13.38 mmol), 4-(dimethylamino)pyridine (0.82 g, 6.69 mmol), 4-pyrrolidinopyridine (0.99 g, 6.69 mmol), and indan-2-ol (0.90 g, 6.72 mmol) in CH_2Cl_2 (80 mL) was stirred under nitrogen at room temperature for 3 days. The resulting solution was filtered through celite to remove *N*,*N*-dicyclohexylurea, and the filtrate concentrated under reduce pressure. The residue was separated by column chromatography on silica gel eluting with hexane/acetone (20:1). The pure product was isolated from the first fraction, giving **3** as red-orange solid. Yield: 1.72 g (81%). Crystals suitable for X-ray analysis were grown by slow evaporation of an acetone/hexane solution of **3**.

Spectroscopic data for **3**: IR (KBr, cm^{-1}): $\nu = 1692$vs (C=O ester), 1459m, 1277s, 1141s. ^{1}H NMR (200 MHz, $CDCl_3$): $\delta = 7.26$ (m, 4H, H_{arom}), 5.70 (m, 1H, –C*H*O–), 4.81 (m, 2H, Cp*H*), 4.41 (m, 2H, Cp*H*), 4.20 (s, 5H, Cp*H*), 3.44 (dd, 2H, $^2J = 16.66$ Hz, $^3J = 6.22$ Hz, –CH_2CHO–), 3.15 (dd, 2H, $^2J = 16.66$ Hz, $^3J = 2.19$ Hz, –CH_2CHO–). $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): $\delta = 171.93$, 140.87, 128.14, 126.05, 75.23, 73.45, 71.68, 70.92, 70.09, 40.05. MS (EI, acetone): *m*/*z*: 346 $[M]^+$. *Anal.* Calc. for $C_{20}H_{18}Fe_1O_2$: C, 69.39; H, 5.24. Found: C, 69.37; H, 5.23%.

2.2.4. [Ru(arene)Cl$_2$]$_2$ (4) (arene = ferrocene carboxylic acid indan-2-yl ester)

To a solution of ruthenium trichloride hydrate (470 mg, 1.80 mmol) in ethanol (50 mL) was added **2** (2.50 g, 7.18 mmol), and the mixture was refluxed for 4 h. After cooling to room temperature, half of the volume was evaporated in vacuo, the orange-brown precipitate was filtered, washed with ether and acetone, dissolved in $CHCl_3$ and filtered through celite to eliminate insoluble particles. After evaporation to dryness, **4** was obtained as orange powder. Yield: 495 mg (53%).

Spectroscopic data for **4**: IR (KBr, cm^{-1}): $\nu = 1709$ vs (C=O ester), 1458m, 1276s, 1137s. ^{1}H NMR for **4a** (400 MHz, dmso-d_6): $\delta = 5.88$ (m, 8H, Ru–H_{arom}), 5.55 (m, 2H, –C*H*O–), 4.79 (m, 4H, Cp*H*), 4.53 (m, 4H, Cp*H*), 4.26 (s, 10H, Cp*H*), 3.36 (dd, 4H, $^2J = 16.18$ Hz, $^3J = 5.56$ Hz, –CH_2CHO–), 2.87 (dd, 4H, $^2J = 16.18$ Hz, $^3J = 2.03$ Hz, –CH_2CHO–). ^{1}H NMR for **4b** (400 MHz, dmso-d_6): $\delta = 6.03$ (m, 8H, Ru–H_{arom}), 5.63 (m, 2H, –C*H*O–), 4.90 (m, 4H, Cp*H*), 4.46 (m, 4H, Cp*H*), 4.29 (s, 10H, Cp*H*), 3.27 (dd, 4H, $^2J = 16.22$ Hz, $^3J = 5.60$ Hz, –CH_2CHO–), 3.15 (dd, 4H, $^2J = 16.22$ Hz, $^3J = 2.07$ Hz, –CH_2CHO–). MS (EI, acetone): *m*/*z*: 1000.5 $[M - Cl]^+$. *Anal.* Calc. for $C_{20}H_{18}Fe_1O_2$: C, 46.36; H, 3.50. Found: C, 46.33; H, 3.52%.

2.3. X-ray crystallography

Crystals of **1** and **2** were mounted on a Stoe Image Plate Diffraction system equipped with a ϕ circle goniometer, using Mo Kα graphite monochromated radiation ($\lambda = 0.71073$ Å) with ϕ range 0–200°, increment of

1.1° and 1.2°, $D_{max} - D_{min} = 12.45 - 0.81$ Å. Crystal of **3** was mounted on a Stoe AED2 4-circle diffractometer using Mo Kα graphite monochromated radiation with $\omega/2\theta$ scans in the 2θ range 4–135°. The structures were solved by direct methods using the program SHELXS-97 [12]. The refinement and all further calculations were carried out using SHELXL-97 [13]. In **1**–**3**, the hydrogen atoms have been included in calculated positions and treated as riding atoms using the SHELXL default parameters, except for the hydroxo H-atom in **1** which was located from difference Fourier maps and refined isotropically. All non-H atoms were refined anisotropically, using weighted full-matrix least-square on F^2. Crystallographic details are summarised in Table 1. Figs. 1 and 3 were drawn with ORTEP [14] and Fig. 2 with the program POV-RAY [15].

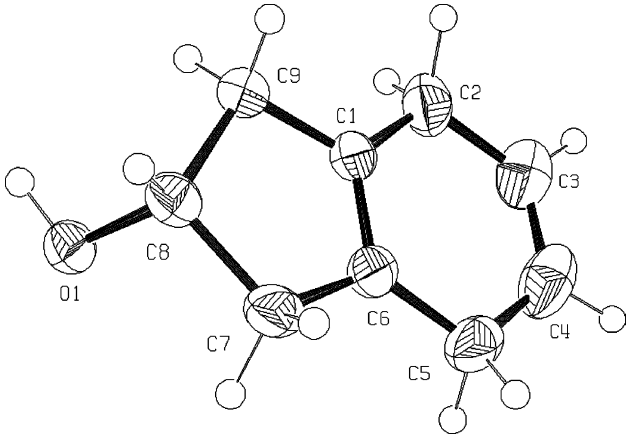

Fig. 1. ORTEP view of **1**, displacement ellipsoids are drawn at the 50% probability level. Selected bond lengths (Å) and angles (°): O(1)–C(8) 1.4321(14), C(1)–C(6) 1.3521(18); O(1)–C(8)–C(7) 107.67(10), O(1)–C(8)–C(9) 111.64(10).

3. Results and discussion

Indan-2-ol as well as 2,3,4,7-tetrahydro-1*H*-inden-2-ol (**1**), accessible by standard Birch reduction of indan-2-ol, react with ferrocenyl carboxylic acid in dichloromethane in the presence of condensation agents (*N*,*N*-dicyclohexylcarbodiimine, 4-(dimethylamino)pyridine, 4-pyrrolidinopyridine) to give the corresponding ferrocenoyl ester derivatives, ferrocene carboxylic acid 2,3,4,7-tetrahydro-1*H*-inden-2-yl ester (**2**) and ferrocene carboxylic acid indan-2-yl ester (**3**), see Scheme 1. Compound **1** can be recrystallised from a slow evaporation of a dichloromethane solution to give colourless crystals, while **2** and **3** can be recrystallised from an acetone–hexane solution to give orange, air-stable crystals.

The molecular structure of **1** is shown in Fig. 1. The indenyl moiety [C(1)–C(9)] is almost planar with a maximum deviation from the mean plane of −0.114(1) Å for C(8), with the oxygen lying out of the plane by 1.446(1) Å.

The hydrogen atom of the hydroxo function, which was located from difference Fourier maps, is involved in a hydrogen bond with the oxygen of a neighbouring

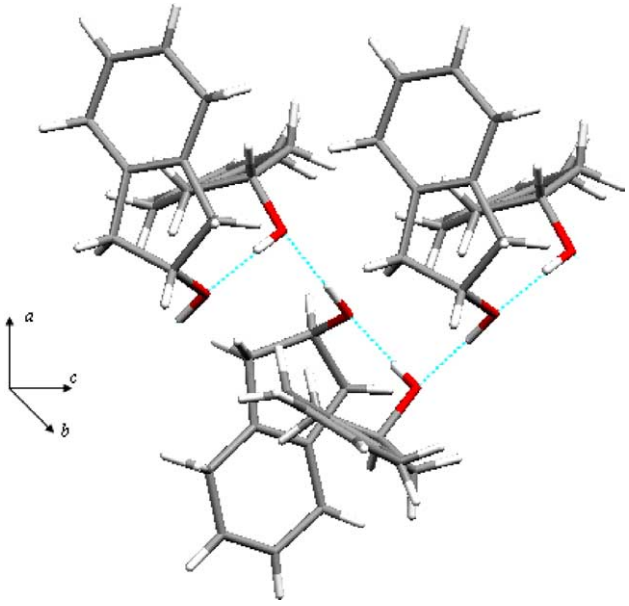

Fig. 2. Hydrogen bonded arrangement of **1** along the *c*-axis.

molecule, distance O···O being 2.7376(9) Å with a O–H···O angle of 175.5(15)°. They form one-dimensional hydrogen-bonded chains along the *c*-axis of the crystal, see Fig. 2.

The infrared spectra of **2** and **3** exhibit the characteristic ν_{CO} absorption at 1709 cm^{-1} for **2** and 1692 cm^{-1} for **3** of the ester function and the bands at 1460, 1277 and 1134 cm^{-1} for **2** and 1459, 1277 and 1141 cm^{-1} for **3** due to the presence of a ferrocene moiety. Single-crystal structure analyses of **2** and **3** have been performed, see Fig. 3. The molecular structure of **2** comprises two independent molecules per asymmetric unit. Fig. 3 shows only one independent molecule of **2**. Selected bond lengths (Å) and angles (°) are given in Table 2.

In both cases, the ferrocene moiety is in the eclipsed conformation. The Cp rings are almost parallel to each other, the angle between the two Cp planes are 2.1(1)°, 3.4(1)° and 2.1(3)°, respectively. The indenyl substituents are rotated out of the Cp-ester plane by 79.7(2)°, 80.6(3)° and 84.5(1)°, respectively, allowing no efficient interaction between the π-system of the Cp ring and the indene moiety. A similar behavior has been observed for

Scheme 2.

benzoylferrocene [16] and for methylenebenzotriazolylferrocene derivatives [10a]. The C(10)–O(1) distance [1.355(5) Å] is shorter than that of ferrocene carboxylic acid benzotriazole ester [1.427(2) Å], which is known to have a weak and reactive ester bond [7a].

The dienyl function of **2** reacts with $RuCl_3 \cdot nH_2O$, in refluxing ethanol to afford in moderate yield $[Ru(arene)Cl_2]_2$ (**4**) (arene = ferrocene carboxylic acid indan-2-yl ester), see Scheme 2.

In **4**, as observed for related complexes $[Ru(trindane)Cl_2]_2$ [17] and $[Ru(indane)Cl_2]_2$ [18], the complexation of the indane to the ruthenium atoms generates diastereotopic methylene protons, the two faces of the arene being non-equivalent. The *endo* and *exo* benzylic protons integrate for two whereas the central methylene proton for one. In principle, the central methylene proton can be folded toward (*endo*) or away (*exo*) from the metal, giving rise to three possible isomers in a 2:1:1 ratio (*exo–endo*:*exo–exo*:*endo–endo*). In fact, only two isomers have been observed by ^1H NMR in a 2:1 ratio (**4a**:**4b**). We believed that the *endo–endo* isomer, where the central methylene protons are folded away from the metals, is sterically disfavoured.

4. Supplementary material

Bis(phosphine) derivatives of diamines

Mireia Rodriguez I. Zubiri, Heather L. Milton, David J. Cole-Hamilton, Alexandra M.Z. Slawin, J. Derek Woollins *

School of Chemistry, University of St. Andrews, St. Andrews, Fife KY16 9ST, UK

Received 11 October 2003; accepted 19 November 2003

Abstract

The synthesis, oxidation and coordination chemistry of new bis(aminophosphines) based on diamines is demonstrated. $Ph_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NPPh_2$, $^iPr_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NP^iPr_2$, $Ph_2PNH(C_{10}H_6)_2NHPPh_2$, $Ph_2PNH(C_{10}H_6)(C_6H_4)NHPPh_2$ were prepared and tested in the hydroformylation of hex-1-to give aldehydes with poor selectivity (up to l:b = 2.5:1) to the desired linear products. Modelling calculations were performed for all ligands. R_2 groups enlarge the natural bite angle when going from $R_2 = Ph_2$ to $R_2 = {}^iPr_2$ which are more bulky. Most of the ligands seem to be rigid (with flexibility ranges of 25°–46°). Four demonstrative X-ray structures are reported.

1. Introduction

Hydroformylation of alkenes is a very important catalytic reaction in industry and great effort has been devoted to obtaining highly active and selective catalysts [1–6]. This is a very important area of investigation since it has been extensively reported that selective catalytic processes are affected by many factors such as the configuration that the ligand may have, i.e., its bite angle and its range of flexibility and the electronic properties of the ligands when binding the precursor metal species [7–12]. These factors influence the direction of approach of the substrate to the active catalyst and therefore the selectivity of the reaction.

By altering the substituents on the phosphorus atoms and keeping the same diamine backbone (piperazine and homopiperazine) [13,14] we were able to conduct a systematic study on the electronic and steric effects of a wide range of the bis(aminophosphines) derivatives of piperazine and homopiperazine. In recent work [13–22], we studied synthesis of new P–N containing ligands and the effect of the electronic properties of different ligands on the regioselectivity of rhodium catalysed hydroformylation of alkenes. Continuing our studies on the preparation of potentially active ligands for homogeneous catalysis, we investigated the synthesis, oxidation and coordination chemistry of new bis(aminophosphines) based on simple diamines in anticipation that the resulting phosphines will have different steric and electronic properties. Here, we report the synthesis of two new phosphines together with hydroformylation studies and four demonstrative X-ray structures.

2. Results and discussion

Reaction of *N*,*N*′-dibenzylethylenediamine with two equivalents of R_2PCl gives **1** and **2** (Eq. (1)). **1** was first prepared by Payne and Stephan [23] and later by Balakrishna et al. [24]. However, they did not report IR or FAB^+ mass spectrometry data and neither did they study its oxidation chemistry nor its activity in homogeneous catalysis. Therefore, we considered it to be of interest to study this compound further, including the preparation of its diselenide derivative and the study of its activity in rhodium catalysed hydroformylation of alkenes whilst **2** offers a steric and electronic variant in this regard.

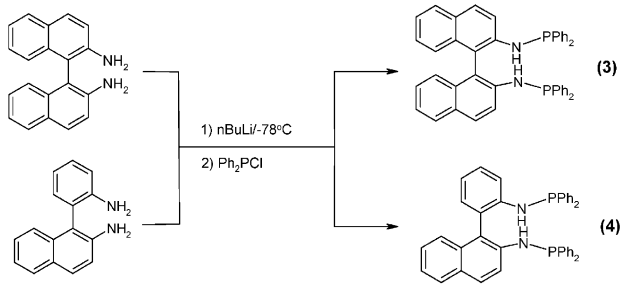
(1)

FAB$^+$ mass spectrometry confirms the proposed identity of the ligands by showing the expected parent-ion peaks and elemental analysis data is in agreement with calculated values.

The $^{31}P\{^1H\}$ NMR spectrum of **2** displays a singlet at δ (P) 89.1 ppm, the large downfield shift when compared to **1** (δ (P) 66.5 ppm) reflecting the close proximity of the phosphorus centres to the isopropyl substituents in **2** instead of the phenyl groups in **1**.

Crystals of compound **2** (Fig. 1) suitable for X-ray analysis were obtained by recrystallisation of the compound from hot toluene. The molecular structure shows that the P–N bonds adopt a *trans* orientation relative to one another. The molecule has a centre of symmetry and, thus, the bond lengths and angles are equal for the two halves of the molecule. P–N bond lengths are typical for this type of compound. The phosphorus atoms adopt a flattened tetrahedral geometry with C–P–N angles somewhat less than 109°, whilst the nitrogen centres have trigonal character (P–N–C angles are closer to 120° than 109°) though the P–N bond is quite long.

Reaction of (S)-(−)-1,1′-binaphthyl-2,2′-diamine and 1-(2-aminophenyl)-2-naphthalene with two equivalents of Ph_2PCl, after deprotonation by *n*BuLi, proceeds in thf to give $Ph_2PNH(C_{10}H_6)_2NHPPh_2$ (**3**) (BDPAB) and $Ph_2PNH(C_{10}H_6)(C_6H_4)NHPPh_2$ (**4**), respectively (Eq. (2))



(2)

The $^{31}P\{^1H\}$ NMR spectrum of **3** comprises a singlet at δ (P) 27.7 ppm. The identity of this compound is supported by FAB$^+$ mass spectrometry (m/z 652 [M$^+$]) and the IR spectrum, because a band associated with a ν(N–H) stretch (3330 cm^{-1}) is observed. ^1H NMR and elemental analysis data are in agreement with the literature. It presents interesting characteristics such as its structural rigidity and chirality and, although it is not a new bis(aminophosphine) [25,26], we considered it important to study it because its, the ligand had not been tested in the rhodium catalysed hydroformylation of alkenes. Recrystallisation from hot toluene gives **3** as colourless crystals. The X-ray structure (Fig. 2) reveals

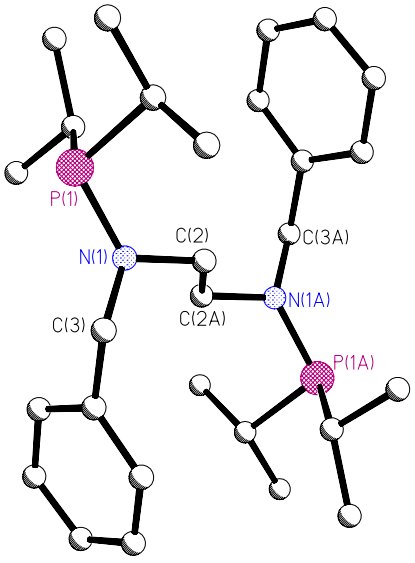


Fig. 1. Solid state structure of $^iPr_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NP^iPr_2$ **2**. Selected bond lengths (Å) and angles (°) N(1)–P(1) 1.704(2), P(1)–C(13) 1.850(3), P(1)–C(10) 1.856(3), N(1)–C(3) 1.466(3), C(3)–N(1)–C(2) 114.9(2), C(3)–N(1)–P(1) 116.26(17), C(2)–N(1)–P(1) 123.11(17), N(1)–P(1)–C(13) 100.49(13), N(1)–P(1)–C(10) 105.72(12), C(13)–P(1)–C(10) 102.85(17).

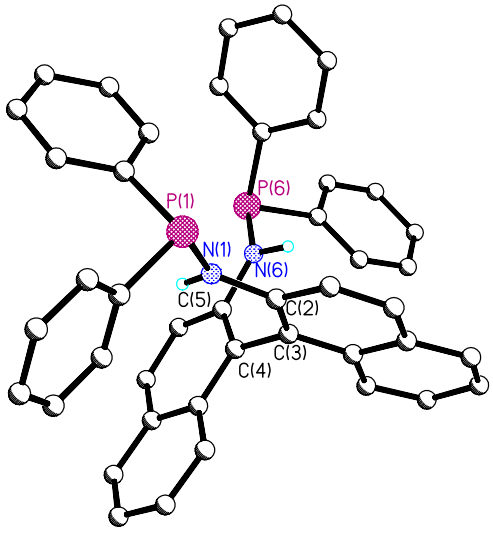

Fig. 2. Solid state structure of $Ph_2PNH(C_{10}H_6)_2NHPPh_2$ **3**. Selected bond lengths (Å) and angles (°) P(1)–N(1) 1.7043(19), P(1)–C(25) 1.836(2), P(1)–C(19) 1.835(2), N(1)–C(2) 1.402(3), C(5)–N(6) 1.403(3), N(6)–C(6) 1.7115(18), N(1)–P(1)–C(25) 103.32(10), N(1)–P(1)–C(19) 99.54(10), C(25)–P(1)–C(19) 101.25(10), C(2)–N(1)–P(1) 125.33(16) C(5)–N(6)–P(6) 126.38(15), N(6)–P(6)–C(7) 99.73(9), N(6)–P(6)-C(13) 102.33(10), C(7)–P(6)–C(13) 99.68(10).

an interesting orientation of the naphthyl rings of the amine backbone relative to one another with a dihedral angle of 98° P–N bond lengths are typical for this type of compound. The two nitrogen atoms in the molecule adopt a geometry close to trigonal whilst, like **2** the phosphorus centres are flattened from tetrahedral.

The magnitude of P–Se J values can be used to assess the donor ability of phosphines [32,33] with better donors having lower $^1J\{^{77}Se–^{31}P\}$ values, as a consequence of the degree of s character in the phosphorus lone pair, etc., i.e., larger coupling constants imply more s character and a poorer donor. Reaction of **1** and **2** with two equivalents of elemental selenium in toluene proceeds smoothly to give $Ph_2P(Se)N(CH_2Ph)CH_2CH_2(CH_2Ph)NP(Se)Ph_2$ (**5**) and $^iPr_2P(Se)N(CH_2Ph)CH_2CH_2(CH_2Ph)NP(Se)^iPr_2$ (**6**). The $^{31}P\{^1H\}$ NMR spectra of **5** and **6** consist of singlets at δ (P) 70.8 and δ (P) 104.1 ppm, respectively, shifted-downfield from the free ligand in both cases, with $^1J(^{77}Se–^{31}P)$ coupling constants of 777 and 741 Hz, respectively, which are in accord with values previously reported for similar selenides [27–31] and suggest that as expected **2**, with electron donating alkyl groups, is the better donor system.

5 and **6** show, in their IR spectra, bands that can be assigned to ν(P–N) [943 cm^{-1} for **5** and 936 cm^{-1} for **6**] and ν(P–Se) at 557 cm^{-1} for **5** and 594 cm^{-1} for **6**.

Slow diffusion of diethyl ether into a dichloromethane solution of **6** gives the product as colourless crystals suitable for X-ray analysis (Fig. 3). The molecular structure shows that the P=Se bonds adopt a *trans* orientation relative to one another. The P–N bond is significantly shorter in this P(V) compound compared to the parent P(III) system which is somewhat counter-intuitive and suggests that in **2** there may be some antibonding π character in the P–N linkage. The P=Se bond lengths are typical for this type of compound. The phosphorus atoms are close to tetrahedral – implying that the selenium atom in **6** is less stereochemically active than the lone pair in **2**.

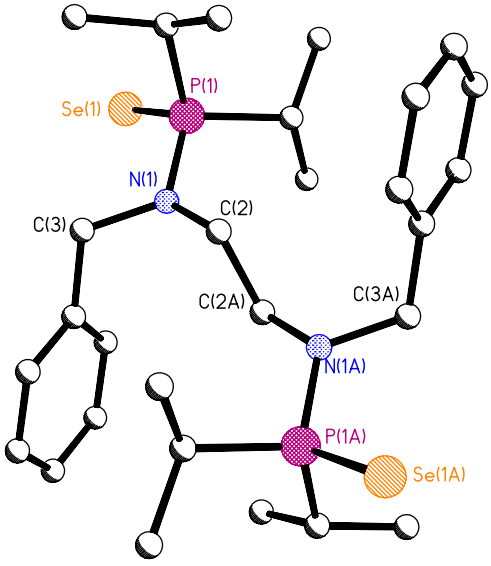

Fig. 3. Solid state structure of $^iPr_2P(Se)N(CH_2Ph)CH_2CH_2(CH_2Ph)NP(Se)^iPr_2$ **6.** Selected bond lengths (Å) and angles (°): Se(1)–P(1) 2.1115(10), P(1)–N(1) 1.679(3), P(1)–C(10) 1.822(4), P(1)–C(13) 1.853(4), N(1)–C(3) 1.477(4), N(1)–C(2) 1.475(4), N(1)–P(1)–C(10) 105.63(18), N(1)–P(1)–C(13) 109.80(17), C(10)–P(1)–C(13) 107.1(2), N(1)–P(1)–Se(1) 111.94(11), C(10)–P(1)–Se(1)111.31(15), C(13)–P(1)–Se(1) 110.86(13), C(3)–N(1)–C(2) 114.3(3), C(3)–N(1)–P(1) 118.9(2), C(2)–N(1)–P(1) 121.2(2).

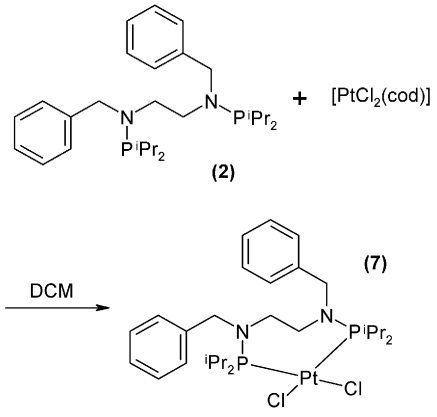
Reaction of **2** with equimolar quantities of $[PtCl_2(cod)]$ in dichloromethane gives the seven-membered, *P P′* chelate *cis*-$[PtCl_2\{^iPr_2PN(CH_2Ph)CH_2CH_2N(CH_2Ph)P^iPr_2\}]$ **7**.



as a colourless solid in good yield (82%).

The $^{31}P\{^1H\}$ NMR spectrum of **7** consists of a singlet (δ (P) 86.7 ppm) with a $^1J(^{195}Pt–^{31}P)$ coupling constants of 4106 Hz. The analogous platinum complex with ligand **1** shows a very similar $^1J(^{195}Pt–^{31}P)$ (4048 Hz) and a singlet (δ (P) 59.1 ppm) at almost 27 ppm upfield because of the presence of phenyl groups on the phosphorus atoms instead of the more electron donating isopropyl groups present in **7**.

FAB^+ mass spectrometry does not show the parent-ion peak and shows instead fragmentation patterns consistent with the loss of one or two chloride ions (m/z) 702/3 [M–Cl^-] and 666/8 [M–$2Cl^-$] and the IR spectrum of **7** shows bands for ν(P–N) (887 cm^{-1}) and ν(Pt–Cl) (337 and 326 cm^{-1}) which supports the *cis* geometry of **7**.

Recrystallisation from hot toluene gives **7** as colourless crystals suitable for X-ray analysis. The X-ray structure of **7** (Fig. 4 and Table 2) reveal that the ligand is bound in a bidentate coordination mode to the platinum centre with *cis* geometry. The complex forms a seven-membered Pt–P–N–C–C–N–P ring and the metal has distorted square planar geometry because the bite angle of the ligand is larger than the ideal 90° and Cl–Pt–Cl is smaller than 90°. The P–N distances are typical of a single bond and are, as was the case for **6**, shorter than that in **2** (see Fig. 4).

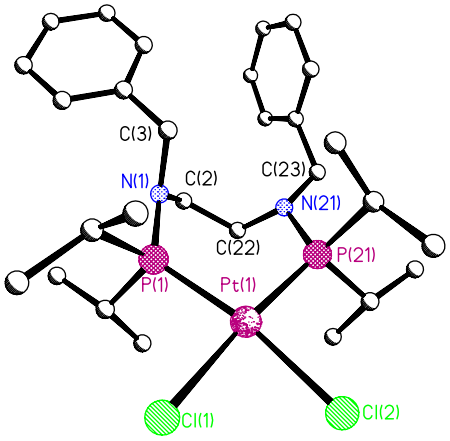


Fig. 4. Solid state structure of *cis*-[$PtCl_2\{^iPr_2PN(CH_2Ph)CH_2CH_2N(CH_2Ph)P^iPr_2\}$] **7**. Selected bond lengths (Å) and angles (°): Pt(1)–P(21) 2.2531(8), Pt(1)–P(1) 2.2594(8), Pt(1)–Cl(1) 2.3724(8), Pt(1)–Cl(2) 2.3777(8), P(1)–N(1) 1.6843(19), P(1)–C(10) 1.844(3), P(1)–C(13) 1.888(2), N(1)–C(3) 1.467(3), N(1)–C(2) 1.489(3), P(21)–Pt(1)–P(1) 100.64(3), P(21)–Pt(1)–Cl(1) 174.60(3), P(1)–Pt(1)-Cl(1) 84.74(3), P(21)–Pt(1)–Cl(2) 88.64(3), P(1)–Pt(1)–Cl(2) 170.44(2), Cl(1)–Pt(1)–Cl(2) 86.01(3), N(1)–P(1)–C(10) 103.84(12), N(1)–P(1)–C(13) 101.26(11), C(10)–P(1)–C(13) 106.58(12), N(1)–P(1)–Pt(1) 123.57(8), C(10)–P(1)–Pt(1) 107.82(9), C(13)–P(1)–Pt(1) 112.42(9), C(3)–N(1)–C(2) 112.06(19), C(3)–N(1)–P(1) 122.52(16),C(2)–N(1)–P(1) 119.13(17).

Ligands **1–4** were tested in the rhodium catalysed hydroformylation of hex-1-ene using a simple batch autoclave (Table 1) Generally the linear:branched selectivity is not particular impressive. We conducted simple molecular modelling calculations (Spartan Pro) of the natural bite angle (β_n) according to the method of Casey and co-workers [34,35] as well as the flexibility range of the ligand (Table 1) since van Leeuwen has proposed that ligands with a natural bite angle of 112°–120° favour equatorial–equatorial coordination during the catalytic cycle and thus give better l:b ratios. We have found a relatively poor correlation between natural bite angle (which specifically ignores metal orbital electronic effects) and the real bite angles, although generally the so-called natural bite angle is somewhat larger than either calculated or measured 'real' bite angle [36,37]. The results obtained with the ligands **1–4** which have natural bite angles in the range 108.9°–127.7° do not support the hypothesis that there is a correlation between bite angle and selectivity (see Table 2).

This work illustrates the usefulness of P–N containing ligands in hydroformylation, in particular the ease of the simple P–N bond forming reaction enables rapid screening of different ligand bite angles and electronic properties. Further work is in progress.

Table 1
Hydroformylation of oct-1-ene catalysed by rhodium complexes with batch autoclave test unit at 100 °C and 20 bar CO/H_2 (1:1); all reactions gave 100% conversion

Compound	Formula	Time (h)	Selectivity to aldehyde %	l:b	β_n	Flexibility range
1	$Ph_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NPPh_2$	22.2	79.8	1.9:1	108.9	28
2	$^iPr_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NP^iPr_2$	5	78.4	1.2:1	127.7	25
3	$Ph_2PNH(C_{10}H_6)_2NHPPh_2$	13.9	94.5	1.8:1	120	46
4	$Ph_2PNH(C_{10}H_6)(C_6H_4)NHPPh_2$	13.9	86.1	2.3:1	115.5	33

β is the natural bite angle [35].

3. Experimental

General conditions for the syntheses and catalytic studies were as previously described [13,14].

$Ph_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NPPh_2$ ***1*** was prepared following the procedure of Balakrishna et al. [24].

A dry and degassed Et_2O (20 ml) solution of chlorodiphenylphosphine (3.2 ml, 3.95 g, 17.95 mmol) was added dropwise over a period of 30 min to a stirred solution of *N*,*N*′-dibenzylethylenediamine (2.050 g, 8.51 mmol) and triethylamine (2.4 ml, 1.72 g, 16.99 mmol) in dry and degassed Et_2O (20 ml) at 0 °C. Stirring was continued overnight, during which time a white precipitate separated from the colourless solution. This precipitate was isolated by suction filtration and consecutively washed with water, methanol and diethyl ether. The product was dried under *vacuum* to give a white solid which was crystallised from CH_2Cl_2–hexane. Yield: 4.25 g, 82%; Microanalysis: Found: (*Anal.* Calc.) C, 78.6 (78.9); H, 6.7 (6.3); N, 4.7 (4.6)%; $^{31}P\{H\}$ NMR ($CDCl_3$): 66.5 (s) ppm; Selected IR data (KBr): *v*(PN) 916 cm^{-1}; FAB^+ MS: *m*/*z* 610 $[M+H]^+$, 632 $[M+Na^+]$.

$(^iPr)_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NP(^iPr)_2$ ***2***. A dry and degassed Et_2O (10 ml) solution of chlorodiisopropylphosphine (3.5 ml, 3.386 g, 22.00 mmol) was added dropwise over a period of 30 min to a stirred solution of *N*,*N*′-dibenzylethylenediamine (2.5 ml, 2.644 g, 11.00 mmol) and triethylamine (3.1 ml, 2.23 g, 22.00 mmol) in dry and degassed Et_2O (40 ml). Stirring was continued for 5 days. The solution was evaporated to dryness in vacuo and thf (30 ml) was added. Triethylammonium hydrochloride separated from the colourless solution. This precipitate was removed by suction filtration under nitrogen. The filtrate was evaporated to dryness in vacuo to give a yellowish oil. Crystallisation from hot toluene gave white crystals.: Yield: 2.391 g, 46%; Microanalysis: Found: (*Anal.* Calc.) C, 70.7 (71.2); H, 10.3 (9.8); N 5.8 (5.9)%; $^{31}P\{H\}$ NMR ($CDCl_3$): 89.1 (s) ppm; FAB^+ MS: *m*/*z* 473 $[M+H^+]$.

$Ph_2PNH(C_{10}H_6)_2NHPPh_2$ ***3*** was prepared following the method of Miyano et al. [25,26].

A dry and degassed thf (10 ml) solution of (S)-(−)-1,1′-binaphthyl-2,2′-diamine (0.446 g, 1.57 mmol) was cooled to −78 °C in an acetone–dry Ice bath. To the cooled solution was added dropwise a hexane solution of BuLi (1.3 ml, 2.5 mol dm^{-3}, 3.28 mmol) over 30 min. After the addition the mixture was stirred at −78 °C for 1 h and another 30 additional min at room temperature. The reaction solution was cooled to −78 °C again and to it was added dropwise a solution of diphenylchlorophosphine (0.6 ml, 0.709 g, 3.21 mmol) in thf (10 ml) over 1 h. Stirring was continued for another 1 h at −78 °C. Then the cooling bath was removed and the mixture was stirred overnight at room temperature. The solution was evaporated to dryness in vacuo and dichloromethane (30 ml) was added. Lithium chloride, which precipitated, was removed by filtration under nitrogen and then the volatiles were evaporated in vacuo to leave a white solid. Recrystallisation from ethanol–benzene gave white crystals. $^{31}P\{H\}$ NMR ($CDCl_3$): 27.7 (s) ppm. IR, Mass Spectroscopy, ^1H NMR and elemental analysis are in agreement with literature data.

$Ph_2PNH(C_{10}H_6)(C_6H_4)NHPPh_2$ ***4***. A dry and degassed thf (25 ml) solution of 1-(2-aminophenyl)-2-naphthylamine (0.998 g, 4.26 mmol) was cooled to −78 °C in an acetone–dry Ice bath. To the cooled solution was added dropwise a hexane solution of BuLi (3.6 ml, 2.5 mol dm^{-3}, 8.91 mmol) over 50 min. After the addition, the mixture was stirred at −78 °C for 1 h and another 30 additional min at room temperature. The reaction solution was cooled to −78 °C again and to it was added dropwise a solution of diphenylchlorophosphine (1.6 ml, 1.928 g, 8.74 mmol) dissolved in thf (10 ml) over 1 h. Stirring was continued for another 1 h at −78 °C. Then the cooling bath was removed and the mixture was stirred overnight at room temperature. The solution was evaporated to dryness in vacuo and dichloromethane (30 ml) was added. Lithium chloride, which precipitated, was removed by filtration under nitrogen and then the volatiles were evaporated in vacuo to leave a white solid. Yield: 2.362 g, 92%; Microanalysis: Found: (*Anal.* Calc.) C, 79.4 (79.7); H, 5.2 (5.4); N, 4.6 (4.7)%; ^1H NMR: δ 7.86–6.86 ppm (m, 20 H, aromatic), 4.3 ppm (d, 1 H, $^2J(PH) = 78.3$ Hz, NH), 4.7 ppm (d, 1 H, $^2J(PH) = 78.3$ Hz, NH); $^{31}P\{H\}$ NMR ($CDCl_3$): 28.8 (s), 28.1 (s) ppm; Selected IR data (KBr): *v*(NH) 3367 and 3322 cm^{-1}, *v*(PN) 891 and 889 cm^{-1}; FAB^+ MS: *m*/*z* 603 $[M+H^+]$.

$Ph_2P(Se)N(CH_2Ph)CH_2CH_2(CH_2Ph)NP(Se)Ph_2$ ***5***. To a dry and degassed toluene (10 ml) solution of selenium (0.026 g, 0.33 mmol) was added solid $Ph_2PN(CH_2Ph)$ $CH_2CH_2(CH_2Ph)NPPh_2$ (0.100 g, 0.16 mmol). The solution was heated to reflux for ca. 2–3 h and allowed to cool to room temperature. The solution was evaporated to dryness in vacuo and the solid was dissolved in dichloromethane (2 ml). The dichloromethane solution was filtered through Celite and diethyl ether (20 ml) was added. The white product was collected by suction filtration and washed with diethyl ether (2×10 ml). Yield: 0.108 g, 88%; Microanalysis: Found: (Anal. Calc.) C, 62.9 (62.7); H, 4.6 (5.0); N, 3.6 (3.6)%; $^{31}P\{H\}$ NMR ($CDCl_3$): 70.8 (s) ppm, $^1J(^{77}Se–^{31}P)$ 777 Hz; Selected IR data (KBr): *v*(PN) 943 cm^{-1}, *v*(PSe) 557 cm^{-1}; FAB^+ MS: *m*/*z* 768 $[M+H^+]$.

$(^iPr)_2P(Se)N(CH_2Ph)CH_2CH_2$ $(CH_2Ph)NP(Se)(^iPr)_2$ ***6***. To a dry and degassed toluene (5 ml) solution of selenium (0.055 g, 0.70 mmol) was added $(^iPr)_2PN(CH_2Ph)CH_2CH_2(CH_2Ph)NP(^iPr)_2$ (0.165 g, 0.35 mmol) in toluene (5 ml). The solution was heated to reflux for ca. 2–3 h and allowed to cool to room temperature. The solution was evaporated to dryness in vacuo and the solid was dissolved in dichloromethane

(2 ml). The dichloromethane solution was filtered through Celite and diethyl ether (20 ml) was added. The white product was collected by suction filtration and washed with diethyl ether (2 × 10 ml). Recrystallisation from Toluene–hexane gave crystals. Yield: 0.159 g, 72%; Microanalysis: Found: (*Anal*. Calc.) C, 53.8 (53.3); H, 7.7 (7.4); N, 4.4 (4.4)%; $^{31}P\{H\}$ NMR ($CDCl_3$): 104.1 (s) ppm, $^{1}J(^{77}Se–^{31}P)$ 741 Hz; Selected IR data (KBr): ν(PN) 936 cm^{-1}, ν(PSe) 594 cm^{-1}; FAB^+ MS: *m/z* 630/2 [M], 655 [M+Na^+].

cis-[PtCl$_2${(^{i}Pr)$_2$PN(CH$_2$Ph)CH$_2$ CH$_2$(CH$_2$Ph)NP(^{i}Pr)$_2$}] 7. To a dichloromethane (10 ml) solution of [$PtCl_2$(cod)] (0.195 g, 0.52 mmol) was added (^{i}Pr)$_2$PN(CH$_2$Ph)CH$_2$CH$_2$(CH$_2$Ph)NP(^{i}Pr)$_2$ (0.246 g, 0.52 mmol) in dichloromethane (5 ml) and the colourless solution stirred for ca. 2–3 h. The solution was concentrated under reduced pressure to ca. 1 ml and diethyl ether (10 ml) added. The white product was collected by suction filtration and washed with diethyl ether (2 × 10 ml). Yield: 0.315 g, 82%; $^{31}P\{H\}$ NMR ($CDCl_3$): 86.7 (s) ppm, $^{1}J(^{195}Pt–^{31}P)$ 4106 Hz; Selected IR data (KBr): ν(PN) 887 cm^{-1}, ν(PtCl) 337 and 326 cm^{-1}; FAB^+MS: *m/z* 702/3 [M–Cl^-], 666/8 [M–2Cl^-].

Catalytic studies [Rh(acac)(CO)$_2$] (0.01 mol dm^{-3}), phosphine (0.023 mol dm^{-3}), hex-1-ene(1 cm^3) were reacted in toluene (4 cm^3) at 100 °C and 20 bar CO/H_2 (1:1) for time stated in Table 1. The rhodium complex, phosphine and toluene were heated at 100 °C and 14 bar CO/H2 (1:1) for 45 min, to allow the active catalyst to form before injection of the hex-1-ene and pressurising to 20 bar.

Crystallography was performed using a Bruker SMART diffractometer; full hemisphere of data with 0.3° 'slices', room temperature, Mo Kα radiation and empirical absorption corrections. All of the non-H atoms were refined anisotropically with the hydrogen atoms being refined in idealised geometries. All calculations employed the SHELXTL program system [38].

4. Supplementary materials

Crystallographic data for the structural analyses has been deposited with the Cambridge Crystallographic data centre, CCDC Nos. 221581–221584 Copies of this information may be obtained free of charge from The Director CCDC, 12 Union Road, Cambridge, CB2 1EZ UK (Fax +44 1223 336-033 or E-mail deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

N,N'-Bis(α-picolinoyl)hydrazine H_2L, a potentially bis-tridentate conjugated ligand in its doubly deprotonated form L^{2-}, has been used to synthesize the diruthenium(II) complex $\{(\mu\text{-L})[Ru(terpy)]_2\}(PF_6)_2$. Its electrochemical and spectroelectrochemical (UV–Vis–NIR, EPR) investigation reveals a mixed-valent ($Ru^{III}Ru^{II}$) intermediate with electrochemical and spectroscopic characteristics related to those of the $\{(\mu\text{-adc-R})[Ru(bpy)_2]_2\}^{3+}$ ions (adc-R^{2-} = bis-bidentate C-substituted diacylhydrazido(2−) ligands): comproportionation constant $K_c = 10^{9.0}$ (CH_2Cl_2), intervalence charge transfer band at 1000 nm ($\varepsilon = 3800\ M^{-1}\ cm^{-1}$), EPR signal at $g_\perp = 2.14$, $g_\parallel = 1.953$. The non-innocent nature of L^{n-} is inferred from comparative analysis of the spectroscopic data.

1. Introduction

Non-innocent bridging ligands such as azo-containing compounds [1,2] are of interest in coordination chemistry because they can strongly modify the metal–metal interaction. The remarkable properties of the bis-bidentate N,N'-diacylhydrazido(2−) ligands (adc-R^{2-}) [1,3,4] such as facile two-step electron transfer involving radical-bridged [4] or mixed-valent intermediates [3] with rather short metal–metal distances of less than 5 Å [4] have motivated our interest in the potentially *bis-tridentate* conjugated bridging ligand N,N'-bis(α-picolinoyl)hydrazido(2−) (L^{2-} = adc-R^{2-} with R = 2-pyridyl). The adc-R/adc-$R^{\cdot-}$/adc-R^{2-} two-step redox system has been shown to exhibit quinonoid characteristics [3,4] with a typically stable radical intermediate, an oxidized (azodicarbonyl) form, and two conceivable resonance structures for the two-electron reduced (dianionic) state (Scheme 1). While the "S frame" conformation of Scheme 1 ensures a relatively short metal–metal distance <5 Å in dinuclear complexes [4], the group R allows for an electronic [3] and, as will be shown here, geometrical tuning. The protonated form [5,6] H_2L of the ligand has been studied before in connection with its anti-HIV and antitumor potential [7].

In this report we describe the synthesis of the bis-terpyridineruthenium complex as prepared from (terpy)(DMSO)Cl_2Ru [8] and H_2L [6], including studies of the $Ru_2^{II,II}$, $Ru_2^{III,II}$ and $Ru_2^{III,III}$ oxidation states. In contrast to bis(N,O)-coordinated complexes [3,4] such as $\{(\mu\text{-adc-R})[Ru(bpy)_2]_2\}^{n+}$ (Scheme 2A) the system $\{(\mu\text{-L})[Ru(terpy)]_2\}^{n+}$ was expected to exhibit a bis(N,N',O)-coordination of the bridging ligand (Scheme 2B).

Conjugated ligands with $\mu, \eta^3{:}\eta^3$ coordination are not very common, examples used in mixed valence chemistry include the π accepting polypyridyl systems 2,3,4,5-tetrakis(2-pyridyl)pyrazine [9] and spacer-linked bis-terpy compounds [10].

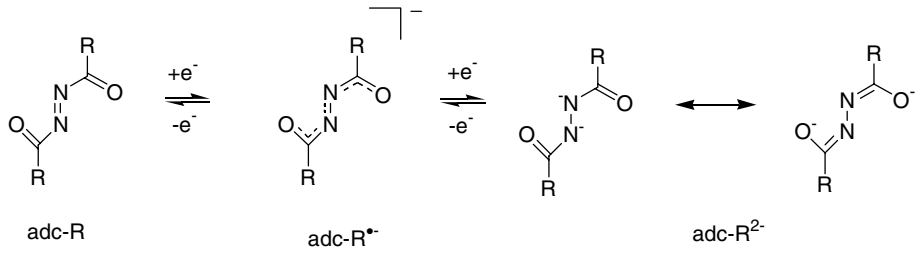
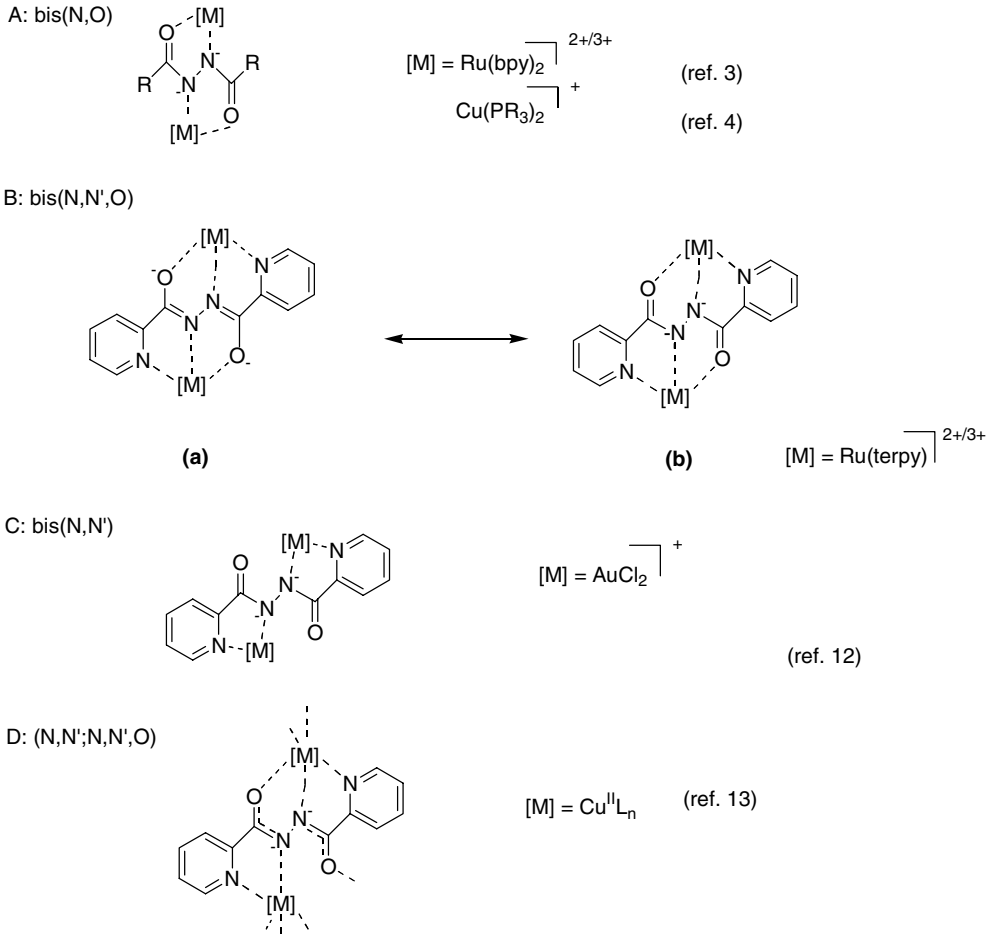


Scheme 1.



Scheme 2.

Considering the continued interest in diruthenum mixed-valent systems [11a], our interest was to study the effect of this different coordination on the properties of the $Ru_2^{II,III}$ intermediate state.

Complexes of L^{2-} have been observed to result from ring-opening reactions of 3,6-bis(2-pyridyl)-1,2,4,5-tetrazine, e.g. with $KAuCl_4$ in aqueous medium to produce a bis(N,N')-coordinated bis(dichlorogold(III)) species (Scheme 2C) [12]; in a similar recent report [13] it was described that the use of copper(II) complexes leads to tetranuclear species with (N,N',O) and (N,N') coordination of L^{2-} (Scheme 2D).

2. Experimental

2.1. Instrumentation

EPR spectra were recorded in the X band on a Bruker System ESP 300 equipped with a Bruker ER035M gaussmeter and a HP 5350B microwave counter. ^{1}H NMR spectra were taken on a Bruker AC 250 spectrometer. UV–Vis–NIR absorption spectra were recorded on a Bruins Instruments Omega 10 spectrophotometer. IR spectra were measured on a Paragon 1000 PC FTIR instrument from Perkin–Elmer. Cyclic

voltammetry was carried out at 100 mV/s scan rate in 0.1 M Bu_4NPF_6 containing solutions using a three-electrode configuration (glassy carbon working electrode, Pt counter electrode, Ag/AgCl reference) and a PAR 273 potentiostat and function generator. The ferrocene/ferrocenium couple served as internal reference. Spectroelectrochemical measurements were performed using an optically transparent thin-layer electrode (OTTLE) cell [14] for UV–Vis spectra and a two-electrode capillary for EPR studies [15].

2.2. Syntheses

N,*N*′-Bis(α-picolinoyl)hydrazine H_2L was prepared from hydrazinium sulfate and α-picolinoyl chloride in aqueous medium according to a general procedure [16]. Its identity was confirmed by comparison with reported spectroscopic and structural characteristics [5,6]. The precursor complex (terpy)(DMSO)Cl_2Ru was obtained as described [8a].

*{(**μ**-L)[Ru(terpy)]$_2$}(PF$_6$)$_2$*. A mixture of 130.2 mg (0.269 mmol) (terpy)(DMSO)Cl_2Ru, 32.6 mg (0.135 mmol) H_2L and 30 mg NaOH, dissolved in 40 ml H_2O and 8 ml CH_3OH, was heated to reflux for 40 h. After cooling to room temperature 0.50 g KPF_6, dissolved in 20 ml water, were added to produce a reddish-brown precipitate which was collected, washed with water and dried to yield 70 mg (43%). *Anal*. Calc. for $C_{42}H_{30}F_{12}N_{10}O_2P_2$ $Ru_2 \cdot 4H_2O$ (1279.90): C, 39.41; H, 3.07; N, 10.95. Found: C, 39.46; H, 2.71; N, 10.56%. ^{1}H NMR (acetone-d_6): 6.86–6.99 (m, 3H), 7.30–7.38 (m, 3H), 7.66 (ddd, 2H), 7.77 (m, 2H), 7.92 (m, 4H), 8.11–8.33 (m, 6H), 8.70 (m, 2H), 8.76–8.95 (m, 7H), 9.16 (ddd, 1H). IR (KBr): 1600br, 1550w, 1487s, 1448m, 1432m, 1376s.

3. Results and discussion

3.1. Synthesis and characterization of {(μ-L)[Ru(terpy)]$_2$}$^{2+}$

The hydrazine form H_2L of the ligand[5] was obtained according to Scheme 3, its identity was established *inter alia* through a confirmation of the reported crystal structure analysis [6]. The well-known precursor complex (terpy)(DMSO)Cl_2Ru was also characterized crystallographically [8b], exhibiting *trans*-positioned chloride ligands, S-bonded DMSO with the S–O bond in the (terpy)Ru plane and a symmetrically coordinated 2,2′:6′,2″-terpyridine ligand.

Reaction of H_2L with two equivalents of (terpy)(DMSO)Cl_2Ru in basic H_2O/MeOH yielded {(μ-L)[Ru(terpy)]$_2$}$(PF_6)_2$. The complex was found to be well behaved but only moderately soluble in non-coordinating dichloromethane, studies in coordinating solvents such as CH_3CN produced unsatisfactory, variable results which we attribute to a competition between the solvent molecules and the presumably weakly bonded carbonyl groups for the metal coordination. In less coordinating acetone-d_6 where the compound is well soluble the NMR data suggest a lower symmetry that C_{2h}, possibly due to nonsymmetrical coordination of the tridentate ligands. The IR spectra in KBr confirm the η^3:η^3 coordination pattern of L: The intense bands at 1709 and 1675 cm^{-1} in the free ligand H_2L are shifted to much lower values of 1487 and 1376 cm^{-1}, in agreement with deprotonation and metal coordination at the carbonyl oxygen atoms. Similar observations were made for $[(bpy)_2Ru(adc\text{-}R)Ru(bpy)_2](PF_6)_2$ [3].

3.2. Cyclic voltammetry

As illustrated in Fig. 1, the diruthenium(II) complex is oxidized in CH_2Cl_2 via two one-electron steps with a separation of 530 mV between the half-wave potentials. The comproportionation constant $K_c = 10^{9.0}$ calculated according to Eq. (2) is similar to the one observed for the related complex $\{(\mu\text{-adc-R})[Ru(bpy)_2]_2\}^{3+}$, R = Ph, with $K_c = 10^{9.7}$ [3]. This similarity reflects a comparable charge and distance situation for both systems.

$$\underset{\text{Red}}{M^n\text{-L-}M^n} \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} \underset{\text{Int}}{M^n\text{-L-}M^{n+1}} \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} \underset{\text{Ox}}{M^{n+1}\text{-L-}M^{n+1}} \qquad (1)$$

$$\text{Comproportionation constant } K_c = \frac{[\text{Int}]^2}{[\text{Red}][\text{Ox}]} = 10^{\Delta E/59mV} \quad \Delta E = E_2 - E_1 \qquad (2)$$

The electrochemical data for the phenyl and 2-pyridyl substituted complexes are compared in Table 1.

The absolute potentials are slightly higher for {(μ-adc-Ph)[Ru(bpy)$_2$]$_2$}$^{n+}$ although the substitution of

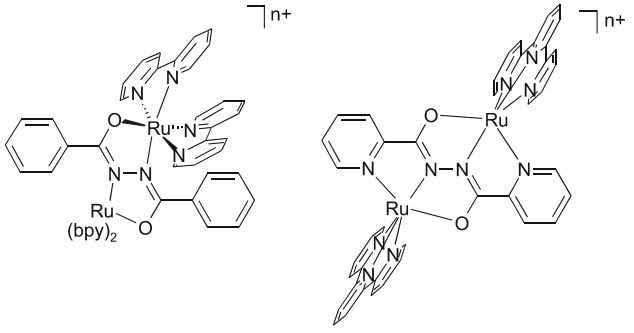
[e] $\Delta E^{3+} = E^{4+/3+} - E^{3+/2+}$.

phenyl by the better accepting 2-pyridyl in $\{(\mu\text{-L})[Ru(terpy)]_2\}^{n+}$ should cause an anodic shift. However, the different coordination arrangements have to be considered (Scheme 4) when formally shifting one 2-pyridyl substituent from each of the $[Ru(bpy)_2]$ fragments to the bridging ligand in L^{2-}. Obviously, interaction between the π ligands in their probably close to perpendicular situation is expected to be smaller for the (terpy)Ru complex.

Reduction occurs irreversibly at two closely spaced peak potentials (Table 1). It is not uncommon that terpy exhibits irreversible reduction because of enhanced reactivity at the 4′ position [17]. Cyclic voltammetry of $(\mu\text{-L})[Ru(terpy)]_2\}(PF_6)_2$ in acetonitrile did not yield straightforward results, additional waves point to partial replacement of donor functions of L^{2-} by the potentially coordinating solvent.



Scheme 4.

3.3. UV–Vis–NIR spectroelectrochemistry

Spectroelectrochemistry in the UV–Vis–NIR region using an OTTLE cell [14] produced characteristic reversible changes (Fig. 2, Table 2). Whereas the $Ru^{II}Ru^{II}$(2+) state exhibits a long-wavelength ligand(L^{2-})-to-ligand(terpy) charge transfer (LLCT) transition and typical [10] metal-to-(terpy-)ligand MLCT absorption bands, the (3+) intermediate is dis-

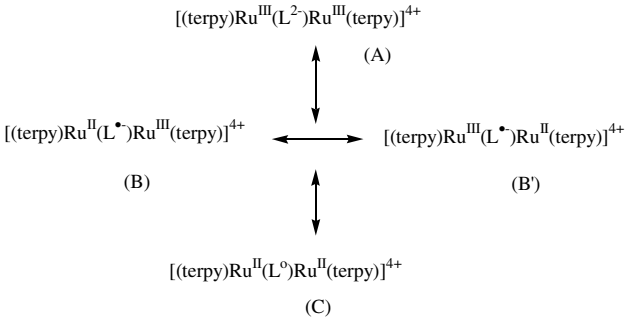
tinguished by two discernible bands in the near infrared region at about 1000 and 840 nm. At least one such band would be typical for the intervalence charge transfer (IVCT) transition of a mixed-valent compound [11] as has been similarly observed [3] albeit at distinctly longer wavelengths for the bis(2,2′-bipyridine) ruthenium complexes of the adc-R ligands (Table 2). The presence of two low-energy CT bands would be in agreement with recent calculations employing a three-state model, including a mediating LMCT or MLCT state, for ligand-bridged mixed-valent systems [11d]. The higher energy for $\{(\mu, \eta^3{:}\eta^3\text{-L})[Ru(terpy)]_2\}^{3+}$ suggests stronger electronic coupling through the bis-tridentate conjugated bridge. If class III behavior [11,18] (valence averaging) is assumed as supported by the large K_c and by the rather small band width (Table 2), the interaction energy can be estimated [11] at $\nu(IVCT)/2 = 5000$ cm^{-1}, a rather high value. For a class II situation, however, the electronic interaction would be calculated [19] at 1307 cm^{-1} according to $H_{AB} = 2.06 \times 10^{-2} R^{-1} \sqrt{\varepsilon \nu_{max} \Delta\nu_{1/2}}$ (ν in cm^{-1}, R estimated at 5 Å [4]). The hypsochromic shifts of the $Ru \rightarrow \pi^*$(terpy) MLCT band on oxidation are as expected [3], reflecting a decreasing relative donor effect of the bridge.

The absence of an intense long-wavelength absorption band for the (4+) form is conspicuous (Table 2). Such band was observed for all dinuclear bis(bipyridine)ruthenium complexes and was assigned to a mixed MLCT/LMCT transition originating from the possible resonance structures (3): LMCT for formulation (3A), MLCT for formulation (3C).

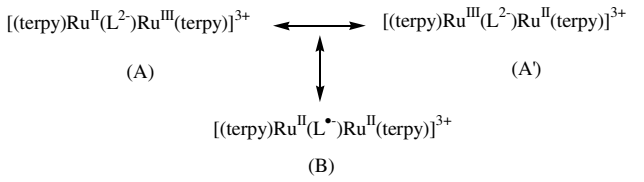


(3)

We interpret the absence of a long-wavelength band to an interrupted π conjugation of μ-adc-py [12], made possibly by the dissociation of the Ru–O coordinative bonds. This would be facilitated especially in formulation (3C) through the absence of negative charge on the bridging ligand which would render the carbonyl oxygen atoms as very weak donors. Although the spectroelectrochemical experiments show fully reversible spectral changes, this does not rule out specific reversible dissociation processes, especially in the presence of a polydentate ligand with rather different donor atoms.

3.4. EPR spectroscopy

The EPR spectrum of the (3+) intermediate should help to clarify whether this is an L^{2-} bridged $Ru^{III}Ru^{II}$ system or a radical complex $Ru^{II}(\mu\text{-}L^{\cdot-})Ru^{II}$ (4).



(4)

The spectrum (Fig. 3) and the data in Table 3 clearly point to the mixed-valent formulation although contributions from the bridging ligand to the singly occupied MO can be expected in a donor-bridged (''hole-transfer'') situation [3,11].

While both the g_{av} value and the sizeable g anisotropy $g_1 - g_3$ rule out a predominant diruthenium(II)-radical situation for which $1.99 < g_{av} < 2.02$ and $g_1 - g_3 < 0.1$ [3,20,21], the distinctly smaller axial g anisotropy for $\{(\mu, \eta^3{:}\eta^3\text{-L})[\mathrm{Ru(terpy)}]_2\}^{3+}$ suggests higher contributions from the more conjugated adc-py ligand to the singly occupied MO (SOMO). In agreement with this interpretation the EPR signal is still observable at 77 K at which temperature the dinuclear bis(bipyridine)ruthenium species are already EPR silent [3]. We thus assume a more delocalized metal/ligand/metal situation for $\{(\mu, \eta^3{:}\eta^3\text{-L})[\mathrm{Ru(terpy)}]_2\}^{3+}$ supported by the conjugated pyridyl rings.

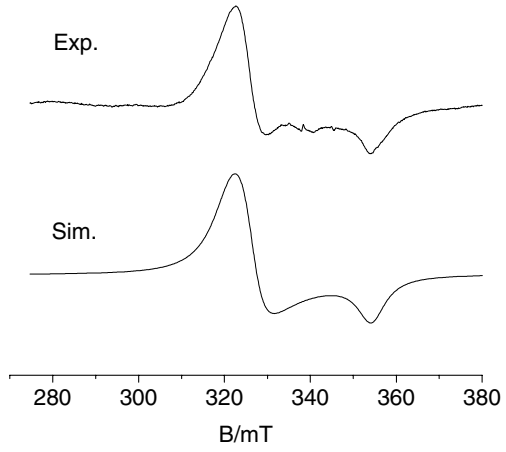


Fig. 3. EPR spectrum of $\{(\mu\text{-L})[\mathrm{Ru(terpy)}]_2\}^{3+}$ in CH_2Cl_2/0.1 M Bu_4NPF_6 at 3.4 K with computer simulation.

Solvent (temperature)	CH_2Cl_2 (3.4 K)	Acetone (3.8 K)

[a] $g_{av} = [(g_1^2 + g_2^2 + g_3^2)/3]^{1/2}$.

3.5. Conclusions

Apparently, the formal transfer of one pyridyl group in $\{(\mu\text{-adc-R})[\mathrm{Ru(bpy)_2}]_2\}^{n+}$ from one bpy to the bridging ligand in $\{(\mu\text{-L})[\mathrm{Ru(terpy)}]_2\}^{n+}$ while converting the polypyridyl set to terpy with its constraint to meridional coordination affects the electronic structure but does not significantly influence the electrochemical coupling.

The N,N'-bis(α-picolinoyl)hydrazido(2−) ligand L^{2-} can act as bis-bidentate, bidentate/tridentate or bis-tridentate ligand due to the very different nature of the donor atoms N_{py}, N_{azo} and O. Whereas the bis(N,N')-coordination in the digold(III) compound (Scheme 2C) allows for a complete twist around the central N–N bond to produce orthogonal and thus non-conjugated molecular halves [12], the bis(N,N',O)-coordination achieved for $\{(\mu\text{-L})[\mathrm{Ru(terpy)}]_2\}^{n+}$ ensures ligand-mediated metal–metal communication, as evident most strikingly from the properties of the mixed-valent intermediate ($n = 3$).

Abstract

Two organic ligands, N,N'-bis(2-pyridylmethyl)urea, "**2u**", and N,N'-bis(3-pyridylmethyl)oxalamide, "**3o**", were employed in the synthesis of three new extended structures. The reaction between $EuCl_3 \cdot 6H_2O$ (**1**) and **2u** afforded a molecular species, Eu(**2u**H_2)Cl_5, which assembled in one-dimensional chains by hydrogen bonding. When $EuCl_3 \cdot 6H_2O$ was replaced by $TbCl_3 \cdot 6H_2O$, the reaction with **2u** yielded another molecular compound, Tb(**2u**H_2)Cl_5, having the same structural features as **1**. **3o** reacted with $EuCl_3 \cdot 6H_2O$ and formed compound **3**, [Eu(**3o**H)$(H_2O)_2Cl_3$]Cl, in which the **3o** ligand acts as a bridge between the metal centers to form an infinite one-dimensional chain structure. The chains are further linked in three dimensions by hydrogen bonds and π–π stacking. Luminescence data for all three compounds are presented.

1. Introduction

Substantial progress has been made recently in the areas of crystal engineering and the rational design of extended frameworks based on multitopic organic ligands for the formation of coordination polymers. The characteristics of the organic ligand (length, flexibility, shape) and the coordination preferences of the metal centers are the primary factors that determine the resultant extended structures [1–6]. Careful management of these factors can lead to a certain predictability and control over the architecture of the products. In this context, control of strong, coordinative covalent forces as well as of weaker non-covalent interactions involving hydrogen bonding and π–π stacking can be envisioned.

Our target was to synthesize new mixed organic–inorganic materials in which covalent interactions would coexist with hydrogen bonds and/or π–π stacking and would lead to the formation of supramolecular assemblies. The approach was to employ a flexible organic ligand capable of multiple hydrogen bonding interactions, hence we decided to employ N,N'-bis(2-pyridylmethyl)urea (**2u**) and N,N'-bis(3-pyridylmethyl)oxalamide (**3o**) (Scheme 1). The organic cores that connect the pyridine rings in **2u** and **3o** have a great potential for participating in non-covalent interactions through the acceptor oxygen atoms and the N–H donor groups [7–14]. The oxygen and the nitrogen atoms, as well as the ortho- and meta-nitrogen atoms on the pyridine rings can be involved in coordinative covalent bonds with metal centers. Our choices for the inorganic components were the lanthanides $EuCl_3 \cdot 6H_2O$ and $TbCl_3 \cdot 6H_2O$. The main interest in these lanthanides resides in their luminescence properties and in the possibility of modulating them by incorporation into organic–inorganic hybrid materials [15–20].

In this paper, we report the synthesis, crystal structures and luminescence properties of three new compounds: two isostructural molecular species,

Eu(**2u**H_2)Cl_5, (**1**) and Tb(**2u**H_2)Cl_5, (**2**) and [Eu(**3o**H)$(H_2O)_2Cl_3$]Cl (**3**), a one-dimensional polymeric chain. Hydrogen bonds and, in the case of **3**, π–π stacking, assemble all the structures into higher dimensionality.

2. Experimental

2.1. Materials

$EuCl_3 \cdot 6H_2O$ (Alfa Aesar, 99.9%), $TbCl_3 \cdot 6H_2O$ (Alfa Aesar, 99.99%), 2-(aminomethyl)pyridine (Aldrich, 98%), 3-(aminomethyl)pyridine (Aldrich, 99+%), diphenyl carbonate (Aldrich, 99%) and diethyl oxalate (Matheson Coleman & Bell) were used without further purification.

2.2. Synthesis of *2u* and *3o*

N,*N*′-bis(2-pyridylmethyl)urea (**2u**) and *N*,*N*′-bis(3-pyridylmethyl)oxalamide (**3o**) were prepared according to the literature [7].

2.3. Synthesis of Eu(*2u*H_2)Cl_5, (*1*)

$EuCl_3 \cdot 6H_2O$ (0.2 mmol, 0.073 g) was dissolved in ethanol (5 ml) and carefully layered onto a solution of **2u** (0.1 mmol, 0.024 g) in chloroform (5 ml). Colorless crystals formed within four days.

2.4. Synthesis of Tb(*2u*H_2)Cl_5, (*2*)

The procedure is identical to that used for the preparation of **1**, except that $TbCl_3 \cdot 6H_2O$ (0.2 mmol, 0.053 g) was used instead of $EuCl_3 \cdot 6H_2O$. Colorless crystals formed.

2.5. Synthesis of [Eu(*3o*H)$(H_2O)_2Cl_3$]Cl (*3*)

The procedure is identical to that used for the preparation of **1**, except that **2u** was replaced by **3o** (0.1 mmol, 0.027 g) and $CHCl_3$ by CH_2Cl_2 (7 ml). Colorless crystals formed.

2.6. Physical measurements

The luminescent emission spectra for all three compounds were carried out on a Jasco FP-6500 spectrometer. Crystalline powders of **1**, **2** and **3** were mounted on the top of a plastic pin and placed in the path of the excitation source. The excitation wavelength for **1** and **2** was 300 nm and for **3** was 275 nm.

2.7. Crystallography

X-ray intensity data for **1**–**3** were measured at 150(1) K on a Bruker SMART APEX diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å) [21]. Raw data frame integration and Lp corrections were performed with SAINT+ [21]. Final unit cell parameters were determined by least-squares refinement of all reflections with $I > 5(\sigma)I$ from each data set (6654 for **1**, 5124 for **2**, 7373 for **3**). An empirical absorption correction was applied to each data set with SADABS [21]. All structures were solved by a combination of direct methods and subsequent difference Fourier syntheses and refined by full-matrix least squares against F^2, using all data, with SHELXTL [22].

Compounds **1** and **2** crystallize in the monoclinic crystal system; the space group $P2_1/n$ was determined in each case by examination of the pattern of systematic absences in the intensity data. Compound **3** crystallizes in the triclinic system; the space group $P\bar{1}$ was assumed and confirmed by the successful solution and refinement of the structure. All non-hydrogen atoms in each structure were refined anisotropically; hydrogen atoms attached to carbon were placed in geometrically idealized positions and included as riding atoms. Hydrogens bound to nitrogen atoms were located in the difference maps and refined freely with isotropic displacement parameters. The water hydrogens in **3** were located in the difference map and refined isotropically with O–H distances restrained to be similar to one another. Further details of the crystallographic refinements are given in Table 1.

3. Results and discussion

3.1. Synthesis

The starting materials *N*,*N*′-bis(2-pyridylmethyl)urea (**2u**) and *N*,*N*′-bis(3-pyridylmethyl)oxalamide (**3o**), were

GOF $= \left\{\sum[w(F_o^2 - F_c^2)^2]/(n-p)\right\}^{1/2}$ (n = number of reflections; p = number of refined parameters). $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where P is $[2F_c^2 + \max(F_o^2, 0)]/3$.
[a] $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$. $wR_2 = \left\{\sum[wF_o^2 - F_c^2)^2] / \sum[w(F_o^2)^2]\right\}^{1/2}$.

synthesized by reaction of 2-aminomethylpyridine with diphenylcarbonate and 3-aminomethylpyridine with diethyloxalate, according to synthetic methods previously reported [7]. N,N'-bis(3-pyridylmethyl)urea (**3u**) and N,N'-bis(2-pyridylmethyl)oxalamide (**2o**) have been similarly prepared, but no new compounds have been isolated with these ligands. Layering an ethanolic solution of $EuCl_3 \cdot 6H_2O$ with **2u** dissolved in chloroform in a 1:1 molar ratio yielded colorless crystals of a new molecular complex, Eu(**2u**H_2)Cl_5 (**1**). When $EuCl_3 \cdot 6H_2O$ is replaced by $TbCl_3$, in the same reaction conditions and molar ratio, another complex, Tb(**2u**H_2)Cl_5 (**2**) forms, displaying the same structural characteristics as **1**. In both of these reactions the ligand has been doubly protonated and the metal has gained two chloride ligands, leading to a neutral complex. The reaction between $EuCl_3 \cdot 6H_2O$ and **3o** generated colorless crystals of [Eu(**3o**H)$(H_2O)_2Cl_3$]Cl (**3**). In this case, the ligand has been singly protonated, leading to a complex with an overall +1 charge, balanced by an uncoordinated chloride ion. All of the resulting compounds are luminescent, and their luminescence properties will be discussed further below.

3.2. Crystal structure of *1*

Compound **1** is a molecular species, of composition Eu(**2u**H_2)Cl_5. Relevant bond distances and angles are compiled in Table 2. The coordination sphere around the europium center is comprised of five chlorine atoms (the Eu–Cl bond length ranges from 2.6258(7) to 2.7215(7) Å) and an oxygen atom from a **2u** ligand (Eu–O = 2.2988(19) Å) (Fig. 1). Although both nitrogen atoms on the pyridine rings of the ligand are protonated, the complex is neutral due to the presence of two additional chloride ligands coordinated to europium. Two different types of hydrogen bonding interactions assemble the molecules into one-dimensional chains

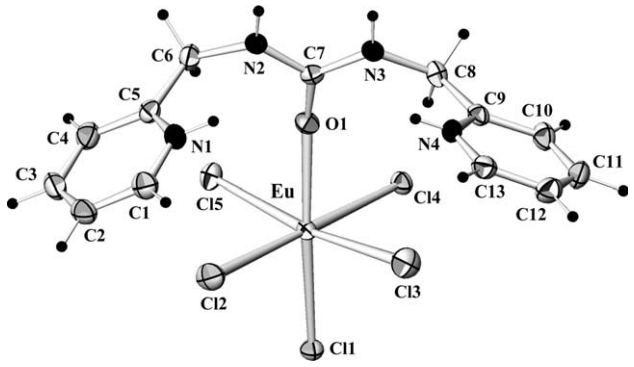

Fig. 1. Drawing of Eu(**2u**H_2)Cl_5 (**1**), shown with 50% probability displacement ellipsoids.

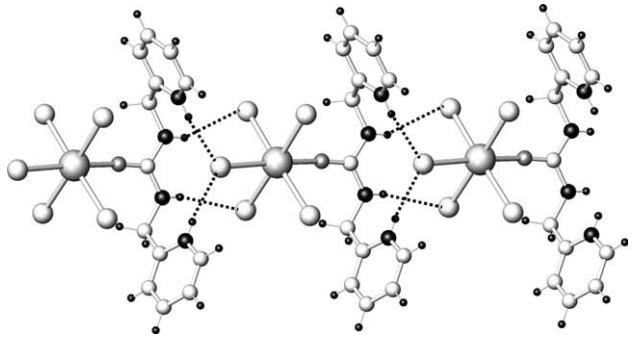

Fig. 2. Molecules of **1** assembled into one-dimensional chains by hydrogen bonding interactions. Eu atoms are shown as large gray circles; Cl, large shaded circles; N, small black circles; O, small gray circles; C, small shaded circles; H, smaller black circles.

(Fig. 2). Both hydrogens on the urea nitrogen atoms are involved in hydrogen bonding with two chlorines coordinated to the adjacent lanthanide (N(2)–H(2N)···Cl(5)#1; D···A = 3.296(3) Å, H···A = 2.60(3) Å, D–H···A = 143(3)°; N(3)–H(3N)···Cl(4)#1; D···A = 3.246(3) Å, H···A = 2.55(3) Å, D–H···A = 144(3)°). The two protons attached to the nitrogens in the pyridine rings of the ligand form hydrogen bond with a third chlorine atom of the same adjacent molecule (N(1)–H(1N)···Cl(1)#1; D···A = 3.123(3) Å, H···A = 2.35(3) Å, D–H···A = 150(3)°; N(4)–H(4N)···Cl(1)#1; D···A = 3.175(3) Å, H···A = 2.47(3) Å, D–H···A = 151(3)°), thus enhancing the intermolecular interactions that lead to the formation of the chains. (Symmetry code #1 is $x-1, y, z$). As shown in Fig. 3(a), sets of interdigitated one-dimensional chains assemble in "layers" in the *bc* plane, which then stack on top of each other (Fig. 3(b)) to form the overall extended structure.

Compound **2**, Tb(**2u**H_2)Cl_5, also a molecular species, is isostructural to compound **1**. The same atom labeling scheme was used for **2** as for **1**, and analogous bond distances and angles are given in Table 2.

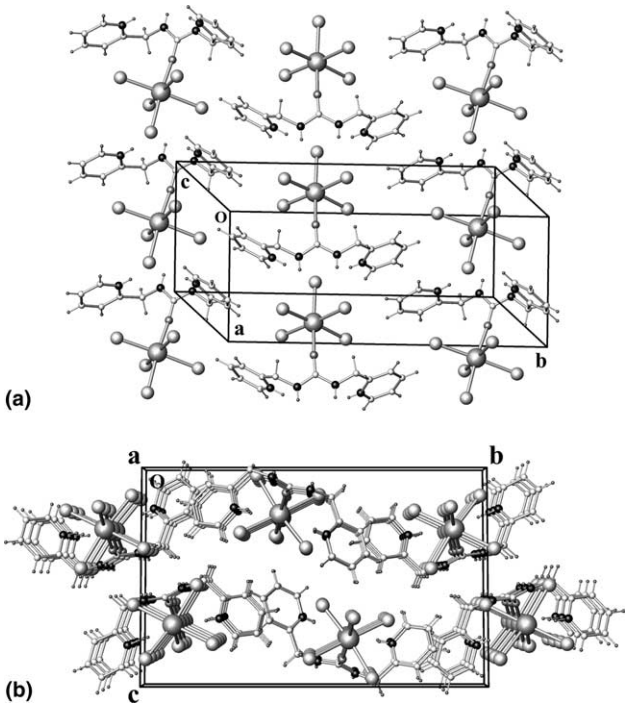

Fig. 3. (a) Schematic view of a "layer" of interdigitated chains in **1**. (b) Packing of two such "layers" of interdigitated chains (the view is rotated 90°).

3.3. Crystal structure of *3*

Single crystal analysis of **3** revealed an infinite one-dimensional structure consisting of chains running along the [1 0 0] direction. As shown in Fig. 4, the europium atoms are hepta-coordinated and are surrounded by three chlorines (Eu–Cl = 2.6735(10), 2.6950(11), 2.6981(10) Å), two molecules of water (Eu–O = 2.368(3), 2.431(3) Å) and two carbonyl oxygens provided by two different **3o** ligands (Eu–O = 2.341(3), 2.380(3) Å, see Table 2). One of the nitrogens on the pyridine rings is protonated, hence the chains are positively charged. The structure is supported by an intricate network of hydrogen bonds. Two types of hydrogen bonds can be distinguished in the overall network of compound **3**. The first type are intrachain hydrogen bonds (Fig. 4) and do not participate in building the extended network. These bonds involve a chlorine atom on the metal center and the hydrogen on one of the oxalamide nitrogen atoms (N(3)–H(3N)···Cl(2); D···A = 3.311(3) Å, H···A = 2.51(4) Å, D–H···A = 163(4)°), as well as a bifurcated hydrogen bond between the hydrogen on the other core nitrogen and two acceptors: the carbonylic oxygen (N(2)–H(2N)···O(2); D···A = 2.715(4) Å, H···A = 2.28(5) Å, D–H···A = 111(4)°) and a chlorine coordinated to the europium (N(2)–H(2N)···Cl(3)#2; D···A = 3.290(3) Å, H···A = 2.47(5) Å, D–H···A = 159(4)°). (Symmetry code #2 is $x+1, y, z$.)

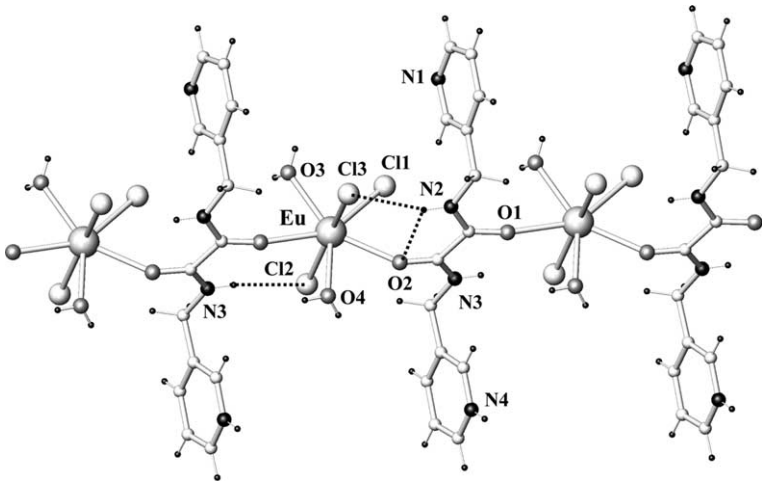

Fig. 4. One-dimensional chains in [Eu(**3o**H)$(H_2O)_2Cl_3$]Cl (**3**), showing intrachain hydrogen bonding. Eu atoms are shown as large gray circles; Cl, large shaded circles; N, small black circles; O, small gray circles; C, small shaded circles; H, smaller black circles.

The second type of hydrogen bond is interchain and organizes the structure into a 2D arrangement. Five such hydrogen bonds are present in the overall network. Adjacent, interdigitated chains are linked in the *ac* plane by one of the europium-coordinated waters, which forms two hydrogen bonding interactions with the free nitrogen on the pyridine ring (O(3)–H(3A)$\cdots$N(1)#4; D$\cdots$A = 2.658(5) Å, H$\cdots$A = 1.90(3) Å, D–H$\cdots$A = 168(5)°) and one chlorine atom (O(3)–H(3B)$\cdots$Cl(1)#5; D$\cdots$A = 3.228(4) Å, H$\cdots$A = 2.49(3) Å, D–H$\cdots$A = 111(4)°), both acceptors being located in the same adjacent chain. (Symmetry code #4 is $-x+1, -y, -z$; symmetry code #5 is $-x, -y, -z$.) The chains are also linked by π–π interactions between the pyridine rings. The ring centroid–centroid distance is 3.725(2) Å, with short contacts in the range 3.443–3.601 Å [23]. Overall, these interactions organize the one-dimensional chains in two-dimensional layers in the *ac* plane (a fragment of a layer is shown in Fig. 5(a)). Further, the layers are linked in three dimensions by another water molecule, O(4), involved in hydrogen bonding. It acts as an acceptor to the proton attached to the nitrogen on the pyridine ring (N(4)–H(4N)$\cdots$O(4); D$\cdots$A = 2.916(5) Å, H$\cdots$A = 2.21(3) Å, D–H$\cdots$A = 148(4)°) (Fig. 5(b)).

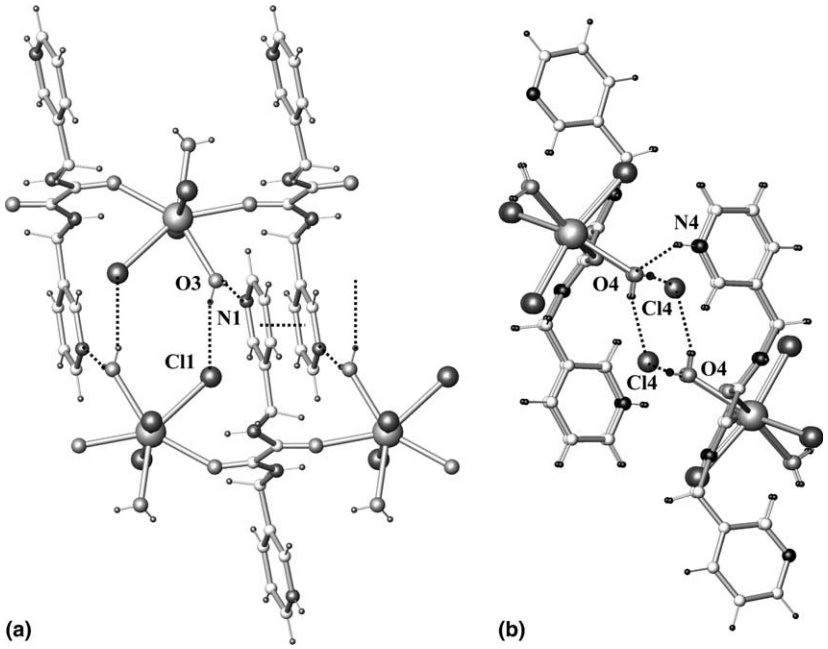

Fig. 5. (a) Fragment of two adjacent chains in **3**, showing interchain hydrogen bond and π–π stacking. (b) Additional interchain hydrogen bonding interactions as viewed down the crystallographic *a*-axis.

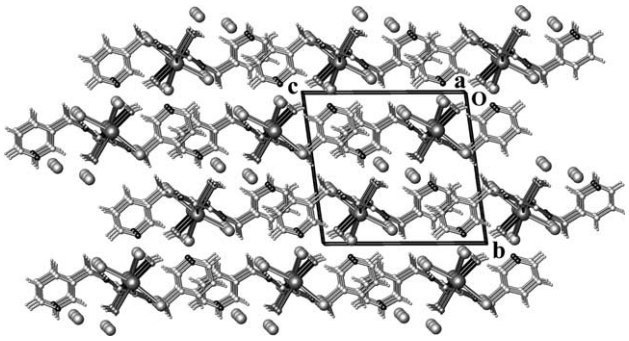

Fig. 6. Packing diagram of **3**, with chlorine anions between chains (hydrogen bonds omitted for clarity).

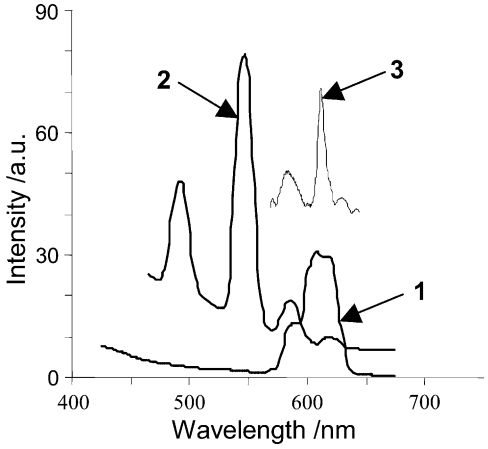

Fig. 7. Luminescence data for **1**, **2** and **3**.

The interstitial chlorine anions support the three-dimensional structure by acting as acceptors in two extra hydrogen bonds. As shown in Fig. 5(b), each chlorine is connected to two hydrogen atoms contained in two O(4) waters from two adjacent chains (O(4)–H(4A)···Cl(4); D···A = 3.050(3) Å, H···A = 2.32(3) Å, D–H···A = 159(5)°; O(4)–H(4B)···Cl(4)#3; D···A =3.052(3) Å, H···A = 2.31(3) Å, D–H···A = 164(4)°). (Symmetry code #3 is $-x+1, -y+1, -z+1$.)

In conclusion, hydrogen bonding and π–π interactions assemble the chains into two-dimensional layers, while additional hydrogen bonding with the interstitial chlorine anions and the proton on the pyridine rings expands the structure into three dimensions (Fig. 6).

3.4. Luminescence measurements

We have measured the luminescence spectra of crystalline powders of **1**, **2** and **3** at room temperature (Fig. 7). **1** and **2** were excited at 300 nm and **3** was excited at 275 nm. Compound **1** emitted red. It has two emission peaks at 589 and 607 nm and they can be assigned to $^5D_0 \rightarrow {}^7F_n$ ($n = 1, 2$) transitions. The first emission corresponds to the $^5D_0 \rightarrow {}^7F_1$ transition and is less intense than the second one, corresponding to $^5D_0 \rightarrow {}^7F_2$, which agrees with the fact that europium centers do not lie on an inversion center [24]. Compound **2** emits green light and shows four maxima at 495, 549, 591, 627 nm. The peaks can be assigned to $^5D_4 \rightarrow {}^7F_n$ ($n = 6, 5, 4, 3$) transitions. In the case of compound **3**, although a different ligand has been incorporated in the structure resulting in a one-dimensional infinite polymeric chain, the emission spectra has not changed very much. It emitted in red, showing two peaks at 583 and 609 nm, corresponding to $^5D_0 \rightarrow {}^7F_n$ ($n = 1, 2$) transitions.

4. Conclusions

In summary, the synthesis, the luminescence properties and the structural characterization of three new compounds have been presented. Compounds **1** and **2** feature the same organic ligand, *N*,*N*′-bis(2-pyridylmethyl)urea, **2u**, in its diprotonated form and are molecular. The molecules are assembled into one-dimensional chains by hydrogen bonding and are isostructural. Compound **3** contains the monoprotonated *N*,*N*′-bis(3-pyridylmethyl)oxalamide ligand, resulting in a markedly different architecture, a polymeric one-dimensional chain. The chains are held in three dimensions by an intricate array of hydrogen bonds. As anticipated, these ligands form complexes that have new supramolecular structures mainly organized by using the hydrogen bonding features built into them. The new complexes exhibit luminescence.

5. Supplementary material

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 213924–213926. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 3 May 2003; accepted 23 September 2003

Abstract

A route for incorporating the chelate molecule, AMP, onto silica gel was established. In the first stage a precursor silylant agent, 3-chloropropyltrimethoxysilane, is reacted with the support. The chelate molecule was then covalently bonded to the precursor surface to give 0.76 mmol of chelate per gram of silica. The immobilization reaction was confirmed through infrared spectroscopy and thermogravimetry. The anchored surface showed ability for adsorbing cations from water solution, presenting the maximum adsorption, calculated from the Langmuir equation, of: 0.84, 0.67, 0.40 and 0.22 mmol g^{-1} for the divalent cations copper, cobalt, nickel and zinc, respectively. All cation/surface interactions showed favorable enthalpic and entropic values, reflected in a thermodynamic stability of the complex formed.

1. Introduction

Heavy metal ion removal from waste-waters has been the subject of extensively technological research and recovering processes can often result in considerable cost saving [1]. Such analytical procedure developments are widely encouraged because many metals attain toxicity at distinct levels [2] or can show either vital or toxic effects in a series of biological systems as a function of concentration [2,3]. Therefore, increasing pressure from environmental authorities forces the establishment of discharge limits, which in turn, require an effective use of decontamination and purification methods [4].

A series of approaches can be applied to metal ion removal from waters, based on precipitation, exchange resins, membrane filtration and adsorbent methods. Among a diversity of adsorptive compounds that are capable of adsorbing metal ions from water, activated charcoal and clays are applied on a large scale [1,5,6]. However, some disadvantages such as heterogeneous pore structure and low selectivity are detected for these materials. Bearing in mind this proposal, new adsorbent materials are now being employed for removal of toxic and valuable compounds from water and other solvents [7–10].

Covalent immobilization onto solid supports of a desired chelate moiety, with the specific purpose of obtaining selectively adsorbent materials, is one of the most important procedures to develop highly selective matrices [11]. Therefore, considering such a proposal, many organic polymers and inorganic oxides have been chemically modified by attaching chelate groups onto the backbone chain, in order to increase their technological and scientific capabilities [12–19]. Among a series of these important supports, silica gel presents a high thermal, chemical and mechanical stability [20] and enables chemical modifications with functional compounds through the available silanol groups dispersed on its surface [21]. Thus, the ability of such a support to be modified leads to the acquisition of new materials, which can be used in many applications, such as chromatography [22], in sensors [23], pesticides removal [24], as well as in catalysis [25].

doi:10.1016/j.poly.2003.11.051

Designed applications to improve environmental quality through metal removal have recently been emerged. Moreover, the versatility of the inorganic silica support to be chemically modified induces its application to produce new materials available to remove contaminants from water and other solvents [26].

The aim of the present investigation is to report the incorporation of the 2-aminomethylpyridine (AMP) molecule onto a previously modified silica gel surface and the ability of this new chelating moiety on this anchored surface for cation removal from water.

2. Experimental

2.1. Chemicals

Reagent grade solvents were used. The compounds 2-aminomethylpyridine (AMP) and 3-chloropropyltrimethoxysilane (CTS) were used without purification. Silica gel with a particle size of 70–230 mesh and average pore diameter of 60 Å was activated in a stream of dry nitrogen by heating at 423 K for 10 h and used immediately [7]. The triethylamine was distilled under reduced pressure before use.

2.2. Organofunctionalization

A sample of 20.0 g of activated silica gel was suspended in 100 cm^3 of dry toluene and 20.0 cm^3 (108.0 mmol) of CTS was added to this suspension. The mixture was mechanically stirred under reflux of the solvent in an inert atmosphere for 72 h. The suspension was filtered and the solid was washed with toluene and dried under vacuum at 230 K for several hours, to give the modified silica, named SiCl [27].

2.3. Incorporation of 2-aminomethylpyridine

A sample of 5.0 g of SiCl reacted with 3.50 cm^3 (0.034 mmol) of the compound AMP in 50 cm^3 of toluene, containing 5.0 cm^3 of triethylamine in order to favor the reaction equilibrium [28]. The suspension was kept under reflux and mechanically stirred for 72 h at 363 K. The final product, SiAMP, was filtered, washed with toluene and ethanol, and dried under vacuum at 230 K for 24 h.

2.4. Characterization

The amounts of the organic pendant chains CTS and 2-aminomethylpyridine, immobilized onto the surfaces were calculated based on the carbon and nitrogen contents, determined through elemental analysis on a Perkin–Elmer PE-2400 elemental analyzer. Samples of the precursor modified silica (SiCl) of ca. 0.10 g was reacted with a large excess of pyridine during 2 h at 380 K. The mixture was treated with nitric acid and filtered. The amount of chlorine was determined by titration with standard silver nitrate solution [29]. The mass loss was followed on a DuPont Model 951 instrument, using approximately 10.0 mg of the sample under nitrogen at a heating rate of 0.17 $K\,s^{-1}$. The surface area of hexagonal mesoporous materials was obtained using the BET equation on a Flowsorb 2300 analyzer. The infrared spectra of solid samples in KBr pellets were performed by diffuse reflectance by accumulating 250 scans on a MB-Bomem FTIR spectrophotometer. Nuclear magnetic resonance spectra of the solid samples were obtained on a Bruker AC 300/P spectrometer at room temperature. For each run, approximately 1 g of modified silica was compacted into a 7-mm zirconium oxide rotor. The measurements were obtained at frequencies of 75.47 and 59.61 MHz, for carbon and silicon, respectively, with a magic-angle spinning speed of 4 Hz. In order to increase the signal-to-noise ratio of the solid-state spectra, the CP/MAS technique was used. ^{29}Si and ^{13}C CP/MAS spectra were obtained with pulse repetitions of 1 and 3 s and contact times of 1 and 5 ms, respectively [30].

2.5. Isotherms of adsorption

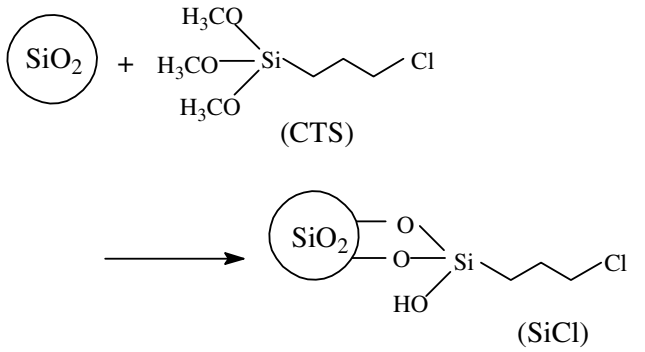
The isotherms of adsorption were obtained by using the batchwise method, in which a series of samples of 50.0 mg of SiAMP were suspended in 20.0 cm^3 of aqueous solution with the desired cations at several concentrations, varying from 1.0 to 15.0 $mmol\,dm^{-3}$. The samples were mechanically stirred for 8 h at 298 ± 1 K and the solid was separated by centrifugation and filtration. The adsorbed content was determined by difference by sampling the filtered supernatant, using a Perkin–Elmer 3000 DV ICP-OES instrument [31–33].

2.6. Calorimetry

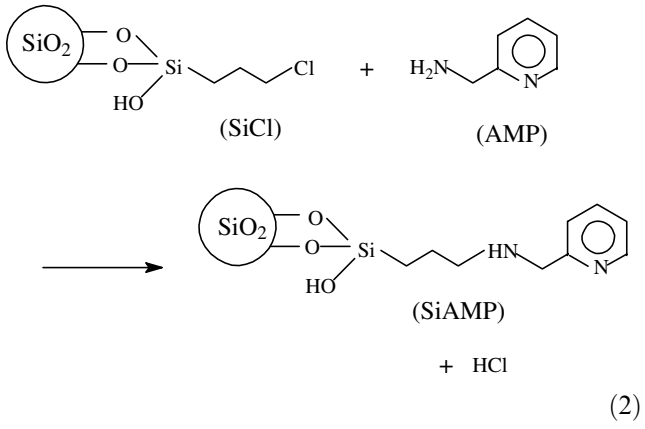
The calorimetric titrations were followed on a differential isothermal LKB 2277 microcalorimetric system. The titration consisted in suspending a sample of approximately 20.0 mg in 2.0 cm^3 of water inside a steel ampoule, which was vigorously stirred at 298.15 ± 0.02 K. After equilibrium, the cation solution was incrementally added through a microsyringe coupled to the calorimetric vessel. For each increment, the thermal effect ($\Delta_{tit}Q$) was recorded and the end if the titration was indicated by a constant thermal effect. The same procedure was employed to monitor the thermal effect of cation dilution ($\Delta_{dil}Q$) without the solid and also of adding water to the surface, which gave a null value. By combining these two heat outputs, the net value ($\sum \Delta_r Q$) can be determined by the expression $\sum \Delta_r Q = \sum[(\Delta_{tit}Q) - (\Delta_{dil}Q)]$ [34,35].

3. Results and discussion

The attachment of the 2-aminomethylpyridine onto silica gel followed a sequence of two distinct steps. The first one consisted in grafting 3-chloropropyltrimethoxysilane (CTS) onto silica gel to yield the new surface, SiCl, as represented in Eq. (1). In the next stage, this precursor was reacted with 2-aminomethylpyridine (AMP) to give the product SiAMP, presented in Eq. (2).



(1)



(2)

The degree of immobilization on the surface was determined by considering the elemental analysis data. From the percentage amount of carbon, 4.73 ± 0.02 and 8.17 ± 0.36 for SiCl and SiAMP, and the percentage of nitrogen 1.88 ± 0.01 for SiAMP, the number of moles of the compounds attached onto surface were calculated as 1.31 ± 0.01 and 0.76 ± 0.04 mmol g^{-1} for the SiCl and SiAMP surfaces, respectively. By considering the existence of two nitrogen atoms on final AMP anchored molecule surface, the 0.66 mmol of the available chlorine atoms bonded on the ends of the organic chain on the SiCl surface was required to react with the basic amino group to attach the desired molecule. In such condition, an excess of 13% of this anchored precursor remaining on surface without reacting.

The immobilization onto the surfaces can be confirmed through infrared spectra for the crude, the modified surface SiCl and the anchored SiAMP final surface. A small difference in spectra is observed in relation to the number and intensities of the displayed bands for activated silica and the immobilized compounds. The main features of the silica spectra are connected to the similarity of bands associated with the inorganic backbone such as (i) a large broad band between 3400 and 3200 cm^{-1}, which is attributed to the presence of the O–H stretching frequency of silanol groups and also to the remaining adsorbed water, (ii) the intense band related to siloxane stretching ν(Si–O–Si) of these groups at 1100 cm^{-1}, (iii) a band assigned to Si–OH stretching frequency for silanol groups at 900 cm^{-1} and (iv) the band around 1650 cm^{-1}, assigned to angular vibration of water molecules. However, the modified silicas, SiCl and SiAMP, presented a characteristic peak at 2950 cm^{-1}, assigned to C–H stretching of the tetrahedral carbon, which confirms the anchoring of the organic molecule onto the silica surface [28].

The surface areas for SiCl and SiAMP silicas were determined through the BET method, gave the results 420.8 ± 3.4, 347.2 ± 9.8 and 121.4 ± 8.6 $m^2\,g^{-1}$, respectively. The decrease in surface area after incorporation of organic groups can be easily interpreted due to the fact that the presence of pendant group partially blocks the adsorption of nitrogen molecules on surface and consequently causes a decrease in the surface area. As shown, this hindrance is more pronounced for the largest organic moiety, originating from the AMP molecule.

The thermogravimetric curves for all surfaces enable the establishing of information on thermal stability and also to confirm the amount of the compounds immobilized, as shown in Fig. 1. The profiles indicate that the SiAMP has more thermal stability than the SiCl surface. The curves also showed distinct mass losses, reflecting the molar mass of the pendant groups covalently bonded to inorganic phase.

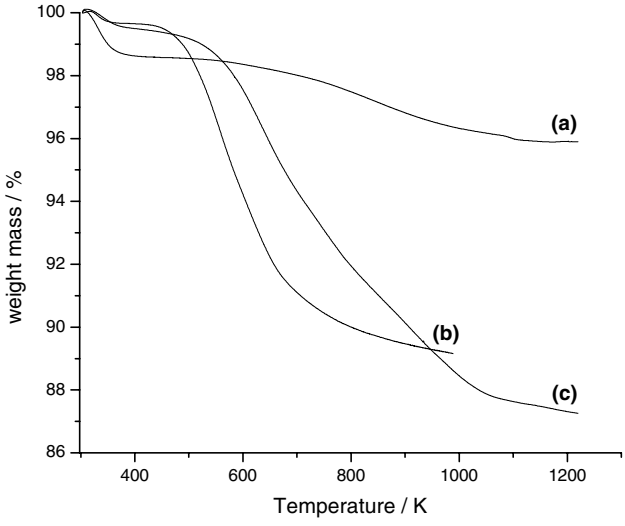


Fig. 1. Thermogravimetric curves of activated silica gel (a), and the chemically modified SiCl (b) and SiAMP (c) samples.

The activated silica gel present a first mass loss stage of 1.52% from 320 to 380 K, assigned to physically adsorbed water. A following stage of 2.56% is attributed to condensation of the silanols, to yield siloxane groups, resulting in water loss, from 670 to 1080 K [36]. Again two distinct mass loss steps were detected for SiCl sample. Thus, for the first one, a small mass loss of 0.35% in the 320–353 K range is attributed to the remaining silanol hydration water, as a consequence of the use of these groups on immobilization process. On the other hand, a pronounced increase of 10.52% in mass loss was observed for the second step, between 550 and 780 K, which corresponds to the organic matter added onto surface during immobilization. As expected, the immobilized SiAMP surface also presented two distinct stages of mass loss. Following the preceding interpretation, the first mass loss of 0.59% in the 320–360 K range is assigned to adsorbed water, and the other mass loss of 13.32%, between 560 and 865 K, was attributed to the organic groups immobilized on surface. The increase in mass loss is in agreement with the increase of the organic chain covalently attached to the inorganic backbone. For both anchored surfaces, the expected small degree of silanol condensation is hidden by the organic matter loss in the second step of decomposition.

Important features related to the immobilization of pendant group on the inorganic structure of the hybrid formed can be obtained through ^{13}C NMR spectra in solid state, as shown for SiAMP in Fig. 2. The proposed attachment of 2-aminomethylpyridine molecule to the precursor spacer modified agent is presented with carbon numbered. The three carbon atoms related to the spacer, numbered 1, 2 and 3 gave signals at 10, 26 and 46 ppm [30]. The ethylene carbon 4 gave a signal at 60 ppm and the aromatic carbons labeled 5–9 were assigned in the 120–160 ppm range, in good agreement with previous report [37]. These peaks corroborate to the expected immobilization of both materials, taking into account that the sequence of peaks are related to pendant carbon atoms of the organic part of these groups, results which support the success of the preparation of this new material.

The ^{29}Si NMR spectra in the solid state for both silicas confirm the covalent bond formed between the silylant agents and the silanol groups dispersed onto silica gel surface, as presented in Fig. 3. These spectra present four peaks located at −59, −69, −100 and −110 ppm. The first one is assigned to the silicon atom of the silylant agent bonded to one OH group and forming two siloxane bonds with silicon of the silica structure, $RSi(OSi)(OH)_2$, usually named as the T^2 signal. The peak at −69 ppm is assigned to $RSi(OSi)_3$, the T^3 signal. Both these signals confirm that organic groups were covalently bonded onto the silica surface. The other two peaks are attributed to pure surface signals described as: $Si(OSi)_4$, Q^4 at −110 ppm and $Si(OSi)_3OH$, Q^3 at −100 ppm [38–40].

The ability of the SiAMP surface in adsorbing cations from water is based on the free pair of electrons present on nitrogen atoms, represented as good Lewis bases of amine the and pyridine centers. Such disposition of pendant chains attached to the inorganic surface can chelate cations from aqueous solution. This adsorption ability was evaluated by measuring the sorption isotherms for a series of divalent cations, copper, nickel, zinc and cobalt. Under equilibrium conditions, the

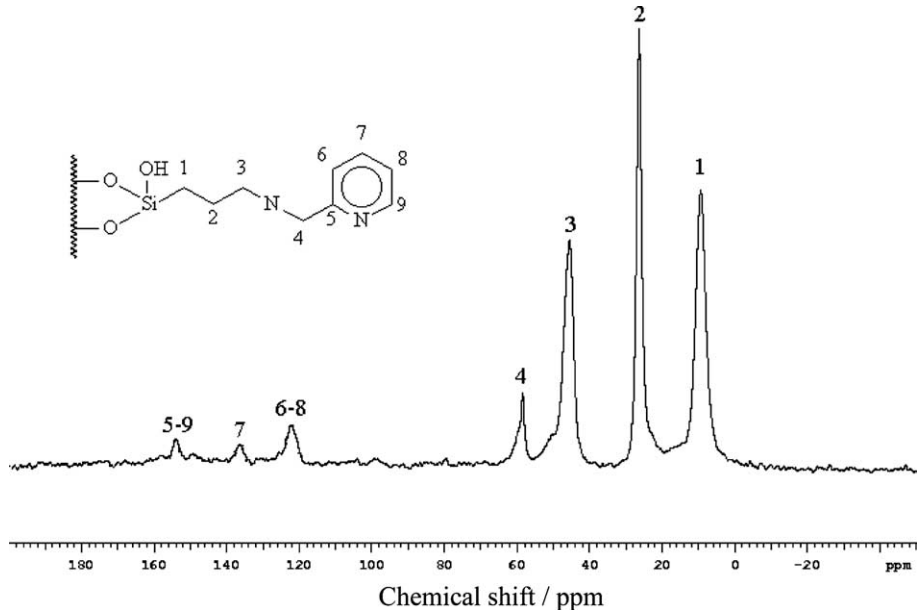

Fig. 2. ^{13}C NMR solid-state spectrum of anchored SiAMP silica.

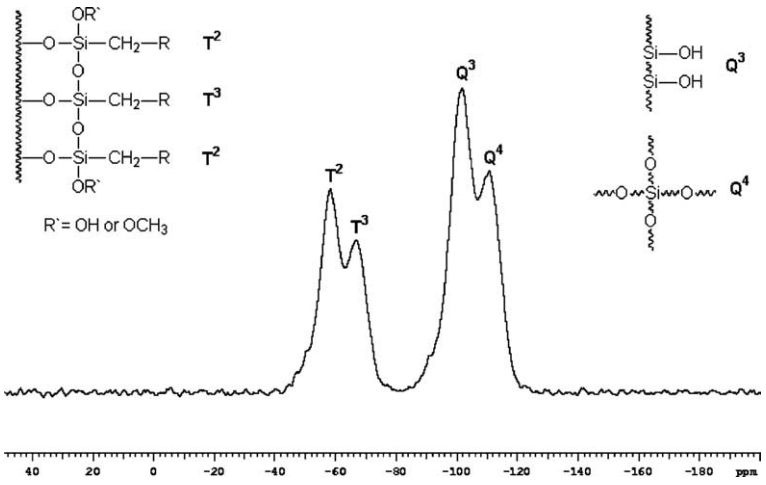

Fig. 3. ^{29}Si NMR solid-state spectrum of anchored SiAMP silica.

original solvent molecules that act as weakly bonded basic species are exchanged with the cations at the solid/liquid interface. The amount involved in this process characterizes the number of moles adsorbed (N_f), for 1 g of the solid. From the experimental point of view, this value was obtained from the initial number of moles of cation (n_i) added to the system and those at equilibrium (n_s) for a mass (m) of the support in grams, by applying the expression: $N_f = (n_i - n_s)/m$.

Profiles of the adsorption isotherms for all cations in water are represented in Fig. 4, in which the number of moles adsorbed versus the concentration at equilibrium condition is illustrated. Taking into account the maximum adsorption values, the isotherms obtained are distinguishable from each selected cation dissolved in water.

The established behavior in this adsorption process at a solid/liquid interface resembles those previously obtained for similar systems [31,32]. Therefore, the present data can be applied to a general equation, based on the Langmuir model, for such kinds of interaction:

$$\frac{C_s}{N_f} = \frac{C_s}{N_s} + \frac{1}{N_s b}.$$

From this expression, C_s is the concentration in solution at equilibrium (mol dm^{-3}), N_f as defined before (mol g^{-1}), N_s the maximum amount of solute adsorbed per gram of surface (mol g^{-1}), which depends on the number of adsorption sites and b is a constant. All these adsorption studies were based on the linearized form of the adsorption isotherm derived from a C_s/N_f as a function of C_s plot, as shown in Fig. 5. From these data, the maximum retention capacity (N_s) was determined for each cation–surface interaction. Thus, N_s and b were obtained from the angular and linear coefficients of the linearized form of the isotherms. These determinations from the obtained data showed that the adsorption followed the sequence Cu > Co > Ni > Zn. The N_s values are listed in Table 1.

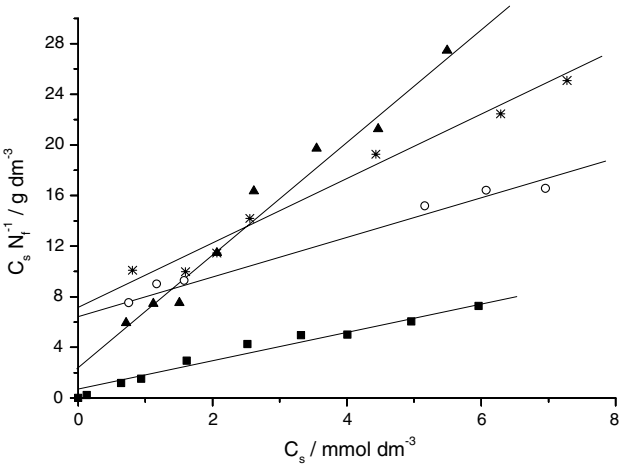

Fig. 5. Linearized Langmuir form of adsorption isotherms from calorimetric data for divalent cations: Cu (■), Ni (●), Co (○) Zn (◆) for SiAMP surface at 298 ± 1 K.

Table 1
The maximum retention capacity (N_s) and thermodynamic data for the interaction between divalent cations M^{2+} (Cu, Ni, Co and Zn) with the SiAMP surface at 298.15 ± 0.02 K

M^{2+}	$-\Delta H$ (kJ mol^{-1})	$-\Delta G$ (kJ mol^{-1})	ΔS (J mol^{-1} K^{-1})	N_s (mmol g^{-1})
Cu	4.09 ± 0.21	8.16 ± 0.30	14 ± 1	0.75 ± 0.04
Ni	1.95 ± 0.11	14.48 ± 0.40	42 ± 1	0.40 ± 0.10
Zn	1.27 ± 0.66	15.49 ± 0.40	48 ± 1	0.22 ± 0.40
Co	0.50 ± 0.01	13.36 ± 0.30	43 ± 1	0.67 ± 0.40

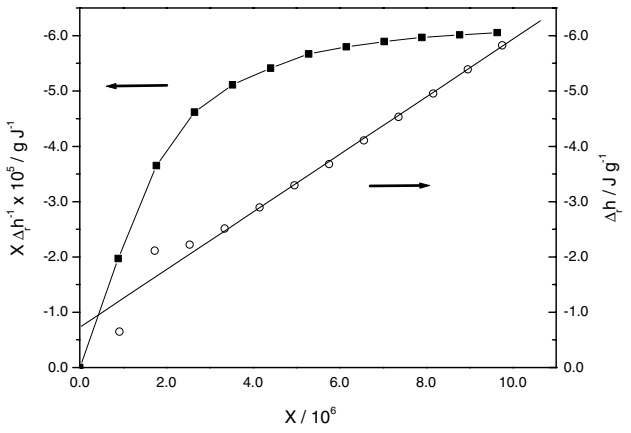

Fig. 6. Isotherm for the integral enthalpy of adsorption ($\sum \Delta h_r$) vs. molar fraction ($\sum X$) obtained from a calorimetric titration of a suspension of 0.020 g of SiAMP, in 2.0 cm^3 of water, with 0.015 mol dm^{-3} $Cu(NO_3)_2$ in the same solvent at 298.15 ± 0.02 K. The straight line is the isotherm.

Cation solutions were incrementally added to SiAMP samples suspended in water and the thermal effects produced were calorimetrically followed, in order to obtain more information about the basic centers/cation interactions at the surface. The thermal effect outputs from the net reactions can be calculated by the expression by $\sum \Delta_r Q = \sum[(\Delta_{tit} Q) - (\Delta_{dil} Q)]$.

The net resultant thermal effect outputs from the reactions were adjusted to a modified Langmuir equation [34,35,41] and were used to obtain the integral enthalpies involved in the formation of a monolayer per unit mass of adsorbate $\Delta_{mono} H$, by applying the expression:

$$\frac{\sum X}{\sum \Delta_r H} = \frac{1}{(K-1)\Delta_{mono} H} + \frac{\sum X}{\Delta_{mono} H}.$$

In this equation, $\sum X$ is the total mole fraction of the cation in solution after adsorption, X values are obtained for each addition of titrand, by using the modified Langmuir equation, whose behavior was shown to be a good adjustable model for such heterogeneous systems [40]. $\Delta_r H$ is the integral enthalpy of adsorption (J g^{-1}) obtained through the net thermal effect of adsorption and the number of moles of the adsorbate, K is a constant of proportionality that also includes the equilibrium constant. By using the angular and linear values from the $\sum X/\Delta_r H$ versus $\sum X$ plot, as illustrated for copper adsorption in Fig. 6, $\Delta_{mono} H$ and the enthalpy of adsorption, $\Delta_{ads} H$, values can be calculated by means of the expression: $\Delta_{ads} H = \Delta_{mono} H / N_s$. From K values, Gibbs free energies were calculated by the expression: $\Delta G = -RT \ln K$, and the entropy values are calculated through $\Delta G = \Delta H - \Delta TS$. All thermodynamic data are listed in Table 1.

For all determinations the cation-basic center interactions on SiAMP samples demonstrated spontaneity for the proposed reactions, as shown by the negative G values. Furthermore, in all cases, the exothermic enthalpic and positive entropic values are favorable conditions for the chelation of the cations by SiAMP, with stable complexes being formed. This anchored silica thus showed to be a good chelating agent to remove heavy metal ions from water. The success of AMP molecule incorporation on grafted silica with high thermal stability, significant adsorption ability and favorable thermodynamic interaction data suggest that this surface can be applied to remove contaminant cations from water.

4. Conclusion

The success of the 2-aminomethylpyridine chelate molecule attachment onto a silica gel surface and the ability of this material in easily adsorbing metal ions from water have been demonstrated. This proposal is confirmed through stable complexes formed between cations and free electron pairs on the nitrogen atoms disposed on the pendant groups, whose behavior was proven by the thermodynamic results. Thus, this new surface is a promising material to be applied to cation removal from aqueous solutions.

Abstract

Tris-chelated $[Ru(o/p\text{-}RaaiR')_3]Cl_2$ (where RaaiR′ = 1-alkyl-(2-arylazo)imidazole, R = H (**5**), *p*-Me (**6**) *p*-OMe (**7**) *o*-OMe (**8**), R′ = Me (**a**), Et (**b**), CH_2Ph (**c**)) were prepared by the microwave technique. Complexes have been characterized by IR, UV–Vis and ^1H NMR spectral data. The structural confirmation has been done in one case, $[Ru(o\text{-}OMeaaiCH_2Ph)_3]Cl_2$. The UV–Vis spectra of the complexes show an intense peak in the visible region (510–570 nm) and it has been assigned to a MLCT transition. Cyclic voltammetry of the complexes shows one metal oxidation Ru(II)/Ru(III) at 1.2–1.5 V and three successive ligand reduction couples negative to SCE as the reference electrode.

Keywords: Ruthenium(II)-tris-chelates; Azoimidazoles; X-ray structure; Electrochemistry

1. Introduction

It is without a doubt that bipyridine and its derivatives have been extensively used to develop the field of ruthenium–diimine chemistry [1–6]. In search of new ligands having similar or higher π-acidity to α-diimines based on pyridine heterocycle a series of arylazopyridines have been used successfully to synthesise ruthenium complexes [7–24]. We have been associated with the exploration of the chemistry of arylazoheterocycles for the last several years and have succeeded in modifying the organic molecule by using imidazole and pyrimidine, and substituting the aryl group by a naphthyl group. We have studied the coordination chemistry of 2-(arylazo)imidazoles [25–28], 2-(naphthylazo)imidazoles [29] and 2-(arylazo)pyrimidines [30]. The ligands are unsymmetric *N*,*N*′-chelators. Dihalo-bis-chelated-{2-(arylazo)heterocycle}ruthenium(II) may exist in five isomeric forms; three of them have *cis*-$RuCl_2$ and two isomers carry a *trans*-$RuCl_2$ configuration [7–9,25]. Complexes with a *trans*-$RuCl_2$ fragment cannot be used for the synthesis of tris chelates. The complexes with *cis*-$RuCl_2$ configuration may act as a precursor to synthesise tris-chelated derivatives [8,9,26].

Usually halide free ruthenium starting material $[Ru(dmf)_6](OTf)_3$ (Otf = trifluoromethane sulfonate) is used [31] or synthetic manipulation has been carried out to phase out halide from the reaction process [26] during preparation of tris-chelates. In the microwave assisted synthetic technique halide is removed forcibly and tris-chelates are isolated. This technique has saved time, energy and minimizes the cost of the reaction. Microwave accelerating chemical transformations is a part of cost benefit green chemical development process and has successfully been employed in organic reactions and synthesis of metal complexes [32].

Metal d^6 tris-complexes with asymmetric chelating ligands can have either facial (*fac*) or meridional (*mer*) configuration. The photophysical and electrochemical properties of facial and meridional isomers have been investigated for a number of Ru(II) complexes having diimine ligands [33,34]. However, for these complexes it

doi:10.1016/j.poly.2003.10.018

has been difficult to achieve control over the synthesis of a specific isomer. Using the present technique of microwave assisted synthesis we have been able to isolate only the meridional isomer. In this article, we report the one pot synthesis of tris-chelated ruthenium(II)-1-alkyl-2-(arylazo)imidazole complexes which have been characterized by their spectra, and electrochemistry. A confirmatory structural study has been done in one case using the single crystal X-ray diffraction technique.

2. Experimental

2.1. Materials

$RuCl_3 \cdot nH_2O$ was obtained from Arrora Matthey, Calcutta and was digested three times with concentrated HCl before use. 1-Alkyl-2-(arylazo)imidazoles were synthesized by the reported procedure [25]. Commercially available silica gel (60–120 mesh) from SRL was used for chromatographic separation. The purification of solvents for electrochemical and spectral work and [*n*-Bu_4N][ClO_4] (TBAP) were prepared as described earlier [28]. Super dry EtOH was obtained from ordinary alcohol following the drying procedure reported elsewhere [35]. All other solvents and chemicals were of reagent grade and were used without further purification.

2.2. Physical measurements

Microanalytical data (C, H, N) were collected using a Perkin–Elmer 2400 CHN Elemental analyzer. Solution electronic spectra were recorded on a JASCO UV–Vis–NIR V-570 spectrophotometer. Infrared (IR) spectra were obtained using a JASCO 420 spectrophotometer (using KBr disks, 4000–200 cm^{-1}). The ^1H NMR spectra in $CDCl_3$ were obtained on a Bruker 500 MHz FT NMR spectrometer using $SiMe_4$ as the internal reference. Solution electrical conductivities were measured using a Systronics 304 conductivity meter with solute concentration $\sim 10^{-3}$ M in acetonitrile. Electrochemical work was carried out using a PAR model 250 Versastat potentiostat/galvanostat with EG and G 270 electrochemistry software. All experiments were performed under a N_2 atmosphere at 298 K using a Pt-disk milli working electrode and Pt-wire auxiliary electrode. All results were referenced to a saturated calomel electrode (SCE). Reported potentials are uncorrected for junction potential. $K_4[Fe(CN)_6]$ was used as a standard showing the Fe(III)/Fe(II) couple at 0.19 V versus SCE in MeCN–0.1(M) TBAP and 50 mV/s scan rate. Molecular orbital calculations have been performed with the use of the ICON software package originally developed by Hoffmann. The crystallographic parameters of **8c** have been used for the calculation.

2.3. Preparation of complexes: tris-{1-benzyl-2-(o-methoxy-phenylazo)imidazole}ruthenium(II) chloride [Ru(o-OMeaaiCH$_2$Ph)$_3$]Cl$_2$(**8c**)

$RuCl_3 \cdot 3H_2O$ (0.25 g, 0.95 mmol) was dissolved in super dry EtOH (20 ml) in a Teflon reactor (100 ml capacity) and dry N_2 gas flushed for a few minutes. The reactor was corked and placed in the microwave oven 450 W for three lots of 5 min with 5 min interval between each step. The solution was cooled and 1-benzyl-2-(*o*-methoxyphenylazo)imidazole (*o*-O-MeaaiCH$_2$Ph) (0.95 g, 3.25 mmol) in degassed warm ethanol (30 ml) was added into it. The reactor was then placed in the microwave oven for another three lots of 5 min with 5 min interval between each step. The red-greenish solution was then evaporated slowly in air and washed with cold water. The dark solid was dried and dissolved in a minimum volume of CH_2Cl_2 and chromatographed over a wet silica gel column prepared in toluene. A light green-blue band was eluted by toluene-MeCN (1:1, v/v) and rejected. The desired red-brown band was eluted with MeOH (2 drops of HCl/100 ml MeOH) and collected. The eluent was slowly evaporated in air, and crystals were filtered and washed with cold water. They were then dried over P_4O_{10}. Yield: 0.63 g, 63%.

Other complexes were prepared under identical conditions; the yields varied in the 55–70% range.

2.4. X-ray structure determination

A crystal suitable for X-ray diffraction study of [Ru(*o*-OMeaaiCH$_2$Ph)$_3$]$Cl_2 \cdot H_2O$ (**8c**) was grown by slow diffusion of hexane into a dichloromethane solution of the complex. X-ray diffraction data were collected at 295 K with the Siemens SMART CCD using graphite-monochromatized Mo Kα radiation (λ =0.71073 Å). Crystal data are summarized in Table 1. The unit cell parameters were determined by least square refinements of all reflections. The intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction was also employed using the SAINT program. The structure was solved by direct methods using SHELXS 97 and followed by successive Fourier and difference Fourier syntheses. Full matrix least-squares refinements on F^2 were carried out using SHELXL 97 with anisotropic displacement parameters for all non hydrogen atoms in all cases. Hydrogen atoms were constrained to ride on the respective carbon atoms with an isotropic displacement parameter equal to 1.2 times the equivalent isotropic displacement parameter of their parent atom. The final difference Fourier map showed the maximum and minimum peak heights at 0.73 and −0.74 e Å^{-3}, respectively, having no chemical significance. Complex neutral atom scattering factors were used throughout. All calculations were carried out using SHELXS 97, SHELXL 97, PLATON 99 and ORTEP 3.

Observed data [$I > 2\sigma(I)$]	9560
R[a]	0.0594
wR_2[b]	0.1290
Goodness-of-fit[c]	1.08

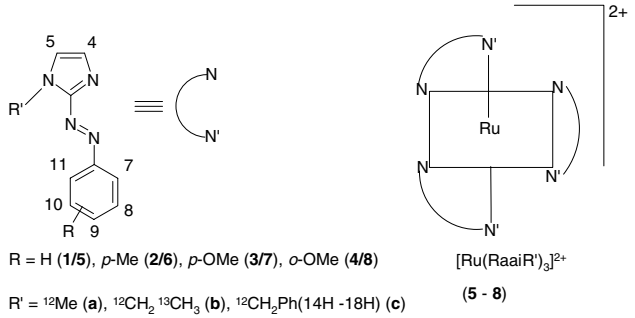
[a] $R = \sum ||F_o| - |F_c|| / \sum |F_o|$.
[b] $wR_2 = [\sum w(F_o^2 - F_c^2)^2 / \sum w(F_o^2)^2]^{1/2}$, $w = 1/[\sigma^2(F_o^2) + (0.0472P)^2 + 2.0068P]$, $P = (F_o^2 + 2F_c^2)/3$.
[c] Goodness-of-fit is defined as $[w(F_o - F_c)/(n_o - n_v)]^{1/2}$, where n_o and n_v denote the number of data and variables, respectively.

3. Results and discussion

3.1. Synthesis and spectroscopic properties

1-Alkyl-2-(*o*/*p*-alkyl-phenylazo)imidazole complexes (*o*-RaaiR′ or *p*-RaaiR′, Scheme 1) of ruthenium(II) have been prepared in super dry EtOH using microwave frequency 450 W in a Teflon reactor. Time and power have been optimized to maximize the yield of $[Ru(RaaiR')_3]Cl_2$. The complexes are purified by chromatography and isolated in 55–70% yield.

The ligands are an unsymmetric *N*,*N*′-chelator. *o*-OMe/OH substituted arylazo ligands exhibit flexidenticity: bidentate or ter-dentate [36,37]. However, in the present reaction *o*-OMeaaiR′ behaves as a bis-chelating *N*,*N*′ system. The composition of the complexes are formulated by elemental analyses and by the structural study of $Ru(o\text{-}OMeaaiCH_2Ph)_3Cl_2$. The complexes show 1:2 conductivity (Λ_M: 210–225 Ω^{-1} cm^2 mol^{-1}) and are diamagnetic (d^6, $S = 0$) in nature.



Scheme 1. Ligands used and their atom numbering scheme.

Assignment of the infrared spectral bands has been made on comparison with the spectra of RaaiR′, *ctc*-$RuCl_2(RaaiR')_2$ [25] (*ctc* refers to *cis–trans–cis* orientation of donor centers around Ru(II) in the sequence of coordination pairs of Cl, N(imidazole), N(azo), respectively) and $[Ru(bpy)(RaaiR')_2](ClO_4)_2$ [26]. Infra-red stretchings at 1370–1375 and 1590–1610 cm^{-1} have been assigned to ν(N=N) and ν(C=N), respectively. High intense transitions in the solution spectra (MeCN) below <400 nm are ligand centered charge transfer transition ($n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$). The visible region of the spectra exhibit high intense transitions at 515–570 along with two high energy transitions below 400 nm (Table 2, Fig. 1). Three transitions are well defined in $[Ru(o\text{-}OMeaaiR')_3]Cl_2$ (**8**) while in $[Ru(p\text{-}OMeaaiR')_3]Cl_2$ two transitions are overlapped (Fig. 1). The extended Huckel molecular orbital calculation (EHMO) using crystallographic parameters of **8c** has shown that the HOMO constitutes 60% metal dπ and the LUMO is 80% ligand character. The high intense transition in the visible region is thus a MLCT transition. Besides, the transition is shifted to the higher energy side in the case of *ortho* substitution, $[Ru(o\text{-}OMeaaiR')_3]Cl_2$ (**8**). Steric crowding may be the reason to destabilize the LUMO (which is ligand dominated as per the EHMO calculation, vide infra) and thus shift the main MLCT band to higher energy (Table 2).

The assignment of ^{1}H NMR signals has been done on considering spin–spin interactions, effect of substituents and on comparing with spectra of free ligands and *ctc*-$RuCl_2(RaaiR')_2$[25]. The proton numbering pattern is shown in Scheme 1 and data for the aliphatic region (1–6 ppm) only are set out in Table 3. The 9-R and 1-R′ groups are useful to support the structure of the compounds. Three ligands in the tris chelates give three sets of separate signals of 9-R and 1-R′. $Ru(RaaiMe)_3Cl_2$ (**5a**–**8a**) show three resonances at av. 4.20, 4.27 and 4.31 ppm. The methylene signals (–CH_2–) of $Ru(RaaiCH_2CH_3)_3Cl_2$ (**5b**–**8b**) exhibit multiplets at 4.65, 4.70 and 4.78 ppm suggesting three unsymmetrical groups. The –CH_3 of –(CH_2)–CH_3 exist as triplets at av. 1.45, 1.50 and 1.54 ppm. $Ru(RaaiCH_2Ph)_3Cl_2$ (**5c**–**8c**) show methylene (–CH_2–) resonances as three pairs of doublets. This suggests that the ligands chelated around Ru(II) are unsymmetrically disposed.

3.2. Structural characterization of $[Ru(o\text{-}OMeaaiCH_2Ph)_3]Cl_2 \cdot H_2O$ (**8c**)

The crystal structure of $[Ru(o\text{-}OMeaaiCH_2Ph)_3]Cl_2 \cdot H_2O$ (**8c**) is shown in Fig. 2. Selected bond distances and

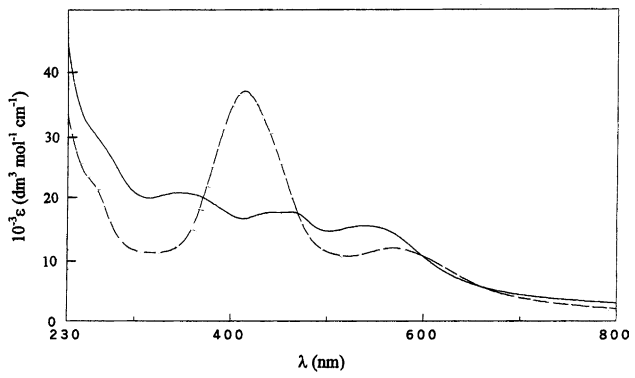

Fig. 1. UV–Vis Spectra of Ru(*o*-OMeaaiCH$_2$Ph)$_3$Cl$_2$ (—) and Ru(*p*-OMeaaiCH$_2$Ph)$_3$Cl$_2$ (---) in MeCN at 298 K.

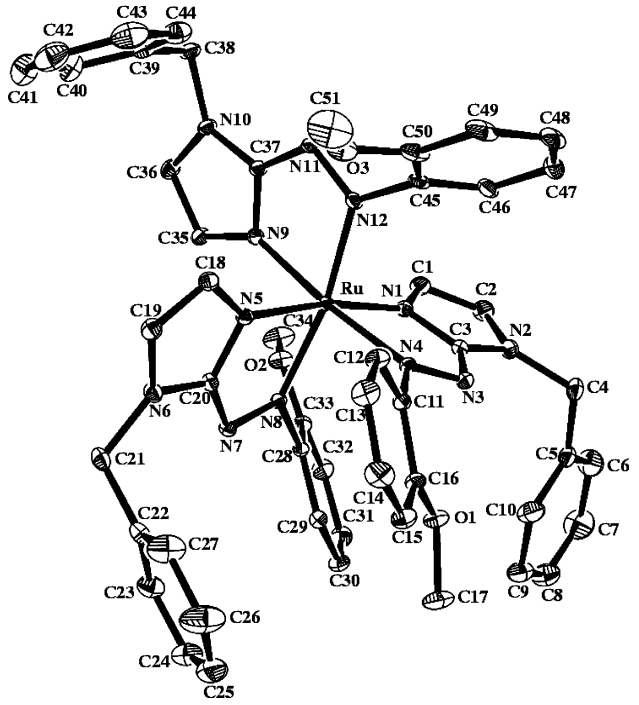

Fig. 2. Perspective view of Ru(*o*-OMeaaiCH$_2$Ph)$_3^{2+}$ showing atom labelling pattern. For clarity, all hydrogen atoms have been omitted.

angles are listed in Table 4. The constraints imposed on the RuN_6 meridional configuration are reflected from the planarity, bond angles and bond length data. The atomic arrangement Ru, N1, C3, N3, N4; Ru, N5, C20, N7, N8 and Ru, N9, C37, N11, N12 constitute three good chelate planes (mean deviation <0.06 Å). The planes are orthogonal to each other and the dihedral angle lie 82°–96°. The pendent *o*-OMeC$_6$H$_4$ group attached to metalated-azoimine chelate plane is no longer planar and is twisted by an acute angle (52°–68°). The atomic arrangements Ru, N1, N4, N5, N9 (plane 1) and Ru, N1, N12, N5, N8 (plane 2) constitute two molecular planes (mean deviation <0.08 Å). Maximum perturbation is observed to N4 in plane 1 which is deviated by 0.11 Å from the mean plane. These two planes make a dihedral angle of ~80°. The groups Ru, N4, N8, N9, N12 (plane 3) exhibit maximum perturbation and suffers deviation from the mean plane by ~0.11 Å. The azo-Ns exhibit maximum perturbation and the deviations from the mean plane are N12, −0.12; N4, 0.12 and N8, −0.15 Å. Thus, plane 3 is not a good plane. The plane 3 makes dihedral angles of 96° and 100° with planes 1 and 2, respectively. No bond lengths and angles are identical. The chelate angles are N9–Ru–N12, 76.42(12)°, N1–Ru–N4, 76.03(11)° and N5–Ru–N8, 76.21(10)°. Bond angle data in Table 2 reflect that N4a is *cis*-oriented with N1 (94.95 (12)°), N4 (99.10 (11)°) and N5 (93.00(12)°) and *trans* oriented with N8 (168.35 (11)°). We may assign *cis* and *trans*-orientation for other N-centres also. Other *trans* angles are N9–Ru–N4, 174.15 (11)° and N1–Ru–N5, 170.53 (10)°.

There are two types of N donor centres: N (imidazole) – N1, N5, N9 and N (azo) – N4, N8, N12. The Ru–N (imidazole) bond lengths are in general less than those of Ru–N(azo) distances. Ru–N(imidazole): Ru–N9/N1/N5: 2.056(3), 2.039(3), 2.051(3) Å; Ru–N(azo): Ru–N12/N4/N8: 2.032(3), 2.070(3), 2.062(3) Å. The Ru–N distances in this complex do not follow any sequence. In an individual chelate ring the Ru–N(imidazole) and Ru–N(azo) distances differ significantly. The Ru–N9 bond is longer ($\Delta d \approx 0.03$ Å) than the Ru–N12 bond while the Ru–N5 bond length is shortened by 0.01 Å from that of the Ru–N8 bond distance. Most significant distortion is observed in the chelate ring constituted by Ru, N1, C3, N3, N4; the Ru–N4 bond is elongated by ~0.03 Å from that of the Ru–N1 bond. The N3–N4 bond length is the shortest in the series, (1.282(4) chelated) and N11–N12 is the longest one (1.297(4) Å). The N7–N8 bond distance is 1.287(4) Å. The N–N length in this complex is longer than the free ligand value (1.250(1) Å) [37,38]. This may be due to the π-back bonding dπ (Ru) → π* (azo) charge transferences.

The molecular packing shows a 1D polymer (Fig. 3) which has been observed due to hydrogen bonding and π–π interaction. The Cl$^-$ forms a hydrogen bonding interaction with the imidazole-H (5-H as per the atom numbering pattern in Scheme 1) and bridges via N(1)–CH(Ph)–H–Cl of the neighbouring molecule (C(19)–H(19)–Cl(1): C(19)–H(19), 0.93; H(19)–Cl(1), 2.71; C(19)–Cl(1), 3.526(4) Å; ∠C(19)–H(19)–Cl(1), 147.0°. C(38)–H(38a)–Cl(1): C(38)–H(38a), 0.97; H(38a)–Cl(1), 2.76; C(38)–Cl(1), 3.661(5) Å; ∠C(38)–H(38a)–Cl(1), 154.0°). The second Cl$^-$ also acts similarly forming a hydrogen bonded cyclic dimer. Each dimer repeats along the *c*-axis and they are under face-to-face π–π interactions of two pendant anicidine rings of two different dimeric units (Cg(12)–Cg(12): 3.530 Å).

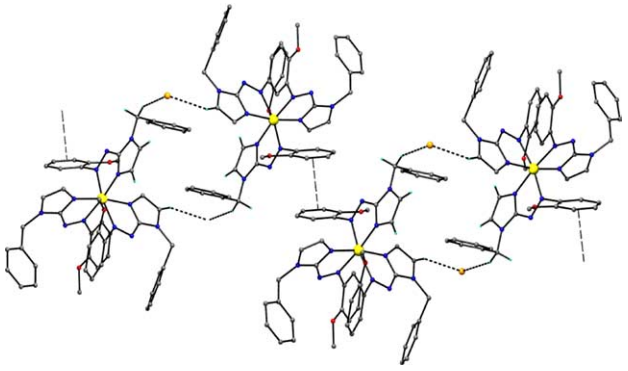

Fig. 3. Packing diagram showing C–H–Cl hydrogen bonded cyclic dimer and π–π interaction between anicidine rings to form a 1D polymer. (Yellow, Ru; blue, N; red, O; black C; orange, Cl; Hs are omitted except hydrogen bonded H for clarity).

3.3. Redox studies

A quasireversible couple at >1.30 V versus SCE reference electrode in MeCN (0.1 M TBAP) has been assigned to the Ru(II)/Ru(III) couple (Table 2, Fig. 4). Two closely spaced reversible to quasireversible redox couples ($\Delta E_p > 70$ mV) at −0.5 to −0.6 and −0.7 to −0.8 V are observed. A third couple, irreversible in nature ($\Delta E_p > 120$ mV), is observed at a potential of >−1.2 V. The one electron nature of the couple is supported from the i_d value in CV and DPV. Three couples at negative to reference potential are assigned to the ligand reduction centered at the azo group. The reduction is electron accommodation in the LUMO. LUMOs are ligand dominated (80%) so voltammograms negative to SCE are correctly assigned to ligand reductions. Since the HOMO possesses 60% metal dπ character; the oxidation may be described as electron extraction from the Ru(II) centre. During coulometric oxidation at a potential of 1.6 V for **6c** we found a continuous current count which may be due to solvent oxidation; one electron stoichiometric reduction becomes difficult because of closely

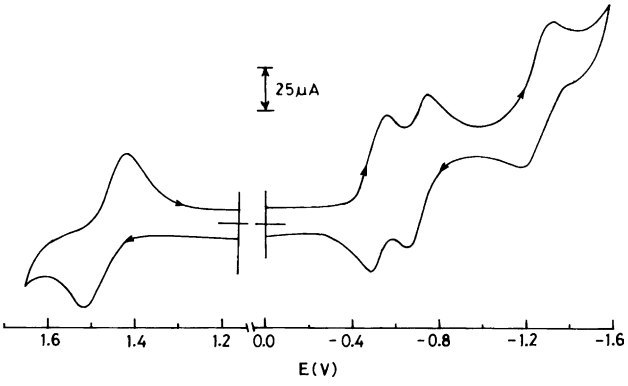

Fig. 4. Cyclic voltammogram of Ru(*o*-OMeaaiCH$_2$Ph)$_3$Cl$_2$ (**8c**) in MeCN using Pt-disk milli electrode, Pt-wire auxiliary, SCE reference electrodes.

spaced reduction couples. Further reduction of the co-ordinated ligand was not observed within the potential window +2.0 to −2.0 V.

4. Conclusion

The work describes microwave assisted one pot synthesis of tris-(1-alkyl-2-(arylazo)imidazole)ruthenium(II) chloride. The complexes have been characterised by spectroscopic data. The X-ray structure shows a bidentate *N*,*N*′-donation mode. The redox properties exhibit a Ru(III)/Ru(II) couple at very high positive potential and ligand reductions.

5. Supplementary data

Supplementary data are available from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ. UK [fax: (internet.) +44-1223/336-033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk] on request. The deposition number is 212243. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html.

Received 17 September 2003; accepted 18 October 2003

Abstract

Adducts of cobalt(II) 2,4-pentanedionate (acac) and 2,2,6,6-tetramethyl-3,5-heptanedionate (thd) with TMEDA (N,N,N',N'-tetramethyl-1,2-diaminoethane) and aminoalcohols, namely 1-dimethylamino-2-propanol (DMAPH) and 2-dimethylaminoethanol (DMAEH), have been synthesized and characterized by elemental analyses, FT-IR, ^{1}H NMR, mass spectrometry and TGA. The molecular structures of $Co(acac)_2$(TMEDA) (**1**) and $[Co(acac)_2(DMAPH)]_2$ (**2**) have been determined by single-crystal X-ray diffraction. **1** is monomeric while **2** is dimeric with two molecules linked by hydrogen bonds (O–H–O distance 2.708 Å av.). The most volatile and stable new adducts $Co(acac)_2$(TMEDA) and $Co(thd)_2$(TMEDA) have been studied as precursors for cobalt oxide deposition by liquid injection MOCVD in DME on monocrystalline $LaAlO_3$ and Si substrates. Films were characterized by XRD and XPS. These preliminary MOCVD experiments showed that epitaxial Co_3O_4 films can be obtained by using both new precursors.

1. Introduction

Cobalt oxides are of great interest due to useful properties, such as high catalytic activity at low cost [1], antiferromagnetism [1], electrochromism [2]. Cobalt oxide films have been considered for uses as magnetic detectors, membranes for oxidation of hydrocarbons, counter electrodes, humidity or oxygen optical sensors [3,4], solar-selective absorbers and protective layers [1,5,6]. Cobalt oxide films have been deposited by a variety of methods including conventional MOCVD [1,2,5–8]. However, despite the interest of MOCVD of Co_3O_4, reports are scarce. $[Co(acac)_2]_4$ was generally used as a precursor [1,5,7,8], although the use of $Co(acac)_3$ [8], $Co(OAc)_2$ [9] and more recently of $Co(thd)_2$ [10] or $Co(NO_3)_3$ [11] has been reported. Another use of cobalt β-diketonates is for the CVD of Co films [12]. A number of cobalt(II) acetylacetonate adducts with N-donors have been described [13–18]. Although some of them such as $Co(acac)_2$(LL) [LL = 2,2′-bipyridyl (130 °C/10^{-2} Torr), 1,10-phenantroline (190 °C/10^{-2} Torr)] [19] and $Co_2(acac)_4$(piperidine) (80 °C/10^{-4} Torr) [20] were volatile, no adduct was used so far for MOCVD applications. Cobalt β-diketonate adducts are also good catalysts for a number of reactions, such as polymerisation, enantioselective Michael addition, etc. [21–23].

We report here the synthesis and structural characterization of some new adducts of cobalt(II) 2,4-pentanedionate and 2,2,6,6-tetramethylheptane-3,5-dionate and the preliminary study of the most volatile and stable new adducts as precursors for the deposition of cobalt oxide films by liquid injection MOCVD.

2. Experimental

2.1. Syntheses

Syntheses of air-sensitive complexes were performed under argon using Schlenk tubes and vacuum line techniques. Solvents were purified by standard methods. TMEDA (N,N,N',N'-tetramethylethylenediamine), DMAEH (2-dimethylaminoethanol), DMAPH (1-dimethylamino-2-propanol), thdH (2,2,6,6-tetramethyl-3,5-heptanedione) and acacH (acetylacetone, 2,4-pentanedione) were distilled and stored over molecular sieves. $Co(thd)_2$ and $Co(acac)_2(H_2O)_2$ were prepared as reported [10,24]. $[Co(acac)_2]_4$ was obtained by sublimation of $Co(acac)_2(H_2O)_2$ at 100–120 °C/2×10^{-4} Torr (67%). It is slightly hygroscopic. FT-IR spectra were recorded with a Perkin–Elmer Paragon 500 Spectrometer as Nujol mulls. Mass spectra were obtained using a Thermofinnigan Mat95XL spectrometer under standard electron ionization conditions ($E_1 = 70$ eV). TGA experiments were performed under air with a Setaram 62 system using a thermal ramp of 10 °C/min. Proton NMR spectra were recorded in the range −130 to +130 ppm using the solvent peak as a reference on an AM250 Bruker spectrometer. Elemental analyses were done at the Centre de microanalyses du CNRS and at Vilnius University.

*$Co(acac)_2(TMEDA)$ (**1**)* was previously reported [15], it was prepared by a modified procedure. TMEDA (10% excess) was added to $Co(acac)_2(H_2O)_2$, the reaction medium was evaporated after 2 h and sublimed at 70 °C/2×10^{-4} Torr (90%). MS (m/z^+, %): M (5), M-acac (26), M-TMEDA (43), M-CH_3-TMEDA (76), M-acac-TMEDA (84), M-acac-CH_3-TMEDA (7), TMEDA (7), acacH (4), $Me_2N{=}CH_2$ (100). ^{1}H NMR ($CDCl_3$, 20 °C): −13.19 broad (Me(acac) + CH, 8H), 10.51 s (6H, Me acac), 38.69 s (2H, CH_2), 47 s (6H, Me_2N), 67 s (2H, CH_2), 78.08 s (6H, Me_2N).

*$[Co(acac)_2(DMAPH)]_2$ (**2**)*. 0.70 g (0.68 mmol) of $[Co(acac)_2]_4$ were dissolved in 20 ml of toluene and 0.37 ml (3.02 mmol) of DMAPH were added. The color of the solution changed from dark violet to red. After stirring for 2 h and concentration, **2** crystallized at −30 °C (0.72 g, 73%). *Anal.* Calc. for $C_{15}H_{27}CoNO_5$: C, 50.00; H, 7.55, N, 3.89. Found: C, 49.50; H, 7.49, N, 3.85%. IR, cm^{-1}: 3390 w (*ν*OH); 1599 vs, 1519 vs (*ν*C=O, *ν*C=C); 558 m, 505 w (*ν*Co–O, *ν*Co–N). ^{1}H NMR ($CDCl_3$, 20 °C): −14.52 s (2H, CH), 12.28 broad [15H, Me(acac) + Me(CH)], 32.85 broad (8H, $Me_2N + CH_2$), 71.93 s (1H, CHO).

*$[Co(acac)_2(DMAEH)]$ (**3**)*. 0.88 g (0.85 mmol) of $[Co(acac)_2]_4$ were dissolved in 25 ml of toluene. Addition of 0.38 ml (3.75 mmol) of DMAEH gave a red precipitate which was filtered after 16 h. A second crop of **3** was obtained by concentration at −30 °C (0.74 g, 72%). *Anal.* Calc. for $C_{14}H_{25}CoNO_5$: C, 48.56; H, 7.28; N, 4.04. Found: C, 48.00; H, 7.30; N, 3.92%. IR, cm^{-1}: 3109 w (*ν*OH); 1595 vs, 1520 vs (*ν*C=O, *ν*C=C); 554 w (*ν*Co–O, *ν*Co–N). ^{1}H NMR ($CDCl_3$, 20 °C): −14.10 s (2H, CH), 12.13 s (12H, Me, acac), 32.85 broad ($Me_2N + CH_2$, 8H), 71.93 s (2H, CH_2O).

*$Co(thd)_2(TMEDA)$ (**4**)*. Same procedure as for **2** applied to 0.32 g (0.75 mmol) of $Co(thd)_2$ in 10 ml of toluene and 0.12 ml (0.83 mmol) of TMEDA. The reaction mixture was evaporated after 2 h and sublimed at 125 °C/2.3×10^{-2} Torr (80%). *Anal.* Calc. for $C_{28}H_{54}CoO_4N_2$: C, 62.09; H, 10.05, N, 5.17. Found: C, 62.73; H, 10.16, N, 5.40%. IR, cm^{-1}: 1594 vs, 1582 vs, 1570 vs; 1531 s, 1504 vs (*ν*C=O, *ν*C=C); 609 w, 586 w, 478 m (*ν*Co–O, *ν*Co–N). MS (m/z^+, %): M (19), M-TMEDA (35), M-^{t}Bu-TMEDA (100), M-$C_{11}H_{19}O_2$ (10), M-$C_{11}H_{19}O_2$-TMEDA (15). thdH (2.8), ^{t}BuCOCH$_2$CO (15), TMEDA (10). ^{1}H NMR ($CDCl_3$, 20 °C): −17.53 s (2H, CH), −5.09 s (18H, ^{t}Bu), 8.06 s (4H, Me_2N), 32.24 (18H, ^{t}Bu), 46.80 (2H, CH_2), 67.82 (2H, CH_2), 78.87 (12H, Me_2N).

All compounds were soluble in usual organic solvents, except for **2** and **3,** insoluble in aliphatic hydrocarbons. Solubility was generally lower in polar solvents (N,N-dimethylformamide, CH_3CN, alcohols). All complexes but **1** are slightly air-sensitive, their colour changed to green on storage for over six months in air, oxidation to Co(III) was faster in solutions especially polar ones.

2.2. Crystallography of *1* and *2*

Crystals of **1** and **2** were obtained by sublimation at 80–85 °C/2.3×10^{-2} Torr and by recrystallisation in toluene at −20 °C, respectively. Data were collected with an Enraf–Nonius MACH3 diffractometer. Unit cell dimensions with estimated standard deviations were obtained from least squares refinements of the setting angles of 25 well-centred reflections. Corrections were made for Lorentz and polarization effects. Empirical absorption correction (Difabs) was applied. Crystallographic data and other pertinent information are summarized in Table 1. Computations were performed using CRYSTALS [25]. Atomic form factors for neutral Co, O, N and C were taken from [26]. Anomalous dispersion was taken in account. All atoms were anisotropically refined. Hydrogen atoms were introduced in calculated positions. Least-squares refinements (full matrix) were carried out by minimizing the function $\sum w(|F_o| - |F_c|)^2$, where F_o and F_c are the observed and calculated structure factors. Models reached convergence with $R = \sum(||F_o| - |F_c||)/\sum|F_o|$ and $R_w = [\sum(|F_o| - |F_c|)^2/\sum w(F_o)^2]^{1/2}$ having values listed in Table 1. A weighting scheme [27] was applied. Criteria for a satisfactory complete analysis were the ratios of rms shift to standard deviation being less than 0.1 and no significant features in the final map.

2.3. CVD experiments and films characterisation

Deposition of Co_3O_4 films was carried out by innovative pulsed liquid injection MOCVD (PI-MOCVD) [28]. Detailed description of this technique and of the reactor is given elsewhere [29,30]. Solutions (0.05 M) of precursors in 1,2-dimethoxyethane (monoglyme) were used for the depositions (injection frequency 2 Hz, microdose mass ~4 mg). The carrier gas was a mixture of Ar (54 l/h) and O_2 (36 l/h). Depositions were performed on monocrystalline $LaAlO_3$(1 0 0) and Si(1 0 0) substrates under 5 Torr total pressure. Substrates were cleaned in boiling toluene and its vapour before use. After deposition, films were cooled down to RT in an O_2 atmosphere (~1 atm).

Films crystallization and texture were studied by X-ray diffraction (XRD) with a Siemens D500 diffractometer (Cu Kα radiation). The film in-plane orientation was studied by XRD in Schultz geometry. X-ray photoelectron spectroscopy (XPS, VG ESCALAB 200R, Al Kα radiation) was also used. The in-depth film purity was evaluated after Ar^+ sputtering at 4 keV, 3.75×10^{-7} Torr argon pressure. A non-linear least-squares program (Eclipse V2.0) adopting Gaussian–Lorentzian peak shapes was used for the raw spectra fitting and for the evaluation of atomic compositions. Thickness of the films on Si(1 0 0) substrates was determined by profilometry (Taylor–Hobson) on a step formed by lithography. The thickness value was used for the calculation of the film growth rate.

3. Results and discussion

3.1. Synthesis and characterization

Adducts of cobalt(II) acetylacetonate with TMEDA, DMAEH and DMAPH were easily obtained either by ligand exchange reaction from $Co(acac)_2(H_2O)_2$ or by decomplexation of $[Co(acac)_2]_4$ at RT. It is noticeable that the decomplexation of $[Co(acac)_2]_4$ by aminoalcohols was more effective than that of $[Ni(acac)_2]_3$ [31]. $[Co(acac)_2]_4$ by contrast did not react with O-donors such as DME, triglyme and tetraglyme even in refluxing toluene for 24 h. These observations account for the absence of decomplexation and/or ligand exchange reactions in DME solutions, the solvent used for the CVD experiments. $Co(thd)_2$ and $Co(thd)_2(TMEDA)$, the first adduct of $Co(thd)_2$ reported, are also stable in DME. The complexes were characterized by elemental analyses, FT-IR, ^{1}H NMR, mass spectrometry and TGA. Their FT-IR spectra display the νC=O and νC=C absorption bands of the β-diketonate ligands in the 1504–1600 cm^{-1} range as well as those of the Lewis base. The spectra of **2** and **3**, the complexes with aminoalcohols, showed also absorptions at 3390 and 3109 cm^{-1}, respectively, due to νOH stretching. Their frequency is lower than that of the corresponding free alcohol – 3433 and 3385 cm^{-1} – respectively suggesting thus coordination. All compounds were volatile, the order of their sublimation rate under vacuum in identical conditions was as follows: $Co(acac)_2(TMEDA) >$

$Co(thd)_2 > Co(thd)_2(TMEDA) > [Co(acac)_2]_4 > [Co(acac)_2(DMAPH)]_2 \gg [Co(acac)_2(DMAEH)]_2$. The two latter adducts sublimed at 80 and 90 °C/10^{-4} Torr, respectively, but with partial loss of the aminoalcohol ligand especially for **3**, the DMAEH adduct. Due to this behaviour, adducts **2** and **3** were not investigated as MOCVD precursors for cobalt oxide films. The complexes with TMEDA were totally recovered as adducts by sublimation under vacuum thus reflecting the higher thermal stability of the N,N-donor Co β-diketonate adducts as compared to those with the O,N-donors. The volatility of the tetramethylheptanedionate derivatives, is, as expected higher than that of the acetylacetonate ones except **1** [32]. TGA-DTA analyses were performed in air. Fig. 1 illustrates the data for **1**. The amount of residue of black Co_3O_4 (18.3%), lower than the theoretical amount (21.5%) and the almost horizontal DTA curve part show that 1 sublimed partially (~15%) in the 130–230 °C temperature range. Subsequent events are the loss of TMEDA and acacH which occurred at temperatures lower than 260 °C and the oxidation of the residue as evidenced by the strong exothermic peak at 370 °C.

The mass spectra of $Co(acac)_2(TMEDA)$ (**1**) and of $Co(thd)_2(TMEDA)$ (**4**) show the molecular ions, the stability being in the favour of **4**. The main decomposition pathways of the molecular ions are the loss of TMEDA then of the methyl groups and acac for **1**, of both TMEDA and butyl groups for **4**. These patterns are in agreement with the literature. [10]. A peak at $m/z = 608$ (25%) attributed to $Co(thd)_3$ was observed for samples of **4** stored in air for ~6 months. The oxidation rate to Co(III) species by air was **1** < **4** < **2** < $[Co(acac)_2]_4$ < $Co(thd)_2$ < **3** according to ^{1}H NMR data. Thus, an advantage of the Co(II)-TMEDA adducts **1** and **4** by comparison to ligand free Co(II) β-diketonates is a higher resistance to oxidation.

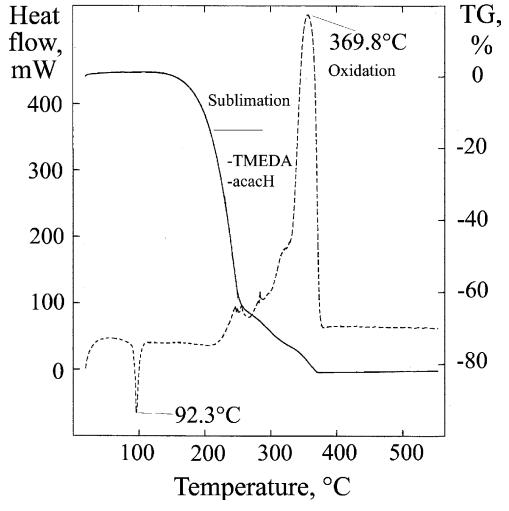

Fig. 1. TGA curve of $Co(acac)_2(TMEDA)$.

Despite the paramagnetic nature of the complexes, proton NMR spectra could be obtained. The NMR signals spread over the range −20 to +90 ppm. The signals are relatively narrow and, for complexes **1** and **4** account for the two types of magnetically non-equivalent substituents on the β-diketonate ring, *cis* and *trans* to the nitrogen donor sites of the TMEDA ligand. The complexes with the aminoalcohols are more stereolabile and only one signal was observed at RT for the substituents of the β-diketonate ring.

3.2. Molecular structures of *1* and *2*

The molecular structures of **1** and **2** were established by single crystal X-ray diffraction. **1** is monomeric (Fig. 2), while **2** contains two different dimeric molecules, **2a** and **2b**, in the asymmetric unit cell (Fig. 3). One molecule corresponds to the association of two monomeric units with chelating η^2-aminoalcohol ligands having an R configuration whereas the other involves chelating aminoalcohol ligands with an S configuration. The dimeric nature of **2** is due to assembly via hydrogen bonds from O(H) on one molecule to an O(acac) of another unit. The O–O distances have values of 2.684(3) and 2.733(3) Å for O(10)H–O′(8) and O(5)H–O′(4),

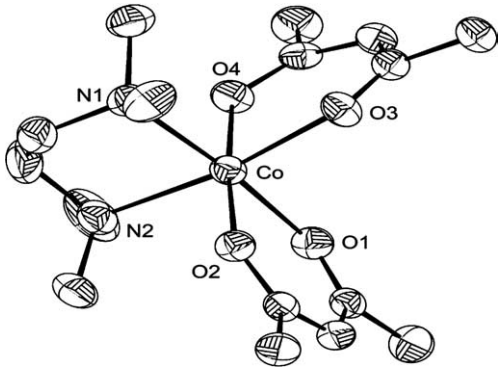

Fig. 2. Molecular structure of $Co(acac)_2(TMEDA)$ showing the atom numbering scheme (thermal ellipsoids at 20% probability).

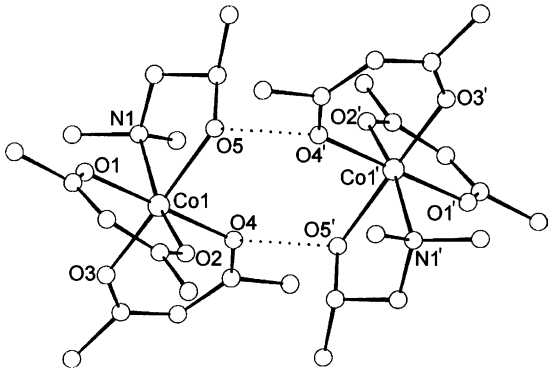

Fig. 3. Molecular structure of $[Co(acac)_2(DMAPH)]_2$ showing the atom numbering scheme (dotted line indicate H bonding).

respectively. Intramolecular hydrogen bonding in complexes with a β-diketonate ligand has been observed previously for instance for $[Ba_2Cu(\mu_3,\eta^2\text{–}OCH\text{-}MeCH_2NMe_2)_2(\mu,\eta^2\text{-thd})_2(\eta^2\text{-thd})(^i PrOH)_2]$ (O–H–O 2.58 Å av.) [33]. The structure of **2** is similar to that of $[Ni(acac)_2(DMAEH)]_2$ [31] or $[Ni(acac)_2(DMAPH)]_2$ [34] (O–H–O 2.54 Å av.). Selected bond distances and angles are collected in Table 2.

All adducts adopt a *cis* geometry, and the metals lie in a distorted octahedral CoO_4N_2 or CoO_5N cores. The Co–O(η^2-acac) bond distances in **1** [2.043(4)–2.076(4) Å] and **2** [2.023(3)–2.079(2) Å], are similar to the literature body as illustrated by $Co(acac)_2$(6-methylquinoline) [35] or $[Co(acac)_2(H_2O)]_2$ [36] for instance. The Co–O bonds in **1** *trans* to the nitrogen atoms [2.076(4)–2.090(4) Å] are longer than those *trans* to the oxygen's [2.044(4) Å av.]. A similar *trans* effect was observed for $Co(acac)_2$(TEEDA) [15] and $Co(thtf)_2$(TMEDA), thtf = 1-(2-thienyl)-4,4,4-trifluoro-1,3-butanedionate [37] but not for $Co(acac)_2$(bipy) [38,39]. The Co–O(H) coordination bonds are as expected longer (2.112(2)–2.125(2) Å) than the Co–O(η^2-acac) ones and similar to those observed in *trans*-$Co(acac)_2(MeOH)_2$ [40]. The Co–N distances [2.227(6) Å av. and 2.257(2) Å av. for **1** and **2**, respectively] are comparable for both compounds. They are in agreement with the values on adducts N-donors such as *N*,*N*,*N*′,*N*′-tetraethyl-1,2-diaminoethane [15], 6-methylquinoline [35] and pyridine [41], but longer than for instance for $Co(thtf)_2$(TMEDA) [37] or $Co(acac)_2$(bipy) [38,39] [2.161(3) and 2.147(5) Å for the α and β forms, respectively]. The major distortions are related to the neutral ligands as observed for the bite angles N–Co–N [82.3(2)°] in **1** or the even smaller N–Co–O ones [78.10(9)° and 78.66(9)°] in **2** and to those related to the ligands in *trans* positions [<O(6)–Co(2)–N(2) 167.5(1)°] and/or involved in H-bonding [<O(3)–Co(1)–O(5) 169.44(9)°].

3.3. MOCVD growth of Co_3O_4 films and film characterization

Deposition of cobalt oxide films was carried out by innovative pulsed liquid injection MOCVD technique (PI-MOCVD) [28]. This technique is based on repetitive injections of microdoses (several microliters) of solution of a volatile precursor, flash evaporation, vapour transport by a carrier gas and decomposition on a hot substrate. One advantage of liquid injection CVD over classical CVD is that it places less demands on the precursor in terms of volatility and stability [28,31,42]. Cobalt oxide films were deposited using the two most volatile and stable new adducts namely $Co(acac)_2$-(TMEDA) and $Co(thd)_2$(TMEDA). The main objective was to evaluate the possibility to apply these new adducts for cobalt oxide deposition. Films were deposited on monocrystalline $LaAlO_3$(1 0 0), and Si(1 0 0) substrates at two different substrate temperatures (450 and 600 °C) and were characterized in order to compare the

behaviour of the precursors at lower and higher deposition temperature.

Films of cubic Co_3O_4 were deposited in all cases due to sufficient excess of oxygen during deposition and cooling (film thickness 100–400 nm). XRD study of Co_3O_4 films deposited on $LaAlO_3$ show that both precursors **1** and **4** give (1 1 0) textured films on $LaAlO_3$ substrates (Fig. 4). Moreover, additional XRD study in Schultz geometry showed that films were grown epitaxially with "cube-on-cube" in-plane orientation of Co_3O_4 crystallites. The formation of (1 1 0) texture during film growth can be explained by a better lattice match between the (0 0 1) plane of the pseudo-cubic substrates and the (1 1 0) plane of cubic Co_3O_4 (mismatch ~0.5%) compared to the (0 0 1) plane of Co_3O_4 (~6% mismatch).

All Co_3O_4 films deposited on Si(1 0 0) substrates were polycrystalline independently of the precursor and deposition temperature used. Films on Si were etched with HF in order to form a step for the determination of film thickness and growth rate. The use of $Co(acac)_2$(TMEDA) lead to higher growth rate (0.7 μm/h at 450 °C and 1.6 μm/h at 600 °C) compared to $Co(thd)_2$(TMEDA) (0.5 μm/h at 450 °C and 1.3 μm/h at 600 °C). Growth of Co_3O_4 films from both precursors was kinetically limited in the temperature range 450–600 °C investigated.

XPS studies of the deposited films were performed in the Co 2p, O 1s region. Fig. 5 shows an Al Kα XPS spectrum in the Co 2p, O 1s region of a film deposited at 600 °C using **1**. The position of the Co $2p_{3/2}$ peak (780.5 eV), the presence of a weak shake up satellite at 790.5 eV and the value of the Auger α parameter (1553.5 eV) confirmed that the film surface consisted of Co_3O_4 [10]. Contamination with carbon (23%) could be reduced to 5.3% after sputtering of the surface by Ar^+ ions.

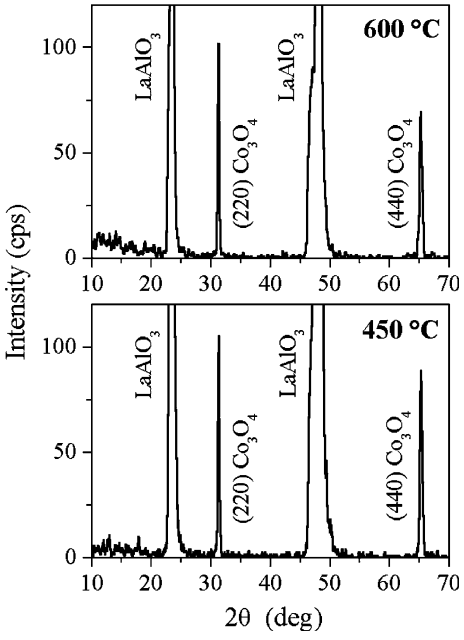

Fig. 4. XRD for Co_3O_4 films deposited on $LaAlO_3$ substrates from $Co(acac)_2$(TMEDA) at 450 and 600 °C. Similar scans were obtained in the case of $Co(thd)_2$(TMEDA).

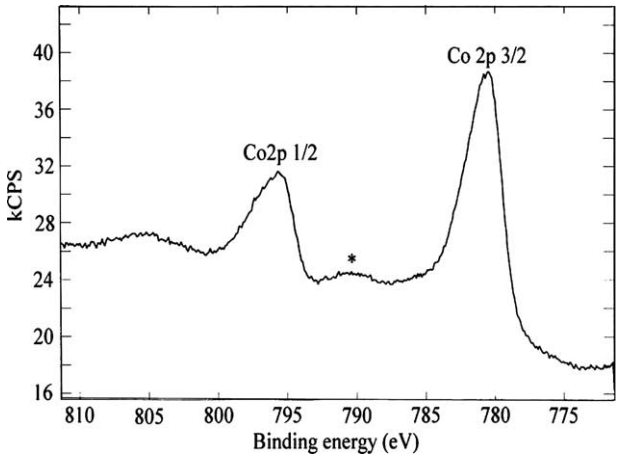

Fig. 5. Part of an XPS spectrum showing the peaks of Co in Co_3O_4 films deposited from $Co(acac)_2$(TMEDA) at 600 °C, the asterisk (*) indicates the weak shake up satellite.

These preliminary MOCVD experiments show that both new Co(II) β-diketonate adducts **1** and **4** can be applied for the deposition of pure, epitaxial Co_3O_4 films by liquid injection MOCVD. They outperform the existing CVD precursors in terms of volatility and oxidation stability; the quite cheap, air stable $Co(acac)_2$ (TMEDA) adduct is most attractive.

4. Supplementary material

Crystallographic data (atomic coordinates, thermal parameters, full lists of bond distances and angles) have been deposited at the Cambridge Crystallographic Data Centre, CCDC No. 186320 and 171430 for **1** and **2**, respectively. Copies of the data can be obtained free of charge from CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.com.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Several complexes of the ligand 4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-7-one (7HtpO) in its anionic form ($7tpO^-$) with divalent metals (the complete first series from Mn to Zn plus Cd) have been synthesized and characterized by means of analytical techniques (elemental analysis, thermogravimetry and differential scanning calorimetry), spectral methods (IR and electronic spectroscopy), magnetic measurements (77–290 K) and EPR in the case of the Cu compound. All compounds display a $M(7tpO)_2 \cdot nH_2O$ stoichiometry. The crystal structure of $[Zn(7tpO)_2(H_2O)_4]$. $2H_2O$ has been solved by single crystal X-ray diffraction. In this compound, the ligand $7tpO^-$ binds the metal ion through the N atom in position 3 and four water molecules complete the slightly distorted octahedral environment with the Zn atom occupying an inversion center. For all other compounds except Cu, infrared data suggest that the ligand binds in a similar fashion whereas visible spectroscopy and magnetic measurements point to octahedral geometry. On the other hand, magnetic and EPR measurements of the copper compound indicate that it is dinuclear with an antiferromagnetic coupling constant $2J = -87.8$ cm^{-1} and a zero-field splitting parameter $D = 0.168$ cm^{-1}.

1. Introduction

The 1,2,4-triazolo[1,5-*a*]pyrimidine ring has a chemical structure similar to purine, differing from it by the presence of a pyrimidime nitrogen atom in a bridgehead position with the disappearance of the acidic H-proton of the five-membered ring [1]. Metal complexes of these heterocycles may be considered as model systems for some naturally occurring metal coordination compounds. The study of the interaction of metal cations with 1,2,4-triazolo[1,5-*a*]pyrimidine derivatives has been carried out by a few research groups including one at the State University of Leiden [2] and more recently another one at the Nicholas Copernicus University at Torun [3], apart from our group at the University of Granada. The work in this field previous to 1999 was reviewed by us [4].

Single crystal X-ray diffraction studies of these metal complexes display an appreciable variability in their molecular structures. There are examples of mononuclear compounds, usually with the ligand monodentately bound through the nitrogen atom at position 3 [5], but with a few cases showing chelating behaviour through an endocyclic N atom and an exocyclic O atom [6] There are also many examples of binuclear or polynuclear compounds in which the metal atoms are bridged either by the triazolopyrimidine derivative [7] or by other auxiliary ligands [8]. The biological activity of a number of these complexes have been tested, finding that some of them inhibit the growth of Gram(+) and Gram(−) bacteria [9,10] as well as other parasites [11]. Antitumour activity has also been detected for several platinum group metals with triazolo[1,5-*a*]pyrimidine derivatives [12].

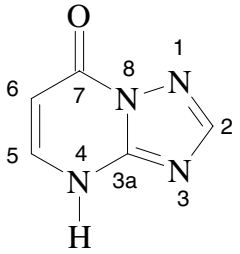

Scheme 1.

Most of the work in this field has been mainly focused on a few metal ions, namely platinum group metals [13], silver(I) [14] and copper(II) [15] with few examples of other divalent cations [16]. Following this research line, we present in this paper the synthesis, spectroscopic characterization, thermal and magnetic behaviour of a series of divalent metal complexes (Mn to Zn plus Cd) bearing the anionic form of 4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-7-one (7HtpO), which is an isomer and mimic of the purine base hypoxanthine. The crystal structure of the zinc compound is described. The molecular structure of the ligand and the numbering scheme for its atoms are shown in Scheme 1.

2. Experimental

2.1. Synthesis of the complexes

The compound 4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-7-one (7HtpO) was prepared according to published method from 3-amino-1,2,4-triazole and malic acid in strong acidic medium [17]. Other reagents were obtained from commercial sources.

Metal complexes were obtained by mixing two aqueous solutions, 10 mL each, one containing 0.1 g of 7HtpO and the other containing 0.1 g of the appropriate salt (sulfate for Mn and Fe, and acetate for Ni, Co, Cu, Zn and Cd). A small pH adjustment was necessary in the case of Mn and Ni, five drops of 1 M NaOH were added in the first case and one drop of concentrated acetic acid was added in the second. From the solution containing 7HtpO and zinc acetate, colorless crystals of the complex suitable for X-ray analysis were isolated after 24 h. The other complexes were obtained as powders from their corresponding solution after 24 h except for Cd for which the compound precipitated immediately. In all cases, the solids were washed with water and ethanol and dried with ether.

From elemental analyses, the following formulae were deduced for the isolated compounds:

$Mn(7tpO)_2 \cdot 6H_2O$ (**1**), white powder. *Anal.* Calc. for $C_{10}N_8O_8H_{18}Mn$: C, 27.72; H, 4.19; N, 25.86. Found: C, 27.4; H, 4.2; N, 25.4%. $Fe(7tpO)_2 \cdot 6H_2O$ (**2**), light brown microcrystals. *Anal.* Calc. for $C_{10}N_8O_8H_{18}Fe$: C, 27.67; H, 4.18; N, 25.81. Found: C, 27.5; H, 4.1; N, 25.4%. $Co(7tpO)_2 \cdot 6H_2O$ (**3**), orange powder. *Anal.* Calc. for $C_{10}N_8O_8H_{18}Co$: C, 27.49; H, 4.15; N, 25.64. Found: C, 27.7; H, 4.1; N, 25.5%. $Ni(7tpO)_2 \cdot 6H_2O$ (**4**), blue powder. *Anal.* Calc. for $C_{10}N_8O_8H_{18}Ni$: C, 27.49; H, 4.15; N, 25.64. Found: C, 27.7; H, 4.5; N, 26.1%. $Cu(7tpO)_2 \cdot 5H_2O$ (**5**), dark green powder. *Anal.* Calc. for $C_{10}N_8O_7H_{16}Cu$: C, 28.34; H, 3.81; N, 26.44. Found: C, 28.8; H, 3.8; N, 26.2%. $Zn(7tpO)_2 \cdot 6H_2O$ (**6**), colourless crystals. *Anal.* Calc. for $C_{10}N_8O_8H_{18}Zn$: C, 27.07; H, 4.09; N, 25.26. Found: C, 27.0; H, 4.1; N, 24.9%. $Cd(7tpO)_2 \cdot 4H_2O$ (**7**), white powder. *Anal.* Calc. for $C_{10}N_8O_6H_{14}Cd$: C, 26.42; H, 3.10; N, 24.06. Found: C, 26.4; H, 3.1; N, 24.1%.

2.2. Instrumentation

Microanalysis of C, H and N were performed in a Fisons Instruments EA-1008 analyzer. Thermal behaviour was studied under an air flow in Shimadzu TGA-50 and Shimadzu DSC-50 equipment. Reflectance diffuse spectra were recorded in a Cary-5 spectrophotometer. Magnetic susceptibility was measured in a Manics DSM-8 Faraday balance. An electron paramagnetic resonance spectrum was obtained in a X-band Bruker ESP-300E apparatus (all this equipment was sited at the Centre of Scientific Instrumentation of the University of Granada). IR spectra were obtained using a FT MIDAC Prospect 1 spectrophotometer with samples dispersed in KBr pellets.

2.3. Crystallography

Data were collected at room temperature for a brick-shaped colourless crystal (dimensions $0.20 \times 0.24 \times 0.32$ mm) in a Stoe Stadi4 diffractometer with Mo Kα radiation ($\lambda = 0.7107$ Å). Data were corrected for absorption (ψ-scans, transmission range, 0.6309–0.7119). The structure was solved by the heavy atom method and refined in F^2 using SHELXL-97 [18]. Hydrogen atoms of the heterocycle were placed in ideal positions and those of water molecules were located and refined with fixed (0.86 Å) O–H distances. Isotropic thermal parameters of all H atoms were fixed to 1.2 times the equivalent isotropic thermal parameter of their parent atoms.

Crystal data for $[Zn(C_5H_3N_4O)_2(H_2O)_4] \cdot 2H_2O$, orthorrombic, space group *Pbca*, $a = 7.5430(8)$, $b = 13.1384(12)$, $c = 17.2599(10)$ Å, $V = 1710.5(3)$ Å^3, $Z = 4$, $D_{calc.} = 1.723$ Mg m^{-3}, $\mu = 1.497$ mm^{-1}, 2487 unique reflections collected (θ range, 2.36°–30°), $wR_2 = 0.2760$, R (for 1389 data with $I > 2\sigma(I)$) $= 0.0872$.

3. Results and discussion

3.1. X-ray structural study of the zinc compound

Fig. 1 displays the molecular structure of compound **6**. The crystal structure comprises separate molecules of $[Zn(7tpO)_2(H_2O)_4]$ in which the metal atom lies in a crystallographic inversion center. Its environment is a slightly distorted octahedron defined by two symmetry related $7tpO^-$ ligands in *trans* disposition, and four water molecules. The two $7tpO^-$ ligands are coordinated in a monodentate manner through the N atom in position 3, which is the most frequent binding site for this type of ligand [4] This behaviour is also found in the analogous 5-methylated derivative, although an example of N1–O7 chelation has also been described for this compound with copper [15] as well as for the 5,7-dioxo derivative with Mn [6]. Two interstitial water molecules complete the structure. Distances and angles in the coordination sphere are listed in Table 1.

The Zn–N3 bond distance is within the range found for similar Zn(II) complexes [19,20]. Comparing bond distances and angles within the ligand with those in free 7HtpO [17], we found noticeable changes in the angles involving the atom C3A (3–4°) and the distances C7–O7 (0.040 Å longer) and C6–C7 (0.042 Å shorter). These changes are probably more attributable to the deprotonation of the ligand rather than to coordination. The plane of the ligand is almost perpendicular to the $Zn(H_2O)_4$ plane (dihedral angle 93.5(2)°) and the projection of the first plane over the second bisects the O1W–Zn–O2W angle (torsion angle C3a–N3–Zn–O1W, – 44.3(5)°) which minimizes steric repulsions.

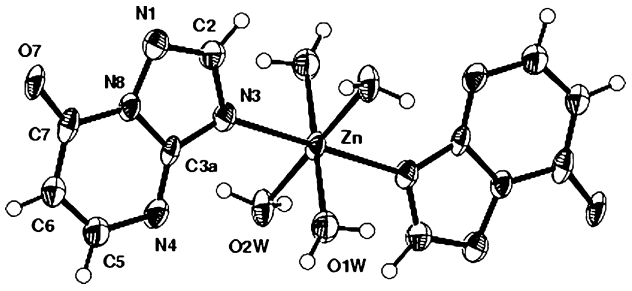

Fig. 1. Molecular structure of compound **6** as deduced from X-ray diffraction data. Nonhydrogen atoms are represented by ellipsoids at the 50% probability level.

Table 1
Selected interatomic distances (Å) and angles (°)

Coordination sphere		
Zn–N3 2.125(5)	N3–Zn–O1W	92.0(2)
Zn–O1W 2.113(4)	N3–Zn–O2W	89.4(2)
Zn–O2W 2.143(5)	O1W–Zn–O2W	89.3(2)
Hydrogen bonds		
O1W···O3W	2.697(6)	
O1W···O3W $(-1/2+x, 1/2-y, 1-z)$	2.765(7)	
O2W···O7 $(1/2-x, 1-y, -1/2+z)$	2.740(6)	
O2W···O7 $(-1/2+x, y, 3/2-z)$	2.892(6)	
O3W···N4 $(1/2+x, 1/2-y, 1-z)$	2.791(6)	
O3W···O7 $(3/2+x, 1-y, -1/2+z)$	2.772(7)	

All hydrogen atoms of both coordinated and non-coordinated water molecules are involved in hydrogen bonds stabilizing the structure (see Table 1). The main acceptor of these bonds is the exocyclic oxygen atom of $7tpO^-$.

3.2. Spectral, thermal, magnetic and EPR studies

The thermal study of these compounds in air has been carried out from their TG and DSC plots. All compounds are hydrated and loss of water is the first step of their thermal decomposition. For compound **5** (Cu), the corresponding effects are very broad showing the unspecific nature of water, the percentage of which is not reproducible. The remaining complexes display well defined weight losses in the range 50–180 °C which agree well with the number of water molecules indicated by their elemental analysis. Dehydration takes place in a single step (endothermic peaks in the range 98–110 °C) except for **4** (Ni) for which two well-defined stages are observed (peaks at 92.2 and 121.4 °C). Dehydration energy is very similar for all the compounds, ranging from 45.5 to 48.8 kJ/mol of water. The anhydrous complexes are stable up to ~350 °C, when pyrolitic decomposition starts.

The infrared spectra of the complexes **1**–**4**, **6** and **7** are virtually identical, differing from that of the free ligand [17] by the presence of a broad band at 3400 cm^{-1} due to ν(O–H) of water molecules, the absence of the intense ν(N–H) band and the batochromic shift of ν(C=O) which appears at 1625–1630 cm^{-1}. On the other hand, the spectrum of **5** (Cu) is noticeably different from the other: thus, the bathochromic shift of the ν(C=O) vibration is smaller (band at 1674 cm^{-1}), which may indicate a different coordination mode of the ligand. Such different behaviour of copper(II) if compared with the rest of the divalent transition ions has also been observed for the complexes of the analogous ligand that contains a second oxygen atom at position 5 [6].

The diffuse reflectance spectra of **2, 3** and **4** are typical of octahedral species [21]. Thus, the spectrum of **2** shows two overlapped bands even if only one is expected ($^5E_g \leftarrow {}^5T_{2g}$) for a d^6 high spin configuration, which can be due to a strong Jahn–Teller distortion of the excited state. The splitting energy between the t_{2g} and e_g levels has been calculated as the average of the two bands, the corresponding value being $\Delta_o = 10\,160$ cm^{-1}. The cobalt complex **3** exhibits a spectrum with two main absorptions: a broad one centered at 8420 cm^{-1}, assigned to the $^4T_{2g}(F) \leftarrow {}^4T_{1g}(F)$ (ν_1) transition and another at 20 325 cm^{-1}, assigned to $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$ (ν_3). This band presents a shoulder at higher wavenumber that could be

Table 2
Magnetic susceptibility data for compounds **1**–**4**

Compound	μ_{eff} (100 K)	μ_{eff} (298 K)	μ_{eff} $(T \rightarrow \infty)$	θ (K)
1 (Mn)	6.08	6.03	6.00	+2.6
2 (Fe)	5.37	5.42	5.42	−1.9
3 (Co)	4.90	4.98	5.03	−5.1
4 (Ni)	3.24	3.24	3.24	+1.2

μ_{eff} values are in BM.

due to the proximity of the $^2A_{2g}$ level or to spin–orbit coupling, which would also be responsible for the asymmetry of the ν_1 band. Ligand field parameters were calculated by Dou equations [22] on the basis of octahedral geometry giving $\Delta_o = 9580$ and $B = 872$ cm^{-1}. The transition $^4A_{2g}(F) \leftarrow {}^4T_{1g}(F)$ (ν_2) may be assigned to the weak shoulder at 18 000 cm^{-1}. The spectrum of **4** shows the typical three bands expected for octahedral Ni(II) complexes at 9530 $(^3T_{2g} \leftarrow {}^3A_{2g})$, 15 600 $(^3T_{1g} \leftarrow {}^3A_{2g})$ and 26 385 cm^{-1} $(^3T_{1g}(P) \leftarrow {}^3A_{2g})$, from which the parameters $\Delta_o = 9530$ cm^{-1} and $B = 982$ cm^{-1} were calculated. Finally, the spectrum of the copper complex **5** presents a very broad band with a shoulder, with a maximum at 17 150 cm^{-1} that can be assigned for a d–d transition in a d^9 configuration with distorted octahedral geometry (this may include tetragonal pyramidal or square planar). An additional band at 25 100 cm^{-1} may be attributed to a ligand–metal charge transfer transition.

The magnetic susceptibility of the paramagnetic compounds has been measured as a function of temperature and corrected for diamagnetism [23]. The values for compounds **1**–**4** have been adjusted by least squares to the Curie–Weiss law yielding the values of θ and μ_{eff} $(T \rightarrow \infty)$ indicated in Table 2, which also collects the values of μ_{eff} at 100 and 298 K. These are normal values for octahedral complexes and the variation with T for **2** and **3** (reflected in the negative values of θ) is attributable to the orbital contribution in a T ground state.

Compound **5** presents a quite different behaviour, the representation of the magnetic susceptibility versus T in the range 5–300 K shows a maximum at 70 K (Fig. 2), which is indicative of an antiferromagnetic interaction between the copper centers. Data have been fitted to the Bleany–Bowers equation for Cu(II) dimers [24] including the correction due to the presence of a small amount of the mononuclear species (indicated by the points at very low T). From this fitting the following values were obtained: $g = 2.17$, $2J = -87.82$ cm^{-1}, $\rho = 0.12$.

The X-band EPR spectrum of a powdered sample of this compound at room temperature also suggest its dinuclear nature. The main features of this spectrum have been assigned to $(S = 1,\ \Delta M_S = 1)$ transitions with axial symmetry. By means of computer simulations with the XEMR program [25], the values $g_{\parallel} = 2.25$, $g_{\perp} = 2.00$, $D = 0.168$ cm^{-1} have been obtained. Fig. 3 represents the experimental and the simulated spectra. The differences are attributable to the signal of the $S = 1/2$ transition (mononuclear species, around 3200–3300 G), not included in the simulation and the possible existence of a $\Delta M_S = 2$ (half-field) transition which should overlap with the strong signal at 1300–1500 G.

The magnetic susceptibility and EPR data are very similar to those found for the dimeric copper complex

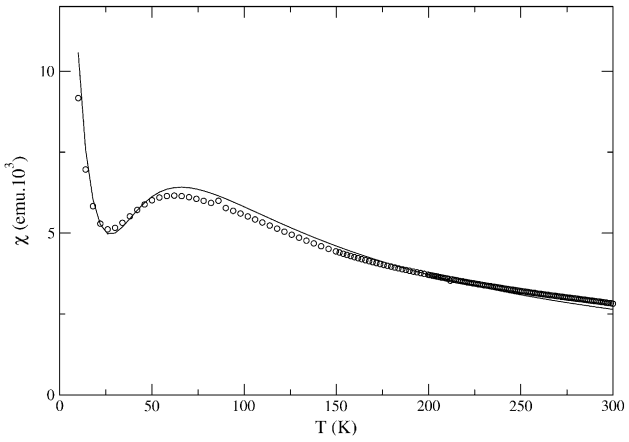

Fig. 2. Magnetic susceptibility of compound **5** as a function of temperature. Experimental data are represented by small circles which have been fitted to the Bleany–Bowers equation (solid line) with the parameters indicated in the text.

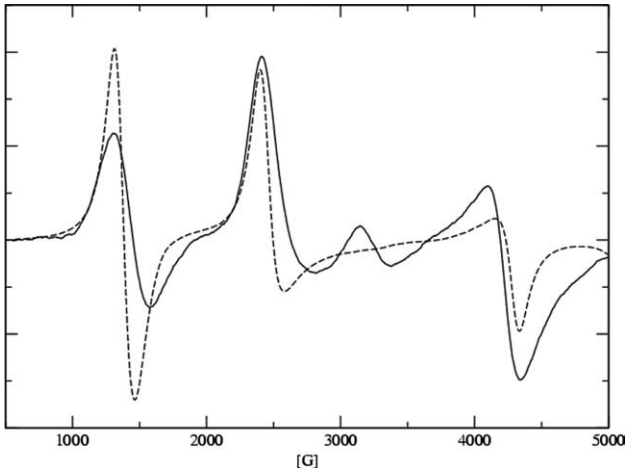

Fig. 3. Experimental (continuous line) and simulated (dashed line) X-band EPR spectra of compound **5**. Parameters for the simulation are indicated in the text.

with the isomeric ligand 4,5-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-5-one (5HtpO) [26], which let us propose for compound **5** a dinuclear structure with two metal atoms bridged by four $7tpO^-$ moieties linked through the N atoms at positions 3 and 4. Copper(II) complexes of purine bases with this kind of structure and strong antiferromagnetic coupling have been described [27] including one of hypoxanthine [28], the purine base for which 7HtpO is a mimic.

4. Supplementary data

The supplementary crystallographic data for this paper have been deposited in the CCDC (Deposition No. CCDC 220311). These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 30 June 2003; accepted 27 October 2003

Abstract

Ferrocenoylacetone [$C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$] reacts with 1,2-diaminoethane in refluxing ethanol to yield three isolated isomers $\mathbf{H_2L}$, $\mathbf{H_2L}^1$ and $\mathbf{H_2L}^2$. In solution, $\mathbf{H_2L}^1$ and $\mathbf{H_2L}^2$ can change into $\mathbf{H_2L}$ on standing over two days. Reaction of the tetradentate enaminone ligand [$C_5H_5FeC_5H_4C(O)CH{=}C(CH_3)NHCH_2]_2$ ($\mathbf{H_2L}$) with hydrated copper acetate and nickel acetate affords complexes **I** (**L**Cu) and **II** (**L**Ni). All compounds have been characterized by elemental analyses, ^{1}HNMR, IR and UV spectroscopies. The X-ray crystallography of complexes **I** and **II** reveals that the enaminone dianion coordinates to the central metal ion (copper and nickel) via two oxygen and two nitrogen atoms, and complex **I** exists as a mixture of the *anti* and *syn* isomers in a molar ratio of 1:1 while the complex **II** exists as a single *syn* isomer.

1. Introduction

Recently cyclic and acyclic multidentate ligands with varying combinations of donor atoms and charges have become increasingly popular for bonding transition metals, lanthanides and main group elements [1–3]. Among them, Group IV metal complexes of enaminones have attracted much attention because such complexes act as possible alternatives to catalysts containing the bent metallocene fragment Cp_2M, and anions generated from the enaminones are another potential isoelectronic alternatives to cyclopentadienyl-based anions [4–7]. Enaminones are easily prepared from inexpensive and readily available starting materials. Moreover, through a judicious choice of primary amine and β-diketone used in their syntheses, the steric and electronic properties of this ligand type can be tuned, and chirality and further functionalization readily introduced [8–10]. Although the reaction of ferrocenoylacetone and 1,2-diaminoethane, and transition metal complexes of the thus formed tetradentate ligand, have been studied, recently we have researched the above reaction in more detail in order to further develop the chemistry of organometallic enaminones [11,12]. Here we report the related results: syntheses and crystal structures of copper and nickel complexes with the tetradentate enaminone ligand [$C_5H_5FeC_5H_4C(O)CH{=}C(CH_3)NHCH_2]_2$ ($\mathbf{H_2L}$).

2. Experimental

2.1. Reagents and general procedures

All chemicals were of reagent grade and used without further purification. Ferrocenoylacetone [$C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$] was synthesized by acylation of acetylferrocene on the substituted cyclopentadienyl ring using ethyl acetate in THF in the presence of sodium

doi:10.1016/j.poly.2003.10.019

ethoxide [13–15]. Progress of the reactions was monitored by TLC (silica gel H). ^{1}H NMR spectra were determined on a Bruker Avance 300 spectrometer using TMS as an external standard in $CDCl_3$. IR spectra were recorded on a Perkin–Elmer 402 spectrometer as KBr disks in the range of 400–4000 cm^{-1}. UV spectra were measured with a Shimadzu UV-240 spectrometer using a solution in DMF. Analyses for C, H and N were performed on an Elementa Vario EL III instrument. Melting points were measured on a Yanagimoto apparatus and are uncorrected.

2.2. Reaction of ferrocenoylacetone and 1,2-diaminoethane

1,2-Diaminoethane (0.305 g, 5 mmol) was added to a solution of ferrocenoylacetone [$C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$] (1.35 g, 5 mmol) in 30 ml of absolute ethanol and then the mixture was refluxed for 10 h, during which time the product $\mathbf{H_2L}$ (0.305 g) was precipitated. The filtrate was evaporated to dryness and isolated by TLC using a mixed solvent of CH_2Cl_2 and ethanol (v/v, 5:2). The first orange band gives 0.282 g of acetylferrocene. The following three orange-yellow bands in the decreasing order of R_f values furnish 0.052 g of $\mathbf{H_2L}$, 0.40 g of $\mathbf{H_2L}^1$ and 0.122 g of $\mathbf{H_2L}^2$. $\mathbf{H_2L}$ (26.4%), D.p. 174 °C. *Anal.* Calc. for $C_{30}H_{32}N_2Fe_2O_2$: C, 63.86; H, 5.72; N, 4.96. 2.3. Syntheses of complexes

A solution of the ligand ($\mathbf{H_2L}$) (0.564 g, 1 mmol) in 15 ml of dichloromethane was added dropwise to a stirred solution of copper acetate monohydrate (0.1997g, 1 mmol) or nickel acetate tetrahydrate (0.2489 g, 1 mmol) in 15 ml of absolute ethanol. The mixture was stirred for 12 h at room temperature and then filtered to afford the crude product. The resulting solid recrystallized from ethanol and dichloromethane gave the corresponding complex. **I**, 0.563 g (90%) as black crystals. M.p. 201–202 °C (dry sample). *Anal.* Calc. for $C_{30}H_{30}N_2Fe_2O_2Cu$: C, 57.58; H, 4.84; N, 4.48. Found: C, 57.69; H, 4.88; N, 4.42%. IR (KBr disk): ν(C=O) 1578 (m), ν(C=C) 1511 (vs) cm^{-1}. UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$) 265 (3.52) (B-band); 344 (6.04) (K-band); 446 (0.48) (CT-band of ferrocenyl groups). **II**, 0.497 g (80%) as brown crystals.

2.4. Crystal structure determination

Single crystals of complex **I** were obtained by slow evaporation of its solution of CH_2Cl_2 and ethanol. Single crystals of complex **II** were obtained by slow evaporation of its solution of CH_2Cl_2 and petroleum ether. X-ray data were collected on an Enraf-Nonius CAD4 diffractometer for complex **I** and a Bruker SMART CCD area detector diffractometer for complex **II** using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 K. The intensity data were corrected using PSI-scan for complex **I** and Multi-scan for complex **II**. The structure was solved by direct methods and refined by full-matrix least-squares methods based on F^2 with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were placed in their calculated positions, assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. All computations were carried out using SHELXS-97 and SHELXL-97 programs [16,17]. ORTEP drawings were made with ORTEP-3 for Windows [18]. The unsubstituted cyclopentadienyl rings of complex **II** are highly disordered. A summary of the data collection and structure refinement parameters for the two complexes is given in Table 1. Selected bond distances (Å) and angles (°) are listed in Tables 2 (complex **I**) and 3 (complex **II**).

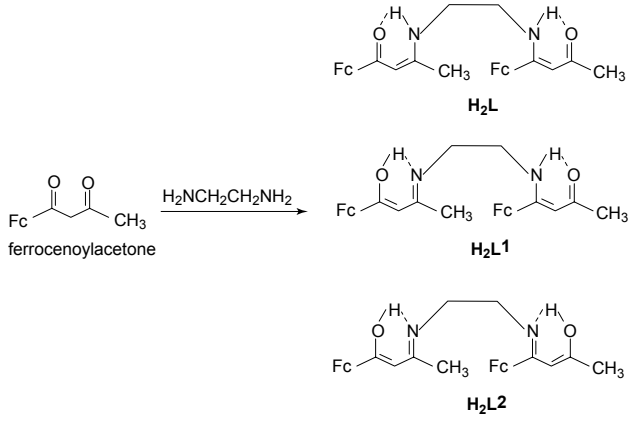
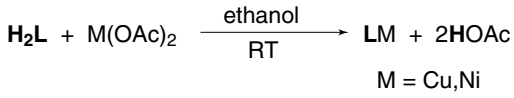
3. Results and discussion

3.1. Reaction of ferrocenoylacetone and 1,2-diaminoethane, and syntheses of complexes

Reaction of ferrocenoylacetone and 1,2-diaminoethane, and the syntheses of complexes are shown in Schemes 1 and 2 respectively. Reaction of ferrocenoylacetone [$C_5H_5FeC_5H_4C(O)CH_2C(O)CH_3$] and 1,2-diaminoethane in refluxing ethanol for 10 h followed by TLC separation affords three isolated isomers $\mathbf{H_2L}$, $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ as orange-yellow crystals in yields of 26.4%, 28.4% and 9%, respectively. In addition, acetylferrocene resulting from heated decomposition of ferrocenoylacetone is also isolated. More interestingly, in the solid state the three isomers cannot interchange whereas in solution either $\mathbf{H_2L^1}$ or $\mathbf{H_2L^2}$ can change into the more stable $\mathbf{H_2L}$ on standing over two days. For this reason, reactions of $\mathbf{H_2L}$ with copper(II) and nickel(II) ions at room temperature have been investigated. TLC analyses of complexes **I** (**L**Cu) and **II** (**L**Ni) show that the former



Scheme 1. Reaction of ferrocenoylacetone and 1,2-diaminoethane.



Scheme 2. Syntheses of complexes.

is a mixture of two isomers whereas the latter is a single isomer. However attempts to isolate any isomer of complex **I** have proven to be unsuccessful. In contrast, the same reaction of ferrocenoylacetone and 1,2-diaminoethane in refluxing methanol for 1.5 h furnished a ligand (H_2bfe) in a yield of 84% [11,12]. An analytical data comparison of the three isolated isomers $\mathbf{H_2L}$, $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ with H_2bfe reveals that $\mathbf{H_2L}$ seems to be H_2bfe [11]. However, none of the three isomers is fully consistent with H_2bfe. Therefore, perhaps H_2bfe is a mixture of the above isomers [13]. Complexes **I** and **II** were prepared in refluxing methanol and dichloromethane for 17 h [12]. In fact, at room temperature, $\mathbf{H_2L}$ can react with copper(II) and nickel(II) ions in ethanol and dichloromethane for 12 h to produce complexes **I** and **II**.

3.2. Spectra

The ^{1}H NMR spectrum of the free ligand ($\mathbf{H_2L}$) shows clearly that it exists entirely in the bis(ketoenamine) form (both acidic protons on enamine nitrogen atoms), namely $[C_5H_5FeC_5H_4COCH{=}C(CH_3)NHCH_2]_2$ [13,19–21]. The protons of the substituted cyclopentadienyl rings display two singlets at δ4.37 and 4.72 ppm, whereas a singlet at δ4.17 ppm is due to protons on the unsubstituted cyclopentadienyl rings. Moreover, methylene protons of the NCH_2 moiety exhibit a triplet at δ3.50 ppm. In contrast, the methyl protons show a singlet at δ2.02 ppm. A singlet at δ5.30 ppm may be assigned to two methine protons. A singlet signal attributed to the enamino NH appears at δ11.10 ppm and disappears in the presence of D_2O. The very downfield position of this signal may be mainly resulted from the intramolecular hydrogen bonding [13,22]. It is obvious that the above evidence is consistent with the proposed structure of the ligand [13,22]. Similarly, two other isomers $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ display corresponding absorptions [13,22]. For example, those of methyl, methylene, methine, unsubstituted cyclopentadienyl and substituted cyclopentadienyl (two triplets) groups appear at δ2.01, 2.03; 3.49, 3.50; 5.30, 5.30; 4.17, 4.19 and 4.36, 4.37 as well as 4.72, 4.72 ppm whereas signals of labile hydrogens are observed at δ11.1 and 11.11 ppm. For complex **II**, the signal corresponding to the enamino NH at ca. 11.1 ppm disappears and the absorption of methylene protons is present as a singlet, indicating that the ligand is deprotonated and bonded to the nickel ion which is also supported by the crystal structure as described below. In addition, all the signals of protons shift highfield in complex **II**, which may be due to the increase of electron density resulting from deprotonation and nickel-to-ligand feedback after forming the complex [12,23].

In the IR spectrum of the ligand, the band at ca. 3100 cm^{-1} due to ν(NH) appears. However, no band assignable to ν(NH) is present in the spectra of the complexes. This fact indicates that the ligand is bonded to copper and nickel ions in the dianionic form. Moreover, the strong bands attributed to the stretching vibrations of the skeleton C=O and C=C groups, which are observed at 1601, 1557 and 1520 cm^{-1} in the ligand, are red-shifted to the region 1576–1578 and 1511–1513 cm^{-1} in the complexes [3,13,19]. This is because the doubly deprotonated ligand ($\mathbf{L^{2-}}$) has a stronger conjugate effect which results in the decrease of the double bond character of C=O and C=C groups [13]. It is noted that $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ display the following absorptions at 3429, 3096, 1600, 1557, 1520 and 3417, 3090, 1599, 1561, 1523 cm^{-1}, respectively. Among the three isomers, the most marked differences result from the relative intensities of the four last characteristic absorptions.

The UV spectrum of the ligand shows three absorptions at 271, 342 and 450 nm, which are attributable to the B-band of the cyclopentadienyl ring, K-band of the skeleton and an intraligand charge transfer transition band [13,23]. Similarly, $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ display three absorptions at 265, 346, 453 and 271, 347, 446 nm, respectively. Because the three isomers have similar curves of UV absorptions, they should have similar conjugated systems. This further supports the proposed structures for the three isomers as described in Scheme 1. For complex **I**, the shortest wavelength absorption which is assigned as the B-band of the cyclopentadienyl ring displays a hypsochromic shift compared with that of the ligand [12,23]. However, the K-band at 344 nm shows a red shift. In addition, complex **I** exhibits an intense absorption band at 446 nm which may be due to a ligand-to-metal charge transfer transition. For complex **II**, interestingly, compared with those absorptions of the ligand, the B-band and K-band show hypsochromic shifts. It is noteworthy that as expected, tetrahedral complex **I** does not show a d–d absorption, however, the theoretically planar nickel complex **II** should exhibit a d–d absorption, in fact, the ligand field band of complex **II** is not observed because the weak d–d transition is obscured by other intense absorptions [13,23].

3.3. Crystal structures

In principle, in view of the planar or tetrahedral coordination geometry of the central metal ion (copper or nickel) and *anti* or *syn* arrangement of the ferrocenyl groups with respect to the mean plane with the central metal ion (copper or nickel) and donor atoms, four-coordinate copper or nickel complexes may have four stereoisomers: planar-*anti*, planar-*syn*, tetrahedral-*anti* and tetrahedral-*syn* [13].

3.3.1. Crystal structure of complex *I*

Complex **I** with solvent molecules belongs to the triclinic space group of $P\bar{1}$. In addition to one water molecule, one methanol molecule and one ethanol molecule, two independent molecules are contained in the asymmetric unit. ORTEP plots of the two independent molecules are shown in Figs. 1 and 2. Each of the two independent copper atoms displays a tetrahedral coordination by two nitrogen atoms and two oxygen atoms of the doubly deprotonated ligand ($\mathbf{L}^{2-}$), and complex **I** exists as a mixture of tetrahedral-*anti* and tetrahedral-*syn* isomers. In the former both ferrocenyl groups are *anti* and the two Fe atoms have a separation of 9.508 Å, while in the other both ferrocenyl groups are *syn* and the two Fe atoms are separated by 8.875 Å. As expected, the two six-membered chelate rings for each isomer are planar. The five-membered rings defined by the copper atom and diaminoethane moiety are definitely nonplanar, the ethylene bridges have a gauche conformation as usually observed, with torsion angles of 37.22° and 38.91° for N(3)–C(32)–C(33)–N(4) (*anti* isomer) and N(1)–C(3)–C(4)–N(2) (*syn* isomer), respectively. The angles O(3)–Cu(2)–N(4) and O(4)–Cu(2)–N(3) (mean 174.4(3)°) for the *anti* isomer and O(1)–Cu(1)–N(1) and O(2)–Cu(1)–N(2) (mean 172.1(3)°) for the *syn* isomer indicate that each coordination geometry of the two independent copper atoms is tetrahedral as described above. The measured N–Cu–N and O–Cu–O angles (Table 2) are close to the corresponding values observed in related structures [24–27]. A comparison of the Cu–O and Cu–N bond lengths (mean 1.924(6) and 1.927(8) Å for the *anti* isomer and 1.913(6) and 1.924(8) Å for the *syn* isomer) reveals them to be considerably shorter than those reported for *N*,*N*′-ethylenebis(acetylacetoneiminato)copper (mean 1.94 and 1.98 Å) [24]. Also, these are slightly smaller than the reported values of the complex bfeCu [11,12]. The bond length pattern within the six-membered ring system suggests partial delocalization of bonding electron density. For example, the C–O bond lengths of 1.27(1) and 1.29(1) Å for the *anti* isomer and 1.28(1) and 1.29(1) Å for the *syn* isomer are between a normal single bond (1.43 Å) and a normal double bond (1.23 Å). It is interesting that the ethylene bond lengths of 1.48(1) (C(32)–C(33)) for the *anti* isomer and 1.46(1) (C(3)–C(4)) for the *syn* isomer are significantly shorter than that for the related complex mentioned above (1.55 Å) and the complex bfeCu (1.514(6) and 1.510(7) Å) [12,24].

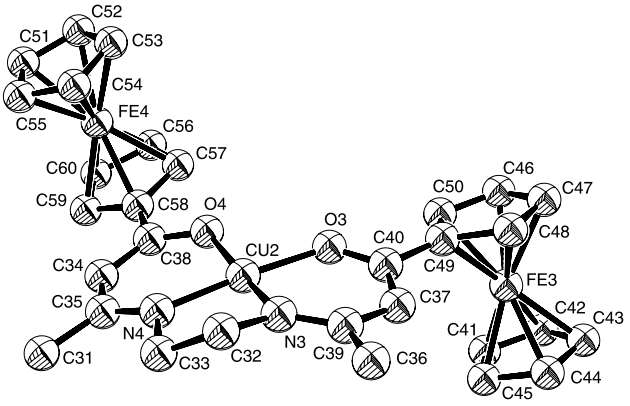


Fig. 1. An ORTEP plot of the *anti* isomer in the asymmetric unit of complex **I**. The atoms are drawn with 50% probability ellipsoids. Hydrogen atoms and solvent molecules are omitted for clarity.

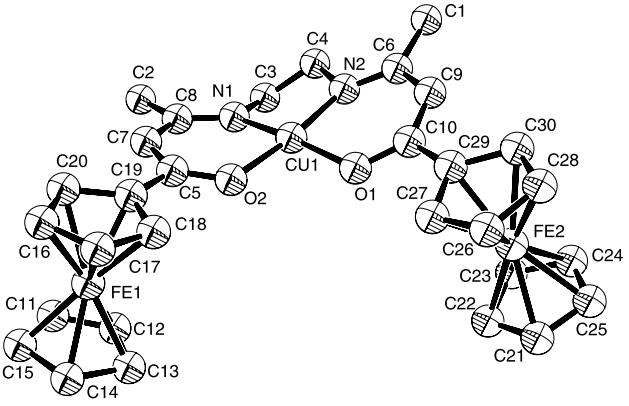

Fig. 2. An ORTEP plot of the *syn* isomer in the asymmetric unit of complex **I**. The atoms are drawn with 50% probability ellipsoids. Hydrogen atoms and solvent molecules are omitted for clarity.

3.3.2. Crystal structure of complex *II*

Complex **II** crystallizes in the monoclinic space group $P2_1/c$. Fig. 3 is its crystal structure. In the molecule of complex **II**, both ferrocenyl groups (the

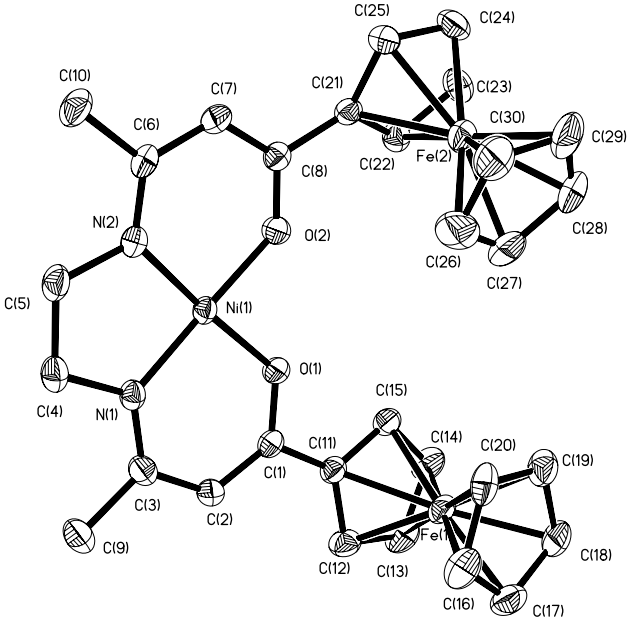

Fig. 3. An ORTEP plot of complex **II**. The atoms are drawn with 40% probability ellipsoids. Hydrogen atoms are omitted for clarity.

distance of the two Fe atoms is 6.604 Å) are *syn* to each other; in other words, complex **II** exists in the planar-*syn* form. The angles O(1)–Ni(1)–N(2) and O(2)–Ni(1)–N(1) (mean 176.7(1)°) indicate that the coordination geometry of the nickel atom is planar as described above, which is in agreement with a measured standard and beautiful ^{1}H NMR spectrum and diamagnetism of complex **II** [12]. The Ni–O distances of 1.839(3) and 1.845(3) Å for Ni(1)–O(1) and Ni(1)–O(2) are very close to the corresponding values in related structures [21]. However, the Ni–N distances of 1.852(4) and 1.850(4) Å for Ni(1)–N(1) and Ni(1)–N(2) are significantly shorter than that for a related complex (1.910(4) Å) [21,28]. It is notable that to our knowledge examples of very close distances of Ni–N and Ni–O bonds are very scarce. The measured N–C, C–C and C–O bond distances in the six-membered rings of complex **II** are very close to the values 1.306(5), 1.361(6), 1.413(7) and 1.297(4) Å reported for a related nickel(II) complex, showing that the enaminoketonate ion is partially delocalized [21,28].

4. Supplementary data

Crystallographic data (CCDC 208967 for complex **I** and CCDC 208966 for complex **II**) have been deposited at the Cambridge Crystallographic Database Centre and is available on request from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (Fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http//www.ccdc.cam.ac.uk).

Abstract

Both the heterometal cluster $\{[FeMo_2O_{10}(FRA)_4(DMF)_4]\cdot 2DMF\}$ (**1**) (FRA = α-furoic acid) and the homometal cluster $\{Fe[DTC]_4\}$ (**2**) (DTC = diethyl-dithiocarbamate) were successfully synthesized by low-temperature solid-state reactions. X-ray single-crystal diffraction studies suggest that compound **1** is a hexanuclear cluster including two solvent DMF molecules, with α-furoic acid and DMF as auxiliary ligands, and compound **2** is a dinuclear neutral cluster. The two compounds were characterized by elemental analyses, IR spectra and UV–Vis spectra. The third-order nonlinear optical (NLO) properties of the clusters were also investigated and all exhibited nice nonlinear absorption and self-defocusing performance with moduli of the hyperpolarizabilities 1.21×10^{-31} esu for **1** and 5.123×10^{-31} esu for **2**.

1. Introduction

It has been found that iron plays a very important role in the biological system [1–6]. For example, the iron protein, one of the essential metalloproteins of nitrogenase, is a very specific ATP-activated electron donor to the other, the molybdenum–iron protein [1]. In iron protein, iron is present with the form of a [4Fe4S] subunit [2]. Some other metalloproteins such as methane monooxygenase (MMO) [3], ribonucleotide reductase (RR) [4], hemerythrin (Hr) [5] and purpleacid phosphatase (PAPs) [6] all belong to the class of non-heme diiron enzymes, which are capable of binding and activating dioxygen [7,8]. Their active sites contain either an Fe(II)-Fe(II)center (MMO, RR, Hr) or a mixed-valent Fe(II)-Fe(III) core (PAPs) which is directly involved in the reaction with dioxygen [9]. During studying the intricate mechanistic and structural details of these metalloproteins, the coordination chemistry of iron has been further developed, and a number of iron complexes have been synthesized in different models. For example, cubane-like clusters $Fe_4S_4(^tBu_3P)_3Cl$ [10], $(Et_3N)_3[(Meida)VFe_3S_4Cl_3]$ [11] (Meida = *N*-methylimidodiacetate(2−)), lineshape cluster $(Bu_4N)_3[(edt)_2M_2Fe_2S_6]$ [12] (M = Mo,W; edt = ethane-1,2-dithiolate) were synthesized to simulate nitrogenase. Several diiron peroxo complexes, such as $[Fe_2(N\text{-}Et\text{-}HPTB)(O_2)(Ph_3PO)_2](BF_4)_3\cdot 3CH_3CN$ (HPTB = *N*,*N*,*N*′,*N*′-tetrabis (2-benzimidazdylmethyl)-2-hydroxo-1,3-diaminopropane) [13] and $[Fe_2(ph\text{-}bimp)(O_2)(C_6H_5COO)](BF_4)_2\cdot 2CH_3CN\cdot C_2H_5OC_2H_5\cdot H_2O$ [14], have been prepared by the reaction of the corresponding diferrous precursor complex with dioxygen, which have been researched in more detail [14,15]. Their spectroscopy characteristics and structures have been studied. However, the third-order nonlinear optical (NLO) properties of them have been less well mentioned. In this paper, we not only describe the syntheses and structures of one heterometal cluster and one homometal cluster but also study their NLO properties.

2. Experimental

2.1. Materials and physical measurements

$(NH_4)_2MoS_4$ was prepared by a modified published procedure [16]. Other reagents were used as received from commercial suppliers without further purification. Infrared spectra of the title clusters were recorded as KBr pellets on a Perkin–Elmer Spectrum One FT-IR spectrometer in the 225–4000 cm^{-1} region. Element analyses were performed on a Perkin–Elmer 2400LSII element analyzer. Electronic spectra were measured on a Shimadzu UV-3100 spectrophotometer.

2.2. Synthesis of compounds

2.2.1. $[Fe_4Mo_2O_{10}(FRA)_4(DMF)_4]\cdot 2DMF$ (1)

A mixture of $(NH_4)_2MoS_4$ (0.3 g, 1 mmol), $FeCl_2\cdot 4H_2O$ (0.4 g, 2 mmol), α-furoic acid (0.5 g, 4.5 mmol) and $(CH_3)_4NBr$ (0.4 g, 2.5 mmol) was pestled for 30 min. After being sealed in a reaction tube, it was heated at 95 °C for 18 h. Then, the mixture was cooled to room temperature and extracted with 10 ml *N*,*N*′-dimethylformamide (DMF). Isopropyl alcohol (30 ml) was added slowly to the filtered extract. After the dark solution had stood without disturbance for one month, dark-red crystals were found (0.15 g, yield 61.4%, based on Mo). IR (KBr pellet, cm^{-1}): $\nu_{(asym,C=O)}$ 1657 (vs), $\nu_{(sym,C=O)}$ 1472 (s), 1427 (s), $\nu_{(Mo=O)}$ 1014 (m), 929 (m), $\nu_{(Mo–O–Fe)}$ 786 (s), $\nu_{(Fe–O)}$ 365 (w). *Anal*. Calc. for $C_{19}H_{27}Fe_2MoN_3O_{14}$: Mo, 26.32; Fe, 30.64; C, 31.29; H, 3.83; N, 5.76. Found: Mo, 26.26; Fe, 30.51; C, 31.20; H, 3.82; N, 5.51%.

2.2.2. $Fe_2[(DTC)_4]$ (2)

A mixture of $(NH_4)_2MoS_4$ (0.2 g, 0.67 mmol), $FeCl_2\cdot 4H_2O$ (0.1 g, 0.5 mmol), cupric tartrate (0.1 g, 0.3 mmol) and sodium diethyl-dithiocarbamate (0.2 g, 1 mmol) was pestled for 30 min. It was heated at 90 °C for 24 h after being sealed in a reaction tube. Then the mixture was cooled to room temperature and extracted with 10 ml CH_2Cl_2. Isopropyl alcohol (10 ml) was added slowly to the filtered extract. After the brown solution had stood without disturbance for one month, black crystals were found (0.069 g, yield 78.3%, based on Fe). IR (KBr pellet, cm^{-1}): $\nu_{(Fe\text{-}S)}$ 327 (s), 359 (s). *Anal*. Calc. for $C_{10}H_{20}FeS_4N_2$: Fe, 15.84; C, 34.09; H, 2.84; N, 7.95. Found: Fe, 16.01; C, 35.1; H, 2.9; N, 7.8%.

2.3. X-ray crystal structure determination

Crystal data and structure refinement for the title compounds are given in Table 1. Selected bond lengths and angles are given in Table 2. Data were collected with Mo Kα radiation ($\lambda = 0.71073$ Å) using a Siemens SMART CCD diffractometer. The structures were solved using direct methods with the SHELXTL program

and refined by full-matrix least-squares techniques. The non-hydrogen atoms were assigned anisotropic displacement parameters in the refinement. The hydrogen atoms were treated using a riding model. The structure was then refined on F^2 using SHELXTL-97.

3. Results and discussion

3.1. Syntheses

Low-temperature solid-state reaction is a very ideal method to synthesize clusters containing sulfur atoms, for example $[MS_4(Cu(P\text{-}MeOC_6H_4)_3P_2)]\cdot 0.5C_6H_{12}$ (M = Mo,W) [17] and $[(n\text{-}Bu)_4N]_3[WS_4Cu_3Cl_3Br]$ [18] were both obtained by this method, with $(NH_4)MS_4$ (M = Mo,W) as a precursor. Mo–Fe–S clusters including auxiliary ligands would have been designed based on this method. Unluckily, in the reaction of compound **1**, there is no sulfur atom in the product, and many light-yellow crystals were found at the bottom of the flask, which were identified as S_8 by its IR spectrum. From these facts it is supposed that all of the sulfur atoms of $(NH_4)_2MoS_4$ were substituted by oxygen atoms from the atmosphere. The reaction can be demonstrated by the following equation:

$$4FeCl_2 \cdot 4H_2O + 2(NH_4)_2MoS_4 + 4C_4H_3OCOOH + 6DMF + 5O_2 \rightarrow [Fe_4Mo_2O_{10}(FRA)_4(DMF)_4] \cdot 2DMF + S_8 + 4HCl + 4NH_4Cl + 16H_2O$$

While in the reaction of compound **2**, only the iron atoms were coordinated by sulfur atoms coming from DTC molecules. So we can conclude that the iron atom is easier to coordinate by DTC than the molybdenum atom.

3.2. Crystal structures

3.2.1. $[Fe_4Mo_2O_{10}(FRA)_4(DMF)_4]\cdot 2DMF$ (1)

The molecular structure of compound **1** is shown in Fig. 1. It is a hexanuclear $[Mo_2Fe_4O_{10}]$ cluster including two solvent DMF molecules, with α-furoic acid and DMF as auxiliary ligands. In each molecule unit there exist crystallographically one unique Mo atom and two Fe atoms. The Mo atom, coordinated by the terminal oxygen atom [O(9)] and three μ_2-oxygen atoms [O(11), O(12), O(13)], is in a tetrahedral coordination circumstance, with a distance to the terminal O(9) of 1.694(4) Å, which is shorter than the ones of Mo–(μ_2-O) [1.777(4)–1.810(4) Å] as expected. The O–Mo–O angles 107.2(2)°–112.50(17)° suggest that the tetrahedron is distorted. Although the two iron atoms are both in octahedrons, they have different coordination circumstances. Fe(1) is coordinated by two μ_3-oxygen atoms [O(10) and O(10A)], two μ_2-oxygen atoms [O(13) and O(12A)] and two oxygen atoms from two carboxyl of α-furoic acid molecules [O(4A) and O(6)]; while μ_3-O(10), μ_2-O(11), two oxygen atoms from DMF molecules [O(1) and O(2)] and two oxygen atoms from carboxyl of α-furoic acid molecules [O(3) and O(5)] coordinate to Fe(2). In the two kinds of octahedrons $[Fe(1)O_6]$ and $[Fe(2)O_6]$, the mean distance of Fe–(μ_2-O) (2.027 Å) is longer than that of Fe(2)–(μ_3-O) (1.883(3) Å) and Fe(1)–(μ_3-O) (1.972(3), 1.985(3) Å), and shorter than the mean length between the iron atom and the oxygen atoms from ligands 2.034 Å. The range of *cis*-angles and *trans*-angles are 83.12(13)°–96.60(14)° and 168.55(15)°–177.94(14)°, respectively, which suggests that the octahedrons are strongly distorted. As shown in Fig. 2, the two octahedrons $[Fe(1)O_6]$ and $[Fe(1A)O_6]$ share an edge O(10)–O(10A) with each other, and also share a corner with $[Fe(2)O_6]$ (or $[Fe(2A)O_6]$) by μ_3-O [O(10) or O(10A)]. Moreover, the tetrahedral $[MoO_4]$ share the corners with its adjacent octahedrons by three μ_2-O atoms [O(11), O(12) and O(13)]. There is a hydrogen bond, C(15)–H···O(13) [3.320Å, 144.5°], between the μ_2-O atom [O(13)] and the C(15) of α-furoic acid in the adjacent iron–molybdate cluster, which connect the cluster units $[Fe_4Mo_2O_{10}]^{4+}$ into a one-dimensional supramolecular chain.

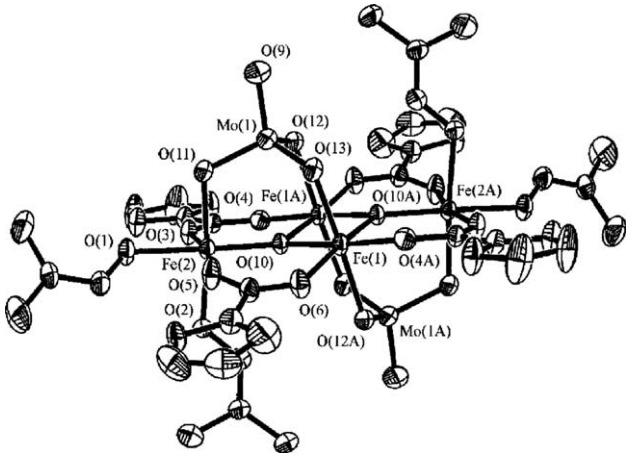

Fig. 1. The view of the structure of $\{Fe_4^{III}Mo_2^{VI}O_{10}(FRA)_4(DMF)_4\}$.

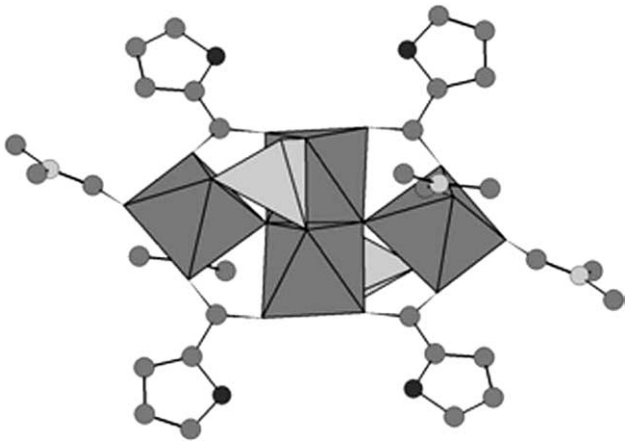

Fig. 2. The polyhedron represents of the structure of compound **1**. The deep grey polyhedrons represent the FeO_6 octahedron, the light ones represent MoO_4 tetrahedron.

3.2.2. $Fe_2[(Dtc)_4]$ (2)

As shown in Fig. 3(a), compound **2** is a dinuclear neutral cluster. The dimer can be described as two distorted square pyramids doubly bridged by the sulfur atoms occupying the axial sites. In the square pyramid, four sulfur atoms coming from two DTC molecules, composing the equatorial plane, meanly deviate 0.1088 Å from the least-squares plane, above which the iron atom is displaced by 0.2774 Å. In the equatorial plane, as S3 is a μ_2 atom, the Fe–S (2.3047(11)–2.3202(8) Å) distance is shorter than Fe(1)–(μ_2-S3) 2.3338(8) Å, while all of them are longer than Fe–SR in Cubane type MFe_3S_4 (M = Mo,W,V) 2.232 Å [19]. The axial direction distance of Fe(1)–(μ_2-S3A) 2.801(26) Å is shorter than the van der Waals 2.965 Å. There are two types of weaker intermolecular interactions (shown in Fig. 3(b)). One exists between the iron atom and the hydrogen atom attached to C4A coming from another dinuclear cluster, and the Fe···H–C distance 3.761 Å and angle 143.5° both can be comparable to those of M···H–C

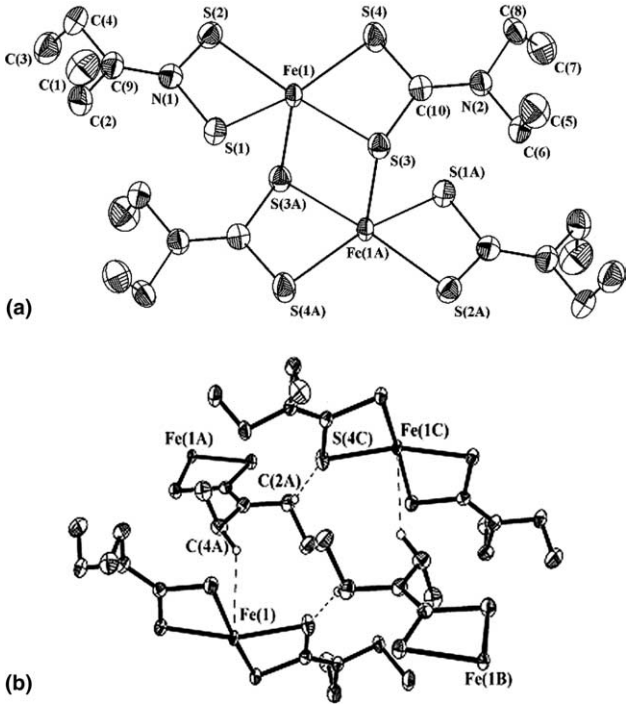

Fig. 3. (a) The perspective view of the molecule of **2**. (b) A view of the intermolecular interactions of **2**.

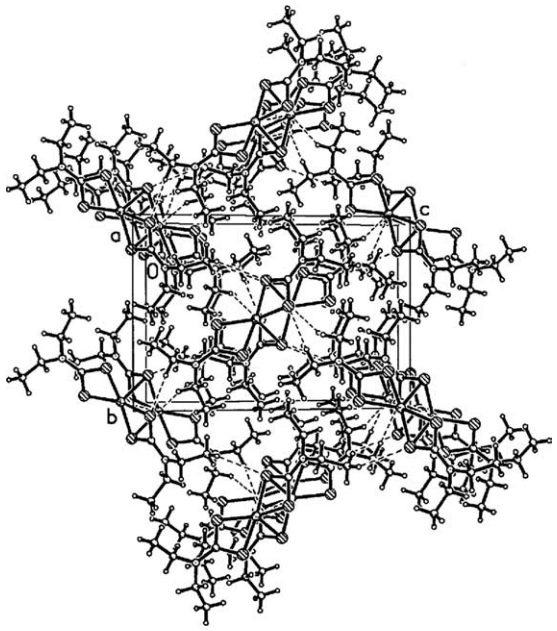

Fig. 4. A view of the packing diagram of compound **2**.

hydrogen bonds reported previously [20], although the ligand, coordinated to the metal center, does not contain electronegative atoms (chiefly oxygen and nitrogen but also sulfur and chlorine). The other is between the C2A atom as the hydrogen-donor and S4C as the acceptor, and the S(4C)···H–C(2A) distance 3.753 Å is longer than that of S···H–C hydrogen bonds (3.44–3.53 Å), which contains electronegative atoms (chlorine) [21]. Because of the intermolecular interactions, a two-dimensional network structure of compound **2** is formed. Fig. 4 shows the packing view of compound **2**.

3.3. Nonlinear optical properties

The electronic spectra of the title compounds were given in Fig. 5 and the absorption band and attribution were listed in Table 3. (The molar extinction coefficient is in the bracket, $cm^{-1}\,mol^{-1}\,dm^3$.) The electronic spectra of the title clusters show relatively low linear absorption in the visible and near-infrared regions, promising low-intensity loss, and little temperature change caused by photon absorption when pulsed light propagates in the materials both show that the clusters have potential as optical limiters have potential as optical limiters [22].

So the NLO properties of the title clusters were evaluated by a Z-scan technique with a Q-switched frequency-doubled Nd:YAG laser at 532 nm with 7 ns pluses. The DMF solution was contained on a 5-mm thick quartz cell with a concentration of 1.71×10^{-4} and 7.804×10^{-4} M

Table 3
The UV-spectra absorption (nm) and attribution

1		2	
Absorption	Attribution	Absorption	Attribution
265.5 nm (5.3×10^5)	(d)Mo ← (π)O	272.4 nm (1.91×10^4)	(d)Fe ← (π)S
316.5 nm (2.4×10^4)	(d)Fe ← (π)O	291.8 nm (1.03×10^4)	(d)Fe ← (π)S
461.5 nm	d ← d	433.5 nm (1.37×10^3)	d ← d
		628.5 nm (1.98×10^3)	d ← d

for **1** and **2**, respectively. The Z-scan data of the cluster **1** and **2** are given in Figs. 6 and 7, respectively, where the open circles represent the experimental data and the solid curves represent the theoretical data based on Z-scan theoretical calculations [23,24]. From the effective third-order NLO absorption coefficient α_2, the effective nonlinear refractive index n_2 (given in Table 4) and the figures, we can conclude that both of the two clusters exhibit strong reverse saturable absorption (RAS) and effective self-defocusing performance. In accordance with the observed α_2 and n_2 values, the modulus of the effective third-order susceptibility $\chi^{(3)}$ can be calculated by the following equation:

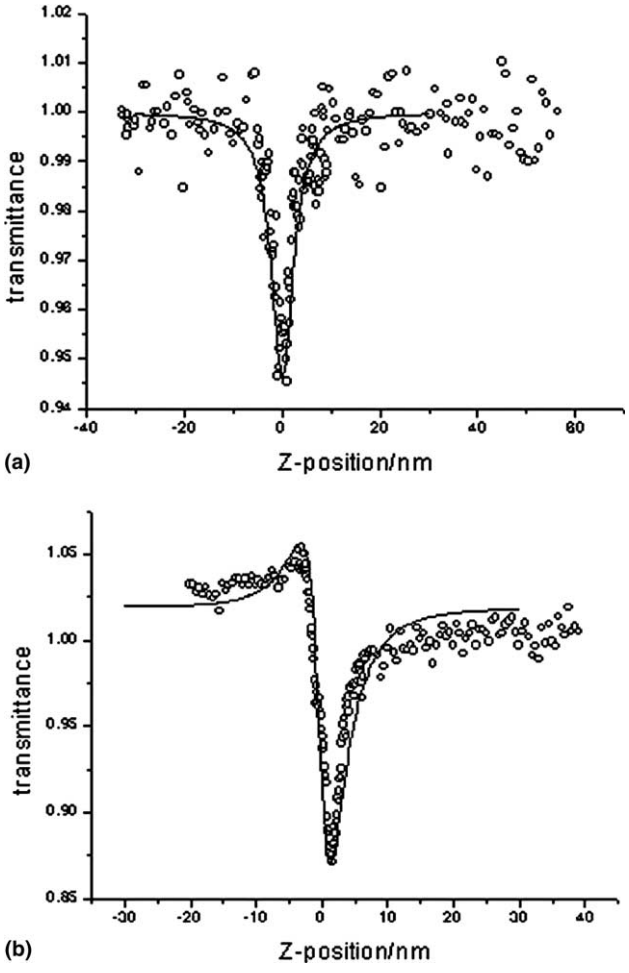

Fig. 6. Open-aperture (a) and close-aperture (b) of Z-scan data (the solid curve is a theoretical fit) of compound **1**.

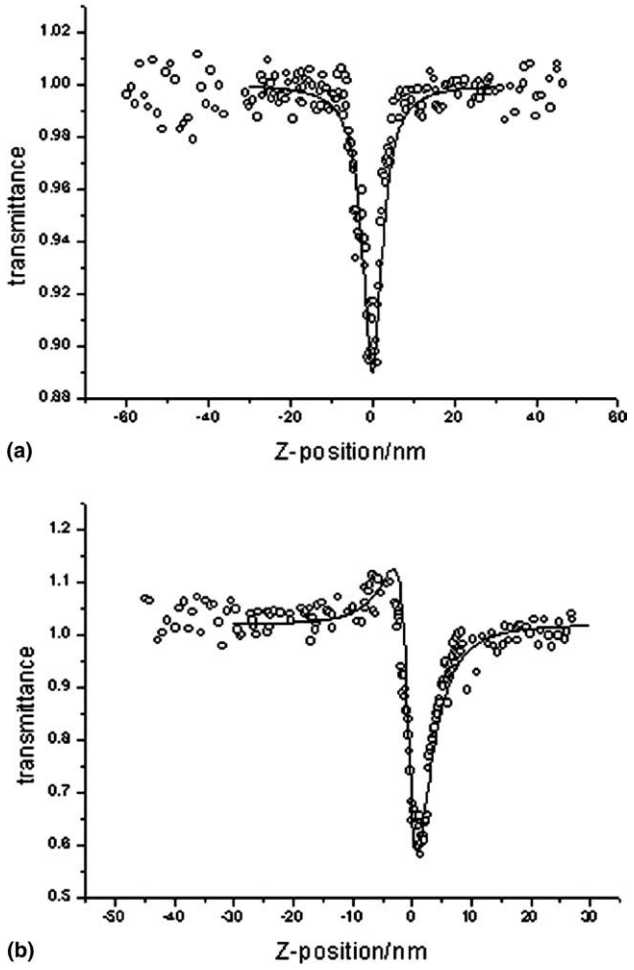

Fig. 7. Open-aperture (a) and close-aperture (b) of Z-scan data (the solid curve is a theoretical fit) of compound **2**.

$$|\chi^{(3)}| = [(9 \times 10^8 \varepsilon_0 n_0^2 c\lambda\alpha_2/8\pi^2)^2 + (n_0^2 c n_2/80\pi^2)^2]^{1/2}.$$

Here, λ is the wavelength of the laser light, n_0 is the linear refractive index of the sample, ε_0 and c are the permittivity and the speed of light in a vacuum, respectively. The corresponding moduli of the hyperpolarizabilities γ was obtained from $|\gamma| = |\chi^{(3)}|/NF^4$, where N is the number density of the clusters in the samples, and $F^4 = [(n^2+2)/3]^4$ (n is the linear refractive index of the solvent, 1.43 for DMF). All the calculated results and some literature data on the NLO properties are listed in Table 4, from which we can see that the NLO

performances of the clusters containing sulfur atoms are better than those of the cluster containing no sulfur atom, and the more sulfur atoms, the stronger the NLO performances. It also has been proved that both the cluster skeletons and the heavy atoms are responsible for the NLO effects [26], but which one plays the more important role is still not clear and needs to be further explored.

4. Supplementary material

Additional details of the two compounds structure determinations and data tables have been deposited at the Cambridge Crystallographic Data Centre (CCDC No. 200991 for **1**, No. 215548 for **2**). Copies of these information may be obtained free of charge from the Director, CCDC 12 Union Road, Cambridge, CB12 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

An effective method for the synthesis of 4,4,5,5-tetramethyl-3-oxide-1-oxyl-4,5-dihydro-1*H*-imidazole-2-carbonitrile (**1**) has been found. 4,4,5,5-Tetramethyl-3-oxide-1-oxyl-4,5-dihydro-1*H*-imidazole-2-carboxylic (**8**) and 4,4,5,5-tetramethyl-1-oxyl-4,5-dihydro-1*H*-imidazole-2-carboxylic (**9**) acid amides have been synthesized and structurally characterized using **1** as the starting compound. Reactions of $Mn(hfac)_2$, $Cu(hfac)_2$ and $Co(hfac)_2$ with **8** and **9** lead to heterospin compounds tending to form in solid bi- or tetranuclear complexes due to intermolecular H-bonding between the peripheral NH_2 groups and the coordinated carbonyl oxygen atoms.

Keywords: Nitronyl nitroxide; Imino nitroxide; Amide; Manganese complexes; Copper complexes; Cobalt complexes

1. Introduction

Nitronyl and imino nitroxides are valuable building blocks for design of heterospin exchange clusters and highly dimensional systems with high energies of exchange between the odd electrons of the paramagnetic centers. This is the reason for sustained interest in these compounds from researchers engaged in molecular magnet design [1–4]. Importantly, the structure of heterospin systems formed by coordination of nitronyl and imino nitroxides to metal ions largely depends on the spatial and electronic characteristics of substituents in the radical molecule. Variation of these substituents is an effective tool for selective control over the magnitude and sign of exchange interaction energies within heterospin exchange clusters [5]. Furthermore, in addition to the substituent effect on the character of exchange interactions between the odd electrons of the paramagnetic centers, introduction of donor groups in the structure of the substituent becomes a significant factor which opens up an opportunity of coordination to the donor atoms of the substituent, drastically enhancing the potential of the given nitroxide in design of magnetically active systems. Multifunctional nitronyl and imino nitroxides, therefore, continuously grow in number. The basic procedure giving new nitronyl and imino nitroxides to be applied to design of heterospin systems and molecular magnets is Ullman's classical method for the synthesis of nitronyl and imino nitroxides [6,7]. In this procedure, 2,3-bis(hydroxylamino)-2,3-dimethylbutane reacts with a specially designed aldehyde or its synthetic equivalent with subsequent oxidation of 1,3-dihydroxyimidazolidine into nitroxide. In view of some essential limitations of this method such as inaccessibility of the aldehyde, an alternative synthetic approach is modification of the substituent itself in the structure of the nitroxide. Using this approach, we have developed syntheses of new compounds – 4,4,5,5-tetramethyl-4,5-dihydro-1*H*-imidazole-3-oxide-1-oxyl-2-carboxylic (**8**) and 4,4,5,5-tetramethyl-1-oxyl-4,5-dihydro-1*H*-imidazole-2-carboxylic (**9**) acid amides using 4,4,5,5-tetramethyl-3-oxide-1-oxyl-4,

5-dihydro-1*H*-imidazole-2-carbonitrile (**1**) as a substrate. Spin-labelled amides **8** and **9** were subsequently employed in syntheses of heterospin complexes based on metal hexafluoroacetylacetonates. Crystallization of these complexes from solution leads to specific bi- or tetranuclear multispin molecules whose synthesis, structure and magnetic properties are discussed in the present paper.

2. Experimental

2.1. Materials and instruments

The reactions were monitored by TLC on Silica gel 60 F_{254} aluminum sheets (Merck). IR spectra were recorded for KBr pellets on a Vector 22 (Bruker) spectrometer. 2-Bromo-4,4,5,5-tetramethyl-4,5-dihydro-1*H*-imidazole-3-oxide-1-oxyl (**3**) was prepared by the procedure described in [8] except that the bromo derivative was recrystallized from ethyl acetate containing ~5% Et_3N. $M(hfac)_2 \cdot nH_2O$, where M = Cu [9], Mn [10], Co [10], was prepared by known procedures. Prior to its use in the synthesis, $Cu(hfac)_2$ was purified by sublimation. All reagents and organic solvents were analytical quality and used as purchased. All solvents were removed at reduced pressures.

2.2. Syntheses of nitroxides

2.2.1. 4,4,5,5-Tetramethyl-3-oxide-1-oxyl-4,5-dihydro-1H-imidazole-2-carbonitrile (*1*)

A mixture of **3** (1.20 g, 5.08 mmol) and Et_3N (0.3 ml) in DMF (7 ml) was stirred in an argon atmosphere for 20 min. Then NaCN (1.0 g, 20 mmol) was added, and the flask was immediately placed on a water bath at ~60 °C. The reaction mixture was stirred for 40 min, diluted with $CHCl_3$ (20 ml) and filtered on a glass filter funnel (porosity 1, ∅ 60 mm) at a pressure of ~300–400 Torr. The filtrate was diluted with benzene (20 ml) and hexane (20 ml) and kept overnight in a refrigerator at ~0 °C. The resulting precipitate was filtered off and recrystallized with filtration from THF (20 ml) to give 0.40 g (43%) of **1** [11].

The filtrates were combined; the solvents were removed on a water bath at a temperature not higher than 60 °C. The residue was dissolved with heating in benzene (15 ml) and chromatographed on a SiO_2 column (1.5 × 22 cm, the product eluted with benzene). The orange fraction was collected, the solvent removed, and the residue recrystallized from hexane to give 0.13 g (15%) of **4**. The greenish-blue fraction additionally gave 0.16 g (18%) of **1**.

2.2.2. 4,4,5,5-Tetramethyl-1-oxyl-4,5-dihydro-1H-imidazole-2-carbonitrile (*4*)

A mixture of **1** (0.50 g, 2.75 mmol), $NaNO_2$ (0.50 g, 7.25 mmol), AcOH (0.8 ml), H_2O (0.8 ml) and $CHCl_3$ (15 ml) was stirred at 40–50 °C for 2 h. The mixture was filtered through an Al_2O_3 column (1.5 × 10 cm); the column was washed with $CHCl_3$. The solvent was removed, and the residue recrystallized from hexane to give 0.35 g (77%) of **4** [6], $\mu_{eff}/\beta = 1.73$ (295 K).

2.2.3. 4,4,5,5-Tetramethyl-4,5-dihydro-1H-imidazole-3-oxide-1-oxyl-2-carboxylic acid amide (*8*)

A mixture of nitrile **1** (50 mg, 0.27 mmol), Et_3N (0.1 ml) and water (2 ml) was stirred for 1 h at room temperature and poured to $CHCl_3$ (30 ml). The resulting mixture was dried with Na_2SO_4 and chromatographed on a SiO_2 column (1.5 × 10 cm, by-products eluted with $CHCl_3$; the product eluted with AcOEt). The solvent was distilled off, the residue was ground with petroleum ether, the solvent was decanted, and the resulting crystals were dissolved in CH_2Cl_2 (2 ml). Then *n*-heptane (2 ml) was added carefully, and the mixture was kept in an open flask at 25 °C to give blue-violet crystals suitable for an X-ray investigation. Yield: 29 mg (53%); m.p. 166–167 °C with decomp. IR (KBr, ν/cm^{-1}): 575, 656, 866, 1140, 1171, 1224, 1308, 1376, 1415, 1460, 1591, 1704, 2989, 3218, 3328. Calc. for $C_8H_{14}N_3O_3$: C, 48.0; H, 7.1; N, 21.0. Found: C, 47.9; H, 7.0; N, 21.0%.

2.2.4. 4,4,5,5-Tetramethyl-1-oxyl-4,5-dihydro-1H-imidazole-2-carboxylic acid amide (*9*)

Procedure 1. A mixture of nitrile **4** (85 mg, 0.51 mmol), Et_3N (0.05 ml) and water (2 ml) was stirred for 6 h at room temperature. The solvent was distilled off and the residue was dissolved in $CHCl_3$ (15 ml). The resulting solution was dried with Na_2SO_4 and chromatographed on a SiO_2 column (1.5 × 5 cm, the product eluted with AcOEt). Then the product was purified as described for **8**. Yield: 52 mg (55%); m.p. 100–101 °C. IR (KBr, ν/cm^{-1}): 580, 651, 816, 883, 957, 1131, 1231, 1371, 1427, 1447, 1587, 1690, 1722, 2986, 3145, 3395. Calc. for $C_8H_{14}N_3O_2$: C, 52.2; H, 7.7; N, 22.8. Found: C, 52.3; H, 7.9; N, 22.9%.

Procedure 2. A mixture of **8** (0.10 mg, 0.50 mmol) and $NaNO_2$ (40 mg, 0.58 mmol) in DMF (3 ml) was stirred at 40–50 °C for 2.5 h. The solvent was distilled off, and the residue extracted with hot hexane (3 × 5 ml). The solution was concentrated to 5 ml and cooled to give 36 mg (39%) of **9**.

2.3. Syntheses of complexes

2.3.1. [Cu(hfac)$_2$*8*] (*10*)

Hexane (10 ml) was added to a solution of $Cu(hfac)_2$ (45 mg, 1 mmol) and **8** (20 mg, 1 mmol) in CH_2Cl_2 (2 ml). The reaction mixture was kept for 1 day in an open flask at room temperature. The perfect red-green dichroic crystals were filtered off, washed with cold hexane, and air dried. Yield: 45 mg (66%). IR (KBr, ν/cm^{-1}): 546, 592, 621, 677, 803, 1087, 1143, 1206, 1258,

1326, 1374, 1403, 1472, 1530, 1552, 1603, 1645, 1699, 3175, 3325. Calc. for $C_{18}H_{16}N_3CuF_{12}O_7$: C, 31.9; H, 2.4; N, 6.2. Found: C, 31.7; H, 2.2; N, 6.0%.

2.3.2. *[Mn(hfac)$_2$**8**] (**11**)*

Hexane (10 ml) was added to a solution of $Mn(hfac)_2 \cdot 2H_2O$ (50.5 mg, 1 mmol) and **8** (20 mg, 1 mmol) in CH_2Cl_2 (2 ml). The reaction mixture was kept for 1 day in a refrigerator. The perfect red-brown crystals were filtered off, washed with cold hexane, and air dried. Yield: 48 mg (74%). IR (KBr, ν/cm^{-1}): 584, 629, 666, 741, 799, 1145, 1210, 1258, 1379, 1397, 1418, 1498, 1532, 1557, 1595, 1648, 1697, 3249, 3295, 3400. Calc. for $C_{18}H_{16}N_3F_{12}MnO_7$: C, 32.3, H,2.4; N, 6.3. Found: C, 32.1; H, 2.7; N, 6.2%.

2.3.3. *[Cu(hfac)$_2$**9**] · C$_6$H$_6$ (**12a**); [Cu(hfac)$_2$**9**] · C$_6$H$_5$CH$_3$ (**12b**)*

Heptane (15 ml) was added to a solution of $Cu(hfac)_2$ (45 mg, 1 mmol) and **9** (20 mg, 1 mmol) in CH_2Cl_2 (5 ml). The reaction mixture was kept for 1 day in an open flask at room temperature. The yellow-brown fine powder precipitate was filtered off, washed with cold heptane, and air dried. According to elemental analysis data, the product had the formula *[Cu(hfac)$_2$**9**]*. Calc. for $C_{18}H_{16}N_3CuF_{12}O_6$: C, 32.7; H, 2.4; N, 6.4. Found: C, 33.1; H, 2.5; N, 6.1%. Yield: 40 mg (62%). Recrystallization from benzene or toluene gave unstable (after separation from the mother solution) solvate single crystals **12a** and **12b** suitable for an X-ray diffraction study. The crystals of *[Cu(hfac)$_2$**9**]* (**12c**) containing no solvate molecules were prepared as follows. A mixture of solid $Cu(hfac)_2$ (45 mg, 1 mmol) and **9** (20 mg, 1 mmol) was dissolved in ethyl acetate (15 ml); the resulting solution was filtered, and the mother solution was kept for five days in an open flask at room temperature. The light brown crystalline precipitate was filtered off, washed with cold heptane, and air dried. Yield: 48 mg (74%). IR (KBr, ν/cm^{-1}): 591, 671, 744, 767, 799, 1091, 1146, 1203, 1258, 1379, 1415, 1457, 1494, 1530, 1557, 1606, 1645, 1712, 3231, 3383. Calc. for $C_{18}H_{16}N_3CuF_{12}O_6$: C, 32.7; H, 2.4; N, 6.4. Found: C, 32.2; H, 2.3; N, 6.1%.

2.3.4. *[Mn(hfac)$_2$**9**] · C$_6$H$_6$ (**13**)*

A mixture of $Mn(hfac)_2 \cdot 2H_2O$ (50.5 mg, 1 mmol) and **9** (20 mg, 1 mmol) was dissolved in benzene (10 ml) and kept for five days in a refrigerator. The brown crystalline precipitate was filtered off and washed with cold hexane. Yield: 55 mg (78%). For an X-ray study, crystals **13** were immediately sealed, because they lost crystallization benzene molecules faster than **12a**. Magnetic measurements were also fulfilled for freshly prepared samples of **13**. Before elemental analysis, compound **13**, which is unstable under normal conditions, was desolvated by thermal storage at 50 °C in a vacuum chamber for 6 h until constant weight. Calc. for $C_{18}H_{16}MnF_{12}N_3O_6$: C, 33.1; H, 2.5; N, 6.4. Found: C, 33.4; H, 2.3; N, 6.1%.

2.3.5. *[Co(hfac)$_2$**9**] (**14**)*

Heptane (15 ml) was added to a solution of $Co(hfac)_2 \cdot 2H_2O$ (51 mg, 1 mmol) and **9** (20 mg, 1 mmol) in CH_2Cl_2 (5 ml). The reaction mixture was kept

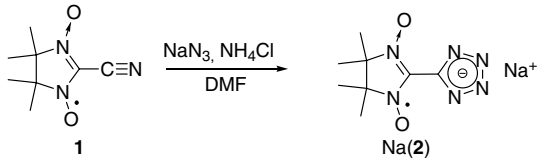
2.4. X-ray structure determination

For **8**, **10**, **11** (P4 Bruker AXS) and **4**, **9**, **12**–**15** (Smart APEX Bruker AXS), data were collected on an automatic diffractometer. The structures were solved by direct methods and refined by the full-matrix least-squares technique on F^2 in an anisotropic approximation for all non-hydrogen atoms. Hydrogen atoms were located from the difference Fourier maps and refined in an isotropic approximation. All calculations were performed using SHELX 97 on an IBM PC AT (Tables 1 and 2).

2.5. Magnetic measurements

All measurements were carried out on an MPMS-5S (''Quantum Design'') SQUID magnetometer at temperatures from 2 to 300 K in an external magnetic field of up to 5 kOe. The molar magnetic susceptibility (χ) of the compounds was calculated using Pascal's additive scheme including diamagnetic corrections and temperature-independent paramagnetism of Cu(II) ions taken to be 60×10^{-6} cm^3/mol. The effective magnetic moment was determined by the formula $\mu_{\text{eff}} = [(3k/N_A\beta^2)\chi T]^{1/2} \approx (8\chi T)^{1/2}$, where k is Boltzmann's constant, N_A is the Avogadro number and β is the Bohr magneton.



Scheme 1.

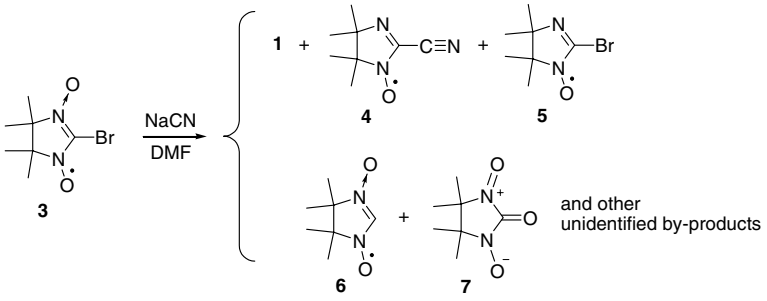
3. Results and discussion

3.1. Synthesis of spin-labelled nitriles

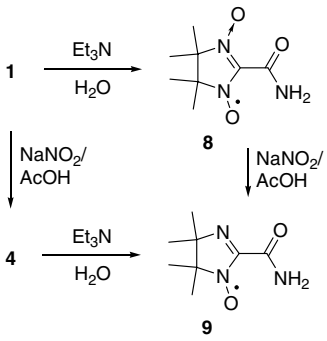
As stated in the Introduction, the increasingly wide use of multifunctional nitronyl and imino nitroxides has stimulated the development of new synthetic approaches. One of these is modification of a substituent in the structure of nitroxide not affecting the free valence. This approach was reported in [8,12]. We have concentrated on the nitrile derivative **1**, because the presence of a –C≡N group opens up an opportunity of nitroxide multifunctionalization in the vicinity of the radical fragment. Thus, recently, we have reported on the synthesis of a new spin-labelled Na(**2**) tetrazole (Scheme 1) and highly dimensional heterospin complexes with this ligand [13], obtained by using **1** as a starting compound.

Compound **1** was first described by Boocock and Ullman [14]; it was noted that the nitroxide is highly reactive. Details of this synthesis were not discussed [14]. A recently suggested procedure for the synthesis of **1** [11] affords this compound in sufficient quantities for further experiments, but is very sensitive to the purity of the bromine-substituted precursor **3**, and also to the reaction temperature and time (Scheme 2). This limitation precludes the use of **1** as a synthon for planning retro syntheses of many new chelate-forming nitronyl and imino nitroxides possessing favorable structures for the preparation of highly dimensional heterospin systems.

Attempts to synthesize **1** face the following difficulty. The reaction of **3** with NaCN in DMF forms a mixture of products among which we identified (by TLC and comparison with authentic samples) nitroxides **1**, **4**, **5**, **6** and zwitterion **7** (Scheme 2). When the reaction is carried out at temperatures above or below the optimal temperature (~65 °C), **7** is the major reaction product. We have found that introduction of Et_3N in the reaction system stabilizes **3**, decreasing the number of by-products. In the presence of Et_3N, **7** is not formed at all. The reaction of **3** with NaCN in DMF in the presence of Et_3N occurs smoothly and does not demand careful preliminary purification of **3**, which is rather labile. The synthetic procedure suggested above in the



Scheme 2.



Scheme 3.

Experimental section simultaneously affords **1** and **4** with yields of the order of 60% and 15%, respectively. Imino nitroxide **4** may be obtained in a high yield (~75%) by reduction of **1** with $NaNO_2$ (Scheme 3).

Structure **1** was described previously [11,15]. An X-ray diffraction study of **4** indicated that the crystal structure of nitroxide **4** is identical to that of **1**. The molecule also has 2mm symmetry suggestive of a planar structure of the imidazoline ring (Fig. 1), and the oxygen atom is also disordered over two positions with weight 0.5. The N–O and C–N distances in the cycle are typical for nitronyl nitroxides (Table 3).

3.2. Syntheses and structures of spin-labelled amides and their complexes

Among the numerous derivatives of imino and nitronyl nitroxides actively employed in design of molecular magnets, amide derivatives **8** and **9** are new compounds. They were synthesized by base-catalyzed hydration of the corresponding nitriles **1** and **4**. Compound **9** may also be prepared by reduction of nitronyl nitroxide **8** (Scheme 3). In contrast to the corresponding acids, amides **8** and **9** are stable under normal conditions. They were isolated as high-quality crystals, whose crystal and molecular structure was completely solved.

Solid compounds **8** and **9** have a polymer chain structure formed from bifurcated intermolecular hydrogen bonds between the amide H atom of one nitroxide molecule and the N–O and amide O atoms (for **8**) or the amide H atoms and the imine N atom (for **9**) of a neighboring nitroxide molecule (Figs. 2 and 3). The other H atom of the amide group forms an intramolecular hydrogen bond with the O atom of the N–O group. All atoms of the nitronyl or imino nitroxide fragments are nearly coplanar with the atoms of the $-C(O)NH_2$ fragments. Selected bond lengths for **8** and **9**, as well as hydrogen bond parameters, are listed in Tables 3 and 4.

All heterospin complexes **10**–**15** were prepared by reaction between the appropriate metal hexafluoroacetylacetonates and **8** or **9**, in which the ratio $M(hfac)_2 \cdot nH_2O$/paramagnetic ligand is 1:1. Compounds **10**, **11** and **14** were isolated as perfect $M(hfac)_2L$ crystals when the reaction was fulfilled in a hexane (or heptane)/CH_2Cl_2 mixture. Under similar conditions, complex **12c** formed as a finely disperse powder. The crystals of this compound suitable for an X-ray diffraction study were obtained by recrystallization of the complex from benzene and toluene in the form of the corresponding solvates **12a** and **12b**. Desolvation of **12a** gave a powder whose IR spectra and magnetic properties were identical to those of **12c** prepared as single crystals in the reaction of $Cu(hfac)_2$ with **9** in ethyl acetate. A crystalline complex of $Mn(hfac)_2$ with **9** could only be isolated in the form of a solvate with benzene (**13**).

All solid complexes except **12c** are packings of centrosymmetric dimer molecules formed by hydrogen bonding between the atoms of the two amide groups (Figs. 4 and 5). The structure of **8** and **9** (Figs. 2(a) and 3(a)) does not change on complexation except that the angle between the planes of the CN_2 fragment of the

imidazoline ring and the amide group slightly increases, reaching 12° in **10**. The coordination number of the central atom is 6. In complexes with **8**, the CuO_6 coordination unit is formed from four O atoms of the cis-coordinated hfac anions and the O atoms of the amide group and the N–O fragment of the paramagnetic ligand. In complexes with **9**, the CuO_5N coordination unit involves the imine N atom of the heterocycle. The chelate rings in **10** and **11** are nonplanar and folded along the $O_{NO}\ldots O_{amide}$ line at an angle of 40.0° in **10**. The angle between the planes of the amide group and the NCN fragment of the imidazoline ring is up to 5.5° in **11**–**14** and 12° in **10**. In the Cu complexes, the coordinated octahedron is tetragonally distorted. The axial Cu–O_{hfac} distances are 2.210–2.257, and the Cu–O_{amide} distances are 2.371–2.482 Å. The equatorial Cu–O_{hfac} distances equal 1.921–1.996, Cu–O_{NO} = 1.973 and Cu–N = 2.022–2.046 Å. In Mn(II) and Co(II) complexes **13** and **14**, respectively, the coordination polyhedra of the metal atoms are isometric. Note, however, that the Mn–O and Mn–N bonds to the donor atoms of the paramagnetic ligand in **13** are longer than those in **11**. Selected bond lengths and hydrogen bond parameters are given in Tables 3 and 4.

The structure of solid **12c** is slightly different from the structure of all other complexes. As in other complexes, $\{Cu(hfac)_2\mathbf{9}\}_4$ tetramer molecules (Fig. 6) are formed with the aid of the bridging N–H…O

intermolecular hydrogen bonds. The difference lies in the fact that in **12c** the NH_2 fragment of the amide group of one $Cu(hfac)_2$**9** molecule is bonded to the O_{amide} atom of another molecule, and NH_{amide} of the latter is bonded to O_{amide} of the third molecule, etc., thus linking four crystallographically independent molecules into a cycle. The coordination polyhedra inside the {$Cu(hfac)_2$**9**} fragments do not differ in structure between **12c** and **12a** (or **12b**). Note that a heterospin tetramer complex could only be obtained for the Cu(II) complex by crystallization from ethyl acetate. For other $M(hfac)_2$ complexes, slow removal of ethyl acetate from the reaction mixture led to a viscous mass solidifying into lacquer-film.

3.3. Magnetic properties of the compounds

In the temperature range 20–300 K, μ_{eff} is the same for radicals **8** and **9** and close to 1.73β. Below 20 K, $\mu_{eff}(T)$ gradually decreases in magnitude for **8** and **9**,

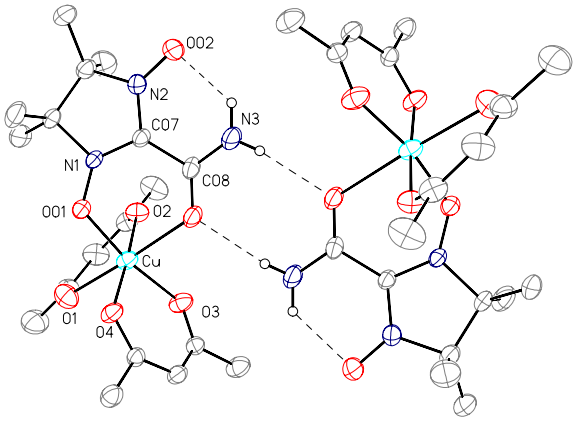

Fig. 4. General view of dimer molecule **10**. Centrosymmetric dimer **11** has a similar structure.

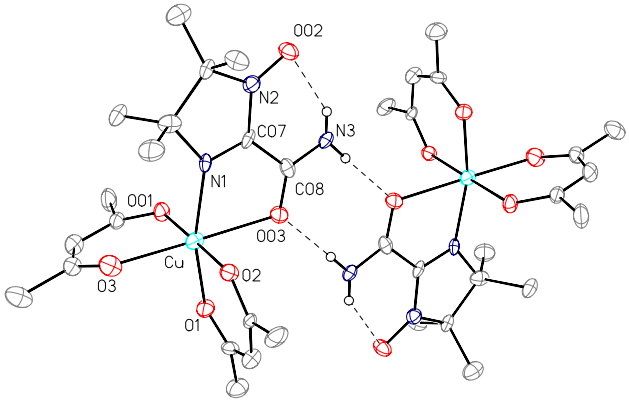

Fig. 5. General view of dimer molecule **12a**. Dimer molecules **12b**, **13**, and **14** have a similar structure.

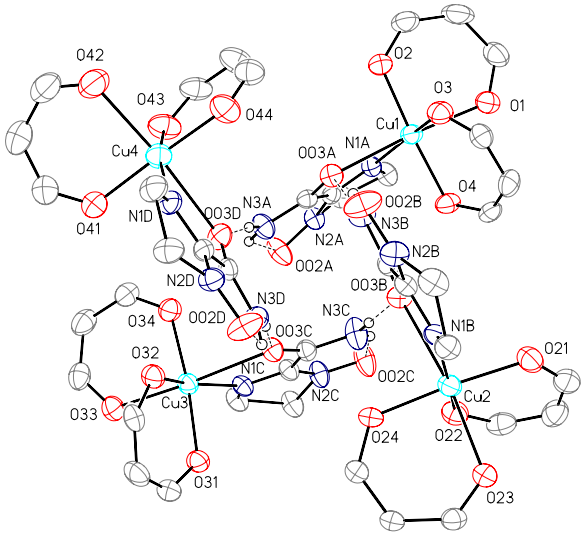

Fig. 6. General view of $[Cu(hfac)_2\mathbf{9}]_4$ tetramer molecule (**12c**).

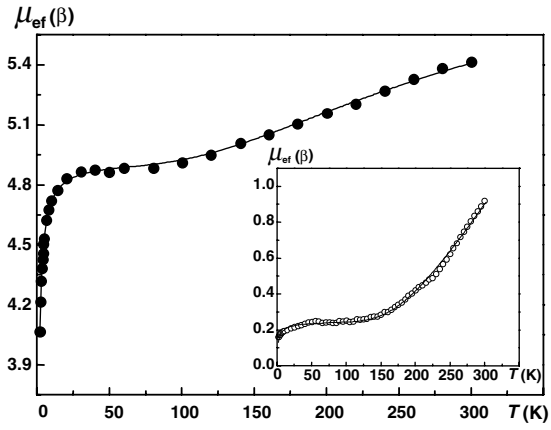

Fig. 7. Dependences $\mu_{eff}(T)$ for **10** (○) and **11** (●).

indicating that the solid nitroxides have only weak antiferromagnetic intermolecular exchange interactions.

The dependences $\mu_{eff}(T)$ for the complexes are presented in Figs. 7 and 8.

The magnetic behavior of complexes **10**, **11** and **13** (Figs. 7 and 8) suggests full spin coupling between the metal and the coordinated radical at temperatures of the order of 120 K due to strong antiferromagnetic exchange interactions. In the region of the plateau, the value of μ_{eff} for **11** and **13** is close to the theoretical value 4.9β for the residual spin $s = 2$ with g-factor 2. In **14**, μ_{eff} increases oppositely with temperature (Fig. 8), indicating that ferromagnetic exchange interactions between the spins of Co(II) and the radical inside the bischelate fragments are dominant.

At 300 K for **12c**, μ_{eff} is 2.85β, which is close to the theoretical value 2.83β for $s = 1$. That is, due to the strong ferromagnetic interaction of spins inside the molecular exchange cluster, the triplet state is the occupied ground state even at room temperature. The decrease in μ_{eff} with temperature, as well as the maximum at 20 K on the $\chi(T)$ curve, point to negative exchange interactions between $\{Cu(hfac)_2\mathbf{9}\}$ exchange clusters in solid **12c**.

For **10**, **11** and **13**, theoretical treatment of experimental data was fulfilled using the isotropic spin Hamiltonian in the framework of an approach suggested earlier [16]. For approximation, we employed two-center exchange clusters. The resulting optimal parameters: the effective g-factor of the metal (g_M), exchange interaction energies (J) inside the exchange cluster and intermolecular interaction energies (nJ') of the complexes are presented in Table 5. The calculated curves are shown as solid lines in Figs. 7 and 8. As is known, antiferromagnetic exchange interactions dominate in the {M–O·–N<} exchange cluster of paramagnetic metal complexes with coordinated nitronyl nitroxides, whereas ferromagnetic exchange interactions prevail in the {M–N=C–N–·O} exchange clusters of complexes with imino nitroxides [17]. The data obtained for **10**–**14** follow this general tendency. However, it is worthwhile to note that

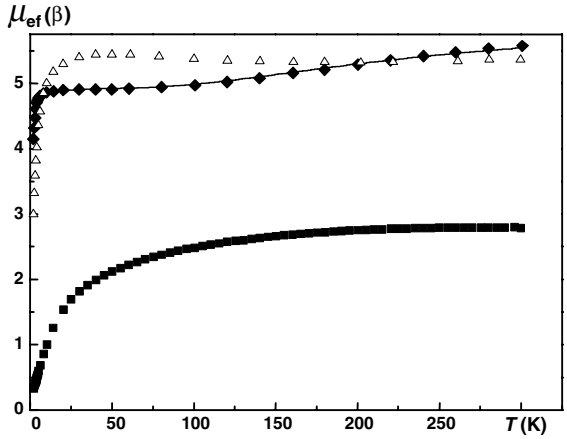

Fig. 8. Dependences $\mu_{eff}(T)$ for **12c** (■), **13** (◆) and **14** (Δ).

Table 5
Exchange parameters for complexes

Compound	g_M	J (cm^{-1})	nJ' (cm^{-1})	σ
10	2.11 ± 0.05	-380 ± 30		0.01428
11	2.008 ± 0.002	-57.2 ± 0.6	-0.15 ± 0.01	0.00016
13	2.02 ± 0.01	-47 ± 2	-0.07 ± 0.01	0.00052

in the {Mn–N=C–N–·O} exchange clusters of complexes with imino nitroxides (**12c**, **13** and **14**), the antiferromagnetic exchange channels are much more effective than those in {Cu–N=C–N–·O} and {Co–N=C–N–·O} clusters.

4. Conclusions

The development of an effective procedure for the synthesis of nitrile **1** has made this compound an easily accessible nitroxide that may be used as a starting compound for syntheses of spin-labelled amides **8** and **9**. Interaction of $M(hfac)_2$ with **8** and **9** affords compounds with $\{M(hfac)_2L\}$ fragments H-bonded into bi- or tetranuclear multispin complexes in the solid state. Exchange interactions in these complexes are concentrated inside the $\{M(hfac)_2L\}$ fragments. In Cu(II) and Mn(II) complexes with nitronyl nitroxide **8**, strong antiferromagnetic exchange interactions take place. In complexes with imino nitroxide **9**, the antiferromagnetic exchange interaction channels in the {Mn–N=C–N–·O} exchange cluster also proved to be much more effective, whereas in {Cu–N=C–N–·O} and {Co–N=C–N–·O} exchange clusters, ferromagnetic exchange interactions prevail.

Hydrothermal synthesis and structure characterization of a Keggin tungstocobaltate $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$

Jing-Yang Niu *, Zi-Liang Wang, Jing-Ping Wang

Received 24 September 2003; accepted 4 November 2003

Abstract

A Keggin-type tungstocobaltate $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$ was prepared by the hydrothermal method for the first time and characterized by elemental analyses, IR, UV, EPR spectra, TG-DTA analyses and X-ray single crystal diffraction, showing that the complex consists of a Keggin anion $[CoW_{12}O_{40}]^{6-}$ and two isolated chiral ions $[Co(2,2'\text{-bipy})_2]^{2+}$. The characteristic band of Keggin anion $[CoW_{12}O_{40}]^{6-}$ appears at 298 nm in the UV spectrum. EPR spectra reveal two Co^{2+} coordination environments in the title compound, high spin state ($g = 5.1$, 4.2) and low spin state ($g = 2.0$). Furthermore, when the temperature increases from 110 K to room temperature, the signal $g = 5.1$ of high spin Co^{2+} disappears, caused by the negative zero-field splitting. Thermal analysis indicates that the Keggin anion skeleton begins to decompose at 560.4 °C.

1. Introduction

Polyoxometalates (POMS), because of having discrete structures of definite sizes, shapes [1] and potential applications in catalysis, medicine, materials science, geochemistry and nuclear waste processing [2–6], have been attracting chemists' interests. As well known, the Keggin POMS continue to have an important place at the forefront of the polyoxometalate field. In recent decades, Keggin polyoxometalates associated with organic donors like ET and TTF construct a series of compounds [7–9] coupling magnetic and conducting properties or with metal coordination cations form a series of novel compounds [10–17]. Among previously reported literature, few of their heteroatoms are transition metals [8,9,13]. Furthermore, most of them are prepared by conventional aqueous solution syntheses. So we attempted to explore hydrothermal routes for preparation of such solid-states materials based on Keggin heteropolyanions using simple reactants, and we succeeded in doing so. This paper describes the hydrothermal synthesis, structure and properties of a new Keggin tungstocobaltate $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$.

2. Experimental

2.1. Materials and measurements

All chemicals were of reagent grade as received from commercial sources and used without further purification. C, H, N elemental analyses were performed on a Perkin–Elmer 240C elemental analyzer. The infrared spectrum was recorded as a KBr pellet on a Nicolet 170SXFT-IR spectrometer in the range 400–4000 cm^{-1}. The UV spectrum was obtained on a Shimzu UV-250 spectrometer in the range 190–350 nm. The EPR spectrum was recorded with a Bruker ER-2000-DSRC10 spectrometer at the X-band, at a temperature of 300 and 110 K. TG-DTA measurements were performed on a Perkin–Elmer7 thermal analyzer in flowing nitrogen gas with a heating rate of 10 °C/min.

2.2. Synthesis of $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$

The title compound was prepared by the hydrothermal method from a mixture of $Na_2WO_4\cdot 2H_2O$ (1.0 g, 3.2 mmol), $CoCl_2\cdot 6H_2O$ (0.076 g, 0.32 mmol), $Co(Ac)_2\cdot 4H_2O$ (0.08 g, 0.32 mmol), 2,2′-bipyridine (0.1 g, 0.64 mmol) and H_2O (15 ml) in the mole ratio 1:0.1:0.1:0.2:260, heated in a Teflon-lined steel autoclave inside a programmable electric furnace at 160 °C for 96 h with a starting pH of 4, adjusted with hydrochloric acid (4 mol/l). After cooling the autoclave to room temperature for 48 h, green crystals were obtained, filtered, washed several times with distilled water and dried in air (yield 25% based on W). *Anal.* Calc. for $C_{60}H_{67}N_{12}O_{49.5}W_{12}Co_3$: C, 17.42; H, 1.62; N, 4.06. Found: C, 17.21; H, 1.66; N, 3.96%.

2.3. X-ray single crystal diffraction analysis

A green single crystal of $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$ with dimensions $0.26\times 0.23\times 0.11$ mm was used for X-ray work. Data collections were made on a Rigaku RAXIS-IV image plate area detector using graphite mono-chromated Mo Kα diffraction ($\lambda = 0.71073$ Å) at 293(2) K. A total of 13 362 independent reflections ($R_{int} = 0.0562$) were measured in the range of $4.42^\circ \leqslant 2\theta \leqslant 50.00^\circ$ with $-16 \leqslant h \leqslant +17$, $-19 \leqslant k \leqslant +20$, $-22 \leqslant l \leqslant +22$. The intensities were corrected by Lorentz-polarization factors and empirical absorption. The structures were solved by direct methods and refined by a full-matrix least-squares technique based on F^2 using the SHELXTL-97 program [18]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were added according to theoretical models. The maximum and minimum peaks on the final difference Fourier map correspond to 2.722 and −3.896 e Å^{-3}, respectively.

The crystallographic data and structure determination parameters for $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$ are summarized in Table 1. Selected bond distances and angles are given in Table 2.

3. Results and discussion

3.1. Structure description

As shown in Fig. 1, the complex consists of one α-Keggin anion $[CoW_{12}O_{40}]^{6-}$, two discrete $[Co(2,2'\text{-bipy})_3]^{2+}$ cations and nine point five crystallization water molecules. As other Keggin anions [1], the $[CoW_{12}O_{40}]^{6-}$ anion includes a CoO_4 tetrahedron surrounded by 12 WO_6 octahedrons, present in the four W_3O_{13} groups. According to the different coordination environments of oxygen atoms in the polyanion, these oxygen atoms can be divided into four groups: O_t (terminal oxygen atoms connecting to one W atom), O_b (atoms located in the shared corners between two W_3O_{13} units), O_c (oxygen atoms connecting edge-sharing WO_6 octahedra in the W_3O_{13} unit) and O_a (oxygen atoms connecting the Zn and W atoms). Relevant W–O bonds can be classified into three categories: (1) W–O_t, 1.694(10)–1.740(12) Å with an average bond length 1.716 Å ; (2) W–$O_{b,c}$, 1.818(11)–2.065(12) Å with a mean bond distance 1.934 Å; (3) W–O_a, 2.123(11)–2.201(10) Å with an average bond distance 2.162 Å. Comparing the W–O bonds with that of the potassium salt $K_6[CoW_{12}O_{40}]$ [19], the W–O_t and W–O_a lengths in the title compound show an obvious increase except for the W–$O_{b,c}$ distances which have no evident change. The results indicate that the static electric interaction between the $[CoW_{12}O_{40}]^{6-}$ anion and discrete $[Co(2,2'\text{-bipy})_3]^{2+}$ cations are relatively weak. For the CoO4 tetrahedron, the Co–O distances are 1.875(10)–1.908(12) Å with an average bond length 1.890 Å, while the O–Co–O angles vary from 108.6(5)° to 110.4(5)°, which are consistent with the literature [19]. The results show that the central CoO_4 tetrahedron, depended upon by the surrounding WO_6 octahedrons, was more regular. Comparing W–O bonds with that of $[Me_4N]_7[VW_{12}O_{40}]\cdot 15H_2O$ [20], the average W–O_t and W–$O_{b,c}$ distances in the title compound elongate 0.008 and 0.021 Å, respectively, while the average W–O_a distance decreases 0.163 Å, which proved that the average W–O_t and W–$O_{b,c}$ distances increase and mean W–O_a length decreases with increase of the heteroatom radius. It should be pointed out that the two discrete Co^{2+} coordination cations have chirality, each Co^{2+} site is defined by six nitrogen atoms from three 2,2′-bipyridine molecules and formed a distorted CoN_6 octahedron with Co(2)–N and

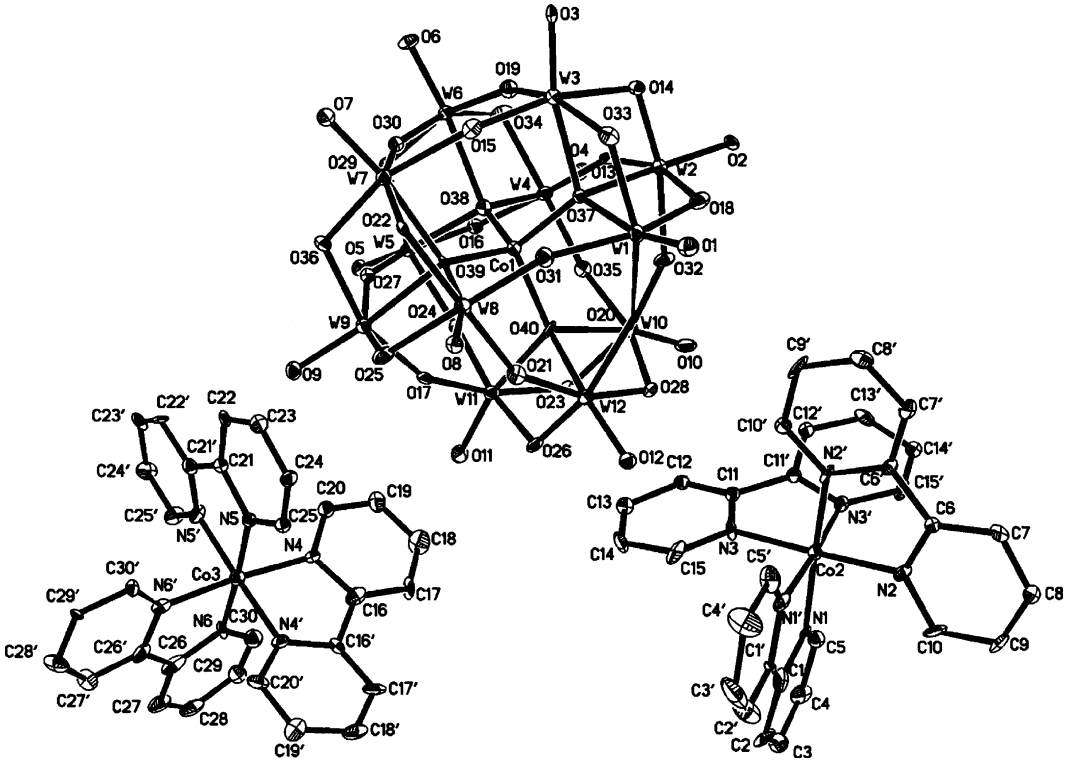

Fig. 1. Molecular structure of the title compound. Water molecules and all hydrogen atoms are omitted for clarity.

Co(3)–N bond lengths in the range of 1.924(13)–1.947(13) Å and 1.915(14)–1.947(14) Å, corresponding to their mean Co(3)–N length 1.933 and 1.932 Å, respectively. While bond angles in the Co(2) and Co(3) are 82.6(6)°–176.8(6)° and 83.3(6)°–95.6(6)°. Furthermore, the dihedral angles among the three ideal 2,2′-bipyridine planes in

$[Co(2)(2,2'\text{-bipy})_3]^{2+}$ are 93.6°, 78.7° and 89.6°. For $[Co(3)(2,2'\text{-bipy})_3]^{2+}$, the three dihedral angles among the three ideal 2,2′-bipyridine planes are 94.6°, 78.7° and 89.6°. The results indicate that the three ideal planes in each $[Co(2,2'\text{-bipy})_3]^{2+}$ ion are not vertical to each other.

3.2. IR spectrum

The IR spectrum of the title compound has some characteristic bands for the cations at 1635, 1448, 1168 and 1106 cm^{-1}. Features at 1635 and 1448 cm^{-1} are attributed to stretching vibrations of C=N and C–N bonds. Features at 1168 and 1106 cm^{-1} are ascribed to ring stretching of 2,2′-bipyridine. In addition, the IR spectrum of the title compound exhibits prominent bands for the anion at 931, 869, 757 and 455 cm^{-1}, attributed to $\nu(W{=}O_t)$, $\nu(W{-}O_b)$, $\nu(W{-}O_c)$ and $\nu(Co{-}O)$, respectively.

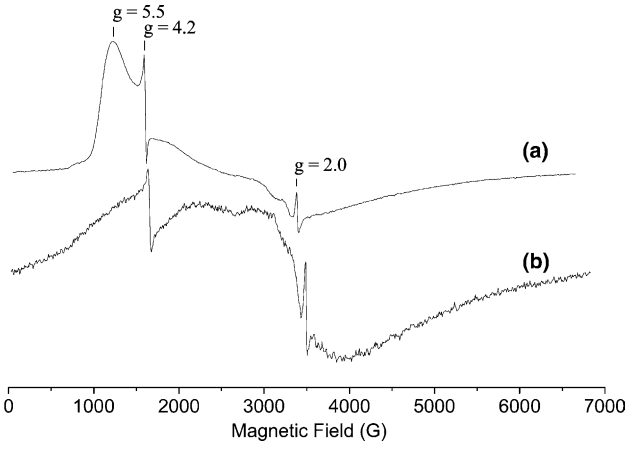

Fig. 2. EPR spectra of $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$: (a) 100 K, 9.4841 GHz; (b) 300 K, 9.7747 GHz.

3.3. UV and EPR spectra

The UV spectrum of the title compound in distilled water solution exhibits two absorption peaks at 194 and 298 nm (characteristic of Keggin anion), ascribed to the charge-transition absorption of $O_t \rightarrow W$ and $O_{b,c} \rightarrow W$, respectively. The EPR spectra (Fig. 2) reveal obviously that there are two kinds of cobalt: high spin state and low spin state in the complex. At 110 K, the EPR spectra display a broad signal $g = 5.5$ and two narrow symmetric bands centered at $g = 4.2$ and 2.0. The signals $g = 5.5$, 4.2 and $g = 2.0$ are attributed to high spin and low spin Co^{2+}, respectively. However, when the temperature increases to room temperature, the EPR signal $g = 5.5$ disappears and at the same time the signal $g = 4.2$ decreases and the signal $g = 2.00$ increases. In addition the noise signals become stronger. The disappearance of the broad signal $g = 5.5$ is caused by the zero-field splitting, which can be explained by the ligand field energy-level diagram of the ground state $^4A_2$ of high spin Co^{2+} [21]. Distortion of the tetrahedron will split the ground state into two Kramers doublets ($Ms = \pm 1/2$ and $Ms = \pm 3/2$). When the temperature increases from 110 K to room temperature, the negative zero-field splitting between $Ms = \pm 1/2$ and $Ms = \pm 3/2$ emerges so that the Co^{2+} ions tend to populate the $Ms = \pm 3/2$ level which is not ESR-active. Thus the ESR signal $g = 5.5$ disappears at room temperature.

3.4. Thermal properties

The thermal decomposition profile (Fig. 3) of the title compound gives a total weight loss of 24.63% in the range 24.5–809.3 °C. The thermal analysis curve can be divided into two stages. In the first stage, the weight loss of 3.03% (< calculated 4.14%, attributed to the loss of

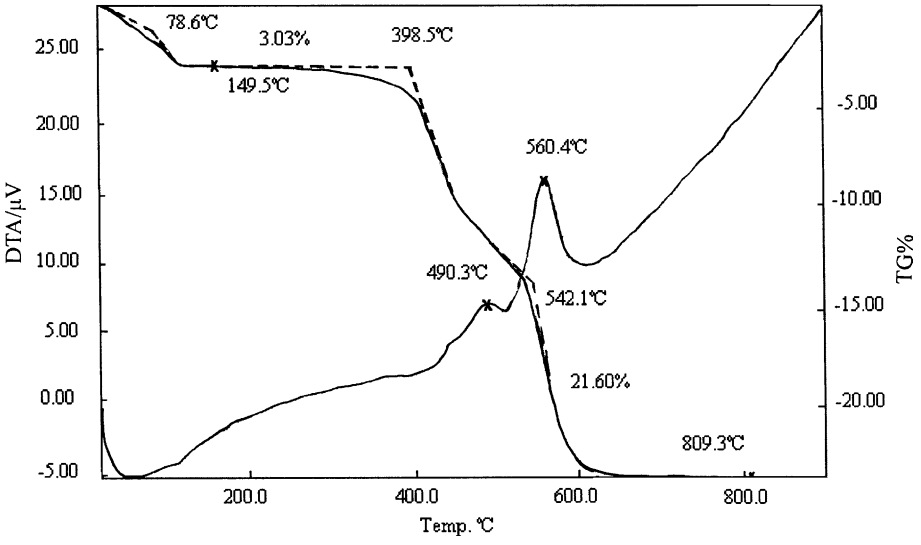

Fig. 3. TG/DTA traces for the $[Co(2,2'\text{-bipy})_3]_2H_2[CoW_{12}O_{40}]\cdot 9.5H_2O$ complex.

surface water of the single crystal) in the range of 24.5–149.5 °C is due to the loss of seven crystallization water molecules. In the second stage, the weight loss of 21.60% in the range 149.5–809.3 °C corresponds to the decomposition of six 2,2′-bipyridine ligands and one structural water, adjoining combustion of the organic ligands in that there is a little exothermal peak at 490.3 °C in the DTA curve. In addition, the other exothermal peak at 560.4 °C shows that the Keggin anion $[CoW_{12}O_{40}]^{6-}$ begins to decompose.

4. Supplementary material

Crystallographic data for the structural analysis of the title compound have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 204618. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk).

Abstract

A series of organotin(IV) complexes with 2-mercapto-6-nitrobenzothiazole (HMNBT) of the type, $[R_nSn(MNBT)_{4-n}]$ ($n = 2$, R = Me, **4**; $n = 3$, R = Me, **5**; *n*-Bu, **6**; Ph, **7**; $PhCH_2$, **8**) were synthesized. All the complexes **4**–**8** have been characterized by elemental, IR and ^1H NMR analyses. Among them, complexes **4**, **7** and **8** were also characterized by X-ray crystallography diffraction analyses, which revealed that the structures of both complexes **7** and **8** are penta-coordinated with R_3Sn coordinated to the thiol S and heterocyclic N atoms, and the structural distortion for each is a displacement from tetragonal towards trigonal bipyramidal geometry. For complex **4**, the geometry of the center tin atom is a distorted trapezoidal bipyramid. Besides, intermolecular S···S and Sn···S non-bonded interactions were recognized in crystal structures of complexes **4** and **7**, respectively. The IR and ^1H NMR spectral data indicate such an inclination that those structures of trialkyltin derivatives are apt to be penta-coordinated and those dialkyltin derivatives are likely in six-coordination.

Keywords: 2-Mercapto-6-nitrobenzothiazole; Organotin(IV); Non-bonded interaction; Crystal structure; X-ray crystallography diffraction

1. Introduction

Organotin compounds have been the subjects of interest for some time because of their biometrical and commercial applications [1,2]. To aid in understanding their biochemical action, it was felt that the coordination chemistry of tin(IV) toward O-, S- and N-containing ligands requires further exploration. Solid state structures of several simple triorganotin thiolates, R_3SnSR', where the R′ groups contain no donor atoms, have been reported before [3,4], and all of them were found to have four-coordinate geometry. However, if the R′ group contains a donor atom (N or O), then the coordination number of tin will increase [5].

Our interest in the structures of organotin(IV) complexes containing {N, S} donor sites has prompted us to embark on a study of the ligand 2-mercapto-6-nitrobenzothiazole (HMNBT). This ligand is interesting because of its potential bidentate coordination possibilities, so that bonding may take place either by the heterocyclic N or the thiol S. In our previous work, we have reported three diorganotin derivatives from the ligand (see Scheme 1): the complexes **1**, **2** and **3**, which take on versatile structures due to the existence of π–π stacking interaction or non-bonded interactions in the crystals [6,7].

To continue our studies in this field, we carried out more experiments with the ligand and obtained another five organotin complexes of the type $[R_nSn(MNBT)_{4-n}]$ ($n = 2$, R = Me, **4**; $n = 3$, R = Me, **5**; *n*-Bu, **6**; Ph, **7**; $PhCH_2$, **8**). All complexes **4**–**8** were characterized by elemental, IR, ^1H NMR analyses. Among them, complexes **4**, **7** and **8** were also characterized by X-ray crystallography diffraction analyses, which reveal that the structures of complexes **7** and **8** are penta-coordinated with R_3Sn coordinated to the thiol S and

heterocyclic N atoms and the structural distortion for each is a displacement from tetragonal towards trigonal bipyramidal geometry. For complex **4**, the geometry of the center tin atom is a distorted trapezoidal bipyramid. It is worth to note that intermolecular S···S and Sn···S non-bonded interactions were recognized in the crystal structures of complexes **4** and **7**, respectively.

2. Experimental

2.1. Materials and measurements

All reagents and solvents were purchased commercially and used without further purification unless otherwise noted. The melting points were obtained on a Kofler micro melting point apparatus and are uncorrected. Infrared spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs and sodium chloride optics. ^{1}H NMR spectra were obtained on a Jeol-FX-90Q NMR spectrometer. Chemical shifts are given in ppm relative to Me_4Si in $CDCl_3$ as solvent. Elemental analyses were performed with a PE-2400 II elemental analyser.

2.2. Syntheses of the complexes *4–8*

2.2.1. *[$Me_2Sn(MNBT)_2$] (4)*

The 2-mercapto-6-nitrobenzothiazole (0.424 g, 2 mmol), sodium ethoxide (0.136 g, 2 mmol) and dimethyltin dichloride (0.220 g, 1 mmol) were added to benzene (20 ml) in turn, stirred for 12 h at 40 °C and then filtered. After removing the solvent, the solid was recrystallized from diethylether–petroleumether. Salmon pink crystals of complex **4** were formed. Yield: 89%; m.p. >200 °C (dec.). *Anal*. Calc. for $C_{16}H_{12}N_4O_4S_4Sn$: C, 33.65; H, 2.12; N, 9.81. Found: C, 33.24; H, 2.33; N, 9.67%. ^{1}H NMR ($CDCl_3$): 7.33–7.86 (m, 3H), 1.42 (s, 6H).

2.2.2. *[$Me_3Sn(MNBT)$] (5)*

The reaction was carried out under dry nitrogen atmosphere. 2-Mercapto-6-nitrobenzothiazole (0.212 g, 1 mmol) and sodium ethoxide (0.068 g, 1 mmol) were added to benzene (20 ml) in a Schlenk flask and stirred for about half an hour. Trimethyltin chloride (0.199 g, 1 mmol) was added to the reactor subsequently. The reaction mixture was stirred for 12 h at 40 °C and then filtered. The filtrate was gradually evaporated under vacuum until a solid product was obtained. The solid was then recrystallized and yellow crystals of complex **5** were obtained. Yield: 88%; m.p.108–110 °C. *Anal*. Calc. for $C_{10}H_{12}N_2O_2S_2Sn$: C, 32.03; H, 3.23; N, 7.47. Found: C, 31.86; H, 3.54; N, 7.65%. ^{1}H NMR ($CDCl_3$): 7.36–7.87 (m, 3H), 0.73 (s, 9H).

2.2.3. *[$(n\text{-}Bu)_3Sn(MNBT)$] (6)*

The solid of complex **6** is made in the same way as complex **5**. Yield: 91%; m.p. 82–84 °C. *Anal*. Calc. for $C_{19}H_{30}N_2O_2S_2Sn$: C, 45.53; H, 6.03; N, 5.59. Found: C, 45.31; H, 6.33; N, 5.74%. ^{1}H NMR ($CDCl_3$): 7.23–7.80 (m, 3H), 0.75–1.22m (t, 9H), 1.22–1.45 (m, 18H).

2.2.4. *[$Ph_3Sn(MNBT)$] (7)*

The procedure is the same as that of complex **5** and yellow crystalline complex **7** was formed in diethylether–dichloromethane (1:3). Yield: 0.50 g (89%); m.p. 189–191 °C. *Anal*. Calc. for $C_{25}H_{18}N_2O_2S_2Sn$: C, 53.50; H, 3.23; N, 4.99. Found: C, 53.13; H, 3.53; N, 4.64%. ^{1}H NMR ($CDCl_3$): 7.39–7.85 (m, 18H).

2.2.5. *[$(PhCH_2)_3Sn(MNBT)$] (8)*

The procedure is the same as that of complex **5** and in diethyl ether yellow crystals of complex **8** were obtained. Yield: 93%; m.p. 100–102 °C. *Anal*. Calc. for $C_{28}H_{24}N_2O_2S_2Sn$: C, 55.74; H, 4.01; N, 4.64. Found: C, 55.36; H, 4.52; N, 4.29%. ^{1}H NMR ($CDCl_3$): 7.24–7.90 (m, 18H), 2.63 (s, 6H).

2.3. X-ray crystallographic studies of complexes *4, 7 and 8*

All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer. Correction for semi-empirical from equivalents was applied, and the structures were solved by direct methods and refined by a full-matrix least squares procedure based on F^2 using the SHELXL 97 program system. All data were collected with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298(2) K. The positions of hydrogen atoms were calculated, and their contributions were included in structural factor calculations.

3. Results and discussion

3.1. Syntheses of the complexes 4–8

The synthesis procedure was as in Scheme 2:

3.2. IR spectroscopic studies of the complexes 4–8

The characteristic IR frequencies (cm^{-1}) of HMNBT and its di- and triorganotin(IV) derivatives **1**–**8** are listed in Table 2.

The explicit feature in the infrared spectra of all complexes **4**–**8** is the absence of the band in the region 2550–2430 cm^{-1}, which appears in the free ligand as the ν(S–H) vibration, indicating metal-ligand bond formation through this site. While in the far-infrared spectra, a strong absorption appears in the range 280–346 cm^{-1} in the spectra of complexes **4**–**8**, which is absent in the spectrum of the ligand, is assigned to the Sn–S stretching mode of vibration. All these values are consistent with that detected in a number of organotin(IV)–sulfur derivatives [8].

The ν(C=N) band, occurring at about 1586 cm^{-1}, is considerably shifted towards lower frequencies with respect to that of the free ligand (1616 cm^{-1}), confirming the coordination of the heterocyclic N atom to tin. The stretching frequency is lowered owing to the displacement of electron density from N to the Sn atom, thus resulting in a weakening of the C=N bond as reported in the literature [9]. Thus, the weak or medium-intensity band appearing at 453, 460, 475, 488 and 480 cm^{-1} for the respective spectra of complexes **4**–**8** may be assigned to Sn–N stretching vibrations.

Besides, in organotin complexes, the IR spectra can provide useful information concerning the geometry of the SnC_n moiety [10]. In the cases of our complexes, for both di- and triorganotin derivatives, two bands were assigned to asymmetric and symmetric Sn–C vibrations, thus suggesting non-linear C–Sn–C units for the dimethyltin derivative **4** and no-planar SnC_3 fragments for the trialkyltin derivatives **5**–**8**, respectively. Thus the bands at 556 and 523 cm^{-1} for complex **4**, 532 and 497 cm^{-1} for **5**, 562 and 544 cm^{-1} for **6**, 570 and 520 cm^{-1} for **7** and 447 and 424 cm^{-1} for **8** can be assigned to ν_{as}(Sn–C) and ν_s(Sn–C), respectively.

3.3. ^1H NMR data of the complexes 4–8

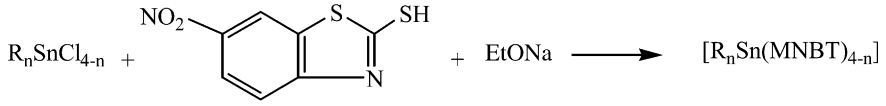
^1H NMR data showed that the signal of the –SH proton in the spectrum of the ligand is absent in all the complexes **4**–**8**, indicating the removal of the –SH proton and the formation of Sn–S bonds. This information agrees with what the IR data have revealed.

3.4. Crystal structures of complexes 4, 7 and 8

The crystal structures or unit cells of complexes **4**, **7** and **8** are shown in Figs. 1–4. All H atoms have been omitted for the purpose of clarity. Table 1 lists the crystal data and structure refinement parameters for complexes **4**, **7** and **8** and their selected bond lengths and angles are shown in Tables 4–6, respectively.

3.4.1. Structure of complex 4

Complex **4** contains a six-coordinated tin atom as its analogous dialkyltin derivatives from the ligand (see



(n=2, R=Me, **4**; n=3, R=Me, **5**; n-Bu, **6**; Ph, **7**; $PhCH_2$, 8)

Scheme 2.

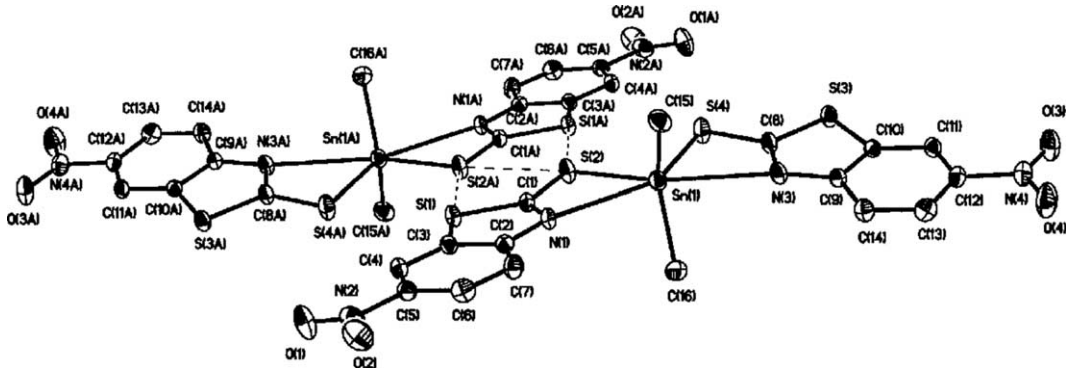


Fig. 1. Crystal structure of complex **4**.

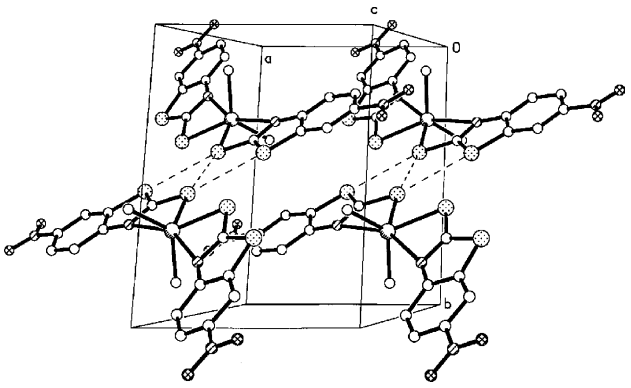

Fig. 2. Unit cell of complex **4**.

Scheme 2(b)) [6]. In this case, the crystal structure of **4** consists of a dimer unit in which tin atoms are coordinated to two methyl carbons and to two sulfur and nitrogen atoms from the two deprotonated ligands. The valence extension is performed via two nitrogen atoms and they occupy *trans* positions with the angle, N(1)–Sn(1)–N(3), 155.68(12)°, while the case for the sulfur bonding vary and they occupy *cis* positions (S(2)–Sn(1)–S(4), 85.82(7)°). On each side of the tin atom, the S and N equatorial ligating atoms belong to the same moiety (S(2)–Sn(1)–N(1): 59.08(11)° and S(4)–Sn(1)–N(3): 59.51(11)°, which are reconcilable with skew-trapezoidal bipyramid geometry), so their positions are fixed and the S–Sn–N angles can only admit very little deformation.

9	HMNBT		2550–2430 ν(S–H)		1616	this work

The geometry around the metal may thus be viewed as a distorted trapezoidal bipyramid with the two methyl carbons in bent axial positions and the trapezoidal plane being defined by the two Sn–S covalent bonds and the two Sn–N secondary interactions. The five equatorial atoms are nearly coplanar, and the sum of angles between the tin atom and the equatorial ligating atoms (i.e., two N and two S in each case) is 360.1°, almost equal to the ideal octahedral value of 360°. It should be mentioned that notably similar *trans*-$R_2SnS_2N_2$ coordination geometries are found in analogous systems of 2-pyridinethiolate and tetrazole-thione ligands [11,12].

As shown in Table 3, the Sn–C distances (2.114(6) and 2.122(6) Å) and Sn–S distances (2.491(3) and 2.524(4) Å) are similar to those found in other dialkyltin derivatives from the ligand (2.13–2.16 and 2.49–2.55 Å, respectively) [6]. The Sn–N distances, 2.815(5) and 2.882(5) Å, are similar to that found in dimethyldi(pyrimidine-2-thiolato)tin (2.83(2) Å) but shorter than that of dimethylbis(1-phenyl-1H-tetrazole-5-thiolate)tin (2.947(4) Å) [11,12], which though less than the sum of the van der Waals radii, 3.75 Å, is one of the largest reported for analogue dialkyltin derivatives from the ligand (2.60–2.86 Å) [6].

Furthermore, intra-molecular non-bonded S···S interactions were recognized in the crystallographic analysis of complex **4,** which help the construction of the dimer. Comparing with other dialkyltin derivatives, the consequence of the formation of non-bond interactions between molecules is $[Me_2Sn(MNBT)_2] \sim [Bu_2Sn(MNBT)_2] > [Ph_2Sn(MNBT)_2]$ (Table 3), which are partly

due to the constraints from R groups (R = Me, Bu and Ph). The non-bonded S···S distances (S(2)···S(1)#, 3.43 and S(2)···S(2)#, 3.42 Å) are longer than those reported in the literature [13,14], shorter than the sum of the van

der Waals radii (S and S) (3.70 Å) [15], but well consistent with those in [(*n*-Bu)$_2$Sn(MNBT)$_2$] [6].

3.4.2. Structures of complexes 7 and 8

The structures of both complexes **7** and **8** are penta-coordinated with R_3Sn coordinated to the thiol S and heterocyclic N atoms of the same ligand and the structural distortion for each is a displacement from tetragonal towards trigonal bipyramidal geometry.

For complex **7**, the central tin atom forms four primary bonds: three to the phenyl groups and one to the sulfur atom. In addition, there is a weak intramolecular Sn–N interaction, the Sn(1)–N(1) bond length (3.14 Å) is longer than the sum of covalent radii (2.15 Å), but is considerably shorter than the sum of van der Waals radii of Sn and N atoms (3.75 Å) [5]. This bond length is almost equal to that in Ph_3Sn(MTS) (3.16 Å) [8], slightly shorter than that of triphenyl-(5-mercapto-1-phenyl-1,2,3,4-tetrazolato)tin(IV) (3.28 Å) [16], but a little longer than that reported in Ph_3Sn(MBZ) (3.07 Å) [8]. Thus complex **7** has a distorted *cis*-trigonal-bipyramidal geometry with the sulfur (S(2)) atom and two carbon atoms (C(14) and C(8)) occupying the equatorial plane, whereas the nitrogen (N(1)) and another carbon atom (C(20)) are in axial positions. The sum of the equatorial angles around the tin atom, (C(14)–Sn(1)–C(8), C(14)–Sn(1)–S(2) and C(8)–Sn(1)–S(2)), is 339.0° and the axial–Sn–axial angle, C(20)–Sn(1)–N(1), is 152.8°. The significant distortion is mainly due to the rigidity of the chelate ring (N(1)–Sn(1)–S(2): 55.8°), together with the large covalent radius of tin(IV). The Sn(1)–S(2) bond length (2.453 (2) Å) is just outside the range (2.39–2.44 Å) found in four-coordinate R_3SnSR' [3] but similar to that reported in the penta-coordinated organotin complex Ph_3Sn(MTS) (2.47 Å) [8].

Besides, intra-molecular non-bonded Sn···S interactions were recognized in the crystallographic analysis of complex **7**. The Sn···S bond length (3.97 Å) is longer than that reported in [2-(Me_2NCH_2)C_6H_4]$SnPh_2$ [S(S)PPh_2] (3.63 Å) and $Ph_2Sn(SCH_2CH_2S)$ (3.89 Å) but shorter than that of tribenzyl(2-thiolatopyridine-N-oxide)tin(IV) (4.15 Å) [17–19]. Due to the very weak intramolecular interaction, complex **7** can be thought of as a dimer.

For complex **8**, there exist two monomers in the asymmetric unit (see Fig. 3), which are different from a crystallographic point of view. Conformations of the two independent molecules are almost the same, with only little differences in bond lengths and bond angles (see Table 5). Each monomer has a distorted *cis*-tigonal-bipyramidal geometry with a tin–nitrogen intramolecular interaction similar to complex **7**. The two chelate bite angles, N(1)–Sn(1)–S(2) and N(3)–Sn(2)–S(4) are 57.81(19)° and 58.61(17)°, respectively. The axial–Sn–axial angles (C(15)–Sn(1)–N(1) = 155.8(3)° and C(43)–Sn(2)–N(3) = 155.2(3)°), strongly affected by the small bite angle, are well removed from the ideal trigonal-bipyramidal angle. The Sn–S bond length is around 2.49 Å (2.501(3) for Sn(1)–S(2) and 2.480(3) Å for Sn(2)–S(4)), which lies in the normal range for those higher-than-four-coordinated organotin structures and is slightly shorter than that reported in tribenzyl(2-thiolatopyridine-*N*-oxide)tin(IV) (2.58 Å) [19]. Concerning the Sn–N bonds, the bond lengths (Sn(1)–N(1): 2.949(10) Å and Sn(2)–N(3): 2.965(9) Å) are just between the sum of the van der Waals and covalent radii of Sn and N (3.74 and 2.15 Å, respectively) but shorter than that in complex **7** (3.14 Å), which evidences the influence of stereo-constraints, the larger the stereo-constraint of R groups, the more difficult the substituent for the nitrogen atom. In this situation, the stereo-constraint of Ph– is larger than that of $PhCH_2$–, so that the Sn–N bonds of complex **8** are stronger than that of complex **7**. Moreover, it is worth to note that both the Sn–N bond lengths of complexes **7** and **8** are consistent with the average Sn–N bond length (>2.39 Å) of active Sn complexes having antitumour activity [20].

The most significant difference between complexes **7** and **8** is that no Sn···S interactions between the molecules were found in the crystals of complex **8**. The possible reason is that in complex **8** three benzyl groups are bigger than the three phenyl groups in complex **7** so that there are more stereo-constraint coming from the $PhCH_2$– than that from Ph– to prevent the heterocyclic sulfur from bonding to the central tin. The drawings of the unit cells for complexes **7** and **8** support our reasoning quite well.

4. Conclusions

A series of organotin complexes based on 2-mercapto-6-nitrobenzothiazole have been synthesized and characterized. Detailed studies on the structures and spectra of these complexes indicate that there exist such an inclination that the structures of those dialkyltin complexes are likely to construct distorted trapezoidal bipyramidal geometry and those trialkyltin complexes are apt to have distorted trigonal bipyramidal geometry. Besides, the stereo-constraints from the R groups of trialkyltin chloride were found to have great influence to the final coordination mode and crystal structures. As for as the stereo-constraint of coordination from the nitrogen atom to the tin atom is concerned, the consequence is $PhCH_2$<Ph, but as to that of construction of a dimer, it is Ph<$PhCH_2$.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC Nos. 220043, 192488 and 192499 for complexes **4**, **7** and **8**, respectively. Copies of these

information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Synthesis and characterization of metal-free and metallo phthalocyanines with four pendant naphthoxy-substituents

H. Yasemin Yenilmez, İbrahim Özçeşmeci, Ali İhsan Okur, Ahmet Gül *

Department of Chemistry, Technical University of Istanbul, Fen-Edebiyat Fakltesi, TR34469 Maslak, Istanbul, Turkey

Received 30 September 2003; accepted 10 November 2003

Abstract

Phthalocyanines with four naphthoxy pendant groups on the periphery were prepared by cyclotetramerization of 4-(1-naphthoxy)phthalonitrile and 4-(2-naphthoxy)phthalonitrile. The new compounds were characterized by elemental analyses, ^{1}H NMR, IR and UV–Vis spectral data. The electronic spectra exhibit an intense $\pi \rightarrow \pi^*$ transition of naphthyl identity together with characteristic Q and B bands of the phthalocyanine core.

1. Introduction

The use of tetrapyrrol derivatives and related compounds as advanced materials has shown a rapid increase in recent decades owing to their special features which make them extremely interesting products in new technological applications such as PDT, eletrochromism and chemical sensors, in addition to their traditional use as dyes and pigments [1–5]. Tailoring of the properties of these compounds by either addition of various groups on the periphery or by insertion of different metal ions brings an outstanding architectural flexibility [6,7]. Long chain alkyl, alkoxy or alkylthio substituents have been often added on the periphery of phthalocyanines to improve solubility in nonpolar solvents; the presence of crown ethers or tetraazamacrocycles at the same position, on the other hand, results in products capable of selectively binding alkali or transtion metal ions, respectively [8–15].

Condensed multicyclic aromatic compounds (e.g., naphthalene derivatives) are functional groups effective in photoemission studies [16]. Naphthalocyanines which might be considered among these compounds are essentially porphyrazine derivatives in which naphthalenyl groups are fused to the tetrapyrrol core. These compounds are discriminated as 1,2-naphthalocyanines or 2,3-naphthalocyanines depending on whether the starting material is a 1,2- or 2,3-naphthalonitrile derivative [17–20]. As bulky electron rich units, the presence of naphthalenyl groups on the periphery of phthalocyanines is also expected to change the ordering of molecules in the solid state. However, in the case of naphthalocyanines, the physical and chemical identity of naphthalene units is no longer distinct. In contrast to the extensive number of studies on naphthalocyanines, the description of phthalocyanines with naphthalenyl substituents are unprecedented, except a recent paper giving the crystal structure of the phthalonitrile derivative with 1-naphthoxy substituents [21] and another recent one giving the synthesis of a phthalocyanine carrying nitro groups together with α-naphthoxy substituents on a peripheral position [22].

2. Experimental

IR spectra were recorded on a Mattison 1000 FTIR spectrophotometer using KBr pellets, electronic spectra on a Unicam UV2 spectrophotometer. Elemental analyses were performed by the Instrumental Analysis Laboratory of the TUBITAK Marmara Research Centre. ^{1}H NMR spectra were recorded on a Bruker

250 MHz spectrometer using TMS as internal reference. 4-Nitro-phthalonitrile (**1**) was prepared as given in the literature [23].

2.1. Synthesis of phthalonitrile derivatives

2.1.1. 4-(1-naphthoxy)Phthalonitrile (**2**)

4-Nitro-phthalonitrile (**1**) (1.73 g, 0.01 mol) and 1-naphthol (1.44 g, 0.01 mol) were added successively with stirring to dry DMSO (15 ml). After they were dissolved, anhydrous K_2CO_3 (2.0 g, 0.014 mol) was added portionwise over 2 h and the mixture was stirred vigorously at room temperature for a further 28 h. Then, the reaction mass was poured into water (100 ml) and the precipitate formed was filtered off, washed with water, and crystallized from EtOH–water to give the product as a yellow, crystalline powder. Yield: 2.05 g, 76%. Melting point 101–102 °C. IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 2238 (C=N), 1574 (Ar C=C), 1268 (Ar–O–Ar), 782; ^{1}H NMR (d-chloroform 250 MHz): 7.17–7.96 (m, H–Ar). UV–Vis λ_{max}(nm) (log ε) in $CHCl_3$: 285 (4.4).

2.1.2. 4-(2-naphthoxy)Phthalonitrile (**3**)

Compound **3** was prepared according to the same procedure as described for the preparation of **2** by starting from 2-naphthol (1.44 g, 0.01 mol) Yield: 2.0 g, 74.3%. Melting point 119–120 °C. IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 2238 (C=N), 1570 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782; ^{1}H NMR (d-chloroform 250 MHz): 7.17–7.97 (m, H–Ar). UV–Vis λ_{max}(nm) (log ε) in $CHCl_3$: 290 (4.0) (sh).

2.2. General procedures for phthalocyanine derivatives (**4a–d**, **5a–c**)

A mixture 0.5 mmol (0.135 g) of phthalonitrile derivative (**2** or **3**), 0.125 mmol of anhydrous metal salt [$CoCl_2$ (0.016 g), $Zn(OAc)_2$ (0.016 g) or $NiCl_2$ (0,016 g)] and 0.04 mmol of 1.8-diazabicyclo [5.4.0] undec-7-ene (DBU) (0.07 ml) in 1.5 ml of hexanol was heated and stirred at 160 °C for 24 h under N_2. For cobalt derivatives (**4a** and **5a**) no DBU and for metal-free phthalocyanines no metal salt was required. The resulting green suspension was cooled to ambient temperature and then filtered off. The precipitate was washed first with water, then with ethanol and then dried in vacuo. Finally, pure phthalocyanine derivatives were obtained by chromatography on silica gel using chloroform or chloroform/hexane (100:1) mixture as eluent.

2.2.1. 2,9,16,23-Tetrakis(1-naphthoxy)-phthalocyaninatocobalt (II) (**4a**)

Yield: 58 mg, 40.9%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 1574 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782.

2.2.2. 2,9,16,23-Tetrakis(1-naphthoxy)-phthalocyanine (**4b**)

Yield: 38 mg, 28%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 3310 (N-H), 1574 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782. ^{1}H NMR (d-chloroform 250 MHz): 6.56–8.81 (m, H–Ar), −7.12 (br s, N–H).

2.2.3. 2,9,16,23-Tetrakis(1-naphthoxy)-phthalocyaninatonickel (II) (**4c**)

Yield: 22 mg, 15.5%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 1574 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782.

2.2.4. 2,9,16,23-Tetrakis(1-naphthoxy)-phthalocyaninatozinc (II) (**4d**)

Yield: 30 mg, 21%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 1574 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782. ^{1}H NMR (d-chloroform 250 MHz): 6.87–8.00 (m, H–Ar).

2.2.5. 2,9,16,23-Tetrakis(2-naphthoxy)-phthalocyaninatocobalt (II) (**5a**)

Yield: 14 mg, 9.82%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3055 (H–Ar), 1620, 1470 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782.

2.2.6. 2,9,16,23-Tetrakis(2-naphthoxy)-phthalocyanine (**5b**)

Yield: 19 mg, 14%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3080 (H–Ar), 3310 (N–H), 1500–1470 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782. ^{1}H NMR (d-chloroform 250 MHz): 6.8–7.8 (m, H–Ar), −4.83 (br s, N–H).

2.2.7. 2,9,16,23-Tetrakis(2-naphthoxy)-phthalocyaninatonickel (**5c**)

Yield: 16 mg, 11.25%. Melting point >200 °C IR (KBr), $\nu(cm^{-1})$: 3055 (H–Ar), 1600–1570 (Ar C=C), 1268, 1242 (Ar–O–Ar), 782. ^{1}H NMR (d-chloroform 250 MHz): 6.4–7.35 (m, H–Ar).

3. Results and discussion

The phthalonitrile derivatives **2** and **3** were obtained through displacement reaction of 4-nitrophthalonitrile **1** with 1-naphthol and 2-naphthol, respectively [24] (Fig. 1). Conversion of **2** and **3** into the corresponding metal-free and metallo-phthalocyanines (**4a–d**, **5a–c**) was accomplished in high-boiling solvents in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene and/or metal salts. All of these new compounds were characterized by elemental analysis, IR, UV–Vis and NMR spectroscopic techniques (Table 1).

The spectroscopic data of the new compounds were in accordance with the structures [7–15]. Naturally, the

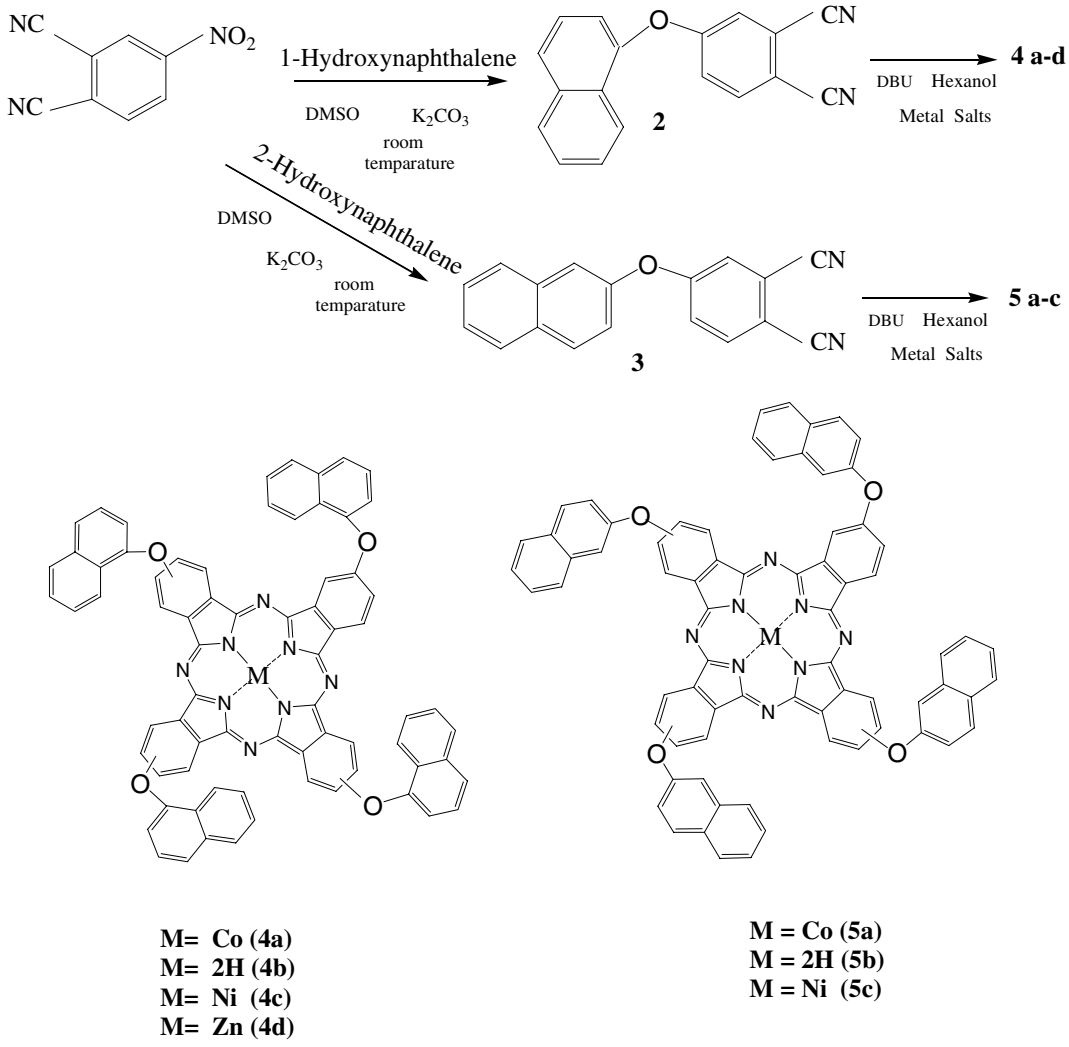

Fig. 1. Napthoxyphthalonitrile derivatives and the phthalocyanines derived from them.

phthalocyanine products synthesized during this work are a mixture of positional isomers while both of the phthalonitrile precursor **2** and **3** carry a single substituent [2,25].

There is only a very slight difference between the chemical shift values of aromatic protons for **2** (7.13–7.96 ppm) and for **3** (7.17–7.97 ppm). In addition, when compared with the IR spectrum of **1**, those of **2** and **3** confirmed the proposed structures by the disappearance of the aromatic $-NO_2$ band at 1548 cm^{-1} and the appearance of an intense new absorption at 1268 cm^{-1} attributable to aromatic C–O–C [24]. After conversion of dinitrile derivatives **2** and **3** to phthalocyanines, the sharp C≡N vibration around 2238 cm^{-1} disappeared. The NH stretching absorption of the inner core of the metal-free phthalocyanines **4b** and **5b** was observed around 3310 cm^{-1}. The N–H protons of the metal-free phthalocyanine **4b** and **5b** were also identified in the ^1H NMR spectrum with a broad peak at $\delta = -7.12$, $\delta = -4.83$ ppm, presenting the typical shielding of inner core protons, which is a common feature of the ^1H NMR spectra of metal-free phthalocyanines [9,15] (Fig. 2). The difference between the chemical shift values of the inner core protons in **4b** and **5b** is a consequence of differences in the concentration of these compounds when taking the spectra. It should be noted that the

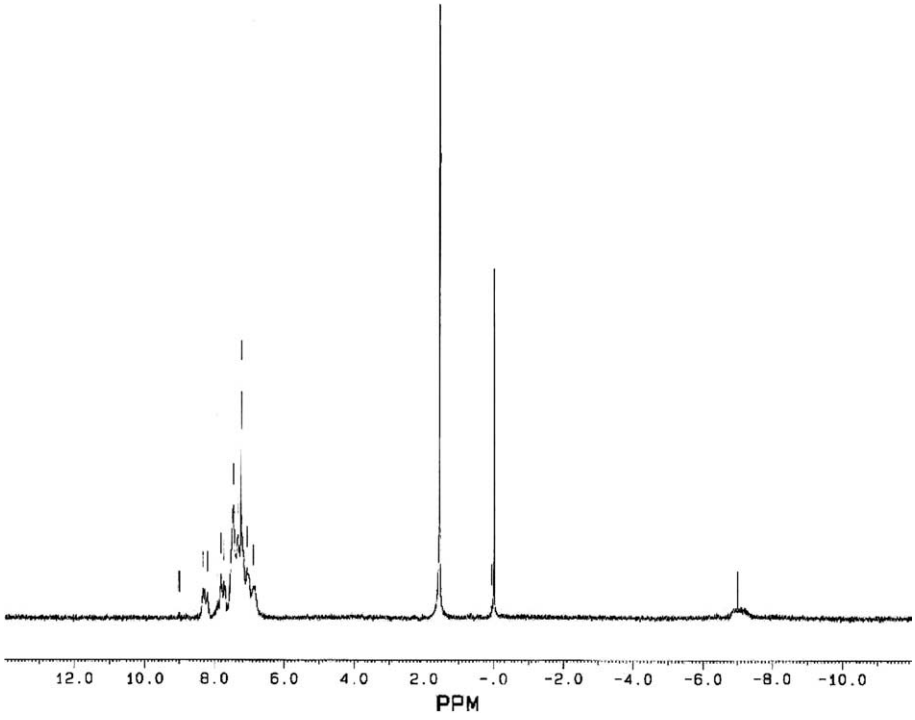

Fig. 2. H^1 NMR spectra of metal-free phthalocyanine **4b**.

chemical shifts of α-protons of the Pc core could not be observed in the case of **5b** and **5c** probably due to aggregation. IR spectra of all phthalocyanine derivatives **4a**–**d**, **5a**–**c** showed aromatic C–O–C peaks at 1268 and 1242 cm^{-1} and a characteristic substituted naphthalene peak at 782 cm^{-1}.

Electronic spectra are especially fruitful to establish the structure of all the phthalocyanines **4a**–**d**, **5a**–**c**. The UV–Vis spectra of the phthalocyanine core is dominated by two intense bands, the Q band around 680 nm and the B band in the near UV region, around 330 nm, both correlate to $\pi \rightarrow \pi^*$ transitions [7–15]. UV–Vis spectra of metallo phthalocyanines (**4a** in THF, **4b**–**d**, **5a**–**c** in $CHCl_3$) exhibited an intense single Q band absorption of the $\pi \rightarrow \pi^*$ transitions around 660–680 nm and B bands in the UV region around 327–343 nm (Fig. 3). For metal-free derivatives **4b** and **5b** (in $CHCl_3$) split Q bands appeared at 702–667 nm, while the B band remained at 339 nm (Table 2). In the case of naphthalocyanines, the naphtho groups are fused to the planar phthalocyanine core and their π-electrons are integrated into the aromatic system of the main core [17–20]. The consequence of this structure is some bathochromic shift to the near IR region, especially in the Q band, while the B band remains almost the same as in the case of the parent phthalocyanine molecules. Here, in the case of the phthalocyanines with appending naphthoxy substituents the electronic spectra appear very similar to those of tetra-substituted phthalocyanines, but additionally an intense absorption due to the $\pi \rightarrow \pi^*$ tran-

sition of naphthalene groups appeared for all these phthalocyanine derivatives **4a**–**d**, **5a**–**c** in the UV region at about 290 nm (Table 2).

In conclusion, we have described the synthesis and spectral characterization of seven new phthalocyanines with 1-naphthoxy and 2-naphthoxy substituents on the periphery; the distinctive property of these compounds is a second absortion in the ultraviolet region of comparable intensity to the intense B band of phthalocyanines.

Abstract

Reaction of $AgNO_3$ and 1-alkyl-2-(naphthyl-(α/β)-azo)imidazole (α-/β-NaiR) in MeOH followed by the addition of $NaClO_4$ has isolated $[Ag(\alpha\text{-/}\beta\text{-NaiR})_2](ClO_4)$ (**3/4**). The complexes are characterized by microanalytical and spectral data. Single crystal X-ray diffraction study of bis-[1-ethyl-2-(naphthyl-α-azo)imidazole]silver(I) perchlorate confirms the structure of the complex. Argentophilicity of imidazole-N and steric crowding by naphthyl groups have forced a {2+2} distorted linear geometry. The structure shows intramolecular and intermolecular H-bonding in a 1D helical framework along with face-to-face π–π interactions.

Keywords: Naphthylazoimidazole; Silver(I) complexes; Helical structure; EHMO

1. Introduction

Imidazole is ubiquitous in chemistry and biology [1]. In this respect, the chemical modification of imidazole to synthesize polydentate ligands is of current interest [2–4]. We are also engaged to synthesize imidazole containing ligands, arylazoimidazoles by anchoring an arylazo (Ar–N=N$^+$) group to the imidazole backbone. As a part of our continuing program of research in the field of azohetereocyclic molecules we have designed arylazoheterocycles of pyridine, pyrimidine and imidazole [5–7]. They differ in their π-acidity in the order of imidazole < pyridine < pyrimidine [8]. Arylazoheterocycles bear the functional group azoimine, –N=N–C=N–, which is an efficient group to stabilize the low valent metal redox state [9–12].

Imidazole, being a five-membered heterocycle, is less π-acidic and a better π-donor than six-membered pyridine/pyrimidine rings. The electronic property of the molecule may be finely adjusted by changing substituents in the aryl group or complete replacement of the aryl group by an α- and/or β-naphthyl group [9–12]. The α- and β-naphthyl moieties also exhibit different thermodynamic stability [13] which may indirectly perturb the electronic levels of the metal complexes.

We have recently reported the coordination chemistry of platinum(II) [9], ruthenium(II) [10], osmium(II) [11] and palladium(II) [12] naphthylazoimidazoles. In recent years the coordination chemistry of coinage metals came into the field for their (i) biological and medicinal importance [14–16], (ii) metal–metal interaction between closed shell (d^{10}–d^{10}) cations or the aurophilic interaction [17–20] and (iii) supramolecular assemblies with particular reference to helicity in silver(I) complexes [21–25]. Several single and double stranded helical polymers of silver(I) and their photophysical and spectrochemical properties are topics of developing interest. Because of the flexibility in coordination number in Ag(I) [26, 27], covalent interaction may lead to the synthesis of coordination polymers [28]. The assembly of coordination networks through H-bonding and π–π stacking

1-alkyl-2-(naphthylazo)imidazole (α-NaiR) (β-NaiR)

R = Me (**a**), Et (**b**), CH_2Ph (**c**)

Scheme 1.

interactions has been of great interest in recent years [29,30]. Presence of suitable oxo counter ions (e.g. NO_3^-, ClO_4^-, $CF_3SO_3^-$, etc) in the complexes may result in secondary interactions, C–H···O and act as a determining factor for crystal packing and helicity [31].

Ag(I)-azoimidazole complexes have been reported by a different researcher [32–36]. In this work, we have selected closely related ligands, 2-(naphthyl-(α/β)-azo)imidazole (α/β-NaiR) (Scheme 1) which provide larger steric crowding and better electron donating ability than a conventional aryl group. In this work we have explored the coordination chemistry of Ag(I)-naphthylazoimidazoles. Synthesis, spectral, electrochemical studies have been carried out and a single crystal X-ray structure of Ag(I)-naphthylazoimidazoles are described.

2. Experimental

2.1. Materials

1-Alkyl-2-(naphthyl-(α/β)-azo)imidazoles (α-NaiR (**1**), β-NaiR (**2**)) were synthesized by a reported procedure [10,12]. $AgNO_3$ and α-/β-naphthylamines were obtained from E. Merck, Germany and $NaClO_4$ was obtained from Fluka, USA. Purification of solvents was performed as in the reported procedure [12]. All other solvents and chemicals were of reagent grade and were used without further purification.

2.2. Physical measurements

Microanalytical (C, H, N) data were collected using a Perkin–Elmer 2400 elemental analyzer. UV–Vis spectra were recorded by a JASCO V-570 UV/Vis/NIR spectrophotometer. IR data were collected from a JASCO-420 FTIR (KBr disk, 4000–200 cm^{-1}). ^1H NMR spectra were collected in $CDCl_3$ using a 500 MHz FT-NMR spectrometer. Electrical conductivity was measured using a Systronics 305 digital conductivity meter with a solution concentration of $\sim 10^{-3}$ M cm^{-3}. Silver was analyzed gravimetrically [37]. Electrochemical measurements were carried out under dinitrogen conditions with the help of an EG&G PARC 270 computer controlled Versastat using a Pt-disk milli working electrode. All results were collected at 298 K with the saturated calomel electrode (SCE) as reference. Reported potentials are uncorrected for junction effects.

Caution! Perchlorate salts of metal complexes are explosive in nature and should be handled carefully.

2.3. Preparation of bis-[1-ethyl-2-(naphthyl-α-azo)imidazole]silver(I) perchlorate, $[Ag(\alpha\text{-NaiEt})_2](ClO_4)$ (**3b**)

The ligand α-NaiEt (0.50 g, 2 mmol) in dry MeOH (20 ml) was added to a methanolic solution of $AgNO_3$ (0.17 g, 1 mmol). The red-brown solution was stirred for 4 h in a dark environment and covered with carbon paper. The solution volume was reduced to half of its original volume by bubbling nitrogen gas. The compound was collected as the perchlorate salt by adding $NaClO_4$(1 g in 2 ml aqueous solution). The brown-red mass was recrystalized from diffusion of a CH_2Cl_2 solution of the complex into hexane. Yield was 0.60 gm (90%). *Anal.* Calc. for $C_{30}H_{28}N_8ClO_4Ag$ (**3b**): C, 50.78; H, 3.87; N, 15.90; Ag, 15.03. Found: C, 50.89; H, 3.96; N, 15.83; Ag, 15.24%. IR (KBr, cm^{-1}): 1384 (N=N), 1582 (C=N).

All other complexes were prepared following an identical procedure and yields were 75–90%. *Anal.* Calc. for $C_{28}H_{24}N_8ClO_4$ Ag (**3a**): C, 49.35; H, 3.91; N, 15.78; Ag, 16.15. 2.4. Crystallographic data collection and refinement

A crystal suitable for X-ray diffraction study was obtained after several trials by slow diffusion of a CH_2Cl_2 solution of the complex into a hexane layer. A suitable single crystal of complex $[Ag(\alpha\text{-NaiEt})_2](ClO_4)$ (**3b**) was mounted on a Siemens CCD diffractometer equipped with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The intensity data were corrected for Lorentz and polarization effects. Details of data collection and structure solution are given in Table 1. The structure was solved by Patterson syntheses and

$R = \sum||F_o| - |F_c||/\sum|F_o|$. $wR_2 = [\sum w(|F_o|^2 - |F_c|^2)^2/\sum w(|F_o|^2)^2]^{1/2}$, $w = 1/[\sigma^2(F_o^2) + (0.0299P)^2]$, $P = (F_o^2 + 2F_c^2)/3$. Goodness-of-fit (GOF) is defined as $[w(F_o - F_c)/(n_0 - n_v)]^{1/2}$ where n_0 and n_v denote the number of data and variables, respectively.

followed by successive Fourier and difference Fourier syntheses. Full-matrix least-squares refinements on F^2 were carried out using SHELXL-97 with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were constrained to ride on the respective carbon atoms with an isotropic displacement parameter equal to 1.2 times the equivalent isotropic displacement parameter of their parent atom. Since the complex was crystallized in a non-centrosymmetric space group, the absolute configuration was determined (Flack × parameter $= -0.00(3)$) [38]. Complex neutral atom scattering factors were used throughout this program. All calculations were carried out using SHELXS 86 [39] SHELXL 97 [40], PLATON 99 and ORTEP-3 [41,42] programs.

3. Results and discussion

3.1. Synthesis

The two classes of ligands used in the present study belong to the azoimine (–N=N–C=N–) family. 1-Alkyl-2-(naphthyl-α-azo)imidazoles are abbreviated as α-NaiMe (**1a**), α-NaiEt (**1b**), α-NaiBz (**1c**); 1-alkyl-2-(naphthyl-β-azo)imidazoles are abbreviated as β-NaiMe (**2a**), β-NaiEt (**2b**) and β-NaiBz (**2c**). They are synthesized by the reported procedure [10–12]. The ligands are an unsymmetric bidentate N,N′ chelating type.

These ligands in MeOH–$CHCl_3$ mixture react with $AgNO_3$in MeOH and the complexes have been isolated as their perchlorate salts. They were purified by crystallization by diffusion of CH_2Cl_2 solution of the complex into hexane. The complexes are highly photosensitive and decomposed with separation of black metallic silver from solution upon exposure to light. The complexes are characterized by elemental analyses, IR, UV–Vis (Table 2), ^{1}H NMR (Table 3) data and support the formulation [Ag(α-/β-NaiR)$_2$][ClO$_4$] (**3**, **4**). The complexes are diamagnetic and 1:1 electrolytes in nitromethane. The structural configuration has been determined by a single crystal X-ray diffraction study of [Ag (α-NaiEt)$_2$][ClO$_4$] (**3b**).

3.2. Spectral properties

The complexes [Ag(NaiR)$_2$]$^+$ exhibit characteristic IR transmissions for *ν*(N=N) and *ν*(C=N) at around 1382 and 1485 cm^{-1}. The free ligand values are 1410 and 1600 cm^{-1}, respectively. The observation is interesting. The *ν*(C=N) is red-shifted by >100 cm^{-1}. This supports very strong interaction of Ag^+ with imidazolic-N compared to azo-N. This is also confirmed by bond length data (Table 4). The perchlorate (ClO_4^-) exhibits bands at 1147, 1108 and 1090 cm^{-1} along with a weak band at 620–625 cm^{-1}. The splitting of *ν*(ClO_4^-) supports reduction in symmetry, which may be due to some hydrogen bonding interaction. This is observed, indeed (vide infra).

Solution electronic spectra of the complexes were recorded in dichloromethane in the range of 600–200 nm. Bathochromic shift relative to the free ligand indicates interaction between Ag^+ and the ligand (Table 2). The silver(I) complexes exhibit the absorption at ca. 400 nm and are assigned to intraligand charge transitions.

The ligands and complexes show highly resolved ^{1}H NMR spectra in $CDCl_3$ at 298 K. 1-Alkyl-2-(naphthylazo)imidazoles (NaiR) have been characterized previously [10,12] and serve as guides to determine the structure of the silver(I) complexes. The spectral data are collected in Table 3. The 1-alkyl groups in [Ag(NaiR)$_2$]$^+$ show significant shifting downfield by 0.1– 0.2 ppm from that of the free ligand values [10–12]. A significant difference is observed in the resonance signal of imidazole protons 4- and 5-H from that of naphthyl protons. Imidazole protons 4- and 5-H appear upfield (6.9–7.2 ppm) and naphthyl protons (8-H–15-H) resonate downfield, 7.5–8.0 ppm. In [Ag(NaiR)$_2$]$^+$ the signal pattern shows that imidazole protons are shifted to the downfield side by 0.4–0.5 ppm and naphthyl protons are shifted to upfield side except 9-H in α-NaiR and 8, 10-H in β-NaiR compared to the free ligand values.

3.3. Molecular structure

A molecular view of the complex [Ag(α-NaiEt)$_2$][ClO$_4$] (**3b**) is shown in Fig. 1 and the bond parameters are given in Table 4. A review of the bond lengths and angles shows that the complex is essentially linear with a further two weak interactions to azo-N of the azoimine group. The N=N distances are equivalent in the two azoimine chelates (1.266(5), 1.265(5) Å). Free ligand bond parameters are available for 1-ethyl-2-(naphthyl-azo)imidazolium hexafluorophosphate, [α-NaiEtH]$^+$[PF_6^-] [43] and the N–N distance is 1.267(3) Å. The N–N distance in 1-methyl-2-(phenylazo)imidazolium perchlorate is 1.250(1) Å [44]. The elongation is likely to be a result of a high steric crowding provided by the naphthyl group relative to the phenyl group. This may be due to better σ-donor character of the ligand compared to the aryl group. The Ag–N distances are as follows: Ag–N (imidazole) [Ag–N(1), 2.124(5); Ag–N(5), 2.128(5) Å]. The distance is shortened by >0.7 Å than that of the proposed Ag–N(azo) distance [Ag–N(4), 2.851(5); Ag–N(8), 2.859(5) Å]. This accounts for the argentophilicity [17,18] of imidazole-N compared to azo-N donor centers. On considering the weak interaction of Ag(I) with the azo-N leading to the chelated structure, the proposed chelate angles are: N(1)–Ag–

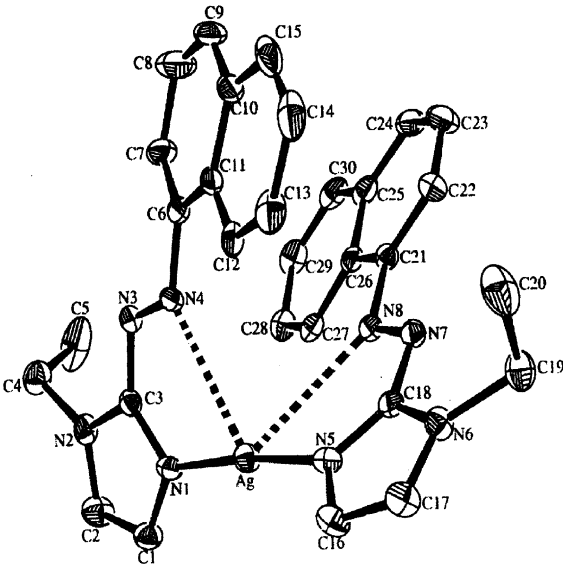

Fig. 1. X-ray crystal structure of $[Ag(\alpha\text{-NaiEt})_2]$ (ClO_4) (**3b**).

N(4), 65.45(2)° and N(5)–Ag–N(8), 64.86(2)°. This example bears the lowest chelate bite angles so far reported in the azoimine family [9–12]. This smallest chelate angle may lead to distortion in the tetrahedral geometry. The naphthyl ring is no longer planar with the chelate plane. The plane-1 (Ag–N(1)–C(3)–N(3)–N(4)) inclines at an angle of 23.4(2)° with the α-naphthyl group whereas plane-2 (Ag–N(5)–C(18)–N(7)–N(8)) makes an angle of 49.89(2)°. Thus, the two naphthyl groups are skewed by 18.9(2)°. The bulky size of the naphthyl groups may provide high steric interaction and may be responsible for the unusual distortion in geometry. The strain is manifested in stereochemical change from tetrahedral to linear symmetry. This has led us to conclude that the structure may be described as a {2+2} distorted linear geometry tending to tetrahedral symmetry. Usually macrocycles are described by [m+n] nomenclature. For brevity we use the {2+2} symbol to designate bi-coordinated linear geometry with some distortion towards tetrahedral symmetry.

1-Ethyl-2-(naphthyl-α-azo)imidazoles (α-NaiEt) and 2-(phenylazo)pyrimidines (papm) [45] have an azoimine, –N=N–C=N–, chelating function with an inbuilt imine (–C=N–) group in a heterocyclic back bone. Imidazole is a five-membered *meta* related two-N heterocycle while pyrimidine is a six-membered two-N heterocycle system. The replacement of a six-membered heterocycle by a five membered one reduces both the σ-donor and π-acceptor character of the system [8] and also introduces angular strain in the chelate ring [2]. This is reflected in the comparison of chelate ring structures of Ag(I)-naphthylazoimidazole and Ag(I)-2-(phenylazo)pyrimidine (Ag(papm) system [28]) molecules (Fig. 2). The elongation of the Ag–N (azo) [Ag–N(4)] distance by ~0.3 Å in Ag(-NaiEt) compared to Ag(papm) is a support of the

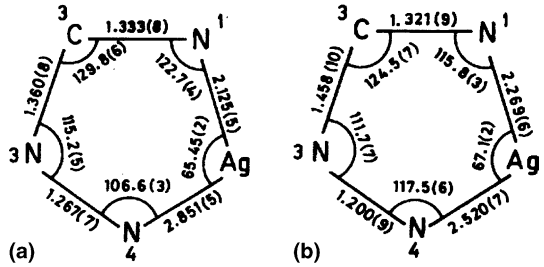

Fig. 2. Dimensions of chelate rings of (a) $Ag(\alpha\text{-NaiEt})_2^+$ and (b) $Ag(papm)^+$.

reduction in σ-donation capacity of α-NaiEt with respect to papm. The naphthyl group is a better electron donor, and provides higher steric strain relative to the phenyl ring and that plays a crucial role to monitor the σ-/π-acidity of the azo function [46]. The π-acidity of naphthyl < phenyl as well as imidazole < pyrimidine [8]. This may support the shortening of the Ag–N(4) bond in Ag-(papm) [28] compared to the present silver(I) complex. The same argument cannot explain the shortening of bond length (by ~0.15 Å) of Ag–N(1) (Ag–N (heterocycle)) in $Ag(\alpha\text{-NaiEt})_2^+$ relative to that of Ag-(papm). The strain that is developed due to replacement of pyrimidine by imidazole has been released by the elongation of the Ag–N(azo) bond length in the $Ag(\alpha\text{-NaiEt})_2^+$ system compared to that of the Ag-(papm) complex. However, the –N=N– bond length is unusually shortened in Ag-papm, which may be due to the helical network and triangular $Ag(N)_3$ coordination in the complex. The phenomena is more likely to be a result of bond alteration in Ag(papm) vs. a bond delocalization in Ag(α-NaiEt) in C3–N3–N4 bond lengths, probably caused by electronic effects.

The packing view of the crystal structure shows (Fig. 3) that $Ag(\alpha\text{-NaiEt})_2^+$ contains an intramolecular and intermolecular H-bonded 1D helical framework. Intramolecular H-bonding is playing between the azo-N and α-H of the naphthyl group [N(4)···H(12), 2.477(8); N(8)···H(27), 2.531(3) Å]. This enhances the acidity of the C(12)–H(12)/C(27)–H(27) group leading to activation of this bond. This is observed by adding $PdCl_4^{2-}$ to the solution of this complex and the cyclopalladated complex has been synthesized by a transmetallation reaction followed by the C–H activation process [12]. Intermolecular H-bonds operate between the two

fragments around the azo group. The C–H group of the imidazole moiety *ortho* to metal coordinated-N (imidazole) [C(1)–H(1)/C(16)–H(16)] develops an electrostatic interaction with perchlorate-O(1)/O(4) while naphthyl C(15)–H(15) gives a H-bonding interaction with the second perchlorate ion. In addition to these, the complex experiences C–H–O as well as face-to-face π–π interactions (Table 5).

3.4. Redox studies

The electrochemical properties of the complexes were examined by cyclic voltammetry in MeCN using $[n\text{Bu}_4\text{N}][\text{ClO}_4]$ as supporting electrolyte at the scan rate 50 mV s^{-1}. The complexes of silver exhibit an irreversible oxidation–reduction response with the Pt-disk working electrode and saturated calomel electrode (SCE) as reference electrode. The complexes undergo reduction processes, which, given the redox non-innocence of the azoimine group [10], are assigned to ligand-centred-processes. The quasireversibility of the reductive process is observed from the peak separation ($\Delta E > 130$ mV) and the reduction is referred to the accommodation of an electron to the azo function dominated orbital of the bound ligand. Such processes, coupled to chemical complications for the reduction of Ag(I) on the electrode surface, result in that the current ratio i_{pa}/i_{pc} is always less than unity (i_{pa}/i_{pc} lies between 0.5 and 0.6). In this connection, the presence of anodic stripping peaks in the backscan ($E_{pa} \sim +0.5$ V, Table 2) looks likely to testify for reoxidation of electro-deposed silver metal. This means that the reduction processes more than likely trigger release of silver ion with its consequent reduction to silver metal [47]. The reoxidation of $Ag(0) \rightarrow Ag(I)$ is associated with very high anodic current at positive to SCE (stripping potential ~+0.5 V) which on repeat scan progressively increases the current. Besides, the approach to more negative potential followed by backscan increases the peak current height. The increase in potential gradient enhances the reaction rate which may cause deposition of larger amounts of Ag on the surface.

3.5. EHMO calculation and correlation with spectral and electrochemical properties

In order to highlight the electronic properties of silver(I)-naphthylazoimidazoles, an MO calculation has been performed in the framework of extended Huckel formalism. Crystallographic data of **3b** are used for the EHMO calculation. The MO pictures are shown in Fig. 4 and the percentage contribution of participating fragment/atomic functions to the MOs are given in Table 6. The HOMO(91) is contributed from 2% silver and 88% [77% azo (N=N), 7.7% naphthyl group and 3.3% N(imidazole)] ligand orbital. The LUMO has no metal contribution, it is mainly ligand orbital, 99.4% [52.5% azo (N=N), 25.5% naphthyl group and 21.4% N(imidazole)]. Other low-lying orbitals (HOMO-1, HOMO-2) show a greater metal contribution but other higher energy orbitals (UMOs) show no metal contribution. It can be concluded that there should be no M → Ligand charge transfer and this happens indeed. The complexes show only the interligand (between imidazole and naphthyl group) charge transition in the lower wavelength region. Because of the weak M–L interaction, Ag^+ is quickly separated from the ligands claw under the electrode field potential and has been deposited on the electrode surface. However, Cu(I)-complexes show somewhat different results because of the higher contribution of copper(I) to the HOMO and other occupied MOs [48].

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 172833 for bis-[1-ethyl-2-(naphthyl-α-azo)imidazole]silver(I) perchlorate. Copies of this information may be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

The titanium tetrazole coordination complex $[TiCl_4 \cdot (PhCN_4H)_2]$ has been prepared by treatment of $TiCl_4$ with two equivalents of 5-phenyltetrazole in dichloromethane and spectroscopically and crystallographically characterised. The solid-state structure of this compound consists of six-coordinate titanium centres with *cis* ligated tetrazoles. The individual $[TiCl_4 \cdot (PhCN_4H)_2]$ dimerise via intermolecular N···H–N hydrogen bonding interactions and are further organised into 2D supramolecular arrays. Mass spectral evidence indicates that the individual tetrazole ligands are only weakly bound, limiting the potential of this complex as a titanium nitride precursor. 3 + 2 cycloaddition of tributyltin azide with 2-toluinitrile at 200 °C has afforded the tributylstannyl tetrazole $[SnBu_3\{5\text{-}(2\text{-}MeC_6H_4)CN_4\}]_n$. Crystallographic analysis shows that this compound exists as a supramolecular coordination polymer propagated via trigonal bipyramidal tin centres linked by N^1–Sn–N^3 interactions. Preliminary reactivity studies of this tin complex with titanium tetrachloride in an effort to synthesise a covalently bound titanium tetrazolyl complex have thus far yielded incomplete elimination of the expected Bu_3SnCl by-product and intractable titanium-containing products.

1. Introduction

The combination of a better conductivity (4698 $kS\,cm^{-1}$) than titanium metal (2381 $kS\,cm^{-1}$), extreme hardness (9–10 Moh) and a refractory nature dictate that titanium nitride (TiN) is perhaps the most extensively applied transition metal nitride in both microelectronic (metal/semiconductor interconnects) and architectural applications (protective coatings) [1,2]. High quality thin films of cubic TiN may be produced by atmospheric pressure chemical vapour deposition (APCVD) in a process which conventionally employs ammonia gas and gaseous titanium tetrachloride transported in an inert carrier [3]. Although efficient, this process suffers problems of pre-reaction and requires removal of the corrosive HCl by-product. These qualities, coupled to inconveniently high substrate temperatures of 600–900 °C required by this process, have prompted a search for alternative 'designed' or 'single source' molecular precursors with more amenable reaction/decomposition characteristics. Although successfully attenuating undesirable prereactions, alternative dual source systems which apply volatile tetrakis(dialkyl)amido titanium precursors such as $Ti(NMe_2)_4$ and $Ti(NEt_2)_4$ and ammonia and mixed $TiCl_4$/alkyl amine feedstocks have provided their own additional problems of carbon contamination and poor step coverage [4–7]. Initial efforts to address these difficulties by design of suitable single source precursors containing a preprogrammed combination of titanium and nitrogen were prompted by speculation about the nature of intermediate products formed by these systems prior to film growth. Accordingly, a number of titanium amido and imido species, such as $[CpTiCl_2\{N(SiMe_3)_2\}]$ and $[\{Ti(\mu\text{-}N^tBu)(NMe_2)_2\}_2]$, have been prepared and examined in this context [8–12]. Neither these nor more recent studies of mono- or bis-azido complexes [for example $[\{Ti(N^tBu)Cl(N_3)(py)_2\}_2]$ and $[\{Ti(NCy)(N_3)_2(py)_2\}_2]$ (py = pyridine)] have, however, yielded effective TiN precursors. Film growth in these latter cases is hampered either by a lack of volatility or unacceptably

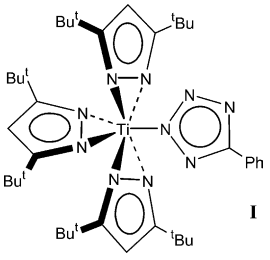
high levels of carbon contamination approaching 35% [13,14].

Pyrazolate anions derived by deprotonation of parent pyrazole heterocycles have been shown to provide a flexible N-donor ligand set in titanium chemistry [15–17]. The use of titanium pyrazolyl derivatives as molecular precursors to TiN is likely to be hampered, however, by similar problems of carbon contamination to those outlined above due to the presence of direct carbon to nitrogen bonds in the delocalised heterocycle. We have turned our attention therefore to the synthesis of titanium tetrazolato derivatives in the hope that the high nitrogen content of this latter ligand type will encourage clean elimination of thermodynamically stable small molecule (N_2 and nitrile) side products and retention of Ti–N linkages at relatively low temperatures.

Although a number of inorganic and organometallic tetrazolyl derivatives have been cystallographically characterised in recent years [18–34], structurally authenticated titanium derivatives are restricted to the seven coordinate tris(3,5-di-*tert*-butylpyrazolato)(5-phenyltetrazolato)titanium (**I**) [31]. Although the subject of a low precision X-ray structural determination and not reported in detail, η_1-N^2 coordination of the tetrazolyl anion to titanium was confirmed. Due to the multiplicity of potential nitrogen donors, many metal-coordinated tetrazoles are prone to coordination polymerisation. The monodenticity of the tetrazolyl ligand of **I** is, most likely, therefore enforced by the η^2-coordination of the three bulky pyrazolato co-ligands. As such co-ligands were reasoned to be of likely detriment to clean precursor decomposition, our initial studies have targeted titanium tetrazole complexes with simple chloride ligands sets. We now report our studies which have resulted in the high yield synthesis of a simple Ti(IV) tetrazole coordination complex along with our initial exploration of an organotin-based strategy that attempts to effect both clean formation of titanium tetrazolyl derivatives and a means by which the steric demands at the C^5 position of the tetrazole ring may be readily modulated.



I

2. Experimental

2.1. General

All reactions were conducted under an atmosphere of dry argon and manipulated either on a double manifold vacuum line or in a dinitrogen-filled drybox operating at less than 1 ppm of O_2. Solvents were purified by distillation from an appropriate drying agent (THF from potassium, CH_2Cl_2 from CaH_2 and hexane from Na/K alloy). NMR spectra were recorded at 300.13 (^{1}H), 125.8 (^{13}C) and 186.4 MHz (^{119}Sn) from samples in $CDCl_3$ or d_8-THF; Chemical shifts are relative to $SiMe_4$ for ^{1}H and ^{13}C NMR. ^{119}Sn NMR were referenced externally to Me_4Sn. Mass spectra were obtained at 70 eV. Tributyltin azide was synthesised by a literature procedure [35].

Caution! All reactions of azides and tetrazole compounds must be treated as potentially explosive and conducted behind a rigid safety screen.

2.2. $[TiCl_4 \cdot (PhCN_4H)_2]$ (**1**)

A solution of titanium tetrachloride (1.97 g, 10.4 mmol) in dichloromethane (30 cm^3) was added at room temperature to a stirred slurry of $PhCN_4H$ (3.04 g, 20.8 mmol) in dichloromethane (40 cm^3). This resulted in the formation of a dense pale yellow precipitate and a yellow solution. The yellow solid, **1** (4.70 g, 94%), was isolated by filtration and dried under vacuum. Cooling of the filtrate to −30 °C resulted in the formation of a small number of yellow crystals suitable for X-ray diffraction after 3 days. Elemental and spectroscopic analysis of the bulk powder was consistent with an unsolvated form. *Anal.* Calc. for $C_{14}H_{12}Cl_4N_8Ti$: C, 34.87; H, 2.51; N, 23.25. Found: C, 34.71; H, 2.36; N, 23.00%. ^{1}H NMR [d^8-THF, 298 K] δ: 7.49 (m, 6H, m, *p*-C_6H_5), 8.01 (m, 4H, *o*-C_6H_5), 15.1 (br.s, 2H, N–H). ^{13}C{^{1}H} NMR [d^8-THF, 298 K] δ: 126.3 (*i*-C_6H_5), 127.4 (*o*-C_6H_5), 129.3 (*m*-C_6H_5), 131.2 (*p*-C_6H_5). MS (EI$^+$, 70 eV), 190 (55%, $TiCl_4$), 153 (100, $TiCl_3$), 118 (70, $TiCl_2$), 103 (25, PhCN), 83 (45, TiCl).

2.3. $[SnBu_3\{5\text{-}(2\text{-}MeC_6H_4)CN_4\}]_n$ (**2**)

Bu_3SnN_3 (3.17 g, 9.75 mmol) and 2-toluinitrile (1.25 g, 9.75 mmol) were heated at 200 °C for 2 h under nitrogen to yield a pale amber glass. This was washed with hexane (30 cm^3) and dried in vacuo. Storage of the resultant colourless glass at room temperature for 3 days induced crystallisation to produce compound **2** in effectively stoichiometric yield. *Anal.* Calc. for $C_{20}H_{34}N_4Sn$: C, 53.47; H, 7.64; N, 12.48. Found: C, 53.56; H, 7.64; N, 12.48%. ^{1}H NMR [$CDCl_3$, 298 K] δ: 0.71 (t, 9H, $(CH_2)_3CH_3$), 1.05–1.34 (m, 18H, $(CH_2)_3CH_3$), 2.17 (s, 3H, Ar–Me), 7.15–7.29 (m, 4H, Ar–H). ^{13}C{^{1}H} NMR [$CDCl_3$, 298 K] δ: 13.6 $(CH_2)_3CH_3$, 18.2 ($CH_2(CH_2)_2CH_3$, $^1J_{117,119\ Sn/C} = 457$ Hz), 20.2 (Ar–Me), 27.0 ($(CH_2)_2CH_2CH_3$, $^3J_{117,119\ Sn/C} = 70.9$ Hz), 28.0 ($CH_2CH_2CH_2CH_3$ $^2J_{117,119\ Sn/C} = 27.9$ Hz), 125.6, 128.6, 129.8, 130.5, 137.7 (Ar–C), 161.5 (CN_4). ^{119}Sn{^{1}H} NMR [$CDCl_3$, 298 K] δ: −17.9 ($\Delta\nu_{1/2}$ −2 kHz).

2.4. Attempted reaction of **2** and $TiCl_4$

To a solution of compound **2** (2.37 g, 5.26 mmol) in dichloromethane (120 cm^3) was added a solution of titanium tetrachloride (1.0 g, 5.26 mmol) in dichloromethane (20 cm^3). This resulted in the immediate formation of an orange solution which darkened to a vivid red over the subsequent 48 h. In vacuo removal of the solvent produced a dark red sticky solid, which was washed with hexane (2×30 cm^3) to produce a yellow solid. The ^1H NMR spectrum of this material in d^8-THF displayed resonances corresponding to both Bu_3Sn and the tetrazole ligand. Crystals which formed in the NMR tube were suitable for X-ray analysis and proved to be a hydrolysis product, the oxo-bridged species $(THF)_2Cl_3Ti–O–TiCl_3(THF)_2$.

3. Results and discussion

Winter [36] has studied the treatment of titanium tetrachloride with two equivalents of a variety of substituted pyrazoles. Reaction with 3,5-di-*tert*-butylpyrazole resulted in HCl elimination and the formation of a mixture of molecular L_2TiCl_4 and ionic $[LH^+]_2[TiCl_6^{2-}]$ (where L = 3,5-di-*tert*-butylpyrazole) products. Conversely, reaction with less sterically demanding heterocycles produced a series of six-coordinate $TiCl_4$. L'_2 adducts (where L′ = 3,5-dimethylpyrazole, 3-methylpyrazole, 4-iodopyrazole), where the adoption of either a *cis* or *trans* coordination geometry was reasoned to be largely dependent upon the steric profile of the pyrazole ligand. Prompted by these observations, and intrigued by the possible divergent reactivity that may be induced by the increased acidity of the tetrazole heterocycle [37], we carried out the analogous reaction between two equivalents of commercially available 5-phenyltetrazole and $TiCl_4$ in dichloromethane. This resulted in the immediate precipitation of compound **1** as a pale yellow powder, which was isolated by filtration. Elemental analysis indicated that a 2:1 adduct had been formed, while the presence of a tetrazole N–H functionality was confirmed by the observation of weak absorptions at 3340 and 3390 cm^{-1} in the infra-red spectrum. Although **1** was not soluble in non-donor solvents, ^1H NMR data collected in THF-d_8 displayed resonances similar to those of the free neutral tetrazole. Although these data do not preclude the presence of compound **1** in solution, we tentatively conclude that the tetrazole ligands are displaced from the titanium coordination sphere by the donor solvent. Despite this problematic insolubility, storage of the pale yellow, dilute but saturated supernatant dichloromethane solution from the original reaction at −30 °C for one week produced a small number of yellow single crystals of **1** as a bis-dichloromethane solvate suitable for an X-ray diffraction analysis. The asymmetric unit resulting from this analysis is illustrated in Fig. 1. Selected bond lengths and angles are provided in Table 1, while details of the X-ray analysis are listed in Table 2.

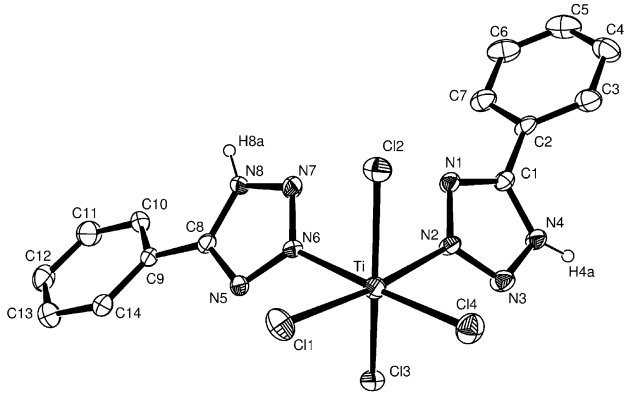


Fig. 1. The asymmetric unit of **1** with thermal ellipsoids drawn at the 30% probability level. All hydrogen atoms apart from H4a, H4b removed for clarity.

Complex **1** is revealed to exist as a six-coordinate adduct with *cis* tetrazole ligands. The coordination sphere exhibits significant deviations from ideal octahedral geometry, with *cis* angles ranging from 81.94(14)° [N(6)–TiCl(3)] to 99.30(8)° [Cl(4)–Ti–Cl(1)] and the *trans* angles between 160.92(8)° [Cl(3)–TiCl(2)] and 174.06(14)° [Cl(4)–Ti–N(6)]. The Ti–Cl(1) [2.231(2) Å] and Ti–Cl(4) [2.216(2) Å] bonds that are *trans* to the tetrazole N-donor atoms are significantly shorter than the mutually *trans* Ti–Cl(2) [2.275(2) Å] and Ti–Cl(3)

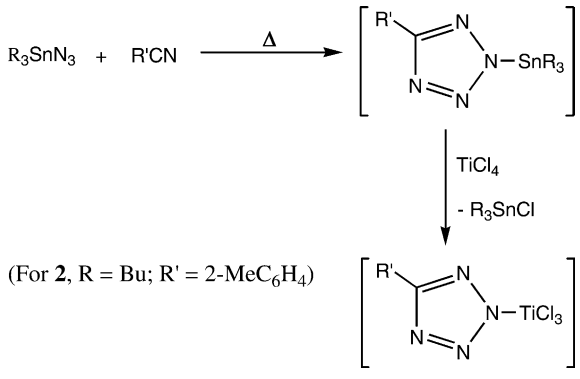
[2.271(2) Å] bonds. These observations and bond lengths are similar to those in other $TiCl_4 \cdot L_2$ *cis* adducted structures including the bis-pyrazole adduct $[TiCl_4(4\text{-}IC_3H_2N_2)_2]$ [36]. The Ti–N bond distances [2.279(5), 2.265(5) Å] of **1** are, however, significantly longer than those reported for this analogous pyrazole adduct [2.235(7) Å] and possibly result from the reduced basicity of the tetrazole moiety [37].

Mass spectral analysis of compound **1** displayed a highest mass fragment at 190 corresponding to the molecular ion $[TiCl_4]^+$. This is an indication that the tetrazole ligands are only weakly bound and most likely inhibits the practical potential of **1** as a nitride precursor. For this reason, we turned our attention to the synthesis of titanium tetrazolyl derivatives containing more robust covalent Ti–N bonds. Winter [31] has reported previously that reactions of the 5-phenyltetrazolyl anion with titanium tetrahalides resulted in intractable mixtures of products, an observation that was confirmed by the present study. Ab initio calculations undertaken as part of the same study highlighted the small energy difference (ca. 5 kcal/mol) that exists between η^1- and η^2-ligated titanium tetrazolyl derivatives while older quantum mechanical calculations have shown that N^1 and N^2 binding are energetically equivalent [38]. The mixture of species that likely results from such facile isomer interconversion, as well as the potential for the formation of complex extended network structures, mitigates therefore against the isolation of simple homo- and heteroleptic titanium tetrazolyl complexes unless the reaction conditions are very carefully controlled. In an attempt to address this issue, we reasoned that enhanced product solubility may result by variation of the tetrazole C^5 substituent steric demands. A very wide range of tetrazole derivatives may be accessed by the straightforward 3 + 2 cycloaddition reaction of organotin azides and RCN dipolarophiles (Scheme 1) [22–27,39]. The ready availability of a great number of substituted nitriles allows facile variation of the resultant tetrazole substituent and provides the heterocycle in a synthetically convenient deprotonated form for subsequent metathesis with $TiCl_4$ (Scheme 1). A similar strategy involving Me_3SiCl elimination has previously been successfully applied to the synthesis of sterically encumbered pyrazolatotrichlotitanium derivatives [16], while R_3SnX elimination from reaction between triorganostannyltetrazoles and alkyl halides has been demonstrated as a straightforward means to tetrazole N-alkylation [40]. Although a great number of potential nitrile precursors are available, our initial



Scheme 1.

efforts identified 2-toluinitrile as a suitable candidate due to the small incremental increase in steric demands over 5-phenyltetrazole and the spectroscopic simplicity of the *ortho*-substituted aryl tetrazolyl product.

Tributyltin azide was synthesised by literature methods [35] while $[SnBu_3\{5\text{-}(2\text{-}MeC_6H_4)CN_4\}]$ (**2**) was synthesised using the well established methodology in which the neat triorganotin azide is heated with a slight excess of the chosen nitrile [39]. The reaction was monitored by the disappearance of the IR bands due to ν(CN) at ca. 2250 cm^{-1} and $\nu_{asym}(N_3)$ at ca. 2060 cm^{-1}. The glassy, crude solid product that was produced upon cooling was washed with hexane to remove excess nitrile and crystallised upon standing at room temperature for three days to produce analytically pure compound **2**.

Compound **2** was sufficiently soluble in $CDCl_3$ to enable the collection of good quality NMR data. The ^1H and ^{13}C NMR spectra were consistent with the proposed structure. The $^1J(^{13}C–^{119}Sn)$ coupling constant of 457 Hz implied a coordination number of >4 about tin, while use of the semiempirical relationship derived by Holecek and Lycka for correlating ^1J data and coordination geometry yielded a value of 123.2° for the C–Sn–C bond angles, consistent with a *trans*-trigonal bipyramidal N_2SnC_3 geometry about tin [41]. These observations are similar to those of previous solution NMR studies of triorganostannyl tetrazoles that have deduced the formation of concentration- and temperature-dependent *N*,*N*′-bridged oligomeric species in solution [22,23,42]. The fluxionality of these systems and similar dynamic behaviour deduced for certain platinum and cobalt tetrazoles [43,44] may also be used to rationalise the broad $^{119}Sn\{^1H\}$ NMR signal ($\Delta\nu_{1/2}$, ca. 2 kHz) observed at −17.9 ppm.

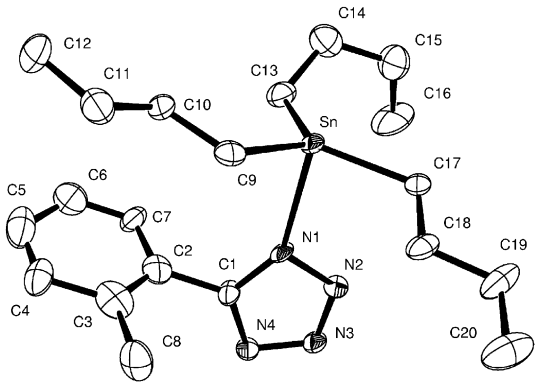


Fig. 2. The asymmetric unit of **2** with thermal ellipsoids drawn at the 50% probability level. All hydrogen atoms removed for clarity.

The solid-state structure of **2** has been crystallographically confirmed. Details of the analysis are listed in Table 2, while selected bond lengths and angles are produced in Table 3. Although the asymmetric unit (Fig. 2) contains only one nitrogen donor, the geometry at tin is best described as trigonal bipyramidal and is defined by *trans*-N_2SnC_3 coordination. The additional tetrazole coordination is provided by a nitrogen atom of an adjacent tetrazole unit. This structural feature is similar to that found in all previously characterised organotin tetrazoles, while both inter- and intramolecular bonding parameters are typical of molecules of this type [22–24]. Within the accuracy of the data, the two Sn–N bonds are identical and serve to propagate a 1D, helical polymeric array along 2_1 screw axes parallel to *c*. This occurs via the $N^1 + N^3$ (N(1)/N(3)) bridging mode, which has previously been observed in a number of related triorganostannyl tetrazole derivatives (Fig. 3)

[22–24]. Although the thermal parameters of for several of the carbon atoms after refinement were large relative to the rest of the structure, this in no way negates our analysis of the overall lattice structure. The thermal parameters of the C_4H_9 units are ascribed to disorder inherent in the packing of the flexible butyl chains. This feature is common to many structures containing the Bu_3Sn fragment and has been commented upon previously with specific reference to organotin tetrazole compounds [22a].

Although attempts to apply **2** to the synthesis of titanium tetrazolyl derivatives have, thus far, met with only limited success, our initial observations are sufficiently encouraging to prompt further study and also serve to illustrate the difficulties inherent in the application of this class of ligand. Reaction of equimolar quantities of **2** and $TiCl_4$ in dichloromethane at room temperature produced a deep red solution which, upon removal of solvent, yielded a sticky red solid. This material was washed with dry hexane to remove eliminated Bu_3SnCl (confirmed by NMR analysis of the hexane filtrate) and the yellow solid produced by this procedure was analysed by ^1H NMR and 70 eV mass spectrometry. This analysis revealed the presence of both the tetrazole ligand and residual Bu_3Sn-, which persisted even upon repeated hexane washing. This observation is suggestive of either incomplete reaction or inclusion of Bu_3SnCl by adduct formation with the Lewis basic tetrazole nitrogen atoms. Indirect evidence for the formation of a titanium tetrazolyl linkage were provided by an X-ray study of a small quantity of yellow crystals obtained from the NMR tube prepared for the analysis of these reaction products in d_8-THF. These were identified as the known μ-oxo complex $(THF)_2Cl_3Ti–O–TiCl_3(THF)_2$ (**II**) [45], and are tentatively suggested as a result of preferential hydrolysis of the Ti–N bond of the target trichloroamido species.

We are continuing to study related reactivity of more sterically encumbered triorganostannyl-substituted tetrazoles in the hope of obtaining more tractable titanium-containing products. These studies and related work on the synthesis of group 5 and 6 metal complexes will be reported in due course.

4. Crystallography

Crystals of **1** and **2** were covered in oil and suitable single crystals were selected under a microscope and mounted on a KappaCCD diffractometer. Data were collected at 173 K; $\lambda(\text{Mo K}\alpha) = 0.71073$ Å; details are given in Table 2. The structures were solved by direct methods (SHELXS 97) [46] and refined by full matrix least squares (SHELXL 97) [47] with non-H atoms anisotropic and H atoms included in riding mode. No absorption correction was applied.

5. Crystal structure data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 221843 and 221844 for compounds **1** and **2**, respectively. Copies may be obtained free of charge from the director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Received 16 September 2003; accepted 13 November 2003

Abstract

Binuclear copper(I) hexafluoroacetylacetonate (hfac) complexes with non-cyclic divinyl ligands of $[Cu^{I}(hfac)]_2L$ composition (**1**) L = 1,5-hexadiene (HD), (**2**) L = allyl ether, (**3**) L = diallyldimethylsilane, (**4**) L = 1,3-divinyltetramethyldisiloxane were prepared. Sublimation tests showed that the complexes **1** and **4** are most thermally stable and can be sublimated at 50–70 °C in a vacuum (5×10^{-4} Torr) with good yield (>80%). The new yellow crystalline complex **4** is air stable at room temperature and **1** is stable under an inert atmosphere. These complexes were characterized by NMR spectroscopy, TG-DSC analysis and single crystal X-ray diffraction. The $[Cu(hfac)]_2L$ composition for both complexes is realized by copper atom coordination to one vinyl and one hexafluoroacetylacetonate group. The main reason of volatility and thermal stability of compounds **1** and **4** is high symmetry and hence low polarity of their molecules resulting in a relatively low energy of the lattice. Higher thermal stability of **4** in comparison with **1** is due to the stronger metal–ligand bonding due to the presence of dimethylsilyl groups.

1. Introduction

A great number of Lewis base stabilized copper(I) β-diketonates have been prepared to date. For the most part, they are homonuclear hexafluoroacetylacetonate complexes of the formula $(hfac)Cu^{I}L$. Interest in these compounds was provoked by the fact that they form a pure copper film through the reaction of disproportionation [1–3]:

$$2(hfac)Cu^{I}L \rightarrow Cu^{0} + Cu^{II}(hfac)_2 + 2L$$

To take advantage of these compounds for copper deposition, they should be volatile, thermally stable at room temperature and susceptible to thermally induced disproportionation at elevated temperatures. As a L ligand, organic compounds like alkenes and alkynes have shown the greatest potential [4–13]. The above-mentioned reaction of disproportionation is bimolecular and occurs on a surface. Due to this reason, the use of a binuclear copper(I) complex towards facilitating the disproptionation of two Cu^{I} centers on a heated surface is desirable. Usually attempts to utilize this approach are faced with the decreased volatility and the decreased thermal stability of binuclear $[Cu^{I}(hfac)]_2L$ complexes [5,8,12]. Formation of air-sensitive products of $[Cu(hfac)]_2L$ composition was observed after heating the monometallic complexes of potentially bidentate donor ligands: hex-3-yn-1-ene, 2-methyl-1-hexen-3-yne [8] and bis(trimethylsilyl)acetylene [12]. Application of tetraalkenesilanes allowed the isolation of low-volatile mono-, bis-, tris- and tetrakis-$Cu^{I}(hfac)$ containing compounds [11]. $[Cu(hfac)]_2L$ type compounds have also been prepared for alkynes [9,14] and 1,3,5,7-cyclooctatetraene [5] mainly by changing the reaction mixture stoichiometry. Stable complex with norbornadiene of composition 2:2:1 was reported to have been prepared

independently of the reactant ratio whereas isoprene and 1,3-butadiene complexes appeared to be unstable [5].

Our idea was to find an approach to prepare volatile and stable complexes containing two atoms of copper. As the L ligand, we tried divinyl organics, which represent a doubled variant of known olefin ligands used to prepare monometallic (hfac)Cu^{I}L complexes. In our opinion, non-cyclic ligands with terminal double bonds bridged by different linkers provide more flexibility for metal coordination (Fig. 1). In this report, we focused mainly on the relation between structure and thermal properties of these new compounds. Compounds **1** and **4** were used for copper film deposition and preliminary results have been reported [15].

2. Results and discussion

2.1. Synthesis and properties

We obtained yellow crystalline complexes of $[Cu^{I}(hfac)]_2L$ composition: (**1**) with L = 1,5-hexadiene (HD), (**2**) with allyl ether, (**3**) with diallyldimethylsilane, (**4**) with 1,3-divinyltetramethyldisiloxane (DVTMSO) (Fig. 1). These copper complexes were prepared by a slightly modified technique described elsewhere [10]. Independent of the reaction stoichiometry, and even at a Cu:hfac:L ratio of 1:1:2, we separated products $[Cu(hfac)]_2L$ with a 2:2:1 ratio as confirmed from elemental analysis. As sublimation tests showed, among this series of complexes (Fig. 1), only two compounds appeared to be volatile and thermally stable: **1** is formed with the HD ligand and **4** with the DVTMSO ligand. Therefore, detailed investigation was carried out for these two compounds and the discussion is focused mainly on them. Complex **4** is air stable at room temperature and **1** is stable under inert atmosphere mostly. Both of them have been purified by sublimation at 50–70 °C in a 10^{-4} Torr vacuum with good yield (>80%). Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) were performed in a dynamic inert atmosphere (Fig. 2). The first peak in the DSC curve indicates a melting point of 71 °C for $[Cu^{I}(hfac)]_2$(DVTMSO) and 101 °C for $[Cu^{I}(hfac)]_2$-(HD). The endothermic peak at around 220 °C for **4** and 160 °C for **1** indicates maximum weight loss rate detected at these temperatures. The percentage of non-volatile residue for both compounds is much below the Cu content in the complex indicating that the complex was not decomposed below the melting point. At the same time the residue amount for compound $[Cu^{I}(hfac)]_2$(DVTMSO) is almost half of that for $[Cu^{I}(hfac)]_2$(HD). A noticeable exothermic peak at 310 °C for $[Cu^{I}(hfac)]_2$(HD) is assigned to a copper crystallization process. Thus, $[Cu^{I}(hfac)]_2$(DVTMSO) is believed to be more stable than $[Cu^{I}(hfac)]_2$(HD). Comparison of volatility was carried out by vapor pressure measurement for compounds **1**, **4** and well-known mononuclear complex (hfac)Cu^{I}(1,5-cyclooctadiene) results has been previously reported [15].

2.2. Structure consideration

To understand the thermal stability of these two complexes with such different donor ligands, we studied their structure and nature of chemical bonding. The crystal structure determination confirmed the new compounds to be bimetal molecules in which the copper(I) ions are tricoordinated by a chelate-bound β-diketonate and η^2-coordinated vinyl unit (Figs. 3 and 4). Here, we concentrate the attention on structural features of both compounds omitting routine description of each structural element in the molecules. Table 1 shows selected structural data that characterize the main differences in these two complexes.

(hfac)Cu^{I}(vinyl) groups in the molecule of compound **1** are oriented in an opposite manner in parallel planes so the molecule has minimum dipole moment (Fig. 3). The hexadiene ligand in the molecule takes the conformation with minimum energy that stabilizes the complex molecule despite of the relatively simple ligand composition, whereas $[Cu^{I}(hfac)]_2L$ complexes with the simplest alkadienes, 1,3-butadiene and isoprene, are known to be very unstable [5].

The complex with DVTMSO **4** has a structure that is more complicated because it is formed by a ligand containing heteroatoms (Fig. 4). Metal-carbon(vinyl) distances in **1** and **4** are distributed in the same manner (Table 1), while in metal-oxygen(hfac) and C=O distances in the chelate cycle, there is a difference. In

contrast to **1**, the following is observed in **4**: if Cu–O(2) is shorter than Cu–O(3), then Cu–C(3) is longer than Cu–C(4). If Cu–O is longer, the adjacent C=O bond is also longer. Such a disordering can be explained by the presence of an intermolecular short contact between O(3) and the copper atom of the nearest molecule. This distance is equal to 2.85 Å. Nevertheless, the molecule as a whole has rotational symmetry, a center of inversion and seems to be non-polar. The angle Si–O–Si is equal

to 180 °C due to a typical $\pi(d_{Si}–p_O)$ interaction between oxygen and silicon in the siloxanes. At the same time, Cu(hfac) groups are oriented in the way of possible $\pi(d_{Cu} \rightarrow d_{Si})$ or even $\pi(d_{Cu} \rightarrow \pi(d_{Si}–p_O))$ interaction. It is noteworthy that the Cu–Si distance is less than the sum of the Van der Waals radii. This interaction seems to be weak but stabilizes the molecule with this structure. The coordinated C=C bond in **4** is a little bit shorter than that in **1** (Table 1) and shorter than that in (hfac)-Cu^{I}(VTMS) (1.38 Å) [4]. Hence, the structural data obtained are indicative of different character in the chemical bonding between metal and donor ligand.

To explore the metal–ligand bonding in detail, we have used NMR. Coordination of olefins to Cu^{+} is thought to be composed of two components: one is σ donation from the π orbitals of the olefin into empty σ 4s orbitals of the metal. The other one is the bonding of filled d orbitals of the metal into empty π^* orbitals of the olefin. For a series of copper olefin complexes, the

relative contribution of each bonding component can be assessed from its ^1H or better from ^{13}C NMR [13]. Typically, the σ component produces a chemical shift in the signals of coordinated olefin protons to weaker field (deshielding) while the back bonding gives the opposite result (shielding). The combination of these two effects results in the absolute chemical shift. The predominant role of $d \rightarrow \pi^*$ back bonding has been shown for alkylsilyl derivatives of olefins and alkynes [4,12]. Data from ^1H and ^{13}C NMR spectra for complexes **1**, **4** and free ligands are presented in Table 2. Comparing chemical shifts, we conclude that the contribution of back bonding from the metal to vinyl group in **1** and **4** is almost equal. But in **4**, there are intermolecular contacts in the crystal between the copper atom and the oxygen atom in the diketonate of the nearest molecule. This indicates that the electron density on the copper atom in **4** is decreased in comparison with **1**, where such contacts are absent. Summarizing all these facts, we believe that in $[Cu^I(hfac)]_2$(DVTMSO), there is donation from filled d-orbitals of copper to silicon in addition to the typical back bonding to the vinyl group. This leads to the higher stability of compound **4** in comparison with **1** and particularly with the monomer analogue, (hfac)-Cu^I(VTMS).

Thus, we believe that the main reason for the volatility of compounds **1** and **4** is high symmetry and hence low polarity of their molecules resulting in relatively low energy of the lattice. Higher thermal stability of **4** in comparison with **1** is from the stronger metal–ligand bonding due to the presence of dimethylsilyl groups.

As to compounds **2** and **3** from the series, we could not obtain good crystal by sublimation owing to their low thermal stability. In the absence of favorable substituents in donor ligand, the minimal dipole moment seems to be one of the dominant factors for increased volatility and thermal stability of the molecule. We believe that low stability and volatility of complex **2** is due to the donor ligand (Fig. 1) that cannot take a suitable conformation to reduce the polarity of the complex. Note that compensation of the dipole moment due to mutual orientation (coupling) of molecules has been observed for monometallic complexes of (hfac)Cu^IL in the solid state [16].

In compound **3**, the electronic effect of the alkylsilyl group upon vinyl is minimized by the presence of the intermediate –CH_2– groups in the ligand reducing the complex stability. In support of this interpretation, the comparison of the properties of copper(I) hexafluoroacetylacetonate complexes with vinyltrimethylsilane and allyltrimethylsilane can be taken into consideration [7].

Table 2

3. Conclusion

The possibility of the preparation of stable and volatile binuclear copper(I) hexafluoroacetylacetonate complexes with non-cyclic ligands having terminal double bonds bridged by different linkers was demonstrated. A simple synthetic technique allowed the isolation of complexes with exact $[Cu^I(hfac)]_2L$ composition. A thermo-analytical study showed that from the series of similar compounds, the most thermally stable and volatile binuclear copper(I) hexafluoroacetylacetonate complexes have been obtained with donor ligands 1,5-hexadiene (HD) and 1,3-divinyltetramethyldisiloxane (DVTMSO). Crystal structure determination confirmed that the $[Cu(hfac)]_2L$ composition is realized by copper atom coordination to one vinyl group in the donor ligand and one hexafluoroacetylacetonate. In spite of the essential distinction in composition, the common feature of HD and DVTMSO ligands is the fact that their conformation provides non-polarity of the complex molecules. Such a structure determines high storage and thermal stability and volatility of these compounds. Higher thermal stability of $[Cu^I(hfac)]_2$(DVTMSO) in comparison with $[Cu^I(hfac)]_2$(HD) is from the stronger metal–ligand bonding due to the presence of dimethylsilyl groups.

4. Experimental

4.1. Measurements

The CHN elemental analyses were carried out with an Elementar Analysensysteme GmbH VarioEL. ^1H and ^{13}C NMR spectra were recorded with DRX300 Bruker instruments at frequencies of 300 and 75 MHz, respectively. Thermal analysis was performed in N_2 atmosphere at a heating rate of 10 °C/min using a SDT 2960 TA Instruments device. Single crystals for X-ray analysis were obtained by sublimation. The intensity data were collected with a Siemens diffractometer equipped with a graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation source and CCD detector. SHELXS 97 and SHELXL 97 implemented with the SHELXTL program package were used to solve and refine the

structure. Experimental details of the structure determination as well as bond lengths, bond angles and thermal parameters are available as supplementary material. (see the online version.)

4.2. Syntheses

All manipulations were carried out under dry nitrogen atmosphere using standard Schlenk techniques. To synthesize $[Cu^{I}(hfac)]_2(HD)$ (**1**), hexafluoroacetylacetone (Hhfac) (5 ml in 10 ml of ether) was added slowly dropwise to the mixture of Cu_2O (5 g), 1,5-hexadiene (5 ml) in 40 ml of ether with stirring under 0 °C. After completing the addition of Hhfac, stirring was maintained for 10 min and then the material was filtered to another flask through a PTFE capillary filter. Solvent was removed under dynamic vacuum. The product consists of yellow crystals (10 g, yield: 90%). *Anal.* Found/Calc. for $C_{16}H_{12}F_{12}O_4Cu_2$: C, 30.21/30.83; H, 1.87/1.94%. ^{1}H NMR (C_6D_6) δ ppm versus TMS: 6.2 (s, 2H, –*CH*– on hfac), 4.3 (m, 2H, –*CH*═), 3.6 (d, $^2J_{H-H} = 12.5$ Hz, 4H, ═*CH*$_2$), 1.4 (q, $^2J_{H-H} = 6.1$ Hz, 4H, –*CH*$_2$–). ^{13}C NMR (C_6D_6) δ ppm versus TMS: 178.0 (q, $^2J_{C-F} = 34.4$ Hz, *C*═*O*), 124.2, 120.4, 116.6, 112.8 (q, $J_{C-F} = 286.8$ Hz, –*CF*$_3$), 104.7 (s, –*CH*– on hfac), 90.3 (s, –*CH*═), 81.0 (s, ═*CH*$_2$), 33.0 (s, –*CH*$_2$–).

To synthesize $[Cu^{I}(hfac)]_2$(DVTMSO) (**4**), Hhfac (5 ml in 10 ml of ether) was added slowly dropwise to the mixture of Cu_2O (5 g), DVTMSO (5.5 ml) and Na_2SO_4 (10 g) in 40 ml of ether with stirring under 0 °C. After completing the addition of Hhfac, stirring was maintained for 10 min and then the material was filtered and transferred to another flask. Solvent was removed under dynamic vacuum. The product consists of yellow crystals (11 g, yield: 86%). *Anal.* Found/Calc. for $C_{18}H_{20}F_{12}O_5Si_2Cu_2$: C, 29.72/29.71; H, 2.82/2.77%. ^{1}H NMR (C_6D_6) δ ppm versus TMS: 6.2 (s, 2H, –*CH*– on hfac), 4.0 (m, 6H, –*CH*═*CH*$_2$), 0.0 (s, 12H, –*Si*(*CH*$_3$)$_2$). ^{13}C NMR (C_6D_6) δ ppm versus TMS: 179.0 (q, $^2J_{C-F} = 34.6$ Hz, *C*═*O*), 124.6, 120.9, 117.1, 113.3 (q, $J_{C-F} = 285.7$ Hz, –*CF*$_3$), 110.0 (s, –*CH*– on hfac), 102.0 (s, –*CH*═), 90.8 (s, ═*CH*$_2$), 1.2 (s, –*Si*(*CH*$_3$)$_2$).

Abstract

Two novel Ru(II) complexes $[Ru(dppt)(dien)](ClO_4)_2$ (**1**) and $[Ru(pta)(dien)](ClO_4)_2$ (**2**) (dppt, pta and dien stand for 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazine, 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazino[5,6-f]acenaphthylene and diethylenetriamine, respectively) were synthesized and characterized by elemental analysis, ES-MS and ^1H NMR spectroscopy. Due to the strong electron donor ability of dien, the oxidation potentials of complexes **1** and **2** are less positive and their MLCT bands significantly shift to lower energies in comparison with those of the homoleptic complexes $[Ru(dppt)_2](ClO_4)_2$ and $[Ru(pta)_2](ClO_4)_2$. The solvatochromic behaviors of the two complexes were also investigated.

Keywords: Ruthenium(II) complexes; Polypyridine ligands; Diethylenetriamine

1. Introduction

Ruthenium(II) polypyridine complexes have attracted a large and increasing amount of interest due to their outstanding redox and photophysical properties [1–4]. However, most studies have primarily focused on complexes involving rigid heterocyclic ligands such as 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) and 2,2′:6′,2″-terpyridine (tpy). Over the past decade quite a large amount of data has been accumulated on the changes in the electrochemical and photophysical properties of complexes effected by substitution in the bpy, phen or tpy rings, or replacement of one or both of the pyridine rings with other nitrogen-containing heterocycles [1–9]. On the other hand, the investigations of ruthenium(II) complexes with aliphatic polyamine ligands still remain scarcely touched. In fact, Ru(II) amine complexes display unique photophysical and electrochemical properties, such as lower energy electronic absorption for MLCT transitions, easy oxidation of the metal center and solvatochromic behavior, getting some utilization in probing DNA structure [10,11], sensitizing the local environment [12–14] and metal-containing pharmaceuticals [15].

In order to further understand the solvent-dependent properties of Ru(II) complexes, as well as laying the foundation for the rational design of biological probes and chemical sensors, we report herein the synthesis and characterization of two novel ruthenium amine complexes $[Ru(dppt)(dien)](ClO_4)_2$ and $[Ru(pta)(dien)](ClO_4)_2$ (dppt and pta stand for 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazine and 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazino[5,6-f]-acenaphthylene, respectively), in which an aliphatic polyamine ligand diethylenetriamine (dien) is introduced and this will have a different effect on the properties of ruthenium complexes in comparison with the polyaromatic ligand tpy and its derivatives. The electrochemistry and spectroscopic properties especially solvatochromism of the complexes are also investigated.

2. Experimental

2.1. Materials and preparations

The compounds 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazine (dppt) [16] and 3-(1,10-phenanthrolin-2-yl)-5,6-diphenyl-as-triazino[5,6-f]acenaphthylene (pta) [16] were synthesized according to literature methods. Other materials were commercially available and of reagent grade.

(*Caution*: perchlorate complexes are potential explosives that must be handled in small quantity and with great care.)

2.1.1. Synthesis of Ru(dppt)Cl$_3$

It was synthesized in a similar manner to that described in the literature [17]. A mixture of $RuCl_3 \cdot nH_2O$ (1 mmol, 0.260 g) and dppt (1 mmol, 0.411 g) in 125 ml of absolute ethanol was heated at reflux for 3 h while vigorous magnetic stirring was maintained. After this time the reaction was cooled to room temperature, and the fine brown powder that had appeared was filtered from the reddish yellow solution. The product was washed with 3×30 ml portions of absolute ethanol followed by 3×30 ml portions of Et_2O and air-dried. Yield: 70.3%. (Found: C, 52.17; H, 2.98; N, 11.04%. $C_{27}H_{17}N_5Cl_3Ru$ requires: C, 52.38; H, 2.75; N, 11.32%). ESMS [CH_3OH, m/z]: 583.1 ([M-Cl]$^+$), 273.8 ([M-2Cl]$^{2+}$), 170.8 ([M-3Cl]$^{3+}$).

2.1.2. Synthesis of Ru(pta)Cl$_3$

This complex was synthesized in a similar manner to that described for Ru(dppt)Cl_3, with pta (1 mmol, 0.383 g) in place of dppt. Yield: 65%. (Found: C, 50.76; H, 2.33; N, 11.61%; $C_{25}H_{13}N_5Cl_3Ru$ requires: C, 50.80; H, 2.20; N, 11.85%). ESMS [CH_3OH, m/z]: 555.1 ([M-Cl]$^+$), 259.8 ([M-2Cl]$^{2+}$), 161.38 ([M-3Cl]$^{3+}$).

2.1.3. Synthesis of [Ru(dppt)(dien)](ClO$_4$)$_2 \cdot 2H_2O$

A mixture of Ru(dppt)Cl_3 (0.150 g, 0.243 mmol), dien (0.025 g, 0.243 mmol) and triethylamine (1 cm^3) in ethanol–water (1:1 v/v, 50 cm^3) was refluxed for 8 h, during this time the solution turned reddish purple. After being cooled to room temperature, the ethanol was removed under reduced pressure and a dark purple precipitate was obtained by addition of a saturated aqueous $NaClO_4$ solution. The product was purified by column chromatography on alumina with acetonitrile as eluent. Yield: 63%. (Found: C, 43.85; H, 3.93; N, 13.26. Calc. for $C_{31}H_{30}N_8Cl_2O_8Ru \cdot 2H_2O$: C, 43.76; H, 4.00; N 13.18%). ES-MS [CH_3CN, m/z]: 715.1 ([M-ClO$_4$]$^+$), 308.3 ([M-2ClO$_4$]$^{2+}$). ^{1}H NMR [$(CD_3)_2SO$, aromatic region]: δ 9.52 (d, 1H, H$_c$, $J = 7.5$), 8.87 (dd, 2H, H$_a$, H$_f$, $J_1 = 8$, $J_2 = 8$), 8.57 (d, 1H, H$_g$, $J = 8$), 8.42 (s, 2H, H$_d$, H$_e$), 8.16 (dd, 1H, H$_b$, $J_1 = 5$, $J_2 = 5.5$), 7.77–7.71 (m, 3H, H$_h$, H$_j$), 7.61–7.51 (m, 5H, H$_i$, H$_k$, H$_l$), 7.49 (dd, 2H, H$_m$, $J = 5$).

2.1.4. Synthesis of [Ru(pta)(dien)](ClO$_4$)$_2 \cdot 2H_2O$

This complex (dark purple) was synthesized in an identical manner to that described for [Ru(dppt)(dien)](ClO$_4$)$_2$ with Ru(pta)Cl_3 (0.093 g, 0.243 mmol) in place of Ru(dppt)Cl_3. The product was purified by column chromatography on alumina with acetonitrile–ethanol (v/v, 50:1) as eluent. Yield: 47% (Found: C, 42.41; H, 3.66; N, 13.70. Calc. for $C_{29}H_{26}N_8Cl_2O_8Ru \cdot 2H_2O$: C, 42.34; H, 3.65; N 13.63%). ES-MS [CH_3CN, m/z]: 687.1 ([M-ClO$_4$]$^+$), 294.3 ([M-2ClO$_4$]$^{2+}$). ^{1}H NMR [$(CD_3)_2SO$, aromatic region]: δ 9.72 (d, 1H, H$_c$, $J = 4.5$), 8.89 (dd, 2H, H$_a$, H$_f$, $J_1 = 8$, $J_2 = 7.5$), 8.58–8.50 (m, 3H, H$_g$, H$_h$, H$_j$), 8.41 (s, 2H, H$_d$, H$_e$), 8.18–8.12 (m, 4H, H$_b$, H$_i$, H$_k$, H$_l$), 8.10 (d, 1H, H$_m$, $J = 6$).

2.2. Physical measurements

Microanalyses (C, H and N) were carried out with a Perkin–Elmer 240Q elemental analyser. US/VIS spectra were recorded on a Shimadzu MPS-2000 spectrophotometer. One dimensional ^{1}H NMR spectra and 2D ^{1}H–^{1}H COSY were measured on a Varian-500 NMR spectrometer with $(CD_3)_2SO$ as solvent at room temperature and the residual signal of the solvent was used as an internal standard. Electrospray mass spectra (ES-MS) were recorded on a LCQ system (Finnigan MAT, USA) using methanol as the mobile phase. The spray voltage, tube lens offset, capillary voltage and capillary temperature were set at 4.50 kV, 30.00, 23.00 V and 200 °C, respectively, and the quoted m/z values are for the major peaks in the isotope distribution.

A BioAnalytical Systems 100-W electrochemical analyzer was used to record the cyclic voltammograms. The supporting electrolyte was 0.1 M tetrabutylammonium perchlorate in acetonitrile freshly distilled from phosphorus pentaoxide and deaerated by purging with nitrogen. The electrochemical measurements were made in a standard three-electrode system using a platinum disk working electrode, platinum-wire auxiliary electrode and a Ag/AgCl reference electrode [0.29 V versus NHE, calibrated using the $Fe(C_5H_5)_2/Fe(C_5H_5)_2^+$ couple (0.665 V versus NHE)]. All cyclic voltammograms were recorded at a scan rate of 200 mV/s.

2.3. Molecular orbital calculations

The molecular structures of the free dppt and pta ligands were optimized by the INDO method [18] with the default parameters packaged in the computer program HyperChem Release 6 (HyperCube, Inc.) [19]. Calculations of the electronic structures were carried out using the extended Hückel approximation [20] with the same program using the default parameters.

3. Results and discussion

3.1. Synthesis and characterization

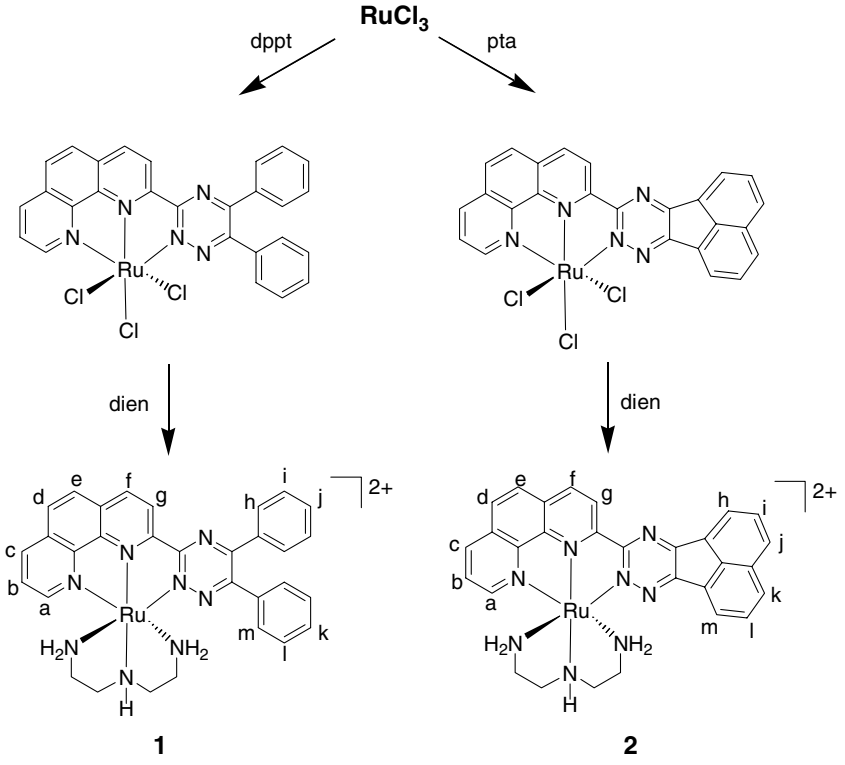
An outline of the syntheses of the ruthenium(II) complexes is illustrated in Scheme 1. Initially, hydrated $RuCl_3$ was reacted with one equivalent dppt or pta in absolute ethanol to obtain the red–brown insoluble $[Ru(dppt)Cl_3]$ or $[Ru(pta)Cl_3]$, respectively. The two precursors were then reacted at reflux with dien in the presence of triethylamine. The resulting ruthenium(II) complexes were isolated as the perchlorates and purified by column chromatography. It is also worth noting that complexes **1** and **2** have relatively strong affinities to the column support Al_2O_3 because of the polar functional group NH or NH_2 in comparison with $[Ru(dppt)_2](ClO_4)_2$ and $[Ru(pta)_2](ClO_4)_2$, bringing difficulty to their elution off the column, so adding a proper quantity of ethanol to the eluent is sometimes necessary.

Electrospray mass spectrometry (ESMS) has recently been shown to be a powerful tool for measuring the molecular mass of non-volatile and thermally unstable compounds [21]. In the ESMS spectra, the two complexes all exhibit the expected peaks due to $[M–ClO_4^-]^+$ and $[M–2ClO_4^-]^{2+}$ cations. The measured molecular weights were consistent with expected values.

All of the new ruthenium(II) complexes give well-defined ^1H NMR spectra. The proton chemical shifts were assigned with the aid of ^1H–^1H COSY experiments and comparison with those of similar compounds [22–25]. A representative ^1H–^1H COSY spectrum of $[Ru(dppt)(dien)]^{2+}$ is shown in Fig. 1. The chemical shifts of all the protons are presented in Section 2. Signals of the protons attached to the phenanthroline moieties, except H_a, appear at lower magnetic fields than those of the free ligands, the downfield shifts of H_c, H_d and H_e, which are at the para position to the coordinated nitrogen, are especially pronounced. At the same time, the protons close to the metal ion all experience much larger shifts, which is most clearly in H_m (0.18 ppm downfield shift for $[Ru(dppt)(dien)]^{2+}$ and 0.65 ppm for $[Ru(pta)(dien)]^{2+}$ in comparison with the corresponding protons of free ligands). This may be mainly attributed to the electron-withdrawing effects of the metal center and indirectly to the σ-donating effect of the trisamine ligand. Furthermore, the difference in chemical shift is strongly pronounced in the pta complex with a planar arrangement of the aromatic rings. In the dppt complex a free rotation of the phenyl rings takes place and therefore the delocalisation of the π-system is less pronounced.

3.2. Molecular orbital calculations

Extended Hückel calculations were carried out in order to obtain compositions and energies of the dppt



Scheme 1. Synthetic routes for the preparation of the ruthenium(II) complexes.

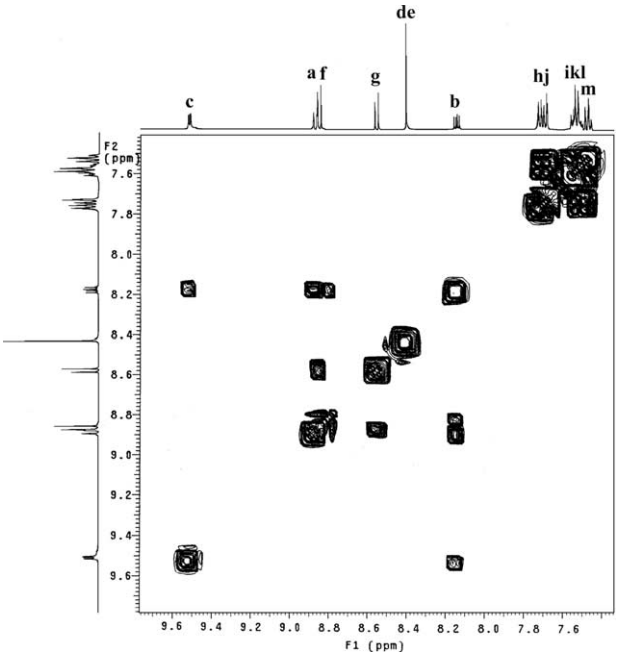


Fig. 1. ^{1}H–^{1}H COSY spectrum of $[Ru(dppt)(dien)]^{2+}$ in $(CD_3)SO$ (500 MHz).

and pta ligand orbitals and to rationalize the electrochemical and spectroscopic results. Fig. 2 shows the graphical illustrations for the three lowest lying unoccupied orbitals of dppt and pta. For the two asymmetric tridentate ligands, we made the following observations: (i) the lowest vacant molecular orbital is centered on the triazine part with the electronic distribution. The LUMO is found at −10.24 eV for complex **1** and −10.29 eV for complex **2**. (ii) The next vacant MO LUMO + 1 lying at higher energy (−9.93 eV for complex **1** and −10.15 eV for complex **2**) is extended on the phenanthroline-type part with a strong weight on the related coordinating nitrogens. (iii) In contrast, the MO LUMO + 2 (−9.64 eV for complex **1** and −9.67 eV for complex **2**) is developed on the phenanthroline-type part, with very little electronic density on the triazine part. This simple electronic approach reflects the non-equivalence of coordinating sites on the asymmetric ligands. This electronic distribution and the orbital energy levels account also for the more pronounced π-acceptor character and the greater energetic stabilization of pta with respect to those of the dppt ligand.

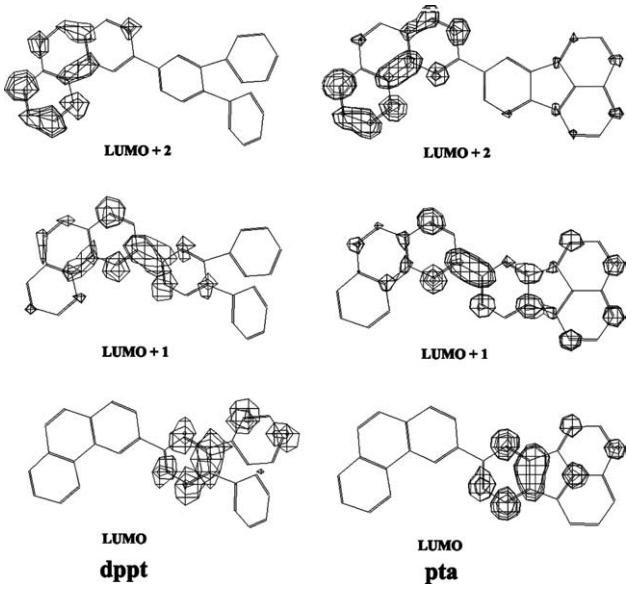

Fig. 2. Graphical illustrations for the three lowest lying unoccupied orbitals of the ligands.

3.3. Electrochemistry

The cyclic voltammograms of complexes **1** and **2** in acetonitrile are shown in Fig. 3. Both complexes exhibit well-defined waves corresponding to the metal-based oxidation and successive ligand-based reductions in the sweep range from −2.0 to 2.0 V, the half-wave potentials of the complexes are collected in Table 1. The anodic

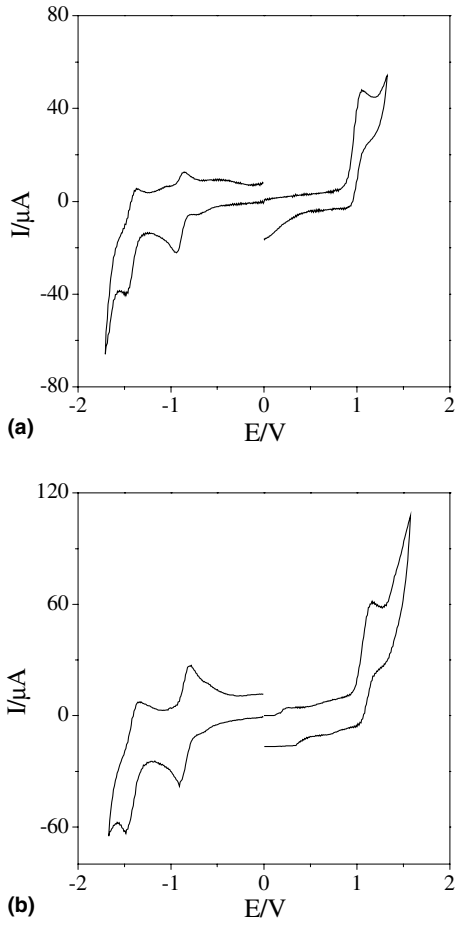

Fig. 3. Cyclic voltammograms of s$[Ru(dppt)(dien)]^{2+}$ (a) and $[Ru(pta)(dien)]^{2+}$ (b) in CH_3CN.

Table 1
Redox potentials for the ruthenium(II) complexes[a]

Complex	Ru^{III}/Ru^{II}	Ligand reduction	
$[Ru(dppt)(dien)]^{2+}$	0.99	−0.92	−1.46
$[Ru(pta)(dien)]^{2+}$	1.11	−0.87	−1.44
$[Ru(dppt)_2]^{2+}$[b]	1.35	−0.83	−1.03
$[Ru(pta)_2]^{2+}$[b]	1.40	−0.75	−0.95

[a] All complexes were measured in 0.1 M NBu_4ClO_4–CH_3CN, error in potentials was ±0.02 V; $T = 23 \pm 1$ °C; scan rate = 100 mV.
[b] Values were taken from [16].

and cathodic peak separations vary from 60 to 73 mV and are nearly scan rate independent, indicating that the processes are reversible one-electron transfers.

Redox processes corresponding to the Ru(III)/Ru(II) couple were observed at 0.99 and 1.10 V for complexes **1** and **2**, respectively. As anticipated, the oxidation of complex **2** shifts to more positive values with the extension of the π framework, which is consistent with the molecular orbital calculation results. At the same time, the oxidation potentials of the complexes are significantly less positive than those of corresponding homoleptic compounds $[Ru(dppt)_2]^{2+}$ and $[Ru(pta)_2]^{2+}$ (Table 1), as a result of the electron-donor capacity of dien that increases the electron density on the Ru(II) center and makes easier for the oxidation of Ru(II) to Ru(III). By comparison with the reductions of similar complexes [13,14,16], the reduction potentials of the two complexes can be rationally attributed to the ligand-based reductions $L^{0/-1}$ and $L^{-1/2}$ (L = dppt, pta).

3.4. Electronic absorption spectra

The absorption spectra of $[Ru(dppt)(dien)]^{2+}$ and $[Ru(pta)(dien)]^{2+}$ were recorded in acetonitrile in the range of wavelengths 250–700 nm (Fig. 4). In order to study the solvatochromic behavior of them, the spectra were obtained in other solvents of increasing polarity (acetone, DMF and DMSO) in the same range of wavelengths (Fig. 5). The absorption spectra for the two complexes are characterized by intense π–π* ligand transitions in the UV and metal-to-ligand charge transfer (MLCT) transitions in the visible region. In $[Ru(dppt)(dien)]^{2+}$ and $[Ru(pta)(dien)]^{2+}$, the absorption maxima of the MLCT bands significantly shift to lower energies compared to those of their homoleptic complexes [16], 488 versus 512 nm for $[Ru(dppt)_2]^{2+}$ versus $[Ru(dppt)(dien)]^{2+}$ and 506 versus 535 nm for $[Ru(pta)_2]^{2+}$ versus $[Ru(pta)(dien)]^{2+}$, respectively. This is consistent with the weak-field ligand character of the amines compared to the aromatic ligand. It is well documented in the literature that the energy of the metal-ligand charge transfer transitions of Ru(II) complexes are influenced by the π-back bonding of ligands [14]. Upon replacing one aromatic ligand with an amine chelate, the back bonding will decrease and the ligand field splitting will be smaller, thus the MLCT transitions will shift to longer wavelengths.

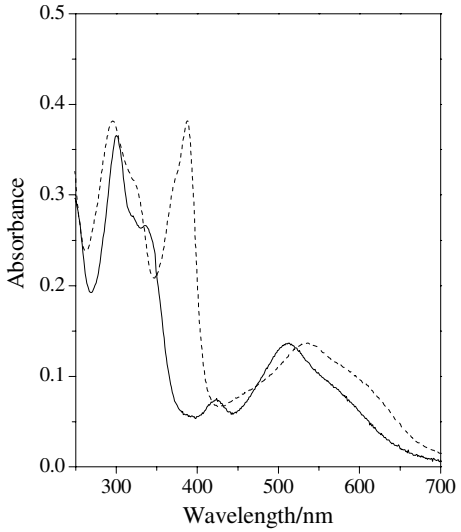

Fig. 4. Absorption spectra of $[Ru(dppt)(dien)]^{2+}$ (solid line) and $[Ru(pta)(dien)]^{2+}$ (dash line) in CH_3CN at room temperature.

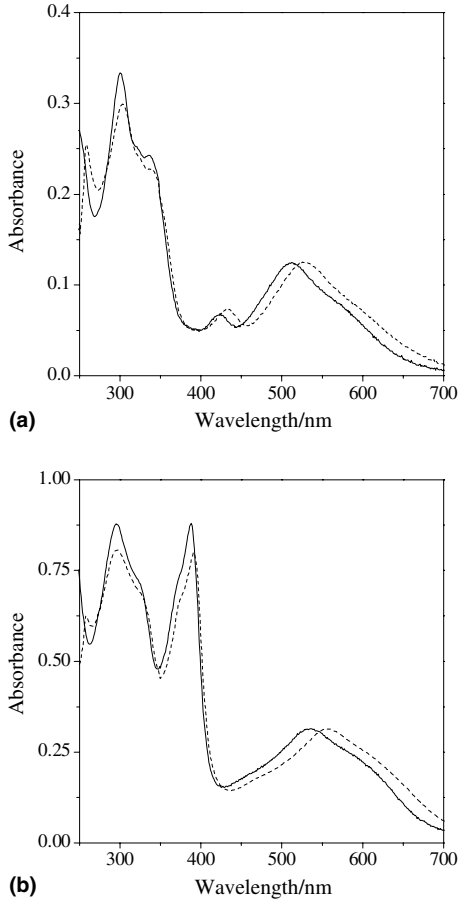

Fig. 5. Absorption spectra of $[Ru(dppt)(dien)]^{2+}$ (a) and $[Ru(pta)(dien)]^{2+}$ (b) in CH_3CN (solid line) and DMSO (dash line) at room temperature.

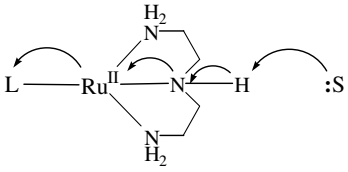
Table 2
Absorption maxima of the ruthenium(II) complexes in various solvents

Solvent	DN[a]	λ_{max} (nm)	
	(kcal/mol)	$[Ru(dppt)(dien)]^{2+}$	$[Ru(pta)(dien)]^{2+}$
Acetonitrile	14.1	512	535
Acetone	17.1	513	539
Dimethyl-formamide	26.6	524	554
Dimethyl sulfoxide	29.8	525	556

[a] The donor number, DN, is a measure of the electron-pair donating ability of the solvent. DN values were taken from [12].

The MLCT transitions maxima of $[Ru(dppt)(dien)]^{2+}$ and $[Ru(pta)(dien)]^{2+}$ are solvatochromic (Table 2). A pronounced red shift in the position of the MLCT absorption band occurs when the electron-pair donating ability of the solvent is increased (Fig. 5). This behavior had been reported for some ruthenium(II) amine complexes [11–13] and is attributed to the interaction between coordinated amine ligands and solvent molecules, which increases the electron density on the ruthenium and raises the energy of the d-orbitals relative to the ligand π^*-orbitals, thus causing the Ru-L MLCT to shift to longer wavelength in these solvents.



Recent quantum-mechanical calculations also support this idea. Zerner and coworkers [26,27] used a mixed quantum-mechanical/molecular-mechanics method to calculate the electronic spectrum of $[Ru(NH_3)_5(pyridine)]^{2+}$ and they found significant charge transfer from the solvent to the complex. Cacelli and Ferretti [28] performed ab initio calculations on the complex $[Ru(NH_3)_5(pyrazine)]^{2+/3+}$ using a polarizable continuum model for the solvent. They observed electron density to be increasingly shifted toward $Ru^{II/III}$ in stronger electron-donating solvents. In all of these studies, solvation was shown to lead to considerable red-shifts of d–π^* transitions.

In $[Ru(dppt)(dien)]^{2+}$ and $[Ru(pta)(dien)]^{2+}$, the solvatochromism of the MLCT transitions is found to be less remarkable than those of $[Ru(bpy)(NH_3)_4]^{2+}$ and $[Ru(phen)(NH_3)_4]^{2+}$ [12,13]. This may be attributed to the stronger π-acceptor character of dppt and pta, resulting in decreasing electron density on the metal and to some extent rendering the complex less susceptible to solvent. Inspection of Table 2 reveals that $[Ru(pta)(dien)]^{2+}$ is more sensitive to solvent effect than $[Ru(dppt)(dien)]^{2+}$ in spite of stronger electron-withdrawing of pta relative to dppt. Changing the solvent from acetone to DMSO, the absorption maximum of the MLCT band of $[Ru(pta)(dien)]^{2+}$ shifts to longer wavelength by about 21 nm at the most; however in $[Ru(dppt)(dien)]^{2+}$ the largest shifting value is only 13 nm. The detailed mechanism is still unclear but similar observations were made for $[Ru(NH_3)_5(py)]^{2+}$ and $[Ru(NH_3)_5(N\text{-Me-}4,4\text{-bpy})]^{2+}$ wherein the MLCT transitions of the latter are more sensitive to solvent [12].

4. Conclusions

In summary, two novel Ru(II) complexes $[Ru(dppt)(dien)](ClO_4)_2$ (**1**) and $[Ru(pta)(dien)](ClO_4)_2$ (**2**) were synthesized and characterized. Molecular orbital calculations reflect the difference between two asymmetric ligands dppt and pta, this is further testified in the electrochemical studies and absorption spectra. Due to the introduction of dien, the oxidation potentials of complexes **1** and **2** are significantly less positive and the MLCT bands of them shift to lower energies in comparison with those of the homoleptic complexes $[Ru(dppt)_2](ClO_4)_2$ and $[Ru(pta)_2](ClO_4)_2$. At the same time, the two ruthenium(II) amine complexes also exhibit interesting solvatochromic properties.

Abstract

A series of novel arylantimony ferrocenylcarboxylate derivatives with the formulae $[C_5H_5FeC_5H_4C(CH_3)=CHCOO]_2SbAr_3$ and $[4\text{-}(C_5H_5FeC_5H_4)C_6H_4COO]_2SbAr_3$ ($Ar = C_6H_5$, 4-$CH_3C_6H_4$, 4-ClC_6H_4, 4-FC_6H_4) were synthesized and characterized by elemental analysis, IR and ^1H NMR. The crystal structures of $[C_5H_5FeC_5H_4C(CH_3)=CHCOO]_2Sb(C_6H_4F\text{-}4)_3$ and $[4\text{-}(C_5H_5FeC_5H_4)C_6H_4COO]_2Sb(C_6H_4F\text{-}4)_3$ were determined by X-ray diffraction. The two sets of crystal X-ray data show that the antimony atom of the former has a special six-coordinate geometry while that of the latter has a general five-coordinate geometry. Three human neoplastic cell lines (HCT-8, Bel-7402 and KB) were used to screen these compounds. The results indicate that $[C_5H_5FeC_5H_4C(CH_3)=CHCO_2]_2Sb(C_6H_4Cl\text{-}4)_3$ and $[C_5H_5FeC_5H_4C(CH_3)=CHCO_2]_2Sb(C_6H_4F\text{-}4)_3$ at 5 μM show relatively good in vitro antitumor activities.

1. Introduction

Numerous main-group metal derivatives have been screened for potential anticancer activity. Among them organotin carboxylates have been most extensively investigated and they exhibit in vitro antitumor activtity against human tumor cell lines, often higher than cisplatin [1,2]. In contrast, organoantimony compounds have received much less attention as potential antitumor drugs. Recently, some organoantimony derivatives have been reported to exhibit marginal antitumor activities [3–7]. Therefore, it was thought worthwhile to explore whether other organoantimony compounds also exhibit antitumor properties. Moreover, it is known that ferrocene derivatives have a wide range of biological activities [8–12]. In this paper, we have prepared a series of arylantimony derivatives of 3-ferrocenyl-2-crotonic acid and 4-ferrocenylbenzoic acid, which contain three active centers, namely the arylantimony(V) moiety and two ferrocenylcarboxylate groups, in order to investigate the influence of the organic ligands at Sb on their antitumor activity.

In addition, the carboxylate ion, RCO_2^-, can coordinate to metals in many ways including as a unidentate ligand, as a chelating ligand, as a bridging bidentate ligand and so on [13]. Therefore, we are also interested in studying the structures of these pentavalent antimony salts of the general formula $Ar_3Sb(O_2CR)_2$ and the influences of electronic and steric effects on the coordination of the antimony atom.

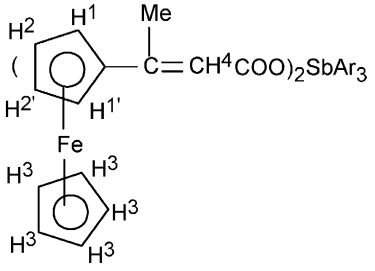
2. Experimental

2.1. General

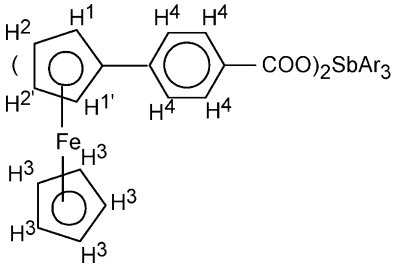
All operations were performed in an atmosphere of dry argon using Schlenk techniques. All solvents were dried by standard methods and distilled prior to use. Elemental analyses were determined on a Yanaco CHN Corder MT-3 elemental analyzer. IR spectra were recorded on a Bruker Equinox 55 spectrometer in KBr discs. ^{1}H NMR spectra were measured on a Bruker AC-200 spectrometer in CD_3COCD_3-d_6 solution (**1**–**4**) or $CDCl_3$ solution (**5**–**8**) with TMS as internal standard. 3-Ferrocenyl-2-crotonic acid and 4-ferrocenylbenzoic acid were prepared according to [14,15]. Ar_3SbBr_2 was prepared by the method reported by Lile and Menzies [16].

2.2. Synthesis of the title compounds

The title compounds were synthesized by a more convenient method. Typically, to acid (1 mmol) and triethylamine (0.8 ml) in toluene (40 ml) was added 0.5 mmol of Ar_3SbBr_2. The reaction mixture was stirred at room temperature for 24 h and filtered. The filtrate was evaporated in vacuo. The obtained red solid was recrystallized from CH_2Cl_2/petroleum ether.



Ar = Ph (**1**); 4-$CH_3C_6H_4$ (**2**); 4-ClC_6H_4(**3**); 4-FC_6H_4 (**4**).



Ar = Ph (**5**); 4-$CH_3C_6H_4$ (**6**); 4-ClC_6H_4(**7**); 4-FC_6H_4 (**8**).

For **6**: yield 70.3%. m.p. 246 °C (dec). *Anal*. Calc. for $C_{55}H_{47}Fe_2O_4Sb \cdot CH_2Cl_2$: C, 61.69; H, 4.53. Found: C, 61.66; H, 4.60%. Important infrared data (KBr, cm^{-1}): ν_{asy} (CO_2) 1639, ν_{sym} (CO_2) 1320, $\Delta\nu$ (CO_2) 319, ν (Sb–C) 481. ^{1}H NMR ($CDCl_3$, ppm) δ: 4.70 (t, 4H, H^1 $H^{1'}$), 4.37 (t, 4H, H^2 $H^{2'}$), 4.06 (s, 10H, H^3), 7.33–8.09 (m's, 20H, Ar and H^4), 2.41 (s, 9H, CH_3).

For **7**: yield 87.5%. m.p. 173–175 °C. *Anal*. Calc. for $C_{52}H_{38}Cl_3Fe_2O_4Sb$: C, 58.55; H, 3.59. Found: C, 58.39; H, 3.61%. Important infrared data (KBr, cm^{-1}): ν_{asy} (CO_2) 1607, ν_{sym} (CO_2) 1326, $\Delta\nu$ (CO_2) 281, ν (Sb–C) 483. ^{1}H NMR ($CDCl_3$, ppm) δ: 4.59 (t, 4H, H^1 $H^{1'}$), 4.26 (t, 4H, H^2 $H^{2'}$), 3.94 (s, 10H, H^3), 7.37–8.05 (m's, 20H, Ar and H^4).

For **8**: yield 69.6%. m.p. 132–134 °C. *Anal*. Calc. for $C_{52}H_{38}F_3Fe_2O_4Sb \cdot 2CH_2Cl_2$: C, 54.63; H, 3.57. Found: C, 54.37; H, 3.92%. Important infrared data (KBr, cm^{-1}): ν_{asy} (CO_2) 1655, ν_{sym} (CO_2) 1316, $\Delta\nu$ (CO_2) 339, ν (Sb–C) 477. ^{1}H NMR ($CDCl_3$, ppm) δ: 4.75 (t, 4H, H^1 $H^{1'}$), 4.44 (t, 4H, H^2 $H^{2'}$), 4.06 (s, 10H, H^3), 7.42–8.14 (m's, 20H, Ar and H^4).

2.3. X-ray crystallography

Diffraction data for compounds **4** and **8** were obtained on a Bruker Smart 1000 CCD diffractometer (graphite monochromatized Mo Kα radiation, $\lambda = 0.71073$ Å). Unit cell dimensions were obtained with least squares refinements and the structure was solved by direct methods using the SHELXS-97 program [17]. Non-hydrogen atoms were refined with anisotropic thermal parameters. All data were corrected using the SADABS method with $T_{max} = 0.8853$ and $T_{min} = 0.7057$. The final refinement was performed by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The hydrogen atoms of the compound were added theoretically, riding on the concerned atoms and refined with fixed thermal factors. Crystal data and structure refinement are given in Table 1.

2.4. In vitro antitumor activity assay

The KB cell lines were obtained from the Institute of Cancer of Tianjin. Other cell lines were derived in the Institute of Materia Medica, Chinese Academy of Medical Sciences and Peking Union Medical College. All cell lines were grown in RPMI 1640 medium with 10% fetal bovine serum, in 5% CO_2 atmosphere.

The cytotoxic activity of these compounds was assayed by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2*H*-tetrazolium bromide (MTT, Thiazolyl blue) method [18]. The cell lines, human nasopharyngeal carcinoma (KB), human hepatocellular carcinoma (Bel-7402) and human colo carcinoma (HCT-8) were used for screening. All cell lines were transferred into the 96-wells culture plate. Aliquots of log-phase cells were incubated for 72 h at 37 °C with four dose levels of each organoantimony complex in triplicate. 50 μl of 0.1% MTT (Sigma) was added to each well. After 4 h incubation, the culture medium was removed, and the blue formazan in the cells was dissolved with 150 μl of 2-propanol by vigorous shaking. The optical density of each well was measured at 570 nm wavelength. The cytotoxicity was determined by expressing the mean optical densities for drug-treated cells at each concentration as a percentage of that of untreated cells.

3. Results and discussion

3.1. Preparations

The title compounds were synthesized under mild conditions. These compounds are red solids and are

stable in air. The compounds are easily soluble in benzene, toluene, CH_2Cl_2, $CHCl_3$ and DMSO, and insoluble in petroleum ether and methanol.

3.2. IR spectra

The infrared spectra of these compounds have been recorded in the range of 4000–400 cm^{-1}. The absorption bands can be assigned on the basis of earlier publications [6,19]. The infrared spectroscopic data provide further support for the molecular constitution of the title compounds. The infrared spectra of all of the organoantimony compounds do not show a strong band in the 3500–3300 cm^{-1} region, due to v (OH), indicating that deprotonation and coordination of the carboxylate group with antimony metal have occurred as expected.

In the majority of organoantimony(V) compounds, antimony has generally a coordination number of five. As the vacant 5d orbital of antimony atom can accept a lone electron pair of ligands, in some cases the antimony may have a coordination number of six [20] or seven [6,19]. The IR stretching vibration frequencies of carbonyl groups in organoantimony carboxylates are very important for determining their structure: When there are interactions between the antimony atom and the carbonyl oxygen atoms of the carboxylate groups, the asymmetric absorption vibration frequencies [v_{asy} (CO_2)] of carboxylate groups decrease, while the symmetric absorption vibration frequencies [v_{sym} (CO_2)] increase. Therefore, their differences [Δv (CO_2)] decrease [2,5]. In the IR spectra of the title compounds, the carboxylate bands are observed in the characteristic regions: v_{asy} (CO_2) between 1655 and 1607 cm^{-1} and v_{sym} (CO_2) between 1374 and 1316 cm^{-1}. On the basis of the difference Δv (CO_2), these compounds can be divided into two categories: Compounds **5**, **6** and **8** show high Δv (CO_2) values (310, 319 and 339 cm^{-1}, respectively) while the other compounds show low Δv (CO_2) values (between 239 and 281 cm^{-1}). To the former, we can assume that there has been weak interaction or no interaction between the antimony atom and the carbonyl oxygen atoms of the carboxylate groups (see the crystal structure of compound **8**). To the latter, we can assume that there has been strong interaction between the carbonyl oxygen atoms of the carboxylate groups and the antimony atom (see the crystal structure of compound **4**). In addition, the frequencies of Sb–C deformations appear between 460 and 510 cm^{-1}, which are consistent with the literature [21,22].

3.3. Crystal structure

3.3.1. Structure of $[C_5H_5FeC_5H_4C(CH_3)=CHCOO]_2Sb(C_6H_4F\text{-}4)_3$

The red crystal of $[C_5H_5FeC_5H_4C(CH_3)=CHCOO]_2Sb(C_6H_4F\text{-}4)_3$ was obtained from a CH_2Cl_2-petroleum ether solution. Fig. 1 shows the molecular structure of compound **4** and gives the atom numbering scheme. Selected bond distances and angles are given in Table 2.

The two ferrocenyl groups and two carboxyl groups in the molecule of compound **4** are all *trans*-configurations. The atoms O(2), C(19), C(20), C(21) and C(22) are coplanar within 0.0228 Å. The distance between O(2) and C(22) is 3.034 Å. The atoms O(4), C(33), C(34), C(35) and C(36) are also coplanar within −0.0332 Å, but the distance between O(4) and C(36) is 4.361 Å, much longer than the corresponding distance between O(2) and C(22). The C=C bond lengths [1.327(8) and 1.331(8) Å] and the Fe–C distances are all consistent with the literature [14,23,24].

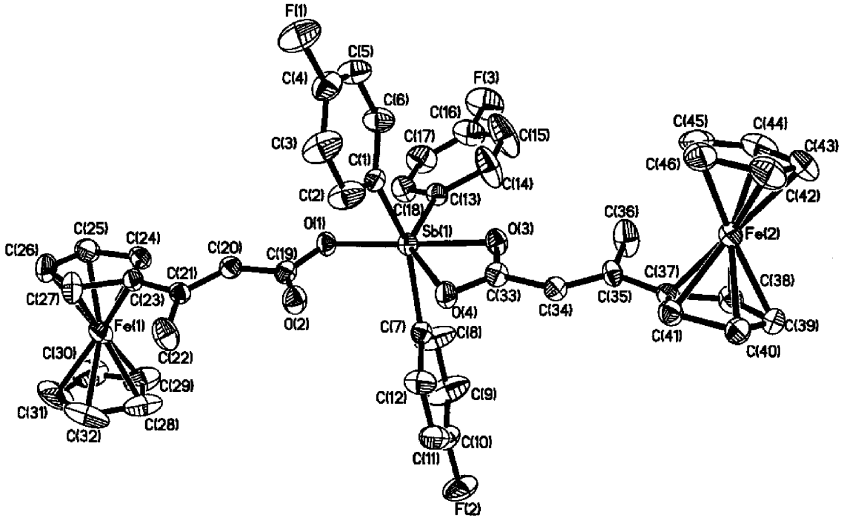

Fig. 1. The molecular structure of $[C_5H_5FeC_5H_4C(CH_3)=CHCOO]_2Sb(C_6H_4F\text{-}4)_3$, showing the atom numbering scheme.

Table 2
Selected bond distances and bond angles of compound **4**

Bond	Distance (Å)	Bond	Angle (°)

Carboxylates are versatile ligands which can be either unidentate or bidentate. Antimony–oxygen bond lengths in organoantimony compounds are extremely variable [25], ranging from 1.935 Å in $(Ph_3SbO)_2$ [26] to 2.506 Å in Ph_4SbOSO_2Ph [27], and the Sb–O distances in **4** [Sb(1)–O(1), 2.099(4) Å and Sb(1)–O(3), 2.123(4) Å] lie within this range. However, the Sb(1)–O(2) distance [2.936(6) Å] is rather longer than the Sb(1)–O(4) distance [2.647(6) Å] and both distances are also significantly different from the corresponding distances in $Ph_3Sb(OCOCF_3)_2$ [3.209, 3.231 Å] [28] and $Ph_3Sb(O_2C\overline{CHCMe_2CMe_2})_2$ [2.800(2) Å] [29]. This indicates that there is a relatively strong coordination interaction between Sb(1) and O(4), while almost no interaction between Sb(1) and O(2). The former is a carboxylate as a bidentate ligand, and the latter a unidentate ligand. The C(1)–Sb(1)–C(7) angle, which is affected by the adjacent O(4), is increased to 149.5(2)°, while the C(1)–Sb(1)–C(13) and C(7)–Sb(1)–C(13) angles are decreased to 105.4(2)° and 105.1(2)°, respectively. The corresponding angles in $Ph_3Sb(OCOCF_3)_2$ are 117.52(21)°, 117.99(21)° and 124.47(13)°, and in $Ph_3Sb(O_2C\overline{CHCMe_2CMe_2})_2$ they are 150.0(3)°, 105.1(2)° and 105.1(2)°. Therefore, the molecule of compound **4** consists of a monomer with a six-coordinated antimony atom surrounded by three oxygens and three aryl groups. The atoms O(1), O(3), O(4), C(13) and Sb(1) are coplanar, and the coplanar data is listed in Table 3. The coordination geometry of antimony can be described as a distorted octahedron with two atoms C(1) and C(7) occupying the axial positions.

The unique configuration can be attributed to the −I effect of F of the aryl groups and the steric effect of the two asymmetrical 3-ferrocenyl-2-crotonate groups in the molecule. On one hand, the −I effect of F enhances the Lewis acidity of Sb and leads to the stronger Sb:O═C coordination interaction [6]. On the other hand, the carbonyl oxygens of the two asymmetrical 3-ferrocenyl-2-crotonate groups have theoretically the equal chances to coordinate with the antimony atom. However, when one carbonyl oxygen of the two 2-crotonate groups has coordinated with the antimony atom, the steric effect of the two asymmetrical 2-crotonate groups is such that it is impossible for the other carbonyl oxygen to coordinate with the antimony atom.

Table 3
The coplanar data of compound **4** (Å)

O(1)	O(3)	O(4)	Sb(1)	C(13)
0.0117	0.0278	−0.0210	0.0035	−0.0220

Inspection of the molecular packing of the compound shows that one molecule contains one dichloromethane molecule. This conforms to the result of elemental analysis.

3.3.2. Structure of $[4\text{-}(C_5H_5FeC_5H_4)C_6H_4COO]_2Sb(C_6H_4F\text{-}4)_3$

The red crystal of $[4\text{-}(C_5H_5FeC_5H_4)C_6H_4COO]_2Sb(C_6H_4F\text{-}4)_3$ was also obtained from CH_2Cl_2-petroleum ether solution. One of the approximate dimensions $0.25 \times 0.20 \times 0.10$ mm was mounted in a glass capillary and used for data collection. Fig. 2 shows the molecular structure of compound **8** and gives the atom numbering scheme. The selected bond distances and angles are listed in Table 4.

The crystal structure of compound **8** consists of isolated molecules which have C_2 molecular symmetry, the Sb(1)–C(24)–C(27) atoms forming the C_2 axis. The coordination geometry around the antimony centre is best described as a distorted trigonal bipyramid (TBP), in which two carboxylate groups occupy the apical sites. The O(1A)–Sb(1)–O(1) angle is 174.1(4)°. In the equatorial plane of the molecule of compound **8**, the C(18A)–Sb(1)–C(18), C(18A)–Sb(1)–C(24) and C(18)–Sb(1)–

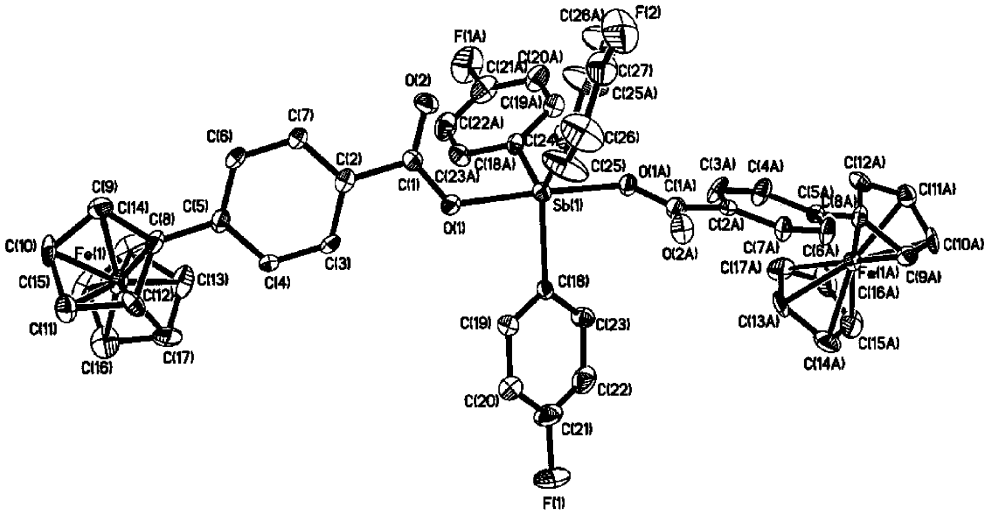

Fig. 2. The molecular structure of $[4\text{-}(C_5H_5FeC_5H_4)C_6H_4COO]_2Sb(C_6H_4F\text{-}4)_3$, showing the atom numbering scheme.

Table 4
Selected bond distances and bond angles of compound **8**

Bond	Distance(Å)	Bond	Angle (°)
Sb(1)–O(1)	2.087(6)	O(1A)–Sb(1)–O(1)	174.1(4)
Sb(1)–O(1A)	2.087(6)	O(1)–Sb(1)–C(18)	84.2(3)
Sb(1)–C(18)	2.123(9)	O(1)–Sb(1)–C(18A)	84.2(3)
Sb(1)–C(18A)	2.123(9)	O(1)–Sb(1)–C(18)	92.9(3)
Sb(1)–C(24)	2.219(15)	O(1)–Sb(1)–C(18A)	92.9(3)
O(1)–C(1)	1.264(12)	C(18A)1–Sb(1)–C(18)	121.8(5)
O(2)–C(1)	1.243(12)	C(18)–Sb(1)–C(24)	119.1(3)
Fe(1)–C(8)	2.057(10)	C(18A)–Sb(1)–C(24)	119.1(3)
Fe(1)–C(15)	1.990(16)	O(1)–Sb(1)–C(24)	92.9(2)
		O(1A)–Sb(1)–C(24)	92.9(2)
		C(9)–Fe(1)–C(8)	41.4(4)
		C(15)–Fe(1)–C(10)	108.8(6)
		O(2)–C(1)–O(1)	124.8(10)

C(24) angles are 121.8(5)°, 119.1(3)° and 119.1(3)°, respectively, which are close to the normal 120°. The Sb–C bond distances [2.123(9) and 2.219(15) Å] are significantly different from the corresponding distances in $Ph_3Sb(OCOCF_3)_2$ [2.078(3), 2.076(3) and 2.092(3) Å] [28]. The Sb–O distances in **8** [both 2.087(6) Å] also lie within the range from 1.935 to 2.506 Å. The non-bonding Sb–O bond, 3.238 Å, is 55% longer than the covalent Sb–O bond and also longer than the corresponding distances in $Ph_3Sb(OCOCF_3)_2$ [3.209 and 3.231 Å]. This indicates that there is no interaction between the metal atom and carbonyl oxygen atoms. For the ferrocenylcarboxylate part, the Fe–C distances are also consistent with the literature [24].

Though the −I effect of F of the aryl groups enhances the Lewis acidity of Sb and leads to the stronger Sb:O═C coordination [6], the large steric effect of the two phenyl groups associated with carboxyl groups outweighs this and results in that the carbonyl oxygen atoms cannot coordinate with the antimony atom.

Inspection of the molecular packing of the compound shows that one molecule contains two dichloromethane molecules. This conforms with the result of elemental analysis, too.

3.4. Antitumor activity

The antitumor activity is assayed by the MTT method [18]. The antitumor activity of the title compounds is listed in Table 5. The results of bioassay indicate that these compounds exhibit certain activities against the three cancer cells in vitro. The compounds **1**–**8** including the ferrocene moiety have relatively higher

Table 5
Antitumor activity of the compounds in vitro

Compound	Inhibition ratio[a] (%) (5 μg/ml)		
	KB	Bel-7402	HCT-8
1	−20.34	−1.30	4.94
2	−2.61	17.53	16.59
3	37.88	72.61	91.19
4	70.76	58.18	73.31
5	−8.42	4.03	12.51
6	4.04	−8.56	1.75
7	58.77	33.96	36.56
8	13.96	8.40	12.51
A[b]	−4.53	−12.31	3.98
B[c]	−3.25	−11.45	−0.11
C[d]	12.66	−32.12	12.24
Cisplatin	92.64	76.25	80.07

[a] Inhibition ratio (%) $= (A_1 - A_2)/A_1 \times 100\%$. Drug is active when the inhibition ratio at 5 μg/ml concentration is $\geqslant 50\%$. A_1, the mean optical densities of untreated cells. A_2, the mean optical densities of drug-treated cells. Negative values indicate that the mean optical densities of drug-treated cells (A_2) is greater than that of untreated cells (A_1), i.e. the drug promoted growth of some tumor cells.

[b] **A**: $C_5H_5FeC_5H_4C(CH_3)$═CHCOOH.

[c] **B**: Ph_3SbBr_2.

[d] **C**: $(PhNHCH_2COO)_2Sb(C_6H_4F\text{-}4)_3$.

antitumor activity than triphenylantimony dibromide. At the same time, the antitumor activity of most of the compounds **1**–**8** is also higher than that of the compound $(PhNHCH_2COO)_2Sb(C_6H_4F\text{-}4)_3$ which is a similar arylantimony carboxylate but not including a ferrocene moiety. The antitumor data indicate that the antitumor activities are affected by the nature of the aryl and the ferrocenylcarboxylate groups. When the ferrocenylcarboxylate group is $C_5H_5FeC_5H_4C(CH_3)=CHCOO$, the compounds whose Ar is $4\text{-}ClC_6H_4$ or $4\text{-}FC_6H_4$ have relatively higher antitumor activities. Specially, the activity of compound **3** against HCT-8 cell is higher than that of cisplatin.

4. Supplementary material

Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 213818 for compound **4** and CCDC No. 212338 for compound **8**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

The reaction of bis(8-quinolinyl)amine $[N^1C_9H_6–N^2H–C_9H_6N^3$, LH] with $Co^{II}(ClO_4)_2 \cdot 6H_2O$ in methanol under aerobic conditions results in a new class of $[Co^{III}N_6]^+$ ($\mathbf{1}^+$) chromophore incorporating an sp^2-amido nitrogen center (N^2) in the ligand frame. During the course of the reaction, the cobalt ion has been oxidized from its starting +2 oxidation state to +3 state in **1**. The reaction of LH with the Cu-acetate yields monomeric square planar complex, $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**). The same copper complex **2** is also obtained from $Cu(ClO_4) \cdot 6H_2O$ in presence of CH_3COONa as base. On the other hand, the reaction of $Zn(ClO_4) \cdot 6H_2O$ with LH results in octahedral complex $Zn^{II}(L)_2$ (**3**). The Cu(II) complex **2** displays a four-line EPR spectrum at room temperature. Crystal structure of the free ligand (LH) shows that the amine proton [N(2)H] is hydrogen-bonded with the terminal quinoline nitrogen centers [N(1) and N(3)]. The crystal structure of **1** confirms the meridional geometry of the complex cation. The square planar geometry of copper complex **2** is confirmed by its crystal structure where the acetate function behaves as a monodentate ligand. The free ligand, LH, is found to be highly acidic in acetonitrile–water (1:1) medium and correspondingly the amine proton (NH) readily dissociates leading to its L^- form even in absence of any external base. The pK_b value of L^- is determined to be 2.6. Both cobalt and copper complexes do not show any expected spin-allowed d–d transitions, possibly have masked by the intense charge-transfer transitions. However, in case of cobalt complex **1**, one very weak unusual spin-forbidden $^1A_{1g} \rightarrow {}^3T_{1g}$ transition has been observed at 935 nm. The quasi-reversible cobalt (III) $\leftrightharpoons$ cobalt(II) reduction of **1** is observed at E^0, −1.0 V versus SCE.

1. Introduction

Although the ligand bis(8-quinolinyl)amine, LH, was synthesized long back [1,2], the complexation property of LH has been studied only recently to a little extent. The first metal complex of L^- was reported to be a tetrahedral copper-complex, $[Cu^{II}(L)Cl]$ [2]. The crystal structure of the complex reveals the presence of a pairwise interaction between the monomeric units in the solid state, where each ionized amine group occupies an apical co-ordination site of the second Cu(II) center producing a square pyramidal geometry around each copper unit. The crystal structure of the lithium complex of L^- shows a dimeric structure $[Li_2(L)_2]$ in which the two lithium ions and two bridging amido nitrogen centers join together to form a parallelepiped that bisects

doi:10.1016/j.poly.2003.11.053

the dimeric complex, whereas the corresponding Tl^{I} complex Tl(L) exists in the monomeric form [3]. The ligand L^- behaves like a pincer ligand with the divalent Ni^{2+}, Pd^{2+} and Pt^{2+} and the Pt^{2+}complex is reported to perform C–H bond activation process of benzene ring in the presence of a base [4]. The metal complexes of L^- have been essentially restricted to tetra-coordinated species so far, therefore, the present work primarily deals with the hexa-coordinated Co^{III}, Zn^{II} and tetra-coordinated Cu^{II} complexes incorporating L^-.

Herein, we report the synthesis and characterizations of octahedral $[Co^{III}(L)_2]^+$ (**1**), $[Zn^{II}(L)_2]$ (**3**) and square planar $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**) complexes, crystal structures of the free ligand (LH), cobalt and copper complexes and their spectral/electrochemical properties.

2. Experimental

2.1. Materials

Cobalt carbonate and copper nitrate were converted into cobalt perchlorate hexahydrate and copper perchlorate hexahydrate, respectively, by using perchloric acid. 8-Amino quinoline and 8-hydroxy quinoline were purchased from Aldrich, USA. Other chemicals and solvents were reagent grade and used as received. For electrochemical studies, HPLC grade acetonitrile was used. Commercial tetraethyl ammonium bromide was converted to pure tetraethylammonium perchlorate (TEAP) by following an available procedure [5].

2.2. Physical measurements

Solution electrical conductivity was checked using a Systronic conductivity bridge-305. Electronic spectra were recorded using Shimadzu UV-160 (1100–200 nm) and UV-2100 (900–200 nm) spectrophotometer. IR spectra were recorded on a Nicolet spectrophotometer with samples prepared as KBr pellets. ^{1}H NMR spectra were obtained with a 300-MH_z Varian spectrometer. Cyclic voltammetric and coulometric measurements were carried out using a PAR model 273A electrochemistry system. A platinum wire working electrode, a platinum wire auxiliary electrode and a saturated calomel reference electrode (SCE) were used in a standard three-electrode configuration. TEAP was the supporting electrolyte and the solution concentration was ca. 10^{-3} M; the scan rate used was 50 mV s^{-1}. A platinum gauze working electrode was used for coulometric experiments. All electrochemical experiments were carried out under dinitrogen atmosphere, and all redox potentials are uncorrected for junction potentials. The elemental analyses were carried out with a Perkin–Elmer 240C elemental analyzer.

2.3. Preparation of ligand and complexes

2.3.1. Preparation of LH $[N^1C_9H_6–N^2H–C_9H_6N^3]$

The ligand, LH, was synthesized by a modified Bucherer reaction [1,2].

2.3.2. Preparation of $[Co(N^1C_9H_6–N^2–C_9H_6N^3)_2](ClO_4)$ (**1**)

To a solution of $Co(ClO_4)_2\cdot 6H_2O$ (100 mg, 0.273 mmol) in methanol, the ligand, LH (185 mg, 0.682 mmol), was added. The reaction mixture was stirred magnetically for a period of 4 h. The brown colored solid thus obtained was filtered off and washed thoroughly with cold methanol followed by cold water. The product was dried over P_4O_{10} under vacuo. The complex **1** was then recrystallized from benzene–acetonitrile (1:1) mixture. Yield: 124 mg (65%). *Anal.* Calc. for **1**: C, 61.86; H, 3.46; N, 12.02. Found: C, 61.46; H, 3.58; N, 11.40%. Λ_M (Ω^{-1} cm^2 mol^{-1}) in CH_3CN; 117. [^{1}H NMR data in $CDCl_3$: δ, ppm (J, H_z): H(2), 8.45(7.8); H(4), 8.08(8.4); H(5), 8.0(5.1); H(3), 7.85(7.8, 8.4); H(7), 7.26(9.6); H(6), 7.16(5.4, 5.4)].

2.3.3. $[Cu(N^1C_9H_6–N^2–C_9H_6N^3)\{OC(=O)CH_3\}]$ (**2**)

The ligand, LH (156 mg, 0.575 mmol), was added to a methanolic solution of anhydrous copper acetate (50 mg, 0.275 mmol) under stirring condition. The reaction mixture was stirred magnetically for a period of 6 h. The reddish brown colored solid thus formed was filtered off and washed thoroughly with cold methanol followed by cold water. The product was then dried over P_4O_{10} under vacuo. The complex **2** was purified by recrystallization from dichloromethane–hexane (1:1) mixture. Yield: 66 mg (61%). *Anal.* Calc. for **2**: C, 61.14; H, 3.85; N, 10.69. Found: C, 60.43; H, 4.03; N, 11.12%.

2.3.4. $[Zn(N^1C_9H_6–N^2–C_9H_6N^3)_2]$ (**3**)

To a solution of $Zn(ClO_4)_2\cdot 6H_2O$ (100 mg, 0.268 mmol) in methanol was added LH (160 mg, 0.589 mmol). The reaction mixture was stirred magnetically for a period of 4 h. The red colored solid thus obtained was filtered off and washed thoroughly with cold methanol followed by cold water. The product was dried over P_4O_{10} under vacuo. The complex **3** was then recrystallized from dichloromethane–hexane (1:1) mixture. Yield: 94 mg (58%). *Anal.* Calc. for **3**: C, 71.35; H, 3.99; N, 13.87. Found: C, 70.66; H, 3.55; N, 14.15%. ^{1}H NMR data in $CDCl_3$: δ, ppm (J, H_z): H(2), 8.19(8.1); H(4), 8.00(5.9); H(5), 7.92(8.3); H(3), 7.59(8.1, 8.1); H(7), complex multiplet centered at δ, 6.95 ppm; H(6), complex multiplet centered at δ, 6.95 ppm.

2.4. X-ray structure determination

The single crystals of LH were grown by slow evaporation of dichloromethane solution of LH. The single

crystals of complex **1** were grown by slow diffusion of an acetonitrile solution of it in benzene followed by slow evaporation at 298 K. Single crystals of copper complex **2** were grown by slow diffusion of dichloromethane solution of **2** into hexane followed by slow evaporation at 298 K. The X-ray data were collected on a PC-controlled Enraf–Nonius CAD-4 (MACH-3) single crystal X-ray diffractometer using Mo Kα radiation. Significant crystal data and data collection parameters are shown in Table 1. The structures were solved by direct method using SHELXS 86 and refined by full-matrix least-squares on F^2 using SHELXL 97 [6]. The X-ray analysis of the complex **1** shows one ClO_4^- anion and half molecule of benzene as solvent of crystallization in the asymmetric unit. The solvent molecule of benzene is found to be highly disordered and hydrogen atoms for this solvent have not been fixed.

3. Results and discussion

3.1. Synthesis and characterization

The ligand bis(8-quinolinyl)amine $[N^1C_9H_6–N^2H–C_9H_6N^3$, LH] comprising one dissociable amine proton (N^2H) has been synthesized from 8-aminoquinoline and 8-hydroxyquinoline following the reported procedure [1,2]. The direct bonding of N^2 center with the two-electron-withdrawing quinoline moieties makes the amine proton (N^2H) in LH substantially acidic. Thus, the NH proton of LH dissociates in acetonitrile–water (1:1) mixture to give the corresponding conjugate base (L^-). In view of that, the UV–Vis spectrum of the free ligand in 1:1 acetonitrile–water fails to show any noticeable changes in spectral behavior on increasing pH. Therefore the pK_b of L^- of 2.6 has been determined by *pH*-titration (Fig. 1). The strong acidic nature of LH facilitates the dissociation of the NH function under

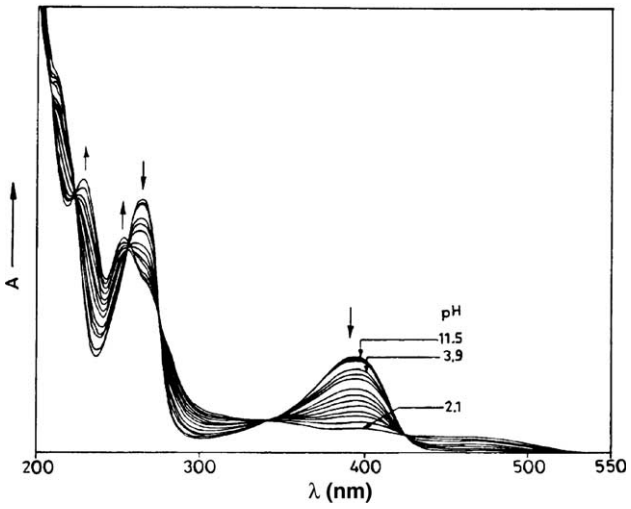

Fig. 1. Electronic spectra of LH at different pH in 1:1 acetonitrile–water. The arrows indicate increase or decrease in band intensities as the reaction proceeds.

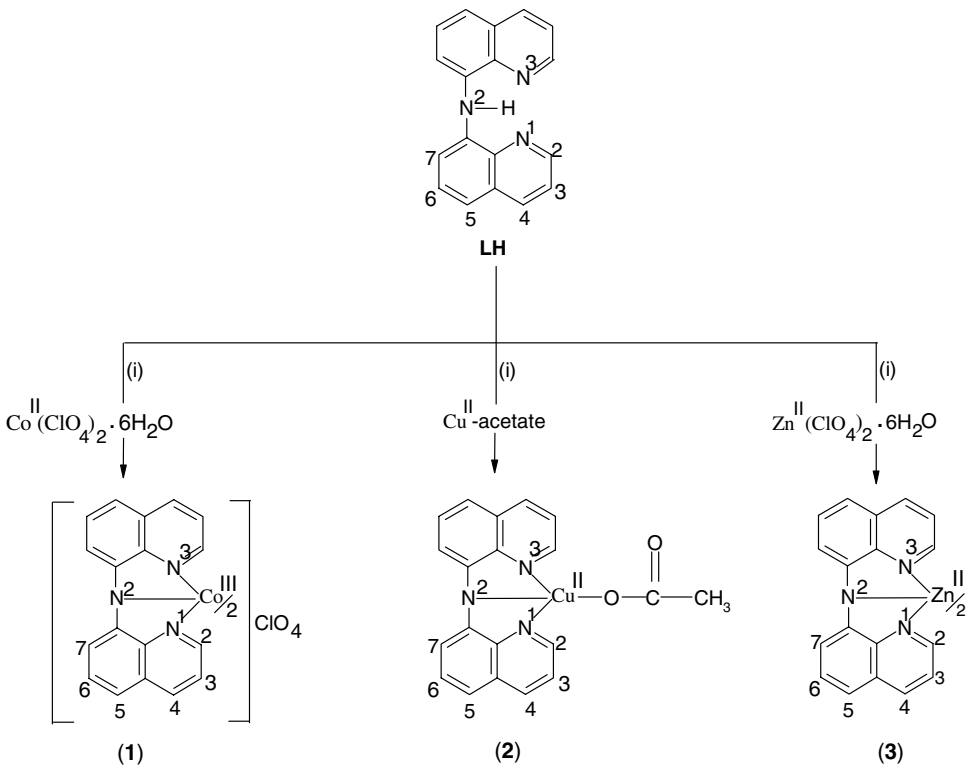
normal reaction conditions (Scheme 1). However, in case of peptide bound amide proton [C(=O)–NH] the presence of a base ($NaOCH_3$ or NaOH) is necessary to deprotonate the –NH proton during metallation process [7]. The complex $[Co^{III}(L)_2]ClO_4$ (**1**) has been synthesized from $Co^{II}(ClO_4)_2 \cdot 6H_2O$ and LH in methanol solvent under aerobic condition (Scheme 1). The synthesis of **1** from cobalt (II) starting salt is attained with the metal oxidation. In view of the low Co(III)–Co(II) reduction potential of **1** (see later) it may be logically considered that aerial oxygen is the most probable oxidant [8]. Under a strict dinitrogen atmosphere corresponding cobalt(II) species $\mathbf{1}^-$ can be generated, however, $\mathbf{1}^-$ is found to be oxidized spontaneously in contact with slight amount of air.

The reaction of LH with copper acetate or copper perchlorate in presence of sodium acetate base results in mononuclear tetra-coordinated copper (II) complex of the composition $Cu^{II}(L)\{^-O–C(=O)CH_3\}$ (**2**) (Scheme 1). On the other hand, the reaction of zinc perchlorate hexahydrate with the ligand, LH, yields bis-octahedral neutral complex $Zn^{II}(L)_2$ (**3**) as like the cobalt complex (Scheme 1).

The cobalt and zinc complexes are diamagnetic and behave as 1:1 conductor and neutral, respectively, in acetonitrile. The electrically neutral copper complex **2** exhibits one-electron paramagnetism ($\mu = 1.87$ BM). All the complexes exhibit satisfactory elemental analysis (Section 2).

3.2. Crystal structures of the free ligand $NC_9H_6–NH–C_9H_6N$ (LH), $[Co^{III}(L)_2]ClO_4$ (1) and $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (2)

The formation of LH was confirmed by its crystal structure determination. Crystal structure is shown in



Scheme 1. (i) MeOH, stir.

Fig. 2 and selective bond distances and angles are shown in Table 2. The bond distances and angles are unremarkable. The amido proton N(1)–H(101) has formed intramolecular hydrogen bonding with the nearby two quinolinic nitrogen centers [N(2) and N(3)] (Table 3).

The crystal structure of $[Co^{III}(L)_2]ClO_4 \cdot 0.5C_6H_6$ (**1**) is shown in Fig. 3. Selected bond distances and angles are listed in Table 2. The lattice consists of one type of molecule. The crystal consists of an array of $[Co(L)_2]^+$ cations, $[ClO_4]^-$ anions and benzene of crystallization in a ratio of 1:1:0.5 stoichiometry. The coordination geometry around the cobalt ion is distorted octahedral. The tridentate anionic ligand (L^-) is bonded to the cobalt ion with the terminal quinoline nitrogen atoms being *trans* to each other. The central amido nitrogen centers [N(1) and N(5)] of two L^- around the metal ion are also in *trans* configuration. The two meridional planes are nearly orthogonal. The sp^2 hybridization about each ionized amine group is reflected by the angles Co–N(1)–C(1), Co–N(1)–C(17), C(1)–N(1)–C(17), Co–N(5)–C(26), Co–N(5)–C(28), C(26)–N(5)–C(28), corresponding to 114.9(3)°, 114.1(4)°, 131.0(5)°, 114.6(4)°, 115.7(4)° and 129.6(5)°, respectively. The *trans* angles N(2)–Co–N(3), N(4)–Co–N(6) and N(1)–Co–N(5) are 168.7(2)°, 168.9(2)° and 178.71(19)°, respectively. The observed Co^{III}–N(quinoline) bond distances [1.913(4)–1.929(4) Å] are shorter than the average Co^{III}–N(pyridine) bond distances [1.94–2.00 Å] [9]. The Co-ionized amine bond distances [Co–N(1), 1.889(4) Å and Co–N(5), 1.879(5) Å] are reasonably shorter than the Co–quinoline N bond distances [Co–N(2), 1.913(4) Å; Co–N(3), 1.929(4) Å; Co–N(4), 1.921(4) Å and Co–N(6), 1.916 Å]. The Co^{III}–N(ionized amine) distances in **1** are appreciably shorter than the observed Co^{III}–NH distances [1.929(7)–1.951(7) Å] [10] and Co^{III}–N(amido) distances [1.929(6)–1.942(3)] [11] which are due to the fact of enhanced π-donor property of the ionized amino function. The perchlorate anion is tetrahedral with an average Cl–O distance of 1.410(6) Å and an average O–Cl–O angle of 109.46(4)°.

O(3) and O(4) atoms of the perchlorate moiety are involved in intermolecular C–H···O hydrogen bonds, sandwiching the solvent benzene molecule sitting on the symmetry position.

The formation of copper complex **2** has been confirmed by its single crystal X-ray structure. The crystal structure is shown in Fig. 4 and selected bond distances and angles are given in Table 2. The lattice consists of one type of molecule. The square planar geometry around the copper ion in $Cu^{II}N_3O$ coordination environment is evidenced from the angles subtended around the copper center (Table 2). The planarity of coordinated L^- is essentially leading to the square planar geometry. The tridentate anionic ligand is bonded to the copper ion with the terminal quinoline nitrogen centers [N(1) and N(3)] and the central amido nitrogen [N(2)]. The sp^2 hybridization of the ionized amine group is confirmed by the angles Cu(1)–N(2)–C(17), 115.5(17)°; Cu(1)–N(2)–C(8), 115.5(17)° and C(8)–N(2)–C(17), 128.9(2)°. The substantial deviation of the C(8)–N(2)–C(17) angle [128.9(2)°] of the coordinated tridentate ligand (L^-) with respect to the expected sp^2 angle of 120° possibly can account for the observed significant decrease in N–Cu–N *cis* angles [N(1)–Cu(1)–N(2), 82.72(9)° and N(2)–Cu(1)–N(3), 82.77(9)°]. The *trans* angles N(2)–Cu(1)–O(1) and N(1)–Cu(1)–N(3) are

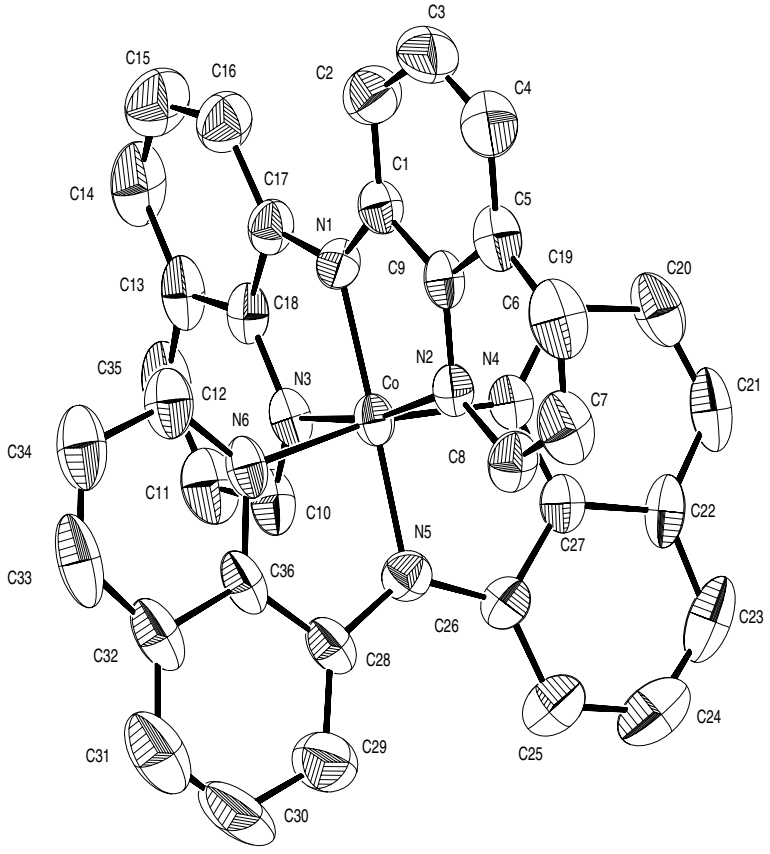

Fig. 3. Crystal structure of $[Co^{III}(L)_2]ClO_4 \cdot 0.5C_6H_6$ (**1**).

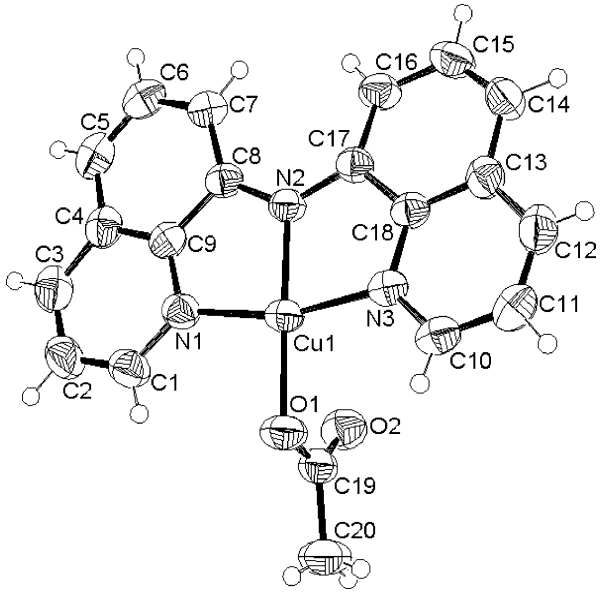

Fig. 4. Crystal structure of $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**).

175.3(9)° and 164.5(9)°, respectively. The Cu^{II}–N (quinoline) distances [Cu(1)–N(1), 1.983(2) Å and Cu(1)–N(3), 1.982(2) Å] are reasonably longer than the corresponding Cu(1)–N(2) (ionized amido nitrogen), 1.932(2) Å which reflects the π-donor ability of the ionized amino function. The Cu(II)–N (quinoline) distances are comparable with those of reported Cu(II)–N (quinoline) distances, 1.972–2.033Å [12]. Cu(1)–O(1) (acetate) distance 1.9495(18) Å is matched well with the reported data of other Cu(II)-monodentate acetate complexes [13]. It is to be noted that the crystal structure of similar reported tetracoordinated $Cu^{II}(L)Cl$ complex shows dimeric interaction through the ionized sp^2 hybridized amido nitrogen [2]. It was proposed that the filled p_z orbital of the sp^2 hybridized amido nitrogen is sufficiently basic to bind to a second copper ion resulting in dimerization. However, any sort of dimerization process has not been observed in the present case which implies that in comparison to the chloro complex the basicity of the amido nitrogen in **2** is significantly less, although the Cu–N(amido nitrogen) distance is almost same in both the complexes [1.932 (2)Å in **2** and 1.935 (2)Å in the corresponding chloro complex $[Cu^{II}(L)Cl]$] [2].

3.3. Spectral properties

The perchlorate vibrations of **1** appeared at 1093 and 629 cm^{-1} in the IR spectrum.

The ^{1}H NMR spectra of **1** and **3** in $CDCl_3$ solvent reveal that half of the individual ligand (L^-) represents the whole molecule due to the presence of internal symmetry (Fig. 5). The absence of NH proton of LH in the NMR spectra supports the bonding of anionic form of the ligand (L^-) to the metal ion in the solution state as well.

The acetonitrile solution of **1** exhibits multiple intense transitions in the UV–Vis region (Fig. 6(a)). [λ_{max}/nm (ε/$M^{-1}\,cm^{-1}$): 505(25 000), 431(9700), 374(5050), 292(57 000) and 217(107 000)]. Based on the high intensities of the visible bands the transitions are assigned to be charge-transfer in nature [14]. Since Co(III) is in the low-spin t_{2g}^6 configuration, the visible energy intense bands at 505 and 431 nm are, therefore, assigned as $L^- \rightarrow e_g(Co^{III})$ ligand-to-metal charge-transfer transitions [8,15]. The UV region moderately strong band at 372 nm and strong bands at 292 and 217 nm are presumably due to intra ligand $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions, respectively [16]. The free ligand (LH) also exhibits strong transitions in the UV-region [λ_{max}/nm (ε/

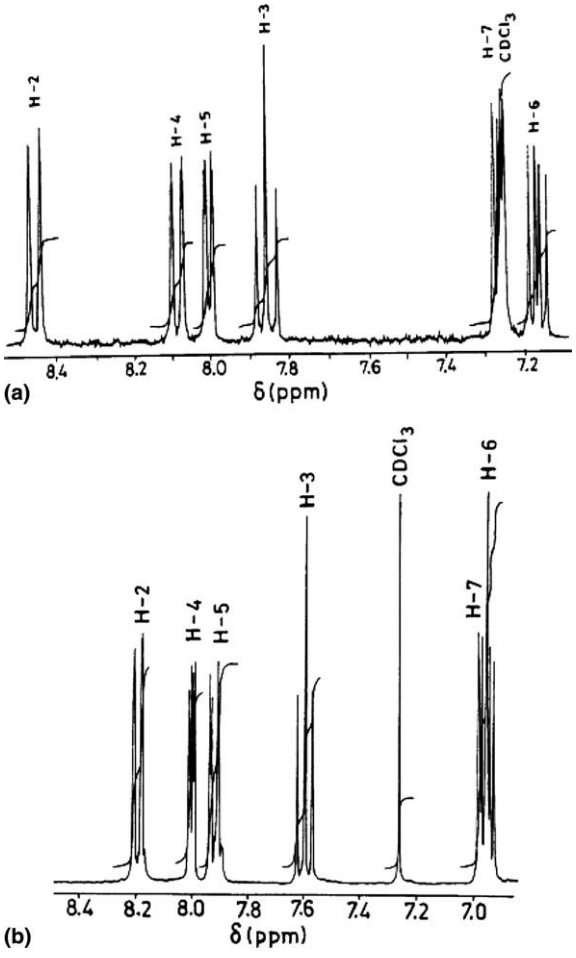

Fig. 5. ^{1}H NMR spectra of: (a) $[Co^{III}(L)_2]ClO_4$ (**1**) and (b) $Zn^{II}(L)_2$ (**3**) in $CDCl_3$.

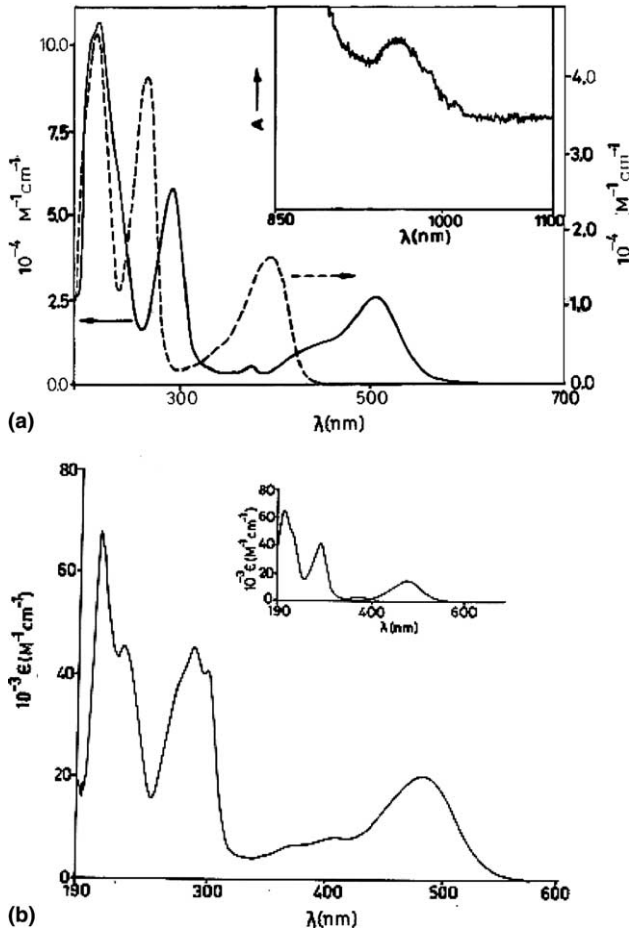

Fig. 6. Electronic spectra of: (a) $[Co^{III}(L)_2]ClO_4$ (**1**) (——) and LH (-----), inset shows the electronic spectrum of **1** in the range of 1100–850 nm; (b) $Zn^{II}(L)_2$ (**3**), inset shows the spectrum of $[Cu^{II}(L)\{OC(=O)CH_3]$ (**2**) in acetonitrile.

$M^{-1}\,cm^{-1}$): 397(16 100); 264(38 900); 214(44 700) in CH_3CN (Fig. 6(a))].

For low-spin octahedral Co(III) complexes having CoN_6 coordination environment the expected two d–d transitions, $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ usually appear near 500 nm and at a higher energy part, respectively ($\varepsilon \sim 10$–300 $M^{-1}\,cm^{-1}$) [17]. Accordingly, the $[Co(trpy)_2]^{3+}$ and Co(III)-peptide complexes exhibit lowest energy $^1A_{1g} \rightarrow {}^1T_{1g}$ transition near 500 nm [7a,18]. However, in **1** no such d–d transitions are detected in the UV–Vis region. The appearance of low energy intense charge-transfer transitions possibly have masked the expected weak d–d bands [8,19]. On the other hand **1** exhibits a very weak band at 955 nm (ε/$M^{-1}\,cm^{-1}$, 11]) (Fig. 6(a), inset). The existence of spin-allowed d–d band at an energy which is much lower than the observed lowest energy LMCT transition ($\lambda = 505$ nm) particularly in an environment consisting of potent electron-rich ligand function (L^-) and the metal ion in relatively higher oxidation state (Co^{3+}) is hard to conceive. It may, therefore, be logical to look for the possible correspondence of the 955-nm band with the

$^1A_{1g} \rightarrow {}^3T_{1g}$ spin-forbidden singlet–triplet transition as an alternative approach. The characteristics of very weak and relatively low energy of the 955 nm band can possibly justify its origin as $^1A_{1g} \rightarrow {}^3T_{1g}$ spin-forbidden transition. It may be noted that the spin-forbidden singlet–triplet transitions have been detected earlier in few other $Co^{III}N_6$ systems such as $Co(NH_3)_6^{3+}$ and $Co(en)_3^{3+}$ complexes [17,20].

The complex **2** exhibits four intense transition in the UV–Vis region (Fig. 6(b), inset): [λ_{max}/nm (ε/M^{-1} cm^{-1}): 476(14 622), 362(2781), 284(42 625) and 206(65 872)]. The intense transitions are believed to be charge transfer in nature. The lowest energy transition at 476 nm possibly originated from $L^- \rightarrow (Cu^{II})$ LMCT transition. The UV region transitions are possibly originated via intraligand $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions. The expected weak d–d transition in the visible region for **2** has not been detected even with its concentrated solution. It may be lost in the low-energy tail of the intense charge-transfer transition at 476 nm.

The complex **3** shows multiple transitions in the UV–Vis region (Fig. 6(b)): λ_{max}/nm (ε/M^{-1} cm^{-1}): 482(20 227), 229(40 568), 287(45 454), 228(45 340) and 207(67 272). In view of their high intensities the transitions are believed to be charge transfer in nature.

The EPR spectrum (Fig. 7) of **2** is recorded in 1:1 chloroform–toluene mixture at 298 K and it displays an equally spaced four-line spectrum (g_{av}, 2.106 and A_{av}, 80 G) due to hyperfine splitting by the copper nucleus ($I = 3/2$) [21].

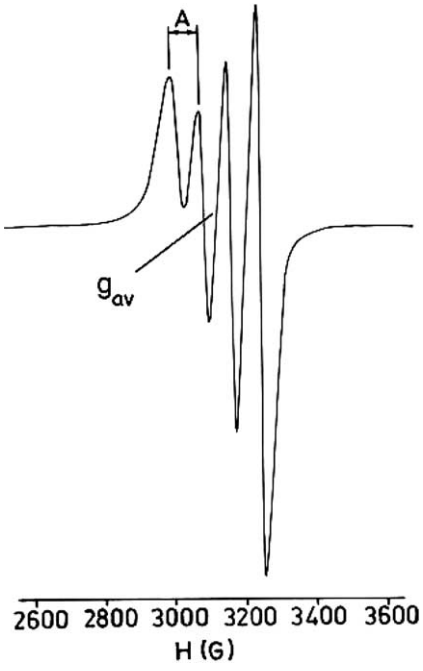

Fig. 7. EPR spectrum of $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**) in 1:1 chloroform–toluene mixture at 298 K.

3.4. Electron-transfer properties

Redox properties of $[Co^{III}(L)_2]^+$ (**1**) and $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**) have been examined in acetonitrile solvent using platinum wire working electrode (Figs. 8 and 9). Cobalt complex **1** displays one quasi-reversible one-electron reductive process E^0, $V(\Delta E_p, mV)$ at −1.0(100) versus SCE (couple-III) (Fig. 8(a)) which is assigned to be $Co(III) \leftrightharpoons Co(II)$ couple. The high negative potential (<−1.0 V) of cobalt(III)–cobalt(II) reduction process can account for the preferential stabilization of cobalt ion in +3 oxidation state in **1** under atmospheric conditions. The cobalt(III)–Cobalt(II) reduction potential of the similar bis octahedral peptido complex {$[Co(L)_2]^+$, $L^- = N$-(2-(4-imidazolyl)ethyl)-pyridine-2-carboxamide} appears at −0.62 V in MeOH, −0.72 V in $(CH_3)_2SO$ and −0.69 V in DMF (acetonitrile data is not available) [22]. The substantial negative shift of Co(III)–Co(II) reduction potential (∼0.3 V) while moving from the deprotonated amido complex to the deprotonated amino complex **1** implies the reasonable difference in basicity between the two sp^2 nitrogen centers. Thus, in case of peptide bound amide proton [C(=O)–NH] the oxidation of cobalt(II) to cobalt(III) takes place only via bubbling of air through the reaction mixture and in the presence of a base ($NaOCH_3$ or NaOH) [22]. The electrochemically generated Co(II) congener $[Co(L)_2]$ ($\mathbf{1}^-$) has been found to be quite unstable, it spontaneously oxidizes to the parent $[Co^{III}(L)_2]^+$ state which has essentially

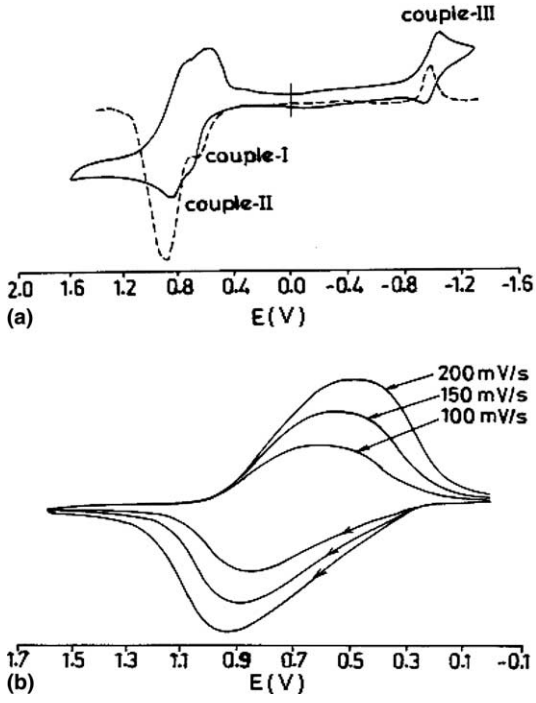

Fig. 8. Cyclic voltammograms of $\sim 10^{-3}$ M solution of $[Co^{III}(L)_2]ClO_4$ (**1**) in acetonitrile: (a) at a scan rate 50 mV s^{-1} and (b) at different scan rates (only for the oxidation processes).

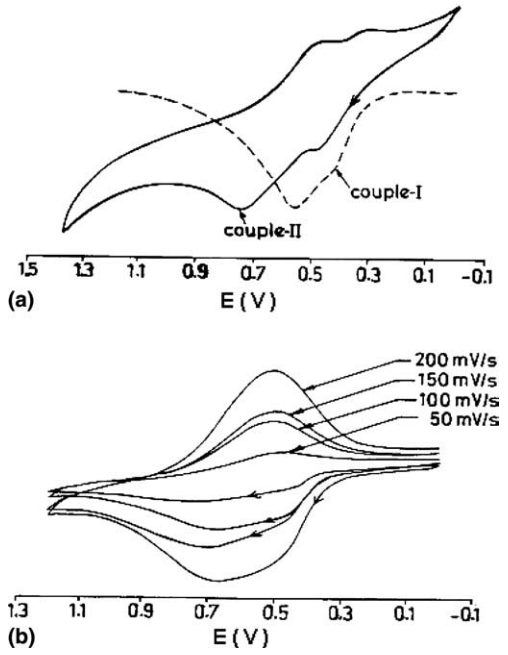

Fig. 9. Cyclic voltammograms of $\sim 10^{-3}$ M solution of $[Cu^{II}(L)\{OC(=O)CH_3\}]$ (**2**) in acetonitrile: (a) at a scan rate 20 mV s^{-1} and (b) at different scan rates (only for the oxidation processes).

precluded the isolation of the corresponding cobalt(II) analogue.

The complex **1** also displays two successive quasi-reversible oxidative responses, E^0, $V(\Delta E_p, \text{mV})$ at 0.64(80) (couple-I) and 0.83(120) (couple-II) (Fig. 8(a)). The one-electron nature of couple-I is confirmed by comparing its differential pulse voltammetric (dpv) current height with that of the Co(III)–Co(II) couple (couple-III). However, relative to couple-I or couple-III, the dpv current height of couple-II appears to be approximately three times greater.

On scan increment (>50 mV s^{-1}), the peaks of the two waves (couples I and II) broaden and merge to a single broad and blunt wave (Fig. 8(b)). The broadness of the profile of voltammograms particularly at a higher scan rate (>50 mV s^{-1}) reveals that the surface based adsorption processes are involved after the usual diffusion controlled based process [23]. In view of this serious electro deposition factor, repeated cleaning of electrode prior to each fresh run is found to be necessary.

The copper(II)-complex **2** shows two successive irreversible oxidation processes E_{pa} at 0.49 and 0.76 V versus SCE at a slower scan rate (20 mV s^{-1}) (Fig. 9(a)). However, on scan increment the shape of the voltammogram changes and at a higher scan rate (>100 mV s^{-1}) it appears to be an overlapping broad wave as like cobalt complex (Fig. 9(b)). Therefore, similar surface confinement processes are also involved during the oxidation steps particularly at a higher scan rate (>20 mV s^{-1}).

The electrogenerated oxidized species decomposes rapidly at room temperature, therefore, further characterization of the oxidized product and subsequent precise assignments of the oxidation processes have not been possible to make.

Since the free ligand (LH) exhibits one irreversible oxidation process at 0.56 V versus SCE in CH_3CN and +4 oxidation state of cobalt ion and +3 state of the copper ion are known to be difficult to stabilize, therefore, it may be logical to assign the oxidative responses as ligand-center based processes.

4. Conclusion

The use of sp^2-amido nitrogen containing tridentate ligand (L^-) leads to the formation of bis chelated octahedral complexes $[Co^{III}(L)_2]^+$ (**1**) and $[Zn^{II}(L)_2]$ (**3**). However, copper ion selectively stabilizes in square planar geometry having $Cu^{II}N_3O$ (**2**) chromophore. The basicity of the anionic sp^2-nitrogen center of L^- is such that it stabilizes the cobalt ion preferentially in trivalent Co^{III} state in **1** under atmospheric conditions. The strongly basic nature of L^- in **1** is also reflected in observed highly negative and reversible $Co^{III} \leftrightharpoons Co^{II}$ couple (−10 V versus SCE). The complexes exhibit strong charge-transfer transitions in UV–Vis region. Although no spin-allowed d–d transition has been observed for both cobalt and copper complexes, the cobalt complex **1** displays one very weak spin-forbidden $^1A_{1g} \rightarrow {}^3T_{1g}$ transition ($\varepsilon/M^{-1}\,cm^{-1}$, 11]) at 955 nm which has so far been rarely observed in few other octahedral Co(III) systems.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the CCDC Nos. 216980, 216979 and 216978 for compounds LH, **1** and **2**, respectively. Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk) on request, quoting the deposition numbers.

Acknowledgements

Financial support received from Council of Scientific and Industrial Research, New Delhi, India, is gratefully acknowledged. The X-ray structural studies were carried out at the National Single Crystal Diffractometer Facility, Indian Institute of Technology, Bombay. Special acknowledgement is made to Sophisticated Analytical Instrument Facility, Indian Institute of

Technology, Bombay for providing the NMR and EPR facilities.

Abstract

Cobalt(II) complexes of 2-methanol-, 2,6-dimethanol- and 2-ethanolpyridines have been prepared by the reaction of the corresponding protonated substituted pyridines with $[Co(sac)_2(H_2O)_4] \cdot 2H_2O$, where sac is saccharinate, and characterised by elemental analyses, IR, UV–Vis, magnetic measurements and single crystal X-ray diffraction. The corresponding 2-methanolpyridine (mpy) complex $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$ is dimeric with chloro bridges and each cobalt(II) ion has an octahedral coordination with two chloro and two bidentate (N, O) ligands. In the 2,6-dimethanolpyridine (dmpy) complex $[Co(dmpy)_2]Cl_2$, dmpy exhibits a tripodal chelating coordination mode through the N and two hydroxyl O atoms forming a CoN_2O_4 chromophore. The protonated 2-ethanolpyridinium cation Hpyet serves as a non-coordinating, but hydrogen bonded counter ion in $[Co(Cl)_4](Hpyet)_2$. Based on the molecular structures, the electronic, IR spectra and thermal behavior of the complexes are discussed.

Keywords: 2-Methanolpyridine; 2,6-Dimethanolpyridine; 2-Ethanolpyridinium; Cobalt(II) complexes; Crystal structures

1. Introduction

Several mixed ligand metal complexes of 2-methanolpyridine (mpy) [1–6], 2,6-dimethanolpyridine (dmpy) [6–10] and 2-ethanolpyridine (pyet) [11–16] have appeared in the literature. Among them, dmpy has received much attention. Mpy and pyet contain two donor sites, namely the py N and hydroxyl O atoms, and behave as chelating bidentate ligands, whereas dmpy acts as a tripodal ligand. These ligands usually form mononuclear complexes. In the case of zinc(II), two polynuclear complexes of mpy were reported [2]. In the protonated form, Hpyet acts as a monodentate ligand through the hydroxyl O atom [17] and it seems that protonation makes the N atom less basic.

In this paper, we report the synthesis, spectroscopic characterization, thermal reactivity and crystal structures of a binuclear cobalt(II) complex of mpy, $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$ and mononuclear cobalt(II) complexes of dmpy, $[Co(dmpy)_2]Cl_2$, and pyet, $[Co(Cl)_4](Hpyet)_2$.

2. Experimental

2.1. Materials

All reagents were purchased from commercial sources and were used without further purification.

2.2. Preparation of metal complexes

About 1.0 mmol (0.53 g) $[Co(sac)_2(H_2O)_4]\cdot 2H_2O$ was dissolved in 30 cm^3 MeOH and mixed with 2.0 mmol of mpy.HCl (0.29 g), dmpy.HCl (0.35 g) and pyet.HCl (0.32 g) dissolved in 1 cm^3 water and stirred for 30 min at 60 °C. Crystals suitable for X-ray diffraction were grown by slow diffusion of ether into the reaction solution at room temperature (r.t.).

$[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2\cdot 2H_2O$: violet. Yield 85%. d.p. 75 °C ($C_{24}H_{32}O_6N_4Cl_4Co_2$ Calc.: C, 39.4; H, 4.4; N, 7.6. Found: C, 39.6; H, 4.2; N, 7.5%). $[Co(dmpy)_2]Cl_2$: pink. Yield 78%. d.p. 88 °C (Found: C, 41.0; H, 4.3; N, 7.0; $C_{14}H_{18}N_2O_4Cl_2Co$ Calc.: C, 41.2; H, 4.4; N, 6.9%) and $[Co(Cl)_4](Hpyet)_2$: blue. Yield 63%. m.p. 79 °C ($C_{14}H_{20}N_2O_2Cl_4Co$ Calc.: C, 37.4; H, 4.5; N, 6.2. Found: C, 37.5; H, 4.3; N, 6.3%).

2.3. Physical measurements

IR spectra were recorded on a Shimadzu FTIR-8900 spectrophotometer as KBr pellets in the frequency range 4000–300 cm^{-1}. Electronic spectra were measured on a Unicam UV2 in the 200–900 nm range. The elemental analyses (C, H and N contents) were performed on a Vario EL Elemental Analyser. Room temperature magnetic susceptibility measurements were carried out using a Sherwood Scientific MXI model Evans magnetic balance. Thermal analysis curves (TG, DTA and DTG) were obtained using a Rigaku TG8110 thermal analyzer in a static air atmosphere. A sample size of 5–10 mg was used.

2.4. X-ray structure determination

The intensity data of the cobalt(II) complexes were collected using a BRUKER SMART 1000 CCD area detector diffractometer (Mo–Kα radiation, $\lambda = 0.71073$ Å) at 133 K. The structures were solved by direct methods using SHELXS-97 [18] and refined by a full-matrix least-squares procedure (SHELXL-97) [19]. The mathematical removal of effects of severely disordered solvent in $[Co(dmpy)_2]Cl_2$ was performed by using the program SQUEEZE incorporated in PLATON [20,21]. All non-hydrogen atoms were refined with anisotropic parameters. Hydrogen atoms bonded to carbon were included using a riding model, while the hydroxyl hydrogen atoms have been refined freely. The details of data collection, refinement and crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

The aim of the work is to prepare cobalt(II) complexes of saccharinate (sac) with protonated mpy, dmpy and pyet. In order to achieve this goal, the protonated py's were reacted with $[Co(sac)_2(H_2O)_4]\cdot 2H_2O$ in solution. During the reaction, the protonated mpy and dmpy behaved as an acid and protonated the sac anions, forming neutral sacH, mpy and dmpy species. It is well known that sacH in the protonated form is very stable and cannot coordinate to metal ions. Therefore, the coordination sphere around cobalt(II) were filled by mpy and dmpy, resulting in $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2\cdot 2H_2O$ and $[Co(dmpy)_2]Cl_2$ complexes. In the case of the protonated pyet (Hpyet), the sac ligands were replaced by the chloride ions and Hpyet acted as a counter ion, giving $[Co(Cl)_4](Hpyet)_2$.

$[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2\cdot 2H_2O$ is soluble in water at r.t. and also in hot MeOH and EtOH. $[Co(dmpy)_2]Cl_2$ and $[Co(Cl)_4](Hpyet)_2$ are soluble in water, MeOH and EtOH at r.t. All three complexes are non-hygroscopic and stable in air.

3.2. Spectral and magnetic properties

The most important IR bands of the complexes are listed in Table 2. The broad and intense bands between 3100 and 3380 cm^{-1} are due to the ν(OH) vibrations of the hydrogen bonded hydroxyl group and water molecules. The absorption band centered at 3175 cm^{-1} are characteristic of the ν(NH) vibration of the protonated pyet. The relatively weak absorption bands between 3000 and 2800 cm^{-1} are assigned to the ν(CH) vibrations. The ν(C=N) and ν(CC) vibrations appear in the frequency range 1630–1570 cm^{-1}as strong bands. The N-coordination of mpy and dmpy is also confirmed by the presence of medium bands at around 700 and 435 cm^{-1} due to in- and out-of-plane ring deformation of py [22].

The electronic spectra of the cobalt(II) complexes with mpy and dmpy exhibit a broad ligand field absorption band centered at 500 nm, whereas $[Co(Cl)_4](Hpyet)_2$ displays three distinct bands at 363, 520 and 666 nm due to d–d transitions.

The magnetic moments of the cobalt(II) complexes measured at r.t. clearly indicate that all three complexes are of high-spin type. $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2\cdot 2H_2O$ has a magnetic moment value of μ_{eff} of 4.3 BM which is noticeably lower than that of the expected value (7.74 BM), indicating an antiferromagnetic interaction in the Co–Co pair. The $[Co(dmpy)_2]Cl_2$ and $[Co(Cl)_4](Hpyet)_2$ complexes have the magnetic moment values of 4.0 and 3.9 BM, respectively, which are similar to the spin-only values.

3.3. Thermal analysis

Thermal decomposition behavior of the complexes were followed up to 700 °C in a static atmosphere of air. Thermoanalytical data including temperature ranges, DTA_{max} and mass loss calculations are presented in Table 3. The suggested decomposition products are based on mass loss calculations. $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2\cdot 2H_2O$ dehydrates between 35 and 145 °C with a two-step mass loss process and the first dehydration step in the temperature range 35–75 °C corresponds to the endothermic elimination of 0.5 mol of water molecules, while the rest of the lattice water molecules are removed at temperatures up to 145 °C. The experimental mass loss of 4.9% is the same as the calculated value. The degradation of the mpy ligands is a complicated process and takes place in the temperature range 145–515 °C with four endothermic DTA peaks (mass loss: found 58.2%, calc. 59.6%), leaving the $CoCl_2$ residue, which decomposes to Co_3O_4 at 675 °C. The total mass loss of all decomposition process is 82.1% (calc. 83.9%).

$[Co(dmpy)_2]Cl_2$ begins to decompose at 88 °C. The decomposition stage between 88 and 422 °C with two endothermic effects at 136 and 210 °C is related to removal of the two dmy ligands with a mass loss of 50.8% (calc. 51.1%). The resulting $CoCl_2$ intermediate decomposes to Co_3O_4 at 610 °C.

$[Co(Cl)_4](Hpyet)_2$ melts at 79 °C and begins to decompose at 180 °C. The thermal decomposition process of the complex is not easy to understand because of unclear decomposition steps. However, the first two endothermic DTA peaks at 214 and 362 °C peaks may be attributed to the removal of the pyet ligands, while

	490–610	556(−)	32.1	32.1	87.0	86.9	Co_3O_4 (at 610 °C)

[a] (+): Endothermic, (−): exothermic.

the exothermic DTA peak appearing as a shoulder at 480 °C may be due to formation and/or elimination of 2 mol of HCl. In the last stage, oxidization of $CoCl_2$ to Co_3O_4 takes place at 610 °C. The total experimental mass loss value of 87.0% agrees well with the calculated value 86.9%.

3.4. Description of crystal structures

3.4.1. $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$

The molecular structure of the title complex with the atom labelling is shown in Fig. 1. The selected bond lengths and angles together with the hydrogen bonding geometry are collected in Table 4. The structure consists of two water molecules, two chloride anions and a $[Co_2(\mu\text{-}Cl)_2(mpy)_4]^{2+}$ unit. In the cation, each cobalt (II) ion is coordinated by two mpy ligands and two chloride anions in a highly distorted octahedral configuration of the $CoN_2O_2Cl_2$ type. Each neutral mpy ligand behaves

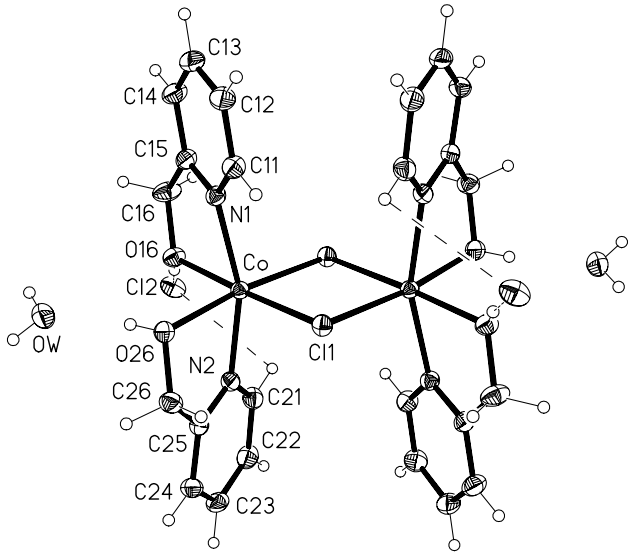

Fig. 1. Dimeric structure of $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$ with the atom labelling scheme and 50% thermal ellipsoids.

C16–H16···Cl2	0.802(17)	2.204(17)	2.9969(8)	170(1)

[a] Symmetry operations: (i) $-x+1,-y,-z+1$; (ii) $x-1,y,z$; (iii) $-x+1,-y,-z$; (iv) $-x+1,-y+1,-z$; (v) $-x+2,-y,-z$; (vi) $x-1,y,z+1$.

as a bidentate ligand through the N and hydroxyl O atoms forming a five-membered chelate ring, while two of the chloride anions act as a bridge between two cobalt(II) ions and the others remain as counter ions.

The mean Co–N and Co–O bond distances are 2.10 and 2.12 Å, respectively, and are similar to those reported for the bis(mpy)cobalt(II) unit [4]. The Co–Cl bond distances are 2.4212(3) and 2.4620(3) Å. The *trans* bond angles range from 160.87(3)° to 176.92(2)° and the highest deviations in the *cis* bond angles occur at the bite angle of the mpy ligand, N1–Co–O16 [75.92(3)°], and at N1–Co–Cl1 [101.00(2)°] which reflects the highly distorted coordination geometry around the cobalt atom.

The py rings are planar and the OH group significantly deviates from the plane of the py ring. The dihedral angles between two py rings in the same coordination polyhedron is 63(5)°. The Co–Cl–Co^{i}–Cl^{i} bridge is also exactly planar. The Co···Co separation is 3.524 Å and indicates an intermetallic interaction. The crystal structure is stabilized by intermolecular hydrogen bonds involving water molecules, uncoordinated chloride anions and CH_2 and py H atoms as listed in Table 4. The H atoms of the water molecules form relatively strong hydrogen bonds with uncoordinated chloride anions and the $[Co_2(\mu\text{-}Cl)_2(mpy)_4]^{2+}$ units are connected through the hydrogen bonds between the uncoordinated Cl atoms and some H atoms of the py rings and CH_2 group creating a three-dimensional network as shown in Fig. 2.

3.4.2. *[Co(dmpy)$_2$]Cl$_2$*

The molecular structure of $[Co(dmpy)_2]Cl_2$ with the atom labelling is shown in Fig. 3. The selected bond lengths and angles are given in Table 5. In fact, the structure has a highly disordered and unidentifiable solvent, which was eliminated by using the program SQUEEZE incorporated in PLATON [20,21]. Although the structure has two chloride anions, Fig. 3 shows three chloride anions. This is because two chloride anions are occupying special positions (mirror planes) with an occupying factor of 0.5. The structure consists of two chloride anions and a $[Co(dmpy)_2]^{2+}$ cation, in which the cobalt(II) ion sits on the center of symmetry and is octahedrally coordinated by a pair of neutral dmpy molecules, constituting a CoN_2O_4 chromophore. Each dmpy ligand acts as a tripodal and tridentate ligand through the N and two hydroxyl O atoms, forming two five-membered symmetric chelate rings.

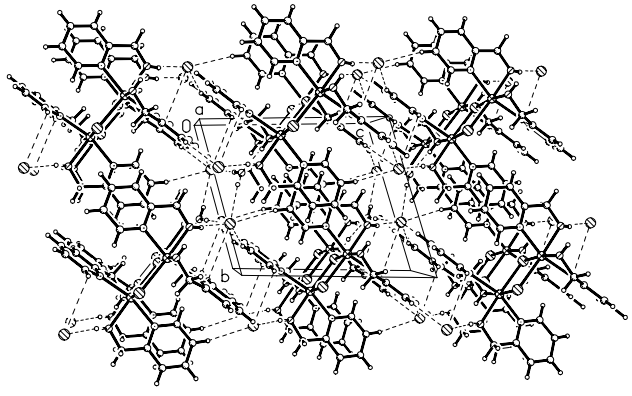

Fig. 2. Packing diagram of $[Co_2(\mu\text{-}Cl)_2(mpy)_4]Cl_2 \cdot 2H_2O$.

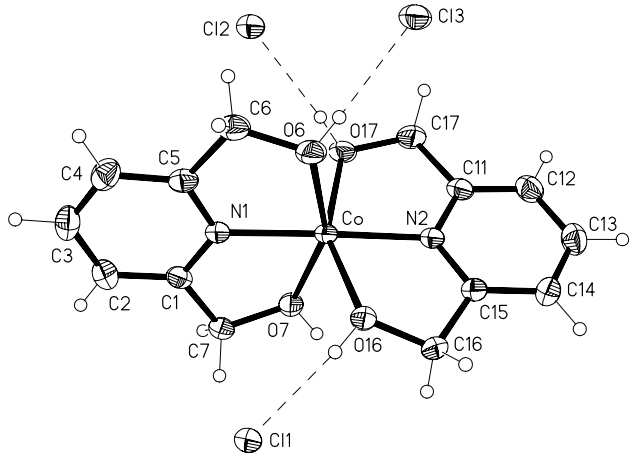

Fig. 3. Molecular structure of $[Co(dmpy)_2]Cl_2$ with the atom labelling scheme and 50% thermal ellipsoids.

The two Co–N bond distances are almost equivalent [2.0220(13) and 2.0241(13) Å], while the Co–O bond distances are in the range 2.1042(11)–2.1406(13) Å. Both Co–N and Co–O bond distances are comparable with those reported for the cobalt(II) complex of dmpy [5]. The Co–N bonds are somewhat shorter than the Co–O bonds and this results in the formation of a compressed distorted octahedral geometry along the Co–N bonds, since the N atoms occupy the axial positions and the O atoms constitute the equatorial plane of the CoN_2O_4 octahedron. Significant distortions in the coordination polyhedra are also deduced from the bond angles. The *trans* and *cis* angles are in the range of 153.20(5)°–177.42(5)° and 76.78(5)°–105.73(5)°. These distortions are presumably a consequence of the steric constraints imposed by the tripodal dmpy ligand.

A packing diagram of $[Co(dmpy)_2]Cl_2$ is shown in Fig. 4 and relevant hydrogen bonds are listed in Table 5. All the hydroxyl hydrogen atoms of the dmpy ligands are involved in hydrogen bonding with the chloride anions, which act as a bridge between the $[Co(dmpy)_2]^{2+}$ units as illustrated in Fig. 4. Additionally, the phenyl H atoms of py also form weak C–H···O and C–H···Cl interactions. The crystal packing of the title complex is determined by these hydrogen bonds forming a three-dimensional network.

3.4.3. *[Co(Cl)$_4$](Hpyet)$_2$*

The structure of the title complex comprises of a tetrachlorocobaltate(II) anion, $[Co(Cl)_4]^{2-}$ and two 2-

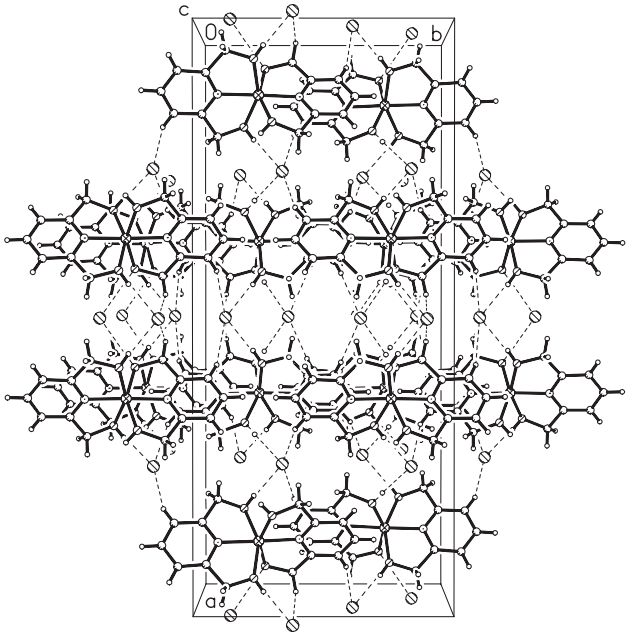

Fig. 4. Packing diagram of $[Co(dmpy)_2]Cl_2$.

ethanolpyridinium (Hpyet) cations as shown in Fig. 5. The geometry about the cobalt atom is essentially tetrahedral. The Co–Cl distances range from 2.2458(4) to 2.3150(3) Å (Table 6), while Cl–Co–Cl bond angles are between 101.921(13)° and 112.243(14)°. The largest differences in Co–Cl bond lengths and Cl–Co–Cl angles are 0.029 Å and 7.76°, respectively, and indicates a significant distortion in the coordination tetrahedron around the cobalt(II) ion. Bond distances and angles are similar to those of other tetrachlorocobaltate anions with protonated amines residing outside the coordination sphere [23].

The two crystallographically distinct, protonated 2-ethanolpyridinium cations serve as non-coordinating, but hydrogen bonded counter ions. As expected, protonation of 2-pyet takes place at the ring nitrogen. The bond lengths of the two independent pyridine rings do not differ significantly and are comparable with those reported for the coordinated Hpyet [17]. The py ring is planar and the ethanol group deviates from the respective pyridine ring plane.

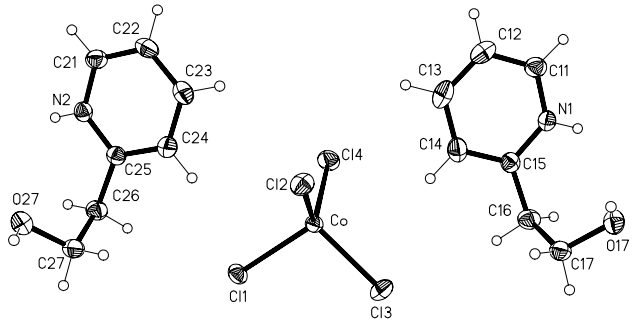

Fig. 5. Molecular structure of $[Co(Cl)_4](Hpyet)_2$ with the atom labelling scheme and 50% thermal ellipsoids.

Received 7 August 2003; accepted 24 November 2003

Abstract

Two copper(II) tripeptide Schiff base complexes: $[Mg(H_2O)_6][CuL]_2 \cdot 3.5H_2O$ (**1**) and $[Cd(H_2O)_4(CuL)_2] \cdot 3.5H_2O$ (**2**) (H_3L = *N*-salicylideneglycylglycylglycine) have been synthesized and structurally characterized. Single crystal X-ray diffraction analyses showed that the copper atom exhibits square-planar geometry, with the chelating ONNO atoms of the deprotonated Schiff base ligand(L) in the basal plane. In **1**, the anions $[CuL]^-$ and cations $[Mg(H_2O)_6]^{2+}$ are stacked in well-separated columns along the *a*-axis. In **2**, two symmetric $[CuL]^-$ groups coordinate to Cd(II) at an inversion center, each via one carboxylate oxygen atom, to form a heterotrinuclear complex. Variable-temperature magnetic susceptibility measurements revealed the occurrence of an antiferromagnetic interaction in **1** and **2**.

Keywords: Copper complexes; Schiff base complexes; Tripeptide complexes

1. Introduction

Transition metal *N*-salicylideneamino acid Schiff base complexes may serve as non-enzymatic models for pyridoxal-amino acid systems, which are of considerable importance as key intermediates in many metabolic reactions of amino acids catalysed by enzymes which require pyridoxal as a cofactor [1–4]. Besides, the complexes of amino-acid Schiff base ligands are considered to constitute a new kind of potential antibacterial and anticancer agent [5–7]. Considerable effort has been devoted to the preparation and structural characterization of Schiff base Cu(II) complexes derived from salicylaldehyde and amino acids [8–21] and reduced salicylidene amino acids [22–24]. However, little attention has been paid to systems in which the Schiff bases are derived from simple peptides [25,26], especially tripeptides, and few such compounds have been synthesized and structurally characterized.

Here, we report the synthesis of two new Schiff base copper(II) complexes with *N*-salicylidene tripeptides. Moreover, the first X-ray structures of mononuclear and carboxylate-bridged trinuclear Schiff base complexes derived from salicylaldehyde and glycylglycylglycine are described.

2. Experimental

2.1. Reagents and physical measurements

The tripeptide, glycylglycylglycine was purchased from Sigma and used without further purification. All other reagents and solvents were purchased from commercial sources and were analytical grade.

The IR spectra were recorded on KBr discs on a Bruker Vector 22 spectrophotometer in the 400–4000 cm^{-1} region. The UV–Vis spectra were recorded with a Shimadzu UV-3100 spectrophotometer. Elemental analyses (C, H, N) were obtained using a Perkin–Elmer 240C elemental analysis instrument. Metallic elements (K, Cu, Cd, Mg) were analyzed using a Perkin–Elmer M2100 atomic absorption spectrophotometer. Electrospray mass spectra were recorded on a LCQ system (Finnigan MAT, USA) using methanol/water as the mobile phase. All ESR spectra were recorded on a Bruker JES-FEIXG spectrometer with the X-band. Variable-temperature magnetic susceptibilities were performed on a CAHN-2000 Faraday balance from 75 to 300 K. Diamagnetic correction for the constituent atoms was made using Pascal's constants.

2.2. Synthesis

2.2.1. Synthesis of the triglycine Schiff base potassium salt ($KH_2L \cdot 1.5H_2O$) (H_3L = N-salicylideneglycylglycylglycine)

Glycylglycylglycine (0.95 g, 5 mmol) was dissolved in 40 cm^3 of aqueous methanol (1:2 by volume mixture) containing KOH (0.28 g, 5 mmol). A solution of salicylaldehyde (0.61 g, 5 mmol) in 10 cm^3 absolute methanol was added dropwise with stirring on a water bath at 35–40 °C for 2 h. The volume of the yellow solution was reduced in vacuo using a rotary evaporator to ca. 5 cm^3. Anhydrous ether was added to deposit a yellowish precipitate, which was then recrystallized from EtOH. Yield: 1.61 g (92%). *Anal.* Calc. for $K(C_{13}H_{14}N_3O_5) \cdot 1.5H_2O$: C, 44.6; H, 4.9; N, 12.0; K, 11.2. Found: C, 44.1; H, 5.2; N, 11.8; K, 11.0%.

2.2.2. Synthesis of Cu(II) Schiff base complex ($K[CuL] \cdot 2H_2O$)

Copper(II) acetate monohydrate (0.40 g, 2 mmol) was dissolved in 10 cm^3 of water. The solution was filtered and added dropwise into 25 cm^3 methanol solution of the triglycine Schiff base potassium salt (0.70 g, 2 mmol). The resulting mixture was adjusted to pH 8–9 with concentrated KOH solution and stirred at 35–40 °C for 2 h, then filtered. The filtrate was concentrated in vacuo using a rotary evaporator to ca. 5 cm^3. The purple product was deposited by adding a large quantity of ethanol with vigorous stirring, recrystallized from water/ethanol, and dried in vacuo at 35 °C over P_2O_5. Yield: 1.88 g (88%). *Anal.* Calc. for $K[Cu(C_{13}H_{12}N_3O_5)] \cdot 2H_2O$: C, 36.40; H, 3.76; N, 9.80; K, 9.12; Cu, 14.82. Found: C, 36.42; H, 3.78; N, 9.75; K, 9.10; Cu, 14.78%. IR (KBr, cm^{-1}): 3381s, 1642s, 1599s, 1551m, 1385m, 1298m. ESI-MS: m/z 353.1 $[CuL]^-$.

2.2.3. Synthesis of Cu(II)–M(II) (M = Mg, Cd) Schiff bases complexes

*2.2.3.1. $[Mg(H_2O)_6][CuL]_2 \cdot 3.5H_2O$ (**1**).* $K[CuL] \cdot 2H_2O$ (1 mmol) was dissolved in 20 cm^3 of H_2O and then filtered. $MgSO_4$ (0.5 mmol) was added to the filtrate with stirring at 25 °C for half an hour. A violet precipitate was obtained, which was recrystallized from hot water (90 °C). The filtrate was allowed to evaporate slowly at room temperature. After several days violet red crystals, which were suitable for X-ray diffraction, were obtained. *Anal.* Calc. for $C_{26}H_{43}N_6O_{19.50}MgCu_2$: C, 34.58; H, 4.80; N, 9.31; Cu, 14.07; Mg, 2.69. Found: C, 34.39; H, 4.88; N, 9.25; Cu, 14.00; Mg, 2.56%. IR (KBr, cm^{-1}): 3417s, 1649s, 1620s, 1544m, 1397m, 1291m.

*2.2.3.2. $[Cd(H_2O)_4(CuL)_2] \cdot 3.5H_2O$ (**2**).* Complex **2** was obtained in similar manner by replacing $MgSO_4$ with $Cd(NO_3)_2 \cdot 6H_2O$. *Anal.* Calc. for $C_{26}H_{39}N_6O_{17.50}CdCu_2$: C, 32.70; H, 4.12; N, 8.80; Cu, 13.31; Cd, 11.77. Found: C, 32.56; H, 4.20; N, 8.66; Cu, 13.11; Cd, 11.52%. IR (KBr, cm^{-1}): 3424s, 1647s, 1600s, 1543m, 1391m, 1303m.

2.3. X-ray crystallography

The diffraction experiments were carried out on a Bruker AXS SMART APEX CCD diffractometer. The structure was solved by direct methods using SHELXTL [27]. All non-hydrogen atoms were refined with anisotropic thermal displacement parameters. Hydrogen atoms were included in the refinement in calculated positions riding on their carrier atoms. A summary of the data collection and structure refinement is listed in Table 1.

3. Results and discussion

3.1. Crystal structure of **1**

An ORTEP plot with non-hydrogen atomic labelling is shown in Fig. 1(a). Selected bond distances and angles are listed in Table 2. The asymmetric unit consists of one $[Mg(H_2O)_6]^{2+}$, two $[CuL]^-$ groups and 3.5 water molecules. The coordination environment of each Cu(II) center is approximately square-planar. The Schiff base ligand is deprotonated, thus acting as a triple negatively charged quadridentate ONNO chelate. The ligand is coordinated to the Cu(II) atom via one phenolic oxygen (Cu(1)–O(1) = 1.851(3) Å, Cu(2)–O(6) = 1.864(3) Å), one imino nitrogen atom (Cu(1)–N(1) = 1.924(3) Å, Cu(2)–N(4) = 1.922(3) Å), one deprotonated amide nitrogen atom (Cu(1)–N(2) = 1.887(3) Å, Cu(2)–N(5) = 1.881(3) Å) and one carbonyl oxygen atom (Cu(1)–

O(3) = 1.989(3) Å, Cu(2)–O(8) = 2.002(3) Å. The carbonyl oxygen atoms O(3) and O(8) are here preferred to the peptide nitrogen atoms N(3) and N(6) as metal-binding sites at pHs where the amide proton of the peptide is not dissociated, as have been reported in the tripeptide complexes of Cu(gly-gly-gly)$^+$ [28], Cu(gly-leu-tyr)$^+$ [29], $[Ru(glyglyglyH_{-1})(PPh_3)]_2$ [30] and $[ReO(MECG_2H_2)]_2$ ($MECG_2H_5$ = mercaptoethyl-carbamoyl-methyl-glycylglycine) [31]. The distance from Cu(II) to the deprotonated amide nitrogen atom is shorter than the distance to the imino nitrogen atom. The distance from Cu(II) to the phenolic oxygen is shorter than the distance to the carbonyl oxygen. A slight distortion in the square-planar geometry of Cu(II) is present (observed bond angles vary from 83.1(1)° and 96.9(1)°). The values 1.495(5) Å for the C(8)–N(1) bond and 1.464(6) Å for the N(4)–C(21) bond, shorter than the usual C–N single bond, and 1.249(5) and 1.270(5) Å for the double bonds C(7)–N(1) and N(4)–C(20) are in good agreement with the values of Schiff base type I [32]. The phenyl ring [C(1)–C(6)] and the chelate ring C(1), C(6), C(7), N(1), O(1), Cu(1) make a small dihedral angle of 3.4°, and the phenyl ring [C(14)–C(19)] and the chelate ring C(14), C(19), C(20), N(4), O(6), Cu(2) make a small dihedral angle of 2.4°, suggesting a large π-electron delocalization. The two $[CuL]^-$ groups have alternate spatial arrangements and their Cu chelate planes are almost parallel with a small dihedral angle of 1.2°, where the distance between two neighboring copper(II) ions is 4.67 Å. The Mg(II) center is almost octahedrally coordinated by six aqua ligands. The six Mg–O bonds in the structure are in the range 2.05–2.10 Å.

One of the structural features of **1** is that the anions and cations are stacked in well-separated columns along the a-axis (Fig. 1(b)). Within each anionic columns, the $[CuL]^-$ anions form a chain with alternate spacings. The Cu···Cu distance is 4.67 and 6.16 Å within the $[CuL]^-$ anion chain. The closest Cu···Cu separation between anion chains is 9.89 Å, which is significantly longer than the Cu separation within a chain.

The presence of intermolecular and intramolecular hydrogen bonds plays an important role in the stabilization of the whole structure. These are formed between the N–H of the amide nitrogen in one $[CuL]^-$ group and the carboxylate oxygen of another $[CuL]^-$ group, between the O–H of $[Mg(H_2O)_6]^{2+}$ and water molecules, between the O–H of a water molecule and a phenolic oxygen atom of $[CuL]^-$, between the O–H of a water molecule and a carbonyl oxygen atom of $[CuL]^-$, and between adjacent water molecules. The presence of

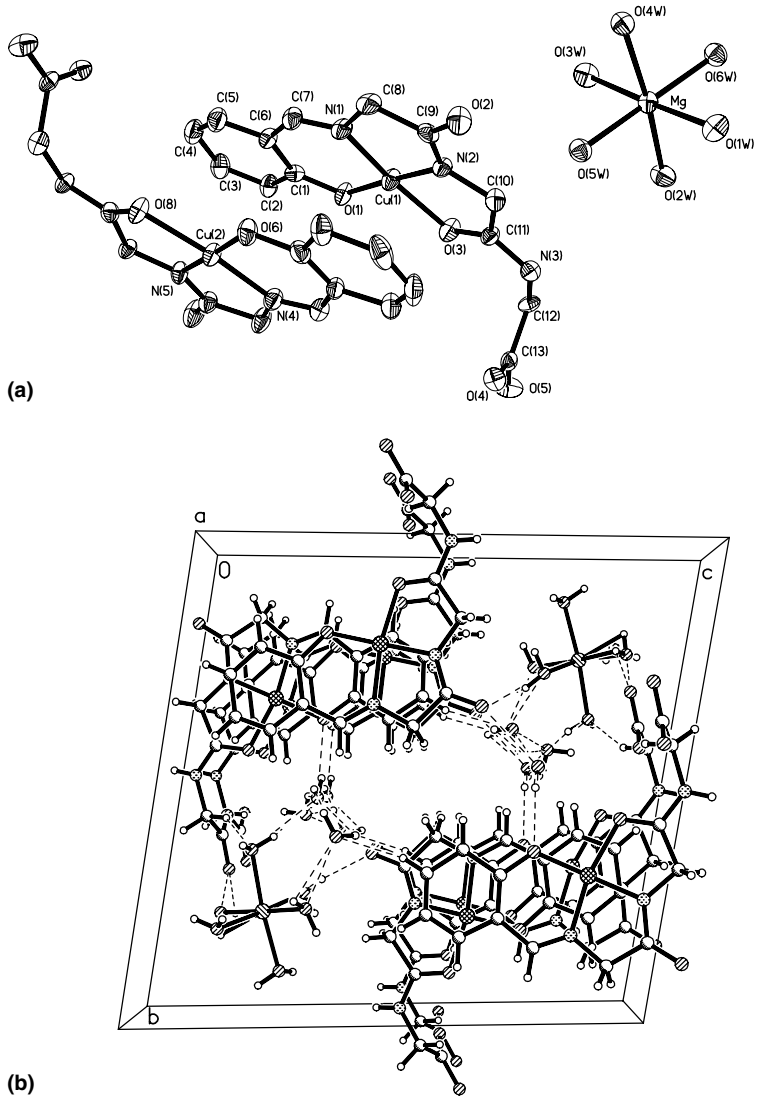

Fig. 1. (a) ORTEP view of **1** with hydrogen atoms and lattice water molecules omitted for clarity. Thermal ellipsoids are drawn at the 35% probability level. (b) The packing diagram of a unit cell of **1** along the *a*-axis.

water molecules and their bridging role with respect to the $[CuL]^-$ and $[Mg(H_2O)_6]^{2+}$ columns allow for the generation of a 3-D hydrogen-bonded network.

The $[CuL]^-$ ligand does not coordinate to the metal ion Mg^{2+} in **1** wherein the Mg^{2+} ion preferentially binds to water molecules, in the form of $[Mg(OH_2)_6]^{2+}$.

3.2. Crystal structure of *2*

Compound **2** consists of a neutral centrosymmetric trinuclear moiety and 3.5 lattice water molecules (Fig. 2(a)). The coordination environment at each Cu(II) center is similar to that in **1**. Selected bond distances and bond angles are given in Table 3.

Comparing with the Mg(II) ion in **1**, the charge–radius ratio of the Cd(II) ion in **2** is higher and Cd(II) is softer than Mg(II). Thus, the Mg(II) ion preferentially binds to harder water molecules in the form of $[Mg(OH_2)_6]^{2+}$ and Cd(II) is propitious to the formation of a bridged polynuclear compound [33,34]. In **2**, each $[CuL]^-$ group coordinates to the Cd(II) center via one carboxylate oxygen atom (O(4)) in a *syn–anti* bridging mode. The Cd(II) center is approximately octahedrally coordinated by two carboxylate oxygens (O(4) and O(4a)) and four aqua ligands.

The most pronounced feature of the crystal structure is the column stacking along the *a*-axis with the $[CuL]^-$ moieties organized in interlaced arrays. The interaction between copper(II) ions and the imino nitrogen atom of an adjacent $[CuL]^-$ group [Cu(II)–N(1A) = 3.301 Å] plays a very important role in the packing scheme. The distance between two copper(II) ions is 3.422 Å. The N(3A)–H proton and one H atom of the ligand water O(7D) hydrogen bond to the carbonyl oxygen atom O(2C) of adjacent $[CuL]^-$ groups to form a 2-D hydrogen-bonded network in the *ab*-plane (Fig. 2(b)).

Symmetry transformations used to generate equivalent atoms: $(-x+1, -y+1, -z+2)$.

In **2**, the N(3)–H proton and the H atoms of two ligand water (O(6), O(7)) and one lattice water (O(8w)) molecules participate in hydrogen bonding. The two H atoms from the ligand water O(6) are all hydrogen bonded to the lattice water oxygen O(8w). Two H atoms from O(8w) are hydrogen bonded to the carbonyl oxygen atom O(2) and the carboxylate oxygen O(4) from another $[CuL]^-$ group, respectively. The hydrogen atom from C(3) in phenyl ring bonds to the carboxylate oxygen O(5) from an adjacent $[CuL]^-$ group forming

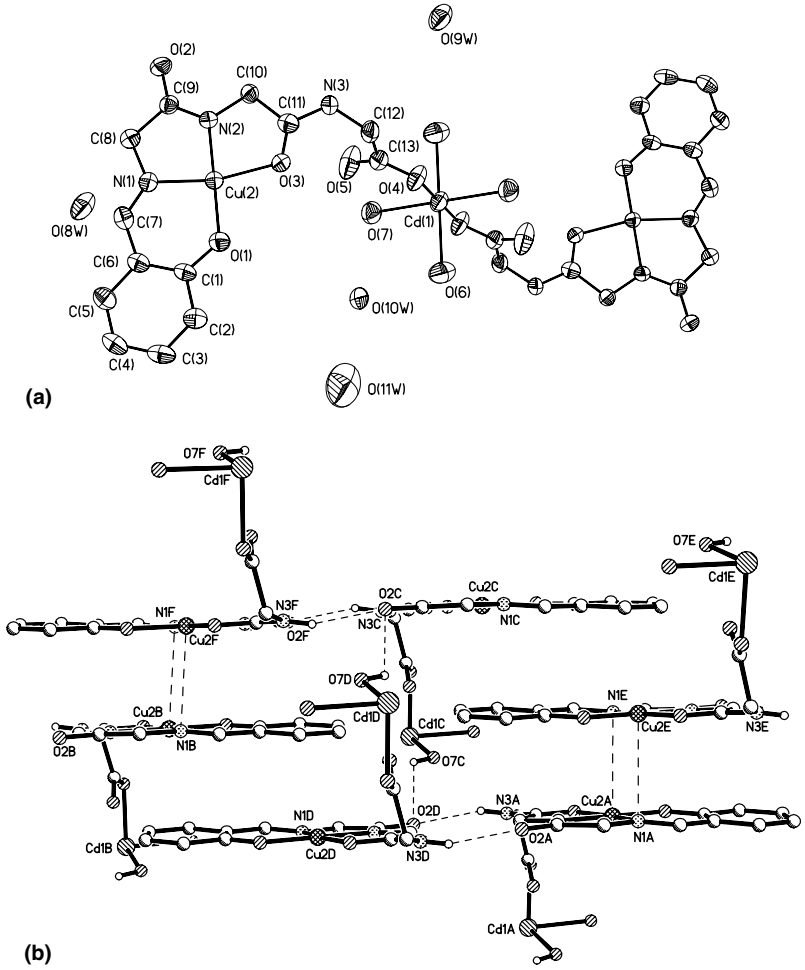

Fig. 2. (a) ORTEP view of **2**, with hydrogen atoms omitted for clarity. Thermal ellipsoids are drawn at the 35% probability level, (b) A view of the packing of **2** along the *c*-axis.

a weak hydrogen bond with the distances C(3)···O(5) = 3.422(9) Å and H···O(5) = 2.58 Å, which is similar to reported values [35,36]. The presence of these intramolecular and intermolecular hydrogen-bondings is an important factor in the stabilization of the whole structure, which allows the compound to form a 3-D network structure.

3.3. Infrared spectra

The infrared spectra of the two compounds show strong typical absorptions at 1649 (**1**) and 1647 cm^{-1} (**2**) related to the ν(C=N) Schiff base imino group. The ν_{as}(COO) is assigned to the strong bands at 1620 (**1**) and 1600 cm^{-1} (**2**) whereas the ν_s(COO) is attributed to the 1397 (**1**) and 1391 cm^{-1} (**2**) peaks. Medium bands present at 1544 (**1**) and 1543 cm^{-1} (**2**) may originate from the vibration of the (Ph–)C–C(=N) bond [37]. Medium bands at 1291 (**1**) and 1303 cm^{-1} (**2**) probably correspond to ν(O–Ph). Both compounds exhibit a broad band in the 3000–3500 cm^{-1} region, which may be ascribed to hydrogen-bonded ν(O–H) and/or ν(N–H), and may also include ν(C–H).

3.4. Electronic spectra

The UV absorption bands observed at 352 (**1**) and 364 nm (**2**) in the two compounds are assigned to the imino n–π^* transitions. The d–d transition spectra of the complexes show broad bands centered at 587 (**1**) and 590 nm (**2**), being suggestive of approximate square-planar geometry at Cu.

3.5. Magnetic properties and ESR spectra

The molar magnetic susceptibility χ_m versus T for each compound shows an antiferromagnetic interaction (Fig. 3). The data for the two compounds have been

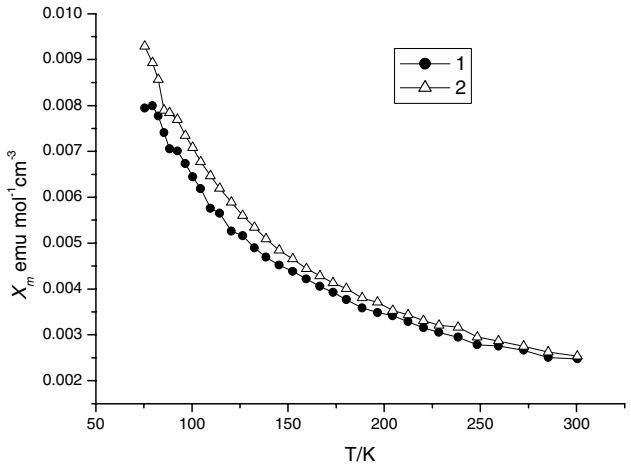

Fig. 3. Temperature dependence of χ_m for **1** (•), **2** (△).

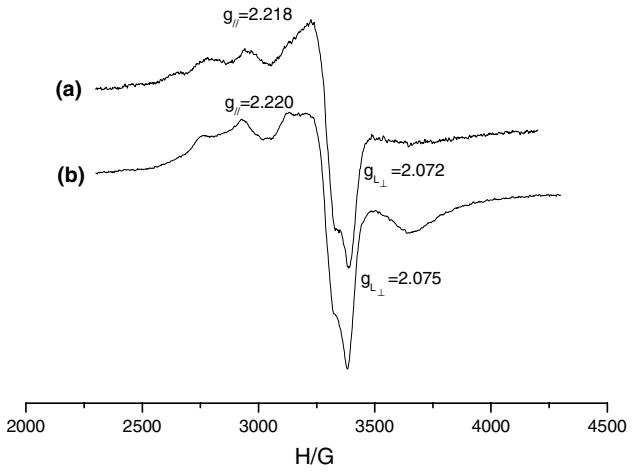

Fig. 4. Experimental ESR spectra of **1** (a) and **2** (b) taken in DMSO at 110 K.

successfully fitted to the Curie–Weiss law ($1/\chi_m = (T-\theta)/C$) (**1**, $C = 0.735$ emu K mol^{-1}, $\theta = -14.430$ K; **2**, $C = 0.734$ emu K mol^{-1}, $\theta = -3.402$ K). The effective magnetic moments are in accordance with diluted monomeric units at 300 K (**1**, $\mu_{eff} = 2.44$ BM; **2**, $\mu_{eff} = 2.47$ BM).

The ESR spectra of **1** and **2** at 110 K in DMSO are shown in Fig. 4. The trends $g_{||}(2.218) > g_\perp(2.072) > g_e(2.0023)$ observed for **1**, $g_{||}(2.220) > g_\perp(2.075) > g_e(2.0023)$ observed for **2** indicate a d(x^2–y^2) ground state. Kivelson and Neiman have shown that $g_{||}$ is a moderately sensitive function for indicating covalence. Relatively speaking, $g_{||} > 2.3$ is characteristic of an ionic environment and $g_{||} < 2.3$ of a covalent environment in M–L bonding [38]. In the present compounds $g_{||}$ indicates a fair degree of covalent character in the Cu–L bonding.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 213115 for compound **1**, 213114 for compound **2**. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +/44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Three new lanthanum coordination polymers $\{[La(\mu\text{-}L)_2L(H_2O)_2](CF_3SO_3)_3\}_n$ (**1**), $\{[La(\mu\text{-}L')(CF_3SO_3)(H_2O)_2(\mu\text{-}L)_{0.5}L](H_2O)_3(CF_3SO_3)\}_n$ (**2**) and $\{[La(\mu\text{-}L')_2(\mu\text{-}L)](H_2O)_{1.5}(CF_3SO_3)\}_n$ (**3**) have been prepared by the reaction of $La(CF_3SO_3)_3$ with 1,2-bis(4-pyridyl)ethane-*N*,*N*′-dioxide (L), or with mixed N-oxide ligands L and L′ (HL′ = isonicotinic acid N-oxide) in different molar ratios. Single-crystal X-ray analysis showed that **1** possesses a three-dimensional coordination framework connected by L ligands, whereas bridging by both L and L′ spacers in different molar ratios results in coordination polymers **2** and **3** that exhibit two- and three-dimensional networks, respectively. Compounds **2** and **3** represent the first metal complexes containing two different N-oxide bridging ligands. Thermogravimetric analysis studies revealed that ligands L and L′ are bound differently in compounds **1**–**3** due to their distinctive coordination modes.

Keywords: Lanthanum trifluoromethanesulfonate; Isonicotinic acid; N-oxide; Mixed ligands; Coordination polymer

1. Introduction

Crystal engineering of metal-organic compounds has developed rapidly in view of their potential applications and unusual topologies [1,2]. It is well established that the assembly processes of coordination networks can be controlled by the choice of metal ions, counter anions, co-existing neutral ligands, temperature, pH and solvents used for crystallization [3–10]. In some instances, two or more complexes of different compositions can be obtained merely by manipulating the ligand/metal molar ratio [11]. The lanthanides have been less studied in this context owing to their weak stereochemical preferences which prevent reliable preconceived molecular assembly in solution [12]. Nevertheless, prior knowledge of persistent structural motifs offers a viable approach to the design of lanthanide coordination networks [13]. A widely applicable strategy using poly(N-oxide) ligands as spacer linkers for assembling coordination networks based on f-block metals has been developed [14]. Recently 4,4′-bipyridine-*N*,*N*′-dioxide [15], 1,2-bis(4-pyridyl)ethane-*N*,*N*′-dioxide and *trans*-1,2-bis(4-pyridyl)ethene-*N*,*N*′-dioxide have been synthesized and used to generate a series of novel lanthanide(III) coordination polymers [16]. Herein, we report the synthesis and structural characterization of $\{[La(\mu\text{-}L)_2L(H_2O)_2](CF_3SO_3)_3\}_n$ (**1**), $\{[La(\mu\text{-}L')(CF_3SO_3)(H_2O)_2(\mu\text{-}L)_{0.5}L](H_2O)_3(CF_3SO_3)\}_n$(**2**) and $\{[La(\mu\text{-}L')_2(\mu\text{-}L)](H_2O)_{1.5}(CF_3SO_3)\}_n$ (**3**), which were self-assembled by La$(CF_3SO_3)_3$ with 1,2-bis(4-pyridly)ethane-*N*,*N*′-dioxide (L) alone, and with both L and L′ (HL′ = isonicotinic acid N-oxide; see Scheme 1) in different molar ratios.

2. Experimental

2.1. General method

IR spectra were recorded with a Nicolet Impact 420 FT-IR spectrometer using KBr pellets. Elemental analyses of C, H and N were performed by MEDAC LTD

Scheme 1.

Brunel Science Centre, UK. Thermal stability of polycrystalline samples **1**–**3** was measured on a Hi-Res TGA 2950 Thermogravimetric Analyzer from 50 to 900 °C under a nitrogen atmosphere at a heating rate of 10 °C/min. 1,2-Bis(4-pyridyl)ethane-*N*,*N*′-dioxide (L) was synthesized as described previously [16]. Lanthanum trifluoromethanesulfonate hydrate and isonicotinic acid N-oxide (HL′) were obtained commercially (Aldrich) and used without further purification.

2.2. Synthesis of $\{[La(\mu\text{-}L)_2L(H_2O)_2](CF_3SO_3)_3\}_n$ (*1*)

To an aqueous solution (3 mL) of $La(CF_3SO_3)_3 \cdot 9H_2O$ (60 mg, 0.08 mmol), an aqueous solution (8 mL) of anhydrous L (100 mg, 0.43 mmol) was added with stirring. The mixture was heated at 70 °C for about 10 min and then filtered. Upon slow evaporation of the filtrate at room temperature, colorless crystals of **1** suitable for X-ray analysis were obtained after several days. Yield ca. 80% (based on $La(CF_3SO_3)_3$). *Anal.* Calc. for $C_{39}H_{40}LaS_3F_9N_6O_{17}$: C, 36.86; H, 3.17; N, 6.61. Found: C, 37.01; H, 3.03; N, 6.32%. IR(KBr, cm^{-1}): 3406sbr, 3117w, 1636w, 1495s, 1453w, 1284s, 1249s, 1171s,1028s, 853m, 771m, 635s, 576w, 510m, 482m.

2.3. Synthesis of $\{[La(\mu\text{-}L')(CF_3SO_3)(H_2O)_2(\mu\text{-}L)_{0.5}L](H_2O)_3(CF_3SO_3)\}_n$ (*2*)

Aqueous solutions of $La(CF_3SO_3)_3 \cdot 9H_2O$ (3 mL; 60 mg, 0.08 mmol) and HL′ (4 mL; 15 mg, 0.1 mmol) were mixed together. Then, an aqueous solution of L (4 mL; 100 mg, 0.2 mmol) was added to the mixture with stirring. After heating at 70 °C for 10 min with stirring, the resultant solution was filtered. Upon slow evaporation of the filtrate at room temperature, colorless crystals of **2** were obtained after several days. Yield ca. 57% (based on $La(CF_3SO_3)_3$). *Anal*. Calc. for $C_{26}H_{32}LaS_2F_6N_4O_{17}$: C, 31.56; H, 3.26; N, 5.66. Found: C, 31.23; H, 3.24; N, 5.44%. IR(KBr, cm^{-1}): 3440sbr, 3120w, 1632w, 1602w, 1548w, 1494m, 1454w, 1407w, 1286s, 1241s, 1175s, 1030s, 856m, 772m, 640s, 576w, 516m, 482m.

2.4. Synthesis of $\{[La(\mu\text{-}L')_2(\mu\text{-}L)](H_2O)_{1.5}(CF_3SO_3)\}_n$ (*3*)

Colorless needle-like crystals of **3** were obtained by a similar procedure to **2** but with a different starting molar ratio of $La(CF_3SO_3)_3$:L:HL′ (1:1:2). Yield ca. 50% (based on $La(CF_3SO_3)_3$). *Anal.* Calc. for $C_{25}H_{23}LaSF_3N_4O_{12.5}$: C, 37.19; H, 2.87; N, 6.94. Found: C, 36.96; H, 2.49; N, 6.72%. IR(KBr, cm^{-1}): 3382sbr, 3115w, 1612w, 1594m, 1546w, 1492s, 1453w, 1406s, 1292s, 1237s, 1174s, 1025s, 859m, 774m, 641s, 485w.

2.5. X-ray crystallography

Selected single crystals of **1**–**3** were used for data collection on a Bruker SMART 1000 CCD diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å at 293 K. An empirical absorption correction was applied using the SADABS program [17]. The structures were solved by direct methods and refined by full-matrix least-squares based on F^2 using the SHELXTL program package [18]. The crystallographic data for complexes **1**–**3** are summarized in Table 1.

3. Results and discussion

3.1. Description of the crystal structures

$[La(\mu\text{-}L)_2L(H_2O)_2](CF_3SO_3)_3$ (**1**). The crystal structure of **1** consists of a three-dimensional (3-D) cationic coordination framework $[La(\mu\text{-}L)_2L(H_2O)_2]^{3+}$ and uncoordinated $CF_3SO_3^-$ counter anions. As shown in Fig. 1, each La^{3+} center coordinates to eight oxygen donors from six adjacent L ligands and two water molecules in a square antiprismatic coordination environment. It is notable that all three independent L ligands display different coordination modes in this structure (see Chart 1): (I) monodendate, (II) bidendate (μ-*O*,*O*′) and (III) unusual tridendate (μ-*O*,*O*,*O*′) bridging mode. The dihedral angles between the pyridyl rings within each kind of independent ligand molecule are 138.5°, 53.0° and 57.3°, respectively. The centrosymmetric dimeric La_2O_2 motifs linked by the μ_3 L ligand (with La···La separation of 4.524 Å) can be considered as 4-connected nodes, which are extended into a 3-D architecture by the L ligands exhibiting bridging fashions (II) and (III), as shown in Fig. 2. The channels of the resultant framework are occupied by the monodendate L ligands and the uncoordinated $CF_3SO_3^-$anions, forming O–H···O hydrogen bonding interactions with the aqua ligands O1W–H···O2a, O2W–H···O7b, O2W–H···O1c (a: $-x+2$, $-y+1$, $-z+1$; b: x, $y+1$, $z+1$, c: $-x+3$, $-y+2$, $-z+1$) that further stabilize the overall crystal structure. It is of interest to compare this structure with that of $[La(NO_3)_3(L)(CH_3OH)] \cdot CH_3OH \cdot CH_2Cl_2$ (**1a**) [16]. In the crystal structure of **1a**, the nitrate anions coordinate to the La(III) center in the chelating mode and the L ligands connect the La(III) ions in bidendate (μ-

O,*O*′) and tetradentate (μ-*O*,*O*,*O*′,*O*′) coordination fashions, leading to a two-dimensional square-grid (4,4) coordination network with centrosymmetric dinuclear La_2O_2 nodes. Although the change in the coordination modes of the ligand L gives rise to different coordination frameworks in **1** and **1a**, the nature of the counter anions also play a dominant role in the as-

sembly of these polymeric nets [19]. As observed in **1**, the uncoordinated $CF_3SO_3^-$ anion accounts for subtle templating effects that cause the L ligands to adopt versatile coordination modes.

$[La(\mu\text{-}L')(CF_3SO_3)(H_2O)_2(\mu\text{-}L)_{0.5}L](H_2O)_3(CF_3SO_3)$ (**2**). The anionic ligand L' can coordinate to metals via its N-oxide and/or carboxylate group [20]. By incorporating it as a co-ligand in the formation of **1**, a different coordination architecture **2** was obtained. Here, the central La(III) atom is surrounded by nine oxygen donors from one $CF_3SO_3^-$ anion, two aqua ligands, two L′ and three adjacent L ligands, adopting a tricapped trigonal prismatic geometry as depicted in Fig. 3. In this structure, coordination modes (I) and (III) of L are observed. The dihedral angles between the pair of pyridyl groups within the two independent L molecules are 6.4° and zero (for the one locate at an inversion center). The L′ ligand exhibits the μ_3, end-to-end bridging mode with unusual symmetric bidentate chelatation of the carboxylic group to connect the La(III) centers into a linear chain. The adjacent La···La nonbonding distance within this coordination chain is 10.588 Å. Furthermore, each La center in this chain is cross-linked to another La atom in a neighboring chain by a pair of oxygen donors from two distinct L molecules in coordination mode III, forming a double-chain ladder architecture as shown in Fig. 4. In the centrosymmetric dimeric La_2O_2 motif, the La···La separation is 4.500 Å. Adjacent parallel pyridine rings in the double chain have a center-to-center distance of 3.538 Å, indicating a significant face-to-face π–π stacking interaction [21].

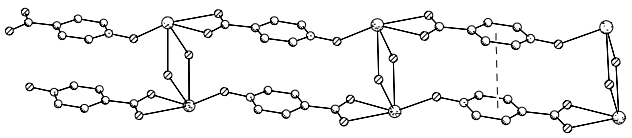

Fig. 4. Double-chain structure of **2** showing π–π stacking interaction.

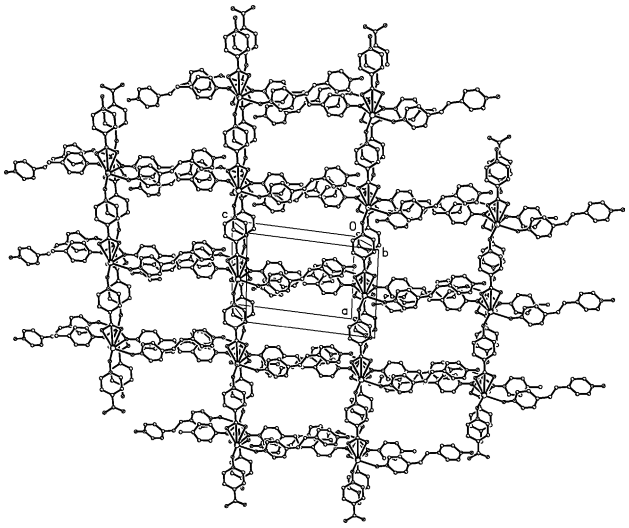

Fig. 5. Square-grid coordination network of **2**.

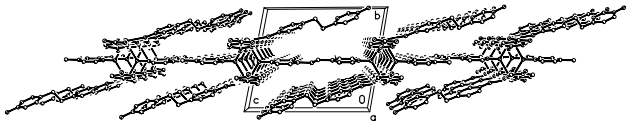

Fig. 6. Side view of the 2-D sheet of **2** showing the outstretched monodendate terminal L ligands.

In addition, these ladder architectures are further connected by the ligand L acting in mode III, resulting in a square grid (see Fig. 5) with the monodendate L ligands protruding at an angle from both sides (see Fig. 6). These 2-D arrays stack along the [0 1 0] direction to generate large channels (representing ca. 24% of the total crystal volume), which are filled by lattice water molecules and anions [22]. The distance between a pair of pyridine rings of the monodendate ligands L from two adjacent layers is only 3.512 Å, indicating significant π–π stacking which further stabilizes the overall 3-D supramolecular system.

$[La(\mu\text{-}L')_2(\mu\text{-}L)](H_2O)(CF_3SO_3)$ (**3**). By altering the starting molar ratio La:L′:L from 1:1:1.5 for **2** to 1:2:1 for **3**, a completely different 3-D coordination polymer was obtained. Here ligand L, occupying a special position of symmetry 2, exhibits bridging mode II in the

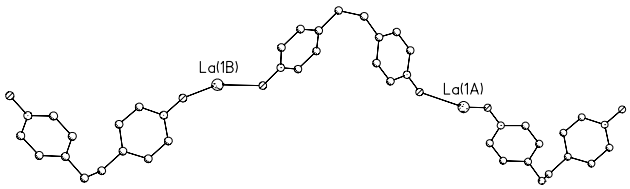

Fig. 7. Infinite zigzag chain bridged by the *gauche* L spacers in **3**.

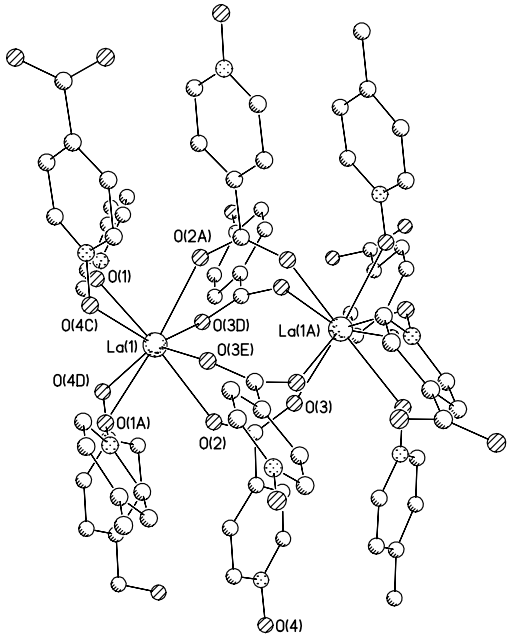

Fig. 8. Coordination geometry of La(III) in the $La_2(L')_4$ paddle wheel of symmetry 222 in **3**. Selected bond lengths (Å) and angles (°): La(1)–O(1): 2.495(2), La(1)–O(2): 2.482(2), La(1)–O(1a): 2.495(2), La(1)–O(3e): 2.527(1), La(1)–O(2a): 2.482(2), La(1)–O(4b): 2.497(1), La(1)–O(4c): 2.497(1), La(1)–O(3d): 2.527(1); O(2)–La(1)–O(1): 141.83(5). Symmetry codes: a $x, -y+5/4, -z+5/4$; b $-x+1, -y+1, -z+1$; c $-x+1, y+1/4, z+1/4$; d $-x+5/4, y, -z+5/4$; e $-x+5/4, -y+5/4, z$.

gauche configuration (the dihedral angle between pyridine rings is 37.3°) to yield an infinite zigzag chain along the [1 1 0] direction, with a nearest La···La separation of 13.081 Å (Fig. 7). The μ_3 spacer L′ takes the end-to-end bridging mode with *syn–syn* coordination of the carboxylic group to La. Each La ion lying on a 2-axis has a LaO_8 square antiprimatic coordination environment, being surrounded by four oxygen donors from the carboxylic groups of four L′, two N-oxide groups of another two L′ and two oxygen atoms from two L molecules. Unlike the dimeric La_2O_2 unit in **1** and **2**, two La(III) centers are connected by four L′ ligands acting in the *syn–syn* carboxylato mode to form a $La_2(L')_4$ paddle wheel of symmetry 222 (Fig. 8) [23]. The La···La distance within this dinuclear unit is 4.637 Å. As shown in Fig. 9, the end-to-end spacers L′ bridge the paddle wheels into a 3-D network with large cavities. As stated above, the ligands L further connect the dimeric units to strengthen the final 3-D framework (Fig. 10). Along the [1 0 0] direction, large channels are occupied by the lattice water molecules and $CF_3SO_3^-$ anions. An analysis of the voids shows 1.49% of empty space even allowing for the guest water molecules and anions in the host framework, and after the removal of them the voids add up to 28.2%.

3.2. TGA studies

It is known that the N-oxide ligand has a higher melting point comparing with the corresponding dipyridine precursor [24], which makes it possible to generate useful porous coordination frameworks with high thermal stability. Thus, thermogravimetric analysis (TGA) of complexes **1**–**3** has been conducted. For

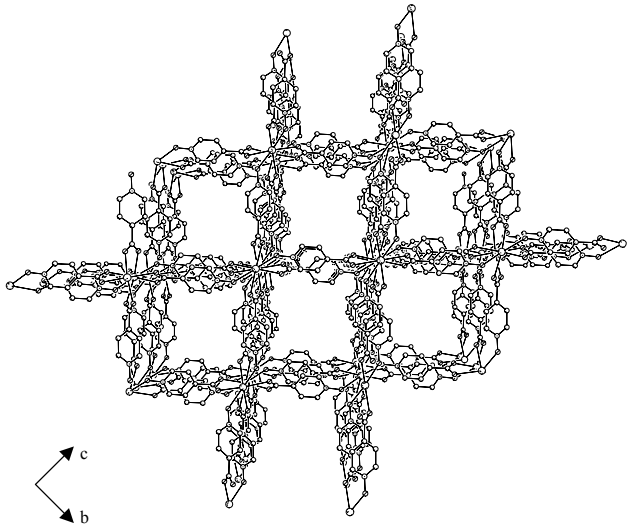

Fig. 9. Three-dimensional framework bridged by L′ ligands viewed along the [1 0 0] direction in **3**.

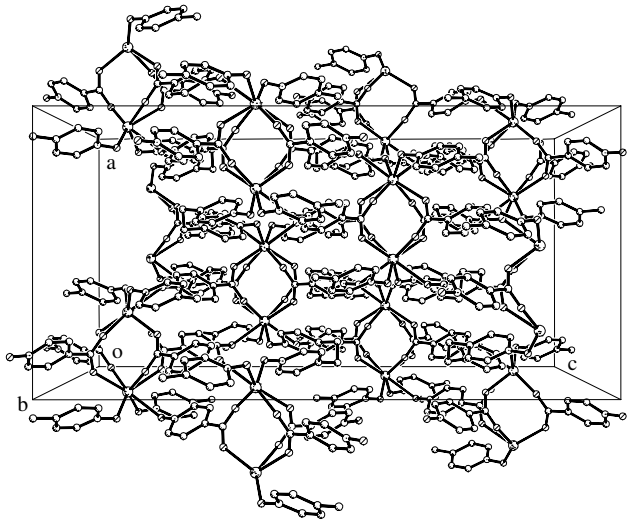

Fig. 10. Three-dimensional framework of **3** viewed along the [0 1 0] direction.

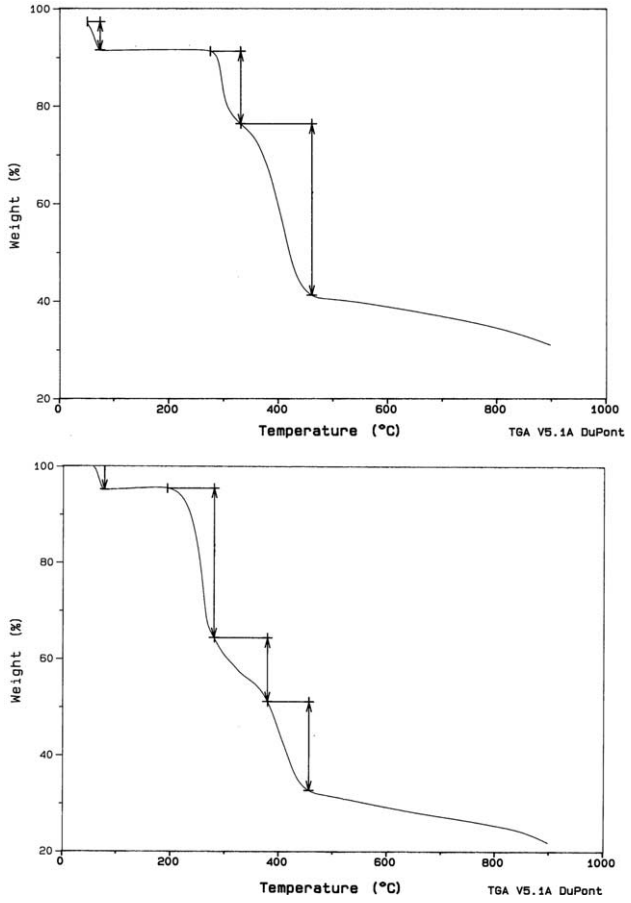

Fig. 11. TGA curves of **2** (top) and **3** (bottom).

complex **1** containing only the L ligand, the first weight loss of 3.18% from 90 to 200 °C corresponds to the loss of two aqua ligands (calculated: 2.83%). The remaining substance does not lose weight upon further heating until two consecutive weight losses occur in the 270–490 °C region (the critical temperature is ca. 340 °C), corresponding to stepwise removal of the first and second L molecules, respectively (observed: 17.17% and 34.55%; calculated: 17.00% and 34.00%). Further heating to 900 °C of the sample indicates a continuous and slow weight loss. For the two-dimensional host framework **2** incorporating both L and L′ spacers (Fig. 11, top), the first weight loss of 6.06% from 50 to 75 °C corresponds to the release of three guest water molecules (calculated: 5.46%). The remaining framework remains intact until two consecutive weight losses occur in the 275–480 °C region (the critical temperature is ca. 330 °C) corresponding to stepwise removal of one L′ molecule plus an aqua ligand (observed: 15.71%; calculated: 15.88%), and 1.5 L plus the second aqua ligand (observed: 34.26%; calculated: 34.56%), respectively. Further heating to 900 °C of the sample only indicates a continuous and slow weight loss. For the 3-D coordination framework **3** (Fig. 11, bottom), the first weight loss of 3.60% from 60 to 85 °C corresponds to the expulsion of 1.5 guest water molecules (calculated: 3.35%). Then, three consecutive weight losses occur in the 200–450 °C region (the critical temperatures are ca. 280 and 380 °C) correspond to stepwise removal of one L molecule (observed: 27.19%; calculated: 26.82%) and two L′ molecules (observed: 35.08%; calculated: 34.52%). Just like **1** and **2**, further heating of **3** to 900 °C indicates a continuous and slow weight loss.

The above observation clearly shows that the thermal behaviors of the frameworks **1**–**3** are quite different, especially in regard to compounds **2** and **3** which have similar compositions but a reversed sequence of weight losses for L and L′. In conformity with the X-ray analysis, this may be attributed to the different coordination/bridging modes of the N-oxide ligands and the co-existing water molecules and $CF_3SO_3^-$ ions, which affect the assembly of the frameworks in the crystal structures.

4. Conclusion

Three novel lanthanum coordination polymers with single or mixed N-oxide ligands have been prepared and structurally characterized. In compound **1**, the flexible ligand 1,2-bis(4-pyridyl)ethane-*N*,*N*′-dioxide (L) exhibits a tridentate (μ-*O*,*O*,*O*′) coordination mode, which together with monodendate and bidendate (μ-*O*,*O*′) bridging modes link the La(III) ions to generate a three-dimensional framework. When the anionic ligand L′ (HL′ = isonicotinic acid N-oxide) was introduced as an added component in the molar ratio of L/L′ (2:1 and 1:2), the network assembly process is greatly affected, leading to two different coordination frameworks **2** and **3**, respectively. TGA studies revealed that due to their different ligation modes, L and L′ show different thermal stabilities in **1**–**3**.

5. Supplementary materials

Crystallographic data for the crystal structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center (CCDC Nos. 217846–217848). This material can be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk).

Abstract

Reaction of isophthaloyl dichloride with two equivalents of benzylamine in the presence of Et_3N gives *N*,*N*′-dibenzyl-1,3-isophthaldiamide which reacts with two equivalents of Ph_2PCl, in the presence of *n*-BuLi at −78 °C to give 1,3-C_6H_4-{C(O)N(PPh_2)CH_2Ph}$_2$ (**1**). Reaction of **1** with [$PtCl_2$(cod)] in dichloromethane gives the *P*, *P*′, *C* tridentate bis-chelate [Pt(Cl){1,3-C_6H_4-{C(O)N(PPh_2)CH_2Ph}$_2$}] (**2**), whilst reaction of **1** with two equivalents of [(C_3H_5)PdCl]$_2$ in thf results in [{PdCl(C_3H_5)}$_2$ {1,3-C_6H_4-{C(O)N(PPh_2)CH_2Ph}$_2$}] (**3**) in which the ligand bridges two palladium centres. The X-ray structures of **2** and **3** are reported.

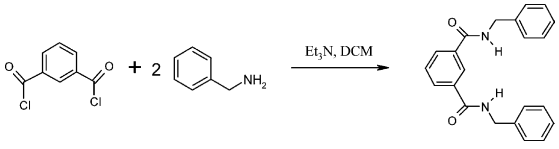
1. Introduction

Imidodiphosphinate anions [$R_2P(E)NP(E')R'_2$]$^-$ (R, R′ = alkyl, aryl or alkoxy; E, E′ = O, S or Se) have received substantial attention in recent years, finding use in applications such as metal extraction agents, NMR shift reagents and in catalytic functions [1–8]. We are currently investigating the chemistry of structurally similar phosphorus(V) derivatised guanidines and amidines $R_2P(E)N{=}C(X)(NH_2)$ (R = alkyl or aryl; E = oxygen or sulfur; X = NH_2 or alkyl). These molecules, readily available from [$R_2P(E)(NCN)$]$^-$ [9–16], possess an ionisable nitrogen-bound proton and have the capacity for delocalisation of the resulting uninegative charge through the π-system of the [$R_2P(E)N{=}C(X)(NH)$]$^-$ anion; hence they could function as *E*,*N*-bidentate ligands in a manner analogous to imidodiphosphinates. We have previously prepared *cis*-[Pt(L^n-*S*,*N*)(PR_3)$_2$]- Cl(PR_3 = PMe_2Ph or 1/2 dppe) from *cis*-[$PtCl_2$(PR_3)$_2$] and the potassium salts of $Me_2P(S)N{=}C(NH_2)_2$, $Ph_2P(S)N{=}C(Me)(NH_2)$ or $Ph_2P(S)N{=}C(NH_2)_2$ in which (L^n)$^-$ form six-membered *S*,*N* chelate rings at platinum(II) [17] and are comparable to [($EPPh_2$)$_2$N]$^-$ (E = S or Se), which generates *cis*-[Pt{($EPPh_2$)$_2$N-*E*,*E*′}(PR_3)$_2$]Cl [18,19]. As part of our continuing studies on phosphine ligands containing P–N bonds [19–23], here we report a new ligand derived from isophthaloyl dichloride which was designed to give six-membered chelate ring systems but surprisingly forms a tridentate and bidentate bridged complexes.

2. Results and discussion

N,*N*′-Dibenzyl-1,3-isophthaldiamide was prepared by reaction of isophthaloyl dichloride with two equivalents of benzylamine in the presence of Et_3N in dichloromethane in the following equation:



(1)

Reaction of *N*,*N*′-dibenzyl-1,3-isophthaldiamide with two equivalents of Ph_2PCl, in the presence of *n*-BuLi at −78 °C, proceeds in thf to give **1** as a pale yellow solid in 76% yield in the following equation:

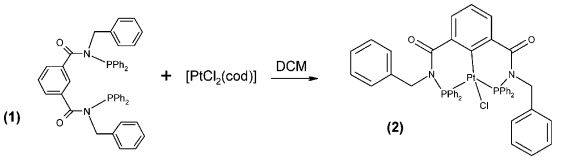
(2)

The $^{31}P–\{^{1}H\}$ NMR spectrum of **1** consists of a singlet at δ (P) 58.5 ppm, the large downfield shift when compared to (1,3-bis(diphenylphosphinoacetyl)benzene, δ (P) 27.2 ppm) [24] reflecting the substitution of the methylene carbon centres in 1,3-bis(diphenylphosphinoacetyl)benzene by nitrogen atoms in **1**.

FAB$^+$ mass spectrometry of **1** shows the expected parent-ion peaks whilst its IR spectrum contains bands that can be assigned to ν(P–N) and ν(C=O) (916 and 1651 cm^{-1}, respectively). Although air- and moisture-stable for short periods in the solid state, **1** is soluble in both thf and dichloromethane and in these solutions it oxidises readily in air.

Reaction of **1** with equimolar quantities of $[PtCl_2(cod)]$ in dichloromethane gives Eq. (3) the P,P',C chelate $[Pt(Cl)\{1,3\text{-}C_6H_4\text{-}\{C(O)N(PPh_2)CH_2Ph\}_2\}]$ (**2**) as a colourless solid in good yield (85%); apart from the expected P,P coordination the central aryl group is metalated by the platinum atom.



(3)

FAB$^+$ mass spectrometry shows the expected parent-ion peak for **2** (m/z 942 [M]). The IR spectrum of **2** shows bands due to ν(P–N) (915 cm^{-1}) and ν(CO) (1651 cm^{-1}), and a single band characteristic of ν(Pt–Cl) (306 cm^{-1}). The $^{31}P–\{^{1}H\}$ NMR spectrum of **2** consists of a singlet (δ (P) 67.9 ppm) with satellites from coupling to ^{195}Pt and a $[^{1}J\{^{195}Pt–^{31}P\}$ 3080 Hz] which is in agreement with the literature data on similar complexes were the metal center is bound to two phosphorus atoms and to a carbon atom from the ligand backbone ring [25].

The X-ray structure of **2** (Fig. 1) confirms that the ligand is bound in a tridentate mode to the platinum. The ligand contains two fused six-membered Pt–P–N–C–C–C-C rings and the metal centre adopts square planar geometry. The square planar geometry of the platinum centre is distorted, the P–Pt–C angles are narrower than the ideal 90° and P–Pt–Cl angles are larger than 90°. The ligand is not planar and the Ph groups on the phosphorus are on opposite faces of the coordination plane. The P–N and Pt–Cl distances are typical of a single bond.

The reaction of **1** with two equivalents of $[(C_3H_5)PdCl]_2$ in thf gives $[\{PdCl(C_3H_5)\}_2\{1,3\text{-}C_6H_4\text{-}\{C(O)N(PPh_2)CH_2Ph\}_2\}]$ (**3**) in which the ligand bridges two Pd centres in the following equation:

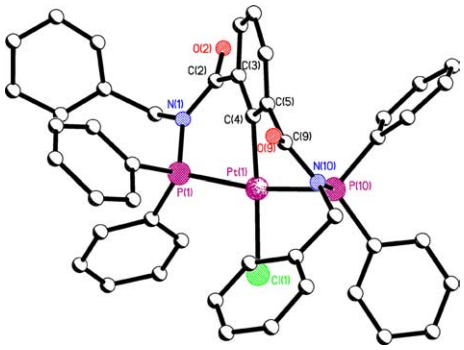


Fig. 1. Solid state structure of $P,P',C[Pt(Cl)\{1,3\text{-}C_6H_4\text{-}\{C(O)N(PPh_2)CH_2Ph\}_2\}]$ (**2**). Selected bond lengths (Å) and angles (°). Numbers in square brackets are the equivalent parameter for the second independent molecule. Pt(1)–C(4) 2.02(1) [2.01(1)], Pt(1)–P(1) 2.259(4) [2.261(4)], Pt(1)–P(10) 2.280(4) [2.273(4)], Pt(1)–Cl(1) 2.357(4) [2.360(4)], P(1)–N(1) 1.73(1) [1.71(1)], N(1)–C(2) 1.37(2) [1.444(18)], N(10)–C(9) 1.397(16) [1.364(17)]; P(1)–Pt(1)–P(10) 168.52(14) [168.68(14)], P(1)–Pt(1)–C(4) 84.5(4) [85.8(4)], P(10)–Pt(1)–C(4) 84.3(4) [83.0(4)], P(1)–Pt(1)–Cl(1) 94.80(13) [94.68(14)], P(10)–Pt(1)–Cl(1) 96.24(14) [96.27(14)].

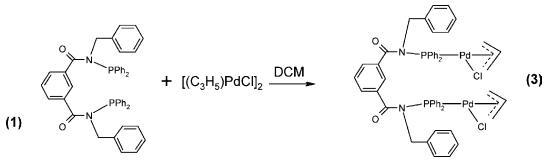

(4)

The $^{31}P–\{^{1}H\}$ NMR spectrum of **3** shows a singlet at δ (P) 72.5 ppm, a downfield shift of approximately 14 ppm from the free ligand. FAB$^+$ mass spectrometry does not show the expected parent-ion peaks and shows instead the fragmentation patterns consistent with the loss of one chloride ion (m/z 1043 [M–Cl$^-$]). Elemental analysis data are in agreement with calculated values and, once again, the IR spectrum of **3** shows bands which can be assigned to ν(P–N) (915 cm^{-1}), ν(C=O) (1648 cm^{-1}) and ν(Pd–Cl) (279 cm^{-1}).

The X-ray structure of **3** (Table 1, Fig. 2) shows that the ligand bridges the palladium atoms, with the molecule having a somewhat helical nature. The P–N and Pd–Cl distances are typical of this type of compound. It is somewhat surprising that the palladium system forms a binuclear product rather than metallating since generally palladium is more prone to metallation than platinum.

In a batch test of the rhodium complex (formed in situ) of **1** as a hydroformylation catalyst for the conversion of 1-hexene at 20 atm CO/H_2 and 100 °C we obtained poor selectivity to aldehyde (29%) with a linear to branched ratio of 1.6:1 suggesting that **1** is only an average ligand for this catalytic process.

3. Experimental

Unless otherwise stated, manipulations were performed under an oxygen-free nitrogen atmosphere using

predried solvents and standard Schlenk techniques. $^{31}P\{^1H\}$ and ^1H NMR spectra (109.4 and 270.0 MHz, $CDCl_3$) were recorded on a JEOL Delta GSX 270 spectrometer, IR spectra (pressed KBr disks) on a Perkin–Elmer System 2000 FTIR/Raman instrument, elemental analyses were performed by the University of St. Andrews Microanalytical Service. Mass spectroscopy were performed by the National Service in Swansea.

3.1. N,N′-Dibenzyl-1,3-isophthalamide

To a dry and degassed dichloromethane (100 ml) solution of isophthaloyl dichloride (5.890 g, 29.00 mmol) and triethylamine (8.5 ml, 6.160 g, 60.90 mmol) was added a dry and degassed dichloromethane (10 ml) solution of benzylamine (6.3 ml, 6.20 g, 58.00 mmol) dropwise over a period of 30 min. The reaction mixture was stirring for 2 h 30 min, during which time triethylammonium hydrochloride separated from the solution. This precipitate was removed by suction filtration and the filtrate was evaporated to dryness in vacuo to give a white solid product. Recrystallisation from ethanol–water–acetone gave white crystals. Yield: 8.789 g, 88%; Microanalysis: Found (Calc.): C, 76.9 (76.7); H, 5.8 (5.9); N, 8.2 (8.1)%; ^1H NMR: δ 8.19 ppm (t, 1 H, aromatic, $J = 2.74$ Hz), 7.91 ppm (dd, 2H, aromatic, $J = 2.74$ and 8.22 Hz), 7.47 ppm (t, 1H, aromatic, $J = 8.22$ Hz), 7.34-7.22 ppm (m, 10 H, aromatic), 6.60 ppm (t, 2 H, NH, $J = 5.48$ Hz); Selected IR data (KBr): ν(NH) 3290 cm^{-1}, ν(CO) 1635 cm^{-1}; FAB$^+$ MS: m/z 344 [M].

3.2. 1,3-C_6H_4-{C(O)N(PPh_2)CH_2Ph}$_2$ (**1**)

A dry and degassed thf (30 ml) solution of 1,3-C_6H_4-{$CONHCH_2Ph$}$_2$ (0.482 g, 1.4 mmol) was cooled to −78 °C in an acetone-dry ice bath. To the cooled solution was added dropwise a hexane solution of *n*-BuLi (1.2 ml, 2.5 mol dm^{-3}, 2.94 mmol) over 30 min. After the addition the mixture was stirred at −78 °C for 1 h and another 30 additional min at room temperature. The reaction solution was cooled to −78 °C again and to it was added dropwise a solution of diphenylchlorophosphine (0.53 ml, 0.649 g, 2.94 mmol) in thf (10 ml) over 30 min. Stirring was continued for another 1 h at −78 °C. Then the cooling bath was removed and the mixture was stirred overnight at room temperature. The solution was evaporated to dryness in vacuo and dichloromethane (30 ml) was added. Lithium chloride, which precipitated, was removed by filtration under nitrogen and then the volatiles were evaporated in vacuo to leave a white solid.

Yield: 0.758 g, 76%; Microanalysis: Found (Calc.): C, 77.5 (77.4); H, 5.2 (5.4); N, 4.5 (3.9)%; $^{31}P–\{^1H\}$ NMR ($CDCl_3$): 58.5 (s) ppm; Selected IR data KBr (CH_2Cl_2): ν(PN) 916 cm^{-1}, ν(C=O) 1651 cm^{-1}; FAB$^+$ MS: m/z 712 [M], 735 [M + Na]$^+$.

3.3. P,P′,C-[Pt(Cl){1,3-C_6H_4-{C(O)N(PPh_2)CH_2Ph}$_2$}] (**2**)

To a dichloromethane (5 ml) solution of [$PtCl_2$(cod)] (0.035 g, 0.094 mmol) was added a solution of 1,3-C_6H_4-{$CON(PPh_2)HCH_2Ph$}$_2$ (0.071 g, 0.10 mmol) in dichloromethane (5 ml) and the colourless solution stirred for ca. 3 days. The solution was concentrated under reduced pressure to ca. 2 ml and diethyl ether (20 ml) added. The white product was collected by suction filtration and washed with diethyl ether (2 × 10 ml). Yield: 75 mg, 85%; Microanalysis: Found (Calc.): C, 58.6 (58.6); H, 3.3 (4.0); N, 2.8 (3.0)%; $^{31}P–\{^1H\}$ NMR ($CDCl_3$): 67.9 (s) ppm, $^1J(^{195}Pt–^{31}P)$ 3080 Hz; Selected

IR data (KBr): ν(CO) 1651 cm^{-1}, ν(PN) 915 cm^{-1}, ν(PtCl) 306; FAB^+ MS: m/z 942 [M].

3.4. [{Pd(C_3H_5)Cl}$_2${1,3-C_6H_4-{(CO)N(PPh_2)CH_2-Ph}$_2$}] (3)

To a dichloromethane (5 ml) solution of $[(C_3H_5)PdCl]_2$ (0.035 g, 0.09 mmol) was added a solution of 1,3-C_6H_4-{$CON(PPh_2)HCH_2Ph$}$_2$ (0.072 g, 0.10 mmol) in dichloromethane (5 ml) and the colourless solution stirred for ca. 3 days. The solution was concentrated under reduced pressure to ca. 2 ml and diethyl ether (20 ml) added. The white product was collected by suction filtration and washed with diethyl ether (2×10 ml). Yield: 86 mg, 80%; Microanalysis: Found (Calc.): C, 54.4 (54.7); H, 4.2 (4.3); N, 2.3 (2.3)%; ^{31}P–{^1H} NMR ($CDCl_3$): 72.5 (s) ppm; Selected IR data (KBr): ν(CO) 1648 cm^{-1}, ν(PN) 915 cm^{-1}, ν(PdCl) 279 cm^{-1}; FAB^+ MS: m/z 1043 [M–Cl^-].

3.5. Hydroformylation studies

Hydroformylation studies were conducted as described previously [26]. The ligand (0.03 mmol, 0.005 mol dm^{-3}), [$Rh(CO)_2$(acac)] (5.16×10^{-3} g, 0.02 mmol, 0.004 mol dm^{-3}) and toluene (4 ml) were charged into a Schlenk tube and stirred until complexation of the rhodium complex with the phosphine species (total dissolution). The phosphine/rhodium ratio used was 3/2. This solution was placed in a glass lined steel autoclave, CO/H_2 added until 20 bar pressure, the autoclave was heated to 100 °C for the appropiate reaction time and stirred magnetically.

3.6. Crystallography

Crystallography (Table 1) was performed using a Bruker SMART at 125 K; in both cases a minimum of a full hemisphere of data with 0.3 'slices' was collected. Mo Kα radiation was used and multiscan absorption corrections were applied. In **2** because of difficulties with crystal quality the carbon and nitrogen atoms were refined isotropically, all of the other non-H atoms were refined anisotropically with the C–H hydrogen atoms being refined in idealised geometries. All calculations employed the SHELXTL program system [27].

4. Supplementary material

Crystallographic Data for the structural analyses has been deposited with the Cambridge Crystallographic data centre, CCDC Nos. 220834 and 220835. Copies of this information may be obtained free of charge from The Director CCDC, 12 Union Road, Cambridge, CB2 1EZ UK (fax +44-1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Received 17 October 2003; accepted 9 December 2003

Abstract

Enforcement of chirality upon a macrocyclic tetramine ligand structure by the introduction of an asymmetric pendent arm which does not significantly modify the macrocycle conformation has no significant effect upon the geometry of the coordination sphere of a bound metal. Where substitution engendering chirality does cause a change in the ligand conformation, in particular for a ligand of restricted stereochemistry, these effects can be much greater. Thus, conversion of 3,7-diazacycloheptane to a macrocycle via attachment of chiral sidearms and ring closure through a template reaction leads to cyclam derivatives with unusual coordination properties.

Keywords: Chirality; Tetra-azamacrocycles; Template reaction; Pendent arm; Conformational isomers

1. Introduction

Tetra-azamacrocycles of the cyclam (1,4,8,11-tetra-azacyclotetradecane) type have been prepared with an extraordinary variety of substituents, a common objective of such syntheses being the formation of metal complexes with various pendent arms which facilitate their applications as sensors and catalysts [1]. In the majority of such complexes [2], the macrocycle adopts the "*trans*-III" or *R,S,S,R*-*gauche*-chair-*gauche* conformation which necessarily defines a limited number of pendent arm substituent orientations with respect to the coordinated macrocycle. This conformation is also inherently achiral [3] and appropriate functionalisation of the macrocycle so as to introduce chiral centres is therefore expected, in general, to induce a preference for other conformations. Perhaps the simplest method of generating a chiral cyclam, that of using a chiral amine to provide the central N of a CNC bridge introduced via a template reaction of a tetramine precursor [4–6], might, however, be expected to have a minimal influence [7] and we provide an illustration here of this circumstance. A more elaborate cyclam derivative in which chirality is induced by functionalisation of the ethylene bridges, in contrast, provides an example of more dramatic effects. This cyclam is one of the relatively uncommon group of bridged, bicyclic tetramines which, in many respects, exhibit unusual properties in their metal ion complexes [8,9], so that some differences from unbridged but functionalised cyclams [10] might have been anticipated. Some related, open-chain tetra-aza ligands,

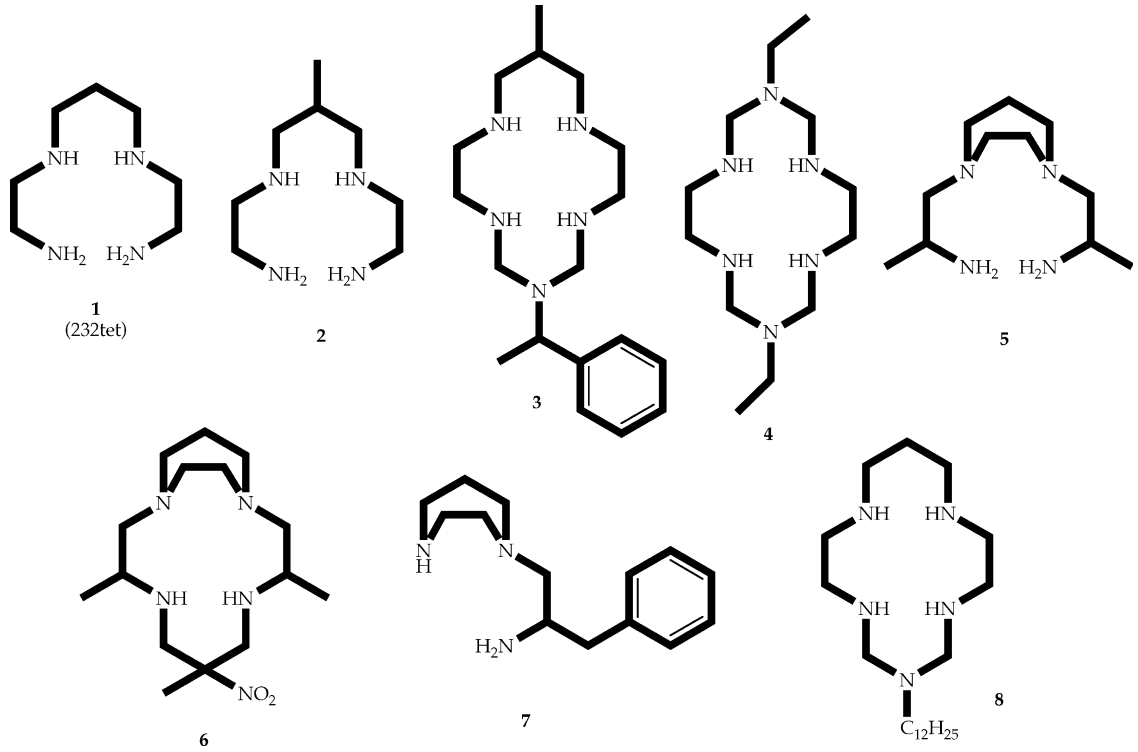

Fig. 1. Polyamine ligands studied in the present work.

derived also from homopiperazine (1,4-diazacycloheptane), are known to be useful as catalysts [11], whereas others are of interest due to their biological activity [12]. All the ligands giving complexes studied in the present work are shown in Fig. 1.

2. Experimental

2.1. Reagents and procedures

(*R*)-1-Phenylethylamine, 3,7-diazaundecane-1,9-diamine ("232tet") (**1**), 1,2-ethanediamine, 1,4-diazacycloheptane, formaldehyde and triethylamine were purchased from the Aldrich Chemical Company and used as received. All organic solvents were distilled prior to use. *N*,*N*′-bis(2-aminoethyl)-2-methylpropane-1,3-diamine (**2**) and its copper(II) complex ([Cu(**2**)]Cl_2) were prepared as described previously [13]. [Cu(**4**)]$(ClO_4)_2$ was prepared by the literature procedure [14] except that the macrocyclic complex was firstly obtained as the chloride and then converted to the perchlorate by precipitation from aqueous solution using $NaClO_4$. *S*,*S*-bis(2-aminopropyl)diazabicyclo[3.2]heptane (**5**) was prepared (from (*S*)-alanine) as a yellowish oil following a literature procedure [15]. Phthaloyl-(*S*)-phenylalanyl chloride was prepared by standard methods [16], as outlined for the alanine analogue in [15].

Ion exchange chromatography was performed under gravity flow using Na^+ form SP-Sephadex C-25 and H^+ form Dowex 50Wx2 (200–400 mesh) cation exchange resins. All eluates were evaporated under reduced pressure (~20 mm Hg) using a Büchi rotary evaporator and a water aspirator.

3. Synthesis

3.1. (3,7-Diazaundecane-1,9-diamine)copper(II) thiocyanate, [Cu(1)NCS]NCS

(This complex was isolated during analysis of the products of a reaction similar to those of present interest but its direct synthesis and structure determination are included here because the structure provides a useful reference point.) 232tet (1.0 g) was added to a solution of $CuCl_2 \cdot 2H_2O$ (1.1 g) in water (50 ml) and the reactants thoroughly mixed. NaNCS (3.0 g) was dissolved in the blue-violet solution produced, a crystalline precipitate then slowly forming as the mixture was cooled on ice. (Yield: 1.3 g.)

3.2. (1,4,6,8,11-Penta-aza-13-methyl-6(1-phenylethyl-cyclotetradecane)copper(II) dithionate (and thiocyanate), [Cu(3)]S_2O_6 (and [Cu(3)]$(NCS)_2$)

(*R*)-1-Phenylethylamine (10 mmol, 0.85 g), triethylamine (22 mmol, 2.5 g) and aqueous formaldehyde (0.1 mol, 8 ml of 37% solution) were added to a methanolic solution (50 ml) of [Cu(**2**)]Cl_2 (10 mmol, 4.1 g) and the

mixture was heated and stirred at 50 °C for 5 h. After evaporation to dryness, the residue was dissolved in water (200 ml) and chromatographed (SP-Sephadex) under elution with 0.3 mol L^{-1} NaCl solution to give a purple leading band of unchanged reactant and a trailing reddish-purple band of the desired macrocyclic product. The second band eluate was taken to dryness and the complex isolated as the chloride, [Cu(**3**]Cl_2(3.2 g), by extraction into ethanol and evaporation of the extract. This was converted to the dithionate by adding $Li_2S_2O_6$ to its concentrated aqueous solution and cooling to ~4 °C. The thiocyanate was obtained similarly, using NaNCS in place of $Li_2S_2O_6$ and the racemic ligand in place of the *R* form. Both compounds formed crystals suitable for diffraction measurements and both structures were solved (see below).

3.3. (9-Methyl-9-nitro-1,4,7,11-tetra-aza-bicyclo[2.3.9] hexadecane)copper(II) perchlorate, [Cu(**6**)]$(ClO_4)_2$ diastereomers

The Cu(II) complex of **5** was prepared by adding $CuCl_2 \cdot 2H_2O$ (1.7 g) to a solution of the crude ligand (2.0 g) in water (100 ml) and was freed of two trace components by chromatography (SP-Sephadex/0.3 mol L^{-1} NaCl). The bulk component eluate was taken to dryness under reduced pressure and the complex extracted from the residue with methanol. Evaporation of the extract gave a blue residue of [Cu(**5**)]Cl_2 which was used directly in the succeeding step. Thus, [Cu(**5**)]Cl_2 (2.0 g) was dissolved in methanol (100 ml) and nitroethane (1.3 g), triethylamine (4 g) and paraformaldehyde (2.2 g) added, before heating the mixture at reflux for three days. The final solution was evaporated to dryness under reduced pressure, dissolved in water (500 ml) and chromatographed on Dowex 50Wx2 with 2 mol L^{-1} HCl to give three bands. Each eluate was evaporated to dryness, giving residues F1 (80 mg), F2 (520 mg) and F3 (880 mg). To obtain crystals suitable for structure determinations, the complexes were converted to their perchlorates by adding $NaClO_4$ to their solutions in ethanol and then adding diethyl ether by vapour diffusion. As in other instances, this resulted in some co-crystallisation with NaCl and $NaClO_4$ but was nonetheless the simplest method for obtaining crystals of sufficient size for the structural work.

3.4. 7 and [Cu(7)Cl]ClO_4

Under a nitrogen atmosphere, a solution of phthaloyl-(*S*)-phenylalanyl chloride (15 g) in DMF (100 ml) was added slowly over 1 h to a cold (0 °C) solution of triethylamine (6 g) and 1,4-diazacycloheptane (2.5 g) in DMF (50 ml). The mixture was stirred overnight and then evaporated to dryness after filtering out a small amount of white solid, presumed to be triethylammonium chloride. A solution of hydrazine hydrate (6 g) in ethanol (500 ml) was added to the residue and the mixture heated at reflux for 3 h. Precipitated phthalhydrazide was filtered out and the filtrate taken to dryness before dissolving the residue in THF (100 ml) and reducing the amide by the gradual addition of $LiAlH_4$ (6 g) under a nitrogen atmosphere, allowing 24 h for reaction. After destroying any excess hydride reagent by the careful addition of water, the reaction mixture was evaporated down to a pasty mass which was transferred to a Soxhlet thimble and the ligand **7** extracted using THF solvent. The extract was evaporated down to a yellow oil. (Yield: 2 g.) Crude ligand (1.0 g) in methanol (100 ml) was mixed with a solution of $CuCl_2 \cdot 2H_2O$ (0.75 g) in methanol (50 ml) and the homogeneous blue solution produced then evaporated to dryness. The residue was dissolved in water (500 ml), absorbed on Na^+ form SP Sephadex C-25 and the column eluted with 0.3 mol L^{-1} NaCl. The bulk of the product eluted rapidly, followed by a very minor, diffuse component which was not further characterised. The blue major-band eluate was evaporated to dryness and the complex extracted into ethanol to separate it from NaCl. Evaporation of the ethanol extract gave 0.7 g of blue powder. Crystals suitable for a structure determination were obtained by vapour diffusion of diethyl ether into an ethanolic solution of the complex containing $NaClO_4$ (see above).

4. Crystallography

The data for [Cu(**6**)($OClO_3$)](ClO_4), [Cu(**6**)(H_2O)]$(ClO_4)_2$ and [Cu(**7**)Cl]ClO_4 were collected in Saclay on a Nonius Kappa-CCD area detector diffractometer [17] using graphite-monochromated Mo Kα radiation (λ 0.71073 Å). The crystals were introduced in glass capillaries with a protecting "Paratone-N" oil (Hampton Research) coating. The unit cell parameters were determined from 10 frames, then refined on all data. A 180° φ-range was scanned with 2° steps during data collection, with a crystal-to-detector distance fixed to 28 mm. The data were processed with DENZO-SMN [18]. The structures were solved by direct methods with SHELXS-97 [19] and subsequent Fourier-difference synthesis and refined by full-matrix least-squares on F^2 with SHELXL-97 [19]. Absorption effects were corrected empirically with the program DELABS from PLATON [20]. The NO_2 and CH_3 groups bound to C10 in [Cu(**6**)(H_2O)]$(ClO_4)_2$ are disordered and have been modelled with two NO_2 groups with occupancy parameters for oxygen atoms constrained to sum to unity, the difference between nitrogen and carbon atoms thus being neglected. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms bound to nitrogen and oxygen atoms were

found on Fourier-difference maps and all the other ones were introduced at calculated positions. All hydrogen atoms were treated as riding atoms with a displacement parameter equal to 1.2 (NH, OH, CH, CH_2) or 1.5 (CH_3) times that of the parent atom. The Flack parameters [21] were refined to values of −0.01(3) and 0.01(3) for the two structures, respectively. Crystal data and structure refinement parameters are given in Table 1 and selected bond lengths and angles in Fig. 2(c). The molecular plots were drawn using the POVRay option within Xtal 3.7 [22]. All calculations were performed on a Silicon Graphics R5000 workstation.

Intensity data at 296 K for the complexes [Cu(**1**)NCS]NCS, [Cu(**3**)NCS]NCS, [Cu(**3**)OS_2O_5], [Cu(**4**)$(OClO_3)_2$], [Cu(**6**)$(OClO_3)$](ClO_4), and [Cu(**8**)Cl]Cl were collected in Brisbane on an Enraf-Nonius CAD4 four-circle diffractometer using graphite monochromated Mo Kα radiation (λ 0.71073 Å) in the ω-2θ scan mode. Lattice dimensions were determined by a least squares fit of the setting parameters of 25 independent reflections. Data reduction and empirical absorption corrections (ψ-scans) were performed with the WINGX package [23]. Structures were solved by heavy-atom methods with SHELXS and refined by full-matrix least-squares analysis with SHELXL97 [19]. All non-H atoms were refined with anisotropic thermal parameters and H-atoms were constrained at estimated positions. The atomic nomenclature is defined in the figures, Fig. 4(b) being drawn with ORTEP3 [24].

Abnormal features: In the structure of racemic [Cu(**3**)NCS]NCS, disorder in the position of the –C*H$(CH_3)C_6H_5$ group (not shown in the figure ahead) was identified as comprising an approximately equal contribution from the *R* and *S* configurations. Refinement was achieved with the aid of restraints on the geometry of the phenyl ring and isotropic displacement parameters were employed to enable resolution of the different contributors. The relatively weak data for [Cu(**8**)Cl]Cl (16% observed reflections) could not support full anisotropic refinement and only the Cu, Cl and N atoms were refined anisotropically. Nevertheless, the geometry of the complex cation is well defined, albeit at lower precision than the other structures reported here.

5. Results and discussion

The structures of [Cu(**1**)NCS]NCS (Fig. 2(a)), [Cu(**2**)$(OClO_3)_2$] [13], [Cu(**2**)$(O\cdot ClO_2\cdot O)]_{\infty-\infty}ClO_4$ [13] and [Cu(**4**)$(OClO_3)_2$] (Fig. 2(b)), all achiral species, can be regarded as defining constituents of the structure of the chiral complexes of ligand **3**. Note that differences in the nature of the axial ligands in previously known [4,6,7,13,25] such complexes do not seem to give rise to very significant differences in the conformations and

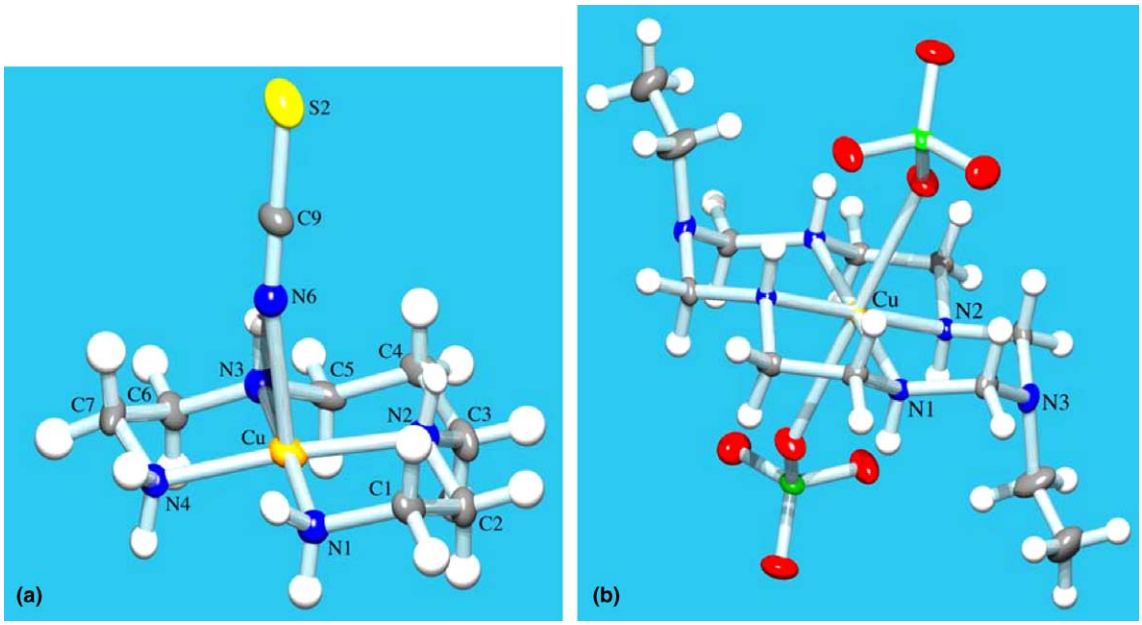

Fig. 2. (a) The complex cation present in the crystal of [Cu(**1**)NCS]NCS. Note that this is actually part of a polymer chain resulting from thiocyanate bridging, with Cu–S 3.240(6) Å. (b) The [Cu(**4**)$(OClO_3)_2$] molecule formally present in crystalline [Cu(**4**)]$(ClO_4)_2$, with Cu–O(ClO_3) 2.586(2) Å. (c) Dimensions (bond angles (upper), bond lengths (lower)) of the essentially planar CuL_4 units found in the present complexes and some reference species.

dimensions of the Cu(II)/tetramine entities. Another example of this is provided in comparing the structure of [Cu(**1**)NCS]NCS with that of [Cu(**1**)$(OClO_3)_2$] [25]. Any differences arising from equatorial vs axial orientations of the methyl substituent in **2** also seem to be slight [13]. The CuN_4 coordination units present in the complexes of ligands **1**, **2** and **4** are identical within NCuN bond angle limits of ±2° and Cu–N bond length limits of ±0.02 Å (Fig. 2(c)) and all, like the complexes of **3**, contain the ligand in a conformation which can be described as *trans*-III. Thus, it is perhaps unsurprising that the chirality of **3** has no dramatic influence on the geometry of the metal ion's primary coordination sphere and that differences associated with the different pendent group and its orientations in the dithionate and thiocyanate complexes of **3** (Figs. 2(c) and 3) are merely comparable to those observed between the other complexes mentioned above. Clearly, if the asymmetry of the pendent arm was to influence reactions at the central metal ion it is unlikely that this could be interpreted in terms of geometric distortions of the coordination geometry. Such differences as are apparent between the dithionate and thiocyanate solids containing $[Cu(\mathbf{3})]^{2+}$ may, of course, reflect that cations of one absolute configuration only are present in the resolved dithionate, whereas enantiomeric species are present in the one lattice for the racemic thiocyanate. That interactions as remote as this must be of negligible influence is, however, suggested by the fact that the geometry of the CuN_4 unit in the complex of a ligand (**8**) analogous to **3** but with a C_{12} chain in place of the phenethyl group [26] and without the methyl substituent lies within the range of those given in Fig. 2(c). Interestingly, when racemic 1-phenylethylamine was used in the synthesis of [Cu(**3**)NCS]NCS, giving crystals belonging to a centric space group, disorder was resolved revealing that the complexes bearing the *R* and *S* forms of the pendent arm occupy the same positions within the lattice with only the C-atoms of the phenylethyl group being disordered. The complex [Cu(**3**)OS_2O_5] obtained from pure (*R*)-1-phenylethylamine of course crystallised in a chiral space group ($P3_1$).

The structure of [Cu(**7**)Cl]ClO_4 (Fig. 4) can be seen as defining part of those of the complexes of **6** and it indicates that both the introduction of a chiral C-centre into a chelate arm and the presence of the mesocyclic homopiperazine moiety have important consequences. The benzyl substituent at the chiral centre is equatorially disposed on the five-membered chelate ring formed in the complex, meaning that the chelate ring must adopt a δ conformation and thus that a 232tet ligand in which both 2-carbon arms are substituted similarly could not coordinate in the usual *gauche*-chair-*gauche* conformation where the two *gauche* units are of opposite chirality (δ and λ). This is well established for many substituted tetramine systems [3,10,27]. Chelation of the homopiperazine unit has perhaps less familiar consequences in that the bond angle subtended at Cu does not lie between those commonly observed for simple 3-carbon and 2-carbon bridges of ~95° and ~85°, respectively, but is considerably smaller than that of a 2-carbon bridge, in [Cu(**7**)Cl]$^+$ being 78.3(2)°. This may to some

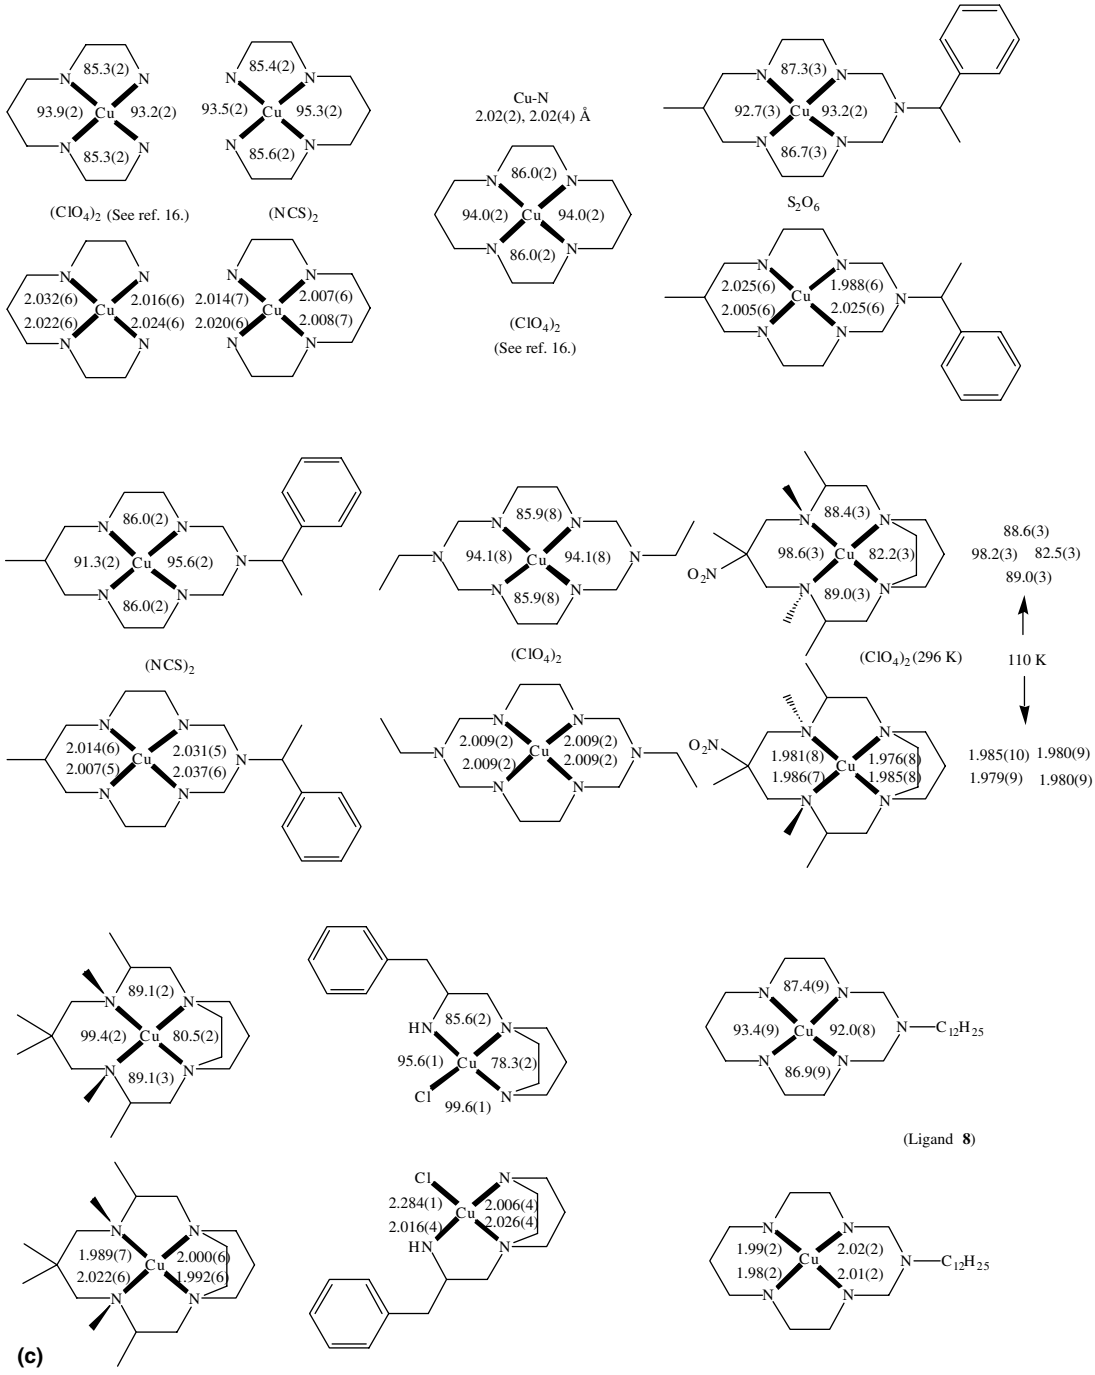

Fig. 2. (*continued*)

extent reflect the fact that there is but a single pendent arm on the mesocycle, since the angle is slightly larger (80.0(2)°) in the Cu(II) complex of a (dipyridyl) tetramine derived from homopiperazine by symmetrical dialkylation of the nitrogen atoms [11], and interestingly this complex has chelate rings formed by the pendent arms which are of the same, rather than opposite, conformation. Thus, it could be said that the small bond angles subtended at Cu(II) by the mesocycle N-donors and the chiral ligand conformations found in complexes of **6** are consistent with their energetics being similar to those of simpler species but the fact that several species are observed indicates that here some factors must be close to being in balance.

Although a clean chromatographic separation of two of the products (F1 and F2) from the reaction leading to the formation of Cu(II) complexes of **6** was achieved, crystal structure determinations on the materials ob-

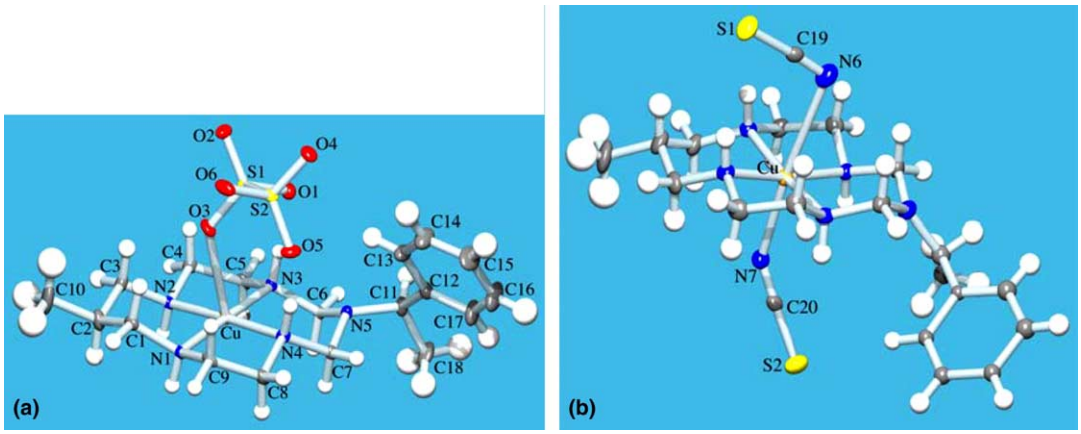

Fig. 3. The coordinated macrocycle units found in (a) the dithionate of optically active $[Cu(\mathbf{3})]^{2+}$ and (b) the thiocyanate of racemic $[Cu(\mathbf{3})]^{2+}$. Disorder not shown in the latter is discussed in the text.

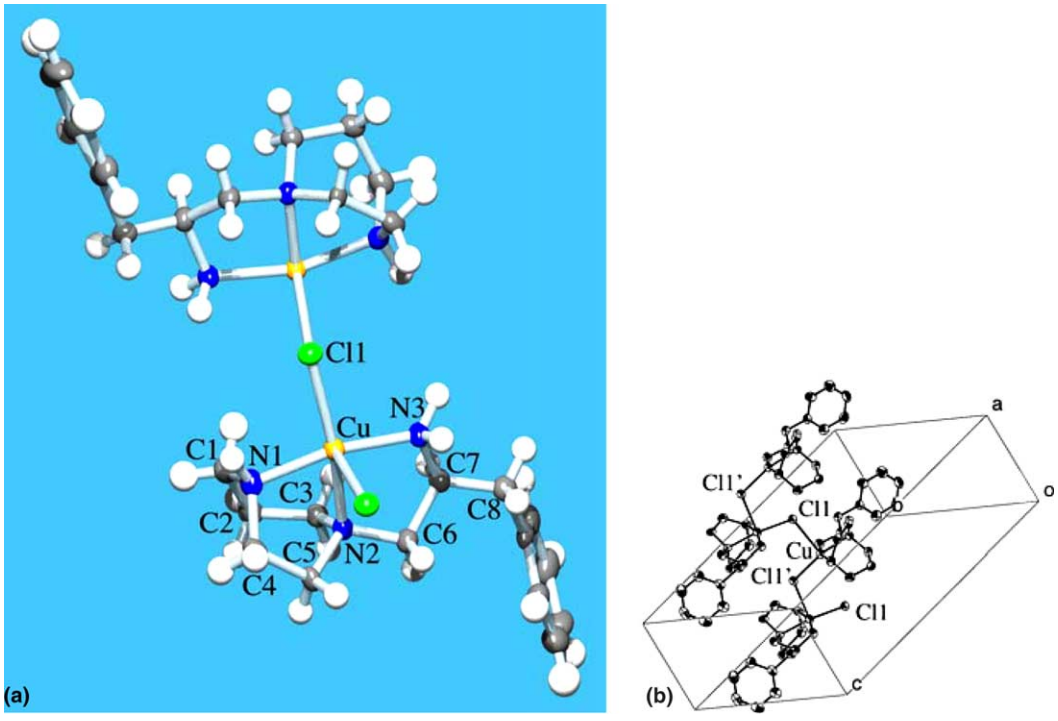

Fig. 4. (a) A view of two $[Cu(\mathbf{7})Cl]^{+}$ entities linked by the chloride bridging which gives rise to their polymerisation. (b) Orientation of the zig-zag $(CuCl)_n$ chains in the unit cell.

tained from the separate eluates proved to be identical. This might be explained by the presence of diastereomers differing with respect to their N-donor configurations which underwent interconversion during the period required for isolation and crystallisation. The result obtained for the structure determination of the product present in F3 of the chromatographic separation, however, requires that the nature of the diastereomer be defined a little more precisely than this.

The two completely independent (Brisbane and Saclay) structure determinations (Fig. 5) on the complex isolated from F1 and F2 are in excellent agreement, especially given a temperature difference of 176 K, the most marked difference being that the bond lengths to perchlorate oxygen atoms (in a tetragonal CuN_4O_2 entity) differ by 0.665 Å at 296 K and by 0.609 Å at 110 K. If indeed it is justified to consider the more remote interaction in both cases as a bond, it is no doubt a very weak one and might therefore be expected to be sensitive to minor structural changes. The structures confirm most obviously the formation of the expected macrocycle, though the 6-membered ring formed by the

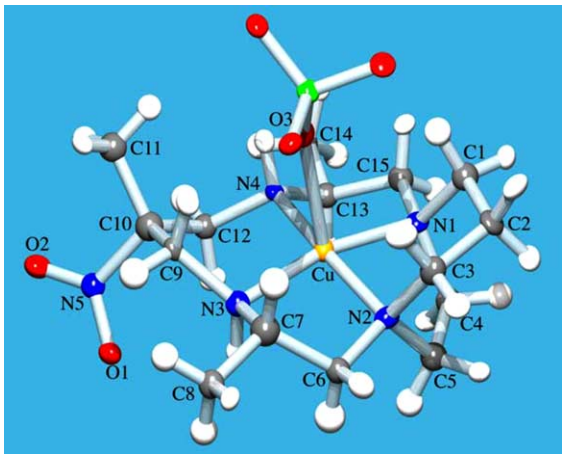

Fig. 5. The complex ion entity formally present in the $[Cu(\mathbf{6})](ClO_4)_2$ species crystallised from the first two chromatographically isolated fractions from the synthesis of the coordinated macrocycle **6**. (Species from the 296 K determination only shown.)

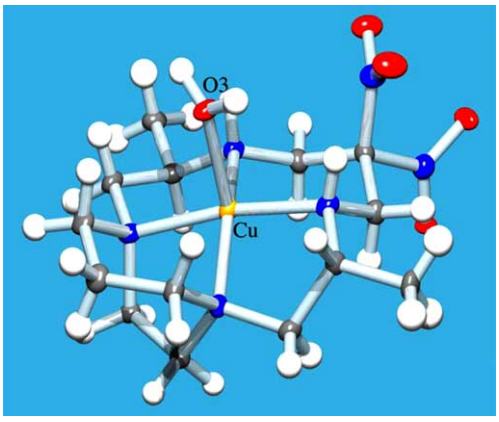

Fig. 6. The complex ion entity formally present in the $[Cu(\mathbf{6})(OH_2)](ClO_4)_2$ species crystallised from the third chromatographically isolated fraction from the synthesis of the coordinated macrocycle **6**. Disorder associated with equal occupancy of both sites on C10 by NO_2 and CH_3 is indicated by showing a nitro group in both positions.

cyclisation reaction is in the uncommon twist-boat conformation, with the two, new chiral-N centres being *R*, *R*. The chiral centres in the 5-membered rings are of the expected *S* configuration (given their derivation from *S*(=L)-alanine), with the methyl substituents equatorial on the rings of δ conformation. There is a stereospecific alignment of the nitro substituent on the side of the near-planar CuN_4 entity bridged by the C_2, rather than the C_3 unit, with one of the nitro-group oxygen atoms being within a hydrogen-bonding distance of one NH. If, by inversion at one N centre, the 6-membered ring were to be converted to its chair form with the nitro substituent in the usual [4,6,13] axial position, the cyclam unit produced would have both 6-membered rings on the same side of the CuN_4 plane, unlike the situation (of being opposite) in the apparently favoured *trans*-III conformation. Though this is hardly a full consideration of the system, it suggests a plausible rationalisation of the observation of two interconverting products, the more stable of which could have the observed structure, as being that there is an unstable diastereomer initially present which does indeed have two chair 6-membered rings, one with an axial nitro substituent, present.

Support for the validity of this argument is provided in the structure obtained for the third reaction product (Fig. 6). Again, the "expected" macrocycle is present but the two chiral N-centres are of opposed configurations (one *R*, one *S*), with the new 6-membered ring being in an essentially chair conformation but defining a cyclam unit where it is on the opposite side of the CuN_4 plane to

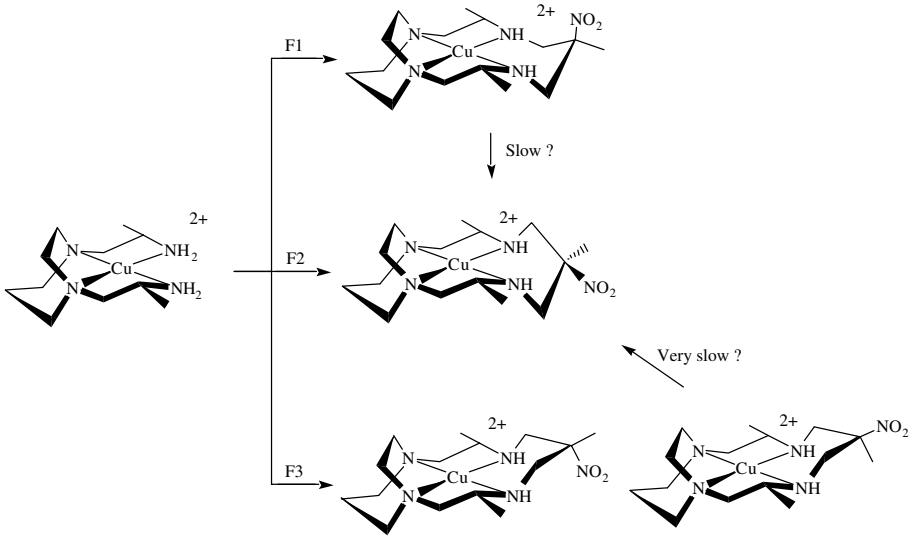

Fig. 7. Proposed products of the reaction of $[Cu(\mathbf{5})]^{2+}$ with HCHO and nitroethane.

the other (derived from the homopiperazine entity). The nitro and methyl substituents on the ring formed by the cyclisation process are disordered equally over axial and equatorial positions, meaning that the isolated material is in fact a mixture of diastereomers. Inversion at the chiral N of *S* configuration would enable the conversion of one of these diastereomers, that where the nitro group is in the "unfavoured" equatorial position, to the same species as that obtained from F1 and F2. This diastereomer is just the other "double chair" species to that postulated to be an unstable form above. Obviously, differences in rates of coordinated-NH deprotonation, coordinated-N inversion or just in stability could explain why one isomer appears to be retained in the system and the other does not. Fig. 7 summarises the proposals presently made for the identity of the various complexes of **6**.

Ignoring features associated with coordination of the macrocycle **6**, the outcome of the cyclisation is such that the reaction may be considered weakly stereoselective, giving the isomer in which the nitro group can be termed "*cis*" with respect to the C_2 bridge of the homopiperazine entity in approximately twice the yield of the "*trans*" isomer. (Although this distribution differs markedly from those for similar isomers observed for 6,13 disubstituted cyclam systems [28], no simple attribution of its cause is obvious.) Presuming the structure determinations to have characterised the predominant species in solution, it appears that it is possible to obtain essentially one Cu(II) complex from each ligand form. The asymmetry of the ligands imposes chirality in different ways upon the metal ion centre, though quantitative measures of these differences remain to be performed. The axial sites of tetragonal Cu(II), occupied here by oxygen atoms from water or perchlorate, are inequivalent but it is not yet clear whether the discrimination is greater or less than that in analogous achiral complexes such as $[Cu(232tet)]^{2+}$. Nonetheless, reduction of the nitro substituent of **6** to an amino group should provide a site for the introduction of various pendent arms upon the macrocycle and thereby allow generation of a group of cyclam-like ligands with properties clearly distinct from those of presently known derivatives.

Abstract

The reactions of the $(C_6H_6)RuCl_2]_2$ complex with pyrazole and dimethylpyrazole have been examined. The ruthenium complexes, $[(C_6H_6)RuCl(C_3N_2H_4)_2]Cl$ and $[(C_6H_6)RuCl(C_5N_2H_8)_2]$, have been obtained and characterized by IR, UV–Vis and ^1H NMR measurements. Crystal, molecular and electronic structures of the complexes have been determined. The geometries of the complexes were optimized with the DFT method and their UV–VIS spectra were calculated with the TDDFT method.

Keywords: Ruthenium arene complexes; Pyrazole; Dimethylpyrazole; X-ray structure; Bond valence

1. Introduction

η^6-Arene ruthenium complexes play a vital role in organometallic chemistry [1a–1e]. Arene ruthenium(II) complexes of the type $[Ru(\eta^6\text{-arene})]^{2+}$ were first made in 1957 by Fisher from anhydrous $RuCl_3$ [2]. These complexes were not convenient precursors to the half-sandwich arene complexes. Winkhaus et al. [3] reported that 1,3-cyclohexadiene undergoes dehydrogenation on reaction with an ethanolic solution of $RuCl_3$ to give the insoluble benzene complex $[(C_6H_6)RuCl_2]_2$. The arene ruthenium halide compounds are key starting materials for the formation of a wide range of natural and cationic ligand derivatives [1d,4a–4d]. The half-sandwich arene ruthenium complexes may serve as excellent catalyst precursors for hydrogenation [4c,5a–5e] and for ring-opening metathesis polymerization [6].

In 1986 McCleverty et al. [7] obtained the complexes $[(C_6H_6)RuCl(HPz)_2]^+$ and $[(C_6H_6)RuCl_2(Me_2HPz)]$. The authors characterized the complexes on the basis of spectroscopic studies (^1H NMR, IR) and noticed that the reaction between $[(C_6H_6)RuCl_2]_2$ and pyrazole gave a mixture, which could not be purified. In this paper we report the syntheses of benzene ruthenium(II) complexes with the pyrazole and dimethylpyrazole ligands and the study of their spectroscopic properties and crystal structures.

2. Experimental

The starting material $[(C_6H_6)RuCl_2]_2$ was synthesized according to the literature procedure [8]. All other reagents were commercially available and were used without further purification.

2.1. Synthesis of $[(C_6H_6)RuCl(HPz)_2]Cl$

A mixture of $[(C_6H_6)RuCl_2]_2$ (0.25 g; 5×10^{-4} mol) and pyrazole (0.21 g; 3×10^{-3} mol) in acetone (100 cm^{-3}) was refluxed for 3 h, cooled and filtered. The yellow crystals suitable for X-ray crystal analysis grew after the reaction mixture was left overnight. Yield 78%. IR(KBr): 3237 ν_{NH}; 3040 $\nu_{CH\text{–pyrazole}}$; 2921, $\nu_{CH\text{–phenyl}}$; 1955, 1872 phenyl; 1569 ν_{CN}, $\nu_{C=C}$; 1480

2.2. Synthesis of $[(C_6H_6)RuCl_2\ (Me_2HPz)]$

A mixture of $[(C_6H_6)RuCl_2]_2$ (0.25 g; 5×10^{-4} mol) and dimethylpyrazole (0.5 g; 3×10^{-3} mol) in acetone (100 cm^{-3}) was refluxed for 4 h, cooled and filtered. The red crystals suitable for X-ray crystal analysis grew after the reaction mixture was left overnight. Yield 64%. IR(KBr): 3240 ν_{NH}; 3040 $\nu_{CH\text{-}pyrazole}$; 2920, $\nu_{CH\text{-}phenyl}$; 1950, 1878 phenyl; 1572 ν_{CN}, $\nu_{C=C}$; 1485 $\delta_{(C–CH\ in\ the\ plane)}$; 1430 $\nu_{Ph(P–Ph)}$; 1262 $\delta_{(NH;CH)}$; 1093, 1025 $\delta_{(C–CH\ in\ the\ plane)}$; 810 $\delta_{(C–C\ out\ of\ the\ plane)}$; 749 $\delta_{(C–C\ out\ of\ the\ plane)}$; 698 $\delta_{(C–C\ in\ the\ plane)}$; 592 $\nu_{P–Ph}$. ^{1}H NMR (δ, $CDCl_3$): 11.01 (NH; H); 5.99 (s, 1H, CH pyrazole); 5.85 (s, 1H, CH pyrazole); 5.76 (s, 6H, C_6H_6); 2.52 (s, 3H, CH_3); 2.21 (s, 3H, CH_3); 1.80 (s, 3H, CH_3) *Anal*. Calc. for $C_{11}H_{14}C_{l2}N_2Ru$: C, 38.16; H, 4.08; N, 8.09. Found: C, 38.10; H, 3.99; N, 8.12%.

2.3. Physical measurements

Infrared spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the sample in the form of a KBr pellet. Electronic spectra were measured on a spectrophotometer Lab Alliance UV-Vis 8500 in the range 800–220 nm in deoxygenated dichloromethane solution. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer. The ^{1}H NMR spectra were recorded on a Bruker DRX-400 spectrometer in $CDCl_3$ solutions.

2.4. DFT calculations

The GAUSSIAN 03 program [9] was used in the calculations. The geometry optimization was carried out with the DFT method with the use of B3LYP functional [10,11]. The electronic spectrum was calculated with the TDDFT method [12]. LANL2DZ basis set [13] was used on the ruthenium atom, 6-31G(d) on the chlorine, nitrogen and carbon atoms and 6-31G basis on the hydrogen atoms in the calculations.

2.5. Crystal structures determination and refinement

A yellow thin plate crystal of $[(C_6H_6)RuCl(HPz)_2]Cl$ and an orange needle crystal of $[(C_6H_6)RuCl(C_3N_2H_4)_2]$ were mounted on a KM-4-CCD automatic diffractometer equipped with CCD detector and used for data collection. X-ray intensity data were collected with graphite monochromated Mo Kα radiation at a temperature of 293.0(2) K, with the ω scan mode. Forty two and 22 s exposure time, respectively, were used and a quarter and a half of the Ewald sphere was collected up

to $2\theta = 50.21°$. The unit cell parameters were determined from least-squares refinement of the setting angles of 3513 and 4793 of the strongest reflections respectively. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption [14] corrections were applied. The structures were solved by direct methods. All the non-hydrogen atoms were refined anisotropically using the full-matrix, least-squares technique on F^2. All the hydrogen atoms were found from difference Fourier synthesis after four cycles of anisotropic refinement and refined as "riding" on the adjacent atom with an individual isotropic temperature factor equal to 1.2 times the value of the equivalent temperature factor of the parent atom. SHELXS 97 [15], SHELXL 97 [16] and SHELXTL [17] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

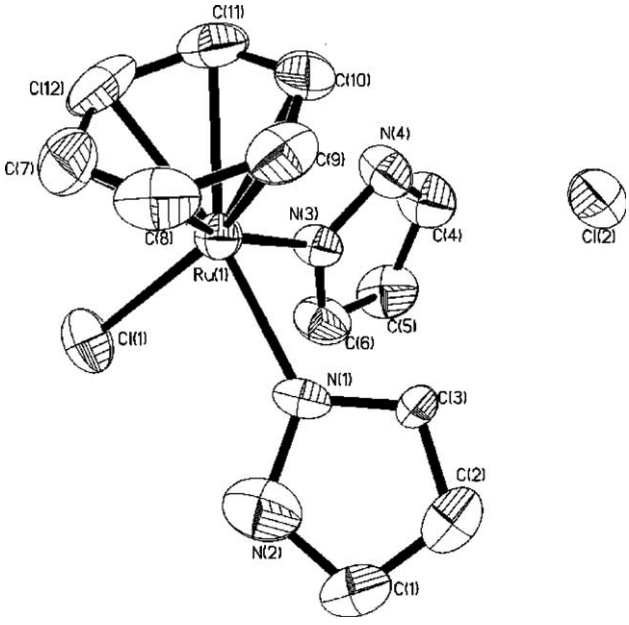

Fig. 1. ORTEP drawing of $[(C_6H_6)RuCl(HPz)_2]Cl$ with 50% probability thermal ellipsoids. Hydrogen atoms have been omitted for clarity.

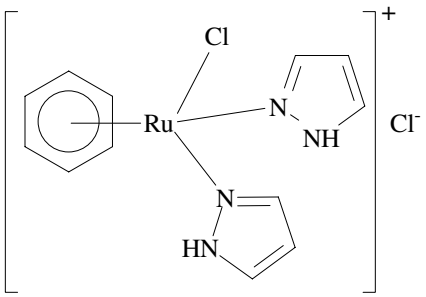

Fig. 2. Structural drawing of $[(C_6H_6)RuCl(HPz)_2]Cl$.

3. Results and discussion

Refluxing of the ruthenium(II) benzene complex $[(C_6H_6)RuCl_2]_2$ with an excess of pyrazole or dimethylpyrazole in acetone leads to the half-sandwich $[(C_6H_6)RuCl(HPz)_2]Cl$ and $[(C_6H_6)RuCl_2(Me_2HPz)]$ complexes in high yield. The elemental analyses of the complexes are in good agreement with their formulation. The characteristic bands of the pyrazole ligand ν(NH) at 3268 cm^{-1} and ν(CN), ν(C=C) at 1516 cm^{-1} are present in the IR spectra of the obtained complexes. The ^1H NMR spectra of the complexes showed the sharp singlets at 6.10 and 5.76 ppm, respectively, characteristic of the coordinated η^6-C_6H_6 ligand. The pyrazole ligand showed a signal at 11.71 ppm (NH) and the sets of signals at 6.40 (t, 2H); 7.72 (d, 2H); 8.01 (d, 2H) from H atoms on different C atoms of the pyrazole ring for the cationic complex and 11.01 (NH); 5.99 (s, 1H); 5.85 (s, 1H); 2.52 (s, 3H); 2.21 (s, 3H); 1.80 (s, 3H) for the complex with the dimethylpyrazole ligand.

3.1. Crystal structures

The $[(C_6H_6)RuCl(HPz)_2]Cl$ complex crystallizes in the monoclinic space group $P2_1/n$. The molecular structure of the compound is shown in Fig. 1 (structural drawing of the complex is presented in Fig. 2). The selected bond lengths and angles are listed in Table 2. The ruthenium atom is in a formally six-coordinate environment, and the structure of the cation complex $[(C_6H_6)RuCl(HPz)_2]^+$ adopts a distorted piano-stool type of geometry with angles around the ruthenium of 82.08(19)° (N(3)–Ru–N(1)), 85.79(14)° (N(3)–Ru–Cl(1)), 87.26(14)° (N(1)–Ru–Cl(1)). The benzene ring is planar and the Ru–C distances are almost equal with an average bond length of 2.182(8) Å (range 2.167(7)–2.194(6) Å). The Ru(1) to benzene centroid distance is 1.676 Å and this is consistent with those values reported for other Ru(II) η^6-arene complexes [4d,18,19]. The Ru–Cl(1) bond length of 2.4026(17) Å is of the same order as in related cationic arene ruthenium(II) compounds [19,20]. The pyrazole Ru–N(1) and Ru–N(2) distances are essentially identical and are in the range of Ru–N distances [21].

Three intermolecular hydrogen bonds [22–24] linking the chlorine anion and pyrazole ring N(4)–H(4)···Cl(2# $-x+1, -y+1, -z$) (D···A distance 3.067(6) Å, D–H···A angle 148.1°), C(1)–H(1)···Cl(2# $-x+1/2, y-1/2, -z-1/2$) (D···A distance 3.559(7) Å, D–H···A angle 147.3°), C(3)–H(3)···Cl(2) (D···A distance 3.068(6) Å, D–H···A angle 175.1°) atoms are observed. Two other intramolecular weak hydrogen bonds are present in the structure of the complex: between arene C(11)–H(11) and Cl(1# $-x+1/2, y+1/2, -z+1/2$) (D···A distance 3.565(8) Å, D–H···A angle 149.7°) and

between pyrazole N(2)–H(2) and Cl(1# $-x$, $-y$, $-z$) (D···A distance 3.833(7) Å, D–H···A angle 119.7°). In this way an infinite three-dimensional hydrogen-bonded net has been created. The possibility of benzene ring stacking interaction was rejected due to the large distance between parallel rings. There are no unusual intermolecular short contacts, except for the described hydrogen bonds.

The bond valences were computed as $v_{ij} = \exp[(R_{ij} - d_{ij})/B]$ [25–27], where R_{ij} is the bond-valence parameter (in the formal sense R_{ij} is the single-bond length between i and j atoms) [28]. The bond valence parameters [25] have been determined only for: Ru(+4) ($R_{Ru–Cl}$), without specification of the oxidation state of Ru ($R_{Ru–N}$), and $R_{Ru–\pi}$ was never determined. Thus, all these parameters were calculated for Ru(+2). The $R_{Ru–N}$ was determined by fit to the bond lengths method [28] for 282 Ru(+2) six-coordinated complexes found in the literature, [2] where donors were coordinating by nitrogen organic ligands. The computed $R_{Ru–N}$ valence parameter was equal to 1.656 Å, and checking statistics of total Ru valence was: mean error = 0.0071; median = 2.014; mode, 2.052; SD, 0.128; sampling variance = 0.0165; kurtosis = 0.494 and skewness = −0.273. Because both types of structures with chelating and monodendate ligands were used for statistics, there might be a systematic error in analysis resulting from steric restrains of chelating ligands. Thus, all calculations were performed for a group of complexes with monodendate ligands, [2] and $R_{Ru–N} = 1.68$ Å and statistics were: 0.0314, 1.975, cannot be calculated, 0.180, 0.0325, 1.249 and 1.453 in the order as above. According to calculated statistics, the difference of 0.02 Å between $R_{Ru–N}$ comes only from the amount of data, thus the value 1.656 Å was used as a proper $R^{II}_{Ru–N}$ value. Because there exists only eight structures with Ru coordinated only by six Cl atoms [2], the $R_{Ru–Cl}$, parameter was based on the cross and fit to the bond lengths method, using structures with a coordination sphere of the general formula $Ru(N_nCl_{6-n})$, where $n \in \langle 0–5 \rangle$. For 145 structures founded in the literature [2], the obtained $R_{Ru–Cl}$ value is 1.932 Å and statistics are: 0.0144, 1.986, 1.944, 0.184, 0.0337, 1.079 and 0.547 in the order as above. The $R_{Ru–\pi}$ parameter was determined in two different ways: by fit to the bond lengths in 41 π–Ru–π complexes for 54 data [2] and by cross and fit to the bond lengths method in 116 π-$Ru(N_nCl_{3-n})$, where $n \in \langle 0–3 \rangle$ [2]. In first case obtained, valence parameter value was 1.731 Å and statistics, ordered as above, were: 0.0097, 2.005, cannot be calculated, 0.071, 0.0051, −0.041 and 0.123. In second case the obtained valence parameter has a value of 1.725 Å and statistics were: 0.0058, 1.999, 1.974, 0.075, 0.0056, 4.391 and 0.751, in the order as above, thus $R_{Ru–\pi} = 1.731$ Å was chosen as a correct value. The value of B was taken as 0.37 according to the literature [26]. The computed bond valences of the ruthenium are $v_{Ru–Cl} = 0.280$, $v_{Ru–N} = 0.292$, 0.296 and $v_{Ru–\pi} = 1.158$ v.u. (Ru-centroid of aromatic ring distance is 1.6766(6) Å), which shows that the Ru–N and Ru–Cl bonds have the same strength and Ru–π is about four times stronger. The total valence of Ru(1) is 2.027 v.u. which agrees with the formal oxidation state of Ru. This also confirms that the calculated valence parameters have proper values because only violation of the valence-sum rule can indicate mistakes in the interpretation of the structure or structural parameters [28,29].

The complex $[(C_6H_6)RuCl_2\ (Me_2HPz)]$ crystallizes in the triclinic space group $P\bar{1}$ and the crystal structure is built up of two independent molecules in the asymmetric unit. The relative orientation of molecules is depicted in Fig. 3 (the structural drawing is presented in Fig. 4) which also shows the thermal vibration ellipsoids of the non-hydrogen atoms. The coordination about ruthenium is formally six and the structure adopts a distorted piano-stool type of geometry. The selected bond lengths and angles are given in Table 3. The distances and the angles between appropriate atoms in the two molecules are similar. Weighted root mean square deviation of superpositioned molecules is 0.054(7). The most different distance is Ru(1)–C(10) 2.149(11) Å and Ru(51)–C(60) 2.188(11) Å, and the most different angles are

[2] The references were collected from the Cambridge Structural Database v 5.24, November 2002. The list of papers is available as supplementary material on request from R. Kruszyński kruszyna@ck-sg.p.lodz.pl.

for Ru(1)–N(1) and 2.125(7) Å for Ru(51)–N(51), which are similar and in the range of Ru–N distances. The ruthenium to benzene centroid distance varies from 1.655(9)Å (Ru(1)) to 1.658(2) Å (Ru(51)). The benzene ring is planar and the Ru–C distances are almost equal with an average bond length of 2.166(11) Å (2.163(10) Å for Ru(1)–C to 2.17(11) Å for Ru(51)–C). The computed bond valences of the Ru(1) atom are $v_{Ru-Cl} = 0.265$, 0.275 $v_{Ru-N} = 0.284$ and $v_{Ru-\pi} = 1.225$ v.u. and for the Ru(2) atom are $v_{Ru-Cl} = 0.273$, 0.270 $v_{Ru-N} = 0.282$ and $v_{Ru-\pi} = 1.217$ v.u. (Ru-centroid of aromatic ring distances are 1.656(6) and 1.658(7) Å for molecules indicated by Ru(1) and Ru(2) atoms, respectively), which shows, like in the above described compound, that the Ru–N and Ru–Cl bonds have the same strength and Ru–π is about four times stronger. The total valence of the Ru(1) atom is 2.049 v.u. and that of the Ru(2) atom is 2.049 v.u., which agrees with the formal oxidation state of Ru. This also confirms that the calculated valence parameters have proper values because only violation of the valence-sum rule can indicate mistakes in the interpretation of the structure or structural parameters [28,29].

The molecules of $[(C_6H_6)RuCl_2(Me_2HPz)]$ (Fig. 4) are linked via multiple intermolecular weak C–H···Cl hydrogen bonds [22–24] to generate the infinite three dimensional network (Table 4).

3.2. Geometry optimization and electronic structure

The geometry of the singlet and triplet state was optimized for the $[(C_6H_6)Ru(Hpz)_2Cl]^+$ cation and $[(C_6H_6)RuCl_2(Me_2HPz)]$ molecule. The triplet–singlet energy difference and the optimized geometry parameters for the singlet state are given in Table 5. In Table 6 the energies of several HOMO and LUMO orbitals of $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and $[(C_6H_6)RuCl_2(Me_2HPz)]$ are gathered. In both cases the singlet state is lower in energy, but the triplet–singlet energy difference is smaller for $[(C_6H_6)RuCl_2(Me_2HPz)]$ (6.1 kcal/mol) than for $[(C_6H_6)Ru(Hpz)_2Cl]^+$ (20.9 kcal/mol). This agrees with the smaller HOMO–LUMO gap in $[(C_6H_6)RuCl_2(Me_2HPz)]$ (3.90 eV) than in $[(C_6H_6)Ru(Hpz)_2Cl]^+$ (4.23 eV). The optimized bond distances agree well with the experimental ones, the largest differences are for the metal–benzene carbon bonds. The shortening of the metal–benzene carbon distances in $[(C_6H_6)RuCl_2(Me_2HPz)]$ relatively to $[(C_6H_6)Ru(Hpz)_2Cl]^+$ is reproduced in the optimized structures.

In Fig. 5 several HOMO and LUMO orbitals of $[(C_6H_6)Ru(Hpz)_2Cl]^+$ are depicted. In the free benzene molecule, the π-electron configuration is $\pi_1(a_{2u})^2$ $\pi_2(e_{1g})^2$ $\pi_3(e_{1g})^2$ $\pi_4^*(e_{2u})^0$ $\pi_5^*(e_{2u})^0$ $\pi_6^*(b_{2g})^0$. The bonding between benzene and ruthenium is formed by the two π orbitals of e_{1g} symmetry (π_2 and π_3) and the empty d_{xz} and d_{yz} orbitals of the metal atom (donation from benzene to ruthenium). The resulting bonding orbitals are HOMO − 10, HOMO − 11 and HOMO − 12, HOMO − 11 in $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and $[(C_6H_6)$

Table 5

$RuCl_2(Me_2HPz)$], respectively, the antibonding are LUMO and LUMO + 1 (Table 6 and Fig. 5). Since the bonding orbitals are of predominantly benzene character and the antibonding ones are predominantly of metal character, in the electronic transitions the former are described as π_{benz} and the latter as d orbitals. In the back-donation (metal to ligand) the occupied $d_{x_2-y_2}$ and d_{xy} metal orbitals and empty π_4^*, π_5^* benzene orbitals participate (HOMO − 1, HOMO and LUMO + 2, LUMO + 3). However, this interaction is weaker, due to a smaller orbital overlap.

3.3. Electronic spectrum

The spin-allowed, singlet transitions were calculated with the TDDFT method. The calculated electronic

The transitions ascribed to the experimental bands are denoted in bold.

transitions are gathered in Table 7. Except for the low energy part of the spectrum, only transitions with oscillator strengths larger than 0.01 are listed.

3.3.1. $[(C_6H_6)Ru(Hpz)_2Cl]^+$

In the calculated electronic spectrum of $[(C_6H_6)Ru(Hpz)_2Cl]^+$, the lowest energy transitions are of d → d origin and they are characterized with small oscillator strengths. The first two (at 478.8 and 461.9 nm) may be attributed to the experimental band at 567.8 nm. The calculated transitions at 434.9 and 422.3 nm, also with d → d character, can be attributed to the experimental band at 557.8 nm. These two experimental bands are of very low intensity ($\varepsilon = 28$ and 30). The next experimental transition occurs at 405.6 nm and has higher intensity ($\varepsilon = 1309$). We attribute this transition to the calculated transition at 379.9 and 371.2 nm also with a d → d character.

The experimental band at 325.4 nm ($\varepsilon = 1739$) can be attributed to the calculated transitions at 308.2. The electronic transitions involved here are of LMCT character (d → π^*_{Hpz}).

The most intense experimental band of $[(C_6H_6)Ru(Hpz)_2Cl]^+$ is found at 231.6 nm ($\varepsilon = 15995$). This band can be attributed to the calculated transitions between 220.4 and 207.2 nm with large oscillator strengths. They are of MLCT (d → π^*_{Hpz}), LLCT ($\pi_{Hpz} \rightarrow \pi^*_{benz}$) and LMCT ($\sigma_{Cl} \rightarrow$ d) character.

3.3.2. $[(C_6H_6)RuCl_2(Me_2HPz)]$

The calculated spectrum for $[(C_6H_6)RuCl_2(Me_2HPz)]$ shows several transitions with small oscillator strengths between 550 and 400 nm. They are LF (d → d) transitions. The first experimental transition at 430.6 nm can be assigned to the calculated transitions at 450.4 and 424.9 nm of LF character. The second experimental band at 370.0 nm may be attributed to the calculated transition at 385.1 nm also of LF type.

The experimental band at 339.2 nm is ascribed to the calculated transitions at 331.4 and 329.4 nm. These

transitions are of LMCT ($\pi_{Hpz} \rightarrow d$, $\pi_{Cl} \rightarrow d$) and MLCT ($d \rightarrow \pi^*_{benz}$) character.

The experimental band at 232.2 nm with $\varepsilon = 13\,509$ can be assigned to the calculated transitions at 263.1 and 246.4 nm with large oscillator strengths. These transitions are of MLCT ($d \rightarrow \pi^*_{benz}$) and LLCT ($\pi_{Hpz} \rightarrow \pi^*_{benz}$) character.

The experimental band at 216.0 nm with $\varepsilon = 5205$ can be attributed to the calculated transitions at 216.7 and 216.0 nm with large oscillator strengths. These transitions are of LMCT ($\sigma_{Cl} \rightarrow d$) and LLCT ($\pi_{Cl} \rightarrow \pi^*_{Hpz}$) type.

The spectra of $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and $[(C_6H_6)RuCl_2(Me_2HPz)]$ according to the TDDFT calculated transitions are similar in the range up to 300 nm. The longest wave transitions are of LF type (567.8, 557.8, 405.6 nm for $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and 430.6, 370.0 for $[(C_6H_6)RuCl_2(Me_2HPz)]$). The bands at 325.4 in $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and 339.2 nm in $[(C_6H_6)RuCl_2(Me_2HPz)]$ arise from $\pi_{Hpz} \rightarrow d$ and $d \rightarrow \pi^*_{benz}$ excitations (plus $\pi_{Cl} \rightarrow d$ in $[(C_6H_6)\ RuCl_2(Me_2HPz)]$). However, in the short wave bands (231.6 for $[(C_6H_6)Ru(Hpz)_2Cl]^+$ and 232.0, 216.0 nm for $[(C_6H_6)RuCl_2(Me_2HPz)]$), a large participation of the pyrazole orbitals is pronounced for the first compound, while the chlorine and benzene orbitals dominate in the transitions of the second one.

4. Supplementary material

Crystallographic data for the structure of the complexes have been deposited at the Cambridge Crystallographic Data Center (CCDC 205958, CCDC 222759). Copies of this information maybe obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2, IEZ, UK (fax: +44-1223-336-033; e-mail: deposit@ccdc.cam.ca.uk or http://www.ccdc.cam.ac.uk). The list of references concerning to bond valence parameters is available on request from R. Kruszyński kruszyna@p.lodz.pl.

Kinetics of oxidation of glyoxylic acid by [ethylenebis(biguanide)]silver(III) in aqueous media

Amit Das, Subrata Mukhopadhyay *

Department of Chemistry, Jadavpur University, Calcutta 700 032, India

Received 28 October 2003; accepted 16 December 2003

Abstract

The complex cation, [ethylenebis(biguanide)]silver(III), $[Ag(H_2L)]^{3+}$, and its conjugate bases, $[Ag(HL)]^{2+}$ and $[AgL]^{+}$ oxidise glyoxylic acid, $CHOCO_2H$ quantitatively to formic acid and carbon dioxide, themselves being reduced to Ag^{+}. Free ethylenebis(biguanide) was recovered in near-quantitative yield. In the investigated pH range (1.00–7.00), the reaction is first order in both [complex] and total glyoxylate, $[HGX]_T$. The reaction proceeds through four parallel paths: $[Ag(H_2L)]^{3+}$ – HGX (k_1), $[Ag(H_2L)]^{3+}$ – GX^{-} (k_2), $[Ag(HL)]^{2+}$ – GX^{-} (k_3), and $[AgL]^{+}$ – GX^{-} (k_4). The respective rate constants (in 10^4 M^{-1} s^{-1}) are, respectively, 7.34, 112, 40.7 and 19.2 at 25.0 °C and $I = 1.0$ M ($NaNO_3$). Formation of adducts by the reducing species with the metal complex via hydrogen-bonding or electrostriction may be proposed for the low-energy pathway for electron-transfer. A substantial rate retardation in presence of the radical scavenger acrylonitrile suggests successive one-electron changes, $Ag^{III} \rightarrow Ag^{II} \rightarrow Ag^{I}$.

1. Introduction

The trivalent silver species [ethylenebis(biguanide)]silver(III) (Fig. 1) is an authentic cationic complex of silver [1–3] stable in aqueous solution over a wide pH range against dechelation and intramolecular redox decomposition [4]. Stabilisation of the silver(III) center by the square-planar acyclic tetraaza ligand is so extensive ($\log K = 52$) [5] that the title complex behaves as a milder oxidant [6], more so than Ag^{+} [7]. The complex is freely soluble in aqueous media below pH ca. 4.5 but ~0.2 mM complex can be made soluble up to pH at least 7.0 if alkali is added carefully with stirring to avoid local excesses. Moreover, the silver(III) retains its identity in strongly acidic and in strongly alkaline media, a property unknown in other higher valent silver complexes. In aqueous solutions the complex behaves as a mild dibasic acid ($pK_{a1} = 3.8$, $pK_{a2} = 6.3$) originating from ligand-based protic equilibria [8] and thus the reactivity studies of different silver(III) species connected through protic equilibria is possible because, in spite of the remarkable thermodynamic stability, the silver(III) complex oxidises [9–20] various organic and inorganic species with a variety of electron transfer pathways – inner sphere for weakly reducing ligands [10,11,13,14,19,20], outer sphere for weakly basic but strongly reducing ligands [15,17] and even by Ag^{+} catalysis [9,10,13].

We report herein the kinetics of oxidation of glyoxylic acid and its conjugate base by the title silver(III) complex. Detailed kinetic studies of the oxidation of glyoxylic acid, one of the smallest carboxylic acids, is of importance as in metabolic processes such as glycine catabolism [21] and in plant physiology [22], higher valent metal ions like manganese(III) complexes play an essential role. Glycine oxidation to CO_2 may occur via glyoxylic acid arising from oxidative deamination of glycine by the enzyme glycine oxidase [23]. The silver(III) species, $[Ag(OH)_4]^{-}$ oxidises glycine [24] in strongly alkaline media to NH_3, HCHO and CO_2. $[AuCl_4]^{-}$ also oxidises glycine [25] to NH_3, HCO_2H and CO_2 in weakly acidic media via the intermediate formation of glyoxylic acid. We observed that the title

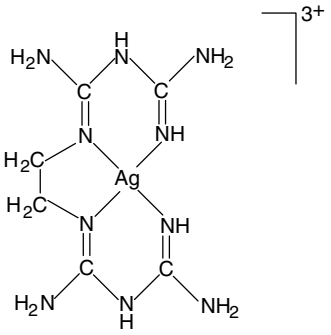

Fig. 1. Structure of [ethylenebis(biguanide)]silver(III) complex.

silver(III) complex reacts very slowly with glycine although it reacts with glyoxylic acid at a moderately fast rate. Under these perspectives it is important to understand the chemistry of Ag(III) – biomolecule interactions. Moreover, the ligand H_2L in $[Ag(H_2L)]^{3+}$ is substitution inert so that Ag^{III} never is released in solution to open extra, complicating pathways in its reduction.

2. Experimental

2.1. Materials

The silver(III) complex, abbreviated as $[Ag(H_2L)]^{3+}$ hereafter, was prepared according to the known procedure [2,3] with a slight modification in the crystallisation process [9]. Aqueous solution of glyoxylic acid were prepared by dissolving solid glyoxylic acid monohydrate (98%, Lancaster) in water and standardised either by standard alkali using Weslow's indicator or spectrophotometrically [26] at 520 nm ($\varepsilon = 17990\ M^{-1}\ cm^{-1}$ as estimated by us, in agreement with the literature [26] value 17 870 $M^{-1}\ cm^{-1}$) after converting glyoxylic acid to 1,5-diphenylformazancarboxylic acid. Both the results agreed well (within 4%). We found that an aqueous solution of ~0.5 M glyoxylic acid is stable for at least one week when kept at low temperature (~5–10 °C) and in the dark. Aqueous solutions of $NaNO_3$ or $NaClO_4$ (both of G.R., E. Merk) were standardised by passing through a Dowex 50W X-8 strong cation exchange resin in the H^+ from and titrating the liberated acid with standard NaOH to a phenolphthalein end point. All measurements were made at 25.0 °C and $I = 1.0$ M ($NaNO_3$ or $NaClO_4$). All solutions were prepared in water, which was deionised and then doubly distilled.

2.2. Physical measurements and kinetics

The acid dissociation constant, K_a of the glyoxylic acid was determined by titrating several aliquots of different strengths with carbonate free deaerated NaOH solution at 1.0 M $NaNO_3$ using a Titrino Autotitrator (Metrohm, 736 GP) at (25 ± 0.1) °C. Production of CO_2 as the gaseous reaction product was qualitatively confirmed by GC analysis. The gaseous product formed during the reaction was collected over a saturated sodium chloride solution and analysed by gas chromatography as described earlier [27] using a Chemito (India) GCHT 8610 equipped with TCD, a Porapack Q and molecular sieve 13X column. Splitless mode injection of 500 μL of sample was used. The oven temperature, injector and detector temperature were kept at 40, 55, and 100 °C, respectively. The carrier hydrogen gas flow was adjusted to 30 ml min^{-1}. All absorbance versus time data were recorded with a Shimadzu (1601 PC) spectrophotometer using 1.00 cm quartz cells. The kinetics was monitored in situ in the 'kinetic mode' of the instrument at 420 nm in the electrically controlled thermostated (25.0 ± 0.1 °C) cell housing (CPS-240A). In this mode the change in absorbance is automatically and continuously recorded. For faster reactions glyoxylic acid solution (adjusted to desired pH) was directly injected into the spectrophotometer cell containing other components of the reaction mixture kept at the same pH. The desired concentration of the complex and reducing agent was achieved after mixing. The solution pH values were adjusted with $HClO_4$ or NaOH. Although the measured pH is usually defined in terms of the activity of hydrogen ions, we used the hydrogen ion concentration by calibrating the pH electrode with analytically prepared solutions as described earlier [28].

2.3. Stoichiometric measurements

The stoichiometry was measured both under kinetic and reverse condition by estimating glyoxylic acid spectrophotometrically and estimating unreacted Ag^{III} in condition when initial $[Ag^{III}]$ is in excess over total glyoxylic acid, $[HGX]_T$ (defined as $[HGX] + [GX^-]$). Excess glyoxylic acid was mixed with the Ag^{III} complex in the pH range 3.0–5.0. After the reaction mixture turned colourless indicating complete reduction of Ag(III) to Ag(I), excess NaCl was added to remove AgCl. Freshly prepared phenylhydrazine hydrochloride (1%) was added (3.0 ml) into each mixture. The resulting solutions were incubated at ~110 °C for 10 min and then cooled to room temperature (~25 °C) followed by successive addition of 2.5 ml each of concentrated HCl and 1% $K_3Fe(CN)_6$. The mixtures were allowed to stand for ~5 min for the quantitative formation of pink coloured formazan derivative of glyoxylic acid [26] that was measured at 520 nm.

Reaction mixtures containing excess Ag^{III} over glyoxylic acid were used to measure the unreacted $[Ag^{III}]$. After completion of reactions (as indicated by no further change in absorbance), measured volumes of dilute HNO_3 were added to reach a final pH within 1.0–2.0

Table 1
Stochiometric results for the oxidation of glyoxylic acid (HGX) by the silver(III) complex at $I = 1.0$ M ($NaNO_3$) and $T = 25$ °C

$[Ag(III)]_T$ (mM)	$[HGX]_T$ (mM)	pH	$[HGX]_{left}$ (mM)	$[Ag(III)]_{left}$ (mM)	$\Delta[HGX]_T/\Delta[Ag(III)]_T$
0.15	0.30	3.1	0.16		0.94
	0.40	4.2	0.24		1.07
	0.60	4.9	0.47		0.87
0.20	0.80	5.3	0.61		0.95
	1.00	4.6	0.79		1.05
0.30	1.00	4.4	0.71		0.97
	1.20	3.9	0.88		1.07
0.45	0.30	3.5		0.13	0.94
1.00	0.50	3.7		0.46	0.93
					Average = 0.98 ± 0.10

and the remaining $[Ag^{III}]$ was estimated at 380 nm ($\varepsilon = 1175\ M^{-1}\,cm^{-1}$) [8]. Both experiments, whether in kinetic or in reverse condition resulted a 1:1 stoichiometry between the redox partners (Table 1).

2.4. Product analysis

Generation of formic acid as one of the oxidation products of the title reaction was tested by the addition of chromotropic acid [29] in the product mixture after removing Ag^+ as AgCl. Formation of CO_2 as the gaseous product was qualitatively confirmed by GC analysis. We also observed that at the end of the reaction, more than 90% of the free ligand (H_2L) can be recovered. For this purpose concentrated (1.0–2.0 mM) solutions of the Ag^{III} complex were reacted with stoichiometric excess glyoxylic acid. Immediately after completion of reaction (absorbance <0.01 at 420 nm), all Ag^+ was precipitated as AgCl and removed by filtration. From the filtrate, the free ligand, ethylenebis(biguanide) was quantitatively isolated [30] as the sparingly soluble [ethylenebis(biguanide)]copper(II) sulfate, and the amount of Cu(II) thus held was estimated iodometrically after decomposing the Cu(II) complex.

3. Results and discussion

3.1. Equilibrium studies and preliminary observations

The pK_a of the glyoxylic acid was found to be 3.20 ± 0.10 at 25.0 °C and at $I = 1.0$ M ($NaNO_3$). Though this value to some extent differs from the reported [31] value (2.91) under similar condition of temperature and ionic strength, we used the value 3.20 for pK_a for the calculation of rate constants. Most of the kinetic runs were performed at 420 nm where all other reaction components except Ag^{III} are transparent. Within the time span of the reactions, autodecomposion of the silver(III) complex was insignificant at the experimental temperature. No external buffer was used in kinetic measurements since buffering (by acetate, for example) affects the spectra of the complex; specific interaction of buffer with the complex was thus indicated. Even in the absence of an external buffer, the media pH before and after the reactions did not change by more than 0.10 units.

3.2. Stoichiometry and the redox reaction

Stoichiometric determination and product analyses clearly indicate the occurrence of reaction (1) in the entire redox process:

$$Ag^{III} + CHOCO_2H + H_2O \rightarrow Ag^{I} + HCO_2H + CO_2 + 2H^+ \quad (1)$$

3.3. Kinetics

No immediate spectrophotometric change was observed on mixing glyoxylic acid with the silver(III) complex over the entire range of experimental pH and total glyoxylate ($[HGX]_T$). However, the absorbance at $\lambda \geqslant 420$ nm gradually decreases to less than 0.01. We measured some k_0 values in the presence of added (1.0 mM) ethylenebis(biguanide) and found to be identical with experiments in its absence within reasonable uncertainties, and we observed no effect of diffused light in our system. The $\log_{10}$ (absorbance) versus time plots were found to be linear for more than 90% completion of reactions and the pseudo-first-order rate constants, k_0, defined by Eq. (2) were obtained from the least-squares slopes of these plots

$$-d[Ag(III)]/dt = k_0[Ag(III)]. \quad (2)$$

Any initial drop in absorbance for faster reactions can be computed from the time of mixing of reactants (~4 s) and the observed-first-order rate constants. Averages of k_0 values from at least three runs were taken and individual runs were reproducible within 3%.

Detailed data of the kinetics of the process were obtained as a function of pH and $[HGX]_T$ and some representative data are summarised in Table 2. Over the entire pH range studied the reaction shows a clear first-order dependence on $[HGX]_T$ and there is no $[HGX]_T$ independent term. The following changes in the reaction conditions had, within the limits of experimental uncertainties, no influence on the values of k_0: a fivefold variation in [Ag(III)] from 0.1 to 0.5 mM, occasional shaking of spectrophotometer cell, presence or absence of dissolved oxygen and a variation in the monitoring wavelength in the range 420–500 nm.

The observed rate constants remarkably depend on the media ionic strength maintained by $NaNO_3$ or $NaClO_4$ (Table 2). A considerable increase in reaction rate at pH > 3.0 with decrease in the ionic strength indicates reaction between oppositely charged ions. [1] However at pH $\leqslant$ 2.0 the reaction rate was found to be practically independent on the media ionic strength probably due to involvement of neutral species glyoxylic acid as the sole reducing component.

Reactions studied in the presence of 6% (v/v) acrylonitrile showed slow polymerisation after ca. 60% consumption of initial Ag^{III}. The $\log_{10}$ (absorbance) versus time plots in this condition showed a definite upward curvature after ca. 50% completion of reactions probably due to heterogeneity in the reaction media. However, the first-order rate constants computed from the initial linear portions of these curves clearly demonstrate much slower reactions in presence of radical scavengers like acrylonitrile.

A plot of k_0 versus pH has a bell shape (Fig. 2) at a particular $[HGX]_T$. Such a pH dependence indicates the involvement of two or more acid–base equilibria [32]. Considering the values for the acid dissociation constants of the complex in aqueous solution [8] (K_{a1} and K_{a2}, which are 1.58×10^{-4} and 5.01×10^{-7} M, respectively) and K_a ($= 6.31 \times 10^{-4}$ M), the measured acid dissociation constant of glyoxylic acid under experimental conditions, Scheme 1 in Eqs. (3)–(9) provides a reasonable explanation for the kinetic observations.

Table 2
Some representative first-order rate constants for oxidation of glyoxylic acid by the silver(III) complex[a]

[a] $T = 25.0$ °C, $I = 1.0$ M ($NaNO_3$), [complex] = 0.15 mM.
[b] 10^4 k_0 (s^{-1}) values are 9.25, 14.0 and 19.0 at $I = 0.5$, 0.2 and 0.1 M ($NaNO_3$), respectively.

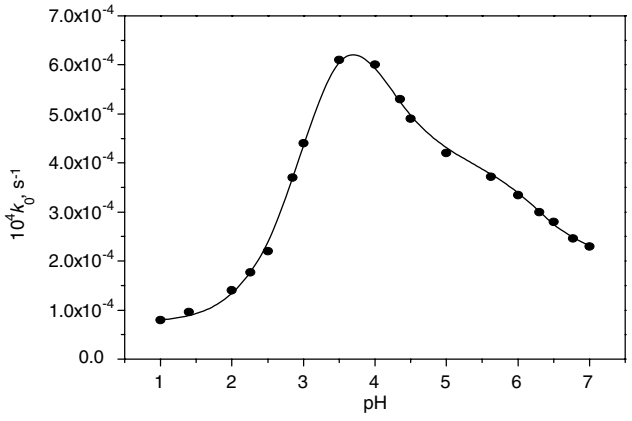

Fig. 2. Dependence of k_0 on pH at $T = 25.0$ °C, $[Ag(III)]_T = 0.15$ mM, $[HGX]_T = 0.10$ M, $I = 1.0$ M ($NaNO_3$). The solid line represents the fit of Eq. (10).

[1] One of the referees suggested that the rate constants might have been changed if $LiClO_4$ is used instead of Na^+ salts for maintaining the ionic strength of the reaction medium. We performed several experiments in presence of varying amount of $LiClO_4$ keeping $I = 1.0$ M. The first-order rate constants thus obtained were found to be substantially higher (15–25%, depending on pH of reaction) than those measured using $NaNO_3$ or $NaClO_4$. The redox partners of the title reaction are oppositely charged and thus conventional metal ion catalysis (M. Gupta, S.K. Saha, P. Banerjee, J. Chem. Soc., Perkin Trans. II (1988) 1781) can be ruled out. A possible reason for the rate enhancement in presence of Li^+ ion may be explained by very high approximate hydration number as estimated by transference data (F.A. Cotton, G. Wilkinson, C.A. Murillo and M. Bochmann, Advanced Inorganic Chemistry (Ch. 3), 6th ed., Wiley, New York, 1999, p. 102) of Li^+ (25.3) than Na^+ (16.6) that results in a major lowering of the effective concentration of solvent water which in turn increases the activity of the redox partners. A similar situation has also been verified with the oxidation of azide by the title silver(III) complex. We also note that the effect of $LiClO_4$ for the rate enhancement is marginal when the reactive form of the reducing agent is uncharged. We will explore in future the finer details of these effects.

$$[Ag(H_2L)]^{3+} \overset{K_{a1}}{\rightleftharpoons} [Ag(HL)]^{2+} + H^+ \quad (3)$$

$$[Ag([HL)]^{2+} \overset{K_{a2}}{\rightleftharpoons} [AgL]^{+} + H^+ \quad (4)$$

$$HGX \overset{K_a}{\rightleftharpoons} H^+ + GX^- \quad (5)$$

$$[Ag(H_2L)]^{3+} + HGX \overset{k_1}{\rightarrow} \text{Products} \quad (6)$$

$$[Ag(H_2L)]^{3+} + GX^- \overset{k_2}{\rightarrow} \text{Products} \quad (7)$$

$$[Ag(HL)]^{2+} + GX^- \overset{k_3}{\rightarrow} \text{Products} \quad (8)$$

$$[AgL]^{+} + GX^- \overset{k_4}{\rightarrow} \text{Products} \quad (9)$$

Scheme 1.

Scheme 1 leads to the rate law

$$k_0[H^+]^3/([HGX]_T\alpha_1\alpha_2) = k_1[H^+]^3 + k_2K_a[H^+]^2 + k_3K_{a1}K_a[H^+] + k_4K_{a1}K_{a2}K_a, \quad (10)$$

where $\alpha_1 = [H^+]^2/([H^+]^2 + K_{a1}[H^+] + K_{a1}K_{a2})$ is the fraction of the silver(III) complex present as $[Ag(H_2L)]^{3+}$ and $\alpha_2 = [H^+]/(K_a + [H^+])$ is the fraction of glyoxylic acid present as HGX.

In the lower pH range (up to pH 2.5), the second dissociation of the dibasic complex may be neglected and reactions (8) and (9) are unnecessary to reproduce the observed k_0 values. On the other hand at pH $\geqslant$ 6.0 we can assume only $[Ag(HL)]^{2+}$ and $[AgL]^+$ as the contributing silver species reacting with GX^-. The rate-laws in these extremes are, respectively,

$$k_0(K_a + [H^+])/[HGX]_T = k_1[H^+] + k_2K_a, \quad (11)$$

$$k_0(K_{a2} + [H^+])/[HGX]_T = k_3[H^+] + k_4K_{a2}. \quad (12)$$

The second-order rate constants (in 10^4 $M^{-1}\,s^{-1}$) evaluated from these linear plots (left-hand sides of Eqs. (11) and (12) versus $[H^+]$) are, respectively, $k_1 = 7.34$, $k_2 = 112$, $k_3 = 40.7$ and $k_4 = 19.2$. They reproduce the observed first-order rate constants satisfactorily (within 10%) using Eq. (10). We also tried to construct a global fit of the left-hand side of Eq. (10) with $[H^+]$; a third-order polynomial fit of the left-hand side of Eq. (10) with $[H^+]$ resulted a very close (within 2%) value of k_1 as found by Eq. (11) and less close agreement for the k_2 value. However, the constant term $k_4K_{a1}K_{a2}K_a$ yielded a negative value that could not be made positive even varying k_1 and k_2 values by more than 50%. We thus used a constant value of the term $k_4K_{a1}K_{a2}K_a$ (using the k_4 values as obtained from Eq. (12) and known K_{a1}, K_{a2} and K_a values) and k_1, and then started iteration to obtain the best values of the coefficients of the $[H^+]^2$ and $[H^+]$ terms, viz. k_2K_a and $k_3K_{a1}K_a$ respectively, until χ^2 for the fitting becomes acceptably small (of the order of 10^{-16}). The rate constants k_2 and k_3 evaluated in this way agree quite well (within 5%) with the values obtained from Eqs. (11) and (12). This is another support for the proposed scheme of reactions.

3.4. Mechanism

The observed sequence of rate constants $k_1 < k_2 > k_3 > k_4$ clearly demonstrates superior kinetic reactivity of protonated oxidants and deprotonated reductant over their counterparts – a trend normally followed in majority of redox reactions [16–19,33–37]. Among the rate constants evaluated (k_1–k_4), we find k_1 is the smallest indicating negligible reactivity of HGX towards the title Ag^{III} complex. We therefore did not include in the scheme the reaction between $[Ag(HL)]^{2+}$ and HGX. Moreover, the acid dissociation constants of $[Ag(H_2L)]^{3+}$ and HGX are quite distant and simultaneous equilibrium generation of both $[Ag(HL)]^{2+}$ and HGX is not appreciable.

The title silver(III) complex is a weak oxidant ($E_{1/2}$ $Ag^{III}/Ag^{II} = 0.05$ V) versus saturated calomel electrode (SCE) [6,38] but the thermodynamics of two electron oxidation of glyoxylic acid is much favourable, estimated to be around 0.3 V versus NHE. [2] Rate retardation in presence of acrylonitrile indicates generation of Ag^{II} and polymerisation initiating radicals, viz. HGX^+ and GX^-. A competitive decay of glyoxylate radicals occurs via fast consumption by Ag^{II} leading to products and initiation of acrylonitrile polymerisation – it explains lowering in reaction rate in presence of acrylonitrile. Generation of glyoxylate radicals by one-electron oxidation of glyoxylic acid is well-established by EPR spectroscopy [39]. However, we observed that the whole reaction course was EPR silent. We infer that the radicals produced from one-electron oxidation of glyoxylic acid react in a fast manner with Ag^{II} before they can escape into bulk solvent, thus evading detection. Unfortunately one electron potential data for HGX/HGX^+ couple as well as its self-exchange rate is unavailable. Thus we are unable to conclude the nature of electron transfer, inner or outer sphere.

Up to pH 2.5, where only $[Ag(H_2L)]^{3+}$ is the kinetically reactive oxidant, preequilibrium formation of any adducts between $[Ag(H_2L)]^{3+}$ and HGX or GX^- is at best poor, estimated to be within a maximum of the order of 10^{-1} M^{-1}. Such a low value does not confirm a

[2] Private communication with Dr. Philip N. Ross, Senior Scientist, Lawrence Berkeley National Laboratory. Glyoxylic acid can thermodynamically be considered as half formic acid and half oxalic acid. The redox potential should therefore be exactly half way between that of formic acid (0.14 V) and oxalic acid (0.49 V).

strong inner sphere attachment of glyoxylic acid with the metal center. Formation of a strong inner sphere adduct by glyoxylate with $[Mn(pd)_2(H_2O)_2]^+$ (Hpd = pentane 2,4 dione) has been proposed [40] and the formation constants of glyoxylate complexes of tripositive rare-earth-metal cations are also high [41]. The in-plane coordinatively saturated Ag^{III} in the title complex makes the situation a different one in aqueous solution where the replaceable water molecules attach only weakly with the axial positions of the Ag^{III} center. Replacement of water molecule by glyoxylate is thus expected to be weak at best. The estimated low value for the formation of adducts in the present study may be assigned to electrostriction [42–45] or any kind of it aided by hydrogen bonding [46,47] in the adducts.

A kinetically indistinguishable scheme where the adducts formed by electrostriction or aided by hydrogen bonding on the basal plane may be proposed. However, this proposition enforces a large separation between the oxidant and the reductant species that inhibits electron transfer within the adduct due to incorrect approach, as it were. Occurrence of electron transfer rather is justified when the reductant approaches the metal center along the axial site of the latter. A comparatively strong adduct formation between the complex and the oxalic acid or bioxalate ion [18] in comparison to glyoxylate indicate a much stronger binding with the more potentially complexing oxalate species inherited by their bidentacy.

Appendix A. Derivation of Eq. (10)

The acid dissociation constants for the title silver(III) complex are

$$K_{a1} = [Ag(HL)^{2+}][H^+]/[Ag(H_2L)^{3+}], \quad (A.1)$$

$$K_{a2} = [AgL^+][H^+]/[Ag(HL)^{2+}]. \quad (A.2)$$

The analytical concentration of the silver(III) complex, T_c, may be written as

$$T_c = [Ag(H_2L)^{3+}] + [Ag(HL)^{2+}] + [AgL^+],$$

Substituting $[Ag(HL)^{2+}]$ and $[AgL^+]$ in terms of $[Ag(H_2L)^{3+}]$ and rearranging, it results

$$T_c = [Ag(H_2L)^{3+}](1 + K_{a1}/[H^+] + K_{a1}K_{a2}/[H^+]^2),$$

whence we may write,

$$[Ag(H_2L)^{3+}]/T_c$$
= fraction of the silver(III)complex present as $[Ag(H_2L)^{3+}]$
$$= [H^+]^2/([H^+]^2 + K_{a1}[H^+] + K_{a1}K_{a2})$$
$$= \alpha_1 \quad \text{(say)}.$$

Thus, using (A.1) and (A.2) it yields

$$[Ag(H_2L)^{3+}] = \alpha_1 T_c; [Ag(HL)^{2+}] = K_{a1}\alpha_1 T_c$$

and

$$[AgL^+] = K_{a1}K_{a2}\alpha_1 T_c/[H^+]^2.$$

From the glyoxylic acid dissociation equilibrium

$$K_a = [GX^-][H^+]/[HGX],$$

it appears

$$[HGX]/([HGX] + [GX^-])$$
= fraction of glyoxylic acid present as

$$[HGX] = [H^+]/(K_a + [H^+]) = \alpha_2 \quad \text{(say)}.$$

Thus,

$$[HGX] = \alpha_2[HGX]_T$$

and

$$[GX^-] = K_a\alpha_2[HGX]_T/[H^+].$$

Now, for the proposed scheme (see text), rate of the reaction becomes

$$\text{Rate} = k_1\alpha_1\alpha_2 T_c[HGX]_T + k_2K_a\alpha_1\alpha_2 T_c[HGX]_T/[H^+] + k_2K_aK_{a1}\alpha_1\alpha_2 T_c[HGX]_T/[H^+]^2 + k_4K_aK_{a1}K_{a2}\alpha_1\alpha_2[HGX]_T/[H^+]^3,$$

whence, it becomes,

$$k_0[H^+]^3/([HGX]_T\alpha_1\alpha_2) = k_1[H^+]^3 + k_2K_a[H^+]^2 + k_3K_{a1}K_a[H^+] + k_4K_{a1}K_{a2}K_a.$$

Abstract

Tetradentate Schiff-base carboxylate-containing ligands, bis(2-pyridylmethyl)amino-2-ethanoic acid (pmea), bis(2-pyridylmethyl)amino-3-propionic acid (pmpa) and bis(2-pyridylmethyl)amino-4-butyric acid (pmba), react with copper(II) perchlorate to give rise to the one-dimensional polymeric chain complexes $\{[Cu(\mu\text{-pmea})](ClO_4)\cdot H_2O\}_n$ (**1**), $\{[Cu(\mu\text{-pmpa})](ClO_4)\cdot 2H_2O\}_n$ (**2**) and $\{[Cu(\mu\text{-pmba})(H_2O)](ClO_4)\cdot 3H_2O\}_n$ (**3**). These complexes have been characterized by X-ray crystallography, UV–Vis spectra and variable-temperature magnetic susceptibility measurements. In complexes **1**–**3**, distorted square-pyramidal copper(II) ions are sequentially bridged by *syn–anti* carboxylate groups. Each of the copper(II) ions exhibit CuN_3O_2 coordination environments with the three nitrogen atoms of the ligand and one oxygen atom belonging to the carboxylate group of an adjacent molecule occupying the basal positions and an oxygen atom (from a carboxylate group in the case of compounds **1**–**2** and from a water molecule in **3**) coordinated in the axial position. The electronic spectra of the complexes are significantly affected by the coordination geometry. Magnetic susceptibility measurements indicate that complexes **1**–**3** exhibit very weak ferromagnetic interactions. The magnetic behavior can be explained on the basis of the structural data.

1. Introduction

Self-assembly of metal ions and multidentate organic ligands has achieved great success in forming coordination polymers and multi-dimensional supramolecular networks [1–24] that can be used as catalysts [5], or exhibit novel properties such as electric conductivities [6], optical properties [7–9] and magnetism [10–24]. The architecture of the metal-organic polymers is based on well-defined coordination chemistry which takes into account the coordination nature of the metal ion, the structure of the organic ligands, and the possible counterion and solvents effects. It is well known that a carboxylate group can bridge two metal ions to give rise to a wide variety of polynuclear complexes ranging from discrete entities to multi-dimensional systems. The inclusion of a carboxylate group into the polydentate ligand allows the formation of trinuclear and tetranuclear complexes with *syn–anti* carboxylate bridging groups and a weak ferromagnetic exchange interaction between the copper(II) ions [18,19]. For example, the *syn–anti* carboxylate bridged linear trinuclear copper(II) complex $[Cu(H_2O)_4\{Cu(HL)\text{-}(H_2O)(ClO_4)\}_2][ClO_4]_2\cdot 2H_2O$ (HL = 6-methylamino-1,3-dimethyl-5-[(2′-carboxyphenyl)azo]uracil) revealed an octahedral and distorted square-pyramidal geometry about the central and terminal copper atoms, which exhibit a weak ferromagnetic interaction between nearest-neighbor copper(II) ions [19]. However, the *syn–anti* conformation corresponds to chain or layer compounds, which are characterized by a weak ferromagnetic

Chart 1.

or antiferromagnetic exchange interaction between the copper(II) ions [20–22]. In a zig-zag chain complex [{Cu(L)(Hpz)(H_2O)} · $2H_2O$] (H_2L = 5-[(2-carboxyphenyl)-azo]-1,3-dimethylbarbituric acid; Hpz = pyrazole) [22], the coordination geometry about the copper(II) ions is distorted square-pyramid, which has the *syn–anti* carboxylate bridging groups and reveals a weak intermolecular antiferromagnetic exchange interaction between the copper(II) ions. To further investigate the differences in the magnetic behavior, we have prepared and characterized the one-dimensional carboxylate-bridged copper(II) complexes {[Cu(μ-pmea)](ClO_4) · H_2O}$_n$ (**1**), {[Cu(μ-pmpa)](ClO_4) · $2H_2O$}$_n$ (**2**) and {[Cu(μ-pmba)-(H_2O)]-(ClO_4) · $3H_2O$}$_n$ (**3**) (where pmea = bis(2-pyridylmethyl) amino-2-ethanoic acid, pmpa = bis(2-pyridylmethyl)amino-3-propionic acid and pmba = bis(2-pyridylmethyl)-amino-4-butyric acid) (see Chart 1). The reactions of the tetradentate Schiff-base carboxylate-containing ligands with copper(II) perchlorate lead to *syn–anti* carboxylate-bridged complexes. Because the ligands do not saturate the coordination positions on the copper(II) ions, self-assembly reactions may occur through the deprotonated carboxylate groups, leading to carboxylate-bridged polymeric one-dimensional chains.

2. Experimental

2.1. Materials and physical methods

All the chemicals used in syntheses were of reagent grade and were used without further purification. Infrared spectra were recorded as KBr pellets on a Perkin–Elmer Paragon 1000 FT-IR spectrometer. Solution electronic spectra were obtained on a Jasco Uvidec-610 spectrophotometer. Solid state electronic spectra were measured by the diffuse reflectance method on a Shimadzu UV2401 PC/DRS spectrophotometer. Magnetic susceptibility data were collected in the temperature range 5.0–300 K in an applied field of 0.5 T with the use of a Quantum Design MPMS7 SQUID magnetometer. The diamagnetic corrections were calculated from Pascal's constants. Elemental analyses were carried out on a Perkin-Elmer 240C analyzer. FAB mass spectra were performed by using a Jeol JMS-HA 110A/110A spectrometer.

2.2. Syntheses of bis(2-pyridylmethyl)amino-2-ethanoic acid (pmea)

To a water solution (25 ml) of 2-picolyl chloride hydrochloride (3.61 g, 22 mmol) was added a water solution (25 ml) of glycine (0.75 g, 10 mmol) and sodium hydroxide (1.6 g, 40 mmol). After the mixture was heated to reflux for one day, the solution was extracted with chloroform. The removal of the solvent yielded the crude white product, which was purified by recrystallization from a 1:1 water–ethanol mixture. Yield: 1.72 g (67%). *Anal.* Calc. for $C_{14}H_{15}N_3O_2$: C, 65.35; H, 5.88; N, 16.33. Found: C, 65.46; H, 5.73; N, 16.42%. FAB mass (*m*/*z*): 257 $(M)^+$.

2.3. Syntheses of bis(2-pyridylmethyl)amino-3-propionic acid (pmpa)

The compound pmpa was prepared as colorless crystals in a manner similar to that of pmea by using β-alanine (0.90 g, 10 mmol) instead of glycine. Yield: 2.03 g (75%). *Anal.* Calc. for $C_{15}H_{17}N_3O_2$: C, 66.40; H, 6.32; N, 15.49. Found: C, 66.28; H, 6.40; N, 15.57%. FAB mass (*m*/*z*): 271 $(M)^+$.

2.4. Syntheses of bis(2-pyridylmethyl)amino-4-butyric acid (pmba)

The compound pmba was prepared as colorless crystals in a manner similar to that of pmea by using 4-aminobutyric acid (1.03 g, 10 mmol) instead of glycine. Yield: 2.04 g (72%). *Anal.* Calc. for $C_{16}H_{19}N_3O_2$: C, 67.35; H, 6.71; N, 14.73. Found: C, 67.43; H, 6.62; N, 14.65%. FAB mass (*m*/*z*): 285 $(M)^+$.

2.5. Syntheses of {[Cu(μ-pmea)](ClO_4) · H_2O}$_n$ (1)

A water solution (20 ml) of $Cu(ClO_4)_2 \cdot 6H_2O$ (185 mg, 0.5 mmol) and pmea (129 mg, 0.5 mmol) was heated to reflux for 1 h and then cooled to room temperature. The solution was filtered and left at room temperature until the blue crystals formed. The product was filtered and recrystallized from a hot water/acetonitrile (1:1 v/v, 10 ml) mixture. Yield: 155 mg (71%). *Anal.* Calc. for $C_{14}H_{16}ClCuN_3O_7$: C, 38.45; H, 3.69; N, 9.61. Found: C, 38.54; H, 3.75; N, 9.49%. IR (KBr, cm^{-1}): *ν*(CO) 1610, 1442; pyridine skeleton 1588, 1487, 1426; *ν*(Cl–O) 1092. FAB mass (*m*/*z*): 437 $(M)^+$.

2.6. Syntheses of $\{[Cu(\mu\text{-pmpa})](ClO_4)\cdot 2H_2O\}_n$ (2)

This compound was synthesized as blue crystals in a reaction similar to that of **1**, except for the use of pmpa (136 mg, 0.5 mmol) instead of pmea. Yield: 153 mg (65%). *Anal*. Calc. for $C_{15}H_{20}ClCuN_3O_8$: C, 38.39; H, 4.30; N, 8.95. Found: C, 38.47; H, 4.36; N, 8.87%. IR (KBr, cm^{-1}): ν(CO) 1610, 1439; pyridine skeleton 1558, 1482, 1421; ν(Cl–O) 1091, 1116. FAB mass (m/z): 469 $(M)^+$.

2.7. Syntheses of $\{[Cu(\mu\text{-pmba})(H_2O)](ClO_4)\cdot 3H_2O\}_n$ (3)

This compound was synthesized as blue crystals in a reaction similar to that of **1**, except for the use of pmba (143 mg, 0.5 mmol) instead of pmea. Yield: 174 mg (67%). *Anal*. Calc. for $C_{16}H_{26}ClCuN_3O_{10}$: C, 37.00; H, 5.05; N, 8.09. Found: C, 36.92; H, 5.14; N, 8.17%. IR (KBr, cm^{-1}): ν(CO) 1609, 1443; pyridine skeleton 1589, 1481, 1449; ν(Cl–O) 1092, 1117. FAB mass (m/z): 519 $(M)^+$.

Caution! Perchlorate salts of metal complexes with organic ligands are potentially explosive and should be handled in small quantities with care.

2.8. X-ray crystal structure analysis

Intensity data for the compounds were measured on an Enraf-Nonius CAD4 diffractometer using graphite-monochromated Mo Kα radiation in the ω–2θ scan mode. Accurate cell parameters and an orientation matrix were determined by least-squares fit of 25 reflections. The intensity data were corrected for Lorentz and polarization effects. All data were corrected for empirical absorption. The structure was solved direct methods [25] and the least-squares refinement of the structure was performed by the program SHELXL-97 [26]. For **1**, all non-hydrogen atoms were refined anisotropically. The hydrogen atoms were placed in calculated positions, allowing them to ride on their attached atoms with $U_{iso}(H) = 1.2U_{eq}(C)$. The two hydrogen atoms of the water molecule were not found. The rather higher R_1 and wR_2 values may be attributed mainly to the bad quality of the sample compound. For **2**, all hydrogen atoms except for the water hydrogen atoms Ow(2) were placed in calculated positions with U_{iso} to be 1.2 times the equivalent isotropic displacement of the parent atom. The two hydrogen atoms of Ow(1) were found from the difference Fourier map and their

positions were fixed with U_{iso} to be 1.2 times the equivalent isotropic displacement of the parent atom, but the hydrogen atoms of Ow(2) were not located. For **3**, all non-hydrogen atoms were refined anisotropically. All hydrogen atoms except for the water hydrogen atoms were placed in calculated positions with U_{iso} to be 1.2 times the equivalent isotropic displacement of the parent atom. The four hydrogen atoms of Ow(3) and Ow(4) were found from the difference Fourier map and their positions were fixed with U_{iso} to be 1.2 times the equivalent isotropic displacement of the parent atom. The rest of the water molecules were not found. Crystal parameters and details of the data collections and refinement are summarized in Table 1.

3. Results and discussion

3.1. Crystal structures

An ORTEP drawing of $\{[Cu(\mu\text{-pmea})](ClO_4)\cdot H_2O\}_n$ (**1**) with the atomic labelling scheme is shown in Fig. 1 and the selected bond lengths and angles are listed in Table 2. The monodeprotonated pmea ligand acts as a tetradentate ligand toward a copper(II) ion and as a monodentate ligand toward a neighboring copper(II) center. The copper atoms are bridged by a *syn–anti* carboxylate group to form a polymeric one-dimensional chain with an intramolecular Cu···Cu distance of 5.350(1) Å. Each copper(II) ion exhibits a CuN_3O_2 coordination environment with the three nitrogen atoms of the ligand and one oxygen atom belonging to the carboxylate group of an adjacent molecule occupying the basal plane [Cu–N(1) 1.978(9) Å, Cu–N(2) 2.060(8) Å, Cu–N(3) 2.002(8) Å, Cu–O(1) 1.947(7) Å] and an oxygen atom from a carboxylate group coordinated the axial position [Cu–O(2)″ 2.246(7) Å]. The geometry is somewhat distorted from square-pyramidal, as is apparent from the observed τ value of 0.25 (values of 0 and 1 are indicative of idealized square pyramidal and trigonal bipyramidal geometries, respectively) [27]. The copper atom lies 0.082(3) Å above the basal plane toward the carboxylate oxygen atom O(2)″. The N(1)–Cu–N(2) and N(2)–Cu–N(3) bite angles of the five-membered chelate rings are 82.7(4)° and 83.9(3)°, respectively. The dihedral angle (α) between the plane of the carboxylate group and CuN_3O plane is 65.8(7)°. The axial Cu–O(2)″ bond is not perfectly perpendicular to the CuN_3O plane with N–Cu–O(2)″ and O(1)–Cu–O(2)″ angles ranging from 81.8(3)° to 99.9(3)°. The secondary Cu–N(1) and Cu–N(3) bond distances are much shorter than the Cu–N(2) (tertiary amine) distance, indicating comparatively strong coordination.

An ORTEP drawing of $\{[Cu(\mu\text{-pmpa})](ClO_4)\cdot 2H_2O\}_n$ (**2**) with the atomic labelling scheme is shown in Fig. 2 and the selected bond lengths and angles are listed in Table 3. Each copper atom is coordinated by *syn–anti* carboxylate bridges to form a one-dimensional polymeric chain with an intramolecular Cu···Cu distance of 5.800(2) Å. The coordination environment of each copper(II) ion reveals a distorted square-pyramid with three nitrogen atoms and one oxygen atom belonging to the carboxylate group of an adjacent molecule [Cu–N(1) 1.982(5) Å, Cu–N(2) 2.023(4) Å, Cu–N(3) 1.980(4) Å, Cu–O(1) 1.943(4) Å] comprising the basal plane, whereas the apical position is filled by the carboxylate oxygen atom of the pmpa ligand [Cu–O(2)″ 2.393(4) Å]. The distortion τ value is 0.19. The copper atom is displaced 0.027(2) Å from the least-squares plane defined by the N_3O basal plane toward the carboxylate oxygen atom O(2)″. The value of the dihedral angle (α) is 77.7(3)°. The Cu–O(2)″ linkage is bent slightly off the

perpendicular to the CuN_3O plane by 0.3–12.1°. The average Cu–N_{py} (secondary) bond distance of 1.981 Å is similar to that found in **1** and shorter than the tertiary Cu–N(2) distance of 2.023(4) Å, giving comparatively strong coordination.

An ORTEP drawing of $\{[Cu(\mu\text{-pmba})(H_2O)](ClO_4)\cdot 3H_2O\}_n$ (**3**) with the atomic labelling scheme is shown in Fig. 3 and the selected bond lengths and angles are listed in Table 4. The copper atoms are bridged by a *syn–anti* carboxylate group of the pmba ligand to form a polymeric one-dimensional chain with an intramolecular Cu···Cu separation of 9.363(2) Å. Each copper(II) ion has a distorted square-pyramidal coordination, in which the basal plane is made up by the three nitrogen atoms of the ligand and one oxygen atom belonging to the carboxylate group of an adjacent molecule [Cu–N(1) 1.978(6) Å, Cu–N(2) 2.022(5) Å, Cu–N(3) 1.979(7) Å, Cu–O(1) 1.927(5) Å], while a water molecule is coordinated at the axial position [(Cu–Ow(1) 2.382(4) Å]. The observed τ value is 0.15. Each copper atom is slightly deviated from the N_3O basal plane by 0.057(2) Å, shifted toward the axially coordinated water molecule Ow(1). The value of the dihedral angle (α) is 86.5(3)°. The Cu–Ow linkage is bent slightly off the perpendicular to the CuN_3O plane by 0.0–5.6°. The average Cu–N (secondary amine) distance of 1.979 Å is shorter than that of Cu–N(2) (tertiary amine) [2.022(5) Å], which is similar to that observed for complex **2**.

3.2. Spectroscopic properties

The infrared spectra of the complexes show ν_{as}(COO) stretching frequencies at 1609–1610 and ν_{sym}(COO) at 1439–1443 cm^{-1}. The difference between ν_{as}(COO) and ν_{sym}(COO) is about 170 cm^{-1}, suggesting a bridging coordination mode for the carboxylate groups. The spectroscopic data of the complexes are listed in Table 5. The UV spectra of the complexes in water and solid state show absorption bands at 254 and 254–255 nm, which are assigned to the intraligand transitions in the complexes. The visible spectra of the complexes in water and solid state also contain broad bands at 675 and 678 nm for **1**, 673 and 675 nm for **2**, and 664 and 667 nm for **3**, characteristic of a copper(II) $d_{zx},d_{yz} \rightarrow d_{x^2-y^2}$

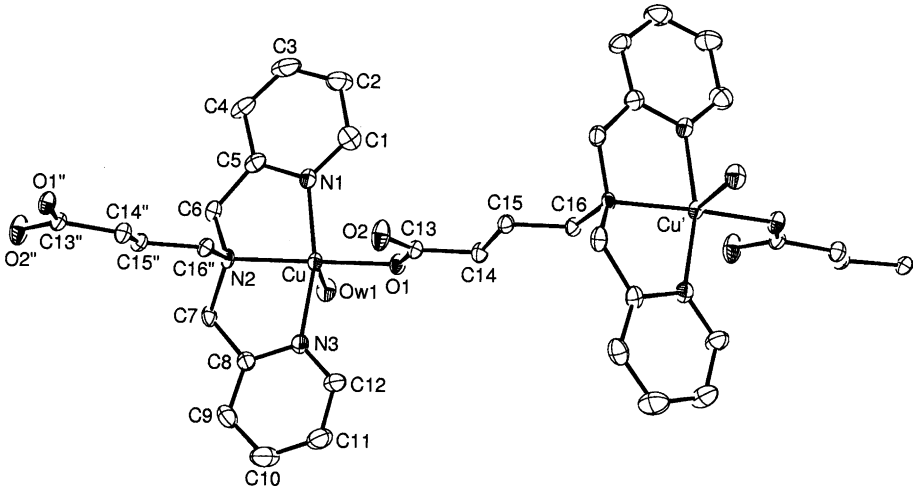

Fig. 3. An ORTEP diagram of $\{[Cu(\mu\text{-pmba})(H_2O)](ClO_4)\cdot 4H_2O\}_n$ (**3**) with the atom-numbering scheme (30% probability ellipsoids shown). The perchlorate, lattice water molecules and hydrogen atoms are omitted for clarity.

($^2B_1 \rightarrow {}^2E$) [28] transition in a tetragonal ligand field, in which the copper(II) has a distorted square-pyramidal coordination environment. The information obtained from the electronic spectra about the coordination configurations of the copper(II) ions in the complexes is in agreement with those found from the structural data.

3.3. Magnetic properties

The magnetic susceptibilities of the powder samples were investigated in the temperature range 5.0–300 K. The magnetic behaviors of the complexes **1**–**3** are shown in Figs. 4–6 in the form of the magnetic susceptibility (χ_m) and the effective magnetic moment (μ_{eff}) versus T plots. For **1**, as shown in Fig. 4, the μ_{eff} value at room temperature, 1.71 μ_B, is similar to the spin-only value for a copper(II) ion (1.73 μ_B). As the temperature is lowered, the μ_{eff} value gradually increases and exhibits a maximum at 19 K (1.86 μ_B) and rapidly decreases to 1.79 μ_B at 5 K. This behavior is indicative of the predominance of a ferromagnetic interaction. The data were fitted following the Baker et al. equation ($S = 1/2$) [29]

$$\chi_m = \frac{Ng^2\beta^2}{4KT}\left[\frac{1+Ax+Bx^2+Cx^3+Dx^4+Ex^5}{1+Fx+Gx^2+Hx^3+Ix^4}\right]^{2/3}, \quad (1)$$

where $x = |2J|/kT$ and $A = 5.7979916$, $B = 16.902653$, $C = 29.376885$, $D = 29.832959$, $E = 14.036918$, $F = 2.7979916$, $G = 7.0086780$, $H = 8.653644$, $I = 4.5743114$. The best fitting of the variable-temperature data to Eq. (1) gives $J = +0.21$ cm^{-1} with $g = 2.01$. The μ_{eff} value for compound **2** is 1.62 μ_B at room temperature, which is slightly lower than 1.73, increases gradually to 1.76 μ_B at 40 K, and then rapidly decreases to 1.54 μ_B at 5 K (Fig. 5), implying the presence of ferromagnetic interactions between Cu(II) atoms. The best fitting to Eq. (1) gives $J = +0.14$ cm^{-1} with $g = 2.02$. As

[b] Ref. [24].
[c] Water molecule.

shown in Fig. 4, the μ_{eff} value for **3** is 1.61 at 300 K, which is slightly lower than 1.73, increases gradually to 1.83 μ_B at 19 K, and then sharply decreases to 1.72 μ_B at 5 K ($J = +0.09$ cm^{-1} with $g = 2.01$), suggesting the existence of very weak ferromagnetic interactions between Cu(II) atoms.

For a comparison purpose, the structural and magnetic data for complexes **1**–**3** are given in Table 6 along with the other *syn–anti* carboxylate-bridged copper(II) complexes. All of the complexes show very weak intramolecular ferromagnetic interactions between the copper(II) centers along the chain via the bridging carboxylate group. The magnetic coupling constant can be expected as a sum of both ferromagnetic and antiferromagnetic contributions [30]. When the copper(II) ions are bridged by polyatomic extended ligands, the ferromagnetic contribution is weak [31]. However, the magnitude of antiferromagnetic interactions is primarily governed by an overlap of two magnetic orbitals centered on the nearest-neighbor copper(II) ions. As pointed out by other authors [18,23,31], for the *syn–anti* conformation of the Cu–O–C–O′–Cu′ bridging network, the contributions between the 2p orbitals of the O and O′ atoms belonging to the magnetic orbitals centered on Cu and Cu′ are unfavorably oriented to give a significant overlap [18,31]. This would lead to a negligible antiferromagnetic contribution so that the weak ferromagnetic one becomes predominant. Furthermore, the non-planarity of the Cu–O–C–O′–Cu′ bridging network is expected to decrease the overlap of the magnetic orbitals in the bridging region, which is favoring ferromagnetic exchange couplings. Similar results are also reported through the carboxylate-bridged copper(II) complexes $\{[Cu(\mu\text{-pmae})(H_2O)](ClO_4)\cdot 2H_2O\}_n$ (pmae = 2-pyridylmethyl-2-aminoethanoic acid, $J = +4.3$ cm^{-1}) [23] and $\{[Cu(\mu\text{-tana})](ClO_4)\}_n$(tana = 1,4,7-triazacyclononane-N-acetic acid, $J = +2.8$ cm^{-1}) [24]. On the other hand, structural factors such as Cu···Cu separation, α dihedral angles and τ parameters seem to be significantly affecting the magnetic magnitude. The values of the ferromagnetic coupling constant decrease in the order **1** > **2** > **3**. This fact may be attributed to the increase of the Cu···Cu separation and α dihedral angles. We can see the distortion parameter (τ) of compounds **1**–**3** and $\{[Cu(\mu\text{-pmae})(H_2O)](ClO_4)\cdot 2H_2O\}_n$, which all exhibit the *syn–anti*-conformation, leading to a ferromagnetic coupling. However, compound **1** shows a smaller J value than $\{[Cu(\mu\text{-pmae})(H_2O)](ClO_4)\cdot 2H_2O\}_n$, in which the τ values are 0.25 and 0.16, respectively. It is indicated that the tetragonal pyramidal geometry with a *syn–anti* bridged copper(II) ion may cause the exchange coupling through the carboxylate group to be less operative in comparison with the geometry close to the square-planar pyramid.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Center, CCDC No. 215289 for compound **1**, 215290 for compound **2** and 215291 for compound **3**. Abstract

The heterovalent heterodinuclear complex $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2](ClO_4)_4 \cdot 3H_2O$ (**1**) and the isovalent homodinuclear complex $[(bpy)_2Ru^{II}(trzdc)Ru^{II}(bpy)_2](ClO_4) \cdot 5H_2O$ (**2**), where H_3pzbzim = pyrazole-3,5-bis(benzimidazole), H_3trzdc = 1,2,4-triazole-3,5-dicarboxylic acid and bpy = 2,2′-bipyridine, have been synthesized and spectroscopically characterized. Complex **1** undergoes one electron oxidation at 1.20 V (versus Ag/AgCl) in acetonitrile, while for complex **2**, two stepwise oxidations occur at 0.63 and 0.81 V with the comproportionation constant K_c, for the equilibrium $Ru^{II}Ru^{II} + Ru^{III}Ru^{III} \rightleftharpoons 2Ru^{II}Ru^{III}$, equal to 1.11×10^3 at 298 K. The acid dissociation constants of the benzimidazole moieties of complex **1** have been determined in acetonitrile–water (3:2) by spectrophotometric titrations. Both complexes **1** and **2** exhibit luminescence spectra and the quantum yields obtained for methanol–ethanol (1:4) glass (at 77 K) are $\varphi = 3.1 \times 10^{-2}$ for **1** and 3.5×10^{-2} for **2**.

1. Introduction

Intramolecular electron and energy transfer processes in di- and oligonuclear ruthenium(II) and osmium(II) polypyridine complexes whose mononuclear entities are linked by conjugated bridging ligands have received considerable attention [1–6]. The directional flow of electron/or energy gets facilitated when there is asymmetry in the multicomponent system. Such asymmetry can be introduced either by using ligands which differ in donor–acceptor property or using heterometallic sites. The features associated with bridging ligands such as length, rigidity, topology, conjugation, charge and the number of dissociable hydrogen atoms play important roles in this context. Two types of bridging ligands are generally used for this. The first type, which have found maximum use, are electron-poor oligomeric pyridine/pyrazine/pyrimidine derivatives and they mediate metal–metal interaction through low-lying π^* orbitals (LUMO) [1,7–9]. The electron-rich second type of ligands which are triazole, pyrazole or benzimidazole derivatives, on the other hand, participate in intermetallic interactions via hole transfer mechanism [10–12]. The second type of ligand can be made anionic by deprotonating the constituent NH protons.

In earlier publications [12–15], we have reported the synthesis, structure, spectroscopic properties and proton-coupled redox activities of mononuclear and diastereoisomerically pure dinuclear ruthenium(II) and osmium(II) polypyridine complexes with pyrazole-3,5-bis(benzimidazole)[H_3pzbzim] and pyrazole-3,5-bis(benzothiazole)[Hpzbzth] as the bridging ligands. More recently [16], we have reported the comparative physico-chemical properties of the homochiral *rac* ($\Lambda\Lambda/\Delta\Delta$) and heterochiral *meso* ($\Lambda\Delta/\Delta\Lambda$) diastereoisomers of $Ru^{II}Ru^{II}$, $Ru^{II}Os^{II}$ and $Os^{II}Os^{II}$ complexes

derived from pyrazole-3,5-dicarboxylic acid (H_3pzdc) and 2,2′-bipyridine (bpy).

The present study is concerned with the chemistry of the heterobimetallic complex $[(bpy)_2Rh^{III}(H_2pzbzim)Ru^{II}(bpy)_2]^{4+}$ on the one hand and 1,2,4-triazole-3,5-dicarboxylic acid [H_3trzdc]-bridged homodinuclear complex $[(bpy)_2Ru^{II}(trzdc)Ru^{II}(bpy)_2]^{+}$ on the other hand.

2. Experimental

2.1. Materials

All chemicals were obtained from commercial sources and were used as received. Pyrazole-3,5-bis(benzimidazole) [13], *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ [17] and *cis*-$[Rh(bpy)_2(H_2O)_2](ClO_4)_3\cdot H_2O$ [18] were prepared according to the reported methods. 1,2,4-triazole-3,5-dicarboxylic acid was prepared by $KMnO_4$ oxidation of 4-amino-3,5-dimethyl-1,2,4-triazole [19] which, in turn, was obtained by a modified method [20]. To a stirred aqueous solution (1 dm^3) of 4-amino-3,5-dimethyl-1,2,4-triazole (25.0 g, 0.22 mol) was added finely ground $KMnO_4$ (158 g, 1 mol) over a period of 2 h, keeping the temperature of the mixture to 90–95 °C. After additional heating and stirring for 8 h, the precipitated MnO_2 was removed by filtration. The filtrate was diluted to ca. 1.5 dm^3, cooled and carefully neutralized with 6 M HCl and then 100 cm^3 of conc. HCl was added. The 1,2,4-triazole-3,5-dicarboxylic acid precipitated was collected by filtration and washed with water, till the washing was free from chloride; yield 28 g (80%).

2.2. Preparation of the complexes

2.2.1. $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2](ClO_4)_4\cdot 3H_2O$ (**1**)

A mixture of $[(bpy)_2Ru(H_3pzbzim)](ClO_4)_2\cdot 2H_2O$ (0.48 g, 0.5 mmol) [13], triethylamine (0.05 g, 0.5 mmol) and *cis*-$[Rh(bpy)_2(H_2O)_2](ClO_4)_3\cdot H_2O$ (0.38 g, 0.5 mmol) [18] in 50 cm^3 of 1:1 ethanol–water mixture was heated under reflux in a nitrogen atmosphere for 60 h. The solution was rotary evaporated to ca. 20 cm^3 and then filtered. To the filtrate 1 g of $NaClO_4$ dissolved in 5 cm^3 water was added and the mixture was kept at 10 °C for 2 h. A brick red microcrystalline product that separated was collected by filtration. The ^1H NMR spectrum of this product indicated it to be a 3:1 mixture of two diastereoisomers. The major diastereoisomer was isolated in pure form after three successive recrystallization from 2:1 ethanol-acetronitrile mixture. Yield: 0.32 g, 40%. *Anal*. Found: C, 43.16; H, 3.34; N, 12.46. $C_{57}H_{49}Cl_4N_{14}O_{19}RuRh$ requires: C, 43.31; H, 3.10; N, 12.41%. IR (KBr): 3400br, 1625s, 1600s, 1495m, 1480m, 1460s, 1440s, 1420s, 1385m, 1360m, 1310m, 1270s, 1245w, 1100s, br, 770s, 750s, 730m, 630s cm^{-1}.

2.2.2. $[(bpy)_2Ru(trzdc)Ru(bpy)_2](ClO_4)\cdot 5H_2O$ (**2**)

To a stirred suspension of *cis*-$[Ru(bpy)_2Cl_2]\cdot 2H_2O$ (1.04 g, 2 mmol) in ethanol (100 cm^3) was added solid $AgClO_4$ (0.84 g, 4 mmol). The precipitated AgCl was filtered off after 0.5 h and the filtrate was then treated with H_3trzdc (0.16 g, 1 mmol) and triethylamine (0.3 g, 3 mmol). The solution was refluxed for 8 h under nitrogen, after which it was filtered and the filtrate was rotary evaporated to ca. 30 cm^3. The solution was kept in an ice chest, during which time a red orange microcrystalline product deposited. This was collected by filtration and recrystallized twice from methanol. Yield: 0.88 g, 75%. *Anal*. Found: C, 44.75; H, 3.72; N, 13.21. $C_{44}H_{42}ClN_{11}O_{13}Ru_2$ requires: C, 45.14; H, 3.59; N, 13.17%. IR (KBr): 3400br, 1610s, 1590m, 1485m, 1460s, 1425s, 1340m, 1315m, 1100s, br, 845m, 772m, 730m, 665w, 630s, 610w cm^{-1}.

Caution! The perchlorate salts reported in this study are potentially explosive and therefore should be handled with care.

2.3. Physical measurements

The C, H and N analyses were performed on a Perkin–Elmer 2400 elemental analyzer. Infrared spectra were recorded on a Perkin–Elmer 783 spectrophotometer using KBr discs. ^1H NMR spectra were recorded on a Bruker Avance DPX 300 spectrometer using $(CD_3)_2SO$ solutions.

The electrochemical measurements were carried out with a BAS 100 B electrochemistry system using a three-electrode assembly comprising a Pt or glassy carbon working electrode, Pt auxiliary electrode and an aqueous Ag/AgCl reference electrode. The electrochemical measurements (CV, DPV and SWV) were carried out at 25 °C under a nitrogen atmosphere in an acetonitrile solution of the complex (ca. 1 mmol dm^{-3}) with tetraethylammonium perchlorate (0.1 mol dm^{-3}) as the supporting electrolyte. The reference electrode was separated from the bulk electrolyte by a salt bridge containing the supporting electrolyte in 1:1 acetonitrile–water. The potentials measured were automatically compensated for the *iR* drop and under this condition

the ferrocene/ferrocenium couple occurred at 0.36 V with a peak-to-peak separation of 62 mV.

Electronic absorption spectra were recorded on a Shimadzu UV-2100 spectrophotometer. For determining the acid dissociation constants of the bridging ligand in complex **1**, spectrophotometric titrations were carried out with a series of acetonitrile–water (3:2) solutions containing the same amount of the complex and buffer solutions were added to adjust the pH in the range 2–12 keeping the ratio of acetonitrile to water (3:2) fixed.

Emission spectra were recorded on a Perkin–Elmer LS 55 fluorescence spectrophotometer in methanol–ethanol (1:4) solution at 298 and 77 K. Quantum yields of the complexes at both the temperatures were determined by a relative method using $[Ru(bpy)_3]^{2+}$ in the same solvent mixture as the standard. The quantum yields were calculated [21] using the following equation:

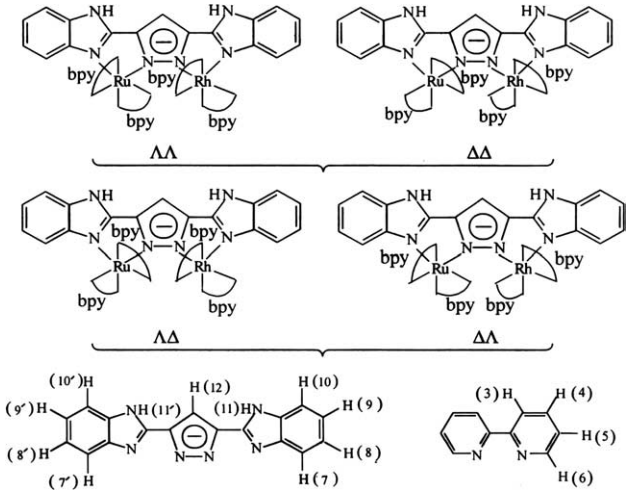
$$\varphi = \varphi_{std}(A_{std}/A)(I/I_{std})\left(\eta^2/\eta^2_{std}\right), \quad (1)$$

where φ and φ_{std} are the quantum yields of unknown and standard samples, A and A_{std} are the absorbances at the excitation wavelength and η and η_{std} are the refractive indices of the solutions.

3. Results and discussion

3.1. $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2](ClO_4)_4 \cdot 3H_2O$ (*1*)

The heterodinuclear complex **1** was obtained by reacting one equivalent each of $[(bpy)_2Ru(H_3pzbzim)](ClO_4)_2 \cdot 2H_2O$ [13], *cis*-$[(bpy)_2Rh(H_2O)_2](ClO_4)_3 \cdot H_2O$ [18] and triethylamine over a long period in ethanol–water (1:1) solution. As shown in Scheme 1, due to the inherent chirality for each of the metal centres the heterobimetallic complex **1** should have two pairs of homochiral ($\Lambda\Lambda/\Delta\Delta$) and heterochiral ($\Lambda\Delta/\Delta\Lambda$) diastereoisomers.



Scheme 1.

3.1.1. ^1H NMR spectra

In a previous publication [13], we have reported that in the homodinuclear ruthenium(II) complexes $[(ppy)_2Ru(H_2pzbzim)Ru(ppy)_2]^{3+}$ (ppy = polypyridine), the aromatic H(7) proton of the bridging ligand (see Scheme 1 for numbering) is most shielded due to the anisotropic ring current effect of the polypyridine ligands. In contrast, the benzimidazole H(11) proton appears at the lowest field. The small but significant differences in chemical shifts observed for the H(7) doublet or the H(11) singlet of the homochiral ($\Lambda\Lambda/\Delta\Delta$) and heterochiral ($\Lambda\Delta/\Delta\Lambda$) diastereoisomers have been used as the markers to identify and quantify the relative amounts of the diastereoisomers in a mixture. In the case of $[(bpy)_2Ru(H_2pzbzim)Ru(bpy)_2]^{3+}$, the H(7) and H(11) resonances of the *meso* ($\Lambda\Delta$) form are observed at 5.04 and 14.38 ppm, respectively, as against those observed at 5.06 and 14.46 ppm for the rac ($\Lambda\Lambda/\Delta\Delta$) form.

As compared to the homodinuclear complexes, the ^1H NMR spectrum of the heterodinuclear complex $[(bpy)_2Ru(H_2pzbzim)Rh(bpy)_2]^{4+}$ (**1**) will be more complex because in this case the two-halves of the bridging ligand $(H_2pzbzim)^-$ are no longer equivalent. Indeed, the ^1H NMR spectrum of complex **1**, as isolated, showed a large number of overlapping signals, including two pairs of doublets at 4.80 and 5.12 ppm (major pair) and 5.07 and 5.21 ppm (minor pair) and two pairs of singlets at 14.44 and 14.36 ppm (major pair) and 14.50 and 14.62 ppm (minor pair). The ratio between the areas of major and minor signals was found to be about a 3:1, indicating that complex **1**, as isolated, contained two diastereoisomers in a 3:1 ratio. The major diastereoisomer was separated in the pure form by recrystallizing the mixture three times from ethanol–acetonitrile (2:1) and its ^1H NMR spectrum is shown in Fig. 1. It should be noted that of the two doublets at 4.80 and 5.12 ppm, the more shielded one can be attributed to H(7 or 7′) in the vicinity of the electron rich

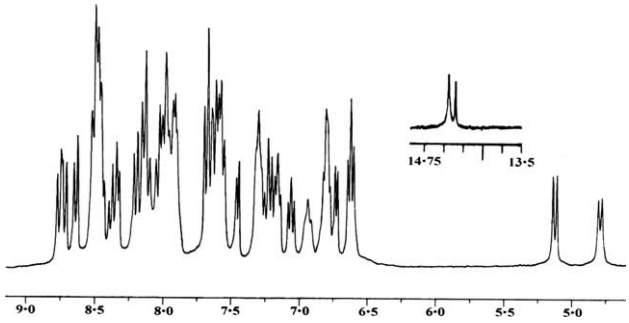


Fig. 1. ^1H NMR spectrum of the major diastereoisomer of $[(bpy)_2Ru(H_2pzbzim)Rh(bpy)_2]^{4+}$ (**1**) in $(CD_3)_2SO$.

ruthenium(II) site. The same consideration applies to the NH(11/11′) proton.

3.1.2. Redox behavior

The redox activities of complex **1** have been studied in acetonitrile solution over the potential range from +1.5 to −2.2 V (versus Ag/AgCl) using CV, DPV and SWV techniques. Fig. 2 shows the cyclic voltammogram of the compound in the positive potential regime. A reversible redox couple due to Ru^{II}/Ru^{III} with $E_{1/2} = 1.20$ V and a peak-to-peak separation of 65 mV is observed. The values of $E^{ox}_{1/2}$ obtained from DPV and SWV have agreed within 5 mV. In the negative potential range from −1 to −2.2 V, the compound undergoes three quasi-reversible reduction processes with $E^{red}_{1/2} = -2.06$, −1.90 and −1.62 V. The current height of the first couple, both in the CV and DPV, is twice that of the second or third, indicating that the first electron transfer process is dielectronic. It should be noted that these electron transfers occur to the π-LUMO of bpy, each of which can accept two electrons.

It is of interest to compare the Ru^{II}/Ru^{III} oxidation potential $E^{ox}_{1/2}$ of $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2]^{4+}$ ($E^{ox}_{1/2} = 1.20$ V) with those of $[(bpy)_2Ru(H_3pzbzim)]^{2+}$ ($E^{ox}_{1/2} = 0.89$ V) [15] and $[(bpy)_2Ru^{II}(H_2pzbzim)Ru^{II}(bpy)_2]^{3+}$ ($E^{ox}_{1/2} = 1.01$ and 1.23 V). As compared to the dicationic mononuclear complex ($E_{1/2} = 0.89$ V), the first metal centre in the tricationic homodinuclear complex is oxidized at a more positive potential (1.01 V). On the other hand, the removal of an electron from the tetrapositively charged $[Ru^{II}Rh^{III}]^{4+}$ cation (1.20 V) is almost as difficult as that of the similarly charged $[Ru^{II}Ru^{III}]^{4+}$ cation (1.23 V). Clearly, the redox behavior of these complex species are strongly dependent on the overall charge of the complex species. Further, when complex **1** is treated with two equivalents of a strong base the two benzimidazole protons of the bridging ligand get deprotonated to produce $[(bpy)_2Ru^{II}(pzbzim)Rh^{III}(bpy)_2](ClO_4)_2$. The $E_{1/2}$ of this dicationic species is shifted to a considerably low positive potential, 0.86 V. This value, in turn, is close to that of the mononuclear dipositively charged $[(bpy)_2Ru^{II}(H_3pzbzim)]^{2+}$ cation (0.89 V).

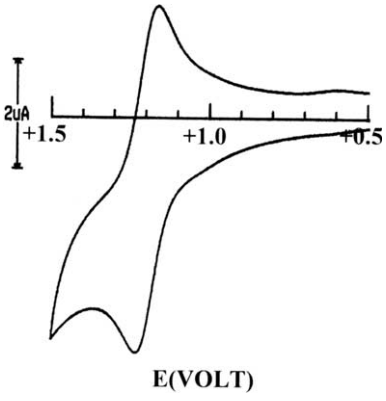

Fig. 2. Cyclic voltammogram of $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2]^{4+}$ (**1**) in acetonitrile.

3.1.3. Absorption spectra and protonic equilibria

The absorption spectrum of complex **1** in acetonitrile exhibits four bands at 295 (67 400), 315sh (49 200), 490 (5490) and 480 nm (6050) with their molar absorptivities (ε/dm^3 mol^{-1} cm^{-1}) given in parentheses. The two bands observed at 295 and 315 nm, which also appeared in a similar region in the mononuclear and homodinuclear ruthenium(II) complexes, are considered to be due to intraligand π–π^* transition. The other two bands at 440 and 480 nm with comparable intensities are due to metal-to-ligand $Ru(d\pi) \rightarrow bpy(\pi^*)$ charge transfer transitions.

Inasmuch as the imidazole NH group of the bridging ligand can be subjected to deprotonation, we have been interested to determine the pK_a values for $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2]^{4+}$ and compare them with those obtained for $[(bpy)_2Ru^{II}(H_3Pzbzim)]^{2+}$ [15] and $[(bpy)_2Ru^{II}(H_2pzbzim)Ru^{II}(bpy)_2]^{3+}$ [13]. The influence of pH on the absorption spectral behavior of complex **1** in acetonitrile–water (3:2) is shown in Fig. 3. With the increase of pH, the intensity of the peak at 430 nm decreases with a concomitant increase of the peak intensity at 490 nm. The consecutive absorption curves pass through two isosbestic points at 395 and 440 nm and indicate the occurrence of the following acid–base equilibria:

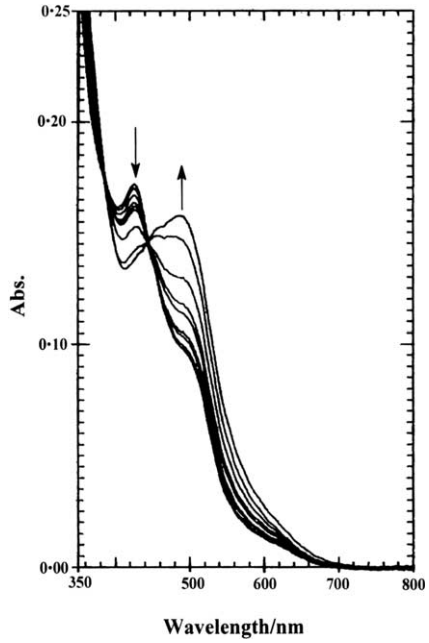

Fig. 3. Changes in the absorption spectrum of $[(bpy)_2Ru(H_2pzbzim)Rh(bpy)_2]^{4+}$ (**1**) with the variation of pH in acetonitrile–water (3:2).

$$\begin{array}{c}[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2]^{4+}\\ K_1 \Uparrow\Downarrow\\ [(bpy)_2Ru^{II}(Hpzbzim)Rh^{III}(bpy)_2]^{3+} + H^+\\ K_2 \Uparrow\Downarrow\\ [(bpy)_2Ru^{II}(pzbzim)Rh^{III}(bpy)_2]^{2+} + H^+\end{array} \quad (2)$$

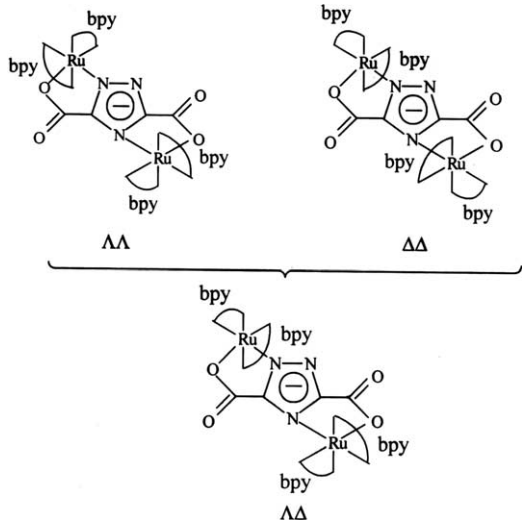
The pK values have been evaluated from the absorption data pertaining to the pH ranges 4–8 for pK_1 and 8–12 for pK_2 using the following equation:

$$pH = pK - \log\frac{A - A_0}{A_f - A}, \quad (3)$$

where A_0, A_f and A refer to the absorbances at the initial, final and intermediate pH values of a given wavelength. The pK values thus obtained are p$K_1 = 5.45(5)$ and p$K_2 = 9.85(5)$. Clearly, pK_1 refers to the dissociation constant of the benzimidazole unit attached to the relatively more electron withdrawing Rh^{III}, while pK_2 is related to the corresponding unit bound to Ru^{II}. It is interesting to note that for $[(bpy)_2Ru^{II}(H_2pzbzim)Ru^{II}(bpy)_2]^{3+}$ p$K_1 = 7.95$ and p$K_2 = 9.75$ [13]. Thus, relative to the Ru^{II} site, coordination of (H_2pzbzim) to Rh^{III} leads to considerable diminution of its first acid dissociation constant, albeit the second dissociation constant remains almost unchanged.

3.1.4. Emission spectrum

The emission spectral behavior of complex **1** has been studied at 298 and 77 K in methanol–ethanol (1:4) solutions and glass, respectively. As shown in the inset of Fig. 4, at room temperature a very weak and broad emission occurs at about 655 nm. On the other hand, at 77 K, excitation of either of the MLCT bands at 435 and 480 nm gives rise to a well defined luminescence spectrum with its peak at 632 nm. The quantum yield of this emission process is 3.1×10^{-2}. It may be mentioned that in the case of $[(bpy)_2Ru(H_2pzbzim)Ru(bpy)_2]^{3+}$, the emission spectrum at 77 K shows its peak at 640 nm with a quantum yield of 7.5×10^{-2} [13].



Scheme 2.

3.2. $[(bpy)_2Ru(trdc)Ru(bpy)_2](ClO_4)\cdot 5H_2O$ (2)

The homodinuclear ruthenium(II) complex **2** was obtained by reacting two equivalents of in situ generated $[(bpy)_2Ru(EtOH)_2]^{2+}$ with one equivalent of 1,2,4-triazole-3,5-dicarboxylic acid (H_3trzdc) and three equivalents of triethylamine in ethanol. As shown in Scheme 2, complex **2** will be formed as a mixture of homochiral (ΛΛ/ΔΔ) *rac* and heterochiral (ΛΔ) *meso* diastereoisomers.

3.2.1. ^1H NMR spectrum

The ^{1}H NMR spectrum of complex **2** is shown in Fig. 5. Since each of the bipyridine signals, if fully resolved, should represent a pair of protons, the observed spectrum on that basis accounts for the presence of 64

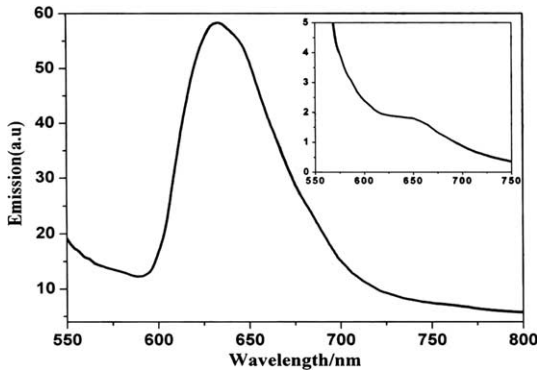


Fig. 4. Luminescence spectrum observed for $[(bpy)_2Ru(H_2pzbzim)Rh(bpy)_2]^{4+}$ (**1**) in frozen methanol–ethanol (1:4) glass at 77 K. Inset shows the spectrum observed at 298 K.

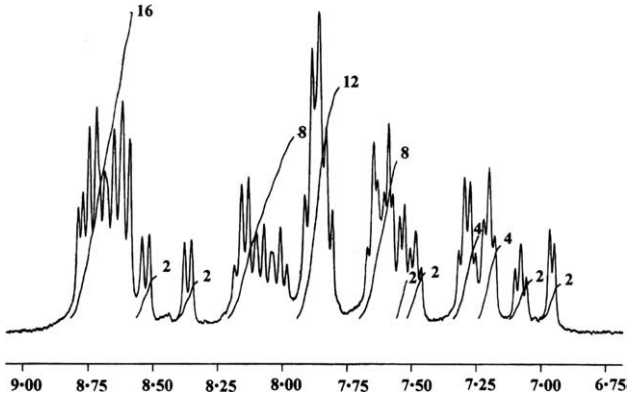

Fig. 5. ^{1}H NMR spectrum of $[(bpy)_2Ru(trzdc)Ru(bpy)_2]^+$ (**2**) in $(CD_3)_2SO$. The integral traces indicate the number of protons involved.

protons, which, however, is double the number of protons that $[(bpy)_2Ru(trzdc)Ru(bpy)_2]^+$ (**2**) contains. Clearly, this indicates that complex **2** is a 1:1 mixture of the homochiral and heterochiral diastereoisomers. This is further borne out by the fact that the proton integral traces in Fig. 5 consistently show 1:1 correspondence of the two diastereoisomers. The separation of the diastereoisomers based on fractional recrystallization turned out to be an unsatisfactory experience. So far, we have not been able to isolate the pure diastereoisomers and consequently subsequent studies have been made with the mixture.

3.2.2. Redox behavior

The electrochemical characteristics of complex **2** have been examined by cyclic voltammetry (CV), square wave voltammetry (SWV) and differential pulse voltammetry (DPV). Fig. 6 shows the occurrence of two fully reversible $Ru^{II}Ru^{II}/Ru^{II}Ru^{III}$ and $Ru^{II}Ru^{III}/Ru^{III}Ru^{III}$ redox couples each with peak-to-peak separation (ΔE_p) of 60 mV. The two $E^{ox}_{1/2}$ values are 0.63 and 0.81 V and the separation between these two redox couples is 0.18 V. It may be mentioned that in the case of the two diastereoisomers of the pyrazolate-3,5-dicarboxylate-bridged diruthenium complex $[(bpy)_2Ru(pzdc)\text{-}Ru(bpy)_2]^+$ the following values were obtained [16]:

$$rac: E^{ox}_{1/2} = 0.75, 0.92\ \text{V}; \quad \Delta E_{1/2} = 0.17\ \text{V},$$

$$meso: E^{ox}_{1/2} = 0.71, 0.91\ \text{V}; \quad \Delta E_{1/2} = 0.20\ \text{V}.$$

Thus, relative to either of the above mentioned diastereoisomers, complex **2** undergoes stepwise oxidations more easily. However, the $\Delta E_{1/2}$ value of **2** is almost same as that of the 1:1 mixture of *rac* and *meso* diastereoisomers of $[(bpy)_2Ru(pzdc)Ru(bpy)_2]^+$. Accordingly, the equilibrium constant K_c for the comproportionation reaction, $Ru^{II}Ru^{II} + Ru^{III}Ru^{III} \rightleftharpoons 2Ru^{II}Ru^{III}$ ($K_c = \exp[nF\Delta E_{1/2}/RT]$), is similar for the two cases ($K_c = 1.11 \times 10^3$ for **2** at 298 K).

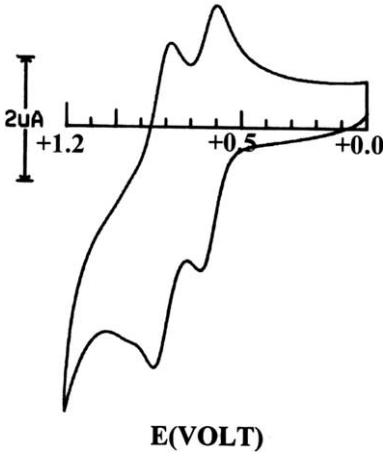

Fig. 6. Cyclic voltammogram of $[(bpy)_2Ru(trzdc)Ru(bpy)_2]^+$ (**2**) in acetonitrile.

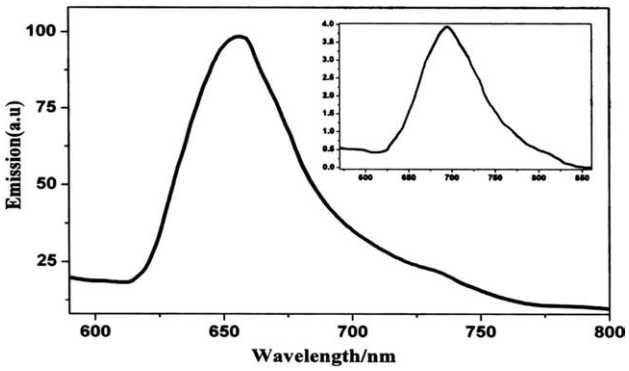

Fig. 7. Luminescence spectrum of $[(bpy)_2Ru(trzdc)Ru(bpy)_2]^+$ (**2**) in frozen methanol–ethanol (1:4) glass at 77 K. Inset shows the spectrum observed at 298 K.

The electrochemical response of complex **2** in the reductive mode is indicative of the occurrence of two bipyridine-based two-electron reductions at −1.65 and −2.10 V. The simultaneous transfer of one electron to two complimentary bipyridine moieties could not be resolved by square wave or differential pulse voltammetric techniques.

3.2.3. Absorption and emission spectra

The absorption spectrum of complex **2** in methanol–ethanol (1:4) solution exhibits two strong bands in the visible region at 420 nm ($\varepsilon = 10\,520$ dm^3 mol^{-1} cm^{-1}) and 500 nm ($\varepsilon = 13\,840$ dm^3 mol^{-1} cm^{-1}), which are considered to be due to metal-to-ligand $Ru(d\pi) \rightarrow bpy(\pi^*)$ charge transfer transitions. The emission spectra of complex **2** have been recorded at 298 and 77 K in methanol–ethanol (1:4) solution and glass, respectively, and the spectra observed are shown in Fig. 7. As shown in the inset of Fig. 7, excitation of the MLCT band at 500 nm at room temperature gives rise to a luminescent band with its peak at 695 nm. This band appears to be due to the emission from a ^{3}MLCT excited state, corresponding to a spin-forbidden $Ru \rightarrow bpy^*$ transition [22]. As compared to the fluid solution spectrum, the luminescence peak of complex **2** in frozen glass at 77 K gets blue-shifted to 655 nm (Fig. 7) with considerable increase in intensity. The quantum yield of complex **2** at 77 K ($\varphi = 3.5 \times 10^{-2}$) is about twenty five times greater than that at 298 K ($\varphi = 1.4 \times 10^{-3}$).

4. Conclusion

Using the bridging ligands pyrazole-3,5-bis(benzimidazole)[H_3pzbzim] and 1,2,4-triazole-3,5-dicarboxylic acid [H_3trzdc] the heterodinuclear complex $[(bpy)_2Ru^{II}(H_2pzbzim)Rh^{III}(bpy)_2](ClO_4)_4 \cdot 3H_2O$ (**1**) and the homodinuclear complex $[(bpy)_2Ru^{II}(trzdc)\text{-}Ru^{II}\text{-}(bpy)_2](ClO_4) \cdot 5H_2O$ (**2**) have been synthesized. The

physico-chemical properties of the major diastereoisomeric form of complex **1** and the 1:1 mixture of the *rac* and *meso* forms of complex **2** have been investigated. The redox potentials for the $Ru^{II}Rh^{III}/Ru^{III}Rh^{III}$ couple in complex **1** ($E_{1/2} = 1.20$ V) has been found to be almost equal to that of the $Ru^{II}Ru^{III}/Ru^{III}Ru^{III}$ couple in the $[(bpy)_2Ru^{II}(H_2pzbzim)Ru^{III}(bpy)_2]^{4+}$ species ($E_{1/2} = 1.23$ V). On the other hand, the deprotonated $[(bpy)_2Ru^{II}(pzbzim)Rh^{III}(bpy)_2]^{2+}$ cation undergoes oxidation at a much less positive potential ($E_{1/2} = 0.86$ V). When the acid dissociation constants determined for the benzimidazole units of complex **1** ($pK_1 = 5.45$ and $pK_2 = 9.85$) are compared with those of $[(bpy)_2Ru^{II}(H_2pzbzim)Ru^{II}(bpy)_2]^{3+}$ ($pK_1 = 7.95$ and $pK_2 = 9.75$) the pK values indicate considerable augmentation of acidity of the benzimidazole unit bound to Rh^{III}. The homodinuclear complex **2** undergoes stepwise oxidations at 0.63 and 0.81 V and the comproporationation constant K_c for the equilibrium $Ru^{II}Ru^{II} + Ru^{III}Ru^{III} \rightleftharpoons 2Ru^{II}Ru^{III}$ is 1.11×10^3 at 298 K. Both complexes **1** and **2** in frozen methanol–ethanol (1:4) glass at 77 K on excitation of their MLCT bands give rise to fairly strong luminescence spectra with their peaks at 632 and 655 nm, respectively, and the corresponding quantum yields are 3.1×10^{-2} for **1** and 3.5×10^{-2} for **2**.

Preparation, structure and catalytic activity of palladium(II) complexes with a carboxyferrocenylphosphine and an ortho-metallated C,N-ligand

Petr Štěpnička *, Martin Lamač, Ivana Císařová

Department of Inorganic Chemistry, Faculty of Science, Charles University, Hlavova 2030, 128 40 Prague 2, Czech Republic

Received 28 July 2003; accepted 12 November 2003

Abstract

The ortho-palladated dimer *trans*-[{Pd(μ-Cl)($C_6H_4CHNMe_2$-κ^2C^1,P)}$_2$] (**1**) reacts with methyl 1′-(diphenylphosphino)ferrocenecarboxylate (**2**) under bridge cleavage to afford [SP-4-4]-[PdCl($C_6H_4CH_2NMe_2$-κ^2C^1,P){Fe(η^5-$C_5H_4PPh_2$-κP)(η^5-$C_5H_4CO_2Me$)}] **(3)** while a reaction between the cationic complexes [Pd($C_6H_4CHNMe_2$-κ^2C^1,P)(MeCN)$_2$]X (**4**, X = ClO_4 (**a**) and BF_4 (**b**)) with **2** gives the products of replacement of one acetonitrile ligand *trans* to nitrogen, [SP-4-3]-[Pd($C_6H_4CHNMe_2$-κ^2C^1,P){Fe(η^5-$C_5H_4PPh_2$-κP(η^5-$C_5H_4CO_2Me$)}(MeCN)]X (**5a**, **5b**). The crystal structures of **4a** and **5a** have been determined by X-ray crystallography. Compounds **3**, **5b** and other in situ generated complexes with the related ferrocene phosphines were tested as catalysts in Suzuki–Miyaura coupling of 4-bromotoluene and phenylboronic acid.

1. Introduction

Chemistry of hybrid carboxyphosphine ligands, including the very basic one, $Ph_2PCH_2CO_2H$, has received considerable attention in the recent past since the acid and closely related compounds, particularly esters, have found applications in synthesis and catalysis [1]. As it has been demonstrated even for the case of one transition metal with a specific coordination environment such as palladium(II) ligated by ortho-metallated *N*,*N*-benzylamine, these functionalized phosphines can coordinate as carboxyphosphines or, after deprotonation, as the respective phosphinocarboxylates(1–) and functionalized alkyls (or enolates) [Ph_2PCHCO_2Et]$^-$. Besides, they may act as normal phosphine ligands with non-coordinated carboxy functions and also as bidentate bridging or chelating ligands [2].

We have recently described the coordination chemistry in an analogous system involving palladium(II) chelated with the 2-(dimethylaminomethyl)phenyl ligand and ligands derived from *rac*-[2-(diphenylphosphino)ferrocenyl]acetic acid: the acid itself, the corresponding acetate (1 –) and methyl ester [3]. This report deals with differences in reactivity observed in an analogous series but with another ferrocene carboxyphosphine, 1′-(diphenylphosphino) ferrocene carboxylic acid (Hdpf), and its methyl ester [4]. We describe the crystal structures of [Pd($C_6H_4CHNMe_2$-κ^2C^1,P) ((MeCN)$_2$]ClO_4 (**4a**) and [SP-4-3]-[Pd($C_6H_4CHNMe_2$-κ^2C^1,P){Fe(η^5-$C_5H_4PPh_2$-κP)(η^5-$C_5H_4CO_2Me$)}(Me- CN)]X, where X = ClO_4 (**5a**) and BF_4 (**5b**), and also the catalytic activity of the obtained products in Suzuki–Miyaura cross-coupling in a comparison with other systems based on related ferrocene phosphines.

2. Results and discussion

The metathesis of ortho-palladated dimer **1** with methyl 1′-(diphenylphosphino)ferrocenecarboxylate (**2**)

doi:10.1016/j.poly.2003.11.057

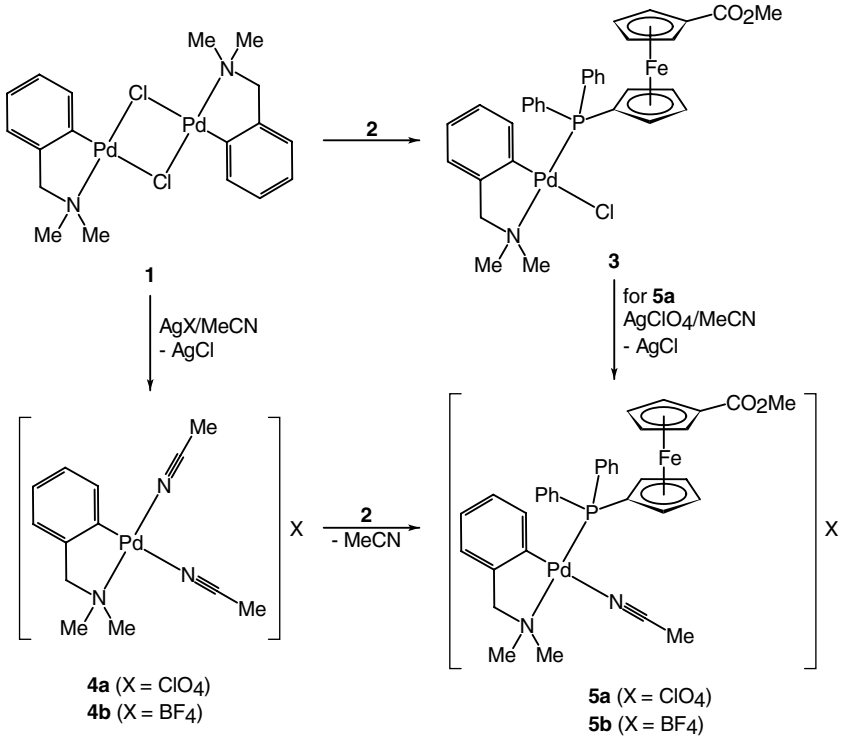
gives the expected product of the bridge-cleavage reaction, complex **3**. On the other hand, the reaction between cationic bis(acetonitrile) complexes **5**, prepared by reacting stoichiometric amounts of **1** and the appropriate silver(I) salt in acetonitrile with one equivalent of **2**, proceeds under a replacement of only one acetonitrile ligand, affording acetonitrile-phosphine complexes [SP-4-3]-[Pd($C_6H_4CHNMe_2$-κ^2C^1, P){Fe(η^5-$C_5H_4PPh_2$-κP)(η^5-$C_5H_4CO_2Me$)} (MeCN)]X, X = ClO_4 (**5a**) and BF_4 (**5b**) (Scheme 1). Perchlorate **5a** can be also synthesized from **3** by removal of a chloride ligand with a stoichiometric amount of $AgClO_4$. The formation of phosphine complexes **5** instead of the anticipated P,O-chelates analogous to [SP-4-3]-[Pd($C_6H_4CHNMe_2$-κ^2C^1, P){Fe(η^5-1-(CH_2CO_2Me-κO^2)-2-(PPh_2-κP)C_5H_3)(η^5-C_5H_5)}]-ClO_4 [3] undoubtedly reflects different steric properties of the involved phosphinoester ligands, pointing to an unfavourable geometry of a Pd(**2**-κ^2P, O) motif [5].

Reactivity of **5a** in substitution reactions towards selected donors was studied on a small scale by ^{1}H and ^{31}P NMR spectroscopy. The experiments revealed that **5a** (0.20 M in $CDCl_3$) does not react within 24 h at room temperature with 2,3-dimethylbut-2-ene (≈50 equiv.) or diphenylacetylene (1 equiv.) but decomposes to complex mixtures upon addition of 1 equiv. of trimethylphosphine, triphenylphosphine and trimethylphosphite under otherwise identical reaction conditions.

Compounds **3** and **5** are air stable and can be stored under ambient conditions for months. Complexes **4** deposit metallic palladium upon prolonged standing but can be easily purified by dissolving in acetonitrile, filtration and crystallization (or precipitation) with diethyl ether. All compounds were characterized by spectral methods and elemental analysis. The ^{1}H and ^{13}C NMR spectra of **3** and **5**, particularly the $^4J_{PH}$ and $^3J_{PC}$ (cf. [2,3]) coupling constants, indicate the complexes to have *trans*-P–N geometry, in accordance with the solid-state structures of **5a** and **5b** determined by X-ray diffraction (see below). The exclusive *P*-coordination of **2** is nicely reflected by ^{31}P NMR spectra, showing a single, downfield shifted resonance [^{31}P coordination shifts, $\Delta_P = \delta_{complex} - \delta_{ligand}$: 50.0 (**3**), 48.6 (**5a**) and 48.7 (**5b**)]. IR spectra of **3** and **5** display virtually unaffected $\nu_{C=O}$ bands (cf. $\nu_{C=O}$ 1710 cm^{-1} for **2**, [4]) and thus rule out any significant involvement of the ester group in coordination. In addition, the spectra show characteristic $\nu_{C\equiv N}$ stretching bands and bands due to the anions (e.g., strong ν_3 bands of ClO_4 and BF_4).

2.1. Solid-state structures

The molecular structure of **4a** (Fig. 1, Table 1) corroborates the expected planar coordination environment around palladium, which is asymmetric only negligibly in the Pd-donor bond lengths but significantly more in the



Scheme 1.

C(2)–C(7)	1.501(3)	C(7)–C(2)–C(1)	115.8(2)
N(2)–C(10)	1.133(3)	N(2)–C(10)–C(11)	179.5(2)
N(3)–C(12)	1.134(3)	N(3)–C(12)–C(13)	179.0(3)

[a] Further data: Pd–N(1)–C angles: 106.0(1)–115.1(1)°. Parameters of the counter ion: Cl–O(1) 1.434(2), Cl–O(2) 1.422(2), Cl–O(3) 1.427(3), Cl–O(4) 1.402(2) Å ; O–Cl–O angles: 108.2(2)–110.7(2)°.

interligand angles, though without any tetrahedral deformation as evidenced by the sum of the interligand angles of exactly 360°. In accordance with a larger *trans*-influence of the aryl ligand, the Pd–N(2) distance is elongated by ≈5% as compared to Pd–N(3). This, as well as the individual bond lengths, correspond well to parameters reported for, e.g., (*R*)-bis(acetonitrile)-{9-[1-(dimethylamino)ethyl-κN] phenanthren-10-yl-κC^{10}}palladium(II) perchlorate [6] and bis(acetonitrile)-{2-[1-(dimethylamino)methyl-κN]-3-methylnaphth-1-yl-κC^1} palladium (II) trifluoromethanesulfonate [7].

The metallated phenyl ring in **4a** is rotated from the coordination plane along the C(1)–C(4) axis at a dihedral angle of 19.12(9)° and the adjacent five-membered palladacycle adopts an envelope conformation (ring puckering parameters [8]: $Q_2 = 0.443(2)$ Å, $\phi_2 = 213.5(3)°$). The solid-state packing of **4a** is molecular, the most prominent intermolecular contact being an interaction between the palladium and a neighbouring aromatic π-electron system (Pd···C(5)^i 3.498(2) Å, *i*. $(1 + x, y, z)$), which interconnects the cations into infinite chains running along the *shortest* lattice parameter *a*. Since solid-state packing is further aided only by weak C–H···O(ClO_4) (C···O 3.4–3.5 Å) and C–H···π-ring (phenyl) interactions, it likely affects macroscopic properties of the crystals, which are obtained as thin needles, readily bent, loosing internal integrity upon only a slight pressure (see Section 3).

As revealed by the solid-state structure of **5a** (Fig. 2, Table 2), the replacement of the acetonitrile ligand with **2** brings about a more pronounced deformation of the coordination sphere. The plane defined by the palladium centre and the four directly bonded atoms (PdL_4) is twisted, the maximum deviation from the least-squares plane being 0.165(2) Å for N(1), which is about 10 times higher than the maximum deviation observed for **4a** [0.012(2) Å for C(1)]. The Pd-donor bond lengths are similar to the respective distances in (S)-acetonitrile-{[1-(dimethylamino)ethyl-κN]phenyl-κC^1}-(3,4-dimethyl-1-phenylphosphole-κP)palladium(II) perchlorate [9] and [(cyanomethylene)triphenylphosphorane-κN]-{[(dimethylamino)methyl-κN]phenyl-κC^1}-(trimethylphosphite)-palladium(II) perchlorate [10]. The palladacycle in **5a** adopts an envelope conformation very much similar to that of **4a** ($Q_2 = 0.429(2)$ Å, $\phi_2 = 212.6(3)°$). Likewise, the phenyl plane is rotated in a similar manner (around the C(25)–C(28) axis) but more than in **4a** (the respective dihedral angle is 27.9(1)°).

The geometry of the carboxyphosphine ligand, apart from a changed conformation of the 1,1′-disubstituted ferrocene core which is *anti*-eclipsed with the torsion angle C(1)–Cg(1)–Cg(2)–C(6) of −145.2(2)°, differs only marginally from an uncoordinated form (e.g., by a slight opening of the C–P–C angles) [4]. The ferrocene unit is rotated with respect to the coordination plane at a dihedral angle between the phosphinylated cyclopentadienyl-ring and PdL_4 plane of 54.9(1)°.

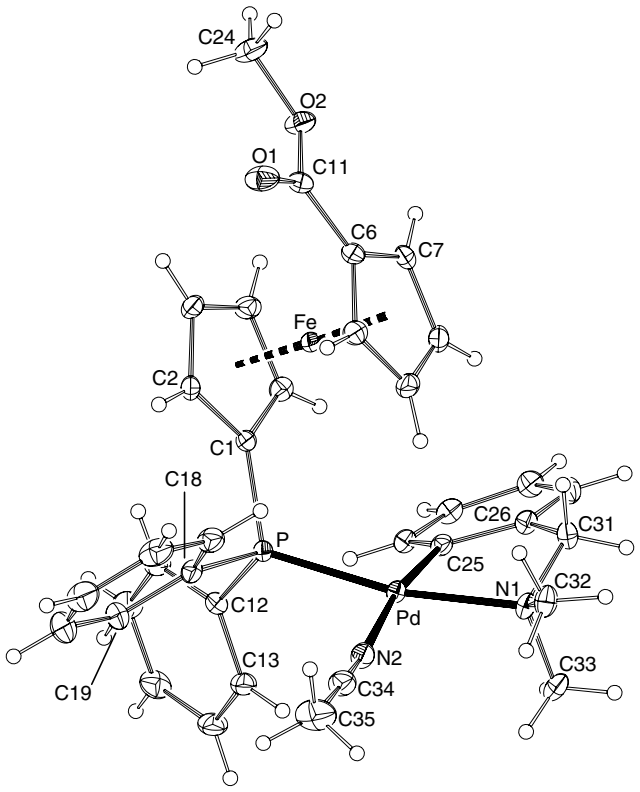

Fig. 2. A view of the cation in the structure of **5a**. The thermal ellipsoids enclose 30% probability level.

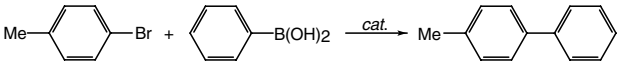
[a] Cg(1) and Cg(2) are the centroids of the C(1–5) and C(6–10) cyclopentadienyl rings, respectively. Further data: P–C(1) 1.810(2), P–C(12) 1.816(2), P–C(18) 1.826(2) Å; C–P–C angles 101.7(1)–105.2(1)°; N(2)–C(34) 1.134(4), C(34)–C(35) 1.450(4); Cl–O distances: O(11) 1.427(2) O(12) 1.406(3), O(13) 1.410(4), O(14) 1.397(3) Å; O–Cl–O angles: 107.2(2)–112.5(2)°.

2.2. Suzuki–Miyaura cross-coupling reactions

The Suzuki–Miyaura cross-coupling is a widely used method for the preparation of aromatic compounds [11]. As a benchmark test for complexes **3** and **5b**, and some related compounds, we used the reaction between 4-bromotoluene and phenylboronic acid in the presence of 1 mol.% of palladium catalyst and potassium carbonate as the base (2 equiv.) in hot toluene. The results obtained with **3**, **5b** (entries 1, 2), defined model compounds (entries 3, 4 and 10) and catalysts generated in situ from Pd-precursors and ferrocenephosphines (entries 5–9) are summarized in Table 3. Generally, the coupling reaction proceeded very well with the expected formation of 4-methylbiphenyl without any apparent formation of homocoupling products and deboronation. The only exception was the reaction with the catalyst formed in situ from $[Pd(cod)Cl_2]$ (cod = η^2:η^2-cycloocta-1,5-diene) and Hdpf (entry 5), where the product was obtained in a rather low yield and contaminated with the educts. Notably, when 4-bromotoluene was replaced with the significantly less reactive 4-chlorotoluene [12], the coupling reactions catalyzed with $[Pd(OAc)_2]$/2 Hpdf or $[PdCl_2(PPh_3)_2]$ did not proceed satisfactorily under otherwise identical conditions: as revealed by GC-MS and NMR analysis, the crude product contained mainly 4-chlorotoluene and biphenyl, the product of homocoupling of the boronic acid, but only traces of 4-methylbiphenyl.

Table 3
Suzuki–Miyaura coupling of 4-bromotoluene and $PhB(OH)_2$[a]



Entry	Catalyst	Isolated yield of 4-methylbiphenyl (%)
1	**3**	80
2	**5b**	85
3	$[PdCl^2(Hdpf\text{-}\kappa P)_2$	80
4	$[PdCl^2(Hdpf\text{-}\kappa P)_2$/2 Hdpf	89
5	$[Pd(cod)Cl_2]$/2 Hdpf[b]	44[c]
6	$[Pd(OAc)_2]$/2 Hdpf[b]	96
7	$[Pd(OAc)_2]$/5 Hdpf[b]	86
8	$[Pd(OAc)_2]$/2 **2**[b]	96
9	$[Pd(OAc)_2]$/2 $FcPPh_2$[b]	94
10	$[PdCl_2(PPh_3)_2]$	80

[a] The yields are based on 4-bromotoluene. For conditions see Section 3.
[b] Catalyst generated in situ by mixing these precursors.
[c] Contaminated with unreacted educts.

The results clearly indicate that the presence of the carboxyl group in the structure of ferrocene phosphine has virtually no influence on the performance of catalysts generated thereof and, hence, can be used for a further catalyst modification (e.g., immobilization). Further work in this area is currently in progress.

3. Experimental

3.1. General comments

All syntheses were carried out under argon with an exclusion of direct daylight. Toluene was dried by standing with potassium metal and freshly distilled under argon. Dichloromethane was dried over anhydrous potassium carbonate. Solvents for crystallizations and chromatography were used without purification. *Trans*-di-μ-chlorobis{(2-(dimethylaminomethyl-κN)phenyl-

κC[1]}dipalladium(II) (**1**) [13], Hdpf, **2** [4], $FcPPh_2$ [14], **4a** [3], $[Pd(cod)Cl_2]$ [15], $[Pd(OAc)_2]$ [16] and $[PdCl_2(Hdpf\text{-}\kappa P)_2]$ [17] were prepared by the literature procedures. All other chemicals were used as obtained from commercial sources.

NMR spectra were recorded on a Varian UNITY Inova 400 spectrometer (^1H, 399.95; ^{13}C, 100.58; ^{31}P, 161.9 MHz) at 298 K. Chemical shifts (δ (ppm)) are given relative to internal tetramethylsilane. The assignment of the NMR signals is based on ^1H,^1H-COSY, ^{13}C APT, ^{13}C gHSQC and ^{13}C gHMBC experiments. IR spectra were recorded on an FT IR Nicolet Magna 650 instrument in the range of 400–4000 cm^{-1}. Melting points were determined on a Kofler apparatus and are uncorrected.

3.2. Synthesis of [SP-4-4]-[PdCl($C_6H_4CH_2NMe_2\kappa^2C^1,P$){Fe($\eta^5$-$C_5H_4PPh_2$-κP)($\eta^5$-$C_5H_4CO_2Me$)}] (3)

Dimer **1** (55.2 mg, 0.10 mmol) and **2** (86.0 mg, 0.20 mmol) were dissolved in dichloromethane (2 ml), and the mixture was stirred for 30 min at room temperature. Then, the product was precipitated by addition of hexane, filtered off, washed with hexane and dried under vacuum (60 °C/0.5 Torr for 1 h) to afford **3** as an orange solid (123.1 mg, 88%).

^1H NMR ($CDCl_3$): δ 2.86 (d, $^4J_{PC} = 2.8$ Hz, 6H, N*Me*$_2$), 3.75 (s, 3H, O*Me*), 4.14 (d, $^4J_{PC} = 2.4$ Hz, 6H, NC*H*$_2$), 4.37 (ddd, $J \approx 1.0$, 1.9, 2.9 Hz, 2H), 4.49 (apparent q, $J \approx 1.9$ Hz, 2H), 4.92–4.95 (m, 4H) (fc, 4 × C*H*); 6.22–7.59 (m, 14H, aromatics). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 32.6 (s). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 50.15 (d, $^3J_{PC} = 3$ Hz, N*Me*$_2$), 51.71 (O*Me*), 71.48 (fc, *C*H), 72.18 (fc, C_{ipso}), 73.60 (d, $J_{PC} = 7$ Hz, fc, *C*H), 73.65 (d, $^3J_{PC} \approx 2$ Hz, NCH_2), 74.92 (fc, *C*H), 75.24 (d, $^1J_{PC} \approx 60$ Hz, fc, C_{ipso}), 76.68 (fc, *C*H), 122.49, 123.76, 124.89 (d, $^3J_{PC} = 5$ Hz) (C_6H_4, *C*H); 128.00 (d, $J_{PC} = 11$ Hz, PPh_2, *C*H), 130.63 (d, $J_{PC} = 3$ Hz, PPh_2, *C*H), 131.28 (d, $^1J_{PC} = 50$ Hz, PPh_2, C_{ipso}), 134.37 (d, $J_{PC} = 12$ Hz, PPh_2, *C*H), 138.35 (d, $J_{PC} = 10$ Hz, C_6H_4, *C*H); 148.16 (d, $J_{PC} = 2$ Hz), 152.23 (C_6H_4, C_{ipso}); 171.52 (*C*O_2Me). IR (Nujol): $\tilde{\nu}/cm^{-1}$ $\nu_{C=O}$ 1716 s, 1706 s; 1281 s, 1194 w, 1166 w, 1138 m, 1099 m, 1032 m, 994 w, 972 m, 834 m, 745 m, 696 m, 521 m, 508 m. *Anal.* Calc. for $C_{33}H_{33}ClFeNO_2P$: C, 56.28; H, 4.72; N, 1.99%. Found: C, 56.22; H, 4.69; N, 1.94%.

3.3. Synthesis of [Pd($C_6H_4CH_2NMe_2$-κ^2C^1,P)(MeCN-κN)$_2$]BF_4 (4b)

A solution of $AgBF_4$ (0.390 g, 2.00 mmol) in acetonitrile (5 ml) was added into a solution of **1** (0.552 g, 1.00 mmol) in dichloromethane (10 ml). The mixture turned immediately from yellow to only slightly yellowish and an off-white volumious precipitate (AgCl) separated. The mixture was stirred for 15 min in the dark, the precipitate was removed by filtration and the filtrate evaporated under reduced pressure. The oily residue was dissolved in acetonitrile (5 ml) and the product precipitated by addition of diethyl ether. The product was filtered off and dried under vacuum (at 2 Torr for 3 h). Yield: 0.710 g (87%), white solid.

^1H NMR ($CDCl_3$): δ 2.37, 2.50 (2 × s, 3H, *Me*CN); 2.84 (s, 6H, N*Me*$_2$), 3.93 (s, 2H, NCH_2), 6.88–7.08 (m, 4H, aromatics). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 2.57, 3.22 (*Me*CN); 52.82 (N*Me*$_2$), 73.23 (NCH_2), 120.23, 121.01 (Me*C*N); 122.32, 125.81, 126.00, 133.33 (C_6H_4, *C*H); 142.15, 147.21 (C_6H_4, C_{ipso}). IR (Nujol): $\tilde{\nu}$ (cm^{-1}) $\nu_{C\equiv N}$ 2333, 2320, 2306, 2293 m; 1580 m, 1564 w, 1289 m; $\nu_3(BF_4)$ 1098 s, 1057 vs br composite; 871 m, 746 vs; 622 m, 521 m, 432 m. *Anal.* Calc. for $C_{13}H_{18}BF_4N_3Pd$: C, 38.13; H, 4.43; N, 10.26%. Found: C, 38.43; H, 4.14; N, 10.02%.

3.4. Synthesis of [SP-4-3]-[Pd($C_6H_4CH_2NMe_2$-κ^2C^1,P){Fe(η^5-$C_5H_4PPh_2$-κP)(η^5-$C_5H_4CO_2Me$)}(MeCN-κN)]X, X = ClO_4 (5a) and BF_4 (5b)

Solid **4a** (105.6 mg, 0.25 mmol) was added into a solution of **2** (112.4 mg, 0.26 mmol) in dichloromethane (3 ml). The solid dissolved quickly to give a clear orange solution, which was crystallized by a careful addition of hexane (as a top layer) and diffusion at room temperature for several days. The crystalline solid formed during several days was filtered off, washed with diethyl ether and dried under vacuum (0.5 Torr for 1 h). Yield of **5a**: 192.1 mg (95%), a rusty orange crystalline solid.

^1H NMR ($CDCl_3$): δ 1.94 (s, 3H, *Me*CN), 2.87 (d, $^4J_{PH} = 2.9$ Hz, N*Me*$_2$), 3.75 (s, 3H, O*Me*), 4.12 (d, $^4J_{PH} = 2.3$ Hz, NCH_2), 4.15 (apparent q, 2H), 4.45 (br s, 2H), 4.48 (apparent q, 2H), 4.85 (apparent t, 2H) (fc, 4 × C*H*); 6.35–7.76 (m, 14H, aromatics). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 31.2 (s). $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 2.54 (*Me*CN), 50.76 (br s, N*Me*$_2$), 52.02 (O*Me*), 71.83 (fc, *C*H), 72.12 (d, $^3J_{PC} = 4$ Hz, NCH_2), 72.59, 73.68 (d, $^1J_{PC} = 56$ Hz) (2 × fc, C_{ipso}); 73.78 (d, $J_{PC} = 7$ Hz), 73.87, 75.45 (d, $J_{PC} = 11$ Hz) (3 × fc, *C*H); ≈120.9 (br, Me*C*N), 123.58, 125.42 (d, $J_{PC} = 5$ Hz), 125.56 (C_6H_4, *C*H); 128.82 (d, $J_{PC} = 11$ Hz, PPh_2, *C*H), 129.74 (d, $^1J_{PC} = 51$ Hz, PPh_2, C_{ipso}), 131.69 (d, $J_{PC} = 2$ Hz), 134.10 (d, $J_{PC} = 12$ Hz (PPh_2, *C*H); 137.47 (d, $J_{PC} = 12$ Hz, C_6H_4, *C*H), 144.39 (br), 148.87 (C_6H_4, C_{ipso}), 171.24 (*C*O_2Me). IR (Nujol): $\tilde{\nu}$ (cm^{-1}) $\nu_{C\equiv N}$ 2323, 2299 m; $\nu_{C=O}$ 1717 vs; 1285 s; 1203 m, 1151 m; $\nu_3(ClO_4)$ 1102 s composite; 977 m, 844 m, 836 m, 777 m, 749 s, 697 s, $\nu_4(ClO_4)$ 623 s; 542 m, 522 s, 507 s, 480 s. *Anal.* Calc. for $C_{35}H_{36}ClFeN_2O_6PPd$: C, 51.94; H, 4.48; N, 3.46%. Found: C, 51.63; H, 4.39; N, 3.24%.

Compound **5a** was also obtained by reacting a solution of **3** (35.6 mg, 0.051 mmol) in dichloromethane with $AgClO_4$ (10.8 mg, 0.052 mmol) dissolved in acetonitrile

(1 ml). A white precipitate which formed immediately (AgCl) was, after stirring for 15 min, filtered off and washed with a little dichloromethane. The clear orange filtrate was evaporated to dryness, redissolved in a mixture of dichloromethane (2 ml) and acetonitrile (five drops), and crystallized by liquid-phase diffusion of diethyl ether over several days. Yield: 36.2 mg (88%), rusty brown needles (identified by IR and NMR spectra).

Complex **5b** was obtained from **4b** (409.6 mg, 1.00 mmol) and **2** (434.0 mg, 1.01 mol) as given above for **5a**. Yield: 771.6 mg (97%), a rusty brown solid. Single crystals were grown by recrystallization from dichloromethane–hexane.

^{1}H NMR ($CDCl_3$): δ 1.90 (s, 3H, *Me*CN), 2.86 (d, $^4J_{PH} = 2.9$ Hz, N*Me*$_2$), 3.75 (s, 3H, O*Me*), 4.12 (d, $^4J_{PH} = 2.1$ Hz, NC*H*$_2$), 4.15 (apparent q, 2H), 4.42 (br apparent t, 2H), 4.50 (apparent q, 2H), 4.86 (br s, 2H) (fc, 4 × C*H*); 6.35–7.77 (m, 14H, aromatics). ^{31}P{^{1}H} NMR ($CDCl_3$): δ 31.3 (s). ^{19}F NMR ($CDCl_3$): δ −153.02 (s, 80%, $^{11}BF_4$), −152.97 (s, 20%, $^{10}BF_4$). ^{13}C{^{1}H} NMR ($CDCl_3$): δ 2.29 (*Me*CN), 50.75 (d, $^3J_{PC} \approx 2$ Hz, N*Me*$_2$), 52.11 (O*Me*), 71.95 (fc, *C*H), 72.11 (d, $^3J_{PC} = 4$ Hz, N*C*H$_2$), 72.48 (br), ≈73.56 (d, $^1J_{PC} \approx 60$ Hz) (2 × fc, C_{ipso}); 73.79 (d, $J_{PC} = 8$ Hz), 73.86, 75.44 (d, $J_{PC} = 11$ Hz) (3 × fc, *C*H); ≈121.5 (br, Me*C*N), 123.56, 125.40 (d, $J_{PC} = 5$ Hz), 125.61 (C_6H_4, *C*H); 128.88 (d, $J_{PC} = 11$ Hz, PPh_2, *C*H), 129.81 (d, $^1J_{PC} = 52$ Hz, PPh_2, C_{ipso}), 131.74 (d, $J_{PC} = 2$ Hz), 134.03 (d, $J_{PC} = 12$ Hz (PPh_2, *C*H); 137.47 (d, $J_{PC} = 12$ Hz, C_6H_4, *C*H), 144.57, 148.99 (C_6H_4, C_{ipso}), ≈171.2 (br, *C*O$_2$Me). IR (Nujol): $\tilde{\nu}$ (cm^{-1}) $\nu_{C\equiv N}$ 2329, 2300 m; $\nu_{C=O}$ 1716 vs, 1704 sh; 1286 s; 1203 m, 1162 s; ν_3 (BF_4) 975–1096 s br composite; 844 m, 836 m, 777 m, 758 m, 750 s, 699 s, 542 m, 522 s, 507 s, 480 s. $C_{35}H_{36}BF_4FeN_2O_2PPd$: C, 52.76; H, 4.55; N, 3.52%. Found: C, 52.48; H, 4.41; N, 3.24%.

3.5. Typical procedure for Suzuki–Miyaura cross-coupling

4-Bromotoluene (1.00 mmol), $PhB(OH)_2$ (1.05 mmol), K_2CO_3 (2.0 mmol) and catalyst (1 mol.% Pd; added as a defined complex or a mixture of a Pd-source and a ligand, see Table 3) were placed into a Schlenk tube equipped with a stirring bar. The tube was sealed with a septum and repeatedly evacuated by an oil pump and filled with argon. Toluene (2 ml, distilled under argon) was added, and the tube was once again evacuated and filled with argon (when the reaction was performed with 4-chlorotoluene, this was added as the last, mixed with the solvent). Then, the mixture was heated in an oil bath kept at 110 °C with stirring overnight (20 h). After cooling to room temperature, the mixture was washed with water (5 × 3 ml), the organic layer was filtered and transferred to a flask with a syringe. The solvent was evaporated under reduced pressure to give crude crystalline product, which was further purified by flash chromatography (silica gel, CH_2Cl_2). Removal of the solvent under vacuum afforded pure 4-methylbiphenyl as a colourless crystalline solid (for yields see Table 3). NMR ($CDCl_3$): δ_H 2.39 (s, 3H, *Me*), 7.21–7.61 (m, 9H, aromatics); δ_C 21.08 (*Me*), 126.96, 126.97, 126.99, 128.70, 129.47 (aromatic *C*H); 137.00, 138.36, 141.16 (aromatic C_{ipso}). M.p. 47–8 °C (hexane; [18], 47–8 °C).

3.6. X-ray crystallography

Compound **4a** was crystallized by liquid-phase diffusion of diethyl ether into an acetonitrile solution and obtained as elongated colourless needles. The crystals were somewhat waxy and could not be cut without an elastic deformation. Hence, a needle with a cross-section ≈0.13 × 0.20 mm^2, exceeding the primary beam area by its length, had to be selected for the measurement. Due to the crystal shape, no explicit absorption correction was applied except for an averaging of the equivalent diffractions (which however gives reliable data, see parameters in Table 4). Single crystals of **5a** were grown from hexane/dichloromethane (rusty orange prism,

Table 4

$0.13 \times 0.18 \times 0.38$ mm). In both cases, the full-set of diffraction data ($\pm h \pm k \pm l$) with $2\theta \leqslant 55°$ were collected on a Nonius KappaCCD diffractometer equipped with Cryostream Cooler (Oxford Cryoystems) at 150 K using graphite monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å and analyzed with the HKL program package by Nonius BV (Table 4).

The structures were solved by direct methods (SIR92 [19]) and refined by weighted full-matrix least-squares procedure on F^2 (SHELXL97 [20]). Final geometric calculations were carried out with a recent version of the Platon program [21]. All non-hydrogen atoms were refined with anisotropic thermal motion parameters whilst all hydrogen atoms were included in the calculated positions [CH bond lengths: 0.93 (aromatic), 0.97 (methylene) and 0.96 (methyl) Å and assigned $U_{iso}(H) = 1.2U_{eq}(C)$ (aromatic and methylene) or 1.5 $U_{eq}(C)$ (methyl).

In the case of **5a**, the final difference electron density maps showed an unusually high residual electron density (1.94 e Å^{-3} in 1.9 Å distance from Pd). A closer inspection revealed that the first two maxima on the map (1.94 and 0.56 e Å^{-3}; intensity of the next most intense positive peak: 0.50 e Å^{-3}) are as distant as Pd and P atoms in the molecule of **5a**, and can be independently refined as Pd and P with equal occupancies of 3%, thus decreasing the *R*-value by 0.3% (another possibly observable maximum due to the iron atom could not be identified because of overlaps). Since these maxima were observed reproducibly in the crystals resulting from different experiments, at different temperatures, and also in the structure of isostructural complex **5b**, [1] these features seem to reflect *the* real structure of crystals, where some parts are rotated with respect to the dominant repeating unit (the bulky ferrocene ligand can act as the pivot in the case of **5a** and **5b**).

4. Supplementary data

Crystallographic data (CIF files) have been deposited with the Cambridge Crystallographic Data Centre under the deposition numbers CCDC-213739 (**4a**) and -213740 (**5a**). Copies of the data may be obtained free of charge upon request to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033, e-mail: deposit@ccdc.cam.ac.uk, www: http://www.ccdc.cam.ac.uk).

[1] Individual geometric parameters for **5b** do not differ significantly from those of the isostructural perchlorate **5a** [**5b**: $C_{35}H_{36}BF_4FeN_2O_2PPd$, $P2_1/n$ (no. 14), $a = 10.1319(1)$, $b = 17.4440(2)$, $c = 19.2608(2)$ Å; $\beta = 101.2538(7)°$, $Z = 4$ at 120 K]. Crystallographic data have been deposited at the Cambridge Crystallographic Data Centre (deposition number CCDC-213741) and will not be discussed here.

Abstract

Metallo-organic complexes with the formula $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$, where M = Fe, Co or Cu ($0 \leqslant x \leqslant 1$), were synthesised and characterised. All of them are isostructural and crystallise in the space group *Pccn*. The crystal structure has been described as a two-dimensional (2D) arrangement of M–malonate layers extended along the (0 1 0) crystallographic plane. Octahedral polyhedra of transition metallic ions are coordinated by bridging malonate ligands, through the O–C–O atoms. The evolution of the cell volume follows Vegard's law. Spectroscopic data are consistent with the transition metallic ions in a high-spin octahedral symmetry, confirming the substitution of the metallic cations. All the iron and cobalt compounds exhibit 2D antiferromagnetic interactions with the presence of weak ferromagnetism. The copper solid solution also shows 2D antiferromagnetic interactions, unlike the $[BaCu(C_3H_2O_4)_2(H_2O)_4]$ complex, which exhibited ferromagnetic ones.

Keywords: Malonate complexes; 2D antiferromagnets; Weak ferromagnetism

1. Introduction

The chemistry of heteronuclear complexes involving bridging carboxylato ligands has created a high interest aimed at designing polynuclear extended systems with specific dimensionality, the results concerning the magnetic properties being of special interest.

The malonate, with two neighbouring carboxylato groups, is a very versatile ligand. It can simultaneously adopt monodentate, various bischelating coordination modes and different carboxylato bridging modes (*syn–syn*, *syn–anti*, and *anti–anti*) giving rise to a variety of structures and being a useful tool for connecting different metals and transmitting different magnetic interactions. The exchange coupling through the carboxylato ligand is dependent, apart from the nature of the metallic ion, on the conformation of the bridge between the interacting metal centers [1–4]. In this way, ferromagnetically [5] or antiferromagnetically [6] coupled dimers, alternating chains [3,4,7], polymeric trinuclear antiferromagnetic complexes [8], two-dimensional ferromagnetic and antiferromagnetic compounds [9,10], and more extended structures [1] have been obtained with the malonate ligand.

In this sense, we have recently reported the study of different malonate complexes with the formula $[AM(C_3H_2O_4)_2(H_2O)_4]$, where AM is SrMn, SrCu, BaMn, BaFe, BaCo and BaCu [9,11]. All of them were found to be isostructural and showed interesting spectroscopic and magnetic properties. The structure was visualised as a lamellar network with MO_6 polyhedra coordinated by bridging malonate ligands. Two-dimensional (2D) magnetic interactions were also found in all compounds, with the presence of antiferromagnetic interactions for manganese(II), iron(II) and cobalt(II) compounds and ferromagnetic for the copper(II) complexes. Furthermore, these complexes can be used as precursors in the synthesis of mixed oxides, being an alternative to the ceramic method. The thermal decomposition of heterometallic complexes permits the preparation of highly homogeneous phases at lower

doi:10.1016/j.poly.2003.12.015

temperatures and with smaller grain sizes than those obtained from the ceramic method. So, taking into account that all of them are isostructural. $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ solid solutions with M = Fe, Co or Cu and $0 \leqslant x \leqslant 1$ have been synthesised, characterised and their spectroscopic, magnetic and thermal properties studied. The complexes will be abbreviated as BaMnFe, BaMnCo and BaMnCu.

2. Experimental

Manganese(II) chloride, cobalt(II) chloride, copper(II) chloride and malonic acid were purchased from Fluka, iron(II) and barium chloride was purchased from Aldrich Co. and sodium carbonate from Merck. All of them were used without further purification.

To a solution of 2.5 mmol of disodium malonate, previously formed from 2.5 mmol (0.2601 g) of malonic acid neutralised with 2.5 mmol (0.7419 g) of sodium carbonate, the stoichiometric amounts of the corresponding transition metallic chlorides were added. The mixture was stirred for 30 min, after which 1 mmol of barium chloride was added. Polycrystalline powders of all the phases were obtained in a few seconds and stirred for 1–2 h for a complete precipitation. For the iron compounds, a closed system with a nitrogen atmosphere was needed to prevent oxidation. The products obtained were filtered and washed in ethanol/water followed by diethyl ether. The complexes were obtained as polycrystalline powders of several colours, white in the case of BaMnFe, light pink for BaMnCo compounds and light blue for BaMnCu ones. The analyses of the C, H and metals agree with the $BaMn_{1-x}M_xC_6H_{12}O_{12}$ stoichiometries and are given as Supplementary Material.

3. Physical measurements

Microanalyses were performed with a LECO CHNS-932 elemental analyzer. Analytical measurements were carried out in an ARL 3410+ICP with Minitorch equipment. The powder X-ray diffraction (XRD) pattern was taken using a Philips X'pert diffractometer equipped with graphite-monochromated Cu Kα1 radiation. Data were collected by scanning in the 2θ range 5–80° with increments of 0.02°. Thermogravimetric measurements were performed in a TA instruments-STD 2960 (simultaneous DSC-TGA) instrument. Crucibles containing 20 mg of sample were heated at 5° min^{-1} under dry air atmosphere. Diffuse reflectance spectra were carried out in a CARY 2415 spectrometer in the range 5000–45 000 cm^{-1}. EPR spectra were recorded on a Bruker ESP300 spectrometer, equipped with a standard Oxford low-temperature device operating at X band. The magnetic field was measured with a Bruker BNM 200 gaussmeter, and the frequency was determined by using a Hewlett-Packard 5352B microwave frequency counter. Magnetic susceptibilities of powdered samples were carried out in the temperature range 1.8–300 K using a Quantum Design MPMS-7 Squid magnetometer. The magnetic measurements were performed at magnetic fields between 0 and 7 T.

4. Results and discussion

4.1. Crystallographic study

Powder X-ray diffraction patterns of the products were performed in the 2θ range 5–80°. Indexation of the diffraction profile and refinement of the cell parameters were made by FULLPROF (pattern-matching analysis) [12] on the basis of the space group *Pccn* and the cell parameters found for a single crystal of [SrCu-$(C_3H_2O_4)_2(H_2O)_4$], previously published [9]. The variation of the calculated crystallographic parameters versus the composition is represented in Fig. 1 (for more information see Supplementary Material). Notable is the gradual decrease of the *a* and *c* crystallographic parameters when the iron and cobalt contents increase, in agreement with the smaller size of these cations in comparison with the manganese one. However, in the case of the copper solid solution, the *a* parameter increases. This fact is due to the Jahn–Teller effect in the copper(II) compounds, which causes the elongation of the metal coordination polyhedra in this direction. The *b* parameter remains practically invariable or slightly increases for the BaMnCo phases. In any case, the cell volume linearly diminishes with the amount of the inserted cations following Vegard's law, according to their smaller size.

Taking these results into account, we consider all the phases as isostructural to the previously characterised SrCu phase. The structure consists of layered networks of octahedral polyhedra of transition metallic ions coordinated by malonate ligands. These carboxylato bridging arrangements form infinite sheets, extended along the (0 1 0) crystallographic plane where the shortest M ··· M exchange distance is found through the O–C–O atoms (see Fig. 2). The alkaline earth cations are located between the M–malonate layers.

4.2. Thermal study

The thermal decomposition steps of the compounds were obtained from their TG curves shown in Fig. 3. Decomposition occurs following three consecutive processes: dehydration, ligand pyrolysis and inorganic residue formation.

The first process takes place in the 75–100 °C temperature range and corresponds to the loss of the four water molecules. This process seems to occur in only one

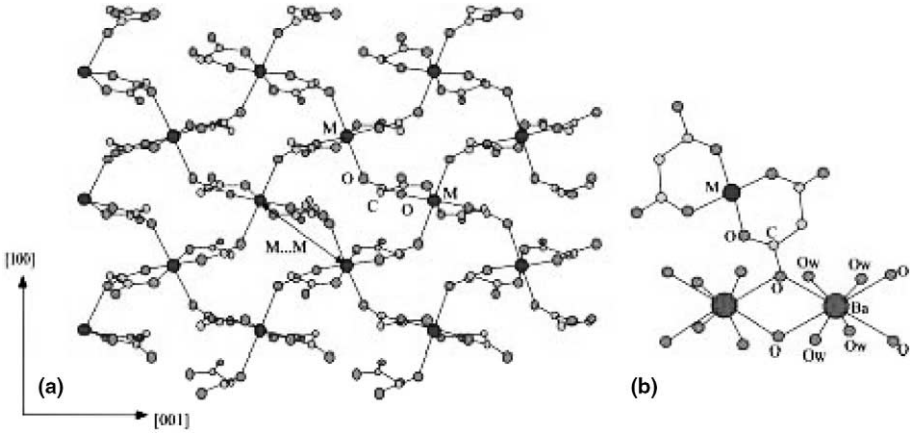

Fig. 2. (a) Two-dimensional network of transition metal polyhedra and (b) alkaline earth centre and linkage to transition metal polyhedra in $[AM(C_3H_2O_4)_2(H_2O)_4]$.

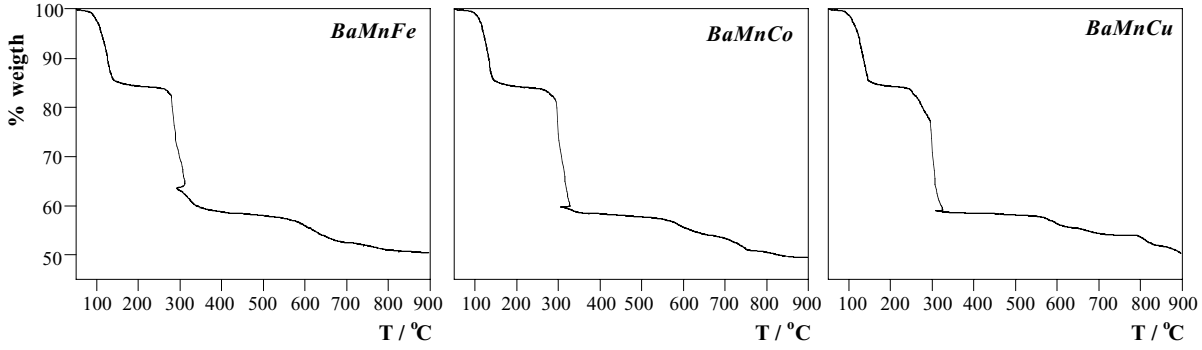

Fig. 3. TG curves in air, for the $BaMn_{0.5}Fe_{0.5}$, $BaMn_{0.5}Co_{0.5}$ and $BaMn_{0.5}Cu_{0.5}$ compounds.

step, suggesting that all the water molecules are similar, as was deduced from the crystallographic data of the SrCu compound. After that, the decarboxylation of the ligand comes and a sharp mass loss in the 250–450 °C temperature range is observed. The weight loss agrees with the formation of $BaCO_3$ and the corresponding transition metal oxides. Above 500 °C, the TG curves show a gradual mass loss, when the carbonate decomposes to yield the mixed oxides. In the case of the BaMnFe and BaMnCo precursors, the evolution of the inorganic residue seems to take place in two steps, concluding in a very slight mass loss. The X-ray diffractograms of the obtained residues indicated the presence of a $BaMn_{1-x}M'_xO_{3-\delta}$ oxide, together with slight amounts of some impurities. The last weight-constant plateau corresponds to the formation of a stable oxide so the attainment of the $BaMn_{1-x}Fe_xO_{3-\delta}$ and $BaMn_{1-x}Co_xO_{3-\delta}$ oxides may occur near 750 °C in both cases. In the case of the BaMnCu precursor, the evolution of the inorganic residue finishes at 850 °C in a slight mass loss step. The residue has been identified as a mixture of $BaMn_{1-x}Cu_xO_{3-\delta}$ and CuO oxides. Consequently, the optimum reaction temperature in order to obtain the $BaMn_{1-x}Cu_xO_{3-\delta}$ oxide could be near 850 °C.

4.3. Diffuse reflectance spectroscopy

The reflectance spectra were recorded at room temperature in the 5000–45 000 cm^{-1} range. Several bands corresponding to high spin iron(II), cobalt(II) and copper(II) ions in octahedral geometry can be seen in the spectra of Fig. 4. The bands due to the manganese(II) ions cannot be observed because they come from forbidden transitions. The assignment of these bands are summarized in Table 1. The intensities change depending on the inserted metal content. For the BaMnFe phases, a single band is observed at around 11 400 cm^{-1}, which is characteristic of a high-spin d^6 configuration in octahedral coordination. The spectra of the BaMnCo compounds show three bands, at around 8200, 18 000 and 21 500 cm^{-1}, which are characteristic of a cobalt(II) compound in octahedral geometry. Finally, the spectra for the copper doped compounds show a main band at 13 800 cm^{-1} (725 nm) and another one at around 6800 cm^{-1} (1470 nm). These bands are typical of copper(II) (d^9) compounds where the copper ion is in tetragonally elongated octahedral coordination [13].

4.4. EPR spectroscopy

The room temperature X-band EPR spectra of some BaMnCu powdered samples are shown in Fig. 5(a). All of them, except the BaCu compound, show isotropic signals centred at around $g = 2$. The presence of only one signal, different from the signal of the parent compounds, indicates that the two different transition metallic ions in the compounds are magnetically coupled,

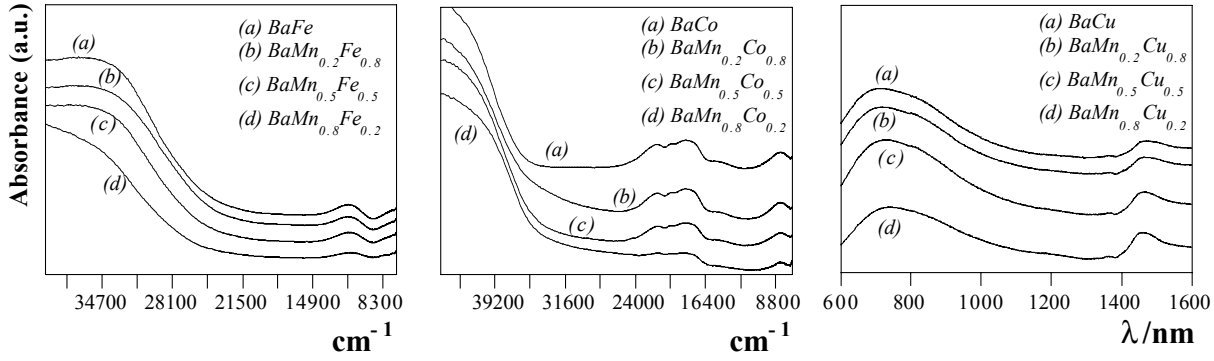

Fig. 4. Diffuse reflectance spectra for the BaMnFe, BaMnco and BaMnCu systems.

Table 1
Assignment of the diffuse reflectance bands for the BaMnFe, BaMnCo and BaMnCu solid solutions

	Position (cm^{-1})	Transition	Metallic cation
BaMnFe	1400	$^5E_g \leftarrow {}^5T_{2g}$	Octahedral Fe^{II} d^6
BaMnCo	8200	$^4T_{2g} \leftarrow {}^4T_{1g}(F)$	Octahedral Co^{II} d^7
	18 000	$^4A_{2g} \leftarrow {}^4T_{1g}(F)$	
	21 500	$^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$

	13 600 (730 nm)	$^2B_{2g}(d_{xy}) \leftarrow {}^2B_{1g}(d_{x^2-y^2})$	Tetragonally elongated octahedral Cu^{II} d^9
	6850 (1460 nm)	$^2A_{1g}(d_{z^2}) \leftarrow {}^2B_{1g}(d_{x^2-y^2})$	

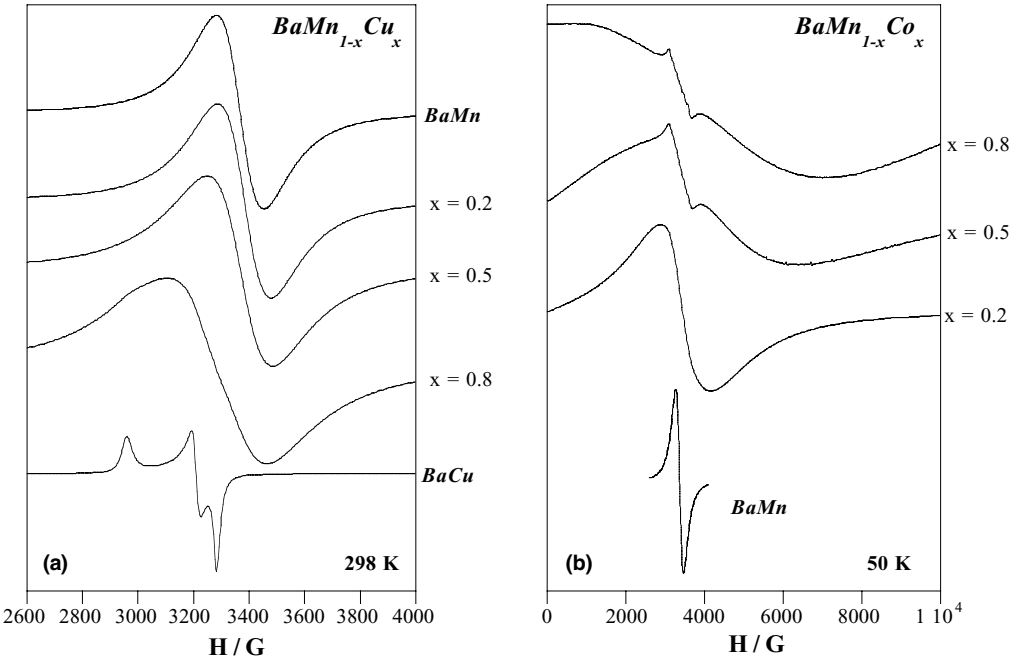

Fig. 5. (a) X-band EPR spectra at room temperature of the BaMnCu family and (b) X-band EPR spectra at 50 K of the BaMnCo family.

confirming the presence of both cations in the structure. It is also worth mentioning the absence of satellite signals from impurities present, and so co-precipitation of the parent compounds can be rejected.

The X-band spectra of the BaMnFe and BaMnCo solid solutions were also measured at room temperature, but the linewidth increased with the iron or cobalt contents and the resolution was really poor. The spectra for the BaMnCo system at 50 K are shown in Fig. 5(b). The linewidth of the signals of the BaMnCo complexes are wider than those of the BaMn compound, and get wider with increasing cobalt content. This fact agrees with the existence of Mn^{II}–Co^{II} interactions, confirming the presence of both metallic cations in the structure. However, at high cobalt contents, the appearance of the hyperfine signal corresponding to the manganese(II) ions indicates the presence of a small paramagnetic impurity in the sample. At lower temperatures (4 K), the main signal becomes wider again, suggesting the presence of significant magnetic interactions.

4.5. Magnetic properties

Variable-temperature magnetic susceptibility measurements were performed on $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ (M = Fe, Co and Cu) powdered samples in the 1.8–300 K temperature range, under a magnetic field of 1 kG. The plots $\chi_m T$ versus T for the $BaMn_{0.5}Fe_{0.5}$ and $BaMn_{0.5}Co_{0.5}$ complexes are shown in Fig. 6 as representative examples. The obtained magnetic parameters

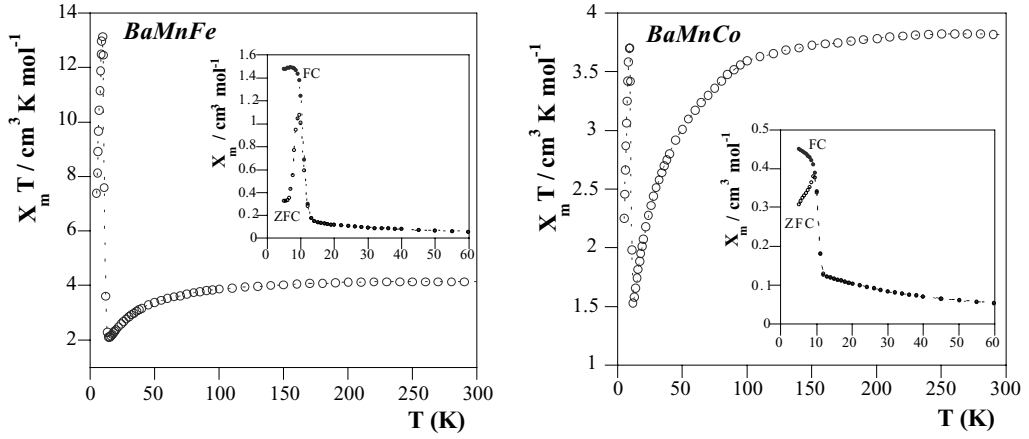

Fig. 6. $\chi_m T$ vs. T curves for $BaMn_{0.5}Fe_{0.5}$ and $BaMn_{0.5}Co_{0.5}$ compounds. χ_m vs. T, FC and ZFC curves in the insets.

Table 2
Magnetic parameters of the $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ (M = Fe, Co, Cu) compounds

		T_N (K)	C_m ($cm^3\,K\,mol^{-1}$)	θ (K)	μ_{eff} (μ_B)

BaCu [9]	FM		0.41	1.8	1.89

The parameters of the parent compounds are given for comparison.

are collected in Table 2. The μ_{eff} values measured at room temperature are 5.75 and 5.52 μ_B for the iron and cobalt compounds, respectively, in accordance with a paramagnetic behaviour of both systems, being in high-spin states. The magnetic moments ($\mu_{eff} = \sqrt{8}\chi_m T$) slowly diminish with decreasing temperature, reaching a minimum value at around 12 K, then sharply increase and near 10 K a maximum appears. From χ_m^{-1} versus T curves Curie–Weiss behaviours have been deduced above 30 K. The values of the Weiss and Curie constants are $\theta = -12.7$ and −13.5 K and $C_m = 4.37$ and 4.02 $cm^3\,K\,mol^{-1}$, for $BaMn_{0.5}Fe_{0.5}$ and $BaMn_{0.5}Co_{0.5}$, respectively. The progressive decrease of both $\chi_m T$ curves up to 15 K, together with the negative values of θ, indicate the presence of antiferromagnetic interactions. Nevertheless, below 15 K the sudden increase of the magnetic moment suggests that total antiparallel alignment of the spins is not reached, with the appearance of a small ferromagnetic component.

Magnetization measurements at low temperatures for $BaMn_{0.5}Fe_{0.5}$ and $BaMn_{0.5}Co_{0.5}$ have been carried out and the curves are represented in Fig. 7. At 5 K, both compounds show small M versus H hysteresis loops with coercive fields near 3000 G and remnant magnetization values of 0.20 and 0.06 (in $N\beta$ units) for the iron and cobalt complexes, respectively. The thermoremnant magnetization curves show Néel temperatures of 12 and 11.5 K for BaMnFe and BaMnCo, respectively. Below T_N, the saturation is rapidly reached with M_r values of 0.20 and 0.06 (in $N\beta$ units), similar to the average value of the parent compounds. Both curves confirm the presence of a small ferromagnetic component at low temperatures.

In the case of the copper compounds, different magnetic behaviours were observed. The magnetic susceptibility data of the $BaMn_{0.8}Cu_{0.2}$, $BaMn_{0.5}Cu_{0.5}$ and $BaMn_{0.2}Cu_{0.8}$ powdered samples are represented in Fig. 8. The μ_{eff} values measured at room temperature are 5.17, 4.48 and 2.91 μ_B (see Table 2), which correspond to the values of paramagnetic behaviour for both spin systems (6.04 and 1.89 μ_B for BaMn and BaCu, respectively). These values decrease with decreasing temperature, suggesting the existence of antiferromagnetic interactions with Néel temperatures below 5 K. The χ_m^{-1} curves were fitted to a Curie–Weiss behaviour with values of θ, −10.6, −10.0, −6.4 K for $BaMn_{0.8}Cu_{0.2}$, $BaMn_{0.5}Cu_{0.5}$ and $BaMn_{0.2}Cu_{0.8}$, in agreement with the presence of antiferromagnetic interactions. Finally, in the case of the $BaMn_{0.8}Cu_{0.2}$ compound, the small minimum observed in the $\chi_m T$ curve at 6 K seems to indicate the presence of a weak ferromagnetic component below 5 K.

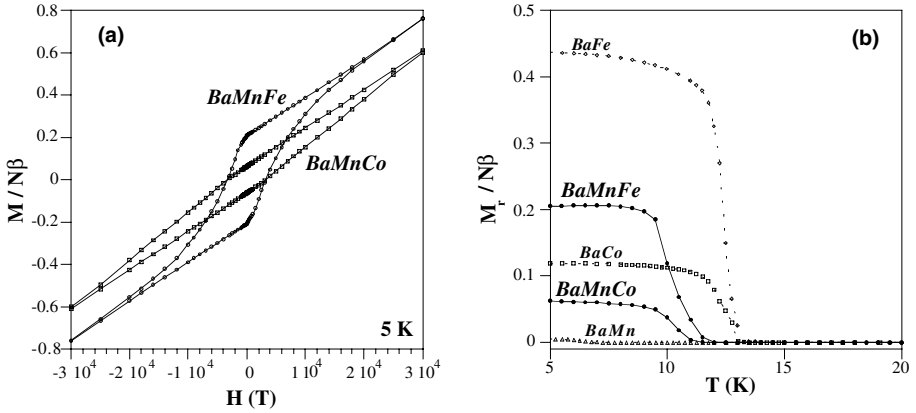

Fig. 7. (a) Hysteresis curves measured at 5 K for $BaMn_{0.5}Fe_{0.5}$ and $BaMn_{0.5}Co_{0.5}$ compounds and (b) zero field magnetization vs. T curves after cooling the samples under a magnetic field of 100 G. BaMn, BaFe and BaCo thermoremnant curves are given for comparison.

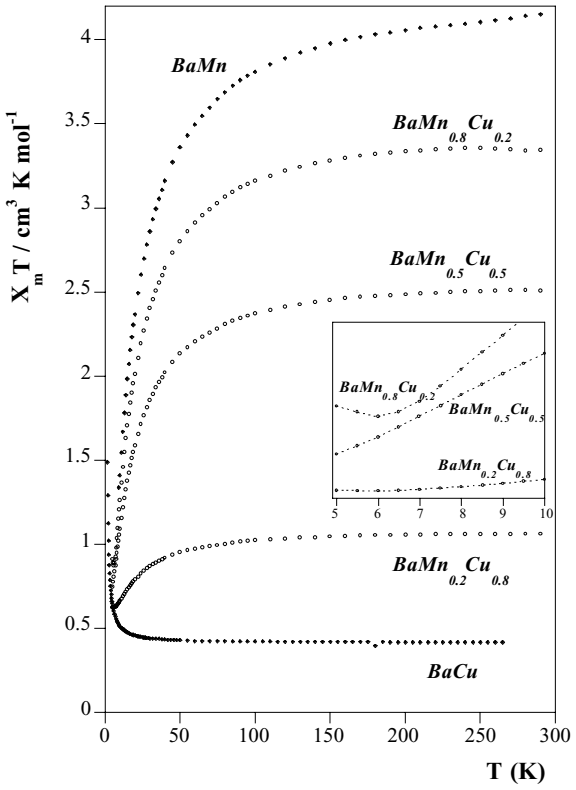

Fig. 8. $\chi_m T$ vs. T curves for $BaMn_{0.8}Cu_{0.2}$, $BaMn_{0.5}Cu_{0.5}$ and $BaMn_{0.2}Cu_{0.8}$ compounds. Low temperature data are magnified in the inset. The curves for BaMn and BaCu are included for comparison.

The magnetic behaviour described for the solid solutions is very similar to that observed for the parent compounds. The BaMn, BaFe and BaCo susceptibility data were fitted to a 2D Heisenberg antiferromagnetic model above T_N [9,11], whereas the BaCu data were fitted to a 2D Heisenberg ferromagnetic model [9]. Therefore, it can be concluded that the BaMnFe and BaMnCo solid solutions exhibit 2D Heisenberg antiferromagnetic behaviour above 15 K, due to a weak intralayer antiferromagnetic interaction between $M^{II}\cdots M^{II}$ cations, through O–C–O bridges. Below this temperature, the misalignment of the spins (or canting) in the layer causes a subsequent long-range ferromagnetic arrangement between layers. Moreover, the magnetization values do not agree with a $Mn^{II}\cdots M^{II}$ ferrimagnetic ordering, so a Mn–M ordered sequence can be rejected. The higher ferromagnetic component, found for the iron compounds, can be mainly attributed to the anisotropy of the metallic cations, but other parameters such as exchange magnetic interactions (bond and angles) should be also considered. Finally, the low Néel temperatures found in the solid solutions can be related to the presence of structural disorder in these phases.

The BaMnCu solid solution also exhibits 2D antiferromagnetic interactions. In this way, the ferromagnetic interactions found for the BaCu compound disappear even with a small content of manganese. This transition can be due to the high spin of the manganese(II) ion (d^5, $S = 5/2$), compared to the spin of the copper(II) ion (d^9, $S = 1/2$). The higher spin of the manganese implies that more magnetic orbitals are present in the different exchange pathways, and therefore more interactions could be competing between them. As a result, the antiferromagnetic interactions can become the more significant ones and the ferromagnetic interactions found in BaCu vanish.

5. Conclusions

The $[BaMn_{1-x}M_x(C_3H_2O_4)_2(H_2O)_4]$ (M = Fe, Co, Cu) solid solutions were synthesised and studied. All the phases are isostructural and exhibit 2D arrangements of M–malonate networks.

Two-dimensional (2D) antiferromagnetic interactions have been proposed for almost all the compounds. In the case of the BaMnFe and BaMnCo systems, weak ferromagnetism below Néel temperatures (12 K) was also detected, as a consequence of a long-range magnetic ordering of the canted spins between layers. The magnitude of this ferromagnetic component can be mainly attributed to the anisotropy of the metallic cations.

Unlike the BaCu phase, which shows ferromagnetic interactions, the BaMnCu solid solution exhibits antiferromagnetic interactions. This fact can be explained as being due to the higher spin of the manganese(II) ions ($S = 5/2$), which implies more exchange pathways, the antiferromagnetic interactions becoming the main ones in this system.

Abstract

Two thiostannates $[Ni(en)_3]_2Sn_2S_6$ (**1**) (en = ethylenediamine) and $[Ni(dien)_2]_2Sn_2S_6$ (**2**) (dien = diethylenetriamine) were prepared by the reaction of $SnCl_4 \cdot 5H_2O$, $NiCl_2 \cdot 6H_2O$ and S_8 in a molar ratio of Sn/Ni/S = 1:1:4 (or $SnCl_4$:$NiCl_2$:S_8 = 1:1:0.5) under solvothermal conditions. Both compounds are composed of the discrete $[Sn_2S_6]^{4-}$ anion. The coordinated cations $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ act as structure directing agents which lead to different packing of the $[Sn_2S_6]^{4-}$ anions. Compounds **1** and **2** decompose at 291 and 310 °C, respectively, and both of them lose all of their organic ligands in one step under a nitrogen stream. The hydrogen bonds are considered to be one of the important reasons for their difference in decomposition temperature.

1. Introduction

Open framework materials based on main group chalcogenometalates are of increasing interest because of their unique properties and potential applications, such as semiconductors [1–3], photoconductivity [4], non-linear optics [5], catalysis [6] and ion exchange capability [7]. Recently, two types of polythiostannates $[Sn_3S_7]^{2-}$ [7–11] and $[Sn_4S_9]^{2-}$ [11–14], which are denoted SnS-1 and SnS-3, respectively, have been synthesized and described. SnS-1 and SnS-3 are synthesized by a hydrothermal reaction using Sn or SnS_2 and S_8 as reactants and amine or tetra-alkylammonium hydroxide as the mineralizer. The dimeric anion $[Sn_2S_6]^{4-}$ is a precursor of SnS-1 which can be obtained from an aqueous solution of $[Sn_2S_6]^{4-}$ simply by precise control of pH through bubbling CO_2 into the mother-liquor [9,11]. The dimeric anion is the predominant tin-containing species in the synthetic systems of Sn/S/amine and a basic building block for the SnS-*n* framework [11].

In most of the thiostannates compounds, the cations, which compensate the anions charge in the structure, are either protonated amine or tetra-alkylammonium [7–13] ions or metal cations [14,15]. Thiostannates which combine with transition metal complex cations as counterions are still a less explored area [16]. The transition metal complex cations may serve as structure-directing agents in growing chalcogenometalates crystals [17]. Bensch et al. [18] very recently reported four compounds of this kind with $[Sn_2S_6]^{4-}$ anions, using elemental nickel, tin and sulphur as starting reactants. In this work, we have successfully prepared thiostannates $[Ni(en)_3]_2Sn_2S_6$ and $[Ni(dien)_2]_2Sn_2S_6$ from the Ni(II)/Sn(IV)/S/en (or dien) (en = ethylenediamine, dien = diethylenetriamine) system under mild solvothermal conditions. This combination of transition metal ions may endue thiostannates with new properties that the transition metals have. The structures of compounds $[Ni(en)_3]_2Sn_2S_6$ and $[Ni(dien)_2]_2Sn_2S_6$ are described and their thermal behaviors have been investigated.

2. Experimental

2.1. Synthesis of $[Ni(en)_3]_2Sn_2S_6$ (1)

The source materials of $NiCl_2 \cdot 6H_2O$ (0.7131 g, 3 mmol), $SnCl_4 \cdot 5H_2O$ (1.052 g, 3 mmol) and S_8 (0.3848 g, 1.5 mmol) dissolved in 10 ml en and were carefully mixed, and then loaded into a Teflon-lined stainless steel autoclave whose volume was about 15 ml. Then the sealed autoclave was heated to 180 °C over 4 h and maintained at this temperature for four days. After cooling to room temperature, purple cubic crystals were isolated and washed with ethanol and ether (yield 65%, based on Sn). IR (cm^{-1}): 3221vs, 3121vs, 2920m, 2870m, 1671w, 1578m, 1451m, 1385m, 1323m, 1281m, 1273m, 1092m, 1011vs, 864m, 675s, 525m, 486m. Elemental analysis Found: C, 15.64; H, 5.38; N, 18.42%. $C_{12}H_{48}Ni_2N_{12}Sn_2S_6$ requires: C, 15.88; H, 5.33; N, 18.52%.

2.2. Synthesis of $[Ni(dien)_2]_2Sn_2S_6$ (2)

The pink prism-like crystals of $[Ni(dien)_2]_2Sn_2S_6$ were prepared by a similar method used in the synthesis of the crystals of **1** except that ethylenediamine was replaced by diethylenetriamine (yield 65%, based on Sn). IR (cm^{-1}): 3237m, 3133m, 2967w, 2863w, 1621m, 1574m, 1470s, 1385m, 1323m, 1281m, 1238m, 1181m, 1080vs, 1042m, 995m, 961vs, 860m, 783m, 675m, 633m, 598s, 532s. Elemental analysis Found: C, 20.08; H, 5.62; N, 17.46%. $C_{16}H_{52}Ni_2N_{12}Sn_2S_6$ requires: C, 20.02; H, 5.46; N, 17.51%.

2.3. Physical measurements

FT-IR spectra were recorded with a Nicolet Magna-IR 550 spectrometer in dry KBr pellets. Elemental analysis was carried out on an EA-1110 elemental analyzer. Thermogravimetric (TG) analysis was conducted on a SDT 2960 TGA-DCS microanalyzer. All the samples were heated under a nitrogen stream of 100 ml/min with a heating rate of 5 °C/min.

2.4. Single crystal structure determination

The measurement was carried out on a Rigaku Mercury CCD diffractometer using the ω-scan method with graphite monochromated Mo Kα radiation ($\lambda = 0.07107$ nm) at -80 ± 1 °C. The X-ray diffraction data of single crystals were collected to a maximum 2θ value of 55.0° for both **1** and **2**. An empirical absorption correction was applied for all compounds and the data were corrected for Lorentz and polarization effects. The structure of **1** was solved by direct methods using the program of SHELX 97 and the structure of **2** was solved by heavy-atom Patterson methods using PATTM (the DIRDIF program system). Both of the structures were expanded using Fourier techniques DIRDIF 99. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model for compound **2**, while the hydrogen atoms of **1** were not dealt with due to the disorder of en. The final cycle of full-matrix least-squares refinement on F^2 was based on definite observed reflections and variable parameters, and converged with unweighted and weighted agreement factors of R_1 and wR_2. A summary of the experimental details and selected results for compounds **1** and **2** is given in Table 1.

3. Results and discussion

3.1. Synthesis of the compounds

Single crystals of $[Ni(en)_3]_2Sn_2S_6$ (**1**) and $[Ni(dien)_2]_2Sn_2S_6$ (**2**) are obtained by using the reaction of $SnCl_4 \cdot 5H_2O$, $NiCl_2 \cdot 6H_2O$ and S_8 in the same molar ratio of Sn/Ni/S = 1:1:4 ($SnCl_4$:$NiCl_2$:S_8 = 1:1:0.5) under mild solvothermal conditions in en and dien solvent, respectively. Stannic chloride was used as the source material instead of Sn powder which is usually used in synthesis of thiostannates under hydrothermal or solvothermal conditions [9,10,18]. The Ozin group had studied the Sn/S/amine (water solution) system in detail and isolated dimeric $[Sn_2S_6]^{4-}$ and $[S_2O_3]^2$ reaction in-

termediates from the solution [11]. The redox disproportionation reaction of S_8 is believed to be one of the sources of the S^{2-} ion (as Eq. (1) [19]) which is used to form the $[Sn_2S_6]^{4-}$ anion.

$$1/2S_8 + 9H_2O \rightarrow 2S^{2-} + S_2O_3^{2-} + 6H_3O^+ \quad (1)$$

In the case of the Sn^{4+}/S/en (dien) system in this work, the S^{2-} ions which are necessary to form $[Sn_2S_6]^{4-}$ might also come from disproportionation of S_8 as Eq. (1), since the metal salts used are hydrated and the solvents are also not absolutely anhydrous. On the other hand, the ethylenediamine in this system might not only act as a solvent, but also offer a source of S^{2-} (or S_m^{2-}) by reacting with elemental sulphur:

$$S + en \rightarrow S^2(\text{or } S_m^{2-}) + (Hen)^+ + \text{oxidized product of amine} \quad (2)$$

Reaction (2) is complicated and has not been studied in detail. When the sulphur reacts with en, a dark brown color is developed immediately and the species of S^{2-}, S_m^{2-} and $(Hen)^+$ have been confirmed by the products, such as $(enH)_4[Sn_2S_6]$, $(enH)_4[Sn_2Se_6]\cdot en$, $(enH)_4[Sn_2Te_6]\cdot en$ [20] and $[Mn(en)_3]Te_4$ [21]. However, the mechanism of the synthetic reaction needs to be further confirmed.

It is noteworthy that transition metal cations $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ are likely better mineralizers than the protonated amines such as enH^+ and $dienH^+$, because the products from the Ni^{2+}/Sn^{4+}/S/en (dien) system are $[Ni(en)_3]_2Sn_2S_6$ and $[Ni(dien)_2]_2Sn_2S_6$ rather than $(enH)_4Sn_2S_6$ and $(dienH)_4Sn_2S_6$. If the nickel salts were not introduced into these systems under the same experimental conditions, crystallization of $(enH)_4[Sn_2S_6]$ is very difficult and the crystals were only obtained after the reaction solution had been left for about one month at room temperature.

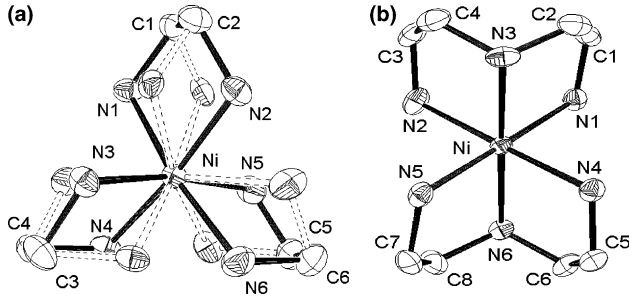

Fig. 1. The structures of the transition metal complex cations in **1** (a) and **2** (b) with the labelling scheme and ellipsoids at 50% probability. Hydrogen atoms have been omitted for clarity.

3.2. Description of the structures

The crystal structures of compounds **1** and **2** were determined by the single-crystal X-ray diffraction method. The results show that compound **1** crystallizes in the orthorhombic space group of *Pbca* (No. 61) and compound **2** in the monoclinic space group of $P2_1/n$ (No. 14). Both compounds consist of discrete $[Sn_2S_6]^{4-}$ anions with $[Ni(en)_3]^{2+}$ or $[Ni(dien)_2]^{2+}$ cations as counterions.

The structure of compound **1** is essentially the same as that of $[Ni(en)_3]_2Sn_2S_6$ which was very recently synthesized by the Bensch group, but they use elemental nickel, tin and sulphur as starting reactants [18]. The Ni^{2+} ion is coordinated by six N atoms of three bidentate ethylenediamine ligands with Ni–N distances ranging from 2.097(4) to 2.146(5) Å. The conformation of $[Ni(en)_3]^{2+}$ cation is difficult to fix due to the disorder of the ethylenediamine ligands. The configurations of the ligands are disordered with Λ ($\delta\delta\delta$):Δ ($\lambda\lambda\lambda$) [or Δ ($\lambda\lambda\lambda$) :Λ ($\delta\delta\delta$) in inversion position] occupation ratios of 0.76:0.24 (Fig. 1(a)). In compound **2**, the Ni^{2+} ion is coordinated by six N atoms of two trichelating dieth-

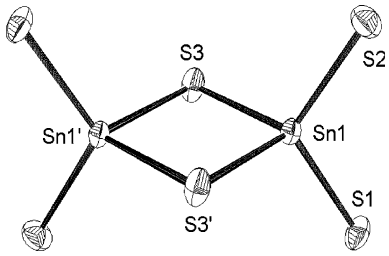

Fig. 2. The structure of the $[Sn_2S_6]^{4-}$ anion with the labelling scheme and ellipsoids at 50% probability.

ylenetriamine ligands. The conformation of octahedral $[Ni(dien)_2]^{2+}$ is s-facial (Fig. 1(b)).

In compounds **1** and **2**, The Ni–N bond lengths are within the range for compounds containing $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ cations [22,23]. The $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ octahedral coordination spheres are distorted, which can be seen from the N–Ni–N_{trans} angles varying from 169.7(2)° to 172.3(2)° and 177.52(8)° to 179.47(7)°, respectively. The three octahedral axial N–Ni–N_{trans} angles of the coordination octahedra are listed in Table 2.

The $[Sn_2S_6]^{4-}$ anion, which is formed by the connection of two SnS_4 tetrahedra sharing a common edge, can be described as a planar Sn_2S_2 four-membered ring with each Sn atom having two terminal Sn–S bonds (Fig. 2). The terminal Sn–S_t bond lengths, being between 2.334(1) and 2.354(1) Å, are shorter than those of the bridging Sn–S_b bonds which vary from 2.461(1) to 2.453(1) Å. Both kinds of bond lengths are in good agreement with corresponding bond lengths in other compounds containing $[Sn_2S_6]^{4-}$ anions [20,24]. The two SnS_4 tetrahedra in the $[Sn_2S_6]^{4-}$dimer are slightly distorted, which is demonstrated by the S_t–Sn–S_t and S_t–Sn–S_b angles deviating from the ideal value of 109.5° (Table 2).

The packing of $[Sn_2S_6]^{4-}$ anions in compounds **1** and **2** is different (shown in Fig. 3). There are eight $[Sn_2S_6]^{4-}$ anions at corners and six at crystal faces per unit cell of **1**, while there are four $[Sn_2S_6]^{4-}$ anions at crystal edges and two at crystal faces of [0 0 1] per unit cell of **2**. One $[Sn_2S_6]^{4-}$ anion is surrounded by four $[Ni(en)_3]^{2+}$ cations in **1**, and by six $[Ni(dien)_2]^{2+}$ cations in **2**.

Between the anion and cation in compound **2**, a lot of short intermolecular N–H···S interactions, which indicate weak hydrogen bonding, are found and one Sn_2S_6 unit is hydrogen bonded to six different cations (Fig. 4(b)). The terminal S(1) and S(2) atoms form hydrogen bonds to H–N groups of $[Ni(dien)_2]^{2+}$ cations with H···S distances ranging from 2.508(3) to 2.888(2) Å and N–H···S angles ranging from 145.0(2)° to

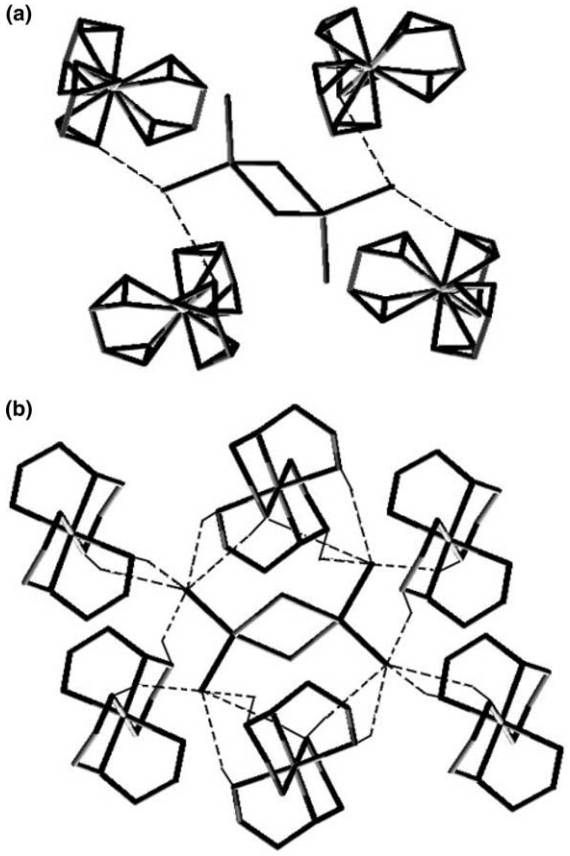

Fig. 4. The views of the $[Sn_2S_6]^{4-}$ anion hydrogen bonding interaction with cations in **1** (a) and **2** (b). Hydrogen atoms have been omitted for clarity.

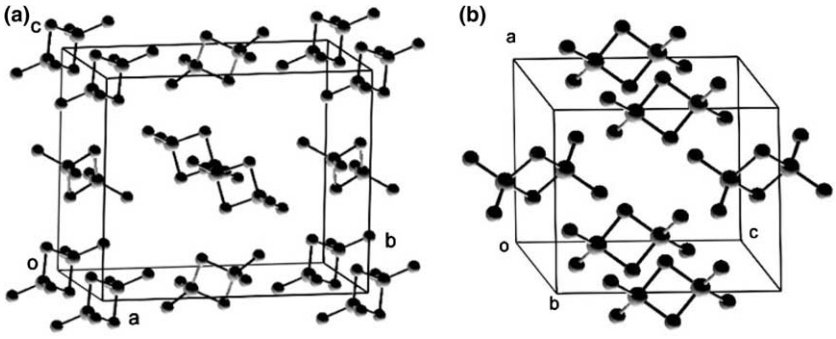

Fig. 3. The packing of the $[Sn_2S_6]^{4-}$ anions in **1** (a) and **2** (b), the cations have been omitted for clarity.

N(3)–H(5)	S(2)	0.924(3)	2.705(2)	3.561(2)	154.5(2)
N(4)–H(14)	S(2)	0.942(3)	2.508(2)	3.407(2)	159.7(2)
N(5)–H(16)	S(2)	0.906(3)	2.846(2)	3.676	153.0(2)

171.7(2)° (Table 3). In compound **1**, the number of interion interactions is less than that in **2** (Fig. 4(a)) and this difference might be the reason of disorder of the ethylenediamine in **1**. The results show that $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ cations have different structure-directing effects, although both of them are actually synthesized under the same conditions except for the amine.

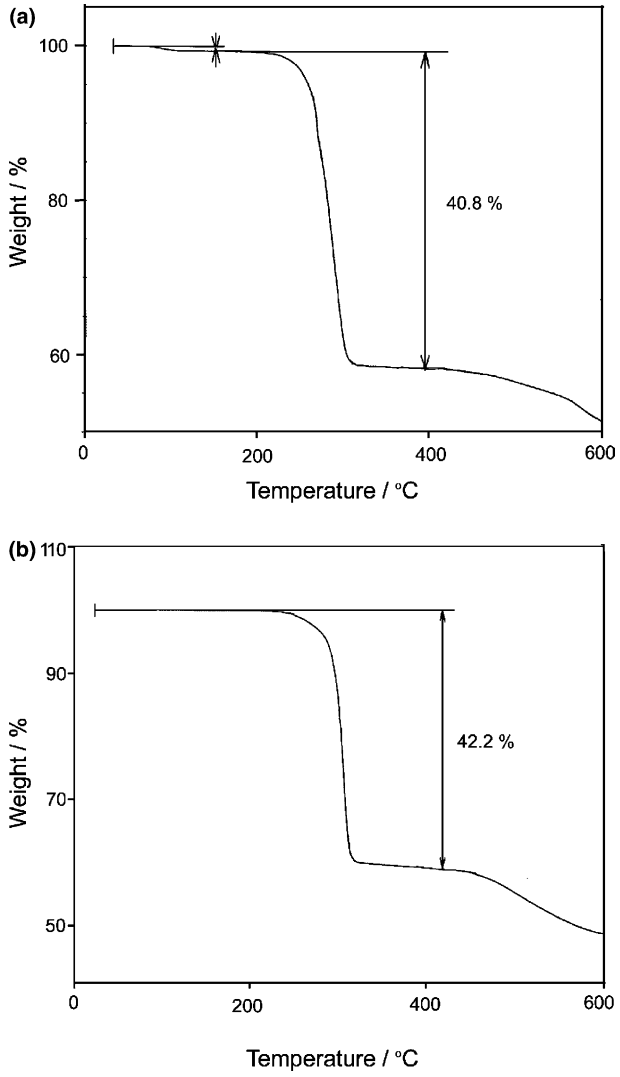

Fig. 5. Thermogravimetric analyses curves of compounds **1** (a) and **2** (b).

3.3. Thermal analysis

The thermal behavior of the title compounds were measured between temperatures of 20 and 600 °C with the DSC-TGA method under nitrogen. The results are shown in Fig. 5. The first step mass loss of **1** (about 0.56% below 100 °C) is attributed to desorption of water (Fig. 5(a)). Compound **1** is decomposed at 291 °C accompanied by one endothermic peak in the DSC curve (peak temperature, T_p). The corresponding loss of 40.8% is in accordance with the complete mass loss of six en ligands (Calc. 39.7% for 6 en).

The decomposition of **2** is at 310 °C (T_p of DSC) and the corresponding loss of 42.2% is in good agreement with the complete mass loss of the four dien ligands (Calc. 43.0% for 4 dien). From the behaviors of thermal decomposition, it is obvious that compounds **1** and **2** remove all of their organic amine ligands in one step under nitrogen. The decomposition temperature of **2** is higher than that of **1** by about 20 °C. This result can be explained reasonably by the structure analysis that shows compound **2** has more N–H···S hydrogen bonds than compound **1**, which makes the organic ligands in **2** more difficult to remove.

4. Conclusions

Single crystals of $[Ni(en)_3]_2Sn_2S_6$ and $[Ni(dien)_2]_2$-Sn_2S_6 can be obtained by reaction of $SnCl_4 \cdot 5H_2O$, $NiCl_2 \cdot 6H_2O$ and S_8 under mild solvothermal conditions. The results presented in this paper demonstrate that the transition metal complex cations can act as a mineralizer in the synthesis of $[Sn_2S_6]^{4-}$ thiostannates from the Ni(II)/Sn(IV)/S/en (dien) system using solvothermal techniques. The $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ cations are likely a better mineralizer than protonated amines, such as enH^+ and $dienH^+$.

The different structure directing effect of $[Ni(en)_3]^{2+}$ and $[Ni(dien)_2]^{2+}$ cations is one of the reasons that $[Sn_2S_6]^{4-}$ anions arrange in a different way in the crystal structures of compounds **1** and **2**. Both title compounds lose all of their amine ligands in one step under nitrogen. The decomposition temperature of **2** is higher than that of **1** by about 20 °C, accounting for the N–H···S hydrogen bonding.

5. Supplementary data

Crystallographic data for the structural analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 217522 and 217523 for com-

pounds **1** and **2**, respectively. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

Abstract

Two copper(II) sodium(I) coordination compounds of formula $[C_{16}H_{12}CuNa_2O_{10}]$ (**1**) and $[C_6H_8CuNa_2O_{10}]$ (**2**) were prepared and their structures were characterized by single-crystal X-ray diffraction, IR spectra and thermal analyses. In complex **1**, the sodium atom is six coordinated with four carboxylate oxygens from two *o*-pthalate ligands, another one oxygen atom from one *o*-pthalate and one water molecule building a distorted octahedron. All the four oxygen atoms in one *o*-pthalate participate in coordination, two of which bridge one sodium and one copper atoms, with another one bridging two sodium atoms and the fourth coordinating one sodium atom. As for complex **2**, the sodium atom is also six-coordinated with tetrakis-monodentate malonate oxygen atoms and two water molecules building a distorted octahedron. For every malonate, three oxygens coordinate out of the total four. Every carboxylate offers an oxygen atom bridging one sodium and one copper atom with the remaining one bridging two sodium atoms. In both cases, each copper atom is in a square planar environment formed by four carboxylate-oxygens from four *o*-pthalates and two malonates respectively. The IR spectra also testify the structure detection. Thermal analyses of the two complexes were also carried out.

Keywords: Herometallacrown; Malonate; *o*-Pthalate; Cu(II) complexes

1. Introduction

Malonate as a bridging ligand has versatile modes in Cu(II) complexes [1–7]. The variety of the coordination modes of the malonate ligand (bidentate through two carboxylate-oxygens and different carboxylate-bridging modes) accounts for the structural complexity of the malonate complexes [8]. The *o*-pthalate ligand can also act as a bidentate or bis-(bidentate) ligand. The coordination ability and versatility of malonate and *o*-pthalate as ligands induced us to investigate the coordination of the mixed-ligand species with the copper(II) ion. Two copper(II) sodium(I) complexes $[C_{16}H_{12}CuNa_2O_{10}]$ (**1**) and $[C_6H_8CuNa_2O_{10}]$ (**2**) have been prepared by the reaction of *o*-pthalic acid anhydride, sodium hydroxide and sodium malonate with $CuCl_2$. Complex **1** belongs to the monoclinic system, $P2_1/c$ space group. Its crystallographic data are: $a = 11.086(2)$ Å, $b = 6.6480(13)$ Å, $c = 12.195(2)$ Å, $\alpha = 90°$, $\beta = 101.88(3)°$, $\gamma = 90°$. The crystal structure data indicates that the Cu(II) ion is coordinated through four oxygen atoms from four *o*-pthalate ligands. The Cu(II) ion has four coordination in the center of a square plane. The Na(I) ion is coordinated with five carboxylate oxygen atoms and one water molecule in a more complicated mode. The crystal is stabilized by π–π stacking interactions between neighboring planes. As for complex **2**, it belongs to the orthorhombic system, *Pbca* space group. The crystallographic data are: $a = 6.8403(14)$ Å, $b = 9.5226(19)$ Å, $c = 16.402(3)$ Å, $\alpha = 90°$, $\beta = 90°$, $\gamma = 90°$. The crystal structure data shows that the Cu(II) ion is coordinated through four oxygen atoms from two bidentate malonates. Cu(II) ion is four coordinate in the center of a square plane. The

doi:10.1016/j.poly.2003.11.059

Na(I) ion is six coordinated with four malonate oxygen atoms and two water molecules in a more complicated mode. These two complexes both qualify as metallacrowns, metal complexes with a structure analogy to crown ethers [9].

2. Experimental

2.1. Materials and physical measurements

The chemicals for the syntheses of the compounds were all of analytical pure grade, purchased from Zhengzhou Chemical Reagent Company and used without further purification. IR spectra were recorded on a Nicolt IR-470 spectrophometer as KBr pellets in the range 4000–400 cm^{-1}. A single crystal was measured on a Rigaku-Raxis-IV X-ray diffractometer and thermal analyses were done with a MKV thermal analyzer in air atmosphere from room temperature to 400 °C.

2.2. Syntheses of complexes *1* and *2*

An aqueous solution containing *o*-pthalic acid anhydride (0.06 g, 0.4 mmol) and sodium malonate (0.06 g, 0.4 mmol) was neutralized to pH 7 with 0.5 M NaOH solution. 2 ml 0.5 M aqueous solution of $CuCl_2$ was added to the above-mentioned solution. Then the resulting mixture was run into a small vial and allowed to evaporate naturally at room temperature. Filtered, washed with anhydrous ethanol and dried naturally, two different color crystals suitable for single-crystal X-ray diffraction analysis were obtained after about three months. One is complex **1**, deep blue; the other is complex **2**, pale blue.

2.3. X-ray crystallography

Intensity data of complexes **1** and **2** were measured with a Rigaku-Raxis-IV X-ray diffractometer using monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation at 291 K. 2859 reflections were measured over the ranges $1.88 \leqslant$

Symmetry transformations used to generate equivalent atoms: #1 $-x, -y-2, -z$; #2 $x, -y-5/2, z+1/2$; #3 $-x, y+1/2, -z-1/2$; #4 $x, y+1, z$; #5 $-x, y-1/2, -z-1/2$; #6 $x, y-1, z$.

$2\theta \leqslant 27.53$, $0 \leqslant h \leqslant 14$, $-8 \leqslant k \leqslant 8$, $-15 \leqslant l \leqslant 15$ yielding 1687 unique reflections for complex **1**. For the case of the second complex, 3484 reflections were measured over the ranges $2.48 \leqslant 2\theta \leqslant 27.49$, $-8 \leqslant h \leqslant 8$, $0 \leqslant k \leqslant 12$, $-19 \leqslant l \leqslant 19$, and yielded 1129 unique reflections. Raw data were corrected and the structures were solved using the SHELX-97 program. Non-hydrogen atoms were located by direct phase determination and subjected to anisotropic refinement. The full-matrix least-squares calculation on F^2 were applied on the final refinement. The refinement converged at $R_1 = 0.0321$ and $wR_2 = 0.0771$ values for reflections with $I > 2\sigma$ for complex **1**, and $R_1 = 0.0412$ and $wR_2 = 0.1147$ values for reflections with $I > 2\sigma$ for complex **2**. Details of the crystal structure determinations are summarized in Tables 1 and 2 of this paper. Full atomic data are available as a file in CIF format.

3. Results and discussion

3.1. IR spectra

In the IR spectrum of either complex **1** or **2**, a strong and broad band in the 3500–3300 cm^{-1} region (O–H stretching vibration) indicates the presence of coordinated water molecules. In the IR spectrum of complex **1**, the presence of malonate accounts for the weak intensity peaks at 2936 cm^{-1} for νC–H, strong peaks at 1606 and 1577 cm^{-1} for ν_{as}COO and medium intensity peaks at

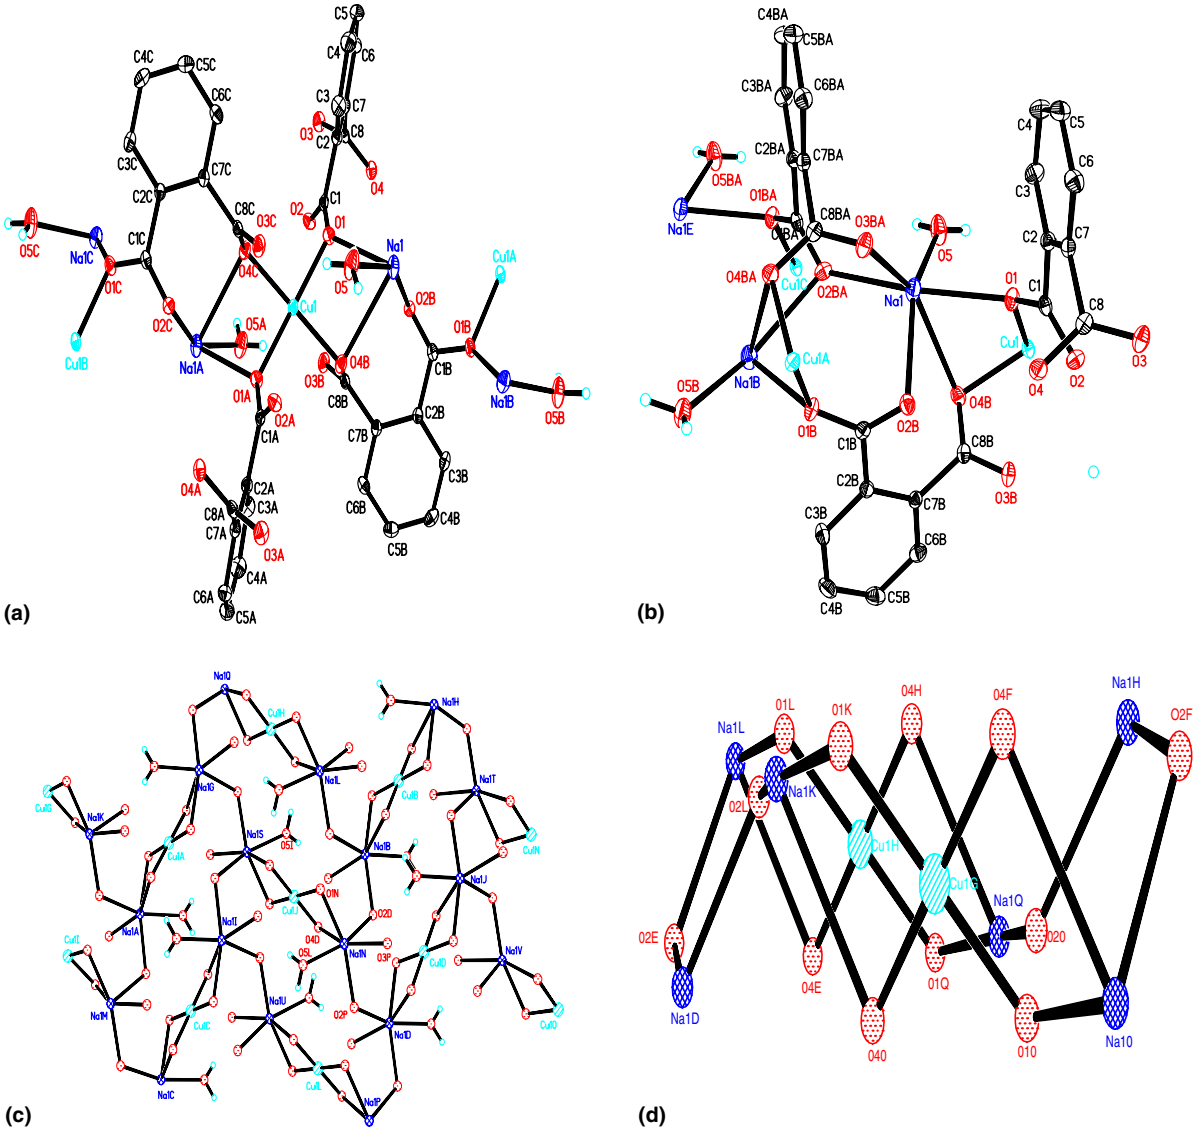

Fig. 1. Perspective drawings of (a) the copper (II) and (b) sodium (I) environments in complex **1** along with the atom numbering. Thermal ellipsoids are drawn at the 50% probability level, (c) two dimensional network of **1**, (d) core of complex **1** as a metallacrown.

1407 and 1366 cm^{-1} for v_sCOO. In the IR spectrum of complex **2**, the medium intensity peaks at 1638, 1572 and 1487 cm^{-1} are consistent with the existence of a benzene cycle. The other strong peaks at 1611 and 1592 cm^{-1}, 1407 and 1366 cm^{-1} can be attributed to v_{as}COO, v_sCOO, respectively.

3.2. Crystal structure of complex *1*

Crystal data and structure determination summaries for complexes **1** and **2** are shown in Table 1. Four oxygen atoms from four *o*-pthalate groups coordinate to the central copper atom and build a near square around it, which is shown in the angle data: O1–Cu1–O1A = 180.0°, O1–Cu1–O4B = 89.12(7)° and O4B–Cu1–O4C = 180°. The values of the copper–oxygen bond lengths are somewhat different [1.9445 Å for Cu1–O1 and Cu1–O1A, 1.9725 Å for Cu1–O4B and Cu1–O4C] (Fig. 1(a)).

Four oxygen atoms from two bidentate *o*-pthalates, another one oxygen atom from a monodentate *o*-pathalate and one water molecule participate in coordinating to the central sodium atom and make a distorted octahedron. O5, O3BA, O2B and O4B build the equatorial plane with O1and O2BA occupying the axial positions (Fig. 1(b)). The selected bond lengths and angles are shown in Table 3.

For each carboxylate there is one oxygen atom bridging a sodium and a copper atom. One of the remaining oxygen atoms in a certain *o*-pthalate group bridges two sodium atoms and the other one coordinate a sodium atom.

The sodium atoms build zigzag chains owing to the coordination of *o*-pthalate groups. These chains are linked through 4-coordinated copper atoms and form macrocycles, which constitute further parallel planes. The distance between neighboring planes is about 10.9 Å. The ring normal and the vector between the ring centroids form an angle of about 47°, with a centroid – centroid distance of 4.639 Å, which indicates that this dimensional structure is stabilized by interplanar π–π stacking between the benzene rings in neighboring planes [10]. The intraplanar structure can be seen in Fig. 1(c).

3.3. Crystal structure description of complex *2*

The copper atoms are 4-coordinated CuO_4. Four oxygen atoms from two bidentate malonate ligands describe a parallelogram environment around the copper atom, as is shown in these angles: O3C–Cu1–O3 = 180.0°, O3C–Cu1–O1C = 93.45(9)°, O1C–Cu1–O1 = 180.00(10)°. And the copper–oxygen bond lengths are 1.9494 Å for Cu1–O3C and Cu1–O3, 1.960(2) Å for Cu1–O1C and Cu1–O1 (Fig. 2(a)).

The sodium atoms are 6-coordinated NaO_6. Four oxygen atoms from four different malonate ligands and two water molecules form a distorted octahedron. Three oxygen atoms from malonate ligands and one water molecule occupy the equatorial sites. The 4th malonate oxygen atom and the other water molecule hold the axial positions. The sodium-water oxygen bond lengths [Na1A–O5A = 2.366(3) Å and Na1A–O5E = 2.387(3) Å] are longer than those of sodium-malonate oxygen bonds [Na1A–O1 = 2.456(2) Å, Na1A–O4A = 2.462(3) Å, Na1A–O4FC = 2.580(3) Å and Na1A–O3C = 2.584(3) Å]. Three oxygen atoms O1, O3C, O4C from malonate and one water molecule oxygen O5E occupy the equatorial sites with large deviations from the ideal value of 90° being observed

Symmetry transformations used to generate equivalent atoms: #1 $-x+2,-y-1,-z$; #2 $x-1/2,-y-1/2,-z$; #3 $-x+5/2,y-1/2,z$; #4 $x-1/2,y,-z+1/2$; #5 $x+1/2,-y-1/2,-z$; #6 $x+1/2,y,-z+1/2$; #7 $-x+5,y+1/2,z$.

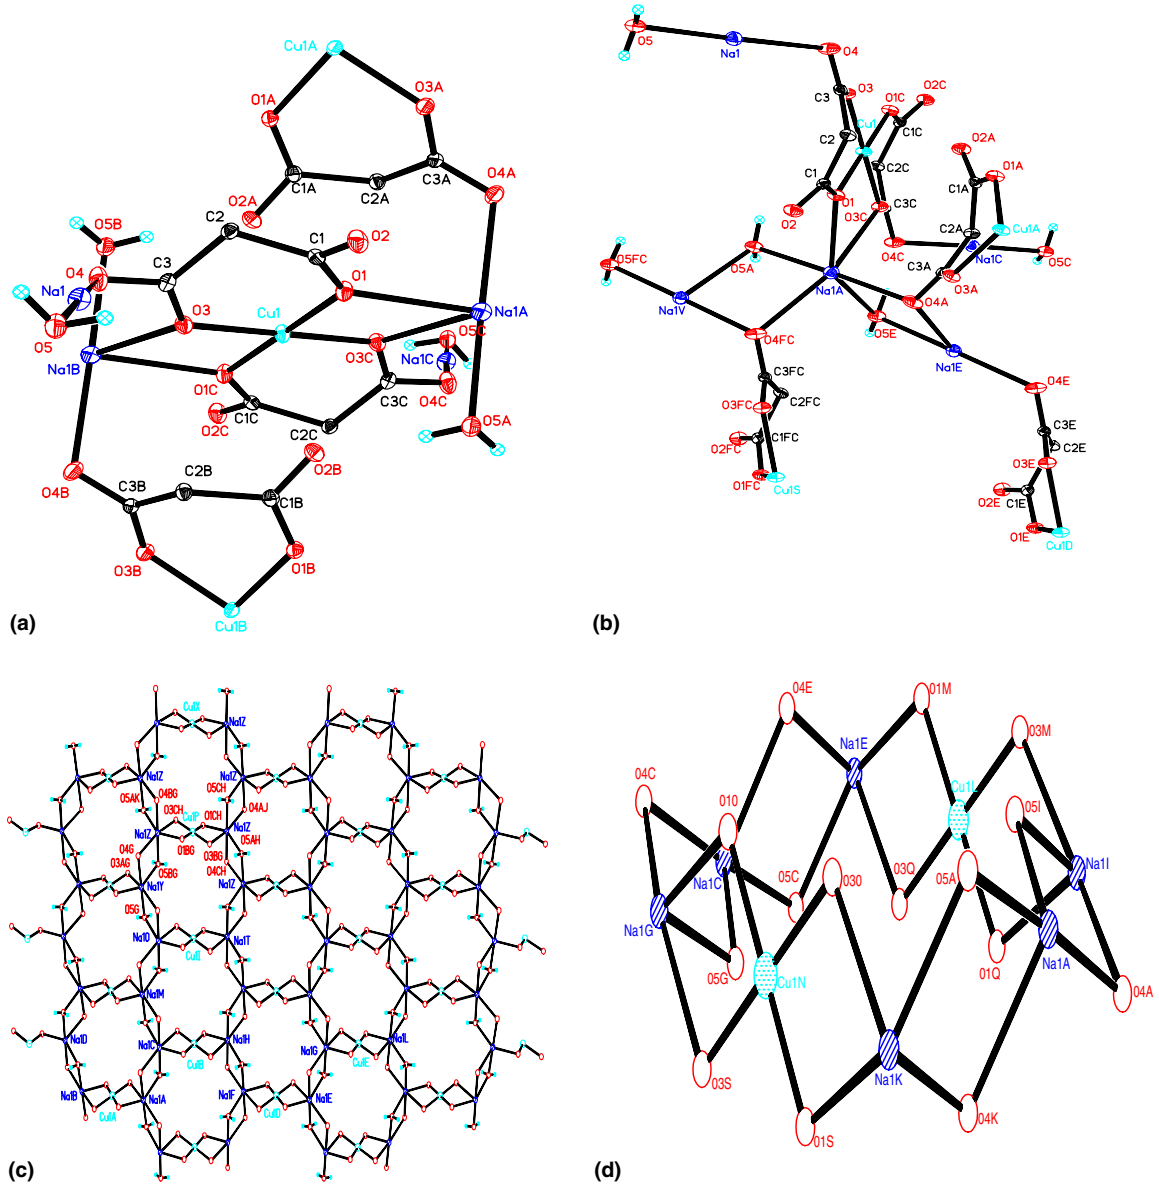

Fig. 2. Perspective drawings of (a) the copper (II) and (b) sodium (I) environments in complex **2** along with the atom numbering. Thermal ellipsoids are drawn at the 50% probability level, (c) diagram of one planar structure in complex **2**, (d) core of complex **2** as a metallacrown.

for some bond angles around the sodium atom [100.34(9)°, 64.18(8)° and 98.20(9)° for O4A–Na1A–O4FC, O1–Na1A–O3C and O4A–Na1A–O3C, respectively]. Some selected bond angles are shown as follows: Cu1–O1–Na1B = 105.87(10)°, Cu1–O3–Na1C = 101.63(9)°, Na1A–O4A–Na1E = 97.46(9)°, Na1A–O5A–Na1V = 105.79(11)° (Fig. 2(b)).

For every malonate ligand there are three oxygen atoms participating in coordinating out of the total four with the other one being free. One oxygen atom from each carboxylate bridges one sodium and one copper atom and the remaining coordinating oxygen atom bridges two sodium atoms.

For each sodium atom there are two coordinating water molecules each of which bridge two different sodium atoms. The oxygen atom from one water molecule exists not only in the equatorial site for one sodium coordination environment, but also at the axial position for another sodium atom's unit.

The sodium atoms form zigzag chains through the coordination of water molecules and malonate-oxygen atoms. These chains are linked by 4-coordinated copper atoms and build 2-D planes (Fig. 2(c)), which constitute further a complicated 3-D structure owing to the coordination effect of the remaining water molecules and malonate-oxygen atoms.

It can be found that the malonate's coordination mode in complex **2** is different not only from those in past copper(II) complexes [1–7], but also from those in other metal complexes [11–14].

The other important characteristic of this crystal structure is that 6 sodium atoms and 2 copper atoms build an 8-center metallocycle through coordination with malonate ligands and water molecules just as in complex **1** (Figs. 1(d) and 2(d)). Both complexes **1** and **2** seem to be so-called heterometallacrown.

3.4. Thermal analysis

Thermogravimetic analysis of compound **1** reveals that it loses two coordinating water molecules at $T < 176$ °C. The decomposition of *o*-pthalate occurs in two steps at about $T = 280$ and $T = 372$ °C. Similarly, the thermogravimetic analysis of compound **2** indicates that it loses a total of two coordinating water molecules at $T < 220$ °C. The decomposition of *o*-pthalate occurs in two steps at $T > 350$ °C.

3.5. Conclusion

The core of complex **1** illustrates that it is a 16-metallacrown-8. Complex **2** has an overall ring structure similar to that of complex **1**. From Figs. 1(d) and 2(d) it can be seen that these two complexes qualify as authentic examples of 16-metallacrown-8 structure types. The difference between them is the different linking system between the copper and sodium atoms replacing the carbon atoms of the 16-crown-8 ether.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 217021 and 217022 for compounds **1** and **2**, respectively. Received 9 September 2003; accepted 1 December 2003

Abstract

One new dimeric manganese(III) complex $[MnL(H_2O)]_2(ClO_4)_2 \cdot H_2O$ **(1)** where [L = *N*,*N*′-bis(2-hydroxyacetophenylidene)-1,2-diaminopropane] has been synthesised and characterised by spectroscopic and electrochemical study, and the single crystal structure of the complex was determined. The crystal structure features the presence of two independent molecules in the asymmetric unit. The dimeric unit is formed by a double Mn–O bridge of one molecule with its centrosymmetric homologue. Low temperature magnetic susceptibility measurements show a ferromagnetic intra-dimer interaction.

Keywords: Dimeric complex; Manganese(III); Crystal structure; Ferromagnetic behaviour

1. Introduction

Exchange interaction between paramagnetic centres of a large number of multi-nuclear complexes has already been investigated. The nature and the tuning of magnetic interactions between metal centres are crucial points in the conception of molecule-based magnetic materials [1]. Binuclear manganese(III) Schiff base compounds are of increasing interest because such dinuclear systems are known to act as a paramagnetic building block for multidimensional expanded structures [2] as well as for their important roles in biological systems, e.g., in many metalloenzymes, redox and non-redox proteins [3,4] and also as a catalyst in olefin epoxidation [5]. Moreover in nature, the oxygen evolving complexes of photosystem II are believed to be catalysed by a cluster of manganese ions. Manganese(III) salen-type complexes are very well studied because this type of Schiff base ligands present suitable biometric properties that can mimic the structural feature of the active site [5,6].

The manganese(III) salen-type compounds are generally in equilibrium between the monomeric and the dimeric species, their solid state form depends on the steric characteristics of the salen-type Schiff bases [1a]. Dimeric manganeses(III) complexes generally exhibit an antiferromagnetic intra-dimer interaction which is very well explored [7–13], but a few examples of ferromagnetic interactions have been reported as well [14–17]. These type of ferromagnetic dimers afford an unusual $S = 4$ ground spin state making themselves appealing candidates for a building block to design new magnetic materials.

Here, for the synthesis of a manganese(III) complex with tetradentate N_2O_2 donor set Schiff base ligands, we employed the poorly coordinating perchlorate ion so that water would be able to complete the coordination sphere of the metal ions and expected an intramolecular interaction between these species, resulting in a dimer.

In this report, we present the synthesis, characterisation, single crystal X-ray structure and low temperature

magnetic behaviour study of one novel out-of-plane manganese(III) Schiff base dimer where two independent molecules are in the asymmetric unit. This phenomenon is very rare in the literature [10]. The dimeric unit is formed by the double Mn–O bridge of one molecule with its centrosymmetric homologue. Interestingly, this complex displays ferromagnetic behaviour at low temperature.

2. Experimental

2.1. Physical measurements

The infrared spectrum was recorded on a Perkin–Elmer FT-IR spectrophotometer as a KBr pellet and the electronic spectrum on a Perkin–Elmer Lambda-40 spectrophotometer using acetonitrile as solvent. Elemental analyses were carried out on a Perkin–Elmer 2400-II instrument. Electrochemical studies were performed on a CH 600A cyclic voltameter instrument using acetonitrile as solvent and tetrabutyl ammonium perchlorate as the supporting electrolyte. Variable-temperature magnetic susceptibility measurements were carried out with a Quantum Design MPMS-5S SQUID magnetometer under an applied magnetic field of 1000 Oe. Diamagnetic corrections were estimated from Pascal tables and magnetic data were corrected for diamagnetic contributions of the sample holder [18].

2.2. Materials

Reagent grade 2-hydroxy acetophenone, 1,2-diaminopropane (Fluka) and manganese(II) perchlorate hexahydrate (Fluka) were obtained commercially. All the solvents used were of reagent grade.

2.3. Preparation

2.3.1. Synthesis of the ligand and complexes

2.3.1.1. Synthesis of the Schiff base ligand. The Schiff base ligand $[HOC_6H_4C(CH_3)NCH_2CH(CH_3)NC(CH_3)C_6H_4OH]$ (H_2L) was obtained by refluxing a methanolic solution (25 ml) of 2-hydroxy acetophenone (2 mmol) and 1,2-diaminopropane (1 mmol) for 30 min. The resulting orange-yellow solution containing the ligand was used without further purification.

Caution! Perchlorate salts are potentially explosive and should be used in small quantities with much care.

2.3.2. Synthesis of the title compound $[MnL(H_2O)]_2(ClO_4)_2 \cdot H_2O$ (**1**)

To a methanolic solution of manganese perchlorate (0.362 g, 1 mmol), a methanolic solution of the Schiff base (1 mmol) was added with constant stirring. The resulting solution was stirred for 5 min at room temperature. After three days crystals suitable for X-ray diffraction were collected and the rest were filtered and air-dried. Yield: 60%. *Anal.* calc. for $C_{19}H_{23}ClMnN_2O_{7.5}$, C, 44.89; H, 4.92; N, 5.51; Mn, 10.82. Found: C, 44.81; H, 4.86; N, 5.48; Mn, 10.79%.

2.4. Crystallographic structure determination of compound **1**

A crystal was mounted on an ENRAF-NONIUS K-CCD diffractometer and analysed using monochromated Mo-Kα X-ray radiation ($\lambda = 0.71073$ Å). The structure was solved by direct methods with the SIR97 program. Least-squares structure refinements based on F^2 were carried out by a user defined block-diagonal matrix. Locations of hydrogen atoms, except some water ones, were generated geometrically (C–H = 1.0 Å) and included in the refinement with isotropic thermal parameters. All non-hydrogen atoms were refined with anisotropic thermal parameters. Atom scattering factors were taken from the International Tables for

Crystallography. Unit-cell parameters were obtained by least-square refinement from 9428 reflections in the range $6.1° \leqslant \theta \leqslant 27.4°$. 268 frames were collected during 15 h by ω scans of 2° giving 17 994 measured reflections. Crystal data and details of data collection are given in Table 1. Final reliability factors converged to $R(F) = 0.049$ and $wR(F^2) = 0.157$. A final difference Fourier map showed residual density of 1.45 e Å.

3. Results and discussion

3.1. Infrared spectrum

The infrared spectrum of compound **1** is very much consistent with the structural data presented in this paper. The bands in the range 3524 and 1620 cm^{-1} are attributable to O–H stretching and bending of coordinated water ligands or water of crystallisation. This also indicates the presence of hydrogen bonding in the complex [19]. The ν(C=N) band appears at 1598 cm^{-1}. The phenolic C–O stretching is present at 1274 and 1286 cm^{-1} [19,20]. Bands in agreement with non-coordinated anions could also be observed for perchlorate compounds, 1172, 1161–1086, 969 cm^{-1} [20,21]. Ligand coordination to the manganese centre is substantiated by two bands appearing at 476 and 456 cm^{-1}, attributable to ν(Mn–N) and ν(Mn–O), respectively.

3.2. Electronic spectrum

Although the electronic spectra of the manganese complexes with multidentate Schiff base ligands is not in general a good indicator of geometry, it can act as a supporter of it [22].

The complex displays two strong absorption bands in the region 225 and 276 nm, which can be assigned to the charge transfer from the ligands to the Mn(III) transition. As usual, the spectrum shows very weak low-intensity absorption bands associated with d–d transitions in the range 490–500 nm for compound **1**.

3.3. Electrochemical study

The electrochemical study of the compound was performed using acetonitrile as the solvent and tetrabutylammonium perchlorate as the supporting eletrolyte at a scan rate of 50 mV s^{-1}. Cyclic voltammetry on compound **1** shows (Fig. 1) two reductive responses on the negative side of SCE (at −0.30, −0.47 V) due to the Mn(II)/Mn(III) redox couple, both of which are irreversible in nature. The observed potential gap (170 mV) between the two reductions indicates the effective communication between the Mn(III) centres through the two phenoxo-bridges. Two irreversible oxidation responses

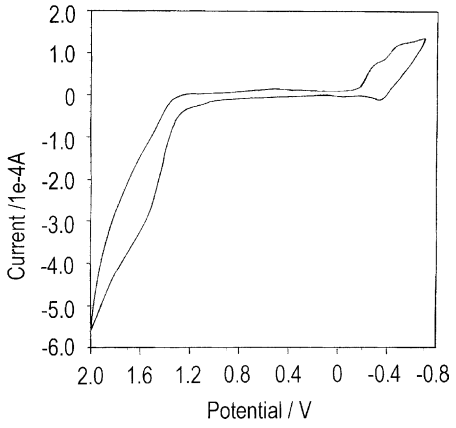

Fig. 1. Cyclic voltammogram of compound **1** in acetonitrile.

are also expected for such a system, but only one such oxidation is observed on the positive side of SCE at 1.57 V [due to oxidation of Mn(III) to Mn(IV)], as the solvent itself oxidises at 2.0 V.

3.4. Crystal structure of compound *1*

The crystal structure determination revealed that compound **1** associates as a dimer in the solid state and two slightly different dimers were found. These are the result of the presence of two independent molecules of **1** in the asymmetric unit. The ORTEP diagram of the independent molecules in the asymmetric unit are depicted in Fig. 2 and a view of the dimer is shown in Fig. 3.

The two independent molecules present in the asymmetric unit are structurally identical except for a slight variation in bond lengths and angles. The presence of a chiral carbon atom on the ligand could have been anticipated to introduce a segregation among the complex units even for a racemic mixture. This is not the case because the compound crystallizes in a centro-symmetric space group. In both independent cationic units **A** and **B**, the Mn(III) ion adopts a distorted octahedral geometry in which the equatorial plane is formed by the coordination of the Schiff base ligand, i.e., two imino-nitrogen and two phenolic-oxygen atoms, and the axial sites are occupied by oxygen atoms of the coordinated water molecule and the bridging O atom. For both molecules **A** and **B**, the equatorial bond distances are slightly shorter than the axial bond distances and the Mn atoms are 0.1040(5) and 0.0897(5) Å out of the equatorial planes. Consequently the environment around each manganese atom can be described as a distorted $N_2O_2O'_2$ octahedron as a result of Jahn–Teller distortion.

Each cationic moiety associates with an identical unit in dimers, **AA** and **BB**, in which the Mn-centers are doubly bridged by two μ-phenoxo oxygen atoms from the Schiff base ligands. Each molecule of a pair is related

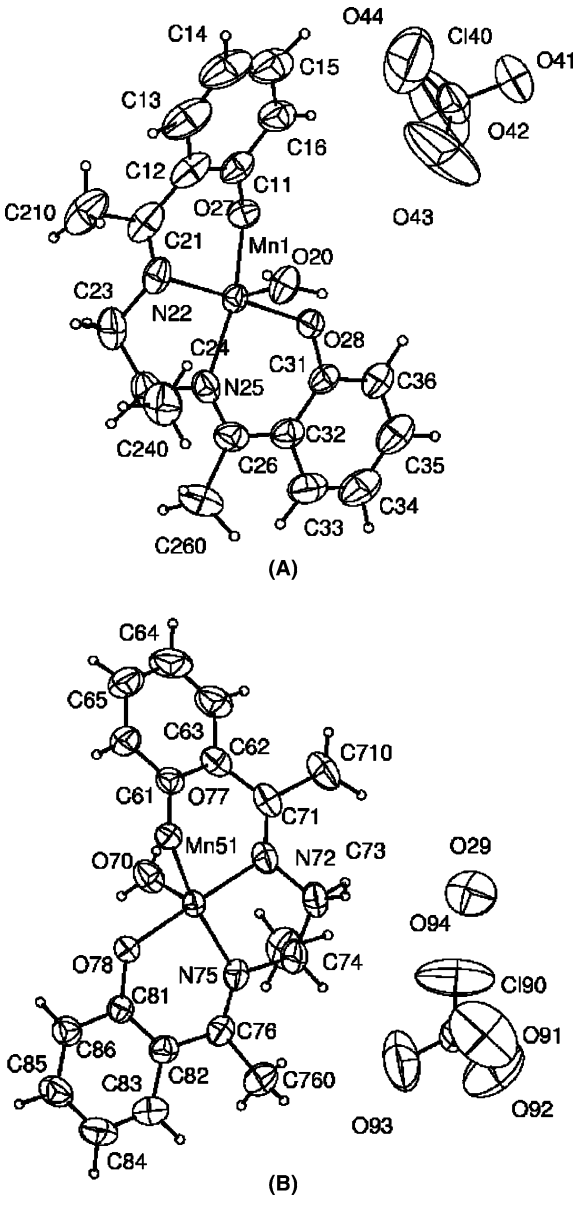

Fig. 2. ORTEP plot of the two independent molecules showing half of a dimer (**A** and **B**) present in the asymmetric units. The thermal ellipsoids are represented at 50% probability level. Selected bond lengths (Å) and angles (°): Unit **A**: Mn1–N22, 1.964(4); Mn1–N25, 1.997(4); Mn1–O27, 1.894(3); Mn1–O28, 1.853(3); Mn1–O20, 2.189(4); Mn1–O27* $(1-x,-y,1-z)$, 2.411(3). Mn1–O27–Mn1*, 100.4. Unit **B**: Mn51–N72, 1.972(4); Mn51–N75, 1.991(4); Mn51–O77, 1.892(3); Mn51–O78, 1.856(3); Mn51–O70, 2.220(4) and Mn51–O77* $(1-x,-y,-z)$, 2.401(3). Mn51–O77–Mn51*, 100.9.

to the other by centro-symmetry therefore whereas the asymmetric carbon atom of one has *R* configuration, the second has *S*. The bridging Mn–O bond distances are 2.411(3) Å for **AA** and 2.401(3) Å for **BB** and intra-dimer Mn–Mn separations are 3.325(1) and 3.326(1) Å, respectively.

The two Mn linked water molecules enable H-bonds between the different dimers (O(20)···O(78), 2.795(5) Å and O(70)···O(28), 2.787(5) Å) as well as with a per-

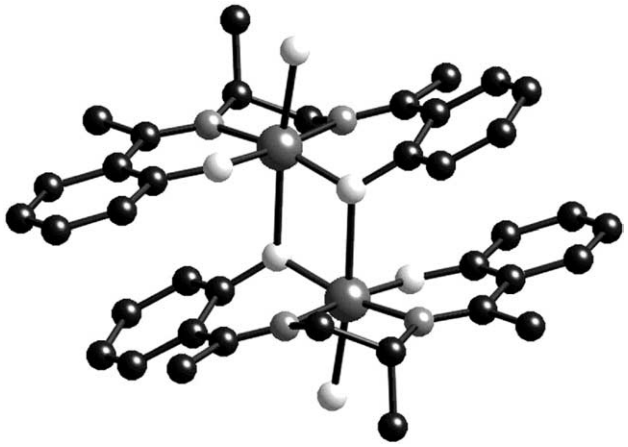

Fig. 3. View of the molecular arrangement for a cationic dimer unit of compound **1** (H atoms are omitted for clarity).

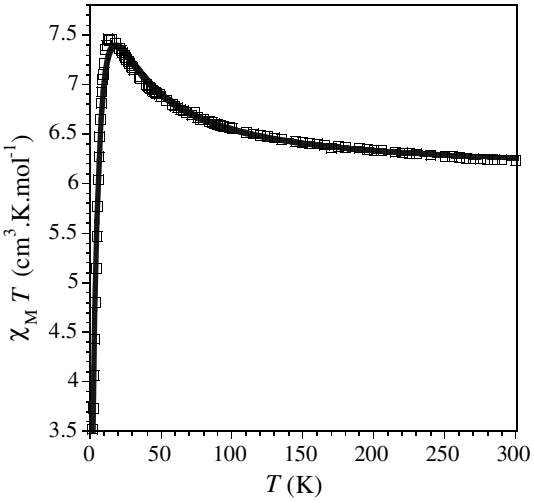

Fig. 5. Temperature dependence of the experimental (□) and calculated (—) $\chi_M T$ for dimer **1**. Best fit yielded $J = 3.7 \pm 0.1$ cm^{-1}, $zJ' = 0.41$ cm^{-1} and $g = 2.015$ (see text).

chlorate ion (O(70)···O(47), 2.78 (1) Å). The free H_2O is linked by H-bonds with the coordinated H_2O of molecule **A** (O(29)···O(20), 2.741(7) Å) and with the perchlorate oxygen O(94) (2.85(1) Å). The packing diagram of compound **1** is shown in Fig. 4.

3.5. Magnetic properties

The temperature dependence of the molar magnetic susceptibility, χ_M, for compound **1** was measured on a polycrystalline sample in the temperature range 2–300 K. Results are depicted in a graph of $\chi_M T$ versus T in Fig. 5. At 300 K, the value for $\chi_M T$ is 6.25 cm^3 K mol^{-1} in good agreement with the expected contribution of two non-interacting Mn(III) ions with $S = 2$ spin. For lower temperature, the value of $\chi_M T$ steadily increases to reach 7.45 cm^3 K mol^{-1} at 15 K before suddenly dropping to 3.50 cm^3 K mol^{-1} for 2 K, the lowest temperature investigated. The behavior in the 300–15 K temperature domain is indicative of a ferromagnetic interaction between the Mn(III) ions within the dimer, whereas the drop of $\chi_M T$ for lower temperatures can be ascribed to two possible contributions. One is due to the zero field splitting (ZFS) of the states of the Mn(III) ions, the second arises from intermolecular exchange interactions and they might be concomitant. The X-ray features for compound **1** show that the dimers are linked through hydrogen bonds established between the H_2O ligands and the phenolate oxygen atoms of neighboring molecules. Such links are known to mediate an exchange interaction between magnetic centers [23,24]. Moreover, the maximum value reached for $\chi_M T$, 7.45 cm^3 K mol^{-1}, is lower than the 10 cm^3 K mol^{-1} expected for a $S = 4$ ground state (assuming $g = 2$) confirming indeed that the decrease of $\chi_M T$ can be ascribed to inter-dimer exchange interactions.

Therefore, the magnetic properties were analyzed by a theoretical model considering the interaction between two $S = 2$ spin centers and, to account for the low temperature behavior, a contribution arising from inter-dimer interactions. The total spin Hamiltonian taking into account the Zeeman perturbation for the dimer is given in Eq. (1) [1c], where J represents the Mn–Mn exchange parameter and S_{Mn} and g_{Mn}, respectively, the spin and the local g-tensor associated to Mn(III). The intermolecular interactions were considered in the mean-field approximation and appear as zJ' in the expression of $\chi_M T$ used to analyze the experimental data (Eq. (2)). The best fit to the experimental data (Fig. 3) was obtained for $J = 3.7 \pm 0.1$ cm^{-1}, $zJ' = 0.41$ cm^{-1} and $g = 2.015$

$$\mathrm{H} = -J_{\hat{S}_{Mn1}\cdot\hat{S}_{Mn2}} + g_{Mn}\beta(\hat{S}_{Mn1} + \hat{S}_{Mn2})\cdot H, \quad (1)$$

$$\chi_M T = \frac{Ng^2\beta^2 F(J,T)T}{kT - zJ'F(J,T)}, \quad (2)$$

with

$$F(J,T) = \frac{60 + 2\exp(-9J/kT) + 10\exp(-7J/kT) + 28\exp(-4J/kT)}{9 + 3\exp(-9J/kT) + 5\exp(-7J/kT) + 7\exp(-4J/kT) + \exp(-10J/kT)}.$$

4. Concluding remarks

Compared to related {Mn(III)salen} dimers, the ferromagnetic interaction for compound **1** is amongst the strongest reported so far. The strength of this exchange coupling is in line with the rather short Mn–O bonds linking the mononuclear units. This bond for compound **1** is very similar to that observed for the salen derivative [5] and shorter than that for salen derivatives with functionalized diaminoethane units [1]. Obviously, the intramolecular separation for such compounds is affected by the steric constraint introduced by the substituents. For compound **1** this does not apply because the methyl group on the diaminoethane moiety of the ligand points outwards; this permits the fragments of the dimer to come close and results in a stronger exchange interaction.

5. Supplementary material

Abstract

^{11}B NMR spectroscopy provided direct evidence that boric acid reacts with Azomethine H to form a 1:1 bischelate complex. A new peak with a −17.9 ppm chemical shift is due to the chelate complex containing tetrahedral boron. It has been quantitatively confirmed that the reaction includes two chemical equilibria; one is related to the ligand formation and the other to the complex formation. The formation constant for the ligand is small, less than 10, whereas that for the complex is relatively large, greater than 10^5. Azomethine H is hydrolyzed in aqueous solution because of its low stability, and the ligand formation is responsible for the nature of its complexation with boric acid.

1. Introduction

A large number of spectrophotometric studies have focused on the development of methods which enable one to determine the concentration of boric acid in an aqueous solution under moderate conditions. The Azomethine H method, proposed by Capelle in 1964 [1], has been employed for the boron analyses of natural and waste waters, soils and plants [2–10]. Azomethine H (8-hydroxy-1-(salicylideneamino)-3,6-naphthalenedisulfonic acid, Fig. 1) is a Schiff base of salicylaldehyde and H-acid (1-amino-8-naphthol-3,6-disulfonic acid), and its solution exhibits an absorption maximum at 412 nm in the presence of boric acid.

A number of studies have been performed for optimization of conditions for boron determination using Azomethine H as a coloring agent. For this purpose, it is very important to understand well the interaction between boric acid and Azomethine H. It has been pointed out in some papers that Azomethine H reacts with boric acid to form chelate complexes in solution, and then the complexes exhibit an absorption maximum in the visible region [4–6]. Some possible complexes are shown in Fig. 2, i.e., a 1:1 monochelate complex of trigonal boric acid (I), a 1:1 bischelate complex with tetrahedral boron (II), a 1:1 monochelate complex with tetrahedral boron (III), and its corresponding 1:2 complex (IV) [4–11]. On the contrary, Harp has suggested that the absorption maximum is due only to the Azomethine H species [7]. However, direct evidence regarding the coloring processes and the structure of the borate complex has not been provided until now.

^{11}B NMR spectroscopy is an excellent tool for studying the reaction of boric acid/borate with chelating ligands. In our previous studies, the nature of the interaction between boric acid/borate and boron-selective adsorbents such as crosslinked dextran gels, chelating resins with functional groups of *N*-methylglucamine and chromotropic acid-presorbed resin had been elucidated [12–17]. In this study, characteristics of the complexation of boric acid with Azomethine H will be discussed using the ^{11}B NMR method.

2. Experimental

2.1. Reagents

All chemicals except Azomethine H and H-acid were of analytical reagent grade. All solutions of chelating agents were freshly prepared. Azomethine H (reagent grade), purchased from Dojindo (Japan) as the disodium salt, was used without further purification. A 20.0 mmol dm^{-3} Azomethine H solution was prepared by dissolving 0.467 g of the reagent in 50 cm^3 of a 10 mmol dm^{-3} ascorbic acid solution. A 20.0 mmol dm^{-3} salicylaldehyde solution was prepared by dissolving 0.122 g of salicylaldehyde in 50 cm^3 water with the addition of a small amount of KOH solution. The H-acid, 1-amino-8-naphthol-3,6-disulfonic acid, was received as a reagent grade monosodium salt (86.1%, Tokyo Kasei, Japan) and was used without further purification. A 10.0 mmol dm^{-3} H-acid solution was prepared by dissolving 0.449 g of H-acid in 100 cm^3 water with the addition of a small amount of KOH solution. Deionized water prepared with a Milli-Q SP system (Millipore, USA) was used throughout. The pH of the solution was adjusted with a 0.1 mol dm^{-3} acetate buffer, phosphate buffer, HEPES buffer, or KOH solution and was measured with a Horiba pH meter, Model F-22. The ionic strength was kept at 0.10 mol dm^{-3} with potassium chloride.

2.2. NMR measurements

^{11}B NMR spectra were recorded on a JEOL JNM-GSX 500 spectrometer (the Center of Advanced Instrumental Analysis, Kyushu University) at a resonance frequency of 160.0 MHz with a 10 mm multinuclear probe at 25 ± 1 °C. The sample solution ($I = 0.10$ mol dm^{-3}, KCl) containing known amounts of boric acid/borate and ligand was prepared, and the pH was adjusted with a small amount of buffer solution. After being allowed to stand for about 1 day, the solution was used for the NMR measurement. The standard NMR parameters were as follows: the flip angle was ca. 90° (36 μs), the pulse repetition time was 1 s, and the spectral width was 31 kHz. The chemical shifts were determined with reference to a 0.1 mol dm^{-3} boric acid solution as an external standard. On this scale the signal of BF_3–OEt_2, the generally accepted reference, came at −19.4 ppm.

3. Results and discussion

3.1. ^{11}B NMR spectra of the boric acid–Azomethine H system

The values of the ^{11}B NMR chemical shifts allow us to estimate the structures of the boron species [18–22]. If free boric acid of a trigonal planer structure is used as an external reference, the signal due to free borate anion having the tetrahedral structure appears around −17.7 ppm. When boric acid reacts with chelating ligands to form a complex with a six-membered ring structure, the 1:1 monochelate complexation shows a signal around −18.3 ppm, and further 1:2 bischelate complexation adds a new peak around −18.9 ppm.

The ^{11}B NMR spectra of boric acid in the presence of Azomethine H in weakly acidic regions varied with a change in the total concentration ratio of Azomethine H to boron. Fig. 3 shows that a new peak due to the complex appears in addition to that of free boric acid and that the chemical shift value for the complex is −17.9 ppm. Moreover, it was apparent that there was only one complex in this system, because no more peaks were observed even at higher Azomethine H concentrations.

The relative peak areas of the ^{11}B NMR spectra are directly proportional to the relative concentration of the respective boron species [19–21]. Fig. 3 shows that the concentration of the complex depends on the relative concentration ratio of ligand to boric acid. On the assumption that the complexation is a simple reaction expressed by Eq. (1), we calculated the concentration quotients, Q, using Eq. (2) and the concentrations estimated by ^{11}B NMR measurements

$$\text{Azomethine H} + \text{B(OH)}_3 \rightleftharpoons \text{complex} \quad (1)$$

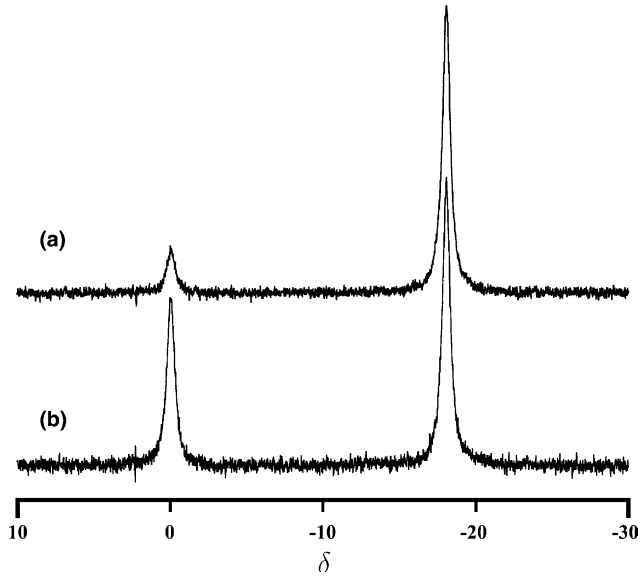

Fig. 3. ^{11}B NMR spectra for the solution containing 10.0 mmol dm^{-3} Azomethine H (pH 6.5). ((a): 5.00 mmol dm^{-3}, (b): 10.0 mmol dm^{-3} boric acid/borate).

$$Q = \frac{[\text{complex}]}{[\text{Azomethine H}][\text{B(OH)}]_3}. \quad (2)$$

The calculated Q had significantly different values when the concentration ratios of boric acid to the total Azomethine H were different, suggesting that such a simple equation could not explain the complexation reaction (Table 1), and therefore some other reactions may be involved in this system.

3.2. ^{11}B NMR spectra of the starting material systems

Azomethine H is a Schiff base and hydrolyzes to yield salicylaldehyde and an H-acid. The ^{11}B NMR spectra for boric acid solutions with the starting materials of Azomethine H are shown in Fig. 4. Both spectra showed not only the peak of free boric acid/borate but also those of complex species with a chemical shift around −17.7 ppm. In the salicylaldehyde system, the peak of the complex species was not observed in weakly acidic solutions. The relative peak areas of chelating boron species were much smaller than that of boric acid–Azomethine H, even if the molar ratios of these ligands to boric acid were higher than that for the Azomethine H system. Thus, the interaction of boric acid only with

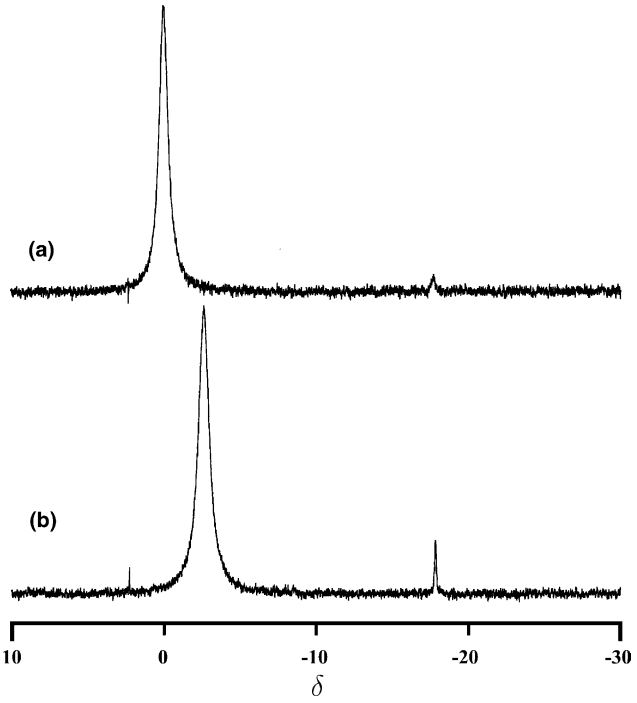

Fig. 4. ^{11}B NMR spectrum for the 10.0 mmol dm^{-3} boric acid/borate solutions containing H-acid or salicylaldehyde. ((a): 10.0 mmol dm^{-3} H-acid, pH 6.5; (b): 50.0 mmol dm^{-3} salicylaldehyde, pH 8.5).

salicylaldehyde or H-acid is negligible in the weakly acidic region. ^{11}B NMR spectra for weakly basic solutions containing ascorbic acid, Azomethine H and boric acid/borate also gave new peaks due to the interaction between borate and ascorbic acid [23], but these peaks were not recorded under weakly acidic conditions.

3.3. The structure of the boric acid–Azomethine H complex

As mentioned above, the interaction of boric acid with Azomethine H gave only one complex with a new peak in the ^{11}B NMR spectrum. The chemical shift value for the complex was −17.9 ppm, indicating that the structure of the chelate complex consisted of tetrahedral boron, not of trigonal boron such as (I) in Fig. 2. The results under the condition of $C_B/C_L = 1.0$ in Table 1 indicate that the boric acid–Azomethine H complex should not be a 1:2 chelate such as in Fig. 2 (IV) but a 1:1 chelate complex, because the equilibrium concentrations of the complex exceeded more than half of the

Table 1
Concentration quotients for the boric acid and Azomethine H system

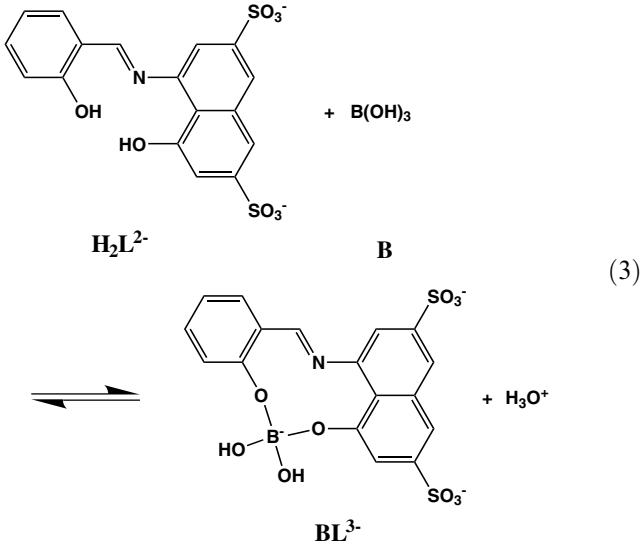
1.0:1.0	4.72	3.8	6.2	2.5
	6.50	3.7	6.3	2.5
0.5:1.0	4.72	0.60	4.4	3.0
	6.43	0.65	4.3	3.0

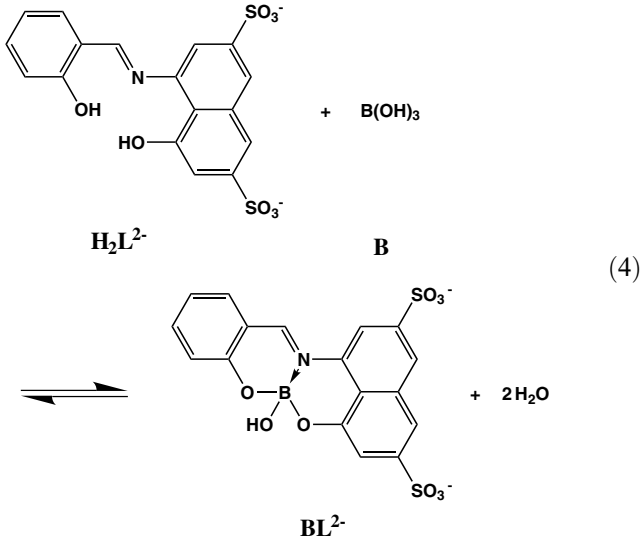
[a] C_L, total concentration of Azomethine H, 10.0 mmol dm^{-3}; C_B, total concentration of boric acid

total concentrations of the ligand. Moreover, the equilibrium concentrations of the complex were independent of the pH of the solutions in weakly acidic regions if other conditions were the same. The complexation of boric acid under acidic conditions progresses with a nucleophilic attack of the ligand on the empty orbital of boric acid [16]. The 1:1 monochelate complex presented in Fig. 2 (III) is excluded as the boric acid–Azomethine H complex, because the complexation equilibrium must be affected by pH, as expressed by Eq. (3).



(3)

Intramolecular hydrogen bonding may suppress the protonation of the nitrogen atom of Azomethine H. In addition, it has been reported that the chemical shift value of the complex with coordination via the nitrogen atom is similar to those generally observed for the complex having a B–O bond [18]. Therefore, the possible structure of the Azomethine H–boric acid complex should be a 1:1 chelate complex having a coordination bond with the nitrogen atom of Azomethine H such as (II) in Fig. 2. As expressed by Eq. (4), such a complexation equilibrium does not involve proton dissociation.



(4)

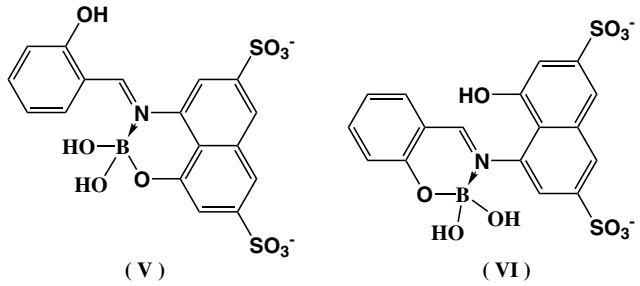


Fig. 5. Possible Azomethine H–boric acid complexes having a coordination bond with a nitrogen atom.

Fig. 5 also shows possible structures of the Azomethine H–boric acid monochelate complex having a coordination bond via the nitrogen atom. According to the ^{11}B NMR spectrum of the H-acid system in Fig. 4, the possibility of the monochelate complex shown in Fig. 5 (V) will be small. Regardless of the presence of 100 mmol dm^{-3} amine derivatives such as 4-aminobenzenesulfonic acid and 6-amino-1,3-naphthalenedisulfonic acid, the solutions containing 10 mmol dm^{-3} boric acid/borate and 50 mmol dm^{-3} salicylaldehyde gave the same spectra as those shown in Fig. 4, indicating that the monochelate complex such as (VI) in Fig. 5 will be unstable. These results suggest that the possible structure is the 1:1 bischelate complex represented by (II) in Fig. 2. If there is a chelate complex with the boron atom having multiple chelate rings, more than one peak is usually observed in the ^{11}B NMR spectrum. In this system, both of the two 1:1 monochelate complexes illustrated in Fig. 5 may not be very stable and may immediately form the bischelate complex. These are the reasons why the interaction between boric acid and Azomethine H provides only one complex.

3.4. Complexation equilibria of the boric acid–Azomethine H system

Similar NMR measurements were performed for solutions containing boric acid, salicylaldehyde and H-acid. The ^{11}B NMR spectra of 5.00 mmol dm^{-3} boric acid and salicylaldehyde solutions to which H-acid had been added at various concentrations at pH 4.94 showed the same peak as that assigned to the complex (Fig. 6). The relative peak area was dependent on the total concentration of H-acid.

Because the reaction of boric acid only with salicylaldehyde or H-acid can be negligible as mentioned above, it was confirmed that the reaction between boric acid and Azomethine H involves two chemical equilibria: one is related to the ligand formation (Eq. (5)) and the other to the complex formation (Eq. (4)).

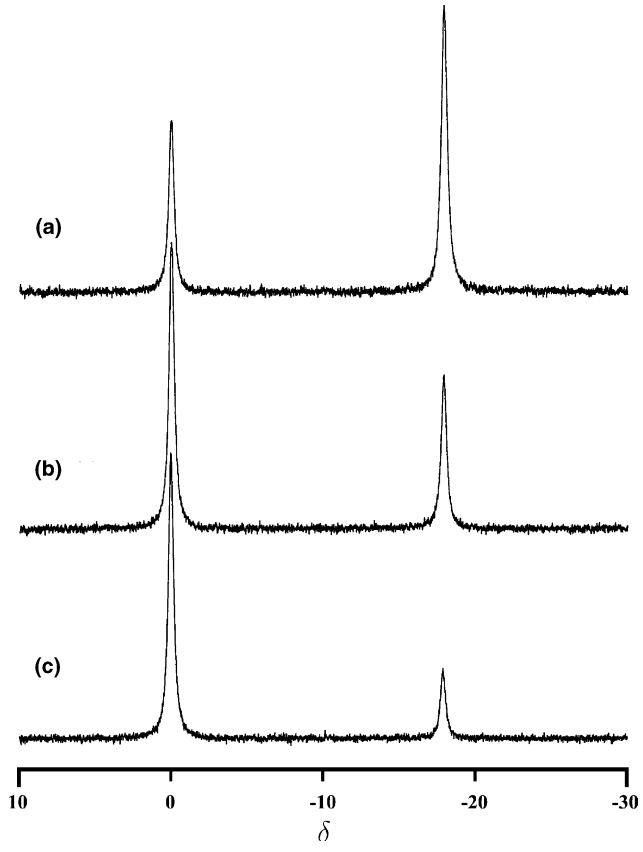

Fig. 6. ^{11}B NMR spectra for the solution containing 5.00 mmol dm^{-3} boric acid, 5.00 mmol dm^{-3} salicylaldehyde and various concentration of H-acid (pH 4.94). ((a) 5.00 mmol dm^{-3}; (b) 2.00 mmol dm^{-3}; (c) 1.00 mmol dm^{-3} H-acid).

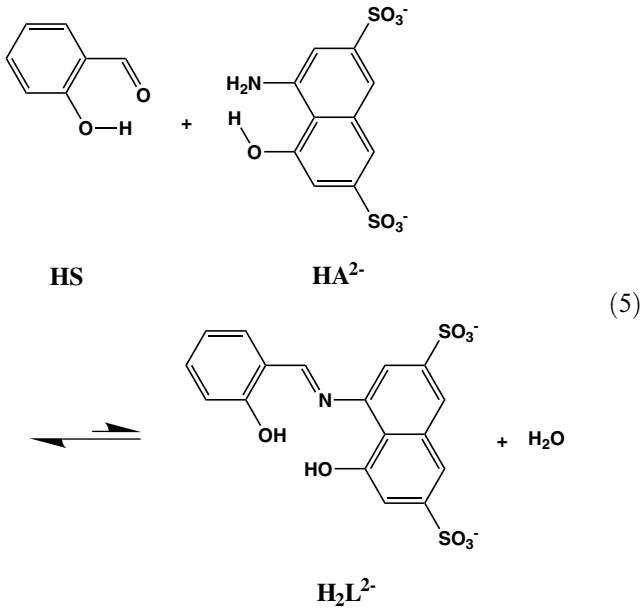

(5)

When dissolved in aqueous solution, almost all of the Azomethine H is hydrolyzed to yield its starting materials. It is well-known that H-acid is unstable in aqueous solution and that the color of Azomethine H solution

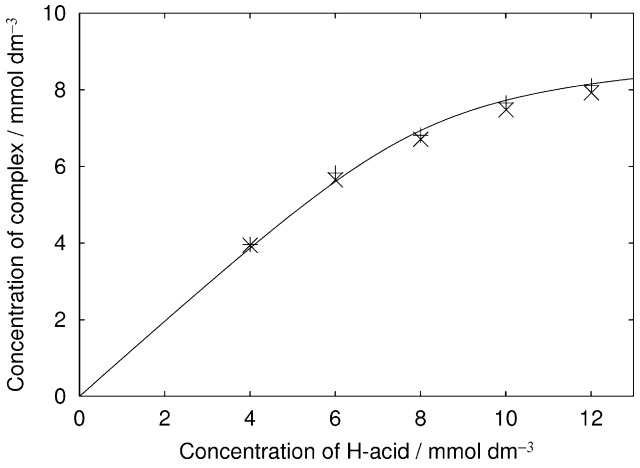

Fig. 7. Effect of increasing concentration of H-acid on the equilibrium concentration of the complex (9.60 mmol dm^{-3} salicylaldehyde, 10.0 mmol dm^{-3} boric acid/borate solution at pH 6.67. Standing time: 1 day (+), 1 week (×)). Solid line: calculated concentration of the complex using the $K_{f(LC)}$ value.

turns brown if the solution is allowed to stand for a long period [2,4,6–8]. The sample solutions containing boric acid, salicylaldehyde and H-acid became apparently browner with the increase in the concentration of uncomplexed H-acid. Fig. 7 shows variations in the equilibrium concentrations of the complex with time at different concentrations of H-acid. Although the changes in sample color resulted in a higher reagent blank for the boron determination, a decrease in the equilibrium concentrations of the complex was not observed. These results indicate that the decomposition of the starting materials of Azomethine H is involved in the reaction.

Fig. 8 shows that the complexation equilibrium is independent on the pH of the solution at least under weakly acidic conditions. Both starting materials of

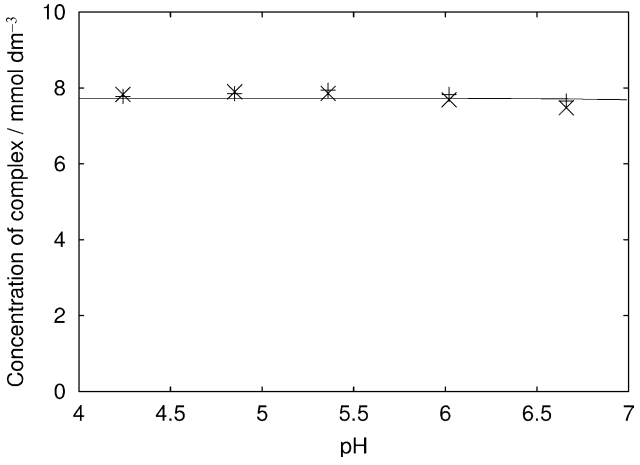

Fig. 8. pH dependence of the equilibrium concentration of the complex (10.0 mmol dm^{-3} salicylaldehyde, boric acid/borate, and H-acid solution. Standing time: 1 day (+), 1 week (×)). Solid line: calculated concentration of the complex using the $K_{f(LC)}$ value.

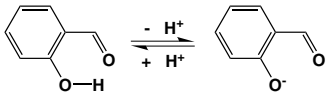
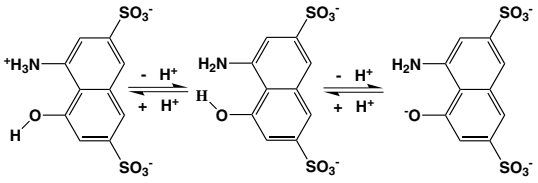
Azomethine H contain functional groups relating to acid dissociation reactions expressed as follows:



(6)



H_2A^- HA^{2-} A^{3-} (7)

Because the Schiff base formation from primary amine and aldehyde proceeds by nucleophilic attack of free amine on the aldehyde [3,24,25], salicylaldehyde condenses with HA^{2-} or A^{3-} of the H-acid species to form Azomethine H. The acid dissociation constant of salicylaldehyde was determined spectrophotometrically to be $10^{-8.14}$ ($I = 0.1$ mol dm^{-3}, KCl, 25 °C), and therefore HS in Eq. (6) is predominant in acidic solution. In the case of H-acid, acid dissociation constants for Eq. (7) were not available from the literature, but the predominant species is supposed to be HA^{2-} in the weakly acidic region because it can form intramolecular hydrogen bonding.

It was concluded that the reaction includes two chemical equilibria with respect to Eqs. (4) and (5). The equilibrium constants ($K_{f(L)}$ and $K_{f(C)}$) are defined by Eqs. (8) and (9), respectively.

$$K_{f(L)} = \frac{[H_2L^{2-}]}{[HS][HA^{2-}]}, \tag{8}$$

$$K_{f(C)} = \frac{[BL^{2-}]}{[H_2L^{2-}][B]}. \tag{9}$$

However, the $K_{f(L)}$ value was too small and could not be experimentally obtained, because the mixed solution of the starting materials did not give any measurable absorption bands due to Azomethine H in the UV and visible regions. Therefore, the overall equilibrium constant, $K_{f(LC)}$, defined by Eq. (10) and the product of $K_{f(L)}$ and $K_{f(C)}$, was estimated

$$K_{f(LC)} = K_{f(L)}K_{f(C)} = \frac{[BL^{2-}]}{[HS][HA^{2-}][B]}. \tag{10}$$

Eq. (11) may account for the overall reaction in this system

$$HS + HA^{2-} + B \rightleftharpoons BL^{2-} + 3H_2O \tag{11}$$

The mass balance equations for the total concentrations of salicylaldehyde (C_S), H-acid (C_A) and boric acid (C_B) are then expressed as follows:

$$C_S = [HS] + [BL^{2-}], \tag{12}$$

$$C_A = [HA^{2-}] + [BL^{2-}], \tag{13}$$

$$C_B = [B] + [BL^{2-}]. \tag{14}$$

The $K_{f(LC)}$ value could be determined based on the relative intensities of the ^{11}B NMR signals. Table 2 shows that the $K_{f(LC)}$ value is constant at $10^{5.91\pm0.07}$ under different conditions.

The equilibrium concentrations of the complex calculated using the constant are compared with those observed experimentally as a function of the total H-acid concentration or pH (Figs. 7 and 8). While almost all of the H-acid reacts to form the bischelate complex in

the presence of excessive amounts of boric acid and salicylaldehyde, increased proportions of the H-acid did not produce any new peaks due to other unexpected complexation reactions. The experimental results were on the calculated solid lines. These figures show that the lines reproduce well the experimental results and that the $K_{f(LC)}$ value can be applicable to any experiments under different conditions. Our results, thus obtained, offer some useful information for optimization of the conditions for boron determination. The Azomethine H method can be performed using a mixed solution of the salicylaldehyde and H-acid instead of their condensation product, as suggested by Harp [10] and Staden [7]. By keeping the H-acid concentration low enough to form the chelate complex, the reagent blank for the boron determination due to the decomposition of H-acid can be reduced as much as possible.

As mentioned above, the $K_{f(L)}$ value was too small and could not be experimentally obtained. On the assumption that the molar absorptivities of Azomethine H are similar to those of its boric acid complex (e.g., 10^3 mol^{-1} dm^3 cm^{-1} at 412 nm), the $K_{f(L)}$ value was roughly calculated. The absorbance of the mixture solution of the starting materials at 10^{-3} mol dm^{-3} was almost the same as the sum of the absorbances of their individual solutions and the difference was less than 0.01. The equilibrium Azomethine H concentration in the mixture solution was estimated to be lower than 10^{-5} mol dm^{-3} and the $K_{f(L)}$ value to be less than 10. Therefore, the $K_{f(C)}$ value should be greater than 10^5. This complexation constant is comparable to those of the most stable 1:2 bischelate complexes (approximately 10^6) [16]. On the contrary, the 1:1 bischelate complex formation constant is much greater than that of the corresponding complex with triethanolamine [18]. Such a large stability is due to the structures of the complex and the ligand. The bischelate complex may be stabilized by the delocalized sp^2 character of the ligand. Intramolecular hydrogen bonding allows the conformation of the free ligand to be that shown in Fig. 1, and the structure is suitable for interaction with boric acid to form the complex.

4. Conclusion

The Azomethine H method is a practical spectrophotometric method for boron analysis applicable under mild conditions. However, the interaction of boric acid with Azomethine H has been unclear for a long time. There are some possible complexes shown in Fig. 2, or a possibility that light absorption in the visible region can only be due to the free ligand. In this work, the complexation of boric acid with Azomethine H could be quantitatively clarified by a ^{11}B NMR study: the starting materials of Azomethine H (H-acid and salicylaldehyde) yield the 1:1 bischelate complex including B–N bonding only in the presence of boric acid.

Abstract

$Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$ [H_4SB: *N*,*N*′-bis(5-hydroxysalicylidene)-1,4-diaminobutane] was synthesised via an electrochemical procedure and its crystal structure was determined. The metal ion assumes a distorted octahedral coordination geometry that involves the two O-atoms of a chelating acetate and the N_2O_2 compartment of the bisdeprotonated diimine, which is asymmetrically folded in a β-*cis* arrangement. Moderate hydrogen bonds between adjacent complex molecules, which also interact with lattice acetonitrile molecules, lead to a linear interaction, predominant in the crystal packing.

Keywords: Iron complexes; Acetate ligands; η^2-Coordination modes; Schiff bases; β-Cis arrangements

1. Introduction

Iron(III) complexes of salen type ligands have received considerable attention as potential models for biologically important enzymes [1] and oxidation catalysts [2]. As a result, some crystal structures of Fe(salen)X complexes, where X is a potentially chelating or bridging ligand such as catecol, hydroquinone, phenanthrenesemiquinone or acetylacetone, have been described [3].

Carboxylato complexes in general and acetato ones, in particular, have also been subject to much interest [4], since they are present in some important enzymes. Among the coordinating modes of the acetate ligand, η^1 and μ modes are very common, whereas the chelating behaviour is not very frequent both for iron proteins and complexes [5].

In the course of our efforts to prepare building-blocks [6] capable of linking two remote moieties yielding trinuclear complexes [7], we have obtained $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$, where H_4SB is *N*,*N*′-bis(5-hydroxysalicylidene)-1,4-diaminobutane (Fig. 1).

2. Experimental

2.1. Materials and methods

Chemicals of the highest commercial grade available (Aldrich) were used as received. An iron metal plate (Aldrich) was washed with a dilute hydrochloric acid solution prior to electrolysis.

Elemental analyses were performed on a Carlo Erba EA 1108 analyser. Mass spectra (ES) were recorded on a LC/MSD Hewlett–Packard 1100 spectrometer with methanol and formic acid (3%) as solvent. The samples had been previously dissolved in dimethylsulfoxide. NMR spectra were recorded on a Bruker 300 AC spectrometer, using DMSO as solvent. Infrared spectra were recorded as KBr pellets on a Bio-Rad FTS 135 spectrophotometer in the range of 4000–600 cm^{-1}. Magnetic susceptibility measurements were performed

2.2. Ligand synthesis

N,*N*′-Bis(2,5-dihydroxybencylidene-1,4-diaminobutane), H_4SB, has been prepared by condensation in chloroform (80 ml) of 2,5-dihydroxybenzaldehyde (1.0 g, 7.2 mmol) with 1,4-diaminobutane (0.32 g, 3.6 mmol). The solution was heated at reflux over a 3 h period and subsequently concentrated in vacuum. The orangey precipitate formed was collected by filtration, washed with diethyl ether (15 ml), and dried in vacuum. Yield: 1.11 g (93%). m.p.: 195 °C. *Anal.* Calc. for $C_{18}H_{20}N_2O_4$: C, 65.85; H, 6.10; N, 8.54. Found: C, 65.56; H, 5.89; N, 8.38%. ES-MS (0 V): 329.0 m/z (82%, M^+). FT-IR (KBr): ν(O–H)$_{OH}$ 3434 (b) and 3258 (b), ν(C=N) 1643 (s), ν(C–H) 1461 (vs), ν(C–O) 1258 (m). ^{1}H NMR (DMSO-d_6, 300 MHz) 12.71 (2H, s, H_1), 8.99 (2H, s, H_2), 8.46 (2H, s, H_3), 6.72–6.40 (6H, m, H_{6-8}), 3.60 (4H, t, H_4), 1.67 (4H, t, H_5).

2.3. Complex synthesis

An acetonitrile solution (80 cm^3) of H_4SB (0.100 g, 0.305 mmol), dipyridyl ketone (0.112 g, 0.609 mmol) and acetic acid (0.036 g, 0.609 mmol), containing about 40 mg of tetramethylammonium perchlorate, was electrolysed [8] for 1 h 40 min using a 10 mA current intensity with an initial voltage of 11.1 V. **Caution:** *Although no problem has been encountered in this work, all perchlorate compounds are potentially explosive, and should be handled in small quantities with great care*! After filtration of the resulting solution, its slow evaporation allowed the obtaining of blackish plate-shaped crystals of Fe(H_2SB)(η^2-O_2CMe)·MeCN, suitable for X-ray diffraction studies. Yield: 0.037 g (25%). *Anal.* Calc. for $C_{22}H_{24}FeN_3O_6$: C, 54.79; H, 5.02; N, 8.71. Found: C, 53.97; H, 4.99; N, 8.53%. ES-MS: 383.1 m/z (100%, M^+–O_2CMe–MeCN). FT-IR (KBr): ν(O–H)$_{OH}$ 3323 (s), ν(C=N) 1613 (vs), $\nu_{asym}(CO_2)$ 1558 (s), ν(C–H) 1472 (vs), $\nu_{sym}(CO_2)$ 1455 (sh,s) ν(C–O) 1296 (vs) cm^{-1}. μ (295 K): 6.2 BM.

2.4. Single-crystal X-ray diffraction studies

X-ray data were collected at room temperature on a Bruker Smart-CCD-1000 diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data collection and processing were carried out using the Bruker SMART programs [9] and empirical absorption correction was applied using SADABS [10]. The structure was solved by direct methods, and refined by full-matrix least-squares based on F^2 using SHELX-97 software [11]. All non-hydrogen atoms were anisotropically refined. Hydrogen atoms were included at geometrically calculated positions with thermal parameters derived from the parent atoms. Table 1 provides a summary of crystal data, data collection and refinement parameters.

3. Results and discussion

The obtaining of H_4SB had been previously reported [7], however, its detailed synthesis and characterisation had not been previously described. With respect to Fe(H_2SB)(η^2-O_2CMe)·MeCN, this was obtained by an electrochemical method [8] in an attempt to prepare an iron complex of di-2-pyridylmethanediol and *N*,*N*′-bis(5-hydroxysalicylidene)-1,4-diaminobutane ligands.

The analytical, ES-MS and IR data led us to postulate the obtaining of Fe(H_2SB)(η^2-O_2CMe)·MeCN, its magnetic moment at room temperature being in agreement with a high-spin d^5 octahedral configuration [12]. The substantial decrease of the ν(C=N) band (30 cm^{-1}) joint to the increase of the ν(C–O) frequency (38 cm^{-1}), compared to the free ligand spectrum, are in agreement with the participation of the phenol and imine donor

atoms in the coordination to the metal centre [8]. The observation of only one of the O–H vibration bands, at about 3323 cm^{-1}, reveals the bideprotonation of H_2SB^{2-}, where the 5-hydroxy positions on each benzylidene ring remain protonated. The two strong bands arising from the C–O stretching vibrations show a frequency difference of 103 cm^{-1}, which according to the literature [5e] corresponds to a chelating coordination mode of the acetate group.

3.1. Single-crystal X-ray diffraction studies of $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$

The molecular structure of the complex is represented in Fig. 2, with the atom labelling scheme used in Table 2, which lists the most relevant bond distances and angles. The asymmetric unit consists of a discrete molecule of $Fe(H_2SB)(\eta^2\text{-}O_2CMe)$ interacting with a lattice acetonitrile molecule.

In $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$, the iron(III) centre is coordinated in a distorted octahedral fashion by H_2SB^{2-} acting as a typical N_2O_2-donor and a chelating acetate ligand. The latter occupies two of the equatorial coordination sites [O(5) and O(6)], whilst the Schiff base fills a meridian [O(4)N(2)N(1)] of the octahedron and the remaining equatorial position [O(1)]. This asymmetric folding of the diimine conforms to the β-*cis* arrangement shown in Fig. 3. Despite it being easier to achieve with a flexible spacer such as $(CH_2)_4$, it is a not very frequent arrangement in mononuclear octahedral complexes of salen-type ligands. The majority of these are *trans* arranged (Fig. 3), but the β-*cis* conformation is adopted by Fe(salen)X complexes when X behaves as *cis* chelating [3a]. Electrochemical studies on $M(R_2\text{-salen})(N'Bu)_2$ (where M = Mo or W) allowed the conclusion that the adoption of the β-*cis* conformation is apparently dictated by electronic rather than steric factors [13].

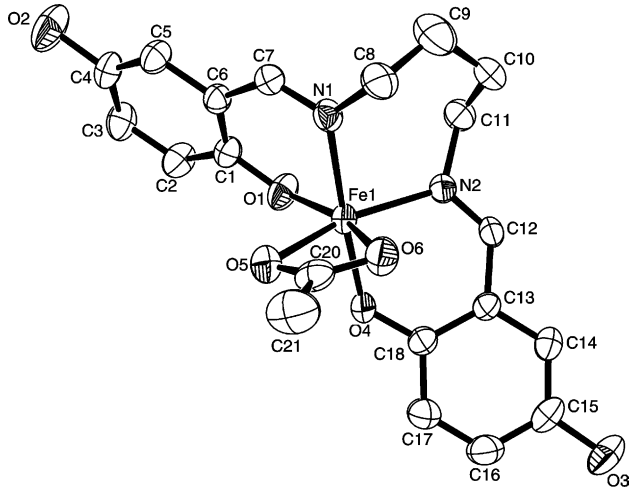

Fig. 2. ORTEP view of $Fe(H_2SB)(\eta^2\text{-}O_2CMe)$. Ellipsoids are drawn at 50% probability. The acetonitrile molecule and parentheses are omitted for clarity.

[a] Symmetry transformations used to generate equivalent atoms: $x-1, y, z$.

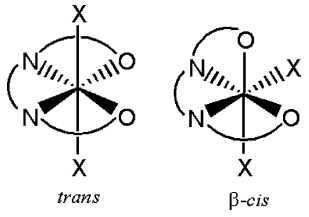

Fig. 3. Schematic representation and nomenclature of two possible geometries for complexes of the type $M(N_2O_2)X_2$.

Although the ribonucleotide reductase iron protein (RR B2) [5c] and other model polynuclear iron complexes, such as $[Fe_2(Py)_2(O_2CMe)_5(OH_2)]Et_4N$ or $[Fe_3(O)(O_2CMe)_7(OH_2)]Et_4N$ [5d], contain terminal η^2-acetato groups, this coordination mode is rather infrequent both for Fe(III) and Fe(II) ions [5]. Thus, to the best of our knowledge $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$ is the first example of a mononuclear iron (η^2-acetato)

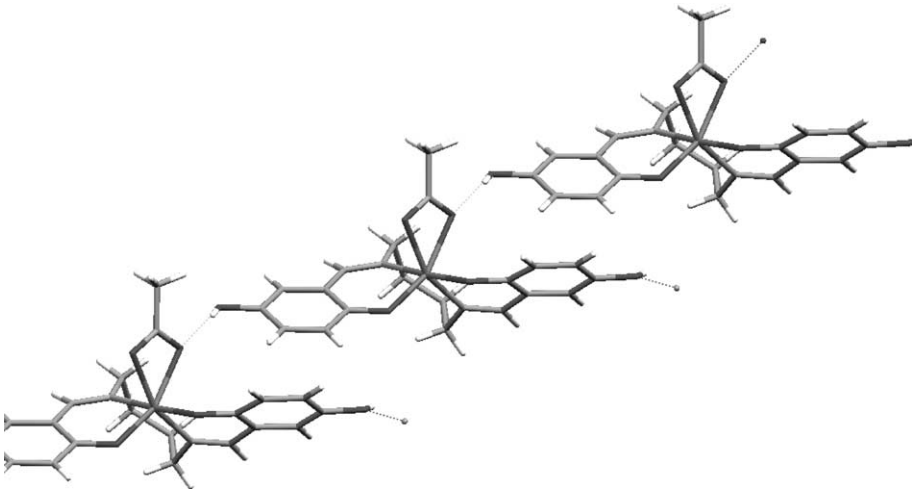

Fig. 4. Stick representation of three molecules of $Fe(H_2SB)(\eta^2\text{-}O_2CMe)$ connected by H bonds between the acetate and one of the outer phenol groups. Each complex molecule is also interacting with an acetonitrile molecule through the remaining protonated phenol group but they have been omitted for clarity.

complex, at least of salen type ligands. This *cis* chelating behaviour of the acetate ligand could be allowed by the flexibility of the Schiff base ligand. Thus, $[Fe^{III}(salen)(\mu\text{-}O_2CMe)]_n$ shows linear polymerisation through bridging bidentate acetate groups [14] with a typical *trans* arrangement of the more rigid ligand (Fig. 3). By contrast, $salbn^{2-}$, which contains the same spacer as $H_2SB_2^-$, assumes the β-*cis* folding even with monodentate ligands such as MeO^- in $[Fe(salbn)(\mu\text{-}OMe)]_2$ [12]. The flexibility, as well as the strain, of the *gauche* conformed $(CH_2)_4$ chain of $H_2SB_2^-$ is revealed by the torsion angles, that also show that one of the bonds is almost eclipsed (Table 2).

In general, although the Fe–N and Fe–O distances related to the Schiff base ligand could be considered within the usual ranges reported for Fe(III) complexes of N,O-donor ligands [14–16], the equatorial bonds (in *trans* positions with respect to the acetate group) are shorter than the apical ones, Fe(1)–(O1) being especially short. With regard to the acetate group, both angles and distances are within the common ranges found for Fe(III) complexes [5d,15] and even for Fe(II) ones [5b,5d], since they are not very different in that respect.

The presence of the outer phenol groups is significant, since they give rise to an H bonding scheme, apart from some C–H$\cdots\pi$ interactions, that is essential for the crystal packing. One of the external phenolic O atoms, O(3), interacts with an acetonitrile molecule, whereas the other one is connected to an acetate group of a neighbouring complex molecule. This interaction leads to an almost linear ''polymerisation'' based on moderate H bonds [17] along the *a* direction (Fig. 4). Since the external phenolic groups, O(2) and O(3), remain protonated and uncoordinated, they allow the additional, and previously confirmed, possibility to behave as a building-block [7].

4. Conclusions

We have synthesised by an electrochemical procedure $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$. The Fe(III) ion assumes a distorted octahedral coordination geometry, afforded by the N_2O_2-donor set of the dianionic diimine and two oxygen atoms of an acetate group. Despite its simplicity, two features of $Fe(H_2SB)(\eta^2\text{-}O_2CMe)\cdot MeCN$ can provide some interest from the point of view of the coordination chemistry: (i) the acetate is coordinated in a hitherto unfamiliar η^2 mode for mononuclear iron complexes; (ii) the Schiff base ligand is β-*cis* folded. These seem to be related, since the atypical chelating coordination of the acetate group could be favoured by the diimine flexibility, and the *cis* chelating behaviour of the acetate involves the β-*cis* folding of the Schiff base.

Abstract

Three novel iron(III) complexes of 2-benzoylpyridine N(4), N(4)-(butyl-1,4-diyl) thiosemicarbazone (HBpypTsc), $[Fe(BpypTsc)_2]ClO_4$ (**1**), $[Fe(BpypTsc)_2]NO_3$ (**2**) and $[Fe(BpypTsc)_2]FeCl_4$ (**3**) were synthesized and physico-chemically characterized by means of partial elemental analyses, magnetic measurements (polycrystalline state), UV–Vis and IR spectroscopies. The spin Hamiltonian parameters, isomer shifts and quadrupolar splitting values of the complexes were assigned by variable temperature EPR and Mössbauer spectra. The presence of a spin-paired iron(III) cation with $d_{xz}^2 d_{yz}^2 d_{xy}^1$ ground state is revealed by the simulated EPR spectral data. The structures of the free ligand HBpypTsc and one of the complexes $[Fe(BpypTsc)_2]FeCl_4$ (**3**) were solved by single crystal X-ray diffraction which authenticated a FeN_4S_2 octahedral coordination in the complex, as envisaged from the spectral data. All complexes except $[Fe(BpypTsc)_2]FeCl_4$ (**3**) were found to be low-spin $S = 1/2$ ($^2T_{2g}$), whereas **3** was found to have both low-spin ($^2T_{2g}$) and high-spin ($^6A_1$) centres.

1. Introduction

The discovery of a low-spin ($S = 1/2$) non-heme $[Fe^{III}N_2S_3]$ centre in the enzyme nitrile hydratase has raised interest in mononuclear model iron(III) complexes with N, S coordination [1,2]. Several groups have structurally characterized iron(III) complexes with N_xS_y coordination and compared their spectroscopic properties with the biological iron site [3,4]. The well-documented biological activities of several heterocyclic thiosemicarbazones have often attributed to a chelation phenomenon with transition metal ions [5]. The success in therapeutic applications of N-heterocyclic thiosemicarbazones for removing excess iron from iron-loaded mice through chelation therapy is quite remarkable [6]. We have previously examined the chelation behavior of some O–N–S and N–N–S donor thiosemicarbazones with several transition metal ions with the aim of gaining more information about their nature of coordination and related structural, spectral and biological properties [7–11]. There are some interesting reports on the iron(III) complexes of biologically active 2-acetylpyridine thiosemicarbazones [12,13]. This paper discusses the syntheses and spectral studies of three iron(III) complexes with the title ligand 2-benzoylpyridine N(4), N(4)-(butane-1,4-diyl)thiosemicarbazone (HBpypTsc) (Scheme 1). A previously reported complex of a 2-acetylpyridine thiosemicarbazone prepared from $FeCl_3$, gave a stoichiometry $FeLCl_2$ which suggested it to be a five-coordinate iron(III) complex having an

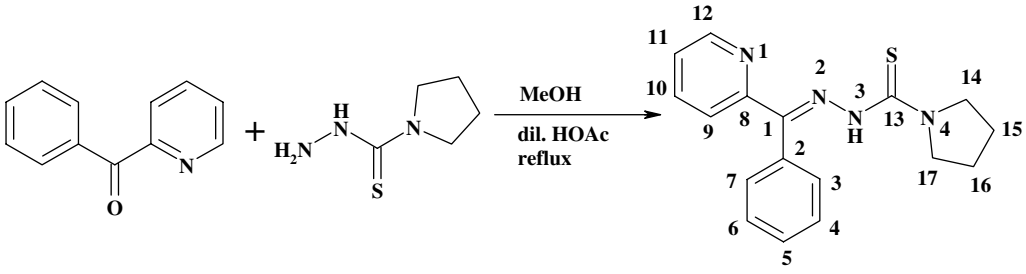

Scheme 1.

intermediate spin state [14]. However the structural information as well as the spectral information obtained for a similar compound, **3** in our case, confirmed that the previous report could be incorrectly formulated.

2. Experimental

2.1. General

2-Benzoylpyridine (Lancaster), ferric chloride (Merck) and ferric nitrate (Merck) was used as received. Ferric perchlorate was prepared from ferric carbonate by digesting it with perchloric acid followed by evaporating the solution on a sand bath followed by subsequent cooling. *Caution! Perchlorate salts are potentially explosive and should be handled with care.* Pyrrolidine-1-thiocarboxylic acid hydrazide was synthesized by adopting and modifying a reported procedure [15]. All solvents were distilled before use.

2.2. Synthesis of HBpypTsc

To a solution of pyrrolidine-1-thiocarboxylic acid hydrazide (0.1 mol) and 2-benzoylpyridine (0.1 mol) in 20 mL methanol, 2 drops of conc. acetic acid was added and the reaction mixture was heated under reflux for 5 h. The reaction mixture was kept for 3 days where the deep yellow colored crystals of HBpypTsc began to separate in a decent yield with satisfactory analytical data. X-ray quality single crystals of the compound were grown from a solution of the compound HBpypTsc in chloroform layered with methanol in 3 days. Melting point 185–186 °C. ^{1}H NMR δ (ppm): NH, 14.3, singlet 1H; 8.73, doublet, aromatic, 1H, $J = 7.5$ Hz; 8.5, aromatic, doublet, 1H; 7.1–7.8, aromatic, multiplet, 7H, 3.8, aliphatic, multiplet, 4H, 1.9, aliphatic, multiplet, 4H.

2.3. Synthesis of $[Fe(BpypTsc)_2]ClO_4$ (**1**)

To a methanolic solution of ferric perchlorate (1 mmol) was added a solution of HBpypTsc (2 mmol) in chloroform and the mixture was refluxed for 30 min. The resulting deep green colored solution was evaporated to half its volume. On cooling dark brown shining crystals of compound **1** separated out and were washed with ether and dried over P_4O_{10} in vacuo.

2.4. Synthesis of $[Fe(BpypTsc)_2]NO_3$ (**2**)

To a methanolic solution of ferric nitrate (1 mmol) was added a solution of HBpypTsc (2 mmol) in chloroform and the mixture was refluxed for 30 min. The resulting deep green colored solution was evaporated to half of its volume. On cooling dark brown shining crystals of compound **2** separated out and were washed with ether and dried over P_4O_{10} in vacuo.

2.5. Synthesis of $[Fe(BpypTsc)_2]FeCl_4$ (**3**)

To a methanolic solution of ferric chloride (1 mmol) was added a solution of HBpypTsc (1 mmol) in chloroform and the mixture was refluxed for 30 min. The resulting deep green colored solution was evaporated to half its volume. On cooling dark brown shining crystals of compound **3** separated out and were washed with ether and dried over P_4O_{10} in vacuo. X-ray quality single crystals of the compound were grown by the slow evaporation of a methanolic solution of the complex in 7 days.

2.6. Physical methods

Microanalyses were carried out using a Heraeus Elemental Analyzer at CDRI, Lucknow, India. Infrared spectra were recorded on a Shimadzu DR 8001 series FT-IR instrument as KBr pellets in the range 400–4000 cm^{-1} and far-IR spectra were recorded in the range 50–500 cm^{-1} on a NICOLET MAGNA 550 FT-IR spectrometer using polyethylene pellets at RSIC, IIT, Bombay, India. Electronic spectra were recorded in the 900–250 nm range in a diffused reflectance mode in MgO matrix in Ocean Optics SD 200 fiber optic Spectrophotometer. Magnetic measurements were made in the polycrystalline state on a home built simple Gouy balance using $Hg[Co(SCN)_4]$ as calibrant. EPR spectra were recorded in a Bruker ESP300, X-band CW spectrometer operating at 9.52 GHz equipped with a liquid

nitrogen cryostat. The spectra were measured with a modulation amplitude of 0.05(0.1) mT and 100 kHz modulation frequency, and the field was calibrated by using 2,2-diphenyl-1-picrylhydrazyl (DPPH) with a g value of 2.0036. NMR spectra were recorded on a Bruker DRX 500 instrument using $CDCl_3$ as the solvent and TMS as the internal reference at the Sophisticated Instruments Facility, Indian Institute of Science, Bangalore, India. The tentative structure of the compound HBpypTsc was assigned on the basis of different NMR experiments, based on the couplings and connectivities of the signals observed. The ^{1}H resonances were assigned on the basis of chemical shifts, multiplicities and coupling constants from ^{1}H NMR experiments. The assignments of the NH and OH hydrogens were made by comparison with the spectra recorded on deuterium exchange. The carbon types were determined by ^{13}C-Spin Echo Fourier Transform (SEFT) experiments. Mössbauer spectra were recorded on a constant-acceleration spectrometer with multi channel analyzer using a ^{57}Co source in a Rhodium matrix at Inter University Consortium, Indore, India.

2.7. X-ray crystallography

A dark brown triclinic crystal of the $[Fe(BpypTsc)_2]$-$FeCl_4$ (**3**) and a deep yellow orthorhombic crystal of HBpypTsc having appropriate dimensions were sealed in a glass capillary, and intensity data were measured at room temperature (293 K) on an Nonius MACH3 diffractometer equipped with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The trial structure was obtained by direct methods using SHELXL-97 and refined by full-matrix least squares on F^2 (SHELXS-97) [16,17]. The non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were geometrically fixed and allowed to refine using a riding model. Absorption corrections were employed using ψ-scan. The crystallographic data along with details of structure solution refinements are given in Table 1.

3. Results and discussions

3.1. Syntheses

The ligand HBpypTsc was synthesized by a direct condensation of the ketone with the thiosemicarbazide. In the ^{1}H NMR spectrum the signal for N(2)H is observed at a low field of $\delta = 14.35$ ppm and this signal disappears on deuterium exchange, which is consistent with the Z configuration of the thiosemicarbazone moiety. The low frequency multiplets at $\delta = 3.8$ (4H)

and 1.9 (4H) ppm were attributed to pyrrolidine ring protons C14 and C15, respectively, which are chemically and magnetically equivalent with C17 and C16 (the numbering scheme of HBpypTsc is given in Scheme 1). Aromatic protons of the pyridine and phenyl ring appear at $\delta = 8.73$, doublet, aromatic, 1H, $J = 7.5$ Hz; 8.5, aromatic, doublet, 1H and 7.1–7.8, aromatic, multiplet, 7H, respectively. The carbon atoms were assigned on the basis of proton decoupled ^{13}C and ^{13}C- Spin Echo Fourier Transform NMR spectra. Eighteen signals were observed in the ^{13}C NMR spectrum, which are assigned as follows. Signals at $\delta = 177.0$ and 177.6 ppm were attributed to C(1)=N(2) and C(13)=S(1) of the thiosemicarbazone moiety. Aromatic carbons of the pyridine and phenyl ring of the 2–benzoylpyridine moiety appear at $\delta = 121.5$ (C5), 123.8 (C4), 126.1 (C6), 128.4 (C10), 129.2 (C11), 129.6 (C3), 129.9 (C9), 137.3 (C7), 143.9 (C2), 148.0 (C9), 149.2 (C12), 152.8 (C8), whereas the peaks at $\delta = 53.4$, 50.4, 26.6 and 24.3 were assigned to aliphatic carbons C14, C17, C15 and C16, respectively, of the pyrrolidine ring.

All complexes were dark brown and are readily soluble in polar organic solvents. Their stoichiometries and partial elemental analysis data are shown in Table 2. Analytical data shows a 1:2:1 ratio of iron, ligand and anions for FeL_2X [$X = ClO_4$, $FeCl_4^-$, NO_3]. From the analytical data obtained for compound **3** two formulations are possible: $[Fe(BpypTsc)_2]FeCl_4$ or $[FeBpypTscCl_2]$, but from the crystallographic as well as the spectroscopic data it is clear the compound isolated is the former one consisting of an ion pair. The compounds were 1:1 electrolytes [18] in DMF with Λ_m values near to 95 $\Omega^{-1}\,cm^2\,mol^{-1}$. The cation centre of all the complexes are expected to contain two deprotonated ligands attached to an iron(III) centre. Magnetic moments have been determined for all the complexes at room temperature in the polycrystalline state. Iron(III) is known to exist in three states with $S = 5/2$ ($^6A_1$, $\mu = 5.92$ BM), 3/2 ($^4A_2$, $\mu = 3.87$ BM) and 1/2 ($^2T_2$, $\mu = 1.73$ BM)[19]. The magnetic moments of the compounds **1** and **2** are 1.89 and 2.33 BM, respectively, indicating these compounds are typical low spin compounds. The high values of susceptibility for compound **3** indicate the presence of a high spin centre in the molecule [20,21]. The complete assignment of the spin states of the complexes were done on the basis of EPR and Mössbauer measurements.

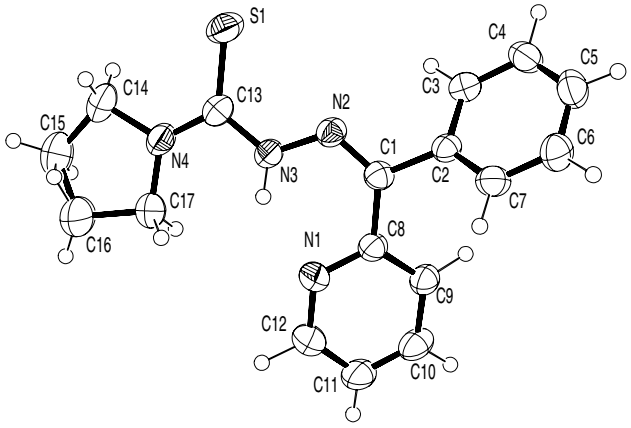

Fig. 1. ORTEP diagram of the compound HBpypTsc, with 54% ellipsoidal probability. Hydrogen atoms are shown as smaller spheres of arbitrary radii.

3.2. Molecular and crystal structure of compound HBpypTsc

Fig. 1 shows the molecular structure of the compound along with the atom numbering scheme. The molecule exists in the E conformation around the N2–N3 bond. The structure reveals quasicoplanarity in the plain of the thiosemicarbazone but both the aromatic rings are bifurcated. The molecular structure reveals that the compound exists in the thione form. Table 3 illustrates selected bond lengths and angles.

The compound has two double bonds in the thiosemicarbazone moiety viz. C1–N2 1.295 Å and C13–S1 1.681 Å which are consistent with the previously reported cases. The planarity in the thiosemicarbazone is revealed by a smaller dihedral angle of the N2–N3–C13–S1 (0.9°) skeleton. A considerable amount of ring bifurcation from the plane of the thiosemicarbazone is indicated by the dihedral angles C1–N2–N3–C13 (−176.9°) and C8–C1–C2–C7 (−44.7°). The S and pyridyl N1 atoms are in E configuration with respect to the C1–N2 bond. The five-membered pentamethyleneimine (pyrrolidine) ring is not planar and tends towards an envelope conformation [22]. The smaller dihedral angles between the pyridyl ring and the phenyl ring of the 2-benzoylpyridine moiety and thiosemicarbazone moiety C2–C1–C8–C9 (−28.2°) and N3–N2–C1–C8 (2.2°), is due to a resonance effect between the π systems. Pyridyl nitrogen N1 is intramolecularly hydrogen bonded to

3.3. Molecular and crystal structure of compound 3

The compound $Fe(BpypTsc)_2FeCl_4 \cdot 2H_2O$ (**3**) crystallizes with two molecules of water of crystallization. Table 4 presents the selected bond lengths and angles. Fig. 2 shows the molecular structure of the compound along with the atom numbering scheme. The low-spin iron(III) ion has a distorted octahedral geometry in the complex. The pattern of coordination is similar to that observed in similar types of complexes [23]. The two molecules of monodeprotonated ligand, coordinate to iron via pyridyl nitrogens, azomethine nitrogens and thiolato sulfur atoms to form four five membered che-

late rings. The crystallographic asymmetric unit contains a [Fe(BpypTsc)$_2$] cation and a tetrachloroferrate ($FeCl_4^-$) anion along with two molecules of lattice water.

Coordination lengthens the ligands C13–S1 and C1–N2 bonds to 1.749 and 1.309 Å, respectively, and this is an explicit indication of the deprotonation followed by the coordination of the ligand moiety. There is a slight shortening of the Fe–N(azomethine) bond distance compared to Fe–N(py) distances; this may be attributed to the fact that the azomethine nitrogen is a stronger base compared with the pyridyl nitrogen. The two azomethine nitrogen atoms are *trans* to each other, while the pyridyl nitrogen atoms and thiolato sulfur atoms are in *cis* positions. The ligands are orthogonal to the metal ion, with the NNS coordination in a meridonal fashion [24]. The chelate rings are almost planar. There exist strong C–H$\cdots\pi$ interactions between these metal containing chelate rings Cg(3) and Cg(4) with pyridyl ring protons. The tetrachloroferrate anion present in the molecule is slightly distorted tetrahedral with equal bond lengths (~2.187 Å) and angles (~109.46°).

3.4. IR spectra

In Table 5 we have compiled the assignments of IR bands most useful for the establishment of the mode of coordination of thiosemicarbazone ligands in their iron(III) coordination. Coordination of the azomethine nitrogen is indicated by the lowering of the band at 1630 cm^{-1} by 30–50 cm^{-1}. The band is not a pure vibrational band of C=N stretching, but it is a combination band of C=C vibrations of the pyridyl ring also [25]. Two bands ≈1340 and 840 cm^{-1} were assigned to the C–S stretching and bending mode of vibrations. These bands also shift to lower energies in all complexes compared to the ligand, indicating the coordination of the thiolato sulfur. Another band which is considered to be sensitive to coordination is ν(N–N) which is raised in energy due to coordination because of the increased double bond character. The newly formed C=N bond due to the deprotonation of the ligand is also observed ≈1630 cm^{-1}. The spectra of the complexes showed an increase in pyridyl ring in-plane and out-of-plane bending mode of vibrations at ≈440 and 650 cm^{-1}.

Table 6 shows the polyatomic anionic vibrations along with the M–L stretching vibrations observed in the far-IR and IR regions. Fig. 3 shows the far-IR spectra of the complexes. The spectra of compound **1**

had broad split bands assignable to $\nu_3(ClO_4) \approx 1105$ cm^{-1}, it is unlikely that the perchlorate ion is bound directly to the iron(III) centre since there is no indication of splitting of $\nu_4(ClO_4) \approx 619$ cm^{-1}. This is also confirmed by the absence of $\nu_1(ClO_4) \approx 920$ cm^{-1}. Besides these $\nu_2(ClO_4)$ is also observed ≈ 470 cm^{-1}. All these bands are split due to the strong H-bonding interactions in the molecule [26]. A similar splitting occurs in the $\nu_3(FeCl_4) \approx 374$ cm^{-1} band in the spectrum of compound **3**. This splitting may be due to the steric factors which reduce the symmetry from tetrahedral [27]. Similarly the band corresponding to $\nu_4 \approx 134$ cm^{-1} is also found to be split due to site effects. The other two stretching modes ν_1 and ν_2 are found at approximately 330 and 114 cm^{-1}, respectively, in the spectrum of compound **3**. The spectrum of compound **2** has two strong bands at 1389 and 1289 cm^{-1} corresponding to ν_1 and ν_4 of the nitrato group. The absence of a combination band ≈ 1740 cm^{-1} assignable to $\nu_1 + \nu_4$ indicates the ionic nature of the group [28]. Bands at ≈ 515 and 355 cm^{-1} are assigned to the Fe–N vibrations of the azomethine and pyridyl nitrogen coordination, respectively. Fe–S bond stretching vibrations are found approximately at 420 cm^{-1} in the spectra of the complexes.

3.5. Electronic spectra

Table 7 shows the electronic spectral values in solid-state DRS mode. Fig. 4 shows the electronic spectrum of compound **3**. The UV region is dominated by two intense intra ligand bands at ~36 000 and 29 000 cm^{-1} assigned to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions.

Usually $n \rightarrow \pi^*$ transitions involving N and S atoms occur at a lower energy than $\pi \rightarrow \pi^*$. Bands which are between 36 000 and 30 000 cm^{-1} in the spectrum of the complexes having pyridyl ligands have been assigned to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions and the bands between 15 000 and 27 000 cm^{-1} are assigned to $d \rightarrow \pi^*$ transitions, $S \rightarrow Fe$ and other ligand-to-metal charge transfer transitions. The bands below 15 000 cm^{-1} are due to $d \rightarrow d$ bands which correspond to a $^2T_{2g} \rightarrow {}^2T_{1g}$ transition of the d^5 spin-paired systems [29]. A comparison of the spectra of **1**, **2** and **3** shows no significant differences indicating that electronic spectra of the cations dominate the spectral properties [30]. Therefore the spin forbidden transitions between 13 700 and 16 600 cm^{-1} of $[FeCl_4]^-$ are too weak to be observed. Unfortunately the electronic spectra of low-spin iron(III) compounds have not been adequately characterized.

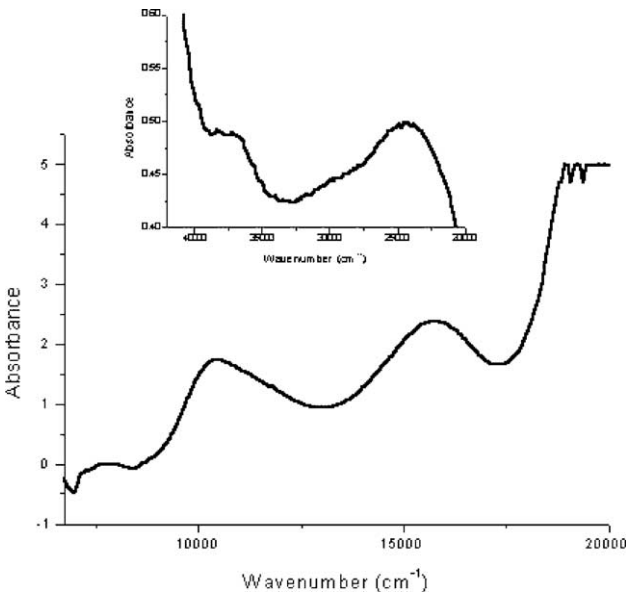

Fig. 4. UV–Vis-NIR spectrum of compound 3 (insight: UV region).

Table 7
Electronic spectral data of the complexes

Compound	$\pi \rightarrow \pi^*$	$n \rightarrow \pi^*$	LMCT	$d \rightarrow d$
HBpypTsc	43 300	29 240, 29 760	–	–
$[Fe(BpypTsc)_2]ClO_4$ (**1**)	36 5136	30 487	26 737, 15 503	10 362
$[Fe(BpypTsc)_2]NO_3$ (**2**)	36 630	29 585	24 509, 15 822	10 373
$[Fe(BpypTsc)_2]FeCl_4$ (**3**)	37 037	30 211	24 390, 211 416, 15 974	10 438

All values are in cm^{-1}.

3.6. Electron paramagnetic resonance spectra

The EPR spin Hamiltonian parameters of the iron(III) complexes obtained after the spectral simulations performed by EasySpin package [31] are presented in Table 8. Figs. 5–7 show the EPR spectra of the complexes recorded under different conditions. The EPR of the d^5 iron(III) is expressed by the spin Hamiltonian [32,33],

$$H = \beta[g_x H_x \cdot S_x + g_y H_y \cdot S_y + g_z H_z \cdot S_z]$$

with $S = 1/2$ and $g = 2.00$.

The polycrystalline EPR spectra of compound **3** consist of a single broad line with a Δpk (peak-to-peak) value ~27 mT and a comparatively higher g value ~2.25. This feature does not change even when the temperature is lowered to 100 K. This is indicative of the presence of a mixture of spin species in the system. The observed g value ≈2.0 and a nearly isotropic spectra indicate spin–spin relaxation via dipole–dipole interactions. However the solid-state spectra of the other two compounds **1** and **2** are rhombic in nature with three g values. This type of feature is common for low spin octahedral complexes [34]. The observed anisotropic character is due to rhombic distortion common for spin paired iron(III) complexes.

The isotropic spectrum of complex **3** in the polycrystalline state changes to a rhombic spectrum in frozen solution in DMF. Since the g_{av} values obtained at both temperatures are similar, it is likely that lattice effects in the solid state may account for this change from isotropic to rhombic and it is common for spin paired iron(III) complexes. The small deviation of the anisotropic g values from 2.0 suggests that the unpaired electron is in the d_{xy} orbital with a $d_{xz}^2 d_{yz}^2 d_{xy}^1$ ground state configuration. It was interesting to note a sharp but small signal corresponding to $g = 4.2603$ indicating the presence of a high spin species which was identified as the $[FeCl_4]^-$ anion. The spectra of the compounds **1** and **2** recorded in dichloromethane at 100 K also show anisotropic spectra with three g values corresponding to a low spin octahedral iron(III) system. However the spectral features were not resolved probably due to poor glass formation.

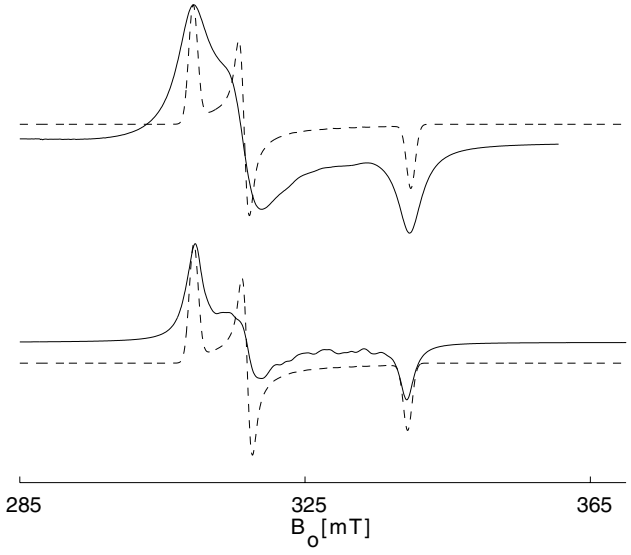

Fig. 5. EPR spectrum of compound **1** in the polycrystalline state: upper trace at 298 K, lower trace at 100 K. Dotted lines shows the simulated best fit spectra of the compound.

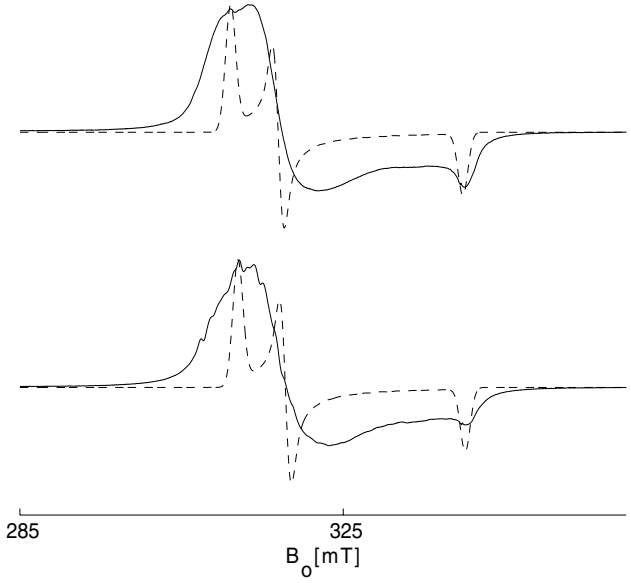

Fig. 6. EPR spectrum of compounds **1** and **2** in a solution of dichloromethane at 100 K: upper trace compound **1**, lower trace compound **2**. Dotted lines show the simulated best fit spectra of the compounds.

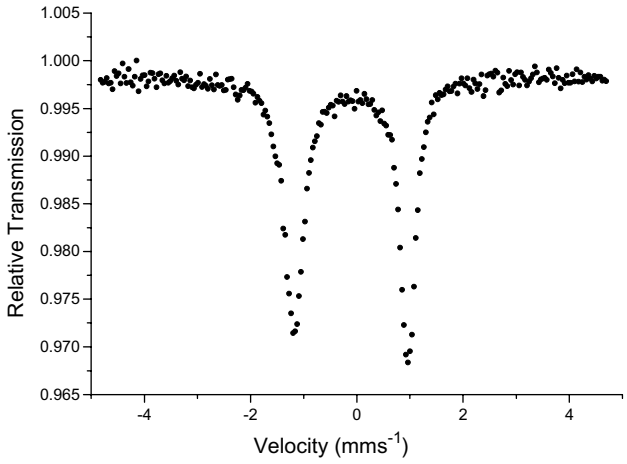

Fig. 8. Mössbauer spectrum of compound **1** (298 K).

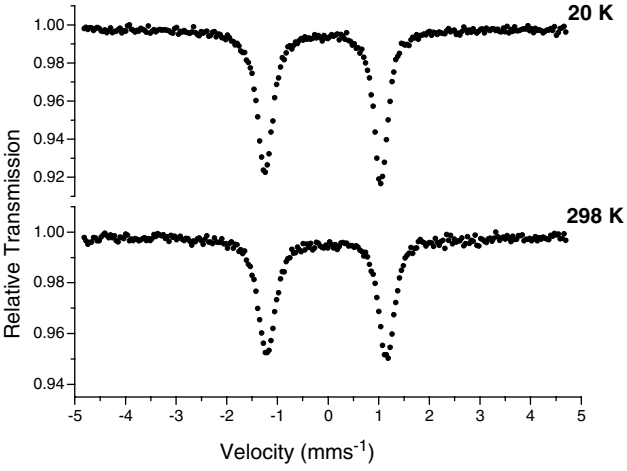

Fig. 9. Mössbauer spectra of compound **2** at different temperatures.

3.7. Mössbauer spectra

Mössbauer spectra of the complexes were recorded at 298 and 20 K in order to understand and confirm the spin behavior of the systems. The Mössbauer parameters calculated from the spectra are presented in Table 9, and Figs. 8–10 show the spectra of the complexes. All values were compared with α-iron as a standard.

The high intensity doublet in the spectra of all the complexes with an isomer shift approximately at −0.12 mm s^{-1}, characterized by a quadrupolar splitting $\Delta E_q \approx 2.1$ mm s^{-1}, is ascribed to the low spin $^2T_{2g}$ ground state of low spin iron(III) [35]. These values change a little when the temperature is lowered. The signals in the low temperature spectra were more intense. The 1:1 ratio between the quadrupole split spectra is not strictly observed due to the anisotropic absorption known as the Goldansky–Karyagin effect. The spectra of compound **3** is unusually interesting with the presence of another broad signal corresponding to $\delta^{is} \approx 0.12$ mm s^{-1} $\Delta E_q \approx 0.67$ mm s^{-1}, ascribed to a tetrahedral high spin iron(III) species [36]. The observation of the broad line with unresolved quadrupolar splitting is assumed to be due to much slower spin relaxation due to the orbital electrons of iron. The high spin signal is temperature dependent and in the 20 K spectrum of compound **3** the signal is found to be shifted compared to the 298 K spectrum, and it was found to be more intensified. There are no changes between the 298 and 20

Table 9
Mössbauer spectral data of the complexes

Compound	Temperature (K)	Spin	δ^{is} (mm s^{-1})	ΔE_q (mm s^{-1})
[Fe(BpypTsc)$_2$]ClO$_4$ (**1**)	298	1/2	−0.17 ($^2T_{2g}$)	2.231 ($^2T_{2g}$)
[Fe(BpypTsc)$_2$]NO$_3$ (**2**)	298	1/2	−0.11 ($^2T_{2g}$)	2.351 ($^2T_{2g}$)
	20	1/2	−0.12 ($^2T_{2g}$)	2.352 ($^2T_{2g}$)
[Fe(BpypTsc)$_2$]FeCl$_4$ (**3**)	298	1/2	−0.10 ($^2T_{2g}$)	2.110 ($^2T_{2g}$)
	20	1/2	−0.11 ($^2T_{2g}$)	2.241 ($^2T_{2g}$)
	298	5/2	0.17 ($^6A_1$)	0.925 ($^6A_1$)
	20	5/2	0.12 ($^2T_{2g}$)	0.625 ($^2T_{2g}$)

All values are relative to α-iron.

Synthesis and structures of unsymmetrical bis- and tris-cyclotriphosphazenes

N. Satish Kumar, K.C. Kumara Swamy *

School of Chemistry, University of Hyderabad, Hyderabad 500046, AP, India

Received 10 September 2003; accepted 10 December 2003

Abstract

Synthesis and characterization of several unsymmetrical bis- and tris-spirocyclic cyclotriphosphazenes that include the ones with chiral 1,1′-bi-2-naphthol are reported. Specifically, the compounds $N_3P_3(OCH_2CMe_2CH_2O)(HNCH_2CMe_2CH_2NH)Cl_2$ (**1**), $N_3P_3(OCH_2CMe_2CH_2O)(HNCH_2CMe_2CH_2NH)[(2,2'\text{-}OC_6H_4)_2]$ (**2**), $N_3P_3(OCH_2CMe_2CH_2O)[(2\text{-}OC_{10}H_6)_2CH_2]Cl_2$ (**3**), $N_3P_3(OCH_2CMe_2CH_2O)[1,1'\text{-}O_2(C_{10}H_6)_2]Cl_2$ (**4**), $N_3P_3(OCH_2CMe_2CH_2O)(HNCH_2CMe_2CH_2NH)$ $(1,1'\text{-}O_2(C_{10}H_6)_2)$ (**5**) and $N_3P_3(OCH_2CMe_2CH_2O)[1,1'\text{-}O_2(C_{10}H_6)_2]_2$ (**6**) are prepared by starting with the mono-spiro compound $N_3P_3(OCH_2CMe_2CH_2O)Cl_4$. No ansa type of compound was isolated from these reactions. X-ray structures of **1** and **2** have been determined. Synthesis of the tris-spiro compound $N_3P_3[1,1'\text{-}O_2(C_{10}H_6)_2]_3$ (**7**), possessing the 1,1′-bi-2-naphthoxy residue is also reported.

Keywords: Cyclophosphazenes; Chiral; Spirocyclic; X-ray structure

1. Introduction

The chemistry of phosphazenes $[NPX_2]_n$ [X = Cl, F] is attractive in view of the diversity of the products that can be obtained by simple substitution of the halogens on phosphorus [1–4]. Cyclophosphazenes are also valuable precursors for speciality polymers [5–8]. While the reaction of monofunctional reagents with halogenocyclophosphazenes leads to, primarily, geminal or nongeminal substitution products, polyfunctional reagents can lead to a greater variety of products that include 'spiro', 'ansa' or 'intermolecular' condensation products in which the phosphazene ring is retained [9–15]. We have been interested in the chemistry of spirocyclic cyclophosphazenes [10,16] and in particular, the unsymmetrically substituted ones of type **I**, because they could be potential molecularly chiral compounds that may be amenable for resolution and use in asymmetric synthesis. In this connection it is noted that although several tris-spirocyclic cyclotriphosphazenes are known [11,17–19], none with three different difunctional reagents has yet been characterized. Such a compound is useful in comparing the variation in bond parameters at phosphorus. Although we have not been able to get a compound of type **I** so far to check the chirality aspects, we have succeeded in obtaining the tris(spiro) derivative **2** with three different difunctional residues, by starting with the bis(spiro) compound **1**. This paper deals with the synthesis and X-ray structural studies on these two compounds. In addition to these, we also report the synthesis of other bis and tris derivatives **3**–**7**. Of these, **4**–**7** possess a 1,1′-bi-2-naphthoxy residue. The latter compounds were synthesized for possible use as bases in asymmetric synthesis at a later stage.

2. Experimental

Chemicals were procured from Aldrich/Fluka or from local manufacturers; they were purified when required. Solvents were purified according to standard procedures [20]. All reactions, unless stated otherwise, were performed under dry nitrogen atmosphere. ^{1}H and $^{31}P\{H\}$ NMR spectra were recorded on a Bruker 200 MHz spectrometer in $CDCl_3$, with shifts referenced to $SiMe_4$ ($\delta = 0$) or 85% H_3PO_4 ($\delta = 0$). Elemental analyses were carried out on a Perkin–Elmer 240C CHN analyzer.

2.1. Synthesis of *1*

A solution of 2,2-dimethyl-1,3-propane diamine (1.02 g, 1.19 mL, 10 mmol) and triethylamine (2.02 g, 20 mmol) in toluene (10 mL) was added dropwise over a period of 10 min with continuous stirring to a solution of $N_3P_3(OCH_2CMe_2CH_2O)Cl_4$ [21], (3.79 g, 10 mmol) in toluene (10 mL) and the reaction mixture was then heated to reflux for 30 h. The triethylamine hydrochloride formed was filtered off. Removal of solvent toluene from the filtrate led to compound **1**. Crystallization (colourless crystals) was done using toluene–hexane (2:1). Yield: 3.1 g (76%). M.p. 166–170 °C. IR (KBr, cm^{-1}): 3426, 3250, 1471, 1379, 1213, 1059, 1013. ^{1}H NMR ($CDCl_3$): δ 0.95, 0.98, 1.10, 1.25 (4 s, 12 H, CH_3), 2.68 (br s, 2 H, N*H*), 2.80–3.10 (m, 4 H, NHCH_2), 3.80–4.28 (m, 4 H, OCH_2). ^{13}C NMR: δ 20.8, 22.1, 24.4, 24.9 (4 s, *C*H_3), 31.7 (*C*(CH_2NH–)$_2$), 31.8 (d, ^{3}J(P–C) = 4.6 Hz, *C*(CH_2O)$_2$), 52.6 (s, NH*C*H_2), 76.4 (s, O*C*H_2). ^{31}P NMR: δ 6.9 (dd to t, ^{2}J(P–P)$\sim$67.0 Hz, O_2P(spiro)), 12.0 (dd to t, ^{2}J(P–P)$\sim$67.0 Hz, N_2P(spiro)), 23.4 (dd to t, ^{2}J(P–P)$\sim$67.0 Hz, *P*Cl_2). *Anal.* Calc. for $C_{10}H_{22}N_5O_2Cl_2$: C, 29.42; H, 5.43; N, 17.15. Found: C, 29.45; H, 5.48; N, 17.22%.

2.2. Synthesis of *2*

To a stirred suspension of NaH (0.05 g, $\sim$2.0 mmol) in THF (20 mL) at 0 °C was added 2,2′-biphenol (0.18 g, 1.0 mmol). After ca. 0.5 h, **1** (0.41 g, 1.0 mmol) was added and the reaction mixture was refluxed for 36 h. After cooling to room temperature, the reaction mixture was carefully quenched with ice, washed with water, extracted with dichloromethane (2×15 mL) and dried (Na_2SO_4). The solvent was removed to obtain a solid, which was purified by column chromatography (ethyl acetate–hexane 6:1). Crystallization (colourless crystals) was done using a dichloromethane–hexane mixture (1:2). Yield: 0.29 g (55%). M.p. >270°C. IR (KBr, cm^{-1}): 3389, 3329, 1475, 1440, 1383, 1246, 1186, 1060, 1016. ^{1}H NMR: δ 0.87, 0.95, 1.00, 1.22 (4 s, 12 H, CH_3), 2.64 (br m, 2 H, N*H*), 2.94, 3.00 (2 d or dd, $J = 6.0$, 11.2 Hz, 4 H, NHCH_2), 3.83–4.30 (m, 4 H, OCH_2), 7.23–7.55 (m, 8 H, Ar–H). ^{13}C NMR: δ 21.0, 22.3, 24.6 (3 s, *C*H_3), 31.5, 32.0 (2 d, ^{3}J(P–C) = 4.8 Hz each, *C*(CH_2O)$_2$ and *C*(CH_2NH)$_2$), 52.8 (s, NH*C*H_2), 75.9 (d, ^{2}J(P–C) = 6.1 Hz, O*C*H_2), 122.1, 125.6, 129.2, 129.4, 148.6, 148.8 (all Ar–*C*). ^{31}P NMR: δ 12.8 (dd to t, ^{2}J(P–P)$\sim$70.0 Hz, O_2P(spiro, 6-membered)), 17.3 (dd to t, ^{2}J(P–P)$\sim$70.0 Hz, N_2P(spiro)), 24.9 (dd to t, ^{2}J(P–P)$\sim$70.0 Hz, O_2P(spiro, 7-membered)). The X-ray structure was taken for the crystals from dichloromethane–hexane, that showed the CH_2Cl_2 peak at δ 5.2 ppm in the ^{1}H NMR.

2.3. Synthesis of *3*

A solution of bis(2-hydroxy-1-naphthyl)methane [22] (0.30 g, 1.0 mmol) and triethylamine (0.20 g, 0.28 mL, 2.0 mmol) in toluene (5 mL) was added dropwise over a

period of 10 min with continuous stirring to a solution of $N_3P_3(OCH_2CMe_2CH_2O)Cl_4$ (0.38 g, 1.0 mmol) in toluene (10 mL) and the reaction mixture was then heated to reflux for 30 h. The triethylamine hydrochloride formed was filtered off and the removal of solvent toluene from the filtrate led to compound **3**. Yield: 0.42 g (70%). M.p. 265 °C. IR (KBr, cm^{-1}): 1595, 1512, 1464, 1386, 1192, 1053, 1003. ^1H NMR: δ 1.03, 1.08 (2 s, 6 H, CH_3), 3.96 (dd, 2 H, ^2J(H–H) = 10.7 Hz, ^3J(P–H) = 13.0 Hz, OCH_2(A)), 3.96 (dd to t, 2 H, ^2J(H–H) = ^3J(P–H) = 10.7 Hz, 2 H, OCH_2(B)), 5.00 (s, 2 H, $ArCH_2$), 7.31–8.34 (m, 12 H, Ar*H*). ^{13}C NMR: δ 21.2, 21.6 (2 s, CH_3), 23.9 (s, $ArCH_2$), 32.2 (s, $C(CH_3)_2$), 76.5 (d, ^2J(P–C) = 10.5 Hz, OCH_2), 121.4, 123.5, 124.2, 125.2, 127.1, 128.9, 129.0, 132.0, 132.8, 148.8 (all Ar- = *C*). ^{31}P NMR: δ 4.9 (A portion of ABX, ^2J(P–P)∼70.6 Hz each, O_2P (spiro, 8-membered)), 6.7 (B portion of ABX, ^2J(P–P)∼70.6 Hz each, O_2P (spiro, 6-membered)), 26.0 (∼ t, ^2J(P–P) = 70.6 Hz each, PCl_2). *Anal.* Calc. for $C_{26}H_{24}N_3O_3P_3Cl_2$: C, 51.50; H, 3.98; N, 6.93. 26.6 (s, O_2P(spiro)). *Anal.* Calc. for $C_{60}H_{36}N_3O_6P_3$: C, 72.95; H, 3.67; N, 4.25. Found C, 73.00; H, 3.69; N, 4.29%.

X-ray data were collected on an Enraf-Nonius-MACH3 X-ray diffractometer at 293 K using Mo K_α ($\lambda = 0.71073$ Å) radiation with the crystals mounted on a glass fibre. The structures were solved by direct methods [23]; all non-hydrogen atoms were refined anisotropically. For the hydrogen atoms except the NH hydrogen atoms in **1**, the riding model was used. The crystal data are summarized in Table 1.

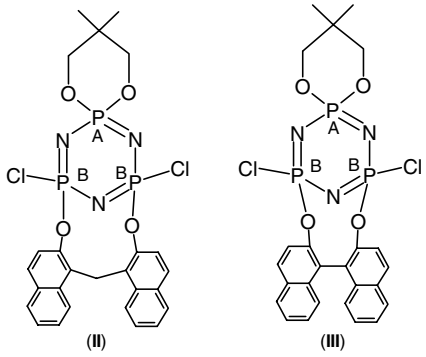
3. Results and discussion

3.1. Synthesis and spectra

Synthesis of all the compounds reported herein is straightforward and utilizes the reaction of the phosphazene precursor with the diamine in the presence of a base or with a diol (as a sodium salt or in the presence of triethylamine).

Among the compounds **1**–**6** with the 1,3,2-dioxaphosphorinane ring, in **1**–**5** the OCH_2 protons show up as a multiplet and the two methyls of the $C(CH_3)_2$ group show two peaks suggesting that this ring is fairly rigid in these compounds. This feature is analogous to that observed for a many other tetra-coordinate compounds bearing this ring [24–28]. When racemic 1,1′-bi-2-naphthol was used in the preparation of **5**, we expected to see separated signals for the possible diastereomers [due to the chirality of the 1,1′-bi-2-naphthoxy residue and possible molecular chirality at the phosphazene due to rigid ring systems], but did not. Compound **5** obtained by starting with either racemic or chiral 1,1′-bi-2-naphthol showed the same ^{31}P NMR spectra.

For compounds **3** and **4** an ABX and AMX pattern, respectively, are observed in the ^{31}P NMR spectra [Fig. 1]. These are consistent with the spirocyclic structures as assigned, but not with the *ansa* products (**II**) or (**III**) wherein an AB_2 (or AX_2) pattern would be expected.



It can be noted the δ(P) values for the P(spiro) atoms with phosphorus being a part of the seven-membered ring system [cf. **2**, **4**–**7**] are always downfield to those with P(spiro) atoms as part of six- or eight-membered rings [cf. **1**–**6**]. For example, in **2**, δ(P) values for O_2P (spiro, 7-membered) and O_2P (spiro, 6-membered) are, respectively, 24.9 and 12.8. Previously such an observation on hypervalent phosphorus compounds has been made by others and by us [29–32]. This feature was rationalized earlier by invoking the rigidity of the seven-membered rings used in these studies [29]. However, it should be noted that the δ(P) values for the tri-coordinate compounds $PhOP(OCH_2CH{=}CHCH_2O)$ [130.4] and $PhOP(OCH_2CH_2CH_2CH_2O)$ [127.3] possessing more flexible seven-membered rings are also quite downfield to $PhOP(OCH_2CMe_2CH_2O)$ [114.6] which possesses a six-membered ring [33]. These observations suggest that phosphorus is shielded when it is a part of an even-membered [six or eight] ring and gets deshielded when it is a part of an odd-membered [five or seven] ring. Earlier workers have, however, have noticed that presence of five-membered rings also deshields phosphorus relative to six-membered rings [29–32,34].

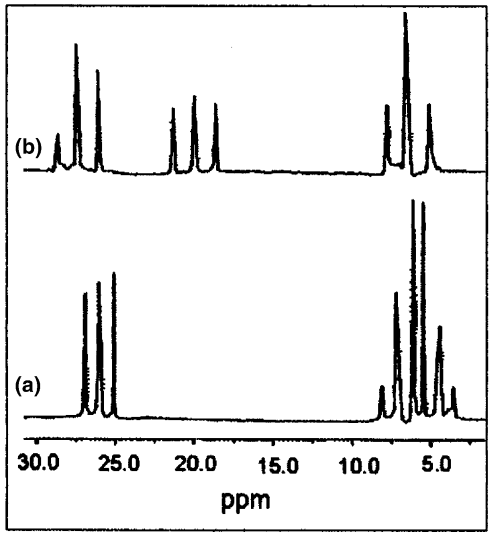


Fig. 1. The ^{31}P NMR spectra of (a) **3** and (b) **4**.

3.2. X-ray structures of *1* and *2*

The structure of **1**, with both the molecules in the asymmetric unit and with hydrogen bonding, is shown in Fig. 2; bond parameters are given in Table 2. The phosphazene P–N bond distances in **1** [1.550–1.618 Å] are in the normal range expected for such compounds [1,35].The variation in the mean P–N distances, considering both the molecules in the asymmetric unit, is in the order: Cl_2P–N<O_2P(spiro)–N<N_2P(spiro)–N. However, the exocyclic P–N single bond distances are fairly close to the phosphazenic P–N bond distances. This suggests substantial additional π-character at the exocyclic P–N bonds. This feature is also reflected in the

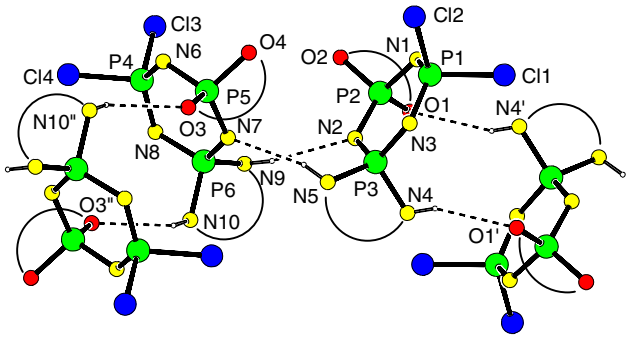

Fig. 2. Molecular structure of **1** showing all non-hydrogen atoms. Curved lines represent the $-CH_2CMe_2CH_2-$ residue. Selected hydrogen bond parameters (Å, °): N(4)–HN(4)···O(1′) 0.75 (4), 2.29 (4), 2.994 (4), 157(4); N(5)–HN(5)···N(7) 0.81 (4), 2.19 (5), 2.975 (4), 163(4); N(9)–HN(9)···N(2) 0.81 (4), 2.36 (5), 3.151 (5), 165(4); N(10)–HN(10)···O(3′) 0.76 (5), 2.34 (5), 2.993 (4), 144(4).

sum of the bond angles at the exocyclic nitrogen atoms N(4), N(5), N(9) and N(10) which are, respectively, 358°, 360°, 347° and 350°; the larger deviation at N(9) and N(10) may be due to higher uncertainties associated with the hydrogen positions. As regards phosphazenic bond angles, there is a marked deviation from the expected 120° at P(3) and P(6) (each connected to four nitrogen atoms); such a feature was observed previously in the spirocyclic compound $N_3P_3(HNCH_2CH_2CH_2NH)Cl_4$ [1,36].

The phosphazene ring in the two molecules of the asymmetric unit of **1** can be considered to be slightly distorted planar with the maximum deviation of 0.125 Å at N(2) and 0.095 Å at N(8) from the respective mean planes. This deviation is to be expected since the susbtituents at the three phosphorus atoms are all different.

Interestingly, the conformations of the 1,3,2-diazaphosporinane rings for the two molecules present in the asymmetric unit of **1** are different. Whereas this saturated ring at P(6) shows the normal chair conformation with P(6) and C(17) on the opposite sides of the mean plane comprising the atoms N(9), N(10), C(16) and C(18), the ring at P(3) has a 'tub' conformation with N(5) and C(6) at the two unique positions [Fig. 3]. It should be noted that the *tub* conformation for a saturated phosphorinane ring is *not common* for tetracoordinate P(V) compounds [21,37–39] and is found mostly for pentacoordinate phosphorus species [31,40]. We believe that this change in conformation in **1** is a result of the hydrogen bonding present in this compound (see below).

As shown in Fig. 2, both the NH protons of the 1,3,2-diazphosphorinane ring are engaged in hydrogen bonding [41,42]. While the ones at N(5) and N(9) are

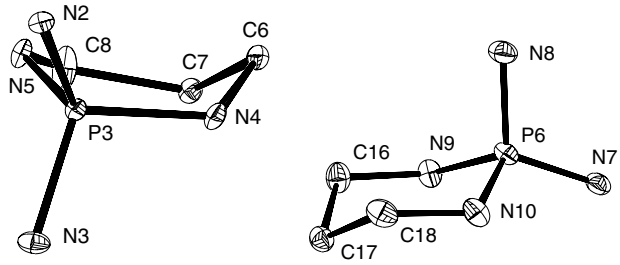

Fig. 3. A drawing showing the different conformations of the 1,3,2-diazaphosphorinane ring in **1**.

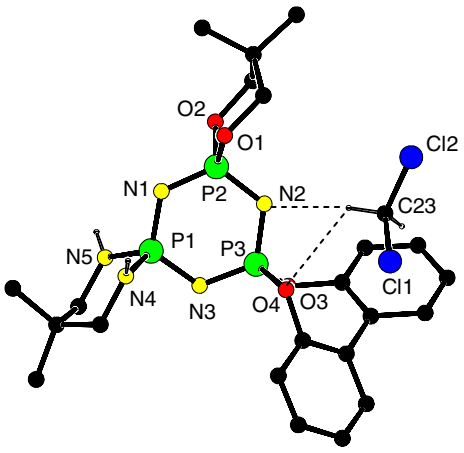

Fig. 4. Molecular structure of **2** showing all the non-hydrogen atoms. The hydrogen bonding interactions involving the solvent CH_2Cl_2 are also shown. Selected (possible) hydrogen bond parameters (Å, °): N(5)–HN(5)···O(2′) 0.86, 2.94, 3.252 (5), 103.8; C(23)–H(23B)···O(4) 0.97, 2.70, 3.289 (8), 119.9; C(23)–H(23B)···N(2) 0.97, 2.64, 3.557 (7), 157.1.

hydrogen bonded to the phosphazene ring nitrogen atoms N(7) and N(2) leading to a dimeric formulation, the hydrogens at N(4) and N(10) are hydrogen bonded to O(1) and O(3) of the 1,3,2-dioxaphosphorinane rings, respectively. It is important to note that the hydrogen bond acceptor sites N(2) and N(7) are elelctron-rich because of the proximity to the phosphorus bearing the 1,3,2-diazaphosphorinane residue which could push some electron density to the phosphazene ring system.

Compound **2** [Fig. 4, Table 2], to our knowledge, is the first unsymmetrical tris-spirocyclic cyclotriphosphazene to be structurally characterized. The phosphazene ring in **2** is planar with a maximum deviation of 0.103 Å at N(3) from the mean plane. The mean phosphazenic P–N bond distances in **2** are shorter at the P(spiro) bearing the oxygen atoms compared to those at the P(spiro) with the 1,3,2-diazaphosphorinane ring, as expected. The P–N single bonds in the 1,3,2-diazaphosphorinane ring are only slightly longer [within 0.02 Å] compared to the phosphazenic P–N bonds, thus showing substantial π-character; these nitrogen atoms [N(4), N(5)] are essentially planar [sum of the angles ~360°]. Both the N–P–N and the P–N–P angles are fairly close to 120° despite the fact the three phosphorus atoms carry *different* non-phosphazenic rings. The saturated six-membered rings have a *chair* conformation [cf. compound **1** above].

In contrast to what is observed for **1**, only very weak intermolecular hydrogen bonding between one of the NH hydrogens and an oxygen atom [O(2)] of the saturated 1,3,2-dioxaphosphorinane ring is present in **2** [not shown in Fig. 4]. The second NH proton does not appear to be participating in hydrogen bonding. Interestingly, a dichloromethane molecule sits very close to the phosphazene ring with a bifurcated C–H···O hydrogen bond involving one of the methylene protons, N(2) of the phosphazene ring and O(4) of the 1,3,2-dioxaphosphocin ring.

4. Summary and outlook

Synthesis and structures of an unsymmetrical bis-spirocyclic cyclotriphosphazene and the first example of an unsymmetrical tris-spirocyclic cyclotriphosphazene has been accomplished. Several new chiral and racemic spirocyclic cyclotriphosphazenes have also been synthesized. The utility of these compounds in the possible chiral induction [e.g. synthesis of hydroxyphosphonates via the Pudovik reaction] has to be investigated further. However, characterization of a cyclotriphosphazene with chirality solely at phosphorus is an interesting target that still has to be accomplished.

5. Supplementary data

Supplementary data are available from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk or www:http://www.ccdc.cam.ac.uk) on request, quoting the Deposition Nos. CCDC 219286 and 219287.

Transformation of maleato manganese(II): temperature effect and coordination modes ☆

Hong-Bin Chen, Hui Zhang, Jin-Mei Yang, Zhao-Hui Zhou *

Department of Chemistry and State Key Laboratory for Physical Chemistry of Solid State Surface, Xiamen University, Xiamen 361005, China

Received 20 July 2003; accepted 11 December 2003

Abstract

Two maleato bipyridine manganese(II) coordination polymers $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**) and $[Mn(male)(bpy)]_n$ (**2**) (H_2male = maleic acid, bpy = 2,2′-bipyridine) were prepared in an ice-bath and at room temperature respectively, and were spectroscopically and structurally characterized. Complex **1** obtained at low temperature, possesses a one-dimensional helical chain in the solid state with hepta-coordination number at the manganese center. At room temperature, the hydrated complex **1** was irreversibly converted into the thermodynamically stable dehydrated product **2** with octahedral coordination. A similar dehydration effect was observed for the maleato manganese(II) complex with a more conjugated phenanthroline (phen) ligand. The maleato manganese(II) coordination polymer $[Mn(male)(phen)]_n \cdot nH_2O$ (**3**) can be converted into the dehydrated product $[Mn(male)(phen)]_n$ (**4**) upon heating, while the resultant product retains a similar pattern of coordination mode.

1. Introduction

Metal-directed self-assembly of coordination polymers with well-defined architectures has presently been one topic of intense interest in the field of supra-molecular chemistry owing to their original topologies, desired properties and potential applications in multidisciplinary areas, e.g., catalysis, nonlinear optics, magnetism, luminescence, gas storage and chemical absorption [1]. Considerable efforts have been made to construct such extended solid materials with manipulated and tunable functionalities. The most common used strategy is to employ appropriate organic building blocks with several metal centers through direct bond formation. However, it still remains a challenge for synthetic chemists to predict and control the way of molecular components assembled in the crystalline phase. This is because the self-assembly processes are heavily influenced by subtle factors, such as templates [2], choice of solvents and counterions [3], and pH values [4]. When the reaction conditions are deliberately controlled, infinite networks with novel topologies can be gained. Though it was clear long ago that temperature can dramatically affect the extended structure of the networks, the influence of temperature in the formation of coordination polymers is less well understood and systematic studies are rare [5]. It is known that in the self-assembly of both synthetic and biological systems the thermodynamic product is usually favored, the kinetic product may also be obtained if the shape of the energy hypersurface is such that the system becomes trapped in local minima [6]. To develop the better understanding of temperature effects on the formation of coordination polymers, in the present contribution, two new maleato manganese(II) polymers formulated as $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**) and $[Mn(male)\ (bpy)]_n$ (**2**) were temperature-dependently prepared and structurally characterized. Irreversible conversion from kinetic maleato manganese **1** to the dehydrate product **2** was investigated.

2. Experimental

All chemicals were commercially available and used without further purification. Elemental microanalyses (C, H and N) were performed on an EA 1100 elemental analyzer. Infrared spectra were recorded from KBr pellets on a Nicolet FT-IR 360 spectrophotometer in the range of 4000–400 cm^{-1}.

2.1. Preparation of $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (1)

Manganese maleate was prepared in situ at 0 °C by mixing $MnCl_2 \cdot 4H_2O$ (0.99 g, 5 mmol) and an equimolar amount of sodium maleate, dissolving in 20 ml double distilled water. After stirring the mixture for 15 min, an equimolar amount of 2,2′-bipyridine (0.780 g, 5 mmol), dissolved in 10 ml methanol, was slowly added and stirring was continued for another 10 min. The solution was kept in the refrigerator. Block-like crystals suitable for single crystal diffraction analysis were obtained a few days later. Yield: 85%. *Anal.* Calcd. for $C_{14}H_{16}N_2O_7Mn$: C, 44.3; H, 4.2; N, 7.4. Found: C, 43.0; H, 4.1; N, 7.3%. IR (KBr, cm^{-1}): ν(O–H) 3377_{vs}, ν_{as}(C=O) 1578_{vs}, ν_s(C=O) 1439_s, ν(Mn–O) 773_s.

2.2. Preparation of $[Mn(male)(bpy)]_n$ (2)

The preparation of **2** was similar to the hydrate product **1** except the reaction was proceeded at ambient temperature. Plate single crystals suitable for X-ray diffraction were obtained after a few weeks. Yield: 90%. *Anal.* Calcd. for $C_{14}H_{10}N_2O_4Mn$: C, 51.7; H, 3.1; N, 8.6. Found: C, 52.2; H, 3.2; N, 8.9%. IR (KBr, cm^{-1}): ν_{as}(C=O) 1593_s, 1547_{vs}, ν_s(C=O) 1429_m, 1398_m, ν(Mn–O) 774_m.

2.3. Conversion of $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (1) to $[Mn(male)(bpy)]_n$ (2)

The crystals of **1** were picked out and put in a beaker with some mother liquid at ambient temperature. A few days later, the block-like yellow crystals segmented into 'chaos' and IR spectra justified it was converted into thermodynamic product **2**.

2.4. Conversion of $[Mn(male)(phen)]_n \cdot nH_2O$ (3) to $[Mn(male)(phen)]_n$ (4)

The maleato phenanthroline manganese complexes **3** and **4** were prepared as reported very recently [7]. Crystals of **3** (0.37g, 1 mmol) in 5 ml water were warmed in a 50 °C warm bath for 8 h. The resultant product was showed to be the dehydrated maleato manganese complex **4** by IR spectra.

2.5. X-ray data collection, structure solution and refinement

Intensity data were collected on a Bruker SMART APEX CCD using Mo Kα radiation ($\lambda = 0.71073$ Å). Both structures were solved by direct methods and refined by full-matrix least squares based on F^2 using

SHELX-97 software [8]. All non-hydrogen atoms were anisotropically refined. Hydrogen atoms were included at geometrically calculated positions with thermal parameters derived from the parent atoms, except those bonded to the water molecules. The water hydrogen atoms were located in the difference map and included at these sites, with a fixed isotropic displacement factor of $U(\mathrm{H}) = 1.2U_{\mathrm{eq}}(\mathrm{O})$. Crystal data, data collection and refinement parameters are summarized in Table 1. Selected bond lengths and bond angles are listed in Table 2.

3. Results and discussion

Based on IR spectra, we can deliberately diagnose the coordination nature of the maleato group in complexes **1** and **2**. Specifically, asymmetric stretching vibrations ν_{as}(COO) appear near 1578 cm^{-1} for **1** and between 1593 and 1547 cm^{-1} for **2**, and the symmetric stretching vibrations ν_s(COO) are observed near 1439 cm^{-1} for **1** and between 1429 and 1398 cm^{-1} for **2**. The separations [ν_{as}(COO)–ν_s(COO)] of complexes **1** and **2** (139 and 118 cm^{-1}) are much smaller than the value of 200 cm^{-1} for the free maleato group, indicating that the coordinated carboxyl group is in a bidentate bridging or chelating mode [9,10].

X-ray diffraction analysis reveals the maleato manganese dihydrate **1** possesses 1D helical chains with the basic building unit Mn(male)(bpy)(H$_2$O). Each manganese atom is primarily coordinated by four oxygen atoms from two bidentated maleates, two nitrogen atoms from bpy and one water molecule, in an irregular pentagonal-bipyramidal configuration (Fig. 1). The carboxyl oxygen atoms O1, O2 chelate to central manganese with an O1–Mn1–O2 bond angle of 56.7°, while O3, O4 of the other carboxyl group bind another manganese center. Thus each maleato unit serves as a bis(bidentate) ligand to link two manganese atoms and yields a half turn of the helical structure. All the carbon atoms of the maleato unit form a common plane, from which both terminal carboxyl groups O1–C1–O3 and O3–C4–O4 are twisted from the carbon backbone by 20.0° and 72.1°, respectively. The four Mn–O bond distances are different from each other to some extent (Table 2), with that to O2 being particularly short [2.2344(2) Å]. Unexpectedly, the shortest bond distance is that to the coordinated water molecule [Mn1–O1w 2.1375(2) Å]. So far, a great majority of structurally characterized Mn(II) complexes take invariably a

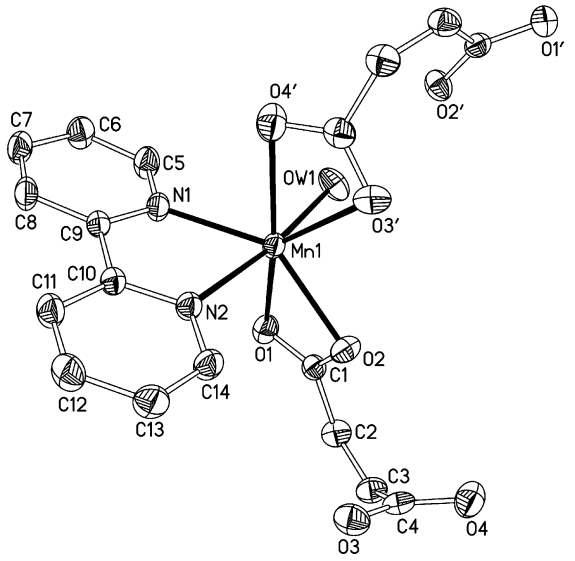

Fig. 1. One of the asymmetric units of $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**) in the Λ-configuration; hydrogen atoms and water molecules were omitted for clarity; thermal ellipsoids are drawn at 30% probability.

six-coordinate octahedral geometry around the metal atom. Complexes with coordination numbers exceeding six are limited to a few examples [11]. To the best of our knowledge, a helical coordination polymer based on a hepta-coordinated manganese center has not yet been documented hitherto. Extension of the basic building unit along the crystallographic 2_1 axis in the *b* direction gives an infinite 1D helical architecture with a long pitch of 8.649 Å. The helical chain is decorated by 2,2′-bpy ligands alternatively at the two sides and the 2,2′-bpy planes on the same side are absolutely parallel one another, while they have a dihedral angle of 42.8° with those on the other side (Fig. 2). The helical chains are further extended through hydrogen bonds between water molecules and carboxyl oxygen atoms into a two-dimensional network.

The asymmetric unit of **2** consists of one manganese center, one maleato group and one bpy ligand. Each manganese center primarily coordinates to two nitrogen atoms from 2,2′-bpy and four carboxylate oxygen atoms from three maleato groups, in a geometry which is best described as a distorted octahedron (Fig. 3). The Mn1–N1 bond distance [2.2688(2) Å] is slightly shorter than the Mn1–N2 bond [2.3286(2) Å] in the same ligand, suggesting some twist in the 2,2′-bpy ligand (dihedral angle 11.5° between the two pyridyl rings). *Cis*-fashioned oxygen atoms O1 and O3 at the two termini of the maleato unit bind the manganese center into a seven-member chelate ring with an O1–Mn1–O3 bond angle of 82.89°, while O2 and O4 bind to the other two manganese atoms. In this way, each maleato group acts as a tetradentate ligand to coordinate three manganese atoms. The dihedral angle (45.0°) between O1–C1–O3 and O3–C4–O4 is much smaller than that in **1** (67.9°). Both terminal carboxyl groups O1–C1–O2 and O3–C4–O4 twist from the carbon backbone C1–C2–C3–C4 by 45.9°and 1°, respectively. The conformations of the maleato units in the two complexes are so different that the explanation why two different topological products were obtained becomes obvious. The coordination mode of the maleato group is to some extent similar to those previously reported for $[Mn_4(male)_2(bpy)_8](ClO_4)_4 \cdot (MeOH)_2(H_2O)_2$ [12], $[Mn(male)(\mu\text{-}4,4'\text{-}bpy)]_n \cdot 0.5nH_2O$ [13] and [Mn(male)(phen)]$_n$ [7,14]. However, the extension of the basic unit and the packing style are different from those related compounds, thus giving rise to topologically different products. In addition, dimeric $[Mn_2(male)_2(bpy)_2]$ may

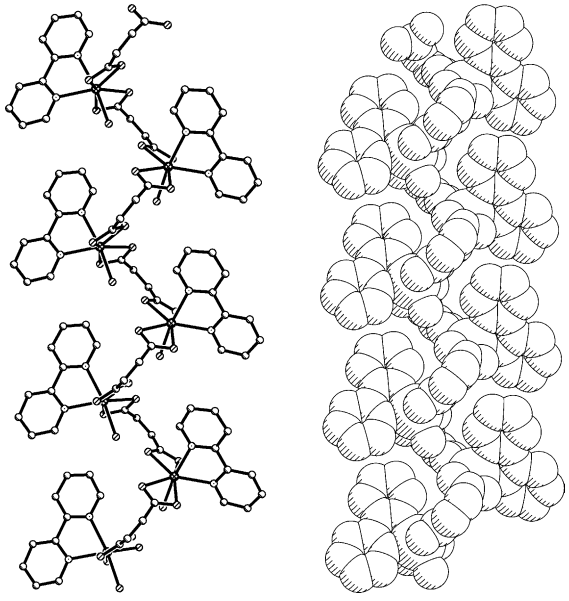

Fig. 2. One of the perspective views of a single helical chain of $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**) in the M-configuration.

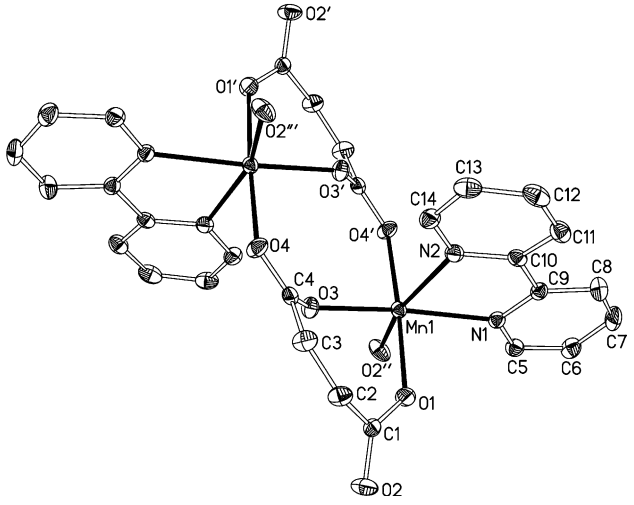

Fig. 3. Asymmetric unit of $[Mn(male)(bpy)]_n$ (**2**) with atom numbering scheme; hydrogen atoms were omitted for clarity; thermal ellipsoids are drawn at 30% probability.

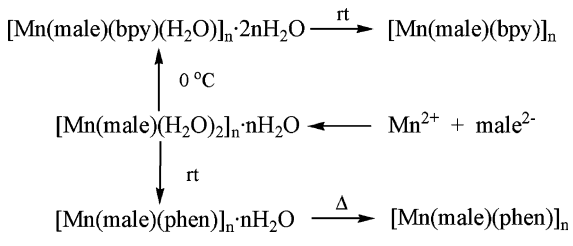
be better as a secondary building unit (SBU) than monomeric [Mn(male)(bpy)] for clearly describing the crystal structure. In the dimeric model, the extension directions of O2 and O2′, O2″ and O2‴ are opposite to each other, respectively, linking and being linked by another four SBUs into a two-dimensional zigzag structure. π–π stacking interactions between bipyridyl planes further extend the two-dimensional structure into a three-dimensional network.

The formation of both maleato manganeses complexes is temperature-dependent. When the reaction proceeded at 0 °C, only the one-dimensional coordination polymer **1** was separated. Whereas at ambient temperature, only the thermodynamic product **2** was isolated. Furthermore, the irreversible conversion from **1** to **2** was observed when **1** was exposed to an ambient temperature for a few days and this reaction could be qualitatively traced by IR spectra. As to the details of how the conversion proceeds requires further theoretical deduction and kinetic measurements. Here the possible mechanism of transformation is depicted as follows. In the first step, the manganese maleate species $[Mn(male)(H_2O)_2]_n \cdot nH_2O$ was formed according to previous reports [15]. Addition of 2,2′-bipyridine ligand replaces the water molecules to complete the formation of the kinetic product $[Mn(male)(bpy)(H_2O)]_n \cdot 2nH_2O$ (**1**) with hepta-coordination. On warming to room temperature, the maleato manganese complex **1** was further compelled into the thermodynamically stable product $[Mn(male)(bpy)]_n$ **2** with dehydration. Very recently, the stable maleato bipyridine manganese species **2** has been separated as the only product in the Mn^{2+}/maleate/bipyridine system in ethanol solution [7]. However, a similar condition with phenanthroline results in the formation of the hydrated product $[Mn(male)(phen)]_n \cdot nH_2O$ (**3**), which can be converted into the dehydrated maleato phenanthroline manganese(II) $[Mn(male)(phen)]_n$ (**4**) [7,14] upon heating in our experiment. This is much related, but having the more conjugated phenanthroline ring in the complexes. The detailed transformations of the maleato manganese complexes is shown in Scheme 1.



Scheme 1. Transformations of maleato manganese complexes with 2,2-bipyridine and phenanthroline groups.

Abstract

The dinuclear compound $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$ (ampym = 2-aminopyrimidine) has been synthesized and characterized by X-ray crystallography and infrared spectroscopy. In addition, EPR and magnetic measurements have been performed and related to the dinuclear structural details.

The compound crystallizes in the monoclinic space group $P2_1/c$, with $a = 8.0190(13)$, $b = 18.2500(11)$, $c = 10.955(2)$ Å, $\beta = 116.390(13)°$, $V = 1436.2(4)$ Å^3 and $Z = 2$. The coordination geometry around the Cu(II) ion is distorted square pyrimidal with the basal plane formed by two nitrogen atoms of two ampym molecules (Cu–N distances 2.002(3) and 2.031(3) Å) and two oxygen atoms of the bridging methoxo molecules (Cu–O distances of 1.936(2) and 1.937(3) Å). The apical position is occupied by a semi-coordinated oxygen of a perchlorate anion (Cu–O distance 2.442(2) Å). The H-bonds, formed by the amino group and the un-coordinated pyrimidine nitrogen atom of a neighbouring ampym molecule, give rise to an interesting Watson–Crick type pairwise aggregation of ampym ligands.

In the far-IR, the Cu–N vibrations are observed at 443 and 265 cm^{-1}, and the Cu–O are observed at 353 and 240 cm^{-1}. At room temperature the compound gives an EPR silent behaviour and magnetic susceptibility measurements, down to 4 K, agree with a strong antiferromagnetic interaction having a very large singlet–triplet splitting ($J = -621$ cm^{-1}). The title compound appears to be a distortion isomer of a recently reported X-ray structure of identical stoichiometry.

1. Introduction

The ligand used in this study, 2-aminopyrimidine (abbreviated as ampym), with two H-bond donor atoms and two H-bond acceptor atoms, is particularly attractive as a very simple self-complementary prototype for chain formation with other organic molecules [1–9]. Metal compounds with ampym as the only organic ligand, or present as a complementary organic ligand, have been increasingly used [10–25]. Quite a few Cu(II) X-ray structures with ampym acting as a complementary organic ligand, together with a variety of other organic ligands, have recently become available in the literature; in these cases ampym is found to act as a monodentate co-ligand [10–14], or as a bridging didentate ligand [15–20].

Different Cu(II) compounds with ampym were investigated by X-ray crystallography depending on the nature of the anion and the synthetic method. With halides as anions, mononuclear and polymeric compounds have been obtained in which ampym acts as a monodentate or a didentate ligand [22–25]. With other anions like sulfate [26,27], triflate [28], nitrate [29] and dicyanamide [30], mononuclear or polynuclear Cu(II) compounds are obtained, all with ampym acting as a monodenate ligand. X-ray structures of a dinuclear Cu(II) methoxo-bridged [31] and a hydroxo-bridged Cu(II) compound [32] were

doi:10.1016/j.poly.2003.12.019

also recently obtained, again with ampym acting as a monodentate ligand. With tetrafluoroborate as an anion surprisingly a very complicated trinuclear-based polymeric structure was obtained [33].

It should also be mentioned that the ligand ampym is known to be useful as a starting material for template synthesis with Cu(II) triflate, forming completely new organic compounds [34,35], in which additions have taken place.

In this study we present the synthesis, characterization and X-ray structure of the dinuclear methoxo-bridged Cu(II) compound $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$, together with spectroscopic and magnetic measurements.

In a recent publication [31], the crystal structure and magnetic measurements have been published of the differently synthesized compound with exactly the same geometry, $[Cu(ampym)_2(\mu\text{-}CH_3O)]_2(ClO_4)_2$, almost similar to the compound used in this study, however, with quite diffferent structural and magnetic properties. The two compounds appear to be distortion isomers, which cannot converted into one another.

2. Experimental

2.1. General

C,H,N determinations were performed on a Perkin–Elmer 2400 Series II analyser. UV–vis spectra were obtained on a Perkin–Elmer Lambda 900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference. X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer using DPPH ($g = 2.0036$) as a standard. FTIR spectra were obtained on a Perkin–Elmer Paragon 1000 FTIR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1}). Far-FTIR spectra were obtained on a Bruker 113v infrared spectrophotometer as polyethylene mulls (500–100 cm^{-1}, res. 2 cm^{-1}).

Magnetic susceptibility measurement (5–300 K) were carried out (at 0.1 T) using a Quantum Design MPMS-5 5T SQUID magnetometer. Data were corrected for the magnetization of the sample holder and for diamagnetic contributions, which were estimated from Pascal constants.

2.2. Synthesis

The ampym ligand was obtained commercially and used without purification. The title compound was obtained by adding 0.2 M ampym dissolved in methanol to a solution of 0.1 M copper(II) perchlorate in methanol. Upon standing at RT, dark green crystals were formed within a few days.Yield 78%, elemental analysis for $C_{18}H_{26}Cl_2Cu_2N_{12}O_{10}$ [found (calc.)]: C, 27.9 (28.1); H, 3.5 (3.4)%; N, 21.8 (21.9)%.

2.3. X-ray crystallography

A crystal was selected and mounted to the glass fiber using the oil-drop method; data were collected on a Nonius KappaCCD diffractometer (graphite-monochromated Mo Kα radiation, $\omega - 2\theta$ scans). The intensity data were corrected for Lorentz and polarization effects, for absorption (psiscan absorption correction) and extinction. The structures were solved by direct methods. The programs COLLECT [36], SHELXS 97 [37] and SHELXL 97 [38] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was done against all reflections. The weighted R factor, wR, and goodness-of-fit S are based on F^2, the conventional R factor is based on F, with F set to zero for negative F^2. All non-hydrogen atoms were refined anisotropically. The H atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Crystallographic data are collected in Table 1.

3. Results and discussion

3.1. Crystal structure of $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$

The structure of the compound is depicted in Fig. 1, with relevant bond length and bond angle information

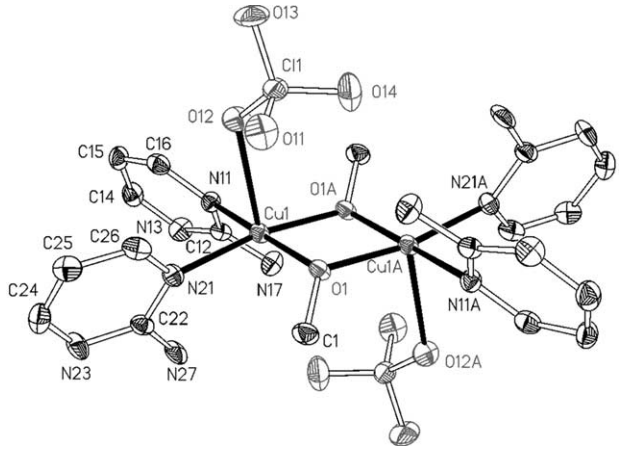

Fig. 1. Atomic displacement plot (50% probability level) of the molecular structure of $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$. Hydrogen atoms are omitted for clarity.

given in Table 2. The dinuclear unit has a centre of symmetry located on the Cu–Cu centre.

The Cu atom has a square–pyramidal geometry with the basal plane consisting of two nitrogens from two ampym ligands (N11, N21) with Cu–N distances of 2.002(3) and 2.031(3) Å and two oxygen atoms of the briding methoxo groups (O1, O1A) with Cu–O distances of 1.936(2) and 1.937(3) Å. The apical position is occupied by an oxygen atom of the coordinating perchlorate anion (Cu–O12 = 2.443(3) Å). In fact this distance is one of the shortest $Cu–O_{(ClO4)}$ distances found so far in Cu(II) methoxo-bridged dinuclear compounds, as related distances found in literature vary from 2.675 to >3.6 Å [31,39–43]. In the isomeric compound $[Cu(ampym)_2(\mu\text{-}CH_3O)]_2(ClO_4)_2$ [31] all $Cu–O_{(ClO4)}$ distances are >3.3 Å. The angles of the nearly square basal plane are deviating between 8° and 11° from planarity, while the Cu–O–Cu angle is 102.21(12)° and the Cu–Cu distance 3.0143(8) Å. In the isomeric compound without coordinating perchlorate anions [31], these angles and distances are 100.0(1)° and 2.951(1) Å, respectively. The distances and angles for the title compound are consistent with other Cu(II) dinuclear methoxo-bridged compounds in the literature [31,39–43].

The crystal lattice is stabilized by a H-bonding system (Watson–Crick type) between the amino nitrogen N17 and the uncoordinated pyrimidine nitrogen atom N13 of a neighbouring ampym ligand (N13···N17 3.061(4) Å). A similar H-bonding pattern was reported earlier for compounds containing ampym as a ligand [31,44,45]. Furthermore some intramolecular H-bonds occur, and more details are given in Table 2.

Another distinct difference between the title compound and the isomeric compound published recently by Zhu et al. [31] is the fact that the two ampym ligands are in *cis* position for the title compound, but in a *trans* position for the compound made by Zhu et al. [31] (Fig. 2). This ligand conformational difference might be responsible for the fact that the perchlorate anion is semi-coordinating in the title compound and non-coordinating in the isomeric compound of Zhu et al. [31], thereby explaining also why both isomers cannot be converted into one another without decomposition.

3.2. Spectroscopy

The ligand-field transition band measured as a solid with the diffuse reflectance technique is found at 17.1×10^3 cm^{-1}, which is a normal ligand field transition for a CuN_2O_2 or a $CuN_2O_2(O)_x$ chromophore

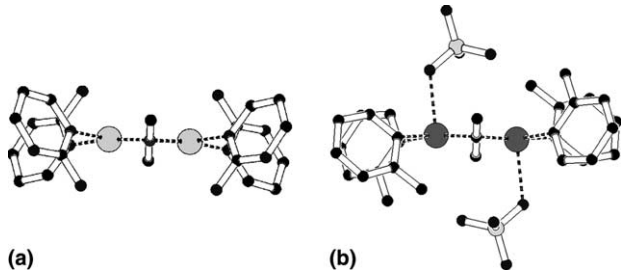

Fig. 2. Figure showing *cis*/*trans* positions of the ligands of (a) $[Cu(ampym)_2(\mu\text{-}CH_3O)]_2(ClO_4)_2$ [31] and (b) $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$.

[41,42,46]. In addition, a second strong and sharp band is found at 26.0×10^3 cm^{-1}, which is known to be characteristic for dinuclear copper(II) compounds, with a square planar $Cu_2O_2N_4$ chromophore and has been assigned to an $(O) \rightarrow (Cu)$ charge-transfer band [41,42,47,48].

In the IR spectra of the title compound, one strong and one somewhat weaker bands are present at 3347 and 3449 cm^{-1}, which can be attributed to OH and NH stretching vibrations. The vibrations of the perchlorate anion were observed as two strong broad bands around 1117 and 1043 cm^{-1}, in agreement with semi-coordination.

In the far-IR region (500–100 cm^{-1}) in general the Cu–N and Cu–O vibrations are observed [49,50]. In an earlier study of methoxo-bridged Cu(II) compounds with the ligand bis(2-benzimidazolyl)propane [41], the Cu–N vibrations were observed at 439–441, 351–357 and 290–285 cm^{-1}. The Cu–O vibrations were found at 390 and 229–231 cm^{-1} [41]. The title compound has promiment bands at 443, 353, 265 and 240 cm^{-1}. Also a sharp, less prominent band is observed at 429 cm^{-1}, but as the free ampym ligand also has an absorption at 405 cm^{-1}, that band may originate from the ligand. So we can assign the Cu–N vibrations for the title compound at 443 and 265 cm^{-1} and the Cu–O at 353 and 240 cm^{-1}. Almost the same observation has been made for the compound $[Cu(ampym)_2(\mu\text{-}CH_3O)(CF_3SO_3)]_2$ for which the same bands are observed at 446, 271 cm^{-1} and 356, 223 cm^{-1} [51]. More evidence comes from the mononuclear compound $Cu(ampym)(NO_3)_2$ in which the Cu–N vibrations are found at 439, 284 cm^{-1}, while the Cu–O vibrations are shifted to 334, 217 cm^{-1} [29].

3.3. Magnetic properties

The EPR of the title compound, measured as a polycrystalline powder at RT, is EPR silent, while at 77 K a weak signal is observed with a $g_\perp = 2.06$, $g_\parallel = 2.32$ and $A_\parallel = 16.1$ mT. The absence of an EPR signal indicates already a very strong AF interaction (vide infra), while the weak signal at 77 K most probably originate from a small mononuclear impurity, which is usually present in dinuclear compounds. Absence of EPR signals is also known for other Cu(II) dinuclear methoxo-bridged compounds [40–42].

The magnetic susceptibility of a powdered sample was measured from 5 to 300 K. The magnetic properties of the complex are depicted in Fig. 3 in the form of μ_{eff} versus T for two Cu(II) ions. At 300 K, the μ_{eff} starts at a value of about 1.16 BM (much below the spin only value for two Cu ions of 2.83 BM) and the μ_{eff} decreases at 300 K to about 0.10 BM. This behaviour indicates a very strong antiferromagnetic interaction.

The theoretical expression for the magnetic susceptibility for two interacting $S = 1/2$ centres, which is based on the general Hamiltonian [52] is: $H_{ex} = -JS_1S_2$, in which the exchange parameter J is negative for antiferromagnetic and positive for ferromagnetic interaction.

The magnetic data were fitted to the equation given in the literature for dinuclear copper compounds [52]:

$$X_m = (2Ng^2\beta^2)[kT - 2zJ'/(3 + \exp(-J/kT))]^{-1} \times [3 + \exp(-J/kT)]^{-1}(1 - p) + X_p p,$$

in which N, g, β, k and T have their usual meanings. The parameter p denotes the fraction of paramagnetic impurity in the sample and zJ' the interaction between neighbouring dinuclear identities. The fit was accomplished by minimization of

$$R = \sum (X_m \cdot T_{calc} - X_m \cdot T_{obs})^2/(X_m \cdot T_{obs})^2$$

by a least-squares procedure. The best fit was obtained for $J = -621$ cm^{-1}, $g = 1.95$, $zJ' = -0.02$ cm^{-1}, $p = 0.005$, with a final R of 7×10^{-2} (see Fig. 3).

With the isomeric methoxo-bridged compound $[Cu(ampym)_2(\mu\text{-}CH_3O)]_2(ClO_4)_2$ [31], a similar magnetic behaviour was observed, but with a much less strong AF interaction of $J = -275$ cm^{-1}, which can be understood from the different Cu–Cu distances and Cu–O–Cu angles

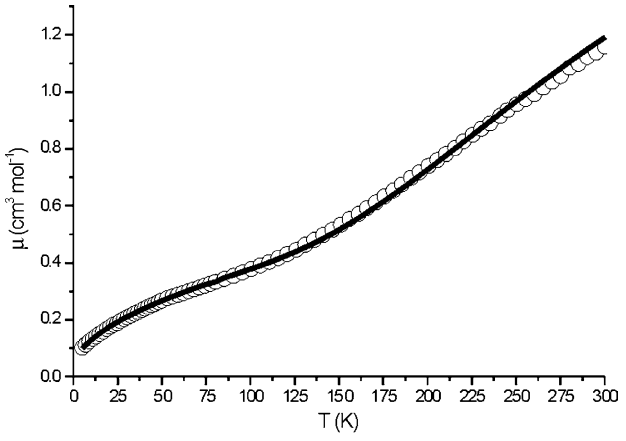

Fig. 3. A plot of the temperature dependence of μ_{eff} vs. T for $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$. The solid line represents the calculated curve for the parameters $J = -621$ cm^{-1}, $g = 1.95$, $zJ' = -0.02$ cm^{-1} (see text).

of both compounds (3.0143(8) Å, 102.21(12)° and 2.951(1) Å, 100.0(1)°, for the title compound and the isomeric compound [31], respectively).

4. Concluding remarks

A methoxo-bridged Cu(II) compound with the ligand 2-aminopyrimidine is reported in this study and is compared with a differently prepared isomeric compound, recently published [31]. The difference in the properties originates from the fact that in the first compound, $[Cu(ampym)_2(\mu\text{-}CH_3O)(ClO_4)]_2$ (**1**), which is synthesized by a straightforward procedure, the perchlorate anions are coordinated to the Cu atom. In the isomeric compound, $[Cu(2\text{-aminopyridine})_2(\mu\text{-}CH_3O)]_2(ClO_4)_2$ (**2**), synthesized with adding terephthalaldehyde [31] to the system, the perchlorate anions are not coordinated to the Cu atom. As shown in this study this difference has a significant influence in the geometry of the compound (*cis*/*trans* orientations of the ligands), as well in the strength of the antiferromagnetic interaction between the Cu atoms, which is $J = -621$ and -275 cm^{-1}, for **1** and **2**, respectively. It appeared impossible to convert our compound into the isomeric species by heating, cooling, or recrystallization. Apparently the presence of terephthalaldehyde in [31] must have some kind of template effect. So we clearly deal with a case of distortion isomerism for two compounds of identical composition and quite similar structures. Only a few related cases are known in the literature [53–55] and usually also involve Cu(II).

5. Supplementary material

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC220300. Copies of available material can be obtained, free of charge, on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44(0)1223336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Synthesis and characterization of coordination polymers of Zn(II) with 1,3-bis(4-pyridyl)propane and 4,4′-pyridine ligands

Ting-Wai Lee, Jasmine Po-Kwan Lau, Wing-Tak Wong *

Department of Chemistry, The University of Hong Kong, Pokfulam Road, Hong Kong, PR China

Received 4 September 2003; accepted 15 December 2003

Abstract

Two new metal-coordination polymers, $[Zn_2(bpy)(OAc)_4]_n$ (**1**) and $[Zn(bpp)(NO_3)_2]_n$ (**2**) were prepared by the layering method using Zn(II) ions, bpy and bpp ligands, and structurally characterized by single-crystal X-ray diffraction analyses. Complexes **1** and **2** were both found to be one-dimensional coordination polymers. The periodic length of the chain between two alternate Zn(II) ions in compound **1** is 26.92 Å which is more than twice the length of compound **2** ($26.92 > 11.92 \times 2$).

Keywords: Zinc; 1,3-Bis(4-pyridyl)propane; 4,4′-Pyridine; Polymeric network; X-ray crystallography

1. Introduction

The metal–organic coordination polymers [1–4] of bpy [4,4′-pyridine] [5–7] and bpp [1,3-bis(4-pyridyl)propane] ligands [8–10] have attracted continuous attention in recent years. A subtle change in the use of conformationally flexible ligands as spacers in the design and construction of coordination polymers may lead to new polymeric networks. The bpy and bpp ligands have been shown to be versatile, and may coordinate to metal ions as spacers through the N atoms. The coordination versatility, together with the coordination requirements of specific metal ions, allows the construction of novel new structures. The chemistry of the new coordination polymers is of considerable interest for potential application in optoelectronic [11], magnetic [12] and microporous materials [13]. In earlier efforts, we have used the bpp [1,3-bis(4-pyridyl)propane] ligand with nickel and manganese ions to form three new metal–organic coordination polymers, $\{[Ni(bpp)_2](ClO_4)_2 \cdot 2H_2O \cdot 2CHCl_3\}_n$, $[Mn(bpp)_2Cl_2 \cdot 2CHCl_3]_n$ and $\{[Mn(bpp)_2(H_2O)_2](ClO_4)_2 \cdot bpp \cdot H_2O\}_n$ [14]. As a continuation of our work, we herein report the synthesis and solid structure of two new compounds, namely $[Zn_2(bpy)(OAc)_4]_n$ (**1**), and $[Zn(bpp)(NO_3)_2]_n$ (**2**) using zinc(II) ions, bpy and bpp ligands.

2. Experimental

2.1. General procedures

All materials were used as received from commercial sources (Sigma–Aldrich, Lancaster, ARCOS or STREM). Elemental analysis for C, H and N of compounds **1** and **2** were carried out on their crystal samples by the Department of Biology and Chemistry at the City University of Hong Kong. Their IR spectra were recorded in the wave number range 4000–400 cm^{-1} on a BIO-RAD FTS-135 Spectrometer that was calibrated with a thin film of polystyrene.

2.2. Preparation of $[Zn_2(bpy)(OAc)_4]_n$ (1)

Crystals of compound **1**, of considerable size (ca. 0.2 mm), formed in 5 days at room temperature upon the slow evaporation of a solution of $Zn(OAc)_2$ (1.010 g, 5.505 mmol; FW: 183.48) and bpy (0.106 g, 0.679 mmol; MW: 156.19) in methanol (5 ml). *Anal.* Calc. for $Zn_2C_{18}H_{20}N_2O_8$: C, 41.33; H, 3.85; N, 5.35. Found: C,

41.75; H, 4.19; N, 5.39%. IR (KBr) ν/cm^{-1}: 3073m, 3046m, 2923m, 2857m, 1613vs, 1491m, 1419s, 1396s, 1338m, 1218w, 1073m, 1047w, 1016m, 813m, 727w, 679w, 643m, 619w, 490w.

2.3. Preparation of $[Zn(bpp)(NO_3)_2]_n$ (2)

A solution of $Zn(NO_3)_2 \cdot 6H_2O$ (1.005 g, 3.378 mmol; FW: 297.49) in acetone (3 mL) was layered on a solution of bpp (0.100 g, 0.504 mmol; MW: 198.27) in chloroform (3 mL). Crystals of compound **2**, of considerable size (ca. 0.5 mm), formed at the interface in 5 weeks at room temperature. *Anal.* Calc. for $ZnC_{13}H_{14}N_4O_6$: C, 40.28; N, 14.45, O, 24.76. Found: C, 40.25; N, 14.20; O, 24.55%. IR (KBr) ν/cm^{-1}: 3062m, 3048m, 2952m, 2938m, 2859m, 1654m, 1624s, 1561m, 1491s, 1434s, 1388s, 1292s, 1229m, 1069m, 1033s, 1014s, 856m, 823m, 760w, 620m, 581w, 529m, 518m.

2.4. X-ray crystallography

All pertinent crystallographic data and other experimental details are summarized in Table 1. Crystals suitable for X-ray analyses were glued on glass fibres with epoxy resin or sealed in 0.3 mm glass capillaries. Intensity data were collected at ambient temperature on a Bruker AXS SMART CCD diffractometer that was equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). All structures were solved by direct methods (SIR 92) [15] and expanded by Fourier-difference technique (DIRDIF 94) [16]. Non-hydrogen atoms were refined anisotropically for all compounds. Hydrogen atoms were generated in their ideal positions and included in the structure factor calculations, but not refined. Calculations were performed on a Silicon Graphics computer using the teXsan [17] crystallographic software package. Tables 2 and 3 list the selected bond lengths and angles.

3. Results and discussion

3.1. Crystal structure of $[Zn_2(bpy)(OAc)_4]_n$ (1)

The molecular structure and selected bond parameters of complex **1** are shown in Fig. 1 and Table 2, respectively. Complex **1** is an infinite one-dimensional coordination polymer in which bpy (spacers) are connected to each other by $Zn(OAc)_2$ dimeric units (nodes), thus forming a zig-zag chain. In each $Zn(OAc)_2$ dimeric unit, two Zn(II) ions are bridged by the carboxylate groups of the two OAc^- ions that are centered at C(7) and C(7*), and O(4) atom of the OAc^- ion centered at C(11). The O(5) atom of the OAc^- ion that is centered

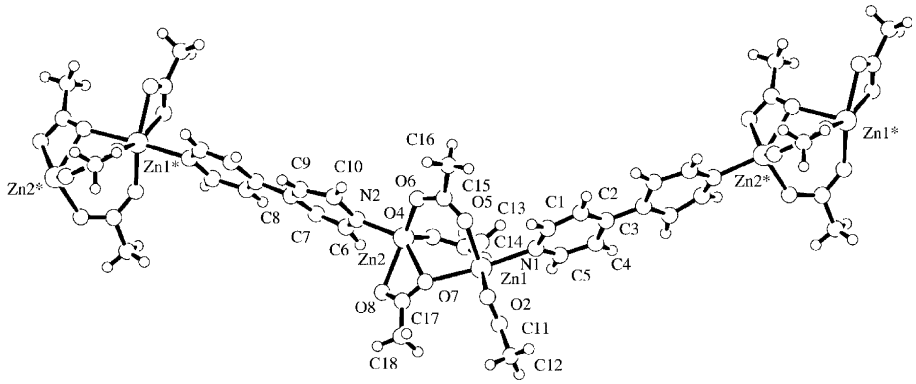

Fig. 1. The molecular structure of $[Zn_2(bpy)(OAc)_4]_n$ (**1**) with the atom numbering scheme.

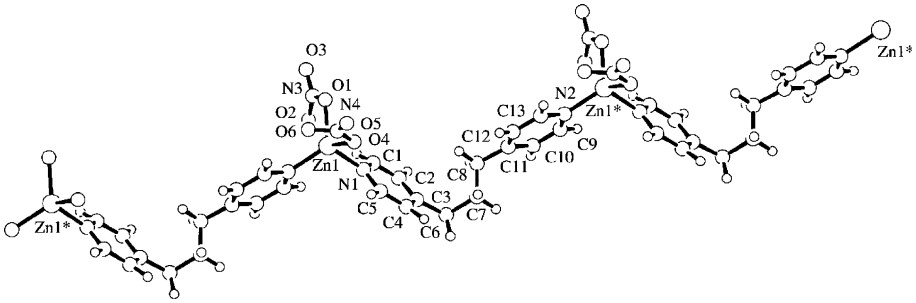

Fig. 2. The molecular structure of $[Zn(bpp)(NO_3)_2]_n$ (**2**) with the atom numbering scheme.

at C(11) coordinates with the Zn(II)(2) ion and exhibits static disorder (not shown for clarity). Consequently, including coordination by bpy, the Zn(II)(1) ion is octahedrally coordinated and the Zn(II)(2) ion is trigonal-pyrimidally coordinated. The periodic length of the chain between two alternate Zn(II)(1) ions is 26.92 Å. The distance between two Zn(II) ions in the $Zn(OAc)_2$ dimeric unit is 3.33 Å. Adjacent polymer chains $[Zn_2(bpy)(OAc)_4]_n$ in the unit cell propagate in two stacks along the *a*-axis and pack along the *b*-axis. Despite the stacking structure, 3% of the crystal volume is available for occupying guest molecules. This network is closely related to another Zn(II)-containing zig-zag chain, $[Zn(pyrazine)Br_2]_n$ [18]. The periodic length of compound **1** is longer than that of $[Zn(pyrazine)Br_2]_n$, due to the use of longer spacers (bpy), and the extension of the zig-zag chain by $Zn(OAc)_2$ dimeric units in **1**.

3.2. Crystal structure of $[Zn(bpp)(NO_3)_2]_n$ (2)

The coordination geometry in compound **2** is shown in Fig. 2. The molecular structure is a one-dimensional coordination polymer in which the ligand 1,3-bis(4-pyridyl)propane, bpp, (spacers) are connected to each other by $Zn(NO_3)_2$ units (nodes). The Zn(II) ion is tetrahedrally coordinated by two $NO_3^{2-}$and two bpp ligands. Each bpp is required by the coordination geometry of the Zn(II) ion to head downward but twist in its trimethylene group. This mode of coordination gives a sinusoidal chain (period 11.92 Å), with the ligand in a TT conformation. The periodic length of compound **1** is more than twice the length of compound **2** ($26.92 > 11.92 \times 2$), even though bpy is shorter than bpp by the length of a trimethylene group. The twisting of the bpp ligand in compound **2** shortens the distance between the two pyridyl N atoms, and the $Zn(OAc)_2$ dimeric units extend the chain in compound **1**. Despite having a conformationally flexible bpp ligand as its spacer, compound **2** is not a helical chain. The type of conformation is also observed in reported systems such as $\{[Ag(bpp)](NO_3)\}_n$ [19], which is a one-dimensional coordination polymer with a Ag(I) ion as the node and bpp as the spacer. This is also not a helical chain, but a sinusoidal chain. Compound **2** propagates in three chains long the *c*-axis and packs long the *a*-axis. Adjacent chains to the *b*-axis have a translational relationship of $c/2$ along the *c*-axis. No significant void volume was found for this compound.

4. Supplementary data

The crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (CCDC) as supplementary publication no. CCDC 211891–CCDC 211892. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (+44) 1223

336-033; deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Four mixed-ligand complexes, $\{Na_2[Cd_2(Htma)_2(ox)(H_2O)_2]\}_n$(**1**) (tma = trimesate, ox = oxalate), $\{[Cd_2(2,2'\text{-bipyridine})_2(ox)_2]\cdot 2H_2O\}_n$ (**2**), $\{Cd_3(4,4'\text{-trimethylenedipyridine})_3(ox)_3\}_n$ (**3**), and $\{Na_2[Cd_4(isonicotinate)_4(ox)_3]\}_n$ (**4**) were synthesized by hydrothermal reactions. The structures of **1**, **2**, **3** and **4** consist of 1D ladder-like chains, 1D zigzag chains, a 2D square network and a 3D framework, respectively, featuring dinuclear (for **1** and **2**), trinuclear (for **3**) and tetranuclear (for **4**) units. The TGA experiments showed that these four complexes were quite thermally stable.

1. Introduction

In recent years, much interest has been focused on the design and synthesis of supramolecular compounds, for their interesting structure motifs and potential applications in ion exchange, porous materials and molecular adsorbents [1–3]. In the process of fabricating these kinds of complexes, some organic N-donors such as bipyridine and related species [4,5] are often chosen as rigid 'tectons' to bind the metal centers. Other approaches to obtain analogous coordination polymers include the reaction of metal ions with multifunctional ligands containing O-donors or mixed N/O-donors such as oxalate, trimesate, isonicotinate ligands and poly-aromatic acids [6–8].

The oxalate ion has been known to function as a bis-bidentate ligand, and its coordination to transition metal ions has been widely researched due to its remarkable ability to mediate strong magnetic interactions between the metal centers [9–12]. By employing different templating cations, a good many infinite 2D and 3D magnetic polymers with the formula $[M^{II}M^{III}(ox)_3]_n^{n-}$ (M^{II} = V, Cr, Mn, Fe, Co, Ni, Cu, Zn; M^{III} = V, Cr, Fe) were synthesized in the last decade [13–15].

Polynuclear cadmium compounds [16,17] have been studied for their novel open-framework structure motifs with channels [18,19]. In this paper, we report four infinite 1D, 2D and 3D mixed-ligand cadmium polymers (**1**–**4**) with oxalate and aromatic co-ligands prepared by hydrothermal synthesis, which exhibit high thermal stabilities.

2. Experimental

All syntheses were performed in poly(tetrafluoroethylene)-lined stainless steel autoclaves under autogenous pressure. Chemicals were commercially purchased and used as received. Elemental analyses were carried out by the Elemental Analysis Laboratory of our Institute, and TGA (thermal gravimetric analysis) was performed under nitrogen at a heating rate of 10 °C min^{-1} using a

TA5200/MDSC2910 system by the Thermal Analysis Laboratory of Huaqiao University. Infrared spectra (KBr pellets) were recorded in the range from 4000 to 400 cm^{-1} on a Nicolet Magna 750 FTIR spectrometer.

2.1. Syntheses, elemental analyses and IR spectra

2.1.1. $\{Na_2[Cd_2(Htma)_2(ox)(H_2O)_2]\}_n$ (1)

Complex **1** was synthesized hydrothermally from the reaction of $Cd(NO_3)_2 \cdot 4H_2O$ (1.0 mmol), H_3 (tma) (1.0 mmol), $Na_2C_2O_4$ (1.0 mmol) and H_2O (10 ml) at 120 °C for two days, and then the reactant was cooled at a rate of 0.3 °C min^{-1} to give a 31% yield of **1** based on Cd as colorless crystals, which were collected by mechanical isolation and washed with water and absolute alcohol. *Anal.* Calc. (Found): C, 29.62 (29.76); O, 35.51 (35.22); H, 1.49 (1.35)%. IR (KBr, cm^{-1}): 3338 (w), 3089 (w), 2066 (w), 1700 (s), 1618 (s), 1579 (s), 1532 (s), 1435 (s), 1385(s), 1322 (m), 1233(m), 1186 (s), 1112 (m), 801 (m), 735 (s), 680 (s), 536 (m).

2.1.2. $\{[Cd_2(2,2'\text{-bipyridine})_2(ox)_2]\cdot 2H_2O\}_n$ (2)

Compound **2** was synthesized and purified by the method like **1**, except that the reactants were $Cd(NO_3)_2 \cdot 4H_2O$ (1.0 mmol), 2,2′-bipyridine (1.0 mmol), $Na_2C_2O_4$ (1.0 mmol) and H_2O (10 ml). The experiment gave colorless crystals with about 37% yield based on Cd. *Anal.* Calc. (Found): C, 38.47 (38.72); O, 21.35 (21.68); H, 2.69 (2.55); N, 7.47 (7.21)%. IR (KBr, cm^{-1}): 3377 (w), 3097 (w), 3066 (w), 1649 (m), 1600 (s), 1579 (s), 1474 (m), 1435 (s), 1311 (s), 1240 (m), 1166 (m), 1011 (m), 770 (s), 735 (m), 649 (m), 621 (m), 528 (m).

2.1.3. $\{Cd_3(4,4'\text{-trimethylenedipyridine})_3(ox)_3\}_n$ (3)

The synthesis and purification of compound **3** were similar to compound **1**, and the reaction of $Cd(NO_3)_2 \cdot 4H_2O$ (1.0 mmol), 4,4′-trimethylenedipyridine (1.0 mmol), $Na_2C_2O_4$ (1.0 mmol) and H_2O (10 ml) gave a 23% yield of **3** based on Cd as yellow crystals. *Anal.* Calc. (Found): C, 45.19 (45.34); O, 16.05 (16.41); H, 3.51 (3.47); N 7.02 (6.85)%. IR (KBr, cm^{-1}): 3455 (w), 3050 (w), 2926 (w), 2860 (w), 1634 (s), 1603 (s), 1556 (m), 1501 (w), 1427 (s), 1303 (s), 1221 (m), 1073 (m), 1014 (m), 793 (s), 582 (w), 501 (m).

2.1.4. $\{Na_2[Cd_4(isonicotinate)_4(ox)_3]\}_n$ (4)

Compound **4** was synthesized by the hydrothermal reaction of $Cd(NO_3)_2 \cdot 4H_2O$ (1.0 mmol), isonicotinic acid (1.0 mmol), $Na_2C_2O_4$ (1.0 mmol) and H_2O (10 ml) to give a 45% yield of **4** based on Cd as colorless crystals. *Anal.* Calc. (Found): C, 28.87 (29.03); O, 25.64 (25.71); H, 1.29 (1.02); N 4.49 (4.33)%. IR (KBr, cm^{-1}): 3451 (w), 3058 (w), 1645 (s), 1614 (s), 1595 (s), 1552 (m), 1420 (s), 1385 (s), 1322 (s), 1217 (m), 1073 (m), 1014 (m), 870 (m), 790 (s), 700 (s), 516 (m).

2.2. The TGA data

Thermogravimetric analysis (TGA) was performed on polycrystalline samples under N_2. The aqua ligands in **1** and co-crystallized water in **2** began to dissociate when the temperature reached ca. 150 and 80 °C, respectively. There was no obvious weight loss until the temperature was increased to 410, 320, 305 and 420 °C for **1**, **2**, **3** and **4**, correspondingly, which showed fairly high thermal stabilities, especially for **1** and **4**.

2.3. Crystal structure determination

Intensity data for the four complexes were collected at 293(2) K on a Siemens Smart CCD diffractometer with Mo Kα radiation ($\lambda = 0.71073$ Å). The structures

were solved by direct methods using SHELXS-97 [20] and refined by full-matrix least-squares methods using SHELXL-97 [21]. Anisotropic displacement parameters were used for all non-hydrogen atoms. No attempt was made to locate the hydrogen atoms of water, and the other hydrogen atoms were added in the riding model but not refined. The crystallographic data are summarized in Table 1, and the selected bond lengths and bond angles of the four compounds are listed in Table 2.

3. Results and discussion

3.1. Syntheses

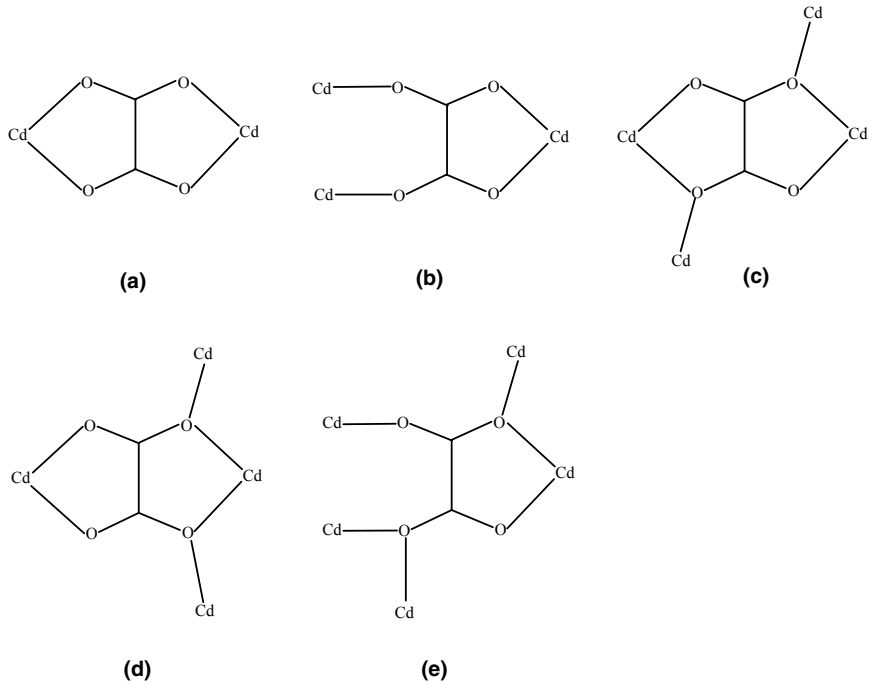
In this paper, four cadmium oxalate polymers with aromatic ligands have been synthesized by hydrothermal reactions. We have made a probe on the reaction of cadmium (II) with mere oxalate ligand under the same conditions. When the molar proportion of ligand versus metal was about 1:1, we got a colorless crystal $\{Cd_2(ox)_2(H_2O)_4\}_n \cdot 2nH_2O$ (**5**) with a 2D layered structure, which has been reported by Orioli et al. [22]. The coordination geometry about each cadmium atom in this complex was approximately that of a pentagonal bipyramid with two coordinated water molecules in the apical and equatorial positions. So it was natural to see whether the two coordinated sites of water could be replaced by other co-ligands such as aromatic ligands and what changes on the structure would take place if these co-ligands were introduced. We tried lots of aromatic ligands and found the following four aromatic ligands H_3 tam, 2,2′-bipyridine, 4,4′-trimethylenedipyridine and isonicotinic acid would coordinate to cadmium with oxalate and form mixed-ligand polymers. Due to the different coordination conformations and abilities of these aromatic ligands with cadmium, the structures showed abundant variation, not only on motifs of the frameworks, but also on coordination modes of cadmium ions with oxalate ligands. Only in **4** did the structure of cadmium with oxalate ligands still exhibit a layer motif. While for **2** and **3** with pyridine co-ligands introduced, they changed to chain structures. In complex **1**, the oxalate only acted as a bridging ligand to bind two metal centers, and the linkages among these binuclear units were accomplished by the Htma ligands.

According to the literatures to date, there are five coordination modes of the oxalate ligand when coordinated to cadmium(II) ions, as shown in Scheme 1. Through one or two combined modes, various architectures have been observed [16,17]. For the polymers reported in this paper, the main coordination modes include (a), (c) and (d), and mode (d) is a new one as far as we know.

These four complexes are very stable in air, insoluble in the usual polar or non-polar solvents such as acetone, chloroform, benzene, H_2O, methanol, CH_3CN, DMF, etc.

3.2. Infrared spectra

All complexes showed the characteristic bands of aromatic and carboxylate ligands. The stretching vibration



Scheme 1. Coordination modes of oxalate to cadmium ions: (a) chelate bis-bidentate; (b) chelate bis-bidentate and bidentate; (c) chelate/bridging bis-bidentate; (d) chelate/bridging bis-bidentate and chelate bis-bidentate; (e) chelate/bridging bis-bidentate and chelate/bridging bidentate.

bands of Ar–H were at 3089 cm^{-1} for **1**, 3097 cm^{-1} for **2**, 3050 cm^{-1} for **3** and 3058 cm^{-1} for **4**. The C–H stretching vibration bands for methylene in **3** were at 2926 and 2860 cm^{-1}. The δ_{Ar-H} (out-of-plane bending vibration) bands appeared at 680, 735 and 801 cm^{-1} for **1**, 735 and 770 cm^{-1} for **2**, 793 cm^{-1} for **3**, 700 and 790 cm^{-1} for **4**. The C=C or C=N stretching vibrations for these four complexes all gave absorption bands from 1474 to 1600 cm^{-1} in the corresponding spectra. The asymmetric and symmetric C=O stretching vibration bands of oxalate groups emerged at 1649, 1435 cm^{-1} for **2** and 1634, 1427 cm^{-1} for **3**, suggesting the chelate bis-bidentate coordination mode of the oxalate ligands. While in **1** and **4**, due to C=O vibrations of the aromatic carboxylate groups, the absorption peaks around these bands split and made the spectra become more complicated. The peak appearing at 1700 cm^{-1} in complex **1** might be assigned to the C=O stretching vibration for the uncoordinated carboxylate group of Htma.

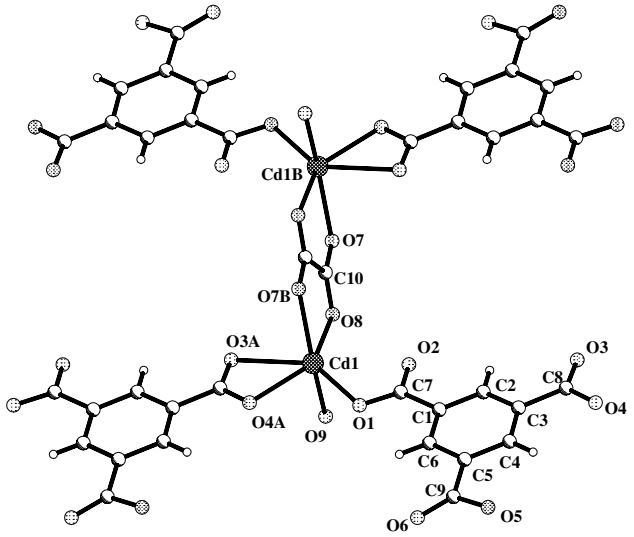


Fig. 1. Perspective view of the coordination environments of Cd1 with atomic labels in **1**.

3.3. Crystal structures

3.3.1. Crystal structure of $\{Na_2[Cd_2(Htma)_2(ox)(H_2O)_2]\}_n$ (1)

Compound **1** exhibits a 1D infinite chain structure motif, in which each cadmium atom has an O_6 distorted octahedral configuration formed by an aqua ligand (Cd1–O9 = 2.424(8) Å), two oxygen atoms from oxalate ions and three oxygen atoms provided by Htma ligands, as shown in Fig. 1. For the oxalate ligand, there is only one kind of coordination fashion (Scheme 1(a)), through which two cadmium atoms are bridged to each other with Cd1–O7B = 2.286(8) Å and Cd1–O8 = 2.317(8) Å. Of the three carboxylate groups in the Htma ligand, there are only two bonding modes; one is unidentate (Cd1–O1 = 2.189(7) Å) and the other is chelating bis-bidentate (Cd1–O3A = 2.621(9) Å and Cd1–O4A = 2.241(8) Å). In this coordination fashion, a centrosymmetric bi-nuclear $[Cd_2(Htma)_2(ox)(H_2O)_2]$ unit is

formed and the connectivity of these units through Htma ligands results in an interesting 1D "ladder-like" linear chain (Fig. 2), which has not been reported previously among related oxalate coordination polymers.

3.3.2. Crystal structure of $\{[Cd_2(2,2'\text{-bipyridine})_2(ox)_2]\cdot 2H_2O\}_n$ (2)

The structure motif of compound **2** is also a 1D infinite chain, yet each octahedron around the cadmium atom is composed of four oxygen atoms from oxalate ions and two nitrogen atoms from 2,2′-bipyridine, as shown in Fig. 3. The two nitrogen atoms are bonded to a cadmium atom to form a five-membered chelating ring ($\angle$N1–Cd1–N2 = 72.0(3)°), which restrains the spacial extension of the cadmium oxalate unit in compound **2**. Thus centrosymmetric di-nuclear $[Cd_2(C_{10}H_8N_2)_2(ox)_2]$ units are constructed, which are interlinked to each other through oxalate ligands, as shown in Fig. 4, to form a 1D zigzag chain. A similar chain has been reported in the structure of $\{Cu(C_{10}H_8N_2)(C_2O_4)\cdot 2H_2O\}_n$ [23].

3.3.3. Crystal structure of $\{Cd_3(4,4'\text{-trimethylenedipyridine})_3(ox)_3\}_n$ (3)

Fig. 5 shows the coordination environment of Cd1 and Cd2 in compound **3**. Each cadmium atom lies inside a distorted octahedron composed of four oxygen atoms from oxalate ions and two nitrogen atoms provided by different 4,4′-trimethylenedipyridine ligands. In the octahedron cage containing Cd1, two nitrogen atoms are adjacent to each other ($\angle$N3–Cd1–N2 = 90.6(3)°), while in the one containing Cd2, the two nitrogen atoms occupy two polar sites. The bonding distances of N2–Cd1, N3–Cd1 and N1–Cd2 are almost equal to each other (2.335(8), 2.319(8) and 2.328(8) Å). The trimethylene units ($-CH_2-CH_2-CH_2-$) in the 4,4′-trimethylenedipyridine ligands are disordered, as shown in Fig. 5 (C18 and C19, C38 and C38C).

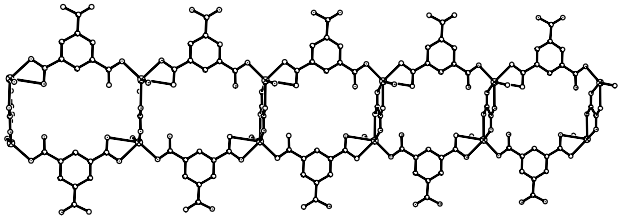

Fig. 2. The "ladder-like" 1D chain structure of **1** featuring dinuclear units.

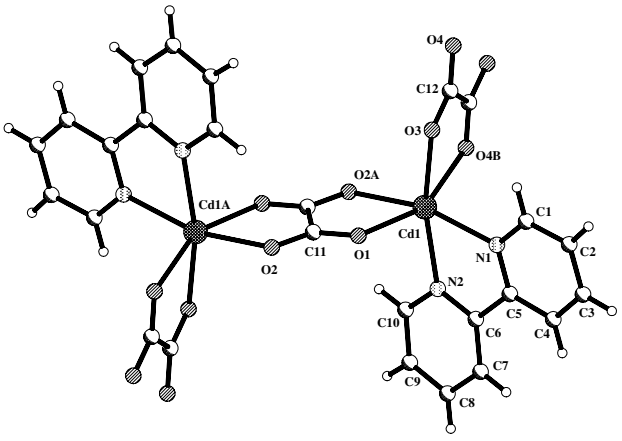

Fig. 3. Perspective view of the coordination environments of Cd1 with atomic labels in **2**.

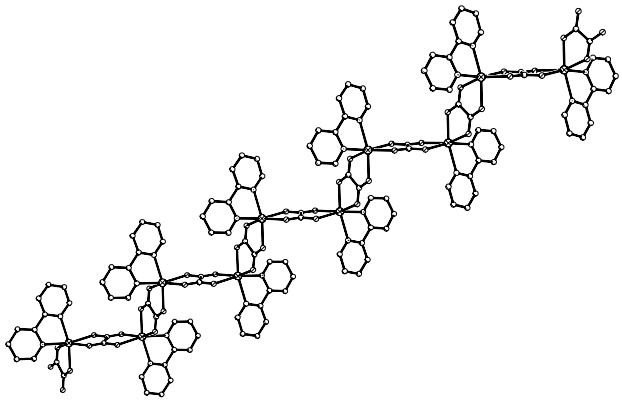

Fig. 4. The 1D zigzag chain structure of **2** viewed along the *c*-axis, featuring dinuclear units.

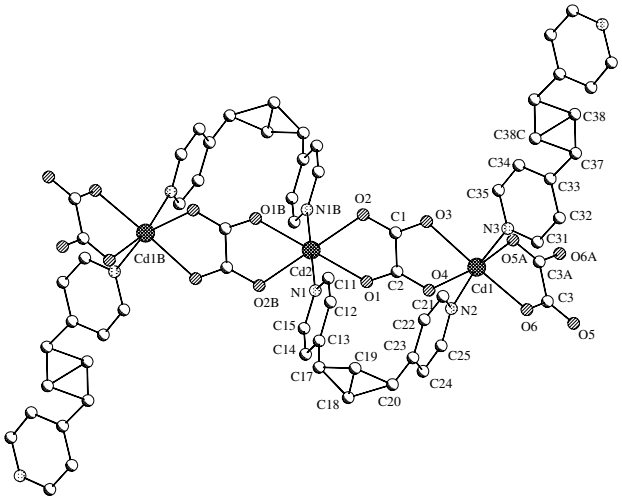

Fig. 5. Perspective view of the coordination environment of Cd atoms with atomic labels in **3**. Noting the trimethylene units ($-CH_2-CH_2-CH_2-$) in 4,4′-trimethylenedipyridine are disordered (C18 and C19, C38 and C38C (symmetry: $-x, -y, 1-z$)).

It has been reported that 1,2-bis(4-pyridyl)ethane can act as a "spacer" in cobalt nitrate polymers by adopting the *gauche* (angular) or *anti* (linear) conformation [24]. It is interesting that the 4,4′-trimethylenedipyridine ligands exhibit a similar coordination mode in this complex. In each tri-nuclear $[Cd_3(C_{13}H_{14}N_2)_3(ox)_3]$ unit, there are also two centrosymmetric *gauche* spacers, exhibiting a "sine-function-like" shape. There is one chelating bis-bidentate oxalate and the remaining *anti* spacers then connect these trinuclear units to fabricate a

novel 2D eight-metal "brick-wall-like" square network with a hole size of about 8×13 Å (Fig. 6).

3.3.4. Crystal structure of $\{Na_2[Cd_4(isonicotinate)_4(ox)_3]\}_n$ (4)

Compound **4** exhibits a 3D structure motif, whose coordination environment of Cd1 and Cd2 are shown in Fig. 7. Unlike the previous three structures, the coordination number of the cadmium atom is seven in this polymer. Around each cadmium atom, the coordination environment includes six oxygen atoms and one nitrogen atom. However, the arrangement of the ligand atoms around Cd1 leads to the formation of a distorted pentagonal bipyramid, while for Cd2 it changes to a distorted mono-capped octahedron. These results are of note since the Cd atom is generally octahedrally coordinated where the coordination number is six, just as described in **1**, **2** and **3**. Furthermore, for the oxalate ligand, there are two types of coordination modes, one is chelate/bridging bis-bidentate (Scheme 1(c)), and the other is chelate/bridging bis-bidentate and chelate bis-bidentate (Scheme 1(d)). A centrosymmetric tetra-nuclear unit, $[Cd_4(ox)_3]$, can be observed from the constructed 2D cadmium oxalate layers viewed along the bc plane, which is shown in Fig. 8(a). As a rigid binding tecton, the isonicotinate ligands then play a role in sustaining these layers to form a novel 3D architecture, as shown in Fig. 8(b).

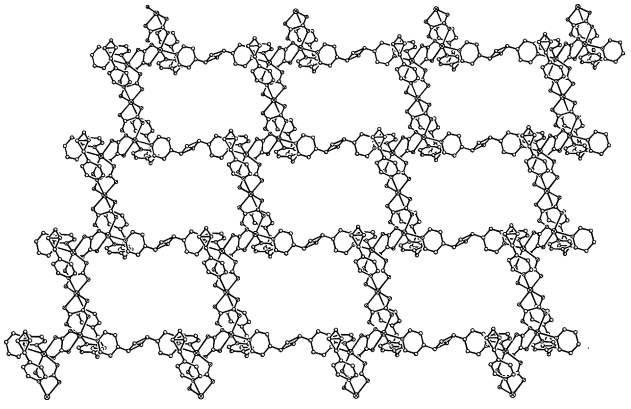

Fig. 6. The "brick-wall-like" square eight-metal network observed in **3** viewed along the *c*-axis, featuring trinuclear units.

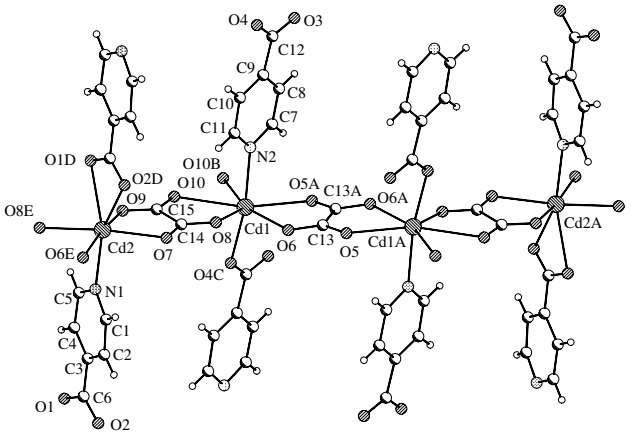

Fig. 7. Perspective view of the coordination environments of Cd atoms with atomic labels in **4**.

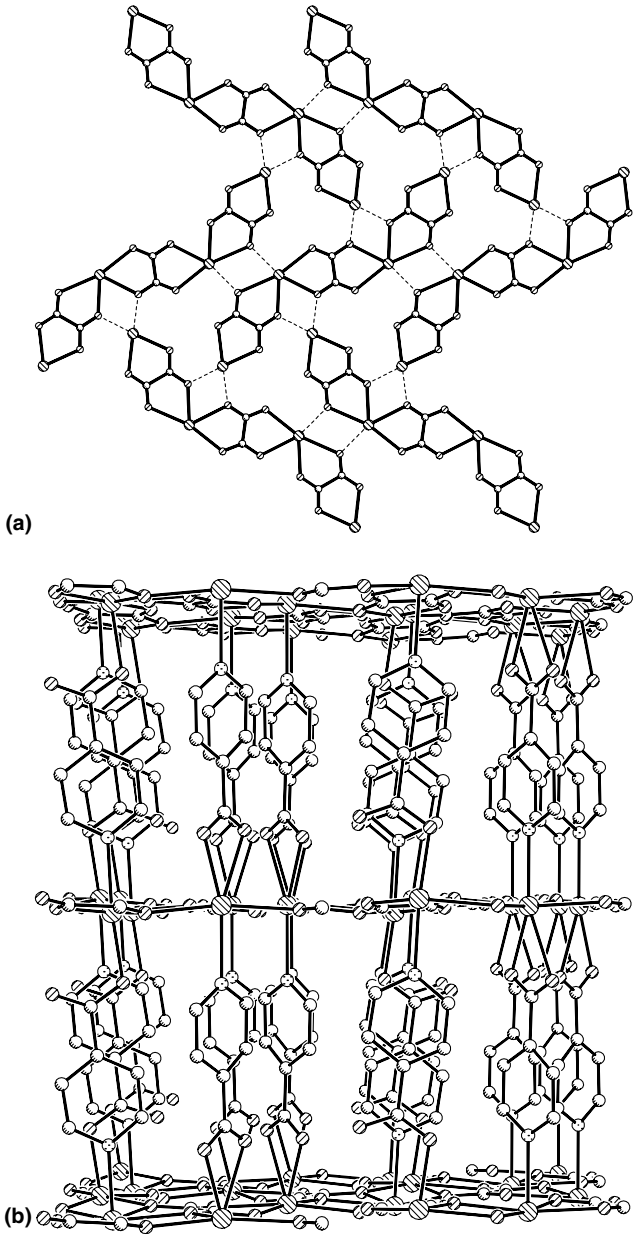

Fig. 8. (a) The layer structure of cadmium oxalate in **4** viewed along *bc* plane, featuring the tetranuclear units (the bonds among the units are shown as dash lines for clarity). (b) The 3D architecture in **4** viewed along the *c*-axis, showing the layers are sustained by the isonicotinate tectons along the *a*-axis.

4. Conclusions

The use of oxalate and different co-ligands in hydrothermal synthesis generates interesting structure

motifs in new cadmium polymers, with dimensions ranging from 1D to 3D, which feature dinuclear, trinuclear and tetranuclear units correspondingly and show relatively high thermal stabilities.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. CCDC 214532–214535 (for compound **1** to **4**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk).

Abstract

The zinc(II) complexes **1a**$ZnCl_2$ and **1b**$ZnCl_2$ (**1a**: 2-(6′,2″-bipyrid-2′-yl)-3-(2-pyridyl)pyrazine; **1b**: 2-(6′,2′-bipyrid-2′-yl)-5,6-dinitrilo-3-(2-pyridyl)pyrazine) were prepared by treatment of the ligands with $ZnCl_2$. The structures of both were investigated by X-ray crystallography and ^{1}H NMR spectroscopy. Both complexes display proton deshielding phenomena that are attributed to a twisted solution-state molecular conformation. In the solid state, **1a**$ZnCl_2$ exhibits a high degree of torsion about the axis through the uncomplexed pyridine ring and the pendant chlorine atoms. The solid-state structure and solution-state self-associative behavior of **1b**$ZnCl_2$ are indicative of a partial self-assembly motif.

Keywords: Pyrazine; Pyridine; X-ray; NMR; Stacking; Twist

1. Introduction

Recently, we described several examples of so-called pyrazine–pyridine hybrids, which self-assemble with particular metal salts to π-stacked, dimeric complexes [1–4]. In unsymmetrical ligands such as **1a**, the 2,3-disubstitution pattern of oligopyridyl chains on the pyrazine ring [5–8] is decisive in a preference for tetrahedral metals [2–4]. The angular arrangement of divergent binding sites leads to a bis-bidentate, instead of bidentate/terdentate complexation mode (Fig. 1). Such complexes also organize through homopyrazine π-stacking, affording a chiral, $\Delta\Delta/\Lambda\Lambda$-configuration, and via the solid-state π-stacking of metallo-cyclophane cations, to provide a high degree of parallel lattice ordering [4,7]. In the native ligands, twisting interactions induce a single-helical molecular conformation [7].

Metallo-organic supramolecular complexes of zinc(II) and oligopyridine-type ligands are attracting attention on account of their excellent excited-state dipolar properties, which render them relevant to applications based on non-linear optical effects [9–12]. These bulk properties can be enhanced through incorporation into highly ordered and polar lattices [12–16]. Symmetrical 2,5-dipyridylpyrazine-type ligands and their 2,6′-bipyridyl homologues self-assemble with zinc(II) salts to linear or bridged polymeric as well as macrocyclic-polymetallic structures and through which stereochemical and chiral features may be efficiently expressed [17,18]. Whereas single-enantiomer chirality is an additional means of organizing transition dipole moments, i.e., via non-centrosymmetric crystal-lattice ordering [16,19], so far equilibrating mixtures of *meso*/chiral metallo-cyclophanes containing octahedral di-zinc(II) have been reported [20,21]. Thus, we were attracted to the use of zinc(II) metallo-cyclophanes and related complexes as novel metallo-organic photonic materials. Preliminary work dictated examining the currently available 2,3-disubstituted ligands' interaction with practical zinc(II) salts, with an emphasis on coordination [22] and ligand geometry, intra/intermolecular stacking effects and long-range interactions. Since the synthesis of analogous 2,3-dicyanopyrazine ligands is possible through our previously-introduced methodology [8], and nitrile substitution increases dipolar alignment [23–26], these materials were also of interest.

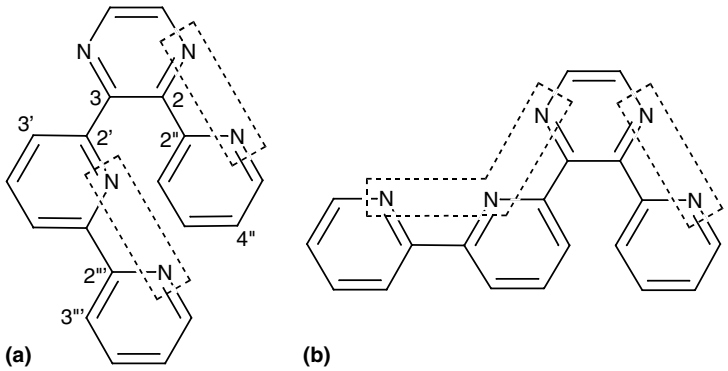

Fig. 1. Potential binding domains in ligand **1a**.

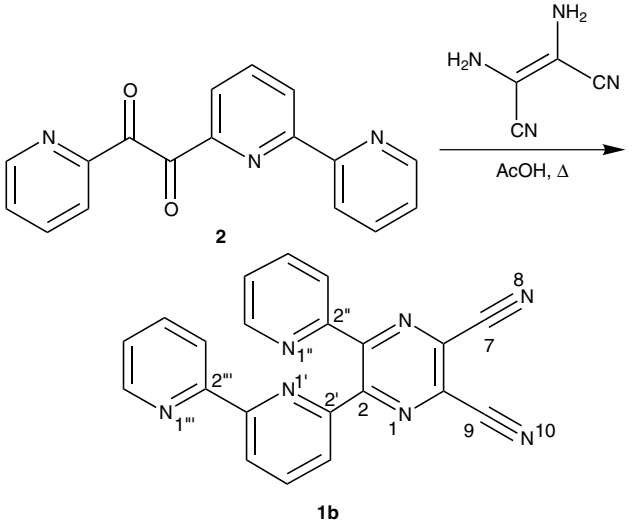
2. Results and discussion

Ligand **1a** was available from earlier studies [7]. Heating of the unsymmetrical α-diketone **2** [8] with one equivalent of diaminomaleonitrile in glacial acetic acid afforded dinitrile-substituted ligand **1b** in 67% yield after purification (Scheme 1). Treatment of **1a** and **1b** with zinc dichloride in acetonitrile or acetonitrile-chloroform under reflux conditions resulted in the precipitation of sparingly-soluble solids that could be recrystallized from hot nitromethane. The results of combustion analyses on these complexes were in agreement with a 1:1:2 stoichiometry of **1a/1b**:Zn:Cl. While the electrospray- and FAB-mass spectra of both complexes displayed m/z signals of monomeric materials, the base signal of the complex from **1b** corresponded to $[\mathbf{1b}_2\mathrm{Zn}]^+$. There was thus just cause to investigate their solid-state structures through X-ray crystal structure analysis, as well as to clarify their organizational priorities (see Section 4 for full details).

The complexation domain of $\mathbf{1a}ZnCl_2$ contains η^3-coordination of **1a** to the metal and has a monomeric constitution (Fig. 2(a)). The metal-nitrogen bond lengths (Table 1) and deviations of the constituent aza-aromatics from co-planarity are indicative of a lopsided terdentate coordination. In particular, the Zn–N lengths to pyridine are shorter than to pyrazine, and the torsional angle between C_5H_3N pyridine and pyrazine is significantly greater than that between the adjacent pyridine rings. The pendant chlorine atoms occupy pseudo-axial positions. While the zinc–chlorine bonding distances are unremarkable, the halogens' orientation with respect to the overall molecular geometry warrants comment. One of these, Cl1, is within 0.05 Å of the mean plane of the C_5H_3N ring, while the other (Cl2) lies 3.04 Å on the other side of the same plane. The zinc–chlorine bond angles to nitrogen of C_5H_3N are correspondingly deformed. The uncomplexed pyridine ring is twisted with respect to and deflected out of the plane of the pyrazine ring. Both of the pyridyl–pyrazine torsions occur at the cost of atomic deviations from the mean plane of pyrazine (0.01–0.09 Å). The location of the uncomplexed C_5H_4N ring on the opposite side to Cl2 gives the entire molecule a shallow helical pitch.



Scheme 1. Synthesis of nitrile disubstituted **1b**.

Two different intermolecular parallel stacking interactions are apparent in the lattice of $\mathbf{1a}ZnCl_2$. The complexed bipyridyl domains stack in offset, anti-parallel pairs related by an inversion center (Fig. 2(b)). Thus, while the individually stacking C_5H_4N and C_5H_3N rings are canted 9.83° overall, the bipyridyl rings are co-planar, with atomic distances from the respective mean ring planes in the 3.14–3.81 Å range. Also, columns of homochiral helices are interdigitated by their racemates (Fig. 2(c)). This interpenetration occurs via anti-parallel pyridylpyrazine stacking interactions, which besides minimizing contact between the $ZnCl_2$ centers, generates an inversion center between them. Short H···Cl contacts [27] to the uncomplexed pyridine ring (Cl1···H5‴ and Cl2···H4‴) between the interdigitating columns are apparent.

The complex $\mathbf{1b}ZnCl_2$ is surprisingly monomeric, and occurs as a solvate with a 2:1 – ratio of nitromethane to complex. Strikingly, layers of nitromethane are sepa-

rated by sheet-like **1b**$ZnCl_2$ complexation domains (Fig. 3(a)). The repeating distance between these two layers is ≈11.8 Å. While the complexation domain observed for **1b**$ZnCl_2$ superficially resembles that of **1a**$ZnCl_2$, significant differences in molecular geometry are apparent (Fig. 3(b)). An increased dissymmetry of the 2,2′:6′,2″-terpyridyl-like binding domain occurs, e.g. the Zn–N(1) (pyrazine) bond length increases by 14% relative to **1a**$ZnCl_2$ (Table 1). The origins of this effect either plausibly involve electronic factors or steric interaction with chlorine atoms (closest contacts of Cl1 and Cl2 to nitrile carbons: 4.29 and 3.41 Å, respectively). The constituent atoms of the dicyanopyrazine ring deviate by 0.01–0.07 Å from their mean plane. This situation appears to reduce the overall ligand strain around the terdentate site, as reflected in extra-annular torsional angles. Deformation of the metal-halogen bonds with respect to the η^3-binding domain is relieved,

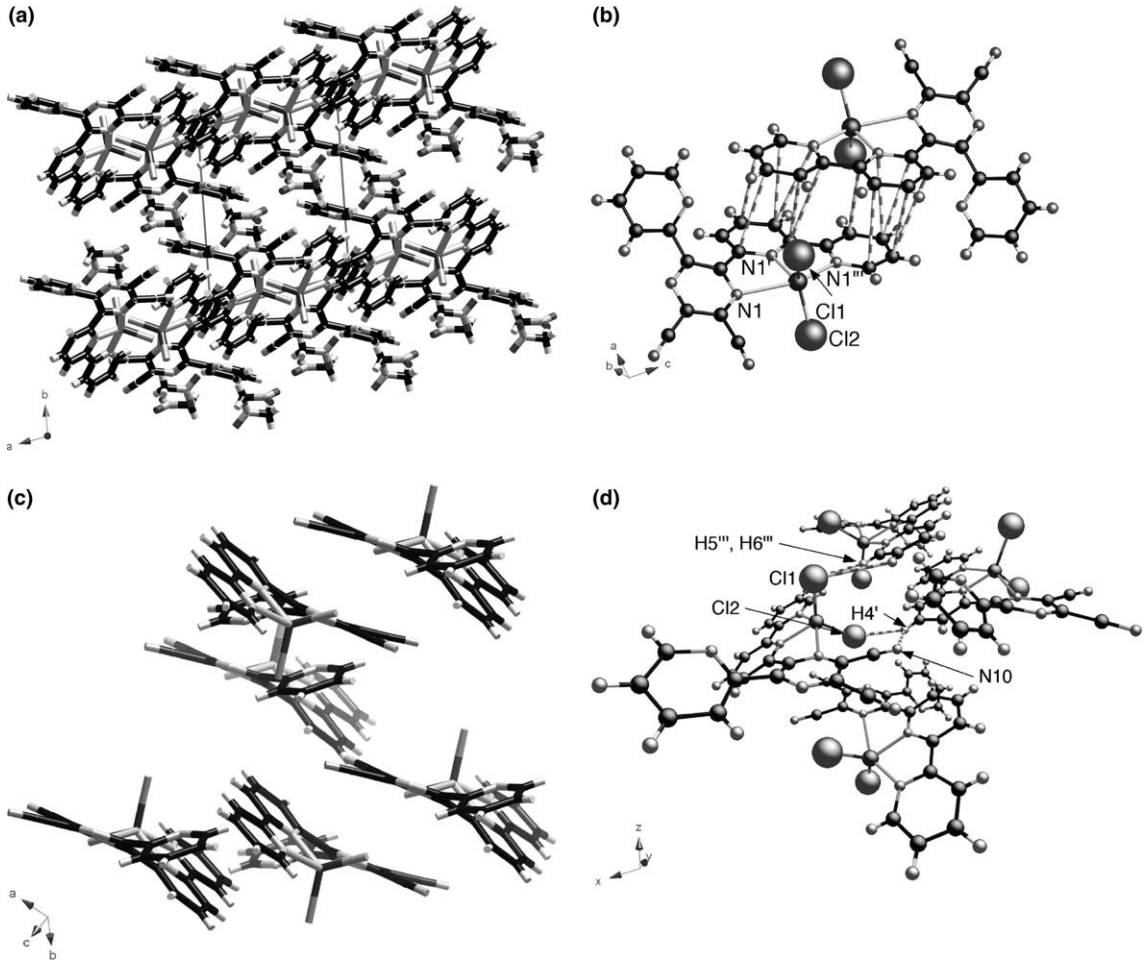

Fig. 3. Complex **1b**$ZnCl_2$ in the solid state: (a) alternating strata of complex and nitromethane; (b) stacked dimeric pairs; (c) stacked 3-(2′-pyridyl)pyrazine subunits [vertical orientation]; (d) likely close contacts.

as shown by the distances of the halogens from the mean plane of C_5H_3N pyridine. The bond angles and atom-to-plane distances involving N of C_5H_3N and the halogen atoms indicate that the Zn–Cl bond vectors are pointed marginally toward, and not away from the un-complexed C_5N_4N ring.

The most prominent intermolecular interaction of **1b**$ZnCl_2$ involves the stacking of inversion center-related pairs of bipyridyl sub-units in **1b** (Fig. 3(b)). These are coplanar to within 0.38° and are characterized by atom-to-mean plane distances in the 3.02–3.30 Å range and closest intermolecular atomic distances of 3.49–3.75 Å. Within this situation, the uncomplexed pyridine rings adapt, as in the case of **1a**$ZnCl_2$, an approximately *anti*-conformation with respect to the pyrazine ring, but are intriguingly twisted inward towards their inversion-related stacking partners to afford estimated short intermolecular $N1'' \cdots H4'''$ contacts of ~2.73 Å; no $Cl \cdots H$ distances within 3 Å are observed. Overall, the geometry and stacking interactions of this situation resemble those in the dicopper(I) metallo-cyclophane of **1a** (atom-to-plane stacking distances: 3.08–3.47 Å).

Another stacking interaction involves the synthon represented by the uncomplexed pyridylpyrazine fragment. This associates with itself to afford atom-to-plane separations and closest-neighbor distances (3.42–3.47 and 3.49–3.75 Å, respectively), bespeaking of an intermediate offset parallel stacking arrangement [28]. Each stacked pyridyl-pyrazinyl pair is coplanar to within 0.61°, although the individual stacking rings are tilted by 3.9° to each other.

Parallel alignment also occurs through the dicyanopyrazine groups, that are oriented in an anti-parallel, dimeric manner (Fig. 3(c)). But also, the nitrile groups interconnect the closely stacked **1b**$ZnCl_2$ pairs from the opposite side of the dicyanopyrazine plane (Fig. 3(d)). For a given equivalent of **1b**$ZnCl_2$, these involve short distances from both nitrile N10 and Cl2 to H4′, as well as $Cl2 \cdots H5'$, on a single molecular neighbor (2.78, 2.67 and 3.72 Å, respectively). Contacts from Cl1 to H5‴ and H6‴ on yet another adjoining molecule (3.56 and 3.11 Å) complete this aspect.

To compare the solid- and solution-state structures of the zinc complexes, their proton NMR spectra were

analysed and assigned. Since the ligand **1b** is previously unreported, its ^{1}H NMR spectrum deserves brief comment. The outstanding feature in this substance is the upfield resonance of H3‴, which is indicative of an edge-on-face stacking interaction between the spatially proximate C_5H_4N pyridine rings containing N1‴ and N1″ [7]. Thus, the presence of the nitrile groups does not interfere with the expected conformational preferences of this heterocyclic system. For the complexes, spectra were assigned with the assistance of pulse field gradient COSY spectra (Fig. 4). The downfield shift of H3‴ and its coupling constants are consistent with those of other terdentate pyridine–pyrazine complexes [29] and are indicative of complexation involving C_5H_4N pyridine of the 2,6′-bipyridyl substituent.

Also in both of the zinc(II) complexes, H3″ of C_5H_4N pyridine undergoes an unusual upfield shift (**1a**$ZnCl_2$ and **1b**$ZnCl_2$: $\Delta\delta$ relative to ligands in $CDCl_3$: 0.51 δ 7.31 and 1.03, respectively). Initially, the assignment of the upfield doublet to H3″ (as opposed to H3′ of the C_5H_3N ring) was not straightforward. However, similar experiments on **1b**$ZnCl_2$ at 270 MHz clearly indicated the connectivity of this shift to the remaining three protons of the uncomplexed C_5H_4N ring. A similar shifting of this position occurs in dimeric metallo-cyclophanes, but in that case arises from an edge-on-face interaction of the orthogonally directed bipyridyl complexation domains [2,3]. Insight into the origins of this new effect is provided through molecular model studies. Orthogonal stacking of the uncomplexed C_5H_4N pyridine ring against the C_5H_3N ring should induce a shielding effect in spatially adjacent positions in the later, but not the former ring. However, other η^3-metalloorganic complexes of 2,3-disubstituted pyrazine–pyridine hybrids exist in highly twisted solution-state geometries [29,30], suggesting that long-range effects, to cause shielding of H3″ by the chlorine atoms, may occur for the current zinc(II) complexes. Since, however no dynamic signal broadening width was observed at 25 °C, any such fluxional processes involving the uncomplexed pyridine ring are rapid on the ^{1}H NMR spectroscopic time scale.

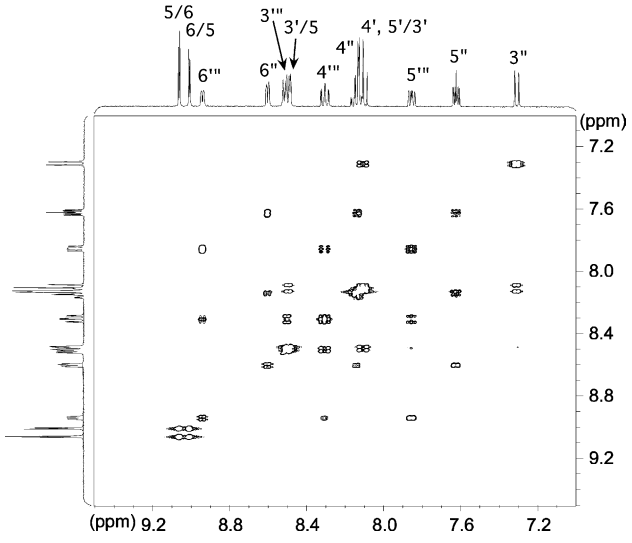

Fig. 4. Pulsed field gradient ^{1}H–^{1}H correlation spectrum for **1a**$ZnCl_2$ (CD_3NO_2, 400 MHz).

3. Concluding remarks

Complexation of the sterically hindered bipyridyl-pyridylpyrazine hybrids **1a** and **1b** with zinc(II) induces a change from bis-bidentate to terdentate complexation geometry, while maintaining related long-range stacking and organizational features as for dimeric metallo-cyclophanes. Tantalizingly, the appearance of mass spectral signals from $[\mathbf{1b}_2Zn]^+$, the weakened Zn–N (pyrazine) bond and the dimeric, multi-interaction solid-state stacking motif of **1b**$ZnCl_2$ suggest that this complex is on the brink of an oligomeric self-assembly program. For both new complexes, solid-state atropisomeric chirality in the form of helicity is observed, and is also probable in solution, a feature that compliments the point chirality of the metallo-cyclophanes. Thus, the precise molecular and crystal lattice topology can be controlled through appropriate substitution of the ligand scaffolding. Indeed, highly polar nitrile substitution, which is desirable from the point of excited-state dipole moment tuning, is tolerated by the observed complexation mode. These studies have revealed to us the complexity of the organizational and topological phenomena possible for such pyrazine–pyridine hybrids, and will aid in the design of monomeric and dimeric zinc(II) complexes appropriate for evaluation excited-state dipolar properties.

4. Experimental

4.1. General procedures and starting materials

Electrospray mass spectra (ES-MS) were recorded on a ThermoFinnigan LCQ Classic by direct injection into a flow of acetonitrile at 5 μl/min, needle voltage 3.5 kV, capillary voltage 30 V and capillary temperature 60 °C. Data was collected manually in Tune Plus and visualised in the Qual Browser of the Excalibur software. FAB-MS spectra were recorded on a VG Instruments 7070E instrument with a FAB inlet system. Infrared spectra were recorded in a Mattson FT-IR spectrometer as KBr disks. UV spectra were recorded on a Unicam apparatus. Elementary analyses were obtained in a Carlo Erba Elemental Analyser. ^{1}H NMR spectra were recorded at 25 °C on Jeol 270 GSX and Bruker Avance 400 spectrometers. ^{13}C NMR spectra were recorded at 67.5 MHz

on the Jeol 270 GSX instrument. All NMR spectra were referred to Me_4Si at δ 0.0 ppm. Except for diketone **2**, all starting materials and solvents were commercially available and used without further purification.

4.2. Syntheses

4.2.1. Ligand *1b*

To a solution of diketone **2** [8] (0.30 g, 1.0 mmol) in AcOH (15 ml) was added diaminomaleonitrile (0.10 g, 1.0 mmol). The reaction was refluxed for 1 h. Afterwards, the mixture was cooled to room temperature, the product extracted (CH_2Cl_2, 3×10 ml), the combined organic extracts were washed (H_2O, 3×10 ml), dried ($MgSO_4$) and the solvent removed by rotary evaporation at atmospheric pressure to give a brown solid. The product was purified by column chromatography (CH_2Cl_2:EtOAc 1:1, alumina, activity stage III) and recrystallized ($CHCl_3$/hexane) to afford colourless crystals in 67% yield. M.p. 185–186 °C; Calc. for $C_{21}H_{11}N_7$: C, 69.80; H, 3.07; N, 27.13. $J = 7.8$ Hz, 1H, H3‴), 8.31 (d, t, $J = 1.6$, 8.0 Hz, 1H, H4″), 8.15 (d, t, $J = 1.5$, 7.8 Hz, 1H, H4″), 8.09–8.14 (m, 2H, H − 5′/3′, H4′), 7.86 (ddd, $J = 1.0$, 5.0, 8.6 Hz, 1H, H5‴), 7.62 (ddd, $J = 2.0$, 4.8, 6.8 Hz, 1H, H5″), 7.31 (dd, $J = 0.5$, 8.1 Hz, 1H, H3″).

4.2.3. *1bZnCl₂*

To a solution of **1b** (0.0124 g, 0.034 mmol) in degassed acetonitrile (2 ml) was added $ZnCl_2$ (0.004 g, 0.03 mmol) under N_2. After a few minutes, a white precipitate was formed. This mixture was refluxed for an hour then cooled to room temperature and the solvent evaporated to give a green solid. Recrystallization from hot nitromethane, followed by slow cooling over 24 h afforded colourless crystals suitable for X-ray diffraction studies. M.p. 290 °C (decomp.); $\nu(cm^{-1})$ (KBr): 1596 (C=C); 1574 (C=C); 785 (Ar–H); no absorptions from the nitrile groups were visibile; Calc. for $C_{21}H_{11}Cl_2N_7Zn(CH_3NO_2)$: C, 48.89%; H, 2.39%; N, 19.89%. 4.3. Crystal structure determination and data collection

Data collection occurred on a Stoe Image Plate Diffraction system, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Image plate distance: 70 mm, ϕ oscillation scans 0–190°, step $\Delta\phi = 1°$. The structures were solved by direct methods (SHELXS-97) and refined anisotropically on F^2 (SHELXL-97). The crystal data and particulars associated with data collection and refinement for each structure are collected in Table 2.

Abstract

Copper(II) and zinc(II) complexes of cross-bridged cyclam and cyclen with primary amide pendant arms (ligands **1** and **2**) have been prepared and structurally characterized. The copper complex of cyclam-derived **1** has a Jahn–Teller distorted Cu(II) octahedral coordination geometry with both amide arms coordinated through the carbonyl oxygens. The Cu(II) complex of the cyclen analogue **2** has been found to exist in three slightly different forms. Both zinc complexes also adopt full N_4O_2 coordination from these potentially hexadentate cross-bridged ligands. These structural data confirm the exclusive *cis*-folded ligand configuration in all four complexes as well as the significantly better fit of ligand **1** towards both Cu(II) and Zn(II) cations when compared to **2**. The complexes of **1** provide the first examples of a [2233]/[2233] cross-bridged cyclam conformation, as opposed to the previously observed [2323]/[2323] conformation.

1. Introduction

Polyazamacrocylic complexes of copper(II) and zinc(II) are of relevance in coordination, catalytic, biological, as well as radiopharmaceutical chemistry [1–4]. We have designed, prepared and studied ethylene cross-bridged cyclam and cyclen ligands (Fig. 1) and their derivatives [5], which have proven to be excellent chelators for a variety of metal ions including Cu(II) and Zn(II) [6–8]. Others have also taken up the study of the coordination chemistry of these interesting ligands [9]. An excellent review of the area by Springborg has recently appeared [10]. The enhanced resistance of the metal complexes of these ligands towards common decomplexation pathways when compared to unbridged tetraamine macrocycles have been amply confirmed [9,11]. This kinetic inertness can be of major significance in their potential applications [12]. A further augmentation of this desirable property can be achieved through attachment of coordinating pendant arms at the two secondary amine sites. Both cyclam and cyclen ligands with amide pendant arms have already received much attention in MRI and biomimetic research areas [2,13–16]. We have previously reported a synthesis of the first copper complex of a diamide-armed cross-bridged cyclam, **1** (4,11-bis(carbamoylmethyl)-1,4,8,11-tetraazabicyclo[6.6.2]hexadecane) [7]. Herein we present the synthesis, spectral, and structural characterization of the Cu(II) and Zn(II) complexes of **1** and its cyclen analogue **2** (4,10-bis(carbamoylmethyl)-1,4,7,10-tetraaazabicyclo[5.5.2]tetradecane) (Fig. 1).

2. Experimental

Ligand **1** was prepared as described previously [7]. Ligand **2**, which has been described in the patent literature [17], was prepared by a variation of our general approach [6,7]. All other reagents and solvents were obtained commercially and used without further

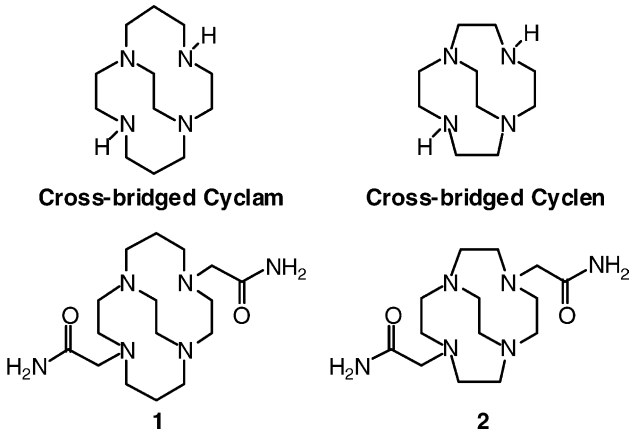

Fig. 1. Cross-bridged cyclam, cross-bridged cyclen, and ligands **1** and **2**.

purification. Reactions were performed under a nitrogen atmosphere. Recrystallizations, however, were carried out in closed containers without special precautions to exclude either air or moisture. Electronic spectra were run on a Cary 5E spectrophotometer while ^{1}H and ^{13}C NMR data were collected on either a Bruker AM-360 or Varian Inova-400 spectrometer. FT-IR (KBr) of the complexes were recorded on a Nicolet MX-1 FT spectrophotometer. Elemental analysis were performed by Atlantic Microlab, Norcross, GA.

2.1. $[Cu \cdot \mathbf{1}](NO_3)_2$

A mixture of $\mathbf{1} \cdot (H_2O)_{0.5}$ (136.9 mg, 0.392 mmol) and $Cu(NO_3)_2 \cdot 3H_2O$ (95.8 mg, 0.397 mmol) in MeOH (16 mL) was refluxed for 17 h to form a dark-blue MeOH solution and some bluish brown precipitate. The MeOH solution was isolated by centrifugation. Et_2O vapor diffusion into this solution yielded 138.7 mg of a blue crystalline solid, which was dissolved in H_2O/MeOH (1:1) and diffused by acetone vapor to form blue crystals. Electronic spectrum (H_2O): $\lambda_{max}(\varepsilon) = 286$ nm (1.348 M^{-1} cm^{-1}), 625 (34 M^{-1} cm^{-1}). IR (KBr): 3285, 3139 cm^{-1} (ν_{OH} and ν_{NH}), 1678(s) $\nu_{C=O}$, 1604 (medium) cm^{-1}. *Anal.* Calc. for $CuC_{16}H_{32}N_6O_2(NO_3)_2H_2O$: C, 35.19; H, 6.28; N, 20.52. Found: C, 34.93; H, 6.24; N, 20.32%.

2.2. $[Cu \cdot \mathbf{2}](ClO_4)_2$

A mixture of ligand $\mathbf{2} \cdot H_2O$ (16.8 mg, 0.0508 mmol) and $Cu(ClO_4)_2 \cdot 6H_2O$ (22.1 mg, 0.0596 mmol) in MeOH (11 mL) was refluxed for 1 day. After cooling to room temperature, this solution was diffused with Et_2O vapor to yield 21.0 mg (72%) of blue crystals. Electronic spectrum (H_2O): $\lambda_{max}(\varepsilon) = 283$ nm (3.351 M^{-1} cm^{-1}), 633 nm (76 M^{-1} cm^{-1}). IR (KBr): 3439, 3359, 3309, 3256 cm^{-1} (ν_{OH} and ν_{NH}), 1682(s), 1661(s) cm^{-1} $\nu_{C=O}$, 1612 (medium), 1593 (medium) cm^{-1} ($\nu_{C=O}$ or NH_2bending). *Anal.* Calc. for $CuCl_2C_{14}H_{28}N_6O_{10}$: C, 29.25; H, 4.91; N, 14.62. Found: C, 29.09; H, 5.19; N, 14.59%.

2.3. $[Zn \cdot \mathbf{1}](ClO_4)_2$

To a MeOH solution (5 mL) of $\mathbf{1} \cdot (H_2O)_{0.5}$ (46.3 mg, 0.132 mmol) which was about 95% pure, a MeOH solution (6 mL) of $Zn(ClO_4)_2 \cdot 6H_2O$ (50.3 mg, 0.135 mmol) was added. This resulting solution was refluxed for 27 h to form a cloudy solution. This solution was then centrifuged to remove the white precipitate. Et_2O vapor diffusion into this supernatant yielded 52.9 mg of a white solid, which was recrystallized from acetone and washed by $CHCl_3$. Then it was redissolved in MeCN and ether diffused into this solution to form pure $[Zn \cdot \mathbf{1}](ClO_4)_2$ as needle-shaped crystals (15.6 mg, 20%). IR (KBr): 3442, 3337, 3293 and 3232 cm^{-1} (ν_{OH} and ν_{NH}), 1673, 1659 cm^{-1} ($\nu_{C=O}$), 1590 cm^{-1} (w, NH_2 bending). ^{1}H NMR in CD_3CN: δ 7.31(2H, s, NH_2), 6.94 (2H, s, NH_2), 3.66 (2H, br A of AB in CH_2CONH_2 arms), 3.47 (2H, B of AB in CH_2CONH_2 arms), 3.35–3.44 (2H, m) 3.15–3.29 (4H, m), 3.08 (4H, broad td, $J = 12.9$, 2.4 Hz), 2.59–2.87 (10H, m), 2.17–2.31 (2H, m, β-CH_{ax}), 1.68 (2H, dp, $J = 17.6$, 2.5 Hz, β $CH_{eq}H$); $^{13}C\{^{1}H\}$ data in CD_3CN: δ 176.88, 62.13, 60.68, 59.71, 58.53, 52.35, 51.52, 23.80. *Anal.* Calc. for $ZnC_{16}H_{32}N_6O_2(ClO_4)_2$: C, 31.78; H, 5.33; N, 13.90. Found: C, 31.99; H, 5.39; N, 13.78%.

2.4. $[Zn \cdot \mathbf{2}](ClO_4)_2$

A mixture of ligand $\mathbf{2} \cdot H_2O$ (74.1 mg, 0.224 mmol) in MeOH (5 mL) and $Zn(ClO_4)_2 \cdot 6H_2O$ (84.0 mg, 0.226 mmol) in MeOH (2 mL) was refluxed for one day. After cooling to room temperature, needle-shaped crystals (53.0 mg) grew out and were centrifuged from this solution. Ether was diffused into the supernatant to produce another 27.2 mg of colorless crystals. The combined yield was 62%. IR (KBr): 3413, 3370, 3296, 3241 cm^{-1} (ν_{NH} or ν_{OH}), 1682(s), 1663(s) cm^{-1} ($\nu_{C=O}$ stretches) 1597 (medium) cm^{-1} (OH or NH_2 bending). ^{1}H NMR of N-deuterated complex in CD_3OD: δ 3.94 (4H, s, CH_2COND_2), 3.32–3.49 (8H, m), 3.11 (4H, s, cross-bridging CH_2CH_2), 3.05 (4H, dd, $J = 12.1$, 4.8 Hz), 2.94 (4H, td, $J = 12.3$, 7.1 Hz); in D_2O (400 MHz): δ 3.98 (4H, s, CH_2COND_2), 3.38 (8H, br dd, $J = 9.4$, 3.0 Hz), 3.07 (4H, s, cross-bridging CH_2CH_2), 2.89–3.06 (8H, m); $^{13}C\{^{1}H\}$ NMR in CD_3OD (N–D complex): δ 177.90, 63.08, 61.73, 57.81, 50.58; in D_2O (N–D complex):δ 77.09, 62.27, 60.98, 56.73, 49.98. *Anal.* Calc. for $ZnCl_2C_{14}H_{28}N_6O_{10}$: C, 29.16; H, 4.89; N, 14.57. Found: C, 29.23; H, 4.98; N, 14.31%.

2.5. X-ray crystal structure determination

Diffraction intensity data were collected with a Siemens P4/CCD ($[Zn \cdot \mathbf{1}](ClO_4)_2$ and $[Zn \cdot \mathbf{2}](ClO_4)_2$) and a Bruker Smart Apex CCD ($[Cu \cdot \mathbf{1}](NO_3)_2$ and $[Cu \cdot \mathbf{2}](ClO_4)_2$) diffractometers. Crystal data, data col-

lection, and refinement parameters are given in Table 1. The structure was solved using direct methods, completed by subsequent difference Fourier syntheses, and refined by full matrix least-squares procedures on F^2. SADABS absorption correction was applied for all data. All non-hydrogen atoms were refined with anisotropic displacement coefficients. In $[Cu \cdot \mathbf{2}](ClO_4)_2$ and $[Zn \cdot \mathbf{2}](ClO_4)_2$ the positions of the H atoms were calculated and in $[Cu \cdot \mathbf{1}](NO_3)_2$ and $[Zn \cdot \mathbf{1}](ClO_4)_2$ the H atoms were found on the difference F-map and refined with isotropic thermal parameters. In $[Cu \cdot \mathbf{1}](NO_3)_2$ disordered solvent molecules (CH_3OH and H_2O) non-involved in coordination of the main molecule were treated by SQUEEZE (Van der Sluis, P., Spek, A.L., Acta Crystallogr., Sect. A 46 (1990) 194–201). Correction of the X-ray data by SQUEEZE (107 electron/cell) was close to the required values (107 electron/cell). All software and sources of scattering factors are contained in the SHELXTL (5.10) program package (G. Sheldrick, Bruker XRD, Madison, WI).

3. Results and discussion

3.1. Synthesis and spectral characterization

Both zinc(II) and copper(II) complexes of ligands **1** and **2** were readily prepared from respective metal salts and ligand in methanol. Diethyl ether diffusion into methanol or acetonitrile solutions of the crude products yielded X-ray quality crystals.

Infra-red spectra of all four complexes feature amide carbonyl stretching bands between 1659 and 1682 cm^{-1}. These data are consistent with O-coordination of the amide pendant arms in the solid-state [18–21] as confirmed by their X-ray structures presented below. Electronic spectra of the copper complexes reveal a charge-transfer as well as a broad d–d band for both $[Cu \cdot \mathbf{1}](NO_3)_2$ (λ_{max} (H_2O) 286 and 625 nm) and $[Cu \cdot \mathbf{2}](ClO_4)_2$ (λ_{max} (H_2O) 283 and 633 nm).

Solution NMR spectra of the zinc complexes confirmed the existence of a single isomer in each case. The $^{13}C\{^1H\}$ NMR spectrum of $[Zn \cdot \mathbf{1}](ClO_4)_2$ contains only eight resonances, consistent with a C_2-symmetric solution species. $[Zn \cdot \mathbf{2}](ClO_4)_2$ exhibits only five distinct

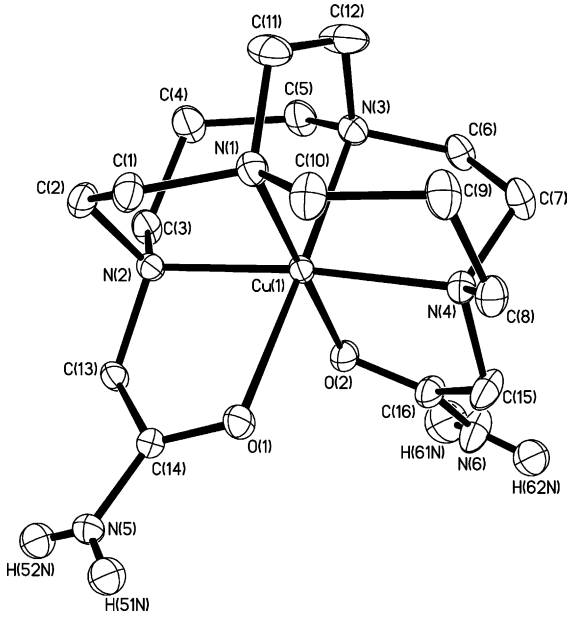

Fig. 2. Molecular structure of $[Cu \cdot \mathbf{1}](NO_3)_2$. Nitrate anions and hydrogens omitted except on the amide nitrogens.

Selected bond distances (Å) and bond angles (°) for $[Cu \cdot \mathbf{1}](NO_3)_2$

Cu(1)–O(1)	2.2643(18)	O(1)–Cu(1)–O(2)	89.93(7)
Cu(1)–O(2)	2.0423(19)	N(1)–Cu(1)–O(2)	179.09(8)
Cu(1)–N(1)	2.043(2)	N(2)–Cu(1)–N(4)	174.38(8)
Cu(1)–N(2)	2.044(2)	N(3)–Cu(1)–O(1)	177.64(8)
Cu(1)–N(3)	2.178(2)	N(1)–Cu(1)–N(2)	86.98(8)
Cu(1)–N(4)	2.061(2)	N(1)–Cu(1)–N(4)	97.44(8)
		N(1)–Cu(1)–N(3)	86.93(9)
		N(2)–Cu(1)–N(3)	98.50(8)
		N(3)–Cu(1)–N(4)	85.24(8)

SD in parentheses.

^{13}C resonances and has singlet ^{1}H resonances for both its cross-bridging ethylene and pendant-arm methylene protons in accord with C_{2v} symmetry in solution. Since retention of the solid-state structure (vide infra) of $[Zn \cdot \mathbf{2}](ClO_4)_2$ in solution would result in only C_2 spectral symmetry, the observed NMR data require onset of dynamic enantiomerization, a process which might or might not involve dissociation of one or more amide pendant arms from the zinc. Proton spectra obtained down to −80 °C revealed extensive signal broadening but unfortunately no slow-exchange data were accessible to allow further delineation of this process.

3.2. X-ray structures

The X-ray structure of $[Cu \cdot \mathbf{1}](NO_3)_2$ reveals a fully enveloped metal center with both amide pendant arms coordinated through their oxygens (Fig. 2). Important bond angles and distances are listed in Table 2. The familiar Jahn–Teller elongation of six-coordinated Cu(II) is manifested along the O(1)–Cu(1)–N(3) axis. Thus the Cu(1)–O(1) bond at 2.264(2) Å is significantly longer than the Cu(1)–O(2) distance of 2.042(2) Å. Similarly, the Cu(1)–N(3) bond-length of 2.178(2) Å can be contrasted with the shorter Cu(1)–N(1) bond at 2.043(2) Å. In the reported structure of the carboxylate-armed analogue of this complex, a similar elongation is observed along one O–Cu–N axis [7]. The good fit of

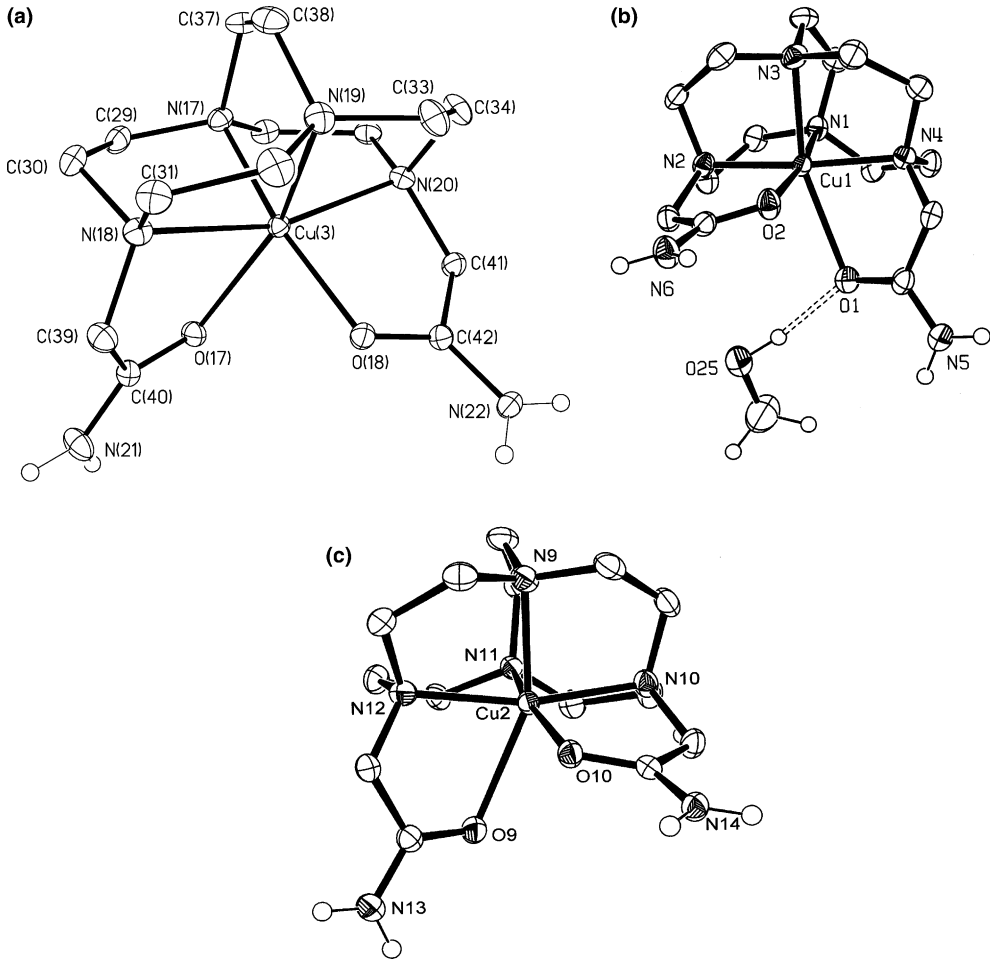

Fig. 3. (a)The first structure of $[Cu \cdot \mathbf{2}](ClO_4)_2$. Perchlorate anions and hydrogens omitted except on the amide nitrogens. (b) The second structure of $[Cu \cdot \mathbf{2}](ClO_4)_2$. Perchlorate anions and hydrogens omitted except on the methanol and amide nitrogens. (c) The third structure of $[Cu \cdot \mathbf{2}](ClO_4)_2$. Perchlorate anions and hydrogens omitted except on the amide nitrogens.

Cu(II) inside the cleft of ligand **1** is confirmed by the near-linear bond angles for N(2)–Cu(1)–N(4) of 185.62(8)°, N(3)–Cu(1)–O(1) of 177.64(8)°, and N(1)–Cu(1)–O(2) of 179.09(8)°. Most literature reports of copper(II) complexes of carbamoylmethyl-armed cyclam and cyclam derivatives have the common *trans-III* configuration and feature axially coordinated amide oxygens [21–23].

Three distinct forms of the $[Cu \cdot \mathbf{2}](ClO_4)_2$ complex are found in its X-ray structure. The first is a direct analogue of the $[Cu \cdot \mathbf{1}](NO_3)_2$ structure featuring full envelopment of the Cu(3) center within the ligand's N_4O_2 donor set (Fig. 3(a)). The Jahn–Teller elongation is along the O(17)–Cu(3)–N(19) axis with long Cu–O (2.231(2) Å) and Cu–N (2.156(2) Å) bonds. The significantly poorer fit of six-coordinate Cu(II) inside the cyclen-derived **2** is revealed in the non-linear bond angles for N(18)–Cu(3)–N(20) of 162.20(7)°, N(19)–Cu(3)–O(17) of 156.87(7)°, and N(17)–Cu(3)–O(18) of 167.62(7)°. The other two structural forms of $[Cu \cdot \mathbf{2}](ClO_4)_2$ both feature more substantial Jahn–Teller elongations with significantly longer axial Cu–O bonds of 2.465(2) and 2.445(2) Å as well as Cu–N bonds of 2.194(2) and 2.176(2) Å, respectively (Figs. 3(b) and (c)). A noteworthy difference between these two structures is the presence of H-bonding between the more loosely coordinated amide oxygen and a methanol solvent molecule in one of them (Fig. 3(b)). Other relevant structural data of all three Cu(II) coordination spheres are listed in Table 3. Surprisingly, no previous structural reports of carbamoylmethyl-functionalized cyclen Cu(II) complexes for comparison purposes are found in a search of the *Cambridge Structural Database*. A single 2-carbamoylethyl-armed cyclen Cu(II) complex has the ligand in the familiar *trans-I* configuration with only a single coordinated amide arm [20].

Overall the X-ray structure of $[Zn \cdot \mathbf{1}](ClO_4)_2$ is similar to that of $[Cu \cdot \mathbf{1}](NO_3)_2$ with the cation fully coordinated by the hexadentate ligand (Fig. 4). Important bond distances and angles are presented in Table 4. Here the complex has exact C_2 symmetry. The Zn(II) cation subtends an obtuse N(2)–Zn(1)–N(2A) angle of 183.9(1)° indicative of its being inside the ligand cleft. Other near-linear angles are O(1)–Zn(1)–N(1A) and O(1A)–Zn(1)–N(1) both at 176.9(7)°. The single structural report of a bis(carbamoylmethyl)-armed dibenzocyclam features a *trans-III* ligand configuration with axially coordinated amide oxygens [18].

The significantly poorer fit of six-coordinate Zn(II) inside ligand **2** in the structure of $[Zn \cdot \mathbf{2}](ClO_4)_2$ is

clearly shown in Fig. 5. Here its protrusion from the ligand cleft is best gauged by its nonlinear N(2)–Zn(1)–N(4) angle of 159.1(1)°. Angles similarly severely distorted from ideal values are O(1)–Zn(1)–N(1) at 157.1(1)° and O(2)–Zn(1)–N(3) at 158.0(1)°. Other relevant structural data are presented in Table 5. Three structures have been reported for Zn(II) complexes of carbamoylmethyl-functionalized cyclen. Interestingly, each of these features a distinct coordination number ranging from five to six to seven [2,24,25]. The five-coordinate structure, however, contains a deprotonated amide nitrogen which is coordinating instead of the oxygen [24].

The conformation of the bicyclo[6.6.2] ligand backbone in the structures of $[Cu \cdot \mathbf{1}](NO_3)_2$ and $[Zn \cdot \mathbf{1}](ClO_4)_2$ was a surprise. Instead of the [2323]/[2323] distorted diamond-lattice conformation that has been observed in all previously published structures of complexes of cross-bridged cyclams, these structures exhibit a new [2233]/[2233] bicyclic conformation. In this conformation, the ethylene cross-bridge torsion angle is of opposite sign and each of the 10-rings is in the quadrangular [2233] conformation [26,27]. As a result, the axial (non-bridgehead) nitrogen lone pairs tend to cant in toward the cleft, making this a slightly more convergent conformation in our estimation. Indeed, both structures exhibit slightly concave N(axial)–M–N(axial) angles. We had been aware of this possibility for some time on the basis of Monte Carlo searches of conformational space of cross-bridged cyclam ligands, but such studies using a variety of force fields also showed the [2233]/[2233] conformation to be higher in steric energy than the [2323]/[2323] conformation by several kcal/mol. Preliminary molecular mechanics (*PCModel* v.8, Serena Software, Bloomington, IN, 2003) suggest that this is also true for the pendant-arm ligand **1** in the complexing conformation of $[Zn \cdot \mathbf{1}](ClO_4)_2$. Why then the adoption of this conformation in both Cu and Zn complexes? We hypothesize that this conformation allows the carbonyls of the relatively short carbamoylmethyl arms to better reach the metals for efficient ligation.

We believe that these structural data confirming the coordination of both pendant amide arms of ligands **1** and **2** with both Cu(II) and Zn(II) anticipate enhanced inertness towards decomplexation. Further, it is expected that the better fit of ligand **1** than **2** should be reflected in relative kinetic stabilities. Relevant studies of pendant-armed cross-bridged ligand complexes of main group and transition metals are in progress.

Monobranched and hyperbranched dendrimers based on cyclophosphazene containing nitrile and phosphine donors and their Fe and Ru organometallic derivatives

Carlos Díaz *, Miguel Barbosa, Zaida Godoy

Departamento de Química, Facultad de Ciencias, Universidad de Chile, Las Palmeras 3425, Casilla 653, Santiago, Chile

Received 25 July 2003; accepted 28 December 2003

Abstract

The series of complexes $[N_3P_3(OC_6H_5)_5X.ML_n]PF_6$, $X = OC_6H_4CH_2CN$, $N(CH_3)(CH_2)_2CN$ or $OC_6H_4PPh_2$, and $[N_3P_3(X)_6 \cdot (ML_n)_6](PF_6)_6$, X = $OC_6H_4CH_2CN$ or $N(CH_3)(CH_2)_2CN$ with ML_n = CpFe(dppe) and $CpRu(PPh_3)_2$ have been synthesized by reaction of the corresponding cyclophosphazene ligands: $N_3P_3(OC_6H_5)_5OC_6H_4CH_2CNL_1$, $N_3P_3(OC_6H_5)_5N(CH_3)(CH_2)_2CNL_2$, $N_3P_3(OC_6H_5)_5OC_6H_4PPh_2L_3$, $N_3P_3(OC_6H_4\ CH_2CN)_6L_4$ and $N_3P_3(N(CH_3)(CH_2)_2CN)_6L_5$ with the respective organometallic CpFe(dppe)I and $CpRu(PPh_3)_2Cl$ in CH_3OH as solvent and in presence or of NH_4PF_6. The new compounds were characterized by elemental analysis and IR, UV–Visible and multinuclear NMR spectroscopy. Cyclic voltammetry studies indicate that the cyclophosphazene dendrimers act as insulators between the organometallic centers.

1. Introduction

Dendrimers chemistry is a rapid developing field of research [1]. Dendrimers offer the prospect of novel material with advantageous properties allowing them to serve, as soluble catalysts [2], dendritic boxes [3], and other supramolecular dendritic arrangements. Since the initial report on this class of molecules by Vögtle in 1978 [4] many different structural classes of dendritic macromolecules have been reported. Two main classes of dendrimers can be distinguished: the classical organic dendrimers [1] and the emergent inorganic dendrimers [5].

The incorporation of transition-metal complexes in both organic and inorganic dendrimers lead to new and interesting materials with specific properties such as the capability to absorb visible light, to give luminescence and to undergo reversible multielectron redox processes [6]. Such species, in fact could find applications as components in molecular electronic and as a photochemical molecular devices for solar energy conversion, information storage and in catalysis [6]. In general metal-containing dendrimers can be classified in two ways: according to the nature of the dendrimer and acording to the nature of the metal. With regarding to the nature of the dendrimer three categories can be distinguished: (see Scheme 1):

(a) Dendrimers with coordination centers at the core.
(b) Dendrimers with coordination centers through all layers and
(c) Dendrimers with coordination centers on the periphery.

On the other hand, with regard to the nature of the metal, dendrimers can be clasified in (i) those that the metal fragments are coordination units and (ii) those that the metal fragments are organometallic units.

Although dendrimers with coordination centers on the periphery have been reported [1,2,6], for those with the dendrimer – core being organic, few examples of inorganic dendrimers with metal coordination or organometallic derivatives on the surface have been reported

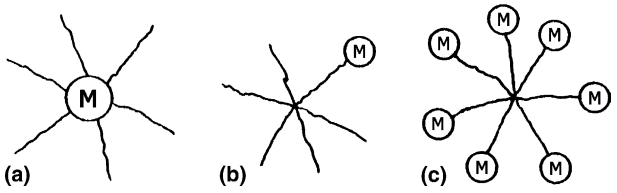
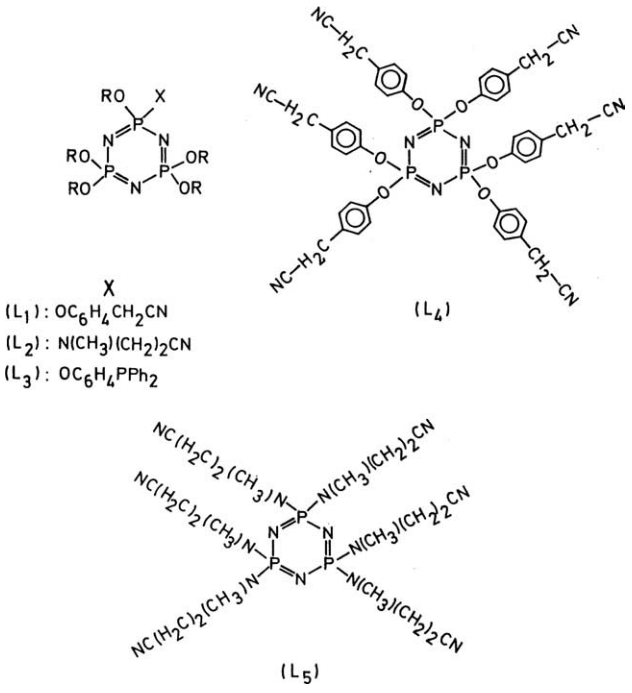


Scheme 1. Schematic representation of three class of metallodendrimers.

[5–8]. In spite of that dendrimers based on cyclophosphazenes have been reported [5], relatively few metal [9] and organometallic [5,8,10] derivatives have been reported. We have recently reported some organometallic derivatives of partially branched cyclophosphazene derivatives [10] and some single transition metal chlorides derivatives [9].

In continuation of our studies, we aimed to investigate the electronic communication between the metallic centers in dendrimers containing six organometallics groups in the peripheral (ligands **L4** and **L5**, see Scheme 2) as well as the influence of the X spacer and the nature of the metal, on the electronic transfer between the phosphorus (ring) atom and the metallic center (ligands **L1**–**L3**).

This communication reports the synthesis and characterization of new inorganic dendrimers based on cyclophosphazene having nitrile and phosphine donor groups and containing their Fe and Ru organometallic derivatives on the surface.



Scheme 2. Formulas for the ligands.

2. Results and discussion

2.1. Synthesis of the ligands

The synthesized ligands are shown in Scheme 2. As expected the synthesis of the dendrimers **L1**, **L3** and **L4** was made by the divergent strategy [1], by reaction of $N_3P_3Cl_6$ or $N_3P_3(OC_6H_5)_5Cl$ with $HO{-}_6H_4CH_2CN$ in acetone and in presence of the K_2CO_3 [9,10]. The ligands **L2** and **L5** were prepared by a similar strategy by reaction of the amine $HN(CH_3)CH_2CH_2CN$ with $N_3P_3Cl_6$ or $N_3P_3(OC_6H_5)_5Cl$ using triethylamine as HCl abstractor. As commonly observed for $N_3P_3(OC_6H_5)_{6-n}(C_6H_5)_n$ or $N_3P_3(OC_6H_5)_{6-}(NHR)_n$ derivatives, the products **L1**, **L3**, **L4** and **L5** were obtained as yellow or white oil, while **L2** was obtained as a white solid. All the new compounds were fully characterized by elemental analisis (or mass spectra for **L1** and **L4**) as well as IR, UV–Visible and ^1H ^{31}P and ^{13}C NMR spectroscopy. The compounds exhibits the typical IR bands of the $N_3P_3(OC_6H_5)_{6-n}(C_6H_5)_n$ ring [11]: ν(C-OP) arounds 1200 cm^{-1}, ν(PN) around 1100 cm^{-1} and ν(P-OC) around 1000 cm^{-1}. Additionally the expected, ν(CN) bands for **L1** , **L2**, **L4** and **L5** were observed in the range 2245–2228 cm^{-1}, see Table 1.

The ^{31}P NMR spectra of the ligands **L1**, **L4** and **L5** exhibit the typical singlet signal expected for these systems while that the ^{31}P NMR spectra for **L2** and **L3** show one triplet and one doublet corresponding to a AB_2 systems. These values are shown in Table 2.

For the ligands **L1**, **L3** and **L4**, their ^{13}C spectra exhibit all the expected signals for the groups (OC_6H_5), (OC_6H_4X) and $P(C_6H_5)_2$ (accordingly correspond see Section 3). Thus the signal of the CN and CH_2 groups were observed around 117 and 24 ppm, respectively. Full data are shown in Section 3.

2.2. Synthesis of the organometallic derivatives

2.2.1. Iron and ruthenium derivatives of ligands L_1, L_4

Using a previously reported methodology [10], the iron and ruthenim organometallic derivatives of the nitrile ligand **L1** and **L4** were prepared by reaction of the respective dendrimer ligands with the organometallic CpFe(dppe)I and $CpRu(PPh_3)_2Cl$ respectively, in methanol as solvent and using NH_4PF_6 as halide abstractor:

(**1**) $[CpFe(dppe)(L_1)][PF_6]$
(**2**) $[CpRu(PPh_3)_2(L_1)][PF_6]$
(**3**) $[[CpFe(dppe)]_6\ (L_4)][PF_6]_6$
(**4**) $[[CpRu(PPh_3)_2]_6(L_4)][PF_6]_6$

Compounds were characterized by elemental analyses, IR, ^1H ^{31}P, and ^{13}C NMR as well as UV–Visible and cyclic voltammetric methods. The IR spectra of the complexes exhibit the expected bands due to ν(N=P) and ν(CN) modes of the free ligand as well as the $\nu(PF_6)$

(**10**) $[CpFe(dppe)]_6(L_5)][PF_6]_6$	18.54	93.6		
(**11**) $[CpRu(PPh_3)_2]_6(L_5)][PF_6]_6$	18.0		34.93	

An heptuplet signal at −148 ppm corresponding to PF_6 anion was also observed.

band. Values are displayed in Table 1. Characteristic splitting of the ν(N=P) bands due to coordination of metal halide to CN groups for dendrimer L_1 and L_4 have been observed recently [9a]. A similar but lesser effect was observed for complexes (**1**)–(**4**). Thus, this splitting pattern appears to be typical of metal coordination [9,10]. The complexes (**1**)–(**4**) exhibit the expected ^{31}P signal for the N_3P_3 ring namely a singlet sligtly shifted to lower values by coordination effects. This small decrese in the ^{31}P chemical shift is typical of coordination of organometallic fragments [10]. On the other hand the ^{31}P signal of the dppe ligand ligated to CpFe fragment for the complexes (**1**) and (**3**) was observed as normal at 100 ppm while the signal of PPh_3 coordinated to the fragment CpRu was normally observed at 44 and 42 ppm. The PF_6 anion was normally observed as a septuplet around −148 ppm. From the ^{13}C NMR spectrum of complexes, it can be clearly corroborated the presence of the groups (OC_6H_5), (OC_6H_4X) $X = CH_2CN$, PPh_2, of the ligands as well as the typical signals of the fragments $P(C_6H_5)_3$ and C_5H_5 (see Section 3).

Thus, these data compare well with those of the nitrile mononuclear model complexes {CpFe(dppe)-NCR][PF_6]} [12], as well as other cyclophosphazene organometallic derivatives [10].

2.2.2. The iron and ruthenium derivatives of the ligand L_3

Following a previously reported procedure [13], the complexes:

(5) [CpFe(dppe)(L_3)][PF_6]

(6) [CpRu(PPh_3)$_2$(L_3)][PF_6]

were synthesized from the reaction of the respective organometallic with L_3 in methanol as solvent and using NH_4PF_6 as halide abstractor. As model, we have also prepared the new complex:

(7) [CpFe(dppe)$PPh_2C_6H_4OH$][PF_6]

by reaction of the known $PPh_2C_6H_4OH$ [8d] with the iron organometallic.

The new complexes (**5**)–(**6**) were characterized by elemental analyses, IR, ^{1}H and ^{31}P NMR, UV–Visible and cyclic voltammetric methods. IR and NMR data for the complexes are not unusual and they are displayed in Tables 1–3 and in Section 3. It is interesting to mention the ν(OH) of (**7**) at 3420 cm^{-1} and the ^{31}P signal of the PPh_2 group at 4.6 ppm significantly shifted from the free value −10 ppm. Similar shifting for the complexes (**5**) and (**6**) were observed. As observed for another cyclophosphazenes and polyphosphazenes containing phosphines [8d] a small fraction of phosphine phosphorus as $O=PPh_2$ was detected by the signals at 28.63 and 26.61 ppm for **5** and **6**, respectively.

2.2.3. Iron and ruthenium derivatives of the ligands L_2 *and* L_5

These compounds were synthesized using the usual methodology for preparing iron–nitrile and ruthenium–nitrile complexes [10,12]:

(8) [CpFe(dppe)($\mathbf{L}_2$)][PF_6]

(9) [CpRu(PPh_3)$_2$($\mathbf{L}_2$)][PF_6]

(10) [[CpFe(dppe)]$_6$ ($\mathbf{L}_5$)][PF_6]$_6$

(11) [[CpRu(PPh_3)$_2$]$_6$($\mathbf{L}_5$)][PF_6]$_6$

Table 3
Electrochemical data for complexes **1**–**11**

	$E1/2$ (V)	ΔE (V)
1	0.81	0.11
2	0.53	0.06
3	0.81	0.14
4	0.50	0.06
5	0.88	0.10
6	0.570	0.088
7	0.884	0.092
8	0.775	0.080
9	0.613	0.073
10	0.767	0.263
11	0.590	0.091

Potential referenced against Ag/AgCl, at 100 mV s^{-1} scan rate, in a 0.1 mol dm^{-3} n-Bu_4N[PF_6].

The compounds were characterized by elemental analyses, IR, ^{1}H, ^{31}P, as well as UV–Visible and cyclic voltammetric methods. The IR spectra of complexes exhibit the expected bands due to ν(N=P) and ν(CN) modes of the free ligand as well as the ν(PF_6) band. Values are displayed in Table 1, The characteristic spliting of ν(N=P) upon coordination was also observed. A decrease of the ν(CN) band upon coordination suggest the link of the ligand through the CN group instead of the N(CH_3) group of the ligand. The complexes (**8**)–(**11**) exhibit the expected ^{31}P signal for the N_3P_3 ring, namely, a singlet (for (**10**) and (**11**)) or a triplet and doublet signals (for (**8**) and (**9**)) at sligthly shifted lower values by coordination effects. As previously mentioned this small decrease of the ^{31}P chemical shift is typical of organometallic fragments coordination [10]. On the other hand, the ^{31}P signal of the dppe ligand ligated to CpFe fragment for the complexes (**8**) and (**10**) was normally observed at 92.4 and 93.6 ppm, respectively. The signal of PPh_3 coordinated to the fragment CpRu was observed at 34.6 and 34.9 ppm for (**9**) and (**11**), respectively. The PF_6 anion was normally observed as a septuplet around −142 ppm. Relatively fast decomposition of the samples in solution precludes the measurements of good ^{13}C NMR spectrum for the complexes.

As previously reported [10c] the ^{31}P chemical shift parameter $\Delta = |\delta\ ^{31}\text{P(free ligand)} - \delta\ ^{31}\text{P(complex)}|$ in the systems similar to the organometallic derivatives (**1**), (**2**), (**5**), (**6**), (**8**) and (**9**) is a measure of the electron transfer between the phosphorus atom and the metal atom. From ^{31}P NMR data shown in Table 2 it can be viewed that the Δ parameter is greater for the ruthenium derivatives than for the iron complexes. Thus this parameter does not correlates with the distance of the X spacer as found in another similar systems [10c].

2.2.4. UV–Visible spectra of the complexes

The UV–Visible spectrum of the complexes is dominated by both, the organometallic chromophore and by the nature of the CN or PPh_2 groups linked to the metal. Iron complexes having the CpFe(dppe) moiety exhibits well defined absorption maxima arounds 450 nm depending of the N or P donor interaction [10,12,13]. Less intense shoulders arounds 526 and 600 nm have been assigned to the metal–ligand charge transfer transitions (MLCT) [12]. Fig. 1 exhibits the UV–Visible spectrum of (**8**). Data are shown in Section 3. On the contrary the ruthenium containing dendrimers (**9**) and (**11**) exhibits a tail beginning around 500 nm, of a more intense absorption band centered at 350 nm. Thus these absorption patterns are typical of [CpFe(dppe)NCR][PF_6], [10,12] of [CpFe(dppe)PPh_2-R][PF_6] [13], [CpRu(PPh_3)$_2$ NCR][PF_6] [10,12] and [CpRu(PPh_3)$_2$$PPh_2$-R][$PF_6$] [13] complexes.

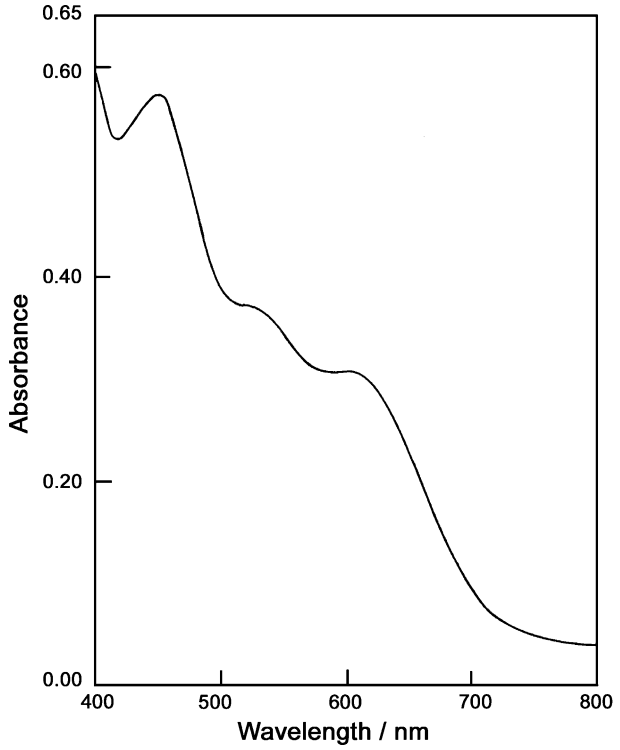

Fig. 1. UV–Visible spectrum for (**8**) in CH_2Cl_2 solution at room temperature.

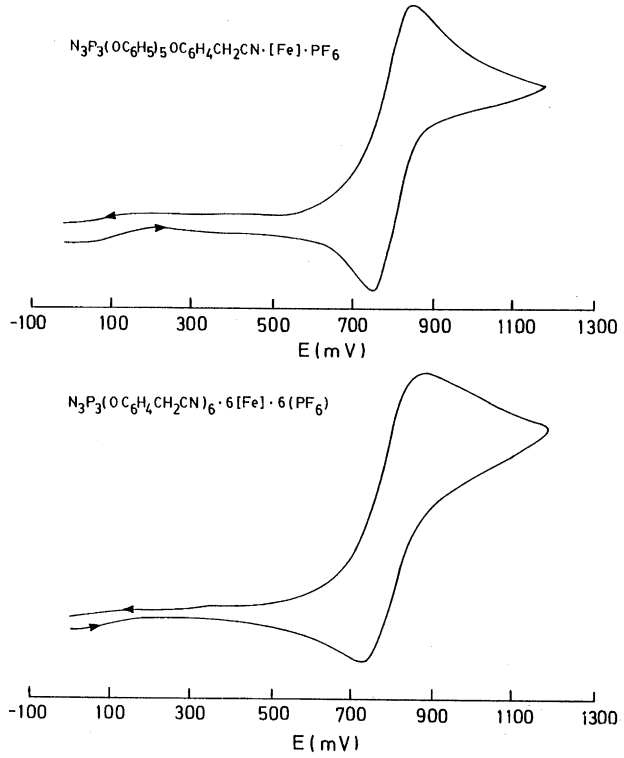

Fig. 2. Cyclic voltammogram of complexes (**1**) and (**3**) on a graphite electrode ($v = 100$ mV s^{-1}) of a CH_2Cl_2(n-$Bu_4N^+PF_6^-$ solution) containing: complex (**1**), (2.11×10^{-3}M) curve upper, and complex (**3**), (3.4×10^{-4}M) curve lower.

2.2.5. Cyclic voltammetry studies

There are few reports of electrochemical studies on cyclophosphazene metal complexes [8–10], Cyclic voltammetry for these type of systems provides some insight into the communication degree between the metal centers along the cyclophosphazene [4]. For all the studied complexes one single oxidation wave was observed. In Fig. 2, the cyclic voltammogram of complex (**1**) having one fragment CpFe(dppe) (symbolized [Fe] in the figure) is compared with that containing six iron group the complex (**3**). As shown in Fig. 2, similar CV (similar intensities and shapes) are obtained, being the concentration of the dendrimer (**1**) six times more larger than the complex (**3**), which indicated that their oxidation wave involves the transfer of six electrons at the same potential. Then, the six CpFe(dppe) groups behave as six electroactive non-interacting redox centers around the periphery of the cyclosphosphazene ring.

As is usually observed for this type of organometallic compounds [8–10], only quasi-reversible waves were observed in all the cases. From Table 3 it can be observed that the potential values clearly depend on the π-acceptor capacity of the group linked to the organometallic fragment. For the fragment CpFe(dppe) the most π-acceptor phosphorus induce the highest electron witdrawing effect provoking the most highest potential value, ≈0.88 V. Consistent with this, the weakest π-acceptor ligand nitrile, decrease their potential values in an amount which depend on the nature of the spacer (X in the Scheme 2). In the $CpRu(PPh_3)_2$ series the opposite tendency was observed. In this case, inductive effects of the group spacer increasing in the order $-C_6H_4O >$ $N(CH_2)_2$ could explain the observed order of the potential.

3. Experimental

3.1. General considerations

Infrared spectra were recorded on a FT-Bruker-66V spectrophotometer in Nujol. NMR spectra were recorded on a Bruker AMX 300 spectrometer in chloroform-d_1 with TMS (H) $\delta = 0.0$ ppm as internal standard or 85% H_3PO_4 and downfield positive to the reference as external standard for the ^{31}P measurements.

UV–Visible absorption spectra were recorded using a Varian DMS-90 spectrophotometer with 1 cm optical path cuvettes in CH_2Cl_2 solutions. Elemental analyses were performed on Fisons-Carlo Erba EA 1108, apparatus by CEPEDEQ, Universidad de Chile.

Mass spectra were recorded with a ICP-MS Fisons VG Plasma Quad mass spectrometers.

Electrochemical measurements were made on a Parc model 370 electrochemistry system, using a three electrode device, employing a carbon glassy working electrode, platinum wire counter electrode and saturated calomel reference electrode. Solutions were 10^{-3} M in the complex and 0.1 M in $[NBu_4]PF_6$ as supporting electrolyte. Under the same experimental conditions, $E1/2$ for the ferrocene–ferrocenium complex was 0.64 V with peak separations of about 0.060 V (internal standard). Reactions were carried out under nitrogen using standard Schlenk-tube techniques. Diethylether and *n*-hexane were dried over sodium and distilled.

$N_3P_3Cl_6$, HO–C_6H_4–CH_2CN, $HNCH_3CH_2CH_2CN$, NH_4PF_6 and $CpRu(PPh_3)_2Cl$ were purchased from Aldrich. CpFe(dppe)I was prepared by a previously reported method [9,10]. $N_3P_3(O–C_6H_5)_5Cl$ was prepared using a previously reported method [10b].

3.2. Preparation of ligand and complexes

3.2.1. Ligands

3.2.1.1. Synthesis of $N_3P_3(O–C_6H_5)_5(O–C_6H_4–CH_2–CN)$ (L_1). A mixture of $N_3P_3(O–C_6H_5)_5Cl$ 2.3 g, (3.62 mmol); HO–C_6H_4–CH_2–CN 0.5 g; (3.75 mmol), K_2CO_3 0.97 g; (7.02 mmol) and $[Bu_4N]Br$ 1.7 g; (5.27 mmol) was refluxed in acetone (40 ml) for 20.17 h. The solution was filtered through celite and the solvent evaporated in vacuo. The red oil residue was extracted with toluene to give a red solution. *n*-Hexane was added to obtain a ligth red oil, which was washed with *n*-hexane and dried under reduce pressure. Mass spectrum (m/e) 732 M^+. Calc. (732); 691 (M^+-CH_3CN)-^{1}H NMR ($CDCl_3$): 7.1–6.9 (m, OC_6H_5), 6.83–6.73 (m OC_6H_4), 3.71, 3.53 (s, CH_2). ^{13}C NMR ($CDCl_3$, ppm): 150.91, 129.9, 125.46, 121.24, 117.87 (OC_6H_4X), 150.91, 129.21, 121.24, 117.87 ($P(OC_6H_5)$), 116.95 (CN), 24.19 (CH_2). UV/Vis(CH_2Cl_2): $\lambda = 232$ nm.

3.2.1.2. Synthesis of $N_3P_3(O–C_6H_4–CH_2–CN)_6$ (L_4). A mixture of $N_3P_3Cl_6$ 0.26 g, (0.75 mmol); HO–C_6H_4–CH_2–CN 0.8 g; (6 mmol), K_2CO_3 1.54 g; (11.14 mmol) and $[Bu_4N]Br$ 1.5 g; (4.65 mmol) was refluxed in acetone (30 ml) for 51 h. The red solution was filtered through celite and the solvent evaporated in vacuo. The red oil residue was dried in vacuum and extracted with dichloromethane and filtered through celite and dried to obtain a ligth red oil, which was dried under reduce pressure. Mass spectrum (m/e) 927 M^+ Calc. (927), 886 (M^+-CH_3CN). ^{1}H NMR (CD_2Cl_2): 7.21–6.93 (m, OC_6H_4) 1.63, 1.43(s, CH_2). ^{13}C NMR ($CDCl_3$): 129.73, 125.63, 121.79, 118.54 (OC_6H_4X): 117.36 (CN), 24.43 (CH_2). UV/Vis(CH_2Cl_2): $\lambda = 234$ nm.

3.2.1.3. Synthesis of $N_3P_3(OC_6H_5)_5N(CH_3)(CH_2)_2CN$ (L_2). A mixture of $N_3P_3(O–C_6H_5)_5Cl$ 1.05 g, (1.65 mmol); $HN(CH_3)(CH_2)_2CN$ 0.154 ml; (1.65 mmol), NEt_3 0.229 ml; (1.65 mmol) were refluxed in benzene (35 ml) for 72 h. The solution was evaporated in vacuo and the yellow pale oil residue was poured into water and was extracted with dichloromethane. The extract was dried over sodium sulphate and filtered trough celite and the same solvent evaporated under vacuum to give a white solid. *Anal.* Calc. for $C_{34}H_{27}O_5N_5P_3$: C, 59.76; H, 4.68; N, 10.25; P, 13.01. Found: C, 57.67; H, 4.25; N, 6.96; P, 13.61%. ^{1}H NMR (CD_2Cl_2): 7.3–7.0 (m, C_6H_5), 2.56 (d, CH_3 $J_{PNH} = 11$ Hz), 2.99 (m, CH_2), 2.03 (t, CH_2). ^{13}C NMR ($CDCl_3$, ppm): 150.59, 129.82, 125.49, 121.35 (P-OC_6H_5), 118.54(CN), 45.56(CH_2), 34.158CH_2), 17.14(CH_3).). UV/Vis(CH_2Cl_2): $\lambda = 261$ nm.

3.2.1.4. Synthesis of $N_3P_3(N(CH_3)(CH_2)_2CN)_6$ (L_5). A mixture of $N_3P_3Cl_6$ 5 g, (14.38 mmol); $HN(CH_3)(CH_2)_2CN$ 8.068 ml (86.31 mmol), in NEt_3 11.96 ml; (86.31 mmol) were refluxed in bencene (50 ml) for 10 h. The pale yellow solution was filtered and the solvent evaporated in vacuo. The oil residue was redissolved in a *n*-hexane/dichloromethane mixture. Purification of the product mixture was made by chromatography using neutral alumna. Elution with a *n*-hexane/dichloromethane mixture and collection of the transparent fraction followed by evaporation under vacuum afford a ligth yellow oil, which was dried under reduce pressure. *Anal.* Calc. for $C_{24}H_{42}N_{15}P_3$; C, 45.51; H, 6.63; N, 33.18; P, 14.30. Found: C, 43.24; H, 6.71; N, 28.03; P, 14.69%. ^{1}H NMR ($CDCl_3$): 2.78 (m C**H**$_2$CN), 2.69(s, CH_3), 2.6(m C**H**$_2$N). ^{13}C NMR ($CDCl_3$): 118.47 (CN), 45.71 (CH_2), 33.58 (CH_2), 17.60(CH_3).

3.2.1.5. Synthesis of $N_3P_3(O–C_6H_5)_5(O–C_6H_4–PPh_2)$ (L_3). A mixture of $N_3P_3(O–C_6H_5)_5Cl$ 0.3052 g, (0.48 mmol); HO–C_6H_4–PPh_2 0.1214 g; (0.849 mmol), Cs_2CO_3 0.294 g; (0.9 mmol) were refluxed in acetone (30 ml) for 2 h. The solution was filtered through celite and the solvent evaporated in vacuo. The yellow pale oil residue was extracted with toluene to give a red solution. *n*-Hexane was added to obtain a ligth red oil, which was washed with *n*-hexane and dried under reduce pressure. *Anal.* Calc. for $C_{48}H_{39}O_6N_3P_4$: C, 65.67; H, 4.78; N, 4.78; P, 13.9. Found: C, 64.28; H, 4.26; N, 4.26; P, 14.14%. ^{1}H NMR (CD_3Cl): 7.1–7.3 (m OC_6H_5), 7.0–6.9 (m, C_6H_4), 3.75 (s, CH_2). ^{13}C NMR ($CDCl_3$, ppm): 151.06, 134.96, 133.47, 125.2, 121.22, 115.87 (OC_6H_4X) 135.74, 133.47, 129.46, 128.76 (–PPh_2), 150.17, 128.41, 124.88, 120.97 (P–OC_6H_5). UV/Vis(CH_2Cl_2): $\lambda = 230$ nm.

3.2.2. Complexes

*3.2.2.1. Synthesis of $[N_3P_3(O–C_6H_5)_5(O–C_6H_4–CH_2–CN)\cdot Fe(Cp)dppe]PF_6$ (**1**).* A mixture of $N_3P_3(O–C_6H_5)_5(O–C_6H_4–CH_2–CN)$ 0.23 g (0.31 mmol), and

CpFe(dppe)I 0.2 g (0.31 mmol) in methanol (20 ml), in presence of NH_4PF_6 0.2 g (1.23 mmol) was stirred for 21 h at room temperature. The solvent was removed under reduced pressure and the residue extracted with CH_2Cl_2 and filtered through celite and concentrated to ≈10 ml. A *n*-hexane/diethylether 4:1 mixture was added and the red powdered precipitate was twice washed with the same solvent mixture and dried under reduced pressure.

Yield: 0.25 g, 49%. *Anal*. Calc. for $C_{69}H_{60}F_6O_6N_4P_6Fe$: C, 61.99; H, 5.00; N, 4.01; P, 13.32. Coupled electron-transfer and spin-exchange reactions of metal–bis[tris(pyrazolyl)methane] complexes

Josie R. Sheets, Franklin A. Schultz *

Department of Chemistry, Indiana University-Purdue University Indianapolis, 402 North Blackford Street, Indianapolis, IN 46202-3274, USA

Received 15 September 2003; accepted 2 January 2004

Abstract

Coupled electron-transfer and spin-exchange reactions of metal(II)–bis[tris(pyrazolyl)methane] complexes, $[M(tpm)_2]^{2+}$, with M = Mn, Fe, Co, or Ni and tpm = $HC(pz)_3$ or $HC(3,5\text{-}Me_2pz)_3$ are reported. Apparent heterogeneous electron-transfer rate constants, $(k_{s,h})_{app}$, for $[M(tpm)_2]^{2+}$ to $[M(tpm)_2]^{3+}$ oxidations are determined from the scan rate dependence of cyclic voltammetric peak potential separations, ΔE_p. Consistent with the expectation that electron-transfer reactions that are accompanied by a change in spin-state are slower than those that are not, $(k_{s,h})_{app}$ for oxidation of high-spin (HS) $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ to low-spin (LS) $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+}$ is 10 times smaller than the value for oxidation of predominantly LS $\{Fe[HC(pz)_3]_2\}^{2+}$ to LS $\{Fe[HC(pz)_3]_2\}^{3+}$. In addition, very small values of $(k_{s,h})_{app}$ are observed for the one-electron oxidations of HS $\{Co[HC(pz)_3]_2\}^{2+}$ and HS $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$. The electrochemical, magnetic, and spectroscopic properties of $[M(tpm)_2]^{2+}$ complexes are similar to those of the corresponding tris(pyrazolyl)borate (pzb^-) complexes with the exception that, because of net charge considerations, the M(III/II) potential is ~1 V more positive for $[M(tpm)_2]^{3+/2+}$ than for $[M(pzb)_2]^{+/0}$ couples. The stability of $[M(tpm)_2]^{2+}$ complexes in CH_3CN and DMF solution is investigated by positive ion electrospray ionization mass spectrometry. It is demonstrated that $\{Fe[HC(pz)_3]_2\}^{2+}$ undergoes ligand dissociation in DMF.

1. Introduction

Poly(pyrazolyl)borate (pzb^-) ligands are well known for their ability to modulate the magnetic, spectroscopic, and catalytic properties of transition metal compounds [1–3]. Complexes containing the isoelectronic tris(pyrazolyl)methane ligand (tpm, Chart 1) [4] also possess this quality, and interest in these compounds is increasing [5]. Both pzb^- [6–8] and tpm [9,10] support spin-state isomerization in their homoleptic iron(II)-bis(ligand) complexes. Two interesting observations have been reported in this regard. (1) In the solid state, $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ undergoes a thermally induced spin-state transition in which the $Fe^{II}N_6$ center converts from all high-spin (HS, $S = 2$) above 206 K to a 50:50 mixture of HS and low-spin (LS, $S = 0$) forms below 200 K; the composition of the mixture does not change upon further decrease in temperature to 5 K [11–13]. (2) In *N*,*N*-dimethylformamide (DMF) solution, $\{Fe[HC(pz)_3]_2\}^{2+}$ is reported to exist as a slowly equilibrating mixture of LS and HS forms detectable by ^1H NMR spectroscopy [14]. Observation of such behavior is unusual [15], because spin-state conversions are rapid processes in solution [16].

Our laboratory is interested in the mechanism and energetics of coupled electron-transfer and spin-exchange reactions [17–21]. These transformations occur as closely coupled events in many chemical and biological systems, and underlie important catalytic processes [22]. Recently, in surveying the electrochemical, magnetic, and spectroscopic properties of metal–bis(pzb) complexes, we detected examples of coupled electron-transfer and spin-exchange and reported on the influence of metal and ligand structure on such behavior

$HC(pz)_3$ R = H

$HC(3,5\text{-}Me_2pz)_3$ R = CH_3

Chart 1. Structures of tris(pyrazolyl)methane (tpm) ligands.

[21]. The present article extends this study to the analogous $[M(tpm)_2]^{2+}$ complexes with M = Mn, Fe, Co, or Ni and tpm = $HC(pz)_3$ or $HC(3,5\text{-}Me_2pz)_3$. Its objectives are to identify additional examples of coupled electron-transfer and spin-exchange and to compare behavior with that of the corresponding pzb^- complexes. In addition, some observations regarding the behavior of $\{Fe[HC(pz)_3]_2\}^{2+}$ in DMF solution are reported.

2. Experimental

2.1. Materials

The $HC(pz)_3$ and $HC(3,5\text{-}Me_2pz)_3$ ligands were prepared from chloroform and the appropriate pyrazole following procedures closely adapted from those of Reger et al. [23]. Details are given in [24]. $\{M[HC(pz)_3]_2\}(BF_4)_2$ and $\{M[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ with M = Fe, Co, and Ni were prepared by drop wise addition of an acetone or tetrahydrofuran (THF) solution of the ligand (2.0 mmol in 10 ml) to a stirred aqueous solution of the hydrated metal(II) tetrafluoroborate (Aldrich, 1.0 mmol in 10 ml). The $HC(pz)_3$ complexes formed as insoluble salts almost immediately. The $HC(3,5\text{-}Me_2pz)_3$ complexes began to form within 5–15 min. These reaction mixtures were stirred overnight to insure complete product formation. $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ formed more slowly than the other complexes. In this case, a 2.5:1 ligand-to-metal mole ratio in THF solvent was employed. Product formation was observed to begin after ca. 30 min, and the reaction mixture was stirred overnight. $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}(NO_3)_2$ was prepared in a manner analogous to the other $HC(3,5\text{-}Me_2pz)_3$ complexes by use of hydrated manganese(II) nitrate. A manganese(II) complex with $HC(pz)_3$ could not be prepared. Products were isolated by filtration, washed with water and acetone, and air-dried. Yields were 52–82%. Elemental analyses were performed by Huffman Laboratories (Golden, CO).

Acetonitrile and DMF used for electrochemical and spectroscopic studies were obtained as high purity Burdick and Jackson reagents from VWR and used as received. Tetra-*n*-butylammonium hexafluorophosphate ($TBAPF_6$) supporting electrolyte was used as received from Aldrich.

2.2. Methods

Cyclic voltammetry (CV) experiments were performed by use of a Bioanalytical Systems (BAS) CV-50W potentiostat and employed a three-electrode cell consisting of a BAS glassy carbon working electrode (0.071 cm^2 area), a BAS Ag/AgCl reference electrode (0.236 V versus NHE [25]), and a Pt wire auxiliary electrode. The glassy carbon electrode was polished with diamond paste or an aqueous slurry of alumina prior to each trial. CV experiments were conducted in CH_3CN or DMF solutions containing 1 mM complex and 0.1 M $TBAPF_6$. Solutions were deoxygenated with argon gas and maintained under a blanket of Ar during measurements. Formal potentials were evaluated as $E^{0\prime} = (E_{pa} + E_{pc})/2$, where E_{pa} and E_{pc} are the anodic and cathodic peak potentials. Peak potential separations were evaluated as $\Delta E_p = |E_{pa} - E_{pc}|$. The ferrocene/ferricenium couple ($Fc^{+/0}$) exhibits an $E^{0\prime}$ value of 0.43 V versus Ag/AgCl in 0.1 M $TBAPF_6/CH_3CN$.

Apparent values of the standard heterogeneous electron-transfer rate constant, $(k_{s,h})_{app}$, were determined from cyclic voltammetric peak potential separations as a function of scan rate [26]. Measured values of ΔE_p were corrected for uncompensated solution resistance as described in [27] using a value of $\rho = 1.3 \times 10^2$ Ω cm [28] for the specific resistance of 0.1 M $TBAPF_6/CH_3CN$. The relationship between ΔE_p and $(k_{s,h})_{app}$ was established by digital simulation (DigiSim 3.03, Bioanalytical Systems [29]) using values of $\alpha = 0.50$, $D = 8.0 \times 10^{-6}$ $cm^2\ s^{-1}$, and $T = 295$ K.

The magnetic susceptibilities of solid samples of the complexes were determined by use of a Johnson Matthey MSB-1 balance at ambient temperature (295 K). The molar susceptibility, χ_M, determined as $\chi_M = \chi_V \times MW/\rho$ from the volume susceptibility (χ_V), density (ρ), and molecular weight (MW) of the sample, was corrected for the diamagnetic contributions of the ligands, metal core electrons, and counter ions [30] to yield $\chi_{M'}$. The effective magnetic moment was calculated as $\mu_{eff} = 2.83(\chi_{M'} \times T)^{1/2}$.

Electrospray ionization mass spectrometry was performed by use of a PE Sciex API III mass analyzer. Dinitrogen, obtained as the boil-off of liquid N_2, was employed as the curtain gas (0.8–1.0 l min^{-1}). The normal operating pressure and temperature were ca. 3×10^{-5} atm and 17 K, respectively. A syringe pump set

at a flow rate of 2–10 μl min^{-1} was used to introduce 1×10^{-3} M solutions of the complexes in CH_3CN or DMF.

Electronic spectra were obtained by use of an Agilent 8453A or a PE Lambda 19 spectrometer. Variable temperature measurements were conducted on the PE instrument equipped with a Neslab RTE-111 temperature control unit.

3. Results

3.1. Synthesis

The complexes were formed by addition of an acetone or THF solution of the ligand to an aqueous solution of the hydrated metal salt. Either acetone or THF is a suitable solvent for these preparations, but a more lustrous microcystalline product is obtained by use of acetone. All results reported are for acetone derived materials with the exception of $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$, in which case it is necessary to use THF as solvent. Elemental analyses are presented in Table 1 and are consistent with the formulation of the products as metal(II)–bis[tris(pyrazolyl)methane] complexes.

3.2. Magnetism and spectroscopy

Magnetic moments of the divalent bis(tpm) salts are collected in Table 1. Results are consistent with a high-spin metal(II) center in all cases except $\{Fe[HC(pz)_3]_2\}(BF_4)_2$, where the value $\mu_{eff} = 0.98\ \mu_B$ is indicative of predominantly low-spin Fe(II). The red-violet color of $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ in comparison with the colorless appearance of $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ is consistent with this observation. The spin-equilibrium behavior of $\{Fe[HC(pz)_3]_2\}^{2+}$ in CH_3CN solution was investigated by visible spectroscopy. The complex exhibits a ligand field absorption band at 523 nm, which obeys Beer's law at 295 K. The intensity of the band increases upon cooling. Analysis of the temperature-dependent absorbance, $A(T)$, from 283 to 338 K by use of following equation [31]:

$$A(T) = A(0)/[\exp(\Delta S^0_{SE}/R)\exp(-\Delta H^0_{SE}/RT) + 1], \quad (1)$$

where $A(0)$ is the absorbance at 0 K (obtained by extrapolation), yields values of $\Delta H^0_{SE} = 25$ kJ mol^{-1}, $\Delta S^0_{SE} = 63$ J mol^{-1} K^{-1}, $\varepsilon_{LS} = 81$ M^{-1} cm^{-1}, and $K^{298}_{SE} = 0.08$ for the $LS \leftrightarrows HS$ equilibrium of $\{Fe[HC(pz)_3]_2\}^{2+}$. These findings are in agreement with the results of McGarvey et al. [9] and indicate the

[a] At 295 K.

presence of ~7% high-spin $\{Fe[HC(pz)_3]_2\}^{2+}$ in CH_3CN solution at 295 K. In contrast, the red-violet color of $\{Fe[HC(pz)_3]_2\}^{2+}$ and its 523-nm absorption band disappear when $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ is dissolved in DMF. These features are partially restored by addition of excess $HC(pz)_3$.

The principal peaks observed by positive ion electrospray mass spectrometry of acetonitrile solutions of the complexes are collected in Table 1. The major signals observed are those corresponding to the doubly charged molecular ion, $[M(tpm)_2]^{2+}$, and to its 1:1 ion pair, $\{[M(tpm)_2](BF_4)\}^{+}$. The mass spectrum of $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ in CH_3CN (Fig. 1(a)), which exhibits peaks at $m/z = 242.0$ ($\{Fe[HC(pz)_3]_2\}^{2+}$) and $m/z = 570.9$ ($\{Fe[HC(pz)_3]_2(BF_4)\}^{+}$), illustrates this behavior. Surprisingly, this compound exhibits a very different mass

spectral response in DMF. As shown in Fig. 1(b), peaks corresponding to the molecular ions are absent and are replaced by peaks assignable to species such as $[Fe(DMF)_6]^{2+}$ ($m/z = 247.8$), $\{Fe[HC(pz)_3]\text{-}(DMF)_4\}^{2+}$ ($m/z = 281.2$), $[Fe(DMF)_5(BF_4)]^{+}$ ($m/z = 508.2$), and $\{Fe[HC(pz)_3](DMF)_3(BF_4)\}^{+}$ ($m/z = 576.1$). In contrast, the mass spectrum of $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ in DMF is unchanged from that in CH_3CN.

3.3. Electrochemistry

The electrochemical behavior of the $[Fe(tpm)_2]^{2+}$ complexes in CH_3CN is illustrated in Fig. 2. Cyclic voltammetric data as a function of scan rate (v) are collected in Table 2. Each complex exhibits a chemically reversible oxidation at ca. 1.1 V corresponding to the electrode reaction in Eq. (2) with M = Fe

$$[M(tpm)_2]^{2+} \leftrightarrows [M(tpm)_2]^{3+} + e^- \quad E^{0\prime}, (k_{s,h})_{app} \qquad (2)$$

For $\{Fe[HC(pz)_3]_2\}^{2+}$, i_p varies linearly with $v^{1/2}$, $i_p/v^{1/2}$ AC exhibits a constant value of 780 ± 20 μA $s^{1/2}$ $V^{-1/2}$ cm^{-2} mM^{-1} that is consistent with a one-electron transfer in CH_3CN [32], and ΔE_p increases to a small extent above the anticipated value of 58 mV [26] as v increases from 0.05 to 1.0 V s^{-1}. These increments in ΔE_p are only 5–10 mV larger than the amounts calculated to arise from the uncompensated solution resistance of 0.1 M $TBAPF_6/CH_3CN$ [27] and are consistent with a value of $(k_{s,h})_{app} \geqslant 0.2$ cm s^{-1} for the $\{Fe[HC(pz)_3]_2\}^{3+/2+}$ couple. For $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$, the anodic wave broadens, the variation of i_p with $v^{1/2}$ is not rigorously linear, and ΔE_p increases to a much greater extent as v is increased over the same scan rate interval. These results are consistent with charge-transfer limitation of the electrode reaction [26]. Comparison of the experimental scan rate dependence of ΔE_p with that obtained by digital simulation leads to a value of $(k_{s,h})_{app} = 1.7 \pm 0.7 \times 10^{-2}$ cm s^{-1} for $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+/2+}$.

The electrochemical behavior of $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ in DMF is similar to that observed in CH_3CN. However, the anodic and cathodic responses that are characteristic of Eq. (2) with M = Fe vanish

Table 3

when $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ is dissolved in DMF. They are replaced by a kinetically sluggish electrode reaction whose characteristics ($E^{0\prime} = 0.6$ V, $i_{pr}/i_{pf} \sim 1$, $\Delta E_p =$ mV at $v = 0.3$ V s^{-1}) are similar to those that appear when $[Fe(H_2O)_6](BF_4)_2$ is added to 0.1 M $TBAPF_6$/DMF. Addition of excess $HC(pz)_3$ to either $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ or $[Fe(H_2O)_6](BF_4)_2$ dissolved in DMF partially restores the voltammetric response at 1.1 V.

The complexes $\{Co[HC(pz)_3]_2\}^{2+}$ and $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ also are electrochemically active in CH_3CN. $\{Co[HC(pz)_3]_2\}^{2+}$exhibits a broad anodic wave extending from 0.8 to 1.6 V that is followed by a more well-defined cathodic peak at 0.6 V on scan reversal (Fig. 3(a)). $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ undergoes oxidation at 1.2–1.6 V followed by a cathodic peak at 1.0 V (Fig. 3(b)). A poorly defined voltammetric oxidation wave (not shown) is observed for $\{Co[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ in CH_3CN. The Ni(II) complexes could not be oxidized within the potential window of the solvent.

The electrochemical responses illustrated in Fig. 3 are assigned to the one-electron electrode reactions described by Eq. (2) with M = Co or Mn. The reactions are electrochemically irreversible, and it is evident based on peak potential separations that the heterogeneous electron-transfer kinetics of these couples are much slower than those of the $[Fe(tpm)_2]^{3+/2+}$ couples. Values of $(k_{s,h})_{app} = 1.3 \times 10^{-6}$ and 7.6×10^{-5} cm s^{-1} are estimated for $\{Co[HC(pz)_3]_2\}^{3+/2+}$ and $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+/2+}$, respectively. Electrochemical data for all $[M(tpm)_2]^{3+/2+}$ couples are summarized in Table 3, where they are compared with results for the corresponding $[M(pzb)_2]^{+/0}$ complexes in 1,2-dichloroethane. Because of the difference in solvents, electrode potentials are referred to the $E^{0\prime}$ of $Fc^{+/0}$.

4. Discussion

4.1. Electrochemical, magnetic, and spectroscopic properties

The homoleptic $[M(tpm)_2]^{2+}$ complexes with M = Mn, Co, and Ni exhibit magnetic and spectroscopic properties that are consistent with assignment of these compounds as HS metal(II) species (Table 1). The magnetic properties of the $[Fe(tpm)_2]^{2+}$ complexes are influenced by the identity of the pyrazole ring substituents. $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ is entirely HS, whereas $\{Fe[HC(pz)_3]_2\}^{2+}$participates in a LS ⇆ HS equilibrium that produces ~7% HS Fe(II) in solution at 295 K. The corresponding $Fe[HB(3,5\text{-}Me_2pz)_3]_2$ and $Fe[HB(pz)_3]_2$ complexes exhibit similar behavior [6–8,20].

Although the magnetic and spectroscopic properties of metal–bis(tpm) and metal–bis(pzb) complexes are quite similar, their electrochemical properties are distinct. As documented in Table 3, values of $E^{0\prime}$ are about 1 V more positive for $[M(tpm)_2]^{3+/2+}$ than for $[M(pzb)_2]^{+/0}$ couples. The difference reflects the importance of net charge on the metal-centered oxidation potentials. However, it is noteworthy that the $\{M[HC(pz)_3]_2\}^{3+/2+}$ potentials also are 0.9–1.7 V more positive than the $E^{0\prime}$ values of the corresponding $[M(tacn)_2]^{3+/2+}$ (tacn = 1,4,7-triazacyclononane) complexes and approximately equal to (or in the case of $\{Co[HC(pz)_3]_2\}^{3+/2+}$ more positive than) the $E^{0\prime}$ values of $[M(bpy)_2]^{3+/2+}$ (bpy = 2,2′-bipyridine) [21]. These observations indicate that tris(pyrazolyl)methane is highly effective in stabilizing M(II) versus M(III) oxidation states.

The tris(pyrazolyl)methane complexes described in this work also undergo coupled electron-transfer and spin-exchange reactions. As shown in Table 3, the apparent kinetics of reaction (2) are a function of the metal ion and the ligand. These factors also influence spin-state distributions. On the basis of ligand field considerations [33], the M(III) species are assigned a low-spin configuration. This is based on the observation that in the corresponding $[M(pzb)_2]^+$ and $[M(tacn)_2]^{3+}$ complexes, where pzb^- and tacn exhibit a ligand field strength comparable to that of tpm [21], the metals also are low-spin. Thus, the largest value of $(k_{s,h})_{app}$ for $[M(tpm)_2]^{3+/2+}$ couples is observed for the reaction in which predominantly LS $\{Fe[HC(pz)_3]_2\}^{2+}$ is oxidized to LS $\{Fe[HC(pz)_3]_2\}^{3+}$. Oxidation of HS $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ to LS $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+}$, which is accompanied by spin conversion, exhibits a value of $(k_{s,h})_{app}$ that is 10 times smaller. The relative values of $(k_{s,h})_{app}$ for $Fe[HB(pz)_3]_2^{+/0}$ and $Fe[HB(3,5\text{-}Me_2pz)_3]_2^{+/0}$ are quite similar (Table 3). These results are consistent with the expectation [34–36] that electron-transfer reactions that are accompanied by a change in spin state are slower than those that are not. Such behavior can be interpreted [19,20] in terms of the mechanistic pathway shown in Fig. 4 (an electrochemical scheme of squares [37]), wherein spin-exchange is viewed as a rapidly established chemical equilibrium that decreases $(k_{s,h})_{app}$ by depleting the population of forms involved in electron-transfer. Relationships between $(k_{s,h})_{app}$ and the thermodynamic spin-equilibrium parameters that describe these distributions are derived in [19,20].

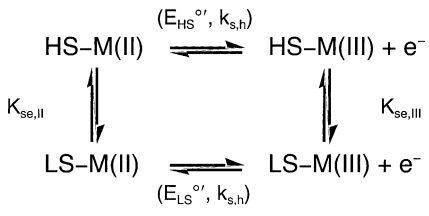

Fig. 4. Mechanism of coupled electron-transfer and spin-exchange.

Slow charge transfer also is observed for $\{Co[HC(pz)_3]_2\}^{3+/2+}$ and $\{Mn[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+/2+}$. In these cases, $(k_{s,h})_{app}$ is much smaller than it is for $\{Fe[HC(pz)_3]_2\}^{3+/2+}$ or $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{3+/2+}$. Moreover, $(k_{s,h})_{app}$ is uniformly 10–100 times smaller for all $[M(tpm)_2]^{3+/2+}$ couples in comparison to $[M(pzb)_2]^{+/0}$. These observations illustrate that metal ion and ligand can alter the apparent kinetics of reactions that involve coupled electron-transfer and spin-exchange. A possible explanation of this behavior is that reactions of this type must proceed through minor HS-M(III) or LS-M(II) intermediates, the populations of which can be very dependent on metal ion or ligand. Investigation of the basis for the observed range of kinetic behavior is continuing in our laboratory.

4.2. Solution behavior of $[Fe(tpm)_2]^{2+}$ complexes

The integrity of $[Fe(tpm)_2]^{2+}$ complexes is maintained in CH_3CN solution. However, $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ undergoes ligand dissociation when dissolved in DMF. Mass spectrometry provides the strongest evidence of this behavior. Ligand dissociation also is evident by visible spectroscopy and electrochemistry. Although discrete complexes such as $\{Fe[HC(3,5\text{-}Me_2pz)_3](H_2O)_3\}^{2+}$ [38] and $[Fe(1,4,7\text{-trimethyl-}1,4,7\text{-triazacyclononane})(CH_3CN)_3]^{2+}$ [39] have been produced under particular conditions, the mass spectrum in Fig. 1(b) suggests that a range of solvated products including completely dissociated forms is produced. Our results support the interpretation of Toftlund [15] that ligand dissociation rather than slow exchange of LS and HS forms of $\{Fe[HC(pz)_3]_2\}^{2+}$ [14] occurs in DMF.

$\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$ exhibits no evidence of ligand dissociation when dissolved in DMF. The difference in behavior between $\{Fe[HC(pz)_3]_2\}^{2+}$ and $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$ is surprising, because it is anticipated that the HS character of the latter complex would promote ligand dissociation. However, it was noted during synthesis that a longer reaction time and excess ligand were required to form $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}(BF_4)_2$, whereas $\{Fe[HC(pz)_3]_2\}(BF_4)_2$ was produced quickly. Thus, the kinetics of ligand binding and dissociation may be slower in the case of $\{Fe[HC(3,5\text{-}Me_2pz)_3]_2\}^{2+}$.

Abstract

The previously reported complex $[ReBr(CO)_3L]$ (L = 1,2-bis[diphenylphosphinite]ethane) was reacted with $AgBF_4$ in dichloromethane to yield *fac*-$[Re(ClCH_2Cl)(CO)_3L][BF_4]$ (**1**). By contrast, reaction of the same starting material with AgOTf (OTf = OSO_2CF_3) afforded the neutral complex *fac*-$[Re(OTf)(CO)_3L]$ (**2**). When **2** was treated with $NaBAr_F$ ($BAr_F = [B\{3,5\text{-}(CF_3)_2C_6H_3\}_4]$) in the same solvent, the complex *fac*-$[Re(ClCH_2Cl)(CO)_3L][BAr_F]$ (**3**) was formed. Substitution of the loosely held ligand CH_2Cl_2 in **1** and **3** resulted in the formation of compounds of the type $[Re(X)(CO)_3L][A]$ ($X = H_2O$, CH_3CN; $A = BF_4^-$, BAr_F^-), whereas the removal of OTf in **2** only was possible to form $[Re(NCCH_3)(CO)_3L][OTf]$. All the new complexes were characterized by ^1H, $^{13}C\{^1H\}$, $^{31}P\{^1H\}$ and $^{19}F\{^1H\}$ NMR as well as by IR spectroscopies. In the case of compounds **2** and $[Re(NCCH_3)(CO)_3L][BF_4]$, X-ray suitable crystals were isolated. In both cases, the Re atom adopts six-coordination by bonding to the three CO ligands, the two P atoms of L and either the oxygen atom of the OTf anion or the N atom of CH_3CN.

1. Introduction

The synthesis of solvent-coordinated cationic complexes possessing a non-coordinating anion is a matter of considerable interest, since they are useful as a source of other species resulting from the substitution of the coordinated solvent for a more basic ligand [1–8]. Furthermore, the lability of the solvent ligand gives easily rise to a highly reactive 16e electrophilic fragment able to activate small molecules such as H_2, alkanes, silanes, etc., and, so that, to provide an important step in many chemical processes. However, the success in isolating this kind of compounds stems, on the one hand, from the good fortune in the choice of the appropriate solvent (polar enough to provide adequate solubility of the ionic complex but not basic enough to bind irreversibly with the metal centre); on the other, from the presence of a non-interacting counterion. In this respect, the isolation of stable dichloromethane complexes where CH_2Cl_2 behaves as either monodentate or bidentate ligand towards a cationic metal centre has been the object of a number of reports, despite this compound has been traditionally considered as a non-coordinating solvent [9,10].

We describe in this paper the synthesis and characterization of some new cationic complexes containing CH_2Cl_2 as a monodentate ligand and BF_4 or BAr_F as counterions, as well as the substitution of dichloromethane, either for tetrafluoroborate (normally thought to be a low-interacting anion), or for more active ligands

such as H_2O and acetonitrile. The crystal structures of two of the prepared complexes are also reported.

2. Experimental

2.1. Materials and instrumentation

All synthetic operations were performed under dry argon. A standard vacuum system and Schlenk type glassware were used in handling metal complexes. Solvents were pre-dried over sodium wire or calcium chloride before reflux and subsequent distillation, under argon, from a suitable drying agent. Deuterated solvents for NMR measurements (Aldrich) were dried over molecular sieves. All the commercially available reagents were used as supplied.

Elemental analyses were performed with a Fisons EA-1108 apparatus. Melting points were determined using a GallenKamp MFB-595 apparatus and were uncorrected. Conductivity measurements were carried out on a Crison GLP-32 conductivity meter. IR spectra of samples in KBr pellets were recorded on a Bruker Vector IFS28 FT spectrophotometer, and NMR spectra (at room temperature) on a Bruker AMX 400 spectrometer. ^1H and $^{13}C\{^1H\}$ signals are referred to internal TMS, $^{31}P\{^1H\}$ chemical shifts to 85% H_3PO_4, and $^{19}F\{^1H\}$ signals to $CFCl_3$ with downfield shifts considered positive. Mass spectra were recorded in the LSIMS, Cs^+ mode on a Micromass Autospec M instrument.

2.2. X-ray diffraction

Crystallographic data were collected on a Bruker Smart 1000 CCD diffractometer at 293 K (complex **2**) or at 120 K (complex **1a**) using Mo Kα radiation ($\lambda = 0.71073$ Å) and were corrected for Lorentz and polarization effects. The frames were integrated with the Bruker *SAINT* [11] software package and the data were corrected for absorption using the program SADABS [12]. The structures were solved by direct methods using the program SHELXS 97 [13]. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F^2 using the program SHELXL 97 [14]. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters. Neutral atom scattering factors and anomalous dispersion corrections were taken from *International Tables for X-ray Crystallography* [15]. Drawings were produced with *PLATON* [16].

Crystallographic data and structure refinement parameters are listed in Table 1. The poor quality of the single crystal led to worse structure refinement parameters in the case of the second compound.

2.3. Synthesis of complexes

2.3.1. *fac*-[Re(ClCH$_2$Cl)(CO)$_3$L][BF$_4$] (**1**)

To a mixture of [ReBr(CO)$_3$L] (100 mg, 0.1 mmol) and AgBF$_4$ (38 mg, 0.2 mmol) 20 ml of dichloromethane were added. The solution was refluxed for 1 h, and the brown precipitate (AgBr) was filtered off through cellite. After sucking dry, the resulting oil was triturated with hexane (4 ml) and a brown solid was formed. Yield: 58 mg (52%). M.p. 183 °C. Λ_M (nitromethane): 66.3 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $C_{30}H_{26}Cl_2O_5P_2BF_4Re$ (872.40): C, 41.30; H, 3.00%. Found: C, 41.48; H, 3.03. IR (KBr pellets, cm^{-1}): 2048s, 1974s, 1921s, ν(CO); 1097s, ν(BF$_4$). ^{1}H NMR (CHCl$_3$-d, 400 MHz): δ (ppm) = 4.00–4.30 (m, 4H, –CH$_2$CH$_2$–); 7.26–7.65 (m, 20H, –Ph). ^{31}P{^{1}H} NMR (CHCl$_3$-d, 161 MHz): δ(ppm) = 120.2 (s). ^{19}F{^{1}H} (CH$_2$Cl$_2$-d_2, 376 MHz): δ(ppm) = −151.3 (s). MS: m/z (referred to the most abundant isotopes): 701 [M-(BF$_4$, CH$_2$Cl$_2$)]; 673 [M-(BF$_4$, CH$_2$Cl$_2$, CO)]; 645 [M-(BF$_4$, CH$_2$Cl$_2$, 2CO)].

2.3.2. *fac*-[Re(OSO$_2$CF$_3$)(CO)$_3$L] (**2**)

Hundred milligram of [ReBr(CO)$_3$L] (0.1 mmol) were mixed with 49 mg of AgOTf (0.2 mmol) and 20 ml of dichloromethane were added. After refluxing for 3 h protected from light, the solid (AgBr) was filtered off, the solution was dried in vacuo and the resulting oil was taken into ether (4 ml), furnishing a white solid. This solid was separated, washed with ether and vacuum dried. Yield: 73 mg (67%). M.p. 244 °C. Λ_M (nitromethane): 4.9 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $C_{30}H_{24}SO_8P_2F_3Re$ (849.73): C, 42.41; H, 2.85. Found: C, 41.83; H, 2.86%. IR (KBr pellets, cm^{-1}): 2046s, 1967s, 1926s, ν(CO); 1321s, $\nu(\eta^1$-OSO$_2$CF$_3$). ^{1}H NMR (CHCl$_3$-d, 400 MHz): δ(ppm) = 4.08–4.18 (m, 4H, –CH$_2$CH$_2$–); 7.16–7.70 (m, 20H, –Ph). ^{13}C{^{1}H} NMR (CHCl$_3$-d, 100 MHz): δ(ppm) = 189.6 (m, C_AO, C_BO); 189.6 (t, C_EO); $^2J_{C-P}$ = 7.3 Hz. 66.4 (s, –CH$_2$–CH$_2$–); 118 (q, CF$_3$); $^2J_{C-F}$ = 319 Hz. ^{31}P{^{1}H} NMR (CHCl$_3$-d, 161 MHz): δ(ppm) = 117.4 (s). ^{19}F{^{1}H} (CHCl$_3$-d, 376 MHz): δ(ppm) = −76.9 (s). MS: m/z (referred to the most abundant isotopes): 850 [M]; 701 [M–O$_3$SCF$_3$]; 673 [M–(O$_3$SCF$_3$, CO)]; 645 [M–(O$_3$SCF$_3$, 2CO)]. Single crystals were obtained by slow evaporation of an EtOH/CHCl$_3$ (10:2, v/v) solution.

2.3.3. *fac*-[Re(ClCH$_2$Cl)(CO)$_3$L][BAr$_F$] (**3**)

A mixture of complex **2** (100 mg, 0.1 mmol) and NaBAr$_F$ (166 mg, 0.2 mmol) was solved in dichloromethane (20 ml). After 1 h stirring at room temperature a precipitate of NaOTf was formed and filtered off. The remaining solution was dried in vacuo and the resulting oil was taken into hexane (4 ml) after which a yellow precipitate was formed. Yield: 190 mg (98%). M.p. 132 °C. Λ_M (nitromethane): 71.4 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $ReC_{62}H_{38}Cl_2O_5P_2BF_{24}$ (1648.81): C, 45.16; H, 2.32. Found: C, 45.34; H, 2.45%. IR (KBr pellets, cm^{-1}): 2053s, 1984s, 1938s, ν(CO). ^{1}H NMR (CHCl$_3$-d, 400 MHz): δ(ppm) = 4.24 (m, 4H, –CH$_2$CH$_2$–); 7.40–7.69 (m, 20H, –Ph). ^{13}C{^{1}H} NMR (CH$_2$Cl$_2$-d$_2$, 100 MHz): δ(ppm) = 190.4 (m, C_AO, C_BO); 192.6 (t, C_EO); $^2J_{C-P}$ = 8.0 Hz. 66.2 (s, –CH$_2$–CH$_2$–); 124.9 (q, CF$_3$); $^2J_{C-F}$ = 271 Hz. ^{31}P{^{1}H} NMR (CHCl$_3$-d, 161 MHz): δ(ppm) = 124.2 (s). ^{19}F{^{1}H} (CHCl$_3$-d, 376 MHz): δ(ppm) = −62.5 (s). MS: m/z (referred to the most abundant isotopes): 757 [M–(BAr$_F$, CO)]; 701 [M–(BAr$_F$, CH$_2$Cl$_2$)]; 673 [M–(BAr$_F$, CH$_2$Cl$_2$, CO)]; 645 [M–(BAr$_F$, CH$_2$Cl$_2$, 2CO)].

Attempts to synthesize this complex by reacting [ReBr(CO)$_3$L] with AgBAr$_F$ were unsuccessful.

2.3.4. *fac*-[Re(NCCH$_3$)(CO)$_3$L][BF$_4$] (**1a**)

To a mixture of [ReBr(CO)$_3$L] (100 mg, 0.1 mmol) and AgBF$_4$ (38 mg, 0.2 mmol) 20 ml of dichloromethane were added. After filtration of the formed solid (AgBr), the solution was treated with CH$_3$CN (7 ml), refluxed for 4 h and vacuum dried, resulting in an oil which was triturated with EtOH (4 ml). The formed white solid was dried in vacuo. Yield: 49 mg (45%). M.p. 229 °C. Λ_M (nitromethane): 93.1 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $ReC_{31}H_{27}O_5P_2NBF_4$ (828.52): C, 44.94; H, 3.28. Found: C, 44.34; H, 3.53%. IR (KBr pellets, cm^{-1}): 2053s, 1990s, 1934s, ν(CO); 2325w, 2295w, ν(CN); 1100s, ν(BF$_4$). ^{1}H NMR (CHCl$_3$-d, 400 MHz): δ(ppm) = 1.91 (s, 3H, CH$_3$CN) 4.16–4.32 (m, 4H, –CH$_2$CH$_2$–); 7.26–7.60 (m, 20H, –Ph). ^{13}C{^{1}H} NMR (CHCl$_3$-d, 100 MHz): δ(ppm) = 186.9 (dd, C_AO); $^2J_{CP(trans)}$ = 47, $^2J_{CP(cis)}$ = 25 Hz; 186.6 (dd, C_BO); $^2J_{CP(trans)}$ = 47 Hz, $^2J_{CP(cis)}$ = 25 Hz; 190.2 (t, C_EO); $^2J_{CP(cis)}$ = 8.4 Hz. 66.1 (s,–CH$_2$–CH$_2$–); 125.8 (s, CN–); 2.6 (s, CH$_3$–). ^{31}P{^{1}H} NMR (CHCl$_3$-d, 161 MHz): δ(ppm) = 115.3 (s). ^{19}F{^{1}H} (CHCl$_3$-d, 376 MHz): δ(ppm) = −153.2 (s). MS: m/z (referred to the most abundant isotopes): 742 [M–BF$_4$]; 701 [M–(BF$_4$, CH$_3$CN)]; 673 [M–(BF$_4$, CH$_3$CN, CO)]; 645 [M–(BF$_4$, CH$_3$CN, 2CO)]. By slow evaporation of an EtOH/CH$_2$Cl$_2$ (10:2, v/v) solution, crystals suitable for X-ray diffractometry were isolated.

2.3.5. *fac*-[Re(OH$_2$)(CO)$_3$L][BF$_4$] (**1b**)

To a mixture of [ReBr(CO)$_3$L] and AgBF$_4$ (100 mg, 0.1 mmol and 38 mg, 0.2 mmol, respectively) 20 ml of CH$_2$Cl$_2$ were added. After 1 h reflux, the precipitate (AgBr) was filtered off and 15 μl of water were added to the solution. After being maintained for 2 h at room temperature the solvent was eliminated in vacuo furnishing a solid which was treated with 5 ml of hexane to yield a grey solid. Yield: 37 mg (39%). M.p. 173 °C. Λ_M (nitromethane): 66.4 Ω^{-1} cm^2 mol^{-1}. *Anal.* Calc. for $ReC_{29}H_{26}O_6P_2BF_4$ (805.48): C, 43.24; H, 3.25. Found: C, 43.59; H, 3.54%. 3. Results and discussion

3.1. Crystal structures

3.1.1. [Re(OTf)(CO)$_3$L] (**2**)

Fig. 1 shows the displacement ellipsoid plot for complex **2** with the atom numbering scheme, and Table 2 lists the chief bond distances and bond angles. The structure consists of discrete [ReOTf$(CO)_3$L] pseudo-octahedral units with the Re atom coordinated to the two phosphorus donors from the bidentate L ligand, one oxygen atom of the OSO_2CF_3 (OTf) anion and the three CO ligands in a *facial* disposition. The Re–P bond lengths have values in the range described for other Re(I) complexes with similar ligands [17], and they are unremarkable. The CO ligand *trans* to the O atom of the triflate anion lies closer to the metal atom [1.889(5) Å] than the other two, *trans* to the P atoms [1.942(5) and 1.970(5) Å, respectively], as expected from both the π-donor character of the oxygen and the *trans* influence of the phosphorus. Moreover, the shortest C–O bond length [1.140(5) Å] corresponds logically with the longest Re–C distance [1.970(5) Å]. The values of the internal distances in the OTf anion denote an S–O donor bond [1.477(3) Å] weaker than the other two S–O bonds [1.425(3), 1.422(3) Å respectively], even though it is quite shorter than an S–O single bond (about 1.70 Å) [18]. All

the bond angles around the Re atom have values very close to 90°, even the P–Re–P angle [88.16(4)°] despite the bite of the bidentate ligand.

3.1.2. $[Re(CH_3CN)(CO)_3L]^+$

The formation of crystals suitable for X-ray crystallography in the case of the compound **1a** allowed the structural study of the cation present in this complex as well as in **2a** and **3a**. The displacement ellipsoid plot for this cation is shown in Fig. 2. As in the structure commented above, the coordination polyhedron around the Re atom is again a pseudo-octahedron formed by the two P atoms of the bidentate L ligand, the N atom of the acetonitrile and three CO ligands in a *facial* arrangement. The two carbonyl ligands *trans* to the P donors are located at practically the same distance from Re [1.949(5) and 1.948(5) Å, respectively] (see Table 2), whereas the third CO (*trans* to the acetonitrile) is nearer [1.904(5) Å]. Furthermore, the C–O bond length in the latter is slightly longer [1.168(6) Å] than in the other two [1.152(5), 1.156(5) Å], and the internal C–N bond length in the acetonitrile ligand [1.121(6) Å] is slightly shorter than in the free ligand (1.158 Å) [18].

3.2. Characterization and reactivity of the complexes

The molar conductivities showed all the new species to be 1:1 electrolytes in nitromethane, with the only exception of complex **2** which is non-ionogenic in this solvent [19].

In the case of complex **1**, its $^{31}P\{^1H\}$ NMR spectrum shows two singlets at 120.2 ppm, which we state as due

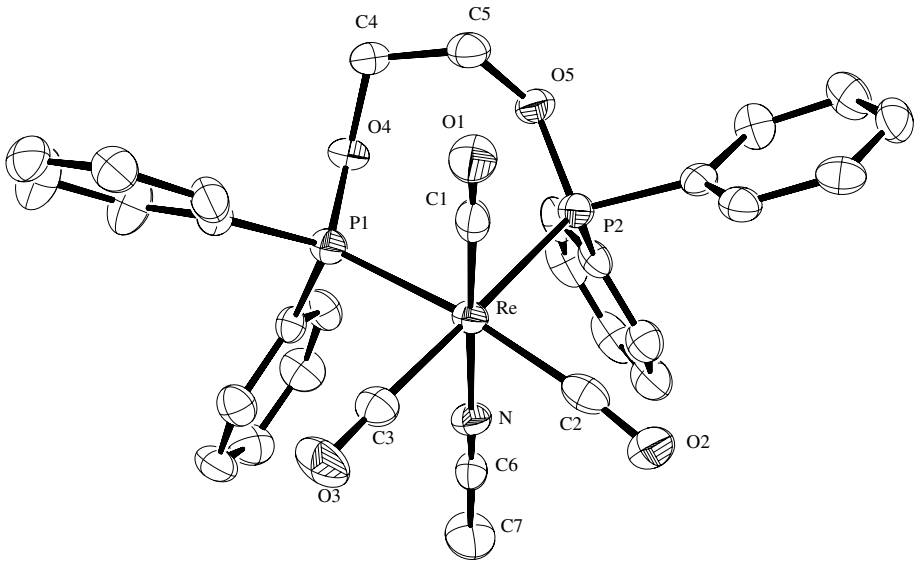

Fig. 2. Displacement ellipsoid plot of the cation $[Re(CH_3CN)(CO)_3L]^+$ with the atom numbering scheme. Ellipsoids at 30% probability.

to the complex containing CH_2Cl_2 as a ligand, and at 120.9 ppm (less intense) which denotes the existence of another species in solution, presumably arisen from the equilibrium:

$$[Re(ClCH_2Cl)(CO)_3L][BF_4] \rightleftharpoons [Re(FBF_3)(CO)_3L] + CH_2Cl_2$$

The existence of this equilibrium seems to be confirmed by the $^{19}F\{^1H\}$ NMR spectrum in dichloromethane at room temperature, which shows, apart from the singlet due to the free BF_4 anion (at −151.3 ppm), another broad signal downfield (at −149.3 ppm, Fig. 3) attributable to the BF_4 ion attached to the Re atom.

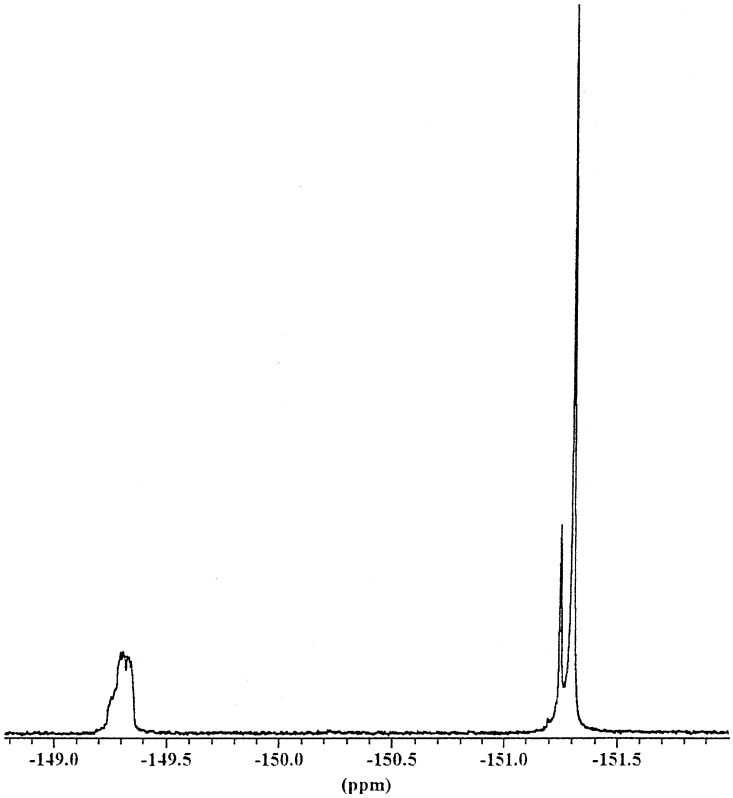

Fig. 3. $^{19}F\{^1H\}$ NMR spectrum of complex **1**.

This signal is located at a position close to that found in similar systems [20].

In order to seek to confirm this supposition, and provided that the ubiquitous *aqua* ligand is very difficult to avoid, the $^{31}P\{^1H\}$ and $^{19}F\{^1H\}$ NMR spectra of this complex in $CDCl_3$ were recorded after adding H_2O to the solution. As a consequence of the presence of water, the signal at 120.2 ppm (presumably due to the $ClCH_2Cl$ complex) disappears in the $^{31}P\{^1H\}$ NMR spectrum, whereas a new signal is observed at 119.8 ppm (attributable to the *aqua* complex), and the singlet located at 120.9 ppm remains, even though it becomes less intense. This seems to indicate that *some* of the BF_4 anions remain attached to Re despite the presence of H_2O. Regarding the $^{19}F\{^1H\}$ spectrum, the two signals commented above survive after adding the water, denoting the existence of both types of BF_4 anion (free and coordinated to Re). These results showed that H_2O takes immediately the place of dichloromethane in the attachment to the metal atom, whereas the displacement of the BF_4 anion takes a longer term. When water is added in excess, the $^{19}F\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectra denote the non-survival of BF_4 as a ligand and no compound but the *aqua* complex is present. By contrast, the spectroscopic studies of complex **3** did not provide any evidence of the existence of such a type of equilibrium, as expected from the non-coordinating character of the BAr_F anion.

The ^1H NMR spectra of complexes **1**, **2** and **3** show the Ph and (CH_2–CH_2) ligand signals at the expected positions, while the singlet due to the $ClCH_2Cl$ ligand is located at about 4.8 ppm in **1** and is not observable in **3,** presumably obscured by the ligand signals.

On the other hand, the $^{13}C\{^1H\}$ NMR spectrum of complex **3** in dichloromethane showed a splitting of the CH_2Cl_2-d_2 signal (Fig. 4). In fact, the quintuplet at 53.8 ppm is accompanied by another less intense signal downfield, at 54.0 ppm, which we attribute to the dichloromethane attached to the metal, despite the fast interchange with the free solvent that usually makes it impossible to observe in the NMR spectra at room temperature [21].

With the aim of testing the liability of both ligands CH_2Cl_2 and OTf against some bases, the three complexes were treated with MeCN and H_2O (see Scheme 1). The substitution of dichloromethane in complexes **1** and **3** by either acetonitrile or water was quite easy in smooth conditions. However, the triflate anion is more difficult to remove, so that its substitution by MeCN to give **2a** needed more drastic requirements (toluene reflux for 1 h), whereas any attempt to displace OTf by H_2O was unsuccessful.

The characterization of the new species **1a**, **2a** and **3a,** arised from the reaction of the complexes **1–3** with MeCN, was carried out by IR and NMR spectroscopies,

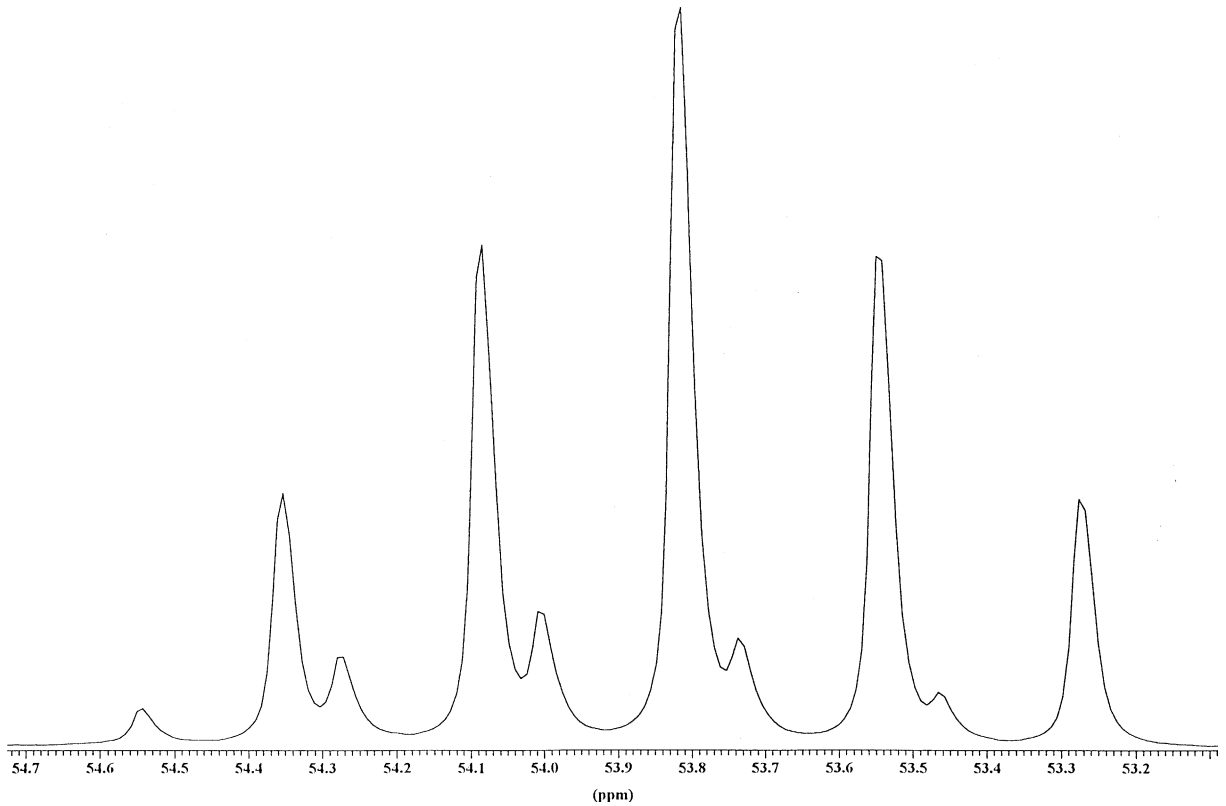

Fig. 4. $^{13}C\{^1H\}$ NMR spectrum of complex **3**.

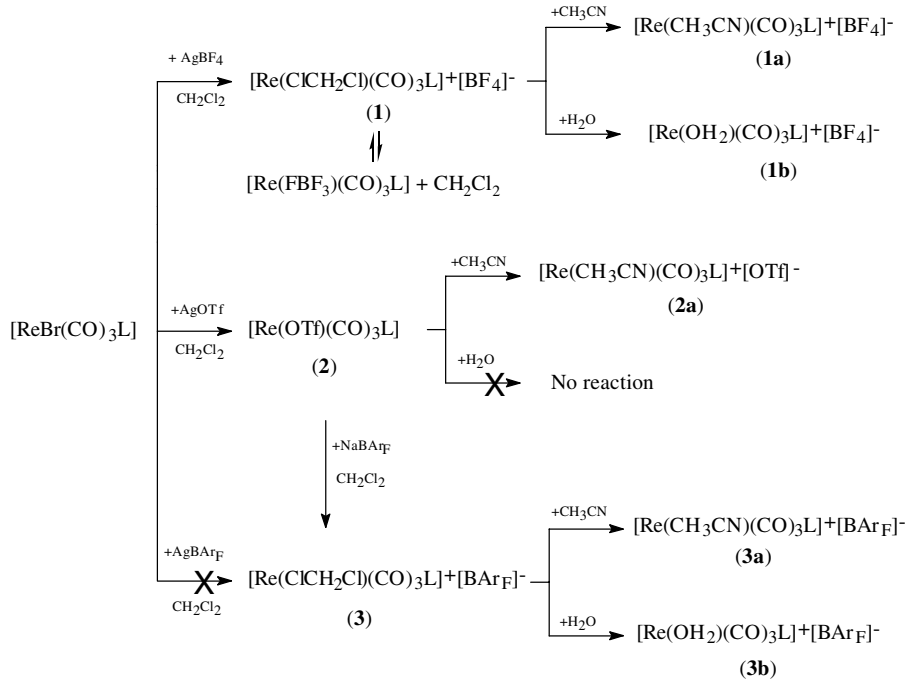

Scheme 1.

and, in the case of complex **1a**, by X-ray diffraction studies, which allowed the structural elucidation of the cation $[Re(CH_3CN)(CO)_3L]^+$ present in all the three compounds.

The IR bands attributable to C–O stretching modes of the carbonyl ligands are in the range reported for similar systems [22,23]. The substitution of CH_2Cl_2 by MeCN causes in these bands only a very slight shift to higher wavenumber, despite the strengthening in the C–O bond to be expected from the π-acceptor character of MeCN in contrast with the π-donor behaviour of the Cl atom of dichloromethane. The acetonitrile complexes exhibit CN stretches in the IR spectra as two weak or very weak bands at higher wavenumber than in the free ligand (2252 cm^{-1}). These bands are in the range 2367–2292 cm^{-1} described previously [24], and are consistent with the strengthening of the C–N bond in MeCN under coordination to the metal as commented in the crystal structure discussion (see above). The singlet in the ^1H NMR spectra of the complexes in $CDCl_3$ (at 1.9, 1.8 and 1.6 ppm for **1a**, **2a** and **3a**, respectively), is consistent with the existence of CH_3CN bound to the metal, whereas the ^{13}C NMR spectra in the same solvent show two singlets, one at 2.6, 2.8 and 1.4 ppm (for **1a**, **2a** and **3a**, respectively), attributable to the methyl group of MeCN, and the other at 125.8, 125.5 and 122.7 ppm, corresponding to the CN group of the same ligand [22,24]. A triplet at around 190 ppm [$J(^{13}C–^{31}P) = 9$ Hz] and two double doublets at 186 ppm [$J_{cis}(^{13}C–^{31}P) \approx 22$ Hz, $J_{trans}(^{13}C–^{31}P) \approx 50$ Hz) are due to the carbonyl ligands. The $^{31}P\{^1H\}$ spectra show a singlet at 115.3, 116.6 and 117.3 ppm for **1a**, **2a** and **3a**, respectively, indicating the magnetic equivalence of the two P nuclei.

Whereas the substitution of the OTf ligand by H_2O was not possible in complex **2,** (even in drastic conditions), the displacement of CH_2Cl_2 in complexes **1** and **3** afforded the new *aqua* complexes **1b** and **3b**, respectively. Both complexes behave as 1:1 electrolytes in nitromethane, as denoted by the values of their molar conductivities in this solvent (see Section 2). The broad singlet in the ^1H NMR spectra at 1.72 and 1.61 ppm for **1b** and **3b**, respectively, indicates the presence of the *acuo* ligand, whereas the singlets at −151.5 (**1b**) and −62.5 ppm (**3b**) in the $^{19}F\{^1H\}$ NMR spectra confirm the existence of the BF_4 and BAr_F anions in the former and the latter, respectively. Finally, the $^{31}P\{^1H\}$ NMR spectra show one singlet for both compounds, denoting the magnetic equivalence of the P atoms of the bidentate ligand.

4. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC nos. 213341 and 213342. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2

Copper(II) complexes of bis- and tetrakis-(2-pyridylsulfanylmethyl)benzenes

David A. McMorran *, Christopher M. Hartshorn, Peter J. Steel

Department of Chemistry, University of Canterbury, Christchurch, Dunedin, New Zealand

Received 12 December 2003; accepted 5 January 2004

Abstract

Reactions of copper(II) salts with the ligand 1,2-bis(2-pyridylsulfanylmethyl)benzene ($\mathbf{L}_1$) and the isomeric ligands 1,2,3,4-tetrakis(2-pyridylsulfanylmethyl)benzene ($\mathbf{L}_2$) and 1,2,4,5-tetrakis(2-pyridylsulfanylmethyl)benzene ($\mathbf{L}_3$) give copper(II) complexes, some of which have been characterised by X-ray crystallography. $[Cu(\mathbf{L}_1)Cl_2]$ is found to be a one-dimensional coordination polymer, containing two subtly different copper atom environments. By contrast, $[Cu_2(\mathbf{L}_2)Cl_4]$ and $[Cu_2(\mathbf{L}_3)(NO_3)_4]$ are discrete species with, in each case, the copper atoms chelated by adjacent ligand arms.

1. Introduction

The construction of metallosupramolecular assemblies, in which organic ligand components are "glued" together by transition metal ions, continues to be an area of great interest [1–6]. A wide variety of assemblies, such as squares [7–9], cubes [10], tetrahedra [11,12] and helicates [13,14], as well as a range of one-, two- and three-dimensional coordination polymers [15–20], are now known. In each case, the metallosupramolecular architecture is the result of the particular structural characteristics of its constituent components. It is clear that components with new geometrical and structural properties might give rise to new and interesting supramolecular assemblies. In particular, so-called multi-armed molecules [21], incorporating donor groups at the ends of each arm, might serve as potential bridging ligands with a number of different coordination modes. Variation in the number, length and relative arrangement of the arms in such ligands might be expected to generate assemblies of varying dimensionalities, with novel structural and functional properties.

As a part of our continuing studies into the consequences for metal-ion binding of incorporating flexible spacers into poly-*N*-heterocyclic ligands [22–28], we have recently reported the synthesis of a series of new multi-armed ligands, in which a benzene, or biphenylene, core unit was appended by up to eight pyridylsulfanylmethyl arms [29]. Silver(I) adducts of some of these have been reported [30] and X-ray crystallographic analyses showed these adducts to be either 2 + 2 metallocyclic or one-dimensional polymeric species. In each case, weak Ag···S interactions played a role in determining the overall structures. We now report the synthesis and structural characterization of copper(II) adducts of three of these ligands, $\mathbf{L}_1$–$\mathbf{L}_3$ (Scheme 1). Each ligand was reacted with copper(II) chloride and copper(II) nitrate to give, in most cases, insoluble green or blue compounds. Three of the products were able to be characterised by X-ray crystallography. Reaction of copper(II) chloride with 1,2-bis(2-pyridylsulfanylmethyl)benzene ($\mathbf{L}_1$) results in the formation of a one-dimensional polymeric structure, with each ligand bridging two dissimilar copper atoms. Reaction of the four-armed ligands 1,2,3,4-tetrakis(2-pyridylsulfanylmethyl)benzene ($\mathbf{L}_2$) and 1,2,4,5-tetrakis(2-pyridylsulfa-

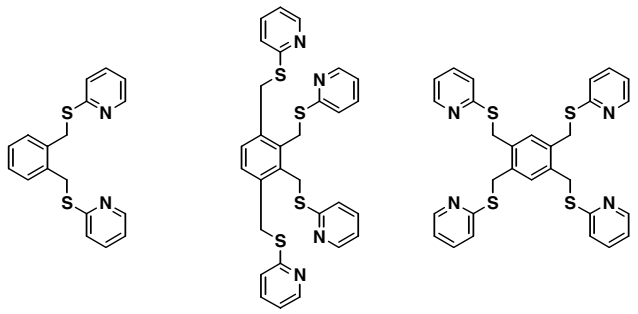

Scheme 1.

nylmethyl)benzene ($\mathbf{L}_3$) with copper(II) chloride and copper(II) nitrate, respectively, gave discrete bimetallic complexes. As was found for the silver adducts, weak sulfur-to-metal bonding interactions are observed in the present complexes in the solid state and, in one case, such bonding appears to be present in solution.

2. Experimental

2.1. General procedure

Ligands $\mathbf{L}_1$ [30], $\mathbf{L}_2$ and $\mathbf{L}_3$ [29] were prepared as described previously. UV–Vis spectra were recorded on a GBC UV/VIS 920 spectrometer. Elemental analyses were performed by the Campbell Microanalytical Laboratory at the University of Otago.

2.2. Preparation of $[Cu(\mathbf{L}_1)(NO_3)_2]$

$Cu(NO_3)_2 \cdot 3H_2O$ (19 mg, 0.080 mmol) in hot methanol (1 mL) was added to $\mathbf{L}_1$ (25 mg, 0.080 mmol) in hot methanol (2 mL) to give a pale green solution. The solvent was removed and the deep green residue redissolved in acetone (2 mL). Addition of diethyl ether gave a blue flocculent precipitate which was filtered off, washed with diethyl ether and dried. Yield: 31 mg (79%). *Anal.* Calc. for $C_{18}H_{16}N_4S_2O_6Cu$: C, 42.22; H, 3.15; N, 10.94. Found: C, 42.10; H, 3.11; N, 10.63%.

2.3. Preparation of $[Cu(\mathbf{L}_1)Cl_2] \cdot CH_3OH$

$CuCl_2 \cdot 2H_2O$ (38 mg, 0.22 mmol) and $\mathbf{L}_1$ (73 mg, 0.22 mmol) were stirred in hot methanol (10 mL). On cooling, green crystals formed which were suitable for X-ray analysis. Yield: 90 mg (83%). *Anal.* Calc. for $C_{18}H_{16}N_2S_2CuCl_2 \cdot CH_3OH$: C, 46.48; H, 4.11; N, 5.71. Found: C, 46.54; H, 3.83; N, 5.75%.

2.4. Preparation of $[Cu_2(\mathbf{L}_2)(NO_3)_4]$

A solution of $Cu(NO_3)_2 \cdot 3H_2O$ (34 mg, 0.14 mmol) in hot acetonitrile (3 mL) was added to a solution of $\mathbf{L}_2$ (40 mg, 0.070 mmol) in hot acetonitrile (3 mL) to give a clear, deep green solution, which rapidly deposited a blue precipitate. The hot suspension was stirred for 10 min, then cooled and the solid filtered off, washed with diethyl ether and dried, giving a pale blue solid. Yield: 60 mg (91%). *Anal.* Calc. for $C_{30}H_{26}N_8S_4O_{12}Cu_2$: C, 38.10; H, 2.77; N, 11.84. Found: C, 38.35; H, 2.97; N, 10.95%.

2.5. Preparation of $[Cu_2(\mathbf{L}_2)Cl_4] \cdot CH_3CN \cdot H_2O$

A solution of $CuCl_2 \cdot 2H_2O$ (19 mg, 0.11 mmol) in hot acetonitrile (2 mL) was added to a solution of $\mathbf{L}_2$ (31 mg, 0.054 mmol) in hot acetonitrile (3 mL) to give a heavy green precipitate. The hot suspension was stirred for 10 min, then cooled and the solid filtered off, washed with diethyl ether and dried, giving a yellow-brown microcrystalline solid. Yield: 39 mg (86%). *Anal.* Calc. for $C_{30}H_{26}N_4S_4Cu_2Cl_4 \cdot CH_3CN \cdot H_2O$: C, 42.76; H, 3.47; N, 7.78. Found: C, 42.22; H, 3.22; N, 7.75%. Crystals suitable for X-ray analysis were obtained by slowly diffusing a solution of $CuCl_2$ (12 mg, 0.014 mmol) in acetonitrile (3 mL) into a solution of $\mathbf{L}_2$ (40 mg, 0.070 mmol) in acetonitrile (3 mL), giving clumps of golden yellow plates. Yield: 20 mg (68%). *Anal.* Calc. for $C_{30}H_{26}N_4S_4Cu_2Cl_4 \cdot 3H_2O \cdot 1/2CH_3CN$: C, 40.72; H, 3.69; N, 6.89. Found: C, 41.18; H, 3.62; 6.98%.

2.6. Preparation of $[Cu_2(\mathbf{L}_3)(NO_3)_4]$

A solution of $Cu(NO_3)_2 \cdot 3H_2O$ (34 mg, 0.14 mmol) in hot acetonitrile (3 mL) was added to a solution of $\mathbf{L}_3$ (40 mg, 0.070 mmol) in hot acetonitrile (3 mL) to give, initially, a dark green solution, which became orange-brown and finally deep green as the $Cu(NO_3)_2$ solution was added. On complete addition, the clear, hot solution was stirred for 10 min, then cooled to give a dark green solid. This was filtered off, washed with diethyl ether and dried to give a green solid. Yield: 47 mg (71%). *Anal.* Calc. for $C_{30}H_{26}N_8S_4O_{12}Cu_2$: C, 38.10; H, 2.77; N, 11.84. Found: C, 38.01; H, 2.78; N, 10.48%. Crystals suitable for X-ray analysis were obtained by carefully layering a solution of $Cu(NO_3)_2 \cdot 6H_2O$ (8.5 mg, 0.035 mmol) in acetonitrile (1 mL) onto a solution of $\mathbf{L}_3$ (10 mg, 0.0017 mmol) in dichloromethane (1 mL), with 2 mL of acetonitrile as a buffer region. On standing, clumps of deep green plates formed. Yield: 12 mg (72%). *Anal.* Calc. for $C_{30}H_{26}N_8S_4O_{12}Cu_2$: C, 38.10; H, 2.77; N, 11.84. Found: C, 38.07; H, 2.56; N, 10.77%.

2.7. Preparation of $[Cu_2(\mathbf{L}_3)Cl_4]$

A solution of $CuCl_2 \cdot 2H_2O$ (15 mg, 0.088 mmol) in hot acetonitrile (1 mL) was added to a solution of $\mathbf{L}_3$ (25 mg, 0.044 mmol) in hot acetonitrile (3 mL) to give a deep red solution which rapidly deposited a green-brown precipitate. The hot suspension was stirred for 10 min, then

cooled and the solid filtered off, washed with diethyl ether and dried, to give an olive green solid. Yield: 32 mg (87%). *Anal*. Calc. for $C_{30}H_{26}N_4S_4Cu_2Cl_4$: C, 42.91; H, 3.12; N, 6.67. Found: C, 42.62; H, 3.16; N, 6.69%.

2.8. X-ray crystallography

The crystal data, data collection and refinement parameters are listed in Table 1. All measurements were made with a Siemens CCD area detector using graphite monochromatised Mo Kα ($\lambda = 0.71073$ Å) radiation. Intensities were corrected for Lorentz and polarisation effects and for absorption. The structures were solved by direct methods using SHELXS [31], and refined on F^2 using all data by full-matrix least-squares procedures with SHELXL-97 [32]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in calculated positions with isotropic displacement parameters 1.3 times the isotropic equivalent of their carrier carbons. The function minimised was $\sum w(F_o^2 - F_c^2)$, with $w = [\sigma^2(F_o^2) + aP^2 + bP]^{-1}$, where $P = [\max(F_o)^2 + 2F_c^2]/3$. In the case of $[Cu_2(\mathbf{L}_3)(NO_3)_4]$, one of the nitrate nitrogens was refined isotropically.

3. Results and discussion

The new copper(II) complexes were prepared by reaction of either copper(II) chloride or copper(II) nitrate with the ligand in acetonitrile or methanol solutions. In each case, the coloured products precipitated from the cooled solutions in good to high yield. These products were, however, poorly soluble and only solutions in dimethyl formamide (dmf) could be obtained. Microanalysis suggested that the product of the reaction of $CuCl_2$ and the bidentate ligand $\mathbf{L}_1$ had a 1:1 Cu:ligand ratio, whereas a 2:1 Cu:ligand ratio was found for the copper complexes of the tetradentate ligands $\mathbf{L}_2$ and $\mathbf{L}_3$. The reactions of the ligands $\mathbf{L}_2$ and $\mathbf{L}_3$ with copper(II) nitrate were also carried out in dmf, giving coloured solutions. However, attempts to isolate a solid product, by slow evaporation or by addition of solvents such as diethyl ether to induce precipitation, gave only ligand.

In the course of the addition of an acetonitrile solution of $Cu(NO_3)_2$ to one of $\mathbf{L}_3$, the reaction mixture underwent an intriguing series of colour changes. On adding the first drops of the copper(II) solution, a dark green solution was obtained. This then changed to a yellow-brown solution and then finally to a green solution, from which a green solid then rapidly precipitated. When the reaction was repeated in dmf solution, only the yellow and final green solutions, and not the initial dark green solution, were observed. On complete addition, the green dmf solution was stable. The colour changes were followed by UV–Vis spectroscopy and it was found that, in the intermediate yellow solution, intense bands in the region up to ca. 500 nm were present, which were not present in the spectra of the free ligand or of the final green species. By contrast, similar be-

haviour was not observed on mixing $Cu(NO_3)_2$ solutions with either $\mathbf{L}_1$ or $\mathbf{L}_2$. Further, analysis of spectral changes on reaction of $Cu(NO_3)_2$ with 2-pyridylsulfanylmethylbenzene, the "one-armed" ligand, also showed no evidence of an intermediate yellow solution.

It has been reported that copper(II) complexes with thioether donors exhibit strong $S\sigma \rightarrow Cu(II)$ LMCT bands, at around 450 nm [33–35]. It is therefore possible that this intermediate species might involve a complex of the type shown in Scheme 2, with a weak Cu···S bond(s). Though rare, complexes involving four-membered chelate rings of this type have been reported [30,36–38]. However, why such a complex should form under these concentration conditions, and for only $\mathbf{L}_3$, is unclear. [1]

Analytically pure crystalline samples were eventually prepared, in good yield, by mixing copper(II) solutions and ligand solutions very slowly, either by layering or by diffusion. In each case, a discrete complex, with adjacent arms of the ligand chelating the copper atom(s), or a polymeric structure, in which the ligand bridges copper atoms, are possible. X-ray crystal structures of the three complexes were therefore undertaken.

Mixing methanol solutions of copper(II) chloride and $\mathbf{L}_1$ yielded green crystals suitable for X-ray analysis. Fig. 1 shows a perspective view of the structure, which crystallises in the triclinic space group $P\bar{1}$ and is found to be a one-dimensional coordination polymer. The asymmetric unit contains two copper atoms, each of which lies on a crystallographic centre of inversion, one $\mathbf{L}_1$ ligand and a methanol solvate molecule. Each copper atom has a square planar geometry, with the pyridine donors lying *trans* to each other. In addition to this, however, each of the sulfur atoms forms weak interactions with the copper, with distances of 3.116(3) Å (Cu1···S10) and 3.019(3) Å (Cu2···S20), giving the copper atoms a tetragonally distorted octahedral geometry. The mean-planes of the pyridine rings are inclined at angles of 87.2(8)° and 53.7(8)° to the central benzene ring and lie at an angle of 56.1(8)° to each other. The two arms of the ligand lie on opposite sides of the central benzene ring. The ligand separates the two copper atoms by 8.693(3) Å.

The methanol solvate molecule is hydrogen bonded to one of the coordinated chlorides, with a Cl···H distance of 2.538 Å and a Cl···H–O angle of 151.0°. Its presence leads to the distinct differences in the environments of the two copper atoms, as depicted in Fig. 2.

Fig. 3 shows an extended view of the one-dimensional polymeric nature of the structure. The chains form a sinusoidal arrangement and propagate perpendicular to

[1] Preliminary investigations of the reaction of $Cu(NO_3)_2$ solutions with hexakis(2-pyridylsulfanylmethyl)benzene also shows these colour changes and gives an intermediate spectrum containing a band at ca. 500 nm, similar to that observed with $\mathbf{L}_3$.

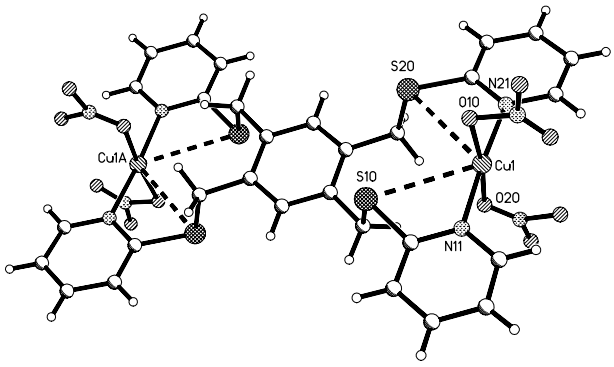

Fig. 5. Perspective view of the structure of $[Cu_2(\mathbf{L}_3)(NO_3)_4]$. Atom XA is related to atom X by the symmetry transformation $[-x,-y,-z]$. Selected bond lengths (Å) and angles (°). Cu1–N11 2.012(3); Cu1–N21 2.014(3); Cu1–O10 1.963(3); Cu1–O20 2.013(4); Cu1–S10 3.155(4); Cu1–S20 3.149(4); N11–Cu1–N21 176.1(2); O10–Cu1–O20 172.4(2); N11–Cu1–O10 91.1(2); N11–Cu1–O20 89.9(2); N11–Cu1–S10 57.1(2); O10–Cu1–S10 85.4(2); S10–Cu1–S20 69.2(2).

the *c* axis. Adjacent chains interact via hydrogen bonding interactions between coordinated chlorides and pyridine hydrogens (Cl···C 3.54 Å, Cl···H–C 152.1°) and also via S···H–C interactions (S···H 2.934 Å, S···H–C 127.4°).

Diffusion of an acetonitrile solution of copper(II) chloride into an acetonitrile solution of $\mathbf{L}_2$ led to the formation of golden yellow crystals suitable for X-ray analysis. Fig. 4 shows a perspective view of the structure of the complex, which crystallises in the triclinic space group $P\bar{1}$. The asymmetric unit contains one $\mathbf{L}_2$ ligand, two copper atoms, four chlorides, three water solvate molecules and half an acetonitrile solvate molecule. The acetonitrile and one of the half water molecules share the occupancy of a site with the second of the half water molecules. Each copper atom is coordinated by two, mutually *trans*, pyridine nitrogens from adjacent arms of the ligand, and two chlorides, which coordinate with Cl–Cu–Cl angles of 137.61(5)° and 127.36(5)°. The copper atoms further form relatively strong bonding interactions to sulfur atoms, with distances between 2.890(4) Å (Cu2···S30) and 3.077(4) Å (Cu1···S10). It appears to be these interactions, which lie approximately *trans* to the coordinated chlorides, which push the chlorides away from being co-planar with the nitrogen donors, giving the copper atoms a highly distorted octahedral geometry. The ligand arms

Cu1–N11 1.991(4); Cu1–N21 1.997(3); Cu1–Cl1 2.2879(13); Cu1–Cl2 2.2651(13); Cu1–S10 3.077(4); Cu1–S20 2.896(4); Cu2–N31 1.978(4); Cu2–N41 1.979(3); Cu2–Cl3 2.2983(14); Cu2–Cl4 2.3217(14); Cu2–S30 2.890(4); Cu2–S40 2.998(4); N11–Cu1–N21 156.73(14); Cl1–Cu1–Cl2 137.61(5); S10–Cu1–S20 73.5(10); N11–Cu1–Cl1 95.56(10); N11–Cu1–Cl2 93.16(10); N11–Cu1–S10 58.8(10); N11–Cu1–S20 99.3(10); N31–Cu2–N41 156.51(13); Cl3–Cu2–Cl4 127.36(5); S30–Cu2–S40 74.0(10); N31–Cu2–Cl3 95.39(10); N31–Cu2–Cl4 93.17(11); N31–Cu2–S30 62.2(10); N31–Cu2–S40 101.3(10).

adopt an up–up–down–down arrangement with respect to the central benzene ring. The two outer pyridine rings lie almost orthogonal to the central benzene ring, with angles between the mean-planes of 101.0(1)° (N11–C16) and 98.4(1)° (N41–C46), while the other two, inner, pyridine rings lie at angles of 45.9(1)° (N21–C26) and 40.7(1)° (N31–C36). The angle between the mean-planes of the pyridine rings are 60.4(1)°, for the rings coordinated to Cu1, and 62.1(1)°, for the rings coordinated to Cu2. The ligand separates the two copper atoms by 10.142(4) Å.

Consideration of the molecular packing shows that adjacent molecules are held together by numerous CH···O, OH···N and OH···Cl hydrogen bonding interactions between each other and to the acetonitrile and water solvate molecules.

Careful layering of a solution of copper(II) nitrate in acetonitrile onto a solution of $\mathbf{L}_3$ in dichloromethane resulted in the formation of deep green crystals suitable for X-ray analysis. Fig. 5 shows a perspective view of the complex, which crystallises in the triclinic space group $P\bar{1}$. The asymmetric unit contains one copper atom, half of a $\mathbf{L}_3$ ligand and two nitrates. The centroid of the central benzene ring of the ligand lies on a crystallographic centre of inversion. As a result, the ligand arms adopt an up–up–down–down arrangement with respect to the central benzene ring. The copper atom enjoys a square planar geometry, being coordinated by the pyridine nitrogens of two adjacent ligand arms and the oxygens of two monodentate nitrate anions. Because of the up–up arrangement of the ligand arms, the nitrogen donors coordinate *trans* to each other and are both coplanar with the two sulfur atoms. An interaction between the copper and the sulfurs, of the type observed for $[Cu_2(\mathbf{L}_2)Cl_4]^{2+}$, would then lead, in this case, to the nitrogen donors being pushed out of the coordination plane. This cannot occur, and so the Cu···S distances are longer than in the case of $[Cu_2(\mathbf{L}_2)Cl_4]^{2+}$, at 3.155(4) Å (Cu1···S10) and 3.149(4) Å (Cu1···S20). The plane containing the two pyridine rings and the copper atom is almost parallel with that of the central benzene ring (angle between the mean planes is 5.2°), giving the molecule a 'stepped' appearance. The ligand separates the two copper atoms by 11.574(4) Å.

The molecules arrange themselves in sheets parallel to the *a* axis, with the uncoordinated oxygens of each of the nitrates forming intramolecular CH···O hydrogen bonding interactions, with O···C distances of 3.24 Å and 3.39 Å and O···H–C angles of 165.4° and 160.4°, respectively: each molecule enjoys such interactions with four neighbouring molecules. Adjacent molecules also form offset π-stacking interactions, parallel to the *c* axis, between the central benzene ring of one molecule and a pyridine ring of the other, with a closest C–C distance of 3.46 Å.

4. Conclusions

We have prepared a series of copper(II) complexes with the ligands $\mathbf{L}_1$, $\mathbf{L}_2$ and $\mathbf{L}_3$. Three of these have been characterised by X-ray crystallography and these show that the solid state structures of the complexes are, at least in part, determined by weak Cu···S bonding interactions. Indeed, in the case of $[Cu_2(\mathbf{L}_3)(NO_3)_4]$, this pseudo-chelating nature of the ligand is perhaps the reason why a discrete dimetallic species, rather than the expected polymeric species, is obtained. Further, we have shown that there is some evidence for such interactions playing a role in the solution chemistry of one of the ligands, $\mathbf{L}_3$. These results provide further evidence that the structures adopted by metallosupramolecular assemblies are the result of a variety of sometimes very subtle interactions. Exploration of the coordination chemistry of these and related ligands continues.

5. Supplementary material

CCDC 220138, 220139 and 220140 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033; e-mail: deposit@ccdc.cam.ac.uk).

Abstract

The crystal structure of $[Ru(NH_3)_5(OH_2)]_2(S_2O_6)_3 \cdot 2H_2O$ has been solved by X-ray diffraction techniques. The relevant average interatomic distances are Ru–$(NH_3)_{eq} = 2.09$ Å, Ru–$(NH_3)_{ax} = 2.08$ Å and Ru–$(OH_2)_{ax} = 2.11$ Å. The aquation rate (k_{H_2O}) and the activation parameters for the reaction

$$trans\text{-}[RuNO(NH_3)_4Cl]^{2+} + H_2O \overset{k_{H_2O}}{\rightarrow} trans\text{-}[RuNO(NH_3)_4(H_2O)]^{3+} + Cl^-$$

have been calculated as 8.4×10^{-6} s^{-1} (0.10 mol L^{-1} CF_3COOH, $\mu = 0.10$ mol L^{-1}, 40 °C), $\Delta H^{\neq}_{-1} = 2.3$ kcal mol^{-1}, $\Delta S^{\neq}_{-1} = 24.0$ cal deg^{-1} mol and $\Delta G^{\neq}_{-1} = 8.6$ kcal mol^{-1}. A comparison between the structural data, kinetic and thermodynamic reactivities of $[Ru(NH_3)_5(OH_2)]^{3+}$ and *trans*-$[RuNO(NH_3)_4(OH_2)]^{3+}$ ions strongly suggests that the substitution of the *trans* NH_3 ligand in the coordination sphere of $[Ru(NH_3)_5(OH_2)]^{2+}$ by NO confers a character of Ru(III) to the formally Ru(II) center.

1. Introduction

There is a growing interest in the research involving nitric oxide (NO) chemistry as this molecule is directly involved in various biological processes such as vasodilatation and neurotransmission, as well as in a number of pathologies including inflammatory and immune diseases [1,2].

Metal complexes are extremely useful to activate the nitric oxide molecule. There is a great deal of effort in many laboratories aiming to develop coordination compounds able to act as NO carriers in biological media [3–7]. One of the key issues for modeling NO delivers or scavengers is to understand the mutual influences of both NO and the ligands *trans* positioned to NO on the coordination sphere, in their respective reactivities [8–10].

The purpose of this paper is to use ruthenium ammines as a model to understand the reactivity and structural effects induced by the presence of NO in the *trans*-$[RuNO(NH_3)_4(OH_2)]^{3+}$ complex as a whole by the comparison between the chemical properties (internuclear distances, pK_a and kinetic and thermodynamic data) of the $[Ru(NH_3)_5(OH_2)]^{3+}$ and *trans*-$[RuNO(NH_3)_4(OH_2)]^{3+}$ ions, and their respective chlorides derivatives.

2. Experimental

2.1. Reagents and materials

All chemicals were reagent grade quality (Aldrich and Merck) and used without further purification. The

doi:10.1016/j.poly.2004.01.007

solvents were purified as described in the literature [11]. Doubly distilled water was used throughout the experiments. Ruthenium trichloride ($RuCl_3 \cdot xH_2O$) was the starting material for the synthesis of the ruthenium complexes. All reactions and measurements were performed under an argon atmosphere, using standard techniques for the manipulations of air-sensitive compounds [12].

2.2. Synthesis of the ruthenium compounds

trans-$[RuNO(NH_3)_4Cl]Cl_2$ [13], $[Ru(NH_3)_5Cl]Cl_2$ [14] and $[Ru(NH_3)_5(H_2O)](CF_3SO_3)_3$ [15] were prepared according to the methods found in the literature, and their characteristics were checked by UV–visible, IR spectroscopy and electrochemical techniques.

2.3. Instrumentation

The elemental analysis were performed on a Perkin–Elmer elemental analyzer 2400 CHN. Ultraviolet and visible spectra were obtained on a Hitachi spectrophotometer model 3501-U. For EPR experiments, a Bruker ESP300e spectrometer operating with an X-band microwave bridge was used at the liquid N_2 temperature.

The electrochemical measurements were taken using a PARC system model 173 potentiostat/galvanostat, a model 175 universal programmer and a model 264A polarographic analyzer. Glassy carbon, saturated calomel (SCE) and platinum wire electrodes were used as working, reference and auxiliary electrodes, respectively.

The aquation for *trans*-$[RuNO(NH_3)_4Cl]Cl_2$ complex [13] was followed using the Hitachi spectrophotometer model 3501-U. The temperatures of the experiments were 40, 45, 49 and 60 ± 0.5 °C and controlled by a thermostated Tecnal TE 184 temperature bath. The solutions were prepared by dissolving the solid in degassed 0.10 mol L^{-1} CF_3COOH, $\mu = 0.10$ mol L^{-1} and quickly transferred, using teflon tubing, to a 1–5 cm quartz glass-sealed cell. The rate constants were graphically obtained from plots of $\log(A_t - A_\infty)$ versus time. The plots were linear from at least three half-lives. The activation parameters were calculated from specific rate constant data at different temperatures, using the Eyring plot ($\ln k/T$ against $1/T$) [16].

2.4. X-ray crystallographic study

The $[Ru(NH_3)_5(OH_2)]_2(S_2O_6)_3 \cdot 2H_2O$ crystals were obtained from the mother-liquor solution resulting from the syntheses of the $[Ru(NH_3)_5(OH_2)](CF_3SO_3)_3$ complex kept in a refrigerator for 2 days. The composition of these crystals was confirmed by elemental analysis and their cyclic voltammetry, electronic and EPR spectroscopy data were compared with the ones described in the literature for the $[Ru(NH_3)_5(OH_2)]^{3+}$ ion. $E_{1/2} = -210$ mV versus SCE [15,17]. UV–visible bands [15,17]: 268 ($\varepsilon = 675$ mol^{-1} L cm^{-1}) and 321 nm ($\varepsilon = 215$ mol^{-1} L cm^{-1}). The EPR spectra powder at different temperatures for $[Ru(NH_3)_5(OH_2)](CF_3SO_3)_3$ exhibit $g_\perp$ equal to 2.60. The $g_\parallel$ peak cannot be detected [18]. The simulation of $[Ru(NH_3)_5(OH_2)](CF_3SO_3)_3$ solid at 77 K gives $g_\perp = 2.62$ and $g_\parallel = 0.6 \geqslant g \geqslant 0$ [18].

Diffraction measurements were performed on an Enraf–Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. The structure was first solved in P_m by the Heavy Atom Patterson method. The structure was refined to an R_1 value of 0.0274. Routine search for further symmetry using the method of Le Page [19] indicated that a center of inversion could have been overlooked. As it turned out, most atom coordinates could be transformed to comply with the $P_{2/m}$ super group symmetry except for the water molecule, which in this group is symmetric related to the NH_3 moiety *trans* to it, by a crystallographic inversion center. Since the Ru–N and Ru–O interatomic distances are equal within experimental error, we decided to describe the structure more economically as a somewhat disordered one but in the higher symmetry space group $P_{2/m}$. A nitrogen atom and

an oxygen one, both with one half occupation factors, were assigned to the site of the water oxygen bonded to ruthenium and were constrained to have the same coordinates and thermal parameters. This model of a partially disordered structure refined to a final R_1 value of 0.0297, somewhat higher than the previous one, as expected, since the number or refined parameters was almost halved. Table 1 shows the data collection and refinement conditions.

3. Results and discussion

3.1. Molecular and crystal structure

There are two independent $[Ru(NH_3)_5OH_2]^{3+}$ moieties in the asymmetric unit, both displaying crystallographic mirror symmetry. The O-atom of the water molecule, the NH_3 *trans* to it and the heavy atom are sited on the crystallographic mirror plane, and the four equatorial NH_3 molecules are related in pairs by this same plane. The three counter-ions are also sited in special positions, each having two sulfur and two oxygen atoms on the crystallographic mirror plane and two other oxygen atoms in general positions. The resulting stoichiometry of three anions $S_2O_6^{2-}$ to two cations $[Ru(NH_3)_5OH_2]^{3+}$ is consistent with the one expected for the Ru(III) oxidation state.

It is interesting to note that in an earlier study [18] on the EPR and NMR of $[(M)(NH_3)_5(OH_2)]^{3+}$ species ($M = Os^{III}$, Ru^{III}), the presence of two forms of $[Os(NH_3)_5(OH_2)]^{3+}$ in the crystalline form was noted due to the presence of two EPR signals. The two forms in the related ruthenium compound could not be detected because the $g_{\|}$ region of the spectrum was outside the range of the spectrometer.

Attempts to obtain good crystals from $[Ru(NH_3)_5(OH_2)](CF_3SO_3)_3$ solutions were unsuccessful in the past [15,17], thus we believe that the $[Ru(NH_3)_5(OH_2)]^{3+}$ fragments prefer to use the $S_2O_6^{2-}$ as counter-ions rather than $CF_3SO_3^-$. In the present reported complex, two ions of the aqua-complex, three $S_2O_6^{2-}$ as counter-ions and two water molecules compose the unit cell $[Ru(NH_3)_5(OH_2)]_2(S_2O_6)_3 \cdot 2H_2O$.

Table 1 shows the X-ray data for $[Ru(NH_3)_5(OH_2)]_2(S_2O_6)_3 \cdot 2H_2O$ and Table 2 shows the relevant observed interatomic distances for this complex as well as for other related ones.

The average interatomic distance Ru–NH_3 in the equatorial plane is 2.09 Å, which is similar to the one found in other ruthenium complexes, such as $[RuCl(NH_3)_5]Cl_2$ (2.10 Å) [14], $[Ru(NH_3)_6]Cl_3$ (2.11 Å) [17] and *trans*-$[RuNO(NH_3)_4(OH_2)]Cl_3 \cdot 3H_2O$ (2.10 Å) [20]. The average interatomic distance Ru–OH_2 (2.11 Å) in the axial plane of the $[Ru(NH_3)_5(OH_2)]^{3+}$ ion, i.e., a Ru(III) species, is larger than the one observed for *trans*-$[RuNO(NH_3)_4(OH_2)]Cl_3 \cdot 3H_2O$ (2.04 Å) [20], where the metal center is formally in the oxidation state II. This Ru(II)–OH_2 distance shortening by replacing the *trans* NH_3 ligand by NO in the Ru(II) species is attributed to the strong $4d_\pi \rightarrow \pi^*NO$ back-bonding (Table 2), which would induce the OH_2 ligand to donate electrons to the Ru(II) center through the np ligand $\rightarrow Ru(II)d_\pi$.

A similar behavior is observed when comparing the Ru–Cl distance [17,20] in the $[Ru^{III}(NH_3)_5Cl)]^{2+}$ and *trans*-$[Ru^{II}NO(NH_3)_4(Cl)]^{2+}$ species, where the Ru–Cl distances for pentaammine and the nitrosyl-tetraammine species are 2.36 and 2.34 Å [19], respectively.

In *trans*-$[Ru^{II}NO(NH_3)_4(Cl)]^{2+}$ and *trans*-$[Ru^{II}NO(NH_3)_4(OH_2)]^{3+}$ species, the Ru–N–O angle is 180.0° and 178.1°, and NO stretching frequency values (ν_{NO}) equal at 1850 and 1912 cm^{-1}. Furthermore, both

[g] This work.

complexes are EPR silent, therefore it is quite reasonable assume the [$Ru^{II}NO^+$] formulation for both species, in which the NO^+ ligand withdrawing the electronic density of the metallic center (II) [20b]. Thus, the Ru–X distance are similar (or even shorter) to the one expected for the Ru(III) center through a cooperative effect along the NO–Ru–X axis (X = Cl^- and OH_2).

The π acidity of NO^+, measured as the Ru–X distance (X = the ligand *trans* to NO), is even higher than the one exhibited by the well-known strong π-acceptor Mepz (1-methylpyrazinium), so-called "organic NO" [21b], as observed from the Ru–NH_3 (*trans*) distance in $[Ru(NH_3)_5(Mepz)]I_3$ (2.17 Å) [21a] and $[Ru(NH_3)_5(NO)]Cl_3$ (2.02 Å) [22] species.

3.2. Kinetic reactivities

Besides the structural effects, the NO influences on the complex ion behavior are easily noticed in solution. A good example is the pK_a value for the coordinated water molecule in such complexes:

$$[Ru(NH_3)_5(H_2O)]^{2+} + H_2O \rightleftharpoons [Ru(NH_3)_5(OH)]^{+} + H_3O^+ \quad (1)$$

$$[Ru(NH_3)_5(H_2O)]^{3+} + H_2O \rightleftharpoons [Ru(NH_3)_5(OH)]^{2+} + H_3O^+ \quad (2)$$

The pK_a values for reactions (1) and (2) are 13.1 [24] and 4.1 [24], respectively, which are consistent with the 2+ and 3+ charges of the aqua species. Enormous change in the acidity of the Ru(II) center, and then in the acidity of the OH_2 ligand, is observed when the NO ligand is present in the coordination sphere, as expressed by the pK_a value of 3.1 [20] for the following reaction:

$$trans\text{-}[RuNO(NH_3)_4(H_2O)]^{3+} + H_2O \rightleftharpoons trans\text{-}[RuNO(NH_3)_4(OH)]^{2+} + H_3O^+ \quad (3)$$

Again, the higher acidity exhibited by the formally Ru(II) center in the *trans*-$[RuNO(NH_3)_4(OH_2)]^{3+}$ species (ν_{NO} = 1912 cm^{-1}, EPR silent, Ru–N–O angle = 178.1°) [20], as compared to the one of the Ru(III) center in the $[Ru(NH_3)_5(OH_2)]^{3+}$ species, is consistent with the smaller Ru–OH_2 distance in the nitrosyl complex (Table 2).

The kinetic reactivity of the metal center is also strongly influenced by the NO presence. The aquation rate constant (k_{H_2O}) values for the chloro-pentaammine species (4), $[Ru(NH_3)_5Cl]^{2+}$ and $[Ru(NH_3)_5Cl]^{+}$, are 5.4×10^{-6} s^{-1} (40 °C) [25] and 2.0×10 s^{-1} (43 °C) [26], respectively. Under comparable experimental conditions (0.10 mol L^{-1} CF_3COOH, μ = 0.10 mol L^{-1}, 40 °C), the k_{H_2O} for *trans*-$[RuNO(NH_3)_4Cl]^{2+}$ species (5) is 8.4×10^{-6} s^{-1}

Table 3
Experimental rate constants for $[Ru(NH_3)_5L]^{n+}$ and *trans*-$[RuNO(NH_3)_4L]^{2+}$ species, where L = Cl^-, the measurement corresponds to k_{H_2O}

Species	k_{H_2O} (s^{-1})	T (°C)
$[Ru(NH_3)_5Cl]^{+}$	20.2[a]	43
$[Ru(NH_3)_5Cl]^{2+}$	5.4×10^{-6}[b]	40
	8.5×10^{-6}[b]	45
	2.3×10^{-5}[b]	53
	6.5×10^{-5}[b]	64
trans-$[RuNO(NH_3)_4Cl]^{2+}$	8.4×10^{-6}[c]	40
	9.4×10^{-6}[c]	45
	2.0×10^{-5}[c]	49
	6.2×10^{-5}[c]	60

[a] Values measured by cyclic voltammetric method [26].
[b] Interpolated from Eyring plot using the experimental data of [25] ($\Delta H^{\neq}_{-1}$ = 2.4 kcal mol^{-1}, $\Delta S^{\neq}_{-1}$ = 30.0 cal deg^{-1} mol and $\Delta G^{\neq}_{-1}$ = 6.5 kcal mol^{-1}).
[c] This paper ($\Delta H^{\neq}_{-1}$ = 2.3 kcal mol^{-1}, $\Delta S^{\neq}_{-1}$ = 24.0 cal deg^{-1} mol^{-1} and $\Delta G^{\neq}_{-1}$ = 8.6 kcal mol^{-1}).

$$[Ru(NH_3)_5Cl]^{2+} + H_2O \xrightarrow{k_{H2O}} [Ru(NH_3)_5(H_2O)]^{3+} + Cl^- \quad (4)$$

$$trans\text{-}[RuNO(NH_3)_4Cl]^{2+} + H_2O \xrightarrow{k_{H2O}} trans\text{-}[RuNO(NH_3)_4(H_2O)]^{3+} + Cl^- \quad (5)$$

The above data clearly stress that the rate of Cl^- dissociation from the Ru(II) center is much slower when the *trans* NH_3 ligand is replaced by NO. Thus, the *trans*-$[RuNO(NH_3)_4Cl]^{2+}$ species exhibits an inertness to Cl^- aquation comparable to the Ru(III) pentaammine complex ions (Table 3).

It is well accepted that the substitution reactions in octahedral complexes follow a dissociate pathway [16]. According to this model, the rate determining step is controlled by a bond breaking process [16]. Therefore, in a series of related compounds the $\Delta H^{\neq}_{-1}$ values, for the dissociation of the same ligand X, will provide an idea of the relative metal–X bond strength.

The activation parameter data ($\Delta H^{\neq}_{-1}$, $\Delta S^{\neq}_{-1}$ and $\Delta G^{\neq}_{-1}$) for *trans*-$[RuNO(NH_3)_4Cl]^{2+}$ complex are 2.3 kcal mol^{-1}, 24.0 cal deg^{-1} mol^{-1} and 8.6 kcal mol^{-1}, respectively. The activation parameter data for *trans*-$[RuNO(NH_3)_4Cl]^{2+}$ complex (Table 3) are similar to the ones reported for $[Ru(NH_3)_5Cl]^{2+}$ complex ($\Delta H^{\neq}_{-1}$ = 2.4 kcal mol^{-1}, $\Delta S^{\neq}_{-1}$ = 30.0 cal deg^{-1} mol and $\Delta G^{\neq}_{-1}$ = 6.5 kcal mol^{-1}), and consistent with the charge of both complex ions and their respective Ru–Cl bond strength.

Thus, all the present experimental data indicate that the ruthenium(II) center bonded to the NO ligand exhibits kinetic and thermodynamic properties similar to the ones of a ruthenium(III) center.

4. Conclusions

According to experimental data (IR, X-ray diffraction and EPR spectroscopies), the *trans*-$[RuNO(NH_3)$-

$_4(H_2O)]^{3+}$ are better represented as $[Ru^{II}NO^+]$, than as $[Ru^{III}NO^0]$. The presence of the nitric oxide ligand in the coordination sphere of $[Ru(NH_3)_4(H_2O)]^{2+}$ moiety shortens to 2.04 Å the Ru^{II}–OH_2 interatomic distance, which is smaller than the value of 2.11 Å observed for the Ru^{III}–OH_2 in $[Ru(NH_3)_5(H_2O)]^{3+}$, thus making the ruthenium(II) center a stronger Lewis acid than the ruthenium(III) center. This behavior is also supported by pK_a values of 3.1 and 4.1 for aqua-nitrosyl-tetraammine(II) and aqua-pentaammine(III) species and by the lower rate of Cl^- replacement in *trans*-$[RuNO(NH_3)_4Cl]^{2+}$ regarding $[Ru(NH_3)_5Cl)]^{2+}$.

5. Supplementary material

Crystallographic data for the structure in this paper have been deposited with the Fachinformationszentrum Karlsruhe (FIZ) as supplementary publication on CSD No. 391231.

Received 5 December 2003; accepted 7 January 2004

Abstract

The reaction of $[CpRu(PPh_3)_2Cl]$ (**1**) ($Cp = \eta^5$-C_5H_5) with excess of some potentially bridging ligands viz. 2,3-bis(α-pyridyl)pyrazine (bpp), 2,3-bis(α-pyridyl)quinoxaline (bpq), 1,3,5-tris(pyridyl)-2,4,6-triazine (tptz) and 2,3,5,6-tetrakis(pyridyl)pyrazine (tppz) yielded cationic mononuclear complexes of the type $[CpRu(PPh_3)(bpp)]^+$ (**2**), $[CpRu(PPh_3)(bpq)]^+$ (**3**), $[CpRu(PPh_3)(tptz)]^+$ (**4**) and $[CpRu(PPh_3)(tppz)]^+$ (**5**), respectively. These complexes have been isolated as hexafluorophosphate salts. They were characterized by FT-IR, ^1H NMR and ^{31}P $\{^1H\}$ NMR spectroscopy. The molecular structures of representative complexes **3** and **5** have been solved by single crystal X-ray crystallography.

Keywords: Ruthenium; Cyclopentadienyl; 2,3-Bis(α-pyridyl)pyrazine; 1,3,5-Tris(pyridyl)-2,4,6-triazine; 2,3,5,6-Tetrakis(pyridyl)pyrazine

1. Introduction

As part of our investigation of the complexes of areneruthenium(II) [1], cyclopentadienylruthenium(II) [2], osmium(II) [3] and indenylruthenium(II) [4] with a variety of nitrogen-based ligands, we here report on complexes of cyclopentadienylruthenium(II) system with some potentially bridging polypyridyl ligands. The current interest in complexes of polypyridyl ligands, 2,2′-bipyridine, 1,10-phenanthroline, 2,2′:6′,2″-terpyridine, etc., is associated with the extremely interesting electrochemical, photophysical and photoelectrochemical properties that they exhibit [5–8]. Complexes with these ligands are also DNA intercalators, showing an ability to inhibit nucleic acid synthesis in vivo [9]. The recent report on the reactivity studies of arene ruthenium(II) with the ligands (Scheme 1) showed that the ligands L = bpp and bpq cleanly cleaved the halide bridge complex $[(\eta^6$-*p*-cymene$)RuCl_2]_2$ to give two products of the formula $[(\eta^6$-*p*-cymene$)RuCl(L)]^+$ and $[\{(\eta^6$-*p*-cymene$)RuCl\}_2(L)]^{2+}$ [1] and the ligands L = tppz, tptz and py-terpy displaced arene moiety as well as chloride ligands to form dicationic complexes of the formula $[LRuL']^{2+}$. However, py-terpy can also acts as a monodentate ligand binding the metal with nitrogen of the pendant 4-pyridyl group to form $[(\eta^6$-*p*-cymene$)RuCl_2$(py-terpy)] when the reaction medium is diethylether [10]. In the present case, we do not observe the formation of dimeric complexes that could be due to the presence of sterically demanding bulky triphenylphosphine.

2. Experimental

The solvents were purified and dried by standard methods and all reactions were carried out under dry nitrogen atmosphere. Infrared spectra were recorded as KBr pellets using on a Perkin–Elmer Model 983 spectrophotometer. ^1H and ^{13}C $\{^1H\}$ NMR spectra were recorded on a Bruker ACF 300, spectrometer and

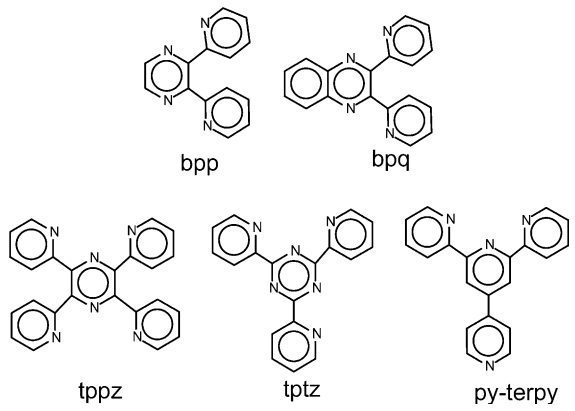

Scheme 1. Ligands used in this work.

referenced to external tetramethylsilane. ^{31}P $\{^1H\}$ NMR chemical shifts are reported relative to H_3PO_4 (85%). Elemental analyses were performed by RSIC, Shillong.

The ligands 2,3-bis(α-pyridyl)pyrazine (bpp), 2,3-bis(α-pyridyl)quinoxaline (bpq), 2,3,5,6-tetrakis(pyridyl)pyrazine (tppz) [11] and py-terpy [12] and $[CpRu(PPh_3)_2Cl]$ [13] were synthesized according to the literature methods. 1,3,5-tris(pyridyl)-2,4,6-triazine (tptz) was purchased from Loba Chemie Private Limited and used as such.

2.1. Preparation of the complexes 2–5

The following general procedure was used for the preparation of these mononuclear complexes.

The mixture of the complex $[CpRu(PPh_3)_2Cl]$ (0.1 g, 0.110 mmol), the ligand (0.220 mmol) and NH_4PF_6 (0.220 mmol) were refluxed in methanol (40 ml) whereby the orange color suspension gradually changes to intense dark red color. It was refluxed for 5 h, then the solvent was rotary evaporated. The residue was extracted with $CHCl_3$ and filtered through short silica gel column to remove insoluble material, the filtrate was again concentrated to about 2 ml and addition of excess diethylether precipitated the product as red-brown solid.

2.1.1. $[CpRu(PPh_3)(bpp)]PF_6$ (**2**PF_6)

^1H NMR (δ, $CDCl_3$): 9.53 (s, 1H), 9.32 (d, 1H, $J = 4.8$ Hz), 8.63 (d, 1H, $J = 4.7$), 8.32 (s, 1H), 8.02 (t, 1H, $J = 6.8$ Hz), 7.65 (d, 1H, $J = 7.6$ Hz), 7.54 (t, 1H, $J = 7.6$ Hz), 7.33–6.98 (m, 17H), 6.56 (d, 1H, $J = 8.2$ Hz), 4.84 (s, 5H).

^{31}P $\{^1H\}$ NMR (δ, $CDCl_3$): 48.81 (s), −143 (sept).

Anal. Calc. for $C_{37}H_{20}N_4RuP_2F_6$: C, 55.02; H, 3.74; N, 6.96. Found: C, 55.20; H, 3.78; N, 7.00%.

UV–Vis (CH_2Cl_2, 10^{-3} M): $\lambda_{max} = 489$ nm.

2.1.2. $[CpRu(PPh_3)(bpq)]PF_6$ (**3**PF_6)

^1H NMR (δ, CD_3CN): 9.23 (d, 1H, $J = 5.4$ Hz), 8.74 (d, 1H, $J = 8.9$ Hz), 8.58 (d, 1H, $J = 4.3$ Hz), 8.10 (t, 1H, $J = 8.1$ Hz), 8.01–7.86 (m, 3H), 7.79 (t, 1H, $J = 6.8$ Hz), 7.60 (t, 1H, $J = 6.9$ Hz), 6.39–7.71 (m, 9H), 7.09 (t, 1H, $J = 9.9$ Hz), 6.90 (m, 7H), 6.76 (d, 1H, 8.4), 5.04 (s, 5H).

^{31}P $\{^1H\}$ NMR (δ, $CDCl_3$): 52.66 (s), −143(sept).

Anal. Calc. for $C_{41}H_{32}N_4RuP_2F_6$: C, 57.41; H, 3.73; N, 6.52. Found: C, 57.56; H, 3.82; N, 6.44%.

UV–Vis (CH_2Cl_2, 10^{-3} M): $\lambda_{max} = 486$ nm.

2.1.3. $[CpRu(PPh_3)(tptz)]PF_6$ (**4**PF_6)

^1H NMR (δ, CD_3CN): 9.30 (d, 1H, $J = 5.2$ Hz), 8.91 (d, 1H, $J = 4.2$ Hz), 8.68 (d, 1H, $J = 7.9$ Hz), 8.64 (d, 1H, $J = 8$ Hz), 8.39 (d, 1H, $J = 4.8$ Hz), 8.03–7.84 (m, 3H), 7.56–7.46 (m, 4H), 8.36–6.96 (m, 17H), 4.53 (s, 5H, Cp).

^{31}P $\{^1H\}$ NMR (δ, $CDCl_3$): 48.98 (s), −143 (sept).

Anal. Calc. for $C_{41}H_{32}N_6RuP_2F_6$: C, 55.60; H, 3.64; N, 9.49. Found: C, 55.83; H, 3.72; N, 9.63%.

UV–Vis (CH_2Cl_2, 10^{-3} M): $\lambda_{max} = 477$ nm.

2.1.4. $[CpRu(PPh_3)(tppz)]PF_6$ (**5**PF_6)

^1H NMR (δ, $CDCl_3$): 8.95 (m, 1H), 8.63 (d, 1H, $J = 6$ Hz), 8.19 (m, 1H), 8.03 (t, 1H, $J = 6.6$), 7.92 (m, 1H), 7.62–6.75 (m, 26H), 4.95 (s, 5H, Cp).

^{31}P $\{^1H\}$ NMR (δ, $CDCl_3$): 46.21 (m), −143 (sept).

Anal. Calc. for $C_{47}H_{36}N_6RuP_2F_6$: C, 58.69; H, 3.74; N, 8.73. Found: C, 58.75; H, 3.67; N, 8.81%.

UV–Vis (CH_2Cl_2, 10^{-3} M): $\lambda_{max} = 461$ nm.

3. Crystal structure determination of 3PF_6 and 5PF_6

Suitable single crystals of **3**PF_6 were grown by slow diffusion of hexane into acetone solution and of **5**PF_6 were grown from hexane into chloroform solution. A suitable size crystal of complex **3**PF_6 was mounted on the end of the glass fiber and mounted on a Nonius MACH3 diffractometer where as complex **5**PF_6 was mounted on Bruker Smart Apex CCD system equipped with graphite monochromatized Mo Kα ($\lambda = 0.70930$ Å) radiation at a temperature of 293 K for the cell determination and intensity data collection. Crystal data collection parameters are summarized in Table 1. The structure was solved by direct methods [14] (SHELXS-1997). Refinement was by full-matrix least-squares based on F^2 using SHELXL-93 [15]. Lorentz and polarization corrections were applied. Non-hydrogen atoms were refined anisotropically only in the case of complex **3**PF_6 and hydrogen atoms were refined using a "riding" model. Figs. 1 and 2 are the ORTEP [16] representation of the molecules with 50% probability thermal ellipsoids displayed. Selected bond distances and angles are given in Tables 2 and 3 for complexes **3**PF_6 and **5**PF_6, respectively.

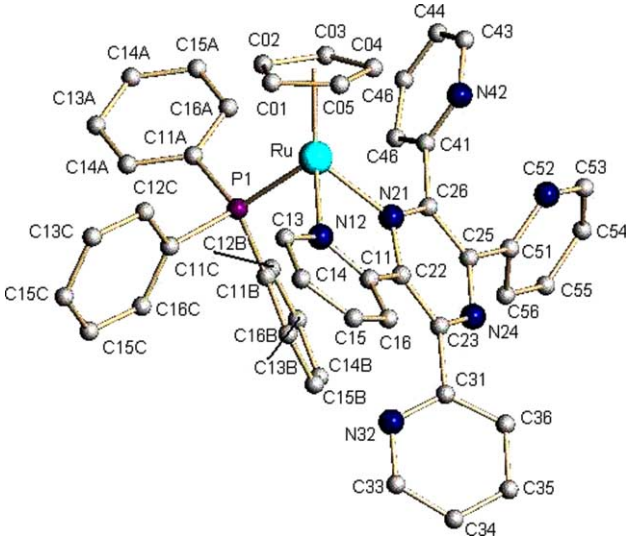

Fig. 2. Molecular structure of $[CpRu(PPh_3)(tppz)]PF_6$ (**3**). The entire hydrogen atoms, PF_6 and chloroform molecules are removed for clarity.

4. Results and discussion

The reaction of the complex $[CpRu(PPh_3)_2Cl]$ (**1**) where $Cp = \eta^5$-$C_5H_5$with excess of the ligands (Scheme 1) in methanol under refluxing condition resulted in the dissociation of one of the triphenylphosphines and chloride ligand to yield the monomeric chelate complexes **2**–**5** (Scheme 2). We are unable to isolate the anticipated dimeric complexes by changing the molar ratio of the starting complex to the corresponding ligand. These complexes are soluble in most of the polar solvents.

All these complexes showed a sharp singlet in the region of 4.53–5.04 ppm in ^{1}H NMR spectra, which can

be assigned unambiguously to the resonance of cyclopentadienyl ligand. The analytical data, integration of the spectrum and a rather complicated peaks originating from the potentially bridging ligands in the ^1H NMR spectrum suggest the unsymmetrical coordinating nature of this ligand to the metal center, i.e. two nitrogens chelate the ruthenium centre leaving other pyridyl groups uncoordinated which inturn reflects the monomeric nature of the complexes. The peaks corresponding to the protons of the triphenylphosphine and the chelate ligands appear in the aromatic region in the range of 7–9 ppm. The ^{31}P $\{^1H\}$ NMR spectrum of these complexes showed single peak at around 48 ppm and septet at −143 ppm for triphenylphosphine and PF_6^- ion, respectively. In the case of complex **5** a multiplet was observed at 46 ppm for triphenylphosphine, which may be due to the interaction between the phosphorus and the protons of the highly strained tppz ligand.

In contrast to the above reactions, the product isolated from the reaction between complex **1** and py-terpy contains a mixture of products. The ^1H NMR spectrum shows three equally intense cyclopentadienyl peaks at 4.4, 4.38 and 4.36 ppm suggesting the presence of three different environments for the cyclopentadienyl ligand. ^{31}P $\{^1H\}$ NMR spectrum is also complicated and shows peaks at 49.7 ppm (singlet), 45.9 ppm (singlet) and 42.8 ppm (multiplets). The UV–Vis spectrum also shows two very broad bands at 450 and 520 nm. An attempt to separate the mixture by crystallization and column chromatography was unsuccessful.

5. Crystal structures

The complex $[CpRu(PPh_3)(bpq)]PF_6$ (**3**PF_6) crystallizes with one acetone per molecule but only two protons of the acetone were located. The geometry about the metal atom can be regarded as distorted octahedral with the bpq ligand chelating the ruthenium atom with two nitrogen atoms and the other coordination sites occupied by triphenylphosphine and a pentahapto bound cyclopentadienyl ligand. The average Ru–C (Cp) bond length is 2.202 Å where the individual bond length falls within the range of 2.172–2.230 Å. The two nitrogens chelate the ruthenium (N1–Ru–N2) with an angle of 76.11° and the bond lengths are almost the same with 2.090 and 2.070 Å for Ru–N1 and Ru–N2, respectively. The angle subtended by N1–Ru–P2 and N2–Ru–P2 is 94° and 95.01°, respectively. The distance between the ruthenium atom and phosphorus atom of the triphenylphosphine ligand is 2.322 Å. Even with the low accuracy of the results from the X-ray determination, all the metrical parameters are in a close agreement with those of complex **5** and other related works [1,2].

The complex $[CpRu(PPh_3)(tppz)]PF_6$ (**5**PF_6) crystallized with three molecules of chloroform per molecule. The crystal diffracts weakly and the maximum angle at which $I > 2\sigma(I)$ is 15°. Due to the small ratio of data to parameter, only the PF_6 and chloroform units were refined anisotropicaly and the rest was refined isotropicaly. The average Ru–C (Cp) bond length is 2.211 Å. The nitrogen atoms N12 and N21 chelate the ruthenium atom with an angle of 75.9°. The bond distance between the ruthenium and N12, N21 and P of PPh_3 is 2.093, 2.113 and 2.336 Å, respectively. The angle subtended by N12–Ru–P1 and N21–Ru–P1 is 93.7° and 92.4°, respectively. The bond angles and bond lengths are comparable in both these structures as well as with those of related complexes.

6. Conclusion

The reaction of $[CpRu(PPh_3)_2Cl]$ with equimolar or excess amount of some potential bridging polypyridyl ligands L, where L = bpp, bpq, tppz and tptz in methanol in refluxing condition yielded mononuclear complexes of the formulations $[CpRu(PPh_3)(L)]^+$ which apparently results from the dissociation of one triphenylphosphine and the chloride ligands.

7. Supplementary material

Crystallographic data for the structural analysis have been deposited at the Cambridge Crystallographic Data Centre (CCDC), CCDC Nos. 222042 for complex **3** and 222043 for complex **5**, respectively. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44-1223-336033; email: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

Abstract

Reaction of two equivalents of tetrahydrofurfuryl indenyl lithium with anhydrous lanthanide trichlorides in THF afforded bis(tetrahydrofurfurylindenyl) lanthanide chlorides $(C_4H_7OCH_2C_9H_6)_2LnCl$, Ln = La(**1**), Pr(**2**), Lu(**3**). Complexes **1** and **3** are characterized by single-crystal analysis. The results of crystal structural determination reveal that they are 9-coordinate monomeric intramolecular complexes with a *trans* arrangement of both the sidearms and indenyl rings in the solid state. The effects of rare earth ionic radii on the structures of $(C_4H_7OCH_2C_9H_6)_2LnCl$ are discussed.

Keywords: Tetrahydrofurfurylindenyl; Lanthanide chlorides; Crystal structure; Ionic radius

1. Introduction

Due to their large radii and relatively low oxidation, rare earth elements generally form complexes which have high coordination numbers and weak metal–ligand bonds. Under the same reaction conditions, reaction of the same reactants with different rare earth elements may afford a series of complexes with uniform molecular formula but different structure, such as $(C_5H_5)_3Ln \cdot THF$ [1], $(C_9H_7)_3Ln \cdot THF$ [2] and $(CH_3OCH_2CH_2C_5H_4)_2$-LnCl [3,4].

So far, most of the organolanthanides bear two substituted or unsubstituted cyclopentadienyl or indenyl ligands. The attempts to synthesize bis-ligand type lanthanides are often frustrated because of the lanthanide contraction and coordination unsaturation (especially, the light rare earth complexes) [5]. Recently, considerable efforts have been devoted to exploring the organometallic chemistry of metallocenes with donor-functionalized side chains [6], because the donor-functionalized side chains can increase the stability of highly reactive organolanthanide complexes by forming an intramolecular chelating coordination with the central metal, and for the light lanthanide complexes, the enhanced stability facilitates the synthesis of the desired complexes. Most of the ligands used are those with ether- or amino-substituted cyclopentadienyl groups. To complete the series of the complexes $(C_4H_7OCH_2$-$C_9H_6)_2LnCl$ [7,8], complexes La(**1**), Pr(**2**) and Lu(**3**) were synthesized, and **1** and **3** were X-ray characterized. Detailed relations between the rare earth ionic radii and the structures of these complexes are described.

2. Results and discussion

2.1. Synthesis

Two equivalents of $C_4H_7OCH_2C_9H_6Li$ and $LnCl_3$-(Ln = La, Pr and Lu) were reacted in THF, followed by centrifugation, removal of the solvent and extraction with mixed solvents (toluene/THF). Crystals of the corresponding complexes were obtained in moderate yields (Scheme 1) after being kept at −10 °C for several days. These complexes are soluble in polar solvents like

Ln = La(**1**), Pr(**2**), Lu(**3**)

Scheme 1.

THF, only dissolved in aromatic solvents such as toluene on heating. All complexes in solution are air- and moisture-sensitive, but their crystals can be kept for long time in air.

The complexes were characterized by elemental analysis, IR and mass spectrometry. The IR spectra of these complexes showed similar patterns and displayed the characteristic absorption peaks of the aromatic group at about 3030, 1600, 750 cm^{-1}, η^5-indenyl moieties at about 3060, 1430, 1290, 1030, 780 cm^{-1}, and the C–O–C band at 1060, 870, 840 cm^{-1}. The EI-MS data of these complexes displayed characteristic fragments, such as $[M]^+$, $[M–Cl]^+$, $[M–L]^+$, $[C_4H_7O]^+$, etc.

Under similar conditions, with the molar ratio of $C_4H_7OCH_2C_9H_6Li$ to $LnCl_3 = 0.8$ or 3, (Ln = La, Pr and Lu), the attempt to synthesize mono- or tri-tetrahydrofurfurylindenyl lanthanides was defeated, only bis(tetrahydrofurfurylindenyl) lanthanocene chlorides were found.

2.2. Crystal structure of *1* and *3*

Due to their similar crystal data with the same crystal system (orthorhombic) and space group ($P2_12_12_1$), complexes **1** and **3** are isostructural. The molecular structure of **1** is shown in Fig. 1. Although the compounds crystallize from mixed solutions (including THF), they remain unsolvated 9-coordinate monomeric complexes in the solid state. The coordination geometry

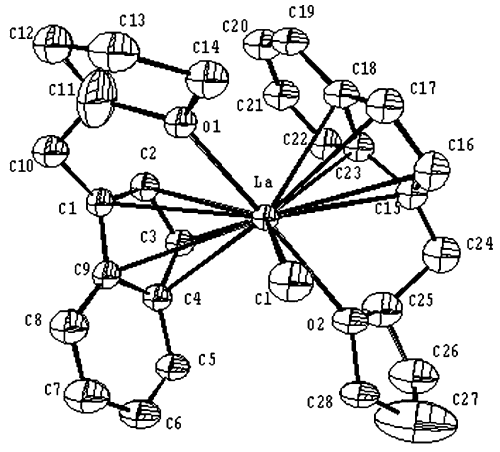

Fig. 1. ORTEP drawing of $(C_4H_7OCH_2C_9H_6)_2LaCl$(**1**) with 40% thermal ellipsoids. Hydrogen atoms are omitted for clarity.

around the central metal atom can be described as a distorted trigonal bipyramid. Two oxygen atoms lie at both apices, and the chlorine atom, the central metal atom and the two centroids of cyclopentadienyl rings of indene form the equatorial plane.

The angles of Cent(1)–La(Lu)–Cl (119.7°, 115.5°), Cent(2)–La(Lu)–Cl (112.2°, 114.7°), Cent(1)–La(Lu)–Cent(2) (128.1°, 129.8°) are close to the ideal angle (120°) of trigonal bipyramid geometry, while the angles of O(1)–La(Lu)–O(2) (161.85°, 159.9°) show large deviation from the ideal angle (180°).

2.3. Effects of ionic radii on the structures of $(C_4H_7OCH_2C_9H_6)_2LnCl$

Including our previous work, effects of the rare earth ionic radii on the structures of $(C_4H_7OCH_2C_9H_6)_2LnCl$ are discussed.

Unlike other series of lanthanides complexes, such as $(C_5H_5)_3Ln \cdot THF$ [1], $(C_9H_7)_3Ln \cdot THF$ [2] and $(CH_3OCH_2CH_2C_5H_4)_2LnCl$ [3,4], all the complexes $(C_4H_7OCH_2C_9H_6)_2LnCl$ (Ln = La, Nd, Sm, Gd, Dy, Y, Ho, Er, Yb, Lu) show the same structure. So, the changes of rare earth ionic radius only influence the bond lengths and bond angles of this series of complexes.
